## Topics In Analysis

Kuttler See Real and Abstract Analysis First. This is merely a collection of topics February 4, 2024

## Contents

1 Preface ..... 23
I Review Of Advanced Calculus ..... 25
2 Set Theory ..... 29
2.1 Basic Definitions ..... 29
2.2 The Schroder Bernstein Theorem ..... 31
2.3 Equivalence Relations ..... 35
2.4 Partially Ordered Sets ..... 35
3 Continuous Functions Of One Variable ..... 37
3.1 Exercises ..... 38
3.2 Theorems About Continuous Functions ..... 38
4 The Riemann Stieltjes Integral ..... 43
4.1 Upper And Lower Riemann Stieltjes Sums ..... 43
4.2 Exercises ..... 47
4.3 Functions Of Riemann Integrable Functions ..... 48
4.4 Properties Of The Integral ..... 50
4.5 Fundamental Theorem Of Calculus ..... 55
4.6 Exercises ..... 58
5 Some Important Linear Algebra ..... 61
5.1 Subspaces Spans And Bases ..... 61
5.2 An Application To Matrices ..... 65
5.3 The Mathematical Theory Of Determinants ..... 66
5.3.1 The Function sgn ..... 66
5.4 The Determinant ..... 69
5.4.1 The Definition ..... 69
5.4.2 Permuting Rows Or Columns ..... 69
5.4.3 A Symmetric Definition ..... 71
5.4.4 The Alternating Property Of The Determinant ..... 71
5.4.5 Linear Combinations And Determinants ..... 72
5.4.6 The Determinant Of A Product ..... 73
5.4.7 Cofactor Expansions ..... 73
5.4.8 Formula For The Inverse ..... 75
5.4.9 Cramer's Rule ..... 76
5.4.10 Upper Triangular Matrices ..... 77
5.5 The Cayley Hamilton Theorem* ..... 77
5.5.1 An Identity of Cauchy ..... 79
5.6 Block Multiplication Of Matrices ..... 81
5.7 Exercises ..... 85
5.8 Shur's Theorem ..... 86
5.9 The Right Polar Decomposition ..... 92
6 Multi-variable Calculus ..... 97
6.1 Continuous Functions ..... 97
6.2 Open And Closed Sets ..... 97
6.3 Continuous Functions ..... 99
6.3.1 Sufficient Conditions For Continuity ..... 99
6.4 Exercises ..... 100
6.5 Limits Of A Function ..... 101
6.6 Exercises ..... 104
6.7 The Limit Of A Sequence ..... 105
6.7.1 Sequences And Completeness ..... 107
6.7.2 Continuity And The Limit Of A Sequence ..... 108
6.8 Properties Of Continuous Functions ..... 108
6.9 Exercises ..... 109
6.10 Proofs Of Theorems ..... 109
6.11 The Space $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ ..... 114
6.11.1 The Operator Norm ..... 114
6.12 The Frechet Derivative ..... 116
$6.13 C^{1}$ Functions ..... 120
$6.14 C^{k}$ Functions ..... 124
6.15 Mixed Partial Derivatives ..... 125
6.16 Implicit Function Theorem ..... 127
6.16.1 More Continuous Partial Derivatives ..... 131
6.17 The Method Of Lagrange Multipliers ..... 132
7 Metric Spaces and Topological Spaces ..... 135
7.1 Metric Space ..... 135
7.2 Open and Closed Sets, Sequences, Limit Points ..... 137
7.3 Cauchy Sequences, Completeness ..... 140
7.4 Closure Of A Set ..... 141
7.5 Separable Metric Spaces ..... 142
7.6 Compactness In Metric Space ..... 143
7.7 Some Applications Of Compactness ..... 147
7.8 Ascoli Arzela Theorem ..... 149
7.9 Another General Version ..... 153
7.10 The Tietze Extension Theorem ..... 155
7.11 Some Simple Fixed Point Theorems ..... 158
7.12 General Topological Spaces ..... 163
7.13 Connected Sets ..... 168
7.14 Exercises ..... 172
8 Normed Linear Spaces ..... 177
8.1 Algebra in $\mathbb{F}^{n}$, Vector Spaces ..... 177
8.2 Subspaces Spans And Bases ..... 178
8.3 Inner Product And Normed Linear Spaces ..... 182
8.3.1 The Inner Product In $\mathbb{F}^{n}$ ..... 182
8.3.2 General Inner Product Spaces ..... 183
8.3.3 Normed Vector Spaces ..... 185
8.3.4 The $p$ Norms ..... 186
8.3.5 Orthonormal Bases ..... 188
8.4 Equivalence Of Norms ..... 190
8.5 Exercises ..... 193
9 Weierstrass Approximation Theorem ..... 195
9.1 The Bernstein Polynomials ..... 195
9.2 Stone Weierstrass Theorem ..... 199
9.2.1 The Case Of Compact Sets ..... 199
9.2.2 The Case Of Locally Compact Sets ..... 201
9.2.3 The Case Of Complex Valued Functions ..... 202
9.3 The Holder Spaces ..... 203
9.4 Exercises ..... 205
10 Brouwer Fixed Point Theorem $\mathbb{R}^{n *}$ ..... 207
10.0.1 Simplices and Triangulations ..... 207
10.0.2 Labeling Vertices ..... 211
10.1 The Brouwer Fixed Point Theorem ..... 213
10.2 Invariance Of Domain ..... 216
II Real And Abstract Analysis ..... 221
11 Abstract Measure And Integration ..... 223
11.1 $\sigma$ Algebras ..... 223
11.2 Exercises ..... 233
11.3 The Abstract Lebesgue Integral ..... 235
11.3.1 Preliminary Observations ..... 235
11.3.2 The Lebesgue Integral Nonnegative Functions ..... 237
11.3.3 The Lebesgue Integral For Nonnegative Simple Functions ..... 238
11.3.4 Simple Functions And Measurable Functions ..... 241
11.3.5 The Monotone Convergence Theorem ..... 245
11.3.6 Other Definitions ..... 246
11.3.7 Fatou's Lemma ..... 247
11.3.8 The Righteous Algebraic Desires Of The Lebesgue Integral ..... 249
11.4 The Space $L^{1}$ ..... 249
11.5 Vitali Convergence Theorem ..... 256
11.6 Measures and Regularity ..... 258
11.7 Regular Measures in a Metric Space ..... 262
11.8 Exercises ..... 264
12 The Construction Of Measures ..... 269
12.1 Outer Measures ..... 269
12.2 Urysohn's lemma ..... 282
12.3 Positive Linear Functionals ..... 288
12.4 One Dimensional Lebesgue Measure ..... 295
12.5 One Dimensional Lebesgue Stieltjes Measure ..... 295
12.6 The Distribution Function ..... 297
12.7 Good Lambda Inequality ..... 299
12.8 The Ergodic Theorem ..... 301
12.9 Product Measures ..... 306
12.10 Alternative Treatment Of Product Measure ..... 318
12.10.1 Monotone Classes And Algebras ..... 318
12.10.2 Product Measure ..... 321
12.11 Completion Of Measures ..... 325
12.12 Another Version Of Product Measures ..... 329
12.12.1 General Theory ..... 329
12.12.2 Completion Of Product Measure Spaces ..... 332
12.13 Disturbing Examples ..... 335
12.14 Exercises ..... 336
13 Lebesgue Measure ..... 339
13.1 Basic Properties ..... 339
13.2 The Vitali Covering Theorem ..... 343
13.3 The Vitali Covering Theorem (Elementary Version) ..... 345
13.4 Vitali Coverings ..... 348
13.5 Change of Variables for Linear Maps ..... 351
13.6 Change Of Variables For $C^{1}$ Functions ..... 354
13.7 Mappings Which Are Not One To One ..... 359
13.8 Lebesgue Measure And Iterated Integrals ..... 360
13.9 Spherical Coordinates In $p$ Dimensions ..... 362
13.10 The Brouwer Fixed Point Theorem ..... 366
13.11 The Brouwer Fixed Point Theorem Another Proof ..... 369
13.12 Invariance Of Domain ..... 372
13.13 Besicovitch Covering Theorem ..... 376
13.14 Vitali Coverings and Radon Measures ..... 381
14 Some Extension Theorems ..... 385
14.1 Algebras ..... 385
14.2 Caratheodory Extension Theorem ..... 387
14.3 The Tychonoff Theorem ..... 389
14.4 Kolmogorov Extension Theorem ..... 392
14.5 Exercises ..... 397
15 The $L^{p}$ Spaces ..... 399
15.1 Basic Inequalities And Properties ..... 399
15.2 Density Considerations ..... 406
15.3 Separability ..... 408
15.4 Continuity Of Translation ..... 410
15.5 Mollifiers And Density Of Smooth Functions ..... 411
15.6 Exercises ..... 415
16 Stone's Theorem ..... 421
16.1 Partitions Of Unity And Stone's Theorem ..... 424
16.2 An Extension Theorem, Retracts ..... 426
16.3 Something Which Is Not A Retract ..... 429
16.4 Exercises ..... 433
17 Banach Spaces ..... 435
17.1 Theorems Based On Baire Category ..... 435
17.1.1 Baire Category Theorem ..... 435
17.1.2 Uniform Boundedness Theorem ..... 438
17.1.3 Open Mapping Theorem ..... 439
17.1.4 Closed Graph Theorem ..... 441
17.2 Hahn Banach Theorem ..... 443
17.2.1 Partially Ordered Sets ..... 444
17.2.2 Gauge Functions And Hahn Banach Theorem ..... 444
17.2.3 The Complex Version Of The Hahn Banach Theorem ..... 446
17.2.4 The Dual Space And Adjoint Operators ..... 448
17.3 Uniform Convexity Of $L^{p}$ ..... 451
17.4 Closed Subspaces ..... 457
17.5 Weak And Weak * Topologies ..... 460
17.5.1 Basic Definitions ..... 460
17.5.2 Banach Alaoglu Theorem ..... 461
17.5.3 Eberlein Smulian Theorem ..... 463
17.6 Operators With Closed Range ..... 466
17.7 Exercises ..... 473
18 Topological Vector Spaces ..... 479
18.1 Fundamental Considerations ..... 479
18.2 Separation Theorems ..... 483
18.2.1 Convex Functionals ..... 487
18.2.2 More Separation Theorems ..... 489
18.3 The Weak And Weak* Topologies ..... 492
18.4 Mean Ergodic Theorem ..... 494
18.5 The Tychonoff And Schauder Fixed Point Theorems ..... 497
18.6 A Variational Principle of Ekeland ..... 506
18.6.1 Cariste Fixed Point Theorem ..... 509
18.6.2 A Density Result ..... 511
18.7 Quotient Spaces ..... 513
19 Hilbert Spaces ..... 517
19.1 Basic Theory ..... 517
19.2 The Hilbert Space $L(U)$ ..... 522
19.3 Approximations In Hilbert Space ..... 528
19.4 The Müntz Theorem ..... 531
19.5 Orthonormal Sets ..... 535
19.6 Fourier Series, An Example ..... 537
19.7 Compact Operators ..... 538
19.7.1 Compact Operators In Hilbert Space ..... 538
19.8 Sturm Liouville Problems ..... 543
19.8.1 Nuclear Operators ..... 551
19.8.2 Hilbert Schmidt Operators ..... 554
19.9 Compact Operators in Banach Space ..... 557
19.10 The Fredholm Alternative ..... 558
19.11 Square Roots ..... 560
19.12 Ordinary Differential Equations in Banach Space ..... 565
19.13 Fractional Powers of Operators ..... 568
19.14 General Theory of Continuous Semigroups ..... 576
19.14.1 An Evolution Equation ..... 585
19.14.2 Adjoints, Hilbert Space ..... 588
19.14.3 Adjoints, Reflexive Banach Space ..... 591
20 Representation Theorems ..... 597
20.1 Radon Nikodym Theorem ..... 597
20.2 Vector Measures ..... 602
20.3 Representation Theorems For The Dual Space Of $L^{p}$ ..... 611
20.4 The Dual Space Of $L^{\infty}(\Omega)$ ..... 618
20.5 Non $\sigma$ Finite Case ..... 622
20.6 The Dual Space Of $C_{0}(X)$ ..... 627
20.7 The Dual Space Of $C_{0}(X)$, Another Approach ..... 632
20.8 More Attractive Formulations ..... 633
20.9 Sequential Compactness In $L^{1}$ ..... 635
20.10 Exercises ..... 641
21 The Bochner Integral ..... 643
21.1 Strong and Weak Measurability ..... 643
21.2 The Bochner Integral ..... 651
21.2.1 Definition and Basic Properties ..... 651
21.2.2 Taking a Closed Operator Out of the Integral ..... 655
21.3 Operator Valued Functions ..... 659
21.3.1 Review of Hilbert Schmidt Theorem ..... 661
21.3.2 Measurable Compact Operators ..... 666
21.4 Fubini’s Theorem for Bochner Integrals ..... 666
21.5 The Spaces $L^{p}(\Omega ; X)$ ..... 669
21.6 Measurable Representatives ..... 676
21.7 Vector Measures ..... 678
21.8 The Riesz Representation Theorem ..... 682
21.8.1 An Example of Polish Space ..... 688
21.9 Pointwise Behavior, Weakly Convergent Sequences ..... 690
21.10 Some Embedding Theorems ..... 690
21.11 Exercises ..... 705
22 The Derivative ..... 707
22.1 Limits Of A Function ..... 707
22.2 Basic Definitions ..... 710
22.3 The Chain Rule ..... 712
22.4 The Derivative Of A Compact Mapping ..... 713
22.5 The Matrix Of The Derivative ..... 713
22.6 A Mean Value Inequality ..... 715
22.7 Higher Order Derivatives ..... 721
22.8 The Derivative And The Cartesian Product ..... 722
22.9 Mixed Partial Derivatives ..... 725
22.10 Implicit Function Theorem ..... 727
22.11 More Derivatives ..... 734
22.12 Lyapunov Schmidt Procedure ..... 735
22.13 Analytic Functions ..... 740
22.14 Ordinary Differential Equations ..... 746
22.15 Exercises ..... 748
23 Degree Theory ..... 753
23.1 Sard's Lemma and Approximation ..... 756
23.2 Properties of the Degree ..... 762
23.3 Borsuk's Theorem ..... 765
23.4 Applications ..... 769
23.5 Product Formula, Jordan Separation Theorem ..... 773
23.6 The Jordan Separation Theorem ..... 777
23.7 Uniqueness of the Degree ..... 781
23.8 A Function With Values In Smaller Dimensions ..... 785
23.9 The Leray Schauder Degree ..... 790
23.10 Exercises ..... 799
24 Critical Points ..... 807
24.1 Mountain Pass Theorem In Hilbert Space ..... 807
24.1.1 A Locally Lipschitz Selection, Pseudogradients ..... 811
24.1.2 Mountain Pass Theorem In Banach Space ..... 817
25 Nonlinear Operators ..... 823
25.1 Some Nonlinear Single Valued Operators ..... 823
25.2 Duality Maps ..... 832
25.3 Penalizaton And Projection Operators ..... 841
25.4 Set-Valued Maps, Pseudomonotone Operators ..... 844
25.5 Sum Of Pseudomonotone Operators ..... 855
25.6 Generalized Gradients ..... 865
25.7 Maximal Monotone Operators ..... 868
25.7.1 The min max Theorem ..... 869
25.7.2 Equivalent Conditions For Maximal Monotone ..... 874
25.7.3 Surjectivity Theorems ..... 882
25.7.4 Approximation Theorems ..... 893
25.7.5 Sum Of Maximal Monotone Operators ..... 902
25.7.6 Convex Functions, An Example ..... 906
25.8 Perturbation Theorems ..... 920
26 Integrals And Derivatives ..... 933
26.1 The Fundamental Theorem Of Calculus ..... 933
26.2 Absolutely Continuous Functions ..... 938
26.3 Weak Derivatives ..... 942
26.4 Lipschitz Functions ..... 946
26.5 Rademacher's Theorem ..... 949
26.6 Rademacher's Theorem ..... 956
26.6.1 Morrey's Inequality ..... 956
26.6.2 Rademacher's Theorem ..... 959
26.7 Differentiation Of Measures ..... 963
26.8 Exercises ..... 968
27 Orlitz Spaces ..... 973
27.1 Basic Theory ..... 973
27.2 Dual Spaces In Orlitz Space ..... 987
28 Hausdorff Measure ..... 993
28.1 The Definition ..... 993
28.1.1 Properties ..... 994
$28.2 \mathscr{H}^{p}$ and $m_{p}$ ..... 996
28.3 Technical Considerations ..... 998
28.3.1 Steiner Symmetrization ..... 1000
28.3.2 The Isodiametric Inequality ..... 1002
28.4 The Proper Value Of $\beta(n)$ ..... 1003
28.4.1 A Formula For $\alpha(n)$ .....  1004
28.4.2 Hausdorff Measure And Linear Transformations .....  1006
29 The Area Formula ..... 1009
29.1 Estimates for Hausdorff Measure ..... 1009
29.2 Comparison Theorems .....  1011
29.3 A Decomposition .....  1012
29.4 Estimates and a Limit .....  1014
29.5 The Area Formula .....  1018
29.6 Mappings that are not One to One .....  1021
29.7 The Divergence Theorem .....  1023
29.8 The Reynolds Transport Formula .....  1031
29.9 The Coarea Formula .....  1034
29.10 Change of Variables .....  1045
29.11 Integration and the Degree .....  1046
29.12 The Case Of $W^{1, p}$ .....  1050
30 Integration Of Differential Forms ..... 1061
30.1 Manifolds .....  1061
30.2 The Binet Cauchy Formula .....  1063
30.3 Integration Of Differential Forms On Manifolds .....  1064
30.3.1 The Derivative Of A Differential Form .....  1068
30.4 Stoke's Theorem And The Orientation Of $\partial \Omega$ .....  1069
30.5 Green's Theorem .....  1074
30.5.1 An Oriented Manifold .....  1074
30.5.2 Green's Theorem .....  1076
30.6 The Divergence Theorem .....  1076
31 Differentiation, Radon Measures ..... 1081
31.1 Fundamental Theorem Of Calculus .....  1081
31.2 Slicing Measures .....  1084
31.3 Differentiation of Radon Measures .....  1090
31.3.1 Radon Nikodym Theorem for Radon Measures ..... 1093
32 Fourier Transforms ..... 1097
32.1 An Algebra Of Special Functions .....  1097
32.2 Fourier Transforms Of Functions In $\mathscr{G}$ .....  1098
32.3 Fourier Transforms Of Just About Anything .....  1100
32.3.1 Fourier Transforms Of $\mathscr{G}^{*}$ .....  1100
32.3.2 Fourier Transforms Of Functions $\operatorname{In} L^{1}\left(\mathbb{R}^{n}\right)$ .....  1104
32.3.3 Fourier Transforms Of Functions In $L^{2}\left(\mathbb{R}^{n}\right)$ .....  1107
32.3.4 The Schwartz Class ..... 1111
32.3.5 Convolution ..... 1113
32.4 Exercises ..... 1115
33 Fourier Analysis In $\mathbb{R}^{n}$ ..... 1119
33.1 The Marcinkiewicz Interpolation Theorem ..... 1119
33.2 The Calderon Zygmund Decomposition ..... 1122
33.3 Mihlin's Theorem .....  1123
33.4 Singular Integrals .....  1136
33.5 Helmholtz Decompositions .....  1146
34 Gelfand Triples And Related Stuff ..... 1155
34.1 An Unnatural Example .....  1157
34.2 Standard Techniques In Evolution Equations ..... 1161
34.3 An Important Formula .....  1171
34.4 The Implicit Case .....  1179
34.5 The Implicit Case, $B=B(t)$ .....  1196
34.6 Another Approach .....  1208
34.7 Some Imbedding Theorems .....  1215
34.8 Some Evolution Inclusions .....  1224
35 Maximal Monotone Operators, Hilbert Space ..... 1229
35.1 Basic Theory .....  1229
35.2 Evolution Inclusions .....  1235
35.3 Subgradients .....  1241
35.3.1 General Results .....  1241
35.3.2 Hilbert Space .....  1254
35.4 A Perturbation Theorem .....  1259
35.5 An Evolution Inclusion .....  1261
35.6 A More Complicated Perturbation Theorem .....  1264
35.7 An Evolution Inclusion .....  1265
III Sobolev Spaces ..... 1273
36 Weak Derivatives ..... 1275
36.1 Weak * Convergence .....  1275
36.2 Test Functions And Weak Derivatives .....  1276
36.3 Weak Derivatives In $L_{l o c}^{p}$ .....  1279
36.4 Morrey's Inequality .....  1282
36.5 Rademacher's Theorem .....  1285
36.6 Change Of Variables Formula Lipschitz Maps .....  1288
37 Integration On Manifolds ..... 1297
37.1 Partitions Of Unity .....  1297
37.2 Integration On Manifolds .....  1300
37.3 Comparison With $\mathscr{H}^{n}$ .....  1306
38 Basic Theory Of Sobolev Spaces ..... 1309
38.1 Embedding Theorems For $W^{m, p}\left(\mathbb{R}^{n}\right)$ .....  1317
38.2 An Extension Theorem .....  1331
38.3 General Embedding Theorems .....  1338
38.4 More Extension Theorems .....  1340
39 Sobolev Spaces Based On $L^{2}$ ..... 1345
39.1 Fourier Transform Techniques .....  1345
39.2 Fractional Order Spaces .....  1349
39.3 An Intrinsic Norm .....  1351
39.4 Embedding Theorems .....  1358
39.5 The Trace On The Boundary Of A Half Space .....  1359
39.6 Sobolev Spaces On Manifolds .....  1367
39.6.1 General Theory .....  1367
39.6.2 The Trace On The Boundary ..... 1371
40 Weak Solutions ..... 1375
40.1 The Lax Milgram Theorem .....  1375
40.2 An Application Of The Mountain Pass Theorem .....  1379
41 Korn's Inequality ..... 1385
41.1 A Fundamental Inequality .....  1385
41.2 Korn's Inequality ..... 1390
42 Elliptic Regularity ..... 1393
42.1 The Case Of A Half Space .....  1393
42.2 The Case Of Bounded Open Sets .....  1402
43 Interpolation In Banach Space ..... 1411
43.1 Some Standard Techniques In Evolution Equations .....  1411
43.1.1 Weak Vector Valued Derivatives .....  1411
43.2 An Important Formula .....  1421
43.3 The Implicit Case .....  1428
43.4 Some Implicit Inclusions .....  1438
43.5 Some Imbedding Theorems ..... 1441
43.6 The $K$ Method .....  1446
43.7 The $J$ Method .....  1451
43.8 Duality And Interpolation ..... 1457
44 Trace Spaces ..... 1467
44.1 Definition And Basic Theory Of Trace Spaces .....  1467
44.2 Trace And Interpolation Spaces .....  1474
45 Traces Of Sobolev Spaces ..... 1481
45.1 Traces Of Sobolev Spaces, Half Space ..... 1481
45.2 A Right Inverse For The Trace For A Half Space ..... 1483
45.3 Intrinsic Norms ..... 1485
45.4 Fractional Order Sobolev Spaces ..... 1506
46 Sobolev Spaces On Manifolds ..... 1511
46.1 Basic Definitions ..... 1511
46.2 The Trace On The Boundary Of An Open Set ..... 1513
IV Multifunctions ..... 1517
47 The Yankov von Neumann Aumann theorem ..... 1519
48 Multifunctions and Their Measurability ..... 1531
48.1 The General Case .....  1531
48.1.1 A Special Case Which Is Easier ..... 1535
48.1.2 Other Measurability Considerations .....  1536
48.2 Existence of Measurable Fixed Points .....  1538
48.2.1 Simplices And Labeling .....  1538
48.2.2 Labeling Vertices .....  1539
48.2.3 Measurability Of Brouwer Fixed Points .....  1541
48.2.4 Measurability Of Schauder Fixed Points .....  1549
48.3 A Set Valued Browder Lemma With Measurability ..... 1556
48.4 A Measurable Kakutani Theorem .....  1563
48.5 Some Variational Inequalities .....  1565
48.6 An Example .....  1570
48.7 Limit Conditions For Nemytskii Operators .....  1576
V Complex Analysis ..... 1593
49 The Complex Numbers ..... 1595
49.1 The Extended Complex Plane .....  1596
49.2 Exercises .....  1598
50 Riemann Stieltjes Integrals ..... 1599
50.1 Exercises .....  1609
51 Fundamentals Of Complex Analysis ..... 1611
51.1 Analytic Functions ..... 1611
51.1.1 Cauchy Riemann Equations ..... 1613
51.1.2 An Important Example .....  1615
51.2 Exercises ..... 1615
51.3 Cauchy's Formula For A Disk .....  1617
51.4 Exercises .....  1624
51.5 Zeros Of An Analytic Function .....  1627
51.6 Liouville's Theorem .....  1629
51.7 The General Cauchy Integral Formula .....  1630

## Chapter 1

## Preface

This is not a book. It is a collection of topics. If you are not interested in something past Page 1000, you should not read it here. Instead, see "Real and Abstract Analysis" or "Analysis of Functions of Complex and Many Variables" two books on this web page. If you are reading something after page 2000 and want to review some elementary topic, I often have a link so you can quickly go to it. That is the only reason elementary topics are present in this conglomeration of topics. You should not read this book to learn standard topics in Advanced calculus or Linear Algebra for example. Also, the presentation tends to be ad hoc and not as well developed as it is elsewhere.

## Part I

## Review Of Advanced Calculus

This is a collection of topics and the presentation is not done as well as in Real and Abstract Analysis. If you are not interested in something after Page 1000, you will probably find it done better in this other book. You should avoid this pile of topics if at all possible. I have elementary material in it only for the convenience of the reader who wants a quick review. It has not been as well maintained as the other books either.

## Chapter 2

## Set Theory

### 2.1 Basic Definitions

A set is a collection of things called elements of the set. For example, the set of integers, the collection of signed whole numbers such as $1,2,-4$, etc. This set whose existence will be assumed is denoted by $\mathbb{Z}$. Other sets could be the set of people in a family or the set of donuts in a display case at the store. Sometimes parentheses, $\}$ specify a set by listing the things which are in the set between the parentheses. For example the set of integers between -1 and 2 , including these numbers could be denoted as $\{-1,0,1,2\}$. The notation signifying $x$ is an element of a set $S$, is written as $x \in S$. Thus, $1 \in\{-1,0,1,2,3\}$. Here are some axioms about sets. Axioms are statements which are accepted, not proved.

1. Two sets are equal if and only if they have the same elements.
2. To every set $A$, and to every condition $S(x)$ there corresponds a set, $B$, whose elements are exactly those elements $x$ of $A$ for which $S(x)$ holds.
3. For every collection of sets there exists a set that contains all the elements that belong to at least one set of the given collection.
4. The Cartesian product of a nonempty family of nonempty sets is nonempty.
5. If $A$ is a set there exists a set, $\mathscr{P}(A)$ such that $\mathscr{P}(A)$ is the set of all subsets of $A$. This is called the power set.

These axioms are referred to as the axiom of extension, axiom of specification, axiom of unions, axiom of choice, and axiom of powers respectively.

It seems fairly clear you should want to believe in the axiom of extension. It is merely saying, for example, that $\{1,2,3\}=\{2,3,1\}$ since these two sets have the same elements in them. Similarly, it would seem you should be able to specify a new set from a given set using some "condition" which can be used as a test to determine whether the element in question is in the set. For example, the set of all integers which are multiples of 2. This set could be specified as follows.

$$
\{x \in \mathbb{Z}: x=2 y \text { for some } y \in \mathbb{Z}\}
$$

In this notation, the colon is read as "such that" and in this case the condition is being a multiple of 2.

Another example of political interest, could be the set of all judges who are not judicial activists. I think you can see this last is not a very precise condition since there is no way to determine to everyone's satisfaction whether a given judge is an activist. Also, just because something is grammatically correct does not mean it makes any sense. For example consider the following nonsense.
$S=\{x \in$ set of dogs $:$ it is colder in the mountains than in the winter $\}$.
So what is a condition?

We will leave these sorts of considerations and assume our conditions make sense. The axiom of unions states that for any collection of sets, there is a set consisting of all the elements in each of the sets in the collection. Of course this is also open to further consideration. What is a collection? Maybe it would be better to say "set of sets" or, given a set whose elements are sets there exists a set whose elements consist of exactly those things which are elements of at least one of these sets. If $\mathscr{S}$ is such a set whose elements are sets,

$$
\cup\{A: A \in \mathscr{S}\} \text { or } \cup \mathscr{S}
$$

signify this union.
Something is in the Cartesian product of a set or "family" of sets if it consists of a single thing taken from each set in the family. Thus $(1,2,3) \in\{1,4, .2\} \times\{1,2,7\} \times\{4,3,7,9\}$ because it consists of exactly one element from each of the sets which are separated by $\times$. Also, this is the notation for the Cartesian product of finitely many sets. If $\mathscr{S}$ is a set whose elements are sets,

$$
\prod_{A \in S} A
$$

signifies the Cartesian product.
The Cartesian product is the set of choice functions, a choice function being a function which selects exactly one element of each set of $\mathscr{S}$. You may think the axiom of choice, stating that the Cartesian product of a nonempty family of nonempty sets is nonempty, is innocuous but there was a time when many mathematicians were ready to throw it out because it implies things which are very hard to believe, things which never happen without the axiom of choice.
$A$ is a subset of $B$, written $A \subseteq B$, if every element of $A$ is also an element of $B$. This can also be written as $B \supseteq A$. $A$ is a proper subset of $B$, written $A \subset B$ or $B \supset A$ if $A$ is a subset of $B$ but $A$ is not equal to $B, A \neq B . A \cap B$ denotes the intersection of the two sets, $A$ and $B$ and it means the set of elements of $A$ which are also elements of $B$. The axiom of specification shows this is a set. The empty set is the set which has no elements in it, denoted as $\emptyset$. $A \cup B$ denotes the union of the two sets, $A$ and $B$ and it means the set of all elements which are in either of the sets. It is a set because of the axiom of unions.

The complement of a set, (the set of things which are not in the given set ) must be taken with respect to a given set called the universal set which is a set which contains the one whose complement is being taken. Thus, the complement of $A$, denoted as $A^{C}$ ( or more precisely as $X \backslash A$ ) is a set obtained from using the axiom of specification to write

$$
A^{C} \equiv\{x \in X: x \notin A\}
$$

The symbol $\notin$ means: "is not an element of". Note the axiom of specification takes place relative to a given set. Without this universal set it makes no sense to use the axiom of specification to obtain the complement.

Words such as "all" or "there exists" are called quantifiers and they must be understood relative to some given set. For example, the set of all integers larger than 3. Or there exists an integer larger than 7 . Such statements have to do with a given set, in this case the integers. Failure to have a reference set when quantifiers are used turns out to be illogical even though such usage may be grammatically correct. Quantifiers are used often enough
that there are symbols for them. The symbol $\forall$ is read as "for all" or "for every" and the symbol $\exists$ is read as "there exists". Thus $\forall \forall \exists \exists$ could mean for every upside down $A$ there exists a backwards $E$.

DeMorgan's laws are very useful in mathematics. Let $\mathscr{S}$ be a set of sets each of which is contained in some universal set, $U$. Then

$$
\cup\left\{A^{C}: A \in \mathscr{S}\right\}=(\cap\{A: A \in \mathscr{S}\})^{C}
$$

and

$$
\cap\left\{A^{C}: A \in \mathscr{S}\right\}=(\cup\{A: A \in \mathscr{S}\})^{C}
$$

These laws follow directly from the definitions. Also following directly from the definitions are:

Let $\mathscr{S}$ be a set of sets then

$$
B \cup \cup\{: A \in \mathscr{S}\}=\cup\{B \cup A: A \in \mathscr{S}\}
$$

and: Let $\mathscr{S}$ be a set of sets show

$$
B \cap \cup\{A: A \in \mathscr{S}\}=\cup\{B \cap A: A \in \mathscr{S}\}
$$

Unfortunately, there is no single universal set which can be used for all sets. Here is why: Suppose there were. Call it $S$. Then you could consider $A$ the set of all elements of $S$ which are not elements of themselves, this from the axiom of specification. If $A$ is an element of itself, then it fails to qualify for inclusion in $A$. Therefore, it must not be an element of itself. However, if this is so, it qualifies for inclusion in $A$ so it is an element of itself and so this can't be true either. Thus the most basic of conditions you could imagine, that of being an element of, is meaningless and so allowing such a set causes the whole theory to be meaningless. The solution is to not allow a universal set. As mentioned by Halmos in Naive set theory, "Nothing contains everything". Always beware of statements involving quantifiers wherever they occur, even this one.

### 2.2 The Schroder Bernstein Theorem

It is very important to be able to compare the size of sets in a rational way. The most useful theorem in this context is the Schroder Bernstein theorem which is the main result to be presented in this section. The Cartesian product is discussed above. The next definition reviews this and defines the concept of a function.

Definition 2.2.1 Let $X$ and $Y$ be sets.

$$
X \times Y \equiv\{(x, y): x \in X \text { and } y \in Y\}
$$

A relation is defined to be a subset of $X \times Y$. A function, $f$, also called a mapping, is a relation which has the property that if $(x, y)$ and $\left(x, y_{1}\right)$ are both elements of the $f$, then $y=y_{1}$. The domain of $f$ is defined as

$$
D(f) \equiv\{x:(x, y) \in f\}
$$

written as $f: D(f) \rightarrow Y$.

It is probably safe to say that most people do not think of functions as a type of relation which is a subset of the Cartesian product of two sets. A function is like a machine which takes inputs, $x$ and makes them into a unique output, $f(x)$. Of course, that is what the above definition says with more precision. An ordered pair, $(x, y)$ which is an element of the function or mapping has an input, $x$ and a unique output, $y$, denoted as $f(x)$ while the name of the function is $f$. "mapping" is often a noun meaning function. However, it also is a verb as in " $f$ is mapping $A$ to $B$ ". That which a function is thought of as doing is also referred to using the word "maps" as in: $f$ maps $X$ to $Y$. However, a set of functions may be called a set of maps so this word might also be used as the plural of a noun. There is no help for it. You just have to suffer with this nonsense.

The following theorem which is interesting for its own sake will be used to prove the Schroder Bernstein theorem.

Theorem 2.2.2 Let $f: X \rightarrow Y$ and $g: Y \rightarrow X$ be two functions. Then there exist sets $A, B, C, D$, such that

$$
\begin{gathered}
A \cup B=X, C \cup D=Y, A \cap B=\emptyset, C \cap D=\emptyset, \\
f(A)=C, g(D)=B .
\end{gathered}
$$

The following picture illustrates the conclusion of this theorem.

Proof: Consider the empty set, $\emptyset \subseteq X$. If $y \in Y \backslash f(\emptyset)$, then $g(y) \notin \emptyset$ because $\emptyset$ has no elements. Also, if $A, B, C$, and $D$ are as described above, $A$ also would have this same property that the empty set has. However, $A$ is probably larger. Therefore, say $A_{0} \subseteq X$ satisfies $\mathscr{P}$ if whenever $y \in Y \backslash f\left(A_{0}\right), g(y) \notin A_{0}$.

$$
\mathscr{A} \equiv\left\{A_{0} \subseteq X: A_{0} \text { satisfies } \mathscr{P}\right\}
$$

Let $A=\cup \mathscr{A}$. If $y \in Y \backslash f(A)$, then for each $A_{0} \in \mathscr{A}, y \in Y \backslash f\left(A_{0}\right)$ and so $g(y) \notin A_{0}$. Since $g(y) \notin A_{0}$ for all $A_{0} \in \mathscr{A}$, it follows $g(y) \notin A$. Hence $A$ satisfies $\mathscr{P}$ and is the largest subset of $X$ which does so. Now define

$$
C \equiv f(A), D \equiv Y \backslash C, B \equiv X \backslash A
$$

It only remains to verify that $g(D)=B$.
Suppose $x \in B=X \backslash A$. Then $A \cup\{x\}$ does not satisfy $\mathscr{P}$ and so there exists $y \in$ $Y \backslash f(A \cup\{x\}) \subseteq D$ such that $g(y) \in A \cup\{x\}$. But $y \notin f(A)$ and so since $A$ satisfies $\mathscr{P}$, it follows $g(y) \notin A$. Hence $g(y)=x$ and so $x \in g(D)$ and this proves the theorem.

Theorem 2.2.3 (Schroder Bernstein) If $f: X \rightarrow Y$ and $g: Y \rightarrow X$ are one to one, then there exists $h: X \rightarrow Y$ which is one to one and onto.

Proof: Let $A, B, C, D$ be the sets of Theorem2.2.2 and define

$$
h(x) \equiv\left\{\begin{array}{cc}
f(x) & \text { if } x \in A \\
g^{-1}(x) & \text { if } x \in B
\end{array}\right.
$$

Then $h$ is the desired one to one and onto mapping.
Recall that the Cartesian product may be considered as the collection of choice functions.

Definition 2.2.4 Let $I$ be a set and let $X_{i}$ be a set for each $i \in I . f$ is a choice function written as

$$
f \in \prod_{i \in I} X_{i}
$$

if $f(i) \in X_{i}$ for each $i \in I$.
The axiom of choice says that if $X_{i} \neq \emptyset$ for each $i \in I$, for $I$ a set, then

$$
\prod_{i \in I} X_{i} \neq \emptyset
$$

Sometimes the two functions, $f$ and $g$ are onto but not one to one. It turns out that with the axiom of choice, a similar conclusion to the above may be obtained.

Corollary 2.2.5 If $f: X \rightarrow Y$ is onto and $g: Y \rightarrow X$ is onto, then there exists $h: X \rightarrow Y$ which is one to one and onto.

Proof: For each $y \in Y, f^{-1}(y) \equiv\{x \in X: f(x)=y\} \neq \emptyset$. Therefore, by the axiom of choice, there exists $f_{0}^{-1} \in \prod_{y \in Y} f^{-1}(y)$ which is the same as saying that for each $y \in Y$, $f_{0}^{-1}(y) \in f^{-1}(y)$. Similarly, there exists $g_{0}^{-1}(x) \in g^{-1}(x)$ for all $x \in X$. Then $f_{0}^{-1}$ is one to one because if $f_{0}^{-1}\left(y_{1}\right)=f_{0}^{-1}\left(y_{2}\right)$, then

$$
y_{1}=f\left(f_{0}^{-1}\left(y_{1}\right)\right)=f\left(f_{0}^{-1}\left(y_{2}\right)\right)=y_{2} .
$$

Similarly $g_{0}^{-1}$ is one to one. Therefore, by the Schroder Bernstein theorem, there exists $h: X \rightarrow Y$ which is one to one and onto.

Definition 2.2.6 A set $S$, is finite if there exists a natural number $n$ and a map $\theta$ which maps $\{1, \cdots, n\}$ one to one and onto $S$. $S$ is infinite if it is not finite. A set $S$, is called countable if there exists a map $\theta$ mapping $\mathbb{N}$ one to one and onto $S$.(When $\theta$ maps a set $A$ to a set $B$, this will be written as $\theta: A \rightarrow B$ in the future.) Here $\mathbb{N} \equiv\{1,2, \cdots$ the natural numbers. $S$ is at most countable if there exists a map $\theta: \mathbb{N} \rightarrow S$ which is onto.

The property of being at most countable is often referred to as being countable because the question of interest is normally whether one can list all elements of the set, designating a first, second, third etc. in such a way as to give each element of the set a natural number. The possibility that a single element of the set may be counted more than once is often not important.

Theorem 2.2.7 If $X$ and $Y$ are both at most countable, then $X \times Y$ is also at most countable. If either $X$ or $Y$ is countable, then $X \times Y$ is also countable.

Proof: It is given that there exists a mapping $\eta: \mathbb{N} \rightarrow X$ which is onto. Define $\eta(i) \equiv x_{i}$ and consider $X$ as the set $\left\{x_{1}, x_{2}, x_{3}, \cdots\right\}$. Similarly, consider $Y$ as the set $\left\{y_{1}, y_{2}, y_{3}, \cdots\right\}$. It follows the elements of $X \times Y$ are included in the following rectangular array.

$$
\begin{array}{ccccc}
\left(x_{1}, y_{1}\right) & \left(x_{1}, y_{2}\right) & \left(x_{1}, y_{3}\right) & \cdots & \leftarrow \text { Those which have } x_{1} \text { in first slot. } \\
\left(x_{2}, y_{1}\right) & \left(x_{2}, y_{2}\right) & \left(x_{2}, y_{3}\right) & \cdots & \leftarrow \text { Those which have } x_{2} \text { in first slot. } \\
\left(x_{3}, y_{1}\right) & \left(x_{3}, y_{2}\right) & \left(x_{3}, y_{3}\right) & \cdots & \leftarrow \text { Those which have } x_{3} \text { in first slot. }
\end{array}
$$

Follow a path through this array as follows.

Thus the first element of $X \times Y$ is $\left(x_{1}, y_{1}\right)$, the second element of $X \times Y$ is $\left(x_{1}, y_{2}\right)$, the third element of $X \times Y$ is $\left(x_{2}, y_{1}\right)$ etc. This assigns a number from $\mathbb{N}$ to each element of $X \times Y$. Thus $X \times Y$ is at most countable.

It remains to show the last claim. Suppose without loss of generality that $X$ is countable. Then there exists $\alpha: \mathbb{N} \rightarrow X$ which is one to one and onto. Let $\beta: X \times Y \rightarrow \mathbb{N}$ be defined by $\beta((x, y)) \equiv \alpha^{-1}(x)$. Thus $\beta$ is onto $\mathbb{N}$. By the first part there exists a function from $\mathbb{N}$ onto $X \times Y$. Therefore, by Corollary 2.2.5, there exists a one to one and onto mapping from $X \times Y$ to $\mathbb{N}$. This proves the theorem.

Theorem 2.2.8 If $X$ and $Y$ are at most countable, then $X \cup Y$ is at most countable. If either $X$ or $Y$ are countable, then $X \cup Y$ is countable.

Proof: As in the preceding theorem,

$$
X=\left\{x_{1}, x_{2}, x_{3}, \cdots\right\}
$$

and

$$
Y=\left\{y_{1}, y_{2}, y_{3}, \cdots\right\}
$$

Consider the following array consisting of $X \cup Y$ and path through it.

Thus the first element of $X \cup Y$ is $x_{1}$, the second is $x_{2}$ the third is $y_{1}$ the fourth is $y_{2}$ etc.
Consider the second claim. By the first part, there is a map from $\mathbb{N}$ onto $X \times Y$. Suppose without loss of generality that $X$ is countable and $\alpha: \mathbb{N} \rightarrow X$ is one to one and onto. Then define $\beta(y) \equiv 1$, for all $y \in Y$, and $\beta(x) \equiv \alpha^{-1}(x)$. Thus, $\beta$ maps $X \times Y$ onto $\mathbb{N}$ and this shows there exist two onto maps, one mapping $X \cup Y$ onto $\mathbb{N}$ and the other mapping $\mathbb{N}$ onto $X \cup Y$. Then Corollary 2.2.5 yields the conclusion. This proves the theorem.

### 2.3 Equivalence Relations

There are many ways to compare elements of a set other than to say two elements are equal or the same. For example, in the set of people let two people be equivalent if they have the same weight. This would not be saying they were the same person, just that they weighed the same. Often such relations involve considering one characteristic of the elements of a set and then saying the two elements are equivalent if they are the same as far as the given characteristic is concerned.

Definition 2.3.1 Let $S$ be a set. $\sim$ is an equivalence relation on $S$ if it satisfies the following axioms.

1. $x \sim x$ for all $x \in S$. (Reflexive)
2. If $x \sim y$ then $y \sim x$. (Symmetric)
3. If $x \sim y$ and $y \sim z$, then $x \sim z$. (Transitive)

Definition 2.3.2 $[x]$ denotes the set of all elements of $S$ which are equivalent to $x$ and $[x]$ is called the equivalence class determined by $x$ or just the equivalence class of $x$.

With the above definition one can prove the following simple theorem.
Theorem 2.3.3 Let $\sim$ be an equivalence class defined on a set, $S$ and let $\mathscr{H}$ denote the set of equivalence classes. Then if $[x]$ and $[y]$ are two of these equivalence classes, either $x \sim y$ and $[x]=[y]$ or it is not true that $x \sim y$ and $[x] \cap[y]=\emptyset$.

### 2.4 Partially Ordered Sets

Definition 2.4.1 Let $\mathscr{F}$ be a nonempty set. $\mathscr{F}$ is called a partially ordered set if there is a relation, denoted here by $\leq$, such that

$$
\begin{gathered}
x \leq x \text { for all } x \in \mathscr{F} \\
\text { If } x \leq y \text { and } y \leq z \text { then } x \leq z
\end{gathered}
$$

$\mathscr{C} \subseteq \mathscr{F}$ is said to be a chain if every two elements of $\mathscr{C}$ are related. This means that if $x, y \in \mathscr{C}$, then either $x \leq y$ or $y \leq x$. Sometimes a chain is called a totally ordered set. $\mathscr{C}$ is said to be a maximal chain if whenever $\mathscr{D}$ is a chain containing $\mathscr{C}, \mathscr{D}=\mathscr{C}$.

The most common example of a partially ordered set is the power set of a given set with $\subseteq$ being the relation. It is also helpful to visualize partially ordered sets as trees. Two points on the tree are related if they are on the same branch of the tree and one is higher than the other. Thus two points on different branches would not be related although they might both be larger than some point on the trunk. You might think of many other things which are best considered as partially ordered sets. Think of food for example. You might find it difficult to determine which of two favorite pies you like better although you may be able to say very easily that you would prefer either pie to a dish of lard topped with whipped cream and mustard. The following theorem is equivalent to the axiom of choice. For a discussion of this, see the appendix on the subject.

Theorem 2.4.2 (Hausdorff Maximal Principle) Let $\mathscr{F}$ be a nonempty partially ordered set. Then there exists a maximal chain.

## Chapter 3

## Continuous Functions Of One Variable

There is a theorem about the integral of a continuous function which requires the notion of uniform continuity. This is discussed in this section. Consider the function $f(x)=\frac{1}{x}$ for $x \in(0,1)$. This is a continuous function because, it is continuous at every point of $(0,1)$. However, for a given $\varepsilon>0$, the $\delta$ needed in the $\varepsilon, \delta$ definition of continuity becomes very small as $x$ gets close to 0 . The notion of uniform continuity involves being able to choose a single $\delta$ which works on the whole domain of $f$. Here is the definition.

Definition 3.0.1 Let $f: D \subseteq \mathbb{R} \rightarrow \mathbb{R}$ be a function. Then $f$ is uniformly continuous iffor every $\varepsilon>0$, there exists a $\delta$ depending only on $\varepsilon$ such that if $|x-y|<\delta$ then $|f(x)-f(y)|<$ $\varepsilon$.

It is an amazing fact that under certain conditions continuity implies uniform continuity.

Definition 3.0.2 A set, $K \subseteq \mathbb{R}$ is sequentially compact if whenever $\left\{a_{n}\right\} \subseteq K$ is a sequence, there exists a subsequence, $\left\{a_{n_{k}}\right\}$ such that this subsequence converges to a point of $K$.

The following theorem is part of the Heine Borel theorem.
Theorem 3.0.3 Every closed interval, $[a, b]$ is sequentially compact.
Proof: Let $\left\{x_{n}\right\} \subseteq[a, b] \equiv I_{0}$. Consider the two intervals $\left[a, \frac{a+b}{2}\right]$ and $\left[\frac{a+b}{2}, b\right]$ each of which has length $(b-a) / 2$. At least one of these intervals contains $x_{n}$ for infinitely many values of $n$. Call this interval $I_{1}$. Now do for $I_{1}$ what was done for $I_{0}$. Split it in half and let $I_{2}$ be the interval which contains $x_{n}$ for infinitely many values of $n$. Continue this way obtaining a sequence of nested intervals $I_{0} \supseteq I_{1} \supseteq I_{2} \supseteq I_{3} \cdots$ where the length of $I_{n}$ is $(b-a) / 2^{n}$. Now pick $n_{1}$ such that $x_{n_{1}} \in I_{1}, n_{2}$ such that $n_{2}>n_{1}$ and $x_{n_{2}} \in I_{2}, n_{3}$ such that $n_{3}>n_{2}$ and $x_{n_{3}} \in I_{3}$, etc. (This can be done because in each case the intervals contained $x_{n}$ for infinitely many values of $n$.) By the nested interval lemma there exists a point, $c$ contained in all these intervals. Furthermore,

$$
\left|x_{n_{k}}-c\right|<(b-a) 2^{-k}
$$

and so $\lim _{k \rightarrow \infty} x_{n_{k}}=c \in[a, b]$. This proves the theorem.
Theorem 3.0.4 Let $f: K \rightarrow \mathbb{R}$ be continuous where $K$ is a sequentially compact set in $\mathbb{R}$. Then $f$ is uniformly continuous on $K$.

Proof: If this is not true, there exists $\varepsilon>0$ such that for every $\delta>0$ there exists a pair of points, $x_{\delta}$ and $y_{\delta}$ such that even though $\left|x_{\delta}-y_{\delta}\right|<\delta,\left|f\left(x_{\delta}\right)-f\left(y_{\delta}\right)\right| \geq \varepsilon$. Taking a succession of values for $\delta$ equal to $1,1 / 2,1 / 3, \cdots$, and letting the exceptional pair of points for $\delta=1 / n$ be denoted by $x_{n}$ and $y_{n}$,

$$
\left|x_{n}-y_{n}\right|<\frac{1}{n},\left|f\left(x_{n}\right)-f\left(y_{n}\right)\right| \geq \varepsilon .
$$

Now since $K$ is sequentially compact, there exists a subsequence, $\left\{x_{n_{k}}\right\}$ such that $x_{n_{k}} \rightarrow$ $z \in K$. Now $n_{k} \geq k$ and so

$$
\left|x_{n_{k}}-y_{n_{k}}\right|<\frac{1}{k}
$$

Consequently, $y_{n_{k}} \rightarrow z$ also. ( $x_{n_{k}}$ is like a person walking toward a certain point and $y_{n_{k}}$ is like a dog on a leash which is constantly getting shorter. Obviously $y_{n_{k}}$ must also move toward the point also. You should give a precise proof of what is needed here.) By continuity of $f$

$$
0=|f(z)-f(z)|=\lim _{k \rightarrow \infty}\left|f\left(x_{n_{k}}\right)-f\left(y_{n_{k}}\right)\right| \geq \varepsilon
$$

an obvious contradiction. Therefore, the theorem must be true.
The following corollary follows from this theorem and Theorem 3.0.3.
Corollary 3.0.5 Suppose $I$ is a closed interval, $I=[a, b]$ and $f: I \rightarrow \mathbb{R}$ is continuous. Then $f$ is uniformly continuous.

### 3.1 Exercises

1. A function, $f: D \subseteq \mathbb{R} \rightarrow \mathbb{R}$ is Lipschitz continuous or just Lipschitz for short if there exists a constant, $K$ such that

$$
|f(x)-f(y)| \leq K|x-y|
$$

for all $x, y \in D$. Show every Lipschitz function is uniformly continuous.
2. If $\left|x_{n}-y_{n}\right| \rightarrow 0$ and $x_{n} \rightarrow z$, show that $y_{n} \rightarrow z$ also.
3. Consider $f:(1, \infty) \rightarrow \mathbb{R}$ given by $f(x)=\frac{1}{x}$. Show $f$ is uniformly continuous even though the set on which $f$ is defined is not sequentially compact.
4. If $f$ is uniformly continuous, does it follow that $|f|$ is also uniformly continuous? If $|f|$ is uniformly continuous does it follow that $f$ is uniformly continuous? Answer the same questions with "uniformly continuous" replaced with "continuous". Explain why.

### 3.2 Theorems About Continuous Functions

In this section, proofs of some theorems which have not been proved yet are given.
Theorem 3.2.1 The following assertions are valid

1. The function, af $+b g$ is continuous at $x$ when $f$, $g$ are continuous at $x \in D(f) \cap D(g)$ and $a, b \in \mathbb{R}$.
2. If and $f$ and $g$ are each real valued functions continuous at $x$, then $f g$ is continuous at $x$. If, in addition to this, $g(x) \neq 0$, then $f / g$ is continuous at $x$.
3. If $f$ is continuous at $x, f(x) \in D(g) \subseteq \mathbb{R}$, and $g$ is continuous at $f(x)$, then $g \circ f$ is continuous at $x$.
4. The function $f: \mathbb{R} \rightarrow \mathbb{R}$, given by $f(x)=|x|$ is continuous.

Proof: First consider 1.) Let $\varepsilon>0$ be given. By assumption, there exist $\delta_{1}>0$ such that whenever $|x-y|<\delta_{1}$, it follows $|f(x)-f(y)|<\frac{\varepsilon}{2(|a|+|b|+1)}$ and there exists $\boldsymbol{\delta}_{2}>0$ such that whenever $|x-y|<\boldsymbol{\delta}_{2}$, it follows that $|g(x)-g(y)|<\frac{\varepsilon}{2(|a|+|b|+1)}$. Then let $0<\boldsymbol{\delta} \leq \min \left(\boldsymbol{\delta}_{1}, \delta_{2}\right)$. If $|x-y|<\delta$, then everything happens at once. Therefore, using the triangle inequality

$$
\begin{gathered}
|a f(x)+b f(x)-(a g(y)+b g(y))| \\
\leq|a||f(x)-f(y)|+|b||g(x)-g(y)| \\
<|a|\left(\frac{\varepsilon}{2(|a|+|b|+1)}\right)+|b|\left(\frac{\varepsilon}{2(|a|+|b|+1)}\right)<\varepsilon .
\end{gathered}
$$

Now consider 2.) There exists $\delta_{1}>0$ such that if $|y-x|<\delta_{1}$, then

$$
|f(x)-f(y)|<1
$$

Therefore, for such $y$,

$$
|f(y)|<1+|f(x)|
$$

It follows that for such $y$,

$$
\begin{aligned}
\mid f g(x) & -f g(y)|\leq|f(x) g(x)-g(x) f(y)|+|g(x) f(y)-f(y) g(y)| \\
& \leq|g(x)||f(x)-f(y)|+|f(y)||g(x)-g(y)| \\
& \leq(1+|g(x)|+|f(y)|)[|g(x)-g(y)|+|f(x)-f(y)|] .
\end{aligned}
$$

Now let $\varepsilon>0$ be given. There exists $\boldsymbol{\delta}_{2}$ such that if $|x-y|<\delta_{2}$, then

$$
|g(x)-g(y)|<\frac{\varepsilon}{2(1+|g(x)|+|f(y)|)}
$$

and there exists $\delta_{3}$ such that if $|x-y|<\delta_{3}$, then

$$
|f(x)-f(y)|<\frac{\varepsilon}{2(1+|g(x)|+|f(y)|)}
$$

Now let $0<\boldsymbol{\delta} \leq \min \left(\boldsymbol{\delta}_{1}, \boldsymbol{\delta}_{2}, \boldsymbol{\delta}_{3}\right)$. Then if $|x-y|<\boldsymbol{\delta}$, all the above hold at once and so

$$
\begin{gathered}
|f g(x)-f g(y)| \leq \\
(1+|g(x)|+|f(y)|)[|g(x)-g(y)|+|f(x)-f(y)|] \\
<(1+|g(x)|+|f(y)|)\left(\frac{\varepsilon}{2(1+|g(x)|+|f(y)|)}+\frac{\varepsilon}{2(1+|g(x)|+|f(y)|)}\right)=\varepsilon
\end{gathered}
$$

This proves the first part of 2.) To obtain the second part, let $\delta_{1}$ be as described above and let $\delta_{0}>0$ be such that for $|x-y|<\delta_{0}$,

$$
|g(x)-g(y)|<|g(x)| / 2
$$

and so by the triangle inequality,

$$
-|g(x)| / 2 \leq|g(y)|-|g(x)| \leq|g(x)| / 2
$$

which implies $|g(y)| \geq|g(x)| / 2$, and $|g(y)|<3|g(x)| / 2$.
Then if $|x-y|<\min \left(\boldsymbol{\delta}_{0}, \boldsymbol{\delta}_{1}\right)$,

$$
\begin{aligned}
& \qquad \left.\frac{f(x)}{g(x)}-\frac{f(y)}{g(y)} \right\rvert\,
\end{aligned}=\left\lvert\, \frac{\left|\frac{f(x) g(y)-f(y) g(x)}{g(x) g(y)}\right|}{} \begin{aligned}
& \leq \frac{|f(x) g(y)-f(y) g(x)|}{\left(\frac{|g(x)|^{2}}{2}\right)} \\
& \\
& =\frac{2|f(x) g(y)-f(y) g(x)|}{|g(x)|^{2}} \\
& \leq \frac{2}{|g(x)|^{2}}[|f(x) g(y)-f(y) g(y)+f(y) g(y)-f(y) g(x)|] \\
& \leq \frac{2}{|g(x)|^{2}}[|g(y)||f(x)-f(y)|+|f(y)||g(y)-g(x)|] \\
& \leq \frac{2}{|g(x)|^{2}}\left[\frac{3}{2}|g(x)||f(x)-f(y)|+(1+|f(x)|)|g(y)-g(x)|\right] \\
& \leq \frac{2}{|g(x)|^{2}}(1+2|f(x)|+2|g(x)|)[|f(x)-f(y)|+|g(y)-g(x)|] \\
& \equiv M[|f(x)-f(y)|+|g(y)-g(x)|]
\end{aligned}\right.
$$

where $M$ is defined by

$$
M \equiv \frac{2}{|g(x)|^{2}}(1+2|f(x)|+2|g(x)|)
$$

Now let $\delta_{2}$ be such that if $|x-y|<\delta_{2}$, then

$$
|f(x)-f(y)|<\frac{\varepsilon}{2} M^{-1}
$$

and let $\delta_{3}$ be such that if $|x-y|<\boldsymbol{\delta}_{3}$, then

$$
|g(y)-g(x)|<\frac{\varepsilon}{2} M^{-1}
$$

Then if $0<\delta \leq \min \left(\delta_{0}, \delta_{1}, \delta_{2}, \delta_{3}\right)$, and $|x-y|<\delta$, everything holds and

$$
\left|\frac{f(x)}{g(x)}-\frac{f(y)}{g(y)}\right| \leq M[|f(x)-f(y)|+|g(y)-g(x)|]
$$

$$
<M\left[\frac{\varepsilon}{2} M^{-1}+\frac{\varepsilon}{2} M^{-1}\right]=\varepsilon
$$

This completes the proof of the second part of 2.)
Note that in these proofs no effort is made to find some sort of "best" $\delta$. The problem is one which has a yes or a no answer. Either is it or it is not continuous.

Now consider 3.). If $f$ is continuous at $x, f(x) \in D(g) \subseteq \mathbb{R}^{p}$, and $g$ is continuous at $f(x)$, then $g \circ f$ is continuous at $x$. Let $\varepsilon>0$ be given. Then there exists $\eta>0$ such that if $|y-f(x)|<\eta$ and $y \in D(g)$, it follows that $|g(y)-g(f(x))|<\varepsilon$. From continuity of $f$ at $x$, there exists $\delta>0$ such that if $|x-z|<\delta$ and $z \in D(f)$, then $|f(z)-f(x)|<\eta$. Then if $|x-z|<\delta$ and $z \in D(g \circ f) \subseteq D(f)$, all the above hold and so

$$
|g(f(z))-g(f(x))|<\varepsilon .
$$

This proves part 3.)
To verify part 4.), let $\varepsilon>0$ be given and let $\delta=\varepsilon$. Then if $|x-y|<\delta$, the triangle inequality implies

$$
\begin{aligned}
|f(x)-f(y)| & =\| x|-|y|| \\
& \leq|x-y|<\delta=\varepsilon
\end{aligned}
$$

This proves part 4.) and completes the proof of the theorem.
Next here is a proof of the intermediate value theorem.
Theorem 3.2.2 Suppose $f:[a, b] \rightarrow \mathbb{R}$ is continuous and suppose $f(a)<c<f(b)$. Then there exists $x \in(a, b)$ such that $f(x)=c$.

Proof: Let $d=\frac{a+b}{2}$ and consider the intervals $[a, d]$ and $[d, b]$. If $f(d) \geq c$, then on $[a, d]$, the function is $\leq c$ at one end point and $\geq c$ at the other. On the other hand, if $f(d) \leq c$, then on $[d, b] f \geq 0$ at one end point and $\leq 0$ at the other. Pick the interval on which $f$ has values which are at least as large as $c$ and values no larger than $c$. Now consider that interval, divide it in half as was done for the original interval and argue that on one of these smaller intervals, the function has values at least as large as $c$ and values no larger than $c$. Continue in this way. Next apply the nested interval lemma to get $x$ in all these intervals. In the $n^{\text {th }}$ interval, let $x_{n}, y_{n}$ be elements of this interval such that $f\left(x_{n}\right) \leq c, f\left(y_{n}\right) \geq c$. Now $\left|x_{n}-x\right| \leq(b-a) 2^{-n}$ and $\left|y_{n}-x\right| \leq(b-a) 2^{-n}$ and so $x_{n} \rightarrow x$ and $y_{n} \rightarrow x$. Therefore,

$$
f(x)-c=\lim _{n \rightarrow \infty}\left(f\left(x_{n}\right)-c\right) \leq 0
$$

while

$$
f(x)-c=\lim _{n \rightarrow \infty}\left(f\left(y_{n}\right)-c\right) \geq 0
$$

Consequently $f(x)=c$ and this proves the theorem.
Lemma 3.2.3 Let $\phi:[a, b] \rightarrow \mathbb{R}$ be a continuous function and suppose $\phi$ is $1-1$ on $(a, b)$. Then $\phi$ is either strictly increasing or strictly decreasing on $[a, b]$.

Proof: First it is shown that $\phi$ is either strictly increasing or strictly decreasing on $(a, b)$.

If $\phi$ is not strictly decreasing on $(a, b)$, then there exists $x_{1}<y_{1}, x_{1}, y_{1} \in(a, b)$ such that

$$
\left(\phi\left(y_{1}\right)-\phi\left(x_{1}\right)\right)\left(y_{1}-x_{1}\right)>0 .
$$

If for some other pair of points, $x_{2}<y_{2}$ with $x_{2}, y_{2} \in(a, b)$, the above inequality does not hold, then since $\phi$ is $1-1$,

$$
\left(\phi\left(y_{2}\right)-\phi\left(x_{2}\right)\right)\left(y_{2}-x_{2}\right)<0 .
$$

Let $x_{t} \equiv t x_{1}+(1-t) x_{2}$ and $y_{t} \equiv t y_{1}+(1-t) y_{2}$. Then $x_{t}<y_{t}$ for all $t \in[0,1]$ because

$$
t x_{1} \leq t y_{1} \text { and }(1-t) x_{2} \leq(1-t) y_{2}
$$

with strict inequality holding for at least one of these inequalities since not both $t$ and $(1-t)$ can equal zero. Now define

$$
h(t) \equiv\left(\phi\left(y_{t}\right)-\phi\left(x_{t}\right)\right)\left(y_{t}-x_{t}\right) .
$$

Since $h$ is continuous and $h(0)<0$, while $h(1)>0$, there exists $t \in(0,1)$ such that $h(t)=0$. Therefore, both $x_{t}$ and $y_{t}$ are points of $(a, b)$ and $\phi\left(y_{t}\right)-\phi\left(x_{t}\right)=0$ contradicting the assumption that $\phi$ is one to one. It follows $\phi$ is either strictly increasing or strictly decreasing on $(a, b)$.

This property of being either strictly increasing or strictly decreasing on $(a, b)$ carries over to $[a, b]$ by the continuity of $\phi$. Suppose $\phi$ is strictly increasing on $(a, b)$, a similar argument holding for $\phi$ strictly decreasing on $(a, b)$. If $x>a$, then pick $y \in(a, x)$ and from the above, $\phi(y)<\phi(x)$. Now by continuity of $\phi$ at $a$,

$$
\phi(a)=\lim _{x \rightarrow a+} \phi(z) \leq \phi(y)<\phi(x) .
$$

Therefore, $\phi(a)<\phi(x)$ whenever $x \in(a, b)$. Similarly $\phi(b)>\phi(x)$ for all $x \in(a, b)$. This proves the lemma.

Corollary 3.2.4 Let $f:(a, b) \rightarrow \mathbb{R}$ be one to one and continuous. Then $f(a, b)$ is an open interval, $(c, d)$ and $f^{-1}:(c, d) \rightarrow(a, b)$ is continuous.

Proof: Since $f$ is either strictly increasing or strictly decreasing, $f(a, b)$ is an open interval, $(c, d)$. Assume $f$ is decreasing. Now let $x \in(a, b)$. Why is $f^{-1}$ is continuous at $f(x)$ ? Since $f$ is decreasing, if $f(x)<f(y)$, then $y \equiv f^{-1}(f(y))<x \equiv f^{-1}(f(x))$ and so $f^{-1}$ is also decreasing. Let $\varepsilon>0$ be given. Let $\varepsilon>\eta>0$ and $(x-\eta, x+\eta) \subseteq(a, b)$. Then $f(x) \in(f(x+\eta), f(x-\eta))$. Let $\delta=\min (f(x)-f(x+\eta), f(x-\eta)-f(x))$. Then if

$$
|f(z)-f(x)|<\delta,
$$

it follows

$$
z \equiv f^{-1}(f(z)) \in(x-\eta, x+\eta) \subseteq(x-\varepsilon, x+\varepsilon)
$$

so

$$
\left|f^{-1}(f(z))-x\right|=\left|f^{-1}(f(z))-f^{-1}(f(x))\right|<\varepsilon
$$

This proves the theorem in the case where $f$ is strictly decreasing. The case where $f$ is increasing is similar.

## Chapter 4

## The Riemann Stieltjes Integral

The integral originated in attempts to find areas of various shapes and the ideas involved in finding integrals are much older than the ideas related to finding derivatives. In fact, Archimedes ${ }^{1}$ was finding areas of various curved shapes about 250 B.C. using the main ideas of the integral. What is presented here is a generalization of these ideas. The main interest is in the Riemann integral but if it is easy to generalize to the so called Stieltjes integral in which the length of an interval, $[x, y]$ is replaced with an expression of the form $F(y)-F(x)$ where $F$ is an increasing function, then the generalization is given. However, there is much more that can be written about Stieltjes integrals than what is presented here. A good source for this is the book by Apostol, [4].

### 4.1 Upper And Lower Riemann Stieltjes Sums

The Riemann integral pertains to bounded functions which are defined on a bounded interval. Let $[a, b]$ be a closed interval. A set of points in $[a, b],\left\{x_{0}, \cdots, x_{n}\right\}$ is a partition if

$$
a=x_{0}<x_{1}<\cdots<x_{n}=b .
$$

Such partitions are denoted by $P$ or $Q$. For $f$ a bounded function defined on $[a, b]$, let

$$
\begin{aligned}
M_{i}(f) & \equiv \sup \left\{f(x): x \in\left[x_{i-1}, x_{i}\right]\right\}, \\
m_{i}(f) & \equiv \inf \left\{f(x): x \in\left[x_{i-1}, x_{i}\right]\right\} .
\end{aligned}
$$

Definition 4.1.1 Let $F$ be an increasing function defined on $[a, b]$ and let $\Delta F_{i} \equiv F\left(x_{i}\right)-$ $F\left(x_{i-1}\right)$. Then define upper and lower sums as

$$
U(f, P) \equiv \sum_{i=1}^{n} M_{i}(f) \Delta F_{i} \text { and } L(f, P) \equiv \sum_{i=1}^{n} m_{i}(f) \Delta F_{i}
$$

respectively. The numbers, $M_{i}(f)$ and $m_{i}(f)$, are well defined real numbers because $f$ is assumed to be bounded and $\mathbb{R}$ is complete. Thus the set $S=\left\{f(x): x \in\left[x_{i-1}, x_{i}\right]\right\}$ is bounded above and below.

In the following picture, the sum of the areas of the rectangles in the picture on the left is a lower sum for the function in the picture and the sum of the areas of the rectangles in the picture on the right is an upper sum for the same function which uses the same partition. In these pictures the function, $F$ is given by $F(x)=x$ and these are the ordinary upper and lower sums from calculus.

[^0]

What happens when you add in more points in a partition? The following pictures illustrate in the context of the above example. In this example a single additional point, labeled $z$ has been added in.

Note how the lower sum got larger by the amount of the area in the shaded rectangle and the upper sum got smaller by the amount in the rectangle shaded by dots. In general this is the way it works and this is shown in the following lemma.

Lemma 4.1.2 If $P \subseteq Q$ then

$$
U(f, Q) \leq U(f, P), \text { and } L(f, P) \leq L(f, Q)
$$

Proof: This is verified by adding in one point at a time. Thus let

$$
P=\left\{x_{0}, \cdots, x_{n}\right\}
$$

and let

$$
Q=\left\{x_{0}, \cdots, x_{k}, y, x_{k+1}, \cdots, x_{n}\right\}
$$

Thus exactly one point, $y$, is added between $x_{k}$ and $x_{k+1}$. Now the term in the upper sum which corresponds to the interval $\left[x_{k}, x_{k+1}\right]$ in $U(f, P)$ is

$$
\begin{equation*}
\sup \left\{f(x): x \in\left[x_{k}, x_{k+1}\right]\right\}\left(F\left(x_{k+1}\right)-F\left(x_{k}\right)\right) \tag{4.1.1}
\end{equation*}
$$

and the term which corresponds to the interval $\left[x_{k}, x_{k+1}\right]$ in $U(f, Q)$ is

$$
\begin{gather*}
\sup \left\{f(x): x \in\left[x_{k}, y\right]\right\}\left(F(y)-F\left(x_{k}\right)\right) \\
+\sup \left\{f(x): x \in\left[y, x_{k+1}\right]\right\}\left(F\left(x_{k+1}\right)-F(y)\right)  \tag{4.1.2}\\
\equiv M_{1}\left(F(y)-F\left(x_{k}\right)\right)+M_{2}\left(F\left(x_{k+1}\right)-F(y)\right)
\end{gather*}
$$

All the other terms in the two sums coincide. Now

$$
\sup \left\{f(x): x \in\left[x_{k}, x_{k+1}\right]\right\} \geq \max \left(M_{1}, M_{2}\right)
$$

and so the expression in 4.1.2 is no larger than

$$
\begin{aligned}
& \sup \left\{f(x): x \in\left[x_{k}, x_{k+1}\right]\right\}\left(F\left(x_{k+1}\right)-F(y)\right) \\
& +\sup \left\{f(x): x \in\left[x_{k}, x_{k+1}\right]\right\}\left(F(y)-F\left(x_{k}\right)\right) \\
= & \sup \left\{f(x): x \in\left[x_{k}, x_{k+1}\right]\right\}\left(F\left(x_{k+1}\right)-F\left(x_{k}\right)\right),
\end{aligned}
$$

the term corresponding to the interval, $\left[x_{k}, x_{k+1}\right]$ and $U(f, P)$. This proves the first part of the lemma pertaining to upper sums because if $Q \supseteq P$, one can obtain $Q$ from $P$ by adding in one point at a time and each time a point is added, the corresponding upper sum either gets smaller or stays the same. The second part about lower sums is similar and is left as an exercise.

Lemma 4.1.3 If $P$ and $Q$ are two partitions, then

$$
L(f, P) \leq U(f, Q)
$$

Proof: By Lemma 4.1.2,

$$
L(f, P) \leq L(f, P \cup Q) \leq U(f, P \cup Q) \leq U(f, Q)
$$

Definition 4.1.4

$$
\begin{aligned}
& \bar{I} \equiv \inf \{U(f, Q) \text { where } Q \text { is a partition }\} \\
& \underline{I} \equiv \sup \{L(f, P) \text { where } P \text { is a partition }\} .
\end{aligned}
$$

Note that $\underline{I}$ and $\bar{I}$ are well defined real numbers.
Theorem 4.1.5 $\underline{I} \leq \bar{I}$.
Proof: From Lemma 4.1.3,

$$
\underline{I}=\sup \{L(f, P) \text { where } P \text { is a partition }\} \leq U(f, Q)
$$

because $U(f, Q)$ is an upper bound to the set of all lower sums and so it is no smaller than the least upper bound. Therefore, since $Q$ is arbitrary,

$$
\begin{aligned}
\underline{I} & =\sup \{L(f, P) \text { where } P \text { is a partition }\} \\
& \leq \inf \{U(f, Q) \text { where } Q \text { is a partition }\} \equiv \bar{I}
\end{aligned}
$$

where the inequality holds because it was just shown that $\underline{I}$ is a lower bound to the set of all upper sums and so it is no larger than the greatest lower bound of this set. This proves the theorem.

Definition 4.1.6 A bounded function $f$ is Riemann Stieltjes integrable, written as

$$
f \in R([a, b])
$$

if

$$
\underline{I}=\bar{I}
$$

and in this case,

$$
\int_{a}^{b} f(x) d F \equiv \underline{I}=\bar{I}
$$

When $F(x)=x$, the integral is called the Riemann integral and is written as

$$
\int_{a}^{b} f(x) d x
$$

Thus, in words, the Riemann integral is the unique number which lies between all upper sums and all lower sums if there is such a unique number.

Recall the following Proposition which comes from the definitions.
Proposition 4.1.7 Let $S$ be a nonempty set and suppose $\sup (S)$ exists. Then for every $\delta>0$,

$$
S \cap(\sup (S)-\delta, \sup (S)] \neq \emptyset
$$

If $\inf (S)$ exists, then for every $\delta>0$,

$$
S \cap[\inf (S), \inf (S)+\delta) \neq \emptyset
$$

This proposition implies the following theorem which is used to determine the question of Riemann Stieltjes integrability.
Theorem 4.1.8 A bounded function $f$ is Riemann integrable if and only if for all $\varepsilon>0$, there exists a partition $P$ such that

$$
\begin{equation*}
U(f, P)-L(f, P)<\varepsilon . \tag{4.1.3}
\end{equation*}
$$

Proof: First assume $f$ is Riemann integrable. Then let $P$ and $Q$ be two partitions such that

$$
U(f, Q)<\bar{I}+\varepsilon / 2, L(f, P)>\underline{I}-\varepsilon / 2
$$

Then since $\underline{I}=\bar{I}$,

$$
U(f, Q \cup P)-L(f, P \cup Q) \leq U(f, Q)-L(f, P)<\bar{I}+\varepsilon / 2-(\underline{I}-\varepsilon / 2)=\varepsilon
$$

Now suppose that for all $\varepsilon>0$ there exists a partition such that 4.1.3 holds. Then for given $\varepsilon$ and partition $P$ corresponding to $\varepsilon$

$$
\bar{I}-\underline{I} \leq U(f, P)-L(f, P) \leq \varepsilon
$$

Since $\varepsilon$ is arbitrary, this shows $\underline{I}=\bar{I}$ and this proves the theorem.
The condition described in the theorem is called the Riemann criterion .
Not all bounded functions are Riemann integrable. For example, let $F(x)=x$ and

$$
f(x) \equiv\left\{\begin{array}{l}
1 \text { if } x \in \mathbb{Q}  \tag{4.1.4}\\
0 \text { if } x \in \mathbb{R} \backslash \mathbb{Q}
\end{array}\right.
$$

Then if $[a, b]=[0,1]$ all upper sums for $f$ equal 1 while all lower sums for $f$ equal 0 . Therefore the Riemann criterion is violated for $\varepsilon=1 / 2$.

### 4.2 Exercises

1. Prove the second half of Lemma 4.1.2 about lower sums.
2. Verify that for $f$ given in 4.1 .4 , the lower sums on the interval $[0,1]$ are all equal to zero while the upper sums are all equal to one.
3. Let $f(x)=1+x^{2}$ for $x \in[-1,3]$ and let $P=\left\{-1,-\frac{1}{3}, 0, \frac{1}{2}, 1,2\right\}$. Find $U(f, P)$ and $L(f, P)$ for $F(x)=x$ and for $F(x)=x^{3}$.
4. Show that if $f \in R([a, b])$ for $F(x)=x$, there exists a partition, $\left\{x_{0}, \cdots, x_{n}\right\}$ such that for any $z_{k} \in\left[x_{k}, x_{k+1}\right]$,

$$
\left|\int_{a}^{b} f(x) d x-\sum_{k=1}^{n} f\left(z_{k}\right)\left(x_{k}-x_{k-1}\right)\right|<\varepsilon
$$

This sum, $\sum_{k=1}^{n} f\left(z_{k}\right)\left(x_{k}-x_{k-1}\right)$, is called a Riemann sum and this exercise shows that the Riemann integral can always be approximated by a Riemann sum. For the general Riemann Stieltjes case, does anything change?
5. Let $P=\left\{1,1 \frac{1}{4}, 1 \frac{1}{2}, 1 \frac{3}{4}, 2\right\}$ and $F(x)=x$. Find upper and lower sums for the function, $f(x)=\frac{1}{x}$ using this partition. What does this tell you about $\ln (2)$ ?
6. If $f \in R([a, b])$ with $F(x)=x$ and $f$ is changed at finitely many points, show the new function is also in $R([a, b])$. Is this still true for the general case where $F$ is only assumed to be an increasing function? Explain.
7. In the case where $F(x)=x$, define a "left sum" as

$$
\sum_{k=1}^{n} f\left(x_{k-1}\right)\left(x_{k}-x_{k-1}\right)
$$

and a "right sum",

$$
\sum_{k=1}^{n} f\left(x_{k}\right)\left(x_{k}-x_{k-1}\right)
$$

Also suppose that all partitions have the property that $x_{k}-x_{k-1}$ equals a constant, $(b-a) / n$ so the points in the partition are equally spaced, and define the integral to be the number these right and left sums get close to as $n$ gets larger and larger. Show that for $f$ given in 4.1.4, $\int_{0}^{x} f(t) d t=1$ if $x$ is rational and $\int_{0}^{x} f(t) d t=0$ if $x$ is irrational. It turns out that the correct answer should always equal zero for that function, regardless of whether $x$ is rational. This is shown when the Lebesgue integral is studied. This illustrates why this method of defining the integral in terms of left and right sums is total nonsense. Show that even though this is the case, it makes no difference if $f$ is continuous.

### 4.3 Functions Of Riemann Integrable Functions

It is often necessary to consider functions of Riemann integrable functions and a natural question is whether these are Riemann integrable. The following theorem gives a partial answer to this question. This is not the most general theorem which will relate to this question but it will be enough for the needs of this book.

Theorem 4.3.1 Let $f, g$ be bounded functions and let

$$
f([a, b]) \subseteq\left[c_{1}, d_{1}\right], g([a, b]) \subseteq\left[c_{2}, d_{2}\right]
$$

Let $H:\left[c_{1}, d_{1}\right] \times\left[c_{2}, d_{2}\right] \rightarrow \mathbb{R}$ satisfy,

$$
\left|H\left(a_{1}, b_{1}\right)-H\left(a_{2}, b_{2}\right)\right| \leq K\left[\left|a_{1}-a_{2}\right|+\left|b_{1}-b_{2}\right|\right]
$$

for some constant $K$. Then if $f, g \in R([a, b])$ it follows that $H \circ(f, g) \in R([a, b])$.
Proof: In the following claim, $M_{i}(h)$ and $m_{i}(h)$ have the meanings assigned above with respect to some partition of $[a, b]$ for the function, $h$.

Claim: The following inequality holds.

$$
\begin{gathered}
\left|M_{i}(H \circ(f, g))-m_{i}(H \circ(f, g))\right| \leq \\
K\left[\left|M_{i}(f)-m_{i}(f)\right|+\left|M_{i}(g)-m_{i}(g)\right|\right] .
\end{gathered}
$$

Proof of the claim: By the above proposition, there exist $x_{1}, x_{2} \in\left[x_{i-1}, x_{i}\right]$ be such that

$$
H\left(f\left(x_{1}\right), g\left(x_{1}\right)\right)+\eta>M_{i}(H \circ(f, g)),
$$

and

$$
H\left(f\left(x_{2}\right), g\left(x_{2}\right)\right)-\eta<m_{i}(H \circ(f, g)) .
$$

Then

$$
\begin{gathered}
\left|M_{i}(H \circ(f, g))-m_{i}(H \circ(f, g))\right| \\
<2 \eta+\left|H\left(f\left(x_{1}\right), g\left(x_{1}\right)\right)-H\left(f\left(x_{2}\right), g\left(x_{2}\right)\right)\right| \\
<2 \eta+K\left[\left|f\left(x_{1}\right)-f\left(x_{2}\right)\right|+\left|g\left(x_{1}\right)-g\left(x_{2}\right)\right|\right] \\
\leq 2 \eta+K\left[\left|M_{i}(f)-m_{i}(f)\right|+\left|M_{i}(g)-m_{i}(g)\right|\right] .
\end{gathered}
$$

Since $\eta>0$ is arbitrary, this proves the claim.
Now continuing with the proof of the theorem, let $P$ be such that

$$
\sum_{i=1}^{n}\left(M_{i}(f)-m_{i}(f)\right) \Delta F_{i}<\frac{\varepsilon}{2 K}, \sum_{i=1}^{n}\left(M_{i}(g)-m_{i}(g)\right) \Delta F_{i}<\frac{\varepsilon}{2 K}
$$

Then from the claim,

$$
\sum_{i=1}^{n}\left(M_{i}(H \circ(f, g))-m_{i}(H \circ(f, g))\right) \Delta F_{i}
$$

$$
<\sum_{i=1}^{n} K\left[\left|M_{i}(f)-m_{i}(f)\right|+\left|M_{i}(g)-m_{i}(g)\right|\right] \Delta F_{i}<\varepsilon
$$

Since $\varepsilon>0$ is arbitrary, this shows $H \circ(f, g)$ satisfies the Riemann criterion and hence $H \circ(f, g)$ is Riemann integrable as claimed. This proves the theorem.

This theorem implies that if $f, g$ are Riemann Stieltjes integrable, then so is $a f+$ $b g,|f|, f^{2}$, along with infinitely many other such continuous combinations of Riemann Stieltjes integrable functions. For example, to see that $|f|$ is Riemann integrable, let $H(a, b)=|a|$. Clearly this function satisfies the conditions of the above theorem and so $|f|=H(f, f) \in R([a, b])$ as claimed. The following theorem gives an example of many functions which are Riemann integrable.

Theorem 4.3.2 Let $f:[a, b] \rightarrow \mathbb{R}$ be either increasing or decreasing on $[a, b]$ and suppose $F$ is continuous. Then $f \in R([a, b])$.

Proof: Let $\varepsilon>0$ be given and let

$$
x_{i}=a+i\left(\frac{b-a}{n}\right), i=0, \cdots, n
$$

Since $F$ is continuous, it follows from Corollary 3.0 .5 on Page 38 that it is uniformly continuous. Therefore, if $n$ is large enough, then for all $i$,

$$
F\left(x_{i}\right)-F\left(x_{i-1}\right)<\frac{\varepsilon}{f(b)-f(a)+1}
$$

Then since $f$ is increasing,

$$
\begin{aligned}
U(f, P)-L(f, P) & =\sum_{i=1}^{n}\left(f\left(x_{i}\right)-f\left(x_{i-1}\right)\right)\left(F\left(x_{i}\right)-F\left(x_{i-1}\right)\right) \\
& \leq \frac{\varepsilon}{f(b)-f(a)+1} \sum_{i=1}^{n}\left(f\left(x_{i}\right)-f\left(x_{i-1}\right)\right) \\
& =\frac{\varepsilon}{f(b)-f(a)+1}(f(b)-f(a))<\varepsilon
\end{aligned}
$$

Thus the Riemann criterion is satisfied and so the function is Riemann Stieltjes integrable. The proof for decreasing $f$ is similar.

Corollary 4.3.3 Let $[a, b]$ be a bounded closed interval and let $\phi:[a, b] \rightarrow \mathbb{R}$ be Lipschitz continuous and suppose $F$ is continuous. Then $\phi \in R([a, b])$. Recall that a function, $\phi$, is Lipschitz continuous if there is a constant, $K$, such that for all $x, y$,

$$
|\phi(x)-\phi(y)|<K|x-y|
$$

Proof: Let $f(x)=x$. Then by Theorem 4.3.2, $f$ is Riemann Stieltjes integrable. Let $H(a, b) \equiv \phi(a)$. Then by Theorem 4.3.1 $H \circ(f, f)=\phi \circ f=\phi$ is also Riemann Stieltjes integrable. This proves the corollary. In fact, it is enough to assume $\phi$ is continuous, although this is harder. This is the content of the next theorem which is where the difficult theorems about continuity and uniform continuity are used. This is the main result on the existence of the Riemann Stieltjes integral for this book.

Theorem 4.3.4 Suppose $f:[a, b] \rightarrow \mathbb{R}$ is continuous and $F$ is just an increasing function defined on $[a, b]$. Then $f \in R([a, b])$.

Proof: By Corollary 3.0.5 on Page 38, $f$ is uniformly continuous on $[a, b]$. Therefore, if $\varepsilon>0$ is given, there exists a $\delta>0$ such that if $\left|x_{i}-x_{i-1}\right|<\delta$, then $M_{i}-m_{i}<\frac{\varepsilon}{F(b)-F(a)+1}$. Let

$$
P \equiv\left\{x_{0}, \cdots, x_{n}\right\}
$$

be a partition with $\left|x_{i}-x_{i-1}\right|<\delta$. Then

$$
\begin{aligned}
U(f, P)-L(f, P) & <\sum_{i=1}^{n}\left(M_{i}-m_{i}\right)\left(F\left(x_{i}\right)-F\left(x_{i-1}\right)\right) \\
& <\frac{\varepsilon}{F(b)-F(a)+1}(F(b)-F(a))<\varepsilon
\end{aligned}
$$

By the Riemann criterion, $f \in R([a, b])$. This proves the theorem.

### 4.4 Properties Of The Integral

The integral has many important algebraic properties. First here is a simple lemma.
Lemma 4.4.1 Let $S$ be a nonempty set which is bounded above and below. Then if $-S \equiv$ $\{-x: x \in S\}$,

$$
\begin{equation*}
\sup (-S)=-\inf (S) \tag{4.4.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\inf (-S)=-\sup (S) \tag{4.4.6}
\end{equation*}
$$

Proof: Consider 4.4.5. Let $x \in S$. Then $-x \leq \sup (-S)$ and so $x \geq-\sup (-S)$. It follows that $-\sup (-S)$ is a lower bound for $S$ and therefore, $-\sup (-S) \leq \inf (S)$. This $\operatorname{implies} \sup (-S) \geq-\inf (S)$. Now let $-x \in-S$. Then $x \in S$ and so $x \geq \inf (S)$ which implies $-x \leq-\inf (S)$. Therefore, $-\inf (S)$ is an upper bound for $-S$ and so $-\inf (S) \geq \sup (-S)$. This shows 4.4.5. Formula 4.4.6 is similar and is left as an exercise.

In particular, the above lemma implies that for $M_{i}(f)$ and $m_{i}(f)$ defined above

$$
M_{i}(-f)=-m_{i}(f) \text { and } m_{i}(-f)=-M_{i}(f)
$$

Lemma 4.4.2 If $f \in R([a, b])$ then $-f \in R([a, b])$ and

$$
-\int_{a}^{b} f(x) d F=\int_{a}^{b}-f(x) d F
$$

Proof: The first part of the conclusion of this lemma follows from Theorem 4.3.2 since the function $\phi(y) \equiv-y$ is Lipschitz continuous. Now choose $P$ such that

$$
\int_{a}^{b}-f(x) d F-L(-f, P)<\varepsilon
$$

Then since $m_{i}(-f)=-M_{i}(f)$,

$$
\varepsilon>\int_{a}^{b}-f(x) d F-\sum_{i=1}^{n} m_{i}(-f) \Delta F_{i}=\int_{a}^{b}-f(x) d F+\sum_{i=1}^{n} M_{i}(f) \Delta F_{i}
$$

which implies

$$
\varepsilon>\int_{a}^{b}-f(x) d F+\sum_{i=1}^{n} M_{i}(f) \Delta F_{i} \geq \int_{a}^{b}-f(x) d F+\int_{a}^{b} f(x) d F
$$

Thus, since $\varepsilon$ is arbitrary,

$$
\int_{a}^{b}-f(x) d F \leq-\int_{a}^{b} f(x) d F
$$

whenever $f \in R([a, b])$. It follows

$$
\int_{a}^{b}-f(x) d F \leq-\int_{a}^{b} f(x) d F=-\int_{a}^{b}-(-f(x)) d F \leq \int_{a}^{b}-f(x) d F
$$

and this proves the lemma.
Theorem 4.4.3 The integral is linear,

$$
\int_{a}^{b}(\alpha f+\beta g)(x) d F=\alpha \int_{a}^{b} f(x) d F+\beta \int_{a}^{b} g(x) d F
$$

whenever $f, g \in R([a, b])$ and $\alpha, \beta \in \mathbb{R}$.
Proof: First note that by Theorem 4.3.1, $\alpha f+\beta g \in R([a, b])$. To begin with, consider the claim that if $f, g \in R([a, b])$ then

$$
\begin{equation*}
\int_{a}^{b}(f+g)(x) d F=\int_{a}^{b} f(x) d F+\int_{a}^{b} g(x) d F \tag{4.4.7}
\end{equation*}
$$

Let $P_{1}, Q_{1}$ be such that

$$
U\left(f, Q_{1}\right)-L\left(f, Q_{1}\right)<\varepsilon / 2, U\left(g, P_{1}\right)-L\left(g, P_{1}\right)<\varepsilon / 2 .
$$

Then letting $P \equiv P_{1} \cup Q_{1}$, Lemma 4.1.2 implies

$$
U(f, P)-L(f, P)<\varepsilon / 2, \text { and } U(g, P)-U(g, P)<\varepsilon / 2
$$

Next note that

$$
m_{i}(f+g) \geq m_{i}(f)+m_{i}(g), M_{i}(f+g) \leq M_{i}(f)+M_{i}(g)
$$

Therefore,

$$
L(g+f, P) \geq L(f, P)+L(g, P), U(g+f, P) \leq U(f, P)+U(g, P)
$$

For this partition,

$$
\begin{aligned}
\int_{a}^{b}(f+g)(x) d F & \in[L(f+g, P), U(f+g, P)] \\
& \subseteq[L(f, P)+L(g, P), U(f, P)+U(g, P)]
\end{aligned}
$$

and

$$
\int_{a}^{b} f(x) d F+\int_{a}^{b} g(x) d F \in[L(f, P)+L(g, P), U(f, P)+U(g, P)] .
$$

Therefore,

$$
\begin{gathered}
\left|\int_{a}^{b}(f+g)(x) d F-\left(\int_{a}^{b} f(x) d F+\int_{a}^{b} g(x) d F\right)\right| \leq \\
U(f, P)+U(g, P)-(L(f, P)+L(g, P))<\varepsilon / 2+\varepsilon / 2=\varepsilon
\end{gathered}
$$

This proves 4.4.7 since $\varepsilon$ is arbitrary.
It remains to show that

$$
\alpha \int_{a}^{b} f(x) d F=\int_{a}^{b} \alpha f(x) d F
$$

Suppose first that $\alpha \geq 0$. Then

$$
\begin{aligned}
& \int_{a}^{b} \alpha f(x) d F \equiv \sup \{L(\alpha f, P): P \text { is a partition }\}= \\
& \alpha \sup \{L(f, P): P \text { is a partition }\} \equiv \alpha \int_{a}^{b} f(x) d F
\end{aligned}
$$

If $\alpha<0$, then this and Lemma 4.4.2 imply

$$
\begin{aligned}
& \int_{a}^{b} \alpha f(x) d F=\int_{a}^{b}(-\alpha)(-f(x)) d F \\
= & (-\alpha) \int_{a}^{b}(-f(x)) d F=\alpha \int_{a}^{b} f(x) d F
\end{aligned}
$$

This proves the theorem.
In the next theorem, suppose $F$ is defined on $[a, b] \cup[b, c]$.
Theorem 4.4.4 If $f \in R([a, b])$ and $f \in R([b, c])$, then $f \in R([a, c])$ and

$$
\begin{equation*}
\int_{a}^{c} f(x) d F=\int_{a}^{b} f(x) d F+\int_{b}^{c} f(x) d F \tag{4.4.8}
\end{equation*}
$$

Proof: Let $P_{1}$ be a partition of $[a, b]$ and $P_{2}$ be a partition of $[b, c]$ such that

$$
U\left(f, P_{i}\right)-L\left(f, P_{i}\right)<\varepsilon / 2, i=1,2
$$

Let $P \equiv P_{1} \cup P_{2}$. Then $P$ is a partition of $[a, c]$ and

$$
U(f, P)-L(f, P)
$$

$$
\begin{equation*}
=U\left(f, P_{1}\right)-L\left(f, P_{1}\right)+U\left(f, P_{2}\right)-L\left(f, P_{2}\right)<\varepsilon / 2+\varepsilon / 2=\varepsilon . \tag{4.4.9}
\end{equation*}
$$

Thus, $f \in R([a, c])$ by the Riemann criterion and also for this partition,

$$
\begin{aligned}
\int_{a}^{b} f(x) d F+\int_{b}^{c} f(x) d F & \in\left[L\left(f, P_{1}\right)+L\left(f, P_{2}\right), U\left(f, P_{1}\right)+U\left(f, P_{2}\right)\right] \\
& =[L(f, P), U(f, P)]
\end{aligned}
$$

and

$$
\int_{a}^{c} f(x) d F \in[L(f, P), U(f, P)]
$$

Hence by 4.4.9,

$$
\left|\int_{a}^{c} f(x) d F-\left(\int_{a}^{b} f(x) d F+\int_{b}^{c} f(x) d F\right)\right|<U(f, P)-L(f, P)<\varepsilon
$$

which shows that since $\varepsilon$ is arbitrary, 4.4.8 holds. This proves the theorem.
Corollary 4.4.5 Let $F$ be continuous and let $[a, b]$ be a closed and bounded interval and suppose that

$$
a=y_{1}<y_{2} \cdots<y_{l}=b
$$

and that $f$ is a bounded function defined on $[a, b]$ which has the property that $f$ is either increasing on $\left[y_{j}, y_{j+1}\right]$ or decreasing on $\left[y_{j}, y_{j+1}\right]$ for $j=1, \cdots, l-1$. Then $f \in R([a, b])$.

Proof: This follows from Theorem 4.4.4 and Theorem 4.3.2.
The symbol, $\int_{a}^{b} f(x) d F$ when $a>b$ has not yet been defined.

Definition 4.4.6 Let $[a, b]$ be an interval and let $f \in R([a, b])$. Then

$$
\int_{b}^{a} f(x) d F \equiv-\int_{a}^{b} f(x) d F
$$

Note that with this definition,

$$
\int_{a}^{a} f(x) d F=-\int_{a}^{a} f(x) d F
$$

and so

$$
\int_{a}^{a} f(x) d F=0
$$

Theorem 4.4.7 Assuming all the integrals make sense,

$$
\int_{a}^{b} f(x) d F+\int_{b}^{c} f(x) d F=\int_{a}^{c} f(x) d F
$$

Proof: This follows from Theorem 4.4.4 and Definition 4.4.6. For example, assume

$$
c \in(a, b)
$$

Then from Theorem 4.4.4,

$$
\int_{a}^{c} f(x) d F+\int_{c}^{b} f(x) d F=\int_{a}^{b} f(x) d F
$$

and so by Definition 4.4.6,

$$
\begin{aligned}
\int_{a}^{c} f(x) d F & =\int_{a}^{b} f(x) d F-\int_{c}^{b} f(x) d F \\
& =\int_{a}^{b} f(x) d F+\int_{b}^{c} f(x) d F
\end{aligned}
$$

The other cases are similar.
The following properties of the integral have either been established or they follow quickly from what has been shown so far.

$$
\begin{gather*}
\text { If } f \in R([a, b]) \text { then if } c \in[a, b], f \in R([a, c]),  \tag{4.4.10}\\
\int_{a}^{b} \alpha d F=\alpha(F(b)-F(a))  \tag{4.4.11}\\
\int_{a}^{b}(\alpha f+\beta g)(x) d F=\alpha \int_{a}^{b} f(x) d F+\beta \int_{a}^{b} g(x) d F  \tag{4.4.12}\\
\int_{a}^{b} f(x) d F+\int_{b}^{c} f(x) d F=\int_{a}^{c} f(x) d F  \tag{4.4.13}\\
\int_{a}^{b} f(x) d F \geq 0 \text { if } f(x) \geq 0 \text { and } a<b  \tag{4.4.14}\\
\left|\int_{a}^{b} f(x) d F\right| \leq\left|\int_{a}^{b}\right| f(x)|d F| \tag{4.4.15}
\end{gather*}
$$

The only one of these claims which may not be completely obvious is the last one. To show this one, note that

$$
|f(x)|-f(x) \geq 0,|f(x)|+f(x) \geq 0
$$

Therefore, by 4.4.14 and 4.4.12, if $a<b$,

$$
\int_{a}^{b}|f(x)| d F \geq \int_{a}^{b} f(x) d F
$$

and

$$
\int_{a}^{b}|f(x)| d F \geq-\int_{a}^{b} f(x) d F
$$

Therefore,

$$
\int_{a}^{b}|f(x)| d F \geq\left|\int_{a}^{b} f(x) d F\right|
$$

If $b<a$ then the above inequality holds with $a$ and $b$ switched. This implies 4.4.15.

### 4.5 Fundamental Theorem Of Calculus

In this section $F(x)=x$ so things are specialized to the ordinary Riemann integral. With these properties, it is easy to prove the fundamental theorem of calculus ${ }^{2}$. Let $f \in R([a, b])$. Then by 4.4.10 $f \in R([a, x])$ for each $x \in[a, b]$. The first version of the fundamental theorem of calculus is a statement about the derivative of the function

$$
x \rightarrow \int_{a}^{x} f(t) d t
$$

Theorem 4.5.1 Let $f \in R([a, b])$ and let

$$
F(x) \equiv \int_{a}^{x} f(t) d t
$$

Then if $f$ is continuous at $x \in(a, b)$,

$$
F^{\prime}(x)=f(x)
$$

Proof: Let $x \in(a, b)$ be a point of continuity of $f$ and let $h$ be small enough that $x+h \in$ $[a, b]$. Then by using 4.4.13,

$$
h^{-1}(F(x+h)-F(x))=h^{-1} \int_{x}^{x+h} f(t) d t
$$

Also, using 4.4.11,

$$
f(x)=h^{-1} \int_{x}^{x+h} f(x) d t
$$

Therefore, by 4.4.15,

$$
\begin{aligned}
\mid h^{-1}(F(x+h)- & F(x))-f(x)\left|=\left|h^{-1} \int_{x}^{x+h}(f(t)-f(x)) d t\right|\right. \\
& \leq\left|h^{-1} \int_{x}^{x+h}\right| f(t)-f(x)|d t|
\end{aligned}
$$

Let $\varepsilon>0$ and let $\delta>0$ be small enough that if $|t-x|<\delta$, then

$$
|f(t)-f(x)|<\varepsilon
$$

Therefore, if $|h|<\delta$, the above inequality and 4.4.11 shows that

$$
\left|h^{-1}(F(x+h)-F(x))-f(x)\right| \leq|h|^{-1} \varepsilon|h|=\varepsilon
$$

Since $\varepsilon>0$ is arbitrary, this shows

$$
\lim _{h \rightarrow 0} h^{-1}(F(x+h)-F(x))=f(x)
$$

[^1]and this proves the theorem.
Note this gives existence for the initial value problem,
$$
F^{\prime}(x)=f(x), F(a)=0
$$
whenever $f$ is Riemann integrable and continuous. ${ }^{3}$
The next theorem is also called the fundamental theorem of calculus.
Theorem 4.5.2 Let $f \in R([a, b])$ and suppose there exists an antiderivative for $f, G$, such that
$$
G^{\prime}(x)=f(x)
$$
for every point of $(a, b)$ and $G$ is continuous on $[a, b]$. Then
\[

$$
\begin{equation*}
\int_{a}^{b} f(x) d x=G(b)-G(a) . \tag{4.5.16}
\end{equation*}
$$

\]

Proof: Let $P=\left\{x_{0}, \cdots, x_{n}\right\}$ be a partition satisfying

$$
U(f, P)-L(f, P)<\varepsilon
$$

Then

$$
\begin{aligned}
G(b)-G(a) & =G\left(x_{n}\right)-G\left(x_{0}\right) \\
& =\sum_{i=1}^{n} G\left(x_{i}\right)-G\left(x_{i-1}\right) .
\end{aligned}
$$

By the mean value theorem,

$$
\begin{aligned}
G(b)-G(a) & =\sum_{i=1}^{n} G^{\prime}\left(z_{i}\right)\left(x_{i}-x_{i-1}\right) \\
& =\sum_{i=1}^{n} f\left(z_{i}\right) \Delta x_{i}
\end{aligned}
$$

where $z_{i}$ is some point in $\left[x_{i-1}, x_{i}\right]$. It follows, since the above sum lies between the upper and lower sums, that

$$
G(b)-G(a) \in[L(f, P), U(f, P)]
$$

and also

$$
\int_{a}^{b} f(x) d x \in[L(f, P), U(f, P)]
$$

Therefore,

$$
\left|G(b)-G(a)-\int_{a}^{b} f(x) d x\right|<U(f, P)-L(f, P)<\varepsilon .
$$

Since $\varepsilon>0$ is arbitrary, 4.5 .16 holds. This proves the theorem.

[^2]The following notation is often used in this context. Suppose $F$ is an antiderivative of $f$ as just described with $F$ continuous on $[a, b]$ and $F^{\prime}=f$ on $(a, b)$. Then

$$
\int_{a}^{b} f(x) d x=F(b)-\left.F(a) \equiv F(x)\right|_{a} ^{b}
$$

Definition 4.5.3 Let $f$ be a bounded function defined on a closed interval $[a, b]$ and let $P \equiv\left\{x_{0}, \cdots, x_{n}\right\}$ be a partition of the interval. Suppose $z_{i} \in\left[x_{i-1}, x_{i}\right]$ is chosen. Then the sum

$$
\sum_{i=1}^{n} f\left(z_{i}\right)\left(x_{i}-x_{i-1}\right)
$$

is known as a Riemann sum. Also,

$$
\|P\| \equiv \max \left\{\left|x_{i}-x_{i-1}\right|: i=1, \cdots, n\right\}
$$

Proposition 4.5.4 Suppose $f \in R([a, b])$. Then there exists a partition, $P \equiv\left\{x_{0}, \cdots, x_{n}\right\}$ with the property that for any choice of $z_{k} \in\left[x_{k-1}, x_{k}\right]$,

$$
\left|\int_{a}^{b} f(x) d x-\sum_{k=1}^{n} f\left(z_{k}\right)\left(x_{k}-x_{k-1}\right)\right|<\varepsilon .
$$

Proof: Choose $P$ such that

$$
U(f, P)-L(f, P)<\varepsilon
$$

and then both $\int_{a}^{b} f(x) d x$ and $\sum_{k=1}^{n} f\left(z_{k}\right)\left(x_{k}-x_{k-1}\right)$ are contained in $[L(f, P), U(f, P)]$ and so the claimed inequality must hold. This proves the proposition.

It is significant because it gives a way of approximating the integral.
The definition of Riemann integrability given in this chapter is also called Darboux integrability and the integral defined as the unique number which lies between all upper sums and all lower sums which is given in this chapter is called the Darboux integral. The definition of the Riemann integral in terms of Riemann sums is given next.

Definition 4.5.5 A bounded function, $f$ defined on $[a, b]$ is said to be Riemann integrable if there exists a number, I with the property that for every $\varepsilon>0$, there exists $\delta>0$ such that if

$$
P \equiv\left\{x_{0}, x_{1}, \cdots, x_{n}\right\}
$$

is any partition having $\|P\|<\delta$, and $z_{i} \in\left[x_{i-1}, x_{i}\right]$,

$$
\left|I-\sum_{i=1}^{n} f\left(z_{i}\right)\left(x_{i}-x_{i-1}\right)\right|<\varepsilon .
$$

The number $\int_{a}^{b} f(x) d x$ is defined as $I$.
Thus, there are two definitions of the Riemann integral. It turns out they are equivalent which is the following theorem of of Darboux.

Theorem 4.5.6 A bounded function defined on $[a, b]$ is Riemann integrable in the sense of Definition 4.5 .5 if and only if it is integrable in the sense of Darboux. Furthermore the two integrals coincide.

The proof of this theorem is left for the exercises in Problems 10-12. It isn't essential that you understand this theorem so if it does not interest you, leave it out. Note that it implies that given a Riemann integrable function $f$ in either sense, it can be approximated by Riemann sums whenever $\|P\|$ is sufficiently small. Both versions of the integral are obsolete but entirely adequate for most applications and as a point of departure for a more up to date and satisfactory integral. The reason for using the Darboux approach to the integral is that all the existence theorems are easier to prove in this context.

### 4.6 Exercises

1. Let $F(x)=\int_{x^{2}}^{x^{3}} \frac{t^{5}+7}{t^{7}+87 t^{6}+1} d t$. Find $F^{\prime}(x)$.
2. Let $F(x)=\int_{2}^{x} \frac{1}{1+t^{4}} d t$. Sketch a graph of $F$ and explain why it looks the way it does.
3. Let $a$ and $b$ be positive numbers and consider the function,

$$
F(x)=\int_{0}^{a x} \frac{1}{a^{2}+t^{2}} d t+\int_{b}^{a / x} \frac{1}{a^{2}+t^{2}} d t
$$

Show that $F$ is a constant.
4. Solve the following initial value problem from ordinary differential equations which is to find a function $y$ such that

$$
y^{\prime}(x)=\frac{x^{7}+1}{x^{6}+97 x^{5}+7}, y(10)=5
$$

5. If $F, G \in \int f(x) d x$ for all $x \in \mathbb{R}$, show $F(x)=G(x)+C$ for some constant, $C$. Use this to give a different proof of the fundamental theorem of calculus which has for its conclusion $\int_{a}^{b} f(t) d t=G(b)-G(a)$ where $G^{\prime}(x)=f(x)$.
6. Suppose $f$ is Riemann integrable on $[a, b]$ and continuous. (In fact continuous implies Riemann integrable.) Show there exists $c \in(a, b)$ such that

$$
f(c)=\frac{1}{b-a} \int_{a}^{b} f(x) d x
$$

Hint: You might consider the function $F(x) \equiv \int_{a}^{x} f(t) d t$ and use the mean value theorem for derivatives and the fundamental theorem of calculus.
7. Suppose $f$ and $g$ are continuous functions on $[a, b]$ and that $g(x) \neq 0$ on $(a, b)$. Show there exists $c \in(a, b)$ such that

$$
f(c) \int_{a}^{b} g(x) d x=\int_{a}^{b} f(x) g(x) d x
$$

Hint: Define $F(x) \equiv \int_{a}^{x} f(t) g(t) d t$ and let $G(x) \equiv \int_{a}^{x} g(t) d t$. Then use the Cauchy mean value theorem on these two functions.
8. Consider the function

$$
f(x) \equiv\left\{\begin{array}{l}
\sin \left(\frac{1}{x}\right) \text { if } x \neq 0 \\
0 \text { if } x=0
\end{array} .\right.
$$

Is $f$ Riemann integrable? Explain why or why not.
9. Prove the second part of Theorem 4.3.2 about decreasing functions.
10. Suppose $f$ is a bounded function defined on $[a, b]$ and $|f(x)|<M$ for all $x \in[a, b]$. Now let $Q$ be a partition having $n$ points, $\left\{x_{0}^{*}, \cdots, x_{n}^{*}\right\}$ and let $P$ be any other partition.
Show that

$$
|U(f, P)-L(f, P)| \leq 2 M n| | P| |+|U(f, Q)-L(f, Q)|
$$

Hint: Write the sum for $U(f, P)-L(f, P)$ and split this sum into two sums, the sum of terms for which $\left[x_{i-1}, x_{i}\right]$ contains at least one point of $Q$, and terms for which $\left[x_{i-1}, x_{i}\right]$ does not contain any points of $Q$. In the latter case, $\left[x_{i-1}, x_{i}\right]$ must be contained in some interval, $\left[x_{k-1}^{*}, x_{k}^{*}\right]$. Therefore, the sum of these terms should be no larger than $|U(f, Q)-L(f, Q)|$.
11. $\uparrow$ If $\varepsilon>0$ is given and $f$ is a Darboux integrable function defined on $[a, b]$, show there exists $\delta>0$ such that whenever $\|P\|<\delta$, then

$$
|U(f, P)-L(f, P)|<\varepsilon .
$$

12. $\uparrow$ Prove Theorem 4.5.6.

## Chapter 5

## Some Important Linear Algebra

This chapter contains some important linear algebra as distinguished from that which is normally presented in undergraduate courses consisting mainly of uninteresting things you can do with row operations.

### 5.1 Subspaces Spans And Bases

Definition 5.1.1 Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ be vectors in $\mathbb{F}^{n}$. A linear combination is any expression of the form

$$
\sum_{i=1}^{p} c_{i} \mathbf{x}_{i}
$$

where the $c_{i}$ are scalars. The set of all linear combinations of these vectors is called $\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)$. If $V \subseteq \mathbb{F}^{n}$, then $V$ is called a subspace if whenever $\alpha, \beta$ are scalars and $\mathbf{u}$ and $\mathbf{v}$ are vectors of $V$, it follows $\alpha \mathbf{u}+\beta \mathbf{v} \in V$. That is, it is "closed under the algebraic operations of vector addition and scalar multiplication". A linear combination of vectors is said to be trivial if all the scalars in the linear combination equal zero. A set of vectors is said to be linearly independent if the only linear combination of these vectors which equals the zero vector is the trivial linear combination. Thus $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}$ is called linearly independent if whenever

$$
\sum_{k=1}^{p} c_{k} \mathbf{x}_{k}=\mathbf{0}
$$

it follows that all the scalars, $c_{k}$ equal zero. A set of vectors, $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$, is called linearly dependent if it is not linearly independent. Thus the set of vectors is linearly dependent if there exist scalars, $c_{i}, i=1, \cdots, n$, not all zero such that $\sum_{k=1}^{p} c_{k} \mathbf{x}_{k}=\mathbf{0}$.

Lemma 5.1.2 $A$ set of vectors $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ is linearly independent if and only if none of the vectors can be obtained as a linear combination of the others.

Proof: Suppose first that $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ is linearly independent. If

$$
\mathbf{x}_{k}=\sum_{j \neq k} c_{j} \mathbf{x}_{j}
$$

then

$$
\mathbf{0}=1 \mathbf{x}_{k}+\sum_{j \neq k}\left(-c_{j}\right) \mathbf{x}_{j}
$$

a nontrivial linear combination, contrary to assumption. This shows that if the set is linearly independent, then none of the vectors is a linear combination of the others.

Now suppose no vector is a linear combination of the others. Is $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ linearly independent? If it is not there exist scalars, $c_{i}$, not all zero such that

$$
\sum_{i=1}^{p} c_{i} \mathbf{x}_{i}=\mathbf{0}
$$

Say $c_{k} \neq 0$. Then you can solve for $\mathbf{x}_{k}$ as

$$
\mathbf{x}_{k}=\sum_{j \neq k}\left(-c_{j}\right) / c_{k} \mathbf{x}_{j}
$$

contrary to assumption. This proves the lemma.
The following is called the exchange theorem.

Theorem 5.1.3 (Exchange Theorem) Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ be a linearly independent set of vectors such that each $\mathbf{x}_{i}$ is in $\operatorname{span}\left(\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right)$. Then $r \leq s$.

Proof: Define span $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\} \equiv V$, it follows there exist scalars, $c_{1}, \cdots, c_{s}$ such that

$$
\begin{equation*}
\mathbf{x}_{1}=\sum_{i=1}^{s} c_{i} \mathbf{y}_{i} \tag{5.1.1}
\end{equation*}
$$

Not all of these scalars can equal zero because if this were the case, it would follow that $\mathbf{x}_{1}=0$ and so $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ would not be linearly independent. Indeed, if $\mathbf{x}_{1}=\mathbf{0}, 1 \mathbf{x}_{1}+$ $\sum_{i=2}^{r} 0 \mathbf{x}_{i}=\mathbf{x}_{1}=\mathbf{0}$ and so there would exist a nontrivial linear combination of the vectors $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ which equals zero.

Say $c_{k} \neq 0$. Then solve (5.1.1) for $\mathbf{y}_{k}$ and obtain

$$
\mathbf{y}_{k} \in \operatorname{span}(\mathbf{x}_{1}, \overbrace{\mathbf{y}_{1}, \cdots, \mathbf{y}_{k-1}, \mathbf{y}_{k+1}, \cdots, \mathbf{y}_{s}}^{\mathrm{s} \text { vel vectors here }}) .
$$

Define $\left\{\mathbf{z}_{1}, \cdots, \mathbf{z}_{s-1}\right\}$ by

$$
\left\{\mathbf{z}_{1}, \cdots, \mathbf{z}_{s-1}\right\} \equiv\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{k-1}, \mathbf{y}_{k+1}, \cdots, \mathbf{y}_{s}\right\}
$$

Therefore, span $\left\{\mathbf{x}_{1}, \mathbf{z}_{1}, \cdots, \mathbf{z}_{s-1}\right\}=V$ because if $\mathbf{v} \in V$, there exist constants $c_{1}, \cdots, c_{s}$ such that

$$
\mathbf{v}=\sum_{i=1}^{s-1} c_{i} \mathbf{z}_{i}+c_{s} \mathbf{y}_{k}
$$

Now replace the $\mathbf{y}_{k}$ in the above with a linear combination of the vectors,

$$
\left\{\mathbf{x}_{1}, \mathbf{z}_{1}, \cdots, \mathbf{z}_{s-1}\right\}
$$

to obtain

$$
\mathbf{v} \in \operatorname{span}\left\{\mathbf{x}_{1}, \mathbf{z}_{1}, \cdots, \mathbf{z}_{s-1}\right\}
$$

The vector $\mathbf{y}_{k}$, in the list $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}$, has now been replaced with the vector $\mathbf{x}_{1}$ and the resulting modified list of vectors has the same span as the original list of vectors, $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}$.

Now suppose that $r>s$ and that

$$
\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{l}, \mathbf{z}_{1}, \cdots, \mathbf{z}_{p}\right)=V
$$

where the vectors, $\mathbf{z}_{1}, \cdots, \mathbf{z}_{p}$ are each taken from the set, $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}$ and $l+p=s$. This has now been done for $l=1$ above. Then since $r>s$, it follows that $l \leq s<r$ and so $l+1 \leq r$. Therefore, $\mathbf{x}_{l+1}$ is a vector not in the list, $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{l}\right\}$ and since

$$
\operatorname{span}\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{l}, \mathbf{z}_{1}, \cdots, \mathbf{z}_{p}\right\}=V
$$

there exist scalars, $c_{i}$ and $d_{j}$ such that

$$
\begin{equation*}
\mathbf{x}_{l+1}=\sum_{i=1}^{l} c_{i} \mathbf{x}_{i}+\sum_{j=1}^{p} d_{j} \mathbf{z}_{j} . \tag{5.1.2}
\end{equation*}
$$

Now not all the $d_{j}$ can equal zero because if this were so, it would follow that $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ would be a linearly dependent set because one of the vectors would equal a linear combination of the others. Therefore, (5.1.2) can be solved for one of the $\mathbf{z}_{i}$, say $\mathbf{z}_{k}$, in terms of $\mathbf{x}_{l+1}$ and the other $\mathbf{z}_{i}$ and just as in the above argument, replace that $\mathbf{z}_{i}$ with $\mathbf{x}_{l+1}$ to obtain

$$
\operatorname{span}(\mathbf{x}_{1}, \cdots \mathbf{x}_{l}, \mathbf{x}_{l+1}, \overbrace{\mathbf{z}_{1}, \cdots \mathbf{z}_{k-1}, \mathbf{z}_{k+1}, \cdots, \mathbf{z}_{p}}^{\mathrm{p}-1 \text { vectors here }})=V .
$$

Continue this way, eventually obtaining

$$
\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{s}\right)=V
$$

But then $\mathbf{x}_{r} \in \operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{s}\right)$ contrary to the assumption that $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ is linearly independent. Therefore, $r \leq s$ as claimed.

Definition 5.1.4 A finite set of vectors, $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ is a basis for $\mathbb{F}^{n}$ if

$$
\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right)=\mathbb{F}^{n}
$$

and $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ is linearly independent.
Corollary 5.1.5 Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ and $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}$ be two bases ${ }^{1}$ of $\mathbb{F}^{n}$. Then $r=s=n$.
Proof: From the exchange theorem, $r \leq s$ and $s \leq r$. Now note the vectors,

$$
\mathbf{e}_{i}=\overbrace{(0, \cdots, 0,1,0 \cdots, 0)}^{1 \text { is in the } i^{\text {th }} \text { slot }}
$$

for $i=1,2, \cdots, n$ are a basis for $\mathbb{F}^{n}$. This proves the corollary.
Lemma 5.1.6 Let $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\}$ be a set of vectors. Then $V \equiv \operatorname{span}\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right)$ is a subspace.

[^3]Proof: Suppose $\alpha, \beta$ are two scalars and let $\sum_{k=1}^{r} c_{k} \mathbf{v}_{k}$ and $\sum_{k=1}^{r} d_{k} \mathbf{v}_{k}$ are two elements of $V$. What about

$$
\alpha \sum_{k=1}^{r} c_{k} \mathbf{v}_{k}+\beta \sum_{k=1}^{r} d_{k} \mathbf{v}_{k} ?
$$

Is it also in $V$ ?

$$
\alpha \sum_{k=1}^{r} c_{k} \mathbf{v}_{k}+\beta \sum_{k=1}^{r} d_{k} \mathbf{v}_{k}=\sum_{k=1}^{r}\left(\alpha c_{k}+\beta d_{k}\right) \mathbf{v}_{k} \in V
$$

so the answer is yes. This proves the lemma.
Definition 5.1.7 A finite set of vectors, $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ is a basis for a subspace, $V$ of $\mathbb{F}^{n}$ if $\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right)=V$ and $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ is linearly independent.

Corollary 5.1.8 Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ and $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}$ be two bases for $V$. Then $r=s$.
Proof: From the exchange theorem, $r \leq s$ and $s \leq r$. Therefore, this proves the corollary.
Definition 5.1.9 Let $V$ be a subspace of $\mathbb{F}^{n}$. Then $\operatorname{dim}(V)$ read as the dimension of $V$ is the number of vectors in a basis.

Of course you should wonder right now whether an arbitrary subspace even has a basis. In fact it does and this is in the next theorem. First, here is an interesting lemma.

Lemma 5.1.10 Suppose $\mathbf{v} \notin \operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)$ and $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right\}$ is linearly independent. Then $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{v}\right\}$ is also linearly independent.

Proof: Suppose $\sum_{i=1}^{k} c_{i} \mathbf{u}_{i}+d \mathbf{v}=\mathbf{0}$. It is required to verify that each $c_{i}=0$ and that $d=$ 0 . But if $d \neq 0$, then you can solve for $\mathbf{v}$ as a linear combination of the vectors, $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right\}$,

$$
\mathbf{v}=-\sum_{i=1}^{k}\left(\frac{c_{i}}{d}\right) \mathbf{u}_{i}
$$

contrary to assumption. Therefore, $d=0$. But then $\sum_{i=1}^{k} c_{i} \mathbf{u}_{i}=0$ and the linear independence of $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right\}$ implies each $c_{i}=0$ also. This proves the lemma.

Theorem 5.1.11 Let $V$ be a nonzero subspace of $\mathbb{F}^{n}$. Then $V$ has a basis.
Proof: Let $\mathbf{v}_{1} \in V$ where $\mathbf{v}_{1} \neq 0$. If $\operatorname{span}\left\{\mathbf{v}_{1}\right\}=V$, stop. $\left\{\mathbf{v}_{1}\right\}$ is a basis for $V$. Otherwise, there exists $\mathbf{v}_{2} \in V$ which is not in span $\left\{\mathbf{v}_{1}\right\}$. By Lemma 5.1.10 $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}$ is a linearly independent set of vectors. If span $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}=V$ stop, $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}$ is a basis for $V$. If $\operatorname{span}\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\} \neq V$, then there exists $\mathbf{v}_{3} \notin \operatorname{span}\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}$ and $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}, \mathbf{v}_{3}\right\}$ is a larger linearly independent set of vectors. Continuing this way, the process must stop before $n+1$ steps because if not, it would be possible to obtain $n+1$ linearly independent vectors contrary to the exchange theorem. This proves the theorem.

In words the following corollary states that any linearly independent set of vectors can be enlarged to form a basis.

Corollary 5.1.12 Let $V$ be a subspace of $\mathbb{F}^{n}$ and let $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\}$ be a linearly independent set of vectors in $V$. Then either it is a basis for $V$ or there exist vectors, $\mathbf{v}_{r+1}, \cdots, \mathbf{v}_{s}$ such that $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}, \mathbf{v}_{r+1}, \cdots, \mathbf{v}_{s}\right\}$ is a basis for $V$.

Proof: This follows immediately from the proof of Theorem 59.16.4. You do exactly the same argument except you start with $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\}$ rather than $\left\{\mathbf{v}_{1}\right\}$.

It is also true that any spanning set of vectors can be restricted to obtain a basis.
Theorem 5.1.13 Let $V$ be a subspace of $\mathbb{F}^{n}$ and suppose $\operatorname{span}\left(\mathbf{u}_{1} \cdots, \mathbf{u}_{p}\right)=V$ where the $\mathbf{u}_{i}$ are nonzero vectors. Then there exist vectors, $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ such that $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\} \subseteq$ $\left\{\mathbf{u}_{1} \cdots, \mathbf{u}_{p}\right\}$ and $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ is a basis for $V$.

Proof: Let $r$ be the smallest positive integer with the property that for some set,

$$
\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\} \subseteq\left\{\mathbf{u}_{1} \cdots, \mathbf{u}_{p}\right\}, \operatorname{span}\left(\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right)=V
$$

Then $r \leq p$ and it must be the case that $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ is linearly independent because if it were not so, one of the vectors, say $\mathbf{v}_{k}$ would be a linear combination of the others. But then you could delete this vector from $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ and the resulting list of $r-1$ vectors would still span $V$ contrary to the definition of $r$. This proves the theorem.

### 5.2 An Application To Matrices

The following is a theorem of major significance.
Theorem 5.2.1 Suppose $A$ is an $n \times n$ matrix. Then $A$ is one to one if and only if $A$ is onto. Also, if $B$ is an $n \times n$ matrix and $A B=I$, then it follows $B A=I$.

Proof: First suppose $A$ is one to one. Consider the vectors, $\left\{A \mathbf{e}_{1}, \cdots, A \mathbf{e}_{n}\right\}$ where $\mathbf{e}_{k}$ is the column vector which is all zeros except for a 1 in the $k^{t h}$ position. This set of vectors is linearly independent because if

$$
\sum_{k=1}^{n} c_{k} A \mathbf{e}_{k}=\mathbf{0}
$$

then since $A$ is linear,

$$
A\left(\sum_{k=1}^{n} c_{k} \mathbf{e}_{k}\right)=\mathbf{0}
$$

and since $A$ is one to one, it follows

$$
\sum_{k=1}^{n} c_{k} \mathbf{e}_{k}=\mathbf{0}^{2}
$$

which implies each $c_{k}=0$. Therefore, $\left\{A \mathbf{e}_{1}, \cdots, A \mathbf{e}_{n}\right\}$ must be a basis for $\mathbb{F}^{n}$ because if not there would exist a vector, $\mathbf{y} \notin \operatorname{span}\left(A \mathbf{e}_{1}, \cdots, A \mathbf{e}_{n}\right)$ and then by Lemma 5.1.10, $\left\{A \mathbf{e}_{1}, \cdots, A \mathbf{e}_{n}, \mathbf{y}\right\}$ would be an independent set of vectors having $n+1$ vectors in it, contrary to the exchange theorem. It follows that for $\mathbf{y} \in \mathbb{F}^{n}$ there exist constants, $c_{i}$ such that

$$
\mathbf{y}=\sum_{k=1}^{n} c_{k} A \mathbf{e}_{k}=A\left(\sum_{k=1}^{n} c_{k} \mathbf{e}_{k}\right)
$$

showing that, since $\mathbf{y}$ was arbitrary, $A$ is onto.
Next suppose $A$ is onto. This means the span of the columns of $A$ equals $\mathbb{F}^{n}$. If these columns are not linearly independent, then by Lemma 5.1.2 on Page 61, one of the columns is a linear combination of the others and so the span of the columns of $A$ equals the span of the $n-1$ other columns. This violates the exchange theorem because $\left\{\mathbf{e}_{1}, \cdots, \mathbf{e}_{n}\right\}$ would be a linearly independent set of vectors contained in the span of only $n-1$ vectors. Therefore, the columns of $A$ must be independent and this equivalent to saying that $A \mathbf{x}=\mathbf{0}$ if and only if $\mathbf{x}=\mathbf{0}$. This implies $A$ is one to one because if $A \mathbf{x}=A \mathbf{y}$, then $A(\mathbf{x}-\mathbf{y})=\mathbf{0}$ and so $\mathbf{x}-\mathbf{y}=\mathbf{0}$.

Now suppose $A B=I$. Why is $B A=I$ ? Since $A B=I$ it follows $B$ is one to one since otherwise, there would exist, $\mathbf{x} \neq \mathbf{0}$ such that $B \mathbf{x}=\mathbf{0}$ and then $A B \mathbf{x}=A \mathbf{0}=\mathbf{0} \neq I \mathbf{x}$. Therefore, from what was just shown, $B$ is also onto. In addition to this, $A$ must be one to one because if $A \mathbf{y}=\mathbf{0}$, then $\mathbf{y}=B \mathbf{x}$ for some $\mathbf{x}$ and then $\mathbf{x}=A B \mathbf{x}=A \mathbf{y}=\mathbf{0}$ showing $\mathbf{y}=\mathbf{0}$. Now from what is given to be so, it follows $(A B) A=A$ and so using the associative law for matrix multiplication,

$$
A(B A)-A=A(B A-I)=0
$$

But this means $(B A-I) \mathbf{x}=\mathbf{0}$ for all $\mathbf{x}$ since otherwise, $A$ would not be one to one. Hence $B A=I$ as claimed. This proves the theorem.

This theorem shows that if an $n \times n$ matrix, $B$ acts like an inverse when multiplied on one side of $A$ it follows that $B=A^{-1}$ and it will act like an inverse on both sides of $A$.

The conclusion of this theorem pertains to square matrices only. For example, let

$$
A=\left(\begin{array}{ll}
1 & 0  \tag{5.2.3}\\
0 & 1 \\
1 & 0
\end{array}\right), B=\left(\begin{array}{ccc}
1 & 0 & 0 \\
1 & 1 & -1
\end{array}\right)
$$

Then

$$
B A=\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right)
$$

but

$$
A B=\left(\begin{array}{ccc}
1 & 0 & 0 \\
1 & 1 & -1 \\
1 & 0 & 0
\end{array}\right)
$$

### 5.3 The Mathematical Theory Of Determinants

### 5.3.1 The Function sgn

The following Lemma will be essential in the definition of the determinant.
Lemma 5.3.1 There exists a function, $\operatorname{sgn}_{n}$ which maps each ordered list of numbers from $\{1, \cdots, n\}$ to one of the three numbers, 0,1 , or -1 which also has the following properties.

$$
\begin{gather*}
\operatorname{sgn}_{n}(1, \cdots, n)=1  \tag{5.3.4}\\
\operatorname{sgn}_{n}\left(i_{1}, \cdots, p, \cdots, q, \cdots, i_{n}\right)=-\operatorname{sgn}_{n}\left(i_{1}, \cdots, q, \cdots, p, \cdots, i_{n}\right) \tag{5.3.5}
\end{gather*}
$$

In words, the second property states that if two of the numbers are switched, the value of the function is multiplied by -1 . Also, in the case where $n>1$ and $\left\{i_{1}, \cdots, i_{n}\right\}=\{1, \cdots, n\}$ so that every number from $\{1, \cdots, n\}$ appears in the ordered list, $\left(i_{1}, \cdots, i_{n}\right)$,

$$
\begin{gather*}
\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{\theta-1}, n, i_{\theta+1}, \cdots, i_{n}\right) \equiv \\
(-1)^{n-\theta} \operatorname{sgn}_{n-1}\left(i_{1}, \cdots, i_{\theta-1}, i_{\theta+1}, \cdots, i_{n}\right) \tag{5.3.6}
\end{gather*}
$$

where $n=i_{\theta}$ in the ordered list, $\left(i_{1}, \cdots, i_{n}\right)$.
Proof: Define $\operatorname{sign}(x)=1$ if $x>0,-1$ if $x<0$ and 0 if $x=0$. If $n=1$, there is only one list and it is just the number 1 . Thus one can define $\operatorname{sgn}_{1}(1) \equiv 1$. For the general case where $n>1$, simply define

$$
\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{n}\right) \equiv \operatorname{sign}\left(\prod_{r<s}\left(i_{s}-i_{r}\right)\right)
$$

This delivers either $-1,1$, or 0 by definition. What about the other claims? Suppose you switch $i_{p}$ with $i_{q}$ where $p<q$ so two numbers in the ordered list $\left(i_{1}, \cdots, i_{n}\right)$ are switched. Denote the new ordered list of numbers as $\left(j_{1}, \cdots, j_{n}\right)$. Thus $j_{p}=i_{q}$ and $j_{q}=i_{p}$ and if $r \notin\{p, q\}, j_{r}=i_{r}$. See the following illustration

$$
\begin{array}{cccccccc}
\frac{i_{1}}{1} & \frac{i_{2}}{2} & \cdots & \frac{i_{p}}{p} & \cdots & \frac{i_{q}}{q} & \cdots & \frac{i_{n}}{n} \\
\frac{i_{1}}{1} & \frac{i_{2}}{2} & \cdots & \frac{i_{q}}{p} & \cdots & \frac{i_{p}}{q} & \cdots & \frac{i_{n}}{n} \\
\frac{j_{1}}{1} & \frac{j_{2}}{2} & \cdots & \frac{j_{p}}{p} & \cdots & \frac{j_{q}}{q} & \cdots & \frac{j_{n}}{n}
\end{array}
$$

Then

$$
\begin{gathered}
\operatorname{sgn}_{n}\left(j_{1}, \cdots, j_{n}\right) \equiv \operatorname{sign}\left(\prod_{r<s}\left(j_{s}-j_{r}\right)\right) \\
=\operatorname{sign}((\begin{array}{c}
\text { both } p, q \\
\left(i_{p}-i_{q}\right)
\end{array} \overbrace{\prod_{p<j<q}\left(i_{j}-i_{q}\right) \prod_{p<j<q}\left(i_{p}-i_{j}\right)}^{\text {one of } p, q} \prod_{r<s, r, s \notin\{p, q\}}^{\text {neither } p \text { nor } q}\left(i_{s}-i_{r}\right))
\end{gathered}
$$

The last product consists of the product of terms which were in the un-switched product $\prod_{r<s}\left(i_{s}-i_{r}\right)$ so produces no change in sign, while the two products in the middle both introduce $q-p-1$ minus signs. Thus their product produces no change in sign. The first factor is of opposite sign to the $i_{q}-i_{p}$ which occured in $\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{n}\right)$. Therefore, this switch introduced a minus sign and

$$
\operatorname{sgn}_{n}\left(j_{1}, \cdots, j_{n}\right)=-\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{n}\right)
$$

Now consider the last claim. In computing $\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{\theta-1}, n, i_{\theta+1}, \cdots, i_{n}\right)$ there will be the product of $n-\theta$ negative terms

$$
\left(i_{\theta+1}-n\right) \cdots\left(i_{n}-n\right)
$$

and the other terms in the product for computing $\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{\theta-1}, n, i_{\theta+1}, \cdots, i_{n}\right)$ are those which are required to compute $\operatorname{sgn}_{n-1}\left(i_{1}, \cdots, i_{\theta-1}, i_{\theta+1}, \cdots, i_{n}\right)$ multiplied by terms of the form $\left(n-i_{j}\right)$ which are nonnegative. It follows that

$$
\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{\theta-1}, n, i_{\theta+1}, \cdots, i_{n}\right)=(-1)^{n-\theta} \operatorname{sgn}_{n-1}\left(i_{1}, \cdots, i_{\theta-1}, i_{\theta+1}, \cdots, i_{n}\right)
$$

It is obvious that if there are repeats in the list the function gives 0 .

Lemma 5.3.2 Every ordered list of distinct numbers from $\{1,2, \cdots, n\}$ can be obtained from every other such ordered list by a finite number of switches. Also, $\operatorname{sgn}_{n}$ is unique.

Proof: This is obvious if $n=1$ or 2. Suppose then that it is true for sets of $n-1$ elements. Take two ordered lists of numbers, $P_{1}, P_{2}$. Make one switch in both to place $n$ at the end. Call the result $P_{1}^{n}$ and $P_{2}^{n}$. Then using induction, there are finitely many switches in $P_{1}^{n}$ so that it will coincide with $P_{2}^{n}$. Now switch the $n$ in what results to where it was in $P_{2}$.

To see $\operatorname{sgn}_{n}$ is unique, if there exist two functions, $f$ and $g$ both satisfying 5.3.4 and 5.3.5, you could start with $f(1, \cdots, n)=g(1, \cdots, n)=1$ and applying the same sequence of switches, eventually arrive at $f\left(i_{1}, \cdots, i_{n}\right)=g\left(i_{1}, \cdots, i_{n}\right)$. If any numbers are repeated, then 5.3.5 gives both functions are equal to zero for that ordered list.

Definition 5.3.3 When you have an ordered list of distinct numbers from $\{1,2, \cdots, n\}$, say

$$
\left(i_{1}, \cdots, i_{n}\right)
$$

this ordered list is called a permutation. The symbol for all such permutations is $S_{n}$. The number $\operatorname{sgn}_{n}\left(i_{1}, \cdots, i_{n}\right)$ is called the sign of the permutation.

A permutation can also be considered as a function from the set

$$
\{1,2, \cdots, n\} \text { to }\{1,2, \cdots, n\}
$$

as follows. Let $f(k)=i_{k}$. Permutations are of fundamental importance in certain areas of math. For example, it was by considering permutations that Galois was able to give a criterion for solution of polynomial equations by radicals, but this is a different direction than what is being attempted here.

In what follows sgn will often be used rather than $\operatorname{sgn}_{n}$ because the context supplies the appropriate $n$.

### 5.4 The Determinant

Definition 5.4.1 Let $f$ be a function which has the set of ordered lists of numbers from $\{1, \cdots, n\}$ as its domain. Define

$$
\sum_{\left(k_{1}, \cdots, k_{n}\right)} f\left(k_{1} \cdots k_{n}\right)
$$

to be the sum of all the $f\left(k_{1} \cdots k_{n}\right)$ for all possible choices of ordered lists $\left(k_{1}, \cdots, k_{n}\right)$ of numbers of $\{1, \cdots, n\}$. For example,

$$
\sum_{\left(k_{1}, k_{2}\right)} f\left(k_{1}, k_{2}\right)=f(1,2)+f(2,1)+f(1,1)+f(2,2) .
$$

### 5.4.1 The Definition

Definition 5.4.2 Let $\left(a_{i j}\right)=A$ denote an $n \times n$ matrix. The determinant of $A$, denoted by $\operatorname{det}(A)$ is defined by

$$
\operatorname{det}(A) \equiv \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{1 k_{1}} \cdots a_{n k_{n}}
$$

where the sum is taken over all ordered lists of numbers from $\{1, \cdots, n\}$. Note it suffices to take the sum over only those ordered lists in which there are no repeats because if there are, $\operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right)=0$ and so that term contributes 0 to the sum.

### 5.4.2 Permuting Rows Or Columns

Let $A$ be an $n \times n$ matrix, $A=\left(a_{i j}\right)$ and let $\left(r_{1}, \cdots, r_{n}\right)$ denote an ordered list of $n$ numbers from $\{1, \cdots, n\}$. Let $A\left(r_{1}, \cdots, r_{n}\right)$ denote the matrix whose $k^{\text {th }}$ row is the $r_{k}$ row of the matrix $A$. Thus

$$
\begin{equation*}
\operatorname{det}\left(A\left(r_{1}, \cdots, r_{n}\right)\right)=\sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{r_{1} k_{1}} \cdots a_{r_{n} k_{n}} \tag{5.4.7}
\end{equation*}
$$

and

$$
A(1, \cdots, n)=A
$$

Proposition 5.4.3 Let

$$
\left(r_{1}, \cdots, r_{n}\right)
$$

be an ordered list of numbers from $\{1, \cdots, n\}$. Then

$$
\begin{align*}
& \operatorname{sgn}\left(r_{1}, \cdots, r_{n}\right) \operatorname{det}(A) \\
= & \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{r_{1} k_{1}} \cdots a_{r_{n} k_{n}}  \tag{5.4.8}\\
= & \operatorname{det}\left(A\left(r_{1}, \cdots, r_{n}\right)\right) \tag{5.4.9}
\end{align*}
$$

Proof: Let $(1, \cdots, n)=(1, \cdots, r, \cdots s, \cdots, n)$ so $r<s$.

$$
\begin{equation*}
\operatorname{det}(A(1, \cdots, r, \cdots, s, \cdots, n))= \tag{5.4.10}
\end{equation*}
$$

$$
\sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{r}, \cdots, k_{s}, \cdots, k_{n}\right) a_{1 k_{1}} \cdots a_{r k_{r}} \cdots a_{s k_{s}} \cdots a_{n k_{n}}
$$

and renaming the variables, calling $k_{s}, k_{r}$ and $k_{r}, k_{s}$, this equals

$$
\begin{gather*}
=\sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{s}, \cdots, k_{r}, \cdots, k_{n}\right) a_{1 k_{1}} \cdots a_{r k_{s}} \cdots a_{s k_{r}} \cdots a_{n k_{n}} \\
=\sum_{\left(k_{1}, \cdots, k_{n}\right)}-\operatorname{sgn}(k_{1}, \cdots, \overbrace{k_{r}, \cdots, k_{s}}^{\text {These got switched }}, \cdots, k_{n}) a_{1 k_{1}} \cdots a_{s k_{r}} \cdots a_{r k_{s}} \cdots a_{n k_{n}} \\
=-\operatorname{det}(A(1, \cdots, s, \cdots, r, \cdots, n)) \tag{5.4.11}
\end{gather*}
$$

Consequently,

$$
\begin{gathered}
\operatorname{det}(A(1, \cdots, s, \cdots, r, \cdots, n))= \\
-\operatorname{det}(A(1, \cdots, r, \cdots, s, \cdots, n))=-\operatorname{det}(A)
\end{gathered}
$$

Now letting $A(1, \cdots, s, \cdots, r, \cdots, n)$ play the role of $A$, and continuing in this way, switching pairs of numbers,

$$
\operatorname{det}\left(A\left(r_{1}, \cdots, r_{n}\right)\right)=(-1)^{p} \operatorname{det}(A)
$$

where it took $p$ switches to obtain $\left(r_{1}, \cdots, r_{n}\right)$ from $(1, \cdots, n)$. By Lemma 5.3.1, this implies

$$
\operatorname{det}\left(A\left(r_{1}, \cdots, r_{n}\right)\right)=(-1)^{p} \operatorname{det}(A)=\operatorname{sgn}\left(r_{1}, \cdots, r_{n}\right) \operatorname{det}(A)
$$

and proves the proposition in the case when there are no repeated numbers in the ordered list, $\left(r_{1}, \cdots, r_{n}\right)$.However, if there is a repeat, say the $r^{\text {th }}$ row equals the $s^{\text {th }}$ row, then the reasoning of 5.4.10 -5.4.11 shows that $\operatorname{det} A\left(r_{1}, \cdots, r_{n}\right)=0$ and also $\operatorname{sgn}\left(r_{1}, \cdots, r_{n}\right)=0$ so the formula holds in this case also.

Observation 5.4.4 There are $n!$ ordered lists of distinct numbers from $\{1, \cdots, n\}$.
To see this, consider $n$ slots placed in order. There are $n$ choices for the first slot. For each of these choices, there are $n-1$ choices for the second. Thus there are $n(n-1)$ ways to fill the first two slots. Then for each of these ways there are $n-2$ choices left for the third slot. Continuing this way, there are $n$ ! ordered lists of distinct numbers from $\{1, \cdots, n\}$ as stated in the observation.

### 5.4.3 A Symmetric Definition

With the above, it is possible to give a more symmetric description of the determinant from which it will follow that $\operatorname{det}(A)=\operatorname{det}\left(A^{T}\right)$.

Corollary 5.4.5 The following formula for $\operatorname{det}(A)$ is valid.

$$
\begin{gather*}
\operatorname{det}(A)=\frac{1}{n!} \\
\sum_{\left(r_{1}, \cdots, r_{n}\right)} \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(r_{1}, \cdots, r_{n}\right) \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{r_{1} k_{1}} \cdots a_{r_{n} k_{n}} \tag{5.4.12}
\end{gather*}
$$

And also $\operatorname{det}\left(A^{T}\right)=\operatorname{det}(A)$ where $A^{T}$ is the transpose of $A$. (Recall that for $A^{T}=\left(a_{i j}^{T}\right)$, $a_{i j}^{T}=a_{j i}$.)

Proof: From Proposition 5.4.3, if the $r_{i}$ are distinct,

$$
\operatorname{det}(A)=\sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(r_{1}, \cdots, r_{n}\right) \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{r_{1} k_{1}} \cdots a_{r_{n} k_{n}}
$$

Summing over all ordered lists, $\left(r_{1}, \cdots, r_{n}\right)$ where the $r_{i}$ are distinct, (If the $r_{i}$ are not distinct, $\operatorname{sgn}\left(r_{1}, \cdots, r_{n}\right)=0$ and so there is no contribution to the sum.)

$$
\begin{gathered}
n!\operatorname{det}(A)= \\
\sum_{\left(r_{1}, \cdots, r_{n}\right)} \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(r_{1}, \cdots, r_{n}\right) \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{r_{1} k_{1}} \cdots a_{r_{n} k_{n}} .
\end{gathered}
$$

This proves the corollary since the formula gives the same number for $A$ as it does for $A^{T}$.

### 5.4.4 The Alternating Property Of The Determinant

Corollary 5.4.6 If two rows or two columns in an $n \times n$ matrix $A$, are switched, the determinant of the resulting matrix equals $(-1)$ times the determinant of the original matrix. If $A$ is an $n \times n$ matrix in which two rows are equal or two columns are equal then $\operatorname{det}(A)=0$. Suppose the $i^{\text {th }}$ row of $A$ equals $\left(x a_{1}+y b_{1}, \cdots, x a_{n}+y b_{n}\right)$. Then

$$
\operatorname{det}(A)=x \operatorname{det}\left(A_{1}\right)+y \operatorname{det}\left(A_{2}\right)
$$

where the $i^{\text {th }}$ row of $A_{1}$ is $\left(a_{1}, \cdots, a_{n}\right)$ and the $i^{\text {th }}$ row of $A_{2}$ is $\left(b_{1}, \cdots, b_{n}\right)$, all other rows of $A_{1}$ and $A_{2}$ coinciding with those of $A$. In other words, det is a linear function of each row A. The same is true with the word "row" replaced with the word "column".

Proof: By Proposition 5.4 .3 when two rows are switched, the determinant of the resulting matrix is $(-1)$ times the determinant of the original matrix. By Corollary 5.4.5 the same holds for columns because the columns of the matrix equal the rows of the transposed matrix. Thus if $A_{1}$ is the matrix obtained from $A$ by switching two columns,

$$
\operatorname{det}(A)=\operatorname{det}\left(A^{T}\right)=-\operatorname{det}\left(A_{1}^{T}\right)=-\operatorname{det}\left(A_{1}\right) .
$$

If $A$ has two equal columns or two equal rows, then switching them results in the same matrix. Therefore, $\operatorname{det}(A)=-\operatorname{det}(A)$ and $\operatorname{so} \operatorname{det}(A)=0$.

It remains to verify the last assertion.

$$
\begin{aligned}
& \operatorname{det}(A) \equiv \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{1 k_{1}} \cdots\left(x a_{k_{i}}+y b_{k_{i}}\right) \cdots a_{n k_{n}} \\
&=x \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{1 k_{1}} \cdots a_{k_{i}} \cdots a_{n k_{n}} \\
&+y \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{1 k_{1}} \cdots b_{k_{i}} \cdots a_{n k_{n}} \\
& \equiv x \operatorname{det}\left(A_{1}\right)+y \operatorname{det}\left(A_{2}\right) .
\end{aligned}
$$

The same is true of columns because $\operatorname{det}\left(A^{T}\right)=\operatorname{det}(A)$ and the rows of $A^{T}$ are the columns of $A$.

### 5.4.5 Linear Combinations And Determinants

Linear combinations have been discussed already. However, here is a review and some new terminology.

Definition 5.4.7 A vector $\mathbf{w}$, is a linear combination of the vectors $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\}$ if there exists scalars, $c_{1}, \cdots c_{r}$ such that $\mathbf{w}=\sum_{k=1}^{r} c_{k} \mathbf{v}_{k}$. This is the same as saying

$$
\mathbf{w} \in \operatorname{span}\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right)
$$

The following corollary is also of great use.
Corollary 5.4.8 Suppose $A$ is an $n \times n$ matrix and some column (row) is a linear combination of $r$ other columns (rows). Then $\operatorname{det}(A)=0$.

Proof: Let $A=\left(\begin{array}{lll}\mathbf{a}_{1} & \cdots & \mathbf{a}_{n}\end{array}\right)$ be the columns of $A$ and suppose the condition that one column is a linear combination of $r$ of the others is satisfied. Then by using Corollary 5.4.6 the determinant of $A$ is zero if and only if the determinant of the matrix $B$, which has this special column placed in the last position, equals zero. Thus $\mathbf{a}_{n}=\sum_{k=1}^{r} c_{k} \mathbf{a}_{k}$ and so

$$
\operatorname{det}(B)=\operatorname{det}\left(\begin{array}{llllll}
\mathbf{a}_{1} & \cdots & \mathbf{a}_{r} & \cdots & \mathbf{a}_{n-1} & \sum_{k=1}^{r} c_{k} \mathbf{a}_{k}
\end{array}\right)
$$

By Corollary 5.4.6

$$
\operatorname{det}(B)=\sum_{k=1}^{r} c_{k} \operatorname{det}\left(\begin{array}{llllll}
\mathbf{a}_{1} & \cdots & \mathbf{a}_{r} & \cdots & \mathbf{a}_{n-1} & \mathbf{a}_{k}
\end{array}\right)=0
$$

because there are two equal columns. The case for rows follows from the fact that $\operatorname{det}(A)=$ $\operatorname{det}\left(A^{T}\right)$.

### 5.4.6 The Determinant Of A Product

Recall the following definition of matrix multiplication.
Definition 5.4.9 If $A$ and $B$ are $n \times n$ matrices, $A=\left(a_{i j}\right)$ and $B=\left(b_{i j}\right), A B=\left(c_{i j}\right)$ where

$$
c_{i j} \equiv \sum_{k=1}^{n} a_{i k} b_{k j} .
$$

One of the most important rules about determinants is that the determinant of a product equals the product of the determinants.

Theorem 5.4.10 Let $A$ and $B$ be $n \times n$ matrices. Then

$$
\operatorname{det}(A B)=\operatorname{det}(A) \operatorname{det}(B)
$$

Proof: Let $c_{i j}$ be the $i j^{t h}$ entry of $A B$. Then by Proposition 5.4.3,

$$
\left.\begin{array}{c}
\operatorname{det}(A B)= \\
=\sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) c_{1 k_{1}} \cdots c_{n k_{n}} \\
=\sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right)\left(\sum_{r_{1}} a_{1 r_{1}} b_{r_{1} k_{1}}\right) \cdots\left(\sum_{r_{n}} a_{n r_{n}} b_{r_{n} k_{n}}\right) \\
=\sum_{\left(r_{1} \cdots, r_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) b_{r_{1} k_{1}} \cdots b_{r_{n} k_{n}}\left(a_{1 r_{1}} \cdots a_{n r_{n}}\right) \\
\operatorname{sgn}\left(r_{1} \cdots, r_{n}\right)
\end{array}\right) a_{1 r_{1}} \cdots a_{n r_{n}} \operatorname{det}(B)=\operatorname{det}(A) \operatorname{det}(B) . I .
$$

### 5.4.7 Cofactor Expansions

Lemma 5.4.11 Suppose a matrix is of the form

$$
M=\left(\begin{array}{cc}
A & *  \tag{5.4.13}\\
\mathbf{0} & a
\end{array}\right)
$$

or

$$
M=\left(\begin{array}{cc}
A & \mathbf{0}  \tag{5.4.14}\\
* & a
\end{array}\right)
$$

where $a$ is a number and $A$ is an $(n-1) \times(n-1)$ matrix and $*$ denotes either a column or a row having length $n-1$ and the 0 denotes either a column or a row of length $n-1$ consisting entirely of zeros. Then $\operatorname{det}(M)=a \operatorname{det}(A)$.

Proof: Denote $M$ by $\left(m_{i j}\right)$. Thus in the first case, $m_{n n}=a$ and $m_{n i}=0$ if $i \neq n$ while in the second case, $m_{n n}=a$ and $m_{i n}=0$ if $i \neq n$. From the definition of the determinant,

$$
\operatorname{det}(M) \equiv \sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}_{n}\left(k_{1}, \cdots, k_{n}\right) m_{1 k_{1}} \cdots m_{n k_{n}}
$$

Letting $\theta$ denote the position of $n$ in the ordered list, $\left(k_{1}, \cdots, k_{n}\right)$ then using Lemma 5.3.1, $\operatorname{det}(M)$ equals

$$
\sum_{\left(k_{1}, \cdots, k_{n}\right)}(-1)^{n-\theta} \operatorname{sgn}_{n-1}\left(k_{1}, \cdots, k_{\theta-1}, \stackrel{\theta}{k_{\theta+1}}, \cdots, \stackrel{n-1}{k_{n}}\right) m_{1 k_{1}} \cdots m_{n k_{n}}
$$

Now suppose 5.4.14. Then if $k_{n} \neq n$, the term involving $m_{n k_{n}}$ in the above expression equals zero. Therefore, the only terms which survive are those for which $\theta=n$ or in other words, those for which $k_{n}=n$. Therefore, the above expression reduces to

$$
a \sum_{\left(k_{1}, \cdots, k_{n-1}\right)} \operatorname{sgn}_{n-1}\left(k_{1}, \cdots k_{n-1}\right) m_{1 k_{1}} \cdots m_{(n-1) k_{n-1}}=a \operatorname{det}(A) .
$$

To get the assertion in the situation of 5.4.13 use Corollary 5.4.5 and 5.4.14 to write

$$
\operatorname{det}(M)=\operatorname{det}\left(M^{T}\right)=\operatorname{det}\left(\left(\begin{array}{cc}
A^{T} & \mathbf{0} \\
* & a
\end{array}\right)\right)=a \operatorname{det}\left(A^{T}\right)=a \operatorname{det}(A)
$$

In terms of the theory of determinants, arguably the most important idea is that of Laplace expansion along a row or a column. This will follow from the above definition of a determinant.

Definition 5.4.12 Let $A=\left(a_{i j}\right)$ be an $n \times n$ matrix. Then a new matrix called the cofactor matrix, $\operatorname{cof}(A)$ is defined by $\operatorname{cof}(A)=\left(c_{i j}\right)$ where to obtain $c_{i j}$ delete the $i^{\text {th }}$ row and the $j^{\text {th }}$ column of $A$, take the determinant of the $(n-1) \times(n-1)$ matrix which results, (This is called the $i j^{\text {th }}$ minor of $A$.) and then multiply this number by $(-1)^{i+j}$. To make the formulas easier to remember, $\operatorname{cof}(A)_{i j}$ will denote the $i j^{\text {th }}$ entry of the cofactor matrix.

The following is the main result. Earlier this was given as a definition and the outrageous totally unjustified assertion was made that the same number would be obtained by expanding the determinant along any row or column. The following theorem proves this assertion.

Theorem 5.4.13 Let $A$ be an $n \times n$ matrix where $n \geq 2$. Then

$$
\begin{equation*}
\operatorname{det}(A)=\sum_{j=1}^{n} a_{i j} \operatorname{cof}(A)_{i j}=\sum_{i=1}^{n} a_{i j} \operatorname{cof}(A)_{i j} . \tag{5.4.15}
\end{equation*}
$$

The first formula consists of expanding the determinant along the $i^{\text {th }}$ row and the second expands the determinant along the $j^{\text {th }}$ column.

Proof: Let $\left(a_{i 1}, \cdots, a_{i n}\right)$ be the $i^{\text {th }}$ row of $A$. Let $B_{j}$ be the matrix obtained from $A$ by leaving every row the same except the $i^{t h}$ row which in $B_{j}$ equals

$$
\left(0, \cdots, 0, a_{i j}, 0, \cdots, 0\right)
$$

Then by Corollary 5.4.6,

$$
\operatorname{det}(A)=\sum_{j=1}^{n} \operatorname{det}\left(B_{j}\right)
$$

Denote by $A^{i j}$ the $(n-1) \times(n-1)$ matrix obtained by deleting the $i^{\text {th }}$ row and the $j^{\text {th }}$ column of $A$. Thus $\operatorname{cof}(A)_{i j} \equiv(-1)^{i+j} \operatorname{det}\left(A^{i j}\right)$. At this point, recall that from Proposition 5.4.3, when two rows or two columns in a matrix $M$, are switched, this results in multiplying the determinant of the old matrix by -1 to get the determinant of the new matrix. Therefore, by Lemma 5.4.11,

$$
\begin{aligned}
\operatorname{det}\left(B_{j}\right) & =(-1)^{n-j}(-1)^{n-i} \operatorname{det}\left(\left(\begin{array}{cc}
A^{i j} & * \\
\mathbf{0} & a_{i j}
\end{array}\right)\right) \\
& =(-1)^{i+j} \operatorname{det}\left(\left(\begin{array}{cc}
A^{i j} & * \\
\mathbf{0} & a_{i j}
\end{array}\right)\right)=a_{i j} \operatorname{cof}(A)_{i j}
\end{aligned}
$$

Therefore,

$$
\operatorname{det}(A)=\sum_{j=1}^{n} a_{i j} \operatorname{cof}(A)_{i j}
$$

which is the formula for expanding $\operatorname{det}(A)$ along the $i^{\text {th }}$ row. Also,

$$
\begin{aligned}
\operatorname{det}(A) & =\operatorname{det}\left(A^{T}\right)=\sum_{j=1}^{n} a_{i j}^{T} \operatorname{cof}\left(A^{T}\right)_{i j} \\
& =\sum_{j=1}^{n} a_{j i} \operatorname{cof}(A)_{j i}
\end{aligned}
$$

which is the formula for expanding $\operatorname{det}(A)$ along the $i^{\text {th }}$ column.

### 5.4.8 Formula For The Inverse

Note that this gives an easy way to write a formula for the inverse of an $n \times n$ matrix.
Theorem 5.4.14 $A^{-1}$ exists if and only if $\operatorname{det}(A) \neq 0$. If $\operatorname{det}(A) \neq 0$, then $A^{-1}=\left(a_{i j}^{-1}\right)$ where

$$
a_{i j}^{-1}=\operatorname{det}(A)^{-1} \operatorname{cof}(A)_{j i}
$$

for $\operatorname{cof}(A)_{i j}$ the $i j^{\text {th }}$ cofactor of $A$.
Proof: By Theorem 5.4.13 and letting $\left(a_{i r}\right)=A$, if $\operatorname{det}(A) \neq 0$,

$$
\sum_{i=1}^{n} a_{i r} \operatorname{cof}(A)_{i r} \operatorname{det}(A)^{-1}=\operatorname{det}(A) \operatorname{det}(A)^{-1}=1
$$

Now consider

$$
\sum_{i=1}^{n} a_{i r} \operatorname{cof}(A)_{i k} \operatorname{det}(A)^{-1}
$$

when $k \neq r$. Replace the $k^{t h}$ column with the $r^{t h}$ column to obtain a matrix $B_{k}$ whose determinant equals zero by Corollary 5.4.6. However, expanding this matrix along the $k^{t h}$ column yields

$$
0=\operatorname{det}\left(B_{k}\right) \operatorname{det}(A)^{-1}=\sum_{i=1}^{n} a_{i r} \operatorname{cof}(A)_{i k} \operatorname{det}(A)^{-1}
$$

Summarizing,

$$
\sum_{i=1}^{n} a_{i r} \operatorname{cof}(A)_{i k} \operatorname{det}(A)^{-1}=\delta_{r k}
$$

Using the other formula in Theorem 5.4.13, and similar reasoning,

$$
\sum_{j=1}^{n} a_{r j} \operatorname{cof}(A)_{k j} \operatorname{det}(A)^{-1}=\delta_{r k}
$$

This proves that if $\operatorname{det}(A) \neq 0$, then $A^{-1}$ exists with $A^{-1}=\left(a_{i j}^{-1}\right)$, where

$$
a_{i j}^{-1}=\operatorname{cof}(A)_{j i} \operatorname{det}(A)^{-1}
$$

Now suppose $A^{-1}$ exists. Then by Theorem 5.4.10,

$$
1=\operatorname{det}(I)=\operatorname{det}\left(A A^{-1}\right)=\operatorname{det}(A) \operatorname{det}\left(A^{-1}\right)
$$

so $\operatorname{det}(A) \neq 0$.
The next corollary points out that if an $n \times n$ matrix $A$ has a right or a left inverse, then it has an inverse.

Corollary 5.4.15 Let $A$ be an $n \times n$ matrix and suppose there exists an $n \times n$ matrix $B$ such that $B A=I$. Then $A^{-1}$ exists and $A^{-1}=B$. Also, if there exists $C$ an $n \times n$ matrix such that $A C=I$, then $A^{-1}$ exists and $A^{-1}=C$.

Proof: Since $B A=I$, Theorem 5.4.10 implies

$$
\operatorname{det} B \operatorname{det} A=1
$$

and so $\operatorname{det} A \neq 0$. Therefore from Theorem 5.4.14, $A^{-1}$ exists. Therefore,

$$
A^{-1}=(B A) A^{-1}=B\left(A A^{-1}\right)=B I=B
$$

The case where $C A=I$ is handled similarly.
The conclusion of this corollary is that left inverses, right inverses and inverses are all the same in the context of $n \times n$ matrices.

Theorem 5.4.14 says that to find the inverse, take the transpose of the cofactor matrix and divide by the determinant. The transpose of the cofactor matrix is called the adjugate or sometimes the classical adjoint of the matrix $A$. It is an abomination to call it the adjoint although you do sometimes see it referred to in this way. In words, $A^{-1}$ is equal to one over the determinant of $A$ times the adjugate matrix of $A$.

### 5.4.9 Cramer's Rule

In case you are solving a system of equations, $A \mathbf{x}=\mathbf{y}$ for $\mathbf{x}$, it follows that if $A^{-1}$ exists,

$$
\mathbf{x}=\left(A^{-1} A\right) \mathbf{x}=A^{-1}(A \mathbf{x})=A^{-1} \mathbf{y}
$$

thus solving the system. Now in the case that $A^{-1}$ exists, there is a formula for $A^{-1}$ given above. Using this formula,

$$
x_{i}=\sum_{j=1}^{n} a_{i j}^{-1} y_{j}=\sum_{j=1}^{n} \frac{1}{\operatorname{det}(A)} \operatorname{cof}(A)_{j i} y_{j} .
$$

By the formula for the expansion of a determinant along a column,

$$
x_{i}=\frac{1}{\operatorname{det}(A)} \operatorname{det}\left(\begin{array}{ccccc}
* & \cdots & y_{1} & \cdots & * \\
\vdots & & \vdots & & \vdots \\
* & \cdots & y_{n} & \cdots & *
\end{array}\right)
$$

where here the $i^{\text {th }}$ column of $A$ is replaced with the column vector $\left(y_{1} \cdots, y_{n}\right)^{T}$, and the determinant of this modified matrix is taken and divided by $\operatorname{det}(A)$. This formula is known as Cramer's rule.

### 5.4.10 Upper Triangular Matrices

Definition 5.4.16 A matrix $M$, is upper triangular if $M_{i j}=0$ whenever $i>j$. Thus such a matrix equals zero below the main diagonal, the entries of the form $M_{i i}$ as shown.

$$
\left(\begin{array}{cccc}
* & * & \cdots & * \\
0 & * & \ddots & \vdots \\
\vdots & \ddots & \ddots & * \\
0 & \cdots & 0 & *
\end{array}\right)
$$

A lower triangular matrix is defined similarly as a matrix for which all entries above the main diagonal are equal to zero.

With this definition, here is a simple corollary of Theorem 5.4.13.
Corollary 5.4.17 Let $M$ be an upper (lower) triangular matrix. Then $\operatorname{det}(M)$ is obtained by taking the product of the entries on the main diagonal.

### 5.5 The Cayley Hamilton Theorem*

Definition 5.5.1 Let A be an $n \times n$ matrix. The characteristic polynomial is defined as

$$
q_{A}(t) \equiv \operatorname{det}(t I-A)
$$

and the solutions to $q_{A}(t)=0$ are called eigenvalues. For A matrix and $p(t)=t^{n}+$ $a_{n-1} t^{n-1}+\cdots+a_{1} t+a_{0}$, denote by $p(A)$ the matrix defined by

$$
p(A) \equiv A^{n}+a_{n-1} A^{n-1}+\cdots+a_{1} A+a_{0} I .
$$

The explanation for the last term is that $A^{0}$ is interpreted as I, the identity matrix.

The Cayley Hamilton theorem states that every matrix satisfies its characteristic equation, that equation defined by $q_{A}(t)=0$. It is one of the most important theorems in linear algebra ${ }^{3}$. The proof in this section is not the most general proof, but works well when the field of scalars is $\mathbb{R}$ or $\mathbb{C}$. The following lemma will help with its proof.

Lemma 5.5.2 Suppose for all $|\lambda|$ large enough,

$$
A_{0}+A_{1} \lambda+\cdots+A_{m} \lambda^{m}=0
$$

where the $A_{i}$ are $n \times n$ matrices. Then each $A_{i}=0$.
Proof: Multiply by $\lambda^{-m}$ to obtain

$$
A_{0} \lambda^{-m}+A_{1} \lambda^{-m+1}+\cdots+A_{m-1} \lambda^{-1}+A_{m}=0
$$

Now let $|\lambda| \rightarrow \infty$ to obtain $A_{m}=0$. With this, multiply by $\lambda$ to obtain

$$
A_{0} \lambda^{-m+1}+A_{1} \lambda^{-m+2}+\cdots+A_{m-1}=0
$$

Now let $|\lambda| \rightarrow \infty$ to obtain $A_{m-1}=0$. Continue multiplying by $\lambda$ and letting $\lambda \rightarrow \infty$ to obtain that all the $A_{i}=0$.

With the lemma, here is a simple corollary.
Corollary 5.5.3 Let $A_{i}$ and $B_{i}$ be $n \times n$ matrices and suppose

$$
A_{0}+A_{1} \lambda+\cdots+A_{m} \lambda^{m}=B_{0}+B_{1} \lambda+\cdots+B_{m} \lambda^{m}
$$

for all $|\lambda|$ large enough. Then $A_{i}=B_{i}$ for all $i$. If $A_{i}=B_{i}$ for each $A_{i}, B_{i}$ then one can substitute an $n \times n$ matrix $M$ for $\lambda$ and the identity will continue to hold.

Proof: Subtract and use the result of the lemma. The last claim is obvious by matching terms.

With this preparation, here is a relatively easy proof of the Cayley Hamilton theorem.
Theorem 5.5.4 Let $A$ be an $n \times n$ matrix and let $q(\lambda) \equiv \operatorname{det}(\lambda I-A)$ be the characteristic polynomial. Then $q(A)=0$.

Proof: Let $C(\lambda)$ equal the transpose of the cofactor matrix of $(\lambda I-A)$ for $|\lambda|$ large. (If $|\lambda|$ is large enough, then $\lambda$ cannot be in the finite list of eigenvalues of $A$ and so for such $\lambda,(\lambda I-A)^{-1}$ exists.) Therefore, by Theorem 5.4.14

$$
C(\lambda)=q(\lambda)(\lambda I-A)^{-1}
$$

Say

$$
q(\lambda)=a_{0}+a_{1} \lambda+\cdots+\lambda^{n}
$$

[^4]Note that each entry in $C(\lambda)$ is a polynomial in $\lambda$ having degree no more than $n-1$. For example, you might have something like

$$
\begin{gathered}
C(\lambda)=\left(\begin{array}{ccc}
\lambda^{2}-6 \lambda+9 & 3-\lambda & 0 \\
2 \lambda-6 & \lambda^{2}-3 \lambda & 0 \\
\lambda-1 & \lambda-1 & \lambda^{2}-3 \lambda+2
\end{array}\right) \\
=\left(\begin{array}{ccc}
9 & 3 & 0 \\
-6 & 0 & 0 \\
-1 & -1 & 2
\end{array}\right)+\lambda\left(\begin{array}{ccc}
-6 & -1 & 0 \\
2 & -3 & 0 \\
1 & 1 & -3
\end{array}\right)+\lambda^{2}\left(\begin{array}{lll}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right)
\end{gathered}
$$

Therefore, collecting the terms in the general case,

$$
C(\lambda)=C_{0}+C_{1} \lambda+\cdots+C_{n-1} \lambda^{n-1}
$$

for $C_{j}$ some $n \times n$ matrix. Then

$$
C(\lambda)(\lambda I-A)=\left(C_{0}+C_{1} \lambda+\cdots+C_{n-1} \lambda^{n-1}\right)(\lambda I-A)=q(\lambda) I
$$

Then multiplying out the middle term, it follows that for all $|\lambda|$ sufficiently large,

$$
\begin{gathered}
a_{0} I+a_{1} I \lambda+\cdots+I \lambda^{n}=C_{0} \lambda+C_{1} \lambda^{2}+\cdots+C_{n-1} \lambda^{n} \\
-\left[C_{0} A+C_{1} A \lambda+\cdots+C_{n-1} A \lambda^{n-1}\right] \\
=-C_{0} A+\left(C_{0}-C_{1} A\right) \lambda+\left(C_{1}-C_{2} A\right) \lambda^{2}+\cdots+\left(C_{n-2}-C_{n-1} A\right) \lambda^{n-1}+C_{n-1} \lambda^{n}
\end{gathered}
$$

Then, using Corollary 5.5.3, one can replace $\lambda$ on both sides with $A$. Then the right side is seen to equal 0 . Hence the left side, $q(A) I$ is also equal to 0 .

### 5.5.1 An Identity of Cauchy

Theorem 5.5.5 Both the left and the right sides in the following yield the same polynomial in the variables $a_{i}, b_{i}$ for $i \leq n$.

$$
\prod_{i, j}\left(a_{i}+b_{j}\right)\left|\begin{array}{ccc}
\frac{1}{a_{1}+b_{1}} & \cdots & \frac{1}{a_{1}+b_{n}}  \tag{5.5.16}\\
\vdots & & \vdots \\
\frac{1}{a_{n}+b_{1}} & \cdots & \frac{1}{a_{n}+b_{n}}
\end{array}\right|=\prod_{j<i}\left(a_{i}-a_{j}\right)\left(b_{i}-b_{j}\right)
$$

Proof: The theorem is true if $n=2$. This follows from some computations. Suppose it
is true for $n-1, n \geq 3$.

$$
\begin{aligned}
& \left|\begin{array}{cccc}
\frac{1}{a_{1}+b_{1}} & \frac{1}{a_{1}+b_{2}} & \cdots & \frac{1}{a_{1}+b_{n}} \\
\vdots & \vdots & \ldots & \vdots \\
\frac{1}{a_{n-1}+b_{1}} & \frac{1}{a_{n-1}+b_{2}} & & \frac{1}{a_{n-1}+b_{n}} \\
\frac{1}{a_{n}+b_{1}} & \frac{1}{a_{n}+b_{2}} & \cdots & \frac{1}{a_{n}+b_{n}}
\end{array}\right| \\
& \frac{a_{n}-a_{1}}{\left(a_{1}+b_{1}\right)\left(b_{1}+a_{n}\right)} \\
& \vdots \\
& \frac{a_{n}-a_{1}}{\left(a_{1}+b_{2}\right)\left(b_{2}+a_{n}\right)} \\
& \frac{a_{n}-1}{\left(a_{n-1}+b_{1}\right)\left(a_{n}+b_{1}\right)} \\
& \frac{1}{a_{n}+b_{1}}
\end{aligned}
$$

Continuing to use the multilinear properties of determinants, this equals

$$
\left|\begin{array}{cccc}
\frac{1}{\left(a_{1}+b_{1}\right)\left(b_{1}+a_{n}\right)} & \frac{1}{\left(a_{1}+b_{2}\right)\left(b_{2}+a_{n}\right)} & \cdots & \frac{1}{\left(a_{1}+b_{n}\right)\left(a_{n}+b_{n}\right)} \\
\vdots & \vdots & \cdots & \vdots \\
\frac{1}{\left(a_{n-1}+b_{1}\right)\left(a_{n}+b_{1}\right)} & \frac{1}{\left(b_{2}+a_{n}\right)\left(b_{2}+a_{n-1}\right)} & & \frac{1}{\left(a_{n}+b_{n}\right)\left(b_{n}+a_{n-1}\right)} \\
\frac{1}{a_{n}+b_{1}} & \frac{1}{a_{n}+b_{2}} & \cdots & \frac{1}{a_{n}+b_{n}}
\end{array}\right| \prod_{k=1}^{n-1}\left(a_{n}-a_{k}\right)
$$

and this equals

$$
\left|\begin{array}{cccc}
\frac{1}{\left(a_{1}+b_{1}\right)} & \frac{1}{\left(a_{1}+b_{2}\right)} & \cdots & \frac{1}{\left(a_{1}+b_{n}\right)} \\
\vdots & \vdots & \cdots & \vdots \\
\frac{1}{\left(a_{n-1}+b_{1}\right)} & \frac{1}{\left(b_{2}+a_{n-1}\right)} & & \frac{1}{\left(b_{n}+a_{n-1}\right)} \\
1 & 1 & \cdots & 1
\end{array}\right| \frac{\prod_{k=1}^{n-1}\left(a_{n}-a_{k}\right)}{\prod_{k=1}^{n}\left(a_{n}+b_{k}\right)}
$$

Now take -1 times the last column and add to each previous column. Thus it equals

$$
\left|\begin{array}{cccc|}
\frac{b_{n}-b_{1}}{\left(a_{1}+b_{1}\right)\left(a_{1}+b_{n}\right)} & \frac{b_{n}-b_{2}}{\left(a_{1}+b_{2}\right)\left(a_{1}+b_{n}\right)} & \cdots & \frac{1}{\left(a_{1}+b_{n}\right)} \\
\vdots & \vdots & \cdots & \vdots \\
\frac{b_{n}-b_{1}}{\left(b_{1}+a_{n-1}\right)\left(b_{n}+a_{n-1}\right)} & \frac{b_{n}-b_{2}}{\left(b_{2}+a_{n-1}\right)\left(b_{n}+a_{n-1}\right)} & & \frac{1}{\left(a_{n-1}+b_{n}\right)}
\end{array}\right| \begin{aligned}
& \prod_{k=1}^{n-1}\left(a_{n}-a_{k}\right) \\
& \prod_{k=1}^{n}\left(a_{n}+b_{k}\right) \\
& 0
\end{aligned}
$$

Now continue simplifying using the multilinear property of the determinant.

$$
\left|\begin{array}{cccc}
\frac{1}{\left(a_{1}+b_{1}\right)} & \frac{1}{\left(a_{1}+b_{2}\right)} & \cdots & 1 \\
\vdots & \vdots & \cdots & \vdots \\
\frac{1}{\left(b_{1}+a_{n-1}\right)} & \frac{1}{\left(b_{2}+a_{n-1}\right)} & & 1 \\
0 & 0 & \cdots & 1
\end{array}\right| \frac{\prod_{k=1}^{n-1}\left(a_{n}-a_{k}\right)}{\prod_{k=1}^{n}\left(a_{n}+b_{k}\right)} \frac{\prod_{k=1}^{n-1}\left(b_{n}-b_{k}\right)}{\prod_{k=1}^{n-1}\left(a_{k}+b_{n}\right)}
$$

Now, expanding along the bottom row, what has just resulted is

$$
\left|\begin{array}{ccc}
\frac{1}{a_{1}+b_{1}} & \cdots & \frac{1}{a_{1}+b_{n-1}} \\
\vdots & \cdots & \vdots \\
\frac{1}{a_{n-1}+b_{1}} & \cdots & \frac{1}{a_{n-1}+b_{n-1}}
\end{array}\right| \frac{\prod_{k=1}^{n-1}\left(a_{n}-a_{k}\right)}{\prod_{k=1}^{n}\left(a_{n}+b_{k}\right)} \frac{\prod_{k=1}^{n-1}\left(b_{n}-b_{k}\right)}{\prod_{k=1}^{n-1}\left(a_{k}+b_{n}\right)}
$$

By induction this equals

$$
\begin{gathered}
\frac{\prod_{k=1}^{n-1}\left(a_{n}-a_{k}\right)}{\prod_{k=1}^{n}\left(a_{n}+b_{k}\right)} \frac{\prod_{k=1}^{n-1}\left(b_{n}-b_{k}\right)}{\prod_{k=1}^{n-1}\left(a_{k}+b_{n}\right)} \frac{\prod_{j<i \leq n-1}\left(a_{i}-a_{j}\right)\left(b_{i}-b_{j}\right)}{\prod_{i, j \leq n-1}\left(a_{i}+b_{j}\right)} \\
=\frac{\prod_{j<i \leq n}\left(a_{i}-a_{j}\right)\left(b_{i}-b_{j}\right)}{\prod_{i, j \leq n}\left(a_{i}+b_{j}\right)}
\end{gathered}
$$

### 5.6 Block Multiplication Of Matrices

Consider the following problem

$$
\left(\begin{array}{ll}
A & B \\
C & D
\end{array}\right)\left(\begin{array}{ll}
E & F \\
G & H
\end{array}\right)
$$

You know how to do this. You get

$$
\left(\begin{array}{cc}
A E+B G & A F+B H \\
C E+D G & C F+D H
\end{array}\right)
$$

Now what if instead of numbers, the entries, $A, B, C, D, E, F, G$ are matrices of a size such that the multiplications and additions needed in the above formula all make sense. Would the formula be true in this case? I will show below that this is true.

Suppose $A$ is a matrix of the form

$$
A=\left(\begin{array}{ccc}
A_{11} & \cdots & A_{1 m}  \tag{5.6.17}\\
\vdots & \ddots & \vdots \\
A_{r 1} & \cdots & A_{r m}
\end{array}\right)
$$

where $A_{i j}$ is a $s_{i} \times p_{j}$ matrix where $s_{i}$ is constant for $j=1, \cdots, m$ for each $i=1, \cdots, r$. Such a matrix is called a block matrix, also a partitioned matrix. How do you get the block $A_{i j}$ ? Here is how for $A$ an $m \times n$ matrix:

$$
\overbrace{\left(\begin{array}{lll}
0 & I_{s_{i} \times s_{i}} & 0
\end{array}\right)}^{s_{i} \times m} A \overbrace{\left(\begin{array}{c}
0  \tag{5.6.18}\\
I_{p_{j} \times p_{j}} \\
0
\end{array}\right)}^{n \times p_{j}} .
$$

In the block column matrix on the right, you need to have $c_{j}-1$ rows of zeros above the small $p_{j} \times p_{j}$ identity matrix where the columns of $A$ involved in $A_{i j}$ are $c_{j}, \cdots, c_{j}+p_{j}$ and in the block row matrix on the left, you need to have $r_{i}-1$ columns of zeros to the left of the $s_{i} \times s_{i}$ identity matrix where the rows of $A$ involved in $A_{i j}$ are $r_{i}, \cdots, r_{i}+s_{i}$. An important observation to make is that the matrix on the right specifies columns to use in the block and the one on the left specifies the rows used. There is no overlap between the blocks of $A$. Thus the identity $n \times n$ identity matrix corresponding to multiplication on the right of $A$ is of the form

$$
\left(\begin{array}{ccc}
I_{p_{1} \times p_{1}} & & 0 \\
& \ddots & \\
0 & & I_{p_{m} \times p_{m}}
\end{array}\right)
$$

these little identity matrices don't overlap. A similar conclusion follows from consideration of the matrices $I_{s_{i} \times s_{i}}$.

Next consider the question of multiplication of two block matrices. Let $B$ be a block matrix of the form

$$
\left(\begin{array}{ccc}
B_{11} & \cdots & B_{1 p}  \tag{5.6.19}\\
\vdots & \ddots & \vdots \\
B_{r 1} & \cdots & B_{r p}
\end{array}\right)
$$

and $A$ is a block matrix of the form

$$
\left(\begin{array}{ccc}
A_{11} & \cdots & A_{1 m}  \tag{5.6.20}\\
\vdots & \ddots & \vdots \\
A_{p 1} & \cdots & A_{p m}
\end{array}\right)
$$

and that for all $i, j$, it makes sense to multiply $B_{i s} A_{s j}$ for all $s \in\{1, \cdots, p\}$. (That is the two matrices, $B_{i s}$ and $A_{s j}$ are conformable.) and that for fixed $i j$, it follows $B_{i s} A_{s j}$ is the same size for each $s$ so that it makes sense to write $\sum_{s} B_{i s} A_{s j}$.

The following theorem says essentially that when you take the product of two matrices, you can do it two ways. One way is to simply multiply them forming $B A$. The other way is to partition both matrices, formally multiply the blocks to get another block matrix and this one will be $B A$ partitioned. Before presenting this theorem, here is a simple lemma which is really a special case of the theorem.

Lemma 5.6.1 Consider the following product.

$$
\left(\begin{array}{l}
\mathbf{0} \\
I \\
\mathbf{0}
\end{array}\right)\left(\begin{array}{lll}
\mathbf{0} & I & \mathbf{0}
\end{array}\right)
$$

where the first is $n \times r$ and the second is $r \times n$. The small identity matrix $I$ is an $r \times r$ matrix and there are $l$ zero rows above $I$ and $l$ zero columns to the left of $I$ in the right matrix. Then the product of these matrices is a block matrix of the form

$$
\left(\begin{array}{lll}
\mathbf{0} & \mathbf{0} & \mathbf{0} \\
\mathbf{0} & I & \mathbf{0} \\
\mathbf{0} & \mathbf{0} & \mathbf{0}
\end{array}\right)
$$

Proof: From the definition of the way you multiply matrices, the product is

$$
\left(\begin{array}{c}
\mathbf{0} \\
I \\
\mathbf{0}
\end{array}\right) \mathbf{0}
$$

which yields the claimed result. In the formula $\mathbf{e}_{j}$ referrs to the column vector of length $r$ which has a 1 in the $j^{t h}$ position. This proves the lemma.

Theorem 5.6.2 Let $B$ be a $q \times p$ block matrix as in 5.6 .19 and let $A$ be a $p \times n$ block matrix as in 5.6.20 such that $B_{i s}$ is conformable with $A_{s j}$ and each product, $B_{i s} A_{s j}$ for $s=1, \cdots, p$ is of the same size so they can be added. Then BA can be obtained as a block matrix such that the $i j^{\text {th }}$ block is of the form

$$
\begin{equation*}
\sum_{s} B_{i s} A_{s j} \tag{5.6.21}
\end{equation*}
$$

Proof: From 5.6.18

$$
B_{i s} A_{s j}=\left(\begin{array}{lll}
\mathbf{0} & I_{r_{i} \times r_{i}} & \mathbf{0}
\end{array}\right) B\left(\begin{array}{c}
\mathbf{0} \\
I_{p_{s} \times p_{s}} \\
\mathbf{0}
\end{array}\right)\left(\begin{array}{lll}
\mathbf{0} & I_{p_{s} \times p_{s}} & \mathbf{0}
\end{array}\right) A\left(\begin{array}{c}
\mathbf{0} \\
I_{q_{j} \times q_{j}} \\
\mathbf{0}
\end{array}\right)
$$

where here it is assumed $B_{i s}$ is $r_{i} \times p_{s}$ and $A_{s j}$ is $p_{s} \times q_{j}$. The product involves the $s^{\text {th }}$ block in the $i^{\text {th }}$ row of blocks for $B$ and the $s^{\text {th }}$ block in the $j^{\text {th }}$ column of $A$. Thus there are the same number of rows above the $I_{p_{s} \times p_{s}}$ as there are columns to the left of $I_{p_{s} \times p_{s}}$ in those two inside matrices. Then from Lemma 5.6.1

$$
\left(\begin{array}{c}
\mathbf{0} \\
I_{p_{s} \times p_{s}} \\
\mathbf{0}
\end{array}\right)\left(\begin{array}{lll}
\mathbf{0} & I_{p_{s} \times p_{s}} & \mathbf{0}
\end{array}\right)=\left(\begin{array}{ccc}
\mathbf{0} & \mathbf{0} & \mathbf{0} \\
\mathbf{0} & I_{p_{s} \times p_{s}} & \mathbf{0} \\
\mathbf{0} & \mathbf{0} & \mathbf{0}
\end{array}\right)
$$

Since the blocks of small identity matrices do not overlap,

$$
\sum_{s}\left(\begin{array}{ccc}
\mathbf{0} & \mathbf{0} & \mathbf{0} \\
\mathbf{0} & I_{p_{s} \times p_{s}} & \mathbf{0} \\
\mathbf{0} & \mathbf{0} & \mathbf{0}
\end{array}\right)=\left(\begin{array}{ccc}
I_{p_{1} \times p_{1}} & & 0 \\
& \ddots & \\
0 & & I_{p_{p} \times p_{p}}
\end{array}\right)=I
$$

and so

$$
\begin{gathered}
\sum_{s} B_{i s} A_{s j}= \\
\\
\sum_{s}\left(\begin{array}{lll}
\mathbf{0} & I_{r_{i} \times r_{i}} & \mathbf{0}
\end{array}\right) B\left(\begin{array}{c}
\mathbf{0} \\
I_{p_{s} \times p_{s}} \\
\mathbf{0}
\end{array}\right)\left(\begin{array}{lll}
\mathbf{0} & I_{p_{s} \times p_{s}} & \mathbf{0}
\end{array}\right) A\left(\begin{array}{c}
\mathbf{0} \\
I_{q_{j} \times q_{j}} \\
\mathbf{0}
\end{array}\right) \\
\left.\mathbf{0} \begin{array}{lll}
I_{r_{i} \times r_{i}} & \mathbf{0}
\end{array}\right) B I A\left(\begin{array}{c}
\mathbf{0} \\
I_{q_{j} \times q_{j}} \\
\mathbf{0}
\end{array}\right)=\left(\begin{array}{lll}
\mathbf{0} & I_{r_{i} \times r_{i}} & \mathbf{0}
\end{array}\right) B A\left(\begin{array}{c}
\mathbf{0} \\
I_{q_{j} \times q_{j}} \\
\mathbf{0}
\end{array}\right)
\end{gathered}
$$

Hence the $i j^{\text {th }}$ block of $B A$ equals the formal multiplication according to matrix multiplication,

$$
\sum_{s} B_{i s} A_{s j} .
$$

This proves the theorem.
Example 5.6.3 Let an $n \times n$ matrix have the form

$$
A=\left(\begin{array}{cc}
a & \mathbf{b} \\
\mathbf{c} & P
\end{array}\right)
$$

where $P$ is $n-1 \times n-1$. Multiply it by

$$
B=\left(\begin{array}{cc}
p & \mathbf{q} \\
\mathbf{r} & Q
\end{array}\right)
$$

where $B$ is also an $n \times n$ matrix and $Q$ is $n-1 \times n-1$.

You use block multiplication

$$
\left(\begin{array}{cc}
a & \mathbf{b} \\
\mathbf{c} & P
\end{array}\right)\left(\begin{array}{cc}
p & \mathbf{q} \\
\mathbf{r} & Q
\end{array}\right)=\left(\begin{array}{cc}
a p+\mathbf{b r} & a \mathbf{q}+\mathbf{b} Q \\
p \mathbf{c}+P \mathbf{r} & \mathbf{c q}+P Q
\end{array}\right)
$$

Note that this all makes sense. For example, $\mathbf{b}=1 \times n-1$ and $\mathbf{r}=n-1 \times 1$ so $\mathbf{b r}$ is a $1 \times 1$. Similar considerations apply to the other blocks.

Here is an interesting and significant application of block multiplication. In this theorem, $p_{M}(t)$ denotes the characteristic polynomial, $\operatorname{det}(t I-M)$. Thus the zeros of this polynomial are the eigenvalues of the matrix, $M$.

Theorem 5.6.4 Let $A$ be an $m \times n$ matrix and let $B$ be an $n \times m$ matrix for $m \leq n$. Then

$$
p_{B A}(t)=t^{n-m} p_{A B}(t),
$$

so the eigenvalues of $B A$ and $A B$ are the same including multiplicities except that $B A$ has $n-m$ extra zero eigenvalues.

Proof: Use block multiplication to write

$$
\begin{aligned}
& \left(\begin{array}{cc}
A B & 0 \\
B & 0
\end{array}\right)\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)=\left(\begin{array}{cc}
A B & A B A \\
B & B A
\end{array}\right) \\
& \left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)\left(\begin{array}{cc}
0 & 0 \\
B & B A
\end{array}\right)=\left(\begin{array}{cc}
A B & A B A \\
B & B A
\end{array}\right)
\end{aligned}
$$

Therefore,

$$
\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)^{-1}\left(\begin{array}{cc}
A B & 0 \\
B & 0
\end{array}\right)\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)=\left(\begin{array}{cc}
0 & 0 \\
B & B A
\end{array}\right)
$$

Since the two matrices above are similar it follows that $\left(\begin{array}{cc}0 & 0 \\ B & B A\end{array}\right)$ and $\left(\begin{array}{cc}A B & 0 \\ B & 0\end{array}\right)$ have the same characteristic polynomials. Therefore, noting that $B A$ is an $n \times n$ matrix and $A B$ is an $m \times m$ matrix,

$$
t^{m} \operatorname{det}(t I-B A)=t^{n} \operatorname{det}(t I-A B)
$$

and so $\operatorname{det}(t I-B A)=p_{B A}(t)=t^{n-m} \operatorname{det}(t I-A B)=t^{n-m} p_{A B}(t)$. This proves the theorem.

### 5.7 Exercises

1. Show that matrix multiplication is associative. That is, $(A B) C=A(B C)$.
2. Show the inverse of a matrix, if it exists, is unique. Thus if $A B=B A=I$, then $B=A^{-1}$.
3. In the proof of Theorem 5.4.14 it was claimed that $\operatorname{det}(I)=1$. Here $I=\left(\delta_{i j}\right)$. Prove this assertion. Also prove Corollary 5.4.17.
4. Let $\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}$ be vectors in $\mathbb{F}^{n}$ and let $M\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right)$ denote the matrix whose $i^{\text {th }}$ column equals $\mathbf{v}_{i}$. Define

$$
d\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right) \equiv \operatorname{det}\left(M\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right)\right)
$$

Prove that $d$ is linear in each variable, (multilinear), that

$$
\begin{equation*}
d\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{i}, \cdots, \mathbf{v}_{j}, \cdots, \mathbf{v}_{n}\right)=-d\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{j}, \cdots, \mathbf{v}_{i}, \cdots, \mathbf{v}_{n}\right) \tag{5.7.22}
\end{equation*}
$$

and

$$
\begin{equation*}
d\left(\mathbf{e}_{1}, \cdots, \mathbf{e}_{n}\right)=1 \tag{5.7.23}
\end{equation*}
$$

where here $\mathbf{e}_{j}$ is the vector in $\mathbb{F}^{n}$ which has a zero in every position except the $j^{\text {th }}$ position in which it has a one.
5. Suppose $f: \mathbb{F}^{n} \times \cdots \times \mathbb{F}^{n} \rightarrow \mathbb{F}$ satisfies 5.7 .22 and 5.7 .23 and is linear in each variable. Show that $f=d$.
6. Show that if you replace a row (column) of an $n \times n$ matrix $A$ with itself added to some multiple of another row (column) then the new matrix has the same determinant as the original one.
7. If $A=\left(a_{i j}\right)$, show $\operatorname{det}(A)=\sum_{\left(k_{1}, \cdots, k_{n}\right)} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) a_{k_{1} 1} \cdots a_{k_{n} n}$.
8. Use the result of Problem 6 to evaluate by hand the determinant

$$
\operatorname{det}\left(\begin{array}{cccc}
1 & 2 & 3 & 2 \\
-6 & 3 & 2 & 3 \\
5 & 2 & 2 & 3 \\
3 & 4 & 6 & 4
\end{array}\right)
$$

9. Find the inverse if it exists of the matrix,

$$
\left(\begin{array}{ccc}
e^{t} & \cos t & \sin t \\
e^{t} & -\sin t & \cos t \\
e^{t} & -\cos t & -\sin t
\end{array}\right)
$$

10. Let $L y=y^{(n)}+a_{n-1}(x) y^{(n-1)}+\cdots+a_{1}(x) y^{\prime}+a_{0}(x) y$ where the $a_{i}$ are given continuous functions defined on a closed interval, $(a, b)$ and $y$ is some function which
has $n$ derivatives so it makes sense to write $L y$. Suppose $L y_{k}=0$ for $k=1,2, \cdots, n$. The Wronskian of these functions, $y_{i}$ is defined as

$$
W\left(y_{1}, \cdots, y_{n}\right)(x) \equiv \operatorname{det}\left(\begin{array}{ccc}
y_{1}(x) & \cdots & y_{n}(x) \\
y_{1}^{\prime}(x) & \cdots & y_{n}^{\prime}(x) \\
\vdots & & \vdots \\
y_{1}^{(n-1)}(x) & \cdots & y_{n}^{(n-1)}(x)
\end{array}\right)
$$

Show that for $W(x)=W\left(y_{1}, \cdots, y_{n}\right)(x)$ to save space,

$$
W^{\prime}(x)=\operatorname{det}\left(\begin{array}{ccc}
y_{1}(x) & \cdots & y_{n}(x) \\
y_{1}^{\prime}(x) & \cdots & y_{n}^{\prime}(x) \\
\vdots & & \vdots \\
y_{1}^{(n)}(x) & \cdots & y_{n}^{(n)}(x)
\end{array}\right)
$$

Now use the differential equation, $L y=0$ which is satisfied by each of these functions, $y_{i}$ and properties of determinants presented above to verify that

$$
W^{\prime}+a_{n-1}(x) W=0
$$

Give an explicit solution of this linear differential equation, Abel's formula, and use your answer to verify that the Wronskian of these solutions to the equation, $L y=0$ either vanishes identically on $(a, b)$ or never.
11. Two $n \times n$ matrices, $A$ and $B$, are similar if $B=S^{-1} A S$ for some invertible $n \times n$ matrix, $S$. Show that if two matrices are similar, they have the same characteristic polynomials.
12. Suppose the characteristic polynomial of an $n \times n$ matrix, $A$ is of the form

$$
t^{n}+a_{n-1} t^{n-1}+\cdots+a_{1} t+a_{0}
$$

and that $a_{0} \neq 0$. Find a formula $A^{-1}$ in terms of powers of the matrix, $A$. Show that $A^{-1}$ exists if and only if $a_{0} \neq 0$.
13. In constitutive modeling of the stress and strain tensors, one sometimes considers sums of the form $\sum_{k=0}^{\infty} a_{k} A^{k}$ where $A$ is a $3 \times 3$ matrix. Show using the Cayley Hamilton theorem that if such a thing makes any sense, you can always obtain it as a finite sum having no more than $n$ terms.

### 5.8 Shur's Theorem

Every matrix is related to an upper triangular matrix in a particularly significant way. This is Shur's theorem and it is the most important theorem in the spectral theory of matrices.

Lemma 5.8.1 Let

$$
\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}
$$

be a basis for $\mathbb{F}^{n}$. Then there exists an orthonormal basis for $\mathbb{F}^{n}$,

$$
\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{n}\right\}
$$

which has the property that for each $k \leq n$,

$$
\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}\right)=\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)
$$

Proof: Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}$ be a basis for $\mathbb{F}^{n}$. Let $\mathbf{u}_{1} \equiv \mathbf{x}_{1} /\left|\mathbf{x}_{1}\right|$. Thus for $k=1$, $\operatorname{span}\left(\mathbf{u}_{1}\right)=$ $\operatorname{span}\left(\mathbf{x}_{1}\right)$ and $\left\{\mathbf{u}_{1}\right\}$ is an orthonormal set. Now suppose for some $k<n, \mathbf{u}_{1}, \cdots, \mathbf{u}_{k}$ have been chosen such that $\left(\mathbf{u}_{j} \cdot \mathbf{u}_{l}\right)=\delta_{j l}$ and span $\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}\right)=\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)$. Then define

$$
\begin{equation*}
\mathbf{u}_{k+1} \equiv \frac{\mathbf{x}_{k+1}-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{j}\right) \mathbf{u}_{j}}{\left|\mathbf{x}_{k+1}-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{j}\right) \mathbf{u}_{j}\right|} \tag{5.8.24}
\end{equation*}
$$

where the denominator is not equal to zero because the $\mathbf{x}_{j}$ form a basis and so

$$
\mathbf{x}_{k+1} \notin \operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}\right)=\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)
$$

Thus by induction,

$$
\mathbf{u}_{k+1} \in \operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{x}_{k+1}\right)=\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}, \mathbf{x}_{k+1}\right)
$$

Also, $\mathbf{x}_{k+1} \in \operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{u}_{k+1}\right)$ which is seen easily by solving 5.8.24 for $\mathbf{x}_{k+1}$ and it follows

$$
\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}, \mathbf{x}_{k+1}\right)=\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{u}_{k+1}\right)
$$

If $l \leq k$,

$$
\begin{aligned}
\left(\mathbf{u}_{k+1} \cdot \mathbf{u}_{l}\right) & =C\left(\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{l}\right)-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{j}\right)\left(\mathbf{u}_{j} \cdot \mathbf{u}_{l}\right)\right) \\
& =C\left(\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{l}\right)-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{j}\right) \delta_{l j}\right) \\
& =C\left(\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{l}\right)-\left(\mathbf{x}_{k+1} \cdot \mathbf{u}_{l}\right)\right)=0
\end{aligned}
$$

The vectors, $\left\{\mathbf{u}_{j}\right\}_{j=1}^{n}$, generated in this way are therefore an orthonormal basis because each vector has unit length.

The process by which these vectors were generated is called the Gram Schmidt process. Recall the following definition.

Definition 5.8.2 An $n \times n$ matrix, $U$, is unitary if $U U^{*}=I=U^{*} U$ where $U^{*}$ is defined to be the transpose of the conjugate of $U$.

Theorem 5.8.3 Let A be an $n \times n$ matrix. Then there exists a unitary matrix, $U$ such that

$$
\begin{equation*}
U^{*} A U=T \tag{5.8.25}
\end{equation*}
$$

where $T$ is an upper triangular matrix having the eigenvalues of $A$ on the main diagonal listed according to multiplicity as roots of the characteristic equation.

Proof: Let $\mathbf{v}_{1}$ be a unit eigenvector for $A$. Then there exists $\lambda_{1}$ such that

$$
A \mathbf{v}_{1}=\lambda_{1} \mathbf{v}_{1},\left|\mathbf{v}_{1}\right|=1
$$

Extend $\left\{\mathbf{v}_{1}\right\}$ to a basis and then use Lemma 5.8.1 to obtain $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right\}$, an orthonormal basis in $\mathbb{F}^{n}$. Let $U_{0}$ be a matrix whose $i^{t h}$ column is $\mathbf{v}_{i}$. Then from the above, it follows $U_{0}$ is unitary. Then $U_{0}^{*} A U_{0}$ is of the form

$$
\left(\begin{array}{llll}
\lambda_{1} & * & \cdots & * \\
0 & & & \\
\vdots & & A_{1} & \\
0 & & &
\end{array}\right)
$$

where $A_{1}$ is an $n-1 \times n-1$ matrix. Repeat the process for the matrix, $A_{1}$ above. There exists a unitary matrix $\widetilde{U}_{1}$ such that $\widetilde{U}_{1}^{*} A_{1} \widetilde{U}_{1}$ is of the form

$$
\left(\begin{array}{llll}
\lambda_{2} & * & \cdots & * \\
0 & & & \\
\vdots & & A_{2} & \\
0 & & &
\end{array}\right)
$$

Now let $U_{1}$ be the $n \times n$ matrix of the form

$$
\left(\begin{array}{cc}
1 & \mathbf{0} \\
\mathbf{0} & \widetilde{U}_{1}
\end{array}\right)
$$

This is also a unitary matrix because by block multiplication,

$$
\begin{aligned}
\left(\begin{array}{cc}
1 & \mathbf{0} \\
\mathbf{0} & \widetilde{U}_{1}
\end{array}\right)^{*}\left(\begin{array}{cc}
1 & \mathbf{0} \\
\mathbf{0} & \widetilde{U}_{1}
\end{array}\right) & =\left(\begin{array}{cc}
1 & \mathbf{0} \\
\mathbf{0} & \widetilde{U}_{1}^{*}
\end{array}\right)\left(\begin{array}{cc}
1 & \mathbf{0} \\
\mathbf{0} & \widetilde{U}_{1}
\end{array}\right) \\
& =\left(\begin{array}{cc}
1 & \mathbf{0} \\
\mathbf{0} & \widetilde{U}_{1}^{*} \widetilde{U}_{1}
\end{array}\right)=\left(\begin{array}{cc}
1 & \mathbf{0} \\
\mathbf{0} & I
\end{array}\right)
\end{aligned}
$$

Then using block multiplication, $U_{1}^{*} U_{0}^{*} A U_{0} U_{1}$ is of the form

$$
\left(\begin{array}{lllll}
\lambda_{1} & * & * & \cdots & * \\
0 & \lambda_{2} & * & \cdots & * \\
0 & 0 & & & \\
\vdots & \vdots & & A_{2} & \\
0 & 0 & & &
\end{array}\right)
$$

where $A_{2}$ is an $n-2 \times n-2$ matrix. Continuing in this way, there exists a unitary matrix, $U$ given as the product of the $U_{i}$ in the above construction such that

$$
U^{*} A U=T
$$

where $T$ is some upper triangular matrix. Since the matrix is upper triangular, the characteristic equation is $\prod_{i=1}^{n}\left(\lambda-\lambda_{i}\right)$ where the $\lambda_{i}$ are the diagonal entries of $T$. Therefore, the $\lambda_{i}$ are the eigenvalues.

What if $A$ is a real matrix and you only want to consider real unitary matrices?

Theorem 5.8.4 Let A be a real $n \times n$ matrix. Then there exists a real unitary matrix, $Q$ and a matrix $T$ of the form

$$
T=\left(\begin{array}{ccc}
P_{1} & \cdots & *  \tag{5.8.26}\\
& \ddots & \vdots \\
0 & & P_{r}
\end{array}\right)
$$

where $P_{i}$ equals either a real $1 \times 1$ matrix or $P_{i}$ equals a real $2 \times 2$ matrix having two complex eigenvalues of $A$ such that $Q^{T} A Q=T$. The matrix, $T$ is called the real Schur form of the matrix $A$.

Proof: Suppose

$$
A \mathbf{v}_{1}=\lambda_{1} \mathbf{v}_{1},\left|\mathbf{v}_{1}\right|=1
$$

where $\lambda_{1}$ is real. Then let $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right\}$ be an orthonormal basis of vectors in $\mathbb{R}^{n}$. Let $Q_{0}$ be a matrix whose $i^{t h}$ column is $\mathbf{v}_{i}$. Then $Q_{0}^{*} A Q_{0}$ is of the form

$$
\left(\begin{array}{llll}
\lambda_{1} & * & \cdots & * \\
0 & & & \\
\vdots & & A_{1} & \\
0 & & &
\end{array}\right)
$$

where $A_{1}$ is a real $n-1 \times n-1$ matrix. This is just like the proof of Theorem 5.8.3 up to this point.

Now in case $\lambda_{1}=\alpha+i \beta$, it follows since $A$ is real that $\mathbf{v}_{1}=\mathbf{z}_{1}+i \mathbf{w}_{1}$ and that $\overline{\mathbf{v}}_{1}=$ $\mathbf{z}_{1}-i \mathbf{w}_{1}$ is an eigenvector for the eigenvalue, $\alpha-i \beta$. Here $\mathbf{z}_{1}$ and $\mathbf{w}_{1}$ are real vectors. It is clear that $\left\{\mathbf{z}_{1}, \mathbf{w}_{1}\right\}$ is an independent set of vectors in $\mathbb{R}^{n}$. Indeed, $\left\{\mathbf{v}_{1}, \overline{\mathbf{v}}_{1}\right\}$ is an independent set and it follows span $\left(\mathbf{v}_{1}, \overline{\mathbf{v}}_{1}\right)=\operatorname{span}\left(\mathbf{z}_{1}, \mathbf{w}_{1}\right)$. Now using the Gram Schmidt theorem in $\mathbb{R}^{n}$, there exists $\left\{\mathbf{u}_{1}, \mathbf{u}_{2}\right\}$, an orthonormal set of real vectors such that $\operatorname{span}\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right)=$ $\operatorname{span}\left(\mathbf{v}_{1}, \overline{\mathbf{v}}_{1}\right)$. Now let $\left\{\mathbf{u}_{1}, \mathbf{u}_{2}, \cdots, \mathbf{u}_{n}\right\}$ be an orthonormal basis in $\mathbb{R}^{n}$ and let $Q_{0}$ be a unitary matrix whose $i^{\text {th }}$ column is $\mathbf{u}_{i}$. Then $A \mathbf{u}_{j}$ are both in $\operatorname{span}\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right)$ for $j=1,2$ and so $\mathbf{u}_{k}^{T} A \mathbf{u}_{j}=0$ whenever $k \geq 3$. It follows that $Q_{0}^{*} A Q_{0}$ is of the form

$$
\left(\begin{array}{cccc}
* & * & \cdots & * \\
* & * & & \\
0 & & & \\
\vdots & & A_{1} & \\
0 & & &
\end{array}\right)
$$

where $A_{1}$ is now an $n-2 \times n-2$ matrix. In this case, find $\widetilde{Q}_{1}$ an $n-2 \times n-2$ matrix to put $A_{1}$ in an appropriate form as above and come up with $A_{2}$ either an $n-4 \times n-4$ matrix or an $n-3 \times n-3$ matrix. Then the only other difference is to let

$$
Q_{1}=\left(\begin{array}{ccccc}
1 & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & & & \\
\vdots & \vdots & & \widetilde{Q}_{1} & \\
0 & 0 & & &
\end{array}\right)
$$

thus putting a $2 \times 2$ identity matrix in the upper left corner rather than a one. Repeating this process with the above modification for the case of a complex eigenvalue leads eventually to 5.8 .26 where $Q$ is the product of real unitary matrices $Q_{i}$ above. Finally,

$$
\lambda I-T=\left(\begin{array}{ccc}
\lambda I_{1}-P_{1} & \cdots & * \\
& \ddots & \vdots \\
0 & & \lambda I_{r}-P_{r}
\end{array}\right)
$$

where $I_{k}$ is the $2 \times 2$ identity matrix in the case that $P_{k}$ is $2 \times 2$ and is the number 1 in the case where $P_{k}$ is a $1 \times 1$ matrix. Now, it follows that $\operatorname{det}(\lambda I-T)=\prod_{k=1}^{r} \operatorname{det}\left(\lambda I_{k}-P_{k}\right)$. Therefore, $\lambda$ is an eigenvalue of $T$ if and only if it is an eigenvalue of some $P_{k}$. This proves the theorem since the eigenvalues of $T$ are the same as those of $A$ because they have the same characteristic polynomial due to the similarity of $A$ and $T$.

Definition 5.8.5 When a linear transformation, $A$, mapping a linear space, $V$ to $V$ has a basis of eigenvectors, the linear transformation is called non defective. Otherwise it is called defective. An $n \times n$ matrix, $A$, is called normal if $A A^{*}=A^{*} A$. An important class of normal matrices is that of the Hermitian or self adjoint matrices. An $n \times n$ matrix, $A$ is self adjoint or Hermitian if $A=A^{*}$.

The next lemma is the basis for concluding that every normal matrix is unitarily similar to a diagonal matrix.

Lemma 5.8.6 If $T$ is upper triangular and normal, then $T$ is a diagonal matrix.
Proof: Since $T$ is normal, $T^{*} T=T T^{*}$. Writing this in terms of components and using the description of the adjoint as the transpose of the conjugate, yields the following for the $i k^{t h}$ entry of $T^{*} T=T T^{*}$.

$$
\sum_{j} t_{i j} t_{j k}^{*}=\sum_{j} t_{i j} \overline{t_{k j}}=\sum_{j} t_{i j}^{*} t_{j k}=\sum_{j} \overline{t_{j i}} t_{j k}
$$

Now use the fact that $T$ is upper triangular and let $i=k=1$ to obtain the following from the above.

$$
\sum_{j}\left|t_{1 j}\right|^{2}=\sum_{j}\left|t_{j 1}\right|^{2}=\left|t_{11}\right|^{2}
$$

You see, $t_{j 1}=0$ unless $j=1$ due to the assumption that $T$ is upper triangular. This shows $T$ is of the form

$$
\left(\begin{array}{cccc}
* & 0 & \cdots & 0 \\
0 & * & \cdots & * \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & *
\end{array}\right)
$$

Now do the same thing only this time take $i=k=2$ and use the result just established. Thus, from the above,

$$
\sum_{j}\left|t_{2 j}\right|^{2}=\sum_{j}\left|t_{j 2}\right|^{2}=\left|t_{22}\right|^{2}
$$

showing that $t_{2 j}=0$ if $j>2$ which means $T$ has the form

$$
\left(\begin{array}{ccccc}
* & 0 & 0 & \cdots & 0 \\
0 & * & 0 & \cdots & 0 \\
0 & 0 & * & \cdots & * \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & 0 & *
\end{array}\right)
$$

Next let $i=k=3$ and obtain that $T$ looks like a diagonal matrix in so far as the first 3 rows and columns are concerned. Continuing in this way it follows $T$ is a diagonal matrix.
Theorem 5.8.7 Let A be a normal matrix. Then there exists a unitary matrix, $U$ such that $U^{*} A U$ is a diagonal matrix.

Proof: From Theorem 5.8.3 there exists a unitary matrix, $U$ such that $U^{*} A U$ equals an upper triangular matrix. The theorem is now proved if it is shown that the property of being normal is preserved under unitary similarity transformations. That is, verify that if $A$ is normal and if $B=U^{*} A U$, then $B$ is also normal. But this is easy.

$$
\begin{aligned}
B^{*} B & =U^{*} A^{*} U U^{*} A U=U^{*} A^{*} A U \\
& =U^{*} A A^{*} U=U^{*} A U U^{*} A^{*} U=B B^{*}
\end{aligned}
$$

Therefore, $U^{*} A U$ is a normal and upper triangular matrix and by Lemma 5.8.6 it must be a diagonal matrix. This proves the theorem.
Corollary 5.8.8 If $A$ is Hermitian, then all the eigenvalues of $A$ are real and there exists an orthonormal basis of eigenvectors.

Proof: Since $A$ is normal, there exists unitary, $U$ such that $U^{*} A U=D$, a diagonal matrix whose diagonal entries are the eigenvalues of $A$. Therefore, $D^{*}=U^{*} A^{*} U=U^{*} A U=$ $D$ showing $D$ is real.

Finally, let

$$
U=\left(\begin{array}{llll}
\mathbf{u}_{1} & \mathbf{u}_{2} & \cdots & \mathbf{u}_{n}
\end{array}\right)
$$

where the $\mathbf{u}_{i}$ denote the columns of $U$ and

$$
D=\left(\begin{array}{ccc}
\lambda_{1} & & 0 \\
& \ddots & \\
0 & & \lambda_{n}
\end{array}\right)
$$

The equation, $U^{*} A U=D$ implies

$$
\begin{aligned}
A U & =\left(\begin{array}{llll}
A \mathbf{u}_{1} & A \mathbf{u}_{2} & \cdots & A \mathbf{u}_{n}
\end{array}\right) \\
& =U D=\left(\begin{array}{llll}
\lambda_{1} \mathbf{u}_{1} & \lambda_{2} \mathbf{u}_{2} & \cdots & \lambda_{n} \mathbf{u}_{n}
\end{array}\right)
\end{aligned}
$$

where the entries denote the columns of $A U$ and $U D$ respectively. Therefore, $A \mathbf{u}_{i}=\lambda_{i} \mathbf{u}_{i}$ and since the matrix is unitary, the $i j^{t h}$ entry of $U^{*} U$ equals $\delta_{i j}$ and so

$$
\delta_{i j}=\overline{\mathbf{u}}_{i}^{T} \mathbf{u}_{j}=\overline{\mathbf{u}_{i}^{T} \overline{\mathbf{u}}_{j}}=\overline{\mathbf{u}_{i} \cdot \mathbf{u}_{j}}
$$

This proves the corollary because it shows the vectors $\left\{\mathbf{u}_{i}\right\}$ form an orthonormal basis.

Corollary 5.8.9 If A is a real symmetric matrix, then $A$ is Hermitian and there exists a real unitary matrix, $U$ such that $U^{T} A U=D$ where $D$ is a diagonal matrix.

Proof: This follows from Theorem 5.8.4 and Corollary 5.8.8.

### 5.9 The Right Polar Decomposition

The right polar decomposition involves writing a matrix as a product of two other matrices, one which preserves distances and the other which stretches and distorts. First here are some lemmas.

Lemma 5.9.1 Let A be a Hermitian matrix such that all its eigenvalues are nonnegative. Then there exists a Hermitian matrix, $A^{1 / 2}$ such that $A^{1 / 2}$ has all nonnegative eigenvalues and $\left(A^{1 / 2}\right)^{2}=A$.

Proof: Since $A$ is Hermitian, there exists a diagonal matrix $D$ having all real nonnegative entries and a unitary matrix $U$ such that $A=U^{*} D U$. Then denote by $D^{1 / 2}$ the matrix which is obtained by replacing each diagonal entry of $D$ with its square root. Thus $D^{1 / 2} D^{1 / 2}=D$. Then define

$$
A^{1 / 2} \equiv U^{*} D^{1 / 2} U
$$

Then

$$
\left(A^{1 / 2}\right)^{2}=U^{*} D^{1 / 2} U U^{*} D^{1 / 2} U=U^{*} D U=A
$$

Since $D^{1 / 2}$ is real,

$$
\left(U^{*} D^{1 / 2} U\right)^{*}=U^{*}\left(D^{1 / 2}\right)^{*}\left(U^{*}\right)^{*}=U^{*} D^{1 / 2} U
$$

so $A^{1 / 2}$ is Hermitian. This proves the lemma.
There is also a useful observation about orthonormal sets of vectors which is stated in the next lemma.

Lemma 5.9.2 Suppose $\left\{\mathbf{x}_{1}, \mathbf{x}_{2}, \cdots, \mathbf{x}_{r}\right\}$ is an orthonormal set of vectors. Then if $c_{1}, \cdots, c_{r}$ are scalars,

$$
\left|\sum_{k=1}^{r} c_{k} \mathbf{x}_{k}\right|^{2}=\sum_{k=1}^{r}\left|c_{k}\right|^{2}
$$

Proof: This follows from the definition. From the properties of the dot product and using the fact that the given set of vectors is orthonormal,

$$
\begin{gathered}
\left|\sum_{k=1}^{r} c_{k} \mathbf{x}_{k}\right|^{2}=\left(\sum_{k=1}^{r} c_{k} \mathbf{x}_{k}, \sum_{j=1}^{r} c_{j} \mathbf{x}_{j}\right) \\
=\sum_{k, j} c_{k} \overline{c_{j}}\left(\mathbf{x}_{k}, \mathbf{x}_{j}\right)=\sum_{k=1}^{r}\left|c_{k}\right|^{2} .
\end{gathered}
$$

This proves the lemma.
Next it is helpful to recall the Gram Schmidt algorithm and observe a certain property stated in the next lemma.

Lemma 5.9.3 Suppose $\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}, \mathbf{v}_{r+1}, \cdots, \mathbf{v}_{p}\right\}$ is a linearly independent set of vectors such that $\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}\right\}$ is an orthonormal set of vectors. Then when the Gram Schmidt process is applied to the vectors in the given order, it will not change any of the $\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}$.

Proof: Let $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{p}\right\}$ be the orthonormal set delivered by the Gram Schmidt process. Then $\mathbf{u}_{1}=\mathbf{w}_{1}$ because by definition, $\mathbf{u}_{1} \equiv \mathbf{w}_{1} /\left|\mathbf{w}_{1}\right|=\mathbf{w}_{1}$. Now suppose $\mathbf{u}_{j}=\mathbf{w}_{j}$ for all $j \leq k \leq r$. Then if $k<r$, consider the definition of $\mathbf{u}_{k+1}$.

$$
\mathbf{u}_{k+1} \equiv \frac{\mathbf{w}_{k+1}-\sum_{j=1}^{k+1}\left(\mathbf{w}_{k+1}, \mathbf{u}_{j}\right) \mathbf{u}_{j}}{\left|\mathbf{w}_{k+1}-\sum_{j=1}^{k+1}\left(\mathbf{w}_{k+1}, \mathbf{u}_{j}\right) \mathbf{u}_{j}\right|}
$$

By induction, $\mathbf{u}_{j}=\mathbf{w}_{j}$ and so this reduces to $\mathbf{w}_{k+1} /\left|\mathbf{w}_{k+1}\right|=\mathbf{w}_{k+1}$. This proves the lemma.
This lemma immediately implies the following lemma.
Lemma 5.9.4 Let $V$ be a subspace of dimension $p$ and let $\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}\right\}$ be an orthonormal set of vectors in $V$. Then this orthonormal set of vectors may be extended to an orthonormal basis for $V$,

$$
\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}, \mathbf{y}_{r+1}, \cdots, \mathbf{y}_{p}\right\}
$$

Proof: First extend the given linearly independent set $\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}\right\}$ to a basis for $V$ and then apply the Gram Schmidt theorem to the resulting basis. Since $\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}\right\}$ is orthonormal it follows from Lemma 5.9.3 the result is of the desired form, an orthonormal basis extending $\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{r}\right\}$. This proves the lemma.

Here is another lemma about preserving distance.
Lemma 5.9.5 Suppose $R$ is an $m \times n$ matrix with $m>n$ and $R$ preserves distances. Then $R^{*} R=I$.

Proof: Since $R$ preserves distances, $|R \mathbf{x}|=|\mathbf{x}|$ for every $\mathbf{x}$. Therefore from the axioms of the dot product,

$$
\begin{aligned}
& |\mathbf{x}|^{2}+|\mathbf{y}|^{2}+(\mathbf{x}, \mathbf{y})+(\mathbf{y}, \mathbf{x}) \\
= & |\mathbf{x}+\mathbf{y}|^{2} \\
= & (R(\mathbf{x}+\mathbf{y}), R(\mathbf{x}+\mathbf{y})) \\
= & (R \mathbf{x}, R \mathbf{x})+(R \mathbf{y}, R \mathbf{y})+(R \mathbf{x}, R \mathbf{y})+(R \mathbf{y}, R \mathbf{x}) \\
= & |\mathbf{x}|^{2}+|\mathbf{y}|^{2}+\left(R^{*} R \mathbf{x}, \mathbf{y}\right)+\left(\mathbf{y}, R^{*} R \mathbf{x}\right)
\end{aligned}
$$

and so for all $\mathbf{x}, \mathbf{y}$,

$$
\left(R^{*} R \mathbf{x}-\mathbf{x}, \mathbf{y}\right)+\left(\mathbf{y}, R^{*} R \mathbf{x}-\mathbf{x}\right)=0
$$

Hence for all $\mathbf{x}, \mathbf{y}$,

$$
\operatorname{Re}\left(R^{*} R \mathbf{x}-\mathbf{x}, \mathbf{y}\right)=0
$$

Now for a $\mathbf{x}, \mathbf{y}$ given, choose $\alpha \in \mathbb{C}$ such that

$$
\alpha\left(R^{*} R \mathbf{x}-\mathbf{x}, \mathbf{y}\right)=\left|\left(R^{*} R \mathbf{x}-\mathbf{x}, \mathbf{y}\right)\right|
$$

Then

$$
\begin{aligned}
0 & =\operatorname{Re}\left(R^{*} R \mathbf{x}-\mathbf{x}, \bar{\alpha} \mathbf{y}\right)=\operatorname{Re} \alpha\left(R^{*} R \mathbf{x}-\mathbf{x}, \mathbf{y}\right) \\
& =\left|\left(R^{*} R \mathbf{x}-\mathbf{x}, \mathbf{y}\right)\right|
\end{aligned}
$$

Thus $\left|\left(R^{*} R \mathbf{x}-\mathbf{x}, \mathbf{y}\right)\right|=0$ for all $\mathbf{x}, \mathbf{y}$ because the given $\mathbf{x}, \mathbf{y}$ were arbitrary. Let $\mathbf{y}=R^{*} R \mathbf{x}-\mathbf{x}$ to conclude that for all $\mathbf{x}$,

$$
R^{*} R \mathbf{x}-\mathbf{x}=\mathbf{0}
$$

which says $R^{*} R=I$ since $\mathbf{x}$ is arbitrary. This proves the lemma.
With this preparation, here is the big theorem about the right polar decomposition.
Theorem 5.9.6 Let $F$ be an $m \times n$ matrix where $m \geq n$. Then there exists a Hermitian $n \times n$ matrix, $U$ which has all nonnegative eigenvalues and an $m \times n$ matrix, $R$ which preserves distances and satisfies $R^{*} R=I$ such that

$$
F=R U .
$$

Proof: Consider $F^{*} F$. This is a Hermitian matrix because

$$
\left(F^{*} F\right)^{*}=F^{*}\left(F^{*}\right)^{*}=F^{*} F
$$

Also the eigenvalues of the $n \times n$ matrix $F^{*} F$ are all nonnegative. This is because if $\mathbf{x}$ is an eigenvalue,

$$
\lambda(\mathbf{x}, \mathbf{x})=\left(F^{*} F \mathbf{x}, \mathbf{x}\right)=(F \mathbf{x}, F \mathbf{x}) \geq 0
$$

Therefore, by Lemma 5.9.1, there exists an $n \times n$ Hermitian matrix, $U$ having all nonnegative eigenvalues such that

$$
U^{2}=F^{*} F .
$$

Consider the subspace $U\left(\mathbb{F}^{n}\right)$. Let $\left\{U \mathbf{x}_{1}, \cdots, U \mathbf{x}_{r}\right\}$ be an orthonormal basis for $U\left(\mathbb{F}^{n}\right) \subseteq$ $\mathbb{F}^{n}$. Note that $U\left(\mathbb{F}^{n}\right)$ might not be all of $\mathbb{F}^{n}$. Using Lemma 5.9.4, extend to an orthonormal basis for all of $\mathbb{F}^{n}$,

$$
\left\{U \mathbf{x}_{1}, \cdots, U \mathbf{x}_{r}, \mathbf{y}_{r+1}, \cdots, \mathbf{y}_{n}\right\}
$$

Next observe that $\left\{F \mathbf{x}_{1}, \cdots, F \mathbf{x}_{r}\right\}$ is also an orthonormal set of vectors in $\mathbb{F}^{m}$. This is because

$$
\begin{aligned}
\left(F \mathbf{x}_{k}, F \mathbf{x}_{j}\right) & =\left(F^{*} F \mathbf{x}_{k}, \mathbf{x}_{j}\right)=\left(U^{2} \mathbf{x}_{k}, \mathbf{x}_{j}\right) \\
& =\left(U \mathbf{x}_{k}, U^{*} \mathbf{x}_{j}\right)=\left(U \mathbf{x}_{k}, U \mathbf{x}_{j}\right)=\delta_{j k}
\end{aligned}
$$

Therefore, from Lemma 5.9.4 again, this orthonormal set of vectors can be extended to an orthonormal basis for $\mathbb{F}^{m}$,

$$
\left\{F \mathbf{x}_{1}, \cdots, F \mathbf{x}_{r}, \mathbf{z}_{r+1}, \cdots, \mathbf{z}_{m}\right\}
$$

Thus there are at least as many $\mathbf{z}_{k}$ as there are $\mathbf{y}_{j}$. Now for $\mathbf{x} \in \mathbb{F}^{n}$, since

$$
\left\{U \mathbf{x}_{1}, \cdots, U \mathbf{x}_{r}, \mathbf{y}_{r+1}, \cdots, \mathbf{y}_{n}\right\}
$$

is an orthonormal basis for $\mathbb{F}^{n}$, there exist unique scalars,

$$
c_{1} \cdots, c_{r}, d_{r+1}, \cdots, d_{n}
$$

such that

$$
\mathbf{x}=\sum_{k=1}^{r} c_{k} U \mathbf{x}_{k}+\sum_{j=r+1}^{n} d_{k} \mathbf{y}_{k}
$$

Define

$$
\begin{equation*}
R \mathbf{x} \equiv \sum_{k=1}^{r} c_{k} F \mathbf{x}_{k}+\sum_{j=r+1}^{n} d_{k} \mathbf{z}_{k} \tag{5.9.27}
\end{equation*}
$$

Then also there exist scalars $b_{k}$ such that

$$
U \mathbf{x}=\sum_{k=1}^{r} b_{k} U \mathbf{x}_{k}
$$

and so from 5.9.27, applied to $U \mathbf{x}$ in place of $\mathbf{x}$

$$
R U \mathbf{x}=\sum_{k=1}^{r} b_{k} F \mathbf{x}_{k}=F\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}\right)
$$

Is $F\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}\right)=F(\mathbf{x})$ ?

$$
\begin{aligned}
& \left(F\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}\right)-F(\mathbf{x}), F\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}\right)-F(\mathbf{x})\right) \\
& =\left(\left(F^{*} F\right)\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}-\mathbf{x}\right),\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}-\mathbf{x}\right)\right) \\
& =\left(U^{2}\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}-\mathbf{x}\right),\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}-\mathbf{x}\right)\right) \\
& =\left(U\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}-\mathbf{x}\right), U\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}-\mathbf{x}\right)\right) \\
& =\left(\sum_{k=1}^{r} b_{k} U \mathbf{x}_{k}-U \mathbf{x}, \sum_{k=1}^{r} b_{k} U \mathbf{x}_{k}-U \mathbf{x}\right)=0
\end{aligned}
$$

Therefore, $F\left(\sum_{k=1}^{r} b_{k} \mathbf{x}_{k}\right)=F(\mathbf{x})$ and this shows

$$
R U \mathbf{x}=F \mathbf{x}
$$

From 5.9.27 and Lemma 5.9.2 $R$ preserves distances. Therefore, by Lemma 5.9.5 $R^{*} R=I$. This proves the theorem.

Here is a useful fact from Linear algebra.

Lemma 5.9.7 Suppose $\operatorname{det}(A)=0$. Then for all sufficiently small nonzero $\varepsilon, \operatorname{det}(A+\varepsilon I) \neq$ 0.

Proof: First suppose $A$ is a $p \times p$ matrix. Suppose also that $\operatorname{det}(A)=0$. Thus, the constant term of $\operatorname{det}(\lambda I-A)$ is 0 . Consider $\varepsilon I+A \equiv A_{\varepsilon}$ for small real $\varepsilon$. The characteristic polynomial of $A_{\varepsilon}$ is

$$
\operatorname{det}\left(\lambda I-A_{\varepsilon}\right)=\operatorname{det}((\lambda-\varepsilon) I-A)
$$

This is of the form

$$
(\lambda-\varepsilon)^{p}+a_{p-1}(\lambda-\varepsilon)^{p-1}+\cdots+(\lambda-\varepsilon)^{m} a_{m}
$$

where the $a_{j}$ are the coefficients in the characteristic equation for $A$ and $m$ is the largest such that $a_{m} \neq 0$. The constant term of this characteristic polynomial for $A_{\varepsilon}$ must be nonzero for all positive $\varepsilon$ small enough because it is of the form

$$
(-1)^{m} \varepsilon^{m} a_{m}+(\text { higher order terms in } \varepsilon)
$$

which shows that $\varepsilon I+A$ is invertible for all $\varepsilon$ small enough but nonzero.

## Chapter 6

## Multi-variable Calculus

### 6.1 Continuous Functions

In what follows, $\mathbb{F}$ will denote either $\mathbb{R}$ or $\mathbb{C}$. It turns out it is more efficient to not make a distinction. However, the main interest is in $\mathbb{R}$ so if you like, you can think $\mathbb{R}$ whenever you see $\mathbb{F}$.

### 6.2 Open And Closed Sets

Eventually, one must consider functions which are defined on subsets of $\mathbb{F}^{n}$ and their properties. The next definition will end up being quite important. It describe a type of subset of $\mathbb{F}^{n}$ with the property that if $\mathbf{x}$ is in this set, then so is $\mathbf{y}$ whenever $\mathbf{y}$ is close enough to $\mathbf{x}$. In all of this, for $\mathbf{x}$ a vector, $|\mathbf{x}|$ is given by $(\mathbf{x}, \mathbf{x})^{1 / 2}$ where this denotes the square root of the inner product of the vector with itself as described earlier. Then the distance between the vectors $\mathbf{x}$ and $\mathbf{y}$ is defined as $|\mathbf{x}-\mathbf{y}|$.

Definition 6.2.1 Let $U \subseteq \mathbb{F}^{n}$. $U$ is an open set if whenever $\mathbf{x} \in U$, there exists $r>0$ such that $B(\mathbf{x}, r) \subseteq U$. More generally, if $U$ is any subset of $\mathbb{F}^{n}, \mathbf{x} \in U$ is an interior point of $U$ if there exists $r>0$ such that $\mathbf{x} \in B(\mathbf{x}, r) \subseteq U$. In other words $U$ is an open set exactly when every point of $U$ is an interior point of $U$.

If there is something called an open set, surely there should be something called a closed set and here is the definition of one.

Definition 6.2.2 A subset, $C$, of $\mathbb{F}^{n}$ is called a closed set if $\mathbb{F}^{n} \backslash C$ is an open set. They symbol, $\mathbb{F}^{n} \backslash C$ denotes everything in $\mathbb{F}^{n}$ which is not in $C$. It is also called the complement of $C$. The symbol, $S^{C}$ is a short way of writing $\mathbb{F}^{n} \backslash S$.

To illustrate this definition, consider the following picture.
$\mathbf{x}$
$B(\mathbf{x}, r)$$\vdots \quad U$

You see in this picture how the edges are dotted. This is because an open set, can not include the edges or the set would fail to be open. For example, consider what would happen if you picked a point out on the edge of $U$ in the above picture. Every open ball centered at that point would have in it some points which are outside $U$. Therefore, such a point would violate the above definition. You also see the edges of $B(\mathbf{x}, r)$ dotted suggesting
that $B(\mathbf{x}, r)$ ought to be an open set. This is intuitively clear but does require a proof. This will be done in the next theorem and will give examples of open sets. Also, you can see that if $\mathbf{x}$ is close to the edge of $U$, you might have to take $r$ to be very small.

It is roughly the case that open sets don't have their skins while closed sets do. Here is a picture of a closed set, $C$.

Note that $\mathbf{x} \notin C$ and since $\mathbb{F}^{n} \backslash C$ is open, there exists a ball, $B(\mathbf{x}, r)$ contained entirely in $\mathbb{F}^{n} \backslash C$. If you look at $\mathbb{F}^{n} \backslash C$, what would be its skin? It can't be in $\mathbb{F}^{n} \backslash C$ and so it must be in $C$. This is a rough heuristic explanation of what is going on with these definitions. Also note that $\mathbb{F}^{n}$ and $\emptyset$ are both open and closed. Here is why. If $\mathbf{x} \in \emptyset$, then there must be a ball centered at $\mathbf{x}$ which is also contained in $\emptyset$. This must be considered to be true because there is nothing in $\emptyset$ so there can be no example to show it false ${ }^{1}$. Therefore, from the definition, it follows $\emptyset$ is open. It is also closed because if $\mathbf{x} \notin \emptyset$, then $B(\mathbf{x}, 1)$ is also contained in $\mathbb{F}^{n} \backslash \emptyset=\mathbb{F}^{n}$. Therefore, $\emptyset$ is both open and closed. From this, it follows $\mathbb{F}^{n}$ is also both open and closed.

Theorem 6.2.3 Let $\mathbf{x} \in \mathbb{F}^{n}$ and let $r \geq 0$. Then $B(\mathbf{x}, r)$ is an open set. Also,

$$
D(\mathbf{x}, r) \equiv\left\{\mathbf{y} \in \mathbb{F}^{n}:|\mathbf{y}-\mathbf{x}| \leq r\right\}
$$

is a closed set.
Proof: Suppose $\mathbf{y} \in B(\mathbf{x}, r)$. It is necessary to show there exists $r_{1}>0$ such that $B\left(\mathbf{y}, r_{1}\right) \subseteq B(\mathbf{x}, r)$. Define $r_{1} \equiv r-|\mathbf{x}-\mathbf{y}|$. Then if $|\mathbf{z}-\mathbf{y}|<r_{1}$, it follows from the above triangle inequality that

$$
\begin{aligned}
|\mathbf{z}-\mathbf{x}| & =|\mathbf{z}-\mathbf{y}+\mathbf{y}-\mathbf{x}| \\
& \leq|\mathbf{z}-\mathbf{y}|+|\mathbf{y}-\mathbf{x}| \\
& <r_{1}+|\mathbf{y}-\mathbf{x}|=r-|\mathbf{x}-\mathbf{y}|+|\mathbf{y}-\mathbf{x}|=r
\end{aligned}
$$

[^5]Note that if $r=0$ then $B(\mathbf{x}, r)=\emptyset$, the empty set. This is because if $\mathbf{y} \in \mathbb{F}^{n},|\mathbf{x}-\mathbf{y}| \geq 0$ and so $\mathbf{y} \notin B(\mathbf{x}, 0)$. Since $\emptyset$ has no points in it, it must be open because every point in it, (There are none.) satisfies the desired property of being an interior point.

Now suppose $\mathbf{y} \notin D(\mathbf{x}, r)$. Then $|\mathbf{x}-\mathbf{y}|>r$ and defining $\delta \equiv|\mathbf{x}-\mathbf{y}|-r$, it follows that if $\mathbf{z} \in B(\mathbf{y}, \boldsymbol{\delta})$, then by the triangle inequality,

$$
\begin{aligned}
|\mathbf{x}-\mathbf{z}| & \geq|\mathbf{x}-\mathbf{y}|-|\mathbf{y}-\mathbf{z}|>|\mathbf{x}-\mathbf{y}|-\delta \\
& =|\mathbf{x}-\mathbf{y}|-(|\mathbf{x}-\mathbf{y}|-r)=r
\end{aligned}
$$

and this shows that $B(\mathbf{y}, \delta) \subseteq \mathbb{F}^{n} \backslash D(\mathbf{x}, r)$. Since $\mathbf{y}$ was an arbitrary point in $\mathbb{F}^{n} \backslash D(\mathbf{x}, r)$, it follows $\mathbb{F}^{n} \backslash D(\mathbf{x}, r)$ is an open set which shows from the definition that $D(\mathbf{x}, r)$ is a closed set as claimed.

A picture which is descriptive of the conclusion of the above theorem which also implies the manner of proof is the following.

### 6.3 Continuous Functions

With the above definition of the norm in $\mathbb{F}^{p}$, it becomes possible to define continuity.
Definition 6.3.1 A function $\mathbf{f}: D(\mathbf{f}) \subseteq \mathbb{F}^{p} \rightarrow \mathbb{F}^{q}$ is continuous at $\mathbf{x} \in D(\mathbf{f})$ if for each $\varepsilon>0$ there exists $\delta>0$ such that whenever $\mathbf{y} \in D(\mathbf{f})$ and

$$
|\mathbf{y}-\mathbf{x}|<\delta
$$

it follows that

$$
|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\varepsilon .
$$

$\mathbf{f}$ is continuous if it is continuous at every point of $D(\mathbf{f})$.
Note the total similarity to the scalar valued case.

### 6.3.1 Sufficient Conditions For Continuity

The next theorem is a fundamental result which will allow us to worry less about the $\varepsilon \delta$ definition of continuity.

Theorem 6.3.2 The following assertions are valid.

1. The function, af $+b \mathbf{g}$ is continuous at $\mathbf{x}$ whenever $\mathbf{f}, \mathbf{g}$ are continuous at $\mathbf{x} \in D(\mathbf{f}) \cap$ $D(\mathbf{g})$ and $a, b \in \mathbb{F}$.
2. If $\mathbf{f}$ is continuous at $\mathbf{x}, \mathbf{f}(\mathbf{x}) \in D(\mathbf{g}) \subseteq \mathbb{F}^{p}$, and $\mathbf{g}$ is continuous at $\mathbf{f}(\mathbf{x})$, then $\mathbf{g} \circ \mathbf{f}$ is continuous at $\mathbf{x}$.
3. If $\mathbf{f}=\left(f_{1}, \cdots, f_{q}\right): D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$, then $\mathbf{f}$ is continuous if and only if each $f_{k}$ is a continuous $\mathbb{F}$ valued function.
4. The function $f: \mathbb{F}^{p} \rightarrow \mathbb{F}$, given by $f(\mathbf{x})=|\mathbf{x}|$ is continuous.

The proof of this theorem is in the last section of this chapter. Its conclusions are not surprising. For example the first claim says that $(a \mathbf{f}+b \mathbf{g})(\mathbf{y})$ is close to $(a \mathbf{f}+b \mathbf{g})(\mathbf{x})$ when $\mathbf{y}$ is close to $\mathbf{x}$ provided the same can be said about $\mathbf{f}$ and $\mathbf{g}$. For the second claim, if $\mathbf{y}$ is close to $\mathbf{x}, \mathbf{f}(\mathbf{x})$ is close to $\mathbf{f}(\mathbf{y})$ and so by continuity of $\mathbf{g}$ at $\mathbf{f}(\mathbf{x}), \mathbf{g}(\mathbf{f}(\mathbf{y}))$ is close to $\mathbf{g}(\mathbf{f}(\mathbf{x}))$. To see the third claim is likely, note that closeness in $\mathbb{F}^{p}$ is the same as closeness in each coordinate. The fourth claim is immediate from the triangle inequality.

For functions defined on $\mathbb{F}^{n}$, there is a notion of polynomial just as there is for functions defined on $\mathbb{R}$.

Definition 6.3.3 Let $\alpha$ be an $n$ dimensional multi-index. This means

$$
\alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right)
$$

where each $\alpha_{i}$ is a natural number or zero. Also, let

$$
|\alpha| \equiv \sum_{i=1}^{n}\left|\alpha_{i}\right|
$$

The symbol, $\mathbf{x}^{\alpha}$,means

$$
\mathbf{x}^{\alpha} \equiv x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \cdots x_{3}^{\alpha_{n}}
$$

An $n$ dimensional polynomial of degree $m$ is a function of the form

$$
p(\mathbf{x})=\sum_{|\alpha| \leq m} d_{\alpha} \mathbf{x}^{\alpha}
$$

where the $d_{\alpha}$ are complex or real numbers.
The above theorem implies that polynomials are all continuous.

### 6.4 Exercises

1. Let $\mathbf{f}(t)=(t, \sin t)$. Show $f$ is continuous at every point $t$.
2. Suppose $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|$ where $K$ is a constant. Show that $\mathbf{f}$ is everywhere continuous. Functions satisfying such an inequality are called Lipschitz functions.
3. Suppose $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|^{\alpha}$ where $K$ is a constant and $\alpha \in(0,1)$. Show that $\mathbf{f}$ is everywhere continuous.
4. Suppose $f: \mathbb{F}^{3} \rightarrow \mathbb{F}$ is given by $f(\mathbf{x})=3 x_{1} x_{2}+2 x_{3}^{2}$. Use Theorem 6.3.2 to verify that $f$ is continuous. Hint: You should first verify that the function, $\pi_{k}: \mathbb{F}^{3} \rightarrow \mathbb{F}$ given by $\pi_{k}(\mathbf{x})=x_{k}$ is a continuous function.
5. Generalize the previous problem to the case where $f: \mathbb{F}^{q} \rightarrow \mathbb{F}$ is a polynomial.
6. State and prove a theorem which involves quotients of functions encountered in the previous problem.

### 6.5 Limits Of A Function

As in the case of scalar valued functions of one variable, a concept closely related to continuity is that of the limit of a function. The notion of limit of a function makes sense at points, $\mathbf{x}$, which are limit points of $D(\mathbf{f})$ and this concept is defined next.

Definition 6.5.1 Let $A \subseteq \mathbb{F}^{m}$ be a set. A point, $\mathbf{x}$, is a limit point of $A$ if $B(\mathbf{x}, r)$ contains infinitely many points of $A$ for every $r>0$.

Definition 6.5.2 Let $\mathbf{f}: D(\mathbf{f}) \subseteq \mathbb{F}^{p} \rightarrow \mathbb{F}^{q}$ be a function and let $\mathbf{x}$ be a limit point of $D(\mathbf{f})$. Then

$$
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L}
$$

if and only if the following condition holds. For all $\varepsilon>0$ there exists $\delta>0$ such that if

$$
0<|\mathbf{y}-\mathbf{x}|<\delta, \text { and } \mathbf{y} \in D(\mathbf{f})
$$

then,

$$
|\mathbf{L}-\mathbf{f}(\mathbf{y})|<\varepsilon .
$$

Theorem 6.5.3 If $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L}$ and $\lim _{y \rightarrow x} \mathbf{f}(\mathbf{y})=\mathbf{L}_{1}$, then $\mathbf{L}=\mathbf{L}_{1}$.
Proof: Let $\varepsilon>0$ be given. There exists $\delta>0$ such that if $0<|\mathbf{y}-\mathbf{x}|<\delta$ and $\mathbf{y} \in D(\mathbf{f})$, then

$$
|\mathbf{f}(\mathbf{y})-\mathbf{L}|<\varepsilon,\left|\mathbf{f}(\mathbf{y})-\mathbf{L}_{1}\right|<\varepsilon .
$$

Pick such a $\mathbf{y}$. There exists one because $\mathbf{x}$ is a limit point of $D(\mathbf{f})$. Then

$$
\left|\mathbf{L}-\mathbf{L}_{1}\right| \leq|\mathbf{L}-\mathbf{f}(\mathbf{y})|+\left|\mathbf{f}(\mathbf{y})-\mathbf{L}_{1}\right|<\varepsilon+\varepsilon=2 \varepsilon .
$$

Since $\varepsilon>0$ was arbitrary, this shows $\mathbf{L}=\mathbf{L}_{1}$.
As in the case of functions of one variable, one can define $\lim _{\mathbf{y} \rightarrow \mathbf{x}} f(\mathbf{x})= \pm \infty$.
Definition 6.5.4 If $f(\mathbf{x}) \in \mathbb{F}, \lim _{\mathbf{y} \rightarrow \mathbf{x}} f(\mathbf{x})=\infty$ if for every number $l$, there exists $\delta>0$ such that whenever $|\mathbf{y}-\mathbf{x}|<\delta$ and $\mathbf{y} \in D(\mathbf{f})$, then $f(\mathbf{x})>l$.

The following theorem is just like the one variable version presented earlier.
Theorem 6.5.5 Suppose $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L}$ and $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{g}(\mathbf{y})=\mathbf{K}$ where $\mathbf{K}, \mathbf{L} \in \mathbb{F}^{q}$. Then if $a, b \in \mathbb{F}$,

$$
\begin{gather*}
\lim _{\mathbf{y} \rightarrow \mathbf{x}}(a \mathbf{f}(\mathbf{y})+b \mathbf{g}(\mathbf{y}))=a \mathbf{L}+b \mathbf{K}  \tag{6.5.1}\\
\lim _{y \rightarrow x} \mathbf{f} \cdot \mathbf{g}(y)=\mathbf{L K} \tag{6.5.2}
\end{gather*}
$$

and if $g$ is scalar valued with $\lim _{\mathbf{y} \rightarrow \mathbf{x}} g(\mathbf{y})=K \neq 0$,

$$
\begin{equation*}
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y}) g(\mathbf{y})=\mathbf{L} K \tag{6.5.3}
\end{equation*}
$$

Also, if $\mathbf{h}$ is a continuous function defined near $\mathbf{L}$, then

$$
\begin{equation*}
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{h} \circ \mathbf{f}(\mathbf{y})=\mathbf{h}(\mathbf{L}) . \tag{6.5.4}
\end{equation*}
$$

Suppose $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L}$. If $|\mathbf{f}(\mathbf{y})-\mathbf{b}| \leq r$ for all $\mathbf{y}$ sufficiently close to $\mathbf{x}$, then $|\mathbf{L}-\mathbf{b}| \leq r$ also.

Proof: The proof of 6.5 .1 is left for you. It is like a corresponding theorem for continuous functions. Now 6.5 .2is to be verified. Let $\varepsilon>0$ be given. Then by the triangle inequality,

$$
\begin{aligned}
|\mathbf{f} \cdot \mathbf{g}(\mathbf{y})-\mathbf{L} \cdot \mathbf{K}| & \leq|\mathbf{f g}(\mathbf{y})-\mathbf{f}(\mathbf{y}) \cdot \mathbf{K}|+|\mathbf{f}(\mathbf{y}) \cdot \mathbf{K}-\mathbf{L} \cdot \mathbf{K}| \\
& \leq|\mathbf{f}(\mathbf{y})||\mathbf{g}(\mathbf{y})-\mathbf{K}|+|\mathbf{K}||\mathbf{f}(\mathbf{y})-\mathbf{L}| .
\end{aligned}
$$

There exists $\delta_{1}$ such that if $0<|\mathbf{y}-\mathbf{x}|<\delta_{1}$ and $\mathbf{y} \in D(\mathbf{f})$, then

$$
|\mathbf{f}(\mathbf{y})-\mathbf{L}|<1
$$

and so for such $\mathbf{y}$, the triangle inequality implies, $|\mathbf{f}(\mathbf{y})|<1+|\mathbf{L}|$. Therefore, for $0<$ $|\mathbf{y}-\mathbf{x}|<\delta_{1}$,

$$
\begin{equation*}
|\mathbf{f} \cdot \mathbf{g}(\mathbf{y})-\mathbf{L} \cdot \mathbf{K}| \leq(1+|\mathbf{K}|+|\mathbf{L}|)[|\mathbf{g}(\mathbf{y})-\mathbf{K}|+|\mathbf{f}(\mathbf{y})-\mathbf{L}|] . \tag{6.5.5}
\end{equation*}
$$

Now let $0<\boldsymbol{\delta}_{2}$ be such that if $\mathbf{y} \in D(\mathbf{f})$ and $0<|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}_{2}$,

$$
|\mathbf{f}(\mathbf{y})-\mathbf{L}|<\frac{\varepsilon}{2(1+|\mathbf{K}|+|\mathbf{L}|)},|\mathbf{g}(\mathbf{y})-\mathbf{K}|<\frac{\varepsilon}{2(1+|\mathbf{K}|+|\mathbf{L}|)}
$$

Then letting $0<\delta \leq \min \left(\delta_{1}, \delta_{2}\right)$, it follows from 6.5.5 that

$$
|\mathbf{f} \cdot \mathbf{g}(\mathbf{y})-\mathbf{L} \cdot \mathbf{K}|<\varepsilon
$$

and this proves 6.5.2.
The proof of 6.5.3 is left to you.
Consider 6.5.4. Since $\mathbf{h}$ is continuous near $\mathbf{L}$, it follows that for $\varepsilon>0$ given, there exists $\eta>0$ such that if $|\mathbf{y}-\mathbf{L}|<\eta$, then

$$
|\mathbf{h}(\mathbf{y})-\mathbf{h}(\mathbf{L})|<\varepsilon
$$

Now since $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L}$, there exists $\delta>0$ such that if $0<|\mathbf{y}-\mathbf{x}|<\boldsymbol{\delta}$, then

$$
|\mathbf{f}(\mathbf{y})-\mathbf{L}|<\eta
$$

Therefore, if $0<|\mathbf{y}-\mathbf{x}|<\boldsymbol{\delta}$,

$$
|\mathbf{h}(\mathbf{f}(\mathbf{y}))-\mathbf{h}(\mathbf{L})|<\varepsilon .
$$

It only remains to verify the last assertion. Assume $|\mathbf{f}(\mathbf{y})-\mathbf{b}| \leq r$ for all $\mathbf{y}$ close enough to $\mathbf{x}$. It is required to show that $|\mathbf{L}-\mathbf{b}| \leq r$. If this is not true, then $|\mathbf{L}-\mathbf{b}|>r$. Consider $B(\mathbf{L},|\mathbf{L}-\mathbf{b}|-r)$. Since $\mathbf{L}$ is the limit of $\mathbf{f}$, it follows $\mathbf{f}(\mathbf{y}) \in B(\mathbf{L},|\mathbf{L}-\mathbf{b}|-r)$ whenever $\mathbf{y} \in D(\mathbf{f})$ is close enough to $\mathbf{x}$. Thus, by the triangle inequality,

$$
|\mathbf{f}(\mathbf{y})-\mathbf{L}|<|\mathbf{L}-\mathbf{b}|-r
$$

and so

$$
\begin{aligned}
r & <|\mathbf{L}-\mathbf{b}|-|\mathbf{f}(\mathbf{y})-\mathbf{L}| \leq||\mathbf{b}-\mathbf{L}|-| \mathbf{f}(\mathbf{y})-\mathbf{L} \| \\
& \leq|\mathbf{b}-\mathbf{f}(\mathbf{y})|
\end{aligned}
$$

a contradiction to the assumption that $|\mathbf{b}-\mathbf{f}(\mathbf{y})| \leq r$.
Theorem 6.5.6 For $\mathbf{f}: D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$ and $\mathbf{x} \in D(\mathbf{f})$ a limit point of $D(\mathbf{f})$, $\mathbf{f}$ is continuous at $\mathbf{x}$ if and only if

$$
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{f}(\mathbf{x})
$$

Proof: First suppose $\mathbf{f}$ is continuous at $\mathbf{x}$ a limit point of $D(\mathbf{f})$. Then for every $\varepsilon>0$ there exists $\delta>0$ such that if $|\mathbf{y}-\mathbf{x}|<\delta$ and $\mathbf{y} \in D(\mathbf{f})$, then $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\varepsilon$. In particular, this holds if $0<|\mathbf{x}-\mathbf{y}|<\delta$ and this is just the definition of the limit. Hence $\mathbf{f}(\mathbf{x})=$ $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})$.

Next suppose $\mathbf{x}$ is a limit point of $D(\mathbf{f})$ and $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{f}(\mathbf{x})$. This means that if $\varepsilon>0$ there exists $\delta>0$ such that for $0<|\mathbf{x}-\mathbf{y}|<\delta$ and $\mathbf{y} \in D(\mathbf{f})$, it follows $|\mathbf{f}(\mathbf{y})-\mathbf{f}(\mathbf{x})|<\varepsilon$. However, if $\mathbf{y}=\mathbf{x}$, then $|\mathbf{f}(\mathbf{y})-\mathbf{f}(\mathbf{x})|=|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{x})|=0$ and so whenever $\mathbf{y} \in D(\mathbf{f})$ and $|\mathbf{x}-\mathbf{y}|<\delta$, it follows $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\varepsilon$, showing $\mathbf{f}$ is continuous at $\mathbf{x}$.

The following theorem is important.
Theorem 6.5.7 Suppose $\mathbf{f}: D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$. Then for $\mathbf{x}$ a limit point of $D(\mathbf{f})$,

$$
\begin{equation*}
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L} \tag{6.5.6}
\end{equation*}
$$

if and only if

$$
\begin{equation*}
\lim _{\mathbf{y} \rightarrow \mathbf{x}} f_{k}(\mathbf{y})=L_{k} \tag{6.5.7}
\end{equation*}
$$

where $\mathbf{f}(\mathbf{y}) \equiv\left(f_{1}(\mathbf{y}), \cdots, f_{p}(\mathbf{y})\right)$ and $\mathbf{L} \equiv\left(L_{1}, \cdots, L_{p}\right)$.
Proof: Suppose 6.5.6. Then letting $\varepsilon>0$ be given there exists $\delta>0$ such that if $0<|\mathbf{y}-\mathbf{x}|<\delta$, it follows

$$
\left|f_{k}(\mathbf{y})-L_{k}\right| \leq|\mathbf{f}(\mathbf{y})-\mathbf{L}|<\varepsilon
$$

which verifies 6.5.7.
Now suppose 6.5.7 holds. Then letting $\varepsilon>0$ be given, there exists $\delta_{k}$ such that if $0<|\mathbf{y}-\mathbf{x}|<\boldsymbol{\delta}_{k}$, then

$$
\left|f_{k}(\mathbf{y})-L_{k}\right|<\frac{\varepsilon}{\sqrt{p}}
$$

Let $0<\boldsymbol{\delta}<\min \left(\delta_{1}, \cdots, \delta_{p}\right)$. Then if $0<|\mathbf{y}-\mathbf{x}|<\boldsymbol{\delta}$, it follows

$$
\begin{aligned}
|\mathbf{f}(\mathbf{y})-\mathbf{L}| & =\left(\sum_{k=1}^{p}\left|f_{k}(\mathbf{y})-L_{k}\right|^{2}\right)^{1 / 2} \\
& <\left(\sum_{k=1}^{p} \frac{\varepsilon^{2}}{p}\right)^{1 / 2}=\varepsilon
\end{aligned}
$$

This proves the theorem.
This theorem shows it suffices to consider the components of a vector valued function when computing the limit.

Example 6.5.8 Find $\lim _{(x, y) \rightarrow(3,1)}\left(\frac{x^{2}-9}{x-3}, y\right)$.
It is clear that $\lim _{(x, y) \rightarrow(3,1)} \frac{x^{2}-9}{x-3}=6$ and $\lim _{(x, y) \rightarrow(3,1)} y=1$. Therefore, this limit equals $(6,1)$.

Example 6.5.9 Find $\lim _{(x, y) \rightarrow(0,0)} \frac{x y}{x^{2}+y^{2}}$.
First of all observe the domain of the function is $\mathbb{F}^{2} \backslash\{(0,0)\}$, every point in $\mathbb{F}^{2}$ except the origin. Therefore, $(0,0)$ is a limit point of the domain of the function so it might make sense to take a limit. However, just as in the case of a function of one variable, the limit may not exist. In fact, this is the case here. To see this, take points on the line $y=0$. At these points, the value of the function equals 0 . Now consider points on the line $y=x$ where the value of the function equals $1 / 2$. Since arbitrarily close to $(0,0)$ there are points where the function equals $1 / 2$ and points where the function has the value 0 , it follows there can be no limit. Just take $\varepsilon=1 / 10$ for example. You can't be within $1 / 10$ of $1 / 2$ and also within $1 / 10$ of 0 at the same time.

Note it is necessary to rely on the definition of the limit much more than in the case of a function of one variable and it is the case there are no easy ways to do limit problems for functions of more than one variable. It is what it is and you will not deal with these concepts without agony.

### 6.6 Exercises

1. Find the following limits if possible
(a) $\lim _{(x, y) \rightarrow(0,0)} \frac{x^{2}-y^{2}}{x^{2}+y^{2}}$
(b) $\lim _{(x, y) \rightarrow(0,0)} \frac{x\left(x^{2}-y^{2}\right)}{\left(x^{2}+y^{2}\right)}$
(c) $\lim _{(x, y) \rightarrow(0,0)} \frac{\left(x^{2}-y^{4}\right)^{2}}{\left(x^{2}+y^{4}\right)^{2}}$ Hint: Consider along $y=0$ and along $x=y^{2}$.
(d) $\lim _{(x, y) \rightarrow(0,0)} x \sin \left(\frac{1}{x^{2}+y^{2}}\right)$
(e) The limit as $(x, y) \rightarrow(1,2)$ of the expression

$$
\frac{-2 y x^{2}+8 y x+34 y+3 y^{3}-18 y^{2}+6 x^{2}-13 x-20-x y^{2}-x^{3}}{-y^{2}+4 y-5-x^{2}+2 x} .
$$

Hint: It might help to write this in terms of the variables $(s, t)=(x-1, y-2)$.
2. In the definition of limit, why must $\mathbf{x}$ be a limit point of $D(\mathbf{f})$ ? Hint: If $\mathbf{x}$ were not a limit point of $D(\mathbf{f})$, show there exists $\delta>0$ such that $B(\mathbf{x}, \boldsymbol{\delta})$ contains no points of $D(\mathbf{f})$ other than possibly $\mathbf{x}$ itself. Argue that 33.3 is a limit and that so is 22 and 7 and 11. In other words the concept is totally worthless.

### 6.7 The Limit Of A Sequence

As in the case of real numbers, one can consider the limit of a sequence of points in $\mathbb{F}^{p}$.
Definition 6.7.1 A sequence $\left\{\mathbf{a}_{n}\right\}_{n=1}^{\infty}$ converges to $\mathbf{a}$, and write

$$
\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a} \text { or } \mathbf{a}_{n} \rightarrow \mathbf{a}
$$

if and only if for every $\varepsilon>0$ there exists $n_{\varepsilon}$ such that whenever $n \geq n_{\varepsilon}$,

$$
\left|\mathbf{a}_{n}-\mathbf{a}\right|<\varepsilon .
$$

In words the definition says that given any measure of closeness, $\varepsilon$, the terms of the sequence are eventually all this close to $\mathbf{a}$. There is absolutely no difference between this and the definition for sequences of numbers other than here bold face is used to indicate $\mathbf{a}_{n}$ and $\mathbf{a}$ are points in $\mathbb{F}^{p}$.

Theorem 6.7.2 If $\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a}$ and $\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a}_{1}$ then $\mathbf{a}_{1}=\mathbf{a}$.
Proof: Suppose $\mathbf{a}_{1} \neq \mathbf{a}$. Then let $0<\varepsilon<\left|\mathbf{a}_{1}-\mathbf{a}\right| / 2$ in the definition of the limit. It follows there exists $n_{\varepsilon}$ such that if $n \geq n_{\varepsilon}$, then $\left|\mathbf{a}_{n}-\mathbf{a}\right|<\varepsilon$ and $\left|\mathbf{a}_{n}-\mathbf{a}_{1}\right|<\varepsilon$. Therefore, for such $n$,

$$
\begin{aligned}
\left|\mathbf{a}_{1}-\mathbf{a}\right| & \leq\left|\mathbf{a}_{1}-\mathbf{a}_{n}\right|+\left|\mathbf{a}_{n}-\mathbf{a}\right| \\
& <\varepsilon+\varepsilon<\left|\mathbf{a}_{1}-\mathbf{a}\right| / 2+\left|\mathbf{a}_{1}-\mathbf{a}\right| / 2=\left|\mathbf{a}_{1}-\mathbf{a}\right|
\end{aligned}
$$

a contradiction.
As in the case of a vector valued function, it suffices to consider the components. This is the content of the next theorem.

Theorem 6.7.3 Let $\mathbf{a}_{n}=\left(a_{1}^{n}, \cdots, a_{p}^{n}\right) \in \mathbb{F}^{p}$. Then $\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a} \equiv\left(a_{1}, \cdots, a_{p}\right)$ if and only if for each $k=1, \cdots, p$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} a_{k}^{n}=a_{k} \tag{6.7.8}
\end{equation*}
$$

Proof: First suppose $\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a}$. Then given $\varepsilon>0$ there exists $n_{\varepsilon}$ such that if $n>n_{\varepsilon}$, then

$$
\left|a_{k}^{n}-a_{k}\right| \leq\left|\mathbf{a}_{n}-\mathbf{a}\right|<\varepsilon
$$

which establishes 6.7.8.
Now suppose 6.7.8 holds for each $k$. Then letting $\varepsilon>0$ be given there exist $n_{k}$ such that if $n>n_{k}$,

$$
\left|a_{k}^{n}-a_{k}\right|<\varepsilon / \sqrt{p} .
$$

Therefore, letting $n_{\varepsilon}>\max \left(n_{1}, \cdots, n_{p}\right)$, it follows that for $n>n_{\varepsilon}$,

$$
\left|\mathbf{a}_{n}-\mathbf{a}\right|=\left(\sum_{k=1}^{n}\left|a_{k}^{n}-a_{k}\right|^{2}\right)^{1 / 2}<\left(\sum_{k=1}^{n} \frac{\varepsilon^{2}}{p}\right)^{1 / 2}=\varepsilon
$$

showing that $\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a}$. This proves the theorem.
Example 6.7.4 Let $\mathbf{a}_{n}=\left(\frac{1}{n^{2}+1}, \frac{1}{n} \sin (n), \frac{n^{2}+3}{3 n^{2}+5 n}\right)$.
It suffices to consider the limits of the components according to the following theorem. Thus the limit is $(0,0,1 / 3)$.

Theorem 6.7.5 Suppose $\left\{\mathbf{a}_{n}\right\}$ and $\left\{\mathbf{b}_{n}\right\}$ are sequences and that

$$
\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a} \text { and } \lim _{n \rightarrow \infty} \mathbf{b}_{n}=\mathbf{b}
$$

Also suppose $x$ and $y$ are numbers in $\mathbb{F}$. Then

$$
\begin{align*}
\lim _{n \rightarrow \infty} x \mathbf{a}_{n}+y \mathbf{b}_{n} & =x \mathbf{a}+y \mathbf{b}  \tag{6.7.9}\\
\lim _{n \rightarrow \infty} \mathbf{a}_{n} \cdot \mathbf{b}_{n} & =\mathbf{a} \cdot \mathbf{b} \tag{6.7.10}
\end{align*}
$$

If $b_{n} \in \mathbb{F}$, then

$$
\mathbf{a}_{n} b_{n} \rightarrow \mathbf{a} b
$$

Proof: The first of these claims is left for you to do. To do the second, let $\varepsilon>0$ be given and choose $n_{1}$ such that if $n \geq n_{1}$ then

$$
\left|\mathbf{a}_{n}-\mathbf{a}\right|<1 .
$$

Then for such $n$, the triangle inequality and Cauchy Schwarz inequality imply

$$
\begin{aligned}
\left|\mathbf{a}_{n} \cdot \mathbf{b}_{n}-\mathbf{a} \cdot \mathbf{b}\right| & \leq\left|\mathbf{a}_{n} \cdot \mathbf{b}_{n}-\mathbf{a}_{n} \cdot \mathbf{b}\right|+\left|\mathbf{a}_{n} \cdot \mathbf{b}-\mathbf{a} \cdot \mathbf{b}\right| \\
& \leq\left|\mathbf{a}_{n}\right|\left|\mathbf{b}_{n}-\mathbf{b}\right|+|\mathbf{b}|\left|\mathbf{a}_{n}-\mathbf{a}\right| \\
& \leq(|\mathbf{a}|+1)\left|\mathbf{b}_{n}-\mathbf{b}\right|+|\mathbf{b}|\left|\mathbf{a}_{n}-\mathbf{a}\right|
\end{aligned}
$$

Now let $n_{2}$ be large enough that for $n \geq n_{2}$,

$$
\left|\mathbf{b}_{n}-\mathbf{b}\right|<\frac{\varepsilon}{2(|\mathbf{a}|+1)}, \text { and }\left|\mathbf{a}_{n}-\mathbf{a}\right|<\frac{\varepsilon}{2(|\mathbf{b}|+1)}
$$

Such a number exists because of the definition of limit. Therefore, let

$$
n_{\varepsilon}>\max \left(n_{1}, n_{2}\right)
$$

For $n \geq n_{\varepsilon}$,

$$
\begin{aligned}
\left|\mathbf{a}_{n} \cdot \mathbf{b}_{n}-\mathbf{a} \cdot \mathbf{b}\right| & \leq(|\mathbf{a}|+1)\left|\mathbf{b}_{n}-\mathbf{b}\right|+|\mathbf{b}|\left|\mathbf{a}_{n}-\mathbf{a}\right| \\
& <(|\mathbf{a}|+1) \frac{\varepsilon}{2(|\mathbf{a}|+1)}+|\mathbf{b}| \frac{\varepsilon}{2(|\mathbf{b}|+1)} \leq \varepsilon
\end{aligned}
$$

This proves 6.7.9. The proof of 6.7.10 is entirely similar and is left for you.

### 6.7.1 Sequences And Completeness

Recall the definition of a Cauchy sequence.
Definition 6.7.6 $\left\{\mathbf{a}_{n}\right\}$ is a Cauchy sequence iffor all $\varepsilon>0$, there exists $n_{\varepsilon}$ such that whenever $n, m \geq n_{\varepsilon}$,

$$
\left|\mathbf{a}_{n}-\mathbf{a}_{m}\right|<\varepsilon .
$$

A sequence is Cauchy means the terms are "bunching up to each other" as $m, n$ get large.

Theorem 6.7.7 Let $\left\{\mathbf{a}_{n}\right\}_{n=1}^{\infty}$ be a Cauchy sequence in $\mathbb{F}^{p}$. Then there exists a unique $\mathbf{a} \in \mathbb{F}^{p}$ such that $\mathbf{a}_{n} \rightarrow \mathbf{a}$.

Proof: Let $\mathbf{a}_{n}=\left(a_{1}^{n}, \cdots, a_{p}^{n}\right)$. Then

$$
\left|a_{k}^{n}-a_{k}^{m}\right| \leq\left|\mathbf{a}_{n}-\mathbf{a}_{m}\right|
$$

which shows for each $k=1, \cdots, p$, it follows $\left\{a_{k}^{n}\right\}_{n=1}^{\infty}$ is a Cauchy sequence in $\mathbb{F}$. This requires that both the real and imaginary parts of $a_{k}^{n}$ are Cauchy sequences in $\mathbb{R}$ which means the real and imaginary parts converge in $\mathbb{R}$. This shows $\left\{a_{k}^{n}\right\}_{n=1}^{\infty}$ must converge to some $a_{k}$. That is $\lim _{n \rightarrow \infty} a_{k}^{n}=a_{k}$. Letting $\mathbf{a}=\left(a_{1}, \cdots, a_{p}\right)$, it follows from Theorem 6.7.3 that

$$
\lim _{n \rightarrow \infty} \mathbf{a}_{n}=\mathbf{a}
$$

This proves the theorem.
Theorem 6.7.8 The set of terms in a Cauchy sequence in $\mathbb{F}^{p}$ is bounded in the sense that for all $n,\left|\mathbf{a}_{n}\right|<M$ for some $M<\infty$.

Proof: Let $\varepsilon=1$ in the definition of a Cauchy sequence and let $n>n_{1}$. Then from the definition,

$$
\left|\mathbf{a}_{n}-\mathbf{a}_{n_{1}}\right|<1
$$

It follows that for all $n>n_{1}$,

$$
\left|\mathbf{a}_{n}\right|<1+\left|\mathbf{a}_{n_{1}}\right| .
$$

Therefore, for all $n$,

$$
\left|\mathbf{a}_{n}\right| \leq 1+\left|\mathbf{a}_{n_{1}}\right|+\sum_{k=1}^{n_{1}}\left|\mathbf{a}_{k}\right|
$$

This proves the theorem.

Theorem 6.7.9 If a sequence $\left\{\mathbf{a}_{n}\right\}$ in $\mathbb{F}^{p}$ converges, then the sequence is a Cauchy sequence.

Proof: Let $\varepsilon>0$ be given and suppose $\mathbf{a}_{n} \rightarrow \mathbf{a}$. Then from the definition of convergence, there exists $n_{\varepsilon}$ such that if $n>n_{\varepsilon}$, it follows that

$$
\left|\mathbf{a}_{n}-\mathbf{a}\right|<\frac{\varepsilon}{2}
$$

Therefore, if $m, n \geq n_{\varepsilon}+1$, it follows that

$$
\left|\mathbf{a}_{n}-\mathbf{a}_{m}\right| \leq\left|\mathbf{a}_{n}-\mathbf{a}\right|+\left|\mathbf{a}-\mathbf{a}_{m}\right|<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
$$

showing that, since $\varepsilon>0$ is arbitrary, $\left\{\mathbf{a}_{n}\right\}$ is a Cauchy sequence.

### 6.7.2 Continuity And The Limit Of A Sequence

Just as in the case of a function of one variable, there is a very useful way of thinking of continuity in terms of limits of sequences found in the following theorem. In words, it says a function is continuous if it takes convergent sequences to convergent sequences whenever possible.

Theorem 6.7.10 A function $\mathbf{f}: D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$ is continuous at $\mathbf{x} \in D(\mathbf{f})$ if and only if, whenever $\mathbf{x}_{n} \rightarrow \mathbf{x}$ with $\mathbf{x}_{n} \in D(\mathbf{f})$, it follows $\mathbf{f}\left(\mathbf{x}_{n}\right) \rightarrow \mathbf{f}(\mathbf{x})$.

Proof: Suppose first that $\mathbf{f}$ is continuous at $\mathbf{x}$ and let $\mathbf{x}_{n} \rightarrow \mathbf{x}$. Let $\varepsilon>0$ be given. By continuity, there exists $\delta>0$ such that if $|\mathbf{y}-\mathbf{x}|<\delta$, then $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\varepsilon$. However, there exists $n_{\delta}$ such that if $n \geq n_{\delta}$, then $\left|\mathbf{x}_{n}-\mathbf{x}\right|<\delta$ and so for all $n$ this large,

$$
\left|\mathbf{f}(\mathbf{x})-\mathbf{f}\left(\mathbf{x}_{n}\right)\right|<\varepsilon
$$

which shows $\mathbf{f}\left(\mathbf{x}_{n}\right) \rightarrow \mathbf{f}(\mathbf{x})$.
Now suppose the condition about taking convergent sequences to convergent sequences holds at $\mathbf{x}$. Suppose $\mathbf{f}$ fails to be continuous at $\mathbf{x}$. Then there exists $\varepsilon>0$ and $\mathbf{x}_{n} \in D(f)$ such that $\left|\mathbf{x}-\mathbf{x}_{n}\right|<\frac{1}{n}$, yet

$$
\left|\mathbf{f}(\mathbf{x})-\mathbf{f}\left(\mathbf{x}_{n}\right)\right| \geq \varepsilon .
$$

But this is clearly a contradiction because, although $\mathbf{x}_{n} \rightarrow \mathbf{x}, \mathbf{f}\left(\mathbf{x}_{n}\right)$ fails to converge to $\mathbf{f}(\mathbf{x})$. It follows $\mathbf{f}$ must be continuous after all. This proves the theorem.

### 6.8 Properties Of Continuous Functions

Functions of $p$ variables have many of the same properties as functions of one variable. First there is a version of the extreme value theorem generalizing the one dimensional case.

Theorem 6.8.1 Let $C$ be closed and bounded and let $f: C \rightarrow \mathbb{R}$ be continuous. Then $f$ achieves its maximum and its minimum on $C$. This means there exist, $\mathbf{x}_{1}, \mathbf{x}_{2} \in C$ such that for all $\mathbf{x} \in C$,

$$
f\left(\mathbf{x}_{1}\right) \leq f(\mathbf{x}) \leq f\left(\mathbf{x}_{2}\right)
$$

There is also the long technical theorem about sums and products of continuous functions. These theorems are proved in the next section.

Theorem 6.8.2 The following assertions are valid

1. The function, af $+b \mathbf{g}$ is continuous at $\mathbf{x}$ when $\mathbf{f}, \mathbf{g}$ are continuous at $\mathbf{x} \in D(\mathbf{f}) \cap D(\mathbf{g})$ and $a, b \in \mathbb{F}$.
2. If and $f$ and $g$ are each $\mathbb{F}$ valued functions continuous at $\mathbf{x}$, then $f g$ is continuous at $\mathbf{x}$. If, in addition to this, $g(\mathbf{x}) \neq 0$, then $f / g$ is continuous at $\mathbf{x}$.
3. If $\mathbf{f}$ is continuous at $\mathbf{x}, \mathbf{f}(\mathbf{x}) \in D(\mathbf{g}) \subseteq \mathbb{F}^{p}$, and $\mathbf{g}$ is continuous at $\mathbf{f}(\mathbf{x})$, then $\mathbf{g} \circ \mathbf{f}$ is continuous at $\mathbf{x}$.
4. If $\mathbf{f}=\left(f_{1}, \cdots, f_{q}\right): D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$, then $\mathbf{f}$ is continuous if and only if each $f_{k}$ is a continuous $\mathbb{F}$ valued function.
5. The function $f: \mathbb{F}^{p} \rightarrow \mathbb{F}$, given by $f(\mathbf{x})=|\mathbf{x}|$ is continuous.

### 6.9 Exercises

1. $\mathbf{f}: D \subseteq \mathbb{F}^{p} \rightarrow \mathbb{F}^{q}$ is Lipschitz continuous or just Lipschitz for short if there exists a constant, $K$ such that

$$
|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

for all $\mathbf{x}, \mathbf{y} \in D$. Show every Lipschitz function is uniformly continuous which means that given $\varepsilon>0$ there exists $\delta>0$ independent of $\mathbf{x}$ such that if $|\mathbf{x}-\mathbf{y}|<\delta$, then $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\varepsilon$.
2. If $\mathbf{f}$ is uniformly continuous, does it follow that $|\mathbf{f}|$ is also uniformly continuous? If $|\mathbf{f}|$ is uniformly continuous does it follow that $\mathbf{f}$ is uniformly continuous? Answer the same questions with "uniformly continuous" replaced with "continuous". Explain why.

### 6.10 Proofs Of Theorems

This section contains the proofs of the theorems which were just stated without proof.
Theorem 6.10.1 The following assertions are valid

1. The function, $a \mathbf{f}+b \mathbf{g}$ is continuous at $\mathbf{x}$ when $\mathbf{f}, \mathbf{g}$ are continuous at $\mathbf{x} \in D(\mathbf{f}) \cap D(\mathbf{g})$ and $a, b \in \mathbb{F}$.
2. If and $f$ and $g$ are each $\mathbb{F}$ valued functions continuous at $\mathbf{x}$, then $f g$ is continuous at $\mathbf{x}$. If, in addition to this, $g(\mathbf{x}) \neq 0$, then $f / g$ is continuous at $\mathbf{x}$.
3. If $\mathbf{f}$ is continuous at $\mathbf{x}, \mathbf{f}(\mathbf{x}) \in D(\mathbf{g}) \subseteq \mathbb{F}^{p}$, and $\mathbf{g}$ is continuous at $\mathbf{f}(\mathbf{x})$, then $\mathbf{g} \circ \mathbf{f}$ is continuous at $\mathbf{x}$.
4. If $\mathbf{f}=\left(f_{1}, \cdots, f_{q}\right): D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$, then $\mathbf{f}$ is continuous if and only if each $f_{k}$ is a continuous $\mathbb{F}$ valued function.
5. The function $f: \mathbb{F}^{p} \rightarrow \mathbb{F}$, given by $f(\mathbf{x})=|\mathbf{x}|$ is continuous.

Proof: Begin with 1.) Let $\varepsilon>0$ be given. By assumption, there exist $\delta_{1}>0$ such that whenever $|\mathbf{x}-\mathbf{y}|<\delta_{1}$, it follows $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\frac{\varepsilon}{2(|a|+|b|+1)}$ and there exists $\boldsymbol{\delta}_{2}>0$ such that whenever $|\mathbf{x}-\mathbf{y}|<\delta_{2}$, it follows that $|\mathbf{g}(\mathbf{x})-\mathbf{g}(\mathbf{y})|<\frac{\varepsilon}{2(|a|+|b|+1)}$. Then let $0<\delta \leq$ $\min \left(\delta_{1}, \boldsymbol{\delta}_{2}\right)$. If $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}$, then everything happens at once. Therefore, using the triangle inequality

$$
\begin{gathered}
|a \mathbf{f}(\mathbf{x})+b \mathbf{f}(\mathbf{x})-(a \mathbf{g}(\mathbf{y})+b \mathbf{g}(\mathbf{y}))| \\
\leq|a||\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|+|b||\mathbf{g}(\mathbf{x})-\mathbf{g}(\mathbf{y})| \\
<|a|\left(\frac{\varepsilon}{2(|a|+|b|+1)}\right)+|b|\left(\frac{\varepsilon}{2(|a|+|b|+1)}\right)<\varepsilon
\end{gathered}
$$

Now begin on 2.) There exists $\delta_{1}>0$ such that if $|\mathbf{y}-\mathbf{x}|<\delta_{1}$, then

$$
|f(\mathbf{x})-f(\mathbf{y})|<1
$$

Therefore, for such $\mathbf{y}$,

$$
|f(\mathbf{y})|<1+|f(\mathbf{x})|
$$

It follows that for such $\mathbf{y}$,

$$
\begin{aligned}
\mid f g(\mathbf{x}) & -f g(\mathbf{y})|\leq|f(\mathbf{x}) g(\mathbf{x})-g(\mathbf{x}) f(\mathbf{y})|+|g(\mathbf{x}) f(\mathbf{y})-f(\mathbf{y}) g(\mathbf{y})| \\
& \leq|g(\mathbf{x})||f(\mathbf{x})-f(\mathbf{y})|+|f(\mathbf{y})||g(\mathbf{x})-g(\mathbf{y})| \\
& \leq(1+|g(\mathbf{x})|+|f(\mathbf{y})|)[|g(\mathbf{x})-g(\mathbf{y})|+|f(\mathbf{x})-f(\mathbf{y})|]
\end{aligned}
$$

Now let $\varepsilon>0$ be given. There exists $\boldsymbol{\delta}_{2}$ such that if $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}_{2}$, then

$$
|g(\mathbf{x})-g(\mathbf{y})|<\frac{\varepsilon}{2(1+|g(\mathbf{x})|+|f(\mathbf{y})|)},
$$

and there exists $\boldsymbol{\delta}_{3}$ such that if $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}_{3}$, then

$$
|f(\mathbf{x})-f(\mathbf{y})|<\frac{\varepsilon}{2(1+|g(\mathbf{x})|+|f(\mathbf{y})|)}
$$

Now let $0<\boldsymbol{\delta} \leq \min \left(\delta_{1}, \delta_{2}, \delta_{3}\right)$. Then if $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}$, all the above hold at once and

$$
\begin{gathered}
|f g(\mathbf{x})-f g(\mathbf{y})| \leq \\
(1+|g(\mathbf{x})|+|f(\mathbf{y})|)[|g(\mathbf{x})-g(\mathbf{y})|+|f(\mathbf{x})-f(\mathbf{y})|] \\
<(1+|g(\mathbf{x})|+|f(\mathbf{y})|)\left(\frac{\varepsilon}{2(1+|g(\mathbf{x})|+|f(\mathbf{y})|)}+\frac{\varepsilon}{2(1+|g(\mathbf{x})|+|f(\mathbf{y})|)}\right)=\varepsilon .
\end{gathered}
$$

This proves the first part of 2.) To obtain the second part, let $\delta_{1}$ be as described above and let $\delta_{0}>0$ be such that for $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}_{0}$,

$$
|g(\mathbf{x})-g(\mathbf{y})|<|g(\mathbf{x})| / 2
$$

and so by the triangle inequality,

$$
-|g(\mathbf{x})| / 2 \leq|g(\mathbf{y})|-|g(\mathbf{x})| \leq|g(\mathbf{x})| / 2
$$

which implies $|g(\mathbf{y})| \geq|g(\mathbf{x})| / 2$, and $|g(\mathbf{y})|<3|g(\mathbf{x})| / 2$.
Then if $|\mathbf{x}-\mathbf{y}|<\min \left(\boldsymbol{\delta}_{0}, \boldsymbol{\delta}_{1}\right)$,

$$
\begin{aligned}
& \left|\frac{f(\mathbf{x})}{g(\mathbf{x})}-\frac{f(\mathbf{y})}{g(\mathbf{y})}\right|=\left|\frac{f(\mathbf{x}) g(\mathbf{y})-f(\mathbf{y}) g(\mathbf{x})}{g(\mathbf{x}) g(\mathbf{y})}\right| \\
& \leq \frac{|f(\mathbf{x}) g(\mathbf{y})-f(\mathbf{y}) g(\mathbf{x})|}{\left(\frac{|g(\mathbf{x})|^{2}}{2}\right)} \\
& =\frac{2|f(\mathbf{x}) g(\mathbf{y})-f(\mathbf{y}) g(\mathbf{x})|}{|g(\mathbf{x})|^{2}} \\
& \leq \frac{2}{|g(\mathbf{x})|^{2}}[|f(\mathbf{x}) g(\mathbf{y})-f(\mathbf{y}) g(\mathbf{y})+f(\mathbf{y}) g(\mathbf{y})-f(\mathbf{y}) g(\mathbf{x})|] \\
& \leq \frac{2}{|g(\mathbf{x})|^{2}}[|g(\mathbf{y})||f(\mathbf{x})-f(\mathbf{y})|+|f(\mathbf{y})||g(\mathbf{y})-g(\mathbf{x})|] \\
& \leq \frac{2}{|g(\mathbf{x})|^{2}}\left[\frac{3}{2}|\mathbf{g}(\mathbf{x})||f(\mathbf{x})-f(\mathbf{y})|+(1+|f(\mathbf{x})|)|g(\mathbf{y})-g(\mathbf{x})|\right] \\
& \leq \frac{2}{|g(\mathbf{x})|^{2}}(1+2|f(\mathbf{x})|+2|g(\mathbf{x})|)[|f(\mathbf{x})-f(\mathbf{y})|+|g(\mathbf{y})-g(\mathbf{x})|] \\
& \equiv M[|f(\mathbf{x})-f(\mathbf{y})|+|g(\mathbf{y})-g(\mathbf{x})|]
\end{aligned}
$$

where

$$
M \equiv \frac{2}{|g(\mathbf{x})|^{2}}(1+2|f(\mathbf{x})|+2|g(\mathbf{x})|)
$$

Now let $\delta_{2}$ be such that if $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}_{2}$, then

$$
|f(\mathbf{x})-f(\mathbf{y})|<\frac{\varepsilon}{2} M^{-1}
$$

and let $\delta_{3}$ be such that if $|\mathbf{x}-\mathbf{y}|<\delta_{3}$, then

$$
|g(\mathbf{y})-g(\mathbf{x})|<\frac{\varepsilon}{2} M^{-1} .
$$

Then if $0<\boldsymbol{\delta} \leq \min \left(\boldsymbol{\delta}_{0}, \boldsymbol{\delta}_{1}, \boldsymbol{\delta}_{2}, \boldsymbol{\delta}_{3}\right)$, and $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}$, everything holds and

$$
\left|\frac{f(\mathbf{x})}{g(\mathbf{x})}-\frac{f(\mathbf{y})}{g(\mathbf{y})}\right| \leq M[|f(\mathbf{x})-f(\mathbf{y})|+|g(\mathbf{y})-g(\mathbf{x})|]
$$

$$
<M\left[\frac{\varepsilon}{2} M^{-1}+\frac{\varepsilon}{2} M^{-1}\right]=\varepsilon
$$

This completes the proof of the second part of 2.) Note that in these proofs no effort is made to find some sort of "best" $\delta$. The problem is one which has a yes or a no answer. Either it is or it is not continuous.

Now begin on 3.). If $\mathbf{f}$ is continuous at $\mathbf{x}, \mathbf{f}(\mathbf{x}) \in D(\mathbf{g}) \subseteq \mathbb{F}^{p}$, and $\mathbf{g}$ is continuous at $\mathbf{f}(\mathbf{x})$, then $\mathbf{g} \circ \mathbf{f}$ is continuous at $\mathbf{x}$. Let $\varepsilon>0$ be given. Then there exists $\eta>0$ such that if $|\mathbf{y}-\mathbf{f}(\mathbf{x})|<\eta$ and $\mathbf{y} \in D(\mathbf{g})$, it follows that $|\mathbf{g}(\mathbf{y})-\mathbf{g}(\mathbf{f}(\mathbf{x}))|<\varepsilon$. It follows from continuity of $\mathbf{f}$ at $\mathbf{x}$ that there exists $\delta>0$ such that if $|\mathbf{x}-\mathbf{z}|<\delta$ and $\mathbf{z} \in D(\mathbf{f})$, then $|\mathbf{f}(\mathbf{z})-\mathbf{f}(\mathbf{x})|<\eta$. Then if $|\mathbf{x}-\mathbf{z}|<\delta$ and $\mathbf{z} \in D(\mathbf{g} \circ \mathbf{f}) \subseteq D(\mathbf{f})$, all the above hold and so

$$
|\mathbf{g}(\mathbf{f}(\mathbf{z}))-\mathbf{g}(\mathbf{f}(\mathbf{x}))|<\varepsilon .
$$

This proves part 3.)
Part 4.) says: If $\mathbf{f}=\left(f_{1}, \cdots, f_{q}\right): D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$, then $\mathbf{f}$ is continuous if and only if each $f_{k}$ is a continuous $\mathbb{F}$ valued function. Then

$$
\begin{align*}
& \left|f_{k}(\mathbf{x})-f_{k}(\mathbf{y})\right| \leq|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})| \\
& \equiv\left(\sum_{i=1}^{q}\left|f_{i}(\mathbf{x})-f_{i}(\mathbf{y})\right|^{2}\right)^{1 / 2} \\
& \quad \leq \sum_{i=1}^{q}\left|f_{i}(\mathbf{x})-f_{i}(\mathbf{y})\right| \tag{6.10.11}
\end{align*}
$$

Suppose first that $\mathbf{f}$ is continuous at $\mathbf{x}$. Then there exists $\delta>0$ such that if $|\mathbf{x}-\mathbf{y}|<\delta$, then $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\varepsilon$. The first part of the above inequality then shows that for each $k=$ $1, \cdots, q,\left|f_{k}(\mathbf{x})-f_{k}(\mathbf{y})\right|<\varepsilon$. This shows the only if part. Now suppose each function, $f_{k}$ is continuous. Then if $\varepsilon>0$ is given, there exists $\boldsymbol{\delta}_{k}>0$ such that whenever $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}_{k}$

$$
\left|f_{k}(\mathbf{x})-f_{k}(\mathbf{y})\right|<\varepsilon / q
$$

Now let $0<\delta \leq \min \left(\delta_{1}, \cdots, \delta_{q}\right)$. For $|\mathbf{x}-\mathbf{y}|<\delta$, the above inequality holds for all $k$ and so the last part of 6.10.11 implies

$$
\begin{aligned}
|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})| & \leq \sum_{i=1}^{q}\left|f_{i}(\mathbf{x})-f_{i}(\mathbf{y})\right| \\
& <\sum_{i=1}^{q} \frac{\varepsilon}{q}=\varepsilon
\end{aligned}
$$

This proves part 4.)
To verify part 5.), let $\varepsilon>0$ be given and let $\delta=\varepsilon$. Then if $|\mathbf{x}-\mathbf{y}|<\delta$, the triangle inequality implies

$$
\begin{aligned}
|f(\mathbf{x})-f(\mathbf{y})| & =\| \mathbf{x}|-|\mathbf{y}|| \\
& \leq|\mathbf{x}-\mathbf{y}|<\delta=\varepsilon
\end{aligned}
$$

This proves part 5.) and completes the proof of the theorem.
Here is a multidimensional version of the nested interval lemma.
The following definition is similar to that given earlier. It defines what is meant by a sequentially compact set in $\mathbb{F}^{p}$.

Definition 6.10.2 $A$ set, $K \subseteq \mathbb{F}^{p}$ is sequentially compact if and only if whenever $\left\{\mathbf{x}_{n}\right\}_{n=1}^{\infty}$ is a sequence of points in $K$, there exists a point, $\mathbf{x} \in K$ and a subsequence, $\left\{\mathbf{x}_{n_{k}}\right\}_{k=1}^{\infty}$ such that $\mathbf{x}_{n_{k}} \rightarrow \mathbf{x}$.

It turns out the sequentially compact sets in $\mathbb{F}^{p}$ are exactly those which are closed and bounded. Only half of this result will be needed in this book and this is proved next. First note that $\mathbb{C}$ can be considered as $\mathbb{R}^{2}$. Therefore, $\mathbb{C}^{p}$ may be considered as $\mathbb{R}^{2 p}$.

Theorem 6.10.3 Let $C \subseteq \mathbb{F}^{p}$ be closed and bounded. Then $C$ is sequentially compact.
Proof: Let $\left\{\mathbf{a}_{n}\right\} \subseteq C$. Then let $\mathbf{a}_{n}=\left(a_{1}^{n}, \cdots, a_{p}^{n}\right)$. It follows the real and imaginary parts of the terms of the sequence, $\left\{a_{j}^{n}\right\}_{n=1}^{\infty}$ are each contained in some sufficiently large closed bounded interval. By Theorem 3.0.3 on Page 37, there is a subsequence of the sequence of real parts of $\left\{a_{j}^{n}\right\}_{n=1}^{\infty}$ which converges. Also there is a further subsequence of the imaginary parts of $\left\{a_{j}^{n}\right\}_{n=1}^{\infty}$ which converges. Thus there is a subsequence, $n_{k}$ with the property that $a_{j}^{n_{k}}$ converges to a point, $a_{j} \in \mathbb{F}$. Taking further subsequences, one obtains the existence of a subsequence, still called $n_{k}$ such that for each $r=1, \cdots, p, a_{r}^{n_{k}}$ converges to a point, $a_{r} \in \mathbb{F}$ as $k \rightarrow \infty$. Therefore, letting $\mathbf{a} \equiv\left(a_{1}, \cdots, a_{p}\right), \lim _{k \rightarrow \infty} \mathbf{a}^{n_{k}}=\mathbf{a}$. Since $C$ is closed, it follows $\mathbf{a} \in C$. This proves the theorem.

Here is a proof of the extreme value theorem.
Theorem 6.10.4 Let $C$ be closed and bounded and let $f: C \rightarrow \mathbb{R}$ be continuous. Then $f$ achieves its maximum and its minimum on $C$. This means there exist, $\mathbf{x}_{1}, \mathbf{x}_{2} \in C$ such that for all $\mathbf{x} \in C$,

$$
f\left(\mathbf{x}_{1}\right) \leq f(\mathbf{x}) \leq f\left(\mathbf{x}_{2}\right)
$$

Proof: Let $M=\sup \{f(\mathbf{x}): \mathbf{x} \in C\}$. Recall this means $+\infty$ if $f$ is not bounded above and it equals the least upper bound of these values of $f$ if $f$ is bounded above. Then there exists a sequence, $\left\{\mathbf{x}_{n}\right\}$ such that $f\left(\mathbf{x}_{n}\right) \rightarrow M$. Since $C$ is sequentially compact, there exists a subsequence, $\mathbf{x}_{n_{k}}$, and a point, $\mathbf{x} \in C$ such that $\mathbf{x}_{n_{k}} \rightarrow \mathbf{x}$. But then since $f$ is continuous at $\mathbf{x}$, it follows from Theorem 6.7.10 on Page 108 that $f(\mathbf{x})=\lim _{k \rightarrow \infty} f\left(\mathbf{x}_{n_{k}}\right)=M$. This proves $f$ achieves its maximum and also shows its maximum is less than $\infty$. Let $\mathbf{x}_{2}=\mathbf{x}$. The case of a minimum is handled similarly.

Recall that a function is uniformly continuous if the following definition holds.
Definition 6.10.5 Let $\mathbf{f}: D(\mathbf{f}) \rightarrow \mathbb{F}^{q}$. Then $\mathbf{f}$ is uniformly continuous iffor every $\varepsilon>0$ there exists $\delta>0$ such that whenever $|\mathbf{x}-\mathbf{y}|<\delta$, it follows $|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|<\varepsilon$.

Theorem 6.10.6 Let $\mathbf{f}: C \rightarrow \mathbb{F}^{q}$ be continuous where $C$ is a closed and bounded set in $\mathbb{F}^{p}$. Then $\mathbf{f}$ is uniformly continuous on $C$.

Proof: If this is not so, there exists $\varepsilon>0$ and pairs of points, $\mathbf{x}_{n}$ and $\mathbf{y}_{n}$ satisfying $\left|\mathbf{x}_{n}-\mathbf{y}_{n}\right|<1 / n$ but $\left|\mathbf{f}\left(\mathbf{x}_{n}\right)-\mathbf{f}\left(\mathbf{y}_{n}\right)\right| \geq \varepsilon$. Since $C$ is sequentially compact, there exists $\mathbf{x} \in C$ and a subsequence, $\left\{\mathbf{x}_{n_{k}}\right\}$ satisfying $\mathbf{x}_{n_{k}} \rightarrow \mathbf{x}$. But $\left|\mathbf{x}_{n_{k}}-\mathbf{y}_{n_{k}}\right|<1 / k$ and so $\mathbf{y}_{n_{k}} \rightarrow \mathbf{x}$ also. Therefore, from Theorem 6.7.10 on Page 108,

$$
\varepsilon \leq \lim _{k \rightarrow \infty}\left|\mathbf{f}\left(\mathbf{x}_{n_{k}}\right)-\mathbf{f}\left(\mathbf{y}_{n_{k}}\right)\right|=|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{x})|=0
$$

a contradiction. This proves the theorem.

### 6.11 The Space $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$

Definition 6.11.1 The symbol, $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ will denote the set of linear transformations mapping $\mathbb{F}^{n}$ to $\mathbb{F}^{m}$. Thus $L \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ means that for $\alpha, \beta$ scalars and $\mathbf{x}, \mathbf{y}$ vectors in $\mathbb{F}^{n}$,

$$
L(\alpha \mathbf{x}+\beta \mathbf{y})=\alpha L(\mathbf{x})+\beta L(\mathbf{y})
$$

It is convenient to give a norm for the elements of $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$. This will allow the consideration of questions such as whether a function having values in this space of linear transformations is continuous.

### 6.11.1 The Operator Norm

How do you measure the distance between linear transformations defined on $\mathbb{F}^{n}$ ? It turns out there are many ways to do this but I will give the most common one here.

Definition 6.11.2 $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ denotes the space of linear transformations mapping $\mathbb{F}^{n}$ to $\mathbb{F}^{m}$. For $A \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$, the operator norm is defined by

$$
\|A\| \equiv \max \left\{|A x|_{\mathbb{F}^{m}}:|x|_{\mathbb{F}^{n}} \leq 1\right\}<\infty
$$

Theorem 6.11.3 Denote by $|\cdot|$ the norm on either $\mathbb{F}^{n}$ or $\mathbb{F}^{m}$. Then $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ with this operator norm is a complete normed linear space of dimension nm with

$$
\|A \mathbf{x}\| \leq\|A\||\mathbf{x}|
$$

Here Completeness means that every Cauchy sequence converges.
Proof: It is necessary to show the norm defined on $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ really is a norm. This means it is necessary to verify

$$
\|A\| \geq 0 \text { and equals zero if and only if } A=0
$$

For $\alpha$ a scalar,

$$
\|\alpha A\|=|\alpha|\|A\|
$$

and for $A, B \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$,

$$
\|A+B\| \leq\|A\|+\|B\|
$$

The first two properties are obvious but you should verify them. It remains to verify the norm is well defined and also to verify the triangle inequality above. First if $|\mathbf{x}| \leq 1$, and $\left(A_{i j}\right)$ is the matrix of the linear transformation with respect to the usual basis vectors, then

$$
\begin{aligned}
\|A\| & =\max \left\{\left(\sum_{i}\left|(A \mathbf{x})_{i}\right|^{2}\right)^{1 / 2}:|\mathbf{x}| \leq 1\right\} \\
& =\max \left\{\left(\sum_{i}\left|\sum_{j} A_{i j} x_{j}\right|^{2}\right)^{1 / 2}:|\mathbf{x}| \leq 1\right\}
\end{aligned}
$$

which is a finite number by the extreme value theorem.
It is clear that a basis for $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ consists of linear transformations whose matrices are of the form $E_{i j}$ where $E_{i j}$ consists of the $m \times n$ matrix having all zeros except for a 1 in the $i j^{t h}$ position. In effect, this considers $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ as $\mathbb{F}^{n m}$. Think of the $m \times n$ matrix as a long vector folded up.

If $\mathbf{x} \neq \mathbf{0}$,

$$
\begin{equation*}
|A \mathbf{x}| \frac{1}{|\mathbf{x}|}=\left|A \frac{\mathbf{x}}{|\mathbf{x}|}\right| \leq \| A| | \tag{6.11.12}
\end{equation*}
$$

It only remains to verify completeness. Suppose then that $\left\{A_{k}\right\}$ is a Cauchy sequence in $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$. Then from 6.11.12 $\left\{A_{k} \mathbf{x}\right\}$ is a Cauchy sequence for each $\mathbf{x} \in \mathbb{F}^{n}$. This follows because

$$
\left|A_{k} \mathbf{x}-A_{l} \mathbf{x}\right| \leq\left\|A_{k}-A_{l}|\||\mathbf{x}|\right.
$$

which converges to 0 as $k, l \rightarrow \infty$. Therefore, by completeness of $\mathbb{F}^{m}$, there exists $A \mathbf{x}$, the name of the thing to which the sequence, $\left\{A_{k} \mathbf{x}\right\}$ converges such that

$$
\lim _{k \rightarrow \infty} A_{k} \mathbf{x}=A \mathbf{x}
$$

Then $A$ is linear because

$$
\begin{aligned}
A(a \mathbf{x}+b \mathbf{y}) & \equiv \lim _{k \rightarrow \infty} A_{k}(a \mathbf{x}+b \mathbf{y}) \\
& =\lim _{k \rightarrow \infty}\left(a A_{k} \mathbf{x}+b A_{k} \mathbf{y}\right) \\
& =a \lim _{k \rightarrow \infty} A_{k} \mathbf{x}+b \lim _{k \rightarrow \infty} A_{k} \mathbf{y} \\
& =a A \mathbf{x}+b A \mathbf{y}
\end{aligned}
$$

By the first part of this argument, $\|A\|<\infty$ and so $A \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$. This proves the theorem.
Proposition 6.11.4 Let $A(\mathbf{x}) \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ for each $\mathbf{x} \in U \subseteq \mathbb{F}^{p}$. Then letting $\left(A_{i j}(\mathbf{x})\right)$ denote the matrix of $A(\mathbf{x})$ with respect to the standard basis, it follows $A_{i j}$ is continuous at $\mathbf{x}$ for each $i, j$ if and only if for all $\varepsilon>0$, there exists a $\delta>0$ such that if $|\mathbf{x}-\mathbf{y}|<\delta$, then $\|A(\mathbf{x})-A(\mathbf{y})\|<\varepsilon$. That is, $A$ is a continuous function having values in $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ at $\mathbf{x}$.

Proof: Suppose first the second condition holds. Then from the material on linear transformations,

$$
\begin{aligned}
\left|A_{i j}(\mathbf{x})-A_{i j}(\mathbf{y})\right| & =\left|\mathbf{e}_{i} \cdot(A(\mathbf{x})-A(\mathbf{y})) \mathbf{e}_{j}\right| \\
& \leq\left|\mathbf{e}_{i}\right|\left|(A(\mathbf{x})-A(\mathbf{y})) \mathbf{e}_{j}\right| \\
& \leq\|A(\mathbf{x})-A(\mathbf{y})\| .
\end{aligned}
$$

Therefore, the second condition implies the first.
Now suppose the first condition holds. That is each $A_{i j}$ is continuous at $\mathbf{x}$. Let $|\mathbf{v}| \leq 1$.

$$
\begin{align*}
|(A(\mathbf{x})-A(\mathbf{y}))(\mathbf{v})| & =\left(\sum_{i}\left|\sum_{j}\left(A_{i j}(\mathbf{x})-A_{i j}(\mathbf{y})\right) v_{j}\right|^{2}\right)^{1 / 2}  \tag{6.11.13}\\
& \leq\left(\sum_{i}\left(\sum_{j}\left|A_{i j}(\mathbf{x})-A_{i j}(\mathbf{y})\right|\left|v_{j}\right|\right)^{2}\right)^{1 / 2} .
\end{align*}
$$

By continuity of each $A_{i j}$, there exists a $\delta>0$ such that for each $i, j$

$$
\left|A_{i j}(\mathbf{x})-A_{i j}(\mathbf{y})\right|<\frac{\varepsilon}{n \sqrt{m}}
$$

whenever $|\mathbf{x}-\mathbf{y}|<\delta$. Then from 6.11.13, if $|\mathbf{x}-\mathbf{y}|<\delta$,

$$
\begin{aligned}
|(A(\mathbf{x})-A(\mathbf{y}))(\mathbf{v})| & <\left(\sum_{i}\left(\sum_{j} \frac{\varepsilon}{n \sqrt{m}}|\mathbf{v}|\right)^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i}\left(\sum_{j} \frac{\varepsilon}{n \sqrt{m}}\right)^{2}\right)^{1 / 2}=\varepsilon
\end{aligned}
$$

This proves the proposition.

### 6.12 The Frechet Derivative

Let $U$ be an open set in $\mathbb{F}^{n}$, and let $\mathbf{f}: U \rightarrow \mathbb{F}^{m}$ be a function.
Definition 6.12.1 A function $\mathbf{g}$ is $o(\mathbf{v})$ if

$$
\begin{equation*}
\lim _{|\mathbf{v}| \rightarrow 0} \frac{\mathbf{g}(\mathbf{v})}{|\mathbf{v}|}=\mathbf{0} \tag{6.12.14}
\end{equation*}
$$

A function $\mathbf{f}: U \rightarrow \mathbb{F}^{m}$ is differentiable at $\mathbf{x} \in U$ if there exists a linear transformation $L \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$ such that

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})=\mathbf{f}(\mathbf{x})+L \mathbf{v}+o(\mathbf{v})
$$

This linear transformation $L$ is the definition of $D \mathbf{f}(\mathbf{x})$. This derivative is often called the Frechet derivative. .

Usually no harm is occasioned by thinking of this linear transformation as its matrix taken with respect to the usual basis vectors.

The definition 6.12.14 means that the error,

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-L \mathbf{v}
$$

converges to $\mathbf{0}$ faster than $|\mathbf{v}|$. Thus the above definition is equivalent to saying

$$
\begin{equation*}
\lim _{|\mathbf{v}| \rightarrow 0} \frac{|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-L \mathbf{v}|}{|\mathbf{v}|}=0 \tag{6.12.15}
\end{equation*}
$$

or equivalently,

$$
\begin{equation*}
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \frac{|\mathbf{f}(\mathbf{y})-\mathbf{f}(\mathbf{x})-D \mathbf{f}(\mathbf{x})(\mathbf{y}-\mathbf{x})|}{|\mathbf{y}-\mathbf{x}|}=0 \tag{6.12.16}
\end{equation*}
$$

Now it is clear this is just a generalization of the notion of the derivative of a function of one variable because in this more specialized situation,

$$
\lim _{|v| \rightarrow 0} \frac{\left|f(x+v)-f(x)-f^{\prime}(x) v\right|}{|v|}=0
$$

due to the definition which says

$$
f^{\prime}(x)=\lim _{v \rightarrow 0} \frac{f(x+v)-f(x)}{v}
$$

For functions of $n$ variables, you can't define the derivative as the limit of a difference quotient like you can for a function of one variable because you can't divide by a vector. That is why there is a need for a more general definition.

The term $o(\mathbf{v})$ is notation that is descriptive of the behavior in 6.12.14 and it is only this behavior that is of interest. Thus, if $t$ and $k$ are constants,

$$
o(\mathbf{v})=o(\mathbf{v})+o(\mathbf{v}), o(t \mathbf{v})=o(\mathbf{v}), k o(\mathbf{v})=o(\mathbf{v})
$$

and other similar observations hold. The sloppiness built in to this notation is useful because it ignores details which are not important. It may help to think of $o(\mathbf{v})$ as an adjective describing what is left over after approximating $\mathbf{f}(\mathbf{x}+\mathbf{v})$ by $\mathbf{f}(\mathbf{x})+D \mathbf{f}(\mathbf{x}) \mathbf{v}$.

Theorem 6.12.2 The derivative is well defined.
Proof: First note that for a fixed vector, $\mathbf{v}, o(t \mathbf{v})=o(t)$. Now suppose both $L_{1}$ and $L_{2}$ work in the above definition. Then let $\mathbf{v}$ be any vector and let $t$ be a real scalar which is chosen small enough that $t \mathbf{v}+\mathbf{x} \in U$. Then

$$
\mathbf{f}(\mathbf{x}+t \mathbf{v})=\mathbf{f}(\mathbf{x})+L_{1} t \mathbf{v}+o(t \mathbf{v}), \mathbf{f}(\mathbf{x}+t \mathbf{v})=\mathbf{f}(\mathbf{x})+L_{2} t \mathbf{v}+o(t \mathbf{v}) .
$$

Therefore, subtracting these two yields $\left(L_{2}-L_{1}\right)(t \mathbf{v})=o(t \mathbf{v})=o(t)$. Therefore, dividing by $t$ yields $\left(L_{2}-L_{1}\right)(\mathbf{v})=\frac{o(t)}{t}$. Now let $t \rightarrow 0$ to conclude that $\left(L_{2}-L_{1}\right)(\mathbf{v})=0$. Since this is true for all $\mathbf{v}$, it follows $L_{2}=L_{1}$. This proves the theorem.

Lemma 6.12.3 Let $\mathbf{f}$ be differentiable at $\mathbf{x}$. Then $\mathbf{f}$ is continuous at $\mathbf{x}$ and in fact, there exists $K>0$ such that whenever $|\mathbf{v}|$ is small enough,

$$
|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})| \leq K|\mathbf{v}|
$$

Proof: From the definition of the derivative, $\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})=D \mathbf{f}(\mathbf{x}) \mathbf{v}+o(\mathbf{v})$. Let $|\mathbf{v}|$ be small enough that $\frac{o(|\mathbf{v}|)}{|\mathbf{v}|}<1$ so that $|o(\mathbf{v})| \leq|\mathbf{v}|$. Then for such $\mathbf{v}$,

$$
\begin{aligned}
|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})| & \leq|D \mathbf{f}(\mathbf{x}) \mathbf{v}|+|\mathbf{v}| \\
& \leq(|D \mathbf{f}(\mathbf{x})|+1)|\mathbf{v}|
\end{aligned}
$$

This proves the lemma with $K=|D \mathbf{f}(\mathbf{x})|+1$.
Theorem 6.12.4 (The chain rule) Let $U$ and $V$ be open sets, $U \subseteq \mathbb{F}^{n}$ and $V \subseteq \mathbb{F}^{m}$. Suppose $\mathbf{f}: U \rightarrow V$ is differentiable at $\mathbf{x} \in U$ and suppose $\mathbf{g}: V \rightarrow \mathbb{F}^{q}$ is differentiable at $\mathbf{f}(\mathbf{x}) \in V$. Then $\mathbf{g} \circ \mathbf{f}$ is differentiable at $\mathbf{x}$ and

$$
D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})=D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x})
$$

Proof: This follows from a computation. Let $B(\mathbf{x}, r) \subseteq U$ and let $r$ also be small enough that for $|\mathbf{v}| \leq r$, it follows that $\mathbf{f}(\mathbf{x}+\mathbf{v}) \in V$. Such an $r$ exists because $\mathbf{f}$ is continuous at $\mathbf{x}$. For $|\mathbf{v}|<r$, the definition of differentiability of $\mathbf{g}$ and $\mathbf{f}$ implies

$$
\begin{gather*}
\mathbf{g}(\mathbf{f}(\mathbf{x}+\mathbf{v}))-\mathbf{g}(\mathbf{f}(\mathbf{x}))= \\
\\
=\quad D \mathbf{g}(\mathbf{f}(\mathbf{x}))(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))+o(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})) \\
=  \tag{6.12.17}\\
D \mathbf{g}(\mathbf{f}(\mathbf{x}))[D \mathbf{f}(\mathbf{x}) \mathbf{v}+o(\mathbf{v})]+o(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))) D \mathbf{f}(\mathbf{x}) \mathbf{v}+o(\mathbf{v})+o(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})) .
\end{gather*}
$$

It remains to show $o(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))=o(\mathbf{v})$.
By Lemma 6.12.3, with $K$ given there, letting $\varepsilon>0$, it follows that for $|\mathbf{v}|$ small enough,

$$
|o(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))| \leq(\varepsilon / K)|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})| \leq(\varepsilon / K) K|\mathbf{v}|=\varepsilon|\mathbf{v}| .
$$

Since $\varepsilon>0$ is arbitrary, this shows $o(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))=o(\mathbf{v})$ because whenever $|\mathbf{v}|$ is small enough,

$$
\frac{|o(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))|}{|\mathbf{v}|} \leq \varepsilon
$$

By 6.12.17, this shows

$$
\mathbf{g}(\mathbf{f}(\mathbf{x}+\mathbf{v}))-\mathbf{g}(\mathbf{f}(\mathbf{x}))=D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x}) \mathbf{v}+o(\mathbf{v})
$$

which proves the theorem.
The derivative is a linear transformation. What is the matrix of this linear transformation taken with respect to the usual basis vectors? Let $\mathbf{e}_{i}$ denote the vector of $\mathbb{F}^{n}$ which has a one in the $i^{t h}$ entry and zeroes elsewhere. Then the matrix of the linear transformation is
the matrix whose $i^{t h}$ column is $D \mathbf{f}(\mathbf{x}) \mathbf{e}_{i}$. What is this? Let $t \in \mathbb{R}$ such that $|t|$ is sufficiently small.

$$
\begin{aligned}
\mathbf{f}\left(\mathbf{x}+t \mathbf{e}_{i}\right)-\mathbf{f}(\mathbf{x}) & =D \mathbf{f}(\mathbf{x}) t \mathbf{e}_{i}+\mathbf{o}\left(t \mathbf{e}_{i}\right) \\
& =D \mathbf{f}(\mathbf{x}) t \mathbf{e}_{i}+\mathbf{o}(t) .
\end{aligned}
$$

Then dividing by $t$ and taking a limit,

$$
D \mathbf{f}(\mathbf{x}) \mathbf{e}_{i}=\lim _{t \rightarrow 0} \frac{\mathbf{f}\left(\mathbf{x}+t \mathbf{e}_{i}\right)-\mathbf{f}(\mathbf{x})}{t} \equiv \frac{\partial \mathbf{f}}{\partial x_{i}}(\mathbf{x}) .
$$

Thus the matrix of $D \mathbf{f}(\mathbf{x})$ with respect to the usual basis vectors is the matrix of the form

$$
\left(\begin{array}{cccc}
f_{1, x_{1}}(\mathbf{x}) & f_{1, x_{2}}(\mathbf{x}) & \cdots & f_{1, x_{n}}(\mathbf{x}) \\
\vdots & \vdots & & \vdots \\
f_{m, x_{1}}(\mathbf{x}) & f_{m, x_{2}}(\mathbf{x}) & \cdots & f_{m, x_{n}}(\mathbf{x})
\end{array}\right) .
$$

As mentioned before, there is no harm in referring to this matrix as $D \mathbf{f}(\mathbf{x})$ but it may also be referred to as $J \mathbf{f}(\mathbf{x})$.

This is summarized in the following theorem.
Theorem 6.12.5 Let $\mathbf{f}: \mathbb{F}^{n} \rightarrow \mathbb{F}^{m}$ and suppose $\mathbf{f}$ is differentiable at $\mathbf{x}$. Then all the partial derivatives $\frac{\partial f_{i}(\mathbf{x})}{\partial x_{j}}$ exist and if $J \mathbf{f}(\mathbf{x})$ is the matrix of the linear transformation with respect to the standard basis vectors, then the $i j^{\text {th }}$ entry is given by $f_{i, j}$ or $\frac{\partial f_{i}}{\partial x_{j}}(\mathbf{x})$.

What if all the partial derivatives of $\mathbf{f}$ exist? Does it follow that $\mathbf{f}$ is differentiable? Consider the following function.

$$
f(x, y)=\left\{\begin{array}{l}
\frac{x y}{x^{2}+y^{2}} \text { if }(x, y) \neq(0,0) \\
0 \text { if }(x, y)=(0,0)
\end{array} .\right.
$$

Then from the definition of partial derivatives,

$$
\lim _{h \rightarrow 0} \frac{f(h, 0)-f(0,0)}{h}=\lim _{h \rightarrow 0} \frac{0-0}{h}=0
$$

and

$$
\lim _{h \rightarrow 0} \frac{f(0, h)-f(0,0)}{h}=\lim _{h \rightarrow 0} \frac{0-0}{h}=0
$$

However $f$ is not even continuous at $(0,0)$ which may be seen by considering the behavior of the function along the line $y=x$ and along the line $x=0$. By Lemma 6.12.3 this implies $f$ is not differentiable. Therefore, it is necessary to consider the correct definition of the derivative given above if you want to get a notion which generalizes the concept of the derivative of a function of one variable in such a way as to preserve continuity whenever the function is differentiable.

### 6.13 $C^{1}$ Functions

However, there are theorems which can be used to get differentiability of a function based on existence of the partial derivatives.

Definition 6.13.1 When all the partial derivatives exist and are continuous the function is called a $C^{1}$ function.

Because of Proposition 6.11.4 on Page 115 and Theorem 6.12 .5 which identifies the entries of $J \mathbf{f}$ with the partial derivatives, the following definition is equivalent to the above.

Definition 6.13.2 Let $U \subseteq \mathbb{F}^{n}$ be an open set. Then $\mathbf{f}: U \rightarrow \mathbb{F}^{m}$ is $C^{1}(U)$ if $\mathbf{f}$ is differentiable and the mapping

$$
\mathbf{x} \rightarrow D \mathbf{f}(\mathbf{x})
$$

is continuous as a function from $U$ to $\mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{m}\right)$.
The following is an important abstract generalization of the familiar concept of partial derivative.

Definition 6.13.3 Let $\mathbf{g}: U \subseteq \mathbb{F}^{n} \times \mathbb{F}^{m} \rightarrow \mathbb{F}^{q}$, where $U$ is an open set in $\mathbb{F}^{n} \times \mathbb{F}^{m}$. Denote an element of $\mathbb{F}^{n} \times \mathbb{F}^{m}$ by $(\mathbf{x}, \mathbf{y})$ where $\mathbf{x} \in \mathbb{F}^{n}$ and $\mathbf{y} \in \mathbb{F}^{m}$. Then the map $\mathbf{x} \rightarrow \mathbf{g}(\mathbf{x}, \mathbf{y})$ is a function from the open set in $\mathbb{F}^{n}$,

$$
\{\mathbf{x}:(\mathbf{x}, \mathbf{y}) \in U\}
$$

to $\mathbb{F}^{q}$. When this map is differentiable, its derivative is denoted by

$$
D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}), \text { or sometimes by } D_{\mathbf{x}} \mathbf{g}(\mathbf{x}, \mathbf{y})
$$

Thus,

$$
\mathbf{g}(\mathbf{x}+\mathbf{v}, \mathbf{y})-\mathbf{g}(\mathbf{x}, \mathbf{y})=D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{v}+o(\mathbf{v})
$$

A similar definition holds for the symbol $D_{\mathbf{y}} \mathbf{g}$ or $D_{2} \mathbf{g}$. The special case seen in beginning calculus courses is where $\mathbf{g}: U \rightarrow \mathbb{F}^{q}$ and

$$
\mathbf{g}_{x_{i}}(\mathbf{x}) \equiv \frac{\partial \mathbf{g}(\mathbf{x})}{\partial x_{i}} \equiv \lim _{h \rightarrow 0} \frac{\mathbf{g}\left(\mathbf{x}+h \mathbf{e}_{i}\right)-\mathbf{g}(\mathbf{x})}{h}
$$

The following theorem will be very useful in much of what follows. It is a version of the mean value theorem. You might call it the mean value inequality.

Theorem 6.13.4 Suppose $U$ is an open subset of $\mathbb{F}^{n}$ and $\mathbf{f}: U \rightarrow \mathbb{F}^{m}$ has the property that $D \mathbf{f}(\mathbf{x})$ exists for all $\mathbf{x}$ in $U$ and that, $\mathbf{x}+t(\mathbf{y}-\mathbf{x}) \in U$ for all $t \in[0,1]$. (The line segment joining the two points lies in $U$.) Suppose also that for all points on this line segment,

$$
\|D \mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))\| \leq M
$$

Then

$$
|\mathbf{f}(\mathbf{y})-\mathbf{f}(\mathbf{x})| \leq M|\mathbf{y}-\mathbf{x}| .
$$

Proof: Let

$$
\begin{gathered}
S \equiv\{t \in[0,1]: \text { for all } s \in[0, t] \\
|\mathbf{f}(\mathbf{x}+s(\mathbf{y}-\mathbf{x}))-\mathbf{f}(\mathbf{x})| \leq(M+\boldsymbol{\varepsilon}) s|\mathbf{y}-\mathbf{x}|\}
\end{gathered}
$$

Then $0 \in S$ and by continuity of $\mathbf{f}$, it follows that if $t \equiv \sup S$, then $t \in S$ and if $t<1$,

$$
\begin{equation*}
|\mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))-\mathbf{f}(\mathbf{x})|=(M+\boldsymbol{\varepsilon}) t|\mathbf{y}-\mathbf{x}| . \tag{6.13.18}
\end{equation*}
$$

If $t<1$, then there exists a sequence of positive numbers, $\left\{h_{k}\right\}_{k=1}^{\infty}$ converging to 0 such that

$$
\left|\mathbf{f}\left(\mathbf{x}+\left(t+h_{k}\right)(\mathbf{y}-\mathbf{x})\right)-\mathbf{f}(\mathbf{x})\right|>(M+\boldsymbol{\varepsilon})\left(t+h_{k}\right)|\mathbf{y}-\mathbf{x}|
$$

which implies that

$$
\begin{gathered}
\left|\mathbf{f}\left(\mathbf{x}+\left(t+h_{k}\right)(\mathbf{y}-\mathbf{x})\right)-\mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))\right| \\
+|\mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))-\mathbf{f}(\mathbf{x})|>(M+\boldsymbol{\varepsilon})\left(t+h_{k}\right)|\mathbf{y}-\mathbf{x}| .
\end{gathered}
$$

By 6.13 .18 , this inequality implies

$$
\left|\mathbf{f}\left(\mathbf{x}+\left(t+h_{k}\right)(\mathbf{y}-\mathbf{x})\right)-\mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))\right|>(M+\varepsilon) h_{k}|\mathbf{y}-\mathbf{x}|
$$

which yields upon dividing by $h_{k}$ and taking the limit as $h_{k} \rightarrow 0$,

$$
|D \mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))(\mathbf{y}-\mathbf{x})| \geq(M+\boldsymbol{\varepsilon})|\mathbf{y}-\mathbf{x}| .
$$

Now by the definition of the norm of a linear operator,
a contradiction. Therefore, $t=1$ and so

$$
|\mathbf{f}(\mathbf{x}+(\mathbf{y}-\mathbf{x}))-\mathbf{f}(\mathbf{x})| \leq(M+\varepsilon)|\mathbf{y}-\mathbf{x}| .
$$

Since $\varepsilon>0$ is arbitrary, this proves the theorem.
The next theorem proves that if the partial derivatives exist and are continuous, then the function is differentiable.

Theorem 6.13.5 Let $\mathbf{g}: U \subseteq \mathbb{F}^{n} \times \mathbb{F}^{m} \rightarrow \mathbb{F}^{q}$. Then $\mathbf{g}$ is $C^{1}(U)$ if and only if $D_{1} \mathbf{g}$ and $D_{2} \mathbf{g}$ both exist and are continuous on $U$. In this case,

$$
D \mathbf{g}(\mathbf{x}, \mathbf{y})(\mathbf{u}, \mathbf{v})=D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{u}+D_{2} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{v}
$$

Proof: Suppose first that $\mathbf{g} \in C^{1}(U)$. Then if $(\mathbf{x}, \mathbf{y}) \in U$,

$$
\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y})-\mathbf{g}(\mathbf{x}, \mathbf{y})=D \mathbf{g}(\mathbf{x}, \mathbf{y})(\mathbf{u}, \mathbf{0})+o(\mathbf{u}) .
$$

Therefore, $D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{u}=D \mathbf{g}(\mathbf{x}, \mathbf{y})(\mathbf{u}, \mathbf{0})$. Then

$$
\left|\left(D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y})-D_{1} \mathbf{g}\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right)(\mathbf{u})\right|=
$$

$$
\begin{aligned}
& \left|\left(D \mathbf{g}(\mathbf{x}, \mathbf{y})-D \mathbf{g}\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right)(\mathbf{u}, \mathbf{0})\right| \leq \\
& \left|\left|D \mathbf{g}(\mathbf{x}, \mathbf{y})-D \mathbf{g}\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right|\right||(\mathbf{u}, \mathbf{0})| .
\end{aligned}
$$

Therefore,

$$
\left|D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y})-D_{1} \mathbf{g}\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right| \leq\left\|D \mathbf{g}(\mathbf{x}, \mathbf{y})-D \mathbf{g}\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right\|
$$

A similar argument applies for $D_{2} \mathbf{g}$ and this proves the continuity of the function, $(\mathbf{x}, \mathbf{y}) \rightarrow$ $D_{i} \mathbf{g}(\mathbf{x}, \mathbf{y})$ for $i=1,2$. The formula follows from

$$
\begin{aligned}
D \mathbf{g}(\mathbf{x}, \mathbf{y})(\mathbf{u}, \mathbf{v}) & =D \mathbf{g}(\mathbf{x}, \mathbf{y})(\mathbf{u}, \mathbf{0})+D \mathbf{g}(\mathbf{x}, \mathbf{y})(\mathbf{0}, \mathbf{v}) \\
& \equiv D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{u}+D_{2} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{v}
\end{aligned}
$$

Now suppose $D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y})$ and $D_{2} \mathbf{g}(\mathbf{x}, \mathbf{y})$ exist and are continuous.

$$
\begin{gather*}
\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}, \mathbf{y})=\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}, \mathbf{y}+\mathbf{v}) \\
+\mathbf{g}(\mathbf{x}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}, \mathbf{y}) \\
=\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y})-\mathbf{g}(\mathbf{x}, \mathbf{y})+\mathbf{g}(\mathbf{x}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}, \mathbf{y})+ \\
{[\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y})-(\mathbf{g}(\mathbf{x}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}, \mathbf{y}))]} \\
=D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{u}+D_{2} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{v}+o(\mathbf{v})+o(\mathbf{u})+ \\
{[\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y})-(\mathbf{g}(\mathbf{x}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}, \mathbf{y}))] .} \tag{6.13.19}
\end{gather*}
$$

Let $\mathbf{h}(\mathbf{x}, \mathbf{u}) \equiv \mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y})$. Then the expression in [ ] is of the form,

$$
\mathbf{h}(\mathbf{x}, \mathbf{u})-\mathbf{h}(\mathbf{x}, \mathbf{0}) .
$$

Also

$$
D_{2} \mathbf{h}(\mathbf{x}, \mathbf{u})=D_{1} \mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})-D_{1} \mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y})
$$

and so, by continuity of $(\mathbf{x}, \mathbf{y}) \rightarrow D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y})$,

$$
\left\|D_{2} \mathbf{h}(\mathbf{x}, \mathbf{u})\right\|<\varepsilon
$$

whenever $\|(\mathbf{u}, \mathbf{v})\|$ is small enough. By Theorem 6.13 .4 on Page 120 , there exists $\delta>0$ such that if $\|(\mathbf{u}, \mathbf{v})\|<\delta$, the norm of the last term in 6.13 .19 satisfies the inequality,

$$
\begin{equation*}
\|\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y})-(\mathbf{g}(\mathbf{x}, \mathbf{y}+\mathbf{v})-\mathbf{g}(\mathbf{x}, \mathbf{y}))\|<\varepsilon\|\mathbf{u}\| . \tag{6.13.20}
\end{equation*}
$$

Therefore, this term is $o((\mathbf{u}, \mathbf{v}))$. It follows from 6.13.20 and 6.13.19 that

$$
\begin{gathered}
\mathbf{g}(\mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v})= \\
\mathbf{g}(\mathbf{x}, \mathbf{y})+D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{u}+D_{2} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{v}+o(\mathbf{u})+o(\mathbf{v})+o((\mathbf{u}, \mathbf{v})) \\
=\mathbf{g}(\mathbf{x}, \mathbf{y})+D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{u}+D_{2} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{v}+o((\mathbf{u}, \mathbf{v}))
\end{gathered}
$$

Showing that $D \mathbf{g}(\mathbf{x}, \mathbf{y})$ exists and is given by

$$
D \mathbf{g}(\mathbf{x}, \mathbf{y})(\mathbf{u}, \mathbf{v})=D_{1} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{u}+D_{2} \mathbf{g}(\mathbf{x}, \mathbf{y}) \mathbf{v}
$$

The continuity of $(\mathbf{x}, \mathbf{y}) \rightarrow D \mathbf{g}(\mathbf{x}, \mathbf{y})$ follows from the continuity of $(\mathbf{x}, \mathbf{y}) \rightarrow D_{i} \mathbf{g}(\mathbf{x}, \mathbf{y})$. This proves the theorem.

Not surprisingly, it can be generalized to many more factors.

Definition 6.13.6 Let $\mathbf{g}: U \subseteq \prod_{i=1}^{n} \mathbb{F}^{r_{i}} \rightarrow \mathbb{F}^{q}$, where $U$ is an open set. Then the map $\mathbf{x}_{i} \rightarrow$ $\mathbf{g}(\mathbf{x})$ is a function from the open set in $\mathbb{F}^{r_{i}}$,

$$
\left\{\mathbf{x}: \mathbf{x}=\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{x}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right) \in U\right\}
$$

to $\mathbb{F}^{q}$. When this map is differentiable, its derivative is denoted by $D_{i} \mathbf{g}(\mathbf{x})$. To aid in the notation, for $\mathbf{v} \in \mathbb{F}^{r_{i}}$, let $\theta_{i} \mathbf{v} \in \prod_{i=1}^{n} \mathbb{F}^{r_{i}}$ be the vector $(\mathbf{0}, \cdots, \mathbf{v}, \cdots, \mathbf{0})$ where the $\mathbf{v}$ is in the $i^{\text {th }}$ slot and for $\mathbf{v} \in \prod_{i=1}^{n} \mathbb{F}^{r_{i}}$, let $\mathbf{v}_{i}$ denote the entry in the $i^{\text {th }}$ slot of $\mathbf{v}$. Thus, by saying $\mathbf{x}_{i} \rightarrow \mathbf{g}(\mathbf{x})$ is differentiable is meant that for $\mathbf{v} \in \mathbb{F}^{r_{i}}$ sufficiently small,

$$
\mathbf{g}\left(\mathbf{x}+\theta_{i} \mathbf{v}\right)-\mathbf{g}(\mathbf{x})=D_{i} \mathbf{g}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v})
$$

Note $D_{i} \mathbf{g}(\mathbf{x}) \in \mathscr{L}\left(\mathbb{F}^{r_{i}}, \prod_{i=1}^{n} \mathbb{F}^{r_{i}}\right)$.
Here is a generalization of Theorem 6.13.5.
Theorem 6.13.7 Let $\mathbf{g}, U, \prod_{i=1}^{n} \mathbb{F}^{r_{i}}$, be given as in Definition 6.13.6. Then $\mathbf{g}$ is $C^{1}(U)$ if and only if $D_{i} \mathbf{g}$ exists and is continuous on $U$ for each i. In this case,

$$
\begin{equation*}
D \mathbf{g}(\mathbf{x})(\mathbf{v})=\sum_{k} D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k} \tag{6.13.21}
\end{equation*}
$$

where $\mathbf{v}=\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right)$.
Proof: Suppose then that $D_{i} \mathbf{g}$ exists and is continuous for each $i$. Note that $\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}=$ $\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{k}, \mathbf{0}, \cdots, \mathbf{0}\right)$. Thus $\sum_{j=1}^{n} \theta_{j} \mathbf{v}_{j}=\mathbf{v}$ and define $\sum_{j=1}^{0} \theta_{j} \mathbf{v}_{j} \equiv \mathbf{0}$. Therefore,

$$
\begin{equation*}
\mathbf{g}(\mathbf{x}+\mathbf{v})-\mathbf{g}(\mathbf{x})=\sum_{k=1}^{n}\left[\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}\right)\right] \tag{6.13.22}
\end{equation*}
$$

Consider the terms in this sum.

$$
\begin{gather*}
\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}\right)=\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}_{k}\right)-\mathbf{g}(\mathbf{x})+  \tag{6.13.23}\\
\left(\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}_{k}\right)\right)-\left(\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}(\mathbf{x})\right) \tag{6.13.24}
\end{gather*}
$$

and the expression in 6.13 .24 is of the form $\mathbf{h}\left(\mathbf{v}_{k}\right)-\mathbf{h}(\mathbf{0})$ where for small $\mathbf{w} \in \mathbb{F}^{r_{k}}$,

$$
\mathbf{h}(\mathbf{w}) \equiv \mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}+\theta_{k} \mathbf{w}\right)-\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{w}\right)
$$

Therefore,

$$
D \mathbf{h}(\mathbf{w})=D_{k} \mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}+\theta_{k} \mathbf{w}\right)-D_{k} \mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{w}\right)
$$

and by continuity, $\|D \mathbf{h}(\mathbf{w})\|<\varepsilon$ provided $|\mathbf{v}|$ is small enough. Therefore, by Theorem 6.13.4, whenever $|\mathbf{v}|$ is small enough, $\left|\mathbf{h}\left(\mathbf{v}_{k}\right)-\mathbf{h}(\mathbf{0})\right| \leq \varepsilon\left|\mathbf{v}_{k}\right| \leq \varepsilon|\mathbf{v}|$ which shows that since $\varepsilon$ is arbitrary, the expression in 6.13.24 is $\mathbf{o}(\mathbf{v})$. Now in 6.13.23

$$
\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}_{k}\right)-\mathbf{g}(\mathbf{x})=D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k}+\mathbf{o}\left(\mathbf{v}_{k}\right)=D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k}+\mathbf{o}(\mathbf{v}) .
$$

Therefore, referring to 6.13.22,

$$
\mathbf{g}(\mathbf{x}+\mathbf{v})-\mathbf{g}(\mathbf{x})=\sum_{k=1}^{n} D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k}+\mathbf{o}(\mathbf{v})
$$

which shows $D \mathbf{g}$ exists and equals the formula given in 6.13.21.
Next suppose $\mathbf{g}$ is $C^{1}$. I need to verify that $D_{k} \mathbf{g}(\mathbf{x})$ exists and is continuous. Let $\mathbf{v} \in \mathbb{F}^{r_{k}}$ sufficiently small. Then

$$
\begin{aligned}
\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}\right)-\mathbf{g}(\mathbf{x}) & =D \mathbf{g}(\mathbf{x}) \theta_{k} \mathbf{v}+\mathbf{o}\left(\theta_{k} \mathbf{v}\right) \\
& =D \mathbf{g}(\mathbf{x}) \theta_{k} \mathbf{v}+\mathbf{o}(\mathbf{v})
\end{aligned}
$$

since $\left|\theta_{k} \mathbf{v}\right|=|\mathbf{v}|$. Then $D_{k} \mathbf{g}(\mathbf{x})$ exists and equals

$$
D \mathbf{g}(\mathbf{x}) \circ \theta_{k}
$$

Since $\mathbf{x} \rightarrow D \mathbf{g}(\mathbf{x})$ is continuous and $\theta_{k}: \mathbb{F}^{r_{k}} \rightarrow \prod_{i=1}^{n} \mathbb{F}^{r_{i}}$ is also continuous, this proves the theorem

The way this is usually used is in the following corollary, a case of Theorem 6.13.7 obtained by letting $\mathbb{F}^{r_{j}}=\mathbb{F}$ in the above theorem.

Corollary 6.13.8 Let $U$ be an open subset of $\mathbb{F}^{n}$ and let $\mathbf{f}: U \rightarrow \mathbb{F}^{m}$ be $C^{1}$ in the sense that all the partial derivatives of $\mathbf{f}$ exist and are continuous. Then $\mathbf{f}$ is differentiable and

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})=\mathbf{f}(\mathbf{x})+\sum_{k=1}^{n} \frac{\partial \mathbf{f}}{\partial x_{k}}(\mathbf{x}) v_{k}+\mathbf{o}(\mathbf{v}) .
$$

### 6.14 $C^{k}$ Functions

Recall the notation for partial derivatives in the following definition.
Definition 6.14.1 Let $\mathbf{g}: U \rightarrow \mathbb{F}^{n}$. Then

$$
\mathbf{g}_{x_{k}}(\mathbf{x}) \equiv \frac{\partial \mathbf{g}}{\partial x_{k}}(\mathbf{x}) \equiv \lim _{h \rightarrow 0} \frac{\mathbf{g}\left(\mathbf{x}+h \mathbf{e}_{k}\right)-\mathbf{g}(\mathbf{x})}{h}
$$

Higher order partial derivatives are defined in the usual way.

$$
\mathbf{g}_{x_{k} x_{l}}(\mathbf{x}) \equiv \frac{\partial^{2} \mathbf{g}}{\partial x_{l} \partial x_{k}}(\mathbf{x})
$$

and so forth.

To deal with higher order partial derivatives in a systematic way, here is a useful definition.

Definition 6.14.2 $\alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right)$ for $\alpha_{1} \cdots \alpha_{n}$ positive integers is called a multi-index. For $\alpha$ a multi-index, $|\alpha| \equiv \alpha_{1}+\cdots+\alpha_{n}$ and if $\mathbf{x} \in \mathbb{F}^{n}$,

$$
\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)
$$

and $\mathbf{f}$ a function, define

$$
\mathbf{x}^{\alpha} \equiv x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \cdots x_{n}^{\alpha_{n}}, D^{\alpha} \mathbf{f}(\mathbf{x}) \equiv \frac{\partial^{|\alpha|} \mathbf{f}(\mathbf{x})}{\partial x_{1}^{\alpha_{1}} \partial x_{2}^{\alpha_{2}} \cdots \partial x_{n}^{\alpha_{n}}}
$$

The following is the definition of what is meant by a $C^{k}$ function.
Definition 6.14.3 Let $U$ be an open subset of $\mathbb{F}^{n}$ and let $\mathbf{f}: U \rightarrow \mathbb{F}^{m}$. Then for $k$ a nonnegative integer, $\mathbf{f}$ is $C^{k}$ if for every $|\alpha| \leq k, D^{\alpha} \mathbf{f}$ exists and is continuous.

### 6.15 Mixed Partial Derivatives

Under certain conditions the mixed partial derivatives will always be equal. This astonishing fact is due to Euler in 1734.

Theorem 6.15.1 Suppose $f: U \subseteq \mathbb{F}^{2} \rightarrow \mathbb{R}$ where $U$ is an open set on which $f_{x}, f_{y}, f_{x y}$ and $f_{y x}$ exist. Then if $f_{x y}$ and $f_{y x}$ are continuous at the point $(x, y) \in U$, it follows

$$
f_{x y}(x, y)=f_{y x}(x, y) .
$$

Proof: Since $U$ is open, there exists $r>0$ such that $B((x, y), r) \subseteq U$. Now let $|t|,|s|<$ $r / 2, t, s$ real numbers and consider

$$
\begin{equation*}
\Delta(s, t) \equiv \frac{1}{s t}\{\overbrace{f(x+t, y+s)-f(x+t, y)}^{h(t)}-\overbrace{(f(x, y+s)-f(x, y))}^{h(0)}\} . \tag{6.15.25}
\end{equation*}
$$

Note that $(x+t, y+s) \in U$ because

$$
\begin{aligned}
|(x+t, y+s)-(x, y)| & =|(t, s)|=\left(t^{2}+s^{2}\right)^{1 / 2} \\
& \leq\left(\frac{r^{2}}{4}+\frac{r^{2}}{4}\right)^{1 / 2}=\frac{r}{\sqrt{2}}<r
\end{aligned}
$$

As implied above, $h(t) \equiv f(x+t, y+s)-f(x+t, y)$. Therefore, by the mean value theorem from calculus and the (one variable) chain rule,

$$
\begin{aligned}
\Delta(s, t) & =\frac{1}{s t}(h(t)-h(0))=\frac{1}{s t} h^{\prime}(\alpha t) t \\
& =\frac{1}{s}\left(f_{x}(x+\alpha t, y+s)-f_{x}(x+\alpha t, y)\right)
\end{aligned}
$$

for some $\alpha \in(0,1)$. Applying the mean value theorem again,

$$
\Delta(s, t)=f_{x y}(x+\alpha t, y+\beta s)
$$

where $\alpha, \beta \in(0,1)$.
If the terms $f(x+t, y)$ and $f(x, y+s)$ are interchanged in 6.15.25, $\Delta(s, t)$ is unchanged and the above argument shows there exist $\gamma, \delta \in(0,1)$ such that

$$
\Delta(s, t)=f_{y x}(x+\gamma t, y+\delta s)
$$

Letting $(s, t) \rightarrow(0,0)$ and using the continuity of $f_{x y}$ and $f_{y x}$ at $(x, y)$,

$$
\lim _{(s, t) \rightarrow(0,0)} \Delta(s, t)=f_{x y}(x, y)=f_{y x}(x, y)
$$

This proves the theorem.
The following is obtained from the above by simply fixing all the variables except for the two of interest.

Corollary 6.15.2 Suppose $U$ is an open subset of $\mathbb{F}^{n}$ and $f: U \rightarrow \mathbb{R}$ has the property that for two indices, $k, l, f_{x_{k}}, f_{x_{l}}, f_{x_{l} x_{k}}$, and $f_{x_{k} x_{l}}$ exist on $U$ and $f_{x_{k} x_{l}}$ and $f_{x_{l} x_{k}}$ are both continuous at $\mathbf{x} \in U$. Then $f_{x_{k} x_{l}}(\mathbf{x})=f_{x_{l} x_{k}}(\mathbf{x})$.

By considering the real and imaginary parts of $f$ in the case where $f$ has values in $\mathbb{F}$ you obtain the following corollary.

Corollary 6.15.3 Suppose $U$ is an open subset of $\mathbb{F}^{n}$ and $f: U \rightarrow \mathbb{F}$ has the property that for two indices, $k, l, f_{x_{k}}, f_{x_{l}}, f_{x_{l} x_{k}}$, and $f_{x_{k} x_{l}}$ exist on $U$ and $f_{x_{k} x_{l}}$ and $f_{x_{l} x_{k}}$ are both continuous at $\mathbf{x} \in U$. Then $f_{x_{k} x_{l}}(\mathbf{x})=f_{x_{l} x_{k}}(\mathbf{x})$.

Finally, by considering the components of $\mathbf{f}$ you get the following generalization.
Corollary 6.15.4 Suppose $U$ is an open subset of $\mathbb{F}^{n}$ and $\mathbf{f}: U \rightarrow \mathbb{F}^{m}$ has the property that for two indices, $k, l, \mathbf{f}_{x_{k}}, \mathbf{f}_{x_{l}}, \mathbf{f}_{x_{l} x_{k}}$, and $\mathbf{f}_{x_{k} x_{l}}$ exist on $U$ and $\mathbf{f}_{x_{k} x_{l}}$ and $\mathbf{f}_{x_{l} x_{k}}$ are both continuous at $\mathbf{x} \in U$. Then $\mathbf{f}_{x_{k} x_{l}}(\mathbf{x})=\mathbf{f}_{x_{l} x_{k}}(\mathbf{x})$.

It is necessary to assume the mixed partial derivatives are continuous in order to assert they are equal. The following is a well known example [6].

Example 6.15.5 Let

$$
f(x, y)=\left\{\begin{array}{l}
\frac{x y\left(x^{2}-y^{2}\right)}{x^{2}+y^{2}} \text { if }(x, y) \neq(0,0) \\
0 \text { if }(x, y)=(0,0)
\end{array}\right.
$$

From the definition of partial derivatives it follows immediately that

$$
f_{x}(0,0)=f_{y}(0,0)=0
$$

Using the standard rules of differentiation, for $(x, y) \neq(0,0)$,

$$
f_{x}=y \frac{x^{4}-y^{4}+4 x^{2} y^{2}}{\left(x^{2}+y^{2}\right)^{2}}, f_{y}=x \frac{x^{4}-y^{4}-4 x^{2} y^{2}}{\left(x^{2}+y^{2}\right)^{2}}
$$

Now

$$
\begin{aligned}
f_{x y}(0,0) & \equiv \lim _{y \rightarrow 0} \frac{f_{x}(0, y)-f_{x}(0,0)}{y} \\
& =\lim _{y \rightarrow 0} \frac{-y^{4}}{\left(y^{2}\right)^{2}}=-1
\end{aligned}
$$

while

$$
\begin{aligned}
f_{y x}(0,0) & \equiv \lim _{x \rightarrow 0} \frac{f_{y}(x, 0)-f_{y}(0,0)}{x} \\
& =\lim _{x \rightarrow 0} \frac{x^{4}}{\left(x^{2}\right)^{2}}=1
\end{aligned}
$$

showing that although the mixed partial derivatives do exist at $(0,0)$, they are not equal there.

### 6.16 Implicit Function Theorem

The implicit function theorem is one of the greatest theorems in mathematics. There are many versions of this theorem. However, I will give a very simple proof valid in finite dimensional spaces.

Theorem 6.16.1 (implicit function theorem) Suppose $U$ is an open set in $\mathbb{R}^{n} \times \mathbb{R}^{m}$. Let $\mathbf{f}: U \rightarrow \mathbb{R}^{n}$ be in $C^{1}(U)$ and suppose

$$
\begin{equation*}
\mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)=\mathbf{0}, D_{1} \mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)^{-1} \in \mathscr{L}\left(\mathbb{R}^{n}, \mathbb{R}^{n}\right) \tag{6.16.26}
\end{equation*}
$$

Then there exist positive constants, $\delta, \eta$, such that for every $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ there exists $a$ unique $\mathbf{x}(\mathbf{y}) \in B\left(\mathbf{x}_{0}, \delta\right)$ such that

$$
\begin{equation*}
\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})=\mathbf{0} \tag{6.16.27}
\end{equation*}
$$

Furthermore, the mapping, $\mathbf{y} \rightarrow \mathbf{x}(\mathbf{y})$ is in $C^{1}\left(B\left(\mathbf{y}_{0}, \eta\right)\right)$.
Proof: Let

$$
\mathbf{f}(\mathbf{x}, \mathbf{y})=\left(\begin{array}{c}
f_{1}(\mathbf{x}, \mathbf{y}) \\
f_{2}(\mathbf{x}, \mathbf{y}) \\
\vdots \\
f_{n}(\mathbf{x}, \mathbf{y})
\end{array}\right)
$$

Define for $\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}\right) \in{\overline{B\left(\mathbf{x}_{0}, \delta\right)}}^{n}$ and $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ the following matrix.

$$
J\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}, \mathbf{y}\right) \equiv\left(\begin{array}{ccc}
f_{1, x_{1}}\left(\mathbf{x}^{1}, \mathbf{y}\right) & \cdots & f_{1, x_{n}}\left(\mathbf{x}^{1}, \mathbf{y}\right) \\
\vdots & & \vdots \\
f_{n, x_{1}}\left(\mathbf{x}^{n}, \mathbf{y}\right) & \cdots & f_{n, x_{n}}\left(\mathbf{x}^{n}, \mathbf{y}\right)
\end{array}\right)
$$

Then by the assumption of continuity of all the partial derivatives, there exists $\delta_{0}>0$ and $\eta_{0}>0$ such that if $\delta<\delta_{0}$ and $\eta<\eta_{0}$, it follows that for all $\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}\right) \in{\overline{B\left(\mathbf{x}_{0}, \delta\right)}}^{n}$ and $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$,

$$
\begin{equation*}
\operatorname{det}\left(J\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}, \mathbf{y}\right)\right)>r>0 \tag{6.16.28}
\end{equation*}
$$

and $\overline{B\left(\mathbf{x}_{0}, \delta_{0}\right)} \times \overline{B\left(\mathbf{y}_{0}, \eta_{0}\right)} \subseteq U$. Pick $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ and suppose there exist $\mathbf{x}, \mathbf{z} \in \overline{B\left(\mathbf{x}_{0}, \delta\right)}$ such that $\mathbf{f}(\mathbf{x}, \mathbf{y})=\mathbf{f}(\mathbf{z}, \mathbf{y})=\mathbf{0}$. Consider $f_{i}$ and let

$$
h(t) \equiv f_{i}(\mathbf{x}+t(\mathbf{z}-\mathbf{x}), \mathbf{y})
$$

Then $h(1)=h(0)$ and so by the mean value theorem, $h^{\prime}\left(t_{i}\right)=0$ for some $t_{i} \in(0,1)$. Therefore, from the chain rule and for this value of $t_{i}$,

$$
\begin{equation*}
h^{\prime}\left(t_{i}\right)=D f_{i}\left(\mathbf{x}+t_{i}(\mathbf{z}-\mathbf{x}), \mathbf{y}\right)(\mathbf{z}-\mathbf{x})=0 \tag{6.16.29}
\end{equation*}
$$

Then denote by $\mathbf{x}^{i}$ the vector, $\mathbf{x}+t_{i}(\mathbf{z}-\mathbf{x})$. It follows from 6.16.29 that

$$
J\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}, \mathbf{y}\right)(\mathbf{z}-\mathbf{x})=\mathbf{0}
$$

and so from $6.16 .28 \mathbf{z}-\mathbf{x}=\mathbf{0}$. Now it will be shown that if $\eta$ is chosen sufficiently small, then for all $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$, there exists a unique $\mathbf{x}(\mathbf{y}) \in B\left(\mathbf{x}_{0}, \boldsymbol{\delta}\right)$ such that $\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})=\mathbf{0}$.

Claim: If $\eta$ is small enough, then the function, $h_{\mathbf{y}}(\mathbf{x}) \equiv|\mathbf{f}(\mathbf{x}, \mathbf{y})|^{2}$ achieves its minimum value on $\overline{B\left(\mathbf{x}_{0}, \delta\right)}$ at a point of $B\left(\mathbf{x}_{0}, \boldsymbol{\delta}\right)$.

Proof of claim: Suppose this is not the case. Then there exists a sequence $\eta_{k} \rightarrow 0$ and for some $\mathbf{y}_{k}$ having $\left|\mathbf{y}_{k}-\mathbf{y}_{0}\right|<\eta_{k}$, the minimum of $h_{\mathbf{y}_{k}}$ occurs on a point of the boundary of $\overline{B\left(\mathbf{x}_{0}, \delta\right)}, \mathbf{x}_{k}$ such that $\left|\mathbf{x}_{0}-\mathbf{x}_{k}\right|=\delta$. Now taking a subsequence, still denoted by $k$, it can be assumed that $\mathbf{x}_{k} \rightarrow \mathbf{x}$ with $\left|\mathbf{x}-\mathbf{x}_{0}\right|=\delta$ and $\mathbf{y}_{k} \rightarrow \mathbf{y}_{0}$. Let $\varepsilon>0$. Then for $k$ large enough, $h_{\mathbf{y}_{k}}\left(\mathbf{x}_{0}\right)<\varepsilon$ because $\mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)=\mathbf{0}$. Therefore, from the definition of $\mathbf{x}_{k}, h_{\mathbf{y}_{k}}\left(\mathbf{x}_{k}\right)<$ $\varepsilon$. Passing to the limit yields $h_{\mathbf{y}_{0}}(\mathbf{x}) \leq \varepsilon$. Since $\varepsilon>0$ is arbitrary, it follows that $h_{\mathbf{y}_{0}}(\mathbf{x})=0$ which contradicts the first part of the argument in which it was shown that for $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ there is at most one point, $\mathbf{x}$ of $\overline{B\left(\mathbf{x}_{0}, \delta\right)}$ where $\mathbf{f}(\mathbf{x}, \mathbf{y})=\mathbf{0}$. Here two have been obtained, $\mathbf{x}_{0}$ and $\mathbf{x}$. This proves the claim.

Choose $\eta<\eta_{0}$ and also small enough that the above claim holds and let $\mathbf{x}(\mathbf{y})$ denote a point of $B\left(\mathbf{x}_{0}, \delta\right)$ at which the minimum of $h_{\mathbf{y}}$ on $\overline{B\left(\mathbf{x}_{0}, \delta\right)}$ is achieved. Since $\mathbf{x}(\mathbf{y})$ is an interior point, you can consider $h_{\mathbf{y}}(\mathbf{x}(\mathbf{y})+t \mathbf{v})$ for $|t|$ small and conclude this function of $t$ has a zero derivative at $t=0$. Thus

$$
D h_{\mathbf{y}}(\mathbf{x}(\mathbf{y})) \mathbf{v}=0=2 \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})^{T} D_{1} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y}) \mathbf{v}
$$

for every vector $\mathbf{v}$. But from 6.16.28 and the fact that $\mathbf{v}$ is arbitrary, it follows $\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})=\mathbf{0}$. This proves the existence of the function $\mathbf{y} \rightarrow \mathbf{x}(\mathbf{y})$ such that $\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})=\mathbf{0}$ for all $\mathbf{y} \in$ $B\left(\mathbf{y}_{0}, \eta\right)$.

It remains to verify this function is a $C^{1}$ function. To do this, let $\mathbf{y}_{1}$ and $\mathbf{y}_{2}$ be points of $B\left(\mathbf{y}_{0}, \eta\right)$. Then as before, consider the $i^{\text {th }}$ component of $\mathbf{f}$ and consider the same argument using the mean value theorem to write

$$
\begin{gathered}
0=f_{i}\left(\mathbf{x}\left(\mathbf{y}_{1}\right), \mathbf{y}_{1}\right)-f_{i}\left(\mathbf{x}\left(\mathbf{y}_{2}\right), \mathbf{y}_{2}\right) \\
=f_{i}\left(\mathbf{x}\left(\mathbf{y}_{1}\right), \mathbf{y}_{1}\right)-f_{i}\left(\mathbf{x}\left(\mathbf{y}_{2}\right), \mathbf{y}_{1}\right)+f_{i}\left(\mathbf{x}\left(\mathbf{y}_{2}\right), \mathbf{y}_{1}\right)-f_{i}\left(\mathbf{x}\left(\mathbf{y}_{2}\right), \mathbf{y}_{2}\right) \\
=D_{1} f_{i}\left(\mathbf{x}^{i}, \mathbf{y}_{1}\right)\left(\mathbf{x}\left(\mathbf{y}_{1}\right)-\mathbf{x}\left(\mathbf{y}_{2}\right)\right)+D_{2} f_{i}\left(\mathbf{x}\left(\mathbf{y}_{2}\right), \mathbf{y}^{i}\right)\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right)
\end{gathered}
$$

Therefore,

$$
\begin{equation*}
J\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}, \mathbf{y}_{1}\right)\left(\mathbf{x}\left(\mathbf{y}_{1}\right)-\mathbf{x}\left(\mathbf{y}_{2}\right)\right)=-M\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right) \tag{6.16.30}
\end{equation*}
$$

where $M$ is the matrix whose $i^{t h}$ row is $D_{2} f_{i}\left(\mathbf{x}\left(\mathbf{y}_{2}\right), \mathbf{y}^{i}\right)$. Then from 6.16 .28 there exists a constant, $C$ independent of the choice of $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ such that

$$
\left\|J\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}, \mathbf{y}\right)^{-1}\right\|<C
$$

whenever $\left(\mathbf{x}^{1}, \cdots, \mathbf{x}^{n}\right) \in{\overline{B\left(\mathbf{x}_{0}, \delta\right)}}^{n}$. By continuity of the partial derivatives of $\mathbf{f}$ it also follows there exists a constant, $C_{1}$ such that $\left\|D_{2} f_{i}(\mathbf{x}, \mathbf{y})\right\|<C_{1}$ whenever, $(\mathbf{x}, \mathbf{y}) \in \overline{B\left(\mathbf{x}_{0}, \boldsymbol{\delta}\right)} \times$ $B\left(\mathbf{y}_{0}, \eta\right)$. Hence $\|M\|$ must also be bounded independent of the choice of $\mathbf{y}_{1}$ and $\mathbf{y}_{2}$ in $B\left(\mathbf{y}_{0}, \eta\right)$. From 6.16.30, it follows there exists a constant, $C$ such that for all $\mathbf{y}_{1}, \mathbf{y}_{2}$ in $B\left(\mathbf{y}_{0}, \eta\right)$,

$$
\begin{equation*}
\left|\mathbf{x}\left(\mathbf{y}_{1}\right)-\mathbf{x}\left(\mathbf{y}_{2}\right)\right| \leq C\left|\mathbf{y}_{1}-\mathbf{y}_{2}\right| \tag{6.16.31}
\end{equation*}
$$

It follows as in the proof of the chain rule that

$$
\begin{equation*}
\mathbf{o}(\mathbf{x}(\mathbf{y}+\mathbf{v})-\mathbf{x}(\mathbf{y}))=\mathbf{o}(\mathbf{v}) . \tag{6.16.32}
\end{equation*}
$$

Now let $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ and let $|\mathbf{v}|$ be sufficiently small that $\mathbf{y}+\mathbf{v} \in B\left(\mathbf{y}_{0}, \eta\right)$. Then

$$
\begin{aligned}
& \mathbf{0}= \mathbf{f}(\mathbf{x}(\mathbf{y}+\mathbf{v}), \mathbf{y}+\mathbf{v})-\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y}) \\
&= \mathbf{f}(\mathbf{x}(\mathbf{y}+\mathbf{v}), \mathbf{y}+\mathbf{v})-\mathbf{f}(\mathbf{x}(\mathbf{y}+\mathbf{v}), \mathbf{y})+\mathbf{f}(\mathbf{x}(\mathbf{y}+\mathbf{v}), \mathbf{y})-\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y}) \\
&=D_{2} \mathbf{f}(\mathbf{x}(\mathbf{y}+\mathbf{v}), \mathbf{y}) \mathbf{v}+D_{1} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})(\mathbf{x}(\mathbf{y}+\mathbf{v})-\mathbf{x}(\mathbf{y}))+\mathbf{o}(|\mathbf{x}(\mathbf{y}+\mathbf{v})-\mathbf{x}(\mathbf{y})|) \\
&= D_{2} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y}) \mathbf{v}+D_{1} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})(\mathbf{x}(\mathbf{y}+\mathbf{v})-\mathbf{x}(\mathbf{y}))+ \\
& \mathbf{o}(|\mathbf{x}(\mathbf{y}+\mathbf{v})-\mathbf{x}(\mathbf{y})|)+\left(D_{2} \mathbf{f}(\mathbf{x}(\mathbf{y}+\mathbf{v}), \mathbf{y}) \mathbf{v}-D_{2} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y}) \mathbf{v}\right) \\
&= D_{2} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y}) \mathbf{v}+D_{1} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})(\mathbf{x}(\mathbf{y}+\mathbf{v})-\mathbf{x}(\mathbf{y}))+\mathbf{o}(\mathbf{v}) .
\end{aligned}
$$

Therefore,

$$
\mathbf{x}(\mathbf{y}+\mathbf{v})-\mathbf{x}(\mathbf{y})=-D_{1} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})^{-1} D_{2} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y}) \mathbf{v}+\mathbf{o}(\mathbf{v})
$$

which shows that $D \mathbf{x}(\mathbf{y})=-D_{1} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})^{-1} D_{2} \mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})$ and $\mathbf{y} \rightarrow D \mathbf{x}(\mathbf{y})$ is continuous. This proves the theorem.

In practice, how do you verify the condition, $D_{1} \mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)^{-1} \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{n}\right)$ ?

$$
\mathbf{f}(\mathbf{x}, \mathbf{y})=\left(\begin{array}{c}
f_{1}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right) \\
\vdots \\
f_{n}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)
\end{array}\right)
$$

The matrix of the linear transformation, $D_{1} \mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)$ is then

$$
\left(\begin{array}{ccc}
\frac{\partial f_{1}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{1}} & \cdots & \frac{\partial f_{1}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{n}} \\
\vdots & & \vdots \\
\frac{\partial f_{n}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{1}} & \cdots & \frac{\partial f_{n}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{n}}
\end{array}\right)
$$

and from linear algebra, $D_{1} \mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)^{-1} \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{n}\right)$ exactly when the above matrix has an inverse. In other words when

$$
\operatorname{det}\left(\begin{array}{ccc}
\frac{\partial f_{1}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{1}} & \cdots & \frac{\partial f_{1}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{n}} \\
\vdots & & \vdots \\
\frac{\partial f_{n}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{1}} & \cdots & \frac{\partial f_{n}\left(x_{1}, \cdots, x_{n}, y_{1}, \cdots, y_{n}\right)}{\partial x_{n}}
\end{array}\right) \neq 0
$$

at $\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)$. The above determinant is important enough that it is given special notation. Letting $\mathbf{z}=\mathbf{f}(\mathbf{x}, \mathbf{y})$, the above determinant is often written as

$$
\frac{\partial\left(z_{1}, \cdots, z_{n}\right)}{\partial\left(x_{1}, \cdots, x_{n}\right)}
$$

Of course you can replace $\mathbb{R}$ with $\mathbb{F}$ in the above by applying the above to the situation in which each $\mathbb{F}$ is replaced with $\mathbb{R}^{2}$.

Corollary 6.16.2 (implicit function theorem) Suppose $U$ is an open set in $\mathbb{F}^{n} \times \mathbb{F}^{m}$. Let $\mathbf{f}: U \rightarrow \mathbb{F}^{n}$ be in $C^{1}(U)$ and suppose

$$
\begin{equation*}
\mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)=\mathbf{0}, D_{1} \mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)^{-1} \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{n}\right) \tag{6.16.33}
\end{equation*}
$$

Then there exist positive constants, $\delta, \eta$, such that for every $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ there exists $a$ unique $\mathbf{x}(\mathbf{y}) \in B\left(\mathbf{x}_{0}, \delta\right)$ such that

$$
\begin{equation*}
\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})=\mathbf{0} . \tag{6.16.34}
\end{equation*}
$$

Furthermore, the mapping, $\mathbf{y} \rightarrow \mathbf{x}(\mathbf{y})$ is in $C^{1}\left(B\left(\mathbf{y}_{0}, \eta\right)\right)$.
The next theorem is a very important special case of the implicit function theorem known as the inverse function theorem. Actually one can also obtain the implicit function theorem from the inverse function theorem. It is done this way in [84] and in [4].

Theorem 6.16.3 (inverse function theorem) Let $\mathbf{x}_{0} \in U \subseteq \mathbb{F}^{n}$ and let $\mathbf{f}: U \rightarrow \mathbb{F}^{n}$. Suppose

$$
\begin{equation*}
\mathbf{f} \text { is } C^{1}(U), \text { and } D \mathbf{f}\left(\mathbf{x}_{0}\right)^{-1} \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{n}\right) \tag{6.16.35}
\end{equation*}
$$

Then there exist open sets, $W$, and $V$ such that

$$
\begin{equation*}
\mathbf{x}_{0} \in W \subseteq U \tag{6.16.36}
\end{equation*}
$$

$$
\begin{equation*}
\mathbf{f}: W \rightarrow V \text { is one to one and onto, } \tag{6.16.37}
\end{equation*}
$$

$$
\begin{equation*}
\mathbf{f}^{-1} \text { is } C^{1} \tag{6.16.38}
\end{equation*}
$$

Proof: Apply the implicit function theorem to the function

$$
\mathbf{F}(\mathbf{x}, \mathbf{y}) \equiv \mathbf{f}(\mathbf{x})-\mathbf{y}
$$

where $\mathbf{y}_{0} \equiv \mathbf{f}\left(\mathbf{x}_{0}\right)$. Thus the function $\mathbf{y} \rightarrow \mathbf{x}(\mathbf{y})$ defined in that theorem is $\mathbf{f}^{-1}$. Now let

$$
W \equiv B\left(\mathbf{x}_{0}, \boldsymbol{\delta}\right) \cap \mathbf{f}^{-1}\left(B\left(\mathbf{y}_{0}, \eta\right)\right)
$$

and

$$
V \equiv B\left(\mathbf{y}_{0}, \eta\right)
$$

This proves the theorem.

### 6.16.1 More Continuous Partial Derivatives

Corollary 6.16 .2 will now be improved slightly. If $\mathbf{f}$ is $C^{k}$, it follows that the function which is implicitly defined is also in $C^{k}$, not just $C^{1}$. Since the inverse function theorem comes as a case of the implicit function theorem, this shows that the inverse function also inherits the property of being $C^{k}$.

Theorem 6.16.4 (implicit function theorem) Suppose $U$ is an open set in $\mathbb{F}^{n} \times \mathbb{F}^{m}$. Let $\mathbf{f}: U \rightarrow \mathbb{F}^{n}$ be in $C^{k}(U)$ and suppose

$$
\begin{equation*}
\mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)=\mathbf{0}, D_{1} \mathbf{f}\left(\mathbf{x}_{0}, \mathbf{y}_{0}\right)^{-1} \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{n}\right) \tag{6.16.39}
\end{equation*}
$$

Then there exist positive constants, $\delta, \eta$, such that for every $\mathbf{y} \in B\left(\mathbf{y}_{0}, \eta\right)$ there exists $a$ unique $\mathbf{x}(\mathbf{y}) \in B\left(\mathbf{x}_{0}, \delta\right)$ such that

$$
\begin{equation*}
\mathbf{f}(\mathbf{x}(\mathbf{y}), \mathbf{y})=\mathbf{0} \tag{6.16.40}
\end{equation*}
$$

Furthermore, the mapping, $\mathbf{y} \rightarrow \mathbf{x}(\mathbf{y})$ is in $C^{k}\left(B\left(\mathbf{y}_{0}, \eta\right)\right)$.
Proof: From Corollary 6.16.2 $\mathbf{y} \rightarrow \mathbf{x}(\mathbf{y})$ is $C^{1}$. It remains to show it is $C^{k}$ for $k>1$ assuming that $\mathbf{f}$ is $C^{k}$. From 6.16.40

$$
\frac{\partial \mathbf{x}}{\partial y^{l}}=-D_{1}(\mathbf{x}, \mathbf{y})^{-1} \frac{\partial \mathbf{f}}{\partial y^{l}}
$$

Thus the following formula holds for $q=1$ and $|\alpha|=q$.

$$
\begin{equation*}
D^{\alpha} \mathbf{x}(\mathbf{y})=\sum_{|\beta| \leq q} M_{\beta}(\mathbf{x}, \mathbf{y}) D^{\beta} \mathbf{f}(\mathbf{x}, \mathbf{y}) \tag{6.16.41}
\end{equation*}
$$

where $M_{\beta}$ is a matrix whose entries are differentiable functions of $D^{\gamma}(\mathbf{x})$ for $|\gamma|<q$ and $D^{\tau} \mathbf{f}(\mathbf{x}, \mathbf{y})$ for $|\tau| \leq q$. This follows easily from the description of $D_{1}(\mathbf{x}, \mathbf{y})^{-1}$ in terms of the cofactor matrix and the determinant of $D_{1}(\mathbf{x}, \mathbf{y})$. Suppose 6.16 .41 holds for $|\alpha|=q<k$. Then by induction, this yields $\mathbf{x}$ is $C^{q}$. Then

$$
\frac{\partial D^{\alpha} \mathbf{x}(\mathbf{y})}{\partial y^{p}}=\sum_{|\beta| \leq|\alpha|} \frac{\partial M_{\beta}(\mathbf{x}, \mathbf{y})}{\partial y^{p}} D^{\beta} \mathbf{f}(\mathbf{x}, \mathbf{y})+M_{\beta}(\mathbf{x}, \mathbf{y}) \frac{\partial D^{\beta} \mathbf{f}(\mathbf{x}, \mathbf{y})}{\partial y^{p}}
$$

By the chain rule $\frac{\partial M_{\beta}(\mathbf{x}, \mathbf{y})}{\partial y^{p}}$ is a matrix whose entries are differentiable functions of $D^{\tau} \mathbf{f}(\mathbf{x}, \mathbf{y})$ for $|\tau| \leq q+1$ and $D^{\gamma}(\mathbf{x})$ for $|\gamma|<q+1$. It follows since $y^{p}$ was arbitrary that for any $|\alpha|=q+1$, a formula like 6.16 .41 holds with $q$ being replaced by $q+1$. By induction, $\mathbf{x}$ is
$C^{k}$. This proves the theorem.
As a simple corollary this yields an improved version of the inverse function theorem.
Theorem 6.16.5 (inverse function theorem) Let $\mathbf{x}_{0} \in U \subseteq \mathbb{F}^{n}$ and let $\mathbf{f}: U \rightarrow \mathbb{F}^{n}$. Suppose for $k$ a positive integer,

$$
\begin{equation*}
\mathbf{f} \text { is } C^{k}(U), \text { and } D \mathbf{f}\left(\mathbf{x}_{0}\right)^{-1} \in \mathscr{L}\left(\mathbb{F}^{n}, \mathbb{F}^{n}\right) \tag{6.16.42}
\end{equation*}
$$

Then there exist open sets, $W$, and $V$ such that

$$
\begin{equation*}
\mathbf{x}_{0} \in W \subseteq U \tag{6.16.43}
\end{equation*}
$$

$$
\begin{align*}
& \mathbf{f}: W \rightarrow V \text { is one to one and onto, }  \tag{6.16.44}\\
& \qquad \mathbf{f}^{-1} \text { is } C^{k} \tag{6.16.45}
\end{align*}
$$

### 6.17 The Method Of Lagrange Multipliers

As an application of the implicit function theorem, consider the method of Lagrange multipliers from calculus. Recall the problem is to maximize or minimize a function subject to equality constraints. Let $f: U \rightarrow \mathbb{R}$ be a $C^{1}$ function where $U \subseteq \mathbb{R}^{n}$ and let

$$
\begin{equation*}
g_{i}(\mathbf{x})=0, i=1, \cdots, m \tag{6.17.46}
\end{equation*}
$$

be a collection of equality constraints with $m<n$. Now consider the system of nonlinear equations

$$
\begin{aligned}
f(\mathbf{x}) & =a \\
g_{i}(\mathbf{x}) & =0, i=1, \cdots, m
\end{aligned}
$$

$\mathbf{x}_{0}$ is a local maximum if $f\left(\mathbf{x}_{0}\right) \geq f(\mathbf{x})$ for all $\mathbf{x}$ near $\mathbf{x}_{0}$ which also satisfies the constraints 6.17.46. A local minimum is defined similarly. Let $\mathbf{F}: U \times \mathbb{R} \rightarrow \mathbb{R}^{m+1}$ be defined by

$$
\mathbf{F}(\mathbf{x}, a) \equiv\left(\begin{array}{c}
f(\mathbf{x})-a  \tag{6.17.47}\\
g_{1}(\mathbf{x}) \\
\vdots \\
g_{m}(\mathbf{x})
\end{array}\right)
$$

Now consider the $m+1 \times n$ Jacobian matrix,

$$
\left(\begin{array}{ccc}
f_{x_{1}}\left(\mathbf{x}_{0}\right) & \cdots & f_{x_{n}}\left(\mathbf{x}_{0}\right) \\
g_{1 x_{1}}\left(\mathbf{x}_{0}\right) & \cdots & g_{1 x_{n}}\left(\mathbf{x}_{0}\right) \\
\vdots & & \vdots \\
g_{m x_{1}}\left(\mathbf{x}_{0}\right) & \cdots & g_{m x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)
$$

If this matrix has rank $m+1$ then some $m+1 \times m+1$ submatrix has nonzero determinant. It follows from the implicit function theorem that there exist $m+1$ variables, $x_{i_{1}}, \cdots, x_{i_{m+1}}$ such that the system

$$
\begin{equation*}
\mathbf{F}(\mathbf{x}, a)=\mathbf{0} \tag{6.17.48}
\end{equation*}
$$

specifies these $m+1$ variables as a function of the remaining $n-(m+1)$ variables and $a$ in an open set of $\mathbb{R}^{n-m}$. Thus there is a solution $(\mathbf{x}, a)$ to 6.17 .48 for some $\mathbf{x}$ close to $\mathbf{x}_{0}$ whenever $a$ is in some open interval. Therefore, $\mathbf{x}_{0}$ cannot be either a local minimum or a local maximum. It follows that if $\mathbf{x}_{0}$ is either a local maximum or a local minimum, then the above matrix must have rank less than $m+1$ which requires the rows to be linearly dependent. Thus, there exist $m$ scalars,

$$
\lambda_{1}, \cdots, \lambda_{m}
$$

and a scalar $\mu$, not all zero such that

$$
\mu\left(\begin{array}{c}
f_{x_{1}}\left(\mathbf{x}_{0}\right)  \tag{6.17.49}\\
\vdots \\
f_{x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)=\lambda_{1}\left(\begin{array}{c}
g_{1 x_{1}}\left(\mathbf{x}_{0}\right) \\
\vdots \\
g_{1 x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)+\cdots+\lambda_{m}\left(\begin{array}{c}
g_{m x_{1}}\left(\mathbf{x}_{0}\right) \\
\vdots \\
g_{m x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)
$$

If the column vectors

$$
\left(\begin{array}{c}
g_{1 x_{1}}\left(\mathbf{x}_{0}\right)  \tag{6.17.50}\\
\vdots \\
g_{1 x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right), \cdots\left(\begin{array}{c}
g_{m x_{1}}\left(\mathbf{x}_{0}\right) \\
\vdots \\
g_{m x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)
$$

are linearly independent, then, $\mu \neq 0$ and dividing by $\mu$ yields an expression of the form

$$
\left(\begin{array}{c}
f_{x_{1}}\left(\mathbf{x}_{0}\right)  \tag{6.17.51}\\
\vdots \\
f_{x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)=\lambda_{1}\left(\begin{array}{c}
g_{1 x_{1}}\left(\mathbf{x}_{0}\right) \\
\vdots \\
g_{1 x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)+\cdots+\lambda_{m}\left(\begin{array}{c}
g_{m x_{1}}\left(\mathbf{x}_{0}\right) \\
\vdots \\
g_{m x_{n}}\left(\mathbf{x}_{0}\right)
\end{array}\right)
$$

at every point $\mathbf{x}_{0}$ which is either a local maximum or a local minimum. This proves the following theorem.

Theorem 6.17.1 Let $U$ be an open subset of $\mathbb{R}^{n}$ and let $f: U \rightarrow \mathbb{R}$ be a $C^{1}$ function. Then if $\mathbf{x}_{0} \in U$ is either a local maximum or local minimum of $f$ subject to the constraints 6.17.46, then 6.17 .49 must hold for some scalars $\mu, \lambda_{1}, \cdots, \lambda_{m}$ not all equal to zero. If the vectors in 6.17 .50 are linearly independent, it follows that an equation of the form 6.17 .51 holds.

## Chapter 7

## Metric Spaces and Topological Spaces

### 7.1 Metric Space

Definition 7.1.1 A metric space is a set, $X$ and a function $d: X \times X \rightarrow[0, \infty)$ which satisfies the following properties.

$$
\begin{gathered}
d(x, y)=d(y, x) \\
d(x, y) \geq 0 \text { and } d(x, y)=0 \text { if and only if } x=y \\
d(x, y) \leq d(x, z)+d(z, y)
\end{gathered}
$$

You can check that $\mathbb{R}^{n}$ and $\mathbb{C}^{n}$ are metric spaces with $d(\mathbf{x}, \mathbf{y})=|\mathbf{x}-\mathbf{y}|$. However, there are many others. The definitions of open and closed sets are the same for a metric space as they are for $\mathbb{R}^{n}$.

Definition 7.1.2 $A$ set, $U$ in a metric space is open if whenever $x \in U$, there exists $r>0$ such that $B(x, r) \subseteq U$. As before, $B(x, r) \equiv\{y: d(x, y)<r\}$. Closed sets are those whose complements are open. A point $p$ is a limit point of a set, $S$ if for every $r>0, B(p, r)$ contains infinitely many points of $S$. A sequence, $\left\{x_{n}\right\}$ converges to a point $x$ if for every $\varepsilon>0$ there exists $N$ such that if $n \geq N$, then $d\left(x, x_{n}\right)<\varepsilon$. $\left\{x_{n}\right\}$ is a Cauchy sequence iffor every $\varepsilon>0$ there exists $N$ such that if $m, n \geq N$, then $d\left(x_{n}, x_{m}\right)<\varepsilon$.

Lemma 7.1.3 In a metric space, $X$ every ball, $B(x, r)$ is open. A set is closed if and only if it contains all its limit points. If $p$ is a limit point of $S$, then there exists a sequence of distinct points of $S,\left\{x_{n}\right\}$ such that $\lim _{n \rightarrow \infty} x_{n}=p$.

Proof: Let $z \in B(x, r)$. Let $\delta=r-d(x, z)$. Then if $w \in B(z, \delta)$,

$$
d(w, x) \leq d(x, z)+d(z, w)<d(x, z)+r-d(x, z)=r
$$

Therefore, $B(z, \delta) \subseteq B(x, r)$ and this shows $B(x, r)$ is open.
The properties of balls are presented in the following theorem.
Theorem 7.1.4 Suppose $(X, d)$ is a metric space. Then the sets $\{B(x, r): r>0, x \in X\}$ satisfy

$$
\begin{equation*}
\cup\{B(x, r): r>0, x \in X\}=X \tag{7.1.1}
\end{equation*}
$$

If $p \in B\left(x, r_{1}\right) \cap B\left(z, r_{2}\right)$, there exists $r>0$ such that

$$
\begin{equation*}
B(p, r) \subseteq B\left(x, r_{1}\right) \cap B\left(z, r_{2}\right) \tag{7.1.2}
\end{equation*}
$$

Proof: Observe that the union of these balls includes the whole space, $X$ so 7.1.1 is obvious. Consider 7.1.2. Let $p \in B\left(x, r_{1}\right) \cap B\left(z, r_{2}\right)$. Consider

$$
r \equiv \min \left(r_{1}-d(x, p), r_{2}-d(z, p)\right)
$$

and suppose $y \in B(p, r)$. Then

$$
d(y, x) \leq d(y, p)+d(p, x)<r_{1}-d(x, p)+d(x, p)=r_{1}
$$

and so $B(p, r) \subseteq B\left(x, r_{1}\right)$. By similar reasoning, $B(p, r) \subseteq B\left(z, r_{2}\right)$. This proves the theorem.

Let $K$ be a closed set. This means $K^{C} \equiv X \backslash K$ is an open set. Let $p$ be a limit point of $K$. If $p \in K^{C}$, then since $K^{C}$ is open, there exists $B(p, r) \subseteq K^{C}$. But this contradicts $p$ being a limit point because there are no points of $K$ in this ball. Hence all limit points of $K$ must be in $K$.

Suppose next that $K$ contains its limit points. Is $K^{C}$ open? Let $p \in K^{C}$. Then $p$ is not a limit point of $K$. Therefore, there exists $B(p, r)$ which contains at most finitely many points of $K$. Since $p \notin K$, it follows that by making $r$ smaller if necessary, $B(p, r)$ contains no points of $K$. That is $B(p, r) \subseteq K^{C}$ showing $K^{C}$ is open. Therefore, $K$ is closed.

Suppose now that $p$ is a limit point of $S$. Let $x_{1} \in(S \backslash\{p\}) \cap B(p, 1)$. If $x_{1}, \cdots, x_{k}$ have been chosen, let

$$
r_{k+1} \equiv \min \left\{d\left(p, x_{i}\right), i=1, \cdots, k, \frac{1}{k+1}\right\}
$$

Let $x_{k+1} \in(S \backslash\{p\}) \cap B\left(p, r_{k+1}\right)$. This proves the lemma.
Lemma 7.1.5 If $\left\{x_{n}\right\}$ is a Cauchy sequence in a metric space, $X$ and if some subsequence, $\left\{x_{n_{k}}\right\}$ converges to $x$, then $\left\{x_{n}\right\}$ converges to $x$. Also if a sequence converges, then it is $a$ Cauchy sequence.

Proof: Note first that $n_{k} \geq k$ because in a subsequence, the indices, $n_{1}, n_{2}, \cdots$ are strictly increasing. Let $\varepsilon>0$ be given and let $N$ be such that for $k>N, d\left(x, x_{n_{k}}\right)<\varepsilon / 2$ and for $m, n \geq N, d\left(x_{m}, x_{n}\right)<\varepsilon / 2$. Pick $k>n$. Then if $n>N$,

$$
d\left(x_{n}, x\right) \leq d\left(x_{n}, x_{n_{k}}\right)+d\left(x_{n_{k}}, x\right)<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon .
$$

Finally, suppose $\lim _{n \rightarrow \infty} x_{n}=x$. Then there exists $N$ such that if $n>N$, then $d\left(x_{n}, x\right)<\varepsilon / 2$. it follows that for $m, n>N$,

$$
d\left(x_{n}, x_{m}\right) \leq d\left(x_{n}, x\right)+d\left(x, x_{m}\right)<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
$$

This proves the lemma.
A useful idea is the idea of distance from a point to a set.

Definition 7.1.6 Let $(X, d)$ be a metric space and let $S$ be a nonempty set in $X$. Then

$$
\operatorname{dist}(x, S) \equiv \inf \{d(x, y): y \in S\}
$$

The following lemma is the fundamental result.
Lemma 7.1.7 The function, $x \rightarrow \operatorname{dist}(x, S)$ is continuous and in fact satisfies

$$
|\operatorname{dist}(x, S)-\operatorname{dist}(y, S)| \leq d(x, y)
$$

Proof: Suppose dist $(x, y)$ is as least as large as dist $(y, S)$. Then pick $z \in S$ such that $d(y, z) \leq \operatorname{dist}(y, S)+\varepsilon$. Then

$$
\begin{aligned}
|\operatorname{dist}(x, S)-\operatorname{dist}(y, S)| & =\operatorname{dist}(x, S)-\operatorname{dist}(y, S) \\
& \leq d(x, z)-(d(y, z)-\varepsilon) \\
& =d(x, z)-d(y, z)+\varepsilon \\
& \leq d(x, y)+d(y, z)-d(y, z)+\varepsilon \\
& =d(x, y)+\varepsilon .
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this proves the lemma.

### 7.2 Open and Closed Sets, Sequences, Limit Points

It is most efficient to discus things in terms of abstract metric spaces to begin with.
Definition 7.2.1 A non empty set $X$ is called a metric space if there is a function $d: X \times$ $X \rightarrow[0, \infty)$ which satisfies the following axioms.

1. $d(x, y)=d(y, x)$
2. $d(x, y) \geq 0$ and equals 0 if and only if $x=y$
3. $d(x, y)+d(y, z) \geq d(x, z)$

This function d is called the metric. We often refer to it as the distance also.
Definition 7.2.2 An open ball, denoted as $B(x, r)$ is defined as follows.

$$
B(x, r) \equiv\{y: d(x, y)<r\}
$$

A set $U$ is said to be open if whenever $x \in U$, it follows that there is $r>0$ such that $B(x, r) \subseteq U$. More generally, a point $x$ is said to be an interior point of $U$ if there exists such a ball. In words, an open set is one for which every point is an interior point.

For example, you could have $X$ be a subset of $\mathbb{R}$ and $d(x, y)=|x-y|$.
Then the first thing to show is the following.
Proposition 7.2.3 An open ball is an open set.
Proof: Suppose $y \in B(x, r)$. We need to verify that $y$ is an interior point of $B(x, r)$. Let $\delta=r-d(x, y)$. Then if $z \in B(y, \boldsymbol{\delta})$, it follows that

$$
d(z, x) \leq d(z, y)+d(y, x)<\delta+d(y, x)=r-d(x, y)+d(y, x)=r
$$

Thus $y \in B(y, \delta) \subseteq B(x, r)$.
Definition 7.2.4 Let $S$ be a nonempty subset of a metric space. Then $p$ is a limit point (accumulation point) of $S$ iffor every $r>0$ there exists a point different than $p$ in $B(p, r) \cap S$. Sometimes people denote the set of limit points as $S^{\prime}$.

The following proposition is fairly obvious from the above definition and will be used whenever convenient. It is equivalent to the above definition and so it can take the place of the above definition if desired.

Proposition 7.2.5 A point $x$ is a limit point of the nonempty set $A$ if and only if every $B(x, r)$ contains infinitely many points of $A$.

Proof: $\Leftarrow$ is obvious. Consider $\Rightarrow$. Let $x$ be a limit point. Let $r_{1}=1$. Then $B\left(x, r_{1}\right)$ contains $a_{1} \neq x$. If $\left\{a_{1}, \cdots, a_{n}\right\}$ have been chosen none equal to $x$ and with no repeats in the list, let $0<r_{n}<\min \left(\frac{1}{n}, \min \left\{d\left(a_{i}, x\right), i=1,2, \cdots n\right\}\right)$. Then let $a_{n+1} \in B\left(x, r_{n}\right)$. Thus every $B(x, r)$ contains $B\left(x, r_{n}\right)$ for all $n$ large enough and hence it contains $a_{k}$ for $k \geq n$ where the $a_{k}$ are distinct, none equal to $x$.

A related idea is the notion of the limit of a sequence. Recall that a sequence is really just a mapping from $\mathbb{N}$ to $X$. We write them as $\left\{x_{n}\right\}$ or $\left\{x_{n}\right\}_{n=1}^{\infty}$ if we want to emphasize the values of $n$. Then the following definition is what it means for a sequence to converge.

Definition 7.2.6 We say that $x=\lim _{n \rightarrow \infty} x_{n}$ when for every $\varepsilon>0$ there exists $N$ such that if $n \geq N$, then

$$
d\left(x, x_{n}\right)<\varepsilon
$$

Often we write $x_{n} \rightarrow x$ for short. This is equivalent to saying

$$
\lim _{n \rightarrow \infty} d\left(x, x_{n}\right)=0
$$

Proposition 7.2.7 The limit is well defined. That is, if $x, x^{\prime}$ are both limits of a sequence, then $x=x^{\prime}$.

Proof: From the definition, there exist $N, N^{\prime}$ such that if $n \geq N$, then $d\left(x, x_{n}\right)<\varepsilon / 2$ and if $n \geq N^{\prime}$, then $d\left(x, x_{n}\right)<\varepsilon / 2$. Then let $M \geq \max \left(N, N^{\prime}\right)$. Let $n>M$. Then

$$
d\left(x, x^{\prime}\right) \leq d\left(x, x_{n}\right)+d\left(x_{n}, x^{\prime}\right)<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
$$

Since $\varepsilon$ is arbitrary, this shows that $x=x^{\prime}$ because $d\left(x, x^{\prime}\right)=0$.
Next there is an important theorem about limit points and convergent sequences.
Theorem 7.2.8 Let $S \neq \emptyset$. Then $p$ is a limit point of $S$ if and only if there exists a sequence of distinct points of $S,\left\{x_{n}\right\}$ none of which equal $p$ such that $\lim _{n \rightarrow \infty} x_{n}=p$.

Proof: $\Longrightarrow$ Suppose $p$ is a limit point. Why does there exist the promissed convergent sequence? Let $x_{1} \in B(p, 1) \cap S$ such that $x_{1} \neq p$. If $x_{1}, \cdots, x_{n}$ have been chosen, let $x_{n+1} \neq p$ be in $B\left(p, \delta_{n+1}\right) \cap S$ where

$$
\delta_{n+1}=\min \left\{\frac{1}{n+1}, d\left(x_{i}, p\right), i=1,2, \cdots, n\right\} .
$$

Then this constructs the necessary convergent sequence.
$\Longleftarrow$ Conversely, if such a sequence $\left\{x_{n}\right\}$ exists, then for every $r>0, B(p, r)$ contains $x_{n} \in S$ for all $n$ large enough. Hence, $p$ is a limit point because none of these $x_{n}$ are equal to $p$.

Definition 7.2.9 $A$ set $H$ is closed means $H^{C}$ is open.
Note that this says that the complement of an open set is closed. If $V$ is open, then the complement of its complement is itself. Thus $\left(V^{C}\right)^{C}=V$ an open set. Hence $V^{C}$ is closed.

Then the following theorem gives the relationship between closed sets and limit points.
Theorem 7.2.10 A set $H$ is closed if and only if it contains all of its limit points.
Proof: $\Longrightarrow$ Let $H$ be closed and let $p$ be a limit point. We need to verify that $p \in H$. If it is not, then since $H$ is closed, its complement is open and so there exists $\delta>0$ such that $B(p, \delta) \cap H=\emptyset$. However, this prevents $p$ from being a limit point.
$\Longleftarrow$ Next suppose $H$ has all of its limit points. Why is $H^{C}$ open? If $p \in H^{C}$ then it is not a limit point and so there exists $\delta>0$ such that $B(p, \delta)$ has no points of $H$. In other words, $H^{C}$ is open. Hence $H$ is closed.

Corollary 7.2.11 $A$ set $H$ is closed if and only if whenever $\left\{h_{n}\right\}$ is a sequence of points of $H$ which converges to a point $x$, it follows that $x \in H$.

Proof: $\Longrightarrow$ Suppose $H$ is closed and $h_{n} \rightarrow x$. If $x \in H$ there is nothing left to show. If $x \notin H$, then from the definition of limit, it is a limit point of $H$ because none of the $h_{n}$ are equal to $x$. Hence $x \in H$ after all.
$\Longleftarrow$ Suppose the limit condition holds, why is $H$ closed? Let $x \in H^{\prime}$ the set of limit points of $H$. By Theorem 7.2.8 there exists a sequence of points of $H,\left\{h_{n}\right\}$ such that $h_{n} \rightarrow x$. Then by assumption, $x \in H$. Thus $H$ contains all of its limit points and so it is closed by Theorem 7.2.10.

Next is the important concept of a subsequence.
Definition 7.2.12 Let $\left\{x_{n}\right\}_{n=1}^{\infty}$ be a sequence. Then if $n_{1}<n_{2}<\cdots$ is a strictly increasing sequence of indices, we say $\left\{x_{n_{k}}\right\}_{k=1}^{\infty}$ is a subsequence of $\left\{x_{n}\right\}_{n=1}^{\infty}$.

The really important thing about subsequences is that they preserve convergence.
Theorem 7.2.13 Let $\left\{x_{n_{k}}\right\}$ be a subsequence of a convergent sequence $\left\{x_{n}\right\}$ where $x_{n} \rightarrow x$. Then

$$
\lim _{k \rightarrow \infty} x_{n_{k}}=x
$$

also.
Proof: Let $\varepsilon>0$ be given. Then there exists $N$ such that

$$
d\left(x_{n}, x\right)<\varepsilon \text { if } n \geq N
$$

It follows that if $k \geq N$, then $n_{k} \geq N$ and so

$$
d\left(x_{n_{k}}, x\right)<\varepsilon \text { if } k \geq N
$$

This is what it means to say $\lim _{k \rightarrow \infty} x_{n_{k}}=x$.

### 7.3 Cauchy Sequences, Completeness

Of course it does not go the other way. For example, you could let $x_{n}=(-1)^{n}$ and it has a convergent subsequence but fails to converge. Here $d(x, y)=|x-y|$ and the metric space is just $\mathbb{R}$.

However, there is a kind of sequence for which it does go the other way. This is called a Cauchy sequence.

Definition 7.3.1 $\left\{x_{n}\right\}$ is called a Cauchy sequence if for every $\varepsilon>0$ there exists $N$ such that if $m, n \geq N$, then

$$
d\left(x_{n}, x_{m}\right)<\varepsilon
$$

Now the major theorem about this is the following.
Theorem 7.3.2 Let $\left\{x_{n}\right\}$ be a Cauchy sequence. Then it converges if and only if any subsequence converges.

Proof: $\Longrightarrow$ This was just done above. $\Longleftarrow$ Suppose now that $\left\{x_{n}\right\}$ is a Cauchy sequence and $\lim _{k \rightarrow \infty} x_{n_{k}}=x$. Then there exists $N_{1}$ such that if $k>N_{1}$, then $d\left(x_{n_{k}}, x\right)<\varepsilon / 2$. From the definition of what it means to be Cauchy, there exists $N_{2}$ such that if $m, n \geq N_{2}$, then $d\left(x_{m}, x_{n}\right)<\varepsilon / 2$. Let $N \geq \max \left(N_{1}, N_{2}\right)$. Then if $k \geq N$, then $n_{k} \geq N$ and so

$$
\begin{equation*}
d\left(x, x_{k}\right) \leq d\left(x, x_{n_{k}}\right)+d\left(x_{n_{k}}, x_{k}\right)<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon \tag{7.3.3}
\end{equation*}
$$

It follows from the definition that $\lim _{k \rightarrow \infty} x_{k}=x$.
Definition 7.3.3 A metric space is said to be complete if every Cauchy sequence converges.
There certainly are metric spaces which are not complete. For example, if you consider $\mathbb{Q}$ with $d(x, y) \equiv|x-y|$, this will not be complete because you can get a sequence which is obtained as $x_{n}$ defined as the $n$ decimal place description of $\sqrt{2}$. However, if a sequence converges, then it must be Cauchy.

Lemma 7.3.4 If $x_{n} \rightarrow x$, then $\left\{x_{n}\right\}$ is a Cauchy sequence.
Proof: Let $\varepsilon>0$. Then there exists $n_{\varepsilon}$ such that if $m \geq n_{\varepsilon}$, then $d\left(x, x_{m}\right)<\varepsilon / 2$. If $m, k \geq n_{\mathcal{E}}$, then by the triangle inequality,

$$
d\left(x_{m}, x_{k}\right) \leq d\left(x_{m}, x\right)+d\left(x, x_{k}\right)<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
$$

showing that the convergent sequence is indeed a Cauchy sequence as claimed.
Another nice thing to note is this.
Proposition 7.3.5 If $\left\{x_{n}\right\}$ is a sequence and if $p$ is a limit point of the set $S=\cup_{n=1}^{\infty}\left\{x_{n}\right\}$ then there is a subsequence $\left\{x_{n_{k}}\right\}$ such that $\lim _{k \rightarrow \infty} x_{n_{k}}=x$.

Proof: By Theorem 7.2.8, there exists a sequence of distinct points of $S$ denoted as $\left\{y_{k}\right\}$ such that none of them equal $p$ and $\lim _{k \rightarrow \infty} y_{k}=p$. Thus $B(p, r)$ contains infinitely many different points of the set $D$, this for every $r$. Let $x_{n_{1}} \in B(p, 1)$ where $n_{1}$ is the first index such that $x_{n_{1}} \in B(p, 1)$. Suppose $x_{n_{1}}, \cdots, x_{n_{k}}$ have been chosen, the $n_{i}$ increasing and let $1>\delta_{1}>\delta_{2}>\cdots>\delta_{k}$ where $x_{n_{i}} \in B\left(p, \delta_{i}\right)$. Then let

$$
\delta_{k+1}<\min \left\{\frac{1}{2^{k+1}}, d\left(p, x_{n_{j}}\right), \delta_{j}, j=1,2 \cdots, k\right\}
$$

Let $x_{n_{k+1}} \in B\left(p, \delta_{k+1}\right)$ where $n_{k+1}$ is the first index such that $x_{n_{k+1}}$ is contained $B\left(p, \delta_{k+1}\right)$. Then

$$
\lim _{k \rightarrow \infty} x_{n_{k}}=p
$$

Another useful result is the following.
Lemma 7.3.6 Suppose $x_{n} \rightarrow x$ and $y_{n} \rightarrow y$. Then $d\left(x_{n}, y_{n}\right) \rightarrow d(x, y)$.
Proof: Consider the following.

$$
d(x, y) \leq d\left(x, x_{n}\right)+d\left(x_{n}, y\right) \leq d\left(x, x_{n}\right)+d\left(x_{n}, y_{n}\right)+d\left(y_{n}, y\right)
$$

so

$$
d(x, y)-d\left(x_{n}, y_{n}\right) \leq d\left(x, x_{n}\right)+d\left(y_{n}, y\right)
$$

Similarly

$$
d\left(x_{n}, y_{n}\right)-d(x, y) \leq d\left(x, x_{n}\right)+d\left(y_{n}, y\right)
$$

and so

$$
\left|d\left(x_{n}, y_{n}\right)-d(x, y)\right| \leq d\left(x, x_{n}\right)+d\left(y_{n}, y\right)
$$

and the right side converges to 0 as $n \rightarrow \infty$.

### 7.4 Closure Of A Set

Next is the topic of the closure of a set.
Definition 7.4.1 Let A be a nonempty subset of $(X, d)$ a metric space. Then $\bar{A}$ is defined to be the intersection of all closed sets which contain $A$. Note the whole space, $X$ is one such closed set which contains $A$. The whole space $X$ is closed because its complement is open, its complement being $\emptyset$. It is certainly true that every point of the empty set is an interior point because there are no points of $\emptyset$.

Lemma 7.4.2 Let $A$ be a nonempty set in $(X, d)$. Then $\bar{A}$ is a closed set and

$$
\bar{A}=A \cup A^{\prime}
$$

where $A^{\prime}$ denotes the set of limit points of $A$.

Proof: First of all, denote by $\mathscr{C}$ the set of closed sets which contain $A$. Then

$$
\bar{A}=\cap \mathscr{C}
$$

and this will be closed if its complement is open. However,

$$
\bar{A}^{C}=\cup\left\{H^{C}: H \in \mathscr{C}\right\}
$$

Each $H^{C}$ is open and so the union of all these open sets must also be open. This is because if $x$ is in this union, then it is in at least one of them. Hence it is an interior point of that one. But this implies it is an interior point of the union of them all which is an even larger set. Thus $\bar{A}$ is closed.

The interesting part is the next claim. First note that from the definition, $A \subseteq \bar{A}$ so if $x \in A$, then $x \in \bar{A}$. Now consider $y \in A^{\prime}$ but $y \notin A$. If $y \notin \bar{A}$, a closed set, then there exists $B(y, r) \subseteq \bar{A}^{C}$. Thus $y$ cannot be a limit point of $A$, a contradiction. Therefore,

$$
A \cup A^{\prime} \subseteq \bar{A}
$$

Next suppose $x \in \bar{A}$ and suppose $x \notin A$. Then if $B(x, r)$ contains no points of $A$ different than $x$, since $x$ itself is not in $A$, it would follow that $B(x, r) \cap A=\emptyset$ and so recalling that open balls are open, $B(x, r)^{C}$ is a closed set containing $A$ so from the definition, it also contains $\bar{A}$ which is contrary to the assertion that $x \in \bar{A}$. Hence if $x \notin A$, then $x \in A^{\prime}$ and so

$$
A \cup A^{\prime} \supseteq \bar{A}
$$

### 7.5 Separable Metric Spaces

Definition 7.5.1 A metric space is called separable if there exists a countable dense subset D. This means two things. First, $D$ is countable, and second, that if $x$ is any point and $r>0$, then $B(x, r) \cap D \neq \emptyset$. A metric space is called completely separable if there exists $a$ countable collection of nonempty open sets $\mathscr{B}$ such that every open set is the union of some subset of $\mathscr{B}$. This collection of open sets is called a countable basis.

For those who like to fuss about empty sets, the empty set is open and it is indeed the union of a subset of $\mathscr{B}$ namely the empty subset.

Theorem 7.5.2 A metric space is separable if and only if it is completely separable.
Proof: $\Longleftarrow$ Let $\mathscr{B}$ be the special countable collection of open sets and for each $B \in \mathscr{B}$, let $p_{B}$ be a point of $B$. Then let $\mathscr{P} \equiv\left\{p_{B}: B \in \mathscr{B}\right\}$. If $B(x, r)$ is any ball, then it is the union of sets of $\mathscr{B}$ and so there is a point of $\mathscr{P}$ in it. Since $\mathscr{B}$ is countable, so is $\mathscr{P}$.
$\Longrightarrow$ Let $D$ be the countable dense set and let $\mathscr{B} \equiv\{B(d, r): d \in D, r \in \mathbb{Q} \cap[0, \infty)\}$. Then $\mathscr{B}$ is countable because the Cartesian product of countable sets is countable. It suffices to show that every ball is the union of these sets. Let $B(x, R)$ be a ball. Let $y \in B(y, \delta) \subseteq B(x, R)$. Then there exists $d \in B\left(y, \frac{\delta}{10}\right)$. Let $\varepsilon \in \mathbb{Q}$ and $\frac{\delta}{10}<\varepsilon<\frac{\delta}{5}$. Then $y \in B(d, \varepsilon) \in \mathscr{B}$. Is $B(d, \varepsilon) \subseteq B(x, R)$ ? If so, then the desired result follows because this
would show that every $y \in B(x, R)$ is contained in one of these sets of $\mathscr{B}$ which is contained in $B(x, R)$ showing that $B(x, R)$ is the union of sets of $\mathscr{B}$. Let $z \in B(d, \varepsilon) \subseteq B\left(d, \frac{\delta}{5}\right)$. Then

$$
d(y, z) \leq d(y, d)+d(d, z)<\frac{\delta}{10}+\varepsilon<\frac{\delta}{10}+\frac{\delta}{5}<\delta
$$

Hence $B(d, \varepsilon) \subseteq B(y, \delta) \subseteq B(x, r)$. Therefore, every ball is the union of sets of $\mathscr{B}$ and, since every open set is the union of balls, it follows that every open set is the union of sets of $\mathscr{B}$.

Definition 7.5.3 Let $S$ be a nonempty set. Then a set of open sets $\mathscr{C}$ is called an open cover of $S$ if $\cup \mathscr{C} \supseteq \mathscr{S}$. (It covers up the set $S$. Think lilly pads covering the surface of a pond.)

One of the important properties possessed by separable metric spaces is the Lindeloff property.

Definition 7.5.4 A metric space has the Lindeloff property if whenever $\mathscr{C}$ is an open cover of a set $S$, there exists a countable subset of $\mathscr{C}$ denoted here by $\mathscr{B}$ such that $\mathscr{B}$ is also an open cover of $S$.

Theorem 7.5.5 Every separable metric space has the Lindeloff property.
Proof: Let $\mathscr{C}$ be an open cover of a set $S$. Let $\mathscr{B}$ be a countable basis. Such exists by Theorem 7.5.2. Let $\hat{\mathscr{B}}$ denote those sets of $\mathscr{B}$ which are contained in some set of $\mathscr{C}$. Thus $\hat{\mathscr{B}}$ is a countable open cover of $S$. Now for $B \in \mathscr{B}$, let $U_{B}$ be a set of $\mathscr{C}$ which contains $B$. Letting $\widehat{\mathscr{C}}$ denote these sets $U_{B}$ it follows that $\widehat{\mathscr{C}}$ is countable and is an open cover of $S$.

Definition 7.5.6 A Polish space is a complete separable metric space. These things turn out to be very useful in probability theory and in other areas.

### 7.6 Compactness In Metric Space

Many existence theorems in analysis depend on some set being compact. Therefore, it is important to be able to identify compact sets. The purpose of this section is to describe compact sets in a metric space.

Definition 7.6.1 Let $A$ be a subset of $X$. A is compact if whenever $A$ is contained in the union of a set of open sets, there exists finitely many of these open sets whose union contains A. (Every open cover admits a finite subcover.) A is "sequentially compact" means every sequence has a convergent subsequence converging to an element of $A$.

In a metric space compact is not the same as closed and bounded!
Example 7.6.2 Let $X$ be any infinite set and define $d(x, y)=1$ if $x \neq y$ while $d(x, y)=0$ if $x=y$.

You should verify the details that this is a metric space because it satisfies the axioms of a metric. The set $X$ is closed and bounded because its complement is $\emptyset$ which is clearly open because every point of $\emptyset$ is an interior point. (There are none.) Also $X$ is bounded because $X=B(x, 2)$. However, $X$ is clearly not compact because $\left\{B\left(x, \frac{1}{2}\right): x \in X\right\}$ is a collection of open sets whose union contains $X$ but since they are all disjoint and nonempty, there is no finite subset of these whose union contains $X$. In fact $B\left(x, \frac{1}{2}\right)=\{x\}$.

From this example it is clear something more than closed and bounded is needed. If you are not familiar with the issues just discussed, ignore them and continue.

Definition 7.6.3 In any metric space, a set $E$ is totally bounded if for every $\varepsilon>0$ there exists a finite set of points $\left\{x_{1}, \cdots, x_{n}\right\}$ such that

$$
E \subseteq \cup_{i=1}^{n} B\left(x_{i}, \varepsilon\right)
$$

This finite set of points is called an $\varepsilon$ net.
The following proposition tells which sets in a metric space are compact. First here is an interesting lemma.

Lemma 7.6.4 Let $X$ be a metric space and suppose $D$ is a countable dense subset of $X$. In other words, it is being assumed $X$ is a separable metric space. Consider the open sets of the form $B(d, r)$ where $r$ is a positive rational number and $d \in D$. Denote this countable collection of open sets by $\mathscr{B}$. Then every open set is the union of sets of $\mathscr{B}$. Furthermore, if $\mathscr{C}$ is any collection of open sets, there exists a countable subset, $\left\{U_{n}\right\} \subseteq \mathscr{C}$ such that $\cup_{n} U_{n}=\cup \mathscr{C}$.

Proof: Let $U$ be an open set and let $x \in U$. Let $B(x, \delta) \subseteq U$. Then by density of $D$, there exists $d \in D \cap B(x, \delta / 4)$. Now pick $r \in \mathbb{Q} \cap(\delta / 4,3 \delta / 4)$ and consider $B(d, r)$. Clearly, $B(d, r)$ contains the point $x$ because $r>\delta / 4$. Is $B(d, r) \subseteq B(x, \delta)$ ? if so, this proves the lemma because $x$ was an arbitrary point of $U$. Suppose $z \in B(d, r)$. Then

$$
d(z, x) \leq d(z, d)+d(d, x)<r+\frac{\delta}{4}<\frac{3 \delta}{4}+\frac{\delta}{4}=\delta
$$

Now let $\mathscr{C}$ be any collection of open sets. Each set in this collection is the union of countably many sets of $\mathscr{B}$. Let $\mathscr{B}^{\prime}$ denote the sets of $\mathscr{B}$ which are contained in some set of $\mathscr{C}$. Thus $\cup \mathscr{B}^{\prime}=\cup \mathscr{C}$. Then for each $B \in \mathscr{B}^{\prime}$, pick $U_{B} \in \mathscr{C}$ such that $B \subseteq U_{B}$. Then $\left\{U_{B}: B \in \mathscr{B}^{\prime}\right\}$ is a countable collection of sets of $\mathscr{C}$ whose union equals $\cup \mathscr{C}$. Therefore, this proves the lemma.

Proposition 7.6.5 Let $(X, d)$ be a metric space. Then the following are equivalent.

$$
\begin{equation*}
(X, d) \text { is compact } \tag{7.6.4}
\end{equation*}
$$

( $X, d$ ) is sequentially compact,

$$
\begin{equation*}
(X, d) \text { is complete and totally bounded. } \tag{7.6.5}
\end{equation*}
$$

Proof: Suppose 7.6.4 and let $\left\{x_{k}\right\}$ be a sequence. Suppose $\left\{x_{k}\right\}$ has no convergent subsequence. If this is so, then no value of the sequence is repeated more than finitely many times. Also $\left\{x_{k}\right\}$ has no limit point because if it did, there would exist a subsequence which converges. To see this, suppose $p$ is a limit point of $\left\{x_{k}\right\}$. Then in $B(p, 1)$ there are infinitely many points of $\left\{x_{k}\right\}$. Pick one called $x_{k_{1}}$. Now if $x_{k_{1}}, x_{k_{2}}, \cdots, x_{k_{n}}$ have been picked with $x_{k_{i}} \in B(p, 1 / i)$, consider $B(p, 1 /(n+1))$. There are infinitely many points of $\left\{x_{k}\right\}$ in this ball also. Pick $x_{k_{n+1}}$ such that $k_{n+1}>k_{n}$. Then $\left\{x_{k_{n}}\right\}_{n=1}^{\infty}$ is a subsequence which converges to $p$ and it is assumed this does not happen. Thus $\left\{x_{k}\right\}$ has no limit points. It follows the set

$$
C_{n}=\cup\left\{x_{k}: k \geq n\right\}
$$

is a closed set because it has no limit points and if

$$
U_{n}=C_{n}^{C}
$$

then

$$
X=\cup_{n=1}^{\infty} U_{n}
$$

but there is no finite subcovering, because no value of the sequence is repeated more than finitely many times. This contradicts compactness of $(X, d)$. Note $x_{k}$ is not in $U_{n}$ whenever $k>n$. Thus 7.6.4 implies 7.6.5.

Now suppose 7.6.5 and let $\left\{x_{n}\right\}$ be a Cauchy sequence. Is $\left\{x_{n}\right\}$ convergent? By sequential compactness $x_{n_{k}} \rightarrow x$ for some subsequence. By Lemma 7.1.5 it follows that $\left\{x_{n}\right\}$ also converges to $x$ showing that $(X, d)$ is complete. If $(X, d)$ is not totally bounded, then there exists $\varepsilon>0$ for which there is no $\varepsilon$ net. Hence there exists a sequence $\left\{x_{k}\right\}$ with $d\left(x_{k}, x_{l}\right) \geq \varepsilon$ for all $l \neq k$. By Lemma 7.1.5 again, this contradicts 7.6.5 because no subsequence can be a Cauchy sequence and so no subsequence can converge. This shows 7.6.5 implies 7.6.6.

Now suppose 7.6.6. What about 7.6.5? Let $\left\{p_{n}\right\}$ be a sequence and let $\left\{x_{i}^{n}\right\}_{i=1}^{m_{n}}$ be a $2^{-n}$ net for $n=1,2, \cdots$. Let

$$
B_{n} \equiv B\left(x_{i_{n}}^{n}, 2^{-n}\right)
$$

be such that $B_{n}$ contains $p_{k}$ for infinitely many values of $k$ and $B_{n} \cap B_{n+1} \neq \emptyset$. To do this, suppose $B_{n}$ contains $p_{k}$ for infinitely many values of $k$. Then one of the sets which intersect $B_{n}, B\left(x_{i}^{n+1}, 2^{-(n+1)}\right)$ must contain $p_{k}$ for infinitely many values of $k$ because all these indices of points from $\left\{p_{n}\right\}$ contained in $B_{n}$ must be accounted for in one of finitely many sets, $B\left(x_{i}^{n+1}, 2^{-(n+1)}\right)$. Thus there exists a strictly increasing sequence of integers, $n_{k}$ such that

$$
p_{n_{k}} \in B_{k} .
$$

Then if $k \geq l$,

$$
\begin{aligned}
d\left(p_{n_{k}}, p_{n_{l}}\right) & \leq \sum_{i=l}^{k-1} d\left(p_{n_{i+1}}, p_{n_{i}}\right) \\
& <\sum_{i=l}^{k-1} 2^{-(i-1)}<2^{-(l-2)}
\end{aligned}
$$

Consequently $\left\{p_{n_{k}}\right\}$ is a Cauchy sequence. Hence it converges because the metric space is complete. This proves 7.6.5.

Now suppose 7.6 .5 and 7.6 .6 which have now been shown to be equivalent. Let $D_{n}$ be a $n^{-1}$ net for $n=1,2, \cdots$ and let

$$
D=\cup_{n=1}^{\infty} D_{n}
$$

Thus $D$ is a countable dense subset of $(X, d)$.
Now let $\mathscr{C}$ be any set of open sets such that $\cup \mathscr{C} \supseteq X$. By Lemma 7.6.4, there exists a countable subset of $\mathscr{C}$,

$$
\tilde{\mathscr{C}}=\left\{U_{n}\right\}_{n=1}^{\infty}
$$

such that $\cup \widetilde{\mathscr{C}}=\cup \mathscr{C}$. If $\mathscr{C}$ admits no finite subcover, then neither does $\tilde{\mathscr{C}}$ and there exists $p_{n} \in X \backslash \cup_{k=1}^{n} U_{k}$. Then since $X$ is sequentially compact, there is a subsequence $\left\{p_{n_{k}}\right\}$ such that $\left\{p_{n_{k}}\right\}$ converges. Say

$$
p=\lim _{k \rightarrow \infty} p_{n_{k}} .
$$

All but finitely many points of $\left\{p_{n_{k}}\right\}$ are in $X \backslash \cup_{k=1}^{n} U_{k}$. Therefore $p \in X \backslash \cup_{k=1}^{n} U_{k}$ for each $n$. Hence

$$
p \notin \cup_{k=1}^{\infty} U_{k}
$$

contradicting the construction of $\left\{U_{n}\right\}_{n=1}^{\infty}$ which required that $\cup_{n=1}^{\infty} U_{n} \supseteq X$. Hence $X$ is compact. This proves the proposition.

Consider $\mathbb{R}^{n}$. In this setting totally bounded and bounded are the same. This will yield a proof of the Heine Borel theorem from advanced calculus.

Lemma 7.6.6 A subset of $\mathbb{R}^{n}$ is totally bounded if and only if it is bounded.
Proof: Let $A$ be totally bounded. Is it bounded? Let $\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}$ be a 1 net for $A$. Now consider the ball $B(\mathbf{0}, r+1)$ where $r>\max \left(\left|\mathbf{x}_{i}\right|: i=1, \cdots, p\right)$. If $\mathbf{z} \in A$, then $\mathbf{z} \in B\left(\mathbf{x}_{j}, 1\right)$ for some $j$ and so by the triangle inequality,

$$
|\mathbf{z}-\mathbf{0}| \leq\left|\mathbf{z}-\mathbf{x}_{j}\right|+\left|\mathbf{x}_{j}\right|<1+r
$$

Thus $A \subseteq B(\mathbf{0}, r+1)$ and so $A$ is bounded.
Now suppose $A$ is bounded and suppose $A$ is not totally bounded. Then there exists $\varepsilon>0$ such that there is no $\varepsilon$ net for $A$. Therefore, there exists a sequence of points $\left\{a_{i}\right\}$ with $\left|a_{i}-a_{j}\right| \geq \varepsilon$ if $i \neq j$. Since $A$ is bounded, there exists $r>0$ such that

$$
A \subseteq[-r, r)^{n}
$$

$\left(\mathbf{x} \in[-r, r)^{n}\right.$ means $x_{i} \in[-r, r)$ for each $i$.) Now define $\mathscr{S}$ to be all cubes of the form

$$
\prod_{k=1}^{n}\left[a_{k}, b_{k}\right)
$$

where

$$
a_{k}=-r+i 2^{-p} r, b_{k}=-r+(i+1) 2^{-p} r
$$

for $i \in\left\{0,1, \cdots, 2^{p+1}-1\right\}$. Thus $\mathscr{S}$ is a collection of $\left(2^{p+1}\right)^{n}$ non overlapping cubes whose union equals $[-r, r)^{n}$ and whose diameters are all equal to $2^{-p} r \sqrt{n}$. Now choose $p$ large enough that the diameter of these cubes is less than $\varepsilon$. This yields a contradiction because one of the cubes must contain infinitely many points of $\left\{a_{i}\right\}$. This proves the lemma.

The next theorem is called the Heine Borel theorem and it characterizes the compact sets in $\mathbb{R}^{n}$.

Theorem 7.6.7 A subset of $\mathbb{R}^{n}$ is compact if and only if it is closed and bounded.
Proof: Since a set in $\mathbb{R}^{n}$ is totally bounded if and only if it is bounded, this theorem follows from Proposition 7.6 .5 and the observation that a subset of $\mathbb{R}^{n}$ is closed if and only if it is complete. This proves the theorem.

Proposition 7.6.8 If $K$ is a closed, nonempty subset of a nonempty compact set $H$, then $K$ is compact.

Proof: Let $\mathscr{C}$ be an open cover for $K$. Then $\mathscr{C} \cup\left\{K^{C}\right\}$ is an open cover for $H$. Thus there are finitely many sets from this last collection of open sets, $U_{1}, \cdots, U_{m}$ which covers $H$. Include only those which are in $\mathscr{C}$. These cover $K$ because $K^{C}$ covers no points of $K$.

### 7.7 Some Applications Of Compactness

The following corollary is an important existence theorem which depends on compactness.
Theorem 7.7.1 Let $X$ be a compact metric space and let $f: X \rightarrow \mathbb{R}$ be continuous. Then $\max \{f(x): x \in X\}$ and $\min \{f(x): x \in X\}$ both exist.

Proof: First it is shown $f(X)$ is compact. Suppose $\mathscr{C}$ is a set of open sets whose union contains $f(X)$. Then since $f$ is continuous $f^{-1}(U)$ is open for all $U \in \mathscr{C}$. Therefore, $\left\{f^{-1}(U): U \in \mathscr{C}\right\}$ is a collection of open sets whose union contains $X$. Since $X$ is compact, it follows finitely many of these, $\left\{f^{-1}\left(U_{1}\right), \cdots, f^{-1}\left(U_{p}\right)\right\}$ contains $X$ in their union. Therefore, $f(X) \subseteq \cup_{k=1}^{p} U_{k}$ showing $f(X)$ is compact as claimed.

Now since $f(X)$ is compact, Theorem 7.6.7 implies $f(X)$ is closed and bounded. Therefore, it contains its inf and its sup. Thus $f$ achieves both a maximum and a minimum.

Definition 7.7.2 Let $X, Y$ be metric spaces and $f: X \rightarrow Y$ a function. $f$ is uniformly continuous if for all $\varepsilon>0$ there exists $\delta>0$ such that whenever $x_{1}$ and $x_{2}$ are two points of $X$ satisfying $d\left(x_{1}, x_{2}\right)<\delta$, it follows that $d\left(f\left(x_{1}\right), f\left(x_{2}\right)\right)<\varepsilon$.

A very important theorem is the following.
Theorem 7.7.3 Suppose $f: X \rightarrow Y$ is continuous and $X$ is compact. Then $f$ is uniformly continuous.

Proof: Suppose this is not true and that $f$ is continuous but not uniformly continuous. Then there exists $\varepsilon>0$ such that for all $\delta>0$ there exist points, $p_{\delta}$ and $q_{\delta}$ such that $d\left(p_{\delta}, q_{\delta}\right)<\delta$ and yet $d\left(f\left(p_{\delta}\right), f\left(q_{\delta}\right)\right) \geq \varepsilon$. Let $p_{n}$ and $q_{n}$ be the points which go with $\delta=1 / n$. By Proposition 7.6.5 $\left\{p_{n}\right\}$ has a convergent subsequence, $\left\{p_{n_{k}}\right\}$ converging to a point, $x \in X$. Since $d\left(p_{n}, q_{n}\right)<\frac{1}{n}$, it follows that $q_{n_{k}} \rightarrow x$ also. Therefore,

$$
\varepsilon \leq d\left(f\left(p_{n_{k}}\right), f\left(q_{n_{k}}\right)\right) \leq d\left(f\left(p_{n_{k}}\right), f(x)\right)+d\left(f(x), f\left(q_{n_{k}}\right)\right)
$$

but by continuity of $f$, both $d\left(f\left(p_{n_{k}}\right), f(x)\right)$ and $d\left(f(x), f\left(q_{n_{k}}\right)\right)$ converge to 0 as $k \rightarrow \infty$ contradicting the above inequality. This proves the theorem.

Another important property of compact sets in a metric space concerns the finite intersection property.

Definition 7.7.4 If every finite subset of a collection of sets has nonempty intersection, the collection has the finite intersection property.

Theorem 7.7.5 Suppose $\mathscr{F}$ is a collection of compact sets in a metric space, $X$ which has the finite intersection property. Then there exists a point in their intersection. $(\cap \mathscr{F} \neq \emptyset)$.

Proof: First I show each compact set is closed. Let $K$ be a nonempty compact set and suppose $p \notin K$. Then for each $x \in K$, let $V_{x}=B(x, d(p, x) / 3)$ and $U_{x}=B(p, d(p, x) / 3)$ so that $U_{x}$ and $V_{x}$ have empty intersection. Then since $V$ is compact, there are finitely many $V_{x}$ which cover $K$ say $V_{x_{1}}, \cdots, V_{x_{n}}$. Then let $U=\cap_{i=1}^{n} U_{x_{i}}$. It follows $p \in U$ and $U$ has empty intersection with $K$. In fact $U$ has empty intersection with $\cup_{i=1}^{n} V_{x_{i}}$. Since $U$ is an open set and $p \in K^{C}$ is arbitrary, it follows $K^{C}$ is an open set.

Consider now the claim about the intersection. If this were not so,

$$
\cup\left\{F^{C}: F \in \mathscr{F}\right\}=X
$$

and so, in particular, picking some $F_{0} \in \mathscr{F}$,

$$
\left\{F^{C}: F \in \mathscr{F}\right\}
$$

would be an open cover of $F_{0}$. Since $F_{0}$ is compact, some finite subcover, $F_{1}^{C}, \cdots, F_{m}^{C}$ exists. But then

$$
F_{0} \subseteq \cup_{k=1}^{m} F_{k}^{C}
$$

which means $\cap_{k=0}^{m} F_{k}=\emptyset$, contrary to the finite intersection property. To see this, note that if $x \in F_{0}$, then it must fail to be in some $F_{k}$ and so it is not in $\cap_{k=0}^{m} F_{k}$. Since this is true for every $x$ it follows $\cap_{k=0}^{m} F_{k}=\emptyset$.

Theorem 7.7.6 Let $X_{i}$ be a compact metric space with metric $d_{i}$. Then $\prod_{i=1}^{m} X_{i}$ is also a compact metric space with respect to the metric, $d(\mathbf{x}, \mathbf{y}) \equiv \max _{i}\left(d_{i}\left(x_{i}, y_{i}\right)\right)$.

Proof: This is most easily seen from sequential compactness. Let $\left\{\mathbf{x}^{k}\right\}_{k=1}^{\infty}$ be a sequence of points in $\prod_{i=1}^{m} X_{i}$. Consider the $i^{t h}$ component of $\mathbf{x}^{k}, x_{i}^{k}$. It follows $\left\{x_{i}^{k}\right\}$ is a
sequence of points in $X_{i}$ and so it has a convergent subsequence. Compactness of $X_{1}$ implies there exists a subsequence of $\mathbf{x}^{k}$, denoted by $\left\{\mathbf{x}^{k_{1}}\right\}$ such that

$$
\lim _{k_{1} \rightarrow \infty} x_{1}^{k_{1}} \rightarrow x_{1} \in X_{1}
$$

Now there exists a further subsequence, denoted by $\left\{\mathbf{x}^{k_{2}}\right\}$ such that in addition to this, $x_{2}^{k_{2}} \rightarrow x_{2} \in X_{2}$. After taking $m$ such subsequences, there exists a subsequence, $\left\{\mathbf{x}^{l}\right\}$ such that $\lim _{l \rightarrow \infty} x_{i}^{l}=x_{i} \in X_{i}$ for each $i$. Therefore, letting $\mathbf{x} \equiv\left(x_{1}, \cdots, x_{m}\right), \mathbf{x}^{l} \rightarrow \mathbf{x}$ in $\prod_{i=1}^{m} X_{i}$. This proves the theorem.

### 7.8 Ascoli Arzela Theorem

Definition 7.8.1 Let $(X, d)$ be a complete metric space. Then it is said to be locally compact if $\overline{B(x, r)}$ is compact for each $r>0$.

Thus if you have a locally compact metric space, then if $\left\{a_{n}\right\}$ is a bounded sequence, it must have a convergent subsequence.

Let $K$ be a compact subset of $\mathbb{R}^{n}$ and consider the continuous functions which have values in a locally compact metric space, $(X, d)$ where $d$ denotes the metric on $X$. Denote this space as $C(K, X)$.

Definition 7.8.2 For $f, g \in C(K, X)$, where $K$ is a compact subset of $\mathbb{R}^{n}$ and $X$ is a locally compact complete metric space define

$$
\rho_{K}(f, g) \equiv \sup \{d(f(\mathbf{x}), g(\mathbf{x})): \mathbf{x} \in K\}
$$

Then $\rho_{K}$ provides a distance which makes $C(K, X)$ into a metric space.
The Ascoli Arzela theorem is a major result which tells which subsets of $C(K, X)$ are sequentially compact.

Definition 7.8.3 Let $A \subseteq C(K, X)$ for $K$ a compact subset of $\mathbb{R}^{n}$. Then $A$ is said to be uniformly equicontinuous iffor every $\varepsilon>0$ there exists a $\delta>0$ such that whenever $\mathbf{x}, \mathbf{y} \in K$ with $|\mathbf{x}-\mathbf{y}|<\delta$ and $f \in A$,

$$
d(f(\mathbf{x}), f(\mathbf{y}))<\varepsilon
$$

The set, $A$ is said to be uniformly bounded if for some $M<\infty$, and $a \in X$,

$$
f(\mathbf{x}) \in B(a, M)
$$

for all $f \in A$ and $\mathbf{x} \in K$.
Uniform equicontinuity is like saying that the whole set of functions, $A$, is uniformly continuous on $K$ uniformly for $f \in A$. The version of the Ascoli Arzela theorem I will present here is the following.

Theorem 7.8.4 Suppose $K$ is a nonempty compact subset of $\mathbb{R}^{n}$ and $A \subseteq C(K, X)$ is uniformly bounded and uniformly equicontinuous. Then if $\left\{f_{k}\right\} \subseteq A$, there exists a function, $f \in C(K, X)$ and a subsequence, $f_{k_{l}}$ such that

$$
\lim _{l \rightarrow \infty} \rho_{K}\left(f_{k_{l}}, f\right)=0
$$

To give a proof of this theorem, I will first prove some lemmas.
Lemma 7.8.5 If $K$ is a compact subset of $\mathbb{R}^{n}$, then there exists $D \equiv\left\{\mathbf{x}_{k}\right\}_{k=1}^{\infty} \subseteq K$ such that $D$ is dense in $K$. Also, for every $\varepsilon>0$ there exists a finite set of points, $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{m}\right\} \subseteq K$, called an $\varepsilon$ net such that

$$
\cup_{i=1}^{m} B\left(\mathbf{x}_{i}, \varepsilon\right) \supseteq K
$$

Proof: For $m \in \mathbb{N}$, pick $x_{1}^{m} \in K$. If every point of $K$ is within $1 / m$ of $x_{1}^{m}$, stop. Otherwise, pick

$$
x_{2}^{m} \in K \backslash B\left(x_{1}^{m}, 1 / m\right)
$$

If every point of $K$ contained in $B\left(x_{1}^{m}, 1 / m\right) \cup B\left(x_{2}^{m}, 1 / m\right)$, stop. Otherwise, pick

$$
x_{3}^{m} \in K \backslash\left(B\left(x_{1}^{m}, 1 / m\right) \cup B\left(x_{2}^{m}, 1 / m\right)\right) .
$$

If every point of $K$ is contained in $B\left(x_{1}^{m}, 1 / m\right) \cup B\left(x_{2}^{m}, 1 / m\right) \cup B\left(x_{3}^{m}, 1 / m\right)$, stop. Otherwise, pick

$$
x_{4}^{m} \in K \backslash\left(B\left(x_{1}^{m}, 1 / m\right) \cup B\left(x_{2}^{m}, 1 / m\right) \cup B\left(x_{3}^{m}, 1 / m\right)\right)
$$

Continue this way until the process stops, say at $N(m)$. It must stop because if it didn't, there would be a convergent subsequence due to the compactness of $K$. Ultimately all terms of this convergent subsequence would be closer than $1 / m$, violating the manner in which they are chosen. Then $D=\cup_{m=1}^{\infty} \cup_{k=1}^{N(m)}\left\{x_{k}^{m}\right\}$. This is countable because it is a countable union of countable sets. If $\mathbf{y} \in K$ and $\varepsilon>0$, then for some $m, 2 / m<\varepsilon$ and so $B(\mathbf{y}, \varepsilon)$ must contain some point of $\left\{x_{k}^{m}\right\}$ since otherwise, the process stopped too soon. You could have picked $\mathbf{y}$.

Lemma 7.8.6 Suppose $D$ is defined above and $\left\{g_{m}\right\}$ is a sequence of functions of $A$ having the property that for every $\mathbf{x}_{k} \in D$,

$$
\lim _{m \rightarrow \infty} g_{m}\left(\mathbf{x}_{k}\right) \text { exists }
$$

Then there exists $g \in C(K, X)$ such that

$$
\lim _{m \rightarrow \infty} \rho\left(g_{m}, g\right)=0
$$

Proof: Define $g$ first on $D$.

$$
g\left(\mathbf{x}_{k}\right) \equiv \lim _{m \rightarrow \infty} g_{m}\left(\mathbf{x}_{k}\right)
$$

Next I show that $\left\{g_{m}\right\}$ converges at every point of $K$. Let $\mathbf{x} \in K$ and let $\varepsilon>0$ be given. Choose $\mathbf{x}_{k}$ such that for all $f \in A$,

$$
d\left(f\left(\mathbf{x}_{k}\right), f(\mathbf{x})\right)<\frac{\varepsilon}{3}
$$

I can do this by the equicontinuity. Now if $p, q$ are large enough, say $p, q \geq M$,

$$
d\left(g_{p}\left(\mathbf{x}_{k}\right), g_{q}\left(\mathbf{x}_{k}\right)\right)<\frac{\varepsilon}{3}
$$

Therefore, for $p, q \geq M$,

$$
\begin{aligned}
d\left(g_{p}(\mathbf{x}), g_{q}(\mathbf{x})\right) & \leq d\left(g_{p}(\mathbf{x}), g_{p}\left(\mathbf{x}_{k}\right)\right)+d\left(g_{p}\left(\mathbf{x}_{k}\right), g_{q}\left(\mathbf{x}_{k}\right)\right)+d\left(g_{q}\left(\mathbf{x}_{k}\right), g_{q}(\mathbf{x})\right) \\
& <\frac{\varepsilon}{3}+\frac{\varepsilon}{3}+\frac{\varepsilon}{3}=\varepsilon
\end{aligned}
$$

It follows that $\left\{g_{m}(\mathbf{x})\right\}$ is a Cauchy sequence having values $X$. Therefore, it converges. Let $g(\mathbf{x})$ be the name of the thing it converges to.

Let $\varepsilon>0$ be given and pick $\delta>0$ such that whenever $\mathbf{x}, \mathbf{y} \in K$ and $|\mathbf{x}-\mathbf{y}|<\delta$, it follows $d(f(\mathbf{x}), f(\mathbf{y}))<\frac{\varepsilon}{3}$ for all $f \in A$. Now let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{m}\right\}$ be a $\delta$ net for $K$ as in Lemma 7.8.5. Since there are only finitely many points in this $\delta$ net, it follows that there exists $N$ such that for all $p, q \geq N$,

$$
d\left(g_{q}\left(\mathbf{x}_{i}\right), g_{p}\left(\mathbf{x}_{i}\right)\right)<\frac{\varepsilon}{3}
$$

for all $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{m}\right\}$. Therefore, for arbitrary $\mathbf{x} \in K$, pick $\mathbf{x}_{i} \in\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{m}\right\}$ such that

$$
\left|\mathbf{x}_{i}-\mathbf{x}\right|<\delta
$$

Then

$$
\begin{aligned}
d\left(g_{q}(\mathbf{x}), g_{p}(\mathbf{x})\right) & \leq d\left(g_{q}(\mathbf{x}), g_{q}\left(\mathbf{x}_{i}\right)\right)+d\left(g_{q}\left(\mathbf{x}_{i}\right), g_{p}\left(\mathbf{x}_{i}\right)\right)+d\left(g_{p}\left(\mathbf{x}_{i}\right), g_{p}(\mathbf{x})\right) \\
& <\frac{\varepsilon}{3}+\frac{\varepsilon}{3}+\frac{\varepsilon}{3}=\varepsilon
\end{aligned}
$$

Since $N$ does not depend on the choice of $\mathbf{x}$, it follows this sequence $\left\{g_{m}\right\}$ is uniformly Cauchy. That is, for every $\varepsilon>0$, there exists $N$ such that if $p, q \geq N$, then

$$
\rho\left(g_{p}, g_{q}\right)<\varepsilon
$$

Next, I need to verify that the function, $g$ is a continuous function. Let $N$ be large enough that whenever $p, q \geq N$, the above holds. Then for all $\mathbf{x} \in K$,

$$
\begin{equation*}
d\left(g(\mathbf{x}), g_{p}(\mathbf{x})\right) \leq \frac{\varepsilon}{3} \tag{7.8.7}
\end{equation*}
$$

whenever $p \geq N$. This follows from observing that for $p, q \geq N$,

$$
d\left(g_{q}(\mathbf{x}), g_{p}(\mathbf{x})\right)<\frac{\varepsilon}{3}
$$

and then taking the limit as $q \rightarrow \infty$ to obtain 7.8.7. In passing to the limit, you can use the following simple claim.

Claim: In a metric space, if $a_{n} \rightarrow a$, then $d\left(a_{n}, b\right) \rightarrow d(a, b)$.
Proof of the claim: You note that by the triangle inequality, $d\left(a_{n}, b\right)-d(a, b) \leq$ $d\left(a_{n}, a\right)$ and $d(a, b)-d\left(a_{n}, b\right) \leq d\left(a_{n}, a\right)$ and so

$$
\left|d\left(a_{n}, b\right)-d(a, b)\right| \leq d\left(a_{n}, a\right)
$$

Now let $p$ satisfy 7.8.7 for all $\mathbf{x}$ whenever $p>N$. Also pick $\delta>0$ such that if $|\mathbf{x}-\mathbf{y}|<$ $\delta$, then

$$
d\left(g_{p}(\mathbf{x}), g_{p}(\mathbf{y})\right)<\frac{\varepsilon}{3}
$$

Then if $|\mathbf{x}-\mathbf{y}|<\boldsymbol{\delta}$,

$$
\begin{aligned}
d(g(\mathbf{x}), g(\mathbf{y})) & \leq d\left(g(\mathbf{x}), g_{p}(\mathbf{x})\right)+d\left(g_{p}(\mathbf{x}), g_{p}(\mathbf{y})\right)+d\left(g_{p}(\mathbf{y}), g(\mathbf{y})\right) \\
& <\frac{\varepsilon}{3}+\frac{\varepsilon}{3}+\frac{\varepsilon}{3}=\varepsilon .
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows that $g$ is continuous.
It only remains to verify that $\rho\left(g, g_{k}\right) \rightarrow 0$. But this follows from 7.8.7.
With these lemmas, it is time to prove Theorem 7.8.4.
Proof of Theorem 7.8.4: Let $D=\left\{\mathbf{x}_{k}\right\}$ be the countable dense set of $K$ gauranteed by Lemma 7.8.5 and let $\{(1,1),(1,2),(1,3),(1,4),(1,5), \cdots\}$ be a subsequence of $\mathbb{N}$ such that

$$
\lim _{k \rightarrow \infty} f_{(1, k)}\left(\mathbf{x}_{1}\right) \text { exists. }
$$

This is where the local compactness of $X$ is being used. Now let

$$
\{(2,1),(2,2),(2,3),(2,4),(2,5), \cdots\}
$$

be a subsequence of $\{(1,1),(1,2),(1,3),(1,4),(1,5), \cdots\}$ which has the property that

$$
\lim _{k \rightarrow \infty} f_{(2, k)}\left(\mathbf{x}_{2}\right) \text { exists. }
$$

Thus it is also the case that

$$
f_{(2, k)}\left(\mathbf{x}_{1}\right) \text { converges to } \lim _{k \rightarrow \infty} f_{(1, k)}\left(\mathbf{x}_{1}\right) .
$$

because every subsequence of a convergent sequence converges to the same thing as the convergent sequence. Continue this way and consider the array

$$
\begin{gathered}
f_{(1,1)}, f_{(1,2)}, f_{(1,3)}, f_{(1,4)}, \cdots \text { converges at } \mathbf{x}_{1} \\
f_{(2,1)}, f_{(2,2)}, f_{(2,3)}, f_{(2,4)} \cdots \text { converges at } \mathbf{x}_{1} \text { and } \mathbf{x}_{2} \\
f_{(3,1)}, f_{(3,2)}, f_{(3,3)}, f_{(3,4)} \cdots \text { converges at } \mathbf{x}_{1}, \mathbf{x}_{2}, \text { and } \mathbf{x}_{3} \\
\vdots
\end{gathered}
$$

Now let $g_{k} \equiv f_{(k, k)}$. Thus $g_{k}$ is ultimately a subsequence of $\left\{f_{(m, k)}\right\}$ whenever $k>m$ and therefore, $\left\{g_{k}\right\}$ converges at each point of $D$. By Lemma 7.8.6 it follows there exists $g \in$ $C(K ; X)$ such that

$$
\lim _{k \rightarrow \infty} \rho\left(g, g_{k}\right)=0
$$

Actually there is an if and only if version of it but the most useful case is what is presented here. The process used to get the subsequence in the proof is called the Cantor diagonalization procedure.

### 7.9 Another General Version

This will use the characterization of compact metric spaces to give a proof of a general version of the Arzella Ascoli theorem. See Naylor and Sell [100] which is where I saw this general formulation.

Definition 7.9.1 Let $\left(X, d_{X}\right)$ be a compact metric space. Let $\left(Y, d_{Y}\right)$ be another complete metric space. Then $C(X, Y)$ will denote the continuous functions which map $X$ to $Y$. Then $\rho$ is a metric on $C(X, Y)$ defined by

$$
\rho(f, g) \equiv \sup _{x \in X} d_{Y}(f(x), g(x)) .
$$

Theorem 7.9.2 $(C(X, Y), \rho)$ is a complete metric space.
Proof: It is first necessary to show that $\rho$ is well defined. In this argument, I will just write $d$ rather than $d_{X}$ or $d_{Y}$. To show this, note that

$$
x \rightarrow d(f(x), g(x))
$$

is a continuous function because $f, g$ are continuous and

$$
|d(f(x), g(x))-d(f(y), g(y))| \leq d(f(x), f(y))+d(g(x), g(y))
$$

This follows from the triangle inequality. Say $d(f(x), g(x)) \geq d(f(y), g(y))$. Otherwise just replace $x$ with $y$ and repeat the argument. Then in this case, it reduces to the claim that

$$
d(f(x), g(x)) \leq d(f(x), f(y))+d(g(x), g(y))+d(f(y), g(y))
$$

However, by the triangle inequality, the right side of the above is at least as large as

$$
d(f(x), f(y))+d(g(x), f(y)) \geq d(f(x), g(x))
$$

It follows that $\rho(f, g)$ is just the maximum of a continuous function defined on a compact set.

Clearly $\rho(f, g)=\rho(g, f)$ and

$$
\begin{aligned}
\rho(f, g)+\rho(g, h) & =\sup _{x \in X} d(f(x), g(x))+\sup _{x \in X} d(g(x), h(x)) \\
& \geq \sup _{x \in X}(d(f(x), g(x))+d(g(x), h(x))) \\
& \geq \sup _{x \in X}(d(f(x), h(x)))=\rho(f, h)
\end{aligned}
$$

so the triangle inequality holds.
It remains to check completeness. Let $\left\{f_{n}\right\}$ be a Cauchy sequence. Then from the definition, $\left\{f_{n}(x)\right\}$ is a Cauchy sequence in $Y$ and so it converges to something called $f(x)$. I have to verify that $x \rightarrow f(x)$ is continuous. Define

$$
\rho^{\prime}\left(f, f_{n}\right) \equiv \lim \sup _{m \rightarrow \infty} \rho\left(f_{m}, f_{n}\right)
$$

Then if $n$ is sufficiently large, $\rho^{\prime}\left(f, f_{n}\right)<\varepsilon / 3$. Also,

$$
\begin{align*}
d\left(f(x), f_{n}(x)\right) & =\lim _{m \rightarrow \infty} d\left(f_{m}(x), f_{n}(x)\right) \\
& \leq \limsup _{m \rightarrow \infty} \rho\left(f_{m}, f_{n}\right)=\rho^{\prime}\left(f, f_{n}\right)<\frac{\varepsilon}{3} \tag{7.9.8}
\end{align*}
$$

Then picking such an $n$,

$$
\begin{aligned}
& d(f(x), f(y)) \leq d\left(f(x), f_{n}(x)\right)+d\left(f_{n}(x), f_{n}(y)\right)+d_{n}\left(f_{n}(y), f(y)\right) \\
& \quad \leq \rho^{\prime}\left(f, f_{n}\right)+d\left(f_{n}(x), f_{n}(y)\right)+\rho^{\prime}\left(f, f_{n}\right)<\frac{2 \varepsilon}{3}+d\left(f_{n}(x), f_{n}(y)\right)
\end{aligned}
$$

which is less than $\varepsilon$ provided $d(x, y)$ is small enough, this by continuity of $f_{n}$. Therefore, $f$ is continuous. By 7.9.8 this shows that, since $x$ is arbitrary, $\rho\left(f, f_{n}\right)<\varepsilon$ whenever $n$ is large enough.

Here is a useful lemma.
Lemma 7.9.3 Let $S$ be a totally bounded subset of $(X, d)$ a metric space. Then $\bar{S}$ is also totally bounded.

Proof: Suppose not. Then there exists a sequence $\left\{p_{n}\right\} \subseteq \bar{S}$ such that $d\left(p_{m}, p_{n}\right) \geq \varepsilon$ for all $m \neq n$. Now let $q_{n} \in B\left(p_{n}, \frac{\varepsilon}{8}\right) \cap S$. Then it follows that

$$
\frac{\varepsilon}{8}+d\left(q_{n}, q_{m}\right)+\frac{\varepsilon}{8} \geq d\left(p_{n}, q_{n}\right)+d\left(q_{n}, q_{m}\right)+d\left(q_{m}, p_{m}\right) \geq d\left(p_{n}, q_{m}\right) \geq \varepsilon
$$

and so $d\left(q_{n}, q_{m}\right)>\frac{\varepsilon}{2}$. This contradicts total boundedness of $S$.
Next, here is an important definition.
Definition 7.9.4 Let $\mathscr{A} \subseteq C(X, Y)$ where $\left(X, d_{X}\right)$ and $\left(Y, d_{Y}\right)$ are metric spaces. Thus $\mathscr{A}$ is a set of continuous functions mapping $X$ to $Y$. Then $\mathscr{A}$ is said to be equicontinuous if for every $\varepsilon>0$ there exists a $\delta>0$ such that if $d_{X}\left(x_{1}, x_{2}\right)<\delta$ then for all $f \in \mathscr{A}$, $d_{Y}\left(f\left(x_{1}\right), f\left(x_{2}\right)\right)<\varepsilon$. (This is uniform continuity which is uniform in $\mathscr{A}$.) $\mathscr{A}$ is said to be pointwise compact if $\{f(x): f \in \mathscr{A}\}$ has compact closure in $Y$.

Here is the Ascoli Arzela theorem.
Theorem 7.9.5 Let $\left(X, d_{X}\right)$ be a compact metric space and let $\left(Y, d_{Y}\right)$ be a complete metric space. Thus $(C(X, Y), \rho)$ is a complete metric space. Let $\mathscr{A} \subseteq C(X, Y)$ be pointwise compact and equicontinuous. Then $\overline{\mathscr{A}}$ is compact. Here the closure is taken in $(C(X, Y), \rho)$. The converse also holds.

Proof: The more useful direction is that the two conditions imply compactness of $\overline{\mathscr{A}}$. I prove this first. Since $\overline{\mathscr{A}}$ is a closed subset of a complete space, it follows that $\overline{\mathscr{A}}$ will be compact if it is totally bounded. In showing this, it follows from Lemma 7.9.3 that it suffices to verify that $\mathscr{A}$ is totally bounded. Suppose this is not so. Then there exists $\varepsilon>0$ and a sequence of points of $\mathscr{A},\left\{f_{n}\right\}$ such that $\rho\left(f_{n}, f_{m}\right) \geq \varepsilon$ whenever $n \neq m$.

By equicontinuity, there exists $\delta>0$ such that if $d(x, y)<\delta$, then $d(f(x), f(y))<\frac{\varepsilon}{8}$ for all $f \in \mathscr{A}$. Let $\left\{x_{i}\right\}_{i=1}^{m}$ be a $\delta / 2$ net for $X$. Since there are only finitely many $x_{i}$, it follows from pointwise compactness that there exists a subsequence, still denoted by $\left\{f_{n}\right\}$ which converges at each $x_{i}$. There exists $x_{m n}$ such that

$$
\begin{align*}
& \rho\left(f_{n}, f_{m}\right)-\frac{\varepsilon}{8}<d\left(f_{n}\left(x_{m n}\right), f_{m}\left(x_{n m}\right)\right) \\
\leq & d\left(f_{n}\left(x_{n m}\right), f_{n}\left(x_{i}\right)\right)+d\left(f_{n}\left(x_{i}\right), f_{m}\left(x_{i}\right)\right)+d\left(f_{m}\left(x_{i}\right), f_{m}\left(x_{n m}\right)\right) \\
< & \frac{\varepsilon}{8}+d\left(f_{n}\left(x_{i}\right), f_{m}\left(x_{i}\right)\right)+\frac{\varepsilon}{8} \tag{7.9.9}
\end{align*}
$$

where here $x_{i}$ is such that $x_{n m} \in B\left(x_{i}, \delta\right)$. From the convergence of $f_{n}$ at each $x_{i}$, there exists $N$ such that if $m, n>N$, then for all $x_{i}$,

$$
d\left(f_{n}\left(x_{i}\right), f_{m}\left(x_{i}\right)\right)<\frac{\varepsilon}{8}
$$

Now 7.9.9 results in the contradiction,

$$
\varepsilon-\frac{\varepsilon}{8}<\frac{\varepsilon}{8}+\frac{\varepsilon}{8}+\frac{\varepsilon}{8}
$$

It follows that $\mathscr{A}$ and hence $\overline{\mathscr{A}}$ is totally bounded. This proves the more important direction.

Next suppose $\overline{\mathscr{A}}$ is compact. Why must $\mathscr{A}$ be pointwise compact and equicontinuous? If it fails to be pointwise compact, then there exists $x \in X$ such that $\{f(x): f \in \mathscr{A}\}$ is not contained in a compact set of $Y$. Thus there exists $\varepsilon>0$ and a sequence of functions in $\mathscr{A}$ $\left\{f_{n}\right\}$ such that $d\left(f_{n}(x), f_{m}(x)\right) \geq \varepsilon$. But this implies $\rho\left(f_{m}, f_{n}\right) \geq \varepsilon$ and so $\overline{\mathscr{A}}$ fails to be totally bounded, a contradiction. Thus $\mathscr{A}$ must be pointwise compact. Now why must it be equicontinuous? If it is not, then for each $n \in \mathbb{N}$ there exists $\varepsilon>0$ and $x_{n}, y_{n} \in X$ such that $d\left(x_{n}, y_{n}\right)<1 / n$ but for some $f_{n} \in \mathscr{A}, d\left(f_{n}\left(x_{n}\right), f_{n}\left(y_{n}\right)\right) \geq \varepsilon$. However, by compactness, there exists a subsequence $\left\{f_{n_{k}}\right\}$ such that $\lim _{k \rightarrow \infty} \rho\left(f_{n_{k}}, f\right)=0$ and also that $x_{n_{k}}, y_{n_{k}} \rightarrow$ $x \in X$. Hence

$$
\begin{aligned}
& \varepsilon \leq d\left(f_{n_{k}}\left(x_{n_{k}}\right), f_{n_{k}}\left(y_{n_{k}}\right)\right) \leq d\left(f_{n_{k}}\left(x_{n_{k}}\right), f\left(x_{n_{k}}\right)\right) \\
&+d\left(f\left(x_{n_{k}}\right), f\left(y_{n_{k}}\right)\right)+d\left(f\left(y_{n_{k}}\right), f_{n_{k}}\left(y_{n_{k}}\right)\right) \\
& \leq \rho\left(f_{n_{k}}, f\right)+d\left(f\left(x_{n_{k}}\right), f\left(y_{n_{k}}\right)\right)+\rho\left(f, f_{n_{k}}\right)
\end{aligned}
$$

and now this is a contradiction because each term on the right converges to 0 . The middle term converges to 0 because $f\left(x_{n_{k}}\right), f\left(y_{n_{k}}\right) \rightarrow f(x)$.

### 7.10 The Tietze Extension Theorem

It turns out that if $H$ is a closed subset of a metric space, $(X, d)$ and if $f: H \rightarrow[a, b]$ is continuous, then there exists $g$ defined on all of $X$ such that $g=f$ on $H$ and $g$ is continuous. This is called the Tietze extension theorem. First it is well to recall continuity in the context of metric space.

Definition 7.10.1 Let $(X, d)$ be a metric space and suppose $f: X \rightarrow Y$ is a function where $(Y, \rho)$ is also a metric space. For example, $Y=\mathbb{R}$. Then $f$ is continuous at $x \in X$ if for every $\varepsilon>0$ there exists $\delta>0$ such that $\rho(f(x), f(z))<\varepsilon$ whenever $d(x, z)<\delta$. As is usual in such definitions, $f$ is said to be continuous if it is continuous at every point of $X$.

The following lemma gives an important example of a continuous real valued function defined on a metric space, $(X, d)$.

Lemma 7.10.2 Let $(X, d)$ be a metric space and let $S \subseteq X$ be a nonempty subset. Define

$$
\operatorname{dist}(x, S) \equiv \inf \{d(x, y): y \in S\}
$$

Then $x \rightarrow \operatorname{dist}(x, S)$ is a continuous function satisfying the inequality,

$$
\begin{equation*}
|\operatorname{dist}(x, S)-\operatorname{dist}(y, S)| \leq d(x, y) \tag{7.10.10}
\end{equation*}
$$

Proof: The continuity of $x \rightarrow \operatorname{dist}(x, S)$ is obvious if the inequality 7.10 .10 is established. So let $x, y \in X$. Without loss of generality, assume $\operatorname{dist}(x, S) \geq \operatorname{dist}(y, S)$ and pick $z \in S$ such that $d(y, z)-\varepsilon<\operatorname{dist}(y, S)$. Then

$$
\begin{aligned}
|\operatorname{dist}(x, S)-\operatorname{dist}(y, S)| & =\operatorname{dist}(x, S)-\operatorname{dist}(y, S) \leq d(x, z)-(d(y, z)-\varepsilon) \\
& \leq d(z, y)+d(x, y)-d(y, z)+\varepsilon=d(x, y)+\varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this proves 7.10.10.
Lemma 7.10.3 Let $H, K$ be two nonempty disjoint closed subsets of a metric space, $(X, d)$. Then there exists a continuous function, $g: X \rightarrow[-1,1]$ such that $g(H)=-1 / 3, g(K)=$ $1 / 3, g(X) \subseteq[-1 / 3,1 / 3]$.

Proof: Let

$$
f(x) \equiv \frac{\operatorname{dist}(x, H)}{\operatorname{dist}(x, H)+\operatorname{dist}(x, K)}
$$

The denominator is never equal to zero because if $\operatorname{dist}(x, H)=0$, then $x \in H$ becasue $H$ is closed. (To see this, pick $h_{k} \in B(x, 1 / k) \cap H$. Then $h_{k} \rightarrow x$ and since $H$ is closed, $x \in H$.) Similarly, if $\operatorname{dist}(x, K)=0$, then $x \in K$ and so the denominator is never zero as claimed. Hence, by Lemma 7.10.2, $f$ is continuous and from its definition, $f=0$ on $H$ and $f=1$ on $K$. Now let $g(x) \equiv \frac{2}{3}\left(f(x)-\frac{1}{2}\right)$. Then $g$ has the desired properties.

Definition 7.10.4 For $f$ a real or complex valued bounded continuous function defined on a metric space, $M$

$$
\|f\|_{M} \equiv \sup \{|f(x)|: x \in M\}
$$

Lemma 7.10.5 Suppose $M$ is a closed set in $X$ where $(X, d)$ is a metric space and suppose $f: M \rightarrow[-1,1]$ is continuous at every point of $M$. Then there exists a function, $g$ which is defined and continuous on all of $X$ such that $\|f-g\|_{M}<\frac{2}{3}$.

Proof: Let $H=f^{-1}([-1,-1 / 3]), K=f^{-1}([1 / 3,1])$. Thus $H$ and $K$ are disjoint closed subsets of $M$. Suppose first $H, K$ are both nonempty. Then by Lemma 7.10.3 there exists $g$ such that $g$ is a continuous function defined on all of $X$ and $g(H)=-1 / 3, g(K)=1 / 3$, and $g(X) \subseteq[-1 / 3,1 / 3]$. It follows $\|f-g\|_{M}<2 / 3$. If $H=\emptyset$, then $f$ has all its values in $[-1 / 3,1]$ and so letting $g \equiv 1 / 3$, the desired condition is obtained. If $K=\emptyset$, let $g \equiv-1 / 3$. This proves the lemma.

Lemma 7.10.6 Suppose $M$ is a closed set in $X$ where $(X, d)$ is a metric space and suppose $f: M \rightarrow[-1,1]$ is continuous at every point of $M$. Then there exists a function, $g$ which is defined and continuous on all of $X$ such that $g=f$ on $M$ and $g$ has its values in $[-1,1]$.

Proof: Let $g_{1}$ be such that $g_{1}(X) \subseteq[-1 / 3,1 / 3]$ and $\left\|f-g_{1}\right\|_{M} \leq \frac{2}{3}$. Suppose $g_{1}, \cdots, g_{m}$ have been chosen such that $g_{j}(X) \subseteq[-1 / 3,1 / 3]$ and

$$
\begin{equation*}
\left\|f-\sum_{i=1}^{m}\left(\frac{2}{3}\right)^{i-1} g_{i}\right\|_{M}<\left(\frac{2}{3}\right)^{m} \tag{7.10.11}
\end{equation*}
$$

Then

$$
\left\|\left(\frac{3}{2}\right)^{m}\left(f-\sum_{i=1}^{m}\left(\frac{2}{3}\right)^{i-1} g_{i}\right)\right\|_{M} \leq 1
$$

and so $\left(\frac{3}{2}\right)^{m}\left(f-\sum_{i=1}^{m}\left(\frac{2}{3}\right)^{i-1} g_{i}\right)$ can play the role of $f$ in the first step of the proof. Therefore, there exists $g_{m+1}$ defined and continuous on all of $X$ such that its values are in $[-1 / 3,1 / 3]$ and

$$
\left\|\left(\frac{3}{2}\right)^{m}\left(f-\sum_{i=1}^{m}\left(\frac{2}{3}\right)^{i-1} g_{i}\right)-g_{m+1}\right\|_{M} \leq \frac{2}{3}
$$

Hence

$$
\left\|\left(f-\sum_{i=1}^{m}\left(\frac{2}{3}\right)^{i-1} g_{i}\right)-\left(\frac{2}{3}\right)^{m} g_{m+1}\right\|_{M} \leq\left(\frac{2}{3}\right)^{m+1}
$$

It follows there exists a sequence, $\left\{g_{i}\right\}$ such that each has its values in $[-1 / 3,1 / 3]$ and for every $m 7.10 .11$ holds. Then let

$$
g(x) \equiv \sum_{i=1}^{\infty}\left(\frac{2}{3}\right)^{i-1} g_{i}(x)
$$

It follows

$$
|g(x)| \leq\left|\sum_{i=1}^{\infty}\left(\frac{2}{3}\right)^{i-1} g_{i}(x)\right| \leq \sum_{i=1}^{m}\left(\frac{2}{3}\right)^{i-1} \frac{1}{3} \leq 1
$$

and since convergence is uniform, $g$ must be continuous. The estimate 7.10 .11 implies $f=g$ on $M$.

The following is the Tietze extension theorem.

Theorem 7.10.7 Let $M$ be a closed nonempty subset of a metric space $(X, d)$ and let $f$ : $M \rightarrow[a, b]$ is continuous at every point of $M$. Then there exists a function, $g$ continuous on all of $X$ which coincides with $f$ on $M$ such that $g(X) \subseteq[a, b]$.

Proof: Let $f_{1}(x)=1+\frac{2}{b-a}(f(x)-b)$. Then $f_{1}$ satisfies the conditions of Lemma 7.10.6 and so there exists $g_{1}: X \rightarrow[-1,1]$ such that $g$ is continuous on $X$ and equals $f_{1}$ on $M$. Let $g(x)=\left(g_{1}(x)-1\right)\left(\frac{b-a}{2}\right)+b$. This works.

### 7.11 Some Simple Fixed Point Theorems

The following is of more interest in the case of normed vector spaces, but there is no harm in stating it in this more general setting. You should verify that the functions described in the following definition are all continuous.

Definition 7.11.1 Let $f: X \rightarrow Y$ where $(X, d)$ and $(Y, \rho)$ are metric spaces. Then $f$ is said to be Lipschitz continuous if for every $x, \hat{x} \in X, \rho(f(x), f(\hat{x})) \leq r d(x, \hat{x})$. The function is called a contraction map if $r<1$.

The big theorem about contraction maps is the following.
Theorem 7.11.2 Let $f:(X, d) \rightarrow(X, d)$ be a contraction map and let $(X, d)$ be a complete metric space. Thus Cauchy sequences converge and also $d(f(x), f(\hat{x})) \leq r d(x, \hat{x})$ where $r<1$. Then $f$ has a unique fixed point. This is a point $x \in X$ such that $f(x)=x$. Also, if $x_{0}$ is any point of $X$, then

$$
d\left(x, x_{0}\right) \leq \frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}
$$

Also, for each n,

$$
d\left(f^{n}\left(x_{0}\right), x_{0}\right) \leq \frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}
$$

and $x=\lim _{n \rightarrow \infty} f^{n}\left(x_{0}\right)$.
Proof: Pick $x_{0} \in X$ and consider the sequence of iterates of the map,

$$
x_{0}, f\left(x_{0}\right), f^{2}\left(x_{0}\right), \cdots
$$

We argue that this is a Cauchy sequence. For $m<n$, it follows from the triangle inequality,

$$
d\left(f^{m}\left(x_{0}\right), f^{n}\left(x_{0}\right)\right) \leq \sum_{k=m}^{n-1} d\left(f^{k+1}\left(x_{0}\right), f^{k}\left(x_{0}\right)\right) \leq \sum_{k=m}^{\infty} r^{k} d\left(f\left(x_{0}\right), x_{0}\right)
$$

The reason for this last is as follows.

$$
\begin{gathered}
d\left(f^{2}\left(x_{0}\right), f\left(x_{0}\right)\right) \leq r d\left(f\left(x_{0}\right), x_{0}\right) \\
d\left(f^{3}\left(x_{0}\right), f^{2}\left(x_{0}\right)\right) \leq r d\left(f^{2}\left(x_{0}\right), f\left(x_{0}\right)\right) \leq r^{2} d\left(f\left(x_{0}\right), x_{0}\right)
\end{gathered}
$$

and so forth. Therefore,

$$
d\left(f^{m}\left(x_{0}\right), f^{n}\left(x_{0}\right)\right) \leq d\left(f\left(x_{0}\right), x_{0}\right) \frac{r^{m}}{1-r}
$$

which shows that this is indeed a Cauchy sequence. Therefore, there exists $x$ such that

$$
\lim _{n \rightarrow \infty} f^{n}\left(x_{0}\right)=x
$$

By continuity,

$$
f(x)=f\left(\lim _{n \rightarrow \infty} f^{n}\left(x_{0}\right)\right)=\lim _{n \rightarrow \infty} f^{n+1}\left(x_{0}\right)=x
$$

Also note that this estimate yields

$$
d\left(x_{0}, f^{n}\left(x_{0}\right)\right) \leq \frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}
$$

Now $d\left(x_{0}, x\right) \leq d\left(x_{0}, f^{n}\left(x_{0}\right)\right)+d\left(f^{n}\left(x_{0}\right), x\right)$ and so

$$
d\left(x_{0}, x\right)-d\left(f^{n}\left(x_{0}\right), x\right) \leq \frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}
$$

Letting $n \rightarrow \infty$, it follows that

$$
d\left(x_{0}, x\right) \leq \frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}
$$

It only remains to verify that there is only one fixed point. Suppose then that $x, x^{\prime}$ are two. Then

$$
d\left(x, x^{\prime}\right)=d\left(f(x), f\left(x^{\prime}\right)\right) \leq r d\left(x^{\prime}, x\right)
$$

and so $d\left(x, x^{\prime}\right)=0$ because $r<1$.
The above is the usual formulation of this important theorem, but we actually proved a better result.

Corollary 7.11.3 Let $B$ be a closed subset of the complete metric space $(X, d)$ and let $f: B \rightarrow X$ be a contraction map

$$
d(f(x), f(\hat{x})) \leq r d(x, \hat{x}), r<1
$$

Also suppose there exists $x_{0} \in B$ such that the sequence of iterates $\left\{f^{n}\left(x_{0}\right)\right\}_{n=1}^{\infty}$ remains in $B$. Then $f$ has a unique fixed point in $B$ which is the limit of the sequence of iterates. This is a point $x \in B$ such that $f(x)=x$. In the case that $B=\overline{B\left(x_{0}, \delta\right)}$, the sequence of iterates satisfies the inequality

$$
d\left(f^{n}\left(x_{0}\right), x_{0}\right) \leq \frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}
$$

and so it will remain in $B$ if

$$
\frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}<\delta
$$

Proof: By assumption, the sequence of iterates stays in $B$. Then, as in the proof of the preceding theorem, for $m<n$, it follows from the triangle inequality,

$$
\begin{aligned}
d\left(f^{m}\left(x_{0}\right), f^{n}\left(x_{0}\right)\right) & \leq \sum_{k=m}^{n-1} d\left(f^{k+1}\left(x_{0}\right), f^{k}\left(x_{0}\right)\right) \\
& \leq \sum_{k=m}^{\infty} r^{k} d\left(f\left(x_{0}\right), x_{0}\right)=\frac{r^{m}}{1-r} d\left(f\left(x_{0}\right), x_{0}\right)
\end{aligned}
$$

Hence the sequence of iterates is Cauchy and must converge to a point $x$ in $X$. However, $B$ is closed and so it must be the case that $x \in B$. Then as before,

$$
x=\lim _{n \rightarrow \infty} f^{n}\left(x_{0}\right)=\lim _{n \rightarrow \infty} f^{n+1}\left(x_{0}\right)=f\left(\lim _{n \rightarrow \infty} f^{n}\left(x_{0}\right)\right)=f(x)
$$

As to the sequence of iterates remaining in $B$ where $B$ is a ball as described, the inequality above in the case where $m=0$ yields

$$
d\left(x_{0}, f^{n}\left(x_{0}\right)\right) \leq \frac{1}{1-r} d\left(f\left(x_{0}\right), x_{0}\right)
$$

and so, if the right side is less than $\delta$, then the iterates remain in $B$. As to the fixed point being unique, it is as before. If $x, x^{\prime}$ are both fixed points in $B$, then $d\left(x, x^{\prime}\right)=d\left(f(x), f\left(x^{\prime}\right)\right) \leq$ $r d\left(x, x^{\prime}\right)$ and so $x=x^{\prime}$.

Sometimes you have the contraction depending on a parameter $\lambda$. Then there is a principle of uniform contractions.

Corollary 7.11.4 Suppose $f: X \times \Lambda \rightarrow X$ where $\Lambda$ is a metric space and $X$ is a complete metric space. Suppose $f$ satisfies

1. $d(f(x, \lambda), f(y, \lambda)) \leq r d(x, y)$ for each $\lambda \in \Lambda$.
2. $\lambda \rightarrow f(x, \lambda)$ is continuous as a map from $\Lambda$ to $X$.

Then if $x(\lambda)$ is the fixed point, it follows that $\lambda \rightarrow x(\lambda)$ is continuous.
Proof: Pick $x_{0} \in X$ and consider the above sequence of iterates, $\left\{f^{n}(x, \lambda)\right\}$. Let $\rho$ be the metric on $\Lambda$. Then there is a fixed point and if $x(\lambda)$ is this unique fixed point,

$$
d\left(x(\lambda), x_{0}\right) \leq \frac{d\left(f\left(x_{0}, \lambda\right), x_{0}\right)}{1-r}
$$

In particular, you could start with $x_{0}=x(\mu)$ and conclude that

$$
\begin{aligned}
& d(x(\lambda), x(\mu)) \leq \frac{d(f(x(\mu), \lambda), x(\mu))}{1-r} \\
\leq & \frac{d(f(x(\mu), \lambda), f(x(\mu), \mu))}{1-r}+\frac{d(f(x(\mu), \mu), x(\mu))}{1-r} \\
= & \frac{d(f(x(\mu), \lambda), f(x(\mu), \mu))}{1-r}
\end{aligned}
$$

Now by continuity of $\lambda \rightarrow f(x, \lambda)$, it follows that if $\rho(\lambda, \mu)$ is small enough, the above is no larger than

$$
\frac{\varepsilon(1-r)}{1-r}=\varepsilon
$$

Hence, if $\rho(\lambda, \mu)$ is small enough, we have

$$
d(x(\lambda), x(\mu))<\varepsilon .
$$

This is called the uniform contraction principle.
The contraction mapping theorem has an extremely useful generalization. In order to get a unique fixed point, it suffices to have some power of $f$ a contraction map.

Theorem 7.11.5 Let $f:(X, d) \rightarrow(X, d)$ have the property that for some $n \in \mathbb{N}$, $f^{n}$ is a contraction map and let $(X, d)$ be a complete metric space. Then there is a unique fixed point for $f$. As in the earlier theorem the sequence of iterates $\left\{f^{n}\left(x_{0}\right)\right\}_{n=1}^{\infty}$ also converges to the fixed point.

Proof: From Theorem 7.11.2 there is a unique fixed point for $f^{n}$. Thus

$$
f^{n}(x)=x
$$

Then

$$
f^{n}(f(x))=f^{n+1}(x)=f(x)
$$

By uniqueness, $f(x)=x$.
Now consider the sequence of iterates. Suppose it fails to converge to $x$. Then there is $\varepsilon>0$ and a subsequence $n_{k}$ such that

$$
d\left(f^{n_{k}}\left(x_{0}\right), x\right) \geq \varepsilon
$$

Now $n_{k}=p_{k} n+r_{k}$ where $r_{k}$ is one of the numbers $\{0,1,2, \cdots, n-1\}$. It follows that there exists one of these numbers which is repeated infinitely often. Call it $r$ and let the further subsequence continue to be denoted as $n_{k}$. Thus

$$
d\left(f^{p_{k} n+r}\left(x_{0}\right), x\right) \geq \varepsilon
$$

In other words,

$$
d\left(f^{p_{k} n}\left(f^{r}\left(x_{0}\right)\right), x\right) \geq \varepsilon
$$

However, from Theorem 7.11.2, as $k \rightarrow \infty, f^{p_{k} n}\left(f^{r}\left(x_{0}\right)\right) \rightarrow x$ which contradicts the above inequality. Hence the sequence of iterates converges to $x$, as it did for $f$ a contraction map.

Definition 7.11.6 Let $f:(X, d) \rightarrow(Y, \rho)$ be a function. Then it is said to be uniformly continuous on $X$ if for every $\varepsilon>0$ there exists a $\delta>0$ such that whenever $x, \hat{x}$ are two points of $X$ with $d(x, \hat{x})<\delta$, it follows that $\rho(f(x), f(\hat{x}))<\varepsilon$.

Note the difference between this and continuity. With continuity, the $\delta$ could depend on $x$ but here it works for any pair of points in $X$.

Lemma 7.11.7 Suppose $x_{n} \rightarrow x$ and $y_{n} \rightarrow y$. Then $d\left(x_{n}, y_{n}\right) \rightarrow d(x, y)$.
Proof: Consider the following.

$$
d(x, y) \leq d\left(x, x_{n}\right)+d\left(x_{n}, y\right) \leq d\left(x, x_{n}\right)+d\left(x_{n}, y_{n}\right)+d\left(y_{n}, y\right)
$$

so

$$
d(x, y)-d\left(x_{n}, y_{n}\right) \leq d\left(x, x_{n}\right)+d\left(y_{n}, y\right)
$$

Similarly

$$
d\left(x_{n}, y_{n}\right)-d(x, y) \leq d\left(x, x_{n}\right)+d\left(y_{n}, y\right)
$$

and so

$$
\left|d\left(x_{n}, y_{n}\right)-d(x, y)\right| \leq d\left(x, x_{n}\right)+d\left(y_{n}, y\right)
$$

and the right side converges to 0 as $n \rightarrow \infty$.
There is a remarkable result concerning compactness and uniform continuity.
Theorem 7.11.8 Let $f:(X, d) \rightarrow(Y, \rho)$ be a continuous function and let $K$ be a compact subset of $X$. Then the restriction of $f$ to $K$ is uniformly continuous.

Proof: First of all, $K$ is a metric space and $f$ restricted to $K$ is continuous. Now suppose it fails to be uniformly continuous. Then there exists $\varepsilon>0$ and pairs of points $x_{n}, \hat{x}_{n}$ such that $d\left(x_{n}, \hat{x}_{n}\right)<1 / n$ but $\rho\left(f\left(x_{n}\right), f\left(\hat{x}_{n}\right)\right) \geq \varepsilon$. Since $K$ is compact, it is sequentially compact and so there exists a subsequence, still denoted as $\left\{x_{n}\right\}$ such that $x_{n} \rightarrow x \in K$. Then also $\hat{x}_{n} \rightarrow x$ also and so

$$
\rho(f(x), f(x))=\lim _{n \rightarrow \infty} \rho\left(f\left(x_{n}\right), f\left(\hat{x}_{n}\right)\right) \geq \varepsilon
$$

which is a contradiction. Note the use of Lemma 7.11.7 in the equal sign.
Next is to consider the meaning of convergence of sequences of functions. There are two main ways of convergence of interest here, pointwise and uniform convergence.

Definition 7.11.9 Let $f_{n}: X \rightarrow Y$ where $(X, d),(Y, \rho)$ are two metric spaces. Then $\left\{f_{n}\right\}$ is said to converge poinwise to a function $f: X \rightarrow Y$ iffor every $x \in X$,

$$
\lim _{n \rightarrow \infty} f_{n}(x)=f(x)
$$

$\left\{f_{n}\right\}$ is said to converge uniformly iffor all $\varepsilon>0$, there exists $N$ such that if $n \geq N$, then

$$
\sup _{x \in X} \rho\left(f_{n}(x), f(x)\right)<\varepsilon
$$

Here is a well known example illustrating the difference between pointwise and uniform convergence.

Example 7.11.10 Let $f_{n}(x)=x^{n}$ on the metric space $[0,1]$. Then this function converges pointwise to

$$
f(x)=\left\{\begin{array}{l}
0 \text { on }[0,1) \\
1 \text { at } 1
\end{array}\right.
$$

but it does not converge uniformly on this interval to $f$.

Note how the target function $f$ in the above example is not continuous even though each function in the sequence is. The nice thing about uniform convergence is that it takes continuity of the functions in the sequence and imparts it to the target function. It does this for both continuity at a single point and uniform continuity. Thus uniform convergence is a very superior thing.

Theorem 7.11.11 Let $f_{n}: X \rightarrow Y$ where $(X, d),(Y, \rho)$ are two metric spaces and suppose each $f_{n}$ is continuous at $x \in X$ and also that $f_{n}$ converges uniformly to $f$ on $X$. Then $f$ is also continuous at $x$. In addition to this, if each $f_{n}$ is uniformly continuous on $X$, then the same is true for $f$.

Proof: Let $\varepsilon>0$ be given. Then

$$
\rho(f(x), f(\hat{x})) \leq \rho\left(f(x), f_{n}(x)\right)+\rho\left(f_{n}(x), f_{n}(\hat{x})\right)+\rho\left(f_{n}(\hat{x}), f(\hat{x})\right)
$$

By uniform convergence, there exists $N$ such that both $\rho\left(f(x), f_{n}(x)\right)$ and $\rho\left(f_{n}(\hat{x}), f(\hat{x})\right)$ are less than $\varepsilon / 3$ provided $n \geq N$. Thus picking such an $n$,

$$
\rho(f(x), f(\hat{x})) \leq \frac{2 \varepsilon}{3}+\rho\left(f_{n}(x), f_{n}(\hat{x})\right)
$$

Now from the continuity of $f_{n}$, there exists $\delta>0$ such that if $d(x, \hat{x})<\delta$, then

$$
\rho\left(f_{n}(x), f_{n}(\hat{x})\right)<\varepsilon / 3 .
$$

Hence, if $d(x, \hat{x})<\delta$, then

$$
\rho(f(x), f(\hat{x})) \leq \frac{2 \varepsilon}{3}+\rho\left(f_{n}(x), f_{n}(\hat{x})\right)<\frac{2 \varepsilon}{3}+\frac{\varepsilon}{3}=\varepsilon
$$

Hence, $f$ is continuous at $x$.
Next consider uniform continuity. It follows from the uniform convergence that if $x, \hat{x}$ are any two points of $X$, then if $n \geq N$, then, picking such an $n$,

$$
\rho(f(x), f(\hat{x})) \leq \frac{2 \varepsilon}{3}+\rho\left(f_{n}(x), f_{n}(\hat{x})\right)
$$

By uniform continuity of $f_{n}$ there exists $\boldsymbol{\delta}$ such that if $d(x, \hat{x})<\boldsymbol{\delta}$, then the term on the right in the above is less than $\varepsilon / 3$. Hence if $d(x, \hat{x})<\delta$, then $\rho(f(x), f(\hat{x}))<\varepsilon$ and so $f$ is uniformly continuous as claimed.

### 7.12 General Topological Spaces

It turns out that metric spaces are not sufficiently general for some applications. This section is a brief introduction to general topology. In making this generalization, the properties of balls which are the conclusion of Theorem 7.1.4 on Page 135 are stated as axioms for a subset of the power set of a given set which will be known as a basis for the topology. More can be found in [83] and the references listed there.

Definition 7.12.1 Let $X$ be a nonempty set and suppose $\mathscr{B} \subseteq \mathscr{P}(X)$. Then $\mathscr{B}$ is a basis for a topology if it satisfies the following axioms.
1.) Whenever $p \in A \cap B$ for $A, B \in \mathscr{B}$, it follows there exists $C \in \mathscr{B}$ such that $p \in C \subseteq$ $A \cap B$.
2.) $\cup \mathscr{B}=X$.

Then a subset, $U$, of $X$ is an open set if for every point, $x \in U$, there exists $B \in \mathscr{B}$ such that $x \in B \subseteq U$. Thus the open sets are exactly those which can be obtained as a union of sets of $\mathscr{B}$. Denote these subsets of $X$ by the symbol $\tau$ and refer to $\tau$ as the topology or the set of open sets.

Note that this is simply the analog of saying a set is open exactly when every point is an interior point.

Proposition 7.12.2 Let $X$ be a set and let $\mathscr{B}$ be a basis for a topology as defined above and let $\tau$ be the set of open sets determined by $\mathscr{B}$. Then

$$
\begin{gather*}
\emptyset \in \tau, X \in \tau  \tag{7.12.12}\\
\text { If } \mathscr{C} \subseteq \tau, \text { then } \cup \mathscr{C} \in \tau  \tag{7.12.13}\\
\text { If } A, B \in \tau, \text { then } A \cap B \in \tau . \tag{7.12.14}
\end{gather*}
$$

Proof: If $p \in \emptyset$ then there exists $B \in \mathscr{B}$ such that $p \in B \subseteq \emptyset$ because there are no points in $\emptyset$. Therefore, $\emptyset \in \tau$. Now if $p \in X$, then by part 2.) of Definition 7.12.1 $p \in B \subseteq X$ for some $B \in \mathscr{B}$ and so $X \in \tau$.

If $\mathscr{C} \subseteq \tau$, and if $p \in \cup \mathscr{C}$, then there exists a set, $B \in \mathscr{C}$ such that $p \in B$. However, $B$ is itself a union of sets from $\mathscr{B}$ and so there exists $C \in \mathscr{B}$ such that $p \in C \subseteq B \subseteq \cup \mathscr{C}$. This verifies 7.12.13.

Finally, if $A, B \in \tau$ and $p \in A \cap B$, then since $A$ and $B$ are themselves unions of sets of $\mathscr{B}$, it follows there exists $A_{1}, B_{1} \in \mathscr{B}$ such that $A_{1} \subseteq A, B_{1} \subseteq B$, and $p \in A_{1} \cap B_{1}$. Therefore, by 1.) of Definition 7.12.1 there exists $C \in \mathscr{B}$ such that $p \in C \subseteq A_{1} \cap B_{1} \subseteq A \cap B$, showing that $A \cap B \in \tau$ as claimed. Of course if $A \cap B=\emptyset$, then $A \cap B \in \tau$. This proves the proposition.

Definition 7.12.3 A set $X$ together with such a collection of its subsets satisfying 7.12.127.12.14 is called a topological space. $\tau$ is called the topology or set of open sets of $X$.

Definition 7.12.4 A topological space is said to be Hausdorff if whenever $p$ and $q$ are distinct points of $X$, there exist disjoint open sets $U, V$ such that $p \in U, q \in V$. In other words points can be separated with open sets.

Definition 7.12.5 A subset of a topological space is said to be closed if its complement is open. Let $p$ be a point of $X$ and let $E \subseteq X$. Then $p$ is said to be a limit point of $E$ if every open set containing $p$ contains a point of $E$ distinct from $p$.

Note that if the topological space is Hausdorff, then this definition is equivalent to requiring that every open set containing $p$ contains infinitely many points from $E$. Why?

Theorem 7.12.6 A subset, $E$, of $X$ is closed if and only if it contains all its limit points.
Proof: Suppose first that $E$ is closed and let $x$ be a limit point of $E$. Is $x \in E$ ? If $x \notin E$, then $E^{C}$ is an open set containing $x$ which contains no points of $E$, a contradiction. Thus $x \in E$.

Now suppose $E$ contains all its limit points. Is the complement of $E$ open? If $x \in E^{C}$, then $x$ is not a limit point of $E$ because $E$ has all its limit points and so there exists an open set, $U$ containing $x$ such that $U$ contains no point of $E$ other than $x$. Since $x \notin E$, it follows that $x \in U \subseteq E^{C}$ which implies $E^{C}$ is an open set because this shows $E^{C}$ is the union of open sets.

Theorem 7.12.7 If $(X, \tau)$ is a Hausdorff space and if $p \in X$, then $\{p\}$ is a closed set.
Proof: If $x \neq p$, there exist open sets $U$ and $V$ such that $x \in U, p \in V$ and $U \cap V=\emptyset$. Therefore, $\{p\}^{C}$ is an open set so $\{p\}$ is closed.

Note that the Hausdorff axiom was stronger than needed in order to draw the conclusion of the last theorem. In fact it would have been enough to assume that if $x \neq y$, then there exists an open set containing $x$ which does not intersect $y$.

Definition 7.12.8 A topological space $(X, \tau)$ is said to be regular if whenever $C$ is a closed set and $p$ is a point not in $C$, there exist disjoint open sets $U$ and $V$ such that $p \in U, C \subseteq V$. Thus a closed set can be separated from a point not in the closed set by two disjoint open sets.

Definition 7.12.9 The topological space, $(X, \tau)$ is said to be normal if whenever $C$ and $K$ are disjoint closed sets, there exist disjoint open sets $U$ and $V$ such that $C \subseteq U, K \subseteq V$. Thus any two disjoint closed sets can be separated with open sets.

Normal

Definition 7.12.10 Let $E$ be a subset of $X . \bar{E}$ is defined to be the smallest closed set containing $E$.

Lemma 7.12.11 The above definition is well defined.
Proof: Let $\mathscr{C}$ denote all the closed sets which contain $E$. Then $\mathscr{C}$ is nonempty because $X \in \mathscr{C}$.

$$
(\cap\{A: A \in \mathscr{C}\})^{C}=\cup\left\{A^{C}: A \in \mathscr{C}\right\},
$$

an open set which shows that $\cap \mathscr{C}$ is a closed set and is the smallest closed set which contains $E$.

Theorem 7.12.12 $\bar{E}=E \cup\{$ limit points of $E\}$.
Proof: Let $x \in \bar{E}$ and suppose that $x \notin E$. If $x$ is not a limit point either, then there exists an open set, $U$,containing $x$ which does not intersect $E$. But then $U^{C}$ is a closed set which contains $E$ which does not contain $x$, contrary to the definition that $\bar{E}$ is the intersection of all closed sets containing $E$. Therefore, $x$ must be a limit point of $E$ after all.

Now $E \subseteq \bar{E}$ so suppose $x$ is a limit point of $E$. Is $x \in \bar{E}$ ? If $H$ is a closed set containing $E$, which does not contain $x$, then $H^{C}$ is an open set containing $x$ which contains no points of $E$ other than $x$ negating the assumption that $x$ is a limit point of $E$.

The following is the definition of continuity in terms of general topological spaces. It is really just a generalization of the $\varepsilon-\delta$ definition of continuity given in calculus.

Definition 7.12.13 Let $(X, \tau)$ and $(Y, \eta)$ be two topological spaces and let $f: X \rightarrow Y . f$ is continuous at $x \in X$ if whenever $V$ is an open set of $Y$ containing $f(x)$, there exists an open set $U \in \tau$ such that $x \in U$ and $f(U) \subseteq V$. $f$ is continuous if $f^{-1}(V) \in \tau$ whenever $V \in \eta$.

You should prove the following.
Proposition 7.12.14 In the situation of Definition $7.12 .13 f$ is continuous if and only if $f$ is continuous at every point of $X$.

Definition 7.12.15 Let $\left(X_{i}, \tau_{i}\right)$ be topological spaces. $\prod_{i=1}^{n} X_{i}$ is the Cartesian product. Define a product topology as follows. Let $\mathscr{B}=\prod_{i=1}^{n} A_{i}$ where $A_{i} \in \tau_{i}$. Then $\mathscr{B}$ is a basis for the product topology.

Theorem 7.12.16 The set $\mathscr{B}$ of Definition 7.12.15 is a basis for a topology.
Proof: Suppose $\mathbf{x} \in \prod_{i=1}^{n} A_{i} \cap \prod_{i=1}^{n} B_{i}$ where $A_{i}$ and $B_{i}$ are open sets. Say

$$
\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)
$$

Then $x_{i} \in A_{i} \cap B_{i}$ for each $i$. Therefore, $\mathbf{x} \in \prod_{i=1}^{n} A_{i} \cap B_{i} \in \mathscr{B}$ and $\prod_{i=1}^{n} A_{i} \cap B_{i} \subseteq \prod_{i=1}^{n} A_{i}$.
The definition of compactness is also considered for a general topological space. This is given next.

Definition 7.12.17 A subset, $E$, of a topological space $(X, \tau)$ is said to be compact if whenever $\mathscr{C} \subseteq \tau$ and $E \subseteq \cup \mathscr{C}$, there exists a finite subset of $\mathscr{C},\left\{U_{1} \cdots U_{n}\right\}$, such that $E \subseteq \cup_{i=1}^{n} U_{i}$. (Every open covering admits a finite subcovering.) $E$ is precompact if $\bar{E}$ is compact. A topological space is called locally compact if it has a basis $\mathscr{B}$, with the property that $\bar{B}$ is compact for each $B \in \mathscr{B}$.

In general topological spaces there may be no concept of "bounded". Even if there is, closed and bounded is not necessarily the same as compactness. However, in any Hausdorff space every compact set must be a closed set.

Theorem 7.12.18 If $(X, \tau)$ is a Hausdorff space, then every compact subset must also be a closed set.

Proof: Suppose $p \notin K$. For each $x \in X$, there exist open sets, $U_{x}$ and $V_{x}$ such that

$$
x \in U_{x}, p \in V_{x},
$$

and

$$
U_{x} \cap V_{x}=\emptyset .
$$

If $K$ is assumed to be compact, there are finitely many of these sets, $U_{x_{1}}, \cdots, U_{x_{m}}$ which cover $K$. Then let $V \equiv \cap_{i=1}^{m} V_{x_{i}}$. It follows that $V$ is an open set containing $p$ which has empty intersection with each of the $U_{x_{i}}$. Consequently, $V$ contains no points of $K$ and is therefore not a limit point of $K$. This proves the theorem.

A useful construction when dealing with locally compact Hausdorff spaces is the notion of the one point compactification of the space.

Definition 7.12.19 Suppose $(X, \tau)$ is a locally compact Hausdorff space. Then let $\widetilde{X} \equiv$ $X \cup\{\infty\}$ where $\infty$ is just the name of some point which is not in $X$ which is called the point at infinity. A basis for the topology $\widetilde{\tau}$ for $\widetilde{X}$ is

$$
\tau \cup\left\{K^{C} \text { where } K \text { is a compact subset of } X\right\} .
$$

The complement is taken with respect to $\widetilde{X}$ and so the open sets, $K^{C}$ are basic open sets which contain $\infty$.

The reason this is called a compactification is contained in the next lemma.
Lemma 7.12.20 If $(X, \tau)$ is a locally compact Hausdorff space, then $(\widetilde{X}, \tilde{\tau})$ is a compact Hausdorff space. Also if $U$ is an open set of $\tilde{\tau}$, then $U \backslash\{\infty\}$ is an open set of $\tau$.

Proof: Since $(X, \tau)$ is a locally compact Hausdorff space, it follows $(\widetilde{X}, \tilde{\tau})$ is a Hausdorff topological space. The only case which needs checking is the one of $p \in X$ and $\infty$. Since $(X, \tau)$ is locally compact, there exists an open set of $\tau, U$ having compact closure which contains $p$. Then $p \in U$ and $\infty \in \bar{U}^{C}$ and these are disjoint open sets containing the points, $p$ and $\infty$ respectively. Now let $\mathscr{C}$ be an open cover of $\widetilde{X}$ with sets from $\widetilde{\tau}$. Then $\infty$ must be in some set, $U_{\infty}$ from $\mathscr{C}$, which must contain a set of the form $K^{C}$ where $K$ is a
compact subset of $X$. Then there exist sets from $\mathscr{C}, U_{1}, \cdots, U_{r}$ which cover $K$. Therefore, a finite subcover of $\widetilde{X}$ is $U_{1}, \cdots, U_{r}, U_{\infty}$.

To see the last claim, suppose $U$ contains $\infty$ since otherwise there is nothing to show. Notice that if $C$ is a compact set, then $X \backslash C$ is an open set. Therefore, if $x \in U \backslash\{\infty\}$, and if $\widetilde{X} \backslash C$ is a basic open set contained in $U$ containing $\infty$, then if $x$ is in this basic open set of $\widetilde{X}$, it is also in the open set $X \backslash C \subseteq U \backslash\{\infty\}$. If $x$ is not in any basic open set of the form $\widetilde{X} \backslash C$ then $x$ is contained in an open set of $\tau$ which is contained in $U \backslash\{\infty\}$. Thus $U \backslash\{\infty\}$ is indeed open in $\tau$.

Definition 7.12.21 If every finite subset of a collection of sets has nonempty intersection, the collection has the finite intersection property.

Theorem 7.12.22 Let $\mathscr{K}$ be a set whose elements are compact subsets of a Hausdorff topological space, $(X, \tau)$. Suppose $\mathscr{K}$ has the finite intersection property. Then $\emptyset \neq \cap \mathscr{K}$.

Proof: Suppose to the contrary that $\emptyset=\cap \mathscr{K}$. Then consider

$$
\mathscr{C} \equiv\left\{K^{C}: K \in \mathscr{K}\right\}
$$

It follows $\mathscr{C}$ is an open cover of $K_{0}$ where $K_{0}$ is any particular element of $\mathscr{K}$. But then there are finitely many $K \in \mathscr{K}, K_{1}, \cdots, K_{r}$ such that $K_{0} \subseteq \cup_{i=1}^{r} K_{i}^{C}$ implying that $\cap_{i=0}^{r} K_{i}=\emptyset$, contradicting the finite intersection property.

Lemma 7.12.23 Let $(X, \tau)$ be a topological space and let $\mathscr{B}$ be a basis for $\tau$. Then $K$ is compact if and only if every open cover of basic open sets admits a finite subcover.

Proof: Suppose first that $X$ is compact. Then if $\mathscr{C}$ is an open cover consisting of basic open sets, it follows it admits a finite subcover because these are open sets in $\mathscr{C}$.

Next suppose that every basic open cover admits a finite subcover and let $\mathscr{C}$ be an open cover of $X$. Then define $\widetilde{\mathscr{C}}$ to be the collection of basic open sets which are contained in some set of $\mathscr{C}$. It follows $\tilde{\mathscr{C}}$ is a basic open cover of $X$ and so it admits a finite subcover, $\left\{U_{1}, \cdots, U_{p}\right\}$. Now each $U_{i}$ is contained in an open set of $\mathscr{C}$. Let $O_{i}$ be a set of $\mathscr{C}$ which contains $U_{i}$. Then $\left\{O_{1}, \cdots, O_{p}\right\}$ is an open cover of $X$. This proves the lemma.

In fact, much more can be said than Lemma 7.12.23. However, this is all which I will present here.

### 7.13 Connected Sets

Stated informally, connected sets are those which are in one piece. More precisely,
Definition 7.13.1 A set, $S$ in a general topological space is separated if there exist sets, $A, B$ such that

$$
S=A \cup B, A, B \neq \emptyset, \text { and } \bar{A} \cap B=\bar{B} \cap A=\emptyset
$$

In this case, the sets $A$ and $B$ are said to separate $S$. A set is connected if it is not separated.

One of the most important theorems about connected sets is the following.

Theorem 7.13.2 Suppose $U$ and $V$ are connected sets having nonempty intersection. Then $U \cup V$ is also connected.

Proof: Suppose $U \cup V=A \cup B$ where $\bar{A} \cap B=\bar{B} \cap A=\emptyset$. Consider the sets, $A \cap U$ and $B \cap U$. Since

$$
\overline{(A \cap U)} \cap(B \cap U)=(A \cap U) \cap(\overline{B \cap U})=\emptyset,
$$

It follows one of these sets must be empty since otherwise, $U$ would be separated. It follows that $U$ is contained in either $A$ or $B$. Similarly, $V$ must be contained in either $A$ or $B$. Since $U$ and $V$ have nonempty intersection, it follows that both $V$ and $U$ are contained in one of the sets, $A, B$. Therefore, the other must be empty and this shows $U \cup V$ cannot be separated and is therefore, connected.

The intersection of connected sets is not necessarily connected as is shown by the following picture.

Theorem 7.13.3 Let $f: X \rightarrow Y$ be continuous where $X$ and $Y$ are topological spaces and $X$ is connected. Then $f(X)$ is also connected.

Proof: To do this you show $f(X)$ is not separated. Suppose to the contrary that $f(X)=$ $A \cup B$ where $A$ and $B$ separate $f(X)$. Then consider the sets, $f^{-1}(A)$ and $f^{-1}(B)$. If $z$ $\in f^{-1}(B)$, then $f(z) \in B$ and so $f(z)$ is not a limit point of $A$. Therefore, there exists an open set, $U$ containing $f(z)$ such that $U \cap A=\emptyset$. But then, the continuity of $f$ implies that $f^{-1}(U)$ is an open set containing $z$ such that $f^{-1}(U) \cap f^{-1}(A)=\emptyset$. Therefore, $f^{-1}(B)$ contains no limit points of $f^{-1}(A)$. Similar reasoning implies $f^{-1}(A)$ contains no limit points of $f^{-1}(B)$. It follows that $X$ is separated by $f^{-1}(A)$ and $f^{-1}(B)$, contradicting the assumption that $X$ was connected.

An arbitrary set can be written as a union of maximal connected sets called connected components. This is the concept of the next definition.

Definition 7.13.4 Let $S$ be a set and let $p \in S$. Denote by $C_{p}$ the union of all connected subsets of $S$ which contain $p$. This is called the connected component determined by $p$.

Theorem 7.13.5 Let $C_{p}$ be a connected component of a set $S$ in a general topological space. Then $C_{p}$ is a connected set and if $C_{p} \cap C_{q} \neq \emptyset$, then $C_{p}=C_{q}$.

Proof: Let $\mathscr{C}$ denote the connected subsets of $S$ which contain $p$. If $C_{p}=A \cup B$ where

$$
\bar{A} \cap B=\bar{B} \cap A=\emptyset,
$$

then $p$ is in one of $A$ or $B$. Suppose without loss of generality $p \in A$. Then every set of $\mathscr{C}$ must also be contained in $A$ also since otherwise, as in Theorem 7.13.2, the set would be separated. But this implies $B$ is empty. Therefore, $C_{p}$ is connected. From this, and Theorem 7.13.2, the second assertion of the theorem is proved.

This shows the connected components of a set are equivalence classes and partition the set.

A set, $I$ is an interval in $\mathbb{R}$ if and only if whenever $x, y \in I$ then $(x, y) \subseteq I$. The following theorem is about the connected sets in $\mathbb{R}$.

Theorem 7.13.6 A set, $C$ in $\mathbb{R}$ is connected if and only if $C$ is an interval.
Proof: Let $C$ be connected. If $C$ consists of a single point, $p$, there is nothing to prove. The interval is just $[p, p]$. Suppose $p<q$ and $p, q \in C$. You need to show $(p, q) \subseteq C$. If

$$
x \in(p, q) \backslash C
$$

let $C \cap(-\infty, x) \equiv A$, and $C \cap(x, \infty) \equiv B$. Then $C=A \cup B$ and the sets, $A$ and $B$ separate $C$ contrary to the assumption that $C$ is connected.

Conversely, let $I$ be an interval. Suppose $I$ is separated by $A$ and $B$. Pick $x \in A$ and $y \in B$. Suppose without loss of generality that $x<y$. Now define the set,

$$
S \equiv\{t \in[x, y]:[x, t] \subseteq A\}
$$

and let $l$ be the least upper bound of $S$. Then $l \in \bar{A}$ so $l \notin B$ which implies $l \in A$. But if $l \notin \bar{B}$, then for some $\delta>0$,

$$
(l, l+\delta) \cap B=\emptyset
$$

contradicting the definition of $l$ as an upper bound for $S$. Therefore, $l \in \bar{B}$ which implies $l \notin A$ after all, a contradiction. It follows $I$ must be connected.

The following theorem is a very useful description of the open sets in $\mathbb{R}$.
Theorem 7.13.7 Let $U$ be an open set in $\mathbb{R}$. Then there exist countably many disjoint open sets, $\left\{\left(a_{i}, b_{i}\right)\right\}_{i=1}^{\infty}$ such that $U=\cup_{i=1}^{\infty}\left(a_{i}, b_{i}\right)$.

Proof: Let $p \in U$ and let $z \in C_{p}$, the connected component determined by $p$. Since $U$ is open, there exists, $\delta>0$ such that $(z-\delta, z+\delta) \subseteq U$. It follows from Theorem 7.13.2 that

$$
(z-\delta, z+\delta) \subseteq C_{p}
$$

This shows $C_{p}$ is open. By Theorem 7.13.6, this shows $C_{p}$ is an open interval, $(a, b)$ where $a, b \in[-\infty, \infty]$. There are therefore at most countably many of these connected components because each must contain a rational number and the rational numbers are countable. Denote by $\left\{\left(a_{i}, b_{i}\right)\right\}_{i=1}^{\infty}$ the set of these connected components. This proves the theorem.

Definition 7.13.8 A topological space, $E$ is arcwise connected if for any two points, $p, q \in$ $E$, there exists a closed interval, $[a, b]$ and a continuous function, $\gamma:[a, b] \rightarrow E$ such that $\gamma(a)=p$ and $\gamma(b)=q$. $E$ is locally connected if it has a basis of connected open sets. $E$ is locally arcwise connected if it has a basis of arcwise connected open sets.

An example of an arcwise connected topological space would be the any subset of $\mathbb{R}^{n}$ which is the continuous image of an interval. Locally connected is not the same as connected. A well known example is the following.

$$
\begin{equation*}
\left\{\left(x, \sin \frac{1}{x}\right): x \in(0,1]\right\} \cup\{(0, y): y \in[-1,1]\} \tag{7.13.15}
\end{equation*}
$$

You can verify that this set of points considered as a metric space with the metric from $\mathbb{R}^{2}$ is not locally connected or arcwise connected but is connected.

Proposition 7.13.9 If a topological space is arcwise connected, then it is connected.
Proof: Let $X$ be an arcwise connected space and suppose it is separated. Then $X=$ $A \cup B$ where $A, B$ are two separated sets. Pick $p \in A$ and $q \in B$. Since $X$ is given to be arcwise connected, there must exist a continuous function $\gamma:[a, b] \rightarrow X$ such that $\gamma(a)=p$ and $\gamma(b)=q$. But then we would have $\gamma([a, b])=(\gamma([a, b]) \cap A) \cup(\gamma([a, b]) \cap B)$ and the two sets, $\gamma([a, b]) \cap A$ and $\gamma([a, b]) \cap B$ are separated thus showing that $\gamma([a, b])$ is separated and contradicting Theorem 7.13.6 and Theorem 7.13.3. It follows that $X$ must be connected as claimed.

Theorem 7.13.10 Let $U$ be an open subset of a locally arcwise connected topological space, $X$. Then $U$ is arcwise connected if and only if $U$ if connected. Also the connected components of an open set in such a space are open sets, hence arcwise connected.

Proof: By Proposition 7.13.9 it is only necessary to verify that if $U$ is connected and open in the context of this theorem, then $U$ is arcwise connected. Pick $p \in U$. Say $x \in U$ satisfies $\mathscr{P}$ if there exists a continuous function, $\gamma:[a, b] \rightarrow U$ such that $\gamma(a)=p$ and $\gamma(b)=x$.

$$
A \equiv\{x \in U \text { such that } x \text { satisfies } \mathscr{P} .\}
$$

If $x \in A$, there exists, according to the assumption that $X$ is locally arcwise connected, an open set, $V$, containing $x$ and contained in $U$ which is arcwise connected. Thus letting $y \in V$, there exist intervals, $[a, b]$ and $[c, d]$ and continuous functions having values in $U$, $\gamma, \eta$ such that $\gamma(a)=p, \gamma(b)=x, \eta(c)=x$, and $\eta(d)=y$. Then let $\gamma_{1}:[a, b+d-c] \rightarrow U$ be defined as

$$
\gamma_{1}(t) \equiv\left\{\begin{array}{l}
\gamma(t) \text { if } t \in[a, b] \\
\eta(t+c-b) \text { if } t \in[b, b+d-c]
\end{array}\right.
$$

Then it is clear that $\gamma_{1}$ is a continuous function mapping $p$ to $y$ and showing that $V \subseteq A$. Therefore, $A$ is open. $A \neq \emptyset$ because there is an open set, $V$ containing $p$ which is contained in $U$ and is arcwise connected.

Now consider $B \equiv U \backslash A$. This is also open. If $B$ is not open, there exists a point $z \in B$ such that every open set containing $z$ is not contained in $B$. Therefore, letting $V$ be one of
the basic open sets chosen such that $z \in V \subseteq U$, there exist points of $A$ contained in $V$. But then, a repeat of the above argument shows $z \in A$ also. Hence $B$ is open and so if $B \neq \emptyset$, then $U=B \cup A$ and so $U$ is separated by the two sets, $B$ and $A$ contradicting the assumption that $U$ is connected.

It remains to verify the connected components are open. Let $z \in C_{p}$ where $C_{p}$ is the connected component determined by $p$. Then picking $V$ an arcwise connected open set which contains $z$ and is contained in $U, C_{p} \cup V$ is connected and contained in $U$ and so it must also be contained in $C_{p}$. This proves the theorem.

As an application, consider the following corollary.
Corollary 7.13.11 Let $f: \Omega \rightarrow \mathbb{Z}$ be continuous where $\Omega$ is a connected open set. Then $f$ must be a constant.

Proof: Suppose not. Then it achieves two different values, $k$ and $l \neq k$. Then $\Omega=$ $f^{-1}(l) \cup f^{-1}(\{m \in \mathbb{Z}: m \neq l\})$ and these are disjoint nonempty open sets which separate $\Omega$. To see they are open, note

$$
f^{-1}(\{m \in \mathbb{Z}: m \neq l\})=f^{-1}\left(\cup_{m \neq l}\left(m-\frac{1}{6}, m+\frac{1}{6}\right)\right)
$$

which is the inverse image of an open set.

### 7.14 Exercises

1. Let $d(x, y)=|x-y|$ for $x, y \in \mathbb{R}$. Show that this is a metric on $\mathbb{R}$.
2. Now consider $\mathbb{R}^{n}$. Let $\|\mathbf{x}\|_{\infty} \equiv \max \left\{\left|x_{i}\right|, i=1, \cdots, n\right\}$. Define

$$
d(\mathbf{x}, \mathbf{y}) \equiv\|\mathbf{x}-\mathbf{y}\|_{\infty}
$$

Show that this is a metric on $\mathbb{R}^{n}$. In the case of $n=2$, describe the ball $B(\mathbf{0}, r)$. Hint: First show that $\|\mathbf{x}+\mathbf{y}\| \leq\|\mathbf{x}\|+\|\mathbf{y}\|$.
3. Let $C([0, T])$ denote the space of functions which are continuous on $[0, T]$. Define

$$
\|f\| \equiv \sup _{t \in[0, T]}|f(t)|=\max _{t \in[0, T]}|f(t)|
$$

Verify the following. $\|f+g\| \leq\|f\|+\|g\|$. Then use to show that $d(f, g) \equiv\|f-g\|$ is a metric and that with this metric, $(C([0, T]), d)$ is a metric space.
4. Recall that $[a, b]$ is compact. This was done in single variable advanced calculus. That is, every sequence has a convergent subsequence. (We will go over it in here as well.) Also recall that a sequence of numbers $\left\{x_{n}\right\}$ is a Cauchy sequence means that for every $\varepsilon>0$ there exists $N$ such that if $m, n>N$, then $\left|x_{n}-x_{m}\right|<\varepsilon$. First show that every Cauchy sequence is bounded. Next, using the compactness of closed intervals, show that every Cauchy sequence has a convergent subsequence. It is shown later that if this is true, the original Cauchy sequence converges. Thus $\mathbb{R}$ with the usual metric just described is complete because every Cauchy sequence converges.
5. Using the result of the above problem, show that $\left(\mathbb{R}^{n},\|\cdot\|_{\infty}\right)$ is a complete metric space. That is, every Cauchy sequence converges. Here $d(\mathbf{x}, \mathbf{y}) \equiv\|\mathbf{x}-\mathbf{y}\|_{\infty}$.
6. Suppose you had $\left(X_{i}, d_{i}\right)$ is a metric space. Now consider the product space

$$
X \equiv \prod_{i=1}^{n} X_{i}
$$

with $d(\mathbf{x}, \mathbf{y})=\max \left\{d\left(x_{i}, y_{i}\right), i=1 \cdots, n\right\}$. Would this be a metric space? If so, prove that this is the case.
Does triangle inequality hold? Hint: For each $i$,

$$
d_{i}\left(x_{i}, z_{i}\right) \leq d_{i}\left(x_{i}, y_{i}\right)+d_{i}\left(y_{i}, z_{i}\right) \leq d(\mathbf{x}, \mathbf{y})+d(\mathbf{y}, \mathbf{z})
$$

Now take max of the two ends.
7. In the above example, if each $\left(X_{i}, d_{i}\right)$ is complete, explain why $(X, d)$ is also complete.
8. Show that $C([0, T])$ is a complete metric space. That is, show that if $\left\{f_{n}\right\}$ is a Cauchy sequence, then there exists $f \in C([0, T])$ such that

$$
\lim _{n \rightarrow \infty} d\left(f, f_{n}\right)=\lim _{n \rightarrow \infty}\left\|f-f_{n}\right\|=0
$$

Hint: First, you know that $\left\{f_{n}(t)\right\}$ is a Cauchy sequence for each $t$. Why? Now let $f(t)$ be the name of the thing to which $f_{n}(t)$ converges. Recall why the uniform convergence implies $t \rightarrow f(t)$ is continuous. Give the proof. It was done in single variable advanced calculus. Review and write down proof. Also show that $\left\|f-f_{n}\right\| \rightarrow 0$.
9. Let $X$ be a nonempty set of points. Say it has infinitely many points. Define $d(x, y)=$ 1 if $x \neq y$ and $d(x, y)=0$ if $x=y$. Show that this is a metric. Show that in $(X, d)$ every point is open and closed. In fact, show that every set is open and every set is closed. Is this a complete metric space? Explain why. Describe the open balls.
10. Show that the union of any set of open sets is an open set. Show the intersection of any set of closed sets is closed. Let $A$ be a nonempty subset of a metric space $(X, d)$. Then the closure of $A$, written as $\bar{A}$ is defined to be the intersection of all closed sets which contain $A$. Show that $\bar{A}=A \cup A^{\prime}$. That is, to find the closure, you just take the set and include all limit points of the set.
11. Let $A^{\prime}$ denote the set of limit points of $A$, a nonempty subset of a metric space $(X, d)$. Show that $A^{\prime}$ is closed.
12. A theorem was proved which gave three equivalent descriptions of compactness of a metric space. One of them said the following: A metric space is compact if and only if it is complete and totally bounded. Suppose $(X, d)$ is a complete metric space and $K \subseteq X$. Then $(K, d)$ is also clearly a metric space having the same metric as $X$.

Show that $(K, d)$ is compact if and only if it is closed and totally bounded. Note the similarity with the Heine Borel theorem on $\mathbb{R}$. Show that on $\mathbb{R}$, every bounded set is also totally bounded. Thus the earlier Heine Borel theorem for $\mathbb{R}$ is obtained.
13. Suppose $\left(X_{i}, d_{i}\right)$ is a compact metric space. Then the Cartesian product is also a metric space. That is $\left(\prod_{i=1}^{n} X_{i}, d\right)$ is a metric space where $d(\mathbf{x}, \mathbf{y}) \equiv \max \left\{d_{i}\left(x_{i}, y_{i}\right)\right\}$. Show that $\left(\prod_{i=1}^{n} X_{i}, d\right)$ is compact. Recall the Heine Borel theorem for $\mathbb{R}$. Explain why

$$
\prod_{i=1}^{n}\left[a_{i}, b_{i}\right]
$$

is compact in $\mathbb{R}^{n}$ with the distance given by $d(\mathbf{x}, \mathbf{y})=\max \left\{\left|x_{i}-y_{i}\right|\right\}$. Hint: It suffices to show that $\left(\prod_{i=1}^{n} X_{i}, d\right)$ is sequentially compact. Let $\left\{\mathbf{x}^{m}\right\}_{m=1}^{\infty}$ be a sequence. Then $\left\{x_{1}^{m}\right\}_{m=1}^{\infty}$ is a sequence in $X_{i}$. Therefore, it has a subsequence $\left\{x_{1}^{k_{1}}\right\}_{k_{1}=1}^{\infty}$ which converges to a point $x_{1} \in X_{1}$. Now consider $\left\{x_{2}^{k_{1}}\right\}_{k_{1}=1}^{\infty}$ the second components. It has a subsequence denoted as $k_{2}$ such that $\left\{x_{2}^{k_{2}}\right\}_{k_{2}=1}^{\infty_{1}=1}$ converges to a point $x_{2}$ in $X_{2}$. Explain why $\lim _{k_{2} \rightarrow \infty} x_{1}^{k_{2}}=x_{1}$. Continue doing this $n$ times. Explain why $\lim _{k_{n} \rightarrow \infty} x_{l}^{k_{n}}=x_{l} \in X_{l}$ for each $l$. Then explain why this is the same as saying $\lim _{k_{n} \rightarrow \infty} \mathbf{x}^{k_{n}}=\mathbf{x}$ in $\left(\prod_{i=1}^{n} X_{i}, d\right)$.
14. If you have a metric space $(X, d)$ and a compact subset of $(X, d) K$, suppose that $L$ is a closed subset of $K$. Explain why $L$ must also be compact. Hint: Go right to the definition. Take an open covering of $L$ and consider this along with the open set $L^{C}$ to obtain an open covering of $K$. Now use compactness of $K$. Use this to explain why every closed and bounded set in $\mathbb{R}^{n}$ is compact. Here the distance is given by $d(\mathbf{x}, \mathbf{y}) \equiv \max _{1 \leq i \leq n}\left\{\left|x_{i}-y_{i}\right|\right\}$.
15. Show that compactness is a topological property in the following sense. If

$$
(X, d),(Y, \rho)
$$

are both metric spaces and $f: X \rightarrow Y$ has the property that $f$ is one to one, onto, and continuous, and also $f^{-1}$ is one to one onto and continuous, then the two metric spaces are compact or not compact together. That is one is compact if and only if the other is.
16. Consider $\mathbb{R}$ the real numbers. Define a distance in the following way.

$$
\rho(x, y) \equiv|\arctan (x)-\arctan (y)|
$$

Show this is a good enough distance and that the open sets which come from this distance are the same as the open sets which come from the usual distance $d(x, y)=$ $|x-y|$. Explain why this yields that the identity mapping $f(x)=x$ is continuous with continuous inverse as a map from $(\mathbb{R}, d)$ to $(\mathbb{R}, \rho)$. To do this, you show that an open ball taken with respect to one of these is also open with respect to the other. However,
$(\mathbb{R}, \rho)$ is not a complete metric space while $(\mathbb{R}, d)$ is. Thus, unlike compactness. Completeness is not a topological property. Hint: To show the lack of completeness of $(\mathbb{R}, \rho)$, consider $x_{n}=n$. Show it is a Cauchy sequence with respect to $\rho$.
17. A very useful idea in metric space is the following distance function. Let $(X, d)$ be a metric space and $S \subseteq X, S \neq \emptyset$. Then $\operatorname{dist}(x, S) \equiv \inf \{d(x, y): y \in S\}$. Show that this always satisfies

$$
|\operatorname{dist}(x, S)-\operatorname{dist}(z, S)| \leq d(x, z)
$$

This is a really neat result.
18. If $K$ is a compact subset of $(X, d)$ and $y \notin K$, show that there always exists $x \in K$ such that $d(x, y)=\operatorname{dist}(y, K)$. Give an example in $\mathbb{R}$ to show that this is might not be so if $K$ is not compact.
19. You know that if $f: X \rightarrow X$ for $X$ a complete metric space, then if $d(f(x), f(y))<$ $r d(x, y)$ it follows that $f$ has a unique fixed point theorem. Let $f: \mathbb{R} \rightarrow \mathbb{R}$ be given by

$$
f(t)=t+\left(1+e^{t}\right)^{-1}
$$

Show that $|f(t)-f(s)|<|t-s|$, but $f$ has no fixed point.
20. If $(X, d)$ is a metric space, show that there is a bounded metric $\rho$ such that the open sets for $(X, d)$ are the same as those for $(X, \rho)$.
21. Let $(X, d)$ be a metric space where $d$ is a bounded metric. Let $\mathscr{C}$ denote the collection of closed subsets of $X$. For $A, B \in \mathscr{C}$, define

$$
\rho(A, B) \equiv \inf \left\{\delta>0: A_{\delta} \supseteq B \text { and } B_{\delta} \supseteq A\right\}
$$

where for a set $S$,

$$
S_{\delta} \equiv\{x: \operatorname{dist}(x, S) \equiv \inf \{d(x, s): s \in S\} \leq \delta\}
$$

Show $x \rightarrow \operatorname{dist}(x, S)$ is continuous and that therefore, $S_{\delta}$ is a closed set containing $S$. Also show that $\rho$ is a metric on $\mathscr{C}$. This is called the Hausdorff metric.
22. $\uparrow$ Suppose $(X, d)$ is a compact metric space. Show $(\mathscr{C}, \rho)$ is a complete metric space. Hint: Show first that if $W_{n} \downarrow W$ where $W_{n}$ is closed, then $\rho\left(W_{n}, W\right) \rightarrow 0$. Now let $\left\{A_{n}\right\}$ be a Cauchy sequence in $\mathscr{C}$. Then if $\varepsilon>0$ there exists $N$ such that when $m, n \geq N$, then $\rho\left(A_{n}, A_{m}\right)<\varepsilon$. Therefore, for each $n \geq N$,

$$
\left(A_{n}\right)_{\varepsilon} \supseteq \overline{\cup_{k=n}^{\infty} A_{k}}
$$

Let $A \equiv \cap_{n=1}^{\infty} \overline{\cup_{k=n}^{\infty} A_{k}}$. By the first part, there exists $N_{1}>N$ such that for $n \geq N_{1}$,

$$
\rho\left(\overline{\cup_{k=n}^{\infty} A_{k}}, A\right)<\varepsilon, \text { and }\left(A_{n}\right)_{\varepsilon} \supseteq \overline{\cup_{k=n}^{\infty} A_{k}} .
$$

Therefore, for such $n, A_{\varepsilon} \supseteq W_{n} \supseteq A_{n}$ and $\left(W_{n}\right)_{\varepsilon} \supseteq\left(A_{n}\right)_{\varepsilon} \supseteq A$ because

$$
\left(A_{n}\right)_{\varepsilon} \supseteq \overline{\cup_{k=n}^{\infty} A_{k}} \supseteq A .
$$

23. $\uparrow$ Let $X$ be a compact metric space. Show $(\mathscr{C}, \rho)$ is compact. Hint: Let $\mathscr{D}_{n}$ be a $2^{-n}$ net for $X$. Let $\mathscr{K}_{n}$ denote finite unions of sets of the form $\overline{B\left(p, 2^{-n}\right)}$ where $p \in \mathscr{D}_{n}$. Show $\mathscr{K}_{n}$ is a $2^{-(n-1)}$ net for $(\mathscr{C}, \rho)$.

## Chapter 8

## Normed Linear Spaces

The thing which is missing in the above material about metric spaces is any kind of algebra. In most applications, we are interested in adding things and multiplying things by scalars and so forth. This requires the notion of a vector space, also called a linear space. The simplest example is $\mathbb{R}^{n}$ which is described next.

In this chapter, $\mathbb{F}$ will refer to either $\mathbb{R}$ or $\mathbb{C}$. It doesn't make any difference to the arguments which it is and so $\mathbb{F}$ is written to symbolize whichever you wish to think about. In multivariable calculus, the main example is where $\mathbb{F}=\mathbb{R}$. However, it is nice to observe that things work more generally. The big changes take place when you start to consider the derivative. As to notation, when it is desired to emphasize that certain quantities are vectors, bold face will often be used. This is not necessarily done consistently. Sometimes context is considered sufficient.

### 8.1 Algebra in $\mathbb{F}^{n}$, Vector Spaces

There are two algebraic operations done with elements of $\mathbb{F}^{n}$. One is addition and the other is multiplication by numbers, called scalars. In the case of $\mathbb{C}^{n}$ the scalars are complex numbers while in the case of $\mathbb{R}^{n}$ the only allowed scalars are real numbers. Thus, the scalars always come from $\mathbb{F}$ in either case.

Definition 8.1.1 If $\mathbf{x} \in \mathbb{F}^{n}$ and $a \in \mathbb{F}$, also called a scalar, then $a \mathbf{x} \in \mathbb{F}^{n}$ is defined by

$$
\begin{equation*}
a \mathbf{x}=a\left(x_{1}, \cdots, x_{n}\right) \equiv\left(a x_{1}, \cdots, a x_{n}\right) . \tag{8.1.1}
\end{equation*}
$$

This is known as scalar multiplication. If $\mathbf{x}, \mathbf{y} \in \mathbb{F}^{n}$ then $\mathbf{x}+\mathbf{y} \in \mathbb{F}^{n}$ and is defined by

$$
\begin{align*}
\mathbf{x}+\mathbf{y} & =\left(x_{1}, \cdots, x_{n}\right)+\left(y_{1}, \cdots, y_{n}\right) \\
& \equiv\left(x_{1}+y_{1}, \cdots, x_{n}+y_{n}\right) \tag{8.1.2}
\end{align*}
$$

the points in $\mathbb{F}^{n}$ are also referred to as vectors.
With this definition, the algebraic properties satisfy the conclusions of the following theorem. These conclusions are called the vector space axioms. Any time you have a set and a field of scalars satisfying the axioms of the following theorem, it is called a vector space.

Theorem 8.1.2 $\operatorname{For} \mathbf{v}, \mathbf{w} \in \mathbb{F}^{n}$ and $\alpha, \beta$ scalars, (real numbers), the following hold.

$$
\begin{equation*}
\mathbf{v}+\mathbf{w}=\mathbf{w}+\mathbf{v}, \tag{8.1.3}
\end{equation*}
$$

the commutative law of addition,

$$
\begin{equation*}
(\mathbf{v}+\mathbf{w})+\mathbf{z}=\mathbf{v}+(\mathbf{w}+\mathbf{z}) \tag{8.1.4}
\end{equation*}
$$

the associative law for addition,

$$
\begin{equation*}
\mathbf{v}+\mathbf{0}=\mathbf{v} \tag{8.1.5}
\end{equation*}
$$

the existence of an additive identity,

$$
\begin{equation*}
\mathbf{v}+(-\mathbf{v})=\mathbf{0} \tag{8.1.6}
\end{equation*}
$$

the existence of an additive inverse, Also

$$
\begin{gather*}
\alpha(\mathbf{v}+\mathbf{w})=\alpha \mathbf{v}+\alpha \mathbf{w}  \tag{8.1.7}\\
(\alpha+\beta) \mathbf{v}=\alpha \mathbf{v}+\beta \mathbf{v}  \tag{8.1.8}\\
\alpha(\beta \mathbf{v})=\alpha \beta(\mathbf{v})  \tag{8.1.9}\\
1 \mathbf{v}=\mathbf{v} \tag{8.1.10}
\end{gather*}
$$

In the above $\mathbf{0}=(0, \cdots, 0)$.
You should verify these properties all hold. For example, consider 8.1.7

$$
\begin{aligned}
\alpha(\mathbf{v}+\mathbf{w}) & =\alpha\left(v_{1}+w_{1}, \cdots, v_{n}+w_{n}\right) \\
& =\left(\alpha\left(v_{1}+w_{1}\right), \cdots, \alpha\left(v_{n}+w_{n}\right)\right) \\
& =\left(\alpha v_{1}+\alpha w_{1}, \cdots, \alpha v_{n}+\alpha w_{n}\right) \\
& =\left(\alpha v_{1}, \cdots, \alpha v_{n}\right)+\left(\alpha w_{1}, \cdots, \alpha w_{n}\right) \\
& =\alpha \mathbf{v}+\alpha \mathbf{w} .
\end{aligned}
$$

As usual subtraction is defined as $\mathbf{x}-\mathbf{y} \equiv \mathbf{x}+(-\mathbf{y})$.

### 8.2 Subspaces Spans And Bases

As mentioned above, $\mathbb{F}^{n}$ is an example of a vector space and this is what is studied in linear algebra. The concept of linear combination is fundamental in all of linear algebra. When one considers only algebraic considerations, it makes no difference what field of scalars you are using. It could be $\mathbb{R}, \mathbb{C}, \mathbb{Q}$ or even a field of residue classes. However, go ahead and think $\mathbb{R}$ or $\mathbb{C}$ since the subject of interest here is analysis.

Definition 8.2.1 Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ be vectors in a vector space, $Y$ having the field of scalars $\mathbb{F}$. A linear combination is any expression of the form

$$
\sum_{i=1}^{p} c_{i} \mathbf{x}_{i}
$$

where the $c_{i}$ are scalars. The set of all linear combinations of these vectors is called $\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)$. A vector $\mathbf{v}$ is said to be in the span of some set $S$ of vectors if $\mathbf{v}$ is a linear combination of vectors of $S$. This means: finite linear combination. If $V \subseteq Y$, then $V$ is called a subspace if whenever $\alpha, \beta$ are scalars and $\mathbf{u}$ and $\mathbf{v}$ are vectors of $V$, it follows $\alpha \mathbf{u}+\beta \mathbf{v} \in V$. That is, it is "closed under the algebraic operations of vector addition and scalar multiplication" and is therefore, a vector space. A linear combination of vectors is said to be trivial if all the scalars in the linear combination equal zero. A set of vectors is said to be linearly independent if the only linear combination of these vectors which
equals the zero vector is the trivial linear combination. Thus $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}$ is called linearly independent if whenever

$$
\sum_{k=1}^{p} c_{k} \mathbf{x}_{k}=\mathbf{0}
$$

it follows that all the scalars, $c_{k}$ equal zero. A set of vectors, $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$, is called linearly dependent if it is not linearly independent. Thus the set of vectors is linearly dependent if there exist scalars, $c_{i}, i=1, \cdots, n$, not all zero such that $\sum_{k=1}^{p} c_{k} \mathbf{x}_{k}=\mathbf{0}$.

Lemma 8.2.2 A set of vectors $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ is linearly independent if and only if none of the vectors can be obtained as a linear combination of the others.

Proof: Suppose first that $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ is linearly independent. If

$$
\mathbf{x}_{k}=\sum_{j \neq k} c_{j} \mathbf{x}_{j}
$$

then

$$
\mathbf{0}=1 \mathbf{x}_{k}+\sum_{j \neq k}\left(-c_{j}\right) \mathbf{x}_{j}
$$

a nontrivial linear combination, contrary to assumption. This shows that if the set is linearly independent, then none of the vectors is a linear combination of the others.

Now suppose no vector is a linear combination of the others. Is $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{p}\right\}$ linearly independent? If it is not, there exist scalars, $c_{i}$, not all zero such that

$$
\sum_{i=1}^{p} c_{i} \mathbf{x}_{i}=\mathbf{0}
$$

Say $c_{k} \neq 0$. Then you can solve for $\mathbf{x}_{k}$ as

$$
\mathbf{x}_{k}=\sum_{j \neq k}\left(-c_{j}\right) / c_{k} \mathbf{x}_{j}
$$

contrary to assumption. This proves the lemma.
The following is called the exchange theorem.

## Theorem 8.2.3 If

$$
\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{r}\right) \subseteq \operatorname{span}\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{s}\right) \equiv V
$$

and $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{r}\right\}$ are linearly independent, then $r \leq s$.
Proof: Suppose $r>s$. Let $F_{p}$ denote the first $p$ vectors in $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{r}\right\}$. In case $p=0, F_{p}$ will denote the empty set. Let $E_{p}$ denote a finite list of vectors of $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{s}\right\}$ and let $\left|E_{p}\right|$ denote the number of vectors in the list. For $0 \leq p \leq s$, let $E_{p}$ have the property

$$
\operatorname{span}\left(F_{p}, E_{p}\right)=V
$$

and $\left|E_{p}\right|$ is as small as possible for this to happen. I claim $\left|E_{p}\right| \leq s-p$ if $E_{p}$ is nonempty.

Here is why. For $p=0$, it is obvious because there are $s$ vectors from $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{s}\right\}$ which span $V$, namely those vectors. Of course there might be a smaller list which does so, and so $\left|E_{p}\right| \leq s$. Suppose true for some $p<s$. Then

$$
\mathbf{u}_{p+1} \in \operatorname{span}\left(F_{p}, E_{p}\right)
$$

and so there are constants, $c_{1}, \cdots, c_{p}$ and $d_{1}, \cdots, d_{m}$ where $m \leq s-p$ such that

$$
\mathbf{u}_{p+1}=\sum_{i=1}^{p} c_{i} \mathbf{u}_{i}+\sum_{j=1}^{m} d_{i} \mathbf{z}_{j}
$$

for

$$
\left\{\mathbf{z}_{1}, \cdots, \mathbf{z}_{m}\right\} \subseteq\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{s}\right\} .
$$

Then not all the $d_{i}$ can equal zero because this would violate the linear independence of the $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{r}\right\}$. Therefore, you can solve for one of the $\mathbf{z}_{k}$ as a linear combination of $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{p+1}\right\}$ and the other $\mathbf{z}_{j}$. Thus you can change $F_{p}$ to $F_{p+1}$ and include one fewer vector in $E_{p}$. Thus $\left|E_{p+1}\right| \leq m-1 \leq s-p-1$. This proves the claim.

Therefore, $E_{s}$ is empty and $\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{s}\right)=V$. However, this gives a contradiction because it would require

$$
\mathbf{u}_{s+1} \in \operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{s}\right)
$$

which violates the linear independence of these vectors.
Alternate proof: Recall from linear algebra that if you have $A$ an $m \times n$ matrix where $m<n$ so there are more columns than rows, then there exists a nonzero solution $\mathbf{x}$ to the equation $A \mathbf{x}=\mathbf{0}$. Recall why this was. You must have free variables. Then by assumption, you have

$$
\mathbf{u}_{j}=\sum_{i=1}^{s} a_{i j} \mathbf{v}_{i}
$$

If $s<r$, then the matrix $\left(a_{i j}\right)$ has more columns than rows and so there exists a nonzero vector $\mathbf{x} \in \mathbb{F}^{r}$ such that $\sum_{j=1}^{r} a_{i j} x_{j}=0$. Then consider the following.

$$
\sum_{j=1}^{r} x_{j} \mathbf{u}_{j}=\sum_{j=1}^{r} x_{j} \sum_{i=1}^{s} a_{i j} \mathbf{v}_{i}=\sum_{i} \sum_{j} a_{i j} x_{j} \mathbf{v}_{i}=\sum_{i} 0 \mathbf{v}_{j}=\mathbf{0}
$$

and since not all $x_{j}=0$, this contradicts the independence of the vectors $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{r}\right\}$.
Definition 8.2.4 A finite set of vectors, $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ is a basis for a vector space $V$ if

$$
\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right)=V
$$

and $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ is linearly independent. Thus if $\mathbf{v} \in V$ there exist unique scalars, $v_{1}, \cdots, v_{r}$ such that $\mathbf{v}=\sum_{i=1}^{r} v_{i} \mathbf{x}_{i}$. These scalars are called the components of $\mathbf{v}$ with respect to the basis $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$.

Corollary 8.2.5 Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ and $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}$ be two bases ${ }^{1}$ of $\mathbb{F}^{n}$. Then $r=s=n$. More generally, if you have two bases for a vector space $V$ then they have the same number of vectors.

Proof: From the exchange theorem, if $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\}$ and $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}$ are two bases for $V$, then $r \leq s$ and $s \leq r$. Now note the vectors,

$$
\mathbf{e}_{i}=\overbrace{(0, \cdots, 0,1,0 \cdots, 0)^{T}}^{1 \text { is in the } i^{\text {th }} \text { slot }}
$$

for $i=1,2, \cdots, n$ are a basis for $\mathbb{F}^{n}$. This proves the corollary.
Lemma 8.2.6 Let $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\}$ be a set of vectors. Then $V \equiv \operatorname{span}\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right)$ is a subspace.

Proof: Suppose $\alpha, \beta$ are two scalars and let $\sum_{k=1}^{r} c_{k} \mathbf{v}_{k}$ and $\sum_{k=1}^{r} d_{k} \mathbf{v}_{k}$ are two elements of $V$. What about

$$
\alpha \sum_{k=1}^{r} c_{k} \mathbf{v}_{k}+\beta \sum_{k=1}^{r} d_{k} \mathbf{v}_{k} ?
$$

Is it also in $V$ ?

$$
\alpha \sum_{k=1}^{r} c_{k} \mathbf{v}_{k}+\beta \sum_{k=1}^{r} d_{k} \mathbf{v}_{k}=\sum_{k=1}^{r}\left(\alpha c_{k}+\beta d_{k}\right) \mathbf{v}_{k} \in V
$$

so the answer is yes. This proves the lemma.
Definition 8.2.7 Let $V$ be a vector space. Then $\operatorname{dim}(V)$ read as the dimension of $V$ is the number of vectors in a basis.

Of course you should wonder right now whether an arbitrary subspace of a finite dimensional vector space even has a basis. In fact it does and this is in the next theorem. First, here is an interesting lemma.

Lemma 8.2.8 Let $\mathbf{v} \notin \operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)$ and $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right\}$ is linearly independent. Then $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{v}\right\}$ is also linearly independent.

Proof: Suppose $\sum_{i=1}^{k} c_{i} \mathbf{u}_{i}+d \mathbf{v}=\mathbf{0}$. It is required to verify that each $c_{i}=0$ and that $d=$ 0 . But if $d \neq 0$, then you can solve for $\mathbf{v}$ as a linear combination of the vectors, $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right\}$,

$$
\mathbf{v}=-\sum_{i=1}^{k}\left(\frac{c_{i}}{d}\right) \mathbf{u}_{i}
$$

contrary to assumption. Therefore, $d=0$. But then $\sum_{i=1}^{k} c_{i} \mathbf{u}_{i}=0$ and the linear independence of $\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right\}$ implies each $c_{i}=0$ also.

[^6]Theorem 8.2.9 Let $V$ be a nonzero subspace of $Y$ a finite dimensional vector space having dimension $n$. Then $V$ has a basis.

Proof: Let $\mathbf{v}_{1} \in V$ where $\mathbf{v}_{1} \neq 0$. If span $\left\{\mathbf{v}_{1}\right\}=V$, stop. $\left\{\mathbf{v}_{1}\right\}$ is a basis for $V$. Otherwise, there exists $\mathbf{v}_{2} \in V$ which is not in span $\left\{\mathbf{v}_{1}\right\}$. By Lemma 8.2.8 $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}$ is a linearly independent set of vectors. If span $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}=V$ stop, $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}$ is a basis for $V$. If $\operatorname{span}\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\} \neq V$, then there exists $\mathbf{v}_{3} \notin \operatorname{span}\left\{\mathbf{v}_{1}, \mathbf{v}_{2}\right\}$ and $\left\{\mathbf{v}_{1}, \mathbf{v}_{2}, \mathbf{v}_{3}\right\}$ is a larger linearly independent set of vectors. Continuing this way, the process must stop before $n+1$ steps because if not, it would be possible to obtain $n+1$ linearly independent vectors contrary to the exchange theorem, Theorem 8.2.3, and the assumed dimension of $Y$.

In words the following corollary states that any linearly independent set of vectors can be enlarged to form a basis.

Corollary 8.2.10 Let $V$ be a subspace of $Y$, a finite dimensional vector space of dimension $n$ and let $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\}$ be a linearly independent set of vectors in $V$. Then either it is a basis for $V$ or there exist vectors, $\mathbf{v}_{r+1}, \cdots, \mathbf{v}_{s}$ such that

$$
\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}, \mathbf{v}_{r+1}, \cdots, \mathbf{v}_{s}\right\}
$$

is a basis for $V$.
Proof: This follows immediately from the proof of Theorem 8.2.9. You do exactly the same argument except you start with $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\}$ rather than $\left\{\mathbf{v}_{1}\right\}$.

It is also true that any spanning set of vectors can be restricted to obtain a basis.
Theorem 8.2.11 Let $V$ be a subspace of $Y$, a finite dimensional vector space of dimension $n$ and suppose span $\left(\mathbf{u}_{1} \cdots, \mathbf{u}_{p}\right)=V$ where the $\mathbf{u}_{i}$ are nonzero vectors. Then there exist vectors, $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ such that $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\} \subseteq\left\{\mathbf{u}_{1} \cdots, \mathbf{u}_{p}\right\}$ and $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ is a basis for $V$.

Proof: Let $r$ be the smallest positive integer with the property that for some set,

$$
\begin{gathered}
\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right\} \subseteq\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{p}\right\} \\
\operatorname{span}\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{r}\right)=V
\end{gathered}
$$

Then $r \leq p$ and it must be the case that $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ is linearly independent because if it were not so, one of the vectors, say $\mathbf{v}_{k}$ would be a linear combination of the others. But then you could delete this vector from $\left\{\mathbf{v}_{1} \cdots, \mathbf{v}_{r}\right\}$ and the resulting list of $r-1$ vectors would still span $V$ contrary to the definition of $r$.

### 8.3 Inner Product And Normed Linear Spaces

### 8.3.1 The Inner Product In $\mathbb{F}^{n}$

To do calculus, you must understand what you mean by distance. For functions of one variable, the distance was provided by the absolute value of the difference of two numbers. This must be generalized to $\mathbb{F}^{n}$ and to more general situations.

Definition 8.3.1 Let $\mathbf{x}, \mathbf{y} \in \mathbb{F}^{n}$. Thus $\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)$ where each $x_{k} \in \mathbb{F}$ and a similar formula holding for $\mathbf{y}$. Then the inner product of these two vectors is defined to be

$$
(\mathbf{x}, \mathbf{y}) \equiv \sum_{j} x_{j} \overline{y_{j}} \equiv x_{1} \overline{y_{1}}+\cdots+x_{n} \overline{y_{n}} .
$$

Sometimes it is denoted as $\mathbf{x} \cdot \mathbf{y}$.
Notice how you put the conjugate on the entries of the vector, $\mathbf{y}$. It makes no difference if the vectors happen to be real vectors but with complex vectors you must involve a conjugate. The reason for this is that when you take the inner product of a vector with itself, you want to get the square of the length of the vector, a positive number. Placing the conjugate on the components of $\mathbf{y}$ in the above definition assures this will take place. Thus

$$
(\mathbf{x}, \mathbf{x})=\sum_{j} x_{j} \overline{x_{j}}=\sum_{j}\left|x_{j}\right|^{2} \geq 0 .
$$

If you didn't place a conjugate as in the above definition, things wouldn't work out correctly. For example,

$$
(1+i)^{2}+2^{2}=4+2 i
$$

and this is not a positive number.
The following properties of the inner product follow immediately from the definition and you should verify each of them.

Properties of the inner product:

1. $(\mathbf{u}, \mathbf{v})=\overline{(\mathbf{v}, \mathbf{u})}$
2. If $a, b$ are numbers and $\mathbf{u}, \mathbf{v}, \mathbf{z}$ are vectors then $((a \mathbf{u}+b \mathbf{v}), \mathbf{z})=a(\mathbf{u}, \mathbf{z})+b(\mathbf{v}, \mathbf{z})$.
3. $(\mathbf{u}, \mathbf{u}) \geq 0$ and it equals 0 if and only if $\mathbf{u}=\mathbf{0}$.

Note this implies $(\mathbf{x}, \alpha \mathbf{y})=\bar{\alpha}(\mathbf{x}, \mathbf{y})$ because

$$
(\mathbf{x}, \alpha \mathbf{y})=\overline{(\alpha \mathbf{y}, \mathbf{x})}=\overline{\alpha(\mathbf{y}, \mathbf{x})}=\bar{\alpha}(\mathbf{x}, \mathbf{y})
$$

The norm is defined as follows.
Definition 8.3.2 For $\mathbf{x} \in \mathbb{F}^{n}$,

$$
|\mathbf{x}| \equiv\left(\sum_{k=1}^{n}\left|x_{k}\right|^{2}\right)^{1 / 2}=(\mathbf{x}, \mathbf{x})^{1 / 2}
$$

### 8.3.2 General Inner Product Spaces

Any time you have a vector space which possesses an inner product, something satisfying the properties 1-3 above, it is called an inner product space.

Here is a fundamental inequality called the Cauchy Schwarz inequality which holds in any inner product space. First here is a simple lemma.

Lemma 8.3.3 If $z \in \mathbb{F}$ there exists $\theta \in \mathbb{F}$ such that $\theta z=|z|$ and $|\theta|=1$.
Proof: Let $\theta=1$ if $z=0$ and otherwise, let $\theta=\frac{\bar{z}}{|z|}$. Recall that for $z=x+i y, \bar{z}=x-i y$ and $\bar{z} z=|z|^{2}$. In case $z$ is real, there is no change in the above.

Theorem 8.3.4 (Cauchy Schwarz)Let H be an inner product space. The following inequality holds for $\mathbf{x}$ and $\mathbf{y} \in H$.

$$
\begin{equation*}
|(\mathbf{x}, \mathbf{y})| \leq(\mathbf{x}, \mathbf{x})^{1 / 2}(\mathbf{y}, \mathbf{y})^{1 / 2} \tag{8.3.11}
\end{equation*}
$$

Equality holds in this inequality if and only if one vector is a multiple of the other.
Proof: Let $\theta \in \mathbb{F}$ such that $|\theta|=1$ and

$$
\theta(\mathbf{x}, \mathbf{y})=|(\mathbf{x}, \mathbf{y})|
$$

Consider $p(t) \equiv(\mathbf{x}+\bar{\theta} t \mathbf{y}, \mathbf{x}+t \bar{\theta} \mathbf{y})$ where $t \in \mathbb{R}$. Then from the above list of properties of the inner product,

$$
\begin{align*}
0 & \leq p(t)=(\mathbf{x}, \mathbf{x})+t \boldsymbol{\theta}(\mathbf{x}, \mathbf{y})+t \overline{\boldsymbol{\theta}}(\mathbf{y}, \mathbf{x})+t^{2}(\mathbf{y}, \mathbf{y}) \\
& =(\mathbf{x}, \mathbf{x})+t \boldsymbol{\theta}(\mathbf{x}, \mathbf{y})+t \overline{\boldsymbol{\theta}}(\mathbf{x}, \mathbf{y})+t^{2}(\mathbf{y}, \mathbf{y}) \\
& =(\mathbf{x}, \mathbf{x})+2 t \operatorname{Re}(\boldsymbol{\theta}(\mathbf{x}, \mathbf{y}))+t^{2}(\mathbf{y}, \mathbf{y}) \\
& =(\mathbf{x}, \mathbf{x})+2 t|(\mathbf{x}, \mathbf{y})|+t^{2}(\mathbf{y}, \mathbf{y}) \tag{8.3.12}
\end{align*}
$$

and this must hold for all $t \in \mathbb{R}$. Therefore, if $(\mathbf{y}, \mathbf{y})=0$ it must be the case that $|(\mathbf{x}, \mathbf{y})|=0$ also since otherwise the above inequality would be violated. Therefore, in this case,

$$
|(\mathbf{x}, \mathbf{y})| \leq(\mathbf{x}, \mathbf{x})^{1 / 2}(\mathbf{y}, \mathbf{y})^{1 / 2} .
$$

On the other hand, if $(\mathbf{y}, \mathbf{y}) \neq 0$, then $p(t) \geq 0$ for all $t$ means the graph of $y=p(t)$ is a parabola which opens up and it either has exactly one real zero in the case its vertex touches the $t$ axis or it has no real zeros. From the quadratic formula this happens exactly when

$$
4|(\mathbf{x}, \mathbf{y})|^{2}-4(\mathbf{x}, \mathbf{x})(\mathbf{y}, \mathbf{y}) \leq 0
$$

which is equivalent to 8.3.11.
It is clear from a computation that if one vector is a scalar multiple of the other that equality holds in 8.3.11. Conversely, suppose equality does hold. Then this is equivalent to saying $4|(\mathbf{x}, \mathbf{y})|^{2}-4(\mathbf{x}, \mathbf{x})(\mathbf{y}, \mathbf{y})=0$ and so from the quadratic formula, there exists one real zero to $p(t)=0$. Call it $t_{0}$. Then

$$
p\left(t_{0}\right) \equiv\left(\mathbf{x}+\bar{\theta} t_{0} \mathbf{y}, \mathbf{x}+t_{0} \bar{\theta} \mathbf{y}\right)=|\mathbf{x}+\bar{\theta} t \mathbf{y}|^{2}=0
$$

and so $\mathbf{x}=-\overline{\boldsymbol{\theta}} t_{0} \mathbf{y}$. This proves the theorem.
Note that in establishing the inequality, I only used part of the above properties of the inner product. It was not necessary to use the one which says that if $(\mathbf{x}, \mathbf{x})=0$ then $\mathbf{x}=\mathbf{0}$.

Now the length of a vector can be defined.

Definition 8.3.5 Let $\mathbf{z} \in H$. Then $|\mathbf{z}| \equiv(\mathbf{z}, \mathbf{z})^{1 / 2}$.
Theorem 8.3.6 For length defined in Definition 8.3.5, the following hold.

$$
\begin{gather*}
|\mathbf{z}| \geq 0 \text { and }|\mathbf{z}|=0 \text { if and only if } \mathbf{z}=\mathbf{0}  \tag{8.3.13}\\
\text { If } \alpha \text { is a scalar, }|\alpha \mathbf{z}|=|\alpha||\mathbf{z}|  \tag{8.3.14}\\
|\mathbf{z}+\mathbf{w}| \leq|\mathbf{z}|+|\mathbf{w}| \tag{8.3.15}
\end{gather*}
$$

Proof: The first two claims are left as exercises. To establish the third,

$$
\begin{aligned}
|\mathbf{z}+\mathbf{w}|^{2} & \equiv(\mathbf{z}+\mathbf{w}, \mathbf{z}+\mathbf{w}) \\
& =(\mathbf{z}, \mathbf{z})+(\mathbf{w}, \mathbf{w})+(\mathbf{w}, \mathbf{z})+(\mathbf{z}, \mathbf{w}) \\
& =|\mathbf{z}|^{2}+|\mathbf{w}|^{2}+2 \operatorname{Re}(\mathbf{w}, \mathbf{z}) \\
& \leq|\mathbf{z}|^{2}+|\mathbf{w}|^{2}+2|(\mathbf{w}, \mathbf{z})| \\
& \leq|\mathbf{z}|^{2}+|\mathbf{w}|^{2}+2|\mathbf{w}||\mathbf{z}|=(|\mathbf{z}|+|\mathbf{w}|)^{2}
\end{aligned}
$$

Note that in an inner product space, you can define

$$
d(\mathbf{x}, \mathbf{y}) \equiv|\mathbf{x}-\mathbf{y}|
$$

and this is a metric for this inner product space. This follows from the above since $d$ satisfies the conditions for a metric,

$$
\begin{gathered}
d(\mathbf{x}, \mathbf{y})=d(\mathbf{y}, \mathbf{x}), d(\mathbf{x}, \mathbf{y}) \geq 0 \text { and equals } 0 \text { if and only if } \mathbf{x}=\mathbf{y} \\
d(\mathbf{x}, \mathbf{y})+d(\mathbf{y}, \mathbf{z})=|\mathbf{x}-\mathbf{y}|+|\mathbf{y}-\mathbf{z}| \geq|\mathbf{x}-\mathbf{y}+\mathbf{y}-\mathbf{z}|=|\mathbf{x}-\mathbf{z}|=d(\mathbf{x}, \mathbf{z}) .
\end{gathered}
$$

It follows that all the theory of metric spaces developed earlier applies to this situation.

### 8.3.3 Normed Vector Spaces

The best sort of a norm is one which comes from an inner product. However, any vector space, $V$ which has a function, $\|\cdot\|$ which maps $V$ to $[0, \infty)$ is called a normed vector space if $\|\cdot\|$ satisfies 8.3.13-8.3.15. That is

$$
\begin{equation*}
\|\mathbf{z}\| \geq 0 \text { and }\|\mathbf{z}\|=0 \text { if and only if } \mathbf{z}=\mathbf{0} \tag{8.3.16}
\end{equation*}
$$

If $\alpha$ is a scalar, $\|\alpha \mathbf{z}\|=|\alpha| \| \mathbf{z}| |$

$$
\begin{equation*}
\|\mathbf{z}+\mathbf{w}\| \leq\|\mathbf{z}\|+\|\mathbf{w}\| \tag{8.3.17}
\end{equation*}
$$

The last inequality above is called the triangle inequality. Another version of this is

$$
\begin{equation*}
\|\mathbf{z}\|-\|\mathbf{w}\| \mid \leq\|\mathbf{z}-\mathbf{w}\| \tag{8.3.19}
\end{equation*}
$$

To see that 8.3.19 holds, note

$$
\|\mathbf{z}\|=\|\mathbf{z}-\mathbf{w}+\mathbf{w}\| \leq\|\mathbf{z}-\mathbf{w}\|+\|\mathbf{w}\|
$$

which implies

$$
\|\mathbf{z}\|-\|\mathbf{w}\| \leq\|\mathbf{z}-\mathbf{w}\|
$$

and now switching $\mathbf{z}$ and $\mathbf{w}$, yields

$$
\|\mathbf{w}\|-\|\mathbf{z}\| \leq\|\mathbf{z}-\mathbf{w}\|
$$

which implies 8.3.19.
Any normed vector space is a metric space, the distance given by

$$
d(\mathbf{x}, \mathbf{y}) \equiv\|\mathbf{x}-\mathbf{y}\|
$$

This satisfies all the axioms of a distance. Therefore, any normed linear space is a metric space with this metric and all the theory of metric spaces applies.

Definition 8.3.7 When $X$ is a normed linear space which is also complete, it is called a Banach space.

### 8.3.4 The $p$ Norms

Examples of norms are the $p$ norms on $\mathbb{C}^{n}$ for $p \neq 2$. These do not come from an inner product but they are norms just the same.

Definition 8.3.8 Let $\mathbf{x} \in \mathbb{C}^{n}$. Then define for $p \geq 1$,

$$
\|\mathbf{x}\|_{p} \equiv\left(\sum_{i=1}^{n}\left|x_{i}\right|^{p}\right)^{1 / p}
$$

The following inequality is called Holder's inequality.
Proposition 8.3.9 For $\mathbf{x}, \mathbf{y} \in \mathbb{C}^{n}$,

$$
\sum_{i=1}^{n}\left|x_{i}\right|\left|y_{i}\right| \leq\left(\sum_{i=1}^{n}\left|x_{i}\right|^{p}\right)^{1 / p}\left(\sum_{i=1}^{n}\left|y_{i}\right|^{p^{\prime}}\right)^{1 / p^{\prime}}
$$

The proof will depend on the following lemma shown later.
Lemma 8.3.10 If $a, b \geq 0$ and $p^{\prime}$ is defined by $\frac{1}{p}+\frac{1}{p^{\prime}}=1$, then

$$
a b \leq \frac{a^{p}}{p}+\frac{b^{p^{\prime}}}{p^{\prime}}
$$

Proof of the Proposition: If $\mathbf{x}$ or $\mathbf{y}$ equals the zero vector there is nothing to prove. Therefore, assume they are both nonzero. Let $A=\left(\sum_{i=1}^{n}\left|x_{i}\right|^{p}\right)^{1 / p}$ and $B=\left(\sum_{i=1}^{n}\left|y_{i}\right|^{p^{\prime}}\right)^{1 / p^{\prime}}$.

Then using Lemma 8.3.10,

$$
\begin{aligned}
\sum_{i=1}^{n} \frac{\left|x_{i}\right|}{A} \frac{\left|y_{i}\right|}{B} & \leq \sum_{i=1}^{n}\left[\frac{1}{p}\left(\frac{\left|x_{i}\right|}{A}\right)^{p}+\frac{1}{p^{\prime}}\left(\frac{\left|y_{i}\right|}{B}\right)^{p^{\prime}}\right] \\
& =\frac{1}{p} \frac{1}{A^{p}} \sum_{i=1}^{n}\left|x_{i}\right|^{p}+\frac{1}{p^{\prime}} \frac{1}{B^{p}} \sum_{i=1}^{n}\left|y_{i}\right|^{p^{\prime}} \\
& =\frac{1}{p}+\frac{1}{p^{\prime}}=1
\end{aligned}
$$

and so

$$
\sum_{i=1}^{n}\left|x_{i}\right|\left|y_{i}\right| \leq A B=\left(\sum_{i=1}^{n}\left|x_{i}\right|^{p}\right)^{1 / p}\left(\sum_{i=1}^{n}\left|y_{i}\right|^{p^{\prime}}\right)^{1 / p^{\prime}}
$$

Theorem 8.3.11 The p norms do indeed satisfy the axioms of a norm.

Proof: It is obvious that $\|\cdot\|_{p}$ does indeed satisfy most of the norm axioms. The only one that is not clear is the triangle inequality. To save notation write $\|\cdot\|$ in place of $\|\cdot\|_{p}$ in what follows. Note also that $\frac{p}{p^{\prime}}=p-1$. Then using the Holder inequality,

$$
\begin{aligned}
\|\mathbf{x}+\mathbf{y}\|^{p} & =\sum_{i=1}^{n}\left|x_{i}+y_{i}\right|^{p} \\
& \leq \sum_{i=1}^{n}\left|x_{i}+y_{i}\right|^{p-1}\left|x_{i}\right|+\sum_{i=1}^{n}\left|x_{i}+y_{i}\right|^{p-1}\left|y_{i}\right| \\
& =\sum_{i=1}^{n}\left|x_{i}+y_{i}\right|^{\frac{p}{p^{\prime}}}\left|x_{i}\right|+\sum_{i=1}^{n}\left|x_{i}+y_{i}\right|^{\frac{p}{p^{\prime}}}\left|y_{i}\right| \\
& \leq\left(\sum_{i=1}^{n}\left|x_{i}+y_{i}\right|^{p}\right)^{1 / p^{\prime}}\left[\left(\sum_{i=1}^{n}\left|x_{i}\right|^{p}\right)^{1 / p}+\left(\sum_{i=1}^{n}\left|y_{i}\right|^{p}\right)^{1 / p}\right] \\
& =\|\mathbf{x}+\mathbf{y}\|^{p / p^{\prime}}\left(\|\mathbf{x}\|_{p}+\|\mathbf{y}\|_{p}\right)
\end{aligned}
$$

so dividing by $\|\mathbf{x}+\mathbf{y}\|^{p / p^{\prime}}$, it follows

$$
\|\mathbf{x}+\mathbf{y}\|^{p}\|\mathbf{x}+\mathbf{y}\|^{-p / p^{\prime}}=\|\mathbf{x}+\mathbf{y}\| \leq\|\mathbf{x}\|_{p}+\|\mathbf{y}\|_{p}
$$

$$
\left(p-\frac{p}{p^{\prime}}=p\left(1-\frac{1}{p^{\prime}}\right)=p \frac{1}{p}=1 .\right) .
$$

It only remains to prove Lemma 8.3.10.
Proof of the lemma: Let $p^{\prime}=q$ to save on notation and consider the following picture:

$$
a b \leq \int_{0}^{a} t^{p-1} d t+\int_{0}^{b} x^{q-1} d x=\frac{a^{p}}{p}+\frac{b^{q}}{q} .
$$

Note equality occurs when $a^{p}=b^{q}$.
Alternate proof of the lemma: First note that if either $a$ or $b$ are zero, then there is nothing to show so we can assume $b, a>0$. Let $b>0$ and let

$$
f(a)=\frac{a^{p}}{p}+\frac{b^{q}}{q}-a b
$$

Then the second derivative of $f$ is positive on $(0, \infty)$ so its graph is convex. Also $f(0)>0$ and $\lim _{a \rightarrow \infty} f(a)=\infty$. Then a short computation shows that there is only one critical point, where $f$ is minimized and this happens when $a$ is such that $a^{p}=b^{q}$. At this point,

$$
f(a)=b^{q}-b^{q / p} b=b^{q}-b^{q-1} b=0
$$

Therefore, $f(a) \geq 0$ for all $a$ and this proves the lemma.
Another example of a very useful norm on $\mathbb{F}^{n}$ is the norm $\|\cdot\|_{\infty}$ defined by

$$
\|\mathbf{x}\|_{\infty} \equiv \max \left\{\left|x_{k}\right|: k=1,2, \cdots, n\right\}
$$

You should verify that this satisfies all the axioms of a norm. Here is the triangle inequality.

$$
\begin{aligned}
\|\mathbf{x}+\mathbf{y}\|_{\infty} & =\max _{k}\left\{\left|x_{k}+y_{k}\right|\right\} \leq \max _{k}\left\{\left|x_{k}\right|+\left|y_{k}\right|\right\} \\
& \leq \max _{k}\left\{\left|x_{k}\right|\right\}+\max _{k}\left\{\left|y_{k}\right|\right\}=\|\mathbf{x}\|_{\infty}+\|\mathbf{y}\|_{\infty}
\end{aligned}
$$

It turns out that in terms of analysis, it makes absolutely no difference which norm you use. This will be explained later. First is a short review of the notion of orthonormal bases which is not needed directly in what follows but is sufficiently important to include.

### 8.3.5 Orthonormal Bases

Not all bases for an inner product space $H$ are created equal. The best bases are orthonormal.

Definition 8.3.12 Suppose $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{k}\right\}$ is a set of vectors in an inner product space $H$. It is an orthonormal set if

$$
\left(\mathbf{v}_{i}, \mathbf{v}_{j}\right)=\delta_{i j}=\left\{\begin{array}{l}
1 \text { if } i=j \\
0 \text { if } i \neq j
\end{array}\right.
$$

Every orthonormal set of vectors is automatically linearly independent.
Proposition 8.3.13 Suppose $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{k}\right\}$ is an orthonormal set of vectors. Then it is linearly independent.

Proof: Suppose $\sum_{i=1}^{k} c_{i} \mathbf{v}_{i}=\mathbf{0}$. Then taking inner products with $\mathbf{v}_{j}$,

$$
0=\left(\mathbf{0}, \mathbf{v}_{j}\right)=\sum_{i} c_{i}\left(\mathbf{v}_{i}, \mathbf{v}_{j}\right)=\sum_{i} c_{i} \boldsymbol{\delta}_{i j}=c_{j}
$$

Since $j$ is arbitrary, this shows the set is linearly independent as claimed.
It turns out that if $X$ is any subspace of $H$, then there exists an orthonormal basis for $X$. The process by which this is done is called the Gram Schmidt process.

Lemma 8.3.14 Let $X$ be a subspace of dimension $n$ which is contained in an inner product space $H$. Let a basis for $X$ be $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}$. Then there exists an orthonormal basis for $X,\left\{\mathbf{u}_{1}, \cdots, \mathbf{u}_{n}\right\}$ which has the property that for each $k \leq n, \operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}\right)=$ $\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)$.

Proof: Let $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}$ be a basis for $X$. Let $\mathbf{u}_{1} \equiv \mathbf{x}_{1} /\left|\mathbf{x}_{1}\right|$. Thus for $k=1$, $\operatorname{span}\left(\mathbf{u}_{1}\right)=$ $\operatorname{span}\left(\mathbf{x}_{1}\right)$ and $\left\{\mathbf{u}_{1}\right\}$ is an orthonormal set. Now suppose for some $k<n, \mathbf{u}_{1}, \cdots, \mathbf{u}_{k}$ have been chosen such that $\left(\mathbf{u}_{j}, \mathbf{u}_{l}\right)=\delta_{j l}$ and $\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}\right)=\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)$. Then define

$$
\begin{equation*}
\mathbf{u}_{k+1} \equiv \frac{\mathbf{x}_{k+1}-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1}, \mathbf{u}_{j}\right) \mathbf{u}_{j}}{\left|\mathbf{x}_{k+1}-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1}, \mathbf{u}_{j}\right) \mathbf{u}_{j}\right|}, \tag{8.3.20}
\end{equation*}
$$

where the denominator is not equal to zero because the $\mathbf{x}_{j}$ form a basis and so

$$
\mathbf{x}_{k+1} \notin \operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}\right)=\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right)
$$

Thus by induction,

$$
\mathbf{u}_{k+1} \in \operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{x}_{k+1}\right)=\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}, \mathbf{x}_{k+1}\right) .
$$

Also, $\mathbf{x}_{k+1} \in \operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{u}_{k+1}\right)$ which is seen easily by solving 8.3.20 for $\mathbf{x}_{k+1}$ and it follows

$$
\operatorname{span}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{k}, \mathbf{x}_{k+1}\right)=\operatorname{span}\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}, \mathbf{u}_{k+1}\right)
$$

If $l \leq k$, then denoting by $C$ the scalar $\left|\mathbf{x}_{k+1}-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1}, \mathbf{u}_{j}\right) \mathbf{u}_{j}\right|^{-1}$,

$$
\begin{aligned}
\left(\mathbf{u}_{k+1}, \mathbf{u}_{l}\right) & =C\left(\left(\mathbf{x}_{k+1}, \mathbf{u}_{l}\right)-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1}, \mathbf{u}_{j}\right)\left(\mathbf{u}_{j}, \mathbf{u}_{l}\right)\right) \\
& =C\left(\left(\mathbf{x}_{k+1}, \mathbf{u}_{l}\right)-\sum_{j=1}^{k}\left(\mathbf{x}_{k+1}, \mathbf{u}_{j}\right) \delta_{l j}\right) \\
& =C\left(\left(\mathbf{x}_{k+1}, \mathbf{u}_{l}\right)-\left(\mathbf{x}_{k+1}, \mathbf{u}_{l}\right)\right)=0
\end{aligned}
$$

The vectors, $\left\{\mathbf{u}_{j}\right\}_{j=1}^{n}$, generated in this way are therefore an orthonormal basis because each vector has unit length.

The process by which these vectors were generated is called the Gram Schmidt process.

### 8.4 Equivalence Of Norms

As mentioned above, it makes absolutely no difference which norm you decide to use. This holds in general finite dimensional normed spaces. First are some simple lemmas featuring one dimensional considerations. In this case, the distance is given by $d(x, y)=|x-y|$ and so the open balls are sets of the form $(x-\boldsymbol{\delta}, x+\boldsymbol{\delta})$.

Also recall the Theorem 3.0.3 which is stated next for convenience.
Lemma 8.4.1 The closed interval $[a, b]$ is sequentially compact.
Corollary 8.4.2 The set $Q \equiv[a, b]+i[c, d] \subseteq \mathbb{C}$ is compact, meaning

$$
\{x+i y: x \in[a, b], y \in[c, d]\}
$$

Proof: Let $\left\{x_{n}+i y_{n}\right\}$ be a sequence in $Q$. Then there is a subsequence such that

$$
\lim _{k \rightarrow \infty} x_{n_{k}}=x \in[a, b] .
$$

There is a further subsequence such that $\lim _{l \rightarrow \infty} y_{n_{k_{l}}}=y \in[c, d]$. Thus, also

$$
\lim _{l \rightarrow \infty} x_{n_{k_{l}}}=x
$$

because subsequences of convergent sequences converge to the same point. Therefore, from the way we measure the distance in $\mathbb{C}$, it follows that $\lim _{l \rightarrow \infty}\left(x_{n_{k_{l}}}+y_{n_{k_{l}}}\right)=x+i y \in$ $Q$.

The next corollary gives the definition of a closed disk and shows that, like a closed interval, a closed disk is compact.

Corollary 8.4.3 In $\mathbb{C}$, let $D(z, r) \equiv\{w \in \mathbb{C}:|z-w| \leq r\}$. Then $D(z, r)$ is compact.
Proof: Note that

$$
D(z, r) \subseteq[\operatorname{Re} z-r, \operatorname{Re} z+r]+i[\operatorname{Im} z-r, \operatorname{Im} z+r]
$$

which was just shown to be compact. Also, if $w_{k} \rightarrow w$ where $w_{k} \in D(z, r)$, then by the triangle inequality,

$$
|z-w|=\lim _{k \rightarrow \infty}\left|z-w_{k}\right| \leq r
$$

and so $D(z, r)$ is a closed subset of a compact set. Hence it is compact by Proposition 7.6.8.
Recall that sequentially compact and compact are the same in any metric space which is the context of the assertions here.

Lemma 8.4.4 Let $K_{i}$ be a nonempty compact set in $\mathbb{F}$. Then $P \equiv \prod_{i=1}^{n} K_{i}$ is compact in $\mathbb{F}^{n}$.
Proof: Let $\left\{\mathbf{x}_{k}\right\}$ be a sequence in $P$. Taking a succession of subsequences as in the proof of Corollary 8.4.2, there exists a subsequence, still denoted as $\left\{\mathbf{x}_{k}\right\}$ such that if $x_{k}^{i}$ is the $i^{\text {th }}$ component of $\mathbf{x}_{k}$, then $\lim _{k \rightarrow \infty} x_{k}^{i}=x^{i} \in K_{i}$. Thus if $\mathbf{x}$ is the vector of $P$ whose $i^{\text {th }}$ component is $x^{i}$,

$$
\lim _{k \rightarrow \infty}\left|\mathbf{x}_{k}-\mathbf{x}\right| \equiv \lim _{k \rightarrow \infty}\left(\sum_{i=1}^{n}\left|x_{k}^{i}-x^{i}\right|^{2}\right)^{1 / 2}=0
$$

It follows that $P$ is sequentially compact, hence compact.
A set $K$ in $\mathbb{F}^{n}$ is said to be bounded if it is contained in some ball $B(\mathbf{0}, r)$.
Theorem 8.4.5 $A$ set $K \subseteq \mathbb{F}^{n}$ is compact if it is closed and bounded. If $f: K \rightarrow \mathbb{R}$, then $f$ achieves its maximum and its minimum on $K$.

Proof: Say $K$ is closed and bounded, being contained in $B(\mathbf{0}, r)$. Then if $\mathbf{x} \in K,\left|x_{i}\right|<r$ where $x_{i}$ is the $i^{t h}$ component. Hence $K \subseteq \prod_{i=1}^{n} D(0, r)$, a compact set by Lemma 8.4.4. By Proposition 7.6.8, since $K$ is a closed subset of a compact set, it is compact. The last claim is just the extreme value theorem, Theorem 7.7.1.

Definition 8.4.6 Let $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right\}$ be a basis for $V$ where $(V,\|\cdot\|)$ is a finite dimensional normed vector space with field of scalars equal to either $\mathbb{R}$ or $\mathbb{C}$. Define $\theta: V \rightarrow \mathbb{F}^{n}$ as follows.

$$
\theta\left(\sum_{j=1}^{n} \alpha_{j} v_{j}\right) \equiv \alpha \equiv\left(\alpha_{1}, \cdots, \alpha_{n}\right)^{T}
$$

Thus $\theta$ maps a vector to its coordinates taken with respect to a given basis.
The following fundamental lemma comes from the extreme value theorem for continuous functions defined on a compact set. Let

$$
f(\alpha) \equiv\left\|\sum_{i} \alpha_{i} \mathbf{v}_{i}\right\| \equiv\left\|\theta^{-1} \alpha\right\|
$$

Then it is clear that $f$ is a continuous function defined on $\mathbb{F}^{n}$. This is because $\alpha \rightarrow \sum_{i} \alpha_{i} \mathbf{v}_{i}$ is a continuous map into $V$ and from the triangle inequality $\mathbf{x} \rightarrow\|\mathbf{x}\|$ is continuous as a map from $V$ to $\mathbb{R}$.

Lemma 8.4.7 There exists $\delta>0$ and $\Delta \geq \delta$ such that

$$
\delta=\min \{f(\alpha):|\alpha|=1\}, \Delta=\max \{f(\alpha):|\alpha|=1\}
$$

Also,

$$
\begin{align*}
\delta|\alpha| & \leq\left\|\theta^{-1} \alpha\right\| \leq \Delta|\alpha|  \tag{8.4.21}\\
\delta|\theta \mathbf{v}| & \leq\|\mathbf{v}\| \leq \Delta|\theta \mathbf{v}| \tag{8.4.22}
\end{align*}
$$

Proof: These numbers exist thanks to Theorem 8.4.5. It cannot be that $\delta=0$ because if it were, you would have $|\alpha|=1$ but $\sum_{j=1}^{n} \alpha_{k} \mathbf{v}_{j}=\mathbf{0}$ which is impossible since $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right\}$ is linearly independent. The first of the above inequalities follows from

$$
\delta \leq\left\|\theta^{-1} \frac{\alpha}{|\alpha|}\right\|=f\left(\frac{\alpha}{|\alpha|}\right) \leq \Delta
$$

the second follows from observing that $\theta^{-1} \alpha$ is a generic vector $\mathbf{v}$ in $V$.
Note that these inequalities yield the fact that convergence of the coordinates with respect to a given basis is equivalent to convergence of the vectors. More precisely, to say that $\lim _{k \rightarrow \infty} \mathbf{v}^{k}=\mathbf{v}$ is the same as saying that $\lim _{k \rightarrow \infty} \theta \mathbf{v}^{k}=\theta \mathbf{v}$. Indeed,

$$
\delta\left|\theta \mathbf{v}_{n}-\theta \mathbf{v}\right| \leq\left\|\mathbf{v}_{n}-\mathbf{v}\right\| \leq \Delta\left|\theta \mathbf{v}_{n}-\theta \mathbf{v}\right|
$$

Now we can draw several conclusions about $(V,\|\cdot\|)$ for $V$ finite dimensional.
Theorem 8.4.8 Let $(V,\|\cdot\|)$ be a finite dimensional normed linear space. Then the compact sets are exactly those which are closed and bounded. Also $(V,\|\cdot\|)$ is complete. If $K$ is a closed and bounded set in $(V,\|\cdot\|)$ and $f: K \rightarrow \mathbb{R}$, then $f$ achieves its maximum and minimum on $K$.

Proof: First note that the inequalities 8.4 .21 and 8.4 .22 show that both $\theta^{-1}$ and $\theta$ are continuous. Thus these take convergent sequences to convergent sequences.

Let $\left\{\mathbf{w}_{k}\right\}_{k=1}^{\infty}$ be a Cauchy sequence. Then from 8.4.22, $\left\{\theta \mathbf{w}_{k}\right\}_{k=1}^{\infty}$ is a Cauchy sequence. Thanks to Theorem 8.4.5, it converges to some $\beta \in \mathbb{F}^{n}$. It follows that $\lim _{k \rightarrow \infty} \theta^{-1} \theta \mathbf{w}_{k}=$ $\lim _{k \rightarrow \infty} \mathbf{w}_{k}=\theta^{-1} \beta \in V$. This shows completeness.

Next let $K$ be a closed and bounded set. Let $\left\{\mathbf{w}_{k}\right\} \subseteq K$. Then $\left\{\theta \mathbf{w}_{k}\right\} \subseteq \theta K$ which is also a closed and bounded set thanks to the inequalities 8.4.21 and 8.4.22. Thus there is a subsequence still denoted with $k$ such that $\theta \mathbf{w}_{k} \rightarrow \beta \in \mathbb{F}^{n}$. Then as just done, $\mathbf{w}_{k} \rightarrow \theta^{-1} \beta$. Since $K$ is closed, it follows that $\theta^{-1} \beta \in K$.

This has just shown that a closed and bounded set in $V$ is sequentially compact hence compact.

Finally, why are the only compact sets those which are closed and bounded? Let $K$ be compact. If it is not bounded, then there is a sequence of points of $K,\left\{\mathbf{k}^{m}\right\}_{m=1}^{\infty}$ such that $\left\|\mathbf{k}^{m}\right\| \geq\left\|\mathbf{k}^{m-1}\right\|+1$. It follows that it cannot have a convergent subsequence because the points are further apart from each other than $1 / 2$. Indeed,

$$
\left\|\mathbf{k}^{m}-\mathbf{k}^{m+1}\right\| \geq\left\|\mathbf{k}^{m+1}\right\|-\left\|\mathbf{k}^{m}\right\| \geq 1>1 / 2
$$

Hence $K$ is not sequentially compact and consequently it is not compact. It follows that $K$ is bounded. If $K$ is not closed, then there exists a limit point $\mathbf{k}$ which is not in $K$. (Recall that closed means it has all its limit points.) By Theorem 7.2.8, there is a sequence of distinct points having no repeats and none equal to $\mathbf{k}$ denoted as $\left\{\mathbf{k}^{m}\right\}_{m=1}^{\infty}$ such that $\mathbf{k}^{m} \rightarrow \mathbf{k}$. Then this sequence $\left\{\mathbf{k}^{m}\right\}$ fails to have a subsequence which converges to a point of $K$. Hence $K$ is not sequentially compact. Thus, if $K$ is compact then it is closed and bounded.

The last part is the extreme value theorem, Theorem 7.7.1.
Next is the theorem which states that any two norms on a finite dimensional vector space are equivalent.

Theorem 8.4.9 Let $\|\cdot\|,\|\mid \cdot\| \|$ be two norms on $V$ a finite dimensional vector space. Then they are equivalent, which means there are constants $0<a<b$ such that for all $\mathbf{v}$,

$$
a\|\mathbf{v}\| \leq\||\mathbf{v}\|\mid \leq b\| \mathbf{v} \|
$$

Proof: In Lemma 8.4 .7 , let $\delta, \Delta$ go with $\|\cdot\|$ and $\hat{\delta}, \hat{\Delta}$ go with $\||\cdot|\|$. Then using the inequalities of this lemma,

$$
\|\mathbf{v}\| \leq \Delta|\theta \mathbf{v}| \leq \frac{\Delta}{\hat{\delta}}\left|\|\mathbf{v}\|\left\|\leq \frac{\Delta \hat{\Delta}}{\hat{\delta}}|\theta \mathbf{v}| \leq \frac{\Delta}{\delta} \frac{\hat{\Delta}}{\hat{\delta}}\right\| \mathbf{v} \|\right.
$$

and so

$$
\frac{\hat{\delta}}{\Delta}\|\mathbf{v}\| \leq\left\|\left|\mathbf{v}\left\|\left\lvert\, \leq \frac{\hat{\Delta}}{\delta}\right.\right\| \mathbf{v} \|\right.\right.
$$

Thus the norms are equivalent.
It follows right away that the closed and open sets are the same with two different norms. Also, all considerations involving limits are unchanged from one norm to another.

Corollary 8.4.10 Consider the metric spaces $\left(V,\|\cdot\|_{1}\right),\left(V,\|\cdot\|_{2}\right)$ where $V$ has dimension $n$. Then a set is closed or open in one of these if and only if it is respectively closed or open in the other. In other words, the two metric spaces have exactly the same open and closed sets. Also, a set is bounded in one metric space if and only if it is bounded in the other.

Proof: This follows from Theorem 7.6.5, the theorem about the equivalent formulations of continuity. Using this theorem, it follows from Theorem 8.4.9 that the identity map $I(\mathbf{x}) \equiv \mathbf{x}$ is continuous. The reason for this is that the inequality of this theorem implies that if $\left\|\mathbf{v}^{m}-\mathbf{v}\right\|_{1} \rightarrow 0$ then $\left\|I \mathbf{v}^{m}-I \mathbf{v}\right\|_{2}=\left\|I\left(\mathbf{v}^{m}-\mathbf{v}\right)\right\|_{2} \rightarrow 0$ and the same holds on switching 1 and 2 in what was just written.

Therefore, the identity map takes open sets to open sets and closed sets to closed sets. In other words, the two metric spaces have the same open sets and the same closed sets.

Suppose $S$ is bounded in $\left(V,\|\cdot\|_{1}\right)$. This means it is contained in $B(\mathbf{0}, r)_{1}$ where the subscript of 1 indicates the norm is $\|\cdot\|_{1}$. Let $\delta\|\cdot\|_{1} \leq\|\cdot\|_{2} \leq \Delta\|\cdot\|_{1}$ as described above. Then

$$
S \subseteq B(\mathbf{0}, r)_{1} \subseteq B(\mathbf{0}, \Delta r)_{2}
$$

so $S$ is also bounded in $\left(V,\|\cdot\|_{2}\right)$. Similarly, if $S$ is bounded in $\|\cdot\|_{2}$ then it is bounded in $\|\cdot\|_{1}$.

One can show that in the case of $\mathbb{R}$ where it makes sense to consider sup and inf, convergence of Cauchy sequences can be shown to imply the other definition of completeness involving sup, and inf.

### 8.5 Exercises

1. Let $K$ be a nonempty closed and convex set in an inner product space $(X,|\cdot|)$ which is complete. For example, $\mathbb{F}^{n}$ or any other finite dimensional inner product space. Let $y \notin K$ and let $\lambda=\inf \{|y-x|: x \in K\}$. Let $\left\{x_{n}\right\}$ be a minimizing sequence. That is
$\lambda=\lim _{n \rightarrow \infty}\left|y-x_{n}\right|$. Explain why such a minimizing sequence exists. Next explain the following using the parallelogram identity in the above problem as follows.

$$
\begin{gathered}
\left|y-\frac{x_{n}+x_{m}}{2}\right|^{2}=\left|\frac{y}{2}-\frac{x_{n}}{2}+\frac{y}{2}-\frac{x_{m}}{2}\right|^{2} \\
=-\left|\frac{y}{2}-\frac{x_{n}}{2}-\left(\frac{y}{2}-\frac{x_{m}}{2}\right)\right|^{2}+\frac{1}{2}\left|y-x_{n}\right|^{2}+\frac{1}{2}\left|y-x_{m}\right|^{2}
\end{gathered}
$$

Hence

$$
\begin{aligned}
\left|\frac{x_{m}-x_{n}}{2}\right|^{2} & =-\left|y-\frac{x_{n}+x_{m}}{2}\right|^{2}+\frac{1}{2}\left|y-x_{n}\right|^{2}+\frac{1}{2}\left|y-x_{m}\right|^{2} \\
& \leq-\lambda^{2}+\frac{1}{2}\left|y-x_{n}\right|^{2}+\frac{1}{2}\left|y-x_{m}\right|^{2}
\end{aligned}
$$

Next explain why the right hand side converges to 0 as $m, n \rightarrow \infty$. Thus $\left\{x_{n}\right\}$ is a Cauchy sequence and converges to some $x \in X$. Explain why $x \in K$ and $|x-y|=\lambda$. Thus there exists a closest point in $K$ to $y$. Next show that there is only one closest point. Hint: To do this, suppose there are two $x_{1}, x_{2}$ and consider $\frac{x_{1}+x_{2}}{2}$ using the parallelogram law to show that this average works better than either of the two points which is a contradiction unless they are really the same point. This theorem is of enormous significance.
2. Let $K$ be a closed convex nonempty set in a complete inner product space $(H,|\cdot|)$ (Hilbert space) and let $y \in H$. Denote the closest point to $y$ by $P x$. Show that $P x$ is characterized as being the solution to the following variational inequality

$$
\operatorname{Re}(z-P y, y-P y) \leq 0
$$

for all $z \in K$. That is, show that $x=P y$ if and only if $\operatorname{Re}(z-x, y-x) \leq 0$ for all $z \in K$. Hint: Let $x \in K$. Then, due to convexity, a generic thing in $K$ is of the form $x+t(z-x), t \in[0,1]$ for every $z \in K$. Then

$$
|x+t(z-x)-y|^{2}=|x-y|^{2}+t^{2}|z-x|^{2}-t 2 \operatorname{Re}(z-x, y-x)
$$

If $x=P x$, then the minimum value of this on the left occurs when $t=0$. Function defined on $[0,1]$ has its minimum at $t=0$. What does it say about the derivative of this function at $t=0$ ? Next consider the case that for some $x$ the inequality $\operatorname{Re}(z-x, y-x) \leq 0$. Explain why this shows $x=P y$.
3. Using Problem 2 and Problem 1 show the projection map, $P$ onto a closed convex subset is Lipschitz continuous with Lipschitz constant 1. That is $|P x-P y| \leq|x-y|$.

## Chapter 9

## Weierstrass Approximation Theorem

### 9.1 The Bernstein Polynomials

This short chapter is on the important Weierstrass approximation theorem. It is about approximating an arbitrary continuous function uniformly by a polynomial. It will be assumed only that $f$ has values in $\mathbb{C}$ and that all scalars are in $\mathbb{C}$. First here is some notation.

Definition 9.1.1 $\alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right)$ for $\alpha_{1} \cdots \alpha_{n}$ positive integers is called a multi-index. For $\alpha$ a multi-index, $|\alpha| \equiv \alpha_{1}+\cdots+\alpha_{n}$ and if $\mathbf{x} \in \mathbb{R}^{n}$,

$$
\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right),
$$

and $f$ a function, define

$$
\mathbf{x}^{\alpha} \equiv x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \cdots x_{n}^{\alpha_{n}}
$$

A polynomial in $n$ variables of degree $m$ is a function of the form

$$
p(\mathbf{x})=\sum_{|\alpha| \leq m} a_{\alpha} \mathbf{x}^{\alpha}
$$

Here $\alpha$ is a multi-index as just described. You could have $a_{\alpha}$ have values in a normed linear space.

The following estimate will be the basis for the Weierstrass approximation theorem. It is actually a statement about the variance of a binomial random variable.

Lemma 9.1.2 The following estimate holds for $x \in[0,1]$.

$$
\sum_{k=0}^{m}\binom{m}{k}(k-m x)^{2} x^{k}(1-x)^{m-k} \leq \frac{1}{4} m
$$

Proof: By the Binomial theorem,

$$
\begin{equation*}
\sum_{k=0}^{m}\binom{m}{k}\left(e^{t} x\right)^{k}(1-x)^{m-k}=\left(1-x+e^{t} x\right)^{m} \tag{9.1.1}
\end{equation*}
$$

Differentiating both sides with respect to $t$ and then evaluating at $t=0$ yields

$$
\sum_{k=0}^{m}\binom{m}{k} k x^{k}(1-x)^{m-k}=m x
$$

Now doing two derivatives of 9.1.1 with respect to $t$ yields

$$
\begin{gathered}
\sum_{k=0}^{m}\binom{m}{k} k^{2}\left(e^{t} x\right)^{k}(1-x)^{m-k}=m(m-1)\left(1-x+e^{t} x\right)^{m-2} e^{2 t} x^{2} \\
+m\left(1-x+e^{t} x\right)^{m-1} x e^{t} .
\end{gathered}
$$

Evaluating this at $t=0$,

$$
\sum_{k=0}^{m}\binom{m}{k} k^{2}(x)^{k}(1-x)^{m-k}=m(m-1) x^{2}+m x
$$

Therefore,

$$
\begin{aligned}
\sum_{k=0}^{m}\binom{m}{k}(k-m x)^{2} x^{k}(1-x)^{m-k} & =m(m-1) x^{2}+m x-2 m^{2} x^{2}+m^{2} x^{2} \\
& =m\left(x-x^{2}\right) \leq \frac{1}{4} m
\end{aligned}
$$

This proves the lemma.
Now for $\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right) \in[0,1]^{n}$ consider the polynomial,

$$
\begin{gather*}
\mathbf{p}_{m}(\mathbf{x}) \equiv \sum_{k_{1}=0}^{m} \cdots \sum_{k_{n}=0}^{m}\binom{m}{k_{1}}\binom{m}{k_{2}} \cdots\binom{m}{k_{n}} x_{1}^{k_{1}}\left(1-x_{1}\right)^{m-k_{1}} x_{2}^{k_{2}}\left(1-x_{2}\right)^{m-k_{2}} \\
\cdots x_{n}^{k_{n}}\left(1-x_{n}\right)^{m-k_{n}} \mathbf{f}\left(\frac{k_{1}}{m}, \cdots, \frac{k_{n}}{m}\right) \tag{9.1.2}
\end{gather*}
$$

where $\mathbf{f}$ is a continuous function which takes $[0,1]^{n}$ to a normed linear space. Also define if $I$ is a compact set in $\mathbb{R}^{n}$

$$
\|\mathbf{h}\|_{I} \equiv \sup \{\|\mathbf{h}(\mathbf{x})\|: \mathbf{x} \in I\}
$$

Thus $\mathbf{p}_{m}$ converges uniformly to $\mathbf{f}$ on a set $I$ if

$$
\lim _{m \rightarrow \infty}\left\|\mathbf{p}_{m}-\mathbf{f}\right\|_{I}=0
$$

Also to simplify the notation, let $\mathbf{k}=\left(k_{1}, \cdots, k_{n}\right)$ where each $k_{i} \in[0, m], \frac{\mathbf{k}}{\mathbf{m}} \equiv\left(\frac{k_{1}}{m}, \cdots, \frac{k_{n}}{m}\right)$, and let

$$
\binom{\mathbf{m}}{\mathbf{k}} \equiv\binom{m}{k_{1}}\binom{m}{k_{2}} \cdots\binom{m}{k_{n}} .
$$

Also define

$$
\begin{gathered}
\|\mathbf{k}\|_{\infty} \equiv \max \left\{k_{i}, i=1,2, \cdots, n\right\} \\
\mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}} \equiv x_{1}^{k_{1}}\left(1-x_{1}\right)^{m-k_{1}} x_{2}^{k_{2}}\left(1-x_{2}\right)^{m-k_{2}} \cdots x_{n}^{k_{n}}\left(1-x_{n}\right)^{m-k_{n}}
\end{gathered}
$$

Thus in terms of this notation,

$$
\mathbf{p}_{m}(\mathbf{x})=\sum_{\|\mathbf{k}\|_{\infty} \leq m}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}} \mathbf{f}\left(\frac{\mathbf{k}}{\mathbf{m}}\right)
$$

Lemma 9.1.3 For $\mathbf{x} \in[0,1]^{n}$, $\mathbf{f}$ a continuous function defined on $[0,1]^{n}$, and $\mathbf{p}_{m}$ given in 9.1.2, $\mathbf{p}_{m}$ converges uniformly to $\mathbf{f}$ on $[0,1]^{n}$ as $m \rightarrow \infty$.

Proof: The function, $\mathbf{f}$ is uniformly continuous because it is continuous on a compact set. Therefore, there exists $\delta>0$ such that if $\|\mathbf{x}-\mathbf{y}\|<\delta$, then

$$
\|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})\|<\varepsilon
$$

Denote by $G$ the set of $\mathbf{k}$ such that $\left(k_{i}-m x_{i}\right)^{2}<\eta^{2} m^{2}$ for each $i$ where $\eta=\delta / \sqrt{n}$. Note this condition is equivalent to saying that for each $i,\left|\frac{k_{i}}{m}-x_{i}\right|<\eta$. By the binomial theorem,

$$
\sum_{\|\mathbf{k}\|_{\infty} \leq m}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}}=1
$$

and so for $\mathbf{x} \in[0,1]^{n}$,

$$
\begin{align*}
\| \mathbf{p}_{m}(\mathbf{x})- & \mathbf{f}(\mathbf{x})\left\|\leq \sum_{\|\mathbf{k}\|_{\infty} \leq m}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}}\right\| \mathbf{f}\left(\frac{\mathbf{k}}{\mathbf{m}}\right)-\mathbf{f}(\mathbf{x}) \| \\
& \leq \sum_{\mathbf{k} \in G}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}}\left\|\mathbf{f}\left(\frac{\mathbf{k}}{\mathbf{m}}\right)-\mathbf{f}(\mathbf{x})\right\| \\
& +\sum_{\mathbf{k} \in G^{C}}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}}\left\|\mathbf{f}\left(\frac{\mathbf{k}}{\mathbf{m}}\right)-\mathbf{f}(\mathbf{x})\right\| \tag{9.1.3}
\end{align*}
$$

Now for $\mathbf{k} \in G$ it follows that for each $i$

$$
\begin{equation*}
\left|\frac{k_{i}}{m}-x_{i}\right|<\frac{\delta}{\sqrt{n}} \tag{9.1.4}
\end{equation*}
$$

and so $\left\|\mathbf{f}\left(\frac{\mathbf{k}}{\mathbf{m}}\right)-\mathbf{f}(\mathbf{x})\right\|<\varepsilon$ because the above implies $\left|\frac{\mathbf{k}}{\mathbf{m}}-\mathbf{x}\right|<\delta$. Therefore, the first sum on the right in 9.1.3 is no larger than

$$
\sum_{\mathbf{k} \in G}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}} \varepsilon \leq \sum_{\|\mathbf{k}\|_{\infty} \leq m}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}} \varepsilon=\varepsilon
$$

Letting $M \geq \max \left\{\|\mathbf{f}(\mathbf{x})\|: \mathbf{x} \in[0,1]^{n}\right\}$ it follows

$$
\begin{aligned}
& \left\|\mathbf{p}_{m}(\mathbf{x})-\mathbf{f}(\mathbf{x})\right\| \\
\leq & \varepsilon+2 M \sum_{\mathbf{k} \in G^{C}}\binom{\mathbf{m}}{\mathbf{k}} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}} \\
\leq & \varepsilon+2 M\left(\frac{1}{\eta^{2} m^{2}}\right)^{n} \sum_{\mathbf{k} \in G^{C}}\binom{\mathbf{m}}{\mathbf{k}} \prod_{j=1}^{n}\left(k_{j}-m x_{j}\right)^{2} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}} \\
\leq & \varepsilon+2 M\left(\frac{1}{\eta^{2} m^{2}}\right)^{n} \sum_{\|\mathbf{k}\|_{\infty} \leq m}\binom{\mathbf{m}}{\mathbf{k}} \prod_{j=1}^{n}\left(k_{j}-m x_{j}\right)^{2} \mathbf{x}^{\mathbf{k}}(\mathbf{1}-\mathbf{x})^{\mathbf{m}-\mathbf{k}}
\end{aligned}
$$

because on $G^{C}$,

$$
\frac{\left(k_{j}-m x_{j}\right)^{2}}{\eta^{2} m^{2}}<1, j=1, \cdots, n
$$

Now by Lemma 9.1.2,

$$
\left\|\mathbf{p}_{m}(\mathbf{x})-\mathbf{f}(\mathbf{x})\right\| \leq \varepsilon+2 M\left(\frac{1}{\eta^{2} m^{2}}\right)^{n}\left(\frac{m}{4}\right)^{n}
$$

Therefore, since the right side does not depend on $\mathbf{x}$, it follows

$$
\lim \sup _{m \rightarrow \infty}\left\|\mathbf{p}_{m}-\mathbf{f}\right\|_{[0,1]^{n}} \leq \varepsilon
$$

and since $\varepsilon$ is arbitrary, this shows $\lim _{m \rightarrow \infty}\left\|\mathbf{p}_{m}-\mathbf{f}\right\|_{[0,1]^{n}}=0$. This proves the lemma.
The following is not surprising.
Lemma 9.1.4 Let $\mathbf{f}$ be a continuous function defined on $[-M, M]^{n}$ having values in a normed linear space. Then there exists a sequence of polynomials, $\left\{\mathbf{p}_{m}\right\}$ converging uniformly to $\mathbf{f}$ on $[-M, M]^{n}$.

Proof: Let $h(t)=-M+2 M t$ so $h:[0,1] \rightarrow[-M, M]$ and let $\mathbf{h}(\mathbf{t}) \equiv\left(h\left(t_{1}\right), \cdots, h\left(t_{n}\right)\right)$. Therefore, $\mathbf{f} \circ \mathbf{h}$ is a continuous function defined on $[0,1]^{n}$. From Lemma 9.1.3 there exists a polynomial, $\mathbf{p}(\mathbf{t})$ such that $\left\|\mathbf{p}_{m}-\mathbf{f} \circ \mathbf{h}\right\|_{[0,1]^{n}}<\frac{1}{m}$. Now for $\mathbf{x} \in[-M, M]^{n}, \mathbf{h}^{-1}(\mathbf{x})=$ $\left(h^{-1}\left(x_{1}\right), \cdots, h^{-1}\left(x_{n}\right)\right)$ and so

$$
\left\|\mathbf{p}_{m} \circ \mathbf{h}^{-1}-\mathbf{f}\right\|_{[-M, M]^{n}}=\left\|\mathbf{p}_{m}-\mathbf{f} \circ \mathbf{h}\right\|_{[0,1]^{n}}<\frac{1}{m}
$$

But $h^{-1}(x)=\frac{x}{2 M}+\frac{1}{2}$ and so $\mathbf{p}_{m}$ is still a polynomial. This proves the lemma.
A similar argument proves the following corollary.
Corollary 9.1.5 Let $\mathbf{f}$ be a continuous function defined on $\prod_{i=1}^{n}\left[a_{i}, b_{i}\right]$ having values in a normed linear space. Then there exists a sequence of polynomials, $\left\{\mathbf{p}_{m}\right\}$ converging uniformly to $\mathbf{f}$ on $\prod_{i=1}^{n}\left[a_{i}, b_{i}\right]$.

Proof: You just let $h_{i}(t)$ map $[0,1]$ one to one and onto $\left[a_{i}, b_{i}\right]$ such that $h_{i}^{-1}(x)$ is a polynomial. Then apply the same argument.

The classical version of the Weierstrass approximation theorem involved showing that a continuous function of one variable defined on a closed and bounded interval is the uniform limit of a sequence of polynomials. This is certainly included as a special case of the above. Now recall the Tietze extension theorem found on Page 158. In the general version about to be presented, the set on which $\mathbf{f}$ is defined is just a compact subset of $\mathbb{R}^{n}$, not the Cartesian product of intervals. For convenience here is the Tietze extension theorem.

Theorem 9.1.6 Let $M$ be a closed nonempty subset of a metric space $(X, d)$ and let $f$ : $M \rightarrow[a, b]$ is continuous at every point of $M$. Then there exists a function, $g$ continuous on all of $X$ which coincides with $f$ on $M$ such that $g(X) \subseteq[a, b]$.

The Weierstrass approximation theorem follows. Here it is assumed the function $\mathbf{f}$ has values in $\mathbb{R}^{p}$. In more general situations, we would need an extension theorem to extend the function off a closed set. There are such theorems, but they have not been presented at this point.

Theorem 9.1.7 Let $K$ be a compact set in $\mathbb{R}^{n}$ and let $\mathbf{f}$ be a continuous function defined on $K$ having values in $\mathbb{R}^{p}$. Then there exists a sequence of polynomials $\left\{\mathbf{p}_{m}\right\}$ converging uniformly to $\mathbf{f}$ on $K$.

Proof: Choose $M$ large enough that $K \subseteq[-M, M]^{n}$ and let $\tilde{f}$ denote a continuous function defined on all of $[-M, M]^{n}$ such that $\tilde{\mathbf{f}}=\mathbf{f}$ on $K$. Such an extension exists by the Tietze extension theorem, Theorem 9.1.6 applied to the components of $\mathbf{f}$. By Lemma 9.1.4 there exists a sequence of polynomials, $\left\{\mathbf{p}_{m}\right\}$ defined on $[-M, M]^{n}$ such that $\left\|\tilde{\mathbf{f}}-\mathbf{p}_{m}\right\|_{[-M, M]^{n}} \rightarrow$ 0 . Therefore, $\left\|\tilde{\mathbf{f}}-\mathbf{p}_{m}\right\|_{K} \rightarrow 0$ also. This proves the theorem.

### 9.2 Stone Weierstrass Theorem

### 9.2.1 The Case Of Compact Sets

There is a profound generalization of the Weierstrass approximation theorem due to Stone.
Definition 9.2.1 $\mathscr{A}$ is an algebra of functions if $\mathscr{A}$ is a vector space and if whenever $f, g \in \mathscr{A}$ then $f g \in \mathscr{A}$.

To begin with assume that the field of scalars is $\mathbb{R}$. This will be generalized later. Theorem 9.1.7 implies the following very special case.

Corollary 9.2.2 The polynomials are dense in $C([a, b])$.
The next result is the key to the profound generalization of the Weierstrass theorem due to Stone in which an interval will be replaced by a compact or locally compact set and polynomials will be replaced with elements of an algebra satisfying certain axioms.

Corollary 9.2.3 On the interval $[-M, M]$, there exist polynomials $p_{n}$ such that

$$
p_{n}(0)=0
$$

and

$$
\lim _{n \rightarrow \infty}\left\|p_{n}-|\cdot|\right\|_{\infty}=0
$$

Proof: By Corollary 9.2 .2 there exists a sequence of polynomials, $\left\{\tilde{p}_{n}\right\}$ such that $\tilde{p}_{n} \rightarrow$ $|\cdot|$ uniformly. Then let $p_{n}(t) \equiv \tilde{p}_{n}(t)-\tilde{p}_{n}(0)$. This proves the corollary.

Definition 9.2.4 An algebra of functions, $\mathscr{A}$ defined on $A$, annihilates no point of $A$ if for all $x \in A$, there exists $g \in \mathscr{A}$ such that $g(x) \neq 0$. The algebra separates points if whenever $x_{1} \neq x_{2}$, then there exists $g \in \mathscr{A}$ such that $g\left(x_{1}\right) \neq g\left(x_{2}\right)$.

The following generalization is known as the Stone Weierstrass approximation theorem.
Theorem 9.2.5 Let $A$ be a compact topological space and let $\mathscr{A} \subseteq C(A ; \mathbb{R})$ be an algebra of functions which separates points and annihilates no point. Then $\mathscr{A}$ is dense in $C(A ; \mathbb{R})$.

Proof: First here is a lemma.

Lemma 9.2.6 Let $c_{1}$ and $c_{2}$ be two real numbers and let $x_{1} \neq x_{2}$ be two points of $A$. Then there exists a function $f_{x_{1} x_{2}}$ such that

$$
f_{x_{1} x_{2}}\left(x_{1}\right)=c_{1}, f_{x_{1} x_{2}}\left(x_{2}\right)=c_{2}
$$

Proof of the lemma: Let $g \in \mathscr{A}$ satisfy

$$
g\left(x_{1}\right) \neq g\left(x_{2}\right) .
$$

Such a $g$ exists because the algebra separates points. Since the algebra annihilates no point, there exist functions $h$ and $k$ such that

$$
h\left(x_{1}\right) \neq 0, k\left(x_{2}\right) \neq 0
$$

Then let

$$
u \equiv g h-g\left(x_{2}\right) h, v \equiv g k-g\left(x_{1}\right) k
$$

It follows that $u\left(x_{1}\right) \neq 0$ and $u\left(x_{2}\right)=0$ while $v\left(x_{2}\right) \neq 0$ and $v\left(x_{1}\right)=0$. Let

$$
f_{x_{1} x_{2}} \equiv \frac{c_{1} u}{u\left(x_{1}\right)}+\frac{c_{2} v}{v\left(x_{2}\right)}
$$

This proves the lemma. Now continue the proof of Theorem 9.2.5.
First note that $\overline{\mathscr{A}}$ satisfies the same axioms as $\mathscr{A}$ but in addition to these axioms, $\overline{\mathscr{A}}$ is closed. The closure of $\mathscr{A}$ is taken with respect to the usual norm on $C(A)$,

$$
\|f\|_{\infty} \equiv \max \{|f(x)|: x \in A\}
$$

Suppose $f \in \overline{\mathscr{A}}$ and suppose $M$ is large enough that

$$
\|f\|_{\infty}<M
$$

Using Corollary 9.2.3, let $p_{n}$ be a sequence of polynomials such that

$$
\left\|p_{n}-|\cdot|\right\|_{\infty} \rightarrow 0, p_{n}(0)=0
$$

It follows that $p_{n} \circ f \in \overline{\mathscr{A}}$ and so $|f| \in \overline{\mathscr{A}}$ whenever $f \in \overline{\mathscr{A}}$. Also note that

$$
\begin{aligned}
& \max (f, g)=\frac{|f-g|+(f+g)}{2} \\
& \min (f, g)=\frac{(f+g)-|f-g|}{2}
\end{aligned}
$$

Therefore, this shows that if $f, g \in \overline{\mathscr{A}}$ then

$$
\max (f, g), \min (f, g) \in \overline{\mathscr{A}}
$$

By induction, if $f_{i}, i=1,2, \cdots, m$ are in $\overline{\mathscr{A}}$ then

$$
\max \left(f_{i}, i=1,2, \cdots, m\right), \min \left(f_{i}, i=1,2, \cdots, m\right) \in \overline{\mathscr{A}}
$$

Now let $h \in C(A ; \mathbb{R})$ and let $x \in A$. Use Lemma 9.2.6 to obtain $f_{x y}$, a function of $\overline{\mathscr{A}}$ which agrees with $h$ at $x$ and $y$. Letting $\varepsilon>0$, there exists an open set $U(y)$ containing $y$ such that

$$
f_{x y}(z)>h(z)-\varepsilon \text { if } z \in U(y)
$$

Since $A$ is compact, let $U\left(y_{1}\right), \cdots, U\left(y_{l}\right)$ cover $A$. Let

$$
f_{x} \equiv \max \left(f_{x y_{1}}, f_{x y_{2}}, \cdots, f_{x y_{l}}\right)
$$

Then $f_{x} \in \overline{\mathscr{A}}$ and

$$
f_{x}(z)>h(z)-\varepsilon
$$

for all $z \in A$ and $f_{x}(x)=h(x)$. This implies that for each $x \in A$ there exists an open set $V(x)$ containing $x$ such that for $z \in V(x)$,

$$
f_{x}(z)<h(z)+\varepsilon
$$

Let $V\left(x_{1}\right), \cdots, V\left(x_{m}\right)$ cover $A$ and let

$$
f \equiv \min \left(f_{x_{1}}, \cdots, f_{x_{m}}\right)
$$

Therefore,

$$
f(z)<h(z)+\varepsilon
$$

for all $z \in A$ and since $f_{x}(z)>h(z)-\varepsilon$ for all $z \in A$, it follows

$$
f(z)>h(z)-\varepsilon
$$

also and so

$$
|f(z)-h(z)|<\varepsilon
$$

for all $z$. Since $\varepsilon$ is arbitrary, this shows $h \in \overline{\mathscr{A}}$ and proves $\overline{\mathscr{A}}=C(A ; \mathbb{R})$. This proves the theorem.

### 9.2.2 The Case Of Locally Compact Sets

Definition 9.2.7 Let $(X, \tau)$ be a locally compact Hausdorff space. $C_{0}(X)$ denotes the space of real or complex valued continuous functions defined on $X$ with the property that if $f \in$ $C_{0}(X)$, then for each $\varepsilon>0$ there exists a compact set $K$ such that $|f(x)|<\varepsilon$ for all $x \notin K$. Define

$$
\|f\|_{\infty}=\sup \{|f(x)|: x \in X\}
$$

Lemma 9.2.8 For $(X, \tau)$ a locally compact Hausdorff space with the above norm, $C_{0}(X)$ is a complete space.

Proof: Let $(\widetilde{X}, \tilde{\tau})$ be the one point compactification described in Lemma 7.12.20.

$$
D \equiv\{f \in C(\widetilde{X}): f(\infty)=0\}
$$

Then $D$ is a closed subspace of $C(\widetilde{X})$. For $f \in C_{0}(X)$,

$$
\widetilde{f}(x) \equiv\left\{\begin{array}{l}
f(x) \text { if } x \in X \\
0 \text { if } x=\infty
\end{array}\right.
$$

and let $\theta: C_{0}(X) \rightarrow D$ be given by $\theta f=\widetilde{f}$. Then $\theta$ is one to one and onto and also satisfies $\|f\|_{\infty}=\|\theta f\|_{\infty}$. Now $D$ is complete because it is a closed subspace of a complete space and so $C_{0}(X)$ with $\|\cdot\|_{\infty}$ is also complete. This proves the lemma.

The above refers to functions which have values in $\mathbb{C}$ but the same proof works for functions which have values in any complete normed linear space.

In the case where the functions in $C_{0}(X)$ all have real values, I will denote the resulting space by $C_{0}(X ; \mathbb{R})$ with similar meanings in other cases.

With this lemma, the generalization of the Stone Weierstrass theorem to locally compact sets is as follows.

Theorem 9.2.9 Let $\mathscr{A}$ be an algebra of functions in $C_{0}(X ; \mathbb{R})$ where $(X, \tau)$ is a locally compact Hausdorff space which separates the points and annihilates no point. Then $\mathscr{A}$ is dense in $C_{0}(X ; \mathbb{R})$.

Proof: Let $(\widetilde{X}, \tilde{\tau})$ be the one point compactification as described in Lemma 7.12.20. Let $\widetilde{\mathscr{A}}$ denote all finite linear combinations of the form

$$
\left\{\sum_{i=1}^{n} c_{i} \widetilde{f}_{i}+c_{0}: f \in \mathscr{A}, c_{i} \in \mathbb{R}\right\}
$$

where for $f \in C_{0}(X ; \mathbb{R})$,

$$
\widetilde{f}(x) \equiv\left\{\begin{array}{l}
f(x) \text { if } x \in X \\
0 \text { if } x=\infty
\end{array}\right.
$$

Then $\widetilde{\mathscr{A}}$ is obviously an algebra of functions in $C(\widetilde{X} ; \mathbb{R})$. It separates points because this is true of $\mathscr{A}$. Similarly, it annihilates no point because of the inclusion of $c_{0}$ an arbitrary element of $\mathbb{R}$ in the definition above. Therefore from Theorem $9.2 .5, \widetilde{\mathscr{A}}$ is dense in $C(\widetilde{X} ; \mathbb{R})$. Letting $f \in C_{0}(X ; \mathbb{R})$, it follows $\widetilde{f} \in C(\widetilde{X} ; \mathbb{R})$ and so there exists a sequence $\left\{h_{n}\right\} \subseteq \widetilde{\mathscr{A}}$ such that $h_{n}$ converges uniformly to $\widetilde{f}$. Now $h_{n}$ is of the form $\sum_{i=1}^{n} c_{i}^{n} \widetilde{f_{i}^{n}}+c_{0}^{n}$ and since $\widetilde{f}(\infty)=0$, you can take each $c_{0}^{n}=0$ and so this has shown the existence of a sequence of functions in $\mathscr{A}$ such that it converges uniformly to $f$. This proves the theorem.

### 9.2.3 The Case Of Complex Valued Functions

What about the general case where $C_{0}(X)$ consists of complex valued functions and the field of scalars is $\mathbb{C}$ rather than $\mathbb{R}$ ? The following is the version of the Stone Weierstrass theorem which applies to this case. You have to assume that for $f \in \mathscr{A}$ it follows $\bar{f} \in \mathscr{A}$. Such an algebra is called self adjoint.

Theorem 9.2.10 Suppose $\mathscr{A}$ is an algebra of functions in $C_{0}(X)$, where $X$ is a locally compact Hausdorff space, which separates the points, annihilates no point, and has the property that if $f \in \mathscr{A}$, then $\bar{f} \in \mathscr{A}$. Then $\mathscr{A}$ is dense in $C_{0}(X)$.

Proof: Let $\operatorname{Re} \mathscr{A} \equiv\{\operatorname{Re} f: f \in \mathscr{A}\}, \operatorname{Im} \mathscr{A} \equiv\{\operatorname{Im} f: f \in \mathscr{A}\}$. First I will show that $\mathscr{A}=\operatorname{Re} \mathscr{A}+i \operatorname{Im} \mathscr{A}=\operatorname{Im} \mathscr{A}+i \operatorname{Re} \mathscr{A}$. Let $f \in \mathscr{A}$. Then

$$
f=\frac{1}{2}(f+\bar{f})+\frac{1}{2}(f-\bar{f})=\operatorname{Re} f+i \operatorname{Im} f \in \operatorname{Re} \mathscr{A}+i \operatorname{Im} \mathscr{A}
$$

and so $\mathscr{A} \subseteq \operatorname{Re} \mathscr{A}+i \operatorname{Im} \mathscr{A}$. Also

$$
f=\frac{1}{2 i}(i f+i \bar{f})-\frac{i}{2}(i f+\overline{(i f)})=\operatorname{Im}(i f)+i \operatorname{Re}(i f) \in \operatorname{Im} \mathscr{A}+i \operatorname{Re} \mathscr{A}
$$

This proves one half of the desired equality. Now suppose $h \in \operatorname{Re} \mathscr{A}+i \operatorname{Im} \mathscr{A}$. Then $h=\operatorname{Re} g_{1}+i \operatorname{Im} g_{2}$ where $g_{i} \in \mathscr{A}$. Then since $\operatorname{Re} g_{1}=\frac{1}{2}\left(g_{1}+\overline{g_{1}}\right)$, it follows $\operatorname{Re} g_{1} \in \mathscr{A}$. Similarly $\operatorname{Im} g_{2} \in \mathscr{A}$. Therefore, $h \in \mathscr{A}$. The case where $h \in \operatorname{Im} \mathscr{A}+i \operatorname{Re} \mathscr{A}$ is similar. This establishes the desired equality.

Now $\operatorname{Re} \mathscr{A}$ and $\operatorname{Im} \mathscr{A}$ are both real algebras. I will show this now. First consider $\operatorname{Im} \mathscr{A}$. It is obvious this is a real vector space. It only remains to verify that the product of two functions in $\operatorname{Im} \mathscr{A}$ is in $\operatorname{Im} \mathscr{A}$. Note that from the first part, $\operatorname{Re} \mathscr{A}, \operatorname{Im} \mathscr{A}$ are both subsets of $\mathscr{A}$ because, for example, if $u \in \operatorname{Im} \mathscr{A}$ then $u+0 \in \operatorname{Im} \mathscr{A}+i \operatorname{Re} \mathscr{A}=\mathscr{A}$. Therefore, if $v, w \in \operatorname{Im} \mathscr{A}$, both $i v$ and $w$ are in $\mathscr{A}$ and so $\operatorname{Im}(i v w)=v w$ and $i v w \in \mathscr{A}$. Similarly, $\operatorname{Re} \mathscr{A}$ is an algebra.

Both $\operatorname{Re} \mathscr{A}$ and $\operatorname{Im} \mathscr{A}$ must separate the points. Here is why: If $x_{1} \neq x_{2}$, then there exists $f \in \mathscr{A}$ such that $f\left(x_{1}\right) \neq f\left(x_{2}\right) . \operatorname{If} \operatorname{Im} f\left(x_{1}\right) \neq \operatorname{Im} f\left(x_{2}\right)$, this shows there is a function in $\operatorname{Im} \mathscr{A}, \operatorname{Im} f$ which separates these two points. If $\operatorname{Im} f$ fails to separate the two points, then $\operatorname{Re} f$ must separate the points and so you could consider $\operatorname{Im}(i f)$ to get a function in $\operatorname{Im} \mathscr{A}$ which separates these points. This shows $\operatorname{Im} \mathscr{A}$ separates the points. Similarly $\operatorname{Re} \mathscr{A}$ separates the points.

Neither $\operatorname{Re} \mathscr{A}$ nor $\operatorname{Im} \mathscr{A}$ annihilate any point. This is easy to see because if $x$ is a point there exists $f \in \mathscr{A}$ such that $f(x) \neq 0$. Thus either $\operatorname{Re} f(x) \neq 0$ or $\operatorname{Im} f(x) \neq 0$. If $\operatorname{Im} f(x) \neq 0$, this shows this point is not annihilated by $\operatorname{Im} \mathscr{A}$. If $\operatorname{Im} f(x)=0$, consider $\operatorname{Im}(i f)(x)=\operatorname{Re} f(x) \neq 0$. Similarly, $\operatorname{Re} \mathscr{A}$ does not annihilate any point.

It follows from Theorem 9.2.9 that $\operatorname{Re} \mathscr{A}$ and $\operatorname{Im} \mathscr{A}$ are dense in the real valued functions of $C_{0}(X)$. Let $f \in C_{0}(X)$. Then there exists $\left\{h_{n}\right\} \subseteq \operatorname{Re} \mathscr{A}$ and $\left\{g_{n}\right\} \subseteq \operatorname{Im} \mathscr{A}$ such that $h_{n} \rightarrow \operatorname{Re} f$ uniformly and $g_{n} \rightarrow \operatorname{Im} f$ uniformly. Therefore, $h_{n}+i g_{n} \in \mathscr{A}$ and it converges to $f$ uniformly. This proves the theorem.

### 9.3 The Holder Spaces

We consider these spaces as spaces of functions defined on an interval $[0,1]$ although one could have $[0, T]$ just as easily. A slightly more general version is in the exercises. They are a very interesting example of spaces which are not separable.

Definition 9.3.1 Let $p>1$. Then $f \in C^{1 / p}([0,1])$ means that $f \in C([0,1])$ and also

$$
\rho_{p}(f) \equiv \sup \left\{\frac{|f(x)-f(y)|}{|x-y|^{1 / p}}: x, y \in X, x \neq y\right\}<\infty
$$

Then the norm is defined as $\|f\|_{C([0,1])}+\rho_{p}(f) \equiv\|f\|_{1 / p}$.
It is an exercise to verify that $C^{1 / p}([0,1])$ is a complete normed linear space.
Let $p>1$. Then $C^{1 / p}([0,1])$ is not separable. Define uncountably many functions, one for each $\varepsilon$ where $\varepsilon$ is a sequence of -1 and 1 . Thus $\varepsilon_{k} \in\{-1,1\}$. Thus $\varepsilon \neq \varepsilon^{\prime}$ if the two sequences differ in at least one slot, one giving 1 and the other equaling -1 . Now define

$$
f_{\varepsilon}(t) \equiv \sum_{k=1}^{\infty} \varepsilon_{k} 2^{-k / p} \sin \left(2^{k} \pi t\right)
$$

Then this is $1 / p$ Holder. Let $s<t$.

$$
\begin{aligned}
\mid f_{\varepsilon}(t)- & f_{\varepsilon}(s)\left|\leq \sum_{k \leq\left|\log _{2}(t-s)\right|}\right| 2^{-k / p} \sin \left(2^{k} \pi t\right)-2^{-k / p} \sin \left(2^{k} \pi s\right) \mid \\
& +\sum_{k>\left|\log _{2}(t-s)\right|}\left|2^{-k / p} \sin \left(2^{k} \pi t\right)-2^{-k / p} \sin \left(2^{k} \pi s\right)\right|
\end{aligned}
$$

If $t=1$ and $s=0$, there is really nothing to show because then the difference equals 0 . There is also nothing to show if $t=s$. From now on, $0<t-s<1$. Let $k_{0}$ be the largest integer which is less than or equal to $\left|\log _{2}(t-s)\right|=-\log _{2}(t-s)$. Note that $-\log (t-s)>0$ because $0<t-s<1$. Then

$$
\begin{aligned}
\left|f_{\varepsilon}(t)-f_{\varepsilon}(s)\right| \leq & \sum_{k \leq k_{0}}\left|2^{-k / p} \sin \left(2^{k} \pi t\right)-2^{-k / p} \sin \left(2^{k} \pi s\right)\right| \\
& +\sum_{k>k_{0}}\left|2^{-k / p} \sin \left(2^{k} \pi t\right)-2^{-k / p} \sin \left(2^{k} \pi s\right)\right| \\
\leq & \sum_{k \leq k_{0}} 2^{-k / p} 2^{k} \pi|t-s|+\sum_{k>k_{0}} 2^{-k / p} 2
\end{aligned}
$$

Now $k_{0} \leq-\log _{2}(t-s)<k_{0}+1$ and so $-k_{0} \geq \log _{2}(t-s) \geq-\left(k_{0}+1\right)$. Hence $2^{-k_{0}} \geq$ $|t-s| \geq 2^{-k_{0}} 2^{-1}$ and so $2^{-k_{0} / p} \geq|t-s|^{1 / p} \geq 2^{-k_{0} / p} 2^{-1 / p}$. Using this in the sums,

$$
\begin{aligned}
& \left|f_{\varepsilon}(t)-f_{\varepsilon}(s)\right| \leq|t-s| C_{p}+\sum_{k>k_{0}} 2^{-k / p} 2^{k_{0} / p} 2^{-k_{0} / p} 2 \\
& \quad \leq|t-s| C_{p}+\sum_{k>k_{0}} 2^{-k / p} 2^{k_{0} / p}\left(2^{1 / p}|t-s|^{1 / p}\right) 2
\end{aligned}
$$

$$
\begin{aligned}
& \leq|t-s| C_{p}+\sum_{k>k_{0}} 2^{-\left(k-k_{0}\right) / p}\left(2^{1 / p}|t-s|^{1 / p}\right) 2 \\
& \leq C_{p}|t-s|+\left(2^{1+1 / p}\right) \sum_{k=1}^{\infty} 2^{-k / p}|t-s|^{1 / p} \\
& =C_{p}|t-s|+D_{p}|t-s|^{1 / p} \leq C_{p}|t-s|^{1 / p}+D_{p}|t-s|^{1 / p}
\end{aligned}
$$

Thus $f_{\varepsilon}$ is indeed $1 / p$ Holder continuous.
Now consider $\varepsilon \neq \varepsilon^{\prime}$. Suppose the first discrepancy in the two sequences occurs with $\varepsilon_{j}$. Thus one is 1 and the other is -1 . Let $t=\frac{i+1}{2^{j+1}}, s=\frac{i}{2^{j+1}}$

$$
\begin{gathered}
\left|f_{\mathcal{E}}(t)-f_{\mathcal{E}}(s)-\left(f_{\varepsilon^{\prime}}(t)-f_{\varepsilon^{\prime}}(s)\right)\right|= \\
\left|\begin{array}{c}
\sum_{k=j}^{\infty} \varepsilon_{k} 2^{-k / p} \sin \left(2^{k} \pi t\right)-\sum_{k=j}^{\infty} \varepsilon_{k} 2^{-k / p} \sin \left(2^{k} \pi s\right) \\
-\left(\sum_{k=j}^{\infty} \varepsilon_{k}^{\prime} 2^{-k / p} \sin \left(2^{k} \pi t\right)-\sum_{k=j}^{\infty} \varepsilon_{k}^{\prime} 2^{-k / p} \sin \left(2^{k} \pi s\right)\right)
\end{array}\right|
\end{gathered}
$$

Now consider what happens for $k>j$. Then $\sin \left(2^{k} \pi \frac{i}{2^{j+1}}\right)=\sin (m \pi)=0$ for some integer $m$. Thus the whole mess reduces to

$$
\begin{aligned}
& \left|\left(\varepsilon_{j}-\varepsilon_{j}^{\prime}\right) 2^{-j / p} \sin \left(\frac{2^{j} \pi(i+1)}{2^{j+1}}\right)-\left(\varepsilon_{j}-\varepsilon_{j}^{\prime}\right) 2^{-j / p} \sin \left(\frac{2^{j} \pi i}{2^{j+1}}\right)\right| \\
= & \left|\left(\varepsilon_{j}-\varepsilon_{j}^{\prime}\right) 2^{-j / p} \sin \left(\frac{\pi(i+1)}{2}\right)-\left(\varepsilon_{j}-\varepsilon_{j}^{\prime}\right) 2^{-j / p} \sin \left(\frac{\pi i}{2}\right)\right| \\
= & 2\left(2^{-j / p}\right)
\end{aligned}
$$

In particular, $|t-s|=\frac{1}{2^{j+1}}$ so $2^{1 / p}|t-s|^{1 / p}=2^{-j / p}$

$$
\left|f_{\varepsilon}(t)-f_{\varepsilon}(s)-\left(f_{\mathcal{\varepsilon}^{\prime}}(t)-f_{\varepsilon^{\prime}}(s)\right)\right|=2\left(2^{1 / p}\right)|t-s|^{1 / p}
$$

which shows that

$$
\sup _{0 \leq s<t \leq 1} \frac{\left|f_{\varepsilon}(t)-f_{\mathcal{\varepsilon}^{\prime}}(t)-\left(f_{\varepsilon}(s)-f_{\mathcal{\varepsilon}^{\prime}}(s)\right)\right|}{|t-s|^{1 / p}} \geq 2^{1 / p}(2)
$$

Thus there exists a set of uncountably many functions in $C^{1 / p}([0, T])$ and for any two of them $f, g$, you get

$$
\|f-g\|_{C^{1 / p}([0,1])}>2
$$

so $C^{1 / p}([0,1])$ is not separable.

### 9.4 Exercises

1. Let $(X, \tau),(Y, \eta)$ be topological spaces and let $A \subseteq X$ be compact. Then if $f: X \rightarrow Y$ is continuous, show that $f(A)$ is also compact.
2. $\uparrow$ In the context of Problem 1, suppose $\mathbb{R}=Y$ where the usual topology is placed on $\mathbb{R}$. Show $f$ achieves its maximum and minimum on $A$.
3. Let $V$ be an open set in $\mathbb{R}^{n}$. Show there is an increasing sequence of compact sets, $K_{m}$, such that $V=\cup_{m=1}^{\infty} K_{m}$. Hint: Let

$$
C_{m} \equiv\left\{\mathbf{x} \in \mathbb{R}^{n}: \operatorname{dist}\left(\mathbf{x}, V^{C}\right) \geq \frac{1}{m}\right\}
$$

where

$$
\operatorname{dist}(\mathbf{x}, S) \equiv \inf \{|\mathbf{y}-\mathbf{x}| \text { such that } \mathbf{y} \in S\}
$$

Consider $K_{m} \equiv C_{m} \cap \overline{\boldsymbol{B}(\mathbf{0}, m)}$.
4. Let $B\left(X ; \mathbb{R}^{n}\right)$ be the space of functions $\mathbf{f}$, mapping $X$ to $\mathbb{R}^{n}$ such that

$$
\sup \{|\mathbf{f}(\mathbf{x})|: \mathbf{x} \in X\}<\infty
$$

Show $B\left(X ; \mathbb{R}^{n}\right)$ is a complete normed linear space if

$$
\|\mathbf{f}\| \equiv \sup \{|\mathbf{f}(\mathbf{x})|: \mathbf{x} \in X\}
$$

5. Let $\alpha \in[0,1]$. Define, for $X$ a compact subset of $\mathbb{R}^{p}$,

$$
C^{\alpha}\left(X ; \mathbb{R}^{n}\right) \equiv\left\{\mathbf{f} \in C\left(X ; \mathbb{R}^{n}\right): \rho_{\alpha}(\mathbf{f})+\|\mathbf{f}\| \equiv\|\mathbf{f}\|_{\alpha}<\infty\right\}
$$

where

$$
\|\mathbf{f}\| \equiv \sup \{|\mathbf{f}(\mathbf{x})|: \mathbf{x} \in X\}
$$

and

$$
\rho_{\alpha}(\mathbf{f}) \equiv \sup \left\{\frac{|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|}{|\mathbf{x}-\mathbf{y}|^{\alpha}}: \mathbf{x}, \mathbf{y} \in X, \mathbf{x} \neq \mathbf{y}\right\}
$$

Show that $\left(C^{\alpha}\left(X ; \mathbb{R}^{n}\right),\|\cdot\|_{\alpha}\right)$ is a complete normed linear space.
6. Let $\left\{\mathbf{f}_{n}\right\}_{n=1}^{\infty} \subseteq C^{\alpha}\left(X ; \mathbb{R}^{n}\right)$ where $X$ is a compact subset of $\mathbb{R}^{p}$ and suppose

$$
\left\|\mathbf{f}_{n}\right\|_{\alpha} \leq M
$$

for all $n$. Show there exists a subsequence, $n_{k}$, such that $\mathbf{f}_{n_{k}}$ converges in $C\left(X ; \mathbb{R}^{n}\right)$. The given sequence is called precompact when this happens. (This also shows the embedding of $C^{\alpha}\left(X ; \mathbb{R}^{n}\right)$ into $C\left(X ; \mathbb{R}^{n}\right)$ is a compact embedding.) Note that it is likely the case that $C^{\alpha}\left(X ; \mathbb{R}^{n}\right)$ is not separable although it embedds continuously into a nice separable space. In fact, $C^{\alpha}\left([0, T] ; \mathbb{R}^{n}\right)$ can be shown to not be separable. See Definition 9.3.1 and the discussion which follows it.
7. Use the general Stone Weierstrass approximation theorem to prove Theorem 9.1.7.

## Chapter 10

## Brouwer Fixed Point Theorem $\mathbb{R}^{n *}$

This is on the Brouwer fixed point theorem and a discussion of some of the manipulations which are important regarding simplices. This here is an approach based on combinatorics or graph theory. It features the famous Sperner's lemma. It uses very elementary concepts from linear algebra in an essential way. However, it is pretty technical stuff. This elementary proof is harder than those which are based on other approaches like integration theory or degree theory.

### 10.0.1 Simplices and Triangulations

Definition 10.0.1 Define an $n$ simplex, denoted by $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$, to be the convex hull of the $n+1$ points, $\left\{\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right\}$ where $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are linearly independent. Thus

$$
\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right] \equiv\left\{\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}: \sum_{i=0}^{n} t_{i}=1, t_{i} \geq 0\right\}
$$

Note that $\left\{\mathbf{x}_{j}-\mathbf{x}_{m}\right\}_{j \neq m}$ are also independent. I will call the $\left\{t_{i}\right\}$ just described the coordinates of a point $\mathbf{x}$.

To see the last claim, suppose $\sum_{j \neq m} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{m}\right)=0$. Then you would have

$$
\begin{gathered}
c_{0}\left(\mathbf{x}_{0}-\mathbf{x}_{m}\right)+\sum_{j \neq m, 0} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{m}\right)=0 \\
=c_{0}\left(\mathbf{x}_{0}-\mathbf{x}_{m}\right)+\sum_{j \neq m, 0} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)+\left(\sum_{j \neq m, 0} c_{j}\right)\left(\mathbf{x}_{0}-\mathbf{x}_{m}\right)=0 \\
=\sum_{j \neq m, 0} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)+\left(\sum_{j \neq m} c_{j}\right)\left(\mathbf{x}_{0}-\mathbf{x}_{m}\right)
\end{gathered}
$$

Then you get $\sum_{j \neq m} c_{j}=0$ and each $c_{j}=0$ for $j \neq m, 0$. Thus $c_{0}=0$ also because the sum is 0 and all other $c_{j}=0$.

Since $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ is an independent set, the $t_{i}$ used to specify a point in the convex hull are uniquely determined. If two of them are

$$
\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}=\sum_{i=0}^{n} s_{i} \mathbf{x}_{i}
$$

Then

$$
\sum_{i=0}^{n} t_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)=\sum_{i=0}^{n} s_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

so $t_{i}=s_{i}$ for $i \geq 1$ by independence. Since the $s_{i}$ and $t_{i}$ sum to 1 , it follows that also $s_{0}=t_{0}$. If $n \leq 2$, the simplex is a triangle, line segment, or point. If $n \leq 3$, it is a tetrahedron, triangle, line segment or point.

Definition 10.0.2 If $S$ is an $n$ simplex. Then it is triangulated if it is the union of smller sub-simplices, the triangulation, such that if $S_{1}, S_{2}$ are two simplices in the triangulation, with

$$
S_{1} \equiv\left[\mathbf{z}_{0}^{1}, \cdots, \mathbf{z}_{m}^{1}\right], S_{2} \equiv\left[\mathbf{z}_{0}^{2}, \cdots, \mathbf{z}_{p}^{2}\right]
$$

then

$$
S_{1} \cap S_{2}=\left[\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right]
$$

where $\left[\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right]$ is in the triangulation and

$$
\left\{\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right\}=\left\{\mathbf{z}_{0}^{1}, \cdots, \mathbf{z}_{m}^{1}\right\} \cap\left\{\mathbf{z}_{0}^{2}, \cdots, \mathbf{z}_{p}^{2}\right\}
$$

or else the two simplices do not intersect.
The following proposition is geometrically fairly clear. It will be used without comment whenever needed in the following argument about triangulations.

Proposition 10.0.3 Say $\left[\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right],\left[\hat{\mathbf{x}}_{1}, \cdots, \hat{\mathbf{x}}_{r}\right],\left[\mathbf{z}_{1}, \cdots, \mathbf{z}_{r}\right]$ are all $r-1$ simplices and

$$
\left[\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right],\left[\hat{\mathbf{x}}_{1}, \cdots, \hat{\mathbf{x}}_{r}\right] \subseteq\left[\mathbf{z}_{1}, \cdots, \mathbf{z}_{r}\right]
$$

and $\left[\mathbf{z}_{1}, \cdots, \mathbf{z}_{r}, \mathbf{b}\right]$ is an $r+1$ simplex and

$$
\begin{equation*}
\left[\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right]=\left[\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right] \cap\left[\hat{\mathbf{x}}_{1}, \cdots, \hat{\mathbf{x}}_{r}\right] \tag{10.0.1}
\end{equation*}
$$

where

$$
\begin{equation*}
\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right\}=\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right\} \cap\left\{\hat{\mathbf{x}}_{1}, \cdots, \hat{\mathbf{x}}_{r}\right\} \tag{10.0.2}
\end{equation*}
$$

Then

$$
\begin{equation*}
\left[\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}, \mathbf{b}\right] \cap\left[\hat{\mathbf{x}}_{1}, \cdots, \hat{\mathbf{x}}_{r}, \mathbf{b}\right]=\left[\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}, \mathbf{b}\right] \tag{10.0.3}
\end{equation*}
$$

Proof: If you have $\sum_{i=1}^{s} t_{i} \mathbf{y}_{i}+t_{s+1} \mathbf{b}$ in the right side, the $t_{i}$ summing to 1 and nonnegative, then it is obviously in both of the two simplices on the left because of 10.0.2. Thus $\left[\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}, \mathbf{b}\right] \cap\left[\hat{\mathbf{x}}_{1}, \cdots, \hat{\mathbf{x}}_{r}, \mathbf{b}\right] \supseteq\left[\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}, \mathbf{b}\right]$.

Now suppose $\mathbf{x}_{k}=\sum_{j=1}^{r} t_{j}^{k} \mathbf{z}_{j}, \hat{\mathbf{x}}_{k}=\sum_{j=1}^{r} \hat{t}_{j}^{k} \mathbf{z}_{j}$, as usual, the scalars adding to 1 and nonnegative.

Consider something in both of the simplices on the left in 10.0.3. Is it in the right? The element on the left is of the form

$$
\sum_{\alpha=1}^{r} s_{\alpha} \mathbf{x}_{\alpha}+s_{r+1} \mathbf{b}=\sum_{\alpha=1}^{r} \hat{s}_{\alpha} \hat{\mathbf{x}}_{\alpha}+\hat{s}_{r+1} \mathbf{b}
$$

where the $s_{\alpha}$, are nonnegative and sum to one, similarly for $\hat{s}_{\alpha}$. Thus

$$
\begin{equation*}
\sum_{j=1}^{r} \sum_{\alpha=1}^{r} s_{\alpha} t_{j}^{\alpha} \mathbf{z}_{j}+s_{r+1} \mathbf{b}=\sum_{\alpha=1}^{r} \sum_{j=1}^{r} \hat{s}_{\alpha} \hat{t}_{j}^{\alpha} \mathbf{z}_{j}+\hat{s}_{r+1} \mathbf{b} \tag{10.0.4}
\end{equation*}
$$

Now observe that

$$
\sum_{j} \sum_{\alpha} s_{\alpha} t_{j}^{\alpha}+s_{r+1}=\sum_{\alpha} \sum_{j} s_{\alpha} t_{j}^{\alpha}+s_{r+1}=\sum_{\alpha} s_{\alpha}+s_{r+1}=1 .
$$

A similar observation holds for the right side of 10.0.4. By uniqueness of the coordinates in an $r+1$ simplex, and assumption that $\left[\mathbf{z}_{1}, \cdots, \mathbf{z}_{r}, \mathbf{b}\right]$ is an $r+1$ simplex, $\hat{s}_{r+1}=s_{r+1}$ and so

$$
\sum_{\alpha=1}^{r} \frac{s_{\alpha}}{1-s_{r+1}} \mathbf{x}_{\alpha}=\sum_{\alpha=1}^{r} \frac{\hat{s}_{\alpha}}{1-s_{r+1}} \hat{\mathbf{x}}_{\alpha}
$$

where $\sum_{\alpha} \frac{s_{\alpha}}{1-s_{r+1}}=\sum_{\alpha} \frac{\hat{s}_{\alpha}}{1-s_{r+1}}=1$, which would say that both sides are a single element of $\left[\mathbf{x}_{1}, \cdots, \mathbf{x}_{r}\right] \cap\left[\hat{\mathbf{x}}_{1}, \cdots, \hat{\mathbf{x}}_{r}\right]=\left[\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}\right]$ and this shows both are equal to something of the form $\sum_{i=1}^{s} t_{i} \mathbf{y}_{i}, \sum_{i} t_{i}=1, t_{i} \geq 0$. Therefore,

$$
\sum_{\alpha=1}^{r} \frac{s_{\alpha}}{1-s_{r+1}} \mathbf{x}_{\alpha}=\sum_{i=1}^{s} t_{i} \mathbf{y}_{i}, \sum_{\alpha=1}^{r} s_{\alpha} \mathbf{x}_{\alpha}=\sum_{i=1}^{s}\left(1-s_{r+1}\right) t_{i} \mathbf{y}_{i}
$$

It follows that

$$
\sum_{\alpha=1}^{r} s_{\alpha} \mathbf{x}_{\alpha}+s_{r+1} \mathbf{b}=\sum_{i=1}^{s}\left(1-s_{r+1}\right) t_{i} \mathbf{y}_{i}+s_{r+1} \mathbf{b} \in\left[\mathbf{y}_{1}, \cdots, \mathbf{y}_{s}, \mathbf{b}\right]
$$

which proves the other inclusion.
Next I will explain why any simplex can be triangulated in such a way that all subsimplices have diameter less than $\varepsilon$.

This is obvious if $n \leq 2$. Supposing it to be true for $n-1$, is it also so for $n$ ? The barycenter $\mathbf{b}$ of a simplex $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ is $\frac{1}{1+n} \sum_{i} \mathbf{x}_{i}$. This point is not in the convex hull of any of the faces, those simplices of the form $\left[\mathbf{x}_{0}, \cdots, \hat{\mathbf{x}}_{k}, \cdots, \mathbf{x}_{n}\right]$ where the hat indicates $\mathbf{x}_{k}$ has been left out. Thus, placing $\mathbf{b}$ in the $k^{t h}$ position, $\left[\mathbf{x}_{0}, \cdots, \mathbf{b}, \cdots, \mathbf{x}_{n}\right]$ is a $n$ simplex also. First note that $\left[\mathbf{x}_{0}, \cdots, \hat{\mathbf{x}}_{k}, \cdots, \mathbf{x}_{n}\right]$ is an $n-1$ simplex. To be sure $\left[\mathbf{x}_{0}, \cdots, \mathbf{b}, \cdots, \mathbf{x}_{n}\right]$ is an $n$ simplex, we need to check that certain vectors are linearly independent. If

$$
\mathbf{0}=\sum_{j=1}^{k-1} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)+a_{k}\left(\frac{1}{n+1} \sum_{i=0}^{n} \mathbf{x}_{i}-\mathbf{x}_{0}\right)+\sum_{j=k+1}^{n} d_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)
$$

then does it follow that $a_{k}=0=c_{j}=d_{j}$ ?

$$
\begin{gathered}
\mathbf{0}=\sum_{j=1}^{k-1} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)+a_{k} \frac{1}{n+1}\left(\sum_{i=0}^{n}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)\right)+\sum_{j=k+1}^{n} d_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right) \\
\mathbf{0}=\sum_{j=1}^{k-1}\left(c_{j}+\frac{a_{k}}{n+1}\right)\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)+a_{k} \frac{1}{n+1}\left(\mathbf{x}_{k}-\mathbf{x}_{0}\right)+\sum_{j=k+1}^{n}\left(d_{j}+\frac{a_{k}}{n+1}\right)\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)
\end{gathered}
$$

Thus $\frac{a_{k}}{n+1}=0$ and each $c_{j}+\frac{a_{k}}{n+1}=0=d_{j}+\frac{a_{k}}{n+1}$ so each $c_{j}$ and $d_{j}$ are also 0 . Thus, this is also an $n$ simplex.

Actually, a little more is needed. Suppose $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n-1}\right]$ is an $n-1$ simplex such that $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n-1}\right] \subseteq\left[\mathbf{x}_{0}, \cdots, \hat{\mathbf{x}}_{k}, \cdots, \mathbf{x}_{n}\right]$. Why is $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n-1}, \mathbf{b}\right]$ an $n$ simplex? We know the vectors $\left\{\mathbf{y}_{j}-\mathbf{y}_{0}\right\}_{k=1}^{n-1}$ are independent and that $\mathbf{y}_{j}=\sum_{i \neq k} t_{i}^{j} \mathbf{x}_{i}$ where $\sum_{i \neq k} t_{i}^{j}=1$ with each being nonnegative. Suppose

$$
\begin{equation*}
\sum_{j=1}^{n-1} c_{j}\left(\mathbf{y}_{j}-\mathbf{y}_{0}\right)+c_{n}\left(\mathbf{b}-\mathbf{y}_{0}\right)=\mathbf{0} \tag{10.0.5}
\end{equation*}
$$

If $c_{n}=0$, then by assumption, each $c_{j}=0$. The proof goes by assuming $c_{n} \neq 0$ and deriving a contradiction. Assume then that $c_{n} \neq 0$. Then you can divide by it and obtain modified constants, still denoted as $c_{j}$ such that

$$
\mathbf{b}=\frac{1}{n+1} \sum_{i=0}^{n} \mathbf{x}_{i}=\mathbf{y}_{0}+\sum_{j=1}^{n-1} c_{j}\left(\mathbf{y}_{j}-\mathbf{y}_{0}\right)
$$

Thus

$$
\begin{gathered}
\frac{1}{n+1} \sum_{i=0}^{n} \sum_{s \neq k} t_{s}^{0}\left(\mathbf{x}_{i}-\mathbf{x}_{s}\right)=\sum_{j=1}^{n-1} c_{j}\left(\mathbf{y}_{j}-\mathbf{y}_{0}\right)=\sum_{j=1}^{n-1} c_{j}\left(\sum_{s \neq k} t_{s}^{j} \mathbf{x}_{s}-\sum_{s \neq k} t_{s}^{0} \mathbf{x}_{s}\right) \\
=\sum_{j=1}^{n-1} c_{j}\left(\sum_{s \neq k} t_{s}^{j}\left(\mathbf{x}_{s}-\mathbf{x}_{0}\right)-\sum_{s \neq k} t_{s}^{0}\left(\mathbf{x}_{s}-\mathbf{x}_{0}\right)\right)
\end{gathered}
$$

Modify the term on the left and simplify on the right to get

$$
\frac{1}{n+1} \sum_{i=0}^{n} \sum_{s \neq k} t_{s}^{0}\left(\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)+\left(\mathbf{x}_{0}-\mathbf{x}_{s}\right)\right)=\sum_{j=1}^{n-1} c_{j}\left(\sum_{s \neq k}\left(t_{s}^{j}-t_{s}^{0}\right)\left(\mathbf{x}_{s}-\mathbf{x}_{0}\right)\right)
$$

Thus,

$$
\begin{aligned}
\frac{1}{n+1} \sum_{i=0}^{n}\left(\sum_{s \neq k} t_{s}^{0}\right)\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)= & \frac{1}{n+1} \sum_{i=0}^{n} \sum_{s \neq k} t_{s}^{0}\left(\mathbf{x}_{s}-\mathbf{x}_{0}\right) \\
& +\sum_{j=1}^{n-1} c_{j}\left(\sum_{s \neq k}\left(t_{s}^{j}-t_{s}^{0}\right)\left(\mathbf{x}_{s}-\mathbf{x}_{0}\right)\right)
\end{aligned}
$$

Then, taking out the $i=k$ term on the left yields

$$
\begin{aligned}
& \frac{1}{n+1}\left(\sum_{s \neq k} t_{s}^{0}\right)\left(\mathbf{x}_{k}-\mathbf{x}_{0}\right)=-\frac{1}{n+1} \sum_{i \neq k}\left(\sum_{s \neq k} t_{s}^{0}\right)\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right) \\
& \frac{1}{n+1} \sum_{i=0}^{n} \sum_{s \neq k} t_{s}^{0}\left(\mathbf{x}_{s}-\mathbf{x}_{0}\right)+\sum_{j=1}^{n-1} c_{j}\left(\sum_{s \neq k}\left(t_{s}^{j}-t_{s}^{0}\right)\left(\mathbf{x}_{s}-\mathbf{x}_{0}\right)\right)
\end{aligned}
$$

That on the right is a linear combination of vectors $\left(\mathbf{x}_{r}-\mathbf{x}_{0}\right)$ for $r \neq k$ so by independence, $\sum_{r \neq k} t_{r}^{0}=0$. However, each $t_{r}^{0} \geq 0$ and these sum to 1 so this is impossible. Hence $c_{n}=0$ after all and so each $c_{j}=0$. Thus $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n-1}, \mathbf{b}\right]$ is an $n$ simplex.

Now in general, if you have an $n$ simplex $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$, its diameter is the maximum of $\left|\mathbf{x}_{k}-\mathbf{x}_{l}\right|$ for all $k \neq l$. Consider $\left|\mathbf{b}-\mathbf{x}_{j}\right|$. It equals

$$
\left|\sum_{i=0}^{n} \frac{1}{n+1}\left(\mathbf{x}_{i}-\mathbf{x}_{j}\right)\right|=\left|\sum_{i \neq j} \frac{1}{n+1}\left(\mathbf{x}_{i}-\mathbf{x}_{j}\right)\right| \leq \frac{n}{n+1} \operatorname{diam}(S)
$$

Next consider the $k^{t h}$ face of $S$

$$
\left[\mathbf{x}_{0}, \cdots, \hat{\mathbf{x}}_{k}, \cdots, \mathbf{x}_{n}\right]
$$

By induction, it has a triangulation into simplices which each have diameter no more than $\frac{n}{n+1} \operatorname{diam}(S)$. Let these $n-1$ simplices be denoted by $\left\{S_{1}^{k}, \cdots, S_{m_{k}}^{k}\right\}$. Then the simplices $\left\{\left[S_{i}^{k}, \mathbf{b}\right]\right\}_{i=1, k=1}^{m_{k}, n+1}$ are a triangulation of $S$ such that $\operatorname{diam}\left(\left[S_{i}^{k}, \mathbf{b}\right]\right) \leq \frac{n}{n+1} \operatorname{diam}(S)$. Do for [ $\left.S_{i}^{k}, \mathbf{b}\right]$ what was just done for $S$ obtaining a triangulation of $S$ as the union of what is obtained such that each simplex has diameter no more than $\left(\frac{n}{n+1}\right)^{2} \operatorname{diam}(S)$. Continuing this way shows the existence of the desired triangulation. You simply do the process $k$ times where $\left(\frac{n}{n+1}\right)^{k} \operatorname{diam}(S)<\varepsilon$.

### 10.0.2 Labeling Vertices

Next is a way to label the vertices. Let $p_{0}, \cdots, p_{n}$ be the first $n+1$ prime numbers. All vertices of a simplex $S=\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ having $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ independent will be labeled with one of these primes. In particular, the vertex $\mathbf{x}_{k}$ will be labeled as $p_{k}$ if the simplex is $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$. The "value" of a simplex will be the product of its labels. Triangulate this $S$.

Consider a 1 simplex whose vertices are from the vertices of $S$, the original $n$ simplex $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$, label $\mathbf{x}_{k_{1}}$ as $p_{k_{1}}$ and $\mathbf{x}_{k_{2}}$ as $p_{k_{2}}$. Then label all other vertices of this triangulation which occur on $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$ either $p_{k_{1}}$ or $p_{k_{2}}$. Note that by independence of $\left\{\mathbf{x}_{k}-\mathbf{x}_{r}\right\}_{k \neq r}$, this cannot introduce an inconsistency because the segment cannot contain any other vertex of $S$. Then obviously there will be an odd number of simplices in this triangulation having value $p_{k_{1}} p_{k_{2}}$, that is a $p_{k_{1}}$ at one end and a $p_{k_{2}}$ at the other. Next consider the 2 simplices $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}, \mathbf{x}_{k_{3}}\right]$ where the $\mathbf{x}_{k_{i}}$ are from $S$. Label all vertices of the triangulation which lie on one of these 2 simplices which have not already been labeled as either $p_{k_{1}}, p_{k_{2}}$, or $p_{k_{2}}$. Continue this way. This labels all vertices of the triangulation of $S$ which have at least one coordinate zero. For the vertices of the triangulation which have all coordinates positive, the interior points of $S$, label these at random from any of $p_{0}, \ldots, p_{n}$. (Essentially, this is the same idea. The "interior" points are the new ones not already labeled.) The idea is to show that there is an odd number of $n$ simplices with value $\prod_{i=0}^{n} p_{i}$ in the triangulation and more generally, for each $m$ simplex $\left[\mathbf{x}_{k_{1}}, \cdots, \mathbf{x}_{k_{m+1}}\right], m \leq n$ with the $\mathbf{x}_{k_{i}}$ an original vertex from $S$, there are an odd number of $m$ simplices of the triangulation contained in $\left[\mathbf{x}_{k_{1}}, \cdots, \mathbf{x}_{k_{m+1}}\right]$, having value $p_{k_{1}} \cdots p_{k_{m+1}}$. It is clear that this is the case for all such 1 simplices. For convenience, call such simplices $\left[\mathbf{x}_{k_{1}}, \cdots, \mathbf{x}_{k_{m+1}}\right] m$ dimensional faces of $S$. An $m$ simplex which is a subspace of this one will have the "correct" value if its value is $p_{k_{1}} \cdots p_{k_{m+1}}$.

Suppose that the labeling has produced an odd number of simplices of the triangulation contained in each $m$ dimensional face of $S$ which have the correct value. Take an $m$ dimensional face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}\right]$. Consider $\hat{S} \equiv\left[\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}, \mathbf{x}_{j_{k+2}}\right]$. Then by induction, there is an odd number of $k$ simplices on the $s^{t h}$ face

$$
\left[\mathbf{x}_{j_{1}}, \ldots, \hat{\mathbf{x}}_{j_{s}}, \cdots, \mathbf{x}_{j_{k+2}}\right]
$$

having value $\prod_{i \neq s} p_{j_{i}}$. In particular, the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ has an odd number of simplices with value $\prod_{i \leq k+1} p_{j_{i}}$.

No simplex in any other face of $\hat{S}$ can have this value by uniqueness of prime factorization. Pick a simplex on the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ which has correct value $\prod_{i \leq k+1} p_{j_{i}}$ and cross this simplex into $\hat{S}$. Continue crossing simplices having value $\prod_{i \leq k+1} p_{j_{i}}$ which have not been crossed till the process ends. It must end because there are an odd number of these simplices having value $\prod_{i \leq k+1} p_{j_{i}}$. If the process leads to the outside of $\hat{S}$, then one can always enter it again because there are an odd number of simplices with value $\prod_{i \leq k+1} p_{j_{i}}$ available and you will have used up an even number. Note that in this process, if you have a simplex with one side labeled $\prod_{i \leq k+1} p_{j_{i}}$, there is either one way in or out of this simplex or two depending on whether the remaining vertex is labeled $p_{j_{k+2}}$. When the process ends, the value of the simplex must be $\prod_{i=1}^{k+2} p_{j_{i}}$ because it will have the additional label $p_{j_{k+2}}$. Otherwise, there would be another route out of this, through the other side labeled $\prod_{i \leq k+1} p_{j_{i}}$. This identifies a simplex in the triangulation with value $\prod_{i=1}^{k+2} p_{j_{i}}$. Then repeat the process with $\prod_{i \leq k+1} p_{j_{i}}$ valued simplices on $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ which have not been crossed. Repeating the process, entering from the outside, cannot deliver a $\prod_{i=1}^{k+2} p_{j_{i}}$ valued simplex encountered earlier because of what was just noted. There is either one or two ways to cross the simplices. In other words, the process is one to one in selecting a $\prod_{i \leq k+1} p_{j_{i}}$ simplex from crossing such a simplex on the selected face of $\hat{S}$. Continue doing this, crossing a $\prod_{i \leq k+1} p_{j_{i}}$ simplex on the face of $\hat{S}$ which has not been crossed previously. This identifies an odd number of simplices having value $\prod_{i=1}^{k+2} p_{j_{i}}$. These are the ones which are "accessible" from the outside using this process. If there are any which are not accessible from outside, applying the same process starting inside one of these, leads to exactly one other inaccessible simplex with value $\prod_{i=1}^{k+2} p_{j_{i}}$. Hence these inaccessible simplices occur in pairs and so there are an odd number of simplices in the triangulation having value $\prod_{i=1}^{k+2} p_{j_{i}}$. We refer to this procedure of labeling as Sperner's lemma. The system of labeling is well defined thanks to the assumption that $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ is independent which implies that $\left\{\mathbf{x}_{k}-\mathbf{x}_{i}\right\}_{k \neq i}$ is also linearly independent. Thus there can be no ambiguity in the labeling of vertices on any "face" the convex hull of some of the original vertices of $S$. The following is a description of the system of labeling the vertices.

Lemma 10.0.4 Let $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ be an $n$ simplex with $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ independent, and let the first $n+1$ primes be $p_{0}, p_{1}, \cdots, p_{n}$. Label $\mathbf{x}_{k}$ as $p_{k}$ and consider a triangulation of this simplex. Labeling the vertices of this triangulation which occur on $\left[\mathbf{x}_{k_{1}}, \cdots, \mathbf{x}_{k_{s}}\right]$ with any of $p_{k_{1}}, \cdots, p_{k_{s}}$, beginning with all 1 simplices $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$ and then 2 simplices and so forth, there are an odd number of simplices $\left[\mathbf{y}_{k_{1}}, \cdots, \mathbf{y}_{k_{s}}\right]$ of the triangulation contained in $\left[\mathbf{x}_{k_{1}}, \cdots, \mathbf{x}_{k_{s}}\right]$ which have value $p_{k_{1}} \cdots p_{k_{s}}$. This for $s=1,2, \cdots, n$.

## A combinatorial method

We now give a brief discussion of the system of labeling for Sperner's lemma from the point of view of counting numbers of faces rather than obtaining them with an algorithm. Let $p_{0}, \cdots, p_{n}$ be the first $n+1$ prime numbers. All vertices of a simplex $S=\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ having $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ independent will be labeled with one of these primes. In particular, the vertex $\mathbf{x}_{k}$ will be labeled as $p_{k}$. The value of a simplex will be the product of its labels. Triangulate this $S$. Consider a 1 simplex coming from the original simplex $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$, label one end as $p_{k_{1}}$ and the other as $p_{k_{2}}$. Then label all other vertices of this triangulation which
occur on $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$ either $p_{k_{1}}$ or $p_{k_{2}}$. The assumption of linear independence assures that no other vertex of $S$ can be in $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$ so there will be no inconsistency in the labeling. Then obviously there will be an odd number of simplices in this triangulation having value $p_{k_{1}} p_{k_{2}}$, that is a $p_{k_{1}}$ at one end and a $p_{k_{2}}$ at the other. Suppose that the labeling has been done for all vertices of the triangulation which are on $\left[\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}\right]$,

$$
\left\{\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}\right\} \subseteq\left\{\mathbf{x}_{0}, \ldots \mathbf{x}_{n}\right\}
$$

any $k$ simplex for $k \leq n-1$, and there is an odd number of simplices from the triangulation having value equal to $\prod_{i=1}^{k+1} p_{j_{i}}$. Consider $\hat{S} \equiv\left[\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}, \mathbf{x}_{j_{k+2}}\right]$. Then by induction, there is an odd number of $k$ simplices on the $s^{t h}$ face

$$
\left[\mathbf{x}_{j_{1}}, \ldots, \hat{\mathbf{x}}_{j_{s}}, \cdots, \mathbf{x}_{j_{k+1}}\right]
$$

having value $\prod_{i \neq s} p_{j_{i}}$. In particular the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ has an odd number of simplices with value $\prod_{i=1}^{k+1} p_{j_{i}}:=\hat{P}_{k}$. We want to argue that some simplex in the triangulation which is contained in $\hat{S}$ has value $\hat{P}_{k+1}:=\prod_{i=1}^{k+2} p_{j_{i}}$. Let $Q$ be the number of $k+1$ simplices from the triangulation contained in $\hat{S}$ which have two faces with value $\hat{P}_{k}$ (A $k+1$ simplex has either 1 or $2 \hat{P}_{k}$ faces.) and let $R$ be the number of $k+1$ simplices from the triangulation contained in $\hat{S}$ which have exactly one $\hat{P}_{k}$ face. These are the ones we want because they have value $\hat{P}_{k+1}$. Thus the number of faces having value $\hat{P}_{k}$ which is described here is $2 Q+R$. All interior $\hat{P}_{k}$ faces being counted twice by this number. Now we count the total number of $\hat{P}_{k}$ faces another way. There are $P$ of them on the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ and by induction, $P$ is odd. Then there are $O$ of them which are not on this face. These faces got counted twice. Therefore,

$$
2 Q+R=P+2 O
$$

and so, since $P$ is odd, so is $R$. Thus there is an odd number of $\hat{P}_{k+1}$ simplices in $\hat{S}$.
We refer to this procedure of labeling as Sperner's lemma. The system of labeling is well defined thanks to the assumption that $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ is independent which implies that $\left\{\mathbf{x}_{k}-\mathbf{x}_{i}\right\}_{k \neq i}$ is also linearly independent. Thus there can be no ambiguity in the labeling of vertices on any "face", the convex hull of some of the original vertices of $S$. Sperner's lemma is now a consequence of this discussion.

### 10.1 The Brouwer Fixed Point Theorem

$S \equiv\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ is a simplex in $\mathbb{R}^{n}$. Assume $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are linearly independent. Thus a typical point of $S$ is of the form

$$
\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}
$$

where the $t_{i}$ are uniquely determined and the map $\mathbf{x} \rightarrow \mathbf{t}$ is continuous from $S$ to the compact set $\left\{\mathbf{t} \in \mathbb{R}^{n+1}: \sum t_{i}=1, t_{i} \geq 0\right\}$. The map $\mathbf{t} \rightarrow \mathbf{x}$ is one to one and clearly continuous. Since $S$ is compact, it follows that the inverse map is also continuous. This is a general consideration but what follows is a short explanation why this is so in this specific example.

To see this, suppose $\mathbf{x}^{k} \rightarrow \mathbf{x}$ in $S$. Let $\mathbf{x}^{k} \equiv \sum_{i=0}^{n} t_{i}^{k} \mathbf{x}_{i}$ with $\mathbf{x}$ defined similarly with $t_{i}^{k}$ replaced with $t_{i}, \mathbf{x} \equiv \sum_{i=0}^{n} t_{i} \mathbf{x}_{i}$. Then

$$
\mathbf{x}^{k}-\mathbf{x}_{0}=\sum_{i=0}^{n} t_{i}^{k} \mathbf{x}_{i}-\sum_{i=0}^{n} t_{i}^{k} \mathbf{x}_{0}=\sum_{i=1}^{n} t_{i}^{k}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

Thus

$$
\mathbf{x}^{k}-\mathbf{x}_{0}=\sum_{i=1}^{n} t_{i}^{k}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right), \mathbf{x}-\mathbf{x}_{0}=\sum_{i=1}^{n} t_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

Say $t_{i}^{k}$ fails to converge to $t_{i}$ for all $i \geq 1$. Then there exists a subsequence, still denoted with superscript $k$ such that for each $i=1, \cdots, n$, it follows that $t_{i}^{k} \rightarrow s_{i}$ where $s_{i} \geq 0$ and some $s_{i} \neq t_{i}$. But then, taking a limit, it follows that

$$
\mathbf{x}-\mathbf{x}_{0}=\sum_{i=1}^{n} s_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)=\sum_{i=1}^{n} t_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

which contradicts independence of the $\mathbf{x}_{i}-\mathbf{x}_{0}$. It follows that for all $i \geq 1, t_{i}^{k} \rightarrow t_{i}$. Since they all sum to 1 , this implies that also $t_{0}^{k} \rightarrow t_{0}$. Thus the claim about continuity is verified.

Let $\mathbf{f}: S \rightarrow S$ be continuous. When doing $\mathbf{f}$ to a point $\mathbf{x}$, one obtains another point of $S$ denoted as $\sum_{i=0}^{n} s_{i} \mathbf{x}_{i}$. Thus in this argument the scalars $s_{i}$ will be the components after doing $\mathbf{f}$ to a point of $S$ denoted as $\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}$.

Consider a triangulation of $S$ such that all simplices in the triangulation have diameter less than $\varepsilon$. The vertices of the simplices in this triangulation will be labeled from $p_{0}, \cdots, p_{n}$ the first $n+1$ prime numbers. If $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]$ is one of these simplices in the triangulation, each vertex is of the form $\sum_{l=0}^{n} t_{l} \mathbf{x}_{l}$ where $t_{l} \geq 0$ and $\sum_{l} t_{l}=1$. Let $\mathbf{y}_{i}$ be one of these vertices, $\mathbf{y}_{i}=\sum_{l=0}^{n} t_{l} \mathbf{x}_{l}$. Define $r_{j} \equiv s_{j} / t_{j}$ if $t_{j}>0$ and $\infty$ if $t_{j}=0$. Then $p\left(\mathbf{y}_{i}\right)$ will be the label placed on $\mathbf{y}_{i}$. To determine this label, let $r_{k}$ be the smallest of these ratios. Then the label placed on $\mathbf{y}_{i}$ will be $p_{k}$ where $r_{k}$ is the smallest of all these extended nonnegative real numbers just described. If there is duplication, pick $p_{k}$ where $k$ is smallest.

Note that for the vertices which are on $\left[\mathbf{x}_{i_{1}}, \cdots, \mathbf{x}_{i_{m}}\right]$, these will be labeled from the list $\left\{p_{i_{1}}, \cdots, p_{i_{m}}\right\}$ because $t_{k}=0$ for each of these and so $r_{k}=\infty$ unless $k \in\left\{i_{1}, \cdots, i_{m}\right\}$. In particular, this scheme labels $\mathbf{x}_{i}$ as $p_{i}$.

By the Sperner's lemma procedure described above, there are an odd number of simplices having value $\prod_{i \neq k} p_{i}$ on the $k^{\text {th }}$ face and an odd number of simplices in the triangulation of $S$ for which the product of the labels on their vertices, referred to here as its value, equals $p_{0} p_{1} \cdots p_{n} \equiv P_{n}$. Thus if $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]$ is one of these simplices, and $p\left(\mathbf{y}_{i}\right)$ is the label for $\mathbf{y}_{i}$,

$$
\prod_{i=0}^{n} p\left(\mathbf{y}_{i}\right)=\prod_{i=0}^{n} p_{i} \equiv P_{n}
$$

What is $r_{k}$, the smallest of those ratios in determining a label? Could it be larger than $1 ? r_{k}$ is certainly finite because at least some $t_{j} \neq 0$ since they sum to 1 . Thus, if $r_{k}>1$, you would have $s_{k}>t_{k}$. The $s_{j}$ sum to 1 and so some $s_{j}<t_{j}$ since otherwise, the sum of the $t_{j}$ equalling 1 would require the sum of the $s_{j}$ to be larger than 1 . Hence $r_{k}$ was not really the smallest after all and so $r_{k} \leq 1$. Hence $s_{k} \leq t_{k}$.

Let $\mathscr{S} \equiv\left\{S_{1}, \cdots, S_{m}\right\}$ denote those simplices whose value is $P_{n}$. In other words, if $\left\{\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right\}$ are the vertices of one of these simplices in $\mathscr{S}$, and

$$
\mathbf{y}_{s}=\sum_{i=0}^{n} t_{i}^{s} \mathbf{x}_{i}
$$

$r_{k_{s}} \leq r_{j}$ for all $j \neq k_{s}$ and $\left\{k_{0}, \cdots, k_{n}\right\}=\{0, \cdots, n\}$. Let $\mathbf{b}$ denote the barycenter of $S_{k}=$ $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]$.

$$
\mathbf{b} \equiv \sum_{i=0}^{n} \frac{1}{n+1} \mathbf{y}_{i}
$$

Do the same system of labeling for each $n$ simplex in a sequence of triangulations where the diameters of the simplices in the $k^{t h}$ triangulation is no more than $2^{-k}$. Thus each of these triangulations has a $n$ simplex having diameter no more than $2^{-k}$ which has value $P_{n}$. Let $\mathbf{b}_{k}$ be the barycenter of one of these $n$ simplices having value $P_{n}$. By compactness, there is a subsequence, still denoted with the index $k$ such that $\mathbf{b}_{k} \rightarrow \mathbf{x}$. This $\mathbf{x}$ is a fixed point.

Consider this last claim. $\mathbf{x}=\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}$ and after applying $\mathbf{f}$, the result is $\sum_{i=0}^{n} s_{i} \mathbf{x}_{i}$. Then $\mathbf{b}_{k}$ is the barycenter of some $\sigma_{k}$ having diameter no more than $2^{-k}$ which has value $P_{n}$. Say $\sigma_{k}$ is a simplex having vertices $\left\{\mathbf{y}_{0}^{k}, \cdots, \mathbf{y}_{n}^{k}\right\}$ and the value of $\left[\mathbf{y}_{0}^{k}, \cdots, \mathbf{y}_{n}^{k}\right]$ is $P_{n}$. Thus also

$$
\lim _{k \rightarrow \infty} \mathbf{y}_{i}^{k}=\mathbf{x}
$$

Re ordering these if necessary, we can assume that the label for $\mathbf{y}_{i}^{k}$ is $p_{i}$ which implies that, as noted above, for each $i=0, \cdots, n$,

$$
\frac{s_{i}}{t_{i}} \leq 1, s_{i} \leq t_{i}
$$

the $i^{\text {th }}$ coordinate of $\mathbf{f}\left(\mathbf{y}_{i}^{k}\right)$ with respect to the original vertices of $S$ decreases and each $i$ is represented for $i=\{0,1, \cdots, n\}$. As noted above,

$$
\mathbf{y}_{i}^{k} \rightarrow \mathbf{x}
$$

and so the $i^{\text {th }}$ coordinate of $\mathbf{y}_{i}^{k}, t_{i}^{k}$ must converge to $t_{i}$. Hence if the $i^{t h}$ coordinate of $\mathbf{f}\left(\mathbf{y}_{i}^{k}\right)$ is denoted by $s_{i}^{k}$,

$$
s_{i}^{k} \leq t_{i}^{k}
$$

By continuity of $\mathbf{f}$, it follows that $s_{i}^{k} \rightarrow s_{i}$. Thus the above inequality is preserved on taking $k \rightarrow \infty$ and so

$$
0 \leq s_{i} \leq t_{i}
$$

this for each $i$. But these $s_{i}$ add to 1 as do the $t_{i}$ and so in fact, $s_{i}=t_{i}$ for each $i$ and so $\mathbf{f}(\mathbf{x})=\mathbf{x}$. This proves the following theorem which is the Brouwer fixed point theorem.

Theorem 10.1.1 Let $S$ be a simplex $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ such that $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are independent. Also let $\mathbf{f}: S \rightarrow S$ be continuous. Then there exists $\mathbf{x} \in S$ such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Corollary 10.1.2 Let $K$ be a closed convex bounded subset of $\mathbb{R}^{n}$. Let $\mathbf{f}: K \rightarrow K$ be continuous. Then there exists $\mathbf{x} \in K$ such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Proof: Let $S$ be a large simplex containing $K$ and let $P$ be the projection map onto $K$. Consider $\mathbf{g}(\mathbf{x}) \equiv \mathbf{f}(P \mathbf{x})$. Then $\mathbf{g}$ satisfies the necessary conditions for Theorem 10.1.1 and so there exists $\mathbf{x} \in S$ such that $\mathbf{g}(\mathbf{x})=\mathbf{x}$. But this says $\mathbf{x} \in K$ and so $\mathbf{g}(\mathbf{x})=\mathbf{f}(\mathbf{x})$.

Definition 10.1.3 $A$ set $B$ has the fixed point property if whenever $f: B \rightarrow B$ for $f$ continuous, it follows that $f$ has a fixed point.

The proof of this corollary is pretty significant. By a homework problem, a closed convex set is a retract of $\mathbb{R}^{n}$. This is what it means when you say there is this continuous projection map which maps onto the closed convex set but does not change any point in the closed convex set. When you have a set $A$ which is a subset of a set $B$ which has the property that continuous functions $\mathbf{f}: B \rightarrow B$ have fixed points, and there is a continuous map $P$ from $B$ to $A$ which leaves points of $A$ unchanged, then it follows that $A$ will have the same "fixed point property". You can probably imagine all sorts of sets which are retracts of closed convex bounded sets. Also, if you have a compact set $B$ which has the fixed point property and $h: B \rightarrow h(B)$ with $h$ one to one and continuous, it will follow that $h^{-1}$ is continuous and that $h(B)$ will also have the fixed point property. This is very easy to show. This will allow further extensions of this theorem. This says that the fixed point property is topological.

### 10.2 Invariance Of Domain

As an application of the inverse function theorem is a simple proof of the important invariance of domain theorem which says that continuous and one to one functions defined on an open set in $\mathbb{R}^{n}$ with values in $\mathbb{R}^{n}$ take open sets to open sets. You know that this is true for functions of one variable because a one to one continuous function must be either strictly increasing or strictly decreasing. This will be used when considering orientations of curves later. However, the $n$ dimensional version isn't at all obvious but is just as important if you want to consider manifolds with boundary for example. The need for this theorem occurs in many other places as well in addition to being extremely interesting for its own sake. The inverse function theorem gives conditions under which a differentiable function maps open sets to open sets. The following lemma, depending on the Brouwer fixed point theorem is the thing which will allow this to be extended to continuous one to one functions. It says roughly that if a continuous function does not move points near $\mathbf{p}$ very far, then the image of a ball centered at $\mathbf{p}$ contains an open set.

Lemma 10.2.1 Let $\mathbf{f}$ be continuous and map $\overline{B(\mathbf{p}, r)} \subseteq \mathbb{R}^{n}$ to $\mathbb{R}^{n}$. Suppose that for all $\mathbf{x} \in \overline{B(\mathbf{p}, r)}$,

$$
|\mathbf{f}(\mathbf{x})-\mathbf{x}|<\varepsilon r
$$

Then it follows that

$$
\mathbf{f}(\overline{B(\mathbf{p}, r)}) \supseteq B(\mathbf{p},(1-\varepsilon) r)
$$

Proof: This is from the Brouwer fixed point theorem, Corollary 10.1.2. Consider for $\mathbf{y} \in B(\mathbf{p},(1-\varepsilon) r)$

$$
\mathbf{h}(\mathbf{x}) \equiv \mathbf{x}-\mathbf{f}(\mathbf{x})+\mathbf{y}
$$

Then $\mathbf{h}$ is continuous and for $\mathbf{x} \in \overline{B(\mathbf{p}, r)}$,

$$
|\mathbf{h}(\mathbf{x})-\mathbf{p}|=|\mathbf{x}-\mathbf{f}(\mathbf{x})+\mathbf{y}-\mathbf{p}|<\varepsilon r+|\mathbf{y}-\mathbf{p}|<\varepsilon r+(1-\varepsilon) r=r
$$

Hence $\mathbf{h}: \overline{B(\mathbf{p}, r)} \rightarrow \overline{B(\mathbf{p}, r)}$ and so it has a fixed point $\mathbf{x}$ by Corollary 10.1.2. Thus

$$
\mathbf{x}-\mathbf{f}(\mathbf{x})+\mathbf{y}=\mathbf{x}
$$

so $\mathbf{f}(\mathbf{x})=\mathbf{y}$.
The notation $\|\mathbf{f}\|_{K}$ means $\sup _{\mathbf{x} \in K}|\mathbf{f}(\mathbf{x})|$. If you have a continuous function $\mathbf{h}$ defined on a compact set $K$, then the Stone Weierstrass theorem implies you can uniformly approximate it with a polynomial $\mathbf{g}$. That is $\|\mathbf{h}-\mathbf{g}\|_{K}$ is small. The following lemma says that you can also have $\mathbf{h}(\mathbf{z})=\mathbf{g}(\mathbf{z})$ and $D \mathbf{g}(\mathbf{z})^{-1}$ exists so that near $\mathbf{z}$, the function $\mathbf{g}$ will map open sets to open sets as claimed by the inverse function theorem.

Lemma 10.2.2 Let $K$ be a compact set in $\mathbb{R}^{n}$ and let $\mathbf{h}: K \rightarrow \mathbb{R}^{n}$ be continuous, $\mathbf{z} \in K$ is fixed. Let $\delta>0$. Then there exists a polynomial $\mathbf{g}$ (each component a polynomial) such that

$$
\|\mathbf{g}-\mathbf{h}\|_{K}<\delta, \mathbf{g}(\mathbf{z})=\mathbf{h}(\mathbf{z}), D \mathbf{g}(\mathbf{z})^{-1} \text { exists }
$$

Proof: By the Weierstrass approximation theorem, Theorem 9.2.5, (apply this theorem to the algebra of real polynomials) there exists a polynomial $\hat{\mathbf{g}}$ such that

$$
\|\hat{\mathbf{g}}-\mathbf{h}\|_{K}<\frac{\delta}{3}
$$

Then define for $\mathbf{y} \in K$

$$
\mathbf{g}(\mathbf{y}) \equiv \hat{\mathbf{g}}(\mathbf{y})+\mathbf{h}(\mathbf{z})-\hat{\mathbf{g}}(\mathbf{z})
$$

Then

$$
\mathbf{g}(\mathbf{z})=\hat{\mathbf{g}}(\mathbf{z})+\mathbf{h}(\mathbf{z})-\hat{\mathbf{g}}(\mathbf{z})=\mathbf{h}(\mathbf{z})
$$

Also

$$
\begin{aligned}
|\mathbf{g}(\mathbf{y})-\mathbf{h}(\mathbf{y})| & \leq|(\hat{\mathbf{g}}(\mathbf{y})+\mathbf{h}(\mathbf{z})-\hat{\mathbf{g}}(\mathbf{z}))-\mathbf{h}(\mathbf{y})| \\
& \leq|\hat{\mathbf{g}}(\mathbf{y})-\mathbf{h}(\mathbf{y})|+|\mathbf{h}(\mathbf{z})-\hat{\mathbf{g}}(\mathbf{z})|<\frac{2 \delta}{3}
\end{aligned}
$$

and so since $\mathbf{y}$ was arbitrary,

$$
\|\mathbf{g}-\mathbf{h}\|_{K} \leq \frac{2 \delta}{3}<\delta
$$

If $D \mathbf{g}(\mathbf{z})^{-1}$ exists, then this is what is wanted. If not, let

$$
0<\eta<\{|\lambda|: \lambda \text { is an eigenvalue of } D \mathbf{g}(\mathbf{z}), \lambda \neq 0\}
$$

Then if $\eta$ is small enough, $\mathbf{g}(\mathbf{y})$ could be replaced with $\mathbf{g}(\mathbf{y})+\eta(\mathbf{y}-\mathbf{z})$ and it will still be the case that $\|\mathbf{g}-\mathbf{h}\|_{K}<\delta$ along with $\mathbf{g}(\mathbf{z})=\mathbf{h}(\mathbf{z})$ but now $D \mathbf{g}(\mathbf{z})$ would have no zero eigenvalues and would therefore be invertible. Simply use the modified $\mathbf{g}$.

The main result is essentially the following lemma which combines the conclusions of the above.

Lemma 10.2.3 Let $\mathbf{f}: \overline{B(\mathbf{p}, r)} \rightarrow \mathbb{R}^{n}$ where the ball is also in $\mathbb{R}^{n}$. Let $\mathbf{f}$ be one to one, $\mathbf{f}$ continuous. Then there exists $\delta>0$ such that

$$
\mathbf{f}(\overline{B(\mathbf{p}, r)}) \supseteq B(\mathbf{f}(\mathbf{p}), \delta) .
$$

In other words, $\mathbf{f}(\mathbf{p})$ is an interior point of $\mathbf{f}(\overline{B(\mathbf{p}, r)})$.
Proof: Since $\mathbf{f}(\overline{B(\mathbf{p}, r)})$ is compact, it follows that $\mathbf{f}^{-1}: \mathbf{f}(\overline{B(\mathbf{p}, r)}) \rightarrow \overline{B(\mathbf{p}, r)}$ is continuous. By Lemma 10.2.2, there exists a polynomial $\mathbf{g}: \mathbf{f}(\overline{B(\mathbf{p}, r)}) \rightarrow \mathbb{R}^{n}$ such that

$$
\left\|\mathbf{g}-\mathbf{f}^{-1}\right\|_{\mathbf{f}(\overline{B(\mathbf{p}, r)})}<\varepsilon r, \varepsilon<1, \quad D \mathbf{g}(\mathbf{f}(\mathbf{p}))^{-1} \text { exists, and } \mathbf{g}(\mathbf{f}(\mathbf{p}))=\mathbf{f}^{-1}(\mathbf{f}(\mathbf{p}))=\mathbf{p}
$$

From the first inequality in the above,

$$
|\mathbf{g}(\mathbf{f}(\mathbf{x}))-\mathbf{x}|=\left|\mathbf{g}(\mathbf{f}(\mathbf{x}))-\mathbf{f}^{-1}(\mathbf{f}(\mathbf{x}))\right| \leq\left\|\mathbf{g}-\mathbf{f}^{-1}\right\|_{\mathbf{f}(\overline{B(\mathbf{p}, r)})}<\varepsilon r
$$

By Lemma 10.2.1,

$$
\mathbf{g} \circ \mathbf{f}(\overline{B(\mathbf{p}, r)}) \supseteq B(\mathbf{p},(1-\varepsilon) r)=B(\mathbf{g}(\mathbf{f}(\mathbf{p})),(1-\varepsilon) r)
$$

Since $D \mathbf{g}(\mathbf{f}(\mathbf{p}))^{-1}$ exists, it follows from the inverse function theorem that $\mathbf{g}^{-1}$ also exists and that $\mathbf{g}, \mathbf{g}^{-1}$ are open maps on small open sets containing $\mathbf{f}(\mathbf{p})$ and $\mathbf{p}$ respectively. Thus there exists $\eta<(1-\varepsilon) r$ such that $\mathbf{g}^{-1}$ is an open map on $B(\mathbf{p}, \eta) \subseteq B(\mathbf{p},(1-\varepsilon) r)$. Thus

$$
\mathbf{g} \circ \mathbf{f}(\overline{B(\mathbf{p}, r)}) \supseteq B(\mathbf{p},(1-\varepsilon) r) \supseteq B(\mathbf{p}, \eta)
$$

So do $\mathbf{g}^{-1^{\star}}$ to both ends. Then you have $\mathbf{g}^{-1}(\mathbf{p})=\mathbf{f}(\mathbf{p})$ is in the open set $\mathbf{g}^{-1}(B(\mathbf{p}, \eta))$. Thus

$$
\mathbf{f}(\overline{B(\mathbf{p}, r)}) \supseteq \mathbf{g}^{-1}(B(\mathbf{p}, \eta)) \supseteq B\left(\mathbf{g}^{-1}(\mathbf{p}), \delta\right)=B(\mathbf{f}(\mathbf{p}), \delta)
$$

With this lemma, the invariance of domain theorem comes right away. This remarkable theorem states that if $\mathbf{f}: U \rightarrow \mathbb{R}^{n}$ for $U$ an open set in $\mathbb{R}^{n}$ and if $\mathbf{f}$ is one to one and continuous, then $\mathbf{f}(U)$ is also an open set in $\mathbb{R}^{n}$.

Theorem 10.2.4 Let $U$ be an open set in $\mathbb{R}^{n}$ and let $\mathbf{f}: U \rightarrow \mathbb{R}^{n}$ be one to one and continuous. Then $\mathbf{f}(U)$ is also an open subset in $\mathbb{R}^{n}$.

Proof: It suffices to show that if $\mathbf{p} \in U$ then $\mathbf{f}(\mathbf{p})$ is an interior point of $\mathbf{f}(U)$. Let $\overline{B(\mathbf{p}, r)} \subseteq U$. By Lemma 10.2.3, $\mathbf{f}(U) \supseteq \mathbf{f}(\overline{B(\mathbf{p}, r)}) \supseteq B(\mathbf{f}(\mathbf{p}), \boldsymbol{\delta})$ so $\mathbf{f}(\mathbf{p})$ is indeed an interior point of $\mathbf{f}(U)$.

The inverse mapping theorem assumed quite a bit about the mapping. In particular it assumed that the mapping had a continuous derivative. The following version of the inverse function theorem seems very interesting because it only needs an invertible derivative at a point.

Corollary 10.2.5 Let $U$ be an open set in $\mathbb{R}^{p}$ and let $\mathbf{f}: U \rightarrow \mathbb{R}^{p}$ be one to one and continuous. Then, $\mathbf{f}^{-1}$ is also continuous on the open set $\mathbf{f}(U)$. If $\mathbf{f}$ is differentiable at $\mathbf{x}_{1} \in U$ and if $D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}$ exists for $\mathbf{x}_{1} \in U$, then it follows that $D \mathbf{f}\left(\mathbf{f}\left(\mathbf{x}_{1}\right)\right)=D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}$.

Proof: $|\cdot|$ will be a norm on $\mathbb{R}^{p}$, whichever is desired. If you like, let it be the Euclidean norm. $\|\cdot\|$ will be the operator norm. The first part of the conclusion of this corollary is from invariance of domain. From the assumption that $D \mathbf{f}\left(\mathbf{x}_{1}\right)$ and $D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}$ exists,

$$
\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)=\mathbf{f}\left(\mathbf{f}^{-1}(\mathbf{y})\right)-\mathbf{f}\left(\mathbf{x}_{1}\right)=D \mathbf{f}\left(\mathbf{x}_{1}\right)\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)+\mathbf{o}\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)
$$

Since $D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}$ exists,

$$
D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right)=\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}+\mathbf{o}\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)
$$

by continuity, if $\left|\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right|$ is small enough, then $\left|\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right|$ is small enough that in the above,

$$
\left|\mathbf{o}\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)\right|<\frac{1}{2}\left|\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right|
$$

Hence, if $\left|\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right|$ is sufficiently small, then from the triangle inequality of the form $|p-q| \geq||p|-|q||$,

$$
\begin{aligned}
&\left\|D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}\right\|\left|\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right)\right| \geq\left|D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right)\right| \\
& \geq\left|\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right|-\frac{1}{2}\left|\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right| \\
&=\frac{1}{2}\left|\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right| \\
&\left|\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right| \geq\left\|D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}\right\|^{-1} \frac{1}{2}\left|\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right|
\end{aligned}
$$

It follows that for $\left|\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right|$ small enough,

$$
\left|\frac{\mathbf{o}\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)}{\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)}\right| \leq\left|\frac{\mathbf{o}\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)}{\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}}\right| \frac{2}{\left\|D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}\right\|^{-1}}
$$

Then, using continuity of the inverse function again, it follows that if $\left|\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right|$ is possibly still smaller, then $\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}$ is sufficiently small that the right side of the above inequality is no larger than $\varepsilon$. Since $\varepsilon$ is arbitrary, it follows

$$
\mathbf{o}\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)=\mathbf{o}\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right)
$$

Now from differentiability of $\mathbf{f}$ at $\mathbf{x}_{1}$,

$$
\begin{aligned}
\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right) & =\mathbf{f}\left(\mathbf{f}^{-1}(\mathbf{y})\right)-\mathbf{f}\left(\mathbf{x}_{1}\right)=D \mathbf{f}\left(\mathbf{x}_{1}\right)\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)+\mathbf{o}\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right) \\
& =D \mathbf{f}\left(\mathbf{x}_{1}\right)\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{x}_{1}\right)+\mathbf{o}\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right) \\
& =D \mathbf{f}\left(\mathbf{x}_{1}\right)\left(\mathbf{f}^{-1}(\mathbf{y})-\mathbf{f}^{-1}\left(\mathbf{f}\left(\mathbf{x}_{1}\right)\right)\right)+\mathbf{o}\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right)
\end{aligned}
$$

Therefore,

$$
\mathbf{f}^{-1}(\mathbf{y})-\mathbf{f}^{-1}\left(\mathbf{f}\left(\mathbf{x}_{1}\right)\right)=D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right)+\mathbf{o}\left(\mathbf{y}-\mathbf{f}\left(\mathbf{x}_{1}\right)\right)
$$

From the definition of the derivative, this shows that $D \mathbf{f}^{-1}\left(\mathbf{f}\left(\mathbf{x}_{1}\right)\right)=D \mathbf{f}\left(\mathbf{x}_{1}\right)^{-1}$.

## Chapter 11

## Abstract Measure And Integration

## 11.1 $\sigma$ Algebras

This chapter is on the basics of measure theory and integration. A measure is a real valued mapping from some subset of the power set of a given set which has values in $[0, \infty]$. Many apparently different things can be considered as measures and also there is an integral defined. By discussing this in terms of axioms and in a very abstract setting, many different topics can be considered in terms of one general theory. For example, it will turn out that sums are included as an integral of this sort. So is the usual integral as well as things which are often thought of as being in between sums and integrals.

Let $\Omega$ be a set and let $\mathscr{F}$ be a collection of subsets of $\Omega$ satisfying

$$
\begin{gather*}
\emptyset \in \mathscr{F}, \Omega \in \mathscr{F},  \tag{11.1.1}\\
E \in \mathscr{F} \text { implies } E^{C} \equiv \Omega \backslash E \in \mathscr{F}, \\
\text { If }\left\{E_{n}\right\}_{n=1}^{\infty} \subseteq \mathscr{F}, \text { then } \cup_{n=1}^{\infty} E_{n} \in \mathscr{F} . \tag{11.1.2}
\end{gather*}
$$

Definition 11.1.1 A collection of subsets of a set, $\Omega$, satisfying Formulas 11.1.1-11.1.2 is called a $\sigma$ algebra.

As an example, let $\Omega$ be any set and let $\mathscr{F}=\mathscr{P}(\Omega)$, the set of all subsets of $\Omega$ (power set). This obviously satisfies Formulas 11.1.1-11.1.2.

Lemma 11.1.2 Let $\mathscr{C}$ be a set whose elements are $\sigma$ algebras of subsets of $\Omega$. Then $\cap \mathscr{C}$ is a $\sigma$ algebra also.

Be sure to verify this lemma. It follows immediately from the above definitions but it is important for you to check the details.

Example 11.1.3 Let $\tau$ denote the collection of all open sets in $\mathbb{R}^{n}$ and let $\sigma(\tau) \equiv$ intersection of all $\sigma$ algebras that contain $\tau . \sigma(\tau)$ is called the $\sigma$ algebra of Borel sets. In general, for a collection of sets, $\Sigma, \sigma(\Sigma)$ is the smallest $\sigma$ algebra which contains $\Sigma$.

This is a very important $\sigma$ algebra and it will be referred to frequently as the Borel sets. Attempts to describe a typical Borel set are more trouble than they are worth and it is not easy to do so. Rather, one uses the definition just given in the example. Note, however, that all countable intersections of open sets and countable unions of closed sets are Borel sets. Such sets are called $G_{\delta}$ and $F_{\sigma}$ respectively.

Definition 11.1.4 Let $\mathscr{F}$ be a $\sigma$ algebra of sets of $\Omega$ and let $\mu: \mathscr{F} \rightarrow[0, \infty] . \mu$ is called $a$ measure if

$$
\begin{equation*}
\mu\left(\bigcup_{i=1}^{\infty} E_{i}\right)=\sum_{i=1}^{\infty} \mu\left(E_{i}\right) \tag{11.1.3}
\end{equation*}
$$

whenever the $E_{i}$ are disjoint sets of $\mathscr{F}$. The triple, $(\Omega, \mathscr{F}, \mu)$ is called a measure space and the elements of $\mathscr{F}$ are called the measurable sets. $(\Omega, \mathscr{F}, \mu)$ is a finite measure space when $\mu(\Omega)<\infty$.

Note that the above definition immediately implies that if $E_{i} \in \mathscr{F}$ and the sets $E_{i}$ are not necessarily disjoint,

$$
\mu\left(\bigcup_{i=1}^{\infty} E_{i}\right) \leq \sum_{i=1}^{\infty} \mu\left(E_{i}\right)
$$

To see this, let $F_{1} \equiv E_{1}, F_{2} \equiv E_{2} \backslash E_{1}, \cdots, F_{n} \equiv E_{n} \backslash \cup_{i=1}^{n-1} E_{i}$, then the sets $F_{i}$ are disjoint sets in $\mathscr{F}$ and

$$
\mu\left(\bigcup_{i=1}^{\infty} E_{i}\right)=\mu\left(\bigcup_{i=1}^{\infty} F_{i}\right)=\sum_{i=1}^{\infty} \mu\left(F_{i}\right) \leq \sum_{i=1}^{\infty} \mu\left(E_{i}\right)
$$

because of the fact that each $E_{i} \supseteq F_{i}$ and so

$$
\mu\left(E_{i}\right)=\mu\left(F_{i}\right)+\mu\left(E_{i} \backslash F_{i}\right)
$$

which implies $\mu\left(E_{i}\right) \geq \mu\left(F_{i}\right)$.
The following theorem is the basis for most of what is done in the theory of measure and integration. It is a very simple result which follows directly from the above definition.

Theorem 11.1.5 Let $\left\{E_{m}\right\}_{m=1}^{\infty}$ be measurable sets in a measure space $(\Omega, \mathscr{F}, \mu)$. Then if $\cdots E_{n} \subseteq E_{n+1} \subseteq E_{n+2} \subseteq \cdots$,

$$
\begin{equation*}
\mu\left(\cup_{i=1}^{\infty} E_{i}\right)=\lim _{n \rightarrow \infty} \mu\left(E_{n}\right) \tag{11.1.4}
\end{equation*}
$$

and if $\cdots E_{n} \supseteq E_{n+1} \supseteq E_{n+2} \supseteq \cdots$ and $\mu\left(E_{1}\right)<\infty$, then

$$
\begin{equation*}
\mu\left(\cap_{i=1}^{\infty} E_{i}\right)=\lim _{n \rightarrow \infty} \mu\left(E_{n}\right) \tag{11.1.5}
\end{equation*}
$$

Stated more succinctly, $E_{k} \uparrow E$ implies $\mu\left(E_{k}\right) \uparrow \mu(E)$ and $E_{k} \downarrow E$ with $\mu\left(E_{1}\right)<\infty$ implies $\mu\left(E_{k}\right) \downarrow \mu(E)$.

Proof: First note that $\cap_{i=1}^{\infty} E_{i}=\left(\cup_{i=1}^{\infty} E_{i}^{C}\right)^{C} \in \mathscr{F}$ so $\cap_{i=1}^{\infty} E_{i}$ is measurable. Also note that for $A$ and $B$ sets of $\mathscr{F}, A \backslash B \equiv\left(A^{C} \cup B\right)^{C} \in \mathscr{F}$. To show 11.1.4, note that 11.1.4 is obviously true if $\mu\left(E_{k}\right)=\infty$ for any $k$. Therefore, assume $\mu\left(E_{k}\right)<\infty$ for all $k$. Thus

$$
\mu\left(E_{k+1} \backslash E_{k}\right)+\mu\left(E_{k}\right)=\mu\left(E_{k+1}\right)
$$

and so

$$
\mu\left(E_{k+1} \backslash E_{k}\right)=\mu\left(E_{k+1}\right)-\mu\left(E_{k}\right)
$$

Also,

$$
\bigcup_{k=1}^{\infty} E_{k}=E_{1} \cup \bigcup_{k=1}^{\infty}\left(E_{k+1} \backslash E_{k}\right)
$$

and the sets in the above union are disjoint. Hence by 11.1.3,

$$
\begin{aligned}
\mu\left(\cup_{i=1}^{\infty} E_{i}\right)= & \mu\left(E_{1}\right)+\sum_{k=1}^{\infty} \mu\left(E_{k+1} \backslash E_{k}\right)=\mu\left(E_{1}\right) \\
& +\sum_{k=1}^{\infty} \mu\left(E_{k+1}\right)-\mu\left(E_{k}\right)
\end{aligned}
$$

$$
=\mu\left(E_{1}\right)+\lim _{n \rightarrow \infty} \sum_{k=1}^{n} \mu\left(E_{k+1}\right)-\mu\left(E_{k}\right)=\lim _{n \rightarrow \infty} \mu\left(E_{n+1}\right) .
$$

This shows part 11.1.4.
To verify 11.1.5,

$$
\mu\left(E_{1}\right)=\mu\left(\cap_{i=1}^{\infty} E_{i}\right)+\mu\left(E_{1} \backslash \cap_{i=1}^{\infty} E_{i}\right)
$$

since $\mu\left(E_{1}\right)<\infty$, it follows $\mu\left(\cap_{i=1}^{\infty} E_{i}\right)<\infty$. Also, $E_{1} \backslash \cap_{i=1}^{n} E_{i} \uparrow E_{1} \backslash \cap_{i=1}^{\infty} E_{i}$ and so by 11.1.4,

$$
\begin{gathered}
\mu\left(E_{1}\right)-\mu\left(\cap_{i=1}^{\infty} E_{i}\right)=\mu\left(E_{1} \backslash \cap_{i=1}^{\infty} E_{i}\right)=\lim _{n \rightarrow \infty} \mu\left(E_{1} \backslash \cap_{i=1}^{n} E_{i}\right) \\
=\mu\left(E_{1}\right)-\lim _{n \rightarrow \infty} \mu\left(\cap_{i=1}^{n} E_{i}\right)=\mu\left(E_{1}\right)-\lim _{n \rightarrow \infty} \mu\left(E_{n}\right)
\end{gathered}
$$

Hence, subtracting $\mu\left(E_{1}\right)$ from both sides,

$$
\lim _{n \rightarrow \infty} \mu\left(E_{n}\right)=\mu\left(\cap_{i=1}^{\infty} E_{i}\right)
$$

This proves the theorem.
It is convenient to allow functions to take the value $+\infty$. You should think of $+\infty$, usually referred to as $\infty$ as something out at the right end of the real line and its only importance is the notion of sequences converging to it. $x_{n} \rightarrow \infty$ exactly when for all $l \in \mathbb{R}$, there exists $N$ such that if $n \geq N$, then

$$
x_{n}>l
$$

This is what it means for a sequence to converge to $\infty$. Don't think of $\infty$ as a number. It is just a convenient symbol which allows the consideration of some limit operations more simply. Similar considerations apply to $-\infty$ but this value is not of very great interest. In fact the set of most interest is the complex numbers or some vector space. Therefore, this topic is not considered.

Lemma 11.1.6 Let $f: \Omega \rightarrow(-\infty, \infty]$ where $\mathscr{F}$ is a $\sigma$ algebra of subsets of $\Omega$. Then the following are equivalent.

$$
\begin{gathered}
f^{-1}((d, \infty]) \in \mathscr{F} \text { for all finite } d, \\
f^{-1}((-\infty, d)) \in \mathscr{F} \text { for all finite } d, \\
f^{-1}([d, \infty]) \in \mathscr{F} \text { for all finite } d, \\
f^{-1}((-\infty, d]) \in \mathscr{F} \text { for all finite } d, \\
f^{-1}((a, b)) \in \mathscr{F} \text { for all } a<b,-\infty<a<b<\infty .
\end{gathered}
$$

Proof: First note that the first and the third are equivalent. To see this, observe

$$
f^{-1}([d, \infty])=\cap_{n=1}^{\infty} f^{-1}((d-1 / n, \infty])
$$

and so if the first condition holds, then so does the third.

$$
f^{-1}((d, \infty])=\cup_{n=1}^{\infty} f^{-1}([d+1 / n, \infty])
$$

and so if the third condition holds, so does the first.
Similarly, the second and fourth conditions are equivalent. Now

$$
f^{-1}((-\infty, d])=\left(f^{-1}((d, \infty])\right)^{C}
$$

so the first and fourth conditions are equivalent. Thus the first four conditions are equivalent and if any of them hold, then for $-\infty<a<b<\infty$,

$$
f^{-1}((a, b))=f^{-1}((-\infty, b)) \cap f^{-1}((a, \infty]) \in \mathscr{F} .
$$

Finally, if the last condition holds,

$$
f^{-1}([d, \infty])=\left(\cup_{k=1}^{\infty} f^{-1}((-k+d, d))\right)^{C} \in \mathscr{F}
$$

and so the third condition holds. Therefore, all five conditions are equivalent. This proves the lemma.

This lemma allows for the following definition of a measurable function having values in $(-\infty, \infty]$.

Definition 11.1.7 Let $(\Omega, \mathscr{F}, \mu)$ be a measure space and let $f: \Omega \rightarrow(-\infty, \infty]$. Then $f$ is said to be measurable if any of the equivalent conditions of Lemma 11.1.6 hold. When the $\sigma$ algebra, $\mathscr{F}$ equals the Borel $\sigma$ algebra, $\mathscr{B}$, the function is called Borel measurable. More generally, if $f: \Omega \rightarrow X$ where $X$ is a topological space, $f$ is said to be measurable if $f^{-1}(U) \in \mathscr{F}$ whenever $U$ is open.

Theorem 11.1.8 Let $f_{n}$ and $f$ be functions mapping $\Omega$ to $(-\infty, \infty]$ where $\mathscr{F}$ is a $\sigma$ algebra of measurable sets of $\Omega$. Then if $f_{n}$ is measurable, and $f(\omega)=\lim _{n \rightarrow \infty} f_{n}(\omega)$, it follows that $f$ is also measurable. (Pointwise limits of measurable functions are measurable.)

Proof: First it is shown $f^{-1}((a, b)) \in \mathscr{F}$. Let

$$
V_{m} \equiv\left(a+\frac{1}{m}, b-\frac{1}{m}\right), \bar{V}_{m}=\left[a+\frac{1}{m}, b-\frac{1}{m}\right]
$$

Then for all $m, V_{m} \subseteq(a, b)$ and

$$
(a, b)=\cup_{m=1}^{\infty} V_{m}=\cup_{m=1}^{\infty} \bar{V}_{m}
$$

Note that $V_{m} \neq \emptyset$ for all $m$ large enough. Since $f$ is the pointwise limit of $f_{n}$,

$$
f^{-1}\left(V_{m}\right) \subseteq\left\{\omega: f_{k}(\omega) \in V_{m} \text { for all } k \text { large enough }\right\} \subseteq f^{-1}\left(\bar{V}_{m}\right)
$$

You should note that the expression in the middle is of the form

$$
\cup_{n=1}^{\infty} \cap_{k=n}^{\infty} f_{k}^{-1}\left(V_{m}\right)
$$

Therefore,

$$
f^{-1}((a, b))=\cup_{m=1}^{\infty} f^{-1}\left(V_{m}\right) \subseteq \cup_{m=1}^{\infty} \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} f_{k}^{-1}\left(V_{m}\right)
$$

$$
\subseteq \cup_{m=1}^{\infty} f^{-1}\left(\bar{V}_{m}\right)=f^{-1}((a, b))
$$

It follows $f^{-1}((a, b)) \in \mathscr{F}$ because it equals the expression in the middle which is measurable. This shows $f$ is measurable.

The following theorem considers the case of functions which have values in a metric space. Its proof is similar to the proof of the above.
Theorem 11.1.9 Let $\left\{f_{n}\right\}$ be a sequence of measurable functions mapping $\Omega$ to $(X, d)$ where $(X, d)$ is a metric space and $(\Omega, \mathscr{F})$ is a measure space. Suppose also that $f(\omega)=$ $\lim _{n \rightarrow \infty} f_{n}(\omega)$ for all $\omega$. Then $f$ is also a measurable function.

Proof: It is required to show $f^{-1}(U)$ is measurable for all $U$ open. Let

$$
V_{m} \equiv\left\{x \in U: \operatorname{dist}\left(x, U^{C}\right)>\frac{1}{m}\right\}
$$

Thus

$$
V_{m} \subseteq\left\{x \in U: \operatorname{dist}\left(x, U^{C}\right) \geq \frac{1}{m}\right\}
$$

and $V_{m} \subseteq \overline{V_{m}} \subseteq V_{m+1}$ and $\cup_{m} V_{m}=U$. Then since $V_{m}$ is open,

$$
f^{-1}\left(V_{m}\right)=\cup_{n=1}^{\infty} \cap_{k=n}^{\infty} f_{k}^{-1}\left(V_{m}\right)
$$

and so

$$
\begin{aligned}
f^{-1}(U) & =\cup_{m=1}^{\infty} f^{-1}\left(V_{m}\right) \\
& =\cup_{m=1}^{\infty} \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} f_{k}^{-1}\left(V_{m}\right) \\
& \subseteq \cup_{m=1}^{\infty} f^{-1}\left(\overline{V_{m}}\right)=f^{-1}(U)
\end{aligned}
$$

which shows $f^{-1}(U)$ is measurable. This proves the theorem.
Now here is a simple observation.
Observation 11.1.10 Let $f: \Omega \rightarrow X$ where $X$ is some topological space. Suppose

$$
f(\omega)=\sum_{k=1}^{m} x_{k} \mathscr{X}_{A_{k}}(\omega)
$$

where each $x_{k} \in X$ and the $A_{k}$ are disjoint measurable sets. (Such functions are often referred to as simple functions.) The sum means the function has value $x_{k}$ on set $A_{k}$. Then $f$ is measurable.

Proof: Letting $U$ be open, $f^{-1}(U)=\cup\left\{A_{k}: x_{k} \in U\right\}$, a finite union of measurable sets.

There is also a very interesting theorem due to Kuratowski [82] which is presented next.
To summarize the proof, you get an increasing sequence of $2^{-n}$ nets $C_{n}$ and you obtain a corresponding sequence of simple functions $\left\{s_{n}\right\}$ such that $\left\{s_{n}(\omega)\right\}_{n=1}^{\infty}$ is a Cauchy sequence, and the maximum value of $x \rightarrow \psi(x, \omega)$ for $x \in C_{n}$ equals $\psi\left(s_{n}(\omega), \omega\right)$. Then you let $f(\omega) \equiv \lim _{n \rightarrow \infty} s_{n}(\omega)$. Thus $f(\omega)$ is measurable and

$$
\sup _{x \in E} \psi(x, \omega) \geq \psi(f(\omega), \omega)=\lim _{n \rightarrow \infty} \psi\left(s_{n}(\omega), \omega\right) \geq \sup _{x \in C_{n}} \psi(x, \omega)
$$

Thus, by continuity in the first entry,

$$
\begin{aligned}
\sup _{x \in E} \psi(x, \omega) & \geq \psi(f(\omega), \omega) \geq \lim _{n \rightarrow \infty} \psi\left(s_{n}(\omega), \omega\right) \\
& \geq \sup _{n} \sup _{x \in C_{n}} \psi(x, \omega)=\sup _{x \in \cup_{n} C_{n}} \psi(x, \omega)=\sup _{x \in E} \psi(x, \omega)
\end{aligned}
$$

Theorem 11.1.11 Let $E$ be a compact metric space and let $(\Omega, \mathscr{F})$ be a measure space. Suppose $\psi: E \times \Omega \rightarrow \mathbb{R}$ has the property that $x \rightarrow \psi(x, \omega)$ is continuous and $\omega \rightarrow \psi(x, \omega)$ is measurable. Then there exists a measurable function, $f$ having values in $E$ such that

$$
\psi(f(\omega), \omega)=\sup _{x \in E} \psi(x, \omega) .
$$

Furthermore, $\omega \rightarrow \psi(f(\omega), \omega)$ is measurable.
Proof: Let $C_{1}$ be a $2^{-1}$ net of $E$. Suppose $C_{1}, \cdots, C_{m}$ have been chosen such that $C_{k}$ is a $2^{-k}$ net and $C_{i+1} \supseteq C_{i}$ for all $i$. Then consider $E \backslash \cup\left\{B\left(x, 2^{-(m+1)}\right): x \in C_{m}\right\}$. If this set is empty, let $C_{m+1}=C_{m}$. If it is nonempty, let $\left\{y_{i}\right\}_{i=1}^{r}$ be a $2^{-(m+1)}$ net for this compact set. Then let $C_{m+1}=C_{m} \cup\left\{y_{i}\right\}_{i=1}^{r}$. It follows $\left\{C_{m}\right\}_{m=1}^{\infty}$ satisfies $C_{m}$ is a $2^{-m}$ net and $C_{m} \subseteq C_{m+1}$.

Let $\left\{x_{k}^{1}\right\}_{k=1}^{m(1)}$ equal $C_{1}$. Let

$$
A_{1}^{1} \equiv\left\{\omega: \psi\left(x_{1}^{1}, \omega\right)=\max _{k} \psi\left(x_{k}^{1}, \omega\right)\right\}
$$

For $\omega \in A_{1}^{1}$, define $s_{1}(\omega) \equiv x_{1}^{1}$. Next let

$$
A_{2}^{1} \equiv\left\{\omega \notin A_{1}^{1}: \psi\left(x_{2}^{1}, \omega\right)=\max _{k} \psi\left(x_{k}^{1}, \omega\right)\right\}
$$

and let $s_{1}(\omega) \equiv x_{2}^{1}$ on $A_{2}^{1}$. Continue in this way to obtain a simple function, $s_{1}$ such that

$$
\psi\left(s_{1}(\omega), \omega\right)=\max \left\{\psi(x, \omega): x \in C_{1}\right\}
$$

and $s_{1}$ has values in $C_{1}$.
Suppose $s_{1}(\omega), s_{2}(\omega), \cdots, s_{m}(\omega)$ are simple functions with the property that if $m>1$,

$$
\begin{aligned}
d\left(s_{k}(\omega), s_{k+1}(\omega)\right)< & 2^{-k} \\
\psi\left(s_{k}(\omega), \omega\right)= & \max \left\{\psi(x, \omega): x \in C_{k}\right\} \\
& s_{k} \text { has values in } C_{k}
\end{aligned}
$$

for each $k+1 \leq m$, only the second and third assertions holding if $m=1$. Letting $C_{m}=$ $\left\{x_{k}\right\}_{k=1}^{N}$, it follows $s_{m}(\omega)$ is of the form

$$
\begin{equation*}
s_{m}(\omega)=\sum_{k=1}^{N} x_{k} \mathscr{X}_{A_{k}}(\omega), A_{i} \cap A_{j}=\emptyset \tag{11.1.6}
\end{equation*}
$$

meaning that $s_{m}(\omega)$ has value $x_{k}$ on $A_{k}$. Denote by $\left\{y_{1 i}\right\}_{i=1}^{n_{1}}$ those points of $C_{m+1}$ which are contained in $B\left(x_{1}, 2^{-m}\right)$. Letting $A_{k}$ play the role of $\Omega$ in the first step in which $s_{1}$ was constructed, for each $\omega \in A_{1}$ let $s_{m+1}(\omega)$ be a simple function which has one of the values $y_{1 i}$ and satisfies

$$
\psi\left(s_{m+1}(\omega), \omega\right)=\max _{i \leq n_{1}} \psi\left(y_{1 i}, \omega\right)
$$

for each $\omega \in A_{1}$. Next let $\left\{y_{2 i}\right\}_{i=1}^{n_{2}}$ be those points of $C_{m+1}$ different than $\left\{y_{1 i}\right\}_{i=1}^{n_{1}}$ which are contained in $B\left(x_{2}, 2^{-m}\right)$. Then define $s_{m+1}(\omega)$ on $A_{2}$ to have values taken from $\left\{y_{2 i}\right\}_{i=1}^{n_{2}}$ and

$$
\psi\left(s_{m+1}(\omega), \omega\right)=\max _{i \leq n_{2}} \psi\left(y_{2 i}, \omega\right)
$$

for each $\omega \in A_{2}$. Continuing this way defines $s_{m+1}$ on all of $\Omega$ and it satisfies

$$
\begin{equation*}
d\left(s_{m}(\omega), s_{m+1}(\omega)\right)<2^{-m} \text { for all } \omega \in \Omega \tag{11.1.7}
\end{equation*}
$$

It remains to verify

$$
\begin{equation*}
\psi\left(s_{m+1}(\omega), \omega\right)=\max \left\{\psi(x, \omega): x \in C_{m+1}\right\} \tag{11.1.8}
\end{equation*}
$$

To see this is so, pick $\omega \in \Omega$. Let

$$
\begin{equation*}
\max \left\{\psi(x, \omega): x \in C_{m+1}\right\}=\psi\left(y_{r j}, \omega\right) \tag{11.1.9}
\end{equation*}
$$

where $y_{r j} \in\left\{y_{r i}\right\}_{i=1}^{n_{r}} \subseteq C_{m+1}$ and out of all the balls $B\left(x_{l}, 2^{-m}\right)$, let the first one which contains $y_{r j}$ be $B\left(x_{k}, 2^{-m}\right)$. Then by the construction, $s_{m+1}(\omega)=y_{r j}$ because $\psi\left(y_{r j}, \omega\right)$ is at least as large as $\psi\left(y_{s j}, \omega\right)$ for all the other $y_{s j}$. This and 11.1.9 verifies 11.1.8.

From 11.1.7 it follows $s_{m}(\omega)$ converges uniformly on $\Omega$ to a measurable function, $f(\omega)$. Then from the construction, $\psi(f(\omega), \omega) \geq \psi\left(s_{m}(\omega), \omega\right)$ for all $m$ and $\omega$. Now pick $\omega \in \Omega$ and let $z$ be such that $\psi(z, \omega)=\max _{x \in E} \psi(x, \omega)$. Letting $y_{k} \rightarrow z$ where $y_{k} \in C_{k}$, it follows from continuity of $\psi$ in the first argument that

$$
\begin{aligned}
\max _{x \in E} \psi(x, \omega) & =\psi(z, \omega)=\lim _{k \rightarrow \infty} \psi\left(y_{k}, \omega\right) \\
& \leq \lim _{m \rightarrow \infty} \psi\left(s_{m}(\omega), \omega\right)=\psi(f(\omega), \omega) \leq \max _{x \in E} \psi(x, \omega)
\end{aligned}
$$

To show $\omega \rightarrow \psi(f(\omega), \omega)$ is measurable, note that since $E$ is compact, there exists a countable dense subset, $D$. Then using continuity of $\psi$ in the first argument,

$$
\begin{aligned}
\psi(f(\omega), \omega) & =\sup _{x \in E} \psi(x, \omega) \\
& =\sup _{x \in D} \psi(x, \omega)
\end{aligned}
$$

which equals a measurable function of $\omega$ because $D$ is countable.
Theorem 11.1.12 Let $\mathscr{B}$ consist of open cubes of the form

$$
Q_{\mathbf{x}} \equiv \prod_{i=1}^{n}\left(x_{i}-\delta, x_{i}+\delta\right)
$$

where $\delta$ is a positive rational number and $\mathbf{x} \in \mathbb{Q}^{n}$. Then every open set in $\mathbb{R}^{n}$ can be written as a countable union of open cubes from $\mathscr{B}$. Furthermore, $\mathscr{B}$ is a countable set.

Proof: Let $U$ be an open set and let $\mathbf{y} \in U$. Since $U$ is open, $B(\mathbf{y}, r) \subseteq U$ for some $r>0$ and it can be assumed $r / \sqrt{n} \in \mathbb{Q}$. Let

$$
\mathbf{x} \in B\left(\mathbf{y}, \frac{r}{10 \sqrt{n}}\right) \cap \mathbb{Q}^{n}
$$

and consider the cube, $Q_{\mathbf{x}} \in \mathscr{B}$ defined by

$$
Q_{\mathbf{x}} \equiv \prod_{i=1}^{n}\left(x_{i}-\boldsymbol{\delta}, x_{i}+\boldsymbol{\delta}\right)
$$

where $\delta=r / 4 \sqrt{n}$. The following picture is roughly illustrative of what is taking place.

Then the diameter of $Q_{\mathbf{x}}$ equals

$$
\left(n\left(\frac{r}{2 \sqrt{n}}\right)^{2}\right)^{1 / 2}=\frac{r}{2}
$$

and so, if $\mathbf{z} \in Q_{\mathbf{x}}$, then

$$
\begin{aligned}
|\mathbf{z}-\mathbf{y}| & \leq|\mathbf{z}-\mathbf{x}|+|\mathbf{x}-\mathbf{y}| \\
& <\frac{r}{2}+\frac{r}{2}=r .
\end{aligned}
$$

Consequently, $Q_{\mathbf{x}} \subseteq U$. Now also,

$$
\left(\sum_{i=1}^{n}\left(x_{i}-y_{i}\right)^{2}\right)^{1 / 2}<\frac{r}{10 \sqrt{n}}
$$

and so it follows that for each $i$,

$$
\left|x_{i}-y_{i}\right|<\frac{r}{4 \sqrt{n}}
$$

since otherwise the above inequality would not hold. Therefore, $\mathbf{y} \in Q_{\mathbf{x}} \subseteq U$. Now let $\mathscr{B}_{U}$ denote those sets of $\mathscr{B}$ which are contained in $U$. Then $\cup \mathscr{B}_{U}=U$.

To see $\mathscr{B}$ is countable, note there are countably many choices for $\mathbf{x}$ and countably many choices for $\delta$. This proves the theorem.

Recall that $g: \mathbb{R}^{n} \rightarrow \mathbb{R}$ is continuous means $g^{-1}$ (open set) $=$ an open set. In particular $g^{-1}((a, b))$ must be an open set.

Theorem 11.1.13 Let $f_{i}: \Omega \rightarrow \mathbb{R}$ for $i=1, \cdots, n$ be measurable functions and let $g: \mathbb{R}^{n} \rightarrow$ $\mathbb{R}$ be continuous where $\mathbf{f} \equiv\left(f_{1} \cdots f_{n}\right)^{T}$. Then $g \circ \mathbf{f}$ is a measurable function from $\Omega$ to $\mathbb{R}$.

Proof: First it is shown

$$
(g \circ \mathbf{f})^{-1}((a, b)) \in \mathscr{F} .
$$

Now $(g \circ \mathbf{f})^{-1}((a, b))=\mathbf{f}^{-1}\left(g^{-1}((a, b))\right)$. Since $g$ is continuous, it follows that $g^{-1}((a, b))$ is an open set which is denoted as $U$ for convenience. Now by Theorem 11.1.12 above, it follows there are countably many open cubes, $\left\{Q_{k}\right\}$ such that

$$
U=\cup_{k=1}^{\infty} Q_{k}
$$

where each $Q_{k}$ is a cube of the form

$$
Q_{k}=\prod_{i=1}^{n}\left(x_{i}-\delta, x_{i}+\delta\right)
$$

Now

$$
\mathbf{f}^{-1}\left(\prod_{i=1}^{n}\left(x_{i}-\boldsymbol{\delta}, x_{i}+\boldsymbol{\delta}\right)\right)=\cap_{i=1}^{n} f_{i}^{-1}\left(\left(x_{i}-\boldsymbol{\delta}, x_{i}+\boldsymbol{\delta}\right)\right) \in \mathscr{F}
$$

and so

$$
\begin{aligned}
(g \circ \mathbf{f})^{-1}((a, b)) & =\mathbf{f}^{-1}\left(g^{-1}((a, b))\right)=\mathbf{f}^{-1}(U) \\
& =\mathbf{f}^{-1}\left(\cup_{k=1}^{\infty} Q_{k}\right)=\cup_{k=1}^{\infty} \mathbf{f}^{-1}\left(Q_{k}\right) \in \mathscr{F} .
\end{aligned}
$$

This proves the theorem.
Corollary 11.1.14 Sums, products, and linear combinations of measurable functions are measurable.

Proof: To see the product of two measurable functions is measurable, let $g(x, y)=x y$, a continuous function defined on $\mathbb{R}^{2}$. Thus if you have two measurable functions, $f_{1}$ and $f_{2}$ defined on $\Omega$,

$$
g \circ\left(f_{1}, f_{2}\right)(\omega)=f_{1}(\omega) f_{2}(\omega)
$$

and so $\omega \rightarrow f_{1}(\omega) f_{2}(\omega)$ is measurable. Similarly you can show the sum of two measurable functions is measurable by considering $g(x, y)=x+y$ and you can show a linear combination of two measurable functions is measurable by considering $g(x, y)=a x+b y$. More than two functions can also be considered as well.

The message of this corollary is that starting with measurable real valued functions you can combine them in pretty much any way you want and you end up with a measurable function.

Here is some notation which will be used whenever convenient.

Definition 11.1.15 Let $f: \Omega \rightarrow[-\infty, \infty]$. Define

$$
[\alpha<f] \equiv\{\omega \in \Omega: f(\omega)>\alpha\} \equiv f^{-1}((\alpha, \infty])
$$

with obvious modifications for the symbols $[\alpha \leq f],[\alpha \geq f],[\alpha \geq f \geq \beta]$, etc.
Definition 11.1.16 For a set $E$,

$$
\mathscr{X}_{E}(\omega)=\left\{\begin{array}{l}
1 \text { if } \omega \in E, \\
0 \text { if } \omega \notin E .
\end{array}\right.
$$

This is called the characteristic function of $E$. Sometimes this is called the indicator function which I think is better terminology since the term characteristic function has another meaning. Note that this "indicates" whether a point, $\omega$ is contained in $E$. It is exactly when the function has the value 1 .

Theorem 11.1.17 (Egoroff) Let $(\Omega, \mathscr{F}, \mu)$ be a finite measure space,

$$
(\mu(\Omega)<\infty)
$$

and let $f_{n}, f$ be complex valued functions such that $\operatorname{Re} f_{n}, \operatorname{Im} f_{n}$ are all measurable and

$$
\lim _{n \rightarrow \infty} f_{n}(\omega)=f(\omega)
$$

for all $\omega \notin E$ where $\mu(E)=0$. Then for every $\varepsilon>0$, there exists a set,

$$
F \supseteq E, \mu(F)<\varepsilon
$$

such that $f_{n}$ converges uniformly to $f$ on $F^{C}$.
Proof: First suppose $E=\emptyset$ so that convergence is pointwise everywhere. It follows then that $\operatorname{Re} f$ and $\operatorname{Im} f$ are pointwise limits of measurable functions and are therefore measurable. Let $E_{k m}=\left\{\omega \in \Omega:\left|f_{n}(\omega)-f(\omega)\right| \geq 1 / m\right.$ for some $\left.n>k\right\}$. Note that

$$
\left|f_{n}(\omega)-f(\omega)\right|=\sqrt{\left(\operatorname{Re} f_{n}(\omega)-\operatorname{Re} f(\omega)\right)^{2}+\left(\operatorname{Im} f_{n}(\omega)-\operatorname{Im} f(\omega)\right)^{2}}
$$

and so, By Theorem 11.1.13,

$$
\left[\left|f_{n}-f\right| \geq \frac{1}{m}\right]
$$

is measurable. Hence $E_{k m}$ is measurable because

$$
E_{k m}=\cup_{n=k+1}^{\infty}\left[\left|f_{n}-f\right| \geq \frac{1}{m}\right]
$$

For fixed $m, \cap_{k=1}^{\infty} E_{k m}=\emptyset$ because $f_{n}$ converges to $f$. Therefore, if $\omega \in \Omega$ there exists $k$ such that if $n>k,\left|f_{n}(\omega)-f(\omega)\right|<\frac{1}{m}$ which means $\omega \notin E_{k m}$. Note also that

$$
E_{k m} \supseteq E_{(k+1) m}
$$

Since $\mu\left(E_{1 m}\right)<\infty$, Theorem 11.1.5 on Page 224 implies

$$
0=\mu\left(\cap_{k=1}^{\infty} E_{k m}\right)=\lim _{k \rightarrow \infty} \mu\left(E_{k m}\right)
$$

Let $k(m)$ be chosen such that $\mu\left(E_{k(m) m}\right)<\varepsilon 2^{-m}$ and let

$$
F=\bigcup_{m=1}^{\infty} E_{k(m) m}
$$

Then $\mu(F)<\varepsilon$ because

$$
\mu(F) \leq \sum_{m=1}^{\infty} \mu\left(E_{k(m) m}\right)<\sum_{m=1}^{\infty} \varepsilon 2^{-m}=\varepsilon
$$

Now let $\eta>0$ be given and pick $m_{0}$ such that $m_{0}^{-1}<\eta$. If $\omega \in F^{C}$, then

$$
\omega \in \bigcap_{m=1}^{\infty} E_{k(m) m}^{C}
$$

Hence $\omega \in E_{k\left(m_{0}\right) m_{0}}^{C}$ so

$$
\left|f_{n}(\omega)-f(\omega)\right|<1 / m_{0}<\eta
$$

for all $n>k\left(m_{0}\right)$. This holds for all $\omega \in F^{C}$ and so $f_{n}$ converges uniformly to $f$ on $F^{C}$.
Now if $E \neq \emptyset$, consider $\left\{\mathscr{X}_{E^{C}} f_{n}\right\}_{n=1}^{\infty}$. Each $\mathscr{X}_{E^{C}} f_{n}$ has real and imaginary parts measurable and the sequence converges pointwise to $\mathscr{X}_{E} f$ everywhere. Therefore, from the first part, there exists a set of measure less than $\varepsilon, F$ such that on $F^{C},\left\{\mathscr{X}_{E^{C}} f_{n}\right\}$ converges uniformly to $\mathscr{X}_{E^{C}} f$. Therefore, on $(E \cup F)^{C},\left\{f_{n}\right\}$ converges uniformly to $f$. This proves the theorem.

Finally here is a comment about notation.

Definition 11.1.18 Something happens for $\mu$ a.e. $\omega$ said as $\mu$ almost everywhere, if there exists $a$ set $E$ with $\mu(E)=0$ and the thing takes place for all $\omega \notin E$. Thus $f(\omega)=g(\omega)$ a.e. if $f(\omega)=g(\omega)$ for all $\omega \notin E$ where $\mu(E)=0$. A measure space, $(\Omega, \mathscr{F}, \mu)$ is $\sigma$ finite if there exist measurable sets, $\Omega_{n}$ such that $\mu\left(\Omega_{n}\right)<\infty$ and $\Omega=\cup_{n=1}^{\infty} \Omega_{n}$.

### 11.2 Exercises

1. Let $\Omega=\mathbb{N}=\{1,2, \cdots\}$. Let $\mathscr{F}=\mathscr{P}(\mathbb{N})$ and let $\mu(S)=$ number of elements in $S$. Thus $\mu(\{1\})=1=\mu(\{2\}), \mu(\{1,2\})=2$, etc. $\operatorname{Show}(\Omega, \mathscr{F}, \mu)$ is a measure space. It is called counting measure. What functions are measurable in this case?
2. Let $\Omega$ be any uncountable set and let $\mathscr{F}=\left\{A \subseteq \Omega\right.$ : either $A$ or $A^{C}$ is countable $\}$. Let $\mu(A)=1$ if $A$ is uncountable and $\mu(A)=0$ if $A$ is countable. Show $(\Omega, \mathscr{F}, \mu)$ is a measure space. This is a well known bad example.
3. Let $\mathscr{F}$ be a $\sigma$ algebra of subsets of $\Omega$ and suppose $\mathscr{F}$ has infinitely many elements. Show that $\mathscr{F}$ is uncountable. Hint: You might try to show there exists a countable sequence of disjoint sets of $\mathscr{F},\left\{A_{i}\right\}$. It might be easiest to verify this by contradiction if it doesn't exist rather than a direct construction. Once this has been done, you can define a map, $\theta$, from $\mathscr{P}(\mathbb{N})$ into $\mathscr{F}$ which is one to one by $\theta(S)=\cup_{i \in S} A_{i}$. Then argue $\mathscr{P}(\mathbb{N})$ is uncountable and so $\mathscr{F}$ is also uncountable.

## 4. Prove Lemma 11.1.2.

5. $g$ is Borel measurable if whenever $U$ is open, $g^{-1}(U)$ is Borel. Let $\mathbf{f}: \Omega \rightarrow \mathbb{R}^{n}$ and let $g: \mathbb{R}^{n} \rightarrow \mathbb{R}$ and $\mathscr{F}$ is a $\sigma$ algebra of sets of $\Omega$. Suppose $\mathbf{f}$ is measurable and $g$ is Borel measurable. Show $g \circ \mathbf{f}$ is measurable. To say $g$ is Borel measurable means $g^{-1}($ open set $)=($ Borel set $)$ where a Borel set is one of those sets in the smallest $\sigma$ algebra containing the open sets of $\mathbb{R}^{n}$. See Lemma 11.1.2. Hint: You should show, using Theorem 11.1.12 that $\mathbf{f}^{-1}$ (open set) $\in \mathscr{F}$. Now let

$$
\mathscr{S} \equiv\left\{E \subseteq \mathbb{R}^{n}: \mathbf{f}^{-1}(E) \in \mathscr{F}\right\}
$$

By what you just showed, $\mathscr{S}$ contains the open sets. Now verify $\mathscr{S}$ is a $\sigma$ algebra. Argue that from the definition of the Borel sets, it follows $\mathscr{S}$ contains the Borel sets.
6. Let $(\Omega, \mathscr{F})$ be a measure space and suppose $f: \Omega \rightarrow \mathbb{C}$. Then $f$ is said to be mesurable if

$$
f^{-1}(\text { open set }) \in \mathscr{F} .
$$

Show $f$ is measurable if and only if $\operatorname{Re} f$ and $\operatorname{Im} f$ are measurable real-valued functions. Thus it suffices to define a complex valued function to be measurable if the real and imaginary parts are measurable. Hint: Argue that $f^{-1}(((a, b)+i(c, d)))=$ $(\operatorname{Re} f)^{-1}((a, b)) \cap(\operatorname{Im} f)^{-1}((c, d))$. Then use Theorem 11.1.12 to verify that if $\operatorname{Re} f$ and $\operatorname{Im} f$ are measurable, it follows $f$ is. Conversely, argue that $(\operatorname{Re} f)^{-1}((a, b))=$ $f^{-1}((a, b)+i \mathbb{R})$ with a similar formula holding for $\operatorname{Im} f$.
7. Let $(\Omega, \mathscr{F}, \mu)$ be a measure space. Define $\bar{\mu}: \mathscr{P}(\Omega) \rightarrow[0, \infty]$ by

$$
\bar{\mu}(A)=\inf \{\mu(B): B \supseteq A, B \in \mathscr{F}\} .
$$

Show $\bar{\mu}$ satisfies

$$
\begin{aligned}
\bar{\mu}(\emptyset) & =0, \text { if } A \subseteq B, \bar{\mu}(A) \leq \bar{\mu}(B) \\
\bar{\mu}\left(\cup_{i=1}^{\infty} A_{i}\right) & \leq \sum_{i=1}^{\infty} \bar{\mu}\left(A_{i}\right), \mu(A)=\bar{\mu}(A) \text { if } A \in \mathscr{F}
\end{aligned}
$$

If $\bar{\mu}$ satisfies these conditions, it is called an outer measure. This shows every measure determines an outer measure on the power set.
8. Let $\left\{E_{i}\right\}$ be a sequence of measurable sets with the property that

$$
\sum_{i=1}^{\infty} \mu\left(E_{i}\right)<\infty .
$$

Let $S=\left\{\omega \in \Omega\right.$ such that $\omega \in E_{i}$ for infinitely many values of $\left.i\right\}$. Show $\mu(S)=0$ and $S$ is measurable. This is part of the Borel Cantelli lemma. Hint: Write $S$ in terms of intersections and unions. Something is in $S$ means that for every $n$ there exists $k>n$ such that it is in $E_{k}$. Remember the tail of a convergent series is small.
9. $\uparrow$ Let $f_{n}, f$ be measurable functions. $f_{n}$ converges in measure if

$$
\lim _{n \rightarrow \infty} \mu\left(x \in \Omega:\left|f(x)-f_{n}(x)\right| \geq \varepsilon\right)=0
$$

for each fixed $\varepsilon>0$. Prove the theorem of F. Riesz. If $f_{n}$ converges to $f$ in measure, then there exists a subsequence $\left\{f_{n_{k}}\right\}$ which converges to $f$ a.e. Hint: Choose $n_{1}$ such that

$$
\mu\left(x:\left|f(x)-f_{n_{1}}(x)\right| \geq 1\right)<1 / 2
$$

Choose $n_{2}>n_{1}$ such that

$$
\mu\left(x:\left|f(x)-f_{n_{2}}(x)\right| \geq 1 / 2\right)<1 / 2^{2}
$$

$n_{3}>n_{2}$ such that

$$
\mu\left(x:\left|f(x)-f_{n_{3}}(x)\right| \geq 1 / 3\right)<1 / 2^{3}
$$

etc. Now consider what it means for $f_{n_{k}}(x)$ to fail to converge to $f(x)$. Then use Problem 8.

### 11.3 The Abstract Lebesgue Integral

### 11.3.1 Preliminary Observations

This section is on the Lebesgue integral and the major convergence theorems which are the reason for studying it. In all that follows $\mu$ will be a measure defined on a $\sigma$ algebra $\mathscr{F}$ of subsets of $\Omega .0 \cdot \infty=0$ is always defined to equal zero. This is a meaningless expression and so it can be defined arbitrarily but a little thought will soon demonstrate that this is the right definition in the context of measure theory. To see this, consider the zero function defined on $\mathbb{R}$. What should the integral of this function equal? Obviously, by an analogy with the Riemann integral, it should equal zero. Formally, it is zero times the length of the set or infinity. This is why this convention will be used.

Lemma 11.3.1 Let $f(a, b) \in[-\infty, \infty]$ for $a \in A$ and $b \in B$ where $A, B$ are sets. Then

$$
\sup _{a \in A} \sup _{b \in B} f(a, b)=\sup _{b \in B} \sup _{a \in A} f(a, b) .
$$

Proof: Note that for all $a, b, f(a, b) \leq \sup _{b \in B} \sup _{a \in A} f(a, b)$ and therefore, for all $a$,

$$
\sup _{b \in B} f(a, b) \leq \sup _{b \in B} \sup _{a \in A} f(a, b)
$$

Therefore,

$$
\sup _{a \in A} \sup _{b \in B} f(a, b) \leq \sup _{b \in B} \sup _{a \in A} f(a, b) .
$$

Repeating the same argument interchanging $a$ and $b$, gives the conclusion of the lemma.

Lemma 11.3.2 If $\left\{A_{n}\right\}$ is an increasing sequence in $[-\infty, \infty]$, then $\sup \left\{A_{n}\right\}=\lim _{n \rightarrow \infty} A_{n}$.
The following lemma is useful also and this is a good place to put it. First $\left\{b_{j}\right\}_{j=1}^{\infty}$ is an enumeration of the $a_{i j}$ if

$$
\cup_{j=1}^{\infty}\left\{b_{j}\right\}=\cup_{i, j}\left\{a_{i j}\right\}
$$

In other words, the countable set, $\left\{a_{i j}\right\}_{i, j=1}^{\infty}$ is listed as $b_{1}, b_{2}, \cdots$.
Lemma 11.3.3 Let $a_{i j} \geq 0$. Then $\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{i j}=\sum_{j=1}^{\infty} \sum_{i=1}^{\infty} a_{i j}$. Also if $\left\{b_{j}\right\}_{j=1}^{\infty}$ is any enumeration of the $a_{i j}$, then $\sum_{j=1}^{\infty} b_{j}=\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{i j}$.

Proof: First note there is no trouble in defining these sums because the $a_{i j}$ are all nonnegative. If a sum diverges, it only diverges to $\infty$ and so $\infty$ is written as the answer.

$$
\begin{align*}
& \sum_{j=1}^{\infty} \sum_{i=1}^{\infty} a_{i j} \geq \sup _{n} \sum_{j=1}^{\infty} \sum_{i=1}^{n} a_{i j}=\sup _{n} \lim _{m \rightarrow \infty} \sum_{j=1}^{m} \sum_{i=1}^{n} a_{i j} \\
= & \sup _{n} \lim _{m \rightarrow \infty} \sum_{i=1}^{n} \sum_{j=1}^{m} a_{i j}=\sup _{n} \sum_{i=1}^{n} \sum_{j=1}^{\infty} a_{i j}=\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{i j} \tag{11.3.10}
\end{align*}
$$

Interchanging the $i$ and $j$ in the above argument the first part of the lemma is proved.
Finally, note that for all $p$,

$$
\sum_{j=1}^{p} b_{j} \leq \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{i j}
$$

and so $\sum_{j=1}^{\infty} b_{j} \leq \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{i j}$. Now let $m, n>1$ be given. Then

$$
\sum_{i=1}^{m} \sum_{j=1}^{n} a_{i j} \leq \sum_{j=1}^{p} b_{j}
$$

where $p$ is chosen large enough that $\left\{b_{1}, \cdots, b_{p}\right\} \supseteq\left\{a_{i j}: i \leq m\right.$ and $\left.j \leq n\right\}$. Therefore, since such a $p$ exists for any choice of $m, n$, it follows that for any $m, n$,

$$
\sum_{i=1}^{m} \sum_{j=1}^{n} a_{i j} \leq \sum_{j=1}^{\infty} b_{j}
$$

Therefore, taking the limit as $n \rightarrow \infty$,

$$
\sum_{i=1}^{m} \sum_{j=1}^{\infty} a_{i j} \leq \sum_{j=1}^{\infty} b_{j}
$$

and finally, taking the limit as $m \rightarrow \infty$,

$$
\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{i j} \leq \sum_{j=1}^{\infty} b_{j}
$$

proving the lemma.

### 11.3.2 The Lebesgue Integral Nonnegative Functions

The following picture illustrates the idea used to define the Lebesgue integral to be like the area under a curve.

You can see that by following the procedure illustrated in the picture and letting $h$ get smaller, you would expect to obtain better approximations to the area under the curve ${ }^{1}$ although all these approximations would likely be too small. Therefore, define

$$
\int f d \mu \equiv \sup _{h>0} \sum_{i=1}^{\infty} h \mu([i h<f])
$$

Lemma 11.3.4 The following inequality holds.

$$
\sum_{i=1}^{\infty} h \mu([i h<f]) \leq \sum_{i=1}^{\infty} \frac{h}{2} \mu\left(\left[i \frac{h}{2}<f\right]\right) .
$$

Also, it suffices to consider only $h$ smaller than a given positive number in the above definition of the integral.

## Proof:

Let $N \in \mathbb{N}$.

$$
\begin{gathered}
\quad \sum_{i=1}^{2 N} \frac{h}{2} \mu\left(\left[i \frac{h}{2}<f\right]\right)=\sum_{i=1}^{2 N} \frac{h}{2} \mu([i h<2 f]) \\
=\sum_{i=1}^{N} \frac{h}{2} \mu([(2 i-1) h<2 f])+\sum_{i=1}^{N} \frac{h}{2} \mu([(2 i) h<2 f]) \\
=\sum_{i=1}^{N} \frac{h}{2} \mu\left(\left[\frac{(2 i-1)}{2} h<f\right]\right)+\sum_{i=1}^{N} \frac{h}{2} \mu([i h<f]) \\
\geq \sum_{i=1}^{N} \frac{h}{2} \mu([i h<f])+\sum_{i=1}^{N} \frac{h}{2} \mu([i h<f])=\sum_{i=1}^{N} h \mu([i h<f]) .
\end{gathered}
$$

Now letting $N \rightarrow \infty$ yields the claim of the lemma.

[^7]To verify the last claim, suppose $M<\int f d \mu$ and let $\delta>0$ be given. Then there exists $h>0$ such that

$$
M<\sum_{i=1}^{\infty} h \mu([i h<f]) \leq \int f d \mu
$$

By the first part of this lemma,

$$
M<\sum_{i=1}^{\infty} \frac{h}{2} \mu\left(\left[i \frac{h}{2}<f\right]\right) \leq \int f d \mu
$$

and continuing to apply the first part,

$$
M<\sum_{i=1}^{\infty} \frac{h}{2^{n}} \mu\left(\left[i \frac{h}{2^{n}}<f\right]\right) \leq \int f d \mu
$$

Choose $n$ large enough that $h / 2^{n}<\delta$. It follows

$$
M<\sup _{\delta>h>0} \sum_{i=1}^{\infty} h \mu([i h<f]) \leq \int f d \mu
$$

Since $M$ is arbitrary, this proves the last claim.

### 11.3.3 The Lebesgue Integral For Nonnegative Simple Functions

Definition 11.3.5 A function, $s$, is called simple if it is a measurable real valued function and has only finitely many values. These values will never be $\pm \infty$. Thus a simple function is one which may be written in the form

$$
s(\omega)=\sum_{i=1}^{n} c_{i} \mathscr{X}_{E_{i}}(\omega)
$$

where the sets, $E_{i}$ are disjoint and measurable. stakes the value $c_{i}$ at $E_{i}$.
Note that by taking the union of some of the $E_{i}$ in the above definition, you can assume that the numbers, $c_{i}$ are the distinct values of $s$. Simple functions are important because it will turn out to be very easy to take their integrals as shown in the following lemma.

Lemma 11.3.6 Let $s(\omega)=\sum_{i=1}^{p} a_{i} \mathscr{X}_{E_{i}}(\omega)$ be a nonnegative simple function with the $a_{i}$ the distinct non zero values of $s$. Then

$$
\begin{equation*}
\int s d \mu=\sum_{i=1}^{p} a_{i} \mu\left(E_{i}\right) \tag{11.3.11}
\end{equation*}
$$

Also, for any nonnegative measurable function, $f$, if $\lambda \geq 0$, then

$$
\begin{equation*}
\int \lambda f d \mu=\lambda \int f d \mu \tag{11.3.12}
\end{equation*}
$$

Proof: Consider 11.3 .11 first. Without loss of generality, you can assume $0<a_{1}<$ $a_{2}<\cdots<a_{p}$ and that $\mu\left(E_{i}\right)<\infty$. Let $\varepsilon>0$ be given and let

$$
\delta_{1} \sum_{i=1}^{p} \mu\left(E_{i}\right)<\varepsilon
$$

Pick $\delta<\delta_{1}$ such that for $h<\delta$ it is also true that

$$
h<\frac{1}{2} \min \left(a_{1}, a_{2}-a_{1}, a_{3}-a_{2}, \cdots, a_{n}-a_{n-1}\right) .
$$

Then for $0<h<\delta$

$$
\begin{align*}
\sum_{k=1}^{\infty} h \mu([s>k h]) & =\sum_{k=1}^{\infty} h \sum_{i=k}^{\infty} \mu([i h<s \leq(i+1) h]) \\
& =\sum_{i=1}^{\infty} \sum_{k=1}^{i} h \mu([i h<s \leq(i+1) h]) \\
& =\sum_{i=1}^{\infty} i h \mu([i h<s \leq(i+1) h]) \tag{11.3.13}
\end{align*}
$$

Because of the choice of $h$ there exist positive integers, $i_{k}$ such that $i_{1}<i_{2}<\cdots,<i_{p}$ and

$$
\begin{aligned}
i_{1} h & <a_{1} \leq\left(i_{1}+1\right) h<\cdots<i_{2} h<a_{2}< \\
& <\left(i_{2}+1\right) h<\cdots<i_{p} h<a_{p} \leq\left(i_{p}+1\right) h
\end{aligned}
$$

Then in the sum of 11.3 .13 the only terms which are nonzero are those for which $i \in$ $\left\{i_{1}, i_{2} \cdots, i_{p}\right\}$. To see this, you might consider the following picture.

When $i h$ and $(i+1) h$ are both in between two of the $a_{i}$ the set $[i h<s \leq(i+1) h]$ must be empty because the only values of the function are one of the $a_{i}$. At an $i_{k}, i_{k} h$ is smaller than $a_{k}$ while $\left(i_{k}+1\right) h$ is at least as large. Therefore, the set $[i h<s \leq(i+1) h]$ equals $E_{k}$ and so

$$
\mu\left(\left[i_{k} h<s \leq\left(i_{k}+1\right) h\right]\right)=\mu\left(E_{k}\right) .
$$

Therefore,

$$
\sum_{k=1}^{\infty} h \mu([s>k h])=\sum_{k=1}^{p} i_{k} h \mu\left(E_{k}\right) .
$$

It follows that for all $h$ this small,

$$
\begin{aligned}
0 & <\sum_{k=1}^{p} a_{k} \mu\left(E_{k}\right)-\sum_{k=1}^{\infty} h \mu([s>k h]) \\
& =\sum_{k=1}^{p} a_{k} \mu\left(E_{k}\right)-\sum_{k=1}^{p} i_{k} h \mu\left(E_{k}\right) \leq h \sum_{k=1}^{p} \mu\left(E_{k}\right)<\varepsilon .
\end{aligned}
$$

Taking the inf for $h$ this small and using Lemma 11.3.4,

$$
\begin{aligned}
0 & \leq \sum_{k=1}^{p} a_{k} \mu\left(E_{k}\right)-\sup _{\delta>h>0} \sum_{k=1}^{\infty} h \mu([s>k h]) \\
& =\sum_{k=1}^{p} a_{k} \mu\left(E_{k}\right)-\int s d \mu \leq \varepsilon
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this proves the first part.
To verify 11.3.12 Note the formula is obvious if $\lambda=0$ because then $[i h<\lambda f]=\emptyset$ for all $i>0$. Assume $\lambda>0$. Then

$$
\begin{aligned}
\int \lambda f d \mu & \equiv \sup _{h>0} \sum_{i=1}^{\infty} h \mu([i h<\lambda f]) \\
& =\sup _{h>0} \sum_{i=1}^{\infty} h \mu([i h / \lambda<f]) \\
& =\sup _{h>0} \lambda \sum_{i=1}^{\infty}(h / \lambda) \mu([i(h / \lambda)<f]) \\
& =\lambda \int f d \mu
\end{aligned}
$$

This proves the lemma.
Lemma 11.3.7 Let the nonnegative simple function, $s$ be defined as

$$
s(\omega)=\sum_{i=1}^{n} c_{i} \mathscr{X}_{E_{i}}(\omega)
$$

where the $c_{i}$ are not necessarily distinct but the $E_{i}$ are disjoint. It follows that

$$
\int s=\sum_{i=1}^{n} c_{i} \mu\left(E_{i}\right)
$$

Proof: Let the values of $s$ be $\left\{a_{1}, \cdots, a_{m}\right\}$. Therefore, since the $E_{i}$ are disjoint, each $a_{i}$ equal to one of the $c_{j}$. Let $A_{i} \equiv \cup\left\{E_{j}: c_{j}=a_{i}\right\}$. Then from Lemma 11.3.6 it follows that

$$
\begin{aligned}
\int s & =\sum_{i=1}^{m} a_{i} \mu\left(A_{i}\right)=\sum_{i=1}^{m} a_{i} \sum_{\left\{j: c_{j}=a_{i}\right\}} \mu\left(E_{j}\right) \\
& =\sum_{i=1}^{m} \sum_{\left\{j: c_{j}=a_{i}\right\}} c_{j} \mu\left(E_{j}\right)=\sum_{i=1}^{n} c_{i} \mu\left(E_{i}\right) .
\end{aligned}
$$

This proves the lemma.
Note that $\int s$ could equal $+\infty$ if $\mu\left(A_{k}\right)=\infty$ and $a_{k}>0$ for some $k$, but $\int s$ is well defined because $s \geq 0$. Recall that $0 \cdot \infty=0$.

Lemma 11.3.8 If $a, b \geq 0$ and if $s$ and $t$ are nonnegative simple functions, then

$$
\int a s+b t=a \int s+b \int t
$$

Proof: Let

$$
s(\omega)=\sum_{i=1}^{n} \alpha_{i} \mathscr{X}_{A_{i}}(\omega), t(\omega)=\sum_{i=1}^{m} \beta_{j} \mathscr{X}_{B_{j}}(\omega)
$$

where $\alpha_{i}$ are the distinct values of $s$ and the $\beta_{j}$ are the distinct values of $t$. Clearly $a s+b t$ is a nonnegative simple function because it is measurable and has finitely many values. Also,

$$
(a s+b t)(\omega)=\sum_{j=1}^{m} \sum_{i=1}^{n}\left(a \alpha_{i}+b \beta_{j}\right) \mathscr{X}_{A_{i} \cap B_{j}}(\omega)
$$

where the sets $A_{i} \cap B_{j}$ are disjoint. By Lemma 11.3.7,

$$
\begin{aligned}
\int a s+b t & =\sum_{j=1}^{m} \sum_{i=1}^{n}\left(a \alpha_{i}+b \beta_{j}\right) \mu\left(A_{i} \cap B_{j}\right) \\
& =a \sum_{i=1}^{n} \alpha_{i} \mu\left(A_{i}\right)+b \sum_{j=1}^{m} \beta_{j} \mu\left(B_{j}\right) \\
& =a \int s+b \int t
\end{aligned}
$$

This proves the lemma.

### 11.3.4 Simple Functions And Measurable Functions

There is a fundamental theorem about the relationship of simple functions to measurable functions given in the next theorem.

Theorem 11.3.9 Let $f \geq 0$ be measurable. Then there exists a sequence of nonnegative simple functions $\left\{s_{n}\right\}$ satisfying

$$
\begin{gather*}
0 \leq s_{n}(\omega)  \tag{11.3.14}\\
\cdots s_{n}(\omega) \leq s_{n+1}(\omega) \cdots \\
f(\omega)=\lim _{n \rightarrow \infty} s_{n}(\omega) \text { for all } \omega \in \Omega \tag{11.3.15}
\end{gather*}
$$

If $f$ is bounded the convergence is actually uniform.
Proof: Letting $I \equiv\{\omega: f(\omega)=\infty\}$, define

$$
t_{n}(\omega)=\sum_{k=0}^{2^{n}} \frac{k}{n} \mathscr{X}_{[k / n \leq f<(k+1) / n]}(\omega)+n \mathscr{X}_{I}(\omega)
$$

Then $t_{n}(\omega) \leq f(\omega)$ for all $\omega$ and $\lim _{n \rightarrow \infty} t_{n}(\omega)=f(\omega)$ for all $\omega$. This is because $t_{n}(\omega)=n$ for $\omega \in I$ and if $f(\omega) \in\left[0, \frac{2^{n}+1}{n}\right)$, then

$$
\begin{equation*}
0 \leq f(\omega)-t_{n}(\omega) \leq \frac{1}{n} \tag{11.3.16}
\end{equation*}
$$

Thus whenever $\omega \notin I$, the above inequality will hold for all $n$ large enough. Let

$$
s_{1}=t_{1}, s_{2}=\max \left(t_{1}, t_{2}\right), s_{3}=\max \left(t_{1}, t_{2}, t_{3}\right), \cdots
$$

Then the sequence $\left\{s_{n}\right\}$ satisfies 11.3.14-11.3.15.
To verify the last claim, note that in this case the term $n \mathscr{X}_{I}(\omega)$ is not present. Therefore, for all $n$ large enough, 11.3.16 holds for all $\omega$. Thus the convergence is uniform. This proves the theorem.

Although it is not needed here, there is a similar theorem which applies to measurable functions which have values in a separable metric space. In this context, a simple function is one which is of the form

$$
\sum_{k=1}^{m} x_{k} \mathscr{X}_{E_{k}}(\omega)
$$

where the $E_{k}$ are disjoint measurable sets and the $x_{k}$ are in $X$. I am abusing notation somewhat by using a sum. You can't add in a general metric space. The symbol means the function has value $x_{k}$ on the set $E_{k}$.

Theorem 11.3.10 Let $(\Omega, \mathscr{F})$ be a measure space and let $f: \Omega \rightarrow X$ where $(X, d)$ is a separable metric space. Then $f$ is a measurable function if and only if there exists a sequence of simple functions, $\left\{f_{n}\right\}$ such that for each $\omega \in \Omega$ and $n \in \mathbb{N}$,

$$
\begin{equation*}
d\left(f_{n}(\omega), f(\omega)\right) \geq d\left(f_{n+1}(\omega), f(\omega)\right) \tag{11.3.17}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{n \rightarrow \infty} d\left(f_{n}(\omega), f(\omega)\right)=0 \tag{11.3.18}
\end{equation*}
$$

Proof: Let $D=\left\{x_{k}\right\}_{k=1}^{\infty}$ be a countable dense subset of $X$. First suppose $f$ is measurable. Then since in a metric space every open set is the countable intersection of closed sets, it follows $f^{-1}($ closed set $) \in \mathscr{F}$. Now let $D_{n}=\left\{x_{k}\right\}_{k=1}^{n}$. Let

$$
A_{1} \equiv\left\{\omega: d\left(x_{1}, f(\omega)\right)=\min _{k \leq n} d\left(x_{k}, f(\omega)\right)\right\}
$$

That is, $A_{1}$ are those $\omega$ such that $f(\omega)$ is approximated best out of $D_{n}$ by $x_{1}$. Why is this a measurable set? It is because $\omega \rightarrow d(x, f(\omega))$ is a real valued measurable function, being the composition of a continuous function, $y \rightarrow d(x, y)$ and a measurable function, $\omega \rightarrow f(\omega)$. Next let

$$
A_{2} \equiv\left\{\omega \notin A_{1}: d\left(x_{2}, f(\omega)\right)=\min _{k \leq n} d\left(x_{k}, f(\omega)\right)\right\}
$$

and continue in this manner obtaining disjoint measurable sets, $\left\{A_{k}\right\}_{k=1}^{n}$ such that for $\omega \in$ $A_{k}$ the best approximation to $f(\omega)$ from $D_{n}$ is $x_{k}$. Then

$$
f_{n}(\omega) \equiv \sum_{k=1}^{n} x_{k} \mathscr{X}_{A_{k}}(\omega)
$$

Note

$$
\min _{k \leq n+1} d\left(x_{k}, f(\omega)\right) \leq \min _{k \leq n} d\left(x_{k}, f(\omega)\right)
$$

and so this verifies 11.3 .17 . It remains to verify 11.3 .18 .
Let $\varepsilon>0$ be given and pick $\omega \in \Omega$. Then there exists $x_{n} \in D$ such that $d\left(x_{n}, f(\omega)\right)<\varepsilon$. It follows from the construction that $d\left(f_{n}(\omega), f(\omega)\right) \leq d\left(x_{n}, f(\omega)\right)<\varepsilon$. This proves the first half.

Now suppose the existence of the sequence of simple functions as described above. Each $f_{n}$ is a measurable function because $f_{n}^{-1}(U)=\cup\left\{A_{k}: x_{k} \in U\right\}$. Therefore, the conclusion that $f$ is measurable follows from Theorem 11.1.9 on Page 227.

In the context of this more general notion of measurable function having values in a metric space, here is a version of Egoroff's theorem.

Theorem 11.3.11 (Egoroff) Let $(\Omega, \mathscr{F}, \mu)$ be a finite measure space,

$$
(\mu(\Omega)<\infty)
$$

and let $f_{n}, f$ be $X$ valued measurable functions where $X$ is a separable metric space and for all $\omega \notin E$ where $\mu(E)=0$

$$
f_{n}(\omega) \rightarrow f(\omega)
$$

Then for every $\varepsilon>0$, there exists a set,

$$
F \supseteq E, \mu(F)<\varepsilon,
$$

such that $f_{n}$ converges uniformly to $f$ on $F^{C}$.
Proof: First suppose $E=\emptyset$ so that convergence is pointwise everywhere. Let

$$
E_{k m}=\left\{\omega \in \Omega: d\left(f_{n}(\omega), f(\omega)\right) \geq 1 / m \text { for some } n>k\right\}
$$

Claim: $\left[\omega: d\left(f_{n}(\omega), f(\omega)\right) \geq \frac{1}{m}\right]$ is measurable.
Proof of claim: Let $\left\{x_{k}\right\}_{k=1}^{\infty}$ be a countable dense subset of $X$ and let $r$ denote a positive rational number, $\mathbb{Q}^{+}$. Then

$$
\begin{align*}
& \cup_{k \in \mathbb{N}, r \in \mathbb{Q}^{+}} f_{n}^{-1}\left(B\left(x_{k}, r\right)\right) \cap f^{-1}\left(B\left(x_{k}, \frac{1}{m}-r\right)\right) \\
= & {\left[d\left(f, f_{n}\right)<\frac{1}{m}\right] } \tag{11.3.19}
\end{align*}
$$

Here is why. If $\omega$ is in the set on the left, then $d\left(f_{n}(\omega), x_{k}\right)<r$ and

$$
d\left(f(\omega), x_{k}\right)<\frac{1}{m}-r .
$$

Therefore,

$$
d\left(f(\omega), f_{n}(\omega)\right)<r+\frac{1}{m}-r=\frac{1}{m}
$$

Thus the left side is contained in the right. Now let $\omega$ be in the right side. That is $d\left(f_{n}(\omega), f(\omega)\right)<\frac{1}{m}$. Choose $2 r<\frac{1}{m}-d\left(f_{n}(\omega), f(\omega)\right)$ and pick $x_{k} \in B\left(f_{n}(\omega), r\right)$. Then

$$
\begin{aligned}
d\left(f(\omega), x_{k}\right) & \leq d\left(f(\omega), f_{n}(\omega)\right)+d\left(f_{n}(\omega), x_{k}\right) \\
& <\frac{1}{m}-2 r+r=\frac{1}{m}-r
\end{aligned}
$$

Thus $\omega \in f_{n}^{-1}\left(B\left(x_{k}, r\right)\right) \cap f^{-1}\left(B\left(x_{k}, \frac{1}{m}-r\right)\right)$ and so $\omega$ is in the left side. Thus the two sets are equal. Now the set on the left in 11.3.19 is measurable because it is a countable union of measurable sets. This proves the claim since

$$
\left[\omega: d\left(f_{n}(\omega), f(\omega)\right) \geq \frac{1}{m}\right]
$$

is the complement of this measurable set.
Hence $E_{k m}$ is measurable because

$$
E_{k m}=\cup_{n=k+1}^{\infty}\left[\omega: d\left(f_{n}(\omega), f(\omega)\right) \geq \frac{1}{m}\right]
$$

For fixed $m, \cap_{k=1}^{\infty} E_{k m}=\emptyset$ because $f_{n}(\omega)$ converges to $f(\omega)$. Therefore, if $\omega \in \Omega$ there exists $k$ such that if $n>k,\left|f_{n}(\omega)-f(\omega)\right|<\frac{1}{m}$ which means $\omega \notin E_{k m}$. Note also that

$$
E_{k m} \supseteq E_{(k+1) m}
$$

Since $\mu\left(E_{1 m}\right)<\infty$, Theorem 11.1.5 on Page 224 implies

$$
0=\mu\left(\cap_{k=1}^{\infty} E_{k m}\right)=\lim _{k \rightarrow \infty} \mu\left(E_{k m}\right)
$$

Let $k(m)$ be chosen such that $\mu\left(E_{k(m) m}\right)<\varepsilon 2^{-m}$ and let

$$
F=\bigcup_{m=1}^{\infty} E_{k(m) m}
$$

Then $\mu(F)<\varepsilon$ because

$$
\mu(F) \leq \sum_{m=1}^{\infty} \mu\left(E_{k(m) m}\right)<\sum_{m=1}^{\infty} \varepsilon 2^{-m}=\varepsilon
$$

Now let $\eta>0$ be given and pick $m_{0}$ such that $m_{0}^{-1}<\eta$. If $\omega \in F^{C}$, then

$$
\omega \in \bigcap_{m=1}^{\infty} E_{k(m) m}^{C}
$$

Hence $\omega \in E_{k\left(m_{0}\right) m_{0}}^{C}$ so

$$
d\left(f(\omega), f_{n}(\omega)\right)<1 / m_{0}<\eta
$$

for all $n>k\left(m_{0}\right)$. This holds for all $\omega \in F^{C}$ and so $f_{n}$ converges uniformly to $f$ on $F^{C}$.
Now if $E \neq \emptyset$, consider $\left\{\mathscr{X}_{E^{C}} f_{n}\right\}_{n=1}^{\infty}$. Then $\mathscr{X}_{E^{C}} f_{n}$ is measurable and the sequence converges pointwise to $\mathscr{X}_{E} f$ everywhere. Therefore, from the first part, there exists a set of measure less than $\varepsilon, F$ such that on $F^{C},\left\{\mathscr{X}_{E^{C}} f_{n}\right\}$ converges uniformly to $\mathscr{X}_{E^{C}} f$. Therefore, on $(E \cup F)^{C},\left\{f_{n}\right\}$ converges uniformly to $f$. This proves the theorem.

### 11.3.5 The Monotone Convergence Theorem

The following is called the monotone convergence theorem. This theorem and related convergence theorems are the reason for using the Lebesgue integral.

Theorem 11.3.12 (Monotone Convergence theorem) Let $f$ have values in $[0, \infty]$ and suppose $\left\{f_{n}\right\}$ is a sequence of nonnegative measurable functions having values in $[0, \infty]$ and satisfying

$$
\begin{gathered}
\lim _{n \rightarrow \infty} f_{n}(\omega)=f(\omega) \text { for each } \omega \\
\cdots f_{n}(\omega) \leq f_{n+1}(\omega) \cdots
\end{gathered}
$$

Then $f$ is measurable and

$$
\int f d \mu=\lim _{n \rightarrow \infty} \int f_{n} d \mu
$$

Proof: From Lemmas 11.3.1 and 11.3.2,

$$
\begin{aligned}
\int f d \mu & \equiv \sup _{h>0} \sum_{i=1}^{\infty} h \mu([i h<f]) \\
& =\sup _{h>0} \sup _{k} \sum_{i=1}^{k} h \mu([i h<f]) \\
& =\sup _{h>0} \sup _{k} \sup _{m} \sum_{i=1}^{k} h \mu\left(\left[i h<f_{m}\right]\right) \\
& =\sup _{m} \sup _{h>0} \sum_{i=1}^{\infty} h \mu\left(\left[i h<f_{m}\right]\right) \\
& \equiv \sup _{m} \int f_{m} d \mu \\
& =\lim _{m \rightarrow \infty} \int f_{m} d \mu
\end{aligned}
$$

The third equality follows from the observation that

$$
\lim _{m \rightarrow \infty} \mu\left(\left[i h<f_{m}\right]\right)=\mu([i h<f])
$$

which follows from Theorem 11.1.5 since the sets, $\left[i h<f_{m}\right]$ are increasing in $m$ and their union equals $[i h<f]$. This proves the theorem.

To illustrate what goes wrong without the Lebesgue integral, consider the following example.

Example 11.3.13 Let $\left\{r_{n}\right\}$ denote the rational numbers in $[0,1]$ and let

$$
f_{n}(t) \equiv\left\{\begin{array}{l}
1 \text { if } t \notin\left\{r_{1}, \cdots, r_{n}\right\} \\
0 \text { otherwise }
\end{array}\right.
$$

Then $f_{n}(t) \uparrow f(t)$ where $f$ is the function which is one on the rationals and zero on the irrationals. Each $f_{n}$ is Riemann integrable (why?) but $f$ is not Riemann integrable. Therefore, you can't write $\int f d x=\lim _{n \rightarrow \infty} \int f_{n} d x$.

A meta-mathematical observation related to this type of example is this. If you can choose your functions, you don't need the Lebesgue integral. The Riemann integral is just fine. It is when you can't choose your functions and they come to you as pointwise limits that you really need the superior Lebesgue integral or at least something more general than the Riemann integral. The Riemann integral is entirely adequate for evaluating the seemingly endless lists of boring problems found in calculus books.

### 11.3.6 Other Definitions

To review and summarize the above, if $f \geq 0$ is measurable,

$$
\begin{equation*}
\int f d \mu \equiv \sup _{h>0} \sum_{i=1}^{\infty} h \mu([f>i h]) \tag{11.3.20}
\end{equation*}
$$

another way to get the same thing for $\int f d \mu$ is to take an increasing sequence of nonnegative simple functions, $\left\{s_{n}\right\}$ with $s_{n}(\omega) \rightarrow f(\omega)$ and then by monotone convergence theorem,

$$
\int f d \mu=\lim _{n \rightarrow \infty} \int s_{n}
$$

where if $s_{n}(\omega)=\sum_{j=1}^{m} c_{i} \mathscr{X}_{E_{i}}(\omega)$,

$$
\int s_{n} d \mu=\sum_{i=1}^{m} c_{i} m\left(E_{i}\right)
$$

Similarly this also shows that for such nonnegative measurable function,

$$
\int f d \mu=\sup \left\{\int s: 0 \leq s \leq f, s \text { simple }\right\}
$$

which is the usual way of defining the Lebesgue integral for nonnegative simple functions in most books. I have done it differently because this approach led to an easier proof of the Monotone convergence theorem. Here is an equivalent definition of the integral. The fact it is well defined has been discussed above.

Definition 11.3.14 For s a nonnegative simple function,

$$
s(\omega)=\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}(\omega), \int s=\sum_{k=1}^{n} c_{k} \mu\left(E_{k}\right) .
$$

For $f$ a nonnegative measurable function,

$$
\int f d \mu=\sup \left\{\int s: 0 \leq s \leq f, \text { s simple }\right\}
$$

### 11.3.7 Fatou's Lemma

Sometimes the limit of a sequence does not exist. There are two more general notions known as limsup and liminf which do always exist in some sense. These notions are dependent on the following lemma.

Lemma 11.3.15 Let $\left\{a_{n}\right\}$ be an increasing/decreasing in $[-\infty, \infty]$. Then $\lim _{n \rightarrow \infty} a_{n}$ exists.
Proof: Suppose first $\left\{a_{n}\right\}$ is increasing. Recall this means $a_{n} \leq a_{n+1}$ for all $n$. If the sequence is bounded above, then it has a least upper bound and so $a_{n} \rightarrow a$ where $a$ is its least upper bound. If the sequence is not bounded above, then for every $l \in \mathbb{R}$, it follows $l$ is not an upper bound and so eventually, $a_{n}>l$. But this is what is meant by $a_{n} \rightarrow \infty$. The situation for decreasing sequences is completely similar.

Now take any sequence, $\left\{a_{n}\right\} \subseteq[-\infty, \infty]$ and consider the sequence $\left\{A_{n}\right\}$ where

$$
A_{n} \equiv \inf \left\{a_{k}: k \geq n\right\}
$$

Then as $n$ increases, the set of numbers whose inf is being taken is getting smaller. Therefore, $A_{n}$ is an increasing sequence and so it must converge. Similarly, defining the sequence $B_{n} \equiv \sup \left\{a_{k}: k \geq n\right\}$, it follows $B_{n}$ is decreasing and so $\left\{B_{n}\right\}$ also must converge. With this preparation, the following definition can be given.

Definition 11.3.16 Let $\left\{a_{n}\right\}$ be a sequence of points in $[-\infty, \infty]$. Then define

$$
\lim \inf _{n \rightarrow \infty} a_{n} \equiv \lim _{n \rightarrow \infty} \inf \left\{a_{k}: k \geq n\right\}
$$

and

$$
\limsup _{n \rightarrow \infty} a_{n} \equiv \lim _{n \rightarrow \infty} \sup \left\{a_{k}: k \geq n\right\}
$$

In the case of functions having values in $[-\infty, \infty]$,

$$
\left(\lim \inf _{n \rightarrow \infty} f_{n}\right)(\omega) \equiv \lim \inf _{n \rightarrow \infty}\left(f_{n}(\omega)\right)
$$

A similar definition applies to $\lim \sup _{n \rightarrow \infty} f_{n}$.
Lemma 11.3.17 Let $\left\{a_{n}\right\}$ be a sequence in $[-\infty, \infty]$. Then $\lim _{n \rightarrow \infty} a_{n}$ exists if and only if

$$
\lim _{n \rightarrow \infty} \inf _{n} a_{n}=\lim \sup _{n \rightarrow \infty} a_{n}
$$

and in this case, the limit equals the common value of these two numbers.
Proof: Suppose first $\lim _{n \rightarrow \infty} a_{n}=a \in \mathbb{R}$. Then, letting $\varepsilon>0$ be given, $a_{n} \in(a-\varepsilon, a+\varepsilon)$ for all $n$ large enough, say $n \geq N$. Therefore, both $\inf \left\{a_{k}: k \geq n\right\}$ and $\sup \left\{a_{k}: k \geq n\right\}$ are contained in $[a-\varepsilon, a+\varepsilon]$ whenever $n \geq N$. It follows $\limsup _{n \rightarrow \infty} a_{n}$ and $\liminf _{n \rightarrow \infty} a_{n}$ are both in $[a-\varepsilon, a+\varepsilon]$, showing

$$
\left|\lim \inf _{n \rightarrow \infty} a_{n}-\lim \sup _{n \rightarrow \infty} a_{n}\right|<2 \varepsilon .
$$

Since $\varepsilon$ is arbitrary, the two must be equal and they both must equal $a$. Next suppose $\lim _{n \rightarrow \infty} a_{n}=\infty$. Then if $l \in \mathbb{R}$, there exists $N$ such that for $n \geq N$,

$$
l \leq a_{n}
$$

and therefore, for such $n$,

$$
l \leq \inf \left\{a_{k}: k \geq n\right\} \leq \sup \left\{a_{k}: k \geq n\right\}
$$

and this shows, since $l$ is arbitrary that

$$
\lim \inf _{n \rightarrow \infty} a_{n}=\lim \sup _{n \rightarrow \infty} a_{n}=\infty
$$

The case for $-\infty$ is similar.
Conversely, suppose $\liminf _{n \rightarrow \infty} a_{n}=\limsup _{n \rightarrow \infty} a_{n}=a$. Suppose first that $a \in \mathbb{R}$. Then, letting $\varepsilon>0$ be given, there exists $N$ such that if $n \geq N$,

$$
\sup \left\{a_{k}: k \geq n\right\}-\inf \left\{a_{k}: k \geq n\right\}<\varepsilon
$$

therefore, if $k, m>N$, and $a_{k}>a_{m}$,

$$
\left|a_{k}-a_{m}\right|=a_{k}-a_{m} \leq \sup \left\{a_{k}: k \geq n\right\}-\inf \left\{a_{k}: k \geq n\right\}<\varepsilon
$$

showing that $\left\{a_{n}\right\}$ is a Cauchy sequence. Therefore, it converges to $a \in \mathbb{R}$, and as in the first part, the liminf and limsup both equal $a$. If $\liminf _{n \rightarrow \infty} a_{n}=\limsup _{n \rightarrow \infty} a_{n}=\infty$, then given $l \in \mathbb{R}$, there exists $N$ such that for $n \geq N$,

$$
\inf _{n>N} a_{n}>l
$$

Therefore, $\lim _{n \rightarrow \infty} a_{n}=\infty$. The case for $-\infty$ is similar. This proves the lemma.
The next theorem, known as Fatou's lemma is another important theorem which justifies the use of the Lebesgue integral.

Theorem 11.3.18 (Fatou's lemma) Let $f_{n}$ be a nonnegative measurable function with values in $[0, \infty]$. Let $g(\omega)=\liminf _{n \rightarrow \infty} f_{n}(\omega)$. Then $g$ is measurable and

$$
\int g d \mu \leq \lim \inf _{n \rightarrow \infty} \int f_{n} d \mu
$$

In other words,

$$
\int\left(\lim \inf _{n \rightarrow \infty} f_{n}\right) d \mu \leq \lim \inf _{n \rightarrow \infty} \int f_{n} d \mu
$$

Proof: Let $g_{n}(\omega)=\inf \left\{f_{k}(\omega): k \geq n\right\}$. Then

$$
g_{n}^{-1}([a, \infty])=\cap_{k=n}^{\infty} f_{k}^{-1}([a, \infty]) \in \mathscr{F} .
$$

Thus $g_{n}$ is measurable by Lemma 11.1.6 on Page 225. Also $g(\omega)=\lim _{n \rightarrow \infty} g_{n}(\omega)$ so $g$ is measurable because it is the pointwise limit of measurable functions. Now the functions
$g_{n}$ form an increasing sequence of nonnegative measurable functions so the monotone convergence theorem applies. This yields

$$
\int g d \mu=\lim _{n \rightarrow \infty} \int g_{n} d \mu \leq \lim \inf _{n \rightarrow \infty} \int f_{n} d \mu
$$

The last inequality holding because

$$
\int g_{n} d \mu \leq \int f_{n} d \mu
$$

(Note that it is not known whether $\lim _{n \rightarrow \infty} \int f_{n} d \mu$ exists.) This proves the Theorem.

### 11.3.8 The Righteous Algebraic Desires Of The Lebesgue Integral

The monotone convergence theorem shows the integral wants to be linear. This is the essential content of the next theorem.

Theorem 11.3.19 Let $f, g$ be nonnegative measurable functions and let $a, b$ be nonnegative numbers. Then

$$
\begin{equation*}
\int(a f+b g) d \mu=a \int f d \mu+b \int g d \mu \tag{11.3.21}
\end{equation*}
$$

Proof: By Theorem 11.3 .9 on Page 241 there exist sequences of nonnegative simple functions, $s_{n} \rightarrow f$ and $t_{n} \rightarrow g$. Then by the monotone convergence theorem and Lemma 11.3.8,

$$
\begin{aligned}
\int(a f+b g) d \mu & =\lim _{n \rightarrow \infty} \int a s_{n}+b t_{n} d \mu \\
& =\lim _{n \rightarrow \infty}\left(a \int s_{n} d \mu+b \int t_{n} d \mu\right) \\
& =a \int f d \mu+b \int g d \mu
\end{aligned}
$$

As long as you are allowing functions to take the value $+\infty$, you cannot consider something like $f+(-g)$ and so you can't very well expect a satisfactory statement about the integral being linear until you restrict yourself to functions which have values in a vector space. This is discussed next.

### 11.4 The Space $L^{1}$

The functions considered here have values in $\mathbb{C}$, a vector space.
Definition 11.4.1 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space and suppose $f: \Omega \rightarrow \mathbb{C}$. Then $f$ is said to be measurable if both $\operatorname{Re} f$ and $\operatorname{Im} f$ are measurable real valued functions.

Definition 11.4.2 A complex simple function will be a function which is of the form

$$
s(\omega)=\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}(\omega)
$$

where $c_{k} \in \mathbb{C}$ and $\mu\left(E_{k}\right)<\infty$. For $s$ a complex simple function as above, define

$$
I(s) \equiv \sum_{k=1}^{n} c_{k} \mu\left(E_{k}\right)
$$

Lemma 11.4.3 The definition, 11.4.2 is well defined. Furthermore, I is linear on the vector space of complex simple functions. Also the triangle inequality holds,

$$
|I(s)| \leq I(|s|)
$$

Proof: Suppose $\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}(\omega)=0$. Does it follow that $\sum_{k} c_{k} \mu\left(E_{k}\right)=0$ ? The supposition implies

$$
\begin{equation*}
\sum_{k=1}^{n} \operatorname{Re} c_{k} \mathscr{X}_{E_{k}}(\omega)=0, \sum_{k=1}^{n} \operatorname{Im} c_{k} \mathscr{X}_{E_{k}}(\omega)=0 \tag{11.4.22}
\end{equation*}
$$

Choose $\lambda$ large and positive so that $\lambda+\operatorname{Re} c_{k} \geq 0$. Then adding $\sum_{k} \lambda \mathscr{X}_{E_{k}}$ to both sides of the first equation above,

$$
\sum_{k=1}^{n}\left(\lambda+\operatorname{Re} c_{k}\right) \mathscr{X}_{E_{k}}(\omega)=\sum_{k=1}^{n} \lambda \mathscr{X}_{E_{k}}
$$

and by Lemma 11.3.8 on Page 241, it follows upon taking $\int$ of both sides that

$$
\sum_{k=1}^{n}\left(\lambda+\operatorname{Re} c_{k}\right) \mu\left(E_{k}\right)=\sum_{k=1}^{n} \lambda \mu\left(E_{k}\right)
$$

which implies $\sum_{k=1}^{n} \operatorname{Re} c_{k} \mu\left(E_{k}\right)=0$. Similarly, $\sum_{k=1}^{n} \operatorname{Im} c_{k} \mu\left(E_{k}\right)=0$ so

$$
\sum_{k=1}^{n} c_{k} \mu\left(E_{k}\right)=0
$$

Thus if

$$
\sum_{j} c_{j} \mathscr{X}_{E_{j}}=\sum_{k} d_{k} \mathscr{X}_{F_{k}}
$$

then $\sum_{j} c_{j} \mathscr{X}_{E_{j}}+\sum_{k}\left(-d_{k}\right) \mathscr{X}_{F_{k}}=0$ and so the result just established verifies $\sum_{j} c_{j} \mu\left(E_{j}\right)-$ $\sum_{k} d_{k} \mu\left(F_{k}\right)=0$ which proves $I$ is well defined.

That $I$ is linear is now obvious. It only remains to verify the triangle inequality.
Let $s$ be a simple function,

$$
s=\sum_{j} c_{j} \mathscr{X}_{E_{j}}
$$

Then pick $\theta \in \mathbb{C}$ such that $\theta I(s)=|I(s)|$ and $|\theta|=1$. Then from the triangle inequality for sums of complex numbers,

$$
\begin{aligned}
|I(s)| & =\theta I(s)=I(\theta s)=\sum_{j} \theta c_{j} \mu\left(E_{j}\right) \\
& =\left|\sum_{j} \theta c_{j} \mu\left(E_{j}\right)\right| \leq \sum_{j}\left|\theta c_{j}\right| \mu\left(E_{j}\right)=I(|s|) .
\end{aligned}
$$

This proves the lemma.
With this lemma, the following is the definition of $L^{1}(\Omega)$.

Definition 11.4.4 $f \in L^{1}(\Omega)$ means there exists a sequence of complex simple functions, $\left\{s_{n}\right\}$ such that

$$
\begin{gather*}
s_{n}(\omega) \rightarrow f(\omega) \text { for all } \omega \in \Omega \\
\lim _{m, n \rightarrow \infty} I\left(\left|s_{n}-s_{m}\right|\right)=\lim _{n, m \rightarrow \infty} \int\left|s_{n}-s_{m}\right| d \mu=0 \tag{11.4.23}
\end{gather*}
$$

Then

$$
\begin{equation*}
I(f) \equiv \lim _{n \rightarrow \infty} I\left(s_{n}\right) \tag{11.4.24}
\end{equation*}
$$

Lemma 11.4.5 Definition 11.4.4 is well defined.
Proof: There are several things which need to be verified. First suppose 11.4.23. Then by Lemma 11.4.3

$$
\left|I\left(s_{n}\right)-I\left(s_{m}\right)\right|=\left|I\left(s_{n}-s_{m}\right)\right| \leq I\left(\left|s_{n}-s_{m}\right|\right)
$$

and for $m, n$ large enough this last is given to be small so $\left\{I\left(s_{n}\right)\right\}$ is a Cauchy sequence in $\mathbb{C}$ and so it converges. This verifies the limit in 11.4.24 at least exists. It remains to consider another sequence $\left\{t_{n}\right\}$ having the same properties as $\left\{s_{n}\right\}$ and verifying $I(f)$ determined by this other sequence is the same. By Lemma 11.4.3 and Fatou's lemma, Theorem 11.3.18 on Page 248,

$$
\begin{aligned}
\left|I\left(s_{n}\right)-I\left(t_{n}\right)\right| & \leq I\left(\left|s_{n}-t_{n}\right|\right)=\int\left|s_{n}-t_{n}\right| d \mu \\
& \leq \int\left|s_{n}-f\right|+\left|f-t_{n}\right| d \mu \\
& \leq \liminf _{k \rightarrow \infty} \int\left|s_{n}-s_{k}\right| d \mu+\liminf _{k \rightarrow \infty} \int\left|t_{n}-t_{k}\right| d \mu<\varepsilon
\end{aligned}
$$

whenever $n$ is large enough. Since $\varepsilon$ is arbitrary, this shows the limit from using the $t_{n}$ is the same as the limit from using $s_{n}$. This proves the lemma.

What if $f$ has values in $[0, \infty)$ ? Earlier $\int f d \mu$ was defined for such functions and now $I(f)$ has been defined. Are they the same? If so, $I$ can be regarded as an extension of $\int d \mu$ to a larger class of functions.
Lemma 11.4.6 Suppose $f$ has values in $[0, \infty)$ and $f \in L^{1}(\Omega)$. Then $f$ is measurable and

$$
I(f)=\int f d \mu
$$

Proof: Since $f$ is the pointwise limit of a sequence of complex simple functions, $\left\{s_{n}\right\}$ having the properties described in Definition 11.4.4, it follows $f(\omega)=\lim _{n \rightarrow \infty} \operatorname{Re} s_{n}(\omega)$ and so $f$ is measurable. Also

$$
\int\left|\left(\operatorname{Re} s_{n}\right)^{+}-\left(\operatorname{Re} s_{m}\right)^{+}\right| d \mu \leq \int\left|\operatorname{Re} s_{n}-\operatorname{Re} s_{m}\right| d \mu \leq \int\left|s_{n}-s_{m}\right| d \mu
$$

where $x^{+} \equiv \frac{1}{2}(|x|+x)$, the positive part of the real number, $x$. ${ }^{2}$ Thus there is no loss of generality in assuming $\left\{s_{n}\right\}$ is a sequence of complex simple functions having values in

[^8]$[0, \infty)$. Then since for such complex simple functions, $I(s)=\int s d \mu$,
\[

$$
\begin{aligned}
& \left|I(f)-\int f d \mu\right| \leq\left|I(f)-I\left(s_{n}\right)\right|+\left|\int s_{n} d \mu-\int f d \mu\right| \\
& \quad<\varepsilon+\mid \int_{\left[s_{n}-f \geq 0\right]} s_{n} d \mu-\int_{\left[s_{n}-f \geq 0\right]} f d \mu \\
& \quad+\int_{\left[s_{n}-f<0\right]} s_{n} d \mu-\int_{\left[s_{n}-f<0\right]} f d \mu \mid \\
& \leq \varepsilon+\left|\int_{\left[s_{n}-f \geq 0\right]}\left(s_{n}-f\right) d \mu\right|+\left|\int_{\left[s_{n}-f<0\right]}\left(s_{n}-f\right) d \mu\right| \\
& \leq \varepsilon+\int_{\left[s_{n}-f \geq 0\right]}\left|s_{n}-f\right| d \mu+\int_{\left[s_{n}-f>0\right]}\left|s_{n}-f\right| d \mu \\
& =\varepsilon+\int\left|s_{n}-f\right| d \mu
\end{aligned}
$$
\]

whenever $n$ is large enough. But by Fatou's lemma, Theorem 11.3.18 on Page 248, the last term is no larger than

$$
\lim _{\inf _{k \rightarrow \infty}} \int\left|s_{n}-s_{k}\right| d \mu<\varepsilon
$$

whenever $n$ is large enough. Since $\varepsilon$ is arbitrary, this shows $I(f)=\int f d \mu$ as claimed.
As explained above, $I$ can be regarded as an extension of $\int d \mu$ so from now on, the usual symbol, $\int d \mu$ will be used. It is now easy to verify $\int d \mu$ is linear on $L^{1}(\Omega)$.

Theorem 11.4.7 $\int d \mu$ is linear on $L^{1}(\Omega)$ and $L^{1}(\Omega)$ is a complex vector space. If $f \in$ $L^{1}(\Omega)$, then $\operatorname{Re} f, \operatorname{Im} f$, and $|f|$ are all in $L^{1}(\Omega)$. Furthermore, for $f \in L^{1}(\Omega)$,

$$
\int f d \mu=\int(\operatorname{Re} f)^{+} d \mu-\int(\operatorname{Re} f)^{-} d \mu+i\left(\int(\operatorname{Im} f)^{+} d \mu-\int(\operatorname{Im} f)^{-} d \mu\right)
$$

Also the triangle inequality holds,

$$
\left|\int f d \mu\right| \leq \int|f| d \mu
$$

Proof: First it is necessary to verify that $L^{1}(\Omega)$ is really a vector space because it makes no sense to speak of linear maps without having these maps defined on a vector space. Let $f, g$ be in $L^{1}(\Omega)$ and let $a, b \in \mathbb{C}$. Then let $\left\{s_{n}\right\}$ and $\left\{t_{n}\right\}$ be sequences of complex simple functions associated with $f$ and $g$ respectively as described in Definition 11.4.4. Consider $\left\{a s_{n}+b t_{n}\right\}$, another sequence of complex simple functions. Then $a s_{n}(\omega)+b t_{n}(\omega) \rightarrow$ $a f(\omega)+b g(\omega)$ for each $\omega$. Also, from Lemma 11.4.3

$$
\int\left|a s_{n}+b t_{n}-\left(a s_{m}+b t_{m}\right)\right| d \mu \leq|a| \int\left|s_{n}-s_{m}\right| d \mu+|b| \int\left|t_{n}-t_{m}\right| d \mu
$$

and the sum of the two terms on the right converge to zero as $m, n \rightarrow \infty$. Thus $a f+b g \in$ $L^{1}(\Omega)$. Also

$$
\begin{aligned}
\int(a f+b g) d \mu & =\lim _{n \rightarrow \infty} \int\left(a s_{n}+b t_{n}\right) d \mu \\
& =\lim _{n \rightarrow \infty}\left(a \int s_{n} d \mu+b \int t_{n} d \mu\right) \\
& =a \lim _{n \rightarrow \infty} \int s_{n} d \mu+b \lim _{n \rightarrow \infty} \int t_{n} d \mu \\
& =a \int f d \mu+b \int g d \mu
\end{aligned}
$$

If $\left\{s_{n}\right\}$ is a sequence of complex simple functions described in Definition 11.4.4 corresponding to $f$, then $\left\{\left|s_{n}\right|\right\}$ is a sequence of complex simple functions satisfying the conditions of Definition 11.4.4 corresponding to $|f|$. This is because $\left|s_{n}(\omega)\right| \rightarrow|f(\omega)|$ and

$$
\int\left|\left|s_{n}\right|-\left|s_{m}\right|\right| d \mu \leq \int\left|s_{m}-s_{n}\right| d \mu
$$

with this last expression converging to 0 as $m, n \rightarrow \infty$. Thus $|f| \in L^{1}(\Omega)$. Also, by similar reasoning, $\left\{\operatorname{Re} s_{n}\right\}$ and $\left\{\operatorname{Im} s_{n}\right\}$ correspond to $\operatorname{Re} f$ and $\operatorname{Im} f$ respectively in the manner described by Definition 11.4.4 showing that $\operatorname{Re} f$ and $\operatorname{Im} f$ are in $L^{1}(\Omega)$. Now $(\operatorname{Re} f)^{+}=$ $\frac{1}{2}(|\operatorname{Re} f|+\operatorname{Re} f)$ and $(\operatorname{Re} f)^{-}=\frac{1}{2}(|\operatorname{Re} f|-\operatorname{Re} f)$ so both of these functions are in $L^{1}(\Omega)$. Similar formulas establish that $(\operatorname{Im} f)^{+}$and $(\operatorname{Im} f)^{-}$are in $L^{1}(\Omega)$.

The formula follows from the observation that

$$
f=(\operatorname{Re} f)^{+}-(\operatorname{Re} f)^{-}+i\left((\operatorname{Im} f)^{+}-(\operatorname{Im} f)^{-}\right)
$$

and the fact shown first that $\int d \mu$ is linear.
To verify the triangle inequality, let $\left\{s_{n}\right\}$ be complex simple functions for $f$ as in Definition 11.4.4. Then

$$
\left|\int f d \mu\right|=\lim _{n \rightarrow \infty}\left|\int s_{n} d \mu\right| \leq \lim _{n \rightarrow \infty} \int\left|s_{n}\right| d \mu=\int|f| d \mu .
$$

This proves the theorem.
The following description of $L^{1}(\Omega)$ is the version most often used because it is easy to verify the conditions for it.

Corollary 11.4.8 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space and let $f: \Omega \rightarrow \mathbb{C}$. Then $f \in L^{1}(\Omega)$ if and only if $f$ is measurable and $\int|f| d \mu<\infty$.

Proof: Suppose $f \in L^{1}(\Omega)$. Then from Definition 11.4.4, it follows both real and imaginary parts of $f$ are measurable. Just take real and imaginary parts of $s_{n}$ and observe the real and imaginary parts of $f$ are limits of the real and imaginary parts of $s_{n}$ respectively. Why is $\int|f| d \mu<\infty$ ? It follows from Theorem 11.4.7. Recall why this was so. Let $\left\{s_{n}\right\}$ be a sequence of simple functions attached to $f$ as in the definition of what it means to be $L^{1}$. Then from the definition of $I(s)$ for $s$ simple,

$$
\left|I\left(\left|s_{n}\right|-\left|s_{m}\right|\right)\right| \leq I\left(\left|s_{n}-s_{m}\right|\right)
$$

which converges to 0 . Since $\left\{I\left(\left|s_{n}\right|\right)\right\}$ is a Cauchy sequence, it is bounded by a constant $C$ and also $\left\{\left|s_{n}\right|\right\}$ is a sequence of simple functions of the right sort which converges pointwise to $|f|$ and so by definition,

$$
\int|f| d \mu=I(f)=\lim _{n \rightarrow \infty} I\left(\left|s_{n}\right|\right) \leq C
$$

This shows the only if part.
The more interesting part is the if part. Suppose then that $f$ is measurable and $\int|f| d \mu<$ $\infty$. Suppose first that $f$ has values in $[0, \infty)$. It is necessary to obtain the sequence of complex simple functions. By Theorem 11.3.9, there exists a sequence of nonnegative simple functions, $\left\{s_{n}\right\}$ such that $s_{n}(\omega) \uparrow f(\omega)$. Then by the monotone convergence theorem,

$$
\lim _{n \rightarrow \infty} \int\left(2 f-\left(f-s_{n}\right)\right) d \mu=\int 2 f d \mu
$$

and so

$$
\lim _{n \rightarrow \infty} \int\left(f-s_{n}\right) d \mu=0
$$

Letting $m$ be large enough, it follows $\int\left(f-s_{m}\right) d \mu<\varepsilon$ and so if $n>m$

$$
\int\left|s_{m}-s_{n}\right| d \mu \leq \int\left|f-s_{m}\right| d \mu<\varepsilon
$$

Therefore, $f \in L^{1}(\Omega)$ because $\left\{s_{n}\right\}$ is a suitable sequence.
The general case follows from considering positive and negative parts of real and imaginary parts of $f$. These are each measurable and nonnegative and their integral is finite so each is in $L^{1}(\Omega)$ by what was just shown. Thus

$$
f=\operatorname{Re} f^{+}-\operatorname{Re} f^{-}+i\left(\operatorname{Im} f^{+}-\operatorname{Im} f^{-}\right)
$$

and so $f \in L^{1}(\Omega)$. This proves the corollary.
Theorem 11.4.9 (Dominated Convergence theorem) Let $f_{n} \in L^{1}(\Omega)$ and suppose

$$
f(\omega)=\lim _{n \rightarrow \infty} f_{n}(\omega)
$$

and there exists a measurable function $g$, with values in $[0, \infty],{ }^{3}$ such that

$$
\left|f_{n}(\omega)\right| \leq g(\omega) \text { and } \int g(\omega) d \mu<\infty
$$

Then $f \in L^{1}(\Omega)$ and

$$
\int f d \mu=\lim _{n \rightarrow \infty} \int f_{n} d \mu
$$

[^9]Proof: $f$ is measurable by Theorem 11.1.8. Since $|f| \leq g$, it follows that

$$
f \in L^{1}(\Omega) \text { and }\left|f-f_{n}\right| \leq 2 g
$$

By Fatou's lemma (Theorem 11.3.18),

$$
\begin{aligned}
\int 2 g d \mu & \leq \liminf _{n \rightarrow \infty} \int 2 g-\left|f-f_{n}\right| d \mu \\
& =\int 2 g d \mu-\lim \sup _{n \rightarrow \infty} \int\left|f-f_{n}\right| d \mu
\end{aligned}
$$

Subtracting $\int 2 g d \mu$,

$$
0 \leq-\lim \sup _{n \rightarrow \infty} \int\left|f-f_{n}\right| d \mu
$$

Hence

$$
\begin{aligned}
0 & \geq \lim \sup _{n \rightarrow \infty}\left(\int\left|f-f_{n}\right| d \mu\right) \geq \lim \sup _{n \rightarrow \infty}\left|\int f d \mu-\int f_{n} d \mu\right| \\
& \geq \lim \inf _{n \rightarrow \infty}\left|\int f d \mu-\int f_{n} d \mu\right| \geq 0
\end{aligned}
$$

This proves the theorem by Lemma 11.3.17 on Page 247 because the limsup and liminf are equal.

Corollary 11.4.10 Suppose $f_{n} \in L^{1}(\Omega)$ and $f(\omega)=\lim _{n \rightarrow \infty} f_{n}(\omega)$. Suppose also there exist measurable functions, $g_{n}, g$ with values in $[0, \infty]$ such that

$$
\lim _{n \rightarrow \infty} \int g_{n} d \mu=\int g d \mu
$$

$g_{n}(\omega) \rightarrow g(\omega) \mu$ a.e. and both $\int g_{n} d \mu$ and $\int g d \mu$ are finite. Also suppose $\left|f_{n}(\omega)\right| \leq$ $g_{n}(\omega)$. Then

$$
\lim _{n \rightarrow \infty} \int\left|f-f_{n}\right| d \mu=0
$$

Proof: It is just like the above. This time $g+g_{n}-\left|f-f_{n}\right| \geq 0$ and so by Fatou's lemma,

$$
\begin{gathered}
\int 2 g d \mu-\lim _{n \rightarrow \infty} \int\left|f-f_{n}\right| d \mu= \\
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \int\left(g_{n}+g\right)-\lim \sup _{n \rightarrow \infty} \int\left|f-f_{n}\right| d \mu \\
=\lim _{n \rightarrow \infty} \int\left(\left(g_{n}+g\right)-\left|f-f_{n}\right|\right) d \mu \geq \int 2 g d \mu
\end{gathered}
$$

and so $-\lim \sup _{n \rightarrow \infty} \int\left|f-f_{n}\right| d \mu \geq 0$.
Definition 11.4.11 Let $E$ be a measurable subset of $\Omega$.

$$
\int_{E} f d \mu \equiv \int f \mathscr{X}_{E} d \mu
$$

If $L^{1}(E)$ is written, the $\sigma$ algebra is defined as

$$
\{E \cap A: A \in \mathscr{F}\}
$$

and the measure is $\mu$ restricted to this smaller $\sigma$ algebra. Clearly, if $f \in L^{1}(\Omega)$, then

$$
f \mathscr{X}_{E} \in L^{1}(E)
$$

and if $f \in L^{1}(E)$, then letting $\tilde{f}$ be the 0 extension of $f$ off of $E$, it follows $\tilde{f} \in L^{1}(\Omega)$.

### 11.5 Vitali Convergence Theorem

The Vitali convergence theorem is a convergence theorem which in the case of a finite measure space is superior to the dominated convergence theorem.

Definition 11.5.1 Let $(\Omega, \mathscr{F}, \mu)$ be a measure space and let $\mathfrak{S} \subseteq L^{1}(\Omega)$. $\mathfrak{S}$ is uniformly integrable iffor every $\varepsilon>0$ there exists $\delta>0$ such that for all $f \in \mathfrak{S}$

$$
\left|\int_{E} f d \mu\right|<\varepsilon \text { whenever } \mu(E)<\delta
$$

Lemma 11.5.2 If $\mathfrak{S}$ is uniformly integrable, then $|\mathfrak{S}| \equiv\{|f|: f \in \mathfrak{S}\}$ is uniformly integrable. Also $\mathfrak{S}$ is uniformly integrable if $\mathfrak{S}$ is finite.

Proof: Let $\varepsilon>0$ be given and suppose $\mathfrak{S}$ is uniformly integrable. First suppose the functions are real valued. Let $\delta$ be such that if $\mu(E)<\delta$, then

$$
\left|\int_{E} f d \mu\right|<\frac{\varepsilon}{2}
$$

for all $f \in \mathfrak{S}$. Let $\mu(E)<\delta$. Then if $f \in \mathfrak{S}$,

$$
\begin{aligned}
\int_{E}|f| d \mu & \leq \int_{E \cap[f \leq 0]}(-f) d \mu+\int_{E \cap[f>0]} f d \mu \\
& =\left|\int_{E \cap[f \leq 0]} f d \mu\right|+\left|\int_{E \cap[f>0]} f d \mu\right| \\
& <\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
\end{aligned}
$$

In general, if $\mathfrak{S}$ is a uniformly integrable set of complex valued functions, the inequalities,

$$
\left|\int_{E} \operatorname{Re} f d \mu\right| \leq\left|\int_{E} f d \mu\right|,\left|\int_{E} \operatorname{Im} f d \mu\right| \leq\left|\int_{E} f d \mu\right|
$$

imply $\operatorname{Re} \mathfrak{S} \equiv\{\operatorname{Re} f: f \in \mathfrak{S}\}$ and $\operatorname{Im} \mathfrak{S} \equiv\{\operatorname{Im} f: f \in \mathfrak{S}\}$ are also uniformly integrable. Therefore, applying the above result for real valued functions to these sets of functions, it follows $|\mathfrak{S}|$ is uniformly integrable also.

For the last part, is suffices to verify a single function in $L^{1}(\Omega)$ is uniformly integrable. To do so, note that from the dominated convergence theorem,

$$
\lim _{R \rightarrow \infty} \int_{[|f|>R]}|f| d \mu=0
$$

Let $\varepsilon>0$ be given and choose $R$ large enough that $\int_{[|f|>R]}|f| d \mu<\frac{\varepsilon}{2}$. Now let $\mu(E)<\frac{\varepsilon}{2 R}$. Then

$$
\begin{aligned}
\int_{E}|f| d \mu & =\int_{E \cap[|f| \leq R]}|f| d \mu+\int_{E \cap[|f|>R]}|f| d \mu \\
& <R \mu(E)+\frac{\varepsilon}{2}<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
\end{aligned}
$$

This proves the lemma.
The following theorem is Vitali's convergence theorem.
Theorem 11.5.3 Let $\left\{f_{n}\right\}$ be a uniformly integrable set of complex valued functions,

$$
\mu(\Omega)<\infty \text { and } f_{n}(x) \rightarrow f(x)
$$

a.e. where $f$ is a measurable complex valued function. Then $f \in L^{1}(\Omega)$ and

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{\Omega}\left|f_{n}-f\right| d \mu=0 \tag{11.5.25}
\end{equation*}
$$

Proof: First it will be shown that $f \in L^{1}(\Omega)$. By uniform integrability, there exists $\delta>0$ such that if $\mu(E)<\delta$, then

$$
\int_{E}\left|f_{n}\right| d \mu<1
$$

for all $n$. By Egoroff's theorem, there exists a set, $E$ of measure less than $\delta$ such that on $E^{C},\left\{f_{n}\right\}$ converges uniformly. Therefore, for $p$ large enough, and $n>p$,

$$
\int_{E^{C}}\left|f_{p}-f_{n}\right| d \mu<1
$$

which implies

$$
\int_{E^{C}}\left|f_{n}\right| d \mu<1+\int_{\Omega}\left|f_{p}\right| d \mu
$$

Then since there are only finitely many functions, $f_{n}$ with $n \leq p$, there exists a constant, $M_{1}$ such that for all $n$,

$$
\int_{E^{C}}\left|f_{n}\right| d \mu<M_{1}
$$

But also,

$$
\begin{aligned}
\int_{\Omega}\left|f_{m}\right| d \mu & =\int_{E^{C}}\left|f_{m}\right| d \mu+\int_{E}\left|f_{m}\right| \\
& \leq M_{1}+1 \equiv M
\end{aligned}
$$

Therefore, by Fatou's lemma,

$$
\int_{\Omega}|f| d \mu \leq \lim \inf _{n \rightarrow \infty} \int\left|f_{n}\right| d \mu \leq M
$$

showing that $f \in L^{1}$ as hoped.
Now $\mathfrak{S} \cup\{f\}$ is uniformly integrable so there exists $\delta_{1}>0$ such that if $\mu(E)<\delta_{1}$, then $\int_{E}|g| d \mu<\varepsilon / 3$ for all $g \in \mathfrak{S} \cup\{f\}$. By Egoroff's theorem, there exists a set, $F$ with $\mu(F)<\delta_{1}$ such that $f_{n}$ converges uniformly to $f$ on $F^{C}$. Therefore, there exists $N$ such that if $n>N$, then

$$
\int_{F^{C}}\left|f-f_{n}\right| d \mu<\frac{\varepsilon}{3}
$$

It follows that for $n>N$,

$$
\begin{aligned}
\int_{\Omega}\left|f-f_{n}\right| d \mu & \leq \int_{F^{C}}\left|f-f_{n}\right| d \mu+\int_{F}|f| d \mu+\int_{F}\left|f_{n}\right| d \mu \\
& <\frac{\varepsilon}{3}+\frac{\varepsilon}{3}+\frac{\varepsilon}{3}=\varepsilon
\end{aligned}
$$

which verifies 11.5.25.

### 11.6 Measures and Regularity

It is often the case that $\Omega$ has more going on than to simply be a set. In particular, it is often the case that $\Omega$ is some sort of topological space, often a metric space. In this case, it is usually if not always the case that the open sets will be in the $\sigma$ algebra of measurable sets. This leads to the following definition.

Definition 11.6.1 A Polish space is a complete separable metric space. For a Polish space $E$ or more generally a metric space or even a general topological space, $\mathscr{B}(E)$ denotes the Borel sets of $E$. This is defined to be the smallest $\sigma$ algebra which contains the open sets. Thus it contains all open sets and closed sets and compact sets and many others.

Don't ever try to describe a generic Borel set. Always work with the definition that it is the smallest $\sigma$ algebra containing the open sets. Attempts to give an explicit description of a "typical" Borel set tend to lead nowhere because there are so many things which can be done. You can take countable unions and complements and then countable intersections of what you get and then another countable union followed by complements and on and on. You just can't get a good useable description in this way. However, it is easy to see that something like $\left(\cap_{i=1}^{\infty} \cup_{j=i}^{\infty} E_{j}\right)^{C}$ is a Borel set if the $E_{j}$ are. This is useful. This said, you can look at Hewitt and Stromberg in their discussion of why there are more Lebesgue measurable sets than Borel measurable sets to see the kind of technicalities which result by describing Borel sets.

For example, $\mathbb{R}$ is a Polish space as is any separable Banach space. Amazing things can be said about finite measures on the Borel sets of a Polish space. First the case of a finite measure on a metric space will be considered.

Definition 11.6.2 A measure $\mu$ defined on $\mathscr{B}(E)$ will be called inner regular if for all $F \in \mathscr{B}(E)$,

$$
\begin{equation*}
\mu(F)=\sup \{\mu(K): K \subseteq F \text { and } K \text { is closed }\} \tag{11.6.26}
\end{equation*}
$$

A measure, $\mu$ defined on $\mathscr{B}(E)$ will be called outer regular if for all $F \in \mathscr{B}(E)$,

$$
\begin{equation*}
\mu(F)=\inf \{\mu(V): V \supseteq F \text { and } V \text { is open }\} \tag{11.6.27}
\end{equation*}
$$

When a measure is both inner and outer regular, it is called regular. Actually, it is more useful and likely more standard to refer to $\mu$ being inner regular as

$$
\begin{equation*}
\mu(F)=\sup \{\mu(K): K \subseteq F \text { and } K \text { is compact }\} \tag{11.6.28}
\end{equation*}
$$

Thus the word "closed" is replaced with "compact". A complete measure defined on a $\sigma$ algebra $\mathscr{F}$ which includes the Borel sets which is finite on compact sets and also satisfies 11.6.27 and 11.6.28 for each $F \in \mathscr{F}$ is called a Radon measure.

For finite measures, defined on the Borel sets of a metric space, the first definition of regularity is automatic. These are always outer and inner regular provided inner regularity refers to closed sets.

Lemma 11.6.3 Let $\mu$ be a finite measure defined on $\mathscr{B}(X)$ where $X$ is a metric space. Then $\mu$ is regular.

Proof: First note every open set is the countable union of closed sets and every closed set is the countable intersection of open sets. Here is why. Let $V$ be an open set and let

$$
K_{k} \equiv\left\{x \in V: \operatorname{dist}\left(x, V^{C}\right) \geq 1 / k\right\} .
$$

Then clearly the union of the $K_{k}$ equals $V$. Thus

$$
\mu(V)=\sup \{\mu(K): K \subseteq V \text { and } K \text { is closed }\}
$$

If $U$ is open and contains $V$, then $\mu(U) \geq \mu(V)$ and so

$$
\mu(V) \leq \inf \{\mu(U): U \supseteq V, U \text { open }\} \leq \mu(V) \text { since } V \subseteq V
$$

Thus $\mu$ is inner and outer regular on open sets. In what follows, $K$ will be closed and $V$ will be open.

Let $\mathscr{K}$ be the open sets. This is a $\pi$ system. Let

$$
\mathscr{G} \equiv\{E \in \mathscr{B}(X): \mu \text { is inner and outer regular on } E\} \text { so } \mathscr{G} \supseteq \mathscr{K} .
$$

For $E \in \mathscr{G}$, let $V \supseteq E \supseteq K$ such that $\mu(V \backslash K)=\mu(V \backslash E)+\mu(E \backslash K)<\varepsilon$. Thus $K^{C} \supseteq E^{C}$ and so $\mu\left(K^{C} \backslash E^{C}\right)=\mu(E \backslash K)<\varepsilon$. Thus $\mu$ is outer regular on $E^{C}$ because

$$
\mu\left(K^{C}\right)=\mu\left(E^{C}\right)+\mu\left(K^{C} \backslash E^{C}\right)<\mu\left(E^{C}\right)+\varepsilon, K^{C} \supseteq E^{C}
$$

Also, $E^{C} \supseteq V^{C}$ and $\mu\left(E^{C} \backslash V^{C}\right)=\mu(V \backslash E)<\varepsilon$ so $\mu$ is inner regular on $E^{C}$ and so $\mathscr{G}$ is closed for complements. If the sets of $\mathscr{G}\left\{E_{i}\right\}$ are disjoint, let $K_{i} \subseteq E_{i} \subseteq V_{i}$ with $\mu\left(V_{i} \backslash K_{i}\right)<$ $\varepsilon 2^{-i}$. Then for $E \equiv \cup_{i} E_{i}$, and choosing $m$ sufficiently large,

$$
\mu(E)=\sum_{i} \mu\left(E_{i}\right) \leq \sum_{i=1}^{m} \mu\left(E_{i}\right)+\varepsilon \leq \sum_{i=1}^{m} \mu\left(K_{i}\right)+2 \varepsilon=\mu\left(\cup_{i=1}^{m} K_{i}\right)+2 \varepsilon
$$

and so $\mu$ is inner regular on $E \equiv \cup_{i} E_{i}$. It remains to show that $\mu$ is outer regular on $E$. Letting $V \equiv \cup_{i} V_{i}$,

$$
\mu(V \backslash E) \leq \mu\left(\cup_{i}\left(V_{i} \backslash E_{i}\right)\right) \leq \sum_{i} \varepsilon 2^{-i}=\varepsilon
$$

Hence $\mu$ is outer regular on $E$ since $\mu(V)=\mu(E)+\mu(V \backslash E) \leq \mu(E)+\varepsilon$ and $V \supseteq E$.
By Dynkin's lemma, $\mathscr{G}=\sigma(\mathscr{K}) \equiv \mathscr{B}(X)$.
One can say more if the metric space is complete and separable. In fact in this case the above definition of inner regularity can be shown to imply the usual one where the closed sets are replaced with compact sets.

Lemma 11.6.4 Let $\mu$ be a finite measure on a $\sigma$ algebra containing $\mathscr{B}(X)$, the Borel sets of $X$, a separable complete metric space. Then if $C$ is a closed set,

$$
\mu(C)=\sup \{\mu(K): K \subseteq C \text { and } K \text { is compact. }\}
$$

It follows that for a finite measure on $\mathscr{B}(X)$ where $X$ is a Polish space, $\mu$ is inner regular in the sense that for all $F \in \mathscr{B}(X)$,

$$
\mu(F)=\sup \{\mu(K): K \subseteq F \text { and } K \text { is compact }\}
$$

Proof: Let $\left\{a_{k}\right\}$ be a countable dense subset of $C$. Thus $\cup_{k=1}^{\infty} B\left(a_{k}, \frac{1}{n}\right) \supseteq C$. Therefore, there exists $m_{n}$ such that

$$
\mu\left(C \backslash \cup_{k=1}^{m_{n}} \overline{B\left(a_{k}, \frac{1}{n}\right)}\right) \equiv \mu\left(C \backslash C_{n}\right)<\frac{\varepsilon}{2^{n}}
$$

Now let $K=C \cap\left(\cap_{n=1}^{\infty} C_{n}\right)$. Then $K$ is a subset of $C_{n}$ for each $n$ and so for each $\varepsilon>0$ there exists an $\varepsilon$ net for $K$ since $C_{n}$ has a $1 / n$ net, namely $a_{1}, \cdots, a_{m_{n}}$. Since $K$ is closed, it is complete and so it is also compact since it is complete and totally bounded, Theorem 7.6.5. Now

$$
\mu(C \backslash K) \leq \mu\left(\cup_{n=1}^{\infty}\left(C \backslash C_{n}\right)\right)<\sum_{n=1}^{\infty} \frac{\varepsilon}{2^{n}}=\varepsilon
$$

Thus $\mu(C)$ can be approximated by $\mu(K)$ for $K$ a compact subset of $C$. The last claim follows from Lemma 11.6.3.

An important example is the case of a random vector and its distribution measure.
Definition 11.6.5 A measurable function $\mathbf{X}:(\Omega, \mathscr{F}, \mu) \rightarrow Z$ a metric space is called a random variable when $\mu(\Omega)=1$. For such a random variable, one can define a distribution measure $\lambda_{\mathbf{x}}$ on the Borel sets of $Z$ as follows.

$$
\lambda_{\mathbf{X}}(G) \equiv \mu\left(\mathbf{X}^{-1}(G)\right)
$$

This is a well defined measure on the Borel sets of $Z$ because it makes sense for every $G$ open and $\mathscr{G} \equiv\left\{G \subseteq Z: \mathbf{X}^{-1}(G) \in \mathscr{F}\right\}$ is a $\sigma$ algebra which contains the open sets, hence the Borel sets. Such a random variable is also called a random vector when $Z$ is a vector space.

Corollary 11.6.6 Let $\mathbf{X}$ be a random variable with values in a separable complete metric space $Z$. Then $\lambda_{\mathbf{x}}$ is an inner and outer regular measure defined on $\mathscr{B}(Z)$.

What if the measure $\mu$ is defined on a Polish space but is not finite. Sometimes one can still get the assertion that $\mu$ is regular. In every case of interest in this book, the measure will also be $\sigma$ finite.

Definition 11.6.7 Let $(E, \mathscr{B}(E), \mu)$ be a measurable space with the measure $\mu$. Then $\mu$ is said to be $\sigma$ finite if there is a sequence of disjoint Borel sets $\left\{B_{i}\right\}_{i=1}^{\infty}$ such that $\cup_{i=1}^{\infty} B_{i}=E$ and $\mu\left(B_{i}\right)<\infty$. More generally, if $(X, \mathscr{F}, \mu)$ is a measure space, it is $\sigma$ finite if there are $X_{n} \in \mathscr{F}$ with $\cup_{n} X_{n}=X$ and $\mu\left(X_{n}\right)<\infty$.

One such example of a complete metric space and a measure which is finite on compact sets is the following where the closures of balls are compact. Thus, this involves finite dimensional situations essentially. Note that if you have a metric space in which the closures of balls are compact sets, then the metric space must be separable. This is because you can pick a point $\xi$ and consider the closures of balls $\overline{B(\xi, n)}$. Then $\overline{B(\xi, n)}$ is complete and totally bounded so it has a countable dense subset $D_{n}$. Let $D=\cup_{n} D_{n}$.

Corollary 11.6.8 Let $\Omega$ be a complete metric space which is the countable union of compact sets $K_{n}$ and suppose, for $\mu$ a Borel measure, $\mu\left(K_{n}\right)$ is finite. Then $\mu$ must be regular. In particular, if $\Omega$ is a metric space and the closure of each ball is compact, and $\mu$ is finite on balls, then $\mu$ must be regular.

Proof: Let the compact sets be increasing without loss of generality, and let $\mu_{n}(E) \equiv$ $\mu\left(K_{n} \cap E\right)$. Thus $\mu_{n}$ is a finite measure defined on the Borel sets of a Polish space so it is regular. Letting $l<\mu(E)$, there exists $n$ such that $l<\mu_{n}(E) \leq \mu(E)$. By what was shown above in Lemma 11.6.4, there exists $H$ compact, $H \subseteq E$ such that also for a large $n, \mu_{n}(H)>l$. Hence $\mu\left(H \cap K_{n}\right)>l$ and so $\mu$ is inner regular. It remains to verify that $\mu$ is outer regular. If $\mu(E)=\infty$, there is nothing to show. Assume then that $\mu(E)<\infty$. Let $V_{n} \supseteq E$ with $\mu_{n}\left(V_{n} \backslash E\right)<\varepsilon 2^{-n}$ so also $\mu\left(V_{n}\right)<\infty$. We can assume also that $V_{n} \supseteq V_{n+1}$ for all $n$. Thus $\mu\left(\left(V_{n} \backslash E\right) \cap K_{n}\right)<2^{-n} \varepsilon$. Let $G=\cap_{k} V_{k}$. Then $G \subseteq V_{n}$ so $\mu\left((G \backslash E) \cap K_{n}\right)<2^{-n} \varepsilon$. Letting $n \rightarrow \infty, \mu(G \backslash E)=0$ and $G \supseteq E$. Then, since $V_{1}$ has finite measure, $\mu(G \backslash E)=\lim _{n \rightarrow \infty} \mu\left(V_{n} \backslash E\right)$ and so for all $n$ large enough, $\mu\left(V_{n} \backslash E\right)<\varepsilon$ so $\mu(E)+\varepsilon>\mu\left(V_{n}\right)$ and so $\mu$ is outer regular. In the last case, if the closure of each ball is compact, then $\Omega$ is automatically complete because every Cauchy sequence is contained in some ball and so has a convergent subsequence. Since the sequence is Cauchy, it also converges by Theorem 7.3.2 on Page 140 .

### 11.7 Regular Measures in a Metric Space

In this section $X$ will be a metric space in which the closed balls are compact. The extra generality involving a metric space instead of $\mathbb{R}^{p}$ would allow the consideration of manifolds for example. However, $\mathbb{R}^{p}$ is an important case.

Definition 11.7.1 The symbol $C_{c}(V)$ for $V$ an open set will denote the continuous functions having compact support which is contained in $V$. Recall that the support of a continuous function $f$ is defined as the closure of the set on which the function is nonzero. $L: C_{c}(X) \rightarrow$ $\mathbb{C}$ is called a positive linear functional if it is linear, $L(\alpha f+\beta g)=\alpha L f+\beta L g$ and satisfies $L f \leq L g$ if $f \leq g$. Also, recall that a measure $\mu$ is regular on some $\sigma$ algebra $\mathscr{F}$ containing the Borel sets iffor every $F \in \mathscr{F}$,

$$
\begin{aligned}
& \mu(F)=\sup \{\mu(K): K \subseteq F \text { and } K \text { compact }\} \\
& \mu(F)=\inf \{\mu(V): V \supseteq F \text { and } V \text { is open }\}
\end{aligned}
$$

A complete measure, finite on compact sets, which is regular as above, is called a Radon measure. A set is called an $F_{\sigma}$ set if it is the countable union of closed sets and a set is $G_{\delta}$ if it is the countable intersection of open sets. If $K$ is compact and $V$ is open, we say $K \prec \phi \prec V$ if $\phi$ is continuous, has values in $[0,1], \phi(x)=1$ for all $x \in K$, and $\overline{\{x: \phi(x) \neq 0\}}$ called $\operatorname{spt}(\phi)$ is contained in $V$.

Remarkable things happen in the above context. Some are described in the following proposition. First is a lemma.

Lemma 11.7.2 Let $(\Omega, d)$ be a metric space in which closed balls are compact. Then if $K$ is a compact subset of an open set $V$, then there exists $\phi$ such that $K \prec \phi \prec V$.

Proof: Since $K$ is compact, the distance between $K$ and $V^{C}$ is positive, $\delta>0$. Otherwise there would be $x_{n} \in K$ and $y_{n} \in V^{C}$ with $d\left(x_{n}, y_{n}\right)<1 / n$. Taking a subsequence, still denoted with $n$, we can assume $x_{n} \rightarrow x$ and $y_{n} \rightarrow x$ but this would imply $x$ is in both $K$ and $V^{C}$ which is not possible. Now consider $\{B(x, \delta / 2)\}$ for $x \in K$. This is an open cover and the closure of each ball is contained in $V$. Since $K$ is compact, finitely many of these balls cover $K$. Denote their union as $W$. Then $\bar{W}$ is compact because it is the finite union of the closed balls. Hence $K \subseteq W \subseteq \bar{W} \subseteq V$. Now consider

$$
\phi(x) \equiv \frac{\operatorname{dist}\left(x, W^{C}\right)}{\operatorname{dist}(x, K)+\operatorname{dist}\left(x, W^{C}\right)}
$$

the denominator is never zero because $x$ cannot be in both $K$ and $W^{C}$. Thus $\phi$ is continuous because the denominator is never 0 and the functions of $x$ are continuous. Also if $x \in K$, then $\phi(x)=1$ and if $x \notin W$, then $\phi(x)=0$.

Proposition 11.7.3 Suppose $(X, d)$ is a metric space in which the balls are compact and $X$ is a countable union of closed balls. Also suppose $(X, \mathscr{F}, \mu)$ is a complete measure space, $\mathscr{F}$ contains the Borel sets, and that $\mu$ is regular and finite on finite balls. Then

1. For each $E \in \mathscr{F}$, there is an $F_{\sigma}$ set $F$ and $a G_{\delta}$ set $G$ such that $F \subseteq E \subseteq G$ and $\mu(G \backslash F)=0$.
2. Also if $f \geq 0$ is $\mathscr{F}$ measurable, then there exists $g \leq f$ such that $g$ is Borel measurable and $g=f$ a.e. and $h \geq f$ such that $h$ is Borel measurable and $h=f$ a.e.
3. If $E \in \mathscr{F}$ is a bounded set contained in a ball $B\left(x_{0}, r\right)=V$, then there exists $a$ sequence of continuous functions in $C_{c}(V)\left\{h_{n}\right\}$ having values in $[0,1]$ and a set of measure zero $N$ such that for $x \notin N, h_{n}(x) \rightarrow \mathscr{X}_{E}(x)$. Also $\int\left|h_{n}-\mathscr{X}_{E}\right| d \mu \rightarrow 0$. Letting $\tilde{N}$ be a $G_{\delta}$ set of measure zero containing $N, h_{n} \mathscr{X}_{\tilde{N}^{C}} \rightarrow \mathscr{X}_{F}$ where $F \subseteq E$ and $\mu(E \backslash F)=0$.
4. If $f \in L^{1}(X, \mathscr{F}, \mu)$, there exists $g \in C_{c}(X)$, such that $\int_{X}|f-g| d \mu<\varepsilon$. There also exists a sequence of functions in $C_{c}(X)\left\{g_{n}\right\}$ which converges pointwise to $f$.

Proof: 1. Let $R_{n} \equiv B\left(x_{0}, n\right), R_{0}=\emptyset$. If $E$ is Lebesgue measurable, let $E_{n} \equiv E \cap$ $\left(R_{n} \backslash R_{n-1}\right)$. Thus these $E_{n}$ are disjoint and their union is $E$. By outer regularity, there exists open $U_{n} \supseteq E_{n}$ such that $\mu\left(U_{n} \backslash E_{n}\right)<\varepsilon / 2^{n}$. Now if $U \equiv \cup_{n} U_{n}$, it follows that $\mu(U \backslash E) \leq \sum_{n=1}^{\infty} \frac{\varepsilon}{2^{n}}=\varepsilon$. Let $V_{n}$ be open, containing $E$ and $\mu\left(V_{n} \backslash E\right)<\frac{1}{2^{n}}, V_{n} \supseteq V_{n+1}$. Let $G \equiv \cap_{n} V_{n}$. This is a $G_{\delta}$ set containing $E$ and $\mu(G \backslash E) \leq \mu\left(V_{n} \backslash E\right)<\frac{1}{2^{n}}$ and so $\mu(G \backslash E)=0$. By inner regularity, there is $F_{n}$ an $F_{\sigma}$ set contained in $E_{n}$ with $\mu\left(E_{n} \backslash F_{n}\right)=0$. Then let $F \equiv \cup_{n} F_{n}$. This is an $F_{\sigma}$ set and $\mu(E \backslash F) \leq \sum_{n} \mu\left(E_{n} \backslash F_{n}\right)=0$. Thus $F \subseteq E \subseteq G$ and $\mu(G \backslash F) \leq \mu(G \backslash E)+\mu(E \backslash F)=0$.
2. If $f$ is measurable and nonnegative, there is an increasing sequence of simple functions $s_{n}$ such that $\lim _{n \rightarrow \infty} s_{n}(x)=f(x)$. Say $\sum_{k=1}^{m_{n}} c_{k}^{n} \mathscr{X}_{E_{k}^{n}}(x)$. Let $m_{p}\left(E_{k}^{n} \backslash F_{k}^{n}\right)=0$ where $F_{k}^{n}$ is an $F_{\sigma}$ set. Replace $E_{k}^{n}$ with $F_{k}^{n}$ and let $\tilde{s}_{n}$ be the resulting simple function. Let $g(x) \equiv \lim _{n \rightarrow \infty} \tilde{S}_{n}(x)$. Then $g$ is Borel measurable and $g \leq f$ and $g=f$ except for a set of measure zero, the union of the sets where $s_{n}$ is not equal to $\tilde{s}_{n}$. As to the other claim, let $h_{n}(x) \equiv \sum_{k=1}^{\infty} \mathscr{X}_{A_{k n}}(x) \frac{k}{2^{n}}$ where $A_{k n}$ is a $G_{\delta}$ set containing $f^{-1}\left(\left(\frac{k-1}{2^{n}}, \frac{k}{2^{n}}\right]\right)$ for which $\mu\left(A_{k n} \backslash f^{-1}\left(\left(\frac{k-1}{2^{n}}, \frac{k}{2^{n}}\right]\right)\right) \equiv \mu\left(D_{k n}\right)=0$. If $N=\cup_{k, n} D_{k n}$, then $N$ is a set of measure zero. On $N^{C}, h_{n}(x) \rightarrow f(x)$. Let $h(x)=\liminf _{n \rightarrow \infty} h_{n}(x)$.
3. Let $K_{n} \subseteq E \subseteq V_{n}$ with $K_{n}$ compact and $V_{n}$ open such that $V_{n} \subseteq B\left(x_{0}, r\right)$ and

$$
\mu\left(V_{n} \backslash K_{n}\right)<2^{-(n+1)}
$$

Then from Lemma 11.7.2, there exists $h_{n}$ with $K_{n} \prec h_{n} \prec V_{n}$. Then $\int\left|h_{n}-\mathscr{X}_{E}\right| d \mu<2^{-n}$ and so

$$
\mu\left(\left|h_{n}-\mathscr{X}_{E}\right|>\left(\frac{2}{3}\right)^{n}\right)<\left(\left(\frac{3}{2}\right)^{n} \int_{\left[\left|h_{n}-\mathscr{X}_{E}\right|>\left(\frac{2}{3}\right)^{n}\right]}\left|h_{n}-\mathscr{X}_{E}\right| d \mu\right) \leq\left(\frac{3}{4}\right)^{n}
$$

Letting $A_{n} \equiv\left[\left|h_{n}-\mathscr{X}_{E}\right|>\left(\frac{2}{3}\right)^{n}\right]$, the set of $x$ which is in infinitely many $A_{n}$ is $N \equiv \cap_{n} \cup_{k \geq n}$ $A_{k}$ and so

$$
\mu\left(\cap_{n} \cup_{k \geq n} A_{k}\right) \leq \mu\left(\cup_{k \geq n} A_{k}\right) \leq \sum_{k=n}^{\infty}\left(\frac{3}{4}\right)^{k}=\left(\frac{3}{4}\right)^{n}\left(\frac{1}{1 / 4}\right)
$$

and since $n$ is arbitrary the set of $x$ in infinitely many $A_{n}$ called $N$ has measure zero. Thus if $x \notin N$, it is in only finitely many of the sets $\left\{\left|h_{n}-\mathscr{X}_{E}\right|>\left(\frac{2}{3}\right)^{n}\right\}$. Thus on $N^{C}$, eventually, for all $k$ large enough, $\left|h_{k}-\mathscr{X}_{E}\right| \leq\left(\frac{2}{3}\right)^{k}$ so $h_{k}(x) \rightarrow \mathscr{X}_{E}(x)$ off $N$. The assertion about convergence of the integrals follows from the dominated convergence theorem and the fact that each $h_{n}$ is nonnegative, bounded by 1 , and is 0 off some ball. In the last claim, it only remains to verify that $h_{n} \mathscr{X}_{\tilde{N}^{c}}$ converges to an indicator function because each $h_{n} \mathscr{X}_{\tilde{N}^{c}}$ is Borel measurable. Thus its limit will also be Borel measurable. However, it converges to 1 on $E \cap \tilde{N}^{C}, 0$ on $E^{C} \cap \tilde{N}^{C}$ and 0 on $\tilde{N}$. Thus $E \cap \tilde{N}^{C}=F$ and $h_{n} \mathscr{X}_{\tilde{N}^{C}}(x) \rightarrow \mathscr{X}_{F}$ where $F \subseteq E$ and $\mu(E \backslash F) \leq \mu(\tilde{N})=0$.
4. It suffices to assume $f \geq 0$ because you can consider the positive and negative parts of the real and imaginary parts of $f$ and reduce to this case. Let $f_{n}(x) \equiv \mathscr{X}_{B\left(x_{0}, n\right)}(x) f(x)$. Then by the dominated convergence theorem, if $n$ is large enough, $\int\left|f-f_{n}\right| d \mu<\varepsilon$. There is a nonnegative simple function $s \leq f_{n}$ such that $\int\left|f_{n}-s\right| d \mu<\varepsilon$. This follows from picking $k$ large enough in an increasing sequence of simple functions $\left\{s_{k}\right\}$ converging to $f_{n}$ and the monotone or dominated convergence theorem. Say $s(x)=\sum_{k=1}^{m} c_{k} \mathscr{X}_{E_{k}}(x)$. Then let $K_{k} \subseteq E_{k} \subseteq V_{k}$ where $K_{k}, V_{k}$ are compact and open respectively and $\sum_{k=1}^{m} c_{k} \mu\left(V_{k} \backslash K_{k}\right)<\varepsilon$. By Lemma 11.7.2, there exists $h_{k}$ with $K_{k} \prec h_{k} \prec V_{k}$. Then

$$
\begin{aligned}
\int\left|\sum_{k=1}^{m} c_{k} \mathscr{X}_{E_{k}}(x)-\sum_{k=1}^{m} c_{k} h_{k}(x)\right| d \mu & \leq \sum_{k} c_{k} \int\left|\mathscr{X}_{E_{k}}(x)-h_{k}(x)\right| d x \\
& <2 \sum_{k} c_{k} \mu\left(V_{k} \backslash K_{k}\right)<2 \varepsilon
\end{aligned}
$$

Let $g \equiv \sum_{k=1}^{m} c_{k} h_{k}(x)$. Thus $\int|s-g| d \mu \leq 2 \varepsilon$. Then

$$
\int|f-g| d \mu \leq \int\left|f-f_{n}\right| d \mu+\int\left|f_{n}-s\right| d \mu+\int|s-g| d \mu<4 \varepsilon
$$

Since $\varepsilon$ is arbitrary, this proves the first part of 4 . For the second part, let $g_{n} \in C_{c}(X)$ such that $\int\left|f-g_{n}\right| d \mu<2^{-n}$. Let $A_{n} \equiv\left\{x:\left|f-g_{n}\right|>\left(\frac{2}{3}\right)^{n}\right\}$. Then

$$
\mu\left(A_{n}\right) \leq\left(\frac{3}{2}\right)^{n} \int_{A_{n}}\left|f-g_{n}\right| d \mu \leq\left(\frac{3}{4}\right)^{n}
$$

Thus, if $N$ is all $x$ in infinitely many $A_{n}$, then by the Borel Cantelli lemma, $\mu(N)=0$ and if $x \notin N$, then $x$ is in only finitely many $A_{n}$ and so for all $n$ large enough, $\left|f(x)-g_{n}(x)\right| \leq$ $\left(\frac{2}{3}\right)^{n}$.

### 11.8 Exercises

1. Let $\Omega=\mathbb{N}=\{1,2, \cdots\}$ and $\mu(S)=$ number of elements in $S$. If

$$
f: \Omega \rightarrow \mathbb{C}
$$

what is meant by $\int f d \mu$ ? Which functions are in $L^{1}(\Omega)$ ? Which functions are measurable?
2. Show that for $f \geq 0$ and measurable, $\int f d \mu \equiv \lim _{h \rightarrow 0+} \sum_{i=1}^{\infty} h \mu([i h<f])$.
3. For the measure space of Problem 1, give an example of a sequence of nonnegative measurable functions $\left\{f_{n}\right\}$ converging pointwise to a function $f$, such that inequality is obtained in Fatou's lemma.
4. Fill in all the details of the proof of Lemma 11.5.2.
5. Let $\sum_{i=1}^{n} c_{i} \mathscr{X}_{E_{i}}(\omega)=s(\omega)$ be a nonnegative simple function for which the $c_{i}$ are the distinct nonzero values. Show with the aid of the monotone convergence theorem that the two definitions of the Lebesgue integral given in the chapter are equivalent.
6. Suppose $(\Omega, \mu)$ is a finite measure space and $\mathfrak{S} \subseteq L^{1}(\Omega)$. Show $\mathfrak{S}$ is uniformly integrable and bounded in $L^{1}(\Omega)$ if there exists an increasing function $h$ which satisfies

$$
\lim _{t \rightarrow \infty} \frac{h(t)}{t}=\infty, \sup \left\{\int_{\Omega} h(|f|) d \mu: f \in \mathfrak{S}\right\}<\infty
$$

$\mathfrak{S}$ is bounded if there is some number, $M$ such that

$$
\int|f| d \mu \leq M
$$

for all $f \in \mathfrak{S}$.
7. Let $\left\{a_{n}\right\},\left\{b_{n}\right\}$ be sequences in $[-\infty, \infty]$ and $a \in \mathbb{R}$. Show

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left(a-a_{n}\right)=a-\lim \sup _{n \rightarrow \infty} a_{n} .
$$

This was used in the proof of the Dominated convergence theorem. Also show

$$
\begin{gathered}
\lim \sup _{n \rightarrow \infty}\left(-a_{n}\right)=-\lim \inf _{n \rightarrow \infty}\left(a_{n}\right) \\
\lim \sup _{n \rightarrow \infty}\left(a_{n}+b_{n}\right) \leq \lim \sup _{n \rightarrow \infty} a_{n}+\lim \sup _{n \rightarrow \infty} b_{n}
\end{gathered}
$$

provided no sum is of the form $\infty-\infty$. Also show strict inequality can hold in the inequality. State and prove corresponding statements for liminf.
8. Let $(\Omega, \mathscr{F}, \mu)$ be a measure space and suppose $f, g: \Omega \rightarrow(-\infty, \infty]$ are measurable. Prove the sets

$$
\{\omega: f(\omega)<g(\omega)\} \text { and }\{\omega: f(\omega)=g(\omega)\}
$$

are measurable. Hint: The easy way to do this is to write

$$
\{\omega: f(\omega)<g(\omega)\}=\cup_{r \in \mathbb{Q}}[f<r] \cap[g>r] .
$$

Note that $l(x, y)=x-y$ is not continuous on $(-\infty, \infty]$ so the obvious idea doesn't work.
9. Let $\left\{f_{n}\right\}$ be a sequence of real or complex valued measurable functions. Let

$$
S=\left\{\omega:\left\{f_{n}(\omega)\right\} \text { converges }\right\}
$$

Show $S$ is measurable. Hint: You might try to exhibit the set where $f_{n}$ converges in terms of countable unions and intersections using the definition of a Cauchy sequence.
10. Let $(\Omega, \mathscr{S}, \mu)$ be a measure space and let $f$ be a nonnegative measurable function defined on $\Omega$. Also let $\phi:[0, \infty) \rightarrow[0, \infty)$ be strictly increasing and have a continuous derivative and $\phi(0)=0$. Suppose $f$ is bounded and that $0 \leq \phi(f(\omega)) \leq M$ for some number, $M$. Show that

$$
\int_{\Omega} \phi(f) d \mu=\int_{0}^{\infty} \phi^{\prime}(s) \mu([s<f]) d s
$$

where the integral on the right is the ordinary improper Riemann integral. Hint: First note that $s \rightarrow \phi^{\prime}(s) \mu([s<f])$ is Riemann integrable because $\phi^{\prime}$ is continuous and $s \rightarrow \mu([s<f])$ is a nonincreasing function, hence Riemann integrable. From the second description of the Lebesgue integral and the assumption that $\phi(f(\omega)) \leq M$, argue that for $[M / h]$ the greatest integer less than $M / h$,

$$
\begin{aligned}
\int_{\Omega} \phi(f) d \mu & =\sup _{h>0}^{[M / h]} \sum_{i=1}^{[M \mu([i h<\phi(f)])} \\
& =\sup _{h>0}^{[M / h]} \sum_{i=1}^{\left[M \mu\left(\left[\phi^{-1}(i h)<f\right]\right)\right.} \\
& =\sup _{h>0} \sum_{i=1}^{[M / h]} \frac{h \Delta_{i}}{\Delta_{i}} \mu\left(\left[\phi^{-1}(i h)<f\right]\right)
\end{aligned}
$$

where $\Delta_{i}=\left(\phi^{-1}(i h)-\phi^{-1}((i-1) h)\right)$. Now use the mean value theorem to write

$$
\begin{aligned}
\Delta_{i} & =\left(\phi^{-1}\right)^{\prime}\left(t_{i}\right) h \\
& =\frac{1}{\phi^{\prime}\left(\phi^{-1}\left(t_{i}\right)\right)} h
\end{aligned}
$$

for some $t_{i}$ between $(i-1) h$ and $i h$. Therefore, the right side is of the form

$$
\sup _{h} \sum_{i=1}^{[M / h]} \phi^{\prime}\left(\phi^{-1}\left(t_{i}\right)\right) \Delta_{i} \mu\left(\left[\phi^{-1}(i h)<f\right]\right)
$$

where $\phi^{-1}\left(t_{i}\right) \in\left(\phi^{-1}((i-1) h), \phi^{-1}(i h)\right)$. Argue that if $t_{i}$ were replaced with $i h$, this would be a Riemann sum for the Riemann integral

$$
\int_{0}^{\phi^{-1}(M)} \phi^{\prime}(t) \mu([t<f]) d t=\int_{0}^{\infty} \phi^{\prime}(t) \mu([t<f]) d t
$$

11. Let $(\Omega, \mathscr{F}, \mu)$ be a measure space and suppose $f_{n}$ converges uniformly to $f$ and that $f_{n}$ is in $L^{1}(\Omega)$. When is

$$
\lim _{n \rightarrow \infty} \int f_{n} d \mu=\int f d \mu ?
$$

12. Suppose $u_{n}(t)$ is a differentiable function for $t \in(a, b)$ and suppose that for $t \in(a, b)$,

$$
\left|u_{n}(t)\right|,\left|u_{n}^{\prime}(t)\right|<K_{n}
$$

where $\sum_{n=1}^{\infty} K_{n}<\infty$. Show

$$
\left(\sum_{n=1}^{\infty} u_{n}(t)\right)^{\prime}=\sum_{n=1}^{\infty} u_{n}^{\prime}(t)
$$

Hint: This is an exercise in the use of the dominated convergence theorem and the mean value theorem.
13. Show that $\left\{\sum_{i=1}^{\infty} 2^{-n} \mu\left(\left[i 2^{-n}<f\right]\right)\right\}$ for $f$ a nonnegative measurable function is an increasing sequence. Could you define

$$
\int f d \mu \equiv \lim _{n \rightarrow \infty} \sum_{i=1}^{\infty} 2^{-n} \mu\left(\left[i 2^{-n}<f\right]\right)
$$

and would it be equivalent to the above definitions of the Lebesgue integral?
14. Suppose $\left\{f_{n}\right\}$ is a sequence of nonnegative measurable functions defined on a measure space, $(\Omega, \mathscr{S}, \mu)$. Show that

$$
\int \sum_{k=1}^{\infty} f_{k} d \mu=\sum_{k=1}^{\infty} \int f_{k} d \mu
$$

Hint: Use the monotone convergence theorem along with the fact the integral is linear.

## Chapter 12

## The Construction Of Measures

### 12.1 Outer Measures

What are some examples of measure spaces? In this chapter, a general procedure is discussed called the method of outer measures. It is due to Caratheodory (1918). This approach shows how to obtain measure spaces starting with an outer measure. This will then be used to construct measures determined by positive linear functionals.

Definition 12.1.1 Let $\Omega$ be a nonempty set and let $\mu: \mathscr{P}(\Omega) \rightarrow[0, \infty]$ satisfy

$$
\begin{gathered}
\mu(\emptyset)=0, \\
\text { If } A \subseteq B, \text { then } \mu(A) \leq \mu(B), \\
\mu\left(\cup_{i=1}^{\infty} E_{i}\right) \leq \sum_{i=1}^{\infty} \mu\left(E_{i}\right) .
\end{gathered}
$$

Such a function is called an outer measure. For $E \subseteq \Omega, E$ is $\mu$ measurable if for all $S \subseteq \Omega$,

$$
\begin{equation*}
\mu(S)=\mu(S \backslash E)+\mu(S \cap E) \tag{12.1.1}
\end{equation*}
$$

To help in remembering 12.1.1, think of a measurable set, $E$, as a process which divides a given set into two pieces, the part in $E$ and the part not in $E$ as in 12.1.1. In the Bible, there are four incidents recorded in which a process of division resulted in more stuff than was originally present. ${ }^{1}$ Measurable sets are exactly those for which no such miracle occurs. You might think of the measurable sets as the nonmiraculous sets. The idea is to show that they form a $\sigma$ algebra on which the outer measure, $\mu$ is a measure.

First here is a definition and a lemma.
Definition 12.1.2 $(\mu\lfloor S)(A) \equiv \mu(S \cap A)$ for all $A \subseteq \Omega$. Thus $\mu\lfloor S$ is the name of a new outer measure, called $\mu$ restricted to $S$.

The next lemma indicates that the property of measurability is not lost by considering this restricted measure.

Lemma 12.1.3 If $A$ is $\mu$ measurable, then $A$ is $\mu\lfloor S$ measurable.
Proof: Suppose $A$ is $\mu$ measurable. It is desired to to show that for all $T \subseteq \Omega$,

$$
(\mu\lfloor S)(T)=(\mu\lfloor S)(T \cap A)+(\mu\lfloor S)(T \backslash A)
$$

[^10]Thus it is desired to show

$$
\begin{equation*}
\mu(S \cap T)=\mu(T \cap A \cap S)+\mu\left(T \cap S \cap A^{C}\right) \tag{12.1.2}
\end{equation*}
$$

But 12.1.2 holds because $A$ is $\mu$ measurable. Apply Definition 12.1.1 to $S \cap T$ instead of $S$.
If $A$ is $\mu\lfloor S$ measurable, it does not follow that $A$ is $\mu$ measurable. Indeed, if you believe in the existence of non measurable sets, you could let $A=S$ for such a $\mu$ non measurable set and verify that $S$ is $\mu\lfloor S$ measurable.

The next theorem is the main result on outer measures. It is a very general result which applies whenever one has an outer measure on the power set of any set. This theorem will be referred to as Caratheodory's procedure in the rest of the book.

Theorem 12.1.4 The collection of $\mu$ measurable sets, $\mathscr{S}$, forms a $\sigma$ algebra and

$$
\begin{equation*}
\text { If } F_{i} \in \mathscr{S}, F_{i} \cap F_{j}=\emptyset, \text { then } \mu\left(\cup_{i=1}^{\infty} F_{i}\right)=\sum_{i=1}^{\infty} \mu\left(F_{i}\right) \tag{12.1.3}
\end{equation*}
$$

If $\cdots F_{n} \subseteq F_{n+1} \subseteq \cdots$, then if $F=\cup_{n=1}^{\infty} F_{n}$ and $F_{n} \in \mathscr{S}$, it follows that

$$
\begin{equation*}
\mu(F)=\lim _{n \rightarrow \infty} \mu\left(F_{n}\right) \tag{12.1.4}
\end{equation*}
$$

If $\cdots F_{n} \supseteq F_{n+1} \supseteq \cdots$, and if $F=\cap_{n=1}^{\infty} F_{n}$ for $F_{n} \in \mathscr{S}$ then if $\mu\left(F_{1}\right)<\infty$,

$$
\begin{equation*}
\mu(F)=\lim _{n \rightarrow \infty} \mu\left(F_{n}\right) \tag{12.1.5}
\end{equation*}
$$

Also, $(\mathscr{S}, \mu)$ is complete. By this it is meant that if $F \in \mathscr{S}$ and if $E \subseteq \Omega$ with $\mu(E \backslash F)+$ $\mu(F \backslash E)=0$, then $E \in \mathscr{S}$.

Proof: First note that $\emptyset$ and $\Omega$ are obviously in $\mathscr{S}$. Now suppose $A, B \in \mathscr{S}$. I will show $A \backslash B \equiv A \cap B^{C}$ is in $\mathscr{S}$. To do so, consider the following picture.

Since $\mu$ is subadditive,

$$
\mu(S) \leq \mu\left(S \cap A \cap B^{C}\right)+\mu(A \cap B \cap S)+\mu\left(S \cap B \cap A^{C}\right)+\mu\left(S \cap A^{C} \cap B^{C}\right)
$$

Now using $A, B \in \mathscr{S}$,

$$
\begin{aligned}
\mu(S) & \leq \mu\left(S \cap A \cap B^{C}\right)+\mu(S \cap A \cap B)+\mu\left(S \cap A^{C} \cap B\right)+\mu\left(S \cap A^{C} \cap B^{C}\right) \\
& =\mu(S \cap A)+\mu\left(S \cap A^{C}\right)=\mu(S)
\end{aligned}
$$

It follows equality holds in the above. Now observe using the picture if you like that

$$
(A \cap B \cap S) \cup\left(S \cap B \cap A^{C}\right) \cup\left(S \cap A^{C} \cap B^{C}\right)=S \backslash(A \backslash B)
$$

and therefore,

$$
\begin{aligned}
\mu(S) & =\mu\left(S \cap A \cap B^{C}\right)+\mu(A \cap B \cap S)+\mu\left(S \cap B \cap A^{C}\right)+\mu\left(S \cap A^{C} \cap B^{C}\right) \\
& \geq \mu(S \cap(A \backslash B))+\mu(S \backslash(A \backslash B))
\end{aligned}
$$

Therefore, since $S$ is arbitrary, this shows $A \backslash B \in \mathscr{S}$.
Since $\Omega \in \mathscr{S}$, this shows that $A \in \mathscr{S}$ if and only if $A^{C} \in \mathscr{S}$. Now if $A, B \in \mathscr{S}, A \cup B=$ $\left(A^{C} \cap B^{C}\right)^{C}=\left(A^{C} \backslash B\right)^{C} \in \mathscr{S}$. By induction, if $A_{1}, \cdots, A_{n} \in \mathscr{S}$, then so is $\cup_{i=1}^{n} A_{i}$. If $A, B \in \mathscr{S}$, with $A \cap B=\emptyset$,

$$
\mu(A \cup B)=\mu((A \cup B) \cap A)+\mu((A \cup B) \backslash A)=\mu(A)+\mu(B)
$$

By induction, if $A_{i} \cap A_{j}=\emptyset$ and $A_{i} \in \mathscr{S}, \mu\left(\cup_{i=1}^{n} A_{i}\right)=\sum_{i=1}^{n} \mu\left(A_{i}\right)$.

Now let $A=\cup_{i=1}^{\infty} A_{i}$ where $A_{i} \cap A_{j}=\emptyset$ for $i \neq j$.

$$
\sum_{i=1}^{\infty} \mu\left(A_{i}\right) \geq \mu(A) \geq \mu\left(\cup_{i=1}^{n} A_{i}\right)=\sum_{i=1}^{n} \mu\left(A_{i}\right) .
$$

Since this holds for all $n$, you can take the limit as $n \rightarrow \infty$ and conclude,

$$
\sum_{i=1}^{\infty} \mu\left(A_{i}\right)=\mu(A)
$$

which establishes 12.1.3. Part 12.1.4 follows from part 12.1 .3 just as in the proof of Theorem 11.1.5 on Page 224. That is, letting $F_{0} \equiv \emptyset$, use part 12.1.3 to write

$$
\begin{aligned}
\mu(F) & =\mu\left(\cup_{k=1}^{\infty}\left(F_{k} \backslash F_{k-1}\right)\right)=\sum_{k=1}^{\infty} \mu\left(F_{k} \backslash F_{k-1}\right) \\
& =\lim _{n \rightarrow \infty} \sum_{k=1}^{n}\left(\mu\left(F_{k}\right)-\mu\left(F_{k-1}\right)\right)=\lim _{n \rightarrow \infty} \mu\left(F_{n}\right)
\end{aligned}
$$

In order to establish 12.1.5, let the $F_{n}$ be as given there. Then from what was just shown,

$$
\mu\left(F_{1} \backslash F_{n}\right)+\mu\left(F_{n}\right)=\mu\left(F_{1}\right)
$$

Then, since $\left(F_{1} \backslash F_{n}\right)$ increases to $\left(F_{1} \backslash F\right)$, 12.1.4 implies

$$
\lim _{n \rightarrow \infty}\left(\mu\left(F_{1} \backslash F_{n}\right)\right)=\lim _{n \rightarrow \infty}\left(\mu\left(F_{1}\right)-\mu\left(F_{n}\right)\right)=\mu\left(F_{1} \backslash F\right)
$$

Now I don't know whether $F \in \mathscr{S}$ and so all that can be said is that

$$
\mu\left(F_{1} \backslash F\right)+\mu(F) \geq \mu\left(F_{1}\right)
$$

but this implies

$$
\mu\left(F_{1} \backslash F\right) \geq \mu\left(F_{1}\right)-\mu(F)
$$

Hence

$$
\lim _{n \rightarrow \infty}\left(\mu\left(F_{1}\right)-\mu\left(F_{n}\right)\right)=\mu\left(F_{1} \backslash F\right) \geq \mu\left(F_{1}\right)-\mu(F)
$$

which implies

$$
\lim _{n \rightarrow \infty} \mu\left(F_{n}\right) \leq \mu(F)
$$

But since $F \subseteq F_{n}$,

$$
\mu(F) \leq \lim _{n \rightarrow \infty} \mu\left(F_{n}\right)
$$

and this establishes 12.1.5. Note that it was assumed $\mu\left(F_{1}\right)<\infty$ because $\mu\left(F_{1}\right)$ was subtracted from both sides.

It remains to show $\mathscr{S}$ is closed under countable unions. Recall that if $A \in \mathscr{S}$, then $A^{C} \in \mathscr{S}$ and $\mathscr{S}$ is closed under finite unions. Let $A_{i} \in \mathscr{S}, A=\cup_{i=1}^{\infty} A_{i}, B_{n}=\cup_{i=1}^{n} A_{i}$. Then

$$
\begin{align*}
\mu(S) & =\mu\left(S \cap B_{n}\right)+\mu\left(S \backslash B_{n}\right)  \tag{12.1.6}\\
& =\left(\mu\lfloor S)\left(B_{n}\right)+\left(\mu\lfloor S)\left(B_{n}^{C}\right)\right.\right.
\end{align*}
$$

By Lemma 12.1.3 $B_{n}$ is $\left(\mu\lfloor S)\right.$ measurable and so is $B_{n}^{C}$. I want to show $\mu(S) \geq \mu(S \backslash A)+$ $\mu(S \cap A)$. If $\mu(S)=\infty$, there is nothing to prove. Assume $\mu(S)<\infty$. Then apply Parts 12.1.5 and 12.1.4 to the outer measure, $\mu\lfloor S$ in 12.1.6 and let $n \rightarrow \infty$. Thus

$$
B_{n} \uparrow A, B_{n}^{C} \downarrow A^{C}
$$

and this yields

$$
\mu(S)=\left(\mu\lfloor S)(A)+\left(\mu\lfloor S)\left(A^{C}\right)=\mu(S \cap A)+\mu(S \backslash A)\right.\right.
$$

Therefore $A \in \mathscr{S}$ and this proves Parts 12.1.3, 12.1.4, and 12.1.5. It remains to prove the last assertion about the measure being complete.

Let $F \in \mathscr{S}$ and let $\mu(E \backslash F)+\mu(F \backslash E)=0$. Consider the following picture.

Then referring to this picture and using $F \in \mathscr{S}$,

$$
\begin{aligned}
\mu(S) & \leq \mu(S \cap E)+\mu(S \backslash E) \\
& \leq \mu(S \cap E \cap F)+\mu((S \cap E) \backslash F)+\mu(S \backslash F)+\mu(F \backslash E) \\
& \leq \mu(S \cap F)+\mu(E \backslash F)+\mu(S \backslash F)+\mu(F \backslash E) \\
& =\mu(S \cap F)+\mu(S \backslash F)=\mu(S)
\end{aligned}
$$

Hence $\mu(S)=\mu(S \cap E)+\mu(S \backslash E)$ and so $E \in \mathscr{S}$. This shows that $(\mathscr{S}, \mu)$ is complete and proves the theorem.

Completeness usually occurs in the following form. $E \subseteq F \in \mathscr{S}$ and $\mu(F)=0$. Then $E \in \mathscr{S}$.

Proposition 12.1.5 Let $(\Omega, \mathscr{F}, \mu)$ be a measure space. Let $\bar{\mu}$ be the outer measure determined by $\mu$. Also denote as $\overline{\mathscr{F}}$, the $\sigma$ algebra of $\bar{\mu}$ measurable sets. Thus $(\Omega, \overline{\mathscr{F}}, \bar{\mu})$ is a complete measure space in which $\overline{\mathscr{F}} \supseteq \mathscr{F}$ and $\bar{\mu}=\mu$ on $\mathscr{F}$. Also, in this situation, if $\bar{\mu}(E)=0$, then $E \in \mathscr{\mathscr { F }}$. No new sets are obtained if $(\Omega, \mathscr{F}, \mu)$ is already complete.

Proof: All that remains to show is the last claim. But this is obvious because if $S$ is a set,

$$
\begin{aligned}
\bar{\mu}(S) & \leq \bar{\mu}(S \cap E)+\bar{\mu}(S \backslash E) \\
& \leq \bar{\mu}(E)+\bar{\mu}(S \backslash E) \\
& =\bar{\mu}(S \backslash E) \leq \bar{\mu}(S)
\end{aligned}
$$

and so all inequalities are equal signs.

Suppose now that $(\Omega, \mathscr{F}, \mu)$ is complete. Let $F \in \overline{\mathscr{F}}$. Then there exists $E \supseteq F$ such that $\mu(E)=\bar{\mu}(F)$. This is obvious if $\bar{\mu}(F)=\infty$. Otherwise, let $E_{n} \supseteq F, \bar{\mu}(F)+\frac{1}{n}>\mu\left(E_{n}\right)$. Just let $E=\cap_{n} E_{n}$. Now $\bar{\mu}(E \backslash F)=0$. Now also, there exists a set of $\mathscr{F}$ called $W$ such that $\mu(W)=0$ and $W \supseteq E \backslash F$. Thus $E \backslash F \subseteq W$, a set of measure zero. Hence by completeness of $(\Omega, \mathscr{F}, \mu)$, it must be the case that $E \backslash F=E \cap F^{C}=G \in \mathscr{F}$. Then taking complements of both sides, $E^{C} \cup F=G^{C} \in \mathscr{F}$. Now take intersections with $E . F \in E \cap G^{C} \in \mathscr{F}$.

In the case of a Hausdorff topological space, the following lemma gives conditions under which the $\sigma$ algebra of $\mu$ measurable sets for an outer measure $\mu$ contains the Borel sets. In words, it assumes the outer measure is inner regular on open sets and outer regular on all sets. Also it assumes you can approximate the measure of an open set with a compact set and the measure of a compact set with an open set.

Lemma 12.1.6 Let $\Omega$ be a Hausdorff space and suppose $\mu$ is an outer measure satisfying $\mu$ is finite on compact sets and the following conditions,

1. $\mu(E)=\inf \{\mu(V), V \supseteq E, V$ open $\}$ for all $E$. (Outer regularity.)
2. For every open set $V, \mu(V)=\sup \{\mu(K): K \subseteq V, K$ compact $\}$ (Inner regularity on open sets.)
3. If $A, B$ are compact disjoint sets, then $\mu(A \cup B)=\mu(A)+\mu(B)$.

Then the following hold.

1. If $\varepsilon>0$ and if $K$ is compact, there exists $V$ open such that $V \supseteq K$ and

$$
\mu(V \backslash K)<\varepsilon
$$

2. If $\varepsilon>0$ and if $V$ is open with $\mu(V)<\infty$, there exists a compact subset $K$ of $V$ such that

$$
\mu(V \backslash K)<\varepsilon
$$

3. Then the $\mu$ measurable sets $\mathscr{S}$ contain the Borel sets and also $\mu$ is inner regular on every open set and for every $E \in \mathscr{S}$ with $\mu(E)<\infty$. Here $\mathscr{S}$ consists of those subsets of $\Omega E$ with the property that for any subset $S$ of $\Omega$,

$$
\mu(S)=\mu(S \cap E)+\mu\left(S \cap E^{C}\right)
$$

Proof: First we establish 1 and 2 and use them to establish the last assertion. Consider 2. Suppose it is not true. Then there exists an open set $V$ having $\mu(V)<\infty$ but for all $K \subseteq V, \mu(V \backslash K) \geq \varepsilon$ for some $\varepsilon>0$. By inner regularity on open sets, there exists $K_{1} \subseteq$ $V, K_{1}$ compact, such that $\mu\left(K_{1}\right) \geq \varepsilon / 2$. Now by assumption, $\mu\left(V \backslash K_{1}\right) \geq \varepsilon$ and so by inner regularity on open sets again, there exists compact $K_{2} \subseteq V \backslash K_{1}$ such that $\mu\left(K_{2}\right) \geq \varepsilon / 2$. Continuing this way, there is a sequence of disjoint compact sets contained in $V\left\{K_{i}\right\}$ such that $\mu\left(K_{i}\right) \geq \varepsilon / 2$.

Now this is an obvious contradiction because by 3,

$$
\mu(V) \geq \mu\left(\cup_{i=1}^{n} K_{i}\right)=\sum_{i=1}^{n} \mu\left(K_{i}\right) \geq n \frac{\varepsilon}{2}
$$

for each $n$, contradicting $\mu(V)<\infty$.
Next consider 1. By outer regularity, there exists an open set $W \supseteq K$ such that $\mu(W)<$ $\mu(K)+1$. By 2 , there exists compact $K_{1} \subseteq W \backslash K$ such that $\mu\left((W \backslash K) \backslash K_{1}\right)<\varepsilon$. Then consider $V \equiv W \backslash K_{1}$. This is an open set containing $K$ and from what was just shown,

$$
\mu\left(\left(W \backslash K_{1}\right) \backslash K\right)=\mu\left((W \backslash K) \backslash K_{1}\right)<\varepsilon .
$$

Now consider the last assertion.
Define

$$
\mathscr{S}_{1}=\{E \in \mathscr{P}(\Omega): E \cap K \in \mathscr{S}\}
$$

for all compact $K$.
First it will be shown the compact sets are in $\mathscr{S}$. From this it will follow the closed sets are in $\mathscr{S}_{1}$. Then you show $\mathscr{S}_{1}=\mathscr{S}$. Thus $\mathscr{S}_{1}=\mathscr{S}$ is a $\sigma$ algebra and so it contains the Borel sets. Finally you show the inner regularity assertion.

Claim 1: Compact sets are in $\mathscr{S}$.
Proof of claim: Let $V$ be an open set with $\mu(V)<\infty$. I will show that for $C$ compact,

$$
\mu(V) \geq \mu(V \backslash C)+\mu(V \cap C)
$$

Here is a diagram to help keep things straight.

By 2, there exists a compact set $K \subseteq V \backslash C$ such that

$$
\mu((V \backslash C) \backslash K)<\varepsilon
$$

and a compact set $H \subseteq V$ such that

$$
\mu(V \backslash H)<\varepsilon
$$

Thus $\mu(V) \leq \mu(V \backslash H)+\mu(H)<\varepsilon+\mu(H)$. Then

$$
\begin{gathered}
\mu(V) \leq \mu(H)+\varepsilon \leq \mu(H \cap C)+\mu(H \backslash C)+\varepsilon \\
\leq \mu(V \cap C)+\mu(V \backslash C)+\varepsilon \leq \mu(H \cap C)+\mu(K)+3 \varepsilon
\end{gathered}
$$

By 3,

$$
=\mu(H \cap C)+\mu(K)+3 \varepsilon=\mu((H \cap C) \cup K)+3 \varepsilon \leq \mu(V)+3 \varepsilon
$$

Since $\varepsilon$ is arbitrary, this shows that

$$
\begin{equation*}
\mu(V)=\mu(V \backslash C)+\mu(V \cap C) \tag{12.1.7}
\end{equation*}
$$

Of course 12.1 .7 is exactly what needs to be shown for arbitrary $S$ in place of $V$. It suffices to consider only $S$ having $\mu(S)<\infty$. If $S \subseteq \Omega$, with $\mu(S)<\infty$, let $V \supseteq S, \mu(S)+\varepsilon>$ $\mu(V)$. Then from what was just shown, if $C$ is compact,

$$
\begin{aligned}
\varepsilon+\mu(S) & >\mu(V)=\mu(V \backslash C)+\mu(V \cap C) \\
& \geq \mu(S \backslash C)+\mu(S \cap C) .
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this shows the compact sets are in $\mathscr{S}$. This proves the claim.
As discussed above, this verifies the closed sets are in $\mathscr{S}_{1}$ because if $H$ is closed and $C$ is compact, then $H \cap C \in \mathscr{S}$. If $\mathscr{S}_{1}$ is a $\sigma$ algebra, this will show that $\mathscr{S}_{1}$ contains the Borel sets. Thus I first show $\mathscr{S}_{1}$ is a $\sigma$ algebra.

To see that $\mathscr{S}_{1}$ is closed with respect to taking complements, let $E \in \mathscr{S}_{1}$ and $K$ a compact set.

$$
K=\left(E^{C} \cap K\right) \cup(E \cap K)
$$

Then from the fact, just established, that the compact sets are in $\mathscr{S}$,

$$
E^{C} \cap K=K \backslash(E \cap K) \in \mathscr{S} .
$$

$\mathscr{S}_{1}$ is closed under countable unions because if $K$ is a compact set and $E_{n} \in \mathscr{S}_{1}$,

$$
K \cap \cup_{n=1}^{\infty} E_{n}=\cup_{n=1}^{\infty} K \cap E_{n} \in \mathscr{S}
$$

because it is a countable union of sets of $\mathscr{S}$. Thus $\mathscr{S}_{1}$ is a $\sigma$ algebra.
Therefore, if $E \in \mathscr{S}$ and $K$ is a compact set, just shown to be in $\mathscr{S}$, it follows $K \cap E \in \mathscr{S}$ because $\mathscr{S}$ is a $\sigma$ algebra which contains the compact sets and so $\mathscr{S}_{1} \supseteq \mathscr{S}$. It remains to verify $\mathscr{S}_{1} \subseteq \mathscr{S}$. Recall that

$$
\mathscr{S}_{1} \equiv\{E: E \cap K \in \mathscr{S} \text { for all } K \text { compact }\}
$$

Let $E \in \mathscr{S}_{1}$ and let $V$ be an open set with $\mu(V)<\infty$ and choose $K \subseteq V$ such that $\mu(V \backslash K)<\varepsilon$. Then since $E \in \mathscr{S}_{1}$, it follows $E \cap K, E^{C} \cap K \in \mathscr{S}$ and so

$$
\begin{aligned}
\mu(V) & \leq \mu(V \backslash E)+\mu(V \cap E) \leq \overbrace{\mu(K \backslash E)+\mu(K \cap E)}^{\text {The two sets are disjoint and in } \mathscr{S}}+2 \varepsilon \\
& =\mu(K)+2 \varepsilon \leq \mu(V)+3 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this shows

$$
\mu(V)=\mu(V \backslash E)+\mu(V \cap E)
$$

which would show $E \in \mathscr{S}$ if $V$ were an arbitrary set.
Now let $S \subseteq \Omega$ be such an arbitrary set. If $\mu(S)=\infty$, then

$$
\mu(S)=\mu(S \cap E)+\mu(S \backslash E)
$$

If $\mu(S)<\infty$, let

$$
V \supseteq S, \mu(S)+\varepsilon \geq \mu(V)
$$

Then

$$
\mu(S)+\varepsilon \geq \mu(V)=\mu(V \backslash E)+\mu(V \cap E) \geq \mu(S \backslash E)+\mu(S \cap E)
$$

Since $\varepsilon$ is arbitrary, this shows that $E \in \mathscr{S}$ and so $\mathscr{S}_{1}=\mathscr{S}$. Thus $\mathscr{S} \supseteq$ Borel sets as claimed.

From $2 \mu$ is inner regular on all open sets. It remains to show that

$$
\mu(F)=\sup \{\mu(K): K \subseteq F\}
$$

for all $F \in \mathscr{S}$ with $\mu(F)<\infty$. It might help to refer to the following crude picture to keep things straight. It also might not help. I am not sure. In the picture, the green marks the boundary of $V$ while red marks $U$ and black marks $F$ and $V^{C} \cap K$. This last set is as shown because $K$ is a comnact subset of $U$ such that $u(U \backslash K)<\varepsilon$.

Let $\mu(F)<\infty$ and let $U$ be an open set, $U \supseteq F, \mu(U)<\infty$. Let $V$ be open, $V \supseteq U \backslash F$, and

$$
\mu(V \backslash(U \backslash F))<\varepsilon
$$

(This can be obtained as follows, because $\mu$ is a measure on $\mathscr{S}$.

$$
\mu(V)=\mu(U \backslash F)+\mu(V \backslash(U \backslash F))
$$

Thus from the outer regularity of $\mu, 1$ above, there exists $V$ such that it contains $U \backslash F$ and

$$
\mu(U \backslash F)+\varepsilon>\mu(V)
$$

and so

$$
\mu(V \backslash(U \backslash F))=\mu(V)-\mu(U \backslash F)<\varepsilon .)
$$

Also,

$$
\begin{aligned}
V \backslash(U \backslash F) & =V \cap\left(U \cap F^{C}\right)^{C} \\
& =V \cap\left[U^{C} \cup F\right] \\
& =(V \cap F) \cup\left(V \cap U^{C}\right) \\
& \supseteq V \cap F
\end{aligned}
$$

and so

$$
\mu(V \cap F) \leq \mu(V \backslash(U \backslash F))<\varepsilon
$$

Since $V \supseteq U \cap F^{C}, V^{C} \subseteq U^{C} \cup F$ so $U \cap V^{C} \subseteq U \cap F=F$. Hence $U \cap V^{C}$ is a subset of $F$. Now let $K \subseteq U, \mu(U \backslash K)<\varepsilon$. Thus $K \cap V^{C}$ is a compact subset of $F$ and

$$
\begin{aligned}
\mu(F) & =\mu(V \cap F)+\mu(F \backslash V) \\
& <\varepsilon+\mu(F \backslash V) \leq \varepsilon+\mu\left(U \cap V^{C}\right) \leq 2 \varepsilon+\mu\left(K \cap V^{C}\right)
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this proves the second part of the lemma.
Where do outer measures come from? One way to obtain an outer measure is to start with a measure $\mu$, defined on a $\sigma$ algebra of sets, $\mathscr{S}$, and use the following definition of the outer measure induced by the measure.

Definition 12.1.7 Let $\mu$ be a measure defined on a $\sigma$ algebra of sets, $\mathscr{S} \subseteq \mathscr{P}(\Omega)$. Then the outer measure induced by $\mu$, denoted by $\bar{\mu}$ is defined on $\mathscr{P}(\Omega)$ as

$$
\bar{\mu}(E)=\inf \{\mu(F): F \in \mathscr{S} \text { and } F \supseteq E\}
$$

A measure space, $(\mathscr{S}, \Omega, \mu)$ is $\sigma$ finite if there exist measurable sets, $\Omega_{i}$ with $\mu\left(\Omega_{i}\right)<\infty$ and $\Omega=\cup_{i=1}^{\infty} \Omega_{i}$.

You should prove the following lemma.
Lemma 12.1.8 If $(\mathscr{S}, \Omega, \mu)$ is $\sigma$ finite then there exist disjoint measurable sets, $\left\{B_{n}\right\}$ such that $\mu\left(B_{n}\right)<\infty$ and $\cup_{n=1}^{\infty} B_{n}=\Omega$.

The following lemma deals with the outer measure generated by a measure which is $\sigma$ finite. It says that if the given measure is $\sigma$ finite and complete then no new measurable sets are gained by going to the induced outer measure and then considering the measurable sets in the sense of Caratheodory.

Lemma 12.1.9 Let $(\Omega, \mathscr{S}, \mu)$ be any measure space and let $\bar{\mu}: \mathscr{P}(\Omega) \rightarrow[0, \infty]$ be the outer measure induced by $\mu$. Then $\bar{\mu}$ is an outer measure as claimed and if $\overline{\mathscr{S}}$ is the set of $\bar{\mu}$ measurable sets in the sense of Caratheodory, then $\overline{\mathscr{S}} \supseteq \mathscr{S}$ and $\bar{\mu}=\mu$ on $\mathscr{S}$. Furthermore, if $\mu$ is $\sigma$ finite and $(\Omega, \mathscr{S}, \mu)$ is complete, then $\overline{\mathscr{S}}=\mathscr{S}$.

Proof: It is easy to see that $\bar{\mu}$ is an outer measure. Let $E \in \mathscr{S}$. The plan is to show $E \in \overline{\mathscr{S}}$ and $\bar{\mu}(E)=\mu(E)$. To show this, let $S \subseteq \Omega$ and then show

$$
\begin{equation*}
\bar{\mu}(S) \geq \bar{\mu}(S \cap E)+\bar{\mu}(S \backslash E) \tag{12.1.8}
\end{equation*}
$$

This will verify that $E \in \overline{\mathscr{S}}$. If $\bar{\mu}(S)=\infty$, there is nothing to prove, so assume $\bar{\mu}(S)<\infty$. Thus there exists $T \in \mathscr{S}, T \supseteq S$, and

$$
\begin{aligned}
\bar{\mu}(S) & >\mu(T)-\varepsilon=\mu(T \cap E)+\mu(T \backslash E)-\varepsilon \\
& \geq \bar{\mu}(T \cap E)+\bar{\mu}(T \backslash E)-\varepsilon \\
& \geq \bar{\mu}(S \cap E)+\bar{\mu}(S \backslash E)-\varepsilon .
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this proves 12.1 .8 and verifies $\mathscr{S} \subseteq \overline{\mathscr{S}}$. Now if $E \in \mathscr{S}$ and $V \supseteq E$ with $V \in \mathscr{S}, \mu(E) \leq \mu(V)$. Hence, taking inf, $\mu(E) \leq \bar{\mu}(E)$. But also $\mu(E) \geq \bar{\mu}(E)$ since $E \in \mathscr{S}$ and $E \supseteq E$. Hence

$$
\bar{\mu}(E) \leq \mu(E) \leq \bar{\mu}(E)
$$

Next consider the claim about not getting any new sets from the outer measure in the case the measure space is $\sigma$ finite and complete.

Suppose first $F \in \overline{\mathscr{S}}$ and $\bar{\mu}(F)<\infty$. Then there exists $E \in \mathscr{S}$ such that $E \supseteq F$ and $\mu(E)=\bar{\mu}(F)$. Since $\bar{\mu}(F)<\infty$,

$$
\bar{\mu}(E \backslash F)=\mu(E)-\bar{\mu}(F)=0
$$

Then there exists $D \supseteq E \backslash F$ such that $D \in \mathscr{S}$ and $\mu(D)=\bar{\mu}(E \backslash F)=0$. Then by completeness of $\mathscr{S}$, it follows $E \backslash F \in \mathscr{S}$ and so

$$
E=(E \backslash F) \cup F
$$

Hence $F=E \backslash(E \backslash F) \in \mathscr{S}$. In the general case where $\bar{\mu}(F)$ is not known to be finite, let $\mu\left(B_{n}\right)<\infty$, with $B_{n} \cap B_{m}=\emptyset$ for all $n \neq m$ and $\cup_{n} B_{n}=\Omega$. Apply what was just shown to $F \cap B_{n}$, obtaining each of these is in $\mathscr{S}$. Then $F=\cup_{n} F \cap B_{n} \in \mathscr{S}$. This proves the Lemma.

Usually $\Omega$ is not just a set. It is also a topological space. It is very important to consider how the measure is related to this topology. The following definition tells what it means for a measure to be regular.

Definition 12.1.10 Let $\mu$ be a measure on a $\sigma$ algebra $\mathscr{S}$, of subsets of $\Omega$, where $(\Omega, \tau)$ is a topological space. $\mu$ is a Borel measure if $\mathscr{S}$ contains all Borel sets. $\mu$ is called outer regular if $\mu$ is Borel and for all $E \in \mathscr{S}$,

$$
\mu(E)=\inf \{\mu(V): V \text { is open and } V \supseteq E\} .
$$

$\mu$ is called inner regular if $\mu$ is Borel and

$$
\mu(E)=\sup \{\mu(K): K \subseteq E, \text { and } K \text { is compact }\}
$$

If the measure is both outer and inner regular, it is called regular.

There is an interesting situation in which regularity is obtained automatically. To save on words, let $\mathscr{B}(E)$ denote the $\sigma$ algebra of Borel sets in $E$, a closed subset of $\mathbb{R}^{n}$. It is a very interesting fact that every finite measure on $\mathscr{B}(E)$ must be regular.

Lemma 12.1.11 Let $\mu$ be a finite measure defined on $\mathscr{B}(E)$ where $E$ is a closed subset of $\mathbb{R}^{n}$. Then for every $F \in \mathscr{B}(E)$,

$$
\begin{gathered}
\mu(F)=\sup \{\mu(K): K \subseteq F, K \text { is closed }\} \\
\mu(F)=\inf \{\mu(V): V \supseteq F, V \text { is open }\}
\end{gathered}
$$

Proof: For convenience, I will call a measure which satisfies the above two conditions "almost regular". It would be regular if closed were replaced with compact. First note every open set is the countable union of compact sets and every closed set is the countable intersection of open sets. Here is why. Let $V$ be an open set and let

$$
K_{k} \equiv\left\{x \in V: \operatorname{dist}\left(x, V^{C}\right) \geq 1 / k\right\}
$$

Then clearly the union of the $K_{k}$ equals $V$ and each is closed because $x \rightarrow \operatorname{dist}(x, S)$ is always a continuous function whenever $S$ is any nonempty set. Next, for $K$ closed let

$$
V_{k} \equiv\{x \in E: \operatorname{dist}(x, K)<1 / k\}
$$

Clearly the intersection of the $V_{k}$ equals $K$. Therefore, letting $V$ denote an open set and $K$ a closed set,

$$
\begin{aligned}
& \mu(V)=\sup \{\mu(K): K \subseteq V \text { and } K \text { is closed }\} \\
& \mu(K)=\inf \{\mu(V): V \supseteq K \text { and } V \text { is open }\}
\end{aligned}
$$

Also since $V$ is open and $K$ is closed,

$$
\begin{aligned}
& \mu(V)=\inf \{\mu(U): U \supseteq V \text { and } V \text { is open }\} \\
& \mu(K)=\sup \{\mu(L): L \subseteq K \text { and } L \text { is closed }\}
\end{aligned}
$$

In words, $\mu$ is almost regular on open and closed sets. Let

$$
\mathscr{F} \equiv\{F \in \mathscr{B}(E) \text { such that } \mu \text { is almost regular on } F\}
$$

Then $\mathscr{F}$ contains the open sets. I want to show $\mathscr{F}$ is a $\sigma$ algebra and then it will follow $\mathscr{F}=\mathscr{B}(E)$.

First I will show $\mathscr{F}$ is closed with respect to complements. Let $F \in \mathscr{F}$. Then since $\mu$ is finite and $F$ is inner regular, there exists $K \subseteq F$ such that $\mu(F \backslash K)<\varepsilon$. But $K^{C} \backslash F^{C}=F \backslash K$ and so $\mu\left(K^{C} \backslash F^{C}\right)<\varepsilon$ showing that $F^{C}$ is outer regular. I have just approximated the measure of $F^{C}$ with the measure of $K^{C}$, an open set containing $F^{C}$. A similar argument works to show $F^{C}$ is inner regular. You start with $V \supseteq F$ such that $\mu(V \backslash F)<\varepsilon$, note $F^{C} \backslash V^{C}=V \backslash F$, and then conclude $\mu\left(F^{C} \backslash V^{C}\right)<\varepsilon$, thus approximating $F^{C}$ with the closed subset, $V^{C}$.

Next I will show $\mathscr{F}$ is closed with respect to taking countable unions. Let $\left\{F_{k}\right\}$ be a sequence of sets in $\mathscr{F}$. Then since $F_{k} \in \mathscr{F}$, there exist $\left\{K_{k}\right\}$ such that $K_{k} \subseteq F_{k}$ and $\mu\left(F_{k} \backslash K_{k}\right)<\varepsilon / 2^{k+1}$. First choose $m$ large enough that

$$
\mu\left(\left(\cup_{k=1}^{\infty} F_{k}\right) \backslash\left(\cup_{k=1}^{m} F_{k}\right)\right)<\frac{\varepsilon}{2} .
$$

Then

$$
\mu\left(\left(\cup_{k=1}^{m} F_{k}\right) \backslash\left(\cup_{k=1}^{m} K_{k}\right)\right) \leq \sum_{k=1}^{m} \frac{\varepsilon}{2^{k+1}}<\frac{\varepsilon}{2}
$$

and so

$$
\begin{aligned}
\mu\left(\left(\cup_{k=1}^{\infty} F_{k}\right) \backslash\left(\cup_{k=1}^{m} K_{k}\right)\right) \leq & \mu\left(\left(\cup_{k=1}^{\infty} F_{k}\right) \backslash\left(\cup_{k=1}^{m} F_{k}\right)\right) \\
& +\mu\left(\left(\cup_{k=1}^{m} F_{k}\right) \backslash\left(\cup_{k=1}^{m} K_{k}\right)\right) \\
< & \frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
\end{aligned}
$$

Since $\mu$ is outer regular on $F_{k}$, there exists $V_{k}$ such that $\mu\left(V_{k} \backslash F_{k}\right)<\varepsilon / 2^{k}$. Then

$$
\begin{aligned}
\mu\left(\left(\cup_{k=1}^{\infty} V_{k}\right) \backslash\left(\cup_{k=1}^{\infty} F_{k}\right)\right) & \leq \sum_{k=1}^{\infty} \mu\left(V_{k} \backslash F_{k}\right) \\
& <\sum_{k=1}^{\infty} \frac{\varepsilon}{2^{k}}=\varepsilon
\end{aligned}
$$

and this completes the demonstration that $\mathscr{F}$ is a $\sigma$ algebra. This proves the lemma.
Theorem 12.1.12 Let $\mu$ be a finite measure defined on $\mathscr{B}(E)$ where $E$ is a closed subset of $\mathbb{R}^{n}$. Then $\mu$ is regular.

Proof: From Lemma $12.1 .11 \mu$ is outer regular. Now let $F \in \mathscr{B}(E)$. Then since $\mu$ is finite, there exists $K \subseteq F$ such that $K$ is closed, $K \subseteq F$, and

$$
\mu(F)<\mu(K)+\varepsilon .
$$

Then let $K_{k} \equiv K \cap \overline{B(\mathbf{0}, k)}$. Thus $K_{k}$ is a closed and bounded, hence compact set and $\cup_{k=1}^{\infty} K_{k}=K$. Therefore, for all $k$ large enough,

$$
\begin{aligned}
& \mu(F) \\
< & \mu\left(K_{k}\right)+\varepsilon \\
< & \sup \{\mu(K): K \subseteq F \text { and } K \text { compact }\}+\varepsilon \\
\leq & \mu(F)+\varepsilon
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, it follows

$$
\sup \{\mu(K): K \subseteq F \text { and } K \text { compact }\}=\mu(F)
$$

This proves the theorem.

It will be assumed in what follows that $(\Omega, \tau)$ is a locally compact Hausdorff space. This means it is Hausdorff: If $p, q \in \Omega$ such that $p \neq q$, there exist open sets, $U_{p}$ and $U_{q}$ containing $p$ and $q$ respectively such that $U_{p} \cap U_{q}=\emptyset$ and Locally compact: There exists a basis of open sets for the topology, $\mathscr{B}$ such that for each $U \in \mathscr{B}, \bar{U}$ is compact. Recall $\mathscr{B}$ is a basis for the topology if $\cup \mathscr{B}=\Omega$ and if every open set in $\tau$ is the union of sets of $\mathscr{B}$. Also recall a Hausdorff space is normal if whenever $H$ and $C$ are two closed sets, there exist disjoint open sets, $U_{H}$ and $U_{C}$ containing $H$ and $C$ respectively. A regular space is one which has the property that if $p$ is a point not in $H$, a closed set, then there exist disjoint open sets, $U_{p}$ and $U_{H}$ containing $p$ and $H$ respectively.

### 12.2 Urysohn's lemma

Urysohn's lemma which characterizes normal spaces is a very important result which is useful in general topology and in the construction of measures. Because it is somewhat technical a proof is given for the part which is needed.

Theorem 12.2.1 (Urysohn) Let $(X, \tau)$ be normal and let $H \subseteq U$ where $H$ is closed and $U$ is open. Then there exists $g: X \rightarrow[0,1]$ such that $g$ is continuous, $g(x)=1$ on $H$ and $g(x)=0$ if $x \notin U$.

Proof: Let $D \equiv\left\{r_{n}\right\}_{n=1}^{\infty}$ be the rational numbers in $(0,1]$. Choose $V_{r_{1}}$ an open set such that

$$
H \subseteq V_{r_{1}} \subseteq \bar{V}_{r_{1}} \subseteq U
$$

This can be done by applying the assumption that $X$ is normal to the disjoint closed sets, $H$ and $U^{C}$, to obtain open sets $V$ and $W$ with

$$
H \subseteq V, U^{C} \subseteq W, \text { and } V \cap W=\emptyset
$$

Then

$$
H \subseteq V \subseteq \bar{V}, \bar{V} \cap U^{C}=\emptyset
$$

and so let $V_{r_{1}}=V$.
Suppose $V_{r_{1}}, \cdots, V_{r_{k}}$ have been chosen and list the rational numbers $r_{1}, \cdots, r_{k}$ in order,

$$
r_{l_{1}}<r_{l_{2}}<\cdots<r_{l_{k}} \text { for }\left\{l_{1}, \cdots, l_{k}\right\}=\{1, \cdots, k\}
$$

If $r_{k+1}>r_{l_{k}}$ then letting $p=r_{l_{k}}$, let $V_{r_{k+1}}$ satisfy

$$
\bar{V}_{p} \subseteq V_{r_{k+1}} \subseteq \bar{V}_{r_{k+1}} \subseteq U
$$

If $r_{k+1} \in\left(r_{l_{i}}, r_{l_{i+1}}\right)$, let $p=r_{l_{i}}$ and let $q=r_{l_{i+1}}$. Then let $V_{r_{k+1}}$ satisfy

$$
\bar{V}_{p} \subseteq V_{r_{k+1}} \subseteq \bar{V}_{r_{k+1}} \subseteq V_{q}
$$

If $r_{k+1}<r_{l_{1}}$, let $p=r_{l_{1}}$ and let $V_{r_{k+1}}$ satisfy

$$
H \subseteq V_{r_{k+1}} \subseteq \bar{V}_{r_{k+1}} \subseteq V_{p}
$$

Thus there exist open sets $V_{r}$ for each $r \in \mathbb{Q} \cap(0,1)$ with the property that if $r<s$,

$$
H \subseteq V_{r} \subseteq \bar{V}_{r} \subseteq V_{s} \subseteq \bar{V}_{s} \subseteq U
$$

Now let

$$
f(x)=\min \left(\inf \left\{t \in D: x \in V_{t}\right\}, 1\right), f(x) \equiv 1 \text { if } x \notin \bigcup_{t \in D} V_{t} .
$$

(Recall $D=\mathbb{Q} \cap(0,1]$.) I claim $f$ is continuous.

$$
f^{-1}([0, a))=\cup\left\{V_{t}: t<a, t \in D\right\}
$$

an open set.
Next consider $x \in f^{-1}([0, a])$ so $f(x) \leq a$. If $t>a$, then $x \in V_{t}$ because if not, then

$$
f(x) \equiv \inf \left\{t \in D: x \in V_{t}\right\}>a .
$$

Thus

$$
f^{-1}([0, a]) \subseteq \cap\left\{V_{t}: t>a\right\}=\cap\left\{\bar{V}_{t}: t>a\right\}
$$

which is a closed set. If $x \in \cap\left\{\bar{V}_{t}: t>a\right\}$, then $x \in \cap\left\{V_{t}: t>a\right\}$ and so $f(x) \leq a$.
If $a=1, f^{-1}([0,1])=f^{-1}([0, a])=X$. Therefore,

$$
f^{-1}((a, 1])=X \backslash f^{-1}([0, a])=\text { open set. }
$$

It follows $f$ is continuous. Clearly $f(x)=0$ on $H$. If $x \in U^{C}$, then $x \notin V_{t}$ for any $t \in D$ so $f(x)=1$ on $U^{C}$. Let $g(x)=1-f(x)$. This proves the theorem.

In any metric space there is a much easier proof of the conclusion of Urysohn's lemma which applies.

Lemma 12.2.2 Let $S$ be a nonempty subset of a metric space, $(X, d)$. Define

$$
f(x) \equiv \operatorname{dist}(x, S) \equiv \inf \{d(x, y): y \in S\}
$$

Then $f$ is continuous.
Proof: Consider $\left|f(x)-f\left(x_{1}\right)\right|$ and suppose without loss of generality that $f\left(x_{1}\right) \geq$ $f(x)$. Then choose $y \in S$ such that $f(x)+\varepsilon>d(x, y)$. Then

$$
\begin{aligned}
\left|f\left(x_{1}\right)-f(x)\right| & =f\left(x_{1}\right)-f(x) \leq f\left(x_{1}\right)-d(x, y)+\varepsilon \\
& \leq d\left(x_{1}, y\right)-d(x, y)+\varepsilon \\
& \leq d\left(x, x_{1}\right)+d(x, y)-d(x, y)+\varepsilon \\
& =d\left(x_{1}, x\right)+\varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, it follows that $\left|f\left(x_{1}\right)-f(x)\right| \leq d\left(x_{1}, x\right)$ and this proves the lemma.
Theorem 12.2.3 (Urysohn's lemma for metric space) Let H be a closed subset of an open set, $U$ in a metric space, $(X, d)$. Then there exists a continuous function, $g: X \rightarrow[0,1]$ such that $g(x)=1$ for all $x \in H$ and $g(x)=0$ for all $x \notin U$.

Proof: If $x \notin C$, a closed set, then $\operatorname{dist}(x, C)>0$ because if not, there would exist a sequence of points of $C$ converging to $x$ and it would follow that $x \in C$. Therefore, $\operatorname{dist}(x, H)+\operatorname{dist}\left(x, U^{C}\right)>0$ for all $x \in X$. Now define a continuous function, $g$ as

$$
g(x) \equiv \frac{\operatorname{dist}\left(x, U^{C}\right)}{\operatorname{dist}(x, H)+\operatorname{dist}\left(x, U^{C}\right)}
$$

It is easy to see this verifies the conclusions of the theorem and this proves the theorem.
Theorem 12.2.4 Every compact Hausdorff space is normal.
Proof: First it is shown that $X$, is regular. Let $H$ be a closed set and let $p \notin H$. Then for each $h \in H$, there exists an open set $U_{h}$ containing $p$ and an open set $V_{h}$ containing $h$ such that $U_{h} \cap V_{h}=\emptyset$. Since $H$ must be compact, it follows there are finitely many of the sets $V_{h}, V_{h_{1}} \cdots V_{h_{n}}$ such that $H \subseteq \cup_{i=1}^{n} V_{h_{i}}$. Then letting $U=\cap_{i=1}^{n} U_{h_{i}}$ and $V=\cup_{i=1}^{n} V_{h_{i}}$, it follows that $p \in U, H \in V$ and $U \cap V=\emptyset$. Thus $X$ is regular as claimed.

Next let $K$ and $H$ be disjoint nonempty closed sets.Using regularity of $X$, for every $k \in K$, there exists an open set $U_{k}$ containing $k$ and an open set $V_{k}$ containing $H$ such that these two open sets have empty intersection. Thus $H \cap \bar{U}_{k}=\emptyset$. Finitely many of the $U_{k}$, $U_{k_{1}}, \cdots, U_{k_{p}}$ cover $K$ and so $\cup_{i=1}^{p} \bar{U}_{k_{i}}$ is a closed set which has empty intersection with $H$. Therefore, $K \subseteq \cup_{i=1}^{p} U_{k_{i}}$ and $H \subseteq\left(\cup_{i=1}^{p} \bar{U}_{k_{i}}\right)^{C}$. This proves the theorem.

A useful construction when dealing with locally compact Hausdorff spaces is the notion of the one point compactification of the space discussed earler. However, it is reviewed here for the sake of convenience or in case you have not read the earlier treatment.

Definition 12.2.5 Suppose $(X, \tau)$ is a locally compact Hausdorff space. Then let $\widetilde{X} \equiv$ $X \cup\{\infty\}$ where $\infty$ is just the name of some point which is not in $X$ which is called the point at infinity. A basis for the topology $\widetilde{\tau}$ for $\widetilde{X}$ is

$$
\tau \cup\left\{K^{C} \text { where } K \text { is a compact subset of } X\right\}
$$

The complement is taken with respect to $\widetilde{X}$ and so the open sets, $K^{C}$ are basic open sets which contain $\infty$.

The reason this is called a compactification is contained in the next lemma.
Lemma 12.2.6 If $(X, \tau)$ is a locally compact Hausdorff space, then $(\widetilde{X}, \tilde{\tau})$ is a compact Hausdorff space. Also if $U$ is an open set of $\widetilde{\tau}$, then $U \backslash\{\infty\}$ is an open set of $\tau$.

Proof: Since $(X, \tau)$ is a locally compact Hausdorff space, it follows $(\widetilde{X}, \tilde{\tau})$ is a Hausdorff topological space. The only case which needs checking is the one of $p \in X$ and $\infty$. Since $(X, \tau)$ is locally compact, there exists an open set of $\tau, U$ having compact closure which contains $p$. Then $p \in U$ and $\infty \in \bar{U}^{C}$ and these are disjoint open sets containing the points, $p$ and $\infty$ respectively. Now let $\mathscr{C}$ be an open cover of $\widetilde{X}$ with sets from $\tilde{\tau}$. Then $\infty$ must be in some set, $U_{\infty}$ from $\mathscr{C}$, which must contain a set of the form $K^{C}$ where $K$ is a
compact subset of $X$. Then there exist sets from $\mathscr{C}, U_{1}, \cdots, U_{r}$ which cover $K$. Therefore, a finite subcover of $\widetilde{X}$ is $U_{1}, \cdots, U_{r}, U_{\infty}$.

To see the last claim, suppose $U$ contains $\infty$ since otherwise there is nothing to show. Notice that if $C$ is a compact set, then $X \backslash C$ is an open set. Therefore, if $x \in U \backslash\{\infty\}$, and if $\widetilde{X} \backslash C$ is a basic open set contained in $U$ containing $\infty$, then if $x$ is in this basic open set of $\widetilde{X}$, it is also in the open set $X \backslash C \subseteq U \backslash\{\infty\}$. If $x$ is not in any basic open set of the form $\widetilde{X} \backslash C$ then $x$ is contained in an open set of $\tau$ which is contained in $U \backslash\{\infty\}$. Thus $U \backslash\{\infty\}$ is indeed open in $\tau$.

Theorem 12.2.7 Let $X$ be a locally compact Hausdorff space, and let $K$ be a compact subset of the open set $V$. Then there exists a continuous function, $f: X \rightarrow[0,1]$, such that $f$ equals 1 on $K$ and $\overline{\{x: f(x) \neq 0\}} \equiv \operatorname{spt}(f)$ is a compact subset of $V$.

Proof: Let $\widetilde{X}$ be the space just described. Then $K$ and $V$ are respectively closed and open in $\tilde{\tau}$. By Theorem 12.2.4 there exist open sets in $\tilde{\tau}, U$, and $W$ such that $K \subseteq U, \infty \in$ $V^{C} \subseteq W$, and $U \cap W=U \cap(W \backslash\{\infty\})=\emptyset$.

Thus $W \backslash\{\infty\}$ is an open set in the original topological space which contains $V^{C}, U$ is an open set in the original topological space which contains $K$, and $W \backslash\{\infty\}$ and $U$ are disjoint.

Now for each $x \in K$, let $U_{x}$ be a basic open set whose closure is compact and such that

$$
x \in U_{x} \subseteq U .
$$

Thus $\overline{U_{x}}$ must have empty intersection with $V^{C}$ because the open set, $W \backslash\{\infty\}$ contains no points of $U_{x}$. Since $K$ is compact, there are finitely many of these sets, $U_{x_{1}}, U_{x_{2}}, \cdots, U_{x_{n}}$ which cover $K$. Now let $H \equiv \cup_{i=1}^{n} U_{x_{i}}$.

Claim: $\bar{H}=\cup_{i=1}^{n} \overline{U_{x_{i}}}$
Proof of claim: Suppose $p \in \bar{H}$. If $p \notin \cup_{i=1}^{n} \overline{U_{x_{i}}}$ then it follows $p \notin \overline{U_{x_{i}}}$ for each $i$. Therefore, there exists an open set, $R_{i}$ containing $p$ such that $R_{i}$ contains no other points of $U_{x_{i}}$. Therefore, $R \equiv \cap_{i=1}^{n} R_{i}$ is an open set containing $p$ which contains no other points of $\cup_{i=1}^{n} U_{x_{i}}=W$, a contradiction. Therefore, $\bar{H} \subseteq \cup_{i=1}^{n} \overline{U_{x_{i}}}$. On the other hand, if $p \in \overline{U_{x_{i}}}$ then $p$ is obviously in $\bar{H}$ so this proves the claim.

From the claim, $K \subseteq H \subseteq \bar{H} \subseteq V$ and $\bar{H}$ is compact because it is the finite union of compact sets. By Urysohn's lemma, there exists $f_{1}$ continuous on $\bar{H}$ which has values in $[0,1]$ such that $f_{1}$ equals 1 on $K$ and equals 0 off $H$. Let $f$ denote the function which extends
$f_{1}$ to be 0 off $\bar{H}$. Then for $\alpha>0$, the continuity of $f_{1}$ implies there exists $U$ open in the topological space such that

$$
f^{-1}((-\infty, \alpha))=f_{1}^{-1}((-\infty, \alpha)) \cup \bar{H}^{C}=(U \cap \bar{H}) \cup \bar{H}^{C}=U \cup \bar{H}^{C}
$$

an open set. If $\alpha \leq 0$,

$$
f^{-1}((-\infty, \alpha))=\emptyset
$$

an open set. If $\alpha>0$, there exists an open set $U$ such that

$$
f^{-1}((\alpha, \infty))=f_{1}^{-1}((\alpha, \infty))=U \cap \bar{H}=U \cap H
$$

because $U$ must be a subset of $H$ since by definition $f=0$ off $H$. If $\alpha \leq 0$, then

$$
f^{-1}((\alpha, \infty))=X
$$

an open set. Thus $f$ is continuous and $\operatorname{spt}(f) \subseteq \bar{H}$, a compact subset of $V$. This proves the theorem.

In fact, the conclusion of the above theorem could be used to prove that the topological space is locally compact. However, this is not needed here.

In case you would like a more elementary proof which does not use the one point compactification idea, here is such a proof.

Theorem 12.2.8 Let $X$ be a locally compact Hausdorff space, and let $K$ be a compact subset of the open set $V$. Then there exists a continuous function, $f: X \rightarrow[0,1]$, such that $f$ equals 1 on $K$ and $\overline{\{x: f(x) \neq 0\}} \equiv \operatorname{spt}(f)$ is a compact subset of $V$.

Proof: To begin with, here is a claim. This claim is obvious in the case of a metric space but requires some proof in this more general case.

Claim: If $k \in K$ then there exists an open set $U_{k}$ containing $k$ such that $\overline{U_{k}}$ is contained in $V$.

Proof of claim: Since $X$ is locally compact, there exists a basis of open sets whose closures are compact, $\mathscr{U}$. Denote by $\mathscr{C}$ the set of all $U \in \mathscr{U}$ which contain $k$ and let $\mathscr{C}^{\prime}$ denote the set of all closures of these sets of $\mathscr{C}$ intersected with the closed set $V^{C}$. Thus $\mathscr{C}^{\prime}$ is a collection of compact sets. I will argue that there are finitely many of the sets of $\mathscr{C}^{\prime}$ which have empty intersection. If not, then $\mathscr{C}^{\prime}$ has the finite intersection property and so there exists a point $p$ in all of them. Since $X$ is a Hausdorff space, there exist disjoint basic open sets from $\mathscr{U}, A, B$ such that $k \in A$ and $p \in B$. Therefore, $p \notin \bar{A}$ contrary to the above requirement that $p$ be in all such sets. It follows there are sets $A_{1}, \cdots, A_{m}$ in $\mathscr{C}$ such that

$$
V^{C} \cap \overline{A_{1}} \cap \cdots \cap \overline{A_{m}}=\emptyset
$$

Let $U_{k}=A_{1} \cap \cdots \cap A_{m}$. Then $\overline{U_{k}} \subseteq \overline{A_{1}} \cap \cdots \cap \overline{A_{m}}$ and so it has empty intersection with $V^{C}$. Thus it is contained in $V$. Also $\overline{U_{k}}$ is a closed subset of the compact set $\overline{A_{1}}$ so it is compact. This proves the claim.

Now to complete the proof of the theorem, since $K$ is compact, there are finitely many $U_{k}$ of the sort just described which cover $K, U_{k_{1}}, \cdots, U_{k_{r}}$. Let

$$
H=\cup_{i=1}^{r} U_{k_{i}}
$$

so it follows

$$
\bar{H}=\cup_{i=1}^{r} \overline{U_{k_{i}}}
$$

and so $K \subseteq H \subseteq \bar{H} \subseteq V$ and $\bar{H}$ is a compact set. By Urysohn's lemma, there exists $f_{1}$ continuous on $\bar{H}$ which has values in $[0,1]$ such that $f_{1}$ equals 1 on $K$ and equals 0 off $H$. Let $f$ denote the function which extends $f_{1}$ to be 0 off $\bar{H}$. Then for $\alpha>0$, the continuity of $f_{1}$ implies there exists $U$ open in the topological space such that

$$
f^{-1}((-\infty, \alpha))=f_{1}^{-1}((-\infty, \alpha)) \cup \bar{H}^{C}=(U \cap \bar{H}) \cup \bar{H}^{C}=U \cup \bar{H}^{C}
$$

an open set. If $\alpha \leq 0$,

$$
f^{-1}((-\infty, \alpha))=\emptyset
$$

an open set. If $\alpha>0$, there exists an open set $U$ such that

$$
f^{-1}((\alpha, \infty))=f_{1}^{-1}((\alpha, \infty))=U \cap \bar{H}=U \cap H
$$

because $U$ must be a subset of $H$ since by definition $f=0$ off $H$. If $\alpha \leq 0$, then

$$
f^{-1}((\alpha, \infty))=X
$$

an open set. Thus $f$ is continuous and $\operatorname{spt}(f) \subseteq \bar{H}$, a compact subset of $V$. This proves the theorem.

Definition 12.2.9 Define $\operatorname{spt}(f)$ (support of $f$ ) to be the closure of the set $\{x: f(x) \neq 0\}$. If $V$ is an open set, $C_{c}(V)$ will be the set of continuous functions $f$, defined on $\Omega$ having $\operatorname{spt}(f) \subseteq V$. Thus in Theorem 12.2.7 or 12.2.8, $f \in C_{c}(V)$.

Definition 12.2.10 If $K$ is a compact subset of an open set, $V$, then $K \prec \phi \prec V$ if

$$
\phi \in C_{c}(V), \phi(K)=\{1\}, \phi(\Omega) \subseteq[0,1]
$$

where $\Omega$ denotes the whole topological space considered. Also for $\phi \in C_{c}(\Omega), K \prec \phi$ if

$$
\phi(\Omega) \subseteq[0,1] \text { and } \phi(K)=1
$$

and $\phi \prec V$ if

$$
\phi(\Omega) \subseteq[0,1] \text { and } \operatorname{spt}(\phi) \subseteq V
$$

Theorem 12.2.11 (Partition of unity) Let $K$ be a compact subset of a locally compact Hausdorff topological space satisfying Theorem 12.2.7 or 12.2.8 and suppose

$$
K \subseteq V=\cup_{i=1}^{n} V_{i}, V_{i} \text { open. }
$$

Then there exist $\psi_{i} \prec V_{i}$ with

$$
\sum_{i=1}^{n} \psi_{i}(x)=1
$$

for all $x \in K$.

Proof: Let $K_{1}=K \backslash \cup_{i=2}^{n} V_{i}$. Thus $K_{1}$ is compact and $K_{1} \subseteq V_{1}$. Let $K_{1} \subseteq W_{1} \subseteq \bar{W}_{1} \subseteq$ $V_{1}$ with $\bar{W}_{1}$ compact. To obtain $W_{1}$, use Theorem 12.2 .7 or 12.2 .8 to get $f$ such that $K_{1} \prec$ $f \prec V_{1}$ and let $W_{1} \equiv\{x: f(x) \neq 0\}$. Thus $W_{1}, V_{2}, \cdots V_{n}$ covers $K$ and $\bar{W}_{1} \subseteq V_{1}$. Let $K_{2}=$ $K \backslash\left(\cup_{i=3}^{n} V_{i} \cup W_{1}\right)$. Then $K_{2}$ is compact and $K_{2} \subseteq V_{2}$. Let $K_{2} \subseteq W_{2} \subseteq \bar{W}_{2} \subseteq V_{2} \bar{W}_{2}$ compact. Continue this way finally obtaining $W_{1}, \cdots, W_{n}, K \subseteq W_{1} \cup \cdots \cup W_{n}$, and $\bar{W}_{i} \subseteq V_{i} \bar{W}_{i}$ compact. Now let $\bar{W}_{i} \subseteq U_{i} \subseteq \bar{U}_{i} \subseteq V_{i}, \bar{U}_{i}$ compact.

By Theorem 12.2.7 or 12.2.8, let $\bar{U}_{i} \prec \phi_{i} \prec V_{i}, \cup_{i=1}^{n} \bar{W}_{i} \prec \gamma \prec \cup_{i=1}^{n} U_{i}$. Define

$$
\psi_{i}(x)=\left\{\begin{array}{l}
\gamma(x) \phi_{i}(x) / \sum_{j=1}^{n} \phi_{j}(x) \text { if } \sum_{j=1}^{n} \phi_{j}(x) \neq 0 \\
0 \text { if } \sum_{j=1}^{n} \phi_{j}(x)=0
\end{array}\right.
$$

If $x$ is such that $\sum_{j=1}^{n} \phi_{j}(x)=0$, then $x \notin \cup_{i=1}^{n} \bar{U}_{i}$. Consequently $\gamma(y)=0$ for all $y$ near $x$ and so $\psi_{i}(y)=0$ for all $y$ near $x$. Hence $\psi_{i}$ is continuous at such $x$. If $\sum_{j=1}^{n} \phi_{j}(x) \neq 0$, this situation persists near $x$ and so $\psi_{i}$ is continuous at such points. Therefore $\psi_{i}$ is continuous. If $x \in K$, then $\gamma(x)=1$ and so $\sum_{j=1}^{n} \psi_{j}(x)=1$. Clearly $0 \leq \psi_{i}(x) \leq 1$ and $\operatorname{spt}\left(\psi_{j}\right) \subseteq V_{j}$. This proves the theorem.

The following corollary won't be needed immediately but is of considerable interest later.

Corollary 12.2.12 If $H$ is a compact subset of $V_{i}$, there exists a partition of unity such that $\psi_{i}(x)=1$ for all $x \in H$ in addition to the conclusion of Theorem 12.2.11.

Proof: Keep $V_{i}$ the same but replace $V_{j}$ with $\widetilde{V}_{j} \equiv V_{j} \backslash H$. Now in the proof above, applied to this modified collection of open sets, if $j \neq i, \phi_{j}(x)=0$ whenever $x \in H$. Therefore, $\psi_{i}(x)=1$ on $H$.

### 12.3 Positive Linear Functionals

Definition 12.3.1 Let $(\Omega, \tau)$ be a topological space. $L: C_{c}(\Omega) \rightarrow \mathbb{C}$ is called a positive linear functional if $L$ is linear,

$$
L\left(a f_{1}+b f_{2}\right)=a L f_{1}+b L f_{2}
$$

and if $L f \geq 0$ whenever $f \geq 0$.
Theorem 12.3.2 (Riesz representation theorem) Let $(\Omega, \tau)$ be a locally compact Hausdorff space and let $L$ be a positive linear functional on $C_{c}(\Omega)$. Then there exists a $\sigma$ algebra $\mathscr{S}$ containing the Borel sets and a unique measure $\mu$, defined on $\mathscr{S}$, such that

$$
\begin{align*}
& \mu \text { is complete },  \tag{12.3.9}\\
\mu(K)< & \infty \text { for all } K \text { compact } \tag{12.3.10}
\end{align*}
$$

$$
\mu(F)=\sup \{\mu(K): K \subseteq F, K \text { compact }\}
$$

for all $F$ open and for all $F \in \mathscr{S}$ with $\mu(F)<\infty$,

$$
\mu(F)=\inf \{\mu(V): V \supseteq F, V \text { open }\}
$$

for all $F \in \mathscr{S}$, and

$$
\begin{equation*}
\int f d \mu=L f \text { for all } f \in C_{c}(\Omega) \tag{12.3.11}
\end{equation*}
$$

The plan is to define an outer measure and then to show that it, together with the $\sigma$ algebra of sets measurable in the sense of Caratheodory, satisfies the conclusions of the theorem. Always, $K$ will be a compact set and $V$ will be an open set.

Definition 12.3.3 $\mu(V) \equiv \sup \{L f: f \prec V\}$ for $V$ open, $\mu(\emptyset)=0$. $\mu(E) \equiv \inf \{\mu(V): V \supseteq$ $E\}$ for arbitrary sets $E$.

Lemma 12.3.4 $\mu$ is a well-defined outer measure.
Proof: First it is necessary to verify $\mu$ is well defined because there are two descriptions of it on open sets. Suppose then that $\mu_{1}(V) \equiv \inf \{\mu(U): U \supseteq V$ and $U$ is open $\}$. It is required to verify that $\mu_{1}(V)=\mu(V)$ where $\mu$ is given as $\sup \{L f: f \prec V\}$. If $U \supseteq V$, then $\mu(U) \geq \mu(V)$ directly from the definition. Hence from the definition of $\mu_{1}$, it follows $\mu_{1}(V) \geq \mu(V)$. On the other hand, $V \supseteq V$ and so $\mu_{1}(V) \leq \mu(V)$. This verifies $\mu$ is well defined.

It remains to show that $\mu$ is an outer measure. Let $V=\cup_{i=1}^{\infty} V_{i}$ and let $f \prec V$. Then $\operatorname{spt}(f) \subseteq \cup_{i=1}^{n} V_{i}$ for some $n$. Let $\psi_{i} \prec V_{i}, \sum_{i=1}^{n} \psi_{i}=1$ on $\operatorname{spt}(f)$.

$$
L f=\sum_{i=1}^{n} L\left(f \psi_{i}\right) \leq \sum_{i=1}^{n} \mu\left(V_{i}\right) \leq \sum_{i=1}^{\infty} \mu\left(V_{i}\right) .
$$

Hence

$$
\mu(V) \leq \sum_{i=1}^{\infty} \mu\left(V_{i}\right)
$$

since $f \prec V$ is arbitrary. Now let $E=\cup_{i=1}^{\infty} E_{i}$. Is $\mu(E) \leq \sum_{i=1}^{\infty} \mu\left(E_{i}\right)$ ? Without loss of generality, it can be assumed $\mu\left(E_{i}\right)<\infty$ for each $i$ since if not so, there is nothing to prove. Let $V_{i} \supseteq E_{i}$ with $\mu\left(E_{i}\right)+\varepsilon 2^{-i}>\mu\left(V_{i}\right)$.

$$
\mu(E) \leq \mu\left(\cup_{i=1}^{\infty} V_{i}\right) \leq \sum_{i=1}^{\infty} \mu\left(V_{i}\right) \leq \varepsilon+\sum_{i=1}^{\infty} \mu\left(E_{i}\right)
$$

Since $\varepsilon$ was arbitrary, $\mu(E) \leq \sum_{i=1}^{\infty} \mu\left(E_{i}\right)$ which proves the lemma.
Lemma 12.3.5 Let $K$ be compact, $g \geq 0, g \in C_{c}(\Omega)$, and $g=1$ on $K$. Then $\mu(K) \leq L g$. Also $\mu(K)<\infty$ whenever $K$ is compact.

Proof: Let $\alpha \in(0,1)$ and $V_{\alpha}=\{x: g(x)>\alpha\}$ so $V_{\alpha} \supseteq K$ and let $h \prec V_{\alpha}$.

Then $h \leq 1$ on $V_{\alpha}$ while $g \alpha^{-1} \geq 1$ on $V_{\alpha}$ and so $g \alpha^{-1} \geq h$ which implies $L\left(g \alpha^{-1}\right) \geq L h$ and that therefore, since $L$ is linear,

$$
L g \geq \alpha L h
$$

Since $h \prec V_{\alpha}$ is arbitrary, and $K \subseteq V_{\alpha}$,

$$
L g \geq \alpha \mu\left(V_{\alpha}\right) \geq \alpha \mu(K)
$$

Letting $\alpha \uparrow 1$ yields $L g \geq \mu(K)$. This proves the first part of the lemma. The second assertion follows from this and Theorem 12.2.7. If $K$ is given, let

$$
K \prec g \prec \Omega
$$

and so from what was just shown, $\mu(K) \leq L g<\infty$. This proves the lemma.
Lemma 12.3.6 If $A$ and $B$ are disjoint compact subsets of $\Omega$, then $\mu(A \cup B)=\mu(A)+\mu(B)$.
Proof: By Theorem 12.2 .7 or 12.2 .8 , there exists $h \in C_{c}(\Omega)$ such that $A \prec h \prec B^{C}$. Let $U_{1}=h^{-1}\left(\left(\frac{1}{2}, 1\right]\right), V_{1}=h^{-1}\left(\left[0, \frac{1}{2}\right)\right)$. Then $A \subseteq U_{1}, B \subseteq V_{1}$ and $U_{1} \cap V_{1}=\emptyset$.

From Lemma 12.3.5 $\mu(A \cup B)<\infty$ and so there exists an open set, $W$ such that

$$
W \supseteq A \cup B, \mu(A \cup B)+\varepsilon>\mu(W)
$$

Now let $U=U_{1} \cap W$ and $V=V_{1} \cap W$. Then

$$
U \supseteq A, V \supseteq B, U \cap V=\emptyset, \text { and } \mu(A \cup B)+\varepsilon \geq \mu(W) \geq \mu(U \cup V)
$$

Let $A \prec f \prec U, B \prec g \prec V$. Then by Lemma 12.3.5,

$$
\mu(A \cup B)+\varepsilon \geq \mu(U \cup V) \geq L(f+g)=L f+L g \geq \mu(A)+\mu(B)
$$

Since $\varepsilon>0$ is arbitrary, this proves the lemma.
From Lemma 12.3.5 the following lemma is obtained.

Lemma 12.3.7 Let $f \in C_{c}(\Omega), f(\Omega) \subseteq[0,1]$. Then $\mu(\operatorname{spt}(f)) \geq L f$. Also, every open set, $V$ satisfies

$$
\mu(V)=\sup \{\mu(K): K \subseteq V\}
$$

Proof: Let $V \supseteq \operatorname{spt}(f)$ and let $\operatorname{spt}(f) \prec g \prec V$. Then $L f \leq L g \leq \mu(V)$ because $f \leq g$. Since this holds for all $V \supseteq \operatorname{spt}(f), L f \leq \mu(\operatorname{spt}(f))$ by definition of $\mu$.

Finally, let $V$ be open and let $l<\mu(V)$. Then from the definition of $\mu$, there exists $f \prec V$ such that $L(f)>l$. Therefore, $l<\mu(\operatorname{spt}(f)) \leq \mu(V)$ and so this shows the claim about inner regularity of the measure on an open set.

At this point, the conditions of Lemma 12.1.6 have been verified. Thus $\mathscr{S}$ contains the Borel sets and $\mu$ is inner regular on sets of $\mathscr{S}$ having finite measure.

It remains to show $\mu$ satisfies 12.3.11.

Lemma 12.3.8 $\int f d \mu=L f$ for all $f \in C_{c}(\Omega)$.
Proof: Let $f \in C_{c}(\Omega), f$ real-valued, and suppose $f(\Omega) \subseteq[a, b]$. Choose $t_{0}<a$ and let $t_{0}<t_{1}<\cdots<t_{n}=b, t_{i}-t_{i-1}<\varepsilon$. Let

$$
\begin{equation*}
E_{i}=f^{-1}\left(\left(t_{i-1}, t_{i}\right]\right) \cap \operatorname{spt}(f) . \tag{12.3.12}
\end{equation*}
$$

Note that $\cup_{i=1}^{n} E_{i}$ is a closed set, and in fact

$$
\begin{equation*}
\cup_{i=1}^{n} E_{i}=\operatorname{spt}(f) \tag{12.3.13}
\end{equation*}
$$

since $\Omega=\cup_{i=1}^{n} f^{-1}\left(\left(t_{i-1}, t_{i}\right]\right)$. Let $V_{i} \supseteq E_{i}, V_{i}$ is open and let $V_{i}$ satisfy

$$
\begin{equation*}
f(x)<t_{i}+\varepsilon \text { for all } x \in V_{i} \tag{12.3.14}
\end{equation*}
$$

$$
\mu\left(V_{i} \backslash E_{i}\right)<\varepsilon / n
$$

By Theorem 12.2 .11 there exists $h_{i} \in C_{c}(\Omega)$ such that

$$
h_{i} \prec V_{i}, \quad \sum_{i=1}^{n} h_{i}(x)=1 \text { on } \operatorname{spt}(f) .
$$

Now note that for each $i$,

$$
f(x) h_{i}(x) \leq h_{i}(x)\left(t_{i}+\varepsilon\right) .
$$

(If $x \in V_{i}$, this follows from 12.3.14. If $x \notin V_{i}$ both sides equal 0 .) Therefore,

$$
\begin{aligned}
L f & =L\left(\sum_{i=1}^{n} f h_{i}\right) \leq L\left(\sum_{i=1}^{n} h_{i}\left(t_{i}+\varepsilon\right)\right) \\
& =\sum_{i=1}^{n}\left(t_{i}+\varepsilon\right) L\left(h_{i}\right) \\
& =\sum_{i=1}^{n}\left(\left|t_{0}\right|+t_{i}+\varepsilon\right) L\left(h_{i}\right)-\left|t_{0}\right| L\left(\sum_{i=1}^{n} h_{i}\right) .
\end{aligned}
$$

Now note that $\left|t_{0}\right|+t_{i}+\varepsilon \geq 0$ and so from the definition of $\mu$ and Lemma 12.3.5, this is no larger than

$$
\begin{gathered}
\sum_{i=1}^{n}\left(\left|t_{0}\right|+t_{i}+\varepsilon\right) \mu\left(V_{i}\right)-\left|t_{0}\right| \mu(\operatorname{spt}(f)) \\
\leq \sum_{i=1}^{n}\left(\left|t_{0}\right|+t_{i}+\varepsilon\right)\left(\mu\left(E_{i}\right)+\varepsilon / n\right)-\left|t_{0}\right| \mu(\operatorname{spt}(f)) \\
\leq\left|t_{0}\right| \sum_{i=1}^{n} \mu\left(E_{i}\right)+\left|t_{0}\right| \varepsilon+\sum_{i=1}^{n} t_{i} \mu\left(E_{i}\right)+\varepsilon\left(\left|t_{0}\right|+|b|\right) \\
\sum_{i=1}^{n} t_{i} \frac{\varepsilon}{n}+\varepsilon \sum_{i=1}^{n} \mu\left(E_{i}\right)+\varepsilon^{2}-\left|t_{0}\right| \mu(\operatorname{spt}(f))
\end{gathered}
$$

From 12.3.13 and 12.3.12, the first and last terms cancel. Therefore this is no larger than

$$
\begin{gathered}
\quad\left(2\left|t_{0}\right|+|b|+\mu(\operatorname{spt}(f))+\varepsilon\right) \varepsilon \\
+\sum_{i=1}^{n} t_{i-1} \mu\left(E_{i}\right)+\varepsilon \mu(\operatorname{spt}(f))+\sum_{i=1}^{n}\left(\left|t_{0}\right|+|b|\right) \frac{\varepsilon}{n} \\
\leq \int f d \mu+\left(2\left|t_{0}\right|+|b|+2 \mu(\operatorname{spt}(f))+\varepsilon\right) \varepsilon+\left(\left|t_{0}\right|+|b|\right) \varepsilon
\end{gathered}
$$

Since $\varepsilon>0$ is arbitrary,

$$
\begin{equation*}
L f \leq \int f d \mu \tag{12.3.15}
\end{equation*}
$$

for all $f \in C_{c}(\Omega), f$ real. Hence equality holds in 12.3.15 because $L(-f) \leq-\int f d \mu$ so $L(f) \geq \int f d \mu$. Thus $L f=\int f d \mu$ for all $f \in C_{c}(\Omega)$. Just apply the result for real functions to the real and imaginary parts of $f$. This proves the Lemma.

This gives the existence part of the Riesz representation theorem.
It only remains to prove uniqueness. Suppose both $\mu_{1}$ and $\mu_{2}$ are measures on $\mathscr{S}$ satisfying the conclusions of the theorem. Then if $K$ is compact and $V \supseteq K$, let $K \prec f \prec V$. Then

$$
\mu_{1}(K) \leq \int f d \mu_{1}=L f=\int f d \mu_{2} \leq \mu_{2}(V)
$$

Thus $\mu_{1}(K) \leq \mu_{2}(K)$ for all $K$. Similarly, the inequality can be reversed and so it follows the two measures are equal on compact sets. By the assumption of inner regularity on open sets, the two measures are also equal on all open sets. By outer regularity, they are equal on all sets of $\mathscr{S}$. This proves the theorem.

An important example of a locally compact Hausdorff space is any metric space in which the closures of balls are compact. For example, $\mathbb{R}^{n}$ with the usual metric is an example of this. Not surprisingly, more can be said in this important special case.

Theorem 12.3.9 Let $(\Omega, \tau)$ be a metric space in which the closures of the balls are compact and let $L$ be a positive linear functional defined on $C_{c}(\Omega)$. Then there exists a measure representing the positive linear functional which satisfies all the conclusions of Theorem 12.2.7 or 12.2.8 and in addition the property that $\mu$ is regular. The same conclusion follows if $(\Omega, \tau)$ is a compact Hausdorff space.

Theorem 12.3.10 Let $(\Omega, \tau)$ be a metric space in which the closures of the balls are compact and let $L$ be a positive linear functional defined on $C_{c}(\Omega)$. Then there exists a measure representing the positive linear functional which satisfies all the conclusions of Theorem 12.2.7 or 12.2.8 and in addition the property that $\mu$ is regular. The same conclusion follows if $(\Omega, \tau)$ is a compact Hausdorff space.

Proof: Let $\mu$ and $\mathscr{S}$ be as described in Theorem 12.3.2. The outer regularity comes automatically as a conclusion of Theorem 12.3.2. It remains to verify inner regularity. Let $F \in \mathscr{S}$ and let $l<k<\mu(F)$. Now let $z \in \Omega$ and $\Omega_{n}=\overline{B(z, n)}$ for $n \in \mathbb{N}$. Thus $F \cap \Omega_{n} \uparrow F$. It follows that for $n$ large enough,

$$
k<\mu\left(F \cap \Omega_{n}\right) \leq \mu(F)
$$

Since $\mu\left(F \cap \Omega_{n}\right)<\infty$ it follows there exists a compact set, $K$ such that $K \subseteq F \cap \Omega_{n} \subseteq F$ and

$$
l<\mu(K) \leq \mu(F)
$$

This proves inner regularity. In case $(\Omega, \tau)$ is a compact Hausdorff space, the conclusion of inner regularity follows from Theorem 12.3.2. This proves the theorem.

The proof of the above yields the following corollary.
Corollary 12.3.11 Let $(\Omega, \tau)$ be a locally compact Hausdorff space and suppose $\mu$ defined on a $\sigma$ algebra, $\mathscr{S}$ represents the positive linear functional $L$ where $L$ is defined on $C_{c}(\Omega)$ in the sense of Theorem 12.2 .7 or 12.2.8. Suppose also that there exist $\Omega_{n} \in \mathscr{S}$ such that $\Omega=\cup_{n=1}^{\infty} \Omega_{n}$ and $\mu\left(\Omega_{n}\right)<\infty$. Then $\mu$ is regular.

The following is on the uniqueness of the $\sigma$ algebra in some cases.
Definition 12.3.12 Let $(\Omega, \tau)$ be a locally compact Hausdorff space and let $L$ be a positive linear functional defined on $C_{c}(\Omega)$ such that the complete measure defined by the Riesz representation theorem for positive linear functionals is inner regular. Then this is called a Radon measure. Thus a Radon measure is complete, and regular.

Corollary 12.3.13 Let $(\Omega, \tau)$ be a locally compact Hausdorff space which is also $\sigma$ compact meaning

$$
\Omega=\cup_{n=1}^{\infty} \Omega_{n}, \Omega_{n} \text { is compact }
$$

and let $L$ be a positive linear functional defined on $C_{c}(\Omega)$. Then if $\left(\mu_{1}, \mathscr{S}_{1}\right)$, and $\left(\mu_{2}, \mathscr{S}_{2}\right)$ are two Radon measures, together with their $\sigma$ algebras which represent $L$ then the two $\sigma$ algebras are equal and the two measures are equal.

Proof: Suppose $\left(\mu_{1}, \mathscr{S}_{1}\right)$ and $\left(\mu_{2}, \mathscr{S}_{2}\right)$ both work. It will be shown the two measures are equal on every compact set. Let $K$ be compact and let $V$ be an open set containing $K$. Then let $K \prec f \prec V$. Then

$$
\mu_{1}(K)=\int_{K} d \mu_{1} \leq \int f d \mu_{1}=L(f)=\int f d \mu_{2} \leq \mu_{2}(V)
$$

Therefore, taking the infimum over all $V$ containing $K$ implies $\mu_{1}(K) \leq \mu_{2}(K)$. Reversing the argument shows $\mu_{1}(K)=\mu_{2}(K)$. This also implies the two measures are equal on all open sets because they are both inner regular on open sets. It is being assumed the two measures are regular. Now let $F \in \mathscr{S}_{1}$ with $\mu_{1}(F)<\infty$. Then there exist sets, $H, G$ such that $H \subseteq F \subseteq G$ such that $H$ is the countable union of compact sets and $G$ is a countable intersection of open sets such that $\mu_{1}(G)=\mu_{1}(H)$ which implies $\mu_{1}(G \backslash H)=0$. Now $G \backslash$ $H$ can be written as the countable intersection of sets of the form $V_{k} \backslash K_{k}$ where $V_{k}$ is open, $\mu_{1}\left(V_{k}\right)<\infty$ and $K_{k}$ is compact. From what was just shown, $\mu_{2}\left(V_{k} \backslash K_{k}\right)=\mu_{1}\left(V_{k} \backslash K_{k}\right)$ so it follows $\mu_{2}(G \backslash H)=0$ also. Since $\mu_{2}$ is complete, and $G$ and $H$ are in $\mathscr{S}_{2}$, it follows $F \in \mathscr{S}_{2}$ and $\mu_{2}(F)=\mu_{1}(F)$. Now for arbitrary $F$ possibly having $\mu_{1}(F)=\infty$, consider $F \cap \Omega_{n}$. From what was just shown, this set is in $\mathscr{S}_{2}$ and $\mu_{2}\left(F \cap \Omega_{n}\right)=\mu_{1}\left(F \cap \Omega_{n}\right)$. Taking the union of these $F \cap \Omega_{n}$ gives $F \in \mathscr{S}_{2}$ and also $\mu_{1}(F)=\mu_{2}(F)$. This shows $\mathscr{S}_{1} \subseteq \mathscr{S}_{2}$. Similarly, $\mathscr{S}_{2} \subseteq \mathscr{S}_{1}$.

The following lemma is often useful.
Lemma 12.3.14 Let $(\Omega, \mathscr{F}, \mu)$ be a measure space where $\Omega$ is a topological space. Suppose $\mu$ is a Radon measure and $f$ is measurable with respect to $\mathscr{F}$. Then there exists a Borel measurable function, $g$, such that $g=f$ a.e.

Proof: Assume without loss of generality that $f \geq 0$. Then let $s_{n} \uparrow f$ pointwise. Say

$$
s_{n}(\omega)=\sum_{k=1}^{P_{n}} c_{k}^{n} \mathscr{X}_{E_{k}^{n}}(\omega)
$$

where $E_{k}^{n} \in \mathscr{F}$. By the outer regularity of $\mu$, there exists a Borel set, $F_{k}^{n} \supseteq E_{k}^{n}$ such that $\mu\left(F_{k}^{n}\right)=\mu\left(E_{k}^{n}\right)$. In fact $F_{k}^{n}$ can be assumed to be a $G_{\delta}$ set. Let

$$
t_{n}(\omega) \equiv \sum_{k=1}^{P_{n}} c_{k}^{n} \mathscr{X}_{F_{k}^{n}}(\omega)
$$

Then $t_{n}$ is Borel measurable and $t_{n}(\omega)=s_{n}(\omega)$ for all $\omega \notin N_{n}$ where $N_{n} \in \mathscr{F}$ is a set of measure zero. Now let $N \equiv \cup_{n=1}^{\infty} N_{n}$. Then $N$ is a set of measure zero and if $\omega \notin N$, then $t_{n}(\omega) \rightarrow f(\omega)$. Let $N^{\prime} \supseteq N$ where $N^{\prime}$ is a Borel set and $\mu\left(N^{\prime}\right)=0$. Then $t_{n} \mathscr{X}_{\left(N^{\prime}\right)}{ }^{C}$ converges pointwise to a Borel measurable function, $g$, and $g(\omega)=f(\omega)$ for all $\omega \notin N^{\prime}$. Therefore, $g=f$ a.e. and this proves the lemma.

### 12.4 One Dimensional Lebesgue Measure

To obtain one dimensional Lebesgue measure, you use the positive linear functional $L$ given by

$$
L f=\int f(x) d x
$$

whenever $f \in C_{c}(\mathbb{R})$. Lebesgue measure, denoted by $m$ is the measure obtained from the Riesz representation theorem such that

$$
\int f d m=L f=\int f(x) d x
$$

From this it is easy to verify that

$$
\begin{equation*}
m([a, b])=m((a, b))=b-a . \tag{12.4.16}
\end{equation*}
$$

This will be done in general a little later but for now, consider the following picture of functions, $f^{k}$ and $g^{k}$. Note that $f^{k} \leq \mathscr{X}_{(a, b)} \leq \mathscr{X}_{[a, b]} \leq g^{k}$.

Then considering lower sums and upper sums in the inequalities on the ends,

$$
\begin{aligned}
\left(b-a-\frac{2}{k}\right) & \leq \int f^{k} d x=\int f^{k} d m \leq m((a, b)) \leq m([a, b]) \\
& =\int \mathscr{X}_{[a, b]} d m \leq \int g^{k} d m=\int g^{k} d x \leq\left(b-a+\frac{2}{k}\right)
\end{aligned}
$$

From this the claim in 12.4.16 follows.

### 12.5 One Dimensional Lebesgue Stieltjes Measure

This is just a generalization of Lebesgue measure. Instead of the functional,

$$
L f \equiv \int f(x) d x, f \in C_{c}(\mathbb{R})
$$

you use the functional

$$
L f \equiv \int f(x) d F(x) f \in C_{c}(\mathbb{R})
$$

where $F$ is an increasing function defined on $\mathbb{R}$. By Theorem 4.3.4 this functional is easily seen to be well defined. Therefore, by the Riesz representation theorem there exists a
unique Radon measure $\mu$ representing the functional. Thus

$$
\int_{\mathbb{R}} f d \mu=\int f d F
$$

for all $f \in C_{c}(\mathbb{R})$. Now consider what this measure does to intervals. To begin with, consider what it does to the closed interval, $[a, b]$. The following picture may help.

In this picture $\left\{a_{n}\right\}$ increases to $a$ and $b_{n}$ decreases to $b$. Also suppose $a, b$ are points of continuity of $F$. Therefore,

$$
F(b)-F(a) \leq L f_{n}=\int_{\mathbb{R}} f_{n} d \mu \leq F\left(b_{n}\right)-F\left(a_{n}\right)
$$

Passing to the limit and using the dominated convergence theorem, this shows

$$
\mu([a, b])=F(b)-F(a)=F(b+)-F(a-) .
$$

Next suppose $a, b$ are arbitrary, maybe not points of continuity of $F$. Then letting $a_{n}$ and $b_{n}$ be as in the above picture which are points of continuity of $F$,

$$
\begin{aligned}
\mu([a, b]) & =\lim _{n \rightarrow \infty} \mu\left(\left[a_{n}, b_{n}\right]\right)=\lim _{n \rightarrow \infty} F\left(b_{n}\right)-F\left(a_{n}\right) \\
& =F(b+)-F(a-) .
\end{aligned}
$$

In particular $\mu(a)=F(a+)-F(a-)$ and so

$$
\begin{aligned}
\mu((a, b))= & F(b+)-F(a-)-(F(a+)-F(a-)) \\
& -(F(b+)-F(b-)) \\
= & F(b-)-F(a+)
\end{aligned}
$$

This shows what $\mu$ does to intervals. This is stated as the following proposition.
Proposition 12.5.1 Let $\mu$ be the measure representing the functional

$$
L f \equiv \int f d F, f \in C_{c}(\mathbb{R})
$$

for $F$ an increasing function defined on $\mathbb{R}$. Then

$$
\begin{aligned}
\mu([a, b]) & =F(b+)-F(a-) \\
\mu((a, b)) & =F(b-)-F(a+) \\
\mu(a) & =F(a+)-F(a-) .
\end{aligned}
$$

Observation 12.5.2 Note that all the above would work as well if

$$
L f \equiv \int f d F, f \in C_{c}([0, \infty))
$$

where $F$ is continuous at 0 and $v$ is the measure representing this functional. This is because you could just extend $F(x)$ to equal $F(0)$ for $x \leq 0$ and apply the above to the extended $F$. In this case, $v([0, b])=F(b+)-F(0)$.

### 12.6 The Distribution Function

There is an interesting connection between the Lebesgue integral of a nonnegative function with something called the distribution function.
Definition 12.6.1 Let $f \geq 0$ and suppose $f$ is measurable. The distribution function is the function defined by

$$
t \rightarrow \mu([t<f])
$$

Lemma 12.6.2 If $\left\{f_{n}\right\}$ is an increasing sequence of functions converging pointwise to $f$ then

$$
\mu([f>t])=\lim _{n \rightarrow \infty} \mu\left(\left[f_{n}>t\right]\right)
$$

Proof: The sets, $\left[f_{n}>t\right]$ are increasing and their union is $[f>t]$ because if $f(\omega)>t$, then for all $n$ large enough, $f_{n}(\omega)>t$ also. Therefore, the desired conclusion follows from properties of measures.
Lemma 12.6.3 Suppose $s \geq 0$ is a measurable simple function,

$$
s(\omega) \equiv \sum_{k=1}^{n} a_{k} \mathscr{X}_{E_{k}}(\omega)
$$

where the $a_{k}$ are the distinct nonzero values of $s, 0<a_{1}<a_{2}<\cdots<a_{n}$. Suppose $\phi$ is a $C^{1}$ function defined on $[0, \infty)$ which has the property that $\phi(0)=0, \phi^{\prime}(t)>0$ for all $t$. Then

$$
\int_{0}^{\infty} \phi^{\prime}(t) \mu([s>t]) d m=\int \phi(s) d \mu .
$$

Proof: First note that if $\mu\left(E_{k}\right)=\infty$ for any $k$ then both sides equal $\infty$ and so without loss of generality, assume $\mu\left(E_{k}\right)<\infty$ for all $k$. Letting $a_{0} \equiv 0$, the left side equals

$$
\begin{aligned}
\sum_{k=1}^{n} \int_{a_{k-1}}^{a_{k}} \phi^{\prime}(t) \mu([s>t]) d m(t) & =\sum_{k=1}^{n} \int_{a_{k-1}}^{a_{k}} \phi^{\prime}(t) \sum_{i=k}^{n} \mu\left(E_{i}\right) d m \\
& =\sum_{k=1}^{n} \sum_{i=k}^{n} \mu\left(E_{i}\right) \int_{a_{k-1}}^{a_{k}} \phi^{\prime}(t) d m \\
& =\sum_{k=1}^{n} \sum_{i=k}^{n} \mu\left(E_{i}\right)\left(\phi\left(a_{k}\right)-\phi\left(a_{k-1}\right)\right) \\
& =\sum_{i=1}^{n} \mu\left(E_{i}\right) \sum_{k=1}^{i}\left(\phi\left(a_{k}\right)-\phi\left(a_{k-1}\right)\right) \\
& =\sum_{i=1}^{n} \mu\left(E_{i}\right) \phi\left(a_{i}\right)=\int \phi(s) d \mu
\end{aligned}
$$

With this lemma the next theorem which is the main result follows easily.
Theorem 12.6.4 Let $f \geq 0$ be measurable and let $\phi$ be a $C^{1}$ function defined on $[0, \infty)$ which satisfies $\phi^{\prime}(t)>0$ for all $t>0$ and $\phi(0)=0$. Then

$$
\int \phi(f) d \mu=\int_{0}^{\infty} \phi^{\prime}(t) \mu([f>t]) d m
$$

Proof: By Theorem 11.3.9 on Page 241 there exists an increasing sequence of nonnegative simple functions, $\left\{s_{n}\right\}$ which converges pointwise to $f$. By the monotone convergence theorem and Lemma 12.6.2,

$$
\begin{aligned}
\int \phi(f) d \mu & =\lim _{n \rightarrow \infty} \int \phi\left(s_{n}\right) d \mu=\lim _{n \rightarrow \infty} \int_{0}^{\infty} \phi^{\prime}(t) \mu\left(\left[s_{n}>t\right]\right) d m \\
& =\int_{0}^{\infty} \phi^{\prime}(t) \mu([f>t]) d m
\end{aligned}
$$

This theorem can be generalized to a situation in which $\phi$ is only increasing and continuous. In the generalization I will replace the symbol $\phi$ with $F$ to coincide with earlier notation.

Lemma 12.6.5 Suppose $s \geq 0$ is a measurable simple function,

$$
s(\omega) \equiv \sum_{k=1}^{n} a_{k} \mathscr{X}_{E_{k}}(\omega)
$$

where the $a_{k}$ are the distinct nonzero values of $s, a_{1}<a_{2}<\cdots<a_{n}$. Suppose $F$ is an increasing function defined on $[0, \infty), F(0)=0, F$ being continuous at 0 from the right and continuous at every $a_{k}$. Then letting $\mu$ be a measure and $(\Omega, \mathscr{F}, \mu)$ a measure space,

$$
\int_{(0, \infty]} \mu([s>t]) d \nu=\int_{\Omega} F(s) d \mu
$$

where the integral on the left is the Lebesgue integral for the measure $v$ given as the Radon measure representing the functional

$$
\int_{0}^{\infty} g d F
$$

for $g \in C_{c}([0, \infty))$.
Proof: This follows from the following computation and Proposition 12.5.1. Since $F$ is continuous at 0 and the values $a_{k}$,

$$
\begin{gathered}
\int_{0}^{\infty} \mu([s>t]) d v(t)=\sum_{k=1}^{n} \int_{\left(a_{k-1}, a_{k}\right]} \mu([s>t]) d v(t) \\
=\sum_{k=1}^{n} \int_{\left(a_{k-1}, a_{k}\right]} \sum_{j=k}^{n} \mu\left(E_{j}\right) d F(t)=\sum_{j=1}^{n} \mu\left(E_{j}\right) \sum_{k=1}^{j} v\left(\left(a_{k-1}, a_{k}\right]\right) \\
=\sum_{j=1}^{n} \mu\left(E_{j}\right) \sum_{k=1}^{j}\left(F\left(a_{k}\right)-F\left(a_{k-1}\right)\right)=\sum_{j=1}^{n} \mu\left(E_{j}\right) F\left(a_{j}\right) \equiv \int_{\Omega} F(s) d \mu
\end{gathered}
$$

Now here is the generalization to nonnegative measurable $f$.

Theorem 12.6.6 Let $f \geq 0$ be measurable with respect to $\mathscr{F}$ where $(\Omega, \mathscr{F}, \mu)$ a measure space, and let $F$ be an increasing continuous function defined on $[0, \infty)$ and $F(0)=0$. Then

$$
\int_{\Omega} F(f) d \mu=\int_{(0, \infty]} \mu([f>t]) d v(t)
$$

where $v$ is the Radon measure representing

$$
L g=\int_{0}^{\infty} g d F
$$

for $g \in C_{c}([0, \infty))$.
Proof: By Theorem 11.3.9 on Page 241 there exists an increasing sequence of nonnegative simple functions, $\left\{s_{n}\right\}$ which converges pointwise to $f$. By the monotone convergence theorem and Lemma 12.6.5,

$$
\begin{aligned}
\int_{\Omega} F(f) d \mu & =\lim _{n \rightarrow \infty} \int_{\Omega} F\left(s_{n}\right) d \mu=\lim _{n \rightarrow \infty} \int_{(0, \infty]} \mu\left(\left[s_{n}>t\right]\right) d v \\
& =\int_{(0, \infty]} \mu([f>t]) d v
\end{aligned}
$$

Note that the function $t \rightarrow \mu([f>t])$ is a decreasing function. Therefore, one can make sense of an improper Riemann Stieltjes integral

$$
\int_{0}^{\infty} \mu([f>t]) d F(t)
$$

With more work, one can have this equal to the corresponding Lebesgue integral above.

### 12.7 Good Lambda Inequality

There is a very interesting and important inequality called the good lambda inequality (I am not sure if there is a bad lambda inequality.) which follows from the above theory of distribution functions. It involves the inequality

$$
\mu([f>\beta \lambda] \cap[g \leq \delta \lambda]) \leq \phi(\delta) \mu([f>\lambda])
$$

for $\beta>1$, nonnegative functions $f, g$ and is supposed to hold for all small positive $\delta$ and $\phi(\boldsymbol{\delta}) \rightarrow 0$ as $\boldsymbol{\delta} \rightarrow 0$. Note the left side is small when $g$ is large and $f$ is small. The inequality involves dominating an integral involving $f$ with one involving $g$ as described below. As above, $v$ is the measure which comes from the functional $\int_{\mathbb{R}} g d F$ for $g \in C_{c}(\mathbb{R})$.

Theorem 12.7.1 Let $(\Omega, \mathscr{F}, \mu)$ be a finite measure space and let $F$ be a continuous increasing function defined on $[0, \infty)$ such that $F(0)=0$. Suppose also that for all $\alpha>1$, there exists a constant $C_{\alpha}$ such that for all $x \in[0, \infty)$,

$$
F(\alpha x) \leq C_{\alpha} F(x)
$$

Also suppose $f, g$ are nonnegative measurable functions and there exists $\beta>1,0<r \leq 1$, such that for all $\lambda>0$ and $1>\delta>0$,

$$
\begin{equation*}
\mu([f>\beta \lambda] \cap[g \leq r \delta \lambda]) \leq \phi(\delta) \mu([f>\lambda]) \tag{12.7.17}
\end{equation*}
$$

where $\lim _{\delta \rightarrow 0+} \phi(\delta)=0$ and $\phi$ is increasing. Under these conditions, there exists a constant $C$ depending only on $\beta, \phi, r$ such that

$$
\int_{\Omega} F(f(\omega)) d \mu(\omega) \leq C \int_{\Omega} F(g(\omega)) d \mu(\omega)
$$

Proof: Let $\beta>1$ be as given above. First suppose $f$ is bounded.

$$
\begin{aligned}
\int_{\Omega} F(f) d \mu & =\int_{\Omega} F\left(\beta \frac{f}{\beta}\right) d \mu \leq C_{\beta} \int_{\Omega} F\left(\frac{f}{\beta}\right) d \mu \\
& =C_{\beta} \int_{0}^{\infty} \mu([f>\beta \lambda]) d \nu
\end{aligned}
$$

Now using the given inequality,

$$
\begin{aligned}
= & C_{\beta} \int_{0}^{\infty} \mu([f>\beta \lambda] \cap[g \leq r \delta \lambda]) d v \\
& +C_{\beta} \int_{0}^{\infty} \mu([f>\beta \lambda] \cap[g>r \delta \lambda]) d v \\
\leq & C_{\beta} \phi(\delta) \int_{0}^{\infty} \mu([f>\lambda]) d v+C_{\beta} \int_{0}^{\infty} \mu([g>r \delta \lambda]) d v \\
\leq & C_{\beta} \phi(\delta) \int_{\Omega} F(f) d \mu+C_{\beta} \int_{\Omega} F\left(\frac{g}{r \delta}\right) d \mu
\end{aligned}
$$

Now choose $\delta$ small enough that $C_{\beta} \phi(\delta)<\frac{1}{2}$ and then subtract the first term on the right in the above from both sides. It follows from the properties of $F$ again that

$$
\frac{1}{2} \int_{\Omega} F(f) d \mu \leq C_{\beta} C_{(r \delta)^{-1}} \int_{\Omega} F(g) d \mu
$$

This establishes the inequality in the case where $f$ is bounded.
In general, let $f_{n}=\min (f, n)$. Then for $n \leq \lambda$, the inequality

$$
\mu([f>\beta \lambda] \cap[g \leq r \delta \lambda]) \leq \phi(\delta) \mu([f>\lambda])
$$

holds with $f$ replaced with $f_{n}$ because both sides equal 0 thanks to $\beta>1$. If $n>\lambda$, then $[f>\lambda]=\left[f_{n}>\lambda\right]$ and so the inequality still holds because in this case,

$$
\begin{aligned}
\mu\left(\left[f_{n}>\beta \lambda\right] \cap[g \leq r \delta \lambda]\right) & \leq \mu([f>\beta \lambda] \cap[g \leq r \delta \lambda]) \\
& \leq \phi(\delta) \mu([f>\lambda])=\phi(\delta) \mu\left(\left[f_{n}>\lambda\right]\right)
\end{aligned}
$$

Therefore, 12.7 .17 is valid with $f$ replaced with $f_{n}$. Now pass to the limit as $n \rightarrow \infty$ and use the monotone convergence theorem.

### 12.8 The Ergodic Theorem

I am putting this theorem here because it seems to fit in well with the material of this chapter.

In this section $(\Omega, \mathscr{F}, \mu)$ will be a finite measure space. This means that $\mu(\Omega)<\infty$. The mapping, $T: \Omega \rightarrow \Omega$ will satisfy the following condition.

$$
\begin{equation*}
T(A), T^{-1}(A) \in \mathscr{F} \text { whenever } A \in \mathscr{F}, T \text { is one to one. } \tag{12.8.18}
\end{equation*}
$$

For example, you could have $T$ a homeomorphism on some topological space $X$ and the $\sigma$ algebra could be the Borel sets.

Lemma 12.8.1 If $T$ satisfies 12.8.18, then $f \circ T$ is measurable whenever $f$ is measurable.
Proof: Let $U$ be an open set. Then

$$
(f \circ T)^{-1}(U)=T^{-1}\left(f^{-1}(U)\right) \in \mathscr{F}
$$

by 12.8.18.
Now suppose that in addition to $12.8 .18, T$ also satisfies

$$
\begin{equation*}
\mu\left(T^{-1} A\right)=\mu(A) \tag{12.8.19}
\end{equation*}
$$

for all $A \in \mathscr{F}$. In words, $T^{-1}$ is measure preserving. Note that also

$$
\mu(T A)=\mu\left(T^{-1} T A\right)=\mu(A)
$$

so also $T$ is measure preserving. Then for $T$ satisfying 12.8 .18 and 12.8.19, we have the following simple lemma.

Lemma 12.8.2 If $T$ satisfies 12.8 .18 and 12.8 .19 then whenever $f$ is nonnegative and measurable,

$$
\begin{equation*}
\int_{\Omega} f(\omega) d \mu=\int_{\Omega} f(T \omega) d \mu \tag{12.8.20}
\end{equation*}
$$

Also 12.8.20 holds whenever $f \in L^{1}(\Omega)$.
Proof: Let $f \geq 0$ and $f$ is measurable. Let $A \in \mathscr{F}$. Then from 12.8.19,

$$
\int_{\Omega} \mathscr{X}_{A}(\omega) d \mu=\mu(A)=\mu\left(T^{-1}(A)\right)=\int_{\Omega} \mathscr{X}_{T^{-1}(A)}(\omega) d \mu=\int_{\Omega} \mathscr{X}_{A}(T(\omega)) d \mu .
$$

It follows that whenever $s$ is a simple function,

$$
\int s(\omega) d \mu=\int s(T \omega) d \mu
$$

If $f \geq 0$ and measurable, Theorem 11.3.9 on Page 241, implies there exists an increasing sequence of simple functions, $\left\{s_{n}\right\}$ converging pointwise to $f$. Then the result follows from monotone convergence theorem. Splitting $f \in L^{1}$ into real and imaginary parts we apply this to the positive and negative parts of these and obtain 12.8 .20 in this case also.

Definition 12.8.3 A measurable function $f$, is said to be invariant if

$$
f(T \omega)=f(\omega)
$$

A set, $A \in \mathscr{F}$ is said to be invariant if $\mathscr{X}_{A}$ is an invariant function. Thus a set is invariant if and only if $T^{-1} A=A .\left(\mathscr{X}_{A}(T \omega)=\mathscr{X}_{T^{-1}(A)}(\omega)\right.$ so to say that $\mathscr{X}_{A}$ is invariant is to say that $T^{-1} A=A$.)

The following theorem, the individual ergodic theorem, is the main result. Define $T^{0}(\omega)=\omega$. Let

$$
S_{n} f(\omega) \equiv \sum_{k=1}^{n} f\left(T^{k-1} \omega\right), S_{0} f(\omega) \equiv 0
$$

Also define the following maximal type function $M_{\infty} f(\omega)$

$$
\begin{equation*}
M_{\infty} f(\omega) \equiv \sup \left\{S_{k} f(\omega): 0 \leq k\right\} \tag{12.8.21}
\end{equation*}
$$

and let

$$
\begin{equation*}
M_{n} f(\omega) \equiv \sup \left\{S_{k} f(\omega): 0 \leq k \leq n\right\} \tag{12.8.22}
\end{equation*}
$$

Then one can prove the following interesting lemma.
Lemma 12.8.4 Let $f \in L^{1}(\mu)$ where $f$ has real values. Then $\int_{\left[M_{\infty} f>0\right]} f d \mu \geq 0$.
Proof: First note that $M_{n} f(\omega) \geq 0$ for all $n$ and $\omega$. This follows easily from the observation that by definition, $S_{0} f(\omega)=0$ and so $M_{n} f(\omega)$ is at least as large. There is certainly something to show here because the integrand is not known to be nonnegative. The integral involves $f$ not $M_{\infty} f$.

Let $T^{*} h \equiv h \circ T$. Thus $T^{*}$ is linear and maps measurable functions to measurable functions by Lemma 12.8.1. It is also clear that if $h \geq 0$, then $T^{*} h \geq 0$ also. Therefore, for large $k \leq n$,

$$
\begin{aligned}
S_{k} f(\omega) & \equiv \sum_{j=1}^{k} f\left(T^{j-1} \omega\right)=f(\omega)+\sum_{j=2}^{k} f\left(T^{j-1} \omega\right) \\
& =f(\omega)+T^{*} \sum_{j=1}^{k-1} f\left(T^{j-1} \omega\right)\left(\text { factored out } T^{*}\right) \\
& =f(\omega)+T^{*} S_{k-1} f(\omega) \leq f(\omega)+T^{*} M_{n} f
\end{aligned}
$$

and so, taking the supremum for $k \leq n$,

$$
M_{n} f(\omega) \leq f(\omega)+T^{*} M_{n} f(\omega)
$$

Now since $M_{n} f \geq 0$,

$$
\begin{aligned}
& \int_{\Omega} M_{n} f(\omega) d \mu=\int_{\left[M_{n} f>0\right]} M_{n} f(\omega) d \mu \\
\leq & \int_{\left[M_{n} f>0\right]} f(\omega) d \mu+\int_{\Omega} T^{*} M_{n} f(\omega) d \mu
\end{aligned}
$$

$$
=\int_{\left[M_{n} f>0\right]} f(\omega) d \mu+\int_{\Omega} M_{n} f(\omega) d \mu
$$

by Lemma 12.8.2. It follows that

$$
\int_{\left[M_{n} f>0\right]} f(\omega) d \mu \geq 0
$$

for each $n$. Also, since $M_{n} f(\omega) \rightarrow M_{\infty} f(\omega)$, the following pointwise convergence holds.

$$
\mathscr{X}_{\left[M_{n} f>0\right]}(\omega) f(\omega) \rightarrow \mathscr{X}_{\left[M_{\infty} f>0\right]}(\omega) f(\omega)
$$

Since $f$ is in $L^{1}$, the dominated convergence theorem implies

$$
\int_{\left[M_{\infty} f>0\right]} f(\omega) d \mu=\lim _{n \rightarrow \infty} \int_{\left[M_{n} f>0\right]} f(\omega) d \mu \geq 0
$$

Theorem 12.8.5 Let $(\Omega, \mathscr{F}, \mu)$ be a probability space and let $T: \Omega \rightarrow \Omega$ satisfy 12.8.18 and 12.8.19, $T^{-1}$ is measure preserving and $T^{-1}$ maps $\mathscr{F}$ to $\mathscr{F}$ and $T$ is one to one. Then if $f \in L^{1}(\Omega)$ having real or complex values and

$$
\begin{equation*}
S_{n} f(\omega) \equiv \sum_{k=1}^{n} f\left(T^{k-1} \omega\right), S_{0} f(\omega) \equiv 0 \tag{12.8.23}
\end{equation*}
$$

it follows there exists a set of measure zero $N$, and an invariant function $g$ such that for all $\omega \notin N$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)=g(\omega) \tag{12.8.24}
\end{equation*}
$$

and also

$$
\lim _{n \rightarrow \infty} \frac{1}{n} S_{n} f=g \text { in } L^{1}(\Omega)
$$

Proof: To begin with, we assume $f$ has real values. Now if $A$ is an invariant set, $\mathscr{X}_{A}\left(T^{m} \omega\right)=\mathscr{X}_{A}(\omega)$ and so

$$
\begin{aligned}
S_{n}\left(\mathscr{X}_{A} f\right)(\omega) & \equiv \sum_{k=1}^{n} f\left(T^{k-1} \omega\right) \mathscr{X}_{A}\left(T^{k-1} \omega\right)=\sum_{k=1}^{n} f\left(T^{k-1} \omega\right) \mathscr{X}_{A}(\omega) \\
& =\mathscr{X}_{A}(\omega) \sum_{k=1}^{n} f\left(T^{k-1} \omega\right)=\mathscr{X}_{A}(\omega) S_{n} f(\omega)
\end{aligned}
$$

Therefore, for such an invariant set,

$$
\begin{equation*}
M_{n}\left(\mathscr{X}_{A} f\right)(\omega)=\mathscr{X}_{A}(\omega) M_{n} f(\omega), M_{\infty}\left(\mathscr{X}_{A} f\right)(\omega)=\mathscr{X}_{A}(\omega) M_{\infty} f(\omega) \tag{12.8.25}
\end{equation*}
$$

Let $-\infty<a<b<\infty$ and define

$$
\begin{equation*}
N_{a b} \equiv\left[-\infty<\lim \inf _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)<a<b<\lim \sup _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)<\infty\right] \tag{12.8.26}
\end{equation*}
$$

Observe that from the definition,

$$
\lim \inf _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)=\lim \inf _{n \rightarrow \infty} \frac{1}{n} S_{n} f(T \omega)
$$

and

$$
\lim \sup _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)=\lim \sup _{n \rightarrow \infty} \frac{1}{n} S_{n} f(T \omega)
$$

Thus if $\omega \in N_{a b}$, it follows that $T \omega \in N_{a b}$ and if $T \omega \in N_{a b}$, then so is $\omega$. Thus $N_{a b}$ is an invariant set. Also, if $\omega \in N_{a b}$, then

$$
a-\lim \inf _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)=\lim \sup _{n \rightarrow \infty}\left(a-\frac{1}{n} S_{n} f(\omega)\right)>0
$$

and

$$
\lim \sup _{n \rightarrow \infty}\left(\frac{1}{n} S_{n} f(\omega)-b\right)>0
$$

It follows that

$$
N_{a b} \subseteq\left[M_{\infty}(f-b)>0\right] \cap\left[M_{\infty}(a-f)>0\right]
$$

Consequently, since $N_{a b}$ is invariant, argued above,

$$
\mathscr{X}_{N_{a b}} M_{\infty}(f-b)=M_{\infty}\left(\mathscr{X}_{N_{a b}}(f-b)\right)
$$

and so from Lemma 12.8.4

$$
\begin{gather*}
\int_{N_{a b}}(f(\omega)-b) d \mu=\int_{\left[\mathscr{X}_{N_{a b}} M_{\infty}(f-b)>0\right]} \mathscr{X}_{N_{a b}}(\omega)(f(\omega)-b) d \mu \\
\quad=\int_{\left[M_{\infty}\left(\mathscr{X}_{N_{a b}}(f-b)\right)>0\right]} \mathscr{X}_{N_{a b}}(\omega)(f(\omega)-b) d \mu \geq 0 \tag{12.8.27}
\end{gather*}
$$

and

$$
\begin{gather*}
\int_{N_{a b}}(a-f(\omega)) d \mu=\int_{\left[\mathscr{X}_{\left.N_{a b} M_{\infty}(a-f)>0\right]} \mathscr{X}_{N_{a b}}(\omega)(a-f(\omega)) d \mu\right.}=\int_{\left[M _ { \infty } \left(\mathscr{X}_{\left.\left.N_{a b}(a-f)\right)>0\right]} \mathscr{X}_{N_{a b}}(\omega)(a-f(\omega)) d \mu \geq 0\right.\right.}
\end{gather*}
$$

It follows that

$$
\begin{equation*}
a \mu\left(N_{a b}\right) \geq \int_{N_{a b}} f d \mu \geq b \mu\left(N_{a b}\right) \tag{12.8.29}
\end{equation*}
$$

Since $a<b$, it follows that $\mu\left(N_{a b}\right)=0$.
Now let

$$
N \equiv \cup\left\{N_{a b}: a<b, a, b \in \mathbb{Q}\right\}
$$

It follows that $\mu(N)=0$. Now $T N_{a, b}=N_{a, b}$ and so

$$
T(N)=\cup_{a, b} T\left(N_{a, b}\right)=\cup_{a, b} N_{a, b}=N
$$

Thus, $T^{n} N=N$ for all $n \in \mathbb{N}$. For $\omega \notin N, \lim _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)$ exists. Now let

$$
g(\omega) \equiv\left\{\begin{array}{l}
0 \text { if } \omega \in N \\
\lim _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega) \text { if } \omega \notin N
\end{array}\right.
$$

Then it is clear $g$ satisfies the conditions of the theorem because if $\omega \in N$, then $T \omega \in N$ also and so in this case, $g(T \omega)=g(\omega) \equiv 0$. On the other hand, if $\omega \notin N$, then

$$
g(T \omega)=\lim _{n \rightarrow \infty} \frac{1}{n} S_{n} f(T \omega)=\lim _{n \rightarrow \infty} \frac{1}{n} S_{n} f(\omega)=g(\omega) .
$$

Which shows that $g$ is invariant. Also, from Lemma 12.8.2,

$$
\begin{aligned}
\int_{\Omega}|g| d \mu & \leq \lim _{n \rightarrow \infty} \int_{\Omega}\left|\frac{1}{n} S_{n} f\right| d \mu \leq \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n} \int_{\Omega}\left|f\left(T^{k-1} \omega\right)\right| d \mu \\
& =\liminf _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n} \int_{\Omega}|f(\omega)| d \mu=\|f\|_{L^{1}}
\end{aligned}
$$

so $g \in L^{1}(\Omega, \mu)$.
The last claim about convergence in $L^{1}$ follows from the Vitali convergence theorem if we verify the sequence, $\left\{\frac{1}{n} S_{n} f\right\}_{n=1}^{\infty}$ is uniformly integrable. To see this is the case, we know $f \in L^{1}(\Omega)$ and so if $\varepsilon>0$ is given, there exists $\delta>0$ such that whenever $B \in \mathscr{F}$ and $\mu(B) \leq \delta$, then $\left|\int_{B} f(\omega) d \mu\right|<\varepsilon$. Taking $\mu(A)<\delta$, it follows

$$
\begin{gathered}
\left|\int_{A} \frac{1}{n} S_{n} f(\omega) d \mu\right|=\left|\frac{1}{n} \sum_{k=1}^{n} \int_{A} f\left(T^{k-1} \omega\right) d \mu\right|=\left|\frac{1}{n} \sum_{k=1}^{n} \int_{\Omega} \mathscr{X}_{A}(\omega) f\left(T^{k-1} \omega\right) d \mu\right| \\
=\left|\frac{1}{n} \sum_{k=1}^{n} \int_{\Omega} \mathscr{X}_{A}\left(T^{k-1} T^{-(k-1)} \omega\right) f\left(T^{k-1} \omega\right) d \mu\right| \\
=\left|\frac{1}{n} \sum_{k=1}^{n} \int_{\Omega} \mathscr{X}_{A}\left(T^{-(k-1)} \omega\right) f(\omega) d \mu\right| \\
=\left|\frac{1}{n} \sum_{k=1}^{n} \int_{T^{k-1}(A)} f(\omega) d \mu\right| \leq \frac{1}{n} \sum_{k=1}^{n}\left|\int_{T^{k-1}(A)} f(\omega) d \mu\right|<\frac{1}{n} \sum_{k=1}^{n} \varepsilon=\varepsilon
\end{gathered}
$$

because $\mu\left(T^{(k-1)} A\right)=\mu(A)$ by assumption. This proves the above sequence is uniformly integrable and so, by the Vitali convergence theorem,

$$
\lim _{n \rightarrow \infty} \int_{\Omega}\left|\frac{1}{n} S_{n} f-g\right| d \mu=0
$$

This proves the theorem in the case the function has real values. In the case where $f$ has complex values, apply the above result to the real and imaginary parts of $f$.

Definition 12.8.6 The above mapping $T$ is ergodic if the only invariant sets have measure 0 or 1 .

If the map, $T$ is ergodic, the following corollary holds.
Corollary 12.8.7 In the situation of Theorem 12.8.5, if $T$ is ergodic, then

$$
g(\omega)=\int f(\omega) d \mu
$$

for a.e. $\omega$.
Proof: Let $g$ be the function of Theorem 12.8 .5 and let $R_{1}$ be a rectangle in $\mathbb{R}^{2}=\mathbb{C}$ of the form $[-a, a] \times[-a, a]$ such that $g^{-1}\left(R_{1}\right)$ has measure greater than 0 . This set is invariant because the function, $g$ is invariant and so it must have measure 1. Divide $R_{1}$ into four equal rectangles, $R_{1}^{\prime}, R_{2}^{\prime}, R_{3}^{\prime}, R_{4}^{\prime}$. Then one of these, renamed $R_{2}$ has the property that $g^{-1}\left(R_{2}\right)$ has positive measure. Therefore, since the set is invariant, it must have measure 1. Continue in this way obtaining a sequence of closed rectangles, $\left\{R_{i}\right\}$ such that the diameter of $R_{i}$ converges to zero and $g^{-1}\left(R_{i}\right)$ has measure 1 . Then let $c=\cap_{j=1}^{\infty} R_{j}$. We know $\mu\left(g^{-1}(c)\right)=\lim _{n \rightarrow \infty} \mu\left(g^{-1}\left(R_{i}\right)\right)=1$. It follows that $g(\omega)=c$ for a.e. $\omega$. Now from Theorem 12.8.5,

$$
c=\int c d \mu=\lim _{n \rightarrow \infty} \frac{1}{n} \int S_{n} f d \mu=\int f d \mu
$$

### 12.9 Product Measures

Let $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{T}, v)$ be two complete measure spaces. In this section consider the problem of defining a product measure, $\overline{\mu \times v}$ which is defined on a $\sigma$ algebra of sets of $X \times Y$ such that $(\overline{\mu \times v})(E \times F)=\mu(E) v(F)$ whenever $E \in \mathscr{S}$ and $F \in \mathscr{T}$. I found the following approach to product measures in [47] and they say they got it from [50].

Definition 12.9.1 Let $\mathscr{R}$ denote the set of countable unions of sets of the form $A \times B$, where $A \in \mathscr{S}$ and $B \in \mathscr{T}$ (Sets of the form $A \times B$ are referred to as measurable rectangles) and also let

$$
\begin{equation*}
\rho(A \times B)=\mu(A) v(B) \tag{12.9.30}
\end{equation*}
$$

More generally, define

$$
\begin{equation*}
\rho(E) \equiv \iint \mathscr{X}_{E}(x, y) d \mu d v \tag{12.9.31}
\end{equation*}
$$

whenever $E$ is such that

$$
\begin{equation*}
x \rightarrow \mathscr{X}_{E}(x, y) \text { is } \mu \text { measurable for all } y \tag{12.9.32}
\end{equation*}
$$

and

$$
\begin{equation*}
y \rightarrow \int \mathscr{X}_{E}(x, y) d \mu \text { is } v \text { measurable. } \tag{12.9.33}
\end{equation*}
$$

Note that if $E=A \times B$ as above, then

$$
\begin{aligned}
\iint \mathscr{X}_{E}(x, y) d \mu d v & =\iint \mathscr{X}_{A \times B}(x, y) d \mu d v \\
& =\iint \mathscr{X}_{A}(x) \mathscr{X}_{B}(y) d \mu d v=\mu(A) v(B)=\rho(E)
\end{aligned}
$$

and so there is no contradiction between 12.9.31 and 12.9.30.
The first goal is to show that for $Q \in \mathscr{R}, 12.9 .32$ and 12.9.33 both hold. That is, $x \rightarrow$ $\mathscr{X}_{Q}(x, y)$ is $\mu$ measurable for all $y$ and $y \rightarrow \int \mathscr{X}_{Q}(x, y) d \mu$ is $v$ measurable. This is done so that it is possible to speak of $\rho(Q)$. The following lemma will be the fundamental result which will make this possible. First here is a picture.

Lemma 12.9.2 Given $C \times D$ and $\left\{A_{i} \times B_{i}\right\}_{i=1}^{n}$, there exist finitely many disjoint rectangles, $\left\{C_{i}^{\prime} \times D_{i}^{\prime}\right\}_{i=1}^{p}$ such that none of these sets intersect any of the $A_{i} \times B_{i}$, each set is contained in $C \times D$ and

$$
\left(\cup_{i=1}^{n} A_{i} \times B_{i}\right) \cup\left(\cup_{k=1}^{p} C_{k}^{\prime} \times D_{k}^{\prime}\right)=(C \times D) \cup\left(\cup_{i=1}^{n} A_{i} \times B_{i}\right) .
$$

Proof: From the above picture, you see that

$$
(C \times D) \backslash\left(A_{1} \times B_{1}\right)=C \times\left(D \backslash B_{1}\right) \cup\left(C \backslash A_{1}\right) \times\left(D \cap B_{1}\right)
$$

and these last two sets are disjoint, have empty intersection with $A_{1} \times B_{1}$, and

$$
\left(C \times\left(D \backslash B_{1}\right) \cup\left(C \backslash A_{1}\right) \times\left(D \cap B_{1}\right)\right) \cup\left(\cup_{i=1}^{n} A_{i} \times B_{i}\right)=(C \times D) \cup\left(\cup_{i=1}^{n} A_{i} \times B_{i}\right)
$$

Now suppose disjoint sets, $\left\{\widetilde{C}_{i} \times \widetilde{D}_{i}\right\}_{i=1}^{m}$ have been obtained, each being a subset of $C \times D$ such that

$$
\left(\cup_{i=1}^{n} A_{i} \times B_{i}\right) \cup\left(\cup_{k=1}^{m} \widetilde{C}_{k} \times \widetilde{D}_{k}\right)=\left(\cup_{i=1}^{n} A_{i} \times B_{i}\right) \cup(C \times D)
$$

and for all $k, \widetilde{C}_{k} \times \widetilde{D}_{k}$ has empty intersection with each set of $\left\{A_{i} \times B_{i}\right\}_{i=1}^{p}$. Then using the same procedure, replace each of $\widetilde{C}_{k} \times \widetilde{D}_{k}$ with finitely many disjoint rectangles such that none of these intersect $A_{p+1} \times B_{p+1}$ while preserving the union of all the sets involved. The process stops when you have gotten to $n$. This proves the lemma.

Lemma 12.9.3 If $Q=\cup_{i=1}^{\infty} A_{i} \times B_{i} \in \mathscr{R}$, then there exist disjoint sets, of the form $A_{i}^{\prime} \times B_{i}^{\prime}$ such that $Q=\cup_{i=1}^{\infty} A_{i}^{\prime} \times B_{i}^{\prime}$, each $A_{i}^{\prime} \times B_{i}^{\prime}$ is a subset of some $A_{i} \times B_{i}$, and $A_{i}^{\prime} \in \mathscr{S}$ while
$B_{i}^{\prime} \in \mathscr{T}$. Also, the intersection of finitely many sets of $\mathscr{R}$ is a set of $\mathscr{R}$. For $\rho$ defined in 12.9.31, it follows that 12.9 .32 and 12.9.33 hold for any element of $\mathscr{R}$. Furthermore,

$$
\rho(Q)=\sum_{i} \mu\left(A_{i}^{\prime}\right) v\left(B_{i}^{\prime}\right)=\sum_{i} \rho\left(A_{i}^{\prime} \times B_{i}^{\prime}\right)
$$

Proof: Let $Q$ be given as above. Let $A_{1}^{\prime} \times B_{1}^{\prime}=A_{1} \times B_{1}$. By Lemma 12.9.2, it is possible to replace $A_{2} \times B_{2}$ with finitely many disjoint rectangles, $\left\{A_{i}^{\prime} \times B_{i}^{\prime}\right\}_{i=2}^{m_{2}}$ such that none of these rectangles intersect $A_{1}^{\prime} \times B_{1}^{\prime}$, each is a subset of $A_{2} \times B_{2}$, and

$$
\cup_{i=1}^{\infty} A_{i} \times B_{i}=\left(\cup_{i=1}^{m_{2}} A_{i}^{\prime} \times B_{i}^{\prime}\right) \cup\left(\cup_{k=3}^{\infty} A_{k} \times B_{k}\right)
$$

Now suppose disjoint rectangles, $\left\{A_{i}^{\prime} \times B_{i}^{\prime}\right\}_{i=1}^{m_{p}}$ have been obtained such that each rectangle is a subset of $A_{k} \times B_{k}$ for some $k \leq p$ and

$$
\cup_{i=1}^{\infty} A_{i} \times B_{i}=\left(\cup_{i=1}^{m_{p}} A_{i}^{\prime} \times B_{i}^{\prime}\right) \cup\left(\cup_{k=p+1}^{\infty} A_{k} \times B_{k}\right) .
$$

By Lemma 12.9.2 again, there exist disjoint rectangles $\left\{A_{i}^{\prime} \times B_{i}^{\prime}\right\}_{i=m_{p}+1}^{m_{p+1}}$ such that each is contained in $A_{p+1} \times B_{p+1}$, none have intersection with any of $\left\{A_{i}^{\prime} \times B_{i}^{\prime}\right\}_{i=1}^{m_{p}}$ and

$$
\cup_{i=1}^{\infty} A_{i} \times B_{i}=\left(\cup_{i=1}^{m_{p+1}} A_{i}^{\prime} \times B_{i}^{\prime}\right) \cup\left(\cup_{k=p+2}^{\infty} A_{k} \times B_{k}\right)
$$

Note that no change is made in $\left\{A_{i}^{\prime} \times B_{i}^{\prime}\right\}_{i=1}^{m_{p}}$. Continuing this way proves the existence of the desired sequence of disjoint rectangles, each of which is a subset of at least one of the original rectangles and such that

$$
Q=\cup_{i=1}^{\infty} A_{i}^{\prime} \times B_{i}^{\prime}
$$

It remains to verify $x \rightarrow \mathscr{X}_{Q}(x, y)$ is $\mu$ measurable for all $y$ and

$$
y \rightarrow \int \mathscr{X}_{Q}(x, y) d \mu
$$

is $v$ measurable whenever $Q \in \mathscr{R}$. Let $Q \equiv \cup_{i=1}^{\infty} A_{i} \times B_{i} \in \mathscr{R}$. Then by the first part of this lemma, there exists $\left\{A_{i}^{\prime} \times B_{i}^{\prime}\right\}_{i=1}^{\infty}$ such that the sets are disjoint and $\cup_{i=1}^{\infty} A_{i}^{\prime} \times B_{i}^{\prime}=Q$. Therefore, since the sets are disjoint,

$$
\mathscr{X}_{Q}(x, y)=\sum_{i=1}^{\infty} \mathscr{X}_{A_{i}^{\prime} \times B_{i}^{\prime}}(x, y)=\sum_{i=1}^{\infty} \mathscr{X}_{A_{i}^{\prime}}(x) \mathscr{X}_{B_{i}^{\prime}}(y) .
$$

It follows $x \rightarrow \mathscr{X}_{Q}(x, y)$ is measurable. Now by the monotone convergence theorem,

$$
\begin{aligned}
\int \mathscr{X}_{Q}(x, y) d \mu & =\int \sum_{i=1}^{\infty} \mathscr{X}_{A_{i}^{\prime}}(x) \mathscr{X}_{B_{i}^{\prime}}(y) d \mu \\
& =\sum_{i=1}^{\infty} \mathscr{X}_{B_{i}^{\prime}}(y) \int \mathscr{X}_{A_{i}^{\prime}}(x) d \mu \\
& =\sum_{i=1}^{\infty} \mathscr{X}_{B_{i}^{\prime}}(y) \mu\left(A_{i}^{\prime}\right) .
\end{aligned}
$$

It follows $y \rightarrow \int \mathscr{X}_{Q}(x, y) d \mu$ is measurable and so by the monotone convergence theorem again,

$$
\begin{align*}
\iint \mathscr{X}_{Q}(x, y) d \mu d v & =\int \sum_{i=1}^{\infty} \mathscr{X}_{B_{i}^{\prime}}(y) \mu\left(A_{i}^{\prime}\right) d v \\
& =\sum_{i=1}^{\infty} \int \mathscr{X}_{B_{i}^{\prime}}(y) \mu\left(A_{i}^{\prime}\right) d v \\
& =\sum_{i=1}^{\infty} v\left(B_{i}^{\prime}\right) \mu\left(A_{i}^{\prime}\right) \tag{12.9.34}
\end{align*}
$$

This shows the measurability conditions, 12.9.32 and 12.9 .33 hold for $Q \in \mathscr{R}$ and also establishes the formula for $\rho(Q), 12.9 .34$.

If $\cup_{i} A_{i} \times B_{i}$ and $\cup_{j} C_{j} \times D_{j}$ are two sets of $\mathscr{R}$, then their intersection is

$$
\cup_{i} \cup_{j}\left(A_{i} \cap C_{j}\right) \times\left(B_{i} \cap D_{j}\right)
$$

a countable union of measurable rectangles. Thus finite intersections of sets of $\mathscr{R}$ are in $\mathscr{R}$. This proves the lemma.

Now note that from the definition of $\mathscr{R}$ if you have a sequence of elements of $\mathscr{R}$ then their union is also in $\mathscr{R}$. The next lemma will enable the definition of an outer measure.

Lemma 12.9.4 Suppose $\left\{R_{i}\right\}_{i=1}^{\infty}$ is a sequence of sets of $\mathscr{R}$ then

$$
\rho\left(\cup_{i=1}^{\infty} R_{i}\right) \leq \sum_{i=1}^{\infty} \rho\left(R_{i}\right)
$$

Proof: Let $R_{i}=\cup_{j=1}^{\infty} A_{j}^{i} \times B_{j}^{i}$. Using Lemma 12.9.3, let $\left\{A_{m}^{\prime} \times B_{m}^{\prime}\right\}_{m=1}^{\infty}$ be a sequence of disjoint rectangles each of which is contained in some $A_{j}^{i} \times B_{j}^{i}$ for some $i, j$ such that

$$
\cup_{i=1}^{\infty} R_{i}=\cup_{m=1}^{\infty} A_{m}^{\prime} \times B_{m}^{\prime} .
$$

Now define

$$
S_{i} \equiv\left\{m: A_{m}^{\prime} \times B_{m}^{\prime} \subseteq A_{j}^{i} \times B_{j}^{i} \text { for some } j\right\}
$$

It is not important to consider whether some $m$ might be in more than one $S_{i}$. The important thing to notice is that

$$
\cup_{m \in S_{i}} A_{m}^{\prime} \times B_{m}^{\prime} \subseteq \cup_{j=1}^{\infty} A_{j}^{i} \times B_{j}^{i}=R_{i}
$$

Then by Lemma 12.9.3,

$$
\begin{aligned}
\rho\left(\cup_{i=1}^{\infty} R_{i}\right) & =\sum_{m} \rho\left(A_{m}^{\prime} \times B_{m}^{\prime}\right) \\
& \leq \sum_{i=1}^{\infty} \sum_{m \in S_{i}} \rho\left(A_{m}^{\prime} \times B_{m}^{\prime}\right) \\
& \leq \sum_{i=1}^{\infty} \rho\left(\cup_{m \in S_{i}} A_{m}^{\prime} \times B_{m}^{\prime}\right) \leq \sum_{i=1}^{\infty} \rho\left(R_{i}\right) .
\end{aligned}
$$

This proves the lemma.
So far, there is no measure and no $\sigma$ algebra. However, the next step is to define an outer measure which will lead to a measure on a $\sigma$ algebra of measurable sets from the Caratheodory procedure. When this is done, it will be shown that this measure can be computed using $\rho$ which implies the important Fubini theorem.

Now it is possible to define an outer measure.
Definition 12.9.5 For $S \subseteq X \times Y$, define

$$
\begin{equation*}
(\overline{\mu \times v})(S) \equiv \inf \{\rho(R): S \subseteq R, R \in \mathscr{R}\} \tag{12.9.35}
\end{equation*}
$$

The following proposition is interesting but is not needed in the development which follows. It gives a different description of $(\overline{\mu \times v})$.

Proposition 12.9.6 $(\overline{\mu \times v})(S)=\inf \left\{\sum_{i=1}^{\infty} \mu\left(A_{i}\right) v\left(B_{i}\right): S \subseteq \cup_{i=1}^{\infty} A_{i} \times B_{i}\right\}$
Proof: Let $\lambda(S) \equiv \inf \left\{\sum_{i=1}^{\infty} \mu\left(A_{i}\right) v\left(B_{i}\right): S \subseteq \cup_{i=1}^{\infty} A_{i} \times B_{i}\right\}$. Suppose $S \subseteq \cup_{i=1}^{\infty} A_{i} \times$ $B_{i} \equiv Q \in \mathscr{R}$. Then by Lemma 12.9.3, $Q=\cup_{i} A_{i}^{\prime} \times B_{i}^{\prime}$ where these rectangles are disjoint. Thus by this lemma, $\rho(Q)=\sum_{i=1}^{\infty} \mu\left(A_{i}^{\prime}\right) v\left(B_{i}^{\prime}\right) \geq \lambda(S)$ and so $\lambda(S) \leq(\overline{\mu \times v})(S)$. If $\lambda(S)=\infty$, this shows $\lambda(S)=(\overline{\mu \times v})(S)$. Suppose then that $\lambda(S)<\infty$ and $\lambda(S)+\varepsilon>$ $\sum_{i=1}^{\infty} \mu\left(A_{i}\right) v\left(B_{i}\right)$ where $Q=\cup_{i=1}^{\infty} A_{i} \times B_{i} \supseteq S$. Then by Lemma 12.9.3 again, $\cup_{i=1}^{\infty} A_{i} \times B_{i}=$ $\cup_{i=1}^{\infty} A_{i}^{\prime} \times B_{i}^{\prime}$ where the primed rectangles are disjoint, each is a subset of some $A_{i} \times B_{i}$ and so

$$
\lambda(S)+\varepsilon \geq \sum_{i=1}^{\infty} \mu\left(A_{i}\right) v\left(B_{i}\right) \geq \sum_{i=1}^{\infty} \mu\left(A_{i}^{\prime}\right) v\left(B_{i}^{\prime}\right)=\rho(Q) \geq(\overline{\mu \times v})(S)
$$

Since $\varepsilon$ is arbitrary, this shows $\lambda(S) \geq(\overline{\mu \times v})(S)$ and this proves the proposition.
Lemma 12.9.7 $\overline{\mu \times v}$ is an outer measure on $X \times Y$ and for $R \in \mathscr{R}$

$$
\begin{equation*}
(\overline{\mu \times v})(R)=\rho(R) . \tag{12.9.36}
\end{equation*}
$$

Proof: First consider 12.9.36. Since $R \supseteq R$, it follows $\rho(R) \geq(\overline{\mu \times v})(R)$. On the other hand, if $Q \in \mathscr{R}$ and $Q \supseteq R$, then $\rho(Q) \geq \rho(R)$ and so, taking the infimum on the left yields $(\overline{\mu \times v})(R) \geq \rho(R)$. This shows 12.9.36.

It is necessary to show that if $S \subseteq T$, then

$$
\begin{align*}
(\overline{\mu \times v})(S) & \leq(\overline{\mu \times v})(T)  \tag{12.9.37}\\
(\overline{\mu \times v})\left(\cup_{i=1}^{\infty} S_{i}\right) & \leq \sum_{i=1}^{\infty}(\overline{\mu \times v})\left(S_{i}\right) . \tag{12.9.38}
\end{align*}
$$

To do this, note that 12.9 .37 is obvious. To verify 12.9 .38 , note that it is obvious if $(\overline{\mu \times v})\left(S_{i}\right)=\infty$ for any $i$. Therefore, assume $(\overline{\mu \times v})\left(S_{i}\right)<\infty$. Then letting $\varepsilon>0$ be given, there exist $R_{i} \in \mathscr{R}$ such that

$$
(\overline{\mu \times v})\left(S_{i}\right)+\frac{\varepsilon}{2^{i}}>\rho\left(R_{i}\right), R_{i} \supseteq S_{i}
$$

Then by Lemma 12.9.4, 12.9.36, and the observation that $\cup_{i=1}^{\infty} R_{i} \in \mathscr{R}$,

$$
\begin{aligned}
(\overline{\mu \times v})\left(\cup_{i=1}^{\infty} S_{i}\right) & \leq(\overline{\mu \times v})\left(\cup_{i=1}^{\infty} R_{i}\right) \\
& =\rho\left(\cup_{i=1}^{\infty} R_{i}\right) \leq \sum_{i=1}^{\infty} \rho\left(R_{i}\right) \\
& \leq \sum_{i=1}^{\infty}\left((\overline{\mu \times v})\left(S_{i}\right)+\frac{\varepsilon}{2^{i}}\right) \\
& =\left(\sum_{i=1}^{\infty}(\overline{\mu \times v})\left(S_{i}\right)\right)+\varepsilon .
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this proves the lemma.
By Caratheodory's procedure, it follows there is a $\sigma$ algebra of subsets of $X \times Y$, denoted here by $\overline{\mathscr{S} \times \mathscr{T}}$ such that $(\overline{\mu \times v})$ is a complete measure on this $\sigma$ algebra. The first thing to note is that every rectangle is in this $\sigma$ algebra.

Lemma 12.9.8 Every rectangle is $(\overline{\mu \times v})$ measurable.
Proof: Let $S \subseteq X \times Y$. The following inequality must be established.

$$
\begin{equation*}
(\overline{\mu \times v})(S) \geq(\overline{\mu \times v})(S \cap(A \times B))+(\overline{\mu \times v})(S \backslash(A \times B)) \tag{12.9.39}
\end{equation*}
$$

The following claim will be used to establish this inequality.
Claim: Let $P, A \times B \in \mathscr{R}$. Then

$$
\rho(P \cap(A \times B))+\rho(P \backslash(A \times B))=\rho(P) .
$$

Proof of the claim: From Lemma 12.9.3, $P=\cup_{i=1}^{\infty} A_{i}^{\prime} \times B_{i}^{\prime}$ where the $A_{i}^{\prime} \times B_{i}^{\prime}$ are disjoint. Therefore,

$$
P \cap(A \times B)=\bigcup_{i=1}^{\infty}\left(A \cap A_{i}^{\prime}\right) \times\left(B \cap B_{i}^{\prime}\right)
$$

while

$$
P \backslash(A \times B)=\bigcup_{i=1}^{\infty}\left(A_{i}^{\prime} \backslash A\right) \times B_{i}^{\prime} \cup \bigcup_{i=1}^{\infty}\left(A \cap A_{i}^{\prime}\right) \times\left(B_{i}^{\prime} \backslash B\right) .
$$

Since all of the sets in the above unions are disjoint,

$$
\begin{gathered}
\rho(P \cap(A \times B))+\rho(P \backslash(A \times B))= \\
\iint \sum_{i=1}^{\infty} \mathscr{X}_{\left(A \cap A_{i}^{\prime}\right)}(x) \mathscr{X}_{B \cap B_{i}^{\prime}}(y) d \mu d v+\iint \sum_{i=1}^{\infty} \mathscr{X}_{\left(A_{i}^{\prime} \backslash A\right)}(x) \mathscr{X}_{B_{i}^{\prime}}(y) d \mu d v \\
+\iint \sum_{i=1}^{\infty} \mathscr{X}_{A \cap A_{i}^{\prime}}(x) \mathscr{X}_{B_{i}^{\prime} \backslash B}(y) d \mu d v
\end{gathered}
$$

$$
\begin{aligned}
& =\sum_{i=1}^{\infty} \mu\left(A \cap A_{i}^{\prime}\right) v\left(B \cap B_{i}^{\prime}\right)+\mu\left(A_{i}^{\prime} \backslash A\right) v\left(B_{i}^{\prime}\right)+\mu\left(A \cap A_{i}^{\prime}\right) v\left(B_{i}^{\prime} \backslash B\right) \\
& =\sum_{i=1}^{\infty} \mu\left(A \cap A_{i}^{\prime}\right) v\left(B_{i}^{\prime}\right)+\mu\left(A_{i}^{\prime} \backslash A\right) v\left(B_{i}^{\prime}\right)=\sum_{i=1}^{\infty} \mu\left(A_{i}^{\prime}\right) v\left(B_{i}^{\prime}\right)=\rho(P) .
\end{aligned}
$$

This proves the claim.
Now continuing to verify 12.9 .39 , without loss of generality, $(\overline{\mu \times v})(S)$ can be assumed finite. Let $P \supseteq S$ for $P \in \mathscr{R}$ and

$$
(\overline{\mu \times v})(S)+\varepsilon>\rho(P) .
$$

Then from the claim,

$$
\begin{aligned}
(\overline{\mu \times v})(S)+\varepsilon & >\rho(P)=\rho(P \cap(A \times B))+\rho(P \backslash(A \times B)) \\
& \geq(\overline{\mu \times v})(S \cap(A \times B))+(\overline{\mu \times v})(S \backslash(A \times B))
\end{aligned}
$$

Since $\varepsilon>0$ this shows $A \times B$ is $\overline{\mu \times v}$ measurable as claimed.
Lemma 12.9.9 Let $\mathscr{R}_{1}$ be defined as the set of all countable intersections of sets of $\mathscr{R}$. Then if $S \subseteq X \times Y$, there exists $R \in \mathscr{R}_{1}$ for which it makes sense to write $\rho(R)$ because 12.9.32 and 12.9.33 hold such that

$$
\begin{equation*}
(\overline{\mu \times v})(S)=\rho(R) \tag{12.9.40}
\end{equation*}
$$

Also, every element of $\mathscr{R}_{1}$ is $\overline{\mu \times v}$ measurable.
Proof: Consider 12.9.40. Let $S \subseteq X \times Y$. If $(\overline{\mu \times v})(S)=\infty$, let $R=X \times Y$ and it follows $\rho(X \times Y)=\infty=(\overline{\mu \times v})(S)$. Assume then that $(\overline{\mu \times v})(S)<\infty$.

Therefore, there exists $P_{n} \in \mathscr{R}$ such that $P_{n} \supseteq S$ and

$$
\begin{equation*}
(\overline{\mu \times v})(S) \leq \rho\left(P_{n}\right)<(\overline{\mu \times v})(S)+1 / n \tag{12.9.41}
\end{equation*}
$$

Let $Q_{n}=\cap_{i=1}^{n} P_{i} \in \mathscr{R}$. Define

$$
P \equiv \cap_{i=1}^{\infty} Q_{i} \supseteq S
$$

Then 12.9.41 holds with $Q_{n}$ in place of $P_{n}$. It is clear that

$$
x \rightarrow \mathscr{X}_{P}(x, y) \text { is } \mu \text { measurable }
$$

because this function is the pointwise limit of functions for which this is so. It remains to consider whether $y \rightarrow \int \mathscr{X}_{P}(x, y) d \mu$ is $v$ measurable. First observe $Q_{n} \supseteq Q_{n+1}, \mathscr{X}_{Q_{i}} \leq$ $\mathscr{X}_{P_{i}}$, and

$$
\begin{equation*}
\rho\left(Q_{1}\right)=\rho\left(P_{1}\right)=\iint \mathscr{X}_{P_{1}}(x, y) d \mu d v<\infty \tag{12.9.42}
\end{equation*}
$$

Therefore, there exists a set of $v$ measure $0, N$, such that if $y \notin N$, then

$$
\int \mathscr{X}_{P_{1}}(x, y) d \mu<\infty .
$$

It follows from the dominated convergence theorem that

$$
\lim _{n \rightarrow \infty} \mathscr{X}_{N^{C}}(y) \int \mathscr{X}_{Q_{n}}(x, y) d \mu=\mathscr{X}_{N^{C}}(y) \int \mathscr{X}_{P}(x, y) d \mu
$$

and so

$$
y \rightarrow \mathscr{X}_{N^{c}}(y) \int \mathscr{X}_{P}(x, y) d \mu
$$

is also measurable. By completeness of $v$,

$$
y \rightarrow \int \mathscr{X}_{P}(x, y) d \mu
$$

must also be $v$ measurable and so it makes sense to write

$$
\iint \mathscr{X}_{P}(x, y) d \mu d v
$$

for every $P \in \mathscr{R}_{1}$. Also, by the dominated convergence theorem,

$$
\begin{aligned}
\iint \mathscr{X}_{P}(x, y) d \mu d v & =\int \mathscr{X}_{N^{C}}(y) \int \mathscr{X}_{P}(x, y) d \mu d v \\
& =\lim _{n \rightarrow \infty} \int \mathscr{X}_{N^{C}}(y) \int \mathscr{X}_{Q_{n}}(x, y) d \mu d v \\
& =\lim _{n \rightarrow \infty} \iint \mathscr{X}_{Q_{n}}(x, y) d \mu d v \\
& =\lim _{n \rightarrow \infty} \rho\left(Q_{n}\right) \in[(\overline{\mu \times v})(S),(\overline{\mu \times v})(S)+1 / n]
\end{aligned}
$$

for all $n$. Therefore,

$$
\rho(P) \equiv \iint \mathscr{X}_{P}(x, y) d \mu d v=(\overline{\mu \times v})(S)
$$

The sets of $\mathscr{R}_{1}$ are $\overline{\mu \times v}$ measurable because these sets are countable intersections of countable unions of rectangles and Lemma 12.9.8 verifies the rectangles are $\overline{\mu \times v}$ measurable. This proves the Lemma.

The following theorem is the main result.
Theorem 12.9.10 Let $E \subseteq X \times Y$ be $\overline{\mu \times v}$ measurable and suppose $(\overline{\mu \times v})(E)<\infty$. Then

$$
x \rightarrow \mathscr{X}_{E}(x, y) \text { is } \mu \text { measurable a.e. } y .
$$

Modifying $\mathscr{X}_{E}$ on a set of measure zero, it is possible to write

$$
\int \mathscr{X}_{E}(x, y) d \mu
$$

The function,

$$
y \rightarrow \int \mathscr{X}_{E}(x, y) d \mu
$$

is $v$ measurable and

$$
(\overline{\mu \times v})(E)=\iint \mathscr{X}_{E}(x, y) d \mu d v
$$

Similarly,

$$
(\overline{\mu \times v})(E)=\iint \mathscr{X}_{E}(x, y) d v d \mu
$$

Proof: By Lemma 12.9.9, there exists $R \in \mathscr{R}_{1}$ such that

$$
\rho(R)=(\overline{\mu \times v})(E), R \supseteq E .
$$

Therefore, since $R$ is $\overline{\mu \times v}$ measurable and $\rho(R)=(\overline{\mu \times v})(R)$, it follows

$$
(\overline{\mu \times v})(R \backslash E)=0
$$

By Lemma 12.9.9 again, there exists $P \supseteq R \backslash E$ with $P \in \mathscr{R}_{1}$ and

$$
\rho(P)=(\overline{\mu \times v})(R \backslash E)=0
$$

Thus

$$
\begin{equation*}
\iint \mathscr{X}_{P}(x, y) d \mu d v=0 \tag{12.9.43}
\end{equation*}
$$

Since $P \in \mathscr{R}_{1}$ Lemma 12.9.9 implies $x \rightarrow \mathscr{X}_{P}(x, y)$ is $\mu$ measurable and it follows from the above there exists a set of $v$ measure zero, $N$ such that if $y \notin N$, then $\int \mathscr{X}_{P}(x, y) d \mu=0$. Therefore, by completeness of $v$,

$$
x \rightarrow \mathscr{X}_{N^{C}}(y) \mathscr{X}_{R \backslash E}(x, y)
$$

is $\mu$ measurable and

$$
\begin{equation*}
\int \mathscr{X}_{N^{C}}(y) \mathscr{X}_{R \backslash E}(x, y) d \mu=0 . \tag{12.9.44}
\end{equation*}
$$

Now also

$$
\begin{equation*}
\mathscr{X}_{N^{C}}(y) \mathscr{X}_{R}(x, y)=\mathscr{X}_{N^{C}}(y) \mathscr{X}_{R \backslash E}(x, y)+\mathscr{X}_{N^{C}}(y) \mathscr{X}_{E}(x, y) \tag{12.9.45}
\end{equation*}
$$

and this shows that

$$
x \rightarrow \mathscr{X}_{N^{C}}(y) \mathscr{X}_{E}(x, y)
$$

is $\mu$ measurable because it is the difference of two functions with this property. Then by 12.9.44 it follows

$$
\int \mathscr{X}_{N^{C}}(y) \mathscr{X}_{E}(x, y) d \mu=\int \mathscr{X}_{N^{C}}(y) \mathscr{X}_{R}(x, y) d \mu
$$

The right side of this equation equals a $v$ measurable function and so the left side which equals it is also a $v$ measurable function. It follows from completeness of $v$ that $y \rightarrow$ $\int \mathscr{X}_{E}(x, y) d \mu$ is $v$ measurable because for $y$ outside of a set of $v$ measure zero, $N$ it equals $\int \mathscr{X}_{R}(x, y) d \mu$. Therefore,

$$
\begin{aligned}
\iint \mathscr{X}_{E}(x, y) d \mu d v & =\iint \mathscr{X}_{N^{C}}(y) \mathscr{X}_{E}(x, y) d \mu d v \\
& =\iint \mathscr{X}_{N^{C}}(y) \mathscr{X}_{R}(x, y) d \mu d v \\
& =\iint \mathscr{X}_{R}(x, y) d \mu d v \\
& =\rho(R)=(\overline{\mu \times v})(E)
\end{aligned}
$$

In all the above there would be no change in writing $d \nu d \mu$ instead of $d \mu d \nu$. The same result would be obtained. This proves the theorem.

Now let $f: X \times Y \rightarrow[0, \infty]$ be $\overline{\mu \times v}$ measurable and

$$
\begin{equation*}
\int f d(\overline{\mu \times v})<\infty \tag{12.9.46}
\end{equation*}
$$

Let $s(x, y) \equiv \sum_{i=1}^{m} c_{i} \mathscr{X}_{E_{i}}(x, y)$ be a nonnegative simple function with $c_{i}$ being the nonzero values of $s$ and suppose

$$
0 \leq s \leq f
$$

Then from the above theorem,

$$
\int s d(\overline{\mu \times v})=\iint s d \mu d v
$$

In which

$$
\int s d \mu=\int \mathscr{X}_{N^{C}}(y) s d \mu
$$

for $N$ a set of $v$ measure zero such that $y \rightarrow \int \mathscr{X}_{N^{C}}(y) s d \mu$ is $v$ measurable. This follows because 12.9.46 implies $(\overline{\mu \times v})\left(E_{i}\right)<\infty$. Now let $s_{n} \uparrow f$ where $s_{n}$ is a nonnegative simple function and

$$
\int s_{n} d(\overline{\mu \times v})=\iint \mathscr{X}_{N_{n}^{C}}(y) s_{n}(x, y) d \mu d v
$$

where

$$
y \rightarrow \int \mathscr{X}_{N_{n}^{C}}(y) s_{n}(x, y) d \mu
$$

is $v$ measurable. Then let $N \equiv \cup_{n=1}^{\infty} N_{n}$. It follows $N$ is a set of $v$ measure zero. Thus

$$
\int s_{n} d(\overline{\mu \times v})=\iint \mathscr{X}_{N^{C}}(y) s_{n}(x, y) d \mu d v
$$

and letting $n \rightarrow \infty$, the monotone convergence theorem implies

$$
\begin{aligned}
\int f d(\overline{\mu \times v}) & =\iint \mathscr{X}_{N^{C}}(y) f(x, y) d \mu d v \\
& =\iint f(x, y) d \mu d v
\end{aligned}
$$

because of completeness of the measures, $\mu$ and $v$. This proves Fubini's theorem.
Theorem 12.9.11 (Fubini) Let $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{T}, v)$ be complete measure spaces and let

$$
(\overline{\mu \times v})(E) \equiv \inf \left\{\iint \mathscr{X}_{R}(x, y) d \mu d v: E \subseteq R \in \mathscr{R}\right\}^{2}
$$

$$
\begin{aligned}
& { }^{2} \text { Recall this is the same as } \\
& \qquad \inf \left\{\sum_{i=1}^{\infty} \mu\left(A_{i}\right) v\left(B_{i}\right): E \subseteq \cup_{i=1}^{\infty} A_{i} \times B_{i}\right\}
\end{aligned}
$$

in which the $A_{i}$ and $B_{i}$ are measurable.
where $A_{i} \in \mathscr{S}$ and $B_{i} \in \mathscr{T}$. Then $\overline{\mu \times v}$ is an outer measure on the subsets of $X \times Y$ and the $\sigma$ algebra of $\overline{\mu \times v}$ measurable sets, $\overline{\mathscr{S} \times \mathscr{T}}$, contains all measurable rectangles. If $f \geq 0$ is a $\overline{\mu \times v}$ measurable function satisfying

$$
\begin{equation*}
\int_{X \times Y} f d(\overline{\mu \times v})<\infty \tag{12.9.47}
\end{equation*}
$$

then

$$
\int_{X \times Y} f d(\overline{\mu \times v})=\int_{Y} \int_{X} f d \mu d v
$$

where the iterated integral on the right makes sense because for $v$ a.e. $y, x \rightarrow f(x, y)$ is $\mu$ measurable and $y \rightarrow \int f(x, y) d \mu$ is $v$ measurable. Similarly,

$$
\int_{X \times Y} f d(\overline{\mu \times v})=\int_{X} \int_{Y} f d v d \mu
$$

In the case where $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{T}, v)$ are both $\sigma$ finite, it is not necessary to assume 12.9.47.

Corollary 12.9.12 (Fubini) Let $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{T}, v)$ be complete measure spaces such that $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{T}, v)$ are both $\sigma$ finite and let

$$
(\overline{\mu \times v})(E) \equiv \inf \left\{\iint \mathscr{X}_{R}(x, y) d \mu d v: E \subseteq R \in \mathscr{R}\right\}
$$

where $A_{i} \in \mathscr{S}$ and $B_{i} \in \mathscr{T}$. Then $\overline{\mu \times v}$ is an outer measure. If $f \geq 0$ is a $\overline{\mu \times v}$ measurable function then

$$
\int_{X \times Y} f d(\overline{\mu \times v})=\int_{Y} \int_{X} f d \mu d v
$$

where the iterated integral on the right makes sense because for $v$ a.e. $y, x \rightarrow f(x, y)$ is $\mu$ measurable and $y \rightarrow \int f(x, y) d \mu$ is $v$ measurable. Similarly,

$$
\int_{X \times Y} f d(\overline{\mu \times v})=\int_{X} \int_{Y} f d v d \mu
$$

Proof: Let $\cup_{n=1}^{\infty} X_{n}=X$ and $\cup_{n=1}^{\infty} Y_{n}=Y$ where $X_{n} \in \mathscr{S}, Y_{n} \in \mathscr{T}, X_{n} \subseteq X_{n+1}, Y_{n} \subseteq Y_{n+1}$ for all $n$ and $\mu\left(X_{n}\right)<\infty, v\left(Y_{n}\right)<\infty$. From Theorem 12.9.11 applied to $X_{n}, Y_{n}$ and $f_{m} \equiv$ $\min (f, m)$,

$$
\int_{X_{n} \times Y_{n}} f_{m} d(\overline{\mu \times v})=\int_{Y_{n}} \int_{X_{n}} f_{m} d \mu d v
$$

Now take $m \rightarrow \infty$ and use the monotone convergence theorem to obtain

$$
\int_{X_{n} \times Y_{n}} f d(\overline{\mu \times v})=\int_{Y_{n}} \int_{X_{n}} f d \mu d v
$$

Then use the monotone convergence theorem again letting $n \rightarrow \infty$ to obtain the desired conclusion. The argument for the other order of integration is similar.

Corollary 12.9.13 If $f \in L^{1}(X \times Y)$, then

$$
\int f d(\overline{\mu \times v})=\iint f(x, y) d \mu d v=\iint f(x, y) d v d \mu
$$

If $\mu$ and $v$ are $\sigma$ finite, then if $f$ is $\overline{\mu \times v}$ measurable having complex values and either $\iint|f| d \mu d \nu<\infty$ or $\iint|f| d v d \mu<\infty$, then $\int|f| d(\overline{\mu \times v})<\infty$ so $f \in L^{1}(X \times Y)$.

Proof: Without loss of generality, it can be assumed that $f$ has real values. Then

$$
f=\frac{|f|+f-(|f|-f)}{2}
$$

and both $f^{+} \equiv \frac{|f|+f}{2}$ and $f^{-} \equiv \frac{|f|-f}{2}$ are nonnegative and are less than $|f|$. Therefore, $\int g d(\overline{\mu \times v})<\infty$ for $g=f^{+}$and $g=f^{-}$so the above theorem applies and

$$
\begin{aligned}
\int f d(\overline{\mu \times v}) & \equiv \int f^{+} d(\overline{\mu \times v})-\int f^{-} d(\overline{\mu \times v}) \\
& =\iint f^{+} d \mu d v-\iint f^{-} d \mu d v \\
& =\iint f d \mu d v
\end{aligned}
$$

It remains to verify the last claim. Suppose $s$ is a simple function,

$$
s(x, y) \equiv \sum_{i=1}^{m} c_{i} \mathscr{X}_{E_{i}} \leq|f|(x, y)
$$

where the $c_{i}$ are the nonzero values of $s$. Then

$$
s \mathscr{X}_{R_{n}} \leq|f| \mathscr{X}_{R_{n}}
$$

where $R_{n} \equiv X_{n} \times Y_{n}$ where $X_{n} \uparrow X$ and $Y_{n} \uparrow Y$ with $\mu\left(X_{n}\right)<\infty$ and $v\left(Y_{n}\right)<\infty$. It follows, since the nonzero values of $s \mathscr{X}_{R_{n}}$ are achieved on sets of finite measure,

$$
\int s \mathscr{X}_{R_{n}} d(\overline{\mu \times v})=\iint s \mathscr{X}_{R_{n}} d \mu d v .
$$

Letting $n \rightarrow \infty$ and applying the monotone convergence theorem, this yields

$$
\begin{equation*}
\int s d(\overline{\mu \times v})=\iint s d \mu d v \tag{12.9.48}
\end{equation*}
$$

Now let $s_{n} \uparrow|f|$ where $s_{n}$ is a nonnegative simple function. From 12.9.48,

$$
\int s_{n} d(\overline{\mu \times v})=\iint s_{n} d \mu d v
$$

Letting $n \rightarrow \infty$ and using the monotone convergence theorem, yields

$$
\int|f| d(\overline{\mu \times v})=\iint|f| d \mu d v<\infty
$$

### 12.10 Alternative Treatment Of Product Measure

### 12.10.1 Monotone Classes And Algebras

Measures are defined on $\sigma$ algebras which are closed under countable unions. It is for this reason that the theory of measure and integration is so useful in dealing with limits of sequences. However, there is a more basic notion which involves only finite unions and differences.

Definition 12.10.1 $\mathscr{A}$ is said to be an algebra of subsets of a set, $Z$ if $Z \in \mathscr{A}, \emptyset \in \mathscr{A}$, and when $E, F \in \mathscr{A}, E \cup F$ and $E \backslash F$ are both in $\mathscr{A}$.

It is important to note that if $\mathscr{A}$ is an algebra, then it is also closed under finite intersections. This is because $E \cap F=\left(E^{C} \cup F^{C}\right)^{C} \in \mathscr{A}$ since $E^{C}=Z \backslash E \in \mathscr{A}$ and $F^{C}=Z \backslash F \in \mathscr{A}$. Note that every $\sigma$ algebra is an algebra but not the other way around.

Something satisfying the above definition is called an algebra because union is like addition, the set difference is like subtraction and intersection is like multiplication. Furthermore, only finitely many operations are done at a time and so there is nothing like a limit involved.

How can you recognize an algebra when you see one? The answer to this question is the purpose of the following lemma.

Lemma 12.10.2 Suppose $\mathscr{R}$ and $\mathscr{E}$ are subsets of $\mathscr{P}(Z)^{3}$ such that $\mathscr{E}$ is defined as the set of all finite disjoint unions of sets of $\mathscr{R}$. Suppose also

$$
\begin{gathered}
\emptyset, Z \in \mathscr{R} \\
A \cap B \in \mathscr{R} \text { whenever } A, B \in \mathscr{R}, \\
A \backslash B \in \mathscr{E} \text { whenever } A, B \in \mathscr{R} .
\end{gathered}
$$

Then $\mathscr{E}$ is an algebra of sets of $Z$.
Proof: Note first that if $A \in \mathscr{R}$, then $A^{C} \in \mathscr{E}$ because $A^{C}=Z \backslash A$.
Now suppose that $E_{1}$ and $E_{2}$ are in $\mathscr{E}$,

$$
E_{1}=\cup_{i=1}^{m} R_{i}, \quad E_{2}=\cup_{j=1}^{n} R_{j}
$$

where the $R_{i}$ are disjoint sets in $\mathscr{R}$ and the $R_{j}$ are disjoint sets in $\mathscr{R}$. Then

$$
E_{1} \cap E_{2}=\cup_{i=1}^{m} \cup_{j=1}^{n} R_{i} \cap R_{j}
$$

which is clearly an element of $\mathscr{E}$ because no two of the sets in the union can intersect and by assumption they are all in $\mathscr{R}$. Thus by induction, finite intersections of sets of $\mathscr{E}$ are in $\mathscr{E}$. Consider the difference of two elements of $\mathscr{E}$ next.

If $E=\cup_{i=1}^{n} R_{i} \in \mathscr{E}$,

$$
E^{C}=\cap_{i=1}^{n} R_{i}^{C}=\text { finite intersection of sets of } \mathscr{E}
$$

[^11]which was just shown to be in $\mathscr{E}$. Now, if $E_{1}, E_{2} \in \mathscr{E}$,
$$
E_{1} \backslash E_{2}=E_{1} \cap E_{2}^{C} \in \mathscr{E}
$$
from what was just shown about finite intersections.
Finally consider finite unions of sets of $\mathscr{E}$. Let $E_{1}$ and $E_{2}$ be sets of $\mathscr{E}$. Then
$$
E_{1} \cup E_{2}=\left(E_{1} \backslash E_{2}\right) \cup E_{2} \in \mathscr{E}
$$
because $E_{1} \backslash E_{2}$ consists of a finite disjoint union of sets of $\mathscr{R}$ and these sets must be disjoint from the sets of $\mathscr{R}$ whose union yields $E_{2}$ because $\left(E_{1} \backslash E_{2}\right) \cap E_{2}=\emptyset$. This proves the lemma.

The following corollary is particularly helpful in verifying the conditions of the above lemma.

Corollary 12.10.3 Let $\left(Z_{1}, \mathscr{R}_{1}, \mathscr{E}_{1}\right)$ and $\left(Z_{2}, \mathscr{R}_{2}, \mathscr{E}_{2}\right)$ be as described in Lemma 14.1.2. Then $\left(Z_{1} \times Z_{2}, \mathscr{R}, \mathscr{E}\right)$ also satisfies the conditions of Lemma 14.1.2 if $\mathscr{R}$ is defined as

$$
\mathscr{R} \equiv\left\{R_{1} \times R_{2}: R_{i} \in \mathscr{R}_{i}\right\}
$$

and

$$
\mathscr{E} \equiv\{\text { finite disjoint unions of sets of } \mathscr{R}\}
$$

Consequently, $\mathscr{E}$ is an algebra of sets.
Proof: It is clear $\emptyset, Z_{1} \times Z_{2} \in \mathscr{R}$. Let $A \times B$ and $C \times D$ be two elements of $\mathscr{R}$.

$$
A \times B \cap C \times D=A \cap C \times B \cap D \in \mathscr{R}
$$

by assumption.

$$
\begin{aligned}
& A \times B \backslash(C \times D)= \\
& A \times \overbrace{(B \backslash D)}^{\in \mathscr{E}_{2}} \cup \overbrace{(A \backslash C)}^{\in \mathscr{E}_{1}} \times \overbrace{(D \cap B)}^{\in \mathscr{R}_{2}} \\
& =(A \times Q) \cup(P \times R)
\end{aligned}
$$

where $Q \in \mathscr{E}_{2}, P \in \mathscr{E}_{1}$, and $R \in \mathscr{R}_{2}$.

Since $A \times Q$ and $P \times R$ do not intersect, it follows the above expression is in $\mathscr{E}$ because each of these terms are. This proves the corollary.

Definition 12.10.4 $\mathscr{M} \subseteq \mathscr{P}(Z)$ is called a monotone class if
a.) $\cdots E_{n} \supseteq E_{n+1} \cdots, E=\cap_{n=1}^{\infty} E_{n}$, and $E_{n} \in \mathscr{M}$, then $E \in \mathscr{M}$.
b.) $\cdots E_{n} \subseteq E_{n+1} \cdots, E=\cup_{n=1}^{\infty} E_{n}$, and $E_{n} \in \mathscr{M}$, then $E \in \mathscr{M}$.
(In simpler notation, $E_{n} \downarrow E$ and $E_{n} \in \mathscr{M}$ implies $E \in \mathscr{M} . E_{n} \uparrow E$ and $E_{n} \in \mathscr{M}$ implies $E \in \mathscr{M}$.)

Theorem 12.10.5 (Monotone Class theorem) Let $\mathscr{A}$ be an algebra of subsets of $Z$ and let $\mathscr{M}$ be a monotone class containing $\mathscr{A}$. Then $\mathscr{M} \supseteq \sigma(\mathscr{A})$, the smallest $\sigma$-algebra containing $\mathscr{A}$.

Proof: Consider all monotone classes which contain $\mathscr{A}$, and take their intersection. The result is still a monotone class which contains $\mathscr{A}$ and is therefore the smallest monotone class containing $\mathscr{A}$. Therefore, assume without loss of generality that $\mathscr{M}$ is the smallest monotone class containing $\mathscr{A}$ because if it is shown the smallest monotone class containing $\mathscr{A}$ contains $\sigma(\mathscr{A})$, then the given monotone class does also. To avoid more notation, let $\mathscr{M}$ denote this smallest monotone class.

The plan is to show $\mathscr{M}$ is a $\sigma$-algebra. It will then follow $\mathscr{M} \supseteq \sigma(\mathscr{A})$ because $\sigma(\mathscr{A})$ is defined as the intersection of all $\sigma$ algebras which contain $\mathscr{A}$. For $A \in \mathscr{A}$, define

$$
\mathscr{M}_{A} \equiv\{B \in \mathscr{M} \text { such that } A \cup B \in \mathscr{M}\}
$$

Clearly $\mathscr{M}_{A}$ is a monotone class containing $\mathscr{A}$. Hence $\mathscr{M}_{A} \supseteq \mathscr{M}$ because $\mathscr{M}$ is the smallest such monotone class. But by construction, $\mathscr{M}_{A} \subseteq \mathscr{M}$. Therefore, $\mathscr{M}=\mathscr{M}_{A}$. This shows that $A \cup B \in \mathscr{M}$ whenever $A \in \mathscr{A}$ and $B \in \mathscr{M}$. Now pick $B \in \mathscr{M}$ and define

$$
\mathscr{M}_{B} \equiv\{D \in \mathscr{M} \text { such that } D \cup B \in \mathscr{M}\} .
$$

It was just shown that $\mathscr{A} \subseteq \mathscr{M}_{B}$. It is clear that $\mathscr{M}_{B}$ is a monotone class. Thus by a similar argument, $\mathscr{M}_{B}=\mathscr{M}$ and it follows that $D \cup B \in \mathscr{M}$ whenever $D \in \mathscr{M}$ and $B \in \mathscr{M}$. This shows $\mathscr{M}$ is closed under finite unions.

Next consider the diference of two sets. Let $A \in \mathscr{A}$

$$
\mathscr{M}_{A} \equiv\{B \in \mathscr{M} \text { such that } B \backslash A \text { and } A \backslash B \in \mathscr{M}\}
$$

Then $\mathscr{M}_{A}$, is a monotone class containing $\mathscr{A}$. As before, $\mathscr{M}=\mathscr{M}_{A}$. Thus $B \backslash A$ and $A \backslash B$ are both in $\mathscr{M}$ whenever $A \in \mathscr{A}$ and $B \in \mathscr{M}$. Now pick $A \in \mathscr{M}$ and consider

$$
\mathscr{M}_{A} \equiv\{B \in \mathscr{M} \text { such that } B \backslash A \text { and } A \backslash B \in \mathscr{M}\}
$$

It was just shown $\mathscr{M}_{A}$ contains $\mathscr{A}$. Now $\mathscr{M}_{A}$ is a monotone class and so $\mathscr{M}_{A}=\mathscr{M}$ as before.

Thus $\mathscr{M}$ is both a monotone class and an algebra. Hence, if $E \in \mathscr{M}$ then $Z \backslash E \in \mathscr{M}$. Next consider the question of whether $\mathscr{M}$ is a $\sigma$-algebra. If $E_{i} \in \mathscr{M}$ and $F_{n}=\cup_{i=1}^{n} E_{i}$, then $F_{n} \in \mathscr{M}$ and $F_{n} \uparrow \cup_{i=1}^{\infty} E_{i}$. Since $\mathscr{M}$ is a monotone class, $\cup_{i=1}^{\infty} E_{i} \in \mathscr{M}$ and so $\mathscr{M}$ is a $\sigma$-algebra. This proves the theorem.

### 12.10.2 Product Measure

Definition 12.10.6 Let $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{F}, \lambda)$ be two measure spaces. A measurable rectangle is a set $A \times B \subseteq X \times Y$ where $A \in \mathscr{S}$ and $B \in \mathscr{F}$. An elementary set will be any subset of $X \times Y$ which is a finite union of disjoint measurable rectangles. $\mathscr{S} \times \mathscr{F}$ will denote the smallest $\sigma$ algebra of sets in $\mathscr{P}(X \times Y)$ containing all elementary sets.

Example 12.10.7 It follows from Lemma 14.1.2 or more easily from Corollary 14.1.3 that the elementary sets form an algebra.

Definition 12.10.8 Let $E \subseteq X \times Y$,

$$
\begin{aligned}
& E_{x}=\{y \in Y:(x, y) \in E\}, \\
& E^{y}=\{x \in X:(x, y) \in E\} .
\end{aligned}
$$

These are called the $x$ and $y$ sections.

Theorem 12.10.9 If $E \in \mathscr{S} \times \mathscr{F}$, then $E_{x} \in \mathscr{F}$ and $E^{y} \in \mathscr{S}$ for all $x \in X$ and $y \in Y$.
Proof: Let

$$
\begin{gathered}
\mathscr{M}=\left\{E \subseteq \mathscr{S} \times \mathscr{F} \text { such that for all } x \in X, E_{x} \in \mathscr{F},\right. \\
\text { and for all } \left.y \in Y, E^{y} \in \mathscr{S} .\right\}
\end{gathered}
$$

Then $\mathscr{M}$ contains all measurable rectangles. If $E_{i} \in \mathscr{M}$,

$$
\left(\cup_{i=1}^{\infty} E_{i}\right)_{x}=\cup_{i=1}^{\infty}\left(E_{i}\right)_{x} \in \mathscr{F} .
$$

Similarly,

$$
\left(\cup_{i=1}^{\infty} E_{i}\right)^{y}=\cup_{i=1}^{\infty} E_{i}^{y} \in \mathscr{S}
$$

It follows $\mathscr{M}$ is closed under countable unions.
If $E \in \mathscr{M}$,

$$
\left(E^{C}\right)_{x}=\left(E_{x}\right)^{C} \in \mathscr{F}
$$

Similarly, $\left(E^{C}\right)^{y} \in \mathscr{S}$. Thus $\mathscr{M}$ is closed under complementation. Therefore $\mathscr{M}$ is a $\sigma$-algebra containing the elementary sets. Hence, $\mathscr{M} \supseteq \mathscr{S} \times \mathscr{F}$ because $\mathscr{S} \times \mathscr{F}$ is the
smallest $\sigma$ algebra containing these elementary sets. But $\mathscr{M} \subseteq \mathscr{S} \times \mathscr{F}$ by definition and so $\mathscr{M}=\mathscr{S} \times \mathscr{F}$. This proves the theorem.

It follows from Lemma 14.1.2 that the elementary sets form an algebra because clearly the intersection of two measurable rectangles is a measurable rectangle and

$$
(A \times B) \backslash\left(A_{0} \times B_{0}\right)=\left(A \backslash A_{0}\right) \times B \cup\left(A \cap A_{0}\right) \times\left(B \backslash B_{0}\right)
$$

an elementary set.
Theorem 12.10.10 If $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{F}, \lambda)$ are both finite measure spaces

$$
(\mu(X), \lambda(Y)<\infty)
$$

then for every $E \in \mathscr{S} \times \mathscr{F}$,
a.) $x \rightarrow \lambda\left(E_{x}\right)$ is $\mu$ measurable, $y \rightarrow \mu\left(E^{y}\right)$ is $\lambda$ measurable
b.) $\int_{X} \lambda\left(E_{x}\right) d \mu=\int_{Y} \mu\left(E^{y}\right) d \lambda$.

Proof: Let

$$
\mathscr{M}=\{E \in \mathscr{S} \times \mathscr{F} \text { such that both } a .) \text { and } b \text {.) hold }\} .
$$

Since $\mu$ and $\lambda$ are both finite, the monotone convergence and dominated convergence theorems imply $\mathscr{M}$ is a monotone class.

Next I will argue $\mathscr{M}$ contains the elementary sets. Let

$$
E=\cup_{i=1}^{n} A_{i} \times B_{i}
$$

where the measurable rectangles, $A_{i} \times B_{i}$ are disjoint. Then

$$
\begin{aligned}
\lambda\left(E_{x}\right) & =\int_{Y} \mathscr{X}_{E}(x, y) d \lambda=\int_{Y} \sum_{i=1}^{n} \mathscr{X}_{A_{i} \times B_{i}}(x, y) d \lambda \\
& =\sum_{i=1}^{n} \int_{Y} \mathscr{X}_{A_{i} \times B_{i}}(x, y) d \lambda=\sum_{i=1}^{n} \mathscr{X}_{A_{i}}(x) \lambda\left(B_{i}\right)
\end{aligned}
$$

which is clearly $\mu$ measurable. Furthermore,

$$
\int_{X} \lambda\left(E_{x}\right) d \mu=\int_{X} \sum_{i=1}^{n} \mathscr{X}_{A_{i}}(x) \lambda\left(B_{i}\right) d \mu=\sum_{i=1}^{n} \mu\left(A_{i}\right) \lambda\left(B_{i}\right) .
$$

Similarly,

$$
\int_{Y} \mu\left(E^{y}\right) d \lambda=\sum_{i=1}^{n} \mu\left(A_{i}\right) \lambda\left(B_{i}\right)
$$

and $y \rightarrow \mu\left(E^{y}\right)$ is $\lambda$ measurable and this shows $\mathscr{M}$ contains the algebra of elementary sets. By the monotone class theorem, $\mathscr{M}=\mathscr{S} \times \mathscr{F}$. This proves the theorem.

One can easily extend this theorem to the case where the measure spaces are $\sigma$ finite.

Theorem 12.10.11 If $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{F}, \lambda)$ are both $\sigma$ finite measure spaces, then for every $E \in \mathscr{S} \times \mathscr{F}$,
a.) $x \rightarrow \lambda\left(E_{x}\right)$ is $\mu$ measurable, $y \rightarrow \mu\left(E^{y}\right)$ is $\lambda$ measurable.
b.) $\int_{X} \lambda\left(E_{x}\right) d \mu=\int_{Y} \mu\left(E^{y}\right) d \lambda$.

Proof: Let $X=\cup_{n=1}^{\infty} X_{n}, Y=\cup_{n=1}^{\infty} Y_{n}$ where,

$$
X_{n} \subseteq X_{n+1}, Y_{n} \subseteq Y_{n+1}, \mu\left(X_{n}\right)<\infty, \lambda\left(Y_{n}\right)<\infty
$$

Let

$$
\mathscr{S}_{n}=\left\{A \cap X_{n}: A \in \mathscr{S}\right\}, \mathscr{F}_{n}=\left\{B \cap Y_{n}: B \in \mathscr{F}\right\} .
$$

Thus $\left(X_{n}, \mathscr{S}_{n}, \mu\right)$ and $\left(Y_{n}, \mathscr{F}_{n}, \lambda\right)$ are both finite measure spaces.
Claim: If $E \in \mathscr{S} \times \mathscr{F}$, then $E \cap\left(X_{n} \times Y_{n}\right) \in \mathscr{S}_{n} \times \mathscr{F}_{n}$.
Proof: Let

$$
\mathscr{M}_{n}=\left\{E \in \mathscr{S} \times \mathscr{F}: E \cap\left(X_{n} \times Y_{n}\right) \in \mathscr{S}_{n} \times \mathscr{F}_{n}\right\} .
$$

Clearly $\mathscr{M}_{n}$ contains the algebra of elementary sets. It is also clear that $\mathscr{M}_{n}$ is a monotone class. Thus $\mathscr{M}_{n}=\mathscr{S} \times \mathscr{F}$.

Now let $E \in \mathscr{S} \times \mathscr{F}$. By Theorem 12.10.10,

$$
\begin{equation*}
\int_{X_{n}} \lambda\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)_{x}\right) d \mu=\int_{Y_{n}} \mu\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)^{y}\right) d \lambda \tag{12.10.49}
\end{equation*}
$$

where the integrands are measurable. Also

$$
\left(E \cap\left(X_{n} \times Y_{n}\right)\right)_{x}=\emptyset
$$

if $x \notin X_{n}$ and a similar observation holds for the second integrand in 12.10.49 if $y \notin Y_{n}$. Therefore,

$$
\begin{aligned}
\int_{X} \lambda\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)_{x}\right) d \mu & =\int_{X_{n}} \lambda\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)_{x}\right) d \mu \\
& =\int_{Y_{n}} \mu\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)^{y}\right) d \lambda \\
& =\int_{Y} \mu\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)^{y}\right) d \lambda .
\end{aligned}
$$

Then letting $n \rightarrow \infty$, the monotone convergence theorem implies b.) and the measurability assertions of a.) are valid because

$$
\begin{aligned}
\lambda\left(E_{x}\right) & =\lim _{n \rightarrow \infty} \lambda\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)_{x}\right) \\
\mu\left(E^{y}\right) & =\lim _{n \rightarrow \infty} \mu\left(\left(E \cap\left(X_{n} \times Y_{n}\right)\right)^{y}\right) .
\end{aligned}
$$

This proves the theorem.
This theorem makes it possible to define product measure.
Definition 12.10.12 For $E \in \mathscr{S} \times \mathscr{F}$ and $(X, \mathscr{S}, \mu),(Y, \mathscr{F}, \lambda) \sigma$ finite,

$$
(\mu \times \lambda)(E) \equiv \int_{X} \lambda\left(E_{x}\right) d \mu=\int_{Y} \mu\left(E^{y}\right) d \lambda
$$

This definition is well defined because of Theorem 12.10.11.
Theorem 12.10.13 If $A \in \mathscr{S}, B \in \mathscr{F}$, then $(\mu \times \lambda)(A \times B)=\mu(A) \lambda(B)$, and $\mu \times \lambda$ is a measure on $\mathscr{S} \times \mathscr{F}$ called product measure.

Proof: The first assertion about the measure of a measurable rectangle was established above. Now suppose $\left\{E_{i}\right\}_{i=1}^{\infty}$ is a disjoint collection of sets of $\mathscr{S} \times \mathscr{F}$. Then using the monotone convergence theorem along with the observation that $\left(E_{i}\right)_{x} \cap\left(E_{j}\right)_{x}=\emptyset$,

$$
\begin{aligned}
(\mu \times \lambda)\left(\cup_{i=1}^{\infty} E_{i}\right) & =\int_{X} \lambda\left(\left(\cup_{i=1}^{\infty} E_{i}\right)_{x}\right) d \mu \\
& =\int_{X} \lambda\left(\cup_{i=1}^{\infty}\left(E_{i}\right)_{x}\right) d \mu=\int_{X} \sum_{i=1}^{\infty} \lambda\left(\left(E_{i}\right)_{x}\right) d \mu \\
& =\sum_{i=1}^{\infty} \int_{X} \lambda\left(\left(E_{i}\right)_{x}\right) d \mu \\
& =\sum_{i=1}^{\infty}(\mu \times \lambda)\left(E_{i}\right)
\end{aligned}
$$

This proves the theorem.
The next theorem is one of several theorems due to Fubini and Tonelli. These theorems all have to do with interchanging the order of integration in a multiple integral.

Theorem 12.10.14 Let $f: X \times Y \rightarrow[0, \infty]$ be measurable with respect to $\mathscr{S} \times \mathscr{F}$ and suppose $\mu$ and $\lambda$ are $\sigma$ finite. Then

$$
\begin{equation*}
\int_{X \times Y} f d(\mu \times \lambda)=\int_{X} \int_{Y} f(x, y) d \lambda d \mu=\int_{Y} \int_{X} f(x, y) d \mu d \lambda \tag{12.10.50}
\end{equation*}
$$

and all integrals make sense.
Proof: For $E \in \mathscr{S} \times \mathscr{F}$,

$$
\int_{Y} \mathscr{X}_{E}(x, y) d \lambda=\lambda\left(E_{x}\right), \int_{X} \mathscr{X}_{E}(x, y) d \mu=\mu\left(E^{y}\right)
$$

Thus from Definition 12.10.12, 12.10.50 holds if $f=\mathscr{X}_{E}$. It follows that 12.10 .50 holds for every nonnegative simple function. By Theorem 11.3.9 on Page 241, there exists an increasing sequence, $\left\{f_{n}\right\}$, of simple functions converging pointwise to $f$. Then

$$
\begin{aligned}
\int_{Y} f(x, y) d \lambda & =\lim _{n \rightarrow \infty} \int_{Y} f_{n}(x, y) d \lambda \\
\int_{X} f(x, y) d \mu & =\lim _{n \rightarrow \infty} \int_{X} f_{n}(x, y) d \mu
\end{aligned}
$$

This follows from the monotone convergence theorem. Since

$$
x \rightarrow \int_{Y} f_{n}(x, y) d \lambda
$$

is measurable with respect to $\mathscr{S}$, it follows that $x \rightarrow \int_{Y} f(x, y) d \lambda$ is also measurable with respect to $\mathscr{S}$. A similar conclusion can be drawn about $y \rightarrow \int_{X} f(x, y) d \mu$. Thus the two iterated integrals make sense. Since 12.10 .50 holds for $f_{n}$, another application of the Monotone Convergence theorem shows 12.10 .50 holds for $f$. This proves the theorem.

Corollary 12.10.15 Let $f: X \times Y \rightarrow \mathbb{C}$ be $\mathscr{S} \times \mathscr{F}$ measurable. Suppose either

$$
\int_{X} \int_{Y}|f| d \lambda d \mu \text { or } \int_{Y} \int_{X}|f| d \mu d \lambda<\infty
$$

Then $f \in L^{1}(X \times Y, \mu \times \lambda)$ and

$$
\begin{equation*}
\int_{X \times Y} f d(\mu \times \lambda)=\int_{X} \int_{Y} f d \lambda d \mu=\int_{Y} \int_{X} f d \mu d \lambda \tag{12.10.51}
\end{equation*}
$$

with all integrals making sense.
Proof: Suppose first that $f$ is real valued. Apply Theorem 12.10 .14 to $f^{+}$and $f^{-}$. Then 12.10.51 follows from observing that $f=f^{+}-f^{-}$; and that all integrals are finite. If $f$ is complex valued, consider real and imaginary parts. This proves the corollary.

Suppose $f$ is product measurable. From the above discussion, and breaking $f$ down into a sum of positive and negative parts of real and imaginary parts and then using Theorem 11.3.9 on Page 241 on approximation by simple functions, it follows that whenever $f$ is $\mathscr{S} \times \mathscr{F}$ measurable, $x \rightarrow f(x, y)$ is $\mu$ measurable, $y \rightarrow f(x, y)$ is $\lambda$ measurable.

### 12.11 Completion Of Measures

Suppose $(\Omega, \mathscr{F}, \mu)$ is a measure space. Then it is always possible to enlarge the $\sigma$ algebra and define a new measure $\bar{\mu}$ on this larger $\sigma$ algebra such that $(\Omega, \overline{\mathscr{F}}, \bar{\mu})$ is a complete measure space. Recall this means that if $N \subseteq N^{\prime} \in \overline{\mathscr{F}}$ and $\bar{\mu}\left(N^{\prime}\right)=0$, then $N \in \overline{\mathscr{F}}$. The following theorem is the main result. The new measure space is called the completion of the measure space.

Theorem 12.11.1 Let $(\Omega, \mathscr{F}, \mu)$ be a $\sigma$ finite measure space. Then there exists a unique measure space, $(\Omega, \overline{\mathscr{F}}, \bar{\mu})$ satisfying

1. $(\Omega, \overline{\mathscr{F}}, \bar{\mu})$ is a complete measure space.
2. $\bar{\mu}=\mu$ on $\mathscr{F}$
3. $\overline{\mathscr{F}} \supseteq \mathscr{F}$
4. For every $E \in \overline{\mathscr{F}}$ there exists $G \in \mathscr{F}$ such that $G \supseteq E$ and $\mu(G)=\bar{\mu}(E)$.
5. For every $E \in \overline{\mathscr{F}}$ there exists $F \in \mathscr{F}$ such that $F \subseteq E$ and $\mu(F)=\bar{\mu}(E)$.

Also for every $E \in \overline{\mathscr{F}}$ there exist sets $G, F \in \mathscr{F}$ such that $G \supseteq E \supseteq F$ and

$$
\begin{equation*}
\mu(G \backslash F)=\bar{\mu}(G \backslash F)=0 \tag{12.11.52}
\end{equation*}
$$

Proof: First consider the claim about uniqueness. Suppose $\left(\Omega, \mathscr{F}_{1}, v_{1}\right)$ and $\left(\Omega, \mathscr{F}_{2}, \nu_{2}\right)$ both work and let $E \in \mathscr{F}_{1}$. Also let $\mu\left(\Omega_{n}\right)<\infty, \cdots \Omega_{n} \subseteq \Omega_{n+1} \cdots$, and $\cup_{n=1}^{\infty} \Omega_{n}=\Omega$. Define $E_{n} \equiv E \cap \Omega_{n}$. Then pick $G_{n} \supseteq E_{n} \supseteq F_{n}$ such that $\mu\left(G_{n}\right)=\mu\left(F_{n}\right)=v_{1}\left(E_{n}\right)$. It follows $\mu\left(G_{n} \backslash F_{n}\right)=0$. Then letting $G=\cup_{n} G_{n}, F \equiv \cup_{n} F_{n}$, it follows $G \supseteq E \supseteq F$ and

$$
\begin{aligned}
\mu(G \backslash F) & \leq \mu\left(\cup_{n}\left(G_{n} \backslash F_{n}\right)\right) \\
& \leq \sum_{n} \mu\left(G_{n} \backslash F_{n}\right)=0 .
\end{aligned}
$$

It follows that $v_{2}(G \backslash F)=0$ also. Now $E \backslash F \subseteq G \backslash F$ and since $\left(\Omega, \mathscr{F}_{2}, v_{2}\right)$ is complete, it follows $E \backslash F \in \mathscr{F}_{2}$. Since $F \in \mathscr{F}_{2}$, it follows $E=(E \backslash F) \cup F \in \mathscr{F}_{2}$. Thus $\mathscr{F}_{1} \subseteq \mathscr{F}_{2}$. Similarly $\mathscr{F}_{2} \subseteq \mathscr{F}_{1}$. Now it only remains to verify $v_{1}=v_{2}$. Thus let $E \in \mathscr{F}_{1}=\mathscr{F}_{2}$ and let $G$ and $F$ be as just described. Since $v_{i}=\mu$ on $\mathscr{F}$,

$$
\begin{aligned}
\mu(F) & \leq v_{1}(E) \\
& =v_{1}(E \backslash F)+v_{1}(F) \\
& \leq v_{1}(G \backslash F)+v_{1}(F) \\
& =v_{1}(F)=\mu(F)
\end{aligned}
$$

Similarly $v_{2}(E)=\mu(F)$. This proves uniqueness. The construction has also verified 12.11.52.

Next define an outer measure, $\bar{\mu}$ on $\mathscr{P}(\Omega)$ as follows. For $S \subseteq \Omega$,

$$
\bar{\mu}(S) \equiv \inf \{\mu(E): E \in \mathscr{F}\}
$$

Then it is clear $\bar{\mu}$ is increasing. It only remains to verify $\bar{\mu}$ is subadditive. Then let $S=$ $\cup_{i=1}^{\infty} S_{i}$. If any $\bar{\mu}\left(S_{i}\right)=\infty$, there is nothing to prove so suppose $\bar{\mu}\left(S_{i}\right)<\infty$ for each $i$. Then there exist $E_{i} \in \mathscr{F}$ such that $E_{i} \supseteq S_{i}$ and

$$
\bar{\mu}\left(S_{i}\right)+\varepsilon / 2^{i}>\mu\left(E_{i}\right)
$$

Then

$$
\begin{aligned}
\bar{\mu}(S) & =\bar{\mu}\left(\cup_{i} S_{i}\right) \\
& \leq \mu\left(\cup_{i} E_{i}\right) \leq \sum_{i} \mu\left(E_{i}\right) \\
& \leq \sum_{i}\left(\bar{\mu}\left(S_{i}\right)+\varepsilon / 2^{i}\right)=\sum_{i} \bar{\mu}\left(S_{i}\right)+\varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this verifies $\bar{\mu}$ is subadditive and is an outer measure as claimed.
Denote by $\overline{\mathscr{F}}$ the $\sigma$ algebra of measurable sets in the sense of Caratheodory. Then it follows from the Caratheodory procedure, Theorem 12.1.4, on Page 270 that $(\Omega, \overline{\mathscr{F}}, \bar{\mu})$ is a complete measure space. This verifies 1 .

Now let $E \in \mathscr{F}$. Then from the definition of $\bar{\mu}$, it follows

$$
\bar{\mu}(E) \equiv \inf \{\mu(F): F \in \mathscr{F} \text { and } F \supseteq E\} \leq \mu(E)
$$

If $F \supseteq E$ and $F \in \mathscr{F}$, then $\mu(F) \geq \mu(E)$ and so $\mu(E)$ is a lower bound for all such $\mu(F)$ which shows that

$$
\bar{\mu}(E) \equiv \inf \{\mu(F): F \in \mathscr{F} \text { and } F \supseteq E\} \geq \mu(E)
$$

This verifies 2 .
Next consider 3. Let $E \in \mathscr{F}$ and let $S$ be a set. I must show

$$
\bar{\mu}(S) \geq \bar{\mu}(S \backslash E)+\bar{\mu}(S \cap E)
$$

If $\bar{\mu}(S)=\infty$ there is nothing to show. Therefore, suppose $\bar{\mu}(S)<\infty$. Then from the definition of $\bar{\mu}$ there exists $G \supseteq S$ such that $G \in \mathscr{F}$ and $\mu(G)=\bar{\mu}(S)$. Then from the definition of $\bar{\mu}$,

$$
\begin{aligned}
\bar{\mu}(S) & \leq \bar{\mu}(S \backslash E)+\bar{\mu}(S \cap E) \\
& \leq \mu(G \backslash E)+\mu(G \cap E) \\
& =\mu(G)=\bar{\mu}(S)
\end{aligned}
$$

This verifies 3.
Claim 4 comes by the definition of $\bar{\mu}$ as used above. The only other case is when $\bar{\mu}(S)=\infty$. However, in this case, you can let $G=\Omega$.

It only remains to verify 5 . Let the $\Omega_{n}$ be as described above and let $E \in \overline{\mathscr{F}}$ such that $E \subseteq \Omega_{n}$. By 4 there exists $H \in \mathscr{F}$ such that $H \subseteq \Omega_{n}, H \supseteq \Omega_{n} \backslash E$, and

$$
\begin{equation*}
\mu(H)=\bar{\mu}\left(\Omega_{n} \backslash E\right) \tag{12.11.53}
\end{equation*}
$$

Then let $F \equiv \Omega_{n} \cap H^{C}$. It follows $F \subseteq E$ and

$$
\begin{aligned}
E \backslash F & =E \cap F^{C}=E \cap\left(H \cup \Omega_{n}^{C}\right) \\
& =E \cap H=H \backslash\left(\Omega_{n} \backslash E\right)
\end{aligned}
$$

Hence from 12.11.53

$$
\bar{\mu}(E \backslash F)=\bar{\mu}\left(H \backslash\left(\Omega_{n} \backslash E\right)\right)=0
$$

It follows

$$
\bar{\mu}(E)=\bar{\mu}(F)=\mu(F)
$$

In the case where $E \in \overline{\mathscr{F}}$ is arbitrary, not necessarily contained in some $\Omega_{n}$, it follows from what was just shown that there exists $F_{n} \in \mathscr{F}$ such that $F_{n} \subseteq E \cap \Omega_{n}$ and

$$
\mu\left(F_{n}\right)=\bar{\mu}\left(E \cap \Omega_{n}\right) .
$$

Letting $F \equiv \cup_{n} F_{n}$

$$
\bar{\mu}(E \backslash F) \leq \bar{\mu}\left(\cup_{n}\left(E \cap \Omega_{n} \backslash F_{n}\right)\right) \leq \sum_{n} \bar{\mu}\left(E \cap \Omega_{n} \backslash F_{n}\right)=0
$$

Therefore, $\bar{\mu}(E)=\mu(F)$ and this proves 5. This proves the theorem.
Now here is an interesting theorem about complete measure spaces.

Theorem 12.11.2 Let $(\Omega, \mathscr{F}, \mu)$ be a complete measure space and let $f \leq g \leq h$ be functions having values in $[0, \infty]$. Suppose also that $f(\omega)=h(\omega)$ a.e. $\omega$ and that $f$ and $h$ are measurable. Then $g$ is also measurable. If $(\Omega, \overline{\mathscr{F}}, \bar{\mu})$ is the completion of a $\sigma$ finite measure space $(\Omega, \mathscr{F}, \mu)$ as described above in Theorem 12.11.1 then if $f$ is measurable with respect to $\overline{\mathscr{F}}$ having values in $[0, \infty]$, it follows there exists $g$ measurable with respect to $\mathscr{F}$ , $g \leq f$, and a set $N \in \mathscr{F}$ with $\mu(N)=0$ and $g=f$ on $N^{C}$. There also exists $h$ measurable with respect to $\mathscr{F}$ such that $h \geq f$, and a set of measure zero, $M \in \mathscr{F}$ such that $f=h$ on $M^{C}$.

Proof: Let $\alpha \in \mathbb{R}$.

$$
[f>\alpha] \subseteq[g>\alpha] \subseteq[h>\alpha]
$$

Thus

$$
[g>\alpha]=[f>\alpha] \cup([g>\alpha] \backslash[f>\alpha])
$$

and $[g>\alpha] \backslash[f>\alpha]$ is a measurable set because it is a subset of the set of measure zero,

$$
[h>\alpha] \backslash[f>\alpha]
$$

Now consider the last assertion. By Theorem 11.3.9 on Page 241 there exists an increasing sequence of nonnegative simple functions, $\left\{s_{n}\right\}$ measurable with respect to $\overline{\mathscr{F}}$ which converges pointwise to $f$. Letting

$$
\begin{equation*}
s_{n}(\omega)=\sum_{k=1}^{m_{n}} c_{k}^{n} \mathscr{X}_{E_{k}^{n}}(\omega) \tag{12.11.54}
\end{equation*}
$$

be one of these simple functions, it follows from Theorem 12.11.1 there exist sets, $F_{k}^{n} \in \mathscr{F}$ such that $F_{k}^{n} \subseteq E_{k}^{n}$ and $\mu\left(F_{k}^{n}\right)=\bar{\mu}\left(E_{k}^{n}\right)$. Then let

$$
t_{n}(\omega) \equiv \sum_{k=1}^{m_{n}} c_{k}^{n} \mathscr{X}_{F_{k}^{n}}(\omega)
$$

Thus $t_{n}=s_{n}$ off a set of measure zero, $N_{n} \in \overline{\mathscr{F}}, t_{n} \leq s_{n}$. Let $N^{\prime} \equiv \cup_{n} N_{n}$. Then by Theorem 12.11.1 again, there exists $N \in \mathscr{F}$ such that $N \supseteq N^{\prime}$ and $\mu(N)=0$. Consider the simple functions,

$$
s_{n}^{\prime}(\omega) \equiv t_{n}(\omega) \mathscr{X}_{N^{C}}(\omega)
$$

It is an increasing sequence so let $g(\omega)=\lim _{n \rightarrow \infty} s_{n^{\prime}}(\omega)$. It follows $g$ is mesurable with respect to $\mathscr{F}$ and equals $f$ off $N$.

Finally, to obtain the function, $h \geq f$, in 12.11.54 use Theorem 12.11.1 to obtain the existence of $F_{k}^{n} \in \mathscr{F}$ such that $F_{k}^{n} \supseteq E_{k}^{n}$ and $\mu\left(F_{k}^{n}\right)=\bar{\mu}\left(E_{k}^{n}\right)$. Then let

$$
t_{n}(\omega) \equiv \sum_{k=1}^{m_{n}} c_{k}^{n} \mathscr{X}_{F_{k}^{n}}(\omega)
$$

Thus $t_{n}=s_{n}$ off a set of measure zero, $M_{n} \in \overline{\mathscr{F}}, t_{n} \geq s_{n}$, and $t_{n}$ is measurable with respect to $\mathscr{F}$. Then define

$$
s_{n}^{\prime}=\max _{k \leq n} t_{n}
$$

It follows $s_{n}^{\prime}$ is an increasing sequence of $\mathscr{F}$ measurable nonnegative simple functions. Since each $s_{n}^{\prime} \geq s_{n}$, it follows that if $h(\omega)=\lim _{n \rightarrow \infty} s_{n}^{\prime}(\omega)$, then $h(\omega) \geq f(\omega)$. Also if $h(\omega)>f(\omega)$, then $\omega \in \cup_{n} M_{n} \equiv M^{\prime}$, a set of $\overline{\mathscr{F}}$ having measure zero. By Theorem 12.11.1, there exists $M \supseteq M^{\prime}$ such that $M \in \mathscr{F}$ and $\mu(M)=0$. It follows $h=f$ off $M$. This proves the theorem.

### 12.12 Another Version Of Product Measures

### 12.12.1 General Theory

Given two finite measure spaces, $(X, \mathscr{F}, \mu)$ and $(Y, \mathscr{S}, v)$, there is a way to define a $\sigma$ algebra of subsets of $X \times Y$, denoted by $\mathscr{F} \times \mathscr{S}$ and a measure, denoted by $\mu \times v$ defined on this $\sigma$ algebra such that

$$
\mu \times v(A \times B)=\mu(A) v(B)
$$

whenever $A \in \mathscr{F}$ and $B \in \mathscr{S}$. This is naturally related to the concept of iterated integrals similar to what is used in calculus to evaluate a multiple integral. The approach is based on something called a $\pi$ system, [36].

Definition 12.12.1 Let $(X, \mathscr{F}, \mu)$ and $(Y, \mathscr{S}, v)$ be two measure spaces. A measurable rectangle is a set of the form $A \times B$ where $A \in \mathscr{F}$ and $B \in \mathscr{S}$.

Definition 12.12.2 Let $\Omega$ be a set and let $\mathscr{K}$ be a collection of subsets of $\Omega$. Then $\mathscr{K}$ is called a $\pi$ system if $\emptyset, \Omega \in \mathscr{K}$ and whenever $A, B \in \mathscr{K}$, it follows $A \cap B \in \mathscr{K}$.

Obviously an example of a $\pi$ system is the set of measurable rectangles because

$$
A \times B \cap A^{\prime} \times B^{\prime}=\left(A \cap A^{\prime}\right) \times\left(B \cap B^{\prime}\right)
$$

The following is the fundamental lemma which shows these $\pi$ systems are useful. This lemma is due to Dynkin.

Lemma 12.12.3 Let $\mathscr{K}$ be a $\pi$ system of subsets of $\Omega$, a set. Also let $\mathscr{G}$ be a collection of subsets of $\Omega$ which satisfies the following three properties.

1. $\mathscr{K} \subseteq \mathscr{G}$
2. If $A \in \mathscr{G}$, then $A^{C} \in \mathscr{G}$
3. If $\left\{A_{i}\right\}_{i=1}^{\infty}$ is a sequence of disjoint sets from $\mathscr{G}$ then $\cup_{i=1}^{\infty} A_{i} \in \mathscr{G}$.

Then $\mathscr{G} \supseteq \sigma(\mathscr{K})$, where $\sigma(\mathscr{K})$ is the smallest $\sigma$ algebra which contains $\mathscr{K}$.
Proof: First note that if

$$
\mathscr{H} \equiv\{\mathscr{G}: 1-3 \text { all hold }\}
$$

then $\cap \mathscr{H}$ yields a collection of sets which also satisfies $1-3$. Therefore, I will assume in the argument that $\mathscr{G}$ is the smallest collection satisfying 1-3. Let $A \in \mathscr{K}$ and define

$$
\mathscr{G}_{A} \equiv\{B \in \mathscr{G}: A \cap B \in \mathscr{G}\} .
$$

I want to show $\mathscr{G}_{A}$ satisfies $1-3$ because then it must equal $\mathscr{G}$ since $\mathscr{G}$ is the smallest collection of subsets of $\Omega$ which satisfies $1-3$. This will give the conclusion that for $A \in \mathscr{K}$ and $B \in \mathscr{G}, A \cap B \in \mathscr{G}$. This information will then be used to show that if $A, B \in \mathscr{G}$ then $A \cap B \in \mathscr{G}$. From this it will follow very easily that $\mathscr{G}$ is a $\sigma$ algebra which will imply it contains $\sigma(\mathscr{K})$. Now here are the details of the argument.

Since $\mathscr{K}$ is given to be a $\pi$ system, $\mathscr{K} \subseteq \mathscr{G}_{A}$. Property 3 is obvious because if $\left\{B_{i}\right\}$ is a sequence of disjoint sets in $\mathscr{G}_{A}$, then

$$
A \cap \cup_{i=1}^{\infty} B_{i}=\cup_{i=1}^{\infty} A \cap B_{i} \in \mathscr{G}
$$

because $A \cap B_{i} \in \mathscr{G}$ and the property 3 of $\mathscr{G}$.
It remains to verify Property 2 so let $B \in \mathscr{G}_{A}$. I need to verify that $B^{C} \in \mathscr{G}_{A}$. In other words, I need to show that $A \cap B^{C} \in \mathscr{G}$. However,

$$
A \cap B^{C}=\left(A^{C} \cup(A \cap B)\right)^{C} \in \mathscr{G}
$$

Here is why. Since $B \in \mathscr{G}_{A}, A \cap B \in \mathscr{G}$ and since $A \in \mathscr{K} \subseteq \mathscr{G}$ it follows $A^{C} \in \mathscr{G}$ by assumption 2. It follows from assumption 3 the union of the disjoint sets, $A^{C}$ and $(A \cap B)$ is in $\mathscr{G}$ and then from 2 the complement of their union is in $\mathscr{G}$. Thus $\mathscr{G}_{A}$ satisfies 1-3 and this implies since $\mathscr{G}$ is the smallest such, that $\mathscr{G}_{A} \supseteq \mathscr{G}$. However, $\mathscr{G}_{A}$ is constructed as a subset of $\mathscr{G}$. This proves that for every $B \in \mathscr{G}$ and $A \in \mathscr{K}, A \cap B \in \mathscr{G}$. Now pick $B \in \mathscr{G}$ and consider

$$
\mathscr{G}_{B} \equiv\{A \in \mathscr{G}: A \cap B \in \mathscr{G}\} .
$$

I just proved $\mathscr{K} \subseteq \mathscr{G}_{B}$. The other arguments are identical to show $\mathscr{G}_{B}$ satisfies 1-3 and is therefore equal to $\mathscr{G}$. This shows that whenever $A, B \in \mathscr{G}$ it follows $A \cap B \in \mathscr{G}$.

This implies $\mathscr{G}$ is a $\sigma$ algebra. To show this, all that is left is to verify $\mathscr{G}$ is closed under countable unions because then it follows $\mathscr{G}$ is a $\sigma$ algebra. Let $\left\{A_{i}\right\} \subseteq \mathscr{G}$. Then let $A_{1}^{\prime}=A_{1}$ and

$$
\begin{aligned}
A_{n+1}^{\prime} & \equiv A_{n+1} \backslash\left(\cup_{i=1}^{n} A_{i}\right) \\
& =A_{n+1} \cap\left(\cap_{i=1}^{n} A_{i}^{C}\right) \\
& =\cap_{i=1}^{n}\left(A_{n+1} \cap A_{i}^{C}\right) \in \mathscr{G}
\end{aligned}
$$

because finite intersections of sets of $\mathscr{G}$ are in $\mathscr{G}$. Since the $A_{i}^{\prime}$ are disjoint, it follows

$$
\cup_{i=1}^{\infty} A_{i}=\cup_{i=1}^{\infty} A_{i}^{\prime} \in \mathscr{G}
$$

Therefore, $\mathscr{G} \supseteq \sigma(\mathscr{K})$ and this proves the Lemma.
With this lemma, it is easy to define product measure.
Let $(X, \mathscr{F}, \mu)$ and $(Y, \mathscr{S}, v)$ be two finite measure spaces. Define $\mathscr{K}$ to be the set of measurable rectangles, $A \times B, A \in \mathscr{F}$ and $B \in \mathscr{S}$. Let

$$
\begin{equation*}
\mathscr{G} \equiv\left\{E \subseteq X \times Y: \int_{Y} \int_{X} \mathscr{X}_{E} d \mu d v=\int_{X} \int_{Y} \mathscr{X}_{E} d v d \mu\right\} \tag{12.12.55}
\end{equation*}
$$

where in the above, part of the requirement is for all integrals to make sense.

Then $\mathscr{K} \subseteq \mathscr{G}$. This is obvious.
Next I want to show that if $E \in \mathscr{G}$ then $E^{C} \in \mathscr{G}$. Observe $\mathscr{X}_{E^{C}}=1-\mathscr{X}_{E}$ and so

$$
\begin{aligned}
\int_{Y} \int_{X} \mathscr{X}_{E^{C}} d \mu d v & =\int_{Y} \int_{X}\left(1-\mathscr{X}_{E}\right) d \mu d v \\
& =\int_{X} \int_{Y}\left(1-\mathscr{X}_{E}\right) d v d \mu \\
& =\int_{X} \int_{Y} \mathscr{X}_{E^{C}} d v d \mu
\end{aligned}
$$

which shows that if $E \in \mathscr{G}$, then $E^{C} \in \mathscr{G}$.
Next I want to show $\mathscr{G}$ is closed under countable unions of disjoint sets of $\mathscr{G}$. Let $\left\{A_{i}\right\}$ be a sequence of disjoint sets from $\mathscr{G}$. Then

$$
\begin{align*}
\int_{Y} \int_{X} \mathscr{X}_{\cup_{i=1}^{\infty} A_{i}} d \mu d \nu & =\int_{Y} \int_{X} \sum_{i=1}^{\infty} \mathscr{X}_{A_{i}} d \mu d \nu \\
& =\int_{Y} \sum_{i=1}^{\infty} \int_{X} \mathscr{X}_{A_{i}} d \mu d \nu \\
& =\sum_{i=1}^{\infty} \int_{Y} \int_{X} \mathscr{X}_{A_{i}} d \mu d \nu \\
& =\sum_{i=1}^{\infty} \int_{X} \int_{Y} \mathscr{X}_{A_{i}} d v d \mu \\
& =\int_{X} \sum_{i=1}^{\infty} \int_{Y} \mathscr{X}_{A_{i}} d v d \mu \\
& =\int_{X} \int_{Y} \sum_{i=1}^{\infty} \mathscr{X}_{A_{i}} d v d \mu \\
& =\int_{X} \int_{Y} \mathscr{X}_{U_{i=1}^{\infty} A_{i}} d v d \mu \tag{12.12.56}
\end{align*}
$$

the interchanges between the summation and the integral depending on the monotone convergence theorem. Thus $\mathscr{G}$ is closed with respect to countable disjoint unions.

From Lemma 12.12.3, $\mathscr{G} \supseteq \sigma(\mathscr{K})$. Also the computation in 12.12 .56 implies that on $\sigma(\mathscr{K})$ one can define a measure, denoted by $\mu \times v$ and that for every $E \in \sigma(\mathscr{K})$,

$$
\begin{equation*}
(\mu \times v)(E)=\int_{Y} \int_{X} \mathscr{X}_{E} d \mu d v=\int_{X} \int_{Y} \mathscr{X}_{E} d v d \mu \tag{12.12.57}
\end{equation*}
$$

Now here is Fubini's theorem.
Theorem 12.12.4 Let $f: X \times Y \rightarrow[0, \infty]$ be measurable with respect to the $\sigma$ algebra, $\sigma(\mathscr{K})$ just defined and let $\mu \times v$ be the product measure of 12.12 .57 where $\mu$ and $v$ are finite measures on $(X, \mathscr{F})$ and $(Y, \mathscr{S})$ respectively. Then

$$
\int_{X \times Y} f d(\mu \times v)=\int_{Y} \int_{X} f d \mu d v=\int_{X} \int_{Y} f d v d \mu
$$

Proof: Let $\left\{s_{n}\right\}$ be an increasing sequence of $\sigma(\mathscr{K})$ measurable simple functions which converges pointwise to $f$. The above equation holds for $s_{n}$ in place of $f$ from what was shown above. The final result follows from passing to the limit and using the monotone convergence theorem.

The symbol, $\mathscr{F} \times \mathscr{S}$ denotes $\sigma(\mathscr{K})$.
Of course one can generalize right away to measures which are only $\sigma$ finite.
Theorem 12.12.5 Let $f: X \times Y \rightarrow[0, \infty]$ be measurable with respect to the $\sigma$ algebra, $\sigma(\mathscr{K})$ just defined and let $\mu \times v$ be the product measure of 12.12 .57 where $\mu$ and $v$ are $\sigma$ finite measures on $(X, \mathscr{F})$ and $(Y, \mathscr{S})$ respectively. Then

$$
\int_{X \times Y} f d(\mu \times v)=\int_{Y} \int_{X} f d \mu d v=\int_{X} \int_{Y} f d v d \mu .
$$

Proof: Since the measures are $\sigma$ finite, there exist increasing sequences of sets, $\left\{X_{n}\right\}$ and $\left\{Y_{n}\right\}$ such that $\mu\left(X_{n}\right)<\infty$ and $v\left(Y_{n}\right)<\infty$. Then $\mu$ and $v$ restricted to $X_{n}$ and $Y_{n}$ respectively are finite. Then from Theorem 12.12.4,

$$
\int_{Y_{n}} \int_{X_{n}} f d \mu d v=\int_{X_{n}} \int_{Y_{n}} f d v d \mu
$$

Passing to the limit yields

$$
\int_{Y} \int_{X} f d \mu d v=\int_{X} \int_{Y} f d v d \mu
$$

whenever $f$ is as above. In particular, you could take $f=\mathscr{X}_{E}$ where $E \in \mathscr{F} \times \mathscr{S}$ and define

$$
(\mu \times v)(E) \equiv \int_{Y} \int_{X} \mathscr{X}_{E} d \mu d v=\int_{X} \int_{Y} \mathscr{X}_{E} d v d \mu .
$$

Then just as in the proof of Theorem 12.12.4, the conclusion of this theorem is obtained. This proves the theorem.

It is also useful to note that all the above holds for $\prod_{i=1}^{n} X_{i}$ in place of $X \times Y$. You would simply modify the definition of $\mathscr{G}$ in 12.12.55 including all permutations for the iterated integrals and for $\mathscr{K}$ you would use sets of the form $\prod_{i=1}^{n} A_{i}$ where $A_{i}$ is measurable. Everything goes through exactly as above. Thus the following is obtained.

Theorem 12.12.6 Let $\left\{\left(X_{i}, \mathscr{F}_{i}, \mu_{i}\right)\right\}_{i=1}^{n}$ be $\sigma$ finite measure spaces and let $\prod_{i=1}^{n} \mathscr{F}_{i}$ denote the smallest $\sigma$ algebra which contains the measurable boxes of the form $\prod_{i=1}^{n} A_{i}$ where $A_{i} \in \mathscr{F}_{i}$. Then there exists a measure, $\lambda$ defined on $\prod_{i=1}^{n} \mathscr{F}_{i}$ such that if $f: \prod_{i=1}^{n} X_{i} \rightarrow[0, \infty]$ is $\prod_{i=1}^{n} \mathscr{F}_{i}$ measurable, and $\left(i_{1}, \cdots, i_{n}\right)$ is any permutation of $(1, \cdots, n)$, then

$$
\int f d \lambda=\int_{X_{i_{n}}} \cdots \int_{X_{i_{1}}} f d \mu_{i_{1}} \cdots d \mu_{i_{n}}
$$

### 12.12.2 Completion Of Product Measure Spaces

Using Theorem 12.11.2 it is easy to give a generalization to yield a theorem for the completion of product spaces.

Theorem 12.12.7 Let $\left\{\left(X_{i}, \mathscr{F}_{i}, \mu_{i}\right)\right\}_{i=1}^{n}$ be $\sigma$ finite measure spaces and let $\prod_{i=1}^{n} \mathscr{F}_{i}$ denote the smallest $\sigma$ algebra which contains the measurable boxes of the form $\prod_{i=1}^{n} A_{i}$ where $A_{i} \in \mathscr{F}_{i}$. Then there exists a measure, $\lambda$ defined on $\prod_{i=1}^{n} \mathscr{F}_{i}$ such that if $f: \prod_{i=1}^{n} X_{i} \rightarrow[0, \infty]$ is $\prod_{i=1}^{n} \mathscr{F}_{i}$ measurable, and $\left(i_{1}, \cdots, i_{n}\right)$ is any permutation of $(1, \cdots, n)$, then

$$
\int f d \lambda=\int_{X_{i_{n}}} \cdots \int_{X_{i_{1}}} f d \mu_{i_{1}} \cdots d \mu_{i_{n}}
$$

Let $\left(\prod_{i=1}^{n} X_{i}, \overline{\prod_{i=1}^{n} \mathscr{F}_{i}}, \bar{\lambda}\right)$ denote the completion of this product measure space and let

$$
f: \prod_{i=1}^{n} X_{i} \rightarrow[0, \infty]
$$

be $\overline{\prod_{i=1}^{n} \mathscr{F}_{i}}$ measurable. Then there exists $N \in \prod_{i=1}^{n} \mathscr{F}_{i}$ such that $\lambda(N)=0$ and a nonnegative function, $f_{1}$ measurable with respect to $\prod_{i=1}^{n} \mathscr{F}_{i}$ such that $f_{1}=f$ off $N$ and if $\left(i_{1}, \cdots, i_{n}\right)$ is any permutation of $(1, \cdots, n)$, then

$$
\int f d \bar{\lambda}=\int_{X_{i_{n}}} \cdots \int_{X_{i_{1}}} f_{1} d \mu_{i_{1}} \cdots d \mu_{i_{n}} .
$$

Furthermore, $f_{1}$ may be chosen to satisfy either $f_{1} \leq f$ or $f_{1} \geq f$.
Proof: This follows immediately from Theorem 12.12.6 and Theorem 12.11.2. By the second theorem, there exists a function $f_{1} \geq f$ such that $f_{1}=f$ for all $\left(x_{1}, \cdots, x_{n}\right) \notin N$, a set of $\prod_{i=1}^{n} \mathscr{F}_{i}$ having measure zero. Then by Theorem 12.11.1 and Theorem 12.12.6

$$
\int f d \bar{\lambda}=\int f_{1} d \lambda=\int_{X_{i_{n}}} \cdots \int_{X_{i_{1}}} f_{1} d \mu_{i_{1}} \cdots d \mu_{i_{n}}
$$

Since $f_{1}=f$ off a set of measure zero, I will dispense with the subscript. Also it is customary to write

$$
\lambda=\mu_{1} \times \cdots \times \mu_{n}
$$

and

$$
\bar{\lambda}=\overline{\mu_{1} \times \cdots \times \mu_{n}} .
$$

Thus in more standard notation, one writes

$$
\int f d\left(\overline{\mu_{1} \times \cdots \times \mu_{n}}\right)=\int_{X_{i_{n}}} \cdots \int_{X_{i_{1}}} f d \mu_{i_{1}} \cdots d \mu_{i_{n}}
$$

This theorem is often referred to as Fubini's theorem. The next theorem is also called this.
Corollary 12.12 .8 Suppose $f \in L^{1}\left(\prod_{i=1}^{n} X_{i}, \overline{\prod_{i=1}^{n} \mathscr{F}_{i}}, \overline{\mu_{1} \times \cdots \times \mu_{n}}\right)$ where each $X_{i}$ is a $\sigma$ finite measure space. Then if $\left(i_{1}, \cdots, i_{n}\right)$ is any permutation of $(1, \cdots, n)$, it follows

$$
\int f d\left(\overline{\mu_{1} \times \cdots \times \mu_{n}}\right)=\int_{X_{i_{n}}} \cdots \int_{X_{i_{1}}} f d \mu_{i_{1}} \cdots d \mu_{i_{n}}
$$

Proof: Just apply Theorem 12.12 .7 to the positive and negative parts of the real and imaginary parts of $f$. This proves the theorem.

Here is another easy corollary.
Corollary 12.12.9 Suppose in the situation of Corollary 12.12.8, $f=f_{1}$ off $N$, a set of $\prod_{i=1}^{n} \mathscr{F}_{i}$ having $\mu_{1} \times \cdots \times \mu_{n}$ measure zero and that $f_{1}$ is a complex valued function measurable with respect to $\prod_{i=1}^{n} \mathscr{F}_{i}$. Suppose also that for some permutation of $(1,2, \cdots, n)$ , $\left(j_{1}, \cdots, j_{n}\right)$

$$
\int_{X_{j_{n}}} \cdots \int_{X_{j_{1}}}\left|f_{1}\right| d \mu_{j_{1}} \cdots d \mu_{j_{n}}<\infty .
$$

Then

$$
f \in L^{1}\left(\prod_{i=1}^{n} X_{i}, \overline{\prod_{i=1}^{n} \mathscr{F}_{i}}, \overline{\mu_{1} \times \cdots \times \mu_{n}}\right)
$$

and the conclusion of Corollary 12.12.8 holds.
Proof: Since $\left|f_{1}\right|$ is $\prod_{i=1}^{n} \mathscr{F}_{i}$ measurable, it follows from Theorem 12.12.6 that

$$
\begin{aligned}
\infty & >\int_{X_{j_{n}}} \cdots \int_{X_{j_{1}}}\left|f_{1}\right| d \mu_{j_{1}} \cdots d \mu_{j_{n}} \\
& =\int\left|f_{1}\right| d\left(\mu_{1} \times \cdots \times \mu_{n}\right) \\
& =\int\left|f_{1}\right| d\left(\overline{\mu_{1} \times \cdots \times \mu_{n}}\right) \\
& =\int|f| d\left(\overline{\mu_{1} \times \cdots \times \mu_{n}}\right) .
\end{aligned}
$$

Thus $f \in L^{1}\left(\prod_{i=1}^{n} X_{i}, \overline{\prod_{i=1}^{n} \mathscr{F}_{i}}, \overline{\mu_{1} \times \cdots \times \mu_{n}}\right)$ as claimed and the rest follows from Corollary 12.12 .8 . This proves the corollary.

The following lemma is also useful.
Lemma 12.12.10 Let $(X, \mathscr{F}, \mu)$ and $(Y, \mathscr{S}, v)$ be $\sigma$ finite complete measure spaces and suppose $f \geq 0$ is $\overline{\mathscr{F}} \times \mathscr{S}$ measurable. Then for a.e. $x$,

$$
y \rightarrow f(x, y)
$$

is $\mathscr{S}$ measurable. Similarly for a.e. y,

$$
x \rightarrow f(x, y)
$$

is $\mathscr{F}$ measurable.
Proof: By Theorem 12.11.2, there exist $\mathscr{F} \times \mathscr{S}$ measurable functions, $g$ and $h$ and a set, $N \in \mathscr{F} \times \mathscr{S}$ of $\mu \times \lambda$ measure zero such that $g \leq f \leq h$ and for $(x, y) \notin N$, it follows that $g(x, y)=h(x, y)$. Then

$$
\int_{X} \int_{Y} g d v d \mu=\int_{X} \int_{Y} h d v d \mu
$$

and so for a.e. $x$,

$$
\int_{Y} g d v=\int_{Y} h d v
$$

Then it follows that for these values of $x, g(x, y)=h(x, y)$ and so by Theorem 12.11.2 again and the assumption that $(Y, \mathscr{S}, v)$ is complete, $y \rightarrow f(x, y)$ is $\mathscr{S}$ measurable. The other claim is similar. This proves the lemma.

### 12.13 Disturbing Examples

There are examples which help to define what can be expected of product measures and Fubini type theorems. Three such examples are given in Rudin [113]. Some of the theorems given above are more general than those in this reference but the same examples are still useful for showing that the hypotheses of the above theorems are all necessary.

Example 12.13.1 Let $\left\{a_{n}\right\}$ be an increasing sequence of numbers in $(0,1)$ which converges to 1. Let $g_{n} \in C_{c}\left(a_{n}, a_{n+1}\right)$ such that $\int g_{n} d x=1$. Now for $(x, y) \in[0,1) \times[0,1)$ define

$$
f(x, y) \equiv \sum_{k=1}^{\infty} g_{n}(y)\left(g_{n}(x)-g_{n+1}(x)\right)
$$

Note this is actually a finite sum for each such $(x, y)$. Therefore, this is a continuous function on $[0,1) \times[0,1)$. Now for a fixed $y$,

$$
\int_{0}^{1} f(x, y) d x=\sum_{k=1}^{\infty} g_{n}(y) \int_{0}^{1}\left(g_{n}(x)-g_{n+1}(x)\right) d x=0
$$

showing that $\int_{0}^{1} \int_{0}^{1} f(x, y) d x d y=\int_{0}^{1} 0 d y=0$. Next fix $x$.

$$
\int_{0}^{1} f(x, y) d y=\sum_{k=1}^{\infty}\left(g_{n}(x)-g_{n+1}(x)\right) \int_{0}^{1} g_{n}(y) d y=g_{1}(x) .
$$

Hence $\int_{0}^{1} \int_{0}^{1} f(x, y) d y d x=\int_{0}^{1} g_{1}(x) d x=1$. The iterated integrals are not equal. Note the function, $g$ is not nonnegative even though it is measurable. In addition, neither $\int_{0}^{1} \int_{0}^{1}|f(x, y)| d x d y$ nor $\int_{0}^{1} \int_{0}^{1}|f(x, y)| d y d x$ is finite and so you Corollary 12.9.13 does not apply. The problem here is the function is not nonnegative and is not absolutely integrable.

Example 12.13.2 This time let $\mu=m$, Lebesgue measure on $[0,1]$ and let $v$ be counting measure on $[0,1]$, in this case, the $\sigma$ algebra is $\mathscr{P}([0,1])$. Let l denote the line segment in $[0,1] \times[0,1]$ which goes from $(0,0)$ to $(1,1)$. Thus $l=(x, x)$ where $x \in[0,1]$. Consider the outer measure of $l$ in $\overline{m \times v}$. Let $l \subseteq \cup_{k} A_{k} \times B_{k}$ where $A_{k}$ is Lebesgue measurable and $B_{k}$ is a subset of $[0,1]$. Let $\mathscr{B} \equiv\left\{k \in \mathbb{N}: v\left(B_{k}\right)=\infty\right\}$. If $m\left(\cup_{k \in \mathscr{B}} A_{k}\right)$ has measure zero, then there are uncountably many points of $[0,1]$ outside of $\cup_{k \in \mathscr{B}} A_{k}$. For $p$ one of these points, $(p, p) \in A_{i} \times B_{i}$ and $i \notin \mathscr{B}$. Thus each of these points is in $\cup_{i \notin \mathscr{B}} B_{i}$, a countable set because these $B_{i}$ are each finite. But this is a contradiction because there need to be uncountably many of these points as just indicated. Thus $m\left(A_{k}\right)>0$ for some $k \in \mathscr{B}$ and so $\overline{m \times v}\left(A_{k} \times B_{k}\right)=\infty$. It follows $\overline{m \times v}(l)=\infty$ and so $l$ is $\overline{m \times v}$ measurable. Thus
$\int \mathscr{X}_{l}(x, y) d \overline{m \times v}=\infty$ and so you cannot apply Fubini's theorem, Theorem 12.9.11. Since $v$ is not $\sigma$ finite, you cannot apply the corollary to this theorem either. Thus there is no contradiction to the above theorems in the following observation.

$$
\iint \mathscr{X}_{l}(x, y) d v d m=\int 1 d m=1, \iint \mathscr{X}_{l}(x, y) d m d v=\int 0 d v=0 .
$$

The problem here is that you have neither $\int f d \overline{m \times v}<\infty$ not $\sigma$ finite measure spaces.
The next example is far more exotic. It concerns the case where both iterated integrals make perfect sense but are unequal. In 1877 Cantor conjectured that the cardinality of the real numbers is the next size of infinity after countable infinity. This hypothesis is called the continuum hypothesis and it has never been proved or disproved ${ }^{4}$. Assuming this continuum hypothesis will provide the basis for the following example. It is due to Sierpinski.

Example 12.13.3 Let $X$ be an uncountable set. It follows from the well ordering theorem which says every set can be well ordered which is presented in the appendix that $X$ can be well ordered. Let $\omega \in X$ be the first element of $X$ which is preceded by uncountably many points of $X$. Let $\Omega$ denote $\{x \in X: x<\omega\}$. Then $\Omega$ is uncountable but there is no smaller uncountable set. Thus by the continuum hypothesis, there exists $a$ one to one and onto mapping, $j$ which maps $[0,1]$ onto $\Omega$. Thus, for $x \in[0,1], j(x)$ is preceeded by countably many points. Let $Q \equiv\left\{(x, y) \in[0,1]^{2}: j(x)<j(y)\right\}$ and let $f(x, y)=\mathscr{X}_{Q}(x, y)$. Then

$$
\int_{0}^{1} f(x, y) d y=1, \int_{0}^{1} f(x, y) d x=0
$$

In each case, the integrals make sense. In the first, for fixed $x, f(x, y)=1$ for all but countably many y so the function of $y$ is Borel measurable. In the second where $y$ is fixed, $f(x, y)=0$ for all but countably many $x$. Thus

$$
\int_{0}^{1} \int_{0}^{1} f(x, y) d y d x=1, \int_{0}^{1} \int_{0}^{1} f(x, y) d x d y=0
$$

The problem here must be that $f$ is not $\overline{m \times m}$ measurable.

### 12.14 Exercises

1. Let $\Omega=\mathbb{N}$, the natural numbers and let $d(p, q)=|p-q|$, the usual distance in $\mathbb{R}$. Show that $(\Omega, d)$ the closures of the balls are compact. Now let $\Lambda f \equiv \sum_{k=1}^{\infty} f(k)$ whenever $f \in C_{c}(\Omega)$. Show this is a well defined positive linear functional on the space $C_{c}(\Omega)$. Describe the measure of the Riesz representation theorem which results from this positive linear functional. What if $\Lambda(f)=f(1)$ ? What measure would result from this functional? Which functions are measurable?

[^12]2. Verify that $\bar{\mu}$ defined in Lemma 12.1.9 is an outer measure.
3. Let $F: \mathbb{R} \rightarrow \mathbb{R}$ be increasing and right continuous. Let $\Lambda f \equiv \int f d F$ where the integral is the Riemann Stieltjes integral of $f$. Show the measure $\mu$ from the Riesz representation theorem satisfies
\[

$$
\begin{aligned}
\mu([a, b]) & =F(b)-F(a-), \mu((a, b])=F(b)-F(a), \\
\mu([a, a]) & =F(a)-F(a-) .
\end{aligned}
$$
\]

4. Let $\Omega$ be a metric space with the closed balls compact and suppose $\mu$ is a measure defined on the Borel sets of $\Omega$ which is finite on compact sets. Show there exists a unique Radon measure, $\bar{\mu}$ which equals $\mu$ on the Borel sets.
5. $\uparrow$ Random vectors are measurable functions $\mathbf{X}$, which map a probability space to $\mathbb{R}^{n}$. A probability space is of the form $(\Omega, P, \mathscr{F})$. Thus $\mathbf{X}(\omega) \in \mathbb{R}^{n}$ for each $\omega \in \Omega$ and $P$ is a probability measure defined on the sets of $\mathscr{F}$, a $\sigma$ algebra of subsets of $\Omega$. For $E$ a Borel set in $\mathbb{R}^{n}$, define

$$
\mu(E) \equiv P\left(\mathbf{X}^{-1}(E)\right) \equiv \text { probability that } \mathbf{X} \in E
$$

Show this is a well defined measure on the Borel sets of $\mathbb{R}^{n}$ and use Problem 4 to obtain a Radon measure, $\lambda_{\mathbf{X}}$ defined on a $\sigma$ algebra of sets of $\mathbb{R}^{n}$ including the Borel sets such that for $E$ a Borel set, $\lambda_{\mathbf{x}}(E)=$ Probability that $(\mathbf{X} \in E)$.
6. Suppose $X$ and $Y$ are metric spaces having compact closed balls. Show

$$
\left(X \times Y, d_{X \times Y}\right)
$$

is also a metric space which has the closures of balls compact. Here

$$
d_{X \times Y}\left(\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right)\right) \equiv \max \left(d\left(x_{1}, x_{2}\right), d\left(y_{1}, y_{2}\right)\right)
$$

Let

$$
\mathscr{A} \equiv\{E \times F: E \text { is a Borel set in } X, F \text { is a Borel set in } Y\} .
$$

Show $\sigma(\mathscr{A})$, the smallest $\sigma$ algebra containing $\mathscr{A}$ contains the Borel sets. Hint: Show every open set in a metric space which has closed balls compact can be obtained as a countable union of compact sets. Next show this implies every open set can be obtained as a countable union of open sets of the form $U \times V$ where $U$ is open in $X$ and $V$ is open in $Y$.
7. Suppose $(\Omega, \mathscr{S}, \mu)$ is a measure space which may not be complete. Could you obtain a complete measure space, $\left(\Omega, \overline{\mathscr{S}}, \mu_{1}\right)$ by simply letting $\overline{\mathscr{S}}$ consist of all sets of the form $E$ where there exists $F \in \mathscr{S}$ such that $(F \backslash E) \cup(E \backslash F) \subseteq N$ for some $N \in \mathscr{S}$ which has measure zero and then let $\mu(E)=\mu_{1}(F)$ ?
8. If $\mu$ and $v$ are Radon measures defined on $\mathbb{R}^{n}$ and $\mathbb{R}^{m}$ respectively, show $\overline{\mu \times v}$ is also a radon measure on $\mathbb{R}^{n+m}$. Hint: Show the $\overline{\mu \times v}$ measurable sets include the open sets using the observation that every open set in $\mathbb{R}^{n+m}$ is the countable union of sets
of the form $U \times V$ where $U$ and $V$ are open in $\mathbb{R}^{n}$ and $\mathbb{R}^{m}$ respectively. Next verify outer regularity by considering $A \times B$ for $A, B$ measurable. Argue sets of $\mathscr{R}$ defined above have the property that they can be approximated in measure from above by open sets. Then verify the same is true of sets of $\mathscr{R}_{1}$. Finally conclude using an appropriate lemma that $\overline{\mu \times v}$ is inner regular as well.
9. Let $(\Omega, \mathscr{S}, \mu)$ be a $\sigma$ finite measure space and let $f: \Omega \rightarrow[0, \infty)$ be measurable. Define

$$
A \equiv\{(x, y): y<f(x)\}
$$

Verify that $A$ is $\overline{\mu \times m}$ measurable. Show that

$$
\int f d \mu=\iint \mathscr{X}_{A}(x, y) d \mu d m=\int \mathscr{X}_{A} d \overline{\mu \times m}
$$

## Chapter 13

## Lebesgue Measure

### 13.1 Basic Properties

Definition 13.1.1 Define the following positive linear functional for $f \in C_{c}\left(\mathbb{R}^{n}\right)$.

$$
\Lambda f \equiv \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} f(\mathbf{x}) d x_{1} \cdots d x_{n}
$$

Then the measure representing this functional is Lebesgue measure.
The following lemma will help in understanding Lebesgue measure.
Lemma 13.1.2 Every open set in $\mathbb{R}^{n}$ is the countable disjoint union of half open boxes of the form

$$
\prod_{i=1}^{n}\left(a_{i}, a_{i}+2^{-k}\right]
$$

where $a_{i}=l 2^{-k}$ for some integers, $l, k$. The sides of these boxes are of equal length. One could also have half open boxes of the form

$$
\prod_{i=1}^{n}\left[a_{i}, a_{i}+2^{-k}\right)
$$

and the conclusion would be unchanged.
Proof: Let

$$
\begin{gathered}
\mathscr{C}_{k}=\left\{\text { All half open boxes } \prod_{i=1}^{n}\left(a_{i}, a_{i}+2^{-k}\right]\right. \text { where } \\
\left.a_{i}=l 2^{-k} \text { for some integer } l .\right\}
\end{gathered}
$$

Thus $\mathscr{C}_{k}$ consists of a countable disjoint collection of boxes whose union is $\mathbb{R}^{n}$. This is sometimes called a tiling of $\mathbb{R}^{n}$. Think of tiles on the floor of a bathroom and you will get the idea. Note that each box has diameter no larger than $2^{-k} \sqrt{n}$. This is because if

$$
\mathbf{x}, \mathbf{y} \in \prod_{i=1}^{n}\left(a_{i}, a_{i}+2^{-k}\right]
$$

then $\left|x_{i}-y_{i}\right| \leq 2^{-k}$. Therefore,

$$
|\mathbf{x}-\mathbf{y}| \leq\left(\sum_{i=1}^{n}\left(2^{-k}\right)^{2}\right)^{1 / 2}=2^{-k} \sqrt{n}
$$

Let $U$ be open and let $\mathscr{B}_{1} \equiv$ all sets of $\mathscr{C}_{1}$ which are contained in $U$. If $\mathscr{B}_{1}, \cdots, \mathscr{B}_{k}$ have been chosen, $\mathscr{B}_{k+1} \equiv$ all sets of $\mathscr{C}_{k+1}$ contained in

$$
U \backslash \cup\left(\cup_{i=1}^{k} \mathscr{B}_{i}\right)
$$

Let $\mathscr{B}_{\infty}=\cup_{i=1}^{\infty} \mathscr{B}_{i}$. In fact $\cup \mathscr{B}_{\infty}=U$. Clearly $\cup \mathscr{B}_{\infty} \subseteq U$ because every box of every $\mathscr{B}_{i}$ is contained in $U$. If $p \in U$, let $k$ be the smallest integer such that $p$ is contained in a box from $\mathscr{C}_{k}$ which is also a subset of $U$. Thus

$$
p \in \cup \mathscr{B}_{k} \subseteq \cup \mathscr{B}_{\infty} .
$$

Hence $\mathscr{B}_{\infty}$ is the desired countable disjoint collection of half open boxes whose union is $U$. The last assertion about the other type of half open rectangle is obvious. This proves the lemma.

Now what does Lebesgue measure do to a rectangle, $\prod_{i=1}^{n}\left(a_{i}, b_{i}\right]$ ?
Lemma 13.1.3 Let $R=\prod_{i=1}^{n}\left[a_{i}, b_{i}\right], R_{0}=\prod_{i=1}^{n}\left(a_{i}, b_{i}\right)$. Then

$$
m_{n}\left(R_{0}\right)=m_{n}(R)=\prod_{i=1}^{n}\left(b_{i}-a_{i}\right)
$$

Proof: Let $k$ be large enough that

$$
a_{i}+1 / k<b_{i}-1 / k
$$

for $i=1, \cdots, n$ and consider functions $g_{i}^{k}$ and $f_{i}^{k}$ having the following graphs.

Let

$$
g^{k}(\mathbf{x})=\prod_{i=1}^{n} g_{i}^{k}\left(x_{i}\right), f^{k}(\mathbf{x})=\prod_{i=1}^{n} f_{i}^{k}\left(x_{i}\right)
$$

Then by elementary calculus along with the definition of $\Lambda$,

$$
\begin{gathered}
\prod_{i=1}^{n}\left(b_{i}-a_{i}+2 / k\right) \geq \Lambda g^{k}=\int g^{k} d m_{n} \geq m_{n}(R) \geq m_{n}\left(R_{0}\right) \\
\geq \int f^{k} d m_{n}=\Lambda f^{k} \geq \prod_{i=1}^{n}\left(b_{i}-a_{i}-2 / k\right)
\end{gathered}
$$

Letting $k \rightarrow \infty$, it follows that

$$
m_{n}(R)=m_{n}\left(R_{0}\right)=\prod_{i=1}^{n}\left(b_{i}-a_{i}\right)
$$

This proves the lemma.

Lemma 13.1.4 Let $U$ be an open or closed set. Then $m_{n}(U)=m_{n}(\mathbf{x}+U)$.
Proof: By Lemma 13.1.2 there is a sequence of disjoint half open rectangles, $\left\{R_{i}\right\}$ such that $\cup_{i} R_{i}=U$. Therefore, $\mathbf{x}+U=\cup_{i}\left(\mathbf{x}+R_{i}\right)$ and the $\mathbf{x}+R_{i}$ are also disjoint rectangles which are identical to the $R_{i}$ but translated. From Lemma 13.1.3, $m_{n}(U)=\sum_{i} m_{n}\left(R_{i}\right)=$ $\sum_{i} m_{n}\left(\mathbf{x}+R_{i}\right)=m_{n}(\mathbf{x}+U)$.

It remains to verify the lemma for a closed set. Let $H$ be a closed bounded set first. Then $H \subseteq B(\mathbf{0}, R)$ for some $R$ large enough. First note that $\mathbf{x}+H$ is a closed set. Thus

$$
\begin{aligned}
m_{n}(B(\mathbf{x}, R)) & =m_{n}(\mathbf{x}+H)+m_{n}((B(\mathbf{0}, R)+\mathbf{x}) \backslash(\mathbf{x}+H)) \\
& =m_{n}(\mathbf{x}+H)+m_{n}((B(\mathbf{0}, R) \backslash H)+\mathbf{x}) \\
& =m_{n}(\mathbf{x}+H)+m_{n}((B(\mathbf{0}, R) \backslash H)) \\
& =m_{n}(B(\mathbf{0}, R))-m_{n}(H)+m_{n}(\mathbf{x}+H) \\
& =m_{n}(B(\mathbf{x}, R))-m_{n}(H)+m_{n}(\mathbf{x}+H)
\end{aligned}
$$

the last equality because of the first part of the lemma which implies $m_{n}(B(\mathbf{x}, R))=$ $m_{n}(B(\mathbf{0}, R))$. Therefore, $m_{n}(\mathbf{x}+H)=m_{n}(H)$ as claimed. If $H$ is not bounded, consider $H_{m} \equiv \overline{B(\mathbf{0}, m)} \cap H$. Then $m_{n}\left(\mathbf{x}+H_{m}\right)=m_{n}\left(H_{m}\right)$. Passing to the limit as $m \rightarrow \infty$ yields the result in general.

Theorem 13.1.5 Lebesgue measure is translation invariant. That is

$$
m_{n}(E)=m_{n}(\mathbf{x}+E)
$$

for all E Lebesgue measurable.
Proof: Suppose $m_{n}(E)<\infty$. By regularity of the measure, there exist sets $G, H$ such that $G$ is a countable intersection of open sets, $H$ is a countable union of compact sets, $m_{n}(G \backslash H)=0$, and $G \supseteq E \supseteq H$. Now $m_{n}(G)=m_{n}(G+\mathbf{x})$ and $m_{n}(H)=m_{n}(H+\mathbf{x})$ which follows from Lemma 13.1.4 applied to the sets which are either intersected to form $G$ or unioned to form $H$. Now

$$
\mathbf{x}+H \subseteq \mathbf{x}+E \subseteq \mathbf{x}+G
$$

and both $\mathbf{x}+H$ and $\mathbf{x}+G$ are measurable because they are either countable unions or countable intersections of measurable sets. Furthermore,

$$
m_{n}(\mathbf{x}+G \backslash \mathbf{x}+H)=m_{n}(\mathbf{x}+G)-m_{n}(\mathbf{x}+H)=m_{n}(G)-m_{n}(H)=0
$$

and so by completeness of the measure, $\mathbf{x}+E$ is measurable. It follows

$$
\begin{aligned}
m_{n}(E) & =m_{n}(H)=m_{n}(\mathbf{x}+H) \leq m_{n}(\mathbf{x}+E) \\
& \leq m_{n}(\mathbf{x}+G)=m_{n}(G)=m_{n}(E)
\end{aligned}
$$

If $m_{n}(E)$ is not necessarily less than $\infty$, consider $E_{m} \equiv B(\mathbf{0}, m) \cap E$. Then $m_{n}\left(E_{m}\right)=$ $m_{n}\left(E_{m}+\mathbf{x}\right)$ by the above. Letting $m \rightarrow \infty$ it follows $m_{n}(E)=m_{n}(E+\mathbf{x})$. This proves the theorem.

Corollary 13.1.6 Let $D$ be an $n \times n$ diagonal matrix and let $U$ be an open set. Then

$$
m_{n}(D U)=|\operatorname{det}(D)| m_{n}(U)
$$

Proof: If any of the diagonal entries of $D$ equals 0 there is nothing to prove because then both sides equal zero. Therefore, it can be assumed none are equal to zero. Suppose these diagonal entries are $k_{1}, \cdots, k_{n}$. From Lemma 13.1.2 there exist half open boxes, $\left\{R_{i}\right\}$ having all sides equal such that $U=\cup_{i} R_{i}$. Suppose one of these is $R_{i}=\prod_{j=1}^{n}\left(a_{j}, b_{j}\right]$, where $b_{j}-a_{j}=l_{i}$. Then $D R_{i}=\prod_{j=1}^{n} I_{j}$ where $I_{j}=\left(k_{j} a_{j}, k_{j} b_{j}\right]$ if $k_{j}>0$ and $I_{j}=\left[k_{j} b_{j}, k_{j} a_{j}\right)$ if $k_{j}<0$. Then the rectangles, $D R_{i}$ are disjoint because $D$ is one to one and their union is $D U$. Also,

$$
m_{n}\left(D R_{i}\right)=\prod_{j=1}^{n}\left|k_{j}\right| l_{i}=|\operatorname{det} D| m_{n}\left(R_{i}\right)
$$

Therefore,

$$
m_{n}(D U)=\sum_{i=1}^{\infty} m_{n}\left(D R_{i}\right)=|\operatorname{det}(D)| \sum_{i=1}^{\infty} m_{n}\left(R_{i}\right)=|\operatorname{det}(D)| m_{n}(U)
$$

and this proves the corollary.
From this the following corollary is obtained.
Corollary 13.1.7 Let $M>0$. Then $m_{n}(B(\mathbf{a}, M r))=M^{n} m_{n}(B(\mathbf{0}, r))$.
Proof: By Lemma 13.1.4 there is no loss of generality in taking $\mathbf{a}=\mathbf{0}$. Let $D$ be the diagonal matrix which has $M$ in every entry of the main diagonal so $|\operatorname{det}(D)|=M^{n}$. Note that $D B(\mathbf{0}, r)=B(\mathbf{0}, M r)$. By Corollary 13.1.6 $m_{n}(B(\mathbf{0}, M r))=m_{n}(D B(\mathbf{0}, r))=$ $M^{n} m_{n}(B(\mathbf{0}, r))$.

There are many norms on $\mathbb{R}^{n}$. Other common examples are

$$
\|\mathbf{x}\|_{\infty} \equiv \max \left\{\left|x_{k}\right|: \mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)\right\}
$$

or

$$
\|\mathbf{x}\|_{p} \equiv\left(\sum_{i=1}^{n}\left|x_{i}\right|^{p}\right)^{1 / p}
$$

With $\|\cdot\|$ any norm for $\mathbb{R}^{n}$ you can define a corresponding ball in terms of this norm.

$$
B(\mathbf{a}, r) \equiv\left\{\mathbf{x} \in \mathbb{R}^{n} \text { such that }\|\mathbf{x}-\mathbf{a}\|<r\right\}
$$

It follows from general considerations involving metric spaces presented earlier that these balls are open sets. Therefore, Corollary 13.1.7 has an obvious generalization.

Corollary 13.1.8 Let $\|\cdot\|$ be a norm on $\mathbb{R}^{n}$. Then for $M>0$,

$$
m_{n}(B(\mathbf{a}, M r))=M^{n} m_{n}(B(\mathbf{0}, r))
$$

where these balls are defined in terms of the norm $\|\cdot\|$.

### 13.2 The Vitali Covering Theorem

The Vitali covering theorem is concerned with the situation in which a set is contained in the union of balls. You can imagine that it might be very hard to get disjoint balls from this collection of balls which would cover the given set. However, it is possible to get disjoint balls from this collection of balls which have the property that if each ball is enlarged appropriately, the resulting enlarged balls do cover the set. When this result is established, it is used to prove another form of this theorem in which the disjoint balls do not cover the set but they only miss a set of measure zero.

Recall the Hausdorff maximal principle, Theorem 2.4.2 on Page 36 which is proved to be equivalent to the axiom of choice in the appendix. For convenience, here it is:

Theorem 13.2.1 (Hausdorff Maximal Principle) Let $\mathscr{F}$ be a nonempty partially ordered set. Then there exists a maximal chain.

I will use this Hausdorff maximal principle to give a very short and elegant proof of the Vitali covering theorem. This follows the treatment in Evans and Gariepy [47] which they got from another book. I am not sure who first did it this way but it is very nice because it is so short. In the following lemma and theorem, the balls will be either open or closed and determined by some norm on $\mathbb{R}^{n}$. When pictures are drawn, I shall draw them as though the norm is the usual norm but the results are unchanged for any norm. Also, I will write (in this section only) $B(\mathbf{a}, r)$ to indicate a set which satisfies

$$
\left\{\mathbf{x} \in \mathbb{R}^{n}:\|\mathbf{x}-\mathbf{a}\|<r\right\} \subseteq B(\mathbf{a}, r) \subseteq\left\{\mathbf{x} \in \mathbb{R}^{n}:\|\mathbf{x}-\mathbf{a}\| \leq r\right\}
$$

and $\widehat{B}(\mathbf{a}, r)$ to indicate the usual ball but with radius 5 times as large,

$$
\left\{\mathbf{x} \in \mathbb{R}^{n}:\|\mathbf{x}-\mathbf{a}\|<5 r\right\}
$$

Lemma 13.2.2 Let $\|\cdot\|$ be a norm on $\mathbb{R}^{n}$ and let $\mathscr{F}$ be a collection of balls determined by this norm. Suppose

$$
\infty>M \equiv \sup \{r: B(\mathbf{p}, r) \in \mathscr{F}\}>0
$$

and $k \in(0, \infty)$. Then there exists $\mathscr{G} \subseteq \mathscr{F}$ such that

$$
\begin{gather*}
\text { if } B(\mathbf{p}, r) \in \mathscr{G} \text { then } r>k,  \tag{13.2.1}\\
\text { if } B_{1}, B_{2} \in \mathscr{G} \text { then } B_{1} \cap B_{2}=\emptyset \tag{13.2.2}
\end{gather*}
$$

$\mathscr{G}$ is maximal with respect to 13.2.1 and 13.2.2.
Note that if there is no ball of $\mathscr{F}$ which has radius larger than $k$ then $\mathscr{G}=\emptyset$.
Proof: Let $\mathscr{H}=\{\mathscr{B} \subseteq \mathscr{F}$ such that 13.2.1 and 13.2.2 hold $\}$. If there are no balls with radius larger than $k$ then $\overline{\mathscr{H}}=\emptyset$ and you let $\mathscr{G}=\emptyset$. In the other case, $\mathscr{H} \neq \emptyset$ because there exists $B(\mathbf{p}, r) \in \mathscr{F}$ with $r>k$. In this case, partially order $\mathscr{H}$ by set inclusion and use the Hausdorff maximal principle (see the appendix on set theory) to let $\mathscr{C}$ be a maximal chain in $\mathscr{H}$. Clearly $\cup \mathscr{C}$ satisfies 13.2 .1 and 13.2.2 because if $B_{1}$ and $B_{2}$ are two balls from $\cup \mathscr{C}$ then since $\mathscr{C}$ is a chain, it follows there is some element of $\mathscr{C}, \mathscr{B}$ such that both $B_{1}$ and $B_{2}$
are elements of $\mathscr{B}$ and $\mathscr{B}$ satisfies 13.2.1 and 13.2.2. If $\cup \mathscr{C}$ is not maximal with respect to these two properties, then $\mathscr{C}$ was not a maximal chain because then there would exist $\mathscr{B} \supsetneq \cup \mathscr{C}$, that is, $\mathscr{B}$ contains $\mathscr{C}$ as a proper subset and $\{\mathscr{C}, \mathscr{B}\}$ would be a strictly larger chain in $\mathscr{H}$. Let $\mathscr{G}=\cup \mathscr{C}$.

Theorem 13.2.3 (Vitali) Let $\mathscr{F}$ be a collection of balls and let

$$
A \equiv \cup\{B: B \in \mathscr{F}\}
$$

Suppose

$$
\infty>M \equiv \sup \{r: B(\mathbf{p}, r) \in \mathscr{F}\}>0
$$

Then there exists $\mathscr{G} \subseteq \mathscr{F}$ such that $\mathscr{G}$ consists of disjoint balls and

$$
A \subseteq \cup\{\widehat{B}: B \in \mathscr{G}\}
$$

Proof: Using Lemma 13.2.2, there exists $\mathscr{G}_{1} \subseteq \mathscr{F} \equiv \mathscr{F}_{0}$ which satisfies

$$
\begin{gather*}
B(\mathbf{p}, r) \in \mathscr{G}_{1} \text { implies } r>\frac{M}{2}  \tag{13.2.3}\\
B_{1}, B_{2} \in \mathscr{G}_{1} \text { implies } B_{1} \cap B_{2}=\emptyset \tag{13.2.4}
\end{gather*}
$$

$\mathscr{G}_{1}$ is maximal with respect to 13.2.3, and 13.2.4.
Suppose $\mathscr{G}_{1}, \cdots, \mathscr{G}_{m}$ have been chosen, $m \geq 1$. Let

$$
\mathscr{F}_{m} \equiv\left\{B \in \mathscr{F}: B \subseteq \mathbb{R}^{n} \backslash \cup\left\{\mathscr{G}_{1} \cup \cdots \cup \mathscr{G}_{m}\right\}\right\}
$$

Using Lemma 13.2.2, there exists $\mathscr{G}_{m+1} \subseteq \mathscr{F}_{m}$ such that

$$
\begin{gather*}
B(\mathbf{p}, r) \in \mathscr{G}_{m+1} \text { implies } r>\frac{M}{2^{m+1}}  \tag{13.2.5}\\
B_{1}, B_{2} \in \mathscr{G}_{m+1} \text { implies } B_{1} \cap B_{2}=\emptyset \tag{13.2.6}
\end{gather*}
$$

$$
\mathscr{G}_{m+1} \text { is a maximal subset of } \mathscr{F}_{m} \text { with respect to 13.2.5 and 13.2.6. }
$$

Note it might be the case that $\mathscr{G}_{m+1}=\emptyset$ which happens if $\mathscr{F}_{m}=\emptyset$. Define

$$
\mathscr{G} \equiv \cup_{k=1}^{\infty} \mathscr{G}_{k}
$$

Thus $\mathscr{G}$ is a collection of disjoint balls in $\mathscr{F}$. I must show $\{\widehat{B}: B \in \mathscr{G}\}$ covers $A$.
Let $\mathbf{x} \in B(\mathbf{p}, r) \in \mathscr{F}$ and let

$$
\frac{M}{2^{m}}<r \leq \frac{M}{2^{m-1}}
$$

Then $B(\mathbf{p}, r)$ must intersect some set, $B\left(\mathbf{p}_{0}, r_{0}\right) \in \mathscr{G}_{1} \cup \cdots \cup \mathscr{G}_{m}$ since otherwise, $\mathscr{G}_{m}$ would fail to be maximal. Then $r_{0}>\frac{M}{2^{m}}$ because all balls in $\mathscr{G}_{1} \cup \cdots \cup \mathscr{G}_{m}$ satisfy this inequality.

Then for $\mathbf{x} \in B(\mathbf{p}, r)$, the following chain of inequalities holds because $r \leq \frac{M}{2^{m-1}}$ and $r_{0}>\frac{M}{2^{m}}$

$$
\begin{aligned}
\left|\mathbf{x}-\mathbf{p}_{0}\right| & \leq|\mathbf{x}-\mathbf{p}|+\left|\mathbf{p}-\mathbf{p}_{0}\right| \leq r+r_{0}+r \\
& \leq \frac{2 M}{2^{m-1}}+r_{0}=\frac{4 M}{2^{m}}+r_{0}<5 r_{0}
\end{aligned}
$$

Thus $B(\mathbf{p}, r) \subseteq \widehat{B}\left(\mathbf{p}_{0}, r_{0}\right)$ and this proves the theorem.

### 13.3 The Vitali Covering Theorem (Elementary Version)

The proof given here is from Basic Analysis [83]. It first considers the case of open balls and then generalizes to balls which may be neither open nor closed or closed.

Lemma 13.3.1 Let $\mathscr{F}$ be a countable collection of balls satisfying

$$
\infty>M \equiv \sup \{r: B(\mathbf{p}, r) \in \mathscr{F}\}>0
$$

and let $k \in(0, \infty)$. Then there exists $\mathscr{G} \subseteq \mathscr{F}$ such that

$$
\begin{gather*}
\text { If } B(\mathbf{p}, r) \in \mathscr{G} \text { then } r>k,  \tag{13.3.7}\\
\text { If } B_{1}, B_{2} \in \mathscr{G} \text { then } B_{1} \cap B_{2}=\emptyset, \tag{13.3.8}
\end{gather*}
$$

$$
\begin{equation*}
\mathscr{G} \text { is maximal with respect to } 13.3 .7 \text { and 13.3.8. } \tag{13.3.9}
\end{equation*}
$$

Proof: If no ball of $\mathscr{F}$ has radius larger than $k$, let $\mathscr{G}=\emptyset$. Assume therefore, that some balls have radius larger than $k$. Let $\mathscr{F} \equiv\left\{B_{i}\right\}_{i=1}^{\infty}$. Now let $B_{n_{1}}$ be the first ball in the list which has radius greater than $k$. If every ball having radius larger than $k$ intersects this one, then stop. The maximal set is just $B_{n_{1}}$. Otherwise, let $B_{n_{2}}$ be the next ball having radius larger than $k$ which is disjoint from $B_{n_{1}}$. Continue this way obtaining $\left\{B_{n_{i}}\right\}_{i=1}^{\infty}$, a finite or infinite sequence of disjoint balls having radius larger than $k$. Then let $\mathscr{G} \equiv\left\{B_{n_{i}}\right\}$. To see that $\mathscr{G}$ is maximal with respect to 13.3 .7 and 13.3.8, suppose $B \in \mathscr{F}, B$ has radius larger than $k$, and $\mathscr{G} \cup\{B\}$ satisfies 13.3.7 and 13.3.8. Then at some point in the process, $B$ would have been chosen because it would be the ball of radius larger than $k$ which has the smallest index. Therefore, $B \in \mathscr{G}$ and this shows $\mathscr{G}$ is maximal with respect to 13.3.7 and 13.3.8.

For the next lemma, for an open ball, $B=B(\mathbf{x}, r)$, denote by $\widetilde{B}$ the open ball, $B(\mathbf{x}, 4 r)$.

Lemma 13.3.2 Let $\mathscr{F}$ be a collection of open balls, and let

$$
A \equiv \cup\{B: B \in \mathscr{F}\}
$$

Suppose

$$
\infty>M \equiv \sup \{r: B(\mathbf{p}, r) \in \mathscr{F}\}>0
$$

Then there exists $\mathscr{G} \subseteq \mathscr{F}$ such that $\mathscr{G}$ consists of disjoint balls and

$$
A \subseteq \cup\{\widetilde{B}: B \in \mathscr{G}\}
$$

Proof: Without loss of generality assume $\mathscr{F}$ is countable. This is because there is a countable subset of $\mathscr{F}, \mathscr{F}^{\prime}$ such that $\cup \mathscr{F}^{\prime}=A$. To see this, consider the set of balls having rational radii and centers having all components rational. This is a countable set of balls and you should verify that every open set is the union of balls of this form. Therefore, you can consider the subset of this set of balls consisting of those which are contained in some open set of $\mathscr{F}, G$ so $\cup G=A$ and use the axiom of choice to define a subset of $\mathscr{F}$ consisting of a single set from $\mathscr{F}$ containing each set of $G$. Then this is $\mathscr{F}^{\prime}$. The union of these sets equals $A$. Then consider $\mathscr{F}^{\prime}$ instead of $\mathscr{F}$. Therefore, assume at the outset $\mathscr{F}$ is countable. By Lemma 13.3.1, there exists $\mathscr{G}_{1} \subseteq \mathscr{F}$ which satisfies 13.3.7, 13.3.8, and 13.3.9 with $k=\frac{2 M}{3}$.

Suppose $\mathscr{G}_{1}, \cdots, \mathscr{G}_{m-1}$ have been chosen for $m \geq 2$. Let

$$
\mathscr{F}_{m}=\{B \in \mathscr{F}: B \subseteq \mathbb{R}^{n} \backslash \overbrace{\cup\left\{\mathscr{G}_{1} \cup \cdots \cup \mathscr{G}_{m-1}\right\}}^{\text {union of the balls in these } \mathscr{G}_{j}}\}
$$

and using Lemma 13.3.1, let $\mathscr{G}_{m}$ be a maximal collection of disjoint balls from $\mathscr{F}_{m}$ with the property that each ball has radius larger than $\left(\frac{2}{3}\right)^{m} M$. Let $\mathscr{G} \equiv \cup_{k=1}^{\infty} \mathscr{G}_{k}$. Let $\mathbf{x} \in B(\mathbf{p}, r) \in$ $\mathscr{F}$. Choose $m$ such that

$$
\left(\frac{2}{3}\right)^{m} M<r \leq\left(\frac{2}{3}\right)^{m-1} M
$$

Then $B(\mathbf{p}, r)$ must have nonempty intersection with some ball from $\mathscr{G}_{1} \cup \cdots \cup \mathscr{G}_{m}$ because if it didn't, then $\mathscr{G}_{m}$ would fail to be maximal. Denote by $B\left(\mathbf{p}_{0}, r_{0}\right)$ a ball in $\mathscr{G}_{1} \cup \cdots \cup \mathscr{G}_{m}$ which has nonempty intersection with $B(\mathbf{p}, r)$. Thus

$$
r_{0}>\left(\frac{2}{3}\right)^{m} M
$$

Consider the picture, in which $\mathbf{w} \in B\left(\mathbf{p}_{0}, r_{0}\right) \cap B(\mathbf{p}, r)$.

Then

$$
\begin{aligned}
\left|\mathbf{x}-\mathbf{p}_{0}\right| & \leq|\mathbf{x}-\mathbf{p}|+|\mathbf{p}-\mathbf{w}|+\overbrace{\left|\mathbf{w}-\mathbf{p}_{0}\right|}^{<r_{0}} \\
& <r+r+r_{0} \leq 2 \overbrace{\left(\frac{2}{3}\right)^{m-1}}^{<\frac{3}{2} r_{0}} M+r_{0} \\
& <2\left(\frac{3}{2}\right) r_{0}+r_{0}=4 r_{0} .
\end{aligned}
$$

This proves the lemma since it shows $B(\mathbf{p}, r) \subseteq B\left(\mathbf{p}_{0}, 4 r_{0}\right)$.
With this Lemma consider a version of the Vitali covering theorem in which the balls do not have to be open. A ball centered at $\mathbf{x}$ of radius $r$ will denote something which contains the open ball, $B(\mathbf{x}, r)$ and is contained in the closed ball, $\overline{B(\mathbf{x}, r)}$. Thus the balls could be open or they could contain some but not all of their boundary points.

Definition 13.3.3 Let $B$ be a ball centered at $\mathbf{x}$ having radius $r$. Denote by $\widehat{B}$ the open ball, $B(\mathbf{x}, 5 r)$.

Theorem 13.3.4 (Vitali) Let $\mathscr{F}$ be a collection of balls, and let

$$
A \equiv \cup\{B: B \in \mathscr{F}\}
$$

Suppose

$$
\infty>M \equiv \sup \{r: B(\mathbf{p}, r) \in \mathscr{F}\}>0
$$

Then there exists $\mathscr{G} \subseteq \mathscr{F}$ such that $\mathscr{G}$ consists of disjoint balls and

$$
A \subseteq \cup\{\widehat{B}: B \in \mathscr{G}\}
$$

Proof: For $B$ one of these balls, say $\overline{B(\mathbf{x}, r)} \supseteq B \supseteq B(\mathbf{x}, r)$, denote by $B_{1}$, the ball $B\left(\mathbf{x}, \frac{5 r}{4}\right)$. Let $\mathscr{F}_{1} \equiv\left\{B_{1}: B \in \mathscr{F}\right\}$ and let $A_{1}$ denote the union of the balls in $\mathscr{F}_{1}$. Apply Lemma 13.3.2 to $\mathscr{F}_{1}$ to obtain

$$
A_{1} \subseteq \cup\left\{\widetilde{B_{1}}: B_{1} \in \mathscr{G}_{1}\right\}
$$

where $\mathscr{G}_{1}$ consists of disjoint balls from $\mathscr{F}_{1}$. Now let $\mathscr{G} \equiv\left\{B \in \mathscr{F}: B_{1} \in \mathscr{G}_{1}\right\}$. Thus $\mathscr{G}$ consists of disjoint balls from $\mathscr{F}$ because they are contained in the disjoint open balls, $\mathscr{G}_{1}$. Then

$$
A \subseteq A_{1} \subseteq \cup\left\{\widetilde{B_{1}}: B_{1} \in \mathscr{G}_{1}\right\}=\cup\{\widehat{B}: B \in \mathscr{G}\}
$$

because for $B_{1}=B\left(\mathbf{x}, \frac{5 r}{4}\right)$, it follows $\widetilde{B_{1}}=B(\mathbf{x}, 5 r)=\widehat{B}$. This proves the theorem.

### 13.4 Vitali Coverings

There is another version of the Vitali covering theorem which is also of great importance. In this one, balls from the original set of balls almost cover the set,leaving out only a set of measure zero. It is like packing a truck with stuff. You keep trying to fill in the holes with smaller and smaller things so as to not waste space. It is remarkable that you can avoid wasting any space at all when you are dealing with balls of any sort provided you can use arbitrarily small balls.

Definition 13.4.1 Let $\mathscr{F}$ be a collection of balls that cover a set $E$, which have the property that if $\mathbf{x} \in E$ and $\varepsilon>0$, then there exists $B \in \mathscr{F}$, diameter of $B<\varepsilon$ and $\mathbf{x} \in B$. Such a collection covers $E$ in the sense of Vitali.

In the following covering theorem, $\overline{m_{n}}$ denotes the outer measure determined by $n$ dimensional Lebesgue measure.

Theorem 13.4.2 Let $E \subseteq \mathbb{R}^{n}$ and suppose $0<\overline{m_{n}}(E)<\infty$ where $\overline{m_{n}}$ is the outer measure determined by $m_{n}, n$ dimensional Lebesgue measure, and let $\mathscr{F}$ be a collection of closed balls of bounded radii such that $\mathscr{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.

Proof: From the definition of outer measure there exists a Lebesgue measurable set, $E_{1} \supseteq E$ such that $m_{n}\left(E_{1}\right)=\overline{m_{n}}(E)$. Now by outer regularity of Lebesgue measure, there exists $U$, an open set which satisfies

$$
m_{n}\left(E_{1}\right)>\left(1-10^{-n}\right) m_{n}(U), U \supseteq E_{1}
$$

Each point of $E$ is contained in balls of $\mathscr{F}$ of arbitrarily small radii and so there exists a covering of $E$ with balls of $\mathscr{F}$ which are themselves contained in $U$. Therefore, by the Vitali covering theorem, there exist disjoint balls, $\left\{B_{i}\right\}_{i=1}^{\infty} \subseteq \mathscr{F}$ such that

$$
E \subseteq \cup_{j=1}^{\infty} \widehat{B}_{j}, B_{j} \subseteq U
$$

Therefore,

$$
\begin{aligned}
m_{n}\left(E_{1}\right) & =\overline{m_{n}}(E) \leq m_{n}\left(\cup_{j=1}^{\infty} \widehat{B}_{j}\right) \leq \sum_{j} m_{n}\left(\widehat{B}_{j}\right) \\
& =5^{n} \sum_{j} m_{n}\left(B_{j}\right)=5^{n} m_{n}\left(\cup_{j=1}^{\infty} B_{j}\right)
\end{aligned}
$$

Then $E_{1}$ and $\cup_{j=1}^{\infty} B_{j}$ are contained in $U$ and so

$$
\begin{gathered}
m_{n}\left(E_{1}\right)>\left(1-10^{-n}\right) m_{n}(U) \\
\geq\left(1-10^{-n}\right)\left[m_{n}\left(E_{1} \backslash \cup_{j=1}^{\infty} B_{j}\right)+m_{n}\left(\cup_{j=1}^{\infty} B_{j}\right)\right] \\
\geq\left(1-10^{-n}\right)[m_{n}\left(E_{1} \backslash \cup_{j=1}^{\infty} B_{j}\right)+5^{-n} \overbrace{\overline{m_{n}}(E)}^{=m_{n}\left(E_{1}\right)}] .
\end{gathered}
$$

and so

$$
\left(1-\left(1-10^{-n}\right) 5^{-n}\right) m_{n}\left(E_{1}\right) \geq\left(1-10^{-n}\right) m_{n}\left(E_{1} \backslash \cup_{j=1}^{\infty} B_{j}\right)
$$

which implies

$$
m_{n}\left(E_{1} \backslash \cup_{j=1}^{\infty} B_{j}\right) \leq \frac{\left(1-\left(1-10^{-n}\right) 5^{-n}\right)}{\left(1-10^{-n}\right)} m_{n}\left(E_{1}\right)
$$

Now a short computation shows

$$
0<\frac{\left(1-\left(1-10^{-n}\right) 5^{-n}\right)}{\left(1-10^{-n}\right)}<1
$$

Hence, denoting by $\theta_{n}$ a number such that

$$
\begin{gathered}
\frac{\left(1-\left(1-10^{-n}\right) 5^{-n}\right)}{\left(1-10^{-n}\right)}<\theta_{n}<1, \\
\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right) \leq m_{n}\left(E_{1} \backslash \cup_{j=1}^{\infty} B_{j}\right)<\theta_{n} m_{n}\left(E_{1}\right)=\theta_{n} \overline{m_{n}}(E)
\end{gathered}
$$

Now using Theorem 11.1.5 on Page 224 there exists $N_{1}$ large enough that

$$
\begin{equation*}
\theta_{n} \overline{m_{n}}(E) \geq m_{n}\left(E_{1} \backslash \cup_{j=1}^{N_{1}} B_{j}\right) \geq \overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{1}} B_{j}\right) \tag{13.4.10}
\end{equation*}
$$

Let $\mathscr{F}_{1}=\left\{B \in \mathscr{F}: B_{j} \cap B=\emptyset, j=1, \cdots, N_{1}\right\}$. If $E \backslash \cup_{j=1}^{N_{1}} B_{j}=\emptyset$, then $\mathscr{F}_{1}=\emptyset$ and

$$
\overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{1}} B_{j}\right)=0
$$

Therefore, in this case let $B_{k}=\emptyset$ for all $k>N_{1}$. Consider the case where

$$
E \backslash \cup_{j=1}^{N_{1}} B_{j} \neq \emptyset
$$

In this case, since the balls are closed and $\mathscr{F}$ is a Vitali cover, $\mathscr{F} 1 \neq \emptyset$ and covers $E \backslash \cup_{j=1}^{N_{1}} B_{j}$ in the sense of Vitali. Repeat the same argument, letting $E \backslash \cup_{j=1}^{N_{1}} B_{j}$ play the role of $E$. (You pick a different $E_{1}$ whose measure equals the outer measure of $E \backslash \cup_{j=1}^{N_{1}} B_{j}$ and proceed as before.) Then choosing $B_{j}$ for $j=N_{1}+1, \cdots, N_{2}$ as in the above argument,

$$
\theta_{n} \overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{1}} B_{j}\right) \geq \overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{2}} B_{j}\right)
$$

and so from 13.4.10,

$$
\theta_{n}^{2} \overline{m_{n}}(E) \geq \overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{2}} B_{j}\right)
$$

Continuing this way

$$
\theta_{n}^{k} \overline{m_{n}}(E) \geq \overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{k}} B_{j}\right)
$$

If it is ever the case that $E \backslash \cup_{j=1}^{N_{k}} B_{j}=\emptyset$, then as in the above argument,

$$
\overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{k}} B_{j}\right)=0
$$

Otherwise, the process continues and

$$
\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right) \leq \overline{m_{n}}\left(E \backslash \cup_{j=1}^{N_{k}} B_{j}\right) \leq \theta_{n}^{k} \overline{m_{n}}(E)
$$

for every $k \in \mathbb{N}$. Therefore, the conclusion holds in this case also.
There is an obvious corollary which removes the assumption that $0<\overline{m_{n}}(E)$.
Corollary 13.4.3 Let $E \subseteq \mathbb{R}^{n}$ and suppose $\overline{m_{n}}(E)<\infty$ where $\overline{m_{n}}$ is the outer measure determined by $m_{n}$, $n$ dimensional Lebesgue measure, and let $\mathscr{F}$, be a collection of closed balls of bounded radii such that $\mathscr{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.

Proof: If $0=\overline{m_{n}}(E)$ you simply pick any ball from $\mathscr{F}$ for your collection of disjoint balls.

It is also not hard to remove the assumption that $\overline{m_{n}}(E)<\infty$.
Corollary 13.4.4 Let $E \subseteq \mathbb{R}^{n}$ and let $\mathscr{F}$, be a collection of closed balls of bounded radii such that $\mathscr{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.

Proof: Let $R_{m} \equiv(-m, m)^{n}$ be the open rectangle having sides of length $2 m$ which is centered at $\mathbf{0}$ and let $R_{0}=\emptyset$. Let $H_{m} \equiv \overline{R_{m}} \backslash R_{m}$. Since both $\overline{R_{m}}$ and $R_{m}$ have the same measure, $(2 m)^{n}$, it follows $m_{n}\left(H_{m}\right)=0$. Now for all $k \in \mathbb{N}, R_{k} \subseteq \overline{R_{k}} \subseteq R_{k+1}$. Consider the disjoint open sets, $U_{k} \equiv R_{k+1} \backslash \overline{R_{k}}$. Thus $\mathbb{R}^{n}=\cup_{k=0}^{\infty} U_{k} \cup N$ where $N$ is a set of measure zero equal to the union of the $H_{k}$. Let $\mathscr{F}_{k}$ denote those balls of $\mathscr{F}$ which are contained in $U_{k}$ and let $E_{k} \equiv U_{k} \cap E$. Then from Theorem 13.4.2, there exists a sequence of disjoint balls, $D_{k} \equiv\left\{B_{i}^{k}\right\}_{i=1}^{\infty}$ of $\mathscr{F}_{k}$ such that $\overline{m_{n}}\left(E_{k} \backslash \cup_{j=1}^{\infty} B_{j}^{k}\right)=0$. Letting $\left\{B_{i}\right\}_{i=1}^{\infty}$ be an enumeration of all the balls of $\cup_{k} D_{k}$, it follows that

$$
\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right) \leq m_{n}(N)+\sum_{k=1}^{\infty} \overline{m_{n}}\left(E_{k} \backslash \cup_{j=1}^{\infty} B_{j}^{k}\right)=0
$$

Also, you don't have to assume the balls are closed.
Corollary 13.4.5 Let $E \subseteq \mathbb{R}^{n}$ and let $\mathscr{F}$, be a collection of open balls of bounded radii such that $\mathscr{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.

Proof: Let $\overline{\mathscr{F}}$ be the collection of closures of balls in $\mathscr{F}$. Then $\overline{\mathscr{F}}$ covers $E$ in the sense of Vitali and so from Corollary 13.4.4 there exists a sequence of disjoint closed balls from $\overline{\mathscr{F}}$ satisfying $\overline{m_{n}}\left(E \backslash \cup_{i=1}^{\infty} \overline{B_{i}}\right)=0$. Now boundaries of the balls, $B_{i}$ have measure zero and so $\left\{B_{i}\right\}$ is a sequence of disjoint open balls satisfying $\overline{m_{n}}\left(E \backslash \cup_{i=1}^{\infty} B_{i}\right)=0$. The reason for this is that

$$
\left(E \backslash \cup_{i=1}^{\infty} B_{i}\right) \backslash\left(E \backslash \cup_{i=1}^{\infty} \overline{B_{i}}\right) \subseteq \cup_{i=1}^{\infty} \overline{B_{i}} \backslash \cup_{i=1}^{\infty} B_{i} \subseteq \cup_{i=1}^{\infty} \overline{B_{i}} \backslash B_{i},
$$

a set of measure zero. Therefore,

$$
E \backslash \cup_{i=1}^{\infty} B_{i} \subseteq\left(E \backslash \cup_{i=1}^{\infty} \overline{B_{i}}\right) \cup\left(\cup_{i=1}^{\infty} \overline{B_{i}} \backslash B_{i}\right)
$$

and so

$$
\begin{aligned}
\overline{m_{n}}\left(E \backslash \cup_{i=1}^{\infty} B_{i}\right) & \leq \overline{m_{n}}\left(E \backslash \cup_{i=1}^{\infty} \overline{B_{i}}\right)+m_{n}\left(\cup_{i=1}^{\infty} \overline{B_{i}} \backslash B_{i}\right) \\
& =\overline{m_{n}}\left(E \backslash \cup_{i=1}^{\infty} \overline{B_{i}}\right)=0 .
\end{aligned}
$$

This implies you can fill up an open set with balls which cover the open set in the sense of Vitali.

Corollary 13.4.6 Let $U \subseteq \mathbb{R}^{n}$ be an open set and let $\mathscr{F}$ be a collection of closed or even open balls of bounded radii contained in $U$ such that $\mathscr{F}$ covers $U$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\overline{m_{n}}(U \backslash$ $\left.\cup_{j=1}^{\infty} B_{j}\right)=0$.

### 13.5 Change of Variables for Linear Maps

To begin with certain kinds of functions map measurable sets to measurable sets. It will be assumed that $U$ is an open set in $\mathbb{R}^{n}$ and that $\mathbf{h}: U \rightarrow \mathbb{R}^{n}$ satisfies

$$
\begin{equation*}
D \mathbf{h}(\mathbf{x}) \text { exists for all } \mathbf{x} \in U \tag{13.5.11}
\end{equation*}
$$

Lemma 13.5.1 Let $\mathbf{h}$ satisfy 13.5.11. If $T \subseteq U$ and $m_{n}(T)=0$, then $m_{n}(\mathbf{h}(T))=0$.
Proof: Let

$$
T_{k} \equiv\{\mathbf{x} \in T:\|D \mathbf{h}(\mathbf{x})\|<k\}
$$

and let $\varepsilon>0$ be given. Now by outer regularity, there exists an open set, $V$, containing $T_{k}$ which is contained in $U$ such that $m_{n}(V)<\varepsilon$. Let $\mathbf{x} \in T_{k}$. Then by differentiability,

$$
\mathbf{h}(\mathbf{x}+\mathbf{v})=\mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x}) \mathbf{v}+o(\mathbf{v})
$$

and so there exist arbitrarily small $r_{\mathbf{x}}<1$ such that $B\left(\mathbf{x}, 5 r_{\mathbf{x}}\right) \subseteq V$ and whenever $|\mathbf{v}| \leq$ $r_{\mathbf{x}},|o(\mathbf{v})|<k|\mathbf{v}|$. Thus

$$
\mathbf{h}\left(B\left(\mathbf{x}, r_{\mathbf{x}}\right)\right) \subseteq B\left(\mathbf{h}(\mathbf{x}), 2 k r_{\mathbf{x}}\right)
$$

From the Vitali covering theorem there exists a countable disjoint sequence of these sets, $\left\{B\left(\mathbf{x}_{i}, r_{i}\right)\right\}_{i=1}^{\infty}$ such that $\left\{B\left(\mathbf{x}_{i}, 5 r_{i}\right)\right\}_{i=1}^{\infty}=\left\{\widehat{B}_{i}\right\}_{i=1}^{\infty}$ covers $T_{k}$ Then letting $\overline{m_{n}}$ denote the outer measure determined by $m_{n}$,

$$
\overline{m_{n}}\left(\mathbf{h}\left(T_{k}\right)\right) \leq \overline{m_{n}}\left(\mathbf{h}\left(\cup_{i=1}^{\infty} \widehat{B}_{i}\right)\right)
$$

$$
\begin{aligned}
& \leq \sum_{i=1}^{\infty} \overline{m_{n}}\left(\mathbf{h}\left(\widehat{B}_{i}\right)\right) \leq \sum_{i=1}^{\infty} m_{n}\left(B\left(\mathbf{h}\left(\mathbf{x}_{i}\right), 2 k r_{\mathbf{x}_{i}}\right)\right) \\
& = \\
& \leq \sum_{i=1}^{\infty} m_{n}\left(B\left(\mathbf{x}_{i}, 2 k r_{\mathbf{x}_{i}}\right)\right)=(2 k)^{n} \sum_{i=1}^{\infty} m_{n}\left(B\left(\mathbf{x}_{i}, r_{\mathbf{x}_{i}}\right)\right) \\
& \leq(2 k)^{n} m_{n}(V) \leq(2 k)^{n} \varepsilon .
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this shows $m_{n}\left(\mathbf{h}\left(T_{k}\right)\right)=0$. Now

$$
m_{n}(\mathbf{h}(T))=\lim _{k \rightarrow \infty} m_{n}\left(\mathbf{h}\left(T_{k}\right)\right)=0
$$

This proves the lemma.
Lemma 13.5.2 Let $\mathbf{h}$ satisfy 13.5.11. If $S$ is a Lebesgue measurable subset of $U$, then $\mathbf{h}(S)$ is Lebesgue measurable.

Proof: Let $S_{k}=S \cap B(\mathbf{0}, k), k \in \mathbb{N}$. By inner regularity of Lebesgue measure, there exists a set, $F$, which is the countable union of compact sets and a set $T$ with $m_{n}(T)=0$ such that

$$
F \cup T=S_{k}
$$

Then $\mathbf{h}(F) \subseteq \mathbf{h}\left(S_{k}\right) \subseteq \mathbf{h}(F) \cup \mathbf{h}(T)$. By continuity of $\mathbf{h}, \mathbf{h}(F)$ is a countable union of compact sets and so it is Borel. By Lemma 13.5.1, $m_{n}(\mathbf{h}(T))=0$ and so $\mathbf{h}\left(S_{k}\right)$ is Lebesgue measurable because of completeness of Lebesgue measure. Now $\mathbf{h}(S)=\cup_{k=1}^{\infty} \mathbf{h}\left(S_{k}\right)$ and so it is also true that $\mathbf{h}(S)$ is Lebesgue measurable. This proves the lemma.

In particular, this proves the following corollary.
Corollary 13.5.3 Suppose $A$ is an $n \times n$ matrix. Then if $S$ is a Lebesgue measurable set, it follows AS is also a Lebesgue measurable set.

Lemma 13.5.4 Let $R$ be unitary $\left(R^{*} R=R R^{*}=I\right)$ and let $V$ be $a$ an open or closed set. Then $m_{n}(R V)=m_{n}(V)$.

Proof: First assume $V$ is a bounded open set. By Corollary 13.4.6 there is a disjoint sequence of closed balls, $\left\{B_{i}\right\}$ such that $V=\cup_{i=1}^{\infty} B_{i} \cup N$ where $m_{n}(N)=0$. Denote by $\mathbf{x}_{i}$ the center of $B_{i}$ and let $r_{i}$ be the radius of $B_{i}$. Then by Lemma 13.5.1 $m_{n}(R V)=\sum_{i=1}^{\infty} m_{n}\left(R B_{i}\right)$. Now by invariance of translation of Lebesgue measure, this equals $\sum_{i=1}^{\infty} m_{n}\left(R B_{i}-R \mathbf{x}_{i}\right)=$ $\sum_{i=1}^{\infty} m_{n}\left(R B\left(\mathbf{0}, r_{i}\right)\right)$. Since $R$ is unitary, it preserves all distances and so $R B\left(\mathbf{0}, r_{i}\right)=B\left(\mathbf{0}, r_{i}\right)$ and therefore,

$$
m_{n}(R V)=\sum_{i=1}^{\infty} m_{n}\left(B\left(\mathbf{0}, r_{i}\right)\right)=\sum_{i=1}^{\infty} m_{n}\left(B_{i}\right)=m_{n}(V)
$$

This proves the lemma in the case that $V$ is bounded. Suppose now that $V$ is just an open set. Let $V_{k}=V \cap B(\mathbf{0}, k)$. Then $m_{n}\left(R V_{k}\right)=m_{n}\left(V_{k}\right)$. Letting $k \rightarrow \infty$, this yields the desired conclusion. This proves the lemma in the case that $V$ is open.

Suppose now that $H$ is a closed and bounded set. Let $B(\mathbf{0}, R) \supseteq H$. Then letting $B=$ $B(\mathbf{0}, R)$ for short,

$$
\begin{aligned}
m_{n}(R H) & =m_{n}(R B)-m_{n}(R(B \backslash H)) \\
& =m_{n}(B)-m_{n}(B \backslash H)=m_{n}(H) .
\end{aligned}
$$

In general, let $H_{m}=H \cap \overline{B(\mathbf{0}, m)}$. Then from what was just shown, $m_{n}\left(R H_{m}\right)=m_{n}\left(H_{m}\right)$. Now let $m \rightarrow \infty$ to get the conclusion of the lemma in general. This proves the lemma.

Lemma 13.5.5 Let $E$ be Lebesgue measurable set in $\mathbb{R}^{n}$ and let $R$ be unitary. Then $m_{n}(R E)=m_{n}(E)$.

Proof: First suppose $E$ is bounded. Then there exist sets, $G$ and $H$ such that $H \subseteq E \subseteq G$ and $H$ is the countable union of closed sets while $G$ is the countable intersection of open sets such that $m_{n}(G \backslash H)=0$. By Lemma 13.5.4 applied to these sets whose union or intersection equals $H$ or $G$ respectively, it follows

$$
m_{n}(R G)=m_{n}(G)=m_{n}(H)=m_{n}(R H) .
$$

Therefore,

$$
m_{n}(H)=m_{n}(R H) \leq m_{n}(R E) \leq m_{n}(R G)=m_{n}(G)=m_{n}(E)=m_{n}(H)
$$

In the general case, let $E_{m}=E \cap B(\mathbf{0}, m)$ and apply what was just shown and let $m \rightarrow \infty$.
Lemma 13.5.6 Let $V$ be an open or closed set in $\mathbb{R}^{n}$ and let $A$ be an $n \times n$ matrix. Then $m_{n}(A V)=|\operatorname{det}(A)| m_{n}(V)$.

Proof: Let $R U$ be the right polar decomposition (Theorem 5.9.6 on Page 94) of $A$ and let $V$ be an open set. Then from Lemma 13.5.5,

$$
m_{n}(A V)=m_{n}(R U V)=m_{n}(U V) .
$$

Now $U=Q^{*} D Q$ where $D$ is a diagonal matrix such that $|\operatorname{det}(D)|=|\operatorname{det}(A)|$ and $Q$ is unitary. Therefore,

$$
m_{n}(A V)=m_{n}\left(Q^{*} D Q V\right)=m_{n}(D Q V)
$$

Now $Q V$ is an open set and so by Corollary 13.1.6 on Page 342 and Lemma 13.5.4,

$$
m_{n}(A V)=|\operatorname{det}(D)| m_{n}(Q V)=|\operatorname{det}(D)| m_{n}(V)=|\operatorname{det}(A)| m_{n}(V)
$$

This proves the lemma in case $V$ is open.
Now let $H$ be a closed set which is also bounded. First suppose $\operatorname{det}(A)=0$. Then letting $V$ be an open set containing $H$,

$$
m_{n}(A H) \leq m_{n}(A V)=|\operatorname{det}(A)| m_{n}(V)=0
$$

which shows the desired equation is obvious in the case where $\operatorname{det}(A)=0$. Therefore, assume $A$ is one to one. Since $H$ is bounded, $H \subseteq B(\mathbf{0}, R)$ for some $R>0$. Then letting $B=B(\mathbf{0}, R)$ for short,

$$
\begin{aligned}
m_{n}(A H) & =m_{n}(A B)-m_{n}(A(B \backslash H)) \\
& =|\operatorname{det}(A)| m_{n}(B)-|\operatorname{det}(A)| m_{n}(B \backslash H)=|\operatorname{det}(A)| m_{n}(H)
\end{aligned}
$$

If $H$ is not bounded, apply the result just obtained to $H_{m} \equiv H \cap \overline{\boldsymbol{B}(\mathbf{0}, m)}$ and then let $m \rightarrow \infty$. With this preparation, the main result is the following theorem.

Theorem 13.5.7 Let $E$ be Lebesgue measurable set in $\mathbb{R}^{n}$ and let $A$ be an $n \times n$ matrix. Then $m_{n}(A E)=|\operatorname{det}(A)| m_{n}(E)$.

Proof: First suppose $E$ is bounded. Then there exist sets, $G$ and $H$ such that $H \subseteq E \subseteq G$ and $H$ is the countable union of closed sets while $G$ is the countable intersection of open sets such that $m_{n}(G \backslash H)=0$. By Lemma 13.5.6 applied to these sets whose union or intersection equals $H$ or $G$ respectively, it follows

$$
m_{n}(A G)=|\operatorname{det}(A)| m_{n}(G)=|\operatorname{det}(A)| m_{n}(H)=m_{n}(A H)
$$

Therefore,

$$
\begin{aligned}
|\operatorname{det}(A)| m_{n}(E) & =|\operatorname{det}(A)| m_{n}(H)=m_{n}(A H) \leq m_{n}(A E) \\
& \leq m_{n}(A G)=|\operatorname{det}(A)| m_{n}(G)=|\operatorname{det}(A)| m_{n}(E)
\end{aligned}
$$

In the general case, let $E_{m}=E \cap B(\mathbf{0}, m)$ and apply what was just shown and let $m \rightarrow \infty$.

### 13.6 Change Of Variables For $C^{1}$ Functions

In this section theorems are proved which generalize the above to $C^{1}$ functions. More general versions can be seen in Kuttler [83], Kuttler [84], and Rudin [113]. There is also a very different approach to this theorem given in [83]. The more general version in [83] follows [113] and both are based on the Brouwer fixed point theorem and a very clever lemma presented in Rudin [113]. The proof will be based on a sequence of easy lemmas.

Lemma 13.6.1 Let $U$ and $V$ be bounded open sets in $\mathbb{R}^{n}$ and let $\mathbf{h}, \mathbf{h}^{-1}$ be $C^{1}$ functions such that $\mathbf{h}(U)=V$. Also let $f \in C_{c}(V)$. Then

$$
\int_{V} f(\mathbf{y}) d m_{n}=\int_{U} f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}
$$

Proof: First note $\mathbf{h}^{-1}(\operatorname{spt}(f))$ is a closed subset of the bounded set, $U$ and so it is compact. Thus $\mathbf{x} \rightarrow f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))|$ is bounded and continuous.

Let $\mathbf{x} \in U$. By the assumption that $\mathbf{h}$ and $\mathbf{h}^{-1}$ are $C^{1}$,

$$
\begin{aligned}
\mathbf{h}(\mathbf{x}+\mathbf{v})-\mathbf{h}(\mathbf{x}) & =D \mathbf{h}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v}) \\
& =D \mathbf{h}(\mathbf{x})\left(\mathbf{v}+D \mathbf{h}^{-1}(\mathbf{h}(\mathbf{x})) \mathbf{o}(\mathbf{v})\right) \\
& =D \mathbf{h}(\mathbf{x})(\mathbf{v}+\mathbf{o}(\mathbf{v}))
\end{aligned}
$$

and so if $r>0$ is small enough then $B(\mathbf{x}, r)$ is contained in $U$ and

$$
\begin{gather*}
\mathbf{h}(B(\mathbf{x}, r))-\mathbf{h}(\mathbf{x})= \\
\mathbf{h}(\mathbf{x}+B(\mathbf{0}, r))-\mathbf{h}(\mathbf{x}) \subseteq D \mathbf{h}(\mathbf{x})(B(\mathbf{0},(1+\varepsilon) r)) \tag{13.6.12}
\end{gather*}
$$

Making $r$ still smaller if necessary, one can also obtain

$$
\begin{equation*}
|f(\mathbf{y})-f(\mathbf{h}(\mathbf{x}))|<\varepsilon \tag{13.6.13}
\end{equation*}
$$

for any $\mathbf{y} \in \mathbf{h}(B(\mathbf{x}, r))$ and also

$$
\begin{equation*}
\left|f\left(\mathbf{h}\left(\mathbf{x}_{1}\right)\right)\right| \operatorname{det}\left(D \mathbf{h}\left(\mathbf{x}_{1}\right)\right)|-f(\mathbf{h}(\mathbf{x}))| \operatorname{det}(D \mathbf{h}(\mathbf{x}))|\mid<\varepsilon \tag{13.6.14}
\end{equation*}
$$

whenever $\mathbf{x}_{1} \in B(\mathbf{x}, r)$. The collection of such balls is a Vitali cover of $U$. By Corollary 13.4.6 there is a sequence of disjoint closed balls $\left\{B_{i}\right\}$ such that $U=\cup_{i=1}^{\infty} B_{i} \cup N$ where $m_{n}(N)=0$. Denote by $\mathbf{x}_{i}$ the center of $B_{i}$ and $r_{i}$ the radius. Then by Lemma 13.5.1, the monotone convergence theorem, and 13.6.12-13.6.14,

$$
\begin{gathered}
\int_{V} f(\mathbf{y}) d m_{n}=\sum_{i=1}^{\infty} \int_{\mathbf{h}\left(B_{i}\right)} f(\mathbf{y}) d m_{n} \\
\leq \varepsilon m_{n}(V)+\sum_{i=1}^{\infty} \int_{\mathbf{h}\left(B_{i}\right)} f\left(\mathbf{h}\left(\mathbf{x}_{i}\right)\right) d m_{n} \\
\leq \varepsilon m_{n}(V)+\sum_{i=1}^{\infty} f\left(\mathbf{h}\left(\mathbf{x}_{i}\right)\right) m_{n}\left(\mathbf{h}\left(B_{i}\right)\right) \\
\leq \varepsilon m_{n}(V)+\sum_{i=1}^{\infty} f\left(\mathbf{h}\left(\mathbf{x}_{i}\right)\right) m_{n}\left(D \mathbf{h}\left(\mathbf{x}_{i}\right)\left(B\left(\mathbf{0},(1+\varepsilon) r_{i}\right)\right)\right) \\
=\varepsilon m_{n}(V)+(1+\varepsilon)^{n} \sum_{i=1}^{\infty} \int_{B_{i}} f\left(\mathbf{h}\left(\mathbf{x}_{i}\right)\right)\left|\operatorname{det}\left(D \mathbf{h}\left(\mathbf{x}_{i}\right)\right)\right| d m_{n} \\
\leq \varepsilon m_{n}(V)+(1+\varepsilon)^{n} \sum_{i=1}^{\infty}\left(\int_{B_{i}} f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}+\varepsilon m_{n}\left(B_{i}\right)\right) \\
\leq \varepsilon m_{n}(V)+(1+\varepsilon)^{n} \sum_{i=1}^{\infty} \int_{B_{i}} f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}+(1+\varepsilon)^{n} \varepsilon m_{n}(U) \\
=\varepsilon m_{n}(V)+(1+\varepsilon)^{n} \int_{U} f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}+(1+\varepsilon)^{n} \varepsilon m_{n}(U)
\end{gathered}
$$

Since $\varepsilon>0$ is arbitrary, this shows

$$
\begin{equation*}
\int_{V} f(\mathbf{y}) d m_{n} \leq \int_{U} f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n} \tag{13.6.15}
\end{equation*}
$$

whenever $f \in C_{c}(V)$. Now $\mathbf{x} \rightarrow f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))|$ is in $C_{c}(U)$ and so using the same argument with $U$ and $V$ switching roles and replacing $\mathbf{h}$ with $\mathbf{h}^{-1}$,

$$
\begin{aligned}
& \int_{U} f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n} \\
\leq & \int_{V} f\left(\mathbf{h}\left(\mathbf{h}^{-1}(\mathbf{y})\right)\right)\left|\operatorname{det}\left(D \mathbf{h}\left(\mathbf{h}^{-1}(\mathbf{y})\right)\right)\right|\left|\operatorname{det}\left(D \mathbf{h}^{-1}(\mathbf{y})\right)\right| d m_{n} \\
= & \int_{V} f(\mathbf{y}) d m_{n}
\end{aligned}
$$

by the chain rule. This with 13.6 .15 proves the lemma.
The next task is to relax the assumption that $f$ is continuous.

Corollary 13.6.2 Let $U$ and $V$ be bounded open sets in $\mathbb{R}^{n}$ and let $\mathbf{h}, \mathbf{h}^{-1}$ be $C^{1}$ functions such that $\mathbf{h}(U)=V$ and $|\operatorname{det}(D \mathbf{h}(\mathbf{x}))|$ is bounded. Also let $E \subseteq V$ be measurable. Then

$$
\int_{V} \mathscr{X}_{E}(\mathbf{y}) d m_{n}=\int_{U} \mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}
$$

Proof: By regularity, there exist compact sets, $K_{k}$ and open sets $G_{k}$ such that

$$
K_{k} \subseteq E \subseteq G_{k}
$$

and $m_{n}\left(G_{k} \backslash K_{k}\right)<2^{-k}$. By Theorem 12.2.7, there exist $f_{k}$ such that $K_{k} \prec f_{k} \prec G_{k}$. Then $f_{k}(\mathbf{y}) \rightarrow \mathscr{X}_{E}(\mathbf{y})$ a.e. because if $\mathbf{y}$ is such that convergence fails, it must be the case that $\mathbf{y}$ is in $G_{k} \backslash K_{k}$ for infinitely many $k$ and $\sum_{k} m_{n}\left(G_{k} \backslash K_{k}\right)<\infty$. This set equals

$$
N=\cap_{m=1}^{\infty} \cup_{k=m}^{\infty} G_{k} \backslash K_{k}
$$

and so for each $m \in \mathbb{N}$

$$
\begin{aligned}
m_{n}(N) & \leq m_{n}\left(\cup_{k=m}^{\infty} G_{k} \backslash K_{k}\right) \\
& \leq \sum_{k=m}^{\infty} m_{n}\left(G_{k} \backslash K_{k}\right)<\sum_{k=m}^{\infty} 2^{-k}=2^{-(m-1)}
\end{aligned}
$$

showing $m_{n}(N)=0$.
Then $f_{k}(\mathbf{h}(\mathbf{x}))$ must converge to $\mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))$ for all $\mathbf{x} \notin \mathbf{h}^{-1}(N)$, a set of measure zero by Lemma 13.5.1. Thus

$$
\int_{V} f_{k}(\mathbf{y}) d m_{n}=\int_{U} f_{k}(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}
$$

By the dominated convergence theorem using a dominating function, $\mathscr{X}_{V}$ in the integral on the left and $\mathscr{X}_{U}|\operatorname{det}(D \mathbf{h})|$ on the right, it follows

$$
\int_{V} \mathscr{X}_{E}(\mathbf{y}) d m_{n}=\int_{U} \mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}
$$

This proves the corollary.
You don't need to assume the open sets are bounded.
Corollary 13.6.3 Let $U$ and $V$ be open sets in $\mathbb{R}^{n}$ and let $\mathbf{h}, \mathbf{h}^{-1}$ be $C^{1}$ functions such that $\mathbf{h}(U)=V$. Also let $E \subseteq V$ be measurable. Then

$$
\int_{V} \mathscr{X}_{E}(\mathbf{y}) d m_{n}=\int_{U} \mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n}
$$

Proof: For each $\mathbf{x} \in U$, there exists $r_{\mathbf{x}}$ such that $\overline{B\left(\mathbf{x}, r_{\mathbf{x}}\right)} \subseteq U$ and $r_{\mathbf{x}}<1$. Then by the mean value inequality Theorem 6.13.4, it follows $\mathbf{h}\left(B\left(\mathbf{x}, r_{\mathbf{x}}\right)\right)$ is also bounded. This is a Vitali cover of $U$ and so by Corollary 13.4.6 there is a sequence of these balls, $\left\{B_{i}\right\}$ such that they are disjoint, $\mathbf{h}\left(B_{i}\right)$ is also bounded and

$$
m_{n}\left(U \backslash \cup_{i} B_{i}\right)=0
$$

It follows from Lemma 13.5.1 that $\mathbf{h}\left(U \backslash \cup_{i} B_{i}\right)$ also has measure zero. Then from Corollary 13.6.2

$$
\begin{aligned}
\int_{V} \mathscr{X}_{E}(\mathbf{y}) d m_{n} & =\sum_{i} \int_{\mathbf{h}\left(B_{i}\right)} \mathscr{X}_{E \cap \mathbf{h}\left(B_{i}\right)}(\mathbf{y}) d m_{n} \\
& =\sum_{i} \int_{B_{i}} \mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n} \\
& =\int_{U} \mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d m_{n} .
\end{aligned}
$$

This proves the corollary.
With this corollary, the main theorem follows.
Theorem 13.6.4 Let $U$ and $V$ be open sets in $\mathbb{R}^{n}$ and let $\mathbf{h}, \mathbf{h}^{-1}$ be $C^{1}$ functions such that $\mathbf{h}(U)=V$. Then if $g$ is a nonnegative Lebesgue measurable function,

$$
\begin{equation*}
\int_{V} g(\mathbf{y}) d y=\int_{U} g(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x \tag{13.6.16}
\end{equation*}
$$

Proof: From Corollary 13.6.3, 13.6.16 holds for any nonnegative simple function in place of $g$. In general, let $\left\{s_{k}\right\}$ be an increasing sequence of simple functions which converges to $g$ pointwise. Then from the monotone convergence theorem

$$
\begin{aligned}
\int_{V} g(\mathbf{y}) d y & =\lim _{k \rightarrow \infty} \int_{V} s_{k} d y=\lim _{k \rightarrow \infty} \int_{U} s_{k}(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x \\
& =\int_{U} g(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x
\end{aligned}
$$

This proves the theorem.
This is a pretty good theorem but it isn't too hard to generalize it. In particular, it is not necessary to assume $\mathbf{h}^{-1}$ is $C^{1}$.

Lemma 13.6.5 (Sard) Let $U$ be an open set in $\mathbb{R}^{n}$ and let $\mathbf{h}: U \rightarrow \mathbb{R}^{n}$ be $C^{1}$. Let

$$
Z \equiv\{\mathbf{x} \in U: \operatorname{det} D \mathbf{h}(\mathbf{x})=0\}
$$

Then $m_{n}(\mathbf{h}(Z))=0$.
Proof: Let $Z_{k}$ denote those points $\mathbf{x}$ of $Z$ such that $\|D \mathbf{h}(\mathbf{x})\| \leq k$ and such that $|\mathbf{x}|<k$. Let $\varepsilon>0$ be given. For $\mathbf{x} \in Z_{k}$,

$$
\mathbf{h}(\mathbf{x}+\mathbf{v})=\mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v})
$$

and so whenever $r$ is small enough,

$$
\mathbf{h}(\mathbf{x}+B(\mathbf{0}, r))=\mathbf{h}(B(\mathbf{x}, r)) \subseteq \mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r)+B(\mathbf{0}, r \varepsilon)
$$

Note $D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r)$ is contained in an $n-1$ dimensional subspace of $\mathbb{R}^{n}$ due to the fact $D \mathbf{h}(\mathbf{x})$ has rank less than $n$. Now let $Q$ denote an orthogonal transformation preserving all distances,

$$
Q Q^{*}=Q^{*} Q=I
$$

such that

$$
Q D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r) \subseteq \mathbb{R}^{n-1}
$$

Then

$$
Q \mathbf{h}(B(\mathbf{x}, r)) \subseteq Q \mathbf{h}(\mathbf{x})+Q D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r)+B(\mathbf{0}, r \varepsilon)
$$

and by translation invariance of Lebesgue measure,

$$
\begin{gathered}
m_{n}(Q \mathbf{h}(B(\mathbf{x}, r))) \leq m_{n}(Q D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r)+B(\mathbf{0}, r \varepsilon)) \\
\leq(\|Q D \mathbf{h}(\mathbf{x})\|(2 r+2 r \varepsilon))^{n-1} 2 r \varepsilon=C(1+\varepsilon)^{n-1} m_{n}(B(\mathbf{0}, r)) \varepsilon
\end{gathered}
$$

These balls give a Vitali cover of $Z_{k}$ and so there exists a disjoint sequence of them $\left\{B_{i}\right\}$, each contained in $B(\mathbf{0}, k)$ which covers $Z_{k}$ except for a set of measure zero which is mapped by $\mathbf{h}$ to a set of measure zero. Therefore using Theorem 13.5.7,

$$
\begin{gathered}
m_{n}\left(\mathbf{h}\left(Z_{k}\right)\right)=m_{n}\left(\mathbf{h}\left(\cup_{i=1}^{\infty} B_{i}\right)\right) \leq \sum_{i=1}^{\infty} m_{n}\left(\mathbf{h}\left(B_{i}\right)\right) \\
=\sum_{i=1}^{\infty} m_{n}\left(Q \mathbf{h}\left(B_{i}\right)\right) \leq C(1+\varepsilon)^{n-1} \varepsilon \sum_{i=1}^{\infty} m_{n}\left(B_{i}\right) \leq C(1+\varepsilon)^{n-1} \varepsilon m_{n}(B(\mathbf{0}, k))
\end{gathered}
$$

and since $\varepsilon$ is arbitrary, this shows $m_{n}\left(\mathbf{h}\left(Z_{k}\right)\right)=0$. Now

$$
m_{n}(\mathbf{h}(Z))=\lim _{k \rightarrow \infty} m_{n}\left(\mathbf{h}\left(Z_{k}\right)\right)=0
$$

This proves the lemma.
With this important lemma, here is a generalization of Theorem 13.6.4.
Theorem 13.6.6 Let $U$ be an open set and let $\mathbf{h}$ be a $1-1, C^{1}$ function with values in $\mathbb{R}^{n}$. Then if $g$ is a nonnegative Lebesgue measurable function,

$$
\begin{equation*}
\int_{\mathbf{h}(U)} g(\mathbf{y}) d y=\int_{U} g(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x \tag{13.6.17}
\end{equation*}
$$

Proof: Let $Z=\{\mathbf{x}: \operatorname{det}(D \mathbf{h}(\mathbf{x}))=0\}$. Then by the inverse function theorem, $\mathbf{h}^{-1}$ is $C^{1}$ on $\mathbf{h}(U \backslash Z)$ and $\mathbf{h}(U \backslash Z)$ is an open set. Therefore, from Lemma 13.6.5 and Theorem 13.6.4,

$$
\begin{aligned}
\int_{\mathbf{h}(U)} g(\mathbf{y}) d y & =\int_{\mathbf{h}(U \backslash Z)} g(\mathbf{y}) d y=\int_{U \backslash Z} g(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x \\
& =\int_{U} g(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x
\end{aligned}
$$

This proves the theorem.
Of course the next generalization considers the case when $\mathbf{h}$ is not even one to one.

### 13.7 Mappings Which Are Not One To One

Now suppose $\mathbf{h}$ is only $C^{1}$, not necessarily one to one. For

$$
U_{+} \equiv\{\mathbf{x} \in U:|\operatorname{det} D \mathbf{h}(x)|>0\}
$$

and $Z$ the set where $|\operatorname{det} D \mathbf{h}(\mathbf{x})|=0$, Lemma 13.6.5 implies $m_{n}(\mathbf{h}(Z))=0$. For $\mathbf{x} \in U_{+}$, the inverse function theorem implies there exists an open set $B_{\mathbf{x}}$ such that $\mathbf{x} \in B_{\mathbf{x}} \subseteq U_{+}, \mathbf{h}$ is one to one on $B_{\mathbf{x}}$.

Let $\left\{B_{i}\right\}$ be a countable subset of $\left\{B_{\mathbf{x}}\right\}_{\mathbf{x} \in U_{+}}$such that $U_{+}=\cup_{i=1}^{\infty} B_{i}$. Let $E_{1}=B_{1}$. If $E_{1}, \cdots, E_{k}$ have been chosen, $E_{k+1}=B_{k+1} \backslash \cup_{i=1}^{k} E_{i}$. Thus

$$
\cup_{i=1}^{\infty} E_{i}=U_{+}, \mathbf{h} \text { is one to one on } E_{i}, E_{i} \cap E_{j}=\emptyset
$$

and each $E_{i}$ is a Borel set contained in the open set $B_{i}$. Now define

$$
n(\mathbf{y}) \equiv \sum_{i=1}^{\infty} \mathscr{X}_{\mathbf{h}\left(E_{i}\right)}(\mathbf{y})+\mathscr{X}_{\mathbf{h}(Z)}(\mathbf{y})
$$

The set, $\mathbf{h}\left(E_{i}\right), \mathbf{h}(Z)$ are measurable by Lemma 13.5.2. Thus $n(\cdot)$ is measurable.
Lemma 13.7.1 Let $F \subseteq \mathbf{h}(U)$ be measurable. Then

$$
\int_{\mathbf{h}(U)} n(\mathbf{y}) \mathscr{X}_{F}(\mathbf{y}) d y=\int_{U} \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x .
$$

Proof: Using Lemma 13.6.5 and the Monotone convergence Theorem or Fubini's Theorem,

$$
\begin{aligned}
& \int_{\mathbf{h}(U)} n(\mathbf{y}) \mathscr{X}_{F}(\mathbf{y}) d y= \int_{\mathbf{h}(U)}(\sum_{i=1}^{\infty} \mathscr{X}_{\mathbf{h}\left(E_{i}\right)}(\mathbf{y})+\overbrace{\mathscr{X}_{\mathbf{h}(Z)}(\mathbf{y})}^{m_{n}(\mathbf{h}(Z))=0}) \mathscr{X}_{F}(\mathbf{y}) d y \\
&=\sum_{i=1}^{\infty} \int_{\mathbf{h}(U)} \mathscr{X}_{\mathbf{h}\left(E_{i}\right)}(\mathbf{y}) \mathscr{X}_{F}(\mathbf{y}) d y \\
&=\sum_{i=1}^{\infty} \int_{\mathbf{h}(U) \cap \mathbf{h}\left(E_{i}\right)} \mathscr{X}_{F}(\mathbf{y}) d y \\
&=\sum_{i=1}^{\infty} \int_{\mathbf{h}\left(B_{i}\right) \cap \mathbf{h}\left(E_{i}\right)} \mathscr{X}_{F}(\mathbf{y}) d y \\
&=\sum_{i=1}^{\infty} \int_{\mathbf{h}\left(B_{i}\right)} \mathscr{X}_{\mathbf{h}\left(E_{i}\right)}(\mathbf{y}) \mathscr{X}_{F}(\mathbf{y}) d y \\
&=\sum_{i=1}^{\infty} \int_{B_{i}} \mathscr{X}_{E_{i}}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x \\
&=\sum_{i=1}^{\infty} \int_{U} \mathscr{X}_{E_{i}}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x \\
&= \int_{U} \sum_{i=1}^{\infty} \mathscr{X}_{E_{i}}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x
\end{aligned}
$$

$$
=\int_{U_{+}} \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x=\int_{U} \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x .
$$

This proves the lemma.
Definition 13.7.2 For $\mathbf{y} \in \mathbf{h}(U)$, define a function, \#, according to the formula

$$
\#(\mathbf{y}) \equiv \text { number of elements in } \mathbf{h}^{-1}(\mathbf{y})
$$

Observe that

$$
\begin{equation*}
\#(\mathbf{y})=n(\mathbf{y}) \quad \text { a.e. } \tag{13.7.18}
\end{equation*}
$$

because $n(\mathbf{y})=\#(\mathbf{y})$ if $\mathbf{y} \notin \mathbf{h}(Z)$, a set of measure 0 . Therefore, \# is a measurable function.
Theorem 13.7.3 Let $g \geq 0, g$ measurable, and let $\mathbf{h}$ be $C^{1}(U)$. Then

$$
\begin{equation*}
\int_{\mathbf{h}(U)} \#(\mathbf{y}) g(\mathbf{y}) d y=\int_{U} g(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x \tag{13.7.19}
\end{equation*}
$$

Proof: From 13.7.18 and Lemma 13.7.1, 13.7.19 holds for all $g$, a nonnegative simple function. Approximating an arbitrary measurable nonnegative function, $g$, with an increasing pointwise convergent sequence of simple functions and using the monotone convergence theorem, yields 13.7 .19 for an arbitrary nonnegative measurable function, $g$. This proves the theorem.

### 13.8 Lebesgue Measure And Iterated Integrals

The following is the main result.
Theorem 13.8.1 Let $f \geq 0$ and suppose $f$ is a Lebesgue measurable function defined on $\mathbb{R}^{n}$ and $\int_{\mathbb{R}^{n}} f d m_{n}<\infty$. Then

$$
\int_{\mathbb{R}^{n}} f d m_{n}=\int_{\mathbb{R}^{k}} \int_{\mathbb{R}^{n-k}} f d m_{n-k} d m_{k}
$$

This will be accomplished by Fubini's theorem, Theorem 12.9.11 and the following lemma.

Lemma 13.8.2 $\overline{m_{k} \times m_{n-k}}=m_{n}$ on the $m_{n}$ measurable sets.
Proof: First of all, let $R=\prod_{i=1}^{n}\left(a_{i}, b_{i}\right]$ be a measurable rectangle and let

$$
R_{k}=\prod_{i=1}^{k}\left(a_{i}, b_{i}\right], R_{n-k}=\prod_{i=k+1}^{n}\left(a_{i}, b_{i}\right]
$$

Then by Fubini's theorem,

$$
\begin{aligned}
\int \mathscr{X}_{R} d\left(\overline{m_{k} \times m_{n-k}}\right) & =\int_{\mathbb{R}^{k}} \int_{\mathbb{R}^{n-k}} \mathscr{X}_{R_{k}} \mathscr{X}_{R_{n-k}} d m_{k} d m_{n-k} \\
& =\int_{\mathbb{R}^{k}} \mathscr{X}_{R_{k}} d m_{k} \int_{\mathbb{R}^{n-k}} \mathscr{X}_{R_{n-k}} d m_{n-k} \\
& =\int \mathscr{X}_{R} d m_{n}
\end{aligned}
$$

and so $\overline{m_{k} \times m_{n-k}}$ and $m_{n}$ agree on every half open rectangle. By Lemma 13.1.2 these two measures agree on every open set. Now if $K$ is a compact set, then $K=\cap_{k=1}^{\infty} U_{k}$ where $U_{k}$ is the open set, $K+B\left(\mathbf{0}, \frac{1}{k}\right)$. Another way of saying this is $U_{k} \equiv\left\{\mathbf{x}: \operatorname{dist}(\mathbf{x}, K)<\frac{1}{k}\right\}$ which is obviously open because $\mathbf{x} \rightarrow \operatorname{dist}(\mathbf{x}, K)$ is a continuous function. Since $K$ is the countable intersection of these decreasing open sets, each of which has finite measure with respect to either of the two measures, it follows that $\overline{m_{k} \times m_{n-k}}$ and $m_{n}$ agree on all the compact sets. Now let $E$ be a bounded Lebesgue measurable set. Then there are sets, $H$ and $G$ such that $H$ is a countable union of compact sets, $G$ a countable intersection of open sets, $H \subseteq E \subseteq G$, and $m_{n}(G \backslash H)=0$. Then from what was just shown about compact and open sets, the two measures agree on $G$ and on $H$. Therefore,

$$
\begin{aligned}
m_{n}(H) & =\overline{m_{k} \times m_{n-k}}(H) \leq \overline{m_{k} \times m_{n-k}}(E) \\
& \leq \overline{m_{k} \times m_{n-k}}(G)=m_{n}(E)=m_{n}(H)
\end{aligned}
$$

By completeness of the measure space for $\overline{m_{k} \times m_{n-k}}$, it follows $E$ is $\overline{m_{k} \times m_{n-k}}$ measurable and

$$
\overline{m_{k} \times m_{n-k}}(E)=m_{n}(E) .
$$

This proves the lemma.
You could also show that the two $\sigma$ algebras are the same. However, this is not needed for the lemma or the theorem.

Proof of Theorem 13.8.1: By the lemma and Fubini's theorem, Theorem 12.9.11,

$$
\int_{\mathbb{R}^{n}} f d m_{n}=\int_{\mathbb{R}^{n}} f d\left(\overline{m_{k} \times m_{n-k}}\right)=\int_{\mathbb{R}^{k}} \int_{\mathbb{R}^{n-k}} f d m_{n-k} d m_{k} .
$$

Corollary 13.8.3 Let $f$ be a nonnegative real valued measurable function. Then

$$
\int_{\mathbb{R}^{n}} f d m_{n}=\int_{\mathbb{R}^{k}} \int_{\mathbb{R}^{n-k}} f d m_{n-k} d m_{k}
$$

Proof: Let $S_{p} \equiv\left\{\mathbf{x} \in \mathbb{R}^{n}: 0 \leq f(\mathbf{x}) \leq p\right\} \cap B(\mathbf{0}, p)$. Then $\int_{\mathbb{R}^{n}} f \mathscr{X}_{S_{p}} d m_{n}<\infty$. Therefore, from Theorem 13.8.1,

$$
\int_{\mathbb{R}^{n}} f \mathscr{X}_{S_{p}} d m_{n}=\int_{\mathbb{R}^{k}} \int_{\mathbb{R}^{n-k}} \mathscr{X}_{S_{p}} f d m_{n-k} d m_{k}
$$

Now let $p \rightarrow \infty$ and use the Monotone convergence theorem and the Fubini Theorem 12.9.11 on Page 315.

Not surprisingly, the following corollary follows from this.

Corollary 13.8.4 Let $f \in L^{1}\left(\mathbb{R}^{n}\right)$ where the measure is $m_{n}$. Then

$$
\int_{\mathbb{R}^{n}} f d m_{n}=\int_{\mathbb{R}^{k}} \int_{\mathbb{R}^{n-k}} f d m_{n-k} d m_{k}
$$

Proof: Apply Corollary 13.8.3 to the postive and negative parts of the real and imaginary parts of $f$.

### 13.9 Spherical Coordinates In $p$ Dimensions

Sometimes there is a need to deal with spherical coordinates in more than three dimensions. In this section, this concept is defined and formulas are derived for these coordinate systems. Recall polar coordinates are of the form

$$
\begin{aligned}
& y_{1}=\rho \cos \theta \\
& y_{2}=\rho \sin \theta
\end{aligned}
$$

where $\rho>0$ and $\theta \in \mathbb{R}$. Thus these transformation equations are not one to one but they are one to one on $(0, \infty) \times[0,2 \pi)$. Here I am writing $\rho$ in place of $r$ to emphasize a pattern which is about to emerge. I will consider polar coordinates as spherical coordinates in two dimensions. I will also simply refer to such coordinate systems as polar coordinates regardless of the dimension. This is also the reason I am writing $y_{1}$ and $y_{2}$ instead of the more usual $x$ and $y$. Now consider what happens when you go to three dimensions. The situation is depicted in the following picture.

From this picture, you see that $y_{3}=\rho \cos \phi_{1}$. Also the distance between $\left(y_{1}, y_{2}\right)$ and $(0,0)$ is $\rho \sin \left(\phi_{1}\right)$. Therefore, using polar coordinates to write $\left(y_{1}, y_{2}\right)$ in terms of $\theta$ and this distance,

$$
\begin{aligned}
& y_{1}=\rho \sin \phi_{1} \cos \theta \\
& y_{2}=\rho \sin \phi_{1} \sin \theta \\
& y_{3}=\rho \cos \phi_{1} .
\end{aligned}
$$

where $\phi_{1} \in \mathbb{R}$ and the transformations are one to one if $\phi_{1}$ is restricted to be in $[0, \pi]$. What was done is to replace $\rho$ with $\rho \sin \phi_{1}$ and then to add in $y_{3}=\rho \cos \phi_{1}$. Having done this, there is no reason to stop with three dimensions. Consider the following picture:

From this picture, you see that $y_{4}=\rho \cos \phi_{2}$. Also the distance between $\left(y_{1}, y_{2}, y_{3}\right)$ and $(0,0,0)$ is $\rho \sin \left(\phi_{2}\right)$. Therefore, using polar coordinates to write $\left(y_{1}, y_{2}, y_{3}\right)$ in terms of $\theta, \phi_{1}$, and this distance,

$$
\begin{aligned}
& y_{1}=\rho \sin \phi_{2} \sin \phi_{1} \cos \theta, \\
& y_{2}=\rho \sin \phi_{2} \sin \phi_{1} \sin \theta, \\
& y_{3}=\rho \sin \phi_{2} \cos \phi_{1}, \\
& y_{4}=\rho \cos \phi_{2}
\end{aligned}
$$

where $\phi_{2} \in \mathbb{R}$ and the transformations will be one to one if

$$
\phi_{2}, \phi_{1} \in(0, \pi), \theta \in(0,2 \pi), \rho \in(0, \infty) .
$$

Continuing this way, given spherical coordinates in $\mathbb{R}^{p}$, to get the spherical coordinates in $\mathbb{R}^{p+1}$, you let $y_{p+1}=\rho \cos \phi_{p-1}$ and then replace every occurance of $\rho$ with $\rho \sin \phi_{p-1}$ to obtain $y_{1} \cdots y_{p}$ in terms of $\phi_{1}, \phi_{2}, \cdots, \phi_{p-1}, \theta$, and $\rho$.

It is always the case that $\rho$ measures the distance from the point in $\mathbb{R}^{p}$ to the origin in $\mathbb{R}^{p}, \mathbf{0}$. Each $\phi_{i} \in \mathbb{R}$ and the transformations will be one to one if each $\phi_{i} \in(0, \pi)$, and $\theta \in(0,2 \pi)$. Denote by $\mathbf{h}_{p}(\rho, \vec{\phi}, \theta)$ the above transformation.

It can be shown using math induction and geometric reasoning that these coordinates map $\prod_{i=1}^{p-2}(0, \pi) \times(0,2 \pi) \times(0, \infty)$ one to one onto an open subset of $\mathbb{R}^{p}$ which is everything except for the set of measure zero $\Psi_{p}(N)$ where $N$ results from having some $\phi_{i}$ equal to 0 or $\pi$ or for $\rho=0$ or for $\theta$ equal to either $2 \pi$ or 0 . Each of these are sets of Lebesgue measure zero and so their union is also a set of measure zero. You can see that $\mathbf{h}_{p}\left(\prod_{i=1}^{p-2}(0, \pi) \times(0,2 \pi) \times(0, \infty)\right)$ omits the union of the coordinate axes except for maybe one of them. This is not important to the integral because it is just a set of measure zero.

Theorem 13.9.1 Let $\mathbf{y}=\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)$ be the spherical coordinate transformations in $\mathbb{R}^{p}$. Then letting $A=\prod_{i=1}^{p-2}(0, \pi) \times(0,2 \pi)$, it follows $\mathbf{h}$ maps $A \times(0, \infty)$ one to one onto all of $\mathbb{R}^{p}$ except a set of measure zero given by $\mathbf{h}_{p}(N)$ where $N$ is the set of measure zero

$$
(\bar{A} \times[0, \infty)) \backslash(A \times(0, \infty))
$$

Also $\left|\operatorname{det} D \mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right|$ will always be of the form

$$
\begin{equation*}
\left|\operatorname{det} D \mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right|=\rho^{p-1} \Phi(\vec{\phi}, \theta) . \tag{13.9.20}
\end{equation*}
$$

where $\Phi$ is a continuous function of $\vec{\phi}$ and $\theta .{ }^{1}$ Then if $f$ is nonnegative and Lebesgue measurable,

$$
\begin{equation*}
\int_{\mathbb{R}^{p}} f(\mathbf{y}) d m_{p}=\int_{\mathbf{h}_{p}(A)} f(\mathbf{y}) d m_{p}=\int_{A} f\left(\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right) \rho^{p-1} \Phi(\vec{\phi}, \theta) d m_{p} \tag{13.9.21}
\end{equation*}
$$

Furthermore whenever $f$ is Borel measurable and nonnegative, one can apply Fubini's theorem and write

$$
\begin{equation*}
\int_{\mathbb{R}^{p}} f(\mathbf{y}) d y=\int_{0}^{\infty} \rho^{p-1} \int_{A} f(\mathbf{h}(\vec{\phi}, \theta, \rho)) \Phi(\vec{\phi}, \theta) d \vec{\phi} d \theta d \rho \tag{13.9.22}
\end{equation*}
$$

where here $d \vec{\phi} d \theta$ denotes $d m_{p-1}$ on $A$. The same formulas hold if $f \in L^{1}\left(\mathbb{R}^{p}\right)$.
Proof: Formula 13.9.20 is obvious from the definition of the spherical coordinates because in the matrix of the derivative, there will be a $\rho$ in $p-1$ columns. The first claim is also clear from the definition and math induction or from the geometry of the above description. It remains to verify 13.9 .21 and 13.9.22. It is clear $\mathbf{h}_{p}$ maps $\bar{A} \times[0, \infty)$ onto $\mathbb{R}^{p}$. Since $\mathbf{h}_{p}$ is differentiable, it maps sets of measure zero to sets of measure zero. Then

$$
\mathbb{R}^{p}=\mathbf{h}_{p}(N \cup A \times(0, \infty))=\mathbf{h}_{p}(N) \cup \mathbf{h}_{p}(A \times(0, \infty)),
$$

the union of a set of measure zero with $\mathbf{h}_{p}(A \times(0, \infty))$. Therefore, from the change of variables formula,

$$
\begin{aligned}
\int_{\mathbb{R}^{p}} f(\mathbf{y}) d m_{p} & =\int_{\mathbf{h}_{p}(A \times(0, \infty))} f(\mathbf{y}) d m_{p} \\
& =\int_{A \times(0, \infty)} f\left(\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right) \rho^{p-1} \Phi(\vec{\phi}, \theta) d m_{p}
\end{aligned}
$$

which proves 13.9.21. This formula continues to hold if $f$ is in $L^{1}\left(\mathbb{R}^{p}\right)$. Finally, if $f \geq 0$ or in $L^{1}\left(\mathbb{R}^{n}\right)$ and is Borel measurable, then it is $\mathscr{F}^{p}$ measurable as well. Recall that $\mathscr{F} p$ includes the smallest $\sigma$ algebra which contains products of open intervals. Hence $\mathscr{F} p$ includes the Borel sets $\mathscr{B}\left(\mathbb{R}^{p}\right)$. Thus from the definition of $m_{p}$

$$
\begin{aligned}
& \int_{A \times(0, \infty)} f\left(\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right) \rho^{p-1} \Phi(\vec{\phi}, \theta) d m_{p} \\
= & \int_{(0, \infty)} \int_{A} f\left(\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right) \rho^{p-1} \Phi(\vec{\phi}, \theta) d m_{p-1} d m \\
= & \int_{(0, \infty)} \rho^{p-1} \int_{A} f\left(\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right) \Phi(\vec{\phi}, \theta) d m_{p-1} d m
\end{aligned}
$$

Now the claim about $f \in L^{1}$ follows routinely from considering the positive and negative parts of the real and imaginary parts of $f$ in the usual way.

[^13]Note that the above equals

$$
\int_{\bar{A} \times[0, \infty)} f\left(\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right) \rho^{p-1} \Phi(\vec{\phi}, \theta) d m_{p}
$$

and the iterated integral is also equal to

$$
\int_{[0, \infty)} \rho^{p-1} \int_{\vec{A}} f\left(\mathbf{h}_{p}(\vec{\phi}, \theta, \rho)\right) \Phi(\vec{\phi}, \theta) d m_{p-1} d m
$$

because the difference is just a set of measure zero.
Notation 13.9.2 Often this is written differently. Note that from the spherical coordinate formulas, $f(\mathbf{h}(\vec{\phi}, \theta, \rho))=f(\rho \omega)$ where $|\omega|=1$. Letting $S^{p-1}$ denote the unit sphere, $\left\{\omega \in \mathbb{R}^{p}:|\omega|=1\right\}$, the inside integral in the above formula is sometimes written as

$$
\int_{S^{p-1}} f(\rho \omega) d \sigma
$$

where $\sigma$ is a measure on $S^{p-1}$. See [83] for another description of this measure. It isn't an important issue here. Either 13.9.22 or the formula

$$
\int_{0}^{\infty} \rho^{p-1}\left(\int_{S^{p-1}} f(\rho \omega) d \sigma\right) d \rho
$$

will be referred to as polar coordinates and is very useful in establishing estimates. Here $\sigma\left(S^{p-1}\right) \equiv \int_{A} \Phi(\vec{\phi}, \theta) d m_{p-1}$.

Example 13.9.3 For what values of $s$ is the integral $\int_{B(\mathbf{0}, R)}\left(1+|\mathbf{x}|^{2}\right)^{s} d y$ bounded independent of $R$ ? Here $B(\mathbf{0}, R)$ is the ball, $\left\{\mathbf{x} \in \mathbb{R}^{p}:|\mathbf{x}| \leq R\right\}$.

I think you can see immediately that $s$ must be negative but exactly how negative? It turns out it depends on $p$ and using polar coordinates, you can find just exactly what is needed. From the polar coordinates formula above,

$$
\begin{aligned}
\int_{B(\mathbf{0}, R)}\left(1+|\mathbf{x}|^{2}\right)^{s} d y & =\int_{0}^{R} \int_{S^{p-1}}\left(1+\rho^{2}\right)^{s} \rho^{p-1} d \sigma d \rho \\
& =C_{p} \int_{0}^{R}\left(1+\rho^{2}\right)^{s} \rho^{p-1} d \rho
\end{aligned}
$$

Now the very hard problem has been reduced to considering an easy one variable problem of finding when

$$
\int_{0}^{R} \rho^{p-1}\left(1+\rho^{2}\right)^{s} d \rho
$$

is bounded independent of $R$. You need $2 s+(p-1)<-1$ so you need $s<-p / 2$.

### 13.10 The Brouwer Fixed Point Theorem

This seems to be a good place to present a short proof of one of the most important of all fixed point theorems. There are many approaches to this but one of the easiest and shortest I have ever seen is the one in Dunford and Schwartz [45]. This is what is presented here. In Evans [48] there is a different proof which depends on integration theory. A good reference for an introduction to various kinds of fixed point theorems is the book by Smart [118]. This book also gives an entirely different approach to the Brouwer fixed point theorem.

The proof given here is based on the following lemma. Recall that for $A$ an $n \times n$ matrix, $\operatorname{cof}(A)_{i j}$ is the determinant of the matrix which results from deleting the $i^{t h}$ row and the $j^{t h}$ column and multiplying by $(-1)^{i+j}$. The following lemma is proved earlier. See Lemma 16.3.1.

Lemma 13.10.1 Let $\mathbf{g}: U \rightarrow \mathbb{R}^{n}$ be $C^{2}$ where $U$ is an open subset of $\mathbb{R}^{n}$. Then

$$
\sum_{j=1}^{n} \operatorname{cof}(D \mathbf{g})_{i j, j}=0
$$

where here $(D \mathbf{g})_{i j} \equiv g_{i, j} \equiv \frac{\partial g_{i}}{\partial x_{j}}$. Also, $\operatorname{cof}(D \mathbf{g})_{i j}=\frac{\partial \operatorname{det}(D \mathbf{g})}{\partial g_{i, j}}$.
To prove the Brouwer fixed point theorem, first consider a version of it valid for $C^{2}$ mappings. This is the following lemma.

Lemma 13.10.2 Let $B_{r}=\overline{B(\mathbf{0}, r)}$ and suppose $\mathbf{g}$ is a $C^{2}$ function defined on $\mathbb{R}^{n}$ which maps $B_{r}$ to $B_{r}$. Then $\mathbf{g}(\mathbf{x})=\mathbf{x}$ for some $\mathbf{x} \in B_{r}$.

Proof: Suppose not. Then $|\mathbf{g}(\mathbf{x})-\mathbf{x}|$ must be bounded away from zero on $B_{r}$. Let $a(\mathbf{x})$ be the larger of the two roots of the equation,

$$
\begin{equation*}
|\mathbf{x}+z(\mathbf{x}-\mathbf{g}(\mathbf{x}))|^{2}=|\mathbf{x}|^{2}+2(\mathbf{x}, \mathbf{x}-\mathbf{g}(\mathbf{x})) z+z^{2}|\mathbf{x}-\mathbf{g}(\mathbf{x})|^{2}=r^{2} \tag{13.10.23}
\end{equation*}
$$

Thus, from the quadratic formula,

$$
\begin{equation*}
a(\mathbf{x})=\frac{-(\mathbf{x},(\mathbf{x}-\mathbf{g}(\mathbf{x})))+\sqrt{(\mathbf{x},(\mathbf{x}-\mathbf{g}(\mathbf{x})))^{2}+\left(r^{2}-|\mathbf{x}|^{2}\right)|\mathbf{x}-\mathbf{g}(\mathbf{x})|^{2}}}{|\mathbf{x}-\mathbf{g}(\mathbf{x})|^{2}} \tag{13.10.24}
\end{equation*}
$$

That under the square root is positive if $|\mathbf{x}|<r$. What if $|\mathbf{x}|=r$ ? In this case, since $\mathbf{g}(\mathbf{x}) \in B_{r}$, you cannot have $(\mathbf{x},(\mathbf{x}-\mathbf{g}(\mathbf{x})))=0$ because if so, you would have

$$
r^{2}=(\mathbf{x}, \mathbf{g}(\mathbf{x}))=|\mathbf{x}||\mathbf{g}(\mathbf{x})| \cos (\theta)
$$

so $r=|\mathbf{g}(\mathbf{x})| \cos \theta$ where $\theta$ is the angle between the vectors $\mathbf{x}, \mathbf{g}(\mathbf{x})$. The only way this can happen is for $\mathbf{g}(\mathbf{x})=\mathbf{x}$ and this is assumed not to occur. Thus what is under the square root sign is always positive. It follows that $a(\cdot)$ is a $C^{2}$ function because $t \rightarrow \sqrt{t}$ is smooth on $t>0$. When $|\mathbf{x}|=r$, one solution to 13.10 .23 is $z=0$. There is also a solution for negative $z$ based on geometric reasoning. Therefore, these are the two roots to 13.10 .23 , one negative
and one 0 , and so $a(\mathbf{x})=0$ when $|\mathbf{x}|=r$. Thus also, if $|\mathbf{x}|=r$, 13.10.24 implies that $0=-(\mathbf{x},(\mathbf{x}-\mathbf{g}(\mathbf{x})))+|(\mathbf{x},(\mathbf{x}-\mathbf{g}(\mathbf{x})))|$ so $(\mathbf{x},(\mathbf{x}-\mathbf{g}(\mathbf{x}))) \geq 0$.

Now define for $t \in[0,1]$,

$$
\mathbf{f}(t, \mathbf{x}) \equiv \mathbf{x}+t a(\mathbf{x})(\mathbf{x}-\mathbf{g}(\mathbf{x}))
$$

The important properties of $\mathbf{f}(t, \mathbf{x})$ and $a(\mathbf{x})$ are that

$$
\begin{equation*}
a(\mathbf{x})=0 \text { if }|\mathbf{x}|=r \tag{13.10.25}
\end{equation*}
$$

and

$$
\begin{equation*}
|\mathbf{f}(t, \mathbf{x})|=r \text { for all }|\mathbf{x}|=r \tag{13.10.26}
\end{equation*}
$$

Also from 13.10.24, $a$ is a $C^{2}$ function near $B_{r}$ because, as shown above, the expression under $\sqrt{ }$ is always positive and $t \rightarrow \sqrt{t}$ is infinitely differentiable for $t>0$.

Now define

$$
I(t) \equiv \int_{B_{r}} \operatorname{det}\left(D_{2} \mathbf{f}(t, \mathbf{x})\right) d x
$$

Then

$$
\begin{equation*}
I(0)=\int_{B_{r}} d x=m_{n}\left(B_{r}\right)>0 \tag{13.10.27}
\end{equation*}
$$

Using the dominated convergence theorem one can differentiate $I(t)$ as follows.

$$
\begin{aligned}
I^{\prime}(t) & =\int_{B_{r}} \sum_{i j} \frac{\partial \operatorname{det}\left(D_{2} \mathbf{f}(t, \mathbf{x})\right)}{\partial f_{i, j}} \frac{\partial f_{i, j}}{\partial t} d x \\
& =\int_{B_{r}} \sum_{i j} \operatorname{cof}\left(D_{2} \mathbf{f}\right)_{i j} \frac{\partial\left(a(\mathbf{x})\left(x_{i}-g_{i}(\mathbf{x})\right)\right)}{\partial x_{j}} d x .
\end{aligned}
$$

Now from 13.10.25 $a(\mathbf{x})=0$ when $|\mathbf{x}|=r$ and so integration by parts and Lemma 16.3.1 yields

$$
\begin{aligned}
I^{\prime}(t) & =\int_{B_{r}} \sum_{i j} \operatorname{cof}\left(D_{2} \mathbf{f}\right)_{i j} \frac{\partial\left(a(\mathbf{x})\left(x_{i}-g_{i}(\mathbf{x})\right)\right)}{\partial x_{j}} d x \\
& =-\int_{B_{r}} \sum_{i j} \operatorname{cof}\left(D_{2} \mathbf{f}\right)_{i j, j} a(\mathbf{x})\left(x_{i}-g_{i}(\mathbf{x})\right) d x=0 .
\end{aligned}
$$

Therefore, $I(1)=I(0)$. However, from 13.10.23

$$
|\mathbf{x}+a(\mathbf{x}) t(\mathbf{x}-\mathbf{g}(\mathbf{x}))|^{2}=|\mathbf{x}|^{2}+2(\mathbf{x}, \mathbf{x}-\mathbf{g}(\mathbf{x})) a(\mathbf{x}) t+(a(\mathbf{x}) t)^{2}|\mathbf{x}-\mathbf{g}(\mathbf{x})|^{2}=r^{2}
$$

it follows that for $t=1$ in the above expression, you have

$$
|\mathbf{f}(1, \mathbf{x})|^{2}=\sum_{i} f_{i} f_{i}=r^{2}
$$

and so, $\sum_{i} f_{i, j} f_{i}=0$ which implies since $|\mathbf{f}(1, \mathbf{x})|=r$ by 13.10.23, that

$$
\operatorname{det}\left(f_{i, j}\right)=\operatorname{det}\left(D_{2} \mathbf{f}(1, \mathbf{x})\right)=0
$$

and so $I(1)=0$, a contradiction to 13.10 .27 since $I(1)=I(0)$.
The following theorem is the Brouwer fixed point theorem for a ball.

Theorem 13.10.3 Let $B_{r}$ be the above closed ball and let $\mathbf{f}: B_{r} \rightarrow B_{r}$ be continuous. Then there exists $\mathbf{x} \in B_{r}$ such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Proof: Let $\mathbf{f}_{k}(\mathbf{x}) \equiv \frac{\mathbf{f}(\mathbf{x})}{1+k^{-1}}$. Thus

$$
\begin{aligned}
\left\|\mathbf{f}_{k}-\mathbf{f}\right\| & =\max _{\mathbf{x} \in B_{r}}\left\{\left|\frac{\mathbf{f}(\mathbf{x})}{1+(1 / k)}-\mathbf{f}(\mathbf{x})\right|\right\}=\max _{\mathbf{x} \in B_{r}}\left\{\left|\frac{\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{x})(1+(1 / k))}{1+(1 / k)}\right|\right\} \\
& =\max _{\mathbf{x} \in B_{r}}\left\{\left|\frac{\mathbf{f}(\mathbf{x})(1 / k)}{1+(1 / k)}\right|\right\} \leq \frac{r}{1+k}
\end{aligned}
$$

Letting $\|\mathbf{h}\| \equiv \max \left\{|\mathbf{h}(\mathbf{x})|: \mathbf{x} \in B_{r}\right\}$, It follows from the Weierstrass approximation theorem, there exists a function whose components are polynomials $\mathbf{g}_{k}$ such that $\left\|\mathbf{g}_{k}-\mathbf{f}_{k}\right\|<$ $\frac{r}{k+1}$. Then if $\mathbf{x} \in B_{r}$, it follows

$$
\begin{aligned}
\left|\mathbf{g}_{k}(\mathbf{x})\right| & \leq\left|\mathbf{g}_{k}(\mathbf{x})-\mathbf{f}_{k}(\mathbf{x})\right|+\left|\mathbf{f}_{k}(\mathbf{x})\right| \\
& <\frac{r}{1+k}+\frac{k r}{1+k}=r
\end{aligned}
$$

and so $\mathbf{g}_{k}$ maps $B_{r}$ to $B_{r}$. By Lemma 13.10.2 each of these $\mathbf{g}_{k}$ has a fixed point $\mathbf{x}_{k}$ such that $\mathbf{g}_{k}\left(\mathbf{x}_{k}\right)=\mathbf{x}_{k}$. The sequence of points, $\left\{\mathbf{x}_{k}\right\}$ is contained in the compact set, $B_{r}$ and so there exists a convergent subsequence still denoted by $\left\{\mathbf{x}_{k}\right\}$ which converges to a point $\mathbf{x} \in B_{r}$. Then

$$
\begin{aligned}
|\mathbf{f}(\mathbf{x})-\mathbf{x}| & \leq\left|\mathbf{f}(\mathbf{x})-\mathbf{f}_{k}(\mathbf{x})\right|+\left|\mathbf{f}_{k}(\mathbf{x})-\mathbf{f}_{k}\left(\mathbf{x}_{k}\right)\right|+|\mathbf{f}_{k}\left(\mathbf{x}_{k}\right)-\overbrace{\mathbf{g}_{k}\left(\mathbf{x}_{k}\right)}^{=\mathbf{x}_{k}}|+\left|\mathbf{x}_{k}-\mathbf{x}\right| \\
& \leq \frac{r}{1+k}+\left|\mathbf{f}(\mathbf{x})-\mathbf{f}\left(\mathbf{x}_{k}\right)\right|+\frac{r}{1+k}+\left|\mathbf{x}_{k}-\mathbf{x}\right| .
\end{aligned}
$$

Now let $k \rightarrow \infty$ in the right side to conclude $\mathbf{f}(\mathbf{x})=\mathbf{x}$.
It is not surprising that the ball does not need to be centered at $\mathbf{0}$.
Corollary 13.10.4 Let $\mathbf{f}: \overline{B(\mathbf{a}, r)} \rightarrow \overline{B(\mathbf{a}, r)}$ be continuous. Then there exists $\mathbf{x} \in \overline{B(\mathbf{a}, r)}$ such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Proof: Let $\mathbf{g}: B_{r} \rightarrow B_{r}$ be defined by $\mathbf{g}(\mathbf{y}) \equiv \mathbf{f}(\mathbf{y}+\mathbf{a})-\mathbf{a}$. Then $\mathbf{g}$ is a continuous map from $B_{r}$ to $B_{r}$. Therefore, there exists $\mathbf{y} \in B_{r}$ such that $\mathbf{g}(\mathbf{y})=\mathbf{y}$. Therefore, $\mathbf{f}(\mathbf{y}+\mathbf{a})-\mathbf{a}=\mathbf{y}$ and so letting $\mathbf{x}=\mathbf{y}+\mathbf{a}, \mathbf{f}$ also has a fixed point as claimed.

Definition 13.10.5 $A$ set $A$ is a retract of a set $B$ if $A \subseteq B$, and there is a continuous map $\mathbf{h}: B \rightarrow A$ such that $\mathbf{h}(\mathbf{x})=\mathbf{x}$ for all $\mathbf{x} \in A$ and $\mathbf{h}$ is onto. $B$ has the fixed point property means that whenever $\mathbf{g}$ is continuous and $\mathbf{g}: B \rightarrow B$, it follows that $\mathbf{g}$ has a fixed point.

Proposition 13.10.6 Let $A$ be a retract of $B$ and suppose $B$ has the fixed point property. Then so does $A$.

Proof: Suppose $\mathbf{f}: A \rightarrow A$. Let $\mathbf{h}$ be the retract of $B$ onto $A$. Then $\mathbf{f} \circ \mathbf{h}: B \rightarrow B$ is continuous. Thus, it has a fixed point $\mathbf{x} \in B$ so $\mathbf{f}(\mathbf{h}(\mathbf{x}))=\mathbf{x}$. However, $\mathbf{h}(\mathbf{x}) \in A$ and $\mathbf{f}: A \rightarrow A$ so in fact, $\mathbf{x} \in A$. Now $h(\mathbf{x})=\mathbf{x}$ and so $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Recall that every convex compact subset $K$ of $\mathbb{R}^{p}$ is a retract of all of $\mathbb{R}^{p}$ obtained by using the projection map. In particular, $K$ is a retract of a large closed ball containing $K$ which has the fixed point property. Therefore, $K$ also has the fixed point property. This shows the following which is often called the Brouwer fixed point theorem.

Theorem 13.10.7 Every convex closed and bounded subset of $\mathbb{R}^{p}$ has the fixed point property.

### 13.11 The Brouwer Fixed Point Theorem Another Proof

This proof is also based on Lemma 16.3.1. I found this proof of the Brouwer fixed point theorem or one close to it in Evans [48]. It is even shorter than the proof just presented. I think it might be easier to remember also. It is also based on Lemma 16.3.1 which is stated next for convenience.

Lemma 13.11.1 Let $\mathbf{g}: U \rightarrow \mathbb{R}^{p}$ be $C^{2}$ where $U$ is an open subset of $\mathbb{R}^{p}$. Then

$$
\sum_{j=1}^{p} \operatorname{cof}(D \mathbf{g})_{i j, j}=0
$$

where here $(D \mathbf{g})_{i j} \equiv g_{i, j} \equiv \frac{\partial g_{i}}{\partial x_{j}}$. Also, $\operatorname{cof}(D \mathbf{g})_{i j}=\frac{\partial \operatorname{det}(D \mathbf{g})}{\partial g_{i, j}}$.
Definition 13.11.2 Let $\mathbf{h}$ be a function defined on an open set, $U \subseteq \mathbb{R}^{p}$. Then $\mathbf{h} \in C^{k}(\bar{U})$ if there exists a function $\mathbf{g}$ defined on an open set, $W$ containng $\bar{U}$ such that $\mathbf{g}=\mathbf{h}$ on $U$ and $\mathbf{g}$ is $C^{k}(W)$.
Lemma 13.11.3 There does not exist $\mathbf{h} \in C^{2}(\overline{B(\mathbf{0}, R)})$ such that $\mathbf{h}: \overline{B(\mathbf{0}, R)} \rightarrow \partial B(\mathbf{0}, R)$ which also has the property that $\mathbf{h}(\mathbf{x})=\mathbf{x}$ for all $\mathbf{x} \in \partial B(\mathbf{0}, R)$. Such a function is called a retract.

Proof: Here and below, let $B_{R}$ denote $\overline{B(\mathbf{0}, R)}$. Suppose such an $\mathbf{h}$ exists. Let $\lambda \in[0,1]$ and let $\mathbf{p}_{\lambda}(\mathbf{x}) \equiv \mathbf{x}+\lambda(\mathbf{h}(\mathbf{x})-\mathbf{x})$. This function, $\mathbf{p}_{\lambda}$ is a homotopy of the identity map and the retraction, $\mathbf{h}$. Let

$$
I(\lambda) \equiv \int_{B(\mathbf{0}, R)} \operatorname{det}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right) d x
$$

Then using the dominated convergence theorem,

$$
\begin{aligned}
I^{\prime}(\lambda) & =\int_{B(\mathbf{0}, R)} \sum_{i . j} \frac{\partial \operatorname{det}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)}{\partial p_{\lambda i, j}} \frac{\partial p_{\lambda i j}(\mathbf{x})}{\partial \lambda} d x \\
& =\int_{B(\mathbf{0}, R)} \sum_{i} \sum_{j} \frac{\partial \operatorname{det}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)}{\partial p_{\lambda i, j}}\left(h_{i}(\mathbf{x})-x_{i}\right)_{, j} d x \\
& =\int_{B(\mathbf{0}, R)} \sum_{i} \sum_{j} \operatorname{cof}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)_{i j}\left(h_{i}(\mathbf{x})-x_{i}\right)_{, j} d x
\end{aligned}
$$

Now by assumption, $h_{i}(\mathbf{x})=x_{i}$ on $\partial B(\mathbf{0}, R)$ and so one can integrate by parts and write

$$
I^{\prime}(\lambda)=-\sum_{i} \int_{B(\mathbf{0}, R)} \sum_{j} \operatorname{cof}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)_{i j, j}\left(h_{i}(\mathbf{x})-x_{i}\right) d x=0
$$

Therefore, $I(\lambda)$ equals a constant. However, $|\mathbf{h}(\mathbf{x})|^{2}=R^{2}$ so $\sum_{i=1}^{p} h_{i}(\mathbf{x}) h_{i}(\mathbf{x})=R^{2}$ and so, differentiating with respect to $j$,

$$
2 \sum_{i=1}^{p} h_{i, j}(\mathbf{x}) h_{i}(\mathbf{x})=0 \text { so } D \mathbf{h}(\mathbf{x})^{T} \mathbf{h}(\mathbf{x})=0
$$

and so, since $\mathbf{h}(\mathbf{x}) \neq \mathbf{0}, D \mathbf{h}(\mathbf{x})^{T}$ is not invertible. Hence $\operatorname{det}(D \mathbf{h}(\mathbf{x}))=0$ and so $I(1)=0 \neq$ $I(0)=m_{p}(B(\mathbf{0}, R))$. This is a contradiction.

The following is the Brouwer fixed point theorem for $C^{2}$ maps.
Lemma 13.11.4 If $\mathbf{h} \in C^{2}(\overline{B(\mathbf{0}, R)})$ and $\mathbf{h}: \overline{B(\mathbf{0}, R)} \rightarrow \overline{B(\mathbf{0}, R)}$, then $\mathbf{h}$ has a fixed point, $\mathbf{x}$ such that $\mathbf{h}(\mathbf{x})=\mathbf{x}$.

Proof: Suppose the lemma is not true. Then for all $\mathbf{x},|\mathbf{x}-\mathbf{h}(\mathbf{x})| \neq 0$. Then define

$$
\mathbf{g}(\mathbf{x})=\mathbf{h}(\mathbf{x})+\frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|} t(\mathbf{x})
$$

where $t(\mathbf{x})$ is nonnegative and is chosen such that $\mathbf{g}(\mathbf{x}) \in \partial B(\mathbf{0}, R)$.
This mapping is illustrated in the following picture.

If $\mathbf{x} \rightarrow t(\mathbf{x})$ is $C^{2}$ near $\overline{B(\mathbf{0}, R)}$, it will follow $\mathbf{g}$ is a $C^{2}$ retraction onto $\partial B(\mathbf{0}, R)$ contrary to Lemma 13.11.3. Thus $t(\mathbf{x})$ is the nonnegative solution to

$$
\begin{equation*}
|\mathbf{h}(\mathbf{x})|^{2}+2\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right) t+t^{2}=R^{2} \tag{13.11.28}
\end{equation*}
$$

then by the quadratic formula,

$$
t(\mathbf{x})=-\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right)+\sqrt{\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right)^{2}+\left(R^{2}-|\mathbf{h}(\mathbf{x})|^{2}\right)}
$$

Is $\mathbf{x} \rightarrow t(\mathbf{x}) C^{2}$ ? If what is under the radical is positive, then there is no problem because $s \rightarrow \sqrt{s}$ is smooth for $s>0$. In fact, this is the case here. The inside of the radical is positive
if $R>|\mathbf{h}(\mathbf{x})|$. If $|\mathbf{h}(\mathbf{x})|=R$, it is still positive because in this case, the angle between $\mathbf{h}(\mathbf{x})$ and $\mathbf{x}-\mathbf{h}(\mathbf{x})$ cannot be $\pi / 2$. This shows that $\mathbf{x} \rightarrow t(\mathbf{x})$ is the composition of $C^{2}$ functions and is therefore $C^{2}$. Thus this $\mathbf{g}(\mathbf{x})$ is a $C^{2}$ retract and by the above lemma, there isn't one.

Now it is easy to prove the Brouwer fixed point theorem. The following theorem is the Brouwer fixed point theorem for a ball.

Theorem 13.11.5 Let $B_{R}$ be the above closed ball and let $\mathbf{f}: B_{R} \rightarrow B_{R}$ be continuous. Then there exists $\mathbf{x} \in B_{R}$ such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Proof: Let $\mathbf{f}_{k}(\mathbf{x}) \equiv \frac{\mathbf{f}(\mathbf{x})}{1+k^{-1}}$. Thus

$$
\begin{aligned}
\left\|\mathbf{f}_{k}-\mathbf{f}\right\| & =\max _{\mathbf{x} \in B_{R}}\left\{\left|\frac{\mathbf{f}(\mathbf{x})}{1+(1 / k)}-\mathbf{f}(\mathbf{x})\right|\right\}=\max _{\mathbf{x} \in B_{R}}\left\{\left|\frac{\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{x})(1+(1 / k))}{1+(1 / k)}\right|\right\} \\
& =\max _{\mathbf{x} \in B_{R}}\left\{\left|\frac{\mathbf{f}(\mathbf{x})(1 / k)}{1+(1 / k)}\right|\right\} \leq \frac{R}{1+k}
\end{aligned}
$$

Letting $\|\mathbf{h}\| \equiv \max \left\{|\mathbf{h}(\mathbf{x})|: \mathbf{x} \in B_{R}\right\}$, It follows from the Weierstrass approximation theorem, there exists a function whose components are polynomials $\mathbf{g}_{k}$ such that $\left\|\mathbf{g}_{k}-\mathbf{f}_{k}\right\|<$ $\frac{R}{k+1}$. Then if $\mathbf{x} \in B_{R}$, it follows

$$
\begin{aligned}
\left|\mathbf{g}_{k}(\mathbf{x})\right| & \leq\left|\mathbf{g}_{k}(\mathbf{x})-\mathbf{f}_{k}(\mathbf{x})\right|+\left|\mathbf{f}_{k}(\mathbf{x})\right| \\
& <\frac{R}{1+k}+\frac{k R}{1+k}=R
\end{aligned}
$$

and so $\mathbf{g}_{k}$ maps $B_{R}$ to $B_{R}$. By Lemma 13.10.2 each of these $\mathbf{g}_{k}$ has a fixed point $\mathbf{x}_{k}$ such that $\mathbf{g}_{k}\left(\mathbf{x}_{k}\right)=\mathbf{x}_{k}$. The sequence of points, $\left\{\mathbf{x}_{k}\right\}$ is contained in the compact set, $B_{R}$ and so there exists a convergent subsequence still denoted by $\left\{\mathbf{x}_{k}\right\}$ which converges to a point $\mathbf{x} \in B_{R}$. Then

$$
\begin{aligned}
|\mathbf{f}(\mathbf{x})-\mathbf{x}| & \leq\left|\mathbf{f}(\mathbf{x})-\mathbf{f}_{k}(\mathbf{x})\right|+\left|\mathbf{f}_{k}(\mathbf{x})-\mathbf{f}_{k}\left(\mathbf{x}_{k}\right)\right|+|\mathbf{f}_{k}\left(\mathbf{x}_{k}\right)-\overbrace{\mathbf{g}_{k}\left(\mathbf{x}_{k}\right)}^{=\mathbf{x}_{k}}|+\left|\mathbf{x}_{k}-\mathbf{x}\right| \\
& \leq \frac{R}{1+k}+\left|\mathbf{f}(\mathbf{x})-\mathbf{f}\left(\mathbf{x}_{k}\right)\right|+\frac{R}{1+k}+\left|\mathbf{x}_{k}-\mathbf{x}\right| .
\end{aligned}
$$

Now let $k \rightarrow \infty$ in the right side to conclude $\mathbf{f}(\mathbf{x})=\mathbf{x}$.
It is not surprising that the ball does not need to be centered at $\mathbf{0}$.
Corollary 13.11.6 Let $\mathbf{f}: \overline{B(\mathbf{a}, R)} \rightarrow \overline{B(\mathbf{a}, R)}$ be continuous. Then there exists $\mathbf{x} \in \overline{B(\mathbf{a}, R)}$ such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Proof: Let $\mathbf{g}: B_{R} \rightarrow B_{R}$ be defined by $\mathbf{g}(\mathbf{y}) \equiv \mathbf{f}(\mathbf{y}+\mathbf{a})-\mathbf{a}$. Then $\mathbf{g}$ is a continuous map from $B_{R}$ to $B_{R}$. Therefore, there exists $\mathbf{y} \in B_{R}$ such that $\mathbf{g}(\mathbf{y})=\mathbf{y}$. Therefore, $\mathbf{f}(\mathbf{y}+\mathbf{a})-$ $\mathbf{a}=\mathbf{y}$ and so letting $\mathbf{x}=\mathbf{y}+\mathbf{a}, \mathbf{f}$ also has a fixed point as claimed.

Definition 13.11.7 $A$ set $A$ is a retract of a set $B$ if $A \subseteq B$, and there is a continuous map $\mathbf{h}: B \rightarrow A$ such that $\mathbf{h}(\mathbf{x})=\mathbf{x}$ for all $\mathbf{x} \in A$ and $\mathbf{h}$ is onto. $B$ has the fixed point property means that whenever $\mathbf{g}$ is continuous and $\mathbf{g}: B \rightarrow B$, it follows that $\mathbf{g}$ has a fixed point.

Proposition 13.11.8 Let $A$ be a retract of $B$ and suppose $B$ has the fixed point property. Then so does $A$.

Proof: Suppose $\mathbf{f}: A \rightarrow A$. Let $\mathbf{h}$ be the retract of $B$ onto $A$. Then $\mathbf{f} \circ \mathbf{h}: B \rightarrow B$ is continuous. Thus, it has a fixed point $\mathbf{x} \in B$ so $\mathbf{f}(\mathbf{h}(\mathbf{x}))=\mathbf{x}$. However, $\mathbf{h}(\mathbf{x}) \in A$ and $\mathbf{f}: A \rightarrow A$ so in fact, $\mathbf{x} \in A$. Now $h(\mathbf{x})=\mathbf{x}$ and so $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Recall that every convex compact subset $K$ of $\mathbb{R}^{p}$ is a retract of all of $\mathbb{R}^{p}$ obtained by using the projection map. In particular, $K$ is a retract of a large closed ball containing $K$ which has the fixed point property. Therefore, $K$ also has the fixed point property. This shows the following which is often called the Brouwer fixed point theorem.

Corollary 13.11.9 Every convex closed and bounded subset of $\mathbb{R}^{p}$ has the fixed point property.

### 13.12 Invariance Of Domain

This principal says that if $\mathbf{f}: U \subseteq \mathbb{R}^{n} \rightarrow \mathbf{f}(U) \subseteq \mathbb{R}^{n}$ where $U$ is open and $\mathbf{f}$ is one to one and continuous, then $\mathbf{f}(U)$ is also open. To do this, we first prove the following lemma. I found something like this on the web. I liked it a lot because it shows how the Brouwer fixed point theorem implies the invariance of domain. The other ways I know about involve degree theory or some sort of algebraic topology. I will give two proofs of the following lemma, the first being somewhat more informal than the second.

Lemma 13.12.1 Let $B$ be a closed ball in $\mathbb{R}^{n}$ centered at a which has radius $r$. Let $\mathbf{f}: B \rightarrow$ $\mathbb{R}^{n}$. Then $\mathbf{f}(\mathbf{a})$ is an interior point of $\mathbf{f}(B)$.

Proof: Since $\mathbf{f}(B)$ is compact and $\mathbf{f}$ is one to one, $\mathbf{f}^{-1}$ is continuous on $\mathbf{f}(B)$. Use Tietze extension theorem on components of $\mathbf{f}^{-1}$ or some such thing to obtain $\mathbf{g}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ such that $\mathbf{g}$ is continuous and equals $\mathbf{f}^{-1}$ on $\mathbf{f}(B)$. Then multiply by a suitable truncation function to get $\mathbf{g}$ uniformly continuous on $\mathbb{R}^{n}$.

Suppose $\mathbf{f}(\mathbf{a})$ is not an interior point of $\mathbf{f}(B)$. Then there exists $\mathbf{c}_{k} \rightarrow \mathbf{f}(\mathbf{a})$ but $\mathbf{c}_{k} \notin \mathbf{f}(B)$. In the picture, let $C_{k}$ be a sphere whose radius is

$$
2\left|\mathbf{c}_{k}-\mathbf{f}(\mathbf{a})\right|
$$

Let $\hat{\mathbf{g}}_{k}$ be $C^{1}$ and let it satisfy

$$
\left\|\hat{\mathbf{g}}_{k}-\mathbf{g}\right\|_{\mathbf{f}(B) \cup D} \equiv \max _{\mathbf{y} \in \mathbf{f}(B) \cup D}|\hat{\mathbf{g}}(\mathbf{y})-\mathbf{g}(\mathbf{y})|<\varepsilon_{k}
$$

$\varepsilon_{k}$ is very small, $\varepsilon_{k} \rightarrow 0$. How small will be considered later. Here $D$ is a large closed disk which contains all of the spheres $C_{k}$ considered above. The idea is to have a large compact set which includes everything of interest below.

To get $\hat{\mathbf{g}}_{k}$,you could use the Weierstrass approximation theorem, Theorem 9.2.9. An easier way involving convolution will be presented in the next chapter. Also let $\mathbf{a} \notin \hat{\mathbf{g}}_{k}\left(C_{k}\right)$. This is no problem. $C_{k}$ has measure zero and so $\hat{\mathbf{g}}\left(C_{k}\right)$ also has measure zero thanks to the assumption that $\hat{\mathbf{g}}$ is $C^{1}$ and Lemma 13.5.1. Therefore, you could simply add a small enough nonzero vector to $\hat{\mathbf{g}}$ to preserve the above inequality of $\hat{\mathbf{g}}$ and $\mathbf{g}$ so that $\hat{\mathbf{g}}\left(C_{k}\right)$ no longer contains $\mathbf{a}$. That is, replace $\hat{\mathbf{g}}$ with $\hat{\mathbf{g}}+\mathbf{a}-\mathbf{b}$ where $|\mathbf{a}-\mathbf{b}|$ is very small but $\mathbf{b} \notin$ $\hat{\mathbf{g}}\left(C_{k}\right)$.

There is a set $\Sigma_{k}$ consisting of that part of $\mathbf{f}(B)$ which is outside of the sphere $C_{k}$ in the picture along with the sphere $C_{k}$ itself. By construction, $\hat{\mathbf{g}}_{k}$ misses a on $C_{k}$. As to the other part of $\Sigma_{k}, \mathbf{g}$ misses a on this part, because $\mathbf{f}$ is one to one and so $\mathbf{f}^{-1}$ is also. Now we will squash the part of $\mathbf{f}(B)$ inside $C_{k}$ onto $C_{k}$ while leaving the rest of $\mathbf{f}(B)$ unchanged.

Let $\Phi_{k}$ be defined on $\mathbf{f}(B)$

$$
\Phi_{k}(\mathbf{y}) \equiv \max \left(\frac{2\left|\mathbf{c}_{k}-\mathbf{f}(\mathbf{a})\right|}{\left|\mathbf{y}-\mathbf{c}_{k}\right|}, 1\right)\left(\mathbf{y}-\mathbf{c}_{k}\right)+\mathbf{c}_{k}
$$

This $\Phi_{k}$ squishes the part of $\mathbf{f}(B)$ inside $C_{k}$ to $C_{k}$ and leaves the rest of $\mathbf{f}(B)$ unchanged. Thus

$$
\Phi_{k}: \mathbf{f}(B) \rightarrow \mathbf{f}(B) \cap\left[\mathbf{y}:\left|\mathbf{y}-\mathbf{c}_{k}\right| \geq 2\left|\mathbf{c}_{k}-\mathbf{f}(\mathbf{a})\right|\right] \cup C_{k}
$$

a compact set. Now $\left\|\hat{\mathbf{g}}_{k} \circ \Phi_{k}-\mathbf{g}\right\|_{\mathbf{f}(B)} \rightarrow 0$ and $\mathbf{g}$ misses a on the part of $\mathbf{f}(B)$ outside of $C_{k}$. In the above, we chose $\hat{\mathbf{g}}_{k}$ so close to $\mathbf{g}$ that it also misses a on the part of $\mathbf{f}(B)$ which is outside of $C_{k}$. Then by construction, $\hat{\mathbf{g}}_{k}$ misses $\mathbf{a}$ on $C_{k}$ and so in fact $\hat{\mathbf{g}}_{k} \circ \Phi_{k}$ misses $\mathbf{a}$ on $\mathbf{f}(B)$. Now consider $\mathbf{a}+\mathbf{x}-\hat{\mathbf{g}}_{k}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)$ for $\mathbf{x} \in B$.

$$
\begin{gathered}
\left|\mathbf{a}+\mathbf{x}-\hat{\mathbf{g}}_{k}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)-\mathbf{a}\right|=|\mathbf{x}-\hat{\mathbf{g}}(\Phi(\mathbf{f}(\mathbf{x})))| \\
=\left|\mathbf{g}(\mathbf{f}(\mathbf{x}))-\hat{\mathbf{g}}_{k}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)\right|
\end{gathered}
$$

For $\mathbf{f}(\mathbf{x})$ outside of $C_{k}$, we could have chosen $\hat{\mathbf{g}}_{k}$ such that $\left\|\mathbf{g}-\hat{\mathbf{g}}_{k}\right\|_{\mathbf{f}(B)}<\frac{r}{2}$ and this was indeed done. When $\mathbf{f}(\mathbf{x})$ is inside $C_{k}$, then eventually, for large $k$, both $\mathbf{g}(\mathbf{f}(\mathbf{x})), \hat{\mathbf{g}}_{k}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)$ are close to $\mathbf{g}(\mathbf{f}(\mathbf{a}))$. To see this,

$$
\begin{aligned}
& \left|\hat{\mathbf{g}}_{k}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)-\mathbf{g}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)\right|+\left|\mathbf{g}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)-\mathbf{g}(\mathbf{f}(\mathbf{x}))\right| \\
\leq & \left\|\hat{\mathbf{g}}_{k}-\mathbf{g}\right\|_{\mathbf{f}(B) \cup D}+\left|\mathbf{g}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)-\mathbf{g}(\mathbf{f}(\mathbf{x}))\right|
\end{aligned}
$$

the last term being small for large $k$, and so for large $k, \mathbf{x} \rightarrow \mathbf{a}+\mathbf{x}-\hat{\mathbf{g}}_{k}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)$ maps $B$ to $B$ and so by Brouwer fixed point theorem, it has a fixed point and hence $\hat{\mathbf{g}}_{k}\left(\Phi_{k}(\mathbf{f}(\mathbf{x}))\right)=\mathbf{a}$ contrary to what was argued above. Hence, $\mathbf{f}(\mathbf{a})$ must be an interior point after all.

Now here is the same lemma with the details.

Lemma 13.12.2 Let $B$ be a closed ball in $\mathbb{R}^{n}$ centered at a which has radius $r$. Let $\mathbf{f}: B \rightarrow$ $\mathbb{R}^{n}$. Then $\mathbf{f}(\mathbf{a})$ is an interior point of $\mathbf{f}(B)$.

Proof: Since $\mathbf{f}(B)$ is compact and $\mathbf{f}$ is one to one, $\mathbf{f}^{-1}$ is continuous on $\mathbf{f}(\boldsymbol{B})$. Use Tietze extension theorem on components of $\mathbf{f}^{-1}$ or some such thing to obtain $\mathbf{g}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ such that $\mathbf{g}$ is continuous and equals $\mathbf{f}^{-1}$ on $\mathbf{f}(B)$.

Suppose $\mathbf{f}(\mathbf{a})$ is not an interior point of $\mathbf{f}(B)$. Then for every $\varepsilon>0$ there exists $\mathbf{c}_{\varepsilon} \in$ $B(\mathbf{f}(\mathbf{a}), \varepsilon) \backslash \mathbf{f}(B)$. So fix $\varepsilon$ small and refer to $\mathbf{c}_{\varepsilon}$ as $\mathbf{c}$. $\varepsilon$ will be so small that

$$
|\mathbf{g}(\mathbf{y})-\mathbf{g}(\mathbf{f}(\mathbf{a}))|<\frac{r}{10} \text { for } \mathbf{y} \in B(\mathbf{f}(\mathbf{a}), 4 \varepsilon)
$$

There is $\delta>0$ such that if $|\mathbf{x}-\hat{\mathbf{x}}|<\boldsymbol{\delta}$, then

$$
\begin{equation*}
|\mathbf{f}(\mathbf{x})-\mathbf{f}(\hat{\mathbf{x}})|<\varepsilon \tag{13.12.29}
\end{equation*}
$$

Let $\hat{\mathbf{g}}$ be $C^{1}$ and on $\mathbf{f}(B)$, let it satisfy

$$
\|\hat{\mathbf{g}}-\mathbf{g}\|_{\mathbf{f}(B)} \equiv \max _{\mathbf{y} \in \mathbf{f}(B)}|\hat{\mathbf{g}}(\mathbf{y})-\mathbf{g}(\mathbf{y})|<\min \left(\frac{r}{10}, \frac{\delta}{2}\right)
$$

To get $\hat{\mathbf{g}}_{k}$,you could use the Weierstrass approximation theorem, Theorem 9.2.9. An easier way involving convolution will be presented in the next chapter. Also let $\mathbf{a} \notin \hat{\mathbf{g}}(\partial B(\mathbf{c}, 2 \varepsilon))$. This is no problem. $\partial B(\mathbf{a}, 2 \varepsilon)$ has measure zero and so $\hat{\mathbf{g}}(\partial B(\mathbf{c}, \varepsilon))$ also has measure zero thanks to the assumption that $\hat{\mathbf{g}}$ is $C^{1}$ and Lemma 13.5.1. Therefore, you could simply add a small enough nonzero vector to $\hat{\mathbf{g}}$ to preserve the above inequality of $\hat{\mathbf{g}}$ and $\mathbf{g}$ so that $\hat{\mathbf{g}}(\partial B(\mathbf{c}, 2 \varepsilon))$ no longer contains $\mathbf{a}$. That is, replace $\hat{\mathbf{g}}$ with $\hat{\mathbf{g}}+\mathbf{a}-\mathbf{b}$ where $|\mathbf{a}-\mathbf{b}|$ is very small but $\mathbf{b} \notin \hat{\mathbf{g}}(\partial B(\mathbf{c}, 2 \varepsilon))$. A summary of the rest of the argument is contained in the following picture in which the sphere has radius $2 \varepsilon$.

There is a set $\Sigma$ consisting of that part of $\mathbf{f}(B)$ which is outside of the sphere $C$ in the picture along with the sphere $C$ itself. By construction, $\hat{\mathbf{g}}$ misses a on $C$. As to the other part of $\Sigma$, that $\mathbf{g}$ misses a on this part, follows from the assumption that $\mathbf{f}$ is one to one and so $\mathbf{f}^{-1}$ is also. Then $\hat{\mathbf{g}}$ missing a follows from $\hat{\mathbf{g}}$ being close enough to $\mathbf{g}$. We define a continuous mapping $\Phi$ which maps $\mathbf{f}(B)$ to this set $\Sigma$. This map squishes that part of $\mathbf{f}(B)$ which is inside $C$ onto $C$ and does nothing to the part of $\mathbf{f}(B)$ which is outside of $C$. This is where $\mathbf{c}$ not in $\mathbf{f}(B)$ but close to $\mathbf{f}(B)$ is used. Then we argue that $\hat{\mathbf{g}} \circ \Phi$ is continuous and close to $\mathbf{g}$ and misses $\mathbf{a}$. It will be close to $\mathbf{g}$ and $\hat{\mathbf{g}}$ because of the above assumption that everything inside $C$ is close to $\mathbf{f}(\mathbf{a})$ and $\mathbf{g}$ and $\hat{\mathbf{g}}$ are continuous. This will yield an easy contradiction from a use of the Brouwer fixed point theorem.

Now let $\Phi$ be defined on $\mathbf{f}(B)$

$$
\Phi(\mathbf{y}) \equiv \max \left(\frac{2 \varepsilon}{|\mathbf{y}-\mathbf{c}|}, 1\right)(\mathbf{y}-\mathbf{c})+\mathbf{c}
$$

If $|\mathbf{y}-\mathbf{c}| \geq 2 \varepsilon$, then $\Phi(\mathbf{y})=\mathbf{y}$. If $|\mathbf{y}-\mathbf{c}|<2 \varepsilon$, then $\Phi(\mathbf{y})=\frac{2 \varepsilon}{|\mathbf{y}-\mathbf{c}|}(\mathbf{y}-\mathbf{c})+\mathbf{c}$ and so

$$
|\Phi(\mathbf{y})-\mathbf{c}|=2 \varepsilon \frac{|\mathbf{y}-\mathbf{c}|}{|\mathbf{y}-\mathbf{c}|}=2 \varepsilon
$$

Note that this function is well defined because $\mathbf{c} \notin \mathbf{f}(B)$. Thus

$$
\Phi: \mathbf{f}(B) \rightarrow \mathbf{f}(B) \cap[\mathbf{y}:|\mathbf{y}-\mathbf{c}| \geq 2 \varepsilon] \cup \partial B(\mathbf{c}, 2 \varepsilon) \equiv \Sigma
$$

a compact set. Now the interesting thing about this set $\Sigma$ is this. For $\mathbf{y} \in \Sigma, \hat{\mathbf{g}}(\mathbf{y}) \neq \mathbf{a}$. Why is this? It is because by construction, $\mathbf{a} \notin \hat{\mathbf{g}}(\partial B(\mathbf{c}, 2 \varepsilon))$. What if $\mathbf{y} \in \mathbf{f}(B) \cap[\mathbf{y}:|\mathbf{y}-\mathbf{c}| \geq 2 \varepsilon]$, the other set in $\Sigma$ ? Could $\hat{\mathbf{g}}(\mathbf{y})=\mathbf{a}$ ? If so, then

$$
|\mathbf{g}(\mathbf{y})-\mathbf{a}| \leq|\mathbf{g}(\mathbf{y})-\hat{\mathbf{g}}(\mathbf{y})|+|\hat{\mathbf{g}}(\mathbf{y})-\mathbf{a}| \leq \frac{\delta}{2}
$$

and so by 13.12.29,

$$
|\mathbf{y}-\mathbf{f}(\mathbf{a})|<\varepsilon
$$

But $|\mathbf{y}-\mathbf{c}| \geq 2 \varepsilon$ and so

$$
|\mathbf{y}-\mathbf{f}(\mathbf{a})| \geq|\mathbf{y}-\mathbf{c}|-|\mathbf{c}-\mathbf{f}(\mathbf{a})| \geq 2 \varepsilon-|\mathbf{c}-\mathbf{f}(\mathbf{a})| \geq 2 \varepsilon-\varepsilon=\varepsilon
$$

which contradicts the above inequality.
Therefore, $\hat{\mathbf{g}}(\mathbf{y}) \neq \mathbf{a}$ for any $\mathbf{y} \in \Sigma$. So consider $\hat{\mathbf{g}}(\Phi(\mathbf{y}))$ for $\mathbf{y} \in \mathbf{f}(B)$.

$$
\begin{align*}
& |\hat{\mathbf{g}}(\Phi(\mathbf{y}))-\mathbf{g}(\mathbf{y})| \leq|\hat{\mathbf{g}}(\Phi(\mathbf{y}))-\mathbf{g}(\Phi(\mathbf{y}))|+|\mathbf{g}(\Phi(\mathbf{y}))-\mathbf{g}(\mathbf{y})| \\
& \quad \leq \frac{r}{10}+|\mathbf{g}(\Phi(\mathbf{y}))-\mathbf{g}(\mathbf{f}(\mathbf{a}))-(\mathbf{g}(\mathbf{y})-\mathbf{g}(\mathbf{f}(\mathbf{a})))| \tag{13.12.30}
\end{align*}
$$

This last equals 0 if $|\mathbf{y}-\mathbf{c}| \geq 2 \varepsilon$. On the other hand, if $|\mathbf{y}-\mathbf{c}|<2 \varepsilon$,

$$
\mathbf{y} \in B(\mathbf{f}(\mathbf{a}), 2 \varepsilon), \Phi(\mathbf{y}) \in \partial B(\mathbf{c}, 2 \varepsilon)
$$

so both $\mathbf{y}, \Phi(\mathbf{y})$ are in $B(\mathbf{f}(\mathbf{a}), 4 \varepsilon)$ and so this last term in 13.12.30 is no larger than $|\mathbf{g}(\Phi(\mathbf{y})-\mathbf{g}(\mathbf{f}(\mathbf{a})))|+|\mathbf{g}(\mathbf{y})-\mathbf{g}(\mathbf{f}(\mathbf{a}))|<\frac{r}{10}+\frac{r}{10}$ and so for all $\mathbf{y} \in \mathbf{f}(B)$,

$$
|\hat{\mathbf{g}}(\Phi(\mathbf{y}))-\mathbf{g}(\mathbf{y})| \leq \frac{3 r}{10}
$$

Now note that for $\mathbf{x} \in B$, from what was just shown,

$$
|\hat{\mathbf{g}}(\Phi(\mathbf{f}(\mathbf{x})))-\mathbf{x}|=|\hat{\mathbf{g}}(\Phi(\mathbf{f}(\mathbf{x})))-\mathbf{g}(\mathbf{f}(\mathbf{x}))| \leq \frac{3 r}{10}
$$

It follows that for every $\mathbf{x} \in B, \mathbf{a}+\mathbf{x}-\hat{\mathbf{g}}(\Phi(\mathbf{f}(\mathbf{x}))) \in B$ and so by the Brouwer fixed point theorem, there is a fixed point $\mathbf{x}$ and hence

$$
\mathbf{a}+\mathbf{x}-\hat{\mathbf{g}}(\Phi(\mathbf{f}(\mathbf{x})))=\mathbf{x}
$$

so $\hat{\mathbf{g}}(\Phi(\mathbf{f}(\mathbf{x})))=\mathbf{a}$ contrary to what was just shown that there is no solution to $\hat{\mathbf{g}}(\mathbf{y})=\mathbf{a}$ for $\mathbf{y} \in \Sigma$.

With the lemma, it is easy to prove the invariance of domain theorem which is as follows.

Theorem 13.12.3 Let $U$ be an open set in $\mathbb{R}^{n}$ and let $\mathbf{f}: U \rightarrow \mathbf{f}(U) \subseteq \mathbb{R}^{n}$. Then $\mathbf{f}(U)$ is also an open set in $\mathbb{R}^{n}$.

Proof: For $\mathbf{a} \in U$, let $\mathbf{a} \in B_{\mathbf{a}} \subseteq U$, where $B_{\mathbf{a}}$ is a closed ball centered at $\mathbf{a}$. Then from Lemma 13.12.2, $\mathbf{f}(\mathbf{a}) \in V_{\mathbf{f}(\mathbf{a})}$ an open subset of $\mathbf{f}\left(B_{\mathbf{a}}\right)$. Hence $\mathbf{f}(U)=\cup_{\mathbf{a} \in U} V_{\mathbf{f}(\mathbf{a})}$ which is open.

### 13.13 Besicovitch Covering Theorem

The Besicovitch covering theorem is one of the most amazing and insightful ideas that I have ever encountered. It is simultaneously elegant, elementary and profound. The next section is an attempt to present this wonderful result.

When dealing with probability distribution functions or some other Radon measure, it is necessary to have a better covering theorem than the Vitali covering theorem which works well for Lebesgue measure. However, for a Radon measure, if you enlarge the ball by making the radius larger, you don't know what happens to the measure of the enlarged
ball except that its measure does not get smaller. Thus the thing required is a covering theorem which does not depend on enlarging balls.

This all works in a normed linear space $(X,\|\cdot\|)$ which has dimension $p$. Here is a sequence of balls from $\mathscr{F}$ in the case that the set of centers of these balls is bounded. I will denote by $r\left(B_{k}\right)$ the radius of a ball $B_{k}$.

## A construction of a sequence of balls

Lemma 13.13.1 Let $\mathscr{F}$ be a nonempty set of nonempty balls in $X$ with

$$
\sup \{\operatorname{diam}(B): B \in \mathscr{F}\}=D<\infty
$$

and let A denote the set of centers of these balls. Suppose $A$ is bounded. Define a sequence of balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{J}$ where $J \leq \infty$ such that

$$
\begin{equation*}
r\left(B_{1}\right)>\frac{3}{4} \sup \{r(B): B \in \mathscr{F}\} \tag{13.13.31}
\end{equation*}
$$

and if

$$
\begin{equation*}
A_{m} \equiv A \backslash\left(\cup_{i=1}^{m} B_{i}\right) \neq \emptyset, \tag{13.13.32}
\end{equation*}
$$

then $B_{m+1} \in \mathscr{F}$ is chosen with center in $A_{m}$ such that

$$
\begin{equation*}
r\left(B_{m}\right)>r\left(B_{m+1}\right)>\frac{3}{4} \sup \left\{r: B(\mathbf{a}, r) \in \mathscr{F}, \mathbf{a} \in A_{m}\right\} \tag{13.13.33}
\end{equation*}
$$

Then letting $B_{j}=B\left(\mathbf{a}_{j}, r_{j}\right)$, this sequence satisfies $\left\{B\left(\mathbf{a}_{j}, r_{j} / 3\right)\right\}_{j=1}^{J}$ are disjoint,.

$$
\begin{equation*}
A \subseteq \cup_{i=1}^{J} B_{i} \tag{13.13.34}
\end{equation*}
$$

Proof: First note that $B_{m+1}$ can be chosen as in 13.13.33. This is because the $A_{m}$ are decreasing and so

$$
\begin{aligned}
& \frac{3}{4} \sup \left\{r: B(\mathbf{a}, r) \in \mathscr{F}, \mathbf{a} \in A_{m}\right\} \\
\leq & \frac{3}{4} \sup \left\{r: B(\mathbf{a}, r) \in \mathscr{F}, \mathbf{a} \in A_{m-1}\right\}<r\left(B_{m}\right)
\end{aligned}
$$

Thus the $r\left(B_{k}\right)$ are strictly decreasing and so no $B_{k}$ contains a center of any other $B_{j}$.
If $\mathbf{x} \in B\left(\mathbf{a}_{j}, r_{j} / 3\right) \cap B\left(\mathbf{a}_{i}, r_{i} / 3\right)$ where these balls are two which are chosen by the above scheme such that $j>i$, then from what was just shown

$$
\left\|\mathbf{a}_{j}-\mathbf{a}_{i}\right\| \leq\left\|\mathbf{a}_{j}-\mathbf{x}\right\|+\left\|\mathbf{x}-\mathbf{a}_{i}\right\| \leq \frac{r_{j}}{3}+\frac{r_{i}}{3} \leq\left(\frac{1}{3}+\frac{1}{3}\right) r_{i}=\frac{2}{3} r_{i}<r_{i}
$$

and this contradicts the construction because $\mathbf{a}_{j}$ is not covered by $B\left(\mathbf{a}_{i}, r_{i}\right)$.
Finally consider the claim that $A \subseteq \cup_{i=1}^{J} B_{i}$. Pick $B_{1}$ satisfying 13.13.31. If $B_{1}, \cdots, B_{m}$ have been chosen, and $A_{m}$ is given in 13.13.32, then if $A_{m}=\emptyset$, it follows $A \subseteq \cup_{i=1}^{m} B_{i}$. Set $J=m$.

Now let a be the center of $B_{\mathbf{a}} \in \mathscr{F}$. If $\mathbf{a} \in A_{m}$ for all $m$, (That is a does not get covered by the $B_{i}$.) then $r_{m+1} \geq \frac{3}{4} r\left(B_{\mathbf{a}}\right)$ for all $m$, a contradiction since the balls $B\left(\mathbf{a}_{j}, \frac{r_{j}}{3}\right)$ are disjoint and $A$ is bounded, implying that $r_{j} \rightarrow 0$. Thus a must fail to be in some $A_{m}$ which means it was covered by some ball in the sequence.

The covering theorem is obtained by estimating how many $B_{j}$ can intersect $B_{k}$ for $j<k$. The thing to notice is that from the construction, no $B_{j}$ contains the center of another $B_{i}$. Also, the $r\left(B_{k}\right)$ is a decreasing sequence.

Let $\alpha>1$. There are two cases for an intersection. Either $r\left(B_{j}\right) \geq \alpha r\left(B_{k}\right)$ or $\alpha r\left(B_{k}\right)>$ $r\left(B_{j}\right)>r\left(B_{k}\right)$.

First consider the case where we have a ball $B(\mathbf{a}, r)$ intersected with other balls of radius larger than $\alpha r$ such that none of the balls contains the center of any other. This is illustrated in the following picture with two balls. This has to do with estimating the number of $B_{j}$ for $j \leq k$ where $r\left(B_{j}\right) \geq \alpha r\left(B_{k}\right)$.

Imagine projecting the center of each big ball as in the above picture onto the surface of the given ball, assuming the given ball has radius 1 . By scaling the balls, you could reduce to this case that the given ball has radius 1 . Then from geometric reasoning, there should be a lower bound to the distance between these two projections depending on dimension. Thus there is an estimate on how many large balls can intersect the given ball with no ball containing a center of another one.

## Intersections with relatively big balls

Lemma 13.13.2 Let the balls $B_{\mathbf{a}}, B_{\mathbf{x}}, B_{\mathbf{y}}$ be as shown, having radii $r, r_{x}, r_{y}$ respectively. Suppose the centers of $B_{\mathbf{x}}$ and $B_{\mathbf{y}}$ are not both in any of the balls shown, and suppose $r_{y} \geq r_{x} \geq \alpha r$ where $\alpha$ is a number larger than 1 . Also let $P_{\mathbf{x}} \equiv \mathbf{a}+r \frac{\mathbf{x}-\mathbf{a}}{\|\mathbf{x}-\mathbf{a}\|}$ with $P_{\mathbf{y}}$ being defined similarly. Then it follows that $\left\|P_{\mathbf{x}}-P_{\mathbf{y}}\right\| \geq \frac{\alpha-1}{\alpha+1} r$. There exists a constant $L(p, \alpha)$ depending on $\alpha$ and the dimension, such that if $B_{1}, \cdots, B_{m}$ are all balls such that any pair are in the same situation relative to $B_{\mathbf{a}}$ as $B_{\mathbf{x}}$, and $B_{\mathbf{y}}$, then $m \leq L(p, \alpha)$.

Proof: From the definition,

$$
\begin{gathered}
\left\|P_{\mathbf{x}}-P_{\mathbf{y}}\right\|=r\left\|\frac{\mathbf{x}-\mathbf{a}}{\|\mathbf{x}-\mathbf{a}\|}-\frac{\mathbf{y}-\mathbf{a}}{\|\mathbf{y}-\mathbf{a}\|}\right\| \\
=r\left\|\frac{(\mathbf{x}-\mathbf{a})\|\mathbf{y}-\mathbf{a}\|-(\mathbf{y}-\mathbf{a})\|\mathbf{x}-\mathbf{a}\|}{\|\mathbf{x}-\mathbf{a}\|\|\mathbf{y}-\mathbf{a}\|}\right\| \\
=r\left\|\frac{\|\mathbf{y}-\mathbf{a}\|(\mathbf{x}-\mathbf{y})+(\mathbf{y}-\mathbf{a})(\|\mathbf{y}-\mathbf{a}\|-\|\mathbf{x}-\mathbf{a}\|)}{\|\mathbf{x}-\mathbf{a}\|\|\mathbf{y}-\mathbf{a}\|}\right\|
\end{gathered}
$$

$$
\begin{align*}
& \geq r \frac{\|\mathbf{x}-\mathbf{y}\|}{\|\mathbf{x}-\mathbf{a}\|}-r \frac{\|\mathbf{y}-\mathbf{a}\| \mid\|\mathbf{y}-\mathbf{a}\|-\|\mathbf{x}-\mathbf{a}\|}{\|\mathbf{x}-\mathbf{a}\|\|\mathbf{y}-\mathbf{a}\|} \\
& =r \frac{\|\mathbf{x}-\mathbf{y}\|}{\|\mathbf{x}-\mathbf{a}\|}-\frac{r}{\|\mathbf{x}-\mathbf{a}\|}|\|\mathbf{y}-\mathbf{a}\|-\|\mathbf{x}-\mathbf{a}\|| . \tag{13.13.35}
\end{align*}
$$

There are two cases. First suppose that $\|\mathbf{y}-\mathbf{a}\|-\|\mathbf{x}-\mathbf{a}\| \geq 0$. Then the above

$$
=r \frac{\|\mathbf{x}-\mathbf{y}\|}{\|\mathbf{x}-\mathbf{a}\|}-\frac{r}{\|\mathbf{x}-\mathbf{a}\|}\|\mathbf{y}-\mathbf{a}\|+r
$$

From the assumptions, $\|\mathbf{x}-\mathbf{y}\| \geq r_{y}$ and also $\|\mathbf{y}-\mathbf{a}\| \leq r+r_{y}$. Hence the above

$$
\begin{aligned}
& \geq r \frac{r_{y}}{\|\mathbf{x}-\mathbf{a}\|}-\frac{r}{\|\mathbf{x}-\mathbf{a}\|}\left(r+r_{y}\right)+r=r-r \frac{r}{\|\mathbf{x}-\mathbf{a}\|} \\
& \geq r\left(1-\frac{r}{\|\mathbf{x}-\mathbf{a}\|}\right) \geq r\left(1-\frac{r}{r_{x}}\right) \geq r\left(1-\frac{1}{\alpha}\right) \geq r \frac{\alpha-1}{\alpha+1} .
\end{aligned}
$$

The other case is that $\|\mathbf{y}-\mathbf{a}\|-\|\mathbf{x}-\mathbf{a}\|<0$ in 13.13.35. Then in this case 13.13.35 equals

$$
\begin{aligned}
& =r\left(\frac{\|\mathbf{x}-\mathbf{y}\|}{\|\mathbf{x}-\mathbf{a}\|}-\frac{1}{\|\mathbf{x}-\mathbf{a}\|}(\|\mathbf{x}-\mathbf{a}\|-\|\mathbf{y}-\mathbf{a}\|)\right) \\
& =\frac{r}{\|\mathbf{x}-\mathbf{a}\|}(\|\mathbf{x}-\mathbf{y}\|-(\|\mathbf{x}-\mathbf{a}\|-\|\mathbf{y}-\mathbf{a}\|))
\end{aligned}
$$

Then since $\|\mathbf{x}-\mathbf{a}\| \leq r+r_{x},\|\mathbf{x}-\mathbf{y}\| \geq r_{y},\|\mathbf{y}-\mathbf{a}\| \geq r_{y}$, and remembering that $r_{y} \geq r_{x} \geq \alpha r$,

$$
\begin{aligned}
& \geq \frac{r}{r_{x}+r}\left(r_{y}-\left(r+r_{x}\right)+r_{y}\right) \geq \frac{r}{r_{x}+r}\left(r_{y}-\left(r+r_{y}\right)+r_{y}\right) \\
& \geq \frac{r}{r_{x}+r}\left(r_{y}-r\right) \geq \frac{r}{r_{x}+r}\left(r_{x}-r\right) \geq \frac{r}{r_{x}+\frac{1}{\alpha} r_{x}}\left(r_{x}-\frac{1}{\alpha} r_{x}\right) \\
& =\frac{r}{1+(1 / \alpha)}(1-1 / \alpha)=\frac{\alpha-1}{\alpha+1} r
\end{aligned}
$$

Replacing $r$ with something larger, $\frac{1}{\alpha} r_{x}$ is justified by the observation that $x \rightarrow \frac{\alpha-x}{\alpha+x}$ is decreasing. This proves the estimate between $P_{\mathbf{x}}$ and $P_{\mathbf{y}}$.

Finally, in the case of the balls $B_{i}$ having centers at $\mathbf{x}_{i}$, then as above, let $P_{\mathbf{x}_{i}}=\mathbf{a}+$ $r \frac{\mathbf{x}_{i}-\mathbf{a}}{\left\|\mathbf{x}_{i}-\mathbf{a}\right\|}$. Then $\left(P_{\mathbf{x}_{i}}-\mathbf{a}\right) r^{-1}$ is on the unit sphere having center $\mathbf{0}$. Furthermore,

$$
\left\|\left(P_{\mathbf{x}_{i}}-\mathbf{a}\right) r^{-1}-\left(P_{\mathbf{y}_{i}}-\mathbf{a}\right) r^{-1}\right\|=r^{-1}\left\|P_{\mathbf{x}_{i}}-P_{\mathbf{y}_{i}}\right\| \geq r^{-1} r \frac{\alpha-1}{\alpha+1}=\frac{\alpha-1}{\alpha+1} .
$$

How many points on the unit sphere can be pairwise this far apart? The unit sphere is compact and so there exists a $\frac{1}{4}\left(\frac{\alpha-1}{\alpha+1}\right)$ net having $L(p, \alpha)$ points. Thus $m$ cannot be any larger than $L(p, \alpha)$ because if it were, then by the pigeon hole principal, two of the points $\left(P_{\mathbf{x}_{i}}-\mathbf{a}\right) r^{-1}$ would lie in a single ball $B\left(p, \frac{1}{4}\left(\frac{\alpha-1}{\alpha+1}\right)\right)$ so they could not be $\frac{\alpha-1}{\alpha+1}$ apart.

The above lemma has to do with balls which are relatively large intersecting a given ball. Next is a lemma which has to do with relatively small balls intersecting a given ball. First is another lemma.

Lemma 13.13.3 Let $\Gamma>1$ and $B(\mathbf{a}, \Gamma r)$ be a ball and suppose $\left\{B\left(\mathbf{x}_{i}, r_{i}\right)\right\}_{i=1}^{m}$ are balls contained in $B(\mathbf{a}, \Gamma r)$ such that $r \leq r_{i}$ and none of these balls contains the center of another ball. Then there is a constant $M(p, \Gamma)$ such that $m \leq M(p, \Gamma)$.

Proof: Let $\mathbf{z}_{i}=\mathbf{x}_{i}-\mathbf{a}$. Then $B\left(\mathbf{z}_{i}, r_{i}\right)$ are balls contained in $B(\mathbf{0}, \Gamma r)$ with no ball containing a center of another. Then $B\left(\frac{\mathbf{z}_{i}}{\Gamma r}, \frac{r_{i}}{\Gamma r}\right)$ are balls in $B(\mathbf{0}, 1)$ with no ball containing the center of another. By compactness, there is a $\frac{1}{8 \Gamma}$ net for $\overline{B(\mathbf{0}, 1)},\left\{\mathbf{y}_{i}\right\}_{i=1}^{M(p, \Gamma)}$. Thus the balls $B\left(\mathbf{y}_{i}, \frac{1}{8 \Gamma}\right)$ cover $\overline{B(\mathbf{0}, 1)}$. If $m \geq M(p, \Gamma)$, then by the pigeon hole principle, one of these $B\left(\mathbf{y}_{i}, \frac{1}{8 \Gamma}\right)$ would contain some $\frac{\mathbf{z}_{i}}{\Gamma r}$ and $\frac{\mathbf{z}_{j}}{\Gamma r}$ which requires $\left\|\frac{\mathbf{z}_{i}}{\Gamma r}-\frac{\mathbf{z}_{j}}{\Gamma r}\right\| \leq \frac{1}{4 \Gamma}<\frac{r_{j}}{4 \Gamma r}$ so $\frac{\mathbf{z}_{i}}{\Gamma r} \in B\left(\frac{\mathbf{z}_{j}}{\Gamma r}, \frac{r_{j}}{\Gamma r}\right)$. Thus $m \leq M(p, \gamma, \Gamma)$.

## Intersections with small balls

Lemma 13.13.4 Let $B$ be a ball having radius $r$ and suppose $B$ has nonempty intersection with the balls $B_{1}, \cdots, B_{m}$ having radii $r_{1}, \cdots, r_{m}$ respectively, and as before, no $B_{i}$ contains the center of any other and the centers of the $B_{i}$ are not contained in B. Suppose $\alpha>1$ and $r \leq \min \left(r_{1}, \cdots, r_{m}\right)$, each $r_{i}<\alpha r$. Then there exists a constant $M(p, \alpha)$ such that $m \leq M(p, \alpha)$.

Proof: Let $B=B(\mathbf{a}, r)$. Then each $B_{i}$ is contained in $B(\mathbf{a}, 2 r+\alpha r+\alpha r)$. This is because if $\mathbf{y} \in B_{i} \equiv B\left(\mathbf{x}_{i}, r_{i}\right)$,

$$
\|\mathbf{y}-\mathbf{a}\| \leq\left\|\mathbf{y}-\mathbf{x}_{i}\right\|+\left\|\mathbf{x}_{i}-\mathbf{a}\right\| \leq r_{i}+r+r_{i}<2 r+\alpha r+\alpha r
$$

Thus $B_{i}$ does not contain the center of any other $B_{j}$. Then these balls are contained in $B(\mathbf{a}, r(2 \alpha+2))$, and each radius is at least as large as $r$. By Lemma 13.13.3 there is a constant $M(p, \alpha)$ such that $m \leq M(p, \alpha)$.

Now here is the Besicovitch covering theorem. In the proof, we are considering the sequence of balls described above.

Theorem 13.13.5 There exists a constant $N_{p}$, depending only on $p$ with the following property. If $\mathscr{F}$ is any collection of nonempty balls in $X$ with

$$
\sup \{\operatorname{diam}(B): B \in \mathscr{F}\}<D<\infty
$$

and if $A$ is the set of centers of the balls in $\mathscr{F}$, then there exist subsets of $\mathscr{F}, \mathscr{H}_{1}, \cdots, \mathscr{H}_{N_{p}}$, such that each $\mathscr{H}_{i}$ is a countable collection of disjoint balls from $\mathscr{F}$ (possibly empty) and

$$
A \subseteq \cup_{i=1}^{N_{p}} \cup\left\{B: B \in \mathscr{H}_{i}\right\}
$$

Proof: To begin with, suppose $A$ is bounded. Let $L(p, \alpha)$ be the constant of Lemma 13.13.2 and let $M_{p}=L(p, \alpha)+M(p, \alpha)+1$. Define the following sequence of subsets of $\mathscr{F}, \mathscr{G}_{1}, \mathscr{G}_{2}, \cdots, \mathscr{G}_{M_{p}}$. Referring to the sequence $\left\{B_{k}\right\}$ considered in Lemma 13.13.1, let $B_{1} \in \mathscr{G}_{1}$ and if $B_{1}, \cdots, B_{m}$ have been assigned, each to a $\mathscr{G}_{i}$, place $B_{m+1}$ in the first $\mathscr{G}_{j}$ such that $B_{m+1}$ intersects no set already in $\mathscr{G}_{j}$. The existence of such a $j$ follows from Lemmas 13.13.2 and 13.13.4 and the pigeon hole principle. Here is why. $B_{m+1}$ can intersect at most $L(p, \alpha)$ sets of $\left\{B_{1}, \cdots, B_{m}\right\}$ which have radii at least as large as $\alpha r\left(B_{m+1}\right)$ thanks to

Lemma 13.13.2. It can intersect at most $M(p, \alpha)$ sets of $\left\{B_{1}, \cdots, B_{m}\right\}$ which have radius smaller than $\alpha r\left(B_{m+1}\right)$ thanks to Lemma 13.13.4. Thus each $\mathscr{G}_{j}$ consists of disjoint sets of $\mathscr{F}$ and the set of centers is covered by the union of these $\mathscr{G}_{j}$. This proves the theorem in case the set of centers is bounded.

Now let $R_{1}=B(\mathbf{0}, 5 D)$ and if $R_{m}$ has been chosen, let

$$
R_{m+1}=B(\mathbf{0},(m+1) 5 D) \backslash R_{m}
$$

Thus, if $|k-m| \geq 2$, no ball from $\mathscr{F}$ having nonempty intersection with $R_{m}$ can intersect any ball from $\mathscr{F}$ which has nonempty intersection with $R_{k}$. This is because all these balls have radius less than $D$. Now let $A_{m} \equiv A \cap R_{m}$ and apply the above result for a bounded set of centers to those balls of $\mathscr{F}$ which intersect $R_{m}$ to obtain sets of disjoint balls $\mathscr{G}_{1}\left(R_{m}\right), \mathscr{G}_{2}\left(R_{m}\right), \cdots, \mathscr{G}_{M_{p}}\left(R_{m}\right)$ covering $A_{m}$. Then simply define $\mathscr{G}_{j}^{\prime} \equiv \cup_{k=1}^{\infty} \mathscr{G}_{j}\left(R_{2 k}\right), \mathscr{G}_{j} \equiv$ $\cup_{k=1}^{\infty} \mathscr{G}_{j}\left(R_{2 k-1}\right)$. Let $N_{p}=2 M_{p}$ and

$$
\left\{\mathscr{H}_{1}, \cdots, \mathscr{H}_{N_{p}}\right\} \equiv\left\{\mathscr{G}_{1}^{\prime}, \cdots, \mathscr{G}_{M_{p}}^{\prime}, \mathscr{G}_{1}, \cdots, \mathscr{G}_{M_{p}}\right\}
$$

Note that the balls in $\mathscr{G}_{j}^{\prime}$ are disjoint. This is because those in $\mathscr{G}_{j}\left(R_{2 k}\right)$ are disjoint and if you consider any ball in $\mathscr{G}_{j}\left(R_{2 m}\right)$, it cannot intersect a ball of $\mathscr{G}_{j}\left(R_{2 k}\right)$ for $m \neq k$ because $|2 k-2 m| \geq 2$. Similar considerations apply to the balls of $\mathscr{G}_{j}$.

Of course, you could pick a particular $\alpha$. If you make $\alpha \operatorname{larger,~} L(p, \alpha)$ should get smaller and $M(p, \alpha)$ should get larger. Obviously one could explore this at length to try and get a best choice of $\alpha$.

### 13.14 Vitali Coverings and Radon Measures

There is another covering theorem which may also be referred to as the Besicovitch covering theorem. As before, the balls can be taken with respect to any norm on $\mathbb{R}^{n}$. At first, the balls will be closed but this assumption will be removed.

Definition 13.14.1 A collection of balls in $\mathbb{R}^{p}, \mathscr{F}$ covers a set $E$ in the sense of Vitali if whenever $\mathbf{x} \in E$ and $\varepsilon>0$, there exists a ball $B \in \mathscr{F}$ whose center is $\mathbf{x}$ having diameter less than $\varepsilon$.

I will give a proof of the following theorem.
Theorem 13.14.2 Let $\mu$ be a Radon measure on $\mathbb{R}^{p}$ and let $E$ be a set with $\bar{\mu}(E)<\infty$. Where $\bar{\mu}$ is the outer measure determined by $\mu$. Suppose $\mathscr{F}$ is a collection of closed balls which cover $E$ in the sense of Vitali. Then there exists a sequence of disjoint balls, $\left\{B_{i}\right\} \subseteq \mathscr{F}$ such that

$$
\bar{\mu}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0
$$

Proof: Let $N_{p}$ be the constant of the Besicovitch covering theorem. Choose $r>0$ such that

$$
(1-r)^{-1}\left(1-\frac{1}{2 N_{p}+2}\right) \equiv \lambda<1
$$

If $\bar{\mu}(E)=0$, there is nothing to prove so assume $\bar{\mu}(E)>0$. Let $U_{1}$ be an open set containing $E$ with $(1-r) \mu\left(U_{1}\right)<\bar{\mu}(E)$ and $2 \bar{\mu}(E)>\mu\left(U_{1}\right)$, and let $\mathscr{F}_{1}$ be those sets of $\mathscr{F}$ which are contained in $U_{1}$ whose centers are in $E$. Thus $\mathscr{F}_{1}$ is also a Vitali cover of $E$. Now by the Besicovitch covering theorem proved earlier, there exist balls, $B$, of $\mathscr{F}_{1}$ such that

$$
E \subseteq \cup_{i=1}^{N_{p}}\left\{B: B \in \mathscr{G}_{i}\right\}
$$

where $\mathscr{G}_{i}$ consists of a collection of disjoint balls of $\mathscr{F}_{1}$. Therefore,

$$
\bar{\mu}(E) \leq \sum_{i=1}^{N_{p}} \sum_{B \in \mathscr{G}_{i}} \mu(B)
$$

and so, for some $i \leq N_{p}$,

$$
\left(N_{p}+1\right) \sum_{B \in \mathscr{G}_{i}} \mu(B)>\bar{\mu}(E)
$$

It follows there exists a finite set of balls of $\mathscr{G}_{i},\left\{B_{1}, \cdots, B_{m_{1}}\right\}$ such that

$$
\begin{equation*}
\left(N_{p}+1\right) \sum_{i=1}^{m_{1}} \mu\left(B_{i}\right)>\bar{\mu}(E) \tag{13.14.36}
\end{equation*}
$$

and so

$$
\left(2 N_{p}+2\right) \sum_{i=1}^{m_{1}} \mu\left(B_{i}\right)>2 \bar{\mu}(E)>\mu\left(U_{1}\right)
$$

Since $2 \bar{\mu}(E) \geq \mu\left(U_{1}\right), 13.14 .36$ implies

$$
\frac{\mu\left(U_{1}\right)}{2 N_{2}+2} \leq \frac{2 \bar{\mu}(E)}{2 N_{2}+2}=\frac{\bar{\mu}(E)}{N_{2}+1}<\sum_{i=1}^{m_{1}} \mu\left(B_{i}\right)
$$

Also $U_{1}$ was chosen such that $(1-r) \mu\left(U_{1}\right)<\bar{\mu}(E)$, and so

$$
\begin{gathered}
\lambda \bar{\mu}(E) \geq \lambda(1-r) \mu\left(U_{1}\right)=\left(1-\frac{1}{2 N_{p}+2}\right) \mu\left(U_{1}\right) \\
\geq \mu\left(U_{1}\right)-\sum_{i=1}^{m_{1}} \mu\left(B_{i}\right)=\mu\left(U_{1}\right)-\mu\left(\cup_{j=1}^{m_{1}} B_{j}\right) \\
=\mu\left(U_{1} \backslash \cup_{j=1}^{m_{1}} B_{j}\right) \geq \bar{\mu}\left(E \backslash \cup_{j=1}^{m_{1}} B_{j}\right)
\end{gathered}
$$

Since the balls are closed, you can consider the sets of $\mathscr{F}$ which have empty intersection with $\cup_{j=1}^{m_{1}} B_{j}$ and this new collection of sets will be a Vitali cover of $E \backslash \cup_{j=1}^{m_{1}} B_{j}$. Letting this collection of balls play the role of $\mathscr{F}$ in the above argument and letting $E \backslash \cup_{j=1}^{m_{1}} B_{j}$ play the role of $E$, repeat the above argument and obtain disjoint sets of $\mathscr{F}$,

$$
\left\{B_{m_{1}+1}, \cdots, B_{m_{2}}\right\}
$$

such that

$$
\lambda \bar{\mu}\left(E \backslash \cup_{j=1}^{m_{1}} B_{j}\right)>\bar{\mu}\left(\left(E \backslash \cup_{j=1}^{m_{1}} B_{j}\right) \backslash \cup_{j=m_{1}+1}^{m_{2}} B_{j}\right)=\bar{\mu}\left(E \backslash \cup_{j=1}^{m_{2}} B_{j}\right),
$$

and so

$$
\lambda^{2} \bar{\mu}(E)>\bar{\mu}\left(E \backslash \cup_{j=1}^{m_{2}} B_{j}\right)
$$

Continuing in this way, yields a sequence of disjoint balls $\left\{B_{i}\right\}$ contained in $\mathscr{F}$ and

$$
\bar{\mu}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right) \leq \bar{\mu}\left(E \backslash \cup_{j=1}^{m_{k}} B_{j}\right)<\lambda^{k} \bar{\mu}(E)
$$

for all $k$. Therefore, $\bar{\mu}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.
It is not necessary to assume $\bar{\mu}(E)<\infty$.
Corollary 13.14.3 Let $\mu$ be a Radon measure on $\mathbb{R}^{p}$. Letting $\bar{\mu}$ be the outer measure determined by $\mu$, suppose $\mathscr{F}$ is a collection of closed balls which cover $E$ in the sense of Vitali. Then there exists a sequence of disjoint balls, $\left\{B_{i}\right\} \subseteq \mathscr{F}$ such that

$$
\bar{\mu}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0
$$

Proof: Since $\mu$ is a Radon measure it is finite on compact sets. Therefore, there are at most countably many numbers, $\left\{b_{i}\right\}_{i=1}^{\infty}$ such that $\mu\left(\partial B\left(\mathbf{0}, b_{i}\right)\right)>0$. It follows there exists an increasing sequence of positive numbers, $\left\{r_{i}\right\}_{i=1}^{\infty}$ such that $\lim _{i \rightarrow \infty} r_{i}=\infty$ and $\mu\left(\partial B\left(\mathbf{0}, r_{i}\right)\right)=0$. Now let

$$
\begin{aligned}
D_{1} & \equiv\left\{\mathbf{x}:\|\mathbf{x}\|<r_{1}\right\}, D_{2} \equiv\left\{\mathbf{x}: r_{1}<\|\mathbf{x}\|<r_{2}\right\} \\
\cdots, D_{m} & \equiv\left\{\mathbf{x}: r_{m-1}<\|\mathbf{x}\|<r_{m}\right\}, \cdots
\end{aligned}
$$

Let $\mathscr{F}_{m}$ denote those closed balls of $\mathscr{F}$ which are contained in $D_{m}$. Then letting $E_{m}$ denote $E \cap D_{m}, \mathscr{F}_{m}$ is a Vitali cover of $E_{m}, \bar{\mu}\left(E_{m}\right)<\infty$, and so by Theorem 13.14.2, there exists a countable sequence of balls from $\mathscr{F}_{m}\left\{B_{j}^{m}\right\}_{j=1}^{\infty}$, such that $\bar{\mu}\left(E_{m} \backslash \cup_{j=1}^{\infty} B_{j}^{m}\right)=0$. Then consider the countable collection of balls, $\left\{B_{j}^{m}\right\}_{j, m=1}^{\infty}$.

$$
\begin{aligned}
\bar{\mu}\left(E \backslash \cup_{m=1}^{\infty} \cup_{j=1}^{\infty} B_{j}^{m}\right) & \leq \bar{\mu}\left(\cup_{j=1}^{\infty} \partial B\left(\mathbf{0}, r_{i}\right)\right)+ \\
+\sum_{m=1}^{\infty} \bar{\mu}\left(E_{m} \backslash \cup_{j=1}^{\infty} B_{j}^{m}\right) & =0 \boldsymbol{\square}
\end{aligned}
$$

You don't need to assume the balls are closed. In fact, the balls can be open, closed or anything in between and the same conclusion can be drawn provided you change the definition of a Vitali cover a little.

Corollary 13.14.4 Let $\mu$ be a Radon measure on $\mathbb{R}^{p}$. Letting $\bar{\mu}$ be the outer measure determined by $\mu$, suppose $\mathscr{F}$ is a collection of balls which cover $E$ in the sense that for all $\varepsilon>0$ there are uncountably many balls of $\mathscr{F}$ centered at $\mathbf{x}$ having radius less than $\varepsilon$. Then there exists a sequence of disjoint balls, $\left\{B_{i}\right\} \subseteq \mathscr{F}$ such that

$$
\bar{\mu}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0
$$

Proof: Let $\mathbf{x} \in E$. Thus $\mathbf{x}$ is the center of arbitrarily small balls from $\mathscr{F}$. Since $\mu$ is a Radon measure, at most countably many radii, $r$ of these balls can have the property that $\mu(\partial B(\mathbf{0}, r))=0$. Let $\mathscr{F}^{\prime}$ denote the closures of the balls of $\mathscr{F}, \overline{B(\mathbf{x}, r)}$ with the property that $\mu(\partial B(\mathbf{x}, r))=0$. Since for each $\mathbf{x} \in E$ there are only countably many exceptions, $\mathscr{F}^{\prime}$ is still a Vitali cover of $E$. Therefore, by Corollary 13.14.3 there is a disjoint sequence of these balls of $\mathscr{F}^{\prime},\left\{\overline{B_{i}}\right\}_{i=1}^{\infty}$ for which

$$
\bar{\mu}\left(E \backslash \cup_{j=1}^{\infty} \overline{B_{j}}\right)=0
$$

However, since their boundaries have $\mu$ measure zero, it follows

$$
\bar{\mu}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0
$$

## Chapter 14

## Some Extension Theorems

### 14.1 Algebras

First of all, here is the definition of an algebra and theorems which tell how to recognize one when you see it. An algebra is like a $\sigma$ algebra except it is only closed with respect to finite unions.

Definition 14.1.1 $\mathscr{A}$ is said to be an algebra of subsets of a set, $Z$ if $Z \in \mathscr{A}, \emptyset \in \mathscr{A}$, and when $E, F \in \mathscr{A}, E \cup F$ and $E \backslash F$ are both in $\mathscr{A}$.

It is important to note that if $\mathscr{A}$ is an algebra, then it is also closed under finite intersections. This is because $E \cap F=\left(E^{C} \cup F^{C}\right)^{C} \in \mathscr{A}$ since $E^{C}=Z \backslash E \in \mathscr{A}$ and $F^{C}=Z \backslash F \in \mathscr{A}$. Note that every $\sigma$ algebra is an algebra but not the other way around.

Something satisfying the above definition is called an algebra because union is like addition, the set difference is like subtraction and intersection is like multiplication. Furthermore, only finitely many operations are done at a time and so there is nothing like a limit involved.

How can you recognize an algebra when you see one? The answer to this question is the purpose of the following lemma.

Lemma 14.1.2 Suppose $\mathscr{R}$ and $\mathscr{E}$ are subsets of $\mathscr{P}(Z)^{1}$ such that $\mathscr{E}$ is defined as the set of all finite disjoint unions of sets of $\mathscr{R}$. Suppose also

$$
\begin{gathered}
\emptyset, Z \in \mathscr{R} \\
A \cap B \in \mathscr{R} \text { whenever } A, B \in \mathscr{R} \\
A \backslash B \in \mathscr{E} \text { whenever } A, B \in \mathscr{R} .
\end{gathered}
$$

Then $\mathscr{E}$ is an algebra of sets of $Z$.
Proof: Note first that if $A \in \mathscr{R}$, then $A^{C} \in \mathscr{E}$ because $A^{C}=Z \backslash A$.
Now suppose that $E_{1}$ and $E_{2}$ are in $\mathscr{E}$,

$$
E_{1}=\cup_{i=1}^{m} R_{i}, \quad E_{2}=\cup_{j=1}^{n} R_{j}
$$

where the $R_{i}$ are disjoint sets in $\mathscr{R}$ and the $R_{j}$ are disjoint sets in $\mathscr{R}$. Then

$$
E_{1} \cap E_{2}=\cup_{i=1}^{m} \cup_{j=1}^{n} R_{i} \cap R_{j}
$$

which is clearly an element of $\mathscr{E}$ because no two of the sets in the union can intersect and by assumption they are all in $\mathscr{R}$. Thus by induction, finite intersections of sets of $\mathscr{E}$ are in $\mathscr{E}$. Consider the difference of two elements of $\mathscr{E}$ next.

If $E=\cup_{i=1}^{n} R_{i} \in \mathscr{E}$,

$$
E^{C}=\cap_{i=1}^{n} R_{i}^{C}=\text { finite intersection of sets of } \mathscr{E}
$$

[^14]which was just shown to be in $\mathscr{E}$. Now, if $E_{1}, E_{2} \in \mathscr{E}$,
$$
E_{1} \backslash E_{2}=E_{1} \cap E_{2}^{C} \in \mathscr{E}
$$
from what was just shown about finite intersections.
Finally consider finite unions of sets of $\mathscr{E}$. Let $E_{1}$ and $E_{2}$ be sets of $\mathscr{E}$. Then
$$
E_{1} \cup E_{2}=\left(E_{1} \backslash E_{2}\right) \cup E_{2} \in \mathscr{E}
$$
because $E_{1} \backslash E_{2}$ consists of a finite disjoint union of sets of $\mathscr{R}$ and these sets must be disjoint from the sets of $\mathscr{R}$ whose union yields $E_{2}$ because $\left(E_{1} \backslash E_{2}\right) \cap E_{2}=\emptyset$. This proves the lemma.

The following corollary is particularly helpful in verifying the conditions of the above lemma.

Corollary 14.1.3 Let $\left(Z_{1}, \mathscr{R}_{1}, \mathscr{E}_{1}\right)$ and $\left(Z_{2}, \mathscr{R}_{2}, \mathscr{E}_{2}\right)$ be as described in Lemma 14.1.2. Then $\left(Z_{1} \times Z_{2}, \mathscr{R}, \mathscr{E}\right)$ also satisfies the conditions of Lemma 14.1.2 if $\mathscr{R}$ is defined as

$$
\mathscr{R} \equiv\left\{R_{1} \times R_{2}: R_{i} \in \mathscr{R}_{i}\right\}
$$

and

$$
\mathscr{E} \equiv\{\text { finite disjoint unions of sets of } \mathscr{R}\}
$$

Consequently, $\mathscr{E}$ is an algebra of sets.
Proof: It is clear $\emptyset, Z_{1} \times Z_{2} \in \mathscr{R}$. Let $A \times B$ and $C \times D$ be two elements of $\mathscr{R}$.

$$
A \times B \cap C \times D=A \cap C \times B \cap D \in \mathscr{R}
$$

by assumption.

$$
\begin{aligned}
A \times & \overbrace{(B \backslash D)}^{\in \mathscr{E}_{2}} \cup \overbrace{(A \backslash C)}^{\in \mathscr{E}_{1}} \times \overbrace{(D \cap B)}^{\in \mathscr{R}_{2}} \\
& =(A \times Q) \cup(P \times R)
\end{aligned}
$$

where $Q \in \mathscr{E}_{2}, P \in \mathscr{E}_{1}$, and $R \in \mathscr{R}_{2}$.

Since $A \times Q$ and $P \times R$ do not intersect, it follows the above expression is in $\mathscr{E}$ because each of these terms are. This proves the corollary.

### 14.2 Caratheodory Extension Theorem

The Caratheodory extension theorem is a fundamental result which makes possible the consideration of measures on infinite products among other things. The idea is that if a finite measure defined only on an algebra is trying to be a measure, then in fact it can be extended to a measure.

Definition 14.2.1 Let $\mathscr{E}$ be an algebra of sets of $\Omega$ and let $\mu_{0}$ be a finite measure on $\mathscr{E}$. This means $\mu_{0}$ is finitely additive and if $E_{i}, E$ are sets of $\mathscr{E}$ with the $E_{i}$ disjoint and

$$
E=\cup_{i=1}^{\infty} E_{i}
$$

then

$$
\mu_{0}(E)=\sum_{i=1}^{\infty} \mu_{0}\left(E_{i}\right)
$$

while $\mu_{0}(\Omega)<\infty$.
In this definition, $\mu_{0}$ is trying to be a measure and acts like one whenever possible. Under these conditions, $\mu_{0}$ can be extended uniquely to a complete measure, $\mu$, defined on a $\sigma$ algebra of sets containing $\mathscr{E}$ such that $\mu$ agrees with $\mu_{0}$ on $\mathscr{E}$. The following is the main result.

Theorem 14.2.2 Let $\mu_{0}$ be a measure on an algebra of sets, $\mathscr{E}$, which satisfies $\mu_{0}(\Omega)<\infty$. Then there exists a complete measure space $(\Omega, \mathscr{S}, \mu)$ such that

$$
\mu(E)=\mu_{0}(E)
$$

for all $E \in \mathscr{E}$. Also if $v$ is any such measure which agrees with $\mu_{0}$ on $\mathscr{E}$, then $v=\mu$ on $\sigma(\mathscr{E})$, the $\sigma$ algebra generated by $\mathscr{E}$.

Proof: Define an outer measure as follows.

$$
\mu(S) \equiv \inf \left\{\sum_{i=1}^{\infty} \mu_{0}\left(E_{i}\right): S \subseteq \cup_{i=1}^{\infty} E_{i}, E_{i} \in \mathscr{E}\right\}
$$

Claim 1: $\mu$ is an outer measure.
Proof of Claim 1: Let $S \subseteq \cup_{i=1}^{\infty} S_{i}$ and let $S_{i} \subseteq \cup_{j=1}^{\infty} E_{i j}$, where

$$
\mu\left(S_{i}\right)+\frac{\varepsilon}{2^{i}} \geq \sum_{j=1}^{\infty} \mu\left(E_{i j}\right)
$$

Then

$$
\mu(S) \leq \sum_{i} \sum_{j} \mu\left(E_{i j}\right)=\sum_{i}\left(\mu\left(S_{i}\right)+\frac{\varepsilon}{2^{i}}\right)=\sum_{i} \mu\left(S_{i}\right)+\varepsilon .
$$

Since $\varepsilon$ is arbitrary, this shows $\mu$ is an outer measure as claimed.
By the Caratheodory procedure, there exists a unique $\sigma$ algebra, $\mathscr{S}$, consisting of the $\mu$ measurable sets such that

$$
(\Omega, \mathscr{S}, \mu)
$$

is a complete measure space. It remains to show $\mu$ extends $\mu_{0}$.
Claim 2: If $\mathscr{S}$ is the $\sigma$ algebra of $\mu$ measurable sets, $\mathscr{S} \supseteq \mathscr{E}$ and $\mu=\mu_{0}$ on $\mathscr{E}$.
Proof of Claim 2: First observe that if $A \in \mathscr{E}$, then $\mu(A) \leq \mu_{0}(A)$ by definition. Letting

$$
\mu(A)+\varepsilon>\sum_{i=1}^{\infty} \mu_{0}\left(E_{i}\right), \cup_{i=1}^{\infty} E_{i} \supseteq A, E_{i} \in \mathscr{E}
$$

it follows

$$
\mu(A)+\varepsilon>\sum_{i=1}^{\infty} \mu_{0}\left(E_{i} \cap A\right) \geq \mu_{0}(A)
$$

since $A=\cup_{i=1}^{\infty} E_{i} \cap A$. Therefore, $\mu=\mu_{0}$ on $\mathscr{E}$.
Consider the assertion that $\mathscr{E} \subseteq \mathscr{S}$. Let $A \in \mathscr{E}$ and let $S \subseteq \Omega$ be any set. There exist sets $\left\{E_{i}\right\} \subseteq \mathscr{E}$ such that $\cup_{i=1}^{\infty} E_{i} \supseteq S$ but

$$
\mu(S)+\varepsilon>\sum_{i=1}^{\infty} \mu\left(E_{i}\right)
$$

Then

$$
\begin{gathered}
\mu(S) \leq \mu(S \cap A)+\mu(S \backslash A) \\
\leq \mu\left(\cup_{i=1}^{\infty} E_{i} \backslash A\right)+\mu\left(\cup_{i=1}^{\infty}\left(E_{i} \cap A\right)\right) \\
\leq \sum_{i=1}^{\infty} \mu\left(E_{i} \backslash A\right)+\sum_{i=1}^{\infty} \mu\left(E_{i} \cap A\right)=\sum_{i=1}^{\infty} \mu\left(E_{i}\right)<\mu(S)+\varepsilon
\end{gathered}
$$

Since $\varepsilon$ is arbitrary, this shows $A \in \mathscr{S}$.
This has proved the existence part of the theorem. To verify uniqueness, Let

$$
\mathscr{G} \equiv\{E \in \sigma(\mathscr{E}): \mu(E)=v(E)\}
$$

Then $\mathscr{G}$ is given to contain $\mathscr{E}$ and is obviously closed with respect to countable disjoint unions and complements. Therefore by Lemma 12.12.3, $\mathscr{G} \supseteq \sigma(\mathscr{E})$ and this proves the lemma.

The following lemma is also very significant.
Lemma 14.2.3 Let $M$ be a metric space with the closed balls compact and suppose $\mu$ is a measure defined on the Borel sets of $M$ which is finite on compact sets. Then there exists a unique Radon measure, $\bar{\mu}$ which equals $\mu$ on the Borel sets. In particular $\mu$ must be both inner and outer regular on all Borel sets.

Proof: Define a positive linear functional, $\Lambda(f)=\int f d \mu$. Let $\bar{\mu}$ be the Radon measure which comes from the Riesz representation theorem for positive linear functionals. Thus for all $f \in C_{0}(M)$,

$$
\int f d \mu=\int f d \bar{\mu}
$$

If $V$ is an open set, let $\left\{f_{n}\right\}$ be a sequence of continuous functions in $C_{0}(M)$ which is increasing and converges to $\mathscr{X}_{V}$ pointwise. Then applying the monotone convergence theorem,

$$
\int \mathscr{X}_{V} d \mu=\mu(V)=\int \mathscr{X}_{V} d \bar{\mu}=\bar{\mu}(V)
$$

and so the two measures coincide on all open sets. Every compact set is a countable intersection of open sets and so the two measures coincide on all compact sets. Now let $B(a, n)$ be a ball of radius $n$ and let $E$ be a Borel set contained in this ball. Then by regularity of $\bar{\mu}$ there exist sets $F, G$ such that $G$ is a countable intersection of open sets and $F$ is a countable union of compact sets such that $F \subseteq E \subseteq G$ and $\bar{\mu}(G \backslash F)=0$. Now $\mu(G)=\bar{\mu}(G)$ and $\mu(F)=\bar{\mu}(F)$. Thus

$$
\begin{aligned}
\bar{\mu}(G \backslash F)+\bar{\mu}(F) & =\bar{\mu}(G) \\
& =\mu(G)=\mu(G \backslash F)+\mu(F)
\end{aligned}
$$

and so $\mu(G \backslash F)=\bar{\mu}(G \backslash F)$. It follows

$$
\mu(E)=\mu(F)=\bar{\mu}(F)=\bar{\mu}(G)=\bar{\mu}(E)
$$

If $E$ is an arbitrary Borel set, then

$$
\mu(E \cap B(a, n))=\bar{\mu}(E \cap B(a, n))
$$

and letting $n \rightarrow \infty$, this yields $\mu(E)=\bar{\mu}(E)$.

### 14.3 The Tychonoff Theorem

Sometimes it is necessary to consider infinite Cartesian products of topological spaces. When you have finitely many topological spaces in the product and each is compact, it can be shown that the Cartesian product is compact with the product topology. It turns out that the same thing holds for infinite products but you have to be careful how you define the topology. The first thing likely to come to mind by analogy with finite products is not the right way to do it.

First recall the Hausdorff maximal principle.

Theorem 14.3.1 (Hausdorff maximal principle) Let $\mathscr{F}$ be a nonempty partially ordered set. Then there exists a maximal chain.

The main tool in the study of products of compact topological spaces is the Alexander subbasis theorem which is presented next. Recall a set is compact if every basic open cover admits a finite subcover. This was pretty easy to prove. However, there is a much smaller set of open sets called a subbasis which has this property. The proof of this result is much harder.

Definition 14.3.2 $\mathscr{S} \subseteq \tau$ is called a subbasis for the topology $\tau$ if the set $\mathscr{B}$ of finite intersections of sets of $\mathscr{S}$ is a basis for the topology, $\tau$.

Theorem 14.3.3 Let $(X, \tau)$ be a topological space and let $\mathscr{S} \subseteq \tau$ be a subbasis for $\tau$. Then if $H \subseteq X, H$ is compact if and only if every open cover of $H$ consisting entirely of sets of $\mathscr{S}$ admits a finite subcover.

Proof: The only if part is obvious because the subasic sets are themselves open.
If every basic open cover admits a finite subcover then the set in question is compact. Suppose then that $H$ is a subset of $X$ having the property that subbasic open covers admit finite subcovers. Is $H$ compact? Assume this is not so. Then what was just observed about basic covers implies there exists a basic open cover of $H, \mathscr{O}$, which admits no finite subcover. Let $\mathscr{F}$ be defined as

$$
\{\mathscr{O}: \mathscr{O} \text { is a basic open cover of } H \text { which admits no finite subcover }\} .
$$

The assumption is that $\mathscr{F}$ is nonempty. Partially order $\mathscr{F}$ by set inclusion and use the Hausdorff maximal principle to obtain a maximal chain, $\mathscr{C}$, of such open covers and let

$$
\mathscr{D}=\cup \mathscr{C} .
$$

If $\mathscr{D}$ admits a finite subcover, then since $\mathscr{C}$ is a chain and the finite subcover has only finitely many sets, some element of $\mathscr{C}$ would also admit a finite subcover, contrary to the definition of $\mathscr{F}$. Therefore, $\mathscr{D}$ admits no finite subcover. If $\mathscr{D}^{\prime}$ properly contains $\mathscr{D}$ and $\mathscr{D}^{\prime}$ is a basic open cover of $H$, then $\mathscr{D}^{\prime}$ has a finite subcover of $H$ since otherwise, $\mathscr{C}$ would fail to be a maximal chain, being properly contained in $\mathscr{C} \cup\left\{\mathscr{D}^{\prime}\right\}$. Every set of $\mathscr{D}$ is of the form

$$
U=\cap_{i=1}^{m} B_{i}, B_{i} \in \mathscr{S}
$$

because they are all basic open sets. If it is the case that for all $U \in \mathscr{D}$ one of the $B_{i}$ is found in $\mathscr{D}$, then replace each such $U$ with the subbasic set from $\mathscr{D}$ containing it. But then this would be a subbasic open cover of $H$ which by assumption would admit a finite subcover contrary to the properties of $\mathscr{D}$. Therefore, one of the sets of $\mathscr{D}$, denoted by $U$, has the property that

$$
U=\cap_{i=1}^{m} B_{i}, B_{i} \in \mathscr{S}
$$

and no $B_{i}$ is in $\mathscr{D}$. Thus $\mathscr{D} \cup\left\{B_{i}\right\}$ admits a finite subcover, for each of the above $B_{i}$ because it is strictly larger than $\mathscr{D}$. Let this finite subcover corresponding to $B_{i}$ be denoted by

$$
V_{1}^{i}, \cdots, V_{m_{i}}^{i}, B_{i}
$$

Consider

$$
\left\{U, V_{j}^{i}, j=1, \cdots, m_{i}, i=1, \cdots, m\right\}
$$

If $p \in H \backslash \cup\left\{V_{j}^{i}\right\}$, then $p \in B_{i}$ for each $i$ and so $p \in U$. This is therefore a finite subcover of $\mathscr{D}$ contradicting the properties of $\mathscr{D}$. Therefore, $\mathscr{F}$ must be empty and this proves the theorem.

Definition 14.3.4 Let I be a set and suppose for each $i \in I,\left(X_{i}, \tau_{i}\right)$ is a nonempty topological space. The Cartesian product of the $X_{i}$, denoted by $\prod_{i \in I} X_{i}$, consists of the set of all choice functions defined on I which select a single element of each $X_{i}$. Thus $f \in \prod_{i \in I} X_{i}$ means for every $i \in I, f(i) \in X_{i}$. The axiom of choice says $\prod_{i \in I} X_{i}$ is nonempty. Let

$$
P_{j}(A) \equiv \prod_{i \in I} B_{i}
$$

where $B_{i} \equiv X_{i}$ if $i \neq j$ and $B_{j}=A$. A subbasis for a topology on the product space consists of all sets $P_{j}(A)$ where $A \in \tau_{j}$. (These sets have an open set from the topology of $X_{j}$ in the $j^{\text {th }}$ slot and the whole space in the other slots.) Thus a basis consists of finite intersections of these sets. Note that the intersection of two of these basic sets is another basic set and their union yields $\prod_{i \in I} X_{i}$. Therefore, they satisfy the condition needed for a collection of sets to serve as a basis for a topology. This topology is called the product topology and is denoted by $\Pi \tau_{i}$.

Proposition 14.3.5 The product topology is the smallest topology $\tau$ for $X \equiv \prod_{i \in I} X_{i}$ such that each $\pi_{i}$ is continuous. Here $\pi_{i}$ is defined in the following manner. For $\mathbf{x} \in X, \pi_{i}(\mathbf{x}) \equiv$ $x_{i}$. Thus $\pi_{i}$ delivers the $i^{\text {th }}$ entry of $\mathbf{x}$.

Proof: If each $\pi_{i}$ is continuous, then for $A \in \tau_{i}, \pi_{i}^{-1}(A)$ must be in $\tau$. However, $\pi_{i}^{-1}(A)=P_{j}(A)$ having $A$ in the $i^{t h}$ slot and $X_{j}$ in every other. Therefore, $\tau$ must contain the sets $P_{j}(A)$. Since it must be a topology, it must also contain all finite intersections of these sets. Thus the topology $\tau$ must contain the product topology described in the above definition. Is it any larger? No, because if it were, it would not be the smallest topology making the coordinate maps continuous, due to the observation that these coordinate maps are indeed continuous with respect to the product topology.

It is tempting to define a basis for a topology to be sets of the form $\prod_{i \in I} A_{i}$ where $A_{i}$ is open in $X_{i}$. This is not the same thing at all. Note that the basis just described has at most finitely many slots filled with an open set which is not the whole space. The thing just mentioned in which every slot may be filled by a proper open set is called the box topology and there exist people who are interested in it.

The Alexander subbasis theorem is used to prove the Tychonoff theorem which says that if each $X_{i}$ is a compact topological space, then in the product topology, $\prod_{i \in I} X_{i}$ is also compact.

Theorem 14.3.6 If $\left(X_{i}, \tau_{i}\right)$ is compact, then so is $\left(\prod_{i \in I} X_{i}, \tau\right)$ where $\tau$ is the product topology.

Proof: By the Alexander subbasis theorem, the theorem will be proved if every subbasic open cover admits a finite subcover. Therefore, let $\mathscr{O}$ be a subbasic open cover of $X \equiv \prod_{i \in I} X_{i}$. Let

$$
\begin{aligned}
\mathscr{O}_{j} & =\left\{Q \in \mathscr{O}: \pi_{i} Q=X_{i} \text { for } i \neq j\right\} \\
\pi_{j} \mathscr{O}_{j} & \equiv\left\{\pi_{j} Q: Q \in \mathscr{O}_{j}\right\}
\end{aligned}
$$

Thus $\mathscr{O}_{j}$ are those sets of $\mathscr{O}$ which might have a proper open subset of $X_{j}$ in the $j^{t h}$ position. If each $\pi_{j} \mathscr{O}_{j}$ fails to cover $X_{j}$, then there exists

$$
f \in \prod_{j \in I} X_{j} \backslash \cup \pi_{j} \mathscr{O}_{j}
$$

Now $f$ is contained in some open set from $\mathscr{O}$ which must be in some $\mathscr{O}_{j}$. Hence $\pi_{j} f=$ $f(j) \in \cup \pi_{j} \mathscr{O}_{j}$ but this does not happen. Hence for some $j, \pi_{j} \mathscr{O}_{j}$ must cover $X_{j}$.

$$
X_{j}=\cup \pi_{j} \mathscr{O}_{j}
$$

and so by compactness of $X_{j}$, there exist $A_{1}, \cdots, A_{m}$, sets in $\tau_{j}$ such that $X_{j} \subseteq \cup_{k=1}^{m} A_{k}$ and letting $\pi_{j} U_{k}=A_{k}$ for $U_{k} \in \mathscr{O}_{j},\left\{U_{k}\right\}_{k=1}^{m}$ covers $\prod_{i \in I} X_{i}$. By the Alexander subbasis theorem this proves $\prod_{i \in I} X_{i}$ is compact.

### 14.4 Kolmogorov Extension Theorem

Let a subbasis for $[-\infty, \infty]$ be sets of the form $[-\infty, a)$ and $(a, \infty]$. Thus with this subbasis, $[-\infty, \infty]$ is a compact Hausdorff space. Also let $M_{t} \equiv[-\infty, \infty]^{n_{t}}$ where $n_{t}$ is a positive integer and endow this product with the product topology so that $M_{t}$ is also a compact Hausdorff space.
$I$ will denote a totally ordered index set, (Like $\mathbb{R})$ and the interest will be in building a measure on the product space, $\prod_{t \in I} M_{t}$. By the well ordering principle, you can always put an order on any index set so this order is no restriction, but we do not insist on a well order and in fact, index sets of great interest are $\mathbb{R}$ or $[0, \infty)$. Also for $X$ a topological space, $\mathscr{B}(X)$ will denote the Borel sets.

Notation 14.4.1 The symbol $J$ will denote a finite subset of $I, J=\left(t_{1}, \cdots, t_{n}\right)$, the $t_{i}$ taken in order. $\mathbf{E}_{J}$ will denote a set which has a set $E_{t}$ of $\mathscr{B}\left(M_{t}\right)$ in the $t^{t h}$ position for $t \in J$ and for $t \notin J$, the set in the $t^{\text {th }}$ position will be $M_{t} . \mathbf{K}_{J}$ will denote a set which has a compact set in the $t^{\text {th }}$ position for $t \in J$ and for $t \notin J$, the set in the $t^{\text {th }}$ position will be $M_{t}$. Thus $\mathbf{K}_{J}$ is compact in the product topology of $\Omega \equiv \prod_{t \in I} M_{t}$.Also denote by $\mathscr{R}_{J}$ the sets $\mathbf{E}_{J}$ and $\mathscr{R}$ the union of the $\mathscr{R}_{J}$. Let $\mathscr{E}_{J}$ denote finite disjoint unions of sets of $\mathscr{R}_{J}$ and let $\mathscr{E}$ denote finite disjoint unions of sets of $\mathscr{R}$. Thus if $\mathbf{F}$ is a set of $\mathscr{E}$, there exists $J$ such that $\mathbf{F}$ is a finite disjoint union of sets of $\mathscr{R}_{J}$. For $\mathbf{F} \in \Omega$, denote by $\pi_{J}(\mathbf{F})$ the set $\prod_{t \in J} F_{t}$ where $\mathbf{F}=\prod_{t \in I} F_{t}$.

Lemma 14.4.2 The sets, $\mathscr{E}, \mathscr{E}_{J}$ defined above form an algebra of sets of $\prod_{t \in I} M_{t}$.
Proof: First consider $\mathscr{R}_{J}$. If $\mathbf{A}, \mathbf{B} \in \mathscr{R}_{J}$, then $\mathbf{A} \cap \mathbf{B} \in \mathscr{R}_{J}$ also. Is $\mathbf{A} \backslash \mathbf{B}$ a finite disjoint union of sets of $\mathscr{R}_{J}$ ? It suffices to verify that $\pi_{J}(\mathbf{A} \backslash \mathbf{B})$ is a finite disjoint union of $\pi_{J}\left(\mathscr{R}_{J}\right)$. Let $|J|$ denote the number of indices in $J$. If $|J|=1$, then it is obvious that $\pi_{J}(\mathbf{A} \backslash \mathbf{B})$ is a finite disjoint union of sets of $\pi_{J}\left(\mathscr{R}_{J}\right)$. In fact, letting $J=(t)$ and the $t^{t h}$ entry of $\mathbf{A}$ is $A$ and the $t^{\text {th }}$ entry of $\mathbf{B}$ is $B$, then the $t^{t h}$ entry of $\mathbf{A} \backslash \mathbf{B}$ is $A \backslash B$, a Borel set of $M_{t}$, a finite disjoint union of Borel sets of $M_{t}$.

Suppose then that for $\mathbf{A}, \mathbf{B}$ sets of $\mathscr{R}_{J}, \pi_{J}(\mathbf{A} \backslash \mathbf{B})$ is a finite disjoint union of sets of $\pi_{J}\left(\mathscr{R}_{J}\right)$ for $|J| \leq n$, and consider $J=\left(t_{1}, \cdots, t_{n}, t_{n+1}\right)$. Let the $t_{i}^{t h}$ entry of $\mathbf{A}$ and $\mathbf{B}$ be respectively $A_{i}$ and $B_{i}$. It follows that $\pi_{J}(\mathbf{A} \backslash \mathbf{B})$ has the following in the entries for $J$

$$
\left(A_{1} \times A_{2} \times \cdots \times A_{n} \times A_{n+1}\right) \backslash\left(B_{1} \times B_{2} \times \cdots \times B_{n} \times B_{n+1}\right)
$$

Letting $A$ represent $A_{1} \times A_{2} \times \cdots \times A_{n}$ and $B$ represent $B_{1} \times B_{2} \times \cdots \times B_{n}$, this is of the form

$$
A \times\left(A_{n+1} \backslash B_{n+1}\right) \cup(A \backslash B) \times\left(A_{n+1} \cap B_{n+1}\right)
$$

By induction, $(A \backslash B)$ is the finite disjoint union of sets of $\mathscr{R}_{\left(t_{1}, \cdots, t_{n}\right)}$. Therefore, the above is the finite disjoint union of sets of $\mathscr{R}_{J}$. It follows that $\mathscr{E}_{J}$ is an algebra.

Now suppose $\mathbf{A}, \mathbf{B} \in \mathscr{R}$. Then for some finite set $J$, both are in $\mathscr{R}_{J}$. Then from what was just shown,

$$
\mathbf{A} \backslash \mathbf{B} \in \mathscr{E}_{J} \subseteq \mathscr{E}, \mathbf{A} \cap \mathbf{B} \in \mathscr{R} .
$$

By Lemma 12.10.2 on Page 318 this shows $\mathscr{E}$ is an algebra.
With this preparation, here is the Kolmogorov extension theorem. In the statement and proof of the theorem, $F_{i}, G_{i}$, and $E_{i}$ will denote Borel sets. Any list of indices from $I$ will always be assumed to be taken in order. Thus, if $J \subseteq I$ and $J=\left(t_{1}, \cdots, t_{n}\right)$, it will always be assumed $t_{1}<t_{2}<\cdots<t_{n}$.

Theorem 14.4.3 For each finite set

$$
J=\left(t_{1}, \cdots, t_{n}\right) \subseteq I
$$

suppose there exists a Borel probability measure, $v_{J}=v_{t_{1} \cdots t_{n}}$ defined on the Borel sets of $\prod_{t \in J} M_{t}$ such that the following consistency condition holds. If

$$
\left(t_{1}, \cdots, t_{n}\right) \subseteq\left(s_{1}, \cdots, s_{p}\right)
$$

then

$$
\begin{equation*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=v_{s_{1} \cdots s_{p}}\left(G_{s_{1}} \times \cdots \times G_{s_{p}}\right) \tag{14.4.1}
\end{equation*}
$$

where if $s_{i}=t_{j}$, then $G_{s_{i}}=F_{t_{j}}$ and if $s_{i}$ is not equal to any of the indices, $t_{k}$, then $G_{s_{i}}=M_{s_{i}}$. Then for $\mathscr{E}$ defined in Definition 14.4.1, there exists a probability measure, $P$ and a $\sigma$ algebra $\mathscr{F}=\sigma(\mathscr{E})$ such that

$$
\left(\prod_{t \in I} M_{t}, P, \mathscr{F}\right)
$$

is a probability space. Also there exist measurable functions, $X_{s}: \prod_{t \in I} M_{t} \rightarrow M_{s}$ defined as

$$
X_{s} \mathbf{x} \equiv x_{s}
$$

for each $s \in I$ such that for each $\left(t_{1} \cdots t_{n}\right) \subseteq I$,

$$
\begin{gather*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=P\left(\left[X_{t_{1}} \in F_{t_{1}}\right] \cap \cdots \cap\left[X_{t_{n}} \in F_{t_{n}}\right]\right) \\
\quad=P\left(\left(X_{t_{1}}, \cdots, X_{t_{n}}\right) \in \prod_{j=1}^{n} F_{t_{j}}\right)=P\left(\prod_{t \in I} F_{t}\right) \tag{14.4.2}
\end{gather*}
$$

where $F_{t}=M_{t}$ for every $t \notin\left\{t_{1} \cdots t_{n}\right\}$ and $F_{t_{i}}$ is a Borel set. Also if $f$ is a nonnegative function of finitely many variables, $x_{t_{1}}, \cdots, x_{t_{n}}$, measurable with respect to $\mathscr{B}\left(\prod_{j=1}^{n} M_{t_{j}}\right)$, then $f$ is also measurable with respect to $\mathscr{F}$ and

$$
\begin{align*}
& \int_{M_{t_{1} \times \cdots \times M_{t_{n}}}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d v_{t_{1} \cdots t_{n}} \\
= & \int_{\Pi_{t \in I} M_{t}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d P \tag{14.4.3}
\end{align*}
$$

Proof: Let $\mathscr{E}$ be the algebra of sets defined in Definition 14.4.1. I want to define a measure on $\mathscr{E}$. For $\mathbf{F} \in \mathscr{E}$, there exists $J$ such that $\mathbf{F}$ is the finite disjoint unions of sets of $\mathscr{R}_{J}$. Define

$$
P_{0}(\mathbf{F}) \equiv v_{J}\left(\pi_{J}(\mathbf{F})\right)
$$

Then $P_{0}$ is well defined because of the consistency condition on the measures $v_{J} . P_{0}$ is clearly finitely additive because the $v_{J}$ are measures and one can pick $J$ as large as desired to include all $t$ where there may be something other than $M_{t}$. Also, from the definition,

$$
P_{0}(\Omega) \equiv P_{0}\left(\prod_{t \in I} M_{t}\right)=v_{t_{1}}\left(M_{t_{1}}\right)=1
$$

Next I will show $P_{0}$ is a finite measure on $\mathscr{E}$. After this it is only a matter of using the Caratheodory extension theorem to get the existence of the desired probability measure $P$.

Claim: Suppose $\mathbf{E}^{n}$ is in $\mathscr{E}$ and suppose $\mathbf{E}^{n} \downarrow \emptyset$. Then $P_{0}\left(\mathbf{E}^{n}\right) \downarrow 0$.
Proof of the claim: If not, there exists a sequence such that although $\mathbf{E}^{n} \downarrow \emptyset, P_{0}\left(\mathbf{E}^{n}\right) \downarrow$ $\varepsilon>0$. Let $\mathbf{E}^{n} \in \mathscr{E}_{J_{n}}$. Thus it is a finite disjoint union of sets of $\mathscr{R}_{J_{n}}$. By regularity of the measures $v_{J}$, there exists a compact set $\mathbf{K}_{J_{n}} \subseteq \mathbf{E}^{n}$ such that

$$
v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{K}_{J_{n}}\right)\right)+\frac{\varepsilon}{2^{n+2}}>v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{E}^{n}\right)\right)
$$

Thus

$$
\begin{aligned}
P_{0}\left(\mathbf{K}_{J_{n}}\right)+\frac{\varepsilon}{2^{n+2}} & \equiv v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{K}_{J_{n}}\right)\right)+\frac{\varepsilon}{2^{n+2}} \\
& >v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{E}^{n}\right)\right) \equiv P_{0}\left(\mathbf{E}^{n}\right)
\end{aligned}
$$

The interesting thing about these $\mathbf{K}_{J_{n}}$ is: they have the finite intersection property. Here is why.

$$
\begin{aligned}
\varepsilon & \leq P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+P_{0}\left(\mathbf{E}^{m} \backslash \cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right) \\
& \leq P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+P_{0}\left(\cup_{k=1}^{m} \mathbf{E}^{k} \backslash \mathbf{K}_{J_{k}}\right) \\
& <P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+\sum_{k=1}^{\infty} \frac{\varepsilon}{2^{k+2}}<P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+\varepsilon / 2
\end{aligned}
$$

and so $P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)>\varepsilon / 2$. Now this yields a contradiction, because this finite intersection property implies the intersection of all the $\mathbf{K}_{J_{k}}$ is nonempty, contradicting $\mathbf{E}^{n} \downarrow \emptyset$ since each $\mathbf{K}_{J_{n}}$ is contained in $\mathbf{E}^{n}$.

With the claim, it follows $P_{0}$ is a measure on $\mathscr{E}$. Here is why: If $\mathbf{E}=\cup_{k=1}^{\infty} \mathbf{E}^{k}$ where $\mathbf{E}, \mathbf{E}^{k} \in \mathscr{E}$, then $\left(\mathbf{E} \backslash \cup_{k=1}^{n} \mathbf{E}_{k}\right) \downarrow \emptyset$ and so

$$
P_{0}\left(\cup_{k=1}^{n} \mathbf{E}_{k}\right) \rightarrow P_{0}(\mathbf{E})
$$

Hence if the $\mathbf{E}_{k}$ are disjoint, $P_{0}\left(\cup_{k=1}^{n} \mathbf{E}_{k}\right)=\sum_{k=1}^{n} P_{0}\left(\mathbf{E}_{k}\right) \rightarrow P_{0}(\mathbf{E})$. Thus for disjoint $\mathbf{E}_{k}$ having $\cup_{k} \mathbf{E}_{k}=\mathbf{E} \in \mathscr{E}$,

$$
P_{0}\left(\cup_{k=1}^{\infty} \mathbf{E}_{k}\right)=\sum_{k=1}^{\infty} P_{0}\left(\mathbf{E}_{k}\right)
$$

Now to conclude the proof, apply the Caratheodory extension theorem to obtain $P$ a probability measure which extends $P_{0}$ to a $\sigma$ algebra which contains $\sigma(\mathscr{E})$ the sigma algebra generated by $\mathscr{E}$ with $P=P_{0}$ on $\mathscr{E}$. Thus for $\mathbf{E}_{J} \in \mathscr{E}, P\left(\mathbf{E}_{J}\right)=P_{0}\left(\mathbf{E}_{J}\right)=v_{J}\left(P_{J} \mathbf{E}_{j}\right)$.

Next, let $\left(\prod_{t \in I} M_{t}, \mathscr{F}, P\right)$ be the probability space and for $\mathbf{x} \in \prod_{t \in I} M_{t}$ let $X_{t}(\mathbf{x})=x_{t}$, the $t^{t h}$ entry of $\mathbf{x}$. It follows $X_{t}$ is measurable (also continuous) because if $U$ is open in $M_{t}$, then $X_{t}^{-1}(U)$ has a $U$ in the $t^{t h}$ slot and $M_{s}$ everywhere else for $s \neq t$. Thus inverse images of open sets are measurable. Also, letting $J$ be a finite subset of $I$ and for $J=\left(t_{1}, \cdots, t_{n}\right)$, and $F_{t_{1}}, \cdots, F_{t_{n}}$ Borel sets in $M_{t_{1}} \cdots M_{t_{n}}$ respectively, it follows $\mathbf{F}_{J}$, where $\mathbf{F}_{J}$ has $F_{t_{i}}$ in the $t_{i}^{t h}$ entry, is in $\mathscr{E}$ and therefore,

$$
\begin{gathered}
P\left(\left[X_{t_{1}} \in F_{t_{1}}\right] \cap\left[X_{t_{2}} \in F_{t_{2}}\right] \cap \cdots \cap\left[X_{t_{n}} \in F_{t_{n}}\right]\right)= \\
P\left(\left[\left(X_{t_{1}}, X_{t_{2}}, \cdots, X_{t_{n}}\right) \in F_{t_{1}} \times \cdots \times F_{t_{n}}\right]\right)=P\left(\mathbf{F}_{J}\right)=P_{0}\left(\mathbf{F}_{J}\right) \\
=v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)
\end{gathered}
$$

Finally consider the claim about the integrals. Suppose $f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right)=\mathscr{X}_{F}$ where $F$ is a Borel set of $\prod_{t \in J} M_{t}$ where $J=\left(t_{1}, \cdots, t_{n}\right)$. To begin with suppose

$$
\begin{equation*}
F=F_{t_{1}} \times \cdots \times F_{t_{n}} \tag{14.4.4}
\end{equation*}
$$

where each $F_{t_{j}}$ is in $\mathscr{B}\left(M_{t_{j}}\right)$. Then

$$
\begin{gather*}
\int_{M_{t_{1} \times \cdots \times M_{t_{n}}}} \mathscr{X}_{F}\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d v_{t_{1} \cdots t_{n}}=v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right) \\
=P\left(\prod_{t \in I} F_{t}\right)=\int_{\Omega} \mathscr{X}_{\prod_{t \in I} F_{t}}(\mathbf{x}) d P \\
=\int_{\Omega} \mathscr{X}_{F}\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d P \tag{14.4.5}
\end{gather*}
$$

where $F_{t}=M_{t}$ if $t \notin J$. Let $\mathscr{K}$ denote sets, $F$ of the sort in 14.4.4. It is clearly a $\pi$ system. Now let $\mathscr{G}$ denote those sets $F$ in $\mathscr{B}\left(\prod_{t \in J} M_{t}\right)$ such that 14.4 .5 holds. Thus $\mathscr{G} \supseteq \mathscr{K}$. It is clear that $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. Hence $\mathscr{G} \supseteq \sigma(\mathscr{K})$ but $\sigma(\mathscr{K})=\mathscr{B}\left(\prod_{t \in J} M_{t}\right)$ because every open set in $\prod_{t \in J} M_{t}$ is the countable union of rectangles like 14.4.4 in which each $F_{t_{i}}$ is open. Therefore, 14.4.5 holds for every $F \in \mathscr{B}\left(\prod_{t \in J} M_{t}\right)$.

Passing to simple functions and then using the monotone convergence theorem yields the final claim of the theorem.

The next task is to consider the case where $M_{t}=(-\infty, \infty)^{n_{t}}$. To consider this case, here is a lemma which will allow this case to be deduced from the above theorem. In this lemma, $M_{t}^{\prime} \equiv[-\infty, \infty]^{n_{t}}$.

Lemma 14.4.4 Let $J$ be a finite subset of $I$. Then $\mathbf{U}$ is a Borel set in $\prod_{t \in J} M_{t}$ if and only if there exists a Borel set, $\mathbf{U}^{\prime}$ in $\prod_{t \in J} M_{t}^{\prime}$ such that $\mathbf{U}=\mathbf{U}^{\prime} \cap \prod_{t \in J} M_{t}$.

Proof: A subbasis for the topology for $[-\infty, \infty]$ is sets of the form $[-\infty, a)$ and $(a, \infty]$. Also a subbasis for the topology of $[-\infty, \infty]^{n}$ consists of sets of the form $\prod_{i=1}^{n}\left[-\infty, a_{i}\right)$ and $\prod_{i=1}^{n}\left(a_{i}, \infty\right]$. Similarly, a subbasis for the topology of $(-\infty, \infty)^{n}$ consists of sets of the form $\prod_{i=1}^{n}\left(-\infty, a_{i}\right)$ and $\prod_{i=1}^{n}\left(a_{i}, \infty\right)$. Thus the basic open sets of $\prod_{t \in J} M_{t}$ are of the form
$\mathbf{U}^{\prime} \cap \prod_{t \in J} M_{t}$ where $\mathbf{U}^{\prime}$ is a basic open set in $\prod_{t \in J} M_{t}^{\prime}$. It follows the open sets of $\prod_{t \in J} M_{t}$ are of the form $\mathbf{U}^{\prime} \cap \prod_{t \in J} M_{t}$ where $\mathbf{U}^{\prime}$ is open in $\prod_{t \in J} M_{t}^{\prime}$. Let $\mathscr{F}$ denote those Borel sets of $\prod_{t \in J} M_{t}$ which are of the form $\mathbf{U}^{\prime} \cap \prod_{t \in J} M_{t}$ for $\mathbf{U}^{\prime}$ a Borel set in $\prod_{t \in J} M_{t}^{\prime}$. Then as just shown, $\mathscr{F}$ contains the $\pi$ system of open sets in $\prod_{t \in J} M_{t}$. Let $\mathscr{G}$ denote those Borel sets of $\prod_{t \in J} M_{t}$ which are of the desired form. It is clearly closed with respect to complements and countable disjoint unions. Hence $\mathscr{G}$ equals the Borel sets of $\prod_{t \in J} M_{t}$.

Now here is the Kolmogorov extension theorem in the desired form. However, a more general version is given later where $M_{t}$ is just a Polish space (complete separable metric space).

Theorem 14.4.5 (Kolmogorov extension theorem) For each finite set

$$
J=\left(t_{1}, \cdots, t_{n}\right) \subseteq I
$$

suppose there exists a Borel probability measure, $v_{J}=v_{t_{1} \cdots t_{n}}$ defined on the Borel sets of $\prod_{t \in J} M_{t}$ for $M_{t}=\mathbb{R}^{n_{t}}$ for $n_{t}$ an integer, such that the following consistency condition holds. If

$$
\left(t_{1}, \cdots, t_{n}\right) \subseteq\left(s_{1}, \cdots, s_{p}\right)
$$

then

$$
\begin{equation*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=v_{s_{1} \cdots s_{p}}\left(G_{s_{1}} \times \cdots \times G_{s_{p}}\right) \tag{14.4.6}
\end{equation*}
$$

where if $s_{i}=t_{j}$, then $G_{s_{i}}=F_{t_{j}}$ and if $s_{i}$ is not equal to any of the indices, $t_{k}$, then $G_{s_{i}}=M_{s_{i}}$. Then for $\mathscr{E}$ defined as in Definition 14.4.1, adjusted so that $\pm \infty$ never appears as any endpoint of any interval, there exists a probability measure, $P$ and a $\sigma$ algebra $\mathscr{F}=\sigma(\mathscr{E})$ such that

$$
\left(\prod_{t \in I} M_{t}, P, \mathscr{F}\right)
$$

is a probability space. Also there exist measurable functions, $X_{s}: \prod_{t \in I} M_{t} \rightarrow M_{s}$ defined as

$$
X_{S} \mathbf{x} \equiv x_{s}
$$

for each $s \in I$ such that for each $\left(t_{1} \cdots t_{n}\right) \subseteq I$,

$$
\begin{gather*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=P\left(\left[X_{t_{1}} \in F_{t_{1}}\right] \cap \cdots \cap\left[X_{t_{n}} \in F_{t_{n}}\right]\right) \\
\quad=P\left(\left(X_{t_{1}}, \cdots, X_{t_{n}}\right) \in \prod_{j=1}^{n} F_{t_{j}}\right)=P\left(\prod_{t \in I} F_{t}\right) \tag{14.4.7}
\end{gather*}
$$

where $F_{t}=M_{t}$ for every $t \notin\left\{t_{1} \cdots t_{n}\right\}$ and $F_{t_{i}}$ is a Borel set. Also if $f$ is a nonnegative function of finitely many variables, $x_{t_{1}}, \cdots, x_{t_{n}}$, measurable with respect to $\mathscr{B}\left(\prod_{j=1}^{n} M_{t_{j}}\right)$, then $f$ is also measurable with respect to $\mathscr{F}$ and

$$
\begin{align*}
& \int_{M_{t_{1} \times \cdots \times M_{t_{n}}}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d v_{t_{1} \cdots t_{n}} \\
= & \int_{\prod_{t \in I} M_{t}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d P \tag{14.4.8}
\end{align*}
$$

Proof: Using Lemma 14.4.4, extend each measure, $v_{J}$ to $M_{t}^{\prime}$, defined by adding in the points $\pm \infty$ at the ends, by letting $v_{J}(\mathbf{E}) \equiv v_{J}\left(\mathbf{E} \cap \prod_{t \in I} M_{t}\right)$ for all $\mathbf{E} \in \mathscr{B}\left(\prod_{t \in I} M_{t}^{\prime}\right)$. Then apply Theorem 14.4 .3 to these extended measures and use the definition of the extensions of each $v_{J}$ to replace each $M_{t}^{\prime}$ with $M_{t}$ everywhere it occurs.

As a special case, you can obtain a version of product measure for possibly infinitely many factors. Suppose in the context of the above theorem that $v_{t}$ is a probability measure defined on the Borel sets of $M_{t} \equiv \mathbb{R}^{n_{t}}$ for $n_{t}$ a positive integer, and let the measures, $v_{t_{1} \cdots t_{n}}$ be defined on the Borel sets of $\prod_{i=1}^{n} M_{t_{i}}$ by

$$
v_{t_{1} \cdots t_{n}}(\mathbf{E}) \equiv \overbrace{\left(v_{t_{1}} \times \cdots \times v_{t_{n}}\right)}^{\text {product measure }}(\mathbf{E}) .
$$

Then these measures satisfy the necessary consistency condition and so the Kolmogorov extension theorem given above can be applied to obtain a measure $P$ defined on a measurable space $\left(\prod_{t \in I} M_{t}, \mathscr{F}\right)$ and measurable functions $X_{s}: \prod_{t \in I} M_{t} \rightarrow M_{s}$ such that for $F_{t_{i}}$ a Borel set in $M_{t_{i}}$,

$$
\begin{gather*}
P\left(\left(X_{t_{1}}, \cdots, X_{t_{n}}\right) \in \prod_{i=1}^{n} F_{t_{i}}\right)=v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right) \\
=v_{t_{1}}\left(F_{t_{1}}\right) \cdots v_{t_{n}}\left(F_{t_{n}}\right) \tag{14.4.9}
\end{gather*}
$$

In particular, $P\left(X_{t} \in F_{t}\right)=v_{t}\left(F_{t}\right)$. Then $P$ in the resulting probability space,

$$
\left(\prod_{t \in I} M_{t}, \mathscr{F}, P\right)
$$

will be denoted as $\prod_{t \in I} v_{t}$. This proves the following theorem which describes an infinite product measure.

Theorem 14.4.6 Let $M_{t}$ for $t \in I$ be given as in Theorem 14.4.5 and let $v_{t}$ be a Borel probability measure defined on the Borel sets of $M_{t}$. Then there exists a measure $P$ and a $\sigma$ algebra $\mathscr{F}=\sigma(\mathscr{E})$ where $\mathscr{E}$ is given in Definition 14.4.1 such that $\left(\prod_{t} M_{t}, \mathscr{F}, P\right)$ is a probability space satisfying 14.4 .9 whenever each $F_{t_{i}}$ is a Borel set of $M_{t_{i}}$. This probability measure is sometimes denoted as $\prod_{t} v_{t}$.

### 14.5 Exercises

1. Let $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{F}, \lambda)$ be two finite measure spaces. A subset of $X \times Y$ is called a measurable rectangle if it is of the form $A \times B$ where $A \in \mathscr{S}$ and $B \in \mathscr{F}$. A subset of $X \times Y$ is called an elementary set if it is a finite disjoint union of measurable rectangles. Denote this set of functions by $\mathscr{E}$. Show that $\mathscr{E}$ is an algebra of sets.
2. $\uparrow$ For $A \in \sigma(\mathscr{E})$, the smallest $\sigma$ algebra containing $\mathscr{E}$, show that $x \rightarrow \mathscr{X}_{A}(x, y)$ is $\mu$ measurable and that

$$
y \rightarrow \int \mathscr{X}_{A}(x, y) d \mu
$$

is $\lambda$ measurable. Show similar assertions hold for $y \rightarrow \mathscr{X}_{A}(x, y)$ and

$$
x \rightarrow \int \mathscr{X}_{A}(x, y) d \lambda
$$

and that

$$
\begin{equation*}
\iint \mathscr{X}_{A}(x, y) d \mu d \lambda=\iint \mathscr{X}_{A}(x, y) d \lambda d \mu . \tag{14.5.10}
\end{equation*}
$$

Hint: Let $\mathscr{M} \equiv\{A \in \sigma(\mathscr{E}): 14.5 .10$ holds $\}$ along with all relevant measurability assertions. Show $\mathscr{M}$ contains $\mathscr{E}$ and is a monotone class. Then apply the Theorem 12.10.5.
3. $\uparrow$ For $A \in \sigma(\mathscr{E})$ define $(\mu \times \lambda)(A) \equiv \iint \mathscr{X}_{A}(x, y) d \mu d \lambda$. Show that $(\mu \times \lambda)$ is a measur on $\sigma(\mathscr{E})$ and that whenever $f \geq 0$ is measurable with respect to $\sigma(\mathscr{E})$,

$$
\int_{X \times Y} f d(\mu \times \lambda)=\iint f(x, y) d \mu d \lambda=\iint f(x, y) d \lambda d \mu .
$$

This is a common approach to Fubini's theorem.
4. $\uparrow$ Generalize the above version of Fubini's theorem to the case where the measure spaces are only $\sigma$ finite.
5. $\uparrow$ Suppose now that $\mu$ and $\lambda$ are both complete $\sigma$ finite measures. Let $\overline{(\mu \times \lambda)}$ denote the completion of this measure. Let the larger measure space be

$$
(X \times Y, \overline{\sigma(\mathscr{E})}, \overline{(\mu \times \lambda)})
$$

Thus if $E \in \overline{\sigma(\mathscr{E})}$, it follows there exists a set $A \in \sigma(\mathscr{E})$ such that $E \cup N=A$ where $\overline{(\mu \times \lambda)}(N)=0$. Now argue that for $\lambda$ a.e. $y, x \rightarrow \mathscr{X}_{N}(x, y)$ is measurable because it is equal to zero $\mu$ a.e. and $\mu$ is complete. Therefore,

$$
\iint \mathscr{X}_{N}(x, y) d \mu d \lambda
$$

makes sense and equals zero. Use to argue that for $\lambda$ a.e. $y, x \rightarrow \mathscr{X}_{E}(x, y)$ is $\mu$ measurable and equals $\int \mathscr{X}_{A}(x, y) d \mu$. Then by completeness of $\lambda, y \rightarrow \int \mathscr{X}_{E}(x, y) d \mu$ is $\lambda$ measurable and

$$
\iint \mathscr{X}_{A}(x, y) d \mu d \lambda=\iint \mathscr{X}_{E}(x, y) d \mu d \lambda=\overline{(\mu \times \lambda)}(E) .
$$

Similarly

$$
\iint \mathscr{X}_{E}(x, y) d \lambda d \mu=\overline{(\mu \times \lambda)}(E)
$$

Use this to give a generalization of the above Fubini theorem. Prove that if $f$ is measurable with respect to the $\sigma$ algebra, $\overline{\sigma(\mathscr{E})}$ and nonnegative, then

$$
\int_{X \times Y} f d \overline{(\mu \times \lambda)}=\iint f(x, y) d \mu d \lambda=\iint f(x, y) d \lambda d \mu
$$

where the iterated integrals make sense.

## Chapter 15

## The $L^{p}$ Spaces

### 15.1 Basic Inequalities And Properties

One of the main applications of the Lebesgue integral is to the study of various sorts of functions space. These are vector spaces whose elements are functions of various types. One of the most important examples of a function space is the space of measurable functions whose absolute values are $p^{t h}$ power integrable where $p \geq 1$. These spaces, referred to as $L^{p}$ spaces, are very useful in applications. In the chapter $(\Omega, \mathscr{S}, \mu)$ will be a measure space.

Definition 15.1.1 Let $1 \leq p<\infty$. Define

$$
L^{p}(\Omega) \equiv\left\{f: f \text { is measurable and } \int_{\Omega}|f(\omega)|^{p} d \mu<\infty\right\}
$$

In terms of the distribution function,

$$
L^{p}(\Omega)=\left\{f: f \text { is measurable and } \int_{0}^{\infty} p t^{p-1} \mu([|f|>t]) d t<\infty\right\}
$$

For each $p>1$ define $q$ by

$$
\frac{1}{p}+\frac{1}{q}=1
$$

Often one uses $p^{\prime}$ instead of $q$ in this context.
$L^{p}(\Omega)$ is a vector space and has a norm. This is similar to the situation for $\mathbb{R}^{n}$ but the proof requires the following fundamental inequality. .

Theorem 15.1.2 (Holder's inequality) If $f$ and $g$ are measurable functions, then if $p>1$,

$$
\begin{equation*}
\int|f||g| d \mu \leq\left(\int|f|^{p} d \mu\right)^{\frac{1}{p}}\left(\int|g|^{q} d \mu\right)^{\frac{1}{q}} \tag{15.1.1}
\end{equation*}
$$

Proof: First here is a proof of Young's inequality .
Lemma 15.1.3 If $p>1$, and $0 \leq a, b$ then $a b \leq \frac{a^{p}}{p}+\frac{b^{q}}{q}$.
Proof: Consider the following picture:

From this picture, the sum of the area between the $x$ axis and the curve added to the
area between the $t$ axis and the curve is at least as large as $a b$. Using beginning calculus, this is equivalent to the following inequality.

$$
a b \leq \int_{0}^{a} t^{p-1} d t+\int_{0}^{b} x^{q-1} d x=\frac{a^{p}}{p}+\frac{b^{q}}{q} .
$$

The above picture represents the situation which occurs when $p>2$ because the graph of the function is concave up. If $2 \geq p>1$ the graph would be concave down or a straight line. You should verify that the same argument holds in these cases just as well. In fact, the only thing which matters in the above inequality is that the function $x=t^{p-1}$ be strictly increasing.

Note equality occurs when $a^{p}=b^{q}$.
Here is an alternate proof.
Lemma 15.1.4 For $a, b \geq 0$,

$$
a b \leq \frac{a^{p}}{p}+\frac{b^{q}}{q}
$$

and equality occurs when if and only if $a^{p}=b^{q}$.
Proof: If $b=0$, the inequality is obvious. Fix $b>0$ and consider

$$
f(a) \equiv \frac{a^{p}}{p}+\frac{b^{q}}{q}-a b
$$

Then $f^{\prime}(a)=a^{p-1}-b$. This is negative when $a<b^{1 /(p-1)}$ and is positive when $a>$ $b^{1 /(p-1)}$. Therefore, $f$ has a minimum when $a=b^{1 /(p-1)}$. In other words, when $a^{p}=$ $b^{p /(p-1)}=b^{q}$ since $1 / p+1 / q=1$. Thus the minimum value of $f$ is

$$
\frac{b^{q}}{p}+\frac{b^{q}}{q}-b^{1 /(p-1)} b=b^{q}-b^{q}=0
$$

It follows $f \geq 0$ and this yields the desired inequality.
Proof of Holder's inequality: If either $\int|f|^{p} d \mu$ or $\int|g|^{p} d \mu$ equals $\infty$, the inequality 15.1.1 is obviously valid because $\infty \geq$ anything. If either $\int|f|^{p} d \mu$ or $\int|g|^{p} d \mu$ equals 0 , then $f=0$ a.e. or that $g=0$ a.e. and so in this case the left side of the inequality equals 0 and so the inequality is therefore true. Therefore assume both $\int|f|^{p} d \mu$ and $\int|g|^{p} d \mu$ are less than $\infty$ and not equal to 0 . Let

$$
\left(\int|f|^{p} d \mu\right)^{1 / p}=I(f)
$$

and let $\left(\int|g|^{p} d \mu\right)^{1 / q}=I(g)$. Then using the lemma,

$$
\int \frac{|f|}{I(f)} \frac{|g|}{I(g)} d \mu \leq \frac{1}{p} \int \frac{|f|^{p}}{I(f)^{p}} d \mu+\frac{1}{q} \int \frac{|g|^{q}}{I(g)^{q}} d \mu=1
$$

Hence,

$$
\int|f||g| d \mu \leq I(f) I(g)=\left(\int|f|^{p} d \mu\right)^{1 / p}\left(\int|g|^{q} d \mu\right)^{1 / q}
$$

This proves Holder's inequality.
The following lemma will be needed.

Lemma 15.1.5 Suppose $x, y \in \mathbb{C}$. Then

$$
|x+y|^{p} \leq 2^{p-1}\left(|x|^{p}+|y|^{p}\right) .
$$

Proof: The function $f(t)=t^{p}$ is concave up for $t \geq 0$ because $p>1$. Therefore, the secant line joining two points on the graph of this function must lie above the graph of the function. This is illustrated in the following picture.

Now as shown above,

$$
\left(\frac{|x|+|y|}{2}\right)^{p} \leq \frac{|x|^{p}+|y|^{p}}{2}
$$

which implies

$$
|x+y|^{p} \leq(|x|+|y|)^{p} \leq 2^{p-1}\left(|x|^{p}+|y|^{p}\right)
$$

and this proves the lemma.
Note that if $y=\phi(x)$ is any function for which the graph of $\phi$ is concave up, you could get a similar inequality by the same argument.

Corollary 15.1.6 (Minkowski inequality) Let $1 \leq p<\infty$. Then

$$
\begin{equation*}
\left(\int|f+g|^{p} d \mu\right)^{1 / p} \leq\left(\int|f|^{p} d \mu\right)^{1 / p}+\left(\int|g|^{p} d \mu\right)^{1 / p} \tag{15.1.2}
\end{equation*}
$$

Proof: If $p=1$, this is obvious because it is just the triangle inequality. Let $p>1$. Without loss of generality, assume

$$
\left(\int|f|^{p} d \mu\right)^{1 / p}+\left(\int|g|^{p} d \mu\right)^{1 / p}<\infty
$$

and $\left(\int|f+g|^{p} d \mu\right)^{1 / p} \neq 0$ or there is nothing to prove. Therefore, using the above lemma,

$$
\int|f+g|^{p} d \mu \leq 2^{p-1}\left(\int|f|^{p}+|g|^{p} d \mu\right)<\infty
$$

Now $|f(\omega)+g(\omega)|^{p} \leq|f(\omega)+g(\omega)|^{p-1}(|f(\omega)|+|g(\omega)|)$. Also, it follows from the definition of $p$ and $q$ that $p-1=\frac{p}{q}$. Therefore, using this and Holder's inequality,

$$
\int|f+g|^{p} d \mu \leq
$$

$$
\begin{aligned}
& \int|f+g|^{p-1}|f| d \mu+\int|f+g|^{p-1}|g| d \mu \\
= & \int|f+g|^{\frac{p}{q}}|f| d \mu+\int|f+g|^{\frac{p}{q}}|g| d \mu \\
\leq & \left(\int|f+g|^{p} d \mu\right)^{\frac{1}{q}}\left(\int|f|^{p} d \mu\right)^{\frac{1}{p}}+\left(\int|f+g|^{p} d \mu\right)^{\frac{1}{q}}\left(\int|g|^{p} d \mu\right)^{\frac{1}{p}} .
\end{aligned}
$$

Dividing both sides by $\left(\int|f+g|^{p} d \mu\right)^{\frac{1}{q}}$ yields 15.1.2. This proves the corollary.
The following follows immediately from the above.
Corollary 15.1.7 Let $f_{i} \in L^{p}(\Omega)$ for $i=1,2, \cdots, n$. Then

$$
\left(\int\left|\sum_{i=1}^{n} f_{i}\right|^{p} d \mu\right)^{1 / p} \leq \sum_{i=1}^{n}\left(\int\left|f_{i}\right|^{p}\right)^{1 / p}
$$

This shows that if $f, g \in L^{p}$, then $f+g \in L^{p}$. Also, it is clear that if $a$ is a constant and $f \in L^{p}$, then $a f \in L^{p}$ because

$$
\int|a f|^{p} d \mu=|a|^{p} \int|f|^{p} d \mu<\infty
$$

Thus $L^{p}$ is a vector space and
a.) $\left(\int|f|^{p} d \mu\right)^{1 / p} \geq 0,\left(\int|f|^{p} d \mu\right)^{1 / p}=0$ if and only if $f=0$ a.e.
b.) $\left(\int|a f|^{p} d \mu\right)^{1 / p}=|a|\left(\int|f|^{p} d \mu\right)^{1 / p}$ if $a$ is a scalar.
c.) $\left(\int|f+g|^{p} d \mu\right)^{1 / p} \leq\left(\int|f|^{p} d \mu\right)^{1 / p}+\left(\int|g|^{p} d \mu\right)^{1 / p}$.
$f \rightarrow\left(\int|f|^{p} d \mu\right)^{1 / p}$ would define a norm if $\left(\int|f|^{p} d \mu\right)^{1 / p}=0$ implied $f=0$. Unfortunately, this is not so because if $f=0$ a.e. but is nonzero on a set of measure zero, $\left(\int|f|^{p} d \mu\right)^{1 / p}=0$ and this is not allowed. However, all the other properties of a norm are available and so a little thing like a set of measure zero will not prevent the consideration of $L^{p}$ as a normed vector space if two functions in $L^{p}$ which differ only on a set of measure zero are considered the same. That is, an element of $L^{p}$ is really an equivalence class of functions where two functions are equivalent if they are equal a.e. With this convention, here is a definition.

Definition 15.1.8 Let $f \in L^{p}(\Omega)$. Define

$$
\|f\|_{p} \equiv\|f\|_{L^{p}} \equiv\left(\int|f|^{p} d \mu\right)^{1 / p}
$$

Then with this definition and using the convention that elements in $L^{p}$ are considered to be the same if they differ only on a set of measure zero, $\left\|\|_{p}\right.$ is a norm on $L^{p}(\Omega)$ because if $\|f\|_{p}=0$ then $f=0$ a.e. and so $f$ is considered to be the zero function because it differs from 0 only on a set of measure zero.

The following is an important definition.

Definition 15.1.9 A complete normed linear space is called a Banach ${ }^{1}$ space.
$L^{p}$ is a Banach space. This is the next big theorem.
Theorem 15.1.10 The following hold for $L^{p}(\Omega)$
a.) $L^{p}(\Omega)$ is complete.
b.) If $\left\{f_{n}\right\}$ is a Cauchy sequence in $L^{p}(\Omega)$, then there exists $f \in L^{p}(\Omega)$ and a subsequence which converges a.e. to $f \in L^{p}(\Omega)$, and $\left\|f_{n}-f\right\|_{p} \rightarrow 0$.

Proof: Let $\left\{f_{n}\right\}$ be a Cauchy sequence in $L^{p}(\Omega)$. This means that for every $\varepsilon>0$ there exists $N$ such that if $n, m \geq N$, then $\left\|f_{n}-f_{m}\right\|_{p}<\varepsilon$. Now select a subsequence as follows. Let $n_{1}$ be such that $\left\|f_{n}-f_{m}\right\|_{p}<2^{-1}$ whenever $n, m \geq n_{1}$. Let $n_{2}$ be such that $n_{2}>n_{1}$ and $\left\|f_{n}-f_{m}\right\|_{p}<2^{-2}$ whenever $n, m \geq n_{2}$. If $n_{1}, \cdots, n_{k}$ have been chosen, let $n_{k+1}>n_{k}$ and whenever $n, m \geq n_{k+1},\left\|f_{n}-f_{m}\right\|_{p}<2^{-(k+1)}$. The subsequence just mentioned is $\left\{f_{n_{k}}\right\}$. Thus, $\left\|f_{n_{k}}-f_{n_{k+1}}\right\|_{p}<2^{-k}$. Let

$$
g_{k+1}=f_{n_{k+1}}-f_{n_{k}} .
$$

Then by the corollary to Minkowski’s inequality,

$$
\infty>\sum_{k=1}^{\infty}\left\|g_{k+1}\right\|_{p} \geq \sum_{k=1}^{m}\left\|g_{k+1}\right\|_{p} \geq\left\|\sum_{k=1}^{m}\left|g_{k+1}\right|\right\|_{p}
$$

for all $m$. It follows that

$$
\begin{equation*}
\int\left(\sum_{k=1}^{m}\left|g_{k+1}\right|\right)^{p} d \mu \leq\left(\sum_{k=1}^{\infty}\left\|g_{k+1}\right\|_{p}\right)^{p}<\infty \tag{15.1.3}
\end{equation*}
$$

for all $m$ and so the monotone convergence theorem implies that the sum up to $m$ in 15.1.3 can be replaced by a sum up to $\infty$. Thus,

$$
\int\left(\sum_{k=1}^{\infty}\left|g_{k+1}\right|\right)^{p} d \mu<\infty
$$

which requires

$$
\sum_{k=1}^{\infty}\left|g_{k+1}(x)\right|<\infty \text { a.e. } x
$$

[^15]Therefore, $\sum_{k=1}^{\infty} g_{k+1}(x)$ converges for a.e. $x$ because the functions have values in a complete space, $\mathbb{C}$, and this shows the partial sums form a Cauchy sequence. Now let $x$ be such that this sum is finite. Then define

$$
f(x) \equiv f_{n_{1}}(x)+\sum_{k=1}^{\infty} g_{k+1}(x)=\lim _{m \rightarrow \infty} f_{n_{m}}(x)
$$

since $\sum_{k=1}^{m} g_{k+1}(x)=f_{n_{m+1}}(x)-f_{n_{1}}(x)$. Therefore there exists a set, $E$ having measure zero such that

$$
\lim _{k \rightarrow \infty} f_{n_{k}}(x)=f(x)
$$

for all $x \notin E$. Redefine $f_{n_{k}}$ to equal 0 on $E$ and let $f(x)=0$ for $x \in E$. It then follows that $\lim _{k \rightarrow \infty} f_{n_{k}}(x)=f(x)$ for all $x$. By Fatou's lemma, and the Minkowski inequality,

$$
\begin{gather*}
\left\|f-f_{n_{k}}\right\|_{p}=\left(\int\left|f-f_{n_{k}}\right|^{p} d \mu\right)^{1 / p} \leq \\
\lim \inf _{m \rightarrow \infty}\left(\int\left|f_{n_{m}}-f_{n_{k}}\right|^{p} d \mu\right)^{1 / p}=\lim _{m \rightarrow \infty} \inf _{m \rightarrow{ }^{2}}\left\|f_{n_{m}}-f_{n_{k}}\right\|_{p} \leq \\
\lim \inf _{m \rightarrow \infty} \sum_{j=k}^{m-1}\left\|\mid f_{n_{j+1}}-f_{n_{j}}\right\|_{p} \leq \sum_{i=k}^{\infty}\left\|f_{n_{i+1}}-f_{n_{i}}\right\|_{p} \leq 2^{-(k-1)} . \tag{15.1.4}
\end{gather*}
$$

Therefore, $f \in L^{p}(\Omega)$ because

$$
\|f\|_{p} \leq\left\|f-f_{n_{k}}\right\|_{p}+\left\|f_{n_{k}}\right\|_{p}<\infty
$$

and $\lim _{k \rightarrow \infty}\left\|f_{n_{k}}-f\right\|_{p}=0$. This proves b.).
This has shown $f_{n_{k}}$ converges to $f$ in $L^{p}(\Omega)$. It follows the original Cauchy sequence also converges to $f$ in $L^{p}(\Omega)$. This is a general fact that if a subsequence of a Cauchy sequence converges, then so does the original Cauchy sequence. You should give a proof of this. This proves the theorem.

In working with the $L^{p}$ spaces, the following inequality also known as Minkowski's inequality is very useful. It is similar to the Minkowski inequality for sums. To see this, replace the integral, $\int_{X}$ with a finite summation sign and you will see the usual Minkowski inequality or rather the version of it given in Corollary 15.1.7.

To prove this theorem first consider a special case of it in which technical considerations which shed no light on the proof are excluded.

Lemma 15.1.11 Let $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{F}, \lambda)$ be finite complete measure spaces and let $f$ be $\overline{\mu \times \lambda}$ measurable and uniformly bounded. Then the following inequality is valid for $p \geq 1$.

$$
\begin{equation*}
\int_{X}\left(\int_{Y}|f(x, y)|^{p} d \lambda\right)^{\frac{1}{p}} d \mu \geq\left(\int_{Y}\left(\int_{X}|f(x, y)| d \mu\right)^{p} d \lambda\right)^{\frac{1}{p}} \tag{15.1.5}
\end{equation*}
$$

Proof: Since $f$ is bounded and $\mu(X), \lambda(Y)<\infty$,

$$
\left(\int_{Y}\left(\int_{X}|f(x, y)| d \mu\right)^{p} d \lambda\right)^{\frac{1}{p}}<\infty .
$$

Let

$$
J(y)=\int_{X}|f(x, y)| d \mu
$$

Note there is no problem in writing this for a.e. $y$ because $f$ is product measurable. Then by Fubini's theorem,

$$
\begin{aligned}
\int_{Y}\left(\int_{X}|f(x, y)| d \mu\right)^{p} d \lambda & =\int_{Y} J(y)^{p-1} \int_{X}|f(x, y)| d \mu d \lambda \\
& =\int_{X} \int_{Y} J(y)^{p-1}|f(x, y)| d \lambda d \mu
\end{aligned}
$$

Now apply Holder's inequality in the last integral above and recall $p-1=\frac{p}{q}$. This yields

$$
\begin{gather*}
\int_{Y}\left(\int_{X}|f(x, y)| d \mu\right)^{p} d \lambda \\
\leq \int_{X}\left(\int_{Y} J(y)^{p} d \lambda\right)^{\frac{1}{q}}\left(\int_{Y}|f(x, y)|^{p} d \lambda\right)^{\frac{1}{p}} d \mu \\
=\left(\int_{Y} J(y)^{p} d \lambda\right)^{\frac{1}{q}} \int_{X}\left(\int_{Y}|f(x, y)|^{p} d \lambda\right)^{\frac{1}{p}} d \mu \\
=\left(\int_{Y}\left(\int_{X}|f(x, y)| d \mu\right)^{p} d \lambda\right)^{\frac{1}{q}} \int_{X}\left(\int_{Y}|f(x, y)|^{p} d \lambda\right)^{\frac{1}{p}} d \mu \tag{15.1.6}
\end{gather*}
$$

Therefore, dividing both sides by the first factor in the above expression,

$$
\begin{equation*}
\left(\int_{Y}\left(\int_{X}|f(x, y)| d \mu\right)^{p} d \lambda\right)^{\frac{1}{p}} \leq \int_{X}\left(\int_{Y}|f(x, y)|^{p} d \lambda\right)^{\frac{1}{p}} d \mu \tag{15.1.7}
\end{equation*}
$$

Note that 15.1.7 holds even if the first factor of 15.1.6 equals zero. This proves the lemma.
Now consider the case where $f$ is not assumed to be bounded and where the measure spaces are $\sigma$ finite.

Theorem 15.1.12 Let $(X, \mathscr{S}, \mu)$ and $(Y, \mathscr{F}, \lambda)$ be $\sigma$-finite measure spaces and let $f$ be product measurable. Then the following inequality is valid for $p \geq 1$.

$$
\begin{equation*}
\int_{X}\left(\int_{Y}|f(x, y)|^{p} d \lambda\right)^{\frac{1}{p}} d \mu \geq\left(\int_{Y}\left(\int_{X}|f(x, y)| d \mu\right)^{p} d \lambda\right)^{\frac{1}{p}} \tag{15.1.8}
\end{equation*}
$$

Proof: Since the two measure spaces are $\sigma$ finite, there exist measurable sets, $X_{m}$ and $Y_{k}$ such that $X_{m} \subseteq X_{m+1}$ for all $m, Y_{k} \subseteq Y_{k+1}$ for all $k$, and $\mu\left(X_{m}\right), \lambda\left(Y_{k}\right)<\infty$. Now define

$$
f_{n}(x, y) \equiv\left\{\begin{array}{l}
f(x, y) \text { if }|f(x, y)| \leq n \\
n \text { if }|f(x, y)|>n
\end{array}\right.
$$

Thus $f_{n}$ is uniformly bounded and product measurable. By the above lemma,

$$
\begin{equation*}
\int_{X_{m}}\left(\int_{Y_{k}}\left|f_{n}(x, y)\right|^{p} d \lambda\right)^{\frac{1}{p}} d \mu \geq\left(\int_{Y_{k}}\left(\int_{X_{m}}\left|f_{n}(x, y)\right| d \mu\right)^{p} d \lambda\right)^{\frac{1}{p}} . \tag{15.1.9}
\end{equation*}
$$

Now observe that $\left|f_{n}(x, y)\right|$ increases in $n$ and the pointwise limit is $|f(x, y)|$. Therefore, using the monotone convergence theorem in 15.1.9 yields the same inequality with $f$ replacing $f_{n}$. Next let $k \rightarrow \infty$ and use the monotone convergence theorem again to replace $Y_{k}$ with $Y$. Finally let $m \rightarrow \infty$ in what is left to obtain 15.1.8. This proves the theorem.

Note that the proof of this theorem depends on two manipulations, the interchange of the order of integration and Holder's inequality. Note that there is nothing to check in the case of double sums. Thus if $a_{i j} \geq 0$, it is always the case that

$$
\left(\sum_{j}\left(\sum_{i} a_{i j}\right)^{p}\right)^{1 / p} \leq \sum_{i}\left(\sum_{j} a_{i j}^{p}\right)^{1 / p}
$$

because the integrals in this case are just sums and $(i, j) \rightarrow a_{i j}$ is measurable.
The $L^{p}$ spaces have many important properties.

### 15.2 Density Considerations

Theorem 15.2.1 Let $p \geq 1$ and let $(\Omega, \mathscr{S}, \mu)$ be a measure space. Then the simple functions are dense in $L^{p}(\Omega)$.

Proof: Recall that a function, $f$, having values in $\mathbb{R}$ can be written in the form $f=$ $f^{+}-f^{-}$where

$$
f^{+}=\max (0, f), f^{-}=\max (0,-f)
$$

Therefore, an arbitrary complex valued function, $f$ is of the form

$$
f=\operatorname{Re} f^{+}-\operatorname{Re} f^{-}+i\left(\operatorname{Im} f^{+}-\operatorname{Im} f^{-}\right) .
$$

If each of these nonnegative functions is approximated by a simple function, it follows $f$ is also approximated by a simple function. Therefore, there is no loss of generality in assuming at the outset that $f \geq 0$.

Since $f$ is measurable, Theorem 11.3.9 implies there is an increasing sequence of simple functions, $\left\{s_{n}\right\}$, converging pointwise to $f(x)$. Now

$$
\left|f(x)-s_{n}(x)\right| \leq|f(x)|
$$

By the Dominated Convergence theorem,

$$
0=\lim _{n \rightarrow \infty} \int\left|f(x)-s_{n}(x)\right|^{p} d \mu
$$

Thus simple functions are dense in $L^{p}$.
Recall that for $\Omega$ a topological space, $C_{c}(\Omega)$ is the space of continuous functions with compact support in $\Omega$. Also recall the following definition.

Definition 15.2.2 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space and suppose $(\Omega, \tau)$ is also a topological space. Then $(\Omega, \mathscr{S}, \mu)$ is called a regular measure space if the $\sigma$ algebra of Borel sets is contained in $\mathscr{S}$ and for all $E \in \mathscr{S}$,

$$
\mu(E)=\inf \{\mu(V): V \supseteq E \text { and } V \text { open }\}
$$

and if $\mu(E)<\infty$,

$$
\mu(E)=\sup \{\mu(K): K \subseteq E \text { and } K \text { is compact }\}
$$

and $\mu(K)<\infty$ for any compact set, $K$.
For example Lebesgue measure is an example of such a measure. More generally these measures are often refered to as Radon measures.

Lemma 15.2.3 Let $\Omega$ be a metric space in which the closed balls are compact and let $K$ be a compact subset of $V$, an open set. Then there exists a continuous function $f: \Omega \rightarrow[0,1]$ such that $f(x)=1$ for all $x \in K$ and $\operatorname{spt}(f)$ is a compact subset of $V$. That is, $K \prec f \prec V$.

Proof: Let $K \subseteq W \subseteq \bar{W} \subseteq V$ and $\bar{W}$ is compact. To obtain this list of inclusions consider a point in $K, x$, and take $B\left(x, r_{x}\right)$ a ball containing $x$ such that $\overline{B\left(x, r_{x}\right)}$ is a compact subset of $V$. Next use the fact that $K$ is compact to obtain the existence of a list, $\left\{B\left(x_{i}, r_{x_{i}} / 2\right)\right\}_{i=1}^{m}$ which covers $K$. Then let

$$
W \equiv \cup_{i=1}^{m} B\left(x_{i}, \frac{r_{x_{i}}}{2}\right) .
$$

It follows since this is a finite union that

$$
\bar{W}=\cup_{i=1}^{m} \overline{B\left(x_{i}, \frac{r_{x_{i}}}{2}\right)}
$$

and so $\bar{W}$, being a finite union of compact sets is itself a compact set. Also, from the construction

$$
\bar{W} \subseteq \cup_{i=1}^{m} B\left(x_{i}, r_{x_{i}}\right)
$$

Define $f$ by

$$
f(x)=\frac{\operatorname{dist}\left(x, W^{C}\right)}{\operatorname{dist}(x, K)+\operatorname{dist}\left(x, W^{C}\right)}
$$

It is clear that $f$ is continuous if the denominator is always nonzero. But this is clear because if $x \in W^{C}$ there must be a ball $B(x, r)$ such that this ball does not intersect $K$. Otherwise, $x$ would be a limit point of $K$ and since $K$ is closed, $x \in K$. However, $x \notin K$ because $K \subseteq W$.

It is not necessary to be in a metric space to do this. You can accomplish the same thing using Urysohn's lemma.

Theorem 15.2.4 Let $(\Omega, \mathscr{S}, \mu)$ be a regular measure space as in Definition 15.2.2 where the conclusion of Lemma 15.2.3 holds. Then $C_{c}(\Omega)$ is dense in $L^{p}(\Omega)$.

Proof: First consider a measurable set, $E$ where $\mu(E)<\infty$. Let $K \subseteq E \subseteq V$ where $\mu(V \backslash K)<\varepsilon$. Now let $K \prec h \prec V$. Then

$$
\int\left|h-\mathscr{X}_{E}\right|^{p} d \mu \leq \int \mathscr{X}_{V \backslash K}^{p} d \mu=\mu(V \backslash K)<\varepsilon
$$

It follows that for each $s$ a simple function in $L^{p}(\Omega)$, there exists $h \in C_{c}(\Omega)$ such that $\|s-h\|_{p}<\varepsilon$. This is because if

$$
s(x)=\sum_{i=1}^{m} c_{i} \mathscr{X}_{E_{i}}(x)
$$

is a simple function in $L^{p}$ where the $c_{i}$ are the distinct nonzero values of $s$ each $\mu\left(E_{i}\right)<\infty$ since otherwise $s \notin L^{p}$ due to the inequality

$$
\int|s|^{p} d \mu \geq\left|c_{i}\right|^{p} \mu\left(E_{i}\right)
$$

By Theorem 15.2.1, simple functions are dense in $L^{p}(\Omega)$, and so this proves the Theorem.

### 15.3 Separability

Theorem 15.3.1 For $p \geq 1$ and $\mu$ a Radon measure, $L^{p}\left(\mathbb{R}^{n}, \mu\right)$ is separable. Recall this means there exists a countable set, $\mathscr{D}$, such that if $f \in L^{p}\left(\mathbb{R}^{n}, \mu\right)$ and $\varepsilon>0$, there exists $g \in \mathscr{D}$ such that $\|f-g\|_{p}<\varepsilon$.

Proof: Let $Q$ be all functions of the form $c \mathscr{X}_{[\mathbf{a}, \mathbf{b})}$ where

$$
[\mathbf{a}, \mathbf{b}) \equiv\left[a_{1}, b_{1}\right) \times\left[a_{2}, b_{2}\right) \times \cdots \times\left[a_{n}, b_{n}\right),
$$

and both $a_{i}, b_{i}$ are rational, while $c$ has rational real and imaginary parts. Let $\mathscr{D}$ be the set of all finite sums of functions in $Q$. Thus, $\mathscr{D}$ is countable. In fact $\mathscr{D}$ is dense in $L^{p}\left(\mathbb{R}^{n}, \mu\right)$. To prove this it is necessary to show that for every $f \in L^{p}\left(\mathbb{R}^{n}, \mu\right)$, there exists an element of $\mathscr{D}, s$ such that $\|s-f\|_{p}<\varepsilon$. If it can be shown that for every $g \in C_{c}\left(\mathbb{R}^{n}\right)$ there exists $h \in \mathscr{D}$ such that $\|g-h\|_{p}<\varepsilon$, then this will suffice because if $f \in L^{p}\left(\mathbb{R}^{n}\right)$ is arbitrary, Theorem 15.2.4 implies there exists $g \in C_{c}\left(\mathbb{R}^{n}\right)$ such that $\|f-g\|_{p} \leq \frac{\varepsilon}{2}$ and then there would exist $h \in C_{c}\left(\mathbb{R}^{n}\right)$ such that $\|h-g\|_{p}<\frac{\varepsilon}{2}$. By the triangle inequality,

$$
\|f-h\|_{p} \leq\|h-g\|_{p}+\|g-f\|_{p}<\varepsilon .
$$

Therefore, assume at the outset that $f \in C_{c}\left(\mathbb{R}^{n}\right)$.
Let $\mathscr{P}_{m}$ consist of all sets of the form $[\mathbf{a}, \mathbf{b}) \equiv \prod_{i=1}^{n}\left[a_{i}, b_{i}\right)$ where $a_{i}=j 2^{-m}$ and $b_{i}=(j+$ 1)2 $2^{-m}$ for $j$ an integer. Thus $\mathscr{P}_{m}$ consists of a tiling of $\mathbb{R}^{n}$ into half open rectangles having diameters $2^{-m} n^{\frac{1}{2}}$. There are countably many of these rectangles; so, let $\mathscr{P}_{m}=\left\{\left[\mathbf{a}_{i}, \mathbf{b}_{i}\right)\right\}_{i=1}^{\infty}$ and $\mathbb{R}^{n}=\cup_{i=1}^{\infty}\left[\mathbf{a}_{i}, \mathbf{b}_{i}\right)$. Let $c_{i}^{m}$ be complex numbers with rational real and imaginary parts satisfying

$$
\left|f\left(\mathbf{a}_{i}\right)-c_{i}^{m}\right|<2^{-m}
$$

$$
\begin{equation*}
\left|c_{i}^{m}\right| \leq\left|f\left(\mathbf{a}_{i}\right)\right| \tag{15.3.10}
\end{equation*}
$$

Let

$$
s_{m}(\mathbf{x})=\sum_{i=1}^{\infty} c_{i}^{m} \mathscr{X}_{\left[\mathbf{a}_{i}, \mathbf{b}_{i}\right)}(\mathbf{x})
$$

Since $f\left(\mathbf{a}_{i}\right)=0$ except for finitely many values of $i$, the above is a finite sum. Then 15.3.10 implies $s_{m} \in \mathscr{D}$. If $s_{m}$ converges uniformly to $f$ then it follows $\left\|s_{m}-f\right\|_{p} \rightarrow 0$ because $\left|s_{m}\right| \leq|f|$ and so

$$
\begin{aligned}
\left\|s_{m}-f\right\|_{p} & =\left(\int\left|s_{m}-f\right|^{p} d \mu\right)^{1 / p} \\
& =\left(\int_{\operatorname{spt}(f)}\left|s_{m}-f\right|^{p} d \mu\right)^{1 / p} \\
& \leq\left[\varepsilon m_{n}(\operatorname{spt}(f))\right]^{1 / p}
\end{aligned}
$$

whenever $m$ is large enough.
Since $f \in C_{c}\left(\mathbb{R}^{n}\right)$ it follows that $f$ is uniformly continuous and so given $\varepsilon>0$ there exists $\delta>0$ such that if $|\mathbf{x}-\mathbf{y}|<\delta,|f(\mathbf{x})-f(\mathbf{y})|<\varepsilon / 2$. Now let $m$ be large enough that every box in $\mathscr{P}_{m}$ has diameter less than $\delta$ and also that $2^{-m}<\varepsilon / 2$. Then if $\left[\mathbf{a}_{i}, \mathbf{b}_{i}\right)$ is one of these boxes of $\mathscr{P}_{m}$, and $\mathbf{x} \in\left[\mathbf{a}_{i}, \mathbf{b}_{i}\right)$,

$$
\left|f(\mathbf{x})-f\left(\mathbf{a}_{i}\right)\right|<\varepsilon / 2
$$

and

$$
\left|f\left(\mathbf{a}_{i}\right)-c_{i}^{m}\right|<2^{-m}<\varepsilon / 2
$$

Therefore, using the triangle inequality, it follows that

$$
\left|f(\mathbf{x})-c_{i}^{m}\right|=\left|s_{m}(\mathbf{x})-f(\mathbf{x})\right|<\varepsilon
$$

and since $\mathbf{x}$ is arbitrary, this establishes uniform convergence. This proves the theorem.
Here is an easier proof if you know the Weierstrass approximation theorem.
Theorem 15.3.2 For $p \geq 1$ and $\mu$ a Radon measure, $L^{p}\left(\mathbb{R}^{n}, \mu\right)$ is separable. Recall this means there exists a countable set, $\mathscr{D}$, such that if $f \in L^{p}\left(\mathbb{R}^{n}, \mu\right)$ and $\varepsilon>0$, there exists $g \in \mathscr{D}$ such that $\|f-g\|_{p}<\varepsilon$.

Proof: Let $\mathscr{P}$ denote the set of all polynomials which have rational coefficients. Then $\mathscr{P}$ is countable. Let $\tau_{k} \in C_{c}\left((-(k+1),(k+1))^{n}\right)$ such that

$$
\overline{[-k, k]^{n}} \prec \tau_{k} \prec(-(k+1),(k+1))^{n} .
$$

Let $\mathscr{D}_{k}$ denote the functions which are of the form, $p \tau_{k}$ where $p \in \mathscr{P}$. Thus $\mathscr{D}_{k}$ is also countable. Let $\mathscr{D} \equiv \cup_{k=1}^{\infty} \mathscr{D}_{k}$. It follows each function in $\mathscr{D}$ is in $C_{c}\left(\mathbb{R}^{n}\right)$ and so it in $L^{p}\left(\mathbb{R}^{n}, \mu\right)$. Let $f \in L^{p}\left(\mathbb{R}^{n}, \mu\right)$. By regularity of $\mu$ there exists $g \in C_{c}\left(\mathbb{R}^{n}\right)$ such that
$\|f-g\|_{L^{p}\left(\mathbb{R}^{n}, \mu\right)}<\frac{\varepsilon}{3}$. Let $k$ be such that $\operatorname{spt}(g) \subseteq(-k, k)^{n}$. Now by the Weierstrass approximation theorem there exists a polynomial $q$ such that

$$
\begin{aligned}
\|g-q\|_{[-(k+1), k+1]^{n}} & \equiv \sup \left\{|g(\mathbf{x})-q(\mathbf{x})|: \mathbf{x} \in[-(k+1),(k+1)]^{n}\right\} \\
& <\frac{\varepsilon}{3 \mu\left((-(k+1), k+1)^{n}\right)}
\end{aligned}
$$

It follows

$$
\begin{aligned}
\left\|g-\tau_{k} q\right\|_{[-(k+1), k+1]^{n}} & =\left\|\tau_{k} g-\tau_{k} q\right\|_{[-(k+1), k+1]^{n}} \\
& <\frac{\varepsilon}{3 \mu\left((-(k+1), k+1)^{n}\right)}
\end{aligned}
$$

Without loss of generality, it can be assumed this polynomial has all rational coefficients. Therefore, $\tau_{k} q \in \mathscr{D}$.

$$
\begin{aligned}
\left\|g-\tau_{k} q\right\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p} & =\int_{(-(k+1), k+1)^{n}}\left|g(\mathbf{x})-\tau_{k}(\mathbf{x}) q(\mathbf{x})\right|^{p} d \mu \\
& \leq\left(\frac{\varepsilon}{3 \mu\left((-(k+1), k+1)^{n}\right)}\right)^{p} \mu\left((-(k+1), k+1)^{n}\right) \\
& <\left(\frac{\varepsilon}{3}\right)^{p} .
\end{aligned}
$$

It follows

$$
\left\|f-\tau_{k} q\right\|_{L^{p}\left(\mathbb{R}^{n}, \mu\right)} \leq\|f-g\|_{L^{p}\left(\mathbb{R}^{n}, \mu\right)}+\left\|g-\tau_{k} q\right\|_{L^{p}\left(\mathbb{R}^{n}, \mu\right)}<\frac{\varepsilon}{3}+\frac{\varepsilon}{3}<\varepsilon
$$

This proves the theorem.
Corollary 15.3.3 Let $\Omega$ be any $\mu$ measurable subset of $\mathbb{R}^{n}$ and let $\mu$ be a Radon measure. Then $L^{p}(\Omega, \mu)$ is separable. Here the $\sigma$ algebra of measurable sets will consist of all intersections of measurable sets with $\Omega$ and the measure will be $\mu$ restricted to these sets.

Proof: Let $\widetilde{\mathscr{D}}$ be the restrictions of $\mathscr{D}$ to $\Omega$. If $f \in L^{p}(\Omega)$, let $F$ be the zero extension of $f$ to all of $\mathbb{R}^{n}$. Let $\varepsilon>0$ be given. By Theorem 15.3 .1 or 15.3.2 there exists $s \in \mathscr{D}$ such that $\|F-s\|_{p}<\varepsilon$. Thus

$$
\|s-f\|_{L^{p}(\Omega, \mu)} \leq\|s-F\|_{L^{p}\left(\mathbb{R}^{n}, \mu\right)}<\varepsilon
$$

and so the countable set $\widetilde{\mathscr{D}}$ is dense in $L^{p}(\Omega)$.

### 15.4 Continuity Of Translation

Definition 15.4.1 Let $f$ be a function defined on $U \subseteq \mathbb{R}^{n}$ and let $\mathbf{w} \in \mathbb{R}^{n}$. Then $f_{\mathbf{w}}$ will be the function defined on $\mathbf{w}+U$ by

$$
f_{\mathbf{w}}(\mathbf{x})=f(\mathbf{x}-\mathbf{w})
$$

Theorem 15.4.2 (Continuity of translation in $\left.L^{p}\right)$ Let $f \in L^{p}\left(\mathbb{R}^{n}\right)$ with the measure being Lebesgue measure. Then

$$
\lim _{\|\mathbf{w}\| \rightarrow 0}\left\|f_{\mathbf{w}}-f\right\|_{p}=0
$$

Proof: Let $\varepsilon>0$ be given and let $g \in C_{c}\left(\mathbb{R}^{n}\right)$ with $\|g-f\|_{p}<\frac{\varepsilon}{3}$. Since Lebesgue measure is translation invariant $\left(m_{n}(\mathbf{w}+E)=m_{n}(E)\right)$,

$$
\left\|g_{\mathbf{w}}-f_{\mathbf{w}}\right\|_{p}=\|g-f\|_{p}<\frac{\varepsilon}{3}
$$

You can see this from looking at simple functions and passing to the limit or you could use the change of variables formula to verify it.

Therefore

$$
\begin{align*}
\left\|f-f_{\mathbf{w}}\right\|_{p} & \leq\|f-g\|_{p}+\left\|g-g_{\mathbf{w}}\right\|_{p}+\left\|g_{\mathbf{w}}-f_{\mathbf{w}}\right\| \\
& <\frac{2 \varepsilon}{3}+\left\|g-g_{\mathbf{w}}\right\|_{p} \tag{15.4.11}
\end{align*}
$$

But $\lim _{|\mathbf{w}| \rightarrow 0} g_{\mathbf{w}}(\mathbf{x})=g(\mathbf{x})$ uniformly in $\mathbf{x}$ because $g$ is uniformly continuous. Now let $B$ be a large ball containing $\operatorname{spt}(g)$ and let $\delta_{1}$ be small enough that $B(\mathbf{x}, \boldsymbol{\delta}) \subseteq B$ whenever $\mathbf{x} \in \operatorname{spt}(g)$. If $\varepsilon>0$ is given there exists $\delta<\delta_{1}$ such that if $|\mathbf{w}|<\delta$, it follows that $|g(\mathbf{x}-\mathbf{w})-g(\mathbf{x})|<\varepsilon / 3\left(1+m_{n}(B)^{1 / p}\right)$. Therefore,

$$
\begin{aligned}
\left\|g-g_{\mathbf{w}}\right\|_{p} & =\left(\int_{B}|g(\mathbf{x})-g(\mathbf{x}-\mathbf{w})|^{p} d m_{n}\right)^{1 / p} \\
& \leq \varepsilon \frac{m_{n}(B)^{1 / p}}{3\left(1+m_{n}(B)^{1 / p}\right)}<\frac{\varepsilon}{3}
\end{aligned}
$$

Therefore, whenever $|\mathbf{w}|<\delta$, it follows $\left\|g-g_{\mathbf{w}}\right\|_{p}<\frac{\varepsilon}{3}$ and so from 15.4.11 $\left\|f-f_{\mathbf{w}}\right\|_{p}<\varepsilon$. This proves the theorem.

### 15.5 Mollifiers And Density Of Smooth Functions

Definition 15.5.1 Let $U$ be an open subset of $\mathbb{R}^{n} . C_{c}^{\infty}(U)$ is the vector space of all infinitely differentiable functions which equal zero for all $\mathbf{x}$ outside of some compact set contained in $U$. Similarly, $C_{c}^{m}(U)$ is the vector space of all functions which are $m$ times continuously differentiable and whose support is a compact subset of $U$.

Example 15.5.2 Let $U=B(\mathbf{z}, 2 r)$

$$
\psi(\mathbf{x})=\left\{\begin{array}{l}
\exp \left[\left(|\mathbf{x}-\mathbf{z}|^{2}-r^{2}\right)^{-1}\right] \text { if }|\mathbf{x}-\mathbf{z}|<r \\
0 \text { if }|\mathbf{x}-\mathbf{z}| \geq r
\end{array}\right.
$$

Then a little work shows $\psi \in C_{c}^{\infty}(U)$. Note that if $\mathbf{z}=\mathbf{0}$ then $\psi(\mathbf{x})=\psi(-\mathbf{x})$. The following also is easily obtained.

Lemma 15.5.3 Let $U$ be any open set. Then $C_{c}^{\infty}(U) \neq \emptyset$.
Proof: Pick $\mathbf{z} \in U$ and let $r$ be small enough that $B(\mathbf{z}, 2 r) \subseteq U$. Then let

$$
\psi \in C_{c}^{\infty}(B(\mathbf{z}, 2 r)) \subseteq C_{c}^{\infty}(U)
$$

be the function of the above example.
Definition 15.5.4 Let $U=\left\{\mathbf{x} \in \mathbb{R}^{n}:|\mathbf{x}|<1\right\}$. A sequence $\left\{\psi_{m}\right\} \subseteq C_{c}^{\infty}(U)$ is called a mollifier (This is sometimes called an approximate identity if the differentiability is not included.) if

$$
\psi_{m}(\mathbf{x}) \geq 0, \psi_{m}(\mathbf{x})=0, \text { if }|\mathbf{x}| \geq \frac{1}{m}
$$

and $\int \psi_{m}(\mathbf{x})=1$. Sometimes it may be written as $\left\{\psi_{\varepsilon}\right\}$ where $\psi_{\varepsilon}$ satisfies the above conditions except $\psi_{\varepsilon}(\mathbf{x})=0$ if $|\mathbf{x}| \geq \varepsilon$. In other words, $\varepsilon$ takes the place of $1 / m$ and in everything that follows $\varepsilon \rightarrow 0$ instead of $m \rightarrow \infty$.

As before, $\int f(\mathbf{x}, \mathbf{y}) d \mu(\mathbf{y})$ will mean $\mathbf{x}$ is fixed and the function $\mathbf{y} \rightarrow f(\mathbf{x}, \mathbf{y})$ is being integrated. To make the notation more familiar, $d x$ is written instead of $d m_{n}(x)$.

Example 15.5.5 Let

$$
\psi \in C_{c}^{\infty}(B(0,1))(B(0,1)=\{\mathbf{x}:|\mathbf{x}|<1\})
$$

with $\psi(\mathbf{x}) \geq 0$ and $\int \psi d m=1$. Let $\psi_{m}(\mathbf{x})=c_{m} \psi(m \mathbf{x})$ where $c_{m}$ is chosen in such a way that $\int \psi_{m} d m=1$. By the change of variables theorem $c_{m}=m^{n}$.

Definition 15.5.6 A function, $f$, is said to be in $L_{l o c}^{1}\left(\mathbb{R}^{n}, \mu\right)$ if $f$ is $\mu$ measurable and if $|f| \mathscr{X}_{K} \in L^{1}\left(\mathbb{R}^{n}, \mu\right)$ for every compact set, $K$. Here $\mu$ is a Radon measure on $\mathbb{R}^{n}$. Usually $\mu=m_{n}$, Lebesgue measure. When this is so, write $L_{\text {loc }}^{1}\left(\mathbb{R}^{n}\right)$ or $L^{p}\left(\mathbb{R}^{n}\right)$, etc. If $f \in L_{l o c}^{1}\left(\mathbb{R}^{n}, \mu\right)$, and $g \in C_{c}\left(\mathbb{R}^{n}\right)$,

$$
f * g(\mathbf{x}) \equiv \int f(\mathbf{y}) g(\mathbf{x}-\mathbf{y}) d \mu
$$

The following lemma will be useful in what follows. It says that one of these very unregular functions in $L_{l o c}^{1}\left(\mathbb{R}^{n}, \mu\right)$ is smoothed out by convolving with a mollifier.

Lemma 15.5.7 Let $f \in L_{l o c}^{1}\left(\mathbb{R}^{n}, \mu\right)$, and $g \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. Then $f * g$ is an infinitely differentiable function. Here $\mu$ is a Radon measure on $\mathbb{R}^{n}$.

Proof: Consider the difference quotient for calculating a partial derivative of $f * g$.

$$
\frac{f * g\left(\mathbf{x}+t \mathbf{e}_{j}\right)-f * g(\mathbf{x})}{t}=\int f(\mathbf{y}) \frac{g\left(\mathbf{x}+t \mathbf{e}_{j}-\mathbf{y}\right)-g(\mathbf{x}-\mathbf{y})}{t} d \mu(y)
$$

Using the fact that $g \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$, the quotient,

$$
\frac{g\left(\mathbf{x}+t \mathbf{e}_{j}-\mathbf{y}\right)-g(\mathbf{x}-\mathbf{y})}{t}
$$

is uniformly bounded. To see this easily, use Theorem 6.13.4 on Page 120 to get the existence of a constant, $M$ depending on

$$
\max \left\{\|D g(\mathbf{x})\|: \mathbf{x} \in \mathbb{R}^{n}\right\}
$$

such that

$$
\left|g\left(\mathbf{x}+t \mathbf{e}_{j}-\mathbf{y}\right)-g(\mathbf{x}-\mathbf{y})\right| \leq M|t|
$$

for any choice of $\mathbf{x}$ and $\mathbf{y}$. Therefore, there exists a dominating function for the integrand of the above integral which is of the form $C|f(\mathbf{y})| \mathscr{X}_{K}$ where $K$ is a compact set depending on the support of $g$. It follows the limit of the difference quotient above passes inside the integral as $t \rightarrow 0$ and

$$
\frac{\partial}{\partial x_{j}}(f * g)(\mathbf{x})=\int f(\mathbf{y}) \frac{\partial}{\partial x_{j}} g(\mathbf{x}-\mathbf{y}) d \mu(y)
$$

Now letting $\frac{\partial}{\partial x_{j}} g$ play the role of $g$ in the above argument, partial derivatives of all orders exist. A similar use of the dominated convergence theorem shows all these partial derivatives are also continuous. This proves the lemma.

Theorem 15.5.8 Let $K$ be a compact subset of an open set, $U$. Then there exists a function, $h \in C_{c}^{\infty}(U)$, such that $h(\mathbf{x})=1$ for all $\mathbf{x} \in K$ and $h(\mathbf{x}) \in[0,1]$ for all $\mathbf{x}$.

Proof: Let $r>0$ be small enough that $K+B(\mathbf{0}, 3 r) \subseteq U$. The symbol, $K+B(\mathbf{0}, 3 r)$ means

$$
\{\mathbf{k}+\mathbf{x}: \mathbf{k} \in K \text { and } \mathbf{x} \in B(\mathbf{0}, 3 r)\}
$$

Thus this is simply a way to write

$$
\cup\{B(\mathbf{k}, 3 r): \mathbf{k} \in K\} .
$$

Think of it as fattening up the set, $K$. Let $K_{r}=K+B(0, r)$. A picture of what is happening follows.

Consider $\mathscr{X}_{K_{r}} * \psi_{m}$ where $\psi_{m}$ is a mollifier. Let $m$ be so large that $\frac{1}{m}<r$. Then from the definition of what is meant by a convolution, and using that $\psi_{m}$ has support in $B\left(\mathbf{0}, \frac{1}{m}\right)$, $\mathscr{X}_{K_{r}} * \psi_{m}=1$ on $K$ and that its support is in $K+B(\mathbf{0}, 3 r)$. Now using Lemma 15.5.7, $\mathscr{X}_{K_{r}} * \psi_{m}$ is also infinitely differentiable. Therefore, let $h=\mathscr{X}_{K_{r}} * \psi_{m}$.

The following corollary will be used later.

Corollary 15.5.9 Let $K$ be a compact set in $\mathbb{R}^{n}$ and let $\left\{U_{i}\right\}_{i=1}^{\infty}$ be an open cover of $K$. Then there exist functions, $\psi_{k} \in C_{c}^{\infty}\left(U_{i}\right)$ such that $\psi_{i} \prec U_{i}$ and for all $\mathbf{x} \in K$,

$$
\sum_{i=1}^{\infty} \psi_{i}(\mathbf{x})=1
$$

If $K_{1}$ is a compact subset of $U_{1}$ there exist such functions such that also $\psi_{1}(\mathbf{x})=1$ for all $\mathbf{x} \in K_{1}$.

Proof: This follows from a repeat of the proof of Theorem 12.2.11 on Page 287, replacing the lemma used in that proof with Theorem 15.5.8.

Note that in the last conclusion of above corollary, the set $U_{1}$ could be replaced with $U_{i}$ for any fixed $i$ by simply renumbering.

Theorem 15.5.10 For each $p \geq 1, C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is dense in $L^{p}\left(\mathbb{R}^{n}\right)$. Here the measure is Lebesgue measure.

Proof: Let $f \in L^{p}\left(\mathbb{R}^{n}\right)$ and let $\varepsilon>0$ be given. Choose $g \in C_{c}\left(\mathbb{R}^{n}\right)$ such that $\|f-g\|_{p}<$ $\frac{\varepsilon}{2}$. This can be done by using Theorem 15.2.4. Now let

$$
g_{m}(\mathbf{x})=g * \psi_{m}(\mathbf{x}) \equiv \int g(\mathbf{x}-\mathbf{y}) \psi_{m}(\mathbf{y}) d m_{n}(y)=\int g(\mathbf{y}) \psi_{m}(\mathbf{x}-\mathbf{y}) d m_{n}(y)
$$

where $\left\{\psi_{m}\right\}$ is a mollifier. It follows from Lemma 15.5.7 $g_{m} \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. It vanishes if $\mathbf{x} \notin \operatorname{spt}(g)+B\left(0, \frac{1}{m}\right)$.

$$
\begin{aligned}
\left\|g-g_{m}\right\|_{p} & =\left(\int\left|g(\mathbf{x})-\int g(\mathbf{x}-\mathbf{y}) \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y})\right|^{p} d m_{n}(\mathbf{x})\right)^{\frac{1}{p}} \\
& \leq\left(\int\left(\int|g(\mathbf{x})-g(\mathbf{x}-\mathbf{y})| \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y})\right)^{p} d m_{n}(\mathbf{x})\right)^{\frac{1}{p}} \\
& \leq \int\left(\int|g(\mathbf{x})-g(\mathbf{x}-\mathbf{y})|^{p} d m_{n}(\mathbf{x})\right)^{\frac{1}{p}} \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y}) \\
& =\int_{B\left(0, \frac{1}{m}\right)}\left\|g-g_{\mathbf{y}}\right\|_{p} \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y})<\frac{\varepsilon}{2}
\end{aligned}
$$

whenever $m$ is large enough thanks to the uniform continuity of $g$. Theorem 15.1.12 was used to obtain the third inequality. There is no measurability problem because the function

$$
(\mathbf{x}, \mathbf{y}) \rightarrow|g(\mathbf{x})-g(\mathbf{x}-\mathbf{y})| \psi_{m}(\mathbf{y})
$$

is continuous. Thus when $m$ is large enough,

$$
\left\|f-g_{m}\right\|_{p} \leq\|f-g\|_{p}+\left\|g-g_{m}\right\|_{p}<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
$$

This proves the theorem.
This is a very remarkable result. Functions in $L^{p}\left(\mathbb{R}^{n}\right)$ don't need to be continuous anywhere and yet every such function is very close in the $L^{p}$ norm to one which is infinitely differentiable having compact support. The same result holds for $L^{p}(U)$ for $U$ an open set. This is the next corollary.

Corollary 15.5.11 Let $U$ be an open set. For each $p \geq 1, C_{c}^{\infty}(U)$ is dense in $L^{p}(U)$. Here the measure is Lebesgue measure.

Proof: Let $f \in L^{p}(U)$ and let $\varepsilon>0$ be given. Choose $g \in C_{c}(U)$ such that $\|f-g\|_{p}<\frac{\varepsilon}{2}$. This is possible because Lebesgue measure restricted to the open set, $U$ is regular. Thus the existence of such a $g$ follows from Theorem 15.2.4. Now let

$$
g_{m}(\mathbf{x})=g * \psi_{m}(\mathbf{x}) \equiv \int g(\mathbf{x}-\mathbf{y}) \psi_{m}(\mathbf{y}) d m_{n}(y)=\int g(\mathbf{y}) \psi_{m}(\mathbf{x}-\mathbf{y}) d m_{n}(y)
$$

where $\left\{\psi_{m}\right\}$ is a mollifier. It follows from Lemma 15.5.7 $g_{m} \in C_{c}^{\infty}(U)$ for all $m$ sufficiently large. It vanishes if $\mathbf{x} \notin \operatorname{spt}(g)+B\left(0, \frac{1}{m}\right)$. Then

$$
\begin{aligned}
\left\|g-g_{m}\right\|_{p} & =\left(\int\left|g(\mathbf{x})-\int g(\mathbf{x}-\mathbf{y}) \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y})\right|^{p} d m_{n}(\mathbf{x})\right)^{\frac{1}{p}} \\
& \leq\left(\int\left(\int|g(\mathbf{x})-g(\mathbf{x}-\mathbf{y})| \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y})\right)^{p} d m_{n}(\mathbf{x})\right)^{\frac{1}{p}} \\
& \leq \int\left(\int|g(\mathbf{x})-g(\mathbf{x}-\mathbf{y})|^{p} d m_{n}(\mathbf{x})\right)^{\frac{1}{p}} \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y}) \\
& =\int_{B\left(0, \frac{1}{m}\right)}\left\|g-g_{\mathbf{y}}\right\|_{p} \psi_{m}(\mathbf{y}) d m_{n}(\mathbf{y})<\frac{\varepsilon}{2}
\end{aligned}
$$

whenever $m$ is large enough thanks to uniform continuity of $g$. Theorem 15.1.12 was used to obtain the third inequality. There is no measurability problem because the function

$$
(\mathbf{x}, \mathbf{y}) \rightarrow|g(\mathbf{x})-g(\mathbf{x}-\mathbf{y})| \psi_{m}(\mathbf{y})
$$

is continuous. Thus when $m$ is large enough,

$$
\left\|f-g_{m}\right\|_{p} \leq\|f-g\|_{p}+\left\|g-g_{m}\right\|_{p}<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
$$

This proves the corollary.
Another thing should probably be mentioned. If you have had a course in complex analysis, you may be wondering whether these infinitely differentiable functions having compact support have anything to do with analytic functions which also have infinitely many derivatives. The answer is no! Recall that if an analytic function has a limit point in the set of zeros then it is identically equal to zero. Thus these functions in $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ are not analytic. This is a strictly real analysis phenomenon and has absolutely nothing to do with the theory of functions of a complex variable.

### 15.6 Exercises

1. Let $E$ be a Lebesgue measurable set in $\mathbb{R}$. Suppose $m(E)>0$. Consider the set

$$
E-E=\{x-y: x \in E, y \in E\}
$$

Show that $E-E$ contains an interval. Hint: Let

$$
f(x)=\int \mathscr{X}_{E}(t) \mathscr{X}_{E}(x+t) d t
$$

Note $f$ is continuous at 0 and $f(0)>0$ and use continuity of translation in $L^{p}$.
2. Establish the inequality $\|f g\|_{r} \leq\|f\|_{p}\|g\|_{q}$ whenever $\frac{1}{r}=\frac{1}{p}+\frac{1}{q}$.
3. Let $(\Omega, \mathscr{S}, \mu)$ be counting measure on $\mathbb{N}$. Thus $\Omega=\mathbb{N}$ and $\mathscr{S}=\mathscr{P}(\mathbb{N})$ with $\mu(S)=$ number of things in $S$. Let $1 \leq p \leq q$. Show that in this case,

$$
L^{1}(\mathbb{N}) \subseteq L^{p}(\mathbb{N}) \subseteq L^{q}(\mathbb{N})
$$

Hint: This is real easy if you consider what $\int_{\Omega} f d \mu$ equals. How are the norms related?
4. Consider the function, $f(x, y)=\frac{x^{p-1}}{p y}+\frac{y^{q-1}}{q x}$ for $x, y>0$ and $\frac{1}{p}+\frac{1}{q}=1$. Show directly that $f(x, y) \geq 1$ for all such $x, y$ and show this implies $x y \leq \frac{x^{p}}{p}+\frac{y^{q}}{q}$.
5. Give an example of a sequence of functions in $L^{p}(\mathbb{R})$ which converges to zero in $L^{p}$ but does not converge pointwise to 0 . Does this contradict the proof of the theorem that $L^{p}$ is complete?
6. Let $K$ be a bounded subset of $L^{p}\left(\mathbb{R}^{n}\right)$ and suppose that there exists $G$ such that $\bar{G}$ is compact with

$$
\int_{\mathbb{R}^{n} \backslash \bar{G}}|u(\mathbf{x})|^{p} d x<\varepsilon^{p}
$$

and for all $\varepsilon>0$, there exist a $\delta>0$ and such that if $|\mathbf{h}|<\delta$, then

$$
\int|u(\mathbf{x}+\mathbf{h})-u(\mathbf{x})|^{p} d x<\varepsilon^{p}
$$

for all $u \in K$. Show that $K$ is precompact in $L^{p}\left(\mathbb{R}^{n}\right)$. Hint: Let $\phi_{k}$ be a mollifier and consider

$$
K_{k} \equiv\left\{u * \phi_{k}: u \in K\right\}
$$

Verify the conditions of the Ascoli Arzela theorem for these functions defined on $\bar{G}$ and show there is an $\varepsilon$ net for each $\varepsilon>0$. Can you modify this to let an arbitrary open set take the place of $\mathbb{R}^{n}$ ?
7. Let $(\Omega, d)$ be a metric space and suppose also that $(\Omega, \mathscr{S}, \mu)$ is a regular measure space such that $\mu(\Omega)<\infty$ and let $f \in L^{1}(\Omega)$ where $f$ has complex values. Show that for every $\varepsilon>0$, there exists an open set of measure less than $\varepsilon$, denoted here by $V$ and a continuous function, $g$ defined on $\Omega$ such that $f=g$ on $V^{C}$. Thus, aside from a set of small measure, $f$ is continuous. If $|f(\omega)| \leq M$, show that it can be assumed that $|g(\omega)| \leq M$. This is called Lusin's theorem. Hint: Use Theorems 15.2.4 and 15.1.10 to obtain a sequence of functions in $C_{c}(\Omega),\left\{g_{n}\right\}$ which converges pointwise a.e. to $f$ and then use Egoroff's theorem to obtain a small set, $W$ of measure less
than $\varepsilon / 2$ such that convergence is uniform on $W^{C}$. Now let $F$ be a closed subset of $W^{C}$ such that $\mu\left(W^{C} \backslash F\right)<\varepsilon / 2$. Let $V=F^{C}$. Thus $\mu(V)<\varepsilon$ and on $F=V^{C}$, the convergence of $\left\{g_{n}\right\}$ is uniform showing that the restriction of $f$ to $V^{C}$ is continuous. Now use the Tietze extension theorem.
8. Let $\phi_{m} \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right), \phi_{m}(\mathbf{x}) \geq 0$, and $\int_{\mathbb{R}^{n}} \phi_{m}(\mathbf{y}) d y=1$ with

$$
\lim _{m \rightarrow \infty} \sup \left\{|\mathbf{x}|: \mathbf{x} \in \operatorname{spt}\left(\phi_{m}\right)\right\}=0
$$

Show if $f \in L^{p}\left(\mathbb{R}^{n}\right), \lim _{m \rightarrow \infty} f * \phi_{m}=f$ in $L^{p}\left(\mathbb{R}^{n}\right)$.
9. Let $\phi: \mathbb{R} \rightarrow \mathbb{R}$ be convex. This means

$$
\phi(\lambda x+(1-\lambda) y) \leq \lambda \phi(x)+(1-\lambda) \phi(y)
$$

whenever $\lambda \in[0,1]$. Verify that if $x<y<z$, then $\frac{\phi(y)-\phi(x)}{y-x} \leq \frac{\phi(z)-\phi(y)}{z-y}$ and that $\frac{\phi(z)-\phi(x)}{z-x} \leq \frac{\phi(z)-\phi(y)}{z-y}$. Show if $s \in \mathbb{R}$ there exists $\lambda$ such that $\phi(s) \leq \phi(t)+\lambda(s-t)$ for all $t$. Show that if $\phi$ is convex, then $\phi$ is continuous.
10. $\uparrow$ Prove Jensen's inequality. If $\phi: \mathbb{R} \rightarrow \mathbb{R}$ is convex, $\mu(\Omega)=1$, and $f: \Omega \rightarrow \mathbb{R}$ is in $L^{1}(\Omega)$, then $\phi\left(\int_{\Omega} f d u\right) \leq \int_{\Omega} \phi(f) d \mu$. Hint: Let $s=\int_{\Omega} f d \mu$ and use Problem 9.
11. Let $\frac{1}{p}+\frac{1}{p^{\prime}}=1, p>1$, let $f \in L^{p}(\mathbb{R}), g \in L^{p^{\prime}}(\mathbb{R})$. Show $f * g$ is uniformly continuous on $\mathbb{R}$ and $|(f * g)(x)| \leq\|f\|_{L^{p}}\|g\|_{L^{p^{\prime}}}$. Hint: You need to consider why $f * g$ exists and then this follows from the definition of convolution and continuity of translation in $L^{p}$.
12. $B(p, q)=\int_{0}^{1} x^{p-1}(1-x)^{q-1} d x, \Gamma(p)=\int_{0}^{\infty} e^{-t} t^{p-1} d t$ for $p, q>0$. The first of these is called the beta function, while the second is the gamma function. Show a.) $\Gamma(p+$ $1)=p \Gamma(p) ;$ b.) $\Gamma(p) \Gamma(q)=B(p, q) \Gamma(p+q)$.
13. Let $f \in C_{c}(0, \infty)$ and define $F(x)=\frac{1}{x} \int_{0}^{x} f(t) d t$. Show

$$
\|F\|_{L^{p}(0, \infty)} \leq \frac{p}{p-1}\|f\|_{L^{p}(0, \infty)} \text { whenever } p>1
$$

Hint: Argue there is no loss of generality in assuming $f \geq 0$ and then assume this is so. Integrate $\int_{0}^{\infty}|F(x)|^{p} d x$ by parts as follows:

$$
\int_{0}^{\infty} F^{p} d x=\overbrace{\left.x F^{p}\right|_{0} ^{\infty}}^{\text {show }=0}-p \int_{0}^{\infty} x F^{p-1} F^{\prime} d x .
$$

Now show $x F^{\prime}=f-F$ and use this in the last integral. Complete the argument by using Holder's inequality and $p-1=p / q$.
14. $\uparrow$ Now suppose $f \in L^{p}(0, \infty), p>1$, and $f$ not necessarily in $C_{c}(0, \infty)$. Show that $F(x)=\frac{1}{x} \int_{0}^{x} f(t) d t$ still makes sense for each $x>0$. Show the inequality of Problem 13 is still valid. This inequality is called Hardy's inequality. Hint: To show this, use the above inequality along with the density of $C_{c}(0, \infty)$ in $L^{p}(0, \infty)$.
15. Suppose $f, g \geq 0$. When does equality hold in Holder's inequality?
16. Prove Vitali's Convergence theorem: Let $\left\{f_{n}\right\}$ be uniformly integrable and complex valued, $\mu(\Omega)<\infty, f_{n}(x) \rightarrow f(x)$ a.e. where $f$ is measurable. Then $f \in L^{1}$ and $\lim _{n \rightarrow \infty} \int_{\Omega}\left|f_{n}-f\right| d \mu=0$. Hint: Use Egoroff's theorem to show $\left\{f_{n}\right\}$ is a Cauchy sequence in $L^{1}(\Omega)$. This yields a different and easier proof than what was done earlier. See Theorem 11.5.3 on Page 257.
17. $\uparrow$ Show the Vitali Convergence theorem implies the Dominated Convergence theorem for finite measure spaces but there exist examples where the Vitali convergence theorem works and the dominated convergence theorem does not.
18. $\uparrow$ Suppose $\mu(\Omega)<\infty,\left\{f_{n}\right\} \subseteq L^{1}(\Omega)$, and

$$
\int_{\Omega} h\left(\left|f_{n}\right|\right) d \mu<C
$$

for all $n$ where $h$ is a continuous, nonnegative function satisfying

$$
\lim _{t \rightarrow \infty} \frac{h(t)}{t}=\infty
$$

Show $\left\{f_{n}\right\}$ is uniformly integrable. In applications, this often occurs in the form of a bound on $\left\|f_{n}\right\|_{p}$.
19. $\uparrow$ Sometimes, especially in books on probability, a different definition of uniform integrability is used than that presented here. A set of functions, $\mathfrak{S}$, defined on a finite measure space, $(\Omega, \mathscr{S}, \mu)$ is said to be uniformly integrable if for all $\varepsilon>0$ there exists $\alpha>0$ such that for all $f \in \mathfrak{S}$,

$$
\int_{[|f| \geq \alpha]}|f| d \mu \leq \varepsilon
$$

Show that this definition is equivalent to the definition of uniform integrability given earlier in Definition 11.5.1 on Page 256 with the addition of the condition that there is a constant, $C<\infty$ such that

$$
\int|f| d \mu \leq C
$$

for all $f \in \mathfrak{S}$.
20. $f \in L^{\infty}(\Omega, \mu)$ if there exists a set of measure zero, $E$, and a constant $C<\infty$ such that $|f(x)| \leq C$ for all $x \notin E$.

$$
\|f\|_{\infty} \equiv \inf \{C:|f(x)| \leq C \text { a.e. }\} .
$$

Show $\left\|\|_{\infty}\right.$ is a norm on $L^{\infty}(\Omega, \mu)$ provided $f$ and $g$ are identified if $f(x)=g(x)$ a.e. Show $L^{\infty}(\Omega, \mu)$ is complete. Hint: You might want to show that $\left[|f|>\|f\|_{\infty}\right]$ has measure zero so $\|f\|_{\infty}$ is the smallest number at least as large as $|f(x)|$ for a.e. $x$. Thus $\|f\|_{\infty}$ is one of the constants, $C$ in the above.
21. Suppose $f \in L^{\infty} \cap L^{1}$. Show $\lim _{p \rightarrow \infty}\|f\|_{L^{p}}=\|f\|_{\infty}$. Hint:

$$
\begin{gathered}
\left(\left|\mid f \|_{\infty}-\varepsilon\right)^{p} \mu\left(\left[|f|>| | f \|_{\infty}-\varepsilon\right]\right) \leq \int_{\left[|f|>| | f \|_{\infty}-\varepsilon\right]}|f|^{p} d \mu \leq\right. \\
\int|f|^{p} d \mu=\int|f|^{p-1}|f| d \mu \leq\|f\|_{\infty}^{p-1} \int|f| d \mu .
\end{gathered}
$$

Now raise both ends to the $1 / p$ power and take liminf and limsup as $p \rightarrow \infty$. You should get $\|f\|_{\infty}-\varepsilon \leq \liminf \|f\|_{p} \leq \limsup \|f\|_{p} \leq\|f\|_{\infty}$
22. Suppose $\mu(\Omega)<\infty$. Show that if $1 \leq p<q$, then $L^{q}(\Omega) \subseteq L^{p}(\Omega)$. Hint Use Holder's inequality.
23. Show $L^{1}(\mathbb{R}) \nsubseteq L^{2}(\mathbb{R})$ and $L^{2}(\mathbb{R}) \nsubseteq L^{1}(\mathbb{R})$ if Lebesgue measure is used. Hint: Consider $1 / \sqrt{x}$ and $1 / x$.
24. Suppose that $\theta \in[0,1]$ and $r, s, q>0$ with

$$
\frac{1}{q}=\frac{\theta}{r}+\frac{1-\theta}{s}
$$

show that

$$
\left(\int|f|^{q} d \mu\right)^{1 / q} \leq\left(\left(\int|f|^{r} d \mu\right)^{1 / r}\right)^{\theta}\left(\left(\int|f|^{s} d \mu\right)^{1 / s}\right)^{1-\theta}
$$

If $q, r, s \geq 1$ this says that

$$
\|f\|_{q} \leq\|f\|_{r}^{\theta}\|f\|_{s}^{1-\theta}
$$

Using this, show that

$$
\ln \left(\|f\|_{q}\right) \leq \theta \ln \left(\|f\|_{r}\right)+(1-\theta) \ln \left(\|f\|_{s}\right)
$$

## Hint:

$$
\int|f|^{q} d \mu=\int|f|^{q \theta}|f|^{q(1-\theta)} d \mu
$$

Now note that $1=\frac{\theta q}{r}+\frac{q(1-\theta)}{s}$ and use Holder's inequality.
25. Suppose $f$ is a function in $L^{1}(\mathbb{R})$ and $f$ is infinitely differentiable. Is $f^{\prime} \in L^{1}(\mathbb{R})$ ? Hint: What if $\phi \in C_{c}^{\infty}(0,1)$ and $f(x)=\phi\left(2^{n}(x-n)\right)$ for $x \in(n, n+1), f(x)=0$ if $x<0$ ?

## Chapter 16

## Stone's Theorem

This section is devoted to Stone's theorem which says that a metric space is paracompact, defined below. See [98] for this which is where I read it. First is the definition of what is meant by a refinement.

Definition 16.0.1 Let $S$ be a topological space. We say that a collection of sets $\mathfrak{D}$ is a refinement of an open cover $\mathfrak{S}$, if every set of $\mathfrak{D}$ is contained in some set of $\mathfrak{S}$. An open refinement would be one in which all sets are open, with a similar convention holding for the term " closed refinement".

Definition 16.0.2 We say that a collection of sets $\mathfrak{D}$, is locally finite if for all $p \in S$, there exists $V$ an open set containing $p$ such that $V$ has nonempty intersection with only finitely many sets of $\mathfrak{D}$.

Definition 16.0.3 We say $S$ is paracompact if it is Hausdorff and for every open cover $\mathfrak{S}$, there exists an open refinement $\mathfrak{D}$ such that $\mathfrak{D}$ is locally finite and $\mathfrak{D}$ covers $S$.

Theorem 16.0.4 If $\mathfrak{D}$ is locally finite then

$$
\cup\{\bar{D}: D \in \mathfrak{D}\}=\overline{\cup\{D: D \in \mathfrak{D}\}}
$$

Proof: It is clear the left side is a subset of the right. Let $p$ be a limit point of

$$
\cup\{D: D \in \mathfrak{D}\}
$$

and let $p \in V$, an open set intersecting only finitely many sets of $\mathfrak{D}, D_{1} \ldots D_{n}$. If $p$ is not in any of $\overline{D_{i}}$ then $p \in W$ where $W$ is some open set which contains no points of $\cup_{i=1}^{n} D_{i}$. Then $V \cap W$ contains no points of any set of $\mathfrak{D}$ and this contradicts the assumption that $p$ is a limit point of

$$
\cup\{D: D \in \mathfrak{D}\} .
$$

Thus $p \in \overline{D_{i}}$ for some $i$.
We say $\mathfrak{S} \subseteq \mathscr{P}(S)$ is countably locally finite if

$$
\mathfrak{S}=\cup_{n=1}^{\infty} \mathfrak{S}_{n}
$$

and each $\mathfrak{S}_{n}$ is locally finite. The following theorem appeared in the 1950's. It will be used to prove Stone's theorem.

Theorem 16.0.5 Let $S$ be a regular topological space. (If $p \in U$ open, then there exists an open set $V$ such that $p \in \bar{V} \subseteq U$. ) The following are equivalent
1.) Every open covering of $S$ has a refinement that is open, covers $S$ and is countably locally finite.
2.) Every open covering of $S$ has a refinement that is locally finite and covers $S$. (The sets in refinement maybe not open.)
3.) Every open covering of $S$ has a refinement that is closed, locally finite, and covers S. (Sets in refinement are closed.)
4.) Every open covering of $S$ has a refinement that is open, locally finite, and covers $S$. (Sets in refinement are open.)

## Proof:

1.) $\Rightarrow 2$.)

Let $\mathfrak{S}$ be an open cover of $S$ and let $\mathfrak{B}$ be an open countably locally finite refinement

$$
\mathfrak{B}=\cup_{n=1}^{\infty} \mathfrak{B}_{n}
$$

where $\mathfrak{B}_{n}$ is an open refinement of $\mathfrak{S}$ and $\mathfrak{B}_{n}$ is locally finite. For $B \in \mathfrak{B}_{n}$, let

$$
E_{n}(B)=B \backslash \bigcup_{k<n}\left(\cup\left\{B: B \in \mathfrak{B}_{k}\right\}\right)
$$

Thus, in words, $E_{n}(B)$ consists of points in $B$ which are not in any set from any $\mathfrak{B}_{k}$ for $k<n$.

Claim: $\left\{E_{n}(B): n \in \mathbb{N}, B \in \mathfrak{B}_{n}\right\}$ is locally finite.
Proof of the claim: Let $p \in S$. Then $p \in B_{0} \in \mathfrak{B}_{n}$ for some $n$. Let $V$ be open, $p \in V$, and $V$ intersects only finitely many sets of $\mathfrak{B}_{1} \cup \ldots \cup \mathfrak{B}_{n}$. Then consider $B_{0} \cap V$. If $m>n$,

$$
\left(B_{0} \cap V\right) \cap E_{m}(B) \subseteq\left[\bigcup_{k<m}\left(\cup\left\{B: B \in \mathfrak{B}_{k}\right)\right]^{C} \subseteq B_{0}^{C}\right.
$$

In words, $E_{m}(B)$ has nothing in it from any of the $\mathfrak{B}_{k}$ for $k<m$. In particular, it has nothing in it from $B_{0}$. Thus $\left(B_{0} \cap V\right) \cap E_{m}(B)=\emptyset$ for $m>n$. Thus $p \in B_{0} \cap V$ which intersects only finitely many sets of $\mathfrak{S}$, no more than those intersected by $V$. This establishes the claim.

Claim: $\left\{E_{n}(B): n \in \mathbb{N}, B \in \mathfrak{B}_{n}\right\}$ covers $S$.
Proof: Let $p \in S$ and let $n=\min \left\{k \in \mathbb{N}: p \in B\right.$ for some $\left.B \in \mathfrak{B}_{k}\right\}$. Let $p \in B \in \mathfrak{B}_{n}$. Then $p \in E_{n}(B)$.

The two claims show that 1.) $\Rightarrow 2$.).
2.) $\Rightarrow 3$.)

Let $\mathfrak{S}$ be an open cover and let

$$
\mathscr{G} \equiv\{U: U \text { is open and } \bar{U} \subseteq V \in \mathfrak{S} \text { for some } V \in \mathfrak{S}\}
$$

Then since $S$ is regular, $\mathscr{G}$ covers $S$. (If $p \in S$, then $p \in U \subseteq \bar{U} \subseteq V \in \mathfrak{S}$.) By 2.), $\mathscr{G}$ has a locally finite refinement $\mathfrak{C}$, covering $S$. Consider

$$
\{\bar{E}: E \in \mathfrak{C}\}
$$

This collection of closed sets covers $S$ and is locally finite because if $p \in S$, there exists $V, p \in V$, and $V$ has nonempty intersections with only finitely many elements of $\mathfrak{C}$, say $E_{1}, \cdots, E_{n}$. If $\bar{E} \cap V \neq \emptyset$, then $E \cap V \neq \emptyset$ and so $V$ intersects only $\overline{E_{1}}, \cdots, \overline{E_{n}}$. This shows 2 .) $\Rightarrow 3$.).

3 .) $\Rightarrow$ 4.) Here is a table of symbols with a short summary of their meaning.

| Open covering | Locally finite refinement |
| :--- | :--- |
| $\mathfrak{S}$ original covering | $\mathfrak{B}$ by 3. can be closed refinement |
| $\mathfrak{F}$ open intersectors | $\mathfrak{C}$ closed refinement |

Let $\mathfrak{S}$ be an open cover and let $\mathfrak{B}$ be a locally finite refinement which covers $S$. By 3.) we can take $\mathfrak{B}$ to be a closed refinement but this is not important here. Let

$$
\mathfrak{F} \equiv\{U: U \text { is open and } U \text { intersects only finitely many sets of } \mathfrak{B}\} .
$$

Then $\mathfrak{F}$ covers $S$ because $\mathfrak{B}$ is locally finite. If $p \in S$, then there exists an open set $U$ containing $p$ which intersects only finitely many sets of $\mathfrak{B}$. Thus $p \in U \in \mathfrak{F}$. By 3 ., $\mathfrak{F}$ has a locally finite closed refinement $\mathfrak{C}$, which covers $S$. Define for $B \in \mathfrak{B}$

$$
\mathfrak{C}(B) \equiv\{C \in \mathfrak{C}: C \cap B=\emptyset\}
$$

Thus these closed sets $C$ do not intersect $B$ and so $B$ is in their complement. We use $\mathfrak{C}(B)$ to fatten up B. Let

$$
E(B) \equiv(\cup\{C: C \in \mathfrak{C}(B)\})^{C}
$$

In words, $E(B)$ is the complement of the union of all closed sets of $\mathfrak{C}$ which do not intersect $B$. Thus $E(B) \supseteq B$, and has fattened up $B$. Then since $\mathfrak{C}(B)$ is locally finite, $E(B)$ is an open set by Theorem 16.0.4. Now let $F(B)$ be defined such that for $B \in \mathfrak{B}$,

$$
B \subseteq F(B) \in \mathfrak{S}
$$

(by definition $B$ is in some set of $\mathfrak{S}$ ), and let

$$
\mathfrak{L}=\{E(B) \cap F(B): B \in \mathfrak{B}\}
$$

The intersection with $F(B)$ is to ensure that $\mathfrak{L}$ is a refinement of $\mathfrak{S}$. The important thing to notice is that if $C \in \mathfrak{C}$ intersects $E(B)$, then it must also intersect $B$. If not, you could include it in the list of closed sets which do not intersect $B$ and whose complement is $E(B)$. Thus $E(B)$ would be too large.

Claim: $\mathfrak{L}$ covers $S$.
This claim is obvious because if $p \in S$ then $p \in B$ for some $B \in \mathfrak{B}$. Hence

$$
p \in E(B) \cap F(B) \in \mathfrak{L}
$$

Claim: $\mathfrak{L}$ is locally finite and a refinement of $\mathfrak{S}$.
Proof: It is clear $\mathfrak{L}$ is a refinement of $\mathfrak{S}$ because every set of $\mathfrak{L}$ is a subset of a set of $\mathfrak{S}, F(B)$. Let $p \in S$. There exists an open set $W$, such that $p \in W$ and $W$ intersects only $C_{1}, \cdots, C_{n}$, elements of $\mathfrak{C}$. Hence $W \subseteq \cup_{i=1}^{n} C_{i}$ since $\mathfrak{C}$ covers $S$.

But $C_{i}$ is contained in a set $U_{i} \in \mathfrak{F}$ which intersects only finitely many sets of $\mathfrak{B}$. Thus each $C_{i}$ intersects only finitely many $B \in \mathfrak{B}$ and so each $C_{i}$ intersects only finitely many of the sets, $E(B)$. (If it intersects $E(B)$, then it intersects $B$.) Thus $W$ intersects only finitely many of the $E(B)$, hence finitely many of the $E(B) \cap F(B)$. It follows that $\mathfrak{L}$ is locally finite.

It is obvious that 4.) $\Rightarrow 1$.).
The following theorem is Stone's theorem.
Theorem 16.0.6 If $S$ is a metric space then $S$ is paracompact (Every open cover has a locally finite open refinement also an open cover.)

Proof: Let $\mathfrak{S}$ be an open cover. Well order $\mathfrak{S}$. For $B \in \mathfrak{S}$,

$$
B_{n} \equiv\left\{x \in B: \operatorname{dist}\left(x, B^{C}\right)<\frac{1}{2^{n}}\right\}, n=1,2, \cdots .
$$

Thus $B_{n}$ is contained in $B$ but approximates it up to $2^{-n}$. Let

$$
E_{n}(B)=B_{n} \backslash \cup\{D: D \prec B \text { and } D \neq B\}
$$

where $\prec$ denotes the well order. If $B, D \in \mathfrak{S}$, then one is first in the well order. Let $D \prec B$. Then from the construction, $E_{n}(B) \subseteq D^{C}$ and $E_{n}(D)$ is further than $1 / 2^{n}$ from $D^{C}$. Hence, assuming neither set is empty,

$$
\operatorname{dist}\left(E_{n}(B), E_{n}(D)\right) \geq 2^{-n}
$$

for all $B, D \in \mathfrak{S}$. Fatten up $E_{n}(B)$ as follows.

$$
\widetilde{E_{n}(B)} \equiv \cup\left\{B\left(x, 8^{-n}\right): x \in E_{n}(B)\right\}
$$

Thus $\widetilde{E_{n}(B)} \subseteq B$ and

$$
\operatorname{dist}\left(\widetilde{E_{n}(B)}, \widetilde{E_{n}(D)}\right) \geq \frac{1}{2^{n}}-2\left(\frac{1}{8}\right)^{n} \equiv \delta_{n}>0
$$

It follows that the collection of open sets

$$
\left\{\widetilde{E_{n}(B)}: B \in \mathfrak{S}\right\} \equiv \mathfrak{B}_{n}
$$

is locally finite. In fact, $B\left(p, \frac{\delta_{n}}{2}\right)$ cannot intersect more than one of them. In addition to this,

$$
S \subseteq \cup\left\{\widetilde{E_{n}(B)}: n \in \mathbb{N}, B \in \mathfrak{S}\right\}
$$

because if $p \in S$, let $B$ be the first set in $\mathfrak{S}$ to contain $p$. Then $p \in E_{n}(B)$ for $n$ large enough because it will not be in anything deleted. Thus this is an open countably locally finite refinement. Thus 1.) in the above theorem is satisfied.

### 16.1 Partitions Of Unity And Stone's Theorem

First observe that if $S$ is a nonempty set, then $\operatorname{dist}(x, S)$ satisfies $|\operatorname{dist}(x, S)-\operatorname{dist}(y, S)| \leq$ $d(x, y)$. To see this,

$$
|\operatorname{dist}(x, S)-\operatorname{dist}(y, S)| \leq d(x, y)
$$

To see this, say dist $(x, S)$ is the larger of the two. Then there exists $z \in S$ such that

$$
\operatorname{dist}(y, S) \geq d(y, z)-\varepsilon
$$

It follows that

$$
\begin{aligned}
& |\operatorname{dist}(x, S)-\operatorname{dist}(y, S)| \\
= & \operatorname{dist}(x, S)-\operatorname{dist}(y, S)
\end{aligned}
$$

$$
\begin{aligned}
& \leq \operatorname{dist}(x, S)-(d(y, z)-\varepsilon) \\
& \leq d(x, z)-d(y, z)+\varepsilon \\
& \leq d(x, y)+d(y, z)-d(y, z)+\varepsilon=d(x, y)+\varepsilon
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this shows the desired conclusion.
Theorem 16.1.1 Let $S$ be a metric space and let $\mathfrak{S}$ be any open cover of $S$. Then there exists a set $\mathfrak{F}$, an open refinement of $\mathfrak{S}$, and functions $\left\{\phi_{F}: F \in \mathfrak{F}\right\}$ such that

$$
\begin{gathered}
\phi_{F}: S \rightarrow[0,1] \\
\phi_{F} \text { is continuous } \\
\phi_{F}(x) \text { equals } 0 \text { for all but finitely many } F \in \mathfrak{F} \\
\sum\left\{\phi_{F}(x): F \in \mathfrak{F}\right\}=1 \text { for all } x \in S .
\end{gathered}
$$

Each $\phi_{F}$ is locally Lipschitz continuous which means that for each $z$ there is an open set $W$ containing $z$ for which, if $x, y \in W$, then there is a constant $K$ such that

$$
\left|\phi_{F}(x)-\phi_{F}(y)\right| \leq K d(x, y)
$$

Proof: By Stone's theorem, there exists a locally finite refinement $\mathfrak{F}$ covering $S$. For $F \in \mathfrak{F}$

$$
g_{F}(x) \equiv \operatorname{dist}\left(x, F^{C}\right)
$$

Let

$$
\phi_{F}(x) \equiv\left(\sum\left\{g_{F}(x): F \in \mathfrak{F}\right\}\right)^{-1} g_{F}(x)
$$

Now

$$
\sum\left\{g_{F}(x): F \in \mathfrak{F}\right\}
$$

is a continuous function because if $x \in S$, then there exists an open set $W$ with $x \in W$ and $W$ has nonempty intersection with only finitely many sets of $F \in \mathfrak{F}$. Then for $y \in W$,

$$
\sum\left\{g_{F}(y): F \in \mathfrak{F}\right\}=\sum_{i=1}^{n} g_{F_{i}}(y)
$$

Since $\mathfrak{F}$ is a cover of $S$,

$$
\sum\left\{g_{F}(x): F \in \mathfrak{F}\right\} \neq 0
$$

for any $x \in S$. Hence $\phi_{F}$ is continuous. This also shows $\phi_{F}(x)=0$ for all but finitely many $F \in \mathfrak{F}$. It is obvious that

$$
\sum\left\{\phi_{F}(x): F \in \mathfrak{F}\right\}=1
$$

from the definition.
Let $z \in S$. Then there is an open set $W$ containing $z$ such that $W$ has nonempty intersection with only finitely many $F \in \mathscr{F}$. Thus for $y, x \in W$,

$$
\left|\phi_{F_{j}}(x)-\phi_{F_{j}}(y)\right| \leq\left|\frac{g_{F_{j}}(x) \sum_{i=1}^{n} g_{F_{i}}(y)-g_{F_{j}}(y) \sum_{i=1}^{n} g_{F_{i}}(x)}{\sum_{i=1}^{n} g_{F_{i}}(x) \sum_{i=1}^{n} g_{F_{i}}(y)}\right|
$$

If $F$ is not one of these $F_{i}$, then $g_{F}(x)=\phi_{F}(x)=\phi_{F}(y)=g_{F}(y)=0$. Thus there is nothing to show for these. It suffices to consider the ones above. Restricting $W$ if necessary, we can assume that for $x \in W$,

$$
\sum_{F} g_{F}(x)=\sum_{i=1}^{n} g_{F_{i}}(x)>\delta>0, g_{F_{j}}(x)<\Delta<\infty, j \leq n
$$

Then, simplifying the above, and letting $x, y \in W$, for each $j \leq n$,

$$
\begin{aligned}
& \left|\phi_{F_{j}}(x)-\phi_{F_{j}}(y)\right| \leq \frac{1}{\delta^{2}}\left|\begin{array}{c}
g_{F_{j}}(x) \sum_{F} g_{F}(y)-g_{F_{j}}(y) \sum_{F} g_{F}(y) \\
+g_{F_{j}}(y) \sum_{F} g_{F}(y)-g_{F_{j}}(y) \sum_{F} g_{F}(x)
\end{array}\right| \\
& \quad \leq \frac{1}{\delta^{2}} \Delta\left|g_{F_{j}}(x)-g_{F_{j}}(y)\right|+\frac{1}{\delta^{2}} \Delta \sum_{i=1}^{n}\left|g_{F_{i}}(y)-g_{F_{i}}(x)\right| \\
& \quad \leq \frac{\Delta}{\delta^{2}} d(x, y)+\frac{\Delta}{\delta^{2}} n d(x, y)=(n+1) \frac{\Delta}{\delta^{2}} d(x, y)
\end{aligned}
$$

Thus on this set $W$ containing $z$, all $\phi_{F}$ are Lipschitz continuous with Lipschitz constant $(n+1) \frac{\Delta}{\delta^{2}}$.

The functions described above are called a partition of unity subordinate to the open cover $\mathfrak{S}$. A useful observation is contained in the following corollary.

Corollary 16.1.2 Let $S$ be a metric space and let $\mathfrak{S}$ be any open cover of $S$. Then there exists a set $\mathfrak{F}$, an open refinement of $\mathfrak{S}$, and functions $\left\{\phi_{F}: F \in \mathfrak{F}\right\}$ such that

$$
\begin{gathered}
\phi_{F}: S \rightarrow[0,1] \\
\phi_{F} \text { is continuous } \\
\phi_{F}(x) \text { equals } 0 \text { for all but finitely many } F \in \mathfrak{F} \\
\sum\left\{\phi_{F}(x): F \in \mathfrak{F}\right\}=1 \text { for all } x \in S
\end{gathered}
$$

Each $\phi_{F}$ is Lipschitz continuous. If $U \in \mathfrak{S}$ and $H$ is a closed subset of $U$, the partition of unity can be chosen such that each $\phi_{F}=0$ on $H$ except for one which equals 1 on $H$.

Proof: Just change your open cover to consist of $U$ and $V \backslash H$ for each $V \in \mathfrak{S}$. Then every function but one equals 0 on $H$ and so exactly one of them equals 1 on $H$.

### 16.2 An Extension Theorem, Retracts

Lemma 16.2.1 Let $A$ be a closed set in a metric space and let $x_{n} \notin A, x_{n} \rightarrow a_{0} \in A$ and $a_{n} \in A$ such that $d\left(a_{n}, x_{n}\right)<6 \operatorname{dist}\left(x_{n}, A\right)$. Then $a_{n} \rightarrow a_{0}$.

Proof: By assumption,

$$
\begin{aligned}
d\left(a_{n}, a_{0}\right) & \leq d\left(a_{n}, x_{n}\right)+d\left(x_{n}, a_{0}\right)<6 \operatorname{dist}\left(x_{n}, A\right)+d\left(x_{n}, a_{0}\right) \\
& \leq 6 d\left(x_{n}, a_{0}\right)+d\left(x_{n}, a_{0}\right)=7 d\left(x_{n}, a_{0}\right)
\end{aligned}
$$

and this converges to 0 .

Note that there was nothing magic about 6 in the above. Another number would work as well.

In the proof of the following theorem, you get a covering of $A^{C}$ with open balls $B$ such that for each of these balls, there exists $a \in A$ such that for all $x \in B,\|x-a\| \leq 6 \operatorname{dist}(x, A)$. The 6 is not important. Any other constant with this property would work. Then you use Stone's theorem.

A Banach space is a normed vector space which is also a complete metric space where the metric comes from the norm.

$$
d(x, y)=\|x-y\|
$$

Thus you can add things in a Banach space. Much more will be considered about Banach spaces a little later.

Definition 16.2.2 A Banach space is a complete normed linear space. If you have a subset $B$ of a Banach space, then $\operatorname{conv}(B)$ denotes the smallest closed convex set which contains $B$. It can be obtained by taking the intersection of all closed convex sets containing $B$. Recall that a set $C$ is convex if whenever $x, y \in C$, then so is $\lambda x+(1-\lambda) y$ for all $\lambda \in[0,1]$. Note how this makes sense in a vector space but maybe not in a general metric space.

In the following theorem, we have in mind both $X$ and $Y$ are Banach spaces, but this is not needed in the proof. All that is needed is that $X$ is a metric space and $Y$ a normed linear space or possibly something more general in which it makes sense to do addition and scalar multiplication.

Theorem 16.2.3 Let $A$ be a closed subset of a metric space $X$ and let $F: A \rightarrow Y, Y$ a normed linear space. Then there exists an extension of $F$ denoted as $\hat{F}$ such that $\hat{F}$ is defined on all of $X$ and agrees with $F$ on A. It has values in $\operatorname{conv}(F(A))$, the convex hull of $F(A)$.

Proof: For each $c \notin A$, let $B_{c}$ be a ball contained in $A^{C}$ centered at $c$ where distance of $c$ to $A$ is at least $\operatorname{diam}\left(B_{c}\right)$.

So for $x \in B_{c}$ what about dist $(x, A)$ ? How does it compare with dist $(c, A)$ ?

$$
\begin{aligned}
\operatorname{dist}(c, A) & \leq d(c, x)+\operatorname{dist}(x, A) \\
& \leq \frac{1}{2} \operatorname{diam}\left(B_{c}\right)+\operatorname{dist}(x, A) \\
& \leq \frac{1}{2} \operatorname{dist}(c, A)+\operatorname{dist}(x, A)
\end{aligned}
$$

so

$$
\operatorname{dist}(c, A) \leq 2 \operatorname{dist}(x, A)
$$

Now the following is also valid. Letting $x \in B_{c}$ be arbitrary, it follows from the assumption on the diameter that there exists $a_{0} \in A$ such that $d\left(c, a_{0}\right)<2 \operatorname{dist}(c, A)$. Then

$$
\begin{gather*}
d\left(x, a_{0}\right) \leq \sup _{y \in B_{c}} d\left(y, a_{0}\right) \leq \sup _{y \in B_{c}}\left(d(y, c)+d\left(c, a_{0}\right)\right) \leq \frac{\operatorname{diam}\left(B_{c}\right)}{2}+2 \operatorname{dist}(c, A) \\
\leq \frac{\operatorname{dist}(c, A)}{2}+2 \operatorname{dist}(c, A)<3 \operatorname{dist}(c, A) \tag{16.2.1}
\end{gather*}
$$

It follows from 16.2.1,

$$
d\left(x, a_{0}\right) \leq 3 \operatorname{dist}(c, A) \leq 6 \operatorname{dist}(x, A)
$$

Thus for any $x \in B_{c}$, there is an $a_{0} \in A$ such that $d\left(x, a_{0}\right)$ is bounded by a fixed multiple of the distance from $x$ to $A$.

By Stone's theorem, there is a locally finite open refinement $\mathscr{R}$. These are open sets each of which is contained in one of the balls just mentioned such that each of these balls is the union of sets of $\mathscr{R}$. Thus $\mathscr{R}$ is a locally finite cover of $A^{C}$. Since $x \in A^{C}$ is in one of those balls, it was just shown that there exists $a_{R} \in A$ such that for all $x \in R \in \mathscr{R}$ we have $d\left(x, a_{R}\right) \leq 6 \operatorname{dist}(x, A)$. Of course there may be more than one because $R$ might be contained in more than one of those special balls. One $a_{R}$ is chosen for each $R \in \mathscr{R}$.

Now let $\phi_{R}(x) \equiv \operatorname{dist}\left(x, R^{C}\right)$. Then let

$$
\hat{F}(x) \equiv\left\{\begin{array}{l}
F(x) \text { for } x \in A \\
\sum_{R \in \mathscr{R}} F\left(a_{R}\right) \frac{\phi_{R}(x)}{\sum_{\hat{R} \in \mathscr{R}} \phi_{\hat{R}}(x)} \text { for } x \notin A
\end{array}\right.
$$

The sum in the bottom is always finite because the covering is locally finite. Also, this sum is never 0 because $\mathscr{R}$ is a covering. Also $\hat{F}$ has values in $\operatorname{conv}(F(K))$. It only remains to verify that $\hat{F}$ is continuous. It is clearly so on the interior of $A$ thanks to continuity of $F$. It is also clearly continuous on $A^{C}$ because the functions $\phi_{R}$ are continuous. So it suffices to consider $x_{n} \rightarrow a \in \partial A \subseteq A$ where $x_{n} \notin A$ and see whether $F(a)=\lim _{n \rightarrow \infty} \hat{F}\left(x_{n}\right)$.

Suppose this does not happen. Then there is a sequence converging to some $a \in \partial A$ and $\varepsilon>0$ such that

$$
\varepsilon \leq\left\|\hat{F}(a)-\hat{F}\left(x_{n}\right)\right\| \text { all } n
$$

For $x_{n} \in R$, it was shown above that $d\left(x_{n}, a_{R_{n}}\right) \leq 6 \operatorname{dist}\left(x_{n}, A\right)$. By the above Lemma 16.2.1, it follows that $a_{R n} \rightarrow a$ and so $F\left(a_{R n}\right) \rightarrow F(a)$.

$$
\varepsilon \leq\left\|\hat{F}(a)-\hat{F}\left(x_{n}\right)\right\| \leq \sum_{R \in \mathscr{R}}\left\|F\left(a_{R n}\right)-F(a)\right\| \frac{\phi_{R}\left(x_{R n}\right)}{\sum_{\hat{R} \in \mathscr{R}} \phi_{\hat{R}}\left(x_{R n}\right)}
$$

By local finiteness of the cover, each $x_{n}$ involves only finitely many $R$ Thus, in this limit process, there are countably many $R$ involved $\left\{R_{j}\right\}_{j=1}^{\infty}$. Thus one can apply Fatou's lemma.

$$
\begin{aligned}
\varepsilon & \leq \lim \inf _{n \rightarrow \infty}\left\|\hat{F}(a)-\hat{F}\left(x_{n}\right)\right\| \\
& \leq \sum_{j=1}^{\infty} \lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\|F\left(a_{R_{j} n}\right)-F(a)\right\| \frac{\phi_{R_{j}}\left(x_{R_{j} n}\right)}{\sum_{j=1}^{\infty} \phi_{\hat{R}_{j}}\left(x_{R_{j} n}\right)} \\
& \leq \sum_{j=1}^{\infty} \lim _{n \rightarrow \infty} \inf _{n}\left\|F\left(a_{R_{j} n}\right)-F(a)\right\|=0 ■
\end{aligned}
$$

The last step is needed because you lose local finiteness as you approach $\partial A$. Note that the only thing needed was that $X$ is a metric space. The addition takes place in $Y$ so it needs to be a vector space. Did it need to be complete? No, this was not used. Nor was completeness of $X$ used. The main interest here is in Banach spaces, but the result is more general than that.

It also appears that $\hat{F}$ is locally Lipschitz on $A^{C}$.
Definition 16.2.4 Let $S$ be a subset of $X$, a Banach space. Then it is a retract if there exists a continuous function $R: X \rightarrow S$ such that $R s=s$ for all $s \in S$. This $R$ is a retraction. More generally, $S \subseteq T$ is called a retract of $T$ if there is a continuous $R: T \rightarrow S$ such that $R s=s$ for all $s \in S$.

Theorem 16.2.5 Let $K$ be closed and convex subset of $X$ a Banach space. Then $K$ is $a$ retract.

Proof: By Theorem 16.2.3, there is a continuous function $\hat{I}$ extending $I$ to all of $X$. Then also $\hat{I}$ has values in $\operatorname{conv}(I K)=\operatorname{conv}(K)=K$. Hence $\hat{I}$ is a continuous function which does what is needed. It maps everything into $K$ and keeps the points of $K$ unchanged.

Sometimes people call the set a retraction also or the function which does the job a retraction. This seems like strange thing to call it because a retraction is the act of repudiating something you said earlier. Nevertheless, I will call it that. Note that if $S$ is a retract of the whole metric space $X$, then it must be a retract of every set which contains $S$.

### 16.3 Something Which Is Not A Retract

The next lemma is a fundamental result which will be used to develop the Brouwer degree. It will also be used to give a short proof of the Brouwer fixed point theorem in the exercises. This major fixed point theorem is probably the most fundamental theorem in nonlinear analysis. The proof outlined in the exercises is from [48].

Lemma 16.3.1 Let $\mathbf{g}: U \rightarrow \mathbb{R}^{n}$ be $C^{2}$ where $U$ is an open subset of $\mathbb{R}^{n}$. Then

$$
\sum_{j=1}^{n} \operatorname{cof}(D \mathbf{g})_{i j, j}=0
$$

where here $(D \mathbf{g})_{i j} \equiv g_{i, j} \equiv \frac{\partial g_{i}}{\partial x_{j}}$. Also, $\operatorname{cof}(D \mathbf{g})_{i j}=\frac{\partial \operatorname{det}(D \mathbf{g})}{\partial g_{i, j}}$.

Proof: From the cofactor expansion theorem,

$$
\operatorname{det}(D \mathbf{g})=\sum_{i=1}^{n} g_{i, j} \operatorname{cof}(D \mathbf{g})_{i j}
$$

and so

$$
\begin{equation*}
\frac{\partial \operatorname{det}(D \mathbf{g})}{\partial g_{i, j}}=\operatorname{cof}(D \mathbf{g})_{i j} \tag{16.3.2}
\end{equation*}
$$

which shows the last claim of the lemma. Also

$$
\begin{equation*}
\delta_{k j} \operatorname{det}(D \mathbf{g})=\sum_{i} g_{i, k}(\operatorname{cof}(D \mathbf{g}))_{i j} \tag{16.3.3}
\end{equation*}
$$

because if $k \neq j$ this is just the cofactor expansion of the determinant of a matrix in which the $k^{t h}$ and $j^{t h}$ columns are equal. Differentiate 16.3 .3 with respect to $x_{j}$ and sum on $j$. This yields

$$
\sum_{r, s, j} \delta_{k j} \frac{\partial(\operatorname{det} D \mathbf{g})}{\partial g_{r, s}} g_{r, s j}=\sum_{i j} g_{i, k j}(\operatorname{cof}(D \mathbf{g}))_{i j}+\sum_{i j} g_{i, k} \operatorname{cof}(D \mathbf{g})_{i j, j}
$$

Hence, using $\delta_{k j}=0$ if $j \neq k$ and 16.3.2,

$$
\sum_{r s}(\operatorname{cof}(D \mathbf{g}))_{r s} g_{r, s k}=\sum_{r s} g_{r, k s}(\operatorname{cof}(D \mathbf{g}))_{r s}+\sum_{i j} g_{i, k} \operatorname{cof}(D \mathbf{g})_{i j, j}
$$

Subtracting the first sum on the right from both sides and using the equality of mixed partials,

$$
\sum_{i} g_{i, k}\left(\sum_{j}(\operatorname{cof}(D \mathbf{g}))_{i j, j}\right)=0
$$

If $\operatorname{det}\left(g_{i, k}\right) \neq 0$ so that $\left(g_{i, k}\right)$ is invertible, this shows $\sum_{j}(\operatorname{cof}(D \mathbf{g}))_{i j, j}=0$. If $\operatorname{det}(D \mathbf{g})=0$, let

$$
g_{k}=g+\varepsilon_{k} I
$$

where $\varepsilon_{k} \rightarrow 0$ and $\operatorname{det}\left(D \mathbf{g}+\varepsilon_{k} I\right) \equiv \operatorname{det}\left(D \mathbf{g}_{k}\right) \neq 0$. Then

$$
\sum_{j}(\operatorname{cof}(D \mathbf{g}))_{i j, j}=\lim _{k \rightarrow \infty} \sum_{j}\left(\operatorname{cof}\left(D \mathbf{g}_{k}\right)\right)_{i j, j}=0
$$

Definition 16.3.2 Let $\mathbf{h}$ be a function defined on an open set, $U \subseteq \mathbb{R}^{n}$. Then $\mathbf{h} \in C^{k}(\bar{U})$ if there exists a function $\mathbf{g}$ defined on an open set, $W$ containng $\bar{U}$ such that $\mathbf{g}=\mathbf{h}$ on $\bar{U}$ and $\mathbf{g}$ is $C^{k}(W)$.

Lemma 16.3.3 There does not exist $\mathbf{h} \in C^{2}(\overline{B(\mathbf{0}, R)})$ such that $\mathbf{h}: \overline{B(\mathbf{0}, R)} \rightarrow \partial B(\mathbf{0}, R)$ which also has the property that $\mathbf{h}(\mathbf{x})=\mathbf{x}$ for all $\mathbf{x} \in \partial B(\mathbf{0}, R)$. That is, there is no retraction of $\overline{B(\mathbf{0}, R)}$ to $\partial B(\mathbf{0}, R)$.

Proof: Suppose such an $\mathbf{h}$ exists. Let $\lambda \in[0,1]$ and let $\mathbf{p}_{\lambda}(\mathbf{x}) \equiv \mathbf{x}+\lambda(\mathbf{h}(\mathbf{x})-\mathbf{x})$. This function, $\mathbf{p}_{\lambda}$ is a homotopy of the identity map and the retraction, $\mathbf{h}$. Let

$$
I(\lambda) \equiv \int_{\overline{B(\mathbf{0}, R)}} \operatorname{det}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right) d x
$$

Then using the dominated convergence theorem,

$$
\begin{aligned}
I^{\prime}(\lambda) & =\int \frac{\overline{B(\mathbf{0}, R)}}{} \sum_{i . j} \frac{\partial \operatorname{det}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)}{\partial p_{\lambda i, j}} \frac{\partial p_{\lambda i j}(\mathbf{x})}{\partial \lambda} \\
& =\int_{\overline{B(\mathbf{0}, R)}} \sum_{i} \sum_{j} \frac{\partial \operatorname{det}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)}{\partial p_{\lambda i, j}}\left(h_{i}(\mathbf{x})-x_{i}\right)_{, j} d x \\
& =\int_{\overline{B(\mathbf{0}, R)}} \sum_{i} \sum_{j} \operatorname{cof}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)_{i j}\left(h_{i}(\mathbf{x})-x_{i}\right)_{, j} d x
\end{aligned}
$$

Now by assumption, $h_{i}(\mathbf{x})=x_{i}$ on $\partial \overline{B(\mathbf{0}, R)}$ and so one can integrate by parts and write

$$
I^{\prime}(\lambda)=-\sum_{i} \int_{\overline{B(\mathbf{0}, R)}} \sum_{j} \operatorname{cof}\left(D \mathbf{p}_{\lambda}(\mathbf{x})\right)_{i j, j}\left(h_{i}(\mathbf{x})-x_{i}\right) d x=0
$$

Therefore, $I(\lambda)$ equals a constant. However,

$$
I(0)=m_{n}(\overline{B(\mathbf{0}, R)})>0
$$

but

$$
I(1)=\int_{B(\mathbf{0}, R)} \operatorname{det}(D \mathbf{h}(\mathbf{x})) d m_{n}=\int_{\partial B(\mathbf{0}, R)} \#(\mathbf{y}) d m_{n}=0
$$

because from polar coordinates or other elementary reasoning, $m_{n}(\partial B(\mathbf{0}, 1))=0$.
The last formula uses the change of variables formula for functions which are not one to one. In this formula, $\#(\mathbf{y})$ equals the number of $\mathbf{x}$ such that $\mathbf{h}(\mathbf{x})=\mathbf{y}$. To see this is so in case you have not seen this, note that $\mathbf{h}$ is $C^{1}$ and so the inverse function theorem from advanced calculus applies. Thus

$$
\begin{aligned}
\int_{\overline{B(\mathbf{0}, R)}} \operatorname{det}(D \mathbf{h}(\mathbf{x})) d m_{n}= & \int_{[\operatorname{det}(D \mathbf{h}(\mathbf{x}))>0]} \operatorname{det}(D \mathbf{h}(\mathbf{x})) d m_{n} \\
& +\int_{[\operatorname{det}(D \mathbf{h}(\mathbf{x}))<0]} \operatorname{det}(D \mathbf{h}(\mathbf{x})) d m_{n}
\end{aligned}
$$

Thus $\mathbf{h}$ is locally one to one on the two open sets $[\operatorname{det}(D \mathbf{h}(\mathbf{x}))>0],[\operatorname{det}(D \mathbf{h}(\mathbf{x}))<0]$. Now use inverse function theorem and change of variables for one to one $\mathbf{h}$ to verify that both of these integrals equal 0 . You cover $[\operatorname{det}(D \mathbf{h}(\mathbf{x}))>0$ ] with countably many balls on which $\mathbf{h}$ is one to one and then use change of variables for each of these integrals over $[\operatorname{det}(D \mathbf{h}(\mathbf{x}))>0]$ intersected with this ball.

The following is the Brouwer fixed point theorem for $C^{2}$ maps.
Lemma 16.3.4 If $\mathbf{h} \in C^{2}(\overline{B(\mathbf{0}, R)})$ and $\mathbf{h}: \overline{B(\mathbf{0}, R)} \rightarrow \overline{B(\mathbf{0}, R)}$, then $\mathbf{h}$ has a fixed point, $\mathbf{x}$ such that $\mathbf{h}(\mathbf{x})=\mathbf{x}$.

Proof: Suppose the lemma is not true. Then for all $\mathbf{x},|\mathbf{x}-\mathbf{h}(\mathbf{x})| \neq 0$. Then define

$$
\mathbf{g}(\mathbf{x})=\mathbf{h}(\mathbf{x})+\frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|} t(\mathbf{x})
$$

where $t(\mathbf{x})$ is nonnegative and is chosen such that $\mathbf{g}(\mathbf{x}) \in \partial B(\mathbf{0}, R)$. This mapping is illustrated in the following picture.

If $\mathbf{x} \rightarrow t(\mathbf{x})$ is $C^{2}$ near $\overline{B(\mathbf{0}, R)}$, it will follow $\mathbf{g}$ is a $C^{2}$ retraction onto $\partial B(\mathbf{0}, R)$ contrary to Lemma 16.3.3. Thus $t(\mathbf{x})$ is the nonnegative solution to

$$
\begin{equation*}
H(\mathbf{x}, t) \equiv|\mathbf{h}(\mathbf{x})|^{2}+2\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right) t+t^{2}=R^{2} \tag{16.3.4}
\end{equation*}
$$

Then

$$
H_{t}(\mathbf{x}, t)=2\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right)+2 t
$$

If this is nonzero for all $\mathbf{x}$ near $\overline{B(\mathbf{0}, R)}$, it follows from the implicit function theorem that $t$ is a $C^{2}$ function of $\mathbf{x}$. Then from 16.3.4

$$
\begin{aligned}
2 t= & -2\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right) \\
& \pm \sqrt{4\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right)^{2}-4\left(|\mathbf{h}(\mathbf{x})|^{2}-R^{2}\right)}
\end{aligned}
$$

and so

$$
\begin{aligned}
H_{t}(\mathbf{x}, t) & =2 t+2\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right) \\
& = \pm \sqrt{4\left(R^{2}-|\mathbf{h}(\mathbf{x})|^{2}\right)+4\left(\mathbf{h}(\mathbf{x}), \frac{\mathbf{x}-\mathbf{h}(\mathbf{x})}{|\mathbf{x}-\mathbf{h}(\mathbf{x})|}\right)^{2}}
\end{aligned}
$$

If $|\mathbf{h}(\mathbf{x})|<R$, this is nonzero. If $|\mathbf{h}(\mathbf{x})|=R$, then it is still nonzero unless

$$
(\mathbf{h}(\mathbf{x}), \mathbf{x}-\mathbf{h}(\mathbf{x}))=0
$$

But this cannot happen because the angle between $\mathbf{h}(\mathbf{x})$ and $\mathbf{x}-\mathbf{h}(\mathbf{x})$ cannot be $\pi / 2$. Alternatively, if the above equals zero, you would need

$$
(\mathbf{h}(\mathbf{x}), \mathbf{x})=|\mathbf{h}(\mathbf{x})|^{2}=R^{2}
$$

which cannot happen unless $\mathbf{x}=\mathbf{h}(\mathbf{x})$ which is assumed not to happen. Therefore, $\mathbf{x} \rightarrow t(\mathbf{x})$ is $C^{2}$ near $\overline{B(\mathbf{0}, R)}$ and so $\mathbf{g}(\mathbf{x})$ given above contradicts Lemma 16.3.3.

Then the Brouwer fixed point theorem is as follows.
Theorem 16.3.5 Let $\mathbf{f}: \overline{B(\mathbf{0}, R)} \rightarrow \overline{B(\mathbf{0}, R)}$ be continuous, this being a ball in $\mathbb{R}^{p}$. Then it has a fixed point $\mathbf{x} \in \overline{B(\mathbf{0}, R)}$ such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Proof: You can extend $\mathbf{f}$ to assume it is defined on all of $\mathbb{R}^{p}, \mathbf{f}\left(\mathbb{R}^{p}\right) \subseteq \overline{B(\mathbf{0}, R)}$, the convex hull of $\overline{B(\mathbf{0}, R)}$. Then letting $\left\{\psi_{n}\right\}$ be a mollifier, let $\mathbf{f}_{n} \equiv \mathbf{f} * \psi_{n}$. Thus

$$
\left|\mathbf{f}_{n}(\mathbf{x})\right|=\left|\int_{\mathbb{R}^{p}} \mathbf{f}(\mathbf{t}) \psi_{n}(\mathbf{x}-\mathbf{t}) d t\right| \leq \int_{\mathbb{R}^{p}}|\mathbf{f}(\mathbf{t})| \psi_{n}(\mathbf{x}-\mathbf{t}) d t \leq R \int_{\mathbb{R}^{p}} \psi_{n}(\mathbf{x}-\mathbf{t}) d t=R
$$

and so the restriction of $\mathbf{f}_{n}$ to $\overline{B(\mathbf{0}, R)}$ is $C^{2}(\overline{B(\mathbf{0}, R)})$. Therefore, there exists $\mathbf{x}_{n} \in \overline{B(\mathbf{0}, R)}$ such that $\mathbf{f}_{n}\left(\mathbf{x}_{n}\right)=\mathbf{x}_{n}$. The functions $\mathbf{f}_{n}$ converge uniformly to $\mathbf{f}$ on $\overline{B(\mathbf{0}, R)}$.

$$
\begin{aligned}
\left|\mathbf{f}(\mathbf{x})-\mathbf{f}_{n}(\mathbf{x})\right| & =\left|\int_{B\left(\mathbf{0}, \frac{1}{n}\right)}(\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{x}-\mathbf{t})) \psi_{n}(\mathbf{t}) d t\right| \\
& \leq \int_{B\left(\mathbf{0}, \frac{1}{n}\right)}|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{x}-\mathbf{t})| \psi_{n}(\mathbf{t}) d t<\varepsilon
\end{aligned}
$$

provided $n$ is large enough, this for every $\mathbf{x} \in \overline{B(\mathbf{0}, R)}$, this by uniform continuity of $\mathbf{f}$ on $\overline{B(\mathbf{0}, R+1)}$. There exists a subsequence, still called $\left\{\mathbf{x}_{n}\right\}$ which converges to $\mathbf{x} \in \overline{B(\mathbf{0}, R)}$. Then using the uniform convergence of $\mathbf{f}_{n}$ to $\mathbf{f}$,

$$
\mathbf{f}(\mathbf{x})=\lim _{n \rightarrow \infty} \mathbf{f}\left(\mathbf{x}_{n}\right)=\lim _{n \rightarrow \infty} \mathbf{f}_{n}\left(\mathbf{x}_{n}\right)=\lim _{n \rightarrow \infty} \mathbf{x}_{n}=\mathbf{x}
$$

Definition 16.3.6 A nonempty topological space $A$ is said to have the fixed point property if every continuous mapping $f: A \rightarrow A$ has a fixed point.

### 16.4 Exercises

1. Suppose you have a Banach space $X$ and a set $A \subseteq X$. Suppose $A$ is a retract of $B$ where $B$ has the fixed point property. By this is meant that $A \subseteq B$ and there is a continuous function $f: B \rightarrow A$ such that $f$ equals the identity on $A$. Show that it follows that then $A$ also has the fixed point property.
2. Show that the fixed point property is a topological property. That is, if you have $A, B$ two topological spaces and there is a continuous one to one onto mapping $f: A \rightarrow B$ which has continuous inverse, then the two topological spaces either both have the fixed point property or neither one does.
3. The Brouwer fixed point theorem says that every closed ball in $\mathbb{R}^{n}$ centered at 0 has the fixed point property. Show that it follows that every bounded convex closed set in $\mathbb{R}^{n}$ has the fixed point property. Hint: You know that the closed convex set is a retract of $\mathbb{R}^{n}$. Now if it is also a bounded set, then you could enclose it in $B(\mathbf{0}, r)$ for some large enough $r$.
4. Convex closed sets in $\mathbb{R}^{n}$ are retracts. Are there other examples of retracts not considered by Theorem 16.2.3?
5. In $\mathbb{R}^{2}$, consider an annulus, $\{\mathbf{x}: 1 \leq|\mathbf{x}| \leq 2\}$. Show that this set does not have the fixed point property. Could it be a retract of $\mathbb{R}^{2}$ ?
6. Does $\left\{\mathbf{x} \in \mathbb{R}^{n}:|\mathbf{x}|=1\right\}$ have the fixed point property?
7. Suppose you have a closed subset $H$ of $X$ a metric space and suppose also that $\mathscr{C}$ is an open cover of $H$. Show there is another open cover $\hat{\mathscr{C}}$ such that the closure of each open set in $\hat{\mathscr{C}}$ is contained in some set of $\mathscr{C}$. Hint: You might want to use the fact that metric space is normal.
8. If $H$ is a closed nonempty subset of $\mathbb{R}^{n}$ and $\mathscr{C}$ is an open cover of $H$, show that there is a refined open cover such that each of the new open sets are bounded. In the partition of unity result obtained above, applied to $H$ show that the functions in the partition of unity can be assumed to be infinitely differentiable with compact support.
9. Check that the conclusion of Theorem 16.2.3 applies for $X$ just a metric space. Then apply it to give another proof of the Tietze extension theorem.
10. Suppose you have that $h_{k}: B \rightarrow B$ for $B$ a compact set and each $h_{k}$ has a fixed point. Suppose also that $h_{k}$ converges to $h$ uniformly on $B$. Then $h$ also has a fixed point. Verify this.
11. The Brouwer fixed point theorem is a finite dimensional creature. Consider a separable Hilbert space $H$ with a complete orthonormal basis $\left\{e_{k}\right\}_{k=1}^{\infty}$. Then define the following map. For $x=\sum_{i=1}^{\infty} x_{i} e_{i}$, define $L\left(\sum_{i=1}^{\infty} x_{i} e_{i}\right) \equiv \sum_{i=1}^{\infty} x_{i} e_{i+1}$. Now let $f(x) \equiv \frac{1}{2}\left(1-\|x\|_{H}\right) e_{1}+L x$. Verify that $f: \overline{B(0,1)} \rightarrow \overline{B(0,1)}$ is continuous and yet it has no fixed point. This example is in [55].

## Chapter 17

## Banach Spaces

### 17.1 Theorems Based On Baire Category

### 17.1.1 Baire Category Theorem

Some examples of Banach spaces that have been discussed up to now are $\mathbb{R}^{n}, \mathbb{C}^{n}$, and $L^{p}(\Omega)$. Theorems about general Banach spaces are proved in this chapter. The main theorems to be presented here are the uniform boundedness theorem, the open mapping theorem, the closed graph theorem, and the Hahn Banach Theorem. The first three of these theorems come from the Baire category theorem which is about to be presented. They are topological in nature. The Hahn Banach theorem has nothing to do with topology. Banach spaces are all normed linear spaces and as such, they are all metric spaces because a normed linear space may be considered as a metric space with $d(x, y) \equiv\|x-y\|$. You can check that this satisfies all the axioms of a metric. As usual, if every Cauchy sequence converges, the metric space is called complete.

Definition 17.1.1 A complete normed linear space is called a Banach space.

The following remarkable result is called the Baire category theorem. To get an idea of its meaning, imagine you draw a line in the plane. The complement of this line is an open set and is dense because every point, even those on the line, are limit points of this open set. Now draw another line. The complement of the two lines is still open and dense. Keep drawing lines and looking at the complements of the union of these lines. You always have an open set which is dense. Now what if there were countably many lines? The Baire category theorem implies the complement of the union of these lines is dense. In particular it is nonempty. Thus you cannot write the plane as a countable union of lines. This is a rather rough description of this very important theorem. The precise statement and proof follow.

Theorem 17.1.2 Let $(X, d)$ be a complete metric space and let $\left\{U_{n}\right\}_{n=1}^{\infty}$ be a sequence of open subsets of $X$ satisfying $\overline{U_{n}}=X$ ( $U_{n}$ is dense). Then $D \equiv \cap_{n=1}^{\infty} U_{n}$ is a dense subset of $X$.

Proof: Let $p \in X$ and let $r_{0}>0$. I need to show $D \cap B\left(p, r_{0}\right) \neq \emptyset$. Since $U_{1}$ is dense, there exists $p_{1} \in U_{1} \cap B\left(p, r_{0}\right)$, an open set. Let $p_{1} \in B\left(p_{1}, r_{1}\right) \subseteq \overline{B\left(p_{1}, r_{1}\right)} \subseteq U_{1} \cap B\left(p, r_{0}\right)$ and $r_{1}<2^{-1}$. This is possible because $U_{1} \cap B\left(p, r_{0}\right)$ is an open set and so there exists $r_{1}$ such that $B\left(p_{1}, 2 r_{1}\right) \subseteq U_{1} \cap B\left(p, r_{0}\right)$. But

$$
B\left(p_{1}, r_{1}\right) \subseteq \overline{B\left(p_{1}, r_{1}\right)} \subseteq B\left(p_{1}, 2 r_{1}\right)
$$

because $\overline{B\left(p_{1}, r_{1}\right)}=\left\{x \in X: d(x, p) \leq r_{1}\right\}$. (Why?)

There exists $p_{2} \in U_{2} \cap B\left(p_{1}, r_{1}\right)$ because $U_{2}$ is dense. Let

$$
p_{2} \in B\left(p_{2}, r_{2}\right) \subseteq \overline{B\left(p_{2}, r_{2}\right)} \subseteq U_{2} \cap B\left(p_{1}, r_{1}\right) \subseteq U_{1} \cap U_{2} \cap B\left(p, r_{0}\right)
$$

and let $r_{2}<2^{-2}$. Continue in this way. Thus

$$
\begin{gathered}
r_{n}<2^{-n}, \\
\overline{B\left(p_{n}, r_{n}\right)} \subseteq U_{1} \cap U_{2} \cap \ldots \cap U_{n} \cap B\left(p, r_{0}\right), \\
\overline{B\left(p_{n}, r_{n}\right)} \subseteq B\left(p_{n-1}, r_{n-1}\right) .
\end{gathered}
$$

The sequence, $\left\{p_{n}\right\}$ is a Cauchy sequence because all terms of $\left\{p_{k}\right\}$ for $k \geq n$ are contained in $B\left(p_{n}, r_{n}\right)$, a set whose diameter is no larger than $2^{-n}$. Since $X$ is complete, there exists $p_{\infty}$ such that

$$
\lim _{n \rightarrow \infty} p_{n}=p_{\infty}
$$

Since all but finitely many terms of $\left\{p_{n}\right\}$ are in $\overline{B\left(p_{m}, r_{m}\right)}$, it follows that $p_{\infty} \in \overline{B\left(p_{m}, r_{m}\right)}$ for each $m$. Therefore,

$$
p_{\infty} \in \cap_{m=1}^{\infty} \overline{B\left(p_{m}, r_{m}\right)} \subseteq \cap_{i=1}^{\infty} U_{i} \cap B\left(p, r_{0}\right)
$$

This proves the theorem.
The following corollary is also called the Baire category theorem.
Corollary 17.1.3 Let $X$ be a complete metric space and suppose $X=\cup_{i=1}^{\infty} F_{i}$ where each $F_{i}$ is a closed set. Then for some $i$, interior $F_{i} \neq \emptyset$.

Proof: If all $F_{i}$ has empty interior, then $F_{i}^{C}$ would be a dense open set. Therefore, from Theorem 17.1.2, it would follow that

$$
\emptyset=\left(\cup_{i=1}^{\infty} F_{i}\right)^{C}=\cap_{i=1}^{\infty} F_{i}^{C} \neq \emptyset
$$

The set $D$ of Theorem 17.1.2 is called a $G_{\delta}$ set because it is the countable intersection of open sets. Thus $D$ is a dense $G_{\delta}$ set.

Recall that a norm satisfies:
a.) $\|x\| \geq 0,\|x\|=0$ if and only if $x=0$.
b.) $\|x+y\| \leq\|x\|+\|y\|$.
c.) $\|c x\|=|c|\|x\|$ if $c$ is a scalar and $x \in X$.

From the definition of continuity, it follows easily that a function is continuous if

$$
\lim _{n \rightarrow \infty} x_{n}=x
$$

implies

$$
\lim _{n \rightarrow \infty} f\left(x_{n}\right)=f(x)
$$

Theorem 17.1.4 Let $X$ and $Y$ be two normed linear spaces and let $L: X \rightarrow Y$ be linear $(L(a x+b y)=a L(x)+b L(y)$ for $a, b$ scalars and $x, y \in X)$. The following are equivalent
a.) $L$ is continuous at 0
b.) $L$ is continuous
c.) There exists $K>0$ such that $\|L x\|_{Y} \leq K\|x\|_{X}$ for all $x \in X$ ( $L$ is bounded).

Proof: a.) $\Rightarrow \mathrm{b}$.) Let $x_{n} \rightarrow x$. It is necessary to show that $L x_{n} \rightarrow L x$. But $\left(x_{n}-x\right) \rightarrow 0$ and so from continuity at 0 , it follows

$$
L\left(x_{n}-x\right)=L x_{n}-L x \rightarrow 0
$$

so $L x_{n} \rightarrow L x$. This shows a.) implies b.).
b. $) \Rightarrow$ c.) Since $L$ is continuous, $L$ is continuous at 0 . Hence $\|L x\|_{Y}<1$ whenever $\|x\|_{X} \leq \delta$ for some $\delta$. Therefore, suppressing the subscript on the \| \|,

$$
\left\|L\left(\frac{\delta x}{\|x\|}\right)\right\| \leq 1
$$

Hence

$$
\|L x\| \leq \frac{1}{\delta}\|x\|
$$

c.) $\Rightarrow$ a.) follows from the inequality given in c .).

Definition 17.1.5 Let $L: X \rightarrow Y$ be linear and continuous where $X$ and $Y$ are normed linear spaces. Denote the set of all such continuous linear maps by $\mathscr{L}(X, Y)$ and define

$$
\begin{equation*}
\|L\|=\sup \{\|L x\|:\|x\| \leq 1\} \tag{17.1.1}
\end{equation*}
$$

This is called the operator norm.
Note that from Theorem 17.1.4 $\|L\|$ is well defined because of part c .) of that Theorem.
The next lemma follows immediately from the definition of the norm and the assumption that $L$ is linear.

Lemma 17.1.6 With $\|L\|$ defined in 17.1.1, $\mathscr{L}(X, Y)$ is a normed linear space. Also $\|L x\| \leq\|L\|\|x\|$.

Proof: Let $x \neq 0$ then $x /\|x\|$ has norm equal to 1 and so

$$
\left\|L\left(\frac{x}{\|x\|}\right)\right\| \leq\|L\|
$$

Therefore, multiplying both sides by $\|x\|,\|L x\| \leq\|L\|\|x\|$. This is obviously a linear space. It remains to verify the operator norm really is a norm. First of all, if $\|L\|=0$, then $L x=0$ for all $\|x\| \leq 1$. It follows that for any $x \neq 0,0=L\left(\frac{x}{\|x\|}\right)$ and so $L x=0$. Therefore, $L=0$. Also, if $c$ is a scalar,

$$
\|c L\|=\sup _{\|x\| \leq 1}\|c L(x)\|=|c| \sup _{\|x\| \leq 1}\|L x\|=|c|\|L\| .
$$

It remains to verify the triangle inequality. Let $L, M \in \mathscr{L}(X, Y)$.

$$
\begin{aligned}
\|L+M\| & \equiv \sup _{\|x\| \leq 1}\|(L+M)(x)\| \leq \sup _{\|x\| \leq 1}(\|L x\|+\|M x\|) \\
& \leq \sup _{\|x\| \leq 1}\|L x\|+\sup _{\|x\| \leq 1}\|M x\|=\|L\|+\|M\| .
\end{aligned}
$$

This shows the operator norm is really a norm as hoped. This proves the lemma.
For example, consider the space of linear transformations defined on $\mathbb{R}^{n}$ having values in $\mathbb{R}^{m}$. The fact the transformation is linear automatically imparts continuity to it. You should give a proof of this fact. Recall that every such linear transformation can be realized in terms of matrix multiplication.

Thus, in finite dimensions the algebraic condition that an operator is linear is sufficient to imply the topological condition that the operator is continuous. The situation is not so simple in infinite dimensional spaces such as $C\left(X ; \mathbb{R}^{n}\right)$. This explains the imposition of the topological condition of continuity as a criterion for membership in $\mathscr{L}(X, Y)$ in addition to the algebraic condition of linearity.

Theorem 17.1.7 If $Y$ is a Banach space, then $\mathscr{L}(X, Y)$ is also a Banach space.
Proof: Let $\left\{L_{n}\right\}$ be a Cauchy sequence in $\mathscr{L}(X, Y)$ and let $x \in X$.

$$
\left\|L_{n} x-L_{m} x\right\| \leq\|x\|\left\|L_{n}-L_{m}\right\|
$$

Thus $\left\{L_{n} x\right\}$ is a Cauchy sequence. Let

$$
L x=\lim _{n \rightarrow \infty} L_{n} x
$$

Then, clearly, $L$ is linear because if $x_{1}, x_{2}$ are in $X$, and $a, b$ are scalars, then

$$
\begin{aligned}
L\left(a x_{1}+b x_{2}\right) & =\lim _{n \rightarrow \infty} L_{n}\left(a x_{1}+b x_{2}\right) \\
& =\lim _{n \rightarrow \infty}\left(a L_{n} x_{1}+b L_{n} x_{2}\right) \\
& =a L x_{1}+b L x_{2}
\end{aligned}
$$

Also $L$ is continuous. To see this, note that $\left\{\left\|L_{n}\right\|\right\}$ is a Cauchy sequence of real numbers because $\left\|\mid L_{n}\right\|-\left\|L_{m}\right\|\|\leq\| L_{n}-L_{m} \|$. Hence there exists $K>\sup \left\{\left\|L_{n}\right\|: n \in \mathbb{N}\right\}$. Thus, if $x \in X$,

$$
\|L x\|=\lim _{n \rightarrow \infty}\left\|L_{n} x\right\| \leq K\|x\|
$$

This proves the theorem.

### 17.1.2 Uniform Boundedness Theorem

The next big result is sometimes called the Uniform Boundedness theorem, or the BanachSteinhaus theorem. This is a very surprising theorem which implies that for a collection of bounded linear operators, if they are bounded pointwise, then they are also bounded
uniformly. As an example of a situation in which pointwise bounded does not imply uniformly bounded, consider the functions $f_{\alpha}(x) \equiv \mathscr{X}_{(\alpha, 1)}(x) x^{-1}$ for $\alpha \in(0,1)$. Clearly each function is bounded and the collection of functions is bounded at each point of $(0,1)$, but there is no bound for all these functions taken together. One problem is that $(0,1)$ is not a Banach space. Therefore, the functions cannot be linear.

Theorem 17.1.8 Let $X$ be a Banach space and let $Y$ be a normed linear space. Let $\left\{L_{\alpha}\right\}_{\alpha \in \Lambda}$ be a collection of elements of $\mathscr{L}(X, Y)$. Then one of the following happens.
a.) $\sup \left\{\left\|L_{\alpha}\right\|: \alpha \in \Lambda\right\}<\infty$
b.) There exists a dense $G_{\delta}$ set, $D$, such that for all $x \in D$,

$$
\sup \left\{\left\|L_{\alpha} x\right\| \alpha \in \Lambda\right\}=\infty
$$

Proof: For each $n \in \mathbb{N}$, define

$$
U_{n}=\left\{x \in X: \sup \left\{\left\|L_{\alpha} x\right\|: \alpha \in \Lambda\right\}>n\right\} .
$$

Then $U_{n}$ is an open set because if $x \in U_{n}$, then there exists $\alpha \in \Lambda$ such that

$$
\left\|L_{\alpha} x\right\|>n
$$

But then, since $L_{\alpha}$ is continuous, this situation persists for all $y$ sufficiently close to $x$, say for all $y \in B(x, \delta)$. Then $B(x, \delta) \subseteq U_{n}$ which shows $U_{n}$ is open.

Case b.) is obtained from Theorem 17.1.2 if each $U_{n}$ is dense.
The other case is that for some $n, U_{n}$ is not dense. If this occurs, there exists $x_{0}$ and $r>0$ such that for all $x \in B\left(x_{0}, r\right),\left\|L_{\alpha} x\right\| \leq n$ for all $\alpha$. Now if $y \in B(0, r), x_{0}+y \in B\left(x_{0}, r\right)$. Consequently, for all such $y,\left\|L_{\alpha}\left(x_{0}+y\right)\right\| \leq n$. This implies that for all $\alpha \in \Lambda$ and $\|y\|<r$,

$$
\left\|L_{\alpha} y\right\| \leq n+\left\|L_{\alpha}\left(x_{0}\right)\right\| \leq 2 n
$$

Therefore, if $\|y\| \leq 1,\left\|\frac{r}{2} y\right\|<r$ and so for all $\alpha$,

$$
\left\|L_{\alpha}\left(\frac{r}{2} y\right)\right\| \leq 2 n
$$

Now multiplying by $r / 2$ it follows that whenever $\|y\| \leq 1,\left\|L_{\alpha}(y)\right\| \leq 4 n / r$. Hence case a.) holds.

### 17.1.3 Open Mapping Theorem

Another remarkable theorem which depends on the Baire category theorem is the open mapping theorem. Unlike Theorem 17.1.8 it requires both $X$ and $Y$ to be Banach spaces.

Theorem 17.1.9 Let $X$ and $Y$ be Banach spaces, let $L \in \mathscr{L}(X, Y)$, and suppose $L$ is onto. Then L maps open sets onto open sets.

To aid in the proof, here is a lemma.

Lemma 17.1.10 Let $a$ and $b$ be positive constants and suppose

$$
B(0, a) \subseteq \overline{L(B(0, b))}
$$

Then

$$
\overline{L(B(0, b))} \subseteq L(B(0,2 b))
$$

Proof of Lemma 17.1.10: Let $y \in \overline{L(B(0, b))}$. There exists $x_{1} \in B(0, b)$ such that $\| y-$ $L x_{1} \|<\frac{a}{2}$. Now this implies

$$
2 y-2 L x_{1} \in B(0, a) \subseteq \overline{L(B(0, b))}
$$

Thus $2 y-2 L x_{1} \in \overline{L(B(0, b))}$ just like $y$ was. Therefore, there exists $x_{2} \in B(0, b)$ such that $\left\|2 y-2 L x_{1}-L x_{2}\right\|<a / 2$. Hence $\left\|4 y-4 L x_{1}-2 L x_{2}\right\|<a$, and there exists $x_{3} \in$ $B(0, b)$ such that $\left\|4 y-4 L x_{1}-2 L x_{2}-L x_{3}\right\|<a / 2$. Continuing in this way, there exist $x_{1}, x_{2}, x_{3}, x_{4}, \ldots$ in $B(0, b)$ such that

$$
\left\|2^{n} y-\sum_{i=1}^{n} 2^{n-(i-1)} L\left(x_{i}\right)\right\|<a
$$

which implies

$$
\begin{equation*}
\left\|y-\sum_{i=1}^{n} 2^{-(i-1)} L\left(x_{i}\right)\right\|=\left\|y-L\left(\sum_{i=1}^{n} 2^{-(i-1)}\left(x_{i}\right)\right)\right\|<2^{-n} a \tag{17.1.2}
\end{equation*}
$$

Now consider the partial sums of the series, $\sum_{i=1}^{\infty} 2^{-(i-1)} x_{i}$.

$$
\left\|\sum_{i=m}^{n} 2^{-(i-1)} x_{i}\right\| \leq b \sum_{i=m}^{\infty} 2^{-(i-1)}=b 2^{-m+2}
$$

Therefore, these partial sums form a Cauchy sequence and so since $X$ is complete, there exists $x=\sum_{i=1}^{\infty} 2^{-(i-1)} x_{i}$. Letting $n \rightarrow \infty$ in 17.1.2 yields $\|y-L x\|=0$. Now

$$
\begin{gathered}
\|x\|=\lim _{n \rightarrow \infty}\left\|\sum_{i=1}^{n} 2^{-(i-1)} x_{i}\right\| \\
\leq \lim _{n \rightarrow \infty} \sum_{i=1}^{n} 2^{-(i-1)}\left\|x_{i}\right\|<\lim _{n \rightarrow \infty} \sum_{i=1}^{n} 2^{-(i-1)} b=2 b .
\end{gathered}
$$

This proves the lemma.
Proof of Theorem 17.1.9: $Y=\cup_{n=1}^{\infty} \overline{L(B(0, n))}$. By Corollary 17.1.3, the set, $\overline{L\left(B\left(0, n_{0}\right)\right)}$ has nonempty interior for some $n_{0}$. Thus $B(y, r) \subseteq \overline{L\left(B\left(0, n_{0}\right)\right)}$ for some $y$ and some $r>0$. Since $L$ is linear $B(-y, r) \subseteq \overline{L\left(B\left(0, n_{0}\right)\right)}$ also. Here is why. If $z \in B(-y, r)$, then
 and $-x_{n} \in B\left(0, n_{0}\right)$ also. Therefore $z \in \overline{L\left(B\left(0, n_{0}\right)\right)}$. Then it follows that

$$
\begin{aligned}
B(0, r) & \subseteq B(y, r)+B(-y, r) \\
& \equiv\left\{y_{1}+y_{2}: y_{1} \in B(y, r) \text { and } y_{2} \in B(-y, r)\right\} \\
& \subseteq \frac{L\left(B\left(0,2 n_{0}\right)\right)}{}
\end{aligned}
$$

The reason for the last inclusion is that from the above, if $y_{1} \in B(y, r)$ and $y_{2} \in B(-y, r)$, there exists $x_{n}, z_{n} \in B\left(0, n_{0}\right)$ such that

$$
L x_{n} \rightarrow y_{1}, L z_{n} \rightarrow y_{2} .
$$

Therefore,

$$
\left\|x_{n}+z_{n}\right\| \leq 2 n_{0}
$$

and so $\left(y_{1}+y_{2}\right) \in \overline{L\left(B\left(0,2 n_{0}\right)\right)}$.
By Lemma 17.1.10, $\overline{L\left(B\left(0,2 n_{0}\right)\right)} \subseteq L\left(B\left(0,4 n_{0}\right)\right)$ which shows

$$
B(0, r) \subseteq L\left(B\left(0,4 n_{0}\right)\right)
$$

Letting $a=r\left(4 n_{0}\right)^{-1}$, it follows, since $L$ is linear, that $B(0, a) \subseteq L(B(0,1))$. It follows since $L$ is linear,

$$
\begin{equation*}
L(B(0, r)) \supseteq B(0, a r) . \tag{17.1.3}
\end{equation*}
$$

Now let $U$ be open in $X$ and let $x+B(0, r)=B(x, r) \subseteq U$. Using 17.1.3,

$$
\begin{aligned}
L(U) & \supseteq L(x+B(0, r)) \\
=L x+L(B(0, r)) & \supseteq L x+B(0, a r)=B(L x, a r) .
\end{aligned}
$$

Hence

$$
L x \in B(L x, a r) \subseteq L(U)
$$

which shows that every point, $L x \in L U$, is an interior point of $L U$ and so $L U$ is open. This proves the theorem.

This theorem is surprising because it implies that if $|\cdot|$ and $\|\cdot\|$ are two norms with respect to which a vector space $X$ is a Banach space such that $|\cdot| \leq K\|\cdot\|$, then there exists a constant $k$, such that $\|\cdot\| \leq k|\cdot|$. This can be useful because sometimes it is not clear how to compute $k$ when all that is needed is its existence. To see the open mapping theorem implies this, consider the identity map id $x=x$. Then id : $(X,\|\cdot\|) \rightarrow(X,|\cdot|)$ is continuous and onto. Hence id is an open map which implies $\mathrm{id}^{-1}$ is continuous. Theorem 17.1.4 gives the existence of the constant $k$.

### 17.1.4 Closed Graph Theorem

Definition 17.1.11 Let $f: D \rightarrow E$. The set of all ordered pairs of the form $\{(x, f(x)): x \in$ $D\}$ is called the graph of $f$.

Definition 17.1.12 If $X$ and $Y$ are normed linear spaces, make $X \times Y$ into a normed linear space by using the norm $\|(x, y)\|=\max (\|x\|,\|y\|)$ along with component-wise addition and scalar multiplication. Thus $a(x, y)+b(z, w) \equiv(a x+b z, a y+b w)$.

There are other ways to give a norm for $X \times Y$. For example, you could define $\|(x, y)\|=$ $\|x\|+\|y\|$

Lemma 17.1.13 The norm defined in Definition 17.1.12 on $X \times Y$ along with the definition of addition and scalar multiplication given there make $X \times Y$ into a normed linear space.

Proof: The only axiom for a norm which is not obvious is the triangle inequality. Therefore, consider

$$
\begin{aligned}
&\left\|\left(x_{1}, y_{1}\right)+\left(x_{2}, y_{2}\right)\right\|=\left\|\left(x_{1}+x_{2}, y_{1}+y_{2}\right)\right\| \\
&=\max \left(\left\|x_{1}+x_{2}\right\|,\left\|y_{1}+y_{2}\right\|\right) \\
& \leq \max \left(\left\|x_{1}\right\|+\left\|x_{2}\right\|,\left\|y_{1}\right\|+\left\|y_{2}\right\|\right) \\
& \leq \max \left(\left\|x_{1}\right\|,\left\|y_{1}\right\|\right)+\max \left(\left\|x_{2}\right\|,\left\|y_{2}\right\|\right) \\
&=\left\|\left(x_{1}, y_{1}\right)\right\|+\left\|\left(x_{2}, y_{2}\right)\right\| .
\end{aligned}
$$

It is obvious $X \times Y$ is a vector space from the above definition. This proves the lemma.
Lemma 17.1.14 If $X$ and $Y$ are Banach spaces, then $X \times Y$ with the norm and vector space operations defined in Definition 17.1.12 is also a Banach space.

Proof: The only thing left to check is that the space is complete. But this follows from the simple observation that $\left\{\left(x_{n}, y_{n}\right)\right\}$ is a Cauchy sequence in $X \times Y$ if and only if $\left\{x_{n}\right\}$ and $\left\{y_{n}\right\}$ are Cauchy sequences in $X$ and $Y$ respectively. Thus if $\left\{\left(x_{n}, y_{n}\right)\right\}$ is a Cauchy sequence in $X \times Y$, it follows there exist $x$ and $y$ such that $x_{n} \rightarrow x$ and $y_{n} \rightarrow y$. But then from the definition of the norm, $\left(x_{n}, y_{n}\right) \rightarrow(x, y)$.

Lemma 17.1.15 Every closed subspace of a Banach space is a Banach space.
Proof: If $F \subseteq X$ where $X$ is a Banach space and $\left\{x_{n}\right\}$ is a Cauchy sequence in $F$, then since $X$ is complete, there exists a unique $x \in X$ such that $x_{n} \rightarrow x$. However this means $x \in \bar{F}=F$ since $F$ is closed.

Definition 17.1.16 Let $X$ and $Y$ be Banach spaces and let $D \subseteq X$ be a subspace. A linear map $L: D \rightarrow Y$ is said to be closed if its graph is a closed subspace of $X \times Y$. Equivalently, $L$ is closed if $x_{n} \rightarrow x$ and $L x_{n} \rightarrow y$ implies $x \in D$ and $y=L x$.

Note the distinction between closed and continuous. If the operator is closed the assertion that $y=L x$ only follows if it is known that the sequence $\left\{L x_{n}\right\}$ converges. In the case of a continuous operator, the convergence of $\left\{L x_{n}\right\}$ follows from the assumption that $x_{n} \rightarrow x$. It is not always the case that a mapping which is closed is necessarily continuous. Consider the function $f(x)=\tan (x)$ if $x$ is not an odd multiple of $\frac{\pi}{2}$ and $f(x) \equiv 0$ at every odd multiple of $\frac{\pi}{2}$. Then the graph is closed and the function is defined on $\mathbb{R}$ but it clearly fails to be continuous. Of course this function is not linear. You could also consider the map,

$$
\frac{d}{d x}:\left\{y \in C^{1}([0,1]): y(0)=0\right\} \equiv D \rightarrow C([0,1])
$$

where the norm is the uniform norm on $C([0,1]),\|y\|_{\infty}$. If $y \in D$, then

$$
y(x)=\int_{0}^{x} y^{\prime}(t) d t
$$

Therefore, if $\frac{d y_{n}}{d x} \rightarrow f \in C([0,1])$ and if $y_{n} \rightarrow y$ in $C([0,1])$ it follows that

$$
\begin{aligned}
y_{n}(x) & =\int_{0}^{x} \frac{d y_{n}(t)}{d x} d t \\
\downarrow & \downarrow \\
y(x) & =\int_{0}^{x} f(t) d t
\end{aligned}
$$

and so by the fundamental theorem of calculus $f(x)=y^{\prime}(x)$ and so the mapping is closed. It is obviously not continuous because it takes $y(x)$ and $y(x)+\frac{1}{n} \sin (n x)$ to two functions which are far from each other even though these two functions are very close in $C([0,1])$. Furthermore, it is not defined on the whole space, $C([0,1])$.

The next theorem, the closed graph theorem, gives conditions under which closed implies continuous.

Theorem 17.1.17 Let $X$ and $Y$ be Banach spaces and suppose $L: X \rightarrow Y$ is closed and linear. Then $L$ is continuous.

Proof: Let $G$ be the graph of $L . G=\{(x, L x): x \in X\}$. By Lemma 17.1.15 it follows that $G$ is a Banach space. Define $P: G \rightarrow X$ by $P(x, L x)=x$. $P$ maps the Banach space $G$ onto the Banach space $X$ and is continuous and linear. By the open mapping theorem, $P$ maps open sets onto open sets. Since $P$ is also one to one, this says that $P^{-1}$ is continuous. Thus $\left\|P^{-1} x\right\| \leq K\|x\|$. Hence

$$
\|L x\| \leq \max (\|x\|,\|L x\|) \leq K\|x\|
$$

By Theorem 17.1.4 on Page 437, this shows $L$ is continuous and proves the theorem.
The following corollary is quite useful. It shows how to obtain a new norm on the domain of a closed operator such that the domain with this new norm becomes a Banach space.

Corollary 17.1.18 Let $L: D \subseteq X \rightarrow Y$ where $X, Y$ are a Banach spaces, and $L$ is a closed operator. Then define a new norm on $D$ by

$$
\|x\|_{D} \equiv\|x\|_{X}+\|L x\|_{Y} .
$$

Then $D$ with this new norm is a Banach space.
Proof: If $\left\{x_{n}\right\}$ is a Cauchy sequence in $D$ with this new norm, it follows both $\left\{x_{n}\right\}$ and $\left\{L x_{n}\right\}$ are Cauchy sequences and therefore, they converge. Since $L$ is closed, $x_{n} \rightarrow x$ and $L x_{n} \rightarrow L x$ for some $x \in D$. Thus $\left\|x_{n}-x\right\|_{D} \rightarrow 0$.

### 17.2 Hahn Banach Theorem

The closed graph, open mapping, and uniform boundedness theorems are the three major topological theorems in functional analysis. The other major theorem is the Hahn-Banach theorem which has nothing to do with topology. Before presenting this theorem, here are some preliminaries about partially ordered sets.

### 17.2.1 Partially Ordered Sets

Definition 17.2.1 Let $\mathscr{F}$ be a nonempty set. $\mathscr{F}$ is called a partially ordered set if there is a relation, denoted here by $\leq$, such that

$$
\begin{gathered}
x \leq x \text { for all } x \in \mathscr{F} \\
\text { If } x \leq y \text { and } y \leq z \text { then } x \leq z
\end{gathered}
$$

$\mathscr{C} \subseteq \mathscr{F}$ is said to be a chain if every two elements of $\mathscr{C}$ are related. This means that if $x, y \in \mathscr{C}$, then either $x \leq y$ or $y \leq x$. Sometimes a chain is called a totally ordered set. $\mathscr{C}$ is said to be a maximal chain if whenever $\mathscr{D}$ is a chain containing $\mathscr{C}, \mathscr{D}=\mathscr{C}$.

The most common example of a partially ordered set is the power set of a given set with $\subseteq$ being the relation. It is also helpful to visualize partially ordered sets as trees. Two points on the tree are related if they are on the same branch of the tree and one is higher than the other. Thus two points on different branches would not be related although they might both be larger than some point on the trunk. You might think of many other things which are best considered as partially ordered sets. Think of food for example. You might find it difficult to determine which of two favorite pies you like better although you may be able to say very easily that you would prefer either pie to a dish of lard topped with whipped cream and mustard. The following theorem is equivalent to the axiom of choice. For a discussion of this, see the appendix on the subject.

Theorem 17.2.2 (Hausdorff Maximal Principle) Let $\mathscr{F}$ be a nonempty partially ordered set. Then there exists a maximal chain.

### 17.2.2 Gauge Functions And Hahn Banach Theorem

Definition 17.2.3 Let $X$ be a real vector space $\rho: X \rightarrow \mathbb{R}$ is called a gauge function if

$$
\begin{align*}
& \rho(x+y) \leq \rho(x)+\rho(y) \\
& \rho(a x)=a \rho(x) \text { if } a \geq 0 . \tag{17.2.4}
\end{align*}
$$

Suppose $M$ is a subspace of $X$ and $z \notin M$. Suppose also that $f$ is a linear real-valued function having the property that $f(x) \leq \rho(x)$ for all $x \in M$. Consider the problem of extending $f$ to $M \oplus \mathbb{R} z$ such that if $F$ is the extended function, $F(y) \leq \rho(y)$ for all $y \in$ $M \oplus \mathbb{R} z$ and $F$ is linear. Since $F$ is to be linear, it suffices to determine how to define $F(z)$. Letting $a>0$, it is required to define $F(z)$ such that the following hold for all $x, y \in M$.

$$
\begin{align*}
& \overbrace{F(x)}^{f(x)}+a F(z)=F(x+a z) \leq \rho(x+a z), \\
& \overbrace{F(y)}^{f(y)}-a F(z)=F(y-a z) \leq \rho(y-a z) . \tag{17.2.5}
\end{align*}
$$

Now if these inequalities hold for all $y / a$, they hold for all $y$ because $M$ is given to be a subspace. Therefore, multiplying by $a^{-1} 17.2 .4$ implies that what is needed is to choose $F(z)$ such that for all $x, y \in M$,

$$
f(x)+F(z) \leq \rho(x+z), f(y)-\rho(y-z) \leq F(z)
$$

and that if $F(z)$ can be chosen in this way, this will satisfy 17.2 .5 for all $x, y$ and the problem of extending $f$ will be solved. Hence it is necessary to choose $F(z)$ such that for all $x, y \in M$

$$
\begin{equation*}
f(y)-\rho(y-z) \leq F(z) \leq \rho(x+z)-f(x) \tag{17.2.6}
\end{equation*}
$$

Is there any such number between $f(y)-\rho(y-z)$ and $\rho(x+z)-f(x)$ for every pair $x, y \in$ $M$ ? This is where $f(x) \leq \rho(x)$ on $M$ and that $f$ is linear is used. For $x, y \in M$,

$$
\begin{gathered}
\rho(x+z)-f(x)-[f(y)-\rho(y-z)] \\
=\rho(x+z)+\rho(y-z)-(f(x)+f(y)) \\
\geq \rho(x+y)-f(x+y) \geq 0 .
\end{gathered}
$$

Therefore there exists a number between

$$
\sup \{f(y)-\rho(y-z): y \in M\}
$$

and

$$
\inf \{\rho(x+z)-f(x): x \in M\}
$$

Choose $F(z)$ to satisfy 17.2 .6 . This has proved the following lemma.
Lemma 17.2.4 Let $M$ be a subspace of $X$, a real linear space, and let $\rho$ be a gauge function on $X$. Suppose $f: M \rightarrow \mathbb{R}$ is linear, $z \notin M$, and $f(x) \leq \rho(x)$ for all $x \in M$. Then $f$ can be extended to $M \oplus \mathbb{R} z$ such that, if $F$ is the extended function, $F$ is linear and $F(x) \leq \rho(x)$ for all $x \in M \oplus \mathbb{R} z$.

With this lemma, the Hahn Banach theorem can be proved.
Theorem 17.2.5 (Hahn Banach theorem) Let $X$ be a real vector space, let $M$ be a subspace of $X$, let $f: M \rightarrow \mathbb{R}$ be linear, let $\rho$ be a gauge function on $X$, and suppose $f(x) \leq \rho(x)$ for all $x \in M$. Then there exists a linear function, $F: X \rightarrow \mathbb{R}$, such that
a.) $F(x)=f(x)$ for all $x \in M$
b.) $F(x) \leq \rho(x)$ for all $x \in X$.

Proof: Let $\mathscr{F}=\{(V, g): V \supseteq M, V$ is a subspace of $X, g: V \rightarrow \mathbb{R}$ is linear, $g(x)=f(x)$ for all $x \in M$, and $g(x) \leq \rho(x)$ for $x \in V\}$. Then $(M, f) \in \mathscr{F}$ so $\mathscr{F} \neq \emptyset$. Define a partial order by the following rule.

$$
(V, g) \leq(W, h)
$$

means

$$
V \subseteq W \text { and } h(x)=g(x) \text { if } x \in V
$$

By Theorem 17.2.2, there exists a maximal chain, $\mathscr{C} \subseteq \mathscr{F}$. Let $Y=\cup\{V:(V, g) \in \mathscr{C}\}$ and let $h: Y \rightarrow \mathbb{R}$ be defined by $h(x)=g(x)$ where $x \in V$ and $(V, g) \in \mathscr{C}$. This is well defined because if $x \in V_{1}$ and $V_{2}$ where $\left(V_{1}, g_{1}\right)$ and $\left(V_{2}, g_{2}\right)$ are both in the chain, then since $\mathscr{C}$ is a chain, the two element related. Therefore, $g_{1}(x)=g_{2}(x)$. Also $h$ is linear because if $a x+b y \in Y$, then $x \in V_{1}$ and $y \in V_{2}$ where $\left(V_{1}, g_{1}\right)$ and $\left(V_{2}, g_{2}\right)$ are elements of $\mathscr{C}$. Therefore, letting $V$ denote the larger of the two $V_{i}$, and $g$ be the function that goes with $V$, it follows $a x+b y \in V$ where $(V, g) \in \mathscr{C}$. Therefore,

$$
\begin{aligned}
h(a x+b y) & =g(a x+b y) \\
& =a g(x)+b g(y) \\
& =a h(x)+b h(y)
\end{aligned}
$$

Also, $h(x)=g(x) \leq \rho(x)$ for any $x \in Y$ because for such $x, x \in V$ where $(V, g) \in \mathscr{C}$.
Is $Y=X$ ? If not, there exists $z \in X \backslash Y$ and there exists an extension of $h$ to $Y \oplus \mathbb{R} z$ using Lemma 17.2.4. Letting $\bar{h}$ denote this extended function, contradicts the maximality of $\mathscr{C}$. Indeed, $\mathscr{C} \cup\{(Y \oplus \mathbb{R} z, \bar{h})\}$ would be a longer chain. This proves the Hahn Banach theorem.

This is the original version of the theorem. There is also a version of this theorem for complex vector spaces which is based on a trick.

### 17.2.3 The Complex Version Of The Hahn Banach Theorem

Corollary 17.2.6 (Hahn Banach) Let $M$ be a subspace of a complex normed linear space, $X$, and suppose $f: M \rightarrow \mathbb{C}$ is linear and satisfies $|f(x)| \leq K| | x| |$ for all $x \in M$. Then there exists a linear function, $F$, defined on all of $X$ such that $F(x)=f(x)$ for all $x \in M$ and $|F(x)| \leq K| | x \|$ for all $x$.

Proof: First note $f(x)=\operatorname{Re} f(x)+i \operatorname{Im} f(x)$ and so

$$
\operatorname{Re} f(i x)+i \operatorname{Im} f(i x)=f(i x)=i f(x)=i \operatorname{Re} f(x)-\operatorname{Im} f(x)
$$

Therefore, $\operatorname{Im} f(x)=-\operatorname{Re} f(i x)$, and

$$
f(x)=\operatorname{Re} f(x)-i \operatorname{Re} f(i x)
$$

This is important because it shows it is only necessary to consider $\operatorname{Re} f$ in understanding $f$. Now it happens that $\operatorname{Re} f$ is linear with respect to real scalars so the above version of the Hahn Banach theorem applies. This is shown next.

If $c$ is a real scalar

$$
\operatorname{Re} f(c x)-i \operatorname{Re} f(i c x)=c f(x)=c \operatorname{Re} f(x)-i c \operatorname{Re} f(i x)
$$

Thus $\operatorname{Re} f(c x)=c \operatorname{Re} f(x)$. Also,

$$
\begin{aligned}
\operatorname{Re} f(x+y)-i \operatorname{Re} f(i(x+y)) & =f(x+y) \\
& =f(x)+f(y)
\end{aligned}
$$

$$
=\operatorname{Re} f(x)-i \operatorname{Re} f(i x)+\operatorname{Re} f(y)-i \operatorname{Re} f(i y)
$$

Equating real parts, $\operatorname{Re} f(x+y)=\operatorname{Re} f(x)+\operatorname{Re} f(y)$. Thus $\operatorname{Re} f$ is linear with respect to real scalars as hoped.

Consider $X$ as a real vector space and let $\rho(x) \equiv K\|x\|$. Then for all $x \in M$,

$$
|\operatorname{Re} f(x)| \leq|f(x)| \leq K \| x| |=\rho(x)
$$

From Theorem 17.2.5, $\operatorname{Re} f$ may be extended to a function, $h$ which satisfies

$$
\begin{aligned}
h(a x+b y) & =a h(x)+b h(y) \text { if } a, b \in \mathbb{R} \\
h(x) & \leq K\|x\| \text { for all } x \in X .
\end{aligned}
$$

Actually, $|h(x)| \leq K\|x\|$. The reason for this is that $h(-x)=-h(x) \leq K\|-x\|=K\|x\|$ and therefore, $h(x) \geq-K\|x\|$. Let

$$
F(x) \equiv h(x)-i h(i x) .
$$

By arguments similar to the above, $F$ is linear.

$$
\begin{aligned}
F(i x) & =h(i x)-i h(-x) \\
& =\operatorname{ih}(x)+h(i x) \\
& =i(h(x)-i h(i x))=i F(x)
\end{aligned}
$$

If $c$ is a real scalar,

$$
\begin{aligned}
F(c x) & =h(c x)-i h(i c x) \\
& =\operatorname{ch}(x)-\operatorname{cih}(i x)=c F(x)
\end{aligned}
$$

Now

$$
\begin{aligned}
F(x+y) & =h(x+y)-i h(i(x+y)) \\
& =h(x)+h(y)-i h(i x)-i h(i y) \\
& =F(x)+F(y)
\end{aligned}
$$

Thus

$$
\begin{aligned}
F((a+i b) x) & =F(a x)+F(i b x) \\
& =a F(x)+i b F(x) \\
& =(a+i b) F(x) .
\end{aligned}
$$

This shows $F$ is linear as claimed.
Now $w F(x)=|F(x)|$ for some $|w|=1$. Therefore

$$
\begin{aligned}
|F(x)| & =w F(x)=h(w x)-\overbrace{i h(i w x)}^{\text {must equal zero }}=h(w x) \\
& =|h(w x)| \leq K\|w x\|=K\|x\| .
\end{aligned}
$$

This proves the corollary.

### 17.2.4 The Dual Space And Adjoint Operators

Definition 17.2.7 Let $X$ be a Banach space. Denote by $X^{\prime}$ the space of continuous linear functions which map $X$ to the field of scalars. Thus $X^{\prime}=\mathscr{L}(X, \mathbb{F})$. By Theorem 17.1.7 on Page 438, $X^{\prime}$ is a Banach space. Remember with the norm defined on $\mathscr{L}(X, \mathbb{F})$,

$$
\|f\|=\sup \{|f(x)|:\|x\| \leq 1\}
$$

$X^{\prime}$ is called the dual space.
Definition 17.2.8 Let $X$ and $Y$ be Banach spaces and suppose $L \in \mathscr{L}(X, Y)$. Then define the adjoint map in $\mathscr{L}\left(Y^{\prime}, X^{\prime}\right)$, denoted by $L^{*}$, by

$$
L^{*} y^{*}(x) \equiv y^{*}(L x)
$$

for all $y^{*} \in Y^{\prime}$.
The following diagram is a good one to help remember this definition.

This is a generalization of the adjoint of a linear transformation on an inner product space. Recall

$$
(A x, y)=\left(x, A^{*} y\right)
$$

What is being done here is to generalize this algebraic concept to arbitrary Banach spaces. There are some issues which need to be discussed relative to the above definition. First of all, it must be shown that $L^{*} y^{*} \in X^{\prime}$. Also, it will be useful to have the following lemma which is a useful application of the Hahn Banach theorem.

Lemma 17.2.9 Let $X$ be a normed linear space and let $x \in X \backslash V$ where $V$ is a closed subspace of $X$. Then there exists $x^{*} \in X^{\prime}$ such that $x^{*}(x)=\|x\|, x^{*}(V)=\{0\}$, and

$$
\left\|x^{*}\right\| \leq \frac{1}{\operatorname{dist}(x, V)}
$$

In the case that $V=\{0\},\left\|x^{*}\right\|=1$.
Proof: Let $f: \mathbb{F} x+V \rightarrow \mathbb{F}$ be defined by $f(\alpha x+v)=\alpha\|x\|$. First it is necessary to show $f$ is well defined and continuous. If $\alpha_{1} x+v_{1}=\alpha_{2} x+v_{2}$ then if $\alpha_{1} \neq \alpha_{2}$, then $x \in V$ which is assumed not to happen so $f$ is well defined. It remains to show $f$ is continuous. Suppose then that $\alpha_{n} x+v_{n} \rightarrow 0$. It is necessary to show $\alpha_{n} \rightarrow 0$. If this does not happen, then there exists a subsequence, still denoted by $\alpha_{n}$ such that $\left|\alpha_{n}\right| \geq \delta>0$. Then $x+\left(1 / \alpha_{n}\right) v_{n} \rightarrow 0$ contradicting the assumption that $x \notin V$ and $V$ is a closed subspace. Hence $f$ is continuous on $\mathbb{F} x+V$. Being a little more careful,

$$
\|f\|=\sup _{\|\alpha x+\nu\| \leq 1}|f(\alpha x+v)|=\sup _{|\alpha|\|x+(v / \alpha)\| \leq 1}|\alpha|\|x\|=\frac{1}{\operatorname{dist}(x, V)}\|x\|
$$

By the Hahn Banach theorem, there exists $x^{*} \in X^{\prime}$ such that $x^{*}=f$ on $\mathbb{F} x+V$. Thus $x^{*}(x)=$ $\|x\|$ and also

$$
\left\|x^{*}\right\| \leq\|f\|=\frac{1}{\operatorname{dist}(x, V)}
$$

In case $V=\{0\}$, the result follows from the above or alternatively,

$$
\|f\| \equiv \sup _{\|\alpha x\| \leq 1}|f(\alpha x)|=\sup _{|\alpha| \leq 1 /\|x\|}|\alpha|\|x\|=1
$$

and so, in this case, $\left\|x^{*}\right\| \leq\|f\|=1$. Since $x^{*}(x)=\|x\|$ it follows

$$
\left\|x^{*}\right\| \geq\left|x^{*}\left(\frac{x}{\|x\|}\right)\right|=\frac{\|x\|}{\|x\|}=1
$$

Thus $\left\|x^{*}\right\|=1$ and this proves the lemma.
Theorem 17.2.10 Let $L \in \mathscr{L}(X, Y)$ where $X$ and $Y$ are Banach spaces. Then
a.) $L^{*} \in \mathscr{L}\left(Y^{\prime}, X^{\prime}\right)$ as claimed and $\left\|L^{*}\right\|=\|L\|$.
b.) If $L$ maps one to one onto a closed subspace of $Y$, then $L^{*}$ is onto.
c.) If $L$ maps onto a dense subset of $Y$, then $L^{*}$ is one to one.

Proof: It is routine to verify $L^{*} y^{*}$ and $L^{*}$ are both linear. This follows immediately from the definition. As usual, the interesting thing concerns continuity.

$$
\left\|L^{*} y^{*}\right\|=\sup _{\|x\| \leq 1}\left|L^{*} y^{*}(x)\right|=\sup _{\|x\| \leq 1}\left|y^{*}(L x)\right| \leq\left\|y^{*}\right\|\|L\| .
$$

Thus $L^{*}$ is continuous as claimed and $\left\|L^{*}\right\| \leq\|L\|$.
By Lemma 17.2.9, there exists $y_{x}^{*} \in Y^{\prime}$ such that $\left\|y_{x}^{*}\right\|=1$ and $y_{x}^{*}(L x)=\|L x\|$.Therefore,

$$
\begin{aligned}
\left\|L^{*}\right\| & =\sup _{\left\|y^{*}\right\| \leq 1}\left\|L^{*} y^{*}\right\|=\sup _{\left\|y^{*}\right\| \leq 1\|x\| \leq 1} \sup \left|L^{*} y^{*}(x)\right| \\
& =\sup _{\left\|y^{*}\right\| \leq 1\|x\| \mid \leq 1} \sup \left|y^{*}(L x)\right|=\sup _{\|x\| \leq 1\left\|y^{*}\right\| \leq 1} \sup \left|y^{*}(L x)\right| \\
& \geq \sup _{\|x\| \leq 1}\left|y_{x}^{*}(L x)\right|=\sup _{\|x\| \leq 1}\|L x\|=\|L\|
\end{aligned}
$$

showing that $\left\|L^{*}\right\| \geq\|L\|$ and this shows part a.).
If $L$ is one to one and onto a closed subset of $Y$, then $L(X)$ being a closed subspace of a Banach space, is itself a Banach space and so the open mapping theorem implies $L^{-1}: L(X) \rightarrow X$ is continuous. Hence

$$
\|x\|=\left\|L^{-1} L x\right\| \leq\left\|L^{-1}\right\|\|L x\|
$$

Now let $x^{*} \in X^{\prime}$ be given. Define $f \in \mathscr{L}(L(X), \mathbb{C})$ by $f(L x)=x^{*}(x)$. The function, $f$ is well defined because if $L x_{1}=L x_{2}$, then since $L$ is one to one, it follows $x_{1}=x_{2}$ and so
$f\left(L\left(x_{1}\right)\right)=x^{*}\left(x_{1}\right)=x^{*}\left(x_{2}\right)=f\left(L\left(x_{1}\right)\right)$. Also, $f$ is linear because

$$
\begin{aligned}
f\left(a L\left(x_{1}\right)+b L\left(x_{2}\right)\right) & =f\left(L\left(a x_{1}+b x_{2}\right)\right) \\
& \equiv x^{*}\left(a x_{1}+b x_{2}\right) \\
& =a x^{*}\left(x_{1}\right)+b x^{*}\left(x_{2}\right) \\
& =a f\left(L\left(x_{1}\right)\right)+b f\left(L\left(x_{2}\right)\right) .
\end{aligned}
$$

In addition to this,

$$
|f(L x)|=\left|x^{*}(x)\right| \leq\left\|x^{*}\right\|\|x\| \leq\left\|x^{*}\right\|\left\|L^{-1}\right\|\|L x\|
$$

and so the norm of $f$ on $L(X)$ is no larger than $\left\|x^{*}\right\|\left\|L^{-1}\right\|$. By the Hahn Banach theorem, there exists an extension of $f$ to an element $y^{*} \in Y^{\prime}$ such that $\left\|y^{*}\right\| \leq\left\|x^{*}\right\|\left\|L^{-1}\right\|$. Then

$$
L^{*} y^{*}(x)=y^{*}(L x)=f(L x)=x^{*}(x)
$$

so $L^{*} y^{*}=x^{*}$ because this holds for all $x$. Since $x^{*}$ was arbitrary, this shows $L^{*}$ is onto and proves b.).

Consider the last assertion. Suppose $L^{*} y^{*}=0$. Is $y^{*}=0$ ? In other words is $y^{*}(y)=0$ for all $y \in Y$ ? Pick $y \in Y$. Since $L(X)$ is dense in $Y$, there exists a sequence, $\left\{L x_{n}\right\}$ such that $L x_{n} \rightarrow y$. But then by continuity of $y^{*}, y^{*}(y)=\lim _{n \rightarrow \infty} y^{*}\left(L x_{n}\right)=\lim _{n \rightarrow \infty} L^{*} y^{*}\left(x_{n}\right)=0$. Since $y^{*}(y)=0$ for all $y$, this implies $y^{*}=0$ and so $L^{*}$ is one to one.

Corollary 17.2.11 Suppose $X$ and $Y$ are Banach spaces, $L \in \mathscr{L}(X, Y)$, and $L$ is one to one and onto. Then $L^{*}$ is also one to one and onto.

There exists a natural mapping, called the James map from a normed linear space, $X$, to the dual of the dual space which is described in the following definition.

Definition 17.2.12 Define $J: X \rightarrow X^{\prime \prime}$ by $J(x)\left(x^{*}\right)=x^{*}(x)$.
Theorem 17.2.13 The map, J, has the following properties.
a.) $J$ is one to one and linear.
b.) $\|J x\|=\|x\|$ and $\|J\|=1$.
c.) $J(X)$ is a closed subspace of $X^{\prime \prime}$ if $X$ is complete.

Also if $x^{*} \in X^{\prime}$,

$$
\left\|x^{*}\right\|=\sup \left\{\left|x^{* *}\left(x^{*}\right)\right|:\left\|x^{* *}\right\| \leq 1, x^{* *} \in X^{\prime \prime}\right\} .
$$

Proof:

$$
\begin{aligned}
J(a x+b y)\left(x^{*}\right) & \equiv x^{*}(a x+b y) \\
& =a x^{*}(x)+b x^{*}(y) \\
& =(a J(x)+b J(y))\left(x^{*}\right)
\end{aligned}
$$

Since this holds for all $x^{*} \in X^{\prime}$, it follows that

$$
J(a x+b y)=a J(x)+b J(y)
$$

and so $J$ is linear. If $J x=0$, then by Lemma 17.2.9 there exists $x^{*}$ such that $x^{*}(x)=\|x\|$ and $\left\|x^{*}\right\|=1$. Then

$$
0=J(x)\left(x^{*}\right)=x^{*}(x)=\|x\| .
$$

This shows a.).
To show b.), let $x \in X$ and use Lemma 17.2.9 to obtain $x^{*} \in X^{\prime}$ such that $x^{*}(x)=\|x\|$ with $\left\|x^{*}\right\|=1$. Then

$$
\begin{aligned}
\|x\| & \geq \sup \left\{\left|y^{*}(x)\right|:\left\|y^{*}\right\| \leq 1\right\} \\
& =\sup \left\{\left|J(x)\left(y^{*}\right)\right|:\left\|y^{*}\right\| \leq 1\right\}=\|J x\| \\
& \geq\left|J(x)\left(x^{*}\right)\right|=\left|x^{*}(x)\right|=\|x\|
\end{aligned}
$$

Therefore, $\|J x\|=\|x\|$ as claimed. Therefore,

$$
\|J\|=\sup \{\|J x\|:\|x\| \leq 1\}=\sup \{\|x\|:\|x\| \leq 1\}=1
$$

This shows b.).
To verify c.), use b.). If $J x_{n} \rightarrow y^{* *} \in X^{\prime \prime}$ then by b.), $x_{n}$ is a Cauchy sequence converging to some $x \in X$ because

$$
\left\|x_{n}-x_{m}\right\|=\left\|J x_{n}-J x_{m}\right\|
$$

and $\left\{J x_{n}\right\}$ is a Cauchy sequence. Then $J x=\lim _{n \rightarrow \infty} J x_{n}=y^{* *}$.
Finally, to show the assertion about the norm of $x^{*}$, use what was just shown applied to the James map from $X^{\prime}$ to $X^{\prime \prime \prime}$ still referred to as $J$.

$$
\begin{gathered}
\left\|x^{*}\right\|=\sup \left\{\left|x^{*}(x)\right|:\|x\| \leq 1\right\}=\sup \left\{\left|J(x)\left(x^{*}\right)\right|:\|J x\| \leq 1\right\} \\
\leq \sup \left\{\left|x^{* *}\left(x^{*}\right)\right|: \mid\left\|x^{* *}\right\| \leq 1\right\}=\sup \left\{\left|J\left(x^{*}\right)\left(x^{* *}\right)\right|:\left\|x^{* *}\right\| \leq 1\right\} \\
\equiv\left\|J x^{*}\right\|=\left\|x^{*}\right\| .
\end{gathered}
$$

This proves the theorem.
Definition 17.2.14 When J maps $X$ onto $X^{\prime \prime}, X$ is called reflexive.
It happens the $L^{p}$ spaces are reflexive whenever $p>1$. This is shown later.

### 17.3 Uniform Convexity Of $L^{p}$

These terms refer roughly to how round the unit ball is. Here is the definition.
Definition 17.3.1 A Banach space is uniformly convex if whenever $\left\|x_{n}\right\|,\left\|y_{n}\right\| \leq 1$ and $\left\|x_{n}+y_{n}\right\| \rightarrow 2$, it follows that $\left\|x_{n}-y_{n}\right\| \rightarrow 0$.

You can show that uniform convexity implies strict convexity. There are various other things which can also be shown. See the exercises for some of these. In this section, it will be shown that the $L^{p}$ spaces are examples of uniformly convex spaces. This involves some inequalities known as Clarkson's inequalities. Before presenting these, here are the backwards Holder inequality and the backwards Minkowski inequality.

Lemma 17.3.2 Let $0<p<1$ and let $f, g$ be measurable functions. Also

$$
\int_{\Omega}|g|^{p /(p-1)} d \mu<\infty, \int_{\Omega}|f|^{p} d \mu<\infty
$$

Then the following backwards Holder inequality holds.

$$
\int_{\Omega}|f g| d \mu \geq\left(\int_{\Omega}|f|^{p} d \mu\right)^{1 / p}\left(\int_{\Omega}|g|^{p /(p-1)} d \mu\right)^{(p-1) / p}
$$

Proof: If $\int|f g| d \mu=\infty$, there is nothing to prove. Hence assume this is finite. Then

$$
\int|f|^{p} d \mu=\int|g|^{-p}|f g|^{p} d \mu
$$

This makes sense because, due to the hypothesis on $g$ it must be the case that $g$ equals 0 only on a set of measure zero, since $p /(p-1)<0$. Then

$$
\begin{aligned}
\int|f|^{p} d \mu & \leq\left(\int|f g| d \mu\right)^{p}\left(\int\left(\frac{1}{|g|^{p}}\right)^{1 /(1-p)} d \mu\right)^{1-p} \\
& =\left(\int|f g| d \mu\right)^{p}\left(\int|g|^{p / p-1} d \mu\right)^{1-p}
\end{aligned}
$$

Now divide and then take the $p^{t h}$ root.
Here is the backwards Minkowski inequality.
Corollary 17.3.3 Let $0<p<1$ and suppose $\int|h|^{p} d \mu<\infty$ for $h=f, g$. Then

$$
\left(\int(|f|+|g|)^{p} d \mu\right)^{1 / p} \geq\left(\int|f|^{p} d \mu\right)^{1 / p}+\left(\int|g|^{p} d \mu\right)^{1 / p}
$$

Proof: If $\int(|f|+|g|)^{p} d \mu=0$ then there is nothing to prove so assume this is not zero.

$$
\int(|f|+|g|)^{p} d \mu=\int(|f|+|g|)^{p-1}(|f|+|g|) d \mu
$$

$(|f|+|g|)^{p} \leq|f|^{p}+|g|^{p}$ and so

$$
\int\left((|f|+|g|)^{p-1}\right)^{p / p-1} d \mu<\infty
$$

Hence the backward Holder inequality applies and it follows that

$$
\begin{aligned}
& \int(|f|+|g|)^{p} d \mu=\int(|f|+|g|)^{p-1}|f| d \mu+\int(|f|+|g|)^{p-1}|g| d \mu \\
\geq & \left(\int\left((|f|+|g|)^{p-1}\right)^{p / p-1}\right)^{(p-1) / p}\left[\left(\int|f|^{p} d \mu\right)^{1 / p}+\left(\int|g|^{p} d \mu\right)^{1 / p}\right] \\
= & \left(\int(|f|+|g|)^{p}\right)^{(p-1) / p}\left[\left(\int|f|^{p} d \mu\right)^{1 / p}+\left(\int|g|^{p} d \mu\right)^{1 / p}\right]
\end{aligned}
$$

and so, dividing gives the desired inequality.
Consider the easy Clarkson inequalities.

Lemma 17.3.4 For any $p \geq 2$ the following inequality holds for any $t \in[0,1]$,

$$
\left|\frac{1+t}{2}\right|^{p}+\left|\frac{1-t}{2}\right|^{p} \leq \frac{1}{2}\left(|t|^{p}+1\right)
$$

Proof: It is clear that, since $p \geq 2$, the inequality holds for $t=0$ and $t=1$.Thus it suffices to consider only $t \in(0,1)$. Let $x=1 / t$. Then, dividing by $1 / t^{p}$, the inequality holds if and only if

$$
\left(\frac{x+1}{2}\right)^{p}+\left(\frac{x-1}{2}\right)^{p} \leq \frac{1}{2}\left(1+x^{p}\right)
$$

for all $x \geq 1$. Let

$$
f(x)=\frac{1}{2}\left(1+x^{p}\right)-\left(\left(\frac{x+1}{2}\right)^{p}+\left(\frac{x-1}{2}\right)^{p}\right)
$$

Then $f(1)=0$ and

$$
f^{\prime}(x)=\frac{p}{2} x^{p-1}-\left(\frac{p}{2}\left(\frac{x+1}{2}\right)^{p-1}+\frac{p}{2}\left(\frac{x-1}{2}\right)^{p-1}\right)
$$

Since $p-1 \geq 1$, by convexity of $f(x)=x^{p-1}$,

$$
f^{\prime}(x) \geq \frac{p}{2} x^{p-1}-p\left(\frac{\frac{x+1}{2}+\frac{x-1}{2}}{2}\right)^{p-1}=\frac{p}{2} x^{p-1}-p\left(\frac{x}{2}\right)^{p-1} \geq 0
$$

Hence $f(x) \geq 0$ for all $x \geq 1$.
Corollary 17.3.5 If $z, w \in \mathbb{C}$ and $p \geq 2$, then

$$
\begin{equation*}
\left|\frac{z+w}{2}\right|^{p}+\left|\frac{z-w}{2}\right|^{p} \leq \frac{1}{2}\left(|z|^{p}+|w|^{p}\right) \tag{17.3.7}
\end{equation*}
$$

Proof: One of $|w|,|z|$ is larger. Say $|z| \geq|w|$. Then dividing both sides of the proposed inequality by $|z|^{p}$ it suffices to verify that for all complex $t$ having $|t| \leq 1$,

$$
\left|\frac{1+t}{2}\right|^{p}+\left|\frac{1-t}{2}\right|^{p} \leq \frac{1}{2}\left(|t|^{p}+1\right)
$$

Say $t=r e^{i \theta}$ where $r \leq 1$.Then consider the expression

$$
\left|\frac{1+r e^{i \theta}}{2}\right|^{p}+\left|\frac{1-r e^{i \theta}}{2}\right|^{p}
$$

It is $2^{-p}$ times

$$
\begin{aligned}
& \left((1+r \cos \theta)^{2}+r^{2} \sin ^{2}(\theta)\right)^{p / 2}+\left((1-r \cos \theta)^{2}+r^{2} \sin ^{2}(\theta)\right)^{p / 2} \\
= & \left(1+r^{2}+2 r \cos \theta\right)^{p / 2}+\left(1+r^{2}-2 r \cos \theta\right)^{p / 2}
\end{aligned}
$$

a continuous periodic function for $\theta \in \mathbb{R}$ which achieves its maximum value when $\theta=0$. This follows from the first derivative test from calculus. Therefore, for $|t| \leq 1$,

$$
\left|\frac{1+t}{2}\right|^{p}+\left|\frac{1-t}{2}\right|^{p} \leq\left|\frac{1+|t|}{2}\right|^{p}+\left|\frac{1-|t|}{2}\right|^{p} \leq \frac{1}{2}\left(1+|t|^{p}\right)
$$

by the above lemma.
With this corollary, here is the easy Clarkson inequality.
Theorem 17.3.6 Let $p \geq 2$. Then

$$
\left\|\frac{f+g}{2}\right\|_{L^{p}}^{p}+\left\|\frac{f-g}{2}\right\|_{L^{p}}^{p} \leq \frac{1}{2}\left(\|f\|_{L^{p}}^{p}+\|g\|_{L^{p}}^{p}\right)
$$

Proof: This follows right away from the above corollary.

$$
\int_{\Omega}\left|\frac{f+g}{2}\right|^{p} d \mu+\int_{\Omega}\left|\frac{f-g}{2}\right|^{p} d \mu \leq \frac{1}{2} \int_{\Omega}\left(|f|^{p}+|g|^{p}\right) d \mu
$$

Now it remains to consider the hard Clarkson inequalities. These pertain to $p<2$. First is the following elementary inequality.

Lemma 17.3.7 For $1<p<2$, the following inequality holds for all $t \in[0,1]$.

$$
\left|\frac{1+t}{2}\right|^{q}+\left|\frac{1-t}{2}\right|^{q} \leq\left(\frac{1}{2}+\frac{1}{2}|t|^{p}\right)^{q / p}
$$

where here $1 / p+1 / q=1$ so $q>2$.
Proof: First note that if $t=0$ or 1 , the inequality holds. Next observe that the map $s \rightarrow \frac{1-s}{1+s}$ maps $(0,1)$ onto $(0,1)$. Replace $t$ with $(1-s) /(1+s)$. Then you get

$$
\left|\frac{1}{s+1}\right|^{q}+\left|\frac{s}{s+1}\right|^{q} \leq\left(\frac{1}{2}+\frac{1}{2}\left|\frac{1-s}{s+1}\right|^{p}\right)^{q / p}
$$

Multiplying both sides by $(1+s)^{q}$, this is equivalent to showing that for all $s \in(0,1)$,

$$
\begin{aligned}
1+s^{q} & \leq\left((1+s)^{p}\right)^{q / p}\left(\frac{1}{2}+\frac{1}{2}\left|\frac{1-s}{s+1}\right|^{p}\right)^{q / p} \\
& =\left(\frac{1}{2}\right)^{q / p}\left((1+s)^{p}+(1-s)^{p}\right)^{q / p}
\end{aligned}
$$

This is the same as establishing

$$
\begin{equation*}
\frac{1}{2}\left((1+s)^{p}+(1-s)^{p}\right)-\left(1+s^{q}\right)^{p-1} \geq 0 \tag{17.3.8}
\end{equation*}
$$

where $p-1=p / q$ due to the definition of $q$ above.

$$
\binom{p}{l} \equiv \frac{p(p-1) \cdots(p-k+1)}{l!}, l \geq 1
$$

and $\binom{p}{0} \equiv 1$. What is the sign of $\binom{p}{l}$ ? Recall that $1<p<2$ so the sign is positive if $l=0, l=1, l=2$. What about $l=3$ ? $\binom{p}{3}=\frac{p(p-1)(p-2)}{3!}$ so this is negative. Then $\binom{p}{4}$ is positive. Thus these alternate between positive and negative with $\binom{p}{2 k}>0$ for all $k$. What about $\binom{p-1}{k}$ ? When $k=0$ it is positive. When $k=1$ it is also positive. When $k=2$ it equals $\frac{(p-1)(p-2)}{2!}<0$. Then when $k=3,\binom{p-1}{3}>0$. Thus $\binom{p-1}{k}$ is positive when $k$ is odd and is negative when $k$ is even.

Now return to 17.3.8. The left side equals

$$
\frac{1}{2}\left(\sum_{k=0}^{\infty}\binom{p}{k} s^{k}+\sum_{k=0}^{\infty}\binom{p}{k}(-s)^{k}\right)-\sum_{k=0}^{\infty}\binom{p-1}{k} s^{q k}
$$

The first term equals 0 . Then this reduces to

$$
\sum_{k=1}^{\infty}\binom{p}{2 k} s^{2 k}-\binom{p-1}{2 k} s^{q 2 k}-\binom{p-1}{2 k-1} s^{q(2 k-1)}
$$

From the above observation about the binomial coefficients, the above is larger than

$$
\sum_{k=1}^{\infty}\binom{p}{2 k} s^{2 k}-\binom{p-1}{2 k-1} s^{q(2 k-1)}
$$

It remains to show the $k^{t h}$ term in the above sum is nonnegative. Now $q(2 k-1)>2 k$ for all $k \geq 1$ because $q>2$. Then since $0<s<1$

$$
\binom{p}{2 k} s^{2 k}-\binom{p-1}{2 k-1} s^{q(2 k-1)} \geq s^{2 k}\left(\binom{p}{2 k}-\binom{p-1}{2 k-1}\right)
$$

However, this is nonnegative because it equals

$$
\begin{aligned}
& s^{2 k}(\frac{p(p-1) \cdots(p-2 k+1)}{(2 k)!}-\frac{\overbrace{(p-1)(p-2) \cdots(p-2 k+1)}}{>0}) \\
\geq & s^{2 k}\left(\frac{p(p-1)!}{(2 k)!}\right) \\
= & s^{2 k} \frac{(p-1)(p-2) \cdots(p-2 k+1)}{(2 k)!}(p-1)>0 .
\end{aligned}
$$

As before, this leads to the following corollary.

Corollary 17.3.8 Let $z, w \in \mathbb{C}$. Then for $p \in(1,2)$,

$$
\left|\frac{z+w}{2}\right|^{q}+\left|\frac{z-w}{2}\right|^{q} \leq\left(\frac{1}{2}|z|^{p}+\frac{1}{2}|w|^{p}\right)^{q / p}
$$

Proof: One of $|w|,|z|$ is larger. Say $|w| \geq|z|$. Then dividing by $|w|^{q}$, for $t=z / w$, showing the above inequality is equivalent to showing that for all $t \in \mathbb{C},|t| \leq 1$,

$$
\left|\frac{t+1}{2}\right|^{q}+\left|\frac{1-t}{2}\right|^{q} \leq\left(\frac{1}{2}|t|^{p}+\frac{1}{2}\right)^{q / p}
$$

Now $q>2$ and so by the same argument given in proving Corollary 17.3.5, for $t=r e^{i \theta}$, the left side of the above inequality is maximized when $\theta=0$. Hence, from Lemma 17.3.7,

$$
\begin{aligned}
\left|\frac{t+1}{2}\right|^{q}+ & \left|\frac{1-t}{2}\right|^{q} \leq\left|\frac{|t|+1}{2}\right|^{q}+\left|\frac{1-|t|}{2}\right|^{q} \\
& \leq\left(\frac{1}{2}|t|^{p}+\frac{1}{2}\right)^{q / p} .
\end{aligned}
$$

From this the hard Clarkson inequality follows. The two Clarkson inequalities are summarized in the following theorem.

Theorem 17.3.9 Let $2 \leq p$. Then

$$
\left\|\frac{f+g}{2}\right\|_{L^{p}}^{p}+\left\|\frac{f-g}{2}\right\|_{L^{p}}^{p} \leq \frac{1}{2}\left(\|f\|_{L^{p}}^{p}+\|g\|_{L^{p}}^{p}\right)
$$

Let $1<p<2$. Then for $1 / p+1 / q=1$,

$$
\left\|\frac{f+g}{2}\right\|_{L^{p}}^{q}+\left\|\frac{f-g}{2}\right\|_{L^{p}}^{q} \leq\left(\frac{1}{2}\|f\|_{L^{p}}^{p}+\frac{1}{2}\|g\|_{L^{p}}^{p}\right)^{q / p}
$$

Proof: The first was established above.

$$
\begin{gathered}
\left\|\frac{f+g}{2}\right\|_{L^{p}}^{q}+\left\|\frac{f-g}{2}\right\|_{L^{p}}^{q} \leq \\
\left(\int_{\Omega}\left|\frac{f+g}{2}\right|^{p} d \mu\right)^{q / p}+\left(\int_{\Omega}\left|\frac{f-g}{2}\right|^{p} d \mu\right)^{q / p} \\
=\left(\int_{\Omega}\left(\left|\frac{f+g}{2}\right|^{q}\right)^{p / q} d \mu\right)^{q / p}+\left(\int_{\Omega}\left(\left|\frac{f-g}{2}\right|^{q}\right)^{p / q} d \mu\right)^{q / p}
\end{gathered}
$$

Now $p / q<1$ and so the backwards Minkowski inequality applies. Thus

$$
\leq\left(\int_{\Omega}\left(\left|\frac{f+g}{2}\right|^{q}+\left|\frac{f-g}{2}\right|^{q}\right)^{p / q} d \mu\right)^{q / p}
$$

From Corollary 17.3.8,

$$
\begin{aligned}
& \leq\left(\int_{\Omega}\left(\left(\frac{1}{2}|f|^{p}+\frac{1}{2}|g|^{p}\right)^{q / p}\right)^{p / q} d \mu\right)^{q / p} \\
& =\left(\int_{\Omega}\left(\frac{1}{2}|f|^{p}+\frac{1}{2}|g|^{p}\right) d \mu\right)^{q / p}=\left(\frac{1}{2}\|f\|_{L^{p}}^{p}+\frac{1}{2}\|g\|_{L^{p}}^{p}\right)^{q / p}
\end{aligned}
$$

Now with these Clarkson inequalities, it is not hard to show that all the $L^{p}$ spaces are uniformly convex.

Theorem 17.3.10 The $L^{p}$ spaces are uniformly convex.
Proof: First suppose $p \geq 2$. Suppose $\left\|f_{n}\right\|_{L^{p}},\left\|g_{n}\right\|_{L^{p}} \leq 1$ and $\left\|\frac{f_{n}+g_{n}}{2}\right\|_{L^{p}} \rightarrow 1$. Then from the first Clarkson inequality,

$$
\left\|\frac{f_{n}+g_{n}}{2}\right\|_{L^{p}}^{p}+\left\|\frac{f_{n}-g_{n}}{2}\right\|_{L^{p}}^{p} \leq \frac{1}{2}\left(\left\|f_{n}\right\|_{L^{p}}^{p}+\left\|g_{n}\right\|_{L^{p}}^{p}\right) \leq 1
$$

and so $\left\|f_{n}-g_{n}\right\|_{L^{p}} \rightarrow 0$.
Next suppose $1<p<2$ and $\left\|\frac{f_{n}+g_{n}}{2}\right\|_{L^{p}} \rightarrow 1$. Then from the second Clarkson inequality

$$
\left\|\frac{f_{n}+g_{n}}{2}\right\|_{L^{p}}^{q}+\left\|\frac{f_{n}-g_{n}}{2}\right\|_{L^{p}}^{q} \leq\left(\frac{1}{2}\left\|f_{n}\right\|_{L^{p}}^{p}+\frac{1}{2}\left\|g_{n}\right\|_{L^{p}}^{p}\right)^{q / p} \leq 1
$$

which shows that $\left\|f_{n}-g_{n}\right\|_{L^{p}} \rightarrow 0$.

### 17.4 Closed Subspaces

Theorem 17.4.1 Let $X$ be a Banach space and let $V=\operatorname{span}\left(x_{1}, \cdots, x_{n}\right)$. Then $V$ is a closed subspace of $X$.

Proof: Without loss of generality, it can be assumed $\left\{x_{1}, \cdots, x_{n}\right\}$ is linearly independent. Otherwise, delete those vectors which are in the span of the others till a linearly independent set is obtained. Let

$$
\begin{equation*}
x=\lim _{p \rightarrow \infty} \sum_{k=1}^{n} c_{k}^{p} x_{k} \in \bar{V} \tag{17.4.9}
\end{equation*}
$$

First suppose $\mathbf{c}^{p} \equiv\left(c_{1}^{p}, \cdots, c_{n}^{p}\right)$ is not bounded in $\mathbb{F}^{n}$. Then $\mathbf{d}^{p} \equiv \mathbf{c}^{p} /\left|\mathbf{c}^{p}\right|_{\mathbb{F}^{n}}$ is a unit vector in $\mathbb{F}^{n}$ and so there exists a subsequence, still denoted by $\mathbf{d}^{p}$ which converges to $\mathbf{d}$ where $|\mathbf{d}|=1$. Then

$$
\mathbf{0}=\lim _{p \rightarrow \infty} \frac{x}{\left\|\mathbf{c}^{p}\right\|}=\lim _{p \rightarrow \infty} \sum_{k=1}^{n} d_{k}^{p} x_{k}=\sum_{k=1}^{n} d_{k} x_{k}
$$

where $\sum_{k}\left|d_{k}\right|^{2}=1$ in contradiction to the linear independence of the $\left\{x_{1}, \cdots, x_{n}\right\}$. Hence it must be the case that $\mathbf{c}^{p}$ is bounded in $\mathbb{F}^{n}$. Then taking a subsequence, still denoted as $p$, it can be assumed $\mathbf{c}^{p} \rightarrow \mathbf{c}$ and then in 17.4.9 it follows

$$
x=\sum_{k=1}^{n} c_{k} x_{k} \in \operatorname{span}\left(x_{1}, \cdots, x_{n}\right)
$$

Proposition 17.4.2 Let $E$ be a separable Banach space. Then there exists an increasing sequence of subspaces, $\left\{F_{n}\right\}$ such that $\operatorname{dim}\left(F_{n+1}\right)-\operatorname{dim}\left(F_{n}\right) \leq 1$ and equals 1 for all $n$ if the dimension of $E$ is infinite. Also $\cup_{n=1}^{\infty} F_{n}$ is dense in $E$. In the case where $E$ is infinite dimensional, $F_{n}=\operatorname{span}\left(e_{1}, \cdots, e_{n}\right)$ where for each $n$

$$
\begin{equation*}
\operatorname{dist}\left(e_{n+1}, F_{n}\right) \geq \frac{1}{2} \tag{17.4.10}
\end{equation*}
$$

and defining,

$$
\begin{gather*}
G_{k} \equiv \operatorname{span}\left(\left\{e_{j}: j \neq k\right\}\right) \\
\operatorname{dist}\left(e_{k}, G_{k}\right) \geq \frac{1}{4} \tag{17.4.11}
\end{gather*}
$$

Proof: Since $E$ is separable, so is $\partial B(0,1)$, the boundary of the unit ball. Let $\left\{w_{k}\right\}_{k=1}^{\infty}$ be a countable dense subset of $\partial B(0,1)$.

Let $e_{1}=w_{1}$. Let $F_{1}=\mathbb{F} e_{1}$. Suppose $F_{n}$ has been obtained and equals span $\left(e_{1}, \cdots, e_{n}\right)$ where $\left\{e_{1}, \cdots, e_{n}\right\}$ is independent, $\left\|e_{k}\right\|=1$, and

$$
\operatorname{dist}\left(e_{n}, \operatorname{span}\left(e_{1}, \cdots, e_{n-1}\right)\right) \geq \frac{1}{2}
$$

For each $n, F_{n}$ is closed by Theorem 17.4.1.
If $F_{n}$ contains $\left\{w_{k}\right\}_{k=1}^{\infty}$, let $F_{m}=F_{n}$ for all $m>n$. Otherwise, pick $w \in\left\{w_{k}\right\}$ to be the point of $\left\{w_{k}\right\}_{k=1}^{\infty}$ having the smallest subscript which is not contained in $F_{n}$. Then $w$ is at a positive distance, $\lambda$ from $F_{n}$ because $F_{n}$ is closed. Therefore, there exists $y \in F_{n}$ such that $\lambda \leq\|y-w\| \leq 2 \lambda$. Let $e_{n+1}=\frac{w-y}{\|w-y\|}$. It follows

$$
w=\|w-y\| e_{n+1}+y \in \operatorname{span}\left(e_{1}, \cdots, e_{n+1}\right) \equiv F_{n+1}
$$

Then if $x \in \operatorname{span}\left(e_{1}, \cdots, e_{n}\right)$,

$$
\begin{aligned}
\left\|e_{n+1}-x\right\| & =\left\|\frac{w-y}{\|w-y\|}-x\right\| \\
& =\left\|\frac{w-y}{\|w-y\|}-\frac{\|w-y\| x}{\|w-y\|}\right\| \\
& \geq \frac{1}{2 \lambda}\|w-y-\| w-y\|x\| \\
& \geq \frac{\lambda}{2 \lambda}=\frac{1}{2}
\end{aligned}
$$

This has shown the existence of an increasing sequence of subspaces, $\left\{F_{n}\right\}$ as described above. It remains to show the union of these subspaces is dense. First note that the union of these subspaces must contain the $\left\{w_{k}\right\}_{k=1}^{\infty}$ because if $w_{m}$ is missing, then it would contradict the construction at the $m^{\text {th }}$ step. That one should have been chosen. However, $\left\{w_{k}\right\}_{k=1}^{\infty}$ is dense in $\partial B(0,1)$. If $x \in E$ and $x \neq 0$, then $\frac{x}{\|x\|} \in \partial B(0,1)$ then there exists

$$
w_{m} \in\left\{w_{k}\right\}_{k=1}^{\infty} \subseteq \cup_{n=1}^{\infty} F_{n}
$$

such that $\left\|w_{m}-\frac{x}{\|x\|}\right\|<\frac{\varepsilon}{\|x\|}$. But then

$$
\left\|\|x\| w_{m}-x\right\|<\varepsilon
$$

and so $\|x\| w_{m}$ is a point of $\cup_{n=1}^{\infty} F_{n}$ which is within $\varepsilon$ of $x$. This proves $\cup_{n=1}^{\infty} F_{n}$ is dense as desired. 17.4.10 follows from the construction. It remains to verify 17.4.11.

Let $y \in G_{k}$. Thus for some $n$,

$$
y=\sum_{j=1}^{k-1} c_{j} e_{j}+\sum_{j=k+1}^{n} c_{j} e_{j}
$$

and I need to show $\left\|y-e_{k}\right\| \geq 1 / 4$. Without loss of generality, $c_{n} \neq 0$ and $n>k$. Suppose 17.4.11 does not hold for some such $y$ so that

$$
\begin{equation*}
\left\|e_{k}-\left(\sum_{j=1}^{k-1} c_{j} e_{j}+\sum_{j=k+1}^{n} c_{j} e_{j}\right)\right\|<\frac{1}{4} . \tag{17.4.12}
\end{equation*}
$$

Then from the construction,

$$
\begin{aligned}
\frac{1}{4} & >\left|c_{n}\right|\left\|e_{k}-\left(\sum_{j=1}^{k-1}\left(c_{j} / c_{n}\right) e_{j}+\sum_{j=k+1}^{n-1}\left(c_{j} / c_{n}\right) e_{j}+e_{n}\right)\right\| \\
& \geq\left|c_{n}\right| \frac{1}{2}
\end{aligned}
$$

and so $\left|c_{n}\right|<1 / 2$. Consider the left side of 17.4.12. By the construction

$$
\begin{gathered}
\left\|c_{n}\left(e_{k}-e_{n}\right)+\left(1-c_{n}\right) e_{k}-\left(\sum_{j=1}^{k-1} c_{j} e_{j}+\sum_{j=k+1}^{n-1} c_{j} e_{j}\right)\right\| \\
\geq\left|1-c_{n}\right|-\left|c_{n}\right|\left\|\left(e_{k}-e_{n}\right)-\left(\sum_{j=1}^{k-1}\left(c_{j} / c_{n}\right) e_{j}+\sum_{j=k+1}^{n-1}\left(c_{j} / c_{n}\right) e_{j}\right)\right\| \\
\geq\left|1-c_{n}\right|-\left|c_{n}\right| \frac{1}{2} \geq 1-\frac{3}{2}\left|c_{n}\right|>1-\frac{3}{2} \frac{1}{2}=\frac{1}{4}
\end{gathered}
$$

a contradiction. This proves the desired estimate.

### 17.5 Weak And Weak * Topologies

### 17.5.1 Basic Definitions

Let $X$ be a Banach space and let $X^{\prime}$ be its dual space. ${ }^{1}$ For $A^{\prime}$ a finite subset of $X^{\prime}$, denote by $\rho_{A^{\prime}}$ the function defined on $X$

$$
\begin{equation*}
\rho_{A^{\prime}}(x) \equiv \max _{x^{*} \in A^{\prime}}\left|x^{*}(x)\right| \tag{17.5.13}
\end{equation*}
$$

and also let $B_{A^{\prime}}(x, r)$ be defined by

$$
\begin{equation*}
B_{A^{\prime}}(x, r) \equiv\left\{y \in X: \rho_{A^{\prime}}(y-x)<r\right\} \tag{17.5.14}
\end{equation*}
$$

Then certain things are obvious. First of all, if $a \in \mathbb{F}$ and $x, y \in X$,

$$
\begin{aligned}
\rho_{A^{\prime}}(x+y) & \leq \rho_{A^{\prime}}(x)+\rho_{A^{\prime}}(y) \\
\rho_{A^{\prime}}(a x) & =|a| \rho_{A^{\prime}}(x)
\end{aligned}
$$

Similarly, letting $A$ be a finite subset of $X$, denote by $\rho_{A}$ the function defined on $X^{\prime}$

$$
\begin{equation*}
\rho_{A}\left(x^{*}\right) \equiv \max _{x \in A}\left|x^{*}(x)\right| \tag{17.5.15}
\end{equation*}
$$

and let $B_{A}\left(x^{*}, r\right)$ be defined by

$$
\begin{equation*}
B_{A}\left(x^{*}, r\right) \equiv\left\{y^{*} \in X^{\prime}: \rho_{A}\left(y^{*}-x^{*}\right)<r\right\} . \tag{17.5.16}
\end{equation*}
$$

It is also clear that

$$
\begin{aligned}
\rho_{A}\left(x^{*}+y^{*}\right) & \leq \rho\left(x^{*}\right)+\rho_{A}\left(y^{*}\right) \\
\rho_{A}\left(a x^{*}\right) & =|a| \rho_{A}\left(x^{*}\right)
\end{aligned}
$$

Lemma 17.5.1 The sets, $B_{A^{\prime}}(x, r)$ where $A^{\prime}$ is a finite subset of $X^{\prime}$ and $x \in X$ form a basis for a topology on $X$ known as the weak topology. The sets $B_{A}\left(x^{*}, r\right)$ where $A$ is a finite subset of $X$ and $x^{*} \in X^{\prime}$ form a basis for a topology on $X^{\prime}$ known as the weak $*$ topology.

Proof: The two assertions are very similar. I will verify the one for the weak topology. The union of these sets, $B_{A^{\prime}}(x, r)$ for $x \in X$ and $r>0$ is all of $X$. Now suppose $z$ is contained in the intersection of two of these sets. Say

$$
z \in B_{A^{\prime}}(x, r) \cap B_{A_{1}^{\prime}}\left(x_{1}, r_{1}\right)
$$

Then let $C^{\prime}=A^{\prime} \cup A_{1}^{\prime}$ and let

$$
0<\delta \leq \min \left(r-\rho_{A^{\prime}}(z-x), r_{1}-\rho_{A_{1}^{\prime}}\left(z-x_{1}\right)\right)
$$

[^16]Consider $y \in B_{C^{\prime}}(z, \boldsymbol{\delta})$. Then

$$
r-\rho_{A^{\prime}}(z-x) \geq \delta>\rho_{C^{\prime}}(y-z) \geq \rho_{A^{\prime}}(y-z)
$$

and so

$$
r>\rho_{A^{\prime}}(y-z)+\rho_{A^{\prime}}(z-x) \geq \rho_{A^{\prime}}(y-x)
$$

which shows $y \in B_{A^{\prime}}(x, r)$. Similar reasoning shows $y \in B_{A_{1}^{\prime}}\left(x_{1}, r_{1}\right)$ and so

$$
B_{C^{\prime}}(z, \boldsymbol{\delta}) \subseteq B_{A^{\prime}}(x, r) \cap B_{A_{1}^{\prime}}\left(x_{1}, r_{1}\right)
$$

Therefore, the weak topology consists of the union of all sets of the form $B_{A}(x, r)$.

### 17.5.2 Banach Alaoglu Theorem

Why does anyone care about these topologies? The short answer is that in the weak * topology, closed unit ball in $X^{\prime}$ is compact. This is not true in the normal topology. This wonderful result is the Banach Alaoglu theorem. First recall the notion of the product topology, and the Tychonoff theorem, Theorem 14.3.6 on Page 391 which are stated here for convenience.

Definition 17.5.2 Let I be a set and suppose for each $i \in I,\left(X_{i}, \tau_{i}\right)$ is a nonempty topological space. The Cartesian product of the $X_{i}$, denoted by $\prod_{i \in I} X_{i}$, consists of the set of all choice functions defined on I which select a single element of each $X_{i}$. Thus $f \in \prod_{i \in I} X_{i}$ means for every $i \in I, f(i) \in X_{i}$. The axiom of choice says $\prod_{i \in I} X_{i}$ is nonempty. Let

$$
P_{j}(A)=\prod_{i \in I} B_{i}
$$

where $B_{i}=X_{i}$ if $i \neq j$ and $B_{j}=A$. A subbasis for a topology on the product space consists of all sets $P_{j}(A)$ where $A \in \tau_{j}$. (These sets have an open set from the topology of $X_{j}$ in the $j^{\text {th }}$ slot and the whole space in the other slots.) Thus a basis consists of finite intersections of these sets. Note that the intersection of two of these basic sets is another basic set and their union yields $\prod_{i \in I} X_{i}$. Therefore, they satisfy the condition needed for a collection of sets to serve as a basis for a topology. This topology is called the product topology and is denoted by $\Pi \tau_{i}$.

Theorem 17.5.3 If $\left(X_{i}, \tau_{i}\right)$ is compact, then so is $\left(\prod_{i \in I} X_{i}, \Pi \tau_{i}\right)$.
The Banach Alaoglu theorem is as follows.
Theorem 17.5.4 Let $B^{\prime}$ be the closed unit ball in $X^{\prime}$. Then $B^{\prime}$ is compact in the weak * topology.

Proof: By the Tychonoff theorem, Theorem 17.5.3

$$
P \equiv \prod_{x \in X} \overline{B(0,\|x\|)}
$$

is compact in the product topology where the topology on $\overline{B(0,\|x\|)}$ is the usual topology of $\mathbb{F}$. Recall $P$ is the set of functions which map a point, $x \in X$ to a point in $\overline{B(0,\|x\|)}$. Therefore, $B^{\prime} \subseteq P$. Also the basic open sets in the weak $*$ topology on $B^{\prime}$ are obtained as the intersection of basic open sets in the product topology of $P$ to $B^{\prime}$ and so it suffices to show $B^{\prime}$ is a closed subset of $P$. Suppose then that $f \in P \backslash B^{\prime}$. Since $|f(x)| \leq\|x\|$ for each $x$, it follows $f$ cannot be linear. There are two ways this can happen. One way is that for some $x, y$

$$
f(x+y) \neq f(x)+f(y)
$$

for some $x, y \in X$. However, if $g$ is close enough to $f$ at the three points, $x+y, x$, and $y$, the above inequality will hold for $g$ in place of $f$. In other words there is a basic open set containing $f$, such that for all $g$ in this basic open set, $g \notin B^{\prime}$. A similar consideration applies in case $f(\lambda x) \neq \lambda f(x)$ for some scalar $\lambda$ and $x$. Since $P \backslash B^{\prime}$ is open, it follows $B^{\prime}$ is a closed subset of $P$ and is therefore, compact.

Sometimes one can consider the weak $*$ topology in terms of a metric space.
Theorem 17.5.5 If $K \subseteq X^{\prime}$ is compact in the weak $*$ topology and $X$ is separable in the weak topology then there exists a metric, $d$, on $K$ such that if $\tau_{d}$ is the topology on $K$ induced by $d$ and if $\tau$ is the topology on $K$ induced by the weak * topology of $X^{\prime}$, then $\tau=\tau_{d}$. Thus one can consider $K$ with the weak $*$ topology as a metric space.

Proof: Let $D=\left\{x_{n}\right\}$ be the dense countable subset in $X$. The metric is

$$
d(f, g) \equiv \sum_{n=1}^{\infty} 2^{-n} \frac{\rho_{x_{n}}(f-g)}{1+\rho_{x_{n}}(f-g)}
$$

where $\rho_{x_{n}}(f)=\left|f\left(x_{n}\right)\right|$. Clearly $d(f, g)=d(g, f) \geq 0$. If $d(f, g)=0$, then this requires $f\left(x_{n}\right)=g\left(x_{n}\right)$ for all $x_{n} \in D$. Is it the case that $f=g ? B_{\{f, g\}}(x, r)$ contains some $x_{n} \in D$. Hence

$$
\max \left\{\left|f\left(x_{n}\right)-f(x)\right|,\left|g\left(x_{n}\right)-g(x)\right|\right\}<r
$$

and $f\left(x_{n}\right)=g\left(x_{n}\right)$. It follows that $|f(x)-g(x)|<2 r$. Since $r$ is arbitrary, this implies $f(x)=g(x)$. It is routine to verify the triangle inequality from the easy to establish inequality,

$$
\frac{x}{1+x}+\frac{y}{1+y} \geq \frac{x+y}{1+x+y}
$$

valid whenever $x, y \geq 0$. Therefore this is a metric.
Thus there are two topological spaces, $(K, \tau)$ and $(K, d)$, the first being $K$ with the weak * topology and the second being $K$ with this metric. It is clear that if $i$ is the identity map, $i:(K, \tau) \rightarrow(K, d)$, then $i$ is continuous. Therefore, sets which are open in $(K, d)$ are open in $(K, \tau)$. Letting $\tau_{d}$ denote those sets which are open with respect to the metric, $\tau_{d} \subseteq \tau$.

Now suppose $U \in \tau$. Is $U$ in $\tau_{d}$ ? Since $K$ is compact with respect to $\tau$, it follows from the above that $K$ is compact with respect to $\tau_{d} \subseteq \tau$. Hence $K \backslash U$ is compact with respect to $\tau_{d}$ and so it is closed with respect to $\tau_{d}$. Thus $U$ is open with respect to $\tau_{d}$.

The fact that this set with the weak $*$ topology can be considered a metric space is very significant because if a point is a limit point in a metric space, one can extract a convergent sequence.

Note that if a Banach space is separable, then it is weakly separable.

Corollary 17.5.6 If $X$ is weakly separable and $K \subseteq X^{\prime}$ is compact in the weak $*$ topology, then $K$ is sequentially compact. That is, if $\left\{f_{n}\right\}_{n=1}^{\infty} \subseteq K$, then there exists a subsequence $f_{n_{k}}$ and $f \in K$ such that for all $x \in X$,

$$
\lim _{k \rightarrow \infty} f_{n_{k}}(x)=f(x)
$$

Proof: By Theorem 17.5.5, $K$ is a metric space for the metric described there and it is compact. Therefore by the characterization of compact metric spaces, Proposition 7.6.5 on Page $144, K$ is sequentially compact. This proves the corollary.

### 17.5.3 Eberlein Smulian Theorem

Next consider the weak topology. The most interesting results have to do with a reflexive Banach space. The following lemma ties together the weak and weak $*$ topologies in the case of a reflexive Banach space.

Lemma 17.5.7 Let $J: X \rightarrow X^{\prime \prime}$ be the James map

$$
J x(f) \equiv f(x)
$$

and let $X$ be reflexive so that $J$ is onto. Then $J$ is a homeomorphism of ( $X$, weak topology) and ( $X^{\prime \prime}$, weak * topology).This means $J$ is one to one, onto, and both $J$ and $J^{-1}$ are continuous.

Proof: Let $f \in X^{\prime}$ and let

$$
B_{f}(x, r) \equiv\{y:|f(x)-f(y)|<r\} .
$$

Thus $B_{f}(x, r)$ is a subbasic set for the weak topology on $X$. I claim that

$$
J B_{f}(x, r)=B_{f}(J x, r)
$$

where $B_{f}(J x, r)$ is a subbasic set for the weak $*$ topology. If $y \in B_{f}(x, r)$, then $\|J y-J x\|=$ $\|x-y\|<r$ and so $J B_{f}(x, r) \subseteq B_{f}(J x, r)$. Now if $x^{* *} \in B_{f}(J x, r)$, then since $J$ is reflexive, there exists $y \in X$ such that $J y=x^{* *}$ and so

$$
\|y-x\|=\|J y-J x\|<r
$$

showing that $J B_{f}(x, r)=B_{f}(J x, r)$. A typical subbasic set in the weak $*$ topology is of the form $B_{f}(J x, r)$. Thus $J$ maps the subbasic sets of the weak topology to the subbasic sets of the weak $*$ topology. Therefore, $J$ is a homeomorphism as claimed.

The following is an easy corollary.
Corollary 17.5.8 If $X$ is a reflexive Banach space, then the closed unit ball is weakly compact.

Proof: Let $B$ be the closed unit ball. Then $B=J^{-1}\left(B^{* *}\right)$ where $B^{* *}$ is the unit ball in $X^{\prime \prime}$ which is compact in the weak $*$ topology. Therefore $B$ is weakly compact because $J^{-1}$ is continuous.

Corollary 17.5.9 Let $X$ be a reflexive Banach space. If $K \subseteq X$ is compact in the weak topology and $X^{\prime}$ is separable in the weak $*$ topology, then there exists a metric $d$, on $K$ such that if $\tau_{d}$ is the topology on $K$ induced by $d$ and if $\tau$ is the topology on $K$ induced by the weak topology of $X$, then $\tau=\tau_{d}$. Thus one can consider $K$ with the weak topology as $a$ metric space.

Proof: This follows from Theorem 17.5.5 and Lemma 17.5.7. Lemma 17.5.7 implies $J(K)$ is compact in $X^{\prime \prime}$. Then since $X^{\prime}$ is separable in the weak $*$ topology, $X$ is separable in the weak topology and so there is a metric, $d^{\prime \prime}$ on $J(K)$ which delivers the weak $*$ topology on $J(K)$. Let $d(x, y) \equiv d^{\prime \prime}(J x, J y)$. Then

$$
\left(K, \tau_{d}\right) \xrightarrow{J}\left(J(K), \tau_{d^{\prime \prime}}\right) \xrightarrow{i d}\left(J(K), \tau_{\text {weak } *}\right) \xrightarrow{J^{-1}}\left(K, \tau_{\text {weak }}\right)
$$

and all the maps are homeomorphisms.
Here is a useful lemma.
Lemma 17.5.10 Let $Y$ be a closed subspace of a Banach space $X$ and let $y \in X \backslash Y$. Then there exists $x^{*} \in X^{\prime}$ such that $x^{*}(Y)=0$ but $x^{*}(y) \neq 0$.

Proof: Define $f(x+\alpha y) \equiv\|y\| \alpha$. Thus $f$ is linear on $Y \oplus \mathbb{F} y$. I claim that $f$ is also continuous on this subspace of $X$. If not, then there exists $x_{n}+\alpha_{n} y \rightarrow 0$ but $\left|f\left(x_{n}+\alpha_{n} y\right)\right| \geq$ $\varepsilon>0$ for all $n$. First suppose $\left|\alpha_{n}\right|$ is bounded. Then, taking a further subsequence, we can assume $\alpha_{n} \rightarrow \alpha$. It follows then that $\left\{x_{n}\right\}$ must also converge to some $x \in Y$ since $Y$ is closed. Therefore, in this case, $x+\alpha y=0$ and so $\alpha=0$ since otherwise, $y \in Y$. In the other case when $\alpha_{n}$ is unbounded, you have $\left(x_{n} / \alpha_{n}+y\right) \rightarrow 0$ and so it would require that $y \in \bar{Y}$ which cannot happen because $Y$ is closed. Hence $f$ is continuous as claimed. It follows that for some $k$,

$$
|f(x+\alpha y)| \leq k\|x+\alpha y\|
$$

Now apply the Hahn Banach theorem to extend $f$ to $x^{*} \in X^{\prime}$.
Next is the Eberlein Smulian theorem which states that a Banach space is reflexive if and only if the closed unit ball is weakly sequentially compact. Actually, only half the theorem is proved here, the more useful only if part. The book by Yoshida [127] has the complete theorem discussed. First here is an interesting lemma for its own sake.

Lemma 17.5.11 A closed subspace of a reflexive Banach space is reflexive.
Proof: Let $Y$ be the closed subspace of the reflexive space, $X$. Consider the following diagram

This diagram follows from Theorem 17.2.10 on Page 449, the theorem on adjoints. Now let $y^{* *} \in Y^{\prime \prime}$. Then $i^{* *} y^{* *}=J_{X}(y)$ because $X$ is reflexive. I want to show that $y \in Y$. If it
is not in $Y$ then since $Y$ is closed, there exists $x^{*} \in X^{\prime}$ such that $x^{*}(y) \neq 0$ but $x^{*}(Y)=0$. Then $i^{*} x^{*}=0$. Hence

$$
0=y^{* *}\left(i^{*} x^{*}\right)=i^{* *} y^{* *}\left(x^{*}\right)=J(y)\left(x^{*}\right)=x^{*}(y) \neq 0
$$

a contradiction. Hence $y \in Y$. Letting $J_{Y}$ denote the James map from $Y$ to $Y^{\prime \prime}$ and $x^{*} \in X^{\prime}$,

$$
\begin{aligned}
y^{* *}\left(i^{*} x^{*}\right) & =i^{* *} y^{* *}\left(x^{*}\right)=J_{X}(y)\left(x^{*}\right) \\
& =x^{*}(y)=x^{*}(i y)=i^{*} x^{*}(y)=J_{Y}(y)\left(i^{*} x^{*}\right)
\end{aligned}
$$

Since $i^{*}$ is onto, this shows $y^{* *}=J_{Y}(y)$.
Theorem 17.5.12 (Eberlein Smulian) The closed unit ball in a reflexive Banach space $X$, is weakly sequentially compact. By this is meant that if $\left\{x_{n}\right\}$ is contained in the closed unit ball, there exists a subsequence, $\left\{x_{n_{k}}\right\}$ and $x \in X$ such that for all $x^{*} \in X^{\prime}$,

$$
x^{*}\left(x_{n_{k}}\right) \rightarrow x^{*}(x) .
$$

Proof: Let $\left\{x_{n}\right\} \subseteq B \equiv \overline{B(0,1)}$. Let $Y$ be the closure of the linear span of $\left\{x_{n}\right\}$. Thus $Y$ is a separable. It is reflexive because it is a closed subspace of a reflexive space so the above lemma applies. By the Banach Alaoglu theorem, the closed unit ball $B^{*}$ in $Y^{\prime}$ is weak * compact. Also by Theorem 17.5.5, $B^{*}$ is a metric space with a suitable metric.

$$
\begin{array}{rlc}
B^{* *} Y^{\prime \prime} & \stackrel{i^{* *} 1-1}{\rightarrow} & X^{\prime \prime} \\
\text { weakly separable } B^{*} Y^{\prime} & \stackrel{i^{*} \text { onto }}{\leftarrow} & X^{\prime} \\
\text { separable } B Y & \xrightarrow{i} & X
\end{array}
$$

Thus $B^{*}$ is complete and totally bounded with respect to this metric and it follows that $B^{*}$ with the weak $*$ topology is separable. This implies $Y^{\prime}$ is also separable in the weak * topology. To see this, let $\left\{y_{n}^{*}\right\} \equiv D$ be a weak $*$ dense set in $B^{*}$ and let $y^{*} \in Y^{\prime}$. Let $p$ be a large enough positive rational number that $y^{*} / p \in B^{*}$. Then if $A$ is any finite set from $Y$, there exists $y_{n}^{*} \in D$ such that $\rho_{A}\left(y^{*} / p-y_{n}^{*}\right)<\frac{\varepsilon}{p}$. It follows $p y_{n}^{*} \in B_{A}\left(y^{*}, \varepsilon\right)$ showing that rational multiples of $D$ are weak $*$ dense in $Y^{\prime}$. Since $Y$ is reflexive, the weak and weak * topologies on $Y^{\prime}$ coincide and so $Y^{\prime}$ is weakly separable. Since $Y^{\prime}$ is weakly separable, Corollary 17.5 .6 implies $B^{* *}$, the closed unit ball in $Y^{\prime \prime}$ is weak $*$ sequentially compact. Then by Lemma 17.5.7 $B$, the unit ball in $Y$, is weakly sequentially compact. It follows there exists a subsequence $x_{n_{k}}$, of the sequence $\left\{x_{n}\right\}$ and a point $x \in Y$, such that for all $f \in Y^{\prime}$,

$$
f\left(x_{n_{k}}\right) \rightarrow f(x) .
$$

Now if $x^{*} \in X^{\prime}$, and $i$ is the inclusion map of $Y$ into $X$,

$$
x^{*}\left(x_{n_{k}}\right)=i^{*} x^{*}\left(x_{n_{k}}\right) \rightarrow i^{*} x^{*}(x)=x^{*}(x) .
$$

which shows $x_{n_{k}}$ converges weakly and this shows the unit ball in $X$ is weakly sequentially compact.

Corollary 17.5.13 Let $\left\{x_{n}\right\}$ be any bounded sequence in a reflexive Banach space $X$. Then there exists $x \in X$ and a subsequence, $\left\{x_{n_{k}}\right\}$ such that for all $x^{*} \in X^{\prime}$,

$$
\lim _{k \rightarrow \infty} x^{*}\left(x_{n_{k}}\right)=x^{*}(x)
$$

Proof: If a subsequence, $x_{n_{k}}$ has $\left\|x_{n_{k}}\right\| \rightarrow 0$, then the conclusion follows. Simply let $x=0$. Suppose then that $\left\|x_{n}\right\|$ is bounded away from 0 . That is, $\left\|x_{n}\right\| \in[\delta, C]$. Take a subsequence such that $\left\|x_{n_{k}}\right\| \rightarrow a$. Then consider $x_{n_{k}} /\left\|x_{n_{k}}\right\|$. By the Eberlein Smulian theorem, this subsequence has a further subsequence, $x_{n_{k_{j}}} /\left\|x_{n_{k_{j}}}\right\|$ which converges weakly to $x \in B$ where $B$ is the closed unit ball. It follows from routine considerations that $x_{n_{k_{j}}} \rightarrow a x$ weakly. This proves the corollary.

### 17.6 Operators With Closed Range

When is $T(X)$ a closed subset of $Y$ for $T \in \mathscr{L}(X, Y)$ ? One way this happens is when $T=I-C$ for $C$ compact.

Definition 17.6.1 Let $C \in \mathscr{L}(X, Y)$ where $X, Y$ are two Banach spaces. Then $C$ is called a compact operator if $C$ (bounded set $)=($ precompact set $)$.

Lemma 17.6.2 Suppose $C \in \mathscr{L}(X, X)$ is compact. Then $(I-C)(X)$ is closed.
Proof: Let $(I-C) x_{n} \rightarrow y$. Let $z_{n} \in \operatorname{ker}(I-C)$ such that

$$
\begin{aligned}
\operatorname{dist}\left(x_{n}, \operatorname{ker}(I-C)\right) & \leq\left\|x_{n}-z_{n}\right\| \\
& \leq\left(1+\frac{1}{n}\right) \operatorname{dist}\left(x_{n}, \operatorname{ker}(I-C)\right)
\end{aligned}
$$

Case 1: $\left\|x_{n}-z_{n}\right\| \rightarrow \infty$.
In this case, you get $(I-C)\left(x_{n}-z_{n}\right) \rightarrow y$ and so there is a subsequence such that $C\left(\frac{x_{n}-z_{n}}{\left\|x_{n}-z_{n}\right\|}\right)$ converges. Also $\frac{x_{n}-z_{n}}{\left\|x_{n}-z_{n}\right\|}$ converges to the same thing. Let it be called $w$. Thus

$$
\begin{gathered}
\frac{x_{n}-z_{n}}{\left\|x_{n}-z_{n}\right\|} \rightarrow w, C \frac{x_{n}-z_{n}}{\left\|x_{n}-z_{n}\right\|} \rightarrow C w \\
C\left(\frac{x_{n}-z_{n}}{\left\|x_{n}-z_{n}\right\|}\right) \rightarrow \quad \rightarrow \text { so } C w=w, w \in \operatorname{ker}(I-C) \\
\left\|\frac{x_{n}-z_{n}}{\left\|x_{n}-z_{n}\right\|}-w\right\|=\frac{1}{\left\|x_{n}-z_{n}\right\|}\|\left(x_{n}-z_{n}\right)-\overbrace{w\left\|x_{n}-z_{n}\right\|}^{\in \operatorname{ker}(I-C)}\| \\
\geq \frac{1}{\left\|x_{n}-z_{n}\right\|} \operatorname{dist}\left(x_{n}, \operatorname{ker}(I-C)\right) \\
\geq \frac{1}{\left(\left(1+\frac{1}{n}\right) \operatorname{dist}\left(x_{n}, \operatorname{ker}(I-C)\right)\right)} \operatorname{dist}\left(x_{n}, \operatorname{ker}(I-C)\right)
\end{gathered}
$$

Now passing to a limit,

$$
0 \geq \lim _{n \rightarrow \infty} \frac{1}{1+1 / n}=1
$$

so Case 1 cannot occur.
Case 2: A subsequence of $\left\|x_{n}-z_{n}\right\|$ is bounded.
Let $n$ denote the subscript for the subsequence. Then there is a further subsequence still denoted with $n$ such that $C\left(x_{n}-z_{n}\right)$ converges. Then also $\left(x_{n}-z_{n}\right)$ converges because $(I-C)\left(x_{n}\right)=(I-C)\left(x_{n}-z_{n}\right)$ is given to converge. Let $\left(x_{n}-z_{n}\right) \rightarrow x$. Then

$$
y=\lim _{n \rightarrow \infty}(I-C) x_{n}=\lim _{n \rightarrow \infty}(I-C)\left(x_{n}-z_{n}\right)=(I-C) x
$$

and so $y \in(I-C)(X)$ showing that $(I-C)(X)$ is closed.
Here is a useful lemma.
Lemma 17.6.3 Suppose $W$ and $V$ are closed subspaces of a Banach space $X$ and $V \varsubsetneqq W$ $(V$ is a proper subset of $W$.) while $(\lambda I-L)(W) \subseteq V, \lambda \neq 0$. Then there exists $w \in W \backslash V$ such that $\|w\|=1$ and

$$
\operatorname{dist}(L w, L V) \geq 1 / 2
$$

Proof: Let $w_{0} \in W \backslash V$. Then let $v \in V$ be such that $\left\|\lambda w_{0}-v\right\| \leq 2 \operatorname{dist}\left(\lambda w_{0}, V\right)$. Then let

$$
w=\frac{\lambda w_{0}-v}{\left\|\lambda w_{0}-v\right\|}
$$

It follows that $\|w\|=1$ and is in $W \backslash V$. Now let $x \in V$. Then

$$
\begin{gathered}
L x-L w=\lambda(x-w)+\overbrace{(L-\lambda I)(x-w)}^{\text {in } V} \\
=\lambda x+(L-\lambda I)(x-w)-\lambda w \\
=\frac{1}{\left\|\lambda w_{0}-v\right\|}\left(\lambda x\left\|\lambda w_{0}-v\right\|+(L-\lambda I)(x-w)\left\|\lambda w_{0}-v\right\|-\lambda\left\|\lambda w_{0}-v\right\| w\right) \\
=\frac{1}{\left\|\lambda w_{0}-v\right\|}\left(\lambda x\left\|\lambda w_{0}-v\right\|+(L-\lambda I)(x-w)\left\|\lambda w_{0}-v\right\|-\lambda\left(\lambda w_{0}-v\right)\right) \\
=\frac{1}{\left\|\lambda w_{0}-v\right\|}(\overbrace{\lambda x\left\|w_{0}-v\right\|+(L-\lambda I)(x-w)\left\|\lambda w_{0}-v\right\|+\lambda v}^{\in V}-\lambda w_{0})
\end{gathered}
$$

Thus

$$
\begin{gathered}
\|L x-L w\| \geq \frac{1}{\left\|\lambda w_{0}-v\right\|}\|\lambda x\| \lambda w_{0}-v\|+(L-\lambda I)(x-w)\| \lambda w_{0}-v\left\|+\lambda v-\lambda w_{0}\right\| \\
\geq \frac{1}{2 \operatorname{dist}\left(\lambda w_{0}, V\right)} \operatorname{dist}\left(\lambda w_{0}, V\right)=\frac{1}{2} \square
\end{gathered}
$$

Here is another fairly elementary lemma a little like the above.

Lemma 17.6.4 Let $Y$ be an infinite dimensional Banach space. Then there exists a sequence $\left\{x_{n}\right\}$ in the unit sphere $S,\left\|x_{n}\right\|=1$, such that $\left\|x_{n}-x_{m}\right\| \geq \frac{1}{2}$ whenever $n \neq m$.

Proof: Pick $x_{1} \in S$. Now the span of $x_{1}$ is not everything and so there exists $u_{2} \notin$ $\operatorname{span}\left(x_{1}\right)$. Let $w_{2}$ be a point of $\operatorname{span}\left(x_{1}\right)$ such that $\left\|u_{2}-w_{2}\right\| \leq 2 \operatorname{dist}\left(u_{2}, \operatorname{span}\left(x_{1}\right)\right)$. Then $x_{2}=\frac{u_{2}-w_{2}}{\left\|u_{2}-w_{2}\right\|}$. Then

$$
\left\|x_{1}-x_{2}\right\|=\left\|\frac{\left\|u_{2}-w_{2}\right\| x_{1}-\left(u_{2}-w_{2}\right)}{\left\|u_{2}-w_{2}\right\|}\right\| \geq \frac{\operatorname{dist}\left(u_{2}, \operatorname{span}\left(x_{1}\right)\right)}{2 \operatorname{dist}\left(u_{2}, \operatorname{span}\left(x_{1}\right)\right)}=\frac{1}{2}
$$

Now repeat the argument with span $\left(x_{1}, x_{2}\right)$ in place of $\operatorname{span}\left(x_{1}\right)$ and continue to get the desired sequence.

Lemma 17.6.5 Let $L$ be a compact linear map. Then the eigenspace of $L$ is finite dimensional for each eigenvalue $\lambda \neq 0$.

Proof: Consider $(L-\lambda I)^{-1}(0) \cap S$ where $S$ is the unit sphere. The eigenspace is just $(L-\lambda I)^{-1}(0)$. Let $Y$ be this inverse image. If $Y$ is infinite dimensional, then the above Lemma 17.6.4 applies. There exists $\left\{x_{n}\right\} \subseteq(L-\lambda I)^{-1}(0) \cap S$ where $\left\|x_{n}-x_{m}\right\| \geq 1 / 2$ for all $n \neq m$. Then there is a subsequence, still denoted with subscript $n$ such that $\left\{L x_{n}\right\}$ is a Cauchy sequence. Thus $L x_{n}=\lambda x_{n}$ and so, since $\lambda \neq 0$, it follows that $\left\{x_{n}\right\}$ is also a Cauchy sequence and converges to some $x$. But this is impossible because of the construction of the $\left\{x_{n}\right\}$ which prevents there being any Cauchy sequence. Thus $Y$ must be finite dimensional.

This lemma is useful in proving the following major spectral theorem about the eigenvalues of a compact operator. I found this theorem in Deimling [38].

Theorem 17.6.6 Let $L \in \mathscr{L}(X, X)$ with $L$ compact. Let $\Lambda$ be the eigenvalues of $L$. That is $\lambda \in \Lambda$ means there exists $x \neq 0$ such that $L x=\lambda x$. It is assumed the field of scalars is $\mathbb{R}$ or $\mathbb{C}$. Let $R_{\lambda} \equiv L-\lambda I$. Then the following hold.

1. If $\mu \in \Lambda$ then $|\mu| \leq\|L\|, \Lambda$ is at most countable and has no limit points other than possibly 0.
2. $R_{\lambda}$ is a homeomorphism onto $X$ whenever $\lambda \notin \Lambda \cup\{0\}$.
3. For all $\lambda \in \Lambda \backslash\{0\}$, there exists a smallest $k=k(\lambda)$,
(a) $R_{\lambda}^{k} X \oplus N\left(R_{\lambda}^{k}\right)=X$ where $N\left(R_{\lambda}^{k}\right)$ is the vectors $x$ such that $R_{\lambda}^{k} x=0 . R_{\lambda}^{k} X$ is closed, $\operatorname{dim}\left(N\left(R_{\lambda}^{k}\right)\right)<\infty$.
(b) $R_{\lambda}^{k} X$ and $N\left(R_{\lambda}^{k}\right)$ are invariant under $L$ and $\left.R_{\lambda}\right|_{R_{k}^{k} X}$ is a homeomorphism onto $R_{\lambda}^{k} X$.
(c) $N\left(R_{\mu}^{k}\right) \subseteq R_{\lambda}^{k} X$ for all $\lambda, \mu \in \Lambda \backslash\{0\}$ where $\lambda \neq \mu$.

Proof: Consider $\lambda \neq 0$. The $N\left(R_{\lambda}^{k}\right)$ are increasing in $k$ and $R_{\lambda}\left(N\left(R_{\lambda}^{k+1}\right)\right) \subseteq N\left(R_{\lambda}^{k}\right)$. This follows from the definition. (It isn't necessary to assume in most of this that $\lambda \in \Lambda$, just a nonzero number will do.) Now

$$
R_{\lambda}=-\lambda\left(I-\frac{1}{\lambda} L\right)
$$

If these things are strictly increasing for infinitely many $k$, then by Lemma 17.6.3, there is an infinite sequence $x_{k}, x_{k} \in N\left(R_{\lambda}^{k+1}\right) \backslash N\left(R_{\lambda}^{k}\right)$, $\operatorname{dist}\left(L x_{k}, L N\left(R_{\lambda}^{k}\right)\right) \geq 1 / 2$. Hence

$$
\left\|L x_{k}-L x_{k-1}\right\| \geq 1 / 2
$$

and this can't happen because $L$ is compact so $\left\{L x_{k}\right\}$ has a Cauchy subsequence. Therefore there exists a smallest $k$ such that

$$
N\left(R_{\lambda}^{k}\right)=N\left(R_{\lambda}^{m}\right), m \geq k
$$

On the other hand, $\left\{R_{\lambda}^{k} X\right\}$ are decreasing in $k$. By similar reasoning using Lemma 17.6.3 and the observation that $R_{\lambda}\left(R_{\lambda}^{k} X\right) \supseteq R_{\lambda}^{k+1} X$ (in fact they are equal) it follows that the $\left\{R_{\lambda}^{k} X\right\}$ are also eventually constant, say for $m \geq l$.

Now if you have $y \in N\left(R_{\lambda}^{k}\right) \cap R_{\lambda}^{k} X$, then $y=R_{\lambda}^{k} w$ and also $R_{\lambda}^{k} y=0$. Hence $R_{\lambda}^{2 k} w=0$ and so, $w \in N\left(R_{\lambda}^{2 k}\right)=N\left(R_{\lambda}^{k}\right)$ which implies $R_{\lambda}^{k} w=0$ and so $y=0$. It follows $N\left(R_{\lambda}^{k}\right) \cap$ $R_{\lambda}^{k} X=\{0\}$.

Now suppose $l>k$. Then there exists $y \in R_{\lambda}^{l-1} X \backslash R_{\lambda}^{l} X$ and so $R_{\lambda} y \in R_{\lambda}^{l} X=R_{\lambda}^{l+1} X=$ $R_{\lambda} R_{\lambda}^{l} X$. So $R_{\lambda} y=R_{\lambda} z$ for some $z \in R_{\lambda}^{l} X$. Thus $y-z \neq 0$ because $y \notin R_{\lambda}^{l} X$ but $z$ is. However, $R_{\lambda}(y-z)=0$ and so

$$
(y-z) \in N\left(R_{\lambda}\right) \cap R_{\lambda}^{k} X \subseteq N\left(R_{\lambda}^{k}\right) \cap R_{\lambda}^{k} X
$$

which cannot happen from the above which showed that $N\left(R_{\lambda}^{k}\right) \cap R_{\lambda}^{k} X=\{0\}$. Thus $l \leq k$.
Next suppose $l<k$. Then you would have $R_{\lambda}^{l} X=R_{\lambda}^{k} X$ and $N\left(R_{\lambda}^{k}\right) \supsetneqq N\left(R_{\lambda}^{l}\right)$. Thus there exists $y \in N\left(R_{\lambda}^{k}\right)$ but not in $N\left(R_{\lambda}^{l}\right)$. Hence $R_{\lambda}^{k} y=0$ but $R_{\lambda}^{l} y \neq 0$. However, $R_{\lambda}^{l} y$ is in $R_{\lambda}^{k} X$ from the definition of $l$ and so there is $u$ such that $R_{\lambda}^{l} y=R_{\lambda}^{k} u$. Thus

$$
0=R_{\lambda}^{k} y=R_{\lambda}^{k-l+l} y=R_{\lambda}^{k-l} R_{\lambda}^{l} y=R_{\lambda}^{k-l} R_{\lambda}^{k} u=R_{\lambda}^{2 k-l} u
$$

Now it follows that $u \in N\left(R_{\lambda}^{2 k-l}\right)=N\left(R_{\lambda}^{k}\right)$. This is a contradiction because it says that $R_{\lambda}^{k} u=0$ but right above the displayed equation, we had $R_{\lambda}^{l} y=R_{\lambda}^{k} u$ and $R_{\lambda}^{l} y \neq 0$. Thus, with the above paragraph, $k=l$.

What about the claim that $R_{\lambda}$ restricted to $R_{\lambda}^{k} X$ is a homeomorphism? It maps $R_{\lambda}^{k} X$ to $R_{\lambda}^{k+1} X=R_{\lambda}^{k} X$. Also, if $R_{\lambda}(y)=0$ for $y \in R_{\lambda}^{k} X$, then $R_{\lambda}^{k} y=0$ also and so $y \in R_{\lambda}^{k} X \cap$ $N\left(R_{\lambda}^{k}\right)$. It was shown above that this implies $y=0$. Thus $R_{\lambda}$ appears to be one to one. By assumption, it is continuous. Also from Lemma 17.6.2,

$$
R_{\lambda}^{k} X \text { is closed. }
$$

This follows from the observation that

$$
\begin{equation*}
R_{\lambda}^{k}=(L-\lambda I)^{k}=\sum_{j=0}^{k}\binom{k}{j} L^{j}(-\lambda I)^{k-j}=(-\lambda)^{k} I+\sum_{j=1}^{k}\binom{k}{j} L^{j}(-\lambda I)^{k-j} \tag{17.6.17}
\end{equation*}
$$

which is a multiple of $I-C$ where $C$ is a compact map. Then by the open mapping theorem, it follows that $R_{\lambda}$ is a homeomorphism onto $R_{\lambda}^{k+1} X=R_{\lambda}^{k} X$.

What about $R_{\lambda}^{k} X \oplus N\left(R_{\lambda}^{k}\right)=X$ ? It only remains to verify that $R_{\lambda}^{k} X+N\left(R_{\lambda}^{k}\right)=X$ because the only vector in the intersection was shown to be 0 . Thus if you have $x+y=0$ where $x$ is in one of these and $y$ in the other, then $x=-y$ so each is in both and hence both are 0 . Pick $x \in X$. Then $R_{\lambda}^{k} x \in R_{\lambda}^{k}\left(R_{\lambda}^{k} X\right)=R_{\lambda}^{k} X$. Therefore, $R_{\lambda}^{k} x=R_{\lambda}^{k}\left(R_{\lambda}^{k} y\right)$ for some $y$ and so $R_{\lambda}^{k}\left(x-R_{\lambda}^{k} y\right)=0$. Hence

$$
x-R_{\lambda}^{k} y \in N\left(R_{\lambda}^{k}\right)
$$

showing that $x \in R_{\lambda}^{k} X+N\left(R_{\lambda}^{k}\right)$.
It is obvious that $R_{\lambda}^{k} X$ and $N\left(R_{\lambda}^{k}\right)$ are invariant under $L$. If $\lambda_{0} \notin \Lambda \backslash\{0\}$, then $L-\lambda_{0} I$ is one to one and so the compactness of $L$ and Lemma 17.6.2 implies that $\left(L-\lambda_{0} I\right) X$ is closed. Hence the open mapping theorem implies $L-\lambda_{0} I$ is a homeomorphism onto $\left(L-\lambda_{0} I\right) X$. Is this last all of $X$ ? There is nothing in the above argument which involved an essential assumption that $\lambda \in \Lambda$. Hence, repeating this argument, you see that $\left(L-\lambda_{0} I\right) X \oplus$ $N\left(L-\lambda_{0} I\right)=X$ but $N\left(L-\lambda_{0} I\right)=0$. Hence $\left(L-\lambda_{0} I\right) X=X$ and so indeed $\left(L-\lambda_{0} I\right)$ is a homeomorphism.

For $\mu \in \Lambda, L x=\mu x$ and so $|\mu|\|x\| \leq\|L\|\|x\|$ so $|\mu| \leq\|L\|$. Why is $\Lambda$ at most countable and has only one possible limit point at 0 ? It was shown that $R_{\lambda}$ is a homeomorphism when restricted to $R_{\lambda}^{k} X$. It follows that for $x \in R_{\lambda}^{k} X,\left\|R_{\lambda} x\right\|>\delta\|x\|$ for some $\delta>0$, this for every such $x \in R_{\lambda}^{k} X$. Now consider $\mu$ close to $\lambda$ and consider $R_{\mu}$. Then for $x \in R_{\lambda}^{k} X,\left\|R_{\mu} x\right\|=$ $\left\|\left(R_{\lambda}+(\lambda-\mu)\right) x\right\| \geq \delta\|x\|-|\lambda-\mu|\|x\|>\frac{\delta}{2}\|x\|$ provided $|\lambda-\mu|<\delta / 2$. Thus for $\mu$ close enough to $\lambda, R_{\mu}$ is one to one on $R_{\lambda}^{k} X$. But also $R_{\mu}$ is one to one on $N\left(R_{\lambda}^{k}\right)$. Lets see why this is so. Suppose $(L-\mu I) x=0$ for $x \in N\left(R_{\lambda}^{k}\right)$. Then

$$
\begin{aligned}
0 & =(L-\mu I+(\mu-\lambda) I)^{k} x \\
& =(\mu-\lambda)^{k} x+\sum_{j=1}^{k}\binom{k}{j}(L-\mu I)^{j}(\mu-\lambda)^{k-j} x
\end{aligned}
$$

and the second term involving the sum yields 0 . Since $R_{\lambda}^{k} X \oplus N\left(R_{\lambda}^{k}\right)=X$, this shows that $(L-\mu I)$ is one to one for $\mu$ near $\lambda$. It follows that for $\mu$ near $\lambda, \mu \notin \Lambda$. Thus the only possible limit point is 0 . Note that there is no restriction on the size of $\mu$ for $(L-\mu I)$ to be one to one on $N\left(R_{\lambda}^{k}\right)$.

Why is $\operatorname{dim}\left(N\left(R_{\lambda}^{k}\right)\right)<\infty$ for each $\lambda \neq 0$. This follows from 17.6.17. $R_{\lambda}^{k}$ is a multiple of $I-C$ for $C$ a compact operator. Hence this is finite dimensional by Lemma 17.6.5.

What about $N\left(R_{\mu}^{k}\right) \subseteq R_{\lambda}^{k} X$ for $\mu$ an eigenvalue different than $\lambda$ ? Say $R_{\mu}^{k} x=0$. Then, does it follow that $x \in R_{\lambda}^{k} X$ ? From what was just shown

$$
x=y+z, y \in R_{\lambda}^{k} X, z \in N\left(R_{\lambda}^{k}\right)
$$

Then

$$
0=R_{\mu}^{p} x=R_{\mu}^{p} y+R_{\mu}^{p} z
$$

Here $p=k(\mu)$. This is where it is important that $\mu \in \Lambda$. However, $N\left(R_{\lambda}^{k}\right)$ and $R_{\lambda}^{k} X$ are invariant under $R_{\mu}^{p}$ since it is clear that $R_{\lambda}$ and $R_{\mu}$ commute. Thus $R_{\mu}^{p} y=-R_{\mu}^{p} z$ and $R_{\mu}^{p} y \in R_{\lambda}^{k} X,-R_{\mu}^{p} z \in N\left(R_{\lambda}^{k}\right)$ and these are equal. Hence they are both 0 . Now it was just shown that $R_{\mu}$ is one to one on $N\left(R_{\lambda}^{k}\right)$ and so $z=0$. Hence $x=y \in R_{\lambda}^{k} X$.

Note that in the last step, we can't conclude that $y=0$ because we only know that $R_{\mu}$ is one to one on $R_{\lambda}^{k} X$ if $\mu$ is sufficiently close to $\lambda$. The above is about compact mappings from a single space to itself. However, there are also mappings which have closed range which map from one space to another. The Fredholm operators have this property that their image is closed. These are discussed next.

Suppose $T \in \mathscr{L}(X, Y)$. Then $T X$ is a subspace of $Y$ and so it has a Hamel basis $\mathscr{B}$. Extending $\mathscr{B}$ to a Hamel basis for $Y$ yields $\mathscr{C}$. Then $Y=\operatorname{span}(\mathscr{B}) \oplus \operatorname{span}(\mathscr{C} \backslash \mathscr{B})$. Thus $Y=T X \oplus E$. For more on this, see [55].

Definition 17.6.7 Let $T \in \mathscr{L}(X, Y)$. Then this is a Fredholm operator means

1. $\operatorname{dim}(\operatorname{ker}(T))<\infty$
2. $\operatorname{dim}(E)<\infty$ where $Y=T X \oplus E$

Proposition 17.6.8 Let $T \in \mathscr{L}(X, Y)$. Then $T X$ is closed if and only if there exists $\delta>0$ such that

$$
\|T x\| \geq \delta \operatorname{dist}(x, \operatorname{ker}(T))
$$

Proof: First suppose $T X$ is closed. Let $\hat{T}: X / \operatorname{ker}(T) \rightarrow Y$ be defined as $\hat{T}([x]) \equiv T x$. Then by Theorem 18.7.2, $\hat{T}$ is one to one and continuous and $X / \operatorname{ker}(T)$ is a Banach space, $\|\hat{T}\| \leq\|T\|$. Also $\hat{T}$ has the same range as $T$. Thus $T X$ is the same as $\hat{T}(X / \operatorname{ker}(T))$ and $\hat{T} \in \mathscr{L}(X / \operatorname{ker}(T), Y)$. By the open mapping theorem, $\hat{T}$ is continuous and has continuous inverse. Recall

$$
\|[x]\| \equiv \inf \{\|x+z\|: z \in \operatorname{ker} T\}=\operatorname{dist}(x, \operatorname{ker}(T))
$$

Then

$$
\operatorname{dist}(x, \operatorname{ker}(T))=\|[x]\|=\left\|\hat{T}^{-1} \hat{T}[x]\right\| \leq\left\|\hat{T}^{-1}\right\|\|\hat{T}[x]\|=\left\|\hat{T}^{-1}\right\|\|T x\|
$$

and so,

$$
\|T x\| \geq \delta \operatorname{dist}(x, \operatorname{ker}(T))
$$

where $\delta=1 /\left\|\hat{T}^{-1}\right\|$.
Next suppose the inequality holds. Why will $T X$ be closed? Say $\left\{T x_{n}\right\}$ is a sequence in $T X$ converging to $y$. Then by the inequality,

$$
\left\|T x_{n}-T x_{m}\right\| \geq \delta \operatorname{dist}\left(x_{n}-x_{m}, \operatorname{ker}(T)\right)=\delta\left\|\left[x_{n}\right]-\left[x_{m}\right]\right\|_{X / \operatorname{ker}(T)}
$$

showing that $\left\{\left[x_{n}\right]\right\}$ is a Cauchy sequence in $X / \operatorname{ker}(T)$. Therefore, since this is a Banach space, there exists $[x]$ such that $\left[x_{n}\right] \rightarrow[x]$ in $X / \operatorname{ker}(T)$ and so $\hat{T}\left(\left[x_{n}\right]\right) \rightarrow \hat{T}([x])$ in $Y$. But this is the same as saying that $T\left(x_{n}\right) \rightarrow T(x)$. It follows that $y=T x$ and so $T X$ is indeed closed.

Theorem 17.6.9 If $T$ is a Fredholm operator, then $T X$ is closed in $Y$.
Proof: Recall that $Y=T X \oplus E$ where $E$ is a closed subspace of $Y$. In fact, $E$ is finite dimensional, but it is only needed that $E$ is closed. Let $T_{0} \in \mathscr{L}(X \times E, T X \oplus E)$ be given by

$$
T_{0}(x, e) \equiv T x+e
$$

Let the norm on $X \times E$ be

$$
\|(x, e)\|_{X \times E} \equiv \max \left\{\|x\|_{X},\|e\|_{E}\right\}
$$

Thus $T_{0}(x, e)=0$ implies both $T x=0$ and $e=0$. Thus $\operatorname{ker}\left(T_{0}\right)=\operatorname{ker}(T) \times\{0\}$. Also, $T_{0}(X \times E)$ is closed in $Y$ because in fact it is all of $Y, T X \oplus E$. By Proposition 17.6.8, there exists $\delta>0$ such that

$$
\begin{aligned}
\left\|T_{0}(x, e)\right\|_{Y} & \geq \delta \operatorname{dist}\left((x, e), \operatorname{ker}\left(T_{0}\right)\right) \\
& =\delta \operatorname{dist}((x, e), \operatorname{ker}(T) \times\{0\}) \geq \delta \operatorname{dist}(x, \operatorname{ker}(T))
\end{aligned}
$$

Then

$$
\|T x\|_{Y} \equiv\left\|T_{0}(x, 0)\right\|_{Y} \geq \delta \operatorname{dist}(x, \operatorname{ker}(T))
$$

and by Proposition 17.6.8, TX is closed.
Actually, the above proves the following corollary.
Corollary 17.6.10 If $T X \oplus E$ is closed in $Y$ and $E$ is a closed subspace of $Y$, then $T X$ is closed. Here $T \in \mathscr{L}(X, Y)$.

Note that it appears that $\operatorname{dim}(\operatorname{ker}(T))<\infty$ was not really needed.
Let $\mathscr{B}$ be a Hamel basis for $T X$ and consider $\mathscr{A} \equiv\{x: T x \in \mathscr{B}\}$. Then this is a linearly independent set of vectors in $X$. Suppose now that $\operatorname{ker}(T)=\operatorname{span}\left(z_{1}, \cdots, z_{n}\right)$ where $\left\{z_{1}, \cdots, z_{n}\right\}$ is linearly independent so here the assumption that $\operatorname{ker}(T)$ has finite dimensions is being used. Then if $x \in X, T x \in T X$ and so there are finitely many vectors $x_{i} \in \mathscr{A}$ such that

$$
T x=\sum_{i} c_{i} T x_{i} .
$$

Hence

$$
T\left(x-\sum_{i} c_{i} x_{i}\right)=0
$$

so

$$
x-\sum_{i} c_{i} x_{i}=\sum_{j=1}^{n} a_{j} z_{j}
$$

Hence $X=\operatorname{span}(\mathscr{A})+\operatorname{ker}(T)$. In fact, $\left\{\mathscr{A},\left\{z_{1}, \cdots, z_{n}\right\}\right\}$ is linearly independent as is easily seen and so this is a basis for $X$. Hence

$$
X=\operatorname{span}(\mathscr{A}) \oplus \operatorname{ker}(T) \equiv X_{1} \oplus \operatorname{ker}(T)
$$

Is $X_{1}$ closed? Define $S: T X \rightarrow X_{1}$ as follows: $S y=x \in X_{1}$ such that $T x=y$. Since $T$ is one to one on $X_{1}$, there is only one such $x$. Is $S$ continuous? Yes, this is so by the open mapping theorem. It is just the inverse of a continuous one to one linear onto map. Now this reduces to the situation discussed above in Corollary 17.6.10. You have $S \in \mathscr{L}\left(T X, X_{1}\right)$ and $S(T X) \oplus \operatorname{ker}(T)$ is all of $X$ and so it is closed in $X$. Therefore, $S(T X)=X_{1}$ is closed. This, along with the above proves the following.

Theorem 17.6.11 Let $T \in \mathscr{L}(X, Y)$ be a Fredholm operator and suppose $\operatorname{ker}(T)$ is finite dimensional and that $Y=T X \oplus E$ where $E$ is a finite dimensional subspace or more generally closed. Then $T X$ is closed and also for $X=X_{1} \oplus \operatorname{ker}(T)$, it follows that $X_{1}$ is closed.

### 17.7 Exercises

1. Is $\mathbb{N}$ a $G_{\delta}$ set? What about $\mathbb{Q}$ ? What about a countable dense subset of a complete metric space?
2. $\uparrow$ Let $f: \mathbb{R} \rightarrow \mathbb{C}$ be a function. Define the oscillation of a function in $B(x, r)$ by $\omega_{r} f(x)=\sup \{|f(z)-f(y)|: y, z \in B(x, r)\}$. Define the oscillation of the function at the point, $x$ by $\omega f(x)=\lim _{r \rightarrow 0} \omega_{r} f(x)$. Show $f$ is continuous at $x$ if and only if $\omega f(x)=0$. Then show the set of points where $f$ is continuous is a $G_{\delta}$ set (try $\left.U_{n}=\left\{x: \omega f(x)<\frac{1}{n}\right\}\right)$. Does there exist a function continuous at only the rational numbers? Does there exist a function continuous at every irrational and discontinuous elsewhere? Hint: Suppose $D$ is any countable set, $D=\left\{d_{i}\right\}_{i=1}^{\infty}$, and define the function, $f_{n}(x)$ to equal zero for every $x \notin\left\{d_{1}, \cdots, d_{n}\right\}$ and $2^{-n}$ for $x$ in this finite set. Then consider $g(x) \equiv \sum_{n=1}^{\infty} f_{n}(x)$. Show that this series converges uniformly.
3. Let $f \in C([0,1])$ and suppose $f^{\prime}(x)$ exists. Show there exists a constant, $K$, such that $|f(x)-f(y)| \leq K|x-y|$ for all $y \in[0,1]$. Let $U_{n}=\{f \in C([0,1])$ such that for each $x \in[0,1]$ there exists $y \in[0,1]$ such that $|f(x)-f(y)|>n|x-y|\}$. Show that $U_{n}$ is open and dense in $C([0,1])$ where for $f \in C([0,1])$,

$$
\|f\| \equiv \sup \{|f(x)|: x \in[0,1]\}
$$

Show that $\cap_{n} U_{n}$ is a dense $G_{\delta}$ set of nowhere differentiable continuous functions. Thus every continuous function is uniformly close to one which is nowhere differentiable.
4. $\uparrow$ Suppose $f(x)=\sum_{k=1}^{\infty} u_{k}(x)$ where the convergence is uniform and each $u_{k}$ is a polynomial. Is it reasonable to conclude that $f^{\prime}(x)=\sum_{k=1}^{\infty} u_{k}^{\prime}(x)$ ? The answer is no. Use the Weierstrass approximation theorem do show this.
5. Let $X$ be a normed linear space. We say $A \subseteq X$ is "weakly bounded" if for each $x^{*} \in X^{\prime}, \sup \left\{\left|x^{*}(x)\right|: x \in A\right\}<\infty$, while $A$ is bounded if $\sup \{\|x\|: x \in A\}<\infty$. Show $A$ is weakly bounded if and only if it is bounded.
6. Let $X$ and $Y$ be two Banach spaces. Define the norm

$$
\|\|(x, y) \mid\| \equiv\| x\left\|_{X}+\right\| y \|_{Y} .
$$

Show this is a norm on $X \times Y$ which is equivalent to the norm given in the chapter for $X \times Y$. Can you do the same for the norm defined for $p>1$ by

$$
|(x, y)| \equiv\left(\|x\|_{X}^{p}+\|y\|_{Y}^{p}\right)^{1 / p_{?}}
$$

7. Let $f$ be a $2 \pi$ periodic locally integrable function on $\mathbb{R}$. The Fourier series for $f$ is given by

$$
\sum_{k=-\infty}^{\infty} a_{k} e^{i k x} \equiv \lim _{n \rightarrow \infty} \sum_{k=-n}^{n} a_{k} e^{i k x} \equiv \lim _{n \rightarrow \infty} S_{n} f(x)
$$

where

$$
a_{k}=\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i k x} f(x) d x
$$

Show

$$
S_{n} f(x)=\int_{-\pi}^{\pi} D_{n}(x-y) f(y) d y
$$

where

$$
D_{n}(t)=\frac{\sin \left(\left(n+\frac{1}{2}\right) t\right)}{2 \pi \sin \left(\frac{t}{2}\right)}
$$

Verify that $\int_{-\pi}^{\pi} D_{n}(t) d t=1$. Also show that if $g \in L^{1}(\mathbb{R})$, then

$$
\lim _{a \rightarrow \infty} \int_{\mathbb{R}} g(x) \sin (a x) d x=0
$$

This last is called the Riemann Lebesgue lemma. Hint: For the last part, assume first that $g \in C_{c}^{\infty}(\mathbb{R})$ and integrate by parts. Then exploit density of the set of functions in $L^{1}(\mathbb{R})$.
8. $\uparrow$ It turns out that the Fourier series sometimes converges to the function pointwise. Suppose $f$ is $2 \pi$ periodic and Holder continuous. That is $|f(x)-f(y)| \leq K|x-y|^{\theta}$ where $\theta \in(0,1]$. Show that if $f$ is like this, then the Fourier series converges to $f$ at every point. Next modify your argument to show that if at every point, $x$, $|f(x+)-f(y)| \leq K|x-y|^{\theta}$ for $y$ close enough to $x$ and larger than $x$ and

$$
|f(x-)-f(y)| \leq K|x-y|^{\theta}
$$

for every $y$ close enough to $x$ and smaller than $x$, then $S_{n} f(x) \rightarrow \frac{f(x+)+f(x-)}{2}$, the midpoint of the jump of the function. Hint: Use Problem 7.
9. $\uparrow$ Let $Y=\{f$ such that $f$ is continuous, defined on $\mathbb{R}$, and $2 \pi$ periodic $\}$. Define $\|f\|_{Y}=\sup \{|f(x)|: x \in[-\pi, \pi]\}$. Show that $\left(Y,\| \|_{Y}\right)$ is a Banach space. Let $x \in \mathbb{R}$ and define $L_{n}(f)=S_{n} f(x)$. Show $L_{n} \in Y^{\prime}$ but $\lim _{n \rightarrow \infty}\left\|L_{n}\right\|=\infty$. Show that for each $x \in \mathbb{R}$, there exists a dense $G_{\delta}$ subset of $Y$ such that for $f$ in this set, $\left|S_{n} f(x)\right|$ is unbounded. Finally, show there is a dense $G_{\delta}$ subset of $Y$ having the property that $\left|S_{n} f(x)\right|$ is unbounded on the rational numbers. Hint: To do the first part, let $f(y)$ approximate $\operatorname{sgn}\left(D_{n}(x-y)\right)$. Here $\operatorname{sgn} r=1$ if $r>0,-1$ if $r<0$ and 0 if $r=0$. This rules out one possibility of the uniform boundedness principle. After this, show the countable intersection of dense $G_{\delta}$ sets must also be a dense $G_{\delta}$ set.
10. Let $\alpha \in(0,1]$. Define, for $X$ a compact subset of $\mathbb{R}^{p}$,

$$
C^{\alpha}\left(X ; \mathbb{R}^{n}\right) \equiv\left\{\mathbf{f} \in C\left(X ; \mathbb{R}^{n}\right): \rho_{\alpha}(\mathbf{f})+\|\mathbf{f}\| \equiv\|\mathbf{f}\|_{\alpha}<\infty\right\}
$$

where

$$
||\mathbf{f}|| \equiv \sup \{|\mathbf{f}(\mathbf{x})|: \mathbf{x} \in X\}
$$

and

$$
\rho_{\alpha}(\mathbf{f}) \equiv \sup \left\{\frac{|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})|}{|\mathbf{x}-\mathbf{y}|^{\alpha}}: \mathbf{x}, \mathbf{y} \in X, \mathbf{x} \neq \mathbf{y}\right\}
$$

Show that $\left(C^{\alpha}\left(X ; \mathbb{R}^{n}\right),\|\cdot\| \|_{\alpha}\right)$ is a complete normed linear space. This is called a Holder space. What would this space consist of if $\alpha>1$ ?
11. $\uparrow$ Now recall Problem 10 about the Holder spaces. Let $X$ be the Holder functions which are periodic of period $2 \pi$. Define $L_{n} f(x)=S_{n} f(x)$ where $L_{n}: X \rightarrow Y$ for $Y$ given in Problem 9. Show $\left\|L_{n}\right\|$ is bounded independent of $n$. Conclude that $L_{n} f \rightarrow f$ in $Y$ for all $f \in X$. In other words, for the Holder continuous and $2 \pi$ periodic functions, the Fourier series converges to the function uniformly. Hint: $L_{n} f(x)$ is given by

$$
L_{n} f(x)=\int_{-\pi}^{\pi} D_{n}(y) f(x-y) d y
$$

where $f(x-y)=f(x)+g(x, y)$ where $|g(x, y)| \leq C|y|^{\alpha}$. Use the fact the Dirichlet kernel integrates to one to write

$$
\begin{array}{r}
\left|\int_{-\pi}^{\pi} D_{n}(y) f(x-y) d y\right| \leq \overbrace{\left|\int_{-\pi}^{\pi} D_{n}(y) f(x) d y\right|}^{=|f(x)|} \\
+C\left|\int_{-\pi}^{\pi} \sin \left(\left(n+\frac{1}{2}\right) y\right)(g(x, y) / \sin (y / 2)) d y\right|
\end{array}
$$

Show the functions, $y \rightarrow g(x, y) / \sin (y / 2)$ are bounded in $L^{1}$ independent of $x$ and get a uniform bound on $\left\|L_{n}\right\|$. Now use a similar argument to show $\left\{L_{n} f\right\}$ is equicontinuous in addition to being uniformly bounded. If $L_{n} f$ fails to converge to $f$ uniformly, then there exists $\varepsilon>0$ and a subsequence, $n_{k}$ such that $\left\|L_{n_{k}} f-f\right\|_{\infty} \geq \varepsilon$ where this is the norm in $Y$ or equivalently the sup norm on $[-\pi, \pi]$. By the Arzela Ascoli theorem, there is a further subsequence, $L_{n_{k_{l}}} f$ which converges uniformly on $[-\pi, \pi]$. But by Problem $8 L_{n} f(x) \rightarrow f(x)$.
12. Let $X$ be a normed linear space and let $M$ be a convex open set containing 0 . Define

$$
\rho(x)=\inf \left\{t>0: \frac{x}{t} \in M\right\} .
$$

Show $\rho$ is a gauge function defined on $X$. This particular example is called a Minkowski functional. It is of fundamental importance in the study of locally convex topological vector spaces. A set, $M$, is convex if $\lambda x+(1-\lambda) y \in M$ whenever $\lambda \in[0,1]$ and $x, y \in M$.
13. $\uparrow$ The Hahn Banach theorem can be used to establish separation theorems. Let $M$ be an open convex set containing 0 . Let $x \notin M$. Show there exists $x^{*} \in X^{\prime}$ such that $\operatorname{Re} x^{*}(x) \geq 1>\operatorname{Re} x^{*}(y)$ for all $y \in M$. Hint: If $y \in M, \rho(y)<1$. Show this. If $x \notin M, \rho(x) \geq 1$. Try $f(\alpha x)=\alpha \rho(x)$ for $\alpha \in \mathbb{R}$. Then extend $f$ to the whole space using the Hahn Banach theorem and call the result $F$, show $F$ is continuous, then fix it so $F$ is the real part of $x^{*} \in X^{\prime}$.
14. A Banach space is said to be strictly convex if whenever $\|x\|=\|y\|$ and $x \neq y$, then

$$
\left\|\frac{x+y}{2}\right\|<\|x\|
$$

$F: X \rightarrow X^{\prime}$ is said to be a duality map if it satisfies the following: a.) $\|F(x)\|=$ $\|x\|$. b.) $F(x)(x)=\|x\|^{2}$. Show that if $X^{\prime}$ is strictly convex, then such a duality map exists. The duality map is an attempt to duplicate some of the features of the Riesz map in Hilbert space which is discussed in the chapter on Hilbert space. Hint: For an arbitrary Banach space, let

$$
F(x) \equiv\left\{x^{*}:\left\|x^{*}\right\| \leq\|x\| \text { and } x^{*}(x)=\|x\|^{2}\right\}
$$

Show $F(x) \neq \emptyset$ by using the Hahn Banach theorem on $f(\alpha x)=\alpha\|x\|^{2}$. Next show $F(x)$ is closed and convex. Finally show that you can replace the inequality in the definition of $F(x)$ with an equal sign. Now use strict convexity to show there is only one element in $F(x)$.
15. Prove the following theorem which is an improved version of the open mapping theorem, [42]. Let $X$ and $Y$ be Banach spaces and let $A \in \mathscr{L}(X, Y)$. Then the following are equivalent.

$$
A X=Y
$$

$A$ is an open map.
There exists a constant $M$ such that for every $y \in Y$, there exists $x \in X$ with $y=A x$ and

$$
\|x\| \leq M\|y\|
$$

Note this gives the equivalence between $A$ being onto and $A$ being an open map. The open mapping theorem says that if $A$ is onto then it is open.
16. Suppose $D \subseteq X$ and $D$ is dense in $X$. Suppose $L: D \rightarrow Y$ is linear and $\|L x\| \leq K\|x\|$ for all $x \in D$. Show there is a unique extension of $L, \widetilde{L}$, defined on all of $X$ with $\|\widetilde{L} x\| \leq K| | x \|$ and $\widetilde{L}$ is linear. You do not get uniqueness when you use the Hahn Banach theorem. Therefore, in the situation of this problem, it is better to use this result.
17. $\uparrow$ A Banach space is uniformly convex if whenever $\left\|x_{n}\right\|,\left\|y_{n}\right\| \leq 1$ and $\left\|x_{n}+y_{n}\right\| \rightarrow$ 2 , it follows that $\left\|x_{n}-y_{n}\right\| \rightarrow 0$. Show uniform convexity implies strict convexity (See Problem 14). Hint: Suppose it is not strictly convex. Then there exist $\|x\|$
and $\|y\|$ both equal to 1 and $\left\|\frac{x_{n}+y_{n}}{2}\right\|=1$ consider $x_{n} \equiv x$ and $y_{n} \equiv y$, and use the conditions for uniform convexity to get a contradiction. It can be shown that $L^{p}$ is uniformly convex whenever $\infty>p>1$. See Hewitt and Stromberg [64] or Ray [109].
18. Show that a closed subspace of a reflexive Banach space is reflexive. Hint: The proof of this is an exercise in the use of the Hahn Banach theorem. Let $Y$ be the closed subspace of the reflexive space $X$ and let $y^{* *} \in Y^{\prime \prime}$. Then $i^{* *} y^{* *} \in X^{\prime \prime}$ and so $i^{* *} y^{* *}=J x$ for some $x \in X$ because $X$ is reflexive. Now argue that $x \in Y$ as follows. If $x \notin Y$, then there exists $x^{*}$ such that $x^{*}(Y)=0$ but $x^{*}(x) \neq 0$. Thus, $i^{*} x^{*}=0$. Use this to get a contradiction. When you know that $x=y \in Y$, the Hahn Banach theorem implies $i^{*}$ is onto $Y^{\prime}$ and for all $x^{*} \in X^{\prime}$,

$$
y^{* *}\left(i^{*} x^{*}\right)=i^{* *} y^{* *}\left(x^{*}\right)=J x\left(x^{*}\right)=x^{*}(x)=x^{*}(i y)=i^{*} x^{*}(y) .
$$

19. We say that $x_{n}$ converges weakly to $x$ if for every $x^{*} \in X^{\prime}, x^{*}\left(x_{n}\right) \rightarrow x^{*}(x) . x_{n} \rightharpoonup x$ denotes weak convergence. Show that if $\left\|x_{n}-x\right\| \rightarrow 0$, then $x_{n} \rightharpoonup x$.
20. $\uparrow$ Show that if $X$ is uniformly convex, then if $x_{n} \rightharpoonup x$ and $\left\|x_{n}\right\| \rightarrow\|x\|$, it follows $\left\|x_{n}-x\right\| \rightarrow 0$. Hint: Use Lemma 17.2.9 to obtain $f \in X^{\prime}$ with $\|f\|=1$ and $f(x)=$ $\|x\|$. See Problem 17 for the definition of uniform convexity. Now by the weak convergence, you can argue that if $x \neq 0, f\left(x_{n} /\left\|x_{n}\right\|\right) \rightarrow f(x /\|x\|)$. You also might try to show this in the special case where $\left\|x_{n}\right\|=\|x\|=1$.
21. Suppose $L \in \mathscr{L}(X, Y)$ and $M \in \mathscr{L}(Y, Z)$. Show $M L \in \mathscr{L}(X, Z)$ and that $(M L)^{*}=$ $L^{*} M^{*}$.
22. Let $X$ and $Y$ be Banach spaces and suppose $f \in \mathscr{L}(X, Y)$ is compact. Recall this means that if $B$ is a bounded set in $X$, then $f(B)$ has compact closure in $Y$. Show that $f^{*}$ is also a compact map. Hint: Take a bounded subset of $Y^{\prime}, S$. You need to show $f^{*}(S)$ is totally bounded. You might consider using the Ascoli Arzela theorem on the functions of $S$ applied to $f(B)$ where $B$ is the closed unit ball in $X$.

## Chapter 18

## Topological Vector Spaces

### 18.1 Fundamental Considerations

The right context to consider certain topics like separation theorems is in locally convex topological vector spaces, a generalization of normed linear spaces. Let $X$ be a vector space and let $\Psi$ be a collection of functions defined on $X$ such that if $\rho \in \Psi$,

$$
\begin{gathered}
\rho(x+y) \leq \rho(x)+\rho(y) \\
\rho(a x)=|a| \rho(x) \text { if } a \in \mathbb{F} \\
\rho(x) \geq 0
\end{gathered}
$$

where $\mathbb{F}$ denotes the field of scalars, either $\mathbb{R}$ or $\mathbb{C}$, assumed to be $\mathbb{C}$ unless otherwise specified. These functions are called seminorms because it is not necessarily true that $x=0$ when $\rho(x)=0$. A basis for a topology, $\mathscr{B}$, is defined as follows.

Definition 18.1.1 For $A$ a finite subset of $\Psi$ and $r>0$,

$$
B_{A}(x, r) \equiv\{y \in X: \rho(x-y)<r \text { for all } \rho \in A\}
$$

Then

$$
\mathscr{B} \equiv\left\{B_{A}(x, r): x \in X, r>0, \text { and } A \subseteq \Psi, A \text { finite }\right\} .
$$

That this really is a basis is the content of the next theorem.
Theorem 18.1.2 $\mathscr{B}$ is the basis for a topology.
Proof: I need to show that if $B_{A}\left(x, r_{1}\right)$ and $B_{B}\left(y, r_{2}\right)$ are two elements of $\mathscr{B}$ and if $z \in$ $B_{A}\left(x, r_{1}\right) \cap B_{B}\left(y, r_{2}\right)$, then there exists $U \in \mathscr{B}$ such that

$$
z \in U \subseteq B_{A}\left(x, r_{1}\right) \cap B_{B}\left(y, r_{2}\right)
$$

Let

$$
\begin{aligned}
r= & \min \left(\min \left\{\left(r_{1}-\rho(z-x)\right): \rho \in A\right\},\right. \\
& \left.\min \left\{\left(r_{2}-\rho(z-y)\right): \rho \in B\right\}\right)
\end{aligned}
$$

and consider $B_{A \cup B}(z, r)$. If $w$ belongs to this set, then for $\rho \in A$,

$$
\rho(w-z)<r_{1}-\rho(z-x) .
$$

Hence

$$
\rho(w-x) \leq \rho(w-z)+\rho(z-x)<r_{1}
$$

for each $\rho \in A$ and so $B_{A \cup B}(z, r) \subseteq B_{A}\left(x, r_{1}\right)$. Similarly, $B_{A \cup B}(z, r) \subseteq B_{B}\left(y, r_{2}\right)$. This proves the theorem.

Let $\tau$ be the topology consisting of unions of all subsets of $\mathscr{B}$. Then $(X, \tau)$ is a locally convex topological vector space.

Theorem 18.1.3 The vector space operations of addition and scalar multiplication are continuous. More precisely,

$$
+: X \times X \rightarrow X, \cdot: \mathbb{F} \times X \rightarrow X
$$

are continuous.
Proof: It suffices to show $+^{-1}(B)$ is open in $X \times X$ and $\cdot^{-1}(B)$ is open in $\mathbb{F} \times X$ if $B$ is of the form

$$
B=\{y \in X: \rho(y-x)<r\}
$$

because finite intersections of such sets form the basis $\mathscr{B}$. (This collection of sets is a subbasis.) Suppose $u+v \in B$ where $B$ is described above. Then

$$
\rho(u+v-x)<\lambda r
$$

for some $\lambda<1$. Consider

$$
B_{\rho}(u, \delta) \times B_{\rho}(v, \boldsymbol{\delta})
$$

If $\left(u_{1}, v_{1}\right)$ is in this set, then

$$
\begin{aligned}
\rho\left(u_{1}+v_{1}-x\right) & \leq \rho(u+v-x)+\rho\left(u_{1}-u\right)+\rho\left(v_{1}-v\right) \\
& <\lambda r+2 \delta .
\end{aligned}
$$

Let $\delta$ be positive but small enough that

$$
2 \delta+\lambda r<r
$$

Thus this choice of $\delta$ shows that $+^{-1}(B)$ is open and this shows + is continuous.
Now suppose $\alpha z \in B$. Then

$$
\rho(\alpha z-x)<\lambda r<r
$$

for some $\lambda \in(0,1)$. Let $\delta>0$ be small enough that $\delta<1$ and also

$$
\lambda r+\delta(\rho(z)+1)+\delta|\alpha|<r
$$

Then consider $(\beta, w) \in B(\alpha, \delta) \times B_{\rho}(z, \delta)$.

$$
\begin{aligned}
\rho(\beta w-x)-\rho(\alpha z-x) & \leq \rho(\beta w-\alpha z) \\
& \leq|\beta-\alpha| \rho(w)+\rho(w-z)|\alpha| \\
& \leq|\beta-\alpha|(\rho(z)+1)+\rho(w-z)|\alpha| \\
& <\delta(\rho(z)+1)+\delta|\alpha|
\end{aligned}
$$

Hence

$$
\rho(\beta w-x)<\lambda r+\delta(\rho(z)+1)+\delta|\alpha|<r
$$

and so

$$
B(\alpha, \delta) \times B_{\rho}(z, \delta) \subseteq \cdot^{-1}(B)
$$

This proves the theorem.

Theorem 18.1.4 Let $x$ be given and let $f_{x}(y)=x+y$. Then $f_{x}$ is $1-1$, onto, and continuous. If $\alpha \neq 0$ and $g_{\alpha}(x)=\alpha x$, then $g_{\alpha}$ is also $1-1$ onto and continuous.

Proof: The assertions about $1-1$ and onto are obvious. It remains to show $f_{x}$ and $g_{\alpha}$ are continuous. Let $B=B_{\rho}(z, r)$ and consider $f_{x}^{-1}(B)$. Then it is easy to see that

$$
f_{x}^{-1}(B)=B_{\rho}(z-x, r)
$$

and so $f_{x}$ is continuous. To see that $g_{\alpha}$ is continuous, note that

$$
g_{\alpha}^{-1}(B)=B_{\rho}\left(\frac{z}{\alpha}, \frac{r}{|\alpha|}\right) .
$$

This proves the theorem.
As in the case of a normed linear space, the vector space of continuous linear functionals, is denoted by $X^{\prime}$.

Definition 18.1.5 Define, for A a finite subset of $\Psi$,

$$
\rho_{A}(x)=\max \{\rho(x): \rho \in A\}
$$

The following theorem is the equivalent to the earlier theorems concerning continuous linear functionals on normed linear spaces.

Theorem 18.1.6 The following are equivalent for $f$, a linear function mapping $X$ to $\mathbb{F}$.

$$
\begin{equation*}
f \text { is continuous at } 0 . \tag{18.1.1}
\end{equation*}
$$

For some $A \subseteq \Psi, A$ finite,

$$
\begin{equation*}
|f(x)| \leq C \rho_{A}(x) \tag{18.1.2}
\end{equation*}
$$

for all $x \in X$ where the constant may depend on $A$ but is independent of $x$.

$$
\begin{equation*}
f \text { is continuous at } x \tag{18.1.3}
\end{equation*}
$$

for all $x$.
Proof: Clearly 18.1.3 implies 18.1.1. Suppose 18.1.1. Then

$$
0=f(0) \in B(0,1) \subseteq \mathbb{F}
$$

Since $f$ is continuous at $0,0 \in f^{-1}(B(0,1))$ and there exists an open set $V \in \tau$ such that

$$
0 \in V \subseteq f^{-1}(B(0,1))
$$

Then $0 \in B_{A}(0, r) \subseteq V$ for some $r$ and some $A \subseteq \Psi, A$ finite. Hence

$$
|f(y)|<1 \text { if } \rho_{A}(y)<r .
$$

Since $f$ is linear

$$
|f(x)| \leq \frac{2}{r} \rho_{A}(x)
$$

To see this, note that if $x \neq 0$, then

$$
\frac{r x}{2 \rho_{A}(x)} \in B_{A}(0, r)
$$

and so

$$
\frac{|f(r x)|}{2 \rho_{A}(x)} \leq 1
$$

which shows that 18.1.1 implies 18.1.2.
Now suppose 18.1.2 and suppose $f(x) \in V$, an open set in $\mathbb{F}$. Then

$$
f(x) \in B(f(x), r) \subseteq V
$$

for some $r>0$. Suppose $\rho_{A}(x-y)<r\left(C_{A}+1\right)^{-1}$. Then

$$
|f(x)-f(y)|=|f(x-y)| \leq C_{A} \rho_{A}(y-x)<r .
$$

Hence

$$
f\left(B_{A}\left(x, r\left(C_{A}+1\right)^{-1}\right)\right) \subseteq B(f(x), r) \subseteq V
$$

Thus $f$ is continuous at $x$. This proves the theorem.
What are some examples of locally convex topological vector spaces? It is obvious that any normed linear space is such an example. More generally, here is a theorem which shows how to make any vector space into a locally convex topological vector space.

Theorem 18.1.7 Let $X$ be a vector space and let $Y$ be a vector space of linear functionals defined on $X$. For each $y \in Y$, define

$$
\rho_{y}(x) \equiv|y(x)| .
$$

Then the collection of seminorms $\left\{\rho_{y}\right\}_{y \in Y}$ defined on $X$ makes $X$ into a locally convex topological vector space and $Y=X^{\prime}$.

Proof: Clearly $\left\{\rho_{y}\right\}_{y \in Y}$ is a collection of seminorms defined on $X$; so, $X$ supplied with the topology induced by this collection of seminorms is a locally convex topological vector space. Is $Y=X^{\prime}$ ?

Let $y \in Y$, let $U \subseteq \mathbb{F}$ be open and let $x \in y^{-1}(U)$. Then $B(y(x), r) \subseteq U$ for some $r>0$. Letting $A=\{y\}$, it is easy to see from the definition that $B_{A}(x, r) \subseteq y^{-1}(U)$ and so $y^{-1}(U)$ is an open set as desired. Thus, $Y \subseteq X^{\prime}$.

Now suppose $z \in X^{\prime}$. Then by 18.1 .2 , there exists a finite subset of $Y, A \equiv\left\{y_{1}, \cdots, y_{n}\right\}$, such that

$$
|z(x)| \leq C \rho_{A}(x)
$$

Let

$$
\pi(x) \equiv\left(y_{1}(x), \cdots, y_{n}(x)\right)
$$

and let $f$ be a linear map from $\pi(X)$ to $\mathbb{F}$ defined by

$$
f(\pi x) \equiv z(x)
$$

(This is well defined because if $\pi(x)=\pi\left(x_{1}\right)$, then $y_{i}(x)=y_{i}\left(x_{1}\right)$ for $i=1, \cdots, n$ and so

$$
\rho_{A}\left(x-x_{1}\right)=0 .
$$

Thus,

$$
\left.\left|z\left(x_{1}\right)-z(x)\right|=\left|z\left(x_{1}-x\right)\right| \leq C \rho_{A}\left(x-x_{1}\right)=0 .\right)
$$

Extend $f$ to all of $\mathbb{F}^{n}$ and denote the resulting linear map by $F$. Then there exists a vector

$$
\alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right) \in \mathbb{F}^{n}
$$

with $\alpha_{i}=F\left(\mathbf{e}_{i}\right)$ such that

$$
F(\beta)=\alpha \cdot \beta
$$

Hence for each $x \in X$,

$$
z(x)=f(\pi x)=F(\pi x)=\sum_{i=1}^{n} \alpha_{i} y_{i}(x)
$$

and so

$$
z=\sum_{i=1}^{n} \alpha_{i} y_{i} \in Y
$$

This proves the theorem.

### 18.2 Separation Theorems

It will always be assumed that $X$ is a locally convex topological vector space. A set, $K$, is said to be convex if whenever $x, y \in K$,

$$
\lambda x+(1-\lambda) y \in K
$$

for all $\lambda \in[0,1]$.
Definition 18.2.1 Let $U$ be an open convex set containing 0 and define

$$
m(x) \equiv \inf \{t>0: x / t \in U\}
$$

This is called a Minkowski functional.
Proposition 18.2.2 Let $X$ be a locally convex topological vector space. Then $m$ is defined on $X$ and satisfies

$$
\begin{gather*}
m(x+y) \leq m(x)+m(y)  \tag{18.2.4}\\
m(\lambda x)=\lambda m(x) \text { if } \lambda>0 . \tag{18.2.5}
\end{gather*}
$$

Thus, $m$ is a gauge function on $X$.

Proof: Let $x \in X$ be arbitrary. There exists $A \subseteq \Psi$ such that

$$
0 \in B_{A}(0, r) \subseteq U
$$

Then

$$
\frac{r x}{2 \rho_{A}(x)} \in B_{A}(0, r) \subseteq U
$$

which implies

$$
\begin{equation*}
\frac{2 \rho_{A}(x)}{r} \geq m(x) \tag{18.2.6}
\end{equation*}
$$

Thus $m(x)$ is defined on $X$.
Let $x / t \in U, y / s \in U$. Then since $U$ is convex,

$$
\frac{x+y}{t+s}=\left(\frac{t}{t+s}\right)\left(\frac{x}{t}\right)+\left(\frac{s}{t+s}\right)\left(\frac{y}{s}\right) \in U .
$$

It follows that

$$
m(x+y) \leq t+s
$$

Choosing $s, t$ such that $t-\varepsilon<m(x)$ and $s-\varepsilon<m(y)$,

$$
m(x+y) \leq m(x)+m(y)+2 \varepsilon .
$$

Since $\varepsilon$ is arbitrary, this shows 18.2.4. It remains to show 18.2.5. Let $x / t \in U$. Then if $\lambda>0$,

$$
\frac{\lambda x}{\lambda t} \in U
$$

and so $m(\lambda x) \leq \lambda t$. Thus $m(\lambda x) \leq \lambda m(x)$ for all $\lambda>0$. Hence

$$
m(x)=m\left(\lambda^{-1} \lambda x\right) \leq \lambda^{-1} m(\lambda x) \leq \lambda^{-1} \lambda m(x)=m(x)
$$

and so

$$
\lambda m(x)=m(\lambda x) .
$$

This proves the proposition.
Lemma 18.2.3 Let $U$ be an open convex set containing 0 and let $q \notin U$. Then there exists $f \in X^{\prime}$ such that

$$
\operatorname{Re} f(q)>\operatorname{Re} f(x)
$$

for all $x \in U$.
Proof: Let $m$ be the Minkowski functional just defined and let

$$
F(c q)=c m(q)
$$

for $c \in \mathbb{R}$. If $c>0$ then

$$
F(c q)=m(c q)
$$

while if $c \leq 0$,

$$
F(c q)=c m(q) \leq 0 \leq m(c q) .
$$

By the Hahn Banach theorem, $F$ has an extension, $g$, defined on all of $X$ satisfying

$$
g(x+y)=g(x)+g(y), g(c x)=c g(x)
$$

for all $c \in \mathbb{R}$, and

$$
g(x) \leq m(x)
$$

Thus, $g(-x) \leq m(-x)$ and so

$$
-m(-x) \leq g(x) \leq m(x)
$$

It follows as in 18.2.6 that for some $A \subseteq \Psi, A$ finite, and $r>0$,

$$
\begin{gathered}
|g(x)| \leq m(x)+m(-x) \\
\leq \frac{2}{r} \rho_{A}(x)+\frac{2}{r} \rho_{A}(-x)=\frac{4}{r} \rho_{A}(x)
\end{gathered}
$$

because

$$
\rho_{A}(-x)=|-1| \rho_{A}(x)=\rho_{A}(x)
$$

Hence $g$ is continuous by Theorem 18.1.6. Now define

$$
f(x) \equiv g(x)-i g(i x)
$$

Thus $f$ is linear and continuous so $f \in X^{\prime}$ and $\operatorname{Re} f(x)=g(x)$. But for $x \in U$, Theorem 18.1.3 implies that $x / t \in U$ for some $t<1$ and so $m(x)<1$. Since $U$ is convex and $0 \in U$, it follows $q / t \notin U$ if $t<1$ because if it were,

$$
q=t\left(\frac{q}{t}\right)+(1-t) 0 \in U
$$

Therefore, $m(q) \geq 1$ and for $x \in U$,

$$
\operatorname{Re} f(x)=g(x) \leq m(x)<1 \leq m(q)=g(q)=\operatorname{Re} f(q)
$$

and this proves the lemma.
Corollary 18.2.4 Let $U$ be an open nonempty convex set and let $q \notin U$. Then there exists $f \in X^{\prime}$ such that

$$
f(q)>f(x)
$$

for all $x \in U$.
Proof: Let $u_{0} \in U$ and consider $\hat{U} \equiv U-u_{0}$. Then $0 \in \hat{U}$ and $q-u_{0} \notin \hat{U}$. By separation theorems, Lemma 18.2.3 there exists $f \in X^{\prime}$ such that

$$
f\left(q-u_{0}\right)>f\left(x-u_{0}\right)
$$

for all $x \in U$. Thus $f(q)>f(x)$ for all $x \in U$.

Theorem 18.2.5 Let $K$ be closed and convex in a locally convex topological vector space and let $p \notin K$. Then there exists a real number $c$, and $f \in X^{\prime}$ such that

$$
\operatorname{Re} f(p)>c>\operatorname{Re} f(k)
$$

for all $k \in K$.
Proof: Since $K$ is closed, and $p \notin K$, there exists a finite subset of $\Psi, A$, and a positive $r>0$ such that

$$
K \cap B_{A}(p, 2 r)=\emptyset .
$$

Pick $k_{0} \in K$ and let

$$
U=K+B_{A}(0, r)-k_{0}, q=p-k_{0}
$$

It follows that $U$ is an open convex set containing 0 and $q \notin U$. Therefore, by Lemma 18.2.3, there exists $f \in X^{\prime}$ such that

$$
\begin{equation*}
\operatorname{Re} f\left(p-k_{0}\right)=\operatorname{Re} f(q)>\operatorname{Re} f\left(k+e-k_{0}\right) \tag{18.2.7}
\end{equation*}
$$

for all $k \in K$ and $e \in B_{A}(0, r)$. If $\operatorname{Re} f(e)=0$ for all $e \in B_{A}(0, r)$, then $\operatorname{Re} f=0$ and 18.2.7 could not hold. Therefore, $\operatorname{Re} f(e)>0$ for some $e \in B_{A}(0, r)$ and so,

$$
\operatorname{Re} f(p)>\operatorname{Re} f(k)+\operatorname{Re} f(e)
$$

for all $k \in K$. Let $c_{1} \equiv \sup \{\operatorname{Re} f(k): k \in K\}$. Then for all $k \in K$,

$$
\operatorname{Re} f(p) \geq c_{1}+\operatorname{Re} f(e)>c_{1}+\frac{\operatorname{Re} f(e)}{2}>\operatorname{Re} f(k)
$$

Let $c=c_{1}+\frac{\operatorname{Re} f(e)}{2}$.

Corollary 18.2.6 In the situation of the above theorem, there exist real numbers $c, d$ such that $\operatorname{Re} f(p)>d>c>\operatorname{Re} f(k)$ for all $k \in K$.

Proof: From the theorem, there exists $\hat{c}$ such that $\operatorname{Re} f(p)>\hat{c}>\operatorname{Re} f(k)$ for all $k \in$ $K$. Thus $\operatorname{Re} f(p)>\hat{c} \geq \sup _{k \in K} \operatorname{Re} f(k)$. Now choose $d, c$ such that $f(p)>d>c>\hat{c} \geq$ $\sup _{k \in K} \operatorname{Re} f(k)>f(k)$.

Note that if the field of scalars comes from $\mathbb{R}$ rather than $\mathbb{C}$ there is no essential change to the above conclusions. Just eliminate all references to the real part.

### 18.2.1 Convex Functionals

As an important application, this theorem gives the basis for proving something about lower semicontinuity of functionals.

Definition 18.2.7 Let $X$ be a Banach space and let $\phi: X \rightarrow(0, \infty]$ be convex and lower semicontinuous. This means whenever $x \in X$ and $\lim _{n \rightarrow \infty} x_{n}=x$,

$$
\phi(x) \leq \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right)
$$

Also assume $\phi$ is not identically equal to $\infty$.
Lemma 18.2.8 Let $X, Y$ be two Banach spaces. Then letting

$$
\|(x, y)\| \equiv \max \left(\|x\|_{X},\|y\|_{Y}\right)
$$

it follows $X \times Y$ is a Banach space and $\phi \in(X \times Y)^{\prime}$ if and only if there exist $x^{*} \in X^{\prime}$ and $y^{*} \in Y^{\prime}$ such that

$$
\phi((x, y))=x^{*}(x)+y^{*}(y) .
$$

The topology coming from this norm is called the strong topology.
Proof: Most of these conclusions are obvious. In particular it is clear $X \times Y$ is a Banach space with the given norm. Let $\phi \in(X \times Y)^{\prime}$. Also let $\pi_{X}(x, y) \equiv(x, 0)$ and $\pi_{Y}(x, y) \equiv$ $(0, y)$. Then each of $\pi_{X}$ and $\pi_{Y}$ is continuous and

$$
\begin{aligned}
\phi((x, y)) & =\phi\left(\pi_{X}+\pi_{Y}\right)((x, y)) \\
& =\phi((x, 0))+\phi((0, y))
\end{aligned}
$$

Thus $\phi \circ \pi_{X}$ and $\phi \circ \pi_{Y}$ are both continuous and their sum equals $\phi$. Let $x^{*}(x) \equiv \phi \circ \pi_{X}(x, 0)$ and let $y^{*} \equiv \phi \circ \pi_{Y}(x, 0)$. Then it is clear both $x^{*}$ and $y^{*}$ are continuous and linear defined on $X$ and $Y$ respectively. Also, if $\left(x^{*}, y^{*}\right) \in X^{\prime} \times Y^{\prime}$, then if $\phi((x, y)) \equiv x^{*}(x)+y^{*}(y)$, it follows $\phi \in(X \times Y)^{\prime}$. This proves the lemma.

Lemma 18.2.9 Let $\phi$ be a functional as described in Definition 18.2.7. Then $\phi$ is lower semicontinuous if and only if the epigraph of $\phi$ is closed in $X \times \mathbb{R}$ with the strong topology. Here the epigraph is defined as

$$
\operatorname{epi}(\phi) \equiv\{(x, y): y \geq \phi(x)\}
$$

In this case the functional is called strongly lower semicontinuous.
Proof: First suppose epi $(\phi)$ is closed and suppose $x_{n} \rightarrow x$. Let $l<\phi(x)$. Then $(x, l) \notin$ epi $(\phi)$ and so there exists $\delta>0$ such that if $|x-y|<\delta$ and $|\alpha-l|<\delta$, then $\alpha<\phi(y)$. This implies that if $|x-y|<\delta$ and $\alpha<l+\delta$, then the above holds. Therefore, $\left(x_{n}, \phi\left(x_{n}\right)\right)$, being in epi $(\phi)$ cannot satisfy both conditions,

$$
\left|x_{n}-x\right|<\delta, \phi\left(x_{n}\right)<l+\delta
$$

However, for all $n$ large enough, the first condition is satisfied. Consequently, for all $n$ large enough, $\phi\left(x_{n}\right) \geq l+\delta \geq l$. Thus

$$
\lim _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq l
$$

and since $l<\phi(x)$ is arbitrary, it follows

$$
\lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq \phi(x)
$$

Next suppose the condition about the liminf. If epi $(\phi)$ is not closed, then there exists $(x, l) \notin \mathrm{epi}(\phi)$ which is a limit point of points of epi $(\phi)$, Thus there exists $\left(x_{n}, l_{n}\right) \in \operatorname{epi}(\phi)$ such that $\left(x_{n}, l_{n}\right) \rightarrow(x, l)$ and so

$$
l=\lim \inf _{n \rightarrow \infty} l_{n} \geq \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq \phi(x)
$$

contradicting $(x, l) \notin$ epi $(\phi)$. This proves the lemma.
Definition 18.2.10 Let $\phi$ be convex and defined on $X$, a Banach space. Then $\phi$ is said to be weakly lower semicontinuous if $\mathrm{epi}(\phi)$ is closed in $X \times \mathbb{R}$ where a basis for the topology of $X \times \mathbb{R}$ consists of sets of the form $U \times(a, b)$ for $U$ a weakly open set in $X$.

Theorem 18.2.11 Let $\phi$ be a lower semicontinuous convex functional as described in Definition 18.2 .7 and let $X$ be a real Banach space. Then $\phi$ is also weakly lower semicontinuous.

Proof: By Lemma 18.2.9 epi $(\phi)$ is closed in $X \times \mathbb{R}$ with the strong topology as well as being convex. Letting $(z, l) \notin \operatorname{epi}(\phi)$, it follows from Theorem 18.2.5 and Lemma 18.2.8 there exists $\left(x^{*}, \alpha\right) \in X^{\prime} \times \mathbb{R}$ such that for some $c$

$$
x^{*}(z)+\alpha l>c>x^{*}(x)+\alpha \beta
$$

whenever $\beta \geq \phi(x)$. Consider $B_{\left\{\left(x^{*}, \alpha\right)\right\}}((z, l), r)$ where $r$ is chosen so small that if $(y, \gamma) \in$ $B_{\left\{\left(x^{*}, \alpha\right)\right\}}((z, l), r)$, then

$$
x^{*}(y)+\alpha \gamma>c .
$$

This shows that the complement of epi $(\phi)$ is weakly open and this proves the theorem.
Corollary 18.2.12 Let $\phi$ be a lower semicontinuous convex functional as described in Definition 18.2 .7 and let $X$ be a real Banach space. Then if $x_{n}$ converges weakly to $x$, it follows that

$$
\phi(x) \leq \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right)
$$

Proof: Let $l<\phi(x)$ so that $(x, l) \notin \operatorname{epi}(\phi)$. Then by Theorem 18.2.11 there exists $B \times(-\infty, l+\delta)$ such that $B$ is a weakly open set in $X$ containing $x$ and

$$
B \times(-\infty, l+\delta) \subseteq \operatorname{epi}(\phi)^{C}
$$

Thus $\left(x_{n}, \phi\left(x_{n}\right)\right) \notin B \times(-\infty, l+\delta)$ for all $n$. However, $x_{n} \in B$ for all $n$ large enough. Therefore, for those values of $n$, it must be the case that $\phi\left(x_{n}\right) \notin(-\infty, l+\delta)$ and so

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq l+\delta \geq l
$$

which shows, since $l<\phi(x)$ is arbitrary that

$$
\lim _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq \phi(x)
$$

This proves the corollary.
The following is a convenient fact which follows from the above.
Proposition 18.2.13 Let $A$ be a linear operator which maps a real normed linear space $\left(X,\|\cdot\|_{X}\right)$ to a real normed linear space $\left(Y,\|\cdot\|_{Y}\right)$. Then $x_{n} \rightarrow x$ strongly implies $A x_{n} \rightarrow A x$ if and only if whenever $x_{n} \rightarrow x$ weakly, it follows that $A x_{n} \rightarrow A x$ weakly.

Proof: $\Rightarrow$ Define $\phi(x) \equiv f(A x)$ where $f \in Y^{\prime}$. Then $\phi$ is convex and continuous. Therefore, if $x_{n} \rightarrow x$ weakly, then

$$
\phi(x)=f(A x) \leq \lim \inf _{n \rightarrow \infty} f\left(A x_{n}\right)=\lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right)
$$

Then substituting $-A$ for $A$,

$$
-f(A x) \leq \lim \inf _{n \rightarrow \infty} f\left(-A x_{n}\right), f(A x) \geq \lim \sup _{n \rightarrow \infty} f\left(A x_{n}\right)
$$

which shows that for each $f \in Y^{\prime}$,

$$
\lim \sup _{n \rightarrow \infty} f\left(A x_{n}\right) \leq f(A x) \leq \lim _{n \rightarrow \infty} f\left(A x_{n}\right)
$$

and so the second condition holds.
$\Leftarrow$ By the second condition, $x \rightarrow f(A x)$ satisfies the condition that if $x_{n} \rightarrow x$ weakly, then

$$
f(A x)=\lim _{n \rightarrow \infty} f\left(A x_{n}\right)
$$

If $A$ is not bounded, then there exists $x_{n},\left\|x_{n}\right\| \leq 1$ but $\left\|A x_{n}\right\| \geq n$. It follows that $x_{n} / \sqrt{n} \rightarrow 0$ and so $A\left(\frac{x_{n}}{\sqrt{n}}\right) \rightarrow 0$ weakly. Therefore, $A\left(\frac{x_{n}}{\sqrt{n}}\right)$ is bounded contrary to the construction which says that $\left\|A\left(\frac{x_{n}}{\sqrt{n}}\right)\right\| \geq \sqrt{n}$. Since $A$ is bounded, it must be continuous.

### 18.2.2 More Separation Theorems

There are other separation theorems which can be proved in a similar way. The next theorem considers the separation of an open convex set from a convex set.
Theorem 18.2.14 Let $A$ and $B$ be disjoint, convex and nonempty sets with $B$ open. Then there exists $f \in X^{\prime}$ such that

$$
\operatorname{Re} f(a)<\operatorname{Re} f(b)
$$

for all $a \in A$ and $b \in B$.

Proof: Let $b_{0} \in B, a_{0} \in A$. Then the set

$$
B-A+a_{0}-b_{0}
$$

is open, convex, contains 0 , and does not contain $a_{0}-b_{0}$. By Lemma 18.2.3 there exists $f \in X^{\prime}$ such that

$$
\operatorname{Re} f\left(a_{0}-b_{0}\right)>\operatorname{Re} f\left(b-a+a_{0}-b_{0}\right)
$$

for all $a \in A$ and $b \in B$. Therefore, for all $a \in A, b \in B$,

$$
\operatorname{Re} f(b)>\operatorname{Re} f(a)
$$

Before giving another separation theorem, here is a lemma.
Lemma 18.2.15 If $B$ is convex, then $\operatorname{int}(B) \equiv$ union of all open sets contained in $B$ is convex. Also, if $\operatorname{int}(B) \neq \emptyset$, then $B \subseteq \overline{\operatorname{int}(B)}$.

Proof: Suppose $x, y \in \operatorname{int}(B)$. Then there exists $r>0$ and a finite set $A \subseteq \Psi$ such that

$$
B_{A}(x, r), B_{A}(y, r) \subseteq B
$$

Let

$$
V \equiv \cup_{\lambda \in[0,1]} \lambda B_{A}(x, r)+(1-\lambda) B_{A}(y, r) .
$$

Then $V$ is open, $V \subseteq B$, and if $\lambda \in[0,1]$, then

$$
\lambda x+(1-\lambda) y \in V \subseteq B
$$

Therefore, $\operatorname{int}(B)$ is convex as claimed.
Now let $y \in B$ and $x \in \operatorname{int}(B)$. Let

$$
x \in B_{A}(x, r) \subseteq \operatorname{int}(B)
$$

and let $x_{\lambda} \equiv(1-\lambda) x+\lambda y$. Define the open cone,

$$
C \equiv \cup_{\lambda \in[0,1)} B_{A}\left(x_{\lambda},(1-\lambda) r\right)
$$

Thus $C$ is represented in the following picture.

I claim $C \subseteq B$ as suggested in the picture. To see this, let

$$
z \in B_{A}\left(x_{\lambda},(1-\lambda) r\right), \lambda \in(0,1)
$$

Then

$$
\rho_{A}\left(z-x_{\lambda}\right)<(1-\lambda) r
$$

and so

$$
\rho_{A}\left(\frac{z}{1-\lambda}-x-\frac{\lambda y}{1-\lambda}\right)<r
$$

Therefore,

$$
\frac{z}{1-\lambda}-\frac{\lambda y}{1-\lambda} \in B_{A}(x, r) \subseteq B .
$$

It follows

$$
(1-\lambda)\left(\frac{z}{1-\lambda}-\frac{\lambda y}{1-\lambda}\right)+\lambda y=z \in B
$$

and so $C \subseteq B$ as claimed. Now this shows $x_{\lambda} \in \operatorname{int}(B)$ and $\lim _{\lambda \rightarrow 1} x_{\lambda}=y$. Thus, $y \in \overline{\operatorname{int}(B)}$ and this proves the lemma.

Note this also shows that $\bar{B}=\overline{\operatorname{int}(B)}$.
Corollary 18.2.16 Let $A, B$ be convex, nonempty sets. Suppose $\operatorname{int}(B) \neq \emptyset$ and $A \cap \operatorname{int}(B)=$ $\emptyset$. Then there exists $f \in X^{\prime}, f \neq 0$, such that for all $a \in A$ and $b \in B$,

$$
\operatorname{Re} f(b) \geq \operatorname{Re} f(a)
$$

Proof: By Theorem 18.2.14, there exists $f \in X^{\prime}$ such that for all $b \in \operatorname{int}(B)$, and $a \in A$,

$$
\operatorname{Re} f(b)>\operatorname{Re} f(a)
$$

Thus, in particular, $f \neq 0$. By Lemma 18.2.15, if $b \in B$ and $a \in A$,

$$
\operatorname{Re} f(b) \geq \operatorname{Re} f(a)
$$

This proves the theorem.
Lemma 18.2.17 If $X$ is a topological Hausdorff space then compact implies closed.
Proof: Let $K$ be compact and suppose $K^{C}$ is not open. Then there exists $p \in K^{C}$ such that

$$
V_{p} \cap K \neq \emptyset
$$

for all open sets $V_{p}$ containing $p$. Let

$$
\mathscr{C}=\left\{\left(\bar{V}_{p}\right)^{C}: V_{p} \text { is an open set containing } p\right\}
$$

Then $\mathscr{C}$ is an open cover of $K$ because if $q \in K$, there exist disjoint open sets $V_{p}$ and $V_{q}$ containing $p$ and $q$ respectively. Thus $q \in\left(\bar{V}_{p}\right)^{C}$. This is an example of an open cover of $K$ which has no finite subcover, contradicting the assumption that $K$ is compact. This proves the lemma.

Lemma 18.2.18 If $X$ is a locally convex topological vector space, and if every point is a closed set, then the seminorms and $X^{\prime}$ separate the points. This means if $x \neq y$, then for some $\rho \in \Psi$,

$$
\rho(x-y) \neq 0
$$

and for some $f \in X^{\prime}$,

$$
f(x) \neq f(y) .
$$

In this case, X is a Hausdorff space.
Proof: Let $x \neq y$. Then by Theorem 18.2.5, there exists $f \in X^{\prime}$ such that $f(x) \neq f(y)$. Thus $X^{\prime}$ separates the points. Since $f \in X^{\prime}$, Theorem 18.1.6 implies

$$
|f(z)| \leq C \rho_{A}(z)
$$

for some $A$ a finite subset of $\Psi$. Thus

$$
0<|f(x-y)| \leq C \rho_{A}(x-y)
$$

and so $\rho(x-y) \neq 0$ for some $\rho \in A \subseteq \Psi$. Now to show $X$ is Hausdorff, let

$$
0<r<\rho(x-y) 2^{-1}
$$

Then the two disjoint open sets containing $x$ and $y$ respectively are

$$
B_{\rho}(x, r) \text { and } B_{\rho}(y, r) .
$$

This proves the lemma.

### 18.3 The Weak And Weak* Topologies

The weak and weak $*$ topologies are examples which make the underlying vector space into a topological vector space. This section gives a description of these topologies. Unless otherwise specified, $X$ is a locally convex topological vector space. For $G$ a finite subset of $X^{\prime}$ define $\delta_{G}: X \rightarrow[0, \infty)$ by

$$
\delta_{G}(x)=\max \{|f(x)|: f \in G\} .
$$

Lemma 18.3.1 The functions $\delta_{G}$ for $G$ a finite subset of $X^{\prime}$ are seminorms and the sets

$$
B_{G}(x, r) \equiv\left\{y \in X: \delta_{G}(x-y)<r\right\}
$$

form a basis for a topology on $X$. Furthermore, $X$ with this topology is a locally convex topological vector space. If each point in $X$ is a closed set, then the same is true of $X$ with respect to this new topology.

Proof: It is obvious that the functions $\delta_{G}$ are seminorms and therefore the proof that the sets $B_{G}(x, r)$ form a basis for a topology is the same as in Theorem 18.1.2. To see every point is a closed set in this new topology, assuming this is true for $X$ with the original
topology, use Lemma 18.2 .18 to assert $X^{\prime}$ separates the points. Let $x \in X$ and let $y \neq x$. There exists $f \in X^{\prime}$ such that $f(x) \neq f(y)$. Let $G=\{f\}$ and consider

$$
B_{G}(y,|f(x-y)| / 2)
$$

Then this open set does not contain $x$. Thus $\{x\}^{C}$ is open and so $\{x\}$ is closed. This proves the Lemma.

This topology for $X$ is called the weak topology for $X$. For $F$ a finite subset of $X$, define $\gamma_{F}: X^{\prime} \rightarrow[0, \infty)$ by

$$
\gamma_{F}(f)=\max \{|f(x)|: x \in F\}
$$

Lemma 18.3.2 The functions $\gamma_{F}$ for $F$ a finite subset of $X$ are seminorms and the sets

$$
B_{F}(f, r) \equiv\left\{g \in X^{\prime}: \gamma_{F}(f-g)<r\right\}
$$

form a basis for a topology on $X^{\prime}$. Furthermore, $X^{\prime}$ with this topology is a locally convex topological vector space having the property that every point is a closed set.

Proof: The proof is similar to that of Lemma 18.3 .1 but there is a difference in the part where every point is shown to be a closed set. Let $f \in X^{\prime}$ and let $g \neq f$. Thus there exists $x \in X$ such that $f(x) \neq g(x)$. Let $F=\{x\}$. Then

$$
B_{F}(g,|(f-g)(x)| / 2)
$$

contains $g$ but not $f$. Thus $\{f\}^{C}$ is open and so $\{f\}$ is closed.
Note that it was not necessary to assume points in $X$ are closed sets to get this.
The topology for $X^{\prime}$ just described is called the weak $*$ topology. In terms of Theorem 18.1.7 the weak topology is obtained by letting $Y=X^{\prime}$ in that theorem while the weak $*$ topology is obtained by letting $Y=X$ with the understanding that $X$ is a vector space of linear functionals on $X^{\prime}$ defined by

$$
x\left(x^{*}\right) \equiv x^{*}(x)
$$

By Theorem 18.2.5, there is a useful result which follows immediately.
Theorem 18.3.3 Let $K$ be closed and convex in a Banach space $X$. Then it is also weakly closed. Furthermore, if $p \notin K$, there exists $f \in X^{\prime}$ such that

$$
\begin{equation*}
\operatorname{Re} f(p)>c>\operatorname{Re} f(k) \tag{18.3.8}
\end{equation*}
$$

for all $k \in K$. If $K^{*}$ is closed and convex in the dual of a Banach space, $X^{\prime}$, then it is also weak $*$ closed.

Proof: By Theorem 18.2.5 there exists $f \in X^{\prime}$ such that 18.3 .8 holds. Therefore, letting $A=\{f\}$, it follows that for $r$ small enough, $B_{A}(p, r) \cap K=\emptyset$. Thus $K$ is weakly closed. This establishes the first part.

For the second part, the seminorms for the weak $*$ toplogy are determined from $X$ and the continuous linear functionals are of the form $x^{*} \rightarrow x^{*}(x)$ where $x \in X$. Thus if $p^{*} \notin K^{*}$, it follows from Theorem 18.2.5 there exists $x \in X$ such that

$$
\operatorname{Re} p^{*}(x)>c>\operatorname{Re} k^{*}(x)
$$

for all $k^{*} \in K^{*}$. Therefore, letting $A=\{x\}, B_{A}\left(p^{*}, r\right) \cap K^{*}=\emptyset$ whenever $r$ is small enough and this shows $K^{*}$ is weak $*$ closed.

### 18.4 Mean Ergodic Theorem

The following theorem is called the mean ergodic theorem.
Theorem 18.4.1 Let $(\Omega, \mathscr{S}, \mu)$ be a finite measure space and let $T: \Omega \rightarrow \Omega$ satisfy

$$
T^{-1}(E) \in \mathscr{S}, T(E) \in \mathscr{S}
$$

for all $E \in \mathscr{S}$. Also suppose for all positive integers, $n$, that

$$
\mu\left(T^{-n}(E)\right) \leq K \mu(E)
$$

For $f \in L^{p}(\Omega)$, and $p>1$, let

$$
\begin{equation*}
T^{*} f \equiv f \circ T \tag{18.4.9}
\end{equation*}
$$

Then $T^{*} \in \mathscr{L}\left(L^{p}(\Omega), L^{p}(\Omega)\right)$, the continuous linear mappings form $L^{p}(\Omega)$ to itself with

$$
\begin{equation*}
\left\|T^{* n}\right\| \leq K^{1 / p} \tag{18.4.10}
\end{equation*}
$$

Defining $A_{n} \in \mathscr{L}\left(L^{p}(\Omega), L^{p}(\Omega)\right)$ by

$$
A_{n} \equiv \frac{1}{n} \sum_{k=0}^{n-1} T^{* k}
$$

there exists $A \in \mathscr{L}\left(L^{p}(\Omega), L^{p}(\Omega)\right)$ such that for all $f \in L^{p}(\Omega)$,

$$
\begin{equation*}
A_{n} f \rightarrow A f \text { weakly } \tag{18.4.11}
\end{equation*}
$$

and $A$ is a projection, $A^{2}=A$, onto the space of all $f \in L^{p}(\Omega)$ such that $T^{*} f=f$. (The invariant functions.) The norm of $A$ satisfies

$$
\begin{equation*}
\|A\| \leq K^{1 / p} \tag{18.4.12}
\end{equation*}
$$

Proof: To begin with, it follows from simple considerations that

$$
\int\left|\mathscr{X}_{A}\left(T^{n}(\omega)\right)\right|^{p} d \mu=\int\left|\mathscr{X}_{T^{-n}(A)}(\omega)\right|^{p} d \mu=\mu\left(T^{-n}(A)\right) \leq K \mu(A)
$$

Hence

$$
\left\|T^{* n}\left(\mathscr{X}_{A}\right)\right\| \leq K^{1 / p} \mu(A)^{1 / p}=K^{1 / p}\left\|\mathscr{X}_{A}\right\|_{L^{p}}
$$

Next suppose you have a simple function $s(\omega)=\sum_{k=1}^{n} \mathscr{X}_{A_{i}}(\omega) c_{i}$ where we assume the $A_{i}$ are disjoint. From the above,

$$
\begin{aligned}
\int\left|\sum_{k=1}^{n} \mathscr{X}_{A_{i}}\left(T^{m}(\omega)\right) c_{i}\right|^{p} d \mu & =\int \sum_{k=1}^{n} \mathscr{X}_{A_{i}}\left(T^{m}(\omega)\right)^{p}\left|c_{i}\right|^{p} d \mu \\
& \leq \sum_{k=1}^{n} K \mu\left(A_{i}\right)\left|c_{i}\right|^{p}=K \int|s|^{p} d \mu
\end{aligned}
$$

and so

$$
\left\|T^{* m} s\right\| \leq K^{1 / p}\|s\|
$$

and so the density of the simple functions implies that $\left\|T^{* m}\right\| \leq K^{1 / p}$.
Next let

$$
M \equiv\left\{g \in L^{p}(\Omega):\left\|A_{n} g\right\|_{p} \rightarrow 0\right\}
$$

It follows from 18.4.10 that $M$ is a closed subspace of $L^{p}(\Omega)$ containing $\left(I-T^{*}\right)\left(L^{p}(\Omega)\right)$. This is shown next.

Claim 1: $M$ is a closed subspace which contains $\left(I-T^{* m}\right)\left(L^{p}(\Omega)\right)$.
First it is shown that this is true if $m=1$ and then it will be observed that the same argument would work for any positive integer $m$.

$$
\begin{aligned}
A_{n}\left(f-T^{*} f\right) & \equiv \frac{1}{n} \sum_{k=0}^{n-1} T^{* k} f-T^{* k+1} f \\
& =\frac{1}{n} \sum_{k=0}^{n-1} T^{* k} f-\frac{1}{n} \sum_{k=1}^{n} T^{* k} f=\frac{1}{n}\left(f-T^{* n} f\right)
\end{aligned}
$$

Hence

$$
\left\|A_{n}\left(f-T^{*} f\right)\right\|_{p} \leq \frac{1}{n}\left(\|f\|_{p}+\left\|T^{* n} f\right\|_{p}\right) \leq \frac{1}{n}\left(\|f\|_{p}+K^{1 / p}\|f\|_{p}\right)
$$

and this clearly converges to 0 . In fact, the same argument shows that $M$ contains the set $\left(I-T^{* m}\right)\left(L^{p}(\Omega)\right)$ for any $m$. Now suppose $g_{n} \in M$ and $g_{n} \rightarrow g$. Does it follow that $g \in M$ also? Note that $T^{* m}$ is clearly linear. Thus

$$
\left\|T^{* m} g\right\| \leq\left\|T^{* m} g-T^{* m} g_{n}\right\|+\left\|T^{* m} g_{n}\right\| \leq K^{1 / p}\left\|g-g_{n}\right\|+\left\|T^{* m} g_{n}\right\|
$$

Now pick $n$ large enough that $\left\|g_{n}-g\right\|<\varepsilon /\left(2 K^{1 / p}\right)$ so that

$$
\left\|T^{* m} g\right\| \leq \frac{\varepsilon}{2}+\left\|T^{* m} g_{n}\right\|
$$

Then for all $m$ large enough, the right side of the above is less than $\varepsilon$ and this shows that $g \in M$. Note that $M$ is also a subspace and so it is a closed subspace.

Claim 2: If $A_{n_{k}} f \rightarrow g$ weakly and $A_{m_{k}} f \rightarrow h$ weakly, then $g=h$.
It is first shown that if $\xi \in L^{p^{\prime}}(\Omega)$ and $\int \xi g d \mu=0$ for all $g \in M$, then $\int \xi(g-h) d \mu=$ 0.

If $\xi \in L^{p^{\prime}}(\Omega)$ is such that $\int \xi g d \mu=0$ for all $g \in M$, then since $M \supseteq\left(I-T^{* n}\right)\left(L^{p}(\Omega)\right)$, it follows that for all $k \in L^{p}(\Omega)$,

$$
\int \xi k d \mu=\int\left(\xi T^{* n} k+\xi\left(I-T^{* n}\right) k\right) d \mu=\int \xi T^{* n} k d \mu
$$

and so from the definition of $A_{n}$ as an average, for such $\xi$,

$$
\begin{equation*}
\int \xi k d \mu=\int \xi A_{n} k d \mu \tag{18.4.13}
\end{equation*}
$$

Since $A_{n_{k}} f \rightarrow g$ weakly and $A_{m_{k}} f \rightarrow h$ weakly. Then 18.4.13 shows that

$$
\begin{equation*}
\int \xi g d \mu=\lim _{k \rightarrow \infty} \int \xi A_{n_{k}} f d \mu=\int \xi f d \mu=\lim _{k \rightarrow \infty} \int \xi A_{m_{k}} f d \mu=\int \xi h d \mu . \tag{18.4.14}
\end{equation*}
$$

Thus for these special $\xi$, it follows that

$$
\begin{equation*}
\int \xi(g-h) d \mu=0 . \tag{18.4.15}
\end{equation*}
$$

Next observe that for each fixed $n$, if $n_{k} \rightarrow \infty$,

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|T^{* n} A_{n_{k}} f-A_{n_{k}} f\right\|=0 \tag{18.4.16}
\end{equation*}
$$

this follows like the arguments given above in Claim 1. Note that if $L \in \mathscr{L}(X, X)$ and $x_{n} \rightarrow x$ weakly in $X$, then for $\phi \in X^{\prime}$

$$
\left\langle\phi, L x_{n}\right\rangle=\left\langle L^{*} \phi, x_{n}\right\rangle \rightarrow\left\langle L^{*} \phi, x\right\rangle=\langle\phi, L x\rangle
$$

and so $L x_{n} \rightarrow L x$ weakly. Therefore, this simple observation along with the above strong convergence 18.4.16 implies

$$
T^{* n} g=\text { weak } \lim _{k \rightarrow \infty} T^{* n} A_{n_{k}} f=\text { weak } \lim _{k \rightarrow \infty} A_{n_{k}} f=g
$$

Similarly $T^{* n} h=h$ where $A_{m_{k}} f \rightarrow h$ weakly. It follows that $A_{n}(g-h)=g-h$ so if $g \neq h$, then $g-h \notin M$ because

$$
A_{n}(g-h) \rightarrow g-h \neq 0
$$

It follows that since $M$ is a closed subspace, there exists $\xi \in L^{p^{\prime}}(\Omega)$ such that

$$
\int \xi(g-h) d \mu \neq 0
$$

but $\int \xi k d \mu=0$ for all $k \in M$, contradicting 18.4.15. This verifies Claim 2.
Now

$$
\begin{align*}
\left\|A_{n} f\right\|_{p} & =\left(\int\left|\frac{1}{n} \sum_{k=0}^{n-1} f\left(T^{k} \omega\right)\right|^{p} d \mu\right)^{1 / p} \leq \frac{1}{n} \sum_{k=0}^{n-1}\left(\int\left|f\left(T^{k} \omega\right)\right|^{p} d \mu\right)^{1 / p} \\
& =\frac{1}{n} \sum_{k=0}^{n-1}\left\|T^{* k} f\right\|_{p} \leq \frac{1}{n} \sum_{k=0}^{n-1} K^{1 / p}\|f\|_{p}=K^{1 / p}\|f\|_{p} \tag{18.4.17}
\end{align*}
$$

Hence, by the Eberlein Smulian theorem, Theorem 17.5.12, in case $p>1$, there is a subsequence for which $A_{n} f$ converges weakly in $L^{p}(\Omega)$. From the above, it follows that the original sequence must converge. That is, $A_{n} f$ converges weakly for each $f \in L^{p}(\Omega)$. Let $A f$ denote this weak limit. Then it is clear that $A$ is linear because this is true for each $A_{n}$. What of the claim about the estimate? From weak lower semicontinuity of the norm, Corollary 18.2.12,

$$
\|A f\|_{p} \leq \lim \inf _{n \rightarrow \infty}\left\|A_{n} f\right\| \leq K^{1 / p}\|f\|_{p}
$$

### 18.5 The Tychonoff And Schauder Fixed Point Theorems

First we give a proof of the Schauder fixed point theorem which is an infinite dimensional generalization of the Brouwer fixed point theorem. This is a theorem which lives in Banach space. After this, we give a generalization to locally convex topological vector spaces where the theorem is sometimes called Tychonoff's theorem. First here is an interesting example [55].

Exercise 18.5.1 Let $B$ be the closed unit ball in a separable Hilbert space $H$ which is infinite dimensional. Then there exists continuous $f: B \rightarrow B$ which has no fixed point.

Let $\left\{e_{k}\right\}_{k=1}^{\infty}$ be a complete orthonormal set in $H$. Let $L \in \mathscr{L}(H, H)$ be defined as follows. $L e_{k}=e_{k+1}$ and then extend linearly. Then in particular,

$$
L\left(\sum_{i} x_{i} e_{i}\right)=\sum_{i} x_{i} e_{i+1}
$$

Then it is clear that $L$ preserves norms and so it is linear and continuous. Note how this would not work at all if the Hilbert space were finite dimensional. Then define $f(x)=$ $\frac{1}{2}\left(1-\|x\|_{H}\right) e_{1}+L x$. Then if $\|x\| \leq 1$,

$$
\|f(x)\|=\frac{1}{2}(1-\|x\|)^{2}+\|L x\|^{2}=\frac{1}{2}(1-\|x\|)^{2}+\|x\|^{2}=\frac{1}{2}\|x\|^{2}+\frac{1}{2} \leq 1
$$

and so $f: B \rightarrow B$ yet has no fixed point because if it did, you would need to have

$$
x=\frac{1}{2}\left(1-\|x\|_{H}\right) e_{1}+L x
$$

and so

$$
\begin{aligned}
&\|x\|^{2}= \frac{1}{4}(1-\|x\|)^{2}+\|L x\|^{2}=\frac{1}{4}(1-\|x\|)^{2}+\|L x\|^{2} \\
&= \frac{1}{4}+\frac{5}{4}\|x\|^{2}-\frac{1}{2}\|x\| \\
& \frac{1}{2}\|x\|=\frac{1}{4}+\frac{1}{4}\|x\|^{2}
\end{aligned}
$$

this requires $\|x\|=1$. But then you would need to have $x=L x$ which is not so because if $x$ is in the closure of the span of $\left\{e_{i}\right\}_{i=m}^{\infty}$, such that the first nonzero Fourier coefficient is the $m^{t h}$, then $L x$ is in the closure of the span of $\left\{e_{i}\right\}_{i=m+1}^{\infty}$.

This shows you need something other than continuity if you want to get a fixed point. This also shows that there is a retraction of $B$ onto $\partial B$ in any infinite dimensional separable Hilbert space. You get it the usual way. Take the line from $x$ to $f(x)$ and the retraction will be the function which gives the point on $\partial B$ which is obtained by extending this line till it hits the boundary of $B$. Thus for Hilbert spaces, those which have $\partial B$ a retraction of $B$
are exactly those which are infinite dimensional. The above reference claims this retraction property holds for any infinite dimensional normed linear space. I think it is fairly clear to see from the above example that this is not a surprising assertion. Recall that one of the proofs of the Brouwer fixed point theorem used the non existence of such a retraction, obtained using integration theory, to prove the theorem.

We let $K$ be a closed convex subset of $X$ a Banach space and let

$$
f \text { be continuous, } f: K \rightarrow K \text {, and } \overline{f(K)} \text { is compact. }
$$

Lemma 18.5.2 For each $r>0$ there exists a finite set of points

$$
\left\{y_{1}, \cdots, y_{n}\right\} \subseteq \overline{f(K)}
$$

and continuous functions $\psi_{i}$ defined on $\overline{f(K)}$ such that for $x \in \overline{f(K)}$,

$$
\begin{gather*}
\sum_{i=1}^{n} \psi_{i}(x)=1  \tag{18.5.18}\\
\psi_{i}(x)=0 \text { if } x \notin B\left(y_{i}, r\right), \psi_{i}(x)>0 \text { if } x \in B\left(y_{i}, r\right)
\end{gather*}
$$

If

$$
\begin{equation*}
f_{r}(x) \equiv \sum_{i=1}^{n} y_{i} \psi_{i}(f(x)) \tag{18.5.19}
\end{equation*}
$$

then whenever $x \in K$,

$$
\left\|f(x)-f_{r}(x)\right\| \leq r
$$

Proof: Using the compactness of $\overline{f(K)}$, there exists

$$
\left\{y_{1}, \cdots, y_{n}\right\} \subseteq \overline{f(K)} \subseteq K
$$

such that

$$
\left\{B\left(y_{i}, r\right)\right\}_{i=1}^{n}
$$

covers $\overline{f(K)}$. Let

$$
\phi_{i}(y) \equiv\left(r-\left\|y-y_{i}\right\|\right)^{+}
$$

Thus $\phi_{i}(y)>0$ if $y \in B\left(y_{i}, r\right)$ and $\phi_{i}(y)=0$ if $y \notin B\left(y_{i}, r\right)$. For $x \in \overline{f(K)}$, let

$$
\psi_{i}(x) \equiv \phi_{i}(x)\left(\sum_{j=1}^{n} \phi_{j}(x)\right)^{-1}
$$

Then 18.5.18 is satisfied. Indeed the denominator is not zero because $x$ is in one of the $B\left(y_{i}, r\right)$. Thus it is obvious that the sum of these equals 1 on $K$. Now let $f_{r}$ be given by 18.5.19 for $x \in K$. For such $x$,

$$
f(x)-f_{r}(x)=\sum_{i=1}^{n}\left(f(x)-y_{i}\right) \psi_{i}(f(x))
$$

Thus

$$
\begin{gathered}
f(x)-f_{r}(x)=\sum_{\left\{i: f(x) \in B\left(y_{i}, r\right)\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x)) \\
+\sum_{\left\{i: f(x) \notin B\left(y_{i}, r\right)\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x)) \\
=\sum_{\left\{i: f(x)-y_{i} \in B(0, r)\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x))= \\
\sum_{\left\{i: f(x)-y_{i} \in B(0, r)\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x))+\sum_{\left\{i: f(x) \notin B\left(y_{i}, r\right)\right\}} 0 \psi_{i}(f(x)) \in B(0, r)
\end{gathered}
$$

because $0 \in B(0, r), B(0, r)$ is convex, and 18.5.18. It is just a convex combination of things in $B(0, r)$.

Note that we could have had the $y_{i}$ in $f(K)$ in addition to being in $\overline{f(K)}$. This would make it possible to eliminate the assumption that $K$ is closed later on. All you really need is that $K$ is convex.

We think of $f_{r}$ as an approximation to $f$. In fact it is uniformly within $r$ of $f$ on $K$. The next lemma shows that this $f_{r}$ has a fixed point. This is the main result and comes from the Brouwer fixed point theorem in $\mathbb{R}^{n}$. It is an approximate fixed point.

Lemma 18.5.3 For each $r>0$, there exists $x_{r} \in$ convex hull of $\overline{f(K)} \subseteq K$ such that

$$
f_{r}\left(x_{r}\right)=x_{r},\left\|f_{r}(x)-f(x)\right\|<r \text { for all } x
$$

Proof: If $f_{r}\left(x_{r}\right)=x_{r}$ and

$$
x_{r}=\sum_{i=1}^{n} a_{i} y_{i}
$$

for $\sum_{i=1}^{n} a_{i}=1$ and the $y_{i}$ described in the above lemma, we need

$$
f_{r}\left(x_{r}\right)=\sum_{i=1}^{n} y_{i} \psi_{i}\left(f\left(x_{r}\right)\right)=\sum_{j=1}^{n} y_{j} \psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}\right)\right)=\sum_{j=1}^{n} a_{j} y_{j}=x_{r}
$$

Also, if this is satisfied, then we have the desired fixed point.
This will be satisfied if for each $j=1, \cdots, n$,

$$
\begin{equation*}
a_{j}=\psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}\right)\right) \tag{18.5.20}
\end{equation*}
$$

so, let

$$
\Sigma_{n-1} \equiv\left\{\mathbf{a} \in \mathbb{R}^{n}: \sum_{i=1}^{n} a_{i}=1, a_{i} \geq 0\right\}
$$

and let $h: \Sigma_{n-1} \rightarrow \Sigma_{n-1}$ be given by

$$
h(\mathbf{a})_{j} \equiv \psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}\right)\right)
$$

Since $h$ is a continuous function of $\mathbf{a}$, the Brouwer fixed point theorem applies and there exists a fixed point for $h$ which is a solution to 18.5.20.

The following is the Schauder fixed point theorem.
Theorem 18.5.4 Let $K$ be a closed and convex subset of $X$, a normed linear space. Let $f: K \rightarrow K$ be continuous and suppose $\overline{f(K)}$ is compact. Then $f$ has a fixed point.

Proof: Recall that $f\left(x_{r}\right)-f_{r}\left(x_{r}\right) \in B(0, r)$ and $f_{r}\left(x_{r}\right)=x_{r}$ with $x_{r} \in$ convex hull of $\overline{f(K)} \subseteq K$.

There is a subsequence, still denoted with subscript $r$ such that $f\left(x_{r}\right) \rightarrow x \in \overline{f(K)}$. Note that the fact that $K$ is convex is what makes $f$ defined at $x_{r} . x_{r}$ is in the convex hull of $\overline{f(K)} \subseteq K$. This is where we use $K$ convex. Then since $f_{r}$ is uniformly close to $f$, it follows that $f_{r}\left(x_{r}\right)=x_{r} \rightarrow x$ also. Thus $x_{r}$ converges strongly to $x$. Therefore,

$$
f(x)=\lim _{r \rightarrow 0} f\left(x_{r}\right)=\lim _{r \rightarrow 0} f_{r}\left(x_{r}\right)=\lim _{r \rightarrow 0} x_{r}=x
$$

We usually have in mind the mapping defined on a Banach space. However, the completeness was never used. Thus the result holds in a normed linear space.

There is a nice corollary of this major theorem which is called the Schaefer fixed point theorem or the Leray Schauder alterative principle [55].

Theorem 18.5.5 Let $f: X \rightarrow X$ be a compact map. Then either

1. There is a fixed point for $t f$ for all $t \in[0,1]$ or
2. For every $r>0$, there exists a solution to $x=t f(x)$ for some $t \in(0,1)$ such that $\|x\|>r$. (The solutions to $x=t f(x)$ for $t \in(0,1)$ are unbounded.)

Proof: Suppose there is $t_{0} \in[0,1]$ such that $t_{0} f$ has no fixed point. Then $t_{0} \neq 0 . t_{0} f$ obviously has a fixed point if $t_{0}=0$. Thus $t_{0} \in(0,1]$. Then let $r_{M}$ be the radial retraction onto $\overline{B(0, M)}$. By Schauder's theorem there exists $x \in \overline{B(0, M)}$ such that $t_{0} r_{M} f(x)=x$. Then if $\|f(x)\| \leq M, r_{M}$ has no effect and so $t_{0} f(x)=x$ which is assumed not to take place. Hence $\|f(x)\|>M$ and so $\left\|r_{M} f(x)\right\|=M$ so $\|x\|=t_{0} M$. Also $t_{0} r_{M} f(x)=t_{0} M \frac{f(x)}{\|f(x)\|}=$ $x$ and so $x=\hat{t} f(x), \hat{t}=t_{0} \frac{M}{\|f(x)\|}<1$. Since $M$ is arbitrary, it follows that the solutions to $x=t f(x)$ for $t \in(0,1)$ are unbounded. It was just shown that there is a solution to $x=\hat{t} f(x), \hat{t}<1$ such that $\|x\|=t_{0} M$ where $M$ is arbitrary. Thus the second of the two alternatives holds.

Proof: Suppose that alternative 2 does not hold and yet alternative 1 also fails to hold. Then there is $M_{0}$ such that if you have any solution to $x=t f(x)$ for $t \in(0,1)$, then $\|x\| \leq$ $M_{0}$. Nevertheless, there is $t \in(0,1]$ for which there is no fixed point for $t f$. (obviously there is a fixed point for $t=0$.) However, there is $x$ such that for $M>M_{0}$,

$$
x=t\left(r_{M} f(x)\right)=t \frac{M f(x)}{\|f(x)\|}=\hat{t} f(x), \hat{t}=\frac{M}{\|f(x)\|} t<t
$$

We must have $\|f(x)\|>M$ and $r_{M} f(x)=\frac{M f(x)}{\|f(x)\|}$ since if $\|f(x)\| \leq M, r_{M} f(x)=f(x)$ and there would be a fixed point for this $t$. Thus, letting $M$ get larger and larger, there are
$t_{M} \in(0,1)$ and $x_{M},\left\|x_{M}\right\| \leq M_{0}$ such that $x_{M}=t_{M} f\left(x_{M}\right),\left\|f\left(x_{M}\right)\right\|>M$. However, $f$ is given to be a compact map so it takes $\overline{B\left(0, M_{0}\right)}$ to a compact set but this shows that $f$ must take this set to an unbounded set which is a contradiction. This results from assuming there is $t$ such that $t f$ fails to have a fixed point for some $t \in[0,1]$. Thus alternative 1 must hold.

Next this is considered in the more general setting of locally convex topological vector space. This is the Tychonoff fixed point theorem. In this theorem, $X$ will be a locally convex topological vector space in which every point is a closed set. Let $\mathscr{B}$ be the basis described earlier and let $\mathscr{B}_{0}$ consist of all sets of $\mathscr{B}$ which are of the form $B_{A}(0, r)$ where $A$ is a finite subset of $\Psi$ as described earlier. Note that for $U \in \mathscr{B}_{0}, U=-U$ and $U$ is convex. Also, if $U \in \mathscr{B}_{0}$, there exists $V \in \mathscr{B}_{0}$ such that

$$
V+V \subseteq U
$$

where

$$
V+V \equiv\left\{v_{1}+v_{2}: v_{i} \in V\right\}
$$

To see this, note

$$
B_{A}(0, r / 2)+B_{A}(0, r / 2) \subseteq B_{A}(0, r)
$$

We let $K$ be a closed convex subset of $X$ and let
$f$ be continuous, $f: K \rightarrow K$, and $\overline{f(K)}$ is compact.
Lemma 18.5.6 For each $U \in \mathscr{B}_{0}$, there exists a finite set of points

$$
\left\{y_{1} \cdots y_{n}\right\} \subseteq \overline{f(K)}
$$

and continuous functions $\psi_{i}$ defined on $\overline{f(K)}$ such that for $x \in \overline{f(K)}$,

$$
\begin{gather*}
\sum_{i=1}^{n} \psi_{i}(x)=1  \tag{18.5.21}\\
\psi_{i}(x)=0 \text { if } x \notin y_{i}+U, \psi_{i}(x)>0 \text { if } x \in y_{i}+U
\end{gather*}
$$

If

$$
\begin{equation*}
f_{U}(x) \equiv \sum_{i=1}^{n} y_{i} \psi_{i}(f(x)) \tag{18.5.22}
\end{equation*}
$$

then whenever $x \in K$,

$$
f(x)-f_{U}(x) \in U
$$

Proof: Let $U=B_{A}(0, r)$. Using the compactness of $\overline{f(K)}$, there exists

$$
\left\{y_{1} \cdots y_{n}\right\} \subseteq \overline{f(K)}
$$

such that

$$
\left\{y_{i}+U\right\}_{i=1}^{n}
$$

covers $\overline{f(K)}$. Let

$$
\phi_{i}(y) \equiv\left(r-\rho_{A}\left(y-y_{i}\right)\right)^{+} .
$$

Thus $\phi_{i}(y)>0$ if $y \in y_{i}+U$ and $\phi_{i}(y)=0$ if $y \notin y_{i}+U$. For $x \in \overline{f(K)}$, let

$$
\psi_{i}(x) \equiv \phi_{i}(x)\left(\sum_{j=1}^{n} \phi_{j}(x)\right)^{-1}
$$

Then 18.5 .21 is satisfied. Now let $f_{U}$ be given by 18.5.22 for $x \in K$. For such $x$,

$$
\begin{aligned}
& f(x)- f_{U}(x)=\sum_{\left\{i: f(x)-y_{i} \in U\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x)) \\
&+\sum_{\left\{i: f(x)-y_{i} \notin U\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x)) \\
&=\sum_{\left\{i: f(x)-y_{i} \in U\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x))= \\
& \sum_{\left\{i: f(x)-y_{i} \in U\right\}}\left(f(x)-y_{i}\right) \psi_{i}(f(x))+\sum_{\left\{i: f(x)-y_{i} \notin U\right\}} 0 \psi_{i}(f(x)) \in U
\end{aligned}
$$

because $0 \in U, U$ is convex, and 18.5.21.
We think of $f_{U}$ as an approximation to $f$.
Lemma 18.5.7 For each $U \in \mathscr{B}_{0}$, there exists $x_{U} \in$ convex hull of $\overline{f(K)} \subseteq K$ such that

$$
f_{U}\left(x_{U}\right)=x_{U}
$$

Proof: If $f_{U}\left(x_{U}\right)=x_{U}$ and

$$
x_{U}=\sum_{i=1}^{n} a_{i} y_{i}
$$

for $\sum_{i=1}^{n} a_{i}=1$, we need

$$
\sum_{j=1}^{n} y_{j} \psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}\right)\right)=\sum_{j=1}^{n} a_{j} y_{j}
$$

Also, if this is satisfied, then we have the desired fixed point. This will be satisfied if for each $j=1, \cdots, n$,

$$
\begin{equation*}
a_{j}=\psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}\right)\right) \tag{18.5.23}
\end{equation*}
$$

so, let

$$
\Sigma_{n-1} \equiv\left\{\mathbf{a} \in \mathbb{R}^{n}: \sum_{i=1}^{n} a_{i}=1, a_{i} \geq 0\right\}
$$

and let $h: \Sigma_{n-1} \rightarrow \Sigma_{n-1}$ be given by

$$
h(\mathbf{a})_{j} \equiv \psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}\right)\right) .
$$

Since $h$ is continuous, the Brouwer fixed point theorem applies and we see there exists a fixed point for $h$ which is a solution to 18.5.23.

Theorem 18.5.8 Let $K$ be a closed and convex subset of $X$, a locally convex topological vector space in which every point is closed. Let $f: K \rightarrow K$ be continuous and suppose $\overline{f(K)}$ is compact. Then $f$ has a fixed point.

Proof: First consider the following claim which will yield a candidate for the fixed point. Recall that $f\left(x_{U}\right)-f_{U}\left(x_{U}\right) \in U$ and $f_{U}\left(x_{U}\right)=x_{U}$ with $x_{U} \in$ convex hull of $\overline{f(K)} \subseteq$ $K$.

Claim: There exists $x \in \overline{f(K)}$ with the property that if $V \in \mathscr{B}_{0}$, there exists $U \subseteq V$, $U \in \mathscr{B}_{0}$, such that

$$
f\left(x_{U}\right) \in x+V
$$

Proof of the claim: If no such $x$ exists, then for each $x \in \overline{f(K)}$, there exists $V_{x} \in \mathscr{B}_{0}$ such that whenever $U \subseteq V_{x}$, with $U \in \mathscr{B}_{0}$,

$$
f\left(x_{U}\right) \notin x+V_{x} .
$$

Since $\overline{f(K)}$ is compact, there exist $x_{1}, \cdots, x_{n} \in \overline{f(K)}$ such that

$$
\left\{x_{i}+V_{x_{i}}\right\}_{i=1}^{n}
$$

cover $\overline{f(K)}$. Let

$$
U \in \mathscr{B}_{0}, U \subseteq \cap_{i=1}^{n} V_{x_{i}}
$$

and consider $x_{U}$.

$$
f\left(x_{U}\right) \in x_{i}+V_{x_{i}}
$$

for some $i$ because these sets cover $\overline{f(K)}$ and $f\left(x_{U}\right)$ is something in $\overline{f(K)}$. But $U \subseteq V_{x_{i}}$, a contradiction. This shows the claim.

Now I show $x$ is the desired fixed point. Let $W \in \mathscr{B}_{0}$ and let $V \in \mathscr{B}_{0}$ with

$$
V+V+V \subseteq W
$$

Since $f$ is continuous at $x$, there exists $V_{0} \in \mathscr{B}_{0}$ such that

$$
V_{0}+V_{0} \subseteq V
$$

and if

$$
y-x \in V_{0}+V_{0}
$$

then

$$
f(x)-f(y) \in V
$$

Using the claim, let $U \in \mathscr{B}_{0}, U \subseteq V_{0}$, such that

$$
f\left(x_{U}\right) \in x+V_{0}
$$

Then

$$
\begin{gathered}
x-x_{U}=x-f\left(x_{U}\right)+f\left(x_{U}\right)-f_{U}\left(x_{U}\right) \in V_{0}+U \\
\subseteq V_{0}+V_{0} \subseteq V
\end{gathered}
$$

and so

$$
\begin{aligned}
f(x)-x & =f(x)-f\left(x_{U}\right)+f\left(x_{U}\right)-f_{U}\left(x_{U}\right)+f_{U}\left(x_{U}\right)-x \\
& =f(x)-f\left(x_{U}\right)+f\left(x_{U}\right)-f_{U}\left(x_{U}\right)+x_{U}-x \\
& \subseteq V+U+V \subseteq W
\end{aligned}
$$

Since $W \in \mathscr{B}_{0}$ is arbitrary, it follows from Lemma 18.2.18 that $f(x)-x=0$.
As an example of the usefulness of this fixed point theorem, consider the following application to the theory of ordinary differential equations. In the context of this theorem, $X=C\left([0, T] ; \mathbb{R}^{n}\right)$, a Banach space with norm given by

$$
\|\mathbf{x}\| \equiv \max \{|\mathbf{x}(t)|: t \in[0, T]\}
$$

Theorem 18.5.9 Let $\mathbf{f}:[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be continuous and suppose there exists $L>0$ such that for all $\lambda \in(0,1)$, if

$$
\begin{equation*}
\mathbf{x}^{\prime}=\lambda \mathbf{f}(t, \mathbf{x}), \mathbf{x}(0)=\mathbf{x}_{0} \tag{18.5.24}
\end{equation*}
$$

for all $t \in[0, T]$, then $\|\mathbf{x}\|<L$. Then there exists a solution to

$$
\begin{equation*}
\mathbf{x}^{\prime}=\mathbf{f}(t, \mathbf{x}), \mathbf{x}(0)=\mathbf{x}_{0} \tag{18.5.25}
\end{equation*}
$$

for $t \in[0, T]$.
Proof: Let

$$
N \mathbf{x}(t) \equiv \int_{0}^{t} \mathbf{f}(s, \mathbf{x}(s)) d s
$$

Thus a solution to the initial value problem exists if there exists a solution to

$$
\mathbf{x}_{0}+N(\mathbf{x})=\mathbf{x}
$$

Let

$$
m \equiv \max \{|\mathbf{f}(t, \mathbf{x})|:(t, \mathbf{x}) \in[0, T] \times \overline{B(0, L)}\}, M \equiv\left|\mathbf{x}_{0}\right|+m T
$$

and let

$$
K \equiv\left\{\mathbf{x} \in C\left(0, T ; \mathbb{R}^{n}\right) \text { such that } \mathbf{x}(0)=\mathbf{x}_{0} \text { and }\|\mathbf{x}\| \leq M\right\}
$$

Now define

$$
A \mathbf{x} \equiv\left\{\begin{array}{l}
\mathbf{x}_{0}+N \mathbf{x} \text { if }\|N \mathbf{x}\| \leq M-\left|\mathbf{x}_{0}\right| \\
\mathbf{x}_{0}+\frac{\left(M-\left|\mathbf{x}_{0}\right| \mid N \mathbf{x}\right.}{\|N \mathbf{x}\|} \text { if }\|N \mathbf{x}\|>M-\left|\mathbf{x}_{0}\right|
\end{array}\right.
$$

Then $A$ is continuous and maps $X$ to $K$ because

$$
\|A \mathbf{x}\| \leq\left|\mathbf{x}_{0}\right|+\|N \mathbf{x}\| \leq M \text { if }\|N \mathbf{x}\| \leq M-\left|\mathbf{x}_{0}\right|
$$

and otherwise,

$$
\|A \mathbf{x}\| \leq\left|\mathbf{x}_{0}\right|+\left\|\frac{\left(M-\left|\mathbf{x}_{0}\right|\right) N \mathbf{x}}{\| N \mathbf{x}| |}\right\| \leq\left|\mathbf{x}_{0}\right|+M-\left|\mathbf{x}_{0}\right|=M
$$

Also $A(K)$ is equicontinuous because

$$
\mathbf{x}_{0}+N \mathbf{x}(t)-\left(\mathbf{x}_{0}+N \mathbf{x}\left(t_{1}\right)\right)=\int_{t_{1}}^{t} \mathbf{f}(s, \mathbf{x}(s)) d s
$$

and the integrand is bounded. Thus $\overline{A(K)}$ is a compact set in $X$ by the Ascoli Arzela theorem. By the Schauder fixed point theorem, $A$ has a fixed point, $\mathbf{x} \in K$.

If $\|N(\mathbf{x})\|>M-\left|\mathbf{x}_{0}\right|$, then

$$
\mathbf{x}_{0}+\lambda N(\mathbf{x})=\mathbf{x}
$$

where

$$
\lambda=\frac{\left(M-\left|\mathbf{x}_{0}\right|\right)}{\|N \mathbf{x}\|}<1
$$

and so 18.5 .24 holds. Therefore, by the assumed estimate on the solutions to 18.5 .24 , it follows that

$$
\|\mathbf{x}\|<L
$$

and so $\|N \mathbf{x}\| \leq m T=M-\left|\mathbf{x}_{0}\right|$, a contradiction. Therefore, it must be the case that

$$
\|N(\mathbf{x})\| \leq M-\left|\mathbf{x}_{0}\right|
$$

which implies that

$$
\mathbf{x}_{0}+N(\mathbf{x})=\mathbf{x}
$$

Since this is equivalent to 18.5 .25 , this proves the theorem.
Here is a neater proof which uses the Leray Schauder alternative, also called the Schaefer fixed point theorem presented above.

Theorem 18.5.10 Let $\mathbf{f}:[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be continuous and suppose there exists $L>0$ such that for all $\lambda \in(0,1)$, if

$$
\begin{equation*}
\mathbf{x}^{\prime}=\lambda \mathbf{f}(t, \mathbf{x}), \mathbf{x}(0)=\mathbf{x}_{0} \tag{18.5.26}
\end{equation*}
$$

for all $t \in[0, T]$, then $\|\mathbf{x}\|<L$. Then there exists a solution to

$$
\begin{equation*}
\mathbf{x}^{\prime}=\mathbf{f}(t, \mathbf{x}), \mathbf{x}(0)=\mathbf{x}_{0} \tag{18.5.27}
\end{equation*}
$$

for $t \in[0, T]$.

Proof: Let $F: X \rightarrow X$ where $X$ described above.

$$
F \mathbf{y}(t) \equiv \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}\right) d s
$$

Let $B$ be a bounded set in $X$. Then $\left|\mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}\right)\right|$ is bounded for $s \in[0, T]$ if $\mathbf{y} \in B$. Say $\left|\mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}\right)\right| \leq C_{B}$. Hence $F(B)$ is bounded in $X$. Also, for $\mathbf{y} \in B, s<t$,

$$
|F \mathbf{y}(t)-F \mathbf{y}(s)| \leq\left|\int_{s}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}\right) d s\right| \leq C_{B}|t-s|
$$

and so $F(B)$ is pre-compact by the Ascoli Arzela theorem. By the Schaefer fixed point theorem, there are two alternatives. Either there are unbounded solutions $\mathbf{y}$ to

$$
\lambda F(\mathbf{y})=\mathbf{y}
$$

for various $\lambda \in(0,1)$ or for all $\lambda \in[0,1]$, there is a fixed point for $\lambda F$. In the first case, there would be unbounded $\mathbf{y}_{\lambda}$ solving

$$
\mathbf{y}_{\lambda}(t)=\lambda \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}_{\lambda}(s)+\mathbf{x}_{0}\right) d s
$$

Then let $\mathbf{x}_{\lambda}(s) \equiv \mathbf{y}_{\lambda}(s)+\mathbf{x}_{0}$ and you get $\left\|\mathbf{x}_{\lambda}\right\|$ also unbounded for various $\lambda \in(0,1)$. The above implies

$$
\mathbf{x}_{\lambda}(t)-\mathbf{x}_{0}=\lambda \int_{0}^{t} \mathbf{f}\left(s, \mathbf{x}_{\lambda}(s)\right) d s
$$

so $\mathbf{x}_{\lambda}^{\prime}=\lambda \mathbf{f}\left(t, \mathbf{x}_{\lambda}\right), \mathbf{x}_{\lambda}(0)=\mathbf{x}_{0}$ and these would be unbounded for $\lambda \in(0,1)$ contrary to the assumption that there exists an estimate for these valid for all $\lambda \in(0,1)$. Hence the first alternative must hold and hence there is $\mathbf{y} \in X$ such that

$$
F \mathbf{y}=\mathbf{y}
$$

Then letting $\mathbf{x}(s) \equiv \mathbf{y}(s)+\mathbf{x}_{0}$, it follows that

$$
\mathbf{x}(t)-\mathbf{x}_{0}=\int_{0}^{t} \mathbf{f}(s, \mathbf{x}(s)) d s
$$

and so $\mathbf{x}$ is a solution to the differential equation on $[0, T]$.
Note that existence for solutions to 18.5 .24 is not assumed, only estimates of possible solutions. These estimates are called a-priori estimates. Also note this is a global existence theorem, not a local one for a solution defined on only a small interval.

### 18.6 A Variational Principle of Ekeland

Definition 18.6.1 A function $\phi: X \rightarrow(-\infty, \infty]$ is called proper if it is not constantly equal to $\infty$. Here $X$ is assumed to be a complete metric space. The function $\phi$ is lower semicontinuous if

$$
x_{n} \rightarrow x \text { implies } \phi(x) \leq \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right)
$$

It is bounded below if there is some constant $C$ such that $C \leq \phi(x)$ for all $x$.

The variational principle of Ekeland is the following theorem [55]. You start with an approximate minimizer $x_{0}$. It says there is $y_{\lambda}$ fairly close to $x_{0}$ such that if you subtract a "cone" from the value of $\phi$ at $y_{\lambda}$, then the resulting function is less than $\phi(x)$ for all $x \neq y_{\lambda}$. This cone is like a supporting plane for a convex function but pertains to functions which are certainly not convex.

Theorem 18.6.2 Let $X$ be a complete metric space and let $\phi: X \rightarrow(-\infty, \infty]$ be proper, lower semicontinuous and bounded below. Let $x_{0}$ be such that

$$
\phi\left(x_{0}\right) \leq \inf _{x \in X} \phi(x)+\varepsilon
$$

Then for every $\lambda>0$ there exists a $y_{\lambda}$ such that

1. $\phi\left(y_{\lambda}\right) \leq \phi\left(x_{0}\right)$
2. $d\left(y_{\lambda}, x_{0}\right) \leq \lambda$
3. $\phi\left(y_{\lambda}\right)-\frac{\varepsilon}{\lambda} d\left(x, y_{\lambda}\right)<\phi(x)$ for all $x \neq y_{\lambda}$

To motivate the proof, see the following picture which illustrates the first two steps. The $S_{i}$ will be sets in $X$ but are denoted symbolically by labeling them in $X \times(-\infty, \infty]$.

Then the end result of this iteration would be a picture like the following.

Thus you would have $\phi\left(y_{\lambda}\right)-\frac{\varepsilon}{\lambda} d\left(y_{\lambda}, x\right) \leq \phi(x)$ for all $x$ which is seen to be what is wanted.

Proof: Let $x_{1}=x_{0}$ and define

$$
S_{1} \equiv\left\{z \in X: \phi(z) \leq \phi\left(x_{1}\right)-\frac{\varepsilon}{\lambda} d\left(z, x_{1}\right)\right\}
$$

Then $S_{1}$ contains $x_{1}$ so it is nonempty. It is also clear that $S_{1}$ is a closed set. This follows from the lower semicontinuity of $\phi$. Let $x_{2}$ be a point of $S_{1}$, possibly different than $x_{1}$ and let

$$
S_{2} \equiv\left\{z \in X: \phi(z) \leq \phi\left(x_{2}\right)-\frac{\varepsilon}{\lambda} d\left(z, x_{2}\right)\right\}
$$

Continue in this way. Now let there be a sequence of points $\left\{x_{k}\right\}$ such that $x_{k} \in S_{k-1}$ and define $S_{k}$ by

$$
S_{k} \equiv\left\{z \in X: \phi(z) \leq \phi\left(x_{k}\right)-\frac{\varepsilon}{\lambda} d\left(z, x_{k}\right)\right\}
$$

where $x_{k}$ is some point of $S_{k-1}$. Then $x_{k}$ is a point of $S_{k}$. Will this yield a nested sequence of nonempty closed sets? Yes, it appears that it would because if $z \in S_{k}$ then

$$
\begin{aligned}
\phi(z) & \leq \phi\left(S_{k-1}\right)-\frac{\varepsilon}{\lambda} d\left(z, x_{k}\right) \leq\left(\phi\left(x_{k-1}\right)-\frac{\varepsilon}{\lambda} d\left(x_{k-1}, x_{k}\right)\right)-\frac{\varepsilon}{\lambda} d\left(z, x_{k}\right) \\
& \leq \phi\left(x_{k-1}\right)-\frac{\varepsilon}{\lambda} d\left(z, x_{k-1}\right)
\end{aligned}
$$

showing that $z$ has what it takes to be in $S_{k-1}$. Thus we would obtain a sequence of nested, nonempty, closed sets according to this scheme.

Now here is how to choose the $x_{k} \in S_{k-1}$. Let

$$
\phi\left(x_{k}\right)<\inf _{x \in S_{k-1}} \phi(x)+\frac{1}{2^{k}}
$$

Then for $z \in S_{n+1} \subseteq S_{n}$,

$$
\phi(z) \leq \phi\left(x_{n+1}\right)-\frac{\varepsilon}{\lambda} d\left(z, x_{n+1}\right)
$$

and so

$$
\begin{aligned}
\frac{\varepsilon}{\lambda} d\left(z, x_{n+1}\right) & \leq \phi\left(x_{n+1}\right)-\phi(z) \leq \inf _{x \in S_{n}} \phi(x)+\frac{1}{2^{n+1}}-\phi(z) \\
& \leq \phi(z)+\frac{1}{2^{n+1}}-\phi(z)=\frac{1}{2^{n+1}}
\end{aligned}
$$

Thus every $z \in S_{n+1}$ is within $\frac{1}{2^{n+1}}$ of the single point $x_{n+1}$ and so the diameter of $S_{n}$ converges to 0 as $n \rightarrow \infty$. By completeness of $X$, there exists a unique $y_{\lambda} \in \cap_{n} S_{n}$. Then it follows in particular that for $x_{0}=x_{1}$ as above,

$$
\phi\left(y_{\lambda}\right) \leq \phi\left(x_{0}\right)-\frac{\varepsilon}{\lambda} d\left(y_{\lambda}, x_{0}\right) \leq \phi\left(x_{0}\right)
$$

which verifies the first of the above conclusions.

As to the second, $\phi\left(x_{0}\right) \leq \inf _{x \in X} \phi(x)+\varepsilon$ and so, for any $x$,

$$
\phi\left(y_{\lambda}\right) \leq \phi\left(x_{0}\right)-\frac{\varepsilon}{\lambda} d\left(y_{\lambda}, x_{0}\right) \leq \phi(x)+\varepsilon-\frac{\varepsilon}{\lambda} d\left(y_{\lambda}, x_{0}\right)
$$

this being true for $x=y_{\lambda}$. Hence $\frac{\varepsilon}{\lambda} d\left(y_{\lambda}, x_{0}\right) \leq \varepsilon$ and so $d\left(y_{\lambda}, x_{0}\right) \leq \lambda$.
Finally consider the third condition. If it does not hold, then there exists $z \neq y_{\lambda}$ such that

$$
\phi\left(y_{\lambda}\right) \geq \phi(z)+\frac{\varepsilon}{\lambda} d\left(z, y_{\lambda}\right)
$$

so that

$$
\phi(z) \leq \phi\left(y_{\lambda}\right)-\frac{\varepsilon}{\lambda} d\left(z, y_{\lambda}\right)
$$

But then, by the definition of $y_{\lambda}$ as being in all the $S_{n}$,

$$
\phi\left(y_{\lambda}\right) \leq \phi\left(x_{n}\right)-\frac{\varepsilon}{\lambda} d\left(x_{n}, y_{\lambda}\right)
$$

and so

$$
\begin{aligned}
\phi(z) & \leq \phi\left(x_{n}\right)-\frac{\varepsilon}{\lambda}\left(d\left(x_{n}, y_{\lambda}\right)+d\left(z, y_{\lambda}\right)\right) \\
& \leq \phi\left(x_{n}\right)-\frac{\varepsilon}{\lambda} d\left(x_{n}, z\right)
\end{aligned}
$$

Since $n$ is arbitrary, this shows that $z \in \cap_{n} S_{n}$ but there is only one element of this intersection and it is $y_{\lambda}$ so $z$ must equal $y_{\lambda}$, a contradiction.

Note how if you make $\lambda$ very small, you could pick $\varepsilon$ very small such that the cone looks pretty flat.

### 18.6.1 Cariste Fixed Point Theorem

As mentioned in [55], the above result can be used to prove a fixed point theorem called the Cariste fixed point theorem.

Theorem 18.6.3 Let $\phi$ be lower semicontinuous, proper, and bounded below on a complete metric space $X$ and let $F: X \rightarrow \mathscr{P}(X)$ be set valued such that $F(x) \neq \emptyset$ for all $x$. Also suppose that for each $x \in X$, there exists $y \in F(x)$ such that

$$
\phi(y) \leq \phi(x)-d(x, y)
$$

Then there exists $x_{0}$ such that $x_{0} \in F\left(x_{0}\right)$.
Proof: In the above Ekeland variational principle, let $\varepsilon=1=\lambda$. Then there exists $x_{0}$ such that for all $y \neq x_{0}$

$$
\begin{equation*}
\phi\left(x_{0}\right)-d\left(y, x_{0}\right)<\phi(y), \text { so } \phi\left(x_{0}\right)<\phi(y)+d\left(y, x_{0}\right) \tag{18.6.28}
\end{equation*}
$$

for all $y \neq x_{0}$.

Suppose $x_{0} \notin F\left(x_{0}\right)$. From the assumption, there is $y \in F\left(x_{0}\right)$ (so $\left.y \neq x_{0}\right)$ such that

$$
\phi(y) \leq \phi\left(x_{0}\right)-d\left(x_{0}, y\right)
$$

Since $y \neq x_{0}$, it follows

$$
\phi(y)+d\left(x_{0}, y\right) \leq \phi\left(x_{0}\right)<\phi(y)+d\left(y, x_{0}\right)
$$

a contradiction. Hence $x_{0} \in F\left(x_{0}\right)$ after all.
It is a funny theorem. It is easy to prove, but you look at it and wonder what it says. If $F$ is single valued, you would need to have a function $\phi$ such that for each $x$,

$$
\phi(F(x)) \leq \phi(x)-d(x, y)
$$

and if you have such a $\phi$ then you can assert there is a fixed point for $F$. Suppose $F$ is single valued and $d(F x, F y) \leq r d(x, y), 0<r<1$. Of course $F$ has a fixed point using easier techniques. However, this also follows from this result. Let

$$
\phi(x)=\frac{1}{1-r} d(x, F(x))
$$

Then is it true that for each $x$, there exists $y \in F(x)$ such that the inequality holds for all $x$ ? Is

$$
\frac{1}{1-r} d(F(x), F(F(x))) \leq \frac{1}{1-r} d(x, F(x))-d(x, F(x))
$$

Yes, this is certainly so because the right side reduces to $\frac{r}{1-r} d(x, F(x))$. Thus this fixed point theorem implies the usual Banach fixed point theorem.

The Ekeland variational principle says that when $\phi$ is lower semicontinuous proper and bounded below, there exists $y$ such that

$$
\phi(y)-d(x, y)<\phi(x) \text { for all } x \neq y
$$

In fact this can be proved from the Cariste fixed point theorem. Suppose the EVP does not hold. This would mean that for all $y$ there exists $x \neq y$ such that

$$
\phi(y)-d(x, y) \geq \phi(x)
$$

Thus, for all $x$ there exists $y \neq x$ such that

$$
\phi(x)-d(x, y) \geq \phi(y)
$$

The inequality is preserved if $x=y$. Then let

$$
F(x) \equiv\{y \neq x: \phi(x)-d(x, y) \geq \phi(y)\} \neq \emptyset
$$

by assumption. This is the hypothesis for the Cariste fixed point theorem. Hence there exists $x_{0} \in F\left(x_{0}\right)=\left\{y \neq x_{0}: \phi\left(x_{0}\right)-d\left(x_{0}, y\right) \geq \phi(y)\right\}$ but this cannot happen because you can't have $x_{0} \neq x_{0}$. Thus the Ekeland variational principle must hold after all.

### 18.6.2 A Density Result

There are several applications of the Ekeland variational principle. For more of them, see [55]. One of these is to show that there is a point where $\phi^{\prime}$ is small assuming $\phi$ is bounded below, lower semicontinuous, and Gateaux differentiable. Here

$$
\left\langle\phi^{\prime}(x), v\right\rangle \equiv \lim _{h \rightarrow 0} \frac{\phi(x+h v)-\phi(x)}{h}, \phi^{\prime}(x) \in X^{\prime}
$$

It is sort of an approximate critical point at a point which causes $\phi$ to be near the infimum.
Theorem 18.6.4 Let $X$ be a Banach space and $\phi: X \rightarrow \mathbb{R}$ be Gateaux differentiable, bounded from below, and lower semicontinuous. Then for every $\varepsilon>0$ there exists $x \in X$ such that

$$
\phi\left(x_{\varepsilon}\right) \leq \inf _{x \in X} \phi(x)+\varepsilon \text { and }\left\|\phi^{\prime}\left(x_{\varepsilon}\right)\right\|_{X^{\prime}} \leq \varepsilon
$$

Proof: From the Ekeland variational principle with $\lambda=1$, there exists $x_{\varepsilon}$ such that

$$
\phi\left(x_{\varepsilon}\right) \leq \phi\left(x_{0}\right) \leq \inf _{x \in X} \phi(x)+\varepsilon
$$

and for all $x$,

$$
\phi\left(x_{\varepsilon}\right)<\phi(x)+\varepsilon\left\|x-x_{\varepsilon}\right\|
$$

Then letting $x=x_{\varepsilon}+h v$ where $\|v\|=1$,

$$
\phi\left(x_{\varepsilon}+h v\right)-\phi\left(x_{\varepsilon}\right)>-\varepsilon|h|
$$

Let $h<0$. Then divide by it

$$
\frac{\phi\left(x_{\varepsilon}+h v\right)-\phi\left(x_{\varepsilon}\right)}{h}<\varepsilon
$$

Passing to a limit as $h \rightarrow 0$ yields

$$
\left\langle\phi^{\prime}\left(x_{\varepsilon}\right), v\right\rangle \leq \varepsilon
$$

Now $v$ was arbitrary with norm 1 and so

$$
\sup _{\|v\|=1}\left\langle\phi^{\prime}\left(x_{\varepsilon}\right), v\right\rangle=\left\|\phi^{\prime}\left(x_{\varepsilon}\right)\right\| \leq \varepsilon
$$

There is another very interesting application of the Ekeland variational principle [55].

Theorem 18.6.5 Let $X$ be a Banach space and $\phi: X \rightarrow \mathbb{R}$ be Gateaux differentiable, bounded from below, and lower semicontinuous. Also suppose there exists $a, c>0$ such that

$$
a\|x\|-c \leq \phi(x) \text { for all } x \in X
$$

Then $\left\{\phi^{\prime}(x): x \in X\right\}$ is dense in the ball of $X^{\prime}$ centered at 0 with radius $a$. Here $\phi^{\prime}(x) \in X^{\prime}$ and is determined by

$$
\left\langle\phi^{\prime}(x), v\right\rangle \equiv \lim _{h \rightarrow 0} \frac{\phi(x+h v)-\phi(x)}{h}
$$

Proof: Let $x^{*} \in X^{\prime},\left\|x^{*}\right\| \leq a$. Let

$$
\psi(x)=\phi(x)-\left\langle x^{*}, x\right\rangle
$$

This is lower semicontinuous. It is also bounded from below because

$$
\psi(x) \geq \phi(x)-a\|x\| \geq(a\|x\|-c)-a\|x\|=-c
$$

It is also clearly Gateaux differentiable and lower semicontinuous because the piece added in is actually continuous. It is clear that the Gateaux derivative is just $\phi^{\prime}(x)-x^{*}$. By Theorem 18.6.4, there exists $x_{\varepsilon}$ such that

$$
\left\|\phi^{\prime}\left(x_{\varepsilon}\right)-x^{*}\right\| \leq \varepsilon
$$

Thus this theorem says that if $\phi(x) \geq a\|x\|-c$ where $\phi$ has the nice properties of the theorem it follows that $\phi^{\prime}(x)$ is dense in $B(0, a)$ in the dual space $X^{\prime}$. It follows that if for every $a$, there exists $c$ such that

$$
\phi(x) \geq a\|x\|-c \text { for all } x \in X
$$

then $\left\{\phi^{\prime}(x): x \in X\right\}$ is dense in $X^{\prime}$. This proves the following lemma.
Lemma 18.6.6 Let $X$ be a Banach space and $\phi: X \rightarrow \mathbb{R}$ be Gateaux differentiable, bounded from below, and lower semicontinuous. Suppose for all $a>0$ there exists a $c>0$ such that

$$
\phi(x) \geq a\|x\|-c \text { for all } x
$$

Then $\left\{\phi^{\prime}(x): x \in X\right\}$ is dense in $X^{\prime}$.
If the above holds, then

$$
\frac{\phi(x)}{\|x\|} \geq a-\frac{c}{\|x\|}
$$

and so, since $a$ is arbitrary, it must be the case that

$$
\begin{equation*}
\lim _{\|x\| \rightarrow \infty} \frac{\phi(x)}{\|x\|}=\infty \tag{18.6.29}
\end{equation*}
$$

In fact, this is sufficient. If not, there would exist $a>0$ such that $\phi\left(x_{n}\right)<a\left\|x_{n}\right\|-n$. Let $-L$ be a lower bound for $\phi(x)$. Then

$$
-L+n \leq a\left\|x_{n}\right\|
$$

and so $\left\|x_{n}\right\| \rightarrow \infty$. Now it follows that

$$
\begin{equation*}
a \geq \frac{\phi\left(x_{n}\right)}{\left\|x_{n}\right\|}+\frac{n}{\left\|x_{n}\right\|} \geq \frac{\phi\left(x_{n}\right)}{\left\|x_{n}\right\|} \tag{18.6.30}
\end{equation*}
$$

which is a contradiction to 18.6 .29 . This proves the following interesting density theorem.
Theorem 18.6.7 Let $X$ be a Banach space and $\phi: X \rightarrow \mathbb{R}$ be Gateaux differentiable, bounded from below, and lower semicontinuous. Also suppose the coercivity condition

$$
\lim _{\|x\| \rightarrow \infty} \frac{\phi(x)}{\|x\|}=\infty
$$

Then $\left\{\phi^{\prime}(x): x \in X\right\}$ is dense in $X^{\prime}$. Here $\phi^{\prime}(x) \in X^{\prime}$ and is determined by

$$
\left\langle\phi^{\prime}(x), v\right\rangle \equiv \lim _{h \rightarrow 0} \frac{\phi(x+h v)-\phi(x)}{h}
$$

### 18.7 Quotient Spaces

A useful idea is that of a quotient space. It is a way to create another Banach space from a given Banach space and a closed subspace. It generalizes similar concepts which are routine in linear algebra.

Definition 18.7.1 Let $X$ be a Banach space and let $V$ be a closed subspace of $X$. Then $X / V$ denotes the set of equivalence classes determined by the equivalence relation which says $x \sim y$ means $x-y \in V$. An individual equivalence class will be denoted by any of the following symbols. $x+V,[x]$, or $[x]_{V}$. Vector space operations are defined as follows:

$$
(x+V)+y+V \equiv x+y+V
$$

or in other symbols,

$$
[x]+[y] \equiv[x+y]
$$

and for $\alpha \in \mathbb{F}$,

$$
\alpha[x] \equiv[\alpha x]
$$

Also a norm is defined by

$$
\|[x]\| \equiv \inf \{\|x+v\|: v \in V\}
$$

It is left as an exercise to verify the above algebraic operations are well defined. With the above definition, here is the major theorem about quotient spaces.

Theorem 18.7.2 Let $X$ be a Banach space and let $V$ be a closed subspace of $X$. Then with the above definitions of vector space operations, $X / V$ is a Banach space. In the case where $V=\operatorname{ker}(A)$ for $A \in \mathscr{L}(X, Y)$ for $Y$ another Banach space, define $\widehat{A}: X / V \rightarrow A(X) \subseteq Y$ by $\widehat{A}([x]) \equiv A x$. Then $\widehat{A}$ is continuous and $1-1$. In fact, $\|\widehat{A}\| \leq\|A\|$.

Proof: First of all, consider the claim that the given norm really is a norm. First note that $\|x+V\| \geq 0$ and $\|x+V\|=0$ only if $x \in V$ because $V$ is closed. Therefore, $x+V=0+V$. Next,

$$
\begin{aligned}
\|\alpha[x]\| & \equiv\|[\alpha x]\| \equiv \inf \{\|\alpha x+v\|: v \in V\} \\
& =\inf \{\|\alpha x+\alpha v\|: v \in V\} \\
& =|\alpha| \inf \{\|x+v\|: v \in V\}=|\alpha|\|[x]\| .
\end{aligned}
$$

Consider the triangle inequality.

$$
\begin{gathered}
\|[x+y]\|=\inf \{\|x+y+v\|: v \in V\} \\
\leq\left\|x+v_{1}\right\|+\left\|y+v_{2}\right\|
\end{gathered}
$$

for any choice of $v_{1}$ and $v_{2}$. Therefore, taking the infimum of both sides over $v_{2}$ yields

$$
\|[x+y]\| \leq\left\|x+v_{1}\right\|+\|[y]\|
$$

and then taking the infimum over all $v_{1}$ yields

$$
\|[x+y]\| \leq\|[x]\|+\|[y]\|
$$

Next consider the claim that $X / V$ is a Banach space. Letting $\left\{\left[x_{n}\right]\right\}$ be a Cauchy sequence in $X / V$, I will show a subsequence of this converges to a point in $X / V$. This is done by defining a suitable sequence in $X$ and then using completeness of $X$. By choosing a subsequence, it can be assumed that $\left\|\left[x_{n}\right]-\left[x_{n+1}\right]\right\|<2^{-n}$. Let $z_{1} \equiv x_{1}$. Then choose $v_{2} \in V$ such that $\left\|x_{2}+v_{2}-z_{1}\right\|<2^{-1}$. Let $z_{2}=x_{2}+v_{2}$. Suppose $\left\{z_{1}, \cdots, z_{n}\right\}$ have been chosen, each having the property that $\left[z_{k}\right]=\left[x_{k}\right]$ and such that $\left\|z_{k}-z_{k+1}\right\|<2^{-k}$. Then let $v_{n+1}$ be chosen such that $\left\|x_{n+1}+v_{n+1}-z_{n}\right\|<2^{-n}$ and let $z_{n+1} \equiv x_{n+1}+v_{n+1}$. Thus $\left\{z_{n}\right\}$ is a Cauchy sequence in $X$ and so it converges to $x \in X$. Then

$$
\left\|[x]-\left[x_{n}\right]\right\| \leq\left\|x-\left(x_{n}+v_{n}\right)\right\|=\left\|x-z_{n}\right\|
$$

and so $\lim _{n \rightarrow \infty}\left[x_{n}\right]=[x]$.
Next consider the claim about $\widehat{A}$. This is well defined and linear because if $[x]=\left[x_{1}\right]$, then $x-x_{1} \in \operatorname{ker}(A)$ and so $A x=A x_{1}$. Thus $\widehat{A}([x])=\widehat{A}\left(\left[x_{1}\right]\right)$. It is linear because

$$
\begin{aligned}
\widehat{A}(\alpha[x]+\beta[y]) & =\widehat{A}([\alpha x+\beta y])=A(\alpha x+\beta y) \\
& =\alpha A x+\beta A y=\alpha \widehat{A}([x])+\beta \widehat{A}([y])
\end{aligned}
$$

Next consider the claim that $\widehat{A}$ is continuous. Letting $v \in V$,

$$
\|\widehat{A}([x])\| \equiv\|A x\|=\|A(x+v)\| \leq\|A\|\|x+v\|
$$

and so, taking the infimum over all $v \in V$,

$$
\|\widehat{A}([x])\| \leq\|A\|\|[x]\|
$$

and this shows $\|\widehat{A}\| \leq\|A\|$.
Now with this theorem, here is an interesting application.

Theorem 18.7.3 Let $X_{1}$ and $X_{2}$ be Banach spaces which are either reflexive or dual spaces for a separable Banach space and let $A_{i} \in \mathscr{L}\left(X_{i}, Y\right)$ for $Y$ a reflexive Banach space. The following are equivalent.

For some $k>0$

$$
\begin{gather*}
A_{1}(\overline{B(0,1)}) \subseteq A_{2}(\overline{B(0, k)})  \tag{18.7.31}\\
\left\|A_{1}^{*} y^{*}\right\| \leq k\left\|A_{2}^{*} y^{*}\right\| \tag{18.7.32}
\end{gather*}
$$

for all $y \in Y^{*}$. If either of the above hold, then

$$
\begin{equation*}
A_{1} X_{1} \subseteq A_{2} X_{2} \tag{18.7.33}
\end{equation*}
$$

Proof: Suppose 18.7.31 first. I show this implies 18.7.33. There are two cases. First suppose $A_{2}$ is one to one. Then in this case, $A_{2}^{-1} A_{1}(\overline{B(0,1)}) \subseteq \overline{B(0, k)}$. Therefore, if $x \in X_{1}$,

$$
A_{2}^{-1} A_{1}(x /\|x\|)=y \in \overline{B(0, k)}
$$

and so

$$
A_{1}(x)=\|x\| A_{2}(y)=A_{2}(\|x\| y) \in A_{2}\left(X_{2}\right)
$$

Next suppose $A_{2}$ is not one to one. In this case, letting $\widehat{A}_{2}$ be the continuous linear map given by

$$
\widehat{A}_{2}([x]) \equiv A_{2} x
$$

it follows $\widehat{A}_{2}$ is $1-1$ on $X_{2} / \operatorname{ker}\left(A_{2}\right)$. Now note that if $\|x\| \leq k$, then it is also the case that $\|[x]\| \leq k$ and so

$$
A_{2}(\overline{B(0, k)}) \subseteq \widehat{A}_{2}\left(\overline{B_{2}(0, k)}\right)
$$

where in the second set, $\overline{B_{2}(0, k)}$ is the unit ball in $X / \operatorname{ker}\left(A_{2}\right)$. It follows from 18.7.31

$$
A_{1}(\overline{B(0,1)}) \subseteq \widehat{A}_{2}\left(\overline{B_{2}(0, k)}\right)
$$

and so $\widehat{A}_{2}^{-1} A_{1}(\overline{B(0,1)}) \subseteq \overline{B_{2}(0, k)}$ which implies

$$
A_{1}(x /\|x\|)=\widehat{A}_{2}[y] \in \widehat{A}_{2}\left(\overline{B_{2}(0, k)}\right)
$$

Therefore, letting $\left[y_{1}\right]=[y]$ be such that $\left\|y_{1}\right\|<2 k$, it follows

$$
A_{1}(x /\|x\|)=\widehat{A}_{2}\left[y_{1}\right]=A_{2}\left(y_{1}\right)
$$

and so

$$
A_{1}(x)=A_{2}\left(\|x\| y_{1}\right) \in A_{2}\left(X_{2}\right)
$$

Next I show the equivalence of 18.7.32 and 18.7.31. First I want to show $A_{i}(\overline{B(0, r)})$ is closed. Suppose then that for $A=A_{1}$ or $A_{2}, A\left(x_{n}\right) \rightarrow y$ where $x_{n} \in \overline{B(0, r)}$. In the case the $X_{i}$ are reflexive, it follows from the Eberlein Smulian theorem there exists a subsequence,
still denoted as $\left\{x_{n}\right\}$ which converges weakly to $x \in \overline{B(0, r)}$. Then $A x_{n} \rightarrow y$ and $x_{n} \rightarrow x$ weakly. Thus $(x, y)$ is in the weak closure of the graph of $A$,

$$
\left\{(x, A x): x \in X_{i}\right\}
$$

This set is strongly closed and convex and hence it is weakly closed by Theorem 18.3.3 so $y=A x$ and this shows $A(\overline{B(0, r)})$ is closed. In the other case where $X_{i}$ is the dual space of a separable Banach space, it follows from Corollary 17.5.6 there exists a subsequence still denoted as $\left\{x_{n}\right\}$ such that $x_{n} \rightarrow x$ weak $*$ and similarly, $(x, y)$ is in the weak $*$ closure of the graph of $A$ which shows again by Theorem 18.3.3 that $(x, y)$ is in the graph of $A$, showing again that $A(\overline{B(0, r)})$ is closed.

Suppose 18.7.31. Then letting $y^{*} \in Y^{\prime}$,

$$
\begin{aligned}
\left\|A_{1}^{*} y^{*}\right\| & =\sup _{\left\|x_{1}\right\|_{X_{1}} \leq 1}\left|y^{*}\left(A_{1} x_{1}\right)\right| \\
& \leq \sup _{\left\|x_{2}\right\|_{X_{2}} \leq k}\left|y^{*}\left(A_{2} x_{2}\right)\right|=k\left\|A_{2}^{*} y^{*}\right\|
\end{aligned}
$$

which shows 18.7.32.
Now suppose 18.7.32. Then if 18.7.31 does not hold, it follows from the first part which gives $A_{i}(\overline{B(0, r)})$ a closed set, there exists

$$
A_{1} x_{0} \in A_{1}(\overline{B(0,1)}) \backslash A_{2}(\overline{B(0, k)})
$$

Now $A_{2}(\overline{B(0, k)})$ is closed and convex, hence weakly closed, and so by Theorem 18.2.5 there exists $y_{0}^{*} \in Y^{\prime}$ such that

$$
\operatorname{Re} y_{0}^{*}\left(A_{2}(\overline{B(0, k)})\right)<c<\operatorname{Re} y_{0}^{*}\left(A_{1} x_{0}\right)
$$

and so

$$
\begin{aligned}
\left\|A_{1}^{*} y_{0}^{*}\right\| & =\sup _{\left\|x_{1}\right\|_{X_{1}} \leq 1}\left|y_{0}^{*}\left(A x_{1}\right)\right| \geq \operatorname{Re} y_{0}^{*}\left(A_{1} x_{0}\right) \\
& >c>\operatorname{Re} y_{0}^{*}\left(A_{2}\left(x_{2}\right)\right)=\operatorname{Re} A_{2}^{*} y_{0}^{*}\left(x_{2}\right)
\end{aligned}
$$

whenever $x_{2} \in \overline{B(0, k)}$ and so, taking the supremum of all such $x_{2}$,

$$
\left\|A_{1}^{*} y_{0}^{*}\right\|>c>k\left\|A_{2}^{*} y_{0}^{*}\right\|
$$

contradicting 18.7.32.

## Chapter 19

## Hilbert Spaces

In this chapter, Hilbert spaces, which have been alluded to earlier are given a complete discussion. These spaces, as noted earlier are just complete inner product spaces.

### 19.1 Basic Theory

Definition 19.1.1 Let $X$ be a vector space. An inner product is a mapping from $X \times X$ to $\mathbb{C}$ if $X$ is complex and from $X \times X$ to $\mathbb{R}$ if $X$ is real, denoted by $(x, y)$ which satisfies the following.

$$
\begin{gather*}
(x, x) \geq 0,(x, x)=0 \text { if and only if } x=0,  \tag{19.1.1}\\
(x, y)=\overline{(y, x) .} \tag{19.1.2}
\end{gather*}
$$

For $a, b \in \mathbb{C}$ and $x, y, z \in X$,

$$
\begin{equation*}
(a x+b y, z)=a(x, z)+b(y, z) \tag{19.1.3}
\end{equation*}
$$

Note that 19.1.2 and 19.1.3 imply $(x, a y+b z)=\bar{a}(x, y)+\bar{b}(x, z)$. Such a vector space is called an inner product space.

The Cauchy Schwarz inequality is fundamental for the study of inner product spaces.
Theorem 19.1.2 (Cauchy Schwarz) In any inner product space

$$
|(x, y)| \leq\|x\|\|y\| .
$$

Proof: Let $\omega \in \mathbb{C},|\omega|=1$, and $\bar{\omega}(x, y)=|(x, y)|=\operatorname{Re}(x, y \omega)$. Let

$$
F(t)=(x+t y \omega, x+t \omega y)
$$

If $y=0$ there is nothing to prove because

$$
(x, 0)=(x, 0+0)=(x, 0)+(x, 0)
$$

and so $(x, 0)=0$. Thus, it can be assumed $y \neq 0$. Then from the axioms of the inner product,

$$
F(t)=\|x\|^{2}+2 t \operatorname{Re}(x, \omega y)+t^{2}\|y\|^{2} \geq 0 .
$$

This yields

$$
\|x\|^{2}+2 t|(x, y)|+t^{2}\|y\|^{2} \geq 0
$$

Since this inequality holds for all $t \in \mathbb{R}$, it follows from the quadratic formula that

$$
4|(x, y)|^{2}-4\|x\|^{2}\|y\|^{2} \leq 0
$$

This yields the conclusion and proves the theorem.
Proposition 19.1.3 For an inner product space, $\|x\| \equiv(x, x)^{1 / 2}$ does specify a norm.

Proof: All the axioms are obvious except the triangle inequality. To verify this,

$$
\begin{aligned}
\|x+y\|^{2} & \equiv(x+y, x+y) \equiv\|x\|^{2}+\|y\|^{2}+2 \operatorname{Re}(x, y) \\
& \leq\|x\|^{2}+\|y\|^{2}+2|(x, y)| \\
& \leq\|x\|^{2}+\|y\|^{2}+2\|x\|\|y\|=(\|x\|+\|y\|)^{2}
\end{aligned}
$$

The following lemma is called the parallelogram identity.

Lemma 19.1.4 In an inner product space,

$$
\|x+y\|^{2}+\|x-y\|^{2}=2\|x\|^{2}+2\|y\|^{2}
$$

The proof, a straightforward application of the inner product axioms, is left to the reader.

Lemma 19.1.5 For $x \in H$, an inner product space,

$$
\begin{equation*}
\|x\|=\sup _{\|y\| \leq 1}|(x, y)| \tag{19.1.4}
\end{equation*}
$$

Proof: By the Cauchy Schwarz inequality, if $x \neq 0$,

$$
\|x\| \geq \sup _{\|y\| \leq 1}|(x, y)| \geq\left(x, \frac{x}{\|x\|}\right)=\|x\| .
$$

It is obvious that 19.1.4 holds in the case that $x=0$.
Definition 19.1.6 A Hilbert space is an inner product space which is complete. Thus a Hilbert space is a Banach space in which the norm comes from an inner product as described above.

In Hilbert space, one can define a projection map onto closed convex nonempty sets.
Definition 19.1.7 $A$ set, $K$, is convex if whenever $\lambda \in[0,1]$ and $x, y \in K, \lambda x+(1-\lambda) y \in K$.
Theorem 19.1.8 Let $K$ be a closed convex nonempty subset of a Hilbert space, $H$, and let $x \in H$. Then there exists a unique point $P x \in K$ such that $\|P x-x\| \leq\|y-x\|$ for all $y \in K$.

Proof: Consider uniqueness. Suppose that $z_{1}$ and $z_{2}$ are two elements of $K$ such that for $i=1,2$,

$$
\begin{equation*}
\left\|z_{i}-x\right\| \leq\|y-x\| \tag{19.1.5}
\end{equation*}
$$

for all $y \in K$. Also, note that since $K$ is convex,

$$
\frac{z_{1}+z_{2}}{2} \in K
$$

Therefore, by the parallelogram identity,

$$
\begin{aligned}
\left\|z_{1}-x\right\|^{2} & \leq\left\|\frac{z_{1}+z_{2}}{2}-x\right\|^{2}=\left\|\frac{z_{1}-x}{2}+\frac{z_{2}-x}{2}\right\|^{2} \\
& =2\left(\left\|\frac{z_{1}-x}{2}\right\|^{2}+\left\|\frac{z_{2}-x}{2}\right\|^{2}\right)-\left\|\frac{z_{1}-z_{2}}{2}\right\|^{2} \\
& =\frac{1}{2}\left\|z_{1}-x\right\|^{2}+\frac{1}{2}\left\|z_{2}-x\right\|^{2}-\left\|\frac{z_{1}-z_{2}}{2}\right\|^{2} \\
& \leq\left\|z_{1}-x\right\|^{2}-\left\|\frac{z_{1}-z_{2}}{2}\right\|^{2}
\end{aligned}
$$

where the last inequality holds because of 19.1.5 letting $z_{i}=z_{2}$ and $y=z_{1}$. Hence $z_{1}=z_{2}$ and this shows uniqueness.

Now let $\lambda=\inf \{\|x-y\|: y \in K\}$ and let $y_{n}$ be a minimizing sequence. This means $\left\{y_{n}\right\} \subseteq K$ satisfies $\lim _{n \rightarrow \infty}\left\|x-y_{n}\right\|=\lambda$. Now the following follows from properties of the norm.

$$
\left\|y_{n}-x+y_{m}-x\right\|^{2}=4\left(\left\|\frac{y_{n}+y_{m}}{2}-x\right\|^{2}\right)
$$

Then by the parallelogram identity, and convexity of $K, \frac{y_{n}+y_{m}}{2} \in K$, and so

$$
\begin{aligned}
\left\|\left(y_{n}-x\right)-\left(y_{m}-x\right)\right\|^{2} & =2\left(\left\|y_{n}-x\right\|^{2}+\left\|y_{m}-x\right\|^{2}\right)-\overbrace{\left(\left\|\frac{y_{n}+y_{m}}{2}-x\right\|^{2}\right)}^{=\left\|y_{n}-x+y_{m}-x\right\|^{2}} \\
& \leq 2\left(\left\|y_{n}-x\right\|^{2}+\left\|y_{m}-x\right\|^{2}\right)-4 \lambda^{2}
\end{aligned}
$$

Since $\left\|x-y_{n}\right\| \rightarrow \lambda$, this shows $\left\{y_{n}-x\right\}$ is a Cauchy sequence. Thus also $\left\{y_{n}\right\}$ is a Cauchy sequence. Since $H$ is complete, $y_{n} \rightarrow y$ for some $y \in H$ which must be in $K$ because $K$ is closed. Therefore

$$
\|x-y\|=\lim _{n \rightarrow \infty}\left\|x-y_{n}\right\|=\lambda
$$

Let $P x=y$.
Corollary 19.1.9 Let $K$ be a closed, convex, nonempty subset of a Hilbert space, $H$, and let $x \in H$. Then for $z \in K, z=P x$ if and only if

$$
\begin{equation*}
\operatorname{Re}(x-z, y-z) \leq 0 \tag{19.1.6}
\end{equation*}
$$

for all $y \in K$.
Before proving this, consider what it says in the case where the Hilbert space is $\mathbb{R}^{n}$.

Condition 19.1.6 says the angle, $\theta$, shown in the diagram is always obtuse. Remember from calculus, the sign of $\mathbf{x} \cdot \mathbf{y}$ is the same as the sign of the cosine of the included angle
between $\mathbf{x}$ and $\mathbf{y}$. Thus, in finite dimensions, the conclusion of this corollary says that $z=P x$ exactly when the indicated angle is obtuse. Surely the picture suggests this is reasonable.

The inequality 19.1 .6 is an example of a variational inequality and this corollary characterizes the projection of $x$ onto $K$ as the solution of this variational inequality.

Proof of Corollary: Let $z \in K$ and let $y \in K$ also. Since $K$ is convex, it follows that if $t \in[0,1]$,

$$
z+t(y-z)=(1-t) z+t y \in K
$$

Furthermore, every point of $K$ can be written in this way. (Let $t=1$ and $y \in K$.) Therefore, $z=P x$ if and only if for all $y \in K$ and $t \in[0,1]$,

$$
\|x-(z+t(y-z))\|^{2}=\|(x-z)-t(y-z)\|^{2} \geq\|x-z\|^{2}
$$

for all $t \in[0,1]$ and $y \in K$ if and only if for all $t \in[0,1]$ and $y \in K$

$$
\|x-z\|^{2}+t^{2}\|y-z\|^{2}-2 t \operatorname{Re}(x-z, y-z) \geq\|x-z\|^{2}
$$

If and only if for all $t \in[0,1]$,

$$
\begin{equation*}
t^{2}\|y-z\|^{2}-2 t \operatorname{Re}(x-z, y-z) \geq 0 \tag{19.1.7}
\end{equation*}
$$

Now this is equivalent to 19.1.7 holding for all $t \in(0,1)$. Therefore, dividing by $t \in(0,1)$, 19.1.7 is equivalent to

$$
t\|y-z\|^{2}-2 \operatorname{Re}(x-z, y-z) \geq 0
$$

for all $t \in(0,1)$ which is equivalent to 19.1.6. This proves the corollary.
Corollary 19.1.10 Let $K$ be a nonempty convex closed subset of a Hilbert space, H. Then the projection map, $P$ is continuous. In fact,

$$
|P x-P y| \leq|x-y|
$$

Proof: Let $x, x^{\prime} \in H$. Then by Corollary 19.1.9,

$$
\operatorname{Re}\left(x^{\prime}-P x^{\prime}, P x-P x^{\prime}\right) \leq 0, \operatorname{Re}\left(x-P x, P x^{\prime}-P x\right) \leq 0
$$

Hence

$$
\begin{aligned}
0 & \leq \operatorname{Re}\left(x-P x, P x-P x^{\prime}\right)-\operatorname{Re}\left(x^{\prime}-P x^{\prime}, P x-P x^{\prime}\right) \\
& =\operatorname{Re}\left(x-x^{\prime}, P x-P x^{\prime}\right)-\left|P x-P x^{\prime}\right|^{2}
\end{aligned}
$$

and so

$$
\left|P x-P x^{\prime}\right|^{2} \leq\left|x-x^{\prime}\right|\left|P x-P x^{\prime}\right|
$$

This proves the corollary.
The next corollary is a more general form for the Brouwer fixed point theorem.
Corollary 19.1.11 Let $\mathbf{f}: K \rightarrow K$ where $K$ is a convex compact subset of $\mathbb{R}^{n}$. Then $\mathbf{f}$ has a fixed point.

Proof: Let $K \subseteq \overline{B(\mathbf{0}, R)}$ and let $P$ be the projection map onto $K$. Then consider the map $\mathbf{f} \circ P$ which maps $\overline{B(\mathbf{0}, R)}$ to $\overline{B(\mathbf{0}, R)}$ and is continuous. By the Brouwer fixed point theorem for balls, this map has a fixed point. Thus there exists $\mathbf{x}$ such that

$$
\mathbf{f} \circ P(\mathbf{x})=\mathbf{x}
$$

Now the equation also requires $\mathbf{x} \in K$ and so $P(\mathbf{x})=\mathbf{x}$. Hence $\mathbf{f}(\mathbf{x})=\mathbf{x}$.
Definition 19.1.12 Let $H$ be a vector space and let $U$ and $V$ be subspaces. $U \oplus V=H$ if every element of $H$ can be written as a sum of an element of $U$ and an element of $V$ in a unique way.

The case where the closed convex set is a closed subspace is of special importance and in this case the above corollary implies the following.

Corollary 19.1.13 Let $K$ be a closed subspace of a Hilbert space, $H$, and let $x \in H$. Then for $z \in K, z=P x$ if and only if

$$
\begin{equation*}
(x-z, y)=0 \tag{19.1.8}
\end{equation*}
$$

for all $y \in K$. Furthermore, $H=K \oplus K^{\perp}$ where

$$
K^{\perp} \equiv\{x \in H:(x, k)=0 \text { for all } k \in K\}
$$

and

$$
\begin{equation*}
\|x\|^{2}=\|x-P x\|^{2}+\|P x\|^{2} . \tag{19.1.9}
\end{equation*}
$$

Proof: Since $K$ is a subspace, the condition 19.1.6 implies $\operatorname{Re}(x-z, y) \leq 0$ for all $y \in K$. Replacing $y$ with $-y$, it follows $\operatorname{Re}(x-z,-y) \leq 0$ which implies $\operatorname{Re}(x-z, y) \geq 0$ for all $y$. Therefore, $\operatorname{Re}(x-z, y)=0$ for all $y \in K$. Now let $|\alpha|=1$ and $\alpha(x-z, y)=|(x-z, y)|$. Since $K$ is a subspace, it follows $\bar{\alpha} y \in K$ for all $y \in K$. Therefore,

$$
0=\operatorname{Re}(x-z, \bar{\alpha} y)=(x-z, \bar{\alpha} y)=\alpha(x-z, y)=|(x-z, y)| .
$$

This shows that $z=P x$, if and only if 19.1.8.
For $x \in H, x=x-P x+P x$ and from what was just shown, $x-P x \in K^{\perp}$ and $P x \in K$. This shows that $K^{\perp}+K=H$. Is there only one way to write a given element of $H$ as a sum of a vector in $K$ with a vector in $K^{\perp}$ ? Suppose $y+z=y_{1}+z_{1}$ where $z, z_{1} \in K^{\perp}$ and $y, y_{1} \in K$. Then $\left(y-y_{1}\right)=\left(z_{1}-z\right)$ and so from what was just shown, $\left(y-y_{1}, y-y_{1}\right)=$ $\left(y-y_{1}, z_{1}-z\right)=0$ which shows $y_{1}=y$ and consequently $z_{1}=z$. Finally, letting $z=P x$,

$$
\begin{aligned}
\|x\|^{2} & =(x-z+z, x-z+z)=\|x-z\|^{2}+(x-z, z)+(z, x-z)+\|z\|^{2} \\
& =\|x-z\|^{2}+\|z\|^{2}
\end{aligned}
$$

This proves the corollary.
The following theorem is called the Riesz representation theorem for the dual of a Hilbert space. If $z \in H$ then define an element $f \in H^{\prime}$ by the rule $(x, z) \equiv f(x)$. It follows from the Cauchy Schwarz inequality and the properties of the inner product that $f \in H^{\prime}$. The Riesz representation theorem says that all elements of $H^{\prime}$ are of this form.

Theorem 19.1.14 Let $H$ be a Hilbert space and let $f \in H^{\prime}$. Then there exists a unique $z \in H$ such that

$$
\begin{equation*}
f(x)=(x, z) \tag{19.1.10}
\end{equation*}
$$

for all $x \in H$.
Proof: Letting $y, w \in H$ the assumption that $f$ is linear implies

$$
f(y f(w)-f(y) w)=f(w) f(y)-f(y) f(w)=0
$$

which shows that $y f(w)-f(y) w \in f^{-1}(0)$, which is a closed subspace of $H$ since $f$ is continuous. If $f^{-1}(0)=H$, then $f$ is the zero map and $z=0$ is the unique element of $H$ which satisfies 19.1.10. If $f^{-1}(0) \neq H$, pick $u \notin f^{-1}(0)$ and let $w \equiv u-P u \neq 0$. Thus Corollary 19.1.13 implies $(y, w)=0$ for all $y \in f^{-1}(0)$. In particular, let $y=x f(w)-f(x) w$ where $x \in H$ is arbitrary. Therefore,

$$
0=(f(w) x-f(x) w, w)=f(w)(x, w)-f(x)\|w\|^{2} .
$$

Thus, solving for $f(x)$ and using the properties of the inner product,

$$
f(x)=\left(x, \frac{\overline{f(w)} w}{\|w\|^{2}}\right)
$$

Let $z=\overline{f(w)} w /\|w\|^{2}$. This proves the existence of $z$. If $f(x)=\left(x, z_{i}\right) i=1,2$, for all $x \in H$, then for all $x \in H$, then $\left(x, z_{1}-z_{2}\right)=0$ which implies, upon taking $x=z_{1}-z_{2}$ that $z_{1}=z_{2}$. This proves the theorem.

If $R: H \rightarrow H^{\prime}$ is defined by $R x(y) \equiv(y, x)$, the Riesz representation theorem above states this map is onto. This map is called the Riesz map. It is routine to show $R$ is linear and $|R x|=|x|$.

### 19.2 The Hilbert Space $L(U)$

Let $L \in \mathscr{L}(U, H)$. Then one can consider the image of $L, L(U)$ as a Hilbert space. This is another interesting application of Theorem 19.1.8. First here is a definition which involves abominable and atrociously misleading notation which nevertheless seems to be well accepted.
Definition 19.2.1 Let $L \in \mathscr{L}(U, H)$, the bounded linear maps from $U$ to $H$ for $U, H$ Hilbert spaces. For $y \in L(U)$, let $L^{-1} y$ denote the unique vector in

$$
\{x: L x=y\} \equiv M_{y}
$$

which is closest in $U$ to 0 .

Note this is a good definition because $\{x: L x=y\}$ is closed thanks to the continuity of $L$ and it is obviously convex. Thus Theorem 19.1.8 applies. With this definition define an inner product on $L(U)$ as follows. For $y, z \in L(U)$,

$$
(y, z)_{L(U)} \equiv\left(L^{-1} y, L^{-1} z\right)_{U}
$$

The notation is abominable because $L^{-1}(y)$ is the normal notation for $M_{y}$.
In terms of linear algebra, this $L^{-1}$ is the Moore Penrose inverse. There you obtain the least squares solution $x$ to $L x=y$ which has smallest norm. Here there is an actual solution and among those solutions you get the one which has least norm. Of course a real honest solution is also a least squares solution so this is the Moore Penrose inverse restricted to $L(U)$.

First I want to understand $L^{-1}$ better. It is actually fairly easy to understand in terms of geometry. Here is a picture of $L^{-1}(y)$ for $y \in L(U)$.

As indicated in the picture, here is a lemma which gives a description of the situation.
Lemma 19.2.2 In the context of the above definition, $L^{-1}(y)$ is characterized by

$$
\begin{aligned}
\left(L^{-1}(y), x\right)_{U} & =0 \text { for all } x \in \operatorname{ker}(L) \\
L\left(L^{-1}(y)\right) & =y, \quad\left(L^{-1}(y) \in M_{y}\right)
\end{aligned}
$$

In addition to this, $L^{-1}$ is linear and the above definition does define an inner product.
Proof: The point $L^{-1}(y)$ is well defined as noted above. I claim it is characterized by the following for $y \in L(U)$

$$
\begin{aligned}
\left(L^{-1}(y), x\right)_{U} & =0 \text { for all } x \in \operatorname{ker}(L) \\
L\left(L^{-1}(y)\right) & =y, \quad\left(L^{-1}(y) \in M_{y}\right)
\end{aligned}
$$

Let $w \in M_{y}$ and suppose

$$
(v, x)_{U}=0, L(v)=y
$$

Then from the above characterization,

$$
\|w\|^{2}=\|\overbrace{w-v}^{\in \operatorname{ker}(L)}+v\|^{2}=\|w-v\|^{2}+\|v\|^{2}
$$

which shows that $w=L^{-1}(y)$ if and only if $w=v$ just described. From this characterization, it is clear that $L^{-1}$ is linear. Then it is also obvious that

$$
(y, z)_{L(U)}=\left(L^{-1} y, L^{-1} z\right)_{U}
$$

also specifies an inner product. The algebraic axioms are all obvious because $L^{-1}$ is linear. If $(y, y)_{L(U)}=0$, then $\left|L^{-1} y\right|_{U}^{2}=0$ and so $L^{-1} y=0$ which requires $y=L\left(L^{-1} y\right)=0$.

With the above definition, here is the main result.
Theorem 19.2.3 Let $U, H$ be Hilbert spaces and let $L \in \mathscr{L}(U, H)$. Then Definition 19.2.1 makes $L(U)$ into a Hilbert space. Also $L: U \rightarrow L(U)$ is continuous and $L^{-1}: L(U) \rightarrow U$ is continuous. Also,

$$
\begin{equation*}
\|L\|_{\mathscr{L}(U, H)}\|L x\|_{L(U)} \geq\|L x\|_{H} \tag{19.2.11}
\end{equation*}
$$

If $U$ is separable, so is $L(U)$. Also $\left(L^{-1}(y), x\right)=0$ for all $x \in \operatorname{ker}(L)$, and $L^{-1}: L(U) \rightarrow U$ is linear. Also, in case that $L$ is one to one, both $L$ and $L^{-1}$ preserve norms.

Proof: First consider the claim that $L: U \rightarrow L(U)$ is continuous and $L^{-1}: L(U) \rightarrow U$ is also continuous. Why is $L$ continuous? Say $u_{n} \rightarrow 0$ in $U$. Then

$$
\left\|L u_{n}\right\|_{L(U)} \equiv\left\|L^{-1}\left(L\left(u_{n}\right)\right)\right\|_{U}
$$

Now $\left\|L^{-1}\left(L\left(u_{n}\right)\right)\right\|_{U} \leq\left\|u_{n}\right\|_{U}$ and so it converges to 0 . (Recall that $L^{-1}\left(L u_{n}\right)$ is the smallest vector in $U$ which maps to $L u_{n}$. Since $u_{n}$ is mapped by $L$ to $L u_{n}$, it follows that $\left.\left\|L^{-1}\left(L\left(u_{n}\right)\right)\right\|_{U} \leq\left\|u_{n}\right\|_{U}.\right)$ Hence $L$ is continuous.

Next, why is $L^{-1}$ continuous? Let $\left\|y_{n}\right\|_{L(U)} \rightarrow 0$. This requires $\left\|L^{-1}\left(y_{n}\right)\right\|_{U} \rightarrow 0$ by definition of the norm in $L(U)$. Thus $L^{-1}$ is continuous.

Why is $L(U)$ a Hilbert space? Let $\left\{y_{n}\right\}$ be a Cauchy sequence in $L(U)$. Then from what was just observed, it follows that $L^{-1}\left(y_{n}\right)$ is a Cauchy sequence in $U$. Hence $L^{-1}\left(y_{n}\right) \rightarrow$ $x \in U$. It follows that $y_{n}=L\left(L^{-1}\left(y_{n}\right)\right) \rightarrow L x$ in $L(U)$. This is in the norm of $L(U)$. It was just shown that $L$ is continuous as a map from $U$ to $L(U)$. This shows that $L(U)$ is a Hilbert space. It was already shown that it is an inner product space and this has shown that it is complete.

If $x \in U$, then $\|L x\|_{H} \leq\|L\|_{\mathscr{L}(U, H)}\|x\|_{U}$. It follows that

$$
\begin{aligned}
\|L(x)\|_{H} & =\left\|L\left(L^{-1}(L(x))\right)\right\|_{H} \leq\|L\|_{\mathscr{L}(U, H)}\left\|L^{-1}(L(x))\right\|_{U} \\
& =\|L\|_{\mathscr{L}(U, H)}\|L(x)\|_{L(U)}
\end{aligned}
$$

This verifies 19.2.11.

If $U$ is separable, then letting $D$ be a countable dense subset, it follows from the continuity of the operators $L, L^{-1}$ discussed above that $L(D)$ is separable in. To see this, note that

$$
\begin{aligned}
\left\|L x_{n}-L x\right\|_{L(U)} & =\left\|L\left(L^{-1}\left(L x_{n}-L x\right)\right)\right\| \\
& \leq\|L\|_{\mathscr{L}(U, H)}\left\|L^{-1}\left(L\left(x_{n}-x\right)\right)\right\|_{U} \\
& \leq\|L\|_{\mathscr{L}(U, H)}\left\|x_{n}-x\right\|_{U}
\end{aligned}
$$

As before, $L^{-1}\left(L\left(x_{n}-x\right)\right)$ is the smallest vector which maps onto $L\left(x_{n}-x\right)$ and so its norm is no larger than $\left\|x_{n}-x\right\|_{U}$.

Consider the last claim. If $L$ is one to one, then for $y \in L(U)$, there is only one vector which maps to $y$. Therefore,

$$
L^{-1}(L(x))=x
$$

Hence for $y \in L(U)$,

$$
\|y\|_{L(U)} \equiv\left\|L^{-1}(y)\right\|_{U}
$$

Also,

$$
\|L u\|_{L(U)} \equiv\left\|L^{-1}(L(u))\right\|_{U} \equiv\|u\|_{U}
$$

Now here is another argument for various continuity claims.

$$
\|L x\|_{L(U)} \equiv\left\|L^{-1}(L x)\right\|_{U} \leq\|x\|_{U}
$$

because $L^{-1}(L x)$ is the smallest thing in $U$ which maps to $L x$ and $x$ is something which maps to $L x$ so it follows that the inequality holds. Hence $L \in \mathscr{L}(U, L(U))$ and in fact, $\|L\|_{\mathscr{L}(U, L(U))}=1$. Next, letting $y \in L(U)$,

$$
\left\|L^{-1} y\right\|_{U} \equiv\|y\|_{L(U)}
$$

and so $\left\|L^{-1}\right\|_{\mathscr{L}(L(U), U)}=1$ and this shows that $L \in \mathscr{L}(U, L(U))$ while $L^{-1} \in \mathscr{L}(L(U), U)$ and both have norm equal to 1 .

Now

$$
\|L x\|_{H}=\left\|L\left(L^{-1}(L x)\right)\right\|_{H} \leq\|L\|_{\mathscr{L}(U, H)}\left\|L^{-1}(L x)\right\|_{U} \equiv\|L\|_{\mathscr{L}(U, H)}\|L x\|_{L(U)}
$$

Now here are some other very interesting results. I am following [108].
Lemma 19.2.4 Let $L \in \mathscr{L}(U, H)$. Then $L(\overline{B(0, r)})$ is closed and convex.
Proof: It is clear this is convex since $L$ is linear. Why is it closed? $\overline{B(0, r)}$ is compact in the weak topology by the Banach Alaoglu theorem, Theorem 17.5.4 on Page 461. Furthermore, $L$ is continuous with respect to the weak topologies on $U$ and $H$. Here is why this is so. Suppose $u_{n} \rightarrow u$ weakly in $U$. Then if $h \in H$,

$$
\left(L u_{n}, h\right)=\left(u_{n}, L^{*} h\right) \rightarrow\left(u, L^{*} h\right)=(L u, h)
$$

which shows $L u_{n} \rightarrow L u$ weakly. Therefore, $L(\overline{B(0, r)})$ is weakly compact because it is the continuous image of a compact set. Therefore, it must also be weakly closed because the weak topology is a Hausdorff space. (See Lemma 18.3.2 on Page 493, and so you can apply the separation theorem, Theorem 18.2.5 on Page 486 to obtain a separating functional. Thus if $x \neq y$, there exists $f \in H^{\prime}$ such that $\operatorname{Re} f(y)>c>\operatorname{Re} f(x)$ and so taking

$$
\begin{gathered}
2 r<\min (c-\operatorname{Re} f(x), \operatorname{Re} f(y)-c), \\
B_{f}(x, r) \cap B_{f}(y, r)=\emptyset
\end{gathered}
$$

where

$$
B_{f}(x, r) \equiv\{y \in H:|f(x-y)|<r\}
$$

is an example of a basic open set in the weak topology.)
Now suppose $p \notin L(\overline{B(0, r)})$. Since the set is weakly closed and convex, it follows by Theorem 18.2.5 and the Riesz representation theorem for Hilbert space that there exists $z \in H$ such that

$$
\operatorname{Re}(p, z)>c>\operatorname{Re}(L x, z)
$$

for all $x \in \overline{B(0, r)}$. Therefore, $p$ cannot be a strong limit point because if it were, there would exist $x_{n} \in \overline{B(0, r)}$ such that $L x_{n} \rightarrow p$ which would require $\operatorname{Re}\left(L x_{n}, z\right) \rightarrow \operatorname{Re}(p, z)$ which is prevented by the above inequality. This proves the lemma.

Now here is a very interesting result about showing that $T_{1}\left(U_{1}\right)=T_{2}\left(U_{2}\right)$ where $U_{i}$ is a Hilbert space and $T_{i} \in \mathscr{L}\left(U_{i}, H\right)$. The situation is as indicated in the diagram.

The question is whether $T_{1} U_{1}=T_{2} U_{2}$.
Theorem 19.2.5 Let $U_{i}, i=1,2$ and $H$ be Hilbert spaces and let $T_{i} \in \mathscr{L}\left(U_{i}, H\right)$. If there exists $c \geq 0$ such that for all $x \in H$

$$
\begin{equation*}
\left\|T_{1}^{*} x\right\|_{1} \leq c\left\|T_{2}^{*} x\right\|_{2} \tag{19.2.12}
\end{equation*}
$$

then

$$
\begin{equation*}
T_{1}(\overline{B(0,1)}) \subseteq T_{2}(\overline{B(0, c)}) \tag{19.2.13}
\end{equation*}
$$

and so $T_{1}\left(U_{1}\right) \subseteq T_{2}\left(U_{2}\right)$. If $\left\|T_{1}^{*} x\right\|_{1}=\left\|T^{*} x\right\|_{2}$ for all $x \in H$, then $T_{1}\left(U_{1}\right)=T_{2}\left(U_{2}\right)$ and in addition to this,

$$
\begin{equation*}
\left\|T_{1}^{-1} x\right\|_{1}=\left\|T_{2}^{-1} x\right\|_{2} \tag{19.2.14}
\end{equation*}
$$

for all $x \in T_{1}\left(U_{1}\right)=T_{2}\left(U_{2}\right)$. In this theorem, $T_{i}^{-1}$ refers to Definition 19.2.1.
Proof: Consider the first claim. If it is not so, then there exists $u_{0},\left\|u_{0}\right\|_{1} \leq 1$ but

$$
T_{1}\left(u_{0}\right) \notin T_{2}(\overline{B(0, c)})
$$

the latter set being a closed convex nonempty set thanks to Lemma 19.2.4. Then by the separation theorem, Theorem 18.2 .5 there exists $z \in H$ such that

$$
\operatorname{Re}\left(T_{1}\left(u_{0}\right), z\right)_{H}>1>\operatorname{Re}\left(T_{2}(v), z\right)_{H}
$$

for all $\|v\|_{2} \leq c$. Therefore, replacing $v$ with $v \theta$ where $\theta$ is a suitable complex number having modulus 1 , it follows

$$
\begin{equation*}
\left\|T_{1}^{*} z\right\|>1>\left|\left(v, T_{2}^{*} z\right)_{U_{2}}\right| \tag{19.2.15}
\end{equation*}
$$

for all $\|v\|_{2} \leq c$. If $c=0,19.2 .15$ gives a contradiction immediately because of 19.2.12. Assume then that $c>0$. From 19.2.15, if $\|v\|_{2} \leq 1$, then

$$
\left|\left(v, T_{2}^{*} z\right)_{U_{2}}\right|<\frac{1}{c}<\frac{1}{c}\left\|T_{1}^{*} z\right\|
$$

Then from 19.2.15,

$$
\left\|T_{2}^{*} z\right\|_{U_{2}}=\sup _{\|v\| \leq 1}\left|\left(v, T_{2}^{*} z\right)_{U_{2}}\right| \leq \frac{1}{c}<\frac{1}{c}\left\|T_{1}^{*} z\right\|
$$

which contradicts 19.2.12. Therefore, it is clear that $T_{1}\left(U_{1}\right) \subseteq T_{2}\left(U_{2}\right)$.
Now consider the second claim. The first part shows $T_{1}\left(U_{1}\right)=T_{2}\left(U_{2}\right)$. Denote by $u_{i} \in U_{i}$, the point $T_{i}^{-1} x$. Without loss of generality, it can be assumed $x \neq 0$ because if $x=0$, then the definition of $T_{i}^{-1}$ gives $T_{i}^{-1}(x)=0$. Thus for $x \neq 0$ neither $u_{i}$ can equal 0 . I need to verify that $\left\|u_{1}\right\|_{1}=\left\|u_{2}\right\|_{2}$. Suppose then that this is not so. Say $\left\|u_{1}\right\|_{1}>\left\|u_{2}\right\|_{2}>0$.

$$
\frac{x}{\left\|u_{2}\right\|_{2}}=T_{2}\left(\frac{u_{2}}{\left\|u_{2}\right\|_{2}}\right) \in T_{2}(\overline{B(0,1)})
$$

But from the first part of the theorem this equals $T_{1}(\overline{B(0,1)})$ and so there exists $u_{1}^{\prime} \in$ $\overline{B(0,1)}$ such that

$$
\frac{x}{\left\|u_{2}\right\|_{2}}=T_{1} u_{1}^{\prime}
$$

Hence

$$
T_{1}\left(u_{1}^{\prime}-\frac{u_{1}}{\left\|u_{2}\right\|_{2}}\right)=\frac{x}{\left\|u_{2}\right\|_{2}}-\frac{x}{\left\|u_{2}\right\|_{2}}=0
$$

From Theorem 19.2.3 this implies

$$
\begin{aligned}
0 & =\left(u_{1}, u_{1}^{\prime}-\frac{u_{1}}{\left\|u_{2}\right\|_{2}}\right) \leq\left\|u_{1}\right\|_{1}\left\|u_{1}^{\prime}\right\|_{1}-\left\|u_{1}\right\|_{1} \frac{\left\|u_{1}\right\|_{1}}{\left\|u_{2}\right\|_{2}} \\
& =\left\|u_{1}\right\|_{1}\left(\left\|u_{1}^{\prime}\right\|_{1}-\frac{\left\|u_{1}\right\|_{1}}{\left\|u_{2}\right\|_{2}}\right) \leq\left\|u_{1}\right\|_{1}\left(1-\frac{\left\|u_{1}\right\|_{1}}{\left\|u_{2}\right\|_{2}}\right)
\end{aligned}
$$

which is a contradiction because it was assumed $\frac{\left\|u_{1}\right\|_{1}}{\left\|u_{2}\right\|_{2}}>1$. This proves the theorem.

### 19.3 Approximations In Hilbert Space

The Gram Schmidt process applies in any Hilbert space.
Theorem 19.3.1 Let $\left\{x_{1}, \cdots, x_{n}\right\}$ be a basis for $M$ a subspace of $H$ a Hilbert space. Then there exists an orthonormal basis for $M,\left\{u_{1}, \cdots, u_{n}\right\}$ which has the property that for each $k \leq n, \operatorname{span}\left(x_{1}, \cdots, x_{k}\right)=\operatorname{span}\left(u_{1}, \cdots, u_{k}\right)$. Also if $\left\{x_{1}, \cdots, x_{n}\right\} \subseteq H$, then

$$
\operatorname{span}\left(x_{1}, \cdots, x_{n}\right)
$$

is a closed subspace.
Proof: Let $\left\{x_{1}, \cdots, x_{n}\right\}$ be a basis for $M$. Let $u_{1} \equiv x_{1} /\left|x_{1}\right|$. Thus for $k=1, \operatorname{span}\left(u_{1}\right)=$ $\operatorname{span}\left(x_{1}\right)$ and $\left\{u_{1}\right\}$ is an orthonormal set. Now suppose for some $k<n, u_{1}, \cdots, u_{k}$ have been chosen such that $\left(u_{j} \cdot u_{l}\right)=\delta_{j l}$ and span $\left(x_{1}, \cdots, x_{k}\right)=\operatorname{span}\left(u_{1}, \cdots, u_{k}\right)$. Then define

$$
\begin{equation*}
u_{k+1} \equiv \frac{x_{k+1}-\sum_{j=1}^{k}\left(x_{k+1} \cdot u_{j}\right) u_{j}}{\left|x_{k+1}-\sum_{j=1}^{k}\left(x_{k+1} \cdot u_{j}\right) u_{j}\right|}, \tag{19.3.16}
\end{equation*}
$$

where the denominator is not equal to zero because the $x_{j}$ form a basis and so

$$
x_{k+1} \notin \operatorname{span}\left(x_{1}, \cdots, x_{k}\right)=\operatorname{span}\left(u_{1}, \cdots, u_{k}\right)
$$

Thus by induction,

$$
u_{k+1} \in \operatorname{span}\left(u_{1}, \cdots, u_{k}, x_{k+1}\right)=\operatorname{span}\left(x_{1}, \cdots, x_{k}, x_{k+1}\right)
$$

Also, $x_{k+1} \in \operatorname{span}\left(u_{1}, \cdots, u_{k}, u_{k+1}\right)$ which is seen easily by solving 19.3 .16 for $x_{k+1}$ and it follows

$$
\operatorname{span}\left(x_{1}, \cdots, x_{k}, x_{k+1}\right)=\operatorname{span}\left(u_{1}, \cdots, u_{k}, u_{k+1}\right)
$$

If $l \leq k$,

$$
\begin{aligned}
\left(u_{k+1} \cdot u_{l}\right) & =C\left(\left(x_{k+1} \cdot u_{l}\right)-\sum_{j=1}^{k}\left(x_{k+1} \cdot u_{j}\right)\left(u_{j} \cdot u_{l}\right)\right) \\
& =C\left(\left(x_{k+1} \cdot u_{l}\right)-\sum_{j=1}^{k}\left(x_{k+1} \cdot u_{j}\right) \delta_{l j}\right) \\
& =C\left(\left(x_{k+1} \cdot u_{l}\right)-\left(x_{k+1} \cdot u_{l}\right)\right)=0
\end{aligned}
$$

The vectors, $\left\{u_{j}\right\}_{j=1}^{n}$, generated in this way are therefore an orthonormal basis because each vector has unit length.

Consider the second claim about finite dimensional subspaces. Without loss of generality, assume $\left\{x_{1}, \cdots, x_{n}\right\}$ is linearly independent. If it is not, delete vectors until a linearly independent set is obtained. Then by the first part, $\operatorname{span}\left(x_{1}, \cdots, x_{n}\right)=\operatorname{span}\left(u_{1}, \cdots, u_{n}\right) \equiv M$ where the $u_{i}$ are an orthonormal set of vectors. Suppose $\left\{y_{k}\right\} \subseteq M$ and $y_{k} \rightarrow y \in H$. Is $y \in M$ ? Let

$$
y_{k} \equiv \sum_{j=1}^{n} c_{j}^{k} u_{j}
$$

Then let $\mathbf{c}^{k} \equiv\left(c_{1}^{k}, \cdots, c_{n}^{k}\right)^{T}$. Then

$$
\begin{aligned}
\left|\mathbf{c}^{k}-\mathbf{c}^{l}\right|^{2} & \equiv \sum_{j=1}^{n}\left|c_{j}^{k}-c_{j}^{l}\right|^{2}=\left(\sum_{j=1}^{n}\left(c_{j}^{k}-c_{j}^{l}\right) u_{j}, \sum_{j=1}^{n}\left(c_{j}^{k}-c_{j}^{l}\right) u_{j}\right) \\
& =\left\|y_{k}-y_{l}\right\|^{2}
\end{aligned}
$$

which shows $\left\{\mathbf{c}^{k}\right\}$ is a Cauchy sequence in $\mathbb{F}^{n}$ and so it converges to $\mathbf{c} \in \mathbb{F}^{n}$. Thus

$$
y=\lim _{k \rightarrow \infty} y_{k}=\lim _{k \rightarrow \infty} \sum_{j=1}^{n} c_{j}^{k} u_{j}=\sum_{j=1}^{n} c_{j} u_{j} \in M
$$

This completes the proof.
Theorem 19.3.2 Let $M$ be the span of $\left\{u_{1}, \cdots, u_{n}\right\}$ in a Hilbert space, $H$ and let $y \in H$. Then Py is given by

$$
\begin{equation*}
P y=\sum_{k=1}^{n}\left(y, u_{k}\right) u_{k} \tag{19.3.17}
\end{equation*}
$$

and the distance is given by

$$
\begin{equation*}
\sqrt{|y|^{2}-\sum_{k=1}^{n}\left|\left(y, u_{k}\right)\right|^{2}} \tag{19.3.18}
\end{equation*}
$$

## Proof:

$$
\begin{aligned}
\left(y-\sum_{k=1}^{n}\left(y, u_{k}\right) u_{k}, u_{p}\right) & =\left(y, u_{p}\right)-\sum_{k=1}^{n}\left(y, u_{k}\right)\left(u_{k}, u_{p}\right) \\
& =\left(y, u_{p}\right)-\left(y, u_{p}\right)=0
\end{aligned}
$$

It follows that

$$
\left(y-\sum_{k=1}^{n}\left(y, u_{k}\right) u_{k}, u\right)=0
$$

for all $u \in M$ and so by Corollary 19.1.13 this verifies 19.3.17.
The square of the distance, $d$ is given by

$$
\begin{aligned}
d^{2} & =\left(y-\sum_{k=1}^{n}\left(y, u_{k}\right) u_{k}, y-\sum_{k=1}^{n}\left(y, u_{k}\right) u_{k}\right) \\
& =|y|^{2}-2 \sum_{k=1}^{n}\left|\left(y, u_{k}\right)\right|^{2}+\sum_{k=1}^{n}\left|\left(y, u_{k}\right)\right|^{2}
\end{aligned}
$$

and this shows 19.3.18.
What if the subspace is the span of vectors which are not orthonormal? There is a very interesting formula for the distance between a point of a Hilbert space and a finite dimensional subspace spanned by an arbitrary basis.

Definition 19.3.3 Let $\left\{x_{1}, \cdots, x_{n}\right\} \subseteq H$, a Hilbert space. Define

$$
\mathscr{G}\left(x_{1}, \cdots, x_{n}\right) \equiv\left(\begin{array}{ccc}
\left(x_{1}, x_{1}\right) & \cdots & \left(x_{1}, x_{n}\right)  \tag{19.3.19}\\
\vdots & & \vdots \\
\left(x_{n}, x_{1}\right) & \cdots & \left(x_{n}, x_{n}\right)
\end{array}\right)
$$

Thus the $i j^{\text {th }}$ entry of this matrix is $\left(x_{i}, x_{j}\right)$. This is sometimes called the Gram matrix. Also define $G\left(x_{1}, \cdots, x_{n}\right)$ as the determinant of this matrix, also called the Gram determinant.

$$
G\left(x_{1}, \cdots, x_{n}\right) \equiv\left|\begin{array}{ccc}
\left(x_{1}, x_{1}\right) & \cdots & \left(x_{1}, x_{n}\right)  \tag{19.3.20}\\
\vdots & & \vdots \\
\left(x_{n}, x_{1}\right) & \cdots & \left(x_{n}, x_{n}\right)
\end{array}\right|
$$

The theorem is the following.
Theorem 19.3.4 Let $M=\operatorname{span}\left(x_{1}, \cdots, x_{n}\right) \subseteq H$, a Real Hilbert space where $\left\{x_{1}, \cdots, x_{n}\right\}$ is a basis and let $y \in H$. Then letting $d$ be the distance from $y$ to $M$,

$$
\begin{equation*}
d^{2}=\frac{G\left(x_{1}, \cdots, x_{n}, y\right)}{G\left(x_{1}, \cdots, x_{n}\right)} \tag{19.3.21}
\end{equation*}
$$

Proof: By Theorem 19.3.1 $M$ is a closed subspace of $H$. Let $\sum_{k=1}^{n} \alpha_{k} x_{k}$ be the element of $M$ which is closest to $y$. Then by Corollary 19.1.13,

$$
\left(y-\sum_{k=1}^{n} \alpha_{k} x_{k}, x_{p}\right)=0
$$

for each $p=1,2, \cdots, n$. This yields the system of equations,

$$
\begin{equation*}
\left(y, x_{p}\right)=\sum_{k=1}^{n}\left(x_{p}, x_{k}\right) \alpha_{k}, p=1,2, \cdots, n \tag{19.3.22}
\end{equation*}
$$

Also by Corollary 19.1.13,

$$
\|y\|^{2}=\overbrace{\left\|y-\sum_{k=1}^{n} \alpha_{k} x_{k}\right\|^{2}}^{d^{2}}+\left\|\sum_{k=1}^{n} \alpha_{k} x_{k}\right\|^{2}
$$

and so, using 19.3.22,

$$
\begin{align*}
\|y\|^{2} & =d^{2}+\sum_{j}\left(\sum_{k} \alpha_{k}\left(x_{k}, x_{j}\right)\right) \alpha_{j} \\
& =d^{2}+\sum_{j}\left(y, x_{j}\right) \alpha_{j}  \tag{19.3.23}\\
& \equiv d^{2}+\mathbf{y}_{x}^{T} \alpha \tag{19.3.24}
\end{align*}
$$

in which

$$
\mathbf{y}_{x}^{T} \equiv\left(\left(y, x_{1}\right), \cdots,\left(y, x_{n}\right)\right), \alpha^{T} \equiv\left(\alpha_{1}, \cdots, \alpha_{n}\right)
$$

Then 19.3.22 and 19.3.23 imply the following system

$$
\left(\begin{array}{cc}
\mathscr{G}\left(x_{1}, \cdots, x_{n}\right) & \mathbf{0} \\
\mathbf{y}_{x}^{T} & 1
\end{array}\right)\binom{\alpha}{d^{2}}=\binom{\mathbf{y}_{x}}{\|y\|^{2}}
$$

By Cramer's rule,

$$
\begin{aligned}
d^{2} & =\frac{\operatorname{det}\left(\begin{array}{cc}
\mathscr{G}\left(x_{1}, \cdots, x_{n}\right) & \mathbf{y}_{x} \\
\mathbf{y}_{x}^{T} & \|y\|^{2}
\end{array}\right)}{\operatorname{det}\left(\begin{array}{cc}
\mathscr{G}\left(x_{1}, \cdots, x_{n}\right) & \mathbf{0} \\
\mathbf{y}_{x}^{T} & 1
\end{array}\right)} \\
& =\frac{\operatorname{det}\left(\begin{array}{cc}
\mathscr{G}\left(x_{1}, \cdots, x_{n}\right) & \mathbf{y}_{x} \\
\mathbf{y}_{x}^{T} & \|y\|^{2}
\end{array}\right)}{\operatorname{det}\left(\mathscr{G}_{1}\left(x_{1}, \cdots, x_{n}\right)\right)} \\
& =\frac{\operatorname{det}\left(\mathscr{G}\left(x_{1}, \cdots, x_{n}, y\right)\right)}{\operatorname{det}\left(\mathscr{G}\left(x_{1}, \cdots, x_{n}\right)\right)}=\frac{G\left(x_{1}, \cdots, x_{n}, y\right)}{G\left(x_{1}, \cdots, x_{n}\right)}
\end{aligned}
$$

and this proves the theorem.

### 19.4 The Müntz Theorem

Recall the polynomials are dense in $C([0,1])$. This is a consequence of the Weierstrass approximation theorem. Now consider finite linear combinations of the functions, $t^{p_{k}}$ where $\left\{p_{0}, p_{1}, p_{2}, \cdots\right\}$ is a sequence of nonnegative real numbers, $p_{0} \equiv 0$. The Müntz theorem says this set, $S$ of finite linear combinations is dense in $C([0,1])$ exactly when $\sum_{k=1}^{\infty} \frac{1}{p_{k}}=\infty$. There are two versions of this theorem, one for density of $S$ in $L^{2}(0,1)$ and one for $C([0,1])$. The presentation follows Cheney [33].

Recall the Cauchy identity presented earlier, Theorem 5.5 .5 on Page 79 which is stated here for convenience.

Theorem 19.4.1 The following identity holds.

$$
\prod_{i, j}\left(a_{i}+b_{j}\right)\left|\begin{array}{ccc}
\frac{1}{a_{1}+b_{1}} & \cdots & \frac{1}{a_{1}+b_{n}}  \tag{19.4.25}\\
\vdots & & \vdots \\
\frac{1}{a_{n}+b_{1}} & \cdots & \frac{1}{a_{n}+b_{n}}
\end{array}\right|=\prod_{j<i}\left(a_{i}-a_{j}\right)\left(b_{i}-b_{j}\right)
$$

Lemma 19.4.2 Let $m, p_{1}, \cdots, p_{n}$ be distinct real numbers larger than $-1 / 2$. Thus the functions, $f_{m}(x) \equiv x^{m}, f_{p_{j}}(x) \equiv x^{p_{j}}$ are all in $L^{2}(0,1)$. Let

$$
M=\operatorname{span}\left(f_{p_{1}}, \cdots, f_{p_{n}}\right)
$$

Then the $L^{2}$ distance, $d$ between $f_{m}$ and $M$ is

$$
d=\frac{1}{\sqrt{2 m+1}} \prod_{j=1}^{n} \frac{\left|m-p_{j}\right|}{m+p_{j}+1}
$$

Proof: By Theorem 19.3.4

$$
\begin{aligned}
d^{2} & =\frac{G\left(f_{p_{1}}, \cdots, f_{p_{n}}, f_{m}\right)}{G\left(f_{p_{1}}, \cdots, f_{p_{n}}\right)} \\
\left(f_{p_{i}}, f_{p_{j}}\right) & =\int_{0}^{1} x^{p_{i}} x^{p_{j}} d x=\frac{1}{1+p_{i}+p_{j}}
\end{aligned}
$$

Therefore,

$$
d^{2}=\frac{\left|\begin{array}{ccccc}
\frac{1}{1+p_{1}+p_{1}} & \frac{1}{1+p_{1}+p_{2}} & \cdots & \frac{1}{1+p_{1}+p_{n}} & \frac{1}{1+m+p_{1}} \\
\frac{1}{1+p_{2}+p_{1}} & \frac{1}{1+p_{2}+p_{2}} & \cdots & \frac{1}{1+p_{2}+p_{n}} & \frac{1}{1+m+p_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{1}{1+p_{n}+p_{1}} & \frac{1}{1+p_{n}+p_{2}} & \cdots & \frac{1}{1+p_{n}+p_{n}} & \frac{1}{1+p_{n}+m} \\
\frac{1}{1+m+p_{1}} & \frac{1}{1+m+p_{2}} & \cdots & \frac{1}{1+m+p_{n}} & \frac{1}{1+m+m}
\end{array}\right|}{\left|\begin{array}{cccc|}
\frac{1}{1+p_{1}+p_{1}} & \frac{1}{1+p_{1}+p_{2}} & \cdots & \frac{1}{1+p_{1}+p_{n}} \\
\frac{1}{1+p_{2}+p_{1}} & \frac{1}{1+p_{2}+p_{2}} & \cdots & \frac{1}{1+p_{2}+p_{n}} \\
\vdots & \vdots & & \vdots \\
\frac{1}{1+p_{n}+p_{1}} & \frac{1}{1+p_{n}+p_{2}} & \cdots & \frac{1}{1+p_{n}+p_{n}}
\end{array}\right|}
$$

Now from the Cauchy identity, letting $a_{i}=p_{i}+\frac{1}{2}$ and $b_{j}=\frac{1}{2}+p_{j}$ with $p_{n+1}=m$, the numerator of the above equals

$$
\begin{gathered}
\frac{\prod_{j<i \leq n+1}\left(p_{i}-p_{j}\right)\left(p_{i}-p_{j}\right)}{\prod_{i, j \leq n+1}\left(p_{i}+p_{j}+1\right)} \\
=\frac{\prod_{k=1}^{n}\left(m-p_{k}\right)^{2} \prod_{j<i \leq n}\left(p_{i}-p_{j}\right)^{2}}{\prod_{i=1}^{n}\left(m+p_{i}+1\right) \prod_{j=1}^{n}\left(m+p_{j}+1\right) \prod_{i, j \leq n}\left(p_{i}+p_{j}+1\right)(2 m+1)} \\
=\frac{\prod_{k=1}^{n}\left(m-p_{k}\right)^{2} \prod_{j<i \leq n}\left(p_{i}-p_{j}\right)^{2}}{\prod_{i=1}^{n}\left(m+p_{i}+1\right)^{2} \prod_{i, j \leq n}\left(p_{i}+p_{j}+1\right)(2 m+1)}
\end{gathered}
$$

while the denominator equals

$$
\frac{\prod_{j<i \leq n}\left(p_{i}-p_{j}\right)^{2}}{\prod_{i, j \leq n}\left(p_{i}+p_{j}+1\right)}
$$

Therefore,

$$
\begin{aligned}
d^{2} & =\frac{\left(\frac{\Pi_{k=1}^{n}\left(m-p_{k}\right)^{2} \Pi_{j<i \leq n}\left(p_{i}-p_{j}\right)^{2}}{\prod_{i=1}^{n}\left(m+p_{i}+1\right)^{2} \Pi_{i, j \leq n}\left(p_{i}+p_{j}+1\right)(2 m+1)}\right)}{\left(\frac{\Pi_{j<i \leq n}\left(p_{i}-p_{j}\right)^{2}}{\prod_{i, j \leq n}\left(p_{i}+p_{j}+1\right)}\right)} \\
& =\frac{\prod_{k=1}^{n}\left(m-p_{k}\right)^{2}}{\prod_{i=1}^{n}\left(m+p_{i}+1\right)^{2}(2 m+1)}
\end{aligned}
$$

which shows

$$
d=\frac{1}{\sqrt{2 m+1}} \prod_{k=1}^{n} \frac{\left|m-p_{k}\right|}{m+p_{k}+1} .
$$

and this proves the lemma.
The following lemma relates an infinite sum to a product. First consider the graph of $\ln (1-x)$ for $x \in\left[0, \frac{1}{2}\right]$. Here is a rough sketch with two lines, $y=-x$ which lies above the graph of $\ln (1-x)$ and $y=-2 x$ which lies below.

Lemma 19.4.3 Let $a_{n} \neq 1, a_{n}>0$, and $\lim _{n \rightarrow \infty} a_{n}=0$. Then

$$
\prod_{k=1}^{\infty}\left(1-a_{n}\right) \equiv \lim _{n \rightarrow \infty} \prod_{k=1}^{n}\left(1-a_{n}\right)=0
$$

if and only if

$$
\sum_{n=1}^{\infty} a_{n}=+\infty
$$

Proof:Without loss of generality, you can assume $a_{n}<1 / 2$ because the two conditions are determined by the values of $a_{n}$ for $n$ large. By the above sketch the following is obtained.

$$
\ln \prod_{k=1}^{n}\left(1-a_{k}\right)=\sum_{k=1}^{n} \ln \left(1-a_{k}\right) \in\left[-2 \sum_{k=1}^{n} a_{k},-\sum_{k=1}^{n} a_{k}\right] .
$$

Therefore,

$$
e^{-2 \sum_{k=1}^{n} a_{k}} \leq \prod_{k=1}^{n}\left(1-a_{k}\right) \leq e^{-\sum_{k=1}^{n} a_{k}}
$$

The conclusion follows.
The following is Müntz's first theorem.
Theorem 19.4.4 Let $\left\{p_{n}\right\}$ be a sequence of real numbers larger than $-1 / 2$ such that $\lim _{n \rightarrow \infty} p_{n}=\infty$. Let $S$ denote the set of finite linear combinations of the functions

$$
\left\{x^{p_{1}}, x^{p_{2}}, \cdots\right\}
$$

Then $S$ is dense in $L^{2}(0,1)$ if and only if

$$
\sum_{i=1}^{\infty} \frac{1}{p_{i}}=\infty
$$

Proof: The polynomials are dense in $L^{2}(0,1)$ and so $S$ is dense in $L^{2}(0,1)$ if and only if for every $\varepsilon>0$ there exists a function $f$ from $S$ such that for each integer $m \geq$ $0,\left(\int_{0}^{1}\left|f(x)-x^{m}\right|^{2} d x\right)^{1 / 2}<\varepsilon$. This happens if and only if for all $n$ large enough, the distance in $L^{2}(0,1)$ between the function, $x \rightarrow x^{m}$ and $\operatorname{span}\left(x^{p_{1}}, x^{p_{2}}, \cdots, x^{p_{n}}\right)$ is less than $\varepsilon$. However, from Lemma 19.4.2 this distance equals

$$
\begin{aligned}
& \frac{1}{\sqrt{2 m+1}} \prod_{k=1}^{n} \frac{\left|m-p_{k}\right|}{m+p_{k}+1} \\
= & \frac{1}{\sqrt{2 m+1}} \prod_{k=1}^{n} 1-\left(1-\frac{\left|m-p_{k}\right|}{m+p_{k}+1}\right)
\end{aligned}
$$

Thus $S$ is dense if and only if

$$
\prod_{k=1}^{\infty}\left(1-\left(1-\frac{\left|m-p_{k}\right|}{m+p_{k}+1}\right)\right)=0
$$

which, by Lemma 19.4.3, happens if and only if

$$
\sum_{k=1}^{\infty}\left(1-\frac{\left|m-p_{k}\right|}{m+p_{k}+1}\right)=+\infty
$$

But this sum equals

$$
\sum_{k=1}^{\infty}\left(\frac{m+p_{k}+1-\left|m-p_{k}\right|}{m+p_{k}+1}\right)
$$

which has the same convergence properties as $\sum \frac{1}{p_{k}}$ by the limit comparison test. This proves the theorem.

The following is Müntz's second theorem.
Theorem 19.4.5 Let $S$ be finite linear combinations of $\left\{1, x^{p_{1}}, x^{p_{2}}, \cdots\right\}$ where $p_{j} \geq 1$ and $\lim _{n \rightarrow \infty} p_{n}=\infty$. Then $S$ is dense in $C([0,1])$ if and only if $\sum_{k=1}^{\infty} \frac{1}{p_{k}}=\infty$.

Proof: If $S$ is dense in $C([0,1])$ then $S$ must also be dense in $L^{2}(0,1)$ and so by Theorem 19.4.4 $\sum_{k=1}^{\infty} \frac{1}{p_{k}}=\infty$.

Suppose then that $\sum_{k=1}^{\infty} \frac{1}{p_{k}}=\infty$ so that by Theorem 19.4.4, $S$ is dense in $L^{2}(0,1)$. The theorem will be proved if it is shown that for all $m$ a nonnegative integer,

$$
\max \left\{\left|x^{m}-f(x)\right|: x \in[0,1]\right\}<\varepsilon
$$

for some $f \in S$. This is true if $m=0$ because $1 \in S$. Suppose then that $m>0$. Let $S^{\prime}$ denote finite linear combinations of the functions

$$
\left\{x^{p_{1}-1}, x^{p_{2}-1}, \cdots\right\}
$$

These functions are also dense in $L^{2}(0,1)$ because $\sum \frac{1}{p_{k}-1}=\infty$ by the limit comparison test. Then by Theorem 19.4.4 there exists $f \in S^{\prime}$ such that

$$
\left(\int_{0}^{1}\left|f(x)-m x^{m-1}\right|^{2} d x\right)^{1 / 2}<\varepsilon
$$

Thus $F(x) \equiv \int_{0}^{x} f(t) d t \in S$ and

$$
\begin{aligned}
\left|F(x)-x^{m}\right| & =\left|\int_{0}^{x}\left(f(t)-m t^{m-1}\right) d t\right| \\
& \leq \int_{0}^{x}\left|f(t)-m t^{m-1}\right| d t \\
& \leq\left(\int_{0}^{1}\left|f(t)-m t^{m-1}\right|^{2} d t\right)^{1 / 2}\left(\int_{0}^{1} d x\right)^{1 / 2} \\
& <\varepsilon
\end{aligned}
$$

and this proves the theorem.

### 19.5 Orthonormal Sets

The concept of an orthonormal set of vectors is a generalization of the notion of the standard basis vectors of $\mathbb{R}^{n}$ or $\mathbb{C}^{n}$.

Definition 19.5.1 Let $H$ be a Hilbert space. $S \subseteq H$ is called an orthonormal set if $\|x\|=1$ for all $x \in S$ and $(x, y)=0$ if $x, y \in S$ and $x \neq y$. For any set, $D$,

$$
D^{\perp} \equiv\{x \in H:(x, d)=0 \text { for all } d \in D\} .
$$

If $S$ is a set, $\operatorname{span}(S)$ is the set of all finite linear combinations of vectors from $S$.
You should verify that $D^{\perp}$ is always a closed subspace of $H$.
Theorem 19.5.2 In any separable Hilbert space, $H$, there exists a countable orthonormal set, $S=\left\{x_{i}\right\}$ such that the span of these vectors is dense in $H$. Furthermore, if $\operatorname{span}(S)$ is dense, then for $x \in H$,

$$
\begin{equation*}
x=\sum_{i=1}^{\infty}\left(x, x_{i}\right) x_{i} \equiv \lim _{n \rightarrow \infty} \sum_{i=1}^{n}\left(x, x_{i}\right) x_{i} \tag{19.5.26}
\end{equation*}
$$

Proof: Let $\mathscr{F}$ denote the collection of all orthonormal subsets of $H$. $\mathscr{F}$ is nonempty because $\{x\} \in \mathscr{F}$ where $\|x\|=1$. The set, $\mathscr{F}$ is a partially ordered set with the order given by set inclusion. By the Hausdorff maximal theorem, there exists a maximal chain, $\mathfrak{C}$ in $\mathscr{F}$. Then let $S \equiv \cup \mathfrak{C}$. It follows $S$ must be a maximal orthonormal set of vectors. Why? It remains to verify that $S$ is countable span $(S)$ is dense, and the condition, 19.5.26 holds. To see $S$ is countable note that if $x, y \in S$, then

$$
\|x-y\|^{2}=\|x\|^{2}+\|y\|^{2}-2 \operatorname{Re}(x, y)=\|x\|^{2}+\|y\|^{2}=2 .
$$

Therefore, the open sets, $B\left(x, \frac{1}{2}\right)$ for $x \in S$ are disjoint and cover $S$. Since $H$ is assumed to be separable, there exists a point from a countable dense set in each of these disjoint balls showing there can only be countably many of the balls and that consequently, $S$ is countable as claimed.

It remains to verify 19.5 .26 and that span $(S)$ is dense. If span $(S)$ is not dense, then $\overline{\operatorname{span}(S)}$ is a closed proper subspace of $H$ and letting $y \notin \overline{\operatorname{span}(S)}$,

$$
z \equiv \frac{y-P y}{\|y-P y\|} \in \operatorname{span}(S)^{\perp}
$$

But then $S \cup\{z\}$ would be a larger orthonormal set of vectors contradicting the maximality of $S$.

It remains to verify 19.5 .26 . Let $S=\left\{x_{i}\right\}_{i=1}^{\infty}$ and consider the problem of choosing the constants, $c_{k}$ in such a way as to minimize the expression

$$
\begin{gathered}
\left\|x-\sum_{k=1}^{n} c_{k} x_{k}\right\|^{2}= \\
\|x\|^{2}+\sum_{k=1}^{n}\left|c_{k}\right|^{2}-\sum_{k=1}^{n} \overline{c_{k}}\left(x, x_{k}\right)-\sum_{k=1}^{n} c_{k} \overline{\left(x, x_{k}\right)} .
\end{gathered}
$$

This equals

$$
\|x\|^{2}+\sum_{k=1}^{n}\left|c_{k}-\left(x, x_{k}\right)\right|^{2}-\sum_{k=1}^{n}\left|\left(x, x_{k}\right)\right|^{2}
$$

and therefore, this minimum is achieved when $c_{k}=\left(x, x_{k}\right)$ and equals

$$
\|x\|^{2}-\sum_{k=1}^{n}\left|\left(x, x_{k}\right)\right|^{2}
$$

Now since span $(S)$ is dense, there exists $n$ large enough that for some choice of constants, $c_{k}$,

$$
\left\|x-\sum_{k=1}^{n} c_{k} x_{k}\right\|^{2}<\varepsilon
$$

However, from what was just shown,

$$
\left\|x-\sum_{i=1}^{n}\left(x, x_{i}\right) x_{i}\right\|^{2} \leq\left\|x-\sum_{k=1}^{n} c_{k} x_{k}\right\|^{2}<\varepsilon
$$

showing that $\lim _{n \rightarrow \infty} \sum_{i=1}^{n}\left(x, x_{i}\right) x_{i}=x$ as claimed. This proves the theorem.
The proof of this theorem contains the following corollary.
Corollary 19.5.3 Let $S$ be any orthonormal set of vectors and let

$$
\left\{x_{1}, \cdots, x_{n}\right\} \subseteq S
$$

Then if $x \in H$

$$
\left\|x-\sum_{k=1}^{n} c_{k} x_{k}\right\|^{2} \geq\left\|x-\sum_{i=1}^{n}\left(x, x_{i}\right) x_{i}\right\|^{2}
$$

for all choices of constants, $c_{k}$. In addition to this, Bessel's inequality

$$
\|x\|^{2} \geq \sum_{k=1}^{n}\left|\left(x, x_{k}\right)\right|^{2}
$$

If $S$ is countable and $\operatorname{span}(S)$ is dense, then letting $\left\{x_{i}\right\}_{i=1}^{\infty}=S, 19.5 .26$ follows.

### 19.6 Fourier Series, An Example

In this section consider the Hilbert space, $L^{2}(0,2 \pi)$ with the inner product,

$$
(f, g) \equiv \int_{0}^{2 \pi} f \bar{g} d m
$$

This is a Hilbert space because of the theorem which states the $L^{p}$ spaces are complete, Theorem 15.1.10 on Page 403. An example of an orthonormal set of functions in $L^{2}(0,2 \pi)$ is

$$
\phi_{n}(x) \equiv \frac{1}{\sqrt{2 \pi}} e^{i n x}
$$

for $n$ an integer. Is it true that the span of these functions is dense in $L^{2}(0,2 \pi)$ ?
Theorem 19.6.1 Let $S=\left\{\phi_{n}\right\}_{n \in \mathbb{Z}}$. Then $\operatorname{span}(S)$ is dense in $L^{2}(0,2 \pi)$.
Proof: By regularity of Lebesgue measure, and Theorem 15.2 .4 that $C_{c}(0,2 \pi)$ is dense in $L^{2}(0,2 \pi)$. Therefore, it suffices to show that for $g \in C_{c}(0,2 \pi)$, then for every $\varepsilon>0$ there exists $h \in \operatorname{span}(S)$ such that $\|g-h\|_{L^{2}(0,2 \pi)}<\varepsilon$.

Let $T$ denote the points of $\mathbb{C}$ which are of the form $e^{i t}$ for $t \in \mathbb{R}$. Let $\mathscr{A}$ denote the algebra of functions consisting of polynomials in $z$ and $1 / z$ for $z \in T$. Thus a typical such function would be one of the form

$$
\sum_{k=-m}^{m} c_{k} z^{k}
$$

for $m$ chosen large enough. This algebra separates the points of $T$ because it contains the function, $p(z)=z$. It annihilates no point of $t$ because it contains the constant function 1. Furthermore, it has the property that for $f \in \mathscr{A}, \bar{f} \in \mathscr{A}$. By the Stone Weierstrass approximation theorem, Theorem 9.2 .10 on Page 203, $\mathscr{A}$ is dense in $C(T)$. Now for $g \in$ $C_{c}(0,2 \pi)$, extend $g$ to all of $\mathbb{R}$ to be $2 \pi$ periodic. Then letting $G\left(e^{i t}\right) \equiv g(t)$, it follows $G$ is well defined and continuous on $T$. Therefore, there exists $H \in \mathscr{A}$ such that for all $t \in \mathbb{R}$,

$$
\left|H\left(e^{i t}\right)-G\left(e^{i t}\right)\right|<\varepsilon^{2} / 2 \pi
$$

Thus $H\left(e^{i t}\right)$ is of the form

$$
H\left(e^{i t}\right)=\sum_{k=-m}^{m} c_{k}\left(e^{i t}\right)^{k}=\sum_{k=-m}^{m} c_{k} e^{i k t} \in \operatorname{span}(S)
$$

Let $h(t)=\sum_{k=-m}^{m} c_{k} e^{i k t}$. Then

$$
\begin{aligned}
\left(\int_{0}^{2 \pi}|g-h|^{2} d x\right)^{1 / 2} & \leq\left(\int_{0}^{2 \pi} \max \{|g(t)-h(t)|: t \in[0,2 \pi]\} d x\right)^{1 / 2} \\
& =\left(\int_{0}^{2 \pi} \max \left\{\left|G\left(e^{i t}\right)-H\left(e^{i t}\right)\right|: t \in[0,2 \pi]\right\} d x\right)^{1 / 2} \\
& <\left(\int_{0}^{2 \pi} \frac{\varepsilon^{2}}{2 \pi}\right)^{1 / 2}=\varepsilon
\end{aligned}
$$

This proves the theorem.
Corollary 19.6.2 For $f \in L^{2}(0,2 \pi)$,

$$
\lim _{m \rightarrow \infty}\left\|f-\sum_{k=-m}^{m}\left(f, \phi_{k}\right) \phi_{k}\right\|_{L^{2}(0,2 \pi)}
$$

Proof: This follows from Theorem 19.5.2 on Page 535.

### 19.7 Compact Operators

### 19.7.1 Compact Operators In Hilbert Space

Definition 19.7.1 Let $A \in \mathscr{L}(H, H)$ where $H$ is a Hilbert space. Then

$$
|(A x, y)| \leq\|A\|\|x\|\|y\|
$$

and so the map, $x \rightarrow(A x, y)$ is continuous and linear. By the Riesz representation theorem, there exists a unique element of $H$, denoted by $A^{*}$ y such that

$$
(A x, y)=\left(x, A^{*} y\right) .
$$

It is clear $y \rightarrow A^{*} y$ is linear and continuous. $A^{*}$ is called the adjoint of $A$. $A$ is a self adjoint operator if $A=A^{*}$. Thus for a self adjoint operator, $(A x, y)=(x, A y)$ for all $x, y \in H$. $A$ is a compact operator if whenever $\left\{x_{k}\right\}$ is a bounded sequence, there exists a convergent subsequence of $\left\{A x_{k}\right\}$. Equivalently, A maps bounded sets to sets whose closures are compact.

The big result is called the Hilbert Schmidt theorem. It is a generalization to arbitrary Hilbert spaces of standard finite dimensional results having to do with diagonalizing a symmetric matrix. There is another statement and proof of this theorem around Page 663.

Theorem 19.7.2 Let A be a compact self adjoint operator defined on a Hilbert space, $H$. Then there exists a countable set of eigenvalues, $\left\{\lambda_{i}\right\}$ and an orthonormal set of eigenvectors, $u_{i}$ satisfying

$$
\begin{equation*}
\lambda_{i} \text { is real, }\left|\lambda_{n}\right| \geq\left|\lambda_{n+1}\right|, A u_{i}=\lambda_{i} u_{i} \tag{19.7.27}
\end{equation*}
$$

and either

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \lambda_{n}=0 \tag{19.7.28}
\end{equation*}
$$

or for some $n$,

$$
\begin{equation*}
\operatorname{span}\left(u_{1}, \cdots, u_{n}\right)=H \tag{19.7.29}
\end{equation*}
$$

In any case,

$$
\begin{equation*}
\operatorname{span}\left(\left\{u_{i}\right\}_{i=1}^{\infty}\right) \text { is dense in } A(H) \tag{19.7.30}
\end{equation*}
$$

and for all $x \in H$,

$$
\begin{equation*}
A x=\sum_{k=1}^{\infty} \lambda_{k}\left(x, u_{k}\right) u_{k} \tag{19.7.31}
\end{equation*}
$$

where the sum might be finite. This sequence of eigenvectors and eigenvalues also satisfies

$$
\begin{equation*}
\left|\lambda_{n}\right|=\left\|A_{n}\right\| \tag{19.7.32}
\end{equation*}
$$

and

$$
\begin{equation*}
A_{n}: H_{n} \rightarrow H_{n} \tag{19.7.33}
\end{equation*}
$$

where $H \equiv H_{1}$ and $H_{n} \equiv\left\{u_{1}, \cdots, u_{n-1}\right\}^{\perp}$ and $A_{n}$ is the restriction of $A$ to $H_{n}$.
Proof: If $\|A\|=0$ then pick $u \in H$ with $\|u\|=1$ and let $\lambda_{1}=0$. Since $A(H)=0$ it follows the span of $u$ is dense in $A(H)$ and this proves the theorem in this uninteresting case.

Assume from now on $A \neq 0$. Let $A_{1}=A$ and let $\lambda_{1}$ be real and $\lambda_{1}^{2} \equiv\|A\|^{2}$. From the definition of $\|A\|$ there exists $x_{n},\left\|x_{n}\right\|=1$, and $\left\|A x_{n}\right\| \rightarrow\|A\|=\left|\lambda_{1}\right|$. Now it is clear that $A^{2}$ is also a compact self adjoint operator. Consider

$$
\left(\left(\lambda_{1}^{2}-A^{2}\right) x_{n}, x_{n}\right)=\lambda_{1}^{2}\left(x_{n}, x_{n}\right)-\left(A^{2} x_{n}, x_{n}\right)=\lambda_{1}^{2}-\left\|A x_{n}\right\|^{2} \rightarrow 0
$$

Since $A$ is compact, there exists a subsequence of $\left\{x_{n}\right\}$ still denoted by $\left\{x_{n}\right\}$ such that $A x_{n}$ converges to some element of $H$. Thus since $\lambda_{1}^{2}-A^{2}$ satisfies

$$
\left(\left(\lambda_{1}^{2}-A^{2}\right) y, y\right) \geq 0
$$

in addition to being self adjoint, it follows $x, y \rightarrow\left(\left(\lambda_{1}^{2}-A^{2}\right) x, y\right)$ satisfies all the axioms for an inner product except for the one which says that $(z, z)=0$ only if $z=0$. Therefore, the Cauchy Schwarz inequality may be used to write

$$
\begin{aligned}
\left|\left(\left(\lambda_{1}^{2}-A^{2}\right) x_{n}, y\right)\right| & \leq\left(\left(\lambda_{1}^{2}-A^{2}\right) y, y\right)^{1 / 2}\left(\left(\lambda_{1}^{2}-A^{2}\right) x_{n}, x_{n}\right)^{1 / 2} \\
& \leq e_{n}\|y\|
\end{aligned}
$$

where $e_{n} \rightarrow 0$ as $n \rightarrow \infty$. Therefore, taking the sup over all $\|y\| \leq 1$,

$$
\lim _{n \rightarrow \infty}\left\|\left(\lambda_{1}^{2}-A^{2}\right) x_{n}\right\|=0
$$

Since $A^{2} x_{n}$ converges, it follows, since $\lambda_{1} \neq 0$ that $\left\{x_{n}\right\}$ is a Cauchy sequence converging to $x$ with $\|x\|=1$. Therefore, $A^{2} x_{n} \rightarrow A^{2} x$ and so

$$
\left\|\left(\lambda_{1}^{2}-A^{2}\right) x\right\|=0
$$

Now

$$
\left(\lambda_{1} I-A\right)\left(\lambda_{1} I+A\right) x=\left(\lambda_{1} I+A\right)\left(\lambda_{1} I-A\right) x=0 .
$$

If $\left(\lambda_{1} I-A\right) x=0$, let $u_{1} \equiv x$. If $\left(\lambda_{1} I-A\right) x=y \neq 0$, let $u_{1} \equiv \frac{y}{\|y\|}$.
Suppose $\left\{u_{1}, \cdots, u_{n}\right\}$ is such that $A u_{k}=\lambda_{k} u_{k}$ and $\left|\lambda_{k}\right| \geq\left|\lambda_{k+1}\right|,\left|\lambda_{k}\right|=\left\|A_{k}\right\|$ and $A_{k}:$ $H_{k} \rightarrow H_{k}$ for $k \leq n$, for

$$
H_{k} \equiv\left\{u_{1}, \cdots, u_{k-1}\right\}^{\perp}, H_{0} \equiv\{0\} \text { so } H_{0}^{\perp}=H_{1}=H
$$

From the above, this results in case $n=1$.
If

$$
\operatorname{span}\left(u_{1}, \cdots, u_{n}\right)=H
$$

this yields the conclusion of the theorem 19.7.29. Therefore, assume the span of these vectors is always a proper subspace of $H$.

It is shown next that $A_{n+1}: H_{n+1} \rightarrow H_{n+1}$. Let

$$
y \in H_{n+1} \equiv\left\{u_{1}, \cdots, u_{n}\right\}^{\perp}
$$

Then for $k \leq n$

$$
\left(A y, u_{k}\right)=\left(y, A u_{k}\right)=\lambda_{k}\left(y, u_{k}\right)=0
$$

showing $A_{n+1}: H_{n+1} \rightarrow H_{n+1}$ as claimed.
Say $\lambda_{k}>0$ for $k \leq n-1$. There are two cases. Either $\lambda_{n}=0$ or it is not. In the case where $\lambda_{n}=0$ it follows $A_{n}=0$ since $\left\|A_{n}\right\|=0$. Every element of $H$ is the sum of one in span $\left(u_{1}, \cdots, u_{n}\right)$ and one in span $\left(u_{1}, \cdots, u_{n}\right)^{\perp}$. (note $\operatorname{span}\left(u_{1}, \cdots, u_{n}\right)$ is a closed subspace.) Thus, if $x \in H, x=y+z$ where $y \in \operatorname{span}\left(u_{1}, \cdots, u_{n}\right)$ and $z \in \operatorname{span}\left(u_{1}, \cdots, u_{n}\right)^{\perp}$ and $A z=0$. Say $y=\sum_{j=1}^{n} c_{j} u_{j}$. Then

$$
A x=A y=\sum_{j=1}^{n} c_{j} A u_{j}=\sum_{j=1}^{n} c_{j} \lambda_{j} u_{j} \in \operatorname{span}\left(u_{1}, \cdots, u_{n-1}\right) .
$$

Thus, if $\lambda_{n}=0,19.7 .30$ holds since $x \in H$ was arbitrary. Hence, from the above sum,

$$
\lambda_{k}\left(x, u_{k}\right)=\left(x, A u_{k}\right)=\left(A x, u_{k}\right)=c_{k} \lambda_{k}
$$

and so it suffices to let $c_{k}=\left(x, u_{k}\right)$ yielding the formula in 19.7.30 for any $x \in H$ with $\lambda_{n}=\lambda_{n+1}=\cdots$ all zero.

Now consider the case where $\lambda_{n} \neq 0$. In this case repeat the above argument used to find $u_{n+1}$ and $\lambda_{n+1}$ for the operator, $A_{n+1}$. This yields $u_{n+1} \in H_{n+1} \equiv\left\{u_{1}, \cdots, u_{n}\right\}^{\perp}$ such that

$$
\left\|u_{n+1}\right\|=1,\left\|A u_{n+1}\right\|=\left|\lambda_{n+1}\right|=\left\|A_{n+1}\right\| \leq\left\|A_{n}\right\|=\left|\lambda_{n}\right|
$$

and if it is ever the case that $\lambda_{n}=0$, it follows from the above argument that the conclusion of the theorem is obtained.

I claim $\lim _{n \rightarrow \infty} \lambda_{n}=0$. If this were not so, then for some $\varepsilon>0,0<\varepsilon=\lim _{n \rightarrow \infty}\left|\lambda_{n}\right|$ but then

$$
\begin{aligned}
\left\|A u_{n}-A u_{m}\right\|^{2} & =\left\|\lambda_{n} u_{n}-\lambda_{m} u_{m}\right\|^{2} \\
& =\left|\lambda_{n}\right|^{2}+\left|\lambda_{m}\right|^{2} \geq 2 \varepsilon^{2}
\end{aligned}
$$

and so there would not exist a convergent subsequence of $\left\{A u_{k}\right\}_{k=1}^{\infty}$ contrary to the assumption that $A$ is compact. This verifies the claim that $\lim _{n \rightarrow \infty} \lambda_{n}=0$.

It remains to verify that span $\left(\left\{u_{i}\right\}\right)$ is dense in $A(H)$. If $w \in \operatorname{span}\left(\left\{u_{i}\right\}\right)^{\perp}$ then $w \in H_{n}$ for all $n$ and so for all $n$,

$$
\|A w\| \leq\left\|A_{n}\right\|\|w\| \leq\left|\lambda_{n}\right|\|w\| .
$$

Therefore, $A w=0$. Now every vector from $H$ can be written as a sum of one from

$$
\operatorname{span}\left(\left\{u_{i}\right\}\right)^{\perp}=\overline{\operatorname{span}\left(\left\{u_{i}\right\}\right)}{ }^{\perp}
$$

and one from $\overline{\operatorname{span}\left(\left\{u_{i}\right\}\right)}$. Therefore, if $x \in H, x=y+w$ where $y \in \overline{\operatorname{span}\left(\left\{u_{i}\right\}\right)}$ and $w \in$ $\overline{\operatorname{span}\left(\left\{u_{i}\right\}\right)}{ }^{\perp}$ and $A w=0$. Also, since $y \in \overline{\operatorname{span}\left(\left\{u_{i}\right\}\right)}$, there exist constants, $c_{k}$ and $n$ such that

$$
\left\|y-\sum_{k=1}^{n} c_{k} u_{k}\right\|<\varepsilon,\left(w, u_{k}\right)=0 \text { for all } u_{k} .
$$

Therefore, from Corollary 19.5.3,

$$
\left\|y-\sum_{k=1}^{n}\left(y, u_{k}\right) u_{k}\right\|=\left\|y-\sum_{k=1}^{n}\left(x, u_{k}\right) u_{k}\right\|<\varepsilon
$$

Therefore,

$$
\|A\| \varepsilon>\left\|A\left(y-\sum_{k=1}^{n}\left(x, u_{k}\right) u_{k}\right)\right\|=\left\|A x-\sum_{k=1}^{n}\left(x, u_{k}\right) \lambda_{k} u_{k}\right\| .
$$

Since $\varepsilon$ is arbitrary, this shows span $\left(\left\{u_{i}\right\}\right)$ is dense in $A(H)$ and also implies 19.7.31.
Define $v \otimes u \in \mathscr{L}(H, H)$ by

$$
v \otimes u(x)=(x, u) v,
$$

then 19.7.31 is of the form

$$
A=\sum_{k=1}^{\infty} \lambda_{k} u_{k} \otimes u_{k}
$$

This is the content of the following corollary.
Corollary 19.7.3 The main conclusion of the above theorem can be written as

$$
A=\sum_{k=1}^{\infty} \lambda_{k} u_{k} \otimes u_{k}
$$

where the convergence of the partial sums takes place in the operator norm.

Proof: Using 19.7.31

$$
\begin{aligned}
& \left|\left(\left(A-\sum_{k=1}^{n} \lambda_{k} u_{k} \otimes u_{k}\right) x, y\right)\right|=\left|\left(A x-\sum_{k=1}^{n} \lambda_{k}\left(x, u_{k}\right) u_{k}, y\right)\right| \\
= & \left|\left(\sum_{k=n}^{\infty} \lambda_{k}\left(x, u_{k}\right) u_{k}, y\right)\right|=\left|\sum_{k=n}^{\infty} \lambda_{k}\left(x, u_{k}\right)\left(u_{k}, y\right)\right| \\
\leq & \left|\lambda_{n}\right|\left(\sum_{k=n}^{\infty}\left|\left(x, u_{k}\right)\right|^{2}\right)^{1 / 2}\left(\sum_{k=n}^{\infty}\left|\left(y, u_{k}\right)\right|^{2}\right)^{1 / 2} \leq\left|\lambda_{n}\right|\|x\|\|y\|
\end{aligned}
$$

It follows

$$
\left\|\left(A-\sum_{k=1}^{n} \lambda_{k} u_{k} \otimes u_{k}\right)(x)\right\| \leq\left|\lambda_{n}\right|\|x\|
$$

Lemma 19.7.4 If $V_{\lambda}$ is the eigenspace for $\lambda \neq 0$ and $B: V_{\lambda} \rightarrow V_{\lambda}$ is a compact self adjoint operator, then $V_{\lambda}$ must be finite dimensional.

Proof: This follows from the above theorem because it gives a sequence of eigenvalues on restrictions of $B$ to subspaces with $\lambda_{k} \downarrow 0$. Hence, eventually $\lambda_{n}=0$ because there is no other eigenvalue in $V_{\lambda}$ than $\lambda$. Hence there can be no eigenvector on $V_{\lambda}$ for $\lambda=0$ and $\operatorname{span}\left(u_{1}, \cdots, u_{n}\right)=V_{\lambda}=A\left(V_{\lambda}\right)$ for some $n$.

Corollary 19.7.5 Let A be a compact self adjoint operator defined on a separable Hilbert space, $H$. Then there exists a countable set of eigenvalues, $\left\{\lambda_{i}\right\}$ and an orthonormal set of eigenvectors, $u_{i}$ satisfying

$$
\begin{equation*}
A v_{i}=\lambda_{i} v_{i},\left\|u_{i}\right\|=1 \tag{19.7.34}
\end{equation*}
$$

$$
\begin{equation*}
\operatorname{span}\left(\left\{v_{i}\right\}_{i=1}^{\infty}\right) \text { is dense in } H . \tag{19.7.35}
\end{equation*}
$$

Furthermore, if $\lambda_{i} \neq 0$, the space, $V_{\lambda_{i}} \equiv\left\{x \in H: A x=\lambda_{i} x\right\}$ is finite dimensional.
Proof: Let $B$ be the restriction of $A$ to $V_{\lambda_{i}}$. Thus $B$ is a compact self adjoint operator which maps $V_{\lambda}$ to $V_{\lambda}$ and has only one eigenvalue $\lambda_{i}$ on $V_{\lambda_{i}}$. By Lemma 19.7.4, $V_{\lambda}$ is finite dimensional. As to the density of some span $\left(\left\{v_{i}\right\}_{i=1}^{\infty}\right)$ in $H$, in the proof of the above theorem, let $W \equiv \overline{\operatorname{span}\left(\left\{u_{i}\right\}\right)}{ }^{\perp}$. By Theorem 19.5.2, there is a maximal orthonormal set of vectors, $\left\{w_{i}\right\}_{i=1}^{\infty}$ whose span is dense in $W$. There are only countably many of these since the space $H$ is separable. As shown in the proof of the above theorem, $A w=0$ for all $w \in W$. Let $\left\{v_{i}\right\}_{i=1}^{\infty}=\left\{u_{i}\right\}_{i=1}^{\infty} \cup\left\{w_{i}\right\}_{i=1}^{\infty}$.

Note the last claim of this corollary about $V_{\lambda}$ being finite dimensional if $\lambda \neq 0$ holds independent of the separability of $H$.

Suppose $\lambda \notin\left\{\lambda_{k}\right\}_{k=1}^{\infty}$, the eigenvalues of $A$, and $\lambda \neq 0$. Then the above formula for $A$, 19.7.31, yields an interesting formula for $(A-\lambda I)^{-1}$. Note first that since $\lim _{n \rightarrow \infty} \lambda_{n}=0$, it follows that $\lambda_{n}^{2} /\left(\lambda_{n}-\lambda\right)^{2}$ must be bounded, say by a positive constant, $M$.

Corollary 19.7.6 Let A be a compact self adjoint operator and let $\lambda \notin\left\{\lambda_{n}\right\}_{n=1}^{\infty}$ and $\lambda \neq 0$ where the $\lambda_{n}$ are the eigenvalues of $A .(A x=\lambda x, x \neq 0)$ Then

$$
\begin{equation*}
(A-\lambda I)^{-1} x=-\frac{1}{\lambda} x+\frac{1}{\lambda} \sum_{k=1}^{\infty} \frac{\lambda_{k}}{\lambda_{k}-\lambda}\left(x, u_{k}\right) u_{k} \tag{19.7.36}
\end{equation*}
$$

Proof: Let $m<n$. Then since the $\left\{u_{k}\right\}$ form an orthonormal set,

$$
\begin{align*}
\left|\sum_{k=m}^{n} \frac{\lambda_{k}}{\lambda_{k}-\lambda}\left(x, u_{k}\right) u_{k}\right| & \leq\left(\sum_{k=m}^{n}\left(\frac{\lambda_{k}}{\lambda_{k}-\lambda}\right)^{2}\left|\left(x, u_{k}\right)\right|^{2}\right)^{1 / 2}  \tag{19.7.37}\\
& \leq M\left(\sum_{k=m}^{n}\left|\left(x, u_{k}\right)\right|^{2}\right)^{1 / 2}
\end{align*}
$$

But from Bessel's inequality, $\sum_{k=1}^{\infty}\left|\left(x, u_{k}\right)\right|^{2} \leq\|x\|^{2}$ and so for $m$ large enough, the first term in 19.7.37 is smaller than $\varepsilon$. This shows the infinite series in 19.7.36 converges. It is now routine to verify that the formula in 19.7.36 is the inverse.

### 19.8 Sturm Liouville Problems

A Sturm Liouville problem involves the differential equation,

$$
\begin{equation*}
\left(p(x) y^{\prime}\right)^{\prime}+(\lambda q(x)+r(x)) y=0, x \in[a, b], p(x) \geq 0 \tag{19.8.38}
\end{equation*}
$$

where we assume that $q(x) \geq 0$ for $x \in[a, b]$ and is positive except for finitely many points. Also, assume it is continuous. Probably, you could generalize this to assume less about $q$ if this is of interest. There will also be boundary conditions at $a, b$. These are typically of the form

$$
\begin{align*}
& C_{1} y(a)+C_{2} y^{\prime}(a)=0 \\
& C_{3} y(b)+C_{4} y^{\prime}(b)=0 \tag{19.8.39}
\end{align*}
$$

where

$$
\begin{equation*}
C_{1}^{2}+C_{2}^{2}>0, \text { and } C_{3}^{2}+C_{4}^{2}>0 \tag{19.8.40}
\end{equation*}
$$

Also we assume here that $a$ and $b$ are finite numbers. In the example, the constants $C_{i}$ are given and $\lambda$ is called the eigenvalue while a solution of the differential equation and given boundary conditions corresponding to $\lambda$ is called an eigenfunction.

There is a simple but important identity related to solutions of the above differential equation. Suppose $\lambda_{i}$ and $y_{i}$ for $i=1,2$ are two solutions of 19.8.38. Thus from the equation, we obtain the following two equations.

$$
\begin{aligned}
& \left(p(x) y_{1}^{\prime}\right)^{\prime} y_{2}+\left(\lambda_{1} q(x)+r(x)\right) y_{1} y_{2}=0, \\
& \left(p(x) y_{2}^{\prime}\right)^{\prime} y_{1}+\left(\lambda_{2} q(x)+r(x)\right) y_{1} y_{2}=0 .
\end{aligned}
$$

Subtracting the second from the first yields

$$
\begin{equation*}
\left(p(x) y_{1}^{\prime}\right)^{\prime} y_{2}-\left(p(x) y_{2}^{\prime}\right)^{\prime} y_{1}+\left(\lambda_{1}-\lambda_{2}\right) q(x) y_{1} y_{2}=0 \tag{19.8.41}
\end{equation*}
$$

Now we note that

$$
\left(p(x) y_{1}^{\prime}\right)^{\prime} y_{2}-\left(p(x) y_{2}^{\prime}\right)^{\prime} y_{1}=\frac{d}{d x}\left(\left(p(x) y_{1}^{\prime}\right) y_{2}-\left(p(x) y_{2}^{\prime}\right) y_{1}\right)
$$

and so integrating 19.8.41 from $a$ to $b$, we obtain

$$
\begin{equation*}
\left.\left(\left(p(x) y_{1}^{\prime}\right) y_{2}-\left(p(x) y_{2}^{\prime}\right) y_{1}\right)\right|_{a} ^{b}+\left(\lambda_{1}-\lambda_{2}\right) \int_{a}^{b} q(x) y_{1}(x) y_{2}(x) d x=0 \tag{19.8.42}
\end{equation*}
$$

We have been purposely vague about the nature of the boundary conditions because of a desire to not lose generality. However, we will always assume the boundary conditions are such that whenever $y_{1}$ and $y_{2}$ are two eigenfunctions, it follows that

$$
\begin{equation*}
\left.\left(\left(p(x) y_{1}^{\prime}\right) y_{2}-\left(p(x) y_{2}^{\prime}\right) y_{1}\right)\right|_{a} ^{b}=0 \tag{19.8.43}
\end{equation*}
$$

In the case where the boundary conditions are given by 19.8.39, and 19.8.40, we obtain 19.8.43. To see why this is so, consider the top limit. This yields

$$
p(b)\left[y_{1}^{\prime}(b) y_{2}(b)-y_{2}^{\prime}(b) y_{1}(b)\right]
$$

However we know from the boundary conditions that

$$
\begin{aligned}
& C_{3} y_{1}(b)+C_{4} y_{1}^{\prime}(b)=0 \\
& C_{3} y_{2}(b)+C_{4} y_{2}^{\prime}(b)=0
\end{aligned}
$$

and that from 19.8.40 that not both $C_{3}$ and $C_{4}$ equal zero. Therefore the determinant of the matrix of coefficients must equal zero. But this implies

$$
\left[y_{1}^{\prime}(b) y_{2}(b)-y_{2}^{\prime}(b) y_{1}(b)\right]=0
$$

which yields the top limit is equal to zero. A similar argument holds for the lower limit. Note that $y_{1}, y_{2}$ satisfy different differential equations because of different eigenvalues.

From now on the boundary condition will be conditions $L, \hat{L}$,

$$
L\left(y(a), y^{\prime}(a)\right)=0, \hat{L}\left(y(b), y^{\prime}(b)\right)=0
$$

which imply that if $y_{i}$ correspond to two different eigenvalues,

$$
\begin{equation*}
\left.\left(\left(p(x) y_{1}^{\prime}\right) y_{2}-\left(p(x) y_{2}^{\prime}\right) y_{1}\right)\right|_{a} ^{b}=0 \tag{*}
\end{equation*}
$$

and if $\alpha$ is a constant, if $L\left(y(a), y^{\prime}(a)\right)=0, \hat{L}\left(y(b), y^{\prime}(b)\right)=0$, then also

$$
L\left(\alpha y(a), \alpha y^{\prime}(a)\right)=0, \hat{L}\left(\alpha y(b), \alpha y^{\prime}(b)\right)=0
$$

For example, maybe one wants to say that $y$ is bounded at $a, b$.
With the identity 19.8.42 here is a result on orthogonality of the eigenfunctions.

Proposition 19.8.1 Suppose $y_{i}$ solves the boundary conditions and the differential equation for $\lambda=\lambda_{i}$ where $\lambda_{1} \neq \lambda_{2}$. Then we have the orthogonality relation

$$
\begin{equation*}
\int_{a}^{b} q(x) y_{1}(x) y_{2}(x) d x=0 \tag{19.8.44}
\end{equation*}
$$

In addition to this, if $u, v$ are two solutions to the differential equation corresponding to a single $\lambda, 19.8 .38$, not necessarily the boundary conditions, (same differential equation) then there exists a constant, $C$ such that

$$
\begin{equation*}
W(u, v)(x) p(x)=C \tag{19.8.45}
\end{equation*}
$$

for all $x \in[a, b]$. In this formula, $W(u, v)$ denotes the Wronskian given by

$$
\operatorname{det}\left(\begin{array}{cc}
u(x) & v(x)  \tag{19.8.46}\\
u^{\prime}(x) & v^{\prime}(x)
\end{array}\right)
$$

Proof: The orthogonality relation, 19.8.44 follows from the fundamental assumption, 19.8.43 and 19.8.42.

It remains to verify 19.8.45. We have from 19.8.41,

$$
\begin{aligned}
0 & =(\lambda-\lambda) q(x) u v+\left(p(x) u^{\prime}\right)^{\prime} v-\left(p(x) v^{\prime}\right)^{\prime} u \\
& =\frac{d}{d x}\left(p(x) u^{\prime} v-p(x) v^{\prime} u\right)=\frac{d}{d x}(p(x) W(v, u)(x))
\end{aligned}
$$

and so $p(x) W(u, v)(x)=-p(x) W(v, u)(x)=C$ as claimed.
Now consider the differential equation,

$$
\begin{equation*}
\left(p(x) y^{\prime}\right)^{\prime}+r(x) y=0 \tag{19.8.47}
\end{equation*}
$$

This is obtained from the one of interest by letting $\lambda=0$.
Criterion 19.8.2 Suppose we are able to find functions, $u$ and $v$ such that they solve the differential equation, 19.8 .47 and $u$ solves the boundary condition at $x=a$ while $v$ solves the boundary condition at $x=b$. Assume both are in $L^{2}(a, b)$ and $W(u, v) \neq 0$. It follows that both are in $L^{2}(a, b, q)$, the $L^{2}$ functions with respect to the measure $q(x) d x$. Thus

$$
(f, g)_{L^{2}(a, b, q)} \equiv \int_{a}^{b} f(x) g(x) q(x) d x
$$

If $p(x)>0$ on $[a, b]$ it is typically clear from the fundamental existence and uniqueness theorems for ordinary differential equations that such functions $u$ and $v$ exist. (See any good differential equations book or Problem 10 on Page 750.)

However, such functions might exist even if $p$ vanishes at the end points.
Lemma 19.8.3 Assume Criterion 19.8.2. A function y is a solution to the boundary conditions along with the equation,

$$
\begin{equation*}
\left(p(x) y^{\prime}\right)^{\prime}+r(x) y=g \tag{19.8.48}
\end{equation*}
$$

if

$$
\begin{equation*}
y(x)=\int_{a}^{b} G(t, x) g(t) d t \tag{19.8.49}
\end{equation*}
$$

where

$$
G(t, x)=\left\{\begin{array}{l}
c^{-1}(v(x) u(t)) \text { if } t<x  \tag{19.8.50}\\
c^{-1}(v(t) u(x)) \text { if } t>x
\end{array} .\right.
$$

where $c$ is the constant of Proposition 19.8.1 which satisfies $p(x) W(u, v)(x)=c$.
Proof: Why does $y$ solve the equation 19.8 .48 along with the boundary conditions?

$$
y(x)=\frac{1}{c} \int_{a}^{x} g(t) u(t) v(x) d t+\frac{1}{c} \int_{x}^{b} g(t) v(t) u(x) d t
$$

Differentiate

$$
\begin{array}{r}
y^{\prime}(x)=\frac{1}{c} g(x) u(x) v(x)+\frac{1}{c} \int_{a}^{x} g(t) u(t) v^{\prime}(x) d t \\
-\frac{1}{c} g(x) v(x) u(x)+\frac{1}{c} \int_{x}^{b} g(t) v(t) u^{\prime}(x) d t \\
=\frac{1}{c} \int_{a}^{x} g(t) u(t) v^{\prime}(x) d t+\frac{1}{c} \int_{x}^{b} g(t) v(t) u^{\prime}(x) d t
\end{array}
$$

Then

$$
p(x) y^{\prime}(x)=\frac{1}{c} \int_{a}^{x} g(t) u(t) p(x) v^{\prime}(x) d t+\frac{1}{c} \int_{x}^{b} g(t) v(t) p(x) u^{\prime}(x) d t
$$

Then $\left(p(x) y^{\prime}(x)\right)^{\prime}=$

$$
\begin{gathered}
\frac{1}{c} g(x) p(x) u(x) v^{\prime}(x)-\frac{1}{c} g(x) p(x) v(x) u^{\prime}(x) \\
+\frac{1}{c} \int_{a}^{x} g(t) u(t)\left(p(x) v^{\prime}(x)\right)^{\prime} d t+\frac{1}{c} \int_{x}^{b} g(t) v(t)\left(p(x) u^{\prime}(x)\right)^{\prime} d t
\end{gathered}
$$

From the definition of $c$, this equals

$$
\begin{gathered}
=g(x)+\frac{1}{c} \int_{a}^{x} g(t) u(t)\left(p(x) v^{\prime}(x)\right)^{\prime} d t+\frac{1}{c} \int_{x}^{b} g(t) v(t)\left(p(x) u^{\prime}(x)\right)^{\prime} d t \\
=g(x)+\frac{1}{c} \int_{a}^{x} g(t) u(t)(-r(x) v(x)) d t+\frac{1}{c} \int_{x}^{b} g(t) v(t)(-r(x) u(x)) d t \\
=g(x)-r(x)\left(\frac{1}{c} \int_{a}^{x} g(t) u(t) v(x) d t+\frac{1}{c} \int_{x}^{b} g(t) v(t) u(x) d t\right) \\
=g(x)-r(x) y(x)
\end{gathered}
$$

Thus

$$
\left(p(x) y^{\prime}(x)\right)^{\prime}+r(x) y(x)=g(x)
$$

so $y$ satisfies the equation. As to the boundary conditions, by assumption,

$$
\hat{L}\left(y(b), y^{\prime}(b)\right)=\hat{L}\left(v(b) \frac{1}{c} \int_{a}^{b} g(t) u(t) d t, v^{\prime}(b) \frac{1}{c} \int_{a}^{b} g(t) u(t) d t\right)=0
$$

because $v$ satisfies the boundary condition at $b$. The other boundary condition is exactly similar.

Now in the case of Criterion 19.8.2, $y$ is a solution to the Sturm Liouville eigenvalue problem, if and only if $y$ solves the boundary conditions and the equation,

$$
\left(p(x) y^{\prime}\right)^{\prime}+r(x) y(x)=-\lambda q(x) y(x) .
$$

This happens if

$$
\begin{gather*}
y(x)=\frac{-\lambda}{c} \int_{a}^{x} q(t) y(t) u(t) v(x) d t \\
+\frac{-\lambda}{c} \int_{x}^{b} q(t) y(t) v(t) u(x) d t \tag{19.8.51}
\end{gather*}
$$

Letting $\mu=\frac{1}{\lambda}$, this is of the form

$$
\begin{equation*}
\mu y(x)=\int_{a}^{b} G(t, x) q(t) y(t) d t \tag{19.8.52}
\end{equation*}
$$

where

$$
G(t, x)=\left\{\begin{array}{l}
-c^{-1}(v(x) u(t)) \text { if } t<x  \tag{19.8.53}\\
-c^{-1}(v(t) u(x)) \text { if } t>x
\end{array} .\right.
$$

Could $\mu=0$ ? If this happened, then from Lemma 19.8.3, we would have that $y=0$ is a solution of 19.8 .48 where the right side is $-q(t) y(t)$ which would imply that $q(t) y(t)=0$ (since the left side is 0 ) for all $t$ which implies $y(t)=0$ for all $t$ thanks to assumptions on $q(t)$. Thus we are not interested in this case. It follows from 19.8.53 that $G:[a, b] \times[a, b] \rightarrow$ $\mathbb{R}$ is continuous and symmetric, $G(t, x)=G(x, t)$.

$$
\begin{aligned}
G(x, t) & \equiv\left\{\begin{array}{l}
-c^{-1}(v(t) u(x)) \text { if } x<t \\
-c^{-1}(v(x) u(t)) \text { if } x>t
\end{array}\right. \\
& =G(t, x)
\end{aligned}
$$

Also we see that for $f \in C([a, b])$, and

$$
w(x) \equiv \int_{a}^{b} G(t, x) q(t) f(t) d t
$$

Lemma 19.8.3 implies $w$ is a solution to the boundary conditions and the equation

$$
\begin{equation*}
\left(p(x) y^{\prime}\right)^{\prime}+r(x) y=-q(x) f(x) \tag{19.8.54}
\end{equation*}
$$

Theorem 19.8.4 Suppose $u, v$ are given in Criterion 19.8.2. Then there exists a sequence of functions, $\left\{y_{n}\right\}_{n=1}^{\infty}$ and real numbers, $\lambda_{n}$ such that

$$
\begin{equation*}
\left(p(x) y_{n}^{\prime}\right)^{\prime}+\left(\lambda_{n} q(x)+r(x)\right) y_{n}=0, x \in[a, b], \tag{19.8.55}
\end{equation*}
$$

$$
\begin{align*}
& L\left(y(a), y^{\prime}(a)\right)=0 \\
& \hat{L}\left(y(b), y^{\prime}(b)\right)=0 \tag{19.8.56}
\end{align*}
$$

and

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left|\lambda_{n}\right|=\infty \tag{19.8.57}
\end{equation*}
$$

such that for all $f \in C([a, b])$, whenever $w$ satisfies 19.8 .54 and the boundary conditions,

$$
\begin{equation*}
w(x)=\sum_{n=1}^{\infty} \frac{1}{\lambda_{n}}\left(f, y_{n}\right) y_{n} . \tag{19.8.58}
\end{equation*}
$$

Also the functions, $\left\{y_{n}\right\}$ form a dense set in $L^{2}(a, b, q)$ which satisfy the orthogonality condition, 19.8.44.

Proof: Let $A y(x) \equiv \int_{a}^{b} G(t, x) q(t) y(t) d t$ where $G$ is defined above in 19.8.53. Then from symmetry and Fubini's theorem,

$$
\begin{aligned}
&(A y, z)_{L^{2}(a, b, q)}= \\
& \int_{a}^{b} \int_{a}^{b} G(t, x) y(t) z(x) q(x) q(t) d t d x=\int_{a}^{b} \int_{a}^{b} G(x, t) y(x) z(t) q(t) q(x) d x d t \\
&=\int_{a}^{b} \int_{a}^{b} G(t, x) z(t) q(t) y(x) q(x) d x d t \\
&=(A z, y)_{L^{2}(a, b, q)}
\end{aligned}
$$

This shows that $A$ is self adjoint. For $y \in L^{2}(a, b, q)$,

$$
A y(x)=\int_{a}^{x}\left(-c^{-1}(v(t) u(x))\right) y(t) q(t) d t+\int_{x}^{b}\left(-c^{-1}(v(x) u(t))\right) q(t) y(t) d t
$$

If you have $y_{n} \rightarrow y$ weakly in $L^{2}(a, b, q)$, then it is clear that $A y_{n}(x) \rightarrow A y(x)$ for each $x$, this from the above formula. Consider now $\left\|A y_{n}-A y\right\|_{L^{2}(a, b, q)}$. Look at the first term in the above. Is it true that the following converges to 0 ?

$$
\begin{equation*}
\int_{a}^{b}\left|\int_{a}^{x}\left(-c^{-1}(v(t) u(x))\right)\left(y_{n}(t)-y(t)\right) q(t) d t\right|^{2} q(x) d x \tag{**}
\end{equation*}
$$

We know that the integrand converges to 0 for each $x$. Is there a dominating function? If so, then the dominated convergence theorem gives the result.

$$
\begin{aligned}
& \quad\left|\int_{a}^{x}\left(-c^{-1}(v(t) u(x))\right) q(t)\left(y_{n}(t)-y(t)\right) d t\right| \\
& \leq|u(x)| C(c) \int_{a}^{x}\left|v(t)\left(y_{n}(t)-y(t)\right)\right| d t \\
& \quad \leq|u(x)| C\|v\|_{L^{2}(a, b, q)} \mid\left\|y_{n}-y\right\|_{L^{2}(a, b, q)}
\end{aligned}
$$

The last factor is uniformly bounded due to the weak convergence of $y_{n}$ to $y$. Therefore, there is a constant $C$ such that the integrand is bounded by $|u(x)|^{2} C$. Hence the dominated convergence theorem applies and we can conclude that $* *$ converges to 0 . Thus $A$ is a compact, self adjoint operator on $L^{2}(a, b, q)$

Therefore, by Theorem 19.7.2, there exist functions $y_{n}$ and real constants, $\mu_{n}$ such that $\left\|y_{n}\right\|_{L^{2}}=1$ and $A y_{n}=\mu_{n} y_{n}$ and

$$
\begin{equation*}
\left|\mu_{n}\right| \geq\left|\mu_{n+1}\right|, A u_{i}=\mu_{i} u_{i} \tag{19.8.59}
\end{equation*}
$$

and either

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \mu_{n}=0 \tag{19.8.60}
\end{equation*}
$$

or for some $n$,

$$
\begin{equation*}
\operatorname{span}\left(y_{1}, \cdots, y_{n}\right)=H \equiv L^{2}(a, b, q) \tag{19.8.61}
\end{equation*}
$$

Of course, $H$ is not finite dimensional and so the second will not hold. Also from Theorem 19.7.2,

$$
\begin{equation*}
\operatorname{span}\left(\left\{y_{i}\right\}_{i=1}^{\infty}\right) \text { is dense in } A(H) \tag{19.8.62}
\end{equation*}
$$

and so for all $f \in C([a, b])$,

$$
\begin{equation*}
A f=\sum_{k=1}^{\infty} \mu_{k}\left(f, y_{k}\right) y_{k} \tag{19.8.63}
\end{equation*}
$$

Thus for $w$ a solution of 19.8 .54 and suitable boundary conditions as above which cause $*$,

$$
w \equiv A f=\sum_{k=1}^{\infty} \frac{1}{\lambda_{k}}\left(f, y_{k}\right) y_{k} .
$$

The last claim follows from Corollary 19.7 .5 and the observation above that $\mu$ is never equal to zero.

Note that if $q(x) \neq 0$ we can say that for a given $g \in C([a, b])$, one can define $f$ by $g(x)=-q(x) f(x)$ and so if $w$ is a solution to the boundary conditions and the equation

$$
\left(p(x) w^{\prime}(x)\right)^{\prime}+r(x) w(x)=g(x)=-q(x) f(x)
$$

one obtains the formula

$$
\begin{aligned}
w(x) & =\sum_{k=1}^{\infty} \frac{1}{\lambda_{k}}\left(f, y_{k}\right) y_{k} \\
& =\sum_{k=1}^{\infty} \frac{1}{\lambda_{k}}\left(\frac{-g}{q}, y_{k}\right) y_{k}
\end{aligned}
$$

More can be said about convergence of these series based on the eigenfunctions of a Sturm Liouville problem. In particular, it can be shown that for reasonable functions the pointwise convergence properties are like those of Fourier series and that the series converges to the midpoint of the jump. This is partly done for the Legendre polynomials in [28]. For more on these topics see the old book by Ince, written in Egypt in the 1920's, [72], [73] or the 1955 book on differential equations by Coddington and Levinson [31].

As an example, consider the following eigenvalue problem

$$
\begin{equation*}
x^{2} y^{\prime \prime}+x y^{\prime}+\left(\lambda x^{2}-n^{2}\right) y=0, C_{1} y(L)+C_{2} y^{\prime}(L)=0, x \in[0, L] \tag{*}
\end{equation*}
$$

not both $C_{i}$ equal zero. Then you can write the equation in "self adjoint" form as

$$
\left(x y^{\prime}\right)^{\prime}+\left(\lambda x-\frac{n^{2}}{x}\right) y=0
$$

Multiply by $y$ and integrate from 0 to $L$. Then the boundary terms cancel and you get

$$
\int_{0}^{L}\left(\lambda x-\frac{n^{2}}{x}\right) y^{2} d x=0
$$

and so you must have $\lambda>0$.
Now it follows that corresponding to different values of $\lambda$ the eigenfunctions are orthogonal with respect to $x$. So what are the values of $\lambda$ and how can we describe the corresponding eigenfunctions?

Let $y$ be an eigenfunction. Let $z(\sqrt{\lambda} x)=y(x)$. Then

$$
\begin{gathered}
0=x^{2} y^{\prime \prime}+x y^{\prime}+\left(\lambda x^{2}-n^{2}\right) y \\
=\lambda x^{2} z^{\prime \prime}(\sqrt{\lambda} x)+\sqrt{\lambda} x z^{\prime}(\sqrt{\lambda} x)+\left(\lambda x^{2}-n^{2}\right) z(\sqrt{\lambda} x)
\end{gathered}
$$

Now replace $\sqrt{\lambda} x$ with $u$. Then

$$
u^{2} z^{\prime \prime}(u)+u z^{\prime}(u)+\left(u^{2}-n^{2}\right) z(u)=0
$$

Then we need

$$
z(\sqrt{\lambda} L)=0
$$

and $z$ is bounded near 0 . This happens if and only if $z(u)=J_{n}(u)$ because the other solution to the Bessel equation is unbounded near 0 . Then $J_{n}(\sqrt{\lambda} L)=0$ and so for some $\alpha$ a zero of $J_{n}$,

$$
\sqrt{\lambda} L=\alpha, \lambda=\frac{\alpha^{2}}{L^{2}}
$$

Thus the eigenvalues are

$$
\frac{\alpha^{2}}{L^{2}}, \alpha \text { a zero of } J_{n}(x)
$$

and the eigenfunctions are

$$
x \rightarrow J_{n}\left(\frac{\alpha}{L} x\right)
$$

Then Theorem 19.8.4 implies that if you have any $f \in L^{2}(a, b, x)$, you can obtain it as an expansion in terms of the functions $x \rightarrow J_{n}\left(\frac{\alpha_{k}}{L} x\right)$ where $\alpha_{k}$ are the zeros of the Bessel function. Note that this theorem and what was shown above also shows that there are countably many zeros of $J_{n}$ also.

### 19.8.1 Nuclear Operators

Definition 19.8.5 A self adjoint operator $A \in \mathscr{L}(H, H)$ for $H$ a separable Hilbert space is called a nuclear operator if for some complete orthonormal set, $\left\{e_{k}\right\}$,

$$
\sum_{k=1}^{\infty}\left|\left(A e_{k}, e_{k}\right)\right|<\infty
$$

To begin with here is an interesting lemma.
Lemma 19.8.6 Suppose $\left\{A_{n}\right\}$ is a sequence of compact operators in $\mathscr{L}(X, Y)$ for two Banach spaces, $X$ and $Y$ and suppose $A \in \mathscr{L}(X, Y)$ and

$$
\lim _{n \rightarrow \infty}\left\|A-A_{n}\right\|=0
$$

Then $A$ is also compact.
Proof: Let $B$ be a bounded set in $X$ such that $\|b\| \leq C$ for all $b \in B$. I need to verify $A B$ is totally bounded. Suppose then it is not. Then there exists $\varepsilon>0$ and a sequence, $\left\{A b_{i}\right\}$ where $b_{i} \in B$ and

$$
\left\|A b_{i}-A b_{j}\right\| \geq \varepsilon
$$

whenever $i \neq j$. Then let $n$ be large enough that

$$
\left\|A-A_{n}\right\| \leq \frac{\varepsilon}{4 C}
$$

Then

$$
\begin{aligned}
\left\|A_{n} b_{i}-A_{n} b_{j}\right\| & =\left\|A b_{i}-A b_{j}+\left(A_{n}-A\right) b_{i}-\left(A_{n}-A\right) b_{j}\right\| \\
& \geq\left\|A b_{i}-A b_{j}\right\|-\left\|\left(A_{n}-A\right) b_{i}\right\|-\left\|\left(A_{n}-A\right) b_{j}\right\| \\
& \geq\left\|A b_{i}-A b_{j}\right\|-\frac{\varepsilon}{4 C} C-\frac{\varepsilon}{4 C} C \geq \frac{\varepsilon}{2}
\end{aligned}
$$

a contradiction to $A_{n}$ being compact. This proves the lemma.
Then one can prove the following lemma. In this lemma, $A \geq 0$ will mean $(A x, x) \geq 0$.
Lemma 19.8.7 Let $A \geq 0$ be a nuclear operator defined on a separable Hilbert space, $H$. Then $A$ is compact and also, whenever $\left\{e_{k}\right\}$ is a complete orthonormal set,

$$
A=\sum_{j=1}^{\infty} \sum_{i=1}^{\infty}\left(A e_{i}, e_{j}\right) e_{i} \otimes e_{j}
$$

Proof: First consider the formula. Since $A$ is given to be continuous,

$$
A x=A\left(\sum_{j=1}^{\infty}\left(x, e_{j}\right) e_{j}\right)=\sum_{j=1}^{\infty}\left(x, e_{j}\right) A e_{j}
$$

the series converging because

$$
x=\sum_{j=1}^{\infty}\left(x, e_{j}\right) e_{j}
$$

Then also since $A$ is self adjoint,

$$
\begin{aligned}
\sum_{j=1}^{\infty} \sum_{i=1}^{\infty}\left(A e_{i}, e_{j}\right) e_{i} \otimes e_{j}(x) & \equiv \sum_{j=1}^{\infty} \sum_{i=1}^{\infty}\left(A e_{i}, e_{j}\right)\left(x, e_{j}\right) e_{i} \\
& =\sum_{j=1}^{\infty}\left(x, e_{j}\right) \sum_{i=1}^{\infty}\left(A e_{i}, e_{j}\right) e_{i} \\
& =\sum_{j=1}^{\infty}\left(x, e_{j}\right) \sum_{i=1}^{\infty}\left(A e_{j}, e_{i}\right) e_{i} \\
& =\sum_{j=1}^{\infty}\left(x, e_{j}\right) A e_{j}
\end{aligned}
$$

Next consider the claim that $A$ is compact. Let $C_{A} \equiv\left(\sum_{j=1}^{\infty}\left|\left(A e_{j}, e_{j}\right)\right|\right)^{1 / 2}$. Let $A_{n}$ be defined by

$$
A_{n} \equiv \sum_{j=1}^{\infty} \sum_{i=1}^{n}\left(A e_{i}, e_{j}\right)\left(e_{i} \otimes e_{j}\right)
$$

Then $A_{n}$ has values in $\operatorname{span}\left(e_{1}, \cdots, e_{n}\right)$ and so it must be a compact operator because bounded sets in a finite dimensional space must be precompact. Then

$$
\begin{aligned}
&\left|\left(A x-A_{n} x, y\right)\right|=\left|\sum_{j=1}^{\infty} \sum_{i=n+1}^{\infty}\left(A e_{i} e_{j}\right)\left(y, e_{j}\right)\left(e_{i}, x\right)\right| \\
&=\left|\sum_{j=1}^{\infty}\left(y, e_{j}\right) \sum_{i=n+1}^{\infty}\left(A e_{i} e_{j}\right)\left(e_{i}, x\right)\right| \\
& \leq\left|\sum_{j=1}^{\infty}\right|\left(y, e_{j}\right)\left|\left(A e_{j}, e_{j}\right)^{1 / 2} \sum_{i=n+1}^{\infty}\left(A e_{i} e_{i}\right)^{1 / 2}\right|\left(e_{i}, x\right)| | \\
& \leq\left(\sum_{j=1}^{\infty}\left|\left(y, e_{j}\right)\right|^{2}\right)^{1 / 2}\left(\sum_{j=1}^{\infty}\left|\left(A e_{j}, e_{j}\right)\right|\right)^{1 / 2} \\
& \cdot\left(\sum_{i=n+1}^{\infty}\left|\left(x, e_{i}\right)\right|^{2}\right)^{1 / 2}\left(\sum_{i=n+1}^{\infty}\left|\left(A e_{i} e_{i}\right)\right|\right)^{1 / 2} \\
& \leq|y||x| C_{A}\left(\sum_{i=n+1}^{\infty}\left|\left(A e_{i}, e_{i}\right)\right|\right)^{1 / 2}
\end{aligned}
$$

and this shows that if $n$ is sufficiently large,

$$
\left|\left(\left(A-A_{n}\right) x, y\right)\right| \leq \varepsilon|x||y|
$$

Therefore,

$$
\lim _{n \rightarrow \infty}\left\|A-A_{n}\right\|=0
$$

and so $A$ is the limit in operator norm of finite rank bounded linear operators, each of which is compact. Therefore, $A$ is also compact.

Definition 19.8.8 The trace of a nuclear operator $A \in \mathscr{L}(H, H)$ such that $A \geq 0$ is defined to equal

$$
\sum_{k=1}^{\infty}\left(A e_{k}, e_{k}\right)
$$

where $\left\{e_{k}\right\}$ is an orthonormal basis for the Hilbert space, $H$.
Theorem 19.8.9 Definition 19.8 .8 is well defined and equals $\sum_{j=1}^{\infty} \lambda_{j}$ where the $\lambda_{j}$ are the eigenvalues of $A$.

Proof: Suppose $\left\{u_{k}\right\}$ is some other orthonormal basis. Then

$$
e_{k}=\sum_{j=1}^{\infty} u_{j}\left(e_{k}, u_{j}\right)
$$

By Lemma 19.8.7 $A$ is compact and so

$$
A=\sum_{k=1}^{\infty} \lambda_{k} u_{k} \otimes u_{k}
$$

where the $u_{k}$ are the orthonormal eigenvectors of $A$ which form a complete orthonormal set. Then

$$
\begin{aligned}
\sum_{k=1}^{\infty}\left(A e_{k}, e_{k}\right) & =\sum_{k=1}^{\infty}\left(A\left(\sum_{j=1}^{\infty} u_{j}\left(e_{k}, u_{j}\right)\right), \sum_{j=1}^{\infty} u_{j}\left(e_{k}, u_{j}\right)\right) \\
& =\sum_{k=1}^{\infty} \sum_{i j}\left(A u_{j}, u_{i}\right)\left(e_{k}, u_{j}\right)\left(u_{i}, e_{k}\right) \\
& =\sum_{k=1}^{\infty} \sum_{j=1}^{\infty}\left(A u_{j}, u_{j}\right)\left|\left(e_{k}, u_{j}\right)\right|^{2} \\
& =\sum_{j=1}^{\infty}\left(A u_{j}, u_{j}\right) \sum_{k=1}^{\infty}\left|\left(e_{k}, u_{j}\right)\right|^{2}=\sum_{j=1}^{\infty}\left(A u_{j}, u_{j}\right)\left|u_{j}\right|^{2} \\
& =\sum_{j=1}^{\infty}\left(A u_{j}, u_{j}\right)=\sum_{j=1}^{\infty} \lambda_{j}
\end{aligned}
$$

and this proves the theorem.
This is just like it is for a matrix. Recall the trace of a matrix is the sum of the eigenvalues.

It is also easy to see that in any separable Hilbert space, there exist nuclear operators. Let $\sum_{k=1}^{\infty}\left|\lambda_{k}\right|<\infty$. Then let $\left\{e_{k}\right\}$ be a complete orthonormal set of vectors. Let

$$
A \equiv \sum_{k=1}^{\infty} \lambda_{k} e_{k} \otimes e_{k}
$$

It is not too hard to verify this works.
Much more can be said about nuclear operators.

### 19.8.2 Hilbert Schmidt Operators

Definition 19.8.10 Let $H$ and $G$ be two separable Hilbert spaces and let $T$ map $H$ to $G$ be linear. Then $T$ is called a Hilbert Schmidt operator if there exists some orthonormal basis for $H,\left\{e_{j}\right\}$ such that

$$
\sum_{j}\left\|T e_{j}\right\|^{2}<\infty
$$

The collection of all such linear maps will be denoted by $\mathscr{L}_{2}(H, G)$.

Theorem 19.8.11 $\mathscr{L}_{2}(H, G) \subseteq \mathscr{L}(H, G)$ and $\mathscr{L}_{2}(H, G)$ is a separable Hilbert space with norm given by

$$
\|T\|_{\mathscr{L}_{2}} \equiv\left(\sum_{k}\left\|T e_{k}\right\|^{2}\right)^{1 / 2}
$$

where $\left\{e_{k}\right\}$ is some orthonormal basis for $H$. Also $\mathscr{L}_{2}(H, G) \subseteq \mathscr{L}(H, G)$ and

$$
\begin{equation*}
\|T\| \leq\|T\|_{\mathscr{L}_{2}} \tag{19.8.64}
\end{equation*}
$$

All Hilbert Schmidt opearators are compact. Also for $X \in H$ and $Y \in G, X \otimes Y \in \mathscr{L}_{2}(H, G)$ and

$$
\begin{equation*}
\|X \otimes Y\|_{\mathscr{L}_{2}}=\|X\|_{H}\|Y\|_{G} \tag{19.8.65}
\end{equation*}
$$

Proof: First I want to show $\mathscr{L}_{2}(H, G) \subseteq \mathscr{L}(H, G)$ and $\|T\| \leq\|T\|_{\mathscr{L}_{2}}$. Pick an orthonormal basis for $H,\left\{e_{k}\right\}$ and an orthonormal basis for $G,\left\{f_{k}\right\}$. Then letting

$$
\begin{gathered}
x=\sum_{k=1}^{n} x_{k} e_{k} \\
T x=T\left(\sum_{k=1}^{n} x_{k} e_{k}\right)=\sum_{k=1}^{n} x_{k} T\left(e_{k}\right)
\end{gathered}
$$

where $x_{k} \equiv\left(x, e_{k}\right)$. Therefore using Minkowski's inequality,

$$
\begin{aligned}
\|T x\| & =\left(\sum_{k=1}^{\infty}\left|\left(T x, f_{k}\right)\right|^{2}\right)^{1 / 2}=\left(\sum_{k=1}^{\infty}\left|\left(\sum_{j=1}^{n} x_{j} T e_{j}, f_{k}\right)\right|^{2}\right)^{1 / 2} \\
& =\left(\sum_{k=1}^{\infty}\left|\sum_{j=1}^{n}\left(x_{j} T e_{j}, f_{k}\right)\right|^{2}\right)^{1 / 2} \leq \sum_{j=1}^{n}\left(\sum_{k=1}^{\infty}\left|\left(x_{j} T e_{j}, f_{k}\right)\right|^{2}\right)^{1 / 2} \\
& \leq \sum_{j=1}^{n}\left|x_{j}\right|\left(\sum_{k=1}^{\infty}\left|\left(T e_{j}, f_{k}\right)\right|^{2}\right)^{1 / 2} \\
& =\sum_{j=1}^{n}\left|x_{j}\right|\left\|T e_{j}\right\| \leq\left(\sum_{j=1}^{n}\left|x_{j}\right|^{2}\right)^{1 / 2}\|T\|_{\mathscr{L}_{2}}=\|x\|\|T\|_{\mathscr{L}_{2}}
\end{aligned}
$$

Therefore, since finite sums of the form $\sum_{k=1}^{n} x_{k} e_{k}$ are dense in $H$, it follows $T \in \mathscr{L}(H, G)$ and $\|T\| \leq\|T\|_{\mathscr{L}_{2}}$

Next consider the norm. I need to verify the norm does not depend on the choice of orthonormal basis. Let $\left\{f_{k}\right\}$ be an orthonormal basis for $G$. Then for $\left\{e_{k}\right\}$ an orthonormal basis for $H$,

$$
\begin{aligned}
\sum_{k}\left\|T e_{k}\right\|^{2} & =\sum_{k} \sum_{j}\left|\left(T e_{k}, f_{j}\right)\right|^{2}=\sum_{k} \sum_{j}\left|\left(e_{k}, T^{*} f_{j}\right)\right|^{2} \\
& =\sum_{j} \sum_{k}\left|\left(e_{k}, T^{*} f_{j}\right)\right|^{2}=\sum_{j}\left\|T^{*} f_{j}\right\|^{2}
\end{aligned}
$$

The above computation makes sense because it was just shown that $T$ is continuous. The same result would be obtained for any other orthonormal basis $\left\{e_{j}^{\prime}\right\}$ and this shows the norm is at least well defined. It is clear that this does indeed satisfy the axioms of a norm. and this proves the above claims.

It only remains to verify $\mathscr{L}_{2}(H, G)$ is a separable Hilbert space. It is clear that it is an inner product space because you only have to pick an orthonormal basis, $\left\{e_{k}\right\}$ and define the inner product as

$$
(S, T) \equiv \sum_{k}\left(S e_{k}, T e_{k}\right)
$$

This satisfies the axioms of an inner product and delivers the well defined norm so it is a well defined inner product. Indeed, we get it from

$$
(S, T) \equiv \frac{1}{4}\left(\|S+T\|_{\mathscr{L}_{2}}^{2}-\|S-T\|_{\mathscr{L}_{2}}^{2}\right)
$$

and the norm is well defined giving the same thing for any choice of the orthonormal basis so the same is true of the inner product.

Consider completeness. Suppose then that $\left\{T_{n}\right\}$ is a Cauchy sequence in $\mathscr{L}_{2}(H, G)$. Then from 19.8.64 $\left\{T_{n}\right\}$ is a Cauchy sequence in $\mathscr{L}(H, G)$ and so there exists a unique
$T$ such that $\lim _{n \rightarrow \infty}\left\|T_{n}-T\right\|=0$. Then it only remains to verify $T \in \mathscr{L}_{2}(H, G)$. But by Fatou's lemma,

$$
\sum_{k}\left\|T e_{k}\right\|^{2} \leq \lim \inf _{n \rightarrow \infty} \sum_{k}\left\|T_{n} e_{k}\right\|^{2}=\lim \inf _{n \rightarrow \infty}\left\|T_{n}\right\|_{\mathscr{L}_{2}}^{2}<\infty
$$

All that remains is to verify $\mathscr{L}_{2}(H, G)$ is separable and these Hilbert Schmidt operators are compact. I will show an orthonormal basis for $\mathscr{L}_{2}(H, G)$ is $\left\{f_{j} \otimes e_{k}\right\}$ where $\left\{f_{k}\right\}$ is an orthonormal basis for $G$ and $\left\{e_{k}\right\}$ is an orthonormal basis for $H$. Here, for $f \in G$ and $e \in H, f \otimes e(x) \equiv(x, e) f$.

I need to show $f_{j} \otimes e_{k} \in \mathscr{L}_{2}(H, G)$ and that it is an orthonormal basis for $\mathscr{L}_{2}(H, G)$ as claimed.

$$
\sum_{k}\left\|f_{j} \otimes e_{i}\left(e_{k}\right)\right\|^{2}=\sum_{k}\left\|f_{j} \delta_{i k}\right\|^{2}=\left\|f_{j}\right\|^{2}=1<\infty
$$

so each of these operators is in $\mathscr{L}_{2}(H, G)$. Next I show they are orthonormal.

$$
\begin{aligned}
\left(f_{j} \otimes e_{k}, f_{s} \otimes e_{r}\right) & =\sum_{p}\left(f_{j} \otimes e_{k}\left(e_{p}\right), f_{s} \otimes e_{r}\left(e_{p}\right)\right) \\
& =\sum_{p} \delta_{r p} \delta_{k p}\left(f_{j}, f_{s}\right)=\sum_{p} \delta_{r p} \delta_{k p} \delta_{j s}
\end{aligned}
$$

If $j=s$ and $k=r$ this reduces to 1 . Otherwise, this gives 0 . Thus these operators are orthonormal.

Now let $T \in \mathscr{L}_{2}(H, G)$. Consider

$$
T_{n} \equiv \sum_{i=1}^{n} \sum_{j=1}^{n}\left(T e_{i}, f_{j}\right) f_{j} \otimes e_{i}
$$

Then

$$
T_{n} e_{k}=\sum_{i=1}^{n} \sum_{j=1}^{n}\left(T e_{i}, f_{j}\right)\left(e_{k}, e_{i}\right) f_{j}=\sum_{j=1}^{n}\left(T e_{k}, f_{j}\right) f_{j}
$$

It follows $\left\|T_{n} e_{k}\right\| \leq\left\|T e_{k}\right\|$ and $\lim _{n \rightarrow \infty} T_{n} e_{k}=T e_{k}$. Therefore, from the dominated convergence theorem,

$$
\lim _{n \rightarrow \infty}\left\|T-T_{n}\right\|_{\mathscr{L}_{2}}^{2} \equiv \lim _{n \rightarrow \infty} \sum_{k}\left\|\left(T-T_{n}\right) e_{k}\right\|^{2}=0
$$

Therefore, the linear combinations of the $f_{j} \otimes e_{i}$ are dense in $\mathscr{L}_{2}(H, G)$ and this proves completeness of the orthonomal basis.

This also shows $\mathscr{L}_{2}(H, G)$ is separable. From 19.8 .64 it also shows that every $T \in$ $\mathscr{L}_{2}(H, G)$ is the limit in the operator norm of a sequence of compact operators. This follows because each of the $f_{j} \otimes e_{i}$ is easily seen to be a compact operator because if $B \subseteq H$ is bounded, then $\left(f_{j} \otimes e_{i}\right)(B)$ is a bounded subset of a one dimensional vector space so it is pre-compact. Thus $T_{n}$ is compact, being a finite sum of these. By Lemma 19.8.6, so is $T$.

Finally, consider 19.8.65.

$$
\begin{gathered}
\|X \otimes Y\|_{\mathscr{L}_{2}}^{2} \equiv \sum_{k}\left|X \otimes Y\left(f_{k}\right)\right|_{H}^{2} \equiv \sum_{k}\left|X\left(f_{k}, Y\right)\right|_{H}^{2} \\
=\|X\|_{H}^{2} \sum_{k}\left|\left(f_{k}, Y\right)\right|^{2}=\|X\|_{H}^{2}\|Y\|_{G}^{2} \square
\end{gathered}
$$

### 19.9 Compact Operators in Banach Space

In general for $A \in \mathscr{L}(X, Y)$ the following definition holds.

Definition 19.9.1 Let $A \in \mathscr{L}(X, Y)$. Then $A$ is compact if whenever $B \subseteq X$ is a bounded set, $A B$ is precompact. Equivalently, if $\left\{x_{n}\right\}$ is a bounded sequence in $X$, then $\left\{A x_{n}\right\}$ has a subsequence which converges in $Y$.

An important result is the following theorem about the adjoint of a compact operator.
Theorem 19.9.2 Let $A \in \mathscr{L}(X, Y)$ be compact. Then the adjoint operator, $A^{*} \in \mathscr{L}\left(Y^{\prime}, X^{\prime}\right)$ is also compact.

Proof: Let $\left\{y_{n}^{*}\right\}$ be a bounded sequence in $Y^{\prime}$. Let $B$ be the closure of the unit ball in $X$. Then $A B$ is precompact. Then it is clear that the functions $\left\{y_{n}^{*}\right\}$ are equicontinuous and uniformly bounded on the compact set, $\overline{A(B)}$. By the Ascoli Arzela theorem, there is a subsequence $\left\{y_{n_{k}}^{*}\right\}$ which converges uniformly to a continuous function, $f$ on $\overline{A(B)}$. Now define $g$ on $A X$ by

$$
g(A x)=\|x\| f\left(A\left(\frac{x}{\|x\|}\right)\right), g(A 0)=0
$$

Thus for $x_{1}, x_{2} \neq 0$, and $a, b$ scalars,

$$
\begin{aligned}
g\left(a A x_{1}+b A x_{2}\right) & \equiv\left\|a x_{1}+b x_{2}\right\| f\left(\frac{A\left(a x_{1}+b x_{2}\right)}{\left\|a x_{1}+b x_{2}\right\|}\right) \\
& \equiv \lim _{k \rightarrow \infty}\left\|a x_{1}+b x_{2}\right\| y_{n_{k}}^{*}\left(\frac{A\left(a x_{1}+b x_{2}\right)}{\left\|a x_{1}+b x_{2}\right\|}\right) \\
& =\lim _{k \rightarrow \infty} a y_{n_{k}}^{*}\left(A x_{1}\right)+b y_{n_{k}}^{*}\left(A x_{2}\right) \\
& =a \lim _{k \rightarrow \infty}\left\|x_{1}\right\| y_{n_{k}}^{*}\left(\frac{A x_{1}}{\left\|x_{1}\right\|}\right)+b \lim _{k \rightarrow \infty}\left\|x_{2}\right\| y_{n_{k}}^{*}\left(\frac{A x_{2}}{\left\|x_{2}\right\|}\right) \\
& =a\left\|x_{1}\right\| f\left(\frac{A x_{1}}{\left\|x_{1}\right\|}\right)+b\left\|x_{2}\right\| f\left(\frac{A x_{2}}{\left\|x_{2}\right\|}\right) \\
& \equiv a g\left(A x_{1}\right)+b g\left(A x_{2}\right)
\end{aligned}
$$

showing that $g$ is linear on $A X$. Also

$$
|g(A x)|=\lim _{k \rightarrow \infty}\left|\|x\| y_{n_{k}}^{*}\left(A\left(\frac{x}{\|x\|}\right)\right)\right| \leq C\|x\|\left\|A\left(\frac{x}{\|x\|}\right)\right\|=C\|A x\|
$$

and so by the Hahn Banach theorem, there exists $y^{*}$ extending $g$ to all of $Y$ having the same operator norm.

$$
y^{*}(A x)=\lim _{k \rightarrow \infty}\|x\| y_{n_{k}}^{*}\left(A\left(\frac{x}{\|x\|}\right)\right)=\lim _{k \rightarrow \infty} y_{n_{k}}^{*}(A x)
$$

Thus $A^{*} y_{n_{k}}^{*}(x) \rightarrow A^{*} y^{*}(x)$ for every $x$. In addition to this, for $x \in B$,

$$
\begin{aligned}
\left\|A^{*} y^{*}(x)-A^{*} y_{n_{k}}^{*}(x)\right\| & =\left\|y^{*}(A x)-y_{n_{k}}^{*}(A x)\right\| \\
& =\left\|g(A x)-y_{n_{k}}^{*}(A x)\right\| \\
& =\| \| x\left\|f\left(A\left(\frac{x}{\|x\|}\right)\right)-\right\| x\left\|y_{n_{k}}^{*}\left(\frac{A x}{\|x\|}\right)\right\| \\
& \leq\left\|f\left(A\left(\frac{x}{\|x\|}\right)\right)-y_{n_{k}}^{*}\left(\frac{A x}{\|x\|}\right)\right\|
\end{aligned}
$$

and this is uniformly small for large $k$ due to the uniform convergence of $y_{n_{k}}^{*}$ to $f$ on $\overline{A(B)}$. Therefore, $\left\|A^{*} y^{*}-A^{*} y_{n_{k}}^{*}\right\| \rightarrow 0$.

### 19.10 The Fredholm Alternative

Recall that if $A$ is an $n \times n$ matrix and if the only solution to the system, $A \mathbf{x}=0$ is $\mathbf{x}=0$ then for any $\mathbf{y} \in \mathbb{R}^{n}$ it follows that there exists a unique solution to the system $A \mathbf{x}=\mathbf{y}$. This holds because the first condition implies $A$ is one to one and therefore, $A^{-1}$ exists. Of course things are much harder in a general Banach space. Here is a simple example for a Hilbert space.

Example 19.10.1 Let $L^{2}(\mathbb{N} ; \mu)=H$ where $\mu$ is counting measure. Thus an element of $H$ is a sequence, $\mathbf{a}=\left\{a_{i}\right\}_{i=1}^{\infty}$ having the property that

$$
\|\mathbf{a}\|_{H} \equiv\left(\sum_{k=1}^{\infty}\left|a_{k}\right|^{2}\right)^{1 / 2}<\infty
$$

Define $A: H \rightarrow H$ by

$$
A \mathbf{a} \equiv \mathbf{b} \equiv\left\{0, a_{1}, a_{2}, \cdots\right\}
$$

Thus A slides the sequence to the right and puts a zero in the first slot. Clearly $A$ is one to one and linear but it cannot be onto because it fails to yield $\mathbf{e}_{1} \equiv\{1,0,0, \cdots\}$.

Notwithstanding the above example, there are theorems which are like the linear algebra theorem mentioned above which hold in an arbitrary Banach spaces in the case where the operator is compact. To begin with here is an interesting lemma.

Lemma 19.10.2 Suppose $A \in \mathscr{L}(X, X)$ is compact for $X$ a Banach space. Then $(I-A)(X)$ is a closed subspace of $X$.

Proof: Suppose $(I-A) x_{n} \rightarrow y$. Let

$$
\alpha_{n} \equiv \operatorname{dist}\left(x_{n}, \operatorname{ker}(I-A)\right)
$$

and let $z_{n} \in \operatorname{ker}(I-A)$ be such that

$$
\alpha_{n} \leq\left\|x_{n}-z_{n}\right\| \leq\left(1+\frac{1}{n}\right) \alpha_{n}
$$

Thus $(I-A)\left(x_{n}-z_{n}\right) \rightarrow y$ because $(I-A) z_{n}=0$.
Case 1: $\left\{x_{n}-z_{n}\right\}$ has a bounded subsequence.
If this is so, the compactness of $A$ implies there exists a subsequence, still denoted by $n$ such that $\left\{A\left(x_{n}-z_{n}\right)\right\}_{n=1}^{\infty}$ is a Cauchy sequence. Since $(I-A)\left(x_{n}-z_{n}\right) \rightarrow y$, this implies $\left\{\left(x_{n}-z_{n}\right)\right\}$ is also a Cauchy sequence converging to a point, $x \in X$. Then, taking the limit as $n \rightarrow \infty,(I-A) x=y$ and so $y \in(I-A)(X)$.

Case 2: $\lim _{n \rightarrow \infty}\left\|x_{n}-z_{n}\right\|=\infty$. I will show this case cannot occur.
In this case, let $w_{n} \equiv \frac{x_{n}-z_{n}}{\left\|x_{n}-z_{n}\right\|}$. Thus $(I-A) w_{n} \rightarrow 0$ and $w_{n}$ is bounded. Therefore, there exists a subsequence, still denoted by $n$ such that $\left\{A w_{n}\right\}$ is a Cauchy sequence. Now it follows

$$
A w_{n}-A w_{m}+e_{n}-e_{m}=w_{n}-w_{m}
$$

where $e_{k} \rightarrow 0$ as $k \rightarrow \infty$. This implies $\left\{w_{n}\right\}$ is a Cauchy sequence which must converge to some $w_{\infty} \in X$. Therefore, $(I-A) w_{\infty}=0$ and so $w_{\infty} \in \operatorname{ker}(I-A)$. However, this is impossible because of the following argument. If $z \in \operatorname{ker}(I-A)$,

$$
\begin{aligned}
\left\|w_{n}-z\right\| & =\frac{1}{\left\|x_{n}-z_{n}\right\|}\left\|x_{n}-z_{n}-\right\| x_{n}-z_{n}\|z\| \\
& \geq \frac{1}{\left\|x_{n}-z_{n}\right\|} \alpha_{n} \geq \frac{\alpha_{n}}{\left(1+\frac{1}{n}\right) \alpha_{n}}=\frac{n}{n+1} .
\end{aligned}
$$

Taking the limit, $\left\|w_{\infty}-z\right\| \geq 1$. Since $z \in \operatorname{ker}(I-A)$ is arbitrary, this shows

$$
\operatorname{dist}\left(w_{\infty}, \operatorname{ker}(I-A)\right) \geq 1
$$

Since Case 2 does not occur, this proves the lemma.
Theorem 19.10.3 Let $A \in \mathscr{L}(X, X)$ be a compact operator and let $f \in X$. Then there exists a solution, x, to

$$
\begin{equation*}
x-A x=f \tag{19.10.66}
\end{equation*}
$$

if and only if

$$
\begin{equation*}
x^{*}(f)=0 \tag{19.10.67}
\end{equation*}
$$

for all $x^{*} \in \operatorname{ker}\left(I-A^{*}\right)$.
Proof: Suppose $x$ is a solution to 19.10 .66 and let $x^{*} \in \operatorname{ker}\left(I-A^{*}\right)$. Then

$$
x^{*}(f)=x^{*}((I-A)(x))=\left(\left(I-A^{*}\right) x^{*}\right)(x)=0 .
$$

Next suppose $x^{*}(f)=0$ for all $x^{*} \in \operatorname{ker}\left(I-A^{*}\right)$. I will show there exists $x$ solving 19.10.66. By Lemma 19.10.2, $(I-A)(X)$ is a closed subspace of $X$. Is $f \in(I-A)(X)$ ? If not, then by the Hahn Banach theorem, there exists $x^{*} \in X^{\prime}$ such that $x^{*}(f) \neq 0$ but $x^{*}((I-A)(x))=0$ for all $x \in X$. However last statement says nothing more nor less than $\left(I-A^{*}\right) x^{*}=0$. This is a contradiction because for such $x^{*}$, it is given that $x^{*}(f)=0$. This proves the theorem.

The following corollary is called the Fredholm alternative.

Corollary 19.10.4 Let $A \in \mathscr{L}(X, X)$ be a compact operator. Then there exists a solution to the equation

$$
\begin{equation*}
x-A x=f \tag{19.10.68}
\end{equation*}
$$

for all $f \in X$ if and only if $\left(I-A^{*}\right)$ is one to one on $X^{\prime}$.
Proof: Suppose $\left(I-A^{*}\right)$ is one to one first. Then if $x^{*}-A^{*} x^{*}=0$ it follows $x^{*}=0$ and so for any $f \in X, x^{*}(f)=0$ for all $x^{*} \in \operatorname{ker}\left(I-A^{*}\right)$. By 19.10.3 there exists a solution to $(I-A) x=f$.

Now suppose there exists a solution, $x$, to $(I-A) x=f$ for every $f \in X$. If $\left(I-A^{*}\right) x^{*}=$ 0 , then for every $x \in X$,

$$
\left(I-A^{*}\right) x^{*}(x)=x^{*}((I-A)(x))=0
$$

Since $(I-A)$ is onto, this shows $x^{*}=0$ and so $\left(I-A^{*}\right)$ is one to one as claimed. This proves the corollary.

The following is just an easier version of the above.
Corollary 19.10.5 In the case where $X$ is a Hilbert space, the conclusions of Corollary 19.10.4, Theorem 19.10.3, and Lemma 19.10.2 remain true if $H^{\prime}$ is replaced by $H$ and the adjoint is understood in the usual manner for Hilbert space. That is

$$
(A x, y)_{H}=\left(x, A^{*} y\right)_{H}
$$

### 19.11 Square Roots

In this section, $H$ will be a Hilbert space, real or complex, and $T$ will denote an operator which satisfies the following definition. A useful theorem about the existence of square roots of certain operators is presented. This proof is very elementary. I found it in [80].

Definition 19.11.1 Let $T \in \mathscr{L}(H, H)$ satisfy $T=T^{*}$ (Hermitian) and for all $x \in H$,

$$
\begin{equation*}
(T x, x) \geq 0 \tag{19.11.69}
\end{equation*}
$$

Such an operator is referred to as positive and self adjoint. It is probably better to refer to such an operator as "nonnegative" since the possibility that $T x=0$ for some $x \neq 0$ is not being excluded. Instead of "self adjoint" you can also use the term, Hermitian. To save on notation, write $T \geq 0$ to mean $T$ is positive, satisfying 19.11.69.

With the above definition here is a fundamental result about positive self adjoint operators.

Proposition 19.11.2 Let $S, T$ be positive and self adjoint such that $S T=T S$. Then $S T$ is also positive and self adjoint.

Proof: It is obvious that $S T$ is self adjoint. The only problem is to show that $S T$ is positive. To show this, first suppose $S \leq I$. The idea is to write

$$
S=S_{n+1}+\sum_{k=0}^{n} S_{k}^{2}
$$

where $S_{0}=S$ and the operators $S_{k}$ are self adjoint. This is a useful idea because it is then obvious that the sum is positive. If we want such a representation as above for each $n$, then it follows that $S_{0} \equiv S$ and

$$
\begin{equation*}
S=S_{n}+\sum_{k=0}^{n-1} S_{k}^{2} \tag{19.11.70}
\end{equation*}
$$

so, subtracting these yields $0=S_{n+1}-S_{n}+S_{n}^{2}$ and so

$$
S_{n+1}=S_{n}-S_{n}^{2}
$$

Thus it is obvious that the $S_{k}$ are all self adjoint and this shows how to define the $S_{k}$ recursively. Say 19.11.70 holds and $S_{n+1}$ is defined above. Then

$$
S=S_{n}+\sum_{k=0}^{n-1} S_{k}^{2}=S_{n+1}+S_{n}^{2}+\sum_{k=0}^{n-1} S_{k}^{2}=S_{n+1}+\sum_{k=0}^{n} S_{k}^{2}
$$

If we start with $S$ self adjoint, then we end up with each of the $S_{n}$ also being self adjoint. Now the assumption that $I \geq S$ is used. Also, the $S_{n}$ are polynomials in $S$.

Claim: $I \geq S_{n} \geq 0$.
Proof of the claim: This is true if $n=0$ by assumption. Assume true for $n$. Then from the definition,

$$
S_{n+1}=S_{n}-S_{n}^{2}=\left(I-S_{n}\right) S_{n}\left(S_{n}+\left(I-S_{n}\right)\right)=S_{n}^{2}\left(I-S_{n}\right)+\left(I-S_{n}\right)^{2} S_{n}
$$

and it is obvious from the definition that the sum of positive operators is positive. Therefore, it suffices to show the two terms in the above are both positive. It is clear from the definition that each $S_{n}$ is Hermitian (self adjoint) because they are just polynomials in $S$. Also each must commute with $T$ for the same reason. Therefore,

$$
\left(S_{n}^{2}\left(I-S_{n}\right) x, x\right)=\left(\left(I-S_{n}\right) S_{n} x, S_{n} x\right) \geq 0
$$

and also

$$
\left(\left(I-S_{n}\right)^{2} S_{n} x, x\right)=\left(S_{n}\left(I-S_{n}\right) x,\left(I-S_{n}\right) x\right) \geq 0
$$

This proves the claim.
Now each $S_{k}$ commutes with $T$ because this is true of $S_{0}$ and succeding $S_{k}$ are polynomials in terms of $S_{0}$. Therefore,

$$
\begin{align*}
(S T x, x) & =\left(\left(S_{n+1}+\sum_{k=0}^{n} S_{k}^{2}\right) T x, x\right)=\left(S_{n+1} T x, x\right)+\sum_{k=0}^{n}\left(S_{k}^{2} T x, x\right) \\
& =\left(T x, S_{n+1} x\right)+\sum_{k=0}^{n}\left(T S_{k} x, S_{k} x\right) \tag{19.11.71}
\end{align*}
$$

Consider $S_{n+1} x$. From the claim,

$$
(S x, x)=\left(S_{n+1} x, x\right)+\sum_{k=0}^{n}\left|S_{k} x\right|^{2} \geq \sum_{k=0}^{n}\left|S_{k} x\right|^{2}
$$

and so $\lim _{n \rightarrow \infty} S_{n} x=0$. Hence from 19.11.71,

$$
\lim \inf _{n \rightarrow \infty}(S T x, x)=(S T x, x)=\lim \inf _{n \rightarrow \infty} \sum_{k=0}^{n}\left(T S_{k} x, S_{k} x\right) \geq 0
$$

All this was based on the assumption that $S \leq I$. The next task is to remove this assumption. Let $S T=T S$ where $T$ and $S$ are positive self adjoint operators. Then consider $S /\|S\|$. This is still a positive self adjoint operator and it commutes with $T$ just like $S$ does. Therefore, from the first part,

$$
0 \leq\left(\frac{S}{\|S\|} T x, x\right)=\frac{1}{\|S\|}(S T x, x)
$$

The proposition is like the familiar statement about real numbers which says that when you multiply two nonnegative real numbers the result is a nonnegative real number. The next lemma is a generalization of the familiar fact that if you have an increasing sequence of real numbers which is bounded above, then the sequence converges.

Lemma 19.11.3 Let $\left\{T_{n}\right\}$ be a sequence of self adjoint operators on a Hilbert space, $H$ and let $T_{n} \leq T_{n+1}$ for all $n$. Also suppose there exists $K$, a self adjoint operator such that for all $n, T_{n} \leq K$. Suppose also that each operator commutes with all the others and that $K$ commutes with all the $T_{n}$. Then there exists a self adjoint continuous operator, $T$ such that for all $x \in H, T_{n} x \rightarrow T x, T \leq K$, and $T$ commutes with all the $T_{n}$ and with $K$.

Proof: Consider $K-T_{n} \equiv S_{n}$. Then the $\left\{S_{n}\right\}$ are decreasing, that is, $\left\{\left(S_{n} x, x\right)\right\}$ is a decreasing sequence and from the hypotheses, $S_{n} \geq 0$ so the above sequence is bounded below by 0 . Therefore, $\lim _{n \rightarrow \infty}\left(S_{n} x, x\right)$ exists. By Proposition 19.11.2, if $n>m$,

$$
S_{m}^{2}-S_{n} S_{m}=S_{m}\left(S_{m}-S_{n}\right) \geq 0
$$

and similarly from the above proposition,

$$
S_{n} S_{m}-S_{n}^{2}=S_{n}\left(S_{m}-S_{n}\right) \geq 0
$$

Therefore, since $S_{n}$ is self adjoint,

$$
\begin{gathered}
\left|T_{n} x-T_{m} x\right|^{2}=\left|S_{n} x-S_{m} x\right|^{2}=\left(\left(S_{n}-S_{m}\right)^{2} x, x\right) \\
=\left(\left(S_{n}^{2}-2 S_{n} S_{m}+S_{m}^{2}\right) x, x\right)=\left(\left(S_{m}^{2}-S_{m} S_{n}\right) x, x\right)+\left(\left(S_{n}^{2}-S_{n} S_{m}\right) x, x\right) \\
\leq\left(\left(S_{m}^{2}-S_{m} S_{n}\right) x, x\right) \leq\left(\left(S_{m}^{2}-S_{n}^{2}\right) x, x\right) \\
=\left(\left(S_{m}-S_{n}\right)\left(S_{m}+S_{n}\right) x, x\right) \leq 2\left(\left(S_{m}-S_{n}\right) K x, x\right) \\
\leq 2\left(\left(S_{m}-S_{n}\right) K x, K x\right)^{1 / 2}\left(\left(S_{m}-S_{n}\right) x, x\right)^{1 / 2}
\end{gathered}
$$

The last step follows from an application of the Cauchy Schwarz inequality along with the fact $S_{m}-S_{n} \geq 0$. The last expression converges to 0 because $\lim _{n \rightarrow \infty}\left(S_{n} x, x\right)$ exists for each
$x$. It follows $\left\{T_{n} x\right\}$ is a Cauchy sequence. Let $T x$ be the thing to which it converges. $T$ is obviously linear and $(T x, x)=\lim _{n \rightarrow \infty}\left(T_{n} x, x\right) \leq(K x, x)$. Also

$$
(K T x, y)=\lim _{n \rightarrow \infty}\left(K T_{n} x, y\right)=\lim _{n \rightarrow \infty}\left(T_{n} K x, y\right)=(T K x, y)
$$

and so $T K=K T$. Similarly, $T$ commutes with all $T_{n}$.
In order to show $T$ is continuous, apply the uniform boundedness principle, Theorem 17.1.8. The convergence of $\left\{T_{n} x\right\}$ implies there exists a uniform bound on the norms, $\left\|T_{n}\right\|$ and so $\left|\left(T_{n} x, y\right)\right| \leq C|x||y|$. Now take the limit as $n \rightarrow \infty$ to conclude $|(T x, y)| \leq C|x||y|$ which shows $\|T\| \leq C$.

With this preparation, here is the theorem about square roots.
Theorem 19.11.4 Let $T \in \mathscr{L}(H, H)$ be a positive self adjoint linear operator. Then there exists a unique square root, $A$ with the following properties. $A^{2}=T, A$ is positive and self adjoint, A commutes with every operator which commutes with $T$.

Proof: First suppose $T \leq I$. Then define

$$
A_{0} \equiv 0, A_{n+1}=A_{n}+\frac{1}{2}\left(T-A_{n}^{2}\right)
$$

From this it follows that every $A_{n}$ is a polynomial in $T$. Therefore, $A_{n}$ commutes with $T$ and with every operator which commutes with $T$.

Claim 1: $A_{n} \leq I$.
Proof of Claim 1: This is true if $n=0$. Suppose it is true for $n$. Then by the assumption that $T \leq I$,

$$
\begin{aligned}
I-A_{n+1} & =I-A_{n}+\frac{1}{2}\left(A_{n}^{2}-T\right) \geq I-A_{n}+\frac{1}{2}\left(A_{n}^{2}-I\right) \\
& =I-A_{n}-\frac{1}{2}\left(I-A_{n}\right)\left(I+A_{n}\right)=\left(I-A_{n}\right)\left(I-\frac{1}{2}\left(I+A_{n}\right)\right) \\
& =\left(I-A_{n}\right)\left(I-A_{n}\right) \frac{1}{2} \geq 0
\end{aligned}
$$

Claim 2: $A_{n} \leq A_{n+1}$
Proof of Claim 2: From the definition of $A_{n}$, this is true if $n=0$ because

$$
A_{1}=T \geq 0=A_{0} .
$$

Suppose true for $n$. Then from Claim 1,

$$
\begin{aligned}
A_{n+2}-A_{n+1} & =A_{n+1}+\frac{1}{2}\left(T-A_{n+1}^{2}\right)-\left[A_{n}+\frac{1}{2}\left(T-A_{n}^{2}\right)\right] \\
& =A_{n+1}-A_{n}+\frac{1}{2}\left(A_{n}^{2}-A_{n+1}^{2}\right) \\
& =\left(A_{n+1}-A_{n}\right)\left(I-\frac{1}{2}\left(A_{n}+A_{n+1}\right)\right) \\
& \geq\left(A_{n+1}-A_{n}\right)\left(I-\frac{1}{2}(2 I)\right)=0
\end{aligned}
$$

Claim 3: $A_{n} \geq 0$
Proof of Claim 3: This is true if $n=0$. Suppose it is true for $n$.

$$
\begin{aligned}
\left(A_{n+1} x, x\right) & =\left(A_{n} x, x\right)+\frac{1}{2}(T x, x)-\frac{1}{2}\left(A_{n}^{2} x, x\right) \\
& \geq\left(A_{n} x, x\right)+\frac{1}{2}(T x, x)-\frac{1}{2}\left(A_{n} x, x\right) \geq 0
\end{aligned}
$$

because $A_{n}-A_{n}^{2}=A_{n}\left(I-A_{n}\right) \geq 0$ by Proposition 19.11.2.
Now $\left\{A_{n}\right\}$ is a sequence of positive self adjoint operators which are bounded above by $I$ such that each of these operators commutes with every operator which commutes with $T$. By Lemma 19.11.3, there exists a bounded linear operator $A$ such that for all $x$, $A_{n} x \rightarrow A x$. Then $A$ commutes with every operator which commutes with $T$ because each $A_{n}$ has this property. Also $A$ is a positive operator because each $A_{n}$ is. From passing to the limit in the definition of $A_{n}$,

$$
A x=A x+\frac{1}{2}\left(T x-A^{2} x\right)
$$

and so $T x=A^{2} x$. This proves the theorem in the case that $T \leq I$.
In the general case, consider $T /\|T\|$. Then

$$
\left(\frac{T}{\|T\|} x, x\right)=\frac{1}{\|T\|}(T x, x) \leq|x|^{2}=(I x, x)
$$

and so $T /\|T\| \leq I$. Therefore, it has a square root, $B$. Let $A=\sqrt{\|T\|} B$. Then $A$ has all the right properties and $A^{2}=\|T\| B^{2}=\|T\|(T /\|T\|)=T$. This proves the existence part of the theorem.

Next suppose both $A$ and $B$ are square roots of $T$ having all the properties stated in the theorem. Then $A B=B A$ because both $A$ and $B$ commute with every operator which commutes with $T$.

$$
\begin{equation*}
(A(A-B) x,(A-B) x),(B(A-B) x,(A-B) x) \geq 0 \tag{19.11.72}
\end{equation*}
$$

Therefore, on adding these,

$$
\begin{aligned}
& \left(\left(A^{2}-A B+B A-B^{2}\right) x,(A-B) x\right)=\left(\left(A^{2}-B^{2}\right) x,(A-B) x\right) \\
= & ((T-T) x,(A-B) x)=0
\end{aligned}
$$

It follows both expressions in 19.11.72 equal 0 since both are nonnegative and when they are added the result is 0 . Now applying the existence part of the theorem to $A$, there exists a positive square root of $A$ which is self adjoint. Thus

$$
(\sqrt{A}(A-B) x, \sqrt{A}(A-B) x)=0
$$

so $\sqrt{A}(A-B) x=0$ which implies $A(A-B) x=0$. Similarly, $B(A-B) x=0$. Subtracting these and taking the inner product with $x$,

$$
0=((A(A-B)-B(A-B)) x, x)=\left((A-B)^{2} x, x\right)=|(A-B) x|^{2}
$$

and so $A x=B x$ which shows $A=B$ since $x$ was arbitrary.

### 19.12 Ordinary Differential Equations in Banach Space

Here we consider the initial value problem for functions which have values in a Banach space. Let $X$ be a Banach space.
Definition 19.12.1 Define $B C([a, b] ; X)$ as the bounded continuous functions $f$ which have values in the Banach space $X$. For $f \in B C([a, b] ; X)$, $\gamma$ a real number. Then

$$
\begin{equation*}
\|f\|_{\gamma} \equiv \sup _{t \in[a, b]}\left\|f(t) e^{\gamma(t-a)}\right\| \tag{19.12.73}
\end{equation*}
$$

Then this is a norm. The usual norm is given by

$$
\|f\| \equiv \sup _{t \in[a, b]}\|f(t)\|
$$

Lemma 19.12.2 $\|\cdot\|_{\gamma}$ is a norm for $B C([a, b] ; X)$ and $B C([a, b] ; X)$ is a complete normed linear space. Also, a sequence is Cauchy in $\|\cdot\|_{\gamma}$ if and only if it is Cauchy in $\|\cdot\|$.

Proof: First consider the claim about $\|\cdot\|_{\gamma}$ being a norm. To simplify notation, let $T=[a, b]$. It is clear that $\|f\|_{\gamma}=0$ if and only if $f=0$ and $\|f\|_{\gamma} \geq 0$. Also,

$$
\|\alpha f\|_{\gamma} \equiv \sup _{t \in T}\left\|\alpha f(t) e^{\gamma(t-a)}\right\|=|\alpha| \sup _{t \in T}\left\|f(t) e^{\gamma(t-a)}\right\|=|\alpha|\|f\|_{\gamma}
$$

so it does what is should for scalar multiplication. Next consider the triangle inequality.

$$
\begin{aligned}
\|f+g\|_{\gamma} & =\sup _{t \in T}\left\|(f(t)+g(t)) e^{\gamma(t-a)}\right\| \leq \sup _{t \in T}\left(\left|f(t) e^{\gamma(t-a)}\right|+\left|g(t) e^{\gamma(t-a)}\right|\right) \\
& \leq \sup _{t \in T}\left|f(t) e^{\gamma(t-a)}\right|+\sup _{t \in T}\left|g(t) e^{\gamma(t-a)}\right|=\|f\|_{\gamma}+\|g\|_{\gamma}
\end{aligned}
$$

The rest follows from the next inequalities.

$$
\begin{aligned}
\|f\| & \equiv \sup _{t \in T}\|f(t)\|=\sup _{t \in T}\left\|f(t) e^{\gamma(t-a)} e^{-\gamma(t-a)}\right\| \leq e^{|\gamma(b-a)|}\|f\|_{\gamma} \\
& \equiv e^{|\gamma(b-a)|} \sup _{t \in T}\left\|f(t) e^{\gamma(t-a)}\right\| \leq\left(e^{|\gamma|(b-a)}\right)^{2} \sup _{t \in T}\|f(t)\|=\left(e^{|\gamma|(b-a)}\right)^{2}\|f\|
\end{aligned}
$$

Now consider the ordinary initial value problem

$$
\begin{equation*}
x^{\prime}(t)+F(t, x(t))=f(t), x(a)=x_{0}, t \in[a, b] \tag{19.12.74}
\end{equation*}
$$

where here $F:[a, b] \times X \rightarrow X$ is continuous and satisfies the Lipschitz condition

$$
\begin{equation*}
\|F(t, x)-F(t, y)\| \leq K\|x-y\|, F:[a, b] \times X \rightarrow X \text { is continuous } \tag{19.12.75}
\end{equation*}
$$

Thanks to the fundamental theorem of calculus, there exists a solution to 19.12 .74 if and only if it is a solution to the integral equation

$$
\begin{equation*}
x(t)=x_{0}-\int_{a}^{t} F(s, x(s)) d s \tag{19.12.76}
\end{equation*}
$$

Then we have the following theorem.

Theorem 19.12.3 Let 19.12.75 hold. Then there exists a unique solution to 19.12 .74 in $B C([a, b] ; X)$.

Proof: Use the norm of 19.12 .73 where $\gamma \neq 0$ is described later. Let $T: B C([a, b] ; X) \rightarrow$ $B C([a, b] ; X)$ be defined by

$$
T x(t) \equiv x_{0}-\int_{a}^{t} F(s, x(s)) d s
$$

Then

$$
\begin{aligned}
& \|T x(t)-T y(t)\|_{X}=\left\|\int_{a}^{t} F(s, x(s)) d s-\int_{a}^{t} F(s, y(s)) d s\right\| \\
\leq & K \int_{a}^{t}\|x(s)-y(s)\| d s=K \int_{a}^{t}\left\|(x(s)-y(s)) e^{\gamma(s-a)} e^{-\gamma(s-a)}\right\| d s \\
\leq & K \int_{a}^{t} e^{-\gamma(s-a)} d s\|x-y\|_{\gamma}=K\left(\frac{e^{-\gamma(t-a)}}{-\gamma}+\frac{1}{\gamma}\right)\|x-y\|_{\gamma}
\end{aligned}
$$

Therefore,

$$
\begin{gathered}
e^{\gamma(t-a)}\|T x(t)-T y(t)\|_{X} \leq K\left(\frac{e^{\gamma(t-a)}}{\gamma}-\frac{1}{\gamma}\right)\|x-y\|_{\gamma} \\
\|T x-T y\|_{\gamma} \leq \sup _{t \in[a, b]} K\left(\frac{e^{\gamma(t-a)}}{\gamma}-\frac{1}{\gamma}\right)\|x-y\|_{\gamma}
\end{gathered}
$$

Letting $\gamma=-m^{2}$, this reduces to

$$
\|T x-T y\|_{-m^{2}} \leq \frac{K}{m^{2}}\|x-y\|_{-m^{2}}
$$

and so if $K / m^{2}<1 / 2$, this shows the solution to the integral equation is the unique fixed point of a contraction mapping defined on $B C([a, b] ; X)$. This shows existence and uniqueness of the initial value problem 19.12.74.

Definition 19.12.4 Let $S:[0, \infty) \rightarrow \mathscr{L}(X, X)$ be continuous and satisfy

1. $S(t+s)=S(t) S(s)$ called the semigroup identity.
2. $S(0)=I$
3. $\lim _{h \rightarrow 0+} \frac{S(h) x-x}{h}=A x$ for $A$ a densely defined closed linear operator whenever $x \in$ $D(A) \subseteq X$.

Then $S$ is called a continuous semigroup and $A$ is said to generate $S$.

Then we have the following corollary of Theorem 19.12.3. First note the following. For $t \geq 0$ and $h \geq 0$, if $x \in D(A)$, the semigroup identity implies

$$
\lim _{h \rightarrow 0} \frac{S(t+h) x-S(t) x}{h}=\lim _{h \rightarrow 0} S(t) \frac{S(h) x-x}{h}=S(t) \lim _{h \rightarrow 0} \frac{S(h) x-x}{h} \equiv S(t) A x
$$

As shown above, $\mathscr{L}(X, X)$ is a perfectly good Banach space with the operator norm whenever $X$ is a Banach space.

Corollary 19.12.5 Let $X$ be a Banach space and let $A \in \mathscr{L}(X, X)$. Let $S(t)$ be the solution in $\mathscr{L}(X, X)$ to

$$
\begin{equation*}
S^{\prime}(t)=A S(t), S(0)=I \tag{19.12.77}
\end{equation*}
$$

Then $t \rightarrow S(t)$ is a continuous semigroup whose generator is $A$. In this case $A$ is actually defined on all of $X$, not just on a dense subset. Furthermore, in this case where $A \in \mathscr{L}(X, X)$, $S(t) A=A S(t)$. If $T(t)$ is any semigroup having $A$ as a generator, then $T(t)=S(t)$. Also you can express $S(t)$ as a power series,

$$
\begin{equation*}
S(t)=\sum_{n=0}^{\infty} \frac{(A t)^{n}}{n!} \tag{19.12.78}
\end{equation*}
$$

Proof: The solution to the initial value problem 19.12.77 exists on $[0, b]$ for all $b$ so it exists on all of $\mathbb{R}$ thanks to the uniqueness on every finite interval. First consider the semigroup property. Let $\Psi(t) \equiv S(t+s), \Phi(t) \equiv S(t) S(s)$. Then

$$
\begin{gathered}
\Psi^{\prime}(t)=S^{\prime}(t+s)=A S(t+s)=A \Psi(t), \Psi(0)=S(s) \\
\Phi^{\prime}(t)=S^{\prime}(t) S(s)=A S(t) S(s)=A \Phi(t), \Phi(0)=S(s)
\end{gathered}
$$

By uniqueness, $\Phi(t)=\Psi(t)$ for all $t \geq 0$. Thus $S(t) S(s)=S(t+s)=S(s) S(t)$. Now from this, for $t>0$

$$
S(t) A=S(t) \lim _{h \rightarrow 0} \frac{S(h)-I}{h}=\lim _{h \rightarrow 0} S(t) \frac{S(h)-I}{h}=\lim _{h \rightarrow 0} \frac{S(h)-I}{h} S(t)=A S(t)
$$

As to $A$ being the generator of $S(t)$, letting $x \in X$, then from the differential equation solved,

$$
\lim _{h \rightarrow 0+} \frac{S(h) x-x}{h}=\lim _{h \rightarrow 0+} \frac{1}{h} \int_{0}^{h} A S(t) x d t=A S(0) x=A x .
$$

If $T(t)$ is a semigroup generated by $A$ then for $t>0$,

$$
T^{\prime}(t) \equiv \lim _{h \rightarrow 0} \frac{T(t+h)-T(t)}{h}=\lim _{h \rightarrow 0} \frac{T(h)-I}{h} T(t)=A T(t)
$$

and $T(0)=I$. However, uniqueness applies because $T$ and $S$ both satisfy the same initial value problem and this yields $T(t)=S(t)$.

To show the power series equals $S(t)$ it suffices to show it satisfies the initial value problem. Using the mean value theorem,

$$
\sum_{n=0}^{\infty} \frac{A^{n}\left((t+h)^{n}-t^{n}\right)}{n!}=\sum_{n=1}^{\infty} \frac{A^{n}\left(t+\theta_{n}(h)\right)^{n-1}}{(n-1)!}
$$

where $\theta_{n}(h) \in(0, h)$. Then taking a limit as $h \rightarrow 0$ and using the dominated convergence theorem, the limit of the difference quotient is

$$
\sum_{n=1}^{\infty} \frac{A^{n} t^{n-1}}{(n-1)!}=A \sum_{n=1}^{\infty} \frac{A^{n-1} t^{n-1}}{(n-1)!}=A \sum_{n=0}^{\infty} \frac{(A t)^{n}}{n!}
$$

Thus $\sum_{n=0}^{\infty}{\frac{(A t)^{n}}{n!}}^{n}$ satisfies the differential equation. It clearly satisfies the initial condition. Hence it equals $S(t)$.

Note that as a consequence of the above argument showing that $T$ and $S$ are the same, it follows that $T(t) A=A T(t)$ so one obtains that if the generator is a bounded linear operator, then the semigroup commutes with this operator.

When dealing with differential equations, one of the best tools is Gronwall's inequality. This is presented next.

Theorem 19.12.6 Suppose $u$ is nonnegative, continuous, and real valued and that

$$
u(t) \leq C+\int_{0}^{t} k u(s) d s, k \geq 0
$$

Then $u(t) \leq C e^{k t}$.
Proof: Let $w(t) \equiv \int_{0}^{t} k u(s) d s$. Then

$$
w^{\prime}(t)=k u(t) \leq k C+k w(t)
$$

and so $w^{\prime}(t)-k w(t) \leq k C$ which implies $\frac{d}{d t}\left(e^{-k t} w(t)\right) \leq k C e^{-k t}$. Therefore,

$$
e^{-k t} w(t) \leq C k \int_{0}^{t} e^{-k s} d s=C k\left(\frac{1}{k}-\frac{1}{k} e^{-k t}\right)
$$

so $w(t) \leq C\left(e^{k t}-1\right)$. From the original inequality, $u(t) \leq C+w(t) \leq C+C e^{k t}-C=C e^{k t}$.

### 19.13 Fractional Powers of Operators

Let $A \in \mathscr{L}(X, X)$ for $X$ a Hilbert space, $A=A^{*}$. We want to define $A^{\alpha}$ for $\alpha \in(0,1)$ in such a way that things work as they should provided that $(A x, x) \geq 0$.

If $A \in(0, \infty)$ we can get $A^{-\alpha}$ for $\alpha \in(0,1)$ as

$$
A^{-\alpha} \equiv \frac{1}{\Gamma(\alpha)} \int_{0}^{\infty} e^{-A t} t^{a-1} d t
$$

Indeed, you change the variable as follows letting $u=A t$,

$$
\begin{aligned}
\int_{0}^{\infty} e^{-A t} t^{a-1} d t & =\int_{0}^{\infty} e^{-u}\left(\frac{u}{A}\right)^{a-1} \frac{1}{A} d u \\
& =\int_{0}^{\infty} e^{-u} u^{\alpha-1} A^{1-\alpha} \frac{1}{A} d u=A^{-\alpha} \Gamma(\alpha)
\end{aligned}
$$

Next we need to define $e^{-A t}$ for $A \in \mathscr{L}(X, X)$.

Definition 19.13.1 By definition, $e^{-A t} x_{0}$ will be $x(t)$ where $x(t)$ is the solution to the initial value problem

$$
x^{\prime}+A x=0, x(0)=x_{0}
$$

Such a solution exists and is unique by standard contraction mapping arguments as in Theorem 19.12.3. Equivalently, one could consider for $\Phi(t) \equiv e^{-A t}$ the solution in $\mathscr{L}(X, X)$ of

$$
\Phi^{\prime}(t)+A \Phi(t)=0, \Phi(0)=I
$$

Now the case of interest here is that $A=A^{*}$ and $(A x, x) \geq \delta|x|^{2}$. We need an estimate for $\left\|e^{-A t}\right\|$.

Lemma 19.13.2 Suppose $A=A^{*}$ and $(A x, x) \geq \varepsilon|x|^{2}$. Then

$$
\left\|e^{-A t}\right\| \leq e^{-\varepsilon t}
$$

Proof: Let $\hat{x}(t)=x(t) e^{\varepsilon t}$. Then the equation for $e^{-A t} x_{0} \equiv x(t)$ becomes

$$
\hat{x}^{\prime}(t)-\varepsilon \hat{x}(t)+A \hat{x}(t)=0, \hat{x}(0)=x_{0}
$$

Then multiplying by $\hat{x}(t)$ and integrating gives

$$
\frac{1}{2}|\hat{x}(t)|^{2}-\varepsilon \int_{0}^{t}|\hat{x}(s)|^{2} d s-\frac{1}{2}\left|x_{0}\right|^{2}+\int_{0}^{t}(A \hat{x}, \hat{x}) d s=0
$$

and so, from the assumed estimate,

$$
\frac{1}{2}|\hat{x}(t)|^{2}-\varepsilon \int_{0}^{t}|\hat{x}(s)|^{2} d s-\frac{1}{2}\left|x_{0}\right|^{2}+\int_{0}^{t} \varepsilon|\hat{x}(s)|^{2} d s \leq 0
$$

and so $|\hat{x}(t)| \leq\left|x_{0}\right|$. Hence, $|x(t)|=\left|e^{-A t} x_{0}\right| \leq\left|x_{0}\right| e^{-\varepsilon t}$. Since $x_{0}$ was arbitrary, it follows that $\left\|e^{-A t}\right\| \leq e^{-\varepsilon t}$.

With this estimate, we can define $A^{-\alpha}$ for $\alpha \in(0,1)$ if $A=A^{*}$ and $(A x, x) \geq \varepsilon|x|^{2}$.
Definition 19.13.3 Let $A \in \mathscr{L}(X, X), A=A^{*}$ and $(A x, x) \geq \varepsilon|x|^{2}$. Then for $\alpha \in(0,1)$,

$$
A^{-\alpha} \equiv \frac{1}{\Gamma(\alpha)} \int_{0}^{\infty} e^{-A t} t^{a-1} d t
$$

The integral is well defined thanks to the estimate of the above lemma which gives $\left\|e^{-A t}\right\| \leq$ $e^{-\varepsilon t}$. You can let the integral be a standard improper Riemann integral since everything in sight is continuous. For such A, define

$$
A^{\alpha} \equiv A A^{-(1-\alpha)}
$$

Note the meaning of the integral. It takes place in $\mathscr{L}(X, X)$ and Riemann sums approximating this integral also take place in $\mathscr{L}(X, X)$. Thus

$$
\int_{0}^{\infty} e^{-A t} t^{a-1} d t\left(x_{0}\right)=\int_{0}^{\infty} t^{a-1} e^{-A t}\left(x_{0}\right) d t
$$

by approximating the improper integral with Riemann sums and using the obvious fact that such an identification holds for each sum in the approximation. Similar reasoning shows that an inner product can be taken inside the integral

$$
\left(\int_{0}^{\infty} e^{-A t} t^{a-1} d t\left(x_{0}\right), y_{0}\right)=\int_{0}^{\infty} e^{-A t}\left(x_{0}, y_{0}\right) t^{a-1} d t
$$

With this observation, the following lemma is fairly easy.
Lemma 19.13.4 For all $x_{0}, \int_{0}^{\infty} e^{-A t} t^{a-1} d t\left(x_{0}\right)=\int_{0}^{\infty} t^{a-1} e^{-A t}\left(x_{0}\right) d t$. Also $A^{-\alpha}$ is Hermitian whenever $A$ is. (This is the case considered here.) Also we have the semigroup property $e^{-A(t+s)}=e^{-A t} e^{-A s}$ for $t, s \geq 0$. In addition to this, if $C A=A C$ then $e^{-A t} C=C e^{-A t}$. In words, $e^{-A t}$ commutes with every $C \in \mathscr{L}(X, X)$ which commutes with A. Also, $e^{-A t}$ is Hermitian whenever $A$ is and so is $A^{-\alpha}$. (This is what is being considered here.)

Proof: The semigroup property follows right away from uniqueness considerations for the ordinary initial value problem. Indeed, letting $s, t \geq 0$, fix $s$ and consider the following for $\Phi(t) \equiv e^{-A t}$. Thus $\Phi(0)=I$ and $\Phi(t) x_{0}$ is the solution to $x^{\prime}+A x=0, x(0)=x_{0}$. Then define

$$
t \rightarrow \Phi(t+s)-\Phi(t) \Phi(s) \equiv Y(t)
$$

Then taking the time derivative, you get the following ordinary differential equation in $\mathscr{L}(X, X)$

$$
\begin{aligned}
Y^{\prime}(t) & =\Phi^{\prime}(t+s)-\Phi^{\prime}(t) \Phi(s)=-A \Phi(t+s)+A \Phi(t) \Phi(s) \\
& =-A(\Phi(t+s)-\Phi(t) \Phi(s))=-A Y(t)
\end{aligned}
$$

also, letting $t=0, Y(0)=\Phi(s)-\Phi(0) \Phi(s)=0$. Thus, by uniqueness of solutions to ordinary differential equations, $Y(t)=0$ for all $t \geq 0$ which shows the semigroup property. See Theorem 19.12.75. Actually, this identity holds in this case for all $s, t \in \mathbb{R}$ but this is not needed and the argument given here generalizes well to situations where one can only consider $t \in[0, \infty)$. Note how this shows that it is also the case that $\Phi(t) \Phi(s)=\Phi(s) \Phi(t)$.

Now consider the claim about commuting with operators which commute with $A$. Let $C A=A C$ for $C \in \mathscr{L}(X, X)$ and let $y(t)$ be given by

$$
y(t) \equiv\left(C e^{-A t} x_{0}-e^{-A t} C x_{0}\right)
$$

Then $y(0)=C x_{0}-C x_{0}=0$ and

$$
\begin{aligned}
y^{\prime}(t) & =C\left(-A\left(e^{-A t} x_{0}\right)\right)+\left(A e^{-A t} C x_{0}\right) \\
& =-A C\left(e^{-A t} x_{0}\right)+A\left(e^{-A t} C x_{0}\right)
\end{aligned}
$$

and so

$$
y^{\prime}(t)+A\left(C e^{-A t} x_{0}-e^{-A t} C x_{0}\right)=y^{\prime}+A y=0, y(0)=0
$$

Therefore, by uniqueness to the ODE one obtains $y(t)=0$ which shows that $C$ commutes with $e^{-A t}$.

Finally consider the claim about $e^{-A t}$ being Hermitian. For $\Phi(t) \equiv e^{-A t}$

$$
\begin{aligned}
\Phi^{\prime}(t)+A \Phi(t) & =0, \Phi(0)=I \\
\Phi^{* \prime}(t)+\Phi^{*}(t) A & =0, \Phi^{*}(0)=I
\end{aligned}
$$

and so, from what was just shown about commuting,

$$
\begin{aligned}
\Phi^{* \prime}(t)+\Phi^{*}(t) A & =0, \Phi^{*}(0)=I \\
\Phi^{\prime}(t)+\Phi(t) A & =0, \Phi(0)=I
\end{aligned}
$$

Thus $\Phi(t)$ and $\Phi^{*}(t)$ satisfy the same initial value problem and so they are the same Thanks to Theorem 19.12.3.

Next it follows that $A^{-\alpha}$ is Hermitian because

$$
\begin{aligned}
\left(A^{-\alpha} x_{0}, y_{0}\right) & \equiv\left(\int_{0}^{\infty} t^{\alpha-1} e^{-A t} x_{0} d t, y_{0}\right)=\int_{0}^{\infty}\left(t^{\alpha-1} e^{-A t} x_{0}, y_{0}\right) d t \\
& =\int_{0}^{\infty}\left(x_{0}, t^{\alpha-1} e^{-A t} y_{0}\right) d t=\left(x_{0}, \int_{0}^{\infty} t^{\alpha-1} e^{-A t}\left(y_{0}\right) d t\right) \\
& =\left(x_{0}, A^{-\alpha} y_{0}\right)
\end{aligned}
$$

Note that Lemma 19.13 .2 shows that $A A^{-\alpha}=A^{-\alpha} A$. Also $A^{-\alpha} A^{-\beta}=A^{-\beta} A^{-\alpha}$ and in fact, $A^{-\alpha}$ commutes with every operator which commutes with $A$. Next is a technical lemma which will prove useful.

Lemma 19.13.5 For $\alpha, \beta>0, \Gamma(\alpha) \Gamma(\beta)=\Gamma(\alpha+\beta) \int_{0}^{1}(1-v)^{\alpha-1} v^{\beta-1} d v$
Proof:

$$
\begin{gathered}
\Gamma(\alpha) \Gamma(\beta) \equiv \int_{0}^{\infty} \int_{0}^{\infty} e^{-(t+s)} t^{\alpha-1} s^{\beta-1} d t d s=\int_{0}^{\infty} \int_{s}^{\infty} e^{-u}(u-s)^{\alpha-1} s^{\beta-1} d u d s \\
=\int_{0}^{\infty} e^{-u} \int_{0}^{u}(u-s)^{\alpha-1} s^{\beta-1} d s d u=\int_{0}^{\infty} e^{-u} \int_{0}^{u}(u-s)^{\alpha-1} s^{\beta-1} d s d u \\
=\int_{0}^{\infty} e^{-u} \int_{0}^{1}(u-u v)^{\alpha-1}(u v)^{\beta-1} u d v d u \\
=\int_{0}^{\infty} e^{-u} \int_{0}^{1} u^{\alpha-1} u^{\beta}(1-v)^{\alpha-1} v^{\beta-1} d v d u \\
=\int_{0}^{1}(1-v)^{\alpha-1} v^{\beta-1} d v \int_{0}^{\infty} u^{\alpha+\beta-1} e^{-u} d u \\
=\Gamma(\alpha+\beta) \int_{0}^{1}(1-v)^{\alpha-1} v^{\beta-1} d v \square
\end{gathered}
$$

Now consider whether $A^{-\alpha}$ acts like it should. In particular, is $A^{-\alpha} A^{-(1-\alpha)}=A^{-1}$ ?

Lemma 19.13.6 For $\alpha \in(0,1), A^{-\alpha} A^{-(1-\alpha)}=A^{-1}$. More generally, if

$$
\alpha+\beta<1, A^{-\alpha} A^{-\beta}=A^{-(\alpha+\beta)}
$$

Proof: The product is the following where $\beta=1-\alpha$

$$
\frac{1}{\Gamma(\alpha)} \int_{0}^{\infty} e^{-A t} t^{a-1} d t \frac{1}{\Gamma(\beta)} \int_{0}^{\infty} e^{-A s} s^{\beta-1} d s
$$

Then this equals

$$
\begin{aligned}
& \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} \int_{0}^{\infty} e^{-A(t+s)} t^{\alpha-1} s^{\beta-1} d t d s \\
= & \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} \int_{s}^{\infty} e^{-A u}(u-s)^{\alpha-1} s^{\beta-1} d u d s \\
= & \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} e^{-A u} \int_{0}^{u}(u-s)^{\alpha-1} s^{\beta-1} d s d u \\
= & \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} u^{\alpha+\beta-1} e^{-A u} \int_{0}^{1}(1-v)^{\alpha-1} v^{\beta-1} d v d u \\
= & \int_{0}^{1}(1-v)^{\alpha-1} v^{\beta-1} d v \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} u^{\alpha+\beta-1} e^{-A u} d u
\end{aligned}
$$

From the above lemma, this equals

$$
\frac{1}{\Gamma(\alpha+\beta)} \int_{0}^{\infty} u^{\alpha+\beta-1} e^{-A u} d u \equiv A^{-(\alpha+\beta)}
$$

Note how this shows that these powers of $A$ all commute with each other. If $\alpha+\beta=1$, this becomes

$$
\int_{0}^{\infty} e^{-A u} d u
$$

Is this the usual inverse or is it something else called $A^{-1}$ but not being the real inverse? We show it is the usual inverse. To see this, consider

$$
A \int_{0}^{\infty} e^{-A u} d u\left(x_{0}\right)=\int_{0}^{\infty} A e^{-A u} x_{0} d u=\int_{0}^{\infty}-x^{\prime}(u) d u
$$

where $x^{\prime}(t)+A x(t)=0, x(0)=x_{0}$ and $|x(t)| \leq e^{-\varepsilon t}\left|x_{0}\right|$. The manipulation is routine from approximating with Riemann sums. Then the right side equals $x_{0}$. Thus $A \int_{0}^{\infty} e^{-A u} d u=I$. Similarly,

$$
\int_{0}^{\infty} e^{-A u} d u A\left(x_{0}\right)=\int_{0}^{\infty} e^{-A u} A x_{0} d u=\int_{0}^{\infty} A e^{-A u} x_{0} d u=x_{0}
$$

and so this shows the desired result.
Now it follows that if $A^{\alpha} \equiv A A^{-(1-\alpha)}$ as defined above, then $A^{1-\alpha}=A A^{-(1-(1-\alpha))}=$ $A A^{-\alpha}$ and so,

$$
A^{\alpha} A^{1-\alpha} \equiv A A^{-(1-\alpha)} A A^{-\alpha}=A^{2} A^{-1}=A
$$

Also, if $\alpha+\beta \leq 1$,

$$
\begin{aligned}
A^{\alpha} A^{\beta}= & A A^{-(1-\alpha)} A A^{-(1-\beta)}=A^{2} A^{-(1-\alpha)} A^{-(1-\beta)} \\
A^{\alpha+\beta} & \equiv A A^{-(1-(\alpha+\beta))}=A^{2} A^{-1} A^{-(1-(\alpha+\beta))} \\
& =A^{2} A^{-\beta} A^{-(1-\beta)} A^{-(1-(\alpha+\beta))} \\
& =A^{2} A^{-(1-\alpha)} A^{-(1-\beta)}=A^{\alpha} A^{\beta}
\end{aligned}
$$

This shows the following.
Lemma 19.13.7 If $\alpha, \beta \in(0,1), \alpha+\beta \leq 1$, then $A^{\alpha} A^{\beta}=A^{\alpha+\beta}$. Also $A^{\alpha}$ commutes with every operator in $\mathscr{L}(X, X)$ which commutes with $A$.

Proof: The last assertion follows right away from the fact noted above that $A^{-(1-\alpha)}$ commutes with all operators which commute with $A$ and that so does $A$. Thus if $C$ is such a commuting operator,

$$
C A^{\alpha}=C A A^{-(1-\alpha)}=A C A^{-(1-\alpha)}=A A^{-(1-\alpha)} C=A^{\alpha} C .
$$

The next task is to remove the assumption that $(A x, x) \geq \varepsilon|x|^{2}$ and replace it with $(A x, x) \geq 0$.

Observation 19.13.8 First note that if $\Phi(t)=e^{-(\varepsilon I+A) t}$, and if $x_{0}$ is given, then if $\Phi(t) x_{0}=$ $y(t)$,

$$
y^{\prime}(t)+(\varepsilon I+A) y(t)=0, y(0)=x_{0}
$$

Then taking inner product of both sides with $y(t)$ and integrating,

$$
\frac{|y(t)|^{2}}{2}-\frac{\left|x_{0}\right|^{2}}{2} \leq 0
$$

and so $\left|\Phi(t) x_{0}\right|=|y(t)| \leq\left|x_{0}\right|$ and so $\|\Phi(t)\| \leq 1$. This will be used in the following lemma.

Lemma 19.13.9 Let $(A x, x) \geq 0$. Then for $\alpha \in(0,1)$,

$$
\lim _{\varepsilon \rightarrow 0+}(\varepsilon I+A)(\varepsilon I+A)^{-\alpha}
$$

exists in $\mathscr{L}(X, X)$.
Proof: Let $\delta>\varepsilon$ and both $\varepsilon$ and $\delta$ are small.

$$
\begin{aligned}
& \left((\varepsilon I+A)(\varepsilon I+A)^{-\alpha}-(\delta I+A)(\delta I+A)^{-\alpha}\right) \Gamma(\alpha)= \\
& \int_{0}^{\infty}\left((\varepsilon I+A) e^{-(\varepsilon I+A) t}-(\delta I+A) e^{-(\delta I+A) t}\right) t^{\alpha-1} d t=
\end{aligned}
$$

$$
\begin{gathered}
=\int_{0}^{\infty}\left((\varepsilon I+A) e^{-(\varepsilon I+A) t}-(\varepsilon I+A) e^{-(\delta I+A) t}\right) t^{\alpha-1} d t \\
+\int_{0}^{\infty}\left((\varepsilon I+A) e^{-(\delta I+A) t}-(\delta I+A) e^{-(\delta I+A) t}\right) t^{\alpha-1} d t \\
=P_{\delta, \varepsilon}+Q_{\delta, \varepsilon} .
\end{gathered}
$$

Then $P_{\delta, \varepsilon}=$

$$
\begin{gathered}
\int_{0}^{\infty}(\varepsilon I+A)\left(e^{-(\varepsilon I+A) t}-e^{-(\delta I+A) t}\right) t^{\alpha-1} d t \\
\left\|P_{\delta, \varepsilon}\right\| \leq \int_{0}^{\infty}\|(\varepsilon I+A)\|\left\|\left(e^{-(\varepsilon I+A) t}-e^{-(\delta I+A) t}\right)\right\| t^{\alpha-1} d t
\end{gathered}
$$

We need to estimate the difference of those semigroups. Call the first, $e^{-(\varepsilon I+A) t} \equiv y$ and the second $x$. Then by definition,

$$
\begin{aligned}
y^{\prime}+(\varepsilon I+A) y & =0, y(0)=x_{0} \\
x^{\prime}+(\delta I+A) x & =0, x(0)=x_{0}
\end{aligned}
$$

Then $\hat{y}(t) \equiv e^{\varepsilon t} y(t), \hat{x}(t) \equiv e^{\delta t} x(t)$

$$
\begin{aligned}
\hat{y}^{\prime}-\varepsilon \hat{y}(t)+(\varepsilon I+A) \hat{y} & =0, \hat{y}(0)=x_{0} \\
\hat{x}^{\prime}-\delta \hat{x}(t)+(\delta I+A) \hat{x} & =0, \hat{x}(0)=x_{0}
\end{aligned}
$$

Thus

$$
\begin{aligned}
\hat{y}^{\prime}+A \hat{y} & =0, \hat{y}(0)=x_{0} \\
\hat{x}^{\prime}+A \hat{x} & =0, \hat{x}(0)=x_{0}
\end{aligned}
$$

By uniqueness, $\hat{x}=\hat{y}$. Thus

$$
\left|e^{\varepsilon t} y(t)-e^{\delta t} x(t)\right|=0
$$

So

$$
e^{\delta t}\left|e^{(\varepsilon-\delta) t} y(t)-x(t)\right|=0
$$

So, since $x_{0}$ was arbitrary,

$$
e^{(\varepsilon-\delta) t} e^{-(\varepsilon I+A) t}-e^{-(\delta I+A) t}=0
$$

Then

$$
\begin{gathered}
\left\|P_{\delta, \varepsilon}\right\| \leq C(\|A\|) \int_{0}^{\infty}\left\|\left(e^{-(\varepsilon I+A) t}-e^{(\varepsilon-\delta) t} e^{-(\varepsilon I+A) t}\right)\right\| t^{\alpha-1} d t \\
\leq C(\|A\|) \int_{0}^{\infty}\left|1-e^{(\varepsilon-\delta) t}\right| t^{\alpha-1} d t=C(\|A\|) \int_{0}^{\infty}\left(1-e^{-(\delta-\varepsilon) t}\right) t^{\alpha-1} d t
\end{gathered}
$$

Now we need an estimate. Suppose $1>\lambda>0$. For $t \geq 0$, is

$$
1-e^{-\lambda t} \leq \lambda e^{-\lambda t} ?
$$

Let $f(t)=\lambda e^{-\lambda t}-e^{-\lambda t}+1$. Then

$$
f^{\prime}(t)=-\lambda^{2} e^{-\lambda t}+\lambda e^{-\lambda t}>0, f(0)=\lambda-1+1>0
$$

Thus

$$
\left\|P_{\delta, \varepsilon}\right\| \leq C(\|A\|) \int_{0}^{\infty}(\delta-\varepsilon) e^{-(\delta-\varepsilon) t} t^{\alpha-1} d t
$$

Now change the variables letting $u=(\delta-\varepsilon) t$. Then

$$
\left\|P_{\delta, \varepsilon}\right\|=C(\|A\|) \int_{0}^{\infty} e^{-u}\left(\frac{u}{\delta-\varepsilon}\right)^{\alpha-1} d u=C(\|A\|) \Gamma(\alpha)|\delta-\varepsilon|^{1-\alpha}
$$

Thus $\lim _{\varepsilon, \delta \rightarrow 0}\left\|P_{\delta \varepsilon}\right\|=0$. Consider $Q_{\delta, \varepsilon}$

$$
\begin{aligned}
\left\|Q_{\delta, \varepsilon}\right\| & \leq \int_{0}^{\infty}\left\|e^{-(\delta I+A) t}\right\|\|((\varepsilon I+A)-(\delta I+A))\| t^{\alpha-1} d t \\
& \leq \int_{0}^{\infty} e^{-\delta t}|\delta-\varepsilon| t^{\alpha-1} d t \leq \int_{0}^{\infty} e^{-(\delta-\varepsilon) t}|\varepsilon-\delta| t^{\alpha-1} d t
\end{aligned}
$$

Now let $u=(\delta-\varepsilon) t, d u=(\delta-\varepsilon) d t$. Then the last integral on the right equals

$$
|\varepsilon-\delta| \int_{0}^{\infty} e^{-u} u^{\alpha-1} \frac{d u}{|\delta-\varepsilon|} \frac{1}{|\delta-\varepsilon|^{\alpha-1}}=\Gamma(\alpha)|\delta-\varepsilon|^{1-\alpha}
$$

so also $\lim _{\varepsilon, \delta \rightarrow 0}\left\|Q_{\delta, \varepsilon}\right\|=0$.
Definition 19.13.10 For $\alpha \in(0,1)$, and $(A x, x) \geq 0$ with $A=A^{*}$, we define

$$
A^{\alpha} \equiv \lim _{\varepsilon \rightarrow 0}(\varepsilon I+A)(\varepsilon I+A)^{-(1-\alpha)}
$$

Theorem 19.13.11 In the situation of the definition, if $\alpha+\beta \leq 1$, for $\alpha, \beta \in(0,1)$,

$$
A^{\alpha} A^{\beta}=A^{\alpha+\beta}
$$

and in particular,

$$
A^{\alpha} A^{1-\alpha}=A
$$

Also, $A^{\alpha}$ commutes with every operator which commutes with A. For A a Hermitian operator as here, it follows that $A^{\alpha}$ is also Hermitian.

Proof: $A^{\alpha+\beta} \equiv \lim _{\varepsilon \rightarrow 0}(\varepsilon I+A)(\varepsilon I+A)^{-(1-(\alpha+\beta))}$. Then since $(\varepsilon I+A)$ commutes with $e^{-(\varepsilon I+A) t}$, it follows that this equals

$$
\begin{gathered}
\lim _{\varepsilon \rightarrow 0}(\varepsilon I+A)(\varepsilon I+A)^{-(1-(\alpha+\beta))}= \\
\lim _{\varepsilon \rightarrow 0}(\varepsilon I+A)^{2}(\varepsilon I+A)^{-(1-\alpha)}(\varepsilon I+A)^{-(1-\beta)}
\end{gathered}
$$

$$
=\lim _{\varepsilon \rightarrow 0}(\varepsilon I+A)(\varepsilon I+A)^{-(1-\alpha)}(\varepsilon I+A)(\varepsilon I+A)^{-(1-\beta)}=A^{\alpha} A^{\beta}
$$

There is nothing to show if $\alpha+\beta=1$. In this case, the limit reduces to $\lim _{\varepsilon \rightarrow 0}(\varepsilon I+A)=A$.
Consider the last claim. Let $C$ be such a commuting operator. and let $A_{\varepsilon} \equiv \varepsilon I+A$. Then

$$
C A^{\alpha}=\lim _{\varepsilon \rightarrow 0} C A_{\varepsilon}^{\alpha}=\lim _{\varepsilon \rightarrow 0} A_{\varepsilon}^{\alpha} C=A^{\alpha} C
$$

Note that $A^{\alpha} \equiv \lim _{\varepsilon \rightarrow 0}(\varepsilon I+A)(\varepsilon I+A)^{-(1-\alpha)} \equiv \lim _{\varepsilon \rightarrow 0} A_{\varepsilon}^{\alpha}$. Finally, consider the claim about $A^{\alpha}$ being Hermitian when $A$ is.

$$
\left(x, A^{\alpha} y\right)=\lim _{\varepsilon \rightarrow 0}\left(x, A_{\varepsilon}^{\alpha} y\right)=\lim _{\varepsilon \rightarrow 0}\left(A_{\varepsilon}^{\alpha} x, y\right)=\left(A^{\alpha} x, y\right)
$$

For more on this kind of thing including generalizations to operators defined on Banach space, see [79].

### 19.14 General Theory of Continuous Semigroups

Much more on semigroups is available in Yosida [127]. This is just an introduction to the subject.
Definition 19.14.1 A strongly continuous semigroup defined on $X$, a Banach space is a function $S:[0, \infty) \rightarrow X$ which satisfies the following for all $x_{0} \in X$.

$$
\begin{aligned}
S(t) & \in \mathscr{L}(X, X), S(t+s)=S(t) S(s) \\
t & \rightarrow S(t) x_{0} \text { is continuous, } \lim _{t \rightarrow 0+} S(t) x_{0}=x_{0}
\end{aligned}
$$

Sometimes such a semigroup is said to be $C_{0}$. It is said to have the linear operator $A$ as its generator if

$$
D(A) \equiv\left\{x: \lim _{h \rightarrow 0} \frac{S(h) x-x}{h} \text { exists }\right\}
$$

and for $x \in D(A), A$ is defined by

$$
\lim _{h \rightarrow 0} \frac{S(h) x-x}{h} \equiv A x
$$

The assertion that $t \rightarrow S(t) x_{0}$ is continuous and that $S(t) \in \mathscr{L}(X, X)$ is not sufficient to say there is a bound on $\|S(t)\|$ for all $t \geq 0$. Also the assertion that for each $x_{0}, \lim _{t \rightarrow 0+} S(t) x_{0}=x_{0}$ is not the same as saying that $S(t) \rightarrow I$ in $\mathscr{L}(X, X)$. It is a much weaker assertion. The next theorem gives information on the growth of $\|S(t)\|$. It turns out it has exponential growth.

Lemma 19.14.2 Let $M \equiv \sup \{\|S(t)\|: t \in[0, T]\}$. Then $M<\infty$.
Proof: If this is not true, then there exists $t_{n} \in[0, T]$ such that $\left\|S\left(t_{n}\right)\right\| \geq n$. That is the operators $S\left(t_{n}\right)$ are not uniformly bounded. By the uniform boundedness principle, Theorem 17.1.8, there exists $x \in X$ such that $\left\|S\left(t_{n}\right) x\right\|$ is not bounded. However, this is impossible because it is given that $t \rightarrow S(t) x$ is continuous on $[0, T]$ and so $t \rightarrow\|S(t) x\|$ must achieve its maximum on this compact set.

Now here is the main result for growth of $\|S(t)\|$.

Theorem 19.14.3 For $M$ described in Lemma 19.14.2, there exists $\alpha$ such that

$$
\|S(t)\| \leq M e^{\alpha t}, t \geq 0
$$

In fact, $\alpha$ can be chosen such that $M^{1 / T}=e^{\alpha}$.
Proof: Let $t$ be arbitrary. Then $t=m T+r(t)$ where $0 \leq r(t)<T$. Then by the semigroup property

$$
\|S(t)\|=\|S(m T+r(t))\|=\left\|S(r(t)) S(T)^{m}\right\| \leq M^{m+1}
$$

Now $m T \leq t \leq m T+r(t) \leq(m+1) T$ and so $m \leq \frac{t}{T} \leq m+1$. Therefore,

$$
\|S(t)\| \leq M^{(t / T)+1}=M\left(M^{1 / T}\right)^{t}
$$

Let $M^{1 / T} \equiv e^{\alpha}$ and then $\|S(t)\| \leq M e^{\alpha t}$
Definition 19.14.4 Let $S(t)$ be a continuous semigroup as described above. It is called a contraction semigroup if for all $t \geq 0$

$$
\|S(t)\| \leq 1
$$

It is called a bounded semigroup if there exists $M$ such that for all $t \geq 0$,

$$
\|S(t)\| \leq M
$$

Note that for $S(t)$ an arbitrary continuous semigroup satisfying $\|S(t)\| \leq M e^{\alpha t}$, It follows that the semigroup, $T(t)=e^{-\alpha t} S(t)$ is a bounded semigroup which satisfies $\|T(t)\| \leq$ $M$.

The next proposition has to do with taking a Laplace transform of a semigroup.
Proposition 19.14.5 Given a continuous semigroup $S(t)$, its generator A exists and is a closed densely defined operator. Furthermore, for

$$
\|S(t)\| \leq M e^{\alpha t}
$$

and $\lambda>\alpha, \lambda I-A$ is one to one and onto from $D(A)$ to $X$. Also $(\lambda I-A)^{-1}$ maps $X$ onto $D(A)$ and is in $\mathscr{L}(X, X)$. Also for these values of $\lambda>\alpha$,

$$
(\lambda I-A)^{-1} x=\int_{0}^{\infty} e^{-\lambda t} S(t) x d t
$$

For $\lambda>\alpha$, the following estimate holds.

$$
\begin{equation*}
\left\|(\lambda I-A)^{-1}\right\| \leq \frac{M}{|\lambda-\alpha|} \tag{19.14.79}
\end{equation*}
$$

Proof: First note $D(A) \neq \emptyset$. In fact $0 \in D(A)$. It follows from Theorem 19.14.3 that for all $\lambda$ larger than $\alpha$, one can define a Laplace transform, $R(\lambda) x \equiv \int_{0}^{\infty} e^{-\lambda t} S(t) x d t \in X$. Here the integral is the ordinary improper Riemann integral. I claim each of these $R(\lambda) x$ for $\lambda$ large is in $D(A)$.

$$
\frac{S(h) \int_{0}^{\infty} e^{-\lambda t} S(t) x d t-\int_{0}^{\infty} e^{-\lambda t} S(t) x d t}{h}
$$

Using the semigroup property and changing the variables in the first of the above integrals, this equals

$$
\begin{gathered}
=\frac{1}{h}\left(e^{\lambda h} \int_{h}^{\infty} e^{-\lambda t} S(t) x d t-\int_{0}^{\infty} e^{-\lambda t} S(t) x d t\right) \\
=\frac{1}{h}\left(\left(e^{\lambda h}-1\right) \int_{0}^{\infty} e^{-\lambda t} S(t) x d t-e^{\lambda h} \int_{0}^{h} e^{-\lambda t} S(t) x d t\right)
\end{gathered}
$$

Then it follows that the limit as $h \rightarrow 0$ exists and equals

$$
\begin{equation*}
\lambda R(\lambda) x-x=\lim _{h \rightarrow 0+} \frac{S(h) R(\lambda) x-R(\lambda) x}{h} \equiv A(R(\lambda) x) \tag{19.14.80}
\end{equation*}
$$

and $R(\lambda) x \in D(A)$ as claimed. Hence

$$
\begin{equation*}
x=(\lambda I-A) R(\lambda) x . \tag{19.14.81}
\end{equation*}
$$

Since $x$ is arbitrary, this shows that for $\lambda>\alpha, \lambda I-A$ is onto. Also, if $x \in D(A)$, you could approximate with Riemann sums and pass to a limit and obtain

$$
\frac{1}{h}(R(\lambda) S(h) x-R(\lambda) x)=\int_{0}^{\infty} e^{-\lambda t} S(t) \frac{S(h) x-x}{h} d t
$$

Then, passing to a limit as $h \rightarrow 0$ using the dominated convergence theorem, one obtains

$$
\lim _{h \rightarrow 0} \frac{1}{h}(R(\lambda) S(h) x-R(\lambda) x)=\int_{0}^{\infty} S(t) e^{-\lambda t} A x d t \equiv R(\lambda) A x
$$

Also, $S(h)$ commutes with $R(\lambda)$. This follows in the usual way by approximating with Riemann sums and taking a limit. Thus for $x \in D(A)$

$$
\begin{aligned}
\lambda R(\lambda) x-x & =\lim _{h \rightarrow 0+} \frac{S(h) R(\lambda) x-R(\lambda) x}{h} \\
& =\lim _{h \rightarrow 0+} \frac{R(\lambda) S(h) x-R(\lambda) x}{h}=R(\lambda) A x
\end{aligned}
$$

and so, for $x \in D(A)$,

$$
\begin{equation*}
x=\lambda R(\lambda) x-R(\lambda) A x=R(\lambda)(\lambda I-A) x \tag{19.14.82}
\end{equation*}
$$

which shows that for $\lambda>\alpha,(\lambda I-A)$ is one to one on $D(A)$. Hence from 19.14.80 and 19.14.82, $(\lambda I-A)$ is an algebraic isomorphism from $D(A)$ onto $X$. Also $R(\lambda)=$
$(\lambda I-A)^{-1}$ on $X$. The estimate 19.14.79 follows easily from the definition of $R(\lambda)$ whenever $\lambda>\alpha$ as follows.

$$
\begin{gathered}
\|R(\lambda) x\|=\left\|(\lambda I-A)^{-1} x\right\|=\left\|\int_{0}^{\infty} e^{-\lambda t} S(t) x d t\right\| \\
\leq \int_{0}^{\infty} e^{-\lambda t} M e^{\alpha t} d t\|x\| \leq \frac{M}{|\lambda-\alpha|}\|x\|
\end{gathered}
$$

Why is $D(A)$ dense? I will show that $\|\lambda R(\lambda) x-x\| \rightarrow 0$ as $\lambda \rightarrow \infty$, and it was shown above that $R(\lambda) x$ and therefore $\lambda R(\lambda) x \in D(A)$ so this will show that $D(A)$ is dense in $X$. For $\lambda>\alpha$ where $\|S(t)\| \leq M e^{\alpha t}$,

$$
\begin{aligned}
&\|\lambda R(\lambda) x-x\|=\left\|\int_{0}^{\infty} \lambda e^{-\lambda t} S(t) x d t-\int_{0}^{\infty} \lambda e^{-\lambda t} x d t\right\| \\
& \leq \int_{0}^{\infty}\left\|\lambda e^{-\lambda t}(S(t) x-x)\right\| d t \\
&= \int_{0}^{h}\left\|\lambda e^{-\lambda t}(S(t) x-x)\right\| d t+\int_{h}^{\infty}\left\|\lambda e^{-\lambda t}(S(t) x-x)\right\| d t \\
& \leq \int_{0}^{h}\left\|\lambda e^{-\lambda t}(S(t) x-x)\right\| d t+\int_{h}^{\infty} \lambda e^{-(\lambda-\alpha) t} d t(M+1)\|x\|
\end{aligned}
$$

Now since $S(t) x-x \rightarrow 0$, it follows that for $h$ sufficiently small

$$
\begin{aligned}
& \leq \frac{\varepsilon}{2} \int_{0}^{h} \lambda e^{-\lambda t} d t+\frac{\lambda}{\lambda-\alpha} e^{-(\lambda-\alpha) h}(M+1)\|x\| \\
& \leq \frac{\varepsilon}{2}+\frac{\lambda}{\lambda-\alpha} e^{-(\lambda-\alpha) h}(M+1)\|x\|<\varepsilon
\end{aligned}
$$

whenever $\lambda$ is large enough. Thus $D(A)$ is dense as claimed.
Why is $A$ a closed operator? Suppose $x_{n} \rightarrow x$ where $x_{n} \in D(A)$ and that $A x_{n} \rightarrow \xi$. I need to show that this implies that $x \in D(A)$ and that $A x=\xi$. Thus $x_{n} \rightarrow x$ and for $\lambda>\alpha$, $(\lambda I-A) x_{n} \rightarrow \lambda x-\xi$. However, 19.14.79 shows that $(\lambda I-A)^{-1}$ is continuous and so

$$
x_{n} \rightarrow(\lambda I-A)^{-1}(\lambda x-\xi)=x
$$

It follows that $x \in D(A)$. Then doing $(\lambda I-A)$ to both sides of the equation, $\lambda x-\xi=$ $\lambda x-A x$ and so $A x=\xi$ showing that $A$ is a closed operator as claimed.

Definition 19.14.6 The linear mapping for $\lambda>\alpha$ where $\|S(t)\| \leq M e^{\alpha t}$ given by

$$
(\lambda I-A)^{-1}=R(\lambda)
$$

is called the resolvent.
The following corollary is also very interesting.

Corollary 19.14.7 Let $S(t)$ be a continuous semigroup and let $A$ be its generator. Then for $0<a<b$ and $x \in D(A)$

$$
S(b) x-S(a) x=\int_{a}^{b} S(t) A x d t
$$

and also for $t>0$ you can take the derivative from the left,

$$
\lim _{h \rightarrow 0+} \frac{S(t) x-S(t-h) x}{h}=S(t) A x
$$

Proof:Letting $y^{*} \in X^{\prime}$,

$$
y^{*}\left(\int_{a}^{b} S(t) A x d t\right)=\int_{a}^{b} y^{*}\left(S(t) \lim _{h \rightarrow 0} \frac{S(h) x-x}{h}\right) d t
$$

The difference quotients are bounded because they converge to $A x$. Therefore, from the dominated convergence theorem,

$$
\begin{aligned}
y^{*}\left(\int_{a}^{b} S(t) A x d t\right) & =\lim _{h \rightarrow 0} \int_{a}^{b} y^{*}\left(S(t) \frac{S(h) x-x}{h}\right) d t \\
& =\lim _{h \rightarrow 0} y^{*}\left(\int_{a}^{b} S(t) \frac{S(h) x-x}{h} d t\right) \\
& =\lim _{h \rightarrow 0} y^{*}\left(\frac{1}{h} \int_{a+h}^{b+h} S(t) x d t-\frac{1}{h} \int_{a}^{b} S(t) x d t\right) \\
& =\lim _{h \rightarrow 0} y^{*}\left(\frac{1}{h} \int_{b}^{b+h} S(t) x d t-\frac{1}{h} \int_{a}^{a+h} S(t) x d t\right) \\
& =y^{*}(S(b) x-S(a) x)
\end{aligned}
$$

Since $y^{*}$ is arbitrary, this proves the first part. Now from what was just shown, if $t>0$ and $h$ is small enough,

$$
\frac{S(t) x-S(t-h) x}{h}=\frac{1}{h} \int_{t-h}^{t} S(s) A x d s
$$

which converges to $S(t) A x$ as $h \rightarrow 0+$. This proves the corollary.
Given a closed densely defined operator, when is it the generator of a continuous semigroup? This is answered in the following theorem which is called the Hille Yosida theorem. It concerns the case of a bounded semigroup. However, if you have an arbitrary continuous semigroup, $S(t)$, then it was shown above that $S(t) e^{-\alpha t}$ is bounded for suitable $\alpha$ so the case discussed below is obtained.

Theorem 19.14.8 Suppose $A$ is a densely defined linear operator which has the property that for all $\lambda>0$,

$$
(\lambda I-A)^{-1} \in \mathscr{L}(X, X)
$$

which means that $\lambda I-A: D(A) \rightarrow X$ is one to one and onto with continuous inverse. Suppose also that for all $n \in \mathbb{N}$,

$$
\begin{equation*}
\left\|\left((\lambda I-A)^{-1}\right)^{n}\right\| \leq \frac{M}{\lambda^{n}} \tag{19.14.83}
\end{equation*}
$$

Then there exists a continuous semigroup $S(t)$ which has $A$ as its generator and satisfies $\|S(t)\| \leq M$ and $A$ is closed. In fact letting

$$
S_{\lambda}(t) \equiv \exp \left(-\lambda+\lambda^{2}(\lambda I-A)^{-1}\right)
$$

it follows $\lim _{\lambda \rightarrow \infty} S_{\lambda}(t) x=S(t) x$ uniformly on finite intervals. Conversely, if $A$ is the generator of $S(t)$, a bounded continuous semigroup having $\|S(t)\| \leq M$, then $(\lambda I-A)^{-1} \in$ $\mathscr{L}(X, X)$ for all $\lambda>0$ and 19.14.83 holds.

Proof: The condition 19.14.83 implies, that

$$
\left\|(\lambda I-A)^{-1}\right\| \leq \frac{M}{\lambda}
$$

Consider, for $\lambda>0$, the operator which is defined on $D(A)$,

$$
\lambda(\lambda I-A)^{-1} A
$$

On $D(A)$, this equals

$$
\begin{equation*}
-\lambda I+\lambda^{2}(\lambda I-A)^{-1} \tag{19.14.84}
\end{equation*}
$$

because

$$
\begin{aligned}
(\lambda I-A) \lambda(\lambda I-A)^{-1} A & =\lambda A \\
(\lambda I-A)\left(-\lambda I+\lambda^{2}(\lambda I-A)^{-1}\right) & =-\lambda(\lambda I-A)+\lambda^{2}=\lambda A
\end{aligned}
$$

and, by assumption, $(\lambda I-A)$ is one to one so these are the same. However, the second one in 19.14.84, $-\lambda I+\lambda^{2}(\lambda I-A)^{-1}$ makes sense on all of $X$. Also

$$
\begin{gathered}
\left(-\lambda I+\lambda^{2}(\lambda I-A)^{-1}\right)(\lambda I-A)=-\lambda(\lambda I-A)+\lambda^{2} I=\lambda A \\
\lambda A(\lambda I-A)^{-1}(\lambda I-A)=\lambda A
\end{gathered}
$$

so, since $(\lambda I-A)$ is onto, it follows that on $X$,

$$
-\lambda I+\lambda^{2}(\lambda I-A)^{-1}=A \lambda(\lambda I-A)^{-1} \equiv A_{\lambda}
$$

Denote this as $A_{\lambda}$ to save notation. Thus on $D(A)$,

$$
\lambda A(\lambda I-A)^{-1}=\lambda(\lambda I-A)^{-1} A=A_{\lambda}
$$

although the $\lambda(\lambda I-A)^{-1} A$ only makes sense on $D(A)$. Note that formally

$$
\lim _{\lambda \rightarrow \infty} \lambda(\lambda I-A)^{-1} A=A
$$

This is summarized next.

Lemma 19.14.9 There is a bounded linear operator given for $\lambda>0$ by

$$
-\lambda I+\lambda^{2}(\lambda I-A)^{-1}=\lambda A(\lambda I-A)^{-1} \equiv A_{\lambda}
$$

On $D(A), A_{\lambda}=\lambda(\lambda I-A)^{-1} A$.
For $x \in D(A)$,

$$
\begin{align*}
& \left\|\lambda(\lambda I-A)^{-1} x-x\right\| \\
= & \left\|(\lambda I-A)^{-1}(\lambda x-(\lambda I-A) x)\right\| \\
= & \left\|(\lambda I-A)^{-1} A x\right\| \leq \frac{M}{\lambda}\|A x\| \tag{19.14.85}
\end{align*}
$$

which converges to 0 as $\lambda \rightarrow \infty$.
Now $L_{\lambda} x \rightarrow x$ on a dense subset of $X, L_{\lambda} \equiv \lambda(\lambda I-A)^{-1}$. Also, from the hypothesis, $\left\|L_{\lambda}\right\| \leq M$. Say $x$ is arbitrary. Then does $L_{\lambda} x \rightarrow x$ ? Let $\hat{x} \in D(A)$ and $\|x-\hat{x}\|<\varepsilon$. Then

$$
\begin{aligned}
\left\|L_{\lambda} x-x\right\| & \leq\left\|L_{\lambda} x-L_{\lambda} \hat{x}\right\|+\left\|L_{\lambda} \hat{x}-\hat{x}\right\|+\|\hat{x}-x\| \\
& <M \varepsilon+\varepsilon+\varepsilon
\end{aligned}
$$

whenever $\lambda$ is large enough and so for all $x \in X$,

$$
\lim _{\lambda \rightarrow \infty} \lambda(\lambda I-A)^{-1} x=x
$$

In particular, this holds whenever $x$ is replaced with $A x$ for some $x \in D(A)$. Thus if $x \in$ $D(A)$,

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty}\left\|A_{\lambda} x-A x\right\|=\lim _{\lambda \rightarrow \infty}\left\|\lambda(\lambda I-A)^{-1} A x-A x\right\|=0 \tag{19.14.86}
\end{equation*}
$$

This is summarized in the following lemma.
Lemma 19.14.10 For all $x \in D(A), \lim _{\lambda \rightarrow \infty}\left\|A_{\lambda} x-A x\right\|=0$.
Now from Corollary 19.12.5, there exists an approximate continuous semigroup $S_{\lambda}(t)$ generated by $A_{\lambda}$ which is the solution to

$$
\begin{equation*}
S_{\lambda}^{\prime}(t)=A_{\lambda} S_{\lambda}(t), S_{\lambda}(0)=I \tag{19.14.87}
\end{equation*}
$$

In terms of power series,

$$
\begin{equation*}
S_{\lambda}(t) \equiv e^{-\lambda t} \sum_{k=0}^{\infty} \frac{t^{k}\left(\lambda^{2}(\lambda I-A)^{-1}\right)^{k}}{k!}=e^{t\left(-\lambda I+\lambda^{2}(\lambda I-A)^{-1}\right)} \tag{19.14.88}
\end{equation*}
$$

Thus, by assumption and triangle inequality,

$$
\begin{equation*}
\left\|S_{\lambda}(t)\right\| \leq e^{-\lambda t} \sum_{k=0}^{\infty} \frac{t^{k}}{k!} \lambda^{2 k} \frac{M}{\lambda^{k}}=e^{-\lambda t} M e^{\lambda t}=M \tag{19.14.89}
\end{equation*}
$$

Note that

$$
\frac{t^{k}\left(\lambda^{2}(\lambda I-A)^{-1}\right)^{k}}{k!} \leq \frac{t^{k}}{k!} \lambda^{2 k} \frac{M}{\lambda^{k}}
$$

so one obtains absolute convergence in 19.14.88.
Next is an easy observation about operators commuting.
Lemma 19.14.11 For $\lambda, \mu>0,(\lambda I-A)^{-1}$ and $(\mu I-A)^{-1}$ commute.
Proof: Suppose

$$
\begin{align*}
& y=(\mu I-A)^{-1}(\lambda I-A)^{-1} x  \tag{19.14.90}\\
& z=(\lambda I-A)^{-1}(\mu I-A)^{-1} x \tag{19.14.91}
\end{align*}
$$

I need to show $y=z$. First note $z, y \in D(A)$. Then also $(\mu I-A) y \in D(A)$ and $(\lambda I-A) z \in$ $D(A)$ and so the following manipulation makes sense.

$$
\begin{aligned}
x & =(\lambda I-A)(\mu I-A) y=(\mu I-A)(\lambda I-A) y \\
x & =(\mu I-A)(\lambda I-A) z
\end{aligned}
$$

so $(\mu I-A)(\lambda I-A) y=(\mu I-A)(\lambda I-A) z$ and since $(\mu I-A),(\lambda I-A)$ are both one to one, this shows $z=y$.

It follows from the description of $S_{\lambda}(t)$ in terms of a power series that $S_{\lambda}(t)$ and $S_{\mu}(s)$ commute and also $A_{\lambda}$ commutes with $S_{\mu}(t)$ for any $t$. One could also exploit uniqueness and the theory of ordinary differential equations to verify this. I will use this fact in what follows whenever needed.

I want to show that for each $x \in D(A)$,

$$
\lim _{\lambda \rightarrow \infty} S_{\lambda}(t) x \equiv S(t) x
$$

where $S(t)$ is the desired semigroup. Let $x \in D(A)$. Then

$$
\begin{aligned}
& S_{\mu}(t) x-S_{\lambda}(t) x=\int_{0}^{t} \frac{d}{d r}\left(S_{\lambda}(t-r) S_{\mu}(r)\right) x d r \\
= & \int_{0}^{t}\left(-S_{\lambda}^{\prime}(t-r) S_{\mu}(r)+S_{\lambda}(t-r) S_{\mu}^{\prime}(r)\right) x d r \\
= & \int_{0}^{t}\left(S_{\lambda}(t-r) S_{\mu}(r) A_{\lambda}-S_{\mu}(r) S_{\lambda}(t-r) A_{\mu}\right) x d r \\
= & \int_{0}^{t} S_{\lambda}(t-r) S_{\mu}(r)\left(A_{\mu} x-A_{\lambda} x\right) d r
\end{aligned}
$$

It follows that

$$
\left\|S_{\mu}(t) x-S_{\lambda}(t) x\right\| \leq \int_{0}^{t}\left\|S_{\lambda}(t-r) S_{\mu}(r)\left(A_{\mu} x-A_{\lambda} x\right)\right\| d r
$$

$$
\leq M^{2} t\left\|A_{\mu} x-A_{\lambda} x\right\| \leq M^{2} t\left(\left\|A_{\mu} x-A x\right\|+\left\|A x-A_{\lambda} x\right\|\right)
$$

Now by Lemma 19.14.10, the right side converges uniformly to 0 in $t \in[0, T]$ an arbitrary finite interval. Denote that to which it converges $S(t) x$. Therefore, $t \rightarrow S(t) x$ is continuous for each $x \in D(A)$ and also from 19.14.89,

$$
\|S(t) x\|=\lim _{\lambda \rightarrow \infty}\left\|S_{\lambda}(t) x\right\| \leq M\|x\|
$$

so that $S(t)$ can be extended to a continuous linear map, still called $S(t)$ defined on all of $X$ which also satisfies $\|S(t)\| \leq M$ since $D(A)$ is dense in $X$.

If $x$ is arbitrary, let $y \in D(A)$ be close to $x$, close enough that $2 M\|x-y\|<\varepsilon$. Then

$$
\begin{aligned}
\left\|S(t) x-S_{\lambda}(t) x\right\| \leq & \|S(t) x-S(t) y\|+\left\|S(t) y-S_{\lambda}(t) y\right\| \\
& +\left\|S_{\lambda}(t) y-S_{\lambda}(t) x\right\|
\end{aligned}
$$

if $\lambda$ is large enough, and so $\lim _{\lambda \rightarrow \infty} S_{\lambda}(t) x=S(t) x$ for all $x$, uniformly on finite intervals. Thus $t \rightarrow S(t) x$ is continuous for any $x \in X$.

It remains to verify $A$ generates $S(t)$ and for all $x, \lim _{t \rightarrow 0+} S(t) x-x=0$. From the above,

$$
\begin{equation*}
S_{\lambda}(t) x=x+\int_{0}^{t} S_{\lambda}(s) A_{\lambda} x d s \tag{19.14.92}
\end{equation*}
$$

and so

$$
\lim _{t \rightarrow 0+}\left\|S_{\lambda}(t) x-x\right\|=0
$$

By the uniform convergence just shown, there exists $\lambda$ large enough that for all $t \in[0, \delta]$,

$$
\left\|S(t) x-S_{\lambda}(t) x\right\|<\varepsilon
$$

Then

$$
\begin{aligned}
{\lim \sup _{t \rightarrow 0+}\|S(t) x-x\|}^{\leq}{\lim \sup _{t \rightarrow 0+}\left(\left\|S(t) x-S_{\lambda}(t) x\right\|+\left\|S_{\lambda}(t) x-x\right\|\right)} & \leq{\lim \sup _{t \rightarrow 0+}}\left(\varepsilon+\left\|S_{\lambda}(t) x-x\right\|\right) \leq \varepsilon
\end{aligned}
$$

It follows $\lim _{t \rightarrow 0+} S(t) x=x$ because $\varepsilon$ is arbitrary.
Next, $\lim _{\lambda \rightarrow \infty} A_{\lambda} x=A x$ for all $x \in D(A)$ by Lemma 19.14.10. Therefore, passing to the limit in 19.14.92 yields from the uniform convergence

$$
S(t) x=x+\int_{0}^{t} S(s) A x d s
$$

and by continuity of $s \rightarrow S(s) A x$, it follows

$$
\lim _{h \rightarrow 0+} \frac{S(h) x-x}{h}=\lim _{h \rightarrow 0} \frac{1}{h} \int_{0}^{h} S(s) A x d s=A x
$$

Thus letting $B$ denote the generator of $S(t), D(A) \subseteq D(B)$ and $A=B$ on $D(A)$. It only remains to verify $D(A)=D(B)$.

To do this, let $\lambda>0$ and consider the following where $y \in X$ is arbitrary.

$$
(\lambda I-B)^{-1} y=(\lambda I-B)^{-1}\left((\lambda I-A)(\lambda I-A)^{-1} y\right)
$$

Now $(\lambda I-A)^{-1} y \in D(A) \subseteq D(B)$ and $A=B$ on $D(A)$ and so

$$
(\lambda I-A)(\lambda I-A)^{-1} y=(\lambda I-B)(\lambda I-A)^{-1} y
$$

which implies,

$$
\begin{gathered}
(\lambda I-B)^{-1} y= \\
(\lambda I-B)^{-1}\left((\lambda I-B)(\lambda I-A)^{-1} y\right)=(\lambda I-A)^{-1} y
\end{gathered}
$$

Recall from Proposition 19.14.5, an arbitrary element of $D(B)$ is of the form $(\lambda I-B)^{-1} y$ and this has shown every such vector is in $D(A)$, in fact it equals $(\lambda I-A)^{-1} y$. Hence $D(B) \subseteq D(A)$ which shows $A$ generates $S(t)$ and this proves the first half of the theorem.

Next suppose $A$ is the generator of a semigroup $S(t)$ having $\|S(t)\| \leq M$. Then by Proposition 19.14.5 for all $\lambda>0,(\lambda I-A)$ is onto and

$$
(\lambda I-A)^{-1}=\int_{0}^{\infty} e^{-\lambda t} S(t) d t
$$

thus

$$
\begin{aligned}
& \left\|\left((\lambda I-A)^{-1}\right)^{n}\right\| \\
= & \left\|\int_{0}^{\infty} \cdots \int_{0}^{\infty} e^{-\lambda\left(t_{1}+\cdots+t_{n}\right)} S\left(t_{1}+\cdots+t_{n}\right) d t_{1} \cdots d t_{n}\right\| \\
\leq & \int_{0}^{\infty} \cdots \int_{0}^{\infty} e^{-\lambda\left(t_{1}+\cdots+t_{n}\right)} M d t_{1} \cdots d t_{n}=\frac{M}{\lambda^{n}} .
\end{aligned}
$$

### 19.14.1 An Evolution Equation

When $\Lambda$ generates a continuous semigroup, one can consider a very interesting theorem about evolution equations of the form

$$
y^{\prime}-\Lambda y=g(t)
$$

provided $t \rightarrow g(t)$ is $C^{1}$.
Theorem 19.14.12 Let $\Lambda$ be the generator of $S(t)$, a continuous semigroup on $X$, a Banach space and let $t \rightarrow g(t)$ be in $C^{1}(0, \infty ; X)$. Then there exists a unique solution to the initial value problem

$$
y^{\prime}-\Lambda y=g, y(0)=y_{0} \in D(\Lambda)
$$

and it is given by

$$
\begin{equation*}
y(t)=S(t) y_{0}+\int_{0}^{t} S(t-s) g(s) d s \tag{19.14.93}
\end{equation*}
$$

This solution is continuous having continuous derivative and has values in $D(\Lambda)$.

Proof: First I show the following claim.
Claim: $\int_{0}^{t} S(t-s) g(s) d s \in D(\Lambda)$ and

$$
\Lambda\left(\int_{0}^{t} S(t-s) g(s) d s\right)=S(t) g(0)-g(t)+\int_{0}^{t} S(t-s) g^{\prime}(s) d s
$$

## Proof of the claim:

$$
\begin{aligned}
& \frac{1}{h}\left(S(h) \int_{0}^{t} S(t-s) g(s) d s-\int_{0}^{t} S(t-s) g(s) d s\right) \\
= & \frac{1}{h}\left(\int_{0}^{t} S(t-s+h) g(s) d s-\int_{0}^{t} S(t-s) g(s) d s\right) \\
= & \frac{1}{h}\left(\int_{-h}^{t-h} S(t-s) g(s+h) d s-\int_{0}^{t} S(t-s) g(s) d s\right) \\
= & \frac{1}{h} \int_{-h}^{0} S(t-s) g(s+h) d s+\int_{0}^{t-h} S(t-s) \frac{g(s+h)-g(s)}{h} \\
& -\frac{1}{h} \int_{t-h}^{t} S(t-s) g(s) d s
\end{aligned}
$$

Using the estimate in Theorem 19.14.3 on Page 577 and the dominated convergence theorem, the limit as $h \rightarrow 0$ of the above equals

$$
S(t) g(0)-g(t)+\int_{0}^{t} S(t-s) g^{\prime}(s) d s
$$

which proves the claim.
Since $y_{0} \in D(\Lambda)$,

$$
\begin{align*}
S(t) \Lambda y_{0} & =S(t) \lim _{h \rightarrow 0} \frac{S(h) y_{0}-y_{0}}{h} \\
& =\lim _{h \rightarrow 0} \frac{S(t+h)-S(t)}{h} y_{0} \\
& =\lim _{h \rightarrow 0} \frac{S(h) S(t) y_{0}-S(t) y_{0}}{h} \tag{19.14.94}
\end{align*}
$$

Since this limit exists, the last limit in the above exists and equals

$$
\begin{equation*}
\Lambda S(t) y_{0} \tag{19.14.95}
\end{equation*}
$$

and so $S(t) y_{0} \in D(\Lambda)$. Now consider 19.14.93.

$$
\begin{gathered}
\frac{y(t+h)-y(t)}{h}=\frac{S(t+h)-S(t)}{h} y_{0}+ \\
\frac{1}{h}\left(\int_{0}^{t+h} S(t-s+h) g(s) d s-\int_{0}^{t} S(t-s) g(s) d s\right)
\end{gathered}
$$

$$
\begin{aligned}
= & \frac{S(t+h)-S(t)}{h} y_{0}+\frac{1}{h} \int_{t}^{t+h} S(t-s+h) g(s) d s \\
& +\frac{1}{h}\left(S(h) \int_{0}^{t} S(t-s) g(s) d s-\int_{0}^{t} S(t-s) g(s) d s\right)
\end{aligned}
$$

From the claim and $19.14 .94,19.14 .95$ the limit of the right side is

$$
\begin{aligned}
& \Lambda S(t) y_{0}+g(t)+\Lambda\left(\int_{0}^{t} S(t-s) g(s) d s\right) \\
= & \Lambda\left(S(t) y_{0}+\int_{0}^{t} S(t-s) g(s) d s\right)+g(t)
\end{aligned}
$$

Hence

$$
y^{\prime}(t)=\Lambda y(t)+g(t)
$$

and from the formula, $y^{\prime}$ is continuous since by the claim and 19.14.95 it also equals

$$
S(t) \Lambda y_{0}+g(t)+S(t) g(0)-g(t)+\int_{0}^{t} S(t-s) g^{\prime}(s) d s
$$

which is continuous. The claim and 19.14.95 also shows $y(t) \in D(\Lambda)$. This proves the existence part of the lemma.

It remains to prove the uniqueness part. It suffices to show that if

$$
y^{\prime}-\Lambda y=0, y(0)=0
$$

and $y$ is $C^{1}$ having values in $D(\Lambda)$, then $y=0$. Suppose then that $y$ is this way. Letting $0<s<t$,

$$
\begin{gathered}
\frac{d}{d s}(S(t-s) y(s)) \\
\equiv \lim _{h \rightarrow 0} S(t-s-h) \frac{y(s+h)-y(s)}{h} \\
-\frac{S(t-s) y(s)-S(t-s-h) y(s)}{h}
\end{gathered}
$$

provided the limit exists. Since $y^{\prime}$ exists and $y(s) \in D(\Lambda)$, this equals

$$
S(t-s) y^{\prime}(s)-S(t-s) \Lambda y(s)=0
$$

Let $y^{*} \in X^{\prime}$. This has shown that on the open interval $(0, t)$ the function $s \rightarrow y^{*}(S(t-s) y(s))$ has a derivative equal to 0 . Also from continuity of $S$ and $y$, this function is continuous on $[0, t]$. Therefore, it is constant on $[0, t]$ by the mean value theorem. At $s=0$, this function equals 0 . Therefore, it equals 0 on $[0, t]$. Thus for fixed $s>0$ and letting $t>s, y^{*}(S(t-s) y(s))=0$. Now let $t$ decrease toward $s$. Then $y^{*}(y(s))=0$ and since $y^{*}$ was arbitrary, it follows $y(s)=0$. This proves uniqueness.

### 19.14.2 Adjoints, Hilbert Space

In Hilbert space, there are some special things which are true.
Definition 19.14.13 Let A be a densely defined closed operator on $H$ a real Hilbert space.
Then $A^{*}$ is defined as follows.

$$
D\left(A^{*}\right) \equiv\{y \in H:|(A x, y)| \leq C|x|\}
$$

Then since $D(A)$ is dense, there exists a unique element of $H$ denoted by $A^{*} y$ such that

$$
(A x, y)=\left(x, A^{*} y\right)
$$

for all $x \in D(A)$.
Lemma 19.14.14 Let $A$ be closed and densely defined on $D(H) \subseteq H$, a Hilbert space. Then $A^{*}$ is also closed and densely defined. Also $\left(A^{*}\right)^{*}=A$. In addition to this, if

$$
(\lambda I-A)^{-1} \in \mathscr{L}(H, H)
$$

then $\left(\lambda I-A^{*}\right)^{-1} \in \mathscr{L}(H, H)$ and

$$
\left(\left((\lambda I-A)^{-1}\right)^{n}\right)^{*}=\left(\left(\lambda I-A^{*}\right)^{-1}\right)^{n}
$$

Proof: Denote by $[x, y]$ an ordered pair in $H \times H$. Define $\tau: H \times H \rightarrow H \times H$ by

$$
\tau[x, y] \equiv[-y, x]
$$

Then the definition of adjoint implies that for $\mathscr{G}(B)$ equal to the graph of $B$,

$$
\begin{equation*}
\mathscr{G}\left(A^{*}\right)=(\tau \mathscr{G}(A))^{\perp} \tag{19.14.96}
\end{equation*}
$$

In this notation the inner product on $H \times H$ with respect to which $\perp$ is defined is given by

$$
([x, y],[a, b]) \equiv(x, a)+(y, b)
$$

Here is why this is so. For $\left[x, A^{*} x\right] \in \mathscr{G}\left(A^{*}\right)$ it follows that for all $y \in D(A)$

$$
\left(\left[x, A^{*} x\right],[-A y, y]\right)=-(A y, x)+\left(y, A^{*} x\right)=0
$$

and so $\left[x, A^{*} x\right] \in\left(\tau_{\mathscr{G}}(A)\right)^{\perp}$ which shows

$$
\mathscr{G}\left(A^{*}\right) \subseteq(\tau \mathscr{G}(A))^{\perp}
$$

To obtain the other inclusion, let $[a, b] \in(\tau \mathscr{G}(A))^{\perp}$. This means that for all $x \in D(A)$,

$$
([a, b],[-A x, x])=0
$$

In other words, for all $x \in D(A)$,

$$
(A x, a)=(x, b)
$$

and so $|(A x, a)| \leq C|x|$ for all $x \in D(A)$ which shows $a \in D\left(A^{*}\right)$ and

$$
\left(x, A^{*} a\right)=(x, b)
$$

for all $x \in D(A)$. Therefore, since $D(A)$ is dense, it follows $b=A^{*} a$ and so $[a, b] \in \mathscr{G}\left(A^{*}\right)$. This shows the other inclusion.

Note that if $V$ is any subspace of the Hilbert space $H \times H$,

$$
\left(V^{\perp}\right)^{\perp}=\bar{V}
$$

and $S^{\perp}$ is always a closed subspace. Also $\tau$ and $\perp$ commute. The reason for this is that $[x, y] \in(\tau V)^{\perp}$ means that

$$
(x,-b)+(y, a)=0
$$

for all $[a, b] \in V$ and $[x, y] \in \tau\left(V^{\perp}\right)$ means $[-y, x] \in V^{\perp}$ so for all $[a, b] \in V$,

$$
(-y, a)+(x, b)=0
$$

which says the same thing. It is also clear that $\tau \circ \tau$ has the effect of multiplication by -1 .
It follows from the above description of the graph of $A^{*}$ that even if $\mathscr{G}(A)$ were not closed it would still be the case that $\mathscr{G}\left(A^{*}\right)$ is closed.

Why is $D\left(A^{*}\right)$ dense? Suppose $z \in D\left(A^{*}\right)^{\perp}$. Then for all $y \in D\left(A^{*}\right)$ so that $[y, A y] \in$ $\mathscr{G}\left(A^{*}\right)$, it follows $[z, 0] \in \mathscr{G}\left(A^{*}\right)^{\perp}=\left((\tau \mathscr{G}(A))^{\perp}\right)^{\perp}=\tau \mathscr{G}(A)$ but this implies

$$
[0, z] \in-\mathscr{G}(A)
$$

and so $z=-A 0=0$. Thus $D\left(A^{*}\right)$ must be dense since there is no nonzero vector in $D\left(A^{*}\right)^{\perp}$.
Since $A$ is a closed operator, meaning $\mathscr{G}(A)$ is closed in $H \times H$, it follows from the above formula that

$$
\begin{aligned}
\mathscr{G}\left(\left(A^{*}\right)^{*}\right) & =\left(\tau\left((\tau \mathscr{G}(A))^{\perp}\right)\right)^{\perp}=\left(\tau(\tau \mathscr{G}(A))^{\perp}\right)^{\perp} \\
& =\left((-\mathscr{G}(A))^{\perp}\right)^{\perp}=\left(\mathscr{G}(A)^{\perp}\right)^{\perp}=\mathscr{G}(A)
\end{aligned}
$$

and so $\left(A^{*}\right)^{*}=A$.
Now consider the final claim. First let $y \in D\left(A^{*}\right)=D\left(\lambda I-A^{*}\right)$. Then letting $x \in H$ be arbitrary,

$$
\begin{gathered}
\left(x,\left((\lambda I-A)(\lambda I-A)^{-1}\right)^{*} y\right) \\
\left((\lambda I-A)(\lambda I-A)^{-1} x, y\right)=\left(x,\left((\lambda I-A)^{-1}\right)^{*}\left(\lambda I-A^{*}\right) y\right)
\end{gathered}
$$

Thus

$$
\begin{equation*}
\left((\lambda I-A)(\lambda I-A)^{-1}\right)^{*}=I=\left((\lambda I-A)^{-1}\right)^{*}\left(\lambda I-A^{*}\right) \tag{19.14.97}
\end{equation*}
$$

on $D\left(A^{*}\right)$. Next let $x \in D(A)=D(\lambda I-A)$ and $y \in H$ arbitrary.

$$
(x, y)=\left((\lambda I-A)^{-1}(\lambda I-A) x, y\right)=\left((\lambda I-A) x,\left((\lambda I-A)^{-1}\right)^{*} y\right)
$$

Now it follows $\left|\left((\lambda I-A) x,\left((\lambda I-A)^{-1}\right)^{*} y\right)\right| \leq|y||x|$ for any $x \in D(A)$ and so

$$
\left((\lambda I-A)^{-1}\right)^{*} y \in D\left(A^{*}\right)
$$

Hence

$$
(x, y)=\left(x,\left(\lambda I-A^{*}\right)\left((\lambda I-A)^{-1}\right)^{*} y\right) .
$$

Since $x \in D(A)$ is arbitrary and $D(A)$ is dense, it follows

$$
\begin{equation*}
\left(\lambda I-A^{*}\right)\left((\lambda I-A)^{-1}\right)^{*}=I \tag{19.14.98}
\end{equation*}
$$

From 19.14.97 and 19.14.98 it follows

$$
\left(\lambda I-A^{*}\right)^{-1}=\left((\lambda I-A)^{-1}\right)^{*}
$$

and $\left(\lambda I-A^{*}\right)$ is one to one and onto with continuous inverse. Finally, from the above,

$$
\left(\left(\lambda I-A^{*}\right)^{-1}\right)^{n}=\left(\left((\lambda I-A)^{-1}\right)^{*}\right)^{n}=\left(\left((\lambda I-A)^{-1}\right)^{n}\right)^{*}
$$

This proves the lemma.
With this preparation, here is an interesting result about the adjoint of the generator of a continuous bounded semigroup. I found this in Balakrishnan [12].

Theorem 19.14.15 Suppose $A$ is a densely defined closed operator which generates a continuous semigroup, $S(t)$. Then $A^{*}$ is also a closed densely defined operator which generates $S^{*}(t)$ and $S^{*}(t)$ is also a continuous semigroup.

Proof: First suppose $S(t)$ is also a bounded semigroup, $\|S(t)\| \leq M$. From Lemma 19.14.14 $A^{*}$ is closed and densely defined. It follows from the Hille Yosida theorem, Theorem 19.14.8 that

$$
\left|\left((\lambda I-A)^{-1}\right)^{n}\right| \leq \frac{M}{\lambda^{n}}
$$

From Lemma 19.14.14 and the fact the adjoint of a bounded linear operator preserves the norm,

$$
\begin{aligned}
\frac{M}{\lambda^{n}} & \geq\left|\left(\left((\lambda I-A)^{-1}\right)^{n}\right)^{*}\right|=\left|\left(\left((\lambda I-A)^{-1}\right)^{*}\right)^{n}\right| \\
& =\left|\left(\left(\lambda I-A^{*}\right)^{-1}\right)^{n}\right|
\end{aligned}
$$

and so by Theorem 19.14 .8 again it follows $A^{*}$ generates a continuous semigroup, $T(t)$ which satisfies $\|T(t)\| \leq M$. I need to identify $T(t)$ with $S^{*}(t)$. However, from the proof of Theorem 19.14.8 and Lemma 19.14.14, it follows that for $x \in D\left(A^{*}\right)$ and a suitable sequence $\left\{\lambda_{n}\right\}$,

$$
(T(t) x, y)=\left(\lim _{n \rightarrow \infty} e^{-\lambda_{n} t} \sum_{k=0}^{\infty} \frac{t^{k}\left(\lambda_{n}^{2}\left(\lambda_{n} I-A^{*}\right)^{-1}\right)^{k}}{k!} x, y\right)
$$

$$
\begin{aligned}
& =\lim _{n \rightarrow \infty}\left(e^{-\lambda_{n} t} \sum_{k=0}^{\infty} \frac{t^{k}\left(\left(\lambda_{n}^{2}\left(\lambda_{n} I-A\right)^{-1}\right)^{k}\right)^{*}}{k!} x, y\right) \\
& =\lim _{n \rightarrow \infty}\left(x, e^{-\lambda_{n} t}\left(\sum_{k=0}^{\infty} \frac{t^{k}\left(\left(\lambda_{n}^{2}\left(\lambda_{n} I-A\right)^{-1}\right)^{k}\right)}{k!}\right) y\right) \\
& =(x, S(t) y)=\left(S^{*}(t) x, y\right) .
\end{aligned}
$$

Therefore, since $y$ is arbitrary, $S^{*}(t)=T(t)$ on $x \in D\left(A^{*}\right)$ a dense set and this shows the two are equal. This proves the proposition in the case where $S(t)$ is also bounded.

Next only assume $S(t)$ is a continuous semigroup. Then by Proposition 19.14.5 there exists $\alpha>0$ such that

$$
\|S(t)\| \leq M e^{\alpha t}
$$

Then consider the operator $-\alpha I+A$ and the bounded semigroup $e^{-\alpha t} S(t)$. For $x \in D(A)$

$$
\begin{aligned}
\lim _{h \rightarrow 0+} \frac{e^{-\alpha h} S(h) x-x}{h} & =\lim _{h \rightarrow 0+}\left(e^{-\alpha h} \frac{S(h) x-x}{h}+\frac{e^{-\alpha h}-1}{h} x\right) \\
& =-\alpha x+A x
\end{aligned}
$$

Thus $-\alpha I+A$ generates $e^{-\alpha t} S(t)$ and it follows from the first part that $-\alpha I+A^{*}$ generates $e^{-\alpha t} S^{*}(t)$. Thus

$$
\begin{aligned}
-\alpha x+A^{*} x & =\lim _{h \rightarrow 0+} \frac{e^{-\alpha h} S^{*}(h) x-x}{h} \\
& =\lim _{h \rightarrow 0+}\left(e^{-\alpha h} \frac{S^{*}(h) x-x}{h}+\frac{e^{-\alpha h}-1}{h} x\right) \\
& =-\alpha x+\lim _{h \rightarrow 0+} \frac{S^{*}(h) x-x}{h}
\end{aligned}
$$

showing that $A^{*}$ generates $S^{*}(t)$. It follows from Proposition 19.14 .5 that $A^{*}$ is closed and densely defined. It is obvious $S^{*}(t)$ is a semigroup. Why is it continuous? This also follows from the first part of the argument which establishes that

$$
e^{-\alpha t} S^{*}(t)
$$

is continuous. This proves the theorem.

### 19.14.3 Adjoints, Reflexive Banach Space

Here the adjoint of a generator of a semigroup is considered. I will show that the adjoint of the generator generates the adjoint of the semigroup in a reflexive Banach space. This is about as far as you can go although a general but less satisfactory result is given in Yosida [127].

Definition 19.14.16 Let A be a densely defined closed operator on $H$ a real Banach space. Then $A^{*}$ is defined as follows.

$$
D\left(A^{*}\right) \equiv\left\{y^{*} \in H^{\prime}:\left|y^{*}(A x)\right| \leq C\|x\| \text { for all } x \in D(A)\right\}
$$

Then since $D(A)$ is dense, there exists a unique element of $H^{\prime}$ denoted by $A^{*} y$ such that

$$
A^{*}\left(y^{*}\right)(x)=y^{*}(A x)
$$

for all $x \in D(A)$.
Lemma 19.14.17 Let $A$ be closed and densely defined on $D(A) \subseteq H$, a Banach space. Then $A^{*}$ is also closed and densely defined. Also $\left(A^{*}\right)^{*}=A$. In addition to this, if $(\lambda I-A)^{-1} \in$ $\mathscr{L}(H, H)$, then $\left(\lambda I-A^{*}\right)^{-1} \in \mathscr{L}\left(H^{\prime}, H^{\prime}\right)$ and

$$
\left(\left((\lambda I-A)^{-1}\right)^{n}\right)^{*}=\left(\left(\lambda I-A^{*}\right)^{-1}\right)^{n}
$$

Proof: Denote by $[x, y]$ an ordered pair in $H \times H$. Define $\tau: H \times H \rightarrow H \times H$ by

$$
\tau[x, y] \equiv[-y, x]
$$

A similar notation will apply to $H^{\prime} \times H^{\prime}$. Then the definition of adjoint implies that for $\mathscr{G}(B)$ equal to the graph of $B$,

$$
\begin{equation*}
\mathscr{G}\left(A^{*}\right)=(\tau \mathscr{G}(A))^{\perp} \tag{19.14.99}
\end{equation*}
$$

For $S \subseteq H \times H$, define $S^{\perp}$ by

$$
\left\{\left[a^{*}, b^{*}\right] \in H^{\prime} \times H^{\prime}: a^{*}(x)+b^{*}(y)=0 \text { for all }[x, y] \in S\right\}
$$

If $S \subseteq H^{\prime} \times H^{\prime}$ a similar definition holds.

$$
\left\{[x, y] \in H \times H: a^{*}(x)+b^{*}(y)=0 \text { for all }\left[a^{*}, b^{*}\right] \in S\right\}
$$

Here is why 19.14 .99 is so. For $\left[x^{*}, A^{*} x^{*}\right] \in \mathscr{G}\left(A^{*}\right)$ it follows that for all $y \in D(A)$

$$
x^{*}(A y)=A^{*} x^{*}(y)
$$

and so for all $[y, A y] \in \mathscr{G}(A)$,

$$
-x^{*}(A y)+A^{*} x^{*}(y)=0
$$

which is what it means to say $\left[x^{*}, A^{*} x^{*}\right] \in\left(\tau_{\mathscr{G}}(A)\right)^{\perp}$. This shows

$$
\mathscr{G}\left(A^{*}\right) \subseteq(\tau \mathscr{G}(A))^{\perp}
$$

To obtain the other inclusion, let $\left[a^{*}, b^{*}\right] \in(\tau \mathscr{G}(A))^{\perp}$. This means that for all $[x, A x] \in$ $\mathscr{G}(A)$,

$$
-a^{*}(A x)+b^{*}(x)=0
$$

In other words, for all $x \in D(A)$,

$$
\left|a^{*}(A x)\right| \leq\left\|b^{*}\right\|\|x\|
$$

which means by definition, $a^{*} \in D\left(A^{*}\right)$ and $A^{*} a^{*}=b^{*}$. Thus $\left[a^{*}, b^{*}\right] \in \mathscr{G}\left(A^{*}\right)$.This shows the other inclusion.

Note that if $V$ is any subspace of $H \times H$,

$$
\left(V^{\perp}\right)^{\perp}=\bar{V}
$$

and $S^{\perp}$ is always a closed subspace. Also $\tau$ and $\perp$ commute. The reason for this is that $\left[x^{*}, y^{*}\right] \in(\tau V)^{\perp}$ means that

$$
-x^{*}(b)+y^{*}(a)=0
$$

for all $[a, b] \in V$ and $\left[x^{*}, y^{*}\right] \in \tau\left(V^{\perp}\right)$ means $\left[-y^{*}, x^{*}\right] \in-\left(V^{\perp}\right)=V^{\perp}$ so for all $[a, b] \in V$,

$$
-y^{*}(a)+x^{*}(b)=0
$$

which says the same thing. It is also clear that $\tau \circ \tau$ has the effect of multiplication by -1 . If $V \subseteq H^{\prime} \times H^{\prime}$, the argument for commuting $\perp$ and $\tau$ is similar.

It follows from the above description of the graph of $A^{*}$ that even if $\mathscr{G}(A)$ were not closed it would still be the case that $\mathscr{G}\left(A^{*}\right)$ is closed.

Why is $D\left(A^{*}\right)$ dense? If it is not dense, then by a typical application of the Hahn Banach theorem, there exists $y^{* *} \in H^{\prime \prime}$ such that $y^{* *}\left(D\left(A^{*}\right)\right)=0$ but $y^{* *} \neq 0$. Since $H$ is reflexive, there exists $y \in H$ such that $x^{*}(y)=0$ for all $x^{*} \in D\left(A^{*}\right)$. Thus

$$
[y, 0] \in \mathscr{G}\left(A^{*}\right)^{\perp}=\left((\tau \mathscr{G}(A))^{\perp}\right)^{\perp}=\tau \mathscr{G}(A)
$$

and so $[0, y] \in \mathscr{G}(A)$ which means $y=A 0=0$, a contradiction. Thus $D\left(A^{*}\right)$ is indeed dense. Note this is where it was important to assume the space is reflexive. If you consider $C([0,1])$ it is not dense in $L^{\infty}([0,1])$ but if $f \in L^{1}([0,1])$ satisfies $\int_{0}^{1} f g d m=0$ for all $g \in C([0,1])$, then $f=0$. Hence there is no nonzero $f \in C([0,1])^{\perp}$.

Since $A$ is a closed operator, meaning $\mathscr{G}(A)$ is closed in $H \times H$, it follows from the above formula that

$$
\begin{aligned}
\mathscr{G}\left(\left(A^{*}\right)^{*}\right) & =\left(\tau\left((\tau \mathscr{G}(A))^{\perp}\right)\right)^{\perp}=\left(\tau(\tau \mathscr{G}(A))^{\perp}\right)^{\perp} \\
& =\left((-\mathscr{G}(A))^{\perp}\right)^{\perp}=\left(\mathscr{G}(A)^{\perp}\right)^{\perp}=\mathscr{G}(A)
\end{aligned}
$$

and so $\left(A^{*}\right)^{*}=A$.
Now consider the final claim. First let $y^{*} \in D\left(A^{*}\right)=D\left(\lambda I-A^{*}\right)$. Then letting $x \in H$ be arbitrary,

$$
\begin{aligned}
y^{*}(x) & =\left((\lambda I-A)(\lambda I-A)^{-1}\right)^{*} y^{*}(x) \\
& =y^{*}\left((\lambda I-A)(\lambda I-A)^{-1} x\right)
\end{aligned}
$$

Since $y^{*} \in D\left(A^{*}\right)$ and $(\lambda I-A)^{-1} x \in D(A)$, this equals

$$
(\lambda I-A)^{*} y^{*}\left((\lambda I-A)^{-1} x\right)
$$

Now by definition, this equals

$$
\left((\lambda I-A)^{-1}\right)^{*}(\lambda I-A)^{*} y^{*}(x)
$$

It follows that for $y^{*} \in D\left(A^{*}\right)$,

$$
\begin{align*}
& \left((\lambda I-A)^{-1}\right)^{*}(\lambda I-A)^{*} y^{*} \\
= & \left((\lambda I-A)^{-1}\right)^{*}\left(\lambda I-A^{*}\right) y^{*}=y^{*} \tag{19.14.100}
\end{align*}
$$

Next let $y^{*} \in H^{\prime}$ be arbitrary and $x \in D(A)$

$$
\begin{aligned}
y^{*}(x) & =y^{*}\left((\lambda I-A)^{-1}(\lambda I-A) x\right) \\
& =\left((\lambda I-A)^{-1}\right)^{*} y^{*}((\lambda I-A) x) \\
& =(\lambda I-A)^{*}\left((\lambda I-A)^{-1}\right)^{*} y^{*}(x)
\end{aligned}
$$

In going from the second to the third line, the first line shows $\left((\lambda I-A)^{-1}\right)^{*} y^{*} \in D\left(A^{*}\right)$ and so the third line follows. Since $D(A)$ is dense, it follows

$$
\begin{equation*}
\left(\lambda I-A^{*}\right)\left((\lambda I-A)^{-1}\right)^{*}=I \tag{19.14.101}
\end{equation*}
$$

Then 19.14 .100 and 19.14 .101 show $\lambda I-A^{*}$ is one to one and onto from $D\left(A^{*}\right)$ to $H^{\prime}$ and

$$
\left(\lambda I-A^{*}\right)^{-1}=\left((\lambda I-A)^{-1}\right)^{*}
$$

Finally, from the above,

$$
\left(\left(\lambda I-A^{*}\right)^{-1}\right)^{n}=\left(\left((\lambda I-A)^{-1}\right)^{*}\right)^{n}=\left(\left((\lambda I-A)^{-1}\right)^{n}\right)^{*}
$$

This proves the lemma.
With this preparation, here is an interesting result about the adjoint of the generator of a continuous bounded semigroup.

Theorem 19.14.18 Suppose $A$ is a densely defined closed operator which generates a continuous semigroup, $S(t)$. Then $A^{*}$ is also a closed densely defined operator which generates $S^{*}(t)$ and $S^{*}(t)$ is also a continuous semigroup.

Proof: First suppose $S(t)$ is also a bounded semigroup, $\|S(t)\| \leq M$. From Lemma 19.14.17 $A^{*}$ is closed and densely defined. It follows from the Hille Yosida theorem, Theorem 19.14.8 that

$$
\left\|\left((\lambda I-A)^{-1}\right)^{n}\right\| \leq \frac{M}{\lambda^{n}}
$$

From Lemma 19.14.17 and the fact the adjoint of a bounded linear operator preserves the norm,

$$
\begin{aligned}
\frac{M}{\lambda^{n}} & \geq\left\|\left(\left((\lambda I-A)^{-1}\right)^{n}\right)^{*}\right\|=\left\|\left(\left((\lambda I-A)^{-1}\right)^{*}\right)^{n}\right\| \\
& =\left\|\left(\left(\lambda I-A^{*}\right)^{-1}\right)^{n}\right\|
\end{aligned}
$$

and so by Theorem 19.14.8 again it follows $A^{*}$ generates a continuous semigroup, $T(t)$ which satisfies $\|T(t)\| \leq M$. I need to identify $T(t)$ with $S^{*}(t)$. However, from the proof of Theorem 19.14.8 and Lemma 19.14.17, it follows that for $x^{*} \in D\left(A^{*}\right)$ and a suitable sequence $\left\{\lambda_{n}\right\}$,

$$
\begin{aligned}
& T(t) x^{*}(y)=\lim _{n \rightarrow \infty} e^{-\lambda_{n} t} \sum_{k=0}^{\infty} \frac{t^{k}\left(\lambda_{n}^{2}\left(\lambda_{n} I-A^{*}\right)^{-1}\right)^{k}}{k!} x^{*}(y) \\
& =\lim _{n \rightarrow \infty} e^{-\lambda_{n} t} \sum_{k=0}^{\infty} \frac{t^{k}\left(\left(\lambda_{n}^{2}\left(\lambda_{n} I-A\right)^{-1}\right)^{k}\right)^{*}}{k!} x^{*}(y) \\
& =\lim _{n \rightarrow \infty} x^{*}\left(e^{-\lambda_{n} t}\left(\sum_{k=0}^{\infty} \frac{t^{k}\left(\left(\lambda_{n}^{2}\left(\lambda_{n} I-A\right)^{-1}\right)^{k}\right)}{k!} y\right)\right) \\
& =x^{*}(S(t) y)=S^{*}(t) x^{*}(y) .
\end{aligned}
$$

Therefore, since $y$ is arbitrary, $S^{*}(t)=T(t)$ on $x \in D\left(A^{*}\right)$ a dense set and this shows the two are equal. In particular, $S^{*}(t)$ is a semigroup because $T(t)$ is. This proves the proposition in the case where $S(t)$ is also bounded.

Next only assume $S(t)$ is a continuous semigroup. Then by Proposition 19.14.5 there exists $\alpha>0$ such that

$$
\|S(t)\| \leq M e^{\alpha t}
$$

Then consider the operator $-\alpha I+A$ and the bounded semigroup $e^{-\alpha t} S(t)$. For $x \in D(A)$

$$
\begin{aligned}
\lim _{h \rightarrow 0+} \frac{e^{-\alpha h} S(h) x-x}{h} & =\lim _{h \rightarrow 0+}\left(e^{-\alpha h} \frac{S(h) x-x}{h}+\frac{e^{-\alpha h}-1}{h} x\right) \\
& =-\alpha x+A x
\end{aligned}
$$

Thus $-\alpha I+A$ generates $e^{-\alpha t} S(t)$ and it follows from the first part that $-\alpha I+A^{*}$ generates the semigroup $e^{-\alpha t} S^{*}(t)$. Thus

$$
\begin{aligned}
-\alpha x+A^{*} x & =\lim _{h \rightarrow 0+} \frac{e^{-\alpha h} S^{*}(h) x-x}{h} \\
& =\lim _{h \rightarrow 0+}\left(e^{-\alpha h} \frac{S^{*}(h) x-x}{h}+\frac{e^{-\alpha h}-1}{h} x\right) \\
& =-\alpha x+\lim _{h \rightarrow 0+} \frac{S^{*}(h) x-x}{h}
\end{aligned}
$$

showing that $A^{*}$ generates $S^{*}(t)$. It follows from Proposition 19.14 .5 that $A^{*}$ is closed and densely defined. It is obvious $S^{*}(t)$ is a semigroup. Why is it continuous? This also follows from the first part of the argument which establishes that

$$
t \rightarrow e^{-\alpha t} S^{*}(t) x
$$

is continuous. This proves the theorem.

## Chapter 20

## Representation Theorems

### 20.1 Radon Nikodym Theorem

This chapter is on various representation theorems. The first theorem, the Radon Nikodym Theorem, is a representation theorem for one measure in terms of another. The approach given here is due to Von Neumann and depends on the Riesz representation theorem for Hilbert space, Theorem 19.1.14 on Page 522.

Definition 20.1.1 Let $\mu$ and $\lambda$ be two measures defined on a $\sigma$-algebra, $\mathscr{S}$, of subsets of a set, $\Omega$. $\lambda$ is absolutely continuous with respect to $\mu$, written as $\lambda \ll \mu$, if $\lambda(E)=0$ whenever $\mu(E)=0$.

It is not hard to think of examples which should be like this. For example, suppose one measure is volume and the other is mass. If the volume of something is zero, it is reasonable to expect the mass of it should also be equal to zero. In this case, there is a function called the density which is integrated over volume to obtain mass. The Radon Nikodym theorem is an abstract version of this notion. Essentially, it gives the existence of the density function.

Theorem 20.1.2 (Radon Nikodym) Let $\lambda$ and $\mu$ be finite measures defined on a $\sigma$-algebra, $\mathscr{S}$, of subsets of $\Omega$. Suppose $\lambda \ll \mu$. Then there exists a unique $f \in L^{1}(\Omega, \mu)$ such that $f(x) \geq 0$ and

$$
\lambda(E)=\int_{E} f d \mu
$$

If it is not necessarily the case that $\lambda \ll \mu$, there are two measures, $\lambda_{\perp}$ and $\lambda_{\|}$such that $\lambda=\lambda_{\perp}+\lambda_{\|}, \lambda_{\|} \ll \mu$ and there exists a set of $\mu$ measure zero, $N$ such that for all $E$ measurable, $\lambda_{\perp}(E)=\lambda(E \cap N)=\lambda_{\perp}(E \cap N)$. In this case the two measures, $\lambda_{\perp}$ and $\lambda_{\|}$ are unique and the representation of $\lambda=\lambda_{\perp}+\lambda_{\|}$is called the Lebesgue decomposition of $\lambda$. The measure $\lambda_{\|}$is the absolutely continuous part of $\lambda$ and $\lambda_{\perp}$ is called the singular part of $\lambda$.

Proof: Let $\Lambda: L^{2}(\Omega, \mu+\lambda) \rightarrow \mathbb{C}$ be defined by

$$
\Lambda g=\int_{\Omega} g d \lambda
$$

By Holder's inequality,

$$
|\Lambda g| \leq\left(\int_{\Omega} 1^{2} d \lambda\right)^{1 / 2}\left(\int_{\Omega}|g|^{2} d(\lambda+\mu)\right)^{1 / 2}=\lambda(\Omega)^{1 / 2}\|g\|_{2}
$$

where $\|g\|_{2}$ is the $L^{2}$ norm of $g$ taken with respect to $\mu+\lambda$. Therefore, since $\Lambda$ is bounded, it follows from Theorem 17.1.4 on Page 437 that $\Lambda \in\left(L^{2}(\Omega, \mu+\lambda)\right)^{\prime}$, the dual space $L^{2}(\Omega, \mu+\lambda)$. By the Riesz representation theorem in Hilbert space, Theorem 19.1.14, there exists a unique $h \in L^{2}(\Omega, \mu+\lambda)$ with

$$
\begin{equation*}
\Lambda g=\int_{\Omega} g d \lambda=\int_{\Omega} h g d(\mu+\lambda) \tag{20.1.1}
\end{equation*}
$$

The plan is to show $h$ is real and nonnegative at least a.e. Therefore, consider the set where $\operatorname{Im} h$ is positive.

$$
E=\{x \in \Omega: \operatorname{Im} h(x)>0\},
$$

Now let $g=\mathscr{X}_{E}$ and use 20.1.1 to get

$$
\begin{equation*}
\lambda(E)=\int_{E}(\operatorname{Re} h+i \operatorname{Im} h) d(\mu+\lambda) \tag{20.1.2}
\end{equation*}
$$

Since the left side of 20.1.2 is real, this shows

$$
\begin{aligned}
0 & =\int_{E}(\operatorname{Im} h) d(\mu+\lambda) \\
& \geq \int_{E_{n}}(\operatorname{Im} h) d(\mu+\lambda) \\
& \geq \frac{1}{n}(\mu+\lambda)\left(E_{n}\right)
\end{aligned}
$$

where

$$
E_{n} \equiv\left\{x: \operatorname{Im} h(x) \geq \frac{1}{n}\right\}
$$

Thus $(\mu+\lambda)\left(E_{n}\right)=0$ and since $E=\cup_{n=1}^{\infty} E_{n}$, it follows $(\mu+\lambda)(E)=0$. A similar argument shows that for

$$
E=\{x \in \Omega: \operatorname{Im} h(x)<0\},
$$

$(\mu+\lambda)(E)=0$. Thus there is no loss of generality in assuming $h$ is real-valued.
The next task is to show $h$ is nonnegative. This is done in the same manner as above. Define the set where it is negative and then show this set has measure zero.

Let $E \equiv\{x: h(x)<0\}$ and let $E_{n} \equiv\left\{x: h(x)<-\frac{1}{n}\right\}$. Then let $g=\mathscr{X}_{E_{n}}$. Since $E=$ $\cup_{n} E_{n}$, it follows that if $(\mu+\lambda)(E)>0$ then this is also true for $(\mu+\lambda)\left(E_{n}\right)$ for all $n$ large enough. Then from 20.1.2

$$
\lambda\left(E_{n}\right)=\int_{E_{n}} h d(\mu+\lambda) \leq-(1 / n)(\mu+\lambda)\left(E_{n}\right)<0
$$

a contradiction. Thus it can be assumed $h \geq 0$.
At this point the argument splits into two cases.
Case Where $\lambda \ll \mu$. In this case, $h<1$.
Let $E=[h \geq 1]$ and let $g=\mathscr{X}_{E}$. Then

$$
\lambda(E)=\int_{E} h d(\mu+\lambda) \geq \mu(E)+\lambda(E)
$$

Therefore $\mu(E)=0$. Since $\lambda \ll \mu$, it follows that $\lambda(E)=0$ also. Thus it can be assumed

$$
0 \leq h(x)<1
$$

for all $x$.

From 20.1.1, whenever $g \in L^{2}(\Omega, \mu+\lambda)$,

$$
\begin{equation*}
\int_{\Omega} g(1-h) d \lambda=\int_{\Omega} h g d \mu \tag{20.1.3}
\end{equation*}
$$

Now let $E$ be a measurable set and define

$$
g(x) \equiv \sum_{i=0}^{n} h^{i}(x) \mathscr{X}_{E}(x)
$$

in 20.1.3. This yields

$$
\begin{equation*}
\int_{E}\left(1-h^{n+1}(x)\right) d \lambda=\int_{E} \sum_{i=1}^{n+1} h^{i}(x) d \mu . \tag{20.1.4}
\end{equation*}
$$

Let $f(x)=\sum_{i=1}^{\infty} h^{i}(x)$ and use the Monotone Convergence theorem in 20.1.4 to let $n \rightarrow \infty$ and conclude

$$
\lambda(E)=\int_{E} f d \mu
$$

$f \in L^{1}(\Omega, \mu)$ because $\lambda$ is finite.
The function, $f$ is unique $\mu$ a.e. because, if $g$ is another function which also serves to represent $\lambda$, consider for each $n \in \mathbb{N}$ the set,

$$
E_{n} \equiv\left[f-g>\frac{1}{n}\right]
$$

and conclude that

$$
0=\int_{E_{n}}(f-g) d \mu \geq \frac{1}{n} \mu\left(E_{n}\right)
$$

Therefore, $\mu\left(E_{n}\right)=0$. It follows that

$$
\mu([f-g>0]) \leq \sum_{n=1}^{\infty} \mu\left(E_{n}\right)=0
$$

Similarly, the set where $g$ is larger than $f$ has measure zero. This proves the theorem.
Case where it is not necessarily true that $\lambda \ll \mu$.
In this case, let $N=[h \geq 1]$ and let $g=\mathscr{X}_{N}$. Then

$$
\lambda(N)=\int_{N} h d(\mu+\lambda) \geq \mu(N)+\lambda(N)
$$

and so $\mu(N)=0$. Now define a measure, $\lambda_{\perp}$ by

$$
\lambda_{\perp}(E) \equiv \lambda(E \cap N)
$$

so $\lambda_{\perp}(E \cap N)=\lambda(E \cap N \cap N) \equiv \lambda_{\perp}(E)$ and let $\lambda_{\|} \equiv \lambda-\lambda_{\perp}$. Therefore,

$$
\mu(E)=\mu\left(E \cap N^{C}\right)
$$

Also,

$$
\lambda_{\|}(E)=\lambda(E)-\lambda_{\perp}(E) \equiv \lambda(E)-\lambda(E \cap N)=\lambda\left(E \cap N^{C}\right)
$$

Suppose $\lambda_{\|}(E)>0$. Therefore, since $h<1$ on $N^{C}$

$$
\begin{aligned}
\lambda_{\|}(E) & =\lambda\left(E \cap N^{C}\right)=\int_{E \cap N^{C}} h d(\mu+\lambda) \\
& <\mu\left(E \cap N^{C}\right)+\lambda\left(E \cap N^{C}\right)=\mu(E)+\lambda_{\|}(E)
\end{aligned}
$$

which is a contradiction unless $\mu(E)>0$. Therefore, $\lambda_{\|} \ll \mu$ because if $\mu(E)=0$, the above inequality cannot hold.

It only remains to verify the two measures $\lambda_{\perp}$ and $\lambda_{\|}$are unique. Suppose then that $v_{1}$ and $v_{2}$ play the roles of $\lambda_{\perp}$ and $\lambda_{\|}$respectively. Let $N_{1}$ play the role of $N$ in the definition of $v_{1}$ and let $f_{1}$ play the role of $f$ for $\nu_{2}$. I will show that $f=f_{1} \mu$ a.e. Let $E_{k} \equiv\left[f_{1}-f>1 / k\right]$ for $k \in \mathbb{N}$. Then on observing that $\lambda_{\perp}-v_{1}=v_{2}-\lambda_{\|}$

$$
\begin{aligned}
0 & =\left(\lambda_{\perp}-v_{1}\right)\left(E_{k} \cap\left(N_{1} \cup N\right)^{C}\right)=\int_{E_{k} \cap\left(N_{1} \cup N\right)^{C}}\left(g_{1}-g\right) d \mu \\
& \geq \frac{1}{k} \mu\left(E_{k} \cap\left(N_{1} \cup N\right)^{C}\right)=\frac{1}{k} \mu\left(E_{k}\right)
\end{aligned}
$$

and so $\mu\left(E_{k}\right)=0$. Therefore, $\mu\left(\left[f_{1}-f>0\right]\right)=0$ because $\left[f_{1}-f>0\right]=\cup_{k=1}^{\infty} E_{k}$. It follows $f_{1} \leq f \mu$ a.e. Similarly, $f_{1} \geq f \mu$ a.e. Therefore, $v_{2}=\lambda_{\|}$and so $\lambda_{\perp}=v_{1}$ also.

The $f$ in the theorem for the absolutely continuous case is sometimes denoted by $\frac{d \lambda}{d \mu}$ and is called the Radon Nikodym derivative.

The next corollary is a useful generalization to $\sigma$ finite measure spaces.
Corollary 20.1.3 Suppose $\lambda \ll \mu$ and there exist sets $S_{n} \in \mathscr{S}$ with

$$
S_{n} \cap S_{m}=\emptyset, \cup_{n=1}^{\infty} S_{n}=\Omega
$$

and $\lambda\left(S_{n}\right), \mu\left(S_{n}\right)<\infty$. Then there exists $f \geq 0$, where $f$ is $\mu$ measurable, and

$$
\lambda(E)=\int_{E} f d \mu
$$

for all $E \in \mathscr{S}$. The function $f$ is $\mu+\lambda$ a.e. unique.
Proof: Define the $\sigma$ algebra of subsets of $S_{n}$,

$$
\mathscr{S}_{n} \equiv\left\{E \cap S_{n}: E \in \mathscr{S}\right\}
$$

Then both $\lambda$, and $\mu$ are finite measures on $\mathscr{S}_{n}$, and $\lambda \ll \mu$. Thus, by Theorem 20.1.2, there exists a nonnegative $\mathscr{S}_{n}$ measurable function $f_{n}$, with $\lambda(E)=\int_{E} f_{n} d \mu$ for all $E \in \mathscr{S}_{n}$. Define $f(x)=f_{n}(x)$ for $x \in S_{n}$. Since the $S_{n}$ are disjoint and their union is all of $\Omega$, this defines $f$ on all of $\Omega$. The function, $f$ is measurable because

$$
f^{-1}((a, \infty])=\cup_{n=1}^{\infty} f_{n}^{-1}((a, \infty]) \in \mathscr{S} .
$$

Also, for $E \in \mathscr{S}$,

$$
\begin{aligned}
\lambda(E) & =\sum_{n=1}^{\infty} \lambda\left(E \cap S_{n}\right)=\sum_{n=1}^{\infty} \int \mathscr{X}_{E \cap S_{n}}(x) f_{n}(x) d \mu \\
& =\sum_{n=1}^{\infty} \int \mathscr{X}_{E \cap S_{n}}(x) f(x) d \mu
\end{aligned}
$$

By the monotone convergence theorem

$$
\begin{aligned}
\sum_{n=1}^{\infty} \int \mathscr{X}_{E \cap S_{n}}(x) f(x) d \mu & =\lim _{N \rightarrow \infty} \sum_{n=1}^{N} \int \mathscr{X}_{E \cap S_{n}}(x) f(x) d \mu \\
& =\lim _{N \rightarrow \infty} \int \sum_{n=1}^{N} \mathscr{X}_{E \cap S_{n}}(x) f(x) d \mu \\
& =\int \sum_{n=1}^{\infty} \mathscr{X}_{E \cap S_{n}}(x) f(x) d \mu=\int_{E} f d \mu
\end{aligned}
$$

This proves the existence part of the corollary.
To see $f$ is unique, suppose $f_{1}$ and $f_{2}$ both work and consider for $n \in \mathbb{N}$

$$
E_{k} \equiv\left[f_{1}-f_{2}>\frac{1}{k}\right]
$$

Then

$$
0=\lambda\left(E_{k} \cap S_{n}\right)-\lambda\left(E_{k} \cap S_{n}\right)=\int_{E_{k} \cap S_{n}} f_{1}(x)-f_{2}(x) d \mu
$$

Hence $\mu\left(E_{k} \cap S_{n}\right)=0$ for all $n$ so

$$
\mu\left(E_{k}\right)=\lim _{n \rightarrow \infty} \mu\left(E \cap S_{n}\right)=0
$$

Hence $\mu\left(\left[f_{1}-f_{2}>0\right]\right) \leq \sum_{k=1}^{\infty} \mu\left(E_{k}\right)=0$. Therefore, $\lambda\left(\left[f_{1}-f_{2}>0\right]\right)=0$ also. Similarly

$$
(\mu+\lambda)\left(\left[f_{1}-f_{2}<0\right]\right)=0
$$

This version of the Radon Nikodym theorem will suffice for most applications, but more general versions are available. To see one of these, one can read the treatment in Hewitt and Stromberg [64]. This involves the notion of decomposable measure spaces, a generalization of $\sigma$ finite.

Not surprisingly, there is a simple generalization of the Lebesgue decomposition part of Theorem 20.1.2.

Corollary 20.1.4 Let $(\Omega, \mathscr{S})$ be a set with a $\sigma$ algebra of sets. Suppose $\lambda$ and $\mu$ are two measures defined on the sets of $\mathscr{S}$ and suppose there exists a sequence of disjoint sets of $\mathscr{S},\left\{\Omega_{i}\right\}_{i=1}^{\infty}$ such that $\lambda\left(\Omega_{i}\right), \mu\left(\Omega_{i}\right)<\infty$. Then there is a set of $\mu$ measure zero, $N$ and measures $\lambda_{\perp}$ and $\lambda_{\|}$such that

$$
\lambda_{\perp}+\lambda_{\|}=\lambda, \lambda_{\|} \ll \mu, \lambda_{\perp}(E)=\lambda(E \cap N)=\lambda_{\perp}(E \cap N)
$$

Proof: Let $\mathscr{S}_{i} \equiv\left\{E \cap \Omega_{i}: E \in \mathscr{S}\right\}$ and for $E \in \mathscr{S}_{i}$, let $\lambda^{i}(E)=\lambda(E)$ and $\mu^{i}(E)=$ $\mu(E)$. Then by Theorem 20.1.2 there exist unique measures $\lambda_{\perp}^{i}$ and $\lambda_{\|}^{i}$ such that $\lambda^{i}=$ $\lambda_{\perp}^{i}+\lambda_{\|}^{i}$, a set of $\mu^{i}$ measure zero, $N_{i} \in \mathscr{S}_{i}$ such that for all $E \in \mathscr{S}_{i}, \lambda_{\perp}^{i}(E)=\lambda^{i}\left(E \cap N_{i}\right)$ and $\lambda_{\|}^{i} \ll \mu^{i}$. Define for $E \in \mathscr{S}$

$$
\lambda_{\perp}(E) \equiv \sum_{i} \lambda_{\perp}^{i}\left(E \cap \Omega_{i}\right), \lambda_{\|}(E) \equiv \sum_{i} \lambda_{\|}^{i}\left(E \cap \Omega_{i}\right), N \equiv \cup_{i} N_{i}
$$

First observe that $\lambda_{\perp}$ and $\lambda_{\|}$are measures.

$$
\begin{aligned}
\lambda_{\perp}\left(\cup_{j=1}^{\infty} E_{j}\right) & \equiv \sum_{i} \lambda_{\perp}^{i}\left(\cup_{j=1}^{\infty} E_{j} \cap \Omega_{i}\right)=\sum_{i} \sum_{j} \lambda_{\perp}^{i}\left(E_{j} \cap \Omega_{i}\right) \\
& =\sum_{j} \sum_{i} \lambda_{\perp}^{i}\left(E_{j} \cap \Omega_{i}\right)=\sum_{j} \sum_{i} \lambda\left(E_{j} \cap \Omega_{i} \cap N_{i}\right) \\
& =\sum_{j} \sum_{i} \lambda_{\perp}^{i}\left(E_{j} \cap \Omega_{i}\right)=\sum_{j} \lambda_{\perp}\left(E_{j}\right) .
\end{aligned}
$$

The argument for $\lambda_{\|}$is similar. Now

$$
\mu(N)=\sum_{i} \mu\left(N \cap \Omega_{i}\right)=\sum_{i} \mu^{i}\left(N_{i}\right)=0
$$

and

$$
\begin{aligned}
\lambda_{\perp}(E) & \equiv \sum_{i} \lambda_{\perp}^{i}\left(E \cap \Omega_{i}\right)=\sum_{i} \lambda^{i}\left(E \cap \Omega_{i} \cap N_{i}\right) \\
& =\sum_{i} \lambda\left(E \cap \Omega_{i} \cap N\right)=\lambda(E \cap N)
\end{aligned}
$$

Also if $\mu(E)=0$, then $\mu^{i}\left(E \cap \Omega_{i}\right)=0$ and so $\lambda_{\|}^{i}\left(E \cap \Omega_{i}\right)=0$. Therefore,

$$
\lambda_{\|}(E)=\sum_{i} \lambda_{\|}^{i}\left(E \cap \Omega_{i}\right)=0
$$

The decomposition is unique because of the uniqueness of the $\lambda_{\|}^{i}$ and $\lambda_{\perp}^{i}$ and the observation that some other decomposition must coincide with the given one on the $\Omega_{i}$.

### 20.2 Vector Measures

The next topic will use the Radon Nikodym theorem. It is the topic of vector and complex measures. The main interest is in complex measures although a vector measure can have values in any topological vector space. Whole books have been written on this subject. See for example the book by Diestal and Uhl [41] titled Vector measures.
Definition 20.2.1 Let $(V,\|\cdot\|)$ be a normed linear space and let $(\Omega, \mathscr{S})$ be a measure space. A function $\mu: \mathscr{S} \rightarrow V$ is a vector measure if $\mu$ is countably additive. That is, if $\left\{E_{i}\right\}_{i=1}^{\infty}$ is a sequence of disjoint sets of $\mathscr{S}$,

$$
\mu\left(\cup_{i=1}^{\infty} E_{i}\right)=\sum_{i=1}^{\infty} \mu\left(E_{i}\right)
$$

Note that it makes sense to take finite sums because it is given that $\mu$ has values in a vector space in which vectors can be summed. In the above, $\mu\left(E_{i}\right)$ is a vector. It might be a point in $\mathbb{R}^{n}$ or in any other vector space. In many of the most important applications, it is a vector in some sort of function space which may be infinite dimensional. The infinite sum has the usual meaning. That is

$$
\sum_{i=1}^{\infty} \mu\left(E_{i}\right)=\lim _{n \rightarrow \infty} \sum_{i=1}^{n} \mu\left(E_{i}\right)
$$

where the limit takes place relative to the norm on $V$.
Definition 20.2.2 Let $(\Omega, \mathscr{S})$ be a measure space and let $\mu$ be a vector measure defined on $\mathscr{S}$. A subset, $\pi(E)$, of $\mathscr{S}$ is called a partition of $E$ if $\pi(E)$ consists of finitely many disjoint sets of $\mathscr{S}$ and $\cup \pi(E)=E$. Let

$$
|\mu|(E)=\sup \left\{\sum_{F \in \pi(E)}\|\mu(F)\|: \pi(E) \text { is a partition of } E\right\} .
$$

$|\mu|$ is called the total variation of $\mu$.
The next theorem may seem a little surprising. It states that, if finite, the total variation is a nonnegative measure.

Theorem 20.2.3 If $|\mu|(\Omega)<\infty$, then $|\mu|$ is a measure on $\mathscr{S}$. Even if $|\mu|(\Omega)=\infty$,

$$
|\mu|\left(\cup_{i=1}^{\infty} E_{i}\right) \leq \sum_{i=1}^{\infty}|\mu|\left(E_{i}\right)
$$

That is $|\mu|$ is subadditive and $|\mu|(A) \leq|\mu|(B)$ whenever $A, B \in \mathscr{S}$ with $A \subseteq B$.
Proof: Consider the last claim. Let $a<|\mu|(A)$ and let $\pi(A)$ be a partition of $A$ such that

$$
a<\sum_{F \in \pi(A)}\|\mu(F)\|
$$

Then $\pi(A) \cup\{B \backslash A\}$ is a partition of $B$ and

$$
|\mu|(B) \geq \sum_{F \in \pi(A)}\|\mu(F)\|+\|\mu(B \backslash A)\|>a .
$$

Since this is true for all such $a$, it follows $|\mu|(B) \geq|\mu|(A)$ as claimed.
Let $\left\{E_{j}\right\}_{j=1}^{\infty}$ be a sequence of disjoint sets of $\mathscr{S}$ and let $E_{\infty}=\cup_{j=1}^{\infty} E_{j}$. Then letting $a<|\mu|\left(E_{\infty}\right)$, it follows from the definition of total variation there exists a partition of $E_{\infty}$, $\pi\left(E_{\infty}\right)=\left\{A_{1}, \cdots, A_{n}\right\}$ such that

$$
a<\sum_{i=1}^{n}\left\|\mu\left(A_{i}\right)\right\|
$$

Also,

$$
A_{i}=\cup_{j=1}^{\infty} A_{i} \cap E_{j}
$$

and so by the triangle inequality, $\left\|\mu\left(A_{i}\right)\right\| \leq \sum_{j=1}^{\infty}\left\|\mu\left(A_{i} \cap E_{j}\right)\right\|$. Therefore, by the above, and either Fubini's theorem or Lemma 11.3.3 on Page 236

$$
\begin{aligned}
a & <\sum_{i=1}^{n} \overbrace{\sum_{j=1}^{\infty}\left\|\mu\left(A_{i} \cap E_{j}\right)\right\|}^{\geq\left\|\mu\left(A_{i}\right)\right\|} \\
& =\sum_{j=1}^{\infty} \sum_{i=1}^{n}\left\|\mu\left(A_{i} \cap E_{j}\right)\right\| \\
& \leq \sum_{j=1}^{\infty}|\mu|\left(E_{j}\right)
\end{aligned}
$$

because $\left\{A_{i} \cap E_{j}\right\}_{i=1}^{n}$ is a partition of $E_{j}$.
Since $a$ is arbitrary, this shows

$$
|\mu|\left(\cup_{j=1}^{\infty} E_{j}\right) \leq \sum_{j=1}^{\infty}|\mu|\left(E_{j}\right)
$$

If the sets, $E_{j}$ are not disjoint, let $F_{1}=E_{1}$ and if $F_{n}$ has been chosen, let $F_{n+1} \equiv E_{n+1} \backslash$ $\cup_{i=1}^{n} E_{i}$. Thus the sets, $F_{i}$ are disjoint and $\cup_{i=1}^{\infty} F_{i}=\cup_{i=1}^{\infty} E_{i}$. Therefore,

$$
|\mu|\left(\cup_{j=1}^{\infty} E_{j}\right)=|\mu|\left(\cup_{j=1}^{\infty} F_{j}\right) \leq \sum_{j=1}^{\infty}|\mu|\left(F_{j}\right) \leq \sum_{j=1}^{\infty}|\mu|\left(E_{j}\right)
$$

and proves $|\mu|$ is always subadditive as claimed regardless of whether $|\mu|(\Omega)<\infty$.
Now suppose $|\mu|(\Omega)<\infty$ and let $E_{1}$ and $E_{2}$ be sets of $\mathscr{S}$ such that $E_{1} \cap E_{2}=\emptyset$ and let $\left\{A_{1}^{i} \cdots A_{n_{i}}^{i}\right\}=\pi\left(E_{i}\right)$, a partition of $E_{i}$ which is chosen such that

$$
|\mu|\left(E_{i}\right)-\varepsilon<\sum_{j=1}^{n_{i}}\left\|\mu\left(A_{j}^{i}\right)\right\| i=1,2
$$

Such a partition exists because of the definition of the total variation. Consider the sets which are contained in either of $\pi\left(E_{1}\right)$ or $\pi\left(E_{2}\right)$, it follows this collection of sets is a partition of $E_{1} \cup E_{2}$ denoted by $\pi\left(E_{1} \cup E_{2}\right)$. Then by the above inequality and the definition of total variation,

$$
|\mu|\left(E_{1} \cup E_{2}\right) \geq \sum_{F \in \pi\left(E_{1} \cup E_{2}\right)} \| \mu(F)| |>|\mu|\left(E_{1}\right)+|\mu|\left(E_{2}\right)-2 \varepsilon,
$$

which shows that since $\varepsilon>0$ was arbitrary,

$$
\begin{equation*}
|\mu|\left(E_{1} \cup E_{2}\right) \geq|\mu|\left(E_{1}\right)+|\mu|\left(E_{2}\right) \tag{20.2.5}
\end{equation*}
$$

Then 20.2.5 implies that whenever the $E_{i}$ are disjoint, $|\mu|\left(\cup_{j=1}^{n} E_{j}\right) \geq \sum_{j=1}^{n}|\mu|\left(E_{j}\right)$. Therefore,

$$
\sum_{j=1}^{\infty}|\mu|\left(E_{j}\right) \geq|\mu|\left(\cup_{j=1}^{\infty} E_{j}\right) \geq|\mu|\left(\cup_{j=1}^{n} E_{j}\right) \geq \sum_{j=1}^{n}|\mu|\left(E_{j}\right) .
$$

Since $n$ is arbitrary,

$$
|\mu|\left(\cup_{j=1}^{\infty} E_{j}\right)=\sum_{j=1}^{\infty}|\mu|\left(E_{j}\right)
$$

which shows that $|\mu|$ is a measure as claimed.
The following corollary is interesting. It concerns the case that $\mu$ is only finitely additive.

Corollary 20.2.4 Suppose $(\Omega, \mathscr{F})$ is a set with a $\sigma$ algebra of subsets $\mathscr{F}$ and suppose $\mu: \mathscr{F} \rightarrow \mathbb{C}$ is only finitely additive. That is, $\mu\left(\cup_{i=1}^{n} E_{i}\right)=\sum_{i=1}^{n} \mu\left(E_{i}\right)$ whenever the $E_{i}$ are disjoint. Then $|\mu|$, defined in the same way as above, is also finitely additive provided $|\mu|$ is finite.

Proof: Say $E \cap F=\emptyset$ for $E, F \in \mathscr{F}$. Let $\pi(E), \pi(F)$ suitable partitions for which the following holds.

$$
|\mu|(E \cup F) \geq \sum_{A \in \pi(E)}|\mu(A)|+\sum_{B \in \pi(F)}|\mu(B)| \geq|\mu|(E)+|\mu|(F)-2 \varepsilon .
$$

Similar considerations apply to any finite union.
Now let $E=\cup_{i=1}^{n} E_{i}$ where the $E_{i}$ are disjoint. Then letting $\pi(E)$ be a partition of $E$,

$$
|\mu|(E)-\varepsilon \leq \sum_{F \in \pi(E)}|\mu(F)|
$$

it follows that

$$
\begin{aligned}
|\mu|(E) & \leq \varepsilon+\sum_{F \in \pi(E)}|\mu(F)|=\varepsilon+\sum_{F \in \pi(E)}\left|\sum_{i=1}^{n} \mu\left(F \cap E_{i}\right)\right| \\
& \leq \varepsilon+\sum_{i=1}^{n} \sum_{F \in \pi(E)}\left|\mu\left(F \cap E_{i}\right)\right| \leq \varepsilon+\sum_{i=1}^{n}|\mu|\left(E_{i}\right)
\end{aligned}
$$

which shows $|\mu|$ is finitely additive.
In the case that $\mu$ is a complex measure, it is always the case that $|\mu|(\Omega)<\infty$.
Theorem 20.2.5 Suppose $\mu$ is a complex measure on $(\Omega, \mathscr{S})$ where $\mathscr{S}$ is a $\sigma$ algebra of subsets of $\Omega$. That is, whenever, $\left\{E_{i}\right\}$ is a sequence of disjoint sets of $\mathscr{S}$,

$$
\mu\left(\cup_{i=1}^{\infty} E_{i}\right)=\sum_{i=1}^{\infty} \mu\left(E_{i}\right) .
$$

Then $|\mu|(\Omega)<\infty$.

Proof: First here is a claim.
Claim: Suppose $|\mu|(E)=\infty$. Then there are disjoint subsets of $E, A$ and $B$ such that $E=A \cup B,|\mu(A)|,|\mu(B)|>1$ and $|\mu|(B)=\infty$.

Proof of the claim: From the definition of $|\mu|$, there exists a partition of $E, \pi(E)$ such that

$$
\begin{equation*}
\sum_{F \in \pi(E)}|\mu(F)|>20(1+|\mu(E)|) . \tag{20.2.6}
\end{equation*}
$$

Here 20 is just a nice sized number. No effort is made to be delicate in this argument. Also note that $\mu(E) \in \mathbb{C}$ because it is given that $\mu$ is a complex measure. Consider the following picture consisting of two lines in the complex plane having slopes 1 and -1 which intersect at the origin, dividing the complex plane into four closed sets, $R_{1}, R_{2}, R_{3}$, and $R_{4}$ as shown.

Let $\pi_{i}$ consist of those sets, $A$ of $\pi(E)$ for which $\mu(A) \in R_{i}$. Thus, some sets, $A$ of $\pi(E)$ could be in two of the $\pi_{i}$ if $\mu(A)$ is on one of the intersecting lines. This is not important. The thing which is important is that if $\mu(A) \in R_{1}$ or $R_{3}$, then $\frac{\sqrt{2}}{2}|\mu(A)| \leq|\operatorname{Re}(\mu(A))|$ and if $\mu(A) \in R_{2}$ or $R_{4}$ then $\frac{\sqrt{2}}{2}|\mu(A)| \leq|\operatorname{Im}(\mu(A))|$ and $\operatorname{Re}(z)$ has the same sign for $z$ in $R_{1}$ and $R_{3}$ while $\operatorname{Im}(z)$ has the same sign for $z$ in $R_{2}$ or $R_{4}$. Then by 20.2.6, it follows that for some $i$,

$$
\begin{equation*}
\sum_{F \in \pi_{i}}|\mu(F)|>5(1+|\mu(E)|) . \tag{20.2.7}
\end{equation*}
$$

Suppose $i$ equals 1 or 3 . A similar argument using the imaginary part applies if $i$ equals 2 or 4. Then,

$$
\begin{aligned}
\left|\sum_{F \in \pi_{i}} \mu(F)\right| & \geq\left|\sum_{F \in \pi_{i}} \operatorname{Re}(\mu(F))\right|=\sum_{F \in \pi_{i}}|\operatorname{Re}(\mu(F))| \\
& \geq \frac{\sqrt{2}}{2} \sum_{F \in \pi_{i}}|\mu(F)|>5 \frac{\sqrt{2}}{2}(1+|\mu(E)|)
\end{aligned}
$$

Now letting $C$ be the union of the sets in $\pi_{i}$,

$$
\begin{equation*}
|\mu(C)|=\left|\sum_{F \in \pi_{i}} \mu(F)\right|>\frac{5}{2}(1+|\mu(E)|)>1 \tag{20.2.8}
\end{equation*}
$$

Define $D \equiv E \backslash C$.

Then $\mu(C)+\mu(E \backslash C)=\mu(E)$ and so

$$
\begin{aligned}
\frac{5}{2}(1+|\mu(E)|) & <|\mu(C)|=|\mu(E)-\mu(E \backslash C)| \\
& =|\mu(E)-\mu(D)| \leq|\mu(E)|+|\mu(D)|
\end{aligned}
$$

and so

$$
1<\frac{5}{2}+\frac{3}{2}|\mu(E)|<|\mu(D)| .
$$

Now since $|\mu|(E)=\infty$, it follows from Theorem 20.2.5 that $\infty=|\mu|(E) \leq|\mu|(C)+|\mu|(D)$ and so either $|\mu|(C)=\infty$ or $|\mu|(D)=\infty$. If $|\mu|(C)=\infty$, let $B=C$ and $A=D$. Otherwise, let $B=D$ and $A=C$. This proves the claim.

Now suppose $|\mu|(\Omega)=\infty$. Then from the claim, there exist $A_{1}$ and $B_{1}$ such that

$$
|\mu|\left(B_{1}\right)=\infty,\left|\mu\left(B_{1}\right)\right|,\left|\mu\left(A_{1}\right)\right|>1
$$

and $A_{1} \cup B_{1}=\Omega$. Let $B_{1} \equiv \Omega \backslash A$ play the same role as $\Omega$ and obtain $A_{2}, B_{2} \subseteq B_{1}$ such that $|\mu|\left(B_{2}\right)=\infty,\left|\mu\left(B_{2}\right)\right|,\left|\mu\left(A_{2}\right)\right|>1$, and $A_{2} \cup B_{2}=B_{1}$. Continue in this way to obtain a sequence of disjoint sets, $\left\{A_{i}\right\}$ such that $\left|\mu\left(A_{i}\right)\right|>1$. Then since $\mu$ is a measure,

$$
\mu\left(\cup_{i=1}^{\infty} A_{i}\right)=\sum_{i=1}^{\infty} \mu\left(A_{i}\right)
$$

but this is impossible because $\lim _{i \rightarrow \infty} \mu\left(A_{i}\right) \neq 0$. This proves the theorem.
Theorem 20.2.6 Let $(\Omega, \mathscr{S})$ be a measure space and let $\lambda: \mathscr{S} \rightarrow \mathbb{C}$ be a complex vector measure. Thus $|\lambda|(\Omega)<\infty$. Let $\mu: \mathscr{S} \rightarrow[0, \mu(\Omega)]$ be a finite measure such that $\lambda \ll \mu$. Then there exists a unique $f \in L^{1}(\Omega)$ such that for all $E \in \mathscr{S}$,

$$
\int_{E} f d \mu=\lambda(E)
$$

Proof: It is clear that $\operatorname{Re} \lambda$ and $\operatorname{Im} \lambda$ are real-valued vector measures on $\mathscr{S}$. Since $|\lambda|(\Omega)<\infty$, it follows easily that $|\operatorname{Re} \lambda|(\Omega)$ and $|\operatorname{Im} \lambda|(\Omega)<\infty$. This is clear because

$$
|\lambda(E)| \geq|\operatorname{Re} \lambda(E)|,|\operatorname{Im} \lambda(E)|
$$

Therefore, each of

$$
\frac{|\operatorname{Re} \lambda|+\operatorname{Re} \lambda}{2}, \frac{|\operatorname{Re} \lambda|-\operatorname{Re}(\lambda)}{2}, \frac{|\operatorname{Im} \lambda|+\operatorname{Im} \lambda}{2}, \text { and } \frac{|\operatorname{Im} \lambda|-\operatorname{Im}(\lambda)}{2}
$$

are finite measures on $\mathscr{S}$. It is also clear that each of these finite measures are absolutely continuous with respect to $\mu$ and so there exist unique nonnegative functions in $L^{1}(\Omega), f_{1}, f_{2}, g_{1}, g_{2}$ such that for all $E \in \mathscr{S}$,

$$
\begin{aligned}
\frac{1}{2}(|\operatorname{Re} \lambda|+\operatorname{Re} \lambda)(E) & =\int_{E} f_{1} d \mu \\
\frac{1}{2}(|\operatorname{Re} \lambda|-\operatorname{Re} \lambda)(E) & =\int_{E} f_{2} d \mu \\
\frac{1}{2}(|\operatorname{Im} \lambda|+\operatorname{Im} \lambda)(E) & =\int_{E} g_{1} d \mu \\
\frac{1}{2}(|\operatorname{Im} \lambda|-\operatorname{Im} \lambda)(E) & =\int_{E} g_{2} d \mu
\end{aligned}
$$

Now let $f=f_{1}-f_{2}+i\left(g_{1}-g_{2}\right)$.
The following corollary is about representing a vector measure in terms of its total variation. It is like representing a complex number in the form $r e^{i \theta}$. The proof requires the following lemma.

Lemma 20.2.7 Suppose $(\Omega, \mathscr{S}, \mu)$ is a measure space and $f$ is a function in $L^{1}(\Omega, \mu)$ with the property that

$$
\left|\int_{E} f d \mu\right| \leq \mu(E)
$$

for all $E \in \mathscr{S}$. Then $|f| \leq 1$ a.e.
Proof of the lemma: Consider the following picture.

where $B(p, r) \cap B(0,1)=\emptyset$. Let $E=f^{-1}(B(p, r))$. In fact $\mu(E)=0$. If $\mu(E) \neq 0$ then

$$
\begin{aligned}
\left|\frac{1}{\mu(E)} \int_{E} f d \mu-p\right| & =\left|\frac{1}{\mu(E)} \int_{E}(f-p) d \mu\right| \\
& \leq \frac{1}{\mu(E)} \int_{E}|f-p| d \mu<r
\end{aligned}
$$

because on $E,|f(x)-p|<r$. Hence

$$
\left|\frac{1}{\mu(E)} \int_{E} f d \mu\right|>1
$$

because it is closer to $p$ than $r$. (Refer to the picture.) However, this contradicts the assumption of the lemma. It follows $\mu(E)=0$. Since the set of complex numbers, $z$ such that $|z|>1$ is an open set, it equals the union of countably many balls, $\left\{B_{i}\right\}_{i=1}^{\infty}$. Therefore,

$$
\begin{aligned}
\mu\left(f^{-1}(\{z \in \mathbb{C}:|z|>1\})\right. & =\mu\left(\cup_{k=1}^{\infty} f^{-1}\left(B_{k}\right)\right) \\
& \leq \sum_{k=1}^{\infty} \mu\left(f^{-1}\left(B_{k}\right)\right)=0
\end{aligned}
$$

Thus $|f(x)| \leq 1$ a.e. as claimed. This proves the lemma.
Corollary 20.2.8 Let $\lambda$ be a complex vector measure with $|\lambda|(\Omega)<\infty^{1}$ Then there exists a unique $f \in L^{1}(\Omega)$ such that $\lambda(E)=\int_{E} f d|\lambda|$. Furthermore, $|f|=1$ for $|\lambda|$ a.e. This is called the polar decomposition of $\lambda$.

Proof: First note that $\lambda \ll|\lambda|$ and so such an $L^{1}$ function exists and is unique. It is required to show $|f|=1$ a.e. If $|\lambda|(E) \neq 0$,

$$
\left|\frac{\lambda(E)}{|\lambda|(E)}\right|=\left|\frac{1}{|\lambda|(E)} \int_{E} f d\right| \lambda| | \leq 1
$$

Therefore by Lemma 20.2.7, $|f| \leq 1,|\lambda|$ a.e. Now let

$$
E_{n}=\left[|f| \leq 1-\frac{1}{n}\right]
$$

Let $\left\{F_{1}, \cdots, F_{m}\right\}$ be a partition of $E_{n}$. Then

$$
\begin{aligned}
\sum_{i=1}^{m}\left|\lambda\left(F_{i}\right)\right| & =\sum_{i=1}^{m}\left|\int_{F_{i}} f d\right| \lambda| | \leq \sum_{i=1}^{m} \int_{F_{i}}|f| d|\lambda| \\
& \leq \sum_{i=1}^{m} \int_{F_{i}}\left(1-\frac{1}{n}\right) d|\lambda|=\sum_{i=1}^{m}\left(1-\frac{1}{n}\right)|\lambda|\left(F_{i}\right) \\
& =|\lambda|\left(E_{n}\right)\left(1-\frac{1}{n}\right)
\end{aligned}
$$

Then taking the supremum over all partitions,

$$
|\lambda|\left(E_{n}\right) \leq\left(1-\frac{1}{n}\right)|\lambda|\left(E_{n}\right)
$$

which shows $|\lambda|\left(E_{n}\right)=0$. Hence $|\lambda|([|f|<1])=0$ because $[|f|<1]=\cup_{n=1}^{\infty} E_{n}$. This proves Corollary 20.2.8.

Corollary 20.2.9 Let $\lambda$ be a complex vector measure such that $\lambda \ll \mu$ where $\mu$ is $\sigma$ finite. Then there exists a unique $g \in L^{1}(\Omega, \mu)$ such that $\lambda(E)=\int_{E} g d \mu$.

[^17]Proof: By Corollary 20.2.8 and Theorem 20.2.5 which says that $|\lambda|$ is finite, there exists a unique $f$ such that $|f|=1|\lambda|$ a.e. and

$$
\lambda(E)=\int_{E} f d|\lambda|
$$

Now $|\lambda| \ll \mu$ and so it follows from Corollary 20.1.3 there exists a unique nonnegative measurable function $h$ such that for all $E$ measurable,

$$
|\lambda|(E)=\int_{E} h d \mu
$$

where since $|\lambda|$ is finite, $h \in L^{1}(\Omega, \mu)$. It follows from approximating $f$ with simple functions and using the above formula that

$$
\lambda(E)=\int_{E} f h d \mu
$$

Then let $g=L^{1}(\Omega, \mu)$. This proves the corollary.
Corollary 20.2.10 Suppose $(\Omega, \mathscr{S})$ is a measure space and $\mu$ is a finite nonnegative measure on $\mathscr{S}$. Then for $h \in L^{1}(\mu)$, define a complex measure, $\lambda$ by

$$
\lambda(E) \equiv \int_{E} h d \mu
$$

Then

$$
|\lambda|(E)=\int_{E}|h| d \mu
$$

Furthermore, $|h|=\bar{g} h$ where $g d|\lambda|$ is the polar decomposition of $\lambda$,

$$
\lambda(E)=\int_{E} g d|\lambda|
$$

Proof: From Corollary 20.2.8 there exists $g$ such that $|g|=1,|\lambda|$ a.e. and for all $E \in \mathscr{S}$

$$
\lambda(E)=\int_{E} g d|\lambda|=\int_{E} h d \mu
$$

Let $s_{n}$ be a sequence of simple functions converging pointwise to $\bar{g}$. Then from the above,

$$
\int_{E} g s_{n} d|\lambda|=\int_{E} s_{n} h d \mu
$$

Passing to the limit using the dominated convergence theorem,

$$
\int_{E} d|\lambda|=\int_{E} \bar{g} h d \mu
$$

It follows $\bar{g} h \geq 0$ a.e. and $|\bar{g}|=1$. Therefore, $|h|=|\bar{g} h|=\bar{g} h$. It follows from the above, that

$$
|\lambda|(E)=\int_{E} d|\lambda|=\int_{E} \bar{g} h d \mu=\int_{E} d|\lambda|=\int_{E}|h| d \mu
$$

and this proves the corollary.

### 20.3 Representation Theorems For The Dual Space Of $L^{p}$

Recall the concept of the dual space of a Banach space in the Chapter on Banach space starting on Page 435. The next topic deals with the dual space of $L^{p}$ for $p \geq 1$ in the case where the measure space is $\sigma$ finite or finite. In what follows $q=\infty$ if $p=1$ and otherwise, $\frac{1}{p}+\frac{1}{q}=1$.

Theorem 20.3.1 (Riesz representation theorem) Let $p>1$ and let $(\Omega, \mathscr{S}, \mu)$ be a finite measure space. If $\Lambda \in\left(L^{p}(\Omega)\right)^{\prime}$, then there exists a unique $h \in L^{q}(\Omega)\left(\frac{1}{p}+\frac{1}{q}=1\right)$ such that

$$
\Lambda f=\int_{\Omega} h f d \mu
$$

This function satisfies $\|h\|_{q}=\|\Lambda\|$ where $\|\Lambda\|$ is the operator norm of $\Lambda$.
Proof: (Uniqueness) If $h_{1}$ and $h_{2}$ both represent $\Lambda$, consider

$$
f=\left|h_{1}-h_{2}\right|^{q-2}\left(\overline{h_{1}}-\overline{h_{2}}\right),
$$

where $\bar{h}$ denotes complex conjugation. By Holder's inequality, it is easy to see that $f \in$ $L^{p}(\Omega)$. Thus

$$
\begin{gathered}
0=\Lambda f-\Lambda f= \\
\int h_{1}\left|h_{1}-h_{2}\right|^{q-2}\left(\overline{h_{1}}-\overline{h_{2}}\right)-h_{2}\left|h_{1}-h_{2}\right|^{q-2}\left(\overline{h_{1}}-\overline{h_{2}}\right) d \mu \\
=\int\left|h_{1}-h_{2}\right|^{q} d \mu
\end{gathered}
$$

Therefore $h_{1}=h_{2}$ and this proves uniqueness.
Now let $\lambda(E)=\Lambda\left(\mathscr{X}_{E}\right)$. Since this is a finite measure space $\mathscr{X}_{E}$ is an element of $L^{p}(\Omega)$ and so it makes sense to write $\Lambda\left(\mathscr{X}_{E}\right)$. In fact $\lambda$ is a complex measure having finite total variation. Let $A_{1}, \cdots, A_{n}$ be a partition of $\Omega$.

$$
\left|\Lambda \mathscr{X}_{A_{i}}\right|=w_{i}\left(\Lambda \mathscr{X}_{A_{i}}\right)=\Lambda\left(w_{i} \mathscr{X}_{A_{i}}\right)
$$

for some $w_{i} \in \mathbb{C},\left|w_{i}\right|=1$. Thus

$$
\begin{gathered}
\sum_{i=1}^{n}\left|\lambda\left(A_{i}\right)\right|=\sum_{i=1}^{n}\left|\Lambda\left(\mathscr{X}_{A_{i}}\right)\right|=\Lambda\left(\sum_{i=1}^{n} w_{i} \mathscr{X}_{A_{i}}\right) \\
\leq\|\Lambda\| \left\lvert\,\left(\int\left|\sum_{i=1}^{n} w_{i} \mathscr{X}_{A_{i}}\right|^{p} d \mu\right)^{\frac{1}{p}}=\|\Lambda\|\left(\int_{\Omega} d \mu\right)^{\frac{1}{p}}=\|\Lambda\| \mu(\Omega)^{\frac{1}{p}} .\right.
\end{gathered}
$$

This is because if $x \in \Omega, x$ is contained in exactly one of the $A_{i}$ and so the absolute value of the sum in the first integral above is equal to 1 . Therefore $|\lambda|(\Omega)<\infty$ because this was an arbitrary partition. Also, if $\left\{E_{i}\right\}_{i=1}^{\infty}$ is a sequence of disjoint sets of $\mathscr{S}$, let

$$
F_{n}=\cup_{i=1}^{n} E_{i}, F=\cup_{i=1}^{\infty} E_{i}
$$

Then by the Dominated Convergence theorem,

$$
\left\|\mathscr{X}_{F_{n}}-\mathscr{X}_{F}\right\|_{p} \rightarrow 0 .
$$

Therefore, by continuity of $\Lambda$,

$$
\lambda(F)=\Lambda\left(\mathscr{X}_{F}\right)=\lim _{n \rightarrow \infty} \Lambda\left(\mathscr{X}_{F_{n}}\right)=\lim _{n \rightarrow \infty} \sum_{k=1}^{n} \Lambda\left(\mathscr{X}_{E_{k}}\right)=\sum_{k=1}^{\infty} \lambda\left(E_{k}\right) .
$$

This shows $\lambda$ is a complex measure with $|\lambda|$ finite.
It is also clear from the definition of $\lambda$ that $\lambda \ll \mu$. Therefore, by the Radon Nikodym theorem, there exists $h \in L^{1}(\Omega)$ with

$$
\lambda(E)=\int_{E} h d \mu=\Lambda\left(\mathscr{X}_{E}\right)
$$

Actually $h \in L^{q}$ and satisfies the other conditions above. Let $s=\sum_{i=1}^{m} c_{i} \mathscr{X}_{E_{i}}$ be a simple function. Then since $\Lambda$ is linear,

$$
\begin{equation*}
\Lambda(s)=\sum_{i=1}^{m} c_{i} \Lambda\left(\mathscr{X}_{E_{i}}\right)=\sum_{i=1}^{m} c_{i} \int_{E_{i}} h d \mu=\int h s d \mu . \tag{20.3.9}
\end{equation*}
$$

Claim: If $f$ is uniformly bounded and measurable, then

$$
\Lambda(f)=\int h f d \mu
$$

Proof of claim: Since $f$ is bounded and measurable, there exists a sequence of simple functions, $\left\{s_{n}\right\}$ which converges to $f$ pointwise and in $L^{p}(\Omega)$. This follows from Theorem 11.3.9 on Page 241 upon breaking $f$ up into positive and negative parts of real and complex parts. In fact this theorem gives uniform convergence. Then

$$
\Lambda(f)=\lim _{n \rightarrow \infty} \Lambda\left(s_{n}\right)=\lim _{n \rightarrow \infty} \int h s_{n} d \mu=\int h f d \mu
$$

the first equality holding because of continuity of $\Lambda$, the second following from 20.3.9 and the third holding by the dominated convergence theorem.

This is a very nice formula but it still has not been shown that $h \in L^{q}(\Omega)$.
Let $E_{n}=\{x:|h(x)| \leq n\}$. Thus $\left|h \mathscr{X}_{E_{n}}\right| \leq n$. Then

$$
\left|h \mathscr{X}_{E_{n}}\right|^{q-2}\left(\bar{h} \mathscr{X}_{E_{n}}\right) \in L^{p}(\Omega) .
$$

By the claim, it follows that

$$
\begin{gathered}
\left\|h \mathscr{X}_{E_{n}}\right\|_{q}^{q}=\int h\left|h \mathscr{X}_{E_{n}}\right|^{q-2}\left(\bar{h} \mathscr{X}_{E_{n}}\right) d \mu=\Lambda\left(\left|h \mathscr{X}_{E_{n}}\right|^{q-2}\left(\bar{h} \mathscr{X}_{E_{n}}\right)\right) \\
\leq\|\Lambda\|\left\|\left|h \mathscr{X}_{E_{n}}\right|^{q-2}\left(\bar{h} \mathscr{X}_{E_{n}}\right)\right\|_{p}=\|\Lambda\|\left\|h \mathscr{X}_{E_{n}}\right\|_{q}^{\frac{q}{p}}
\end{gathered}
$$

the last equality holding because $q-1=q / p$ and so

$$
\begin{aligned}
\left(\int\left|\left|h \mathscr{X}_{E_{n}}\right|^{q-2}\left(\bar{h} \mathscr{X}_{E_{n}}\right)\right|^{p} d \mu\right)^{1 / p} & =\left(\int\left(\left|h \mathscr{X}_{E_{n}}\right|^{q / p}\right)^{p} d \mu\right)^{1 / p} \\
& =\|\left. h \mathscr{X}_{E_{n}}\right|_{q} ^{q}
\end{aligned}
$$

Therefore, since $q-\frac{q}{p}=1$, it follows that

$$
\left\|h \mathscr{X}_{E_{n}}\right\|_{q} \leq\|\Lambda\| .
$$

Letting $n \rightarrow \infty$, the Monotone Convergence theorem implies

$$
\begin{equation*}
\|h\|_{q} \leq\|\Lambda\| \tag{20.3.10}
\end{equation*}
$$

Now that $h$ has been shown to be in $L^{q}(\Omega)$, it follows from 20.3.9 and the density of the simple functions, Theorem 15.2.1 on Page 406, that

$$
\Lambda f=\int h f d \mu
$$

for all $f \in L^{p}(\Omega)$.
It only remains to verify the last claim.

$$
\|\Lambda\|=\sup \left\{\int h f:\|f\|_{p} \leq 1\right\} \leq\|h\|_{q} \leq\|\Lambda\|
$$

by 20.3.10, and Holder's inequality. This proves the theorem.
To represent elements of the dual space of $L^{1}(\Omega)$, another Banach space is needed.
Definition 20.3.2 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space. $L^{\infty}(\Omega)$ is the vector space of measurable functions such that for some $M>0,|f(x)| \leq M$ for all $x$ outside of some set of measure zero $\left(|f(x)| \leq M\right.$ a.e.). Define $f=g$ when $f(x)=g(x)$ a.e. and $\|f\|_{\infty} \equiv \inf \{M$ : $|f(x)| \leq M$ a.e. $\}.$

Theorem 20.3.3 $L^{\infty}(\Omega)$ is a Banach space.
Proof: It is clear that $L^{\infty}(\Omega)$ is a vector space. Is $\left\|\|_{\infty}\right.$ a norm?
Claim: If $f \in L^{\infty}(\Omega)$, then $|f(x)| \leq\|f\|_{\infty}$ a.e.
Proof of the claim: $\left\{x:|f(x)| \geq\|f\|_{\infty}+n^{-1}\right\} \equiv E_{n}$ is a set of measure zero according to the definition of $\|f\|_{\infty}$. Furthermore, $\left\{x:|f(x)|>| | f \|_{\infty}\right\}=\cup_{n} E_{n}$ and so it is also a set of measure zero. This verifies the claim.

Now if $\|f\|_{\infty}=0$ it follows that $f(x)=0$ a.e. Also if $f, g \in L^{\infty}(\Omega)$,

$$
|f(x)+g(x)| \leq|f(x)|+|g(x)| \leq\|f\|_{\infty}+\|g\|_{\infty}
$$

a.e. and so $\|f\|_{\infty}+\|g\|_{\infty}$ serves as one of the constants, $M$ in the definition of $\|f+g\|_{\infty}$. Therefore,

$$
\|f+g\|_{\infty} \leq\|f\|_{\infty}+\|g\|_{\infty}
$$

Next let $c$ be a number. Then $|c f(x)|=|c||f(x)| \leq|c|\|f\|_{\infty}$ and so $\|c f\|_{\infty} \leq|c|\|f\|_{\infty}$. Therefore since $c$ is arbitrary, $\|f\|_{\infty}=\|c(1 / c) f\|_{\infty} \leq\left|\frac{1}{c}\right|\|c f\|_{\infty}$ which implies $|c|\|f\|_{\infty} \leq$ $\|c f\|_{\infty}$. Thus $\left\|\|_{\infty}\right.$ is a norm as claimed.

To verify completeness, let $\left\{f_{n}\right\}$ be a Cauchy sequence in $L^{\infty}(\Omega)$ and use the above claim to get the existence of a set of measure zero, $E_{n m}$ such that for all $x \notin E_{n m}$,

$$
\left|f_{n}(x)-f_{m}(x)\right| \leq\left\|f_{n}-f_{m}\right\|_{\infty}
$$

Let $E=\cup_{n, m} E_{n m}$. Thus $\mu(E)=0$ and for each $x \notin E,\left\{f_{n}(x)\right\}_{n=1}^{\infty}$ is a Cauchy sequence in $\mathbb{C}$. Let

$$
f(x)=\left\{\begin{array}{c}
0 \text { if } x \in E \\
\lim _{n \rightarrow \infty} f_{n}(x) \text { if } x \notin E
\end{array}=\lim _{n \rightarrow \infty} \mathscr{X}_{E^{C}}(x) f_{n}(x) .\right.
$$

Then $f$ is clearly measurable because it is the limit of measurable functions. If

$$
F_{n}=\left\{x:\left|f_{n}(x)\right|>\left\|f_{n}\right\|_{\infty}\right\}
$$

and $F=\cup_{n=1}^{\infty} F_{n}$, it follows $\mu(F)=0$ and that for $x \notin F \cup E$,

$$
|f(x)| \leq \lim \inf _{n \rightarrow \infty}\left|f_{n}(x)\right| \leq \lim \inf _{n \rightarrow \infty}\left\|f_{n}\right\|_{\infty}<\infty
$$

because $\left\{\left|\mid f_{n} \|_{\infty}\right\}\right.$ is a Cauchy sequence. $\left(\left\|\left\|f_{n}\right\|_{\infty}-\right\| f_{m}\left\|_{\infty} \mid \leq\right\| f_{n}-f_{m} \|_{\infty}\right.$ by the triangle inequality.) Thus $f \in L^{\infty}(\Omega)$. Let $n$ be large enough that whenever $m>n$,

$$
\left\|f_{m}-f_{n}\right\|_{\infty}<\varepsilon
$$

Then, if $x \notin E$,

$$
\begin{aligned}
\left|f(x)-f_{n}(x)\right| & =\lim _{m \rightarrow \infty}\left|f_{m}(x)-f_{n}(x)\right| \\
& \leq \lim _{m \rightarrow \infty} \inf \left\|f_{m}-f_{n}\right\|_{\infty}<\varepsilon
\end{aligned}
$$

Hence $\left\|f-f_{n}\right\|_{\infty}<\varepsilon$ for all $n$ large enough. This proves the theorem.
The next theorem is the Riesz representation theorem for $\left(L^{1}(\Omega)\right)^{\prime}$.
Theorem 20.3.4 (Riesz representation theorem) Let $(\Omega, \mathscr{S}, \mu)$ be a finite measure space. If $\Lambda \in\left(L^{1}(\Omega)\right)^{\prime}$, then there exists a unique $h \in L^{\infty}(\Omega)$ such that

$$
\Lambda(f)=\int_{\Omega} h f d \mu
$$

for all $f \in L^{1}(\Omega)$. If $h$ is the function in $L^{\infty}(\Omega)$ representing $\Lambda \in\left(L^{1}(\Omega)\right)^{\prime}$, then $\|h\|_{\infty}=$ $|\mid \Lambda \|$.

Proof: Just as in the proof of Theorem 20.3.1, there exists a unique $h \in L^{1}(\Omega)$ such that for all simple functions, $s$,

$$
\begin{equation*}
\Lambda(s)=\int h s d \mu \tag{20.3.11}
\end{equation*}
$$

To show $h \in L^{\infty}(\Omega)$, let $\varepsilon>0$ be given and let

$$
E=\{x:|h(x)| \geq\|\Lambda\|+\varepsilon\} .
$$

Let $|k|=1$ and $h k=|h|$. Since the measure space is finite, $k \in L^{1}(\Omega)$. As in Theorem 20.3.1 let $\left\{s_{n}\right\}$ be a sequence of simple functions converging to $k$ in $L^{1}(\Omega)$, and pointwise. It follows from the construction in Theorem 11.3.9 on Page 241 that it can be assumed $\left|s_{n}\right| \leq 1$. Therefore

$$
\Lambda\left(k \mathscr{X}_{E}\right)=\lim _{n \rightarrow \infty} \Lambda\left(s_{n} \mathscr{X}_{E}\right)=\lim _{n \rightarrow \infty} \int_{E} h s_{n} d \mu=\int_{E} h k d \mu
$$

where the last equality holds by the Dominated Convergence theorem. Therefore,

$$
\begin{aligned}
\|\Lambda\| \mu(E) & \geq\left|\Lambda\left(k \mathscr{X}_{E}\right)\right|=\left|\int_{\Omega} h k \mathscr{X}_{E} d \mu\right|=\int_{E}|h| d \mu \\
& \geq(\|\Lambda\|+\varepsilon) \mu(E)
\end{aligned}
$$

It follows that $\mu(E)=0$. Since $\varepsilon>0$ was arbitrary, $\|\Lambda\| \geq\|h\|_{\infty}$. It was shown that $h \in L^{\infty}(\Omega)$, the density of the simple functions in $L^{1}(\Omega)$ and 20.3 .11 imply

$$
\begin{equation*}
\Lambda f=\int_{\Omega} h f d \mu,\|\Lambda\| \geq\|h\|_{\infty} \tag{20.3.12}
\end{equation*}
$$

This proves the existence part of the theorem. To verify uniqueness, suppose $h_{1}$ and $h_{2}$ both represent $\Lambda$ and let $f \in L^{1}(\Omega)$ be such that $|f| \leq 1$ and $f\left(h_{1}-h_{2}\right)=\left|h_{1}-h_{2}\right|$. Then

$$
0=\Lambda f-\Lambda f=\int\left(h_{1}-h_{2}\right) f d \mu=\int\left|h_{1}-h_{2}\right| d \mu
$$

Thus $h_{1}=h_{2}$. Finally,

$$
\|\Lambda\|=\sup \left\{\left|\int h f d \mu\right|:\|f\|_{1} \leq 1\right\} \leq\|h\|_{\infty} \leq\|\Lambda\|
$$

by 20.3.12.
Next these results are extended to the $\sigma$ finite case.
Lemma 20.3.5 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space and suppose there exists a measurable function, $r$ such that $r(x)>0$ for all $x$, there exists $M$ such that $|r(x)|<M$ for all $x$, and $\int r d \mu<\infty$. Then for

$$
\Lambda \in\left(L^{p}(\Omega, \mu)\right)^{\prime}, p \geq 1
$$

there exists a unique $h \in L^{p^{\prime}}(\Omega, \mu), L^{\infty}(\Omega, \mu)$ if $p=1$ such that

$$
\Lambda f=\int h f d \mu
$$

Also $\|h\|=\|\Lambda\| .\left(\|h\|=\|h\|_{p^{\prime}}\right.$ if $p>1,\|h\|_{\infty}$ if $\left.p=1\right)$. Here

$$
\frac{1}{p}+\frac{1}{p^{\prime}}=1
$$

Proof: Define a new measure $\tilde{\mu}$, according to the rule

$$
\begin{equation*}
\widetilde{\mu}(E) \equiv \int_{E} r d \mu \tag{20.3.13}
\end{equation*}
$$

Thus $\widetilde{\mu}$ is a finite measure on $\mathscr{S}$. Now define a mapping, $\eta: L^{p}(\Omega, \mu) \rightarrow L^{p}(\Omega, \widetilde{\mu})$ by

$$
\eta f=r^{-\frac{1}{p}} f
$$

Then

$$
\|\eta f\|_{L^{p}(\widetilde{\mu})}^{p}=\int\left|r^{-\frac{1}{p}} f\right|^{p} r d \mu=\|f\|_{L^{p}(\mu)}^{p}
$$

and so $\eta$ is one to one and in fact preserves norms. I claim that also $\eta$ is onto. To see this, let $g \in L^{p}(\Omega, \widetilde{\mu})$ and consider the function, $r^{\frac{1}{p}} g$. Then

$$
\int\left|r^{\frac{1}{p}} g\right|^{p} d \mu=\int|g|^{p} r d \mu=\int|g|^{p} d \widetilde{\mu}<\infty
$$

Thus $r^{\frac{1}{p}} g \in L^{p}(\Omega, \mu)$ and $\eta\left(r^{\frac{1}{p}} g\right)=g$ showing that $\eta$ is onto as claimed. Thus $\eta$ is one to one, onto, and preserves norms. Consider the diagram below which is descriptive of the situation in which $\eta^{*}$ must be one to one and onto.

| $h, L^{p^{\prime}}(\widetilde{\mu})$ | $L^{p}(\widetilde{\mu})^{\prime}, \widetilde{\Lambda}$ | $\eta^{*}$ <br>  <br> $L^{p}(\widetilde{\mu})$ | $L^{p}(\mu)^{\prime}, \Lambda$ |
| :---: | :---: | :---: | :---: |
|  | $\leftarrow$ | $L^{p}(\mu)$ |  |

Then for $\Lambda \in L^{p}(\mu)^{\prime}$, there exists a unique $\tilde{\Lambda} \in L^{p}(\widetilde{\mu})^{\prime}$ such that $\eta^{*} \widetilde{\Lambda}=\Lambda,\|\widetilde{\Lambda}\|=\|\Lambda\|$. By the Riesz representation theorem for finite measure spaces, there exists a unique $h \in L^{p^{\prime}}(\widetilde{\mu})$ which represents $\widetilde{\Lambda}$ in the manner described in the Riesz representation theorem. Thus $\|h\|_{L^{p^{\prime}}(\widetilde{\mu})}=\|\widetilde{\Lambda}\|=\|\Lambda\|$ and for all $f \in L^{p}(\mu)$,

$$
\begin{aligned}
\Lambda(f) & =\eta^{*} \widetilde{\Lambda}(f) \equiv \widetilde{\Lambda}(\eta f)=\int h(\eta f) d \widetilde{\mu}=\int r h\left(f^{-\frac{1}{p}} f\right) d \mu \\
& =\int r^{\frac{1}{p^{\prime}}} h f d \mu
\end{aligned}
$$

Now

$$
\int\left|r^{\frac{1}{p^{\prime}}} h\right|^{p^{\prime}} d \mu=\int|h|^{p^{\prime}} r d \mu=\|\left. h\right|_{L^{p^{\prime}}(\widetilde{\mu})} ^{p^{\prime}}<\infty .
$$

Thus $\left\|r^{\frac{1}{p^{\prime}}} h\right\|_{L^{p^{\prime}}(\mu)}=\|h\|_{L^{p^{\prime}}(\widetilde{\mu})}=\|\widetilde{\Lambda}\|=\|\Lambda\|$ and represents $\Lambda$ in the appropriate way. If $p=1$, then $1 / p^{\prime} \equiv 0$. This proves the Lemma.

A situation in which the conditions of the lemma are satisfied is the case where the measure space is $\sigma$ finite. In fact, you should show this is the only case in which the conditions of the above lemma hold.

Theorem 20.3.6 (Riesz representation theorem) Let $(\Omega, \mathscr{S}, \mu)$ be $\sigma$ finite and let

$$
\Lambda \in\left(L^{p}(\Omega, \mu)\right)^{\prime}, p \geq 1
$$

Then there exists a unique $h \in L^{q}(\Omega, \mu), L^{\infty}(\Omega, \mu)$ if $p=1$ such that

$$
\Lambda f=\int h f d \mu
$$

Also $\|h\|=\|\Lambda\| .\left(\|h\|=\|h\|_{q}\right.$ if $p>1,\|h\|_{\infty}$ if $\left.p=1\right)$. Here

$$
\frac{1}{p}+\frac{1}{q}=1
$$

Proof: Let $\left\{\Omega_{n}\right\}$ be a sequence of disjoint elements of $\mathscr{S}$ having the property that

$$
0<\mu\left(\Omega_{n}\right)<\infty, \cup_{n=1}^{\infty} \Omega_{n}=\Omega
$$

Define

$$
r(x)=\sum_{n=1}^{\infty} \frac{1}{n^{2}} \mathscr{X}_{\Omega_{n}}(x) \mu\left(\Omega_{n}\right)^{-1}, \widetilde{\mu}(E)=\int_{E} r d \mu
$$

Thus

$$
\int_{\Omega} r d \mu=\widetilde{\mu}(\Omega)=\sum_{n=1}^{\infty} \frac{1}{n^{2}}<\infty
$$

so $\widetilde{\mu}$ is a finite measure. The above lemma gives the existence part of the conclusion of the theorem. Uniqueness is done as before.

With the Riesz representation theorem, it is easy to show that

$$
L^{p}(\Omega), p>1
$$

is a reflexive Banach space. Recall Definition 17.2.14 on Page 451 for the definition.
Theorem 20.3.7 For $(\Omega, \mathscr{S}, \mu)$ a $\sigma$ finite measure space and $p>1, L^{p}(\Omega)$ is reflexive.
Proof: Let $\delta_{r}:\left(L^{r}(\Omega)\right)^{\prime} \rightarrow L^{r^{\prime}}(\Omega)$ be defined for $\frac{1}{r}+\frac{1}{r^{\prime}}=1$ by

$$
\int\left(\delta_{r} \Lambda\right) g d \mu=\Lambda g
$$

for all $g \in L^{r}(\Omega)$. From Theorem 20.3.6 $\delta_{r}$ is one to one, onto, continuous and linear. By the open map theorem, $\delta_{r}^{-1}$ is also one to one, onto, and continuous ( $\delta_{r} \Lambda$ equals the representor of $\Lambda$ ). Thus $\delta_{r}^{*}$ is also one to one, onto, and continuous by Corollary 17.2.11. Now observe that $J=\delta_{p}^{*} \circ \delta_{q}^{-1}$. To see this, let $z^{*} \in\left(L^{q}\right)^{\prime}, y^{*} \in\left(L^{p}\right)^{\prime}$,

$$
\begin{aligned}
\delta_{p}^{*} \circ \delta_{q}^{-1}\left(\boldsymbol{\delta}_{q} z^{*}\right)\left(y^{*}\right) & =\left(\delta_{p}^{*} z^{*}\right)\left(y^{*}\right) \\
& =z^{*}\left(\boldsymbol{\delta}_{p} y^{*}\right) \\
& =\int\left(\boldsymbol{\delta}_{q} z^{*}\right)\left(\boldsymbol{\delta}_{p} y^{*}\right) d \mu
\end{aligned}
$$

$$
\begin{aligned}
J\left(\boldsymbol{\delta}_{q} z^{*}\right)\left(y^{*}\right) & =y^{*}\left(\boldsymbol{\delta}_{q} z^{*}\right) \\
& =\int\left(\boldsymbol{\delta}_{p} y^{*}\right)\left(\boldsymbol{\delta}_{q} z^{*}\right) d \mu
\end{aligned}
$$

Therefore $\delta_{p}^{*} \circ \delta_{q}^{-1}=J$ on $\delta_{q}\left(L^{q}\right)^{\prime}=L^{p}$. But the two $\delta$ maps are onto and so $J$ is also onto.

### 20.4 The Dual Space Of $L^{\infty}(\Omega)$

What about the dual space of $L^{\infty}(\Omega)$ ? This will involve the following Lemma. Also recall the notion of total variation defined in Definition 20.2.2.

Lemma 20.4.1 Let $(\Omega, \mathscr{F})$ be a measure space. Denote by $B V(\Omega)$ the space of finitely additive complex measures $v$ such that $|v|(\Omega)<\infty$. Then defining $\|v\| \equiv|v|(\Omega)$, it follows that $B V(\Omega)$ is a Banach space.

Proof: It is obvious that $B V(\Omega)$ is a vector space with the obvious conventions involving scalar multiplication. Why is $\|\cdot\|$ a norm? All the axioms are obvious except for the triangle inequality. However, this is not too hard either.

$$
\begin{aligned}
\|\mu+v\| & \equiv|\mu+v|(\Omega)=\sup _{\pi(\Omega)}\left\{\sum_{A \in \pi(\Omega)}|\mu(A)+v(A)|\right\} \\
& \leq \sup _{\pi(\Omega)}\left\{\sum_{A \in \pi(\Omega)}|\mu(A)|\right\}+\sup _{\pi(\Omega)}\left\{\sum_{A \in \pi(\Omega)}|v(A)|\right\} \\
& \equiv|\mu|(\Omega)+|v|(\Omega)=\|v\|+\|\mu\| .
\end{aligned}
$$

Suppose now that $\left\{v_{n}\right\}$ is a Cauchy sequence. For each $E \in \mathscr{F}$,

$$
\left|v_{n}(E)-v_{m}(E)\right| \leq\left\|v_{n}-v_{m}\right\|
$$

and so the sequence of complex numbers $v_{n}(E)$ converges. That to which it converges is called $v(E)$. Then it is obvious that $v(E)$ is finitely additive. Why is $|v|$ finite? Since $\|\cdot\|$ is a norm, it follows that there exists a constant $C$ such that for all $n$,

$$
\left|v_{n}\right|(\Omega)<C
$$

Let $\pi(\Omega)$ be any partition. Then

$$
\sum_{A \in \pi(\Omega)}|v(A)|=\lim _{n \rightarrow \infty} \sum_{A \in \pi(\Omega)}\left|v_{n}(A)\right| \leq C .
$$

Hence $v \in B V(\Omega)$. Let $\varepsilon>0$ be given and let $N$ be such that if $n, m>N$, then

$$
\left\|v_{n}-v_{m}\right\|<\varepsilon / 2
$$

Pick any such $n$. Then choose $\pi(\Omega)$ such that

$$
\begin{gathered}
\left|v-v_{n}\right|(\Omega)-\varepsilon / 2<\sum_{A \in \pi(\Omega)}\left|v(A)-v_{n}(A)\right| \\
=\lim _{m \rightarrow \infty} \sum_{A \in \pi(\Omega)}\left|v_{m}(A)-v_{n}(A)\right|<\lim _{m \rightarrow \infty} \inf _{m}\left|v_{n}-v_{m}\right|(\Omega) \leq \varepsilon / 2
\end{gathered}
$$

It follows that

$$
\lim _{n \rightarrow \infty}\left\|v-v_{n}\right\|=0
$$

Corollary 20.4.2 Suppose $(\Omega, \mathscr{F})$ is a measure space as above and suppose $\mu$ is a measure defined on $\mathscr{F}$. Denote by $B V(\Omega ; \mu)$ those finitely additive measures of $B V(\Omega) v$ such that $v \ll \mu$ in the usual sense that if $\mu(E)=0$, then $v(E)=0$. Then $B V(\Omega ; \mu)$ is a closed subspace of $B V(\Omega)$.

Proof: It is clear that it is a subspace. Is it closed? Suppose $v_{n} \rightarrow v$ and each $v_{n}$ is in $B V(\Omega ; \mu)$. Then if $\mu(E)=0$, it follows that $v_{n}(E)=0$ and so $v(E)=0$ also, being the limit of 0 .

Definition 20.4.3 For s a simple function $s(\omega)=\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}(\omega)$ and $v \in B V(\Omega)$, define an "integral" with respect to $v$ as follows.

$$
\int s d v \equiv \sum_{k=1}^{n} c_{k} v\left(E_{k}\right)
$$

For $f$ function which is in $L^{\infty}(\Omega ; \mu)$, define $\int f d v$ as follows. Applying Theorem 11.3.9, to the positive and negative parts of real and imaginary parts of $f$, there exists a sequence of simple functions $\left\{s_{n}\right\}$ which converges uniformly to $f$ off a set of $\mu$ measure zero. Then

$$
\int f d v \equiv \lim _{n \rightarrow \infty} \int s_{n} d v
$$

Lemma 20.4.4 The above definition of the integral with respect to a finitely additive measure in $B V(\Omega ; \mu)$ is well defined.

Proof: First consider the claim about the integral being well defined on the simple functions. This is clearly true if it is required that the $c_{k}$ are disjoint and the $E_{k}$ also disjoint having union equal to $\Omega$. Thus define the integral of a simple function in this manner. First write the simple function as

$$
\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}
$$

where the $c_{k}$ are the values of the simple function. Then use the above formula to define the integral. Next suppose the $E_{k}$ are disjoint but the $c_{k}$ are not necessarily distinct. Let the distinct values of the $c_{k}$ be $a_{1}, \cdots, a_{m}$

$$
\begin{aligned}
\sum_{k} c_{k} \mathscr{X}_{E_{k}} & =\sum_{j} a_{j}\left(\sum_{i: c_{i}=a_{j}} \mathscr{X}_{E_{i}}\right)=\sum_{j} a_{j} v\left(\bigcup_{i: c_{i}=a_{j}} E_{i}\right) \\
& =\sum_{j} a_{j} \sum_{i: c_{i}=a_{j}} v\left(E_{i}\right)=\sum_{k} c_{k} v\left(E_{k}\right)
\end{aligned}
$$

and so the same formula for the integral of a simple function is obtained in this case also. Now consider two simple functions

$$
s=\sum_{k=1}^{n} a_{k} \mathscr{X}_{E_{k}}, t=\sum_{j=1}^{m} b_{j} \mathscr{X}_{F_{j}}
$$

where the $a_{k}$ and $b_{j}$ are the distinct values of the simple functions. Then from what was just shown,

$$
\begin{aligned}
\int(\alpha s+\beta t) d v & =\int\left(\sum_{k=1}^{n} \sum_{j=1}^{m} \alpha a_{k} \mathscr{X}_{E_{k} \cap F_{j}}+\sum_{j=1}^{m} \sum_{k=1}^{n} \beta b_{j} \mathscr{X}_{E_{k} \cap F_{j}}\right) d v \\
& =\int\left(\sum_{j, k} \alpha a_{k} \mathscr{X}_{E_{k} \cap F_{j}}+\beta b_{j} \mathscr{X}_{E_{k} \cap F_{j}}\right) d v \\
& =\sum_{j, k}\left(\alpha a_{k}+\beta b_{j}\right) v\left(E_{k} \cap F_{j}\right) \\
= & \sum_{k=1}^{n} \sum_{j=1}^{m} \alpha a_{k} v\left(E_{k} \cap F_{j}\right)+\sum_{j=1}^{m} \sum_{k=1}^{n} \beta b_{j} v\left(E_{k} \cap F_{j}\right) \\
= & \sum_{k=1}^{n} \alpha a_{k} v\left(E_{k}\right)+\sum_{j=1}^{m} \beta b_{j} v\left(F_{j}\right) \\
= & \alpha \int s d v+\beta \int t d v
\end{aligned}
$$

Thus the integral is linear on simple functions so, in particular, the formula given in the above definition is well defined regardless.

So what about the definition for $f \in L^{\infty}(\Omega ; \mu)$ ? Since $f \in L^{\infty}$, there is a set of $\mu$ measure zero $N$ such that on $N^{C}$ there exists a sequence of simple functions which converges uniformly to $f$ on $N^{C}$. Consider $s_{n}$ and $s_{m}$. As in the above, they can be written as

$$
\sum_{k=1}^{p} c_{k}^{n} \mathscr{X}_{E_{k}}, \sum_{k=1}^{p} c_{k}^{m} \mathscr{X}_{E_{k}}
$$

respectively, where the $E_{k}$ are disjoint having union equal to $\Omega$. Then by uniform convergence, if $m, n$ are sufficiently large, $\left|c_{k}^{n}-c_{k}^{m}\right|<\varepsilon$ or else the corresponding $E_{k}$ is contained in $N^{C}$ a set of $v$ measure 0 thanks to $v \ll \mu$. Hence

$$
\begin{aligned}
\left|\int s_{n} d v-\int s_{m} d v\right| & =\left|\sum_{k=1}^{p}\left(c_{k}^{n}-c_{k}^{m}\right) v\left(E_{k}\right)\right| \\
& \leq \sum_{k=1}^{p}\left|c_{k}^{n}-c_{k}^{m}\right|\left|v\left(E_{k}\right)\right| \leq \boldsymbol{\varepsilon}\|v\|
\end{aligned}
$$

and so the integrals of these simple functions converge. Similar reasoning shows that the definition is not dependent on the choice of approximating sequence.

Note also that for $s$ simple,

$$
\left|\int s d v\right| \leq\|s\|_{L^{\infty}}|v|(\Omega)=\|s\|_{L^{\infty}}\|v\|
$$

Next the dual space of $L^{\infty}(\Omega ; \mu)$ will be identified with $B V(\Omega ; \mu)$. First here is a simple observation. Let $v \in B V(\Omega ; \mu)$. Then define the following for $f \in L^{\infty}(\Omega ; \mu)$.

$$
T_{v}(f) \equiv \int f d v
$$

Lemma 20.4.5 For $T_{v}$ just defined,

$$
\left|T_{v} f\right| \leq\|f\|_{L^{\infty}}\|v\|
$$

Proof: As noted above, the conclusion true if $f$ is simple. Now if $f$ is in $L^{\infty}$, then it is the uniform limit of simple functions off a set of $\mu$ measure zero. Therefore, by the definition of the $T_{V}$,

$$
\left|T_{v} f\right|=\lim _{n \rightarrow \infty}\left|T_{v} s_{n}\right| \leq \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\|s_{n}\right\|_{L^{\infty}}\|v\|=\|f\|_{L^{\infty}}\|v\| .
$$

Thus each $T_{v}$ is in $\left(L^{\infty}(\Omega ; \mu)\right)^{\prime}$
Here is the representation theorem, due to Kantorovitch, for the dual of $L^{\infty}(\Omega ; \mu)$.
Theorem 20.4.6 Let $\theta: B V(\Omega ; \mu) \rightarrow\left(L^{\infty}(\Omega ; \mu)\right)^{\prime}$ be given by $\theta(v) \equiv T_{v}$. Then $\theta$ is one to one, onto and preserves norms.

Proof: It was shown in the above lemma that $\theta$ maps into $\left(L^{\infty}(\Omega ; \mu)\right)^{\prime}$. It is obvious that $\theta$ is linear. Why does it preserve norms? From the above lemma,

$$
\|\theta v\| \equiv \sup _{\|f\|_{\infty} \leq 1}\left|T_{v} f\right| \leq\|v\|
$$

It remains to turn the inequality around. Let $\pi(\Omega)$ be a partition. Then

$$
\sum_{A \in \pi(\Omega)}|v(A)|=\sum_{A \in \pi(\Omega)} \operatorname{sgn}(v(A)) v(A) \equiv \int f d v
$$

where $\operatorname{sgn}(v(A))$ is defined to be a complex number of modulus 1 such that

$$
\operatorname{sgn}(v(A)) v(A)=|v(A)|
$$

and

$$
f(\omega)=\sum_{A \in \pi(\Omega)} \operatorname{sgn}(v(A)) \mathscr{X}_{A}(\omega)
$$

Therefore, choosing $\pi(\Omega)$ suitably, since $\|f\|_{\infty} \leq 1$,

$$
\begin{aligned}
\|v\|-\varepsilon & =|v|(\Omega)-\varepsilon \leq \sum_{A \in \pi(\Omega)}|v(A)|=T_{v}(f) \\
& =\left|T_{v}(f)\right|=|\theta(v)(f)| \leq\|\theta(v)\| \leq\|v\|
\end{aligned}
$$

Thus $\theta$ preserves norms. Hence it is one to one also. Why is $\theta$ onto?
Let $\Lambda \in\left(L^{\infty}(\Omega ; \mu)\right)^{\prime}$. Then define

$$
\begin{equation*}
v(E) \equiv \Lambda\left(\mathscr{X}_{E}\right) \tag{20.4.14}
\end{equation*}
$$

This is obviously finitely additive because $\Lambda$ is linear. Also, if $\mu(E)=0$, then $\mathscr{X}_{E}=0$ in $L^{\infty}$ and so $\Lambda\left(\mathscr{X}_{E}\right)=0$. If $\pi(\Omega)$ is any partition of $\Omega$, then

$$
\begin{aligned}
\sum_{A \in \pi(\Omega)}|v(A)| & =\sum_{A \in \pi(\Omega)}\left|\Lambda\left(\mathscr{X}_{A}\right)\right|=\sum_{A \in \pi(\Omega)} \operatorname{sgn}\left(\Lambda\left(\mathscr{X}_{A}\right)\right) \Lambda\left(\mathscr{X}_{A}\right) \\
& =\Lambda\left(\sum_{A \in \pi(\Omega)} \operatorname{sgn}\left(\Lambda\left(\mathscr{X}_{A}\right)\right) \mathscr{X}_{A}\right) \leq\|\Lambda\|
\end{aligned}
$$

and so $\|v\| \leq\|\Lambda\|$ showing that $v \in B V(\Omega ; \mu)$. Also from 20.4.14, if $s=\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}$ is a simple function,

$$
\int s d v=\sum_{k=1}^{n} c_{k} v\left(E_{k}\right)=\sum_{k=1}^{n} c_{k} \Lambda\left(\mathscr{X}_{E_{k}}\right)=\Lambda\left(\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}\right)=\Lambda(s)
$$

Then letting $f \in L^{\infty}(\Omega ; \mu)$, there exists a sequence of simple functions converging to $f$ uniformly off a set of $\mu$ measure zero and so passing to a limit in the above with $s$ replaced with $s_{n}$ it follows that

$$
\Lambda(f)=\int f d v
$$

and so $\theta$ is onto.

### 20.5 Non $\sigma$ Finite Case

It turns out that for $p>1$, you don't have to assume the measure space is $\sigma$ finite. The Riesz representation theorem holds always. The proof involves the notion of uniform convexity. First recall Clarkson's inequalities. These fundamental inequalities were used to verify that $L^{p}(\Omega)$ is uniformly convex. More precisely, the unit ball in $L^{p}(\Omega)$ is uniformly convex.

Lemma 20.5.1 Let $2 \leq p$. Then

$$
\left\|\frac{f+g}{2}\right\|_{L^{p}}^{p}+\left\|\frac{f-g}{2}\right\|_{L^{p}}^{p} \leq \frac{1}{2}\left(\|f\|_{L^{p}}^{p}+\|g\|_{L^{p}}^{p}\right)
$$

Let $1<p<2$. then for $1 / p+1 / q=1$,

$$
\left\|\frac{f+g}{2}\right\|_{L^{p}}^{q}+\left\|\frac{f-g}{2}\right\|_{L^{p}}^{q} \leq\left(\frac{1}{2}\|f\|_{L^{p}}^{p}+\frac{1}{2}\|g\|_{L^{p}}^{p}\right)^{q / p}
$$

Recall the following definition of uniform convexity.
Definition 20.5.2 A Banach space, $X$, is said to be uniformly convex if whenever $\left\|x_{n}\right\| \leq 1$ and $\left\|\frac{x_{n}+x_{m}}{2}\right\| \rightarrow 1$ as $n, m \rightarrow \infty$, then $\left\{x_{n}\right\}$ is a Cauchy sequence and $x_{n} \rightarrow x$ where $\|x\|=1$.

Observe that Clarkson's inequalities imply $L^{p}$ is uniformly convex for all $p>1$. Uniformly convex spaces have a very nice property which is described in the following lemma. Roughly, this property is that any element of the dual space achieves its norm at some point of the closed unit ball.

Lemma 20.5.3 Let $X$ be uniformly convex and let $\phi \in X^{\prime}$. Then there exists $x \in X$ such that

$$
\|x\|=1, \phi(x)=\|\phi\| .
$$

Proof: Let $\left\|\left\|\widetilde{x}_{n}\right\| \leq 1\right.$ and $\left.\left|\phi\left(\widetilde{x}_{n}\right)\right| \rightarrow\right\| \phi \|$. Let $x_{n}=w_{n} \widetilde{x}_{n}$ where $\left|w_{n}\right|=1$ and

$$
w_{n} \phi \widetilde{x}_{n}=\left|\phi \widetilde{x}_{n}\right| .
$$

Thus $\phi\left(x_{n}\right)=\left|\phi\left(x_{n}\right)\right|=\left|\phi\left(\widetilde{x}_{n}\right)\right| \rightarrow \| \phi| |$.

$$
\phi\left(x_{n}\right) \rightarrow\|\phi\|,\left\|x_{n}\right\| \leq 1 .
$$

We can assume, without loss of generality, that

$$
\phi\left(x_{n}\right)=\left|\phi\left(x_{n}\right)\right| \geq \frac{\|\phi\|}{2}
$$

and $\phi \neq 0$.
Claim $\left\|\frac{x_{n}+x_{m}}{2}\right\| \rightarrow 1$ as $n, m \rightarrow \infty$.
Proof of Claim: Let $n, m$ be large enough that $\phi\left(x_{n}\right), \phi\left(x_{m}\right) \geq\|\phi\|-\frac{\varepsilon}{2}$ where $0<\varepsilon$. Then $\left\|x_{n}+x_{m}\right\| \neq 0$ because if it equals 0 , then $x_{n}=-x_{m}$ so $-\phi\left(x_{n}\right)=\phi\left(x_{m}\right)$ but both $\phi\left(x_{n}\right)$ and $\phi\left(x_{m}\right)$ are positive. Therefore consider $\frac{x_{n}+x_{m} \|}{\left\|x_{n}+x_{m}\right\|}$, a vector of norm 1. Thus,

$$
\|\phi\| \geq\left|\phi\left(\frac{\left(x_{n}+x_{m}\right)}{\left\|x_{n}+x_{m}\right\|}\right)\right| \geq \frac{2\|\phi\|-\varepsilon}{\left\|x_{n}+x_{m}\right\|} .
$$

Hence

$$
\left\|\left\|x_{n}+x_{m}\right\|\right\| \phi\|\geq 2\| \phi \|-\varepsilon .
$$

Since $\varepsilon>0$ is arbitrary, $\lim _{n, m \rightarrow \infty}\left\|x_{n}+x_{m}\right\|=2$. This proves the claim.
By uniform convexity, $\left\{x_{n}\right\}$ is Cauchy and $x_{n} \rightarrow x,\|x\|=1$. Thus

$$
\phi(x)=\lim _{n \rightarrow \infty} \phi\left(x_{n}\right)=\|\phi\|
$$

The proof of the Riesz representation theorem will be based on the following lemma which says that if you can show a directional derivative exists, then it can be used to represent a functional in terms of this directional derivative. It is very interesting for its own sake.

Lemma 20.5.4 (McShane) Let $X$ be a complex normed linear space and let $\phi \in X^{\prime}$. Suppose there exists $x \in X,\|x\|=1$ with $\phi(x)=\|\phi\| \neq 0$. Let $y \in X$ and let $\psi_{y}(t)=\| x+$ ty $\|$ for $t \in \mathbb{R}$. Suppose $\psi_{y}^{\prime}(0)$ exists for each $y \in X$. Then for all $y \in X$,

$$
\psi_{y}^{\prime}(0)+i \psi_{-i y}^{\prime}(0)=\|\phi\|^{-1} \phi(y)
$$

Proof: Suppose first that $\|\phi\|=1$. Then by assumption, there is $x$ such that $\|x\|=1$ and $\phi(x)=1=\|\phi\|$. Then $\phi(y-\phi(y) x)=0$ and so

$$
\phi(x+t(y-\phi(y) x))=\phi(x)=1=\|\phi\| .
$$

Therefore, $\|x+t(y-\phi(y) x)\| \geq 1$ since otherwise $\|x+t(y-\phi(y) x)\|=r<1$ and so

$$
\phi\left((x+t(y-\phi(y) x)) \frac{1}{r}\right)=\frac{1}{r} \phi(x)=\frac{1}{r}
$$

which would imply that $\|\phi\|>1$.
Also for small $t,|\phi(y) t|<1$, and so

$$
\begin{gathered}
1 \leq\|x+t(y-\phi(y) x)\|=\|(1-\phi(y) t) x+t y\| \\
\leq|1-\phi(y) t|\left\|x+\frac{t}{1-\phi(y) t} y\right\| .
\end{gathered}
$$

Divide both sides by $|1-\phi(y) t|$. Using the standard formula for the sum of a geometric series,

$$
1+t \phi(y)+o(t)=\frac{1}{1-t \phi(y)}
$$

Therefore,

$$
\begin{equation*}
\frac{1}{|1-\phi(y) t|}=|1+\phi(y) t+o(t)| \leq\left\|x+\frac{t}{1-\phi(y) t} y\right\|=\|x+t y+o(t)\| \tag{20.5.15}
\end{equation*}
$$

where $\lim _{t \rightarrow 0} o(t)\left(t^{-1}\right)=0$. Thus,

$$
|1+\phi(y) t| \leq\|x+t y\|+o(t)
$$

Now $|1+t \phi(y)|-1 \geq 1+t \operatorname{Re} \phi(y)-1=t \operatorname{Re} \phi(y)$.
Thus for $t>0$,

$$
\operatorname{Re} \phi(y) \leq \frac{|1+t \phi(y)|-1}{t} \stackrel{\|x\|=1}{\leq} \frac{\|x+t y\|-\|x\|}{t}+\frac{o(t)}{t}
$$

and for $t<0$,

$$
\operatorname{Re} \phi(y) \geq \frac{|1+t \phi(y)|-1}{t} \geq \frac{\|x+t y\|-\|x\|}{t}+\frac{o(t)}{t}
$$

By assumption, letting $t \rightarrow 0+$ and $t \rightarrow 0-$,

$$
\operatorname{Re} \phi(y)=\lim _{t \rightarrow 0} \frac{\|x+t y\|-\|x\|}{t}=\psi_{y}^{\prime}(0)
$$

Now

$$
\phi(y)=\operatorname{Re} \phi(y)+i \operatorname{Im} \phi(y)
$$

so

$$
\phi(-i y)=-i(\phi(y))=-i \operatorname{Re} \phi(y)+\operatorname{Im} \phi(y)
$$

and

$$
\phi(-i y)=\operatorname{Re} \phi(-i y)+i \operatorname{Im} \phi(-i y)
$$

Hence

$$
\operatorname{Re} \phi(-i y)=\operatorname{Im} \phi(y) .
$$

Consequently,

$$
\begin{aligned}
\phi(y)=\operatorname{Re} \phi(y) & +i \operatorname{Im} \phi(y)=\operatorname{Re} \phi(y)+i \operatorname{Re} \phi(-i y) \\
& =\psi_{y}^{\prime}(0)+i \psi_{-i y}^{\prime}(0)
\end{aligned}
$$

This proves the lemma when $\|\phi\|=1$. For arbitrary $\phi \neq 0$, let $\phi(x)=\|\phi\|,\|x\|=1$. Then from above, if $\phi_{1}(y) \equiv\|\phi\|^{-1} \phi(y),\left\|\phi_{1}\right\|=1$ and so from what was just shown,

$$
\phi_{1}(y)=\frac{\phi(y)}{\|\phi\|}=\psi_{y}^{\prime}(0)+i \psi_{-i y}(0)
$$

Now here are some short observations. For $t \in \mathbb{R}, p>1$, and $x, y \in \mathbb{C}, x \neq 0$

$$
\begin{align*}
\lim _{t \rightarrow 0} \frac{|x+t y|^{p}-|x|^{p}}{t} & =p|x|^{p-2}(\operatorname{Re} x \operatorname{Re} y+\operatorname{Im} x \operatorname{Im} y) \\
& =p|x|^{p-2} \operatorname{Re}(\bar{x} y) \tag{20.5.16}
\end{align*}
$$

Also from convexity of $f(r)=r^{p}$, for $|t|<1$,

$$
\begin{aligned}
& |x+t y|^{p}-|x|^{p} \leq||x|+|t|| y| |^{p}-|x|^{p} \\
& =\left[(1+|t|)\left(\frac{|x|+|t||y|}{1+|t|}\right)\right]^{p}-|x|^{p} \\
& \leq(1+|t|)^{p} \frac{|x|^{p}}{1+|t|}+\frac{|t||y|^{p}}{1+|t|}-|x|^{p} \\
& \leq(1+|t|)^{p-1}\left(|x|^{p}+|t||y|^{p}\right)-|x|^{p} \\
& \leq\left((1+|t|)^{p-1}-1\right)|x|^{p}+2^{p-1}|t||y|^{p}
\end{aligned}
$$

Now for $f(t) \equiv(1+t)^{p-1}, f^{\prime}(t)$ is uniformly bounded, depending on $p$, for $t \in[0,1]$. Hence the above is dominated by an expression of the form

$$
\begin{equation*}
C_{p}\left(|x|^{p}+|y|^{p}\right)|t| \tag{20.5.17}
\end{equation*}
$$

The above lemma and uniform convexity of $L^{p}$ can be used to prove a general version of the Riesz representation theorem next. Let $p>1$ and let $\eta: L^{q} \rightarrow\left(L^{p}\right)^{\prime}$ be defined by

$$
\begin{equation*}
\eta(g)(f)=\int_{\Omega} g f d \mu \tag{20.5.18}
\end{equation*}
$$

Theorem 20.5.5 (Riesz representation theorem $p>1$ ) The map $\eta$ is 1-1, onto, continuous, and

$$
\|\eta g\|=\|g\|,\|\eta\|=1
$$

Proof: Obviously $\eta$ is linear. Suppose $\eta g=0$. Then $0=\int g f d \mu$ for all $f \in L^{p}$. Let $f=|g|^{q-2} \bar{g}$. Then $f \in L^{p}$ and so $0=\int|g|^{q} d \mu$. Hence $g=0$ and $\eta$ is one to one. That $\eta g \in\left(L^{p}\right)^{\prime}$ is obvious from the Holder inequality. In fact,

$$
|\eta(g)(f)| \leq\|g\|_{q}\|f\|_{p}
$$

and so $\|\eta(g)\| \leq\|g\|_{q}$. To see that equality holds, let

$$
f=|g|^{q-2} \bar{g}\|g\|_{q}^{1-q}
$$

Then $\|f\|_{p}=1$ and

$$
\eta(g)(f)=\int_{\Omega}|g|^{q} d \mu\|g\|_{q}^{1-q}=\|g\|_{q} .
$$

Thus $\|\eta\|=1$.
It remains to show $\eta$ is onto. Let $\phi \in\left(L^{p}\right)^{\prime}$. Is $\phi=\eta g$ for some $g \in L^{q}$ ? Without loss of generality, assume $\phi \neq 0$. By uniform convexity of $L^{p}$, Lemma 20.5.3, there exists $g$ such that

$$
\phi g=\|\phi\|, g \in L^{p},\|g\|=1
$$

For $f \in L^{p}$, define $\phi_{f}(t) \equiv \int_{\Omega}|g+t f|^{p} d \mu$. Thus

$$
\psi_{f}(t) \equiv\|g+t f\|_{p} \equiv \phi_{f}(t)^{\frac{1}{p}}
$$

Does $\phi_{f}^{\prime}(0)$ exist? Let $[g=0]$ denote the set $\{x: g(x)=0\}$.

$$
\frac{\phi_{f}(t)-\phi_{f}(0)}{t}=\int \frac{\left(|g+t f|^{p}-|g|^{p}\right)}{t} d \mu
$$

From 20.5.17, the integrand is bounded by $C_{p}\left(|f|^{p}+|g|^{p}\right)$. Therefore, using 20.5.16, the dominated convergence theorem applies and it follows $\phi_{f}^{\prime}(0)=$

$$
\begin{gathered}
\lim _{t \rightarrow 0} \frac{\phi_{f}(t)-\phi_{f}(0)}{t}=\lim _{t \rightarrow 0}\left[\int_{[g=0]}|t|^{p-1}|f|^{p} d \mu+\int_{[g \neq 0]} \frac{\left(|g+t f|^{p}-|g|^{p}\right)}{t} d \mu\right] \\
=p \int_{[g \neq 0]}|g|^{p-2} \operatorname{Re}(\bar{g} f) d \mu=p \int|g|^{p-2} \operatorname{Re}(\bar{g} f) d \mu
\end{gathered}
$$

Hence

$$
\psi_{f}^{\prime}(0)=\|g\|^{\frac{-p}{q}} \int|g(x)|^{p-2} \operatorname{Re}(g(x) \bar{f}(x)) d \mu
$$

Note $\frac{1}{p}-1=-\frac{1}{q}$. Therefore,

$$
\psi_{-i f}^{\prime}(0)=\|g\|^{\frac{-p}{q}} \int|g(x)|^{p-2} \operatorname{Re}(i g(x) \bar{f}(x)) d \mu
$$

But $\operatorname{Re}(i g \bar{f})=\operatorname{Im}(-g \bar{f})$ and so by the McShane lemma,

$$
\begin{aligned}
\phi(f) & =\|\phi\|\|g\|^{\frac{-p}{q}} \int|g(x)|^{p-2}[\operatorname{Re}(g(x) \bar{f}(x))+i \operatorname{Re}(i g(x) \bar{f}(x))] d \mu \\
& =\|\phi\|\|g\|^{\frac{-p}{q}} \int|g(x)|^{p-2}[\operatorname{Re}(g(x) \bar{f}(x))+i \operatorname{Im}(-g(x) \bar{f}(x))] d \mu \\
& =\|\phi\|\|g\|^{\frac{-p}{q}} \int|g(x)|^{p-2} \bar{g}(x) f(x) d \mu
\end{aligned}
$$

This shows that

$$
\phi=\eta\left(\|\phi\|\|g\|^{\frac{-p}{q}}|g|^{p-2} \bar{g}\right)
$$

and verifies $\eta$ is onto.

### 20.6 The Dual Space Of $C_{0}(X)$

Consider the dual space of $C_{0}(X)$ where $X$ is a locally compact Hausdorff space. It will turn out to be a space of measures. To show this, the following lemma will be convenient. Recall this space is defined as follows.

Definition 20.6.1 $f \in C_{0}(X)$ means that for every $\varepsilon>0$ there exists a compact set $K$ such that $|f(x)|<\varepsilon$ whenever $x \notin K$. Recall the norm on this space is

$$
\|f\|_{\infty} \equiv\|f\| \equiv \sup \{|f(x)|: x \in X\}
$$

Lemma 20.6.2 Suppose $\lambda$ is a mapping which has nonnegative values which is defined on the nonnegative functions in $C_{0}(X)$ such that

$$
\begin{equation*}
\lambda(a f+b g)=a \lambda(f)+b \lambda(g) \tag{20.6.19}
\end{equation*}
$$

whenever $a, b \geq 0$ and $f, g \geq 0$. Then there exists a unique extension of $\lambda$ to all of $C_{0}(X)$, $\Lambda$ such that whenever $f, g \in C_{0}(X)$ and $a, b \in \mathbb{C}$, it follows

$$
\Lambda(a f+b g)=a \Lambda(f)+b \Lambda(g)
$$

If

$$
|\lambda(f)| \leq C| | f \|_{\infty}
$$

then

$$
|\Lambda f| \leq C| | f \|_{\infty}
$$

Proof: Let $C_{0}(X ; \mathbb{R})$ be the real-valued functions in $C_{0}(X)$ and define

$$
\Lambda_{R}(f)=\lambda f^{+}-\lambda f^{-}
$$

for $f \in C_{0}(X ; \mathbb{R})$. Use the identity

$$
\left(f_{1}+f_{2}\right)^{+}+f_{1}^{-}+f_{2}^{-}=f_{1}^{+}+f_{2}^{+}+\left(f_{1}+f_{2}\right)^{-}
$$

and 20.6.19 to write

$$
\lambda\left(f_{1}+f_{2}\right)^{+}-\lambda\left(f_{1}+f_{2}\right)^{-}=\lambda f_{1}^{+}-\lambda f_{1}^{-}+\lambda f_{2}^{+}-\lambda f_{2}^{-}
$$

it follows that $\Lambda_{R}\left(f_{1}+f_{2}\right)=\Lambda_{R}\left(f_{1}\right)+\Lambda_{R}\left(f_{2}\right)$. To show that $\Lambda_{R}$ is linear, it is necessary to verify that $\Lambda_{R}(c f)=c \Lambda_{R}(f)$ for all $c \in \mathbb{R}$. But

$$
(c f)^{ \pm}=c f^{ \pm}
$$

if $c \geq 0$ while

$$
(c f)^{+}=-c(f)^{-}
$$

if $c<0$ and

$$
(c f)^{-}=(-c) f^{+}
$$

if $c<0$. Thus, if $c<0$,

$$
\begin{gathered}
\Lambda_{R}(c f)=\lambda(c f)^{+}-\lambda(c f)^{-}=\lambda\left((-c) f^{-}\right)-\lambda\left((-c) f^{+}\right) \\
=-c \lambda\left(f^{-}\right)+c \lambda\left(f^{+}\right)=c\left(\lambda\left(f^{+}\right)-\lambda\left(f^{-}\right)\right)=c \Lambda_{R}(f)
\end{gathered}
$$

A similar formula holds more easily if $c \geq 0$. Now let

$$
\Lambda f=\Lambda_{R}(\operatorname{Re} f)+i \Lambda_{R}(\operatorname{Im} f)
$$

for arbitrary $f \in C_{0}(X)$. This is linear as desired.
Here is why. It is obvious that $\Lambda(f+g)=\Lambda(f)+\Lambda(g)$ from the fact that taking the real and imaginary parts are linear operations. The only thing to check is whether you can factor out a complex scalar.

$$
\begin{gathered}
\Lambda((a+i b) f)=\Lambda(a f)+\Lambda(i b f) \\
\equiv \Lambda_{R}(a \operatorname{Re} f)+i \Lambda_{R}(a \operatorname{Im} f)+\Lambda_{R}(-b \operatorname{Im} f)+i \Lambda_{R}(b \operatorname{Re} f)
\end{gathered}
$$

because $i b f=i b \operatorname{Re} f-b \operatorname{Im} f$ and so $\operatorname{Re}(i b f)=-b \operatorname{Im} f$ and $\operatorname{Im}(i b f)=b \operatorname{Re} f$. Therefore, the above equals

$$
\begin{aligned}
& =(a+i b) \Lambda_{R}(\operatorname{Re} f)+i(a+i b) \Lambda_{R}(\operatorname{Im} f) \\
& =\quad(a+i b)\left(\Lambda_{R}(\operatorname{Re} f)+i \Lambda_{R}(\operatorname{Im} f)\right)=(a+i b) \Lambda f
\end{aligned}
$$

The extension is obviously unique because all the above is required in order for $\Lambda$ to be linear.

It remains to verify the claim about continuity of $\Lambda$. From the definition of $\lambda$, if $0 \leq$ $g \leq f$, then

$$
\begin{gathered}
\lambda(f)=\lambda(f-g+g)=\lambda(f-g)+\lambda(g) \geq \lambda(g) \\
\left|\Lambda_{R} f\right| \equiv\left|\lambda f^{+}-\lambda f^{-}\right| \leq \max \left(\lambda f^{+}, \lambda f^{-}\right) \leq \lambda(|f|) \leq C| | f \|_{\infty}
\end{gathered}
$$

Then letting $\omega \Lambda f=|\Lambda f|,|\omega|=1$, and using the above,

$$
\begin{aligned}
|\Lambda f| & =\omega \Lambda f=\Lambda(\omega f) \equiv \Lambda_{R}(\operatorname{Re}(\omega f))=\left|\Lambda_{R}(\operatorname{Re}(\omega f))\right| \\
& \leq C\|\operatorname{Re}(\omega f)\| \leq C\|f\|_{\infty}
\end{aligned}
$$

This proves the lemma.
Let $L \in C_{0}(X)^{\prime}$. Also denote by $C_{0}^{+}(X)$ the set of nonnegative continuous functions defined on $X$. Define for $f \in C_{0}^{+}(X)$

$$
\lambda(f)=\sup \{|L g|:|g| \leq f\} .
$$

Note that $\lambda(f)<\infty$ because $|L g| \leq\|L|\||g\|\leq\| L|\|| \mid f\|$ for $|g| \leq f$. Then the following lemma is important.

Lemma 20.6.3 If $c \geq 0, \lambda(c f)=c \lambda(f), f_{1} \leq f_{2}$ implies $\lambda f_{1} \leq \lambda f_{2}$, and

$$
\lambda\left(f_{1}+f_{2}\right)=\lambda\left(f_{1}\right)+\lambda\left(f_{2}\right)
$$

Also

$$
0 \leq \lambda(f) \leq\|L\|\|f\|_{\infty}
$$

Proof: The first two assertions are easy to see so consider the third.
For $f_{j} \in C_{0}^{+}(X)$, there exists $g_{i} \in C_{0}(X)$ such that $\left|g_{i}\right| \leq f_{i}$ and

$$
\begin{aligned}
\lambda\left(f_{1}\right)+\lambda\left(f_{2}\right) & \leq\left|L\left(g_{1}\right)\right|+\left|L\left(g_{2}\right)\right|+2 \varepsilon \\
& =L\left(\omega_{1} g_{1}\right)+L\left(\omega_{2} g_{2}\right)+2 \varepsilon \\
& =L\left(\omega_{1} g_{1}+\omega_{2} g_{2}\right)+2 \varepsilon \\
& =\left|L\left(\omega_{1} g_{1}+\omega_{2} g_{2}\right)\right|+2 \varepsilon
\end{aligned}
$$

where $\left|g_{i}\right| \leq f_{i}$ and $\left|\omega_{i}\right|=1$ and $\omega_{i} L\left(g_{i}\right)=\left|L\left(g_{i}\right)\right|$. Now

$$
\left|\omega_{1} g_{1}+\omega_{2} g_{2}\right| \leq\left|g_{1}\right|+\left|g_{2}\right| \leq f_{1}+f_{2}
$$

and so the above shows

$$
\lambda\left(f_{1}\right)+\lambda\left(f_{2}\right) \leq \lambda\left(f_{1}+f_{2}\right)+2 \varepsilon
$$

Since $\varepsilon$ is arbitrary, $\lambda\left(f_{1}\right)+\lambda\left(f_{2}\right) \leq \lambda\left(f_{1}+f_{2}\right)$. It remains to verify the other inequality.
Now let $|g| \leq f_{1}+f_{2},|L g| \geq \lambda\left(f_{1}+f_{2}\right)-\varepsilon$. Let

$$
h_{i}(x)=\left\{\begin{array}{l}
\frac{f_{i}(x) g(x)}{f_{1}(x)+f_{2}(x)} \text { if } f_{1}(x)+f_{2}(x)>0 \\
0 \text { if } f_{1}(x)+f_{2}(x)=0
\end{array}\right.
$$

Then $h_{i}$ is continuous and $h_{1}(x)+h_{2}(x)=g(x),\left|h_{i}\right| \leq f_{i}$. The reason it is continuous at a point where $f_{1}(x)+f_{2}(x)=0$ is that at every point $y$ where $f_{1}(y)+f_{2}(y)>0$, the top description of the function gives

$$
\left|\frac{f_{i}(y) g(y)}{f_{1}(y)+f_{2}(y)}\right| \leq|g(y)|
$$

Therefore,

$$
\begin{aligned}
-\varepsilon+\lambda\left(f_{1}+f_{2}\right) & \leq|L g| \leq\left|L h_{1}+L h_{2}\right| \leq\left|L h_{1}\right|+\left|L h_{2}\right| \\
& \leq \lambda\left(f_{1}\right)+\lambda\left(f_{2}\right) .
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this shows

$$
\lambda\left(f_{1}+f_{2}\right) \leq \lambda\left(f_{1}\right)+\lambda\left(f_{2}\right) \leq \lambda\left(f_{1}+f_{2}\right)
$$

The last assertion follows from

$$
\lambda(f)=\sup \{|L g|:|g| \leq f\} \leq \sup _{\|g\|_{\infty} \leq\|f\|_{\infty}}\|L\|\|g\|_{\infty} \leq\|L\|\|f\|_{\infty}
$$

which proves the lemma.
Let $\Lambda$ be defined in Lemma 20.6.2. Then $\Lambda$ is linear by this lemma and also satisfies

$$
\begin{equation*}
|\Lambda f| \leq\|L\|\|f\|_{\infty} \tag{20.6.20}
\end{equation*}
$$

Also, if $f \geq 0$,

$$
\Lambda f=\Lambda_{R} f=\lambda(f) \geq 0
$$

Therefore, $\Lambda$ is a positive linear functional on $C_{0}(X)$. In particular, it is a positive linear functional on $C_{c}(X)$. By Theorem 12.3.2 on Page 288, there exists a unique measure $\mu$ such that

$$
\Lambda f=\int_{X} f d \mu
$$

for all $f \in C_{c}(X)$. This measure is inner regular on all open sets and on all measurable sets having finite measure. In fact, it is actually a finite measure.

Lemma 20.6.4 Let $L \in C_{0}(X)^{\prime}$ as above. Then letting $\mu$ be the Radon measure just described, it follows $\mu$ is finite and

$$
\mu(X)=\|\Lambda\|=\|L\|
$$

Proof: First of all, why is $\|\Lambda\|=\|L\|$ ? From 20.6 .20 it follows $\|\Lambda\| \leq\|L\|$. But also

$$
|L g| \leq \lambda(|g|)=\Lambda(|g|) \leq\|\Lambda\|\|g\|_{\infty}
$$

and so by definition of the operator norm, $\|L\| \leq\|\Lambda\|$.
Now $X$ is an open set and so

$$
\mu(X)=\sup \{\mu(K): K \subseteq X\}
$$

and so letting $K \prec f \prec X$ for one of these $K$, it also follows

$$
\mu(X)=\sup \{\Lambda f: f \prec X\}
$$

However, for such $f \prec X$,

$$
0 \leq \Lambda f=\Lambda_{R} f \leq\|L\|\|f\|_{\infty}=\|L\|
$$

and so

$$
\mu(X) \leq\|L\|
$$

Now since $C_{c}(X)$ is dense in $C_{0}(X)$, there exists $f \in C_{c}(X)$ such that $\|f\| \leq 1$ and

$$
|\Lambda f|+\varepsilon>\|\Lambda\|=\|L\|
$$

Then also $f \prec X$ and so

$$
\|L\|-\varepsilon<|\Lambda f|=\Lambda f \leq \mu(X)
$$

Since $\varepsilon$ is arbitrary, this shows $\|L\|=\mu(X)$. This proves the lemma.
What follows is the Riesz representation theorem for $C_{0}(X)^{\prime}$.
Theorem 20.6.5 Let $L \in\left(C_{0}(X)\right)^{\prime}$ for $X$ a locally compact Hausdorf space. Then there exists a finite Radon measure $\mu$ and a function $\sigma \in L^{\infty}(X, \mu)$ such that for all $f \in C_{0}(X)$,

$$
L(f)=\int_{X} f \sigma d \mu
$$

Furthermore,

$$
\mu(X)=\|L\|,|\sigma|=1 \text { a.e. }
$$

and if

$$
v(E) \equiv \int_{E} \sigma d \mu
$$

then $\mu=|v|$
Proof: From the above there exists a unique Radon measure $\mu$ such that for all $f \in$ $C_{c}(X)$,

$$
\Lambda f=\int_{X} f d \mu
$$

Then for $f \in C_{c}(X)$,

$$
|L f| \leq \Lambda(|f|)=\int_{X}|f| d \mu=\|f\|_{L^{1}(\mu)}
$$

Since $\mu$ is both inner and outer regular thanks to it being finite, $C_{c}(X)$ is dense in $L^{1}(X, \mu)$. (See Theorem 15.2.4 for more than is needed.) Therefore $L$ extends uniquely to an element of $\left(L^{1}(X, \mu)\right)^{\prime}, \widetilde{L}$. By the Riesz representation theorem for $L^{1}$ for finite measure spaces, there exists a unique $\sigma \in L^{\infty}(X, \mu)$ such that for all $f \in L^{1}(X, \mu)$,

$$
\widetilde{L} f=\int_{X} f \sigma d \mu
$$

In particular, for all $f \in C_{0}(X)$,

$$
L f=\int_{X} f \sigma d \mu
$$

and it follows from Lemma 20.6.4, $\mu(X)=\|L\|$.
It remains to verify $|\sigma|=1$ a.e. For any $f \geq 0$,

$$
\Lambda f \equiv \int_{X} f d \mu \geq|L f|=\left|\int_{X} f \sigma d \mu\right|
$$

Now if $E$ is measurable, the regularity of $\mu$ implies there exists a sequence of bounded functions $f_{n} \in C_{c}(X)$ such that $f_{n}(x) \rightarrow \mathscr{X}_{E}(x)$ a.e. Then using the dominated convergence theorem in the above,

$$
\int_{E} d \mu=\lim _{n \rightarrow \infty} \int_{X} f_{n} d \mu \geq \lim _{n \rightarrow \infty}\left|\int_{X} f_{n} \sigma d \mu\right|=\left|\int_{E} \sigma d \mu\right|
$$

and so if $\mu(E)>0$,

$$
1 \geq\left|\frac{1}{\mu(E)} \int_{E} \sigma d \mu\right|
$$

which shows from Lemma 20.2.7 that $|\sigma| \leq 1$ a.e. But also, choosing $f_{1}$ appropriately, $\left\|f_{1}\right\|_{\infty} \leq 1$, and letting $\omega L f_{1}=\left|L f_{1}\right|$,

$$
\begin{aligned}
\mu(X) & =\|L\|=\sup _{\|f\|_{\infty} \leq 1}|L f| \leq\left|L f_{1}\right|+\varepsilon \\
& \leq \int_{X} f_{1} \omega \sigma d \mu+\varepsilon=\int_{X} \operatorname{Re}\left(f_{1} \omega \sigma\right) d \mu+\varepsilon \\
& \leq \int_{X}|\sigma| d \mu+\varepsilon
\end{aligned}
$$

and since $\varepsilon$ is arbitrary,

$$
\mu(X) \leq \int_{X}|\sigma| d \mu
$$

which requires $|\sigma|=1$ a.e. since it was shown to be no larger than 1 and if it is smaller than 1 on a set of positive measure, then the above could not hold.

It only remains to verify $\mu=|v|$. By Corollary 20.2.10,

$$
|v|(E)=\int_{E}|\sigma| d \mu=\int_{E} 1 d \mu=\mu(E)
$$

and so $\mu=|v|$. This proves the Theorem.
Sometimes people write

$$
\int_{X} f d v \equiv \int_{X} f \sigma d|v|
$$

where $\sigma d|v|$ is the polar decomposition of the complex measure $v$. Then with this convention, the above representation is

$$
L(f)=\int_{X} f d v,|v|(X)=\|L\|
$$

### 20.7 The Dual Space Of $C_{0}(X)$, Another Approach

It is possible to obtain the above theorem by a slick trick after first proving it for the special case where $X$ is a compact Hausdorff space. For $X$ a locally compact Hausdorff space, $\widetilde{\widetilde{X}}$ denotes the one point compactification of $X$. Thus, $\widetilde{X}=X \cup\{\infty\}$ and the topology of $\widetilde{X}$ consists of the usual topology of $X$ along with all complements of compact sets which are defined as the open sets containing $\infty$. Also $C_{0}(X)$ will denote the space of continuous functions, $f$, defined on $X$ such that in the topology of $\widetilde{X}, \lim _{x \rightarrow \infty} f(x)=0$. For this space of functions, $\left||f|_{0} \equiv \sup \{|f(x)|: x \in X\}\right.$ is a norm which makes this into a Banach space. Then the generalization is the following corollary.

Corollary 20.7.1 Let $L \in\left(C_{0}(X)\right)^{\prime}$ where $X$ is a locally compact Hausdorff space. Then there exists $\sigma \in L^{\infty}(X, \mu)$ for $\mu$ a finite Radon measure such that for all $f \in C_{0}(X)$,

$$
L(f)=\int_{X} f \sigma d \mu
$$

Proof: Let

$$
\widetilde{D} \equiv\{f \in C(\widetilde{X}): f(\infty)=0\}
$$

Thus $\widetilde{D}$ is a closed subspace of the Banach space $C(\widetilde{X})$. Let $\theta: C_{0}(X) \rightarrow \widetilde{D}$ be defined by

$$
\theta f(x)=\left\{\begin{array}{l}
f(x) \text { if } x \in X \\
0 \text { if } x=\infty
\end{array}\right.
$$

Then $\theta$ is an isometry of $C_{0}(X)$ and $\widetilde{D} .(\|\theta u\|=\|u\|$.$) The following diagram is obtained.$

$$
\begin{array}{lllll}
C_{0}(X)^{\prime} & \stackrel{\theta^{*}}{\leftarrow} & (\widetilde{D})^{\prime} & \stackrel{i^{*}}{\leftarrow} & C(\widetilde{X})^{\prime} \\
C_{0}(X) & \underset{\theta}{\rightarrow} & \widetilde{D} & \rightarrow & C(\widetilde{X})
\end{array}
$$

By the Hahn Banach theorem, there exists $L_{1} \in C(\widetilde{X})^{\prime}$ such that $\theta^{*} i^{*} L_{1}=L$. Now apply Theorem 20.6 .5 to get the existence of a finite Radon measure, $\mu_{1}$, on $\widetilde{X}$ and a function $\sigma \in L^{\infty}\left(\widetilde{X}, \mu_{1}\right)$, such that

$$
L_{1} g=\int_{\widetilde{X}} g \sigma d \mu_{1}
$$

Letting the $\sigma$ algebra of $\mu_{1}$ measurable sets be denoted by $\mathscr{S}_{1}$, define

$$
\mathscr{S} \equiv\left\{E \backslash\{\infty\}: E \in \mathscr{S}_{1}\right\}
$$

and let $\mu$ be the restriction of $\mu_{1}$ to $\mathscr{S}$. If $f \in C_{0}(X)$,

$$
L f=\theta^{*} i^{*} L_{1} f \equiv L_{1} i \theta f=L_{1} \theta f=\int_{\widetilde{X}} \theta f \sigma d \mu_{1}=\int_{X} f \sigma d \mu
$$

This proves the corollary.

### 20.8 More Attractive Formulations

In this section, Corollary 20.7 .1 will be refined and placed in an arguably more attractive form. The measures involved will always be complex Borel measures defined on a $\sigma$ algebra of subsets of $X$, a locally compact Hausdorff space.

Definition 20.8.1 Let $\lambda$ be a complex measure. Then $\int f d \lambda \equiv \int f h d|\lambda|$ where $h d|\lambda|$ is the polar decomposition of $\lambda$ described above. The complex measure, $\lambda$ is called regular if $|\lambda|$ is regular.

The following lemma says that the difference of regular complex measures is also regular.

Lemma 20.8.2 Suppose $\lambda_{i}, i=1,2$ is a complex Borel measure with total variation finite ${ }^{2}$ defined on $X$, a locally compact Hausdorf space. Then $\lambda_{1}-\lambda_{2}$ is also a regular measure on the Borel sets.

Proof: Let $E$ be a Borel set. That way it is in the $\sigma$ algebras associated with both $\lambda_{i}$. Then by regularity of $\lambda_{i}$, there exist $K$ and $V$ compact and open respectively such that $K \subseteq E \subseteq V$ and $\left|\lambda_{i}\right|(V \backslash K)<\varepsilon / 2$. Therefore,

$$
\begin{aligned}
\sum_{A \in \pi(V \backslash K)}\left|\left(\lambda_{1}-\lambda_{2}\right)(A)\right| & =\sum_{A \in \pi(V \backslash K)}\left|\lambda_{1}(A)-\lambda_{2}(A)\right| \\
& \leq \sum_{A \in \pi(V \backslash K)}\left|\lambda_{1}(A)\right|+\left|\lambda_{2}(A)\right| \\
& \leq\left|\lambda_{1}\right|(V \backslash K)+\left|\lambda_{2}\right|(V \backslash K)<\varepsilon .
\end{aligned}
$$

Therefore, $\left|\lambda_{1}-\lambda_{2}\right|(V \backslash K) \leq \varepsilon$ and this shows $\lambda_{1}-\lambda_{2}$ is regular as claimed.
Theorem 20.8.3 Let $L \in C_{0}(X)^{\prime}$ Then there exists a unique complex measure, $\lambda$ with $|\lambda|$ regular and Borel, such that for all $f \in C_{0}(X)$,

$$
L(f)=\int_{X} f d \lambda
$$

Furthermore, $\|L\|=|\lambda|(X)$.
Proof: By Corollary 20.7.1 there exists $\sigma \in L^{\infty}(X, \mu)$ where $\mu$ is a Radon measure such that for all $f \in C_{0}(X)$,

$$
L(f)=\int_{X} f \sigma d \mu
$$

Let a complex Borel measure, $\lambda$ be given by

$$
\lambda(E) \equiv \int_{E} \sigma d \mu
$$

This is a well defined complex measure because $\mu$ is a finite measure. By Corollary 20.2.10

$$
\begin{equation*}
|\lambda|(E)=\int_{E}|\sigma| d \mu \tag{20.8.21}
\end{equation*}
$$

and $\sigma=g|\sigma|$ where $g d|\lambda|$ is the polar decomposition for $\lambda$. Therefore, for $f \in C_{0}(X)$,

$$
\begin{equation*}
L(f)=\int_{X} f \sigma d \mu=\int_{X} f g|\sigma| d \mu=\int_{X} f g d|\lambda| \equiv \int_{X} f d \lambda \tag{20.8.22}
\end{equation*}
$$

From 20.8.21 and the regularity of $\mu$, it follows that $|\lambda|$ is also regular.

[^18]What of the claim about $\|L\|$ ? By the regularity of $|\lambda|$, it follows that $C_{0}(X)$ (In fact, $\left.C_{c}(X)\right)$ is dense in $L^{1}(X,|\lambda|)$. Since $|\lambda|$ is finite, $g \in L^{1}(X,|\lambda|)$. Therefore, there exists a sequence of functions in $C_{0}(X),\left\{f_{n}\right\}$ such that $f_{n} \rightarrow \bar{g}$ in $L^{1}(X,|\lambda|)$. Therefore, there exists a subsequence, still denoted by $\left\{f_{n}\right\}$ such that $f_{n}(x) \rightarrow \bar{g}(x)|\lambda|$ a.e. also. But since $|\bar{g}(x)|=1$ a.e. it follows that $h_{n}(x) \equiv \frac{f_{n}(x)}{\left|f_{n}(x)\right|+\frac{1}{n}}$ also converges pointwise $|\lambda|$ a.e. Then from the dominated convergence theorem and 20.8.22

$$
\|L\| \geq \lim _{n \rightarrow \infty} \int_{X} h_{n} g d|\lambda|=|\lambda|(X)
$$

Also, if $\|f\|_{C_{0}(X)} \leq 1$, then

$$
|L(f)|=\left|\int_{X} f g d\right| \lambda| | \leq \int_{X}|f| d|\lambda| \leq|\lambda|(X)\|f\|_{C_{0}(X)}
$$

and so $\|L\| \leq|\lambda|(X)$. This proves everything but uniqueness.
Suppose $\lambda$ and $\lambda_{1}$ both work. Then for all $f \in C_{0}(X)$,

$$
0=\int_{X} f d\left(\lambda-\lambda_{1}\right)=\int_{X} f h d\left|\lambda-\lambda_{1}\right|
$$

where $h d\left|\lambda-\lambda_{1}\right|$ is the polar decomposition for $\lambda-\lambda_{1}$. By Lemma 20.8.2 $\lambda-\lambda_{1}$ is regular and so, as above, there exists $\left\{f_{n}\right\}$ such that $\left|f_{n}\right| \leq 1$ and $f_{n} \rightarrow \bar{h}$ pointwise. Therefore, $\int_{X} d\left|\lambda-\lambda_{1}\right|=0$ so $\lambda=\lambda_{1}$. This proves the theorem.

### 20.9 Sequential Compactness In $L^{1}$

Lemma 20.9.1 Let $\mathscr{C} \equiv\left\{E_{i}\right\}_{i=1}^{\infty}$ be a countable collection of sets and let $\Omega_{1} \equiv \cup_{i=1}^{\infty} E_{i}$. Then there exists an algebra of sets, $\mathscr{A}$, such that $\mathscr{A} \supseteq \mathscr{C}$ and $\mathscr{A}$ is countable.

Proof: Let $\mathscr{C}_{1}$ denote all finite unions of sets of $\mathscr{C}$ and also include $\Omega_{1}$ and $\emptyset$. Thus $\mathscr{C}_{1}$ is countable. Next let $\mathscr{B}_{1}$ denote all sets of the form $\Omega_{1} \backslash A$ such that $A \in \mathscr{C}_{1}$. Next let $\mathscr{C}_{2}$ denote all finite unions of sets of $\mathscr{B}_{1} \cup \mathscr{C}_{1}$. Then let $\mathscr{B}_{2}$ denote all sets of the form $\Omega_{1} \backslash A$ such that $A \in \mathscr{C}_{2}$ and let $\mathscr{C}_{3}=\mathscr{B}_{2} \cup \mathscr{C}_{2}$. Continuing this way yields an increasing sequence, $\left\{\mathscr{C}_{n}\right\}$ each of which is countable. Let

$$
\mathscr{A} \equiv \cup_{i=1}^{\infty} \mathscr{C}_{i}
$$

Then $\mathscr{A}$ is countable. Also $\mathscr{A}$ is an algebra. Here is why. Suppose $A, B \in \mathscr{A}$. Then there exists $n$ such that both $A, B \in \mathscr{C}_{n-1}$. It follows $A \cup B \in \mathscr{C}_{n} \subseteq \mathscr{A}$ from the construction. It only remains to show that $A \backslash B \in \mathscr{A}$. Taking complements with respect to $\Omega_{1}$, it follows from the construction that $A^{C}, B^{C}$ are both in $\mathscr{B}_{n-1} \subseteq \mathscr{C}_{n}$. Thus,

$$
A^{C} \cup B \in \mathscr{C}_{n}
$$

and so

$$
A \backslash B=\left(A^{C} \cup B\right)^{C} \in \mathscr{B}_{n} \subseteq \mathscr{C}_{n+1} \subseteq \mathscr{A}
$$

This shows $\mathscr{A}$ is an algebra of sets of $\Omega_{1}$ which is also countable and contains $\mathscr{C}$.

Lemma 20.9.2 Let $\left\{f_{n}\right\}$ be a sequence of functions in $L^{1}(\Omega, \mathscr{S}, \mu)$. Then there exists a $\sigma$ finite set of $\mathscr{S}, \Omega_{1}$, and a $\sigma$ algebra of subsets of $\Omega_{1}, \mathscr{S}_{1}$, such that $\mathscr{S}_{1} \subseteq \mathscr{S}, f_{n}=0$ off $\Omega_{1}, f_{n} \in L^{1}\left(\Omega_{1}, \mathscr{S}_{1}, \mu\right)$, and $\mathscr{S}_{1}=\sigma(\mathscr{A})$, the $\sigma$ algebra generated by $\mathscr{A}$, for some $\mathscr{A}$ a countable algebra.

Proof: Let $\mathscr{E}_{n}$ denote the sets which are of the form

$$
\left\{f_{n}^{-1}(B(z, r)): z \in \mathbb{Q}+i \mathbb{Q}, r>0, r \in \mathbb{Q}, \text { and } 0 \notin \overline{B(z, r)}\right\}
$$

Since each $\mathscr{E}_{n}$ is countable, so is

$$
\mathscr{E} \equiv \cup_{n=1}^{\infty} \mathscr{E}_{n}
$$

Now let $\Omega_{1} \equiv \cup \mathscr{E}$. I claim $\Omega_{1}$ is $\sigma$ finite. To see this, let

$$
W_{n}=\left\{\omega \in \Omega:\left|f_{k}(\omega)\right|>\frac{1}{n} \text { for some } k=1,2, \cdots, n\right\}
$$

Thus if $\omega \in W_{n}$, it follows that for some $r \in \mathbb{Q}, z \in \mathbb{Q}+i \mathbb{Q}$ sufficiently close to $f_{k}(\omega)$

$$
\omega \in f_{k}^{-1}(B(z, r)) \in \mathscr{E}_{k}
$$

and so $\omega \in \cup_{k=1}^{n} \mathscr{E}_{k}$ and consequently, $W_{n} \in \cup_{k=1}^{n} \mathscr{E}_{k}$. Also

$$
\mu\left(W_{n}\right) \frac{1}{n} \leq \int_{W_{n}} \sum_{k=1}^{n}\left|f_{k}(\omega)\right| d \mu<\infty .
$$

Now if $\omega \in \Omega_{1}$, then for some $k, \omega$ is contained in a set of $\mathscr{E}_{k}$. Therefore, for that $k$,

$$
f_{k}(\omega) \in B(z, r)
$$

where $r$ is a positive rational number and $z \in \mathbb{Q}+i \mathbb{Q}$ and $\overline{B(z, r)}$ does not contain 0 . Therefore, $f_{k}(\omega)$ is at a positive distance from 0 and so for large enough $n, \omega \in W_{n}$. Take $n$ so large that $1 / n$ is less than the distance from $\overline{B(z, r)}$ to 0 and also larger than $k$.

By Lemma 20.9.1 there exists a countable algebra of sets $\mathscr{A}$ which contains $\mathscr{E}$. Let $\mathscr{S}_{1} \equiv \sigma(\mathscr{A})$. It remains to show $f_{n}(\omega)=0$ off $\Omega_{1}$ for all $n$. Let $\omega \notin \Omega_{1}$. Then $\omega$ is not contained in any set of $\mathscr{E}_{k}$ and so $f_{k}(\omega)$ cannot be nonzero. Hence $f_{k}(\omega)=0$. This proves the lemma.

The following Theorem is the main result on sequential compactness in $L^{1}(\Omega, \mathscr{S}, \mu)$.
Theorem 20.9.3 Let $K \subseteq L^{1}(\Omega, \mathscr{S}, \mu)$ be such that for some $C>0$ and all $f \in K$,

$$
\begin{equation*}
\|f\|_{L^{1}} \leq C \tag{20.9.23}
\end{equation*}
$$

and $K$ also satisfies the property that if $\left\{E_{n}\right\}$ is a decreasing sequence of measurable sets such that $\cap_{n=1}^{\infty} E_{n}=\emptyset$, then for all $\varepsilon>0$ there exists $n_{\varepsilon}$ such that if $n \geq n_{\varepsilon}$, then

$$
\begin{equation*}
\left|\int_{E_{n}} f d \mu\right|<\varepsilon \tag{20.9.24}
\end{equation*}
$$

for all $f \in K$. Then every sequence of functions of $K$ has an $L^{1}(\Omega, \mu)$ weakly convergent subsequence.

Proof: Take $\left\{f_{n}\right\}$ a sequence in $K$ and let $\mathscr{A}, \mathscr{S}_{1}, \Omega_{1}$ be as in Lemma 20.9.2. Thus $\mathscr{A}$ is a countable algebra and by assumption, for each $E \in \mathscr{A}$,

$$
\left\{\int_{E} f_{n} d \mu\right\}
$$

is a bounded sequence and so there exists a convergent subsequence. Therefore, from a Cantor diagonalization argument, there exists a subsequence, denoted by $\left\{g_{n}\right\}$ such that

$$
\left\{\int_{E} g_{n} d \mu\right\}
$$

converges for every $E \in \mathscr{A}$.
Let

$$
\mathscr{M} \equiv\left\{E \in \mathscr{S}_{1}=\sigma(\mathscr{A}) \text { such that } \lim _{n \rightarrow \infty} \int_{E} g_{n} d \mu \text { exists }\right\}
$$

Then it has been shown that $\mathscr{A} \subseteq \mathscr{M}$. Suppose $E_{k} \uparrow E$ where $E_{k} \in \mathscr{M}$. Then letting $\varepsilon>0$ be given, the assumption shows that for $k$ large enough,

$$
\left|\int_{E \backslash E_{k}} g_{n} d \mu\right|<\varepsilon
$$

for all $g_{n}$. Therefore, picking such a $k$,

$$
\left|\int_{E} g_{n} d \mu-\int_{E} g_{m} d \mu\right| \leq 2 \varepsilon+\left|\int_{E_{k}} g_{n} d \mu-\int_{E_{k}} g_{m} d \mu\right|<3 \varepsilon
$$

provided $m, n$ are large enough. Therefore, $\left\{\int_{E} g_{n} d \mu\right\}$ is a Cauchy sequence and so it converges.

In the case that $E_{k} \downarrow E$ use the assumption to conclude there exists a $k$ large enough that

$$
\left|\int_{E_{k} \backslash E} g_{n} d \mu\right|<\varepsilon
$$

for all $g_{n}$. Then

$$
\begin{aligned}
\left|\int_{E} g_{n} d \mu-\int_{E} g_{m} d \mu\right|= & \left|\int_{E_{k}} g_{n} d \mu-\int_{E_{k}} g_{m} d \mu\right| \\
& +\left|\int_{E_{k} \backslash E} g_{n} d \mu\right|+\left|\int_{E_{k} \backslash E} g_{m} d \mu\right| \\
\leq & \left|\int_{E_{k}} g_{n} d \mu-\int_{E_{k}} g_{m} d \mu\right|+2 \varepsilon<3 \varepsilon
\end{aligned}
$$

provided $m, n$ large enough. Again $\left\{\int_{E} g_{n} d \mu\right\}$ is a Cauchy sequence. This shows $\mathscr{M}$ is a monotone class and so by the monotone class theorem, Theorem 12.10.5 on Page 320 it follows $\mathscr{M}=\mathscr{S}_{1} \equiv \sigma(\mathscr{A})$.

Therefore, picking $E \in \mathscr{S}_{1}$, you can define a complex measure,

$$
\lambda(E) \equiv \lim _{n \rightarrow \infty} \int_{E} g_{n} d \mu
$$

Then $\lambda \ll \mu$ and so by Corollary 20.2.9 on Page 609 and the fact shown above that $\Omega_{1}$ is $\sigma$ finite there exists a unique $\mathscr{S}_{1}$ measurable $g \in L^{1}\left(\Omega_{1}, \mu\right)$ such that

$$
\lambda(E)=\int_{E} g d \mu \equiv \lim _{n \rightarrow \infty} \int_{E} g_{n} d \mu
$$

Extend $g$ to equal 0 outside $\Omega_{1}$.
It remains to show $\left\{g_{n}\right\}$ converges weakly. It has just been shown that for every $s$ a simple function measurable with respect to $\mathscr{S}_{1}$

$$
\int_{\Omega} g_{n} s d \mu=\int_{\Omega_{1}} g_{n} s d \mu \rightarrow \int_{\Omega_{1}} g s d \mu=\int_{\Omega} g s d \mu
$$

Now let $f \in L^{\infty}\left(\Omega_{1}, \mathscr{S}_{1}, \mu\right)$ and pick a uniformly bounded representative of this function. Then by Theorem 11.3.9 on Page 241 there exists a sequence of simple functions converging uniformly to $f$ and so

$$
\left\{\int_{\Omega} g_{n} f d \mu\right\}
$$

converges because

$$
\begin{aligned}
\left|\int_{\Omega} g_{n} f d \mu-\int_{\Omega} g f d \mu\right| \leq & \left|\int_{\Omega} g_{n} s d \mu-\int_{\Omega} g s d \mu\right| \\
& +\int_{\Omega}\left|g_{n}\right| \varepsilon d \mu+\int_{\Omega}|g| \varepsilon d \mu \\
\leq & C \varepsilon+\left|\left|g \|_{1} \varepsilon+\left|\int_{\Omega} g_{n} s d \mu-\int_{\Omega} g s d \mu\right|\right.\right.
\end{aligned}
$$

for suitable simple $s$ satisfying $\sup _{\omega \in \Omega_{1}}|s(\omega)-f(\omega)|<\varepsilon$ and the last term converges to 0 as $n \rightarrow \infty$.
$\left(L^{1}(\Omega, \mathscr{S}, \mu)\right)^{\prime}$ is a space I don't know much about due to a possible lack of $\sigma$ finiteness of $\Omega$. However, it does follow that for $i$ the inclusion map of $L^{1}\left(\Omega_{1}, \mathscr{S}_{1}, \mu\right)$ into $L^{1}(\Omega, \mathscr{S}, \mu)$ which merely extends the function as 0 off $\Omega_{1}$ and $f \in\left(L^{1}(\Omega, \mathscr{S}, \mu)\right)^{\prime}$, there exists $h \in L^{\infty}\left(\Omega_{1}\right)$ such that for all $g \in L^{1}\left(\Omega_{1}, \mathscr{S}_{1}, \mu\right)$

$$
i^{*} f(g)=\int_{\Omega_{1}} h g d \mu
$$

This is because $i^{*} f \in\left(L^{1}\left(\Omega_{1}, \mathscr{S}_{1}, \mu\right)\right)^{\prime}$ and $\Omega_{1}$ is $\sigma$ finite and so the Riesz representation theorem applies to get a unique such $h \in L^{\infty}\left(\Omega_{1}\right)$. Then since all the $g_{n}$ equal 0 off $\Omega_{1}$,

$$
f\left(g_{n}\right)=i^{*} f\left(g_{n}\right)=\int_{\Omega_{1}} h g_{n} d \mu
$$

for a unique $h \in L^{\infty}\left(\Omega_{1}, \mathscr{S}_{1}, \mu\right)$ due to the Riesz representation theorem which holds here because $\Omega_{1}$ was shown to be $\sigma$ finite. Therefore,

$$
\lim _{n \rightarrow \infty} f\left(g_{n}\right)=\lim _{n \rightarrow \infty} \int_{\Omega_{1}} h g_{n} d \mu=\int_{\Omega_{1}} h g d \mu=i^{*} f(g)=f(g)
$$

This proves the theorem.
For more on this theorem see [45]. I have only discussed the sufficiency of the conditions to give sequential compactness. They also discuss the necessity of these conditions.

There is another nice condition which implies the above results which is seen in books on probability. It is the concept of equi integrability.

Definition 20.9.4 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space in which $\mu(\Omega)<\infty$. Then

$$
K \subseteq L^{1}(\Omega, \mathscr{S}, \mu)
$$

is said to be equi integrable if

$$
\lim _{\lambda \rightarrow \infty} \sup _{f \in K} \int_{[|f| \geq \lambda]}|f| d \mu=0
$$

Lemma 20.9.5 Let $K$ be an equi integrable set. Then there exists $C>0$ such that for all $f \in K$,

$$
\begin{equation*}
\|f\|_{L^{1}} \leq C \tag{20.9.25}
\end{equation*}
$$

and $K$ also satisfies the property that if $\left\{E_{n}\right\}$ is a decreasing sequence of measurable sets such that $\cap_{n=1}^{\infty} E_{n}=\emptyset$, then for all $\varepsilon>0$ there exists $n_{\varepsilon}$ such that if $n \geq n_{\varepsilon}$, then

$$
\begin{equation*}
\left|\int_{E_{n}} f d \mu\right|<\varepsilon \tag{20.9.26}
\end{equation*}
$$

for all $f \in K$.
Proof: Choose $\lambda_{0}$ such that

$$
\sup _{f \in K} \int_{\left[|f| \geq \lambda_{0}\right]}|f| d \mu \leq 1
$$

Then for $f \in K$,

$$
\begin{aligned}
\int_{\Omega}|f| d \mu & =\int_{\left[|f| \geq \lambda_{0}\right]}|f| d \mu+\int_{\left[|f|<\lambda_{0}\right]}|f| d \mu \\
& \leq 1+\lambda_{0} \mu(\Omega) \equiv C
\end{aligned}
$$

and this proves 20.9.25.
Next suppose $\left\{E_{n}\right\}$ is a decreasing sequence which has empty intersection and let $\varepsilon>0$ and choose $\lambda_{\varepsilon}$ such that

$$
\sup _{f \in K} \int_{\left[|f| \geq \lambda_{\varepsilon}\right]}|f| d \mu \leq \varepsilon / 2 .
$$

Then since $\mu$ is finite, there exists $n_{\varepsilon}$ such that if $n \geq n_{\varepsilon}$, then $\mu\left(E_{n}\right) \leq \varepsilon / 2\left(1+\lambda_{\varepsilon}\right)$. Then letting $f \in K$,

$$
\begin{aligned}
\int_{E_{n}}|f| d \mu & =\int_{E_{n} \cap\left[|f| \geq \lambda_{\varepsilon}\right]}|f| d \mu+\int_{E_{n} \cap\left[|f|<\lambda_{\varepsilon}\right]}|f| d \mu \\
& \leq \varepsilon / 2+\int_{E_{n}} \lambda_{\varepsilon} d \mu<\varepsilon / 2+\varepsilon / 2=\varepsilon
\end{aligned}
$$

This proves 20.9.26
Corollary 20.9.6 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space in which $\mu(\Omega)<\infty$ and let $K \subseteq$ $L^{1}(\Omega, \mathscr{S}, \mu)$ be equi integrable. Then every sequence from $K$ has a weakly convergent subsequence.

Proof: From Lemma 20.9.5 the hypotheses of Theorem 20.9.3 are satisfied.
It is also convenient to consider the following proposition.
Proposition 20.9.7 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space in which $\mu(\Omega)<\infty$. Then $K \subseteq$ $L^{1}(\Omega, \mathscr{S}, \mu)$ is equi integrable if and only if $K$ is uniformly integrable and there exists a constant, $M$ such that for all $f \in K,\|f\|_{L^{1}} \leq M$.

Proof: First suppose $K$ is equi integrable. Then pick $\lambda$ such that for all $f \in K$,

$$
\int_{[|f| \geq \lambda]}|f| d \mu<1
$$

Then for $f \in K$

$$
\begin{aligned}
\int_{\Omega}|f| d \mu & =\int_{[|f| \geq \lambda]}|f| d \mu+\int_{[|f|<\lambda]}|f| d \mu \\
& \leq 1+\lambda \mu(\Omega) \equiv M
\end{aligned}
$$

Also, if $\varepsilon>0$, pick $\lambda$ so large that for all $f \in K$

$$
\int_{[|f| \geq \lambda]}|f| d \mu<\frac{\varepsilon}{2}
$$

Then letting $A \in \mathscr{S}$,

$$
\begin{aligned}
\int_{A}|f| d \mu & =\int_{A \cap[|f| \geq \lambda]}|f| d \mu+\int_{A \cap[|f|<\lambda]}|f| d \mu \\
& <\frac{\varepsilon}{2}+\lambda P(A)
\end{aligned}
$$

and so if $P(A)$ is sufficiently small, this is less than $\varepsilon$. Thus $K$ is uniformly integrable.
Now suppose $\|f\|_{1} \leq M$ for all $f \in K$ and $K$ is uniformly integrable. Then

$$
\int_{[|f| \geq \lambda]}|f| d \mu \geq \lambda P([|f| \geq \lambda])
$$

and so

$$
P([|f| \geq \lambda]) \leq \frac{1}{\lambda} \int_{[|f| \geq \lambda]}|f| d \mu \leq \frac{1}{\lambda} \int_{\Omega}|f| d \mu \leq \frac{M}{\lambda}
$$

and so, by the assumption of uniform integrability,

$$
\int_{[|f| \geq \lambda]}|f| d \mu<\varepsilon
$$

for all $f \in K$ provided $\lambda$ is large enough. This proves the proposition.

### 20.10 Exercises

1. Suppose $\mu$ is a vector measure having values in $\mathbb{R}^{n}$ or $\mathbb{C}^{n}$. Can you show that $|\mu|$ must be finite? Hint: You might define for each $\mathbf{e}_{i}$, one of the standard basis vectors, the real or complex measure, $\mu_{\mathbf{e}_{i}}$ given by $\mu_{\mathbf{e}_{i}}(E) \equiv \mathbf{e}_{i} \cdot \mu(E)$. Why would this approach not yield anything for an infinite dimensional normed linear space in place of $\mathbb{R}^{n}$ ?
2. The Riesz representation theorem of the $L^{p}$ spaces can be used to prove a very interesting inequality. Let $r, p, q \in(1, \infty)$ satisfy

$$
\frac{1}{r}=\frac{1}{p}+\frac{1}{q}-1
$$

Then

$$
\frac{1}{q}=1+\frac{1}{r}-\frac{1}{p}>\frac{1}{r}
$$

and so $r>q$. Let $\theta \in(0,1)$ be chosen so that $\theta r=q$. Then also we have

$$
\frac{1}{r}=(\overbrace{1-\frac{1}{p^{\prime}}}^{1 / p+1 / p^{\prime}=1})+\frac{1}{q}-1=\frac{1}{q}-\frac{1}{p^{\prime}}
$$

and so

$$
\frac{\theta}{q}=\frac{1}{q}-\frac{1}{p^{\prime}}
$$

which implies $p^{\prime}(1-\theta)=q$. Now let $f \in L^{p}\left(\mathbb{R}^{n}\right), g \in L^{q}\left(\mathbb{R}^{n}\right), f, g \geq 0$. Justify the steps in the following argument using what was just shown that $\theta r=q$ and $p^{\prime}(1-\theta)=q$. Let

$$
\begin{gathered}
h \in L^{r^{\prime}}\left(\mathbb{R}^{n}\right) \cdot\left(\frac{1}{r}+\frac{1}{r^{\prime}}=1\right) \\
\int f * g(\mathbf{x})|h(\mathbf{x})| d x=\iint f(\mathbf{y}) g(\mathbf{x}-\mathbf{y})|h(\mathbf{x})| d x d y \\
\leq \iint|f(\mathbf{y})||g(\mathbf{x}-\mathbf{y})|^{\theta}|g(\mathbf{x}-\mathbf{y})|^{1-\theta}|h(\mathbf{x})| d y d x
\end{gathered}
$$

$$
\begin{gather*}
\leq \int\left(\int\left(|g(\mathbf{x}-\mathbf{y})|^{1-\theta}|h(\mathbf{x})|\right)^{r^{\prime}} d x\right)^{1 / r^{\prime}} \cdot \\
\left(\int\left(|f(\mathbf{y})||g(\mathbf{x}-\mathbf{y})|^{\theta}\right)^{r} d x\right)^{1 / r} d y \\
\leq\left[\int\left(\int\left(|g(\mathbf{x}-\mathbf{y})|^{1-\theta}|h(\mathbf{x})|\right)^{r^{\prime}} d x\right)^{p^{\prime} / r^{\prime}} d y\right]^{1 / p^{\prime}} \cdot \\
\leq\left[\int\left(\int\left(|g(\mathbf{x}-\mathbf{y})|^{1-\theta}|h(\mathbf{x})|\right)^{p^{\prime}} d y\right)^{r^{\prime} / p^{\prime}} d x\right]^{1 / r^{\prime}} \cdot \\
\left.\left.\leq\left[\left.\int(\mathbf{y})| | g(\mathbf{x}-\mathbf{y})\right|^{\theta}\right)^{r} d x\right)^{p / r} d y\right]^{1 / p} \\
=\left[\int|h(\mathbf{x})|^{r^{\prime}}\left(\int|g(\mathbf{x}-\mathbf{y})|^{(1-\theta) p^{\prime}} d y\right)^{r^{\prime} / p^{\prime}} d x\right]^{1 / r^{\prime}}\|g\|_{q}^{q / r}\|f\|_{p} \\
=\left[\left.\int(\mathbf{y})\right|^{p}\left(\int|g(\mathbf{x}-\mathbf{y})|^{\theta r} d x\right)^{1 / r} d y\right]^{1 / p} \\
=\|g\|_{q}^{q / r}\|g\|_{q}^{q / p^{\prime}}\|f\|_{p}\|h\|_{r^{\prime}=\|g\|_{q}\|f\|_{p}\|h\|_{r^{\prime}} .} \tag{20.10.27}
\end{gather*}
$$

Young's inequality says that

$$
\begin{equation*}
\|f * g\|_{r} \leq\|g\|_{q}\|f\|_{p} \tag{20.10.28}
\end{equation*}
$$

Therefore $\|f * g\|_{r} \leq\|g\|_{q}\|f\|_{p}$. How does this inequality follow from the above computation? Does 20.10 .27 continue to hold if $r, p, q$ are only assumed to be in $[1, \infty]$ ? Explain. Does 20.10.28 hold even if $r, p$, and $q$ are only assumed to lie in $[1, \infty]$ ?
3. Show that in a reflexive Banach space, weak and weak $*$ convergence are the same.
4. Suppose $(\Omega, \mu, \mathscr{S})$ is a finite measure space and that $\left\{f_{n}\right\}$ is a sequence of functions which converge weakly to 0 in $L^{p}(\Omega)$. Suppose also that $f_{n}(x) \rightarrow 0$ a.e. Show that then $f_{n} \rightarrow 0$ in $L^{p-\varepsilon}(\Omega)$ for every $p>\varepsilon>0$.
5. Give an example of a sequence of functions in $L^{\infty}(-\pi, \pi)$ which converges weak $*$ to zero but which does not converge pointwise a.e. to zero.

## The Bochner Integral

### 21.1 Strong and Weak Measurability

In this chapter $(\Omega, \mathscr{S}, \mu)$ will be a $\sigma$ finite measure space and $X$ will be a Banach space which contains the values of either a function or a measure. The Banach space will be either a real or a complex Banach space but the field of scalars does not matter and so it is denoted by $\mathbb{F}$ with the understanding that $\mathbb{F}=\mathbb{C}$ unless otherwise stated. The theory presented here includes the case where $X=\mathbb{R}^{n}$ or $\mathbb{C}^{n}$ but it does not include the situation where $f$ could have values in something like $[0, \infty]$ which is not a vector space. To begin with here is a definition.

Definition 21.1. 1 A function, $x: \Omega \rightarrow X$, for $X$ a Banach space, is a simple function if it is of the form

$$
x(s)=\sum_{i=1}^{n} a_{i} \mathscr{X}_{B_{i}}(s)
$$

where $B_{i} \in \mathscr{S}$ and $\mu\left(B_{i}\right)<\infty$ for each $i$. A function $x$ from $\Omega$ to $X$ is said to be strongly measurable if there exists a sequence of simple functions $\left\{x_{n}\right\}$ converging pointwise to $x$. The function $x$ is said to be weakly measurable if, for each $f \in X^{\prime}, f \circ x$ is a scalar valued measurable function.

The approximating simple functions can be modified so that the norm of each is no more than $2\|x(s)\|$. This is a useful observation.

Lemma 21.1.2 Let $x$ be strongly measurable. Then $\|x\|$ is a real valued measurable function. There exists a sequence of simple functions $\left\{y_{n}\right\}$ which converges to $f(s)$ pointwise and also $\left\|y_{n}(s)\right\| \leq 2\|x(s)\|$ for all $s$.

Proof: Consider the first claim. Letting $x_{n}$ be a sequence of simple functions converging to $x$ pointwise, it follows that $\left\|x_{n}\right\|$ is a real valued measurable function. Since $\|x\|$ is a pointwise limit, so is $\|x\|$ a real valued measurable function.

Let $x_{n}(s)$ be simple functions converging to $x(s)$ pointwise as above. Let

$$
x_{n}(s) \equiv \sum_{k=1}^{m_{n}} a_{k}^{n} \mathscr{X}_{E_{k}^{n}}(s)
$$

Then

$$
y_{n}(s) \equiv\left\{\begin{array}{c}
x_{n}(s) \text { if }\left\|x_{n}(s)\right\|<2\|x(s)\| \\
0 \text { if }\left\|x_{n}(s)\right\| \geq 2\|x(s)\|
\end{array}\right.
$$

Thus, for $\left[\left\|a_{k}^{n}\right\| \leq 2\|x\|\right] \equiv\left\{s:\left\|a_{k}^{n}\right\| \leq 2\|x(s)\|\right\}$,

$$
y_{n}(s)=\sum_{k=1}^{m_{n}} a_{k}^{n} \mathscr{X}_{E_{k}^{n} \cap\left[\left\|a_{k}^{n}\right\| \leq 2\|x\|\right]}(s)
$$

It follows $y_{n}$ is a simple function. If $\|x(s)\|=0$, then $y_{n}(s)=0$ and so $y_{n}(s) \rightarrow x(s)$. If $\|x(s)\|>0$, then eventually, $y_{n}(s)=x_{n}(s)$ and so in this case, $y_{n}(s) \rightarrow x(s)$.

Earlier, a function was measurable if inverse images of open sets were measurable. Something similar holds here. The difference is that another condition needs to hold about the values being separable. First is a somewhat obvious lemma.

Lemma 21.1.3 Suppose $S$ is a nonempty subset of a metric space $(X, d)$ and $S \subseteq T$ where $T$ is separable. Then there exists a countable dense subset of $S$.

Proof: Let $D$ be the countable dense subset of $T$. Now consider the countable set $\mathscr{B}$ of balls having center at a point of $D$ and radius a positive rational number such that also, each ball in $\mathscr{B}$ has nonempty intersection with $S$. Let $\mathscr{D}$ consist of a point from $S \cap B$ whenever $B \in \mathscr{B}$. Let $s \in S$ and consider $B(s, \varepsilon)$. Let $r$ be rational with $r<\varepsilon$. Now $B\left(s, \frac{r}{10}\right)$ contains a point $d \in D$. Thus $B\left(d, \frac{r}{10}\right) \in \mathscr{B}$ and in fact, $s \in B\left(d, \frac{r}{10}\right)$. Let $\hat{d} \in \mathscr{D}$. Thus $d(s, \hat{d})<\frac{r}{5}<r<\varepsilon$ so $\hat{d} \in B(s, \varepsilon)$ and this shows that $\mathscr{D}$ is a countable dense subset of $S$ as claimed.

Theorem 21.1.4 $x$ is strongly measurable if and only if $x^{-1}(U)$ is measurable for all $U$ open in $X$ and $x(\Omega)$ is separable. Thus, if $X$ is separable, $x$ is strongly measurable if and only if $x^{-1}(U)$ is measurable for all $U$ open.

Proof: Suppose first $x^{-1}(U)$ is measurable for all $U$ open in $X$ and $x(\Omega)$ is separable. Let $\left\{a_{n}\right\}_{n=1}^{\infty}$ be the dense subset of $x(\Omega)$. It follows $x^{-1}(B)$ is measurable for all $B$ Borel because

$$
\left\{B: x^{-1}(B) \text { is measurable }\right\}
$$

is a $\sigma$ algebra containing the open sets. Let

$$
U_{k}^{n} \equiv\left\{z \in X:\left\|z-a_{k}\right\| \leq \min \left\{\left\{\left\|z-a_{l}\right\|\right\}_{l=1}^{n}\right\} .\right.
$$

In words, $U_{k}^{m}$ is the set of points of $X$ which are as close to $a_{k}$ as they are to any of the $a_{l}$ for $l \leq n$.

$$
B_{k}^{n} \equiv x^{-1}\left(U_{k}^{n}\right), D_{k}^{n} \equiv B_{k}^{n} \backslash\left(\cup_{i=1}^{k-1} B_{i}^{n}\right), D_{1}^{n} \equiv B_{1}^{n}
$$

and $x_{n}(s) \equiv \sum_{k=1}^{n} a_{k} \mathscr{X}_{D_{k}^{n}}(s)$.Thus $x_{n}(s)$ is a closest approximation to $x(s)$ from $\left\{a_{k}\right\}_{k=1}^{n}$ and so $x_{n}(s) \rightarrow x(s)$ because $\left\{a_{n}\right\}_{n=1}^{\infty}$ is dense in $x(\Omega)$. Furthermore, $x_{n}$ is measurable because each $D_{k}^{n}$ is measurable.

Since $(\Omega, \mathscr{S}, \mu)$ is $\sigma$ finite, there exists $\Omega_{n} \uparrow \Omega$ with $\mu\left(\Omega_{n}\right)<\infty$. Let

$$
y_{n}(s) \equiv \mathscr{X}_{\Omega_{n}}(s) x_{n}(s)
$$

Then $y_{n}(s) \rightarrow x(s)$ for each $s$ because for any $s, s \in \Omega_{n}$ if $n$ is large enough. Also $y_{n}$ is a simple function because it equals 0 off a set of finite measure.

Now suppose that $x$ is strongly measurable. Then some sequence of simple functions, $\left\{x_{n}\right\}$, converges pointwise to $x$. Then $x_{n}^{-1}(W)$ is measurable for every open set $W$ because it is just a finite union of measurable sets. Thus, $x_{n}^{-1}(W)$ is measurable for every Borel set $W$. This follows by considering $\left\{W: x_{n}^{-1}(W)\right.$ is measurable $\}$ and observing this is a $\sigma$ algebra which contains the open sets. Since $X$ is a metric space, it follows that if $U$ is an open set in $X$, there exists a sequence of open sets, $\left\{V_{n}\right\}$ which satisfies

$$
\bar{V}_{n} \subseteq U, \bar{V}_{n} \subseteq V_{n+1}, U=\cup_{n=1}^{\infty} V_{n}
$$

Then

$$
x^{-1}\left(V_{m}\right) \subseteq \bigcup_{n<\infty} \bigcap_{k \geq n} x_{k}^{-1}\left(V_{m}\right) \subseteq x^{-1}\left(\bar{V}_{m}\right)
$$

This implies

$$
\begin{gathered}
x^{-1}(U)=\bigcup_{m<\infty} x^{-1}\left(V_{m}\right) \\
\subseteq \bigcup_{m<\infty} \bigcup_{n<\infty} \bigcap_{k \geq n} x_{k}^{-1}\left(V_{m}\right) \subseteq \bigcup_{m<\infty} x^{-1}\left(\bar{V}_{m}\right) \subseteq x^{-1}(U)
\end{gathered}
$$

Since

$$
x^{-1}(U)=\bigcup_{m<\infty} \bigcup_{n<\infty} \bigcap_{k \geq n} x_{k}^{-1}\left(V_{m}\right),
$$

it follows that $x^{-1}(U)$ is measurable for every open $U$. It remains to show $x(\Omega)$ is separable. Let

$$
D \equiv \text { all values of the simple functions } x_{n}
$$

Then $x(\Omega) \subseteq \bar{D}$, which has a countable dense subset. By Lemma 21.1.3, $x(\Omega)$ is separable.
The next lemma is interesting for its own sake. Roughly it says that if a Banach space is separable, then the unit ball in the dual space is weak $*$ separable. This will be used to prove Pettis's theorem, one of the major theorems in this subject which relates weak measurability to strong measurability. First here is a standard application which comes from earlier material on the Hahn Banach theorem.

Lemma 21.1.5 Let $x \in X$ a normed linear space. Then there exists $f \in X^{\prime}$ such that $\|f\|=1$ and $f(x)=\|x\|$.

Proof: Consider the one dimensional subspace

$$
M \equiv\left\{\alpha \frac{x}{\|x\|}: \alpha \in \mathbb{F}\right\}
$$

and define a continuous linear functional on $M$ by $g\left(\alpha \frac{x}{\|x\|}\right) \equiv \alpha$. Then the norm of $\|g\| \equiv$ $\sup _{|\alpha| \leq 1}|\alpha|=1$. Extend $g$ to all of $X$ using the Hahn Banach theorem calling the extended function $f$. Then $\|f\|=1$ and $f(x)=f\left(\|x\| \frac{x}{\|x\|}\right)=\|x\|$.

Lemma 21.1.6 If $X$ is a separable Banach space with $B^{\prime}$ the closed unit ball in $X^{\prime}$, then there exists a sequence $\left\{f_{n}\right\}_{n=1}^{\infty} \equiv D^{\prime} \subseteq B^{\prime}$ with the property that for every $x \in X$,

$$
\|x\|=\sup _{f \in D^{\prime}}|f(x)|
$$

If $H$ is a dense subset of $X^{\prime}$ then $D^{\prime}$ may be chosen to be contained in $H$.

Proof: Let $\left\{a_{k}\right\}_{k=1}^{\infty}$ be a countable dense set in $X$ and consider the mapping

$$
\phi_{n}: B^{\prime} \rightarrow \mathbb{F}^{n}
$$

given by

$$
\phi_{n}(f) \equiv\left(f\left(a_{1}\right), \cdots, f\left(a_{n}\right)\right)
$$

Then $\phi_{n}\left(B^{\prime}\right)$ is contained in a compact subset of $\mathbb{F}^{n}$ because $\left|f\left(a_{k}\right)\right| \leq\left\|a_{k}\right\|$. Therefore, there exists a countable dense subset of $\phi_{n}\left(B^{\prime}\right),\left\{\phi_{n}\left(f_{k}\right)\right\}_{k=1}^{\infty}$. Then pick $h_{j}^{k} \in H \cap B^{\prime}$ such that $\lim _{j \rightarrow \infty}\left\|f_{k}-h_{j}^{k}\right\|=0$. Then $\left\{\phi_{n}\left(h_{j}^{k}\right), k, j\right\}$ must also be dense in $\phi_{n}\left(B^{\prime}\right)$. Let $D_{n}^{\prime}=$ $\left\{h_{j}^{k}, k, j\right\}$. Thus $D_{n}^{\prime}$ is a countable collection of $f \in B^{\prime}$ which can be used to approximate each $\left\|a_{k}\right\|, k \leq n$. Indeed, if $x$ is arbitrary, there exists $f_{x} \in B^{\prime}$ with $f_{x}(x)=\|x\|$. Thus $\left\|a_{k}\right\|$ is contained in $\phi_{n}\left(B^{\prime}\right)$. Define

$$
D^{\prime} \equiv \cup_{n=1}^{\infty} D_{n}^{\prime}
$$

From the construction, $D^{\prime}$ is countable and can be used to approximate each $\left\|a_{m}\right\|$. That is,

$$
\left\|a_{m}\right\|=\sup \left\{\left|f\left(a_{m}\right)\right|: f \in D^{\prime}\right\}
$$

Then, for $x$ arbitrary, $|f(x)| \leq\|x\|$ and so

$$
\begin{aligned}
\|x\| & \leq\left\|x-a_{m}\right\|+\left\|a_{m}\right\|=\left\|x-a_{m}\right\|+\sup \left\{\left|f\left(a_{m}\right)\right|: f \in D^{\prime}\right\} \\
& \leq \sup \left\{\left|f\left(a_{m}-x\right)+f(x)\right|: f \in D^{\prime}\right\}+\left\|x-a_{m}\right\| \\
& \leq \sup \left\{|f(x)|: f \in D^{\prime}\right\}+2\left\|x-a_{m}\right\| \leq\|x\|+2\left\|x-a_{m}\right\|
\end{aligned}
$$

Since $a_{m}$ is arbitrary and the $\left\{a_{m}\right\}_{m=1}^{\infty}$ are dense, this establishes the claim of the lemma.
Note that the proof would work the same if $H$ were only given to be weak $*$ dense.
The next theorem is one of the most important results in the subject. It is due to Pettis and appeared in 1938 [107].

Theorem 21.1.7 If $x$ has values in a separable Banach space $X$, then $x$ is weakly measurable if and only if $x$ is strongly measurable.

Proof: $\Rightarrow$ It is necessary to show $x^{-1}(U)$ is measurable whenever $U$ is open. Since every open set is a countable union of balls, it suffices to show $x^{-1}(B(a, r))$ is measurable for any ball, $B(a, r)$. Since every open ball is the countable union of closed balls, it suffices to verify $x^{-1}(\overline{B(a, r)})$ is measurable. For $D^{\prime}$ described in Lemma 21.1.6,

$$
\begin{aligned}
x^{-1}(\overline{B(a, r)}) & =\{s:\|x(s)-a\| \leq r\}=\left\{s: \sup _{f \in D^{\prime}}|f(x(s)-a)| \leq r\right\} \\
& =\cap_{f \in D^{\prime}}\{s:|f(x(s)-a)| \leq r\}=\cap_{f \in D^{\prime}}\{s:|f(x(s))-f(a)| \leq r\} \\
& =\cap_{f \in D^{\prime}}(f \circ x)^{-1} \overline{B(f(a), r)}
\end{aligned}
$$

which equals a countable union of measurable sets because it is assumed that $f \circ x$ is measurable for all $f \in X^{\prime}$.
$\Leftarrow$ Next suppose $x$ is strongly measurable. Then there exists a sequence of simple functions $x_{n}$ which converges to $x$ pointwise. Hence for all $f \in X^{\prime}, f \circ x_{n}$ is measurable and $f \circ x_{n} \rightarrow f \circ x$ pointwise. Thus $x$ is weakly measurable.

The same method of proof yields the following interesting corollary.
Corollary 21.1.8 Let $X$ be a separable Banach space and let $\mathscr{B}(X)$ denote the $\sigma$ algebra of Borel sets. Let $H$ be a dense subset of $X^{\prime}$. Then $\mathscr{B}(X)=\sigma(H) \equiv \mathscr{F}$, the smallest $\sigma$ algebra of subsets of $X$ which has the property that every function, $x^{*} \in H$ is measurable.

Proof: First I need to show $\mathscr{F}$ contains open balls because then $\mathscr{F}$ will contain the open sets and hence the Borel sets. As noted above, it suffices to show $\mathscr{F}$ contains closed balls. Let $D^{\prime}$ be those functionals in $B^{\prime}$ defined in Lemma 21.1.6 contained in $H$. Then

$$
\begin{aligned}
\{x:\|x-a\| \leq r\} & =\left\{x: \sup _{x^{*} \in D^{\prime}}\left|x^{*}(x-a)\right| \leq r\right\} \\
& =\cap_{x^{*} \in D^{\prime}}\left\{x:\left|x^{*}(x-a)\right| \leq r\right\} \\
& =\cap_{x^{*} \in D^{\prime}}\left\{x:\left|x^{*}(x)-x^{*}(a)\right| \leq r\right\} \\
& =\cap_{x^{*} \in D^{\prime}} x^{*-1}\left(\overline{B\left(x^{*}(a), r\right)}\right) \in \sigma(H)
\end{aligned}
$$

which is measurable because this is a countable intersection of measurable sets. Thus $\mathscr{F}$ contains open sets so $\sigma(H) \equiv \mathscr{F} \supseteq \mathscr{B}(X)$.

To show the other direction for the inclusion, note that each $x^{*}$ is $\mathscr{B}(X)$ measurable because $x^{*-1}($ open set $)=$ open set. Therefore, $\mathscr{B}(X) \supseteq \sigma(H)$.

It is important to verify the limit of strongly measurable functions is itself strongly measurable. This happens under very general conditions.

Lemma 21.1.9 Let $X$ be a metric space and suppose $V$ is an open set in $V$. Then there exists open sets $V_{m}$ such that

$$
\begin{equation*}
\cdots V_{m} \subseteq \bar{V}_{m} \subseteq V_{m+1} \subseteq \cdots, V=\bigcup_{m=1}^{\infty} V_{m} \tag{21.1.1}
\end{equation*}
$$

Proof: Recall that if $S$ is a nonempty set, $x \rightarrow \operatorname{dist}(x, S)$ is a continuous map from $X$ to $\mathbb{R}$. First assume $V \neq X$. Let

$$
V_{m} \equiv\left\{x \in V: \operatorname{dist}\left(x, V^{C}\right)>\frac{1}{m}\right\}
$$

Then for large enough $m$, this set is nonempty and contained in $V$. Furthermore, if $x \in V$ then it is at a positive distance to the closed set $V^{C}$ so eventually, $x \in V_{m}$. Now

$$
V_{m} \subseteq \overline{V_{m}} \subseteq\left\{x \in V: \operatorname{dist}\left(x, V^{C}\right) \geq \frac{1}{m}\right\} \subseteq V
$$

Indeed, if $p$ is a limit point of $V_{m}$, then there are $x_{n} \in V_{m}$ with $x_{n} \rightarrow p$. Thus dist $\left(x_{n}, V^{C}\right) \rightarrow$ $\operatorname{dist}\left(p, V^{C}\right)$ and so $p$ is in the set on the right. In case $X=V$, let $V_{m} \equiv B(\xi, m)$. Then $V_{m} \subseteq \overline{V_{m}} \subseteq\left\{x \in V: \operatorname{dist}\left(x, V^{C}\right) \geq \frac{1}{m}\right\}$ and the union of these $V_{m}$ equals $V$.

What of limits of measurable functions? The next theorem says that the usual theorem about limits of measurable functions being measurable holds.

Theorem 21.1.10 Let $x_{n}$ and $x$ be functions mapping $\Omega$ to $X$ where $\mathscr{F}$ is a $\sigma$ algebra of measurable sets of $\Omega$ and $X$ is a Banach space. Thus $X$ satisfies 21.1.1. Then if $x_{n}$ is strongly measurable, and $x(s)=\lim _{n \rightarrow \infty} x_{n}(s)$, it follows that $x$ is also strongly measurable. (Pointwise limits of measurable functions are measurable.)

Proof: Let $\left\{V_{m}\right\}$ be the sequence of 21.1.1. Since $x$ is the pointwise limit of $x_{n}$,

$$
x^{-1}\left(V_{m}\right) \subseteq\left\{s: x_{k}(s) \in V_{m} \text { for all } k \text { large enough }\right\} \subseteq x^{-1}\left(\overline{V_{m}}\right)
$$

Therefore,

$$
\begin{gathered}
x^{-1}(V)=\cup_{m=1}^{\infty} x^{-1}\left(V_{m}\right) \subseteq \cup_{m=1}^{\infty} \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} x_{k}^{-1}\left(V_{m}\right) \\
\subseteq \cup_{m=1}^{\infty} x^{-1}\left(\overline{V_{m}}\right)=x^{-1}(V) .
\end{gathered}
$$

It follows $x^{-1}(V) \in \mathscr{F}$ because it equals the expression in the middle which is measurable. Note that this shows the characterization of measurability in terms of inverse images of open sets being measureable sets. Thus the theorem is proved in the case of separable Banach spaces. However, Lemma 21.1.3 can be applied to conclude that this holds in general because each $x_{n}$ is separably valued given they are each strongly measurable and $x(\Omega) \subseteq \bar{D}$ where $D=\cup_{n} D_{n}$ for $D_{n}$ a countable dense subset of $x_{n}(\Omega)$.

Note that the same conclusion in terms of inverse images being measurable would hold for any metric space.

Corollary 21.1.11 $x$ is strongly measurable if and only if $x(\Omega)$ is separable and $x$ is weakly measurable.

Proof: Strong measurability clearly implies weak measurability. If $x_{n}(s) \rightarrow x(s)$ where $x_{n}$ is simple, then $f\left(x_{n}(s)\right) \rightarrow f(x(s))$ for all $f \in X^{\prime}$. Hence $f \circ x$ is measurable by Theorem 21.1.10 because it is the limit of a sequence of measurable functions. Let $D$ denote the set of all values of $x_{n}$. Then $\bar{D}$ is a separable set containing $x(\Omega)$. Thus $\bar{D}$ is a separable metric space. Therefore $x(\Omega)$ is separable also by the last part of the proof of Theorem 21.1.4.

Now suppose $D$ is a countable dense subset of $x(\Omega)$ and $x$ is weakly measurable. Let $Z$ be the subset consisting of all finite linear combinations of $D$ with the scalars coming from the set of rational points of $\mathbb{F}$. Thus, $Z$ is countable. Letting $Y=\bar{Z}, Y$ is a separable Banach space containing $x(\Omega)$. If $f \in Y^{\prime}, f$ can be extended to an element of $X^{\prime}$ by the Hahn Banach theorem. Therefore, $x$ is a weakly measurable $Y$ valued function. Now use Theorem 21.1.7 to conclude $x$ is strongly measurable.

Weakly measurable as defined above means $s \rightarrow x^{*}(x(s))$ is measurable for every $x^{*} \in$ $X^{\prime}$. The next lemma ties this weak measurability to the usual version of measurability in which a function is measurable when inverse images of open sets are measurable.

Lemma 21.1.12 Let $X$ be a Banach space and let $x:(\Omega, \mathscr{F}) \rightarrow K \subseteq X$ where $K$ is weakly compact and $X^{\prime}$ is separable. Then $x$ is weakly measurable if and only if $x^{-1}(U) \in \mathscr{F}$ whenever $U$ is a weakly open set.

Proof: By Corollary 17.5 .9 on Page 464, there exists a metric $d$, such that the metric space topology with respect to $d$ coincides with the weak topology on $K$. Since $K$ is compact, it follows that $K$ is also separable. Hence it is completely separable and so there exists
a countable basis of open sets $\mathscr{B}$ for the weak topology on $K$. It follows that if $U$ is any weakly open set, covered by basic sets of the form $B_{A}(x, r)$ where $A$ is a finite subset of $X^{\prime}$, there exists a countable collection of these sets of the form $B_{A}(x, r)$ which covers $U$.

Suppose now that $x$ is weakly measurable. To show $x^{-1}(U) \in \mathscr{F}$ whenever $U$ is weakly open, it suffices to verify $x^{-1}\left(B_{A}(z, r)\right) \in \mathscr{F}$ for any set, $B_{A}(z, r)$. Let $A=\left\{x_{1}^{*}, \cdots, x_{m}^{*}\right\}$. Then

$$
\begin{aligned}
x^{-1}\left(B_{A}(z, r)\right) & =\left\{s \in \Omega: \rho_{A}(x(s)-z)<r\right\} \\
& \equiv\left\{s \in \Omega: \max _{x^{*} \in A}\left|x^{*}(x(s)-z)\right|<r\right\} \\
& =\cup_{i=1}^{m}\left\{s \in \Omega:\left|x_{i}^{*}(x(s)-z)\right|<r\right\} \\
& =\cup_{i=1}^{m}\left\{s \in \Omega:\left|x_{i}^{*}(x(s))-x_{i}^{*}(z)\right|<r\right\}
\end{aligned}
$$

which is measurable because each $x_{i}^{*} \circ x$ is given to be measurable.
Next suppose $x^{-1}(U) \in \mathscr{F}$ whenever $U$ is weakly open. Then in particular this holds when $U=B_{x^{*}}(z, r)$ for arbitrary $x^{*}$. Hence

$$
\left\{s \in \Omega: x(s) \in B_{x^{*}}(z, r)\right\} \in \mathscr{F} .
$$

But this says the same as

$$
\left\{s \in \Omega:\left|x^{*}(x(s))-x^{*}(z)\right|<r\right\} \in \mathscr{F}
$$

Since $x^{*}(z)$ can be a completely arbitrary element of $\mathbb{F}$, it follows $x^{*} \circ x$ is an $\mathbb{F}$ valued measurable function. In other words, $x$ is weakly measurable according to the former definition.

One can also define weak $*$ measurability and prove a theorem just like the Pettis theorem above. The next lemma is the analogue of Lemma 21.1.6.

Lemma 21.1.13 Let $B$ be the closed unit ball in $X$. If $X^{\prime}$ is separable, there exists a sequence $\left\{x_{m}\right\}_{m=1}^{\infty} \equiv D \subseteq B$ with the property that for all $y^{*} \in X^{\prime}$,

$$
\left\|y^{*}\right\|=\sup _{x \in D}\left|y^{*}(x)\right| .
$$

Proof: Let $\left\{x_{k}^{*}\right\}_{k=1}^{\infty}$ be the dense subset of $X^{\prime}$. Define $\phi_{n}: B \rightarrow \mathbb{F}^{n}$ by

$$
\phi_{n}(x) \equiv\left(x_{1}^{*}(x), \cdots, x_{n}^{*}(x)\right) .
$$

Then $\left|x_{k}^{*}(x)\right| \leq\left\|x_{k}^{*}\right\|$ and so $\phi_{n}(B)$ is contained in a compact subset of $\mathbb{F}^{n}$. Therefore, there exists a countable set, $D_{n} \subseteq B$ such that $\phi_{n}\left(D_{n}\right)$ is dense in $\phi_{n}(B)$. That is, $\left\{\left(x_{1}^{*}(x), \cdots, x_{n}^{*}(x)\right): x \in D_{n}\right\}$ is dense in $\phi_{n}(B)$.

$$
D \equiv \cup_{n=1}^{\infty} D_{n}
$$

It remains to verify this works. Let $y^{*} \in X^{\prime}$. I want to show that $\left\|y^{*}\right\|=\sup _{x \in D}\left|y^{*}(x)\right|$. There exists $y,\|y\| \leq 1$, such that

$$
\left|y^{*}(y)\right|>\left\|y^{*}\right\|-\varepsilon
$$

By density, there exists one of the $x_{k}^{*}$ from the countable dense subset of $X^{\prime}$ such that also

$$
\left\|x_{k}^{*}-y^{*}\right\|<\varepsilon, \text { so }\left|x_{k}^{*}(y)\right|>\left\|y^{*}\right\|-2 \varepsilon
$$

Now $x_{k}^{*}(y) \in \phi_{k}(B)$ and so there exists $x \in D_{k} \subseteq D \subseteq B$ such that also

$$
\left|x_{k}^{*}(x)\right|>\left\|y^{*}\right\|-2 \varepsilon
$$

Then since $\left\|x_{k}^{*}-y^{*}\right\|<\varepsilon$, this implies

$$
\left\|y^{*}\right\| \geq\left|y^{*}(x)\right|=\left|\left(y^{*}-x_{k}^{*}\right)(x)+x_{k}^{*}(x)\right| \geq\left|x_{k}^{*}(x)\right|-\varepsilon>\left\|y^{*}\right\|-3 \varepsilon
$$

It follows that

$$
\left\|y^{*}\right\|-3 \varepsilon \leq \sup _{x \in D}\left|y^{*}(x)\right| \leq\left\|y^{*}\right\|
$$

This proves the lemma because $\varepsilon$ is arbitrary.
The next theorem is another version of the Pettis theorem. First here is a definition.
Definition 21.1.14 A function y having values in $X^{\prime}$ is weak $*$ measurable, when for each $x \in X, y(\cdot)(x)$ is a measurable scalar valued function.

Theorem 21.1.15 If $X^{\prime}$ is separable and $y: \Omega \rightarrow X^{\prime}$ is weak $*$ measurable meaning $s \rightarrow$ $y(s)(x)$ is a $\mathbb{F}$ valued measurable function, then $y$ is strongly measurable.

Proof: It is necessary to show $y^{-1}\left(B\left(a^{*}, r\right)\right)$ is measurable for $a^{*} \in X^{\prime}$. This will suffice because the separability of $X^{\prime}$ implies every open set is the countable union of such balls of the form $B\left(a^{*}, r\right)$. It also suffices to verify inverse images of closed balls are measurable because every open ball is the countable union of closed balls. From Lemma 21.1.13,

$$
\begin{aligned}
y^{-1}\left(\overline{B\left(a^{*}, r\right)}\right) & =\left\{s:\left\|y(s)-a^{*}\right\| \leq r\right\} \\
& =\left\{s: \sup _{x \in D}\left|\left(y(s)-a^{*}\right)(x)\right| \leq r\right\} \\
& =\left\{s: \sup _{x \in D}\left|y(s)(x)-a^{*}(x)\right| \leq r\right\} \\
& =\cap_{x \in D} y(\cdot)(x)^{-1}\left(\overline{B\left(a^{*}(x), r\right)}\right)
\end{aligned}
$$

which is a countable intersection of measurable sets by hypothesis.
The following are interesting consequences of the theory developed so far and are of interest independent of the theory of integration of vector valued functions.

Theorem 21.1.16 If $X^{\prime}$ is separable, then so is $X$.
Proof: Let $D=\left\{x_{m}\right\} \subseteq B$, the unit ball of $X$, be the sequence promised by Lemma 21.1.13. Let $V$ be all finite linear combinations of elements of $\left\{x_{m}\right\}$ with rational scalars. Thus $\bar{V}$ is a separable subspace of $X$. The claim is that $\bar{V}=X$. If not, there exists

$$
x_{0} \in X \backslash \bar{V}
$$

But by the Hahn Banach theorem there exists $x_{0}^{*} \in X^{\prime}$ satisfying $x_{0}^{*}\left(x_{0}\right) \neq 0$, but $x_{0}^{*}(v)=0$ for every $v \in \bar{V}$. Hence

$$
\left\|x_{0}^{*}\right\|=\sup _{x \in D}\left|x_{0}^{*}(x)\right|=0
$$

a contradiction.
Corollary 21.1.17 If $X$ is reflexive, then $X$ is separable if and only if $X^{\prime}$ is separable.
Proof: From the above theorem, if $X^{\prime}$ is separable, then so is $X$. Now suppose $X$ is separable with a dense subset equal to $D$. Then since $X$ is reflexive, $J(D)$ is dense in $X^{\prime \prime}$ where $J$ is the James map satisfying $J x\left(x^{*}\right) \equiv x^{*}(x)$. Then since $X^{\prime \prime}$ is separable, it follows from the above theorem that $X^{\prime}$ is also separable.

Note how this shows that $L^{1}\left(\mathbb{R}^{p}, m_{p}\right)$ is not reflexive because this is a separable space, but $L^{\infty}\left(\mathbb{R}^{p}, m_{p}\right)$ is clearly not. For example, you could consider $\mathscr{X}_{[0, r]}$ for $r$ a positive irrational number. There are uncountably many of these functions in $L^{\infty}([0,1])$ and

$$
\left\|\mathscr{X}_{[0, r]}-\mathscr{X}_{[0, \hat{r}]}\right\|_{\infty}=1
$$

### 21.2 The Bochner Integral

### 21.2.1 Definition and Basic Properties

Definition 21.2.1 Let $a_{k} \in X$, a Banach space and let a simple function $s \rightarrow x(s)$ be

$$
\begin{equation*}
x(s)=\sum_{k=1}^{n} a_{k} \mathscr{X}_{E_{k}}(s) \tag{21.2.2}
\end{equation*}
$$

where for each $k, E_{k}$ is measurable and $\mu\left(E_{k}\right)<\infty$. Then define

$$
\int_{\Omega} x(s) d \mu \equiv \sum_{k=1}^{n} a_{k} \mu\left(E_{k}\right)
$$

Proposition 21.2.2 Definition 21.2.1 is well defined, the integral is linear on simple functions and

$$
\left\|\int_{\Omega} x(s) d \mu\right\| \leq \int_{\Omega}\|x(s)\| d \mu
$$

whenever $x$ is a simple function.
Proof: It suffices to verify that if $\sum_{k=1}^{n} a_{k} \mathscr{X}_{E_{k}}(s)=0$, then $\sum_{k=1}^{n} a_{k} \mu\left(E_{k}\right)=0$. Let $f \in$ $X^{\prime}$. Then

$$
f\left(\sum_{k=1}^{n} a_{k} \mathscr{X}_{E_{k}}(s)\right)=\sum_{k=1}^{n} f\left(a_{k}\right) \mathscr{X}_{E_{k}}(s)=0
$$

and, therefore,

$$
0=\int_{\Omega}\left(\sum_{k=1}^{n} f\left(a_{k}\right) \mathscr{X}_{E_{k}}(s)\right) d \mu=\sum_{k=1}^{n} f\left(a_{k}\right) \mu\left(E_{k}\right)=f\left(\sum_{k=1}^{n} a_{k} \mu\left(E_{k}\right)\right)
$$

Since $f \in X^{\prime}$ is arbitrary, and $X^{\prime}$ separates the points of $X$, it follows that $\sum_{k=1}^{n} a_{k} \mu\left(E_{k}\right)=0$ as hoped. It is now obvious that the integral is linear on simple functions.

As to the triangle inequality, say $x(s)=\sum_{k=1}^{n} a_{k} \mathscr{X}_{E_{k}}(s)$. Then from the triangle inequality,

$$
\left\|\int_{\Omega} x(s) d \mu\right\|=\left\|\sum_{k=1}^{n} a_{k} \mu\left(E_{k}\right)\right\| \leq \sum_{k=1}^{n}\left\|a_{k}\right\| \mu\left(E_{k}\right)=\int_{\Omega}\|x(s)\| d \mu
$$

Definition 21.2.3 A strongly measurable function $x$ is Bochner integrable if there exists a sequence of simple functions $x_{n}$ converging to $x$ pointwise and satisfying

$$
\begin{equation*}
\int_{\Omega}\left\|x_{n}(s)-x_{m}(s)\right\| d \mu \rightarrow 0 \text { as } m, n \rightarrow \infty \tag{21.2.3}
\end{equation*}
$$

If $x$ is Bochner integrable, define

$$
\begin{equation*}
\int_{\Omega} x(s) d \mu \equiv \lim _{n \rightarrow \infty} \int_{\Omega} x_{n}(s) d \mu \tag{21.2.4}
\end{equation*}
$$

First it is important to show that this integral is well defined. When this is done, an easier to use condition will be developed. Note that by Lemma 21.1.2, if $x$ is strongly measurable, $\|x\|$ is a measurable real valued function. Thus, it makes sense to consider $\int_{\Omega}\|x\| d \mu$ and also $\int_{\Omega}\left\|x-x_{n}\right\| d \mu$.

Theorem 21.2.4 The definition of Bochner integrability is well defined. Also, a strongly measurable function $x$ is Bochner integrable if and only if $\int_{\Omega}\|x\| d \mu<\infty$. In this case that the function is Bochner integrable, an approximating sequence $\left\{y_{n}\right\}$ exists such that $\left\|y_{n}(s)\right\| \leq 2\|x(s)\|$ for all $s$ and

$$
\lim _{n \rightarrow \infty} \int_{\Omega}\left\|y_{n}(s)-x(s)\right\| d \mu=0
$$

Proof: $\Rightarrow$ First consider the claim about the integral being well defined. Let $\left\{x_{n}\right\}$ be a sequence of simple functions converging pointwise to $x$ and satisfying the conditions given above for $x$ to be Bochner integrable. Then

$$
\left|\int_{\Omega}\left\|x_{n}(s)\right\| d \mu-\int_{\Omega}\left\|x_{m}(s)\right\| d \mu\right| \leq \int_{\Omega}\left\|x_{n}-x_{m}\right\| d \mu
$$

which is given to converge to 0 as $n, m \rightarrow \infty$ which shows that $\left\{\int_{\Omega}\left\|x_{n}(s)\right\| d \mu\right\}_{n=1}^{\infty}$ is a Cauchy sequence. Hence it is bounded and so, by Fatou's lemma,

$$
\int_{\Omega}\|x(s)\| d \mu \leq \lim \inf _{n \rightarrow \infty} \int_{\Omega}\left\|x_{n}(s)\right\| d \mu<\infty
$$

The limit in 21.2.4 exists because

$$
\left\|\int_{\Omega} x_{n} d \mu-\int_{\Omega} x_{m} d \mu\right\|=\left\|\int_{\Omega}\left(x_{n}-x_{m}\right) d \mu\right\| \leq \int_{\Omega}\left\|x_{n}-x_{m}\right\| d \mu
$$

and the last term is no more than $\varepsilon$ whenever $n, m$ are large enough. From Fatou's lemma, if $n$ is large enough,

$$
\int_{\Omega}\left\|x_{n}-x\right\| d \mu<\varepsilon
$$

Now if you have another sequence $\left\{\hat{x}_{n}\right\}$ satisfying the condition 21.2.3 along with pointwise convergence to $x$,

$$
\begin{aligned}
\left\|\int_{\Omega} x_{n} d \mu-\int_{\Omega} \hat{x}_{n} d \mu\right\| & =\left\|\int_{\Omega}\left(x_{n}-\hat{x}_{n}\right) d \mu\right\| \leq \int_{\Omega}\left\|x_{n}-\hat{x}_{n}\right\| d \mu \\
& \leq \int_{\Omega}\left\|x_{n}-x\right\| d \mu+\int_{\Omega}\left\|x-\hat{x}_{n}\right\| d \mu<2 \varepsilon
\end{aligned}
$$

if $n$ is large enough. Hence convergence of the integrals of the simple functions takes place and these integrals converge to the same thing. Thus the definition is well defined and $\int_{\Omega}\|x\| d \mu<\infty$.
$\Leftarrow$ Next suppose $\int_{\Omega}\|x\| d \mu<\infty$ for $x$ strongly measurable. By Lemma 21.1.2, there is a sequence of simple functions $\left\{y_{n}\right\}$ with $\left\|y_{n}(s)\right\| \leq 2\|x(s)\|$ and $y_{n}(s) \rightarrow x(s)$ for each $s$. Then by the dominated convergence theorem for scalar valued functions,

$$
\lim _{n \rightarrow \infty} \int_{\Omega}\left\|y_{n}-x\right\| d \mu=0
$$

Thus,

$$
\int_{\Omega}\left\|y_{n}-y_{m}\right\| d \mu \leq \int_{\Omega}\left\|y_{n}-x\right\| d \mu+\int_{\Omega}\left\|x-y_{m}\right\| d \mu<\varepsilon
$$

if $m, n$ are large enough so $\left\{y_{n}\right\}$ is a suitable approximating sequence for $x$.
This is a very nice theorem. It says that all you have to do is verify measurability and absolute integrability just like the case of scalar valued functions. Other things which are totally similar are that the integral is linear, the triangle inequality holds, and you can take a continuous linear functional inside the integral. These things are considered in the following theorem.

Theorem 21.2.5 The Bochner integral is well defined and if $x$ is Bochner integrable and $f \in X^{\prime}$,

$$
\begin{equation*}
f\left(\int_{\Omega} x(s) d \mu\right)=\int_{\Omega} f(x(s)) d \mu \tag{21.2.5}
\end{equation*}
$$

and the triangle inequality is valid,

$$
\begin{equation*}
\left\|\int_{\Omega} x(s) d \mu\right\| \leq \int_{\Omega}\|x(s)\| d \mu \tag{21.2.6}
\end{equation*}
$$

Also, the Bochner integral is linear. That is, if $a, b$ are scalars and $x, y$ are two Bochner integrable functions, then

$$
\begin{equation*}
\int_{\Omega}(a x(s)+b y(s)) d \mu=a \int_{\Omega} x(s) d \mu+b \int_{\Omega} y(s) d \mu \tag{21.2.7}
\end{equation*}
$$

Proof: Theorem 21.2.4 shows $\int_{\Omega}\|x(s)\| d \mu<\infty$ and that the definition of the integral is well defined.

It remains to verify the triangle inequality on Bochner integral functions and the claim about passing a continuous linear functional inside the integral. First of all, consider the triangle inequality. From Lemma 21.1.2, there is a sequence of simple functions $\left\{y_{n}\right\}$ satisfying 21.2.3 and converging to $x$ pointwise such that also $\left\|y_{n}(s)\right\| \leq 2\|x(s)\|$. Thus,

$$
\left\|\int_{\Omega} x(s) d \mu\right\| \equiv \lim _{n \rightarrow \infty}\left\|\int_{\Omega} y_{n}(s) d \mu\right\| \leq \lim _{n \rightarrow \infty} \int_{\Omega}\left\|y_{n}(s)\right\| d \mu=\int_{\Omega}\|x(s)\| d \mu
$$

the last step coming from the dominated convergence theorem since $\left\|y_{n}(s)\right\| \leq 2\|x(s)\|$ and $\left\|y_{n}(s)\right\| \rightarrow\|x(s)\|$ for each $s$. This shows the triangle inequality.

From Definition 21.2.1 and Theorem 21.2.4 and $\left\{y_{n}\right\}$ being the approximating sequence described there,

$$
f\left(\int_{\Omega} y_{n} d \mu\right)=\int_{\Omega} f\left(y_{n}\right) d \mu
$$

Thus,

$$
f\left(\int_{\Omega} x d \mu\right)=\lim _{n \rightarrow \infty} f\left(\int_{\Omega} y_{n} d \mu\right)=\lim _{n \rightarrow \infty} \int_{\Omega} f\left(y_{n}\right) d \mu=\int_{\Omega} f(x) d \mu
$$

the last equation holding from the dominated convergence theorem $\left(\left|f\left(y_{n}\right)\right| \leq\|f\|\left\|y_{n}\right\| \leq\right.$ $2\|f\|\|x\|)$. This shows 21.2.5.

It remains to verify 21.2.7. Let $f \in X^{\prime}$. Then from 21.2.5

$$
\begin{aligned}
f\left(\int_{\Omega}(a x(s)+b y(s)) d \mu\right) & =\int_{\Omega}(a f(x(s))+b f(y(s))) d \mu \\
& =a \int_{\Omega} f(x(s)) d \mu+b \int_{\Omega} f(y(s)) d \mu \\
& =f\left(a \int_{\Omega} x(s) d \mu+b \int_{\Omega} y(s) d \mu\right)
\end{aligned}
$$

Since $X^{\prime}$ separates the points of $X$, it follows

$$
\int_{\Omega}(a x(s)+b y(s)) d \mu=a \int_{\Omega} x(s) d \mu+b \int_{\Omega} y(s) d \mu
$$

and this proves 21.2.7.
A similar result is the following corollary.
Corollary 21.2.6 Let an $X$ valued function $x$ be Bochner integrable and let $L \in \mathscr{L}(X, Y)$ where $Y$ is another Banach space. Then $L x$ is a $Y$ valued Bochner integrable function and

$$
L\left(\int_{\Omega} x(s) d \mu\right)=\int_{\Omega} L x(s) d \mu
$$

Proof: From Theorem 21.2.4 there is a sequence of simple functions $\left\{y_{n}\right\}$ having the properties listed in that theorem. Then consider $\left\{L y_{n}\right\}$ which converges pointwise to $L x$. Since $L$ is continuous and linear,

$$
\int_{\Omega}\left\|L y_{n}-L x\right\|_{Y} d \mu \leq\|L\| \int_{\Omega}\left\|y_{n}-x\right\|_{X} d \mu
$$

which converges to 0 . This implies

$$
\lim _{m, n \rightarrow \infty} \int_{\Omega}\left\|L y_{n}-L y_{m}\right\| d \mu=0
$$

and so by definition $L x$ is Bochner integrable. Also

$$
\begin{gathered}
\int_{\Omega} x(s) d \mu=\lim _{n \rightarrow \infty} \int_{\Omega} y_{n}(s) d \mu \\
\int_{\Omega} L x(s) d \mu=\lim _{n \rightarrow \infty} \int_{\Omega} L y_{n}(s) d \mu=\lim _{n \rightarrow \infty} L \int_{\Omega} y_{n}(s) d \mu \\
\left\|L\left(\int_{\Omega} x(s) d \mu\right)-\int_{\Omega} L x(s) d \mu\right\|_{Y} \\
\leq\left\|L\left(\int_{\Omega} x(s) d \mu\right)-L \int_{\Omega} y_{n}(s) d \mu\right\|_{Y} \\
+\left\|\int_{\Omega} L y_{n}(s) d \mu-\int_{\Omega} L x(s) d \mu\right\|_{Y}<\varepsilon / 2+\varepsilon / 2=\varepsilon
\end{gathered}
$$

whenever $n$ large enough.

### 21.2.2 Taking a Closed Operator Out of the Integral

Now let $X$ and $Y$ be separable Banach spaces and suppose $A: D(A) \subseteq X \rightarrow Y$ be a closed operator. Recall this means that the graph of $A$,

$$
G(A) \equiv\{(x, A x): x \in D(A)\}
$$

is a closed subset of $X \times Y$ with respect to the product topology obtained from the norm

$$
\|(x, y)\|=\max (\|x\|,\|y\|)
$$

Thus also $G(A)$ is a separable Banach space with the above norm. You can also consider $D(A)$ as a separable Banach space having the graph norm

$$
\begin{equation*}
\|x\|_{D(A)} \equiv \max (\|x\|,\|A x\|) \tag{21.2.8}
\end{equation*}
$$

which is isometric to $G(A)$ with the mapping, $\theta x \equiv(x, A x)$. Recall why this is. It is clear that $\theta$ is one to one and onto $G(A)$. Is it continuous? If $x_{n} \rightarrow x$ in $D(A)$, this means that $x_{n} \rightarrow x$ in $X$ and $A x_{n} \rightarrow y$. Then, since $A$ is closed, it follows that $y=A x$ so $\left(x_{n}, A x_{n}\right) \rightarrow$ $(x, A x)$ in $G(A)$. Hence $\theta$ is indeed continuous and onto. Similar reasoning shows that $D(A)$ with this norm is complete. Hence it is a Banach space. Thus $\theta^{-1}$ is also continuous. The following lemma is a fundamental result which was proved earlier in the discussion on the Eberlein Smulian theorem in which this was an essential fact to allow the case of a reflexive Banach space which maybe was not separable. See Lemma 17.5.11 for the proof.

Lemma 21.2.7 A closed subspace of a reflexive Banach space is reflexive.

Then, with this lemma, one has the following corollary.
Corollary 21.2.8 Suppose $Y$ is a reflexive Banach space and $X$ is a Banach space such that there exists a continuous one to one mapping, $g: X \rightarrow Y$ such that $g(X)$ is a closed subset of $Y$. Then $X$ is reflexive.

Proof: By the open mapping theorem, $g(X)$ and $X$ are homeomorphic since $g^{-1}$ must also be continuous. Therefore, since $g(X)$ is reflexive because it is a closed subspace of a reflexive space, it follows $X$ is also reflexive.

Lemma 21.2.9 Suppose $V$ is a reflexive Banach space and that $V$ is a dense subset of $W$, another Banach space in the topology of $W$. Then $i^{*} W^{\prime}$ is a dense subset of $V^{\prime}$ where here $i$ is the inclusion map of $V$ into $W$.

Proof: First note that $i^{*}$ is one to one. If $i^{*} w^{*}=0$ for $w^{*} \in W^{\prime}$, then this means that for all $v \in V$,

$$
i^{*} w(v)=w^{*}(v)=0
$$

and since $V$ is dense in $W$, this shows $w^{*}=0$.
Consider the following diagram

$$
\begin{array}{lll}
V^{\prime \prime} & \stackrel{i^{* *}}{\rightarrow} & W^{\prime \prime} \\
V^{\prime} & \stackrel{i^{*}}{\leftarrow} & W^{\prime} \\
V & \xrightarrow{i} & W
\end{array}
$$

in which $i$ is the inclusion map. Next suppose $i^{*} W^{\prime}$ is not dense in $V^{\prime}$. Then, using the Hahn Banach theorem, there exists $v^{* *} \in V^{\prime \prime}$ such that $v^{* *} \neq 0$ but $v^{* *}\left(i^{*} W^{\prime}\right)=0$. It follows from $V$ being reflexive, that $v^{* *}=J v_{0}$ where $J$ is the James map from $V$ to $V^{\prime \prime}$ for some $v_{0} \in V$. Thus for every $w^{*} \in W^{\prime}$,

$$
\begin{aligned}
0 & =v^{* *}\left(i^{*} w^{*}\right) \equiv i^{* *} v^{* *}\left(w^{*}\right) \\
& =i^{* *} J v_{0}\left(w^{*}\right)=J v_{0}\left(i^{*} w^{*}\right) \\
& \equiv i^{*} w^{*}\left(v_{0}\right)=w^{*}\left(v_{0}\right)
\end{aligned}
$$

and since $W^{\prime}$ separates the points of $W$, it follows $v_{0}=0$ which contradicts $v^{* *} \neq 0$.
Note that in the proof, only $V$ reflexive was used.
This lemma implies an easy corollary.
Corollary 21.2.10 Let $E$ and $F$ be reflexive Banach spaces and let $A$ be a closed operator $A: D(A) \subseteq E \rightarrow F$. Suppose also that $D(A)$ is dense in $E$. Then making $D(A)$ into a Banach space by using the above graph norm given in 21.2.8, it follows that $D(A)$ is a Banach space and $i^{*} E^{\prime}$ is a dense subspace of $D(A)^{\prime}$.

Proof: First note that $E \times F$ is a reflexive Banach space and $\mathscr{G}(A)$ is a closed subspace of $E \times F$ so it is also a reflexive Banach space. Now $D(A)$ is isometric to $\mathscr{G}(A)$ and so it follows $D(A)$ is a dense subspace of $E$ which is reflexive. Therefore, from Lemma 21.2.9 the conclusion follows.

With this preparation, here is another interesting theorem. This one is about taking outside the integral a closed linear operator as opposed to a continuous linear operator.

Theorem 21.2.11 Let $X, Y$ be separable Banach spaces and let $A: D(A) \subseteq X \rightarrow Y$ be a closed operator where $D(A)$ is a dense separable subset of $X$ with respect to the graph norm on $D(A)$ described above ${ }^{1}$. Suppose also that $i^{*} X^{\prime}$ is a dense subspace of $D(A)^{\prime}$ where $D(A)$ is a Banach space having the graph norm described in 21.2.8. Suppose that $(\Omega, \mathscr{F}, \mu)$ is a $\sigma$ finite measure space and $x: \Omega \rightarrow X$ is strongly measurable and it happens that $x(s) \in D(A)$ for all $s \in \Omega$. Then $x$ is strongly measurable as a mapping into $D(A)$. Also Ax is strongly measurable as a map into $Y$ and if

$$
\begin{equation*}
\int_{\Omega}\|x(s)\| d \mu, \int_{\Omega}\|A x(s)\| d \mu<\infty \tag{21.2.9}
\end{equation*}
$$

then

$$
\begin{equation*}
\int_{\Omega} x(s) d \mu \in D(A) \tag{21.2.10}
\end{equation*}
$$

and

$$
\begin{equation*}
A \int_{\Omega} x(s) d \mu=\int_{\Omega} A x(s) d \mu \tag{21.2.11}
\end{equation*}
$$

Proof: First of all, consider the assertion that $x$ is strongly measurable into $D(A)$. Letting $f \in D(A)^{\prime}$ be given, there exists a sequence, $\left\{g_{n}\right\} \subseteq i^{*} X^{\prime}$ such that $g_{n} \rightarrow f$ in $D(A)^{\prime}$. Therefore, $s \rightarrow g_{n}(x(s))$ is measurable by assumption and $g_{n}(x(s)) \rightarrow f(x(s))$, which shows that $s \rightarrow f(x(s))$ is measurable. By the Pettis theorem, it follows that $s \rightarrow x(s)$ is strongly measurable as a map into $D(A)$.

It follows from Theorem 21.2.4 there exists a sequence of simple functions, $\left\{x_{n}\right\}$ of the form

$$
x_{n}(s)=\sum_{k=1}^{m_{n}} a_{k}^{n} \mathscr{X}_{E_{k}^{n}}(s), x_{n}(s) \in D(A)
$$

which converges strongly and pointwise to $x(s)$ in $D(A)$. Thus

$$
x_{n}(s) \rightarrow x(s), A x_{n}(s) \rightarrow A x(s)
$$

which shows $s \rightarrow A x(s)$ is stongly measurable in $Y$ as claimed.
It remains to verify the assertions about the integral. 21.2.9 implies $x$ is Bochner integrable as a function having values in $D(A)$ with the norm on $D(A)$ described above. Therefore, by Theorem 21.2.4 there exists a sequence of simple functions $\left\{y_{n}\right\}$ having values in $D(A)$,

$$
\lim _{m, n \rightarrow \infty} \int_{\Omega}\left\|y_{n}-y_{m}\right\|_{D(A)} d \mu=0
$$

$y_{n}(s)$ converging pointwise to $x(s)$,

$$
\left\|y_{n}(s)\right\|_{D(A)} \leq 2\|x(s)\|_{D(A)}
$$

and

$$
\lim _{n \rightarrow \infty} \int_{\Omega}\left\|x(s)-y_{n}(s)\right\|_{D(A)} d s=0
$$

[^19]Therefore,

$$
\int_{\Omega} y_{n}(s) d \mu \in D(A), \int_{\Omega} y_{n}(s) d \mu \rightarrow \int_{\Omega} x(s) d \mu \text { in } X
$$

and since $y_{n}$ is a simple function and $A$ is linear,

$$
A \int_{\Omega} y_{n}(s) d \mu=\int_{\Omega} A y_{n}(s) d \mu \rightarrow \int_{\Omega} A x(s) d \mu \text { in } Y
$$

It follows, since $A$ is a closed operator, that $\int_{\Omega} x(s) d \mu \in D(A)$ and

$$
A \int_{\Omega} x(s) d \mu=\int_{\Omega} A x(s) d \mu
$$

Here is another version of this theorem which has different hypotheses.
Theorem 21.2.12 Let $X$ and $Y$ be separable Banach spaces and let $A: D(A) \subseteq X \rightarrow Y$ be a closed operator. Also let $(\Omega, \mathscr{F}, \mu)$ be a $\sigma$ finite measure space and let $x: \Omega \rightarrow X$ be Bochner integrable such that $x(s) \in D(A)$ for all s. Also suppose Ax is Bochner integrable. Then

$$
\int A x d \mu=A \int x d \mu
$$

and $\int x d \mu \in D(A)$.
Proof: Consider the graph of $A$,

$$
G(A) \equiv\{(x, A x): x \in D(A)\} \subseteq X \times Y
$$

Then since $A$ is closed, $G(A)$ is a closed separable Banach space with the norm $\|(x, y)\| \equiv$ $\max (\|x\|,\|y\|)$. Therefore, for $g^{*} \in G(A)^{\prime}$, one can apply the Hahn Banach theorem and obtain $\left(x^{*}, y^{*}\right) \in(X \times Y)^{\prime}$ such that $g^{*}(x, A x)=\left(x^{*}(x), y^{*}(A x)\right)$. Now it follows from the assumptions that $s \rightarrow\left(x^{*}(x(s)), y^{*}(A x(s))\right)$ is measurable with values in $G(A)$. It is also separably valued because this is true of $G(A)$. By the Pettis theorem, $s \rightarrow(x(s), A(x(s)))$ must be strongly measurable. Also $\int\|x(s)\|+\|A(x(s))\| d \mu<\infty$ by assumption and so there exists a sequence of simple functions having values in $G(A),\left\{\left(x_{n}(s), A x_{n}(s)\right)\right\}$ which converges to $(x(s), A(s))$ pointwise such that $\int\left\|\left(x_{n}, A x_{n}\right)-(x, A x)\right\| d \mu \rightarrow 0$ in $G(A)$. Now for simple functions is it routine to verify that

$$
\int\left(x_{n}, A x_{n}\right) d \mu=\left(\int x_{n} d \mu, \int A x_{n} d \mu\right)=\left(\int x_{n} d \mu, A \int x_{n} d \mu\right)
$$

Also

$$
\begin{aligned}
\left\|\int x_{n} d \mu-\int x d \mu\right\| & \leq \int\left\|x_{n}-x\right\| d \mu \\
& \leq \int\left\|\left(x_{n}, A x_{n}\right)-(x, A x)\right\| d \mu
\end{aligned}
$$

which converges to 0 . Also

$$
\begin{aligned}
\left\|\int A x_{n} d \mu-\int A x d \mu\right\| & =\left\|A \int x_{n} d \mu-\int A x d \mu\right\| \\
& \leq \int\left\|A x_{n}-A x\right\| d \mu \\
& \leq \int\left\|\left(x_{n}, A x_{n}\right)-(x, A x)\right\| d \mu
\end{aligned}
$$

and this converges to 0 . Therefore, $\int x_{n} d \mu \rightarrow \int x d \mu$ and $A \int x_{n} d \mu \rightarrow \int A x d \mu$. Since each $\int x_{n} d \mu \in D(A)$, and $A$ is closed, this implies $\int x d \mu \in D(A)$ and $A \int x d \mu=\int A x d \mu$.

### 21.3 Operator Valued Functions

Consider the case where $A(s) \in \mathscr{L}(X, Y)$ for $X$ and $Y$ separable Banach spaces. With the operator norm $\mathscr{L}(X, Y)$ is a Banach space and so if $A$ is strongly measurable, the Bochner integral can be defined as before. However, it is also possible to define the Bochner integral of such operator valued functions for more general situations. In this section, $(\Omega, \mathscr{F}, \mu)$ will be a $\sigma$ finite measure space as usual.

Lemma 21.3.1 Let $x \in X$ and suppose $A$ is strongly measurable. Then

$$
s \rightarrow A(s) x
$$

is strongly measurable as a map into $Y$.
Proof: Since $A$ is assumed to be strongly measurable, it is the pointwise limit of simple functions of the form

$$
A_{n}(s) \equiv \sum_{k=1}^{m_{n}} A_{k}^{n} \mathscr{X}_{E_{k}^{n}}(s)
$$

where $A_{k}^{n}$ is in $\mathscr{L}(X, Y)$. It follows $A_{n}(s) x \rightarrow A(s) x$ for each $s$ and so, since $s \rightarrow A_{n}(s) x$ is a simple $Y$ valued function, $s \rightarrow A(s) x$ must be strongly measurable.

Definition 21.3.2 Suppose $A(s) \in \mathscr{L}(X, Y)$ for each $s \in \Omega$ where $X, Y$ are separable Banach spaces. Suppose also that for each $x \in X$,

$$
\begin{equation*}
s \rightarrow A(s) x \text { is strongly measurable } \tag{21.3.12}
\end{equation*}
$$

and there exists $C$ such that for each $x \in X$,

$$
\begin{equation*}
\int_{\Omega}\|A(s) x\| d \mu<C\|x\| \tag{21.3.13}
\end{equation*}
$$

Then $\int_{\Omega} A(s) d \mu \in \mathscr{L}(X, Y)$ is defined by the following formula.

$$
\begin{equation*}
\left(\int_{\Omega} A(s) d \mu\right)(x) \equiv \int_{\Omega} A(s) x d \mu \tag{21.3.14}
\end{equation*}
$$

Lemma 21.3.3 The above definition is well defined. Furthermore, if 21.3.12 holds then $s \rightarrow\|A(s)\|$ is measurable and if 21.3.13 holds, then

$$
\left\|\int_{\Omega} A(s) d \mu\right\| \leq \int_{\Omega}\|A(s)\| d \mu
$$

Proof: It is clear that in case $s \rightarrow A(s) x$ is measurable for all $x \in X$ there exists a unique $\Psi \in \mathscr{L}(X, Y)$ such that

$$
\Psi(x)=\int_{\Omega} A(s) x d \mu
$$

This is because $x \rightarrow \int_{\Omega} A(s) x d \mu$ is linear and continuous. It is continuous because

$$
\left\|\int_{\Omega} A(s) x d \mu\right\| \leq \int_{\Omega}\|A(s) x\| d \mu \leq \int_{\Omega}\|A(s)\| d \mu\|x\|
$$

Thus $\Psi=\int_{\Omega} A(s) d \mu$ and the definition is well defined.
Now consider the assertion about $s \rightarrow\|A(s)\|$. Let $D^{\prime} \subseteq B^{\prime}$ the closed unit ball in $Y^{\prime}$ be such that $D^{\prime}$ is countable and

$$
\|y\|=\sup _{y^{*} \in D^{\prime}}\left|y^{*}(y)\right|
$$

This is from Lemma 21.1.6. Recall $X$ is separable. Also let $D$ be a countable dense subset of $B$, the unit ball of $X$. Then

$$
\begin{aligned}
\{s:\|A(s)\|>\alpha\} & =\left\{s: \sup _{x \in D}\|A(s) x\|>\alpha\right\} \\
& =\cup_{x \in D}\{s:\|A(s) x\|>\alpha\} \\
& =\cup_{x \in D}\left(\cup_{y^{*} \in D^{\prime}}\left\{\left|y^{*}(A(s) x)\right|>\alpha\right\}\right)
\end{aligned}
$$

and this is measurable because $s \rightarrow A(s) x$ is strongly, hence weakly measurable.
Now suppose 21.3.13 holds. Then for all $x$,

$$
\int_{\Omega}\|A(s) x\| d \mu<C\|x\|
$$

It follows that for $\|x\| \leq 1$,

$$
\left\|\left(\int_{\Omega} A(s) d \mu\right)(x)\right\|=\left\|\int_{\Omega} A(s) x d \mu\right\| \leq \int_{\Omega}\|A(s) x\| d \mu \leq \int_{\Omega}\|A(s)\| d \mu
$$

and so

$$
\left\|\int_{\Omega} A(s) d \mu\right\| \leq \int_{\Omega}\|A(s)\| d \mu
$$

Now it is interesting to consider the case where $A(s) \in \mathscr{L}(H, H)$ where $s \rightarrow A(s) x$ is strongly measurable and $A(s)$ is compact and self adjoint. Recall the Kuratowski measurable selection theorem, Theorem 11.1.11 on Page 228 listed here for convenience.

Theorem 21.3.4 Let $E$ be a compact metric space and let $(\Omega, \mathscr{F})$ be a measure space. Suppose $\psi: E \times \Omega \rightarrow \mathbb{R}$ has the property that $x \rightarrow \psi(x, \omega)$ is continuous and $\omega \rightarrow \psi(x, \omega)$ is measurable. Then there exists a measurable function, $f$ having values in $E$ such that

$$
\psi(f(\omega), \omega)=\sup _{x \in E} \psi(x, \omega) .
$$

Furthermore, $\omega \rightarrow \psi(f(\omega), \omega)$ is measurable.

### 21.3.1 Review of Hilbert Schmidt Theorem

This section is a review of earlier material and is presented a little differently. I think it does not hurt to repeat some things relative to Hilbert space. I will give a proof of the Hilbert Schmidt theorem which will generalize to a result about measurable operators. It will be a little different then the earlier proof. Recall the following.

Definition 21.3.5 Define $v \otimes u \in \mathscr{L}(H, H)$ by

$$
v \otimes u(x)=(x, u) v .
$$

$A \in \mathscr{L}(H, H)$ is a compact operator if whenever $\left\{x_{k}\right\}$ is a bounded sequence, there exists a convergent subsequence of $\left\{A x_{k}\right\}$. Equivalently, A maps bounded sets to sets whose closures are compact or to use other terminology, A maps bounded sets to sets which are precompact.

Next is a convenient description of compact operators on a Hilbert space.
Lemma 21.3.6 Let $H$ be a Hilbert space and suppose $A \in \mathscr{L}(H, H)$ is a compact operator. Then

1. A is a compact operator if and only if whenever if $x_{n} \rightarrow x$ weakly in $H$, it follows that $A x_{n} \rightarrow A x$ strongly in $H$.
2. For $u, v \in H, v \otimes u: H \rightarrow H$ is a compact operator.
3. Let $B$ be the closed unit ball in $H$. If $A$ is self adjoint and compact, then if $x_{n} \rightarrow x$ weakly on $B$, it follows that $\left(A x_{n}, x_{n}\right) \rightarrow(A x, x)$ so $x \rightarrow|(A x, x)|$ achieves its maximum value on $B$.
4. The function, $v \otimes u$ is compact and the operator $u \otimes u$ is self adjoint.

Proof: Consider $\Rightarrow$ of 1 . Suppose then that $x_{n} \rightarrow x$ weakly. Since $\left\{x_{n}\right\}$ is weakly bounded, it follows from the uniform boundedness principle that $\left\{\left\|x_{n}\right\|\right\}$ is bounded. Let $x_{n} \in \hat{B}$ for $\hat{B}$ some closed ball. If $A x_{n}$ fails to converge to $A x$, then there is $\varepsilon>0$ and a subsequence still denoted as $\left\{x_{n}\right\}$ such that $x_{n} \rightarrow x$ weakly but $\left\|A x_{n}-A x\right\| \geq \varepsilon>0$. Then $A(\hat{B})$ is precompact because $A$ is compact so there is a further subsequence, still denoted by $\left\{x_{n}\right\}$ such that $A x_{n}$ converges to some $y \in H$. Therefore,

$$
\begin{aligned}
(y, w) & =\lim _{n \rightarrow \infty}\left(A x_{n}, w\right)=\lim _{n \rightarrow \infty}\left(x_{n}, A^{*} w\right) \\
& =\left(x, A^{*} w\right)=(A x, w)
\end{aligned}
$$

which shows $A x=y$ since $w$ is arbitrary. However, this is a contradiction to $\left\|A x_{n}-A x\right\| \geq$ $\varepsilon>0$.

Consider $\Leftarrow$ of 1 . Why is $A$ compact if it satisfies the property that it takes weakly convergent sequences to strongly convergent ones? If $A$ is not compact, then there exists $\hat{B}$ a bounded set such that $A(\hat{B})$ is not precompact. Thus, there exists a sequence $\left\{A x_{n}\right\}_{n=1}^{\infty} \subseteq$ $A(\hat{B})$ which has no convergent subsequence where $x_{n} \in \hat{B}$ the bounded set. However, there is a subsequence $\left\{x_{n}\right\} \in \hat{B}$ which converges weakly to some $x \in H$ because of weak compactness. Hence $A x_{n} \rightarrow A x$ by assumption and so this is a contradiction to there being no convergent subsequence of $\left\{A x_{n}\right\}_{n=1}^{\infty}$.

Next consider 2. Letting $\left\{x_{n}\right\}$ be a bounded sequence,

$$
v \otimes u\left(x_{n}\right)=\left(x_{n}, u\right) v .
$$

There exists a weakly convergent subsequence of $\left\{x_{n}\right\}$ say $\left\{x_{n_{k}}\right\}$ converging weakly to $x \in H$. Therefore,

$$
\left\|v \otimes u\left(x_{n_{k}}\right)-v \otimes u(x)\right\|=\left\|\left(x_{n_{k}}, u\right)-(x, u)\right\|\|v\|
$$

which converges to 0 . Thus $v \otimes u$ is compact as claimed. It takes bounded sets to precompact sets.

Next consider 3. To verify the assertion about $x \rightarrow(A x, x)$, let $x_{n} \rightarrow x$ weakly. Since $A$ is compact, $A x_{n} \rightarrow A x$ by part 1. Then, since $A$ is self adjoint,

$$
\begin{aligned}
& \left|\left(A x_{n}, x_{n}\right)-(A x, x)\right| \\
\leq & \left|\left(A x_{n}, x_{n}\right)-\left(A x, x_{n}\right)\right|+\left|\left(A x, x_{n}\right)-(A x, x)\right| \\
\leq & \left|\left(A x_{n}, x_{n}\right)-\left(A x, x_{n}\right)\right|+\left|\left(A x_{n}, x\right)-(A x, x)\right| \\
\leq & \left\|A x_{n}-A x\right\|\left\|x_{n}\right\|+\left\|A x_{n}-A x\right\|\|x\| \leq 2\left\|A x_{n}-A x\right\|
\end{aligned}
$$

which converges to 0 . Now let $\left\{x_{n}\right\}$ be a maximizing sequence for $|(A x, x)|$ for $x \in B$ and let $\lambda \equiv \sup \{|(A x, x)|: x \in B\}$. There is a subsequence still denoted as $\left\{x_{n}\right\}$ which converges weakly to some $x \in B$ by weak compactness. Hence $|(A x, x)|=\lim _{n \rightarrow \infty}\left|\left(A x_{n}, x_{n}\right)\right|=\lambda$.

Next consider 4. It only remains to verify that $u \otimes u$ is self adjoint. This follows from the definition.

$$
\begin{aligned}
((u \otimes u) x, y) & \equiv(u(x, u), y)=(x, u)(u, y) \\
(x,(u \otimes u) y) & \equiv(x, u(y, u))=(u, y)(x, u)
\end{aligned}
$$

the same thing.
Observation 21.3.7 Note that if $A$ is any self adjoint operator,

$$
\overline{(A x, x)}=(x, A x)=(A x, x)
$$

so $(A x, x)$ is real valued.
From Lemma 21.3.6, the maximum of $|(A x, x)|$ exists on the closed unit ball $B$.

Lemma 21.3.8 Let $A \in \mathscr{L}(H, H)$ and suppose it is self adjoint and compact. Let $B$ denote the closed unit ball in $H$. Let $e \in B$ be such that

$$
|(A e, e)|=\max _{x \in B}|(A x, x)|
$$

Then letting $\lambda=(A e, e)$, it follows $A e=\lambda e$. You can always assume $\|e\|=1$.
Proof: From the above observation, $(A x, x)$ is always real and since $A$ is compact, $|(A x, x)|$ achieves a maximum at $e$. It remains to verify $e$ is an eigenvector. If $|(A e, e)|=0$ for all $e \in B$, then $A$ is a self adjoint nonnegative $((A x, x) \geq 0)$ operator and so by Cauchy Schwarz inequality,

$$
(A e, x) \leq(A x, x)^{1 / 2}(A e, e)^{1 / 2}=0
$$

and so $A e=0$ for all $e$. Assume then that $A$ is not 0 . You can always make $|(A e, e)|$ at least as large by replacing $e$ with $e /\|e\|$. Thus, there is no loss of generality in letting $\|e\|=1$ in every case.

Suppose $\lambda=(A e, e) \geq 0$ where $|(A e, e)|=\max _{x \in B}|(A x, x)|$. Thus

$$
((\lambda I-A) e, e)=\lambda\|e\|^{2}-\lambda=0
$$

Then it is easy to verify that $\lambda I-A$ is a nonnegative $(((\lambda I-A) x, x) \geq 0$ for all $x$.) and self adjoint operator. To see this, note that

$$
((\lambda I-A) x, x)=\|x\|^{2}\left((\lambda I-A) \frac{x}{\|x\|}, \frac{x}{\|x\|}\right)=\|x\|^{2} \lambda-\|x\|^{2}\left(A \frac{x}{\|x\|}, \frac{x}{\|x\|}\right) \geq 0
$$

Therefore, the Cauchy Schwarz inequality can be applied to write

$$
((\lambda I-A) e, x) \leq((\lambda I-A) e, e)^{1 / 2}((\lambda I-A) x, x)^{1 / 2}=0
$$

Since this is true for all $x$ it follows $A e=\lambda e$. Just pick $x=(\lambda I-A) e$.
Next suppose $\max _{x \in B}|(A x, x)|=-(A e, e)$. Let $-\lambda=(-A e, e)$ and the previous result can be applied to $-A$ and $-\lambda$. Thus $-\lambda e=-A e$ and so $A e=\lambda e$.

With these lemmas here is a major theorem, the Hilbert Schmidt theorem. I think this proof is a little slicker than the more standard proof given earlier.

Theorem 21.3.9 Let $A \in \mathscr{L}(H, H)$ be a compact self adjoint operator on a Hilbert space. Then there exist real numbers $\left\{\lambda_{k}\right\}_{k=1}^{\infty}$ and vectors $\left\{e_{k}\right\}_{k=1}^{\infty}$ such that

$$
\begin{gather*}
\left\|e_{k}\right\|=1, \\
\left(e_{k}, e_{j}\right)_{H}=0 \text { if } k \neq j, \\
A e_{k}=\lambda_{k} e_{k} \\
\left|\lambda_{n}\right| \geq\left|\lambda_{n+1}\right| \text { for all } n, \\
\lim _{n \rightarrow \infty} \lambda_{n}=0 \\
\lim _{n \rightarrow \infty}\left\|A-\sum_{k=1}^{n} \lambda_{k}\left(e_{k} \otimes e_{k}\right)\right\|_{\mathscr{L}(H, H)}=0 \tag{21.3.15}
\end{gather*}
$$

Proof: This is done by considering a sequence of compact self adjoint operators, $A, A_{1}, A_{2}, \cdots$. Here is how these are defined. Using Lemma 21.3.8 let $e_{1}, \lambda_{1}$ be given by that lemma such that

$$
\left|\left(A e_{1}, e_{1}\right)\right|=\max _{x \in B}|(A x, x)|, \lambda_{1}=\left(A e_{1}, e_{1}\right) \Rightarrow A e_{1}=\lambda_{1} e_{1}
$$

Then by that lemma, $A e_{1}=\lambda_{1} e_{1}$ and $\left\|e_{1}\right\|=1$. Now define $A_{1}=A-\lambda_{1} e_{1} \otimes e_{1}$. This is compact and self adjoint by Lemma 21.3.6. Thus, one could repeat the argument.

If $A_{n}$ has been obtained, use Lemma 21.3.8 to obtain $e_{n+1}$ and $\lambda_{n+1}$ such that

$$
\left|\left(A_{n} e_{n+1}, e_{n+1}\right)\right|=\max _{x \in B}\left|\left(A_{n} x, x\right)\right|, \lambda_{n+1}=\left(A_{n} e_{n+1}, e_{n+1}\right)
$$

By that lemma again, $A_{n} e_{n+1}=\lambda_{n+1} e_{n+1}$ and $\left\|e_{n+1}\right\|=1$. Then

$$
A_{n+1} \equiv A_{n}-\lambda_{n+1} e_{n+1} \otimes e_{n+1}
$$

Thus iterating this,

$$
\begin{equation*}
A_{n}=A-\sum_{k=1}^{n} \lambda_{k} e_{k} \otimes e_{k} \tag{21.3.16}
\end{equation*}
$$

Assume for $j, k \leq n,\left(e_{k}, e_{j}\right)=\delta_{j k}$. Then the new vector $e_{n+1}$ will be orthogonal to the earlier ones. This is the next claim.

Claim 1: If $k<n+1$ then $\left(e_{n+1}, e_{k}\right)=0$. Also $A e_{k}=\lambda_{k} e_{k}$ for all $k$ and from the construction, $A_{n} e_{n+1}=\lambda_{n+1} e_{n+1}$.

Proof of claim: From the above,

$$
\lambda_{n+1} e_{n+1}=A_{n} e_{n+1}=A e_{n+1}-\sum_{k=1}^{n} \lambda_{k}\left(e_{n+1}, e_{k}\right) e_{k}
$$

From the above and induction hypothesis that $\left(e_{k}, e_{j}\right)=\delta_{j k}$ for $j, k \leq n$,

$$
\begin{aligned}
\lambda_{n+1}\left(e_{n+1}, e_{j}\right) & =\left(A e_{n+1}, e_{j}\right)-\sum_{k=1}^{n} \lambda_{k}\left(e_{n+1}, e_{k}\right)\left(e_{k}, e_{j}\right) \\
& =\left(e_{n+1}, A e_{j}\right)-\sum_{k=1}^{n} \lambda_{k}\left(e_{n+1}, e_{k}\right)\left(e_{k}, e_{j}\right) \\
& =\lambda_{j}\left(e_{n+1}, e_{j}\right)-\lambda_{j}\left(e_{n+1}, e_{j}\right)=0
\end{aligned}
$$

To verify the second part of this claim,

$$
\lambda_{n+1} e_{n+1}=A_{n} e_{n+1}=A e_{n+1}-\sum_{k=1}^{n} \lambda_{k} e_{k}\left(e_{n+1}, e_{k}\right)=A e_{n+1}
$$

This proves the claim.
Claim 2: $\left|\lambda_{n}\right| \geq\left|\lambda_{n+1}\right|$.

Proof of claim: From 21.3.16 and the definition of $A_{n}$ and $e_{k} \otimes e_{k}$,

$$
\begin{aligned}
\left(A_{n-1} e_{n+1}, e_{n+1}\right) & =\left(\left(A-\sum_{k=1}^{n-1} \lambda_{k} e_{k} \otimes e_{k}\right) e_{n+1}, e_{n+1}\right) \\
& =\left(A e_{n+1}, e_{n+1}\right)=\left(A_{n} e_{n+1}, e_{n+1}\right)
\end{aligned}
$$

Thus,

$$
\begin{aligned}
\lambda_{n+1} & =\left(A_{n} e_{n+1}, e_{n+1}\right) \\
& =\left(A_{n-1} e_{n+1}, e_{n+1}\right)-\lambda_{n}\left|\left(e_{n}, e_{n+1}\right)\right|^{2} \\
& =\left(A_{n-1} e_{n+1}, e_{n+1}\right)
\end{aligned}
$$

By the previous claim. Therefore,

$$
\left|\lambda_{n+1}\right|=\left|\left(A_{n-1} e_{n+1}, e_{n+1}\right)\right| \leq\left|\left(A_{n-1} e_{n}, e_{n}\right)\right|=\left|\lambda_{n}\right|
$$

by the definition of $\left|\lambda_{n}\right|$. ( $e_{n}$ makes $\left|\left(A_{n-1} x, x\right)\right|$ as large as possible.)
Claim 3: $\lim _{n \rightarrow \infty} \lambda_{n}=0$.
Proof of claim: If for some $n, \lambda_{n}=0$, then $\lambda_{k}=0$ for all $k>n$ by claim 2. Thus, for some n,

$$
A=\sum_{k=1}^{n} \lambda_{k} e_{k} \otimes e_{k}
$$

Assume then that $\lambda_{k} \neq 0$ for any $k$. Then if $\lim _{k \rightarrow \infty}\left|\lambda_{k}\right|=\varepsilon>0$, one contradicts, $\left\|e_{k}\right\|=1$ for all $k$ because

$$
\begin{aligned}
\left\|A e_{n}-A e_{m}\right\|^{2} & =\left\|\lambda_{n} e_{n}-\lambda_{m} e_{m}\right\|^{2} \\
& =\lambda_{n}^{2}+\lambda_{m}^{2} \geq 2 \varepsilon^{2}
\end{aligned}
$$

which shows there is no Cauchy subsequence of $\left\{A e_{n}\right\}_{n=1}^{\infty}$, which contradicts the compactness of $A$. This proves the claim.

Claim 4: $\left\|A_{n}\right\| \rightarrow 0$
Proof of claim: Let $x, y \in B$

$$
\begin{aligned}
\left|\lambda_{n+1}\right| & \geq\left|\left(A_{n} \frac{x+y}{2}, \frac{x+y}{2}\right)\right| \\
& =\left|\frac{1}{4}\left(A_{n} x, x\right)+\frac{1}{4}\left(A_{n} y, y\right)+\frac{1}{2}\left(A_{n} x, y\right)\right| \\
& \geq \frac{1}{2}\left|\left(A_{n} x, y\right)\right|-\frac{1}{4}\left|\left(A_{n} x, x\right)+\left(A_{n} y, y\right)\right| \\
& \geq \frac{1}{2}\left|\left(A_{n} x, y\right)\right|-\frac{1}{4}\left(\left|\left(A_{n} x, x\right)\right|+\left|\left(A_{n} y, y\right)\right|\right) \\
& \geq \frac{1}{2}\left|\left(A_{n} x, y\right)\right|-\frac{1}{2}\left|\lambda_{n+1}\right|
\end{aligned}
$$

and so

$$
3\left|\lambda_{n+1}\right| \geq\left|\left(A_{n} x, y\right)\right|
$$

It follows $\left\|A_{n}\right\| \leq 3\left|\lambda_{n+1}\right|$. By 21.3 .16 this proves 21.3 .15 and completes the proof.

### 21.3.2 Measurable Compact Operators

Here the operators will be of the form $A(s)$ where $s \in \Omega$ and $s \rightarrow A(s) x$ is strongly measurable and $A(s)$ is a compact operator in $\mathscr{L}(H, H)$.

Theorem 21.3.10 Let $A(s) \in \mathscr{L}(H, H)$ be a compact self adjoint operator and $H$ is a separable Hilbert space such that $s \rightarrow A(s) x$ is strongly measurable. Then there exist real numbers $\left\{\lambda_{k}(s)\right\}_{k=1}^{\infty}$ and vectors $\left\{e_{k}(s)\right\}_{k=1}^{\infty}$ such that

$$
\begin{gathered}
\left\|e_{k}(s)\right\|=1 \\
\left(e_{k}(s), e_{j}(s)\right)_{H}=0 \text { if } k \neq j \\
A(s) e_{k}(s)=\lambda_{k}(s) e_{k}(s) \\
\left|\lambda_{n}(s)\right| \geq\left|\lambda_{n+1}(s)\right| \text { for all } n \\
\lim _{n \rightarrow \infty} \lambda_{n}(s)=0 \\
\lim _{n \rightarrow \infty}\left\|A(s)-\sum_{k=1}^{n} \lambda_{k}(s)\left(e_{k}(s) \otimes e_{k}(s)\right)\right\|_{\mathscr{L}(H, H)}=0
\end{gathered}
$$

The function $s \rightarrow \lambda_{j}(s)$ is measurable and $s \rightarrow e_{j}(s)$ is strongly measurable.
Proof: It is simply a repeat of the above proof of the Hilbert Schmidt theorem except at every step when the $e_{k}$ and $\lambda_{k}$ are defined, you use the Kuratowski measurable selection theorem, Theorem 21.3.4 on Page 661 to obtain $\lambda_{k}(s)$ is measurable and that $s \rightarrow e_{k}(s)$ is also measurable. This follows because the closed unit ball in a separable Hilbert space is a compact metric space.

When you consider $\max _{x \in B}\left|\left(A_{n}(s) x, x\right)\right|$, let $\psi(x, s)=\left|\left(A_{n}(s) x, x\right)\right|$. Then $\psi$ is continuous in $x$ by Lemma 21.3.6 on Page 661 and it is measurable in $s$ by assumption. Therefore, by the Kuratowski theorem, $e_{k}(s)$ is measurable in the sense that inverse images of weakly open sets in $B$ are measurable. However, by Lemma 21.1.12 on Page 648 this is the same as weakly measurable. Since $H$ is separable, this implies $s \rightarrow e_{k}(s)$ is also strongly measurable. The measurability of $\lambda_{k}$ and $e_{k}$ is the only new thing here and so this completes the proof.

### 21.4 Fubini's Theorem for Bochner Integrals

Now suppose $\left(\Omega_{1}, \mathscr{F}, \mu\right)$ and $\left(\Omega_{2}, \mathscr{S}, \lambda\right)$ are two $\sigma$ finite measure spaces. Recall the notion of product measure. There was a $\sigma$ algebra, denoted by $\mathscr{F} \times \mathscr{S}$ which is the smallest $\sigma$ algebra containing the elementary sets, (finite disjoint unions of measurable rectangles) and a measure, denoted by $\mu \times \lambda$ defined on this $\sigma$ algebra such that for $E \in \mathscr{F} \times \mathscr{S}$,

$$
s_{1} \rightarrow \lambda\left(E_{s_{1}}\right),\left(E_{s_{1}} \equiv\left\{s_{2}:\left(s_{1}, s_{2}\right) \in E\right\}\right)
$$

is $\mu$ measurable and

$$
s_{2} \rightarrow \mu\left(E_{s_{2}}\right),\left(E_{s_{2}} \equiv\left\{s_{1}:\left(s_{1}, s_{2}\right) \in E\right\}\right)
$$

is $\lambda$ measurable. In terms of nonnegative functions which are $\mathscr{F} \times \mathscr{S}$ measurable,

$$
\begin{aligned}
& s_{1} \rightarrow f\left(s_{1}, s_{2}\right) \text { is } \mu \text { measurable } \\
& s_{2} \rightarrow f\left(s_{1}, s_{2}\right) \text { is } \lambda \text { measurable } \\
& s_{1} \rightarrow \int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) d \lambda \text { is } \mu \text { measurable } \\
& s_{2} \rightarrow \int_{\Omega_{1}} f\left(s_{1}, s_{2}\right) d \mu \text { is } \lambda \text { measurable }
\end{aligned}
$$

and the conclusion of Fubini's theorem holds.

$$
\begin{aligned}
\int_{\Omega_{1} \times \Omega_{2}} f d(\mu \times \lambda) & =\int_{\Omega_{1}} \int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) d \lambda d \mu \\
& =\int_{\Omega_{2}} \int_{\Omega_{1}} f\left(s_{1}, s_{2}\right) d \mu d \lambda
\end{aligned}
$$

The following theorem is the version of Fubini's theorem valid for Bochner integrable functions.

Theorem 21.4.1 Let $f: \Omega_{1} \times \Omega_{2} \rightarrow X$ be strongly measurable with respect to $\mu \times \lambda$ and suppose

$$
\begin{equation*}
\int_{\Omega_{1} \times \Omega_{2}}\left\|f\left(s_{1}, s_{2}\right)\right\| d(\mu \times \lambda)<\infty . \tag{21.4.17}
\end{equation*}
$$

Then there exist a set of $\mu$ measure zero, $N$ and a set of $\lambda$ measure zero, $M$ such that the following formula holds with all integrals making sense.

$$
\begin{aligned}
\int_{\Omega_{1} \times \Omega_{2}} f\left(s_{1}, s_{2}\right) d(\mu \times \lambda) & =\int_{\Omega_{1}} \int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N}\left(s_{1}\right) d \lambda d \mu \\
& =\int_{\Omega_{2}} \int_{\Omega_{1}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{M}\left(s_{2}\right) d \mu d \lambda
\end{aligned}
$$

Proof: First note that from 21.4.17 and the usual Fubini theorem for nonnegative valued functions,

$$
\int_{\Omega_{1} \times \Omega_{2}}\left\|f\left(s_{1}, s_{2}\right)\right\| d(\mu \times \lambda)=\int_{\Omega_{1}} \int_{\Omega_{2}}\left\|f\left(s_{1}, s_{2}\right)\right\| d \lambda d \mu
$$

and so

$$
\begin{equation*}
\int_{\Omega_{2}}\left\|f\left(s_{1}, s_{2}\right)\right\| d \lambda<\infty \tag{21.4.18}
\end{equation*}
$$

for $\mu$ a.e. $s_{1}$. Say for all $s_{1} \notin N$ where $\mu(N)=0$.
Let $\phi \in X^{\prime}$. Then $\phi \circ f$ is $\mathscr{F} \times \mathscr{S}$ measurable and

$$
\begin{aligned}
& \int_{\Omega_{1} \times \Omega_{2}}\left|\phi \circ f\left(s_{1}, s_{2}\right)\right| d(\mu \times \lambda) \\
\leq & \int_{\Omega_{1} \times \Omega_{2}}\|\phi\|\left\|f\left(s_{1}, s_{2}\right)\right\| d(\mu \times \lambda)<\infty
\end{aligned}
$$

and so from the usual Fubini theorem for complex valued functions,

$$
\begin{equation*}
\int_{\Omega_{1} \times \Omega_{2}} \phi \circ f\left(s_{1}, s_{2}\right) d(\mu \times \lambda)=\int_{\Omega_{1}} \int_{\Omega_{2}} \phi \circ f\left(s_{1}, s_{2}\right) d \lambda d \mu . \tag{21.4.19}
\end{equation*}
$$

Now also if you fix $s_{2}$, it follows from the definition of strongly measurable and the properties of product measure mentioned above that

$$
s_{1} \rightarrow f\left(s_{1}, s_{2}\right)
$$

is strongly measurable. Also, by 21.4.18

$$
\int_{\Omega_{2}}\left\|f\left(s_{1}, s_{2}\right)\right\| d \lambda<\infty
$$

for $s_{1} \notin N$. Therefore, by Theorem 21.2.4 $s_{2} \rightarrow f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right)$ is Bochner integrable. By 21.4.19 and 21.2.5

$$
\begin{align*}
& \int_{\Omega_{1} \times \Omega_{2}} \phi \circ f\left(s_{1}, s_{2}\right) d(\mu \times \lambda) \\
= & \int_{\Omega_{1}} \int_{\Omega_{2}} \phi \circ f\left(s_{1}, s_{2}\right) d \lambda d \mu \\
= & \int_{\Omega_{1}} \int_{\Omega_{2}} \phi\left(f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right)\right) d \lambda d \mu \\
= & \int_{\Omega_{1}} \phi\left(\int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right) d \lambda\right) d \mu . \tag{21.4.20}
\end{align*}
$$

Each iterated integral makes sense and

$$
\begin{align*}
s_{1} & \rightarrow \int_{\Omega_{2}} \phi\left(f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right)\right) d \lambda \\
& =\phi\left(\int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right) d \lambda\right) \tag{21.4.21}
\end{align*}
$$

is $\mu$ measurable because

$$
\begin{aligned}
\left(s_{1}, s_{2}\right) & \rightarrow \phi\left(f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right)\right) \\
& =\phi\left(f\left(s_{1}, s_{2}\right)\right) \mathscr{X}_{N^{C}}\left(s_{1}\right)
\end{aligned}
$$

is product measurable. Now consider the function,

$$
\begin{equation*}
s_{1} \rightarrow \int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right) d \lambda \tag{21.4.22}
\end{equation*}
$$

I want to show this is also Bochner integrable with respect to $\mu$ so I can factor out $\phi$ once again. It's measurability follows from the Pettis theorem and the above observation 21.4.21.

Also,

$$
\begin{aligned}
& \int_{\Omega_{1}}\left\|\int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right) d \lambda\right\| d \mu \\
\leq & \int_{\Omega_{1}} \int_{\Omega_{2}}\left\|f\left(s_{1}, s_{2}\right)\right\| d \lambda d \mu \\
= & \int_{\Omega_{1} \times \Omega_{2}}\left\|f\left(s_{1}, s_{2}\right)\right\| d(\mu \times \lambda)<\infty .
\end{aligned}
$$

Therefore, the function in 21.4.22 is indeed Bochner integrable and so in 21.4.20 the $\phi$ can be taken outside the last integral. Thus,

$$
\begin{aligned}
& \phi\left(\int_{\Omega_{1} \times \Omega_{2}} f\left(s_{1}, s_{2}\right) d(\mu \times \lambda)\right) \\
= & \int_{\Omega_{1} \times \Omega_{2}} \phi \circ f\left(s_{1}, s_{2}\right) d(\mu \times \lambda) \\
= & \int_{\Omega_{1}} \int_{\Omega_{2}} \phi \circ f\left(s_{1}, s_{2}\right) d \lambda d \mu \\
= & \int_{\Omega_{1}} \phi\left(\int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right) d \lambda\right) d \mu \\
= & \phi\left(\int_{\Omega_{1}} \int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right) d \lambda d \mu\right) .
\end{aligned}
$$

Since $X^{\prime}$ separates the points,

$$
\int_{\Omega_{1} \times \Omega_{2}} f\left(s_{1}, s_{2}\right) d(\mu \times \lambda)=\int_{\Omega_{1}} \int_{\Omega_{2}} f\left(s_{1}, s_{2}\right) \mathscr{X}_{N^{C}}\left(s_{1}\right) d \lambda d \mu .
$$

The other formula follows from similar reasoning.

### 21.5 The Spaces $L^{p}(\Omega ; X)$

Recall that $x$ is Bochner when it is strongly measurable and $\int_{\Omega}\|x(s)\| d \mu<\infty$. It is natural to generalize to $\int_{\Omega}\|x(s)\|^{p} d \mu<\infty$.
Definition 21.5.1 $x \in L^{p}(\Omega ; X)$ for $p \in[1, \infty)$ if $x$ is strongly measurable and

$$
\int_{\Omega}\|x(s)\|^{p} d \mu<\infty
$$

Also

$$
\begin{equation*}
\|x\|_{L^{p}(\Omega ; X)} \equiv\|x\|_{p} \equiv\left(\int_{\Omega}\|x(s)\|^{p} d \mu\right)^{1 / p} \tag{21.5.23}
\end{equation*}
$$

As in the case of scalar valued functions, two functions in $L^{p}(\Omega ; X)$ are considered equal if they are equal a.e. With this convention, and using the same arguments found in the presentation of scalar valued functions it is clear that $L^{p}(\Omega ; X)$ is a normed linear space with the norm given by 21.5.23. In fact, $L^{p}(\Omega ; X)$ is a Banach space. This is the main contribution of the next theorem.

Lemma 21.5.2 If $x_{n}$ is a Cauchy sequence in $L^{p}(\Omega ; X)$ satisfying

$$
\sum_{n=1}^{\infty}\left\|x_{n+1}-x_{n}\right\|_{p}<\infty
$$

then there exists $x \in L^{p}(\Omega ; X)$ such that $x_{n}(s) \rightarrow x(s)$ a.e. and

$$
\left\|x-x_{n}\right\|_{p} \rightarrow 0
$$

Proof: Let $g_{N}(s) \equiv \sum_{n=1}^{N}\left\|x_{n+1}(s)-x_{n}(s)\right\|_{X}$. Then by the triangle inequality,

$$
\begin{aligned}
\left(\int_{\Omega} g_{N}(s)^{p} d \mu\right)^{1 / p} & \leq \sum_{n=1}^{N}\left(\int_{\Omega}\left\|x_{n+1}(s)-x_{n}(s)\right\|^{p} d \mu\right)^{1 / p} \\
& \leq \sum_{n=1}^{\infty}\left\|x_{n+1}-x_{n}\right\|_{p}<\infty
\end{aligned}
$$

Let

$$
g(s)=\lim _{N \rightarrow \infty} g_{N}(s)=\sum_{n=1}^{\infty}\left\|x_{n+1}(s)-x_{n}(s)\right\|_{X}
$$

By the monotone convergence theorem,

$$
\left(\int_{\Omega} g(s)^{p} d \mu\right)^{1 / p}=\lim _{N \rightarrow \infty}\left(\int_{\Omega} g_{N}(s)^{p} d \mu\right)^{1 / p}<\infty
$$

Therefore, there exists a measurable set of measure 0 called $E$, such that for $s \notin E$, it follows that $g(s)<\infty$. Hence, for $s \notin E, \lim _{N \rightarrow \infty} x_{N+1}(s)$ exists because

$$
x_{N+1}(s)=x_{N+1}(s)-x_{1}(s)+x_{1}(s)=\sum_{n=1}^{N}\left(x_{n+1}(s)-x_{n}(s)\right)+x_{1}(s) .
$$

Thus, if $N>M$, and $s$ is a point where $g(s)<\infty$,

$$
\begin{aligned}
\left\|x_{N+1}(s)-x_{M+1}(s)\right\|_{X} & \leq \sum_{n=M+1}^{N}\left\|x_{n+1}(s)-x_{n}(s)\right\|_{X} \\
& \leq \sum_{n=M+1}^{\infty}\left\|x_{n+1}(s)-x_{n}(s)\right\|_{X}
\end{aligned}
$$

which shows that $\left\{x_{N+1}(s)\right\}_{N=1}^{\infty}$ is a Cauchy sequence for each $s \notin E$. Now let

$$
x(s) \equiv\left\{\begin{array}{l}
\lim _{N \rightarrow \infty} x_{N}(s) \text { if } s \notin E \\
0 \text { if } s \in E
\end{array}\right.
$$

Theorem 21.1.10 shows that $x$ is strongly measurable. By Fatou's lemma,

$$
\int_{\Omega}\left\|x(s)-x_{N}(s)\right\|^{p} d \mu \leq \lim _{M \rightarrow \infty} \inf _{\Omega}\left\|x_{M}(s)-x_{N}(s)\right\|^{p} d \mu .
$$

But if $N$ and $M$ are large enough with $M>N$,

$$
\left(\int_{\Omega}\left\|x_{M}(s)-x_{N}(s)\right\|^{p} d \mu\right)^{1 / p} \leq \sum_{n=N}^{M}\left\|x_{n+1}-x_{n}\right\|_{p} \leq \sum_{n=N}^{\infty}\left\|x_{n+1}-x_{n}\right\|_{p}<\varepsilon
$$

and this shows, since $\varepsilon$ is arbitrary, that

$$
\lim _{N \rightarrow \infty} \int_{\Omega}\left\|x(s)-x_{N}(s)\right\|^{p} d \mu=0
$$

It remains to show $x \in L^{p}(\Omega ; X)$. This follows from the above and the triangle inequality. Thus, for $N$ large enough,

$$
\begin{gathered}
\left(\int_{\Omega}\|x(s)\|^{p} d \mu\right)^{1 / p} \leq\left(\int_{\Omega}\left\|x_{N}(s)\right\|^{p} d \mu\right)^{1 / p} \\
+\left(\int_{\Omega}\left\|x(s)-x_{N}(s)\right\|^{p} d \mu\right)^{1 / p} \leq\left(\int_{\Omega}\left\|x_{N}(s)\right\|^{p} d \mu\right)^{1 / p}+\varepsilon<\infty
\end{gathered}
$$

Theorem 21.5.3 $L^{p}(\Omega ; X)$ is complete. Also every Cauchy sequence has a subsequence which converges pointwise.

Proof: If $\left\{x_{n}\right\}$ is Cauchy in $L^{p}(\Omega ; X)$, extract a subsequence $\left\{x_{n_{k}}\right\}$ satisfying

$$
\left\|x_{n_{k+1}}-x_{n_{k}}\right\|_{p} \leq 2^{-k}
$$

and apply Lemma 21.5.2. The pointwise convergence of this subsequence was established in the proof of this lemma. This proves the theorem because if a subsequence of a Cauchy sequence converges, then the Cauchy sequence must also converge.

Observation 21.5.4 If the measure space is Lebesgue measure then you have continuity of translation in $L^{p}\left(\mathbb{R}^{n} ; X\right)$ in the usual way. More generally, for $\mu$ a Radon measure on $\Omega$ a locally compact Hausdorff space, $C_{c}(\Omega ; X)$ is dense in $L^{p}(\Omega ; X)$. Here $C_{c}(\Omega ; X)$ is the space of continuous $X$ valued functions which have compact support in $\Omega$. The proof of this little observation follows immediately from approximating with simple functions and then applying the appropriate considerations to the simple functions.

Clearly Fatou's lemma and the monotone convergence theorem make no sense for functions with values in a Banach space but the dominated convergence theorem holds in this setting.

Theorem 21.5.5 If $x$ is strongly measurable and $x_{n}(s) \rightarrow x(s)$ a.e. (for $s$ off a set of measure zero) with

$$
\left\|x_{n}(s)\right\| \leq g(s) \text { a.e. }
$$

where $\int_{\Omega} g d \mu<\infty$, then $x$ is Bochner integrable and

$$
\int_{\Omega} x(s) d \mu=\lim _{n \rightarrow \infty} \int_{\Omega} x_{n}(s) d \mu .
$$

Proof: The measurability of $x$ follows from Theorem 21.1.10 if convergence happens for each $s$. Otherwise, $x$ is measurable by assumption. Then $\left\|x_{n}(s)-x(s)\right\| \leq 2 g(s)$ a.e. so, from Fatou's lemma,

$$
\begin{aligned}
\int_{\Omega} 2 g(s) d \mu & \leq \liminf _{n \rightarrow \infty} \int_{\Omega}\left(2 g(s)-\left\|x_{n}(s)-x(s)\right\|\right) d \mu \\
& =\int_{\Omega} 2 g(s) d \mu-\lim \sup _{n \rightarrow \infty} \int_{\Omega}\left\|x_{n}(s)-x(s)\right\| d \mu
\end{aligned}
$$

and so,

$$
\lim \sup _{n \rightarrow \infty} \int_{\Omega}\left\|x_{n}(s)-x(s)\right\| d \mu \leq 0
$$

Also, from Fatou's lemma again,

$$
\int_{\Omega}\|x(s)\| d \mu \leq \lim \inf _{n \rightarrow \infty} \int_{\Omega}\left\|x_{n}(s)\right\| d \mu<\int_{\Omega} g(s) d \mu<\infty
$$

so $x \in L^{1}$. Then by the triangle inequality,

$$
\lim \sup _{n \rightarrow \infty}\left\|\int_{\Omega} x(s) d \mu-\int_{\Omega} x_{n}(s) d \mu\right\| \leq \lim \sup _{n \rightarrow \infty} \int_{\Omega}\left\|x_{n}(s)-x(s)\right\| d \mu=0
$$

One can also give a version of the Vitali convergence theorem.
Definition 21.5.6 Let $\mathscr{A} \subseteq L^{1}(\Omega ; X)$. Then $\mathscr{A}$ is said to be uniformly integrable if for every $\varepsilon>0$ there exists $\delta>0$ such that whenever $\mu(E)<\delta$, it follows

$$
\int_{E}\|f\|_{X} d \mu<\varepsilon
$$

for all $f \in \mathscr{A}$. It is bounded if

$$
\sup _{f \in \mathscr{A}} \int_{\Omega}\|f\|_{X} d \mu<\infty .
$$

Theorem 21.5.7 Let $(\Omega, \mathscr{F}, \mu)$ be a finite measure space and let $X$ be a separable Banach space. Let $\left\{f_{n}\right\} \subseteq L^{1}(\Omega ; X)$ be uniformly integrable and bounded such that $f_{n}(\omega) \rightarrow f(\omega)$ for each $\omega \in \Omega$. Then $f \in L^{1}(\Omega ; X)$ and

$$
\lim _{n \rightarrow \infty} \int_{\Omega}\left\|f_{n}-f\right\|_{X} d \mu=0
$$

Proof: Let $\varepsilon>0$ be given. Then by uniform integrability there exists $\delta>0$ such that if $\mu(E)<\delta$ then

$$
\int_{E}\left\|f_{n}\right\| d \mu<\varepsilon / 3
$$

By Fatou's lemma the same inequality holds for $f$. Also Fatou's lemma shows $f \in L^{1}(\Omega ; X)$, $f$ being measurable because of Theorem 11.1.9.

By Egoroff's theorem, Theorem 11.3.11, there exists a set of measure less than $\delta, E$ such that the convergence of $\left\{f_{n}\right\}$ to $f$ is uniform off $E$. Therefore,

$$
\begin{aligned}
\int_{\Omega}\left\|f-f_{n}\right\| d \mu & \leq \int_{E}\left(\|f\|_{X}+\left\|f_{n}\right\|_{X}\right) d \mu+\int_{E^{C}}\left\|f-f_{n}\right\|_{X} d \mu \\
& <\frac{2 \varepsilon}{3}+\int_{E^{C}} \frac{\varepsilon}{(\mu(\Omega)+1) 3} d \mu<\varepsilon
\end{aligned}
$$

if $n$ is large enough.
Note that a convenient way to achieve uniform integrability is to say $\left\{f_{n}\right\}$ is bounded in $L^{p}(\Omega ; X)$ for some $p>1$. This follows from Holder's inequality.

$$
\int_{E}\left\|f_{n}\right\| d \mu \leq\left(\int_{E} d \mu\right)^{1 / p^{\prime}}\left(\int_{\Omega}\left\|f_{n}\right\|^{p} d \mu\right)^{1 / p} \leq C \mu(E)^{1 / p^{\prime}}
$$

The following theorem is interesting.
Theorem 21.5.8 Let $1 \leq p<\infty$ and let $p<r \leq \infty$. Then $L^{r}([0, T], X)$ is a Borel subset of $L^{p}([0, T] ; X)$. Letting $C([0, T] ; X)$ denote the functions having values in $X$ which are continuous, $C([0, T] ; X)$ is also a Borel subset of $L^{p}([0, T] ; X)$. Here the measure is ordinary one dimensional Lebesgue measure on $[0, T]$.

Proof: First consider the claim about $L^{r}([0, T] ; X)$. Let

$$
B_{M} \equiv\left\{x \in L^{p}([0, T] ; X):\|x\|_{L^{r}([0, T] ; X)} \leq M\right\}
$$

Then $B_{M}$ is a closed subset of $L^{p}([0, T] ; X)$. Here is why. If $\left\{x_{n}\right\}$ is a sequence of elements of $B_{M}$ and $x_{n} \rightarrow x$ in $L^{p}([0, T] ; X)$, then passing to a subsequence, still denoted by $x_{n}$, it can be assumed $x_{n}(s) \rightarrow x(s)$ a.e. Hence Fatou's lemma can be applied to conclude

$$
\int_{0}^{T}\|x(s)\|^{r} d s \leq \lim _{n \rightarrow \infty} \inf _{0} \int_{0}^{T}\left\|x_{n}(s)\right\|^{r} d s \leq M^{r}<\infty
$$

Now $\cup_{M=1}^{\infty} B_{M}=L^{r}([0, T] ; X)$. Note this did not depend on the measure space used. It would have been equally valid on any measure space.

Consider now $C([0, T] ; X)$. The norm on this space is the usual norm, $\|\cdot\|_{\infty}$. The argument above shows $\|\cdot\|_{\infty}$ is a Borel measurable function on $L^{p}([0, T] ; X)$. This is because $B_{M} \equiv\left\{x \in L^{p}([0, T] ; X):\|x\|_{\infty} \leq M\right\}$ is a closed, hence Borel subset of $L^{p}([0, T] ; X)$. Now let $\theta \in \mathscr{L}\left(L^{p}([0, T] ; X), L^{p}(\mathbb{R} ; X)\right)$ such that $\theta(x(t))=x(t)$ for all $t \in[0, T]$ and also $\theta \in \mathscr{L}(C([0, T] ; X), B C(\mathbb{R} ; X))$ where $B C(\mathbb{R} ; X)$ denotes the bounded continuous functions with a norm given by $\|x\| \equiv \sup _{t \in \mathbb{R}}\|x(t)\|$, and $\theta x$ has compact support.

For example, you could define

$$
\widetilde{x}(t) \equiv\left\{\begin{array}{l}
x(t) \text { if } t \in[0, T] \\
x(2 T-t) \text { if } t \in[T, 2 T] \\
x(-t) \text { if } t \in[-T, 0] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

and let $\Phi \in C_{c}^{\infty}(-T, 2 T)$ such that $\Phi(t)=1$ for $t \in[0, T]$. Then you could let

$$
\theta x(t) \equiv \Phi(t) \widetilde{x}(t)
$$

Then let $\left\{\phi_{n}\right\}$ be a mollifier and define

$$
\psi_{n} x(t) \equiv \phi_{n} * \theta x(t)
$$

It follows $\psi_{n} x$ is uniformly continuous because

$$
\begin{aligned}
& \left\|\psi_{n} x(t)-\psi_{n} x\left(t^{\prime}\right)\right\|_{X} \\
\leq & \int_{\mathbb{R}}\left|\phi_{n}\left(t^{\prime}-s\right)-\phi_{n}(t-s)\right|\|\theta x(s)\|_{X} d s \\
\leq & C\|x\|_{p}\left(\int_{\mathbb{R}}\left|\phi_{n}\left(t^{\prime}-s\right)-\phi_{n}(t-s)\right|^{p^{\prime}} d s\right)^{1 / p^{\prime}}
\end{aligned}
$$

Also for $x \in C([0, T] ; X)$, it follows from usual mollifier arguments that

$$
\left\|\psi_{n} x-x\right\|_{L^{\infty}([0, T] ; X)} \rightarrow 0
$$

Here is why. For $t \in[0, T]$,

$$
\begin{aligned}
\left\|\psi_{n} x(t)-x(t)\right\|_{X} & \leq \int_{\mathbb{R}} \phi_{n}(s)\|\theta x(t-s)-\theta x(t)\| d s \\
& \leq C_{\theta} \int_{-1 / n}^{1 / n} \phi_{n}(s) d s \varepsilon=C_{\theta} \varepsilon
\end{aligned}
$$

provided $n$ is large enough due to the compact support and consequent uniform continuity of $\theta x$.

If $\left\|\psi_{n} x-x\right\|_{L^{\infty}([0, T] ; X)} \rightarrow 0$, then $\left\{\psi_{n} x\right\}$ must be a Cauchy sequence in $C([0, T] ; X)$ and this requires that $x$ equals a continuous function a.e. Thus $C([0, T] ; X)$ consists exactly of those functions, $x$ of $L^{p}([0, T] ; X)$ such that $\left\|\psi_{n} x-x\right\|_{\infty} \rightarrow 0$. It follows

$$
\begin{gather*}
C([0, T] ; X)= \\
\cap_{n=1}^{\infty} \cup_{m=1}^{\infty} \cap_{k=m}^{\infty}\left\{x \in L^{p}([0, T] ; X):\left\|\psi_{k} x-x\right\|_{\infty} \leq \frac{1}{n}\right\} \tag{21.5.24}
\end{gather*}
$$

It only remains to show

$$
S \equiv\left\{x \in L^{p}([0, T] ; X):\left\|\psi_{k} x-x\right\|_{\infty} \leq \alpha\right\}
$$

is a Borel set. Suppose then that $x_{n} \in S$ and $x_{n} \rightarrow x$ in $L^{p}([0, T] ; X)$. Then there exists a subsequence, still denoted by $n$ such that $x_{n} \rightarrow x$ pointwise a.e. as well as in $L^{p}$. There exists a set of measure 0 such that for all $n$, and $t$ not in this set,

$$
\begin{aligned}
\left\|\psi_{k} x_{n}(t)-x_{n}(t)\right\| & \equiv\left\|\int_{-1 / k}^{1 / k} \phi_{k}(s)\left(\theta x_{n}(t-s)\right) d s-x_{n}(t)\right\| \leq \alpha \\
x_{n}(t) & \rightarrow x(t)
\end{aligned}
$$

Then

$$
\begin{aligned}
& \left\|\psi_{k} x_{n}(t)-x_{n}(t)-\left(\psi_{k} x(t)-x(t)\right)\right\| \\
\leq & \left\|x_{n}(t)-x(t)\right\|_{X}+\left\|\int_{-1 / k}^{1 / k} \phi_{k}(s)\left(\theta x_{n}(t-s)-\theta x(t-s)\right) d s\right\| \\
\leq & \left\|x_{n}(t)-x(t)\right\|_{X}+C_{k, \theta}\left\|x_{n}-x\right\|_{L^{p}(0, T ; X)}
\end{aligned}
$$

which converges to 0 as $n \rightarrow \infty$. It follows that for a.e. $t$,

$$
\left\|\psi_{k} x(t)-x(t)\right\| \leq \alpha
$$

Thus $S$ is closed and so the set in 21.5.24 is a Borel set.
As in the scalar case, the following lemma holds in this more general context.
Lemma 21.5.9 Let $(\Omega, \mu)$ be a regular measure space where $\Omega$ is a locally compact Hausdorff space. Then $C_{c}(\Omega ; X)$ the space of continuous functions having compact support and values in $X$ is dense in $L^{p}(0, T ; X)$ for all $p \in[0, \infty)$. For any $\sigma$ finite measure space, the simple functions are dense in $L^{p}(0, T ; X)$.

Proof: First is it shown the simple functions are dense in $L^{p}(0, T ; X)$. Let $f$ be a function in $L^{p}(0, T ; X)$ and let $\left\{x_{n}\right\}$ denote a sequence of simple functions which converge to $f$ pointwise which also have the property that

$$
\left\|x_{n}(s)\right\| \leq 2\|f(s)\|
$$

Then

$$
\int_{\Omega}\left\|x_{n}(s)-f(s)\right\|^{p} d \mu \rightarrow 0
$$

from the dominated convergence theorem. Therefore, the simple functions are indeed dense in $L^{p}(0, T ; X)$.

Next suppose $(\Omega, \mu)$ is a regular measure space. If $x(s) \equiv \sum_{i} a_{i} \mathscr{X}_{E_{i}}(s)$ is a simple function, then by regularity, there exist compact sets, $K_{i}$ and open sets, $V_{i}$ such that $K_{i} \subseteq$ $E_{i} \subseteq V_{i}$ and $\mu\left(V_{i} \backslash K_{i}\right)^{1 / p}<\varepsilon / \sum_{i}\left\|a_{i}\right\|$. Let $K_{i} \prec h_{i} \prec V_{i}$. Then consider

$$
\sum_{i} a_{i} h_{i} \in C_{c}(\Omega)
$$

By the triangle inequality,

$$
\begin{aligned}
& \left(\int_{\Omega}\left\|\sum_{i} a_{i} h_{i}(s)-a_{i} \mathscr{X}_{E_{i}}(s)\right\|^{p} d \mu\right)^{1 / p} \leq \sum_{i}\left(\int_{\Omega}\left\|a_{i}\left(h_{i}(s)-\mathscr{X}_{E_{i}}(s)\right)\right\|^{p} d \mu\right)^{1 / p} \\
\leq & \sum_{i}\left(\int_{\Omega}\left\|a_{i}\right\|^{p}\left|h_{i}(s)-\mathscr{X}_{E_{i}}(s)\right|^{p} d \mu\right)^{1 / p} \leq \sum_{i}\left\|a_{i}\right\|\left(\int_{V_{i} \backslash K_{i}} d \mu\right)^{1 / p} \\
\leq & \sum_{i}\left\|a_{i}\right\| \mu\left(V_{i} \backslash K_{i}\right)^{1 / p}<\varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this and the first part of the lemma shows $C_{c}(\Omega ; X)$ is dense in $L^{p}(\Omega ; X)$.

### 21.6 Measurable Representatives

In this section consider the special case where $X=L^{1}(B, v)$ where $(B, \mathscr{F}, v)$ is a $\sigma$ finite measure space and $x \in L^{1}(\Omega ; X)$. Thus for each $s \in \Omega, x(s) \in L^{1}(B, v)$. In general, the map

$$
(s, t) \rightarrow x(s)(t)
$$

will not be product measurable, but one can obtain a measurable representative. This is important because it allows the use of Fubini's theorem on the measurable representative.

By Theorem 21.2.4, there exists a sequence of simple functions, $\left\{x_{n}\right\}$, of the form

$$
\begin{equation*}
x_{n}(s)=\sum_{k=1}^{m} a_{k} \mathscr{X}_{E_{k}}(s) \tag{21.6.25}
\end{equation*}
$$

where $a_{k} \in L^{1}(B, v)$ which satisfy the conditions of Definition 21.2.3 and

$$
\begin{equation*}
\left\|x_{n}-x_{m}\right\|_{L^{1}\left(\Omega, L^{1}(B)\right)} \rightarrow 0 \text { as } m, n \rightarrow \infty \tag{21.6.26}
\end{equation*}
$$

For such a simple function, you can assume the $E_{k}$ are disjoint and then

$$
\begin{aligned}
\left\|x_{n}\right\|_{L^{1}\left(\Omega, L^{1}(B)\right)} & =\sum_{k=1}^{m}\left\|a_{k}\right\|_{L^{1}(B)} \mu\left(E_{k}\right)=\sum_{k=1}^{m} \int_{B}\left|a_{k}\right| d v \mu\left(E_{k}\right) \\
& =\int_{\Omega} \int_{B}\left|a_{k}(t)\right| d v(t) \mathscr{X}_{E_{k}}(s) d \mu(s) \\
& =\int_{\Omega} \int_{B}\left|x_{n}\right| d v d \mu
\end{aligned}
$$

Also, each $x_{n}$ is product measurable. Thus from 21.6.26,

$$
\left\|x_{n}-x_{m}\right\|_{L^{1}\left(\Omega, L^{1}(B)\right)}=\int_{\Omega} \int_{B}\left|x_{n}-x_{m}\right| d \nu d \mu
$$

which shows that $\left\{x_{n}\right\}$ is a Cauchy sequence in $L^{1}(\Omega \times B, \mu \times \lambda)$. Then there exists $y \in$ $L^{1}(\Omega \times B, \mu \times \lambda)$ and a subsequence still called $\left\{x_{n}\right\}$ such that

$$
\lim _{n \rightarrow \infty} \int_{\Omega} \int_{B}\left|x_{n}-y\right| d v d \mu=\lim _{n \rightarrow \infty} \int_{\Omega}\left\|x_{n}-y\right\|_{L^{1}(B)} d \mu=\left\|x_{n}-y\right\|_{L^{1}\left(\Omega, L^{1}(B)\right)}=0
$$

Now consider 21.6.26. Since $\lim _{m \rightarrow \infty} x_{m}(s)=x(s)$ in $L^{1}(B)$, it follows from Fatou's lemma that

$$
\left\|x_{n}-x\right\|_{L^{1}\left(\Omega, L^{1}(B)\right)} \leq \lim \inf _{m \rightarrow \infty}\left\|x_{n}-x_{m}\right\|_{L^{1}\left(\Omega, L^{1}(B)\right)}<\varepsilon
$$

for all $n$ large enough. Hence

$$
\lim _{n \rightarrow \infty}\left\|x_{n}-x\right\|_{L^{1}\left(\Omega, L^{1}(B)\right)}=0
$$

and so

$$
x(s)=y(s) \text { in } L^{1}(B) \mu \text { a.e. } s
$$

In particular, for a.e. $s$, it follows that

$$
x(s)(t)=y(s, t) \text { for a.e. } t
$$

Now $\int_{\Omega} x(s) d \mu \in X=L^{1}(B, v)$ so it makes sense to ask for $\left(\int_{\Omega} x(s) d \mu\right)(t)$, at least $\mu$ a.e. $t$. To find what this is, note

$$
\left\|\int_{\Omega} x_{n}(s) d \mu-\int_{\Omega} x(s) d \mu\right\|_{X} \leq \int_{\Omega}\left\|x_{n}(s)-x(s)\right\|_{X} d \mu .
$$

Therefore, since the right side converges to 0 ,

$$
\begin{gathered}
\lim _{n \rightarrow \infty}\left\|\int_{\Omega} x_{n}(s) d \mu-\int_{\Omega} x(s) d \mu\right\|_{X}= \\
\lim _{n \rightarrow \infty} \int_{B}\left|\left(\int_{\Omega} x_{n}(s) d \mu\right)(t)-\left(\int_{\Omega} x(s) d \mu\right)(t)\right| d v=0 .
\end{gathered}
$$

But

$$
\left(\int_{\Omega} x_{n}(s) d \mu\right)(t)=\int_{\Omega} x_{n}(s, t) d \mu \text { a.e. } t
$$

Therefore

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{B}\left|\int_{\Omega} x_{n}(s, t) d \mu-\left(\int_{\Omega} x(s) d \mu\right)(t)\right| d v=0 \tag{21.6.27}
\end{equation*}
$$

Also, since $x_{n} \rightarrow y$ in $L^{1}(\Omega \times B)$,

$$
\begin{align*}
& 0=\lim _{n \rightarrow \infty} \int_{B} \int_{\Omega}\left|x_{n}(s, t)-y(s, t)\right| d \mu d v \geq \\
& \lim _{n \rightarrow \infty} \int_{B}\left|\int_{\Omega} x_{n}(s, t) d \mu-\int_{\Omega} y(s, t) d \mu\right| d v \tag{21.6.28}
\end{align*}
$$

From 21.6.27 and 21.6.28

$$
\int_{\Omega} y(s, t) d \mu=\left(\int_{\Omega} x(s) d \mu\right)(t) \text { a.e. } t
$$

Theorem 21.6.1 Let $X=L^{1}(B)$ where $(B, \mathscr{F}, v)$ is a $\sigma$ finite measure space and let

$$
x \in L^{1}(\Omega ; X)
$$

Then there exists a measurable representative, $y \in L^{1}(\Omega \times B)$, such that

$$
x(s)=y(s, \cdot) \text { a.e. } s \text { in } \Omega, \text { the equation in } L^{1}(B)
$$

and

$$
\int_{\Omega} y(s, t) d \mu=\left(\int_{\Omega} x(s) d \mu\right)(t) \text { a.e. } t .
$$

### 21.7 Vector Measures

There is also a concept of vector measures.
Definition 21.7.1 Let $(\Omega, \mathscr{S})$ be a set and a $\sigma$ algebra of subsets of $\Omega$. A mapping

$$
F: \mathscr{S} \rightarrow X
$$

is said to be a vector measure if

$$
F\left(\cup_{i=1}^{\infty} E_{i}\right)=\sum_{i=1}^{\infty} F\left(E_{i}\right)
$$

whenever $\left\{E_{i}\right\}_{i=1}^{\infty}$ is a sequence of disjoint elements of $\mathscr{S}$. For $F$ a vector measure,

$$
|F|(A) \equiv \sup \left\{\sum_{F \in \pi(A)}\|\mu(F)\|: \pi(A) \text { is a partition of } A\right\} .
$$

This is the same definition that was given in the case where $F$ would have values in $\mathbb{C}$, the only difference being the fact that now $F$ has values in a general Banach space $X$ as the vector space of values of the vector measure. Recall that a partition of $A$ is a finite set, $\left\{F_{1}, \cdots, F_{m}\right\} \subseteq \mathscr{S}$ such that $\cup_{i=1}^{m} F_{i}=A$. The same theorem about $|F|$ proved in the case of complex valued measures holds in this context with the same proof. For completeness, it is included here.

Theorem 21.7.2 If $|F|(\Omega)<\infty$, then $|F|$ is a measure on $\mathscr{S}$.
Proof: Let $E_{1}$ and $E_{2}$ be sets of $\mathscr{S}$ such that $E_{1} \cap E_{2}=\emptyset$ and let $\left\{A_{1}^{i}, \cdots, A_{n_{i}}^{i}\right\}=\pi\left(E_{i}\right)$, a partition of $E_{i}$ which is chosen such that

$$
|F|\left(E_{i}\right)-\varepsilon<\sum_{j=1}^{n_{i}}\left\|F\left(A_{j}^{i}\right)\right\| i=1,2
$$

Consider the sets which are contained in either of $\pi\left(E_{1}\right)$ or $\pi\left(E_{2}\right)$, it follows this collection of sets is a partition of $E_{1} \cup E_{2}$ which is denoted here by $\pi\left(E_{1} \cup E_{2}\right)$. Then by the above inequality and the definition of total variation,

$$
|F|\left(E_{1} \cup E_{2}\right) \geq \sum_{F \in \pi\left(E_{1} \cup E_{2}\right)}\|F(F)\|>|F|\left(E_{1}\right)+|F|\left(E_{2}\right)-2 \varepsilon
$$

which shows that since $\varepsilon>0$ was arbitrary,

$$
\begin{equation*}
|F|\left(E_{1} \cup E_{2}\right) \geq|F|\left(E_{1}\right)+|F|\left(E_{2}\right) . \tag{21.7.29}
\end{equation*}
$$

Let $\left\{E_{j}\right\}_{j=1}^{\infty}$ be a sequence of disjoint sets of $\mathscr{S}$ and let $E_{\infty}=\cup_{j=1}^{\infty} E_{j}$. Then by the definition of total variation there exists a partition of $E_{\infty}, \pi\left(E_{\infty}\right)=\left\{A_{1}, \cdots, A_{n}\right\}$ such that

$$
|F|\left(E_{\infty}\right)-\varepsilon<\sum_{i=1}^{n}\left\|F\left(A_{i}\right)\right\|
$$

Also,

$$
A_{i}=\cup_{j=1}^{\infty} A_{i} \cap E_{j}, \text { so } F\left(A_{j}\right)=\sum_{j=1}^{\infty} F\left(A_{i} \cap E_{j}\right)
$$

and so by the triangle inequality, $\left\|F\left(A_{i}\right)\right\| \leq \sum_{j=1}^{\infty}\left\|F\left(A_{i} \cap E_{j}\right)\right\|$. Therefore, by the above,

$$
|F|\left(E_{\infty}\right)-\varepsilon<\sum_{i=1}^{n} \overbrace{\sum_{j=1}^{\infty}\left\|F\left(A_{i} \cap E_{j}\right)\right\|}^{\geq\left\|F\left(A_{i}\right)\right\|}=\sum_{j=1}^{\infty} \sum_{i=1}^{n}\left\|F\left(A_{i} \cap E_{j}\right)\right\| \leq \sum_{j=1}^{\infty}|F|\left(E_{j}\right)
$$

because $\left\{A_{i} \cap E_{j}\right\}_{i=1}^{n}$ is a partition of $E_{j}$.
Since $\varepsilon>0$ is arbitrary, this shows

$$
|F|\left(\cup_{j=1}^{\infty} E_{j}\right) \leq \sum_{j=1}^{\infty}|F|\left(E_{j}\right)
$$

Also, 21.7.29 implies that whenever the $E_{i}$ are disjoint, $|F|\left(\cup_{j=1}^{n} E_{j}\right) \geq \sum_{j=1}^{n}|F|\left(E_{j}\right)$. Therefore,

$$
\sum_{j=1}^{\infty}|F|\left(E_{j}\right) \geq|F|\left(\cup_{j=1}^{\infty} E_{j}\right) \geq|F|\left(\cup_{j=1}^{n} E_{j}\right) \geq \sum_{j=1}^{n}|F|\left(E_{j}\right)
$$

Since $n$ is arbitrary,

$$
|F|\left(\cup_{j=1}^{\infty} E_{j}\right)=\sum_{j=1}^{\infty}|F|\left(E_{j}\right)
$$

which shows that $|F|$ is a measure as claimed.
Definition 21.7.3 A Banach space is said to have the Radon Nikodym property if whenever

$$
\begin{gathered}
(\Omega, \mathscr{S}, \mu) \text { is a finite measure space } \\
F: \mathscr{S} \rightarrow X \text { is a vector measure with }|F|(\Omega)<\infty \\
F \ll \mu
\end{gathered}
$$

then one may conclude there exists $g \in L^{1}(\Omega ; X)$ such that

$$
F(E)=\int_{E} g(s) d \mu
$$

for all $E \in \mathscr{S}$.
Some Banach spaces have the Radon Nikodym property and some don't. No attempt is made to give a complete answer to the question of which Banach spaces have this property, but the next theorem gives examples of many spaces which do. This next lemma was used earlier. I am presenting it again.

Lemma 21.7.4 Suppose $v$ is a complex measure defined on $\mathscr{S}$ a $\sigma$ algebra where $(\Omega, \mathscr{S})$ is a measurable space, and let $\mu$ be a measure on $\mathscr{S}$ with $|v(E)| \leq r \mu(E)$ and suppose there is $h \in L^{1}(\Omega, \mu)$ such that for all $E \in \mathscr{S}$,

$$
v(E)=\int_{E} h d \mu,
$$

Then $|h| \leq r$ a.e.
Proof: Let $B(p, \delta) \subseteq \mathbb{C} \backslash \overline{B(0, r)}$ and let $E \equiv h^{-1}(B(p, \delta))$. If $\mu(E)>0$. Then

$$
\left|\frac{1}{\mu(E)} \int_{E} h d \mu-p\right| \leq \frac{1}{\mu(E)} \int_{E}|h(\omega)-p| d \mu<\delta
$$

Thus, $\left|\frac{v(E)}{\mu(E)}-p\right|<\delta$ and so $|v(E)-p \mu(E)|<\delta \mu(E)$ which implies

$$
|v(E)| \geq(|p|-\delta) \mu(E)>r \mu(E) \geq|v(E)|
$$

which contradicts the assumption. Hence $h^{-1}(B(p, \delta))$ is a set of $\mu$ measure zero for all such balls contained in $\mathbb{C} \backslash \overline{B(0, r)}$ and so, since countably many of these balls cover $\mathbb{C} \backslash \overline{B(0, r)}$, it follows that $\mu\left(h^{-1}(\mathbb{C} \backslash \overline{B(0, r)})\right)=0$ and so $|h(\omega)| \leq r$ for a.e. $\omega$.
Theorem 21.7.5 Suppose $X^{\prime}$ is a separable dual space. Then $X^{\prime}$ has the Radon Nikodym property.

Proof: By Theorem 21.1.16, $X$ is separable. Let $D$ be a countable dense subset of $X$. Let $F \ll \mu, \mu$ a finite measure and $F$ a vector measure and let $|F|(\Omega)<\infty$. Pick $x \in X$ and consider the map

$$
E \rightarrow F(E)(x)
$$

for $E \in \mathscr{S}$. This defines a complex measure which is absolutely continuous with respect to $|F|$. Therefore, by the earlier Radon Nikodym theorem, there exists $f_{x} \in L^{1}(\Omega,|F|)$ such that

$$
\begin{equation*}
F(E)(x)=\int_{E} f_{x}(s) d|F| \tag{21.7.30}
\end{equation*}
$$

Also, by definition $\|F(E)\| \leq|F|(E)$ so $|F(E)(x)| \leq|F|(E)\|x\|$. By Lemma 21.7.4, $\left|f_{x}(s)\right| \leq\|x\|$ for $|F|$ a.e. $s$. Let $\tilde{D}$ consist of all finite linear combinations of the form $\sum_{i=1}^{m} a_{i} x_{i}$ where $a_{i}$ is a rational point of $\mathbb{F}$ and $x_{i} \in D$. For each of these countably many vectors, there is an exceptional set of measure zero off which $\left|f_{x}(s)\right| \leq\|x\|$. Let $N$ be the union of all of them and define $f_{x}(s) \equiv 0$ if $s \notin N$. Then since $F(E)$ is in $X^{\prime}$, it is linear and so for $\sum_{i=1}^{m} a_{i} x_{i} \in \tilde{D}$,

$$
\int_{E} f_{\sum_{i=1}^{m} a_{i} x_{i}}(s) d|F|=F(E)\left(\sum_{i=1}^{m} a_{i} x_{i}\right)=\sum_{i=1}^{m} a_{i} F(E)\left(x_{i}\right)=\int_{E} \sum_{i=1}^{m} a_{i} f_{x_{i}}(s) d|F|
$$

and so by uniqueness in the Radon Nikodym theorem,

$$
f_{\sum_{i=1}^{m} a_{i} x_{i}}(s)=\sum_{i=1}^{m} a_{i} f_{x_{i}}(s)|F| \text { a.e. }
$$

and so, we can regard this as holding for all $s \notin N$. Also, if $x \in \tilde{D},\left|f_{x}(s)\right| \leq\|x\|$. Now for $x, y \in \tilde{D}$,

$$
\left|f_{x}(s)-f_{y}(s)\right|=\left|f_{x-y}(s)\right| \leq\|x-y\|
$$

and so, by density of $\tilde{D}$, we can define

$$
h_{x}(s) \equiv \lim _{n \rightarrow \infty} f_{x_{n}}(s) \text { where } x_{n} \rightarrow x, x_{n} \in \tilde{D}
$$

For $s \in N$, all functions equal 0 . Thus for all $x,\left|h_{x}(s)\right| \leq\|x\|$. The dominated convergence theorem and continuity of $F(E)$ implies that for $x_{n} \rightarrow x$, with $x_{n} \in \tilde{D}$,

$$
\begin{equation*}
\int_{E} h_{x}(s) d|F|=\lim _{n \rightarrow \infty} \int_{E} f_{x_{n}}(s) d|F|=\lim _{n \rightarrow \infty} F(E)\left(x_{n}\right)=F(E)(x) . \tag{21.7.31}
\end{equation*}
$$

It follows from the density of $\tilde{D}$ that for all $x, y \in X, s \notin N$, and $a, b \in \mathbb{F}$, let $x_{n} \rightarrow x, y_{n} \rightarrow$ $y, a_{n} \rightarrow a, b_{n} \rightarrow b$, with $x_{n}, y_{n} \in \tilde{D}$ and $a_{n}, b_{n} \in \mathbb{Q}$ or $\mathbb{Q}+i \mathbb{Q}$ in case $\mathbb{F}=\mathbb{C}$. Then

$$
\begin{equation*}
h_{a x+b y}(s)=\lim _{n \rightarrow \infty} f_{a_{n} x_{n}+b_{n} y_{n}}(s)=\lim _{n \rightarrow \infty} a_{n} f_{x_{n}}(s)+b_{n} f_{y_{n}}(s) \equiv a h_{x}(s)+b h_{y}(s) \tag{21.7.32}
\end{equation*}
$$

Let $\theta(s)$ be given by $\theta(s)(x)=h_{x}(s)$ if $s \notin N$ and let $\theta(s)=0$ if $s \in N$. By 21.7.32 it follows that $\theta(s) \in X^{\prime}$ for each $s$. Also

$$
\theta(s)(x)=h_{x}(s) \in L^{1}(\Omega)
$$

so $\theta(\cdot)$ is weak $*$ measurable. Since $X^{\prime}$ is separable, Theorem 21.1.15 implies that $\theta$ is strongly measurable. Furthermore, by 21.7.32,

$$
\|\theta(s)\| \equiv \sup _{\|x\| \leq 1}|\theta(s)(x)| \leq \sup _{\|x\| \leq 1}\left|h_{x}(s)\right| \leq 1
$$

Therefore, $\int_{\Omega}\|\theta(s)\| d|F|<\infty$ so $\theta \in L^{1}\left(\Omega ; X^{\prime}\right)$. Thus, if $E \in \mathscr{S}$,

$$
\begin{equation*}
\int_{E} h_{x}(s) d|F|=\int_{E} \theta(s)(x) d|F|=\left(\int_{E} \theta(s) d|F|\right)(x) . \tag{21.7.33}
\end{equation*}
$$

From 21.7.31 and 21.7.33, $\left(\int_{E} \theta(s) d|F|\right)(x)=F(E)(x)$ for all $x \in X$ and therefore,

$$
\int_{E} \theta(s) d|F|=F(E)
$$

Finally, since $F \ll \mu,|F| \ll \mu$ also and so there exists $k \in L^{1}(\Omega)$ such that

$$
|F|(E)=\int_{E} k(s) d \mu
$$

for all $E \in \mathscr{S}$, by the scalar Radon Nikodym Theorem. It follows

$$
F(E)=\int_{E} \theta(s) d|F|=\int_{E} \theta(s) k(s) d \mu .
$$

Letting $g(s)=\theta(s) k(s)$, this has proved the theorem.
Since each reflexive Banach spaces is a dual space, the following corollary holds.
Corollary 21.7.6 Any separable reflexive Banach space has the Radon Nikodym property.
It is not necessary to assume separability in the above corollary. For the proof of a more general result, consult Vector Measures by Diestal and Uhl, [41].

### 21.8 The Riesz Representation Theorem

The Riesz representation theorem for the spaces $L^{p}(\Omega ; X)$ holds under certain conditions. The proof follows the proofs given earlier for scalar valued functions.

Definition 21.8.1 If $X$ and $Y$ are two Banach spaces, $X$ is isometric to $Y$ if there exists $\theta \in \mathscr{L}(X, Y)$ such that

$$
\|\theta x\|_{Y}=\|x\|_{X} .
$$

This will be written as $X \cong Y$. The map $\theta$ is called an isometry.
The next theorem says that $L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$ is always isometric to a subspace of $\left(L^{p}(\Omega ; X)\right)^{\prime}$ for any Banach space, $X$.

Theorem 21.8.2 Let $X$ be any Banach space and let $(\Omega, \mathscr{S}, \mu)$ be a finite measure space. Let $p \geq 1$ and let $1 / p+1 / p^{\prime}=1$. (If $p=1, p^{\prime} \equiv \infty$.) Then $L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$ is isometric to a subspace of $\left(L^{p}(\Omega ; X)\right)^{\prime}$. Also, for $g \in L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$,

$$
\sup _{\|f\|_{p} \leq 1}\left|\int_{\Omega} g(s)(f(s)) d \mu\right|=\|g\|_{p^{\prime}}
$$

Proof: First observe that for $f \in L^{p}(\Omega ; X)$ and $g \in L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$,

$$
s \rightarrow g(s)(f(s))
$$

is a function in $L^{1}(\Omega)$. (To obtain measurability, write $f$ as a limit of simple functions. Holder's inequality then yields the function is in $L^{1}(\Omega)$.) Define

$$
\theta: L^{p^{\prime}}\left(\Omega ; X^{\prime}\right) \rightarrow\left(L^{p}(\Omega ; X)\right)^{\prime}
$$

by

$$
\theta g(f) \equiv \int_{\Omega} g(s)(f(s)) d \mu
$$

Holder's inequality implies

$$
\begin{equation*}
\|\theta g\| \leq\|g\|_{p^{\prime}} \tag{21.8.34}
\end{equation*}
$$

and it is also clear that $\theta$ is linear. Next it is required to show $\|\theta g\|=\|g\|$.
This will first be verified for simple functions. Let

$$
g(s)=\sum_{i=1}^{m} c_{i}^{*} \mathscr{X}_{E_{i}}(s)
$$

where $c_{i}^{*} \in X^{\prime}$, the $E_{i}$ are disjoint and $\cup_{i=1}^{m} E_{i}=\Omega$. Then $\|g\| \in L^{p^{\prime}}(\Omega ; \mathbb{R}),\|g(s)\|=$ $\sum_{i=1}^{m}\left\|c_{i}^{*}\right\| \mathscr{X}_{E_{i}}(s)$.

Let $h(s) \equiv\|g(s)\|^{p^{\prime}-1} /\|g\|_{p^{\prime}}^{p^{\prime}-1}$. Then

$$
\begin{equation*}
\int_{\Omega}\|g(s)\|_{X^{\prime}} h(s) d \mu=\int_{\Omega} \frac{\|g(s)\|_{X^{\prime}}^{p^{\prime}}}{\|g\|_{p^{\prime}}^{p^{\prime}-1}} d \mu=\|g\|_{L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)} \tag{21.8.35}
\end{equation*}
$$

Also $h \in L^{p}(\Omega ; \mathbb{R})$ and

$$
\int_{\Omega}|h(s)|^{p} d \mu=\int_{\Omega} \frac{\|g(s)\|^{p^{\prime}}}{\|g\|_{p^{\prime}}^{p^{\prime}}}=\frac{\|g\|_{p^{\prime}}}{\|g\|_{p^{\prime}}}=1
$$

so $\|h\|_{p}=1$. Since the measure space is finite, $h \in L^{1}(\Omega ; \mathbb{R})$.
Now let $d_{i}$ be chosen such that

$$
c_{i}^{*}\left(d_{i}\right) \geq\left\|c_{i}^{*}\right\|_{X^{\prime}}-\varepsilon /\|h\|_{L^{1}(\Omega)}
$$

and $\left\|d_{i}\right\|_{X}=1$. Let

$$
f(s) \equiv \sum_{i=1}^{m} d_{i} h(s) \mathscr{X}_{E_{i}}(s)
$$

Thus $f \in L^{p}(\Omega ; X)$ and $\|f\|_{L^{p}(\Omega ; X)}=1$. This follows from

$$
\|f\|_{p}^{p}=\int_{\Omega} \sum_{i=1}^{m}\left\|d_{i}\right\|_{X}^{p}|h(s)|^{p} \mathscr{X}_{E_{i}}(s) d \mu=\sum_{i=1}^{m}\left(\int_{E_{i}}|h(s)|^{p} d \mu\right)=1
$$

Also

$$
\begin{gathered}
\|\theta g\| \geq|\theta g(f)|=\left|\int_{\Omega} g(s)(f(s)) d \mu\right| \geq \\
\left|\int_{\Omega} \sum_{i=1}^{m}\left(\left\|c_{i}^{*}\right\|_{X^{\prime}}-\varepsilon /\|h\|_{L^{1}(\Omega)}\right) h(s) \mathscr{X}_{E_{i}}(s) d \mu\right|
\end{gathered}
$$

Then from 21.8.35

$$
\geq\left|\int_{\Omega}\|g(s)\|_{X^{\prime}} h(s) d \mu\right|-\varepsilon\left|\int_{\Omega} h(s) /\|h\|_{L^{1}(\Omega)} d \mu\right|=\|g\|_{L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)}-\varepsilon
$$

Since $\varepsilon$ was arbitrary, $\|\theta g\| \geq\|g\|$ and from 21.8.34 this shows equality holds whenever $g$ is a simple function.

In general, let $g \in L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$ and let $g_{n}$ be a sequence of simple functions converging to $g$ in $L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$. Such a sequence exists by Lemma 21.1.2. Let $g_{n}(s) \rightarrow g(s),\left\|g_{n}(s)\right\| \leq$ $2\|g(s)\|$. Then each $g_{n}$ is in $L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$ and by the dominated convergence theorem they converge to $g$ in $L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$. Then for $\|\cdot\|$ the norm in $\left(L^{p}(\Omega ; X)\right)^{\prime}$,

$$
\|\theta g\|=\lim _{n \rightarrow \infty}\left\|\theta g_{n}\right\|=\lim _{n \rightarrow \infty}\left\|g_{n}\right\|=\|g\|
$$

This proves the theorem and shows $\theta$ is the desired isometry.
Theorem 21.8.3 If $X$ is a Banach space and $X^{\prime}$ has the Radon Nikodym property, then if $(\Omega, \mathscr{S}, \mu)$ is a finite measure space,

$$
\left(L^{p}(\Omega ; X)\right)^{\prime} \cong L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)
$$

and in fact the mapping $\theta$ of Theorem 21.8.2 is onto.

Proof: Let $l \in\left(L^{p}(\Omega ; X)\right)^{\prime}$ and define $F(E) \in X^{\prime}$ by

$$
F(E)(x) \equiv l\left(\mathscr{X}_{E}(\cdot) x\right) .
$$

Lemma 21.8.4 $F$ defined above is a vector measure with values in $X^{\prime}$ and $|F|(\Omega)<\infty$.
Proof of the lemma: Clearly $F(E)$ is linear. Also

$$
\begin{gathered}
\|F(E)\|=\sup _{\|x\| \leq 1}\|F(E)(x)\| \\
\leq\|l\| \sup _{\|x\| \leq 1}\left\|\mathscr{X}_{E}(\cdot) x\right\|_{L^{p}(\Omega ; X)} \leq\|l\| \mu(E)^{1 / p}
\end{gathered}
$$

Let $\left\{E_{i}\right\}_{i=1}^{\infty}$ be a sequence of disjoint elements of $\mathscr{S}$ and let $E=\cup_{n<\infty} E_{n}$.

$$
\begin{align*}
\left|F(E)(x)-\sum_{k=1}^{n} F\left(E_{k}\right)(x)\right| & =\left|l\left(\mathscr{X}_{E}(\cdot) x\right)-\sum_{i=1}^{n} l\left(\mathscr{X}_{E_{i}}(\cdot) x\right)\right|  \tag{21.8.36}\\
& \leq\|l\|\left\|\mathscr{X}_{E}(\cdot) x-\sum_{i=1}^{n} \mathscr{X}_{E_{i}}(\cdot) x\right\|_{L^{p}(\Omega ; X)} \\
& \leq\|l\| \mu\left(\bigcup_{k>n} E_{k}\right)^{1 / p}\|x\| .
\end{align*}
$$

Since $\mu(\Omega)<\infty, \lim _{n \rightarrow \infty} \mu\left(\bigcup_{k>n} E_{k}\right)^{1 / p}=0$ and so inequality 21.8.36 shows that

$$
\lim _{n \rightarrow \infty}\left\|F(E)-\sum_{k=1}^{n} F\left(E_{k}\right)\right\|_{X^{\prime}}=0
$$

To show $|F|(\Omega)<\infty$, let $\varepsilon>0$ be given, let $\left\{H_{1}, \cdots, H_{n}\right\}$ be a partition of $\Omega$, and let $\left\|x_{i}\right\| \leq 1$ be chosen in such a way that

$$
F\left(H_{i}\right)\left(x_{i}\right)>\left\|F\left(H_{i}\right)\right\|-\varepsilon / n
$$

Thus

$$
\begin{gathered}
-\varepsilon+\sum_{i=1}^{n}\left\|F\left(H_{i}\right)\right\|<\sum_{i=1}^{n} l\left(\mathscr{X}_{H_{i}}(\cdot) x_{i}\right) \leq\|l\|\left\|\sum_{i=1}^{n} \mathscr{X}_{H_{i}}(\cdot) x_{i}\right\|_{L^{p}(\Omega ; X)} \\
\leq\|l\|\left(\int_{\Omega} \sum_{i=1}^{n} \mathscr{X}_{H_{i}}(s) d \mu\right)^{1 / p}=\|l\| \mu(\Omega)^{1 / p}
\end{gathered}
$$

Since $\varepsilon>0$ was arbitrary, $\sum_{i=1}^{n}\left\|F\left(H_{i}\right)\right\|<\|l\| \mu(\Omega)^{1 / p}$. Since the partition was arbitrary, this shows $|F|(\Omega) \leq\|l\| \mu(\Omega)^{1 / p}$ and this proves the lemma.

Continuing with the proof of Theorem 21.8.3, note that $F \ll \mu$. Since $X^{\prime}$ has the Radon Nikodym property, there exists $g \in L^{1}\left(\Omega ; X^{\prime}\right)$ such that

$$
F(E)=\int_{E} g(s) d \mu
$$

Also, from the definition of $F(E)$,

$$
\begin{align*}
& l\left(\sum_{i=1}^{n} x_{i} \mathscr{X}_{E_{i}}(\cdot)\right)=\sum_{i=1}^{n} l\left(\mathscr{X}_{E_{i}}(\cdot) x_{i}\right) \\
= & \sum_{i=1}^{n} F\left(E_{i}\right)\left(x_{i}\right)=\sum_{i=1}^{n} \int_{E_{i}} g(s)\left(x_{i}\right) d \mu . \tag{21.8.37}
\end{align*}
$$

It follows from 21.8.37 that whenever $h$ is a simple function,

$$
\begin{equation*}
l(h)=\int_{\Omega} g(s)(h(s)) d \mu \tag{21.8.38}
\end{equation*}
$$

Let $G_{n} \equiv\left\{s:\|g(s)\|_{X^{\prime}} \leq n\right\}$ and let $j: L^{p}\left(G_{n} ; X\right) \rightarrow L^{p}(\Omega ; X)$ be given by

$$
j h(s)=\left\{\begin{array}{l}
h(s) \text { if } s \in G_{n}, \\
0 \text { if } s \notin G_{n} .
\end{array}\right.
$$

Letting $h$ be a simple function in $L^{p}\left(G_{n} ; X\right)$,

$$
\begin{equation*}
j^{*} l(h)=l(j h)=\int_{G_{n}} g(s)(h(s)) d \mu . \tag{21.8.39}
\end{equation*}
$$

Since the simple functions are dense in $L^{p}\left(G_{n} ; X\right)$, and $g \in L^{p^{\prime}}\left(G_{n} ; X^{\prime}\right)$, it follows 21.8.39 holds for all $h \in L^{p}\left(G_{n} ; X\right)$. By Theorem 21.8.2,

$$
\|g\|_{L^{p^{\prime}}\left(G_{n} ; X^{\prime}\right)}=\left\|j^{*} l\right\|_{\left(L^{p}\left(G_{n} ; X\right)\right)^{\prime}} \leq\|l\|_{\left(L^{p}(\Omega ; X)\right)^{\prime}} .
$$

By the monotone convergence theorem,

$$
\|g\|_{L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)}=\lim _{n \rightarrow \infty}\|g\|_{L^{p^{\prime}}\left(G_{n} ; X^{\prime}\right)} \leq\|l\|_{\left(L^{p}(\Omega ; X)\right)^{\prime}} .
$$

Therefore $g \in L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)$ and since simple functions are dense in $L^{p}(\Omega ; X), 21.8 .38$ holds for all $h \in L^{p}(\Omega ; X)$. Thus $l=\theta g$ and the theorem is proved because, by Theorem 21.8.2, $\|l\|=\|g\|$ and the mapping $\theta$ is onto because $l$ was arbitrary.

As in the scalar case, everything generalizes to the case of $\sigma$ finite measure spaces. The proof is almost identical.

Lemma 21.8.5 Let $(\Omega, \mathscr{S}, \mu)$ be a $\sigma$ finite measure space and let $X$ be a Banach space such that $X^{\prime}$ has the Radon Nikodym property. Then there exists a measurable function, $r$ such that $r(x)>0$ for all $x$, such that $|r(x)|<M$ for all $x$, and $\int r d \mu<\infty$. For

$$
\Lambda \in\left(L^{p}(\Omega ; X)\right)^{\prime}, p \geq 1
$$

there exists a unique $h \in L^{p^{\prime}}\left(\Omega ; X^{\prime}\right), L^{\infty}\left(\Omega ; X^{\prime}\right)$ if $p=1$ such that

$$
\Lambda f=\int h(f) d \mu
$$

Also $\|h\|=\|\Lambda\| .\left(\|h\|=\|h\|_{p^{\prime}}\right.$ if $p>1,\|h\|_{\infty}$ if $\left.p=1\right)$. Here

$$
\frac{1}{p}+\frac{1}{p^{\prime}}=1
$$

Proof: First suppose $r$ exists as described. Also, to save on notation and to emphasize the similarity with the scalar case, denote the norm in the various spaces by $|\cdot|$. Define a new measure $\widetilde{\mu}$, according to the rule

$$
\begin{equation*}
\widetilde{\mu}(E) \equiv \int_{E} r d \mu \tag{21.8.40}
\end{equation*}
$$

Thus $\widetilde{\mu}$ is a finite measure on $\mathscr{S}$. Now define a mapping, $\eta: L^{p}(\Omega ; X, \mu) \rightarrow L^{p}(\Omega ; X, \widetilde{\mu})$ by $\eta f=r^{-\frac{1}{p}} f$. Then

$$
\|\eta f\|_{L^{p}(\widetilde{\mu})}^{p}=\int\left|r^{-\frac{1}{p}} f\right|^{p} r d \mu=\|f\|_{L^{p}(\mu)}^{p}
$$

and so $\eta$ is one to one and in fact preserves norms. I claim that also $\eta$ is onto. To see this, let $g \in L^{p}(\Omega ; X, \widetilde{\mu})$ and consider the function, $r^{\frac{1}{p}} g$. Then

$$
\int\left|r^{\frac{1}{p}} g\right|^{p} d \mu=\int|g|^{p} r d \mu=\int|g|^{p} d \widetilde{\mu}<\infty
$$

Thus $r^{\frac{1}{p}} g \in L^{p}(\Omega ; X, \mu)$ and $\eta\left(r^{\frac{1}{p}} g\right)=g$ showing that $\eta$ is onto as claimed. Thus $\eta$ is one to one, onto, and preserves norms. Consider the diagram below which is descriptive of the situation in which $\eta^{*}$ must be one to one and onto.

$$
\begin{array}{cccc}
h, L^{p^{\prime}}(\widetilde{\mu}) & L^{p}(\widetilde{\mu})^{\prime}, \widetilde{\Lambda} & \stackrel{\eta^{*}}{\rightarrow} & L^{p}(\mu)^{\prime}, \Lambda \\
& \eta & \\
L^{p}(\widetilde{\mu}) & \leftarrow & L^{p}(\mu)
\end{array}
$$

Then for $\Lambda \in L^{p}(\mu)^{\prime}$, there exists a unique $\widetilde{\Lambda} \in L^{p}(\widetilde{\mu})^{\prime}$ such that $\eta^{*} \widetilde{\Lambda}=\Lambda,\|\widetilde{\Lambda}\|=\|\Lambda\|$. By the Riesz representation theorem for finite measure spaces, there exists a unique $h \in$ $L^{p^{\prime}}(\widetilde{\mu}) \equiv L^{p^{\prime}}\left(\Omega ; X^{\prime}, \widetilde{\mu}\right)$ which represents $\widetilde{\Lambda}$ in the manner described in the Riesz representation theorem. Thus $\|h\|_{L^{p^{\prime}}(\widetilde{\mu})}=\|\widetilde{\Lambda}\|=\|\Lambda\|$ and for all $f \in L^{p}(\mu)$,

$$
\begin{aligned}
\Lambda(f) & =\eta^{*} \widetilde{\Lambda}(f) \equiv \widetilde{\Lambda}(\eta f)=\int h(\eta f) d \widetilde{\mu}=\int r h\left(r^{-\frac{1}{p}} f\right) d \mu \\
& =\int r^{\frac{1}{p}} h f d \mu
\end{aligned}
$$

Now

$$
\int\left|r^{\frac{1}{p^{\prime}}} h\right|^{p^{\prime}} d \mu=\int|h|^{p^{\prime}} r d \mu=\|h\|_{L^{p^{\prime}}(\widetilde{\mu})}^{p^{\prime}}<\infty
$$

Thus $\left\|r^{\frac{1}{p^{\prime}}}\right\|_{L_{p^{\prime}(\mu)}}=\|h\|_{L^{p^{\prime}}(\widetilde{\mu})}=\|\widetilde{\Lambda}\|=\|\Lambda\|$ and represents $\Lambda$ in the appropriate way. If $p=1$, then $1 / p^{\prime} \equiv 0$. Now consider the existence of $r$. Since the measure space is $\sigma$ finite, there exist $\left\{\Omega_{n}\right\}$ disjoint, each having positive measure and their union equals $\Omega$. Then define

$$
r(\omega) \equiv \sum_{n=1}^{\infty} \frac{1}{n^{2}} \mu\left(\Omega_{n}\right)^{-1} \mathscr{X}_{\Omega_{n}}(\omega)
$$

This proves the Lemma.

Theorem 21.8.6 (Riesz representation theorem) Let $(\Omega, \mathscr{S}, \mu)$ be $\sigma$ finite and let $X^{\prime}$ have the Radon Nikodym property. Then for

$$
\Lambda \in\left(L^{p}(\Omega ; X, \mu)\right)^{\prime}, p \geq 1
$$

there exists a unique $h \in L^{q}\left(\Omega, X^{\prime}, \mu\right), L^{\infty}\left(\Omega, X^{\prime}, \mu\right)$ if $p=1$ such that

$$
\Lambda f=\int h(f) d \mu
$$

Also $\|h\|=\|\Lambda\| .\left(\|h\|=\|h\|_{q}\right.$ if $p>1,\|h\|_{\infty}$ if $\left.p=1\right)$. Here

$$
\frac{1}{p}+\frac{1}{q}=1
$$

Proof: The above lemma gives the existence part of the conclusion of the theorem. Uniqueness is done as before.

Corollary 21.8.7 If $X^{\prime}$ is separable, then for $(\Omega, \mathscr{S}, \mu)$ a $\sigma$ finite measure space,

$$
\left(L^{p}(\Omega ; X)\right)^{\prime} \cong L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)
$$

Corollary 21.8.8 If $X$ is separable and reflexive, then for $(\Omega, \mathscr{S}, \mu)$ a $\sigma$ finite measure space,

$$
\left(L^{p}(\Omega ; X)\right)^{\prime} \cong L^{p^{\prime}}\left(\Omega ; X^{\prime}\right)
$$

Corollary 21.8.9 If $X$ is separable and reflexive and $(\Omega, \mathscr{S}, \mu)$ is a $\sigma$ finite measure space, then if $p \in(1, \infty)$, then $L^{p}(\Omega ; X)$ is reflexive.

Proof: This is just like the scalar valued case.

### 21.8.1 An Example of Polish Space

Here is an interesting example. Obviously $L^{\infty}(0, T, H)$ is not separable with the normed topology. However, bounded sets turn out to be metric spaces which are complete and separable. This is the next lemma. Recall that a Polish space is a complete separable metric space. In this example, $H$ is a separable real Hilbert space or more generally a separable real Banach space.

Lemma 21.8.10 Let $B=\overline{B(\mathbf{0}, L)}$ be a closed ball in $L^{\infty}(0, T, H)$. Then $B$ is a Polish space with respect to the weak $*$ topology. The closure is taken with respect to the usual topology.

Proof: Let $\left\{\mathbf{z}_{k}\right\}_{k=1}^{\infty}=X$ be a dense countable subspace in $L^{1}(0, T, H)$. You start with a dense countable set and then consider all finite linear combinations having coefficients in $\mathbb{Q}$. Then the metric on $B$ is

$$
d(\mathbf{f}, \mathbf{g}) \equiv \sum_{k=1}^{\infty} 2^{-k} \frac{\left|\left\langle\mathbf{f}-\mathbf{g}, \mathbf{z}_{k}\right\rangle_{L^{\infty}, L^{1}}\right|}{1+\left|\left\langle\mathbf{f}-\mathbf{g}, \mathbf{z}_{k}\right\rangle_{L^{\infty}, L^{1}}\right|}
$$

Is $B$ complete? Suppose you have a Cauchy sequence $\left\{\mathbf{f}_{n}\right\}$. This happens if and only if $\left\{\left\langle\mathbf{f}_{n}, \mathbf{z}_{k}\right\rangle\right\}_{n=1}^{\infty}$ is a Cauchy sequence for each $k$. Therefore, there exists

$$
\xi\left(\mathbf{z}_{k}\right)=\lim _{n \rightarrow \infty}\left\langle\mathbf{f}_{n}, \mathbf{z}_{k}\right\rangle .
$$

Then for $a, b \in \mathbb{Q}$, and $\mathbf{z}, \mathbf{w} \in X$

$$
\xi(a \mathbf{z}+b \mathbf{w})=\lim _{n \rightarrow \infty}\left\langle\mathbf{f}_{n}, a \mathbf{z}+b \mathbf{w}\right\rangle=\lim _{n \rightarrow \infty} a\left\langle\mathbf{f}_{n}, \mathbf{z}\right\rangle+b\left\langle\mathbf{f}_{n}, \mathbf{w}\right\rangle=a \xi(\mathbf{z})+b \xi(\mathbf{w})
$$

showing that $\xi$ is linear on $X$ a dense subspace of $L^{1}(0, T, H)$. Is $\xi$ bounded on this dense subspace with bound $L$ ? For $\mathbf{z} \in X$,

$$
|\xi(\mathbf{z})| \equiv \lim _{n \rightarrow \infty}\left|\left\langle\mathbf{f}_{n}, \mathbf{z}\right\rangle\right| \leq \lim \sup _{n \rightarrow \infty}\left\|\mathbf{f}_{n}\right\|_{L^{\infty}}\|\mathbf{z}\|_{L^{1}} \leq L\|\mathbf{z}\|_{L^{1}}
$$

Hence $\xi$ is also bounded on this dense subset of $L^{1}(0, T, H)$. Therefore, there is a unique bounded linear extension of $\xi$ to all of $L^{1}(0, T, H)$ still denoted as $\xi$ such that its norm in $L^{1}(0, T, H)^{\prime}$ is no larger than $L$. It follows from the Riesz representation theorem that there exists a unique $\mathbf{f} \in L^{\infty}(0, T, H)$ such that for all $\mathbf{w} \in L^{1}(0, T, H), \boldsymbol{\xi}(\mathbf{w})=\langle\mathbf{f}, \mathbf{w}\rangle$ and $\|\mathbf{f}\| \leq L$. This $\mathbf{f}$ is the limit of the Cauchy sequence $\left\{\mathbf{f}_{n}\right\}$ in $B$. Thus $B$ is complete.

Is $B$ separable? Let $\mathbf{f} \in B$. Let $\varepsilon>0$ be given. Choose $M$ such that

$$
\sum_{k=M+1}^{\infty} 2^{-k}<\frac{\varepsilon}{4}
$$

Then the finite set $\left\{\mathbf{z}_{1}, \cdots, \mathbf{z}_{M}\right\}$ is uniformly integrable. There exists $\delta>0$ such that if $m(S)<\delta$, then

$$
\int_{S}\left|\mathbf{z}_{k}\right|_{H} d m<\left(\frac{\varepsilon}{4\left(1+\|\mathbf{f}\|_{L^{\infty}}\right)}\right)
$$

Then there is a sequence of simple functions $\left\{\mathbf{s}_{n}\right\}$ which converge uniformly to $\mathbf{f}$ off a set of measure zero, $N,\left\|\mathbf{s}_{n}\right\|_{L^{\infty}} \leq\|\mathbf{f}\|_{L^{\infty}}$. By regularity of the measure, there exists a continuous function with compact support $\mathbf{h}_{n}$ such that $\mathbf{s}_{n}=\mathbf{h}_{n}$ off a set of measure no more than $\delta / 4^{n}$ and also $\left\|\mathbf{h}_{n}\right\|_{L^{\infty}} \leq\|\mathbf{f}\|_{L^{\infty}}$. Then off a set of measure no more than $\frac{1}{3} \delta, \mathbf{h}_{n}(r) \rightarrow \mathbf{f}(r)$. Now by Eggorov's theorem and outer regularity, one can enlarge this exceptional set to obtain an open set $S$ of measure no more than $\delta / 2$ such that the convergence is uniform off this exceptional set. Thus $\mathbf{f}$ equals the uniform limit of continuous functions on $S^{C}$. Define

$$
\mathbf{h}(r) \equiv\left\{\begin{array}{l}
\lim _{n \rightarrow \infty} \mathbf{h}_{n}(r)=\mathbf{f}(r) \text { on } S^{C} \\
\mathbf{0} \text { on } S \backslash N \\
\mathbf{0} \text { on } N
\end{array}\right.
$$

Then $\|\mathbf{h}\|_{L^{\infty}} \leq\|\mathbf{f}\|_{L^{\infty}}$. Now consider

$$
\overline{\mathbf{h}} * \psi_{m}(r)
$$

where $\psi_{r}$ is approximate identity.

$$
\psi_{m}(t)=\frac{1}{2} m \mathscr{X}_{[-1 / m, 1 / m]}(t), \overline{\mathbf{h}} * \psi_{m}(t)=\frac{1}{2} m \int_{-1 / m}^{1 / m} \overline{\mathbf{h}}(t-s) d s=\frac{1}{2} m \int_{t-1 / m}^{t+1 / m} \overline{\mathbf{h}}(s) d s
$$

where we define $\bar{h}$ to be the 0 extension of $\bar{h}$ off $[0, T]$. This is a continuous function of $t$. Also a.e.t is a Lebesgue point and so for a.e.t,

$$
\begin{gathered}
\left|\frac{1}{2} m \int_{t-1 / m}^{t+1 / m} \overline{\mathbf{h}}(s) d s-\overline{\mathbf{h}}(t)\right| \rightarrow 0 \\
\left|\overline{\mathbf{h}} * \psi_{m}(r)\right| \equiv\left|\int_{\mathbb{R}} \overline{\mathbf{h}}(r-s) \psi_{m}(s) d s\right| \leq\|\mathbf{h}\|_{L^{\infty}} \leq\|\mathbf{f}\|_{L^{\infty}}
\end{gathered}
$$

Thus this continuous function is in $L^{\infty}(0, T, H)$. Letting $\mathbf{z}=\mathbf{z}_{k} \in L^{1}(0, T, H)$ be one of those defined above,

$$
\begin{gather*}
\left|\int_{0}^{T}\left\langle\overline{\mathbf{h}} * \psi_{m}(t)-\mathbf{f}(t), \mathbf{z}(t)\right\rangle d t\right| \leq \int_{0}^{T}\left|\left\langle\overline{\mathbf{h}} * \psi_{m}(t)-\mathbf{h}(t), \mathbf{z}(t)\right\rangle\right| d t \\
+\int_{0}^{T}|\langle\mathbf{h}(t)-\mathbf{f}(t), \mathbf{z}(t)\rangle| d t \tag{21.8.41}
\end{gather*}
$$

for a.e. $t, \overline{\mathbf{h}} * \psi_{m}(t)-\mathbf{h}(t) \rightarrow 0$ and the integrand in the first integral is bounded by the expression $2\|\mathbf{f}\|_{L^{\infty}}|\mathbf{z}(t)|_{H}$ so by the dominated convergence theorem, as $m \rightarrow \infty$, the first integral converges to 0 . As to the second, it is dominated by

$$
\int_{S}|\langle\mathbf{h}(t)-\mathbf{f}(t), \mathbf{z}(t)\rangle| d t \leq 2\|\mathbf{f}\|_{L^{\infty}} \int_{S}|\mathbf{z}(t)| d t<\frac{2\|\mathbf{f}\|_{L^{\infty}} \varepsilon}{4\left(1+\|\mathbf{f}\|_{L^{\infty}}\right)} \leq \frac{\varepsilon}{2}
$$

Therefore, choosing $m$ large enough so that the first integral on the right in 21.8.41 is less than $\frac{\varepsilon}{4}$ for each $\mathbf{z}_{k}$ for $k \leq M$, then for each of these,

$$
\begin{aligned}
d\left(\mathbf{f}, \overline{\mathbf{h}} * \psi_{m}\right) & \leq \frac{\varepsilon}{4}+\sum_{k=1}^{M} 2^{-k} \frac{(\varepsilon / 4)+(\varepsilon / 2)}{1+((\varepsilon / 4)+(\varepsilon / 2))}=\frac{\varepsilon}{4}+\sum_{k=1}^{M} 2^{-k} \frac{3}{4} \frac{\varepsilon}{\frac{3}{4} \varepsilon+1} \\
& \leq \frac{\varepsilon}{4}+\frac{3 \varepsilon}{4} \sum_{k=1}^{M} 2^{-k}<\frac{\varepsilon}{4}+\frac{3 \varepsilon}{4}=\varepsilon
\end{aligned}
$$

which appears to show that $C([0, T], H)$ is weak $*$ dense in $L^{\infty}(0, T, H)$. However, this last space is obviously separable in terms of the norm topology. Let $D$ be a countable dense subset of $C([0, T], H)$. For $\mathbf{f} \in L^{\infty}(0, T, H)$ let $\mathbf{g} \in C([0, T], H)$ such that $d(\mathbf{f}, \mathbf{g})<\frac{\varepsilon}{4}$. Then let $\mathbf{h} \in D$ be so close to $\mathbf{g}$ in $C([0, T], H)$ that

$$
\sum_{k=1}^{M} 2^{-k} \frac{\left|\left\langle\mathbf{h}-\mathbf{g}, \mathbf{z}_{k}\right\rangle_{L^{\infty}, L^{1}}\right|}{1+\left|\left\langle\mathbf{h}-\mathbf{g}, \mathbf{z}_{k}\right\rangle_{L^{\infty}, L^{1}}\right|}<\frac{\varepsilon}{2}
$$

Then

$$
d(\mathbf{f}, \mathbf{h}) \leq d(\mathbf{f}, \mathbf{g})+d(\mathbf{g}, \mathbf{h})<\frac{\varepsilon}{4}+\frac{\varepsilon}{2}+\frac{\varepsilon}{4}=\varepsilon
$$

It appears that $D$ is dense in $B$ in the weak $*$ topology.

### 21.9 Pointwise Behavior, Weakly Convergent Sequences

There is an interesting little result which relates to weak limits in $L^{2}(\Gamma, E)$ for $E$ a Banach space. I am not sure where to put this thing but think that this would be a good place for it. It obviously generalizes to $L^{p}$ spaces.

Proposition 21.9.1 Let $E$ be a Banach space and let $\left\{u_{n}\right\}$ be a sequence in $L^{2}(\Gamma, E)$ and let $G(x)$ be a weakly compact set in $E$, and $u_{n}(x) \in G(x)$ a.e. for each $n$. Let $\lim \sup \left\{u_{n}(x)\right\}$ denote the set of all weak limits of subsequences of $\left\{u_{n}(x)\right\}$ and let $H(x)$ be the closure of the convex hull of $\lim \sup \left\{u_{n}(x)\right\}$. Then if $u_{n} \rightarrow u$ weakly in $L^{2}(\Gamma, E)$, then $u(x) \in H(x)$ for a.e. $x$.

Proof: Let $H=\left\{w \in L^{2}(\Gamma, E): w(x) \in H(x)\right.$ a.e. $\}$. Then $H$ is convex. If you have $w_{i} \in H$, then since each $H(x)$ is convex, it follows that $\lambda w_{1}(x)+(1-\lambda) w_{2}(x) \in H$ for a.e. $x$ and $\lambda \in[0,1]$. Is $H$ closed? Suppose you have $w_{n} \in H$ and $w_{n} \rightarrow w$ in $L^{2}(\Gamma, E)$. Then there is a subsequence such that pointwise convergence happens a.e. and so since $H$ is closed, you have $w(x) \in H$ for a.e. $x$. Hence $H$ is also weakly closed in $L^{2}(\Gamma, H)$. Thus if $u$ is the weak limit of $\left\{u_{n}\right\}$ in $L^{2}(\Gamma, E)$, it must be the case that $u(x) \in H(x)$ a.e.

As a case of this which might be pretty interesting, suppose $G(x)$ is not just weakly compact but also convex. Then $H(x)=G(x)$ and you can say that $u(x) \in H(x)$ a.e. whenever it is a weak limit in $L^{2}(\Gamma, E)$ of functions $u_{n}$ for which $u_{n}(x) \in G(x)$.

### 21.10 Some Embedding Theorems

The next lemma is a very useful little result which involves embeddings of Banach spaces.

Lemma 21.10.1 Suppose $V \subseteq W$ and the injection map is compact, hence continuous. Suppose also that $W \subseteq U$ with continuous injection. Then for any $\varepsilon>0$ there exists $C_{\varepsilon}$ such that for all $v \in V$,

$$
\|v\|_{W} \leq \varepsilon\|v\|_{V}+C_{\varepsilon}\|v\|_{U}
$$

Proof: Suppose not. Then there exists $\varepsilon>0$ for which things don't work out. Thus there exists $v_{n} \in V$ such that

$$
\left\|v_{n}\right\|_{W}>\varepsilon\left\|v_{n}\right\|_{V}+n\left\|v_{n}\right\|_{U}
$$

Dividing by $\left\|v_{n}\right\|_{V}$, it can also be assumed that $\left\|v_{n}\right\|_{V}=1$. Thus

$$
\left\|v_{n}\right\|_{W}>\varepsilon+n\left\|v_{n}\right\|_{U}
$$

and so $\left\|v_{n}\right\|_{U} \rightarrow 0$. However, $v_{n}$ is contained in the closed unit ball of $V$ which is, by assumption precompact in $W$. Hence, there exists a subsequence, still denoted as $\left\{v_{n}\right\}$ such that $v_{n} \rightarrow v$ in $W$. But it was just determined that $v=0$ and so

$$
0 \geq \lim \sup _{n \rightarrow \infty}\left(\varepsilon+n\left\|v_{n}\right\|_{U}\right) \geq \varepsilon
$$

which is a contradiction.
Recall the following definition, this time for the space of continuous functions defined on a compact set with values in a Banach space.

Definition 21.10.2 Let $\mathscr{A} \subseteq C(K ; V)$ where the last symbol denotes the continuous functions defined on a compact set $K \subseteq X$ a metric space having values in $V$ a Banach space. Then $\mathscr{A}$ is equicontinuous if for every $\varepsilon>0$, there exists $\delta>0$ such that for every $f \in \mathscr{A}$, if $d(x, y)<\delta$, then

$$
\|f(x)-f(y)\|_{V}<\varepsilon
$$

Also $\mathscr{A} \subseteq C(K ; V)$ is uniformly bounded means

$$
\sup _{f \in \mathscr{A}}\|f\|_{\infty, V}<\infty \text { where }\|f\|_{\infty, V} \equiv \max _{x \in K}\|f(x)\|_{V}
$$

Here is a general version of the Ascoli Arzela theorem valid for Banach spaces.
Theorem 21.10.3 Let $V \subseteq W \subseteq U$ where the injection map of $V$ into $W$ is compact and $W$ embedds continuously into $U$, these being Banach spaces. Assume:

1. $\mathscr{A} \subseteq C(K ; U)$ where $K$ is compact and $\mathscr{A}$ is equicontinuous.
2. $\sup _{f \in \mathscr{A}}\|f\|_{\infty, V}<\infty$ where $\|f\|_{\infty, V} \equiv \max _{x \in K}\|f(x)\|_{V}$.

## Then

1. $\mathscr{A} \subseteq C(K ; W)$ and $\mathscr{A}$ is equicontinuous into $W$
2. $\mathscr{A}$ is pre-compact in $C(K ; W)$. Recall this means that $\overline{\mathscr{A}}$ is compact in $C(K ; W)$.

Proof: Let $C \equiv \sup _{f \in \mathscr{A}}\|f\|_{\infty, V}<\infty$. Let $\varepsilon>0$ be given. Then from Lemma 21.10.1,

$$
\|f(x)-f(y)\|_{W} \leq \frac{\varepsilon}{5 C}\|f(x)-f(y)\|_{V}+C_{\varepsilon}\|f(x)-f(y)\|_{U}
$$

$$
\leq \frac{2 \varepsilon}{5}+C_{\varepsilon}\|f(x)-f(y)\|_{U}
$$

By equicontinuity in $C(K, U)$, there exists a $\delta>0$ such that if $d(x, y)<\delta$, then for all $f \in \mathscr{A}$,

$$
C_{\varepsilon}\|f(x)-f(y)\|_{U}<\frac{2 \varepsilon}{5}
$$

Thus if $d(x, y)<\delta$, then $\|f(x)-f(y)\|_{W}<\varepsilon$ for all $f \in \mathscr{A}$.
It remains to verify that $\mathscr{A}$ is pre-compact in $C(K ; W)$. Since this space of continuous functions is complete, it suffices to verify that for all $\varepsilon>0, \mathscr{A}$ has an $\varepsilon$ net. Suppose then that for some $\varepsilon>0$ there is no $\varepsilon$ net. Thus there is an infinite sequence $\left\{f_{n}\right\}$ for which $\left\|f_{n}-f_{m}\right\|_{\infty, W} \geq \varepsilon$ whenever $m \neq n$. There exists $\delta>0$ such that if $d(x, y)<\delta$, then for all $f_{n}$,

$$
\left\|f_{n}(x)-f_{n}(y)\right\|_{W}<\frac{\varepsilon}{5}
$$

Let $\left\{x_{k}\right\}_{k=1}^{p}$ be a $\delta / 2$ net for $K$. This is where we use $K$ is compact. By compactness of the embedding of $V$ into $W$, there exists a further subsequence, still called $\left\{f_{n}\right\}$ such that each $\left\{f_{n}\left(x_{k}\right)\right\}_{n=1}^{\infty}$ converges, this for each $x_{k}$ in that $\delta / 2$ net. Thus there is a single $N$ such that if $n>N$, then for all $m, n>N$, and $k \leq p$,

$$
\left\|f_{n}\left(x_{k}\right)-f_{m}\left(x_{k}\right)\right\|_{W}<\frac{\varepsilon}{5}
$$

Now letting $x \in K$ be arbitrary, it is in $B\left(x_{k}, \delta / 2\right)$ for some $x_{k}$. Therefore, for $n, m$ larger than $N$,

$$
\begin{aligned}
\left\|f_{n}(x)-f_{m}(x)\right\|_{W} \leq & \left\|f_{n}(x)-f_{n}\left(x_{k}\right)\right\|_{W} \\
& +\left\|f_{n}\left(x_{k}\right)-f_{m}\left(x_{k}\right)\right\|_{W} \\
& +\left\|f_{m}\left(x_{k}\right)-f_{m}(x)\right\| \\
<\frac{\varepsilon}{5}+\frac{\varepsilon}{5}+ & \frac{\varepsilon}{5}=\frac{3 \varepsilon}{5}
\end{aligned}
$$

Taking the maximum for all $x$, for $m, n>N$,

$$
\left\|f_{n}-f_{m}\right\|_{W, \infty} \leq \frac{3 \varepsilon}{5}<\varepsilon
$$

contrary to the assumption that every pair is further apart than $\varepsilon$. Thus $\mathscr{A}$ is totally bounded so its closure would also be totally bounded and complete. In other words, $\mathscr{A}$ is precompact in $C(K ; W)$.

In the following theorem about compact subsets of an $L^{p}$ space, the measure will be Lebesgue measure. It depends on the above version of the Ascoli Arzela theorem. First note the following which I will use when convenient. For $a, b \geq 0$, and $p \geq 1$,

$$
(a+b)^{p} \leq 2^{p-1}\left(a^{p}+b^{p}\right)
$$

This follows from the convexity of $y=x^{p}$ for $x>0$. Also, for such $p$,

$$
(a+b)^{1 / p} \leq a^{1 / p}+b^{1 / p}
$$

Usually the thing of interest in this theorem is the case where $V=W=U=\mathbb{R}$. However, the more general version to be presented is interesting I think. Of course closed and bounded sets are compact in $\mathbb{R}$ so the usual case works as a special case of what is about to be presented.

Theorem 21.10.4 Let $V \subseteq W \subseteq U$ where these are Banach spaces such that the injection map of $V$ into $W$ is compact and the injection map of $W$ into $U$ is continuous. Let $\Omega$ be an open set in $\mathbb{R}^{m}$ and let $\mathscr{A}$ be a bounded subset of $L^{p}(\Omega ; V)$ and suppose that for all $\varepsilon>0$, there exist a $\delta>0$ such that if $|\mathbf{h}|<\delta$, then for $\tilde{u}$ denoting the zero extension of $u$ off $\Omega$,

$$
\begin{equation*}
\int_{\mathbb{R}^{m}}\|\widetilde{u}(\mathbf{x}+\mathbf{h})-\widetilde{u}(\mathbf{x})\|_{U}^{p} d x<\varepsilon^{p} \tag{21.10.42}
\end{equation*}
$$

Suppose also that for each $\varepsilon>0$ there exists an open set, $G_{\varepsilon} \subseteq \Omega$ such that $\overline{G_{\varepsilon}} \subseteq \Omega$ is compact and for all $u \in \mathscr{A}$,

$$
\begin{equation*}
\int_{\Omega \backslash \overline{G_{\varepsilon}}}\|u(\mathbf{x})\|_{W}^{p} d x<\varepsilon^{p} \tag{21.10.43}
\end{equation*}
$$

Then $\mathscr{A}$ is precompact in $L^{p}\left(\mathbb{R}^{n} ; W\right)$.
Proof: Let $\infty>M \geq \sup _{u \in L^{p}(\Omega ; V)}\|u\|_{L^{p}(\Omega ; V)}^{p}$. Let $\left\{\psi_{n}\right\}$ be a mollifier with support in $B(\mathbf{0}, 1 / n)$. I need to show that $\mathscr{A}$ has an $\eta$ net in $L^{p}(\Omega ; W)$ for every $\eta>0$. Suppose for some $\eta>0$ it fails to have an $\eta$ net. Without loss of generality, let $\eta<1$. Then by 21.10.43, it follows that for small enough $\varepsilon>0, \mathscr{A}_{\varepsilon} \equiv\left\{u \mathscr{X}_{\overline{G_{\varepsilon}}}: u \in \mathscr{A}\right\}$ fails to have an $\eta / 2$ net. Indeed, pick $\varepsilon$ small enough that for all $u \in \mathscr{A}$,

$$
\left\|u \mathscr{X}_{\overline{G_{\varepsilon}}}-u\right\|_{L^{p}(\Omega ; W)}<\frac{\eta}{5}
$$

Then if $\left\{u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}\right\}_{k=1}^{r}$ is an $\eta / 2$ net for $\mathscr{A}_{\varepsilon}$, so that $\cup_{k=1}^{r} B\left(u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}, \frac{\eta}{2}\right) \supseteq \mathscr{A}_{\varepsilon}$, then for $w \in \mathscr{A}, w \mathscr{X}_{\overline{G_{\varepsilon}}} \in B\left(u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}, \frac{\eta}{2}\right)$ for some $u_{k}$. Hence,

$$
\begin{gathered}
\left\|w-u_{k}\right\|_{L^{p}(\Omega ; W)} \leq\left\|w-w \mathscr{X}_{\overline{G_{\varepsilon}}}\right\|_{L^{p}(\Omega ; W)}+\left\|w \mathscr{X}_{\overline{G_{\varepsilon}}}-u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}\right\|_{L^{p}(\Omega ; W)} \\
+\left\|u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}-u_{k}\right\|_{L^{p}(\Omega ; W)} \\
\quad \leq \frac{\eta}{5}+\frac{\eta}{2}+\frac{\eta}{5}<\eta
\end{gathered}
$$

and so $\left\{u_{k}\right\}_{k=1}^{r}$ would be an $\eta$ net for $\mathscr{A}$ which is assumed to not exist.
Pick this $\varepsilon$ in all that follows. By compactness, Lemma 21.10.1, there exists $C_{\eta}$ such that for all $u \in V$,

$$
\begin{equation*}
\|u\|_{W}^{p} \leq \frac{\eta}{50\left(2^{p-1}\right) M}\|u\|_{V}^{p}+C_{\eta}\|u\|_{U}^{p} \tag{21.10.44}
\end{equation*}
$$

Let $\mathscr{A}_{\varepsilon n}$ consist of $\mathscr{A}_{\varepsilon n} \equiv\left\{u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}: u \in \mathscr{A}\right\}$. I want to show that $\mathscr{A}_{\varepsilon n}$ satisfies the conditions for Theorem 21.10.3.

Lemma 21.10.5 For each $n, \mathscr{A}_{\varepsilon n}$ satisfies the conditions of Theorem 21.10.3.
Proof: First consider the equicontinuity condition of that theorem. It suffices to show that if $\eta>0$ then there exists $\delta>0$ such that if $|\mathbf{h}|<\delta$, then for any $u \in \mathscr{A}$ and $\mathbf{x} \in \overline{G_{\mathcal{\varepsilon}}}$,

$$
\left\|u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}(\mathbf{x}+\mathbf{h})-u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}(\mathbf{x})\right\|_{U}<\eta
$$

Always assume $|\mathbf{h}|<\operatorname{dist}\left(\overline{G_{\varepsilon}}, \Omega^{C}\right)$, and $\mathbf{x} \in \overline{G_{\varepsilon}}$. Also assume that $|\mathbf{h}|$ is small enough that

$$
\begin{gather*}
\left(\int_{\mathbb{R}^{m}}\left|\left(\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}-\mathbf{y}+\mathbf{h})-\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}-\mathbf{y})\right) \psi_{n}(\mathbf{y})\right|^{p^{\prime}} d z\right)^{1 / p^{\prime}}= \\
\left(\int_{\mathbb{R}^{m}}\left|\left(\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h})-\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z})\right) \psi_{n}(\mathbf{x}-\mathbf{z})\right|^{p^{\prime}} d z\right)^{1 / p^{\prime}}<\frac{\eta}{2 M} \tag{21.10.45}
\end{gather*}
$$

This can be obtained because by Holder's inequality,

$$
\begin{gathered}
\left(\int_{\mathbb{R}^{m}}\left|\left(\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h})-\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z})\right) \psi_{n}(\mathbf{x}-\mathbf{z})\right|^{p^{\prime}} d z\right)^{1 / p^{\prime}} \\
\leq\left(\int_{\mathbb{R}^{m}}\left|\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h})-\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z})\right|^{2 p^{\prime}} d z\right)^{\frac{1}{2 p^{\prime}}}\left(\int_{\mathbb{R}^{m}} \psi_{n}(\mathbf{x}-\mathbf{z})^{2 p^{\prime}} d z\right)^{\frac{1}{2 p^{\prime}}}
\end{gathered}
$$

which is small independent of $\mathbf{x}$ for $|\mathbf{h}|$ small enough, thanks to continuity of translation in $L^{2 p^{\prime}}\left(\mathbb{R}^{m}\right)$. Then

$$
\begin{aligned}
& \left\|u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}(\mathbf{x}+\mathbf{h})-u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}(\mathbf{x})\right\|_{U} \\
= & \left\|\int_{\mathbb{R}^{m}}\left(\tilde{u}(\mathbf{x}+\mathbf{h}-\mathbf{y}) \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}+\mathbf{h}-\mathbf{y})-\tilde{u}(\mathbf{x}-\mathbf{y}) \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}-\mathbf{y})\right) \psi_{n}(\mathbf{y}) d y\right\|_{U} \\
\leq & \int_{\mathbb{R}^{m}}\left\|\left(\tilde{u}(\mathbf{x}+\mathbf{h}-\mathbf{y}) \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}+\mathbf{h}-\mathbf{y})-\tilde{u}(\mathbf{x}-\mathbf{y}) \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}-\mathbf{y})\right)\right\|_{U} \psi_{n}(\mathbf{y}) d y
\end{aligned}
$$

Changing the variables,

$$
\begin{align*}
\leq & \int_{\mathbb{R}^{m}}\left\|\begin{array}{c}
(\tilde{u}(\mathbf{z}+\mathbf{h})-\tilde{u}(\mathbf{z})) \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h}) \\
+\tilde{u}(\mathbf{z})\left(\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h})-\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z})\right)
\end{array}\right\|_{U} \psi_{n}(\mathbf{x}-\mathbf{z}) d z \\
\leq & \int_{\mathbb{R}^{m}}\left\|(\tilde{u}(\mathbf{z}+\mathbf{h})-\tilde{u}(\mathbf{z})) \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h})\right\|_{U} \psi_{n}(\mathbf{x}-\mathbf{z}) d z \\
& \quad+\int_{\mathbb{R}^{m}}\|\tilde{u}(\mathbf{z})\|_{U}\left|\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h})-\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z})\right| \psi_{n}(\mathbf{x}-\mathbf{z}) d z \tag{21.10.46}
\end{align*}
$$

The first integral

$$
\leq\left(\int_{\mathbb{R}^{m}}\|\tilde{u}(\mathbf{z}+\mathbf{h})-\tilde{u}(\mathbf{z})\|_{U}^{p}\right)^{1 / p}\left(\int_{\mathbb{R}^{m}} \psi_{n}^{p^{\prime}}(\mathbf{x}-\mathbf{z}) d z\right)^{1 / p^{\prime}}
$$

You make the obvious change here in case $p=1$. Instead of the above, you would have

$$
\leq \int_{\mathbb{R}^{m}}\|\tilde{u}(\mathbf{z}+\mathbf{h})-\tilde{u}(\mathbf{z})\|_{U} d z 2\left\|\psi_{n}\right\|_{\infty}
$$

Since Lebesgue measure is translation independent, there is a constant $C_{n}$ such that the above is

$$
\leq C_{n}\left(\int_{\mathbb{R}^{m}}\|\tilde{u}(\mathbf{z}+\mathbf{h})-\tilde{u}(\mathbf{z})\|_{U}^{p}\right)^{1 / p}<\eta / 2
$$

and this holds for all $u \in \mathscr{A}$. As for the second integral in 21.10.46, from 21.10.45, it follows that this term is no larger than

$$
\leq\left(\int_{\mathbb{R}^{m}}\|\tilde{u}(\mathbf{z})\|_{U}^{p} d z\right)^{1 / p}\left(\int_{\mathbb{R}^{m}}\left(\left|\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z}+\mathbf{h})-\mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{z})\right| \psi_{n}(\mathbf{x}-\mathbf{z})\right)^{p^{\prime}} d z\right)^{1 / p^{\prime}}
$$

and by 21.10.45,

$$
<M \frac{\eta}{2 M}=\frac{\eta}{2}
$$

Thus, if $\delta<\operatorname{dist}\left(\overline{G_{\varepsilon}}, \Omega^{C}\right)$ and 21.10.45 holds, then for all $u \in \mathscr{A}$, when $|\mathbf{h}|<\delta$,

$$
\left\|u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}(\mathbf{x}+\mathbf{h})-u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}(\mathbf{x})\right\|_{U}<\eta
$$

and so the desired equicontinuity condition holds for $\mathscr{A}_{\varepsilon n}$. Note that $\delta$ does depend on $n$ but for each $n$, things work out well.

I also need to verify that the functions in $\mathscr{A}_{\varepsilon n}$ are uniformly bounded. For $\mathbf{x} \in \overline{G_{\varepsilon}}$ and $u \in \mathscr{A}$,

$$
\begin{gathered}
\left\|u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}(\mathbf{x})\right\|_{V} \leq \int_{\overline{G_{\varepsilon}}}\|u(\mathbf{z})\| \psi_{n}(\mathbf{x}-\mathbf{z}) d z \\
\leq\left(\int_{\Omega}\|u(\mathbf{z})\|^{p} d z\right)^{1 / p}\left(\int_{\Omega} \psi_{n}(\mathbf{x}-\mathbf{z})^{p^{\prime}}\right)^{1 / p^{\prime}} \leq M C_{n}
\end{gathered}
$$

Now is a general statement about norms, indicating that the $L^{p}$ norm is no more than a constant times the norm involving the maximum.

$$
\left(\int_{\overline{G_{\varepsilon}}}\|v(\mathbf{x})\|_{W}^{p} d x\right)^{1 / p} \leq \max _{\mathbf{x} \in \overline{G_{\varepsilon}}}\|v(\mathbf{x})\|_{W} m\left(\overline{G_{\varepsilon}}\right) \equiv m\left(\overline{G_{\varepsilon}}\right)\|v\|_{W, \infty}
$$

It follows from Theorem 21.10.3 that for every $\eta>0$, there exists a $\eta$ net in $C\left(\overline{G_{\varepsilon}} ; W\right)$ for $\mathscr{A}_{\varepsilon n}$, this for each $n$. Then from the above inequality, it follows that for each $\eta$, there exists an $\eta$ net in $L^{p}\left(\overline{G_{\varepsilon}} ; W\right)$ for $\mathscr{A}_{\varepsilon n}$.

Recall also, from the assumption that the theorem is not true, $\mathscr{A}_{\varepsilon} \equiv\left\{u \mathscr{X}_{\overline{G_{\varepsilon}}}: u \in \mathscr{A}\right\}$ has no $\eta / 2$ net in $L^{p}\left(\overline{G_{\varepsilon}} ; W\right)$. Next I estimate the distance in $L^{p}\left(\overline{G_{\varepsilon}} ; W\right)$ between $u \mathscr{X}_{\overline{G_{\varepsilon}}}$ for $u \in \mathscr{A}$ and $u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}$. The idea is that for each $n, \mathscr{A}_{\varepsilon n}$ has an $\eta / 8$ net and for $n$ large enough, $u \mathscr{X}_{\overline{G_{\varepsilon}}}$ is close to $u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}$ so a contradiction will result if the functions of the
second sort are totally bounded while those functions of the first sort don't. Assume always that $1 / n<\operatorname{dist}\left(\overline{G_{\varepsilon}}, \Omega^{C}\right)$. Using Minkowski's inequality,

$$
\begin{gathered}
\left\|u \mathscr{X}_{\overline{G_{\varepsilon}}}-u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)}= \\
\left(\int_{\mathbb{R}^{m}}\left\|\int_{\mathbb{R}^{m}}\left(u \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x})-u \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}-\mathbf{y})\right) \psi_{n}(\mathbf{y}) d y\right\|_{W}^{p} d x\right)^{1 / p} \\
\leq \int_{B(\mathbf{0}, 1 / n)} \psi_{n}(\mathbf{y})\left(\int_{\mathbb{R}^{m}}\left\|\left(u \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x})-u \mathscr{X}_{\overline{G_{\varepsilon}}}(\mathbf{x}-\mathbf{y})\right)\right\|_{W}^{p} d x\right)^{1 / p} d y \\
\leq \int_{B(\mathbf{0}, 1 / n)} \psi_{n}(\mathbf{y})\left(\int_{\mathbb{R}^{m}}\|(\tilde{u}(\mathbf{x})-\tilde{u}(\mathbf{x}-\mathbf{y}))\|_{W}^{p} d x\right)^{1 / p} d y \\
\leq \int_{B(\mathbf{0}, 1 / n)} \psi_{n}(\mathbf{y})\binom{\int_{\mathbb{R}^{m}} \frac{\eta}{50\left(2^{p-1}\right) M}\|\tilde{u}(\mathbf{x})-\tilde{u}(\mathbf{x}-\mathbf{y})\|_{V}^{p}}{+C_{\eta}\|\tilde{u}(\mathbf{x})-\tilde{u}(\mathbf{x}-\mathbf{y})\|_{U}^{p} d x}^{1 / p} d y \\
\leq \int_{B\left(\mathbf{0}, \frac{1}{n}\right)} \psi_{n}(\mathbf{y})\left(\begin{array}{c}
\int_{\mathbb{R}^{m}} \frac{\eta}{5\left(C_{\eta} \int_{\mathbb{R}^{p}}^{p-1}\right) M} 2^{p-1} 2\left(\|\tilde{u}(\mathbf{x})-\tilde{u}(\mathbf{x})\|_{V}^{p}\right) d x \\
\leq
\end{array} \int_{B\left(\mathbf{x}, \frac{1}{n}\right)}^{1 / p} \psi_{n}(\mathbf{y})\left(\begin{array}{c}
\int_{U}^{p} d x
\end{array}\right)^{\int_{\mathbb{R}^{m}} \frac{\eta}{25 M}\left(\|\tilde{u}(\mathbf{x})\|_{V}^{p}\right) d x} \begin{array}{l}
\mathbb{R}^{m} C_{\eta}\|\tilde{u}(\mathbf{x})-\tilde{u}(\mathbf{x}-\mathbf{y})\|_{U}^{p} d x
\end{array}\right)^{1 / p} d y \\
\leq \int_{B\left(\mathbf{0}, \frac{1}{n}\right)} \psi_{n}(\mathbf{y})\left(\frac{\eta}{25}+\int_{\mathbb{R}^{m}} C_{\eta}\|\tilde{u}(\mathbf{x})-\tilde{u}(\mathbf{x}-\mathbf{y})\|_{U}^{p} d x\right)^{1 / p} d y
\end{gathered}
$$

By assumption 21.10.42, there exists $N$ such that if $n \geq N$, then $|\mathbf{y}|<\frac{1}{n}$ and for all $u \in \mathscr{A}$,

$$
\begin{aligned}
&\left\|u \mathscr{X}_{\overline{G_{\varepsilon}}}-u \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)} \leq \\
& \int_{B\left(\mathbf{0}, \frac{1}{n}\right)} \psi_{n}(\mathbf{y})\left(\frac{\eta}{25}+\frac{\eta^{p}}{8^{p}}\right)^{1 / p} d y \\
& \leq \int_{B\left(\mathbf{0}, \frac{1}{n}\right)} \psi_{n}(\mathbf{y})\left(\frac{\eta}{25}+\frac{\eta}{8}\right) d y \\
&= \frac{\eta}{25}+\frac{\eta}{8}
\end{aligned}
$$

Recall $\eta<1$.
Let $n$ be this large. Then let $\left\{u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\}_{k=1}^{r}$ be a $\eta / 8$ net for $\mathscr{A}_{\varepsilon n}$ in $L^{p}\left(\overline{G_{\varepsilon}} ; W\right)$. Then consider the balls $B\left(u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}, \frac{\eta}{4}\right)$ in $L^{p}\left(\overline{G_{\varepsilon}} ; W\right)$. If $w \mathscr{X}_{\overline{G_{\varepsilon}}}$ is in $\mathscr{A}_{\varepsilon}$, is it in some $B\left(u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}, \frac{\eta}{2}\right)$ ? By what was just shown, there is $k$ such that

$$
\left\|w \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}-u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)}<\frac{\eta}{8}
$$

and also

$$
\begin{aligned}
\left\|w \mathscr{X}_{\overline{G_{\varepsilon}}}-w \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)}<\frac{\eta}{8}+\frac{\eta}{25} \\
\left\|u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}-u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)}<\frac{\eta}{8}+\frac{\eta}{25}
\end{aligned}
$$

Thus,

$$
\begin{aligned}
\left\|w \mathscr{X}_{\overline{G_{\varepsilon}}}-u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}\right\|_{L^{p}\left(G_{\varepsilon} ; W\right)} \leq & \left\|w \mathscr{X}_{\overline{G_{\varepsilon}}}-w \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)} \\
& +\left\|w \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}-u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)} \\
& +\left\|u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}} * \psi_{n}-u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}\right\|_{L^{p}\left(\overline{G_{\varepsilon}} ; W\right)} \\
< & \frac{3 \eta}{8}+\frac{2 \eta}{25}<\frac{\eta}{2}
\end{aligned}
$$

It follows that $\left\{u_{k} \mathscr{X}_{\overline{G_{\varepsilon}}}\right\}_{k=1}^{r}$ is a $\eta / 2$ net for $L^{p}\left(\overline{G_{\varepsilon}} ; W\right)$ contrary to the construction. Thus $\mathscr{A}$ has an $\eta$ net after all.

In case $\Omega$ is a closed interval, there are several versions of these sorts of embeddings which are enormously useful in the study of nonlinear evolution equations or inclusions.

The following theorem is an infinite dimensional version of the Ascoli Arzela theorem. It is like a well known result due to Simon [117]. It is an appropriate generalization when you do not necessarily have weak derivatives.
Theorem 21.10.6 Let $q>1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$
\left\{u \text { such that }\|u(t)\|_{E} \leq R \text { for all } t \in[a, b], \text { and }\|u(s)-u(t)\|_{X} \leq R|t-s|^{1 / q}\right\}
$$

Thus $S$ is bounded in $L^{\infty}(a, b, E)$ and in addition, the functions are uniformly Holder continuous into $X$. Then $S \subseteq C([a, b] ; W)$ and if $\left\{u_{n}\right\} \subseteq S$, there exists a subsequence, $\left\{u_{n_{k}}\right\}$ which converges to a function $u \in C([a, b] ; W)$ in the following way.

$$
\lim _{k \rightarrow \infty}\left\|u_{n_{k}}-u\right\|_{\infty, W}=0
$$

Proof: First consider the issue of $S$ being a subset of $C([a, b] ; W)$. Let $\varepsilon>0$ be given. Then by Lemma 21.10.1, there exists a constant, $C_{\varepsilon}$ such that for all $u \in W$

$$
\|u\|_{W} \leq \frac{\varepsilon}{6 R}\|u\|_{E}+C_{\varepsilon}\|u\|_{X}
$$

Therefore, for all $u \in S$,

$$
\begin{align*}
\|u(t)-u(s)\|_{W} & \leq \frac{\varepsilon}{6 R}\|u(t)-u(s)\|_{E}+C_{\varepsilon}\|u(t)-u(s)\|_{X} \\
& \leq \frac{\varepsilon}{6 R}\left(\|u(t)\|_{E}+\|u(s)\|_{E}\right)+C_{\varepsilon}\|u(t)-u(s)\|_{X} \\
& \leq \frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q} \tag{21.10.47}
\end{align*}
$$

Since $\varepsilon$ is arbitrary, it follows $u \in C([a, b] ; W)$.
Let $D=\mathbb{Q} \cap[a, b]$ so $D$ is a countable dense subset of $[a, b]$. Let $D=\left\{t_{n}\right\}_{n=1}^{\infty}$. By compactness of the embedding of $E$ into $W$, there exists a subsequence $u_{(n, 1)}$ such that as $n \rightarrow \infty, u_{(n, 1)}\left(t_{1}\right)$ converges to a point in $W$. Now take a subsequence of this, called $(n, 2)$ such that as $n \rightarrow \infty, u_{(n, 2)}\left(t_{2}\right)$ converges to a point in $W$. It follows that $u_{(n, 2)}\left(t_{1}\right)$ also converges to a point of $W$. Continue this way. Now consider the diagonal sequence, $u_{k} \equiv$ $u_{(k, k)}$ This sequence is a subsequence of $u_{(n, l)}$ whenever $k>l$. Therefore, $u_{k}\left(t_{j}\right)$ converges for all $t_{j} \in D$.

Claim: Let $\left\{u_{k}\right\}$ be as just defined, converging at every point of $D \equiv[a, b] \cap \mathbb{Q}$. Then $\left\{u_{k}\right\}$ converges at every point of $[a, b]$.

Proof of claim: Let $\varepsilon>0$ be given. Let $t \in[a, b]$. Pick $t_{m} \in D \cap[a, b]$ such that in 21.10.47 $C_{\varepsilon} R\left|t-t_{m}\right|<\varepsilon / 3$. Then there exists $N$ such that if $l, n>N$, then

$$
\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\|_{X}<\varepsilon / 3 .
$$

It follows that for $l, n>N$,

$$
\begin{aligned}
\left\|u_{l}(t)-u_{n}(t)\right\|_{W} \leq & \left\|u_{l}(t)-u_{l}\left(t_{m}\right)\right\|_{W}+\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\|_{W} \\
& +\left\|u_{n}\left(t_{m}\right)-u_{n}(t)\right\|_{W} \\
\leq & \frac{2 \varepsilon}{3}+\frac{\varepsilon}{3}+\frac{2 \varepsilon}{3}<2 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows $\left\{u_{k}(t)\right\}_{k=1}^{\infty}$ is a Cauchy sequence. Since $W$ is complete, this shows this sequence converges.

Now for $t \in[a, b]$, it was just shown that if $\varepsilon>0$ there exists $N_{t}$ such that if $n, m>N_{t}$, then

$$
\left\|u_{n}(t)-u_{m}(t)\right\|_{W}<\frac{\varepsilon}{3}
$$

Now let $s \neq t$. Then

$$
\left\|u_{n}(s)-u_{m}(s)\right\|_{W} \leq\left\|u_{n}(s)-u_{n}(t)\right\|_{W}+\left\|u_{n}(t)-u_{m}(t)\right\|_{W}+\left\|u_{m}(t)-u_{m}(s)\right\|_{W}
$$

From 21.10.47

$$
\left\|u_{n}(s)-u_{m}(s)\right\|_{W} \leq 2\left(\frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q}\right)+\left\|u_{n}(t)-u_{m}(t)\right\|_{W}
$$

and so it follows that if $\delta$ is sufficiently small and $s \in B(t, \delta)$, then when $n, m>N_{t}$

$$
\left\|u_{n}(s)-u_{m}(s)\right\|<\varepsilon
$$

Since $[a, b]$ is compact, there are finitely many of these balls, $\left\{B\left(t_{i}, \delta\right)\right\}_{i=1}^{p}$, such that for $s \in B\left(t_{i}, \boldsymbol{\delta}\right)$ and $n, m>N_{t_{i}}$, the above inequality holds. Let $N>\max \left\{N_{t_{1}}, \cdots, N_{t_{p}}\right\}$. Then if $m, n>N$ and $s \in[a, b]$ is arbitrary, it follows the above inequality must hold. Therefore, this has shown the following claim.

Claim: Let $\varepsilon>0$ be given. Then there exists $N$ such that if $m, n>N$, then

$$
\left\|u_{n}-u_{m}\right\|_{\infty, W}<\varepsilon
$$

Now let $u(t)=\lim _{k \rightarrow \infty} u_{k}(t)$.

$$
\begin{equation*}
\|u(t)-u(s)\|_{W} \leq\left\|u(t)-u_{n}(t)\right\|_{W}+\left\|u_{n}(t)-u_{n}(s)\right\|_{W}+\left\|u_{n}(s)-u(s)\right\|_{W} \tag{21.10.48}
\end{equation*}
$$

Let $N$ be in the above claim and fix $n>N$. Then

$$
\left\|u(t)-u_{n}(t)\right\|_{W}=\lim _{m \rightarrow \infty}\left\|u_{m}(t)-u_{n}(t)\right\|_{W} \leq \varepsilon
$$

and similarly, $\left\|u_{n}(s)-u(s)\right\|_{W} \leq \varepsilon$. Then if $|t-s|$ is small enough, 21.10 .47 shows the middle term in 21.10.48 is also smaller than $\varepsilon$. Therefore, if $|t-s|$ is small enough,

$$
\|u(t)-u(s)\|_{W}<3 \varepsilon
$$

Thus $u$ is continuous. Finally, let $N$ be as in the above claim. Then letting $m, n>N$, it follows that for all $t \in[a, b]$,

$$
\left\|u_{m}(t)-u_{n}(t)\right\|_{W}<\varepsilon
$$

Therefore, letting $m \rightarrow \infty$, it follows that for all $t \in[a, b]$,

$$
\left\|u(t)-u_{n}(t)\right\|_{W} \leq \varepsilon
$$

and so $\left\|u-u_{n}\right\|_{\infty, W} \leq \varepsilon$.
Here is an interesting corollary. Recall that for $E$ a Banach space $C^{0, \alpha}([0, T], E)$ is the space of continuous functions $u$ from $[0, T]$ to $E$ such that

$$
\|u\|_{\alpha, E} \equiv\|u\|_{\infty, E}+\rho_{\alpha, E}(u)<\infty
$$

where here

$$
\rho_{\alpha, E}(u) \equiv \sup _{t \neq s} \frac{\|u(t)-u(s)\|_{E}}{|t-s|^{\alpha}}
$$

Corollary 21.10.7 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then if $\gamma>\alpha$, the embedding of $C^{0, \gamma}([0, T], E)$ into $C^{0, \alpha}([0, T], X)$ is compact.

Proof: Let $\phi \in C^{0, \gamma}([0, T], E)$

$$
\begin{gathered}
\frac{\|\phi(t)-\phi(s)\|_{X}}{|t-s|^{\alpha}} \leq\left(\frac{\|\phi(t)-\phi(s)\|_{W}}{|t-s|^{\gamma}}\right)^{\alpha / \gamma}\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)} \\
\leq\left(\frac{\|\phi(t)-\phi(s)\|_{E}}{|t-s|^{\gamma}}\right)^{\alpha / \gamma}\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)} \leq \rho_{\gamma, E}(\phi)\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)}
\end{gathered}
$$

Now suppose $\left\{u_{n}\right\}$ is a bounded sequence in $C^{0, \gamma}([0, T], E)$. By Theorem 21.10.6 above, there is a subsequence still called $\left\{u_{n}\right\}$ which converges in $C^{0}([0, T], W)$. Thus from the above inequality

$$
\begin{aligned}
& \frac{\left\|u_{n}(t)-u_{m}(t)-\left(u_{n}(s)-u_{m}(s)\right)\right\|_{X}}{|t-s|^{\alpha}} \\
\leq & \rho_{\gamma, E}\left(u_{n}-u_{m}\right)\left\|u_{n}(t)-u_{m}(t)-\left(u_{n}(s)-u_{m}(s)\right)\right\|_{W}^{1-(\alpha / \gamma)} \\
\leq & C\left(\left\{u_{n}\right\}\right)\left(2\left\|u_{n}-u_{m}\right\|_{\infty, W}\right)^{1-(\alpha / \gamma)}
\end{aligned}
$$

which converges to 0 as $n, m \rightarrow \infty$. Thus

$$
\rho_{\alpha, X}\left(u_{n}-u_{m}\right) \rightarrow 0 \text { as } n, m \rightarrow \infty
$$

Also $\left\|u_{n}-u_{m}\right\|_{\infty, X} \rightarrow 0$ as $n, m \rightarrow \infty$ so this is a Cauchy sequence in $C^{0, \alpha}([0, T], X)$.
The next theorem is a well known result probably due to Lions, Temam, or Aubin.
Theorem 21.10.8 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $p \geq 1$, let $q>1$, and define

$$
\begin{gathered}
S \equiv\left\{u \in L^{p}([a, b] ; E): \text { for some } C,\|u(t)-u(s)\|_{X} \leq C|t-s|^{1 / q}\right. \\
\text { and } \left.\|u\|_{L^{p}([a, b] ; E)} \leq R\right\} .
\end{gathered}
$$

Thus $S$ is bounded in $L^{p}([a, b] ; E)$ and Holder continuous into $X$. Then $S$ is precompact in $L^{p}([a, b] ; W)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b] ; W)$.

Proof: It suffices to show $S$ has an $\eta$ net in $L^{p}([a, b] ; W)$ for each $\eta>0$.
If not, there exists $\eta>0$ and a sequence $\left\{u_{n}\right\} \subseteq S$, such that

$$
\begin{equation*}
\left\|u_{n}-u_{m}\right\| \geq \eta \tag{21.10.49}
\end{equation*}
$$

for all $n \neq m$ and the norm refers to $L^{p}([a, b] ; W)$. Let

$$
a=t_{0}<t_{1}<\cdots<t_{k}=b, t_{i}-t_{i-1}=(b-a) / k
$$

Now define

$$
\bar{u}_{n}(t) \equiv \sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t), \bar{u}_{n_{i}} \equiv \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s
$$

The idea is to show that $\bar{u}_{n}$ approximates $u_{n}$ well and then to argue that a subsequence of the $\left\{\bar{u}_{n}\right\}$ is a Cauchy sequence yielding a contradiction to 21.10.49.

Therefore,

$$
\begin{gathered}
u_{n}(t)-\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{n}(t) \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(t) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{gathered}
$$

It follows from Jensen's inequality that

$$
\begin{aligned}
& \left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} \\
= & \sum_{i=1}^{k}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
\leq & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{aligned}
$$

and so

$$
\begin{align*}
& \int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \\
\leq & \int_{a}^{b} \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) d t \\
= & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s d t . \tag{21.10.50}
\end{align*}
$$

From Lemma 21.10.1 if $\varepsilon>0$, there exists $C_{\varepsilon}$ such that

$$
\begin{gathered}
\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} \leq \varepsilon\left\|u_{n}(t)-u_{n}(s)\right\|_{E}^{p}+C_{\varepsilon}\left\|u_{n}(t)-u_{n}(s)\right\|_{X}^{p} \\
\leq 2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}|t-s|^{p / q}
\end{gathered}
$$

This is substituted in to 21.10 .50 to obtain

$$
\begin{gathered}
\int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \leq \\
\\
\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left(2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}|t-s|^{p / q}\right) d s d t \\
=\sum_{i=1}^{k} 2^{p} \varepsilon \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)\right\|_{W}^{p}+\frac{C_{\varepsilon}}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}|t-s|^{p / q} d s d t \\
\leq \quad 2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}} d s d t \\
= \\
2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q}\left(t_{i}-t_{i-1}\right)^{2} \\
\leq \\
\leq 2^{p} \varepsilon R^{p}+C_{\varepsilon} \sum_{i=1}^{k}\left(t_{i}-t_{i-1}\right)^{1+p / q}=2^{p} \varepsilon R^{p}+C_{\varepsilon} k\left(\frac{b-a}{k}\right)^{1+p / q} .
\end{gathered}
$$

Taking $\varepsilon$ so small that $2^{p} \varepsilon R^{p}<\eta^{p} / 8^{p}$ and then choosing $k$ sufficiently large, it follows

$$
\left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}([a, b] ; W)}<\frac{\eta}{4} .
$$

Thus $k$ is fixed and $\bar{u}_{n}$ at a step function with $k$ steps having values in $E$. Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that $\left\{\bar{u}_{n}\right\}$ is Cauchy in $L^{p}(a, b ; W)$ and use this to contradict 21.10.49. The details follow.

Suppose $\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{i}^{n} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)$. Thus

$$
\left\|\bar{u}_{n}(t)\right\|_{E}=\sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
$$

and so

$$
R \geq \int_{a}^{b}\left\|\bar{u}_{n}(t)\right\|_{E}^{p} d t=\frac{T}{k} \sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E}^{p}
$$

Therefore, the $\left\{u_{i}^{n}\right\}$ are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence $\left\{u_{n_{k}}\right\}$ such that $u_{n_{k}}$ is a Cauchy sequence in $L^{p}(a, b ; W)$. You simply get a subsequence such that $u_{i}^{n_{k}}$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,

$$
\begin{aligned}
\left\|u_{n}-u_{m}\right\|_{L^{p}(a, b ; W)} \leq & \left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}(a, b ; W)} \\
& +\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\left\|\bar{u}_{m}-u_{m}\right\|_{L^{p}(a, b ; W)} \\
\leq & \frac{\eta}{4}+\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\frac{\eta}{4}<\eta
\end{aligned}
$$

provided $m, n$ are large enough, contradicting 21.10.49.
You can give a different version of the above to include the case where there is, instead of a Holder condition, a bound on $u^{\prime}$ for $u \in S$. It is stated next. We are assuming a situation in which

$$
\int_{a}^{b} u^{\prime}(t) d t=u(b)-u(a)
$$

This happens, for example, if $u^{\prime}$ is the weak derivative. See [117].
Corollary 21.10.9 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $p \geq 1$, let $q>1$, and define

$$
\begin{gathered}
S \equiv\left\{u \in L^{p}([a, b] ; E): \text { for some } C,\|u(t)-u(s)\|_{X} \leq C|t-s|^{1 / q}\right. \\
\text { and } \left.\|u\|_{L^{p}([a, b] ; E)} \leq R\right\}
\end{gathered}
$$

Thus $S$ is bounded in $L^{p}([a, b] ; E)$ and Holder continuous into $X$. Then $S$ is precompact in $L^{p}([a, b] ; W)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b] ; W)$. The same conclusion can be drawn if it is known instead of the Holder condition that $\left\|u^{\prime}\right\|_{L^{1}([a, b] ; X)}$ is bounded.

Proof: The first part was done earlier. Therefore, we just prove the new stuff which involves a bound on the $L^{1}$ norm of the derivative. It suffices to show $S$ has an $\eta$ net in $L^{p}([a, b] ; W)$ for each $\eta>0$.

If not, there exists $\eta>0$ and a sequence $\left\{u_{n}\right\} \subseteq S$, such that

$$
\begin{equation*}
\left\|u_{n}-u_{m}\right\| \geq \eta \tag{21.10.51}
\end{equation*}
$$

for all $n \neq m$ and the norm refers to $L^{p}([a, b] ; W)$. Let

$$
a=t_{0}<t_{1}<\cdots<t_{k}=b, t_{i}-t_{i-1}=(b-a) / k
$$

Now define

$$
\bar{u}_{n}(t) \equiv \sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t), \bar{u}_{n_{i}} \equiv \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s
$$

The idea is to show that $\bar{u}_{n}$ approximates $u_{n}$ well and then to argue that a subsequence of the $\left\{\bar{u}_{n}\right\}$ is a Cauchy sequence yielding a contradiction to 21.10.51.

Therefore,

$$
\begin{gathered}
u_{n}(t)-\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{n}(t) \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(t) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{gathered}
$$

It follows from Jensen's inequality that

$$
\begin{aligned}
& \left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} \\
= & \sum_{i=1}^{k}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{aligned}
$$

And so

$$
\begin{align*}
& \int_{0}^{T}\left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} d t=\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} d t \\
& \leq \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}} \varepsilon\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{E}^{p} d t \\
&+C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{X}^{p} d t \tag{21.10.52}
\end{align*}
$$

Consider the second of these. It equals

$$
C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{s}^{t} u_{n}^{\prime}(\tau) d \tau d s\right\|_{X}^{p} d t
$$

This is no larger than

$$
\begin{gathered}
\leq C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left(\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau d s\right)^{p} d t \\
=C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left(\int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p} d t \\
=C_{\varepsilon} \sum_{i=1}^{k}\left(\left(t_{i}-t_{i-1}\right)^{1 / p} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p}
\end{gathered}
$$

Since $\frac{b-a}{k}=t_{i}-t_{i-1}$,

$$
\begin{aligned}
& =C_{\varepsilon}\left(\sum_{i=1}^{k}\left(t_{i}-t_{i-1}\right)^{1 / p} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p} \\
& =C_{\varepsilon}\left(\sum_{i=1}^{k}\left(\frac{b-a}{k}\right)^{1 / p} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p} \\
& \leq \frac{C_{\varepsilon}(b-a)}{k}\left(\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p} \\
& =\frac{C_{\varepsilon}(b-a)}{k}\left(\left\|u_{n}^{\prime}\right\|_{L^{1}([a, b], X)}\right)^{p}<\frac{\eta^{p}}{10^{p}}
\end{aligned}
$$

if $k$ is chosen large enough. Now consider the first in 21.10.52. By Jensen's inequality

$$
\begin{gathered}
\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}} \varepsilon\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{E}^{p} d t \leq \\
\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}} \varepsilon \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{E}^{p} d s d t \\
\leq \quad \varepsilon 2^{p-1} \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right) d s d t \\
=\quad 2 \varepsilon 2^{p-1} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left(\left\|u_{n}(t)\right\|^{p}\right) d t=\varepsilon(2)\left(2^{p-1}\right)\left\|u_{n}\right\|_{L^{p}([a, b], E)} \leq M \varepsilon
\end{gathered}
$$

Now pick $\varepsilon$ sufficiently small that $M \varepsilon<\frac{\eta^{p}}{10^{p}}$ and then $k$ large enough that the second term in 21.10 .52 is also less than $\eta^{p} / 10^{p}$. Then it will follow that

$$
\left\|\bar{u}_{n}-u_{n}\right\|_{L^{p}([a, b], W)}<\left(\frac{2 \eta^{p}}{10^{p}}\right)^{1 / p}=2^{1 / p} \frac{\eta}{10} \leq \frac{\eta}{5}
$$

Thus $k$ is fixed and $\bar{u}_{n}$ at a step function with $k$ steps having values in $E$. Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that $\left\{\bar{u}_{n}\right\}$ is Cauchy in $L^{p}([a, b] ; W)$ and use this to contradict 21.10.51. The details follow.

Suppose $\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{i}^{n} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)$. Thus

$$
\left\|\bar{u}_{n}(t)\right\|_{E}=\sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
$$

and so

$$
R \geq \int_{a}^{b}\left\|\bar{u}_{n}(t)\right\|_{E}^{p} d t=\frac{T}{k} \sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E}^{p}
$$

Therefore, the $\left\{u_{i}^{n}\right\}$ are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence $\left\{u_{n_{k}}\right\}$ such that $u_{n_{k}}$ is a Cauchy sequence in $L^{p}([a, b] ; W)$. You simply get a subsequence such that $u_{i}^{n_{k}}$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,

$$
\begin{aligned}
\left\|u_{n}-u_{m}\right\|_{L^{p}(a, b ; W)} \leq & \left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}(a, b ; W)} \\
& +\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\left\|\bar{u}_{m}-u_{m}\right\|_{L^{p}(a, b ; W)} \\
\leq & \frac{\eta}{4}+\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\frac{\eta}{4}<\eta
\end{aligned}
$$

provided $m, n$ are large enough, contradicting 21.10.51.

### 21.11 Exercises

1. Show $L^{1}(\mathbb{R})$ is not reflexive. Hint: $L^{1}(\mathbb{R})$ is separable. What about $L^{\infty}(\mathbb{R})$ ?
2. If $f \in L^{1}\left(\mathbb{R}^{n} ; X\right)$ for $X$ a Banach space, does the usual fundamental theorem of calculus work? That is, can you say $\lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} f(t) d m=f(x)$ a.e.?
3. Does the Vitali convergence theorem hold for Bochner integrable functions? If so, give a statement of the appropriate theorem and a proof.
4. Suppose $g \in L^{1}([a, b] ; X)$ where $X$ is a Banach space. Then if $\int_{a}^{b} g(t) \phi(t) d t=0$ for all $\phi \in C_{c}^{\infty}(a, b)$, then $g(t)=0$ a.e. Show that this is the case. Hint: It will likely depend on the regularity properties of Lebesgue measure.
5. Suppose $f \in L^{1}(a, b ; X)$ and for all $\phi \in C_{c}^{\infty}(a, b), \int_{a}^{b} f(t) \phi^{\prime}(t) d t=0$.Then there exists a constant, $a \in X$ such that $f(t)=a$ a.e. Hint: Let

$$
\psi_{\phi}(x) \equiv \int_{a}^{x}\left[\phi(t)-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right] d t, \phi_{0} \in C_{c}^{\infty}(a, b), \int_{a}^{b} \phi_{0}(x) d x=1
$$

Then explain why $\psi_{\phi} \in C_{c}^{\infty}(a, b), \psi_{\phi}^{\prime}=\phi-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}$. Then use the assumption on $\psi_{\phi}$. Next use the above problem. Verify that

$$
f(y)=\int_{a}^{b} f(t) \phi_{0}(t) d t \text { a.e. } y
$$

6. Let $f \in L^{1}([a, b], X)$. Then we say that the weak derivative of $f$ is in $L^{1}([a, b], X)$ if there is a function denoted as $f^{\prime} \in L^{1}([a, b], X)$ such that for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
-\int_{a}^{b} f(t) \phi^{\prime}(t) d t=\int_{a}^{b} f^{\prime}(t) \phi(t) d t
$$

Show that this definition is well defined. Next, using the above problems, show that if $f, f^{\prime} \in L^{1}([a, b], X)$, it follows that there is a continuous function, denoted by $t \rightarrow \hat{f}(t)$ such that $\hat{f}(t)=f(t)$ a.e. $t$ and

$$
\hat{f}(t)=\hat{f}(a)+\int_{0}^{t} f^{\prime}(s) d s
$$

Thus, unlike the classical definition of the derivative, when a function and its derivative are both in $L^{1}$, it has a representative $\hat{f}$ which equals the function a.e. such that $\hat{f}$ can be recovered from its derivative. Recall the well known example of this not working out which is based on the Cantor function which you should see in a real analysis course. This function had zero derivative a.e. and yet it climbed from 0 to 1 on the unit interval. Thus one could not recover it from integrating its classical derivative.

## Chapter 22

## The Derivative

### 22.1 Limits Of A Function

As in the case of scalar valued functions of one variable, a concept closely related to continuity is that of the limit of a function. The notion of limit of a function makes sense at points $\mathbf{x}$, which are limit points of $D(\mathbf{f})$ and this concept is defined next. In all that follows $(V,\|\cdot\|)$ and $(W,\|\cdot\|)$ are two normed linear spaces. Recall the definition of limit point first.

Definition 22.1.1 Let $A \subseteq W$ be a set. A point $\mathbf{x}$, is a limit point of $A$ if $B(\mathbf{x}, r)$ contains infinitely many points of A for every $r>0$.

Definition 22.1.2 Let $\mathbf{f}: D(\mathbf{f}) \subseteq V \rightarrow W$ be a function and let $\mathbf{x}$ be a limit point of $D(\mathbf{f})$. Then

$$
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L}
$$

if and only if the following condition holds. For all $\varepsilon>0$ there exists $\delta>0$ such that if

$$
0<\|\mathbf{y}-\mathbf{x}\|<\delta, \text { and } \mathbf{y} \in D(\mathbf{f})
$$

then,

$$
\|\mathbf{L}-\mathbf{f}(\mathbf{y})\|<\varepsilon
$$

Theorem 22.1.3 If $\lim _{\mathbf{y} \rightarrow \mathbf{x}} \mathbf{f}(\mathbf{y})=\mathbf{L}$ and $\lim _{y \rightarrow x} \mathbf{f}(\mathbf{y})=\mathbf{L}_{1}$, then $\mathbf{L}=\mathbf{L}_{1}$.
Proof: Let $\varepsilon>0$ be given. There exists $\delta>0$ such that if $0<|\mathbf{y}-\mathbf{x}|<\delta$ and $\mathbf{y} \in D(\mathbf{f})$, then

$$
\|\mathbf{f}(\mathbf{y})-\mathbf{L}\|<\varepsilon,\left\|\mathbf{f}(\mathbf{y})-\mathbf{L}_{1}\right\|<\varepsilon .
$$

Pick such a $\mathbf{y}$. There exists one because $\mathbf{x}$ is a limit point of $D(\mathbf{f})$. Then

$$
\left\|\mathbf{L}-\mathbf{L}_{1}\right\| \leq\|\mathbf{L}-\mathbf{f}(\mathbf{y})\|+\left\|\mathbf{f}(\mathbf{y})-\mathbf{L}_{1}\right\|<\varepsilon+\varepsilon=2 \varepsilon
$$

Since $\varepsilon>0$ was arbitrary, this shows $\mathbf{L}=\mathbf{L}_{1}$.
As in the case of functions of one variable, one can define $\lim _{\mathbf{y} \rightarrow \mathbf{x}} f(\mathbf{x})= \pm \infty$.
Definition 22.1.4 If $f(\mathbf{x}) \in \mathbb{R}, \lim _{\mathbf{y} \rightarrow \mathbf{x}} f(\mathbf{x})=\infty$ if for every number $l$, there exists $\delta>0$ such that whenever $\|\mathbf{y}-\mathbf{x}\|<\delta$ and $\mathbf{y} \in D(\mathbf{f})$, then $f(\mathbf{x})>l . \lim _{\mathbf{y} \rightarrow \mathbf{x}} f(\mathbf{x})=-\infty$ if for every number $l$, there exists $\delta>0$ such that whenever $\|\mathbf{y}-\mathbf{x}\|<\delta$ and $\mathbf{y} \in D(\mathbf{f})$, then $f(\mathbf{x})<l$.

The following theorem is just like the one variable version of calculus.
Theorem 22.1.5 Suppose $\mathbf{f}: D(\mathbf{f}) \subseteq V \rightarrow \mathbb{F}^{m}$. Then for $\mathbf{x}$ a limit point of $D(\mathbf{f})$,

$$
\begin{equation*}
\lim _{y \rightarrow x} \mathbf{f}(\mathbf{y})=\mathbf{L} \tag{22.1.1}
\end{equation*}
$$

if and only if

$$
\begin{equation*}
\lim _{y \rightarrow x} f_{k}(\mathbf{y})=L_{k} \tag{22.1.2}
\end{equation*}
$$

where $\mathbf{f}(\mathbf{y}) \equiv\left(f_{1}(\mathbf{y}), \cdots, f_{p}(\mathbf{y})\right)$ and $\mathbf{L} \equiv\left(L_{1}, \cdots, L_{p}\right)$.
Suppose here that $f$ has values in $W$, a normed linear space and

$$
\lim _{y \rightarrow \mathbf{x}} f(y)=L, \lim _{y \rightarrow \mathbf{x}} g(y)=K
$$

where $K, L \in W$. Then if $a, b \in \mathbb{F}$,

$$
\begin{equation*}
\lim _{y \rightarrow x}(a f(y)+b g(y))=a L+b K \tag{22.1.3}
\end{equation*}
$$

If $W$ is an inner product space,

$$
\begin{equation*}
\lim _{y \rightarrow x}(f, g)(y)=(L, K) \tag{22.1.4}
\end{equation*}
$$

If $g$ is scalar valued with $\lim _{y \rightarrow x} g(y)=K$,

$$
\begin{equation*}
\lim _{y \rightarrow x} f(y) g(y)=L K \tag{22.1.5}
\end{equation*}
$$

Also, if $h$ is a continuous function defined near $L$, then

$$
\begin{equation*}
\lim _{y \rightarrow x} h \circ f(y)=h(L) . \tag{22.1.6}
\end{equation*}
$$

Suppose $\lim _{y \rightarrow \mathbf{x}} f(y)=L$. If $\|f(y)-b\| \leq r$ for all $y$ sufficiently close to $\mathbf{x}$, then $|L-b| \leq r$ also.

Proof: Suppose 22.1.1. Then letting $\varepsilon>0$ be given there exists $\delta>0$ such that if $0<\|y-x\|<\delta$, it follows

$$
\left|f_{k}(y)-L_{k}\right| \leq\|\mathbf{f}(y)-\mathbf{L}\|<\varepsilon
$$

which verifies 22.1.2.
Now suppose 22.1.2 holds. Then letting $\varepsilon>0$ be given, there exists $\delta_{k}$ such that if $0<\|y-x\|<\delta_{k}$, then

$$
\left|f_{k}(y)-L_{k}\right|<\varepsilon
$$

Let $0<\delta<\min \left(\delta_{1}, \cdots, \delta_{p}\right)$. Then if $0<\|y-x\|<\delta$, it follows

$$
\|\mathbf{f}(y)-\mathbf{L}\|_{\infty}<\varepsilon
$$

Any other norm on $\mathbb{F}^{m}$ would work out the same way because the norms are all equivalent.
Each of the remaining assertions follows immediately from the coordinate descriptions of the various expressions and the first part. However, I will give a different argument for these.

The proof of 22.1.3 is left for you. Now 22.1.4 is to be verified. Let $\varepsilon>0$ be given. Then by the triangle inequality,

$$
\begin{aligned}
|(f, g)(y)-(L, K)| & \leq|(f, g)(y)-(f(y), K)|+|(f(y), K)-(L, K)| \\
& \leq\|f(y)\|\|g(y)-K\|+\|K\|\|f(y)-L\|
\end{aligned}
$$

There exists $\delta_{1}$ such that if $0<\|y-x\|<\delta_{1}$ and $y \in D(f)$, then

$$
\|f(y)-L\|<1
$$

and so for such $y$, the triangle inequality implies, $\|f(y)\|<1+\|L\|$. Therefore, for $0<$ $\|y-x\|<\delta_{1}$,

$$
\begin{equation*}
|(f, g)(y)-(L, K)| \leq(1+\|K\|+\|L\|)[\|g(y)-K\|+\|f(y)-L\|] . \tag{22.1.7}
\end{equation*}
$$

Now let $0<\delta_{2}$ be such that if $y \in D(f)$ and $0<\|x-y\|<\delta_{2}$,

$$
\|f(y)-L\|<\frac{\varepsilon}{2(1+\|K\|+\|L\|)},\|g(y)-K\|<\frac{\varepsilon}{2(1+\|K\|+\|L\|)}
$$

Then letting $0<\boldsymbol{\delta} \leq \min \left(\boldsymbol{\delta}_{1}, \boldsymbol{\delta}_{2}\right)$, it follows from 22.1.7 that

$$
|(f, g)(y)-(L, K)|<\varepsilon
$$

and this proves 22.1.4.
The proof of 22.1.5 is left to you.
Consider 22.1.6. Since $h$ is continuous near $L$, it follows that for $\varepsilon>0$ given, there exists $\eta>0$ such that if $\|y-L\|<\eta$, then

$$
\|h(y)-h(L)\|<\varepsilon
$$

Now since $\lim _{y \rightarrow x} f(y)=L$, there exists $\delta>0$ such that if $0<\|y-x\|<\delta$, then

$$
\|f(y)-L\|<\eta
$$

Therefore, if $0<\|y-x\|<\delta$,

$$
\|h(f(y))-h(L)\|<\varepsilon
$$

It only remains to verify the last assertion. Assume $\|f(y)-b\| \leq r$. It is required to show that $\|L-b\| \leq r$. If this is not true, then $\|L-b\|>r$. Consider $B(L,\|L-b\|-r)$. Since $L$ is the limit of $f$, it follows $f(y) \in B(L,\|L-b\|-r)$ whenever $y \in D(f)$ is close enough to $x$. Thus, by the triangle inequality,

$$
\|f(y)-L\|<\|L-b\|-r
$$

and so

$$
\begin{aligned}
r & <\|L-b\|-\|f(y)-L\| \leq|\|b-L\|-\|f(y)-L\|| \\
& \leq\|b-f(y)\|
\end{aligned}
$$

a contradiction to the assumption that $\|b-f(y)\| \leq r$.
The relation between continuity and limits is as follows.

Theorem 22.1.6 For $f: D(f) \rightarrow W$ and $x \in D(f)$ a limit point of $D(f), f$ is continuous at $x$ if and only if

$$
\lim _{y \rightarrow x} f(y)=f(x)
$$

Proof: First suppose $f$ is continuous at $x$ a limit point of $D(f)$. Then for every $\varepsilon>0$ there exists $\delta>0$ such that if $\|x-y\|<\delta$ and $y \in D(f)$, then $|f(x)-f(y)|<\varepsilon$. In particular, this holds if $0<\|x-y\|<\delta$ and this is just the definition of the limit. Hence $f(x)=\lim _{y \rightarrow x} f(y)$.

Next suppose $x$ is a limit point of $D(f)$ and $\lim _{y \rightarrow x} f(y)=f(x)$. This means that if $\varepsilon>$ 0 there exists $\delta>0$ such that for $0<\|x-y\|<\delta$ and $y \in D(f)$, it follows $|f(y)-f(x)|<$ $\varepsilon$. However, if $y=x$, then $|f(y)-f(x)|=|f(x)-f(x)|=0$ and so whenever $y \in D(f)$ and $\|x-y\|<\delta$, it follows $|f(x)-f(y)|<\varepsilon$, showing $f$ is continuous at $x$.

Example 22.1.7 Find $\lim _{(x, y) \rightarrow(3,1)}\left(\frac{x^{2}-9}{x-3}, y\right)$.
It is clear that $\lim _{(x, y) \rightarrow(3,1)} \frac{x^{2}-9}{x-3}=6$ and $\lim _{(x, y) \rightarrow(3,1)} y=1$. Therefore, this limit equals $(6,1)$.

Example 22.1.8 Find $\lim _{(x, y) \rightarrow(0,0)} \frac{x y}{x^{2}+y^{2}}$.
First of all, observe the domain of the function is $\mathbb{R}^{2} \backslash\{(0,0)\}$, every point in $\mathbb{R}^{2}$ except the origin. Therefore, $(0,0)$ is a limit point of the domain of the function so it might make sense to take a limit. However, just as in the case of a function of one variable, the limit may not exist. In fact, this is the case here. To see this, take points on the line $y=0$. At these points, the value of the function equals 0 . Now consider points on the line $y=x$ where the value of the function equals $1 / 2$. Since, arbitrarily close to $(0,0)$, there are points where the function equals $1 / 2$ and points where the function has the value 0 , it follows there can be no limit. Just take $\varepsilon=1 / 10$ for example. You cannot be within $1 / 10$ of $1 / 2$ and also within $1 / 10$ of 0 at the same time.

Note it is necessary to rely on the definition of the limit much more than in the case of a function of one variable and there are no easy ways to do limit problems for functions of more than one variable. It is what it is and you will not deal with these concepts without suffering and anguish.

### 22.2 Basic Definitions

The concept of derivative generalizes right away to functions defined on a normed linear space. However, no attempt will be made to consider derivatives from one side or another. This is because there isn't a well defined side. However, it is certainly the case that there are more general notions which include such things. I will present a fairly general notion of the derivative of a function which is defined on a normed vector space which has values in a normed vector space.

In what follows, $X, Y$ will denote normed vector spaces. Recall that $\mathscr{L}(X, Y)$ will denote the bounded linear transformations from $X$ to $Y$.

Let $U$ be an open set in $X$, and let $\mathbf{f}: U \rightarrow Y$ be a function.

Definition 22.2.1 A function $\mathbf{g}$ is $\mathbf{O}(\mathbf{v})$ if

$$
\begin{equation*}
\lim _{\|\mathbf{v}\| \rightarrow 0} \frac{\mathbf{g}(\mathbf{v})}{\|\mathbf{v}\|}=\mathbf{0} \tag{22.2.8}
\end{equation*}
$$

A function $\mathbf{f}: U \rightarrow Y$ is differentiable at $\mathbf{x} \in U$ if there exists a linear transformation $L \in$ $\mathscr{L}(X, Y)$ such that

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})=\mathbf{f}(\mathbf{x})+L \mathbf{v}+\mathbf{o}(\mathbf{v})
$$

This linear transformation $L$ is the definition of $D \mathbf{f}(\mathbf{x})$. This derivative is often called the Frechet derivative.

In finite dimensions, the question whether a given function is differentiable is independent of the norm used on the finite dimensional vector space. That is, a function is differentiable with one norm if and only if it is differentiable with another norm. This is because all norms are equivalent on a finite dimensional space.

The definition 22.2.8 means the error,

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-L \mathbf{v}
$$

converges to $\mathbf{0}$ faster than $\|\mathbf{v}\|$. Thus the above definition is equivalent to saying

$$
\begin{equation*}
\lim _{\|\mathbf{v}\| \rightarrow 0} \frac{\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-L \mathbf{v}\|}{\|\mathbf{v}\|}=0 \tag{22.2.9}
\end{equation*}
$$

or equivalently,

$$
\begin{equation*}
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \frac{\|\mathbf{f}(\mathbf{y})-\mathbf{f}(\mathbf{x})-D \mathbf{f}(\mathbf{x})(\mathbf{y}-\mathbf{x})\|}{\|\mathbf{y}-\mathbf{x}\|}=0 \tag{22.2.10}
\end{equation*}
$$

The symbol $\mathbf{0}(\mathbf{v})$ should be thought of as an adjective. Thus, if $t$ and $k$ are constants,

$$
\mathbf{o}(\mathbf{v})=\mathbf{o}(\mathbf{v})+\mathbf{o}(\mathbf{v}), \mathbf{o}(t \mathbf{v})=\mathbf{o}(\mathbf{v}), k \mathbf{o}(\mathbf{v})=\mathbf{o}(\mathbf{v})
$$

and other similar observations hold.
Theorem 22.2.2 The derivative is well defined.
Proof: First note that for a fixed vector $\mathbf{v}, \mathbf{o}(t \mathbf{v})=\mathbf{o}(t)$. This is because

$$
\lim _{t \rightarrow 0} \frac{\mathbf{o}(t \mathbf{v})}{|t|}=\lim _{t \rightarrow 0}\|\mathbf{v}\| \frac{\mathbf{o}(t \mathbf{v})}{\|t \mathbf{v}\|}=\mathbf{0}
$$

Now suppose both $L_{1}$ and $L_{2}$ work in the above definition. Then let $\mathbf{v}$ be any vector and let $t$ be a real scalar which is chosen small enough that $t \mathbf{v}+\mathbf{x} \in U$. Then

$$
\mathbf{f}(\mathbf{x}+t \mathbf{v})=\mathbf{f}(\mathbf{x})+L_{1} t \mathbf{v}+\mathbf{o}(t \mathbf{v}), \mathbf{f}(\mathbf{x}+t \mathbf{v})=\mathbf{f}(\mathbf{x})+L_{2} t \mathbf{v}+\mathbf{o}(t \mathbf{v})
$$

Therefore, subtracting these two yields $\left(L_{2}-L_{1}\right)(t \mathbf{v})=\mathbf{o}(t \mathbf{v})=\mathbf{o}(t)$. Therefore, dividing by $t$ yields $\left(L_{2}-L_{1}\right)(\mathbf{v})=\frac{\mathbf{o}(t)}{t}$. Now let $t \rightarrow 0$ to conclude that $\left(L_{2}-L_{1}\right)(\mathbf{v})=0$. Since this is true for all $\mathbf{v}$, it follows $L_{2}=L_{1}$. This proves the theorem.

Lemma 22.2.3 Let $\mathbf{f}$ be differentiable at $\mathbf{x}$. Then $\mathbf{f}$ is continuous at $\mathbf{x}$ and in fact, there exists $K>0$ such that whenever $\|\mathbf{v}\|$ is small enough,

$$
\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\| \leq K\|\mathbf{v}\|
$$

Also if $\mathbf{f}$ is differentiable at $\mathbf{x}$, then

$$
\mathbf{o}(\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\|)=\mathbf{o}(\mathbf{v})
$$

Proof: From the definition of the derivative,

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})=D \mathbf{f}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v}) .
$$

Let $\|\mathbf{v}\|$ be small enough that $\frac{\mathbf{o}(\|\mathbf{v}\|)}{\|\mathbf{v}\|}<1$ so that $\|\mathbf{o}(\mathbf{v})\| \leq\|\mathbf{v}\|$. Then for such $\mathbf{v}$,

$$
\begin{aligned}
\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\| & \leq\|D \mathbf{f}(\mathbf{x}) \mathbf{v}\|+\|\mathbf{v}\| \\
& \leq(\|D \mathbf{f}(\mathbf{x})\|+1)\|\mathbf{v}\|
\end{aligned}
$$

This proves the lemma with $K=\|D \mathbf{f}(\mathbf{x})\|+1$. Recall the operator norm discussed in Definition 17.1.5.

The last assertion is implied by the first as follows. Define

$$
\mathbf{h}(\mathbf{v}) \equiv\left\{\begin{array}{l}
\frac{\mathbf{o}(\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\|)}{\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\|} \text { if }\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\| \neq 0 \\
\mathbf{0} \text { if }\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\|=0
\end{array}\right.
$$

Then $\lim _{\|\mathbf{v}\| \rightarrow 0} \mathbf{h}(\mathbf{v})=\mathbf{0}$ from continuity of $\mathbf{f}$ at $\mathbf{x}$ which is implied by the first part. Also from the above estimate,

$$
\left\|\frac{\mathbf{o}(\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\|)}{\|\mathbf{v}\|}\right\|=\|\mathbf{h}(\mathbf{v})\| \frac{\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})\|}{\|\mathbf{v}\|} \leq\|\mathbf{h}(\mathbf{v})\|(\|D \mathbf{f}(\mathbf{x})\|+1)
$$

This establishes the second claim.
Here $\|D \mathbf{f}(\mathbf{x})\|$ is the operator norm of the linear transformation $D \mathbf{f}(\mathbf{x})$.

### 22.3 The Chain Rule

With the above lemma, it is easy to prove the chain rule.
Theorem 22.3.1 (The chain rule) Let $U$ and $V$ be open sets $U \subseteq X$ and $V \subseteq Y$. Suppose $\mathbf{f}: U \rightarrow V$ is differentiable at $\mathbf{x} \in U$ and suppose $\mathbf{g}: V \rightarrow \mathbb{F}^{q}$ is differentiable at $\mathbf{f}(\mathbf{x}) \in V$. Then $\mathbf{g} \circ \mathbf{f}$ is differentiable at $\mathbf{x}$ and

$$
D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})=D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x})
$$

Proof: This follows from a computation. Let $B(\mathbf{x}, r) \subseteq U$ and let $r$ also be small enough that for $\|\mathbf{v}\| \leq r$, it follows that $\mathbf{f}(\mathbf{x}+\mathbf{v}) \in V$. Such an $r$ exists because $\mathbf{f}$ is continuous at $\mathbf{x}$. For $\|\mathbf{v}\|<r$, the definition of differentiability of $\mathbf{g}$ and $\mathbf{f}$ implies

$$
\mathbf{g}(\mathbf{f}(\mathbf{x}+\mathbf{v}))-\mathbf{g}(\mathbf{f}(\mathbf{x}))=
$$

$$
\begin{align*}
& D \mathbf{g}(\mathbf{f}(\mathbf{x}))(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))+\mathbf{o}(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})) \\
= & D \mathbf{g}(\mathbf{f}(\mathbf{x}))[D \mathbf{f}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v})]+\mathbf{o}(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})) \\
= & D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v})+\mathbf{o}(\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x}))  \tag{22.3.11}\\
= & D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v})
\end{align*}
$$

By Lemma 22.2.3. From the definition of the derivative $D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})$ exists and equals $D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x})$.

### 22.4 The Derivative Of A Compact Mapping

Here is a little definition about compact mappings. It turns out that if you have a differentiable mapping which is also compact, then the derivative must also be compact.

Definition 22.4.1 Let $C \in \mathscr{L}(X, Y)$. It is said to be compact if it takes bounded sets to precompact sets. If $f$ is a function defined on an open subset $U$ of $X$, then $f$ is called compact if $f$ (bounded set $)=($ precompact $)$.

Theorem 22.4.2 Let $f: U \subseteq X \rightarrow Y$ where $f$ takes bounded sets to precompact sets. Then $D f(x)$ also takes bounded sets in $X$ to precompact sets in $Y$.

Proof: If this is not so, then there exists a bounded set $B$ in $X$ and for some $\varepsilon>0$ a sequence of points $D f(x) b_{n}$ such that all these points are further apart than $\varepsilon$. Without loss of generality, one can assume $B=B(0, r)$, a ball. In fact, one can assume that $r>0$ is as small as desired because if $D f(x) B(0, r)$ is precompact, then so is $D f(x) B(0, R), R>$ $r$. Just get an $\varepsilon \frac{r}{R}$ net $\left\{D f(x) x_{n}\right\}_{n=1}^{N}$ for $D f(x) B(0, r)$ and consider $\left\{\frac{R}{r} D f(x) x_{n}\right\}_{n=1}^{N}$. $\cup_{n} B\left(D f(x) x_{n}, \varepsilon \frac{r}{R}\right)$ covers $D f(x) B(0, R)$, so $\cup_{n} B\left(\frac{R}{r} D f(x) x_{n}, \varepsilon\right)$ covers $D f(x) B(0, R)$.

Choose $r$ very small so that $r<\varepsilon / 4$ and

$$
f\left(x+x_{n}\right)-f(x)=D f(x) x_{n}+o\left(x_{n}\right),\left\|o\left(x_{n}\right)\right\|<\left\|x_{n}\right\|
$$

and there are infinitely many $D f(x) x_{n}$ further apart than $\varepsilon, x_{n} \in B(0, r)$. Then consider $B(x, r)$ and $\left\{f\left(x+x_{n}\right)\right\}_{n=1}^{\infty}$.

$$
\begin{aligned}
\left\|f\left(x+x_{n}\right)-f\left(x+x_{m}\right)\right\| & \geq\left\|D f(x) x_{n}-D f(x) x_{m}\right\|-\left\|o\left(x_{n}\right)-o\left(x_{m}\right)\right\| \\
& \geq \varepsilon-2 \frac{\varepsilon}{4}=\frac{\varepsilon}{2}
\end{aligned}
$$

contradicting the assertion that $f$ takes bounded sets to precompact sets.

### 22.5 The Matrix Of The Derivative

The case of most interest here is the only one I will discuss. It is the case where $X=\mathbb{R}^{n}$ and $Y=\mathbb{R}^{m}$, the function being defined on an open subset of $\mathbb{R}^{n}$. Of course this all generalizes to arbitrary vector spaces and one considers the matrix taken with respect to various bases. As above, $\mathbf{f}$ will be defined and differentiable on an open set $U \subseteq \mathbb{R}^{n}$.

The matrix of $D \mathbf{f}(\mathbf{x})$ is the matrix having the $i^{t h}$ column equal to $D \mathbf{f}(\mathbf{x}) \mathbf{e}_{i}$ and so it is only necessary to compute this. Let $t$ be a small real number such that both

$$
\frac{\mathbf{f}\left(\mathbf{x}+t \mathbf{e}_{i}\right)-\mathbf{f}(\mathbf{x})-D \mathbf{f}(\mathbf{x})\left(t \mathbf{e}_{i}\right)}{t}=\frac{\mathbf{o}(t)}{t}
$$

Therefore,

$$
\frac{\mathbf{f}\left(\mathbf{x}+t \mathbf{e}_{i}\right)-\mathbf{f}(\mathbf{x})}{t}=D \mathbf{f}(\mathbf{x})\left(\mathbf{e}_{i}\right)+\frac{\mathbf{o}(t)}{t}
$$

The limit exists on the right and so it exists on the left also. Thus

$$
\frac{\partial \mathbf{f}(\mathbf{x})}{\partial x_{i}} \equiv \lim _{t \rightarrow 0} \frac{\mathbf{f}\left(\mathbf{x}+t \mathbf{e}_{i}\right)-\mathbf{f}(\mathbf{x})}{t}=D \mathbf{f}(\mathbf{x})\left(\mathbf{e}_{i}\right)
$$

and so the matrix of the derivative is just the matrix which has the $i^{t h}$ column equal to the $i^{\text {th }}$ partial derivative of $\mathbf{f}$. Note that this shows that whenever $\mathbf{f}$ is differentiable, it follows that the partial derivatives all exist. It does not go the other way however as discussed later.

Theorem 22.5.1 Let $\mathbf{f}: U \subseteq \mathbb{F}^{n} \rightarrow \mathbb{F}^{m}$ and suppose $\mathbf{f}$ is differentiable at $\mathbf{x}$. Then all the partial derivatives $\frac{\partial f_{i}(\mathbf{x})}{\partial x_{j}}$ exist and if $J \mathbf{f}(\mathbf{x})$ is the matrix of the linear transformation, $D \mathbf{f}(\mathbf{x})$ with respect to the standard basis vectors, then the $i j^{\text {th }}$ entry is given by $\frac{\partial f_{i}}{\partial x_{j}}(\mathbf{x})$ also denoted as $f_{i, j}$ or $f_{i, x_{j}}$. It is the matrix whose $i^{\text {th }}$ column is

$$
\frac{\partial \mathbf{f}(\mathbf{x})}{\partial x_{i}} \equiv \lim _{t \rightarrow 0} \frac{\mathbf{f}\left(\mathbf{x}+t \mathbf{e}_{i}\right)-\mathbf{f}(\mathbf{x})}{t} .
$$

Of course there is a generalization of this idea called the directional derivative.
Definition 22.5.2 In general, the symbol

$$
D_{\mathbf{v}} \mathbf{f}(\mathbf{x})
$$

is defined by

$$
\lim _{t \rightarrow 0} \frac{\mathbf{f}(\mathbf{x}+t \mathbf{v})-\mathbf{f}(\mathbf{x})}{t}
$$

where $t \in \mathbb{F}$. In case $|\mathbf{v}|=1$ and the norm is the standard Euclidean norm, this is called the directional derivative. More generally, with no restriction on the size of $\mathbf{v}$ and in any linear space, it is called the Gateaux derivative. $\mathbf{f}$ is said to be Gateaux differentiable at $\mathbf{x}$ if there exists $D_{\mathbf{v}} \mathbf{f}(\mathbf{x})$ such that

$$
\lim _{t \rightarrow 0} \frac{\mathbf{f}(\mathbf{x}+t \mathbf{v})-\mathbf{f}(\mathbf{x})}{t}=D_{\mathbf{v}} \mathbf{f}(\mathbf{x})
$$

where $\mathbf{v} \rightarrow D_{\mathbf{v}} \mathbf{f}(\mathbf{x})$ is linear. Thus we say it is Gateaux differentiable if the Gateaux derivative exists for each $\mathbf{v}$ and $\mathbf{v} \rightarrow D_{\mathbf{v}} \mathbf{f}(\mathbf{x})$ is linear. ${ }^{1}$

[^20]What if all the partial derivatives of $\mathbf{f}$ exist? Does it follow that $\mathbf{f}$ is differentiable? Consider the following function, $f: \mathbb{R}^{2} \rightarrow \mathbb{R}$,

$$
f(x, y)=\left\{\begin{array}{l}
\frac{x y}{x^{2}+y^{2}} \text { if }(x, y) \neq(0,0) \\
0 \text { if }(x, y)=(0,0)
\end{array} .\right.
$$

Then from the definition of partial derivatives,

$$
\lim _{h \rightarrow 0} \frac{f(h, 0)-f(0,0)}{h}=\lim _{h \rightarrow 0} \frac{0-0}{h}=0
$$

and

$$
\lim _{h \rightarrow 0} \frac{f(0, h)-f(0,0)}{h}=\lim _{h \rightarrow 0} \frac{0-0}{h}=0
$$

However $f$ is not even continuous at $(0,0)$ which may be seen by considering the behavior of the function along the line $y=x$ and along the line $x=0$. By Lemma 22.2.3 this implies $f$ is not differentiable. Therefore, it is necessary to consider the correct definition of the derivative given above if you want to get a notion which generalizes the concept of the derivative of a function of one variable in such a way as to preserve continuity whenever the function is differentiable.

### 22.6 A Mean Value Inequality

The following theorem will be very useful in much of what follows. It is a version of the mean value theorem as is the next lemma.

Lemma 22.6.1 Let $Y$ be a normed vector space and suppose $\mathbf{h}:[0,1] \rightarrow Y$ is differentiable and satisfies

$$
\left\|\mathbf{h}^{\prime}(t)\right\| \leq M
$$

Then

$$
\|\mathbf{h}(1)-\mathbf{h}(0)\| \leq M
$$

Proof: Let $\varepsilon>0$ be given and let

$$
S \equiv\{t \in[0,1]: \text { for all } s \in[0, t],\|\mathbf{h}(s)-\mathbf{h}(0)\| \leq(M+\varepsilon) s\}
$$

Then $0 \in S$. Let $t=\sup S$. Then by continuity of $\mathbf{h}$ it follows

$$
\begin{equation*}
\|\mathbf{h}(t)-\mathbf{h}(0)\|=(M+\boldsymbol{\varepsilon}) t \tag{22.6.12}
\end{equation*}
$$

Suppose $t<1$. Then there exist positive numbers, $h_{k}$ decreasing to 0 such that

$$
\left\|\mathbf{h}\left(t+h_{k}\right)-\mathbf{h}(0)\right\|>(M+\varepsilon)\left(t+h_{k}\right)
$$

and now it follows from 22.6.12 and the triangle inequality that

$$
\begin{aligned}
& \left\|\mathbf{h}\left(t+h_{k}\right)-\mathbf{h}(t)\right\|+\|\mathbf{h}(t)-\mathbf{h}(0)\| \\
= & \left\|\mathbf{h}\left(t+h_{k}\right)-\mathbf{h}(t)\right\|+(M+\varepsilon) t>(M+\varepsilon)\left(t+h_{k}\right)
\end{aligned}
$$

and so

$$
\left\|\mathbf{h}\left(t+h_{k}\right)-\mathbf{h}(t)\right\|>(M+\varepsilon) h_{k}
$$

Now dividing by $h_{k}$ and letting $k \rightarrow \infty$

$$
\left\|\mathbf{h}^{\prime}(t)\right\| \geq M+\varepsilon
$$

a contradiction. Thus $t=1$.
Theorem 22.6.2 Suppose $U$ is an open subset of $X$ and $\mathbf{f}: U \rightarrow Y$ has the property that $D \mathbf{f}(\mathbf{x})$ exists for all $\mathbf{x}$ in $U$ and that, $\mathbf{x}+t(\mathbf{y}-\mathbf{x}) \in U$ for all $t \in[0,1]$. (The line segment joining the two points lies in $U$.) Suppose also that for all points on this line segment,

$$
\|D \mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))\| \leq M
$$

Then

$$
\|\mathbf{f}(\mathbf{y})-\mathbf{f}(\mathbf{x})\| \leq M\|\mathbf{y}-\mathbf{x}\|
$$

Proof: Let

$$
\mathbf{h}(t) \equiv \mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x})) .
$$

Then by the chain rule,

$$
\mathbf{h}^{\prime}(t)=D \mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))(\mathbf{y}-\mathbf{x})
$$

and so

$$
\begin{aligned}
\left\|\mathbf{h}^{\prime}(t)\right\| & =\|D \mathbf{f}(\mathbf{x}+t(\mathbf{y}-\mathbf{x}))(\mathbf{y}-\mathbf{x})\| \\
& \leq M\|\mathbf{y}-\mathbf{x}\|
\end{aligned}
$$

by Lemma 22.6.1

$$
\|\mathbf{h}(1)-\mathbf{h}(0)\|=\|\mathbf{f}(\mathbf{y})-\mathbf{f}(\mathbf{x})\| \leq M\|\mathbf{y}-\mathbf{x}\|
$$

Here is a little result which will help to tie the case of $\mathbb{R}^{n}$ in to the abstract theory presented for arbitrary spaces.

Theorem 22.6.3 Let $X$ be a normed vector space having basis $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right\}$ and let $Y$ be another normed vector space having basis $\left\{\mathbf{w}_{1}, \cdots, \mathbf{w}_{m}\right\}$. Let $U$ be an open set in $X$ and let $\mathbf{f}: U \rightarrow Y$ have the property that the Gateaux derivatives,

$$
D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) \equiv \lim _{t \rightarrow 0} \frac{\mathbf{f}\left(\mathbf{x}+t \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})}{t}
$$

exist and are continuous functions of $\mathbf{x}$. Then D $\mathbf{f}(\mathbf{x})$ exists and

$$
D \mathbf{f}(\mathbf{x}) \mathbf{v}=\sum_{k=1}^{n} D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) a_{k}
$$

where

$$
\mathbf{v}=\sum_{k=1}^{n} a_{k} \mathbf{v}_{k}
$$

Furthermore, $\mathbf{x} \rightarrow$ Df( $\mathbf{x})$ is continuous; that is

$$
\lim _{\mathbf{y} \rightarrow \mathbf{x}}\|D \mathbf{f}(\mathbf{y})-D \mathbf{f}(\mathbf{x})\|=0
$$

Proof: Let $\mathbf{v}=\sum_{k=1}^{n} a_{k} \mathbf{v}_{k}$. Then

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})=\mathbf{f}\left(\mathbf{x}+\sum_{k=1}^{n} a_{k} \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})
$$

Then letting $\sum_{k=1}^{0} \equiv 0, \mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})$ is given by

$$
\begin{gather*}
\sum_{k=1}^{n}\left[\mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k} a_{j} \mathbf{v}_{j}\right)-\mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k-1} a_{j} \mathbf{v}_{j}\right)\right] \\
=\sum_{k=1}^{n}\left[\mathbf{f}\left(\mathbf{x}+a_{k} \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})\right]+ \\
\sum_{k=1}^{n}\left[\left(\mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k} a_{j} \mathbf{v}_{j}\right)-\mathbf{f}\left(\mathbf{x}+a_{k} \mathbf{v}_{k}\right)\right)-\left(\mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k-1} a_{j} \mathbf{v}_{j}\right)-\mathbf{f}(\mathbf{x})\right)\right] \tag{22.6.13}
\end{gather*}
$$

Consider the $k^{\text {th }}$ term in 22.6.13. Let

$$
\mathbf{h}(t) \equiv \mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k-1} a_{j} \mathbf{v}_{j}+t a_{k} \mathbf{v}_{k}\right)-\mathbf{f}\left(\mathbf{x}+t a_{k} \mathbf{v}_{k}\right)
$$

for $t \in[0,1]$. Then

$$
\begin{aligned}
\mathbf{h}^{\prime}(t)= & a_{k} \lim _{h \rightarrow 0} \frac{1}{a_{k} h}\left(\mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k-1} a_{j} \mathbf{v}_{j}+(t+h) a_{k} \mathbf{v}_{k}\right)-\mathbf{f}\left(\mathbf{x}+(t+h) a_{k} \mathbf{v}_{k}\right)\right. \\
& \left.-\left(\mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k-1} a_{j} \mathbf{v}_{j}+t a_{k} \mathbf{v}_{k}\right)-\mathbf{f}\left(\mathbf{x}+t a_{k} \mathbf{v}_{k}\right)\right)\right)
\end{aligned}
$$

and this equals

$$
\begin{equation*}
\left(D_{\mathbf{v}_{k}} \mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k-1} a_{j} \mathbf{v}_{j}+t a_{k} \mathbf{v}_{k}\right)-D_{\mathbf{v}_{k}} \mathbf{f}\left(\mathbf{x}+t a_{k} \mathbf{v}_{k}\right)\right) a_{k} \tag{22.6.14}
\end{equation*}
$$

Now without loss of generality, it can be assumed that the norm on $X$ is given by

$$
\|\mathbf{v}\| \equiv \max \left\{\left|a_{k}\right|: \mathbf{v}=\sum_{j=1}^{n} a_{k} \mathbf{v}_{k}\right\}
$$

because this is a finite dimensional space, all norms on $X$ are equivalent. Therefore, from 22.6.14 and the assumption that the Gateaux derivatives are continuous,

$$
\begin{aligned}
\left\|\mathbf{h}^{\prime}(t)\right\| & =\left\|\left(D_{\mathbf{v}_{k}} \mathbf{f}\left(\mathbf{x}+\sum_{j=1}^{k-1} a_{j} \mathbf{v}_{j}+t a_{k} \mathbf{v}_{k}\right)-D_{\mathbf{v}_{k}} \mathbf{f}\left(\mathbf{x}+t a_{k} \mathbf{v}_{k}\right)\right) a_{k}\right\| \\
& \leq \varepsilon\left|a_{k}\right| \leq \boldsymbol{\varepsilon}\|\mathbf{v}\|
\end{aligned}
$$

provided $\|\mathbf{v}\|$ is sufficiently small. Since $\varepsilon$ is arbitrary, it follows from Lemma 22.6.1 the expression in 22.6.13 is $\mathbf{0}(\mathbf{v})$ because this expression equals a finite sum of terms of the form $\mathbf{h}(1)-\mathbf{h}(0)$ where $\left\|\mathbf{h}^{\prime}(t)\right\| \leq \varepsilon\|\mathbf{v}\|$ whenever $\|\mathbf{v}\|$ is small enough. Thus

$$
\begin{gathered}
\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})=\sum_{k=1}^{n}\left[\mathbf{f}\left(\mathbf{x}+a_{k} \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})\right]+\mathbf{o}(\mathbf{v}) \\
=\sum_{k=1}^{n} D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) a_{k}+\sum_{k=1}^{n}\left[\mathbf{f}\left(\mathbf{x}+a_{k} \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) a_{k}\right]+\mathbf{o}(\mathbf{v})
\end{gathered}
$$

Consider the $k^{\text {th }}$ term in the second sum.

$$
\mathbf{f}\left(\mathbf{x}+a_{k} \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) a_{k}=a_{k}\left(\frac{\mathbf{f}\left(\mathbf{x}+a_{k} \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})}{a_{k}}-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x})\right)
$$

where the expression in the parentheses converges to 0 as $a_{k} \rightarrow 0$. Thus whenever $\|\mathbf{v}\|$ is sufficiently small,

$$
\left\|\mathbf{f}\left(\mathbf{x}+a_{k} \mathbf{v}_{k}\right)-\mathbf{f}(\mathbf{x})-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) a_{k}\right\| \leq \boldsymbol{\varepsilon}\left|a_{k}\right| \leq \varepsilon\|\mathbf{v}\|
$$

which shows the second sum is also $\mathbf{0}(\mathbf{v})$. Therefore,

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})=\sum_{k=1}^{n} D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) a_{k}+\mathbf{o}(\mathbf{v})
$$

Defining

$$
D \mathbf{f}(\mathbf{x}) \mathbf{v} \equiv \sum_{k=1}^{n} D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x}) a_{k}
$$

where $\mathbf{v}=\sum_{k} a_{k} \mathbf{v}_{k}$, it follows $D \mathbf{f}(\mathbf{x}) \in \mathscr{L}(X, Y)$ and is given by the above formula.
It remains to verify $\mathbf{x} \rightarrow D \mathbf{f}(\mathbf{x})$ is continuous.

$$
\begin{aligned}
& \|(D \mathbf{f}(\mathbf{x})-D \mathbf{f}(\mathbf{y})) \mathbf{v}\| \\
\leq & \sum_{k=1}^{n}\left\|\left(D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x})-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{y})\right) a_{k}\right\| \\
\leq & \max \left\{\left|a_{k}\right|, k=1, \cdots, n\right\} \sum_{k=1}^{n}\left\|D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x})-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{y})\right\| \\
= & \|\mathbf{v}\| \sum_{k=1}^{n}\left\|D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x})-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{y})\right\|
\end{aligned}
$$

(Note that $\|\mathbf{v}\| \equiv \max \left\{\left|a_{k}\right|, k=1, \cdots, n\right\}$ where $\mathbf{v}=\sum_{k} a_{k} \mathbf{v}_{k}$ ) and so

$$
\|D \mathbf{f}(\mathbf{x})-D \mathbf{f}(\mathbf{y})\| \leq \sum_{k=1}^{n}\left\|D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x})-D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{y})\right\|
$$

which proves the continuity of $D \mathbf{f}$ because of the assumption the Gateaux derivatives are continuous.

In particular, if $D_{\mathbf{v}_{k}} \mathbf{f}(\mathbf{x})$ exist and are continuous functions of $\mathbf{x}$, this shows that $\mathbf{f}$ is Gateaux differentiable and in fact the Gateaux derivatives are continuous. The following gives the corresponding result for functions defined on infinite dimensional spaces.

Theorem 22.6.4 Suppose $\mathbf{f}: U \rightarrow Y$ where $U$ is an open set in $X$, a normed linear space. Suppose that $\mathbf{f}$ is Gateaux differentiable on $U$ and that the Gateaux derivative is continuous on an open set containing $\mathbf{x}$. Then $\mathbf{f}$ is Frechet differentiable at $\mathbf{x}$.

Proof: Denote by $G(\mathbf{x}) \in \mathscr{L}(X, Y)$ the Gateaux derivative. Thus

$$
G(\mathbf{x}) \mathbf{v} \equiv \lim _{\lambda \rightarrow 0} \frac{\mathbf{f}(\mathbf{x}+\lambda \mathbf{v})-\mathbf{f}(\mathbf{x})}{\lambda}
$$

It is desired to show that $G(\mathbf{x})=D \mathbf{f}(\mathbf{x})$. Since $G$ is continuous, one can obtain

$$
\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})=\int_{0}^{1} G(\mathbf{x}+t \mathbf{v}) \mathbf{v} d t
$$

where this is the ordinary Riemann integral.

$$
\begin{aligned}
& \left\|\frac{\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-G(\mathbf{x}) \mathbf{v}}{\|\mathbf{v}\|}\right\|=\left\|\frac{\int_{0}^{1} G(\mathbf{x}+t \mathbf{v}) \mathbf{v} d t-G(\mathbf{x}) \mathbf{v}}{\|\mathbf{v}\|}\right\| \\
= & \left\|\frac{\int_{0}^{1} G(\mathbf{x}+t \mathbf{v}) \mathbf{v}-G(\mathbf{x}) \mathbf{v} d t}{\|\mathbf{v}\|}\right\| \leq \frac{1}{\|\mathbf{v}\|} \int_{0}^{1}\|G(\mathbf{x}+t \mathbf{v})-G(\mathbf{x})\| d t\|\mathbf{v}\|
\end{aligned}
$$

which is small provided $\|\mathbf{v}\|$ is sufficiently small. Thus $G(\mathbf{x})=D \mathbf{f}(\mathbf{x})$ as hoped.
Recall the following.
Lemma 22.6.5 Let $\|x\|=\sup _{\left\|y^{*}\right\|_{X^{\prime}} \leq 1}\left|\left\langle y^{*}, x\right\rangle\right|$.
Proof: Let $f(k x)=k\|x\|$. Then

$$
\sup _{\|k x\| \leq 1}|\langle f, x\rangle|=\sup _{|k| \leq 1 /\|x\|}|k|\|x\|=1
$$

Then by Hahn Banach theorem, there is $y^{*} \in X^{\prime}$ which extends $f$ and $\left\|y^{*}\right\| \leq 1$. Then

$$
\|x\| \geq \sup _{\left\|z^{*}\right\|_{x^{\prime}} \leq 1}\left|\left\langle z^{*}, x\right\rangle\right| \geq\left|\left\langle y^{*}, x\right\rangle\right|=\|x\|
$$

One does not need continuity of $G$ near $\mathbf{x}$. It suffices to have continuity at $\mathbf{x}$. Let $\mathbf{y}^{*} \in Y^{\prime}$. Then by the mean value theorem,

$$
\left\langle\mathbf{y}^{*}, \mathbf{f}(\mathbf{x}+\mathbf{v})\right\rangle-\left\langle\mathbf{y}^{*}, \mathbf{f}(\mathbf{x})\right\rangle=\left\langle\mathbf{y}^{*}, G(\mathbf{x}+t \mathbf{v}) \mathbf{v}\right\rangle, t \in[0,1]
$$

Then

$$
\begin{aligned}
& \frac{1}{\|\mathbf{v}\|}\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-G(\mathbf{x}) \mathbf{v}\|=\frac{1}{\|\mathbf{v}\|} \sup _{\left\|\mathbf{y}^{*}\right\| \leq 1}\left|\left\langle\mathbf{y}^{*}, \mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-G(\mathbf{x}) \mathbf{v}\right\rangle\right| \\
& =\frac{1}{\|\mathbf{v}\|} \sup _{\left\|\mathbf{y}^{*}\right\| \leq 1}\left|\left\langle\mathbf{y}^{*}, G(\mathbf{x}+t \mathbf{v}) \mathbf{v}-G(\mathbf{x}) \mathbf{v}\right\rangle\right| \leq \sup _{|t| \leq 1}\|G(\mathbf{x}+t \mathbf{v})-G(\mathbf{x})\|_{\mathscr{L}(X, Y)}
\end{aligned}
$$

which converges to 0 as $\|\mathbf{v}\| \rightarrow 0$ thanks to continuity of $G$ at $\mathbf{x}$. This proves the following.

Theorem 22.6.6 Suppose $\mathbf{f}: U \rightarrow Y$ where $U$ is an open set in $X$, a normed linear space. Suppose that $\mathbf{f}$ is Gateaux differentiable on $U$ and that the Gateaux derivative is continuous at $\mathbf{x}$. Then $\mathbf{f}$ is Frechet differentiable at $\mathbf{x}$ and $D \mathbf{f}(\mathbf{x}) \mathbf{v}=D_{\mathbf{v}} \mathbf{f}(\mathbf{x})$.

Example 22.6.7 Let $X$ be $C_{0}^{2}(\bar{\Omega})$ where $\Omega$ is a bounded open set in $\mathbb{R}^{n}$ consisting of those functions which are twice continuously differentiable and vanish near $\partial \Omega$. The norm will be

$$
\|u\|_{X} \equiv\|u\|_{\infty}+\max \left\{\|u, i\|_{\infty}, i\right\}+\max \left\{\left\|u u_{, i j}\right\|_{\infty} i, j\right\}
$$

Then let $f: X \rightarrow \mathbb{R}$ be defined by

$$
f(u) \equiv \frac{1}{2} \int_{\Omega} \nabla u \cdot \nabla u d x
$$

Show $f$ is differentiable at $u \in X$.
Consider the Gateaux differentiability.

$$
\lim _{t \rightarrow 0} \frac{f(u+t v)-f(u)}{t}=\lim _{t \rightarrow 0} \frac{t \int_{\Omega} \nabla u \cdot \nabla v d x}{t}+t \frac{1}{2} \int_{\Omega} \nabla v \cdot \nabla v
$$

so it converges to

$$
\int_{\Omega} \nabla u \cdot \nabla v d x=-\int_{\Omega} \Delta u v d x
$$

the last step comes from the divergence theorem. Clearly $v \rightarrow-\int_{\Omega} \Delta u v d x$ is linear and $\mathbb{R}$ valued.

$$
\left|-\int_{\Omega} \Delta u v d x\right| \leq\|v\|_{X} \int_{\Omega}|\Delta u| d x \leq\|v\|_{X} m(\Omega)\|u\|_{X}
$$

Thus this appears to be in $\mathscr{L}(X, \mathbb{R})$. This also shows that,

$$
\sup _{\|v\| \leq 1}\left|D_{v} f(u)-D_{v} f(\hat{u})\right| \leq m(\Omega)\|u-\hat{u}\|_{X}
$$

and so $u \rightarrow D_{(\cdot)}(u)$ is continuous as a map from $X$ to $\mathscr{L}(X, \mathbb{R})$ so it seems that this is a differentiable function and

$$
D f(u)(v)=-\int_{\Omega} \Delta u v d x
$$

Definition 22.6.8 Let $\mathbf{f}: U \rightarrow Y$ where $U$ is an open set in $X$. Then $\mathbf{f}$ is called $C^{1}(U)$ if it Gateaux differentiable and the Gateaux derivative is continuous on $U$.

As shown, this implies $\mathbf{f}$ is differentiable and the Gateaux derivative is the Frechet derivative. It is good to keep in mind the following simple example or variations of it.

Example 22.6.9 Define

$$
f(x) \equiv\left\{\begin{array}{l}
x^{2} \sin \left(\frac{1}{x}\right) x \neq 0 \\
0 \text { if } x=0
\end{array}\right.
$$

This function has the property that it is differentiable everywhere but is not $C^{1}(\mathbb{R})$. In fact the derivative fails to be continuous at 0 .

### 22.7 Higher Order Derivatives

If $f: U \subseteq X \rightarrow Y$ for $U$ an open set, then

$$
\mathbf{x} \rightarrow D \mathbf{f}(\mathbf{x})
$$

is a mapping from $U$ to $\mathscr{L}(X, Y)$, a normed vector space. Therefore, it makes perfect sense to ask whether this function is also differentiable.

Definition 22.7.1 The following is the definition of the second derivative.

$$
D^{2} \mathbf{f}(\mathbf{x}) \equiv D(D \mathbf{f}(\mathbf{x}))
$$

Thus,

$$
D \mathbf{f}(\mathbf{x}+\mathbf{v})-D \mathbf{f}(\mathbf{x})=D^{2} \mathbf{f}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v})
$$

This implies

$$
D^{2} \mathbf{f}(\mathbf{x}) \in \mathscr{L}(X, \mathscr{L}(X, Y)), D^{2} \mathbf{f}(\mathbf{x})(\mathbf{u})(\mathbf{v}) \in Y
$$

and the map

$$
(\mathbf{u}, \mathbf{v}) \rightarrow D^{2} \mathbf{f}(\mathbf{x})(\mathbf{u})(\mathbf{v})
$$

is a bilinear map having values in $Y$. In other words, the two functions,

$$
\mathbf{u} \rightarrow D^{2} \mathbf{f}(\mathbf{x})(\mathbf{u})(\mathbf{v}), \mathbf{v} \rightarrow D^{2} \mathbf{f}(\mathbf{x})(\mathbf{u})(\mathbf{v})
$$

are both linear.
The same pattern applies to taking higher order derivatives. Thus,

$$
D^{3} \mathbf{f}(\mathbf{x}) \equiv D\left(D^{2} \mathbf{f}(\mathbf{x})\right)
$$

and $D^{3} \mathbf{f}(\mathbf{x})$ may be considered as a trilinear map having values in $Y$. In general $D^{k} \mathbf{f}(\mathbf{x})$ may be considered a $k$ linear map. This means the function

$$
\left(\mathbf{u}_{1}, \cdots, \mathbf{u}_{k}\right) \rightarrow D^{k} \mathbf{f}(\mathbf{x})\left(\mathbf{u}_{1}\right) \cdots\left(\mathbf{u}_{k}\right)
$$

has the property

$$
\mathbf{u}_{j} \rightarrow D^{k} \mathbf{f}(\mathbf{x})\left(\mathbf{u}_{1}\right) \cdots\left(\mathbf{u}_{j}\right) \cdots\left(\mathbf{u}_{k}\right)
$$

is linear.
Also, instead of writing

$$
D^{2} \mathbf{f}(\mathbf{x})(\mathbf{u})(\mathbf{v}), \text { or } D^{3} \mathbf{f}(\mathbf{x})(\mathbf{u})(\mathbf{v})(\mathbf{w})
$$

the following notation is often used.

$$
D^{2} \mathbf{f}(\mathbf{x})(\mathbf{u}, \mathbf{v}) \text { or } D^{3} \mathbf{f}(\mathbf{x})(\mathbf{u}, \mathbf{v}, \mathbf{w})
$$

with similar conventions for higher derivatives than 3. Another convention which is often used is the notation

$$
D^{k} \mathbf{f}(\mathbf{x}) \mathbf{v}^{k}
$$

instead of

$$
D^{k} \mathbf{f}(\mathbf{x})(\mathbf{v}, \cdots, \mathbf{v})
$$

Note that for every $k, D^{k} \mathbf{f}$ maps $U$ to a normed vector space. As mentioned above, $D \mathbf{f}(\mathbf{x})$ has values in $\mathscr{L}(X, Y), D^{2} \mathbf{f}(\mathbf{x})$ has values in $\mathscr{L}(X, \mathscr{L}(X, Y))$, etc. Thus it makes sense to consider whether $D^{k} \mathbf{f}$ is continuous. This is described in the following definition.

Definition 22.7.2 Let $U$ be an open subset of $X$, a normed vector space, and let $\mathbf{f}: U \rightarrow Y$. Then $\mathbf{f}$ is $C^{k}(U)$ if $\mathbf{f}$ and its first $k$ derivatives are all continuous. Also, $D^{k} \mathbf{f}(\mathbf{x})$ when it exists can be considered a $Y$ valued multi-linear function. Sometimes these are called tensors in case $\mathbf{f}$ has scalar values.

### 22.8 The Derivative And The Cartesian Product

There are theorems which can be used to get differentiability of a function based on existence and continuity of the partial derivatives. A generalization of this was given above. Here a function defined on a product space is considered. It is very much like what was presented above and could be obtained as a special case but to reinforce the ideas, I will do it from scratch because certain aspects of it are important in the statement of the implicit function theorem.

The following is an important abstract generalization of the concept of partial derivative presented above. Insead of taking the derivative with respect to one variable, it is taken with respect to several but not with respect to others. This vague notion is made precise in the following definition. First here is a lemma.

Lemma 22.8.1 Suppose $U$ is an open set in $X \times Y$. Then the set, $U_{\mathbf{y}}$ defined by

$$
U_{\mathbf{y}} \equiv\{\mathbf{x} \in X:(\mathbf{x}, \mathbf{y}) \in U\}
$$

is an open set in $X$. Here $X \times Y$ is a finite dimensional vector space in which the vector space operations are defined componentwise. Thus for $a, b \in \mathbb{F}$,

$$
a\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right)+b\left(\mathbf{x}_{2}, \mathbf{y}_{2}\right)=\left(a \mathbf{x}_{1}+b \mathbf{x}_{2}, a \mathbf{y}_{1}+b \mathbf{y}_{2}\right)
$$

and the norm can be taken to be

$$
\|(\mathbf{x}, \mathbf{y})\| \equiv \max (\|\mathbf{x}\|,\|\mathbf{y}\|)
$$

Proof: In finite dimensions it doesn't matter how this norm is defined because all are equivalent. It obviously satisfies most axioms of a norm. The only one which is not obvious is the triangle inequality. I will show this now.

$$
\begin{aligned}
\left\|(\mathbf{x}, \mathbf{y})+\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right)\right\| & \equiv\left\|\left(\mathbf{x}+\mathbf{x}_{1}, \mathbf{y}+\mathbf{y}_{1}\right)\right\| \equiv \max \left(\left\|\mathbf{x}+\mathbf{x}_{1}\right\|,\left\|\mathbf{y}+\mathbf{y}_{1}\right\|\right) \\
& \leq \max \left(\|\mathbf{x}\|+\left\|\mathbf{x}_{1}\right\|,\|\mathbf{y}\|+\left\|\mathbf{y}_{1}\right\|\right) \\
& \leq \max (\|\mathbf{x}\|,\|\mathbf{y}\|)+\max \left(\left\|\mathbf{x}_{1}\right\|,\left\|\mathbf{y}_{1}\right\|\right) \\
& \equiv\|(\mathbf{x}, \mathbf{y})\|+\left\|\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right)\right\|
\end{aligned}
$$

Let $\mathbf{x} \in U_{\mathbf{y}}$. Then $(\mathbf{x}, \mathbf{y}) \in U$ and so there exists $r>0$ such that

$$
B((\mathbf{x}, \mathbf{y}), r) \in U
$$

This says that if $(\mathbf{u}, \mathbf{v}) \in X \times Y$ such that $\|(\mathbf{u}, \mathbf{v})-(\mathbf{x}, \mathbf{y})\|<r$, then $(\mathbf{u}, \mathbf{v}) \in U$. Thus if

$$
\|(\mathbf{u}, \mathbf{y})-(\mathbf{x}, \mathbf{y})\|=\|\mathbf{u}-\mathbf{x}\|<r
$$

then $(\mathbf{u}, \mathbf{y}) \in U$. This has just said that $B(\mathbf{x}, r)$, the ball taken in $X$ is contained in $U_{\mathbf{y}}$. This proves the lemma.

Or course one could also consider

$$
U_{\mathbf{x}} \equiv\{\mathbf{y}:(\mathbf{x}, \mathbf{y}) \in U\}
$$

in the same way and conclude this set is open in $Y$. Also, the generalization to many factors yields the same conclusion. In this case, for $\mathbf{x} \in \prod_{i=1}^{n} X_{i}$, let

$$
\|\mathbf{x}\| \equiv \max \left(\left\|\mathbf{x}_{i}\right\|_{X_{i}}: \mathbf{x}=\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)\right)
$$

Then a similar argument to the above shows this is a norm on $\prod_{i=1}^{n} X_{i}$. Consider the triangle inequality.

$$
\begin{gathered}
\left\|\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)+\left(\mathbf{y}_{1}, \cdots, \mathbf{y}_{n}\right)\right\|=\max _{i}\left(\left\|\mathbf{x}_{i}+\mathbf{y}_{i}\right\|_{X_{i}}\right) \leq \max _{i}\left(\left\|\mathbf{x}_{i}\right\|_{X_{i}}+\left\|\mathbf{y}_{i}\right\|_{X_{i}}\right) \\
\leq \max _{i}\left(\left\|\mathbf{x}_{i}\right\|_{X_{i}}\right)+\max _{i}\left(\left\|\mathbf{y}_{i}\right\|_{X_{i}}\right)
\end{gathered}
$$

Corollary 22.8.2 Let $U \subseteq \prod_{i=1}^{n} X_{i}$ be an open set and let

$$
U_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)} \equiv\left\{\mathbf{x} \in \mathbb{F}^{r_{i}}:\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{x}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right) \in U\right\}
$$

Then $U_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)}$ is an open set in $\mathbb{F}^{r_{i}}$.
Proof: Let $\mathbf{z} \in U_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)}$. Then $\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{z}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right) \equiv \mathbf{x} \in U$ by definition. Therefore, since $U$ is open, there exists $r>0$ such that $B(\mathbf{x}, r) \subseteq U$. It follows that for $B(\mathbf{z}, r)_{X_{i}}$ denoting the ball in $X_{i}$, it follows that $B(\mathbf{z}, r)_{X_{i}} \subseteq U_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)}$ because to say that $\|\mathbf{z}-\mathbf{w}\|_{X_{i}}<r$ is to say that

$$
\left\|\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{z}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)-\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{w}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)\right\|<r
$$

and so $\mathbf{w} \in U_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)}$.
Next is a generalization of the partial derivative.
Definition 22.8.3 Let $\mathbf{g}: U \subseteq \prod_{i=1}^{n} X_{i} \rightarrow Y$, where $U$ is an open set. Then the map

$$
\mathbf{z} \rightarrow \mathbf{g}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{z}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)
$$

is a function from the open set in $X_{i}$,

$$
\left\{\mathbf{z}: \mathbf{x}=\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{z}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right) \in U\right\}
$$

to $Y$. When this map is differentiable, its derivative is denoted by $D_{i} \mathbf{g}(\mathbf{x})$. To aid in the notation, for $\mathbf{v} \in X_{i}$, let $\theta_{i} \mathbf{v} \in \prod_{i=1}^{n} X_{i}$ be the vector $(\mathbf{0}, \cdots, \mathbf{v}, \cdots, \mathbf{0})$ where the $\mathbf{v}$ is in the $i^{\text {th }}$ slot and for $\mathbf{v} \in \prod_{i=1}^{n} X_{i}$, let $\mathbf{v}_{i}$ denote the entry in the $i^{\text {th }}$ slot of $\mathbf{v}$. Thus, by saying

$$
\mathbf{z} \rightarrow \mathbf{g}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i-1}, \mathbf{z}, \mathbf{x}_{i+1}, \cdots, \mathbf{x}_{n}\right)
$$

is differentiable is meant that for $\mathbf{v} \in X_{i}$ sufficiently small,

$$
\mathbf{g}\left(\mathbf{x}+\theta_{i} \mathbf{v}\right)-\mathbf{g}(\mathbf{x})=D_{i} \mathbf{g}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v}) .
$$

Note $D_{i} \mathbf{g}(\mathbf{x}) \in \mathscr{L}\left(X_{i}, Y\right)$.
Definition 22.8.4 Let $U \subseteq X$ be an open set. Then $\mathbf{f}: U \rightarrow Y$ is $C^{1}(U)$ if $\mathbf{f}$ is differentiable and the mapping

$$
\mathbf{x} \rightarrow D \mathbf{f}(\mathbf{x})
$$

is continuous as a function from $U$ to $\mathscr{L}(X, Y)$.
With this definition of partial derivatives, here is the major theorem. Note the resemblance with the matrix of the derivative of a function having values in $\mathbb{R}^{m}$ in terms of the partial derivatives.

Theorem 22.8.5 Let $\mathbf{g}, U, \prod_{i=1}^{n} X_{i}$, be given as in Definition 22.8.3. Then $\mathbf{g}$ is $C^{1}(U)$ if and only if $D_{i} \mathbf{g}$ exists and is continuous on $U$ for each $i$. In this case, $\mathbf{g}$ is differentiable and

$$
\begin{equation*}
D \mathbf{g}(\mathbf{x})(\mathbf{v})=\sum_{k} D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k} \tag{22.8.15}
\end{equation*}
$$

where $\mathbf{v}=\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{n}\right)$.
Proof: Suppose then that $D_{i} \mathbf{g}$ exists and is continuous for each $i$. Note that

$$
\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}=\left(\mathbf{v}_{1}, \cdots, \mathbf{v}_{k}, \mathbf{0}, \cdots, \mathbf{0}\right)
$$

Thus $\sum_{j=1}^{n} \theta_{j} \mathbf{v}_{j}=\mathbf{v}$ and define $\sum_{j=1}^{0} \theta_{j} \mathbf{v}_{j} \equiv \mathbf{0}$. Therefore,

$$
\begin{equation*}
\mathbf{g}(\mathbf{x}+\mathbf{v})-\mathbf{g}(\mathbf{x})=\sum_{k=1}^{n}\left[\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}\right)\right] \tag{22.8.16}
\end{equation*}
$$

Consider the terms in this sum.

$$
\begin{gather*}
\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}\right)=\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}_{k}\right)-\mathbf{g}(\mathbf{x})+  \tag{22.8.17}\\
\left(\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}_{k}\right)\right)-\left(\mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}\right)-\mathbf{g}(\mathbf{x})\right) \tag{22.8.18}
\end{gather*}
$$

and the expression in 22.8 .18 is of the form $\mathbf{h}\left(\mathbf{v}_{k}\right)-\mathbf{h}(\mathbf{0})$ where for small $\mathbf{w} \in X_{k}$,

$$
\mathbf{h}(\mathbf{w}) \equiv \mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}+\theta_{k} \mathbf{w}\right)-\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{w}\right)
$$

Therefore,

$$
D \mathbf{h}(\mathbf{w})=D_{k} \mathbf{g}\left(\mathbf{x}+\sum_{j=1}^{k-1} \theta_{j} \mathbf{v}_{j}+\theta_{k} \mathbf{w}\right)-D_{k} \mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{w}\right)
$$

and by continuity, $\|D \mathbf{h}(\mathbf{w})\|<\varepsilon$ provided $\|\mathbf{v}\|$ is small enough. Therefore, by Theorem 22.6.2, the mean value inequality, whenever $\|\mathbf{v}\|$ is small enough,

$$
\left\|\mathbf{h}\left(\mathbf{v}_{k}\right)-\mathbf{h}(\mathbf{0})\right\| \leq \varepsilon\|\mathbf{v}\|
$$

which shows that since $\varepsilon$ is arbitrary, the expression in 6.13.24 is $\boldsymbol{o}(\mathbf{v})$. Now in 22.8.17

$$
\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}_{k}\right)-\mathbf{g}(\mathbf{x})=D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k}+\mathbf{o}\left(\mathbf{v}_{k}\right)=D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k}+\mathbf{o}(\mathbf{v}) .
$$

Therefore, referring to 22.8.16,

$$
\mathbf{g}(\mathbf{x}+\mathbf{v})-\mathbf{g}(\mathbf{x})=\sum_{k=1}^{n} D_{k} \mathbf{g}(\mathbf{x}) \mathbf{v}_{k}+\mathbf{o}(\mathbf{v})
$$

which shows $D \mathbf{g}(\mathbf{x})$ exists and equals the formula given in 22.8.15. Also $\mathbf{x} \rightarrow D \mathbf{g}(\mathbf{x})$ is continuous since each of the $D_{k} \mathbf{g}(\mathbf{x})$ are.

Next suppose $\mathbf{g}$ is $C^{1}$. I need to verify that $D_{k} \mathbf{g}(\mathbf{x})$ exists and is continuous. Let $\mathbf{v} \in X_{k}$ sufficiently small. Then

$$
\begin{aligned}
\mathbf{g}\left(\mathbf{x}+\theta_{k} \mathbf{v}\right)-\mathbf{g}(\mathbf{x}) & =D \mathbf{g}(\mathbf{x}) \theta_{k} \mathbf{v}+\mathbf{o}\left(\theta_{k} \mathbf{v}\right) \\
& =D \mathbf{g}(\mathbf{x}) \theta_{k} \mathbf{v}+\mathbf{o}(\mathbf{v})
\end{aligned}
$$

since $\left\|\theta_{k} \mathbf{v}\right\|=\|\mathbf{v}\|$. Then $D_{k} \mathbf{g}(\mathbf{x})$ exists and equals

$$
D \mathbf{g}(\mathbf{x}) \circ \theta_{k}
$$

Now $\mathbf{x} \rightarrow D \mathbf{g}(\mathbf{x})$ is continuous. It is clear that $\theta_{k}: X_{k} \rightarrow \prod_{i=1}^{n} X_{i}$ is also continuous because $\theta_{k} \mathbf{v}$ places $\mathbf{v}$ in the $k^{t h}$ position and $\mathbf{0}$ in every other position.

Note that the above argument also works at a single point $\mathbf{x}$. That is, continuity at $\mathbf{x}$ of the partials implies $D \mathbf{g}(\mathbf{x})$ exists and is continuous at $\mathbf{x}$.

### 22.9 Mixed Partial Derivatives

Let $U$ be an open set in $\prod_{i=1}^{n} X_{i}$ where the norm is the one described above and let $\mathbf{f}: U \rightarrow Y$ be a function for which the higher order partial derivatives of the sort described above exist. As in the case of functions defined on open sets of $\mathbb{R}^{n}$ one can ask whether the mixed partials are equal.

Results of this sort were known to Euler in around 1734. The theorem was proved by Clairaut some time later. It turns out that the mixed partial derivatives, if continuous will end up being equal. It will also work in the more general situation just described.

Theorem 22.9.1 Let $U$ be an open subset of $\prod_{i=1}^{n} X_{i}$ where each $X_{i}$ is a normed linear space and $\|\mathbf{x}\|=\max _{i}\left\|x_{i}\right\|_{i}$. Let $\mathbf{f}: U \rightarrow Y$ have mixed partial derivatives $D_{i} D_{j} \mathbf{f}$ and $D_{j} D_{i} \mathbf{f}$. Then if these are continuous at $\mathbf{x} \in U$, it follows they will be equal in the sense that $D_{j} D_{i} \mathbf{f}(\mathbf{x})(\mathbf{u}, \mathbf{v})=D_{i} D_{j} \mathbf{f}(\mathbf{x})(\mathbf{v}, \mathbf{u})$.

Proof: It suffices to assume that there are only two spaces and $U$ is an open subset of $X_{1} \times X_{2}$ because one simply specializes to two of the variables in the general case. We denote the variable for $X_{1}$ as $\mathbf{x}$ and the one from $X_{2}$ as $\mathbf{y}$. Also, to simplify this, first assume $\mathbf{f}$ has values in $\mathbb{R}$. Thus it will be denoted as $f$ rather than $\mathbf{f}$. Since $U$ is open, there exists $r>0$ such that $B((\mathbf{x}, \mathbf{y}), r) \subseteq U$. Now let $t, s$ be small real numbers and consider

$$
\Delta(s, t) \equiv \frac{1}{s t}\{\overbrace{f(\mathbf{x}+t \mathbf{u}, \mathbf{y}+s \mathbf{v})-f(\mathbf{x}+t \mathbf{u}, \mathbf{y})}^{h(t)}-\overbrace{(f(\mathbf{x}, \mathbf{y}+s \mathbf{v})-f(\mathbf{x}, \mathbf{y}))}^{h(0)}\}
$$

Then $h^{\prime}(t)=D_{1} f(\mathbf{x}+t \mathbf{u}, \mathbf{y}+s \mathbf{v})(\mathbf{u})-D_{1} f(\mathbf{x}+t \mathbf{u}, \mathbf{y})(\mathbf{u})$. By the mean value theorem,

$$
\Delta(s, t)=\frac{1}{s} h^{\prime}(\theta t)=\frac{1}{s}\left(D_{1} f(\mathbf{x}+\theta t \mathbf{u}, \mathbf{y}+s \mathbf{v})(\mathbf{u})-D_{1} f(\mathbf{x}+\theta t \mathbf{u}, \mathbf{y})(\mathbf{u})\right)
$$

where $\theta \in(0,1)$. Now use the mean value theorem again to obtain

$$
\Delta(s, t)=D_{2} D_{1} f(\mathbf{x}+\theta t \mathbf{u}, \mathbf{y}+\alpha s \mathbf{v})(\mathbf{u})(\mathbf{v}), \alpha \in(0,1)
$$

Similarly doing things in the other order writing

$$
\Delta(s, t)=\frac{1}{s t}\{(f(\mathbf{x}+t \mathbf{u}, \mathbf{y}+s \mathbf{v})-f(\mathbf{x}, \mathbf{y}+s \mathbf{v}))-(f(\mathbf{x}+t \mathbf{u}, \mathbf{y})-f(\mathbf{x}, \mathbf{y}))\}
$$

and taking the derivative first with respect to $s$ and next with respect to $t$, one can obtain

$$
\Delta(s, t)=D_{1} D_{2} f(\mathbf{x}+\hat{\theta} t \mathbf{u}, \mathbf{y}+\hat{\alpha} s \mathbf{v})(\mathbf{v})(\mathbf{u})
$$

where $\hat{\boldsymbol{\theta}}, \hat{\alpha}$ are also in $(0,1)$. Then letting $(s, t) \rightarrow(0,0)$ and using continuity of the mixed partial derivatives, one obtains that

$$
D_{2} D_{1} f(\mathbf{x}, \mathbf{y})(\mathbf{u})(\mathbf{v})=D_{1} D_{2} f(\mathbf{x}, \mathbf{y})(\mathbf{v})(\mathbf{u})
$$

Letting $\mathbf{v}=\mathbf{u}$ yields the desired result.
The general case follows right away by applying this result to $\left\langle\mathbf{y}^{*}, \mathbf{f}\right\rangle$. Thus one obtains

$$
\left\langle\mathbf{y}^{*}, D_{2} D_{1} f(\mathbf{x}, \mathbf{y})(\mathbf{u})(\mathbf{v})\right\rangle=\left\langle\mathbf{y}^{*}, D_{1} D_{2} f(\mathbf{x}, \mathbf{y})(\mathbf{v})(\mathbf{u})\right\rangle
$$

for every $\mathbf{y}^{*} \in Y^{\prime}$. Hence, since $Y^{\prime}$ separates the points, it follows that the mixed partials are equal.

It is necessary to assume the mixed partial derivatives are continuous in order to assert they are equal. The following is a well known example [6].

Example 22.9.2 Let

$$
f(x, y)=\left\{\begin{array}{l}
\frac{x y\left(x^{2}-y^{2}\right)}{x^{2}+y^{2}} \text { if }(x, y) \neq(0,0) \\
0 \text { if }(x, y)=(0,0)
\end{array}\right.
$$

From the definition of partial derivatives it follows immediately that

$$
f_{x}(0,0)=f_{y}(0,0)=0
$$

Using the standard rules of differentiation, for $(x, y) \neq(0,0)$,

$$
f_{x}=y \frac{x^{4}-y^{4}+4 x^{2} y^{2}}{\left(x^{2}+y^{2}\right)^{2}}, f_{y}=x \frac{x^{4}-y^{4}-4 x^{2} y^{2}}{\left(x^{2}+y^{2}\right)^{2}}
$$

Now

$$
f_{x y}(0,0) \equiv \lim _{y \rightarrow 0} \frac{f_{x}(0, y)-f_{x}(0,0)}{y}=\lim _{y \rightarrow 0} \frac{-y^{4}}{\left(y^{2}\right)^{2}}=-1
$$

while

$$
f_{y x}(0,0) \equiv \lim _{x \rightarrow 0} \frac{f_{y}(x, 0)-f_{y}(0,0)}{x}=\lim _{x \rightarrow 0} \frac{x^{4}}{\left(x^{2}\right)^{2}}=1
$$

showing that although the mixed partial derivatives do exist at $(0,0)$, they are not equal there.

Incidentally, the graph of this function appears very innocent. Its fundamental sickness is not apparent. It is like one of those whited sepulchers mentioned in the Bible.

### 22.10 Implicit Function Theorem

Recall the following notation. $\mathscr{L}(X, Y)$ is the space of bounded linear mappings from $X$ to $Y$ where here $\left(X,\|\cdot\|_{X}\right)$ and $\left(Y,\|\cdot\|_{Y}\right)$ are normed linear spaces. Recall that this means that for each $L \in \mathscr{L}(X, Y)$

$$
\|L\| \equiv \sup _{\|x\| \leq 1}\|L x\|<\infty
$$

As shown earlier, this makes $\mathscr{L}(X, Y)$ into a normed linear space. In case $X$ is finite dimensional, $\mathscr{L}(X, Y)$ is the same as the collection of linear maps from $X$ to $Y$. In what
follows $X, Y$ will be Banach spaces, complete normed linear spaces. Thus these are complete normed linear space and $\mathscr{L}(X, Y)$ is the space of bounded linear maps. I will also cease trying to write the vectors in bold face partly to emphasize that these are not in $\mathbb{R}^{n}$.

Definition 22.10.1 Let $\left(X,\|\cdot\|_{X}\right)$ and $\left(Y,\|\cdot\|_{Y}\right)$ be two normed linear spaces. Then $\mathscr{L}(X, Y)$ denotes the set of linear maps from $X$ to $Y$ which also satisfy the following condition. For $L \in \mathscr{L}(X, Y)$,

$$
\lim _{\|x\|_{X} \leq 1}\|L x\|_{Y} \equiv\|L\|<\infty
$$

Recall that this operator norm is less than infinity is always the case where $X$ is finite dimensional. However, if you wish to consider infinite dimensional situations, you assume the operator norm is finite as a qualification for being in $\mathscr{L}(X, Y)$. Then here is an important theorem.

Theorem 22.10.2 If $Y$ is a Banach space, then $\mathscr{L}(X, Y)$ is also a Banach space.
Proof: Let $\left\{L_{n}\right\}$ be a Cauchy sequence in $\mathscr{L}(X, Y)$ and let $x \in X$.

$$
\left\|L_{n} x-L_{m} x\right\| \leq\|x\|\left\|L_{n}-L_{m}\right\| .
$$

Thus $\left\{L_{n} x\right\}$ is a Cauchy sequence. Let

$$
L x=\lim _{n \rightarrow \infty} L_{n} x
$$

Then, clearly, $L$ is linear because if $x_{1}, x_{2}$ are in $X$, and $a, b$ are scalars, then

$$
\begin{aligned}
L\left(a x_{1}+b x_{2}\right) & =\lim _{n \rightarrow \infty} L_{n}\left(a x_{1}+b x_{2}\right) \\
& =\lim _{n \rightarrow \infty}\left(a L_{n} x_{1}+b L_{n} x_{2}\right) \\
& =a L x_{1}+b L x_{2}
\end{aligned}
$$

Also $L$ is bounded. To see this, note that $\left\{\left\|L_{n}\right\|\right\}$ is a Cauchy sequence of real numbers because $\left\|\mid L_{n}\right\|-\left\|L_{m}\right\|\|\leq\| L_{n}-L_{m} \|$. Hence there exists $K>\sup \left\{\left\|L_{n}\right\|: n \in \mathbb{N}\right\}$. Thus, if $x \in X$,

$$
\|L x\|=\lim _{n \rightarrow \infty}\left\|L_{n} x\right\| \leq K\|x\| .
$$

The following theorem is really nice. The series in this theorem is called the Neuman series.

Lemma 22.10.3 Let $(X,\|\cdot\|)$ is a Banach space, and if $A \in \mathscr{L}(X, X)$ and $\|A\|=r<1$, then

$$
(I-A)^{-1}=\sum_{k=0}^{\infty} A^{k} \in \mathscr{L}(X, X)
$$

where the series converges in the Banach space $\mathscr{L}(X, X)$. If $\mathscr{O}$ consists of the invertible maps in $\mathscr{L}(X, X)$, then $\mathscr{O}$ is open and if $\mathfrak{I}$ is the mapping which takes $A$ to $A^{-1}$, then $\mathfrak{I}$ is continuous.

Proof: First of all, why does the series make sense?

$$
\left\|\sum_{k=p}^{q} A^{k}\right\| \leq \sum_{k=p}^{q}\left\|A^{k}\right\| \leq \sum_{k=p}^{q}\|A\|^{k} \leq \sum_{k=p}^{\infty} r^{k} \leq \frac{r^{p}}{1-r}
$$

and so the partial sums are Cauchy in $\mathscr{L}(X, X)$. Therefore, the series converges to something in $\mathscr{L}(X, X)$ by completeness of this normed linear space. Now why is it the inverse?

$$
\sum_{k=0}^{\infty} A^{k}(I-A)=\lim _{n \rightarrow \infty} \sum_{k=0}^{n} A^{k}(I-A)=\lim _{n \rightarrow \infty}\left(\sum_{k=0}^{n} A^{k}-\sum_{k=1}^{n+1} A^{k}\right)=\lim _{n \rightarrow \infty}\left(I-A^{n+1}\right)=I
$$

because $\left\|A^{n+1}\right\| \leq\|A\|^{n+1} \leq r^{n+1}$. Similarly,

$$
(I-A) \sum_{k=0}^{\infty} A^{k}=\lim _{n \rightarrow \infty}\left(I-A^{n+1}\right)=I
$$

and so this shows that this series is indeed the desired inverse.
Next suppose $A \in \mathscr{O}$ so $A^{-1} \in \mathscr{L}(X, X)$. Then suppose $\|A-B\|<\frac{r}{1+\left\|A^{-1}\right\|}, r<1$. Does it follow that $B$ is also invertible?

$$
B=A-(A-B)=A\left[I-A^{-1}(A-B)\right]
$$

Then $\left\|A^{-1}(A-B)\right\| \leq\left\|A^{-1}\right\|\|A-B\|<r$ and so $\left[I-A^{-1}(A-B)\right]^{-1}$ exists. Hence

$$
B^{-1}=\left[I-A^{-1}(A-B)\right]^{-1} A^{-1}
$$

Thus $\mathscr{O}$ is open as claimed. As to continuity, let $A, B$ be as just described. Then using the Neuman series,

$$
\begin{aligned}
&\|\Im A-\Im B\|=\left\|A^{-1}-\left[I-A^{-1}(A-B)\right]^{-1} A^{-1}\right\| \\
&=\left\|A^{-1}-\sum_{k=0}^{\infty}\left(A^{-1}(A-B)\right)^{k} A^{-1}\right\|=\left\|\sum_{k=1}^{\infty}\left(A^{-1}(A-B)\right)^{k} A^{-1}\right\| \\
& \leq \sum_{k=1}^{\infty}\left\|A^{-1}\right\|^{k+1}\|A-B\|^{k}=\|A-B\|\left\|A^{-1}\right\|^{2} \sum_{k=0}^{\infty}\left\|A^{-1}\right\|^{k}\left(\frac{r}{1+\left\|A^{-1}\right\|}\right)^{k} \\
& \leq\|B-A\|\left\|A^{-1}\right\|^{2} \frac{1}{1-r} .
\end{aligned}
$$

Thus $\mathfrak{I}$ is continuous at $A \in \mathscr{O}$.
Lemma 22.10.4 Let

$$
\mathscr{O} \equiv\left\{A \in \mathscr{L}(X, Y): A^{-1} \in \mathscr{L}(Y, X)\right\}
$$

and let

$$
\mathfrak{I}: \mathscr{O} \rightarrow \mathscr{L}(Y, X), \Im A \equiv A^{-1}
$$

Then $\mathscr{O}$ is open and $\mathfrak{I}$ is in $C^{m}(\mathscr{O})$ for all $m=1,2, \cdots$. Also

$$
\begin{equation*}
D \mathfrak{I}(A)(B)=-\Im(A)(B) \Im(A) . \tag{22.10.19}
\end{equation*}
$$

In particular, $\mathfrak{I}$ is continuous.
Proof: Let $A \in \mathscr{O}$ and let $B \in \mathscr{L}(X, Y)$ with

$$
\|B\| \leq \frac{1}{2}\left\|A^{-1}\right\|^{-1}
$$

Then

$$
\left\|A^{-1} B\right\| \leq\left\|A^{-1}\right\|\|B\| \leq \frac{1}{2}
$$

and so by Lemma 22.10.3,

$$
\left(I+A^{-1} B\right)^{-1} \in \mathscr{L}(X, X)
$$

It follows that

$$
(A+B)^{-1}=\left(A\left(I+A^{-1} B\right)\right)^{-1}=\left(I+A^{-1} B\right)^{-1} A^{-1} \in \mathscr{L}(Y, X)
$$

Thus $\mathscr{O}$ is an open set.
Thus

$$
\begin{gathered}
(A+B)^{-1}=\left(I+A^{-1} B\right)^{-1} A^{-1}=\sum_{n=0}^{\infty}(-1)^{n}\left(A^{-1} B\right)^{n} A^{-1} \\
=\left[I-A^{-1} B+o(B)\right] A^{-1}
\end{gathered}
$$

which shows that $\mathscr{O}$ is open and, also,

$$
\begin{aligned}
\mathfrak{I}(A+B)-\mathfrak{I}(A) & =\sum_{n=0}^{\infty}(-1)^{n}\left(A^{-1} B\right)^{n} A^{-1}-A^{-1} \\
& =-A^{-1} B A^{-1}+o(B) \\
& =-\mathfrak{I}(A)(B) \mathfrak{I}(A)+o(B)
\end{aligned}
$$

which demonstrates 22.10.19. It follows from this that we can continue taking derivatives of $\mathfrak{I}$. For $\left\|B_{1}\right\|$ small,

$$
\begin{gathered}
-\left[D \mathfrak{I}\left(A+B_{1}\right)(B)-D \mathfrak{I}(A)(B)\right]= \\
\mathfrak{I}\left(A+B_{1}\right)(B) \mathfrak{I}\left(A+B_{1}\right)-\mathfrak{I}(A)(B) \mathfrak{I}(A) \\
= \\
\mathfrak{I}\left(A+B_{1}\right)(B) \mathfrak{I}\left(A+B_{1}\right)-\mathfrak{I}(A)(B) \mathfrak{I}\left(A+B_{1}\right)+ \\
\mathfrak{I}(A)(B) \mathfrak{I}\left(A+B_{1}\right)-\mathfrak{I}(A)(B) \mathfrak{I}(A) \\
\\
{\left[\mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)+o\left(B_{1}\right)\right](B) \mathfrak{I}\left(A+B_{1}\right)+} \\
\mathfrak{I}(A)(B)\left[\mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)+o\left(B_{1}\right)\right]
\end{gathered}
$$

$$
\begin{aligned}
= & {\left[\mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)+o\left(B_{1}\right)\right](B)\left[A^{-1}-A^{-1} B_{1} A^{-1}+o\left(B_{1}\right)\right]+} \\
& \mathfrak{I}(A)(B)\left[\mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)+o\left(B_{1}\right)\right] \\
= & \mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)(B) \mathfrak{I}(A)+\mathfrak{I}(A)(B) \mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)+o\left(B_{1}\right)
\end{aligned}
$$

and so

$$
D^{2} \mathfrak{I}(A)\left(B_{1}\right)(B)=\mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)(B) \mathfrak{I}(A)+\mathfrak{I}(A)(B) \mathfrak{I}(A)\left(B_{1}\right) \mathfrak{I}(A)
$$

which shows $\mathfrak{I}$ is $C^{2}(\mathscr{O})$. Clearly we can continue in this way which shows $\mathfrak{I}$ is in $C^{m}(\mathscr{O})$ for all $m=1,2, \cdots$.

Here are the two fundamental results presented earlier which will make it easy to prove the implicit function theorem. First is the fundamental mean value inequality.

Theorem 22.10.5 Suppose $U$ is an open subset of $X$ and $f: U \rightarrow Y$ has the property that $D f(x)$ exists for all $x$ in $U$ and that, $x+t(y-x) \in U$ for all $t \in[0,1]$. (The line segment joining the two points lies in $U$.) Suppose also that for all points on this line segment,

$$
\|D f(x+t(y-x))\| \leq M .
$$

Then

$$
\|f(y)-f(x)\| \leq M|y-x|
$$

Next recall the following theorem about fixed points of a contraction map. It was Corollary 7.11.3.

Corollary 22.10.6 Let $B$ be a closed subset of the complete metric space $(X, d)$ and let $f: B \rightarrow X$ be a contraction map

$$
d(f(x), f(\hat{x})) \leq r d(x, \hat{x}), r<1
$$

Also suppose there exists $x_{0} \in B$ such that the sequence of iterates $\left\{f^{n}\left(x_{0}\right)\right\}_{n=1}^{\infty}$ remains in $B$. Then $f$ has a unique fixed point in $B$ which is the limit of the sequence of iterates. This is a point $x \in B$ such that $f(x)=x$. In the case that $B=\overline{B\left(x_{0}, \delta\right)}$, the sequence of iterates satisfies the inequality

$$
d\left(f^{n}\left(x_{0}\right), x_{0}\right) \leq \frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}
$$

and so it will remain in $B$ if

$$
\frac{d\left(x_{0}, f\left(x_{0}\right)\right)}{1-r}<\delta
$$

The implicit function theorem deals with the question of solving, $f(\mathbf{x}, \mathbf{y})=0$ for $x$ in terms of $y$ and how smooth the solution is. It is one of the most important theorems in mathematics. The proof I will give holds with no change in the context of infinite dimensional complete normed vector spaces when suitable modifications are made on what is meant by $\mathscr{L}(X, Y)$. There are also even more general versions of this theorem than to normed vector spaces.

Recall that for $X, Y$ normed vector spaces, the norm on $X \times Y$ is of the form

$$
\|(x, y)\|=\max (\|x\|,\|y\|) .
$$

Theorem 22.10.7 (implicit function theorem) Let $X, Y, Z$ be Banach spaces and suppose $U$ is an open set in $X \times Y$. Let $f: U \rightarrow Z$ be in $C^{1}(U)$ and suppose

$$
\begin{equation*}
f\left(x_{0}, y_{0}\right)=0, D_{1} f\left(x_{0}, y_{0}\right)^{-1} \in \mathscr{L}(Z, X) \tag{22.10.20}
\end{equation*}
$$

Then there exist positive constants, $\delta, \eta$, such that for every $y \in B\left(y_{0}, \eta\right)$ there exists $a$ unique $x(y) \in B\left(x_{0}, \delta\right)$ such that

$$
\begin{equation*}
f(x(y), y)=0 . \tag{22.10.21}
\end{equation*}
$$

Furthermore, the mapping, $y \rightarrow x(y)$ is in $C^{1}\left(B\left(y_{0}, \eta\right)\right)$.
Proof: Let $T(x, y) \equiv x-D_{1} f\left(x_{0}, y_{0}\right)^{-1} f(x, y)$. Therefore,

$$
\begin{equation*}
D_{1} T(x, y)=I-D_{1} f\left(x_{0}, y_{0}\right)^{-1} D_{1} f(x, y) \tag{22.10.22}
\end{equation*}
$$

by continuity of the derivative which implies continuity of $D_{1} T$, it follows there exists $\delta>0$ such that if $\left\|x-x_{0}\right\|<\delta$ and $\left\|y-y_{0}\right\|<\delta$, then

$$
\begin{equation*}
\left\|D_{1} T(x, y)\right\|<\frac{1}{2}, D_{1} f(x, y)^{-1} \text { exists } \tag{22.10.23}
\end{equation*}
$$

The second claim follows from Lemma 22.10.4. By the mean value inequality, Theorem 22.10.5, whenever $x, x^{\prime} \in B\left(x_{0}, \boldsymbol{\delta}\right)$ and $y \in B\left(y_{0}, \boldsymbol{\delta}\right)$,

$$
\begin{equation*}
\left\|T(x, y)-T\left(x^{\prime}, y\right)\right\| \leq \frac{1}{2}\left\|x-x^{\prime}\right\| . \tag{22.10.24}
\end{equation*}
$$

Also, it can be assumed $\delta$ is small enough that for some $M$ and all such $(x, y)$,

$$
\begin{equation*}
\left\|D_{1} f\left(x_{0}, y_{0}\right)^{-1}\right\|\left\|D_{2} f(x, y)\right\|<M \tag{22.10.25}
\end{equation*}
$$

Next, consider only $y$ such that $\left\|y-y_{0}\right\|<\eta$ where $\eta$ is so small that

$$
\left\|T\left(x_{0}, y\right)-x_{0}\right\|<\frac{\delta}{3}
$$

Then for such $y$, consider the mapping $T_{y}(x)=T(x, y)$. Thus by Corollary 22.10.6, for each $n \in \mathbb{N}$,

$$
\delta>\frac{2}{3} \delta \geq \frac{\left\|T_{y}\left(x_{0}\right)-x_{0}\right\|}{1-(1 / 2)} \geq\left\|T_{y}^{n}\left(x_{0}\right)-x_{0}\right\|
$$

Then by 22.10 .24 , the sequence of iterations of this map $T_{y}$ converges to a unique fixed point $x(y)$ in the ball $B\left(x_{0}, \delta\right)$. Thus, from the definition of $T, f(x(y), y)=0$. This is the implicitly defined function.

Next we show that this function is Lipschitz continuous. For $y, \hat{y}$ in $B\left(y_{0}, \eta\right)$,

$$
\begin{gathered}
\|T(x, y)-T(x, \hat{y})\|= \\
\left\|D_{1} f\left(x_{0}, y_{0}\right)^{-1} f(x, y)-D_{1} f\left(x_{0}, y_{0}\right)^{-1} f(x, \hat{y})\right\| \leq M\|y-\hat{y}\|
\end{gathered}
$$

thanks to the above estimate 22.10 .25 and the mean value inequality, Theorem 22.10.5. Note how convexity of $B\left(y_{0}, \eta\right)$ which says that the line segment joining $y, \hat{y}$ is contained in $B\left(y_{0}, \eta\right)$ is important to use this theorem. Then from this,

$$
\begin{aligned}
\|x(y)-x(\hat{y})\|= & \|T(x(y), y)-T(x(\hat{y}), \hat{y})\| \leq\|T(x(y), y)-T(x(y), \hat{y})\| \\
+ & \|T(x(y), \hat{y})-T(x(\hat{y}), \hat{y})\| \\
& \leq M\|y-\hat{y}\|+\frac{1}{2}\|x(y)-x(\hat{y})\|
\end{aligned}
$$

Hence,

$$
\begin{equation*}
\|x(y)-x(\hat{y})\| \leq 2 M\|y-\hat{y}\| \tag{22.10.26}
\end{equation*}
$$

Finally consider the claim that this implicitly defined function is $C^{1}$.

$$
\begin{align*}
0= & f(x(y+u), y+u)-f(x(y), y) \\
= & D_{1} f(x(y), y)(x(y+u)-x(y))+D_{2} f(x(y), y) u \\
& +o(x(y+u)-x(y), u) \tag{22.10.27}
\end{align*}
$$

Consider the last term. $o(x(y+u)-x(y), u) /\|u\|$ equals

$$
\left\{\begin{array}{l}
\frac{o(x(y+u)-x(y), u)}{\|(x(y+u)-x(y), u)\|_{X \times Y}} \frac{\max (\|x(y+u)-x(y)\|,\|u\|)}{\|u\|} \text { if }\|(x(y+u)-x(y), u)\|_{X \times Y} \neq 0 \\
0 \text { if }\|(x(y+u)-x(y), u)\|_{X \times Y}=0
\end{array}\right.
$$

Now the Lipschitz condition just established shows that

$$
\frac{\max (\|x(y+u)-x(y)\|,\|u\|)}{\|u\|}
$$

is bounded for nonzero $u$ sufficiently small that $y, y+u \in B\left(y_{0}, \eta\right)$. Therefore,

$$
\lim _{u \rightarrow 0} \frac{o(x(y+u)-x(y), u)}{\|u\|}=0
$$

Then 22.10.27 shows that

$$
0=D_{1} f(x(y), y)(x(y+u)-x(y))+D_{2} f(x(y), y) u+o(u)
$$

Therefore, solving for $x(y+u)-x(y)$, it follows that

$$
\begin{aligned}
x(y+u)-x(y) & =-D_{1} f(x(y), y)^{-1} D_{2} f(x(y), y) u+D_{1} f(x(y), y)^{-1} o(u) \\
& =-D_{1} f(x(y), y)^{-1} D_{2} f(x(y), y) u+o(u)
\end{aligned}
$$

and now, the continuity of the partial derivatives $D_{1} f, D_{2} f$, continuity of the map $A \rightarrow A^{-1}$, along with the continuity of $y \rightarrow x(y)$ shows that $y \rightarrow x(y)$ is $C^{1}$ with derivative equal to $-D_{1} f(x(y), y)^{-1} D_{2} f(x(y), y)$.

It is easy to give a version of this theorem in which the function $f$ also depends on a parameter $\lambda \in \Lambda$, a metric space.

Corollary 22.10.8 Let $X, Y, Z$ be Banach spaces and suppose $U$ is an open set in $X \times Y$. Let $f: U \times \Lambda \rightarrow Z$ satisfy $f(\cdot, \cdot, \lambda)$ is in $C^{1}(U)$ and suppose for each $\lambda$,

$$
\begin{equation*}
f\left(x_{0}, y_{0}, \lambda\right)=0, D_{1} f\left(x_{0}, y_{0}, \lambda\right)^{-1} \in \mathscr{L}(Z, X) . \tag{22.10.28}
\end{equation*}
$$

Also suppose $(x, y) \rightarrow D_{1} f(x, y, \lambda)$ is continuous uniformly in $\lambda$ and $D_{2}(x, y, \lambda)$ is uniformly bounded in $\lambda$ for $(x, y)$ sufficiently close to $\left(x_{0}, y_{0}\right)$. Then there exist positive constants, $\delta, \eta$, such that for every $y \in B\left(y_{0}, \eta\right)$ there exists a unique $x(y, \lambda) \in B\left(x_{0}, \delta\right)$ such that

$$
\begin{equation*}
f(x(y, \lambda), y, \lambda)=0 \tag{22.10.29}
\end{equation*}
$$

Furthermore, the mapping, $y \rightarrow x(y, \lambda)$ is in $C^{1}\left(B\left(y_{0}, \eta\right)\right)$ and $\lambda \rightarrow x(y, \lambda)$ is continuous.
Proof: It is just a repeat of the above proof except you use the uniform contraction principle, Corollary 7.11.4 to get the fixed point.

The next theorem is a very important special case of the implicit function theorem known as the inverse function theorem. Actually one can also obtain the implicit function theorem from the inverse function theorem. It is done this way in [84], [96] and in [6].

Theorem 22.10.9 (inverse function theorem) Let $x_{0} \in U$, an open set in $X$, and let $f: U \rightarrow$ $Y$ where $X, Y$ are finite dimensional normed vector spaces. Suppose

$$
\begin{equation*}
f \text { is } C^{1}(U), \text { and } D f\left(x_{0}\right)^{-1} \in \mathscr{L}(Y, X) \tag{22.10.30}
\end{equation*}
$$

Then there exist open sets $W$, and $V$ such that

$$
\begin{gather*}
x_{0} \in W \subseteq U  \tag{22.10.31}\\
f: W \rightarrow V \text { is one to one and onto, }  \tag{22.10.32}\\
f^{-1} \text { is } C^{1} \tag{22.10.33}
\end{gather*}
$$

Proof: Apply the implicit function theorem to the function

$$
F(x, y) \equiv f(x)-y
$$

where $y_{0} \equiv f\left(x_{0}\right)$. Thus the function $y \rightarrow x(y)$ defined in that theorem is $f^{-1}$. Now let

$$
W \equiv B\left(x_{0}, \delta\right) \cap f^{-1}\left(B\left(y_{0}, \eta\right)\right)
$$

and

$$
V \equiv B\left(y_{0}, \eta\right)
$$

### 22.11 More Derivatives

When you consider a $C^{k}$ function $f$ defined on an open set $U$, you obtain the following

$$
D f(x) \in \mathscr{L}(X, Y), D^{2} f(x) \in \mathscr{L}(X, \mathscr{L}(X, Y)), D^{3} f(x) \in \mathscr{L}(X, \mathscr{L}(X, \mathscr{L}(X, Y)))
$$

and so forth. Thus they can each be considered as a linear transformation with values in some vector space. When you consider the vector spaces, you see that these can also be considered as multilinear functions on $X$ with values in $Y$. Now consider the product of two linear transformations $A(y) B(y) w$, where everything is given to make sense and here $w$ is an appropriate vector. Then if each of these linear transformations can be differentiated, you would do the following simple computation.

$$
\begin{gathered}
(A(y+u) B(y+u)-A(y) B(y))(w) \\
=(A(y+u) B(y+u)-A(y) B(y+u)+A(y) B(y+u)-A(y) B(y))(w) \\
=((D A(y) u+o(u)) B(y+u)+A(y)(D B(y) u+o(u)))(w) \\
=(D A(y)(u) B(y+u)+A(y) D B(y)(u)+o(u))(w) \\
=(D A(y)(u) B(y)+A(y) D B(y)(u)+o(u))(w)
\end{gathered}
$$

Then

$$
u \rightarrow(D A(y)(u) B(y)+A(y) D B(y)(u))(w)
$$

is clearly linear and

$$
(u, w) \rightarrow(D A(y)(u) B(y)+A(y) D B(y)(u))(w)
$$

is bilinear and continuous as a function of $y$. By this we mean that for a fixed choice of $(u, w)$ the resulting $Y$ valued function just described is continuous. Now if each of $A, B, D A, D B$ can be differentiated, you could replace $y$ with $y+\hat{u}$ and do a similar computation to obtain as many differentiations as desired, the $k^{t h}$ differentiation yielding a $k$ linear function. You can do this as long as $A$ and $B$ have derivatives. Now in the case of the implicit function theorem, you have

$$
\begin{equation*}
D x(y)=-D_{1} f(x(y), y)^{-1} D_{2} f(x(y), y) \tag{22.11.34}
\end{equation*}
$$

By Lemma 22.10.4 and the implicit function theorem and the chain rule, this is the situation just discussed. Thus $D^{2} x(y)$ can be obtained. Then the formula for it will only involve $D x$ which is known to be continuous. Thus one can continue in this way finding derivatives till $f$ fails to have them. The inverse map never creates difficulties because it is differentiable of order $m$ for any $m$ thanks to Lemma 22.10.4. Thus one can conclude the following corollary.

Corollary 22.11.1 In the implicit and inverse function theorems, you can replace $C^{1}$ with $C^{k}$ in the statements of the theorems for any $k \in \mathbb{N}$.

### 22.12 Lyapunov Schmidt Procedure

You have $f: X \times \Lambda \rightarrow Y$ where here $X, \Lambda$ are Banach spaces. Suppose $(0,0) \in X \times \Lambda$ and $f(0,0)=0$. Then if $D_{1} f(0,0)^{-1}$ is in $\mathscr{L}(Y, X)$, the implicit function theorem says that there exists $x(\lambda)$ a $C^{p}$ function such that locally $f(x(\lambda), \lambda)=0$. So what if $D_{1} f(0,0)$ fails to be one to one? Sometimes this case is also considered. It may be that $D_{1} f(0,0)$
is one to one on some subspace and other nice things happen. In particular, suppose the following.

Letting $X_{2} \equiv \operatorname{ker} D_{1} f(0,0)$ assume

$$
X=X_{1} \oplus X_{2}, \operatorname{dim}\left(X_{2}\right)<\infty
$$

where $X_{1}$ is a closed subspace. Thus $D_{1} f(0,0)$ is one to one on $X_{1}$. We let

$$
Y_{1}=D_{1} f(0,0)\left(X_{1}\right)
$$

and suppose that $Y=Y_{1} \oplus Y_{2}$ where $\operatorname{dim}\left(Y_{2}\right)<\infty, Y_{1}$ also a closed subspace.

$$
\begin{gathered}
X_{1} \xrightarrow{D_{1} f(0,0)} Y_{1}=D_{1} f(0,0)\left(X_{1}\right), Y_{1} \text { closed }<\infty \\
\quad Y=Y_{1} \oplus Y_{2}, \operatorname{dim}\left(Y_{2}\right)<\infty
\end{gathered}
$$

By the open mapping theorem, $D_{1} f(0,0)^{-1}$ is also continuous.
Let $Q$ be a continuous projection onto $Y_{1}$ which is assumed to exist ${ }^{2}$ so that $(I-Q)$ is a projection onto $Y_{2}$. Then the equation $f(x(\lambda), \lambda)=0$ can be written as the pair

$$
\begin{aligned}
Q f(x, \lambda) & =0 \\
(I-Q) f(x, \lambda) & =0
\end{aligned}
$$

Consider the top. For $x=x_{1}+x_{2}$ where $x_{i} \in X_{i}$, this is

$$
Q f\left(x_{1}+x_{2}, \lambda\right)=0
$$

Then if $g\left(x_{1}, x_{2}, \lambda\right)=Q f\left(x_{1}+x_{2}, \lambda\right)$, one has $g: X_{1} \times X_{2} \times \Lambda \rightarrow Y_{1}$

$$
D_{1} g\left(x_{1}, x_{2}, \lambda\right) h=D_{1} Q f\left(x_{1}+x_{2}, \lambda\right) h, h \in X_{1}
$$

Thus $D_{1} g(0,0,0)^{-1}$ is continuous by the open mapping theorem $\left(D_{1} f(0,0)\right.$ is one to one on $X_{1}$ ), and by the implicit function theorem, there is a solution to

$$
Q f\left(x_{1}+x_{2}, \lambda\right)=0
$$

for $x_{1}=x_{1}\left(x_{2}, \lambda\right)$. (Note how it is important that $X_{1}$ and $Y_{1}$ be Banach spaces.) Then the other equation yields

$$
(I-Q) f\left(x_{1}\left(x_{2}, \lambda\right)+x_{2}, \lambda\right)=0
$$

and so for fixed $\lambda$, this is a finite set of equations of a variable in a finite dimensional space.
This depends on being able to write $X=X_{1} \oplus X_{2}$ where $X_{1}$ is closed, $X_{2}=\operatorname{ker} D_{1} f(0,0)$, a similar situation for $Y=Y_{1} \oplus Y_{2}$. So when does this happen? Are there conditions on $D_{1} f(0,0)$ which will cause it to occur?

There are such conditions. For example, $D_{1} f(0,0)$ could be a Fredholm operator defined in Definition 17.6.7. The following are some easy examples in which all that nonsense about things being finite dimensional and part of a direct sum does not need to be considered.

[^21]Example 22.12.1 Say $X=\mathbb{R}^{2}$ and $\Lambda=\mathbb{R}$. Let $f(x, y, \lambda)=x+x y+y^{2}+\lambda$. Then

$$
D_{1} f(0,0,0)=(1,0)
$$

this $1 \times 2$ matrix mapping $\mathbb{R}^{2}$ to $\mathbb{R}$. Thus $X_{2}=(0, \alpha)^{T}: \alpha \in \mathbb{R}$ and $X_{1}=(\alpha, 0)^{T}: \alpha \in \mathbb{R}$. In this case, $Y_{1}=\mathbb{R}$ and so $Q=I$. Thus the above reduces to the single equation

$$
f((\alpha, 0)+(0, \beta), \lambda)=0
$$

and so since $D_{1} f(0,0,0)$ is one to one, $x_{1}=(\alpha, 0)=x_{1}((0, \beta), \lambda)$. Of course this is completely obvious because if you consider $f$ in the natural way as a function of three variables, then the implicit function theorem immediately gives $x=x(y, \lambda)$ which is essentially the same result. We just write $(\alpha, 0)$ in place of $\alpha$. The first independent variable is a function of the other two.

Example 22.12.2 Here is another easy example. $\mathbf{f}: \mathbb{R}^{2} \times \mathbb{R} \rightarrow \mathbb{R}^{2}$

$$
\mathbf{f}(x, y, \lambda)=\binom{x+x y+y^{2}+\sin (\lambda)}{x+y^{2}-x^{2}+\lambda}
$$

Then

$$
D_{1} \mathbf{f}(x, y, \lambda)=\left(\begin{array}{cc}
1+y & x+2 y \\
1-2 x & 2 y
\end{array}\right)
$$

So

$$
D_{1} \mathbf{f}((0,0), 0)=\left(\begin{array}{ll}
1 & 0 \\
1 & 0
\end{array}\right)
$$

Then

$$
X_{2}=\operatorname{ker} D_{1} \mathbf{f}((0,0), 0)=\left\{\binom{0}{\beta}: \beta \in \mathbb{R}\right\}
$$

and $X_{1}=\left\{\binom{\alpha}{0}: \alpha \in \mathbb{R}\right\}$ and clearly $D_{1} \mathbf{f}((0,0), 0)$ is indeed one to one on $X_{1}$.

$$
D_{1} \mathbf{f}(\mathbf{0}, 0)\left(X_{1}\right)=\left\{\binom{y}{y}: y \in \mathbb{R}\right\}=Y_{1}
$$

In this case, let

$$
Q\binom{\alpha}{\beta}=\binom{\frac{\alpha+\beta}{2}}{\frac{\alpha+\beta}{2}}=\left(\begin{array}{ll}
1 / 2 & 1 / 2 \\
1 / 2 & 1 / 2
\end{array}\right)\binom{\alpha}{\beta}
$$

so $(I-Q)=\left(\begin{array}{cc}1 / 2 & -1 / 2 \\ -1 / 2 & 1 / 2\end{array}\right)$. Thus the equations are

$$
\begin{aligned}
Q \mathbf{f}(\mathbf{x}, \lambda) & =0 \\
(I-Q) \mathbf{f}(\mathbf{x}, \lambda) & =0
\end{aligned}
$$

This reduces to

$$
\left.\left.\begin{array}{rl}
\left(-\frac{1}{2} x^{2}+\frac{1}{2} x y+x+y^{2}+\frac{1}{2} \lambda+\frac{1}{2} \sin \lambda\right. \\
-\frac{1}{2} x^{2}+\frac{1}{2} x y+x+y^{2}+\frac{1}{2} \lambda+\frac{1}{2} \sin \lambda
\end{array}\right)=\binom{0}{0} . \begin{array}{l}
\frac{1}{2} x^{2}+\frac{1}{2} y x-\frac{1}{2} \lambda+\frac{1}{2} \sin \lambda \\
-\frac{1}{2} x^{2}-\frac{1}{2} y x+\frac{1}{2} \lambda-\frac{1}{2} \sin \lambda
\end{array}\right)=\binom{0}{0} .
$$

Note how in both the top and the bottom, there is only one equation and one can solve for $x$ in terms of $y, \lambda$ near $(0,0,0)$ which is what the above general argument shows. Of course you can see this directly using the implicit function theorem. Then can you solve for $y=y(\lambda)$ ? This would involve trying to solve for $y$ as a function of $\lambda$ in the following where $x(y, \lambda)$ comes from the first equations.

$$
\frac{1}{2} x^{2}(y, \lambda)+\frac{1}{2} y x(y, \lambda)-\frac{1}{2} \lambda+\frac{1}{2} \sin \lambda=0
$$

If you can do this, then you would have found $(x, y)$ as a function of $\lambda$ for small $\lambda$.
In this example, in the top equation, at $(0,0,0), x_{y}=0$. Also $x_{\lambda}=-1$ so $x(y, \lambda) \approx-\lambda$ other than higher order terms for small $y, \lambda$. Then in the bottom equation, for all variables very small, you would have $\lambda^{2}+y(-\lambda)-\lambda+\sin (\lambda)=0, y(\lambda)=-1+\frac{\sin (\lambda)}{\lambda}+\lambda$ at least approximately. Thus it seems there is a nonzero solution to the equation $\mathbf{f}(x, y, \lambda)=0$ which is valid for small $\lambda, x, y$, this in addition to the zero solution. Note that for small nonzero $\lambda,-1+\frac{\sin (\lambda)}{\lambda}+\lambda \neq 0$. It equals approximately $\lambda-\frac{\lambda^{2}}{3!}$ for small $\lambda$ from the power series for $\sin$.

In the next example, the same procedure gives a solution to a problem $\mathbf{f}((x, y), \lambda)=\mathbf{0}$ such that for small $\boldsymbol{\lambda},(x, y)$ is a function of $\lambda$ which is nonzero and $\mathbf{f}((0,0), \lambda)=\mathbf{0}$. Thus for small $\lambda$, there are two solutions to the nonlinear system of equations.

Example 22.12.3 Let

$$
\mathbf{f}((x, y), \lambda)=\binom{x+x y+y^{2}+x \sin (\lambda)}{x+y^{2}-x^{2}+x \lambda}
$$

In this case $\mathbf{f}((0,0), \lambda)=\mathbf{0}$ even though $\lambda$ might not be 0 . The Lyapunov Schmidt procedure will be used to show that there are nonzero solutions $x(\boldsymbol{\lambda}), y(\lambda)$ such that

$$
f((x(\lambda), y(\lambda)), \lambda)=0
$$

At origin,

$$
D_{1} \mathbf{f}((0,0), 0)=\left(\begin{array}{ll}
1 & 0 \\
1 & 0
\end{array}\right)
$$

Thus $X_{1}=\operatorname{span}\left(e_{1}\right)$ and $X_{2}=\operatorname{span}\left(e_{2}\right)$. Then $Y_{1}=\operatorname{span}\left(e_{1}+e_{2}\right)$ and $Y_{2}=\operatorname{span}\left(e_{1}-e_{2}\right)$. Also $D_{1} \mathbf{f}((0,0), 0)$ is one to one on $X_{1}$ and its range is $Y_{1}$. Then let

$$
Q\binom{\alpha}{\beta}=\binom{\frac{\alpha+\beta}{2}}{\frac{\alpha+\beta}{2}}=\left(\begin{array}{ll}
1 / 2 & 1 / 2 \\
1 / 2 & 1 / 2
\end{array}\right)\binom{\alpha}{\beta}
$$

$$
(I-Q)=\left(\begin{array}{cc}
1 / 2 & -1 / 2 \\
-1 / 2 & 1 / 2
\end{array}\right)
$$

Then $Q \mathbf{f}=\mathbf{0}$ is yields the equation

$$
x+\frac{1}{2} x \lambda+\frac{1}{2} x \sin \lambda+\frac{1}{2} x y-\frac{1}{2} x^{2}+y^{2}=0
$$

Also $(I-Q) \mathbf{f}=\mathbf{0}$ yields the equation

$$
\frac{1}{2} x \sin \lambda-\frac{1}{2} x \lambda+\frac{1}{2} x y+\frac{1}{2} x^{2}=0
$$

Now consider $x_{y}$ and $x_{\lambda}$ at $(0,0)$ from the first equation. Both of these are easily seen to be 0 . Now consider $x_{y y}$. After some computations, this is seen to be $x_{y y}=-2$. Similarly, $x_{y \lambda}(0,0)=0, x_{\lambda \lambda}(0,0)=0$ also. Thus up to terms of degree 3,

$$
x(y, \lambda)=-y^{2}=\frac{1}{2}(-2) y^{2}
$$

Place this in the bottom equation.

$$
\frac{1}{2} y^{2} \lambda-\frac{1}{2} y^{2} \sin \lambda-\frac{1}{2} y^{3}+\frac{1}{2} y^{4}=0
$$

Now the idea is to find $y=y(\lambda)$, hopefully nonzero. Divide by $y^{2}$ and multiply by 2 .

$$
y^{2}-y+\lambda-\sin \lambda=0
$$

Then for small $\lambda$ this is approximately equal to

$$
y^{2}-y+\frac{\lambda^{3}}{6}=0
$$

Then a solution for $y$ for small $\lambda$ is

$$
y=\frac{1+\sqrt{1-\frac{2}{3} \lambda^{3}}}{2}
$$

Of course there is another solution as well, when you replace the + with a minus sign. This is the one we want because when $\lambda=0$ it reduces to $y=0$. This shows that there exist solutions to the equations $\mathbf{f}((x, y), \boldsymbol{\lambda})=\mathbf{0}$ which for small $\lambda$ are approximately

$$
(x(\lambda), y(\lambda))=\left(-y^{2}, \frac{1-\sqrt{1-\frac{2}{3} \lambda^{3}}}{2}\right)
$$

In terms of $\lambda$ very small,

$$
(x(\lambda), y(\lambda))=\left(\frac{1}{6} \lambda^{3}+\frac{1}{6} \sqrt{3} \sqrt{3-2 \lambda^{3}}-\frac{1}{2}, \frac{1-\sqrt{1-\frac{2}{3} \lambda^{3}}}{2}\right)
$$

Using a power series in $\lambda$ to approximate these functions, this reduces to

$$
(x(\lambda), y(\lambda))=\left(-\frac{1}{36} \lambda^{6}, \frac{1}{6} \lambda^{3}+\frac{1}{36} \lambda^{6}+\frac{1}{108} \lambda^{9}\right)
$$

where higher order terms are neglected. Thus there exist other solutions than the zero solution even though $\lambda$ may be nonzero. Note that in this example, $\mathbf{f}((0,0), \lambda)=0$.

### 22.13 Analytic Functions

In calculus, there was a difference between functions of a real variable and functions of a complex variable. In the latter case the existence of a single derivative implied the existence of all derivatives and in fact the Taylor series converged to the function. It is reasonable to ask if a similar phenomenon occurs in the case of complex Banach spaces versus real Banach spaces. This section presents a quick introduction to this topic based on the assumption that the reader has had some exposure to complex analysis. Some of the details involving questions of convergence and term by term differentiation are left to the reader. Also if $h$ maps an open subset of $\mathbb{C}$ to a complex Banach space $X$, and has a first derivative, then the usual Cauchy integral formula,

$$
h(z)=\frac{1}{2 \pi i} \int_{C} \frac{h(w)}{w-z} d w
$$

holds if $C$ is a circle contained, together with its interior, in the open set on which $h$ has a derivative. The integral can be defined as the ordinary Riemann integral using Riemann sums or it can be defined in terms of a Bochner integral. These details are routine and are left to the reader. There are several equivalent definitions of an analytic function defined on a complex Banach space. The following is the one we will use since it resembles the familiar definition encountered in undergraduate complex variable courses.

Definition 22.13.1 Let $X$ and $Y$ be complex Banach spaces and let $U \subseteq X$ be an open set. We say $f: U \rightarrow Y$ is analytic and bounded on $U$ if

$$
z \rightarrow f(x+z h) \text { is analytic for } x \in U, h \in X \text { and }|z| \text { small enough }
$$

exists for all $x \in U$ and also $\|f(x)\| \leq M<\infty$ for all $x \in U$. Here $z \in \mathbb{C}$ and $x, h \in X$.
Let $\mathbf{h} \in X^{l}$ and consider all $\mathbf{z} \in \mathbb{C}^{l}$ with $\|\mathbf{z}\|_{\mathbb{C}^{l}} \equiv \max \left(\left|z_{m}\right|, m=1, \cdots, l\right)$ sufficiently small. Let $C_{1}$ be a sufficiently small circle centered at 0 . Then consider

$$
z_{m} \rightarrow f\left(x+\sum_{m=1}^{l} z_{m} h_{m}\right)
$$

which is analytic on and inside $C_{1}$. Thus using the Cauchy integral formula,

$$
f\left(x+z_{1} h_{1}+\sum_{m=2}^{l} z_{m} h_{m}\right)
$$

$$
\begin{gathered}
=\frac{1}{2 \pi i} \int_{C_{1}} \frac{f\left(x+w_{1} h_{1}+\sum_{m=2}^{l} z_{m} h_{m}\right)}{\left(w_{1}-z_{1}\right)} d w_{1} \\
=\left(\frac{1}{2 \pi i}\right)^{2} \int_{C_{1}} \frac{1}{w_{1}-z_{1}} . \\
\int_{C_{1}} \frac{f\left(x+w_{1} h_{1}+w_{2} h_{2}+\sum_{m=3}^{l} z_{m} h_{m}\right)}{\left(w_{2}-z_{2}\right)} d w_{2} d w_{1}= \\
\left(\frac{1}{2 \pi i}\right)^{l} \int_{C_{1}} \cdots \int_{C_{1}} \frac{f\left(x+w_{1} h_{1}+w_{2} h_{2}+\cdots+w_{l} h_{l}\right)}{\prod_{m=1}^{l}\left(w_{m}-z_{m}\right)} d w_{l} \cdots d w_{1}
\end{gathered}
$$

Consider the case when $l=2$.

$$
\begin{gathered}
\left(\frac{1}{2 \pi i}\right)^{2} \int_{C_{1}} \int_{C_{1}} \frac{f\left(x+w_{1} h_{1}+w_{2} h_{2}\right)}{\left(w_{1}-z_{1}\right)\left(w_{2}-z_{2}\right)} d w_{2} d w_{1}= \\
\left(\frac{1}{2 \pi i}\right)^{2} \int_{C_{1}} \int_{C_{1}} f\left(x+w_{1} h_{1}+w_{2} h_{2}\right) \\
\sum_{k_{2}=0}^{\infty} \frac{z_{2}^{k_{2}}}{w_{2}^{k_{2}+1}} \sum_{k_{1}=0}^{\infty} \frac{z_{1}^{k_{1}}}{w_{1}^{k_{1}+1}} d w_{2} d w_{1}= \\
\left(\frac{1}{2 \pi i}\right)^{2} \sum_{k_{2}=0}^{\infty} \sum_{k_{1}=0}^{\infty}\left(\int_{C_{1}} \int_{C_{1}} \frac{f\left(x+w_{1} h_{1}+w_{2} h_{2}\right)}{w_{2}^{k_{2}+1} w_{1}^{k_{1}+1}} d w_{2} d w_{1}\right) z_{2}^{k_{2}} z_{1}^{k_{1}} .
\end{gathered}
$$

Similarly, for arbitrary $l$, and letting $C$ be any circle centered at 0 with radius smaller than $\frac{\delta}{l}$,

$$
\begin{equation*}
f\left(x+\sum_{m=1}^{l} z_{m} h_{m}\right)=\sum_{k_{l}=0}^{\infty} \cdots \sum_{k_{1}=0}^{\infty} a_{k_{1} \cdots k_{l}}\left(x, h_{l}, \cdots, h_{1}\right) z_{1}^{k_{1}} \cdots z_{l}^{k_{k}} \tag{22.13.35}
\end{equation*}
$$

where

$$
\begin{gather*}
a_{k_{1} \cdots k_{l}}\left(x, h_{l}, \cdots, h_{1}\right) \\
=\left(\frac{1}{2 \pi i}\right)^{l} \int_{C} \cdots \int_{C} \frac{f\left(x+\sum_{m=1}^{l} w_{m} h_{m}\right)}{\prod_{m=1}^{l} w_{m}^{k_{m}+1}} d w_{1} \cdots d w_{l} . \tag{22.13.36}
\end{gather*}
$$

Lemma 22.13.2 Let $l \geq 1$ and let $t_{m} \in \mathbb{C}$. Then if $\mathbf{h} \in X^{l}$, then whenever $|z|$ is small enough, 22.13.35 holds. Also the coefficients satisfy

$$
\begin{equation*}
a_{k_{1} \cdots k_{l}}\left(x, t_{l} h_{l}, \cdots, t_{1} h_{1}\right)=\left(\prod_{m=1}^{l} t_{m}^{k_{m}}\right) a_{k_{1} \cdots k_{l}}\left(x, h_{l}, \cdots, h_{1}\right) \tag{22.13.37}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\|a_{k_{1} \cdots k_{l}}\left(x, h_{l}, \cdots, h_{1}\right)\right\| \leq C \prod_{m=1}^{l}\left\|h_{m}\right\| \tag{22.13.38}
\end{equation*}
$$

for some constant $C$.

Proof: Let $C$ be small enough that the circles $t_{m} C$ for all $m=1, \cdots, l$ and $C$ have radius less than $\frac{\delta}{l}$. First assume $t_{m} \neq 0$ for all $m$. Then

$$
\begin{gathered}
a_{k_{1} \cdots k_{l}}\left(x, t_{l} h_{l}, \cdots, t_{1} h_{1}\right) \\
=\left(\frac{1}{2 \pi i}\right)^{l} \int_{C} \cdots \int_{C} \frac{f\left(x+\sum_{m=1}^{l} w_{m} t_{m} h_{m}\right)}{\prod_{m=1}^{l}\left(w_{m} t_{m}\right)^{k_{m}+1}} . \\
\prod_{m=1}^{l} t_{m}^{k_{m}+1} d w_{1} \cdots d w_{l}
\end{gathered}
$$

Here we just multiplied and divided by $\prod_{m=1}^{l} t_{m}^{k_{m}+1}$.

$$
\begin{gathered}
=\left(\frac{1}{2 \pi i}\right)^{l} \int_{t_{l} C} \cdots \int_{t_{1} C} \frac{f\left(x+\sum_{m=1}^{l} u_{m} h_{m}\right)}{\prod_{m=1}^{l}\left(u_{m}\right)^{k_{m}+1}} d u_{1} \cdots d u_{l} \prod_{m=1}^{l} t_{m}^{k_{m}} \\
=a_{k_{1} \cdots k_{l}}\left(x, h_{l}, \cdots, h_{1}\right) \prod_{m=1}^{l} t_{m}^{k_{m}} .
\end{gathered}
$$

Formally, $w_{i} \in C$ and so $t_{i} w_{i} \equiv u_{i} \in t_{i} C$. Then $t_{i} d w_{i}=d u_{i}$ and so $d w_{i}=\left(1 / t_{i}\right) d u_{i}$. This is why $\prod_{m=1}^{l} t_{m}^{k_{m}+1}$ gets changed to $\prod_{m=1}^{l} t_{m}^{k_{m}}$.

If $t_{m}=0$ for any $m$, the result of both sides in the above equals zero due to the fact that

$$
\int_{C} \frac{1}{w_{m}^{k_{m}+1}} d w_{m}=0
$$

whenever $k_{m} \geq 1$.
To verify 22.13 .38 , use 22.13 .37 to conclude

$$
\begin{gathered}
\left\|a_{k_{1} \cdots k_{l}}\left(x, h_{l} \cdots h_{1}\right)\right\| \leq \\
\left\|a_{k_{1} \cdots k_{l}}\left(x, \frac{h_{l}}{\left\|h_{l}\right\|} \cdots \frac{h_{1}}{\left\|h_{1}\right\|}\right)\right\| \prod_{m=1}^{l}\left\|h_{m}\right\|^{k_{m}}
\end{gathered}
$$

and $\left\|a_{k_{1} \cdots k_{l}}\left(x, \frac{h_{l}}{\left\|h_{l}\right\|} \cdots \frac{h_{1}}{\left\|h_{1}\right\|}\right)\right\|$ is bounded by

$$
\frac{M}{(2 \pi)^{l}} \int_{C} \cdots \int_{C} \frac{1}{\prod_{m=1}^{l}\left|w_{m}\right|^{k_{m}+1}} d\left|w_{1}\right| \cdots d\left|w_{l}\right| \equiv C
$$

Lemma 22.13.3 Suppose

$$
g(x+z h)=g(x)+\sum_{m=1}^{\infty} b_{m}(x, h) z^{m}
$$

for all $z$ small enough. Then

$$
b_{1}\left(x, h_{1}+h_{2}\right)=b_{1}\left(x, h_{1}\right)+b_{1}\left(x, h_{2}\right) .
$$

Proof: Recall that

$$
f\left(x+\sum_{m=1}^{l} z_{m} h_{m}\right)=\sum_{k_{l}=0}^{\infty} \cdots \sum_{k_{1}=0}^{\infty} a_{k_{1} \cdots k_{l}}\left(x, h_{l}, \cdots, h_{1}\right) z_{1}^{k_{1}} \cdots z_{l}^{k_{k}}
$$

and so one can write the following where $g_{n m}$ is defined in the following expression.

$$
g\left(x+z_{1} h_{1}+z_{2} h_{2}\right)=\sum_{m=0}^{\infty} \sum_{n=0}^{\infty} g_{m n}\left(x, h_{1}, h_{2}\right) z_{1}^{m} z_{2}^{n}
$$

Thus,

$$
\begin{gathered}
g\left(x+z_{1} h_{1}\right)=\sum_{m=0}^{\infty} g_{m 0}\left(x, h_{1}, h_{2}\right) z_{1}^{m}=g(x)+\sum_{m=1}^{\infty} b_{m}(x, h) z_{1}^{m}, \\
g\left(x+z_{2} h_{2}\right)=\sum_{n=0}^{\infty} g_{0 n}\left(x, h_{1}, h_{2}\right) z_{2}^{n}=g(x)+\sum_{n=1}^{\infty} b_{n}(x, h) z_{2}^{n}
\end{gathered}
$$

which implies

$$
g_{m 0}\left(x, h_{1}, h_{2}\right)=b_{m}\left(x, h_{1}\right), g_{0 n}\left(x, h_{1}, h_{2}\right)=b_{n}\left(x, h_{2}\right)
$$

Now let $z_{1}=z_{2}=z$. Then

$$
\begin{gathered}
g\left(x+z\left(h_{1}+h_{2}\right)\right)=g(x)+\sum_{n=0}^{\infty} b_{n}\left(x, h_{1}+h_{2}\right) z^{n} \\
=g(x)+z\left(g_{10}\left(x, h_{1}, h_{2}\right)+g_{01}\left(x, h_{1}, h_{2}\right)\right)+\text { higher order terms in } z .
\end{gathered}
$$

Therefore,

$$
\begin{aligned}
b_{1}\left(x, h_{1}+h_{2}\right) & =g_{10}\left(x, h_{1}, h_{2}\right)+g_{01}\left(x, h_{1} h_{2}\right) \\
& =b_{1}\left(x, h_{1}\right)+b_{1}\left(x, h_{2}\right)
\end{aligned}
$$

Lemma 22.13.4 Suppose $a\left(x, h_{l}, \cdots, h_{1}\right)$ is multilinear, $\left(h_{i} \rightarrow a\left(x, h_{l}, \cdots, h_{1}\right)\right.$ is linear $)$,

$$
\left\|a\left(x, h_{l}, \cdots, h_{1}\right)\right\| \leq C \prod_{m=1}^{l}\left\|h_{m}\right\|
$$

and

$$
\begin{gathered}
D^{l-1} f\left(x+h_{l}\right)\left(h_{l-1}\right) \cdots\left(h_{1}\right)-D^{l-1} f(x)\left(h_{l-1}\right) \cdots\left(h_{1}\right) \\
-a\left(x, h_{l}, \cdots, h_{1}\right)=o\left(\left\|h_{l}\right\|\right)
\end{gathered}
$$

Then $D^{l} f(x)$ exists and

$$
D^{l} f(x)\left(h_{l}\right)\left(h_{l-1}\right) \cdots\left(h_{1}\right)=a\left(x, h_{l}, \cdots, h_{1}\right) .
$$

Proof: If $l=1$, the conclusion is obvious and is nothing more than the definition of the derivative.

$$
f(x+h)-f(x)-a(x, h)=o(\|h\|)
$$

and so from the definition of the derivative, $a(x, h)=D f(x) h$.
Next let $n=2$. By assumption,

$$
D f(x+h)\left(h_{1}\right)-D f(x)\left(h_{1}\right)-a\left(x, h, h_{1}\right)=o(\|h\|) .
$$

Let $L(x)$ be defined by

$$
L(x)(h)\left(h_{1}\right) \equiv a\left(x, h, h_{1}\right)
$$

Then $L(x) \in \mathscr{L}(U, \mathscr{L}(X, Y))$ because

$$
\|L(x)\| \equiv \sup _{\|h\| \leq 1}\|L(x)(h)\| \equiv \sup _{\|h\| \leq 1\left\|h_{1}\right\| \leq 1} \sup _{\|}\left\|L(x)(h)\left(h_{1}\right)\right\| \leq C .
$$

Also

$$
\begin{gathered}
\|D f(x+h)-D f(x)-L(x) h\| \\
\equiv \sup _{\left\|h_{1}\right\| \leq 1}\left\|D f(x+h)\left(h_{1}\right)-D f(x)\left(h_{1}\right)-L(x)(h)\left(h_{1}\right)\right\| \\
=\sup _{\left\|h_{1}\right\| \leq 1}\left\|D f(x+h)\left(h_{1}\right)-D f(x)\left(h_{1}\right)-a\left(x, h, h_{1}\right)\right\|=o(\|h\|)
\end{gathered}
$$

and so $L(x)=D^{2} f(x)$. Continuing in this way, we verify the conclusion of the lemma.
Lemma 22.13.5 If $f$ is analytic on $U$, then $f \in C^{\infty}(U)$. Also
Proof: By Lemma 22.13.3 applied to $g=f$ and Lemma 22.13.2, $D f(x)$ exists and

$$
D f(x)(h)=a_{1}(x, h)
$$

These lemmas implied that $h \rightarrow a_{1}(x, h)$ was linear. Suppose $D^{l-1} f(x)$ exists for $l \geq 2$.

$$
f\left(x+\sum_{m=1}^{l} z_{m} h_{m}\right)=\sum_{n_{l}=0}^{\infty} \cdots \sum_{n_{1}=0}^{\infty} a_{n_{1} \cdots n_{l}}\left(x, h_{l}, \cdots, h_{1}\right) z_{1}^{n_{1}} \cdots z_{l}^{n_{l}}
$$

Differentiate with respect to $z_{1}, \cdots, z_{l-1}$ to obtain

$$
\begin{gathered}
D^{l-1} f\left(x+\sum_{m=1}^{l-1} z_{m} h_{m}+z_{l} h_{l}\right)\left(h_{l-1}\right) \cdots\left(h_{1}\right)= \\
\sum_{n_{l}=0}^{\infty} \sum_{n_{l-1}=1}^{\infty} \cdots \sum_{n_{1}=1}^{\infty} a_{n l n_{l-1} \cdots n_{1}}\left(x, h_{1} \cdots h_{l}\right)\left(\prod_{m=1}^{l-1} n_{m}\right) z_{1}^{n_{1}-1} \cdots z_{l-1}^{n_{l-1}-1} z_{l}^{n_{l}} .
\end{gathered}
$$

Take $z_{i}=0$ for $i=1, \cdots, l-1$. Then

$$
\begin{equation*}
D^{l-1} f\left(x+z_{l} h_{l}\right)\left(h_{l-1}\right) \cdots\left(h_{1}\right)=\sum_{n_{l}=0}^{\infty} a_{n_{l} 1 \cdots 1}\left(x, h_{l}, \cdots, h_{1}\right) z_{l}^{n_{l}} . \tag{22.13.39}
\end{equation*}
$$

Now we apply Lemma 22.13.3 to the function

$$
z_{l} \rightarrow D^{l-1} f\left(x+z_{l} h_{l}\right)\left(h_{l-1}\right) \cdots\left(h_{1}\right)
$$

and conclude

$$
h_{l} \rightarrow a_{1 \cdots 1}\left(x, h_{l}, \cdots, h_{1}\right)
$$

is linear. This involved taking $n_{l}=1$ to get $a_{1 \cdots 1}\left(x, h_{l}, \cdots, h_{1}\right)$. Thus from 22.13.39,

$$
\begin{gather*}
D^{l-1} f\left(x+z_{l} h_{l}\right)\left(h_{l-1}\right) \cdots\left(h_{1}\right)-D^{l-1} f(x)\left(h_{l-1}\right) \cdots\left(h_{1}\right) \\
=a_{1 \cdots 1}\left(x, h_{l}, \cdots, h_{1}\right) z_{l}+o\left(z_{l} h_{l}\right) . \tag{22.13.40}
\end{gather*}
$$

From this equation, it follows that

$$
\begin{gathered}
a_{1 \cdots 1}\left(x, h_{l} \cdots h_{i}+\widehat{h}_{i} \cdots h_{1}\right) z_{l}-a_{1 \cdots 1}\left(x, h_{l} \cdots h_{i} \cdots h_{1}\right) z_{l} \\
-a_{1 \cdots 1}\left(x, h_{l} \cdots \widehat{h}_{i} \cdots h_{1}\right) z_{l}=o\left(z_{l} h_{l}\right)
\end{gathered}
$$

because for each $z_{l}$, the left side of 22.13 .40 is linear in $h_{i}$ for each $i \leq l-1$. Dividing both sides of the above by $z_{l}$ and then letting $z_{l} \rightarrow 0$, we see that $a_{n_{l} 1 \cdots 1}$ is linear in each of the $h_{i}$. Denoting $z_{l} h_{l}$ by $h_{l}$,

$$
\begin{gathered}
D^{l-1} f\left(x+h_{l}\right)\left(h_{l-1}\right) \cdots\left(h_{1}\right)-D^{l-1} f(x)\left(h_{l-1}\right) \cdots\left(h_{1}\right) \\
=a_{1 \cdots 1}\left(x, h_{l}, \cdots, h_{1}\right)+o\left(\left\|h_{l}\right\|\right)
\end{gathered}
$$

and so by Lemma 22.13.4, $D^{l} f(x)$ exists and

$$
D^{l} f(x)\left(h_{l}\right) \cdots\left(h_{1}\right)=a_{1 \cdots 1}\left(x, h_{l}, \cdots, h_{1}\right)
$$

With these lemmas, the main result can be established. This is the generalization of the well known result for analytic functions.

Theorem 22.13.6 Let $X$ and $Y$ be two complex Banach spaces and let $U$ be an open set in $X$. Then $f: U \rightarrow Y$ is analytic on $U$ if and only if $D f(x)$ exists for each $x \in U$ and in this case, $f \in C^{\infty}(U)$, and if $h \in X$, then whenever $z$ is small enough,

$$
f(x+z h)=f(x)+\sum_{n=1}^{\infty} \frac{D^{n} f(x) h^{n} z^{n}}{n!} .
$$

Proof: We know

$$
f(x+z h)=f(x)+\sum_{n=1}^{\infty} a_{n}(x, h) z^{n} .
$$

Differentiating, we obtain

$$
D^{k} f(x+z h) h^{k}=k!a_{k}(x, h)+\sum_{n=k+1}^{\infty} n(n-1) \cdots(n-k+1) z^{n-k}
$$

Letting $z=0$ this shows

$$
D^{k} f(x) h^{k}=k!a_{k}(x, h)
$$

and this proves half the theorem.
Conversely, if $D f(x)$ exists on $U$, it is clear that $f$ is analytic on some ball, $B(x, r) \subseteq$ $U, z \rightarrow f(y+z h)$ is analytic for $y \in B(x, r)$ and small enough $z$. Therefore the formula involving the series follows.

### 22.14 Ordinary Differential Equations

In this section we give an application to ordinary differential equations. To begin with, here are two Banach spaces which will be of use. Let $Z$ be a complex Banach space and let $X$ be the space of functions mapping $\overline{B(0,1)} \equiv D_{1}$ to $Z$ such that the functions are continuous on $D_{1}$ and analytic on $B_{1} \equiv B(0,1)$, the derivative is the restriction to $B_{1}$ of a continuous function defined on $D_{1}$, and the function equals 0 at 0 .

$$
X \equiv\left\{\phi \in C\left(D_{1}, X\right): \phi(0)=0\right\}
$$

The norm on $X$ will be

$$
\|\phi\|_{X} \equiv\|\phi\|_{\infty}+\left\|\phi^{\prime}\right\|_{\infty}
$$

where

$$
\|\phi\|_{\infty} \equiv \sup \left\{\|\phi(t)\|_{Z}: t \in B_{1}\right\}
$$

(Note that for a function continuous on $D_{1}$ it does not matter in the above definition of $\|\cdot\|_{\infty}$ whether we use $B_{1}$ or $D_{1}$ in the definition.) We define $Y$ to be the space of continuous functions which are defined on $D_{1}$ having values in $Z$ which are also analytic on $B_{1}$. The norm on $Y$ is defined as

$$
\|\phi\|_{\infty} \equiv\|\phi\|_{Y} .
$$

Note that $B_{1}$ is in $\mathbb{C}$.
Lemma 22.14.1 The spaces $X$ and $Y$ with the given norms are Banach spaces and if $L$ : $X \rightarrow Y$ is defined as $L \phi(t)=\phi^{\prime}(t)$ for all $t \in B_{1}$, then $L$ is one to one, onto and continuous.

Proof: It is clear that $X$ and $Y$ are both normed linear spaces. It remains to show they are Banach spaces. Suppose $\left\{\phi_{n}\right\}$ is a Cauchy sequence in $X$. Then $\phi_{n} \rightarrow \phi$ uniformly and $\phi_{n}^{\prime} \rightarrow \psi$ uniformly where $\psi$ and $\phi$ are continuous on $D_{1}$. We need to verify that $\psi=\phi^{\prime}$ on $B_{1}$. Letting $C_{1}$ be the unit circle, the Cauchy integral formula implies for $t \in B_{1}$,

$$
\phi(t)=\lim _{n \rightarrow \infty} \phi_{n}(t)=\lim _{n \rightarrow \infty} \frac{1}{2 \pi i} \int_{C_{1}} \frac{\phi_{n}(w)}{w-t} d w=\frac{1}{2 \pi i} \int_{C_{1}} \frac{\phi(w)}{w-t} d w
$$

which shows $\phi^{\prime}(t)$ exists on $B_{1}$. Also for $t \in B_{1}$,

$$
\begin{aligned}
\psi(t)= & \lim _{n \rightarrow \infty} \phi_{n}^{\prime}(t)=\lim _{n \rightarrow \infty} \frac{1}{2 \pi i} \int_{C_{1}} \frac{\phi_{n}(w)}{(w-t)^{2}} d w \\
& =\frac{1}{2 \pi i} \int_{C_{1}} \frac{\phi(w)}{(w-t)^{2}} d w=\phi^{\prime}(t)
\end{aligned}
$$

This shows $X$ is a Banach space. A similar argument using the Cauchy integral theorem shows $Y$ is a Banach space also. It is obvious that $L$ is continuous. It remains to show $L$ is one to one and onto.

Let $\phi \in Y$. We need to show $\phi=L \psi$ for some $\psi \in X$. Let

$$
\psi(t) \equiv \int_{\Gamma} \phi(w) d w
$$

where $\Gamma$ is any piecewise smooth curve from 0 to $t$. By the Cauchy integral theorem, this definition is well defined and it is clear that $\psi(0)=0, \psi^{\prime}(t)=\phi(t)$, and $\psi$ is continuous on $D_{1}$. This shows $L$ is onto.

It only remains to show $L$ is one to one. Suppose $L \phi=0$. Since $\phi(0)=0$,

$$
\phi(t)=\int_{0}^{1} \phi^{\prime}(t s) t d s=0
$$

if $t \neq 0$. But $\phi(0)$ is given to equal zero. Thus $L$ is one to one as claimed.
Theorem 22.14.2 Let $\Lambda$ and $Z$ be complex Banach spaces and let $W$ be an open subset of $\mathbb{C} \times Z \times \Lambda$ containing $\left(0, y_{0}, \lambda\right)$. Also let $f: W \rightarrow Z$ be analytic. Then there exists a unique $y=y\left(y_{0}, \lambda\right)$ solving

$$
\begin{equation*}
y^{\prime}=f(t, y, \lambda), y(0)=y_{0} \tag{22.14.41}
\end{equation*}
$$

valid for $t \in D_{\alpha} \equiv \overline{B(0,|\alpha|)}$ where $\alpha=\alpha\left(y_{0}, \lambda\right)$. Furthermore, the map

$$
\left(t, y_{0}, \lambda\right) \rightarrow y\left(y_{0}, \lambda\right)(t)
$$

is analytic.
Proof: Let $\alpha s=t$ and define $\phi(s) \equiv y(t)-\underline{y_{0}}$. Then $y$ is a solution to 22.14.41 for $t \in D_{\alpha}$ if and only if $\phi$ is a solution for $s \in D_{1} \equiv \overline{B(0,1)}$ to the equations

$$
\phi^{\prime}(s)=\alpha f\left(\alpha s, \phi(s)+y_{0}, \lambda\right), \phi(0)=0 .
$$

Let $X, Y$, and $L$ be given above and define

$$
\begin{gathered}
\widetilde{W} \equiv\left\{\left(\alpha, \widehat{y_{0}}, \mu, \phi\right) \in \mathbb{C} \times Z \times \Lambda \times X:\right. \\
\text { for } \left.s \in D_{1},\left(s \alpha, \widehat{y_{0}}+\phi(s), \mu\right) \in W\right\} .
\end{gathered}
$$

For a given $\left(\alpha, \widehat{y_{0}}, \mu, \phi\right) \in \widetilde{W}$,

$$
\left\{\left(s \alpha, \widehat{y_{0}}+\phi(s), \mu\right): s \in D_{1}\right\}
$$

is a compact subset of $W$. This is because you have $s \rightarrow\left(\alpha, \widehat{y_{0}}+\phi(s), \mu\right)$ is the continuous image of a compact set which is assumed to be in $W$. Consequently, the distance from this set to $W^{C}$ is positive and so if $\left(\beta, y_{0}, \lambda, \psi\right)$ is sufficiently close to $\left(\alpha, \widehat{y_{0}}, \mu, \phi\right)$ in $\mathbb{C} \times Z \times$ $\Lambda \times X$ it follows $\left(\beta, y_{0}, \lambda, \psi\right)$ is also in $\widetilde{W}$. This shows $\widetilde{W}$ is an open subset of $\mathbb{C} \times Z \times \Lambda \times X$.

Now define $F: \widetilde{W} \rightarrow Y$ (Recall that $Y$ was a space of functions.) by

$$
F\left(\alpha, \widehat{y_{0}}, \mu, \phi\right)(s) \equiv L \phi(s)-\alpha f\left(\alpha s, \phi(s)+\widehat{y_{0}}, \mu\right)
$$

Then

$$
F\left(0, y_{0}, \lambda, 0\right)=L \phi=0
$$

and $F$ is analytic in $\widetilde{W}$. Also

$$
D_{4} F\left(0, y_{0}, \lambda, 0\right) \psi=L \psi=\psi^{\prime}
$$

and so $D_{4} F\left(0, y_{0}, \lambda, 0\right) \in \mathscr{L}(X, Y)$, is one to one, onto and continuous by Lemma 22.14.1.
By the open mapping theorem, its inverse is also continuous. Therefore, the conditions of the implicit function theorem are satisfied and so there exists $r>0$ such that if

$$
|\alpha|+\|\mu-\lambda\|+\left\|\widehat{y_{0}}-y_{0}\right\|<r
$$

then there exists a unique $\phi \in X$ such that

$$
F\left(\alpha, \widehat{y_{0}}, \mu, \phi\right)=0
$$

and $\phi$ is an analytic function of $\left(\alpha, \widehat{y_{0}}, \mu\right)$. Fixing $0<\alpha<r$, it follows

$$
\left(\widehat{y_{0}}, \mu\right) \rightarrow y\left(\widehat{y_{0}}, \mu\right)
$$

is analytic on an open subset of $Z \times \Lambda$. Also $t \rightarrow y\left(\widehat{y_{0}}, \mu\right)(t)$ is an analytic function because of the definition of $y$ in terms of $\phi, \phi(s) \equiv y(t)-y_{0}$. It follows that for $t \in B(0,|\alpha|)$,

$$
\left(\widehat{y_{0}}, \mu\right) \rightarrow y\left(\widehat{y_{0}}, \mu\right)(t) \text { and } t \rightarrow y\left(\widehat{y_{0}}, \mu\right)(t)
$$

are both analytic.

### 22.15 Exercises

1. Suppose $L \in \mathscr{L}(X, Y)$ where $X$ and $Y$ are two finite dimensional normed vector spaces and suppose $L$ is one to one. Show there exists $r>0$ such that for all $\mathbf{x} \in X$,

$$
\|L \mathbf{x}\| \geq r\|\mathbf{x}\|
$$

Hint: Show that $\|\mathbf{x}\| \equiv\|L \mathbf{x}\|$ is a norm. Now suppose $L \in \mathscr{L}(X, Y)$ is one to one and onto for $X, Y$ Banach spaces. Explain why the same result holds. Hint: Recall open mapping theorem.
2. Suppose $B$ is an open ball in $X$, a Banach space, and $f: B \rightarrow Y$ is differentiable. Suppose also there exists $L \in \mathscr{L}(X, Y)$ such that

$$
\|D f(x)-L\|<k
$$

for all $x \in B$. Show that if $x_{1}, x_{2} \in B$,

$$
\left\|f\left(x_{1}\right)-f\left(x_{2}\right)-L\left(x_{1}-x_{2}\right)\right\| \leq k\left\|x_{1}-x_{2}\right\|
$$

Hint: Consider $T x=f(x)-L x$ and argue $\|D T(x)\|<k$.
3. $\uparrow$ Let $U$ be an open subset of $X, f: U \rightarrow Y$ where $X, Y$ are finite dimensional normed linear spaces and suppose $f \in C^{1}(U)$ and $D f\left(x_{0}\right)$ is one to one. Then show $f$ is one to one near $x_{0}$. Hint: Show using the assumption that $f$ is $C^{1}$ that there exists $\delta>0$ such that if

$$
x_{1}, x_{2} \in B\left(x_{0}, \delta\right),
$$

then

$$
\begin{equation*}
\left|f\left(x_{1}\right)-f\left(x_{2}\right)-D f\left(x_{0}\right)\left(x_{1}-x_{2}\right)\right| \leq \frac{r}{2}\left|x_{1}-x_{2}\right| \tag{22.15.42}
\end{equation*}
$$

then use Problem 1. In case $X, Y$ are Banach spaces, assume $D f\left(x_{0}\right)$ is one to one and onto.
4. Suppose $U \subseteq X$ is an open subset of $X$ a Banach space and that $f: U \rightarrow Y$ is differentiable at $x_{0} \in U$ such that $D f\left(x_{0}\right)$ is one to one and onto from $X$ to $Y$. $\left(D f\left(x_{0}\right)^{-1} \in \mathscr{L}(Y, X)\right)$ Then show that $f(x) \neq f\left(x_{0}\right)$ for all $x$ sufficiently near but not equal to $x_{0}$. In this case, you only know the derivative exists at $x_{0}$.
5. Suppose $M \in \mathscr{L}(X, Y)$ where $X$ and $Y$ are finite dimensional linear spaces and suppose $M$ is onto. Show there exists $L \in \mathscr{L}(Y, X)$ such that

$$
L M \mathbf{x}=P \mathbf{x}
$$

where $P \in \mathscr{L}(X, X)$, and $P^{2}=P$. Also show $L$ is one to one and onto from $X_{1}$ to $Y$. Hint: Let $\left\{\mathbf{y}_{1} \cdots \mathbf{y}_{n}\right\}$ be a basis of $Y$ and let $M \mathbf{x}_{i}=\mathbf{y}_{i}$. Then define

$$
L \mathbf{y}=\sum_{i=1}^{n} \alpha_{i} \mathbf{x}_{i} \text { where } \mathbf{y}=\sum_{i=1}^{n} \alpha_{i} \mathbf{y}_{i}
$$

Show $\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}$ is a linearly independent set and show you can obtain

$$
\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}, \cdots, \mathbf{x}_{m}\right\}
$$

a basis for $X$ in which $M \mathbf{x}_{j}=\mathbf{0}$ for $j>n$. Then let

$$
P \mathbf{x} \equiv \sum_{i=1}^{n} \alpha_{i} \mathbf{x}_{i}
$$

where

$$
\mathbf{x}=\sum_{i=1}^{m} \alpha_{i} \mathbf{x}_{i}
$$

6. $\uparrow$ Let $\mathbf{f}: U \subseteq X \rightarrow Y$, $\mathbf{f}$ is $C^{1}$, and $D \mathbf{f}(\mathbf{x})$ is onto for each $\mathbf{x} \in U$. Then show $\mathbf{f}$ maps open subsets of $U$ onto open sets in $Y$. Hint: Let $P=L D \mathbf{f}(\mathbf{x})$ as in Problem 5. Argue $L$ maps open sets from $Y$ to open sets of $X_{1} \equiv P X$ and $L^{-1}$ maps open sets from $X_{1}$ to open sets of $Y$. Then $L \mathbf{f}(\mathbf{x}+\mathbf{v})=L \mathbf{f}(\mathbf{x})+L D \mathbf{f}(\mathbf{x}) \mathbf{v}+\mathbf{o}(\mathbf{v})$. Now for $\mathbf{z} \in X_{1}$, let $\mathbf{h}(\mathbf{z})=L \mathbf{f}(\mathbf{x}+\mathbf{z})-L \mathbf{f}(\mathbf{x})$. Then $\mathbf{h}$ is $C^{1}$ on some small open subset of $X_{1}$ containing $\mathbf{0}$ and $D \mathbf{h}(\mathbf{0})=L D \mathbf{f}(\mathbf{x})$ which is seen to be one to one and onto and in $\mathscr{L}\left(X_{1}, X_{1}\right)$. Therefore, if $r$ is small enough, $\mathbf{h}(B(\mathbf{0}, r))$ equals an open set in $X_{1}, V$. This is by the inverse function theorem. Hence $L(\mathbf{f}(\mathbf{x}+B(\mathbf{0}, r))-\mathbf{f}(\mathbf{x}))=V$ and so $\mathbf{f}(\mathbf{x}+B(\mathbf{0}, r))-\mathbf{f}(\mathbf{x})=L^{-1}(V)$, an open set in $Y$.
7. Suppose $U \subseteq \mathbb{R}^{2}$ is an open set and $\mathbf{f}: U \rightarrow \mathbb{R}^{3}$ is $C^{1}$. Suppose $D \mathbf{f}\left(s_{0}, t_{0}\right)$ has rank two and

$$
\mathbf{f}\left(s_{0}, t_{0}\right)=\left(\begin{array}{c}
x_{0} \\
y_{0} \\
z_{0}
\end{array}\right)
$$

Show that for $(s, t)$ near $\left(s_{0}, t_{0}\right)$, the points $\mathbf{f}(s, t)$ may be realized in one of the following forms.

$$
\left\{(x, y, \phi(x, y)):(x, y) \text { near }\left(x_{0}, y_{0}\right)\right\}
$$

$$
\left\{(\phi(y, z), y, z):(y, z) \text { near }\left(y_{0}, z_{0}\right)\right\}
$$

or

$$
\left\{(x, \phi(x, z), z,):(x, z) \text { near }\left(x_{0}, z_{0}\right)\right\} .
$$

This shows that parametrically defined surfaces can be obtained locally in a particularly simple form.
8. Let $f: U \rightarrow Y, D f(x)$ exists for all $x \in U, B\left(x_{0}, \delta\right) \subseteq U$, and there exists $L \in$ $\mathscr{L}(X, Y)$, such that $L^{-1} \in \mathscr{L}(Y, X)$, and for all $x \in B\left(x_{0}, \delta\right)$

$$
\|D f(x)-L\|<\frac{r}{\left\|L^{-1}\right\|}, r<1 .
$$

Show that there exists $\varepsilon>0$ and an open subset of $B\left(x_{0}, \delta\right), V$, such that $f: V \rightarrow$ $B\left(f\left(x_{0}\right), \varepsilon\right)$ is one to one and onto. Also $D f^{-1}(y)$ exists for each $y \in B\left(f\left(x_{0}\right), \varepsilon\right)$ and is given by the formula

$$
D f^{-1}(y)=\left[D f\left(f^{-1}(y)\right)\right]^{-1}
$$

Hint: Let

$$
T_{y}(x) \equiv T(x, y) \equiv x-L^{-1}(f(x)-y)
$$

for $\left|y-f\left(x_{0}\right)\right|<\frac{(1-r) \delta}{2\left\|L^{-1}\right\|}$, consider $\left\{T_{y}^{n}\left(x_{0}\right)\right\}$. This is a version of the inverse function theorem for $f$ only differentiable, not $C^{1}$.
9. Denote by $C([0, T], X)$ the space of functions which are continuous having values in $X$ and define a norm on this linear space as follows.

$$
\|f\|_{\lambda} \equiv \max \left\{|f(t)| e^{\lambda t}: t \in[0, T]\right\}
$$

Show for each $\lambda \in \mathbb{R}$, this is a norm and that $C([0, T] ; X)$ is a complete normed linear space with this norm.
10. $\uparrow$ Let $f:[0, T] \times X \rightarrow X$ be continuous and suppose $f$ satisfies a Lipschitz condition,

$$
|f(t, x)-f(t, y)| \leq K|x-y|
$$

and let $x_{0} \in X$. Show there exists a unique solution to the Cauchy problem,

$$
x^{\prime}=f(t, x), x(0)=x_{0}
$$

for $t \in[0, T]$. Hint: Consider the map

$$
G: C([0, T] ; X) \rightarrow C([0, T] ; X)
$$

defined by

$$
G x(t) \equiv x_{0}+\int_{0}^{t} f(s, x(s)) d s
$$

where the integral is defined componentwise. Show $G$ is a contraction map for $\|\cdot\|_{\lambda}$ given in Problem 9 for a suitable choice of $\lambda$ and that therefore, it has a unique fixed point in $C([0, T] ; X)$. Next argue, using the fundamental theorem of calculus, that this fixed point is the unique solution to the Cauchy problem.
11. $\uparrow$ Use Theorem 7.11 .5 to give another proof of the above theorem. Hint: Use the same mapping and show that a large power is a contraction map.
12. Suppose you know that $u(t) \leq a+\int_{0}^{t} k(s) u(s) d s$ where $k(s) \geq 0$ and $k \in L^{1}([0, T])$. Show that then $u(t) \leq a \exp \left(\int_{0}^{t} k(s) d s\right)$. This is a version of Gronwall's inequality. Hint: Let $W(t)=\int_{0}^{t} k(s) u(s) d s$. Then explain why $W^{\prime}(t)-k(t) W(t) \leq a k(t)$. Now use the usual technique of an integrating factor you saw in beginning differential equations.
13. $\uparrow$ Use the above Gronwall's inequality to establish a result of continuous dependence on the initial condition and $f$ in the ordinary differential equation of Problem 10.
14. The existence of partial derivatives does not imply continuity as was shown in an example. However, much more can be said than this. Consider

$$
f(x, y)=\left\{\begin{array}{l}
\frac{\left(x^{2}-y^{4}\right)^{2}}{\left(x^{2}+y^{4}\right)^{2}} \text { if }(x, y) \neq(0,0), \\
1 \text { if }(x, y)=(0,0) .
\end{array}\right.
$$

Show the directional derivative of $f$ at $(0,0)$ exists and equals 0 for every direction. The directional derivative in the direction $\left(v_{1}, v_{2}\right)$ is defined as

$$
\lim _{t \rightarrow 0} \frac{f\left(x+t v_{1}, y+t v_{2}\right)-f(x, y)}{t}
$$

Now consider the curve $x^{2}=y^{4}$ and the curve $y=0$ to verify the function fails to be continuous at $(0,0)$.
15. Let

$$
f(x, y)=\left\{\begin{array}{l}
\frac{x^{2} y^{4}}{x^{2}+y^{8}} \text { if }(x, y) \neq(0,0) \\
0 \text { if }(x, y)=(0,0)
\end{array}\right.
$$

Show that this function is not continuous at $(0,0)$ but that it has all directional derivatives at $(0,0)$ and they all equal 0 .
16. Let $X_{i}$ be a normed linear space having norm $\|\cdot\|_{i}$. Then we can make $\prod_{i=1}^{n} X_{i}$ into a normed linear space by defining a norm on $\mathbf{x} \in \prod_{i=1}^{n} X_{i}$ by

$$
\|\mathbf{x}\| \equiv \max \left\{\left\|x_{i}\right\|_{i}: i=1, \cdots, n\right\}
$$

Show this is a norm on $\prod_{i=1}^{n} X_{i}$ as claimed.
17. Suppose $f: U \subseteq X \times Y \rightarrow Z$ and $D_{2} f\left(x_{0}, y_{0}\right)^{-1} \in \mathscr{L}(X, Y)$ exists and $f$ is $C^{1}$ so the conditions of the implicit function theorem are satisfied. Also suppose that all these are complex Banach spaces. Show that then the implicitly defined function $y=y(x)$ is analytic. Thus it has infinitely many derivatives and can be given as a power series as described above.

## Chapter 23

## Degree Theory

This chapter is on the Brouwer degree, a very useful concept with numerous and important applications. The degree can be used to prove some difficult theorems in topology such as the Brouwer fixed point theorem, the Jordan separation theorem, and the invariance of domain theorem. A couple of these big theorems have been presented earlier, but when you have degree theory, they get much easier. Degree theory is also used in bifurcation theory and many other areas in which it is an essential tool. The degree will be developed for $\mathbb{R}^{p}$ first. When this is understood, it is not too difficult to extend to versions of the degree which hold in Banach space. There is more on degree theory in the book by Deimling [38] and much of the presentation here follows this reference. Another more recent book which is really good is [43]. This is a whole book on degree theory.

The original reference for the approach given here, based on analysis, is [62] and dates from 1959. The degree was developed earlier by Brouwer and others using different methods.

To give you an idea what the degree is about, consider a real valued $C^{1}$ function defined on an interval $I$, and let $y \in f(I)$ be such that $f^{\prime}(x) \neq 0$ for all $x \in f^{-1}(y)$. In this case the degree is the sum of the signs of $f^{\prime}(x)$ for $x \in f^{-1}(y)$, written as $d(f, I, y)$.

In the above picture, $d(f, I, y)$ is 0 because there are two places where the sign is 1 and two where it is -1 .

The amazing thing about this is the number you obtain in this simple manner is a specialization of something which is defined for continuous functions and which has nothing to do with differentiability. An outline of the presentation is as follows. First define the degree for smooth functions at regular values and then extend to arbitrary values and finally to continuous functions. The reason this is possible is an integral expression for the degree which is insensitive to homotopy. It is very similar to the winding number of complex analysis. The difference between the two is that with the degree, the integral which ties it all together is taken over the open set while the winding number is taken over the boundary, although proofs of in the case of the winding number sometimes involve Green's theorem which involves an integral over the open set.

In this chapter $\Omega$ will refer to a bounded open set.
Definition 23.0.1 For $\Omega$ a bounded open set, denote by $C(\bar{\Omega})$ the set of functions which
are restrictions of functions in $C_{c}\left(\mathbb{R}^{p}\right)$, equivalently $C\left(\mathbb{R}^{p}\right)$ to $\bar{\Omega}$ and by $C^{m}(\bar{\Omega}), m \leq \infty$ the space of restrictions of functions in $C_{c}^{m}\left(\mathbb{R}^{p}\right)$, equivalently $C^{m}\left(\mathbb{R}^{p}\right)$ to $\bar{\Omega}$. If $f \in C(\bar{\Omega})$ the symbol $f$ will also be used to denote a function defined on $\mathbb{R}^{p}$ equalling $f$ on $\bar{\Omega}$ when convenient. The subscript c indicates that the functions have compact support. The norm in $C(\bar{\Omega})$ is defined as follows.

$$
\|f\|_{\infty, \bar{\Omega}}=\|f\|_{\infty} \equiv \sup \{|f(\mathbf{x})|: \mathbf{x} \in \bar{\Omega}\}
$$

If the functions take values in $\mathbb{R}^{p}$ write $C^{m}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ or $C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ for these functions if there is no differentiability assumed. The norm on $C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ is defined in the same way as above,

$$
\|\mathbf{f}\|_{\infty, \bar{\Omega}}=\|\mathbf{f}\|_{\infty} \equiv \sup \{|\mathbf{f}(\mathbf{x})|: \mathbf{x} \in \bar{\Omega}\}
$$

Of course if $m=\infty$, the notation means that there are infinitely many derivatives. Also, $C\left(\Omega ; \mathbb{R}^{p}\right)$ consists of functions which are continuous on $\Omega$ that have values in $\mathbb{R}^{p}$ and $C^{m}\left(\Omega ; \mathbb{R}^{p}\right)$ denotes the functions which have $m$ continuous derivatives defined on $\Omega$. Also let $\mathscr{P}$ consist of functions $\mathbf{f}(\mathbf{x})$ such that $f_{k}(\mathbf{x})$ is a polynomial, meaning an element of the algebra of functions generated by $\left\{1, x_{1}, \cdots, x_{p}\right\}$. Thus a typical polynomial is of the form $\sum_{i_{1} \cdots i_{p}} a\left(i_{1} \cdots i_{p}\right) x^{i_{1}} \cdots x^{i_{p}}$ where the $i_{j}$ are nonnegative integers and $a\left(i_{1} \cdots i_{p}\right)$ is a real number.

Some of the theorems are simpler if you base them on the Weierstrass approximation theorem.

Note that, by applying the Tietze extension theorem to the components of the function, one can always extend a function continuous on $\bar{\Omega}$ to all of $\mathbb{R}^{p}$ so there is no loss of generality in simply regarding functions continuous on $\bar{\Omega}$ as restrictions of functions continuous on $\mathbb{R}^{p}$. Next is the idea of a regular value.
Definition 23.0.2 For $W$ an open set in $\mathbb{R}^{p}$ and $\mathbf{g} \in C^{1}\left(W ; \mathbb{R}^{p}\right) \mathbf{y}$ is called a regular value of $\mathbf{g}$ if whenever $\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})$, $\operatorname{det}(D \mathbf{g}(\mathbf{x})) \neq 0$. Note that if $\mathbf{g}^{-1}(\mathbf{y})=\emptyset$, it follows that $\mathbf{y}$ is a regular value from this definition. That is, $\mathbf{y}$ is a regular value if and only if

$$
\mathbf{y} \notin \mathbf{g}(\{\mathbf{x} \in W: \operatorname{det} D \mathbf{g}(\mathbf{x})=0\})
$$

Denote by $S_{\mathbf{g}}$ the set of singular values of $\mathbf{g}$, those $\mathbf{y}$ such that $\operatorname{det}(\operatorname{dg}(\mathbf{x}))=0$ for some $\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})$.

Also, $\partial \Omega$ will often be referred to. It is those points with the property that every open set (or open ball) containing the point contains points not in $\Omega$ and points in $\Omega$. Then the following simple lemma will be used frequently.

Lemma 23.0.3 Define $\partial U$ to be those points $\mathbf{x}$ with the property that for every $r>0$, $B(\mathbf{x}, r)$ contains points of $U$ and points of $U^{C}$. Then for $U$ an open set,

$$
\begin{equation*}
\partial U=\bar{U} \backslash U \tag{23.0.1}
\end{equation*}
$$

Let $C$ be a closed subset of $\mathbb{R}^{p}$ and let $\mathscr{K}$ denote the set of components of $\mathbb{R}^{p} \backslash C$. Then if $K$ is one of these components, it is open and

$$
\partial K \subseteq C
$$

Proof: First consider claim 23.0.1. Let $\mathbf{x} \in \bar{U} \backslash U$. If $B(\mathbf{x}, r)$ contains no points of $U$, then $\mathbf{x} \notin \bar{U}$. If $B(\mathbf{x}, r)$ contains no points of $U^{C}$, then $\mathbf{x} \in U$ and so $\mathbf{x} \notin \bar{U} \backslash U$. Therefore, $\bar{U} \backslash U \subseteq \partial U$. Now let $\mathbf{x} \in \partial U$. If $\mathbf{x} \in U$, then since $U$ is open there is a ball containing $\mathbf{x}$ which is contained in $U$ contrary to $\mathbf{x} \in \partial U$. Therefore, $\mathbf{x} \notin U$. If $\mathbf{x}$ is not a limit point of $U$, then some ball containing $\mathbf{x}$ contains no points of $U$ contrary to $\mathbf{x} \in \partial U$. Therefore, $\mathbf{x} \in \bar{U} \backslash U$ which shows the two sets are equal.

Why is $K$ open for $K$ a component of $\mathbb{R}^{p} \backslash C$ ? This follows from Theorem 7.13.10 and results from open balls being connected. Thus if $k \in K$, letting $B(k, r) \subseteq C^{C}$, it follows $K \cup B(k, r)$ is connected and contained in $C^{C}$ and therefore is contained in $K$ because $K$ is maximal with respect to being connected and contained in $C^{C}$.

Now for $K$ a component of $\mathbb{R}^{p} \backslash C$, why is $\partial K \subseteq C$ ? Let $\mathbf{x} \in \partial K$. If $\mathbf{x} \notin C$, then $\mathbf{x} \in K_{1}$, some component of $\mathbb{R}^{p} \backslash C$. If $K_{1} \neq K$ then $\mathbf{x}$ cannot be a limit point of $K$ and so it cannot be in $\partial K$. Therefore, $K=K_{1}$ but this also is a contradiction because if $\mathbf{x} \in \partial K$ then $\mathbf{x} \notin K$ thanks to 23.0.1.

Note that for an open set $U \subseteq \mathbb{R}^{p}$, and $\mathbf{h}: \bar{U} \rightarrow \mathbb{R}^{p}, \operatorname{dist}(\mathbf{h}(\partial U), \mathbf{y}) \geq \operatorname{dist}(\mathbf{h}(\bar{U}), \mathbf{y})$ because $\bar{U} \supseteq \partial U$.

The following lemma will be nice to keep in mind.
Lemma 23.0.4 $\mathbf{f} \in C\left(\bar{\Omega} \times[a, b] ; \mathbb{R}^{p}\right)$ if and only if $t \rightarrow \mathbf{f}(\cdot, t)$ is in $C\left([a, b] ; C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)\right)$. Also

$$
\|\mathbf{f}\|_{\infty, \bar{\Omega} \times[a, b]}=\max _{t \in[a, b]}\left(\|\mathbf{f}(\cdot, t)\|_{\infty, \bar{\Omega}}\right)
$$

Proof: $\Rightarrow$ By uniform continuity, if $\varepsilon>0$ there is $\delta>0$ such that if $|t-s|<\delta$, then for all $\mathbf{x} \in \bar{\Omega},\|\mathbf{f}(\mathbf{x}, t)-\mathbf{f}(\mathbf{x}, s)\|<\frac{\varepsilon}{2}$. It follows that $\|\mathbf{f}(\cdot, t)-\mathbf{f}(\cdot, s)\|_{\infty} \leq \frac{\varepsilon}{2}<\varepsilon$.
$\Leftarrow$ Say $\left(\mathbf{x}_{n}, t_{n}\right) \rightarrow(\mathbf{x}, t)$. Does it follow that $\mathbf{f}\left(\mathbf{x}_{n}, t_{n}\right) \rightarrow \mathbf{f}(\mathbf{x}, t)$ ?

$$
\begin{aligned}
\left\|\mathbf{f}\left(\mathbf{x}_{n}, t_{n}\right)-\mathbf{f}(\mathbf{x}, t)\right\| & \leq\left\|\mathbf{f}\left(\mathbf{x}_{n}, t_{n}\right)-\mathbf{f}\left(\mathbf{x}_{n}, t\right)\right\|+\left\|\mathbf{f}\left(\mathbf{x}_{n}, t\right)-\mathbf{f}(\mathbf{x}, t)\right\| \\
& \leq\left\|\mathbf{f}\left(\cdot, t_{n}\right)-\mathbf{f}(\cdot, t)\right\|_{\infty}+\left\|\mathbf{f}\left(\mathbf{x}_{n}, t\right)-\mathbf{f}(\mathbf{x}, t)\right\|
\end{aligned}
$$

both terms converge to 0 , the first because $\mathbf{f}$ is continuous into $C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ and the second because $\mathbf{x} \rightarrow \mathbf{f}(\mathbf{x}, t)$ is continuous.

The claim about the norms is next. Let $(\mathbf{x}, t)$ be such that $\|\mathbf{f}\|_{\infty, \bar{\Omega} \times[a, b]}<\|\mathbf{f}(\mathbf{x}, t)\|+\varepsilon$. Then

$$
\|\mathbf{f}\|_{\infty, \bar{\Omega} \times[a, b]}<\|\mathbf{f}(\mathbf{x}, t)\|+\varepsilon \leq \max _{t \in[a, b]}\left(\|\mathbf{f}(\cdot, t)\|_{\infty, \bar{\Omega}}\right)+\varepsilon
$$

and so $\|\mathbf{f}\|_{\infty, \bar{\Omega} \times[a, b]} \leq \max _{t \in[a, b]} \max \left(\|\mathbf{f}(\cdot, t)\|_{\infty, \bar{\Omega}}\right)$ because $\varepsilon$ is arbitrary. However, the same argument works in the other direction. There exists $t$ such that

$$
\|\mathbf{f}(\cdot, t)\|_{\infty, \bar{\Omega}}=\max _{t \in[a, b]}\left(\|\mathbf{f}(\cdot, t)\|_{\infty, \bar{\Omega}}\right)
$$

by compactness of the interval. Then by compactness of $\bar{\Omega}$, there is $\mathbf{x}$ such that $\|\mathbf{f}(\cdot, t)\|_{\infty, \bar{\Omega}}=$ $\|\mathbf{f}(\mathbf{x}, t)\| \leq\|\mathbf{f}\|_{\infty, \bar{\Omega} \times[a, b]}$ and so the two norms are the same.

### 23.1 Sard's Lemma and Approximation

First are easy assertions about approximation of continuous functions with smooth ones.
The following is the Weierstrass approximation theorem. It is Corollary 9.1.5 presented earlier.

Corollary 23.1.1 If $f \in C([a, b] ; X)$ where $X$ is a normed linear space, then there exists $a$ sequence of polynomials which converge uniformly to $f$ on $[a, b]$. The polynomials are of the form

$$
\begin{equation*}
\sum_{k=0}^{m}\binom{m}{k}\left(l^{-1}(t)\right)^{k}\left(1-l^{-1}(t)\right)^{m-k} f\left(l\left(\frac{k}{m}\right)\right) \tag{23.1.2}
\end{equation*}
$$

where $l$ is a linear one to one and onto map from $[0,1]$ to $[a, b]$.
Applying the Weierstrass approximation theorem, Theorem 9.2.9 or Theorem 9.2.5 to the components of a vector valued function yields the following corollary

Theorem 23.1.2 If $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ for $\Omega$ a bounded subset of $\mathbb{R}^{p}$, then for all $\varepsilon>0$, there exists $\mathbf{g} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ such that

$$
\|\mathbf{g}-\mathbf{f}\|_{\infty, \bar{\Omega}}<\varepsilon
$$

Recall Sard's lemma, shown earlier. It is Lemma 13.6.5. I am stating it here for convenience.

Lemma 23.1.3 (Sard) Let $U$ be an open set in $\mathbb{R}^{p}$ and let $\mathbf{h}: U \rightarrow \mathbb{R}^{p}$ be differentiable. Let

$$
S \equiv\{\mathbf{x} \in U: \operatorname{det} D \mathbf{h}(\mathbf{x})=0\}
$$

Then $m_{p}(\mathbf{h}(S))=0$.
First note that if $\mathbf{y} \notin \mathbf{g}(\Omega)$, then we are calling it a regular value because whenever $\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})$ the desired conclusion follows vacuously. Thus, for $\mathbf{g} \in C^{\infty}\left(\bar{\Omega}, \mathbb{R}^{p}\right), \mathbf{y}$ is a regular value if and only if $\mathbf{y} \notin \mathbf{g}(\{\mathbf{x} \in \bar{\Omega}: \operatorname{det} D \mathbf{g}(\mathbf{x})=0\})$.

Observe that any uncountable set in $\mathbb{R}^{p}$ has a limit point. To see this, tile $\mathbb{R}^{p}$ with countably many congruent boxes. One of them has uncountably many points. Now subdivide this into $2^{p}$ congruent boxes. One has uncountably many points. Continue subdividing this way to obtain a limit point as the unique point in the intersection of a nested sequence of compact sets whose diameters converge to 0 .

Lemma 23.1.4 Let $\mathbf{g} \in C^{\infty}\left(\mathbb{R}^{p} ; \mathbb{R}^{p}\right)$ and let $\left\{\mathbf{y}_{i}\right\}_{i=1}^{\infty}$ be points of $\mathbb{R}^{p}$ and let $\eta>0$. Then there exists $\mathbf{e}$ with $\|\mathbf{e}\|<\eta$ and $\mathbf{y}_{i}+\mathbf{e}$ is a regular value for $\mathbf{g}$.

Proof: Let $S=\left\{\mathbf{x} \in \mathbb{R}^{p}: \operatorname{det} D \mathbf{g}(\mathbf{x})=0\right\}$. By Sard's lemma, $\mathbf{g}(S)$ has measure zero. Let $N \equiv \cup_{i=1}^{\infty}\left(\mathbf{g}(S)-\mathbf{y}_{i}\right)$. Thus $N$ has measure 0 . Pick $\mathbf{e} \in B(\mathbf{0}, \eta) \backslash N$. Then for each $i, \mathbf{y}_{i}+\mathbf{e} \notin \mathbf{g}(S)$.

Lemma 23.1.5 Let $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ and let $\left\{\mathbf{y}_{i}\right\}_{i=1}^{\infty}$ be points not in $\mathbf{f}(\partial \Omega)$ and let $\delta>0$. Then there exists $\mathbf{g} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ such that $\|\mathbf{g}-\mathbf{f}\|_{\infty, \bar{\Omega}}<\delta$ and $\mathbf{y}_{i}$ is a regular value for $\mathbf{g}$ for each i. That is, if $\mathbf{g}(\mathbf{x})=\mathbf{y}_{i}$, then $D \mathbf{g}(\mathbf{x})^{-1}$ exists. Also, if $\delta<\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})$ for some $\mathbf{y}$ a regular value of $\mathbf{g} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$, then $\mathbf{g}^{-1}(\mathbf{y})$ is a finite set of points in $\Omega$. Also, if $\mathbf{y}$ is a regular value of $\mathbf{g} \in C^{\infty}\left(\mathbb{R}^{p}, \mathbb{R}^{p}\right)$, then $\mathbf{g}^{-1}(\mathbf{y})$ is countable.

Proof: Pick $\tilde{\mathbf{g}} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right),\|\tilde{\mathbf{g}}-\mathbf{f}\|_{\infty, \bar{\Omega}}<\delta . \mathbf{g} \equiv \tilde{\mathbf{g}}-\mathbf{e}$ where $\mathbf{e}$ is from the above Lemma 23.1.4 and $\eta$ so small that $\|\mathbf{g}-\mathbf{f}\|_{\infty, \bar{\Omega}}<\delta$. Then if $\mathbf{g}(\mathbf{x})=\mathbf{y}_{i}$, you get $\tilde{\mathbf{g}}(\mathbf{x})=\mathbf{y}_{i}+\mathbf{e}$ a regular value of $\tilde{\mathbf{g}}$ and so $\operatorname{det}(D \mathbf{g}(\mathbf{x}))=\operatorname{det}(D \tilde{\mathbf{g}}(\mathbf{x})) \neq 0$ so this shows the first part.

It remains to verify the last claims. Since $\|\mathbf{g}-\mathbf{f}\|_{\bar{\Omega}, \infty}<\delta$, if $\mathbf{x} \in \partial \Omega$, then

$$
\|\mathbf{g}(\mathbf{x})-\mathbf{y}\| \geq\|\mathbf{f}(\mathbf{x})-\mathbf{y}\|-\|\mathbf{f}(\mathbf{x})-\mathbf{g}(\mathbf{x})\| \geq \operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})-\delta>\delta-\delta=0
$$

and so $\mathbf{y} \notin \mathbf{g}(\partial \Omega)$, so if $\mathbf{g}(\mathbf{x})=\mathbf{y}$, then $\mathbf{x} \in \Omega$. If there are infinitely many points in $\mathbf{g}^{-1}(\mathbf{y})$, then there would be a subsequence converging to a point $\mathbf{x} \in \bar{\Omega}$. Thus $\mathbf{g}(\mathbf{x})=\mathbf{y}$ so $\mathbf{x} \notin \partial \Omega$. However, this would violate the inverse function theorem because $\mathbf{g}$ would fail to be one to one on an open ball containing $\mathbf{x}$ and contained in $\Omega$. Therefore, there are only finitely many points in $\mathbf{g}^{-1}(\mathbf{y})$ and at each point, the determinant of the derivative of $\mathbf{g}$ is nonzero. For $\mathbf{y}$ a regular value, $\mathbf{g}^{-1}(\mathbf{y})$ is countable since otherwise, there would be a limit point $\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})$ and $\mathbf{g}$ would fail to be one to one near $\mathbf{x}$ contradicting the inverse function theorem.

Now with this, here is a definition of the degree.
Definition 23.1.6 Let $\Omega$ be a bounded open set in $\mathbb{R}^{p}$ and let $\mathbf{f}: \bar{\Omega} \rightarrow \mathbb{R}^{p}$ be continuous. Let $\mathbf{y} \notin \mathbf{f}(\partial \Omega)$. Then the degree is defined as follows: Let $\mathbf{g}$ be infinitely differentiable, $\|\mathbf{f}-\mathbf{g}\|_{\infty, \bar{\Omega}}<\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})$, and $\mathbf{y}$ is a regular value of $\mathbf{g}$.Then

$$
d(\mathbf{f}, \Omega, \mathbf{y}) \equiv \sum\left\{\operatorname{sgn}(\operatorname{det}(D \mathbf{g}(\mathbf{x}))): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})\right\}
$$

From Lemma 23.1.5 the definition at least makes sense because the sum is finite and such a $\mathbf{g}$ exists. The problem is whether the definition is well defined in the sense that we get the same answer if a different $\mathbf{g}$ is used. Suppose it is shown that the definition is well defined. If $\mathbf{y} \notin \mathbf{f}(\Omega)$, then you could pick $\mathbf{g}$ such that $\|\mathbf{g}-\mathbf{f}\|_{\bar{\Omega}}<\operatorname{dist}(\mathbf{y}, \mathbf{f}(\bar{\Omega}))$. However, this requires that $\mathbf{g}(\bar{\Omega})$ does not contain $\mathbf{y}$ because if $\mathbf{x} \in \bar{\Omega}$, then

$$
\begin{aligned}
\|\mathbf{g}(\mathbf{x})-\mathbf{y}\| & =\|(\mathbf{y}-\mathbf{f}(\mathbf{x}))-(\mathbf{g}(\mathbf{x})-\mathbf{f}(\mathbf{x}))\| \geq\|\mathbf{f}(\mathbf{x})-\mathbf{y}\|-\|\mathbf{g}(\mathbf{x})-\mathbf{f}(\mathbf{x})\| \\
& >\operatorname{dist}(\mathbf{y}, \mathbf{f}(\bar{\Omega}))-\operatorname{dist}(\mathbf{y}, \mathbf{f}(\bar{\Omega}))=0
\end{aligned}
$$

Therefore, $\mathbf{y}$ is a regular value of $\mathbf{g}$ because every point in $\mathbf{g}^{-1}(\mathbf{y})$ is such that the determinant of the derivative at this point is non zero since there are no such points. Thus if $\mathbf{f}^{-1}(\mathbf{y})=\emptyset, d(\mathbf{f}, \Omega, \mathbf{y})=0$.

If $\mathbf{f}(\mathbf{z})=\mathbf{y}$, then there is $\mathbf{g}$ having $\mathbf{y}$ a regular value and $\mathbf{g}(\mathbf{z})=\mathbf{y}$ by the above lemma.
Lemma 23.1.7 Suppose $\mathbf{g}, \hat{\mathbf{g}}$ both satisfy the above definition,

$$
\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})>\delta>\|\mathbf{f}-\mathbf{g}\|_{\infty, \bar{\Omega}}, \operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})>\delta>\|\mathbf{f}-\hat{\mathbf{g}}\|_{\infty, \bar{\Omega}}
$$

Then for $t \in[0,1]$ so does $t \mathbf{g}+(1-t) \hat{\mathbf{g}}$. In particular, $\mathbf{y} \notin(t \mathbf{g}+(1-t) \hat{\mathbf{g}})(\partial \Omega)$. More generally, if

$$
\|\mathbf{h}-\mathbf{f}\|<\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})
$$

then $0<\operatorname{dist}(\mathbf{h}(\partial \Omega), \mathbf{y})$. Also $d(\mathbf{f}-\mathbf{y}, \Omega, \mathbf{0})=d(\mathbf{f}, \Omega, \mathbf{y})$.
Proof: From the triangle inequality, if $t \in[0,1]$,

$$
\|\mathbf{f}-(t \mathbf{g}+(1-t) \hat{\mathbf{g}})\|_{\infty} \leq t\|\mathbf{f}-\mathbf{g}\|_{\infty}+(1-t)\|\mathbf{f}-\hat{\mathbf{g}}\|_{\infty}<t \delta+(1-t) \delta=\delta .
$$

If $\|\mathbf{h}-\mathbf{f}\|_{\infty}<\delta<\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})$, as was just shown for $\mathbf{h} \equiv t \mathbf{g}+(1-t) \hat{\mathbf{g}}$, then if $\mathbf{x} \in \partial \Omega$,

$$
\|\mathbf{y}-\mathbf{h}(\mathbf{x})\| \geq\|\mathbf{y}-\mathbf{f}(\mathbf{x})\|-\|\mathbf{h}(\mathbf{x})-\mathbf{f}(\mathbf{x})\|>\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})-\delta \geq \delta-\delta=0
$$

Now consider the last claim. This follows because $\|\mathbf{g}-\mathbf{f}\|_{\infty}$ small is the same as $\|\mathbf{g}-\mathbf{y}-(\mathbf{f}-\mathbf{y})\|_{\infty}$ being small. They are the same. Also, $(\mathbf{g}-\mathbf{y})^{-1}(\mathbf{0})=\mathbf{g}^{-1}(\mathbf{y})$ and $D \mathbf{g}(\mathbf{x})=D(\mathbf{g}-\mathbf{y})(\mathbf{x})$.

First is an identity. It was Lemma 16.3.1 on Page 429.
Lemma 23.1.8 Let $\mathbf{g}: U \rightarrow \mathbb{R}^{p}$ be $C^{2}$ where $U$ is an open subset of $\mathbb{R}^{p}$. Then

$$
\sum_{j=1}^{p} \operatorname{cof}(D \mathbf{g})_{i j, j}=0
$$

where here $(D \mathbf{g})_{i j} \equiv g_{i, j} \equiv \frac{\partial g_{i}}{\partial x_{j}}$. Also, $\operatorname{cof}(D \mathbf{g})_{i j}=\frac{\partial \operatorname{det}(D \mathbf{g})}{\partial g_{i, j}}$.
Next is an integral representation of $\sum\left\{\operatorname{sgn}(\operatorname{det}(D \mathbf{g}(\mathbf{x}))): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})\right\}$ but first is a little lemma about disjoint sets.

Lemma 23.1.9 Let $K$ be a compact set and $C$ a closed set in $\mathbb{R}^{p}$ such that $K \cap C=\emptyset$. Then

$$
\operatorname{dist}(K, C) \equiv \inf \{\|\mathbf{k}-\mathbf{c}\|: \mathbf{k} \in K, \mathbf{c} \in C\}>0
$$

Proof: Let

$$
d \equiv \inf \{\|\mathbf{k}-\mathbf{c}\|: \mathbf{k} \in K, \mathbf{c} \in C\}
$$

Let $\left\{\mathbf{k}_{i}\right\},\left\{\mathbf{c}_{i}\right\}$ be such that

$$
d+\frac{1}{i}>\left\|\mathbf{k}_{i}-\mathbf{c}_{i}\right\|
$$

Since $K$ is compact, there is a subsequence still denoted by $\left\{\mathbf{k}_{i}\right\}$ such that $\mathbf{k}_{i} \rightarrow \mathbf{k} \in K$. Then also

$$
\left\|\mathbf{c}_{i}-\mathbf{c}_{m}\right\| \leq\left\|\mathbf{c}_{i}-\mathbf{k}_{i}\right\|+\left\|\mathbf{k}_{i}-\mathbf{k}_{m}\right\|+\left\|\mathbf{c}_{m}-\mathbf{k}_{m}\right\|
$$

If $d=0$, then as $m, i \rightarrow \infty$ it follows $\left\|\mathbf{c}_{i}-\mathbf{c}_{m}\right\| \rightarrow 0$ and so $\left\{\mathbf{c}_{i}\right\}$ is a Cauchy sequence which must converge to some $\mathbf{c} \in C$. But then $\|\mathbf{c}-\mathbf{k}\|=\lim _{i \rightarrow \infty}\left\|\mathbf{c}_{i}-\mathbf{k}_{i}\right\|=0$ and so $\mathbf{c}=\mathbf{k} \in C \cap K$, a contradiction to these sets being disjoint.

In particular the distance between a point and a closed set is always positive if the point is not in the closed set. Of course this is obvious even without the above lemma.

Definition 23.1.10 Let $\mathbf{g} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ where $\Omega$ is a bounded open set. Also let $\phi_{\varepsilon}$ be $a$ mollifier.

$$
\phi_{\varepsilon} \in C_{c}^{\infty}(B(\mathbf{0}, \varepsilon)), \phi_{\varepsilon} \geq 0, \int \phi_{\varepsilon} d x=1
$$

The idea is that $\varepsilon$ will converge to 0 to get suitable approximations.
First, here is a technical lemma which will be used to identify the degree with an integral.

Lemma 23.1.11 Let $\mathbf{y} \notin \mathbf{g}(\partial \Omega)$ for $\mathbf{g} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$. Also suppose $\mathbf{y}$ is a regular value of g. Then for all positive $\varepsilon$ small enough,

$$
\int_{\Omega} \phi_{\varepsilon}(\mathbf{g}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{g}(\mathbf{x}) d x=\sum\left\{\operatorname{sgn}(\operatorname{det} D \mathbf{g}(\mathbf{x})): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})\right\}
$$

Proof: First note that the sum is finite from Lemma 23.1.5. It only remains to verify the equation.

I need to show the left side of this equation is constant for $\varepsilon$ small enough and equals the right side. By what was just shown, there are finitely many points, $\left\{\mathbf{x}_{i}\right\}_{i=1}^{m}=\mathbf{g}^{-1}(\mathbf{y})$. By the inverse function theorem, there exist disjoint open sets $U_{i}$ with $\mathbf{x}_{i} \in U_{i}$, such that $\mathbf{g}$ is one to one on $U_{i}$ with $\operatorname{det}(D \mathbf{g}(\mathbf{x}))$ having constant sign on $U_{i}$ and $\mathbf{g}\left(U_{i}\right)$ is an open set containing $\mathbf{y}$. Then let $\varepsilon$ be small enough that $B(\mathbf{y}, \boldsymbol{\varepsilon}) \subseteq \cap_{i=1}^{m} \mathbf{g}\left(U_{i}\right)$. Also, $\mathbf{y} \notin \mathbf{g}\left(\bar{\Omega} \backslash\left(\cup_{i=1}^{n} U_{i}\right)\right)$, a compact set. Let $\varepsilon$ be still smaller, if necessary, so that $B(\mathbf{y}, \boldsymbol{\varepsilon}) \cap \mathbf{g}\left(\bar{\Omega} \backslash\left(\cup_{i=1}^{n} U_{i}\right)\right)=\emptyset$ and let $V_{i} \equiv \mathbf{g}^{-1}(B(\mathbf{y}, \varepsilon)) \cap U_{i}$.

Therefore, for any $\varepsilon$ this small,

$$
\int_{\Omega} \phi_{\varepsilon}(\mathbf{g}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{g}(\mathbf{x}) d x=\sum_{i=1}^{m} \int_{V_{i}} \phi_{\varepsilon}(\mathbf{g}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{g}(\mathbf{x}) d x
$$

The reason for this is as follows. The integrand on the left is nonzero only if $\mathbf{g}(\mathbf{x})-$ $\mathbf{y} \in B(\mathbf{0}, \varepsilon)$ which occurs only if $\mathbf{g}(\mathbf{x}) \in B(\mathbf{y}, \varepsilon)$ which is the same as $\mathbf{x} \in \mathbf{g}^{-1}(B(\mathbf{y}, \varepsilon))$. Therefore, the integrand is nonzero only if $\mathbf{x}$ is contained in exactly one of the disjoint sets, $V_{i}$. Now using the change of variables theorem, $\left(\mathbf{z}=\mathbf{g}(\mathbf{x})-\mathbf{y}, \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})=\mathbf{x}.\right)$

$$
=\sum_{i=1}^{m} \int_{\mathbf{g}\left(V_{i}\right)-\mathbf{y}} \phi_{\varepsilon}(\mathbf{z}) \operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\left|\operatorname{det} D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right| d z
$$

By the chain rule, $I=D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right) D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})$ and so

$$
\begin{gathered}
\operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\left|\operatorname{det} D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right| \\
=\operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\right)\left|\operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\right|\left|\operatorname{det} D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right| \\
=\operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\right) \\
=\operatorname{sgn}(\operatorname{det} D \mathbf{g}(\mathbf{x}))=\operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right) .
\end{gathered}
$$

Therefore, this reduces to

$$
\begin{gathered}
\sum_{i=1}^{m} \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right) \int_{\mathbf{g}\left(V_{i}\right)-\mathbf{y}} \phi_{\varepsilon}(\mathbf{z}) d z= \\
\sum_{i=1}^{m} \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right) \int_{B(\mathbf{0}, \boldsymbol{\varepsilon})} \phi_{\varepsilon}(\mathbf{z}) d z=\sum_{i=1}^{m} \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right)
\end{gathered}
$$

In case $\mathbf{g}^{-1}(\mathbf{y})=\emptyset$, there exists $\varepsilon>0$ such that $\mathbf{g}(\bar{\Omega}) \cap B(\mathbf{y}, \varepsilon)=\emptyset$ and so for $\varepsilon$ this small,

$$
\int_{\Omega} \phi_{\varepsilon}(\mathbf{g}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{g}(\mathbf{x}) d x=0
$$

As noted above, this will end up being $d(\mathbf{g}, \Omega, \mathbf{y})$ in this last case where $\mathbf{g}^{-1}(\mathbf{y})=\emptyset$.
Next is an important result on homotopy.
Lemma 23.1.12 If $\mathbf{h}$ is in $C^{\infty}\left(\bar{\Omega} \times[a, b], \mathbb{R}^{p}\right)$, and $\mathbf{0} \notin \mathbf{h}(\partial \Omega \times[a, b])$ then for $0<\varepsilon<$ $\operatorname{dist}(\mathbf{0}, \mathbf{h}(\partial \Omega \times[a, b]))$,

$$
t \rightarrow \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t)) \operatorname{det} D_{1} \mathbf{h}(\mathbf{x}, t) d x
$$

is constant for $t \in[a, b]$. As a special case, $d(\mathbf{f}, \Omega, \mathbf{y})$ is well defined. Also, if $\mathbf{y} \notin \mathbf{f}(\bar{\Omega})$, then $d(\mathbf{f}, \Omega, \mathbf{y})=0$.

Proof: By continuity of $\mathbf{h}, \mathbf{h}(\partial \Omega \times[a, b])$ is compact and so is at a positive distance from 0 . Let $\varepsilon>0$ be such that for all $t \in[a, b]$,

$$
\begin{equation*}
B(\mathbf{0}, \varepsilon) \cap \mathbf{h}(\partial \Omega \times[a, b])=\emptyset \tag{23.1.3}
\end{equation*}
$$

Define for $t \in(a, b)$,

$$
H(t) \equiv \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t)) \operatorname{det} D_{1} \mathbf{h}(\mathbf{x}, t) d x
$$

I will show that $H^{\prime}(t)=0$ on $(a, b)$. Then, since $H$ is continuous on $[a, b]$, it will follow from the mean value theorem that $H(t)$ is constant on $[a, b]$. If $t \in(a, b)$,

$$
H^{\prime}(t)=\int_{\Omega} \sum_{\alpha} \phi_{\varepsilon, \alpha}(\mathbf{h}(\mathbf{x}, t)) h_{\alpha, t}(\mathbf{x}, t) \operatorname{det} D_{1} \mathbf{h}(\mathbf{x}, t) d x
$$

$$
\begin{equation*}
+\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t)) \sum_{\alpha, j} \operatorname{det} D_{1}(\mathbf{h}(\mathbf{x}, t))_{, \alpha j} h_{\alpha, j t} d x \equiv \mathbf{A}+\mathbf{B} . \tag{23.1.4}
\end{equation*}
$$

In this formula, the function det is considered as a function of the $n^{2}$ entries in the $n \times n$ matrix and the, $\alpha j$ represents the derivative with respect to the $\alpha j^{\text {th }}$ entry $h_{\alpha, j}$. Now as in the proof of Lemma 16.3.1 on Page 429,

$$
\operatorname{det} D_{1}(\mathbf{h}(\mathbf{x}, t))_{, \alpha_{j}}=\left(\operatorname{cof} D_{1}(\mathbf{h}(\mathbf{x}, t))\right)_{\alpha_{j}}
$$

and so

$$
\mathbf{B}=\int_{\Omega} \sum_{\alpha} \sum_{j} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t))\left(\operatorname{cof} D_{1}(\mathbf{h}(\mathbf{x}, t))\right)_{\alpha j} h_{\alpha, j t} d x .
$$

By hypothesis

$$
\mathbf{x} \rightarrow \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t))\left(\operatorname{cof} D_{1}(\mathbf{h}(\mathbf{x}, t))\right)_{\alpha_{j}} \text { for } \mathbf{x} \in \Omega
$$

is in $C_{c}^{\infty}(\Omega)$ because if $\mathbf{x} \in \partial \Omega$, it follows that for all $t \in[a, b], \mathbf{h}(\mathbf{x}, t) \notin B(\mathbf{0}, \varepsilon)$ and so $\phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t))=0$ off some compact set contained in $\Omega$. Therefore, integrate by parts and write

$$
\begin{aligned}
\mathbf{B}=- & \int_{\Omega} \sum_{\alpha} \sum_{j} \frac{\partial}{\partial x_{j}}\left(\phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t))\right)\left(\operatorname{cof} D_{1}(\mathbf{h}(\mathbf{x}, t))\right)_{\alpha j} h_{\alpha, t} d x+ \\
& -\int_{\Omega} \sum_{\alpha} \sum_{j} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, t))(\operatorname{cof} D(\mathbf{h}(\mathbf{x}, t)))_{\alpha j, j} h_{\alpha, t} d x
\end{aligned}
$$

The second term equals zero by Lemma 23.1.8. Simplifying the first term yields

$$
\begin{aligned}
\mathbf{B} & =-\int_{\Omega} \sum_{\alpha} \sum_{j} \sum_{\beta} \phi_{\varepsilon, \beta}(\mathbf{h}(\mathbf{x}, t)) h_{\beta, j} h_{\alpha, t}\left(\operatorname{cof} D_{1}(\mathbf{h}(\mathbf{x}, t))\right)_{\alpha j} d x \\
& =-\int_{\Omega} \sum_{\alpha} \sum_{\beta} \phi_{\varepsilon, \beta}(\mathbf{h}(\mathbf{x}, t)) h_{\alpha, t} \sum_{j} h_{\beta, j}\left(\operatorname{cof} D_{1}(\mathbf{h}(\mathbf{x}, t))\right)_{\alpha_{j}} d x
\end{aligned}
$$

Now the sum on $j$ is the dot product of the $\beta^{\text {th }}$ row with the $\alpha^{t h}$ row of the cofactor matrix which equals zero unless $\beta=\alpha$ because it would be a cofactor expansion of a matrix with two equal rows. When $\beta=\alpha$, the sum on $j$ reduces to $\operatorname{det}\left(D_{1}(\mathbf{h}(\mathbf{x}, t))\right)$. Thus $\mathbf{B}$ reduces to

$$
=-\int_{\Omega} \sum_{\alpha} \phi_{\varepsilon, \alpha}(\mathbf{h}(\mathbf{x}, t)) h_{\alpha, t} \operatorname{det}\left(D_{1}(\mathbf{h}(\mathbf{x}, t))\right) d x
$$

Which is the same thing as $\mathbf{A}$, but with the opposite sign. Hence $\mathbf{A}+\mathbf{B}$ in 23.1.4 is 0 and $H^{\prime}(t)=0$ and so $H$ is a constant on $[a, b]$.

Finally consider the last claim. If $\mathbf{g}, \hat{\mathbf{g}}$ both work in the definition for the degree, then consider $\mathbf{h}(\mathbf{x}, t) \equiv \operatorname{tg}(\mathbf{x})+(1-t) \hat{\mathbf{g}}(\mathbf{x})-\mathbf{y}$ for $t \in[0,1]$. From Lemma 23.1.7, $\mathbf{h}$ satisfies what is needed for the first part of this lemma. Then from Lemma 23.1.11 and the first part of this lemma, if $0<\varepsilon<\operatorname{dist}(\mathbf{0}, \mathbf{h}(\partial \Omega \times[0,1]))$ is sufficiently small that the second and
last equations hold in what follows,

$$
\begin{aligned}
d(\mathbf{f}, \Omega, \mathbf{y}) & =\sum\left\{\operatorname{sgn}(\operatorname{det}(D \mathbf{g}(\mathbf{x}))): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})\right\} \\
& =\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, 1)) \operatorname{det} D_{1} \mathbf{h}(\mathbf{x}, 1) d x \\
& =\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x}, 0)) \operatorname{det} D_{1} \mathbf{h}(\mathbf{x}, 0) d x \\
& =\sum\left\{\operatorname{sgn}(\operatorname{det}(D \hat{\mathbf{g}}(\mathbf{x}))): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})\right\}
\end{aligned}
$$

The last claim was noted earlier. If $\mathbf{y} \notin \mathbf{f}(\bar{\Omega})$, then letting $\mathbf{g}$ be smooth with $\|\mathbf{f}-\mathbf{g}\|_{\infty, \bar{\Omega}}<$ $\delta<\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})$, it follows that if $\mathbf{x} \in \partial \Omega$,

$$
\|\mathbf{g}(\mathbf{x})-\mathbf{y}\| \geq\|\mathbf{y}-\mathbf{f}(\mathbf{x})\|-\|\mathbf{g}(\mathbf{x})-\mathbf{f}(\mathbf{x})\|>\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{y})-\delta \geq 0
$$

Thus, from the definition, $d(\mathbf{f}, \Omega, \mathbf{y})=0$.

### 23.2 Properties of the Degree

Now that the degree for a continuous function has been defined, it is time to consider properties of the degree. In particular, it is desirable to prove a theorem about homotopy invariance which depends only on continuity considerations.

Theorem 23.2.1 If $\mathbf{h}$ is in $C\left(\bar{\Omega} \times[a, b], \mathbb{R}^{p}\right)$, and $\mathbf{0} \notin \mathbf{h}(\partial \Omega \times[a, b])$ then

$$
t \rightarrow d(\mathbf{h}(\cdot, t), \Omega, \mathbf{0})
$$

is constant for $t \in[a, b]$.
Proof: Let $0<\delta<\min _{t \in[a, b]} \operatorname{dist}(\mathbf{h}(\partial \Omega \times[a, b]), \mathbf{0})$. By Corollary 23.1.1, there exists

$$
\mathbf{h}_{m}(\cdot, t)=\sum_{k=0}^{m} p_{k}(t) \mathbf{h}\left(\cdot, t_{k}\right)
$$

for $p_{k}(t)$ some polynomial in $t$ of degree $m$ such that

$$
\begin{equation*}
\max _{t \in[a, b]}\left\|\mathbf{h}_{m}(\cdot, t)-\mathbf{h}(\cdot, t)\right\|_{\infty, \bar{\Omega}}<\delta \tag{23.2.5}
\end{equation*}
$$

Letting $\psi_{n}$ be a mollifier,

$$
C_{c}^{\infty}\left(B\left(\mathbf{0}, \frac{1}{n}\right)\right), \int_{\mathbb{R}^{p}} \psi_{n}(\mathbf{u}) d u=1
$$

let

$$
\mathbf{g}_{n}(\cdot, t) \equiv \mathbf{h}_{m} * \psi_{n}(\cdot, t)
$$

Thus,

$$
\begin{aligned}
\mathbf{g}_{n}(\mathbf{x}, t) & \equiv \int_{\mathbb{R}^{p}} \mathbf{h}_{m}(\mathbf{x}-\mathbf{u}, t) \psi_{n}(\mathbf{u}) d u=\sum_{k=0}^{m} p_{k}(t) \int_{\mathbb{R}^{p}} \mathbf{h}\left(\mathbf{x}-\mathbf{u}, t_{k}\right) \psi_{n}(\mathbf{u}) d u \\
& =\sum_{k=0}^{m} p_{k}(t) \int_{\mathbb{R}^{p}} \mathbf{h}\left(\mathbf{u}, t_{k}\right) \psi_{n}(\mathbf{x}-\mathbf{u}) d u \equiv \sum_{k=0}^{m} p_{k}(t) \mathbf{h}\left(\cdot, t_{k}\right) * \psi_{n}(\mathbf{x})(23.2 .6)
\end{aligned}
$$

so $\mathbf{x} \rightarrow \mathbf{g}_{n}(\mathbf{x}, t)$ is in $C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$. Also,

$$
\left\|\mathbf{g}_{n}(\mathbf{x}, t)-\mathbf{h}_{m}(\mathbf{x}, t)\right\| \leq \int_{B\left(\mathbf{0}, \frac{1}{n}\right)}\|\mathbf{h}(\mathbf{x}-\mathbf{u}, t)-\mathbf{h}(\mathbf{z}, t)\| d u<\varepsilon
$$

provided $n$ is large enough. This follows from uniform continuity of $\mathbf{h}$ on the compact set $\bar{\Omega} \times[a, b]$. It follows that if $n$ is large enough, one can replace $\mathbf{h}_{m}$ in 23.2 .5 with $\mathbf{g}_{n}$ and obtain for large enough $n$

$$
\begin{equation*}
\max _{t \in[a, b]}\left\|\mathbf{g}_{n}(\cdot, t)-\mathbf{h}(\cdot, t)\right\|_{\infty, \bar{\Omega}}<\delta \tag{23.2.7}
\end{equation*}
$$

Now $\mathbf{g}_{n} \in C^{\infty}\left(\bar{\Omega} \times[a, b] ; \mathbb{R}^{p}\right)$ because all partial derivatives with respect to either $t$ or $\mathbf{x}$ are continuous. Here

$$
\mathbf{g}_{n}(\mathbf{x}, t)=\sum_{k=0}^{m} p_{k}(t) \mathbf{h}\left(\cdot, t_{k}\right) * \psi_{n}(\mathbf{x})
$$

Let $\tau \in(a, b]$. Let $\mathbf{g}_{a \tau}(\mathbf{x}, t) \equiv \mathbf{g}_{n}(\mathbf{x}, t)-\left(\frac{\tau-t}{\tau-a} \mathbf{y}_{a}+\mathbf{y}_{\tau} \frac{t-a}{\tau-a}\right)$ where $\mathbf{y}_{a}$ is a regular value of $\mathbf{g}_{n}(\cdot, a), \mathbf{y}_{\tau}$ is a regular value of $\mathbf{g}_{n}(\mathbf{x}, \tau)$ and both $\mathbf{y}_{a}, \mathbf{y}_{\tau}$ are so small that

$$
\begin{equation*}
\max _{t \in[a, b]}\left\|\mathbf{g}_{a \tau}(\cdot, t)-\mathbf{h}(\cdot, t)\right\|_{\infty, \bar{\Omega}}<\delta \tag{23.2.8}
\end{equation*}
$$

This uses Lemma 23.1.3. Thus if $\mathbf{g}_{a \tau}(\mathbf{x}, \tau)=\mathbf{0}$, then $\mathbf{g}_{n}(\mathbf{x}, \tau)-\mathbf{y}_{\tau}=\mathbf{0}$ so $\mathbf{0}$ is a regular value for $\mathbf{g}_{a \tau}(\cdot, \tau)$. If $\mathbf{g}_{a \tau}(\mathbf{x}, a)=\mathbf{0}$, then $\mathbf{g}_{n}(\mathbf{x}, t)=\mathbf{y}_{a}$ so $\mathbf{0}$ is also a regular value for $\mathbf{g}_{a \tau}(\cdot, a)$. From 23.2.8, $\operatorname{dist}\left(\mathbf{g}_{a \tau}(\partial \Omega \times[a, b]), \mathbf{0}\right)>0$ as in Lemma 23.1.5. Choosing $\varepsilon<$ $\operatorname{dist}\left(\mathbf{g}_{a \tau}(\partial \Omega \times[a, b]), \mathbf{0}\right)$, it follows from Lemma 23.1.12, the definition of the degree, and Lemma 23.1.11 in the first and last equations that for $\varepsilon$ small enough,

$$
\begin{aligned}
d(\mathbf{h}(\cdot, a), \Omega, \mathbf{0}) & =\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{g}_{a \tau}(\mathbf{x}, a)\right) \operatorname{det} D_{1} \mathbf{g}_{a \tau}(\mathbf{x}, a) d x \\
& =\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{g}_{a \tau}(\mathbf{x}, \tau)\right) \operatorname{det} D_{1} \mathbf{g}_{a \tau}(\mathbf{x}, \tau) d x=d(\mathbf{h}(\cdot, \tau), \Omega, \mathbf{0})
\end{aligned}
$$

Since $\tau$ is arbitrary, this proves the theorem.
Now the following theorem is a summary of the main result on properties of the degree.
Theorem 23.2.2 Definition 23.1.6 is well defined and the degree satisfies the following properties.

1. (homotopy invariance) If $\mathbf{h} \in C\left(\bar{\Omega} \times[0,1], \mathbb{R}^{p}\right)$ and $\mathbf{y}(t) \notin \mathbf{h}(\partial \Omega, t)$ for all $t \in[0,1]$ where $\mathbf{y}$ is continuous, then

$$
t \rightarrow d(\mathbf{h}(\cdot, t), \Omega, \mathbf{y}(t))
$$

is constant for $t \in[0,1]$.
2. If $\Omega \supseteq \Omega_{1} \cup \Omega_{2}$ where $\Omega_{1} \cap \Omega_{2}=\emptyset$, for $\Omega_{i}$ an open set, then if $\mathbf{y} \notin \mathbf{f}\left(\bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)\right)$, then

$$
d\left(\mathbf{f}, \Omega_{1}, \mathbf{y}\right)+d\left(\mathbf{f}, \Omega_{2}, \mathbf{y}\right)=d(\mathbf{f}, \Omega, \mathbf{y})
$$

3. $d(I, \Omega, \mathbf{y})=1$ if $\mathbf{y} \in \Omega$.
4. $d(\mathbf{f}, \Omega, \cdot)$ is continuous and constant on every connected component of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$.
5. $d(\mathbf{g}, \Omega, \mathbf{y})=d(\mathbf{f}, \Omega, \mathbf{y})$ if $\left.\mathbf{g}\right|_{\partial \Omega}=\left.\mathbf{f}\right|_{\partial \Omega}$.
6. If $\mathbf{y} \notin \mathbf{f}(\partial \Omega)$, and if $(\mathbf{f}, \Omega, \mathbf{y}) \neq 0$, then there exists $\mathbf{x} \in \Omega$ such that $\mathbf{f}(\mathbf{x})=\mathbf{y}$.

Proof: That the degree is well defined follows from Lemma 23.1.12.
Consider 1., the first property about homotopy. This follows from Theorem 23.2.1 applied to $H(\mathbf{x}, t) \equiv \mathbf{h}(\mathbf{x}, t)-\mathbf{y}(t)$.

Consider 2. where $\mathbf{y} \notin \mathbf{f}\left(\bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)\right)$. Note that

$$
\operatorname{dist}\left(\mathbf{y}, \mathbf{f}\left(\bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)\right)\right) \leq \operatorname{dist}(\mathbf{y}, \mathbf{f}(\partial \Omega))
$$

Then let $\mathbf{g}$ be in $C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ and

$$
\begin{aligned}
\|\mathbf{g}-\mathbf{f}\|_{\infty} & <\operatorname{dist}\left(\mathbf{y}, \mathbf{f}\left(\bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)\right)\right) \\
& \leq \min \left(\operatorname{dist}\left(\mathbf{y}, \mathbf{f}\left(\partial \Omega_{1}\right)\right), \operatorname{dist}\left(\mathbf{y}, \mathbf{f}\left(\partial \Omega_{2}\right)\right), \operatorname{dist}(\mathbf{y}, \mathbf{f}(\partial \Omega))\right)
\end{aligned}
$$

where $\mathbf{y}$ is a regular value of $\mathbf{g}$. Then by definition,

$$
\begin{aligned}
& d(\mathbf{f}, \Omega, \mathbf{y}) \equiv \sum\left\{\operatorname{det}(D \mathbf{g}(\mathbf{x})): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})\right\} \\
&= \sum\left\{\operatorname{det}(D \mathbf{g}(\mathbf{x})): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y}), \mathbf{x} \in \Omega_{1}\right\} \\
&+\sum\left\{\operatorname{det}(D \mathbf{g}(\mathbf{x})): \mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y}), \mathbf{x} \in \Omega_{2}\right\} \\
& \equiv d\left(\mathbf{f}, \Omega_{1}, \mathbf{y}\right)+d\left(\mathbf{f}, \Omega_{2}, \mathbf{y}\right)
\end{aligned}
$$

It is of course obvious that this can be extended by induction to any finite number of disjoint open sets $\Omega_{i}$.

Note that 3. is obvious because $I(\mathbf{x})=\mathbf{x}$ and so if $\mathbf{y} \in \Omega$, then $I^{-1}(\mathbf{y})=\mathbf{y}$ and $D I(\mathbf{x})=I$ for any $\mathbf{x}$ so the definition gives 3 .

Now consider 4. Let $U$ be a connected component of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$. This is open as well as connected and arc wise connected by Theorem 7.13.10. Hence, if $\mathbf{u}, \mathbf{v} \in U$, there is a continuous function $\mathbf{y}(t)$ which is in $U$ such that $\mathbf{y}(0)=\mathbf{u}$ and $\mathbf{y}(1)=\mathbf{v}$. By homotopy invariance, it follows $d(\mathbf{f}, \Omega, \mathbf{y}(t))$ is constant. Thus $d(\mathbf{f}, \Omega, \mathbf{u})=d(\mathbf{f}, \Omega, \mathbf{v})$.

Next consider 5. When $\mathbf{f}=\mathbf{g}$ on $\partial \Omega$, it follows that if $\mathbf{y} \notin \mathbf{f}(\partial \Omega)$, then $\mathbf{y} \notin \mathbf{f}(\mathbf{x})+$ $t(\mathbf{g}(\mathbf{x})-\mathbf{f}(\mathbf{x}))$ for $t \in[0,1]$ and $\mathbf{x} \in \partial \Omega$ so

$$
d(\mathbf{f}+t(\mathbf{g}-\mathbf{f}), \Omega, \mathbf{y})
$$

is constant for $t \in[0,1]$ by homotopy invariance in part 1 . Therefore, let $t=0$ and then $t=1$ to obtain 5 .

Claim 6. follows from Lemma 23.1.12 which says that if $\mathbf{y} \notin \mathbf{f}(\bar{\Omega})$, then $d(\mathbf{f}, \Omega, \mathbf{y})=0$.
From the above, there is an easy corollary which gives related properties of the degree.

Corollary 23.2.3 The following additional properties of the degree are also valid.

1. If $\mathbf{y} \notin \mathbf{f}\left(\bar{\Omega} \backslash \Omega_{1}\right)$ and $\Omega_{1}$ is an open subset of $\Omega$, then $d(\mathbf{f}, \Omega, \mathbf{y})=d\left(\mathbf{f}, \Omega_{1}, \mathbf{y}\right)$.
2. $d(\cdot, \Omega, \mathbf{y})$ is defined and constant on

$$
\left\{\mathbf{g} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right):\|\mathbf{g}-\mathbf{f}\|_{\infty}<r\right\}
$$

where $r=\operatorname{dist}(\mathbf{y}, \mathbf{f}(\partial \Omega))$.
3. If $\operatorname{dist}(\mathbf{y}, \mathbf{f}(\partial \Omega)) \geq \delta$ and $|\mathbf{z}-\mathbf{y}|<\delta$, then $d(\mathbf{f}, \Omega, \mathbf{y})=d(\mathbf{f}, \Omega, \mathbf{z})$.

Proof: Consider 1. You can take $\Omega_{2}=\emptyset$ in 2 of Theorem 23.2.2 or you can modify the proof of 2 slightly. Consider 2. To verify, let $\mathbf{h}(\mathbf{x}, t)=\mathbf{f}(\mathbf{x})+t(\mathbf{g}(\mathbf{x})-\mathbf{f}(\mathbf{x}))$. Then note that $\mathbf{y} \notin \mathbf{h}(\partial \Omega, t)$ and use Property 1 of Theorem 23.2.2. Finally, consider 3. Let $\mathbf{y}(t) \equiv(1-t) \mathbf{y}+t \mathbf{z}$. Then for $\mathbf{x} \in \partial \Omega$

$$
\begin{aligned}
|(1-t) \mathbf{y}+t \mathbf{z}-\mathbf{f}(\mathbf{x})| & =|\mathbf{y}-\mathbf{f}(\mathbf{x})+t(\mathbf{z}-\mathbf{y})| \\
& \geq \delta-t|\mathbf{z}-\mathbf{y}|>\delta-\delta=0
\end{aligned}
$$

Then by 1 of Theorem 23.2.2, $d(\mathbf{f}, \Omega,(1-t) \mathbf{y}+t \mathbf{z})$ is constant. When $t=0$ you get $d(\mathbf{f}, \Omega, \mathbf{y})$ and when $t=1$ you get $d(\mathbf{f}, \Omega, \mathbf{z})$.

Another simple observation is that if you have $\mathbf{y}_{1}, \cdots, \mathbf{y}_{r}$ in $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$, then if $\tilde{\mathbf{f}}$ has the property that $\|\tilde{\mathbf{f}}-\mathbf{f}\|_{\infty}<\min _{i \leq r} \operatorname{dist}\left(\mathbf{y}_{i}, \mathbf{f}(\partial \Omega)\right)$, then

$$
d\left(\mathbf{f}, \Omega, \mathbf{y}_{i}\right)=d\left(\tilde{\mathbf{f}}, \Omega, \mathbf{y}_{i}\right)
$$

for each $\mathbf{y}_{i}$. This follows right away from the above arguments and the homotopy invariance applied to each of the finitely many $\mathbf{y}_{i}$. Just consider $d\left(\mathbf{f}+t(\tilde{\mathbf{f}}-\mathbf{f}), \Omega, \mathbf{y}_{i}\right), t \in[0,1]$. If $\mathbf{x} \in \partial \Omega, \mathbf{f}+t(\tilde{\mathbf{f}}-\mathbf{f})(\mathbf{x}) \neq \mathbf{y}_{i}$ and so $d\left(\mathbf{f}+t(\tilde{\mathbf{f}}-\mathbf{f}), \Omega, \mathbf{y}_{i}\right)$ is constant on $[0,1]$, this for each $i$.

### 23.3 Borsuk's Theorem

In this section is an important theorem which can be used to verify that $d(\mathbf{f}, \Omega, \mathbf{y}) \neq 0$. This is significant because when this is known, it follows from Theorem 23.2.2 that $\mathbf{f}^{-1}(\mathbf{y}) \neq \emptyset$. In other words there exists $\mathbf{x} \in \Omega$ such that $\mathbf{f}(\mathbf{x})=\mathbf{y}$.

Definition 23.3.1 A bounded open set, $\Omega$ is symmetric if $-\Omega=\Omega$. A continuous function, $\mathbf{f}: \bar{\Omega} \rightarrow \mathbb{R}^{p}$ is odd if $\mathbf{f}(-\mathbf{x})=-\mathbf{f}(\mathbf{x})$.

Suppose $\Omega$ is symmetric and $\mathbf{g} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ is an odd map for which $\mathbf{0}$ is a regular value. Then the chain rule implies $D \mathbf{g}(-\mathbf{x})=D \mathbf{g}(\mathbf{x})$ and so $d(\mathbf{g}, \Omega, \mathbf{0})$ must equal an odd integer because if $\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{0})$, it follows that $-\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{0})$ also and since $D \mathbf{g}(-\mathbf{x})=D \mathbf{g}(\mathbf{x})$, it follows the overall contribution to the degree from $\mathbf{x}$ and $-\mathbf{x}$ must be an even integer. Also $\mathbf{0} \in \mathbf{g}^{-1}(\mathbf{0})$ and so the degree equals an even integer added to sgn $(\operatorname{det} D \mathbf{g}(\mathbf{0}))$, an odd integer, either -1 or 1 . It seems reasonable to expect that something like this would hold for an arbitrary continuous odd function defined on symmetric $\Omega$. In fact this is the
case and this is next. The following lemma is the key result used. This approach is due to Gromes [57]. See also Deimling [38] which is where I found this argument.

The idea is to start with a smooth odd map and approximate it with a smooth odd map which also has $\mathbf{0}$ a regular value. Note that $\mathbf{0}$ is achieved because $\mathbf{g}(\mathbf{0})=-\mathbf{g}(\mathbf{0})$.

Lemma 23.3.2 Let $\mathbf{g} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ be an odd map. Then for every $\varepsilon>0$, there exists $\mathbf{h}$ $\in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ such that $\mathbf{h}$ is also an odd map, $\|\mathbf{h}-\mathbf{g}\|_{\infty}<\varepsilon$, and $\mathbf{0}$ is a regular value of $\mathbf{h}, \mathbf{0} \notin \mathbf{g}(\partial \Omega)$. Here $\Omega$ is a symmetric bounded open set. In addition, $d(\mathbf{g}, \Omega, \mathbf{0})$ is an odd integer.

Proof: In this argument $\eta>0$ will be a small positive number. Let $\mathbf{h}_{0}(\mathbf{x})=\mathbf{g}(\mathbf{x})+\eta \mathbf{x}$ where $\eta$ is chosen such that $\operatorname{det} D \mathbf{h}_{0}(\mathbf{0}) \neq 0$. Just let $-\eta$ not be an eigenvalue of $D \mathbf{g}(\mathbf{0})$ also see Lemma 5.9.7. Note that $\mathbf{h}_{0}$ is odd and $\mathbf{0}$ is a value of $\mathbf{h}_{0}$ thanks to $\mathbf{h}_{0}(\mathbf{0})=\mathbf{0}$. This has taken care of $\mathbf{0}$. However, it is not known whether $\mathbf{0}$ is a regular value of $\mathbf{h}_{0}$ because there may be other $\mathbf{x}$ where $\mathbf{h}_{0}(\mathbf{x})=\mathbf{0}$. These other points must be accounted for. The eventual function will be of the form

$$
\mathbf{h}(\mathbf{x}) \equiv \mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{p} \mathbf{y}^{j} x_{j}^{3}, \sum_{j=1}^{0} \mathbf{y}^{j} x_{j}^{3} \equiv 0
$$

Note that $\mathbf{h}(\mathbf{0})=\mathbf{0}$ and $\operatorname{det}(D \mathbf{h}(\mathbf{0}))=\operatorname{det}\left(D \mathbf{h}_{0}(\mathbf{0})\right) \neq 0$. This is because when you take the matrix of the derivative, those terms involving $x_{j}^{3}$ will vanish when $\mathbf{x}=\mathbf{0}$ because of the exponent 3 .

The idea is to choose small $\mathbf{y}^{j},\left\|\mathbf{y}^{j}\right\|<\eta$ in such a way that $\mathbf{0}$ is a regular value for $\mathbf{h}$ for each $\mathbf{x} \neq \mathbf{0}$ such that $\mathbf{x} \in \mathbf{h}^{-1}(\mathbf{0})$. As just noted, the case where $\mathbf{x}=\mathbf{0}$ creates no problems. Let

$$
\Omega_{i} \equiv\left\{\mathbf{x} \in \Omega: x_{i} \neq 0\right\}, \text { so } \cup_{j=1}^{p} \Omega_{j}=\left\{\mathbf{x} \in \mathbb{R}^{p}: \mathbf{x} \neq \mathbf{0}\right\}, \Omega_{0} \equiv\{\mathbf{0}\}
$$

Each $\Omega_{i}$ is a symmetric open set while $\Omega_{0}$ is the single point $\mathbf{0}$. Then let $\mathbf{h}_{1}(\mathbf{x}) \equiv \mathbf{h}_{0}(\mathbf{x})-$ $\mathbf{y}^{1} x_{1}^{3}$ on $\Omega_{1}$. If $\mathbf{h}_{1}(\mathbf{x})=\mathbf{0}$, then

$$
\begin{equation*}
\mathbf{h}_{0}(\mathbf{x})=\mathbf{y}^{1} x_{1}^{3} \text { so } \mathbf{y}^{1}=\frac{\mathbf{h}_{0}(\mathbf{x})}{x_{1}^{3}} \tag{23.3.9}
\end{equation*}
$$

The set of singular values of $\mathbf{x} \rightarrow \frac{\mathbf{h}_{0}(\mathbf{x})}{x_{1}^{3}}$ for $\mathbf{x} \in \Omega_{1}$ contains no open sets. Hence there exists a regular value $\mathbf{y}^{1}$ for $\mathbf{x} \rightarrow \frac{\mathbf{h}_{0}(\mathbf{x})}{x_{1}^{3}}$ such that $\left\|\mathbf{y}^{1}\right\|<\eta$. Then if $\mathbf{y}^{1}=\frac{\mathbf{h}_{0}(\mathbf{x})}{x_{1}^{3}}$, abusing notation a little, the matrix of the derivative at this $\mathbf{x}$ is

$$
\begin{aligned}
D \mathbf{h}_{1}(\mathbf{x})_{r s} & =\frac{h_{0 r, s}(\mathbf{x}) x_{1}^{3}-\left(x_{1}\right)_{, x_{s}}^{3} h_{0 r}(\mathbf{x})}{x_{1}^{6}}=\frac{h_{0 r, s}(\mathbf{x}) x_{1}^{3}-\left(x_{1}\right)_{, x_{s}}^{3} y_{r}^{1} x_{1}^{3}}{x_{1}^{6}} \\
& =\frac{h_{0 r, s}(\mathbf{x})-\left(x_{1}\right)_{, x_{s}}^{3} y_{r}^{1}}{x_{1}^{3}}
\end{aligned}
$$

and so, choosing $\mathbf{y}^{1}$ this way in 23.3.9, this derivative is non-singular if and only if

$$
\operatorname{det}\left(h_{0 r, s}(\mathbf{x})-\left(x_{1}\right)_{, x_{s}}^{3} y_{r}^{1}\right)=\operatorname{det} D\left(\mathbf{h}_{1}(\mathbf{x})\right) \neq 0
$$

which of course is exactly what is wanted. Thus there is a small $\mathbf{y}^{1},\left\|\mathbf{y}^{1}\right\|<\eta$ such that if $\mathbf{h}_{1}(\mathbf{x})=\mathbf{0}$, for $\mathbf{x} \in \Omega_{1}$, then $\operatorname{det} D\left(\mathbf{h}_{1}(\mathbf{x})\right) \neq 0$. That is, $\mathbf{0}$ is a regular value of $\mathbf{h}_{1}$. Thus, 23.3.9 is how to choose $\mathbf{y}^{1}$ for $\left\|\mathbf{y}^{1}\right\|<\eta$.

Then the theorem will be proved by doing the same process, going from $\Omega_{1}$ to $\Omega_{1} \cup \Omega_{2}$ and so forth. If for each $k \leq p$, there exist $\mathbf{y}^{i},\left\|\mathbf{y}^{i}\right\|<\eta, i \leq k$ and $\mathbf{0}$ is a regular value of

$$
\mathbf{h}_{k}(\mathbf{x}) \equiv \mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{k} \mathbf{y}^{j} x_{j}^{3} \text { for } \mathbf{x} \in \cup_{i=0}^{k} \Omega_{i}
$$

Then the theorem will be proved by considering $\mathbf{h}_{p} \equiv \mathbf{h}$. For $k=0,1$ this is done. Suppose then that this holds for $k-1, k \geq 2$. Thus $\mathbf{0}$ is a regular value for

$$
\mathbf{h}_{k-1}(\mathbf{x}) \equiv \mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{k-1} \mathbf{y}^{j} x_{j}^{3} \text { on } \cup_{i=0}^{k-1} \Omega_{i}
$$

What should $\mathbf{y}^{k}$ be? Keeping $\mathbf{y}^{1}, \cdots, \mathbf{y}^{k-1}$, it follows that if $x_{k}=0, \mathbf{h}_{k}(\mathbf{x})=\mathbf{h}_{k-1}(\mathbf{x})$. For $\mathbf{x} \in \Omega_{k}$ where $x_{k} \neq 0$,

$$
\mathbf{h}_{k}(\mathbf{x}) \equiv \mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{k} \mathbf{y}^{j} x_{j}^{3}=\mathbf{0}
$$

if and only if

$$
\frac{\mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{k-1} \mathbf{y}^{j} x_{j}^{3}}{x_{k}^{3}}=\mathbf{y}^{k}
$$

So let $\mathbf{y}^{k}$ be a regular value of $\frac{\mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{k-1} \mathbf{y}^{j} x_{j}^{3}}{x_{k}^{3}}$ on $\Omega_{k},\left(x_{k} \neq 0\right)$ and also $\left\|\mathbf{y}^{k}\right\|<\eta$. This is the same reasoning as before, the set of singular values does not contain any open set. Then for such $\mathbf{x}$ satisfying

$$
\begin{equation*}
\frac{\mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{k-1} \mathbf{y}^{j} x_{j}^{3}}{x_{k}^{3}}=\mathbf{y}^{k} \text { on } \Omega_{k}, \tag{23.3.10}
\end{equation*}
$$

and using the quotient rule as before,

$$
0 \neq \operatorname{det}\left(\frac{\left(h_{0 r, s}-\sum_{j=1}^{k-1} y_{r}^{j} \partial_{x_{s}}\left(x_{j}^{3}\right)\right) x_{k}^{3}-\left(h_{0 r}(\mathbf{x})-\sum_{j=1}^{k-1} y_{r}^{j} x_{j}^{3}\right) \partial_{x_{s}}\left(x_{k}^{3}\right)}{x_{k}^{6}}\right)
$$

and $h_{0 r}(\mathbf{x})-\sum_{j=1}^{k-1} y_{r}^{j} x_{j}^{3}=y_{r}^{k} x_{k}^{3}$ from 23.3.10 and so

$$
\begin{aligned}
& 0 \neq \operatorname{det}\left(\frac{\left(h_{0 r, s}-\sum_{j=1}^{k-1} y_{r}^{j} \partial_{x_{s}}\left(x_{j}^{3}\right)\right) x_{k}^{3}-y_{r}^{k} x_{k}^{3} \partial_{x_{s}}\left(x_{k}^{3}\right)}{x_{k}^{6}}\right) \\
& 0 \neq \operatorname{det}\left(\frac{\left(h_{0 r, s}-\sum_{j=1}^{k-1} y_{r}^{j} \partial_{x_{s}}\left(x_{j}^{3}\right)\right)-y_{r}^{k} \partial_{x_{s}}\left(x_{k}^{3}\right)}{x_{k}^{3}}\right)
\end{aligned}
$$

which implies

$$
0 \neq \operatorname{det}\left(\left(h_{0 r, s}-\sum_{j=1}^{k-1} y_{r}^{j} \partial_{x_{s}}\left(x_{j}^{3}\right)\right)-y_{r}^{k} \partial_{x_{s}}\left(x_{k}^{3}\right)\right)=\operatorname{det}\left(D\left(\mathbf{h}_{k}(\mathbf{x})\right)\right)
$$

If $\mathbf{x} \in \Omega_{k},\left(x_{k} \neq 0\right)$ this has shown that $\operatorname{det}\left(D \mathbf{h}_{k}(\mathbf{x})\right) \neq 0$ whenever $\mathbf{h}_{k}(\mathbf{x})=\mathbf{0}$ and $\mathbf{x}_{k} \in \Omega_{k}$. If $\mathbf{x} \notin \Omega_{k}$, then $x_{k}=0$ and so, since $\mathbf{h}_{k}(\mathbf{x})=\mathbf{h}_{0}(\mathbf{x})-\sum_{j=1}^{k} \mathbf{y}^{j} x_{j}^{3}$, because of the power of 3 in $x_{k}^{3}, D \mathbf{h}_{k}(\mathbf{x})=D \mathbf{h}_{k-1}(\mathbf{x})$ which has nonzero determinant by induction if $\mathbf{h}_{k-1}(\mathbf{x})=\mathbf{0}$. Thus for each $k \leq p$, there is a function $\mathbf{h}_{k}$ of the form described above, such that if $\mathbf{x} \in \cup_{j=1}^{k} \Omega_{k}$, with $\mathbf{h}_{k}(\mathbf{x})=\mathbf{0}$, it follows that $\operatorname{det}\left(D \mathbf{h}_{k}(\mathbf{x})\right) \neq 0$. Thus $\mathbf{0}$ is a regular value for $\mathbf{h}_{k}$ on $\cup_{j=1}^{k} \Omega_{j}$. Let $\mathbf{h} \equiv \mathbf{h}_{p}$. Then

$$
\begin{aligned}
\|\mathbf{h}-\mathbf{g}\|_{\infty, \bar{\Omega}} & \leq \max _{\mathbf{x} \in \Omega}\left\{\|\eta \mathbf{x}\|+\sum_{k=1}^{p}\left\|\mathbf{y}^{k}\right\|\|\mathbf{x}\|\right\} \\
& \leq \eta((p+1) \operatorname{diam}(\Omega))<\varepsilon<\operatorname{dist}(\mathbf{g}(\partial \Omega), \mathbf{0})
\end{aligned}
$$

provided $\eta$ was chosen sufficiently small to begin with.
So what is $d(\mathbf{h}, \Omega, \mathbf{0})$ ? Since $\mathbf{0}$ is a regular value and $\mathbf{h}$ is odd,

$$
\mathbf{h}^{-1}(\mathbf{0})=\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{r},-\mathbf{x}_{1}, \cdots,-\mathbf{x}_{r}, \mathbf{0}\right\} .
$$

So consider $D \mathbf{h}(\mathbf{x})$ and $D \mathbf{h}(-\mathbf{x})$.

$$
\begin{aligned}
D \mathbf{h}(-\mathbf{x}) \mathbf{u}+\mathbf{o}(\mathbf{u}) & =\mathbf{h}(-\mathbf{x}+\mathbf{u})-\mathbf{h}(-\mathbf{x}) \\
& =-\mathbf{h}(\mathbf{x}+(-\mathbf{u}))+\mathbf{h}(\mathbf{x}) \\
& =-(D \mathbf{h}(\mathbf{x})(-\mathbf{u}))+\mathbf{o}(-\mathbf{u}) \\
& =D \mathbf{h}(\mathbf{x})(\mathbf{u})+\mathbf{o}(\mathbf{u})
\end{aligned}
$$

Hence $D \mathbf{h}(\mathbf{x})=D \mathbf{h}(-\mathbf{x})$ and so the determinants of these two are the same. It follows from the definition that $d(\mathbf{g}, \Omega, \mathbf{0})=$

$$
\begin{aligned}
d(\mathbf{h}, \Omega, \mathbf{0})= & \sum_{i=1}^{r} \operatorname{sgn}\left(\operatorname{det}\left(D \mathbf{h}\left(\mathbf{x}_{i}\right)\right)\right)+\sum_{i=1}^{r} \operatorname{sgn}\left(\operatorname{det}\left(D \mathbf{h}\left(-\mathbf{x}_{i}\right)\right)\right) \\
& +\operatorname{sgn}(\operatorname{det}(D \mathbf{h}(\mathbf{0}))) \\
= & 2 m \pm 1 \text { some integer } m
\end{aligned}
$$

Theorem 23.3.3 (Borsuk) Let $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ be odd and let $\Omega$ be symmetric and $\mathbf{0} \notin \mathbf{f}(\partial \Omega)$. Then $d(\mathbf{f}, \Omega, \mathbf{0})$ equals an odd integer.

Proof: Let $\psi_{n}$ be a mollifier which is symmetric, $\psi(-\mathbf{x})=\psi(\mathbf{x})$. Also recall that $\mathbf{f}$ is the restriction to $\bar{\Omega}$ of a continuous function, still denoted as $\mathbf{f}$ which is defined on all of $\mathbb{R}^{p}$. Let $\mathbf{g}$ be the odd part of this function. That is,

$$
\mathbf{g}(\mathbf{x}) \equiv \frac{1}{2}(\mathbf{f}(\mathbf{x})-\mathbf{f}(-\mathbf{x}))
$$

Since $\mathbf{f}$ is odd, $\mathbf{g}=\mathbf{f}$ on $\bar{\Omega}$. Then

$$
\begin{gathered}
\mathbf{g}_{n}(-\mathbf{x}) \equiv \mathbf{g} * \psi_{n}(-\mathbf{x})=\int_{\Omega} \mathbf{g}(-\mathbf{x}-\mathbf{y}) \psi_{n}(\mathbf{y}) d y \\
=-\int_{\Omega} \mathbf{g}(\mathbf{x}+\mathbf{y}) \psi_{n}(\mathbf{y}) d y=-\int_{\Omega} \mathbf{g}(\mathbf{x}-(-\mathbf{y})) \psi_{n}(-\mathbf{y}) d y=-\mathbf{g}_{n}(\mathbf{x})
\end{gathered}
$$

Thus $\mathbf{g}_{n}$ is odd and is infinitely differentiable. Let $n$ be large enough that $\left\|\mathbf{g}_{n}-\mathbf{g}\right\|_{\infty, \bar{\Omega}}<$ $\delta<\operatorname{dist}(\mathbf{f}(\partial \Omega), \mathbf{0})$. Then by definition of the degree,

$$
d(\mathbf{f}, \Omega, \mathbf{0})=d(\mathbf{g}, \Omega, \mathbf{0})=d\left(\mathbf{g}_{n}, \Omega, \mathbf{0}\right)
$$

and by Lemma 23.3.2 this is an odd integer.

### 23.4 Applications

With these theorems it is possible to give easy proofs of some very important and difficult theorems.

Definition 23.4.1 If $\mathbf{f}: U \subseteq \mathbb{R}^{p} \rightarrow \mathbb{R}^{p}$ where $U$ is an open set. Then $\mathbf{f}$ is locally one to one if for every $\mathbf{x} \in U$, there exists $\delta>0$ such that $\mathbf{f}$ is one to one on $B(\mathbf{x}, \boldsymbol{\delta})$.

As a first application, consider the invariance of domain theorem. This result says that a one to one continuous map takes open sets to open sets. It is an amazing result which is essential to understand if you wish to study manifolds. In fact, the following theorem only requires $\mathbf{f}$ to be locally one to one. First here is a lemma which has the main idea.

Lemma 23.4.2 Let $\mathbf{g}: \overline{B(\mathbf{0}, r)} \rightarrow \mathbb{R}^{p}$ be one to one and continuous where here $B(\mathbf{0}, r)$ is the ball centered at $\mathbf{0}$ of radius $r$ in $\mathbb{R}^{p}$. Then there exists $\delta>0$ such that

$$
\mathbf{g}(\mathbf{0})+B(\mathbf{0}, \boldsymbol{\delta}) \subseteq \mathbf{g}(B(\mathbf{0}, r))
$$

The symbol on the left means: $\{\mathbf{g}(\mathbf{0})+\mathbf{x}: \mathbf{x} \in B(\mathbf{0}, \boldsymbol{\delta})\}$.
Proof: For $t \in[0,1]$, let

$$
\mathbf{h}(\mathbf{x}, t) \equiv \mathbf{g}\left(\frac{\mathbf{x}}{1+t}\right)-\mathbf{g}\left(\frac{-t \mathbf{x}}{1+t}\right)
$$

Then for $\mathbf{x} \in \partial B(\mathbf{0}, r), \mathbf{h}(\mathbf{x}, t) \neq \mathbf{0}$ because if this were so, the fact $\mathbf{g}$ is one to one implies

$$
\frac{\mathbf{x}}{1+t}=\frac{-t \mathbf{x}}{1+t}
$$

and this requires $\mathbf{x}=\mathbf{0}$ which is not the case since $\|\mathbf{x}\|=r$. Then $d(\mathbf{h}(\cdot, t), B(\mathbf{0}, r), \mathbf{0})$ is constant. Hence it is an odd integer for all $t$ thanks to Borsuk's theorem, because $\mathbf{h}(\cdot, 1)$ is odd. Now let $B(\mathbf{0}, \boldsymbol{\delta})$ be such that $B(\mathbf{0}, \boldsymbol{\delta}) \cap \mathbf{h}(\partial \Omega, 0)=\emptyset$. Then $d(\mathbf{h}(\cdot, 0), B(\mathbf{0}, r), \mathbf{0})=$
$d(\mathbf{h}(\cdot, 0), B(\mathbf{0}, r), \mathbf{z})$ for $\mathbf{z} \in B(\mathbf{0}, \boldsymbol{\delta})$ because the degree is constant on connected components of $\mathbb{R}^{p} \backslash \mathbf{h}(\partial \Omega, 0)$. Hence $\mathbf{z}=\mathbf{h}(\mathbf{x}, 0)=\mathbf{g}(\mathbf{x})-\mathbf{g}(\mathbf{0})$ for some $\mathbf{x} \in B(0, r)$. Thus

$$
\mathbf{g}(B(\mathbf{0}, r)) \supseteq \mathbf{g}(\mathbf{0})+B(\mathbf{0}, \boldsymbol{\delta})
$$

Now with this lemma, it is easy to prove the very important invariance of domain theorem.

A function $\mathbf{f}$ is locally one to one on an open set $\Omega$ if for every $\mathbf{x}_{0} \in \Omega$, there exists $B\left(\mathbf{x}_{0}, r\right) \subseteq \Omega$ such that $\mathbf{f}$ is one to one on $B\left(\mathbf{x}_{0}, r\right)$.

Theorem 23.4.3 (invariance of domain)Let $\Omega$ be any open subset of $\mathbb{R}^{p}$ and let $\mathbf{f}: \Omega \rightarrow \mathbb{R}^{p}$ be continuous and locally one to one. Then $\mathbf{f}$ maps open subsets of $\Omega$ to open sets in $\mathbb{R}^{p}$.

Proof: Let $\overline{B\left(\mathbf{x}_{0}, r\right)} \subseteq \Omega$ where $\mathbf{f}$ is one to one on $\overline{B\left(\mathbf{x}_{0}, r\right)}$. Let $\mathbf{g}$ be defined on $\overline{B(\mathbf{0}, r)}$ given by

$$
\mathbf{g}(\mathbf{x}) \equiv \mathbf{f}\left(\mathbf{x}+\mathbf{x}_{0}\right)
$$

Then $\mathbf{g}$ satisfies the conditions of Lemma 23.4.2, being one to one and continuous. It follows from that lemma there exists $\delta>0$ such that

$$
\begin{aligned}
\mathbf{f}(\Omega) & \supseteq \mathbf{f}\left(B\left(\mathbf{x}_{0}, r\right)\right)=\mathbf{f}\left(\mathbf{x}_{0}+B(\mathbf{0}, r)\right) \\
& =\mathbf{g}(B(\mathbf{0}, r)) \supseteq \mathbf{g}(\mathbf{0})+B(\mathbf{0}, \boldsymbol{\delta}) \\
& =\mathbf{f}\left(\mathbf{x}_{0}\right)+B(\mathbf{0}, \boldsymbol{\delta})=B\left(\mathbf{f}\left(\mathbf{x}_{0}\right), \delta\right)
\end{aligned}
$$

This shows that for any $\mathbf{x}_{0} \in \Omega, \mathbf{f}\left(\mathbf{x}_{0}\right)$ is an interior point of $\mathbf{f}(\Omega)$ which shows $\mathbf{f}(\Omega)$ is open.
With the above, one gets easily the following amazing result. It is something which is clear for linear maps but this is a statement about continuous maps.

Corollary 23.4.4 If $p>m$ there does not exist a continuous one to one map from $\mathbb{R}^{p}$ to $\mathbb{R}^{m}$.

Proof: Suppose not and let $\mathbf{f}$ be such a continuous map,

$$
\mathbf{f}(\mathbf{x}) \equiv\left(f_{1}(\mathbf{x}), \cdots, f_{m}(\mathbf{x})\right)^{T}
$$

Then let $\mathbf{g}(\mathbf{x}) \equiv\left(f_{1}(\mathbf{x}), \cdots, f_{m}(\mathbf{x}), 0, \cdots, 0\right)^{T}$ where there are $p-m$ zeros added in. Then $\mathbf{g}$ is a one to one continuous map from $\mathbb{R}^{p}$ to $\mathbb{R}^{p}$ and so $\mathbf{g}\left(\mathbb{R}^{p}\right)$ would have to be open from the invariance of domain theorem and this is not the case.

Corollary 23.4.5 If $\mathbf{f}$ is locally one to one and continuous, $\mathbf{f}: \mathbb{R}^{p} \rightarrow \mathbb{R}^{p}$, and

$$
\lim _{|\mathbf{x}| \rightarrow \infty}|\mathbf{f}(\mathbf{x})|=\infty
$$

then $\mathbf{f}$ maps $\mathbb{R}^{p}$ onto $\mathbb{R}^{p}$.

Proof: By the invariance of domain theorem, $\mathbf{f}\left(\mathbb{R}^{p}\right)$ is an open set. It is also true that $\mathbf{f}\left(\mathbb{R}^{p}\right)$ is a closed set. Here is why. If $\mathbf{f}\left(\mathbf{x}_{k}\right) \rightarrow \mathbf{y}$, the growth condition ensures that $\left\{\mathbf{x}_{k}\right\}$ is a bounded sequence. Taking a subsequence which converges to $\mathbf{x} \in \mathbb{R}^{p}$ and using the continuity of $\mathbf{f}$, it follows $\mathbf{f}(\mathbf{x})=\mathbf{y}$. Thus $\mathbf{f}\left(\mathbb{R}^{p}\right)$ is both open and closed which implies $\mathbf{f}$ must be an onto map since otherwise, $\mathbb{R}^{p}$ would not be connected.

The next theorem is the famous Brouwer fixed point theorem.
