Then 67.5.13 holds for the stopped process $X^{\tau_{n}}$ and $\Phi$ and $\phi$ replaced with $\Phi \mathscr{X}_{\left[0, \tau_{n}\right]}$ and $\phi \mathscr{X}_{\left[0, \tau_{n}\right]}$ respectively. Then let $n \rightarrow \infty$ in this expression, using the continuity of $X$ and the fact that $\tau_{n} \rightarrow \infty$ to to recover 67.5.13 without the restriction on $|X|$.

### 67.6 The General Stochastically Integrable Case

Now suppose that $\Phi$ is only progressively measurable and stochastically integrable

$$
P\left(\left[\int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t<\infty\right]\right)=1
$$

Also $\phi$ is only progressively measurable and Bochner integrable in $t$. Define a stopping time

$$
\tau(\omega)=\inf \left\{t \geq 0:|X(t, \omega)|_{H}+\int_{0}^{t}\|\Phi\|^{2} d s+\int_{0}^{t}|\phi| d s>C\right\}
$$

This is just the first hitting time of an open set so it is a stopping time. For $t \leq \tau$, all of the above quantities must be no larger than $C$. In particular,

$$
\mathscr{X}_{[0, \tau]} \Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right) .
$$

Then

$$
X^{\tau}(t)=X_{0}+\int_{0}^{t} \mathscr{X}_{[0, \tau]} \phi d s+\int_{0}^{t} \mathscr{X}_{[0, \tau]} \Phi d W
$$

and so 67.5.13 holds with $X \rightarrow X^{\tau}, \Phi \rightarrow \mathscr{X}_{[0, \tau]} \Phi$ and $\phi \rightarrow \mathscr{X}_{[0, \tau]} \phi$. Now simply let $C \rightarrow \infty$ and exploit the continuity of $X$ given by the formula 67.5.12 to obtain the validity of 67.5.13 without any reference to the stopping time. Of course arbitrary $t$ can replace $T$. This leads to the main result.

Theorem 67.6.1 Let $\Phi$ be a progressively measurable with values in $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ which is stochastically integrable in $[0, T]$ because

$$
P\left(\left[\int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t<\infty\right]\right)=1
$$

and let $\phi:[0, T] \times \Omega \rightarrow H$ be progressively measurable and Bochner integrable on $[0, T]$ for a.e. $\omega$, and let $X_{0}$ be $\mathscr{F}_{0}$ measurable and $H$ valued. Let

$$
X(t) \equiv X_{0}+\int_{0}^{t} \phi(s) d s+\int_{0}^{t} \Phi d W
$$

Let $F:[0, T] \times H \times \Omega \rightarrow \mathbb{R}^{1}$ be progressively measurable, have continuous partial derivatives $F_{t}, F_{X}, F_{X X}$ which are uniformly continuous on bounded subsets of $[0, T] \times H$ independent of $\omega \in \Omega$. Also assume $F_{X X}$ is bounded and let $F_{X X X}$ exist and be bounded. Then the following formula holds for a.e. $\omega$.

$$
\begin{gathered}
F(t, X(t))=F\left(0, X_{0}\right)+\int_{0}^{t} F_{X}(\cdot, X(\cdot)) \Phi d W+ \\
\int_{0}^{t} F_{t}(s, X(s))+F_{X}(s, X(s)) \phi(s) d s+\frac{1}{2} \int_{0}^{t}\left(F_{X X}(s, X(s)) \Phi, \Phi\right)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d s
\end{gathered}
$$

The dependence of $F$ on $\omega$ is suppressed.
That last term is interesting and can be written differently. Let $\left\{g_{j}\right\}$ be an orthonormal basis for $Q^{1 / 2} U$. Then this integrand equals

$$
\sum_{i=1}^{L}\left(F_{X X}(s, X(s)) \Phi g_{i}, \Phi g_{i}\right)_{H}=\sum_{i=1}^{L}\left(\Phi^{*} F_{X X}(s, X(s)) \Phi g_{i}, g_{i}\right)_{Q^{1 / 2} H}
$$

and we write this as

$$
\operatorname{trace}\left(\Phi^{*}(s) F_{X X}(s, X(s)) \Phi(s)\right)
$$

A simple special case is where $Q=I$ and then $Q^{1 / 2} U=U$. Thus it is only required that $\Phi$ have values in $\mathscr{L}_{2}(U, H)$.

### 67.7 Remembering The Formula

I find it almost impossible to remember this formula. Here is a way to do it. Recall that $|\Delta W|^{2}$ is like $\Delta t$. Therefore, in what follows, neglect all terms which are like $d W d t, d t^{2}$, but keep terms which are $d W, d t, d W^{2}$. Then you start with $d X=\phi d t+\Phi d W$. Thus for $F(t, X)$,

$$
d F=F_{t} d t+F_{X} d X+\frac{1}{2}\left(F_{X X} d X, d X\right)
$$

other terms from Taylor's formula are neglected because they involve $d t d W$ or $d t^{2}$. Now the above equals

$$
d F=F_{t} d t+F_{X}(\phi d t+\Phi d W)+\frac{1}{2}\left(F_{X X} \Phi d W, \Phi d W\right)
$$

Since the $d W$ occurs twice, in that inner product, you get a $d t$ out of it. Hence you get

$$
d F=\left(F_{t}+F_{X} \phi\right) d t+\frac{1}{2}\left(F_{X X} \Phi, \Phi\right) d t+F_{X} \Phi d W
$$

Now place an $\int_{0}^{t}$ in front of everything and you have the Ito formula.

### 67.8 An Interesting Formula

Suppose everything is real valued and $\phi$ is progressively measurable and in

$$
L^{2}([0, T] \times \Omega)
$$

Let

$$
X(t)=\int_{0}^{t} \phi d W-\frac{1}{2} \int_{0}^{t} \phi^{2} d s
$$

and consider $F(X)=e^{X}$. Then from the Ito formula,

$$
\begin{gathered}
d F=-\left(e^{X} \phi^{2} \frac{1}{2}\right) d t+\frac{1}{2} e^{X} \phi^{2} d t+e^{X} \phi d W \\
d F=e^{X} \phi d W
\end{gathered}
$$

and then do an integral

$$
e^{X(t)}-1=\int_{0}^{t} e^{X} \phi d W
$$

Thus

$$
e^{X(t)}=1+\int_{0}^{t} e^{X(s)} \phi d W
$$

That expression on the right is obviously a local martingale and so the expression on the left is also. To see this, you can use a localizing sequence of stopping times which depend on the size of $X(t)$. This will work fine because $X(t)$ is continuous.

### 67.9 Some Representation Theorems

In this section is a very interesting representation theorem which comes from the Ito formula. In all of this, $\mathbf{W}$ will be a $Q$ Wiener process having values in $\mathbb{R}^{n}$ for which $Q=I$. Recall that, letting

$$
\mathscr{G}_{t} \equiv \sigma(\mathbf{W}(s): s \leq t)
$$

the normal filtration determined by the Wiener process is given by

$$
\mathscr{F}_{t} \equiv \cap_{s>t} \overline{\mathscr{G}}_{s}
$$

where $\overline{\mathscr{G}_{s}}$ is the completion of $\mathscr{G}_{s}$. In this section, the theorems will all feature the smaller filtration $\mathscr{G}_{t}$, not the filtration $\mathscr{F}_{t}$. First here are some simple observations which tie this specialized material to what was presented earlier.

When you have $\mathbf{f}$ an $\mathscr{G}_{t}$ adapted function in $L^{2}\left(\Omega, \mathbb{R}^{n}\right)$, you can consider

$$
\mathbf{f}^{T} \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} \mathbb{R}^{n}, \mathbb{R}\right)\right)
$$

as follows. Letting $\left\{\mathbf{g}_{i}\right\}$ be an orthonormal basis for the subspace $Q^{1 / 2} \mathbb{R}^{n}$ in the norm of $Q^{1 / 2} \mathbb{R}^{n}$,

$$
\|\mathbf{f}\|_{\mathscr{L}_{2}\left(Q^{1 / 2} \mathbb{R}^{n}, \mathbb{R}\right)}^{2} \equiv \sum_{i}\left(\mathbf{f}^{T} \mathbf{g}_{i}\right)^{2}<\infty
$$

For simplicity, let $Q=I$. Then you have the simple situation that

$$
\left\|\mathbf{f}^{T}\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} \mathbb{R}^{n}, \mathbb{R}\right)}=\|\mathbf{f}\|_{\mathbb{R}^{n}}^{2}
$$

In what follows $\mathbf{W}_{t}$ will be the $Q$ Wiener process on $\mathbb{R}^{n}$ where $Q=I$. Then the Ito isometry is nothing more than the following lemma.

Lemma 67.9.1 Let $\mathbf{f}$ be $\mathscr{F}_{t}$ adapted in the sense that every component is $\mathscr{F}_{t}$ adapted and $\mathbf{f} \in L^{2}\left(\Omega ; \mathbb{R}^{n}\right)$. Here $\mathscr{F}_{t}$ is the normal filtration coming from the Wiener process. Then

$$
\left\|\int_{0}^{T} \mathbf{f}(s)^{T} d \mathbf{W}\right\|_{L^{2}(\Omega)}=\|\mathbf{f}\|_{L^{2}\left(\Omega \times[0, T] ; \mathbb{R}^{n}\right)}
$$

Lemma 67.9.2 Let $X \geq 0$ and measurable and integrable. Also define a finite measure $v$ on $\mathscr{B}\left(\mathbb{R}^{p}\right)$ by

$$
v(B) \equiv \int_{\Omega} X \mathscr{X}_{B}(\mathbf{Y}) d P
$$

Then

$$
\int_{\Omega} g(\mathbf{Y}) X d P=\int_{\mathbb{R}^{p}} g(\mathbf{y}) d v(y)
$$

where here $\mathbf{Y}$ is a measurable function with values in $\mathbb{R}^{p}$ and $g \geq 0$ is Borel measurable. Formally, $X d P=d \nu$.

Proof: First say $X=\mathscr{X}_{D}$ and replace $g(\mathbf{Y})$ with $\mathscr{X}_{\mathbf{Y}^{-1}(B)}$. Let

$$
\mu(B) \equiv \int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{B}(\mathbf{Y}) d P
$$

Then

$$
\begin{aligned}
& \int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{\mathbf{Y}^{-1}(B)} d P=P\left(D \cap \mathbf{Y}^{-1}(B)\right) \\
& \int_{\mathbb{R}^{p}} \mathscr{X}_{B}(\mathbf{y}) d \mu(y)=\mu(B) \equiv \int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{B}(\mathbf{Y}) d P \\
&=\int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{\mathbf{Y}^{-1}(B)} d P=P\left(D \cap \mathbf{Y}^{-1}(B)\right)
\end{aligned}
$$

Thus

$$
\int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{\mathbf{Y}^{-1}(B)} d P=\int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{B}(\mathbf{Y}) d P=\int_{\mathbb{R}^{p}} \mathscr{X}_{B}(\mathbf{y}) d \mu(y)
$$

Now let $s_{n}(\mathbf{y}) \uparrow g(\mathbf{y})$, and let $s_{n}(\mathbf{y})=\sum_{k=1}^{m} c_{k} \mathscr{X}_{B_{k}}(\mathbf{y})$ where $B_{k}$ is a Borel set. Then

$$
\begin{gathered}
\int_{\mathbb{R}^{p}} s_{n}(\mathbf{y}) d \mu(y)=\int_{\mathbb{R}^{p}} \sum_{k=1}^{m} c_{k} \mathscr{X}_{B_{k}}(\mathbf{y}) d \mu(\mathbf{y})=\sum_{k=1}^{m} c_{k} \int_{\mathbb{R}^{p}} \mathscr{X}_{B_{k}}(\mathbf{y}) d \mu(\mathbf{y}) \\
=\sum_{k=1}^{m} c_{k} P\left(D \cap \mathbf{Y}^{-1}\left(B_{k}\right)\right) \\
\int_{\Omega} s_{n}(\mathbf{Y}) \mathscr{X}_{D} d P=\sum_{k=1}^{m} c_{k} \int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{B_{k}}(\mathbf{Y}) d P=\sum_{k=1}^{m} c_{k} P\left(D \cap \mathbf{Y}^{-1}\left(B_{k}\right)\right)
\end{gathered}
$$

which is the same thing. Therefore,

$$
\int_{\Omega} s_{n}(\mathbf{Y}) \mathscr{X}_{D} d P=\int_{\mathbb{R}^{p}} s_{n}(\mathbf{y}) d \mu(y)
$$

Now pass to a limit using the monotone convergence theorem to obtain

$$
\int_{\Omega} g(\mathbf{Y}) \mathscr{X}_{D} d P=\int_{\mathbb{R}^{p}} g(\mathbf{y}) d \mu(y)
$$

Next replace $\mathscr{X}_{D}$ with $\sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}}(\omega) \equiv s_{n}(\omega)$, a simple function. Then from what was just shown,

$$
\begin{gathered}
\int_{\Omega} g(\mathbf{Y}) \sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}} d P=\sum_{k=1}^{m} d_{k} \int_{\Omega} g(\mathbf{Y}) \mathscr{X}_{D_{k}} d P \\
=\sum_{k=1}^{m} d_{k} \int_{\mathbb{R}^{p}} g(\mathbf{y}) d \mu_{k}
\end{gathered}
$$

where $\mu_{k}(B) \equiv \int_{\Omega} \mathscr{X}_{D_{k}} \mathscr{X}_{B}(\mathbf{Y}) d P$. Now let

$$
v_{n}(B) \equiv \int_{\Omega} \sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}} \mathscr{X}_{B}(\mathbf{Y})=\int_{\Omega} s_{n} \mathscr{X}_{B}(\mathbf{Y}) d P
$$

Then

$$
v_{n}(B)=\sum_{k=1}^{m} d_{k} \int_{\Omega} \mathscr{X}_{D_{k}} \mathscr{X}_{B}(\mathbf{Y}) d P=\sum_{k=1}^{m} d_{k} \mu_{k}(B)
$$

Hence

$$
\begin{aligned}
\int_{\Omega} g(\mathbf{Y}) s_{n} d P & =\int_{\Omega} g(\mathbf{Y}) \sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}} d P=\sum_{k=1}^{m} d_{k} \int_{\mathbb{R}^{p}} g(\mathbf{y}) d \mu_{k} \\
& =\int_{\mathbb{R}^{p}} g(\mathbf{y}) \sum_{k=1}^{m} d_{k} d \mu_{k}=\int_{\mathbb{R}^{p}} g(\mathbf{y}) d v_{n}
\end{aligned}
$$

Then let $s_{n}(\omega) \uparrow X(\omega)$. Clearly $v_{n} \ll v$ and so by the Radon Nikodym theorem $d v_{n}=$ $h_{n} d v$. Then by the monotone convergence theorem, for any $B$ Borel in $\mathbb{R}^{p}$,

$$
\int_{B} h_{n} d v=v_{n}(B) \equiv \int_{\Omega} s_{n}(\omega) \mathscr{X}_{B}(\mathbf{Y}(\omega)) d P \uparrow \int_{\Omega} X(\omega) \mathscr{X}_{B}(\mathbf{Y}(\omega)) d P \equiv v(B)
$$

Thus for each $B$ Borel, $0 \leq h_{n} \leq 1$ and

$$
\int_{B} h_{n} d v \rightarrow v(B)
$$

and so $h_{n} \uparrow 1 v$ a.e. Thus, from the above,

$$
\int_{\Omega} g(\mathbf{Y}) s_{n} d P=\int_{\mathbb{R}^{p}} g(\mathbf{y}) d v_{n}=\int_{\mathbb{R}^{p}} g(\mathbf{y}) h_{n}(\mathbf{y}) d v
$$

It follows from the monotone convergence theorem that one can pass to a limit in the above and obtain

$$
\int_{\Omega} g(\mathbf{Y}) X d P=\int_{\mathbb{R}^{p}} g(\mathbf{y}) d v
$$

Note that the same conclusion will hold if the functions are suitably integrable without any restriction on the sign. In particular, this will hold if $g(\mathbf{y})$ is bounded. One just considers positive and negative parts of real and imaginary parts of $g$ and applies the above lemma.

Let

$$
\mathscr{G}_{t} \equiv \sigma(\mathbf{W}(s): s \leq t)
$$

thus the normal filtration for the Wiener process and the Ito integral and so forth is

$$
\mathscr{F}_{t}=\cap_{s>t} \overline{\mathscr{G}_{s}}
$$

Lemma 67.9.3 Let $\mathbf{h}$ be a deterministic step function of the form

$$
\mathbf{h}=\sum_{i=0}^{m-1} \mathbf{a}_{i} \mathscr{X}_{\left[t_{i}, t_{i+1}\right)}, t_{m}=t
$$

Then for $\mathbf{h}$ of this form, linear combinations of functions of the form

$$
\begin{equation*}
\exp \left(\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} \int_{0}^{t} \mathbf{h} \cdot \mathbf{h} d \tau\right) \tag{67.9.14}
\end{equation*}
$$

are dense in $L^{2}\left(\Omega, \mathscr{G}_{t}, P\right)$ for each $t$.

Proof: I will show in the process of the proof that functions of the form 67.9.14 are in $L^{2}(\Omega, P)$. Let $g \in L^{2}\left(\Omega, \mathscr{G}_{t}, P\right)$ be such that

$$
\begin{aligned}
& \int_{\Omega} g(\omega) \exp \left(\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} \int_{0}^{t} \mathbf{h} \cdot \mathbf{h} d \tau\right) d P \\
= & \exp \left(-\frac{1}{2} \int_{0}^{t} \mathbf{h} \cdot \mathbf{h} d \tau\right) \int_{\Omega} g(\omega) \exp \left(\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}\right) d P=0
\end{aligned}
$$

for all such $\mathbf{h}$. It is required to show that whenever this happens for all such functions $\exp \left(\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} \int_{0}^{t} \mathbf{h} \cdot \mathbf{h} d t\right)$ then $g=0$.

Letting $\mathbf{h}$ be given as above, $\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}$

$$
\begin{align*}
& =\sum_{i=0}^{m-1} \mathbf{a}_{i}^{T}\left(\mathbf{W}\left(t_{i+1}\right)-\mathbf{W}\left(t_{i}\right)\right)  \tag{67.9.15}\\
& =\sum_{i=1}^{m} \mathbf{a}_{i-1}^{T} \mathbf{W}\left(t_{i}\right)-\sum_{i=0}^{m-1} \mathbf{a}_{i}^{T} \mathbf{W}\left(t_{i}\right) \\
& =\sum_{i=1}^{m-1}\left(\mathbf{a}_{i-1}^{T}-\mathbf{a}_{i}^{T}\right) \mathbf{W}\left(t_{i}\right)+\mathbf{a}_{0}^{T} \mathbf{W}\left(t_{0}\right)+\mathbf{a}_{n-1}^{T} \mathbf{W}\left(t_{n}\right) . \tag{67.9.16}
\end{align*}
$$

Also 67.9.15 shows $\exp \left(\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}\right)$ is in $L^{2}(\Omega, P)$. To see this recall the $\mathbf{W}\left(t_{i+1}\right)-\mathbf{W}\left(t_{i}\right)$ are independent and the density of $\mathbf{W}\left(t_{i+1}\right)-\mathbf{W}\left(t_{i}\right)$ is

$$
C\left(n, \Delta t_{i}\right) \exp \left(-\frac{1}{2} \frac{|\mathbf{x}|^{2}}{\left(t_{i+1}-t_{i}\right)}\right), \Delta t_{i} \equiv t_{i+1}-t_{i}
$$

so

$$
\begin{aligned}
& \int_{\Omega}\left(\exp \left(\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}\right)\right)^{2} d P=\int_{\Omega} \exp \left(2 \int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}\right) d P \\
& =\int_{\Omega} \exp \left(\sum_{i=0}^{m-1} 2 \mathbf{a}_{i}^{T}\left(\mathbf{W}\left(t_{i+1}\right)-\mathbf{W}\left(t_{i}\right)\right)\right) d P \\
& =\int_{\Omega}^{m-1} \prod_{i=0}^{m} \exp \left(2 \mathbf{a}_{i}^{T}\left(\mathbf{W}\left(t_{i+1}\right)-\mathbf{W}\left(t_{i}\right)\right)\right) d P \\
& =\prod_{i=0}^{m-1} \int_{\Omega} \exp \left(2 \mathbf{a}_{i}^{T}\left(\mathbf{W}\left(t_{i+1}\right)-\mathbf{W}\left(t_{i}\right)\right)\right) d P \\
& =\prod_{i=0}^{m-1} \int_{\mathbb{R}^{n}} C\left(n, \Delta t_{i}\right) \exp \left(2 \mathbf{a}_{i}^{T} \mathbf{x}\right) \exp \left(-\frac{1}{2} \frac{|\mathbf{x}|^{2}}{\Delta t_{i}}\right) d x<\infty
\end{aligned}
$$

Choosing the $\mathbf{a}_{i}$ appropriately in 67.9.16, the formula in 67.9.16 is of the form

$$
\sum_{i=0}^{m} \mathbf{y}_{i}^{T} \mathbf{W}_{t_{i}}
$$

where $\mathbf{y}_{i}$ is an arbitrary vector in $\mathbb{R}^{n}$. It follows that for all choices of $\mathbf{y}_{j} \in \mathbb{R}^{n}$,

$$
\int_{\Omega} g(\omega) \exp \left(\sum_{j=0}^{m} \mathbf{y}_{j}^{T} \mathbf{W}_{t_{j}}(\omega)\right) d P=0
$$

Now the mapping

$$
\mathbf{y}=\left(\mathbf{y}_{0}, \cdots, \mathbf{y}_{m}\right) \rightarrow \int_{\Omega} g(\omega) \exp \left(\sum_{j=0}^{m} \mathbf{y}_{j}^{T} \mathbf{W}_{t_{j}}(\omega)\right) d P
$$

is analytic on $\mathbb{C}^{(m+1) n}$ and equals zero on $\mathbb{R}^{(m+1) n}$ so from standard complex variable theory, this analytic function must equal zero on $\mathbb{C}^{(m+1) n}$, not just on $\mathbb{R}^{(m+1) n}$. In particular, for all $\mathbf{y}=\left(\mathbf{y}_{0}, \cdots, \mathbf{y}_{m}\right) \in \mathbb{R}^{n(m+1)}$,

$$
\begin{equation*}
\int_{\Omega} g(\omega) \exp \left(\sum_{j=0}^{m} i \mathbf{y}_{j}^{T} \mathbf{W}_{t_{j}}(\omega)\right) d P=0 \tag{67.9.17}
\end{equation*}
$$

This left side equals

$$
\int_{\Omega} g_{+}(\omega) \exp \left(\sum_{j=0}^{m} i \mathbf{y}_{j}^{T} \mathbf{W}_{t_{j}}(\omega)\right) d P-\int_{\Omega} g_{-}(\omega) \exp \left(\sum_{j=0}^{m} i \mathbf{y}_{j}^{T} \mathbf{W}_{t_{j}}(\omega)\right) d P
$$

where $g_{+}$and $g_{-}$are the positive and negative parts of $g$. By the Lemma 67.9.2 and the observation at the end, this equals

$$
\int_{\mathbb{R}^{n m}} \exp \left(\sum_{j=0}^{m} i \mathbf{y}_{j}^{T} \mathbf{x}_{j}\right) d v_{+}-\int_{\mathbb{R}^{n m}} \exp \left(\sum_{j=0}^{m} i \mathbf{y}_{j}^{T} \mathbf{x}_{j}\right) d v_{-}
$$

where $v_{+}(B) \equiv \int_{\Omega} g_{+}(\omega) \mathscr{X}_{B}\left(\mathbf{W}_{t_{1}}(\omega), \cdots, \mathbf{W}_{t_{m}}(\omega)\right) d P$ and $v_{-}$is defined similarly. Then letting $v$ be the measure $v_{+}-v_{-}$, it follows that

$$
0=\int_{\mathbb{R}^{n m}} \exp \left(\sum_{j=0}^{m} i \mathbf{y}_{j}^{T} \mathbf{x}_{j}\right) d v(y)
$$

and this just says that the inverse Fourier transform of $v$ is 0 . It follows that $v=0$. Thus

$$
\begin{aligned}
& \int_{\Omega} g(\omega) \mathscr{X}_{B}\left(\mathbf{W}_{t_{1}}(\omega), \cdots, \mathbf{W}_{t_{m}}(\omega)\right) d P \\
= & \int_{\Omega} g(\omega) \mathscr{X}_{\mathbf{W}_{m}^{-1}(B)}(\omega) d P=0
\end{aligned}
$$

for every $B$ Borel in $\mathbb{R}^{n m}$ where

$$
\mathbf{W}_{m}(\omega) \equiv\left(\mathbf{W}_{t_{1}}(\omega), \cdots, \mathbf{W}_{t_{m}}(\omega)\right)
$$

Let $\mathscr{K}$ be the $\pi$ system defined as $\mathbf{W}_{m}^{-1}(B)$ for $B$ of the form $\prod_{i=1}^{m} U_{i}$ where $U_{i}$ is open in $\mathbb{R}^{n}$, this for some $m$ a positive integer. This is indeed a $\pi$ system because it includes
$\mathbf{W}_{1}^{-1}\left(\mathbb{R}^{n}\right)=\Omega$ and the empty set. Also it is closed with respect to intersections because, in the situation where each $s_{i}$ is larger than every $t_{i}$,

$$
\begin{aligned}
& \left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m_{1}}}\right)^{-1}\left(\prod_{i=1}^{m_{1}} U_{i}\right) \cap\left(\mathbf{W}_{s_{1}}, \cdots, \mathbf{W}_{s_{m_{2}}}\right)^{-1}\left(\prod_{i=1}^{m_{2}} V_{i}\right)= \\
& \left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m_{1}}}, \mathbf{W}_{s_{1}}, \cdots, \mathbf{W}_{s_{m_{2}}}\right)^{-1}\left(\prod_{i=1}^{m_{1}} U_{i} \times \prod_{k=1}^{m_{2}} \mathbb{R}^{n}\right) \\
& \cap\left(\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m_{1}}}, \mathbf{W}_{s_{1}}, \cdots, \mathbf{W}_{s_{m_{2}}}\right)^{-1}\left(\prod_{i=1}^{m_{1}} \mathbb{R}^{n} \times \prod_{k=1}^{m_{2}} V_{i}\right)\right) \\
& =\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m_{1}}}, \mathbf{W}_{s_{1}}, \cdots, \mathbf{W}_{s_{m_{2}}}\right)^{-1}\left(\prod_{i=1}^{m_{1}} U_{i} \times \prod_{k=1}^{m_{2}} V_{k}\right)
\end{aligned}
$$

In general, you would just make the obvious modification where you insert a copy of $\mathbb{R}^{n}$ in the appropriate position after rearranging so that the indices are increasing. It was just shown that $\mathscr{K} \subseteq \mathscr{G}$ where

$$
\mathscr{G} \equiv\left\{U \in \mathscr{G}_{t}: \int_{\Omega} g \mathscr{X}_{U} d P=0\right\}
$$

Now it is clear that $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. The case of complements goes as follows. $\Omega \in \mathscr{K}$ and so if $U \in \mathscr{G}$,

$$
\int_{\Omega} g \mathscr{X}_{U}{ }^{C} d P+\int_{\Omega} g \mathscr{X}_{U} d P=\int_{\Omega} g d P
$$

The last on the left and the integral on the right are both 0 so it follows that $\int_{\Omega} g \mathscr{X}_{U}{ }^{c} d P=0$ also. It follows from Dynkin's lemma that $\mathscr{G} \supseteq \sigma(\mathscr{K})$. Now $\sigma(\mathscr{K})$ is $\sigma(\mathbf{W}(u): u \leq t) \equiv$ $\mathscr{G}_{t}$. Hence, $\mathscr{G}=\mathscr{G}_{t}$ and so $g$ is in $L^{2}\left(\Omega, \mathscr{G}_{t}\right)$ and for every $U \in \mathscr{G}_{t}$,

$$
\int_{\Omega} g \mathscr{X}_{U} d P=0
$$

which requires $g=0$. Thus functions of the above form are indeed dense in $L^{2}\left(\Omega, \mathscr{G}_{t}\right)$.
Note that this involves $g$ being $\mathscr{G}_{t}$ measurable, not $\mathscr{F}_{t}$ measurable. It is not clear to me whether it suffices to assume only that $g$ is $\mathscr{F}_{t}$ measurable. If true, this above has not proved it. The problem is the argument at the end using Dynkin's lemma to conclude that $g=0$.

Why such a funny lemma? It is because of the following computation which depends on Itô's formula. Let

$$
X=\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} \int_{0}^{t} \mathbf{h} \cdot \mathbf{h} d \tau
$$

and $g(x)=e^{x}$ and consider $g(X)=Y$. Recall the Ito formula. Formally,

$$
d Y=g^{\prime}(X) d X+\frac{1}{2} g^{\prime \prime}(X)(d X)^{2}
$$

$$
\begin{aligned}
& d Y= g(X)\left(\mathbf{h}^{T} d \mathbf{W}-\frac{1}{2}|\mathbf{h}|^{2} d t\right) \\
&+\frac{1}{2} g(X)\left(\mathbf{h}^{T} d \mathbf{W}-\frac{1}{2}|\mathbf{h}|^{2} d t\right)\left(\mathbf{h}^{T} d \mathbf{W}-\frac{1}{2}|\mathbf{h}|^{2} d t\right) \\
&=Y\left(\mathbf{h}^{T} d \mathbf{W}-\frac{1}{2}|\mathbf{h}|^{2} d t\right)+\frac{1}{2} Y\left[\left(\mathbf{h}^{T} d \mathbf{W}\right)\left(\mathbf{h}^{T} d \mathbf{W}\right)-\mathbf{h}^{T} d \mathbf{W}|\mathbf{h}|^{2} d t+\frac{1}{4}|\mathbf{h}|^{2} d t^{2}\right]
\end{aligned}
$$

Then neglecting the terms of the form $d \mathbf{W} d t, d t^{2}$ and so forth,

$$
d Y=Y \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} Y|\mathbf{h}|^{2} d t+\frac{1}{2} Y\left(\mathbf{h}^{T} d \mathbf{W}\right)\left(\mathbf{h}^{T} d \mathbf{W}\right)
$$

Now the $d \mathbf{W}$ occurs twice in the last term so it leads to a $d t$ and you get

$$
\begin{aligned}
d Y & =Y \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} Y|\mathbf{h}|^{2} d t+\frac{1}{2}\left(Y \mathbf{h}^{T}, \mathbf{h}^{T}\right) d t \\
d Y & =Y \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} Y|\mathbf{h}|^{2} d t+\frac{1}{2} Y|\mathbf{h}|^{2} d t \\
d Y & =Y \mathbf{h}^{T} d \mathbf{W}
\end{aligned}
$$

Note that $\left\|\mathbf{h}^{T}\right\|_{\mathscr{L}_{2}\left(\mathbb{R}^{n}, \mathbb{R}\right)} \equiv \sum_{k=1}^{n}\left(\mathbf{h}^{T} \mathbf{e}_{k}\right)^{2}=|\mathbf{h}|_{\mathbb{R}^{n}}^{2}$. Place an $\int_{0}^{t}$ in place of both sides to obtain

$$
\begin{align*}
Y(t)-Y(0) & =\int_{0}^{t} Y \mathbf{h}^{T} d \mathbf{W} \\
Y(t) & =1+\int_{0}^{t} Y \mathbf{h}^{T} d \mathbf{W} \tag{67.9.18}
\end{align*}
$$

Now here is the interesting part of this formula.

$$
E\left(\int_{0}^{t} Y \mathbf{h}^{T} d \mathbf{W}\right)=0
$$

because the stochastic integral is a martingale and equals 0 at $t=0$.

$$
E\left(\int_{0}^{t} Y \mathbf{h}^{T} d \mathbf{W}\right)=E\left(E\left(\int_{0}^{t} Y \mathbf{h}^{T} d \mathbf{W} \mid \mathscr{F}_{0}\right)\right)=0
$$

Thus

$$
E(Y(t))=1
$$

and for $Y$ one obtains

$$
\begin{aligned}
Y(t) & =E(Y(t))+\int_{0}^{t} Y \mathbf{h}^{T} d \mathbf{W} \\
& \equiv E(Y(t))+\int_{0}^{t} \mathbf{f}^{T} d \mathbf{W}
\end{aligned}
$$

where $\mathbf{f}^{T}$ is adapted and square integrable. It is just $Y \mathbf{h}^{T}$ where $\mathbf{h}$ does not depend on $\omega$ and $Y$ is a function of an adapted function.

Does such a function $\mathbf{f}$ exist for all $F \in L^{2}\left(\Omega, \mathscr{G}_{t}, P\right)$ ? The answer is yes and this is the content of the next theorem which is called the Itô representation theorem.

Theorem 67.9.4 Let $F \in L^{2}\left(\Omega, \mathscr{G}_{t}, P\right)$. Then there exists a unique $\mathscr{G}_{t}$ adapted

$$
\mathbf{f} \in L^{2}\left(\Omega \times[0, t] ; \mathbb{R}^{n}\right)
$$

such that $F=E(F)+\int_{0}^{t} \mathbf{f}(s, \omega)^{T} d \mathbf{W}$.
Proof: By Lemma 67.9.3, the span of functions of the form

$$
\exp \left(\int_{0}^{t} \mathbf{h}^{T} d \mathbf{W}-\frac{1}{2} \int_{0}^{t} \mathbf{h} \cdot \mathbf{h} d t\right)
$$

where $\mathbf{h}$ is a vector valued deterministic step function of the sort described in this lemma, are dense in $L^{2}\left(\Omega, \mathscr{G}_{t}, P\right)$. Given $F \in L^{2}\left(\Omega, \mathscr{G}_{t}, P\right),\left\{G_{k}\right\}_{k=1}^{\infty}$ be functions in the subspace of linear combinations of the above functions which converge to $F$ in $L^{2}\left(\Omega, \mathscr{G}_{t}, P\right)$. For each of these functions there exists $\mathbf{f}_{k}$ an adapted step function such that

$$
G_{k}=E\left(G_{k}\right)+\int_{0}^{t} \mathbf{f}_{k}(s, \omega)^{T} d \mathbf{W}
$$

Then from the Itô isometry, and the observation that $E\left(G_{k}-G_{l}\right)^{2} \rightarrow 0$ as $k, l \rightarrow \infty$ by the above definition of $G_{k}$ in which the $G_{k}$ converge to $F$ in $L^{2}(\Omega)$,

$$
\begin{align*}
& 0= \lim _{k, l \rightarrow \infty} E\left(\left(G_{k}-G_{l}\right)^{2}\right) \\
&= \lim _{k, l \rightarrow \infty} E\left(\left(E\left(G_{k}\right)+\int_{0}^{t} \mathbf{f}_{k}(s, \omega)^{T} d \mathbf{W}-\left(E\left(G_{l}\right)+\int_{0}^{t} \mathbf{f}_{l}(s, \omega)^{T} d \mathbf{W}\right)\right)^{2}\right) \\
&= \lim _{k, l \rightarrow \infty}\left\{E\left(G_{k}-G_{l}\right)^{2}+2 E\left(G_{k}-G_{l}\right) \int_{\Omega} \int_{0}^{t}\left(\mathbf{f}_{k}-\mathbf{f}_{l}\right)^{T} d \mathbf{W} d P\right. \\
&\left.+\int_{\Omega}\left(\int_{0}^{t}\left(\mathbf{f}_{k}-\mathbf{f}_{l}\right)^{T} d \mathbf{W}\right)^{2} d P\right\} \\
&= \lim _{k, l \rightarrow \infty}\left\{E\left(G_{k}-G_{l}\right)^{2}+\int_{\Omega}\left(\int_{0}^{t}\left(\mathbf{f}_{k}-\mathbf{f}_{l}\right)^{T} d \mathbf{W}\right)^{2} d P\right\}= \\
& \lim _{k, l \rightarrow \infty} \int_{\Omega}\left(\int_{0}^{t}\left(\mathbf{f}_{k}-\mathbf{f}_{l}\right)^{T} d \mathbf{W}\right)^{2} d P=\lim _{k, l \rightarrow \infty}\left\|\mathbf{f}_{k}-\mathbf{f}_{l}\right\|_{L^{2}\left(\Omega \times[0, T] ; \mathbb{R}^{n}\right)} \tag{67.9.19}
\end{align*}
$$

Going from the third to the fourth equations, is justified because

$$
\int_{\Omega} \int_{0}^{t}\left(\mathbf{f}_{k}-\mathbf{f}_{l}\right)^{T} d \mathbf{W} d P=0
$$

thanks to the fact that the Ito integral is a martingale which equals 0 at $t=0$.
This shows $\left\{\mathbf{f}_{k}\right\}_{k=1}^{\infty}$ is a Cauchy sequence in $L^{2}\left(\Omega \times[0, t] ; \mathbb{R}^{n}, \mathscr{P}\right)$, where $\mathscr{P}$ denotes the progressively measurable sets. It follows there exists a subsequence and

$$
\mathbf{f} \in L^{2}\left(\Omega \times[0, t] ; \mathbb{R}^{n}\right)
$$

such that $\mathbf{f}_{k}$ converges to $\mathbf{f}$ in $L^{2}\left(\Omega \times[0, t] ; \mathbb{R}^{n}, \mathscr{P}\right)$ with $\mathbf{f}$ being progressively measurable. Then by the Itô isometry and the equation

$$
G_{k}=E\left(G_{k}\right)+\int_{0}^{t} \mathbf{f}_{k}(s, \omega)^{T} d \mathbf{W}
$$

you can pass to the limit as $k \rightarrow \infty$ and obtain

$$
F=E(F)+\int_{0}^{t} \mathbf{f}(s, \omega)^{T} d \mathbf{W}
$$

Now $E\left(G_{k}\right) \rightarrow E(F)$. Consider the stochastic integrals. By the maximal estimate, Theorem 62.9.4, and the Ito isometry,

$$
\begin{aligned}
& P(\sup _{s \in[0, t]} \overbrace{\left|\int_{0}^{s} \mathbf{f}_{k}(\cdot, \omega)^{T} d \mathbf{W}-\int_{0}^{s} \mathbf{f}(\cdot, \omega)^{T} d \mathbf{W}\right|}^{\text {nonnegative submartingale }}>\delta) \\
< & \frac{E\left(\left|\int_{0}^{t} \mathbf{f}_{k}(\cdot, \omega)^{T} d \mathbf{W}-\int_{0}^{t} \mathbf{f}(\cdot, \omega)^{T} d \mathbf{W}\right|^{2}\right)}{\delta^{2}} \\
= & \frac{E\left(\int_{0}^{t}\left\|\mathbf{f}_{k}-\mathbf{f}\right\|_{\mathbb{R}^{n}}^{2} d s\right)}{\delta^{2}}
\end{aligned}
$$

From the above convergence result and an application of the Borel Cantelli lemma, there is a set of measure zero $N$ and a subsequence, still denoted as $\mathbf{f}_{k}$ such that for $\omega \notin N$, the convergence of the stochastic integrals for this subsequence is uniform. Thus for $\omega \notin N$,

$$
F=E(F)+\int_{0}^{t} \mathbf{f}(s, \omega)^{T} d \mathbf{W}
$$

This proves the existence part of this theorem.
It remains to consider the uniqueness. Suppose then that

$$
F=E(F)+\int_{0}^{T} \mathbf{f}(t, \omega)^{T} d \mathbf{W}=E(F)+\int_{0}^{T} \mathbf{f}_{1}(t, \omega)^{T} d \mathbf{W}
$$

Then

$$
\int_{0}^{T} \mathbf{f}(t, \omega)^{T} d \mathbf{W}=\int_{0}^{T} \mathbf{f}_{1}(t, \omega)^{T} d \mathbf{W}
$$

and so

$$
\int_{0}^{T}\left(\mathbf{f}(t, \omega)^{T}-\mathbf{f}_{1}(t, \omega)^{T}\right) d \mathbf{W}=0
$$

and by the Itô isometry,

$$
0=\left\|\int_{0}^{T}\left(\mathbf{f}(t, \omega)^{T}-\mathbf{f}_{1}(t, \omega)^{T}\right) d \mathbf{W}\right\|_{L^{2}(\Omega)}=\left\|\mathbf{f}-\mathbf{f}_{1}\right\|_{L^{2}\left(\Omega \times[0, T] ; \mathbb{R}^{n}\right)}
$$

which proves uniqueness.
With the above major result, here is another interesting representation theorem. Recall that if you have an $\mathscr{F}_{t}$ adapted function $\mathbf{f}$ and $\mathbf{f} \in L^{2}\left(\Omega \times[0, T] ; \mathbb{R}^{n}\right)$, then $\int_{0}^{t} \mathbf{f}^{T} d \mathbf{W}$ is a martingale. The next theorem is sort of a converse. It starts with a $\mathscr{G}_{t}$ martingale and represents it as an Itô integral. In this theorem, $\mathscr{G}_{t}$ continues to be the filtration determined by $n$ dimensional Wiener process.

Theorem 67.9.5 Let $M$ be an $\mathscr{G}_{t}$ martingale and suppose $M(t) \in L^{2}(\Omega)$ for all $t \geq 0$. Then there exists a unique stochastic process, $\mathbf{g}(s, \omega)$ such that $\mathbf{g}$ is $\mathscr{G}_{t}$ adapted and in $L^{2}(\Omega \times[0, t])$ for each $t>0$, and for all $t \geq 0$,

$$
M(t)=E(M(0))+\int_{0}^{t} \mathbf{g}^{T} d \mathbf{W}
$$

Proof: First suppose $\mathbf{f}$ is an adapted function of the sort that $\mathbf{g}$ is. Then the following claim is the first step in the proof.

Claim: Let $t_{1}<t_{2}$. Then

$$
E\left(\int_{t_{1}}^{t_{2}} \mathbf{f}^{T} d \mathbf{W} \mid \mathscr{G}_{t_{1}}\right)=0
$$

Proof of claim: This follows from the fact that the Ito integral is a martingale adapted to $\mathscr{G}_{t}$. Hence the above reduces to

$$
E\left(\int_{0}^{t_{2}} \mathbf{f}^{T} d \mathbf{W}-\int_{0}^{t_{1}} \mathbf{f}^{T} d \mathbf{W} \mid \mathscr{G}_{t_{1}}\right)=\int_{0}^{t_{1}} \mathbf{f}^{T} d \mathbf{W}-\int_{0}^{t_{1}} \mathbf{f}^{T} d \mathbf{W}=0
$$

Now to prove the theorem, it follows from Theorem 67.9.4 and the assumption that $M$ is a martingale that for $t>0$ there exists $\mathbf{f}^{t} \in L^{2}\left(\Omega \times[0, T] ; \mathbb{R}^{n}\right)$ such that

$$
\begin{aligned}
M(t) & =E(M(t))+\int_{0}^{t} \mathbf{f}^{t}(s, \cdot)^{T} d \mathbf{W} \\
& =E(M(0))+\int_{0}^{t} \mathbf{f}^{t}(s, \cdot)^{T} d \mathbf{W}
\end{aligned}
$$

Now let $t_{1}<t_{2}$. Then since $M$ is a martingale and so is the Ito integral,

$$
\begin{gathered}
M\left(t_{1}\right)=E\left(M\left(t_{2}\right) \mid \mathscr{G}_{t_{1}}\right)=E\left(E(M(0))+\int_{0}^{t_{2}} \mathbf{f}^{t_{2}}(s, \cdot)^{T} d \mathbf{W} \mid \mathscr{G}_{t_{1}}\right) \\
=E(M(0))+E\left(\int_{0}^{t_{1}} \mathbf{f}^{t_{2}}(s, \cdot)^{T} d \mathbf{W}\right)
\end{gathered}
$$

Thus

$$
M\left(t_{1}\right)=E(M(0))+\int_{0}^{t_{1}} \mathbf{f}^{t_{2}}(s, \cdot)^{T} d \mathbf{W}=E(M(0))+\int_{0}^{t_{1}} \mathbf{f}^{t_{1}}(s, \cdot)^{T} d \mathbf{W}
$$

and so

$$
0=\int_{0}^{t_{1}} \mathbf{f}^{t_{1}}(s, \cdot)^{T} d \mathbf{W}-\int_{0}^{t_{1}} \mathbf{f}^{t_{2}}(s, \cdot)^{T} d \mathbf{W}
$$

and so by the Itô isometry,

$$
\left\|\mathbf{f}^{t_{1}}-\mathbf{f}^{t_{2}}\right\|_{L^{2}\left(\Omega \times\left[0, t_{1}\right] ; \mathbb{R}^{n}\right)}=0
$$

Letting $N \in \mathbb{N}$, it follows that

$$
M(t)=E(M(0))+\int_{0}^{t} \mathbf{f}^{N}(s, \cdot)^{T} d \mathbf{W}
$$

for all $t \leq N$. Let $\mathbf{g}=\mathbf{f}^{N}$ for $t \in[0, N]$. Then asside from a set of measure zero, this is well defined and for all $t \geq 0$

$$
M(t)=E(M(0))+\int_{0}^{t} \mathbf{g}(s, \cdot)^{T} d \mathbf{W}
$$

Surely this is an incredible theorem. Note that it implies all the martingales adapted to $\mathscr{G}_{t}$ which are in $L^{2}$ for each $t$ must be continuous a.e. and are obtained from an Ito integral. Also, any such martingale satisfies $M(0)=E(M(0))$. Isn't that amazing? Also note that this featured $\mathbb{R}^{n}$ as where $\mathbf{W}$ has its values and $n$ was arbitrary. One could have $n=1$ if desired.

The above theorems can also be obtained from another approach. It involves showing that random variables of the form

$$
\phi\left(\mathbf{W}\left(t_{1}\right), \cdots, \mathbf{W}\left(t_{k}\right)\right)
$$

are dense in $L^{2}\left(\Omega, \mathscr{G}_{T}\right)$. This theorem is interesting for its own sake and it involves interesting results discussed earlier. Recall the Doob Dynkin lemma, Lemma 59.3.6 on Page 1866 which is listed here.

Lemma 67.9.6 Suppose $\mathbf{X}, \mathbf{Y}_{1}, \mathbf{Y}_{2}, \cdots, \mathbf{Y}_{k}$ are random vectors, $\mathbf{X}$ having values in $\mathbb{R}^{n}$ and $\mathbf{Y}_{j}$ having values in $\mathbb{R}^{p_{j}}$ and

$$
\mathbf{X}, \mathbf{Y}_{j} \in L^{1}(\Omega)
$$

Suppose $\mathbf{X}$ is $\sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ measurable. Thus

$$
\left\{\mathbf{X}^{-1}(E): E \text { Borel }\right\} \subseteq\left\{\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)^{-1}(F): F \text { is Borel in } \prod_{j=1}^{k} \mathbb{R}^{p_{j}}\right\}
$$

Then there exists a Borel function, $\mathbf{g}: \prod_{j=1}^{k} \mathbb{R}^{p_{j}} \rightarrow \mathbb{R}^{n}$ such that

$$
\mathbf{X}=\mathbf{g}(\mathbf{Y}) .
$$

Recall also the submartingale convergence theorem.
Theorem 67.9.7 (submartingale convergence theorem) Let

$$
\left\{\left(X_{i}, \mathscr{S}_{i}\right)\right\}_{i=1}^{\infty}
$$

be a submartingale with $K \equiv \sup E\left(\left|X_{n}\right|\right)<\infty$. Then there exists a random variable $X$, such that $E(|X|) \leq K$ and

$$
\lim _{n \rightarrow \infty} X_{n}(\omega)=X(\omega) \text { a.e. }
$$

Recall

$$
\mathscr{G}_{t} \equiv \sigma(\mathbf{W}(u)-\mathbf{W}(r): 0 \leq r<u \leq t)
$$

It suffices to consider only $t$ and $u, r$ in a countable dense subset of $\mathbb{R}$ denoted as $D$. This follows from continuity of the Wiener process. To see this, let $0 \leq r<u \leq t U$ be open and $U_{n} \uparrow U$ where each $U_{n}$ is open and $\overline{U_{n}} \subseteq U_{n+1}, \cup_{n} U_{n}=U$. Then letting $u_{n} \uparrow u$ and $r_{n} \uparrow r, u_{n} r_{n}$ being in the countable dense set,

$$
\begin{aligned}
(\mathbf{W}(u)-\mathbf{W}(r))^{-1}\left(U_{n}\right) & \subseteq \cup_{k=1}^{\infty} \cap_{j \geq k}\left(\mathbf{W}\left(u_{j}\right)-\mathbf{W}\left(r_{j}\right)\right)^{-1}\left(U_{n}\right) \\
& \subseteq(\mathbf{W}(u)-\mathbf{W}(r))^{-1}\left(\overline{U_{n}}\right)
\end{aligned}
$$

and so

$$
\begin{aligned}
(\mathbf{W}(u)-\mathbf{W}(r))^{-1}(U) & =\cup_{n}(\mathbf{W}(u)-\mathbf{W}(r))^{-1}\left(U_{n}\right) \\
& \subseteq \cup_{n=1}^{\infty} \cup_{k=1}^{\infty} \cap_{j \geq k}\left(\mathbf{W}\left(u_{j}\right)-\mathbf{W}\left(r_{j}\right)\right)^{-1}\left(U_{n}\right) \\
& \subseteq \cup_{n}(\mathbf{W}(u)-\mathbf{W}(r))^{-1}\left(\overline{U_{n}}\right)=(\mathbf{W}(u)-\mathbf{W}(r))^{-1}(U)
\end{aligned}
$$

Now the set in the middle which has two countable unions and a countable intersection is in

$$
\sigma(\mathbf{W}(u)-\mathbf{W}(r): 0 \leq r<u \leq t, r, u \in D)
$$

Thus in particular, one would get the same filtration from

$$
\mathscr{G}_{t}=\sigma(\mathbf{W}(u)-\mathbf{W}(r): 0 \leq r<u \leq t, r, u \in D)
$$

Since $\mathbf{W}(0)=\mathbf{0}$, this is the same as

$$
\mathscr{G}_{t}=\sigma(\mathbf{W}(u): 0 \leq u \leq t, u \in D)
$$

Lemma 67.9.8 Random variables of the form

$$
\phi\left(\mathbf{W}\left(t_{1}\right), \cdots, \mathbf{W}\left(t_{k}\right)\right), \phi \in C_{c}^{\infty}\left(\mathbb{R}^{k}\right)
$$

are dense in $L^{2}\left(\Omega, \mathscr{G}_{T}, P\right)$ where $t_{1}<t_{2} \cdots<t_{k}$ is a finite increasing sequence of

$$
(\mathbb{Q} \cup\{T\}) \cap[0, T] .
$$

Proof: Let $g \in L^{2}\left(\Omega, \mathscr{G}_{T}, P\right)$. Also let $\left\{t_{j}\right\}_{j=1}^{\infty}$ be the points of $(\mathbb{Q} \cup\{T\}) \cap[0, T]$. Let

$$
\mathscr{G}_{m} \equiv \sigma\left(\mathbf{W}\left(t_{k}\right): k \leq m\right)
$$

Thus the $\mathscr{G}_{m}$ are increasing but each is generated by finitely many $\mathbf{W}\left(t_{k}\right)$. Also as explained above,

$$
\begin{aligned}
\mathscr{G}_{T} & =\sigma(\mathbf{W}(u): 0 \leq u \leq T, u \in(\mathbb{Q} \cup\{T\}) \cap[0, T]) \\
& =\sigma\left(\mathscr{G}_{m}, m<\infty\right)
\end{aligned}
$$

Now consider the martingale, $\left\{E\left(g_{M} \mid \mathscr{G}_{m}\right)\right\}_{m=1}^{\infty}$. where here

$$
g_{M}(\omega) \equiv\left\{\begin{array}{l}
g(\omega) \text { if } g(\omega) \in[-M, M] \\
M \text { if } g(\omega)>M \\
-M \text { if } g(\omega)<-M
\end{array}\right.
$$

and $M$ is chosen large enough that

$$
\begin{equation*}
\left\|g-g_{M}\right\|_{L^{2}(\Omega)}<\varepsilon / 4 \tag{67.9.20}
\end{equation*}
$$

Now the terms of this martingale are uniformly bounded by $M$ because

$$
\left|E\left(g_{M} \mid \mathscr{G}_{m}\right)\right| \leq E\left(\left|g_{M}\right| \mid \mathscr{G}_{m}\right) \leq E\left(M \mid \mathscr{G}_{m}\right)=M
$$

It follows the martingale is certainly bounded in $L^{1}$ and so the martingale convergence theorem stated above can be applied, and so there exists $f$ measurable in $\sigma\left(\mathscr{G}_{m}, m<\infty\right)$ such that $\lim _{m \rightarrow \infty} E\left(g_{M} \mid \mathscr{G}_{m}\right)(\omega)=f(\omega)$ a.e. Also $|f(\omega)| \leq M$ a.e. Since all functions are bounded, it follows that this convergence is also in $L^{2}(\Omega)$.

Now letting $A \in \sigma\left(\mathscr{G}_{m}, m<\infty\right)$, it follows from the dominated convergence theorem that

$$
\int_{A} f d P=\lim _{m \rightarrow \infty} \int_{A} E\left(g_{M} \mid \mathscr{G}_{m}\right) d P=\int_{A} g_{M} d P
$$

Now $\mathscr{G}_{T}=\sigma\left(\mathbf{W}\left(t_{k}\right), t_{k} \leq T\right)=\sigma\left(\mathscr{G}_{m}, m \geq 1\right)$ and so the above equation implies that $f=$ $g_{M}$ a.e.

By the Doob Dynkin lemma listed above, there exists a Borel measurable $h: \mathbb{R}^{n m} \rightarrow \mathbb{R}$ such that

$$
E\left(g_{M} \mid \mathscr{G}_{m}\right)=h\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right) \text { a.e. }
$$

Of course $h$ is not in $C_{c}^{\infty}\left(\mathbb{R}^{n m}\right)$. Let $m$ be large enough that

$$
\begin{equation*}
\left\|g_{M}-E\left(g_{M} \mid \mathscr{G}_{m}\right)\right\|_{L^{2}}=\left\|f-E\left(g_{M} \mid \mathscr{G}_{m}\right)\right\|_{L^{2}}<\frac{\varepsilon}{4} . \tag{67.9.21}
\end{equation*}
$$

Let $\lambda_{\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right)}$ be the distribution measure of the random vector $\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right)$. Thus $\lambda_{\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t m}\right)}$ is a Radon measure and so there exists $\phi \in C_{c}\left(\mathbb{R}^{n m}\right)$ such that

$$
\begin{gathered}
\left(\int_{\Omega}\left|E\left(g_{M} \mid \mathscr{G}_{m}\right)-\phi\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right)\right|^{2} d P\right)^{1 / 2} \\
=\left(\int_{\Omega}\left|h\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right)-\phi\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right)\right|^{2} d P\right)^{1 / 2} \\
=\left(\int_{\mathbb{R}^{n m}}\left|h\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{m}\right)-\phi\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{m}\right)\right|^{2} d \lambda\left(\mathbf{W}_{\left.t_{1}, \cdots, \mathbf{W}_{t_{m}}\right)}\right)^{1 / 2}<\varepsilon / 4 .\right.
\end{gathered}
$$

By convolving with a mollifier, one can assume that $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n m}\right)$ also. It follows from 67.9.20 and 67.9.21 that

$$
\begin{aligned}
& \left\|g-\phi\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right)\right\|_{L^{2}} \\
\leq & \left\|g-g_{M}\right\|_{L^{2}}+\left\|g_{M}-E\left(g_{M} \mid \mathscr{G}_{m}\right)\right\|_{L^{2}} \\
& +\left\|E\left(g_{M} \mid \mathscr{G}_{m}\right)-\phi\left(\mathbf{W}_{t_{1}}, \cdots, \mathbf{W}_{t_{m}}\right)\right\|_{L^{2}} \\
\leq & 3\left(\frac{\varepsilon}{4}\right)<\varepsilon
\end{aligned}
$$

## Chapter 68

## A Different Kind Of Stochastic Integration

For more on this material, see [102] which is what this is based on. Recall the following corollary. It is Corollary 59.20.3 on Page 1934.

Corollary 68.0.1 Let $H$ be a real Hilbert space. Then there exist random variables $W(h)$ for $h \in H$ such that each is normally distributed with mean 0 and for every $h, g$, it follows that $(W(h), W(g))$ is normally distributed and

$$
E(W(h) W(g))=(h, g)_{H}
$$

Furthermore, if $\left\{e_{i}\right\}$ is an orthogonal set of vectors of $H$, then $\left\{W\left(e_{i}\right)\right\}$ are independent random variables. Also for any finite set $\left\{f_{1}, f_{2}, \cdots, f_{n}\right\}$,

$$
\left(W\left(f_{1}\right), W\left(f_{2}\right), \cdots, W\left(f_{n}\right)\right)
$$

is normally distributed.
Here are some simple examples.
Example 68.0.2 Let $H=L^{2}([0, T])$. For $f \in H$, let

$$
W(f) \equiv \int_{0}^{T} f(u) d W
$$

where $W(t)$ is the one dimensional Wiener process.
First of all, note that the integrand is adapted to the usual filtration determined by the Wiener process. This is because $f$ does not depend on $\omega$. That $W(f)$ is normally distributed can be seen from the approximation of the Ito integral with the integral of elementary functions. These are clearly normally distributed because they are just linear combinations of increments of the Wiener process. Recall these increments were independent. Thus the integrals of these elementary functions are all normally distributed. If $I_{n}(\omega)$ is one of these, then $I_{n} \rightarrow I$ in $L^{2}(\Omega)$ where $I$ is the above Ito integral. It follows that

$$
E\left(e^{i I t}\right)=\lim _{n \rightarrow \infty} E\left(e^{i I_{n} t}\right)=\lim _{n \rightarrow \infty} e^{-(1 / 2)\left\|f_{n}\right\|_{L^{2}}^{2}}=e^{-(1 / 2)\|f\|_{L^{2}}^{2}}
$$

so in fact, $W(f)$ is normally distributed with mean 0 and variance $\|f\|_{L^{2}}^{2}$. As to the other condition, the Ito isometry implies that

$$
E(W(f) W(g))=\int_{0}^{T} f(u) g(u) d u=(f, g)_{H}
$$

One can verify this by considering $E\left(W(f+g)^{2}\right), E\left(W(f-g)^{2}\right)$.
This example is called the isonormal Gaussian process. There is a measure space $(\Omega, \mathscr{F}, P)$ where $\overline{\sigma(W(s): s \leq T)} \equiv \mathscr{F}$. There must be an underlying measure space which comes from having to define the Wiener process.

Example 68.0.3 You could let $H=\mathbb{R}$ and let $\xi$ be normally distributed density with mean 0 and variance 1. Then let $W(a) \equiv \xi$ a. Does it work?

$$
E\left(a b \xi^{2}\right)=a b E\left(\xi^{2}\right)=a b
$$

Is $W(a)$ normally distributed? $E\left(e^{i a \xi t}\right)=\int_{\mathbb{R}} e^{i a x t} \xi d x=e^{-(1 / 2) a^{2} t^{2}}$ which is the characteristic function of a normally distributed random variable having mean 0 and variance $a^{2}$. It is clear that any linear combination of $a_{i} \xi$ is normally distributed and so the vector $\left(a_{1} \xi, \cdots, a_{n} \xi\right)$ is normally distributed. This is by Theorem 59.16.4.

The above implies $W$ is actually linear.

$$
\begin{gathered}
E\left((W(f+g)-(W(f)+W(g)))^{2}\right) \\
=E\binom{(W(f+g))^{2}+\left[W(f)^{2}+W(g)^{2}+2 W(f) W(g)\right]}{-2[W(f+g) W(f)+W(f+g) W(g)]} \\
=E\left((W(f+g))^{2}\right)+E\left(W(f)^{2}\right)+E\left(W(g)^{2}\right)+E(W(f) W(g)) \\
-2(E(W(f+g) W(f))+E(W(f+g) W(g)))
\end{gathered}
$$

which from the above equals

$$
\begin{aligned}
& |f+g|^{2}+|f|^{2}+|g|^{2}+2(f, g)-2[(f+g, f)+(f+g), g] \\
= & 2|f|^{2}+2|g|^{2}+4(f, g)-2\left[|f|^{2}+|g|^{2}+2(f, g)\right]=0
\end{aligned}
$$

Thus $W(f+g)-(W(f)+W(g))=0$. Is it true that

$$
(W(a f))=a W(f) ?
$$

This is easier to show.

$$
\begin{aligned}
E((W(a f) & \left.-a W(f))^{2}\right)=E\left(W(a f)^{2}-2 W(a f) a W(f)+a^{2} W(f)^{2}\right) \\
& =|a f|^{2}-2 a E(W(a f) W(f))+a^{2} E\left(W(f)^{2}\right) \\
& =a^{2}|f|^{2}-2 a^{2}|f|^{2}+a^{2}|f|^{2}=0
\end{aligned}
$$

Thus $W$ is indeed linear.

### 68.1 Hermite Polynomials

Consider

$$
\exp \left(t x-\frac{t^{2}}{2}\right)=\exp \left(\frac{x^{2}}{2}-\frac{1}{2}(x-t)^{2}\right)
$$

Now the Hermite polynomials are the coefficients of the power series of this function expanded in powers of $t$. Thus the $n^{t h}$ one of these is

$$
\begin{equation*}
H_{n}(x)=\left.\exp \left(\frac{x^{2}}{2}\right) \frac{1}{n!} \frac{d^{n}}{d t^{n}}\left(\exp \left(-\frac{1}{2}(x-t)^{2}\right)\right)\right|_{t=0} \tag{68.1.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\exp \left(t x-\frac{t^{2}}{2}\right)=\sum_{n=0}^{\infty} H_{n}(x) t^{n} \tag{68.1.2}
\end{equation*}
$$

Note that $H_{0}(x)=1$,

$$
\begin{aligned}
H_{1}(x) & =\left.\exp \left(\frac{x^{2}}{2}\right) \frac{d}{d t}\left(\exp \left(-\frac{1}{2}(x-t)^{2}\right)\right)\right|_{t=0} \\
& =-\left.e^{-\frac{1}{2}(t-x)^{2}} e^{\frac{1}{2} x^{2}}(t-x)\right|_{t=0}=x
\end{aligned}
$$

From 68.1.2, differentiating both sides formally with respect to $x$,

$$
t \exp \left(t x-\frac{t^{2}}{2}\right)=\sum_{n=1}^{\infty} H_{n}^{\prime}(x) t^{n}
$$

and so

$$
\sum_{n=0}^{\infty} H_{n}(x) t^{n}=\exp \left(t x-\frac{t^{2}}{2}\right)=\sum_{n=1}^{\infty} H_{n}^{\prime}(x) t^{n-1}=\sum_{n=0}^{\infty} H_{n+1}^{\prime}(x) t^{n}
$$

showing that

$$
H_{n}^{\prime}(x)=H_{n-1}(x), n \geq 1, \quad H_{0}(x)=0, H_{1}(x)=x
$$

which could have been obtained with more work from 68.1.1. Also, differentiating both sides of 68.1.2 with respect to $t$,

$$
-\exp \left(t x-\frac{t^{2}}{2}\right)(t-x)=\sum_{n=0}^{\infty} n H_{n}(x) t^{n-1}
$$

Thus

$$
(x-t) \sum_{n=0}^{\infty} H_{n}(x) t^{n}=\sum_{n=0}^{\infty} n H_{n}(x) t^{n-1}=\sum_{n=0}^{\infty}(n+1) H_{n+1}(x) t^{n}
$$

and so

$$
\sum_{n=0}^{\infty} x H_{n}(x) t^{n}-\sum_{n=0}^{\infty} H_{n}(x) t^{n+1}=\sum_{n=0}^{\infty}(n+1) H_{n+1}(x) t^{n}
$$

and so

$$
\sum_{n=0}^{\infty} x H_{n}(x) t^{n}-\sum_{n=1}^{\infty} H_{n-1}(x) t^{n}=\sum_{n=0}^{\infty}(n+1) H_{n+1}(x) t^{n}
$$

Thus for $n \geq 1$,

$$
x H_{n}(x)-H_{n-1}(x)=(n+1) H_{n+1}(x)
$$

Now also

$$
\exp \left(t(-x)-\frac{t^{2}}{2}\right)=\sum_{n=0}^{\infty} H_{n}(-x) t^{n}
$$

and taking successive derivatives with respect to $t$ of the left side and evaluating at $t=0$ yields

$$
H_{n}(-x)=(-1)^{n} H_{n}(x)
$$

Summarizing these as in [102],

$$
\begin{align*}
& H_{n}^{\prime}(x)=H_{n-1}(x), n \geq 1, \quad H_{0}(x)=0, H_{1}(x)=x \\
& x H_{n}(x)-H_{n-1}(x)=(n+1) H_{n+1}(x), \quad n \geq 1  \tag{68.1.3}\\
& H_{n}(-x)=(-1)^{n} H_{n}(x)
\end{align*}
$$

Clearly, these relations show that all of these $H_{n}$ are polynomials. Also the degree of $H_{n}(x)$ is $n$ and the coefficient of $x^{n}$ is $1 / n!$.

Definition 68.1.1 You can also consider Hermite polynomials which depend on $\lambda$. These are defined as follows:

$$
H_{n}(x, \lambda) \equiv \frac{(-\lambda)^{n}}{n!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n}}{\partial x^{n}}\left(e^{-\frac{1}{2 \lambda} x^{2}}\right)
$$

You can see clearly that these are polynomials in $x$. For example, let $n=2$. Then you would have from the above definition.

$$
\begin{gathered}
H_{0}(x, \lambda)=1, H_{1}(x, \lambda)=\frac{(-\lambda)^{1}}{1!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial}{\partial x}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right)=x \\
H_{2}(x, \lambda) \equiv \frac{(-\lambda)^{2}}{2!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{2}}{\partial x^{2}}\left(e^{-\frac{1}{2 \lambda} x^{2}}\right)=\frac{1}{2} x^{2}-\frac{1}{2} \lambda
\end{gathered}
$$

The idea is you end up with polynomials of degree $n$ times $e^{-x^{2} / 2 \lambda}$ in the derivative part and then this cancels with $e^{x^{2} / 2 \lambda}$ to leave you with a polynomial of degree $n$. Also the leading term will always be $\frac{x^{n}}{n!}$ which is easily seen from the above. Then there are some relationships satisfied by these.

Say $n>1$ in what follows.

$$
\begin{gathered}
\frac{\partial}{\partial x} H_{n}(x, \lambda)=\frac{x}{\lambda} \frac{(-\lambda)^{n} e^{\frac{1}{2} \frac{x^{2}}{\lambda}}}{n!} \frac{\partial^{n}}{\partial x^{n}}\left(e^{-\frac{1}{2 \lambda} x^{2}}\right)+\frac{(-\lambda)^{n}}{n!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n}}{\partial x^{n}}\left(\frac{\partial}{\partial x} e^{-\frac{1}{2 \lambda} x^{2}}\right) \\
=\frac{x}{\lambda} \frac{(-\lambda)^{n} e^{\frac{1}{2} \frac{x^{2}}{\lambda}}}{n!} \frac{\partial^{n}}{\partial x^{n}}\left(e^{-\frac{1}{2 \lambda} x^{2}}\right)+\frac{(-\lambda)^{n}}{n!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n}}{\partial x^{n}}\left(-\frac{x}{\lambda} e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right)
\end{gathered}
$$

Now since $n>1$, that last term reduces to

$$
\frac{(-\lambda)^{n}}{n!} e^{\frac{1}{2 \lambda} x^{2}}\left[-\frac{x}{\lambda} \frac{\partial^{n}}{\partial x^{n}}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right)+n \frac{\partial}{\partial x}\left(-\frac{x}{\lambda}\right) \frac{\partial^{n-1}}{\partial x^{n-1}}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right)\right]
$$

,this by Leibniz formula. Thus this cancels with the first term to give

$$
\begin{aligned}
\frac{\partial}{\partial x} H_{n}(x, \lambda) & =\frac{(-\lambda)^{n} n}{n!}\left(-\frac{1}{\lambda}\right) e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n-1}}{\partial x^{n-1}}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right) \\
& =\frac{(-\lambda)^{n-1}}{(n-1)!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n-1}}{\partial x^{n-1}}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right) \equiv H_{n-1}(x, \lambda)
\end{aligned}
$$

In case of $n=1$, this appears to also work. $\frac{\partial}{\partial x} H_{1}(x, \lambda)=1=H_{0}(x, \lambda)$ from the above computations. This shows that

$$
\frac{\partial}{\partial x} H_{n}(x, \lambda)=H_{n-1}(x, \lambda)
$$

Next, is the claim that

$$
(n+1) H_{n+1}(x, \lambda)=x H_{n}(x, \lambda)-\lambda H_{n-1}(x, \lambda)
$$

If $n=1$, this says that

$$
\begin{aligned}
2 H_{2}(x, \lambda) & =x H_{1}(x, \lambda)-\lambda H_{0}(x, \lambda) \\
& =x^{2}-\lambda
\end{aligned}
$$

and so the formula does indeed give the correct description of $H_{2}(x, \lambda)$ when $n=1$. Thus assume $n>1$ in what follows. The left side equals

$$
\frac{(-\lambda)^{n+1}}{n!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n+1}}{\partial x^{n+1}}\left(e^{-\frac{1}{2 \lambda} x^{2}}\right)
$$

This equals

$$
\frac{(-\lambda)^{n+1}}{n!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n}}{\partial x^{n}}\left(-\frac{x}{\lambda} e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right)
$$

Now by Liebniz formula,

$$
\begin{aligned}
& =\frac{(-\lambda)^{n+1}}{n!} e^{\frac{1}{2 \lambda} x^{2}}\left[-\frac{x}{\lambda} \frac{\partial^{n}}{\partial x^{n}} e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}+n\left(\frac{-1}{\lambda}\right) \frac{\partial^{n-1}}{\partial x^{n-1}}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right)\right] \\
& =\frac{(-\lambda)^{n+1}}{n!} e^{\frac{1}{2 \lambda} x^{2}}\left(-\frac{x}{\lambda} \frac{\partial^{n}}{\partial x^{n}} e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right)+\frac{(-\lambda)^{n+1}}{n!} e^{\frac{1}{2 \lambda} x^{2}} n\left(\frac{-1}{\lambda}\right) \frac{\partial^{n-1}}{\partial x^{n-1}}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right) \\
& =x \frac{(-\lambda)^{n}}{n!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n}}{\partial x^{n}} e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}+\frac{(-\lambda)^{n}}{(n-1)!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n-1}}{\partial x^{n-1}}\left(e^{-\frac{1}{2} \frac{x^{2}}{\lambda}}\right) \\
& =x H_{n}(x, \lambda)-\lambda H_{n-1}(x, \lambda)
\end{aligned}
$$

which shows the formula is valid for all $n \geq 1$.
Next is the claim that

$$
H_{n}(-x, \lambda)=(-1)^{n} H_{n}(x, \lambda)
$$

This is easy to see from the observation that

$$
\frac{\partial}{\partial x}=\frac{\partial}{\partial(-x)}(-1)
$$

Thus if it involves $n$ derivatives, you end up multiplying by $(-1)^{n}$.
Finally is the claim that

$$
\frac{\partial}{\partial \lambda} H_{n}(x, \lambda)=-\frac{1}{2} \frac{\partial^{2}}{\partial x^{2}} H_{n}(x, \lambda)
$$

It is certainly true for $n=0,1,2$. So suppose it is true for all $k \leq n$. Then from earlier claims and induction,

$$
\begin{gathered}
(n+1) H_{(n+1) \lambda}(x, \lambda)=x H_{n \lambda}(x, \lambda)-H_{(n-1)}(x, \lambda)-\lambda H_{(n-1) \lambda}(x, \lambda) \\
=x\left(\frac{-1}{2}\right) H_{n x x}-H_{n-1}+\lambda \frac{1}{2} H_{(n-1) x x}=x\left(\frac{-1}{2}\right) H_{n-2}-H_{n-1}+\lambda \frac{1}{2} H_{(n-3)} \\
=-\frac{1}{2}\left(x H_{n-2}-\lambda H_{n-3}+2 H_{n-1}\right)=-\frac{1}{2}\left((n-1) H_{n-1}+2 H_{n-1}\right)=-\frac{1}{2}\left((n+1) H_{n-1}\right)
\end{gathered}
$$

comparing the ends,

$$
H_{(n+1) \lambda}=-\frac{1}{2} H_{n-1}=-\frac{1}{2} H_{(n+1) x x}
$$

This proves the following theorem.
Theorem 68.1.2 Let $H_{n}(x, \lambda)$ be defined by

$$
H_{n}(x, \lambda) \equiv \frac{(-\lambda)^{n}}{n!} e^{\frac{1}{2 \lambda} x^{2}} \frac{\partial^{n}}{\partial x^{n}}\left(e^{-\frac{1}{2 \lambda} x^{2}}\right)
$$

for $\lambda>0$. Then the following properties are valid.

$$
\begin{gather*}
\frac{\partial}{\partial x} H_{n}(x, \lambda)=H_{n-1}(x, \lambda)  \tag{68.1.4}\\
(n+1) H_{n+1}(x, \lambda)=x H_{n}(x, \lambda)-\lambda H_{n-1}(x, \lambda)  \tag{68.1.5}\\
H_{n}(-x, \lambda)=(-1)^{n} H_{n}(x, \lambda)  \tag{68.1.6}\\
\frac{\partial}{\partial \lambda} H_{n}(x, \lambda)=-\frac{1}{2} \frac{\partial^{2}}{\partial x^{2}} H_{n}(x, \lambda) \tag{68.1.7}
\end{gather*}
$$

With this theorem, one can also prove the following.
Theorem 68.1.3 The Hermite polynomials are the coefficients of a certain power series. Specifically,

$$
\exp \left(t x-\frac{1}{2} t^{2} \lambda\right)=\sum_{n=0}^{\infty} H_{n}(x, \lambda) t^{n}
$$

Proof: Replace $H_{n}$ with $K_{n}$ which really are the coefficients of the power series and then show $K_{n}=H_{n}$. Thus

$$
\exp \left(t x-\frac{1}{2} t^{2} \lambda\right)=\sum_{n=0}^{\infty} K_{n}(x, \lambda) t^{n}
$$

Then $K_{0}=1=H_{0}(x)$. Also $K_{1}(x)=x=H_{1}(x)$.

$$
\begin{gathered}
\frac{\partial}{\partial t}\left(\exp \left(t x-\frac{1}{2} t^{2} \lambda\right)\right)=\exp \left(t x-\frac{1}{2} t^{2} \lambda\right)(x-t \lambda) \\
=\sum_{n=0}^{\infty} x K_{n}(x, \lambda) t^{n}-\sum_{n=0}^{\infty} \lambda K_{n}(x, \lambda) t^{n+1}=\sum_{n=0}^{\infty} x K_{n}(x, \lambda) t^{n}-\sum_{n=1}^{\infty} \lambda K_{n-1}(x, \lambda) t^{n}
\end{gathered}
$$

Also,

$$
\frac{\partial}{\partial t}\left(\exp \left(t x-\frac{1}{2} t^{2} \lambda\right)\right)=\sum_{n=1}^{\infty} n K_{n}(x, \lambda) t^{n-1}=\sum_{n=0}^{\infty}(n+1) K_{n+1}(x, \lambda) t^{n}
$$

It follows that for $n \geq 1$,

$$
(n+1) K_{n+1}(x, \lambda)=x K_{n}(x, \lambda)-\lambda K_{n-1}(x, \lambda)
$$

Thus the first two $K_{0}, K_{1}$ coincide with $H_{0}$ and $H_{1}$ respectively. Then since both $K_{n}$ and $H_{n}$ satisfy the recursion relation 68.1.5, it follows that $K_{n}=H_{n}$ for all $n$.

The first version is just letting $\lambda=1$ in the second version.
There is something very interesting about these Hermite polynomials $H_{n}(x, \lambda)$. Let $W$ be the real Wiener process. Consider the stochastic process $H_{n}(W(t), t), n \geq 1$. This ends up being a martingale. Using Ito's formula, the easy to remember version of it presented above, and the above properties of the Hermite polynomials,

$$
\begin{aligned}
& d H_{n}=H_{n x}(W(t), t) d W+H_{n t}(W(t), t) d t+\frac{1}{2} H_{n x x}(W(t), t) d W^{2} \\
& \quad=H_{n-1}(W(t), t) d W-\frac{1}{2} H_{n x x}(W(t), t) d t+\frac{1}{2} H_{n x x}(W(t), t) d t
\end{aligned}
$$

Note that if $n<2$, both of the last two terms are 0 . In general, they cancel and so

$$
d H_{n}=H_{n-1}(W(t), t) d W
$$

and so

$$
H_{n}(W(t), t)=H_{n}(W(0), 0)+\int_{0}^{t} H_{n-1}(W(t), t) d W
$$

now the constant term in the above equation is $\mathscr{F}_{0}$ measurable and the stochastic integral is a martingale. Thus this is indeed a martingale assuming everything is suitably integrable. However, this is not hard to see because these $H_{n}$ are just polynomials. It was shown in Theorem 64.1.3 that $W(t) \in L^{q}(\Omega)$ for all $q$. Hence there is no integrability issue in doing
these things. Actually, $H_{n}(W(0), 0)=0$ To see this, note that $E\left(W(0)^{2}\right)=(0,0)_{H}=0$ and so $W(0)=0$. Now it is not hard to see that $H_{n}(0,0)=0$. Indeed,

$$
\exp \left(t x-\frac{1}{2} t^{2} \lambda\right)=\sum_{n=0}^{\infty} H_{n}(x, \lambda) t^{n}
$$

Thus $H_{n}(x, 0)=\sum_{n=0}^{\infty} H_{n}(x, 0) t^{n}=\exp (t x)=\sum_{n=0}^{\infty} \frac{(t x)^{n}}{n!}=\sum_{n=0}^{\infty} x^{n} \frac{t^{n}}{n!}$ and so for all $n \geq$ $1, H_{n}(0,0)=0$. Thus in fact, for $n \geq 1, t \rightarrow H_{n}(W(t), t)$ is a martingale which equals 0 when $t=0$.

### 68.2 A Remarkable Theorem, Hermite Polynomials

Lemma 68.2.1 Say $(X, Y)$ is generalized normally distributed and

$$
E(X)=E(Y)=0, E\left(X^{2}\right)=E\left(Y^{2}\right)=1
$$

Then for $m, n \geq 0$,

$$
E\left(H_{n}(X) H_{m}(Y)\right)=\left\{\begin{array}{c}
0 \text { if } n \neq m \\
\frac{1}{n!}(E(X Y))^{n} \text { if } n=m
\end{array}\right.
$$

Proof: By assumption, $s X+t Y$ is normal distributed with mean 0 . This follows from Theorem 59.16.4. Also

$$
\sigma^{2} \equiv E\left((s X+t Y)^{2}\right)=s^{2}+t^{2}+2 E(X Y) s t
$$

and so its characteristic function is

$$
E(\exp (i \lambda(s X+t Y)))=\phi_{s X+t Y}(\lambda)=e^{-\frac{1}{2} \sigma^{2} \lambda^{2}}=e^{-\frac{1}{2}\left(s^{2}+t^{2}\right) \lambda^{2}} e^{-E(X Y) s t \lambda^{2}}
$$

So let $\lambda=-i$. You can do this because both sides are analytic in $\lambda \in \mathbb{C}$ and they are equal for real $\lambda$, a set with a limit point. This leads to

$$
E(\exp (s X+t Y))=e^{\frac{1}{2}\left(s^{2}+t^{2}\right)} e^{E(X Y) s t}
$$

Hence, multiplying both sides by $e^{-\frac{1}{2}\left(s^{2}+t^{2}\right)}$,

$$
\begin{aligned}
e^{-\frac{1}{2}\left(s^{2}+t^{2}\right)} E(\exp (s X+t Y)) & =E\left(\exp \left(s X-\frac{s^{2}}{2}\right) \exp \left(t Y-\frac{t^{2}}{2}\right)\right) \\
& =\exp (s t E(X Y))
\end{aligned}
$$

Now take $\frac{\partial^{n+m}}{\partial^{n} s \partial^{m} t}$ of both sides. Recall the description of the Hermite polynomials given above

$$
n!H_{n}(x)=\left.\frac{d^{n}}{d t^{n}} \exp \left(t x-\frac{t^{2}}{2}\right)\right|_{t=0}
$$

Thus

$$
E\left(n!H_{n}(X) m!H_{m}(Y)\right)=\left.\frac{\partial^{n+m}}{\partial^{n} s \partial^{m} t} \exp (s t E(X Y))\right|_{s=t=0}
$$

Consider $m<n$

$$
\frac{\partial^{n+m}}{\partial^{n} s \partial^{m} t} \exp (s t E(X Y))=\frac{\partial^{m}}{\partial t^{m}}\left((t E(X Y))^{n} \exp (s t E(X Y))\right)
$$

You have something like

$$
\frac{\partial^{m}}{\partial t^{m}}\left[t^{n}\left((E(X Y))^{n} \exp (s t E(X Y))\right)\right]
$$

and $m<n$ so when you take partial derivatives with respect to $t, m$ times and set $s, t=0$, you must have 0 . Hence, if $n>m$,

$$
E\left(n!H_{n}(X) m!H_{m}(Y)\right)=0
$$

Similarly this equals 0 if $m>n$. So assume $m=n$. Then you will go through the same process just described but this time at the end you will have something of the form

$$
n!E(X Y)^{n}+\text { terms multiplied by } s \text { or } t
$$

Hence, in this case,

$$
E\left(n!H_{n}(X) n!H_{n}(Y)\right)=n!E(X Y)^{n}
$$

and so

$$
E\left(H_{n}(X) H_{n}(Y)\right)=\frac{1}{n!} E(X Y)^{n}
$$

Let $W$ be the function defined above, $W(h)$ is normally distributed with mean 0 and variance $|h|^{2}$ and $E(W(h) W(g))=(h, g)_{H}$. Then from Lemma 68.2.1,

$$
\begin{aligned}
E\left(H_{n}(W(h)) H_{m}(W(g))\right) & =\left\{\begin{array}{c}
0 \text { if } n \neq m \\
\frac{1}{n!}(E(W(h) W(g)))^{n} \text { if } n=m
\end{array}\right. \\
& =\left\{\begin{array}{c}
0 \text { if } n \neq m \\
\frac{1}{n!}(h, g)_{H}^{n} \text { if } n=m
\end{array}\right.
\end{aligned}
$$

This is a really neat result. From definition of $W$,

$$
E\left((W(h) W(g))^{1}\right)=(h, g)_{H}
$$

Note this is a special case of the above result because $H_{1}(x)=x$. However, we don't know that $E\left((W(h) W(g))^{n}\right)$ is equal to something times $(h, g)_{H}^{n}$ but we know that this is true of some $n^{\text {th }}$ degree polynomials in $W(h)$ and $W(g)$.
Definition 68.2.2 Let $\mathscr{H}_{n} \equiv \overline{\operatorname{span}\left\{H_{n}(W(h)): h \in H,|h|_{H}=1\right\}}$.
Thus $\mathscr{H}_{n}$ is a closed subspace of $L^{2}(\Omega, \mathscr{F})$. Recall $\mathscr{F} \equiv \sigma(W(h): h \in H)$. This subspace $\mathscr{H}_{n}$ is called the Wiener chaos of order $n$.

Theorem 68.2.3 $L^{2}(\Omega, \mathscr{F}, P)=\oplus_{n=0}^{\infty} \mathscr{H}_{n}$. The symbol denotes the infinite orthogonal sum of the closed subspaces $\mathscr{H}_{n}$. That is, if $f \in L^{2}(\Omega)$, there exists $f_{n} \in \mathscr{H}_{n}$ and constants such that $f=\sum_{n} c_{n} f_{n}$ and if $f \in \mathscr{H}_{n}, g \in \mathscr{H}_{n}$, then $(f, g)_{L^{2}(\Omega)}=0$.

Proof: Clearly each $\mathscr{H}_{n}$ is a closed subspace. Also, if $f \in \mathscr{H}_{n}$ and $g \in \mathscr{H}_{m}$ for $n \neq m$, what about $(f, g)_{L^{2}(\Omega)}$ ?

$$
\begin{gathered}
(f, g)_{L^{2}(\Omega)}=\lim _{l \rightarrow \infty} E\left(\sum_{k=1}^{M_{l}} a_{k}^{l} H_{n}\left(W\left(h_{k}^{l}\right)\right), \sum_{j=1}^{M_{p}} a_{j}^{l} H_{m}\left(W\left(h_{j}^{l}\right)\right)\right) \\
=\lim _{l \rightarrow \infty} \sum_{k, j} a_{k}^{l} a_{j}^{l} E\left(H_{n}\left(W\left(h_{k}^{l}\right)\right) H_{m}\left(W\left(h_{j}^{l}\right)\right)\right)=0
\end{gathered}
$$

Thus these are orthogonal subspaces. Clearly $L^{2}(\Omega) \supseteq \oplus \mathscr{H}_{n}$. Suppose $X$ is orthogonal to each $\mathscr{H}_{n}$. Is $X=0$ ? Each $x^{n}$ can be obtained as a linear combination of the $H_{k}(x)$ for $k \leq n$. This is clear because the space of polynomials of degree $n$ is of dimension $n+1$ and $\left\{H_{0}(x), H_{1}(x), \cdots, H_{n}(x)\right\}$ is independent on $\mathbb{R}$.

This is easily seen as follows. Suppose

$$
\sum_{k=0}^{n} c_{k} H_{k}(x)=0
$$

and that not all $c_{k}=0$. Let $m$ be the smallest index such that

$$
\sum_{k=0}^{m} c_{k} H_{k}(x)=0
$$

with $c_{m} \neq 0$. Then just differentiate both sides and obtain

$$
\sum_{k=1}^{m} c_{k} H_{k-1}(x)=0
$$

contradicting the choice of $m$.
Therefore, each $x^{n}$ is really a unique linear combination of the $H_{k}$ as claimed. Say

$$
x^{n}=\sum_{k=0}^{n} c_{k} H_{k}(x)
$$

Then for $|h|=1$,

$$
W(h)^{n}=\sum_{k=0}^{n} c_{k} H_{k}(W(h)) \in \mathscr{H}_{n}
$$

Hence $\left(X, W(h)^{n}\right)_{L^{2}(\Omega)}=0$ whenever $|h|=1$. It follows that for $h \in H$ arbitrary, and the fact that $W$ is linear,

$$
\left(X, W(h)^{n}\right)_{L^{2}}=\left(X,\left(|h| W\left(\frac{h}{|h|}\right)\right)^{n}\right)=|h|^{n}\left(X, W\left(\frac{h}{|h|}\right)^{n}\right)=0
$$

Therefore, $X$ is perpendicular to $e^{W(h)}$ for every $h \in H$ and so from Lemma 64.6.5, $X=0$. Thus $\oplus \mathscr{H}_{n}$ is dense in $L^{2}(\Omega)$.

Note that from Lemma 64.6.4, every polynomial in $W(h)$ is in $L^{p}(\Omega)$ for all $p>1$. Now what is next is really tricky.

Corollary 68.2.4 Let $\mathscr{P}_{n}^{0}$ denote all polynomials of the form

$$
p\left(W\left(h_{1}\right), \cdots, W\left(h_{k}\right)\right), \text { degree of } p \leq n, \text { some } h_{1}, \cdots, h_{k}
$$

Also let $\mathscr{P}_{n}$ denote the closure in $L^{2}(\Omega, \mathscr{F}, P)$ of $\mathscr{P}_{n}^{0}$. Then

$$
\mathscr{P}_{n}=\oplus_{i=0}^{n} \mathscr{H}_{i}
$$

Proof: It is obvious that $\mathscr{P}_{n} \supseteq \oplus_{i=0}^{n} \mathscr{H}_{i}$ because the thing on the right is just the closure of a set of polynomials of degree no more than $n$, a possibly smaller set than the polynomials used to determine $\mathscr{P}_{n}^{0}$ and hence $\mathscr{P}_{n}$. If $\mathscr{P}_{n}$ is orthogonal to $\mathscr{H}_{m}$ for all $m>n$, then from the above Theorem 68.2.3, you must have $\mathscr{P}_{n} \subseteq \oplus_{i=0}^{n} \mathscr{H}_{i}$. So consider $H_{m}(W(h))$. Recall that $\mathscr{H}_{m}$ is the closure of the span of things like this for $|h|_{H}=1$. Thus we need to consider

$$
E\left(p\left(W\left(h_{1}\right), \cdots, W\left(h_{k}\right)\right) H_{m}(W(h))\right),|h|_{H}=1
$$

and show that this is 0 . Now here is the tricky part. Let $\left\{e_{1}, \cdots, e_{s}, h\right\}$ be an orthonormal basis for

$$
\operatorname{span}\left(h_{1}, \cdots, h_{k}, h\right)
$$

Then since $W$ is linear, there is a polynomial $q$ of degree no more than $n$ such that

$$
p\left(W\left(h_{1}\right), \cdots, W\left(h_{k}\right)\right)=q\left(W\left(e_{1}\right), \cdots, W\left(e_{s}\right), W(h)\right)
$$

Then consider a term of $q\left(W\left(e_{1}\right), \cdots, W\left(e_{s}\right), W(h)\right) H_{m}(W(h))$

$$
a W\left(e_{1}\right)^{r_{1}} \cdots W\left(e_{s}\right)^{r_{s}} W(h)^{r} H_{m}(W(h))
$$

Now from Corollary 64.6 .1 these random variables $\left\{W\left(e_{1}\right), \cdots, W\left(e_{s}\right), W(h)\right\}$ are independent due to the fact that the vector $\left(W\left(e_{1}\right), \cdots, W\left(e_{s}\right), W(h)\right)$ is multivariate normally distributed and the covariance is diagonal. Therefore,

$$
\begin{gathered}
E\left(a W\left(e_{1}\right)^{r_{1}} \cdots W\left(e_{s}\right)^{r_{s}} W(h)^{r} H_{m}(W(h))\right) \\
=a E\left(W\left(e_{1}\right)^{r_{1}}\right) \cdots E\left(W\left(e_{s}\right)^{r_{s}}\right) E\left(W(h)^{r} H_{m}(W(h))\right)
\end{gathered}
$$

Now since $r \leq n, W(h)^{r}=\sum_{k=1}^{r} c_{k} H_{k}(W(h))$ for some choice of scalars $c_{k}$. By Lemma 68.2.1, this last term,

$$
E\left(W(h)^{r} H_{m}(W(h))\right)=\sum_{k} c_{k} E\left(H_{k}(W(h)) H_{m}(W(h))\right)=0
$$

since each $k<m$.
Note how remarkable this is. $\mathscr{P}_{n}^{0}$ includes all polynomials in $W\left(h_{1}\right), \cdots, W\left(h_{k}\right)$ some $h_{1}, \cdots, h_{k}$, of degree no more than $n$, including those which have mixed terms but a typical thing in $\oplus_{i=0}^{n} \mathscr{H}_{i}$ is a sum of Hermite polynomials in $W\left(h_{k}\right)$. It is not the case that you would have terms like $W\left(h_{1}\right) W\left(h_{2}\right)$ as could happen in the case of $\mathscr{P}_{n}$.

Obviously it would be a good idea to obtain an orthonormal basis for $L^{2}(\Omega, \mathscr{F}, P)$. This is done next. Let $\Lambda$ be the multiindices, $\left(a_{1}, a_{2}, \cdots\right)$ each $a_{k}$ a nonnegative integer. Also in the description of $\Lambda$ assume that $a_{k}=0$ for all $k$ large enough. For such a multiindex $\mathbf{a} \in \Lambda$,

$$
\mathbf{a}!\equiv \prod_{i=1}^{\infty} a_{i}!, \quad|\mathbf{a}| \equiv \sum_{i} a_{i}
$$

Also for $\mathbf{a} \in \Lambda$, define

$$
H_{\mathbf{a}}(x) \equiv \prod_{j=1}^{\infty} H_{a_{i}}(x)
$$

This is well defined because $H_{0}(x)=1$ and all but finitely many terms of this infinite product are therefore equal to 1 . Now let $\left\{e_{i}\right\}$ be an orthonormal basis for $H$. For $\mathbf{a} \in \Lambda$,

$$
\Phi_{\mathbf{a}} \equiv \sqrt{\mathbf{a}!} \prod_{i=1}^{\infty} H_{a_{i}}\left(W\left(e_{i}\right)\right) \in L^{2}(\Omega)
$$

Suppose $\mathbf{a}, \mathbf{b} \in \Lambda$.

$$
\int_{\Omega} \Phi_{\mathbf{a}} \Phi_{\mathbf{b}} d P=\sqrt{\mathbf{a}!} \sqrt{\mathbf{b}!} \int_{\Omega} \prod_{i=1}^{\infty} H_{a_{i}}\left(W\left(e_{i}\right)\right) H_{b_{i}}\left(W\left(e_{i}\right)\right) d P
$$

Now recall from Corollary 64.6 .1 the random variables $\left\{W\left(e_{i}\right)\right\}$ are independent. Therefore, the above equals

$$
\sqrt{\mathbf{a}!} \sqrt{\mathbf{b}}!\prod_{i=1}^{\infty} \int_{\Omega} H_{a_{i}}\left(W\left(e_{i}\right)\right) H_{b_{i}}\left(W\left(e_{i}\right)\right) d P=\left\{\begin{array}{l}
1 \text { if } \mathbf{a}=\mathbf{b} \\
0 \text { if } \mathbf{a} \neq \mathbf{b}
\end{array}\right.
$$

Thus $\left\{\Phi_{\mathbf{a}}: \mathbf{a} \in \Lambda\right\}$ is an orthonormal set in $L^{2}(\Omega)$.
Lemma 68.2.5 If $s_{k} \rightarrow h$, then for $n \in \mathbb{N}$, there is a subsequence, still called $s_{k}$ for which $W\left(s_{k}\right)^{n} \rightarrow W(h)^{n}$ in $L^{2}(\Omega)$.

Proof: If $s_{k} \rightarrow h$, does $W\left(s_{k}\right)^{n} \rightarrow W(h)^{n}$ in $L^{2}(\Omega)$ for some subsequence? First of all,

$$
\left\|W(h)-W\left(s_{k}\right)\right\|_{L^{2}(\Omega)}^{2}=\left|s_{k}-h\right|_{H}^{2} \rightarrow 0
$$

and so there is a subsequence, still called $k$ such that $W\left(s_{k}\right)(\omega) \rightarrow W(h)(\omega)$ for a.e. $\omega$. Consider

$$
\begin{equation*}
\int_{\Omega}\left|W(h)^{n}-W\left(s_{k}\right)^{n}\right|^{2} d P \tag{68.2.8}
\end{equation*}
$$

Does this converge to 0 ? The integrand is bounded by $2\left(W(h)^{2 n}+W\left(s_{k}\right)^{2 n}\right)$. Since $W(h), W\left(s_{k}\right)$ are symmetric,

$$
\begin{aligned}
& \int_{\Omega}\left(2\left(W(h)^{2 n}+W\left(s_{k}\right)^{2 n}\right)\right)^{2} d P \leq 8 \int_{\Omega}\left(W(h)^{4 n}+W\left(s_{k}\right)^{4 n}\right) d P \\
& \quad=16 \int_{\Omega \cap[W(h) \geq 0]} e^{4 n W(h)} d P+16 \int_{\Omega \cap\left[W\left(s_{k}\right) \geq 0\right]} e^{4 n W\left(s_{k}\right)} d P \\
& \quad \leq 16 \int_{\Omega} e^{4 n W(h)} d P+16 \int_{\Omega} e^{4 n W\left(s_{k}\right)} d P \\
& \quad \leq 16 e^{\frac{1}{2}|4 n h|}+16 e^{\frac{1}{2}\left|4 n s_{k}\right|}
\end{aligned}
$$

which is bounded independent of $k$, the last step following from Lemma 64.6.4. Therefore, the Vitali convergence theorem applies in 68.2.8.

Given an $h \in H$, let $s_{k}=\sum_{j=1}^{k}\left(h, e_{j}\right) e_{j}$, the $k^{t h}$ partial sum in the Fourier series for $h$.

$$
W\left(s_{k}\right)^{m}=\left(\sum_{j=1}^{k}\left(h, e_{j}\right) W\left(e_{j}\right)\right)^{m}=p\left(W\left(e_{1}\right), \cdots, W\left(e_{k}\right)\right)
$$

where $p$ is a homogeneous polynomial of degree $m$. Now this equals

$$
q\left(H_{0}\left(W\left(e_{1}\right)\right), \cdots, H_{0}\left(W\left(e_{k}\right)\right) \cdots H_{m}\left(W\left(e_{1}\right)\right), \cdots, H_{m}\left(W\left(e_{k}\right)\right)\right)
$$

where $q$ is a polynomial. This is because each $W\left(e_{j}\right)^{r}$ is a linear combination of $H_{s}\left(W\left(e_{j}\right)\right)$ for $s \leq r$. Now you look at terms of this polynomial. They are all of the form $c \Phi_{\mathbf{a}}$ for some constant $c$ and $\mathbf{a} \in \Lambda$. Therefore, if $X \in L^{2}(\Omega)$, there is a subsequence, still denoted as $\left\{s_{k}\right\}$ such that

$$
E\left(W(h)^{n} X\right)=\lim _{k \rightarrow \infty} E\left(W\left(s_{k}\right)^{n} X\right)
$$

Now if $X$ is orthogonal to each $\Phi_{\mathbf{a}}$, then for any $h$ and $n$, there is a subsequence still denoted with $k$ such that

$$
E\left(W(h)^{n} X\right)=\lim _{k \rightarrow \infty} E\left(W\left(s_{k}\right)^{n} X\right)=0
$$

It follows from Lemma 64.6.4, the part about the convergence of the partial sums to $e^{W(h)}$ that $X$ is orthogonal to $e^{W(h)}$ for any $h$. Here are the details. From the lemma, for large $n$,

$$
\left|E\left(e^{W(h)} X\right)-E\left(\sum_{j=0}^{n} \frac{W(h)^{j}}{j!} X\right)\right|<\varepsilon
$$

Also for large $k$,

$$
\left|E\left(\sum_{j=0}^{n} \frac{W(h)^{j}}{j!} X\right)-E\left(\sum_{j=0}^{n} \frac{W\left(s_{k}\right)^{j}}{j!} X\right)\right|=\left|E\left(\sum_{j=0}^{n} \frac{W(h)^{j}}{j!} X\right)\right|<\varepsilon
$$

Therefore,

$$
\left|E\left(e^{W(h)} X\right)\right|<2 \varepsilon
$$

Since $\varepsilon$ is arbitrary, this proves the desired result. By Lemma 64.6.5, $X=0$ and this shows that $\left\{\Phi_{\mathbf{a}}, \mathbf{a} \in \Lambda\right\}$ is complete.

Proposition 68.2.6 $\left\{\Phi_{\mathbf{a}}: \mathbf{a} \in \Lambda\right\}$ is a complete orthonormal set for $L^{2}(\Omega, \mathscr{F}, P)$.

### 68.3 A Multiple Integral

Consider trying to find

$$
\int_{0}^{1} \int_{0}^{1} d B_{s} d B_{t}
$$

Here $B_{t}$ is just one dimensional Wiener process. You would want it to equal

$$
2 \int_{0}^{1} \int_{0}^{t} d B_{s} d B_{t}=2 \int_{0}^{1} B_{t} d B_{t}
$$

So what should this equal? Let $F(x)=x^{2}$ so $F^{\prime}(x)=2 x, F^{\prime \prime}(x)=2$. Consider $F\left(B_{t}\right)$. Then using the formalism for the Ito formula,

$$
\begin{aligned}
d F\left(B_{t}\right) & =d\left(B_{t}^{2}\right)=2 B_{t} d B_{t}+\frac{1}{2}(2)\left(d B_{t}\right)^{2} \\
& =2 B_{t} d B_{t}+d t
\end{aligned}
$$

Therefore,

$$
B_{t}^{2}=2 \int_{0}^{t} B_{s} d B_{s}+t
$$

and letting $t=1$,

$$
\frac{1}{2} B_{1}^{2}-\frac{1}{2}=\int_{0}^{1} B_{s} d B_{s}=\int_{0}^{1} \int_{0}^{s} d B_{r} d B_{s}
$$

and so we would want to have

$$
B_{1}^{2}-1=2 \int_{0}^{1} \int_{0}^{s} d B_{r} d B_{s}
$$

and we want this to equal $\int_{0}^{1} \int_{0}^{1} d B_{s} d B_{t}$ so we need to be defining this in a way such that this will result. Of course, this is just the simplest example of an iterated integral with respect to these one dimensional Wiener processes.

Now partition $[0,1)$ as $0=t_{0}<t_{1}<\cdots, t_{n}=1$. Then sum over all $\left[t_{i-1}, t_{i}\right) \times\left[t_{j-1}, t_{j}\right)$ but leave out those which are on the "diagonal". These would be of the form $\left[t_{i-1}, t_{i}\right) \times\left[t_{i-1}, t_{i}\right)$. Here you would have in the sum products of the form $\left(B_{t_{i}}-B_{t_{i-1}}\right)\left(B_{t_{j}}-B_{t_{j-1}}\right)$. Thus you would have

$$
\begin{gathered}
\sum_{i, j}\left(B_{t_{i}}-B_{t_{i-1}}\right)\left(B_{t_{j}}-B_{t_{j-1}}\right)-\sum_{i=1}^{n}\left(B_{t_{i}}-B_{t_{i-1}}\right)^{2} \\
=\left(\sum_{i} B_{t_{i}}-B_{t_{i-1}}\right)^{2}-\sum_{i=1}^{n}\left(B_{t_{i}}-B_{t_{i-1}}\right)^{2} \\
=\left(B_{1}-B_{0}\right)^{2}-\sum_{i=1}^{n}\left(B_{t_{i}}-B_{t_{i-1}}\right)^{2}
\end{gathered}
$$

Then of course you take a limit as the norm of the partition goes to 0 . This yields in the limit

$$
B_{1}^{2}-1
$$

which is the thing which is wanted. Thus the idea is to consider only functions which are equal to 0 on the "diagonal" and define an integral for these. Then hopefully these will be dense in $L^{2}\left([0, T]^{n}\right)$ and the multiple integral can then be defined as some sort of limit.

Now in the above construction, from now on, unless indicated otherwise, $H=L^{2}(T)$ where the measure is ordinary Lebesgue measure on $T=[0, T]$ or $[0, \infty)$ or some other interval of time. However, it could be more general, but for the sake of simplicity let it be Lebesgue measure. Generalities appear to be nothing but identifying that which works in the case of Lebesgue measure. If $\mu \ll m$ everything would work also. A careful description of what kind of measures work is in [102]. Also, for $A$ a Borel set having finite Lebesgue measure,

$$
W(A) \equiv W\left(\mathscr{X}_{A}\right)
$$

This is a random variable, and as explained earlier, since any finite set of these is normally distributed, if all the sets are pairwise disjoint, the random variables are independent because the covariance is a diagonal matrix.

Definition 68.3.1 Let $D \equiv\left\{\left(t_{1}, \cdots, t_{m}\right): t_{i}=t_{j}\right.$ for some $\left.i \neq j\right\}$. This is called the diagonal set. Here $D \subseteq T^{m}$ where $T$ is an interval $[0, T)$. Assume $T<\infty$ here. Let

$$
0=\tau_{0}<\tau_{1}<\cdots<\tau_{k}=T
$$

Then this can be used to partition $T^{m}$ into sets of the form

$$
\left[\tau_{i_{1}-1}, \tau_{i_{1}}\right) \times \cdots \times\left[\tau_{i_{m}-1}, \tau_{i_{m}}\right)
$$

such that $T^{m}$ is the disjoint union of these. An off diagonal step function $f$ is one which is of the form

$$
f\left(t_{1}, \cdots, t_{m}\right)=\sum_{i_{1} \cdots, i_{m}}^{k} a_{i_{1}, \cdots, i_{m}} \mathscr{X}_{\left[\tau_{i_{1}-1}, \tau_{i_{1}}\right) \times \cdots \times\left[\tau_{i_{m}-1}, \tau_{i_{m}}\right)}\left(t_{1}, \cdots, t_{m}\right)
$$

where $a_{i_{1}, \cdots, i_{m}}=0$ if $i_{p}=i_{q}$. This would correspond to a diagonal term because it would result in a repeated half open interval. Thus we assume all these are equal to 0 . The collection of all such off diagonal step functions will be denoted as $\mathscr{E}_{m}$. The $m$ corresponds to the dimension.

Definition 68.3.2 Let $I_{m}: \mathscr{E}_{m} \rightarrow L^{2}(\Omega)$ be defined in the obvious way.

$$
\begin{gathered}
I_{m}\left(\sum_{i_{1} \cdots, i_{m}}^{k} a_{i_{1}, \cdots, i_{m}} \mathscr{X}_{\left[\tau_{i_{1}-1}, \tau_{i_{1}}\right) \times \cdots \times\left[\tau_{i_{m}-1}, \tau_{i_{m}}\right)}\left(t_{1}, \cdots, t_{m}\right)\right) \\
\equiv \sum_{i_{1} \cdots, i_{m}}^{k} a_{i_{1}, \cdots, i_{m}} \prod_{p=1}^{m}\left(B_{\tau_{i_{p}}}-B_{\tau_{i_{p}-1}}\right)
\end{gathered}
$$

Then $I_{m}$ is linear. If you had two different partitions, you could take the union of them both and by letting coefficients be repeated on the smaller boxes, one can assume that a single partition is being used. This is why it is clear that $I_{m}$ is linear.

Definition 68.3.3 Let $f \in L^{2}\left(T^{m}\right)$. The symetrization of $f$ is given by

$$
\tilde{f}\left(t_{1}, \cdots, t_{m}\right) \equiv \frac{1}{m!} \sum_{\sigma \in S_{m}} f\left(t_{\sigma_{1}}, \cdots, t_{\sigma_{m}}\right)
$$

Lemma 68.3.4 The following holds for $f \in \mathscr{E}_{m}$

$$
\|\tilde{f}\|_{L^{2}\left(T^{m}\right)} \leq\|f\|_{L^{2}\left(T^{m}\right)}
$$

also

$$
I_{m}(f)=I_{m}(\tilde{f})
$$

Proof: This follows because, thanks to the properties of Lebesgue measure,

$$
\begin{aligned}
\int_{T^{m}}\left|f\left(t_{1}, \cdots, t_{m}\right)\right|^{2} d t_{1} \cdots d t_{m} & =\int_{T^{m}}\left|f\left(t_{\sigma_{1}}, \cdots, t_{\sigma_{m}}\right)\right|^{2} d t_{1} \cdots d t_{m} \\
& \equiv \int_{T^{m}}\left|f_{\sigma}\right|^{2} d t_{1} \cdots d t_{m}
\end{aligned}
$$

therefore,

$$
\|\tilde{f}\|_{L^{2}\left(T^{m}\right)} \leq \frac{1}{m!} \sum_{\sigma \in S_{m}}\left\|f_{\sigma}\right\|_{L^{2}\left(T^{m}\right)}=\frac{1}{m!} \sum_{\sigma \in S_{m}}\|f\|_{L^{2}\left(T^{m}\right)}=\|f\|_{L^{2}\left(T^{m}\right)}
$$

The next claim follows because on the right, the terms making up the sum just happen in a different order for each $\sigma$.

More generally, here is a lemma about off diagonal things. It uses sets $A_{i}$ rather than intervals $[a, b)$.

Lemma 68.3.5 Let $\left\{A_{1}, \cdots, A_{m}\right\}$ be pairwise disjoint sets in $\mathscr{B}(T)$ each having finite measure. Then the products $A_{i_{1}} \times \cdots \times A_{i_{n}}$ are pairwise disjoint. Also to say that the function

$$
\left(t_{1}, \cdots, t_{n}\right) \rightarrow \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\left(t_{1}, \cdots, t_{n}\right)
$$

equals 0 whenever some $t_{j}=t_{i}, i \neq j$ is to say that $c_{\mathbf{i}}=0$ whenever there is a repeated index in $\mathbf{i}$.

Proof: Suppose the condition that the $A_{k}$ are pairwise disjoint holds and consider two of these products, $A_{i_{1}} \times \cdots \times A_{i_{n}}$ and $A_{j_{1}} \times \cdots \times A_{j_{n}}$. If the two ordered lists ( $i_{1}, \cdots, i_{n}$ ) and $\left(j_{1}, \cdots, j_{n}\right)$ are different, then since the $A_{k}$ are disjoint the two products have empty intersection because they differ in some position.

Now suppose that $c_{\mathbf{i}}=0$ whenever there is a repeated index. Then the sum is taken over all permutations of $n$ things taken from $\{1, \cdots, m\}$ and so if some $t_{r}=t_{s}$ for $r \neq s$, all terms of the sum equal zero because $\mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}} \neq 0$ only if $\mathbf{t} \in A_{i_{1}} \times \cdots \times A_{i_{n}}$ and since $t_{r}=t_{s}$ and the sets $\left\{A_{k}\right\}$ are disjoint, there must be the same set in positions $r$ and $s$ so $c_{\mathbf{i}}=0$. Hence the function equals 0 .

Conversely, suppose the sum $\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1} \times \cdots \times A_{i_{n}}}}$ equals zero whenever some $t_{r}=t_{s}$ for $s \neq r$. Does it follow that $c_{\mathbf{i}}=0$ whenever some $t_{r}=t_{s}$ ? The value of this function at $\mathbf{t} \in A_{i_{1}} \times \cdots \times A_{i_{n}}$ is $c_{\mathbf{i}}$ because for any other ordered list of indices, the resulting product has empty intersecton with $A_{i_{1}} \times \cdots \times A_{i_{n}}$. Thus, since $t_{r}=t_{s}$, it is given that this function equals 0 which equals $c_{i}$.

This says that when you consider such a function $\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}$ with the $A_{k}$ pairwise disjoint, then to say that it equals 0 whenever some $t_{i}=t_{j}$ is to say that it is really a sum over all permutations of $n$ indices taken from $\{1, \cdots, m\}$. Thus there are $\binom{m}{n} n!=P(m, n)$ possible non zero terms in this sum.

Lemma 68.3.6 Consider the set of all ordered lists of $n$ indices from $\{1,2, \cdots, m\}$. Thus two lists are the same if they consist of the same numbers in the same positions. We denote by $\mathbf{i}$ or $\mathbf{j}$ such an index, $\mathbf{i}$ from $\{1, \cdots, m\}$ and $\mathbf{j}$ from $\{1, \cdots, q\}$. Also let

$$
\left\{A_{1}, \cdots, A_{m}\right\},\left\{B_{1}, \cdots, B_{q}\right\}
$$

are two lists of pairwise disjoint Borel sets from T having finite Lebesgue measure. Also suppose

$$
\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}=\sum_{\mathbf{j}} d_{\mathbf{j}} \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n}}}
$$

Then

$$
\sum_{\mathbf{i}} c_{\mathbf{i}} \prod_{k=1}^{n} W\left(A_{i_{k}}\right)=\sum_{\mathbf{j}} d_{\mathbf{j}} \prod_{k=1}^{n} W\left(B_{j_{k}}\right)
$$

Proof: Suppose that $n=1$ first. Then you have

$$
\begin{equation*}
\sum_{i} c_{i} \mathscr{X}_{A_{i}}=\sum_{j} d_{j} \mathscr{X}_{B_{j}} \tag{68.3.9}
\end{equation*}
$$

where the sets $\left\{A_{i}\right\}$ and $\left\{B_{j}\right\}$ are disjoint. Clearly

$$
\begin{equation*}
A_{i} \supseteq \cup_{j} A_{i} \cap B_{j} \tag{68.3.10}
\end{equation*}
$$

Consider

$$
\begin{equation*}
c_{i} \mathscr{X}_{A_{i}}, \sum_{j} c_{i} \mathscr{X}_{A_{i} \cap B_{j}} \tag{68.3.11}
\end{equation*}
$$

If strict inequality holds in 68.3.10, then you must have a point in $A_{i} \backslash \cup_{j} A_{i} \cap B_{j}$ where the left side of $\sum_{i} c_{i} \mathscr{X}_{A_{i}}$ equals $c_{i}$ but the right side would equal 0 . Hence $c_{i}=0$ and so $\sum_{j} c_{i} \mathscr{X}_{A_{i} \cap B_{j}}=0$ which shows that the two expressions in 68.3.11 are equal. If $A_{i}=$ $\cup_{j} A_{i} \cap B_{j}$, it is also true that the two expressions in 68.3.11 are equal. Thus

$$
\sum_{i} c_{i} \mathscr{X}_{A_{i}}=\sum_{i} \sum_{j} c_{i} \mathscr{X}_{A_{i} \cap B_{j}}
$$

Similar considerations apply to the right side. Thus

$$
\begin{gathered}
\sum_{i} \sum_{j} c_{i} \mathscr{X}_{A_{i} \cap B_{j}}=\sum_{j} \sum_{i} d_{j} \mathscr{X}_{A_{i} \cap B_{j}} \\
\sum_{i, j}\left(c_{i}-d_{j}\right) \mathscr{X}_{A_{i} \cap B_{j}}=0
\end{gathered}
$$

hence if $W\left(A_{i} \cap B_{j}\right) \neq 0$, then, since these sets are disjoint, $c_{i}-d_{j}=0$. It follows that

$$
\sum_{i, j}\left(c_{i}-d_{j}\right) W\left(A_{i} \cap B_{j}\right)=0
$$

and so

$$
\sum_{i} c_{i} W\left(A_{i}\right)=\sum_{i} \sum_{j} c_{i} W\left(A_{i} \cap B_{j}\right)=\sum_{j} \sum_{i} d_{j} W\left(A_{i} \cap B_{j}\right)=\sum_{j} d_{j} W\left(B_{j}\right)
$$

This proves the theorem if $n=1$. Consider the general case. Let $\mathbf{i}^{\prime}$ be

$$
\begin{gathered}
\left(i_{1}, \cdots, i_{n-1}\right), i_{k} \leq m \\
\sum_{i_{n}=1}^{m} \sum_{\mathbf{i}^{\prime}} c_{\left(\mathbf{i}^{\prime}, i_{n}\right)} \mathscr{X}_{A_{i_{n}}}\left(t_{n}\right) \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n-1}}}=\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}} \\
=\sum_{\mathbf{j}} d_{\mathbf{j}} \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n}}}=\sum_{j_{n}=1}^{m} \sum_{\mathbf{j}^{\prime}} d_{\left(\mathbf{j}^{\prime}, j_{n}\right)} \mathscr{X}_{B_{j_{n}}}\left(t_{n}\right) \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n-1}}}
\end{gathered}
$$

Now pick $\left(t_{1}, \cdots, t_{n-1}\right)$. The above is then

$$
\begin{aligned}
& \sum_{i_{n}=1}^{m}\left(\sum_{\mathbf{i}^{\prime}} c_{\left(\mathbf{i}^{\prime}, i_{n}\right)} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n-1}}}\left(t_{1}, \cdots, t_{n-1}\right)\right) \mathscr{X}_{A_{i_{n}}}\left(t_{n}\right) \\
= & \sum_{j_{n}=1}^{m}\left(\sum_{\mathbf{j}^{\prime}} d_{\left(\mathbf{j}^{\prime}, j_{n}\right)} \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n-1}}}\left(t_{1}, \cdots, t_{n-1}\right)\right) \mathscr{X}_{B_{j_{n}}}\left(t_{n}\right)
\end{aligned}
$$

and by what was just shown for $n=1$, for each such choice,

$$
\begin{aligned}
& \sum_{i_{n}}\left(\sum_{\mathbf{i}^{\prime}} c_{\left(\mathbf{i}^{\prime}, i_{n}\right)} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n-1}}}\right) W\left(A_{i_{n}}\right) \\
= & \sum_{j_{n}}\left(\sum_{\mathbf{j}^{\prime}} d_{\left(\mathbf{j}^{\prime}, j_{n}\right)} \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n-1}}}\right) W\left(B_{j_{n}}\right)
\end{aligned}
$$

Then

$$
\begin{aligned}
& \sum_{\mathbf{i}^{\prime}}(\overbrace{\sum_{i_{n}} W\left(A_{i_{n}}\right) c_{\left(\mathbf{i}^{\prime}, i_{n}\right)}}^{\text {function of } \omega}) \overbrace{\mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n-1}}}}^{\text {not a function of } \omega}= \\
& \sum_{\mathbf{j}^{\prime}}\left(\sum_{j_{n}} W\left(B_{j_{n}}\right) d_{\left(\mathbf{j}^{\prime}, j_{n}\right)}\right) \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n-1}}}
\end{aligned}
$$

Pick $\omega=\omega_{0}$. Then by induction,

$$
\begin{aligned}
& \sum_{\mathbf{i}^{\prime}}\left(\sum_{i_{n}} W\left(A_{i_{n}}\right)\left(\omega_{0}\right) c_{\left(\mathbf{i}^{\prime}, i_{n}\right)}\right) W\left(A_{i_{1}}\right) \cdots W\left(A_{i_{n-1}}\right) \\
= & \sum_{\mathbf{j}^{\prime}}\left(\sum_{j_{n}} W\left(B_{j_{n}}\right)\left(\omega_{0}\right) d_{\left(\mathbf{j}^{\prime}, j_{n}\right)}\right) W\left(B_{j_{1}}\right) \cdots W\left(B_{j_{n-1}}\right)
\end{aligned}
$$

and this reduces to what was to be shown because $\omega_{0}$ was arbitrary.
In what follows it will be assumed $c_{\mathbf{i}}=0$ if any two of the $i_{k}$ are equal. That is

$$
\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1} \times \cdots \times A_{i_{n}}}}\left(t_{1}, \cdots, t_{n}\right)=0
$$

if any $t_{i}=t_{j}$.
Definition 68.3.7 Let $\mathscr{E}_{n}$ be functions of the form

$$
f\left(t_{1}, \cdots, t_{n}\right) \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\left(t_{1}, \cdots, t_{n}\right)
$$

where the $A_{k}$ come from some list of the form $\left\{A_{1}, A_{2}, \cdots, A_{m}\right\}$ where this list of sets is pairwise disjoint, each $A_{k} \neq \emptyset$ and $c_{\mathbf{i}}=0$ whenever two indices are equal. By Lemma 68.3.5 this is the same as saying that $f=0$ if $t_{i}=t_{j}$ for some $i \neq j$. A function of $n$ variables $f$ is symmetric means that for $\sigma$ a permutation,

$$
f\left(t_{1}, \cdots, t_{n}\right)=f\left(t_{\sigma(1)}, \cdots, t_{\sigma(n)}\right)
$$

Lemma 68.3.8 Let $f\left(t_{1}, \cdots, t_{n}\right) \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1} \times \cdots \times A_{i_{n}}}}\left(t_{1}, \cdots, t_{n}\right)$. Then $f$ is symmetric if and only iffor all $\left\{c_{i_{1}}, \cdots, i_{n}\right\}$

$$
c_{i_{1}, \cdots, i_{n}}=c_{i_{\sigma(1)}, \cdots, i_{\sigma(n)}}
$$

Proof: First of all, every $c_{\mathbf{i}}=0$ if there are repeated indices so it suffices to consider only the case where all indices are distinct.

Consider all the terms associated with a particular set of indices $\left\{i_{1}, \cdots, i_{n}\right\}$. Then, since these sets $A_{i_{k}}$ are disjoint, the function $f$ is symmetric if and only if the part of the sum in the definition of $f$ associated with each such set of indices is symmetric. To save on notation, denote such a list by $\{1,2, \cdots, n\}$. It suffices then to show that

$$
f\left(t_{1}, \cdots, t_{n}\right)=\sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}}\left(t_{1}, \cdots, t_{n}\right)
$$

is symmetric if and only if for all $\sigma, c_{\sigma(1) \cdots \sigma(n)}=c_{1 \cdots n}$. Suppose then that $f$ is symmetric. Then

$$
\begin{aligned}
f\left(t_{\beta(1)}, \cdots, t_{\beta(n)}\right) & =\sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}}\left(t_{\beta(1)}, \cdots, t_{\beta(n)}\right) \\
& =\sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}}\left(t_{1}, \cdots, t_{n}\right)=f\left(t_{1}, \cdots, t_{n}\right)
\end{aligned}
$$

However,

$$
\begin{align*}
& \sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}}\left(t_{\beta(1)}, \cdots, t_{\beta(n)}\right) \\
= & \sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\beta^{-1} \sigma(1)} \times \cdots \times A_{\beta^{-1} \sigma(n)}}\left(t_{1}, \cdots, t_{n}\right) \tag{68.3.12}
\end{align*}
$$

It is supposed to equal

$$
\begin{align*}
& \sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}}\left(t_{1}, \cdots, t_{n}\right) \\
= & \sum_{\sigma \in S_{n}} c_{\beta^{-1} \sigma(1) \cdots \beta^{-1} \sigma(n)} \mathscr{X}_{A_{\beta^{-1} \sigma(1)} \times \cdots \times A_{\beta^{-1} \sigma(n)}}\left(t_{1}, \cdots, t_{n}\right) \tag{68.3.13}
\end{align*}
$$

Thus

$$
\begin{align*}
& \sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\beta^{-1} \sigma(1)} \times \cdots \times A_{\beta^{-1} \sigma(n)}}\left(t_{1}, \cdots, t_{n}\right) \\
= & \sum_{\sigma \in S_{n}} c_{\beta^{-1} \sigma(1) \cdots \beta^{-1} \sigma(n)} \mathscr{X}_{A_{\beta^{-1} \sigma(1)} \times \cdots \times A_{\beta^{-1} \sigma(n)}}\left(t_{1}, \cdots, t_{n}\right) \tag{68.3.14}
\end{align*}
$$

Since the sets $A_{k}$ are distinct, as explained above, this requires that

$$
\mathscr{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} \neq \mathscr{X}_{A_{\alpha(1)} \times \cdots \times A_{\alpha(n)}}
$$

if $\alpha \neq \sigma$. Therefore, 68.3 .14 requires that for all $\beta$ and each $\sigma$,

$$
c_{\sigma(1) \cdots \sigma(n)}=c_{\beta^{-1} \sigma(1) \cdots \beta^{-1} \sigma(n)}
$$

In particular, this is true if $\beta=\sigma$ and so $c_{\sigma(1) \cdots \sigma(n)}=c_{1 \cdots n}$.
The converse of this is also clear. If $c_{\sigma(1) \cdots \sigma(n)}=c_{1 \cdots n}$ for each $\sigma$, then

$$
\begin{aligned}
f\left(t_{\beta(1)}, \cdots, t_{\beta(n)}\right) & =\sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}}\left(t_{\beta(1)}, \cdots, t_{\beta(n)}\right) \\
& =\sum_{\sigma \in S_{n}} c_{\sigma(1) \cdots \sigma(n)} \mathscr{X}_{A_{\beta^{-1} \sigma(1)} \times \cdots \times A_{\beta^{-1} \sigma(n)}}\left(t_{1}, \cdots, t_{n}\right) \\
& =\sum_{\sigma \in S_{n}} c_{1 \cdots n} \mathscr{X}_{A_{\beta^{-1} \sigma(1)} \times \cdots \times A_{\beta^{-1} \sigma(n)}}\left(t_{1}, \cdots, t_{n}\right) \\
& =\sum_{\alpha \in S_{n}} c_{1 \cdots n} \mathscr{X}_{A_{\alpha(1)} \times \cdots \times A_{\alpha(n)}\left(t_{1}, \cdots, t_{n}\right)} \\
& =\sum_{\alpha \in S_{n}} c_{\alpha(1) \cdots \alpha(n)} \mathscr{X}_{A_{\alpha(1)} \times \cdots \times A_{\alpha(n)}}\left(t_{1}, \cdots, t_{n}\right) \\
& =f\left(t_{1}, \cdots, t_{n}\right) \boldsymbol{\square}
\end{aligned}
$$

Observe that $\mathscr{E}_{n}$ is a vector space because if you have two such functions

$$
\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\left(t_{1}, \cdots, t_{n}\right), \sum_{\mathbf{i}} d_{\mathbf{i}} \mathscr{X}_{B_{i_{1}} \times \cdots \times B_{i_{n}}}\left(t_{1}, \cdots, t_{n}\right)
$$

where the $A_{i_{k}}$ are from $\left\{A_{1}, A_{2}, \cdots, A_{m}\right\}$ and the $B_{i_{k}}$ are from $\left\{B_{1}, B_{2}, \cdots, B_{q}\right\}$. Then consider the single list consisting of the sets of the form $A_{k} \cap B_{j}$. You could write each of these functions in terms of indicator functions of products of these disjoint sets. Thus the sum of the two functions can be written in the desired form. Since each are equal to 0 when some $t_{j}=t_{k}$, the same is true of their sum. Thus $\mathscr{E}_{n}$ is closed with respect to sums. It is obviously
closed with respect to scalar multiplication. Hence it is a subspace of the vector space of all functions and it is therefore, a vector space.

Following [102], for $f$ one of these elementary functions,

$$
f\left(t_{1}, \cdots, t_{n}\right) \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\left(t_{1}, \cdots, t_{n}\right)
$$

where if any two indices are repeated, then $c_{\mathbf{i}}=0$, and the $A_{k}$ are all disjoint,

$$
I_{n}(f) \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} W\left(A_{i_{1}}\right) \cdots W\left(A_{i_{n}}\right)
$$

Lemma 68.3.9 $I_{n}$ is linear on $\mathscr{E}_{n}$. If $f \in \mathscr{E}_{n}$ and $\sigma$ is a permutation of $(1, \cdots, n)$ and

$$
f_{\sigma}\left(t_{1}, \cdots, t_{n}\right) \equiv f\left(t_{\sigma(1)}, \cdots, t_{\sigma\left(t_{n}\right)}\right),
$$

and $f$ is symmetric, then

$$
I_{n}\left(f_{\sigma}\right)=I_{n}(f)
$$

For $f=\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}$, one can conclude that

$$
\begin{equation*}
I_{n}(f)=n!\sum_{i_{1}<i_{2}<\cdots<i_{n}} c_{i_{1}, \cdots, i_{n}} \prod W\left(A_{i_{n}}\right) \tag{68.3.15}
\end{equation*}
$$

Also, the following holds for the expectation. For $f, g \in \mathscr{E}_{n}, \mathscr{E}_{m}$ respectively,

$$
E\left(I_{n}(f) I_{m}(g)\right)=\left\{\begin{array}{l}
0 \text { if } n \neq m \\
n!(\tilde{f}, \tilde{g})_{L^{2}\left(T^{n}\right)}
\end{array} \text { if } n=m\right.
$$

where $\tilde{f}$ denotes the symetrization of $f$ given by

$$
\tilde{f}\left(t_{1}, \cdots, t_{n}\right) \equiv \frac{1}{n!} \sum_{\sigma \in S_{n}} f\left(t_{\sigma(1)}, \cdots, t_{\sigma(n)}\right)
$$

Proof: It is clear from the definition being well defined that $I_{n}$ is linear. In particular, consider

$$
I_{n}\left(a \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}+b \sum_{\mathbf{j}} d_{\mathbf{j}} \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n}}}\right) .
$$

As explained above in the observation that $\mathscr{E}_{n}$ is a vector space, it can be assumed that the $A_{i_{k}}$ and $B_{j_{k}}$ are all from a single set of disjoint Borel sets of $T$. Then the above is of the form

$$
\begin{aligned}
& a \sum_{\mathbf{i}} c_{\mathbf{i}} \prod_{k} W\left(A_{i_{k}}\right)+b \sum_{\mathbf{j}} d_{\mathbf{j}} \prod_{k} W\left(B_{j_{k}}\right) \\
= & a I_{n}\left(\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\right)+b I_{n}\left(\sum_{\mathbf{j}} d_{\mathbf{j}} \mathscr{X}_{B_{j_{1}} \times \cdots \times B_{j_{n}}}\right)
\end{aligned}
$$

Next consider for $\mathbf{i}=\left(i_{1} \cdots i_{n}\right)$,

$$
\begin{aligned}
f_{\sigma}\left(t_{1}, \cdots, t_{n}\right) & =\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\left(t_{\sigma(1)}, \cdots, t_{\sigma(n)}\right) \\
& =\sum_{\mathbf{i}} c_{\mathbf{i}} \prod_{j=1}^{n} \mathscr{X}_{A_{i_{j}}}\left(t_{\sigma(j)}\right)=\sum_{\mathbf{i}} c_{\mathbf{i}} \prod_{j=1}^{n} \mathscr{X}_{A_{\sigma^{-1}(j)}}\left(t_{j}\right) \\
& =\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{\sigma^{-1}(1)}}} \times \cdots \times A_{i_{\sigma^{-1}(n)}}\left(t_{1}, \cdots, t_{n}\right)
\end{aligned}
$$

Thus, it appears that $f_{\sigma} \neq f$. However,

$$
\begin{equation*}
I_{n}\left(f_{\sigma}\right) \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} \prod_{k=1}^{n} W\left(A_{i_{\sigma^{-1}(k)}}\right)=I_{n}(f) \tag{68.3.16}
\end{equation*}
$$

because one just considers the factors in a different order than the other. The permutation acts on $\left(i_{1} \cdots i_{n}\right)$. Define the symetrization of $f$ by $\tilde{f}$ given by

$$
\tilde{f}\left(t_{1}, \cdots, t_{n}\right) \equiv \frac{1}{n!} \sum_{\sigma} f_{\sigma}\left(t_{1}, \cdots, t_{n}\right)
$$

Then $I_{n}(\tilde{f})=I_{n}(f)$ and

$$
\tilde{f}\left(t_{\sigma(1)}, \cdots, t_{\sigma(n)}\right)=\tilde{f}\left(t_{1}, \cdots, t_{n}\right) .
$$

If $f\left(t_{\sigma(1)}, \cdots, t_{\sigma(n)}\right)=f\left(t_{1}, \cdots, t_{n}\right)$ for all $\sigma$ then $\tilde{f}=f$. From the above, $\tilde{f}$ equals

$$
\frac{1}{n!} \sum_{\sigma} \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i^{-1}(1)}} \times \cdots \times A_{\sigma^{-1}(n)}\left(t_{1}, \cdots, t_{n}\right)
$$

Note that 68.3.16 implies that

$$
\begin{equation*}
I_{n}(f)=I_{n}(\tilde{f})=n!\sum_{i_{1}<i_{2}<\cdots<i_{n}} c_{i_{1}, \cdots, i_{n}} \prod_{k} W\left(A_{i_{k}}\right) \tag{68.3.17}
\end{equation*}
$$

Now consider

$$
\tilde{f}=\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}} \text { and } \tilde{g}=\sum_{\mathbf{i}} d_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}
$$

where without loss of generality, these sets $A_{k}$ come from a single list of disjoint sets. As above, $I_{n}(f)=I_{n}(\tilde{f})$ and so it follows that

$$
E\left(I_{n}(f) I_{n}(g)\right)=E\left(I_{n}(\tilde{f}) I_{n}(\tilde{g})\right)
$$

From the above, $E\left(I_{n}(\tilde{f}) I_{n}(\tilde{g})\right)=$

$$
\begin{align*}
& E\left((n!)^{2} \sum_{i_{1}<\cdots<i_{n}} \sum_{j_{1}<\cdots<j_{n}} c_{i_{1}, \cdots, i_{n}} d_{j_{1}, \cdots, j_{n}} \prod_{k} W\left(A_{i_{k}}\right) \prod_{l} W\left(A_{j_{l}}\right)\right) \\
&=(n!)^{2} \sum_{i_{1}<\cdots<i_{n}} \sum_{j_{1}<\cdots<j_{n}} c_{i_{1}, \cdots, i_{n}} d_{j_{1}, \cdots, j_{n}} E\left(\prod_{k} W\left(A_{i_{k}}\right) \prod_{l} W\left(A_{j_{l}}\right)\right) \\
&=\quad(n!)^{2} \sum_{i_{1}<\cdots<i_{n}} \sum_{j_{1}<\cdots<j_{n}} c_{i_{1}, \cdots, i_{n}} d_{j_{1}, \cdots, j_{n}} E\left(\prod_{k} W\left(A_{i_{k}}\right) W\left(A_{j_{k}}\right)\right) \tag{68.3.18}
\end{align*}
$$

That product is of independent random variables. Recall any collection of the $W\left(A_{k}\right)$ are normally distributed and also the covariance is diagonal and so these will all be independent random variables. If any one of them is not repeated, say $W\left(A_{i_{k}}\right)$, then

$$
E\left(\prod_{k} W\left(A_{i_{k}}\right) W\left(A_{j_{k}}\right)\right)=E\left(W\left(A_{i_{k}}\right)\right)(\text { stuff })=0
$$

It follows that to get something nonzero out of this, all $A_{i_{k}}$ are repeated. That is, you must have $\mathbf{j}=\mathbf{i}$ and 68.3.18 reduces to $E\left(I_{n}(f) I_{n}(g)\right)=$

$$
\begin{align*}
& (n!)^{2} \sum_{i_{1}<\cdots<i_{n}} c_{i_{1}, \cdots, i_{n}} d_{i_{1}, \cdots, i_{n}} E\left(\prod_{k} W\left(A_{i_{k}}\right)^{2}\right) \\
= & (n!)^{2} \sum_{i_{1}<\cdots<i_{n}} c_{i_{1}, \cdots, i_{n}} d_{i_{1}, \cdots, i_{n}} \prod_{k} E\left(W\left(A_{i_{k}}\right)^{2}\right) \\
= & (n!)^{2} \sum_{i_{1}<\cdots<i_{n}} c_{i_{1}, \cdots, i_{n}} d_{i_{1}, \cdots, i_{n}} \prod_{k} m\left(A_{i_{k}}\right) \tag{68.3.19}
\end{align*}
$$

By Lemma 68.3.8, used at the end of the following string of equalities, and the observation that

$$
\mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}} \mathscr{X}_{A_{j_{1}} \times \cdots \times A_{j_{n}}}=0
$$

to eliminate mixed terms,

$$
\begin{gathered}
(\tilde{f}, \tilde{g})_{L^{2}\left(T^{n}\right)}= \\
=\int_{0}^{\infty} \cdots \int_{0}^{\infty}\left(\sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\right)\left(\sum_{\mathbf{i}} d_{\mathbf{i}} \mathscr{X}_{A_{i_{1} \times \cdots \times A_{i_{n}}}}\right) d t \cdots d t \\
=\int_{0}^{\infty} \cdots \int_{0}^{\infty}\left(\sum_{\mathbf{i}} c_{\mathbf{i}} d_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\right) d t \cdots d t \\
=\sum_{\mathbf{i}} c_{\mathbf{i}} d_{\mathbf{i}} \prod_{k} m\left(A_{i_{k}}\right)=n!\sum_{i_{1}<\cdots<i_{n}} c_{i_{1} \cdots i_{n}} d_{i_{1} \cdots i_{n}} \prod_{k} m\left(A_{i_{k}}\right)
\end{gathered}
$$

Now it follows from this and 68.3.19 that

$$
E\left(I_{n}(f) I_{n}(g)\right)=n!(\tilde{f}, \tilde{g})_{L^{2}\left(T^{n}\right)}
$$

What happens if you consider $E\left(I_{n}(f) I_{m}(g)\right)$ where $m<n$ ? You would still get $E\left(I_{n}(f) I_{m}(g)\right)=E\left(I_{n}(\tilde{f}) I_{m}(\tilde{g})\right)$

$$
=E\binom{(n!)(m!) \sum_{i_{1}<i_{2}<\cdots<i_{n}} \sum_{j_{1}<\cdots<j_{j}} c_{i_{1}, \cdots, i_{n}} d_{j_{1}, \cdots, j_{m}} W\left(A_{i_{1}}\right)}{\cdots W\left(A_{i_{n}}\right) W\left(A_{j_{1}}\right) \cdots W\left(A_{j_{m}}\right)}
$$

Then at least one of the $W\left(A_{i_{k}}\right)$ is not repeated. This is because $n>m$. That product is a product of independent random variables at least one of which is of the form $W\left(A_{i_{k}}\right)$.

Hence the expectation of the product it is of the form $E\left(W\left(A_{i_{k}}\right)\right)$ (Other terms) $=0$. Thus if $n \neq m$, the result is 0 as claimed.

An integral has now been defined on the functions of the form

$$
f\left(t_{1}, \cdots, t_{n}\right) \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1}} \times \cdots \times A_{i_{n}}}\left(t_{1}, \cdots, t_{n}\right)
$$

where $f=0$ if any $t_{i}=t_{j}$ for $i \neq j$. This integral defined on these elementary functions is interesting because for such functions $f, g$

$$
E\left(I_{n}(f) I_{m}(g)\right)=\left\{\begin{array}{l}
0 \text { if } n \neq m \\
n!(\tilde{f}, \tilde{g})_{L^{2}\left(T^{n}\right)}
\end{array} \text { if } n=m\right.
$$

where $\tilde{f}$ is the symmetrization of $f$. It is desired to extend this integral to $L^{2}\left(T^{n}\right)$. Simple functions are always dense in $L^{2}(T)$. Also, there is an easy lemma which can be concluded for $L^{2}\left(T^{n}\right)$.

Lemma 68.3.10 Let $\mathscr{B}_{0}(T)$ be the Borel sets having finite measure. Linear combinations of functions of the form

$$
\mathscr{X}_{A_{1} \times \cdots \times A_{n}}
$$

where $A_{i} \in \mathscr{B}_{0}(T)$ are dense in $L^{2}\left(T, \mathscr{B}^{n}\right)$ where of course $\mathscr{B}^{n}$ refers to the product $\sigma$ algebra.

Proof: If you have $U=A_{1} \times \cdots \times A_{n}$ in $T^{n}$ one can approximate $\mathscr{X}_{U \cap R_{p}}$ for $R_{p} \equiv$ $(-p, p)^{n}$ in $L^{2}$ with linear combinations of sets of the desired form. In fact, you just consider $\mathscr{X}_{A_{1} \cap(-p, p) \times \cdots \times A_{n}(-p, p)}$ and you get equality. Now let $\mathscr{K}$ denote the $\pi$ system of sets of this sort. Let $\mathscr{G}$ denote those Borel sets $G$ such that there exists a sequence of linear combinations of sets of the form $\mathscr{X}_{\mathbf{A}}, \mathbf{A}=A_{1} \times \cdots \times A_{n}$ which converges to $\mathscr{X}_{G \cap R_{p}}$ in $L^{2}\left(T^{n}\right)$. Thus $\mathscr{G} \supseteq \mathscr{K}$.

Let $\left\{G_{k}\right\}$ be a disjoint sequence of sets of $\mathscr{G}$. Is $G \equiv \cup_{k} G_{k} \in \mathscr{G}$ ? By monotone convergence theorem,

$$
\left\|\mathscr{X}_{G \cap R_{p}}-\sum_{k=1}^{m} \mathscr{X}_{G_{k} \cap R_{p}}\right\|_{L^{2}\left(T^{n}\right)}<\varepsilon
$$

provided $m$ is large enough. Now by definition of $\mathscr{G}$ there exists $L_{k}$ a linear combination of these special sets such that

$$
\left\|\mathscr{X}_{G_{k} \cap R_{p}}-L_{k}\right\|_{L^{2}\left(T^{n}\right)}<\frac{\varepsilon}{m}
$$

It follows that

$$
\begin{aligned}
&\left\|\mathscr{X}_{G \cap R_{p}}-\sum_{k=1}^{m} L_{k}\right\|_{L^{2}} \leq\left\|\mathscr{X}_{G \cap R_{p}}-\sum_{k=1}^{m} \mathscr{X}_{G_{k} \cap R_{p}}\right\|_{L^{2}} \\
&+\left\|\sum_{k=1}^{m} \mathscr{X}_{G_{k} \cap R_{p}}-\sum_{k=1}^{m} L_{k}\right\|<\varepsilon+\varepsilon
\end{aligned}
$$

and so, it follows that $G \in \mathscr{G}$. If $G \in \mathscr{G}$, does it follow that $G^{C}$ is also?

$$
\mathscr{X}_{R_{p}}=\mathscr{X}_{R_{p} \cap G}+\mathscr{X}_{R^{p} \cap G^{C}}
$$

Hence

$$
\mathscr{X}_{R_{p}}-\mathscr{X}_{R_{p} \cap G}=\mathscr{X}_{R^{p} \cap G^{C}}
$$

Both of the functions on the left can be approximated in $L^{2}$ by the desired kind of functions and so the one on the right can also. It follows from Dynkin's lemma that $\mathscr{G} \equiv \sigma(\mathscr{K})$ which is the product measurable sets. Thus if $U$ is any set in $\mathscr{B}^{n}$, it follows that $\mathscr{X}_{U}$ can be approximated in $L^{2}\left(T^{n}\right)$ with linear combinations of sets like $\mathscr{X}_{A_{1} \times \cdots \times A_{n}}$.

Of course nothing is known about whether the sets $A_{i}$ are disjoint. Also it is not known whether these linear combinations of these functions equals 0 if $t_{i}=t_{j}$. Thus there is something which needs to be proved.

Lemma 68.3.11 The functions in $\mathscr{E}_{n}$ mentioned above are dense in $L^{2}\left(T^{n}\right)$.
Proof: From Lemma 68.3.10, it suffices to show that $\mathscr{X}_{A_{1} \times \cdots \times A_{n}}$ can be approximated in $L^{2}\left(T^{n}\right)$ with functions in $\mathscr{E}_{n}$. This is where it will be important that the measure is sufficiently like Lebesgue measure. Let $\left\{B_{k}^{i}\right\}_{k=1}^{m}$ be a partition of $A_{i}$ such that $m\left(B_{k}^{i}\right) \leq$ $\frac{2 m\left(A_{i}\right)}{m}$. Let $\left\{B_{k}\right\}_{k=1}^{p}$ denote all these sets so $p=m n$. They are not necessarily disjoint because it is not known that the $A_{i}$ are disjoint. However, one can say that it is possible to choose $e_{\mathbf{i}}$ equal to either 0 or 1 such that

$$
\mathscr{X}_{A_{1} \times \cdots \times A_{n}}=\sum_{\mathbf{i}} e_{\mathbf{i}} \mathscr{X}_{B_{i_{1}} \times \cdots \times B_{i_{n}}}
$$

where we can have $B_{i_{k}} \subseteq A_{k}$. Let $J$ be those indices $\mathbf{i}$ which involve a repeated set. That is some $B_{i_{j}}=B_{i_{k}}$ for some $j \neq k$. How many possibilities are there? There are no more than $C(n, 2) m$ because there are $C(n, 2)$ possibilities for duplicates among the $A_{k}$ and then there are $m$ sets in the partition of $A_{k}$.

$$
\begin{aligned}
& \int_{T} \cdots \int_{T}\left(\sum_{i \in J} e_{i} \mathscr{X}_{B_{i_{1}} \times \cdots \times B_{i_{n}}}\right)^{2} d t \cdots d t \\
= & \int_{T} \cdots \int_{T} C(n, 2) m \mathscr{X}_{B_{i_{1}} \times \cdots \times B_{i_{n}}} d t \cdots d t \\
\leq & C(n, 2) m \prod_{k=1}^{n} m\left(B_{i_{k}}\right)
\end{aligned}
$$

The mixed terms are 0 because for a fixed $k,\left\{B_{i_{k}}\right\}_{i=1}^{m}$ are disjoint. Now from the description of these, $m\left(B_{i_{k}}\right) m<m\left(A_{k}\right)$ and so

$$
\begin{aligned}
& \int_{T} \cdots \int_{T}\left(\sum_{\mathbf{i} \in J} e_{i} \mathscr{X}_{B_{i_{1}} \times \cdots \times B_{i_{n}}}\right)^{2} d t \cdots d t \\
\leq & C(n, 2) m \prod_{k=1}^{n} \frac{2 m\left(A_{k}\right)}{m}=\frac{C(n, 2) m}{m^{n}} \prod_{k=1}^{n} m\left(A_{k}\right)
\end{aligned}
$$

which clearly converges to 0 as $m \rightarrow \infty$ provided that $n \geq 2$. In case $n=1$, all you have to do is approximate $\mathscr{X}_{A}$ from something in $\mathscr{E}_{1}$ and of course you just use $\mathscr{X}_{A}$.

Let $f, g \in \mathscr{E}_{n}$. Then from Lemma 68.3.9,

$$
\begin{aligned}
& E\left(\left(I_{n}(f-g)\right)^{2}\right)=n!\|\tilde{f}-\tilde{g}\|_{L^{2}\left(T^{n}\right)}^{2} \\
&\|\tilde{f}\|_{L^{2}\left(T^{n}\right)}=\left(\int_{T} \cdots \int_{T}|\tilde{f}(\mathbf{t})|^{2} d \mathbf{t}\right)^{1 / 2} \\
&=\left(\int_{T} \cdots \int_{T}\left|\frac{1}{n!} \sum_{\sigma} f\left(t_{\sigma(1)}, \cdots, t_{\sigma(n)}\right)\right|^{2} d \mathbf{t}\right)^{1 / 2} \\
& \leq \frac{1}{n!} \sum_{\sigma}\left(\int_{T} \cdots \int_{T}\left|f\left(t_{\sigma(1)}, \cdots, t_{\sigma(n)}\right)\right|^{2} d \mathbf{t}\right)^{1 / 2} \\
&= \frac{1}{n!} \sum_{\sigma}\|f\|_{L^{2}\left(T^{n}\right)}=\|f\|_{L^{2}\left(T^{n}\right)}
\end{aligned}
$$

Therefore,

$$
\begin{equation*}
E\left(\left(I_{n}(f-g)\right)^{2}\right)=n!\|\tilde{f}-\tilde{g}\|_{L^{2}\left(T^{n}\right)}^{2} \leq n!\|f-g\|_{L^{2}\left(T^{n}\right)}^{2} \tag{68.3.20}
\end{equation*}
$$

The following theorem comes right away from this and Lemma 68.3.11.
Theorem 68.3.12 The integral $I_{n}$ defined on $\mathscr{E}_{n}$ extends uniquely to an integral $I_{n}$ defined on $L^{2}\left(T^{n}\right)$. This integral satisfies

$$
I_{n}(f) \in L^{2}(\Omega)
$$

Also

$$
E\left(I_{n}(f) I_{n}(g)\right)=n!(\tilde{f}, \tilde{g})_{L^{2}\left(T^{n}\right)}
$$

Proof: This follows right away from the density of $\mathscr{E}_{n}$ in $L^{2}\left(T^{n}\right)$ and the inequality 68.3.20.

Obviously one wonders whether linear combinations $\sum_{n} c_{n} I_{n}\left(f_{n}\right)$ are dense in $L^{2}(\Omega)$. It looks like the important thing to notice is that for $f \in \mathscr{E}_{n}, I_{n}(f)$ is a polynomial in $W\left(A_{i_{k}}\right) \equiv$ $W\left(\mathscr{X}_{A_{i_{k}}}\right)$. Recall the corollary above, Corollary 68.2.4,

Corollary 68.3.13 Let $\mathscr{P}_{n}^{0}$ denote all polynomials of the form

$$
p\left(W\left(h_{1}\right), \cdots, W\left(h_{k}\right)\right), \text { degree of } p \leq n, \text { some } h_{1}, \cdots, h_{k}
$$

Also let $\mathscr{P}_{n}$ denote the closure in $L^{2}(\Omega, \mathscr{F}, P)$ of $\mathscr{P}_{n}^{0}$. Then

$$
\mathscr{P}_{n}=\oplus_{i=0}^{n} \mathscr{H}_{i}
$$

Consider $\cup_{p \leq n}\left\{I_{p}(f): f \in \mathscr{E}_{p}\right\}$. This is a subset of $\mathscr{P}_{n}^{0}$ and so it is a subset of $\oplus_{i=0}^{n} \mathscr{H}_{i}$. Now for $h \in L^{2}\left(T^{n}\right)$, it was shown above that there exists a sequence $g_{k} \rightarrow h$ in $L^{2}\left(T^{n}\right)$ where each $h_{k} \in \mathscr{E}_{n}$. Then $I_{n}\left(g_{k}\right) \rightarrow I_{n}(h)$. In particular, if $h \in L^{2}(T) \equiv H$, then there is a sequence $g_{k} \in \mathscr{E}_{1}$ such that $g_{k} \rightarrow h$ in $L^{2}(T)$. Then clearly

$$
E\left(\left|W\left(g_{k}\right)-W(h)\right|^{2}\right)=E\left(\left|W\left(g_{k}-h\right)\right|^{2}\right)=\left\|g_{k}-h\right\|_{L^{2}(T)}^{2} \rightarrow 0
$$

and so each polynomial $p\left(W\left(h_{1}\right), \cdots, W\left(h_{k}\right)\right)$ can be approximated in $L^{2}(\Omega)$ by one which is of the form $p\left(W\left(g_{1}\right), \cdots, W\left(g_{k}\right)\right)$ where each $g_{j} \in \mathscr{E}_{1}$. Corresponding to each $g_{j}$ there is a list of disjoint sets. Now consider the union of all the sets just described and let $\left\{A_{k}\right\}$ be a partition of this union such that the $A_{k}$ are pairwise disjoint and for each $j$, every set corresponding to $g_{j}$ is partitioned by a subset of the $\left\{A_{k}\right\}$. Thus

$$
g_{j}=\sum_{i} c_{i} \mathscr{X}_{B_{i}}=\sum_{i} c_{i} \sum_{s=1}^{m_{j}} \mathscr{X}_{A_{s}^{i}}
$$

where $B_{i}$ is partitioned by the $A_{s}^{i}$. Then consider $p\left(g_{1}, \cdots, g_{k}\right)$. Then the terms of degree $m$ are of the form

$$
\begin{equation*}
p_{m} \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} \mathscr{X}_{A_{i_{1} \times \cdots \times A_{i_{m}}}} \tag{68.3.21}
\end{equation*}
$$

where the $A_{i_{k}}$ come from the list of disjoint sets $\left\{A_{k}\right\}$. The terms of degree $m$ in

$$
p\left(W\left(g_{1}\right), \cdots, W\left(g_{k}\right)\right)
$$

are also of the form

$$
p_{m}\left(W\left(g_{1}\right), \cdots, W\left(g_{k}\right)\right) \equiv \sum_{\mathbf{i}} c_{\mathbf{i}} \prod_{k} W\left(A_{i_{k}}\right)
$$

The problem is that 68.3 .21 is not in $\mathscr{E}_{m}$ because it is not known whether $c_{\mathbf{i}}=0$ if two indices are repeated. However, as explained in the proof of Lemma 68.3.11 there is a further partition such that the contribution of those terms corresponding to $\mathbf{i}$ in which two indices are repeated can be made as small as desired. Therefore, the terms of order $m$ are approximated in $L^{2}\left(T^{m}\right)$ by $g_{m} \in \mathscr{E}_{m}$. Assume this approximation is good enough that, from the estimates given above in Lemma 68.3.9,

$$
E\left(\left|I_{m}\left(g_{m}\right)-p_{m}\left(W\left(g_{1}\right), \cdots, W\left(g_{k}\right)\right)\right|^{2}\right)^{1 / 2}<\frac{\varepsilon}{n+1}
$$

Thus, taking a succession of partitions if necessary,

$$
\begin{aligned}
& E\left(\left|p\left(W\left(g_{1}\right), \cdots, W\left(g_{k}\right)\right)-\sum_{m=0}^{n} I_{m}\left(g_{m}\right)\right|^{2}\right)^{1 / 2} \\
\leq & \sum_{m=1}^{n} E\left(\left|I_{m}\left(g_{m}\right)-p_{m}\left(W\left(g_{1}\right), \cdots, W\left(g_{k}\right)\right)\right|^{2}\right)^{1 / 2}<\sum_{m=1}^{n} \frac{\varepsilon}{n+1}<\varepsilon .
\end{aligned}
$$

This has proved the following lemma.

Lemma 68.3.14 Let $n$ be given. Then $\cup_{p \leq n}\left\{I_{p}(f): f \in \mathscr{E}_{p}\right\}$ is dense in $\mathscr{P}_{n}=\oplus_{i=0}^{n} \mathscr{H}_{i}$. Consequently, every $f \in L^{2}(\Omega, \mathscr{F})$ may be written as an infinite sum

$$
f=\sum_{k=1}^{\infty} c_{k} I_{k}\left(g_{k}\right)
$$

where $g_{k} \in \mathscr{E}_{k}$ and it can also be assumed that $g_{k}$ is symmetric.
Proof: It only remains to verify that $g_{k}$ can be symmetric. However, this is obvious because if $g_{k}$ is replaced with $\tilde{g}_{k}$ the integral $I_{k}$ is unchanged.

### 68.4 The Skorokhod Integral

This integral allows for one to obtain a stochastic integral of functions which are not adapted. It is a generalization of the Ito integral. There is also a strange sort of derivative which can be defined and the two are related in a natural way.

### 68.4.1 The Derivative

Let $F: \mathbb{R}^{n} \rightarrow \mathbb{R}$ be smooth and have polynomial growth. Then consider

$$
F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)
$$

where $W$ is defined above. Recall that $h \in H$ a separable real Hilbert space and $W(h) \in$ $L^{2}(\Omega, \mathscr{F}, P)$ where $\mathscr{F}=\sigma(W(h), h \in H)$. Also $\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)$ is multivariate normal and $E(W(g) W(h))=(h, g)_{H}$.

Definition 68.4.1 In the above situation,

$$
D F \equiv \sum_{k=1}^{n} D_{k} F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right) h_{k}
$$

Thus from Lemma 64.6.4, $F, D_{k} F$ are in $L^{p}(\Omega)$ and so $D F$ is in $L^{p}(\Omega ; H)$ for every $p$.
First it is good to consider whether $D F$ is well defined.
Lemma 68.4.2 The derivative is well defined. Also, if $F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)=0$ for $\left\{h_{1}, \cdots, h_{n}\right\}$ independent, then for all $\mathbf{x}, F(\mathbf{x})=0$.

Proof: Suppose

$$
F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)=0
$$

Is it true that $D F=0$ ? Let $\lambda$ be the distribution measure of $\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right) \equiv \mathbf{W}(\mathbf{h})$. Then the above requires that for any ball $B$ in $\mathbb{R}^{n}$,

$$
E\left(\mathscr{X}_{B}(\mathbf{W}(\mathbf{h})) F^{2}(\mathbf{W}(\mathbf{h}))\right)=\int_{B} F^{2}(\mathbf{x}) d \lambda(\mathbf{x})=0
$$

If $\left\{h_{1}, \cdots, h_{n}\right\}$ is independent, then $\lambda$ has a normal density function and $\lambda \ll m_{n}$ and so $F^{2}(\mathbf{x})=0$ for a.e. $\mathbf{x}$. Since $F$ is smooth, this means that $F=0$ everywhere. Hence $D_{k} F=0$ and so $D F=0$. Thus the case where the $h_{i}$ are independent is easy.

Next suppose without loss of generality that a basis for

$$
\operatorname{span}\left(h_{1}, \cdots, h_{n}\right)
$$

is

$$
\left\{h_{1}, \cdots, h_{r}\right\}
$$

where $r<n$. Say $h_{k}=\sum_{i=1}^{r} c_{i}^{k} h_{i}$ for $k>r$. Then

$$
\begin{aligned}
0 & =F\left(W\left(h_{1}\right), \cdots W\left(h_{r}\right), W\left(\sum_{i=1}^{r} c_{i}^{r+1} h_{i}\right) \cdots W\left(\sum_{i=1}^{r} c_{i}^{n} h_{i}\right)\right) \\
& =F\left(W\left(h_{1}\right), \cdots W\left(h_{r}\right), \sum_{j=1}^{r} c_{j}^{r+1} W\left(h_{j}\right) \cdots \sum_{j=1}^{r} c_{j}^{n} W\left(h_{j}\right)\right) \\
& \equiv G\left(W\left(h_{1}\right), \cdots W\left(h_{r}\right)\right)
\end{aligned}
$$

and so in terms of $\left\{h_{1}, \cdots, h_{r}\right\}$,

$$
\begin{aligned}
D F & =\sum_{i=1}^{r}\left(D_{i} F\right) h_{i}+\sum_{i=r+1}^{n}\left(D_{i} F\right) \overbrace{\sum_{j=1}^{r} c_{j}^{i} h_{j}}^{=h_{i}} \\
& =\sum_{j=1}^{r}\left(D_{j} F\right) h_{j}+\sum_{j=1}^{r} \sum_{i=r+1}^{n}\left(D_{i} F\right) c_{j}^{i} h_{j} \\
& =\sum_{j=1}^{r}\left(D_{j} F+\sum_{i=r+1}^{n}\left(D_{i} F\right) c_{j}^{i}\right) h_{j}
\end{aligned}
$$

Now it was just shown that $G(\mathbf{x})$ is identically 0 and so $D_{j} G=0, j \leq r$. So what is $D_{j} G$ ? From the above, it equals

$$
D_{j} F+\sum_{i=r+1}^{n}\left(D_{i} F\right) c_{j}^{i}=0
$$

Hence $D F=0$. Now if $F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)=G\left(W\left(k_{1}\right), \cdots, W\left(k_{m}\right)\right)$, then $F-G=0$ and so from what was just shown, $D(F-G)=D F-D G=0$. Thus the derivative is well defined.

Lemma 68.4.3 Let $\mathscr{P}$ denote the set of all polynomials in $W(h)$ for $h \in H$. Then $\mathscr{P}$ is dense in $L^{p}(\Omega)$.

Proof: Let $g \in L^{p^{\prime}}(\Omega)$ and suppose that for every $f \in D, \int_{\Omega} g f d P=0$. Does it follow that $g=0$ ? If so, then by the Riesz representation theorem, $\mathscr{P}$ is dense in $L^{p}(\Omega)$. From

Lemma 64.6.4, for a given $h$, there is a sequence of functions of $\mathscr{P},\left\{f_{n}\right\}$ which converges to $e^{W(h)}$ in $L^{p}(\Omega)$. It follows that

$$
\int_{\Omega} g e^{W(h)} d P=\lim _{n \rightarrow \infty} \int_{\Omega} g f_{n} d P=0
$$

Hence by Lemma 64.6 .5 it follows that $g=0$. Hence $\mathscr{P}$ is dense in $L^{p}(\Omega)$.
Let $D^{1, p}$ denote the closure in $L^{p}(\Omega)$ of functions in $\mathscr{P}$ with respect to the seminorm

$$
\|f\|_{1, p} \equiv\left(\|f\|_{L^{p}(\Omega)}^{p}+\|D f\|_{L^{p}(\Omega, H)}^{p}\right)^{1 / p}
$$

By this we mean the following. The above $\|f\|_{1, p}$ makes perfect sense for every $f \in \mathscr{P}$ and is algebraically like a norm. Thus it makes $\mathscr{P}$ into a normed linear space. $D^{1, p}$ is just the completion of this normed linear space. Then for $f \in D^{1, p}$, we define $D f \equiv \lim _{n \rightarrow \infty} D f_{n}$ in $L^{p}(\Omega, H)$ where $f_{n} \in \mathscr{P}$.

### 68.4.2 The Integral

The derivative has been defined above. Now here is the definition of the integral defined on functions in $L^{p^{\prime}}(\Omega, H)$, possibly not all of them.

Definition 68.4.4 We say a random variable $F$ is "smooth" if it is of the form $F(\omega)=$ $F\left(W\left(h_{1}\right), \cdots W\left(h_{r}\right)\right)$ where $\mathbf{x} \rightarrow F(\mathbf{x})$ is a smooth function of the real variables $x_{i}$. It has polynomial growth if

$$
\frac{|F(\mathbf{x})|}{\left(1+|\mathbf{x}|^{2}\right)^{m}}
$$

is bounded for some positive integer $m$. Let $u \in L^{p^{\prime}}(\Omega, H)$. Then $u \in D(\delta)$ if for all $F$ smooth having polynomial growth in the $W(h)$,

$$
|E\langle D F, u\rangle| \leq C(u)\|F\|_{L^{p}(\Omega)}
$$

Then $\delta u \in L^{p^{\prime}}(\Omega)$ is defined by

$$
E\langle D F, u\rangle \equiv E(F \delta u)
$$

Thus you have $\delta$ is the adjoint of $D$.

$$
\begin{array}{ccc}
L^{p^{\prime}}(\Omega) & \stackrel{\delta}{\leftarrow} & D(\delta) \subseteq L^{p^{\prime}}(\Omega, H) \\
L^{p}(\Omega) \supseteq D(D) & \stackrel{D}{\longrightarrow} & L^{p}(\Omega, H)
\end{array}
$$

Next it is shown that there are functions in $D(\boldsymbol{\delta})$ by giving examples of them. It turns out that functions of the form $\sum_{i} F_{i} h_{i}$ where $F_{i}$ is smooth with polynomial growth are in $D(\delta)$. Consider

$$
E\left\langle D G, F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right) h\right\rangle
$$

where $G=G\left(W\left(k_{1}\right), \cdots, W\left(k_{p}\right)\right)$ and for simplicity, $\|h\|_{H}=1$.
Consider the vectors $\left\{h, h_{1}, \cdots, h_{n}, k_{1}, \cdots, k_{p}\right\}$. Starting with the left and moving toward the right, delete vectors which are dependent on the preceding vectors, obtaining a linearly independent set of vectors which includes $h$. Then let $\left\{h, e_{1}, \cdots, e_{q}\right\}$ be an orthonormal basis having the same span as the original vectors $\left\{h, h_{1}, \cdots, h_{n}, k_{1}, \cdots, k_{p}\right\}$. Then from the fact that $W$ is linear, there are smooth functions having polynomial growth $\hat{G}, \hat{F}$ such that

$$
\begin{aligned}
G\left(W\left(k_{1}\right), \cdots, W\left(k_{p}\right)\right) & =\hat{G}\left(W(h), W\left(e_{1}\right), \cdots, W\left(e_{q}\right)\right) \\
F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right) & =\hat{F}\left(W(h), W\left(e_{1}\right), \cdots, W\left(e_{q}\right)\right)
\end{aligned}
$$

Note that $h_{i}=\sum_{j=1}^{q}\left(h_{i}, e_{j}\right) e_{j}+\left(h_{i}, h\right) h$. Thus

$$
\begin{gathered}
F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)= \\
=F\left(W\left(\sum_{j=1}^{q}\left(h_{1}, e_{j}\right) e_{j}+\left(h_{1}, h\right) h\right), \cdots, W\left(\sum_{j=1}^{q}\left(h_{n}, e_{j}\right) e_{j}+\left(h_{n}, h\right) h\right)\right) \\
\left.\left.=h_{1}, e_{j}\right) W\left(e_{j}\right)+\left(h_{1}, h\right) W(h), \cdots, \sum_{j=1}^{q}\left(h_{n}, e_{j}\right) W\left(e_{j}\right)+\left(h_{n}, h\right) W(h)\right)
\end{gathered}
$$

and so, $D_{1} \hat{F}$ is given by

$$
D_{1} \hat{F}=\sum_{i=1}^{n} D_{i}\left(F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)\right)\left(h_{i}, h\right)
$$

Then by Lemma 68.4.2

$$
\begin{gathered}
E\left\langle D G, F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right) h\right\rangle=E\langle D \hat{G}, \hat{F} h\rangle \\
=E\left\langle D_{1}(\hat{G}) h+\sum_{k=1}^{q} D_{k}(\hat{G}) e_{k}, \hat{F} h\right\rangle=E\left(D_{1}(\hat{G}) \hat{F}\right) \\
=\frac{1}{(\sqrt{2 \pi})^{q+1}} \int_{\mathbb{R}^{q}} \int_{\mathbb{R}} D_{1} \hat{G}(\mathbf{x}) \hat{F}(\mathbf{x}) e^{-\frac{1}{2}|\mathbf{x}|^{2}} d x_{1} d \hat{\mathbf{x}}_{1} \\
=\frac{-1}{(\sqrt{2 \pi})^{q+1}} \int_{\mathbb{R}^{q}} \int_{\mathbb{R}} \hat{G}(\mathbf{x}) D_{1}\left(\hat{F}(\mathbf{x}) e^{-\frac{1}{2}|\mathbf{x}|^{2}}\right) d x_{1} d \hat{\mathbf{x}}_{1} \\
=\frac{-1}{(\sqrt{2 \pi})^{q+1}} \int_{\mathbb{R}^{q}} \int_{\mathbb{R}} \hat{G}(\mathbf{x})\left(\left(D_{1} \hat{F}\right)(\mathbf{x}) e^{-\frac{1}{2}|\mathbf{x}|^{2}}-\hat{F}(\mathbf{x}) x_{1} e^{-\frac{1}{2}|\mathbf{x}|^{2}}\right) d x_{1} d \hat{\mathbf{x}}_{1} \\
=E\left(\left(\hat{F} W(h)-D_{1} \hat{F}\right) \hat{G}\right)=E\left(\left(F W(h)-\sum_{i=1}^{n} D_{i}(F)\left(h_{i}, h\right)\right) G\right)
\end{gathered}
$$

Thus $F h \in D(\delta)$ and

$$
\delta(F h)=F W(h)-\sum_{i=1}^{n} D_{i}(F)\left(h_{i}, h\right)
$$

Since $\delta$ is an adjoint map, it is clearly linear. Hence, if $h$ is arbitrary, $h \neq 0$ of course,

$$
\begin{align*}
\delta(F h) & =\|h\| \delta\left(F\left(\frac{W(h)}{\|h\|}\right)\right)=\|h\| F \frac{W(h)}{\|h\|}-\|h\| \sum_{i=1}^{n} D_{i}(F)\left(h_{i}, \frac{h}{\|h\|}\right) \\
& =F W(h)-\sum_{i=1}^{n} D_{i}(F)\left(h_{i}, h\right)_{H}=F W(h)-\langle D F, h\rangle \tag{68.4.22}
\end{align*}
$$

Note how this looks just like integration by parts. More generally,

$$
\delta\left(\sum_{j=1}^{m} F_{j} h_{j}\right)=\sum_{j=1}^{m} \delta\left(F_{j} h_{j}\right)=\sum_{j=1}^{m} F_{j} W\left(h_{j}\right)-\left\langle D F_{j}, h_{j}\right\rangle
$$

Are functions like $\sum_{j=1}^{m} F_{j} h_{j}$ where $F_{j}$ is a polynomial in variables of the form $W(h)$ dense in $L^{p}(\Omega, H)$ ? It was shown earlier in Lemma 68.4.3 that polynomial functions $F$ in the $W(h)$ are dense in $L^{p}(\Omega)$ for any $p$. Let $s(\omega)=\sum_{k=1}^{n} h_{k} \mathscr{X}_{E_{k}}$ be a simple function. Then $\mathscr{X}_{E_{k}}$ is clearly in $L^{p}(\Omega)$ and so there exists $F_{k}$ a polynomial in the $W(h)$ which is as close as desired to $\mathscr{X}_{E_{k}}$ in $L^{p}$. Hence $\sum_{k=1}^{n} h_{k} F_{k}$ is close to $s$ in $L^{p}(\Omega, H)$ and so since these simple functions are dense, it follows that these kinds of functions are indeed dense in $L^{p}(\Omega, H)$, this for any $p>1$. The above discussion is summarized in the following lemma.

Lemma 68.4.5 Functions of the form $\sum_{k=1}^{n} F_{k} h_{k}$ where $F_{k}$ is a polynomial in the $W(h)$ $\left(F_{j} \in \mathscr{P}\right)$ are dense in $L^{p}(\Omega, H)$ for any $p>1$. Also each function of this form is in $D \delta$ and

$$
\delta\left(\sum_{j=1}^{m} F_{j} h_{j}\right)=\sum_{j=1}^{m} \delta\left(F_{j} h_{j}\right)=\sum_{j=1}^{m} F_{j} W\left(h_{j}\right)-\left\langle D F_{j}, h_{j}\right\rangle
$$

What does $D$ do to $\delta(F h)$ ? It is shown above that $\delta(F h)=F W(h)-\langle D F, h\rangle$. Say $F=F\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)$. Then when you do $D$ to $\delta(F h)$, you would get

$$
F h+\sum_{k=1}^{n} D_{k}(F) W(h) h_{k}-\sum_{k=1}^{n} \sum_{j=1}^{n} D_{j}\left(D_{k}(F)\right) h_{j}\left(h_{k}, h\right)
$$

In other words,

$$
F h+W(h) D(F)-D\langle D F, h\rangle
$$

Recall that $D G$ is well defined. This means that we can replace $\left\{h_{1}, \cdots, h_{n}, h\right\}$ with an orthonormal basis $\left\{e_{1}, \cdots, e_{p}, h\right\}$ as in

$$
G\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right), W(h)\right)=\hat{G}\left(W\left(e_{1}\right), \cdots, W\left(e_{p}\right), W(h)\right)
$$

where we assume $\|h\|=1$ for simplicity. Thus the above equals

$$
D(\delta(F))=D(\delta(\hat{F}))=\hat{F} h+W(h) D(\hat{F})-D\langle D \hat{F}, h\rangle
$$

Now consider $E\left(\delta(F h)^{2}\right)=E\langle D(\delta(F h)), F h\rangle$. Thus the following must be considered.

$$
\begin{equation*}
E\langle\hat{F} h+W(h) D(\hat{F})-D\langle D \hat{F}, h\rangle, \hat{F} h\rangle \tag{68.4.23}
\end{equation*}
$$

Consider the terms involved. The first term is just $E\left(\|\hat{F} h\|_{H}^{2}\right)=E\left(\|F h\|_{H}^{2}\right)$. Now consider the third term. It equals

$$
\begin{gathered}
-E\left(D\left(D_{p+1}(\hat{F})\right), \hat{F} h\right)=-E\left(D_{p+1}^{2}(\hat{F}) \hat{F}\right) \\
=\frac{-1}{(\sqrt{2 \pi})^{p+1}} \int_{\mathbb{R}^{p}} \int_{\mathbb{R}} D_{p+1}^{2}(\hat{F}(\mathbf{x})) \hat{F}(\mathbf{x}) e^{-\frac{1}{2}|\mathbf{x}|^{2}} d x_{p+1} d \hat{\mathbf{x}}_{p+1} \\
=\frac{1}{(\sqrt{2 \pi})^{p+1}} \int_{\mathbb{R}^{p}} \int_{\mathbb{R}} D_{p+1}(\hat{F}(\mathbf{x})) D_{p+1}(\hat{F}(\mathbf{x})) e^{-\frac{1}{2}|\mathbf{x}|^{2}} d x_{p+1} d \hat{\mathbf{x}}_{p+1} \\
-\frac{1}{(\sqrt{2 \pi})^{p+1}} \int_{\mathbb{R}^{p}} \int_{\mathbb{R}} D_{p+1}(\hat{F}(\mathbf{x}))\left(x_{p+1} \hat{F}(\mathbf{x})\right) e^{-\frac{1}{2}|\mathbf{x}|^{2}} d x_{p+1} d \hat{\mathbf{x}}_{p+1} \\
=E\left(\left(D_{p+1} \hat{F}\right)^{2}\right)-E\left(W(h) D_{p+1}(\hat{F}) \hat{F}\right) \\
=E\left(\left(D_{p+1} \hat{F}\right)^{2}\right)-E(W(h) D(\hat{F}), \hat{F} h)
\end{gathered}
$$

Hence 68.4.23 reduces to

$$
\begin{aligned}
E\left(\|\hat{F} h\|^{2}\right)+E\left(\left(D_{p+1} \hat{F}\right)^{2}\right) & =E\left(\|\hat{F} h\|^{2}\right)+E\left(\langle D(\hat{F}), h\rangle^{2}\right) \\
& =E\left(\|F h\|^{2}\right)+E\left(\langle D(F), h\rangle^{2}\right)
\end{aligned}
$$

This assumed that $\|h\|=1$. For arbitrary nonzero $h$,

$$
\begin{aligned}
E\left(\delta(F h)^{2}\right) & =\|h\|^{2} E\left(\delta\left(F \frac{h}{\|h\|}\right)^{2}\right) \\
& =\|h\|^{2}\left(E\left(\left\|F \frac{h}{\|h\|}\right\|^{2}\right)+E\left(\left\langle D(F), \frac{h}{\|h\|}\right\rangle^{2}\right)\right) \\
& =E\left(\|F h\|^{2}\right)+E\left(\langle D(F), h\rangle^{2}\right)
\end{aligned}
$$

Next consider a generalization, $u=\sum_{j=1}^{m} F_{j} h_{j}$ where the $\left\{h_{j}\right\}$ is an orthonormal set of vectors. Say $F_{j}=F_{j}\left(W\left(k_{1}\right), \cdots, W\left(k_{n_{j}}\right)\right)$. Let $\left\{h_{1}, \cdots, h_{m}, e_{1}, \cdots, e_{p}\right\}=\left\{g_{i}\right\}_{i=1}^{m+p}$ be an orthonormal basis for the span of all the $h_{j}$ and $k_{i}$. Thus $g_{i}=h_{i}$ for $i \leq m$. Then let

$$
F_{j}\left(W\left(k_{1}\right), \cdots, W\left(k_{n_{j}}\right)\right)=\hat{F}_{j}\left(W\left(h_{1}\right), \cdots, W\left(h_{m}\right), W\left(e_{1}\right), \cdots, W\left(e_{p}\right)\right)
$$

The computations will be done with respect to this orthonormal set because it will be simpler. Also, the above argument using the density function for the normal distribution will be used without explicitly repeating it.

It is desired to consider $E\left(\delta(u)^{2}\right)$. Recall that

$$
D(\delta(F h))=F h+W(h) D(F)-D\langle D F, h\rangle .
$$

Thus $E\left(\delta(u)^{2}\right)=$

$$
\begin{gathered}
\sum_{j, k=1}^{m} E\left(\delta\left(\hat{F}_{j} h_{j}\right) \delta\left(\hat{F}_{k} h_{k}\right)\right)=\sum_{j, k=1}^{m} E\left(\left\langle D\left(\delta\left(\hat{F}_{j} h_{j}\right)\right),\left(\hat{F}_{k} h_{k}\right)\right\rangle\right) \\
\sum_{j, k=1}^{m} E\left(\left\langle\hat{F}_{j} h_{j}+W\left(h_{j}\right) D\left(\hat{F}_{j}\right)-D\left\langle D \hat{F}_{j}, h_{j}\right\rangle,\left(\hat{F}_{k} h_{k}\right)\right\rangle\right)
\end{gathered}
$$

Separating out the first term this is

$$
\begin{align*}
= & E\left(\sum_{k=1}^{m}\left\|\hat{F}_{k}\right\|^{2}\right)+\sum_{k, k} E\left(\left\langle W\left(h_{j}\right) D\left(\hat{F}_{j}\right), \hat{F}_{k} h_{k}\right\rangle\right) \\
& -\sum_{j, k} E\left(D_{k}\left(D_{j} \hat{F}_{j}\right) F_{k}\right) \\
= & E\left(\sum_{k=1}^{m}\left\|\hat{F}_{k}\right\|^{2}\right)+\sum_{k, k} E\left(\left\langle W\left(h_{j}\right) D\left(\hat{F}_{j}\right), \hat{F}_{k} h_{k}\right\rangle\right) \\
& -\sum_{j, k} E\left(D_{k}\left(D_{j} \hat{F}_{j}\right) \hat{F}_{k}\right) \\
= & E\left(\sum_{k=1}^{m}\left\|\hat{F}_{k}\right\|^{2}\right)+\sum_{k, k} E\left(W\left(h_{j}\right) D_{k}\left(\hat{F}_{j}\right) \hat{F}_{k}\right) \\
& \quad-\sum_{j, k} E\left(D_{k}\left(D_{j} \hat{F}_{j}\right) \hat{F}_{k}\right) \tag{68.4.24}
\end{align*}
$$

By equality of mixed partial derivatives, the third term equals

$$
-\sum_{j, k} E\left(D_{j}\left(D_{k} \hat{F}_{j}\right) \hat{F}_{k}\right)=\sum_{j, k} E\left(\left(D_{k} \hat{F}_{j}\right)\left(D_{j} \hat{F}_{k}\right)\right)-\sum_{j, k} E\left(D_{k}\left(\hat{F}_{j}\right) \hat{F}_{k} W\left(h_{j}\right)\right)
$$

Therefore, 68.4.24 reduces to

$$
\begin{aligned}
E\left(\delta\left(\sum_{j=1}^{m} F_{j} h_{j}\right)^{2}\right) & =E\left(\sum_{k=1}^{m}\left\|\hat{F}_{k}\right\|_{H}^{2}\right)+\sum_{j, k=1}^{m} E\left(\left(D_{k} \hat{F}_{j}\right)\left(D_{j} \hat{F}_{k}\right)\right) \\
& =E\left(\sum_{k=1}^{m}\left\|\hat{F}_{k}\right\|_{H}^{2}\right)+\sum_{j, k=1}^{m} E\left(\left\langle D \hat{F}_{j}, h_{k}\right\rangle\left\langle D \hat{F}_{k}, h_{j}\right\rangle\right) \\
& =E\left(\sum_{k=1}^{m}\left\|F_{k}\right\|_{H}^{2}\right)+\sum_{j, k=1}^{m} E\left(\left\langle D F_{j}, h_{k}\right\rangle\left\langle D F_{k}, h_{j}\right\rangle\right)
\end{aligned}
$$

because the derivative is well defined. All of this assumes the $h_{k}$ form an orthonormal set. Suppose these are just orthogonal but nonzero. Then

$$
E\left(\delta\left(\sum_{j=1}^{m} F_{j} h_{j}\right)^{2}\right)=E\left(\left(\sum_{j=1}^{m} \delta\left(F_{j} h_{j}\right)\right)^{2}\right)=E\left(\sum_{j, k} \delta\left(F_{j} h_{j}\right) \delta\left(F_{k} h_{k}\right)\right)
$$

$$
=E\left(\sum_{j, k}\left\|h_{j}\right\|\left\|h_{k}\right\| \delta\left(F_{j} h_{j} /\left\|h_{j}\right\|\right) \boldsymbol{\delta}\left(F_{k} h_{k} /\left\|h_{k}\right\|\right)\right)
$$

and doing exactly the same steps but keeping the factor $\left\|h_{j}\right\|\left\|h_{k}\right\|$ throughout, this yields

$$
\begin{aligned}
& E\left(\sum_{k=1}^{m}\left\|h_{k}\right\|^{2}\left\|F_{k}\right\|_{H}^{2}\right)+\sum_{j, k=1}^{m} E\left(\left\|h_{j}\right\|\left\|h_{k}\right\|\left\langle D F_{j}, h_{k} /\left\|h_{k}\right\|\right\rangle\left\langle D F_{k}, h_{j} /\left\|h_{j}\right\|\right\rangle\right) \\
= & E\left(\sum_{k=1}^{m}\left\|F_{k} h_{k}\right\|_{H}^{2}\right)+\sum_{j, k=1}^{m} E\left(\left\langle D F_{j}, h_{k}\right\rangle\left\langle D F_{k}, h_{j}\right\rangle\right) \\
= & E\left(\left\|\sum_{k=1}^{m} F_{k} h_{k}\right\|_{H}^{2}\right)+\sum_{j, k=1}^{m} E\left(\left\langle D F_{j}, h_{k}\right\rangle\left\langle D F_{k}, h_{j}\right\rangle\right)
\end{aligned}
$$

It appears from the computations to be correct, but it does not look right. This is because the second term is not clearly nonnegative. It is the expectation of the trace of $A^{2}$ where $A$ is the matrix whose $j k^{t h}$ entry is $\left\langle D F_{j}, h_{k}\right\rangle$. One wonders whether the end result is nonnegative.

### 68.4.3 The Ito And Skorokhod Integrals

If you let $H=L^{2}(0, \infty ; U)$ where $U$ is a separable Hilbert space, and if $f \in D(\boldsymbol{\delta})$, it is very natural to ask whether $f \mathscr{X}_{(0, t)} \in D(\delta)$. This is not so. There is a counter example given in [102]. However, this is true if you change the definition of the integral such that in the definition of $\delta$, it is only necessary for

$$
|\langle D F, G\rangle| \leq C\|F\|_{L^{p}(\Omega)}
$$

where $F$ is in $\mathscr{P}$. When you see why this is so, it will be clear why it is not so for the definition given above.

Lemma 68.4.6 Suppose the definition of the Skorokhod integral $\delta$ is changed so that it is only necessary to have

$$
|\langle D F, G\rangle| \leq C\|F\|_{L^{p}(\Omega)}
$$

for all $F$ in $\mathscr{P}$. Then let $H \equiv L^{2}(0, \infty ; U)$ or $L^{2}([0, T] ; U)$ where $U$ is a separable real Hilbert space. For this modified definition of the integral, if $f \in D(\boldsymbol{\delta})$, it follows that $f \mathscr{X}_{(0, t)} \in D(\boldsymbol{\delta})$.

Proof: The case $L^{2}(0, \infty ; U)$ is considered here. The other case is similar. $\delta$ will be defined on some things in $L^{2}\left(\Omega, L^{2}(0, \infty ; U), \mathscr{F}\right)$ where, as discussed earlier,

$$
\mathscr{F}=\sigma(W(h): h \in H)
$$

Then if you have $f \in D(\boldsymbol{\delta})$ so $f \in L^{2}\left(\Omega, L^{2}(0, \infty ; U)\right)$, does it follow that $f \mathscr{X}_{[0, t]} \in D(\boldsymbol{\delta})$ also? Let $F$ be one of those polynomial functions of some $W(h)$. Assume first that $a_{0}$, the
constant term is 0 and consider

$$
E\left\langle D F, f \mathscr{X}_{[0, t]}\right\rangle \equiv E\left\langle\sum_{k} D_{k}(F) h_{k}, f \mathscr{X}_{[0, t]}\right\rangle
$$

Since $h_{k} \in H=L^{2}(0, \infty ; U)$, so is $h_{k} \mathscr{X}_{[0, t]}$. Thus the above reduces to

$$
=\sum_{k} E\left\langle D_{k}(F) h_{k}, f \mathscr{X}_{[0, t]}\right\rangle=\sum_{k} E\left(\int_{0}^{\infty} D_{k}\left(F\left(W\left(h_{1}\right), \cdots W\left(h_{n}\right)\right)\right) h_{k} \mathscr{X}_{[0, t]} f d t\right)
$$

Since $F$ is just a polynomial and $W$ is linear and $\mathscr{X}_{[0, t]}^{q}=\mathscr{X}_{[0, t]}$, this equals

$$
\sum_{k} E\left(\int_{0}^{\infty} D_{k}\left(F\left(W\left(\mathscr{X}_{[0, t]} h_{1}\right), \cdots W\left(\mathscr{X}_{[0, t]} h_{n}\right)\right)\right) h_{k} \mathscr{X}_{[0, t]} f d t\right)
$$

Let $F_{t}=F\left(W\left(\mathscr{X}_{[0, t]} h_{1}\right), \cdots W\left(\mathscr{X}_{[0, t]} h_{n}\right)\right)$ and so the above is nothing more than

$$
E\left\langle D F, f \mathscr{X}_{[0, t]}\right\rangle=E\left\langle D F_{t}, f\right\rangle
$$

and since $f \in D(\boldsymbol{\delta})$,

$$
\left|E\left\langle D F, f \mathscr{X}_{[0, t]}\right\rangle\right|=\left|E\left\langle D F_{t}, f\right\rangle\right| \leq C(f)\left\|F_{t}\right\|_{L^{2}(\Omega)}
$$

Also

$$
\begin{aligned}
\left\|F_{t}\right\|_{L^{2}(\Omega)}^{2} & =\int_{\Omega} F\left(W\left(\mathscr{X}_{[0, t]} h_{1}\right), \cdots W\left(\mathscr{X}_{[0, t]} h_{n}\right)\right)^{2} d P \\
& =\int_{\Omega} \mathscr{X}_{[0, t]} F\left(W\left(h_{1}\right), \cdots W\left(h_{n}\right)\right)^{2} d P \\
& \leq \int_{\Omega} F\left(W\left(h_{1}\right), \cdots W\left(h_{n}\right)\right)^{2} d P
\end{aligned}
$$

Thus for such $F$ which have zero constant term,

$$
\left|E\left\langle D F, f \mathscr{X}_{[0, t]}\right\rangle\right| \leq C\|F\|_{L^{2}(\Omega)}
$$

Now what if $F$ is a constant $a$ ? In this case, $D F=D a=0$

$$
\left|E\left\langle D a, f \mathscr{X}_{[0, t]}\right\rangle\right|=0 \leq\|a\|_{L^{2}(\Omega)}
$$

It follows that $\mathscr{X}_{[0, t]} f \in D(\boldsymbol{\delta})$ whenever $f$ is.
Note how it was essential in this argument to have $F$ be a polynomial or perhaps more generally an analytic function. However, in the definition of the Skorokhod integral, one must test with functions $F$ which are smooth and have polynomial growth. In particular, this would include functions which are infinitely differentiable with compact support, none of which have valid power series.

How does the Skorokhod integral relate to the Ito integral? What about elementary functions and so forth? Let $0=t_{0}<t_{1}<\cdots<t_{n}=T$. Consider

$$
\sum_{k=0}^{n-1} F_{k} \mathscr{X}_{\left(t_{k}, t_{k+1}\right)}
$$

As shown above, this is one of the things in $D(\delta)$.

$$
\begin{gathered}
\delta\left(\mathscr{X}_{(0, t)} \sum_{k=0}^{n-1} F_{k} \mathscr{X}_{\left(t_{k}, t_{k+1}\right)}\right)=\delta\left(\sum_{k=0}^{n-1} F_{k} \mathscr{X}_{\left[t_{k} \wedge t, t \wedge t_{k+1}\right]}\right) \\
=\sum_{k=0}^{n-1} F_{k} W\left(\mathscr{X}_{\left[t_{k} \wedge t, t \wedge t_{k+1}\right]}\right)-\left\langle D F_{k}, \mathscr{X}_{\left[t_{k} \wedge t, t \wedge t_{k+1}\right]}\right\rangle \\
=\sum_{k=0}^{n-1} F_{k}\left(W\left(\mathscr{X}_{\left(0, t \wedge t_{k+1}\right)}\right)-W\left(\mathscr{X}_{\left(0, t \wedge t_{k}\right)}\right)\right)-\left\langle D F_{k}, \mathscr{X}_{\left[t_{k} \wedge t, t \wedge t_{k+1}\right]}\right\rangle
\end{gathered}
$$

In terms of the Wiener process, this is of the form

$$
=\sum_{k=0}^{n-1} F_{k}\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right)-\left\langle D F_{k}, \mathscr{X}_{\left[0, t \wedge t_{k+1}\right]}-\mathscr{X}_{\left[0, t \wedge t_{k}\right]}\right\rangle_{H}
$$

What if

$$
F_{k}=F_{k}\left(W\left(\mathscr{X}_{\left[0, t_{k}\right]} h_{1}\right), \cdots W\left(\mathscr{X}_{\left[0, t_{k}\right]} h_{n}\right)\right) ?
$$

Let $\mathscr{F}_{t} \equiv \sigma\left(W\left(\mathscr{X}_{[0, t]} h\right): h \in H\right)$. Then this is clearly a filtration. If $F_{k}$ is as just described, then $F_{k}$ is $\mathscr{F}_{t_{k}}$ adapted.

$$
\left\langle D F_{k}, \mathscr{X}_{\left[0, t \wedge t_{k+1}\right]}-\mathscr{X}_{\left[0, t \wedge t_{k}\right]}\right\rangle=\int_{0}^{\infty} \sum_{s} D_{s}\left(F_{k}\right) \mathscr{X}_{\left(0, t_{k}\right)} h_{s} \mathscr{X}_{\left(t \wedge t_{k}, t \wedge t_{k+1}\right)}=0
$$

because the intervals are disjoint. In this case, the troublesome term at the end vanishes and you are left with

$$
\begin{equation*}
\sum_{k=0}^{n-1} F_{k}\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right) \tag{68.4.25}
\end{equation*}
$$

which is similar to the usual definition for the Ito integral.
What if $F \in L^{2}(\Omega \times[0, T])$ and is progressively measurable. Does it have a Skorokhod integral, and if so, is it the same as the Ito integral? Recall the following useful lemma. It is Lemma 65.3.1 on Page 2231.

Lemma 68.4.7 Let $\Phi:[0, T] \times \Omega \rightarrow E$, be $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable and suppose

$$
\Phi \in K \equiv L^{p}([0, T] \times \Omega ; E), p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
\Phi_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t) \\
\Phi_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t)
\end{aligned}
$$

both converge to $\Phi$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

Also, each $\Phi\left(t_{j}^{k}\right), \Phi\left(t_{j-1}^{k}\right)$ is in $L^{p}(\Omega ; E)$. One can also assume that $\Phi(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$
\left|t_{j}^{k}-t_{j-1}^{k}\right|=2^{-n_{k}}
$$

except for the case where $j=1$ or $j=m_{n_{k}}$ when this is so, you could have $\left|t_{j}^{k}-t_{j-1}^{k}\right|<2^{-n_{k}}$.
Theorem 68.4.8 Let $F \in L^{2}(\Omega \times[0, T])$ and is progressively measurable. Then it has $a$ Skorokhod integral which coincides with the Ito integral.

Proof: From Lemma 68.4.7, there is a sequence of left step functions denoted here as $\left\{F_{k}^{l}\right\}_{k=1}^{\infty}$ which converges to $F$ in $L^{2}(\Omega \times[0, T])$ where $F_{k}^{l}\left(t_{j}^{k}\right)=F\left(t_{j}^{k}\right)$. We can take a subsequence if necessary and assume

$$
\left\|F_{k}^{l}-F\right\|_{L^{2}([0, T] \times \Omega)}<2^{-k}
$$

Here the $\left\{t_{j}^{k}\right\}$ are mesh points corresponding to the $k^{t h}$ partition described above. Thus each $F_{k}^{l}\left(t_{j}^{k}\right)$ is in $L^{2}(\Omega)$. By Lemma 68.4.3 there exists a random variable $G_{k}^{l}\left(t_{j}^{k}\right)$ which is a polynomial function of some $W(h)$ for $h \in L^{2}\left(0, t_{j}^{k}\right)$ which can approximate $F_{k}^{l}\left(t_{j}^{k}\right)$ as closely as desired in $L^{2}(\Omega)$. Then choosing these sufficiently close, it can be assumed that the step functions

$$
G_{k}^{l} \equiv \sum_{j=0}^{m_{k}-1} G_{k}^{l}\left(t_{j}^{k}\right) \mathscr{X}_{\left(t_{j}^{k}, t_{j+1}^{k}\right)}
$$

also converge in $L^{2}(\Omega \times[0, T])$ to $F$. Of course, each of these last step functions are in $D(\delta)$.

The idea is to show that $\delta\left(G_{k}^{l}\right)$ is Cauchy in $L^{2}(\Omega)$ as $k \rightarrow \infty$ and then use the fact that, since $\delta$ is an adjoint, it must be a closed operator. This will show that $F \in L^{2}(\Omega \times[0, T])$, considered as a subspace of $L^{2}\left(\Omega ; L^{2}(0, \infty, \mathbb{R})\right)$, is in $D(\delta)$ and $\delta(F)$ is equal to the above
limit. Using 68.4.25 which comes from the fact that the functions are adapted to the given filtration,

$$
\begin{aligned}
& \left\|\delta\left(\mathscr{X}_{[0, T]} G_{k}^{l}\right)-\delta\left(\mathscr{X}_{[0, T]} G_{k+1}^{l}\right)\right\|_{L^{2}(\Omega)}^{2} \\
= & E\left(\sum_{j=0}^{m_{k+1}-1}\left(G_{k}^{l}\left(t_{j+1}^{k+1}\right)-G_{k+1}^{l}\left(t_{j}^{k+1}\right)\right)\left(W\left(t_{j+1}^{k+1}\right)-W\left(t_{j}^{k+1}\right)\right)\right)^{2}
\end{aligned}
$$

Consider a mixed term. To save on space, let $\Delta_{j}=G_{k}^{l}\left(t_{j+1}^{k+1}\right)-G_{k+1}^{l}\left(t_{j}^{k+1}\right)$ and say $i<j$. Then

$$
E\left(\left(\Delta_{j}\right)\left(\Delta_{i}\right)\left(W\left(t_{j+1}^{k+1}\right)-W\left(t_{j}^{k+1}\right)\right)\left(W\left(t_{i+1}^{k+1}\right)-W\left(t_{i}^{k+1}\right)\right)\right)
$$

By independence of the increments for $W$, this is

$$
E\left(W\left(t_{j+1}^{k+1}\right)-W\left(t_{j}^{k+1}\right)\right) E\left(\left(\Delta_{j}\right)\left(\Delta_{i}\right)\left(W\left(t_{i+1}^{k+1}\right)-W\left(t_{i}^{k+1}\right)\right)\right)=0
$$

and so the above reduces to

$$
\begin{gathered}
\sum_{j=0}^{m_{k+1}^{-1}} E\left(\Delta_{j}^{2}\left(W\left(t_{j+1}^{k+1}\right)-W\left(t_{j}^{k+1}\right)\right)^{2}\right) \\
=\sum_{j=0}^{m_{k+1}^{-1}} E\left(\Delta_{j}^{2}\right) E\left(\left(W\left(t_{j+1}^{k+1}\right)-W\left(t_{j}^{k+1}\right)\right)^{2}\right) \\
=\sum_{j=0}^{m_{k+1}-1} E\left(\left(G_{k}^{l}\left(t_{j+1}^{k+1}\right)-G_{k+1}^{l}\left(t_{j}^{k+1}\right)\right)^{2}\right)\left(t_{j+1}^{k+1}-t_{j}^{k+1}\right) \\
=E\left(\int_{0}^{T}\left(G_{k}^{l}-G_{k+1}^{l}\right)^{2} d t\right) \leq 2\left(E \int_{0}^{T}\left(G_{k}^{l}-F\right)^{2} d t+E \int_{0}^{T}\left(F-G_{k+1}^{l}\right)^{2} d t\right)
\end{gathered}
$$

which is given to converge to 0 as $k \rightarrow \infty$. It follows that

$$
\mathscr{X}_{[0, T]} G_{k}^{l} \rightarrow \mathscr{X}_{[0, T]} F
$$

in $L^{2}\left(\Omega, L^{2}(0, \infty, \mathbb{R})\right)$ by construction and $\delta\left(\mathscr{X}_{[0, T]} G_{k}^{l}\right)$ is a Cauchy sequence in $L^{2}(\Omega)$. Therefore, it converges to something in $L^{2}(\Omega)$ and since $\delta$ is a closed operator, that which it converges to is $\delta(F)$.

However, by the definition of the Ito integral, $\delta\left(\mathscr{X}_{[0, T]} G_{k}^{l}\right)$ also converges to the Ito integral $\int_{0}^{T} F d W$.

It follows that the Skorokhod integral is more general than the Ito integral but it gives the Ito integral in the special case where the function is adapted. This also shows that the progressively measurable functions in $L^{2}([0, T] \times \Omega)$ are in $D(\delta)$, but as shown above, there are many other functions which are not progressively measurable but which are still in $D(\boldsymbol{\delta})$. Just consider, for example $\sum_{k=1}^{n} F h_{k}$ where $F$ is just a polynomial in $W(h)$ for $h \in L^{2}(0, \infty ; \mathbb{R})$.

## Chapter 69

## Gelfand Triples

Let $H$ be a separable real Hilbert space and let $V \subseteq H$ be a separable Banach space which is embedded continuously into $H$ and which is also dense in $H$. Then identifying $H$ and $H^{\prime}$ you can write

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

This is called a Gelfand triple. If $V$ is reflexive, you could conclude separability of $V$ from the separability of $H$. However, if $V$ is not reflexive, this might not happen. For example, you could take $V=L^{\infty}(0,1)$ and $H=L^{2}(0,1)$.

Proposition 69.0.1 Suppose $V$ is reflexive and a subset of $H$ a separable Hilbert space with the inclusion map continuous. Suppose also that $V$ is dense in $H$. Then identifying $H$ and $H^{\prime}$, it follows that $H$ is dense in $V^{\prime}$ and $V$ is separable.

Proof: If $H$ is not dense in $V^{\prime}$, then by the Hahn Banach theorem, there exists $\phi^{* *} \in V^{\prime \prime}$ such that $\phi^{* *}(H)=0$ but $\phi^{* *}\left(\phi^{*}\right) \neq 0$ for some $\phi^{*} \in V^{\prime} \backslash \bar{H}$. Since $V$ is reflexive there exists $v \in V$ such that $\phi^{* *}=J v$ for $J$ the standard mapping from $V$ to $V^{\prime \prime}$. Thus

$$
\phi^{* *}(h) \equiv\langle h, v\rangle \equiv(v, h)_{H}=0
$$

for all $h \in H$. Therefore, $v=0$ and so $J v=0=\phi^{* *}$ which contradicts $\phi^{* *}\left(\phi^{*}\right) \neq 0$. Therefore, $H$ is dense in $V^{\prime}$. Now by Theorem 21.1.16 which says separability of the dual space implies separability of the space, it follows $V$ is separable as claimed. This proves the proposition.

From now on, it is assumed $V$ and $V^{\prime}$ are both separable and that $H$ is dense in $V^{\prime}$. This is summarized in the following definition.

Definition 69.0.2 $V, H, V^{\prime}$ will be called a Gelfand triple if $V, V^{\prime}$ are separable, $V \subseteq H$ with the inclusion map continuous, $H=H^{\prime}$, and $H=H^{\prime}$ is dense in $V^{\prime}$.

What about the Borel sets on $V$ and $H$ ?
Proposition 69.0.3 Denote by $\mathscr{B}(X)$ the Borel sets of $X$ where $X$ is any separable Banach space. Then

$$
\mathscr{B}(X)=\sigma\left(X^{\prime}\right)
$$

Here $\sigma\left(X^{\prime}\right)$ is the smallest $\sigma$ algebra such that each $\phi \in X^{\prime}$ is measurable. Also in the context of the above definition, $\mathscr{B}(V)=\sigma\left(i^{*} H^{\prime}\right)$ because $H^{\prime}$ is dense in $V^{\prime}$. Here $i^{*}$ is the restriction to $V$ so that $i^{*} h(v) \equiv h(v) \equiv(h, v)_{H}$ for all $v \in V$ and $\sigma\left(i^{*} H^{\prime}\right)$ denotes the smallest $\sigma$ algebra such that $i^{*} h$ is measurable for each $h \in H^{\prime}$.

Proof: By Lemma 21.1.6 there exists a countable subset of the unit ball in $X^{\prime}$

$$
\left\{\phi_{n}\right\}_{n=1}^{\infty}=D^{\prime}
$$

such that

$$
\|v\|_{X}=\sup \left\{|\phi(v)|: \phi \in D^{\prime}\right\} .
$$

Consider a closed ball $\overline{B\left(v_{0}, r\right)}$ in $X$. This equals

$$
\left\{v \in X: \sup _{n}\left|\phi_{n}(v)-\phi_{n}\left(v_{0}\right)\right| \leq r\right\}=\cap_{n=1}^{\infty} \phi_{n}^{-1}\left(\overline{B\left(\phi_{n}\left(v_{0}\right), r\right)}\right)
$$

and this last set is in $\sigma\left(D^{\prime}\right)$. Therefore, every closed ball is in $\sigma\left(D^{\prime}\right)$ which implies every open ball is also in $\sigma\left(D^{\prime}\right)$ since open balls are the countable union of closed balls. Since $X$ is separable, it follows every open set is the countable union of balls and so every open set is in $\sigma\left(D^{\prime}\right)$. It follows $\mathscr{B}(X) \subseteq \sigma\left(D^{\prime}\right) \subseteq \sigma\left(X^{\prime}\right)$. On the other hand, every $\phi \in X^{\prime}$ is continuous and so it is Borel measurable. Hence $\sigma\left(X^{\prime}\right) \subseteq \mathscr{B}(X)$.

Now consider the last claim. From Lemma 21.1.6 and density of $H^{\prime}=H$ in $V^{\prime}$, it can be assumed $D^{\prime} \subseteq H=H^{\prime}$. Therefore, from the first part of the argument

$$
\mathscr{B}(V) \subseteq \sigma\left(D^{\prime}\right) \subseteq \sigma\left(i^{*} H^{\prime}\right)
$$

Also each $i^{*} h$ is continuous on $V$ so in fact, equality holds in the above because $\sigma\left(i^{*} H^{\prime}\right) \subseteq$ $\mathscr{B}(V)$. This proves the proposition.

Next I want to verify that $V$ is in $\mathscr{B}(H)$. This will be true if $V$ is reflexive. More generally, here is an interesting result.

Proposition 69.0.4 Let $X \subseteq Y, X$ dense in $Y$ and suppose $X, Y$ are Banach spaces and that $X$ is reflexive. Then $X \in \mathscr{B}(Y)$.

Proof: Define the functional

$$
\phi(x) \equiv\left\{\begin{array}{l}
\|x\|_{X} \text { if } x \in X \\
\infty \text { if } x \in Y \backslash X
\end{array}\right.
$$

Then $\phi$ is lower semicontinuous on $Y$. Here is why. Suppose $(x, a) \notin \operatorname{epi}(\phi)$ so that $a<$ $\phi(x)$. I need to verify this situation persists for $(x, b)$ near $(x, a)$. If this is not so, there exists $x_{n} \rightarrow x$ and $a_{n} \rightarrow a$ such that $a_{n} \geq \phi\left(x_{n}\right)$. If $\liminf _{n \rightarrow \infty} \phi\left(x_{n}\right)<\infty$, then there exists a subsequence still denoted by $n$ such that $\left\|x_{n}\right\|_{X}$ is bounded. Then by the Eberlein Smulian theorem, there exists a further subsequence such that $x_{n}$ converges weakly in $X$ to some $z$. Now since $X$ is dense in $Y$ it follows $Y^{\prime}$ can be considered a subspace of $X^{\prime}$ and so for $f \in Y^{\prime}$

$$
f\left(x_{n}\right) \rightarrow f(z), f\left(x_{n}\right) \rightarrow f(x)
$$

and so $f(z-x)=0$ for all $f \in Y^{\prime}$ which requires $z=x$. Now $x \rightarrow\|x\|_{X}$ is convex and lower semicontinuous on $X$ so it follows from Corollary 18.2.12

$$
a=\lim \inf _{n \rightarrow \infty} a_{n} \geq \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq \phi(x)>a
$$

which is a contradiction. If $\liminf _{n \rightarrow \infty} \phi\left(x_{n}\right)=\infty$, then

$$
\infty>a=\lim \inf _{n \rightarrow \infty} a_{n}=\infty
$$

another contradiction. Therefore, epi $(\phi)$ is closed and so $\phi$ is lower semicontinuous as claimed. Therefore,

$$
X=Y \backslash\left(\cap_{n=1}^{\infty} \phi^{-1}((n, \infty))\right)
$$

and since $\phi$ is lower semicontinuous, each $\phi^{-1}((n, \infty))$ is open. Hence $X$ is a Borel subset of $Y$. This proves the proposition.

### 69.1 An Unnatural Example

Recall Gelfand triples are of the form

$$
V \subseteq H \subseteq V^{\prime}
$$

where $H$ is a Hilbert space and $V$ is a Banach space contained in $H$ and each of the above inclusions is continuous and each space is dense in the next one. The standard example of a Gelfand triple is $H_{0}^{1}(D) \subseteq L^{2}(D) \subseteq\left(H_{0}^{1}(D)\right)^{\prime}$ with the convention that $L^{2}(D)$ is identified with its dual space. Thus for $f \in L^{2}(D), f$ is considered as something in $\left(H_{0}^{1}(D)\right)^{\prime}$ according to the rule

$$
\langle f, \phi\rangle \equiv(f, \phi)_{L^{2}(D)}
$$

This is a very pleasant thing to contemplate and it is natural and transparent. However, there are other ways to come up with a Gelfand triple which are much more perverse. The following is an example of such a thing along with an application. See [108] and references given there.

First consider the following situation.

$$
X \xrightarrow{\theta} Y
$$

where $\theta$ is continuous, linear and one to one and $X$ is a Banach space. Then $\theta(X) \subseteq Y$ and you could define

$$
\|\theta x\|_{\theta(X)} \equiv\|x\|_{X} .
$$

Then $\theta(X)$ can be considered the same thing as $X$ because $\theta$ preserves distances and all algebraic properties. Thus people write $X \subseteq Y$ to save space. In the above simple example, it is obvious what $\theta$ is. This is because the things in $H_{0}^{1}$ and things in $L^{2}$ are both functions defined on $D$ and we can simply take $\theta$ to be the identity map. However, you might have $H$ be the dual space of something. Thus it consists of bounded linear transformations defined on some Banach space. Then it becomes necessary to specify the manner in which vectors in $V$ can be considered as vectors of $H$.

Let $\infty>p \geq 2$. Then letting $D$ be a bounded open set, $H_{0}^{1}(D)$ embedds continuously into $L^{p^{\prime}}(D)$. That is

$$
\begin{equation*}
\|\phi\|_{L^{p^{\prime}}} \leq C\|\phi\|_{H_{0}^{1}} \tag{69.1.1}
\end{equation*}
$$

Here $\frac{1}{p^{\prime}}+\frac{1}{p}=1$. Also note that an equivalent inner product on $H_{0}^{1}(D)$ is

$$
(f, g)_{H_{0}^{1}} \equiv \int_{D} \nabla f \cdot \nabla g d x
$$

Then with respect to this inner product, the Riesz map is given by $-\Delta$.

$$
-\Delta: H_{0}^{1}(D) \rightarrow\left(H_{0}^{1}(D)\right)^{\prime}
$$

Thus a typical vector of $\left(H_{0}^{1}(D)\right)^{\prime}$ is of the form $-\Delta \phi$ where $\phi \in H_{0}^{1}(D)$ and the following hold.

$$
(\phi, \psi)_{H_{0}^{1}} \equiv\langle-\Delta \phi, \psi\rangle,(-\Delta \phi,-\Delta \psi)_{\left(H_{0}^{1}\right)^{\prime}} \equiv(\phi, \psi)_{H_{0}^{1}}=\langle-\Delta \psi, \phi\rangle
$$

The following is about the Gelfand triple

$$
V=L^{p}(D) \subseteq\left(H_{0}^{1}\right)^{\prime} \subseteq\left(L^{p}(D)\right)^{\prime}
$$

Lemma 69.1.1 It is possible to consider $L^{p}(D) \equiv V$ as a dense subspace of $\left(H_{0}^{1}\right)^{\prime} \equiv H$ as follows. For $f \in L^{p}(D)$ and $\phi \in H_{0}^{1}(D)$,

$$
\langle f, \phi\rangle \equiv \int_{D} f(x) \phi(x) d x
$$

One can also consider $H \equiv\left(H_{0}^{1}\right)^{\prime}$ as a dense subspace of $\left(L^{p}(D)\right)^{\prime} \equiv V^{\prime}$ as follows. For $-\Delta \phi \in H$ and $f \in L^{p}(D)$,

$$
\langle-\Delta \phi, f\rangle \equiv(-\Delta \phi, f)_{H} \equiv\langle f, \phi\rangle
$$

$-\Delta$ maps $H_{0}^{1}(D)$ to $H \equiv\left(H_{0}^{1}\right)^{\prime} \subseteq V^{\prime} .-\Delta$ can be extended to yield a map $-\Delta_{1}$ from $L^{p^{\prime}}(D)$ to $V^{\prime}$.

$$
\begin{aligned}
& H_{0}^{1}(D) \xrightarrow{-\Delta}\left(H_{0}^{1}\right)^{\prime} \\
& L^{p^{\prime}}(D)=V \xrightarrow{-\Delta_{1}} V^{\prime}
\end{aligned}
$$

Proof: First of all, note that by 69.1.1

$$
|\langle f, \phi\rangle| \leq\|f\|_{L^{p}}\|\phi\|_{L^{p^{\prime}}} \leq C\|f\|_{L^{p}}\|\phi\|_{H_{0}^{1}}
$$

and so it is certainly possible to consider $L^{p} \subseteq H \equiv\left(H_{0}^{1}\right)^{\prime}$ as just claimed. Now why can $L^{p}(D)$ be considered dense in $H \equiv\left(H_{0}^{1}\right)^{\prime}$ ? If it isn't dense, then there exists $\psi \in$ $H_{0}^{1}(D), \psi \neq 0$ such that

$$
(-\Delta \psi, f)_{H}=0
$$

for all $f \in L^{p}(D)$. However, the above would say that for all $f \in L^{p}$,

$$
(-\Delta \psi, f)_{H} \equiv\langle f, \psi\rangle \equiv \int_{D} f \psi=0
$$

But $\psi \in L^{p^{\prime}}(D)$ because $H_{0}^{1}(D)$ embedds continuously into $L^{p^{\prime}}(D)$ and so the above holding for all $f \in L^{p}(D)$ implies by the usual Riesz representation theorem that $\psi=0$ contrary to the way $\psi$ was chosen.

Now consider the next claim. For $-\Delta \phi \in H \equiv\left(H_{0}^{1}\right)^{\prime}$ and $f \in L^{p}(D)$ and from the first part

$$
|\langle-\Delta \phi, f\rangle| \equiv\left|(-\Delta \phi, f)_{H}\right| \equiv|\langle f, \phi\rangle| \leq C\|f\|_{L^{p}}\|\phi\|_{H_{0}^{1}(D)}
$$

Thus $-\Delta \phi \in H$ can be considered in $\left(L^{p}(D)\right)^{\prime}$. Why should $H$ be dense in $\left(L^{p}(D)\right)^{\prime}$ ? If it is not dense, then there exists $g^{*} \in\left(L^{p}(D)\right)^{\prime}$ which is not the limit of vectors of $H$. Then
since $L^{p}(D)$ is reflexive, an application of the Hahn Banach theorem shows there exists $f \in L^{p}(D)$ such that

$$
\begin{equation*}
\left\langle g^{*}, f\right\rangle_{\left(L^{p}(D)\right)^{\prime}, L^{p}(D)} \neq 0,\langle-\Delta \phi, f\rangle_{\left(L^{p}(D)\right)^{\prime}, L^{p}(D)}=0 \tag{69.1.2}
\end{equation*}
$$

for all $-\Delta \phi \in H$. However, it was just shown $H$ could be considered a subset of $\left(L^{p}(D)\right)^{\prime}$ in the manner described above. Therefore, the last equation in the above is of the form

$$
0=(-\Delta \phi, f)_{H}=\langle f, \phi\rangle=\int_{D} f \phi d x
$$

and since this holds for all $\phi \in H_{0}^{1}(D)$, it follows by density of $H_{0}^{1}(D)$ in $L^{p^{\prime}}(D)$, that $f=0$ and now this contradicts the inequality in 69.1.2.

Now $\Delta$ is defined on $H_{0}^{1}(D)$ and it delivers something in $\left(H_{0}^{1}\right)^{\prime} \equiv H$. Of course $H_{0}^{1}(D)$ is dense in $L^{p^{\prime}}(D)$. Can $\Delta$ be extended to all of $L^{p^{\prime}}(D)$ ? The answer is yes and it is more of the same given above. For $\phi \in H_{0}^{1}(D),-\Delta \phi \in H \subseteq\left(L^{p}(D)\right)^{\prime}$. Then by the above, for $\phi \in H_{0}^{1}(D)$ and $f \in L^{p}(D)$,

$$
\begin{gathered}
\langle-\Delta \phi, f\rangle \equiv\langle f, \phi\rangle \equiv \int_{D} f \phi d x \\
|\langle-\Delta \phi, f\rangle| \equiv|\langle f, \phi\rangle| \equiv\left|\int_{D} f \phi d s\right| \leq\|\phi\|_{L^{p^{\prime}(D)}}\|f\|_{L^{p}(D)}
\end{gathered}
$$

and so $-\Delta$ is a continuous linear mapping defined on a dense subspace $H_{0}^{1}(D)$ of $L^{p^{\prime}}(D)$ and so this does indeed extend to a continuous linear map defined on all of $L^{p^{\prime}}(D)$ given by the formula

$$
\langle-\Delta g, f\rangle \equiv \int_{D} f g d x
$$

This proves the lemma.
Thus letting $V \equiv L^{p}(D)$, and $H \equiv\left(H_{0}^{1}(D)\right)^{\prime}$, it follows $V \subseteq H \subseteq V^{\prime}$ is a Gelfand triple with the understanding of what it means for one space to be included in another described above. To emphasize the above, for $-\Delta \phi \in H, f \in L^{p}$,

$$
\langle-\Delta \phi, f\rangle \equiv(-\Delta \phi, f)_{H} \equiv\langle f, \phi\rangle \equiv \int_{D} f \phi d x
$$

More generally, for $g \in L^{p^{\prime}}(D),-\Delta g \in\left(L^{p}(D)\right)^{\prime}$ according to the rule

$$
\langle-\Delta g, f\rangle \equiv \int_{D} f g d x
$$

With this example of a Gelfand triple, one can define a "porous medium operator" $A: V \rightarrow V^{\prime}$. Let $\Psi$ be a real valued function defined on $\mathbb{R}$ which satisfies

$$
\begin{equation*}
\Psi \text { is continuous } \tag{69.1.3}
\end{equation*}
$$

$$
\begin{equation*}
(t-s)(\Psi(t)-\Psi(s)) \geq 0 \tag{69.1.4}
\end{equation*}
$$

There exists $p \geq 2, p<\infty$ and $\alpha \in(0, \infty)$ such that for all $s \in \mathbb{R}$

$$
\begin{equation*}
s \Psi(s) \geq \alpha|s|^{p}-c \tag{69.1.5}
\end{equation*}
$$

There exist $c_{3}, c_{4} \in(0, \infty)$ such that for all $s \in \mathbb{R}$

$$
\begin{equation*}
|\Psi(s)| \leq c_{4}+c_{3}|s|^{p-1} \tag{69.1.6}
\end{equation*}
$$

Note that 69.1.6 implies that if $v \in L^{p}(D)$, Then

$$
\int_{D}|\Psi(v)|^{p^{\prime}} d x \leq C \int_{D}\left(1+|v|^{p^{\prime}(p-1)}\right) d x=C \int_{D}\left(1+|v|^{p}\right) d x<\infty .
$$

Thus for $v \in L^{p}(D), \Psi(v)$ is something you can do $\Delta$ to and obtain something in $V^{\prime}$. The porous medium operator $A: V \rightarrow V^{\prime}$ is given as follows.

$$
\langle A v, w\rangle_{V^{\prime}, V} \equiv\langle\Delta \Psi(v), w\rangle_{V^{\prime}, V} \equiv-\int_{D} \Psi(v) w d x
$$

What are the properties of $A$ ?

$$
\langle A(u+\lambda v), w\rangle \equiv-\int_{D} \Psi(u+\lambda v) w d x
$$

and this is easily seen to be a continuous function of $\lambda$ Thus $A$ is Hemicontinuous.

$$
\langle A(u)-A(v), u-v\rangle \equiv-\int_{D} \Psi(u)(u-v) d x+\int_{D} \Psi(v)(u-v) d x \leq 0
$$

Thus $-A$ is monotone. Also there is a coercivity estimate which is routine.

$$
\langle A(v), v\rangle \equiv-\int_{D} \Psi(v) v \leq \int_{D} c-\alpha|v|^{p} d x=C-\alpha\|v\|_{V}^{p}
$$

This operator also has a boundedness estimate.

$$
\begin{aligned}
& \|A(v)\|_{V^{\prime}} \equiv \sup _{\|w\|_{V} \leq 1}|\langle A(v), w\rangle| \equiv \sup _{\|w\|_{V} \leq 1}\left|\int_{D} \Psi(v) w\right| \\
& \leq \sup _{\|w\|_{V} \leq 1}\left(\int_{D}\left(c_{4}+c_{3}|v|^{p-1}\right) w d x\right) \\
& \leq\left(\int_{D} C\left(1+|v|^{p}\right) d x\right)^{1 / p^{\prime}} \leq C+C\left(\int_{D}|v|^{p} d x\right)^{1 / p^{\prime}} \\
& =C+C\|v\|_{V}^{p / p^{\prime}}=C+C\|v\|_{V}^{p-1} .
\end{aligned}
$$

Since $\Psi$ is continuous, it will also follow that $A$ is $\mathscr{B}(V)$ measurable. Consider

$$
u \rightarrow\langle A u, w\rangle \equiv-\int_{D} \Psi(u) w d x
$$

for fixed $w \in V$. Suppose $u_{n} \rightarrow u$ in $V$ and fix $w \in L^{\infty}(D) \subseteq V$. Then it follows from an easy argument using the Vitali convergence theorem and the fact that from the estimates above

$$
\Psi\left(u_{n}\right) w
$$

is uniformly integrable that

$$
u \rightarrow-\int_{D} \Psi(u) w d x
$$

is continuous. For general $w \in L^{p}(D)$, let $w_{n} \rightarrow w$ in $L^{p}(D)$ where each $w_{n}$ is in $L^{\infty}(D)$. Then the function

$$
\begin{equation*}
u \rightarrow-\int_{D} \Psi(u) w d x \equiv\langle A u, w\rangle \tag{69.1.7}
\end{equation*}
$$

is the limit of the continuous functions

$$
u \rightarrow-\int_{D} \Psi(u) w_{n} d x
$$

and so the function 69.1.7 is Borel measurable. Now by the Pettis theorem this shows $A: V \rightarrow V^{\prime}$ is $\mathscr{B}(V)$ measurable. This shows $A$ is an example of an operator which satisfies some conditions which will be considered later.

### 69.2 Standard Techniques In Evolution Equations

In this section, several significant theorems are presented. Unless indicated otherwise, the measure will be Lebesgue measure. First here is a lemma.

Lemma 69.2.1 Suppose $g \in L^{1}([a, b] ; X)$ where $X$ is a Banach space. If $\int_{a}^{b} g(t) \phi(t) d t=0$ for all $\phi \in C_{c}^{\infty}(a, b)$, then $g(t)=0$ a.e.

Proof: Let $E$ be a measurable subset of $(a, b)$ and let $K \subseteq E \subseteq V \subseteq(a, b)$ where $K$ is compact, $V$ is open and $m(V \backslash K)<\varepsilon$. Let $K \prec h \prec V$ as in the proof of the Riesz representation theorem for positive linear functionals. Enlarging $K$ slightly and convolving with a mollifier, it can be assumed $h \in C_{c}^{\infty}(a, b)$. Then

$$
\begin{aligned}
\left|\int_{a}^{b} \mathscr{X}_{E}(t) g(t) d t\right| & =\left|\int_{a}^{b}\left(\mathscr{X}_{E}(t)-h(t)\right) g(t) d t\right| \\
& \leq \int_{a}^{b}\left|\mathscr{X}_{E}(t)-h(t)\right|\|g(t)\| d t \\
& \leq \int_{V \backslash K}\|g(t)\| d t
\end{aligned}
$$

Now let $K_{n} \subseteq E \subseteq V_{n}$ with $m\left(V_{n} \backslash K_{n}\right)<2^{-n}$. Then from the above,

$$
\left|\int_{a}^{b} \mathscr{X}_{E}(t) g(t) d t\right| \leq \int_{a}^{b} \mathscr{X}_{V_{n} \backslash K_{n}}(t)\|g(t)\| d t
$$

and the integrand of the last integral converges to 0 a.e. as $n \rightarrow \infty$ because $\sum_{n} m\left(V_{n} \backslash K_{n}\right)<$ $\infty$. By the dominated convergence theorem, this last integral converges to 0 . Therefore, whenever $E \subseteq(a, b)$,

$$
\int_{a}^{b} \mathscr{X}_{E}(t) g(t) d t=0
$$

Since the endpoints have measure zero, it also follows that for any measurable $E$, the above equation holds.

Now $g \in L^{1}([a, b] ; X)$ and so it is measurable. Therefore, $g([a, b])$ is separable. Let $D$ be a countable dense subset and let $E$ denote the set of linear combinations of the form $\sum_{i} a_{i} d_{i}$ where $a_{i}$ is a rational point of $\mathbb{F}$ and $d_{i} \in D$. Thus $E$ is countable. Denote by $Y$ the closure of $E$ in $X$. Thus $Y$ is a separable closed subspace of $X$ which contains all the values of $g$.

Now let $S_{n} \equiv g^{-1}\left(B\left(y_{n},\left\|y_{n}\right\| / 2\right)\right)$ where $E=\left\{y_{n}\right\}_{n=1}^{\infty}$. Thus, $\cup_{n} S_{n}=g^{-1}(X \backslash\{0\})$. This follows because if $x \in Y$ and $x \neq 0$, then in $B\left(x, \frac{\|x\|}{4}\right)$ there is a point of $E, y_{n}$. Therefore, $\left\|y_{n}\right\|>\frac{3}{4}\|x\|$ and so $\frac{\left\|y_{n}\right\|}{2}>\frac{3\|x\|}{8}>\frac{\|x\|}{4}$ so $x \in B\left(y_{n},\left\|y_{n}\right\| / 2\right)$. It follows that if each $S_{n}$ has measure zero, then $g(t)=0$ for a.e. $t$. Suppose then that for some $n$, the set, $S_{n}$ has positive measure. Then from what was shown above,

$$
\begin{aligned}
\left\|y_{n}\right\| & =\left\|\frac{1}{m\left(S_{n}\right)} \int_{S_{n}} g(t) d t-y_{n}\right\|=\left\|\frac{1}{m\left(S_{n}\right)} \int_{S_{n}} g(t)-y_{n} d t\right\| \\
& \leq \frac{1}{m\left(S_{n}\right)} \int_{S_{n}}\left\|g(t)-y_{n}\right\| d t \leq \frac{1}{m\left(S_{n}\right)} \int_{S_{n}}\left\|y_{n}\right\| / 2 d t=\left\|y_{n}\right\| / 2
\end{aligned}
$$

and so $y_{n}=0$ which implies $S_{n}=\emptyset$, a contradiction to $m\left(S_{n}\right)>0$. This contradiction shows each $S_{n}$ has measure zero and so as just explained, $g(t)=0$ a.e.

Definition 69.2.2 For $f \in L^{1}(a, b ; X)$, define an extension, $\bar{f}$ defined on

$$
[2 a-b, 2 b-a]=[a-(b-a), b+(b-a)]
$$

as follows.

$$
\bar{f}(t) \equiv\left\{\begin{array}{l}
f(t) \text { if } t \in[a, b] \\
f(2 a-t) \text { if } t \in[2 a-b, a] \\
f(2 b-t) \text { if } t \in[b, 2 b-a]
\end{array}\right.
$$

Definition 69.2.3 Also if $f \in L^{p}(a, b ; X)$ and $h>0$, define for $t \in[a, b], f_{h}(t) \equiv \bar{f}(t-h)$ for all $h<b-a$. Thus the map $f \rightarrow f_{h}$ is continuous and linear on $L^{p}(a, b ; X)$. It is continuous because

$$
\begin{aligned}
\int_{a}^{b}\left\|f_{h}(t)\right\|^{p} d t & =\int_{a}^{a+h}\|f(2 a-t+h)\|^{p} d t+\int_{a}^{b-h}\|f(t)\|^{p} d t \\
& =\int_{a}^{a+h}\|f(t)\|^{p} d t+\int_{a}^{b-h}\|f(t)\|^{p} d t \leq 2\|f\|_{p}^{p}
\end{aligned}
$$

The following lemma is on continuity of translation in $L^{p}(a, b ; X)$.

Lemma 69.2.4 Let $\bar{f}$ be as defined in Definition 69.2.2. Then for $f \in L^{p}(a, b ; X)$ for $p \in$ $[1, \infty)$,

$$
\lim _{\delta \rightarrow 0} \int_{a}^{b}\|\bar{f}(t-\delta)-f(t)\|_{X}^{p} d t=0
$$

Proof: Regarding the measure space as $(a, b)$ with Lebesgue measure, by regularity of the measure, there exists $g \in C_{c}(a, b ; X)$ such that $\|f-g\|_{p}<\varepsilon$. Here the norm is the norm in $L^{p}(a, b ; X)$. Therefore,

$$
\begin{aligned}
\left\|f_{h}-f\right\|_{p} & \leq\left\|f_{h}-g_{h}\right\|_{p}+\left\|g_{h}-g\right\|_{p}+\|g-f\|_{p} \\
& \leq\left(2^{1 / p}+1\right)\|f-g\|_{p}+\left\|g_{h}-g\right\|_{p} \\
& <\left(2^{1 / p}+1\right) \varepsilon+\varepsilon
\end{aligned}
$$

whenever $h$ is sufficiently small. This is because of the uniform continuity of $g$. Therefore, since $\varepsilon>0$ is arbitrary, this proves the lemma.

Definition 69.2.5 Let $f \in L^{1}(a, b ; X)$. Then the distributional derivative in the sense of $X$ valued distributions is given by

$$
f^{\prime}(\phi) \equiv-\int_{a}^{b} f(t) \phi^{\prime}(t) d t
$$

Then $f^{\prime} \in L^{1}(a, b ; X)$ if there exists $h \in L^{1}(a, b ; X)$ such that for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
f^{\prime}(\phi)=\int_{a}^{b} h(t) \phi(t) d t
$$

Then $f^{\prime}$ is defined to equal $h$. Here $f$ and $f^{\prime}$ are considered as vector valued distributions in the same way as was done for scalar valued functions.

Lemma 69.2.6 The above definition is well defined.
Proof: Suppose both $h$ and $g$ work in the definition. Then for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b}(h(t)-g(t)) \phi(t) d t=0
$$

Therefore, by Lemma 69.2.1, $h(t)-g(t)=0$ a.e.
The other thing to notice about this is the following lemma. It follows immediately from the definition.

Lemma 69.2.7 Suppose $f, f^{\prime} \in L^{1}(a, b ; X)$. Then if $[c, d] \subseteq[a, b]$, it follows that $\left(\left.f\right|_{[c, d]}\right)^{\prime}=$ $\left.f^{\prime}\right|_{[c, d]}$. This notation means the restriction to $[c, d]$.

Recall that in the case of scalar valued functions, if you had both $f$ and its weak derivative, $f^{\prime}$ in $L^{1}(a, b)$, then you were able to conclude that $f$ is almost everywhere equal to a continuous function, still denoted by $f$ and

$$
f(t)=f(a)+\int_{a}^{t} f^{\prime}(s) d s
$$

In particular, you can define $f(a)$ to be the initial value of this continuous function. It turns out that an identical theorem holds in this case. To begin with here is the same sort of lemma which was used earlier for the case of scalar valued functions. It says that if $f^{\prime}=0$ where the derivative is taken in the sense of $X$ valued distributions, then $f$ equals a constant.

Lemma 69.2.8 Suppose $f \in L^{1}(a, b ; X)$ and for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b} f(t) \phi^{\prime}(t) d t=0
$$

Then there exists a constant, $a \in X$ such that $f(t)=a$ a.e.
Proof: Let $\phi_{0} \in C_{c}^{\infty}(a, b), \int_{a}^{b} \phi_{0}(x) d x=1$ and define for $\phi \in C_{c}^{\infty}(a, b)$

$$
\psi_{\phi}(x) \equiv \int_{a}^{x}\left[\phi(t)-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right] d t
$$

Then $\psi_{\phi} \in C_{c}^{\infty}(a, b)$ and $\psi_{\phi}^{\prime}=\phi-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}$. Then

$$
\begin{aligned}
\int_{a}^{b} f(t)(\phi(t)) d t & =\int_{a}^{b} f(t)\left(\psi_{\phi}^{\prime}(t)+\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right) d t \\
& =\overbrace{\int_{a}^{b} f(t) \psi_{\phi}^{\prime}(t) d t}^{=0 \text { by assumption }}+\left(\int_{a}^{b} \phi(y) d y\right) \int_{a}^{b} f(t) \phi_{0}(t) d t \\
& =\left(\int_{a}^{b}\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right) \phi(y) d y\right) .
\end{aligned}
$$

It follows that for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b}\left(f(y)-\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right)\right) \phi(y) d y=0
$$

and so by Lemma 69.2.1,

$$
f(y)-\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right)=0 \text { a.e. } y
$$

Theorem 69.2.9 Suppose $f, f^{\prime}$ both are in $L^{1}(a, b ; X)$ where the derivative is taken in the sense of $X$ valued distributions. Then there exists a unique point of $X$, denoted by $f(a)$ such that the following formula holds a.e. $t$.

$$
f(t)=f(a)+\int_{a}^{t} f^{\prime}(s) d s
$$

## Proof:

$$
\int_{a}^{b}\left(f(t)-\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t=\int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t
$$

Now consider $\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t$. Let $\Lambda \in X^{\prime}$. Then it is routine from approximating $f^{\prime}$ with simple functions to verify

$$
\Lambda\left(\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t\right)=\int_{a}^{b} \int_{a}^{t} \Lambda\left(f^{\prime}(s)\right) \phi^{\prime}(t) d s d t
$$

Now the ordinary Fubini theorem can be applied to obtain

$$
=\int_{a}^{b} \int_{s}^{b} \Lambda\left(f^{\prime}(s)\right) \phi^{\prime}(t) d t d s=\Lambda\left(\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s\right)
$$

Since $X^{\prime}$ separates the points of $X$, it follows

$$
\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t=\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s
$$

Therefore,

$$
\begin{aligned}
& \int_{a}^{b}\left(f(t)-\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} f^{\prime}(s) \int_{s}^{b} \phi^{\prime}(t) d t d s \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{a}^{b} f^{\prime}(s) \phi(s) d s=0 .
\end{aligned}
$$

Therefore, by Lemma 69.2.8, there exists a constant, denoted as $f(a)$ such that

$$
f(t)-\int_{a}^{t} f^{\prime}(s) d s=f(a)
$$

The integration by parts formula is also important.

Corollary 69.2.10 Suppose $f, f^{\prime} \in L^{1}(a, b ; X)$ and suppose $\phi \in C^{1}([a, b])$. Then the following integration by parts formula holds.

$$
\int_{a}^{b} f(t) \phi^{\prime}(t) d t=f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(t) \phi(t) d t
$$

Proof: From Theorem 69.2.9

$$
\begin{aligned}
& \int_{a}^{b} f(t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b}\left(f(a)+\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) d s \phi^{\prime}(t) d t \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} f^{\prime}(s) \int_{s}^{b} \phi^{\prime}(t) d t d s \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} f^{\prime}(s)(\phi(b)-\phi(s)) d s \\
= & f(a)(\phi(b)-\phi(a))-\int_{a}^{b} f^{\prime}(s) \phi(s) d s+(f(b)-f(a)) \phi(b) \\
= & f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(s) \phi(s) d s .
\end{aligned}
$$

The interchange in order of integration is justified as in the proof of Theorem 69.2.9.
With this integration by parts formula, the following interesting lemma is obtained. This lemma shows why it was appropriate to define $\bar{f}$ as in Definition 69.2.2.

Lemma 69.2.11 Let $\bar{f}$ be given in Definition 69.2 .2 and suppose $f, f^{\prime} \in L^{1}(a, b ; X)$. Then $\bar{f}, \bar{f}^{\prime} \in L^{1}(2 a-b, 2 b-a ; X)$ also and

$$
\bar{f}^{\prime}(t) \equiv\left\{\begin{array}{l}
f^{\prime}(t) \text { if } t \in[a, b]  \tag{69.2.8}\\
-f^{\prime}(2 a-t) \text { if } t \in[2 a-b, a] \\
-f^{\prime}(2 b-t) \text { if } t \in[b, 2 b-a]
\end{array}\right.
$$

Proof: It is clear from the definition of $\bar{f}$ that $\bar{f} \in L^{1}(2 a-b, 2 b-a ; X)$ and that in fact

$$
\begin{equation*}
\|\bar{f}\|_{L^{1}(2 a-b, 2 b-a ; X)} \leq 3\|f\|_{L^{1}(a, b ; X)} \tag{69.2.9}
\end{equation*}
$$

Let $\phi \in C_{c}^{\infty}(2 a-b, 2 b-a)$. Then from the integration by parts formula,

$$
\begin{aligned}
& \int_{2 a-b}^{2 b-a} \bar{f}(t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{b}^{2 b-a} f(2 b-t) \phi^{\prime}(t) d t+\int_{2 a-b}^{a} f(2 a-t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{a}^{b} f(u) \phi^{\prime}(2 b-u) d u+\int_{a}^{b} f(u) \phi^{\prime}(2 a-u) d u \\
= & f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(t) \phi(t) d t-f(b) \phi(b)+f(a) \phi(2 b-a) \\
& +\int_{a}^{b} f^{\prime}(u) \phi(2 b-u) d u-f(b) \phi(2 a-b) \\
& +f(a) \phi(a)+\int_{a}^{b} f^{\prime}(u) \phi(2 a-u) d u \\
= & -\int_{a}^{b} f^{\prime}(t) \phi(t) d t+\int_{a}^{b} f^{\prime}(u) \phi(2 b-u) d u+\int_{a}^{b} f^{\prime}(u) \phi(2 a-u) d u \\
= & -\int_{a}^{b} f^{\prime}(t) \phi(t) d t-\int_{b}^{2 b-a}-f^{\prime}(2 b-t) \phi(t) d t-\int_{2 a-b}^{a}-f^{\prime}(2 a-t) \phi(t) d t \\
= & -\int_{2 a-b}^{2 b-a} \bar{f}^{\prime}(t) \phi(t) d t
\end{aligned}
$$

where $\bar{f}^{\prime}(t)$ is given in 69.2.8.
Definition 69.2.12 Let $V$ be a Banach space and let $H$ be a Hilbert space. (Typically $H=L^{2}(\Omega)$ ) Suppose $V \subseteq H$ is dense in $H$ meaning that the closure in $H$ of $V$ gives $H$. Then it is often the case that $H$ is identified with its dual space, and then because of the density of $V$ in $H$, it is possible to write

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

When this is done, $H$ is called a pivot space. Another notation which is often used is $\langle f, g\rangle$ to denote $f(g)$ for $f \in V^{\prime}$ and $g \in V$. This may also be written as $\langle f, g\rangle_{V^{\prime}, V}$. Another term is that $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ is called a Gelfand triple.

The next theorem is an example of a trace theorem. In this theorem, $f \in L^{p}(0, T ; V)$ while $f^{\prime} \in L^{p}\left(0, T ; V^{\prime}\right)$. It makes no sense to consider the initial values of $f$ in $V$ because it is not even continuous with values in $V$. However, because of the derivative of $f$ it will turn out that $f$ is continuous with values in a larger space and so it makes sense to consider initial values of $f$ in this other space. This other space is called a trace space.

Theorem 69.2.13 Let $V$ and $H$ be a Banach space and Hilbert space as described in Definition 69.2.12. Suppose $f \in L^{p}(0, T ; V)$ and $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$. Then $f$ is a.e. equal to $a$ continuous function mapping $[0, T]$ to $H$. Furthermore, there exists $f(0) \in H$ such that

$$
\begin{equation*}
\frac{1}{2}|f(t)|_{H}^{2}-\frac{1}{2}|f(0)|_{H}^{2}=\int_{0}^{t}\left\langle f^{\prime}(s), f(s)\right\rangle d s \tag{69.2.10}
\end{equation*}
$$

and for all $t \in[0, T]$,

$$
\begin{equation*}
\int_{0}^{t} f^{\prime}(s) d s \in H \tag{69.2.11}
\end{equation*}
$$

and for a.e. $t \in[0, T]$,

$$
\begin{equation*}
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } H \tag{69.2.12}
\end{equation*}
$$

Here $f^{\prime}$ is being taken in the sense of $V^{\prime}$ valued distributions and $\frac{1}{p}+\frac{1}{p^{\prime}}=1$ and $p \geq 2$.
Proof: Let $\Psi \in C_{c}^{\infty}(-T, 2 T)$ satisfy $\Psi(t)=1$ if $t \in[-T / 2,3 T / 2]$ and $\Psi(t) \geq 0$. For $t \in \mathbb{R}$, define

$$
\widehat{f}(t) \equiv\left\{\begin{array}{l}
\bar{f}(t) \Psi(t) \text { if } t \in[-T, 2 T] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

and

$$
\begin{equation*}
f_{n}(t) \equiv \int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s \tag{69.2.13}
\end{equation*}
$$

where $\phi_{n}$ is a mollifier having support in $(-1 / n, 1 / n)$. Then by Minkowski's inequality

$$
\begin{aligned}
\| f_{n}- & \widehat{f} \|_{L^{p}(\mathbb{R} ; V)}=\left(\int_{\mathbb{R}}\left\|\widehat{f}(t)-\int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s\right\|_{V}^{p} d t\right)^{1 / p} \\
& =\left(\int_{\mathbb{R}}\left\|\int_{-1 / n}^{1 / n}(\widehat{f}(t)-\widehat{f}(t-s)) \phi_{n}(s) d s\right\|_{V}^{p} d t\right)^{1 / p} \\
& \leq\left(\int_{\mathbb{R}}\left(\int_{-1 / n}^{1 / n}\|\widehat{f}(t)-\widehat{f}(t-s)\|_{V} \phi_{n}(s) d s\right)^{p} d t\right)^{1 / p} \\
& \leq \int_{-1 / n}^{1 / n} \phi_{n}(s)\left(\int_{\mathbb{R}}\|\widehat{f}(t)-\widehat{f}(t-s)\|_{V}^{p} d t\right)^{1 / p} d s \\
& \leq \int_{-1 / n}^{1 / n} \phi_{n}(s) \varepsilon d s=\varepsilon
\end{aligned}
$$

provided $n$ is large enough. This follows from continuity of translation in $L^{p}$ with Lebesgue measure. Since $\varepsilon>0$ is arbitrary, it follows $f_{n} \rightarrow \widehat{f}$ in $L^{p}(\mathbb{R} ; V)$. Similarly, $f_{n} \rightarrow f$ in $L^{2}(\mathbb{R} ; H)$. This follows because $p \geq 2$ and the norm in $V$ and norm in $H$ are related by $|x|_{H} \leq C\|x\|_{V}$ for some constant, $C$. Now

$$
\widehat{f}(t)=\left\{\begin{array}{l}
\Psi(t) f(t) \text { if } t \in[0, T] \\
\Psi(t) f(2 T-t) \text { if } t \in[T, 2 T] \\
\Psi(t) f(-t) \text { if } t \in[0, T] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

An easy modification of the argument of Lemma 69.2.11 yields

$$
\widehat{f}^{\prime}(t)=\left\{\begin{array}{l}
\Psi^{\prime}(t) f(t)+\Psi(y) f^{\prime}(t) \text { if } t \in[0, T] \\
\Psi^{\prime}(t) f(2 T-t)-\Psi(t) f^{\prime}(2 T-t) \text { if } t \in[T, 2 T] \\
\Psi^{\prime}(t) f(-t)-\Psi(t) f^{\prime}(-t) \text { if } t \in[-T, 0] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

Recall

$$
\begin{aligned}
f_{n}(t) & =\int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s=\int_{\mathbb{R}} \widehat{f}(t-s) \phi_{n}(s) d s \\
& =\int_{\mathbb{R}} \widehat{f}(s) \phi_{n}(t-s) d s
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
f_{n}^{\prime}(t) & =\int_{\mathbb{R}} \widehat{f}(s) \phi_{n}^{\prime}(t-s) d s=\int_{-T-\frac{1}{n}}^{2 T+\frac{1}{n}} \widehat{f}(s) \phi_{n}^{\prime}(t-s) d s \\
& =\int_{-T-\frac{1}{n}}^{2 T+\frac{1}{n}} \widehat{f}^{\prime}(s) \phi_{n}(t-s) d s=\int_{\mathbb{R}} \widehat{f}^{\prime}(s) \phi_{n}(t-s) d s \\
& =\int_{\mathbb{R}} \widehat{f}^{\prime}(t-s) \phi_{n}(s) d s=\int_{-1 / n}^{1 / n} \widehat{f}^{\prime}(t-s) \phi_{n}(s) d s
\end{aligned}
$$

and it follows from the first line above that $f_{n}^{\prime}$ is continuous with values in $V$ for all $t \in \mathbb{R}$. Also note that both $f_{n}^{\prime}$ and $f_{n}$ equal zero if $t \notin[-T, 2 T]$ whenever $n$ is large enough. Exactly similar reasoning to the above shows that $f_{n}^{\prime} \rightarrow \widehat{f}^{\prime}$ in $L^{p^{\prime}}\left(\mathbb{R} ; V^{\prime}\right)$.

Now let $\phi \in C_{c}^{\infty}(0, T)$.

$$
\begin{align*}
\int_{\mathbb{R}}\left|f_{n}(t)\right|_{H}^{2} \phi^{\prime}(t) d t & =\int_{\mathbb{R}}\left(f_{n}(t), f_{n}(t)\right)_{H} \phi^{\prime}(t) d t  \tag{69.2.14}\\
=-\int_{\mathbb{R}} 2\left(f_{n}^{\prime}(t), f_{n}(t)\right) \phi(t) d t & =-\int_{\mathbb{R}} 2\left\langle f_{n}^{\prime}(t), f_{n}(t)\right\rangle \phi(t) d t
\end{align*}
$$

Now

$$
\begin{aligned}
& \left|\int_{\mathbb{R}}\left\langle f_{n}^{\prime}(t), f_{n}(t)\right\rangle \phi(t) d t-\int_{\mathbb{R}}\left\langle f^{\prime}(t), f(t)\right\rangle \phi(t) d t\right| \\
\leq & \int_{\mathbb{R}}\left(\left|\left\langle f_{n}^{\prime}(t)-f^{\prime}(t), f_{n}(t)\right\rangle\right|+\left|\left\langle f^{\prime}(t), f_{n}(t)-f(t)\right\rangle\right|\right) \phi(t) d t
\end{aligned}
$$

From the first part of this proof which showed that $f_{n} \rightarrow \widehat{f}$ in $L^{p}(\mathbb{R} ; V)$ and $f_{n}^{\prime} \rightarrow \widehat{f}^{\prime}$ in $L^{p^{\prime}}\left(\mathbb{R} ; V^{\prime}\right)$, an application of Holder's inequality shows the above converges to 0 as $n \rightarrow \infty$. Therefore, passing to the limit as $n \rightarrow \infty$ in the 69.2.15,

$$
\int_{\mathbb{R}}|\widehat{f}(t)|_{H}^{2} \phi^{\prime}(t) d t=-\int_{\mathbb{R}} 2\left\langle\widehat{f}^{\prime}(t), \widehat{f}(t)\right\rangle \phi(t) d t
$$

which shows $t \rightarrow|\widehat{f}(t)|_{H}^{2}$ equals a continuous function a.e. and it also has a weak derivative equal to $2\left\langle\widehat{f}^{\prime}, \widehat{f}\right\rangle$.

It remains to verify that $\widehat{f}$ is continuous on $[0, T]$. Of course $\widehat{f}=f$ on this interval. Let
$N$ be large enough that $f_{n}(-T)=0$ for all $n>N$. Then for $m, n>N$ and $t \in[-T, 2 T]$

$$
\begin{aligned}
\left|f_{n}(t)-f_{m}(t)\right|_{H}^{2} & =2 \int_{-T}^{t}\left(f_{n}^{\prime}(s)-f_{m}^{\prime}(s), f_{n}(s)-f_{m}(s)\right) d s \\
& =2 \int_{-T}^{t}\left\langle f_{n}^{\prime}(s)-f_{m}^{\prime}(s), f_{n}(s)-f_{m}(s)\right\rangle_{V^{\prime}, V} d s \\
& \leq 2 \int_{\mathbb{R}}\left\|f_{n}^{\prime}(s)-f_{m}^{\prime}(s)\right\|_{V^{\prime}}\left\|f_{n}(s)-f_{m}(s)\right\|_{V} d s \\
& \leq 2\left\|f_{n}-f_{m}\right\|_{L^{p^{\prime}\left(\mathbb{R} ; V^{\prime}\right)}}\left\|f_{n}-f_{m}\right\|_{L^{p}(\mathbb{R} ; V)}
\end{aligned}
$$

which shows from the above that $\left\{f_{n}\right\}$ is uniformly Cauchy on $[-T, 2 T]$ with values in $H$. Therefore, there exists $g$ a continuous function defined on $[-T, 2 T]$ having values in $H$ such that

$$
\lim _{n \rightarrow \infty} \max \left\{\left|f_{n}(t)-g(t)\right|_{H} ; t \in[-T, 2 T]\right\}=0
$$

However, $g=\widehat{f}$ a.e. because $f_{n}$ converges to $f$ in $L^{p}(0, T ; V)$. Therefore, taking a subsequence, the convergence is a.e. It follows from the fact that $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ and Theorem 69.2.9, there exists $f(0) \in V^{\prime}$ such that for a.e. $t$,

$$
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } V^{\prime}
$$

Now $g=f$ a.e. and $g$ is continuous with values in $H$ hence continuous with values in $V^{\prime}$ and so

$$
g(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } V^{\prime}
$$

for all $t$. Since $g$ is continuous with values in $H$ it is continuous with values in $V^{\prime}$. Taking the limit as $t \downarrow 0$ in the above, $g(a)=\lim _{t \rightarrow 0+} g(t)=f(0)$, showing that $f(0) \in H$. Therefore, for a.e. $t$,

$$
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } H, \int_{0}^{t} f^{\prime}(s) d s \in H
$$

Note that if $f \in L^{p}(0, T ; V)$ and $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$, then you can consider the initial value of $f$ and it will be in $H$. What if you start with something in $H$ ? Is it an initial condition for a function $f \in L^{p}(0, T ; V)$ such that $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ ? This is worth thinking about. If it is not so, what is the space of initial values? How can you give this space a norm? What are its properties? It turns out that if $V$ is a closed subspace of the Sobolev space, $W^{1, p}(\Omega)$ which contains $W_{0}^{1, p}(\Omega)$ for $p \geq 2$ and $H=L^{2}(\Omega)$ the answer to the above question is yes. Not surprisingly, there are many generalizations of the above ideas.

### 69.3 An Important Formula

It is not necessary to have $p>2$ in order to do the sort of thing just described. Here is a major result which will have a much more difficult stochastic version presented later. First is an approximation theorem of Doob. See Lemma 65.3.1.

Lemma 69.3.1 Let $Y:[0, T] \rightarrow E$, be $\mathscr{B}([0, T])$ measurable and suppose

$$
Y \in L^{p}(0, T ; E) \equiv K, p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
Y_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} Y\left(t_{j}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t) \\
Y_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} Y\left(t_{j-1}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t)
\end{aligned}
$$

both converge to $Y$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

Also, each $Y\left(t_{j}^{k}\right), Y\left(t_{j-1}^{k}\right)$ is in $E$. One can also assume that $Y(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$
\left|t_{j}^{k}-t_{j-1}^{k}\right|=2^{-n_{k}}
$$

except for the case where $j=1$ or $j=m_{n_{k}}$ when this might not be so. In the case of the last subinterval defined by the partition, we can assume

$$
\left|t_{m}^{k}-t_{m-1}^{k}\right|=\left|T-t_{m-1}^{k}\right| \geq 2^{-\left(n_{k}+1\right)}
$$

Theorem 69.3.2 Let $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ be a Gelfand triple and suppose $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right) \equiv$ $K^{\prime}$ and

$$
\begin{equation*}
X(t)=X_{0}+\int_{0}^{t} Y(s) d s \text { in } V^{\prime} \tag{69.3.15}
\end{equation*}
$$

where $X_{0} \in H$, and it is known that $X \in L^{p}(0, T, V) \equiv K$ for $p>1$. Then $t \rightarrow X(t)$ is in $C([0, T], H)$ and also

$$
\frac{1}{2}|X(t)|_{H}^{2}=\frac{1}{2}\left|X_{0}\right|_{H}^{2}+\int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Proof: By Lemma 65.3.1, there exists a sequence of uniform partitions $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}=$ $\mathscr{P}_{n}, \mathscr{P}_{n} \subseteq \mathscr{P}_{n+1}$, of $[0, T]$ such that the step functions

$$
\begin{aligned}
\sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{l}(t) \\
\sum_{k=0}^{m_{n}-1} X\left(t_{k+1}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{r}(t)
\end{aligned}
$$

converge to $X$ in $K$ and in $L^{2}([0, T], H)$.

Lemma 69.3.3 Let $s<t$. Then for $X, Y$ satisfying 69.3.15

$$
\begin{equation*}
|X(t)|^{2}=|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-|X(t)-X(s)|^{2} \tag{69.3.16}
\end{equation*}
$$

Proof: It follows from the following computations

$$
\begin{gathered}
X(t)-X(s)=\int_{s}^{t} Y(u) d u \\
-|X(t)-X(s)|^{2}=-|X(t)|^{2}+2(X(t), X(s))-|X(s)|^{2} \\
=-|X(t)|^{2}+2\left(X(t), X(t)-\int_{s}^{t} Y(u) d u\right)-|X(s)|^{2} \\
=-|X(t)|^{2}+2|X(t)|^{2}-2\left\langle\int_{s}^{t} Y(u) d u, X(t)\right\rangle-|X(s)|^{2}
\end{gathered}
$$

Hence

$$
|X(t)|^{2}=|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-|X(t)-X(s)|^{2}
$$

Lemma 69.3.4 In the above situation,

$$
\sup _{t \in[0, T]}|X(t)|_{H} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Also, $t \rightarrow X(t)$ is weakly continuous with values in $H$.
Proof: From the above formula applied to the $k^{t h}$ partition of $[0, T]$ described above,

$$
\begin{aligned}
& \left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=\sum_{j=0}^{m-1}\left|X\left(t_{j+1}\right)\right|^{2}-\left|X\left(t_{j}\right)\right|^{2} \\
= & \sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle d u-\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2} \\
= & \sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u-\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2}
\end{aligned}
$$

Thus, discarding the negative terms and denoting by $\mathscr{P}_{k}$ the $k^{t h}$ of these partitions,

$$
\begin{gathered}
\sup _{t_{j} \in \mathscr{P}_{k}}\left|X\left(t_{j}\right)\right|_{H}^{2} \leq\left|X_{0}\right|^{2}+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u \\
\quad \leq\left|X_{0}\right|^{2}+2 \int_{0}^{T}\|Y(u)\|_{V^{\prime}}\left\|X_{k}^{r}(u)\right\|_{V} d u
\end{gathered}
$$

$$
\leq\left|X_{0}\right|^{2}+2\left(\int_{0}^{T}\|Y(u)\|_{V^{\prime}}^{p^{\prime}} d u\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p} d u\right)^{1 / p} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

because these partitions are chosen such that

$$
\lim _{k \rightarrow \infty}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p}\right)^{1 / p}=\left(\int_{0}^{T}\|X(u)\|_{V}^{p}\right)^{1 / p}
$$

and so these are bounded. This has shown that for the dense subset of $[0, T], D \equiv \cup_{k} \mathscr{P}_{k}$,

$$
\sup _{t \in D}|X(t)|<C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Now let $\left\{g_{k}\right\}_{k=1}^{\infty}$ be linearly independent vectors of $V$ whose span is dense in $V$. This is possible because $V$ is separable. Then let $\left\{e_{j}\right\}_{j=1}^{\infty}$ be an orthonormal basis for $H$ such that $e_{k} \in \operatorname{span}\left(g_{1}, \ldots, g_{k}\right)$ and each $g_{k} \in \operatorname{span}\left(e_{1}, \ldots, e_{k}\right)$. This is done with the Gram Schmidt process. Then it follows that span $\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ is dense in $V$. I claim

$$
|y|_{H}^{2}=\sum_{j=1}^{\infty}\left|\left\langle y, e_{j}\right\rangle\right|^{2}
$$

This is certainly true if $y \in H$ because

$$
\left\langle y, e_{j}\right\rangle=\left(y, e_{j}\right)_{H}
$$

If $y \notin H$, then the series must diverge since otherwise, you could consider the infinite sum

$$
\sum_{j=1}^{\infty}\left\langle y, e_{j}\right\rangle e_{j} \in H
$$

because

$$
\left|\sum_{j=p}^{q}\left\langle y, e_{j}\right\rangle e_{j}\right|^{2}=\sum_{j=p}^{q}\left|\left\langle y, e_{j}\right\rangle\right|^{2} \rightarrow 0 \text { as } p, q \rightarrow \infty
$$

Letting $z=\sum_{j=1}^{\infty}\left\langle y, e_{j}\right\rangle e_{j}$, it follows that $\left\langle y, e_{j}\right\rangle$ is the $j^{\text {th }}$ Fourier coefficient of $z$ and that

$$
\langle z-y, v\rangle=0
$$

for all $v \in \operatorname{span}\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ which is dense in $V$. Therefore, $z=y$ in $V^{\prime}$ and so $y \in H$.
It follows

$$
|X(t)|^{2}=\sup _{n} \sum_{j=1}^{n}\left|\left\langle X(t), e_{j}\right\rangle\right|^{2}
$$

which is just the sup of continuous functions of $t$. Therefore, $t \rightarrow|X(t)|^{2}$ is lower semicontinuous. It follows that for any $t$, letting $t_{j} \rightarrow t$ for $t_{j} \in D$,

$$
|X(t)|^{2} \leq \lim \inf _{j \rightarrow \infty}\left|X\left(t_{j}\right)\right|^{2} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

This proves the first claim of the lemma.
Consider now the claim that $t \rightarrow X(t)$ is weakly continuous. Letting $v \in V$,

$$
\lim _{t \rightarrow s}(X(t), v)=\lim _{t \rightarrow s}\langle X(t), v\rangle=\langle X(s), v\rangle=(X(s), v)
$$

Since it was shown that $|X(t)|$ is bounded independent of $t$, and since $V$ is dense in $H$, the claim follows.

Now

$$
\begin{aligned}
-\sum_{j=0}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2} & =\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}-\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u \\
& =\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}-2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u
\end{aligned}
$$

Thus, since the partitions are nested, eventually $\left|X\left(t_{m}\right)\right|^{2}$ is constant for all $k$ large enough and the integral term converges to

$$
\int_{0}^{t_{m}}\langle Y(u), X(u)\rangle d u
$$

It follows that the term on the left does converge to something. It just remains to consider what it does converge to. However, from the equation solved by $X$,

$$
X\left(t_{j+1}\right)-X\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Y(u) d u
$$

Therefore, this term is dominated by an expression of the form

$$
\begin{gathered}
\sum_{j=0}^{m_{k}-1}\left(\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right) \\
=\sum_{j=0}^{m_{k}-1}\left\langle\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle d u \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle-\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j}\right)\right\rangle \\
=\int_{0}^{T}\left\langle Y(u), X^{r}(u)\right\rangle d u-\int_{0}^{T}\left\langle Y(u), X^{l}(u)\right\rangle d u
\end{gathered}
$$

However, both $X^{r}$ and $X^{l}$ converge to $X$ in $K=L^{p}(0, T, V)$. Therefore, this term must converge to 0 . Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t$,

$$
|X(t)|^{2}=\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

It remains to verify that this holds for all $t$. Let $t \notin D$ and let $t(k) \in \mathscr{P}_{k}$ be the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$
X(t(m))=X_{0}+\int_{0}^{t(m)} Y(s) d s
$$

a similar formula for $X(t(k))$. Thus for $t>t(m)$,

$$
X(t)-X(t(m))=\int_{t(m)}^{t} Y(s) d s
$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $X_{0}=0$. Therefore,

$$
|X(t(k))-X(t(m))|^{2}=2 \int_{t(m)}^{t(k)}\langle Y(s), X(s)-X(t(m))\rangle d s
$$

Thus, for $m \leq k$

$$
\lim _{m, k \rightarrow \infty}|X(t(k))-X(t(m))|^{2}=0
$$

Hence $\{X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $H$. Does it converge to $X(t)$ ? Let $\xi(t) \in H$ be what it does converge to. Let $v \in V$. Then

$$
(\xi(t), v)=\lim _{k \rightarrow \infty}(X(t(k)), v)=\lim _{k \rightarrow \infty}\langle X(t(k)), v\rangle=\langle X(t), v\rangle=(X(t), v)
$$

because it is known that $t \rightarrow X(t)$ is continuous into $V^{\prime}$ and it is also known that $X(t) \in H$ and that the $X(t)$ for $t \in[0, T]$ are uniformly bounded. Therefore, since $V$ is dense in $H$, it follows that $\xi(t)=X(t)$.

Now for every $t \in D$, it was shown above that

$$
|X(t)|^{2}=\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Thus, using what was just shown, if $t \notin D$ and $t_{k} \rightarrow t$,

$$
\begin{aligned}
|X(t)|^{2} & =\lim _{k \rightarrow \infty}\left|X\left(t_{k}\right)\right|^{2}=\lim _{k \rightarrow \infty}\left(\left|X_{0}\right|^{2}+2 \int_{0}^{t_{k}}\langle Y(s), X(s)\rangle d s\right) \\
& =\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(s), X(s)\rangle d s
\end{aligned}
$$

which proves the desired formula. From this it follows right away that $t \rightarrow X(t)$ is continuous into $H$ because it was just shown that $t \rightarrow|X(t)|$ is continuous and $t \rightarrow X(t)$ is weakly continuous. Since Hilbert space is uniformly convex, this implies the $t \rightarrow X(t)$ is continuous. To see this in the special cas of Hilbert space,

$$
|X(t)-X(s)|^{2}=|X(t)|^{2}-2(X(s), X(t))+|X(s)|^{2}
$$

Then $\lim _{t \rightarrow s}\left(|X(t)|^{2}-2(X(s), X(t))+|X(s)|^{2}\right)=0$ by weak convergence of $X(t)$ to $X(s)$ and the convergence of $|X(t)|^{2}$ to $|X(s)|^{2}$.

### 69.4 The Implicit Case

The above theorem can be generalized to the case where the formula is of the form

$$
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s
$$

This involves an operator $B \in \mathscr{L}\left(W, W^{\prime}\right)$ and $B$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle
$$

for

$$
V \subseteq W, W^{\prime} \subseteq V^{\prime}
$$

Where $V$ is dense in the Hilbert space $W$. Before giving the theorem, here is a technical lemma.

Lemma 69.4.1 Suppose $V, W$ are separable Banach spaces, $W$ also a Hilbert space such that $V$ is dense in $W$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle, B \neq 0 .
$$

Then there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2},
$$

and also

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

the series converging in $W^{\prime}$.
Proof: Let $\left\{g_{k}\right\}_{k=1}^{\infty}$ be linearly independent vectors of $V$ whose span is dense in $V$. This is possible because $V$ is separable. Thus, their span is also dense in $W$. Let $n_{1}$ be the first index such that $\left\langle B g_{n_{1}}, g_{n_{1}}\right\rangle \neq 0$.

Claim: If there is no such index, then $B=0$.
Proof of claim: First note that if there is no such first index, then if $x=\sum_{i=1}^{k} a_{i} g_{i}$

$$
\begin{aligned}
|\langle B x, x\rangle| & =\left|\sum_{i \neq j} a_{i} a_{j}\left\langle B g_{i}, g_{j}\right\rangle\right| \leq \sum_{i \neq j}\left|a_{i}\right|\left|a_{j}\right|\left|\left\langle B g_{i}, g_{j}\right\rangle\right| \\
& \leq \sum_{i \neq j}\left|a_{i}\right|\left|a_{j}\right|\left\langle B g_{i}, g_{i}\right\rangle^{1 / 2}\left\langle B g_{j}, g_{j}\right\rangle^{1 / 2}=0
\end{aligned}
$$

Therefore, if $x$ is given, you could take $x_{k}$ in the span of $\left\{g_{1}, \cdots, g_{k}\right\}$ such that $\left\|x_{k}-x\right\|_{W} \rightarrow$ 0 . Then

$$
|\langle B x, y\rangle|=\lim _{k \rightarrow \infty}\left|\left\langle B x_{k}, y\right\rangle\right| \leq \lim _{k \rightarrow \infty}\left\langle B x_{k}, x_{k}\right\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2}=0
$$

because $\left\langle B x_{k}, x_{k}\right\rangle$ is zero by what was just shown.
Thus assume there is such a first index. Let

$$
e_{1} \equiv \frac{g_{n_{1}}}{\left\langle B g_{n_{1}}, g_{n_{1}}\right\rangle^{1 / 2}}
$$

Then $\left\langle B e_{1}, e_{1}\right\rangle=1$. Now if you have constructed $e_{j}$ for $j \leq k$,

$$
e_{j} \in \operatorname{span}\left(g_{n_{1}}, \cdots, g_{n_{k}}\right),\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

$g_{n_{j+1}}$ being the first for which

$$
\left\langle B g_{n_{j+1}}-\sum_{i=1}^{j}\left\langle B g_{n_{j+1}}, e_{i}\right\rangle B e_{i}, g_{n_{j+1}}-\sum_{i=1}^{j}\left\langle B g_{n j}, e_{i}\right\rangle e_{i}\right\rangle \neq 0,
$$

and

$$
\operatorname{span}\left(g_{n_{1}}, \cdots, g_{n_{k}}\right)=\operatorname{span}\left(e_{1}, \cdots, e_{k}\right)
$$

let $g_{n_{k+1}}$ be such that $g_{n_{k+1}}$ is the first in the list $\left\{g_{n_{k}}\right\}$ such that

$$
\left\langle B g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle B e_{i}, g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right\rangle \neq 0
$$

Note the difference between this and the Gram Schmidt process. Here you don't necessarily use all of the $g_{k}$ due to the possible degeneracy of $B$.

Claim: If there is no such first $g_{n_{k+1}}$, then $B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)=B W$ so in this case, $\left\{B e_{i}\right\}_{i=1}^{k}$ is actually a basis for $B W$.

Proof: Let $x \in W$. Let $x_{r} \in \operatorname{span}\left(g_{1}, \cdots, g_{r}\right), r>n_{k}$ such that $\lim _{r \rightarrow \infty} x_{r}=x$ in $W$. Then

$$
\begin{equation*}
x_{r}=\sum_{i=1}^{k} c_{i}^{r} e_{i}+\sum_{i \notin\left\{n_{1}, \cdots, n_{k}\right\}}^{r} d_{i}^{r} g_{i} \equiv y_{r}+z_{r} \tag{69.4.17}
\end{equation*}
$$

If $l \notin\left\{n_{1}, \cdots, n_{k}\right\}$, then by the construction and the above assumption, for some $j \leq k$

$$
\begin{equation*}
\left\langle B g_{l}-\sum_{i=1}^{j}\left\langle B g_{l}, e_{i}\right\rangle B e_{i}, g_{l}-\sum_{i=1}^{j}\left\langle B g_{l}, e_{i}\right\rangle e_{i}\right\rangle=0 \tag{69.4.18}
\end{equation*}
$$

If $l<n_{k}$, this follows from the construction. If the above is nonzero all $j \leq k$, then $l$ would have been chosen but it wasn't. Thus

$$
B g_{l}=\sum_{i=1}^{j}\left\langle B g_{l}, e_{i}\right\rangle B e_{i}
$$

If $l>n_{k}$, then by assumption, 69.4.18 holds for $j=k$. Thus, in any case, it follows that for each $l \notin\left\{n_{1}, \cdots, n_{k}\right\}$,

$$
B g_{l} \in B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)
$$

Now it follows from 69.4.17 that

$$
\begin{aligned}
B x_{r} & =\sum_{i=1}^{k} c_{i}^{r} B e_{i}+\sum_{i \notin\left\{n_{1}, \cdots, n_{k}\right\}}^{r} d_{i}^{r} B g_{i} \\
& =\sum_{i=1}^{k} c_{i}^{r} B e_{i}+\sum_{i \notin\left\{n_{1}, \cdots, n_{k}\right\}}^{r} d_{i}^{r} \sum_{j=1}^{k} c_{j}^{i} B e_{j}
\end{aligned}
$$

and so $B x_{r} \in B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)$. Then

$$
B x=\lim _{r \rightarrow \infty} B x_{r}=\lim _{r \rightarrow \infty} B y_{r}
$$

where $y_{r} \in \operatorname{span}\left(e_{i}, \cdots, e_{k}\right)$. Say

$$
B x_{r}=\sum_{i=1}^{k} a_{i}^{r} B e_{i}
$$

It follows easily that $\left\langle B x_{r}, e_{j}\right\rangle=a_{j}^{r}$. (Act on $e_{j}$ by both sides and use $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$.) Now since $x_{r}$ is bounded, it follows that these $a_{j}^{r}$ are also bounded. Hence, defining $y_{r} \equiv \sum_{i=1}^{k} a_{i}^{r} e_{i}$, it follows that $y_{r}$ is bounded in $\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)$ and so, there exists a subsequence, still denoted by $r$ such that $y_{r} \rightarrow y \in \operatorname{span}\left(e_{i}, \cdots, e_{k}\right)$. Therefore, $B x=$ $\lim _{r \rightarrow \infty} B y_{r}=B y$. In other words, $B W=B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)$ as claimed. This proves the claim.

If this happens, the process being described stops. You have found what is desired which has only finitely many vectors involved.

As long as the process does not stop, let

$$
e_{k+1} \equiv \frac{g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}}{\left\langle B\left(g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right), g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right\rangle^{1 / 2}}
$$

Thus, as in the usual argument for the Gram Schmidt process, $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$ for $i, j \leq k+1$. This is already known for $i, j \leq k$. Letting $l \leq k$, and using the orthogonality already shown,

$$
\begin{aligned}
\left\langle B e_{k+1}, e_{l}\right\rangle & =C\left\langle B\left(g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right), e_{l}\right\rangle \\
& =C\left(\left\langle B g_{k+1}, e_{l}\right\rangle-\left\langle B g_{n_{k+1}}, e_{l}\right\rangle\right)=0
\end{aligned}
$$

Consider

$$
\left\langle B g_{p}-B\left(\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right), g_{p}-\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right\rangle
$$

Either this equals 0 because $p$ is never one of the $n_{k}$ or eventually it equals 0 for some $k$ because $g_{p}=g_{n_{k}}$ for some $n_{k}$ and so, from the construction, $g_{n_{k}}=g_{p} \in \operatorname{span}\left(e_{1}, \cdots, e_{k}\right)$ and therefore,

$$
g_{p}=\sum_{j=1}^{k} a_{j} e_{j}
$$

which requires easily that

$$
B g_{p}=\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle B e_{i}
$$

the above holding for all $k$ large enough. It follows that for any $x \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$, (finite linear combination of vectors in $\left\{g_{k}\right\}_{k=1}^{\infty}$ )

$$
\begin{equation*}
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i} \tag{69.4.19}
\end{equation*}
$$

because for all $k$ large enough,

$$
B x=\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

Also note that for such $x \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$,

$$
\begin{aligned}
\langle B x, x\rangle & =\left\langle\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}, x\right\rangle=\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle\left\langle B x, e_{i}\right\rangle \\
& =\sum_{i=1}^{k}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
\end{aligned}
$$

Now for $x$ arbitrary, let $x_{k} \rightarrow x$ in $W$ where $x_{k} \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$. Then by Fatou's lemma,

$$
\begin{align*}
\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2} & \leq \lim \inf _{k \rightarrow \infty} \sum_{i=1}^{\infty}\left|\left\langle B x_{k}, e_{i}\right\rangle\right|^{2} \\
& =\lim \inf _{k \rightarrow \infty}\left\langle B x_{k}, x_{k}\right\rangle=\langle B x, x\rangle  \tag{69.4.20}\\
& \leq\|B x\|_{W^{\prime}}\|x\|_{W} \leq\|B\|\|x\|_{W}^{2}
\end{align*}
$$

Thus the series on the left converges. Then also, from the above inequality,

$$
\begin{aligned}
& \left|\left\langle\sum_{i=p}^{q}\left\langle B x, e_{i}\right\rangle B e_{i}, y\right\rangle\right| \leq \sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|\left|\left\langle B e_{i}, y\right\rangle\right| \\
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=p}^{q}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}
\end{aligned}
$$

By 69.4.20,

$$
\leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\|B\|\|y\|_{W}^{2}\right)^{1 / 2} \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}\|y\|_{W}
$$

It follows that

$$
\begin{equation*}
\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i} \tag{69.4.21}
\end{equation*}
$$

converges in $W^{\prime}$ because it was just shown that

$$
\left\|\sum_{i=p}^{q}\left\langle B x, e_{i}\right\rangle B e_{i}\right\|_{W^{\prime}} \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}
$$

and it was shown above that $\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}<\infty$, so the partial sums of the series 69.4.21 are a Cauchy sequence in $W^{\prime}$. Also, the above estimate shows that for $\|y\|=1$,

$$
\begin{aligned}
\left|\left\langle\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}, y\right\rangle\right| & \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}
\end{aligned}
$$

and so

$$
\begin{equation*}
\left\|\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\|_{W^{\prime}} \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2} \tag{69.4.22}
\end{equation*}
$$

Now for $x$ arbitrary, let $x_{k} \in \operatorname{span}\left(\left\{g_{j}\right\}_{j=1}^{\infty}\right)$ and $x_{k} \rightarrow x$ in $W$. Then for a fixed $k$ large enough,

$$
\begin{gathered}
\left\|B x-\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\| \leq\left\|B x-B x_{k}\right\| \\
+\left\|B x_{k}-\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}\right\|+\left\|\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}-\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\| \\
\leq \varepsilon+\left\|\sum_{i=1}^{\infty}\left\langle B\left(x_{k}-x\right), e_{i}\right\rangle B e_{i}\right\|
\end{gathered}
$$

the term

$$
\left\|B x_{k}-\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}\right\|
$$

equaling 0 by 69.4.19. From 69.4.22 and 69.4.20,

$$
\begin{aligned}
& \leq \varepsilon+\|B\|^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B\left(x_{k}-x\right), e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq \varepsilon+\|B\|^{1 / 2}\left\langle B\left(x_{k}-x\right), x_{k}-x\right\rangle^{1 / 2}<2 \varepsilon
\end{aligned}
$$

whenever $k$ is large enough. Therefore,

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

in $W^{\prime}$. It follows that

$$
\langle B x, x\rangle=\lim _{k \rightarrow \infty}\left\langle\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}, x\right\rangle=\lim _{k \rightarrow \infty} \sum_{i=1}^{k}\left|\left\langle B x, e_{i}\right\rangle\right|^{2} \equiv \sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
$$

Theorem 69.4.2 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, $W$ a separable Hilbert space, and let $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right) \equiv K^{\prime}$ and

$$
\begin{equation*}
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s \text { in } V^{\prime} \tag{69.4.23}
\end{equation*}
$$

where $X_{0} \in W$, and it is known that $X \in L^{p}(0, T, V) \equiv K$ for $p>1$. Then $t \rightarrow B X(t)$ is in $C\left([0, T], W^{\prime}\right)$ and also

$$
\frac{1}{2}\langle B X(t), X(t)\rangle=\frac{1}{2}\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Proof: By Lemma 65.3.1, there exists a sequence of uniform partitions $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}=$ $\mathscr{P}_{n}, \mathscr{P}_{n} \subseteq \mathscr{P}_{n+1}$, of $[0, T]$ such that the step functions

$$
\begin{aligned}
\sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{l}(t) \\
\sum_{k=0}^{m_{n}-1} X\left(t_{k+1}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{r}(t)
\end{aligned}
$$

converge to $X$ in $K$ and also $B X^{l}, B X^{r} \rightarrow B X$ in $L^{2}\left([0, T], W^{\prime}\right)$.
Lemma 69.4.3 Let $s<t$. Then for $X, Y$ satisfying 69.4.23

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\langle B X(s), X(s)\rangle \\
+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle \tag{69.4.24}
\end{gather*}
$$

Proof: It follows from the following computations

$$
B(X(t)-X(s))=\int_{s}^{t} Y(u) d u
$$

and so

$$
\begin{aligned}
& 2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle \\
= & 2\langle B(X(t)-X(s)), X(t)\rangle-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle
\end{aligned}
$$

$$
\begin{gathered}
=\quad 2\langle B X(t), X(t)\rangle-2\langle B X(s), X(t)\rangle-\langle B X(t), X(t)\rangle \\
+2\langle B X(s), X(t)\rangle-\langle B X(s), X(s)\rangle \\
=\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle
\end{gathered}
$$

Thus

$$
\begin{gathered}
\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle \\
=2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle
\end{gathered}
$$

Lemma 69.4.4 In the above situation,

$$
\sup _{t \in[0, T]}\langle B X(t), X(t)\rangle \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Also, $t \rightarrow B X(t)$ is weakly continuous with values in $W^{\prime}$.
Proof: From the above formula applied to the $k^{t h}$ partition of $[0, T]$ described above,

$$
\begin{aligned}
& \left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle=\sum_{j=0}^{m-1}\left\langle B X\left(t_{j+1}\right), X\left(t_{j+1}\right)\right\rangle-\left\langle B X\left(t_{j}\right), X\left(t_{j}\right)\right\rangle \\
& =\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle d u-\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle \\
& =\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u-\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle
\end{aligned}
$$

Thus, discarding the negative terms and denoting by $\mathscr{P}_{k}$ the $k^{t h}$ of these partitions,

$$
\begin{gathered}
\sup _{t_{j} \in \mathscr{P}_{k}}\left\langle B X\left(t_{j}\right), X\left(t_{j}\right)\right\rangle \leq\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u \\
\leq\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{T}\|Y(u)\|_{V^{\prime}}\left\|X_{k}^{r}(u)\right\|_{V} d u \\
\leq\left\langle B X_{0}, X_{0}\right\rangle+2\left(\int_{0}^{T}\|Y(u)\|_{V^{\prime}}^{p^{\prime}} d u\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p} d u\right)^{1 / p} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
\end{gathered}
$$

because these partitions are chosen such that

$$
\lim _{k \rightarrow \infty}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p}\right)^{1 / p}=\left(\int_{0}^{T}\|X(u)\|_{V}^{p}\right)^{1 / p}
$$

and so these are bounded. This has shown that for the dense subset of $[0, T], D \equiv \cup_{k} \mathscr{P}_{k}$,

$$
\sup _{t \in D}\langle B X(t), X(t)\rangle<C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

From Lemma 69.4.1 above, there exists $\left\{e_{i}\right\} \subseteq V$ such that $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$ and

$$
\langle B X(t), X(t)\rangle=\sum_{k=1}^{\infty}\left|\left\langle B X(t), e_{i}\right\rangle\right|^{2}=\sup _{m} \sum_{k=1}^{m}\left|\left\langle B X(t), e_{i}\right\rangle\right|^{2}
$$

Since each $e_{i} \in V$, and since $t \rightarrow B X(t)$ is continuous into $V^{\prime}$ thanks to the formula 69.4.23, it follows that $t \rightarrow \sum_{k=1}^{m}\left|\left\langle B X(t), e_{i}\right\rangle\right|$ is continuous and so $t \rightarrow\langle B X(t), X(t)\rangle$ is the sup of continuous functions. Therefore, this function of $t$ is lower semicontinuous. Since $D$ is dense in $[0, T]$, it follows that for all $t$,

$$
\langle B X(t), X(t)\rangle \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

It only remains to verify the claim about weak continuity.
Consider now the claim that $t \rightarrow B X(t)$ is weakly continuous. Letting $v \in V$,

$$
\begin{equation*}
\lim _{t \rightarrow s}\langle B X(t), v\rangle=\langle B X(s), v\rangle=\langle B X(s), v\rangle \tag{69.4.25}
\end{equation*}
$$

The limit follows from the formula 69.4.23 which implies $t \rightarrow B X(t)$ is continuous into $V^{\prime}$. Now

$$
\|B X(t)\|=\sup _{\|v\| \leq 1}|\langle B X(t), v\rangle| \leq\langle B v, v\rangle^{1 / 2}\langle B X(t), X(t)\rangle^{1 / 2}
$$

which was shown to be bounded for $t \in[0, T]$. Now let $w \in W$. Then

$$
|\langle B X(t), w\rangle-\langle B X(s), w\rangle| \leq|\langle B X(t)-B X(s), w-v\rangle|+|\langle B X(t)-B X(s), v\rangle|
$$

Then the first term is less than $\varepsilon$ if $v$ is close enough to $w$ and the second converges to 0 so 69.4.25 holds for all $v \in W$ and so this shows the weak continuity.

Now pick $t \in D$, the union of all the mesh points. Then for all $k$ large enough, $t \in \mathscr{P}_{k}$. Say $t=t_{m}$. From Lemma 69.4.3,

$$
\begin{gathered}
-\sum_{j=0}^{m-1}\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right),\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right)\right\rangle= \\
\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle-2 \sum_{j=0}^{m-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u
\end{gathered}
$$

Thus, $\left\langle\boldsymbol{B X}\left(t_{m}\right), X\left(t_{m}\right)\right\rangle$ is constant for all $k$ large enough and the integral term converges to

$$
\int_{0}^{t_{m}}\langle Y(u), X(u)\rangle d u
$$

It follows that the term on the left does converge to something as $k \rightarrow \infty$. It just remains to consider what it does converge to. However, from the equation solved by $X$,

$$
B X\left(t_{j+1}\right)-B X\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Y(u) d u
$$

Therefore, this term is dominated by an expression of the form

$$
\begin{gathered}
\sum_{j=0}^{m_{k}-1}\left(\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right) \\
=\sum_{j=0}^{m_{k}-1}\left\langle\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle d u \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle-\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j}\right)\right\rangle \\
=\int_{0}^{T}\left\langle Y(u), X^{r}(u)\right\rangle d u-\int_{0}^{T}\left\langle Y(u), X^{l}(u)\right\rangle d u
\end{gathered}
$$

However, both $X^{r}$ and $X^{l}$ converge to $X$ in $K=L^{p}(0, T, V)$. Therefore, this term must converge to 0 . Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t \in D$,

$$
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

It remains to verify that this holds for all $t$. Let $t \notin D$ and let $t(k) \in \mathscr{P}_{k}$ be the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$
B X(t(m))=B X_{0}+\int_{0}^{t(m)} Y(s) d s
$$

a similar formula for $X(t(k))$. Thus for $t>t(m)$,

$$
B X(t)-B X(t(m))=\int_{t(m)}^{t} Y(s) d s
$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $X_{0}=0$. Therefore,

$$
\begin{aligned}
& \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle \\
= & 2 \int_{t(m)}^{t(k)}\langle Y(s), X(s)-X(t(m))\rangle d s
\end{aligned}
$$

Thus, for $m \leq k$

$$
\begin{equation*}
\lim _{m, k \rightarrow \infty}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle=0 \tag{69.4.26}
\end{equation*}
$$

Hence $\{B X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $W^{\prime}$ because

$$
\begin{aligned}
& |\langle B(X(t(k))-X(t(m))), y\rangle| \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2} \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\|B\|^{1 / 2}\|y\|_{W}
\end{aligned}
$$

Does it converge to $B X(t)$ ? Let $\xi(t) \in W^{\prime}$ be what it does converge to. Let $v \in V$. Then

$$
\langle\xi(t), v\rangle=\lim _{k \rightarrow \infty}\langle B X(t(k)), v\rangle=\lim _{k \rightarrow \infty}\langle B X(t(k)), v\rangle=\langle B X(t), v\rangle
$$

because it is known that $t \rightarrow B X(t)$ is continuous into $V^{\prime}$. It is also known that $B X(t) \in$ $W^{\prime} \subseteq V^{\prime}$ and that the $B X(t)$ for $t \in[0, T]$ are uniformly bounded in $W^{\prime}$. Therefore, since $V$ is dense in $W$, it follows that $\xi(t)=B X(t)$.

Now for every $t \in D$, it was shown above that

$$
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

Also it was just shown that $B X(t(k)) \rightarrow B X(t)$. Then

$$
\begin{gathered}
|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle| \\
\leq|\langle B X(t(k)), X(t(k))-X(t)\rangle|+|\langle B X(t(k))-B X(t), X(t)\rangle|
\end{gathered}
$$

Then the second term converges to 0 . The first equals

$$
\begin{aligned}
& |\langle B X(t(k))-B X(t), X(t(k))\rangle| \\
\leq & \langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2}\langle B X(t(k)), X(t(k))\rangle^{1 / 2}
\end{aligned}
$$

From the above, this is dominated by an expression of the form

$$
\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2} C
$$

Then using the lower semicontinuity of $t \rightarrow\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle$ which follows from the above, this is no larger than

$$
\lim \inf _{m \rightarrow \infty}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2} C<\varepsilon
$$

provided $k$ is large enough. This follows from 69.4.26. Since $\varepsilon$ is arbitrary, it follows that

$$
\lim _{k \rightarrow \infty}|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle|=0
$$

Then from the formula,

$$
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

valid for $t \in D$, it follows that the same formula holds for all $t$. This formula implies $t \rightarrow\langle B X(t), X(t)\rangle$ is continuous. Also recall that $t \rightarrow B X(t)$ was shown to be weakly continuous into $W^{\prime}$. Then

$$
\begin{aligned}
& \langle B(X(t)-X(s)), X(t)-X(s)\rangle \\
= & \langle B X(t), X(t)\rangle-2\langle B X(t), X(s)\rangle+\langle B X(s), X(s)\rangle
\end{aligned}
$$

From this, it follows that $t \rightarrow B X(t)$ is continuous into $W^{\prime}$ because $\lim _{t \rightarrow s}$ of the right side gives 0 and so the same is true of the left. Hence,

$$
\begin{aligned}
|\langle B(X(t)-X(s)), y\rangle| & \leq\langle B y, y\rangle^{1 / 2}\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2} \\
& \leq\|B\|^{1 / 2}\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2}\|y\|
\end{aligned}
$$

so

$$
\|B(X(t)-X(s))\|_{W^{\prime}} \leq\|B\|^{1 / 2}\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2}
$$

which converges to 0 as $t \rightarrow s$.

### 69.5 Some Imbedding Theorems

The next theorem is very useful in getting estimates in partial differential equations. It is called Erling's lemma.

Definition 69.5.1 Let $E, W$ be Banach spaces such that $E \subseteq W$ and the injection map from $E$ into $W$ is continuous. The injection map is said to be compact if every bounded set in $E$ has compact closure in $W$. In other words, if a sequence is bounded in $E$ it has a convergent subsequence converging in $W$. This is also referred to by saying that bounded sets in $E$ are precompact in $W$.

Theorem 69.5.2 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then for every $\varepsilon>0$ there exists a constant, $C_{\varepsilon}$ such that for all $u \in E$,

$$
\|u\|_{W} \leq \varepsilon\|u\|_{E}+C_{\varepsilon}\|u\|_{X}
$$

Proof: Suppose not. Then there exists $\varepsilon>0$ and for each $n \in \mathbb{N}, u_{n}$ such that

$$
\left\|u_{n}\right\|_{W}>\varepsilon\left\|u_{n}\right\|_{E}+n\left\|u_{n}\right\|_{X}
$$

Now let $v_{n}=u_{n} /\left\|u_{n}\right\|_{E}$. Therefore, $\left\|v_{n}\right\|_{E}=1$ and

$$
\left\|v_{n}\right\|_{W}>\varepsilon+n\left\|v_{n}\right\|_{X}
$$

It follows there exists a subsequence, still denoted by $v_{n}$ such that $v_{n}$ converges to $v$ in $W$. However, the above inequality shows that $\left\|v_{n}\right\|_{X} \rightarrow 0$. Therefore, $v=0$. But then the above inequality would imply that $\left\|v_{n}\right\|>\varepsilon$ and passing to the limit yields $0>\varepsilon$, a contradiction.

Definition 69.5.3 Define $C([a, b] ; X)$ the space of functions continuous at every point of $[a, b]$ having values in $X$.

You should verify that this is a Banach space with norm

$$
\|u\|_{\infty, X}=\max \left\{\left\|u_{n_{k}}(t)-u(t)\right\|_{X}: t \in[a, b]\right\} .
$$

The following theorem is an infinite dimensional version of the Ascoli Arzela theorem. It is like a well known result due to Simon. It is the appropriate generalization to stochastic problems in which you do not have weak derivatives. See Theorem 65.12.1 on the Holder continuity of the stochastic integral.

Theorem 69.5.4 Let $q>1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$
\left\{u \text { such that }\|u(t)\|_{E} \leq R \text { for all } t \in[a, b], \text { and }\|u(s)-u(t)\|_{X} \leq R|t-s|^{1 / q}\right\} .
$$

Thus $S$ is bounded in $L^{\infty}(0, T, E)$ and in addition, the functions are uniformly Holder continuous into $X$. Then $S \subseteq C([a, b] ; W)$ and if $\left\{u_{n}\right\} \subseteq S$, there exists a subsequence, $\left\{u_{n_{k}}\right\}$ which converges to a function $u \in C([a, b] ; W)$ in the following way.

$$
\lim _{k \rightarrow \infty}\left\|u_{n_{k}}-u\right\|_{\infty, W}=0
$$

Proof: First consider the issue of $S$ being a subset of $C([a, b] ; W)$. Let $\varepsilon>0$ be given. Then by Theorem 69.5.2 there exists a constant, $C_{\varepsilon}$ such that for all $u \in W$

$$
\|u\|_{W} \leq \frac{\varepsilon}{4 R}\|u\|_{E}+C_{\varepsilon}\|u\|_{X}
$$

Therefore, for all $u \in S$,

$$
\begin{align*}
\|u(t)-u(s)\|_{W} & \leq \frac{\varepsilon}{6 R}\|u(t)-u(s)\|_{E}+C_{\varepsilon}\|u(t)-u(s)\|_{X} \\
& \leq \frac{\varepsilon}{6 R}\left(\|u(t)\|_{E}+\|u(s)\|_{E}\right)+C_{\varepsilon}\|u(t)-u(s)\|_{X} \\
& \leq \frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q} \tag{69.5.27}
\end{align*}
$$

Since $\varepsilon$ is arbitrary, it follows $u \in C([a, b] ; W)$.
Let $D=\mathbb{Q} \cap[a, b]$ so $D$ is a countable dense subset of $[a, b]$. Let $D=\left\{t_{n}\right\}_{n=1}^{\infty}$. By compactness of the embedding of $E$ into $W$, there exists a subsequence $u_{(n, 1)}$ such that as $n \rightarrow \infty, u_{(n, 1)}\left(t_{1}\right)$ converges to a point in $W$. Now take a subsequence of this, called $(n, 2)$ such that as $n \rightarrow \infty, u_{(n, 2)}\left(t_{2}\right)$ converges to a point in $W$. It follows that $u_{(n, 2)}\left(t_{1}\right)$ also converges to a point of $W$. Continue this way. Now consider the diagonal sequence, $u_{k} \equiv$ $u_{(k, k)}$ This sequence is a subsequence of $u_{(n, l)}$ whenever $k>l$. Therefore, $u_{k}\left(t_{j}\right)$ converges for all $t_{j} \in D$.

Claim: Let $\left\{u_{k}\right\}$ be as just defined, converging at every point of $D \equiv[a, b] \cap \mathbb{Q}$. Then $\left\{u_{k}\right\}$ converges at every point of $[a, b]$.

Proof of claim: Let $\varepsilon>0$ be given. Let $t \in[a, b]$. Pick $t_{m} \in D \cap[a, b]$ such that in 69.5.27 $C_{\varepsilon} R\left|t-t_{m}\right|<\varepsilon / 3$. There exists $N$ such that if $l, n>N$, then $\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\|_{X}<$ $\varepsilon / 3$. It follows that for $l, n>N$,

$$
\begin{aligned}
\left\|u_{l}(t)-u_{n}(t)\right\|_{W} \leq & \left\|u_{l}(t)-u_{l}\left(t_{m}\right)\right\|_{W}+\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\|_{W} \\
& +\left\|u_{n}\left(t_{m}\right)-u_{n}(t)\right\|_{W} \\
\leq & \frac{2 \varepsilon}{3}+\frac{\varepsilon}{3}+\frac{2 \varepsilon}{3}<2 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows $\left\{u_{k}(t)\right\}_{k=1}^{\infty}$ is a Cauchy sequence. Since $W$ is complete, this shows this sequence converges.

Now for $t \in[a, b]$, it was just shown that if $\varepsilon>0$ there exists $N_{t}$ such that if $n, m>N_{t}$, then

$$
\left\|u_{n}(t)-u_{m}(t)\right\|_{W}<\frac{\varepsilon}{3}
$$

Now let $s \neq t$. Then

$$
\left\|u_{n}(s)-u_{m}(s)\right\|_{W} \leq\left\|u_{n}(s)-u_{n}(t)\right\|_{W}+\left\|u_{n}(t)-u_{m}(t)\right\|_{W}+\left\|u_{m}(t)-u_{m}(s)\right\|_{W}
$$

From 69.5.27

$$
\left\|u_{n}(s)-u_{m}(s)\right\|_{W} \leq 2\left(\frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q}\right)+\left\|u_{n}(t)-u_{m}(t)\right\|_{W}
$$

and so it follows that if $\delta$ is sufficiently small and $s \in B(t, \boldsymbol{\delta})$, then when $n, m>N_{t}$

$$
\left\|u_{n}(s)-u_{m}(s)\right\|<\varepsilon
$$

Since $[a, b]$ is compact, there are finitely many of these balls, $\left\{B\left(t_{i}, \delta\right)\right\}_{i=1}^{p}$, such that for $s \in B\left(t_{i}, \boldsymbol{\delta}\right)$ and $n, m>N_{t_{i}}$, the above inequality holds. Let $N>\max \left\{N_{t_{1}}, \cdots, N_{t_{p}}\right\}$. Then if $m, n>N$ and $s \in[a, b]$ is arbitrary, it follows the above inequality must hold. Therefore, this has shown the following claim.

Claim: Let $\varepsilon>0$ be given. There exists $N$ such that if $m, n>N$, then $\left\|u_{n}-u_{m}\right\|_{\infty, W}<\varepsilon$.
Now let $u(t)=\lim _{k \rightarrow \infty} u_{k}(t)$.

$$
\begin{equation*}
\|u(t)-u(s)\|_{W} \leq\left\|u(t)-u_{n}(t)\right\|_{W}+\left\|u_{n}(t)-u_{n}(s)\right\|_{W}+\left\|u_{n}(s)-u(s)\right\|_{W} \tag{69.5.28}
\end{equation*}
$$

Let $N$ be in the above claim and fix $n>N$. Then

$$
\left\|u(t)-u_{n}(t)\right\|_{W}=\lim _{m \rightarrow \infty}\left\|u_{m}(t)-u_{n}(t)\right\|_{W} \leq \varepsilon
$$

and similarly, $\left\|u_{n}(s)-u(s)\right\|_{W} \leq \varepsilon$. Then if $|t-s|$ is small enough, 69.5 .27 shows the middle term in 69.5.28 is also smaller than $\varepsilon$. Therefore, if $|t-s|$ is small enough,

$$
\|u(t)-u(s)\|_{W}<3 \varepsilon
$$

Thus $u$ is continuous. Finally, let $N$ be as in the above claim. Then letting $m, n>N$, it follows that for all $t \in[a, b]$,

$$
\left\|u_{m}(t)-u_{n}(t)\right\|_{W}<\varepsilon
$$

Therefore, letting $m \rightarrow \infty$, it follows that for all $t \in[a, b]$,

$$
\left\|u(t)-u_{n}(t)\right\|_{W} \leq \varepsilon
$$

and so $\left\|u-u_{n}\right\|_{\infty, W} \leq \varepsilon$.
Here is an interesting corollary. Recall that for $E$ a Banach space $C^{0, \alpha}([0, T], E)$ is the space of continuous functions $u$ from $[0, T]$ to $E$ such that

$$
\|u\|_{\alpha, E} \equiv\|u\|_{\infty, E}+\rho_{\alpha, E}(u)<\infty
$$

where here

$$
\rho_{\alpha, E}(u) \equiv \sup _{t \neq s} \frac{\|u(t)-u(s)\|_{E}}{|t-s|^{\alpha}}
$$

Corollary 69.5.5 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then if $\gamma>\alpha$, the embedding of $C^{0, \gamma}([0, T], E)$ into $C^{0, \alpha}([0, T], X)$ is compact.

Proof: Let $\phi \in C^{0, \gamma}([0, T], E)$

$$
\begin{gathered}
\frac{\|\phi(t)-\phi(s)\|_{X}}{|t-s|^{\alpha}} \leq\left(\frac{\|\phi(t)-\phi(s)\|_{W}}{|t-s|^{\gamma}}\right)^{\alpha / \gamma}\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)} \\
\leq\left(\frac{\|\phi(t)-\phi(s)\|_{E}}{|t-s|^{\gamma}}\right)^{\alpha / \gamma}\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)} \leq \rho_{\gamma, E}(\phi)\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)}
\end{gathered}
$$

Now suppose $\left\{u_{n}\right\}$ is a bounded sequence in $C^{0, \gamma}([0, T], E)$. By Theorem 69.5.4 above, there is a subsequence still called $\left\{u_{n}\right\}$ which converges in $C^{0}([0, T], W)$. Thus from the above inequality

$$
\begin{aligned}
& \frac{\left\|u_{n}(t)-u_{m}(t)-\left(u_{n}(s)-u_{m}(s)\right)\right\|_{X}}{|t-s|^{\alpha}} \\
\leq & \rho_{\gamma, E}\left(u_{n}-u_{m}\right)\left\|u_{n}(t)-u_{m}(t)-\left(u_{n}(s)-u_{m}(s)\right)\right\|_{W}^{1-(\alpha / \gamma)} \\
\leq & C\left(\left\{u_{n}\right\}\right)\left(2\left\|u_{n}-u_{m}\right\|_{\infty, W}\right)^{1-(\alpha / \gamma)}
\end{aligned}
$$

which converges to 0 as $n, m \rightarrow \infty$. Thus

$$
\rho_{\alpha, X}\left(u_{n}-u_{m}\right) \rightarrow 0 \text { as } n, m \rightarrow \infty
$$

Also $\left\|u_{n}-u_{m}\right\|_{\infty, X} \rightarrow 0$ as $n, m \rightarrow \infty$ so this is a Cauchy sequence in $C^{0, \alpha}([0, T], X)$.
The next theorem is a well known result probably due to Lions.
Theorem 69.5.6 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $p \geq 1$, let $q>1$, and define

$$
S \equiv\left\{u \in L^{p}([a, b] ; E): \text { for some } C,\|u(t)-u(s)\|_{X} \leq C|t-s|^{1 / q}\right.
$$

$$
\text { and } \left.\|u\|_{L^{p}([a, b] ; E)} \leq R\right\} .
$$

Thus $S$ is bounded in $L^{p}([a, b] ; E)$ and Holder continuous into $X$. Then $S$ is precompact in $L^{p}([a, b] ; W)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b] ; W)$.

Proof: By Proposition 7.6 .5 on Page 144 it suffices to show that $S$ has an $\eta$ net in $L^{p}([a, b] ; W)$ for each $\eta>0$.

If not, there exists $\eta>0$ and a sequence $\left\{u_{n}\right\} \subseteq S$, such that

$$
\begin{equation*}
\left\|u_{n}-u_{m}\right\| \geq \eta \tag{69.5.29}
\end{equation*}
$$

for all $n \neq m$ and the norm refers to $L^{p}([a, b] ; W)$. Let

$$
a=t_{0}<t_{1}<\cdots<t_{k}=b, t_{i}-t_{i-1}=(b-a) / k
$$

Now define

$$
\bar{u}_{n}(t) \equiv \sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t), \bar{u}_{n_{i}} \equiv \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s
$$

The idea is to show that $\bar{u}_{n}$ approximates $u_{n}$ well and then to argue that a subsequence of the $\left\{\bar{u}_{n}\right\}$ is a Cauchy sequence yielding a contradiction to 69.5.29.

Therefore,

$$
\begin{gathered}
u_{n}(t)-\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{n}(t) \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(t) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{gathered}
$$

It follows from Jensen's inequality that

$$
\begin{aligned}
& \left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} \\
= & \sum_{i=1}^{k}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
\leq & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{aligned}
$$

and so

$$
\begin{align*}
& \int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \\
\leq & \int_{a}^{b} \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) d t \\
= & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s d t . \tag{69.5.30}
\end{align*}
$$

From Theorem 69.5.2 if $\varepsilon>0$, there exists $C_{\varepsilon}$ such that

$$
\begin{gathered}
\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} \leq \varepsilon\left\|u_{n}(t)-u_{n}(s)\right\|_{E}^{p}+C_{\varepsilon}\left\|u_{n}(t)-u_{n}(s)\right\|_{X}^{p} \\
\leq 2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}|t-s|^{p / q}
\end{gathered}
$$

This is substituted in to 69.5 .30 to obtain

$$
\begin{gathered}
\int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \leq \\
\\
\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left(2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}|t-s|^{p / q}\right) d s d t \\
= \\
\sum_{i=1}^{k} 2^{p} \varepsilon \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)\right\|_{W}^{p}+\frac{C_{\varepsilon}}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}|t-s|^{p / q} d s d t \\
\leq \quad 2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}} d s d t \\
= \\
2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q}\left(t_{i}-t_{i-1}\right)^{2} \\
\leq \\
2^{p} \varepsilon R^{p}+C_{\varepsilon} \sum_{i=1}^{k}\left(t_{i}-t_{i-1}\right)^{1+p / q}=2^{p} \varepsilon R^{p}+C_{\varepsilon} k\left(\frac{b-a}{k}\right)^{1+p / q} .
\end{gathered}
$$

Taking $\varepsilon$ so small that $2^{p} \varepsilon R^{p}<\eta^{p} / 8^{p}$ and then choosing $k$ sufficiently large, it follows

$$
\left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}([a, b] ; W)}<\frac{\eta}{4} .
$$

Thus $k$ is fixed and $\bar{u}_{n}$ at a step function with $k$ steps having values in $E$. Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that $\left\{\bar{u}_{n}\right\}$ is Cauchy in $L^{p}(a, b ; W)$ and use this to contradict 69.5.29. The details follow.

Suppose $\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{i}^{n} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)$. Thus

$$
\left\|\bar{u}_{n}(t)\right\|_{E}=\sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
$$

and so

$$
R \geq \int_{a}^{b}\left\|\bar{u}_{n}(t)\right\|_{E}^{p} d t=\frac{T}{k} \sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E}^{p}
$$

Therefore, the $\left\{u_{i}^{n}\right\}$ are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence $\left\{u_{n_{k}}\right\}$ such that $u_{n_{k}}$ is a Cauchy sequence in $L^{p}(a, b ; W)$. You simply get a subsequence such that $u_{i}^{n_{k}}$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,

$$
\begin{aligned}
\left\|u_{n}-u_{m}\right\|_{L^{p}(a, b ; W)} \leq & \left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}(a, b ; W)} \\
& +\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\left\|\bar{u}_{m}-u_{m}\right\|_{L^{p}(a, b ; W)} \\
\leq & \frac{\eta}{4}+\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\frac{\eta}{4}<\eta
\end{aligned}
$$

provided $m, n$ are large enough, contradicting 69.5.29.

## Chapter 70

## Measurability Without Uniqueness

With the Ito formula which holds for a single space, it is time to consider stochastic ordinary differential equations. First is a general theory which allows one to consider measurable solutions to stochastic equations in which there is no uniqueness available. Unfortunately, it does not include obtaining adapted solutions. Instead, it includes measurability of functions with respect to a single $\sigma$ algebra. Then when path uniqueness is available, one can include the concept of adapted solutions rather easily and this will be done for ordinary differential equations. First is a general result about multifunctions.

### 70.1 Multifunctions And Their Measurability

Let $X$ be a separable complete metric space and let $(\Omega, \mathscr{C}, \mu)$ be a set, a $\sigma$ algebra of subsets of $\Omega$, and a measure $\mu$ such that this is a complete $\sigma$ finite measure space. Also let $\Gamma: \Omega \rightarrow \mathscr{P}_{F}(X)$, the closed subsets of $X$.

Definition 70.1.1 We define $\Gamma^{-}(S) \equiv\{\omega \in \Omega: \Gamma(\omega) \cap S \neq \emptyset\}$
We will consider a theory of measurability of set valued functions. The following theorem is the main result in the subject. In this theorem the third condition is what we will refer to as measurable. The second condition is called strongly measurable. More can be said than what we will prove here.

Theorem 70.1.2 In the following, $1 . \Rightarrow 2 . \Rightarrow 3 . \Rightarrow 4$.

1. For all B a Borel set in $X, \Gamma^{-}(B) \in \mathscr{C}$.
2. For all $F$ closed in $X, \Gamma^{-}(F) \in \mathscr{C}$
3. For all $U$ open in $X, \Gamma^{-}(U) \in \mathscr{C}$
4. There exists a sequence, $\left\{\sigma_{n}\right\}$ of measurable functions satisfying $\sigma_{n}(\omega) \in \Gamma(\omega)$ such that for all $\omega \in \Omega$,

$$
\Gamma(\omega)=\overline{\left\{\sigma_{n}(\omega): n \in \mathbb{N}\right\}}
$$

These functions are called measurable selections.
Also $4 . \Rightarrow 3$. If $\Gamma(\omega)$ is compact for each $\omega$, then also $3 . \Rightarrow 2$.
Proof: It is obvious that 1.) $\Rightarrow 2$.). To see that 2.) $\Rightarrow$ 3.) note that $\Gamma^{-}\left(\cup_{i=1}^{\infty} F_{i}\right)=$ $\cup_{i=1}^{\infty} \Gamma^{-}\left(F_{i}\right)$. Since any open set in $X$ can be obtained as a countable union of closed sets, this implies 2.) $\Rightarrow 3$.).

Now we verify that 3.) $\Rightarrow 4$.). Let $\left\{x_{n}\right\}_{n=1}^{\infty}$ be a countable dense subset of $X$. For $\omega \in \Omega$, let $\psi_{1}(\omega)=x_{n}$ where $n$ is the smallest integer such that $\Gamma(\omega) \cap B\left(x_{n}, 1\right) \neq \emptyset$. Therefore, $\psi_{1}(\omega)$ has countably many values, $x_{n_{1}}, x_{n_{2}}, \cdots$ where $n_{1}<n_{2}<\cdots$. Now

$$
\left\{\omega: \psi_{1}=x_{n}\right\}=
$$

$$
\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 1\right) \neq \emptyset\right\} \cap\left[\Omega \backslash \cup_{k<n}\left\{\omega: \Gamma(\omega) \cap B\left(x_{k}, 1\right) \neq \emptyset\right\}\right] \in \mathscr{C}
$$

Thus we see that $\psi_{1}$ is measurable and $\operatorname{dist}\left(\psi_{1}(\omega), \Gamma(\omega)\right)<1$. Let

$$
\Omega_{n} \equiv\left\{\omega \in \Omega: \psi_{1}(\omega)=x_{n}\right\}
$$

Then $\Omega_{n} \in \mathscr{C}$ and $\Omega_{n} \cap \Omega_{m}=\emptyset$ for $n \neq m$ and $\cup_{n=1}^{\infty} \Omega_{n}=\Omega$. Let $D_{n} \equiv\left\{x_{k}: x_{k} \in B\left(x_{n}, 1\right)\right\}$. Now for each $n$, and $\omega \in \Omega_{n}$, let $\psi_{2}(\omega)=x_{k}$ where $k$ is the smallest index such that $x_{k} \in$ $D_{n}$ and $B\left(x_{k}, \frac{1}{2}\right) \cap \Gamma(\omega) \neq \emptyset$. Thus dist $\left(\psi_{2}(\omega), \Gamma(\omega)\right)<\frac{1}{2}$ and $d\left(\psi_{2}(\omega), \psi_{1}(\omega)\right)<1$. Continue this way obtaining $\psi_{k}$ a measurable function such that

$$
\operatorname{dist}\left(\psi_{k}(\omega), \Gamma(\omega)\right)<\frac{1}{2^{k-1}}, d\left(\psi_{k}(\omega), \psi_{k+1}(\omega)\right)<\frac{1}{2^{k-2}}
$$

Then for each $\omega,\left\{\psi_{k}(\omega)\right\}$ is a Cauchy sequence converging to a point, $\sigma(\omega) \in \Gamma(\omega)$. This has shown that if $\Gamma$ is measurable there exists a measurable selection, $\sigma(\omega) \in \Gamma(\omega)$. It remains to show there exists a sequence of these measurable selections, $\sigma_{n}$ such that the conclusion of 4.) holds. To do this we define

$$
\Gamma_{n i}(\omega) \equiv\left\{\begin{array}{l}
\Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \text { if } \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \neq \emptyset \\
\Gamma(\omega) \text { otherwise }
\end{array}\right.
$$

First we show that $\Gamma_{n i}$ is measurable. Let $U$ be open. Then

$$
\begin{gathered}
\left\{\omega: \Gamma_{n i}(\omega) \cap U \neq \emptyset\right\}=\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \cap U \neq \emptyset\right\} \cup \\
{\left[\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right)=\emptyset\right\} \cap\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}\right]} \\
=\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \cap U \neq \emptyset\right\} \cup \\
{\left[\left(\Omega \backslash\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \neq \emptyset\right\}\right) \cap\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}\right]}
\end{gathered}
$$

a measurable set. By what was just shown there exists $\sigma_{n i}$, a measurable function such that $\sigma_{n i}(\omega) \in \Gamma_{n i}(\omega) \subseteq \Gamma(\omega)$ for all $\omega \in \Omega$. If $x \in \Gamma(\omega)$, then $x \in B\left(x_{n}, 2^{-i}\right)$ whenever $x_{n}$ is close enough to $x$. Therefore, $\left|\sigma_{n i}(\omega)-x\right|<2^{-i}$. And it follows that condition 4.) holds.

Now we verify that 4.) $\Rightarrow 3$.). Suppose there exist measurable selections $\sigma_{n}(\omega) \in$ $\Gamma(\omega)$ satisfying condition 4.). Let $U$ be open. Then

$$
\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}=\cup_{n=1}^{\infty} \sigma_{n}^{-1}(U) \in \mathscr{C}
$$

Now suppose $\Gamma(\omega)$ is compact for every $\omega$ and that $\Gamma^{-}(U) \in \mathscr{C}$ for every $U$ open. Then let $F$ be a closed set and let $\left\{U_{n}\right\}$ be a decreasing sequence of open sets whose intersection equals $F$ such that also, for all $n, U_{n} \supseteq \overline{U_{n+1}}$. Then

$$
\Gamma(\omega) \cap F=\cap_{n} \Gamma(\omega) \cap U_{n}=\cap_{n} \Gamma(\omega) \cap \overline{U_{n}}
$$

Now because of compactness, the set on the left is nonempty if and only if each set on the right is also nonempty. Thus $\Gamma^{-}(F)=\cap_{n} \Gamma^{-1}\left(U_{n}\right) \in \mathscr{C}$.

Actually these are all equivalent in the case of complete measure spaces but we do not need this and it is much harder to show.

### 70.2 A Measurable Selection

This section deals with the problem of getting product measurable functions in a context of no uniqueness. The following is the main result. It is stated in great generality because it has fairly wide application although it will be used first in finite dimensions.

Theorem 70.2.1 Let $V$ be a reflexive separable Banach space and $V^{\prime}$ its dual and $\frac{1}{p}+\frac{1}{p^{\prime}}=$ 1 where $p>1$ as usual. For $n \in \mathbb{N}$ let the functions $t \rightarrow u_{n}(t, \omega)$ be in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ and $(t, \omega) \rightarrow u_{n}(t, \omega)$ be $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable into $V^{\prime}$. Suppose there is a set of measure zero $N$ such that if $\omega \notin N$, then for all $n$,

$$
\sup _{t \in[0, T]}\left\|u_{n}(t, \omega)\right\|_{V^{\prime}} \leq C(\omega)
$$

Also suppose for each $\omega \notin N$, each subsequence of $\left\{u_{n}\right\}$ has a further subsequence which converges weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ to $u(\cdot, \omega) \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ such that $t \rightarrow u(t, \omega)$ is weakly continuous into $V^{\prime}$. Then there exists u product measurable, with $t \rightarrow u(t, \omega)$ being weakly continuous into $V^{\prime}$. Moreover, there exists, for each $\omega \notin N$, a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$.

Note that the exceptional set is given. It could be the empty set with no change in the conclusion of the theorem.

Let $X=\prod_{k=1}^{\infty} C([0, T])$ with the product topology. One can consider this as a metric space using the metric

$$
d(\mathbf{f}, \mathbf{g}) \equiv \sum_{k=1}^{\infty} 2^{-k} \frac{\left\|f_{k}-g_{k}\right\|}{1+\left\|f_{k}-g_{k}\right\|}
$$

where the norm is the maximum norm in $C([0, T])$. With this metric, $X$ is complete and separable.

Lemma 70.2.2 Let $\left\{\mathbf{f}_{n}\right\}$ be a sequence in $X$ and suppose that the $k^{\text {th }}$ components $f_{n k}$ are bounded in $C^{0,1}([0, T])$. (This refers to the Hölder space with $\gamma=1$.) Then there exists a subsequence converging to some $\mathbf{f} \in X$. Thus if $\left\{\mathbf{f}_{n}\right\}$ has each component bounded in $C^{0,1}([0, T])$, then $\left\{\mathbf{f}_{n}\right\}$ is pre-compact in $X$.

Proof: By the Ascoli-Arzelà theorem, there exists a subsequence $n_{1}$ such that the first component $f_{n_{1} 1}$ converges in $C([0, T])$. Then taking a subsequence, one can obtain $n_{2}$ a subsequence of $n_{1}$ such that both the first and second components of $\mathbf{f}_{n_{2}}$ converge. Continuing this way one obtains a sequence of subsequences, each a subsequence of the previous one such that $\mathbf{f}_{n_{j}}$ has the first $j$ components converging to functions in $C([0, T])$. Therefore, the diagonal subsequence has the property that it has every component converging to a function in $C([0, T])$. The resulting function in $\prod_{k} C([0, T])$ is $\mathbf{f}$.

Now for $m \in \mathbb{N}$ and $\phi \in V^{\prime}$, define $l_{m}(t) \equiv \max (0, t-(1 / m))$ and

$$
\psi_{m, \phi}: L^{p^{\prime}}\left([0, T] ; V^{\prime}\right) \rightarrow C([0, T])
$$

as follows

$$
\psi_{m, \phi} u(t) \equiv \int_{0}^{T}\left\langle m \phi \mathscr{X}_{\left[l_{m}(t), t\right]}(s), u(s)\right\rangle_{V, V^{\prime}} d s=m \int_{l_{m}(t)}^{t}\langle\phi, u(s)\rangle_{V, V^{\prime}} d s
$$

Let $\mathscr{D}=\left\{\phi_{r}\right\}_{r=1}^{\infty}$ denote a countable dense subset of $V$. Then the pairs $(\phi, m)$ for $\phi \in \mathscr{D}$ and $m \in \mathbb{N}$ yield a countable set. Let $\left(m_{k}, \phi_{r_{k}}\right)$ denote an enumeration of these pairs $(m, \phi) \in \mathbb{N} \times \mathscr{D}$. To save notation, we denote

$$
f_{k}(u)(t) \equiv \psi_{m_{k}, \phi_{r_{k}}}(u)(t)=m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u(s)\right\rangle_{V, V^{\prime}} d s
$$

For fixed $\omega \notin N$ and $k$, the functions $\left\{t \rightarrow f_{k}\left(u_{j}(\cdot, \omega)\right)(t)\right\}_{j}$ are uniformly bounded and equicontinuous because they are in $C^{0,1}([0, T])$. Indeed,

$$
\left|f_{k}\left(u_{j}(\cdot, \omega)\right)(t)\right|=\left|m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V, V^{\prime}} d s\right| \leq C(\omega)\left\|\phi_{r_{k}}\right\|_{V}
$$

and for $t \leq t^{\prime}$

$$
\begin{aligned}
& \left|f_{k}\left(u_{j}(\cdot, \omega)\right)(t)-f_{k}\left(u_{j}(\cdot, \omega)\right)\left(t^{\prime}\right)\right| \\
\leq & \left|m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V, V^{\prime}} d s-m_{k} \int_{l_{m_{k}}\left(t^{\prime}\right)}^{t^{\prime}}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V, V^{\prime}} d s\right| \\
\leq & 2 m_{k}\left|t^{\prime}-t\right|\left\|\phi_{r_{k}}\right\|_{V^{\prime}} C(\omega) .
\end{aligned}
$$

By Lemma 70.2.2, the set of functions $\left\{\mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right\}_{j=n}^{\infty}$ is pre-compact in the space defined as $X=\prod_{k} C([0, T])$. Then define a set valued map $\Gamma^{n}: \Omega \rightarrow X$ as follows.

$$
\Gamma^{n}(\omega) \equiv \overline{\cup_{j \geq n}\left\{\mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right\}}
$$

where the closure is taken in $X$. Then $\Gamma^{n}(\omega)$ is the closure of a pre-compact set in $\prod_{k} C([0, T])$ and so $\Gamma^{n}(\omega)$ is compact in $\prod_{k} C([0, T])$. From the definition, a function $\mathbf{f}$ is in $\Gamma^{n}(\omega)$ if and only if $d\left(\mathbf{f}, \mathbf{f}\left(w_{l}\right)\right) \rightarrow 0$ as $l \rightarrow \infty$, where each $w_{l}$ is one of the $u_{j}(\cdot, \omega)$ for $j \geq n$. From the topology on $X$ this happens if and only if for every $k$,

$$
f_{k}(t)=\lim _{l \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, w_{l}(s, \omega)\right\rangle_{V, V^{\prime}} d s
$$

where the limit is the uniform limit in $t$.
Note that in the case of a filtration, instead of a single $\sigma$-algebra $\mathscr{F}$ where each $u_{j}$ is progressively measurable, if the sequence $w_{l}$ does not have the index $l$ dependent on $\omega$, then if such a limit holds for each $\omega$, it follows that $(t, \omega) \rightarrow f_{k}(t, \omega)$ will inherit progressive measurability from the $w_{l}$. This situation will be typical when dealing with stochastic equations with path uniqueness known. Thus this is a reasonable way to attempt to consider measurability and the more difficult question of whether a process is adapted.

Lemma 70.2.3 $\omega \rightarrow \Gamma^{n}(\omega)$ is a $\mathscr{F}$ measurable set valued map with values in $X$. If $\sigma$ is a measurable selection, $\left(\sigma(\omega) \in \Gamma^{n}(\omega)\right.$ so $\sigma=\sigma(\cdot, \omega)$ a continuous function. To have this measurable would mean that $\sigma_{k}^{-1}($ open $) \in \mathscr{F}$ where the open set is in $C([0, T])$.) then for each $t, \omega \rightarrow \sigma(t, \omega)$ is $\mathscr{F}$ measurable and $(t, \omega) \rightarrow \sigma(t, \omega)$ is $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable.

Proof: Let $O$ be a basic open set in $X$. Thus $O=\prod_{k=1}^{\infty} O_{k}$ where $O_{k}$ is a proper open set of $C([0, T])$ only for $k \in\left\{k_{1}, \cdots, k_{r}\right\}$. We need to consider whether

$$
\Gamma^{n-}(O) \equiv\left\{\omega: \Gamma^{n}(\omega) \cap O \neq \emptyset\right\} \in \mathscr{F} .
$$

Now $\Gamma^{n-}(O)$ equals

$$
\cap_{i=1}^{r}\left\{\omega: \Gamma^{n}(\omega)_{k_{i}} \cap O_{k_{i}} \neq \emptyset\right\}
$$

Thus we consider whether

$$
\begin{equation*}
\left\{\omega: \Gamma^{n}(\omega)_{k_{i}} \cap O_{k_{i}} \neq \emptyset\right\} \in \mathscr{F} \tag{70.2.1}
\end{equation*}
$$

From the definition of $\Gamma^{n}(\omega)$, this is equivalent to the condition that for some $j \geq n$,

$$
f_{k_{i}}\left(u_{j}(\cdot, \omega)\right)=\left(\mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}} \in O_{k_{i}}
$$

and so the above set in 70.2 .1 is of the form

$$
\cup_{j=n}^{\infty}\left\{\omega:\left(\mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}} \in O_{k_{i}}\right\}
$$

Now $\omega \rightarrow\left(\mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}}$ is $\mathscr{F}$ measurable into $C([0, T])$ and so the above set is in $\mathscr{F}$. To see this, let $g \in C([0, T])$ and consider the inverse image of the ball $B(g, r)$,

$$
\left\{\omega:\left\|\left(\mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}}-g\right\|_{C([0, T])}<r\right\} .
$$

By continuity considerations,

$$
\left\|\left(\mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}}-g\right\|_{C([0, T])}=\sup _{t \in \mathbb{Q} \cap[0, T]}\left|\left(\mathbf{f}\left(u_{j}(t, \omega)\right)\right)_{k_{i}}-g(t)\right|
$$

which is the sup of countably many $\mathscr{F}$ measurable functions. Thus it is $\mathscr{F}$ measurable. Since every open set is the countable union of such balls, it follows that the claim about $\mathscr{F}$ measurability is valid. Thus $\Gamma^{n-}(O)$ is $\mathscr{F}$ measurable whenever $O$ is a basic open set.

Now $X$ is a separable metric space and so every open set is a countable union of these basic sets. Let $U$ be an open set in $X$ and let $U=\cup_{l=1}^{\infty} O^{l}$ where $O^{l}$ is a basic open set as above. Then

$$
\Gamma^{n-}(U)=\cup_{l=1}^{\infty} \Gamma^{n-}\left(O^{l}\right) \in \mathscr{F}
$$

That there exists a measurable selection follows from the standard theory of measurable multi-functions [10], [70]. This is proved in Theorem 70.1.2 above. For $\sigma$ one of these measurable selections, the evaluation at $t$ is $\mathscr{F}$ measurable. Thus $\omega \rightarrow \sigma(t, \omega)$ is $\mathscr{F}$ measurable with values in $\mathbb{R}^{\infty}$. Also $t \rightarrow \sigma(t, \omega)$ is continuous, and so it follows that in fact $\sigma$ is product measurable as claimed.

Definition 70.2.4 Let $\Gamma(\omega) \equiv \cap_{n=1}^{\infty} \Gamma^{n}(\omega)$.
Lemma 70.2.5 $\Gamma$ is a nonempty $\mathscr{F}$ measurable set valued function having values in the compact sub-sets of $X$. There exists a measurable selection $\gamma$. For $\gamma$ a $\mathscr{F}$ measurable selection, $(t, \omega) \rightarrow \gamma(t, \omega)$ is $\mathscr{P}$ measurable. Also, for each $\omega$, there exists a subsequence, $u_{n(\omega)}(\cdot, \omega)$ such that for each $k$,

$$
\gamma_{k}(t, \omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(u_{n(\omega)}(t, \omega)\right)_{k}=\lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{n(\omega)}(s, \omega)\right\rangle_{V, V^{\prime}} d s
$$

Proof: Consider $\Gamma(\omega)=\cap_{n=1}^{\infty} \Gamma^{n}(\omega)$. Then $\omega \rightarrow \Gamma(\omega)$ is a compact set valued map in $X$. It is nonempty because each $\Gamma^{n}(\omega)$ is nonempty and compact, and these sets are nested. Is it $\mathscr{F}$ measurable? Each $\Gamma^{n}$ is compact valued and $\mathscr{F}$ measurable. Hence if $F$ is closed,

$$
\Gamma(\omega) \cap F=\cap_{n=1}^{\infty} \Gamma^{n}(\omega) \cap F
$$

and the left is non empty if and only if each $\Gamma^{n}(\omega) \cap F \neq \emptyset$. Hence for $F$ closed,

$$
\{\omega: \Gamma(\omega) \cap F \neq \emptyset\}=\cap_{n}\left\{\omega: \Gamma^{n}(\omega) \cap F \neq \emptyset\right\}
$$

and so

$$
\Gamma^{-}(F)=\cap_{n} \Gamma^{n-}(F) \in \mathscr{F}
$$

The last claim follows from the theory of multi-functions Theorem 70.1.2, [10], [70]. Since $\Gamma^{n}(\omega)$ is compact, the measurability of $\Gamma^{n}$, that $\Gamma^{n-}(U) \in \mathscr{F}$ for $U$ open implies the strong measurability of $\Gamma^{n}$, that $\Gamma^{n-}(F) \in \mathscr{F}$. Thus $\omega \rightarrow \Gamma(\omega)$ is non empty compact valued in $X$ and $\mathscr{F}$ measurable.

From standard theory of measurable multi-functions, Theorem 70.1.2, [10], [70], there exists a $\mathscr{F}$ measurable selection $\omega \rightarrow \gamma(\omega)$ with $\gamma(\omega) \in \Gamma(\omega)$ for each $\omega$. Now it follows that $t \rightarrow \gamma_{k}(t, \omega)$ is continuous. This is what it means for $\gamma(\omega) \in X$. What of the product measurability of $\gamma_{k}$ ? We know that $\omega \rightarrow \gamma_{k}(\omega)$ is $\mathscr{F}$ measurable into $C([0, T])$ and so since pointwise evaluation is continuous, $\omega \rightarrow \gamma_{k}(t, \omega)$ is $\mathscr{F}$ measurable. Then since $t \rightarrow$ $\gamma_{k}(t, \omega)$ is continuous, it follows that $\gamma_{k}$ is a $\mathscr{P}$ measurable real valued function and that $\gamma$ is a $\mathscr{P}$ measurable $\mathbb{R}^{\infty}$ valued function.

Since $\gamma(\omega) \in \Gamma(\omega)$, it follows that for each $n, \gamma(\omega) \in \Gamma^{n}(\omega)$. Therefore, there exists $j_{n} \geq n$ such that for each $\omega$,

$$
d\left(\mathbf{f}\left(u_{j_{n}}(\cdot, \omega)\right), \gamma(\omega)\right)<2^{-n}
$$

It follows that, taking a suitable subsequence, denoted as $\left\{u_{n(\omega)}(\cdot, \omega)\right\}$,

$$
\gamma(\omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(u_{n(\omega)}(\cdot, \omega)\right)
$$

for each $\omega$. In particular, for each $k$

$$
\begin{equation*}
\gamma_{k}(t, \omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(u_{n(\omega)}(t, \omega)\right)_{k}=\lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{n(\omega)}(s, \omega)\right\rangle_{V, V^{\prime}} d s \tag{70.2.2}
\end{equation*}
$$

for each $t$.
Note that it is not clear that $(t, \omega) \rightarrow \mathbf{f}\left(u_{n(\omega)}(t, \omega)\right)$ is $\mathscr{P}$ measurable although $(t, \omega) \rightarrow$ $\gamma(t, \omega)$ is $\mathscr{P}$ measurable.

Proof of the theorem: By assumption, there exists a further subsequence still denoted by $n(\omega)$ such that, in addition to 70.2.2 above, the weak limit

$$
\lim _{n(\omega) \rightarrow \infty} u_{n(\omega)}(\cdot, \omega)=u(\cdot, \omega)
$$

exists in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ such that $t \rightarrow u(t, \omega)$ is weakly continuous into $V^{\prime}$. Then the above equation 70.2.2 continues to hold for this further subsequence and in addition to this,

$$
m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u(s, \omega)\right\rangle_{V, V^{\prime}} d s=\lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{n(\omega)}(s, \omega)\right\rangle_{V, V^{\prime}} d s=\gamma_{k}(t, \omega)
$$

Letting $\phi \in \mathscr{D}$ given, there exists a sub-sequence denoted by $k$ such that $m_{k} \rightarrow \infty$ and $\phi_{r_{k}}=\phi$ for all $k$. Then passing to a limit and using the assumed continuity of $s \rightarrow u(s, \omega)$, the left side of this equation converges to $\langle\phi, u(t, \omega)\rangle_{V, V^{\prime}}$ and so the right side, $\gamma_{k}(t, \omega)$ must also converge, this for each $\omega$. Since the right side is a product measurable function of $(t, \omega)$, it follows that the pointwise limit is also product measurable. Hence $(t, \omega) \rightarrow$ $\langle\phi, u(t, \omega)\rangle_{V, V^{\prime}}$ is product measurable, this for each $\phi \in \mathscr{D}$. Since $\mathscr{D}$ is a dense set, it follows that $(t, \omega) \rightarrow\langle\phi, u(t, \omega)\rangle_{V, V^{\prime}}$ is $\mathscr{P}$ measurable for all $\phi \in V$ and so by the Pettis theorem, [127], $(t, \omega) \rightarrow u(t, \omega)$ is $\mathscr{P}$ measurable into $V^{\prime}$.

One can say more about the measurability of the approximating sequence. In fact, we can obtain one for which $\omega \rightarrow u_{n(\omega)}(t, \omega)$ is also $\mathscr{F}$ measurable.

Lemma 70.2.6 Suppose, $u_{n(\omega)} \rightarrow u$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ where $u$ is product measurable measurable and $\left\{u_{n(\omega)}\right\}$ is a subsequence of $\left\{u_{n}\right\}$ where

$$
\sup _{t \in[0, T]}\left\|u_{n}(t, \omega)\right\|_{V^{\prime}}<C(\omega), \text { for } \omega \notin N \text { a set of measure zero, }
$$

Then for each $\omega \notin N$, there exists a subsequence of $\left\{u_{n}\right\}$ denoted as $\left\{u_{k(\omega)}\right\}$ such that $u_{k(\omega)} \rightarrow u$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right), \omega \rightarrow k(\omega)$ is $\mathscr{F}$ measurable, and $\omega \rightarrow u_{k(\omega)}(t, \omega)$ is also $\mathscr{F}$ measurable, the last assertions holding for all $\omega \notin N$.

Proof: For $f, g \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right) \equiv \mathscr{V}^{\prime}, L^{p}([0, T] ; V) \equiv \mathscr{V}$, let $\left\{\phi_{k}\right\}$ be a countable dense subset of $L^{p}([0, T] ; V)$. Then a bounded set in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ with the weak topology can be considered a complete metric space using the following metric.

$$
d(f, g) \equiv \sum_{j=1}^{\infty} 2^{-j} \frac{\left|\left\langle\phi_{k}, f-g\right\rangle_{\mathscr{V}, \mathscr{V}^{\prime}}\right|}{1+\left|\left\langle\phi_{k}, f-g\right\rangle_{\mathscr{V}, \mathscr{V}^{\prime}}\right|}
$$

Now let $k(\omega)$ be the first index from the indices of $\left\{u_{n}\right\}$ at least as large as $k$ such that

$$
d\left(u_{k(\omega)}, u\right) \leq 2^{-k}
$$

Such an index exists because there exists a convergent sequence $u_{n(\omega)}$ which does converge weakly to $u$. This is just picking another one which happens to also retain measurability. In fact,

$$
\{\omega: k(\omega)=l\}=\left\{\omega: d\left(u_{l}, u\right) \leq 2^{-k}\right\} \cap \cap_{j=k}^{k-1}\left\{\omega: d\left(u_{j}, u\right)>2^{-k}\right\}
$$

Since $u$ is product measurable and each $u_{l}$ is also product measurable, these are all measurable sets with respect to $\mathscr{F}$ and so $\omega \rightarrow k(\omega)$ is $\mathscr{F}$ measurable. Now we have $u_{k(\omega)} \rightarrow u$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ for each $\omega$ with each function being $\mathscr{F}$ measurable because

$$
u_{k(\omega)}(t, \omega)=\sum_{j=1}^{\infty} \mathscr{X}_{[k(\omega)=j]} u_{j}(t, \omega)
$$

and every term in the sum is $\mathscr{F}$ measurable.
The following obvious corollary shows the significance of this lemma.
Corollary 70.2.7 Let $V$ be a reflexive separable Banach space and $V^{\prime}$ its dual and $\frac{1}{p}+$ $\frac{1}{p^{\prime}}=1$ where $p>1$ as usual. Let the functions $t \rightarrow u_{n(\omega)}(t, \omega)$ be in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ and $(t, \omega) \rightarrow u_{n(\omega)}(t, \omega)$ be $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable into $V^{\prime}$. Here $\left\{u_{n(\omega)}\right\}_{n=1}^{\infty}$ is a sequence, one for each $\omega$. Suppose there is a set of measure zero $N$ such that if $\omega \notin N$, then for all $n$,

$$
\sup _{t \in[0, T]}\left\|u_{n(\omega)}(t, \omega)\right\|_{V^{\prime}} \leq C(\omega)
$$

Also suppose for each $\omega \notin N$, each subsequence of $\left\{u_{n(\omega)}\right\}$ has a further subsequence which converges weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ to $u(\cdot, \omega) \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ such that $t \rightarrow u(t, \omega)$ is weakly continuous into $V^{\prime}$. Then there exists u product measurable, with $t \rightarrow u(t, \omega)$ being weakly continuous into $V^{\prime}$. Moreover, there exists, for each $\omega \notin N$, a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$.

Proof: It suffices to consider the functions $v_{n}(t, \omega) \equiv u_{n(\omega)}(t, \omega)$ and use the result of Theorem 70.2.1.

Of course when you have all functions having values in $H$ a separable Hilbert space, there is no change in the argument to obtain the following theorem.

Theorem 70.2.8 Let $H$ be a real separable Hilbert space. For $n \in \mathbb{N}$ let the functions $t \rightarrow$ $u_{n}(t, \omega)$ be in $L^{2}([0, T] ; H)$ and $(t, \omega) \rightarrow u_{n}(t, \omega)$ be $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable into $H$. Suppose there is a set of measure zero $N$ such that if $\omega \notin N$, then for all $n$,

$$
\sup _{t \in[0, T]}\left|u_{n}(t, \omega)\right|_{H} \leq C(\omega)
$$

Also suppose for each $\omega \notin N$, each subsequence of $\left\{u_{n}\right\}$ has a further subsequence which converges weakly in $L^{2}([0, T] ; H)$ to $u(\cdot, \omega) \in L^{2}([0, T] ; H)$ such that $t \rightarrow u(t, \omega)$ is weakly continuous into $H$. Then there exists u product measurable, with $t \rightarrow u(t, \omega)$ being weakly continuous into $H$. Moreover, there exists, for each $\omega \notin N$, a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $L^{2}([0, T] ; H)$.

### 70.3 Measurability In Finite Dimensional Problems

What follows is like the Peano existence theorem from ordinary differential equations except that it provides a solution which retains product measurability. It is a nice example of the above theory. It will be used in the next section in the Galerkin method.

Lemma 70.3.1 Suppose $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \in \mathbb{R}^{d}$ for $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbb{R}^{d}, t \in[0, T]$ and

$$
(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)
$$

is progressively measurable relative to the filtration consisting of the single $\sigma$ algebra $\mathscr{F}$. Also suppose that $(t, \mathbf{u}, \mathbf{v}, \mathbf{w}) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)$ is continuous and that also $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)$ is uniformly bounded in $(t, \mathbf{u}, \mathbf{v}, \mathbf{w})$ by $M(\omega)$. Let $\mathbf{f}$ be $\mathscr{P}$ measurable and $\mathbf{f}(\cdot, \omega) \in$ $L^{2}\left([0, T] ; \mathbb{R}^{d}\right)$. Then for $h>0$, there exists a $\mathscr{P}$ measurable solution $\mathbf{u}$ to the integral equation

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega) \omega) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s
$$

Here $\mathbf{u}_{0}$ has values in $\mathbb{R}^{d}$ and is $\mathscr{F}$ measurable, $\mathbf{u}(s-h, \omega) \equiv \mathbf{u}_{0}(\omega)$ if $s-h<0$ and for $\mathbf{w}_{0}$ a given $\mathscr{F}$ measurable function,

$$
\mathbf{w}(t, \omega) \equiv \mathbf{w}_{0}(\omega)+\int_{0}^{t} \mathbf{u}(s, \omega) d s
$$

Proof: Let $\mathbf{u}_{n}$ be the solution to the following equation:

$$
\begin{aligned}
& \mathbf{u}_{n}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}\left(s, \tau_{1 / n} \mathbf{u}_{n}(s, \omega), \mathbf{u}_{n}(s-h, \omega), \tau_{1 / n} \mathbf{w}_{n}(s, \omega), \omega\right) d s \\
= & \int_{0}^{t} \mathbf{f}(s, \omega) d s
\end{aligned}
$$

where here $\tau_{1 / n}$ is defined as follows. For $\delta>0$,

$$
\tau_{\delta} \mathbf{u}(s) \equiv\left\{\begin{array}{l}
\mathbf{u}(s-\delta) \text { if } s>\delta \\
\mathbf{0} \text { if } s-\delta \leq 0
\end{array}\right.
$$

It follows that $(t, \omega) \rightarrow \mathbf{u}_{n}(t, \omega)$ is $\mathscr{P}$ measurable. From the assumptions on $\mathbf{N}$, it follows that for fixed $\omega,\left\{\mathbf{u}_{n}(\cdot, \omega)\right\}$ is uniformly bounded:

$$
\sup _{t \in[0, T]}\left|\mathbf{u}_{n}(t, \omega)\right| \leq\left|\mathbf{u}_{0}(\omega)\right|+\int_{0}^{T} M(\omega) d s+\int_{0}^{T}|\mathbf{f}(s, \omega)| d s=: C(\omega),
$$

and is also equicontinuous because for $s<t$,

$$
\begin{aligned}
& \left|\mathbf{u}_{n}(t, \omega)-\mathbf{u}_{n}(s, \omega)\right| \\
\leq & \int_{s}^{t}\left|\mathbf{N}\left(r, \tau_{1 / n} \mathbf{u}_{n}(r, \omega), \mathbf{u}_{n}(r-h, \omega), \tau_{1 / n} \mathbf{w}_{n}(r, \omega), \omega\right)\right| d r
\end{aligned}
$$

$$
+\int_{s}^{t}|\mathbf{f}(r, \omega)| d r \leq C(\omega, \mathbf{f})|t-s|^{1 / 2}
$$

Therefore, by the Ascoli-Arzelà theorem, for each $\omega$, there exists a subsequence $\tilde{n}(\omega)$ depending on $\omega$ and a function $\tilde{\mathbf{u}}(t, \omega)$ such that

$$
\mathbf{u}_{\tilde{n}(\omega)}(t, \omega) \rightarrow \tilde{\mathbf{u}}(t, \omega) \text { uniformly in } C\left([0, T] ; \mathbb{R}^{d}\right)
$$

This verifies the assumptions of Theorem 70.2.8.
It follows that there exists $\overline{\mathbf{u}}$ product measurable and a subsequence $\left\{\mathbf{u}_{n(\omega)}\right\}$ for each $\omega$ such that

$$
\lim _{n(\omega) \rightarrow \infty} \mathbf{u}_{n(\omega)}(\cdot, \omega)=\overline{\mathbf{u}}(\cdot, \omega) \text { weakly in } L^{2}\left([0, T] ; \mathbb{R}^{d}\right)
$$

and that $t \rightarrow \overline{\mathbf{u}}(t, \omega)$ is continuous. (Note that weak continuity is the same as continuity in $\mathbb{R}^{d}$.) The same argument given above applied to the $\mathbf{u}_{n(\omega)}$ for a fixed $\omega$ yields a further subsequence, denoted as $\left\{\mathbf{u}_{\bar{n}(\omega)}(\cdot, \omega)\right\}$ which converges uniformly to a function $\mathbf{u}(\cdot, \omega)$ on $[0, T]$. So $\overline{\mathbf{u}}(t, \omega)=\mathbf{u}(t, \omega)$ in $L^{2}\left([0, T] ; \mathbb{R}^{d}\right)$. Since both of these functions are continuous in $t$, they must be equal for all $t$. Hence, $(t, \omega) \rightarrow \mathbf{u}(t, \omega)$ is product measurable. Passing to the limit in the equation solved by $\left\{\mathbf{u}_{\bar{n}(\omega)}(\cdot, \omega)\right\}$ using the dominated convergence theorem, we obtain

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s
$$

Thus $t \rightarrow \mathbf{u}(t, \omega)$ is a product measurable solution to the integral equation.
This lemma gives the existence of the approximate solutions in the following theorem in which the assumption that the integrand is bounded is replaced with an estimate. The following elementary consideration will be used whenever convenient. Note that it holds for all $\omega$.

Remark 70.3.2 When $\mathbf{w}(t) \equiv \mathbf{w}_{0}(\omega)+\int_{0}^{t} \mathbf{u}(s, \omega) d s$,

$$
\mathbf{v}(t)=\left\{\begin{array}{c}
\mathbf{u}(t-h) \text { if } t \geq h \\
\mathbf{u}_{0} \text { if } t<h
\end{array}\right.
$$

and when the estimate

$$
(\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega), \mathbf{u}) \geq-C(t, \omega)-\mu\left(|\mathbf{u}|^{2}+|\mathbf{v}|^{2}+|\mathbf{w}|^{2}\right)
$$

holds, it follows that

$$
\int_{0}^{t}(\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega), \mathbf{u}) d s \geq-C\left(C(\omega)+\int_{0}^{t}|\mathbf{u}|^{2} d s\right)
$$

for some constant $C$ depending on the initial data but not on $\mathbf{u}$.
To see this,

$$
\int_{0}^{t}|\mathbf{u}(s-h)|^{2} d s=\int_{0}^{h}\left|\mathbf{u}_{0}\right|^{2} d s+\int_{h}^{t}|\mathbf{u}(s-h)|^{2} d s
$$

$$
=\left|\mathbf{u}_{0}\right|^{2} h+\int_{0}^{t-h}|\mathbf{u}(s)|^{2} d s \leq\left|\mathbf{u}_{0}\right|^{2} h+\int_{0}^{t}|\mathbf{u}(s)|^{2} d s
$$

if $t \geq h$ and if $s<h$, this is dominated by

$$
\left|\mathbf{u}_{0}\right|^{2} t \leq\left|\mathbf{u}_{0}\right|^{2} h \leq\left|\mathbf{u}_{0}\right|^{2} h+\int_{0}^{t}|\mathbf{u}(s)|^{2} d s
$$

As to the terms from $\mathbf{w}$,

$$
\begin{aligned}
& \int_{0}^{t}|\mathbf{w}(s)|^{2} d s \\
\leq & \int_{0}^{t}\left|\mathbf{w}_{0}+\int_{0}^{s} \mathbf{u}(r) d r\right|^{2} d s \leq \int_{0}^{t}\left(\left|\mathbf{w}_{0}\right|+\left|\int_{0}^{s} \mathbf{u}(r) d r\right|\right)^{2} d s \\
\leq & \int_{0}^{t}\left(\left|\mathbf{w}_{0}\right|^{2}+2\left|\mathbf{w}_{0}\right|\left|\int_{0}^{s} \mathbf{u}(r) d r\right|+\left|\int_{0}^{s} \mathbf{u}(r) d r\right|^{2}\right) d s \\
\leq & T\left|\mathbf{w}_{0}\right|^{2}+T\left|\mathbf{w}_{0}\right|^{2}+\int_{0}^{t}\left|\int_{0}^{s} \mathbf{u}(r) d r\right|^{2} d s+\int_{0}^{t}\left|\int_{0}^{s} \mathbf{u}(r) d r\right|^{2} d s \\
\leq & 2 T\left|\mathbf{w}_{0}\right|^{2}+2 \int_{0}^{t}\left(\int_{0}^{s}|\mathbf{u}(r)| d r\right)^{2} d s \leq 2 T\left|\mathbf{w}_{0}\right|^{2}+2 \int_{0}^{t} s \int_{0}^{s}|\mathbf{u}(r)|^{2} d r d s \\
\leq & 2 T\left|\mathbf{w}_{0}\right|^{2}+2 T \int_{0}^{t} \int_{0}^{s}|\mathbf{u}(r)|^{2} d r d s \leq 2 T\left|\mathbf{w}_{0}\right|^{2}+2 T^{2} \int_{0}^{t}|\mathbf{u}(r)|^{2} d r
\end{aligned}
$$

From this, the claimed result follows.
Theorem 70.3.3 Suppose $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \in \mathbb{R}^{d}$ for $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbb{R}^{d}, t \in[0, T]$ and

$$
(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)
$$

is progressively measurable with respect to a constant filtration $\mathscr{F}_{t}=\mathscr{F}$. Also suppose $(t, \mathbf{u}, \mathbf{v}, \mathbf{w}) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)$ is continuous and satisfies $C(\cdot, \omega) \geq 0$ in $L^{1}([0, T])$ and some $\mu>0$ :

$$
(\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega), \mathbf{u}) \geq-C(t, \omega)-\mu\left(|\mathbf{u}|^{2}+|\mathbf{v}|^{2}+|\mathbf{w}|^{2}\right)
$$

Also let $\mathbf{f}$ be product measurable and $\mathbf{f}(\cdot, \omega) \in L^{2}\left([0, T] ; \mathbb{R}^{d}\right)$. Then for $h>0$, there exists a product measurable solution $\mathbf{u}$ to the integral equation

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s
$$

where $\mathbf{u}_{0}$ has values in $\mathbb{R}^{d}$ and is $\mathscr{F}$ measurable. Here $\mathbf{u}(s-h, \omega) \equiv \mathbf{u}_{0}(\omega)$ for all $s-h \leq 0$ and for $\mathbf{w}_{0}$ a given $\mathscr{F}$ measurable function,

$$
\mathbf{w}(t, \omega) \equiv \mathbf{w}_{0}(\omega)+\int_{0}^{t} \mathbf{u}(s, \omega) d s
$$

Proof: Let $P_{m}$ denote the projection onto the closed ball $\overline{B\left(\mathbf{0}, 9^{m}\right)}$. Then from the above lemma, there exists a product measurable solution $\mathbf{u}_{m}$ to the integral equation

$$
\begin{aligned}
& \mathbf{u}_{m}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}\left(s, P_{m} \mathbf{u}_{m}(s, \omega), P_{m} \mathbf{u}_{m}(s-h, \omega), P_{m} \mathbf{w}_{m}(s, \omega), \omega\right) d s \\
= & \int_{0}^{t} \mathbf{f}(s, \omega) d s
\end{aligned}
$$

Define a stopping time

$$
\tau_{m}(\omega) \equiv \inf \left\{t \in[0, T]:\left|\mathbf{u}_{m}(t, \omega)\right|^{2}+\left|\mathbf{w}_{m}(t, \omega)\right|^{2}>2^{m}\right\}
$$

where $\inf \emptyset \equiv T$. Localizing with the stopping time,

$$
\begin{aligned}
& \mathbf{u}_{m}^{\tau_{m}}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{m}\right]} \mathbf{N}\left(s, \mathbf{u}_{m}^{\tau_{m}}(s, \omega), \mathbf{u}_{m}^{\tau_{m}}(s-h, \omega), \mathbf{w}_{m}^{\tau_{m}}(s, \omega), \omega\right) d s \\
= & \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{m}\right]} \mathbf{f}(s, \omega) d s .
\end{aligned}
$$

Note how the stopping time allowed the elimination of the projection map in the equation. Then we get

$$
\begin{aligned}
& \frac{1}{2}\left|\mathbf{u}_{m}^{\tau_{m}}(t, \omega)\right|^{2}-\frac{1}{2}\left|\mathbf{u}_{0}(\omega)\right|^{2} \\
& +\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{m}\right]} \mathbf{N}\left(s, \mathbf{u}_{m}^{\tau_{m}}(s, \omega), \mathbf{u}_{m}^{\tau_{m}}(s-h, \omega), \mathbf{w}_{m}^{\tau_{m}}(s, \omega), \omega\right), \mathbf{u}_{m}^{\tau_{m}}(s, \omega)\right) d s \\
= & \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{m}\right]}\left(\mathbf{f}(s, \omega), \mathbf{u}_{m}^{\tau_{m}}(s, \omega)\right) d s .
\end{aligned}
$$

From the estimate,

$$
\begin{aligned}
\frac{1}{2}\left|\mathbf{u}_{m}^{\tau_{m}}(t, \omega)\right|^{2}- & \frac{1}{2}\left|\mathbf{u}_{0}(\omega)\right|^{2} \leq \int_{0}^{t}\left(\mu\left(\left|\mathbf{u}_{m}^{\tau_{m}}(s, \omega)\right|^{2}+\left|\mathbf{u}_{m}^{\tau_{m}}(s-h, \omega)\right|^{2}+\left|\mathbf{w}_{m}^{\tau_{m}}(s, \omega)\right|^{2}\right)\right. \\
& \left.+C(s, \omega)+\frac{1}{2}|\mathbf{f}(s, \omega)|^{2}\right) d s+\frac{1}{2} \int_{0}^{t}\left|\mathbf{u}_{m}^{\tau_{m}}(s, \omega)\right|^{2} d s
\end{aligned}
$$

Note that

$$
\left|\mathbf{u}_{0}\right|^{2} h+\int_{0}^{t}\left|\mathbf{u}_{n}^{\tau_{n}}(s)\right|^{2} d s \geq \int_{0}^{t}\left|\mathbf{u}_{n}^{\tau_{n}}(s-h, \omega)\right|^{2} d s
$$

and

$$
\begin{aligned}
& \int_{0}^{t}\left|\mathbf{w}_{n}^{\tau_{n}}(s, \omega)\right|^{2} d s=\int_{0}^{t}\left|\mathbf{w}_{0}+\int_{0}^{s} \mathscr{X}_{\left[0, \tau_{n}\right]} \mathbf{u}_{n}(r) d r\right|^{2} d s \\
&=\int_{0}^{t}\left|\mathbf{w}_{0}+\int_{0}^{s} \mathscr{X}_{\left[0, \tau_{n}\right]} \mathbf{u}_{n}^{\tau_{n}}(r) d r\right|^{2} d s \\
& \leq C\left(\mathbf{w}_{0}(\omega)\right)+C T \int_{0}^{t}\left|\mathbf{u}_{n}^{\tau_{n}}\right|^{2} d s
\end{aligned}
$$

By Gronwall's inequality,

$$
\begin{aligned}
\left|\mathbf{u}_{m}^{\tau_{m}}(t, \omega)\right|^{2} & \leq C\left(\mathbf{u}_{0}(\omega), \mathbf{w}_{0}(\omega), \mu,\|C(\cdot, \omega)\|_{L^{1}\left([0, T] ; \mathbb{R}^{d}\right)}, T,\|\mathbf{f}(\cdot, \omega)\|_{L^{2}\left([0, T] ; \mathbb{R}^{d}\right)}\right) \\
& \equiv C(\omega)
\end{aligned}
$$

Thus, for a.e. $\omega, \tau_{m}=T$ for all $m$ large enough, say for $m \geq M(\omega)$ where

$$
C(\omega) \leq 2^{M(\omega)}
$$

Then define the functions

$$
\mathbf{y}_{n}(t, \omega) \equiv \mathbf{u}_{n}^{\tau_{n}}(t, \omega)
$$

These are product measurable and

$$
\begin{aligned}
& \mathbf{y}_{n}(t, \omega)-\mathbf{u}_{0}(\omega)+ \\
& \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} \mathbf{N}\left(s, \mathbf{y}_{n}(s, \omega), \mathbf{y}_{n}(s-h, \omega), \mathbf{w}_{0}(\omega)+\int_{0}^{s} \mathbf{y}_{n}(r, \omega) d r, \omega\right) d s \\
= & \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} \mathbf{f}(s, \omega) d s .
\end{aligned}
$$

So each is continuous in $t$. For large enough $n, \tau_{n}=T$ and hence

$$
\begin{aligned}
& \mathbf{y}_{n}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}\left(s, \mathbf{y}_{n}(s, \omega), \mathbf{y}_{n}(s-h, \omega), \mathbf{w}_{0}(\omega)+\int_{0}^{s} \mathbf{y}_{n}(r, \omega) d r, \omega\right) d s \\
= & \int_{0}^{t} \mathbf{f}(s, \omega) d s
\end{aligned}
$$

Also these satisfy the inequality

$$
\begin{equation*}
\sup _{t \in[0, T]}\left|\mathbf{y}_{n}(t, \omega)\right|^{2} \leq C(\omega) \leq 2^{M(\omega)}<9^{M(\omega)} \tag{70.3.4}
\end{equation*}
$$

the constant on the right not depending on $n$. Thus for fixed $\omega$, we can regard $\mathbf{N}$ as bounded and the same reasoning used in the above lemma involving the Ascoli-Arzelà theorem implies that every subsequence has a further subsequence which converges to a solution to the integral equation for that $\omega$. Thus it is continuous into $\mathbb{R}^{d}$. It follows from the measurable selection theorem above that there exists $\mathbf{u}$ product measurable and continuous in $t$ such that $\mathbf{u}(\cdot, \omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{y}_{n(\omega)}(\cdot, \omega)$ in $L^{2}\left([0, T] ; \mathbb{R}^{d}\right)$. By the reasoning of the above lemma, there is a further subsequence, denoted the same way, for which $\lim _{n \rightarrow \infty} \mathbf{y}_{n(\omega)}$ in $C\left([0, T] ; \mathbb{R}^{d}\right)$ solves the integral equation for a fixed $\omega$. Thus $\mathbf{u}$ is a product measurable solution to the integral equation as claimed.

We made use of an estimate in order to get the conclusion of this theorem. However, all that is really needed is the following.

Corollary 70.3.4 Suppose $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \in \mathbb{R}^{d}$ for $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbb{R}^{d}, t \in[0, T]$ and

$$
(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)
$$

is progressively measurable with respect to a constant filtration $\mathscr{F}_{t}=\mathscr{F}$. Also suppose $(t, \mathbf{u}, \mathbf{v}, \mathbf{w}) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)$ is continuous. Suppose for each $\omega$, there exists an estimate for any solution $\mathbf{u}(\cdot, \omega)$ to the integral equation

$$
\begin{equation*}
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s \tag{70.3.5}
\end{equation*}
$$

which is of the form

$$
\sup _{t \in[0, T]}|\mathbf{u}(t, \omega)| \leq C(\omega)<\infty
$$

Also let $\mathbf{f}$ be product measurable and $\mathbf{f}(\cdot, \omega) \in L^{1}\left([0, T] ; \mathbb{R}^{d}\right)$. Here $\mathbf{u}_{0}$ has values in $\mathbb{R}^{d}$ and is $\mathscr{F}$ measurable and $\mathbf{u}(s-h, \omega) \equiv \mathbf{u}_{0}(\omega)$ whenever $s-h \leq 0$ and

$$
\mathbf{w}(t, \omega) \equiv \mathbf{w}_{0}(\omega)+\int_{0}^{t} \mathbf{u}(s, \omega) d s
$$

where $\mathbf{w}_{0}$ is a given $\mathscr{F}$ measurable function. Then for $h>0$, there exists a product measurable solution $\mathbf{u}$ to the integral equation 70.3.5.

Of course the same conclusions apply when there is no dependence in the integral equation on $\mathbf{u}(s-h, \omega)$ or the integral $\mathbf{w}(t, \omega)$. Note that these theorems hold for all $\omega$.

### 70.4 The Navier-Stokes Equations

In this section, we study the stochastic Navier-Stokes equations of arbitrary dimension. We prove there exists a global solution which is product measurable. The main result is Theorem 70.4.6. We use the Galerkin method and Theorem 70.3.3 to get product measurable approximate solutions. Then we take weak limits and get path solutions. After this, we apply Theorem 70.2.8 to get product measurable global solutions.

As in [15], an important part of our argument is the theorem in Lions [91] which follows. See Theorem 69.5.6.

Theorem 70.4.1 Let $W, H$, and $V^{\prime}$ be separable Banach spaces. Suppose $W \subseteq H \subseteq V^{\prime}$ where the injection map is continuous from $H$ to $V^{\prime}$ and compact from $W$ to $H$. Let $q_{1} \geq 1$, $q_{2}>1$, and define

$$
\begin{aligned}
& S \equiv\left\{u \in L^{q_{1}}([a, b] ; W): u^{\prime} \in L^{q_{2}}\left([a, b] ; V^{\prime}\right)\right. \\
& \text { and } \left.\|u\|_{L^{q_{1}}([a, b] ; W)}+\left\|u^{\prime}\right\|_{L^{q_{2}}\left([a, b] ; V^{\prime}\right)} \leq R\right\} .
\end{aligned}
$$

Then $S$ is pre-compact in $L^{q_{1}}([a, b] ; H)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{q_{1}}([a, b] ; H)$.

A proof of a generalization of this theorem is found on Page 2385. Let $U$ be a bounded open set in $\mathbb{R}^{d}$ and let $S$ denote the functions which are infinitely differentiable having zero divergence and also having compact support in $U$. We have in mind $d=3$, but the approach is not limited by dimension. We use the same Galerkin method found in [15], the details being included in slightly abbreviated form for convenience of the reader. The difference is
that we switch the roles of $V$ and $W$ along with a few other minor modifications. This is the part of the argument which gives a solution for each $\omega$ and it is standard material. Define

$$
V \equiv \bar{S} \text { in }\left(H^{d^{*}}(U)\right)^{d}, W \equiv \bar{S} \text { in }\left(H^{1}(U)\right)^{d}, \text { and } H \equiv \bar{S} \text { in }\left(L^{2}(U)\right)^{d}
$$

where $d^{*}$ is such that for $\mathbf{w} \in\left(H^{d^{*}}(U)\right)^{d}$ then $\|D \mathbf{w}\|_{L^{\infty}(U)}<\infty$. For example, you could take $d^{*}=3$ for $d=3$. In [15], they take $d^{*}=8$ which is large enough to work for all dimensions of interest.

Let $A: W \rightarrow W^{\prime}$ and $N: W \rightarrow V^{\prime}$ be defined by

$$
\langle A \mathbf{u}, \mathbf{v}\rangle \equiv \int_{U} \nabla u_{i} \cdot \nabla v_{i} d x, \quad\langle N \mathbf{u}, \mathbf{v}\rangle \equiv-\int_{U} u_{i} u_{j} v_{j, i} d x
$$

Then $N$ is a continuous function. Indeed, pick $\mathbf{v} \in V$ and suppose $\mathbf{u}_{n} \rightarrow \mathbf{u}$ in $W$, then

$$
\begin{aligned}
& \left|\left\langle N \mathbf{u}-N \mathbf{u}_{n}, \mathbf{v}\right\rangle\right| \\
\leq & \int_{U}\left|\sum_{i, j}\left(u_{n i} u_{n j}-u_{i} u_{j}\right) v_{j, i}\right| d x \leq C\|\mathbf{v}\|_{V} \int_{U}\left(\left|\mathbf{u}_{n}\right|+|\mathbf{u}|\right)\left(\left|\mathbf{u}_{n}-\mathbf{u}\right|\right) d x \\
\leq & C\|\mathbf{v}\|_{V}\left(\int_{U}\left|\mathbf{u}_{n}\right|^{2}+|\mathbf{u}|^{2} d x\right)^{1 / 2}\left(\int_{U}\left|\mathbf{u}_{n}-\mathbf{u}\right|^{2} d x\right)^{1 / 2},
\end{aligned}
$$

where what multiplies $\|\mathbf{v}\|_{V}$ clearly converges to 0 .
An abstract form for the incompressible Navier-Stokes equations is

$$
\mathbf{u}^{\prime}+v A \mathbf{u}+N \mathbf{u}=\mathbf{f}, \mathbf{u}(0)=\mathbf{u}_{0}
$$

where $\mathbf{f} \in L^{2}\left([0, T] ; W^{\prime}\right)$, for some fixed $T>0$. As in [15], we will let $v=1$ to simplify the presentation. A stochastic version of this would be the integral equation in $V^{\prime}$

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{u}(s, \omega)) d s+\int_{0}^{t} N(\mathbf{u}(s, \omega)) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s+\mathbf{q}(t, \omega)
$$

where $\mathbf{q}(\cdot, \omega)$ will be continuous into $V,(t, \omega) \rightarrow \mathbf{q}(t, \omega)$ will be product measurable having values in $V$, and $\mathbf{q}(0, \omega)=\mathbf{0}$. So $\mathbf{q}$ here is a fixed stochastic process, which serves as the random source. Also $(t, \omega) \rightarrow \mathbf{f}(t, \omega)$ will be product measurable into $W^{\prime}$ as well as having $t \rightarrow \mathbf{f}(t, \omega)$ in $L^{2}\left([0, T] ; W^{\prime}\right)$. Our problem is to show the existence of a product measurable solution.

Let $T$ be any fixed positive number and let $\mathbf{q}$ be any fixed process satisfying the above.
Definition 70.4.2 A global solution to the above integral equation is a process $\mathbf{u}(t, \omega)$, for which $\omega \rightarrow \mathbf{u}(t, \omega)$ is $\mathscr{F}$ measurable and satisfies for each $\omega$ outside a set of measure zero and all $t \in[0, T]$,

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{u}(s, \omega)) d s+\int_{0}^{t} N(\mathbf{u}(s, \omega)) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s+\mathbf{q}(t, \omega) .
$$

In order to apply the earlier result, let $\mathbf{w}(t, \omega)=\mathbf{u}(t, \omega)-\mathbf{q}(t, \omega)$ and write the equation in terms of $\mathbf{w}$,

$$
\begin{aligned}
& \mathbf{w}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{w}(\mathbf{s}, \omega)+\mathbf{q}(\mathbf{s}, \omega)) d s+\int_{0}^{t} N(\mathbf{w}(\mathbf{s}, \omega)+\mathbf{q}(\mathbf{s}, \omega)) d s \\
= & \int_{0}^{t} \mathbf{f}(s, \omega) d s
\end{aligned}
$$

It turns out that it is convenient to define

$$
\langle B(\mathbf{u}, \mathbf{v}), \mathbf{w}\rangle \equiv-\int_{U} u_{i} v_{j} w_{j, i} d x
$$

and write the equation in the following form:

$$
\mathbf{w}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{w}(s, \omega)) d s+\int_{0}^{t} \hat{N}(\mathbf{w}(s, \omega)) d s=\int_{0}^{t} \hat{\mathbf{f}}(s, \omega) d s
$$

where

$$
\begin{aligned}
\hat{N}(\mathbf{w}(t, \omega)) & \equiv & & N(\mathbf{w}(t, \omega))+B(\mathbf{w}(t, \omega), \mathbf{q}(t, \omega))+B(\mathbf{q}(t, \omega), \mathbf{w}(t, \omega)) \\
\hat{\mathbf{f}}(t, \omega) & \equiv & & \mathbf{f}(t, \omega)-A(\mathbf{q}(t, \omega))-N(\mathbf{q}(t, \omega))
\end{aligned}
$$

This is an equation in $V^{\prime}$. Moreover, we have the following:
Lemma 70.4.3 For fixed $\omega \in \Omega, \hat{\mathbf{f}} \in L^{2}\left([0, T] ; W^{\prime}\right)$, and

$$
(t, \mathbf{w}) \rightarrow B(\mathbf{w}, \mathbf{q}(t, \omega)),(t, \mathbf{w}) \rightarrow B(\mathbf{q}(t, \omega), \mathbf{w})
$$

are continuous functions having values in $W^{\prime}$. For fixed $\mathbf{w} \in W$,

$$
(t, \omega) \rightarrow B(\mathbf{w}, \mathbf{q}(t, \omega)),(t, \omega) \rightarrow B(\mathbf{q}(t, \omega), \mathbf{w})
$$

are product measurable. In addition to this, if $\mathbf{z} \in W$,

$$
\begin{aligned}
|\langle B(\mathbf{w}, \mathbf{q}(t, \omega)), \mathbf{z}\rangle| & \leq C\|\mathbf{q}(t, \omega)\|_{V}\|\mathbf{w}\|_{H}\|\mathbf{z}\|_{H}, \\
|\langle B(\mathbf{q}(t, \omega), \mathbf{w}), \mathbf{z}\rangle| & \leq C\|\mathbf{q}(t, \omega)\|_{V}\|\mathbf{w}\|_{H}\|\mathbf{z}\|_{H} .
\end{aligned}
$$

Proof: The first claim is straightforward to prove from the definition of $A$ and $N$. Consider the next claim about continuity. Let $\mathbf{z} \in W$ be given. Then from the fact that all the functions are divergence free,

$$
\begin{aligned}
& |\langle B(\mathbf{w}, \mathbf{q}(t))-B(\overline{\mathbf{w}}, \mathbf{q}(s)), \mathbf{z}\rangle| \\
\equiv & \left|\int_{U}\left(w_{i} q_{j}(t)-\bar{w}_{i} q_{j}(s)\right) z_{j, i} d x\right|=\left|\int_{U}\left(w_{i} q_{j, i}(t)-\bar{w}_{i} q_{j, i}(s)\right) z_{j} d x\right| \\
\leq & \left|\int_{U}\left(w_{i} q_{j, i}(t)-\bar{w}_{i} q_{j, i}(t)\right) z_{j} d x\right|+\left|\int_{U}\left(\bar{w}_{i} q_{j, i}(t)-\bar{w}_{i} q_{j, i}(s)\right) z_{j} d x\right| \\
\leq & C\left(\|\mathbf{q}(t)\|_{V} \int_{U}|\mathbf{w}-\overline{\mathbf{w}}||\mathbf{z}| d x+\|\mathbf{q}(t)-\mathbf{q}(s)\|_{V} \int_{U}|\overline{\mathbf{w}}||\mathbf{z}| d x\right) \\
\leq & C\left(\|\mathbf{q}(t)\|_{V}|\mathbf{w}-\overline{\mathbf{w}}|_{H}+\|\mathbf{q}(t)-\mathbf{q}(s)\|_{V}|\overline{\mathbf{w}}|_{H}\right)|\mathbf{z}|_{H},
\end{aligned}
$$

where we have suppressed the dependence of $\mathbf{q}$ on $\omega$ to simplify the notation. The other function is similar.

As to the claim about product measurability, this follows from the above definition and assumptions about $\mathbf{q}$ being product measurable. For the estimates,

$$
|\langle B(\mathbf{w}, \mathbf{q}), \mathbf{z}\rangle|=\left|\int_{U} w_{i} q_{j} z_{j, i}\right|=\left|\int_{U} w_{i} q_{j, i} z_{j}\right| \leq C\|\mathbf{q}\|_{V} \int_{U}|\mathbf{w}||\mathbf{z}| d x
$$

and apply Hölder's inequality. The other estimate is similar.
This has shown that it suffices to verify that there exists a global solution $\mathbf{u}$ to the equation

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{u}(s, \omega)) d s+\int_{0}^{t} \hat{N}(\mathbf{u}(s, \omega)) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s
$$

where $\mathbf{f}(\cdot, \omega) \in L^{2}\left([0, T] ; W^{\prime}\right)$ for each $\omega \in \Omega$.
Let $R$ be the Riesz map from $V$ to $V^{\prime}$, so $\left\langle R \mathbf{v}_{1}, \mathbf{v}_{2}\right\rangle_{V^{\prime}, V}=\left(\mathbf{v}_{1}, \mathbf{v}_{2}\right)_{V}$ for any $\mathbf{v}_{1}, \mathbf{v}_{2} \in V$. The compactness of the embeddings imply that $R^{-1}$ is a compact self adjoint operator on $H$ and so there is a complete orthonormal basis $\left\{\mathbf{w}_{k}\right\}$ for $H$ such that $R^{-1} \mathbf{w}_{k}=\mu_{k} \mathbf{w}_{k}$, where $\left\{\mu_{k}\right\}$ is a decreasing sequence of positive numbers which converges to 0 . Thus $R \mathbf{w}_{k}=\lambda_{k} \mathbf{w}_{k}$, where $\lim _{k \rightarrow \infty} \lambda_{k}=\infty$. $\left\{\mathbf{w}_{k}\right\}$ is a special basis. It is orthonormal in $H$ and orthogonal in $V$, since $\left(\mathbf{w}_{k}, \mathbf{w}_{l}\right)_{V}=\left\langle R \mathbf{w}_{k}, \mathbf{w}_{l}\right\rangle=\left(\lambda_{k} \mathbf{w}_{k}, \mathbf{w}_{l}\right)_{H}$.

To use the Galerkin method, let $V_{n}=\operatorname{span}\left(\mathbf{w}_{1}, \cdots, \mathbf{w}_{n}\right)$. Clearly $\cup_{n} V_{n}$ is dense in $H$. This is also dense in $V$. If not, then there exists $\phi \in V^{\prime}$ such that $\phi \neq 0$ but $\cup_{n} V_{n} \subseteq \operatorname{ker} \phi$. Then $\phi=R \mathbf{y}$. Hence for $\mathbf{z} \in \cup_{n=1}^{M} V_{n}$

$$
0=\langle R \mathbf{y}, \mathbf{z}\rangle=\langle R \mathbf{z}, \mathbf{y}\rangle=(R \mathbf{z}, \mathbf{y})_{H}
$$

But $R \mathbf{z} \in \operatorname{span}\left(\mathbf{w}_{1}, \cdots, \mathbf{w}_{M}\right)$ and in fact, $R$ maps $V_{n}$ onto $V_{n}$ and so this shows that $\mathbf{y}$ is perpendicular to $\operatorname{span}\left(\mathbf{w}_{1}, \cdots, \mathbf{w}_{M}\right)$ for each $M$ so $\mathbf{y}=\mathbf{0}$ and $\phi=0$ after all. Thus $\cup_{n} V_{n}$ is also dense in $V$ and hence it is also dense in $W$.

Let $\mathbf{u}_{n}(t, \omega)=\sum_{k=1}^{n} x_{k}(t, \omega) \mathbf{w}_{k}$, where $\mathbf{x}(t, \omega)=\left(x_{1}(t, \omega), \cdots, x_{n}(t, \omega)\right)^{T} \in \mathbb{R}^{n}$. We consider the problem of finding $\mathbf{x}(t, \omega)$ such that for all $\mathbf{w}_{k}, k \leq n$,

$$
\begin{gather*}
\left(\mathbf{u}_{n}(t, \omega), \mathbf{w}_{k}\right)_{H}-\left(\mathbf{u}_{0 n}(\omega), \mathbf{w}_{k}\right)_{H}+\int_{0}^{t}\left\langle A\left(\mathbf{u}_{n}(s, \omega)\right), \mathbf{w}_{k}\right\rangle d s \\
\quad+\int_{0}^{t}\left\langle\hat{N}\left(\mathbf{u}_{n}(s, \omega)\right), \mathbf{w}_{k}\right\rangle d s=\int_{0}^{t}\left\langle\mathbf{f}(s, \omega), \mathbf{w}_{k}\right\rangle d s, \tag{70.4.6}
\end{gather*}
$$

where $\mathbf{u}_{0 n}$ is the orthogonal projection of $\mathbf{u}_{0}$ onto $V_{n}$.
By the continuity of the operators described above, and the orthogonality of the $\mathbf{w}_{k}$, this is nothing but an ordinary differential equation for the vector $\mathbf{x}(t, \omega)$. By Theorem 70.2 .8 , there exists a product measurable solution $\mathbf{x}$ and therefore, $\mathbf{u}_{n}(t, \omega)$ is also product measurable in $H$.

Take the derivative, multiply by $x_{k}(t, \omega)$, add, and integrate again in the usual way to obtain

$$
\begin{aligned}
& \frac{1}{2}\left|\mathbf{u}_{n}(t, \omega)\right|_{H}^{2}-\frac{1}{2}\left|\mathbf{u}_{0 n}(\omega)\right|_{H}^{2} \\
= & -\int_{0}^{t}\left\langle A\left(\mathbf{u}_{n}(s, \omega)\right), \mathbf{u}_{n}(s, \omega)\right\rangle d s-\int_{0}^{t}\left\langle\hat{N}\left(\mathbf{u}_{n}(s, \omega)\right), \mathbf{u}_{n}(s, \omega)\right\rangle d s \\
& +\int_{0}^{t}\left\langle\mathbf{f}(s, \omega), \mathbf{u}_{n}(s, \omega)\right\rangle d s .
\end{aligned}
$$

Recall that $\hat{N}(\mathbf{u}(t, \omega))=N(\mathbf{u}(t, \omega))+B(\mathbf{u}(t, \omega), \mathbf{q}(s, \omega))+B(\mathbf{q}(t, \omega), \mathbf{u}(t, \omega))$. From the above lemma and that all functions are divergence free, we obtain

$$
\int_{0}^{t}\left\langle B\left(\mathbf{q}(s, \omega), \mathbf{u}_{n}(s, \omega)\right), \mathbf{u}_{n}(s, \omega)\right\rangle d s=0
$$

and

$$
\left|\int_{0}^{t}\left\langle B\left(\mathbf{u}_{n}(s, \omega), \mathbf{q}(s, \omega)\right), \mathbf{u}_{n}(s, \omega)\right\rangle d s\right| \leq C \int_{0}^{t}\|\mathbf{q}(s, \omega)\|_{V}\left|\mathbf{u}_{n}(s, \omega)\right|_{H}^{2} d s
$$

Then one can obtain an inequality of the following form

$$
\begin{aligned}
& \frac{1}{2}\left|\mathbf{u}_{n}(t, \omega)\right|_{H}^{2}+\int_{0}^{t}\left\|\mathbf{u}_{n}(s, \omega)\right\|_{W}^{2} d s \\
\leq \quad & \frac{1}{2}\left|\mathbf{u}_{0 n}(\omega)\right|_{H}^{2}+C \int_{0}^{t}\|\mathbf{q}(s, \omega)\|_{V}\left|\mathbf{u}_{n}(s, \omega)\right|_{H}^{2} d s \\
& +C \int_{0}^{t}\|\mathbf{f}(s, \omega)\|_{W^{\prime}}^{2} d s+\frac{1}{2} \int_{0}^{t}\left\|\mathbf{u}_{n}(s, \omega)\right\|_{W}^{2} d s
\end{aligned}
$$

Since $t \rightarrow\|\mathbf{q}(t, \omega)\|_{V}$ is continuous, it follows from Gronwall's inequality that there is an estimate of the form

$$
\begin{equation*}
\left|\mathbf{u}_{n}(t, \omega)\right|_{H}^{2}+\int_{0}^{t}\left\|\mathbf{u}_{n}(s, \omega)\right\|_{W}^{2} d s \leq C\left(\mathbf{u}_{0}, \mathbf{f}, \mathbf{q}, T, \omega\right) \tag{70.4.7}
\end{equation*}
$$

The next task is to estimate $\left\|\mathbf{u}_{n}^{\prime}(\omega)\right\|_{L^{2}\left([0, T] ; V^{\prime}\right)}$ for each fixed $\omega \in \Omega$. We will suppress the dependence on $\omega$ of all functions whenever it is appropriate. With 70.4.6, the fundamental theorem of calculus implies that for each $\mathbf{w} \in V_{n}$,

$$
\left\langle\mathbf{u}_{n}^{\prime}(t), \mathbf{w}\right\rangle_{V^{\prime}, V}+\left\langle A\left(\mathbf{u}_{n}(t)\right), \mathbf{w}\right\rangle_{V^{\prime}, V}+\left\langle\hat{N}\left(\mathbf{u}_{n}(t)\right), \mathbf{w}\right\rangle=\langle\mathbf{f}(t), \mathbf{w}\rangle .
$$

In terms of inner products in $V$,

$$
\left(R^{-1} \mathbf{u}_{n}^{\prime}(t)+R^{-1} A\left(\mathbf{u}_{n}(t)\right)+R^{-1} \hat{N}\left(\mathbf{u}_{n}(t)\right)-R^{-1} \mathbf{f}(t), \mathbf{w}\right)_{V}=0
$$

for all $\mathbf{w} \in V_{n}$. This is equivalent to saying that for $P_{n}$ the orthogonal projection in $V$ onto $V_{n}$,

$$
\left(R^{-1} \mathbf{u}_{n}^{\prime}(t)+R^{-1} A\left(\mathbf{u}_{n}(t)\right)+R^{-1} \hat{N}\left(\mathbf{u}_{n}(t)\right)-R^{-1} \mathbf{f}(t), P_{n} \mathbf{w}\right)_{V}=0
$$

for all $\mathbf{w} \in V$. This is to say that

$$
R^{-1} \mathbf{u}_{n}^{\prime}(t)+P_{n} R^{-1} A\left(\mathbf{u}_{n}(t)\right)+P_{n} R^{-1} \hat{N}\left(\mathbf{u}_{n}(t)\right)=P_{n} R^{-1} \mathbf{f}(t) .
$$

Now the projection map decreases norms and $R^{-1}$ preserves norms. Hence

$$
\left\|\mathbf{u}_{n}^{\prime}(t)\right\|_{V^{\prime}}=\left\|R^{-1} \mathbf{u}_{n}^{\prime}(t)\right\|_{V} \leq\left\|A\left(\mathbf{u}_{n}(t)\right)\right\|_{V^{\prime}}+\left\|\hat{N}\left(\mathbf{u}_{n}(t)\right)\right\|_{V^{\prime}}+\|\mathbf{f}(t)\|_{V^{\prime}}
$$

from which it follows that $\mathbf{u}_{n}^{\prime}$ is bounded in $L^{2}\left([0, T] ; V^{\prime}\right)$. Indeed, this is the case because $A\left(\mathbf{u}_{n}\right)$ and $\hat{N}\left(\mathbf{u}_{n}\right)$ are both bounded in $L^{2}\left([0, T] ; V^{\prime}\right)$. The term $\left\|\hat{N}\left(\mathbf{u}_{n}(t)\right)\right\|_{V^{\prime}}$ can be split further into terms involving $\left\|N\left(\mathbf{u}_{n}\right)\right\|,\left\|B\left(\mathbf{u}_{n}, \mathbf{q}\right)\right\|$, and $\left\|B\left(\mathbf{q}, \mathbf{u}_{n}\right)\right\|$. For example, consider $N\left(\mathbf{u}_{n}\right)$ which is the least obvious. Let $\mathbf{w} \in L^{2}([0, T] ; V)$. From the definitions,

$$
\begin{aligned}
& \left|\left\langle N\left(\mathbf{u}_{n}\right), \mathbf{w}\right\rangle_{L^{2}([0, T], V)}\right|=\left|\int_{0}^{T} \int_{U} u_{n i} u_{n j} w_{j, i} d x d t\right| \\
& \quad \leq C \int_{0}^{T}\|\mathbf{w}(t)\|_{V}\left|\mathbf{u}_{n}\right|_{H}^{2} d t \\
& \quad \leq C\|\mathbf{w}\|_{L^{2}([0, T], V)} C\left(\mathbf{u}_{0}, \mathbf{f}, \mathbf{q}, T, \omega\right)
\end{aligned}
$$

We have now shown that

$$
\begin{equation*}
\sup _{t \in[0, T]}\left|\mathbf{u}_{n}(t, \omega)\right|_{H}^{2}+\int_{0}^{T}\left\|\mathbf{u}_{n}(s, \omega)\right\|_{W}^{2} d s+\left\|\mathbf{u}_{n}^{\prime}(\omega)\right\|_{L^{2}\left([0, T] ; V^{\prime}\right)} \leq C\left(\mathbf{u}_{0}, \mathbf{f}, \mathbf{q}, T, \omega\right) \tag{70.4.8}
\end{equation*}
$$

This condition holds for all $\omega$. Now for each $\omega$, one can take a subsequence such that a solution to the evolution equation is obtained. Then, when this is done, we will apply the measurable selection result to obtain a product measurable solution.

It follows from the above estimate 70.4 .8 that there is a subsequence, still denoted as $n$ and a function $\mathbf{u}(t, \omega)$ such that

$$
\begin{align*}
\mathbf{u}_{n} & \rightarrow \mathbf{u} \text { weak } * \text { in } L^{\infty}([0, T] ; H),  \tag{70.4.9}\\
\mathbf{u}_{n}^{\prime} & \rightarrow \mathbf{u}^{\prime} \text { weakly in } L^{2}\left([0, T] ; V^{\prime}\right), \\
\mathbf{u}_{n} & \rightarrow \mathbf{u} \text { weakly in } L^{2}([0, T] ; W), \\
\mathbf{u}_{n} & \rightarrow \mathbf{u} \text { strongly in } L^{2}([0, T] ; H) . \tag{70.4.10}
\end{align*}
$$

This last convergence follows from Theorem 70.4.1. The sequence is bounded in the space $L^{2}([0, T] ; W)$ and the derivative is bounded in $L^{2}\left([0, T] ; V^{\prime}\right)$ so such a strongly convergent subsequence exists. Since $A$ is linear, we can also assume that

$$
\begin{equation*}
A \mathbf{u}_{n} \rightarrow A \mathbf{u} \text { weakly in } L^{2}\left([0, T] ; W^{\prime}\right) \tag{70.4.11}
\end{equation*}
$$

What happens with the nonlinear operator $\hat{N}$ ? Let $\mathbf{w} \in L^{\infty}([0, T] ; V)$. A computation shows then that

$$
\begin{aligned}
& \left|\int_{0}^{T}\left\langle N \mathbf{u}_{n}(t)-N \mathbf{u}(t), \mathbf{w}(t)\right\rangle d t\right| \\
= & \left|\int_{0}^{T} \int_{U}\left(u_{n i}(t) u_{n j}(t)-u_{i}(t) u_{j}(t)\right) w_{j, i} d x d t\right| \\
\leq & \|\mathbf{w}\|_{L^{\infty}([0, T], V)} \int_{0}^{T} \int_{U}\left(\left|\mathbf{u}_{n}(t)\right|+|\mathbf{u}(t)|\right)\left(\left|\mathbf{u}(t)-\mathbf{u}_{n}(t)\right|\right) d x d t \\
\leq & \|\mathbf{w}\|_{L^{\infty}([0, T], V)}\left(\int_{0}^{T} \int_{U}\left(\left|\mathbf{u}_{n}\right|+|\mathbf{u}|\right)^{2} d x d t\right)^{1 / 2}\left(\int_{0}^{T} \int_{U}\left(\left|\mathbf{u}-\mathbf{u}_{n}\right|\right)^{2} d x d t\right)^{1 / 2}
\end{aligned}
$$

This converges to 0 thanks to the estimates and the strong convergence 70.4.10. Similar convergence holds for the other nonlinear terms $B\left(\mathbf{u}_{n}(t), \mathbf{q}\right), B\left(\mathbf{q}, \mathbf{u}_{n}(t)\right)$.

We have shown that for any $n \geq m$, and $\mathbf{w} \in V_{m}$,

$$
\begin{equation*}
\left\langle\mathbf{u}_{n}^{\prime}(t), \mathbf{w}\right\rangle_{V^{\prime}, V}+\left\langle A\left(\mathbf{u}_{n}(t)\right), \mathbf{w}\right\rangle_{V^{\prime}, V}+\left\langle\hat{N}\left(\mathbf{u}_{n}(t)\right), \mathbf{w}\right\rangle=\langle\mathbf{f}(t), \mathbf{w}\rangle \tag{70.4.12}
\end{equation*}
$$

Let $\zeta \in C^{\infty}([0, T])$ be such that $\zeta(T)=0$. Then

$$
\left\langle\mathbf{u}_{n}^{\prime}(t), \mathbf{w} \zeta(t)\right\rangle_{V^{\prime}, V}+\left\langle A\left(\mathbf{u}_{n}(t)\right), \mathbf{w} \zeta(t)\right\rangle_{V^{\prime}, V}+\left\langle\hat{N}\left(\mathbf{u}_{n}(t)\right), \mathbf{w} \zeta(t)\right\rangle=\langle\mathbf{f}(t), \mathbf{w} \zeta(t)\rangle
$$

Integrating this equation from 0 to $T$ we obtain

$$
\begin{aligned}
& -\left(\mathbf{u}_{0 n}(\omega), \mathbf{w} \zeta(0)\right)_{H}-\int_{0}^{T} \zeta^{\prime}(s)\left(\mathbf{u}_{n}(s, \omega), \mathbf{w}\right)_{H} d s \\
= & -\int_{0}^{T}\left\langle A\left(\mathbf{u}_{n}(s, \omega)\right), \mathbf{w} \zeta(s)\right\rangle d s-\int_{0}^{T}\left\langle\hat{N}\left(\mathbf{u}_{n}(s, \omega)\right), \mathbf{w} \zeta(s)\right\rangle d s \\
& +\int_{0}^{T}\langle\mathbf{f}(s, \omega), \mathbf{w} \zeta(s)\rangle d s
\end{aligned}
$$

Now letting $n \rightarrow \infty$, from the above list of convergent sequences,

$$
\begin{aligned}
& -\left(\mathbf{u}_{0}(\omega), \mathbf{w} \zeta(0)\right)_{H}-\int_{0}^{T} \zeta^{\prime}(s)(\mathbf{u}(s, \omega), \mathbf{w})_{H} d s \\
= & -\int_{0}^{T}\langle A(\mathbf{u}(s, \omega)), \mathbf{w} \zeta(s)\rangle d s-\int_{0}^{T}\langle\hat{N}(\mathbf{u}(s, \omega)), \mathbf{w} \zeta(s)\rangle d s \\
& +\int_{0}^{T}\langle\mathbf{f}(s), \mathbf{w} \zeta(s)\rangle d s .
\end{aligned}
$$

It follows that in the sense of $V^{\prime}$ valued distributions,

$$
\begin{equation*}
\mathbf{u}^{\prime}(\omega)+A(\mathbf{u}(\omega))+\hat{N}(\mathbf{u}(\omega))=\mathbf{f}(\omega) \tag{70.4.13}
\end{equation*}
$$

along with the initial condition

$$
\begin{equation*}
\mathbf{u}(0)=\mathbf{u}_{0} \tag{70.4.14}
\end{equation*}
$$

This has proved most of the following lemma:

Lemma 70.4.4 Let $\mathbf{u}_{0}$ have values in $H$ and be $\mathscr{F}$ measurable, and let $\mathbf{u}_{n}$ be a solution to 70.4.6. Then for each $\omega$, the estimate 70.4 .8 holds. Also there is a subsequence, still called $\mathbf{u}_{n}$ such that the convergence for 70.4.9-70.4.11 are valid. For all $\omega$, the function $\mathbf{u}(\cdot, \omega)$ is a solution to 70.4.13-70.4.14 and satisfies

$$
\mathbf{u}(\cdot, \omega) \in L^{\infty}([0, T] ; H) \cap L^{2}([0, T] ; W), \mathbf{u}^{\prime} \in L^{2}\left([0, T] ; V^{\prime}\right)
$$

This solution is also weakly continuous into $H$ for each $\omega$.
Proof: All that remains to show is the last claim about weak continuity into $H$. The equation 70.4.13 shows that $\mathbf{u}(\cdot, \omega)$ is continuous into $V^{\prime}$. However, the weak convergence and the estimate 70.4.8 show that $\mathbf{u}(\cdot, \omega)$ is bounded in $H$. It follows from density of $V$ in $H$ that $t \rightarrow \mathbf{u}(t, \omega)$ is weakly continuous into $H$.

From 70.4.13, 70.4.14, the following integral equation for a path solution holds:

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{u}(s, \omega)) d s+\int_{0}^{t} \hat{N}(\mathbf{u}(s, \omega)) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s
$$

We apply Theorem 70.2.8 to prove the above solution could be taken product measurable.
Theorem 70.4.5 Let $\mathbf{f}(t, \omega)$, $\mathbf{q}(t, \omega)$ be product measurable and $\mathbf{u}_{0}$ be measurable, such that for each $\omega \in \Omega, \mathbf{f}(\cdot, \omega) \in L^{2}\left([0, T] ; W^{\prime}\right), \mathbf{q}(\cdot, \omega) \in C([0, T] ; V)$ with $\mathbf{q}(0)=\mathbf{0}$, and $\mathbf{u}_{0}(\omega) \in H$. Then there exists a global solution to the integral equation

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{u}(s, \omega)) d s+\int_{0}^{t} \hat{N}(\mathbf{u}(s, \omega)) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s
$$

Proof: Letting $\mathbf{u}_{n}$ be a solution to 70.4.6, we verify the conditions of Theorem 70.2.8 for $\mathbf{u}_{n}$.

The assumption in this theorem that the $\mathbf{u}_{n}$ are bounded follows from the above estimate 70.4.8. Then it was shown in the above lemma that whenever a sequence satisfies the estimate 70.4.8, it has a subsequence which converges as in 70.4.9-70.4.11 to a weakly continuous $\mathbf{u}(\cdot, \omega)$. Therefore, by Theorem 70.2 .8 there is a subsequence $\mathbf{u}_{n(\omega)}(\cdot, \omega)$ converging weakly to $\mathbf{u}(\cdot, \omega)$, such that $(t, \omega) \rightarrow \mathbf{u}(t, \omega)$ is a product measurable function into $H$. Then a further subsequence converges to a path solution to the above integral equation, which must be the same function because when a sequence converges, all subsequences converge to the same thing. In addition to this, $\mathbf{u}$ is also product measurable into $W$. This follows from the above estimate 70.4.8. For $\phi \in H,(t, \omega) \rightarrow(\phi, \mathbf{u}(t, \omega))$ is product measurable. However, $H$ is dense in $W^{\prime}$ and so if $\psi \in W^{\prime}$, there is a sequence $\left\{\phi_{n}\right\}$ in $H$ such that $\phi_{n} \rightarrow \psi$. Then

$$
\langle\psi, \mathbf{u}\rangle=\lim _{n \rightarrow \infty}\left(\phi_{n}, \mathbf{u}\right),
$$

so by the Pettis theorem [127], $\mathbf{u}$ is product measurable into $W$ also.
This shows much of the following theorem which is the main result.
Theorem 70.4.6 Let $\mathbf{f}(t, \omega)$, $\mathbf{q}(t, \omega)$ be product measurable and $\mathbf{u}_{0}$ be measurable, such that for each $\omega \in \Omega, \mathbf{f}(\cdot, \omega) \in L^{2}\left([0, T] ; W^{\prime}\right), \mathbf{q}(\cdot, \omega) \in C([0, T] ; V)$ with $\mathbf{q}(0)=\mathbf{0}$, and $\mathbf{u}_{0}(\omega) \in H$. Then there exists a global solution to the integral equation

$$
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} A(\mathbf{u}(s, \omega)) d s+\int_{0}^{t} N(\mathbf{u}(s, \omega)) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s+\mathbf{q}(t, \omega)
$$

In addition to this, $t \rightarrow \mathbf{u}(t, \omega)$ is continuous into $H$ and satisfies

$$
\mathbf{u}(\cdot, \omega) \in L^{\infty}([0, T] ; H) \cap L^{2}([0, T] ; W)
$$

If, in addition to the above, $\mathbf{u}_{0} \in L^{2}(\Omega ; H)$ and $\mathbf{f} \in L^{2}\left([0, T] \times \Omega ; W^{\prime}\right)$ and

$$
\mathbf{q} \in L^{2}([0, T] \times \Omega ; V)
$$

then the solution $\mathbf{u}$ is in $L^{2}([0, T] \times \Omega ; H) \cap L^{2}([0, T] \times \Omega ; W)$.
Proof: The last claim follows from the estimates used in the Galerkin method, taking expectations and passing to a limit. To verify the continuity into $H$, one can observe that from the integral equation, $\mathbf{u}$ is continuous into $V^{\prime}$. One has

$$
|\mathbf{u}(t)|_{H}^{2}=\sum_{k=1}^{\infty}\left(\mathbf{u}(t), \mathbf{w}_{k}\right)^{2}=\sum_{k=1}^{\infty}\left\langle\mathbf{u}(t), \mathbf{w}_{k}\right\rangle^{2},
$$

and so $t \rightarrow|\mathbf{u}(t)|_{H}^{2}$ is lower semi-continuous. Since it is in $L^{\infty}$, this implies this function is bounded. Hence the continuity into $V^{\prime}$ and density of $V$ in $H$ implies that $\mathbf{u}(t)$ is weakly continuous into $H$. Then one can use the formulation in Theorem 70.4.5 to verify $t \rightarrow$ $|\mathbf{u}(t)|_{H}$ is continuous and apply uniform convexity of the Hilbert space $H$.

One can replace $\mathbf{q}(t, \omega)$ with $\mathbf{q}(t, \omega, \mathbf{u})$ and $\mathbf{f}(t, \omega)$ with $\mathbf{f}(t, \omega, \mathbf{u})$ in the above with no change in the argument, provided it is assumed that

$$
(t, \omega, \mathbf{u}) \rightarrow \mathbf{q}(t, \omega, \mathbf{u}), \mathbf{f}(t, \omega, \mathbf{u})
$$

are product measurable, continuous in $(t, \mathbf{u})$ and bounded.

### 70.5 A Friction contact problem

In this section we will consider a friction contact problem which has a coefficient of friction which is dependent on the slip speed.

$$
\begin{gather*}
\ddot{u}_{i}=\sigma_{i j, j}(\mathbf{u}, \dot{\mathbf{u}})+f_{i} \text { for }(t, \mathbf{x}) \in(0, T) \times U,  \tag{70.5.15}\\
\mathbf{u}(0, \mathbf{x})=\mathbf{u}_{0}(\mathbf{x}),  \tag{70.5.16}\\
\dot{\mathbf{u}}(0, \mathbf{x})=\mathbf{v}_{0}(\mathbf{x}), \tag{70.5.17}
\end{gather*}
$$

where $U$ is a bounded open subset of $\mathbb{R}^{3}$ having Lipschitz boundary, along with some boundary conditions which pertain to a part of the boundary of $U, \Gamma_{C}$. For $\mathbf{x} \in \Gamma_{C}$,

$$
\begin{equation*}
\sigma_{n}=-p\left(\left(u_{n}-g\right)_{+}\right) C_{n}, \tag{70.5.18}
\end{equation*}
$$

This is the normal compliance boundary condition.

$$
\begin{gather*}
\left|\sigma_{T}\right| \leq F\left(\left(u_{n}-g\right)_{+}\right) \mu\left(\left|\dot{\mathbf{u}}_{T}-\dot{\mathbf{U}}_{T}\right|\right)  \tag{70.5.19}\\
\left|\sigma_{T}\right|<F\left(\left(u_{n}-g\right)_{+}\right) \mu\left(\left|\dot{\mathbf{u}}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \text { implies } \dot{\mathbf{u}}_{T}-\dot{\mathbf{U}}_{T}=\mathbf{0} \tag{70.5.20}
\end{gather*}
$$

$$
\begin{equation*}
\left|\sigma_{T}\right|=F\left(\left(u_{n}-g\right)_{+}\right) \mu\left(\left|\dot{\mathbf{u}}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \text { implies } \dot{\mathbf{u}}_{T}-\dot{\mathbf{U}}_{T}=-\lambda \sigma_{T}(\mathbf{u}, \dot{\mathbf{u}}) \tag{70.5.21}
\end{equation*}
$$

Here $C_{n}$ is a positive function in $L^{\infty}\left(\Gamma_{C}\right)$, which we take equal to 1 to simplify notation, $\dot{\mathbf{U}}_{T}$ is the velocity of the foundation, $\lambda$ is non negative, and $\mu$ is a bounded positive function having a bounded continuous derivative. We could also let $\mu$ depend on $\mathbf{x} \in \Gamma_{C}$ to model the roughness of the contact surface but we will suppress this dependence in the interest of simpler notation. Also, $\mathbf{n}$ is the unit outward normal to $\partial U$ and $u_{n}, \mathbf{u}_{T}, \sigma_{T}$, and $\sigma_{n}$ are defined by the following.

$$
\begin{gathered}
u_{n}=\mathbf{u} \cdot \mathbf{n} \\
\mathbf{u}_{T}=\mathbf{u}-(\mathbf{u} \cdot \mathbf{n}) \mathbf{n} \\
\sigma_{n}=\sigma_{i j} n_{j} n_{i} \\
\sigma_{T i}=\sigma_{i j} n_{j}-\sigma_{n} n_{i}
\end{gathered}
$$

written more simply,

$$
\sigma_{T}=\sigma \mathbf{n}-\sigma_{n} \mathbf{n}
$$

Systems like the above model dynamic friction contact problems [93], [51] [46]. The function $g$ represents the gap between the contact surface of $U, \Gamma_{C}$, and a foundation which is sliding tangent to $\Gamma_{C}$ with tangential velocity $\dot{\mathbf{U}}_{T}$.

The new ingredient in this paper is that we allow

$$
g=g(t, \mathbf{x}, \omega)
$$

where $\omega \in(\Omega, \mathscr{F})$ and we assume $(t, \mathbf{x}, \omega) \rightarrow g(\mathbf{x}, \omega)$ is $\mathscr{B}\left([0, T] \times \Gamma_{C}\right) \times \mathscr{F}$ measurable. Also, we make the reasonable assumption that

$$
0 \leq g(t, \mathbf{x}, \omega) \leq l<\infty
$$

for all $(t, \mathbf{x}, \omega)$. We also assume that the given motion of the foundation $\dot{\mathbf{U}}_{T}$ is a stochastic process

$$
\dot{\mathbf{U}}_{T}=\dot{\mathbf{U}}_{T}(t, \mathbf{x}, \omega)
$$

and is $\mathscr{B}\left([0, T] \times \Gamma_{C}\right) \times \mathscr{F}$ measurable. Here $\mathscr{B}\left([0, T] \times \Gamma_{C}\right)$ denotes the Borel sets of $[0, T] \times \Gamma_{C}$. We make the reasonable assumption that $\dot{\mathbf{U}}_{T}(t, \mathbf{x}, \omega)$ is uniformly bounded. In the interest of notation, we will often suppress the dependence on $t, \mathbf{x}$, and $\omega$.

The condition 70.5 .18 is the contact condition. It says the normal component of the traction force density is dependent on the normal penetration of the body into the foundation surface. Conditions 70.5.19-70.5.21 model friction. They say that the tangential part of the traction force density is bounded by a function determined by the normal force or penetration. No sliding takes place until $\left|\sigma_{T}\right|$ reaches this bound, $F\left(\left(u_{n}-g\right)_{+}\right) \mu(0)$, 70.5.20. When this occurs, the tangential force density has a direction opposite the relative tangential velocity 70.5 .21 . The dependence of the friction coefficient on the magnitude of the slip velocity, $\left|\dot{\mathbf{u}}_{T}-\dot{\mathbf{U}}_{T}\right|$ may be experimentally verified and so it has been included. The new feature in this model is the assumption that the gap is a random variable for each $\mathbf{x} \in \Gamma_{C}$ and we want to consider measurability of the solutions. Thus for a fixed $\omega$, we have a standard friction problem and it is the measurability which is of interest here.

In this paper, we assume the following on $p$ and $F$. The functions $p$ and $F$ are increasing and

$$
\begin{gather*}
\delta^{2} r-K \leq p(r) \leq K(1+r), r \geq 0  \tag{70.5.22}\\
p(r)=0, r<0 \\
F(r) \leq K(1+r) r \geq 0  \tag{70.5.23}\\
F(r)=0 \text { if } r<0 \\
\left|\mu\left(r_{1}\right)-\mu\left(r_{2}\right)\right| \leq \operatorname{Lip}(\mu)\left|r_{1}-r_{2}\right|, \quad\|\mu\|_{\infty} \leq C \tag{70.5.24}
\end{gather*}
$$

and for $a=F, p$, and $r_{1}, r_{2} \geq 0$,

$$
\begin{equation*}
\left|a\left(r_{1}\right)-a\left(r_{2}\right)\right| \leq K\left|r_{1}-r_{2}\right| . \tag{70.5.25}
\end{equation*}
$$

One can consider more general growth conditions than this, but we are keeping this part simple to emphasize the new stochastic considerations.

It will be assumed that

$$
\begin{equation*}
\sigma_{i j}=A_{i j k l} u_{k, l}+C_{i j k l} \dot{u}_{k, l}, \tag{70.5.26}
\end{equation*}
$$

where $A$ and $C$ are in $L^{\infty}(U)$ and for $B=A$ or $C$, we have the following symmetries.

$$
\begin{equation*}
B_{i j k l}=B_{i j l k}, B_{j i k l}=B_{i j k l}, B_{i j k l}=B_{k l i j} \tag{70.5.27}
\end{equation*}
$$

and we also assume for $B=A$ or $C$ that

$$
\begin{equation*}
B_{i j k l} H_{i j} H_{k l} \geq \varepsilon H_{r s} H_{r s} \tag{70.5.28}
\end{equation*}
$$

for all symmetric $H$.
Throughout the paper, $V$ will be a closed subspace of $\left(H^{1}(U)\right)^{3}$ containing the test functions $\left(C_{0}^{\infty}(U)\right)^{3}, \rightharpoonup$ will denote weak or weak $*$ convergence while $\rightarrow$ will mean strong convergence. $\gamma$ will denote the trace map from $W^{12}(U)$ into $L^{2}(\partial U)$. $H$ will denote ( $\left.L^{2}(U)\right)^{3}$ and we will always identify $H$ and $H^{\prime}$ to write

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

We define

$$
\mathscr{V}=L^{2}(0, T ; V), \mathscr{H}=L^{2}(0, T, H), \mathscr{V}^{\prime}=L^{2}\left(0, T ; V^{\prime}\right)
$$

### 70.5.1 The Abstract Problem

We shall use two theorems found in Lions [91], and Simon [117] respectively. These theorems apply for fixed $\omega$. Proofs of generalizations of these theorems begin on Page 2383.

Theorem 70.5.1 If $p \geq 1, q>1$, and $W \subseteq U \subseteq Y$ where the inclusion map of $W$ into $U$ is compact and the inclusion map of $U$ into $Y$ is continuous, let

$$
\begin{aligned}
S= & \left\{\mathbf{u} \in L^{p}(0, T ; W): \mathbf{u}^{\prime} \in L^{q}(0, T ; Y)\right. \text { and } \\
& \left.\|\mathbf{u}\|_{L^{p}(0, T ; W)}+\left\|\mathbf{u}^{\prime}\right\|_{L^{q}(0, T ; Y)}<R\right\}
\end{aligned}
$$

Then $S$ is pre compact in $L^{p}(0, T ; U)$.

Theorem 70.5.2 Let $W, U$, and $Y$ be as in Theorem 70.5.1 and let

$$
S=\left\{\mathbf{u}:\|\mathbf{u}(t)\|_{W}+\left\|\mathbf{u}^{\prime}\right\|_{L^{q}(0, T ; Y)} \leq R \text { for } t \in[0, T]\right\}
$$

for $q>1$. Then $S$ is pre compact in $C(0, T ; U)$.
Now we give an abstract formulation of the problem described roughly in 70.5.1570.5.21. We begin by defining several operators. Let $M, A: V \rightarrow V^{\prime}$ be given by

$$
\begin{align*}
\langle M \mathbf{u}, \mathbf{v}\rangle & =\int_{U} C_{i j k l} \mathbf{u}_{k, l} \mathbf{v}_{i, j} d x  \tag{70.5.29}\\
\langle A \mathbf{u}, \mathbf{v}\rangle & =\int_{U} A_{i j k l} \mathbf{u}_{k, l} \mathbf{v}_{i, j} d x \tag{70.5.30}
\end{align*}
$$

Also let the operator $\mathbf{v} \rightarrow P(\mathbf{u})$ map $\mathscr{V}$ to $\mathscr{V}^{\prime}$ be given by

$$
\begin{equation*}
\langle P(\mathbf{u}), \mathbf{w}\rangle=\int_{0}^{T} \int_{\Gamma_{C}} p\left(\left(u_{n}-g\right)_{+}\right) w_{n} d \alpha d t \tag{70.5.31}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathbf{u}(t)=\mathbf{u}_{0}+\int_{0}^{t} \mathbf{v}(s) d s \tag{70.5.32}
\end{equation*}
$$

for $\mathbf{u}_{0} \in V_{q}$. (Technically, $P$ depends on $\mathbf{u}_{0}$ but we suppress this in favor of simpler notation ). Let

$$
\gamma_{T}^{*}: L^{2}\left(0, T ; L^{2}\left(\Gamma_{C}\right)^{3}\right) \rightarrow \mathscr{V}^{\prime}
$$

is defined as

$$
\left\langle\gamma_{T}^{*} \xi, \mathbf{w}\right\rangle \equiv \int_{0}^{T} \int_{\Gamma_{C}} \xi \cdot \mathbf{w}_{T} d \alpha d t
$$

Now the abstract form of the problem, denoted by $\mathscr{P}$, is the following.

$$
\begin{gather*}
\mathbf{v}^{\prime}+M \mathbf{v}+A \mathbf{u}+P \mathbf{u}+\gamma_{T}^{*} \xi=\mathbf{f} \text { in } \mathscr{V}^{\prime}  \tag{70.5.33}\\
\mathbf{v}(0)=\mathbf{v}_{0} \in H \tag{70.5.34}
\end{gather*}
$$

where

$$
\begin{equation*}
\mathbf{u}(t)=\mathbf{u}_{0}+\int_{0}^{t} \mathbf{v}(s) d s, \mathbf{u}_{0} \in V_{p} \tag{70.5.35}
\end{equation*}
$$

and for all $\mathbf{w} \in \mathscr{V}$,

$$
\begin{gather*}
\left\langle\gamma_{T}^{*} \xi, \mathbf{w}\right\rangle \leq \int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{n}-g\right)_{+}\right) \mu\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \\
{\left[\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}+\mathbf{w}_{T}\right|-\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right] d \alpha d t} \tag{70.5.36}
\end{gather*}
$$

Also $\mathbf{f} \in L^{2}\left(0, T ; V^{\prime}\right)$ so $\mathbf{f}$ can include the body force as well as traction forces on various parts of $\partial U$. If $\mathbf{v}$ solves the above abstract problem, then $\mathbf{u}$ can be considered a weak
solution to 70.5.15-70.5.21 along with other variational and stable boundary conditions depending on the choice of $W$ and $\mathbf{f} \in L^{2}\left(0, T ; V^{\prime}\right)$.

In order to carry out our existence and uniqueness proofs, we assume $M$ and $A$ satisfy the following for some $\delta>0, \lambda \geq 0$.

$$
\begin{equation*}
\langle B \mathbf{u}, \mathbf{u}\rangle \geq \delta^{2}\|\mathbf{u}\|_{W}^{2}-\lambda|\mathbf{u}|_{H}^{2},\langle B \mathbf{u}, \mathbf{u}\rangle \geq 0,\langle B \mathbf{u}, \mathbf{v}\rangle=\langle B \mathbf{v}, \mathbf{u}\rangle, \tag{70.5.37}
\end{equation*}
$$

for $B=M$ or $A$. This is the assumption that we use, and we note that 70.5 .37 is a consequence of 70.5.26-70.5.28 and Korn's inequality [104].

### 70.5.2 An Approximate Problem

We will use the Galerkin method. To do this, we will first regularize that subgradient material. Let

$$
\psi_{\varepsilon}(\mathbf{r})=\sqrt{|\mathbf{r}|^{2}+\varepsilon}
$$

Then this is a convex, Lipschitz continuous function having bounded derivative which converges uniformly to $\psi(\mathbf{r})=|\mathbf{r}|$ on $\mathbb{R}$. Also

$$
\left|\psi_{\varepsilon}(\mathbf{x})-\psi_{\varepsilon}(\mathbf{y})\right| \leq|\mathbf{x}-\mathbf{y}|, \quad\left|\psi_{\varepsilon}^{\prime}(\mathbf{t})\right| \leq 1
$$

And finally, $\psi_{\varepsilon}^{\prime}$ is Lipschitz continuous with a Lipschitz constant $C / \sqrt{\varepsilon}$. Here $\psi_{\varepsilon}^{\prime}$ denotes the gradient or Frechet derivative of the scalar valued function.

Our approximate problem for which we will apply the Galerkin method will be $\mathscr{P}_{\varepsilon}$ given by

$$
\begin{gather*}
\mathbf{v}^{\prime}+M \mathbf{v}+A \mathbf{u}+P \mathbf{u}+\gamma_{T}^{*} F\left(\left(u_{n}-g\right)_{+}\right) \mu\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right)=\mathbf{f} \text { in } \mathscr{V}^{\prime},  \tag{70.5.38}\\
\mathbf{v}(0)=\mathbf{v}_{0} \in H, \tag{70.5.39}
\end{gather*}
$$

where

$$
\begin{equation*}
\mathbf{u}(t)=\mathbf{u}_{0}+\int_{0}^{t} \mathbf{v}(s) d s, \mathbf{u}_{0} \in V \tag{70.5.40}
\end{equation*}
$$

Here the long operator on the left is defined in the following manner.

$$
\begin{aligned}
& \left\langle\gamma_{T}^{*} F\left(\left(u_{n}-g\right)_{+}\right) \mu\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right), \mathbf{w}\right\rangle \\
= & \int_{\Gamma_{C}} F\left(\left(u_{n}-g\right)_{+}\right) \mu\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right) \cdot \mathbf{w}_{T} d S
\end{aligned}
$$

Let $R$ denote the Riesz map from $V$ to $V^{\prime}$ defined by $\langle R \mathbf{u}, \mathbf{v}\rangle=(\mathbf{u}, \mathbf{v})_{V}$. Then $R^{-1}: H \rightarrow$ $V$ is a compact self adjoint operator and so there exists a complete orthonormal basis for $H,\left\{\mathbf{e}_{k}\right\} \subseteq V$ such that

$$
R \mathbf{e}_{k}=\lambda_{k} \mathbf{e}_{k}
$$

where $\lambda_{k} \rightarrow \infty$. Let $V_{n}=\operatorname{span}\left(\mathbf{e}_{1}, \cdots, \mathbf{e}_{n}\right)$. Thus $\cup_{n} V_{n}$ is dense in $H$. In addition $\cup_{n} V_{n}$ is dense in $V$ and $\left\{\mathbf{e}_{k}\right\}$ is also orthogonal in $V$. To see first that $\left\{\mathbf{e}_{k}\right\}$ is orthogonal in $V$,

$$
0=\left(\mathbf{e}_{k}, \mathbf{e}_{l}\right)_{H}=\frac{1}{\lambda_{k}}\left(R \mathbf{e}_{k}, \mathbf{e}_{l}\right)_{H}=\frac{1}{\lambda_{k}}\left\langle R \mathbf{e}_{k}, \mathbf{e}_{l}\right\rangle=\frac{1}{\lambda_{k}}\left(\mathbf{e}_{l}, \mathbf{e}_{k}\right)_{V}
$$

Next consider why $\cup_{n} V_{n}$ is dense in $V$. If this is not so, then there exists $f \in V^{\prime}, f \neq 0$ such that $\cup_{n} V_{n}$ is in $\operatorname{ker}(f)$. But $f=R \mathbf{u}$ and so

$$
0=\left\langle R \mathbf{u}, \mathbf{e}_{k}\right\rangle=\left\langle R \mathbf{e}_{k}, \mathbf{u}\right\rangle=\lambda_{k}\left(\mathbf{e}_{k}, \mathbf{u}\right)_{H}
$$

for all $\mathbf{e}_{k}$ and so $\mathbf{u}=\mathbf{0}$ by density of $\cup_{n} V_{n}$ in $H$. Hence $R \mathbf{u}=0=f$ after all, a contradiction. Hence $\cup_{n} V_{n}$ is dense in $V$ as claimed.

Now we set up the Galerkin method for Problem $\mathscr{P}_{\varepsilon}$. Let

$$
\mathbf{v}_{k}(t, \omega)=\sum_{j=1}^{k} x_{j}(t, \omega) \mathbf{e}_{j}, \mathbf{u}_{k}(t)=\mathbf{u}_{0}+\int_{0}^{t} \mathbf{v}_{k}(s) d s
$$

and let $\mathbf{v}_{k}$ be the solution to the following integral equation for each $\omega$ and $j \leq k$. The dependence on $\omega$ is suppressed in most terms in order to save space.

$$
\begin{gather*}
\left\langle\mathbf{v}_{k}(t)-\mathbf{v}_{0 k}+\int_{0}^{t} M \mathbf{v}_{k}+A \mathbf{u}_{k}+P \mathbf{u}_{k}+\gamma_{T}^{*} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \cdot\right. \\
\mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}\right\rangle  \tag{70.5.41}\\
=\int_{0}^{t}\left\langle\mathbf{f}, \mathbf{e}_{j}\right\rangle d s
\end{gather*}
$$

Here $\mathbf{v}_{0 k} \rightarrow \mathbf{v}_{0} \in H$ and the equation holds for each $\mathbf{e}_{j}$ for each $j \leq k$. Then this integral equation reduces to a system of ordinary differential equations for the vector $\mathbf{x}(t, \omega)$ whose $j^{\text {th }}$ component is $x_{j}(t, \omega)$ mentioned above. Differentiate, multiply by $x_{j}$ and add. Then integrate. This will yield some terms which need to be estimated. Here is the one which comes from the long term.

$$
\begin{aligned}
& \int_{0}^{t} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \cdot \mathbf{v}_{k T} d S d s \\
&= \int_{0}^{t} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \\
& \cdot\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) d S d s \\
& \quad+\int_{0}^{t} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \cdot \dot{\mathbf{U}}_{T} d S d s
\end{aligned}
$$

The first of these is nonnegative and the second is bounded below by an expression of the form

$$
\begin{aligned}
-C \int_{0}^{t} \int_{\Gamma_{C}}\left(1+\left|u_{k n}\right|\right)\left|\dot{\mathbf{U}}_{T}\right| d S d s & \geq-C \int_{0}^{t}\left\|\mathbf{u}_{k}\right\|_{W}\left\|\dot{\mathbf{U}}_{T}\right\|_{L^{2}\left(\Gamma_{C}\right)^{3}} d s-C \\
& \geq-C \int_{0}^{t}\left\|\mathbf{u}_{k}\right\|_{W}-C
\end{aligned}
$$

Where $W$ embedds compactly into $V$ and the trace map from $W$ to $L^{2}\left(\Gamma_{C}\right)^{3}$ is continuous. In the above, $C$ is independent of $\varepsilon, \omega$ and $k$. To estimate the term from $P$ one exploits the linear growth condition of $P$ in 70.5 .22 to obtain a suitable estimate.

It follows from equivalence of norms in finite dimensional spaces, the assumed estimates on $M, A$, and $P$ and standard manipulations depending on compact embeddings that there exists an estimate suitable to apply Theorem 70.3.3 to obtain the existence of a solution such that $(t, \omega) \rightarrow \mathbf{x}(t, \omega)$ is measurable into $\mathbb{R}^{k}$ which implies that $(t, \omega) \rightarrow \mathbf{v}_{k}(t, \omega)$ is product measurable into $V$ and $H$. This yields the measurable Galerkin approximation.

Also, the estimates and compact embedding results for Sobolev spaces imply an inequality of the form

$$
\begin{equation*}
\left|\mathbf{v}_{k}(t)\right|_{H}^{2}+\int_{0}^{T}\left\|\mathbf{v}_{k}\right\|_{V}^{2} d s+\left\|\mathbf{u}_{k}(t)\right\|_{V}^{2} \leq C \tag{70.5.42}
\end{equation*}
$$

where in fact $C$ does not depend on $\varepsilon, \omega$ or $k$. Everything would work if $C$ depended on $\omega$ but because of our simplifying assumptions, we can get a single $C$ as above.

Next we need to estimate the time derivative in $\mathscr{V}^{\prime}$. The integral equation implies that for all $\mathbf{w} \in V_{k}$,

$$
\begin{gather*}
\left\langle\mathbf{v}_{k}^{\prime}(t), \mathbf{w}\right\rangle_{V^{\prime}, V}+\left\langle\begin{array}{c}
M \mathbf{v}_{k}+A \mathbf{u}_{k}+P \mathbf{u}_{k}+\gamma_{T}^{*} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \cdot \\
\mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \\
=\langle\mathbf{f}, \mathbf{w}\rangle
\end{array}, \quad\right\rangle_{V^{\prime}, V} \\ \tag{70.5.43}
\end{gather*}
$$

where the dependence on $t$ and $\omega$ is suppressed in most terms. In terms of inner products in $V$ this reduces to

$$
\begin{gathered}
\left(R^{-1} \mathbf{v}_{k}^{\prime}(t), \mathbf{w}\right)_{V}+\left(R^{-1}\binom{M \mathbf{v}_{k}+A \mathbf{u}_{k}+P \mathbf{u}_{k}+\gamma_{T}^{*} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \cdot}{\mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right)}, \mathbf{w}\right)_{V} \\
=\left(R^{-1} \mathbf{f}, \mathbf{w}\right)_{V}
\end{gathered}
$$

In terms of $P_{k}$ the orthogonal projection in $V$ onto $V_{k}$, this takes the form

$$
\begin{gathered}
\left(R^{-1} \mathbf{v}_{k}^{\prime}(t), P_{k} \mathbf{w}\right)_{V}+ \\
\left(R^{-1}\binom{M \mathbf{v}_{k}+A \mathbf{u}_{k}+P \mathbf{u}_{k}+\gamma_{T}^{*} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \cdot}{\mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right)}, P_{k} \mathbf{w}\right)_{V} \\
=\left(R^{-1} \mathbf{f}, P_{k} \mathbf{w}\right)_{V}
\end{gathered}
$$

for all $\mathbf{w} \in V$. Now $\mathbf{v}_{k}^{\prime}(t) \in V_{k}$ and so the first term can be simplified and we can write

$$
\begin{gathered}
\left(R^{-1} \mathbf{v}_{k}^{\prime}(t), \mathbf{w}\right)_{V}+ \\
\left(R^{-1}\binom{M \mathbf{v}_{k}+A \mathbf{u}_{k}+P \mathbf{u}_{k}+\gamma_{T}^{*} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \cdot}{\mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right)}, P_{k} \mathbf{w}\right)_{V} \\
=\left(R^{-1} \mathbf{f}, P_{k} \mathbf{w}\right)_{V}
\end{gathered}
$$

for all $\mathbf{w} \in V$. Then it follows that for all $\mathbf{w} \in V$,

$$
\left(R^{-1} \mathbf{v}_{k}^{\prime}(t), \mathbf{w}\right)_{V}+
$$

$$
\left(P_{k} R^{-1}\left(\begin{array}{c}
M \mathbf{v}_{k}+A \mathbf{u}_{k}+P \mathbf{u}_{k}+\gamma_{T}^{*} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \cdot \\
\mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \\
=\left(P_{k} R^{-1} \mathbf{f}, \mathbf{w}\right)_{V}
\end{array}\right), \mathbf{w}\right)_{V}
$$

Thus in $V$ we have

$$
R^{-1} \mathbf{v}_{k}^{\prime}(t)+P_{k} R^{-1}\binom{M \mathbf{v}_{k}+A \mathbf{u}_{k}+P \mathbf{u}_{k}+\gamma_{T}^{*} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \cdot}{\mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right)}=P_{k} R^{-1} \mathbf{f}
$$

and $R^{-1}$ preserves norms while $P_{k}$ decreases them. Hence the estimate 70.5 .42 implies that $\left\|\mathbf{v}_{k}^{\prime}\right\|_{\mathscr{V}^{\prime}}$ is also bounded independent of $\varepsilon, \omega$ and $k$. Then summarizing this yields

$$
\begin{equation*}
\left|\mathbf{v}_{k}(t, \omega)\right|_{H}+\left\|\mathbf{v}_{k}(\cdot, \omega)\right\|_{\mathscr{V}}+\left\|\mathbf{v}_{k}^{\prime}(\cdot, \omega)\right\|_{\mathscr{V}^{\prime}}+\left\|\mathbf{u}_{k}(t, \omega)\right\|_{V} \leq C(\omega) \tag{70.5.44}
\end{equation*}
$$

where $C$ is some constant which does not depend on $\varepsilon, \omega$, and $k$. Also, integrating 70.5.43, it follows that

$$
\begin{gather*}
i_{k}^{*}\left(\mathbf{v}_{k}(t)-\mathbf{v}_{0 k}+\int_{0}^{t} M \mathbf{v}_{k} d s+\int_{0}^{t} A \mathbf{u}_{k} d s+\int_{0}^{t} P \mathbf{u}_{k} d s+\right. \\
\left.\int_{0}^{t} \gamma_{T}^{*} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) d s\right)=i_{k}^{*} \int_{0}^{t} \mathbf{f} d s \tag{70.5.45}
\end{gather*}
$$

Where $i_{k}^{*}$ is the dual map to the inclusion map $i_{k}: V_{k} \rightarrow V$.
Let

$$
V \subseteq W, V \text { dense in } W
$$

where the embedding is compact and the trace map onto the boundary of $U$ is continuous. Using Theorem 70.5.2 and 70.5.1, it follows that for a fixed $\omega$, there exist the following convergences valid for a suitable subsequence, still denoted as $\left\{\mathbf{v}_{k}\right\}$ which may depend on $\omega$.

$$
\begin{gather*}
\mathbf{v}_{k} \rightharpoonup \mathbf{v} \text { in } \mathscr{V}  \tag{70.5.46}\\
\mathbf{v}_{k}^{\prime} \rightharpoonup \mathbf{v}^{\prime} \text { in } \mathscr{V}^{\prime}  \tag{70.5.47}\\
\mathbf{v}_{k} \rightarrow \mathbf{v} \text { strongly in } C\left([0, T], W^{\prime}\right)  \tag{70.5.48}\\
\mathbf{v}_{k} \rightarrow \mathbf{v} \text { strongly in } L^{2}([0, T] ; W)  \tag{70.5.49}\\
\mathbf{v}_{k}(t) \rightarrow \mathbf{v}(t) \text { in } W \text { for } \text { a.e.t }  \tag{70.5.50}\\
\mathbf{u}_{k} \rightarrow \mathbf{u} \text { strongly in } C([0, T] ; W)  \tag{70.5.51}\\
A \mathbf{u}_{k} \rightharpoonup A \mathbf{u} \text { in } \mathscr{V}^{\prime}  \tag{70.5.52}\\
M \mathbf{v}_{k} \rightharpoonup M \mathbf{v} \text { in } \mathscr{V}^{\prime} \tag{70.5.53}
\end{gather*}
$$

Now from these convergences and the density of $\cup_{n} V_{n}$, it follows on passing to a limit and using dominated convergence theorem and the strong convergences above in the nonlinear terms, we obtain the following equation which holds in $V^{\prime}$.

$$
\mathbf{v}(t)-\mathbf{v}_{0}+\int_{0}^{t} M \mathbf{v} d s+\int_{0}^{t} A \mathbf{u} d s+\int_{0}^{t} P \mathbf{u} d s+
$$

$$
\begin{equation*}
\left.\int_{0}^{t} \gamma_{T}^{*} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{\varepsilon}^{\prime}\left(\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right) d s\right)=\int_{0}^{t} \mathbf{f} d s \tag{70.5.54}
\end{equation*}
$$

Thus $t \rightarrow \mathbf{v}(t, \omega)$ is continuous into $V^{\prime}$. This along with the estimate 70.5 .44 , implies that the conditions of Theorem 70.2 .1 are satisfied. It follows that there is a function $\overline{\mathbf{v}}$ which is product measurable into $V^{\prime}$ and weakly continuous in $t$ and for each $\omega$, a subsequence $\mathbf{v}_{k(\omega)}$ such that $\mathbf{v}_{k(\omega)}(\cdot, \omega) \rightharpoonup \overline{\mathbf{v}}(\cdot, \omega)$ in $\mathscr{V}^{\prime}$. Then by a repeat of the above argument, for each $\omega$, there exists a further subsequence still denoted as $\mathbf{v}_{k(\omega)}$ which converges in $\mathscr{V}^{\prime}$ to $\mathbf{v}(\cdot, \omega)$ which is a solution to the above integral equation which is continuous into $V^{\prime}$. Hence, $\overline{\mathbf{v}}(\cdot, \omega)=\mathbf{v}(\cdot, \omega)$ and since these are both weakly continuous into $V^{\prime}$ they must be the same function. Hence, there is a product measurable solution $\mathbf{v}$.

Next we pass to a limit as $\varepsilon \rightarrow 0$. Denoting the product measurable solution to the above integral equation as $\mathbf{v}_{k}$, where $\varepsilon=1 / k$. The estimate 70.5.42 is obtained as before. Then we get a subsequence, still denoted as $\mathbf{v}_{k}$ which has the same convergences as in 70.5.46-70.5.53. Thus we obtain these convergences along with the fact that $\mathbf{v}_{k}$ is product measurable and for each $\omega$, it is a solution of

$$
\begin{gather*}
\mathbf{v}_{k}(t)-\mathbf{v}_{0}+\int_{0}^{t} M \mathbf{v}_{k} d s+\int_{0}^{t} A \mathbf{u}_{k} d s+\int_{0}^{t} P \mathbf{u}_{k} d s+ \\
\int_{0}^{t} \gamma_{T}^{*} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{1 / k}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) d s=\int_{0}^{t} \mathbf{f} d s \tag{70.5.55}
\end{gather*}
$$

Now in addition to these convergences, we can also obtain

$$
\psi_{1 / k}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \rightharpoonup \xi \text { in } L^{\infty}\left([0, T] ; L^{\infty}\left(\Gamma_{C}\right)^{3}\right)
$$

We have also

$$
\psi_{1 / k}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \cdot \mathbf{w}_{T} \leq \psi_{1 / k}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}+\mathbf{w}_{T}\right)-\psi_{1 / k}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right)
$$

and so, passing to a limit, using the strong convergence of $\mathbf{v}_{k T}$ to $\mathbf{v}_{T}$ in $L^{2}([0, T] ; W)$, uniform convergence of $\psi_{1 / k}$ to $\|\cdot\|$, and pointwise convergence in $W$, we obtain using the dominated convergence theorem that for $\mathbf{w} \in \mathscr{V}$,

$$
\begin{aligned}
& \int_{0}^{t} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \psi_{1 / k}^{\prime}\left(\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right) \cdot \mathbf{w}_{T} d x d s \\
\rightarrow & \int_{0}^{t} \int_{\Gamma_{C}} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \xi \cdot \mathbf{w}_{T} d x d s
\end{aligned}
$$

where

$$
\begin{equation*}
\int_{0}^{t} \int_{\Gamma_{C}} \xi \cdot \mathbf{w}_{T} d \alpha d s \leq \int_{0}^{t} \int_{\Gamma_{C}}\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}+\mathbf{w}_{T}\right|-\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right| d \alpha d s \tag{70.5.56}
\end{equation*}
$$

Then passing to the limit in the integral equation 70.5.55, we obtain that $\mathbf{v}$ is a solution for each $\omega$ to the integral equation

$$
\mathbf{v}(t)-\mathbf{v}_{0}+\int_{0}^{t} M \mathbf{v} d s+\int_{0}^{t} A \mathbf{u} d s+\int_{0}^{t} P \mathbf{u} d s+
$$

$$
\begin{equation*}
\int_{0}^{t} \gamma_{T}^{*} F\left(\left(u_{n}-g(\omega)\right)_{+}\right) \mu\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right) \xi d s=\int_{0}^{t} \mathbf{f} d s \tag{70.5.57}
\end{equation*}
$$

where $\xi$ satisfies the inequality 70.5 .56 . In particular, $\mathbf{v}$ is continuous into $V^{\prime}$ and now, the conclusion of the measurable selection theorem applies and yields the existence of a measurable solution to the integral equation just displayed for each $\omega$. Taking a weak derivative, it follows that we have obtained a measurable solution to the system 70.5.3370.5.36.

In this case of Lipschitz $\mu$ one can show that the solution for each $\omega$ to the above integral equation is unique although this it is not an obvious theorem. This follows standard procedures involving Gronwall's inequality and estimates. Therefore, it is possible to obtain the measurability using more elementary methods. In addition, it becomes possible to include a stochastic integral of the form $\int_{0}^{t} \Phi d W$. In this case one must consider a filtration and obtain solutions which are adapted to the filtration. In the next section we consider the case of discontinuous friction coefficient and in this case it is not clear whether there is uniqueness but we have still obtained a measurable solution.

### 70.5.3 Discontinuous coefficient of friction

In this section we consider the case where the coefficient of friction is a discontinuous function of the slip speed. This is the case described in elementary physics courses which state that the coefficient of sliding friction is less than the coefficient of static friction. Specifically, we assume the function $\mu$, has a jump discontinuity at 0 , becoming smaller when the speed is positive.

Fig. 2. The graph of $\mu$ vs. the slip rate $\left|\mathbf{v}_{*}\right|$, and $v$.
We assume the function $\mu_{s}$ of the picture is Lipschitz continuous and decreasing just as shown. The new function $v$ is extended for $r<0$ as shown and is just $\mu_{s}(r)+\eta$ for $r>0$.

Let

$$
\begin{aligned}
& h_{\varepsilon}(r) \equiv\left(\eta^{2} r^{2}+\varepsilon\right)^{1 / 2} \\
& \mu_{\varepsilon}(r)=v(r)-h_{\varepsilon}^{\prime}(r)
\end{aligned}
$$

Thus $\mu_{\varepsilon}$ is bounded, Lipschitz continuous and as $\varepsilon \rightarrow 0, \mu_{\varepsilon}(r) \rightarrow \mu(r)$ for $r>0$. Thus,
for each $\varepsilon=1 / k$, there exists a measurable solution to the integral equation

$$
\begin{array}{r}
\mathbf{v}_{k}(t)-\mathbf{v}_{0}+\int_{0}^{t} M \mathbf{v}_{k} d s+\int_{0}^{t} A \mathbf{u}_{k} d s+\int_{0}^{t} P \mathbf{u}_{k} d s+ \\
\int_{0}^{t} \gamma_{T}^{*} F\left(\left(u_{k n}-g(\omega)\right)_{+}\right) \mu_{1 / k}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \xi_{k} d s=\int_{0}^{t} \mathbf{f} d s \tag{70.5.58}
\end{array}
$$

where

$$
\begin{equation*}
\int_{0}^{t} \int_{\Gamma_{C}} \xi_{k} \cdot \mathbf{w}_{T} d \alpha d s \leq \int_{0}^{t} \int_{\Gamma_{C}}\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}+\mathbf{w}_{T}\right|-\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right| d \alpha d s \tag{70.5.59}
\end{equation*}
$$

Now for a given $\omega$, the same estimate obtained earlier, 70.5.42 is available. Thus

$$
\left|\mathbf{v}_{k}(t)\right|_{H}^{2}+\int_{0}^{T}\left\|\mathbf{v}_{k}\right\|_{V}^{2} d s+\left\|\mathbf{u}_{k}(t)\right\|_{V}^{2} \leq C
$$

where $C$ is not dependent on $k$. Recall also that $\xi_{k}$ is bounded. Hence from 70.5 .58 , and this estimate, it also follows that $\mathbf{v}_{k}^{\prime}$ is bounded in $\mathscr{V}^{\prime}$. Thus

$$
\left|\mathbf{v}_{k}(t)\right|_{H}^{2}+\int_{0}^{T}\left\|\mathbf{v}_{k}\right\|_{V}^{2} d s+\left\|\mathbf{u}_{k}(t)\right\|_{V}^{2}+\left\|\mathbf{v}_{k}^{\prime}\right\|_{\mathscr{V}^{\prime}} \leq C
$$

As earlier, we can take $C$ independent of $k$ and $\omega$ although we do not need this constant to be independent of $\omega$. Now for fixed $\omega$, there exists a subsequence, still denoted as $\left\{\mathbf{v}_{k}\right\}$ such that the convergences obtained earlier all hold, that is 70.5.46-70.5.53. Taking a further subsequence, we may assume also that

$$
\begin{gathered}
\psi-h_{1 / k}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \rightharpoonup 0 \text { in } L^{\infty}\left([0, T], L^{\infty}\left(\Gamma_{C}\right)\right) \\
\xi_{k} \rightharpoonup \xi \text { weak } * \text { in } L^{\infty}\left([0, T], L^{\infty}\left(\Gamma_{C}\right)^{3}\right)
\end{gathered}
$$

That is, $h_{1 / k}^{\prime}\left(\left|\mathbf{v}_{(1 / k) T}-\dot{\mathbf{U}}_{T}\right|\right)$ converges weak $*$ in $L^{\infty}\left([0, T], L^{\infty}\left(\Gamma_{C}\right)\right)$ to some $\psi$. This is because

$$
h_{\varepsilon}^{\prime}(r)=\frac{\eta^{2} r}{\sqrt{r^{2} \eta^{2}+\varepsilon}}
$$

and this is bounded. Letting $w \in L^{1}\left([0, T] ; L^{1}\left(\Gamma_{C}\right)\right)$,

$$
\begin{aligned}
& \int_{0}^{T} \int_{\Gamma_{C}} h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) w d \alpha d t \\
\leq & \int_{0}^{T} \int_{\Gamma_{C}} h_{(1 / k)}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|+w\right)-h_{(1 / k)}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) d \alpha d t
\end{aligned}
$$

Thanks to the strong convergences and the uniform convergence of $h_{(1 / k)}(r)$ to $|\eta r|$,

$$
\int_{0}^{T} \int_{\Gamma_{C}} \psi w d \alpha d t \leq \int_{0}^{T} \int_{\Gamma_{C}}\left|\eta\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|+w\right)\right|-\eta\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right| d \alpha d t
$$

Therefore, for a.e.t, $\psi(t, \mathbf{x}, \omega)$ is in the subgradient of the function $\phi_{\eta}(r)=|\eta r|$ for a.e. $\mathbf{x} \in$ $\Gamma_{C}$ at the point $r=\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|$. In particular, $\psi \in[-\eta, \eta]$ so that $v\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)-\psi$ is between $\mu_{s}(0)$ and $\mu_{0}$ if $\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|=0$. If this quantity is positive, then $\psi=\eta$ and $v\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)-\psi$ reduces to $\mu_{s}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)$. Thus

$$
\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|, v\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)-\psi\right)
$$

is in the graph of $\mu$ a.e. Similar reasoning based on strong convergence and 70.5.59 implies that for a.e.t, $\xi \in \partial \gamma$ where $\gamma(\mathbf{y})=|\mathbf{y}|$ at the point $\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}$ for a.e. $\mathbf{x} \in \Gamma_{C}$.

Consider the friction terms in 70.5.58. Letting $\mathbf{w} \in \mathscr{V}$ and recalling that $\mu_{(1 / k)}(r)=$ $v(r)-h_{(1 / k)}^{\prime}(r)$,

$$
\begin{gather*}
\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right) \mu_{(1 / k)}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) \xi_{k} \cdot \mathbf{w}_{T} d \alpha d t \\
=\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(v\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)\right) \xi_{k} \cdot \mathbf{w}_{T} d \alpha d t \\
=\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(v\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)-\psi\right) \xi_{k} \cdot \mathbf{w}_{T} d \alpha d t  \tag{70.5.60}\\
+\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(\psi-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)\right) \xi_{k} \cdot \mathbf{w}_{T} d \alpha d t \tag{70.5.61}
\end{gather*}
$$

Now consider the first integral. The strong convergence yields that this integral in 70.5.60 converges to

$$
\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{n}-g\right)_{+}\right)\left(v\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right)-\psi\right) \xi \cdot \mathbf{w}_{T} d \alpha d t
$$

where $v\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right)-\psi$ is in the graph of $\mu$ a.e.
Consider the second integral in 70.5.61.

$$
\begin{gathered}
\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(\psi-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)\right) \xi_{k} \cdot \mathbf{w}_{T} d \alpha d t \\
\leq \int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(\psi-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)\right) \\
\quad\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}+\mathbf{w}_{T}\right|-\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) d \alpha d t
\end{gathered}
$$

Similarly,

$$
\begin{gathered}
-\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(\psi-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)\right) \xi_{k} \cdot \mathbf{w}_{T} d \alpha d t \\
\quad \leq \int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(\psi-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)\right) \\
\quad\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}-\mathbf{w}_{T}\right|-\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right) d \alpha d t
\end{gathered}
$$

Each of these integrals on the right side converge to 0 because, from the strong convergence results,

$$
F\left(\left(u_{k n}-g\right)_{+}\right)\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T} \pm \mathbf{w}_{T}\right|-\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)
$$

converges in $L^{1}\left([0, T], L^{1}\left(\Gamma_{C}\right)\right)$ and so the weak $*$ convergence to 0 of

$$
\psi-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)
$$

implies that these integrals converge to 0 . Thus the integral in 70.5.61

$$
\int_{0}^{T} \int_{\Gamma_{C}} F\left(\left(u_{k n}-g\right)_{+}\right)\left(\psi-h_{(1 / k)}^{\prime}\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|\right)\right) \xi_{k} \cdot \mathbf{w}_{T} d \alpha d t
$$

is between two sequences each of which converges to 0 so it also converges to 0 .
To save space, denote by

$$
\hat{\mu}=v\left(\left|\mathbf{v}_{T}-\dot{\mathbf{U}}_{T}\right|\right)-\psi
$$

Then passing to the limit in this subsequence, we obtain for fixed $\omega$ the existence of a solution to the following integral equation.

$$
\begin{equation*}
\mathbf{v}(t)-\mathbf{v}_{0}+\int_{0}^{t} M \mathbf{v} d s+\int_{0}^{t} A \mathbf{u} d s+\int_{0}^{t} P \mathbf{u} d s+\int_{0}^{t} \gamma_{T}^{*} F\left(\left(u_{n}-g\right)_{+}\right) \hat{\mu} \xi d s=\int_{0}^{t} \mathbf{f} d s \tag{70.5.62}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathbf{u}(t)=\mathbf{u}_{0}+\int_{0}^{t} \mathbf{v}(s) d s \tag{70.5.63}
\end{equation*}
$$

and $\left(\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right|, \hat{\mu}\right)$ is contained in the graph of $\mu$ a.e. Also for each $\mathbf{w} \in \mathscr{V}$,

$$
\begin{equation*}
\int_{0}^{T} \int_{\Gamma_{C}} \xi \cdot \mathbf{w}_{T} d \alpha d s \leq \int_{0}^{T} \int_{\Gamma_{C}}\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}+\mathbf{w}_{T}\right|-\left|\mathbf{v}_{k T}-\dot{\mathbf{U}}_{T}\right| d \alpha d s \tag{70.5.64}
\end{equation*}
$$

The remaining issue concerns the existence of a measurable solution. However, this follows in the same way as before from the measurable selection theorem, Theorem 70.2.1. From the above reasoning, for fixed $\omega$ any sequence has a subsequence which leads to a solution to the integral equation $70.5 .62-70.5 .64$ which is continuous into $V^{\prime}$. There is also an estimate of the right sort for all of the $\mathbf{v}_{k}$. Therefore, from this theorem, there is a function $\mathbf{v}(\cdot, \omega)$ in $\mathscr{V}^{\prime}$ which is weakly continuous into $V^{\prime}$ and a sequence $\mathbf{v}_{k(\omega)}(\cdot, \omega)$ converging to $\mathbf{v}(\cdot, \omega)$. Then from the above argument, a subsequence converges to a solution to the integral equation and since both are weakly continuous into $V^{\prime}$, it follows that the solution to the integral equation equals this measurable function for all $t$, this for each $\omega$. Thus there is a measurable solution to the stochastic friction problem. The result is stated in the following theorem.

Theorem 70.5.3 For each $\omega$ let $\mathbf{u}_{0}(\omega) \in V, \mathbf{v}_{0}(\omega) \in H$. Let $\mathbf{f} \in \mathscr{V}^{\prime}$. Also assume the gap $g$ and sliding velocity $\dot{\mathbf{U}}_{T}$ are $\mathscr{F}$ measurable. Then there exists a solution $\mathbf{v}$, to the problem summarized in 70.5.62-70.5.64 for each $\omega$. This solution $(t, \omega) \rightarrow \mathbf{v}(t, \omega)$ is measurable into $V^{\prime}, H^{\prime}$ and $V^{\prime}$.

It only remains to check the last claim about measurability into the other spaces. By density of $V$ into $H$, it follows that $H^{\prime}$ is dense in $V^{\prime}$ and so a simple Pettis theorem argument implies right away that $\omega \rightarrow \mathbf{v}(t, \omega)$ is $\mathscr{F}$ measurable into both $V$ and $H$.

## Chapter 71

## Stochastic O.D.E. One Space

### 71.1 Adapted Solutions With Uniqueness

Instead of a single $\sigma$ algebra $\mathscr{F}$, one can generalize to the case of a normal filtration $\mathscr{F}_{t}$ and obtain adapted solutions to finite dimensional theorems, provided one also knows path uniqueness of the solutions. Recall that a filtration is normal includes the following condition which is what we will use.

$$
\begin{equation*}
\mathscr{F}_{t}=\cap_{s>t} \mathscr{F}_{s} \tag{71.1.1}
\end{equation*}
$$

Theorem 71.1.1 Suppose $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \in \mathbb{R}^{d}$ for $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbb{R}^{d}, t \in[0, T]$ and

$$
(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)
$$

is progressively measurable with respect to a normal filtration or more generally one which satisfies 71.1.1. Also suppose $(t, \mathbf{u}, \mathbf{v}, \mathbf{w}) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)$ is continuous. Suppose for each $\omega$, there exists an estimate for any solution $\mathbf{u}(\cdot, \omega)$ to the integral equation

$$
\begin{equation*}
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s \tag{71.1.2}
\end{equation*}
$$

which is of the form

$$
\sup _{t \in[0, T]}|\mathbf{u}(t, \omega)| \leq C(\omega)<\infty
$$

Also let $\mathbf{f}$ be progressively measurable and $\mathbf{f}(\cdot, \omega) \in L^{1}\left([0, T] ; \mathbb{R}^{d}\right)$. Here $\mathbf{u}_{0}$ has values in $\mathbb{R}^{d}$ and is $\mathscr{F}_{0}$ measurable and $\mathbf{u}(s-h, \omega) \equiv \mathbf{u}_{0}(\omega)$ whenever $s-h \leq 0$ and

$$
\mathbf{w}(t, \omega) \equiv \mathbf{w}_{0}(\omega)+\int_{0}^{t} \mathbf{u}(s, \omega) d s
$$

where $\mathbf{w}_{0}$ is a given $\mathscr{F}_{0}$ measurable function. Also assume that for each $\omega$ there is at most one solution to the integral equation 71.1.2. Then for $h>0$, there exists a progressively measurable solution $\mathbf{u}$ to the integral equation 71.1.2.

Proof: Let $0=t_{0}<t_{1}<\cdots<t_{n}=T$. From Theorem 70.3.3, there exists a solution to the integral equation $\mathbf{u}$ which has the property that $\mathbf{u}\left(t \wedge t_{j}\right)$ is $\mathscr{F}_{t_{j}}$ measurable. One simply applies this theorem to the succession of intervals determined by the given partition. Now suppose $\mathscr{P}^{n}$ consists of the points $k 2^{-n} T \equiv t_{j}^{n}$ so that these satisfy $\mathscr{P}^{n} \subseteq \mathscr{P}^{n+1}$ and the lengths of the sub-intervals decreases to 0 with increasing $n$. Let $\mathbf{u}_{n}$ denote the solution just described corresponding to $\mathscr{P}^{n}$ such that $\mathbf{u}_{n}\left(t \wedge t_{j}^{n}\right)$ is $\mathscr{F}_{t_{j}^{n}}$ measurable. As before, using the estimate, these $\mathbf{u}_{n}(\cdot, \omega)$ for a fixed $\omega$ are uniformly bounded and equicontinuous. This is because it is a solution to the integral equation for each $\omega$ and so by assumption, there is an estimate. Therefore, for fixed $\omega$, there exists $\mathbf{u}(\cdot, \omega)$ and a subsequence, denoted as $\mathbf{u}_{n}(\cdot, \omega)$ which converges uniformly to $\mathbf{u}(\cdot, \omega)$ on $[0, T]$. Therefore, $\mathbf{u}(\cdot, \omega)$ will be a
solution to the integral equation for that $\omega$. It follows from the uniqueness assumption, that it is not necessary to take a subsequence. Thus

$$
\mathbf{u}(t, \omega)=\lim _{n \rightarrow \infty} \mathbf{u}_{n}(t, \omega)
$$

For $t \in\left(t_{j-1}^{n}, t_{j}^{n}\right]$, it follows that $\omega \rightarrow \mathbf{u}(t, \omega)$ is $\mathscr{F}_{t_{j}^{n}}$ measurable. Since this is true for each $n$ and the filtration is assumed to be a normal filtration, we conclude that $\omega \rightarrow \mathbf{u}(t, \omega)$ is $\mathscr{F}_{t}$ measurable.

Why can't this be generalized to the situation where no uniqueness is known? We have been unable to do this. It appears that the difficulty is related to the need to use theorems about measurable selections and these theorems pertain to a single $\sigma$ algebra. Attempts to use the $\sigma$ - algebra of progressively measurable sets have not been successful either.

### 71.2 Including Stochastic Integrals

It is not surprising that Theorem 71.1.1 is sufficient to allow the inclusion of a stochastic integral. Thus, with the same descriptions of the symbols used in that theorem, one could consider the following integral equation.

$$
\begin{aligned}
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega)+ & \int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s \\
& =\int_{0}^{t} \mathbf{f}(s, \omega) d s+\int_{0}^{t} \Phi d W
\end{aligned}
$$

where, as usual $\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, \mathbb{R}^{d}\right)\right)$ where $U$ is a Hilbert space. It could be $\mathbb{R}^{d}$ of course. To include a stochastic integral, you define a new variable.

$$
\hat{\mathbf{u}}(t)=\mathbf{u}(t)-\int_{0}^{t} \Phi d W
$$

Then in terms of this new variable, the integral equation is

$$
\begin{gathered}
\hat{\mathbf{u}}(t, \omega)-\mathbf{u}_{0}(\omega)+\int_{0}^{t} \mathbf{N}\left(s, \hat{\mathbf{u}}(s, \omega)+\int_{0}^{s} \Phi d W, \hat{\mathbf{u}}(s-h, \omega)+\int_{0}^{s-h} \Phi d W\right. \\
\left.\int_{0}^{s}\left(\hat{\mathbf{u}}(r)+\int_{0}^{r} \Phi d W\right) d r, \omega\right) d s=\int_{0}^{t} \mathbf{f}(s, \omega) d s
\end{gathered}
$$

This is in the situation of Theorem 71.1.1 provided $\mathbf{N}$ is progressively measurable with respect to the normal filtration $\mathscr{F}_{t}$ determined by the Wiener process and there exists an estimate of the sort in this theorem and for a given $\omega$ there is at most one solution $t \rightarrow$ $\hat{\mathbf{u}}(t, \omega)$ to the above integral equation.

Theorem 71.2.1 Suppose $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \in \mathbb{R}^{d}$ for $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbb{R}^{d}, t \in[0, T]$ and

$$
(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)
$$

is progressively measurable with respect to the normal filtration $\mathscr{F}_{t}$ determined by a given Wiener process $W(t)$. Also suppose

$$
(t, \mathbf{u}, \mathbf{v}, \mathbf{w}) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)
$$

is continuous and satisfies the following conditions for $C(\cdot, \omega) \geq 0$ in $L^{1}([0, T])$ and some $\mu>0$ :

$$
\begin{equation*}
(\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega), \mathbf{u}) \geq-C(t, \omega)-\mu\left(|\mathbf{u}|^{2}+|\mathbf{v}|^{2}+|\mathbf{w}|^{2}\right) . \tag{71.2.3}
\end{equation*}
$$

Also let $\mathbf{f}$ be progressively measurable and $\mathbf{f}(\cdot, \omega) \in L^{2}\left([0, T] ; \mathbb{R}^{d}\right)$. Let

$$
\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, \mathbb{R}^{d}\right)\right)
$$

where $U$ is some Hilbert space, $\mathbb{R}^{d}$, for example. Also suppose path uniqueness. That is, for each $\omega$, there is at most one solution to the integral equation

$$
\begin{align*}
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega) & +\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s \\
& =\int_{0}^{t} \mathbf{f}(s, \omega) d s+\int_{0}^{t} \Phi d W \tag{71.2.4}
\end{align*}
$$

Then for $h>0$, there exists a unique progressively measurable solution $\mathbf{u}$ to the integral equation 71.2 .4 where $\mathbf{u}_{0}$ has values in $\mathbb{R}^{d}$ and is $\mathscr{F}_{0}$ measurable. Here $\mathbf{u}(s-h, \omega) \equiv$ $\mathbf{u}_{0}(\omega)$ for all $s-h \leq 0$ and for $\mathbf{w}_{0}$ a given $\mathscr{F}_{0}$ measurable function,

$$
\mathbf{w}(t, \omega) \equiv \mathbf{w}_{0}(\omega)+\int_{0}^{t} \mathbf{u}(s, \omega) d s
$$

Proof: The only thing left is to observe that the given estimate is sufficient to obtain an estimate for the solutions to the integral equation for $\hat{\mathbf{u}}$ defined above. Then from Theorem 71.1.1, there exists a unique progressively measurable solution for $\hat{\mathbf{u}}$ and hence for $\mathbf{u}$.

Note that the integral equation holds for all $t$ for each $\omega$. There is no exceptional set of measure zero which might depend on the initial condition needed.

What is a sufficient condition for path uniqueness? Suppose the following weak monotonicity condition for $\mu=\mu(\omega)$.

$$
\begin{align*}
& \left(\mathbf{N}\left(t, \mathbf{u}_{1}, \mathbf{v}_{1}, \mathbf{w}_{1}, \omega\right)-\mathbf{N}\left(t, \mathbf{u}_{2}, \mathbf{v}_{2}, \mathbf{w}_{2}, \omega\right), \mathbf{u}_{1}-\mathbf{u}_{2}\right) \\
\geq \quad & -\mu\left(\left|\mathbf{u}_{1}-\mathbf{u}_{2}\right|^{2}+\left|\mathbf{v}_{1}-\mathbf{v}_{2}\right|^{2}+\left|\mathbf{w}_{1}-\mathbf{w}_{2}\right|^{2}\right) \tag{71.2.5}
\end{align*}
$$

Then path uniqueness will hold. This follows from subtracting the two integral equations, one for $\mathbf{u}_{1}$ and one for $\mathbf{u}_{2}$, using the estimate and then applying Gronwall's inequality.

Recall the Ito formula

$$
u(t)-u_{0}+\int_{0}^{t} N d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W
$$

where $u(t) \in H$ a Hilbert space. Consider $F(u)=\frac{1}{2}|u|^{2}$. Also let $R$ denote the Riesz map from $H \rightarrow H^{\prime}$ such that $\langle R x, y\rangle \equiv(x, y)_{H}$. Then proceding formally, to see what the Ito formula says,

$$
d F=D F(u) d u+\frac{1}{2} D^{2} F(u)(d u, d u)+O\left(d u^{3}\right)
$$

Recall then that $d u=-N d t+f d t+\Phi d W$ and so recalling $(d W, d W)=d t$,

$$
R(u)(-N d t+f d t+\Phi d W)+\frac{1}{2}\|\Phi\|^{2} d t
$$

Hence

$$
\frac{1}{2}|u(t)|_{H}^{2}-\frac{1}{2}\left|u_{0}\right|_{H}^{2}+\int_{0}^{t}(N, u)_{H} d s-\frac{1}{2} \int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s=\int_{0}^{t}(f, u) d s+\int_{0}^{t} R u(\Phi) d W
$$

The last term is a martingale or local martingale $M$ whose quadratic variation is given by

$$
[M](t)=\int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2}|u|^{2} d s
$$

This is all that is of importance in what follows. Therefore, this martingale may be simply denoted as $M(t)$ in what follows.

Under the assumption 71.2.5 you can include instead of the term $\int_{0}^{t} \Phi d W$, the more general term $\int_{0}^{t} \sigma(s, \mathbf{u}, \omega) d W$. This will be shown by doing the argument and indicating what extra assumptions are needed as this is done. Let $\mathbf{z}$ be progressively measurable and in $L^{2}\left(\Omega ; C\left([0, T] ; \mathbb{R}^{n}\right)\right)$. Also assume that $\sigma$ has linear growth. That is

$$
\begin{equation*}
\|\sigma(s, \mathbf{u}, \omega)\|_{\mathscr{L}_{2}} \leq a+b|\mathbf{u}|_{\mathbb{R}^{n}} \tag{71.2.6}
\end{equation*}
$$

Then from the above theorem, there exists a unique progressively measurable solution $\mathbf{u}$ to

$$
\begin{align*}
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega) & +\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s \\
= & \int_{0}^{t} \mathbf{f}(s, \omega) d s+\int_{0}^{t} \sigma(s, \mathbf{z}) d W \tag{71.2.7}
\end{align*}
$$

This holds for all $\omega$. There is no exceptional set needed. Now assume

$$
\begin{equation*}
\mathbf{u}_{0} \in L^{2}(\Omega) \tag{71.2.8}
\end{equation*}
$$

and also a Lipschitz condition

$$
\begin{equation*}
\|\sigma(s, \mathbf{u}, \omega)-\sigma(s, \hat{\mathbf{u}}, \omega)\|_{\mathscr{L}_{2}} \leq K|\mathbf{u}-\hat{\mathbf{u}}| \tag{71.2.9}
\end{equation*}
$$

Then let $\mathbf{u}$ coincide with $\mathbf{z}$ and $\hat{\mathbf{u}}$ come from $\hat{\mathbf{z}}$. Then applying the Ito formula, one can obtain the following for a constant $C$ which does not depend on $\mathbf{u}, \hat{\mathbf{u}}$.

$$
\frac{1}{2}|\mathbf{u}(t)-\hat{\mathbf{u}}(t)|^{2}-C \int_{0}^{t}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2} d s-K \int_{0}^{t}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2} d s=M(t)
$$

where $M(t)$ is a local martingale whose quadratic variation satisfies

$$
[M](t)=\int_{0}^{t}\|\sigma(s, \mathbf{z}, \omega)-\sigma(s, \hat{\mathbf{z}}, \omega)\|_{\mathscr{L}_{2}}^{2}|\mathbf{u}-\hat{\mathbf{u}}|^{2} d s
$$

Thus, simplifying the constants,

$$
\sup _{s \in[0, t]}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2} \leq C \int_{0}^{t}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2} d s+M^{*}(t)
$$

where $M^{*}(t)=\sup _{s \in[0, t]}|M(s)|$. Then by Gronwall's inequality,

$$
\sup _{s \in[0, t]}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2} \leq C M^{*}(t)
$$

Then take the expectation of both sides. Using the Burkholder Davis Gundy inequality,

$$
E\left(\sup _{s \in[0, t]}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2}\right) \leq C E\left(\left(\int_{0}^{t} K|\mathbf{z}-\hat{\mathbf{z}}|^{2}|\mathbf{u}-\hat{\mathbf{u}}|^{2} d s\right)^{1 / 2}\right)
$$

Then adjusting the constant again,

$$
\leq \frac{1}{2} E\left(\sup _{s \in[0, t]}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2}\right)+C E\left(\int_{0}^{t} K|\mathbf{z}-\hat{\mathbf{z}}|^{2} d s\right)
$$

and so,

$$
E\left(\sup _{s \in[0, t]}|\mathbf{u}(s)-\hat{\mathbf{u}}(s)|^{2}\right) \leq C \int_{0}^{t} E\left(\sup _{r \in[0, s]}|\mathbf{z}(s)-\hat{\mathbf{z}}(s)|^{2}\right) d s
$$

Letting $\mathscr{T} \mathbf{z}=\mathbf{u}$ where $\mathbf{u}$ is defined from $\mathbf{z}$ in the integral equation 71.2.7, the above inequality implies that

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left|\mathscr{T}^{n} \mathbf{z}_{1}(s)-\mathscr{T}^{n} \mathbf{z}_{2}(s)\right|_{H}^{2}\right) \leq C \int_{0}^{t} E\left(\sup _{r \in[0, s]}\left|\mathscr{T}^{n-1} \mathbf{z}_{1}(r)-\mathscr{T}^{n-1} \mathbf{z}_{2}(r)\right|^{2}\right) d s \\
\leq C^{2} \int_{0}^{t} \int_{0}^{s} E\left(\sup _{r_{1} \in[0, r]}\left|\mathscr{T}^{n-2} \mathbf{z}_{1}\left(r_{1}\right)-\mathscr{T}^{n-2} \mathbf{z}_{2}\left(r_{1}\right)\right|^{2}\right) d r d s
\end{gathered}
$$

One can iterate this, eventually finding that

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left|\mathscr{T}^{n} \mathbf{z}_{1}(s)-\mathscr{T}^{n} \mathbf{z}_{2}(s)\right|_{H}^{2}\right) \\
\leq C^{n} \int_{0}^{t} \int_{0}^{t_{1}} \cdots \int_{0}^{t_{n-1}} d t_{n-1} \cdots d t E\left(\sup _{s \in[0, t]}\left|\mathbf{z}_{1}(s)-\mathbf{z}_{2}(s)\right|_{H}^{2}\right) \\
=\frac{C^{n} T^{n}}{(n!)} E\left(\sup _{s \in[0, t]}\left|\mathbf{z}_{1}(s)-\mathbf{z}_{2}(s)\right|_{H}^{2}\right)
\end{gathered}
$$

In particular, this holds for $t=T$ and so, letting $\mathbf{z} \in L^{2}\left(\Omega, C\left([0, T], \mathbb{R}^{n}\right)\right),\left\{\mathscr{T}^{n} \mathbf{z}\right\}$ is a Cauchy sequence in this space because a high enough power is a contraction map, so it converges to a unique fixed point $\mathbf{u}$. Each $\mathscr{T}^{n} \mathbf{z}$ is progressively measurable and so the fixed point is also. In $L^{2}\left(\Omega, C\left([0, T], \mathbb{R}^{n}\right)\right)$, you get the integral equation

$$
\begin{align*}
\mathbf{u}(t, \omega)-\mathbf{u}_{0}(\omega) & +\int_{0}^{t} \mathbf{N}(s, \mathbf{u}(s, \omega), \mathbf{u}(s-h, \omega), \mathbf{w}(s, \omega), \omega) d s \\
= & \int_{0}^{t} \mathbf{f}(s, \omega) d s+\int_{0}^{t} \sigma(s, \mathbf{u}) d W \tag{71.2.10}
\end{align*}
$$

Thus off a set of measure zero, the equation holds for all $t$ and $\mathbf{u}$ is progressively measurable. The place where $\mathbf{u}_{0} \in L^{2}(\Omega)$ is needed is in having $\mathscr{T} \mathbf{z} \in L^{2}\left(\Omega, C\left([0, T] ; \mathbb{R}^{n}\right)\right)$. One uses a similar procedure involving the Ito formula, the growth condition

$$
(\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega), \mathbf{u}) \geq-C(t, \omega)-\mu\left(|\mathbf{u}|^{2}+|\mathbf{v}|^{2}+|\mathbf{w}|^{2}\right)
$$

and the Burkholder Davis Gundy inequality to verify this. Since $\mathscr{T}$ depends on $\mathbf{u}_{0}$, it appears that the set of measure zero, off which the integral equation holds, will also depend on $\mathbf{u}_{0}$. It appears that this ultimately results from the need to take an expectation in order to deal with the stochastic integral. If this integral could be generalized in such a way that it made sense for each $\omega$ as in the usual Riemann Stieltjes integral, then likely this restriction could be removed. It is a problem because the Wiener process is not of bounded variation.

Theorem 71.2.2 Suppose the weak monotonicity condition 71.2.5 and the growth estimate 71.2.3. Also assume $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \in \mathbb{R}^{d}$ for $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbb{R}^{d}, t \in[0, T]$ and $(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega) \rightarrow$ $\mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)$ is progressively measurable with respect to the normal filtration $\mathscr{F}_{t}$ determined by a given Wiener process $W(t)$. Also suppose $(t, \mathbf{u}, \mathbf{v}, \mathbf{w}) \rightarrow \mathbf{N}(t, \mathbf{u}, \mathbf{v}, \mathbf{w}, \omega)$ is continuous. Let $\mathbf{f} \in L^{2}\left(\Omega, C\left([0, T], \mathbb{R}^{n}\right)\right)$ and $(t, \mathbf{u}, \omega) \rightarrow \sigma(t, \mathbf{u}, \omega)$ is progressively measurable and satisfies the linear growth condition 71.2.6 and the Lipschitz condition 71.2.9. Also suppose $\mathbf{u}_{0}$ is $\mathscr{F}_{0}$ measurable and in $L^{2}\left(\Omega, \mathbb{R}^{n}\right)$. Then there exists a progressively measurable solution $\mathbf{u}$ to 71.2.10. If $\hat{\mathbf{u}}$ is another such solution, then there is a set of measure zero $N$ such that for $\omega \notin N, \hat{\mathbf{u}}(t)=\mathbf{u}(t)$ for all $t$.

Proof: It only remains to verify the uniqueness assertion. This happens because the fixed point is unique in $L^{2}\left(\Omega, C\left([0, T], \mathbb{R}^{n}\right)\right)$. Therefore, off a set of measure zero the two solutions are equal for all $t$.

### 71.3 Stochastic Differential Equations

In this section, ordinary differential equations in Hilbert space which are of the form

$$
d u+N(u) d t=f d t+\sigma(u) d W
$$

are considered under Lipschitz assumptions on $N$ and $\sigma$. A very satisfactory theorem can be proved.

The assumptions made are as follows.

$$
\begin{equation*}
\|\sigma(t, u, \omega)-\sigma(t, \hat{u}, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} \leq K|u-\hat{u}|_{H} \tag{71.3.11}
\end{equation*}
$$

$$
\begin{equation*}
\left|N\left(t, u_{1}, v_{1}, w_{1}, \omega\right)-N\left(t, u_{2}, v_{2}, w_{2}, \omega\right)\right| \leq K\left(\left|u_{1}-u_{2}\right|+\left|v_{1}-v_{2}\right|+\left|w_{1}-w_{2}\right|\right) \tag{71.3.12}
\end{equation*}
$$

where the norms $|\cdot|$ refer here to the Hilbert space $H$. Assume $N, \sigma$ are both progressively measurable. From the Lipschitz condition given above,

$$
|N(t, u, v, w, \omega)-N(t, 0,0,0, \omega)| \leq K(|u|+|v|+|w|)
$$

and it is assumed that

$$
\begin{equation*}
t \rightarrow N(t, 0,0,0, \omega) \tag{71.3.13}
\end{equation*}
$$

is in $L^{2}(\Omega, C([0, T] ; H))$. Also consider the growth condition which is implied by the above condition and the Lipschitz assumption.

$$
\begin{equation*}
(N(t, u, v, w, \omega), u) \geq-C(t, \omega)-\mu\left(|u|^{2}+|v|^{2}+|w|^{2}\right) \tag{71.3.14}
\end{equation*}
$$

where $C \in L^{1}([0, T] \times \Omega)$ and the linear growth condition for $\sigma$,

$$
\begin{equation*}
\|\sigma(t, u, \omega)\| \leq a+b|u|_{H} \tag{71.3.15}
\end{equation*}
$$

### 71.3.1 The Lipschitz Case

Theorem 71.3.1 Suppose 71.3.11, 71.3.13, 71.3.15, 71.3.12 and let

$$
w(t)=w_{0}+\int_{0}^{t} u(s) d s, w_{0} \in L^{2}(\Omega), w_{0} \text { is } \mathscr{F}_{0} \text { measurable. }
$$

Then there exists a unique progressively measurable solution $u$ to the integral equation

$$
\begin{gather*}
u(t, \omega)-u_{0}(\omega)+\int_{0}^{t} N(s, u(s, \omega), u(s-h, \omega), w(s, \omega), \omega) d s \\
=\int_{0}^{t} f(s, \omega) d s+\int_{0}^{t} \sigma(s, u, \omega) d W \tag{71.3.16}
\end{gather*}
$$

71.3.16 where $u \in L^{2}(\Omega, C([0, T] ; H)), u_{0} \in L^{2}(\Omega), u_{0}$ is $\mathscr{F}_{0}$ measurable, $f$ is progressively measurable and in $L^{2}([0, T] \times \Omega ; H)$. Here there is a set of measure zero such that if $\omega$ is not in this set, then $u(\cdot, \omega)$ solves the above integral equation 71.3 .16 and furthermore, if $\hat{u}(\cdot, \omega)$ is another solution to it, then $u(t, \omega)=\hat{u}(t, \omega)$ for all $t$ if $\omega$ is off some set of measure zero.

Proof: Let $v \in L^{2}(\Omega ; C([0, T] ; H))$ where $v$ is also progressively measurable. Then let $u$ be given by

$$
\begin{gather*}
u(t, \omega)-u_{0}(\omega)+\int_{0}^{t} N(s, v(s, \omega), v(s-h, \omega), w(s, \omega), \omega) d s \\
=\int_{0}^{t} f(s, \omega) d s+\int_{0}^{t} \sigma(s, v, \omega) d W \tag{71.3.17}
\end{gather*}
$$

The Lipschitz condition 71.3.12, the assumption 71.3.13, and the linear growth assertion 71.3.15, implies that $u$ is also in $L^{2}(\Omega ; C([0, T] ; H))$. The proof of this involves the same
arguments about to be given in order to show that this determines a mapping which has a sufficiently high power a contraction map. They are also the same arguments to be used in the following theorem to establish estimates which imply a stopping time is eventually infinity.

Let $v_{1}, v_{2}$ be two given functions of this sort and let the corresponding $u$ be denoted by $u_{1}, u_{2}$ respectively. Then

$$
\begin{gathered}
u_{1}(t)-u_{2}(t)+\int_{0}^{t} N\left(s, v_{1}(s), v_{1}(s-h), w_{1}(s)\right)-N\left(s, v_{2}(s), v_{2}(s-h), w_{2}(s)\right) d s \\
=\int_{0}^{t} \sigma\left(s, v_{1}, \omega\right)-\sigma\left(s, v_{2}, \omega\right) d W
\end{gathered}
$$

Use the Ito formula and the Lipschitz condition on $N$ to obtain an expression of the form

$$
\begin{gathered}
\frac{1}{2}\left|u_{1}(t)-u_{2}(t)\right|^{2}-C \int_{0}^{t}\left|v_{1}-v_{2}\right|^{2} d s-C \int_{0}^{t}\left|u_{1}-u_{2}\right|^{2} d s \\
\quad-\frac{1}{2} \int_{0}^{t}\left\|\sigma\left(s, v_{1}, \omega\right)-\sigma\left(s, v_{2}, \omega\right)\right\|^{2} d s \leq|M(t)|
\end{gathered}
$$

where $M(t)$ is a martingale whose quadratic variation is dominated by

$$
C \int_{0}^{t}\left\|\sigma\left(s, v_{1}, \omega\right)-\sigma\left(s, v_{2}, \omega\right)\right\|^{2}\left|u_{1}-u_{2}\right|^{2} d s
$$

Therefore, using the Lipschitz condition on $\sigma$ and the Burkholder-Davis-Gundy inequality, the above implies

$$
\begin{aligned}
E\left(\sup _{s \in[0, t]}\left|u_{1}(s)-u_{2}(s)\right|^{2}\right) \leq & C E \int_{0}^{t} \sup _{r \in[0, s]}\left|u_{1}(r)-u_{2}(r)\right|^{2} d s \\
& +C E \int_{0}^{t} \sup _{r \in[0, s]}\left|v_{1}(r)-v_{2}(r)\right|^{2} d s \\
\quad+ & C E\left(\left(\int_{0}^{t}\left\|\sigma\left(s, v_{1}, \omega\right)-\sigma\left(s, v_{2}, \omega\right)\right\|^{2}\left|u_{1}-u_{2}\right|^{2} d s\right)^{1 / 2}\right)
\end{aligned}
$$

Then a use of Gronwall's inequality allows this to be simplified to an expression of the form

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left|u_{1}(s)-u_{2}(s)\right|^{2}\right) \leq C E \int_{0}^{t} \sup _{r \in[0, s]}\left|v_{1}(r)-v_{2}(r)\right|^{2} d s \\
+C E\left(\left(\int_{0}^{t}\left\|\sigma\left(s, v_{1}, \omega\right)-\sigma\left(s, v_{2}, \omega\right)\right\|^{2}\left|u_{1}-u_{2}\right|^{2} d s\right)^{1 / 2}\right) \\
\leq C \int_{0}^{t} E\left(\sup _{r \in[0, s]}\left|v_{1}(r)-v_{2}(r)\right|^{2}\right) d s+\frac{1}{2} E\left(\sup _{s \in[0, t]}\left|u_{1}(s)-u_{2}(s)\right|^{2}\right)
\end{gathered}
$$

$$
+C E\left(\int_{0}^{t}\left\|\sigma\left(s, v_{1}, \omega\right)-\sigma\left(s, v_{2}, \omega\right)\right\|^{2} d s\right)
$$

Now using the Lipschitz condition on $\sigma$, this simplifies further to give an inequality of the form

$$
E\left(\sup _{s \in[0, t]}\left|u_{1}(s)-u_{2}(s)\right|^{2}\right) \leq C \int_{0}^{t} E\left(\sup _{r \in[0, s]}\left|v_{1}(r)-v_{2}(r)\right|^{2}\right) d s
$$

Letting $\mathscr{T} v=u$ where $u$ is defined from $v$ in the integral equation 71.3.17, the above inequality implies that

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left|\mathscr{T}^{n} v_{1}(s)-\mathscr{T}^{n} v_{2}(s)\right|_{H}^{2}\right) \leq C \int_{0}^{t} E\left(\sup _{r \in[0, s]}\left|\mathscr{T}^{n-1} v_{1}(r)-\mathscr{T}^{n-1} v_{2}(r)\right|^{2}\right) d s \\
\leq C^{2} \int_{0}^{t} \int_{0}^{s} E\left(\sup _{r_{1} \in[0, r]}\left|\mathscr{T}^{n-2} v_{1}\left(r_{1}\right)-\mathscr{T}^{n-2} v_{2}\left(r_{1}\right)\right|^{2}\right) d r d s
\end{gathered}
$$

One can iterate this, eventually finding that

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left|\mathscr{T}^{n} v_{1}(s)-\mathscr{T}^{n} v_{2}(s)\right|_{H}^{2}\right) \\
\leq C^{n} \int_{0}^{t} \int_{0}^{t_{1}} \cdots \int_{0}^{t_{n-1}} d t_{n-1} \cdots d t E\left(\sup _{s \in[0, t]}\left|v_{1}(s)-v_{2}(s)\right|_{H}^{2}\right) \\
=\frac{C^{n} T^{n}}{(n!)} E\left(\sup _{s \in[0, t]}\left|v_{1}(s)-v_{2}(s)\right|_{H}^{2}\right)
\end{gathered}
$$

In particular, one could take $t=T$. This shows that for all $n$ large enough, $\mathscr{T}^{n}$ is a contraction map on $L^{2}(\Omega, C([0, T] ; H))$. Therefore, picking $v \in L^{2}(\Omega, C([0, T] ; H))$, such that $v$ is also progressively measurable, $\left\{\mathscr{T}^{k} v\right\}_{k=1}^{\infty}$ converges in $L^{2}(\Omega, C([0, T] ; H))$ to the unique fixed point of $\mathscr{T}$ denoted as $u$. Thus $\mathscr{T} u=u$ in $L^{2}(\Omega ; C([0, T] ; H))$. That is,

$$
\int_{\Omega} \sup _{t}|\mathscr{T} u-u|^{2} d P=0
$$

It follows that there is a set of measure zero such that for $\omega$ not in this set,

$$
\begin{gather*}
u(t, \omega)-u_{0}(\omega)+\int_{0}^{t} N(s, u(s, \omega), u(s-h, \omega), w(s, \omega), \omega) d s \\
=\int_{0}^{t} f(s, \omega) d s+\int_{0}^{t} \sigma(s, u, \omega) d W \tag{71.3.18}
\end{gather*}
$$

The function $u$ is progressively measurable because each $\mathscr{T}^{n} v$ is progressively measurable and there exists a subsequence still indexed with $n$ such that for $\omega$ off a set of measure zero, $\mathscr{T}^{n} v(\cdot, \omega) \rightarrow u(\cdot, \omega)$ in $C([0, T] ; H)$.

Note that the fixed point of $\mathscr{T}$ is unique in the space $L^{2}(\Omega ; C([0, T] ; H))$ and so any solution to the integral equation in this space must equal this one. Hence, there exists a set of measure zero such that for $\omega$ off this set, the two solutions are equal for all $t$.

### 71.3.2 The Locally Lipschitz Case

Now replace the Lipschitz assumpton 71.3 .12 with the locally Lipschitz assumption which says that if $\max (|u|,|v|,|w|)<R$, then there is a constant $K_{R}$ such that

$$
\begin{equation*}
\left|N\left(t, u_{1}, v_{1}, w_{1}, \omega\right)-N\left(t, u_{2}, v_{2}, w_{2}, \omega\right)\right| \leq K(R)\left(\left|u_{1}-u_{2}\right|+\left|v_{1}-v_{2}\right|+\left|w_{1}-w_{2}\right|\right) \tag{71.3.19}
\end{equation*}
$$

Also assume the growth condition

$$
\begin{equation*}
(N(t, u, v, w, \omega), u) \geq-C(t, \omega)-\mu\left(|u|^{2}+|v|^{2}+|w|^{2}\right) \tag{71.3.20}
\end{equation*}
$$

and the linear growth condition on $\sigma$

$$
\|\sigma(t, u, \omega)\| \leq a+b|u|_{H}
$$

and the Lipschitz condition on $\sigma$ 71.3.11. This can likely be relaxed as in the case of the Lipschitz condition for $N$ but for simplicity, we keep it.

Theorem 71.3.2 Suppose 71.3.11, 71.3.14, 71.3.15,71.3.13, 71.3.19 and let

$$
w(t)=w_{0}+\int_{0}^{t} u(s) d s, w_{0} \in L^{2}(\Omega), w_{0} \text { is } \mathscr{F}_{0} \text { measurable. }
$$

Then there exists a unique progressively measurable solution $u$ to the integral equation

$$
\begin{gather*}
u(t, \omega)-u_{0}(\omega)+\int_{0}^{t} N(s, u(s, \omega), u(s-h, \omega), w(s, \omega), \omega) d s \\
=\int_{0}^{t} f(s, \omega) d s+\int_{0}^{t} \sigma(s, u, \omega) d W \tag{71.3.21}
\end{gather*}
$$

71.3.16 where $u \in L^{2}(\Omega, C([0, T] ; H)), u_{0} \in L^{2}(\Omega, H)$, $u_{0}$ is $\mathscr{F}_{0}$ measurable, $f$ is progressively measurable and in $L^{2}([0, T] \times \Omega ; H)$. Here there is a set of measure zero such that if $\omega$ is not in this set, then $u(\cdot, \omega)$ solves the above integral equation 71.3.16 and furthermore, if $\hat{u}(\cdot, \omega)$ is another solution to it, then $u(t, \omega)=\hat{u}(t, \omega)$ for all $t$ if $\omega$ is off some set of measure zero.

Proof: Let $u_{n}$ be the unique solution to the integral equation

$$
\begin{align*}
u_{n}(t, \omega)-u_{0}(\omega) & +\int_{0}^{t} N\left(s, P_{n} u_{n}(s, \omega), P_{n} u_{n}(s-h, \omega), P_{n} w_{n}(s, \omega), \omega\right) d s \\
& =\int_{0}^{t} f(s, \omega) d s+\int_{0}^{t} \sigma\left(s, u_{n}, \omega\right) d W \tag{71.3.22}
\end{align*}
$$

where $P_{n}$ is the projection onto $\overline{B\left(0,9^{n}\right)}$. Thus the modified problem is in the situation of Theorem 71.3.1 so there exists such a solution. Then let

$$
\tau_{n}=\inf \left\{t:\left|u_{n}(t)\right|+\left|w_{n}(t)\right|>2^{n}\right\}
$$

Then stopping the equation with this stopping time, we can write

$$
\begin{gather*}
u_{n}^{\tau_{n}}(t, \omega)-u_{0}(\omega)+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} N\left(s, u_{n}^{\tau_{n}}(s, \omega), u_{n}^{\tau_{n}}(s-h, \omega), w_{n}^{\tau_{n}}(s, \omega), \omega\right) d s \\
=\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} f(s, \omega) d s+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} \sigma\left(s, u_{n}^{\tau_{n}}, \omega\right) d W \tag{71.3.23}
\end{gather*}
$$

Then using the growth condition 71.3.20 and the Ito formula,

$$
\frac{1}{2}\left|u_{n}^{\tau_{n}}(t)\right|_{H}^{2} \leq C\left(u_{0}, w_{0}, f\right)+C \int_{0}^{t}\left|u_{n}^{\tau_{n}}\right|_{H}^{2} d s+\sup _{s \in[0, t]}|M(t)|
$$

where $M(t)$ is a martingale whose quadratic variation is dominated by

$$
\int_{0}^{t}\left\|\sigma\left(s, u_{n}^{\tau_{n}}\right)\right\|^{2}\left|u_{n}^{\tau_{n}}\right|^{2} d s
$$

Then it follows by the Burkholder-Davis-Gundy inequality

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left|u_{n}^{\tau_{n}}(s)\right|_{H}^{2}\right) \leq E\left(C\left(u_{0}, w_{0}, f\right)\right)+C \int_{0}^{t} E\left(\sup _{r \in[0, s]}\left|u_{n}^{\tau_{n}}(r)\right|^{2} d r\right) d s \\
+C E\left(\left(\int_{0}^{t}\left\|\sigma\left(s, u_{n}^{\tau_{n}}\right)\right\|^{2}\left|u_{n}^{\tau_{n}}\right|^{2} d s\right)^{1 / 2}\right)
\end{gathered}
$$

Now apply Gronwall's inequality and modify the constants so that

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left|u_{n}^{\tau_{n}}(s)\right|_{H}^{2}\right) \leq E\left(C\left(u_{0}, w_{0}, f\right)\right)+C E\left(\left(\int_{0}^{t}\left\|\sigma\left(s, u_{n}^{\tau_{n}}\right)\right\|^{2}\left|u_{n}^{\tau_{n}}\right|^{2} d s\right)^{1 / 2}\right) \\
\quad \leq E\left(C\left(u_{0}, w_{0}, f\right)\right)+\frac{1}{2} E\left(\sup _{s \in[0, t]}\left|u_{n}^{\tau_{n}}(s)\right|_{H}^{2}\right)+C E\left(\int_{0}^{t}\left\|\sigma\left(s, u_{n}^{\tau_{n}}\right)\right\|^{2} d s\right)
\end{gathered}
$$

Then, using the linear growth condition on $\sigma$, it follows on modification of the constants again that

$$
\begin{aligned}
E\left(\sup _{s \in[0, t]}\left|u_{n}^{\tau_{n}}(s)\right|_{H}^{2}\right) & \leq E\left(C\left(u_{0}, w_{0}, f\right)\right)+C E\left(\int_{0}^{t}\left|u_{n}^{\tau_{n}}\right|^{2} d s\right) \\
& \leq E\left(C\left(u_{0}, w_{0}, f\right)\right)+C E\left(\int_{0}^{t} \sup _{r \in[0, s]}\left|u_{n}^{\tau_{n}}\right|^{2} d r\right)
\end{aligned}
$$

and so, another application of Gronwall's inequality implies that

$$
E\left(\sup _{s \in[0, T]}\left|u_{n}^{\tau_{n}}(s)\right|_{H}^{2}\right) \leq E\left(C\left(u_{0}, w_{0}, f\right)\right)<\infty
$$

Then

$$
P\left(\sup _{s \in[0, T]}\left|u_{n}^{\tau_{n}}(s)\right|_{H}^{2}>\left(\frac{3}{2}\right)^{n}\right) \leq E\left(C\left(u_{0}, w_{0}, f\right)\right)\left(\frac{2}{3}\right)^{n}
$$

Now an application of the Borel Cantelli lemma shows that there exists a set of measure zero $\hat{N}$ such that for $\omega \notin \hat{N}$, it follows that for all $n$ large enough,

$$
\sup _{s \in[0, T]}\left|u_{n}^{\tau_{n}}(s)\right|_{H}^{2}<(3 / 2)^{n}
$$

and so $\tau_{n}=\infty$ for all $n$ large enough.
Claim: For $m<n$, there is a set of measure zero $N_{m n}$ such that if $\omega \notin N_{m n}$, then $u_{n}^{\tau_{n}}(s)=$ $u_{m}^{\tau_{m}}(s)$ on $\left[0, T \wedge \tau_{m}\right]$.

Proof of the claim: Note that $\tau_{m} \leq \tau_{n}$. Therefore, these are both progressively measurable solutions to the integral equation

$$
\begin{align*}
u\left(t \wedge \tau_{m}, \omega\right) & -u_{0}(\omega)+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{m}\right]} N\left(s, u(s, \omega), u(s-h, \omega), w_{u}(s, \omega), \omega\right) d s \\
& =\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{m}\right]} f(s, \omega) d s+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{m}\right]} \sigma(s, u, \omega) d W \tag{71.3.24}
\end{align*}
$$

where

$$
w_{u}(t)=w_{0}+\int_{0}^{t} u(s) d s
$$

To save notation, refer to these functions as $u, v$ and let $\tau_{m}=\tau$. Subtract and use the Ito formula to obtain

$$
\begin{aligned}
& \frac{1}{2}|u(t \wedge \tau)-v(t \wedge \tau)|_{H}^{2} \leq \\
& \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{m}\right]}\left(N\left(s, u(s), u(s-h), w_{u}(s)\right)-N\left(s, v(s), v(s-h), w_{u-v}(s)\right), u-v\right) d s \\
& +\sup _{s \in[0, t]}|M(t)|
\end{aligned}
$$

where the quadratic variation of the martingale $M(t)$ is dominated by

$$
\int_{0}^{t} \mathscr{X}_{[0, \tau]}\|\sigma(s, u, \omega)-\sigma(s, v, \omega)\|^{2}|u-v|^{2} d s
$$

Then from the assumption that $N$ is locally Lipschitz and routine manipulations,

$$
\frac{1}{2}|u(t \wedge \tau)-v(t \wedge \tau)|_{H}^{2} \leq C_{m} \int_{0}^{t} \mathscr{X}_{[0, \tau]}|u-v|^{2} d s+\sup _{s \in[0, t]}|M(s)|
$$

and so, adjusting the constants yields

$$
\begin{aligned}
& \sup _{s \in[0, t]}|u(s \wedge \tau)-v(s \wedge \tau)|_{H}^{2} \\
\leq & C_{m} \int_{0}^{t} \mathscr{X}_{[0, \tau]} \sup _{r \in[0, s]}|u(r \wedge \tau)-v(r \wedge \tau)|^{2} d s+\sup _{s \in[0, t]}|M(s)|
\end{aligned}
$$

and so, by Gronwall's inequality followed by the Burkholder-Davis-Gundy inequality,

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}|u(s \wedge \tau)-v(s \wedge \tau)|_{H}^{2}\right) \leq \\
C E\left(\left(\int_{0}^{t} \mathscr{X}_{[0, \tau]}\|\sigma(s, u, \omega)-\sigma(s, v, \omega)\|^{2}|u(s \wedge \tau)-v(s \wedge \tau)|^{2} d s\right)^{1 / 2}\right) \\
\leq \frac{1}{2} E\left(\sup _{s \in[0, t]}|u(s \wedge \tau)-v(s \wedge \tau)|_{H}^{2}\right)+C E\left(\int_{0}^{t} \mathscr{X}_{[0, \tau]}\|\sigma(s, u)-\sigma(s, v)\|^{2} d s\right)
\end{gathered}
$$

and so, adjusting the constant again,

$$
\begin{aligned}
& E\left(\sup _{s \in[0, t]}|u(s \wedge \tau)-v(s \wedge \tau)|_{H}^{2}\right) \\
\leq & C E\left(\int_{0}^{t} \mathscr{X}_{[0, \tau]}\|\sigma(s, u(s \wedge \tau))-\sigma(s, v(s \wedge \tau))\|^{2} d s\right) \\
\leq & C E\left(\int_{0}^{t} \mathscr{X}_{[0, \tau]} K|u(s \wedge \tau)-v(s \wedge \tau)|^{2} d s\right) \\
\leq & C \int_{0}^{t} E\left(\sup _{r \in[0, s]}|u(r \wedge \tau)-v(r \wedge \tau)|^{2}\right) d s
\end{aligned}
$$

and so, Gronwall's inequality shows that for every $t$,

$$
E\left(\sup _{s \in[0, t]}|u(s \wedge \tau)-v(s \wedge \tau)|_{H}^{2}\right)=0
$$

In particular, for $t=T$ this holds. Hence

$$
E\left(\sup _{s \in[0, T]}|u(s \wedge \tau)-v(s \wedge \tau)|_{H}^{2}\right)=0
$$

It follows that

$$
E\left(\sup _{s \in[0, \tau \wedge T]}|u(s)-v(s)|_{H}^{2}\right)=0
$$

so that off a set of measure zero, $u(s)=v(s)$ for all $s \in[0, \tau]$. This proves the claim.
Now let the set of measure zero $N$ be given by $N \equiv \cup_{m<n} N_{m n} \cup \hat{N}$ where $\hat{N}$ is the set of measure zero off which $\tau_{m}=\infty$ for all $m$ large enough. Then for $\omega \notin N$, it follows that $u_{n}^{\tau_{n}}(s)=u_{m}^{\tau_{m}}(s)$ on $\left[0, \tau_{m} \wedge T\right]$ and, for all $m$ large enough, $\tau_{m}=\infty$. Hence for all $m$ large enough, and such $\omega, u_{n}(s, \omega)=u_{m}(s, \omega)$ for all $s \in[0, T]$. Thus, for $\omega$ off $N$, it follows that $\lim _{m \rightarrow \infty} u_{m}^{\tau_{m}}(s, \omega) \equiv u(s, \omega)$ exists, this for each $s \in[0, T]$ and $\omega$ off a fixed set of measure zero. In fact, this convergence is uniform on $[0, T]$ because for all $n$ sufficiently large
and for such a fixed $\omega \notin N$, there is no change in increasing $m$. Hence, $u$ is progressively measurable and satisfies the integral equation 71.3.21.

It remains to verify uniqueness. Suppose there are two solutions $u, v$ each progressively measurable solutions of the given integral equation. Then let $\tau_{n}$ be a stopping time

$$
\tau_{n}=\inf \left\{t:|u(t)|+|v(t)|>2^{n}\right\}
$$

Then a repeat of the arguments given in the above claim shows that on $\left[0, \tau_{n} \wedge T\right]$ the two functions $u^{\tau_{n}}, v^{\tau_{n}}$ are equal on $\left[0, \tau_{n} \wedge T\right]$ off a set of measure zero $N_{n}$. Let $N$ be the union of the exceptional sets. Then for $\omega \notin N, u(t, \omega)=v(t, \omega)$ for all $t \in\left[0, \tau_{n} \wedge T\right]$. However, $\tau_{n}(\omega)=\infty$ for all $n$ large enough because each of these functions is continuous. Hence, the two functions are equal on $[0, T]$ for such $\omega$. This shows uniqueness.

## Chapter 72

## The Hard Ito Formula

Recall the following definition of stochastically continuous.
$X$ is stochastically continuous at $t_{0} \in I$ means: for all $\varepsilon>0$ and $\delta>0$ there exists $\rho>0$ such that

$$
P\left(\left[\left|\mid X(t)-X\left(t_{0}\right) \| \geq \varepsilon\right]\right) \leq \delta \text { whenever }\left|t-t_{0}\right|<\rho, t \in I\right.
$$

Note the above condition says that for each $\varepsilon>0$,

$$
\lim _{t \rightarrow t_{0}} P\left(\left[\left\|X(t)-X\left(t_{0}\right)\right\| \geq \varepsilon\right]\right)=0
$$

### 72.1 Predictable And Stochastic Continuity

Definition 72.1.1 Let $\mathscr{F}_{t}$ be a filtration. The predictable sets consists of those sets which are in the smallest $\sigma$ algebra which contains the sets $E \times\{0\}$ for $E \in \mathscr{F}_{0}$ and $E \times(a, b]$ where $E \in \mathscr{F}_{a}$. Thus every predictable set is a progressively measurable set.

First of all, here is an important observation.
Proposition 72.1.2 Let $X(t)$ be a stochastic process having values in $E$ a complete metric space and let it be $\mathscr{F}_{t}$ adapted and left continuous where $\mathscr{F}_{t}$ is a normal filtration. Then it is predictable. If $t \rightarrow X(t, \omega)$ is continuous for all $\omega \notin N, P(N)=0$, then $(t, \omega) \rightarrow$ $X(t, \omega) \mathscr{X}_{N^{C}}(\omega)$ is predictable. Also, if $X(t)$ is stochastically continuous and adapted on $[0, T]$, then it has a predictable version. If $X \in C\left([0, T] ; L^{p}(\Omega ; F)\right), p \geq 1$ for $F$ a Banach space, then $X$ is stochastically continuous.

Proof: First suppose $X$ is continuous for all $\omega \in \Omega$. Define

$$
I_{m, k} \equiv\left((k-1) 2^{-m} T, k 2^{-m} T\right]
$$

if $k \geq 1$ and $I_{m, 0}=\{0\}$ if $k=1$. Then define

$$
\begin{aligned}
X_{m}(t) \equiv & \sum_{k=1}^{2^{m}} X\left(T(k-1) 2^{-m}\right) \mathscr{X}_{\left((k-1) 2^{-m} T, k 2^{-m} T\right]}(t) \\
& +X(0) \mathscr{X}_{[0,0]}(t)
\end{aligned}
$$

Here the sum means that $X_{m}(t)$ has value $X\left(T(k-1) 2^{-m}\right)$ on the interval

$$
\left((k-1) 2^{-m} T, k 2^{-m} T\right]
$$

Thus $X_{m}$ is predictable because each term in the formal sum is. Thus

$$
\begin{gathered}
X_{m}^{-1}(U)=\cup_{k=1}^{2^{m}}\left(X\left(T(k-1) 2^{-m}\right) \mathscr{X}_{\left((k-1) 2^{-m} T, k 2^{-m} T\right]}\right)^{-1}(U) \\
=\cup_{k=1}^{2^{m}}\left((k-1) 2^{-m} T, k 2^{-m} T\right] \times\left(X\left(T(k-1) 2^{-m}\right)\right)^{-1}(U),
\end{gathered}
$$

a finite union of predictable sets. Since $X$ is left continuous,

$$
X(t, \omega)=\lim _{m \rightarrow \infty} X_{m}(t, \omega)
$$

and so $X$ is predictable.
Now suppose that for $\omega \notin N, P(N)=0, t \rightarrow X(t, \omega)$ is continuous. Then applying the above argument to $X(t) \mathscr{X}_{N^{C}}$ it follows $X(t) \mathscr{X}_{N^{C}}$ is predictable by completeness of $\mathscr{F}_{t}$, $X(t) \mathscr{X}_{N^{C}}$ is $\mathscr{F}_{t}$ measurable.

Next consider the other claim. Since $X$ is stochastically continuous on $[0, T]$ it is uniformly stochastically continuous on this interval by Lemma 62.1.1. Therefore, there exists a sequence of partitions of $[0, T]$, the $m^{\text {th }}$ being

$$
0=t_{m, 0}<t_{m, 1}<\cdots<t_{m, n(m)}=T
$$

such that for $X_{m}$ defined as above, then for each $t$

$$
\begin{equation*}
P\left(\left[d\left(X_{m}(t), X(t)\right) \geq 2^{-m}\right]\right) \leq 2^{-m} \tag{72.1.1}
\end{equation*}
$$

Then as above, $X_{m}$ is predictable. Let $A$ denote those points of $\mathscr{P}_{T}$ at which $X_{m}(t, \omega)$ converges. Thus $A$ is a predictable set because it is just the set where $X_{m}(t, \omega)$ is a Cauchy sequence. Now define the predictable function $Y$

$$
Y(t, \omega) \equiv\left\{\begin{array}{l}
\lim _{m \rightarrow \infty} X_{m}(t, \omega) \text { if }(t, \omega) \in A \\
0 \text { if }(t, \omega) \notin A
\end{array}\right.
$$

From 72.1.1 it follows from the Borel Cantelli lemma that for fixed $t$, the set of $\omega$ which are in infinitely many of the sets,

$$
\left[d\left(X_{m}(t), X(t)\right) \geq 2^{-m}\right]
$$

has measure zero. Therefore, for each $t$, there exists a set of measure zero, $N(t)$ such that for $\omega \notin N(t)$ and all $m$ large enough

$$
\left[d\left(X_{m}(t, \omega), X(t, \omega)\right)<2^{-m}\right]
$$

Hence for $\omega \notin N(t),(t, \omega) \in A$ and so $X_{m}(t, \omega) \rightarrow Y(t, \omega)$ which shows

$$
d(Y(t, \omega), X(t, \omega))=0 \text { if } \omega \notin N(t)
$$

The predictable version of $X(t)$ is $Y(t)$.
Finally consider the claim about the specific example where

$$
\begin{gathered}
X \in C\left([0, T] ; L^{p}(\Omega ; F)\right) . \\
P\left(\left[\|X(t)-X(s)\|_{F} \geq \varepsilon\right]\right) \varepsilon^{p} \leq \int_{\Omega}\|X(t)-X(s)\|_{F}^{p} d P \leq \varepsilon^{p} \delta
\end{gathered}
$$

provided $|s-t|$ sufficiently small. Thus

$$
P\left(\left[\|X(t)-X(s)\|_{F} \geq \varepsilon\right]\right)<\delta
$$

when $|s-t|$ is small enough.

### 72.2 Approximating With Step Functions

This Ito formula seems to be the fundamental idea which allows one to obtain solutions to stochastic partial differential equations using a variational point of view. I am following the treatment found in [108]. The following lemma is fundamental to the presentation. It approximates a function with a sequence of two step functions $X_{k}^{r}, X_{k}^{l}$ where $X_{k}^{r}$ has the value of $X$ at the right end of each interval and $X_{k}^{l}$ gives the value $X$ at the left end of the interval. The lemma is very interesting for its own sake. You can obviously do this sort of thing for a continuous function but here the function is not continuous and in addition, it is a stochastic process depending on $\omega$ also. This lemma was proved earlier Lemma 65.3.1.

Lemma 72.2.1 Let $\Phi:[0, T] \times \Omega \rightarrow V$, be $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable and suppose

$$
\Phi \in K \equiv L^{p}([0, T] \times \Omega ; E), p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
\Phi_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t) \\
\Phi_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t)
\end{aligned}
$$

both converge to $\Phi$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

Also, each $\Phi\left(t_{j}^{k}\right), \Phi\left(t_{j-1}^{k}\right)$ is in $L^{p}(\Omega ; E)$. One can also assume that $\Phi(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$
\left|t_{j}^{k}-t_{j-1}^{k}\right|=2^{-n_{k}}
$$

except for the case where $j=1$ or $j=m_{n_{k}}$ when this might not be so. In the case of the last subinterval defined by the partition, we can assume

$$
\left|t_{m}^{k}-t_{m-1}^{k}\right|=\left|T-t_{m-1}^{k}\right| \geq 2^{-\left(n_{k}+1\right)}
$$

The following lemma is convenient.
Lemma 72.2.2 Let $f_{n} \rightarrow f$ in $L^{p}([0, T] \times \Omega, E)$. Then there exists a subsequence $n_{k}$ and a set of measure zero $N$ such that if $\omega \notin N$, then

$$
f_{n_{k}}(\cdot, \omega) \rightarrow f(\cdot, \omega)
$$

in $L^{p}([0, T], E)$ and for a.e. $t$.

Proof: We have

$$
\begin{aligned}
P\left(\left[\left\|f_{n}-f\right\|_{L^{p}([0, T], E)}>\lambda\right]\right) & \leq \frac{1}{\lambda} \int_{\Omega}\left\|f_{n}-f\right\|_{L^{p}([0, T], E)} d P \\
& \leq \frac{1}{\lambda}\left\|f_{n}-f\right\|_{L^{p}([0, T] \times \Omega, E)}
\end{aligned}
$$

Hence there exists a subsequence $n_{k}$ such that

$$
P\left(\left[\left\|f_{n_{k}}-f\right\|_{L^{p}([0, T], E)}>2^{-k}\right]\right) \leq 2^{-k}
$$

Then by the Borel Cantelli lemma, it follows that there exists a set of measure zero $N$ such that for all $k$ large enough and $\omega \notin N$,

$$
\left\|f_{n_{k}}-f\right\|_{L^{p}([0, T], E)} \leq 2^{-k}
$$

Because of this lemma, it can also be assumed that for a.e. $\omega$ pointwise convergence is obtained on $[0, T]$ as well as convergence in $L^{p}([0, T])$. This kind of assumption will be tacitly made whenever convenient in the context of the above lemma.

Also recall the diagram for the definition of the integral.

$$
\begin{aligned}
& U \\
& \begin{array}{l}
\downarrow Q^{1 / 2} \\
Q^{1 / 2} U
\end{array} \\
& \Phi_{n} \searrow \\
& \downarrow \Phi \\
& \text { H }
\end{aligned}
$$

The idea was to get $\int_{0}^{t} \Phi d W$ where $\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Here $W(t)$ was a cylindrical Wiener process. This meant that it was a $Q_{1}$ Wiener process on $U_{1}$ for $Q_{1}=J J^{*}$ and $J$ was a Hilbert Schmidt operator mapping $Q^{1 / 2} U$ to $U_{1}$.

### 72.3 The Situation

Now consider the following situation.
Situation 72.3.1 Let $X$ satisfy the following.

$$
\begin{equation*}
X(t)=X_{0}+\int_{0}^{t} Y(s) d s+\int_{0}^{t} Z(s) d W(s) \tag{72.3.2}
\end{equation*}
$$

$X_{0} \in L^{2}(\Omega ; H)$ and is $\mathscr{F}_{0}$ measurable, where $Z$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ progressively measurable and

$$
\int_{0}^{T} \int_{\Omega}\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d P d t<\infty
$$

so that the stochastic integral makes sense. Also $X$ has a measurable representative $\bar{X}$ which has values in $V$. (For a.e.t, $\bar{X}(t)=X(t)$ for $P$ a.e. $\omega$ ). This representative satisfies

$$
\bar{X} \in L^{2}([0, T] \times \Omega, \mathscr{B}([0, T] \times \mathscr{F}, H)) \cap L^{p}([0, T] \times \Omega, \mathscr{B}([0, T]) \times \mathscr{F}, V)
$$

Assume $Y(s)$ satisfies

$$
Y \in K^{\prime}=L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)
$$

where $1 / p^{\prime}+1 / p=1$ and $Y$ is $V^{\prime}$ progressively measurable. The situation in which the equation holds is as follows. For a.e. $\omega$, the equation holds for all $t \in[0, T]$ in $V^{\prime}$. Thus it follows that $X(t)$ is automatically progressively measurable into $V^{\prime}$ from Proposition 72.1.2. Also $W(t)$ is a Wiener process on $U_{1}$ in the above diagram. Thus $X$ is continuous into $V^{\prime}$ off a set of measure zero, and it is also $V^{\prime}$ predictable.

The goal is to prove the following Ito formula.

$$
\begin{align*}
|X(t)|^{2}= & \left|X_{0}\right|^{2}+\int_{0}^{t}\left(2\langle Y(s), \bar{X}(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
& +2 \int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \bar{X}(s)\right) \circ J d W(s) \tag{72.3.3}
\end{align*}
$$

where $\mathscr{R}$ is the Riesz map which takes $U_{1}$ to $U_{1}^{\prime}$. The main thing is that the last term above be a local martingale.

In all that follows, the mesh points $t_{j}$ will be points where $\bar{X}\left(t_{j}\right)=X\left(t_{j}\right)$ a.e. $\omega$.
Lemma 72.3.2 Let $X$ be as in Situation 72.3.1 and let $X_{k}^{l}$ be as in Lemma 72.2.1 corresponding to $\bar{X}$ above. Say

$$
X_{k}^{l}(t)=\sum_{j=0}^{m_{k}} \bar{X}\left(t_{j}\right) \mathscr{X}_{\left[t_{j}, t_{j+1)}\right.}(t), X_{k}^{l}(0) \equiv 0
$$

Then each term in the above sum for which $t_{j}>0$ is predictable into $H$. As mentioned earlier, we can take $X(0) \equiv 0$ in the definition of the "left step function". Since, at the mesh points, $\bar{X}=X$ a.e., it makes no difference off a set of measure zero whether we use $\bar{X}\left(t_{j}\right)$ or $X\left(t_{j}\right)$ at the left end point.

Proof: This is a step function and a typical term is of the form $X(a) \mathscr{X}_{[a, b)}(t)$. I will try and show this is predictable. Let $a_{n}$ be an increasing sequence converging to $a$ and let $b_{n}$ be an increasing sequence converging to $b$. Then for a.e. $\omega$,

$$
X\left(a_{n}\right) \mathscr{X}_{\left(a_{n}, b_{n}\right]}(t) \rightarrow X(a) \mathscr{X}_{[a, b)}(t)
$$

in $V^{\prime}$ due to the fact that $t \rightarrow X(t)$ is continuous into $V^{\prime}$ for a.e. $\omega$. Therefore, letting $v \in V$ be given, it follows that for a.e. $\omega$

$$
\left\langle X\left(a_{n}\right) \mathscr{X}_{\left(a_{n}, b_{n}\right]}(t), v\right\rangle \rightarrow\left\langle X(a) \mathscr{X}_{[a, b)}(t), v\right\rangle,
$$

and since the filtration is a normal filtration in which all sets of measure zero from $\mathscr{F}_{T}$ are in $\mathscr{F}_{0}$, this shows

$$
(t, \omega) \rightarrow\left\langle X(a) \mathscr{X}_{[a, b)}(t), v\right\rangle
$$

is real predictable because it is the pointwise limit of real predictable functions, those in the sequence being real predictable because of the continuity of $X(t)$ into $V^{\prime}$ and Propositon 72.1.2. Now since $H \subseteq V^{\prime}$ it follows that for all $v \in V$,

$$
(t, \omega) \rightarrow\left(X(a) \mathscr{X}_{[a, b)}(t), v\right)
$$

is real predictable. This holds for $h \in H$ replacing $v$ in the above because $V$ is dense in $H$. By the Pettis theorem, this proves the lemma.

Lemma 72.3.3 In Situation 72.3.1 the following formula holds for a.e. $\omega$ for $0<s<t$ where $M(t) \equiv \int_{0}^{t} Z(u) d W(u)$. Here and elsewhere, $|\cdot|$ denotes the norm in $H$ and $\langle\cdot, \cdot\rangle$ denotes the duality pairing between $V, V^{\prime}$. Also $X=\bar{X}$ for a.e. $\omega$ at $t, s$ so that it makes no difference off a set of measure zero whether we write $\langle Y(u), X(t)\rangle$ or $\langle Y(u), \bar{X}(t)\rangle$

$$
\begin{align*}
|X(t)|^{2} & =|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+2(X(s), M(t)-M(s)) \\
& +|M(t)-M(s)|^{2}-|X(t)-X(s)-(M(t)-M(s))|^{2} \tag{72.3.4}
\end{align*}
$$

Also for $t>0$

$$
\begin{align*}
|X(t)|^{2}= & \left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(u), X(t)\rangle d u+2\left(X_{0}, M(t)\right) \\
& +|M(t)|^{2}-\left|X(t)-X_{0}-M(t)\right|^{2} \tag{72.3.5}
\end{align*}
$$

Proof: The formula is a straight forward computation which holds a.e. $\omega$.

$$
\begin{aligned}
& \mid M(t)-\left.M(s)\right|^{2}-|X(t)-X(s)-(M(t)-M(s))|^{2}+2(X(s), M(t)-M(s)) \\
&=|M(t)-M(s)|^{2}-|X(t)-X(s)|^{2}-|M(t)-M(s)|^{2} \\
&+2(X(t)-X(s), M(t)-M(s))+2(X(s), M(t)-M(s)) \\
&=-|X(t)-X(s)|^{2}+2(X(t), M(t)-M(s)) \\
&=-|X(t)-X(s)|^{2}+2(X(t), X(t)-X(s))-2\left\langle\int_{s}^{t} Y(u) d u, X(t)\right\rangle \\
&=\quad-|X(t)|^{2}-|X(s)|^{2}+2(X(t), X(s))+2|X(t)|^{2}-2(X(t), X(s)) \\
&-2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u \\
& \quad=|X(t)|^{2}-|X(s)|^{2}-2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u
\end{aligned}
$$

Comparing the ends of this string of equations,

$$
\begin{aligned}
|X(t)|^{2}= & |X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+2(X(s), M(t)-M(s)) \\
& +|M(t)-M(s)|^{2}-|X(t)-X(s)-(M(t)-M(s))|^{2}
\end{aligned}
$$

which is what was to be shown.
Now it is time to prove the other assertion.

$$
\begin{gathered}
|M(t)|^{2}-\left|X(t)-X_{0}-M(t)\right|^{2}+2\left(X_{0}, M(t)\right) \\
=-\left|X(t)-X_{0}\right|^{2}+2\left(X(t)-X_{0}, M(t)\right)+2\left(X_{0}, M(t)\right) \\
=-\left|X(t)-X_{0}\right|^{2}+2(X(t), M(t)) \\
=-\left|X(t)-X_{0}\right|^{2}+2\left(X(t), X(t)-X_{0}\right)-2\left\langle\int_{0}^{t} Y(s) d s, X(t)\right\rangle \\
=|X(t)|^{2}-\left|X_{0}\right|^{2}-2\left\langle\int_{0}^{t}\langle Y(s), X(t)\rangle d s\right\rangle
\end{gathered}
$$

Noting that $X(0)=X_{0} \in L^{2}(\Omega, H)$ and is $\mathscr{F}_{0}$ measurable, the first formula works in both cases.

### 72.4 The Main Estimate

The following phenomenal estimate holds and it is this estimate which is the main idea in proving the Ito formula. The last assertion about continuity is like the well known result that if $y \in L^{p}(0, T ; V)$ and $y^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$, then $y$ is actually continuous with values in $H$. Later, this continuity result is strengthened further to give strong continuity.

Lemma 72.4.1 In the Situation 72.3.1,

$$
E\left(\sup _{t \in[0, T]}|X(t)|_{H}^{2}\right)<C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|X_{0}\right\|_{L^{2}(\Omega, H)}\right)<\infty
$$

where

$$
\begin{aligned}
J & =L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U ; H\right)\right), K \equiv L^{p}([0, T] \times \Omega ; V), \\
K^{\prime} & \equiv L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right) .
\end{aligned}
$$

Also, $C$ is a continuous function of its arguments and $C(0,0,0,0)=0$. Thus for a.e. $\omega$,

$$
\sup _{t \in[0, T]}|X(t, \omega)|_{H} \leq C(\omega)<\infty .
$$

Also for a.e. $\omega, t \rightarrow X(t, \omega)$ is weakly continuous with values in $H$.

Proof: Consider the formula in Lemma 72.3.3.

$$
\begin{align*}
|X(t)|^{2} & =|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+2(X(s), M(t)-M(s)) \\
& +|M(t)-M(s)|^{2}-|X(t)-X(s)-(M(t)-M(s))|^{2} \tag{72.4.6}
\end{align*}
$$

Now let $t_{j}$ denote a point of $\mathscr{P}_{k}$ from Lemma 72.2.1. Then for $t_{j}>0, X\left(t_{k}\right)$ is just the value of $X$ at $t_{k}$ but when $t=0$, the definition of $X(0)$ in this step function is $X(0) \equiv 0$. Thus

$$
\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=\sum_{j=1}^{m-1}\left|X\left(t_{j+1}\right)\right|^{2}-\left|X\left(t_{j}\right)\right|^{2}+\left|X\left(t_{1}\right)\right|^{2}-\left|X_{0}\right|^{2}
$$

Using the formula in Lemma 72.3.3, for $t=t_{m}$ this yields

$$
\begin{gather*}
\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=2 \sum_{j=1}^{m-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
+2 \sum_{j=1}^{m-1}\left(\int_{t_{j}}^{t_{j+1}} Z(u) d W, X\left(t_{j}\right)\right)_{H}+\sum_{j=1}^{m-1}\left|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right|^{2} \\
-\sum_{j=1}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2} \\
+2 \int_{0}^{t_{1}}\left\langle Y(u), X\left(t_{1}\right)\right\rangle d u+2\left(X_{0}, \int_{0}^{t_{1}} Z(u) d W\right)+\left|M\left(t_{1}\right)\right|^{2} \\
-\left|X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right|^{2} \tag{72.4.7}
\end{gather*}
$$

Of course

$$
2 \int_{0}^{t_{1}}\left\langle Y(u), X\left(t_{1}\right)\right\rangle d u+2\left(X_{0}, \int_{0}^{t_{1}} Z(u) d W\right)+\left|M\left(t_{1}\right)\right|^{2}
$$

converges to 0 for a.e. $\omega$ as $k \rightarrow \infty$ because the norms of the partitions converge to 0 and the stochastic integral is continuous off a set of measure zero. Actually this is not completely clear for the first of the above terms. This term is dominated by

$$
\begin{aligned}
& \left(\int_{0}^{t_{1}}\|Y(u)\|^{p^{\prime}} d u\right)^{1 / p}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|^{p} d u\right)^{1 / p} \\
\leq & C(\omega)\left(\int_{0}^{t_{1}}\|Y(u)\|^{p^{\prime}} d u\right)^{1 / p}
\end{aligned}
$$

Hence this converges to 0 for a.e. $\omega$. At this time, not much is known about the last term in 72.4.7, but it is negative and is about to be neglected anyway.The Ito isometry implies the other two terms converge to 0 in $L^{1}(\Omega)$ also, in addition to converging for a.e. $\omega$. At this time, not much is known about the last term in 72.4.7, but it is negative and is about to be neglected anyway.

The term involving the stochastic integral equals

$$
2 \sum_{j=1}^{m-1}\left(\int_{t_{j}}^{t_{j+1}} Z(u) d W, X\left(t_{j}\right)\right)_{H}
$$

By Theorem 65.14.1, this equals

$$
2 \int_{t_{1}}^{t_{m}} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W
$$

$t \rightarrow \int_{0}^{t} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W$ being a local martingale. Therefore, 72.4.7 equals

$$
\begin{gathered}
\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+e(k) \\
2 \int_{t_{1}}^{t_{m}} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W+\sum_{j=1}^{m-1}\left|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right|^{2} \\
-\sum_{j=1}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}-\left|X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right|^{2}
\end{gathered}
$$

where $e(k)$ converges to 0 in $L^{1}(\Omega)$ and for a.e. $\omega$. Note that $X_{k}^{l}(u)=0$ on $\left[0, t_{1}\right)$ and so that stochastic integral equals

$$
\int_{0}^{t_{m}} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W .
$$

Therefore, from the above,

$$
\begin{gathered}
\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+e(k) \\
2 \int_{0}^{t_{m}} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W+\sum_{j=0}^{m-1}\left|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right|^{2}-\left|M\left(t_{1}\right)\right|^{2} \\
-\sum_{j=1}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}-\left|X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right|^{2}
\end{gathered}
$$

Then since $\left|M\left(t_{1}\right)\right|^{2}$ converges to 0 in $L^{1}(\Omega)$ and for a.e. $\omega$, as discussed above,

$$
\begin{gathered}
\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+e(k) \\
+2 \int_{0}^{t_{m}} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W+\sum_{j=0}^{m-1}\left|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right|^{2} \\
-\left|X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right|^{2}
\end{gathered}
$$

$$
\begin{equation*}
-\sum_{j=1}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2} \tag{72.4.8}
\end{equation*}
$$

where $e(k) \rightarrow 0$ for a.e. $\omega$ and also in $L^{1}(\Omega)$.
Now it follows on discarding the negative terms,

$$
\begin{gathered}
\sup _{t_{j} \in \mathscr{P}_{k}}\left|X\left(t_{j}\right)\right|^{2} \leq\left|X_{0}\right|^{2}+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u \\
+2 \sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W\right|+\sum_{j=0}^{m_{k}-1}\left|\int_{t_{j}}^{t_{j+1}} Z(u) d W\right|^{2}
\end{gathered}
$$

where there are $m_{k}+1$ points in $\mathscr{P}_{k}$.
Do $\int_{\Omega}$ to both sides. Using the Ito isometry, this yields

$$
\begin{gathered}
\int_{\Omega}\left(\sup _{t_{j} \in \mathscr{P}_{k}}\left|X\left(t_{j}\right)\right|^{2}\right) d P \leq \\
\\
+\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}} \int_{\Omega}\left\|Z\left(\left|X_{0}\right|^{2}\right)+2\right\| Y\left\|_{K^{\prime}}| |\right\|_{k}^{r} \|_{K} d P d u \\
+2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{T} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W\right|\right) d P+E(|e(k)|) \\
\leq C+\int_{0}^{T} \int_{\Omega}\|Z(u)\|^{2} d P d u+ \\
+2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{T} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W\right|\right) d P \\
\leq C+2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{T} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W\right|\right) d P
\end{gathered}
$$

where the result of Lemma 72.2 .1 that $X_{k}^{r}$ converges to $\bar{X}$ in $K$ shows that the term which is the product $2\|Y\|_{K^{\prime}}\left\|X_{k}^{r}\right\|_{K}$ is bounded. The constant $C$ is a continuous function of

$$
\|Y\|_{K^{\prime}},\|\bar{X}\|_{K},\|Z\|_{J},\left\|X_{0}\right\|_{L^{2}(\Omega, H)}
$$

which equals zero when all are equal to zero. The term involving the stochastic integral is next.

Applying the Burkholder Davis Gundy inequality, Theorem 63.4.4 for $F(r)=r$ along with the description of the quadratic variation of the Ito integral found in Corollary 65.11.1

$$
\begin{aligned}
& \int_{\Omega_{t_{j} \in \mathscr{P}_{k}}} \sup _{k}\left|X\left(t_{k}\right)\right|^{2} d P \\
\leq & C+C \int_{\Omega}\left(\int_{0}^{T}\left\|\mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J\right\|^{2} d u\right)^{1 / 2} d P
\end{aligned}
$$

$$
\leq C+C \int_{\Omega}\left(\int_{0}^{T}\|Z(u)\|^{2}\left|X_{k}^{l}(u)\right|^{2} d u\right)^{1 / 2} d P
$$

Now for each $\omega$, there are only finitely many values of $X_{k}^{l}(u)$ and they equal $X\left(t_{j}\right)$ for $t_{j} \in \mathscr{P}_{k}$ with the convention that $X(0)=0$. Therefore, the above is dominated by

$$
\begin{aligned}
& C+C \int_{\Omega}\left(\sup _{t_{j} \in \mathscr{P}_{k}}\left|X\left(t_{j}\right)\right|^{2}\right)^{1 / 2}\left(\int_{0}^{T}\|Z(u)\|^{2} d u\right)^{1 / 2} d P \\
\leq & C+\frac{1}{2} \int_{\Omega_{t_{j} \in \mathscr{P}_{k}}} \sup \left|X\left(t_{j}\right)\right|^{2}+C \int_{\Omega} \int_{0}^{T}\|Z(u)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d u d P
\end{aligned}
$$

and so

$$
\frac{1}{2} \int_{\Omega_{t_{j}} \in \sup _{k}}\left|X\left(t_{k}\right)\right|^{2} d P \leq C
$$

for some constant $C$ independent of $\mathscr{P}_{k}$ dependent on $\int_{\Omega} \int_{0}^{T}\|Z(u)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d u d P$. This constant is dependent on $\|Y\|_{K^{\prime}},\|\bar{X}\|_{K},\|Z\|_{J},\left\|X_{0}\right\|_{L^{2}(\Omega, H)}$ and equals zero when all of these quantities equal 0 .

Let $D$ denote the union of all the $\mathscr{P}_{k}$. Thus $D$ is a dense subset of $[0, T]$ and it has just been shown that for a constant $C$ independent of $\mathscr{P}_{k}$,

$$
E\left(\sup _{t \in D}|X(t)|^{2}\right) \leq C
$$

Let $\left\{e_{j}\right\}$ be an orthonormal basis for $H$ which is also contained in $V$ and has the property that $\operatorname{span}\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ is dense in $V$. I claim that for $y \in V^{\prime}$

$$
|y|_{H}^{2}=\sup _{n} \sum_{j=1}^{n}\left|\left\langle y, e_{j}\right\rangle\right|^{2}
$$

This is certainly true if $y \in H$ because in this case

$$
\left\langle y, e_{j}\right\rangle=\left(y, e_{j}\right)
$$

If $y \notin H$, then the series must diverge. If not, you could consider the infinite sum

$$
z \equiv \sum_{j=1}^{\infty}\left\langle y, e_{j}\right\rangle e_{j} \in H
$$

and argue that $\langle z-y, v\rangle=0$ for all $v \in \operatorname{span}\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ which would also imply that this is true for all $v \in V$. Then since $z=y$ in $V^{\prime}$, it follows that $y \in H$ contrary to the assumption that $y \notin H$.

It follows

$$
|X(t)|^{2}=\sup _{n} \sum_{j=1}^{n}\left|\left\langle X(t), e_{j}\right\rangle\right|^{2}
$$

and for a.e. $\omega$, this is just the sup of continuous functions of $t$. Therefore, for given $\omega$ off a set of measure zero,

$$
t \rightarrow|X(t)|^{2}
$$

is lower semicontinuous. Hence letting $t \in[0, T]$ and $t_{j} \rightarrow t$ where $t_{j} \in D$,

$$
|X(t)|^{2} \leq \lim \inf _{j \rightarrow \infty}\left|X\left(t_{j}\right)\right|^{2}
$$

so it follows for a.e. $\omega$

$$
\sup _{t \in[0, T]}|X(t)|^{2} \leq \sup _{t \in D}|X(t)|^{2} \leq \sup _{t \in[0, T]}|X(t)|^{2}
$$

Hence

$$
\begin{equation*}
E\left(\sup _{t \in[0, T]}|X(t)|^{2}\right) \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|X_{0}\right\|_{L^{2}(\Omega, H)}\right) \tag{72.4.9}
\end{equation*}
$$

Note the above shows that for a.e. $\omega, \sup _{t \in[0, T]}|X(t)|_{H}<\infty$ so that for such $\omega, X(t)$ has values in $H$. Note that we began by assuming it had a representative with values in $H$ although the equation only held in $V^{\prime}$. Say

$$
|X(t, \omega)| \leq C(\omega)
$$

Hence if $v \in V$, then for a.e. $\omega$

$$
\lim _{t \rightarrow s}(X(t), v)=\lim _{t \rightarrow s}\langle X(t), v\rangle=\langle X(s), v\rangle=(X(s), v)
$$

Therefore, since for such $\omega,|X(t, \omega)|$ is bounded, the above holds for all $h \in H$ in place of $v$ as well. Therefore, for a.e. $\omega, t \rightarrow X(t, \omega)$ is weakly continuous with values in $H$.

Eventually, it is shown that in fact, the function $t \rightarrow X(t, \omega)$ is continuous with values in $H$.

This lemma also provides a way to simplify one of the formulas derived earlier in the case that $X_{0} \in L^{p}(\Omega, V)$. Refer to 72.4.8. One term there is $\left|X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right|^{2}$.

$$
\left|X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right|^{2} \leq 2\left|X\left(t_{1}\right)-X_{0}\right|^{2}+2\left|M\left(t_{1}\right)\right|^{2}
$$

It was shown above that $2\left|M\left(t_{1}\right)\right|^{2} \rightarrow 0$ a.e. and also in $L^{1}(\Omega)$ as $k \rightarrow \infty$. Apply the above lemma to $\left|X(t)-X_{0}\right|^{2}$ using $\left[0, t_{1}\right]$ instead of $[0, T]$. The new $X_{0}$ equals 0 . Then from the estimate 72.4.9, it follows that

$$
E\left(\left|X\left(t_{1}\right)-X_{0}\right|^{2}\right) \rightarrow 0
$$

as $k \rightarrow \infty$. Taking a subsequence, we could also assume that $\left|X\left(t_{1}\right)-X_{0}\right|^{2} \rightarrow 0$ a.e. $\omega$ as $k \rightarrow \infty$. Then, using this subsequence, it would follow from 72.4.8,

$$
\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+e(k)
$$

$$
\begin{gather*}
+2 \int_{0}^{t_{m}} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W+\sum_{j=0}^{m-1}\left|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right|^{2} \\
\quad-\sum_{j=1}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2} \tag{72.4.10}
\end{gather*}
$$

where $e(k) \rightarrow 0$ in $L^{1}(\Omega)$ and a.e. $\omega$.
Can you obtain something similar even in case $X_{0}$ is not assumed to be in $L^{p}(\Omega, V)$ ? Let $Z_{0 k} \in L^{p}(\Omega, V) \cap L^{2}(\Omega, H), Z_{0 k} \rightarrow X_{0}$ in $L^{2}(\Omega, H)$. Then

$$
\left|X\left(t_{1}\right)-X_{0}\right| \leq\left|X\left(t_{1}\right)-Z_{0 k}\right|+\left|Z_{0 k}-X_{0}\right|
$$

Also, restoring the superscript to identify the parition,

$$
X\left(t_{1}^{k}\right)-Z_{0 k}=X_{0}-Z_{0 k}+\int_{0}^{t_{1}^{k}} Y(s) d s+\int_{0}^{t_{1}^{k}} Z(s) d W
$$

Of course $\left\|\bar{X}-Z_{0 k}\right\|_{K}$ is not bounded but for each $k$ it is at least finite. There is a sequence of partitions $\mathscr{P}_{k},\left\|\mathscr{P}_{k}\right\| \rightarrow 0$ such that all the above holds. In the definitions of $K, K^{\prime}, J$ replace $[0, T]$ with $[0, t]$ and let the resulting spaces be denoted by $K_{t}, K_{t}^{\prime}, J_{t}$. Let $n_{k}$ denote a subsequence of $\{k\}$ such that

$$
\left\|\bar{X}-Z_{0 k}\right\|_{K_{t_{1} n_{k}}}<1 / k
$$

Then from the above lemma,

$$
\begin{aligned}
& E\left(\sup _{t \in\left[0, t_{1}^{n_{k}}\right]}\left|X\left(t_{1}^{n_{k}}\right)-Z_{0 k}\right|_{H}^{2}\right) \\
\leq & C\left(\|Y\|_{\substack{K_{t_{1}}^{\prime} \\
t_{1}}},\left\|\bar{X}-Z_{0 k}\right\|_{K_{t_{1} n_{k}}},\|Z\|_{J_{t_{1} n_{k}}},\left\|X_{0}-Z_{0 k}\right\|_{L^{2}(\Omega, H)}\right) \\
\leq & C\left(\|Y\|_{\substack{K_{n_{1}}^{\prime} \\
t_{1}}}, \frac{1}{k},\|Z\|_{\substack{J_{t_{1} n_{k}} \\
t_{1}}},\left\|X_{0}-Z_{0 k}\right\|_{L^{2}(\Omega, H)}\right)
\end{aligned}
$$

Hence

$$
\begin{aligned}
& E\left(\left|X\left(t_{1}^{n_{k}}\right)-X_{0}\right|^{2}\right) \leq 2 E\left(\left|X\left(t_{1}^{n_{k}}\right)-Z_{0 k}\right|_{H}^{2}\right)+2 E\left(\left|Z_{0 k}-X_{0}\right|_{H}^{2}\right) \\
& \leq 2 C\left(\|Y\|_{\substack{K_{t_{1}}^{\prime}, t_{1}}}, \frac{1}{k},\|Z\|_{\substack{J_{t_{1}} k_{k}}},\left\|X_{0}-Z_{0 k}\right\|_{L^{2}(\Omega, H)}\right)+2\left\|Z_{0 k}-X_{0}\right\|^{2}
\end{aligned}
$$

which converges to 0 as $k \rightarrow \infty$. It follows that there exists a suitable subsequence such that 72.4.10 holds even in the case that $X_{0}$ is only known to be in $L^{2}(\Omega, H)$. From now on, assume this subsequence for the paritions $\mathscr{P}_{k}$. Thus $k$ will really be $n_{k}$.

### 72.5 Converging In Probability

I am working toward the Ito formula 72.3.3. In order to get this, there is a technical result which will be needed.

Lemma 72.5.1 Let $X(s)-X_{k}^{l}(s) \equiv \Delta_{k}(s)$. Then the following limit occurs.

$$
\begin{equation*}
\lim _{k \rightarrow \infty} P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon\right]\right)=0 \tag{72.5.11}
\end{equation*}
$$

That is,

$$
\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{k}^{l}(s)\right)\right) \circ J d W(s)\right|
$$

converges to 0 in probability. Also the stochastic integral makes sense because $X$ is $H$ predictable.

Proof: First note that from Lemma 72.4.1, for a.e. $\omega, X(t)$ has values in $H$ for $t \in[0, T]$ and so it makes sense to consider it in the stochastic integral provided it is $H$ progressively measurable. However, as noted in Situation 72.3.1, this function is automatically $V^{\prime}$ predictable. Therefore,

$$
\langle X(t), v\rangle=(X(t), v)
$$

is real predictable for every $v \in V$. Now if $h \in H$, let $v_{n} \rightarrow h$ in $H$ and so for each $\omega$,

$$
\left(X(t, \omega), v_{n}\right) \rightarrow(X(t, \omega), h)
$$

By the Pettis theorem, $X$ is $H$ predictable, hence progressively measurable. Also it was shown above that $t \rightarrow X(t)$ is weakly continuous into $H$. Therefore, the desired result follows from Lemma 65.14.3 on Page 2265.

### 72.6 The Ito Formula

Now at long last, here is the first version of the Ito formula.
Lemma 72.6.1 In Situation 72.3.1, let $D$ be as above, the union of all the positive mesh points for all the $\mathscr{P}_{k}$. Also assume $X_{0} \in L^{2}(\Omega ; H)$. Then for every $t \in D$,

$$
\begin{align*}
|X(t)|^{2}= & \left|X_{0}\right|^{2}+\int_{0}^{t}\left(2\langle Y(s), \bar{X}(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
& +2 \int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} X(s)\right) \circ J d W(s) \tag{72.6.12}
\end{align*}
$$

Note that it was shown above that $X(t, \omega)$ has values in $H$ for a.e. $\omega$.
Proof: Let $t \in D$. Then $t \in \mathscr{P}_{k}$ for all $k$ large enough. Consider 72.4.10,

$$
|X(t)|^{2}-\left|X_{0}\right|^{2}=2 \int_{0}^{t}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u
$$

$$
\begin{align*}
& +2 \int_{0}^{t} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X_{k}^{l}(u)\right) \circ J d W+\sum_{j=0}^{q_{k}-1}\left|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right|^{2} \\
& -\sum_{j=1}^{q_{k}-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}+e(k) \tag{72.6.13}
\end{align*}
$$

where $t_{q_{k}}=t$. By Lemma 72.5 .1 the second term on the right, the stochastic integral, converges to

$$
2 \int_{0}^{t} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} \bar{X}(u)\right) \circ J d W
$$

in probability. The first term on the right converges to

$$
2 \int_{0}^{t}\langle Y(u), \bar{X}(u)\rangle d u
$$

in $L^{1}(\Omega)$ because $X_{k}^{r} \rightarrow X$ in $K$. Therefore, this also happens in probability. Consider the next term.

$$
E\left(\sum_{j=0}^{q_{k}-1}\left|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right|^{2}\right) .
$$

It is known from the theory of the quadratic variation that this term converges in probability to $[M](t)=\int_{0}^{t}\|Z(s)\|^{2} d s$. See Theorem 63.6.4 on Page 2147 and the description of the quadratic variation in Corollary 65.11.1.

Thus all the terms in 72.6 .13 converge in probability except for the last term which also must converge in probability because it equals the sum of terms which do. It remains to find what this last term converges to. Thus

$$
\begin{gathered}
|X(t)|^{2}-\left|X_{0}\right|^{2}=2 \int_{0}^{t}\langle Y(u), \bar{X}(u)\rangle d u \\
+2 \int_{0}^{t} \mathscr{R}\left(\left(Z(u) \circ J^{-1}\right)^{*} X(u)\right) \circ J d W+\int_{0}^{t}\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s-a
\end{gathered}
$$

where $a$ is the limit in probability of the term

$$
\sum_{j=1}^{q_{k}-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}
$$

Let $P_{n}$ be the projection onto span $\left(e_{1}, \cdots, e_{n}\right)$ as before where $\left\{e_{k}\right\}$ is an orthonormal basis for $H$ with each $e_{k} \in V$. Then using

$$
X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)=\int_{t_{j}}^{t_{j+1}} Y(s) d s
$$

the troublesome term above is of the form

$$
\begin{equation*}
\sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X\left(t_{j+1}\right)-X\left(t_{j}\right)-P_{n}\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle d s \tag{72.6.14}
\end{equation*}
$$

$$
\begin{equation*}
-\sum_{j=1}^{q_{k}-1}\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right),\left(I-P_{n}\right)\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right) \tag{72.6.15}
\end{equation*}
$$

The sum in 72.6 .15 is dominated by

$$
\begin{gather*}
\left(\sum_{j=1}^{q_{k}-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}\right)^{1 / 2} \\
\left(\sum_{j=1}^{q_{k}-1}\left|\left(I-P_{n}\right)\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}\right)^{1 / 2} \tag{72.6.16}
\end{gather*}
$$

Now it is known that $\sum_{j=1}^{q_{k}-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}$ converges in probability to $a$. If you take the expectation of the other factor it is

$$
\begin{gathered}
E\left(\sum_{j=1}^{q_{k}-1}\left|\left(I-P_{n}\right) \int_{t_{j}}^{t_{j+1}} Z(s) d W(s)\right|^{2}\right) \\
=\sum_{j=1}^{q_{k}-1} E\left(\left|\int_{t_{j}}^{t_{j+1}}\left(I-P_{n}\right) Z(s) d W(s)\right|^{2}\right) \\
=\sum_{j=1}^{q_{k}-1} E\left(\int_{t_{j}}^{t_{j+1}}\left\|\left(I-P_{n}\right) Z(s)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
\leq E\left(\int_{0}^{T}\left\|\left(I-P_{n}\right) Z(s)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s\right) \\
=\int_{\Omega} \int_{0}^{T} \sum_{i=n+1}^{\infty}\left(Z(s), e_{i}\right)^{2} d s d P
\end{gathered}
$$

The integrand converges to 0 as $n \rightarrow \infty$ and is dominated by $\sum_{i=1}^{\infty}\left(Z(s), e_{i}\right)^{2}$ which is given to be in $L^{1}([0, T] \times \Omega)$. Therefore, it converges to 0 .

Thus the expression in 72.6 .16 is of the form $f_{k} g_{n k}$ where $f_{k}$ converges in probability to $a$ as $k \rightarrow \infty$ and $g_{n k}$ converges in probability to 0 as $n \rightarrow \infty$ independently of $k$. Now this implies $f_{k} g_{n k}$ converges in probability to 0 . Here is why.

$$
\begin{aligned}
P\left(\left[\left|f_{k} g_{n k}\right|>\varepsilon\right]\right) & \leq P\left(2 \delta\left|f_{k}\right|>\varepsilon\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right) \\
& \leq P\left(2 \delta\left|f_{k}-a\right|+2 \delta|a|>\varepsilon\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right)
\end{aligned}
$$

where $\delta\left|f_{k}\right|+C_{\delta}\left|g_{k n}\right|>\left|f_{k} g_{n k}\right|$ and $\lim _{\delta \rightarrow 0} C_{\delta}=\infty$. Pick $\delta$ small enough that $\varepsilon-2 \delta|a|>$ $\varepsilon / 2$. Then this is dominated by

$$
\leq P\left(2 \delta\left|f_{k}-a\right|>\varepsilon / 2\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right)
$$

Fix $n$ large enough that the second term is less than $\eta$. Now taking $k$ large enough, the above is less than $\eta$. It follows the expression in 72.6 .16 and consequently in 72.6 .15 converges to 0 in probability.

Now consider the other term, 72.6 .14 using the $n$ just determined. This term is of the form

$$
\begin{aligned}
& \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)-P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s \\
= & \int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)-P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s
\end{aligned}
$$

where $M_{k}^{r}$ denotes the step function

$$
M_{k}^{r}(t)=\sum_{i=0}^{m_{k}-1} M\left(t_{i+1}\right) \mathscr{X}_{\left(t_{i}, t_{i+1}\right]}(t)
$$

and $M_{k}^{l}$ is defined similarly. The term

$$
\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s
$$

converges to 0 for a.e. $\omega$ as $k \rightarrow \infty$. This is because the integrand converges to 0 thanks to the continuity of $M(t)$ and also since this is a projection onto a finite dimensional subspace of $V$, Therefore, for each $\omega$ off a set of measure zero,

$$
\begin{aligned}
& \int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s \\
\leq & \int_{t_{1}}^{t}\|Y(s)\|_{V^{\prime}}\left\|P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\|_{V} d s
\end{aligned}
$$

and this last integral converges to 0 as $k \rightarrow \infty$ because $P_{n}(M(s))$ is uniformly bounded in $V$ so there is no problem getting a dominating function for the dominated convergence theorem. Let

$$
A_{k} \equiv\left[\left|\int_{t_{1}}^{t}\|Y(s)\|_{V^{\prime}}\left\|P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\|_{V} d s\right|>\varepsilon\right]
$$

Then since the partitions are increasing, these sets are decreasing as $k$ increases and their intersection has measure zero. Hence $P\left(A_{k}\right) \rightarrow 0$. It follows that

$$
\begin{gathered}
\lim _{k \rightarrow \infty} P\left(\left[\left|\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s\right|>\varepsilon\right]\right) \leq \\
\lim _{k \rightarrow \infty} P\left(\left[\left|\int_{t_{1}}^{t}\|Y(s)\|_{V^{\prime}}\left\|P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\|_{V} d s\right|>\varepsilon\right]\right)=0
\end{gathered}
$$

Now consider

$$
\int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)\right\rangle d s
$$

This converges to 0 in $L^{1}(\Omega)$ because it is of the form

$$
\int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{r}(s)\right\rangle d s-\int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{l}(s)\right\rangle d s
$$

and both $X_{k}^{l}$ and $X_{k}^{r}$ converge to $X$ in $K$. Therefore, the expression

$$
\sum_{j=1}^{q_{k}-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right|^{2}
$$

converges to 0 in probability.
In fact, the formula 72.6 .12 is valid for all $t \in[0, T]$.
Theorem 72.6.2 In Situation 72.3.1, off a set of measure zero, for every $t \in[0, T]$,

$$
\begin{align*}
|X(t)|^{2}= & \left|X_{0}\right|^{2}+\int_{0}^{t}\left(2\langle Y(s), \bar{X}(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
& +2 \int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} X(s)\right) \circ J d W(s) \tag{72.6.17}
\end{align*}
$$

Furthermore, for $t \in[0, T], t \rightarrow X(t)$ is continuous as a map into $H$ for a.e. $\omega$. In addition to this,

$$
\begin{equation*}
E\left(|X(t)|^{2}\right)=E\left(\left|X_{0}\right|^{2}\right)+E\left(\int_{0}^{t}\left(2\langle Y(s), \bar{X}(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s\right) \tag{72.6.18}
\end{equation*}
$$

Proof: Let $t \notin D$. For $t>0$, let $t(k)$ denote the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m)<t(k)$. Hence $m \leq k$. Then

$$
X(t(m))=X_{0}+\int_{0}^{t(m)} Y(s) d s+\int_{0}^{t(m)} Z(s) d W(s)
$$

a similar formula holding for $X(t(k))$. Thus for $t>t(m)$,

$$
X(t)-X(t(m))=\int_{t(m)}^{t} Y(s) d s+\int_{t(m)}^{t} Z(s) d W(s)
$$

which is the same sort of thing studied so far except that it starts at $t(m)$ rather than at 0 and $X_{0}=0$. Therefore, from Lemma 72.6.1 it follows

$$
\begin{align*}
& |X(t(k))-X(t(m))|^{2}=\int_{t(m)}^{t(k)}\left(2\langle Y(s), X(s)-X(t(m))\rangle+\|Z(s)\|^{2}\right) d s \\
& \quad+2 \int_{t(m)}^{t(k)} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}(X(s)-X(t(m)))\right) \circ J d W(s) \tag{72.6.19}
\end{align*}
$$

Consider that last term. It equals

$$
\begin{equation*}
2 \int_{t(m)}^{t(k)} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{m}^{l}(s)\right)\right) \circ J d W(s) \tag{72.6.20}
\end{equation*}
$$

This is dominated by

$$
\begin{aligned}
& 2 \mid \int_{0}^{t(k)} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{m}^{l}(s)\right)\right) \circ J d W(s) \\
& -2 \int_{0}^{t(m)} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{m}^{l}(s)\right)\right) \circ J d W(s) \mid
\end{aligned}
$$

$$
\begin{aligned}
& \leq 2\left|\int_{0}^{t(k)} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{m}^{l}(s)\right)\right) \circ J d W(s)\right| \\
& \quad+2\left|\int_{0}^{t(m)} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{m}^{l}(s)\right)\right) \circ J d W(s)\right| \\
& \leq 4 \sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{m}^{l}(s)\right)\right) \circ J d W(s)\right|
\end{aligned}
$$

In Lemma 72.5.1 the above expression was shown to converge to 0 in probability. Therefore, by the usual appeal to the Borel Canteli lemma, there is a subsequence still referred to as $\{m\}$, such that it converges to 0 pointwise in $\omega$ for all $\omega$ off some set of measure 0 as $m \rightarrow \infty$. It follows there is a set of measure 0 such that for $\omega$ not in that set, 72.6.20 converges to 0 in $\mathbb{R}$. Note that $t>0$ is arbitrary. Similar reasoning shows the first term in the non stochastic integral of 72.6 .19 is dominated by an expression of the form

$$
4 \int_{0}^{T}\left|\left\langle Y(s), \bar{X}(s)-X_{m}^{l}(s)\right\rangle\right| d s
$$

which clearly converges to 0 for $\omega$ not in some set of measure zero because $X_{m}^{l}$ converges in $K$ to $\bar{X}$. Finally, it is obvious that

$$
\lim _{m \rightarrow \infty} \int_{t(m)}^{t(k)}\|Z(s)\|^{2} d s=0 \text { for a.e. } \omega
$$

due to the assumptions on $Z$.
This shows that for $\omega$ off a set of measure 0

$$
\lim _{m, k \rightarrow \infty}|X(t(k))-X(t(m))|^{2}=0
$$

and so $\{X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $H$. Does it converge to $X(t)$ ? Let $\xi(t) \in$ $H$ be what it converges to. Let $v \in V$ then

$$
(\xi(t), v)=\lim _{k \rightarrow \infty}(X(t(k)), v)=\lim _{k \rightarrow \infty}\langle X(t(k)), v\rangle=\langle X(t), v\rangle=(X(t), v)
$$

and now, since $V$ is dense in $H$, this implies $\xi(t)=X(t)$.
Now for every $t \in D$,

$$
\begin{aligned}
|X(t)|^{2}= & \left|X_{0}\right|^{2}+\int_{0}^{t}\left(2\langle Y(s), \bar{X}(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
& +2 \int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \bar{X}(s)\right) \circ J d W(s)
\end{aligned}
$$

and so, using what was just shown along with the obvious continuity of the functions of $t$ on the right of the equal sign, it follows the above holds for all $t \in[0, T]$ off a set of measure zero.

It only remains to verify $t \rightarrow X(t)$ is continuous with values in $H$. However, the above shows $t \rightarrow|X(t)|^{2}$ is continuous and it was shown in Lemma 72.4.1 that $t \rightarrow X(t)$ is weakly
continuous into $H$. Therefore, from the uniform convexity of the norm in $H$ it follows $t \rightarrow X(t)$ is continuous.This is very easy to see in Hilbert space. Say $a_{n} \rightharpoonup a$ and $\left|a_{n}\right| \rightarrow|a|$. From the parallelogram identity.

$$
\left|a_{n}-a\right|^{2}+\left|a_{n}+a\right|^{2}=2\left|a_{n}\right|^{2}+2|a|^{2}
$$

so

$$
\left|a_{n}-a\right|^{2}=2\left|a_{n}\right|^{2}+2|a|^{2}-\left(\left|a_{n}\right|^{2}+2\left(a_{n}, a\right)+|a|^{2}\right)
$$

Then taking limsup both sides,

$$
0 \leq \lim \sup _{n \rightarrow \infty}\left|a_{n}-a\right|^{2} \leq 2|a|^{2}+2|a|^{2}-\left(|a|^{2}+2(a, a)+|a|^{2}\right)=0
$$

Of course this fact also holds in any uniformly convex Banach space.
Now consider the last claim. If the last term in 72.6 .17 were a martingale, then there would be nothing to prove. This is because if $M(t)$ is a martingale which equals 0 when $t=0$, then

$$
E(M(t))=E\left(E\left(M(t) \mid \mathscr{F}_{0}\right)\right)=E(M(0))=0
$$

However, that last term is unfortunately only a local martingale. One can obtain a localizing sequence as follows.

$$
\tau_{n}(\omega) \equiv \inf \{t:|X(t, \omega)|>n\}
$$

where as usual $\inf (\emptyset) \equiv \infty$. This is all right because it was shown above that $t \rightarrow X(t, \omega)$ is continuous into $H$ for a.e. $\omega$. Then stopping both processes on the two sides of 72.6.17 with $\tau_{n}$,

$$
\begin{aligned}
\left|X\left(t \wedge \tau_{n}\right)\right|^{2} & =\left|X_{0}\right|^{2}+\int_{0}^{t \wedge \tau_{n}}\left(2\langle Y(s), X(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
& +2 \int_{0}^{t \wedge \tau_{n}} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} X(s)\right) \circ J d W(s)
\end{aligned}
$$

Now from Lemma 65.10.5,

$$
\begin{aligned}
\left|X\left(t \wedge \tau_{n}\right)\right|^{2}= & \left|X_{0}\right|^{2}+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s)\left(2\langle Y(s), X(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
& +2 \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s) \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} X(s)\right) \circ J d W(s)
\end{aligned}
$$

That last term is now a martingale and so you can take the expectation of both sides. This gives

$$
\begin{gathered}
E\left(\left|X\left(t \wedge \tau_{n}\right)\right|^{2}\right)=E\left(\left|X_{0}\right|^{2}\right) \\
+E\left(\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s)\left(2\langle Y(s), \bar{X}(s)\rangle+\|Z(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s\right)
\end{gathered}
$$

Letting $n \rightarrow \infty$ and using the dominated convergence theorem and $\tau_{n} \rightarrow \infty$ yields the desired result.

Notation 72.6.3 The stochastic integrals are unpleasant to look at.

$$
\begin{aligned}
& \int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} X(s)\right) \circ J d W(s) \\
\equiv & \int_{0}^{t}(X(s), Z(s) d W(s))
\end{aligned}
$$

## Chapter 73

## The Hard Ito Formula, Implicit Case

### 73.1 Approximating With Step Functions

This Ito formula seems to be the fundamental idea which allows one to obtain solutions to stochastic partial differential equations using a variational point of view. I am following the treatment found in [108]. The following lemma is fundamental to the presentation. It approximates a function with a sequence of two step functions $X_{k}^{r}, X_{k}^{l}$ where $X_{k}^{r}$ has the value of $X$ at the right end of each interval and $X_{k}^{l}$ gives the value $X$ at the left end of the interval. The lemma is very interesting for its own sake. You can obviously do this sort of thing for a continuous function but here the function is not continuous and in addition, it is a stochastic process depending on $\omega$ also. This lemma was proved earlier, Lemma 65.3.1.

Lemma 73.1.1 Let $\Phi:[0, T] \times \Omega \rightarrow V$, be $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable and suppose

$$
\Phi \in K \equiv L^{p}([0, T] \times \Omega ; E), p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
\Phi_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t) \\
\Phi_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t)
\end{aligned}
$$

both converge to $\Phi$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

Also, each $\Phi\left(t_{j}^{k}\right), \Phi\left(t_{j-1}^{k}\right)$ is in $L^{p}(\Omega ; E)$. One can also assume that $\Phi(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$
\left|t_{j}^{k}-t_{j-1}^{k}\right|=2^{-n_{k}}
$$

except for the case where $j=1$ or $j=m_{n_{k}}$ when this might not be so. In the case of the last subinterval defined by the partition, we can assume

$$
\left|t_{m}^{k}-t_{m-1}^{k}\right|=\left|T-t_{m-1}^{k}\right| \geq 2^{-\left(n_{k}+1\right)}
$$

The following lemma is convenient.

Lemma 73.1.2 Let $f_{n} \rightarrow f$ in $L^{p}([0, T] \times \Omega, E)$. Then there exists a subsequence $n_{k}$ and a set of measure zero $N$ such that if $\omega \notin N$, then

$$
f_{n_{k}}(\cdot, \omega) \rightarrow f(\cdot, \omega)
$$

in $L^{p}([0, T], E)$ and for a.e. $t$.
Proof: We have

$$
\begin{aligned}
P\left(\left[\left\|f_{n}-f\right\|_{L^{p}([0, T], E)}>\lambda\right]\right) & \leq \frac{1}{\lambda} \int_{\Omega}\left\|f_{n}-f\right\|_{L^{p}([0, T], E)} d P \\
& \leq \frac{1}{\lambda}\left\|f_{n}-f\right\|_{L^{p}([0, T] \times \Omega, E)}
\end{aligned}
$$

Hence there exists a subsequence $n_{k}$ such that

$$
P\left(\left[\left\|f_{n_{k}}-f\right\|_{L^{p}([0, T], E)}>2^{-k}\right]\right) \leq 2^{-k}
$$

Then by the Borel Cantelli lemma, it follows that there exists a set of measure zero $N$ such that for all $k$ large enough and $\omega \notin N$,

$$
\left\|f_{n_{k}}-f\right\|_{L^{p}([0, T], E)} \leq 2^{-k}
$$

Now by the usual arguments used in proving completeness, $f_{n_{k}}(t) \rightarrow f(t)$ for a.e.t.
Because of this lemma, it can also be assumed that for a.e. $\omega$, pointwise convergence is obtained on $[0, T]$ as well as convergence in $L^{p}([0, T])$. This kind of assumption will be tacitly made whenever convenient.

Also recall the diagram for the definition of the integral which has values in a Hilbert space $W$.

$$
\begin{array}{cccc} 
& & & \\
U_{1} & \supseteq J Q^{1 / 2} U & \stackrel{y}{1-1} & \downarrow \\
& & Q^{1 / 2} U \\
& Z_{n} \quad \searrow & & \downarrow \\
& & & W
\end{array}
$$

The idea was to get $\int_{0}^{t} Z d W$ where $Z \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)$. Here $W(t)$ was a cylindrical Wiener process. This meant that it was a $Q_{1}$ Wiener process on $U_{1}$ for $Q_{1}=J J^{*}$ and $J$ was a Hilbert Schmidt operator mapping $Q^{1 / 2} U$ to $U_{1}$. To get $\int_{0}^{t} Z d W, Z \circ J^{-1}$ was approximated by a sequence of elementary functions $\left\{Z_{n}\right\}$ having values in $\mathscr{L}\left(U_{1}, W\right)$. Then

$$
\int_{0}^{t} Z d W \equiv \lim _{n \rightarrow \infty} \int_{0}^{t} Z_{n} d W
$$

and this limit exists in $L^{2}(\Omega, W)$ and is independent of the choice of $U_{1}$ and $J$. In fact, $U_{1}$ can be assumed to be $U$.

### 73.2 The Situation

Now consider the following situation. There are real separable Banach spaces $V, W$ such that $W$ is a Hilbert space and

$$
V \subseteq W, \quad W^{\prime} \subseteq V^{\prime}
$$

where $V$ is dense in $W$. Also let $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfy

$$
\langle B w, w\rangle \geq 0,\langle B u, v\rangle=\langle B v, u\rangle
$$

Note that $B$ does not need to be one to one. Also allowed is the case where $B$ is the Riesz map. It could also happen that $V=W$.

Situation 73.2.1 Let $X$ have values in $V$ and satisfy the following

$$
\begin{equation*}
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s+B \int_{0}^{t} Z(s) d W(s) \tag{73.2.1}
\end{equation*}
$$

$X_{0} \in L^{2}(\Omega ; W)$ and is $\mathscr{F}_{0}$ measurable, where $Z$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)$ progressively measurable and

$$
\|Z\|_{L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)}<\infty .
$$

This is what is needed to define the stochastic integral in the above formula. Here $Q$ is a nonnegative self adjoint operator defined on $U$. It could even be $I$.

Assume $X, Y$ satisfy

$$
B X, Y \in K^{\prime} \equiv L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)
$$

the $\sigma$ algebra of measurable sets defining $K^{\prime}$ will be the progressively measurable sets. Here $1 / p^{\prime}+1 / p=1, p>1$.

Also the sense in which the equation holds is as follows. For a.e. $\omega$, the equation holds in $V^{\prime}$ for all $t \in[0, T]$. Thus we are considering a particular representative $X$ of $K$ for which this happens. Also it is only assumed that $B X(t)=B(X(t))$ for a.e. t. Thus $B X$ is the name of a function having values in $V^{\prime}$ for which $B X(t)=B(X(t))$ for a.e. $t$. Assume that $X$ is progressively measurable also and

$$
X \in L^{p}([0, T] \times \Omega, V)
$$

Also $W(t)$ is a $J J^{*}$ Wiener process on $U_{1}$ in the above diagram. $U_{1}$ can be assumed to be $U$.

The goal is to prove the following Ito formula valid for a.e. $t$ for each $\omega$ off a set of measure zero.

$$
\begin{align*}
\langle B X(t), X(t)\rangle= & \left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s \\
& +\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W \tag{73.2.2}
\end{align*}
$$

The most significant feature of the last term is that it is a local martingale. The term $\langle B Z, Z\rangle_{\mathscr{L}_{2}}$ will be discussed later, as will the meaning of the stochastic integral.

The idea is that $\left(Z \circ J^{-1}\right)^{*} B X \circ J$ has values in $\mathscr{L}_{2}\left(Q^{1 / 2} U, \mathbb{R}\right)$ and so it makes sense to consider this stochastic integral. To see this, $B X \in W^{\prime}$ and

$$
\left(Z \circ J^{-1}\right)^{*} \in \mathscr{L}_{2}\left(W^{\prime},\left(J Q^{1 / 2} U\right)^{\prime}\right)
$$

and so

$$
\left(Z \circ J^{-1}\right)^{*} B X \in\left(J Q^{1 / 2} U\right)^{\prime}
$$

and so $\left(Z \circ J^{-1}\right)^{*} B X \circ J \in \mathscr{L}_{2}\left(Q^{1 / 2} U, \mathbb{R}\right)=\left(Q^{1 / 2} U\right)^{\prime}$. Note that in general $H^{\prime}=\mathscr{L}_{2}(H, \mathbb{R})$ because if you have $\left\{e_{i}\right\}$ an orthonormal basis in $H$, then for $f \in H^{\prime}$,

$$
\sum_{i}\left|\left(R^{-1} f, e_{i}\right)\right|^{2}=\sum_{i}\left|\left\langle f, e_{i}\right\rangle\right|^{2}=\|f\|_{H^{\prime}}^{2}
$$

The main item of interest relative to this stochastic integral will be a statement about its quadratic variation. It appears to depend on $J$ but this is not the case because the other terms in the formula do not.

### 73.3 Preliminary Results

Here are discussed some preliminary results which will be needed. From the integral equation, if $\phi \in L^{q}(\Omega ; V)$ and $\psi \in C_{c}^{\infty}(0, T)$ for $q=\max (p, 2)$,

$$
\begin{aligned}
& \int_{\Omega} \int_{0}^{T}\left((B X)(t)-B \int_{0}^{t} Z(s) d W(s)-B X_{0}\right) \psi^{\prime} \phi d t d P \\
= & \int_{\Omega} \int_{0}^{T} \int_{0}^{t} Y(s) \psi^{\prime}(t) d s \phi d t d P
\end{aligned}
$$

Then the term on the right equals

$$
\int_{\Omega} \int_{0}^{T} \int_{s}^{T} Y(s) \psi^{\prime}(t) d t d s \phi(\omega) d P=\int_{\Omega}\left(-\int_{0}^{T} Y(s) \psi(s) d s\right) \phi(\omega) d P
$$

It follows that, since $\phi$ is arbitrary,

$$
\int_{0}^{T}\left((B X)(t)-B \int_{0}^{t} Z(s) d W(s)-B X_{0}\right) \psi^{\prime}(t) d t=-\int_{0}^{T} Y(s) \psi(s) d s
$$

in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)$ and so the weak time derivative of

$$
t \rightarrow(B X)(t)-B \int_{0}^{t} Z(s) d W(s)-B X_{0}
$$

equals $Y$ in $L^{q^{\prime}}\left([0, T] ; L^{q^{\prime}}\left(\Omega, V^{\prime}\right)\right)$.Thus, by Theorem 34.2.9, for a.e. $t$, say $t \notin \hat{N} \subseteq$ $[0, T], m(\hat{N})=0$,

$$
B\left(X(t)-\int_{0}^{t} Z(s) d W(s)\right)=B X_{0}+\int_{0}^{t} Y(s) d s \text { in } L^{q^{\prime}}\left(\Omega, V^{\prime}\right)
$$

That is,

$$
(B X)(t)=B X_{0}+\int_{0}^{t} Y(s) d s+B \int_{0}^{t} Z(s) d W(s)
$$

holds in $L^{q^{\prime}}\left(\Omega, V^{\prime}\right)$ where $(B X)(t)=B(X(t))$ a.e. $t$, in addition to holding for all $t$ for each $\omega$. Now let $\left\{t_{k}^{n}\right\}_{k=1 n=1}^{m_{n} \infty}$ be partitions for which, from Lemma 73.1.1 there are left and right step functions $X_{k}^{l}, X_{k}^{r}$, which converge in $L^{p}([0, T] \times \Omega ; V)$ to $X$ and such that each $\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}}$ has empty intersection with the set of measure zero $\hat{N}$ where, in $L^{p^{\prime}}\left(\Omega ; V^{\prime}\right)$, $(B X)(t) \neq B(X(t))$ in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)$. Thus for $t_{k}$ a generic partition point,

$$
B X\left(t_{k}\right)=B\left(X\left(t_{k}\right)\right) \text { in } L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)
$$

Hence there is an exceptional set of measure zero, $N\left(t_{k}\right) \subseteq \Omega$ such that for

$$
\omega \notin N\left(t_{k}\right), B X\left(t_{k}\right)(\omega)=B\left(X\left(t_{k}, \omega\right)\right) .
$$

We define an exceptional set $N \subseteq \Omega$ to be the union of all these $N\left(t_{k}\right)$. There are countably many and so $N$ is also a set of measure zero. Then for $\omega \notin N$, and $t_{k}$ any mesh point at all, $B X\left(t_{k}\right)(\omega)=B\left(X\left(t_{k}, \omega\right)\right)$. This will be important in what follows. In addition to this, from the integral equation, for each of these $\omega \notin N, B X(t)(\omega)=B(X(t, \omega))$ for all $t \notin N_{\omega} \subseteq[0, T]$ where $N_{\omega}$ is a set of Lebesgue measure zero. Thus the $t_{k}$ from the various partitions are always in $N_{\omega}^{C}$. By Lemma 69.4.1, there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=0}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}, B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

Thus the conclusion of the above discussion is that at the mesh points, it is valid to write

$$
\begin{aligned}
\left\langle(B X)\left(t_{k}\right), X\left(t_{k}\right)\right\rangle & =\left\langle B\left(X\left(t_{k}\right)\right), X\left(t_{k}\right)\right\rangle \\
& =\sum_{i}\left\langle(B X)\left(t_{k}\right), e_{i}\right\rangle^{2}=\sum_{i}\left\langle B\left(X\left(t_{k}\right)\right), e_{i}\right\rangle^{2}
\end{aligned}
$$

just as would be the case if $(B X)(t)=B(X(t))$ for every $t$. In all which follows, the mesh points will be like this and an appropriate set of measure zero which may be replaced with a larger set of measure zero finitely many times is being neglected. Obviously, one can take a subsequence of the sequence of partitions described above without disturbing the above observations. We will denote these partitions as $\mathscr{P}_{k}$. As a case of this, we obtain the following interesting lemma.

Lemma 73.3.1 In the above situation, there exists a set of measure zero $N \subseteq \Omega$ and a dense subset of $[0, T], D$ such that for $\omega \notin N, B X(t, \omega)=B(X(t, \omega))$ for all $t \in D$.

Theorem 73.3.2 Let $Z$ be progressively measurable and in

$$
L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)
$$

Also suppose $X$ is progressively measurable and in $L^{2}([0, T] \times \Omega, W)$. Let $\left\{t_{j}^{n}\right\}_{j=0}^{m_{n}}$ be a sequence of partitions of the sort in Lemma 73.1.1 such that if

$$
X_{n}(t) \equiv \sum_{j=0}^{m_{n}-1} X\left(t_{j}^{n}\right) \mathscr{X}_{\left[t_{j}^{n}, t_{j+1}^{n}\right)}(t) \equiv X_{n}^{l}(t)
$$

then $X_{n} \rightarrow X$ in $L^{p}([0, T] \times \Omega, W)$. Also, it can be assumed that none of these mesh points are in the exceptional set off which $B X(t)=B(X(t))$. (Thus it will make no difference whether we write $B X(t)$ or $B(X(t))$ in what follows for all $t$ one of these mesh points.) Then the expression

$$
\begin{equation*}
\sum_{j=0}^{m_{n}-1}\left\langle B \int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z d W, X\left(t_{j}^{n}\right)\right\rangle=\sum_{j=0}^{m_{n}-1}\left\langle B X\left(t_{j}^{n}\right), \int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z d W\right\rangle \tag{73.3.3}
\end{equation*}
$$

is a local martingale which can be written in the form

$$
\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X_{n}^{l} \circ J d W
$$

where

$$
X_{n}^{l}(t)=\sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left[t_{k}^{n}, t_{k+1}^{n}\right)}(t)
$$

Proof: First suppose that $\left\langle B X\left(t_{k}^{n}\right), X\left(t_{k}^{n}\right)\right\rangle \in L^{\infty}(\Omega)$. Then

$$
\left\langle B X\left(t_{j}^{n}\right), \int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z d W\right\rangle
$$

is in $L^{1}(\Omega)$ for each $t$ since both entries are in $L^{2}(\Omega)$. Why is this a martingale?

$$
\begin{gathered}
E\left(\left\langle B X\left(t_{j}^{n}\right), \int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z d W\right\rangle\right)=E\left(E\left(\left\langle B X\left(t_{j}^{n}\right), \int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z d W\right\rangle \mid \mathscr{F}_{t_{j}^{n}}\right)\right) \\
\quad=E\left(\left\langle B X\left(t_{j}^{n}\right), E\left(\int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z d W \mid \mathscr{F}_{t_{j}^{n}}\right)\right\rangle\right)=E\left(\left\langle B X\left(t_{j}^{n}\right), 0\right\rangle\right)=0
\end{gathered}
$$

because the stochastic integral is a martingale. Now let $\sigma$ be a bounded stopping time.

$$
\begin{gathered}
E\left(\left\langle B X\left(t_{j}^{n}\right), \int_{t_{j}^{n} \wedge \sigma}^{t_{j+1}^{n} \wedge \sigma} Z d W\right\rangle\right)=E\left(E\left(\left\langle B X\left(t_{j}^{n}\right), \int_{t_{j}^{n} \wedge \sigma}^{t_{j+1}^{n} \wedge \sigma} Z d W\right\rangle \mid \mathscr{F}_{t_{j}^{n}}\right)\right) \\
=E\left(\left\langle B X\left(t_{j}^{n}\right),\left(E \int_{t_{j}^{n} \wedge \sigma}^{t_{j+1}^{n} \wedge \sigma} Z d W \mid \mathscr{F}_{t_{j}^{n}}\right)\right\rangle\right)
\end{gathered}
$$

$$
\begin{aligned}
& =E\left(\left\langle B X\left(t_{j}^{n}\right), E\left(\int_{0}^{t_{j+1}^{n} \wedge \sigma} Z d W-\int_{0}^{t_{j}^{n} \wedge \sigma} Z d W \mid \mathscr{F}_{t_{j}^{n}}\right)\right\rangle\right) \\
& =E\left(\left\langle B X\left(t_{j}^{n}\right), 0\right\rangle\right)=0
\end{aligned}
$$

and so this is a martingale by Lemma 63.1.1. I want to write the formula in 73.3 .3 as a stochastic integral. First note that $W$ has values in $U_{1}$.

Consider one of the terms of the sum more simply as

$$
\left\langle B \int_{a}^{b} Z d W, X(a)\right\rangle, a=t_{k}^{n} \wedge t, b=t_{k+1}^{n} \wedge t
$$

Then from the definition of the integral, let $Z_{n}$ be a sequence of elementary functions converging to $Z \circ J^{-1}$ in $L^{2}\left([a, b] \times \Omega, \mathscr{L}_{2}\left(J Q^{1 / 2} U, W\right)\right)$ and

$$
\left\|\int_{a}^{t} Z d W-\int_{a}^{t} Z_{n} d W\right\|_{L^{2}(\Omega, W)} \rightarrow 0
$$

Using a maximal inequality and the fact that the two integrals are martingales along with the Borel Cantelli lemma, there exists a set of measure $0 N$ such that for $\omega \notin N$, the convergence of a suitable subsequence of these integrals, still denoted by $n$, is uniform for $t \in[a, b]$. It follows that for such $\omega$,

$$
\begin{equation*}
\left\langle B \int_{a}^{t} Z d W, X(a)\right\rangle=\lim _{n \rightarrow \infty}\left\langle B \int_{a}^{t} Z_{n} d W, X(a)\right\rangle \tag{73.3.4}
\end{equation*}
$$

Say

$$
Z_{n}(u)=\sum_{k=0}^{m_{n}-1} Z_{k}^{n} \mathscr{X}_{\left[t_{k}^{n}, t_{k+1}^{n}\right)}(u)
$$

where $Z_{k}^{n}$ has finitely many values in $\mathscr{L}\left(U_{1}, W\right)_{0}$, the restrictions of maps in $\mathscr{L}\left(U_{1}, W\right)$ to $J Q^{1 / 2} U$, and the $t_{k}^{n}$ refer to a partition of $[a, b]$. Then the product on the right in 73.3.4 is of the form

$$
\sum_{k=0}^{m_{n}-1}\left\langle B Z_{k}^{n}\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right), X(a)\right\rangle_{W^{\prime}, W}
$$

Note that it makes sense because $Z_{k}^{n}$ is the restriction to $J\left(Q^{1 / 2} U\right)$ of a map from $U_{1}$ to $W$ and so $B Z_{k}^{n}$ is a map from $U_{1}$ to $W^{\prime}$. Then the Wiener process has values in $U_{1}$ so when you apply $B Z_{k}^{n}$ to $W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)$, you get something in $W^{\prime}$ and so the duality pairing is between $W^{\prime}$ and $W$ as shown. Also, $Z_{k}^{n}\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right)$ gives something in $W$ because the Wiener process has values in $U_{1}$ and $Z_{k}^{n}$ acts on these things to give something in $W$. Thus the above equals

$$
=\sum_{k=0}^{m_{n}-1}\left\langle B X(a), Z_{k}^{n}\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right)\right\rangle_{W^{\prime}, W}
$$

$$
\begin{aligned}
& =\sum_{k=0}^{m_{n}-1}\left\langle\left(Z_{k}^{n}\right)^{*} B X(a),\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right)\right\rangle_{U_{1}^{\prime}, U_{1}} \\
& =\sum_{k=0}^{m_{n}-1}\left(Z_{k}^{n}\right)^{*} B X(a)\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right) \\
& =\int_{a}^{t} Z_{n}^{*} B X(a) d W
\end{aligned}
$$

Note that the restriction of $\left(Z_{n}\right)^{*} B X(a)$ is in

$$
\mathscr{L}\left(U_{1}, \mathbb{R}\right)_{0} \subseteq \mathscr{L}_{2}\left(J Q^{1 / 2} U, \mathbb{R}\right)
$$

Recall also that the space on the left is dense in the one on the right. Now let $\left\{g_{i}\right\}$ be an orthonormal basis for $Q^{1 / 2} U$, so that $\left\{J g_{i}\right\}$ is an orthonormal basis for $J Q^{1 / 2} U$. Then

$$
\begin{gathered}
\sum_{i=1}^{\infty}\left|\left(\left(Z_{n}\right)^{*} B X(a)-\left(Z \circ J^{-1}\right)^{*} B X(a)\right)\left(J g_{i}\right)\right|^{2} \\
=\sum_{i=1}^{\infty}\left|\left\langle B X(a),\left(Z_{n}-Z \circ J^{-1}\right)\left(J g_{i}\right)\right\rangle\right|^{2} \\
\leq\langle B X(a), X(a)\rangle \sum_{i=1}^{\infty}\left\langle B\left(Z_{n}-Z \circ J^{-1}\right)\left(J g_{i}\right),\left(Z_{n}-Z \circ J^{-1}\right)\left(J g_{i}\right)\right\rangle \\
\leq\langle B X(a), X(a)\rangle\|B\| \sum_{i=1}^{\infty}\left\|\left(Z_{n}-Z \circ J^{-1}\right)\left(J g_{i}\right)\right\|_{W}^{2} \\
=\langle B X(a), X(a)\rangle\|B\|\left\|Z_{n}-Z \circ J^{-1}\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, W\right)}^{2}
\end{gathered}
$$

When integrated over $[a, b] \times \Omega$, it is given that this converges to 0 , if it is assumed that $\langle B X(a), X(a)\rangle \in L^{\infty}(\Omega)$, which is assumed for now.

It follows that, with this assumption,

$$
Z_{n}^{*} B X(a) \rightarrow\left(Z \circ J^{-1}\right)^{*} B X(a)
$$

in $L^{2}\left([a, b] \times \Omega, \mathscr{L}_{2}\left(J Q^{1 / 2} U, \mathbb{R}\right)\right)$. Writing this differently, it says

$$
Z_{n}^{*} B X(a) \rightarrow\left(\left(Z \circ J^{-1}\right)^{*} B X(a) \circ J\right) \circ J^{-1} \text { in } L^{2}\left([a, b] \times \Omega, \mathscr{L}_{2}\left(J Q^{1 / 2} U, \mathbb{R}\right)\right)
$$

It follows from the definition of the integral that the Ito integrals converge. Therefore,

$$
\left\langle B \int_{a}^{t} Z d W, X(a)\right\rangle=\int_{a}^{t}\left(Z \circ J^{-1}\right)^{*} B X(a) \circ J d W
$$

The term on the right is a martingale because the one on the left is.

Next it is necessary to drop the assumption that $\langle B X(a), X(a)\rangle \in L^{\infty}(\Omega)$. Note that $X_{n}^{l}$ is right continuous and $B X_{n}^{l}$ progressively measurable. Thus,

$$
\left\langle B X_{n}^{l}(t), X_{n}^{l}(t)\right\rangle=\sum_{i}\left\langle B X_{n}^{l}(t), e_{i}\right\rangle^{2}
$$

where $\left\{e_{i}\right\}$ is the set defined in Lemma 76.2.1 each in $V$. Thus $\left\langle B X_{n}^{l}, X_{n}^{l}\right\rangle$ is also progressively measurable and right continuous, and one can define the stopping time

$$
\begin{equation*}
\sigma_{q}^{n} \equiv \inf \left\{t:\left\langle B X_{n}^{l}(t), X_{n}^{l}(t)\right\rangle>q\right\} \tag{73.3.5}
\end{equation*}
$$

the first hitting time of an open set. Also, for each $\omega$, there are only finitely many values for $\left\langle B X_{n}^{l}(t), X_{n}^{l}(t)\right\rangle$ and so $\sigma_{q}^{n}=\infty$ for all $q$ large enough.

From localization of the stochastic integral,

$$
\begin{aligned}
\left\langle B \int_{a \wedge \sigma_{q}^{n}}^{t \wedge \sigma_{q}^{n}} Z d W, X(a)\right\rangle & =\left\langle B \int_{a}^{t} \mathscr{X}_{\left[0, \sigma_{q}^{n}\right]} Z d W, X(a)\right\rangle \\
& =\int_{a}^{t}\left(\mathscr{X}_{\left[0, \sigma_{q}^{n}\right]} Z \circ J^{-1}\right)^{*} B X(a) \circ J d W \\
& =\int_{a \wedge \sigma_{q}^{n}}^{t \wedge \sigma_{q}^{n}}\left(Z \circ J^{-1}\right)^{*} B X(a) \circ J d W
\end{aligned}
$$

Then it follows that, using the stopping time,

$$
\sum_{j=0}^{m_{n}-1}\left\langle B \int_{t_{j}^{n} \wedge t \wedge \sigma_{q}^{n}}^{t_{j+1}^{n} \wedge t \wedge \sigma_{q}^{n}} Z d W, X\left(t_{j}^{n}\right)\right\rangle=\int_{0}^{t \wedge \sigma_{q}^{n}}\left(Z \circ J^{-1}\right)^{*} B X_{n}^{l} \circ J d W
$$

where $X_{n}^{l}$ is the step function

$$
X_{n}^{l}(t)=\sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left[t_{k}^{n}, t_{k+1}^{n}\right)}(t)
$$

Thus the given sum equals the local martingale

$$
\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X_{n}^{l} \circ J d W
$$

Note that the sum 73.3 .3 does not depend on $J$ or on $U_{1}$ so the same must be true of what it equals although it does not look that way. The question of convergence as $n \rightarrow \infty$ is considered later.

What follows is the main estimate and discrete formulas.

### 73.4 The Main Estimate

The argument will be based on a formula which follows in the next lemma.

Lemma 73.4.1 In Situation 73.2.1 the following formula holds for a.e. $\omega$ for $0<s<t$ where $M(t) \equiv \int_{0}^{t} Z(u) d W(u)$ which has values in $W$. In the following, $\langle\cdot, \cdot\rangle$ denotes the duality pairing between $V, V^{\prime}$.

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\langle B X(s), X(s)\rangle+ \\
+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+\langle B(M(t)-M(s)), M(t)-M(s)\rangle \\
-\langle B X(t)-B X(s)-(M(t)-M(s)), X(t)-X(s)-(M(t)-M(s))\rangle \\
+2\langle B X(s), M(t)-M(s)\rangle \tag{73.4.6}
\end{gather*}
$$

Also for $t>0$

$$
\begin{align*}
& \langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(t)\rangle d u+2\left\langle B X_{0}, M(t)\right\rangle+ \\
& \langle B M(t), M(t)\rangle-\left\langle B X(t)-B X_{0}-B M(t), X(t)-X_{0}-M(t)\right\rangle \tag{73.4.7}
\end{align*}
$$

Proof: From the formula which is assumed to hold,

$$
\begin{aligned}
& B X(t)=B X_{0}+\int_{0}^{t} Y(u) d u+B M(t) \\
& B X(s)=B X_{0}+\int_{0}^{s} Y(u) d u+B M(s)
\end{aligned}
$$

Then

$$
B M(t)-B M(s)+\int_{s}^{t} Y(u) d u=B X(t)-B X(s)
$$

It follows that

$$
\begin{gathered}
\langle B(M(t)-M(s)), M(t)-M(s)\rangle- \\
\langle B X(t)-B X(s)-(M(t)-M(s)), X(t)-X(s)-(M(t)-M(s))\rangle \\
+2\langle B X(s), M(t)-M(s)\rangle \\
=\quad\langle B(M(t)-M(s)), M(t)-M(s)\rangle-\langle B X(t)-B X(s), X(t)-X(s)\rangle \\
+2\langle B X(t)-B X(s), M(t)-M(s)\rangle \\
-\langle B(M(t)-M(s)), M(t)-M(s)\rangle+2\langle B X(s), M(t)-M(s)\rangle
\end{gathered}
$$

Some terms cancel and this yields

$$
\begin{aligned}
=-\langle B X(t)- & B X(s), X(t)-X(s)\rangle+2\langle B X(t), M(t)-M(s)\rangle \\
=-\langle B X(t)- & B X(s), X(t)-X(s)\rangle+2\langle B(M(t)-M(s)), X(t)\rangle \\
= & -\langle B(X(t)-X(s)), X(t)-X(s)\rangle \\
& +2\left\langle B X(t)-B X(s)-\int_{s}^{t} Y(u) d u, X(t)\right\rangle
\end{aligned}
$$

$$
\begin{aligned}
&=-\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle \\
&+2\langle B X(t), X(s)\rangle+2\langle B X(t), X(t)\rangle \\
&-2\langle B X(s), X(t)\rangle-2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u \\
&=\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle-2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u
\end{aligned}
$$

Therefore,

$$
\begin{gathered}
\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle \\
=2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+\langle B(M(t)-M(s)), M(t)-M(s)\rangle \\
-\langle B X(t)-B X(s)-(M(t)-M(s)), X(t)-X(s)-(M(t)-M(s))\rangle \\
+2\langle B X(s), M(t)-M(s)\rangle
\end{gathered}
$$

The case with $X_{0}$ is similar.
The following phenomenal estimate holds and it is this estimate which is the main idea in proving the Ito formula. The last assertion about continuity is like the well known result that if $y \in L^{p}(0, T ; V)$ and $y^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$, then $y$ is actually continuous a.e. with values in $H$, for $V, H, V^{\prime}$ a Gelfand triple. Later, this continuity result is strengthened further to give strong continuity. In all of this, $X_{k}^{l}$ and $X_{k}^{r}$ are as described above, converging in $K$ to $X$.

Lemma 73.4.2 In the Situation 73.2.1, the following holds. For a.e. $t$

$$
\begin{align*}
& E(\langle B X(t), X(t)\rangle) \\
< & C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)<\infty . \tag{73.4.8}
\end{align*}
$$

where $K, K^{\prime}$ were defined earlier and

$$
J=L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U ; W\right)\right)
$$

In fact,

$$
E\left(\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}\right) \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)
$$

Also, $C$ is a continuous function of its arguments, increasing in each one, and $C(0,0,0,0)=$ 0 . Thus for a.e. $\omega$,

$$
\sup _{t \notin N_{\omega}^{C}}\langle B X(t, \omega), X(t, \omega)\rangle \leq C(\omega)<\infty
$$

Also for $\omega$ off a set of measure zero described earlier, $t \rightarrow B X(t)(\omega)$ is weakly continuous with values in $W^{\prime}$ on $[0, T]$. Also $t \rightarrow\langle B X(t), X(t)\rangle$ is lower semicontinuous on $N_{\omega}^{C}$.

Proof: Consider the formula in Lemma 73.4.1.

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\langle B X(s), X(s)\rangle \\
+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+\langle B(M(t)-M(s)), M(t)-M(s)\rangle \\
-\langle B(X(t)-X(s)-(M(t)-M(s))), X(t)-X(s)-(M(t)-M(s))\rangle \\
+2\langle B X(s), M(t)-M(s)\rangle \tag{73.4.9}
\end{gather*}
$$

Now let $t_{j}$ denote a point of $\mathscr{P}_{k}$ from Lemma 73.1.1. Then for $t_{j}>0, X\left(t_{j}\right)$ is just the value of $X$ at $t_{j}$ but when $t=0$, the definition of $X(0)$ in this step function is $X(0) \equiv 0$. Thus

$$
\begin{aligned}
& \sum_{j=1}^{m-1}\left\langle B X\left(t_{j+1}\right), X\left(t_{j+1}\right)\right\rangle-\left\langle B X\left(t_{j}\right), X\left(t_{j}\right)\right\rangle \\
& +\left\langle B X\left(t_{1}\right), X\left(t_{1}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle \\
& \quad=\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle
\end{aligned}
$$

Using the formula in Lemma 73.4.1, for $t=t_{m}$ this yields

$$
\begin{gather*}
\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle=2 \sum_{j=1}^{m-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
+2 \sum_{j=1}^{m-1}\left\langle B \int_{t_{j}}^{t_{j+1}} Z(u) d W, X\left(t_{j}\right)\right\rangle \\
+\sum_{j=1}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
-\sum_{j=1}^{m-1}\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right),\right. \\
\left.X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle \\
+2 \int_{0}^{t_{1}}\left\langle Y(u), X\left(t_{1}\right)\right\rangle d u+2\left\langle B X_{0}, \int_{0}^{t_{1}} Z(u) d W\right\rangle+\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle \\
-\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle \tag{73.4.10}
\end{gather*}
$$

First consider

$$
2 \int_{0}^{t_{1}}\left\langle Y(u), X\left(t_{1}\right)\right\rangle d u+2\left\langle B X_{0}, \int_{0}^{t_{1}} Z(u) d W\right\rangle+\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle .
$$

Each term of the above converges to 0 for a.e. $\omega$ as $k \rightarrow \infty$ and in $L^{1}(\Omega)$. This follows right away for the second two terms from the Ito isometry and continuity properties of the stochastic integral. Consider the first term. This term is dominated by

$$
\begin{aligned}
& \left(\int_{0}^{t_{1}}\|Y(u)\|^{p^{\prime}} d u\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|^{p} d u\right)^{1 / p} \\
\leq & C(\omega)\left(\int_{0}^{t_{1}}\|Y(u)\|^{p^{\prime}} d u\right)^{1 / p^{\prime}},\left(\int_{\Omega} C(\omega)^{p} d P\right)^{1 / p}<\infty
\end{aligned}
$$

Hence this converges to 0 for a.e. $\omega$ and also converges to 0 in $L^{1}(\Omega)$.
At this time, not much is known about the last term in 73.4.10, but it is negative and is about to be neglected anyway.

The term involving the stochastic integral equals

$$
2 \sum_{j=1}^{m-1}\left\langle B \int_{t_{j}}^{t_{j+1}} Z(u) d W, X\left(t_{j}\right)\right\rangle
$$

By Theorem 73.3.2 this equals

$$
2 \int_{t_{1}}^{t_{m}}\left(Z \circ J^{-1}\right)^{*} B X_{k}^{l} \circ J d W
$$

Also note that since $\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle$ converges to 0 in $L^{1}(\Omega)$ and for a.e. $\omega$, the sum involving

$$
\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle
$$

can be started at 0 rather than 1 at the expense of adding in a term which converges to 0 a.e. and in $L^{1}(\Omega)$. Thus 73.4.10 is of the form

$$
\begin{align*}
& \left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle=e(k)+2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
& \quad+2 \int_{0}^{t_{m}}\left(Z \circ J^{-1}\right)^{*} B X_{k}^{l} \circ J d W \\
& \quad+\sum_{j=0}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
& \quad-\sum_{j=1}^{m-1}\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right)\right. \\
& \left.\quad X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle \\
& \quad-\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle \tag{73.4.11}
\end{align*}
$$

where $e(k) \rightarrow 0$ for a.e. $\omega$ and also in $L^{1}(\Omega)$.

By definition, $M\left(t_{j+1}\right)-M\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Z d W$. Now it follows, on discarding the negative terms,

$$
\begin{aligned}
& \left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle \leq e(k)+2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
& +2 \int_{0}^{t_{m}}\left(Z \circ J^{-1}\right)^{*} B X_{k}^{l} \circ J d W+\sum_{j=0}^{m-1}\left\langle B \int_{t_{j}}^{t_{j+1}} Z d W, \int_{t_{j}}^{t_{j+1}} Z d W\right\rangle
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
& \sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle \leq\left\langle B X_{0}, X_{0}\right\rangle+e(k)+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u+ \\
&+2 \sup _{t_{m} \in \mathscr{P}_{k}}\left|\int_{0}^{t_{m}}\left(Z \circ J^{-1}\right)^{*} B X_{k}^{l} \circ J d W\right| \\
&+\sum_{j=0}^{m_{k}-1}\left\langle B\left(\int_{t_{j}}^{t_{j+1}} Z(u) d W\right), \int_{t_{j}}^{t_{j+1}} Z(u) d W\right\rangle
\end{aligned}
$$

where there are $m_{k}+1$ points in $\mathscr{P}_{k}$.
The next task is to somehow take the expectation of both sides. However, this is problematic because the stochastic integral is only a local martingale. Let

$$
\tau_{p}=\inf \left\{t:\left\langle B X_{k}^{l}(t), X_{k}^{l}(t)\right\rangle>p\right\}
$$

By right continuity this is a well defined stopping time. Then you obtain the above inequality for $\left(X_{k}^{l}\right)^{\tau_{p}}$ in place of $X_{k}^{l}$. Take the expectation and use the Ito isometry to obtain

$$
\begin{gather*}
\int_{\Omega}\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right),\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right)\right\rangle\right) d P \\
\leq E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+2\|Y\|_{K^{\prime}}\left\|X_{k}^{r}\right\|_{K} \\
+\|B\| \sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}} \int_{\Omega}\|Z(u)\|^{2} d P d u \\
+2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J d W\right|\right) d P+E(|e(k)|) \\
\leq C+\|B\| \int_{0}^{T} \int_{\Omega}\|Z(u)\|^{2} d P d u+E(|e(k)|) \\
+2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J d W\right|\right) d P \leq \\
C+E(|e(k)|)+2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J d W\right|\right) d P \tag{73.4.12}
\end{gather*}
$$

where the convergence of $X_{k}^{r}$ to $X$ in $K$ shows the term $2\|Y\|_{K^{\prime}}\left\|X_{k}^{r}\right\|_{K}$ is bounded. Thus the constant $C$ can be assumed to be a continuous function of

$$
\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}
$$

which equals zero when all are equal to zero and is increasing in each. The term involving the stochastic integral is next.

Let $\mathscr{M}(t)=\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J d W$. Then thanks to Corollary 65.11.1

$$
d[\mathscr{M}]=\left\|\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J\right\|^{2} d s
$$

Applying the Burkholder Davis Gundy inequality, Theorem 63.4.4 for $F(r)=r$ in that stochastic integral,

$$
\begin{array}{r}
2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J d W\right|\right) d P \\
\leq C \int_{\Omega}\left(\int_{0}^{T}\left\|\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, \mathbb{R}\right)}^{2} d s\right)^{1 / 2} d P \tag{73.4.13}
\end{array}
$$

So let $\left\{g_{i}\right\}$ be an orthonormal basis for $Q^{1 / 2} U$ and consider the integrand in the above. It equals

$$
\begin{aligned}
& \sum_{i=1}^{\infty}\left(\left(\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}}\right)\left(J\left(g_{i}\right)\right)\right)^{2}=\sum_{i=1}^{\infty}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}, Z\left(g_{i}\right)\right\rangle^{2} \\
& \quad \leq \sum_{i=1}^{\infty}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}},\left(X_{k}^{l}\right)^{\tau_{p}}\right\rangle\left\langle B Z\left(g_{i}\right), Z\left(g_{i}\right)\right\rangle \\
& \quad \leq\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right),\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right)\right\rangle\right)\|B\|\|Z\|_{\mathscr{L}_{2}}^{2}
\end{aligned}
$$

It follows that the integral in 73.4.13 is dominated by

$$
C \int_{\Omega_{t_{m} \in \mathscr{P}_{k}}} \sup _{k}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right),\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right)\right\rangle^{1 / 2}\|B\|^{1 / 2}\left(\int_{0}^{T}\|Z\|_{\mathscr{L}_{2}}^{2} d s\right)^{1 / 2} d P
$$

Now return to 73.4.12. From what was just shown,

$$
\begin{gathered}
E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right),\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right)\right\rangle\right) \\
\leq C+E(|e(k)|)+2 \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B\left(X_{k}^{l}\right)^{\tau_{p}} \circ J d W\right|\right) d P \\
\leq C+C \int_{\Omega_{t_{m} \in \mathscr{P}_{k}}} \sup _{k}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right),\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right)\right\rangle^{1 / 2} \\
\|B\|^{1 / 2}\left(\int_{0}^{T}\|Z\|_{\mathscr{L}_{2}}^{2} d s\right)^{1 / 2} d P+E(|e(k)|)
\end{gathered}
$$

$$
\begin{aligned}
\leq & C+\frac{1}{2} E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right),\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right)\right\rangle\right) \\
& +C\|Z\|_{\mathscr{L}^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\right)}^{2}+E(|e(k)|) .
\end{aligned}
$$

It follows that

$$
\frac{1}{2} E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right),\left(X_{k}^{l}\right)^{\tau_{p}}\left(t_{m}\right)\right\rangle\right) \leq C+E(|e(k)|)
$$

Now let $p \rightarrow \infty$ and use the monotone convergence theorem to obtain

$$
\begin{equation*}
E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X_{k}^{l}\left(t_{m}\right), X_{k}^{l}\left(t_{m}\right)\right\rangle\right)=E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle\right) \leq C+E(|e(k)|) \tag{73.4.14}
\end{equation*}
$$

As mentioned above, this constant $C$ is a continuous function of

$$
\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega, H)}
$$

and equals zero when all of these quantities equal 0 and is increasing with respect to each of the above quantities. Also, for each $\varepsilon>0$,

$$
E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle\right) \leq C+\varepsilon
$$

whenever $k$ is large enough.
Let $D$ denote the union of all the $\mathscr{P}_{k}$. Thus $D$ is a dense subset of $[0, T]$ and it has just been shown, since the $\mathscr{P}_{k}$ are nested, that for a constant $C$ dependent only on the above quantities which is independent of $\mathscr{P}_{k}$,

$$
E\left(\sup _{t \in D}\langle B X(t), X(t)\rangle\right) \leq C+\varepsilon
$$

Since $\varepsilon>0$ is arbitrary,

$$
\begin{equation*}
E\left(\sup _{t \in D}\langle B X(t), X(t)\rangle\right) \leq C \tag{73.4.15}
\end{equation*}
$$

Thus, enlarging $N$, for $\omega \notin N$,

$$
\begin{equation*}
\sup _{t \in D}\langle B X(t), X(t)\rangle=C(\omega)<\infty \tag{73.4.16}
\end{equation*}
$$

where $\int_{\Omega} C(\omega) d P<\infty$. By Lemma 69.4.1, there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=0}^{\infty}\left\langle B x, e_{i}\right\rangle^{2}, B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

Thus for $t$ not in a set of measure zero off which $B X(t)=B(X(t))$,

$$
\langle B X(t), X(t)\rangle=\sum_{i=0}^{\infty}\left\langle B X(t), e_{i}\right\rangle^{2}=\sup _{m} \sum_{k=1}^{m}\left\langle B X(t), e_{i}\right\rangle^{2}
$$

Now from the formula for $B X(t)$, it follows that $B X$ is continuous into $V^{\prime}$. For any $t \notin \hat{N}$ so that $(B X)(t)=B(X(t))$ in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)$ and letting $t_{k} \rightarrow t$ where $t_{k} \in D$, Fatou's lemma implies

$$
\begin{gathered}
E(\langle B X(t), X(t)\rangle)=\sum_{i} E\left(\left\langle B X(t), e_{i}\right\rangle^{2}\right)=\sum_{i} \lim _{k \rightarrow \infty} E\left(\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2}\right) \\
\quad \leq \quad \lim \inf _{k \rightarrow \infty} \sum_{i} E\left(\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2}\right)=\lim \inf _{k \rightarrow \infty} E\left(\left\langle B X\left(t_{k}\right), X\left(t_{k}\right)\right\rangle\right) \\
\quad \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)
\end{gathered}
$$

In addition to this, for arbitrary $t \in[0, T]$, and $t_{k} \rightarrow t$ from $D$,

$$
\sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2} \leq \lim \inf _{k \rightarrow \infty} \sum_{i}\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2} \leq \sup _{s \in D}\langle B X(s), X(s)\rangle
$$

Hence

$$
\begin{aligned}
\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2} & \leq \sup _{s \in D}\langle B X(s), X(s)\rangle \\
& =\sup _{s \in D} \sum_{i}\left\langle B X(s), e_{i}\right\rangle^{2} \leq \sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}
\end{aligned}
$$

It follows that $\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}$ is measurable and

$$
\begin{aligned}
& E\left(\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}\right) \leq E\left(\sup _{s \in D}\langle B X(s), X(s)\rangle\right) \\
\leq & C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)
\end{aligned}
$$

And so, for $\omega$ off a set of measure zero, $\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}$ is bounded above.
Also for $t \notin N_{\omega}$ and a given $\omega \notin N$, letting $t_{k} \rightarrow t$ for $t_{k} \in D$,

$$
\begin{aligned}
\langle B X(t), X(t)\rangle & =\sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2} \leq \lim \inf _{k \rightarrow \infty} \sum_{i}\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2} \\
& =\lim \inf _{k \rightarrow \infty}\left\langle B X\left(t_{k}\right), X\left(t_{k}\right)\right\rangle \leq \sup _{t \in D}\langle B X(t), X(t)\rangle
\end{aligned}
$$

and so

$$
\sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle \leq \sup _{t \in D}\langle B X(t), X(t)\rangle \leq \sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle
$$

From 73.4.16,

$$
\sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle=C(\omega) \text { a.e. } \omega
$$

where $\int_{\Omega} C(\omega) d P<\infty$. In particular, $\sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle$ is bounded for a.e. $\omega$ say for $\omega \notin N$ where $N$ includes the earlier sets of measure zero. This shows that $B X(t)$ is bounded in $W^{\prime}$ for $t \in N_{\omega}^{C}$.

If $v \in V$, then for $\omega \notin N$,

$$
\lim _{t \rightarrow s}\langle B X(t), v\rangle=\langle B X(s), v\rangle, t, s
$$

Therefore, since for such $\omega,\|B X(t)\|_{W^{\prime}}$ is bounded for $t \notin N_{\omega}$, the above holds for all $v \in W$ also. Therefore, for a.e. $\omega, t \rightarrow B X(t, \omega)$ is weakly continuous with values in $W^{\prime}$ for $t \notin N_{\omega}$.

Note also that

$$
\begin{aligned}
\|B X\|_{W^{\prime}}^{2} & \equiv\left(\sup _{\|y\|_{W} \leq 1}\langle B X, y\rangle\right)^{2} \leq \sup _{\|y\| \leq 1}\left(\langle B X, X\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2}\right)^{2} \\
& \leq\langle B X, X\rangle\|B\|
\end{aligned}
$$

and so

$$
\begin{align*}
& \int_{0}^{T} \int_{\Omega}\|B X(t)\|^{2} d P d t \leq \int_{\Omega} \int_{0}^{T}\|B\|\langle B X(t), X(t)\rangle d t d P \\
& \quad \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)\|B\| T \tag{73.4.17}
\end{align*}
$$

Eventually, it is shown that in fact, the function $t \rightarrow B X(t, \omega)$ is continuous with values in $W^{\prime}$. The above shows that $B X \in L^{2}\left([0, T] \times \Omega, W^{\prime}\right)$.

Finally consider the claim of weak continuity of $B X$ into $W^{\prime}$. From the integral equation, $B X$ is continuous into $V^{\prime}$. Also $B X$ is bounded on $N_{\omega}^{C}$. Let $s \in[0, T]$ be arbitrary. I claim that if $t_{n} \rightarrow s, t_{n} \in D$, it follows that $B X\left(t_{n}\right) \rightarrow B X(s)$ weakly in $W^{\prime}$. If not, then there is a subsequence, still denoted as $t_{n}$ such that $B X\left(t_{n}\right) \rightarrow Y$ weakly in $W^{\prime}$ but $Y \neq B X(s)$. However, the continuity into $V^{\prime}$ means that for all $v \in V$,

$$
\langle Y, v\rangle=\lim _{n \rightarrow \infty}\left\langle B X\left(t_{n}\right), v\right\rangle=\langle B X(s), v\rangle
$$

which is a contradiction since $V$ is dense in $W$. This establishes the claim. Also this shows that $B X(s)$ is bounded in $W^{\prime}$.

$$
|\langle B X(s), w\rangle|=\lim _{n \rightarrow \infty}\left|\left\langle B X\left(t_{n}\right), w\right\rangle\right| \leq \lim \inf _{n \rightarrow \infty}\left\|B X\left(t_{n}\right)\right\|_{W^{\prime}}\|w\|_{W} \leq C(\omega)\|w\|_{W}
$$

Now a repeat of the above argument shows that $s \rightarrow B X(s)$ is weakly continuous into $W^{\prime}$.

### 73.5 A Simplification Of The Formula

This lemma also provides a way to simplify one of the formulas derived earlier in the case that $X_{0} \in L^{p}(\Omega, V)$ so that $X-X_{0} \in L^{p}([0, T] \times \Omega, V)$. Refer to 73.4.11. One term there is

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle
$$

Also,

$$
\begin{gathered}
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle \\
\leq \\
2\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle+2\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle
\end{gathered}
$$

It was observed above that $2\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle \rightarrow 0$ a.e. and also in $L^{1}(\Omega)$ as $k \rightarrow \infty$. Apply the above lemma to $\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle$ using $\left[0, t_{1}\right]$ instead of $[0, T]$. The new $X_{0}$ equals 0 . Then from the estimate 73.4.8, it follows that

$$
E\left(\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle\right) \rightarrow 0
$$

as $k \rightarrow \infty$. Taking a subsequence, we could also assume that

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle \rightarrow 0
$$

a.e. $\omega$ as $k \rightarrow \infty$. Then, using this subsequence, it would follow from 73.4.11,

$$
\begin{align*}
\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle- & \left\langle B X_{0}, X_{0}\right\rangle=e(k)+2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
& +2 \int_{0}^{t_{m}}\left(Z \circ J^{-1}\right)^{*} B X_{k}^{l} \circ J d W \\
+ & \sum_{j=0}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
- & \sum_{j=1}^{m-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle \tag{73.5.18}
\end{align*}
$$

where $e(k) \rightarrow 0$ in $L^{1}(\Omega)$ and a.e. $\omega$ and

$$
\Delta X\left(t_{j}\right) \equiv X\left(t_{j+1}\right)-X\left(t_{j}\right)
$$

$\Delta M\left(t_{j}\right)$ being defined similarly. Note how this eliminated the need to consider the term

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle
$$

in passing to a limit. This is a very desirable thing to be able to conclude.
Can you obtain something similar even in case $X_{0}$ is not assumed to be in $L^{p}(\Omega, V)$ ? Let $Z_{0 k} \in L^{p}(\Omega, V) \cap L^{2}(\Omega, W), Z_{0 k} \rightarrow X_{0}$ in $L^{2}(\Omega, W)$. Then from the usual arguments involving the Cauchy Schwarz inequality,

$$
\begin{aligned}
\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle^{1 / 2} \leq & \left\langle B\left(X\left(t_{1}\right)-Z_{0 k}\right), X\left(t_{1}\right)-Z_{0 k}\right\rangle^{1 / 2} \\
& +\left\langle B\left(Z_{0 k}-X_{0}\right), Z_{0 k}-X_{0}\right\rangle^{1 / 2}
\end{aligned}
$$

Also, restoring the superscript to identify the parition,

$$
B\left(X\left(t_{1}^{k}\right)-Z_{0 k}\right)=B\left(X_{0}-Z_{0 k}\right)+\int_{0}^{t_{1}^{k}} Y(s) d s+B \int_{0}^{t_{1}^{k}} Z(s) d W
$$

Of course $\left\|X-Z_{0 k}\right\|_{K}$ is not bounded, but for each $k$ it is finite. There is a sequence of partitions $\mathscr{P}_{k},\left\|\mathscr{P}_{k}\right\| \rightarrow 0$ such that all the above holds. In the definitions of $K, K^{\prime}, J$ replace $[0, T]$ with $[0, t]$ and let the resulting spaces be denoted by $K_{t}, K_{t}^{\prime}, J_{t}$. Let $n_{k}$ denote a subsequence of $\{k\}$ such that

$$
\left\|X-Z_{0 k}\right\|_{\substack{K_{t_{1}} n_{k}}}<1 / k
$$

Then from the above lemma,

$$
\begin{gathered}
E\left(\left\langle B\left(X\left(t_{1}^{n_{k}}\right)-Z_{0 k}\right), X\left(t_{1}^{n_{k}}\right)-Z_{0 k}\right\rangle\right) \\
\leq C\left(\|Y\|_{K_{K_{1}^{\prime}}^{\prime},},\left\|X-Z_{0 k}\right\|_{K_{t_{1} n_{k}}},\|Z\|_{J_{t_{1} n_{k}}},\left\langle B\left(X_{0}-Z_{0 k}\right), X_{0}-Z_{0 k}\right\rangle_{L^{1}(\Omega)}\right) \\
\leq C\left(\|Y\|_{\substack{K_{n_{k}}^{\prime} \\
t_{1}}}, \frac{1}{k},\|Z\|_{J_{t_{1} n_{k}}},\left\langle B\left(X_{0}-Z_{0 k}\right), X_{0}-Z_{0 k}\right\rangle_{L^{1}(\Omega)}\right)
\end{gathered}
$$

Hence

$$
\begin{gathered}
E\left(\left\langle B\left(X\left(t_{1}^{n_{k}}\right)-X_{0}\right), X\left(t_{1}^{n_{k}}\right)-X_{0}\right\rangle\right) \\
\leq 2 E\left(\left\langle B\left(X\left(t_{1}^{n_{k}}\right)-Z_{0 k}\right), X\left(t_{1}^{n_{k}}\right)-Z_{0 k}\right\rangle\right)+2 E\left(\left\langle B\left(Z_{0 k}-X_{0}\right), Z_{0 k}-X_{0}\right\rangle\right) \\
\leq 2 C\left(\|Y\|_{K_{t_{1}^{\prime} n_{k}},}, \frac{1}{k},\|Z\|_{J_{t_{1} n_{k}}},\left\langle B\left(X_{0}-Z_{0 k}\right), X_{0}-Z_{0 k}\right\rangle_{L^{1}(\Omega)}\right) \\
+2\|B\|\left\|Z_{0 k}-X_{0}\right\|_{L^{2}(\Omega, W)}^{2}
\end{gathered}
$$

which converges to 0 as $k \rightarrow \infty$. It follows that there exists a suitable subsequence such that 73.5.18 holds even in the case that $X_{0}$ is only known to be in $L^{2}(\Omega, W)$. From now on, assume this subsequence for the partitions $\mathscr{P}_{k}$. Thus $k$ will really be $n_{k}$ and it suffices to consider the limit as $k \rightarrow \infty$ of the equation of 73.5 .18 . To emphasize this point again, the reason for the above observations is to argue that, even when $X_{0}$ is only in $L^{2}(\Omega, W)$, one can neglect

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle
$$

in passing to the limit as $k \rightarrow \infty$ provided a suitable subsequence is used.

### 73.6 Convergence

The question is whether the above stochastic integral $\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X_{n}^{l} \circ J d W$ converges as $n \rightarrow \infty$ in some sense to

$$
\begin{equation*}
\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W \tag{73.6.19}
\end{equation*}
$$

and whether the above is also a local martingale. Maybe it is well to pause and consider the integral and and what it means. $Z \circ J^{-1}$ maps $J Q^{1 / 2} U$ to $W$ and so $\left(Z \circ J^{-1}\right)^{*}$ maps $W^{\prime}$ to $\left(J Q^{1 / 2} U\right)^{\prime}$. Thus

$$
\left(Z \circ J^{-1}\right)^{*} B X \in\left(J Q^{1 / 2} U\right)^{\prime}, \text { so }\left(Z \circ J^{-1}\right)^{*} B X \circ J \in Q^{1 / 2}(U)^{\prime}=\mathscr{L}_{2}\left(Q^{1 / 2} U, \mathbb{R}\right)
$$

Thus it has the right values.
Does the stochastic integral just written even make sense? The integrand is Hilbert Schmidt and has values in $\mathbb{R}$ so it seems like we ought to be able to define an integral. The problem is that the integrand is not in $L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, \mathbb{R}\right)\right)$.

By assumption, $t \rightarrow B X(t)$ is continuous into $V^{\prime}$ thanks to the integral equation solved, and also $B X(t)=B(X(t))$ for $t \notin N_{\omega}$ a set of measure zero. For such $t$, it follows from Lemma 69.4.1,

$$
\langle B X(t), X(t)\rangle=\sum_{i}\left\langle B X(t), e_{i}\right\rangle_{V^{\prime}, V}^{2} \text { a.e. } \omega
$$

and so $t \rightarrow \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}$ is lower semicontinuous and so it equals $\langle B X(t), X(t)\rangle$ for a.e. $t$, this for each $\omega \notin N$, a single set of measure zero. Also, $t \rightarrow \sum_{i}\left\langle B X(t), e_{i}\right\rangle_{V^{\prime}, V}^{2}$ is progressively measurable and lower semicontinuous in $t$ so by Proposition 62.7.6, one can define a stopping time

$$
\begin{equation*}
\tau_{p} \equiv \inf \left\{t: \sum_{i}\left\langle B X(t), e_{i}\right\rangle_{V^{\prime}, V}^{2}>p\right\}, \tau_{0} \equiv 0 \tag{73.6.20}
\end{equation*}
$$

Instead of referring to this Proposition, you could consider

$$
\tau_{p}^{m} \equiv \inf \left\{t: \sum_{i=1}^{m}\left\langle B X(t), e_{i}\right\rangle_{V^{\prime}, V}^{2}>p\right\}
$$

which is clearly a stopping time because $t \rightarrow \sum_{i=1}^{m}\left\langle B X(t), e_{i}\right\rangle_{V^{\prime}, V}^{2}$ is a continuous process. Then observe that $\tau_{p}=\sup _{m} \tau_{p}^{m}$. Then

$$
\left[\tau_{p} \leq t\right]=\cup_{m}\left[\tau_{p}^{m} \leq t\right] \in \mathscr{F}_{t}
$$

Is it the case that $\tau_{p}=\infty$ for all $p$ large enough? Yes, this follows from Lemma 73.4.2.
Lemma 73.6.1 Suppose $\tau_{p}=\infty$ for all plarge enough off a set of measure zero, then

$$
P\left(\int_{0}^{T}\left|\left(Z \circ J^{-1}\right)^{*} B X \circ J\right|^{2} d t<\infty\right)=1
$$

Also $\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W$ can be defined as a local martingale.
Proof: Let

$$
A \equiv\left\{\omega: \int_{0}^{T}\left|\left(Z \circ J^{-1}\right)^{*} B X \circ J\right|^{2} d t=\infty\right\}
$$

Then from the assumption that $\tau_{p}=\infty$ for all $p$ large enough, it follows that

$$
A=\cup_{m=1}^{\infty} A \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)
$$

Now

$$
\begin{equation*}
P\left(A \cap\left[\tau_{m}=\infty\right]\right) \leq P\left(\omega: \int_{0}^{T} \mathscr{X}_{\left[0, \tau_{m}\right]}\left|\left(Z \circ J^{-1}\right)^{*} B X \circ J\right|^{2} d t=\infty\right) \tag{73.6.21}
\end{equation*}
$$

Consider the integrand. What is the meaning of $\left|\left(Z \circ J^{-1}\right)^{*} B X \circ J\right|^{2}$ ? You have $\left(Z \circ J^{-1}\right)^{*} \in$ $\mathscr{L}_{2}\left(W^{\prime}, J\left(Q^{1 / 2} U\right)^{\prime}\right)$ while $B X \in W^{\prime}$ and so $\left(Z \circ J^{-1}\right)^{*} B X \in \mathscr{L}_{2}\left(J\left(Q^{1 / 2} U\right)^{\prime}, \mathbb{R}\right)$ which is just $\left(J\left(Q^{1 / 2} U\right)\right)^{\prime}$. Thus $\left(Z \circ J^{-1}\right)^{*} B X \circ J$ would be in $\left(Q^{1 / 2} U\right)^{\prime}$ and to get the $\mathscr{L}_{2}$ norm, you would take an orthonormal basis in $Q^{1 / 2} U$ denoted as $\left\{g_{i}\right\}$ and the square of this norm is just

$$
\begin{aligned}
\sum_{i}\left[\left(\left(Z \circ J^{-1}\right)^{*} B X \circ J\right)\left(g_{i}\right)\right]^{2} & \equiv \sum_{i}\left[\left(Z \circ J^{-1}\right)^{*} B X\left(J g_{i}\right)\right]^{2} \\
& \equiv \sum_{i}\left[B X\left(Z \circ J^{-1}\left(J g_{i}\right)\right)\right]^{2} \\
& =\sum_{i}\left[(B X)\left(Z g_{i}\right)\right]^{2} \\
& \leq \sum_{i}\|B X\|^{2}\left\|Z g_{i}\right\|_{W}^{2}
\end{aligned}
$$

Now incorporating the stopping time, you know that for a.e. $t$,

$$
\langle B X, X\rangle(t)=\langle B X(t), X(t)\rangle \leq m
$$

and so $\|B X(t)\|$ can be estimated in terms of $m$ as follows.

$$
\begin{aligned}
|\langle B(X(t)), w\rangle| & \leq\langle B(X(t)), X(t)\rangle^{1 / 2}\|B\|^{1 / 2}\|w\|_{W} \\
& =\left(\sum_{i}\left\langle B X(t), e_{i}\right\rangle_{V^{\prime}, V}^{2}\right)^{1 / 2}\|B\|^{1 / 2}\|w\|_{W} \\
& \leq \sqrt{m}\|B\|^{1 / 2}\|w\|_{W}, \text { so }\|B X(t)\| \leq m\|B\|^{1 / 2}
\end{aligned}
$$

Thus the integrand satisfies for a.e. $t$

$$
\mathscr{X}_{\left[0, \tau_{m}\right]}\left|\left(Z \circ J^{-1}\right)^{*} B X \circ J\right|^{2} \leq m\|B\|\|Z\|_{\mathscr{L}_{2}}^{2}
$$

Hence, from 73.6.21, $P\left(A \cap\left[\tau_{m}=\infty\right]\right)$

$$
\leq P\left(\omega: \int_{0}^{T}\|Z\|_{\mathscr{L}_{2}}^{2} m\|B\| d t=\infty\right)
$$

However,

$$
\int_{\Omega} \int_{0}^{T}\|Z\|_{\mathscr{L}_{2}}^{2} m\|B\| d t d P<\infty
$$

by the assumptions on $Z$. Therefore, $P\left(A \cap\left[\tau_{m}=\infty\right]\right)=0$. It follows that

$$
P(A)=\sum_{m} P\left(A \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)\right)=\sum_{m} 0=0
$$

It follows that $P\left(\int_{0}^{T}\left|\left(Z \circ J^{-1}\right)^{*} B X \circ J\right|^{2} d t<\infty\right)=1$ and so from Definition 65.10.3, one can define $\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W$ as a local martingale.

Convergence will be shown for a subsequence and from now on every sequence will be a subsequence of this one. As part of Lemma 73.4.2, see 73.4.17, it was shown that $B X \in L^{2}\left([0, T] \times \Omega, W^{\prime}\right)$. Therefore, there exist partitions of $[0, T]$ like the above such that

$$
B X_{k}^{r}, B X_{k}^{l} \rightarrow B X \text { in } L^{2}\left([0, T] \times \Omega, W^{\prime}\right)
$$

in addition to the convergence of $X_{k}^{l}, X_{k}^{r}$ to $X$ in $K$. From now on, the argument will involve a subsequence of these.

Lemma 73.6.2 There exists a subsequence still denoted with the subscript $k$ and an enlarged set of measure zero $N$ including the earlier one such that $B X_{k}^{l}(t), B X_{k}^{r}(t)$ also converges pointwise a.e. to $B X(t)$ in $W^{\prime}$ and $X_{k}^{l}(t), X_{k}^{r}(t)$ converge pointwise a.e. in $V$ to $X(t)$ for $\omega \notin N$ as well as having convergence of $X_{k}^{l}(\cdot, \omega)$ to $X(\cdot, \omega)$ in $L^{p}([0, T] ; V)$ and $B X_{k}^{l}(\cdot, \omega)$ to $B X(\cdot, \omega)$ in $L^{2}([0, T] ; W)$.

Proof: To see that such a sequence exists, let $n_{k}$ be such that

$$
\begin{gathered}
\int_{\Omega} \int_{0}^{T}\left\|B X_{n_{k}}^{r}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t d P+\int_{\Omega} \int_{0}^{T}\left\|X_{n_{k}}^{r}(t)-X(t)\right\|_{V}^{p} d t d P+ \\
\int_{\Omega} \int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t d P+\int_{\Omega} \int_{0}^{T}\left\|X_{n_{k}}^{l}(t)-X(t)\right\|_{V}^{p} d t d P<4^{-k}
\end{gathered}
$$

Then

$$
\begin{gathered}
P\left(\int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{r}(t)-X(t)\right\|_{V}^{p} d t+\right. \\
\left.\int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{l}(t)-X(t)\right\|_{V}^{p} d t>2^{-k}\right) \\
\leq 2^{k}\left(4^{-k}\right)=2^{-k}
\end{gathered}
$$

and so by Borel Cantelli lemma, there is a set of measure zero $N$ such that if $\omega \notin N$,

$$
\begin{gathered}
\int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{r}(t)-X(t)\right\|_{V}^{p} d t+ \\
\int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{l}(t)-X(t)\right\|_{V}^{p} d t \leq 2^{-k}
\end{gathered}
$$

for all $k$ large enough. By the usual proof of completeness of $L^{p}$, it follows that $X_{n_{k}}^{l}(t) \rightarrow$ $X(t)$ for a.e. $t$, this for each $\omega \notin N$, a similar assertion holding for $X_{n_{k}}^{r}$. We denote these subsequences as $\left\{X_{k}^{r}\right\}_{k=1}^{\infty},\left\{X_{k}^{l}\right\}_{k=1}^{\infty}$.

Now with this preparation, it is possible to show the desired convergence.

Lemma 73.6.3 In the above context, let $X(s)-X_{k}^{l}(s) \equiv \Delta_{k}(s)$. Then the integral

$$
\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W
$$

exists as a local martingale and the following limit is valid for the subsequence of Lemma 73.6.2

$$
\lim _{k \rightarrow \infty} P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k} \circ J d W\right| \geq \varepsilon\right]\right)=0
$$

That is,

$$
\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k} \circ J d W\right|
$$

converges to 0 in probability.
Proof: In the argument $\tau_{m}$ will be defined in 73.6.20. Let

$$
A_{k} \equiv\left\{\omega: \sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k} \circ J d W\right| \geq \varepsilon\right\}
$$

then

$$
A_{k} \cap\left\{\omega: \tau_{m}=\infty\right\} \subseteq\left\{\omega: \sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k}^{\tau_{m}} \circ J d W\right| \geq \varepsilon\right\}
$$

By Burkholder Davis Gundy inequality,

$$
\begin{aligned}
P\left(A_{k} \cap\left\{\omega: \tau_{m}=\infty\right\}\right) & \leq \frac{C}{\varepsilon} \int_{\Omega_{t \in[0, T]}} \sup \left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k}^{\tau_{m}} \circ J d W\right| d P \\
& \leq \frac{C}{\varepsilon} \int_{\Omega}\left(\int_{0}^{T}\|Z\|_{\mathscr{L}_{2}}^{2}\left\|B \Delta_{k}^{\tau_{m}}\right\|^{2} d t\right)^{1 / 2} d P \\
& \leq \frac{C}{\varepsilon}\left(\int_{\Omega} \int_{0}^{T}\|Z\|_{\mathscr{L}_{2}}^{2}\left\|B \Delta_{k}^{\tau_{m}}\right\|^{2} d t d P\right)^{1 / 2}
\end{aligned}
$$

Recall that if $\langle B x, x\rangle \leq m$, then $\|B x\|_{W^{\prime}} \leq m^{1 / 2}\|B\|^{1 / 2}$. Then the integrand is bounded for a.e. $t$ by $\|Z\|_{\mathscr{L}_{2}}^{2} 4 m\|B\|$. Next use the result of Lemma 73.6 .2 and the dominated convergence theorem to conclude that the above converges to 0 as $k \rightarrow \infty$. Then from the assumption that $\tau_{m}=\infty$ for all $m$ large enough,

$$
P\left(A_{k}\right)=\sum_{m=1}^{\infty} P\left(A_{k} \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)\right)
$$

Now $\sum_{m} P\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)=1$ and so, one can apply the dominated convergence theorem to conclude that

$$
\lim _{k \rightarrow \infty} P\left(A_{k}\right)=\sum_{m=1}^{\infty} \lim _{k \rightarrow \infty} P\left(A_{k} \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)\right)=0
$$

Lemma 73.6.4 Let $X$ be as in Situation 73.2.1 and let $X_{k}^{l}$ be as in Lemma 73.1.1 corresponding to $X$ above. Let $X_{k}^{l}$ and $X_{k}^{r}$ both converge to $X$ in $K$ and also

$$
B X_{k}^{l}, B X_{k}^{r} \rightarrow B X \text { in } L^{2}\left([0, T] \times \Omega, W^{\prime}\right)
$$

Say

$$
\begin{align*}
X_{k}^{l}(t) & =\sum_{j=0}^{m_{k}} X\left(t_{j}\right) \mathscr{X}_{\left[t_{j}, t_{j+1)}\right.}(t),  \tag{73.6.22}\\
B X_{k}^{l}(t) & =\sum_{j=0}^{m_{k}} B X\left(t_{j}\right) \mathscr{X}_{\left[t_{j}, t_{j+1)}\right.}(t) \tag{73.6.23}
\end{align*}
$$

Then the sum in 73.6.23 is progressively measurable into $W^{\prime}$. As mentioned earlier, we can take $X(0) \equiv 0$ in the definition of the "left step function".

Proof: This follows right away from the definition of progressively measurable.
One can take a further subsequence such that uniform convergence of the stochastic integral is obtained.

Lemma 73.6.5 Let $X(s)-X_{k}^{l}(s) \equiv \Delta_{k}(s)$. Then the following limit occurs.

$$
\lim _{k \rightarrow \infty} P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k} \circ J d W\right| \geq \varepsilon\right]\right)=0
$$

The stochastic integral

$$
\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W
$$

makes sense because $B X$ is $W^{\prime}$ progressively measurable and is in $L^{2}\left([0, T] \times \Omega ; W^{\prime}\right)$. Also, there exists a further subsequence, still denoted as $k$ such that

$$
\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X_{k}^{l} \circ J d W \rightarrow \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W
$$

uniformly on $[0, T]$ for a.e. $\omega$.
Proof: This follows from Lemma 73.6.3. The last conclusion follows from the usual use of the Borel Cantelli lemma. There exists a further subsequence, still denoted with subscript $k$ such that

$$
P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k} \circ J d W\right| \geq \frac{1}{k}\right]\right)<2^{-k}
$$

Then by the Borel Cantelli lemma, one can enlarge the set of measure zero such that for $\omega \notin N$,

$$
\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B \Delta_{k} \circ J d W\right|<\frac{1}{k}
$$

for all $k$ large enough. That is, the claimed uniform convergence holds.
From now on, the sequence will either be this subsequence or a further subsequence.

### 73.7 The Ito Formula

Now at long last, here is the first version of the Ito formula valid on the partition points.
Lemma 73.7.1 In Situation 73.2.1, let $D$ be as above, the union of all the positive mesh points for all the $\mathscr{P}_{k}$. Also assume $X_{0} \in L^{2}(\Omega ; W)$. Then for $\omega \notin N$ the exceptional set of measure zero in $\Omega$ and every $t \in D$,

$$
\begin{align*}
\langle B X(t), X(t)\rangle= & \left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s \\
& +2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W \tag{73.7.24}
\end{align*}
$$

where, in the above formula,

$$
\langle B Z, Z\rangle_{\mathscr{L}_{2}} \equiv\left(R^{-1} B Z, Z\right)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}
$$

for $R$ the Riesz map from $W$ to $W^{\prime}$.
Note first that for $\left\{g_{i}\right\}$ an orthonormal basis for $Q^{1 / 2}(U)$,

$$
\left(R^{-1} B Z, Z\right)_{\mathscr{L}_{2}} \equiv \sum_{i}\left(R^{-1} B Z\left(g_{i}\right), Z\left(g_{i}\right)\right)_{W}=\sum_{i}\left\langle B Z\left(g_{i}\right), Z\left(g_{i}\right)\right\rangle_{W^{\prime} W} \geq 0
$$

Proof: Let $t \in D$. Then $t \in \mathscr{P}_{k}$ for all $k$ large enough. Consider 73.5.18,

$$
\begin{gather*}
\langle B X(t), X(t)\rangle-\left\langle B X_{0}, X_{0}\right\rangle=e(k)+2 \int_{0}^{t}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u \\
+2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X_{k}^{l} \circ J d W+\sum_{j=0}^{q_{k}-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
-\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle \tag{73.7.25}
\end{gather*}
$$

where $t_{q_{k}}=t, \Delta X\left(t_{j}\right)=X\left(t_{j+1}\right)-X\left(t_{j}\right)$ and $e(k) \rightarrow 0$ in probability. By Lemma 73.6.5 the stochastic integral on the right converges uniformly for $t \in[0, T]$ to

$$
2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W
$$

for $\omega$ off a set of measure zero. The deterministic integral on the right converges uniformly for $t \in[0, T]$ to

$$
2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

thanks to Lemma 73.6.2.

$$
\begin{aligned}
\left|\int_{0}^{t}\langle Y(u), X(u)\rangle d u-\int_{0}^{t}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u\right| & \leq \int_{0}^{T}\|Y(u)\|_{V^{\prime}}\left\|X(u)-X_{k}^{r}(u)\right\|_{V} \\
& \leq\|Y\|_{L^{p^{\prime}}([0, T])} 2^{-k}
\end{aligned}
$$

for all $k$ large enough. Consider the fourth term. It equals

$$
\begin{equation*}
\sum_{j=0}^{q_{k}-1}\left(R^{-1} B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)_{W} \tag{73.7.26}
\end{equation*}
$$

where $R^{-1}$ is the Riesz map from $W$ to $W^{\prime}$. This equals

$$
\begin{aligned}
& \frac{1}{4}\left(\sum_{j=0}^{q_{k}-1}\left\|R^{-1} B M\left(t_{j+1}\right)+M\left(t_{j+1}\right)-\left(R^{-1} B M\left(t_{j}\right)+M\left(t_{j}\right)\right)\right\|^{2}\right. \\
& \left.-\sum_{j=0}^{q_{k}-1}\left\|R^{-1} B M\left(t_{j+1}\right)-M\left(t_{j+1}\right)-\left(R^{-1} B M\left(t_{j}\right)-M\left(t_{j}\right)\right)\right\|^{2}\right)
\end{aligned}
$$

From Theorem 63.6.4, as $k \rightarrow \infty$, the above converges in probability to ( $t_{q_{k}}=t$ )

$$
\frac{1}{4}\left(\left[R^{-1} B M+M\right](t)-\left[R^{-1} B M-M\right](t)\right)
$$

However, from the description of the quadratic variation of $M$, the above equals

$$
\frac{1}{4}\left(\int_{0}^{t}\left\|R^{-1} B Z+Z\right\|_{\mathscr{L}_{2}}^{2} d s-\int_{0}^{t}\left\|R^{-1} B Z-Z\right\|_{\mathscr{L}_{2}}^{2} d s\right)
$$

which equals

$$
\int_{0}^{t}\left(R^{-1} B Z, Z\right)_{\mathscr{L}_{2}} d s \equiv \int_{0}^{t}\langle B Z, Z\rangle_{\mathscr{L}_{2}} d s
$$

This is what was desired.
Note that in the case of a Gelfand triple, when $W=H=H^{\prime}$, the term $\langle B Z, Z\rangle_{\mathscr{L}_{2}}$ will end up reducing to nothing more than $\|Z\|_{\mathscr{L}_{2}}^{2}$.

Thus all the terms in 73.7.25 converge in probability except for the last term which also must converge in probability because it equals the sum of terms which do. It remains to find what this last term converges to. Thus

$$
\begin{aligned}
& \langle B X(t), X(t)\rangle-\left\langle B X_{0}, X_{0}\right\rangle=2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u \\
& +2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W+\int_{0}^{t}\langle B Z, Z\rangle_{\mathscr{L}_{2}} d s-a
\end{aligned}
$$

where $a$ is the limit in probability of the term

$$
\begin{equation*}
\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle \tag{73.7.27}
\end{equation*}
$$

Let $P_{n}$ be the projection onto span $\left(e_{1}, \cdots, e_{n}\right)$ where $\left\{e_{k}\right\}$ is an orthonormal basis for $W$ with each $e_{k} \in V$. Then using

$$
B X\left(t_{j+1}\right)-B X\left(t_{j}\right)-\left(B M\left(t_{j+1}\right)-B M\left(t_{j}\right)\right)=\int_{t_{j}}^{t_{j+1}} Y(s) d s
$$

the troublesome term of 73.7.27 above is of the form

$$
\begin{aligned}
& \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle d s \\
& =\sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), \Delta X\left(t_{j}\right)-P_{n} \Delta M\left(t_{j}\right)\right\rangle d s \\
& \quad+\sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s),-\left(I-P_{n}\right) \Delta M\left(t_{j}\right)\right\rangle d s
\end{aligned}
$$

which equals

$$
\begin{align*}
& \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X\left(t_{j+1}\right)-X\left(t_{j}\right)-P_{n}\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle d s  \tag{73.7.28}\\
& +\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right),-\left(I-P_{n}\right)\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle \tag{73.7.29}
\end{align*}
$$

The reason for the $P_{n}$ is to get $P_{n}\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)$ in $V$. The sum in 73.7.29 is dominated by

$$
\begin{align*}
& \left(\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right),\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right)\right\rangle\right)^{1 / 2} \\
& \left(\sum_{j=1}^{q_{k}-1}\left|\left\langle B\left(I-P_{n}\right) \Delta M\left(t_{j}\right),\left(I-P_{n}\right) \Delta M\left(t_{j}\right)\right\rangle\right|^{2}\right)^{1 / 2} \tag{73.7.30}
\end{align*}
$$

Now it is known from the above that $\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right),\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right)\right\rangle$ converges in probability to $a \geq 0$. If you take the expectation of the square of the other factor, it is no larger than

$$
\begin{gathered}
\|B\| E\left(\sum_{j=1}^{q_{k}-1}\left\|\left(I-P_{n}\right) \Delta M\left(t_{j}\right)\right\|_{W}^{2}\right) \\
=\|B\| E\left(\sum_{j=1}^{q_{k}-1}\left\|\left(I-P_{n}\right) \int_{t_{j}}^{t_{j+1}} Z(s) d W(s)\right\|_{W}^{2}\right) \\
=\|B\| \sum_{j=1}^{q_{k}-1} E\left(\left\|\int_{t_{j}}^{t_{j+1}}\left(I-P_{n}\right) Z(s) d W(s)\right\|^{2}\right) \\
=\|B\| \sum_{j=1}^{q_{k}-1} E\left(\int_{t_{j}}^{t_{j+1}}\left\|\left(I-P_{n}\right) Z(s)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}^{2} d s\right) \\
\leq\|B\| E\left(\int_{0}^{T}\left\|\left(I-P_{n}\right) Z(s)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s\right)
\end{gathered}
$$

Now letting $\left\{g_{i}\right\}$ be an orthonormal basis for $Q^{1 / 2} U$,

$$
\begin{equation*}
=\|B\| \int_{\Omega} \int_{0}^{T} \sum_{i=1}^{\infty}\left\|\left(I-P_{n}\right) Z(s)\left(g_{i}\right)\right\|_{W}^{2} d s d P \tag{73.7.31}
\end{equation*}
$$

The integrand $\sum_{i=1}^{\infty}\left\|\left(I-P_{n}\right) Z(s)\left(g_{i}\right)\right\|_{W}^{2}$ converges to 0 . Also, it is dominated by

$$
\sum_{i=1}^{\infty}\left\|Z(s)\left(g_{i}\right)\right\|_{W}^{2} \equiv\|Z\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}^{2}
$$

which is given to be in $L^{1}([0, T] \times \Omega)$. Therefore, from the dominated convergence theorem, the expression in 73.7 .31 converges to 0 as $n \rightarrow \infty$.

Thus the expression in 73.7 .30 is of the form $f_{k} g_{n k}$ where $f_{k}$ converges in probability to $a^{1 / 2}$ as $k \rightarrow \infty$ and $g_{n k}$ converges in probability to 0 as $n \rightarrow \infty$ independently of $k$. Now this implies $f_{k} g_{n k}$ converges in probability to 0 . Here is why.

$$
\begin{aligned}
P\left(\left[\left|f_{k} g_{n k}\right|>\varepsilon\right]\right) & \leq P\left(2 \delta\left|f_{k}\right|>\varepsilon\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right) \\
& \leq P\left(2 \delta\left|f_{k}-a^{1 / 2}\right|+2 \delta\left|a^{1 / 2}\right|>\varepsilon\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right)
\end{aligned}
$$

where $\delta\left|f_{k}\right|+C_{\delta}\left|g_{k n}\right|>\left|f_{k} g_{n k}\right|$ and $\lim _{\delta \rightarrow 0} C_{\delta}=\infty$. Pick $\delta$ small enough that $\varepsilon-2 \delta a^{1 / 2}>$ $\varepsilon / 2$. Then this is dominated by

$$
\leq P\left(2 \delta\left|f_{k}-a^{1 / 2}\right|>\varepsilon / 2\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right)
$$

Fix $n$ large enough that the second term is less than $\eta$ for all $k$. Now taking $k$ large enough, the above is less than $\eta$. It follows the expression in 73.7.30 and consequently in 73.7.29 converges to 0 in probability.

Now consider the other term 73.7.28 using the $n$ just determined. This term is of the form

$$
\begin{aligned}
& \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X\left(t_{j+1}\right)-X\left(t_{j}\right)-P_{n}\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle d s= \\
& \quad \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)-P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s \\
& =\int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)-P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s
\end{aligned}
$$

where $M_{k}^{r}$ denotes the step function

$$
M_{k}^{r}(t)=\sum_{i=0}^{m_{k}-1} M\left(t_{i+1}\right) \mathscr{X}_{\left(t_{i}, t_{i+1}\right]}(t)
$$

and $M_{k}^{l}$ is defined similarly. The term

$$
\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s
$$

converges to 0 for a.e. $\omega$ as $k \rightarrow \infty$ thanks to continuity of $t \rightarrow M(t)$. However, more is needed than this. Define the stopping time

$$
\tau_{p}=\inf \left\{t>0:\|M(t)\|_{W}>p\right\}
$$

Then $\tau_{p}=\infty$ for all $p$ large enough, this for a.e. $\omega$. Let

$$
\begin{gather*}
A_{k}=\left[\left|\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s\right|>\varepsilon\right] \\
P\left(A_{k}\right)=\sum_{p=0}^{\infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right) \tag{73.7.32}
\end{gather*}
$$

Now

$$
\begin{aligned}
& P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right) \leq P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right]\right)\right) \\
\leq & P\left(\left[\left|\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(\left(M^{\tau_{p}}\right)_{k}^{r}(s)-\left(M^{\tau_{p}}\right)_{k}^{l}(s)\right)\right\rangle d s\right|>\varepsilon\right]\right)
\end{aligned}
$$

This is so because if $\tau_{p}=\infty$, then it has no effect but also it could happen that the defining inequality may hold even if $\tau_{p}<\infty$ hence the inequality. This is no larger than an expression of the form

$$
\begin{equation*}
\frac{C_{n}}{\varepsilon} \int_{\Omega} \int_{0}^{T}\|Y(s)\|_{V^{\prime}}\left\|\left(M^{\tau_{p}}\right)_{k}^{r}(s)-\left(M^{\tau_{p}}\right)_{k}^{l}(s)\right\|_{W} d s d P \tag{73.7.33}
\end{equation*}
$$

The inside integral converges to 0 by continuity of $M$. Also, thanks to the stopping time, the inside integral is dominated by an expression of the form

$$
\int_{0}^{T}\|Y(s)\|_{V^{\prime}} 2 p d s
$$

and this is a function in $L^{1}(\Omega)$ by assumption on $Y$. It follows that the integral in 73.7.33 converges to 0 as $k \rightarrow \infty$ by the dominated convergence theorem. Hence

$$
\lim _{k \rightarrow \infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right]\right)\right)=0
$$

Since the sets $\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]$ are disjoint, the sum of their probabilities is finite. Hence there is a dominating function in 73.7 .32 and so, by the dominated convergence theorem applied to the sum,

$$
\lim _{k \rightarrow \infty} P\left(A_{k}\right)=\sum_{p=0}^{\infty} \lim _{k \rightarrow \infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right)=0
$$

Thus $\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s$ converges to 0 in probability as $k \rightarrow \infty$.
Now consider

$$
\begin{aligned}
\left|\int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)\right\rangle d s\right| \leq & \int_{0}^{T}\left|\left\langle Y(s), X_{k}^{r}(s)-X(s)\right\rangle\right| d s \\
& +\int_{0}^{T}\left|\left\langle Y(s), X_{k}^{l}(s)-X(s)\right\rangle\right| d s
\end{aligned}
$$

$$
\leq 2\|Y(\cdot, \omega)\|_{L^{p^{\prime}}(0, T)} 2^{-k}
$$

for all $k$ large enough, this by Lemma 73.6.2. Therefore,

$$
\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle
$$

converges to 0 in probability. This establishes the desired formula for $t \in D$.
In fact, the formula 73.7.24 is valid for all $t \in N_{\omega}^{C}$.
Theorem 73.7.2 In Situation 73.2.1, for $\omega$ off a set of measure zero, for every $t \notin N_{\omega}$,

$$
\begin{align*}
\langle B X(t), X(t)\rangle= & \left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s \\
& +2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W \tag{73.7.34}
\end{align*}
$$

Also, there exists a unique continuous, progressively measurable function $\langle B X, X\rangle$ such that it equals $\langle B X(t), X(t)\rangle$ for a.e. $t$ and $\langle B X, X\rangle(t)$ equals the right side of the above for all $t$. In addition to this,

$$
\begin{gather*}
E(\langle B X, X\rangle(t))= \\
E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+E\left(\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s\right) \tag{73.7.35}
\end{gather*}
$$

Also the quadratic variation of the stochastic integral in 73.7.34 is dominated by

$$
\begin{equation*}
C \int_{0}^{t}\|Z\|_{\mathscr{L}_{2}}^{2}\|B X\|_{W^{\prime}}^{2} d s \tag{73.7.36}
\end{equation*}
$$

for a suitable constant $C$. Also $t \rightarrow B X(t)$ is continuous with values in $W^{\prime}$ for $t \in N_{\omega}^{C}$.
Proof: Let $t \in N_{\omega}^{C} \backslash D$. For $t>0$, let $t(k)$ denote the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m)<t(k)$. Hence $m \leq k$. Then

$$
B X(t(m))=B X_{0}+\int_{0}^{t(m)} Y(s) d s+B \int_{0}^{t(m)} Z(s) d W(s)
$$

a similar formula holding for $X(t(k))$. Thus for $t>t(m), t \notin N_{\omega}$,

$$
B(X(t)-X(t(m)))=\int_{t(m)}^{t} Y(s) d s+B \int_{t(m)}^{t} Z(s) d W(s)
$$

which is the same sort of thing studied so far except that it starts at $t(m)$ rather than at 0 and $B X_{0}=0$. Therefore, from Lemma 73.7.1 it follows

$$
\begin{gathered}
\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle \\
=\int_{t(m)}^{t(k)}\left(2\langle Y(s), X(s)-X(t(m))\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s
\end{gathered}
$$

$$
\begin{equation*}
+2 \int_{t(m)}^{t(k)}\left(Z \circ J^{-1}\right)^{*} B(X(s)-X(t(m))) \circ J d W \tag{73.7.37}
\end{equation*}
$$

Consider that last term. It equals

$$
\begin{equation*}
2 \int_{t(m)}^{t(k)}\left(Z \circ J^{-1}\right)^{*} B\left(X(s)-X_{m}^{l}(s)\right) \circ J d W \tag{73.7.38}
\end{equation*}
$$

This is dominated by

$$
\begin{aligned}
& 2 \mid \int_{0}^{t(k)}\left(Z \circ J^{-1}\right)^{*} B\left(X(s)-X_{m}^{l}(s)\right) \circ J d W \\
& -\int_{0}^{t(m)}\left(Z \circ J^{-1}\right)^{*} B\left(X(s)-X_{m}^{l}(s)\right) \circ J d W \mid \\
\leq & 4 \sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B\left(X(s)-X_{m}^{l}(s)\right) \circ J d W\right|
\end{aligned}
$$

In Lemma 73.6 .5 the above expression was shown to converge to 0 in probability. Therefore, by the usual appeal to the Borel Canteli lemma, there is a subsequence still referred to as $\{m\}$, such that it converges to 0 pointwise in $\omega$ for all $\omega$ off some set of measure 0 as $m \rightarrow \infty$. It follows there is a set of measure 0 including the earlier one such that for $\omega$ not in that set, 73.7 .38 converges to 0 in $\mathbb{R}$. Similar reasoning shows the first term on the right in the non stochastic integral of 73.7 .37 is dominated by an expression of the form

$$
4 \int_{0}^{T}\left|\left\langle Y(s), X(s)-X_{m}^{l}(s)\right\rangle\right| d s
$$

which clearly converges to 0 thanks to Lemma 73.6.2. Finally, it is obvious that

$$
\lim _{m \rightarrow \infty} \int_{t(m)}^{t(k)}\langle B Z, Z\rangle_{\mathscr{L}_{2}} d s=0 \text { for a.e. } \omega
$$

due to the assumptions on $Z$. For $\left\{g_{i}\right\}$ an orthonormal basis of $Q^{1 / 2}(U)$,

$$
\begin{aligned}
\langle B Z, Z\rangle_{\mathscr{L}_{2}} & \equiv \sum_{i}\left(R^{-1} B Z\left(g_{i}\right), Z\left(g_{i}\right)\right)=\sum_{i}\left\langle B Z\left(g_{i}\right), Z\left(g_{i}\right)\right\rangle \\
& \leq\|B\| \sum_{i}\left\|Z\left(g_{i}\right)\right\|_{W}^{2} \in L^{1}(0, T) \text { a.e. }
\end{aligned}
$$

This shows that for $\omega$ off a set of measure 0

$$
\lim _{m, k \rightarrow \infty}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle=0
$$

Then for $x \in W$,

$$
\begin{aligned}
& |\langle B(X(t(k))-X(t(m))), x\rangle| \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\langle B x, x\rangle^{1 / 2} \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\|B\|^{1 / 2}\|x\|_{W}
\end{aligned}
$$

and so

$$
\lim _{m, k \rightarrow \infty}\|B X(t(k))-B X(t(m))\|_{W^{\prime}}=0
$$

Recall $t$ was arbitrary in $N_{\omega}^{C}$ and $\{t(k)\}$ is a sequence converging to $t$. Then the above has shown that $\{B X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $W^{\prime}$. Does it converge to $B X(t)$ ? Let $\xi(t) \in W^{\prime}$ be what it converges to. Letting $v \in V$ then, since the integral equation shows that $t \rightarrow B X(t)$ is continuous into $V^{\prime}$,

$$
\langle\xi(t), v\rangle=\lim _{k \rightarrow \infty}\langle B X(t(k)), v\rangle=\langle B X(t), v\rangle,
$$

and now, since $V$ is dense in $W$, this implies $\xi(t)=B X(t)=B(X(t))$. Recall also that it was shown earlier that $B X$ is weakly continuous into $W^{\prime}$ hence the strong convergence of $\{B X(t(k))\}_{k=1}^{\infty}$ in $W^{\prime}$ implies that it converges to $B X(t)$, this for any $t \in N_{\omega}^{C}$.

For every $t \in D$ and for $\omega$ off the exceptional set of measure zero described earlier,

$$
\begin{align*}
\langle B(X(t)), X(t)\rangle= & \left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}} d s\right) d s \\
& +2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W \tag{73.7.39}
\end{align*}
$$

Does this formula hold for all $t \in[0, T]$ ? Maybe not. However, it will hold for $t \notin N_{\omega}$. So let $t \notin N_{\omega}$.

$$
\begin{gathered}
|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle| \\
\leq|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t(k))\rangle| \\
+|\langle B X(t), X(t(k))\rangle-\langle B X(t), X(t)\rangle| \\
=|\langle B(X(t(k))-X(t)), X(t(k))\rangle|+|\langle B(X(t(k))-X(t)), X(t)\rangle|
\end{gathered}
$$

Then using the Cauchy Schwarz inequality on each term,

$$
\begin{aligned}
\leq & \langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2} \\
& \cdot\left(\langle B X(t(k)), X(t(k))\rangle^{1 / 2}+\langle B X(t), X(t)\rangle^{1 / 2}\right)
\end{aligned}
$$

As before, one can use the lower semicontinuity of

$$
t \rightarrow\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle
$$

on $N_{\omega}^{C}$ along with the boundedness of $\langle B X(t), X(t)\rangle$ also shown earlier $\mathbf{o f f} N_{\omega}$ to conclude

$$
\begin{gathered}
|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle| \\
\leq C\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2} \\
\leq C \lim \inf _{m \rightarrow \infty}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}<\varepsilon
\end{gathered}
$$

provided $k$ is sufficiently large. Since $\varepsilon$ is arbitrary,

$$
\lim _{k \rightarrow \infty}\langle B X(t(k)), X(t(k))\rangle=\langle B X(t), X(t)\rangle
$$

It follows that the formula 73.7 .39 is valid for all $t \notin N_{\omega}$. Now define the function $\langle B X, X\rangle(t)$ as

$$
\langle B X, X\rangle(t) \equiv\left\{\begin{array}{c}
\langle B(X(t)), X(t)\rangle, t \notin N_{\omega} \\
\text { The right side of 73.7.39 if } t \in N_{\omega}
\end{array}\right.
$$

Then in short, $\langle B X, X\rangle(t)$ equals the right side of 73.7.39 for all $t \in[0, T]$ and is consequently progressively measurable and continuous. Furthermore, for a.e. $t$, this function equals $\langle B(X(t)), X(t)\rangle$. Since it is known on a dense subset, it must be unique.

This implies that $t \rightarrow B X(t)$ is continuous with values in $W^{\prime}$ for $t \notin N_{\omega}$. Here is why. The fact that the formula 73.7.39 holds for all $t \notin N_{\omega}$ implies that $t \rightarrow\langle B X(t), X(t)\rangle$ is continuous on $N_{\omega}^{C}$. Then for $x \in W$,

$$
\begin{equation*}
|\langle B X(t)-B X(s), x\rangle| \leq\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2}\|B\|^{1 / 2}\|x\|_{W} \tag{73.7.40}
\end{equation*}
$$

Also

$$
\begin{aligned}
& \langle B(X(t)-X(s)), X(t)-X(s)\rangle \\
= & \langle B X(t), X(t)\rangle+\langle B X(s), X(s)\rangle-2\langle B X(t), X(s)\rangle
\end{aligned}
$$

By weak continuity of $t \rightarrow B X(t)$ shown earlier,

$$
\lim _{t \rightarrow s}\langle B X(t), X(s)\rangle=\langle B X(s), X(s)\rangle
$$

Therefore,

$$
\lim _{t \rightarrow s}\langle B(X(t)-X(s)), X(t)-X(s)\rangle=0
$$

and so the inequality 73.7.40 implies the continuity of $t \rightarrow B X(t)$ into $W^{\prime}$ for $t \notin N_{\omega}$. Note that by assumption this function is continuous into $V^{\prime}$ for all $t$. It was also shown that it is weakly continuous into $W^{\prime}$ on $[0, T]$ and hence it is bounded in $W^{\prime}$.

Now consider the claim about the expectation. Since the stochastic integral

$$
2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W
$$

is only a local martingale, it is necessary to employ a stopping time. We use the function $\langle B X, X\rangle$ to define this stopping time as

$$
\tau_{p} \equiv \inf \{t>0:\langle B X, X\rangle(t)>p\}
$$

This is the first hitting time of a continuous process and so it is a valid stopping time. Using this, leads to

$$
\langle B X, X\rangle^{\tau_{p}}(t)=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}(s)\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}} d s\right) d s
$$

$$
\begin{equation*}
+2 \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}(s)\left(Z \circ J^{-1}\right)^{*} B X^{\tau_{p}} \circ J d W \tag{73.7.41}
\end{equation*}
$$

By continuity of $\langle B X, X\rangle, \tau_{p}=\infty$ for all $p$ large enough. Take expectation of both sides of the above. In the integrand of the last term, $B X$ refers to the function $B X(t, \omega) \equiv$ $B(X(t, \omega))$ and so it is progressively measurable because $X$ is assumed to be so. Hence $B X^{\tau_{p}}$ is also progressively measurable and for a.e. Also, for a.e. $s,\left\|B X\left(s \wedge \tau_{p}\right)\right\|_{W^{\prime}} \leq$ $\sqrt{p} \sqrt{\|B\|}$. Therefore, one can take expectations and get

$$
\begin{gathered}
E\left(\langle B X, X\rangle^{\tau_{p}}(t)\right)=E\left(\left\langle B X_{0}, X_{0}\right\rangle\right) \\
+E\left(\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}(s)\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}} d s\right) d s\right)
\end{gathered}
$$

Now let $p \rightarrow \infty$ and use the monotone convergence theorem on the left and the dominated convergence theorem on the right to obtain the desired result 73.7.35. The claim about the quadratic variation follows from Corollary 65.11.1.

## Chapter 74

## A More Attractive Version

The following lemma is convenient.
Lemma 74.0.1 Let $f_{n} \rightarrow f$ in $L^{p}([0, T] \times \Omega, E)$. Then there exists a subsequence $n_{k}$ and a set of measure zero $N$ such that if $\omega \notin N$, then

$$
f_{n_{k}}(\cdot, \omega) \rightarrow f(\cdot, \omega)
$$

in $L^{p}([0, T], E)$ and for a.e. t.
Proof: We have

$$
\begin{aligned}
P\left(\left[\left\|f_{n}-f\right\|_{L^{p}([0, T], E)}>\lambda\right]\right) & \leq \frac{1}{\lambda} \int_{\Omega}\left\|f_{n}-f\right\|_{L^{p}([0, T], E)} d P \\
& \leq \frac{1}{\lambda}\left\|f_{n}-f\right\|_{L^{p}([0, T] \times \Omega, E)}
\end{aligned}
$$

Hence there exists a subsequence $n_{k}$ such that

$$
P\left(\left[\left\|f_{n_{k}}-f\right\|_{L^{p}([0, T], E)}>2^{-k}\right]\right) \leq 2^{-k}
$$

Then by the Borel Cantelli lemma, it follows that there exists a set of measure zero $N$ such that for all $k$ large enough and $\omega \notin N$,

$$
\left\|f_{n_{k}}-f\right\|_{L^{p}([0, T], E)} \leq 2^{-k}
$$

Now by the usual arguments used in proving completeness, $f_{n_{k}}(t) \rightarrow f(t)$ for a.e.t.
Also, we have the approximation lemma proved earlier, Lemma 65.3.1.
Lemma 74.0.2 Let $\Phi:[0, T] \times \Omega \rightarrow V$, be $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable and suppose

$$
\Phi \in K \equiv L^{p}([0, T] \times \Omega ; E), p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
\Phi_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t) \\
\Phi_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t)
\end{aligned}
$$

both converge to $\Phi$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

Also, each $\Phi\left(t_{j}^{k}\right), \Phi\left(t_{j-1}^{k}\right)$ is in $L^{p}(\Omega ; E)$. One can also assume that $\Phi(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$
\left|t_{j}^{k}-t_{j-1}^{k}\right|=2^{-n_{k}}
$$

except for the case where $j=1$ or $j=m_{n_{k}}$ when this might not be so. In the case of the last subinterval defined by the partition, we can assume

$$
\left|t_{m}^{k}-t_{m-1}^{k}\right|=\left|T-t_{m-1}^{k}\right| \geq 2^{-\left(n_{k}+1\right)}
$$

### 74.1 The Situation

Now consider the following situation. There are real separable Banach spaces $V, W$ such that $W$ is a Hilbert space and

$$
V \subseteq W, \quad W^{\prime} \subseteq V^{\prime}
$$

where $V$ is dense in $W$. Also let $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfy

$$
\langle B w, w\rangle \geq 0,\langle B u, v\rangle=\langle B v, u\rangle
$$

Note that $B$ does not need to be one to one. Also allowed is the case where $B$ is the Riesz map. It could also happen that $V=W$. Assume that $B=B(\omega)$ where $B$ is $\mathscr{F}_{0}$ measurable into $\mathscr{L}\left(W, W^{\prime}\right)$. This dependence on $\omega$ will be suppressed in the interest of simpler notation. For convenience, assume $\|B(\omega)\|$ is bounded. This is assumed mainly so that an estimate can be made on $\left\langle B X_{0}, X_{0}\right\rangle$ for $X_{0}$ given in $L^{2}(\Omega)$. It probably suffices to simply give an estimate on $\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}$ along with something else on the Ito integral. However, it seems at this time like this is more trouble than it is worth.

Situation 74.1.1 Let $X$ have values in $V$ and satisfy the following

$$
\begin{equation*}
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s+B M(t) \tag{74.1.1}
\end{equation*}
$$

$X_{0} \in L^{2}(\Omega ; W)$ and is $\mathscr{F}_{0}$ measurable. Here $M(t)$ is a continuous $L^{2}$ martingale having values in $W$. By this is meant that $\lim _{t \rightarrow 0+}\|M(t)\|_{L^{2}(\Omega)}=0$ and for each $\omega, \lim _{t \rightarrow 0+} M(t)=$ $0,\|M\|_{W}^{2} \in L^{2}([0, T] \times \Omega)$. Assume that $d[M]=k d m$ for $k \in L^{1}([0, T] \times \Omega)$, that is, the measure determined by the quadratic variation for the martingale is absolutely continuous with respect to Lebesgue measure as just described.

Assume Y satisfies

$$
Y \in K^{\prime} \equiv L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)
$$

the $\sigma$ algebra of measurable sets defining $K^{\prime}$ will be the progressively measurable sets. Here $1 / p^{\prime}+1 / p=1, p>1$.

Also the sense in which the equation holds is as follows. For a.e. $\omega$, the equation holds in $V^{\prime}$ for all $t \in[0, T]$. Thus we are considering a particular representative $X$ for which this happens. Also it is only assumed that $B X(t)=B(X(t))$ for a.e. $t$. Thus $B X$ is the name
of a function having values in $V^{\prime}$ for which $B X(t)=B(X(t))$ for a.e. $t$. Assume that $X$ is progressively measurable also and $X \in L^{p}([0, T] \times \Omega, V)$.

The goal is to prove the following Ito formula valid for a.e. $t$ for each $\omega$ off a set of measure zero.

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}(2\langle Y(s), X(s)\rangle) d s \\
+\left[R^{-1} B M, M\right](t)+2 \int_{0}^{t}\langle B X, d M\rangle \tag{74.1.2}
\end{gather*}
$$

where $R$ is the Riesz map from $W$ to $W^{\prime}$. The most significant feature of the last term is that it is a local martingale. The third term on the right is the covariation of the two martingales $R^{-1} B M$ and $M$. It will follow from the argument that this will be nonnegative.

Note that the assumptions on $M$ imply that $[M] \in L^{1}([0, T] \times \Omega)$.

### 74.2 Preliminary Results

Here are discussed some preliminary results which will be needed. From the integral equation, if $\phi \in L^{q}(\Omega ; V)$ and $\psi \in C_{c}^{\infty}(0, T)$ for $q=\max (p, 2)$,

$$
\begin{aligned}
& \int_{\Omega} \int_{0}^{T}\left((B X)(t)-B M(t)-B X_{0}\right) \psi^{\prime} \phi d t d P \\
= & \int_{\Omega} \int_{0}^{T} \int_{0}^{t} Y(s) \psi^{\prime}(t) d s \phi d t d P
\end{aligned}
$$

Then the term on the right equals

$$
\int_{\Omega} \int_{0}^{T} \int_{s}^{T} Y(s) \psi^{\prime}(t) d t d s \phi(\omega) d P=\int_{\Omega}\left(-\int_{0}^{T} Y(s) \psi(s) d s\right) \phi(\omega) d P
$$

It follows that, since $\phi$ is arbitrary,

$$
\int_{0}^{T}\left((B X)(t)-B M(t)-B X_{0}\right) \psi^{\prime}(t) d t=-\int_{0}^{T} Y(s) \psi(s) d s
$$

in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)$ and so the weak time derivative of

$$
t \rightarrow(B X)(t)-B M(t)-B X_{0}
$$

equals $Y$ in $L^{q^{\prime}}\left([0, T] ; L^{q^{\prime}}\left(\Omega, V^{\prime}\right)\right)$.Thus, by Theorem 34.2.9, for a.e. $t$,

$$
B(X(t)-M(t))=B X_{0}+\int_{0}^{t} Y(s) d s \text { in } L^{q^{\prime}}\left(\Omega, V^{\prime}\right)
$$

That is,

$$
(B X)(t)=B X_{0}+\int_{0}^{t} Y(s) d s+B M(t), t \notin \hat{N}, m(\hat{N})=0
$$

holds in $L^{q^{\prime}}\left(\Omega, V^{\prime}\right)$ where $(B X)(t)=B(X(t))$ a.e. $t$ in this space, for all $t \notin \hat{N}$, a set of Lebesgue measure zero, in addition to holding for all $t$ for each $\omega$. Now let $\left\{t_{k}^{n}\right\}_{k=1 n=1}^{m_{n} \infty}$ be partitions for which, from Lemma 74.0.2 there are left and right step functions $X_{k}^{l}, X_{k}^{r}$, which converge in $L^{p}([0, T] \times \Omega ; V)$ to $X$ and such that each $\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}}$ has empty intersection with the set of measure zero $\hat{N}$ where, in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right),(B X)(t) \neq B(X(t))$ in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)$. Thus for $t_{k}$ a generic partition point,

$$
B X\left(t_{k}\right)=B\left(X\left(t_{k}\right)\right) \text { in } L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)
$$

Hence there is an exceptional set of measure zero, $N\left(t_{k}\right) \subseteq \Omega$ such that for

$$
\omega \notin N\left(t_{k}\right), B X\left(t_{k}\right)(\omega)=B\left(X\left(t_{k}, \omega\right)\right) .
$$

Define an exceptional set $N \subseteq \Omega$ to be the union of all these $N\left(t_{k}\right)$. There are countably many and so $N$ is also a set of measure zero. Then for $\omega \notin N$, and $t_{k}$ any mesh point at all, $B X\left(t_{k}\right)(\omega)=B\left(X\left(t_{k}, \omega\right)\right)$. This will be important in what follows. In addition to this, from the integral equation, for each of these $\omega \notin N, B X(t)(\omega)=B(X(t, \omega))$ for all $t \notin N_{\omega} \subseteq[0, T]$ where $N_{\omega}$ is a set of Lebesgue measure zero. Thus the $t_{k}$ from the various partitions are always in $N_{\omega}$. By Lemma 69.4.1, there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=0}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}, B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

By this lemma, if $B=B(\omega)$ where $B$ is $\mathscr{F}_{0}$ measurable into $\mathscr{L}\left(W, W^{\prime}\right)$, then the $e_{i}$ are also $\mathscr{F}_{0}$ measurable into $V$. Thus the conclusion of the above discussion is that at the mesh points, it is valid to write

$$
\begin{aligned}
\left\langle(B X)\left(t_{k}\right), X\left(t_{k}\right)\right\rangle & =\left\langle B\left(X\left(t_{k}\right)\right), X\left(t_{k}\right)\right\rangle \\
& =\sum_{i}\left\langle(B X)\left(t_{k}\right), e_{i}\right\rangle^{2}=\sum_{i}\left\langle B\left(X\left(t_{k}\right)\right), e_{i}\right\rangle^{2}
\end{aligned}
$$

just as would be the case if $(B X)(t)=B(X(t))$ for every $t$. In all which follows, the mesh points will be like this and an appropriate set of measure zero which may be replaced with a larger set of measure zero finitely many times is being neglected. Obviously, one can take a subsequence of the sequence of partitions described above without disturbing the above observations. We will denote these partitions as $\mathscr{P}_{k}$. Thus we obtain the following interesting lemma.

Lemma 74.2.1 In the above situation, there exists a set of measure zero $N \subseteq \Omega$ and $a$ dense subset of $[0, T], D$ such that for $\omega \notin N, B X(t, \omega)=B(X(t, \omega))$ for all $t \in D$. This set $D$ is the union of nested paritions $\left\{\mathscr{P}_{k}\right\}=\left\{t_{j}^{k}\right\}_{j=1, k=1}^{m_{k} \infty}$ such that the left and right step functions $\left\{X_{k}^{l}\right\},\left\{X_{k}^{r}\right\}$ converge to $X$ in $L^{p}([0, T] \times \Omega ; V)$. There is also a set of Lebesgue
measure zero $\hat{N} \subseteq[0, T]$ such that $B X(t)=B(X(t))$ in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)$ for all $t \notin \hat{N}$. Thus for such $t, B X(t)(\omega)=B(X(t, \omega))$ for a.e. $\omega$. In particular, for such $t \notin \hat{N}$,

$$
\langle B X(t)(\omega), X(t, \omega)\rangle=\sum_{i}\left\langle B(X(t)), e_{i}\right\rangle^{2} \text { a.e. } \omega
$$

$D$ has empty intersection with $\hat{N}$. There is also a set of Lebesgue measure zero $N_{\omega}$ for each $\omega \notin N$ defined by $B X(t, \omega)=B(X(t, \omega))$ for all $t \notin N_{\omega}$.

Now define a stopping time.

$$
\begin{equation*}
\sigma_{q}^{n} \equiv \inf \left\{t:\left\langle B X_{n}^{l}(t), X_{n}^{l}(t)\right\rangle>q\right\} \tag{74.2.3}
\end{equation*}
$$

Thus this pertains to the $n^{t h}$ partition. Since $X_{n}^{l}$ is right continuous, this will be a well defined stopping time. Thus, for $t$ one of the partition points,

$$
\begin{equation*}
\left\langle B X^{\sigma_{q}^{n}}(t, \omega), X^{\sigma_{q}^{n}}(t, \omega)\right\rangle \leq q \tag{74.2.4}
\end{equation*}
$$

From the definition of $X_{n}^{l}$ and the observation that these partitions are nested,

$$
\lim _{n \rightarrow \infty} \sigma_{q}^{n} \equiv \sigma_{q}
$$

exists because this is a decreasing sequence. There are more available times to consider as $n$ gets larger and so when the inf is taken, it can only get smaller. Thus

$$
\left[\sigma_{q} \leq t\right]=\cap_{m=1}^{\infty} \cup_{k=1}^{\infty} \cap_{n \geq k}\left[\sigma_{q}^{n} \leq t+\frac{1}{m}\right] \in \cap_{m=1}^{\infty} \mathscr{F}_{t+(1 / m)}=\mathscr{F}_{t}
$$

since it is assumed that the filtration is normal. Thus this appears to be a stopping time. However, I don't know how to use this.

Theorem 74.2.2 Let $\left\{t_{j}^{n}\right\}_{j=0}^{m_{n}}$ be the above sequence of partitions of the sort in Lemma 74.0.2 such that if

$$
X_{n}^{l}(t) \equiv \sum_{j=0}^{m_{n}-1} X\left(t_{j}^{n}\right) \mathscr{X}_{\left[t_{j}^{n}, t_{j+1}^{n}\right)}(t)
$$

then $X_{n} \rightarrow X$ in $L^{p}([0, T] \times \Omega, V)$ with the other conditions holding which were discussed above. In particular, $B X(t)=B(X(t))$ for $t$ one of these mesh points. Then the expression

$$
\begin{align*}
& \sum_{j=0}^{m_{n}-1}\left\langle B\left(M\left(t_{j+1}^{n} \wedge t\right)-M\left(t_{j}^{n} \wedge t\right)\right), X\left(t_{j}^{n}\right)\right\rangle \\
= & \sum_{j=0}^{m_{n}-1}\left\langle B X\left(t_{j}^{n}\right),\left(M\left(t_{j+1}^{n} \wedge t\right)-M\left(t_{j}^{n} \wedge t\right)\right)\right\rangle \tag{74.2.5}
\end{align*}
$$

is a local martingale

$$
\int_{0}^{t}\left\langle B X_{k}^{l}, d M\right\rangle
$$

with $\left\{\sigma_{q}^{n}\right\}_{q=1}^{\infty}$ being a localizing sequence.

Proof: This follows from Lemma 66.0.20. This can be seen because, thanks to the fact that $B X_{k}^{l \sigma_{q}^{k}}$ is bounded, the function $B X_{k}^{l}$ is in the set $\mathscr{G}$ described there. This is a place where we use that $d[M]=k d t$.

### 74.3 The Main Estimate

The argument will be based on a formula which follows in the next lemma.
Lemma 74.3.1 In Situation 74.1.1 the following formula holds for a.e. $\omega$ for $0<s<t$. In the following, $\langle\cdot, \cdot\rangle$ denotes the duality pairing between $V, V^{\prime}$.

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\langle B X(s), X(s)\rangle+ \\
+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+\langle B(M(t)-M(s)), M(t)-M(s)\rangle \\
-\langle B X(t)-B X(s)-(M(t)-M(s)), X(t)-X(s)-(M(t)-M(s))\rangle \\
+2\langle B X(s), M(t)-M(s)\rangle \tag{74.3.6}
\end{gather*}
$$

Also for $t>0$

$$
\begin{align*}
& \langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(t)\rangle d u+2\left\langle B X_{0}, M(t)\right\rangle+ \\
& \langle B M(t), M(t)\rangle-\left\langle B X(t)-B X_{0}-B M(t), X(t)-X_{0}-M(t)\right\rangle \tag{74.3.7}
\end{align*}
$$

Proof: From the formula which is assumed to hold,

$$
\begin{aligned}
& B X(t)=B X_{0}+\int_{0}^{t} Y(u) d u+B M(t) \\
& B X(s)=B X_{0}+\int_{0}^{s} Y(u) d u+B M(s)
\end{aligned}
$$

Then

$$
B M(t)-B M(s)+\int_{s}^{t} Y(u) d u=B X(t)-B X(s)
$$

It follows that

$$
\begin{gathered}
\langle B(M(t)-M(s)), M(t)-M(s)\rangle- \\
\langle B X(t)-B X(s)-(M(t)-M(s)), X(t)-X(s)-(M(t)-M(s))\rangle \\
+2\langle B X(s), M(t)-M(s)\rangle \\
=\quad\langle B(M(t)-M(s)), M(t)-M(s)\rangle-\langle B X(t)-B X(s), X(t)-X(s)\rangle \\
+2\langle B X(t)-B X(s), M(t)-M(s)\rangle \\
-\langle B(M(t)-M(s)), M(t)-M(s)\rangle+2\langle B X(s), M(t)-M(s)\rangle
\end{gathered}
$$

Some terms cancel and this yields

$$
\begin{aligned}
=-\langle B X(t)- & B X(s), X(t)-X(s)\rangle+2\langle B X(t), M(t)-M(s)\rangle \\
=-\langle B X(t)- & B X(s), X(t)-X(s)\rangle+2\langle B(M(t)-M(s)), X(t)\rangle \\
= & -\langle B(X(t)-X(s)), X(t)-X(s)\rangle \\
& +2\left\langle B X(t)-B X(s)-\int_{s}^{t} Y(u) d u, X(t)\right\rangle \\
= & -\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle \\
& +2\langle B X(t), X(s)\rangle+2\langle B X(t), X(t)\rangle \\
& -2\langle B X(s), X(t)\rangle-2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u \\
= & \langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle-2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u
\end{aligned}
$$

Therefore,

$$
\begin{gathered}
\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle \\
=2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+\langle B(M(t)-M(s)), M(t)-M(s)\rangle \\
-\langle B X(t)-B X(s)-(M(t)-M(s)), X(t)-X(s)-(M(t)-M(s))\rangle \\
+2\langle B X(s), M(t)-M(s)\rangle
\end{gathered}
$$

The following phenomenal estimate holds and it is this estimate which is the main idea in proving the Ito formula. The last assertion about continuity is like the well known result that if $y \in L^{p}(0, T ; V)$ and $y^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$, then $y$ is actually continuous a.e. with values in $H$, for $V, H, V^{\prime}$ a Gelfand triple. Later, this continuity result is strengthened further to give strong continuity.
Lemma 74.3.2 In the Situation 74.1.1, the following holds for all $t \notin \hat{N}$,

$$
\begin{align*}
& E(\langle B X(t), X(t)\rangle) \\
< & C\left(\|Y\|_{K^{\prime}},\|X\|_{K}, E([M](T)),\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)<\infty . \tag{74.3.8}
\end{align*}
$$

where $K, K^{\prime}$ were defined earlier. In fact,

$$
E\left(\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}\right) \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}, E([M](T)),\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)
$$

Also, $C$ is a continuous function of its arguments, increasing in each one, and $C(0,0,0,0)=$ 0 . Thus for a.e. $\omega$,

$$
\sup _{t \notin N_{\omega}^{C}}\langle B X(t, \omega), X(t, \omega)\rangle \leq C(\omega)<\infty
$$

Also for $\omega$ off a set of measure zero described earlier, $t \rightarrow B X(t)(\omega)$ is weakly continuous with values in $W^{\prime}$ on $[0, T]$. Also $t \rightarrow\langle B X(t), X(t)\rangle$ is lower semicontinuous on $N_{\omega}^{C}$.

Proof: Consider the formula in Lemma 74.3.1.

$$
\begin{align*}
& \qquad\langle B X(t), X(t)\rangle=\langle B X(s), X(s)\rangle \\
& +2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u+\langle B(M(t)-M(s)), M(t)-M(s)\rangle \\
& -\langle B(X(t)-X(s)-(M(t)-M(s))), X(t)-X(s)-(M(t)-M(s))\rangle \\
& +2\langle B X(s), M(t)-M(s)\rangle \tag{74.3.9}
\end{align*}
$$

Now let $t_{j}$ denote a point of $\mathscr{P}_{k}$ from Lemma 74.0.2. Then for $t_{j}>0, X\left(t_{j}\right)$ is just the value of $X$ at $t_{j}$ but when $t=0$, the definition of $X(0)$ in this step function is $X(0) \equiv 0$. Thus

$$
\begin{aligned}
& \sum_{j=1}^{m-1}\left\langle B X\left(t_{j+1}\right), X\left(t_{j+1}\right)\right\rangle-\left\langle B X\left(t_{j}\right), X\left(t_{j}\right)\right\rangle \\
& +\left\langle B X\left(t_{1}\right), X\left(t_{1}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle \\
& \quad=\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle
\end{aligned}
$$

Using the formula in Lemma 74.3.1, for $t=t_{m}$ this yields

$$
\begin{align*}
& \left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle=2 \sum_{j=1}^{m-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
& +2 \sum_{j=1}^{m-1}\left\langle B X\left(t_{j}\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
& \quad+\sum_{j=1}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
& \quad-\sum_{j=1}^{m-1}\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right)\right. \\
& \left.X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle \\
& +2 \int_{0}^{t_{1}}\left\langle Y(u), X\left(t_{1}\right)\right\rangle d u+2\left\langle B X_{0}, M\left(t_{1}\right)\right\rangle+\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle \\
& \quad-\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle \tag{74.3.10}
\end{align*}
$$

First consider

$$
2 \int_{0}^{t_{1}}\left\langle Y(u), X\left(t_{1}\right)\right\rangle d u+2\left\langle B X_{0}, M\left(t_{1}\right)\right\rangle+\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle .
$$

Each term of the above converges to 0 for a.e. $\omega$ as $k \rightarrow \infty$ and in $L^{1}(\Omega)$. This follows right away for the second two terms from the assumptions on $M$ given in the situation.

Recall it was assumed that $\|B(\omega)\|$ is bounded. This is where it is convenient to make this assumption. Consider the first term. This term is dominated by

$$
\begin{aligned}
& \left(\int_{0}^{t_{1}}\|Y(u)\|^{p^{\prime}} d u\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|^{p} d u\right)^{1 / p} \\
\leq & C(\omega)\left(\int_{0}^{t_{1}}\|Y(u)\|^{p^{\prime}} d u\right)^{1 / p^{\prime}},\left(\int_{\Omega} C(\omega)^{p} d P\right)^{1 / p}<\infty
\end{aligned}
$$

Hence this converges to 0 for a.e. $\omega$ and also converges to 0 in $L^{1}(\Omega)$.
At this time, not much is known about the last term in 74.3.10, but it is negative and is about to be neglected anyway.

The second term on the right equals

$$
2 \int_{t_{1}}^{t_{m}}\left\langle B X_{k}^{l}, d M\right\rangle=2 \int_{0}^{t_{m}}\left\langle B X_{k}^{l}, d M\right\rangle+e(k)
$$

where $e(k) \rightarrow 0$ for a.e. $\omega$ and in $L^{1}(\Omega)$. Also note that since $\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle$ converges to 0 in $L^{1}(\Omega)$ and for a.e. $\omega$, the sum involving

$$
\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle
$$

can be started at 0 rather than 1 at the expense of adding in a term which converges to 0 a.e. and in $L^{1}(\Omega)$. Thus 74.3 .10 is of the form

$$
\begin{align*}
& \left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle=e(k)+2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
& \quad+2 \int_{0}^{t_{m}}\left\langle B X_{k}^{l}, d M\right\rangle \\
& \quad+\sum_{j=0}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
& \quad-\sum_{j=1}^{m-1}\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right)\right. \\
& \left.\quad X\left(t_{j+1}\right)-X\left(t_{j}\right)-\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle \\
& \quad-\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle \tag{74.3.11}
\end{align*}
$$

where $e(k) \rightarrow 0$ for a.e. $\omega$ and also in $L^{1}(\Omega)$.
Now it follows, on discarding the negative terms,

$$
\begin{aligned}
& \left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle \leq e(k)+2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u+ \\
+ & 2 \int_{0}^{t_{m}}\left\langle B X_{k}^{l}, d M\right\rangle+\sum_{j=0}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle
\end{aligned}
$$

Therefore,

$$
\begin{align*}
\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X\left(t_{m}\right)\right. & \left., X\left(t_{m}\right)\right\rangle \leq\left\langle B X_{0}, X_{0}\right\rangle+e(k)+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u+ \\
& +2 \sup _{t_{m} \in \mathscr{P}_{k}}\left|\int_{0}^{t_{m}}\left\langle B X_{k}^{l}, d M\right\rangle\right| \\
& +\sum_{j=0}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \tag{74.3.12}
\end{align*}
$$

where there are $m_{k}+1$ points in $\mathscr{P}_{k}$. Consider that last term. It is no larger than

$$
\|B\| \sum_{j=0}^{m-1}\left\|M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\|^{2}
$$

Say the last point in the partition is $t_{p}=T$ and consider the sum

$$
\begin{aligned}
& \sum_{j=0}^{p-1}\left\|M\left(t_{j+1} \wedge t\right)-M\left(t_{j} \wedge t\right)\right\|^{2}=\sum_{j=0}^{p-1}\left\|M^{t_{j+1}}-M^{t_{j}}\right\|^{2}(t) \\
= & \sum_{j=0}^{p-1}\left[M^{t_{j+1}}-M^{t_{j}}\right](t)+N_{j}(t)=\sum_{j=0}^{p-1}[M]^{t_{j+1}}(t)-[M]^{t_{j}}(t)+N_{j}(t)
\end{aligned}
$$

for $N_{j}$ a martingale which equals 0 for $t \leq t_{j}$. Now when you put in $t=t_{m}$, this becomes

$$
\sum_{j=0}^{m-1}[M]^{t_{j+1}}\left(t_{m}\right)-[M]^{t_{j}}\left(t_{m}\right)+N_{j}\left(t_{m}\right)
$$

Thus the expectation of that last term in 74.3 .12 is no larger than

$$
\|B\| E\left(\sum_{j=0}^{m-1}[M]^{t_{j+1}}\left(t_{m}\right)-[M]^{t_{j}}\left(t_{m}\right)\right)=\|B\| E\left([M]\left(t_{m}\right)\right)
$$

The next task is to take the expectation of both sides of 74.3.12. Of course there is a small problem with things not being in $L^{1}$. Hence it is appropriate to localize with the stopping time $\sigma_{q}^{k}$ defined in 74.2.3. That is, we obtain all of the above with $X$ replaced with $X^{\sigma_{q}^{k}}$, stopping the original integral equation by introducing $\mathscr{X}_{\left[0, \sigma_{q}^{k}\right]}$ in the integrals. Then carry out the following argument and pass to a limit as $q \rightarrow \infty$. In fact $\sigma_{q}^{k}=\infty$ if $q$ is large enough. Then carry out everything with $X^{\sigma_{q}^{k}}$. We don't write it, but this is what is being done in the following argument.

$$
E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle\right) \leq E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+E(|e(k)|)+2\|Y\|_{K^{\prime}}\left\|X_{k}^{r}\right\|_{K}
$$

$$
+2 E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left|\int_{0}^{t_{m}}\left\langle B X_{k}^{l}, d M\right\rangle\right|\right)+\|B\| E([M](T))
$$

Now using the Burkholder Davis Gundy inequality and the inequality for the quadratic variation of that funny integral involving $\left\langle B X_{k}^{l}, d M\right\rangle$,

$$
\begin{aligned}
\leq & E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+E(|e(k)|)+2\|Y\|_{K^{\prime}}\left\|X_{k}^{r}\right\|_{K} \\
& +C E\left(\left(\int_{0}^{T}\left\|B X_{k}^{l}\right\|^{2} d[M]\right)^{1 / 2}\right)+\|B\| E([M](T))
\end{aligned}
$$

Now $\|B v\|_{W^{\prime}}^{2} \leq\|B\|\langle B v, v\rangle$. Hence the above reduces to the following after adjusting the constant $C$,

$$
\begin{aligned}
\leq & E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+E(|e(k)|)+2\|Y\|_{K^{\prime}}\left\|X_{k}^{r}\right\|_{K} \\
& +C E\left(\left(\int_{0}^{T}\left\langle B X_{k}^{l}, X_{k}^{l}\right\rangle d[M]\right)^{1 / 2}\right)+\|B\| E([M](T)) \\
\leq & \frac{1}{2} \sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle+(C+\|B\|) E([M](T)) \\
& +C\left(E\left(\left\langle B X_{0}, X_{0}\right\rangle\right),\|Y\|_{K^{\prime}},\left\|X_{k}^{r}\right\|_{K}\right)+E(|e(k)|)
\end{aligned}
$$

It follows on subtracting the first term on the right and adjusting constants again,

$$
\begin{gathered}
E\left(\sup _{t_{m} \in \mathscr{P}_{k}}\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle\right) \\
\leq(C+\|B\|) E([M](T))+C\left(E\left(\left\langle B X_{0}, X_{0}\right\rangle\right),\|Y\|_{K^{\prime}},\left\|X_{k}^{r}\right\|_{K}\right)+E(|e(k)|)
\end{gathered}
$$

Now let $q \rightarrow \infty$ and use the monotone convergence theorem which yields the above for un-modified $X$.

Observe that these partitions are nested and that the constant $C(\cdots)$ is continuous and increasing in each argument with $C(\mathbf{0})=0, C(\cdots)$ not depending on $T$. Thus the left side is increasing and for given $\varepsilon>0$, there exists $N$ such that $k \geq N$ implies the right side is no larger than

$$
\begin{equation*}
C\left(E\left(\left\langle B X_{0}, X_{0}\right\rangle\right),\|Y\|_{K^{\prime}},\|X\|_{K}\right)+(C+\|B\|) E([M](T))+\varepsilon \tag{74.3.13}
\end{equation*}
$$

Now let $D$ denote the union of these nested partitions. Then from the monotone convergence theorem,

$$
E\left(\sup _{t \in D}\langle B X(t), X(t)\rangle\right)
$$

is no larger than the right side of 74.3 .13 . Since this is true for all $\varepsilon>0$, it follows

$$
\begin{equation*}
E\left(\sup _{t \in D}\langle B X(t), X(t)\rangle\right) \leq C\left(E\left(\left\langle B X_{0}, X_{0}\right\rangle\right),\|Y\|_{K^{\prime}},\|X\|_{K}, E([M](T))\right) \tag{74.3.14}
\end{equation*}
$$

where $C(\cdots)$ is increasing in each argument, continuous, and $C(\mathbf{0})=0$. Thus, enlarging $N$, for $\omega \notin N$,

$$
\begin{equation*}
\sup _{t \in D}\langle B X(t), X(t)\rangle=C(\omega)<\infty \tag{74.3.15}
\end{equation*}
$$

where $\int_{\Omega} C(\omega) d P<\infty$. By Lemma 69.4.1, there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=0}^{\infty}\left\langle B x, e_{i}\right\rangle^{2}, B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

Thus for $t$ not in a set of measure zero off which $B X(t)=B(X(t))$,

$$
\langle B X(t), X(t)\rangle=\sum_{i=0}^{\infty}\left\langle B X(t), e_{i}\right\rangle^{2}=\sup _{m} \sum_{k=1}^{m}\left\langle B X(t), e_{i}\right\rangle^{2}
$$

Now from the formula for $B X(t)$, it follows that $B X$ is continuous into $V^{\prime}$. For any $t \notin \hat{N}$ so that $(B X)(t)=B(X(t))$ in $L^{q^{\prime}}\left(\Omega ; V^{\prime}\right)$ and letting $t_{k} \rightarrow t$ where $t_{k} \in D$, Fatou's lemma implies

$$
\begin{aligned}
& E(\langle B X(t), X(t)\rangle)=\sum_{i} E\left(\left\langle B X(t), e_{i}\right\rangle^{2}\right)=\sum_{i} \lim _{k \rightarrow \infty} E\left(\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2}\right) \\
& \quad \leq \lim \inf _{k \rightarrow \infty} \sum_{i} E\left(\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2}\right)=\lim _{k \rightarrow \infty} E\left(\left\langle B X\left(t_{k}\right), X\left(t_{k}\right)\right\rangle\right) \\
& \quad \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)
\end{aligned}
$$

In addition to this, for arbitrary $t \in[0, T]$, and $t_{k} \rightarrow t$ from $D$,

$$
\sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2} \leq \lim _{k \rightarrow \infty} \inf _{k} \sum_{i}\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2} \leq \sup _{s \in D}\langle B X(s), X(s)\rangle
$$

Hence

$$
\begin{aligned}
\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2} & \leq \sup _{s \in D}\langle B X(s), X(s)\rangle \\
& =\sup _{s \in D} \sum_{i}\left\langle B X(s), e_{i}\right\rangle^{2} \leq \sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}
\end{aligned}
$$

It follows that $\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}$ is measurable and

$$
\begin{aligned}
& E\left(\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}\right) \leq E\left(\sup _{s \in D}\langle B X(s), X(s)\rangle\right) \\
\leq & C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)
\end{aligned}
$$

And so, for $\omega$ off a set of measure zero, $\sup _{t \in[0, T]} \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}$ is bounded above. Include this exceptional set in $N$.

Also for $t \notin N_{\omega}$ and a given $\omega \notin N$, letting $t_{k} \rightarrow t$ for $t_{k} \in D$,

$$
\begin{aligned}
\langle B X(t), X(t)\rangle & =\sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2} \leq \lim _{k \rightarrow \infty} \inf _{k \rightarrow \infty} \sum_{i}\left\langle B X\left(t_{k}\right), e_{i}\right\rangle^{2} \\
& =\lim _{k \rightarrow \infty}\left\langle B X\left(t_{k}\right), X\left(t_{k}\right)\right\rangle \leq \sup _{t \in D}\langle B X(t), X(t)\rangle
\end{aligned}
$$

and so

$$
\sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle \leq \sup _{t \in D}\langle B X(t), X(t)\rangle \leq \sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle
$$

From 74.3.15,

$$
\sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle=C(\omega) \text { a.e. } \omega
$$

where $\int_{\Omega} C(\omega) d P<\infty$. In particular, $\sup _{t \notin N_{\omega}}\langle B X(t), X(t)\rangle$ is bounded for a.e. $\omega$ say for $\omega \notin N$ where $N$ includes the earlier sets of measure zero. This shows that $B X(t)$ is bounded in $W^{\prime}$ for $t \in N_{\omega}^{C}$.

If $v \in V$, then for $\omega \notin N$,

$$
\lim _{t \rightarrow s}\langle B X(t), v\rangle=\langle B X(s), v\rangle, t, s
$$

Therefore, since for such $\omega,\|B X(t)\|_{W^{\prime}}$ is bounded for $t \notin N_{\omega}$, the above holds for all $v \in W$ also. Therefore, for a.e. $\omega, t \rightarrow B X(t, \omega)$ is weakly continuous with values in $W^{\prime}$ for $t \notin N_{\omega}$.

Note also that

$$
\begin{align*}
& \int_{0}^{T} \int_{\Omega}\|B X(t)\|^{2} d P d t \leq \int_{\Omega} \int_{0}^{T}\|B\|^{1 / 2}\langle B X(t), X(t)\rangle d t d P \\
\leq & C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)\|B\|^{1 / 2} T \tag{74.3.16}
\end{align*}
$$

Eventually, it is shown that in fact, the function $t \rightarrow B X(t, \omega)$ is continuous with values in $W^{\prime}$. The above shows that $B X \in L^{2}\left([0, T] \times \Omega, W^{\prime}\right)$.

Finally consider the claim of weak continuity of $B X$ into $W^{\prime}$. From the integral equation, $B X$ is continuous into $V^{\prime}$. Also $t \rightarrow B X(t)$ is bounded in $W^{\prime}$ on $N_{\omega}^{C}$. Let $s \in[0, T]$ be arbitrary. I claim that if $t_{n} \rightarrow s, t_{n} \in D$, it follows that $B X\left(t_{n}\right) \rightarrow B X(s)$ weakly in $W^{\prime}$. If not, then there is a subsequence, still denoted as $t_{n}$ such that $B X\left(t_{n}\right) \rightarrow Y$ weakly in $W^{\prime}$ but $Y \neq B X(s)$. However, the continuity into $V^{\prime}$ means that for all $v \in V$,

$$
\langle Y, v\rangle=\lim _{n \rightarrow \infty}\left\langle B X\left(t_{n}\right), v\right\rangle=\langle B X(s), v\rangle
$$

which is a contradiction since $V$ is dense in $W$. This establishes the claim. Also this shows that $B X(s)$ is bounded in $W^{\prime}$.

$$
|\langle B X(s), w\rangle|=\lim _{n \rightarrow \infty}\left|\left\langle B X\left(t_{n}\right), w\right\rangle\right| \leq \lim \inf _{n \rightarrow \infty}\left\|B X\left(t_{n}\right)\right\|_{W^{\prime}}\|w\|_{W} \leq C(\omega)\|w\|_{W}
$$

Now a repeat of the above argument shows that $s \rightarrow B X(s)$ is weakly continuous into $W^{\prime}$.

### 74.4 A Simplification Of The Formula

This estimate in Lemma 74.3 .2 also provides a way to simplify one of the formulas derived earlier in the case that $X_{0} \in L^{p}(\Omega, V)$ so that $X-X_{0} \in L^{p}([0, T] \times \Omega, V)$. Refer to 74.3.11. One term there is

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle
$$

Also,

$$
\begin{gathered}
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle \\
\leq 2\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle+2\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle
\end{gathered}
$$

It was observed above that $2\left\langle B M\left(t_{1}\right), M\left(t_{1}\right)\right\rangle \rightarrow 0$ a.e. and also in $L^{1}(\Omega)$ as $k \rightarrow \infty$. Apply the above lemma to $\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle$ using $\left[0, t_{1}\right]$ instead of $[0, T]$. The new $X_{0}$ equals 0 . Then from the estimate 74.3.8, it follows that

$$
E\left(\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle\right) \rightarrow 0
$$

as $k \rightarrow \infty$. Taking a subsequence, we could also assume that

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle \rightarrow 0
$$

a.e. $\omega$ as $k \rightarrow \infty$. Then, using this subsequence, it would follow from 74.3.11,

$$
\begin{gather*}
\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle=e(k)+ \\
2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u++2 \int_{0}^{t_{m}}\left\langle B X_{k}^{l}, d M\right\rangle \\
+\sum_{j=0}^{m-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle \\
-\sum_{j=1}^{m-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle \tag{74.4.17}
\end{gather*}
$$

where $e(k) \rightarrow 0$ in $L^{1}(\Omega)$ and a.e. $\omega$ and

$$
\Delta X\left(t_{j}\right) \equiv X\left(t_{j+1}\right)-X\left(t_{j}\right)
$$

$\Delta M\left(t_{j}\right)$ being defined similarly. Note how this eliminated the need to consider the term

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle
$$

in passing to a limit. This is a very desirable thing to be able to conclude.
Can you obtain something similar even in case $X_{0}$ is not assumed to be in $L^{p}(\Omega, V)$ ? Let $X_{0 k} \in L^{p}(\Omega, V) \cap L^{2}(\Omega, W), X_{0 k} \rightarrow X_{0}$ in $L^{2}(\Omega, W)$. Then from the usual arguments involving the Cauchy Schwarz inequality,

$$
\begin{aligned}
\left\langle B\left(X\left(t_{1}\right)-X_{0}\right), X\left(t_{1}\right)-X_{0}\right\rangle^{1 / 2} \leq & \left\langle B\left(X\left(t_{1}\right)-X_{0 k}\right), X\left(t_{1}\right)-X_{0 k}\right\rangle^{1 / 2} \\
& +\left\langle B\left(X_{0 k}-X_{0}\right), X_{0 k}-X_{0}\right\rangle^{1 / 2}
\end{aligned}
$$

Also, restoring the superscript to identify the parition,

$$
B\left(X\left(t_{1}^{k}\right)-X_{0 k}\right)=B\left(X_{0}-X_{0 k}\right)+\int_{0}^{t_{1}^{k}} Y(s) d s+B M\left(t_{1}^{k}\right)
$$

Of course $\left\|X-X_{0 k}\right\|_{K}$ is not bounded, but for each $k$ it is finite. There is a sequence of partitions $\mathscr{P}_{k},\left\|\mathscr{P}_{k}\right\| \rightarrow 0$ such that all the above holds. In the definitions of $K, K^{\prime}, E([M](T))$ replace $[0, T]$ with $[0, t]$ and let the resulting spaces be denoted by $K_{t}, K_{t}^{\prime}$. Let $n_{k}$ denote a subsequence of $\{k\}$ such that

$$
\left\|X-X_{0 k}\right\|_{K_{t_{1}} n_{k}}<1 / k
$$

Then from the above lemma,

$$
\begin{gather*}
E\left(\left\langle B\left(X\left(t_{1}^{n_{k}}\right)-X_{0 k}\right), X\left(t_{1}^{n_{k}}\right)-X_{0 k}\right\rangle\right) \\
\leq C\left(\left\langle B\left(X_{0}-X_{0 k}\right), X_{0}-X_{0 k}\right\rangle_{L^{1}(\Omega)},\|Y\|_{K_{t_{n_{1}}^{\prime}}^{\prime}},\left\|X-X_{0 k}\right\|_{K_{t_{1} n_{k}}}, E\left([M]\left(t_{1}^{n_{k}}\right)\right)\right)  \tag{74.4.18}\\
\leq C\left(\left\langle B\left(X_{0}-X_{0 k}\right), X_{0}-X_{0 k}\right\rangle_{L^{1}(\Omega)},\|Y\|_{\substack{K_{n_{k}}^{\prime} \\
t_{1}}}, \frac{1}{k}, E\left([M]\left(t_{1}^{n_{k}}\right)\right)\right)
\end{gather*}
$$

Hence

$$
\begin{gathered}
E\left(\left\langle B\left(X\left(t_{1}^{n_{k}}\right)-X_{0}\right), X\left(t_{1}^{n_{k}}\right)-X_{0}\right\rangle\right) \\
\leq 2 E\left(\left\langle B\left(X\left(t_{1}^{n_{k}}\right)-X_{0 k}\right), X\left(t_{1}^{n_{k}}\right)-X_{0 k}\right\rangle\right)+2 E\left(\left\langle B\left(X_{0 k}-X_{0}\right), X_{0 k}-X_{0}\right\rangle\right) \\
\leq \quad 2 C\left(\left\langle B\left(X_{0}-X_{0 k}\right), X_{0}-X_{0 k}\right\rangle_{L^{1}(\Omega)},\|Y\|_{\substack{K_{t_{1}}^{\prime},}}, \frac{1}{k}, E\left([M]\left(t_{1}^{n_{k}}\right)\right)\right) \\
\quad+2\|B\|\left\|X_{0 k}-X_{0}\right\|_{L^{2}(\Omega, W)}^{2}
\end{gathered}
$$

which converges to 0 as $k \rightarrow \infty$. It follows that there exists a suitable subsequence such that 74.4.17 holds even in the case that $X_{0}$ is only known to be in $L^{2}(\Omega, W)$. From now on, assume this subsequence for the partitions $\mathscr{P}_{k}$. Thus $k$ will really be $n_{k}$ and it suffices to consider the limit as $k \rightarrow \infty$ of the equation of 74.4.17. To emphasize this point again, the reason for the above observations is to argue that, even when $X_{0}$ is only in $L^{2}(\Omega, W)$, one can neglect

$$
\left\langle B\left(X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right), X\left(t_{1}\right)-X_{0}-M\left(t_{1}\right)\right\rangle
$$

in passing to the limit as $k \rightarrow \infty$ provided a suitable subsequence is used.

### 74.5 Convergence

Convergence will be shown for a subsequence and from now on every sequence will be a subsequence of this one. Since $B X \in L^{2}\left([0, T] \times \Omega ; W^{\prime}\right)$ which was shown above, there exists a sequence of partitions of the sort described above such that also, in addition to the other claims

$$
B X_{k}^{l} \rightarrow B X, B X_{k}^{r} \rightarrow B X
$$

in $L^{2}\left([0, T] \times \Omega, W^{\prime}\right)$. Then the next lemma improves on this.

Lemma 74.5.1 There exists a subsequence still denoted with the subscript $k$ and an enlarged set of measure zero $N$ including the earlier one such that $B X_{k}^{l}(t), B X_{k}^{r}(t)$ also converges pointwise a.e. to to $B X(t)$ in $W^{\prime}$ and $X_{k}^{l}(t), X_{k}^{r}(t)$ converge pointwise a.e. in $V$ to $X(t)$ for $\omega \notin N$ as well as having convergence of $X_{k}^{l}(\cdot, \omega)$ to $X(\cdot, \omega)$ in $L^{p}([0, T] ; V)$ and $B X_{k}^{l}(\cdot, \omega)$ to $B X(\cdot, \omega)$ in $L^{2}\left([0, T] ; W^{\prime}\right)$.

Proof: To see that such a sequence exists, let $n_{k}$ be such that

$$
\begin{aligned}
& \int_{\Omega} \int_{0}^{T}\left\|B X_{n_{k}}^{r}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t d P+\int_{\Omega} \int_{0}^{T}\left\|X_{n_{k}}^{r}(t)-X(t)\right\|_{V}^{p} d t d P+ \\
& \int_{\Omega} \int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t d P+\int_{\Omega} \int_{0}^{T}\left\|X_{n_{k}}^{l}(t)-X(t)\right\|_{V}^{p} d t d P<4^{-k} .
\end{aligned}
$$

Then

$$
\begin{gathered}
P\left(\int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{r}(t)-X(t)\right\|_{V}^{p} d t+\right. \\
\left.\int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{l}(t)-X(t)\right\|_{V}^{p} d t>2^{-k}\right) \\
\leq 2^{k}\left(4^{-k}\right)=2^{-k}
\end{gathered}
$$

and so by Borel Cantelli lemma, there is a set of measure zero $N$ such that if $\omega \notin N$,

$$
\begin{aligned}
& \int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{r}(t)-X(t)\right\|_{V}^{p} d t+ \\
& \int_{0}^{T}\left\|B X_{n_{k}}^{l}(t)-B X(t)\right\|_{W^{\prime}}^{2} d t+\int_{0}^{T}\left\|X_{n_{k}}^{l}(t)-X(t)\right\|_{V}^{p} d t \leq 2^{-k}
\end{aligned}
$$

for all $k$ large enough. By the usual proof of completeness of $L^{p}$, it follows that $X_{n_{k}}^{l}(t) \rightarrow$ $X(t)$ for a.e. $t$, this for each $\omega \notin N$, a similar assertion holding for $X_{n_{k}}^{r}$. Also $B X_{n_{k}}^{l}(t) \rightarrow$ $B X(t)$ for a.e. $t$, similar for $B X_{n_{k}}^{r}(t)$. Denote these subsequences as $\left\{X_{k}^{r}\right\}_{k=1}^{\infty},\left\{X_{k}^{l}\right\}_{k=1}^{\infty}$.

Define the following stopping time.

$$
\tau_{p} \equiv \inf \left\{t: \sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}>p\right\}
$$

By Lemma 74.3.2 $\tau_{p}=\infty$ for all $p$ large enough off some set of measure zero. Also, $B X(t)(\omega)=B(X(t, \omega))$ for a.e. $t$ and so for a.e.t, $\langle B X(t), X(t)\rangle=\sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2}$ and so $\left\|B X^{\tau_{p}}(t)\right\|_{W^{\prime}} \leq\|B\| \sqrt{p}$ for a.e.t. Hence $B X^{\tau_{p}} \in L^{\infty}\left([0, T] \times \Omega, W^{\prime}\right)$.

Lemma 74.5.2 The process $\int_{0}^{t}\left\langle B X_{k}^{l}, d M\right\rangle$ converges in probability as $k \rightarrow \infty$ to $\int_{0}^{t}\langle B X, d M\rangle$ which is a local martingale. Also, there is a subsequence and an enlarged set of measure zero $N$ such that for $\omega$ not in this set, the convergence is uniform on $[0, T]$.

Proof: By assumption, $d[M]=k d t$ for some $k \in L^{1}([0, T] \times \Omega)$ and so $B X^{\tau_{p}} \in \mathscr{G}$ where $\mathscr{G}$ was the class of functions for which one can write $\int_{0}^{t}\langle B X, d M\rangle$. By the Burkholder Davis Gundy inequality,

$$
\begin{align*}
& P\left(\sup _{t}\left|\int_{0}^{t \wedge \tau_{p}}\left\langle B\left(X_{k}^{l}\right)-B X, d M\right\rangle\right|>\varepsilon\right) \\
= & P\left(\sup _{t}\left|\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}\left\langle B\left(X_{k}^{l}\right)-B X, d M\right\rangle\right|>\varepsilon\right) \\
\leq & \frac{C}{\varepsilon} \int_{\Omega}\left(\int_{0}^{T \wedge \tau_{p}}\left\|B\left(X_{k}^{l}\right)-B X\right\|_{W}^{2} k d t\right)^{1 / 2} d P \\
= & \frac{C}{\varepsilon} \int_{\Omega}\left(\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left\|B\left(X_{k}^{l}\right)-B X\right\|_{W}^{2} k d t\right)^{1 / 2} d P \tag{74.5.19}
\end{align*}
$$

Let

$$
A_{k}=\left[\sup _{t}\left|\int_{0}^{t}\left\langle B X_{k}^{l}-B X, d M\right\rangle\right|>\varepsilon\right]
$$

Then, since $\tau_{p}=\infty$ for all $p$ large enough,

$$
A_{k}=\cup_{p=0}^{\infty} A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1} \neq \infty\right]\right)
$$

Consider $B X_{k}^{l \tau_{p}}$. If $t>\tau_{p}$, what of the values of $B X_{k}^{l \tau_{p}}$ ? It equals $B X(s)$ where $s$ is one of the mesh points $s \leq \tau_{p}$ because this is a left step function. Therefore,

$$
\begin{gathered}
\left\langle B X_{k}^{l \tau_{p}}(s), X_{k}^{l \tau_{p}}(s)\right\rangle=\left\langle B\left(X_{k}^{l \tau_{p}}(s)\right), X_{k}^{l \tau_{p}}(s)\right\rangle \\
=\sum_{i}\left\langle B X(s), e_{i}\right\rangle^{2} \leq p
\end{gathered}
$$

As to $\mathscr{X}_{\left[0, \tau_{p}\right]} B X$, it follows that for all $t \leq \tau_{p}$ you have $\sum_{i}\left\langle B X(t), e_{i}\right\rangle^{2} \leq p$ and so, since this equals $\langle B(X(t)), X(t)\rangle$ a.e. $t$, it follows that $\left\|\mathscr{X}_{\left[0, \tau_{p}\right]} B X(t)\right\|_{W^{\prime}}$ is bounded by a constant depending on $p$ for a.e.t. It follows that $B X$ and $B X_{k}^{l}$ are bounded. Now by Lemma 74.5.1, $B X_{k}^{l}(t) \rightarrow B X(t)$ a.e. $t$ and the term $\left\|B\left(X_{k}^{l}\right)-B X\right\|_{W}^{2}$ is essentially bounded. Therefore, in 74.5.19, the integral converges to 0 . From this formula,

$$
\begin{aligned}
& P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1} \neq \infty\right]\right)\right) \leq P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right]\right)\right) \\
& \quad \leq \frac{C}{\varepsilon} \int_{\Omega}\left(\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left\|B\left(X_{k}^{l}\right)-B X\right\|_{W}^{2} k d t\right)^{1 / 2} d P
\end{aligned}
$$

Thus

$$
\lim _{k \rightarrow \infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1} \neq \infty\right]\right)\right)=0
$$

Then

$$
P\left(A_{k}\right)=\sum_{p=1}^{\infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1} \neq \infty\right]\right)\right)
$$

and taking limits using the dominated convergence theorem on the sum on the right,

$$
\lim _{k \rightarrow \infty} P\left(A_{k}\right)=\sum_{p=1}^{\infty} \lim _{k \rightarrow \infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1} \neq \infty\right]\right)\right)=0
$$

This proves convergence in probability.

$$
\lim _{k \rightarrow \infty} P\left(\sup _{t}\left|\int_{0}^{t}\left\langle B\left(X_{k}^{l}\right)-B X, d M\right\rangle\right|>\varepsilon\right)=0
$$

Then selecting a subsequence, still denoted with $k$, we can obtain

$$
P\left(\sup _{t}\left|\int_{0}^{t}\left\langle B\left(X_{k}^{l}\right)-B X, d M\right\rangle\right|>\frac{1}{k}\right)<2^{-k}
$$

and so, by the Borel Cantelli lemma, there is a set of measure zero $N$ such that for this subsequence, for all $\omega \notin N$,

$$
\sup _{t}\left|\int_{0}^{t}\left\langle B\left(X_{k}^{l}\right)-B X, d M\right\rangle\right| \leq \frac{1}{k}
$$

for all $k$ large enough. Thus convergence is uniform.
From now on, include $N$ in the exceptional set and every subsequence will be a subsequence of this one.

### 74.6 The Ito Formula

Now at long last, here is the first version of the Ito formula valid on the partition points.
Lemma 74.6.1 In Situation 74.1.1, let $D$ be as above, the union of all the positive mesh points for all the $\mathscr{P}_{k}$. Also assume $X_{0} \in L^{2}(\Omega ; W)$. Then for $\omega \notin N$ the exceptional set of measure zero in $\Omega$ and every $t \in D$,

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t} 2\langle Y(s), X(s)\rangle d s \\
+\left[R^{-1} B M, M\right](t)+2 \int_{0}^{t}\langle B X, d M\rangle \tag{74.6.20}
\end{gather*}
$$

for $R$ the Riesz map from $W$ to $W^{\prime}$. The covariation term $\left[R^{-1} B M, M\right](t)$ is nonnegative.
Proof: Let $t \in D$. Then $t \in \mathscr{P}_{k}$ for all $k$ large enough. Consider 74.4.17,

$$
\begin{gathered}
\langle B X(t), X(t)\rangle-\left\langle B X_{0}, X_{0}\right\rangle=e(k)+2 \int_{0}^{t}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u \\
+2 \int_{0}^{t}\left\langle B X_{k}^{l}, d M\right\rangle+\sum_{j=0}^{q_{k}-1}\left\langle B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right\rangle
\end{gathered}
$$

$$
\begin{equation*}
-\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle \tag{74.6.21}
\end{equation*}
$$

where $t_{q_{k}}=t, \Delta X\left(t_{j}\right)=X\left(t_{j+1}\right)-X\left(t_{j}\right)$ and $e(k) \rightarrow 0$ in probability. By Lemma 74.5.2 the stochastic integral on the right converges uniformly for $t \in[0, T]$ to

$$
2 \int_{0}^{t}\langle B X, d M\rangle
$$

for $\omega$ off a set of measure zero. The deterministic integral on the right converges uniformly for $t \in[0, T]$ to

$$
2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

Thanks to Lemma 74.5.1.

$$
\begin{aligned}
& \left|\int_{0}^{t}\langle Y(u), X(u)\rangle d u-\int_{0}^{t}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u\right| \\
\leq & \int_{0}^{T}\|Y(u)\|_{V^{\prime}}\left\|X(u)-X_{k}^{r}(u)\right\|_{V} \\
\leq & \|Y\|_{L^{p^{\prime}}([0, T])}\left(2^{-k}\right)^{1 / p}
\end{aligned}
$$

for all $k$ large enough. Consider the fourth term. It equals

$$
\begin{equation*}
\sum_{j=0}^{q_{k}-1}\left(R^{-1} B\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right), M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)_{W} \tag{74.6.22}
\end{equation*}
$$

where $R^{-1}$ is the Riesz map from $W$ to $W^{\prime}$. This equals

$$
\begin{aligned}
& \frac{1}{4}\left(\sum_{j=0}^{q_{k}-1}\left\|R^{-1} B M\left(t_{j+1}\right)+M\left(t_{j+1}\right)-\left(R^{-1} B M\left(t_{j}\right)+M\left(t_{j}\right)\right)\right\|^{2}\right. \\
& \left.-\sum_{j=0}^{q_{k}-1}\left\|R^{-1} B M\left(t_{j+1}\right)-M\left(t_{j+1}\right)-\left(R^{-1} B M\left(t_{j}\right)-M\left(t_{j}\right)\right)\right\|^{2}\right)
\end{aligned}
$$

From Theorem 63.6.4, as $k \rightarrow \infty$, the above converges in probability to ( $t_{q_{k}}=t$ )

$$
\frac{1}{4}\left(\left[R^{-1} B M+M\right](t)-\left[R^{-1} B M-M\right](t)\right) \equiv\left[R^{-1} B M, M\right](t)
$$

Also note that from 74.6.22, this term must be nonnegative since it is a limit of nonnegative quantities. This is what was desired.

Thus all the terms in 74.6 .21 converge in probability except for the last term which also must converge in probability because it equals the sum of terms which do. It remains to find what this last term converges to. Thus

$$
\langle B X(t), X(t)\rangle-\left\langle B X_{0}, X_{0}\right\rangle=2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

$$
+2 \int_{0}^{t}\langle B X, d M\rangle+\left[R^{-1} B M, M\right](t)-a
$$

where $a$ is the limit in probability of the term

$$
\begin{equation*}
\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle \tag{74.6.23}
\end{equation*}
$$

Let $P_{n}$ be the projection onto span $\left(e_{1}, \cdots, e_{n}\right)$ where $\left\{e_{k}\right\}$ is an orthonormal basis for $W$ with each $e_{k} \in V$. Then using

$$
B X\left(t_{j+1}\right)-B X\left(t_{j}\right)-\left(B M\left(t_{j+1}\right)-B M\left(t_{j}\right)\right)=\int_{t_{j}}^{t_{j+1}} Y(s) d s
$$

the troublesome term of 74.6.23 above is of the form

$$
\begin{aligned}
& \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle d s \\
& =\sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), \Delta X\left(t_{j}\right)-P_{n} \Delta M\left(t_{j}\right)\right\rangle d s \\
& \quad+\sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s),-\left(I-P_{n}\right) \Delta M\left(t_{j}\right)\right\rangle d s
\end{aligned}
$$

which equals

$$
\begin{align*}
& \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X\left(t_{j+1}\right)-X\left(t_{j}\right)-P_{n}\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle d s  \tag{74.6.24}\\
& +\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right),-\left(I-P_{n}\right)\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle \tag{74.6.25}
\end{align*}
$$

The reason for the $P_{n}$ is to get $P_{n}\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)$ in $V$. The sum in 74.6.25 is dominated by

$$
\begin{align*}
& \left(\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right),\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right)\right\rangle\right)^{1 / 2} . \\
& \left(\sum_{j=1}^{q_{k}-1}\left|\left\langle B\left(I-P_{n}\right) \Delta M\left(t_{j}\right),\left(I-P_{n}\right) \Delta M\left(t_{j}\right)\right\rangle\right|^{2}\right)^{1 / 2} \tag{74.6.26}
\end{align*}
$$

Now it is known from the above that

$$
\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right),\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right)\right\rangle
$$

converges in probability to $a \geq 0$. If you take the expectation of the square of the other factor, it is no larger than

$$
\begin{gathered}
\|B\| E\left(\sum_{j=1}^{q_{k}-1}\left\|\left(I-P_{n}\right) \Delta M\left(t_{j}\right)\right\|_{W}^{2}\right) \\
=\|B\| E\left(\sum_{j=1}^{q_{k}-1}\left\|\left(I-P_{n}\right)\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\|_{W}^{2}\right) \\
=\|B\| \sum_{j=1}^{q_{k}-1} E\left(\left\|\left(I-P_{n}\right)\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\|_{W}^{2}\right)
\end{gathered}
$$

Then

$$
\begin{gathered}
\left\|\left(I-P_{n}\right)\left(M\left(t_{j+1} \wedge t\right)-M\left(t_{j} \wedge t\right)\right)\right\|_{W}^{2}=\left[\left(1-P_{n}\right) M^{t_{j+1}}-\left(1-P_{n}\right) M^{t_{j}}\right](t)+N(t) \\
=\left[\left(1-P_{n}\right) M\right]^{t_{j+1}}(t)-\left[\left(1-P_{n}\right) M\right]^{t_{j}}(t)+N(t)
\end{gathered}
$$

for $N(t)$ a martingale. In particular, taking $t=t_{q_{k}}$, the above reduces to

$$
\begin{aligned}
& \|B\| \sum_{j=1}^{q_{k}-1} E\left(\left\|\left(I-P_{n}\right)\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\|_{W}^{2}\right) \\
= & \|B\| \sum_{j=1}^{q_{k}-1} E\left(\left[\left(1-P_{n}\right) M\right]\left(t_{j+1}\right)-\left[\left(1-P_{n}\right) M\right]\left(t_{j}\right)\right) \\
= & \|B\| E\left(\left[\left(1-P_{n}\right) M\right]\left(t_{q_{k}}\right)\right)=\|B\| E\left(\left\|\left(1-P_{n}\right) M\left(t_{q_{k}}\right)\right\|_{W}^{2}\right)
\end{aligned}
$$

From maximal theorems, Theorem 62.9.4,

$$
\|B\| E\left(\sup _{t_{q_{k}}}\left\|\left(1-P_{n}\right) M\left(t_{q_{k}}\right)\right\|_{W}^{2}\right) \leq 2\|B\| E\left(\left\|\left(1-P_{n}\right) M(T)\right\|_{W}^{2}\right)
$$

and this on the right converges to zero as $n \rightarrow \infty$ by assumption that $M(t)$ is in $L^{2}$ and the dominated convergence theorem. In particular, this shows that

$$
\left(\sum_{j=1}^{q_{k}-1}\left|\left\langle B\left(I-P_{n}\right) \Delta M\left(t_{j}\right),\left(I-P_{n}\right) \Delta M\left(t_{j}\right)\right\rangle\right|^{2}\right)^{1 / 2}
$$

converges to 0 in $L^{2}(\Omega)$ independent of $k$ as $n \rightarrow \infty$.
Thus the expression in 74.6 .26 is of the form $f_{k} g_{n k}$ where $f_{k}$ converges in probability to $a^{1 / 2}$ as $k \rightarrow \infty$ and $g_{n k}$ converges in probability to 0 as $n \rightarrow \infty$ independent of $k$. Now this implies $f_{k} g_{n k}$ converges in probability to 0 . Here is why.

$$
\begin{aligned}
P\left(\left[\left|f_{k} g_{n k}\right|>\varepsilon\right]\right) & \leq P\left(2 \delta\left|f_{k}\right|>\varepsilon\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right) \\
& \leq P\left(2 \delta\left|f_{k}-a^{1 / 2}\right|+2 \delta\left|a^{1 / 2}\right|>\varepsilon\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right)
\end{aligned}
$$

where $\delta\left|f_{k}\right|+C_{\delta}\left|g_{k n}\right|>\left|f_{k} g_{n k}\right|$ and $\lim _{\delta \rightarrow 0} C_{\delta}=\infty$. Pick $\delta$ small enough that $\varepsilon-2 \delta a^{1 / 2}>$ $\varepsilon / 2$. Then this is dominated by

$$
\leq P\left(2 \delta\left|f_{k}-a^{1 / 2}\right|>\varepsilon / 2\right)+P\left(2 C_{\delta}\left|g_{n k}\right|>\varepsilon\right)
$$

Fix $n$ large enough that the second term is less than $\eta$ for all $k$. Now taking $k$ large enough, the above is less than $\eta$. It follows the expression in 74.6 .26 and consequently in 74.6 .25 converges to 0 in probability.

Now consider the other term 74.6.24 using the $n$ just determined. This term is of the form

$$
\begin{aligned}
& \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X\left(t_{j+1}\right)-X\left(t_{j}\right)-P_{n}\left(M\left(t_{j+1}\right)-M\left(t_{j}\right)\right)\right\rangle d s= \\
& \quad \sum_{j=1}^{q_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)-P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s \\
& =\int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)-P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s
\end{aligned}
$$

where $M_{k}^{r}$ denotes the step function

$$
M_{k}^{r}(t)=\sum_{i=0}^{m_{k}-1} M\left(t_{i+1}\right) \mathscr{X}_{\left(t_{i}, t_{i+1}\right]}(t)
$$

and $M_{k}^{l}$ is defined similarly. The term

$$
\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s
$$

converges to 0 for a.e. $\omega$ as $k \rightarrow \infty$ thanks to continuity of $t \rightarrow M(t)$. However, more is needed than this. Define the stopping time

$$
\tau_{p}=\inf \left\{t>0:\|M(t)\|_{W}>p\right\}
$$

Then $\tau_{p}=\infty$ for all $p$ large enough, this for a.e. $\omega$. Let

$$
\begin{gather*}
A_{k}=\left[\left|\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s\right|>\varepsilon\right] \\
P\left(A_{k}\right)=\sum_{p=0}^{\infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right) \tag{74.6.27}
\end{gather*}
$$

Now

$$
\begin{aligned}
& P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right) \leq P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right]\right)\right) \\
\leq & P\left(\left[\left|\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(\left(M^{\tau_{p}}\right)_{k}^{r}(s)-\left(M^{\tau_{p}}\right)_{k}^{l}(s)\right)\right\rangle d s\right|>\varepsilon\right]\right)
\end{aligned}
$$

This is so because if $\tau_{p}=\infty$, then it has no effect but also it could happen that the defining inequality may hold even if $\tau_{p}<\infty$ hence the inequality. This is no larger than an expression of the form

$$
\begin{equation*}
\frac{C_{n}}{\varepsilon} \int_{\Omega} \int_{0}^{T}\|Y(s)\|_{V^{\prime}}\left\|\left(M^{\tau_{p}}\right)_{k}^{r}(s)-\left(M^{\tau_{p}}\right)_{k}^{l}(s)\right\|_{W} d s d P \tag{74.6.28}
\end{equation*}
$$

The inside integral converges to 0 by continuity of $M$. Also, thanks to the stopping time, the inside integral is dominated by an expression of the form

$$
\int_{0}^{T}\|Y(s)\|_{V^{\prime}} 2 p d s
$$

and this is a function in $L^{1}(\Omega)$ by assumption on $Y$. It follows that the integral in 74.6.28 converges to 0 as $k \rightarrow \infty$ by the dominated convergence theorem. Hence

$$
\lim _{k \rightarrow \infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right]\right)\right)=0
$$

Since the sets $\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]$ are disjoint, the sum of their probabilities is finite. Hence there is a dominating function in 74.6 .27 and so, by the dominated convergence theorem applied to the sum,

$$
\lim _{k \rightarrow \infty} P\left(A_{k}\right)=\sum_{p=0}^{\infty} \lim _{k \rightarrow \infty} P\left(A_{k} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right)=0
$$

Thus $\int_{t_{1}}^{t}\left\langle Y(s), P_{n}\left(M_{k}^{r}(s)-M_{k}^{l}(s)\right)\right\rangle d s$ converges to 0 in probability as $k \rightarrow \infty$.
Now consider

$$
\begin{aligned}
&\left|\int_{t_{1}}^{t}\left\langle Y(s), X_{k}^{r}(s)-X_{k}^{l}(s)\right\rangle d s\right| \leq \int_{0}^{T}\left|\left\langle Y(s), X_{k}^{r}(s)-X(s)\right\rangle\right| d s \\
&+\int_{0}^{T}\left|\left\langle Y(s), X_{k}^{l}(s)-X(s)\right\rangle\right| d s \\
& \leq 2\|Y(\cdot, \omega)\|_{L^{p^{\prime}}(0, T)}\left(2^{-k}\right)^{1 / p}
\end{aligned}
$$

for all $k$ large enough, this by Lemma 74.5.1. Therefore,

$$
\sum_{j=1}^{q_{k}-1}\left\langle B\left(\Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right), \Delta X\left(t_{j}\right)-\Delta M\left(t_{j}\right)\right\rangle
$$

converges to 0 in probability. This establishes the desired formula for $t \in D$.
In fact, the formula 74.6.20 is valid for all $t \in N_{\omega}^{C}$.
Theorem 74.6.2 In Situation 74.1.1, for $\omega$ off a set of measure zero, it follows that for every $t \in N_{\omega}^{C}$,

$$
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t} 2\langle Y(s), X(s)\rangle d s
$$

$$
\begin{equation*}
\left[R^{-1} B M, M\right](t)+2 \int_{0}^{t}\langle B X, d M\rangle \tag{74.6.29}
\end{equation*}
$$

Also, there exists a unique continuous, progressively measurable function which is denoted here as $\langle B X, X\rangle$ such that it equals $\langle B X(t), X(t)\rangle$ for a.e. $t$ and $\langle B X, X\rangle(t)$ equals the right side of the above for all $t$. In addition to this,

$$
\begin{gather*}
E(\langle B X, X\rangle(t))= \\
E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+E\left(\int_{0}^{t} 2\langle Y(s), X(s)\rangle d s+\left[R^{-1} B M, M\right](t)\right) \tag{74.6.30}
\end{gather*}
$$

Also the quadratic variation of the stochastic integral in 74.6.29 is dominated by

$$
\begin{equation*}
\int_{0}^{t}\|B X\|_{W^{\prime}}^{2} d[M] \tag{74.6.31}
\end{equation*}
$$

Also $t \rightarrow B X(t)$ is continuous with values in $W^{\prime}$ for $t \in N_{\omega}^{C}$.
Proof: Let $t \in N_{\omega}^{C} \backslash D$. For $t>0$, let $t(k)$ denote the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m)<t(k)$. Hence $m \leq k$. Then

$$
B X(t(m))=B X_{0}+\int_{0}^{t(m)} Y(s) d s+B M(t(m))
$$

a similar formula holding for $X(t(k))$. Thus for $t>t(m), t \in N_{\omega}^{C}$,

$$
B(X(t)-X(t(m)))=\int_{t(m)}^{t} Y(s) d s+B(M(t)-M(t(m)))
$$

which is the same sort of thing studied so far except that it starts at $t(m)$ rather than at 0 and $B X_{0}=0$. Therefore, from Lemma 74.6.1 it follows

$$
\begin{align*}
& \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle \\
= & \int_{t(m)}^{t(k)} 2\langle Y(s), X(s)-X(t(m))\rangle d s \\
+ & {\left[R^{-1} B M, M\right](t(k))-\left[R^{-1} B M, M\right](t(m)) } \\
& +2 \int_{t(m)}^{t(k)}\langle B(X-X(t(m))), d M\rangle \tag{74.6.32}
\end{align*}
$$

Consider that last term. It equals

$$
\begin{equation*}
2 \int_{t(m)}^{t(k)}\left\langle B\left(X-X_{m}^{l}\right), d M\right\rangle \tag{74.6.33}
\end{equation*}
$$

This is dominated by

$$
2\left|\int_{0}^{t(k)}\left\langle B\left(X-X_{m}^{l}\right), d M\right\rangle-\int_{0}^{t(m)}\left\langle B\left(X-X_{m}^{l}\right), d M\right\rangle\right|
$$

$$
\leq 4 \sup _{t \in[0, T]}\left|\int_{0}^{t}\left\langle B\left(X-X_{m}^{l}\right), d M\right\rangle\right|
$$

In Lemma 74.5.2 the above expression converges to 0 . It follows there is a set of measure 0 including the earlier one such that for $\omega$ not in that set, 74.6 .33 converges to 0 in $\mathbb{R}$. Similar reasoning shows the first term on the right in the non stochastic integral of 74.6.32 is dominated by an expression of the form

$$
4 \int_{0}^{T}\left|\left\langle Y(s), X(s)-X_{m}^{l}(s)\right\rangle\right| d s
$$

which clearly converges to 0 thanks to Lemma 74.5.1. Finally, it is obvious that

$$
\lim _{m, k \rightarrow \infty}\left[R^{-1} B M, M\right](t(k))-\left[R^{-1} B M, M\right](t(m))=0 \text { for a.e. } \omega
$$

due to the continuity of the quadratic variation.
This shows that for $\omega$ off a set of measure 0

$$
\lim _{m, k \rightarrow \infty}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle=0
$$

Then for $x \in W$,

$$
\begin{aligned}
& |\langle B(X(t(k))-X(t(m))), x\rangle| \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\langle B x, x\rangle^{1 / 2} \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\|B\|^{1 / 2}\|x\|_{W}
\end{aligned}
$$

and so

$$
\lim _{m, k \rightarrow \infty}\|B X(t(k))-B X(t(m))\|_{W^{\prime}}=0
$$

Recall $t$ was arbitrary and $\{t(k)\}$ is a sequence converging to $t$. Then the above has shown that $\{B X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $W^{\prime}$. Does it converge to $B X(t)$ ? Let $\xi(t) \in$ $W^{\prime}$ be what it converges to. Letting $v \in V$ then, since the integral equation shows that $t \rightarrow B X(t)$ is continuous into $V^{\prime}$,

$$
\langle\xi(t), v\rangle=\lim _{k \rightarrow \infty}\langle B X(t(k)), v\rangle=\langle B X(t), v\rangle,
$$

and now, since $V$ is dense in $W$, this implies $\xi(t)=B X(t)=B(X(t))$ since $t \notin N_{\omega}$. Recall also that it was shown earlier that $B X$ is weakly continuous into $W^{\prime}$ on $[0, T]$ hence the strong convergence of $\{B X(t(k))\}_{k=1}^{\infty}$ in $W^{\prime}$ implies that it converges to $B X(t)$, this for any $t \in N_{\omega}^{C}$.

For every $t \in D$ and for $\omega$ off the exceptional set of measure zero described earlier,

$$
\begin{gather*}
\langle B(X(t)), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t} 2\langle Y(s), X(s)\rangle d s+ \\
{\left[R^{-1} B M, M\right](t)+2 \int_{0}^{t}\langle B X, d M\rangle} \tag{74.6.34}
\end{gather*}
$$

Does this formula hold for all $t \in[0, T]$ ? Maybe not. However, it will hold for $t \notin N_{\omega}$. So let $t \notin N_{\omega}$.

$$
\begin{gathered}
|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle| \\
\leq \begin{array}{l}
|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t(k))\rangle| \\
+|\langle B X(t), X(t(k))\rangle-\langle B X(t), X(t)\rangle|
\end{array} \\
=|\langle B(X(t(k))-X(t)), X(t(k))\rangle|+|\langle B(X(t(k))-X(t)), X(t)\rangle|
\end{gathered}
$$

Then using the Cauchy Schwarz inequality on each term,

$$
\begin{aligned}
\leq & \langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2} \\
& \cdot\left(\langle B X(t(k)), X(t(k))\rangle^{1 / 2}+\langle B X(t), X(t)\rangle^{1 / 2}\right)
\end{aligned}
$$

As before, one can use the lower semicontinuity of

$$
t \rightarrow\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle
$$

on $N_{\omega}^{C}$ along with the boundedness of $\langle B X(t), X(t)\rangle$ also shown earlier $\mathbf{o f f} N_{\omega}$ to conclude

$$
\begin{gathered}
|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle| \\
\leq C\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2} \\
\leq C \lim _{m \rightarrow \infty} \inf _{m}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}<\varepsilon
\end{gathered}
$$

provided $k$ is sufficiently large. Since $\varepsilon$ is arbitrary,

$$
\lim _{k \rightarrow \infty}\langle B X(t(k)), X(t(k))\rangle=\langle B X(t), X(t)\rangle
$$

It follows that the formula 74.6 .34 is valid for all $t \in N_{\omega}^{C}$. Now define the function $\langle B X, X\rangle(t)$ as

$$
\langle B X, X\rangle(t) \equiv\left\{\begin{array}{c}
\langle B(X(t)), X(t)\rangle, t \notin N_{\omega} \\
\text { The right side of 74.6.34 if } t \in N_{\omega}
\end{array}\right.
$$

Then in short, $\langle B X, X\rangle(t)$ equals the right side of 74.6 .34 for all $t \in[0, T]$ and is consequently progressively measurable and continuous. Furthermore, for a.e. $t$, this function equals $\langle B(X(t)), X(t)\rangle$. Since it is known on a dense subset, it must be unique.

This implies that $t \rightarrow B X(t)$ is continuous with values in $W^{\prime}$ for $t \in N_{\omega}^{C}$. Here is why. The fact that the formula 74.6 .34 holds for all $t \in N_{\omega}^{C}$ implies that $t \rightarrow\langle B X(t), X(t)\rangle$ is continuous on $N_{\omega}^{C}$. Then for $x \in W, t, s \in N_{\omega}^{C}$

$$
\begin{equation*}
|\langle B X(t)-B X(s), x\rangle| \leq\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2}\|B\|^{1 / 2}\|x\|_{W} \tag{74.6.35}
\end{equation*}
$$

Also

$$
\begin{aligned}
& \langle B(X(t)-X(s)), X(t)-X(s)\rangle \\
= & \langle B X(t), X(t)\rangle+\langle B X(s), X(s)\rangle-2\langle B X(t), X(s)\rangle
\end{aligned}
$$

By weak continuity of $t \rightarrow B X(t)$ shown earlier,

$$
\lim _{t \rightarrow s}\langle B X(t), X(s)\rangle=\langle B X(s), X(s)\rangle .
$$

Therefore,

$$
\lim _{t \rightarrow s}\langle B(X(t)-X(s)), X(t)-X(s)\rangle=0
$$

and so the inequality 74.6.35 implies the continuity of $t \rightarrow B X(t)$ into $W^{\prime}$ for $t \notin N_{\omega}$. Note that by assumption this function is continuous into $V^{\prime}$ for all $t$.

Now consider the claim about the expectation. Use the function $\langle B X, X\rangle$ to define a stopping time as

$$
\tau_{p} \equiv \inf \{t>0:\langle B X, X\rangle(t)>p\}
$$

This is the first hitting time of a continuous process and so it is a valid stopping time. Using this, leads to

$$
\begin{gather*}
\langle B X, X\rangle^{\tau_{p}}(t)=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]} 2\langle Y(s), X(s)\rangle d s+ \\
{\left[R^{-1} B M, M\right]^{\tau_{p}}(t)+2 \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}\langle B X, d M\rangle} \tag{74.6.36}
\end{gather*}
$$

The term at the end is now a martingale because $\mathscr{X}_{\left[0, \tau_{p}\right]} B X$ is bounded. Hence the expectation of the martingale at the end equals 0 . Thus you obtain

$$
\begin{gathered}
E\left(\langle B X, X\rangle^{\tau_{p}}(t)\right)=E\left(\left\langle B X_{0}, X_{0}\right\rangle\right) \\
+E\left(\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]} 2\langle Y(s), X(s)\rangle d s\right)+E\left(\left[R^{-1} B M, M\right]^{\tau_{p}}(t)\right)
\end{gathered}
$$

Now use the monotone convergence theorem and the dominated convergence theorem to pass to a limit as $p \rightarrow \infty$ and obtain 74.6.30. The claim about the quadratic variation follows from Theorem 66.0.22.

What of the special case where $W=H=H^{\prime}$ and you are in the context of a Gelfand triple

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

and $B$ is simply the identity. Then we obtain the following theorem as a special case.
Theorem 74.6.3 In Situation 74.1.1 in which $W=H=H^{\prime}$ and $B=I$, it follows that off a set of measure zero, for every $t \in[0, T]$, there is a set of measure zero $N$ such that for $\omega \notin N$, there is a continuous function $\langle X, X\rangle$ which equals $|X(t)|_{H}^{2}$ for a.e. $t$ such that

$$
\begin{align*}
\langle X, X\rangle(t) & =\left|X_{0}\right|_{H}^{2}+\int_{0}^{t} 2\langle Y(s), X(s)\rangle d s \\
+ & {[M](t)+2 \int_{0}^{t}(X, d M) } \tag{74.6.37}
\end{align*}
$$

Furthermore,off a set of measure zero, $t \rightarrow X(t)$ is continuous as a map into $H$ for a.e. $\omega$. In addition to this,

$$
\begin{gather*}
E(\langle X, X\rangle(t))= \\
E\left(\left|X_{0}\right|^{2}\right)+E\left(\int_{0}^{t} 2\langle Y(s), X(s)\rangle d s\right)+E([M](t)) \tag{74.6.38}
\end{gather*}
$$

The quadratic variation of the stochastic integral satisfies

$$
\left[\int_{0}^{(\cdot)}(X, d M)\right](t) \leq \int_{0}^{t}\|X\|_{H}^{2} d[M]
$$

It is more attractive to write $|X(t)|_{H}^{2}$ in place of $\langle X, X\rangle(t)$. However, I guess this is not strictly right although the discrepancy is only on a set of measure zero so it seems fairly harmless to indulge in this sloppiness. However, for $t \notin N_{\omega}$,

$$
|X(t)|_{H}^{2}=\sum_{i}\left(X(t), e_{i}\right)^{2}
$$

where the orthonormal basis $\left\{e_{i}\right\}$ is in $V$. Then for $s \in N_{\omega}$, you can get the following. Let $t_{n} \rightarrow s$ where $t_{n} \in N_{\omega}$. Then in the above notation,

$$
\sum_{i}\left\langle X(s), e_{i}\right\rangle^{2} \leq \lim \inf _{n \rightarrow \infty} \sum_{i}\left(X\left(t_{n}\right), e_{i}\right)_{H}^{2}=\lim _{n \rightarrow \infty}\left|X\left(t_{n}\right)\right|_{H}^{2} \leq C(\omega)
$$

It follows that in fact $X(s) \in H$ and you can take $X(s)=\sum_{i}\left\langle X(s), e_{i}\right\rangle e_{i} \in H$ because $\sum_{i}\left\langle X(s), e_{i}\right\rangle^{2}<\infty$. Hence

$$
|X(s)|^{2}=\sum_{i}\left\langle X(s), e_{i}\right\rangle^{2} \leq \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left|X\left(t_{n}\right)\right|_{H}^{2}
$$

so $X$ has values in $H$ and is lower semicontinuous on $[0, T]$.

## Chapter 75

## Some Nonlinear Operators

In this chapter is a description and properties of some standard nonlinear maps.

### 75.1 An Assortment Of Nonlinear Operators

Definition 75.1.1 For $V$ a real Banach space, $A: V \rightarrow V^{\prime}$ is a pseudomonotone map if whenever

$$
\begin{equation*}
u_{n} \rightharpoonup u \tag{75.1.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq 0 \tag{75.1.2}
\end{equation*}
$$

it follows that for all $v \in V$,

$$
\begin{equation*}
\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle \tag{75.1.3}
\end{equation*}
$$

The half arrows denote weak convergence.
Definition 75.1.2 $A: V \rightarrow V^{\prime}$ is monotone if for all $v, u \in V$,

$$
\langle A u-A v, u-v\rangle \geq 0
$$

and $A$ is Hemicontinuous iffor all $v, u \in V$,

$$
\lim _{t \rightarrow 0+}\langle A(u+t(v-u)), u-v\rangle=\langle A u, u-v\rangle .
$$

Theorem 75.1.3 Let $V$ be a Banach space and let $A: V \rightarrow V^{\prime}$ be monotone and hemicontinuous. Then $A$ is pseudomonotone.

Proof: Let $A$ be monotone and Hemicontinuous. First here is a claim.
Claim: If 75.1.1 and 75.1.2 hold, then $\lim _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=0$.
Proof of the claim: Since $A$ is monotone,

$$
\left\langle A u_{n}-A u, u_{n}-u\right\rangle \geq 0
$$

so

$$
\left\langle A u_{n}, u_{n}-u\right\rangle \geq\left\langle A u, u_{n}-u\right\rangle .
$$

Therefore,

$$
0=\lim \inf _{n \rightarrow \infty}\left\langle A u, u_{n}-u\right\rangle \leq \lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq \lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq 0
$$

Now using that $A$ is monotone again, then letting $t>0$,

$$
\left\langle A u_{n}-A(u+t(v-u)), u_{n}-u+t(u-v)\right\rangle \geq 0
$$

and so

$$
\left\langle A u_{n}, u_{n}-u+t(u-v)\right\rangle \geq\left\langle A(u+t(v-u)), u_{n}-u+t(u-v)\right\rangle .
$$

Taking the liminf on both sides and using the claim and $t>0$,

$$
t \lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u-v\right\rangle \geq t\langle A(u+t(v-u)),(u-v)\rangle
$$

Next divide by $t$ and use the Hemicontinuity of $A$ to conclude that

$$
\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u-v\right\rangle \geq\langle A u, u-v\rangle
$$

From the claim,

$$
\begin{aligned}
\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u-v\right\rangle & =\lim \inf _{n \rightarrow \infty}\left(\left\langle A u_{n}, u_{n}-v\right\rangle+\left\langle A u_{n}, u-u_{n}\right\rangle\right) \\
& =\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle .
\end{aligned}
$$

Monotonicity is very important in the above proof. The next example shows that even if the operator is linear and bounded, it is not necessarily pseudomonotone.

Example 75.1.4 Let $H$ be any Hilbert space and let $A: H \rightarrow H^{\prime}$ be given by

$$
\langle A x, y\rangle \equiv(-x, y)_{H}
$$

Then A fails to be pseudomonotone.
Proof: Let $\left\{x_{n}\right\}_{n=1}^{\infty}$ be an orthonormal set of vectors in $H$. Then Parsevall's inequality implies

$$
\|x\|^{2} \geq \sum_{n=1}^{\infty}\left|\left(x_{n}, x\right)\right|^{2}
$$

and so for any $x \in H, \lim _{n \rightarrow \infty}\left(x_{n}, x\right)=0$. Thus $x_{n} \rightharpoonup 0 \equiv x$. Also

$$
\begin{gathered}
\lim \sup _{n \rightarrow \infty}\left\langle A x_{n}, x_{n}-x\right\rangle= \\
\lim \sup _{n \rightarrow \infty}\left\langle A x_{n}, x_{n}-0\right\rangle=\lim \sup _{n \rightarrow \infty}\left(-| | x_{n} \|^{2}\right)=-1 \leq 0
\end{gathered}
$$

If $A$ were pseudomonotone, we would need to be able to conclude that for all $y \in H$,

$$
\lim \inf _{n \rightarrow \infty}\left\langle A x_{n}, x_{n}-y\right\rangle \geq\langle A x, x-y\rangle=0
$$

However,

$$
\lim \inf _{n \rightarrow \infty}\left\langle A x_{n}, x_{n}-0\right\rangle=-1<0=\langle A 0,0-0\rangle
$$

Now the following proposition is useful.
Proposition 75.1.5 Suppose $A: V \rightarrow V^{\prime}$ is pseudomonotone and bounded where $V$ is separable. Then it must be demicontinuous. This means that if $u_{n} \rightarrow u$, then $A u_{n} \rightharpoonup A u$.

Proof: Since $u_{n} \rightarrow u$ is strong convergence and since $A u_{n}$ is bounded, it follows

$$
\limsup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=0
$$

Suppose this is not so that $A u_{n}$ converges weakly to $A u$. Since $A$ is bounded, there exists a subsequence, still denoted by $n$ such that $A u_{n} \rightharpoonup \xi$ weak $*$. I need to verify $\xi=A u$. From the above, it follows that for all $v \in V$

$$
\begin{aligned}
\langle A u, u-v\rangle & \leq \lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \\
& =\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u-v\right\rangle=\langle\xi, u-v\rangle
\end{aligned}
$$

Hence $\xi=A u$.
There is another type of operator which is more general than pseudomonotone.
Definition 75.1.6 Let $A: V \rightarrow V^{\prime}$ be an operator. Then $A$ is called type $M$ if whenever $u_{n} \rightharpoonup u$ and $A u_{n} \rightharpoonup \xi$, and

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

it follows that $A u=\xi$.
Proposition 75.1.7 If $A$ is pseudomonotone, then $A$ is type $M$.
Proof: Suppose $A$ is pseudomonotone and $u_{n} \rightharpoonup u$ and $A u_{n} \rightharpoonup \xi$, and

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

Then

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle-\langle\xi, u\rangle \leq 0
$$

Hence

$$
\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle
$$

for all $v \in V$. Consequently, for all $v \in V$,

$$
\begin{aligned}
\langle A u, u-v\rangle & \leq \liminf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \\
& =\lim _{n \rightarrow \infty}\left(\left\langle A u_{n}, u-v\right\rangle+\left\langle A u_{n}, u_{n}-u\right\rangle\right) \\
& =\langle\xi, u-v\rangle+\lim _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq\langle\xi, u-v\rangle
\end{aligned}
$$

and so $A u=\xi$.
An interesting result is the the following which states that a monotone linear function added to a type M is also type M .

Proposition 75.1.8 Suppose $A: V \rightarrow V^{\prime}$ is type $M$ and suppose $L: V \rightarrow V^{\prime}$ is monotone, bounded and linear. Then $L+A$ is type $M$. Let $V$ be separable or reflexive so that the weak convergences in the following argument are valid.

Proof: Suppose $u_{n} \rightharpoonup u$ and $A u_{n}+L u_{n} \rightharpoonup \xi$ and also that

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}+L u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

Does it follow that $\xi=A u+L u$ ? Suppose not. There exists a further subsequence, still called $n$ such that $L u_{n} \rightharpoonup L u$. This follows because $L$ is linear and bounded. Then from monotonicity,

$$
\left\langle L u_{n}, u_{n}\right\rangle \geq\left\langle L u_{n}, u\right\rangle+\left\langle L(u), u_{n}-u\right\rangle
$$

Hence with this further subsequence, the limsup is no larger and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle+\lim _{n \rightarrow \infty}\left(\left\langle L u_{n}, u\right\rangle+\left\langle L(u), u_{n}-u\right\rangle\right) \leq\langle\xi, u\rangle
$$

and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi-L u, u\rangle
$$

It follows since $A$ is type $M$ that $A u=\xi-L u$, which contradicts the assumption that $\xi \neq$ $A u+L u$.

There is also the following useful generalization of the above proposition.
Corollary 75.1.9 Suppose $A: V \rightarrow V^{\prime}$ is type $M$ and suppose $L: V \rightarrow V^{\prime}$ is monotone, bounded and linear. Then for $u_{0} \in V$ define $M(u) \equiv L\left(u-u_{0}\right)$. Then $M+A$ is type $M$. Let $V$ be separable or reflexive so that the weak convergences in the following argument are valid.

Proof: Suppose $u_{n} \rightharpoonup u$ and $A u_{n}+M u_{n} \rightharpoonup \xi$ and also that

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}+M u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

Does it follow that $\xi=A u+M u$ ? Suppose not. By assumption, $u_{n}-u_{0} \rightharpoonup u-u_{0}$ and so, since $L$ is bounded, there is a further subsequence, still called $n$ such that

$$
M u_{n}=L\left(u_{n}-u_{0}\right) \rightharpoonup L\left(u-u_{0}\right)=M u .
$$

Since $M$ is monotone,

$$
\left\langle M u_{n}-M u, u_{n}-u\right\rangle \geq 0
$$

Thus

$$
\left\langle M u_{n}, u_{n}\right\rangle-\left\langle M u_{n}, u\right\rangle-\left\langle M u, u_{n}\right\rangle+\langle M u, u\rangle \geq 0
$$

and so

$$
\left\langle M u_{n}, u_{n}\right\rangle \geq\left\langle M u_{n}, u\right\rangle+\left\langle M u, u_{n}-u\right\rangle
$$

Hence with this further subsequence, the lim sup is no larger and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle+\lim _{n \rightarrow \infty}\left(\left\langle M u_{n}, u\right\rangle+\left\langle M(u), u_{n}-u\right\rangle\right) \leq\langle\xi, u\rangle
$$

and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi-M u, u\rangle
$$

It follows since $A$ is type $M$ that $A u=\xi-M u$, which contradicts the assumption that $\xi \neq A u+M u$.

The following is Browder's lemma. It is a very interesting application of the Brouwer fixed point theorem.

Lemma 75.1.10 (Browder) Let $K$ be a convex closed and bounded set in $\mathbb{R}^{n}$ and let $A$ : $K \rightarrow \mathbb{R}^{n}$ be continuous and $\mathbf{f} \in \mathbb{R}^{n}$. Then there exists $\mathbf{x} \in K$ such that for all $\mathbf{y} \in K$,

$$
(\mathbf{f}-A \mathbf{x}, \mathbf{y}-\mathbf{x}) \leq 0
$$

Proof: Let $P_{K}$ denote the projection onto $K$. Thus $P_{K}$ is Lipschitz continuous.

$$
\mathbf{x} \rightarrow P_{K}(\mathbf{f}-A \mathbf{x}+\mathbf{x})
$$

is a continuous map from $K$ to $K$. By the Brouwer fixed point theorem, it has a fixed point $\mathbf{x} \in K$. Therefore, for all $\mathbf{y} \in K$,

$$
(\mathbf{f}-A \mathbf{x}+\mathbf{x}-\mathbf{x}, \mathbf{y}-\mathbf{x})=(\mathbf{f}-A \mathbf{x}, \mathbf{y}-\mathbf{x}) \leq 0
$$

From this lemma, there is an interesting theorem on surjectivity.
Proposition 75.1.11 Let $A: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be continuous and coercive,

$$
\lim _{|\mathbf{x}| \rightarrow \infty} \frac{\left(A\left(\mathbf{x}+\mathbf{x}_{0}\right), \mathbf{x}\right)}{|\mathbf{x}|}=\infty
$$

for some $\mathbf{x}_{0}$. Then for all $\mathbf{f} \in \mathbb{R}^{n}$, there exists $\mathbf{x} \in \mathbb{R}^{n}$ such that $A \mathbf{x}=\mathbf{f}$.
Proof: Define the closed convex sets $B_{n} \equiv \overline{B\left(\mathbf{x}_{0}, n\right)}$. By Browder's lemma, there exists $\mathbf{x}_{n}$ such that

$$
\left(\mathbf{f}-A \mathbf{x}_{n}, \mathbf{y}-\mathbf{x}_{n}\right) \leq 0
$$

for all $\mathbf{y} \in B_{n}$. Then taking $\mathbf{y}=\mathbf{x}_{0}$, it follows from the coercivity condition that the $\mathbf{x}_{n}-\mathbf{x}_{0}$ are bounded. It follows that for large $n, \mathbf{x}_{n}$ is an interior point of $B_{n}$. Therefore,

$$
\left(\mathbf{f}-A \mathbf{x}_{n}, \mathbf{z}\right) \leq 0
$$

for all $\mathbf{z}$ in some open ball centered at $\mathbf{x}_{0}$. Hence $\mathbf{f}=A \mathbf{x}_{n}$.
Lemma 75.1.12 Let $A: V \rightarrow V^{\prime}$ be type $M$ and bounded and suppose $V$ is reflexive or $V$ is separable. Then $A$ is demicontinuous.

Proof: Suppose $u_{n} \rightarrow u$ and $A u_{n}$ fails to converge weakly to $A u$. Then there is a further subsequence, still denoted as $u_{n}$ such that $A u_{n} \rightharpoonup \zeta \neq A u$. Then thanks to the strong convergence, you have

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle=\left\langle\zeta, u_{n}\right\rangle
$$

which implies $\zeta=A u$ after all.
With these lemmas and the above proposition, there is a very interesting surjectivity result.

Theorem 75.1.13 Let $A: V \rightarrow V^{\prime}$ be type $M$, bounded, and coercive

$$
\begin{equation*}
\lim _{\|u\| \rightarrow \infty} \frac{\left\langle A\left(u+u_{0}\right), u\right\rangle}{\|u\|}=\infty \tag{75.1.4}
\end{equation*}
$$

for some $u_{0}$, where $V$ is a separable reflexive Banach space. Then $A$ is surjective.
Proof: Since $V$ is separable, there exists an increasing sequence of finite dimensional subspaces $\left\{V_{n}\right\}$ such that $\overline{\cup_{n} V_{n}}=V$. Say span $\left(v_{1}, \cdots, v_{n}\right)=V_{n}$. Then consider the following diagram.

$$
\begin{array}{lllll}
\mathbb{R}^{n} & \stackrel{\theta^{*}}{\leftarrow} & V_{n}^{\prime} & \stackrel{i^{*}}{\leftarrow} & V^{\prime} \\
\mathbb{R}^{n} & \stackrel{\theta}{\rightarrow} & V_{n} & \xrightarrow{i} & V
\end{array}
$$

Here the map $\theta$ is the one which does the following.

$$
\theta(\mathbf{x})=\sum_{i=1}^{n} x_{i} v_{i}
$$

The map $i$ is the inclusion map. Consider the map $\theta^{*} i^{*} A i \theta$. By Lemma 75.1.12 this map is continuous. The map $\theta$ is continuous, one to one, and onto. Thus its inverse is also continuous. Let $\mathbf{x}_{0}$ correspond to $u_{0}$. Then for some constant $C$,

$$
\frac{\left(\theta^{*} i^{*} A i \theta\left(\mathbf{x}+\mathbf{x}_{0}\right), \mathbf{x}\right)}{|\mathbf{x}|} \geq \frac{\left\langle A i \theta\left(\mathbf{x}+\mathbf{x}_{0}\right), i \theta \mathbf{x}\right\rangle}{C\|i \theta \mathbf{x}\|_{V}}
$$

and to say $|\mathbf{x}| \rightarrow \infty$ is the same as saying that $\|i \theta \mathbf{x}\|_{V} \rightarrow \infty$. Hence $\theta^{*} i^{*} A i \theta$ is coercive. Let $f \in V^{\prime}$. Then from 75.1.11, there exists $\mathbf{x}_{n}$ such that

$$
\theta^{*} i^{*} A i \theta \mathbf{x}_{n}=\theta^{*} i^{*} \mathbf{f}
$$

Thus, $i^{*} A i \theta \mathbf{x}_{n}=i^{*} f$ and this implies that for $v_{n} \equiv \theta \mathbf{x}_{n}$,

$$
i^{*} A i v_{n}=i^{*} f
$$

In other words,

$$
\begin{equation*}
\left\langle A v_{n}, y\right\rangle=\langle f, y\rangle \tag{75.1.5}
\end{equation*}
$$

for all $y \in V_{n}$. Then from the coercivity condition 75.1.4, the $v_{n}$ are bounded independent of $n$. Since $V$ is reflexive, there is a subsequence, still called $\left\{v_{n}\right\}$ which converges weakly to $v \in V$. Since $A$ is bounded, it can also be assumed that $A v_{n} \rightharpoonup \zeta \in V^{\prime}$. Then

$$
\lim \sup _{n \rightarrow \infty}\left\langle A v_{n}, v_{n}\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle f, v_{n}\right\rangle=\langle f, v\rangle
$$

Also, passing to the limit in 75.1.5,

$$
\langle\zeta, y\rangle=\langle f, y\rangle
$$

for any $y \in V_{n}$, this for any $n$. Since the union of these $V_{n}$ is dense, it follows that the above equation holds for all $y \in V$. Therefore, $f=\zeta$ and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A v_{n}, v_{n}\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle f, v_{n}\right\rangle=\langle f, v\rangle=\langle\zeta, v\rangle
$$

Since $A$ is type $M$,

$$
A v=\zeta=f
$$

### 75.2 Duality Maps

The duality map is an attempt to duplicate some of the features of the Riesz map in Hilbert space which is discussed in the chapter on Hilbert space.

Definition 75.2.1 A Banach space is said to be strictly convex if whenever $\|x\|=\|y\|$ and $x \neq y$, then

$$
\left\|\frac{x+y}{2}\right\|<\|x\| .
$$

$F: X \rightarrow X^{\prime}$ is said to be a duality map if it satisfies the following: a.) $\|F(x)\|=\|x\|^{p-1} . b$.) $F(x)(x)=\|x\|^{p}$, where $p>1$.

Duality maps exist. Here is why. Let

$$
F(x) \equiv\left\{x^{*}:\left\|x^{*}\right\| \leq\|x\|^{p-1} \text { and } x^{*}(x)=\|x\|^{p}\right\}
$$

Then $F(x)$ is not empty because you can let $f(\alpha x)=\alpha\|x\|^{p}$. Then $f$ is linear and defined on a subspace of $X$. Also

$$
\sup _{\|\alpha x\| \leq 1}|f(\alpha x)|=\sup _{\|\alpha x\| \leq 1}|\alpha|\|x\|^{p} \leq\|x\|^{p-1}
$$

Also from the definition,

$$
f(x)=\|x\|^{p}
$$

and so, letting $x^{*}$ be a Hahn Banach extension, it follows $x^{*} \in F(x)$. Also, $F(x)$ is closed and convex. It is clearly closed because if $x_{n}^{*} \rightarrow x^{*}$, the condition on the norm clearly holds and also the other one does too. It is convex because

$$
\left\|x^{*} \lambda+(1-\lambda) y^{*}\right\| \leq \lambda\left\|x^{*}\right\|+(1-\lambda)\left\|y^{*}\right\| \leq \lambda\|x\|^{p-1}+(1-\lambda)\|x\|^{p-1}
$$

If the conditions hold for $x^{*}$, then we can show that in fact $\left\|x^{*}\right\|=\|x\|^{p-1}$. This is because

$$
\left\|x^{*}\right\| \geq\left|x^{*}\left(\frac{x}{\|x\|}\right)\right|=\frac{1}{\|x\|}\left|x^{*}(x)\right|=\|x\|^{p-1}
$$

Now how many things are in $F(x)$ assuming the norm on $X^{\prime}$ is strictly convex? Suppose $x_{1}^{*}$, and $x_{2}^{*}$ are two things in $F(x)$. Then by convexity, so is $\left(x_{1}^{*}+x_{2}^{*}\right) / 2$. Hence by strict convexity, if the two are different, then

$$
\left\|\frac{x_{1}^{*}+x_{2}^{*}}{2}\right\|=\|x\|^{p-1}<\frac{1}{2}\left\|x_{1}^{*}\right\|+\frac{1}{2}\left\|x_{2}^{*}\right\|=\|x\|^{p-1}
$$

which is a contradiction. Therefore, $F$ is an actual mapping.
What are some of its properties? First is one which is similar to the Cauchy Schwarz inequality. Since $p-1=p / p^{\prime}$,

$$
\sup _{\|y\| \leq 1}|\langle F x, y\rangle|=\|x\|^{p / p^{\prime}}
$$

and so for arbitrary $y \neq 0$,

$$
\begin{aligned}
|\langle F x, y\rangle| & =\|y\|\left|\left\langle F x, \frac{y}{\|y\| \|}\right\rangle\right| \leq\|y\|\|x\|^{p / p^{\prime}} \\
& =|\langle F y, y\rangle|^{1 / p}|\langle F x, x\rangle|^{1 / p^{\prime}}
\end{aligned}
$$

Next we can show that $F$ is monotone.

$$
\begin{aligned}
\langle F x-F y, x-y\rangle & =\langle F x, x\rangle-\langle F x, y\rangle-\langle F y, x\rangle+\langle F y, y\rangle \\
& \geq\|x\|^{p}+\|y\|^{p}-\|y\|\|x\|^{p / p^{\prime}}-\|y\|^{p / p^{\prime}}\|x\| \\
\geq\|x\|^{p}+\|y\|^{p} & -\left(\frac{\|y\|^{p}}{p}+\frac{\|x\|^{p}}{p^{\prime}}\right)-\left(\frac{\|y\|^{p}}{p^{\prime}}+\frac{\|x\|^{p}}{p}\right)=0
\end{aligned}
$$

Next it can be shown that $F$ is hemicontinuous. By the construction, $F(x+t y)$ is bounded as $t \rightarrow 0$. Let $t \rightarrow 0$ be a subsequence such that

$$
F(x+t y) \rightarrow \xi \text { weak } *
$$

Then we ask: Does $\xi$ do what it needs to do in order to be $F(x)$ ? The answer is yes. First of all $\|F(x+t y)\|=\|x+t y\|^{p-1} \rightarrow\|x\|^{p-1}$. The set

$$
\left\{x^{*}:\left\|x^{*}\right\| \leq\|x\|^{p-1}+\varepsilon\right\}
$$

is closed and convex and so it is weak $*$ closed as well. For all small enough $t$, it follows $F(x+t y)$ is in this set. Therefore, the weak limit is also in this set and it follows $\|\xi\| \leq$ $\|x\|^{p-1}+\varepsilon$. Since $\varepsilon$ is arbitrary, it follows $\|\xi\| \leq\|x\|^{p-1}$. Is $\xi(x)=\|x\|^{p}$ ? We have

$$
\begin{aligned}
\|x\|^{p} & =\lim _{t \rightarrow 0}\|x+t y\|^{p}=\lim _{t \rightarrow 0}\langle F(x+t y), x+t y\rangle \\
& =\lim _{t \rightarrow 0}\langle F(x+t y), x\rangle=\langle\xi, x\rangle
\end{aligned}
$$

and so, $\xi$ does what it needs to do to be $F(x)$. This would be clear if $\|\xi\|=\|x\|^{p-1}$. However, $|\langle\xi, x\rangle|=\|x\|^{p}$ and so $\|\xi\| \geq\left|\left\langle\xi, \frac{x}{\|x\|}\right\rangle\right|=\|x\|^{p-1}$. Thus $\|\xi\|=\|x\|^{p-1}$ which shows $\xi$ does everyting it needs to do to equal $F(x)$ and so it is $F(x)$. Since this conclusion follows for any convergent sequence, it follows that $F(x+t y)$ converges to $F(x)$ weakly as $t \rightarrow 0$. This is what it means to be hemicontinuous. This proves the following theorem. One can show also that $F$ is demicontinuous which means strongly convergent sequences go to weakly convergent sequences. Here is a proof for the case where $p=2$. You can clearly do the same thing for arbitrary $p$.

Lemma 75.2.2 Let $F$ be a duality map for $p=2$ where $X, X^{\prime}$ are reflexive and have strictly convex norms. (If $X$ is reflexive, there is always an equivalent strictly convex norm [8].) Then $F$ is demicontinuous.

Proof: Say $x_{n} \rightarrow x$. Then does it follow that $F x_{n} \rightharpoonup F x$ ? Suppose not. Then there is a subsequence, still denoted as $x_{n}$ such that $x_{n} \rightarrow x$ but $F x_{n} \rightharpoonup y \neq F x$ where here $\rightharpoonup$ denotes weak convergence. This follows from the Eberlein Smulian theorem. Then

$$
\langle y, x\rangle=\lim _{n \rightarrow \infty}\left\langle F x_{n}, x_{n}\right\rangle=\lim _{n \rightarrow \infty}\left\|x_{n}\right\|^{2}=\|x\|^{2}
$$

Also, there exists $z,\|z\|=1$ and $\langle y, z\rangle \geq\|y\|-\varepsilon$. Then

$$
\|y\|-\varepsilon \leq\langle y, z\rangle=\lim _{n \rightarrow \infty}\left\langle F x_{n}, z\right\rangle \leq \lim \inf _{n \rightarrow \infty}\left\|F x_{n}\right\|=\lim \inf _{n \rightarrow \infty}\left\|x_{n}\right\|=\|x\|
$$

and since $\varepsilon$ is arbitrary, $\|y\| \leq\|x\|$. It follows from the above construction of $F x$, that $y=F x$ after all, a contradiction.

Theorem 75.2.3 Let $X$ be a reflexive Banach space with $X^{\prime}$ having strictly convex norm ${ }^{1}$. Then for $p>1$, there exists a mapping $F: X \rightarrow X^{\prime}$ which is bounded, monotone, hemicontinuous, coercive in the sense that $\lim _{|x| \rightarrow \infty}\langle F x, x\rangle /|x|=\infty$, which also satisfies the inequalities

$$
|\langle F x, y\rangle| \leq|\langle F x, x\rangle|^{1 / p^{\prime}}|\langle F y, y\rangle|^{1 / p}
$$

Note that these conclusions about duality maps show that they map onto the dual space.
The duality map was onto and it was monotone. This was shown above. Consider the form of a duality map for the $L^{p}$ spaces. Let $F: L^{p} \rightarrow\left(L^{p}\right)^{\prime}$ be the one which satisfies

$$
\|F f\|=\|f\|^{p-1},\langle F f, f\rangle=\|f\|^{p}
$$

Then in this case,

$$
F f=|f|^{p-2} \bar{f}
$$

This is because it does what it needs to do.

$$
\begin{aligned}
\|F f\|_{L^{p^{\prime}}} & =\left(\int_{\Omega}\left(|f|^{p-1}\right)^{p^{\prime}} d \mu\right)^{1 / p^{\prime}}=\left(\int_{\Omega}\left(|f|^{p / p^{\prime}}\right)^{p^{\prime}} d \mu\right)^{1 / p^{\prime}} \\
& =\left(\int_{\Omega}|f|^{p} d \mu\right)^{1-(1 / p)}=\left(\left(\int_{\Omega}|f|^{p} d \mu\right)^{1 / p}\right)^{p-1}=\|f\|_{L^{p}}^{p-1}
\end{aligned}
$$

while it is obvious that

$$
\langle F f, f\rangle=\int_{\Omega}|f|^{p} d \mu=\|f\|_{L^{p}(\Omega)}^{p}
$$

Now here is an interesting inequality which I will only consider in the case where the quantities are real valued.

Lemma 75.2.4 Let $p>2$. Then for $a, b$ real numbers,

$$
\left(|a|^{p-2} a-|b|^{p-2} b\right)(a-b) \geq C|a-b|^{p}
$$

for some constant $C$ independent of $a, b$.

[^44]Proof: There is nothing to show if $a=b$. Without loss of generality, assume $a>b$. Also assume $p \geq 2$. There is nothing to show if $p=2$. I want to show that there exists a constant $C$ such that for $a>b$,

$$
\begin{equation*}
\frac{|a|^{p-2} a-|b|^{p-2} b}{|a-b|^{p-1}} \geq C \tag{75.2.6}
\end{equation*}
$$

First assume also that $b \geq 0$. Now it is clear that as $a \rightarrow \infty$, the quotient above converges to 1. Take the derivative of this quotient. This yields

$$
(p-1)|a-b|^{p-2} \frac{|a|^{p-2}|a-b|-\left(|a|^{p-2} a-|b|^{p-2} b\right)}{|a-b|^{2 p-2}}
$$

Now remember $a>b$. Then the above reduces to

$$
(p-1)|a-b|^{p-2} b \frac{|b|^{p-2}-|a|^{p-2}}{|a-b|^{2 p-2}}
$$

Since $b \geq 0$, this is negative and so 1 would be a lower bound. Now suppose $b<0$. Then the above derivative is negative for $b<a \leq-b$ and then it is positive for $a>-b$. It equals 0 when $a=-b$. Therefore the quotient in 75.2.6 achieves its minimum value when $a=-b$. This value is

$$
\frac{|-b|^{p-2}(-b)-|b|^{p-2} b}{|-b-b|^{p-1}}=|b|^{p-2} \frac{-2 b}{|2 b|^{p-1}}=|b|^{p-2} \frac{1}{|2 b|^{p-2}}=\frac{1}{2^{p-2}}
$$

Therefore, the conclusion holds whenever $p \geq 2$. That is

$$
\left(|a|^{p-2} a-|b|^{p-2} b\right)(a-b) \geq \frac{1}{2^{p-2}}|a-b|^{p}
$$

This proves the lemma.
This holds for $p>1$ also, but I don't remember how to show this at this time.
However, in the context of strictly convex norms on the reflexive Banach space $X$, the following important result holds. I will give it for the case where $p=2$ since this is the case of most interest.

Theorem 75.2.5 Let $X$ be a reflexive Banach space and $X, X^{\prime}$ have strictly convex norms as discussed above. Let $F$ be the duality map with $p=2$. Then $F$ is strictly monotone. This means

$$
\langle F u-F v, u-v\rangle \geq 0
$$

and it equals 0 if and only if $u-v$.
Proof: First why is it monotone? By definition of $F,\langle F(u), u\rangle=\|u\|^{2}$ and $\|F(u)\|=$ $\|u\|$. Then

$$
|\langle F u, v\rangle|=\left|\left\langle F u, \frac{v}{\|v\|}\right\rangle\right|\|v\| \leq\|F u\|\|v\|=\|u\|\|v\|
$$

Hence

$$
\begin{aligned}
\langle F u-F v, u-v\rangle & =\|u\|^{2}+\|v\|^{2}-\langle F u, v\rangle-\langle F v, u\rangle \\
& \geq\|u\|^{2}+\|v\|^{2}-2\|u\|\|v\| \geq 0
\end{aligned}
$$

Now suppose $\|x\|=\|y\|=1$ but $x \neq y$. Then

$$
\left\langle F x, \frac{x+y}{2}\right\rangle \leq\left\|\frac{x+y}{2}\right\|<\frac{\|x\|+\|y\|}{2}=1
$$

It follows that

$$
\frac{1}{2}\langle F x, x\rangle+\frac{1}{2}\langle F x, y\rangle=\frac{1}{2}+\frac{1}{2}\langle F x, y\rangle<1
$$

and so

$$
\langle F x, y\rangle<1
$$

For arbitrary $x, y, x /\|x\| \neq y /\|y\|$

$$
\langle F x, y\rangle=\|x\|\|y\|\left\langle F\left(\frac{x}{\|x\|}\right),\left(\frac{y}{\|y\|}\right)\right\rangle
$$

It is easy to check that $F(\alpha x)=\alpha F(x)$. Therefore,

$$
|\langle F x, y\rangle|=\|x\|\|y\|\left\langle F\left(\frac{x}{\|x\|}\right),\left(\frac{y}{\|y\|}\right)\right\rangle<\|x\|\|y\|
$$

Now say that $x \neq y$ and consider

$$
\langle F x-F y, x-y\rangle
$$

First suppose $x=\alpha y$. Then the above is

$$
\begin{aligned}
\langle F(\alpha y)-F y,(\alpha-1) y\rangle & =(\alpha-1)\left(\langle F(\alpha y), y\rangle-\|y\|^{2}\right) \\
& =(\alpha-1)\left(\langle\alpha F(y), y\rangle-\|y\|^{2}\right) \\
& =(\alpha-1)^{2}\|y\|^{2}>0
\end{aligned}
$$

The other case is that $x /\|x\| \neq y /\|y\|$ and in this case,

$$
\begin{gathered}
\langle F x-F y, x-y\rangle=\|x\|^{2}+\|y\|^{2}-\langle F x, y\rangle-\langle F y, x\rangle \\
>\|x\|^{2}+\|y\|^{2}-2\|x\|\|y\| \geq 0
\end{gathered}
$$

Thus $F$ is strictly monotone as claimed.
Another useful observation about duality maps for $p=2$ is that $\left\|F^{-1} y^{*}\right\|_{V}=\left\|y^{*}\right\|_{V^{\prime}}$. This is because

$$
\left\|y^{*}\right\|_{V^{\prime}}=\left\|F F^{-1} y^{*}\right\|_{V^{\prime}}=\left\|F^{-1} y^{*}\right\|_{V}
$$

also from similar reasoning,

$$
\left\langle y^{*}, F^{-1} y^{*}\right\rangle=\left\langle F F^{-1} y^{*}, F^{-1} y^{*}\right\rangle=\left\|F^{-1} y^{*}\right\|_{V}^{2}=\left\|y^{*}\right\|_{V^{\prime}}^{2}
$$

## Chapter 76

## Implicit Stochastic Equations

### 76.1 Introduction

In this chapter, implicit evolution equations are considered. These are of the form

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u(t, \omega), \omega) d s=\int_{0}^{t} f(s) d s+B \int_{0}^{t} \Phi d W
$$

the term on the end being a stochastic integral. The novelty is in allowing $B$ to be an operator which could vanish or have other interesting features. Thus the integral equation could degenerate to a non stochastic elliptic equation. This generalization of evolution equations has proven useful in the study of deterministic evolution equations and we give some interesting examples which indicate that this may be true in the case of stochastic equations also. In any case, it is an interesting generalization and equations of the usual form are recovered by using a Gelfand triple in which $B=I$.

Like deterministic equations, there are many ways to consider stochastic equations. Here it is based on an approach due to Bardos and Brezis [14] which avoids the consideration of finite dimensional problems. A generalized Ito formula is summarized in the next section. It is Theorem 76.2.3.

### 76.2 Preliminary Results

Let $X$ have values in $W$ and satisfy the following

$$
\begin{equation*}
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s+B \int_{0}^{t} Z(s) d W(s) \tag{76.2.1}
\end{equation*}
$$

$X_{0} \in L^{2}(\Omega ; W)$ and is $\mathscr{F}_{0}$ measurable, where $Z$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)$ progressively measurable and

$$
\|Z\|_{L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)}<\infty .
$$

This is what is needed to define the stochastic integral in the above formula. Here $Q$ is a nonnegative self adjoint operator defined on a separable real Hilbert space $U$. In what follows, $J$ will denote a one to one Hilbert Schmidt operator mapping $Q^{1 / 2} U$ into another separable Hilbert space $U_{1}$. For more explanation on this situation see [108].

Assume $X, Y$ satisfy

$$
X \in K \equiv L^{p}([0, T] \times \Omega ; V), Y \in K^{\prime}=L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)
$$

where $1 / p^{\prime}+1 / p=1, p>1$, and $X, Y$ are progressively measurable into $V$ and $V^{\prime}$ respectively.

The sense in which the equation 76.2 .1 holds is as follows. For a.e. $\omega$, the equation holds in $V^{\prime}$ for all $t \in[0, T]$. Assume that

$$
\begin{gathered}
X \in L^{2}([0, T] \times \Omega, W), \\
B X \in L^{2}\left([0, T] \times \Omega, \mathscr{B}([0, T]) \times \mathscr{F}, W^{\prime}\right), X \in L^{p}([0, T] \times \Omega, \mathscr{B}([0, T]) \times \mathscr{F}, V)
\end{gathered}
$$

Note that, since $X$ is progressively measurable into $V$, this implies that $B X$ is progressively measurable into $W^{\prime}$. Also $W(t)$ is a $J J^{*}$ Wiener process on $U_{1}$ in the following diagram. ( $W$ is a cylindrical Wiener process.)

$$
\begin{aligned}
& U \\
& \downarrow \quad Q^{1 / 2} \\
& Q^{1 / 2} U \\
& \downarrow \quad \Phi \\
& W
\end{aligned}
$$

We will also make use of the following generalization of familiar concepts from Hilbert space.

Lemma 76.2.1 Suppose $V, W$ are separable Banach spaces, $W$ also a Hilbert space such that $V$ is dense in $W$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle, B \neq 0 .
$$

Then there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
$$

and also

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i},
$$

the series converging in $W^{\prime}$.
Then in the above situation, we have the following fundamental estimate.
Lemma 76.2.2 In the above situation where, off a set of measure zero, 76.2.1 holds for all $t \in[0, T]$, and $X$ is progressively measurable into $V$,

$$
\begin{aligned}
& E\left(\sup _{t \in[0, T]}\langle B X, X\rangle(t)\right) \\
< & C\left(\|Y\|_{K^{\prime}},\|X\|_{K},\|Z\|_{J},\left\|\left\langle B X_{0}, X_{0}\right\rangle\right\|_{L^{1}(\Omega)}\right)<\infty .
\end{aligned}
$$

where $\langle B X, X\rangle(t)=\langle B(X(t)), X(t)\rangle$ a.e. and $\langle B X, X\rangle$ is progressively measurable and continuous in $t$.

$$
\begin{aligned}
J & =L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U ; W\right)\right), K \equiv L^{p}([0, T] \times \Omega ; V) \\
K^{\prime} & \equiv L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)
\end{aligned}
$$

Also, $C$ is a continuous function of its arguments and $C(0,0,0,0)=0$. Thus for a.e. $\omega$,

$$
\sup _{t \in[0, T]}\langle B X, X\rangle(t) \leq C(\omega)<\infty .
$$

For a.e. $\omega, t \rightarrow B X(t, \omega)$ is weakly continuous with values in $W^{\prime}$ for $t$ off a set of measure zero. Also $t \rightarrow\langle B X(t), X(t)\rangle$ is lower semicontinuous off a set of measure zero.

Then from this fundamental lemma, the following Ito formula is valid. The proof of this theorem follows the same methods used for a similar result in [108].

Theorem 76.2.3 Off a set of measure zero, for every $t \in[0, T]$,

$$
\begin{gather*}
\langle B X, X\rangle(t)=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s \\
+2 \int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W \tag{76.2.2}
\end{gather*}
$$

Also

$$
\begin{gather*}
E(\langle B X, X\rangle(t))= \\
E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+E\left(\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s\right) \tag{76.2.3}
\end{gather*}
$$

The quadratic variation of the stochastic integral is dominated by

$$
\begin{equation*}
C \int_{0}^{t}\|Z\|_{\mathscr{L}_{2}}^{2}\|B X\|_{W^{\prime}}^{2} d s \tag{76.2.4}
\end{equation*}
$$

for a suitable constant $C$. Also $t \rightarrow B X(t)$ is continuous with values in $W^{\prime}$ for $t \in N_{\omega}^{C}$.
We will often abuse the notation and write $\langle B X(t), X(t)\rangle$ instead of the more precise $\langle B X, X\rangle(t)$. No harm is done because these two are equal a.e.

In addition to the above, we will use the following basic theorems about nonlinear operators. This is Proposition 75.1.8 above.

Proposition 76.2.4 Suppose $A: V \rightarrow V^{\prime}$ is type $M$, see [91], and suppose $L: V \rightarrow V^{\prime}$ is monotone, bounded and linear. Here $V$ is a separable reflexive Banach space. Then $L+A$ is type $M$.

As an important example, we give the following definition.
Definition 76.2.5 Let $f:[0, T] \times \Omega \rightarrow V$

$$
\tau_{h} f(t, \omega) \equiv\left\{\begin{array}{l}
f(t-h, \omega) \text { if } t \geq h \\
0 \text { if } t<h
\end{array}\right.
$$

Then letting $B$ be a monotone nonnegative, self adjoint operator, $B: W \rightarrow W^{\prime}$ for $W$ a separable Hilbert space, consider the linear operator $L: L^{2}(0, T, W) \equiv \mathscr{W} \rightarrow L^{2}\left(0, T, W^{\prime}\right) \equiv$ $\mathscr{W}^{\prime}$ given as

$$
L u \equiv\left(\frac{I-\tau_{h}}{h}\right) B u .
$$

Is it the case that $L$ is monotone? Clearly it is linear and so it suffices to consider $\langle L u, u\rangle_{\mathscr{W}^{\prime}, \mathscr{W}}$ which equals

$$
\begin{align*}
& \frac{1}{h} \int_{0}^{T}\langle B u(t), u(t)\rangle d t-\frac{1}{h} \int_{h}^{T}\langle B u(t-h), u(t)\rangle d t \\
& =\frac{1}{h} \int_{0}^{T}\langle B u(t), u(t)\rangle d t-\frac{1}{h} \int_{0}^{T-h}\langle B u(t), u(t+h)\rangle d t \\
& \geq \frac{1}{h} \int_{0}^{T}\langle B u(t), u(t)\rangle d t \\
& -\frac{1}{h} \int_{0}^{T-h}\left(\frac{1}{2}\langle B u(t), u(t)\rangle+\frac{1}{2}\langle B u(t+h), u(t+h)\rangle\right) d t \\
& =\frac{1}{2 h} \int_{0}^{T-h}\langle B u(t), u(t)\rangle d t+\frac{1}{h} \int_{T-h}^{T}\langle B u(t), u(t)\rangle d t \\
& -\frac{1}{2 h} \int_{0}^{T-h}\langle B u(t+h), u(t+h)\rangle d t \\
& =\frac{1}{2 h} \int_{0}^{T-h}\langle B u(t), u(t)\rangle d t+\frac{1}{h} \int_{T-h}^{T}\langle B u(t), u(t)\rangle d t \\
& -\frac{1}{2 h} \int_{h}^{T}\langle B u(t), u(t)\rangle d t \\
& =\frac{1}{2 h} \int_{h}^{T-h}\langle B u(t), u(t)\rangle d t+\frac{1}{2 h} \int_{0}^{h}\langle B u(t), u(t)\rangle d t \\
& +\frac{1}{h} \int_{T-h}^{T}\langle B u(t), u(t)\rangle d t-\frac{1}{2 h} \int_{h}^{T}\langle B u(t), u(t)\rangle d t \\
& =\frac{1}{2 h} \int_{h}^{T-h}\langle B u(t), u(t)\rangle d t+\frac{1}{h} \int_{T-h}^{T}\langle B u(t), u(t)\rangle d t \\
& -\frac{1}{2 h} \int_{h}^{T-h}\langle B u(t), u(t)\rangle d t \\
& +\frac{1}{2 h} \int_{0}^{h}\langle B u(t), u(t)\rangle d t-\frac{1}{2 h} \int_{T-h}^{T}\langle B u(t), u(t)\rangle d t \\
& =\frac{1}{2 h} \int_{T-h}^{T}\langle B u(t), u(t)\rangle d t+\frac{1}{2 h} \int_{0}^{h}\langle B u(t), u(t)\rangle d t \geq 0 \tag{76.2.5}
\end{align*}
$$

The following is a restatement of Theorem 75.1.13

Theorem 76.2.6 Let $A: V \rightarrow V^{\prime}$ be type $M$, bounded, and coercive

$$
\begin{equation*}
\lim _{\|u\| \rightarrow \infty} \frac{\left\langle A\left(u+u_{0}\right), u\right\rangle}{\|u\|}=\infty \tag{76.2.6}
\end{equation*}
$$

for some $u_{0} \in V$, where $V$ is a separable reflexive Banach space. Then $A$ is surjective.
In addition, there is a fundamental definition and theorem about weak derivatives which will be used.

Definition 76.2.7 Let $f \in L^{1}\left(a, b, V^{\prime}\right)$ where $V^{\prime}$ is the dual of a Banach space $V$. Let $\mathscr{D}^{*}(a, b)$ linear mappings from $C_{c}^{\infty}(a, b)$ to $V^{\prime}$. Then we can consider $f \in \mathscr{D}^{*}(a, b)$, the linear transformations defined on $C_{c}^{\infty}(a, b)$ as follows.

$$
f(\phi) \equiv \int_{a}^{b} f \phi d s
$$

This is well defined due to regularity considerations for Lebesgue measure. Then define $D f \in \mathscr{D}^{*}(a, b)$ by

$$
D f(\phi) \equiv-\int_{a}^{b} f \phi^{\prime} d s
$$

To say that $D f \in L^{1}\left(a, b, V^{\prime}\right)$ is to say that there exists $g \in L^{1}\left(a, b, V^{\prime}\right)$ such that

$$
D f(\phi) \equiv-\int_{a}^{b} f \phi^{\prime} d s=\int_{a}^{b} g \phi d s
$$

for all $\phi \in C_{c}^{\infty}(a, b)$. Note that regularity considerations imply that $g$ is unique if it exists.
The following is Theorem 69.2.9.
Theorem 76.2.8 Suppose that $f$ and $D f$ are both in $L^{1}\left(a, b, V^{\prime}\right)$. Then $f$ is equal to $a$ continuous function a.e., still denoted by $f$ and

$$
f(x)=f(a)+\int_{a}^{x} D f(t) d t
$$

In the next section are theorems about how shifts in time relate to progressive measurability.

### 76.3 The Existence Of Approximate Solutions

The situation is as follows. There are spaces $V \subseteq W$ where $V$ is a reflexive separable Banach space and $W$ is a separable Hilbert space. It is assumed that $V$ is dense in $W$. Define the spaces

$$
\mathscr{V} \equiv L^{p}([0, T] \times \Omega, V), \mathscr{W} \equiv L^{2}([0, T] \times \Omega, W)
$$

where in each case, the $\sigma$ algebra of measurable sets will be the progressively measurable sets. Thus, from the Riesz representation theorem,

$$
\mathscr{V}^{\prime}=L^{p^{\prime}}\left([0, T] \times \Omega, V^{\prime}\right), \mathscr{W}^{\prime}=L^{2}\left([0, T] \times \Omega, W^{\prime}\right)
$$

It will be assumed for the sake of convenience that $p \geq 2$. It follows that

$$
\mathscr{V} \subseteq \mathscr{W}, \mathscr{W}^{\prime} \subseteq \mathscr{V}^{\prime}
$$

The entire presentation will be based on the following lemma.
Lemma 76.3.1 Let $\mathscr{V} \equiv L^{p}([0, T] \times \Omega, V)$ where $V$ is a separable Banach space and the $\sigma$ algebra of measurable sets consists of those which are progressively measurable. Then for $h \in(0, T), \tau_{h}: \mathscr{V} \rightarrow \mathscr{V}$.

Proof: First consider $Q$ which is a progressively measurable set. Is it the case that $\tau_{h} \mathscr{X}_{Q}$ is also progressively measurable? Define $Q+h$ as

$$
Q+h \equiv\{(t+h, \omega):(t, \omega) \in Q\}
$$

Then

$$
\tau_{h} \mathscr{X}_{Q}(t, \omega)=\left\{\begin{array}{l}
\mathscr{X}_{Q+h}(t, \omega) \text { if } t \geq h \\
0 \text { if } t<h
\end{array}\right.
$$

Is this function progressively measurable? For $(s, \omega) \in[0, t] \times \Omega$, we have the following

$$
\begin{gathered}
0<\alpha \leq 1,\left[(s, \omega): \tau_{h} \mathscr{X}_{Q}(s, \omega) \geq \alpha\right]=[h, t] \times \Omega \cap(Q+h) \\
\alpha>1,\left[(s, \omega): \tau_{h} \mathscr{X}_{Q}(s, \omega) \geq \alpha\right]=\emptyset \in \mathscr{B}([0, t]) \times \mathscr{F}_{t} \\
\alpha \leq 0,\left[(s, \omega): \tau_{h} \mathscr{X}_{Q}(s, \omega) \geq \alpha\right]=[0, t] \times \Omega \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}
\end{gathered}
$$

It suffices to show that for $t \geq h,[h, t] \times \Omega \cap(Q+h)$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable. It is known that $[0, t] \times \Omega \cap Q$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable and also that $[0, t-h] \times \Omega \cap Q$ is $\mathscr{B}([0, t-h]) \times \mathscr{F}_{t-h}$ measurable. Let

$$
\mathscr{G} \equiv\left\{Q \in \mathscr{B}([0, t-h]) \times \mathscr{F}_{t-h}:[h, t] \times \Omega \cap Q+h \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}\right\}
$$

First consider $I \times B$ where $I$ is an interval in $\mathscr{B}([0, t-h])$ and $B \in \mathscr{F}_{t-h}$. Then

$$
\begin{gathered}
=h+I \times B \\
{[h, t] \times \Omega \cap(I+h) \times B=I^{\prime} \times B}
\end{gathered}
$$

where $I^{\prime}$ is in $\mathscr{B}([0, t])$ and of course $B \in \mathscr{F}_{t-h} \subseteq \mathscr{F}_{t}$. Thus the sets of this form, are in $\mathscr{G}$. Next suppose $Q \in \mathscr{G}$. Is $Q^{C} \in \mathscr{G}$ ?

$$
\left([h, t] \times \Omega \cap\left(Q^{C}+h\right)\right) \cup[h, t] \times \Omega \cap(Q+h) \cup[0, h) \times \Omega=[0, t] \times \Omega
$$

Then all of these disjoint sets but the first are in $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$. It follows that the first is also in $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$. It is clear that $\mathscr{G}$ is also closed with respect to countable disjoint unions. Therefore, $\mathscr{G}$ contains the $\pi$ system of sets of the form $I \times B$ just described. It follows that $\mathscr{G}=\mathscr{B}([0, t-h]) \times \mathscr{F}_{t-h}$.

Now if $Q$ is progressively measurable, then $[0, t-h] \times \Omega \cap Q$ is $\mathscr{B}([0, t-h]) \times \mathscr{F}_{t-h}$ measurable and so from what was just shown, $[h, t] \times \Omega \cap Q+h \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}$. Thus $\tau_{h} \mathscr{X}_{Q}$ is progressively measurable. It follows that if $f \in \mathscr{V}$, you could consider $\phi(f)$ for
$\phi \in V^{\prime}$ and the positive and negative parts of this function. Each of these is the limit of a sequence of simple functions involving combinations of indicator functions of the form $\mathscr{X}_{Q}$. Thus $\tau_{h} \phi(f)=\phi\left(\tau_{h} f\right)$ is the limit of simple functions involving combinations of functions $\tau_{h} \mathscr{X}_{Q}$ and, as just shown, these simple functions are progressively measurable. Thus $\tau_{h} f$ is also progressively measurable by the Pettis theorem.

This Lemma states that you can do $\tau_{h}$ to progressively measurable functions and end up with one which is progressively measurable. Let

$$
B \in \mathscr{L}\left(W, W^{\prime}\right)
$$

satisfy

$$
\begin{equation*}
\langle B x, y\rangle=\langle B y, x\rangle,\langle B x, x\rangle \geq 0 \tag{76.3.7}
\end{equation*}
$$

Also suppose that

$$
\begin{equation*}
A \text { is monotone and hemicontinuous from } \mathscr{V} \text { to } \mathscr{V}^{\prime} \tag{76.3.8}
\end{equation*}
$$

This means the operator is monotone:

$$
\langle A u-A u, u-v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq 0
$$

and hemicontinuous:

$$
\lim _{t \rightarrow 0}\langle A(u+t v), w\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\langle A u, w\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

Also we assume that $A$ is bounded and takes the form

$$
A u(t, \omega)=A(t, u(t, \omega), \omega)
$$

for $u \in \mathscr{V}$. Such an operator is type $M$ and this is what we use. Such an operator is defined by:

If $u_{n} \rightarrow u$ weakly in $\mathscr{V}$ and $A u_{n} \rightarrow \xi$ weakly in $\mathscr{V}^{\prime}$ and $\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle$
Then the above implies

$$
A u=\xi
$$

We define $\mathscr{V}_{\omega}$ as $L^{p}(0, T, V)$ with the definition of $\mathscr{V}_{\omega}^{\prime}$ similar, the subscript denoting that $\omega$ is fixed, the $\sigma$ algebra of measurable sets being the Borel sets, $\mathscr{B}([0, T])$. Also,

$$
\begin{equation*}
(t, u, \omega) \rightarrow A(t, u, \omega) \tag{76.3.9}
\end{equation*}
$$

is progressively measurable.
Suppose $A(\omega)$ is monotone and hemicontinuous and bounded from $\mathscr{V}_{\omega}$ to $\mathscr{V}_{\omega}^{\prime}$. Thus

$$
\begin{equation*}
A(\omega) \text { is type } M \text { from } \mathscr{V}_{\omega} \text { to } \mathscr{V}_{\omega}^{\prime} \tag{76.3.10}
\end{equation*}
$$

where

$$
A(\omega) u \equiv A(t, u, \omega)
$$

We assume the estimates found in the next lemma.

Lemma 76.3.2 If $p \geq 2$ and

$$
\begin{gather*}
\langle A(t, u, \omega), u\rangle_{V} \geq \delta\|u\|_{V}^{p}-c(t, \omega)  \tag{76.3.11}\\
\|A(t, u, \omega)\|_{V^{\prime}} \leq k\|u\|_{V}^{p-1}+c^{1 / p^{\prime}}(t, \omega) \tag{76.3.12}
\end{gather*}
$$

where $c \geq 0, c \in L^{1}([0, T] \times \Omega)$, then if $(t, \omega) \rightarrow q(t, \omega)$ is in $\mathscr{V}$,, it follows that for a.e. $\omega$, similar inequalities hold for $\bar{A}$ given by

$$
\begin{equation*}
\bar{A}(t, u, \omega) \equiv A(t, u+q(t, \omega), \omega) \tag{76.3.13}
\end{equation*}
$$

Proof: Letting $q$ be progressively measurable, $q(t, \omega) \in V$ only consider $\omega$ such that $t \rightarrow q(t, \omega)$ is in $L^{p}(0, T, V)$.

$$
\langle\bar{A}(t, u, \omega), u\rangle=
$$

$$
\langle A(t, u+q(t, \omega), \omega), u\rangle=\langle A(t, u+q(t, \omega), \omega), u+q(t, \omega)\rangle
$$

$$
-\langle A(t, u+q(t, \omega), \omega), q(t, \omega)\rangle
$$

$$
\geq \delta\|u+q(t, \omega)\|_{V}^{p}-k\|u+q(t, \omega)\|_{V}^{p-1}\|q(t, \omega)\|_{V}-c^{1 / p^{\prime}}(t, \omega)\|q(t, \omega)\|_{V}-c(t, \omega)
$$

$$
\geq \delta\|u+q(t, \omega)\|_{V}^{p}-k\|u+q(t, \omega)\|_{V}^{p-1}\|q(t, \omega)\|_{V}-\|q(t, \omega)\|_{V}^{p}-2 c(t, \omega)
$$

$$
\geq \frac{\delta}{2}\|u+q(t, \omega)\|_{V}^{p}-C(k, \delta, T)\|q(t, \omega)\|_{V}^{p}-2 c(t, \omega)
$$

Now

$$
\|u+q(t, \omega)\| \geq\|u\|-\|q(t, \omega)\|
$$

and so by convexity,

$$
\frac{\|u+q(t, \omega)\|^{p}+\|q(t, \omega)\|^{p}}{2} \geq\left(\frac{\|u+q(t, \omega)\|+\|q(t, \omega)\|}{2}\right)^{p} \geq\left(\frac{\|u\|}{2}\right)^{p}
$$

This implies

$$
\|u+q(t, \omega)\|^{p} \geq 2\left(\frac{\|u\|^{p}}{2^{p}}-\frac{\|q(t, \omega)\|^{p}}{2}\right)
$$

Therefore,

$$
\begin{gathered}
\langle\bar{A}(t, u, \omega), u\rangle= \\
\langle A(t, u+q(t, \omega), \omega), u\rangle \geq \frac{\delta}{2}\left(2\left(\frac{\|u\|^{p}}{2^{p}}-\frac{\|q(t, \omega)\|^{p}}{2}\right)\right) \\
-C(k, \delta, T)\|q(t, \omega)\|_{V}^{p}-2 c(t, \omega) \\
\geq \frac{\delta}{2^{p}}\|u\|^{p}-c^{\prime}(t, \omega)
\end{gathered}
$$

where $c^{\prime} \in L^{1}([0, T] \times \Omega)$.

Consider the other inequality. Let $\|z\|_{V} \leq 1$.Then

$$
|\langle A(t, u+q(t, \omega), \omega), z\rangle| \leq k\|u+q(t, \omega)\|^{p-1}+c^{1 / p^{\prime}}(t, \omega)
$$

Since $p \geq 2$, a convexity argument shows that

$$
\begin{aligned}
\langle A(t, u+q(t, \omega), \omega), z\rangle & \leq k\left(2^{p-2}\|u\|^{p-1}+2^{p-2}\|q(t, \omega)\|^{p-1}\right)+c^{1 / p^{\prime}}(t, \omega) \\
& =2^{p-2} k\|u\|^{p-1}+(\bar{c}(t, \omega))^{1 / p^{\prime}}
\end{aligned}
$$

where $\bar{c} \in L^{1}([0, T] \times \Omega)$. Thus the same two inequalities continue to hold.
In what follows, $c \geq 0$ and is in $L^{1}([0, T] \times \Omega)$, the $\sigma$ algebra being $\mathscr{B}([0, T]) \times \mathscr{F}_{T}$.

$$
\begin{gather*}
\langle A(t, u, \omega), u\rangle_{V} \geq \delta\|u\|_{V}^{p}-c(t, \omega)  \tag{76.3.14}\\
\|A(t, u, \omega)\|_{V^{\prime}} \leq k\|u\|_{V}^{p-1}+c^{1 / p^{\prime}}(t, \omega) \tag{76.3.15}
\end{gather*}
$$

Letting $\bar{A}$ be defined above in 76.3.13,

$$
\bar{A}(t, u, \omega) \equiv A(t, u+q, \omega) \equiv \bar{A}(\omega)(t, u)
$$

Assume the following pathwise uniqueness condition which is the hypothesis of the following lemma.

Lemma 76.3.3 Suppose it is true that whenever $u, v \in \mathscr{V}_{\omega}$ and

$$
\begin{equation*}
B u(t)-B v(t)+\int_{0}^{t} A(u)-A(v)=0 \tag{76.3.16}
\end{equation*}
$$

it follows that $u=v$. Then if

$$
\begin{align*}
(B u)^{\prime}+\bar{A}(\omega) u & =f \text { in } \mathscr{V}_{\omega}^{\prime}, B u(0)=B u_{0} \\
(B v)^{\prime}+\bar{A}(\omega) v & =f \text { in } \mathscr{V}_{\omega}^{\prime}, B v(0)=B u_{0} \tag{76.3.17}
\end{align*}
$$

it follows that $u=v$ in $\mathscr{V}_{\omega}$. Here $u_{0} \in W$.
Proof: If $(B u)^{\prime}+\bar{A}(\omega) u=f$ and $(B v)^{\prime}+\bar{A}(\omega) v=f$, then

$$
B u(t)-B v(t)+\int_{0}^{t} A(u+q)-A(v+q) d s=0
$$

Hence

$$
B(u(t)+q(t))-B(v(t)+q(t))+\int_{0}^{t} A(u+q)-A(v+q) d s=0
$$

and so $u+q=v+q$ showing that $u=v$.
We give the following measurability lemma.

Lemma 76.3.4 Suppose $f_{n}$ is progressively measurable and converges weakly to $\bar{f}$ in

$$
L^{\alpha}\left([0, T] \times \Omega, X, \mathscr{B}([0, T]) \times \mathscr{F}_{T}\right), \alpha>1
$$

where $X$ is a reflexive separable Banach space. Also suppose that for each $\omega \notin N$ a set of measure zero,

$$
f_{n}(\cdot, \omega) \rightarrow f(\cdot, \omega) \text { weakly in } L^{\alpha}(0, T, X)
$$

Then there is an enlarged set of measure zero, still denoted as $N$ such that for $\omega \notin N$,

$$
\bar{f}(\cdot, \omega)=f(\cdot, \omega) \text { in } L^{\alpha}(0, T, X)
$$

Also $\bar{f}$ is progressively measurable.
Proof: By the Pettis theorem, $\bar{f}$ is progressively measurable. Letting

$$
\phi \in L^{\alpha^{\prime}}\left([0, T] \times \Omega, X^{\prime}, \mathscr{B}([0, T]) \times \mathscr{F}_{T}\right),
$$

it is known that for a.e. $\omega$,

$$
\int_{0}^{T}\left\langle\phi(t, \omega), f_{n}(t, \omega)\right\rangle d t \rightarrow \int_{0}^{T}\langle\phi(t, \omega), f(t, \omega)\rangle d t
$$

Therefore, the function of $\omega$ on the right is at least $\mathscr{F}_{T}$ measurable. Now let

$$
g \in L^{\infty}\left(\Omega, X^{\prime}, \mathscr{F}_{T}\right)
$$

and let $\psi \in C([0, T])$. Then for $1<p \leq \alpha$,

$$
\begin{aligned}
& \int_{\Omega}\left|\int_{0}^{T}\left\langle g(\omega) \psi(t), f_{n}(t, \omega)\right\rangle d t\right|^{p} d P \\
\leq & C(T) \int_{\Omega}\|g\|_{L^{\infty}\left(\Omega, X^{\prime}\right)}^{p} \int_{0}^{T}|\psi(t)|^{p}\left\|f_{n}(t, \omega)\right\|_{X}^{p} d t d P \\
\leq & C(T, g, \psi) \int_{\Omega} \int_{0}^{T}\left\|f_{n}(t, \omega)\right\|_{X}^{p} d t d P \leq C<\infty
\end{aligned}
$$

for some $C$. Since $\int_{0}^{T}\left\langle g(\omega) \psi(t), f_{n}(t, \omega)\right\rangle d t$ is bounded in $L^{p}(\Omega)$ independent of $n$ because $\int_{\Omega} \int_{0}^{T}\left\|f_{n}(t, \omega)\right\|_{X}^{p} d t d P$ is given to be bounded, it follows that the functions

$$
\omega \rightarrow \int_{0}^{T}\left\langle g(\omega) \psi(t), f_{n}(t, \omega)\right\rangle d t
$$

are uniformly integrable and so it follows from the Vitali convergence theorem that

$$
\int_{\Omega} \int_{0}^{T}\left\langle g(\omega) \psi(t), f_{n}(t, \omega)\right\rangle d t d P \rightarrow \int_{\Omega} \int_{0}^{T}\langle g(\omega) \psi(t), f(t, \omega)\rangle d t d P
$$

But also from the assumed weak convergence to $\bar{f}$

$$
\int_{\Omega} \int_{0}^{T}\left\langle g(\omega) \psi(t), f_{n}(t, \omega)\right\rangle d t d P \rightarrow \int_{\Omega} \int_{0}^{T}\langle g(\omega) \psi(t), \bar{f}(t, \omega)\rangle d t d P
$$

It follows that

$$
\int_{\Omega}\left\langle g(\omega), \int_{0}^{T}(f-\bar{f}) \psi(t) d t\right\rangle d P=0
$$

This is true for every such $g \in L^{\infty}\left(\Omega, X^{\prime}\right)$, and so for a fixed $\psi \in C([0, T])$ and the Riesz representation theorem,

$$
\int_{\Omega}\left\|\int_{0}^{T}(f-\bar{f}) \psi(t) d t\right\|_{X} d P=0
$$

Therefore, there exists $N_{\psi}$ such that if $\omega \notin N_{\psi}$, then

$$
\int_{0}^{T}(f-\bar{f}) \psi(t) d t=0
$$

Enlarge $N$, the exceptional set to also include $\cup_{\psi \in \mathscr{D}} N_{\psi}$ where $\mathscr{D}$ is a countable dense subset of $C([0, T])$. Therefore, if $\omega \notin N$, then the above holds for all $\psi \in C([0, T])$. It follows that for such $\omega, f(t, \omega)=\bar{f}(t, \omega)$ for a.e. $t$. Therefore, $f(\cdot, \omega)=\bar{f}(\cdot, \omega)$ in $L^{\alpha}(0, T, X)$ for all $\omega \notin N$.

Then one can obtain the following existence theorem using a technique of Bardos and Brezis [14].

Lemma 76.3.5 Let $q \in \mathscr{V}$ and let the conditions 76.3.14-76.3.17 be valid. Let $f \in \mathscr{V}^{\prime}$ be given. Then for each $\omega$ off a set of measure zero, there exists $u(\cdot, \omega) \in \mathscr{V}_{\omega}$ such that $(B u)^{\prime}(\cdot, \omega) \in \mathscr{V}_{\omega}^{\prime}$ and

$$
B u(0, \omega)=0
$$

and also the following equation holds in $\mathscr{V}_{\omega}^{\prime}$ for a.e. $\omega$

$$
(B u)^{\prime}(\cdot, \omega)+\bar{A}(\omega)(\cdot, u(\cdot, \omega))=f(\cdot, \omega)
$$

In addition to this, it can be assumed that $(t, \omega) \rightarrow u(t, \omega)$ is progressively measurable into $V$. That is, for each $\omega$ off a set of measure zero, $t \rightarrow u(t, \omega)$ can be modified on a set of measure zero in $[0, T]$ such that the resulting $u$ is progressively measurable.

Proof: Consider the equation

$$
\begin{equation*}
L_{h} B u+\bar{A} u=\frac{1}{h}\left(I-\tau_{h}\right)(B u)+\bar{A} u=f \text { in } \mathscr{V}^{\prime} \tag{76.3.18}
\end{equation*}
$$

By Proposition 76.2.4 and Theorem 76.2.6, there exists a solution to the above equation if the left side is coercive. However, it was shown above in the computations leading to 76.2.5 that $L_{h} \circ B$ is monotone. Hence the coercivity follows right away from Lemma 76.3.2.

Thus 76.3.18 holds in $\mathscr{V}^{\prime}$. It follows that, indexing the solution by $h$,

$$
\int_{\Omega} \int_{0}^{T}\left\|\frac{1}{h}\left(I-\tau_{h}\right)\left(B u_{h}\right)+\bar{A} u_{h}-f\right\|_{V^{\prime}}^{p^{\prime}} d t d P=0
$$

and so there exists a set of measure zero $N_{h}$ such that for $\omega \notin N_{h}$, the following equation holds in $\mathscr{V}_{\omega}^{\prime}$

$$
\frac{1}{h}\left(I-\tau_{h}\right)\left(B u_{h}(\cdot, \omega)\right)+\bar{A}(\omega)\left(u_{h}(\cdot, \omega)\right)=f(\cdot, \omega)
$$

Let $h$ denote a sequence converging to 0 and let $N$ be a set of measure zero which includes $\cup_{h} N_{h}$.

Letting $u_{h} \in \mathscr{V}$ be the above solution to 76.3 .18 , it also follows from the above estimates 76.3.14-76.3.15 that for $\omega$ off $N,\left\|u_{h}(\cdot, \omega)\right\|_{\mathscr{V}_{\omega}}$ is bounded independent of $h$. Thus, for such $\omega$ off this set, there exists a subsequence still called $u_{h}$ such that the following convergences hold.

$$
\begin{gathered}
u_{h} \rightharpoonup u \text { in } \mathscr{V}_{\omega} \\
\bar{A}(\omega) u_{h} \rightharpoonup \xi \text { in } \mathscr{V}_{\omega}^{\prime} \\
\frac{1}{h}\left(I-\tau_{h}\right)\left(B u_{h}\right) \rightharpoonup \zeta \text { in } \mathscr{V}_{\omega}^{\prime}
\end{gathered}
$$

First we need to identify $\zeta$. Let $\phi \in C^{\infty}([0, T])$ where $\phi=0$ near $T$ and let $w \in V$. Then

$$
\begin{gathered}
\left\langle\int_{0}^{T} \zeta \phi, w\right\rangle=\lim _{h \rightarrow 0}\left\langle\int_{0}^{T} \frac{1}{h}\left(I-\tau_{h}\right)\left(B u_{h}\right), w \phi\right\rangle \\
=\lim _{h \rightarrow 0}\left\langle\int_{0}^{T} \frac{B u_{h}(t)}{h} \phi(t)-\int_{h}^{T} \frac{B u_{h}(t-h)}{h} \phi(t), w\right\rangle \\
=\lim _{h \rightarrow 0}\left\langle\int_{0}^{T} \frac{B u_{h}(t)}{h} \phi(t)-\int_{0}^{T-h} \frac{B u_{h}(t)}{h} \phi(t+h), w\right\rangle \\
=\lim _{h \rightarrow 0}\left(\left\langle\int_{0}^{T-h} B u_{h} \frac{\phi(t)-\phi(t+h)}{h}, w\right\rangle+\int_{T-h}^{T} \frac{B u_{h}(t)}{h} \phi(t)\right) \\
=\left\langle-\int_{0}^{T} B u(t) \phi^{\prime}(t), w\right\rangle
\end{gathered}
$$

Since this holds for all $\phi \in C_{c}^{\infty}(0, T)$, it follows that $\zeta=(B u)^{\prime}$. Hence letting $\phi$ be an arbitrary function in $C^{\infty}([0, T])$ which equals zero near $T$, this implies from the above that

$$
\begin{aligned}
&\left\langle-\int_{0}^{T} \zeta \phi, w\right\rangle=\left\langle\int_{0}^{T} B u(t) \phi^{\prime}(t), w\right\rangle \\
&=\left\langle\int_{0}^{T}\left(B u(0)+\int_{0}^{t}(B u)^{\prime}(s) d s\right) \phi^{\prime}(t), w\right\rangle \\
&=\int_{0}^{T}\langle B u(0), w\rangle \phi^{\prime}(t) d t+\left\langle\int_{0}^{T} \int_{0}^{t}(B u)^{\prime}(s) d s \phi^{\prime}(t), w\right\rangle \\
&=-\langle B u(0), w\rangle \phi(0)+\left\langle\int_{0}^{T}(B u)^{\prime}(s) \int_{s}^{T} \phi^{\prime}(t) d t d s, w\right\rangle \\
&=-\langle B u(0), w\rangle \phi(0)-\left\langle\int_{0}^{T}(B u)^{\prime}(s) \phi(s) d s, w\right\rangle
\end{aligned}
$$

Hence, since $\zeta=(B u)^{\prime}$,

$$
0=-\langle B u(0), w\rangle \phi(0)
$$

Then it follows that, $\langle B u(0), w\rangle=0$. Since $w$ was arbitrary, $B u(0)=0$ and $\zeta=(B u)^{\prime}$.
Thus, passing to a limit in 76.3.18,

$$
(B u)^{\prime}+\xi=f \text { in } \mathscr{V}_{\omega}^{\prime}, B u(0)=0
$$

It is desired to identify $\xi$ with $\bar{A}(\omega) u$. First let

$$
L_{h} \equiv \frac{I-\tau_{h}}{h}
$$

Then

$$
L_{h}(B u)(t)=\left\{\begin{array}{l}
\frac{1}{h} \int_{t-h}^{t}(B u)^{\prime} d s \text { if } t \geq h \\
\frac{1}{h} \int_{0}^{t}(B u)^{\prime} d s \text { if } t<h
\end{array}\right.
$$

Then from standard considerations involving approximate identities,

$$
\begin{equation*}
\lim _{h \rightarrow 0} L_{h}(B u)=(B u)^{\prime} \text { strongly in } \mathscr{V}_{\omega}^{\prime} \tag{76.3.19}
\end{equation*}
$$

Thus

$$
\begin{gathered}
\left\langle L_{h}\left(B u_{h}\right)-(B u)^{\prime}, u_{h}-u\right\rangle= \\
\geq\left\langle L_{h}\left(B u_{h}\right)-L_{h}(B u), u_{h}-u\right\rangle+\left\langle L_{h}(B u)-(B u)^{\prime}, u_{h}-u\right\rangle \\
\geq\left\langle L_{h}(B u)-(B u)^{\prime}, u_{h}-u\right\rangle
\end{gathered}
$$

and the above strong convergence implies that this converges to 0 . Therefore, from 76.3.18,

$$
L_{h} B u_{h}+\bar{A} u_{h}=f \text { in } \mathscr{V}_{\omega}^{\prime}
$$

and so

$$
\left\langle L_{h} B u_{h}, u_{h}-u\right\rangle+\left\langle\bar{A} u_{h}, u_{h}-u\right\rangle=\left\langle f, u_{h}-u\right\rangle
$$

From the above,

$$
\left\langle(B u)^{\prime}, u_{h}-u\right\rangle+\left\langle L_{h}(B u)-(B u)^{\prime}, u_{h}-u\right\rangle+\left\langle\bar{A} u_{h}, u_{h}-u\right\rangle \leq\left\langle f, u_{h}-u\right\rangle
$$

and so, taking limsup ${ }_{h \rightarrow 0}$ of both sides, it follows from 76.3.19 that

$$
\lim \sup _{h \rightarrow 0}\left\langle\bar{A} u_{h}, u_{h}-u\right\rangle \leq 0, \quad \lim \sup _{h \rightarrow 0}\left\langle\bar{A} u_{h}, u_{h}\right\rangle \leq\langle\xi, u\rangle
$$

Since $A$ is monotone and hemicontinuous, the same is true of $\bar{A}$ and so

$$
\bar{A} u=\xi
$$

Thus

$$
\begin{equation*}
\left((B u)^{\prime}(\cdot, \omega)\right)+\bar{A}(\omega) u(\cdot, \omega)=f(\cdot, \omega) \text { in } \mathscr{V}_{\omega}^{\prime}, B u(0, \omega)=0 \tag{76.3.20}
\end{equation*}
$$

It follows from the uniqueness assumption 76.3 .17 that for each $\omega$ off a set of measure zero, there exists a unique solution to

$$
\begin{aligned}
(B u)^{\prime}(\cdot, \omega)+\bar{A}(\cdot, u(\cdot, \omega), \omega) & =f(\cdot, \omega) \text { in } \mathscr{V}_{\omega}^{\prime}, \\
B(u(\cdot, \omega))(0) & =0
\end{aligned}
$$

You can consider the function of two variables $u(t, \omega)$. Is this function progressively measurable? Right now, this is not clear because we have done nothing more than solve a problem for each $\omega$.

However, we can at least say that $u_{h}$ is progressively measurable because $u_{h} \in \mathscr{V}$. Recall also that

$$
\frac{1}{h}\left(I-\tau_{h}\right) B u_{h}+\bar{A}(\omega) u_{h}=f, u_{h} \in \mathscr{V}
$$

Next we show that because of uniqueness, one can assume that $u$ is progressively measurable. To do this, we show that the sequence for which convergence holds in the above can be chosen independent of $\omega$.

Claim: A single sequence $h \rightarrow 0$ works for all $\omega$ off a set of measure zero.
Proof: Since there is only one solution to the above initial value problem for $\omega \notin N$, then letting $h \rightarrow 0$ be a single sequence, one can conclude that $u_{h}(\cdot, \omega) \rightharpoonup u(\cdot, \omega)$ in $\mathscr{V}_{\omega}=$ $L^{p}(0, T, V)$. Otherwise, from the above argument, one could obtain another subsequence which converges to a solution different than $u(\cdot, \omega)$ which would violate uniqueness.

From the coercivity condition, it follows that there exists a constant $C(f)$ depending on $f$ such that for all $h$,

$$
\left\|u_{h}\right\|_{\mathscr{V}} \leq C(f)
$$

Therefore, there is a further subsequence still denoted by $h$ such that

$$
\begin{equation*}
u_{h} \rightharpoonup \bar{u} \text { in } L^{p}([0, T] \times \Omega ; V) \tag{76.3.21}
\end{equation*}
$$

where the measurable sets are just the product measurable sets $\mathscr{B}([0, T]) \times \mathscr{F}_{T}$. Then it follows from Lemma 76.3.4 that $u(\cdot, \omega)=\bar{u}(\cdot, \omega)$ in $\mathscr{V}_{\omega}$ for all $\omega$ off a set of measure zero. It follows that in all of the above, we could substitute $\bar{u}$ for $u$ at least for $\omega$ off a single set of measure zero. Thus $u$ can be assumed progressively measurable.

Note the importance of path uniqueness in obtaining the result on progressive measurability of the solutions.

We will write $u$ rather than $\bar{u}$ to save notation. Now with this lemma, it is easy to obtain the following proposition.

Proposition 76.3.6 Let $q \in \mathscr{V}$ such that $t \rightarrow q(t, \omega)$ is continuous and $q(0, \omega)=0$, and let the conditions 76.3.14-76.3.17 be valid. Also let $u_{0} \in L^{2}(\Omega, V)$ such that $u_{0}$ is $\mathscr{F}_{0}$ measurable. Let $f \in \mathscr{V}^{\prime}$ be given. Then for each $\omega$ off a set of measure zero, there exists $u(\cdot, \omega) \in \mathscr{V}_{\omega}$ such that $(B u)^{\prime}(\cdot, \omega) \in \mathscr{V}_{\omega}^{\prime}$ and

$$
B u(0, \omega)=B u_{0}
$$

and also the following equation holds in $\mathscr{V}_{\omega}^{\prime}$ for a.e. $\omega$

$$
(B u-B q)^{\prime}(\cdot, \omega)+A(\cdot, u(\cdot, \omega), \omega)=f(\cdot, \omega)
$$

In addition to this, it can be assumed that $(t, \omega) \rightarrow u(t, \omega)$ is progressively measurable into $V$. That is, for each $\omega$ off a set of measure zero, $t \rightarrow u(t, \omega)$ can be modified on a set of measure zero in $[0, T]$ such that the resulting $u$ is progressively measurable. Then one also obtains that $u$ is the unique solution to the integral equation which holds for a.e. $\omega$

$$
\begin{equation*}
B u(t, \omega)-B u_{0}+\int_{0}^{t} A(s, u(s, \omega), \omega) d s=\int_{0}^{t} f(s, \omega) d s+B q(t, \omega) \tag{76.3.22}
\end{equation*}
$$

Proof: Recall

$$
\bar{A}(\omega)(t, u) \equiv A(t, u+q(t, \omega), \omega)
$$

where $q$ was in $\mathscr{V}$. Therefore, replace this definition of $\bar{A}$ with

$$
\bar{A}(\omega)(t, u) \equiv A\left(t, u+q(t, \omega)+u_{0}, \omega\right)
$$

Then from Lemma 76.3.5, there exists $w \in \mathscr{V}$ such that

$$
(B w)^{\prime}(\cdot, \omega)+A\left(\cdot, w(\cdot, \omega)+q(\cdot, \omega)+u_{0}(\omega), \omega\right)=f(\cdot, \omega), B w(0)=0
$$

Let $u(t, \omega)=w(t, \omega)+q(t, \omega)+u_{0}(\omega)$. Then for fixed $\omega, B u(0)=B w(0)+B u_{0}=B u_{0}$. Also

$$
(B(u-q))^{\prime}+A(\cdot, u, \omega)=f(\cdot, \omega), B u(0)=B u_{0}
$$

Then an integration yields 76.3.22. Uniqueness follows from the above uniqueness assumption 76.3.17.

One can easily generalize this using an exponential shift argument.
Corollary 76.3.7 Suppose the situation of the above proposition but that all that is known is that $\lambda B+A$ is monotone and hemicontinuous on $\mathscr{V}_{\omega}$ and $\mathscr{V}$ for all $\lambda$ sufficiently large. Then defining

$$
\left\langle A_{\lambda}(t, w, \omega), v\right\rangle_{V^{\prime}, V} \equiv\left\langle e^{-\lambda t} A\left(t, e^{\lambda t} w, \omega\right), v\right\rangle_{V^{\prime}, V}
$$

for such $\lambda$, it follows that $\lambda B+A_{\lambda}$ is also monotone and hemicontinuous. Then replace the coercivity, and boundedness conditions above with the following weaker conditions

$$
\begin{equation*}
\lambda\langle B u, u\rangle+\langle A(t, u, \omega), u\rangle_{V} \geq \delta\|u\|_{V}^{p}-c(t, \omega) \tag{76.3.23}
\end{equation*}
$$

for all $\lambda$ large enough.

$$
\begin{equation*}
\|A(t, u, \omega)\|_{V^{\prime}} \leq k\|u\|_{V}^{p-1}+c^{1 / p^{\prime}}(t, \omega) \tag{76.3.24}
\end{equation*}
$$

where $c \in L^{1}([0, T] \times \Omega), c \geq 0$. Then the conclusion of Proposition 76.3 .6 is still valid. There exists a unique $u \in \mathscr{V}$ such that for a.e. $\omega$,

$$
\begin{equation*}
(B u-B q)^{\prime}(\cdot, \omega)+A(\omega)(u(\cdot, \omega))=f(\cdot, \omega), B(u-q)(0)=B u_{0} \tag{76.3.25}
\end{equation*}
$$

Proof: That $\lambda B+A_{\lambda}$ is monotone and hemicontinuous follows from the definition. Also, from the above estimates,

$$
\lambda\langle B u, u\rangle+\left\langle A_{\lambda}(t, u, \omega), u\right\rangle_{V} \geq e^{-2 \lambda t}\left(\lambda\left\langle B\left(e^{\lambda t} u\right), e^{\lambda t} u\right\rangle+\left\langle A\left(t, e^{\lambda t} u, \omega\right), e^{\lambda t} u\right\rangle\right)
$$

$$
\begin{gathered}
\geq e^{-2 \lambda t}\left(\delta\left\|e^{\lambda t} u\right\|_{V}^{p}-c(t, \omega)\right) \geq e^{-2 \lambda t}\left(\delta\left\|e^{\lambda t} u\right\|_{V}^{p}-e^{\lambda p t} e^{-\lambda p t} c(t, \omega)\right) \\
\geq e^{-2 \lambda t} e^{p \lambda t}\left(\delta\|u\|_{V}^{p}-e^{-\lambda p t} c(t, \omega)\right) \geq \delta\|u\|_{V}^{p}-e^{-\lambda p t} c(t, \omega)
\end{gathered}
$$

which is of the right form.
Similarly

$$
\begin{gathered}
\left\|\lambda B w+A_{\lambda}(t, w, \omega)\right\|_{V^{\prime}} \leq\|\lambda B w\|_{V^{\prime}}+\left\|e^{-\lambda t} A\left(t, e^{\lambda t} w, \omega\right)\right\|_{V^{\prime}} \\
\leq \lambda\|B\|\|w\|_{V}+e^{-\lambda t}\left\|A\left(t, e^{\lambda t} w, \omega\right)\right\|_{V^{\prime}} \\
\leq \lambda\|B\|\|w\|_{V}+e^{-\lambda t} k\left\|e^{\lambda t} w\right\|^{p-1}+e^{-\lambda t} c^{1 / p^{\prime}}(t, \omega)
\end{gathered}
$$

Since $p \geq 2$, this is no larger than

$$
\begin{aligned}
\leq & (\lambda\|B\|)^{p /\left(p-p^{\prime}\right)}+\|w\|_{V}^{p-1}+e^{(p-1) \lambda t} e^{-\lambda t} k\|w\|_{V}^{p-1}+e^{-\lambda t} c^{1 / p^{\prime}}(t, \omega) \\
& \leq\left(e^{(p-2) \lambda T} k+1\right)\|w\|_{V}^{p-1}+e^{-\lambda t} c^{1 / p^{\prime}}(t, \omega)+(\lambda\|B\|)^{p /\left(p-p^{\prime}\right)} \\
& \equiv \bar{k}\|w\|_{V}^{p-1}+\bar{c}(t, \omega)^{1 / p^{\prime}}
\end{aligned}
$$

Now note that $w$ is a solution to

$$
\begin{gathered}
\quad B\left(w-e^{-\lambda(\cdot)} q\right)^{\prime}+\lambda B w+e^{-\lambda(\cdot)} A\left(t, e^{\lambda(\cdot)} w, \omega\right) \\
=e^{-\lambda(\cdot)} f(\cdot, \omega)+\lambda B e^{-\lambda(\cdot)} q(\cdot, \omega) \text { in } \mathscr{V}_{\omega} \\
B\left(w-e^{-\lambda(\cdot)} q\right)(0)=B u_{0}
\end{gathered}
$$

if and only if $u(t) \equiv e^{\lambda t} w(t)$ is a solution to

$$
(B(u-q))^{\prime}+A(t, u, \omega)=f(\cdot, \omega), B(u-q)(0)=B u_{0}
$$

Thus the necessary uniqueness condition holds for the initial value problem for $w$ and hence it follows from Proposition 76.3.6 that there exists a unique progressively measurable solution to the initial value problem for $w$ and hence a unique progressively measurable solution to the above one for $u$.

Now suppose the situation of the above corollary and let $E$ be a separable Hilbert space which is dense in $V$ and let

$$
\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, E\right)\right), \Phi \text { being progressively measurable }
$$

so that one can consider the stochastic integral $\int_{0}^{t} \Phi d W$. Let

$$
\tau_{n} \equiv \inf \left\{t:\left\|\int_{0}^{t} \Phi d W\right\|_{E}>2^{n}\right\}
$$

Thus

$$
\left\|\int_{0}^{t \wedge \tau_{n}} \Phi d W\right\|_{E} \leq 2^{n}
$$

Then you could pick $u_{0} \in L^{p}(\Omega, V), u_{0}$ being $\mathscr{F}_{0}$ measurable, and let

$$
q(t, \omega)=\int_{0}^{t \wedge \tau_{n}} \Phi d W
$$

The result is clearly in $\mathscr{V}$ and is continuous in $t$. Therefore, from Corollary 76.3.7, there exists a unique solution $u \in \mathscr{V}$ to the initial value problem

$$
\left(B u-B \int_{0}^{t \wedge \tau_{n}} \Phi d W\right)^{\prime}(\cdot, \omega)+A(\omega)(u(\cdot, \omega))=f(\cdot, \omega), B u(0)=B u_{0}
$$

Integrating, one obtains a unique solution $u_{n} \in \mathscr{V}$ to the integral equation

$$
B u_{n}(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A\left(s, u_{n}, \omega\right) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t \wedge \tau_{n}} \Phi d W
$$

This holds in $\mathscr{V}_{\omega}^{\prime}$ and is so for all $\omega$ off a set of measure zero $N_{n}$. Let $N=\cup_{n} N_{n}$. For $\omega \notin N, t \rightarrow \int_{0}^{t} \Phi d W$ is continuous and so for all $n$ large enough, $\tau_{n}=\infty$. Thus for a fixed $\omega$, it follows that for all $n$ large enough $\tau_{n}=\infty$ and so one obtains

$$
B u_{n}(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A\left(s, u_{n}, \omega\right) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi d W
$$

Then for $k$ some other index sufficiently large, the same holds for $u_{k}$. By the uniqueness assumption 76.3.17, $u_{k}(t, \omega)=u_{n}(t, \omega)$ and so it follows that $\lim _{n \rightarrow \infty} u_{n}(t, \omega)$ exists because for each $\omega$ off a set of measure zero, there is eventually no change in $u_{n}$. Defining $u(t, \omega) \equiv \lim _{n \rightarrow \infty} u_{n}(t, \omega) \equiv u_{n}(t, \omega)$ for all $n$ large enough, it follows that $u$ is progressively measurable since it is the pointwise limit of progressively measurable functions and

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi d W
$$

This has shown the following lemma.
Lemma 76.3.8 Let $(t, u, \omega) \rightarrow A(t, u, \omega)$ be progressively measurable into $V^{\prime}$ and suppose for some $\lambda$,

$$
\begin{aligned}
\lambda B+A(\omega) & : \\
\lambda B+A & : \mathscr{V}_{\omega} \rightarrow \mathscr{V}_{\omega}^{\prime} \\
\lambda & \mathscr{V} \rightarrow \mathscr{V}^{\prime}
\end{aligned}
$$

are both monotone bounded and hemicontinuous. Also suppose the two estimates giving boundedness and coercivity 76.3.23-76.3.24 of Corollary 76.3.7 above. Here V,W are as described above $V \subseteq W, W^{\prime} \subseteq V^{\prime}, W$ is a separable Hilbert space and $V$ is a separable reflexive Banach space. $B: W \rightarrow W^{\prime}$ is nonnegative and self adjoint. Let $f \in \mathscr{V}^{\prime}$ and let $u_{0} \in L^{p}(\Omega, V)$ where $u_{0}$ is $\mathscr{F}_{0}$ measurable. Then if $\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, E\right)\right), \Phi$
being progressively measurable, into $E$, where $E$ is a Hilbert space dense in $V$ with $\|u\|_{E} \geq$ $\|u\|_{V}$, then there exists a unique solution to the integral equation

$$
B u(t)-B u_{0}+\int_{0}^{t} A(s, u, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi d W
$$

in the sense that $u$ is in $\mathscr{V}$ and there exists a set of measure zero $N$ such that if $\omega \notin N$, then the above integral equation holds for all $t$.

### 76.4 The General Case

Suppose $\lambda B+A(\omega), \lambda B+A$ are both monotone bounded and hemicontinuous on $\mathscr{V}_{\omega}$ and $\mathscr{V}$ respectively for $\lambda$ sufficiently large. Also suppose the two estimates giving boundedness and coercivity 76.3.23-76.3.24 of Corollary 76.3.7 above. We strengthen the assumption that $\lambda B+A(\omega)$ is monotone as follows. In the usual case where $B$ is the identity, this conclusion is obvious, but here we need to assume it.

$$
\begin{equation*}
\langle(\lambda B+A(\omega))(u)-(\lambda B+A(\omega))(v), u-v\rangle \geq \delta\|u-v\|_{U}^{\alpha}, \alpha \geq 1 \tag{76.4.26}
\end{equation*}
$$

where here $U$ is a reflexive Banach space such that $V \subseteq U$ and the inclusion map is continuous, $V$ being dense in $U$. In regards to this monotonicity condition, here is a simple lemma which will be used later.

Lemma 76.4.1 Suppose $u_{n} \rightarrow w$ weakly in $\mathscr{V}_{\omega}$ and that for a.e.t, $u_{n}(t) \rightarrow u(t)$ in $U$. Then $w(t)=u(t)$ a.e.

Proof: You know that $\left\|u_{n}\right\|_{L^{p}([0, T], V)}$ is bounded. Now consider $\phi \in U^{\prime}$ and $\psi \in$ $C([0, T])$. Then the weak convergence implies

$$
\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle\phi, u_{n}\right\rangle_{U^{\prime}, U} \psi d t=\int_{0}^{T}\langle\phi, w\rangle_{U^{\prime}, U} \psi d t
$$

because it is also the case that $u_{n} \rightarrow w$ weakly in $L^{p}([0, T], U)$. However, the fact that $\left\|u_{n}\right\|_{L^{p}([0, T], V)}$ is bounded means that, by the assumed pointwise convergence,

$$
\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle\phi, u_{n}\right\rangle_{U^{\prime}, U} \psi d t=\int_{0}^{T}\langle\phi, u\rangle_{U^{\prime}, U} \psi d t
$$

It follows that

$$
\int_{0}^{T}\langle\phi, u-w\rangle \psi d t=0
$$

Since this is true for all $\psi \in C([0, T])$, there exists a set of measure zero $Q_{\phi}$ such that for $t \notin Q_{\phi}$,

$$
\langle\phi, u(t)-w(t)\rangle=0
$$

Letting $Q=\cup_{\phi \in D} Q_{\phi}$, where $D$ is a countable dense subset of $U^{\prime}$, it follows that for $t \notin Q$, the above holds for all $\phi \in U^{\prime}$. Hence $u(t)=w(t)$ for $t \notin Q$ and $m(Q)=0$.

Typically $\alpha=2$ and $U=W$.

Recall that

$$
V \subseteq W, \quad W^{\prime} \subseteq V^{\prime}
$$

each space dense in the one to its right and the inclusion maps are continuous.
Assume only

$$
\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)
$$

By density of $E$ into $W$, there exists a sequence

$$
\Phi_{n} \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, E\right)\right)
$$

such that

$$
\begin{gathered}
\left\|\Phi_{n}-\Phi\right\|_{L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)} \rightarrow 0 \\
\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \leq\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}
\end{gathered}
$$

Also let $u_{0 n} \in L^{p}(\Omega, V)$ where $u_{0 n}$ is $\mathscr{F}_{0}$ measurable and such that $u_{0 n} \in L^{p}(\Omega, V)$ and

$$
\left\|u_{0 n}(\omega)-u_{0}(\omega)\right\|_{W} \rightarrow 0,\left\langle B u_{0 n}, u_{0 n}\right\rangle \leq 2\left\langle B u_{0}, u_{0}\right\rangle
$$

for each $\omega$. The existence of such an approximating sequence follows from density considerations of $E$ into $V$ and of $V$ into $W$.

By Lemma 76.3.8 there is a solution $u_{n}$ to the integral equation

$$
\begin{equation*}
B u_{n}(t)-B u_{0 n}+\int_{0}^{t} A\left(s, u_{n}, \omega\right) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi_{n} d W \tag{76.4.27}
\end{equation*}
$$

Then by the Implicit Ito formula there is a set of measure zero such that for all $n, m$

$$
\begin{aligned}
& \frac{1}{2}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(t)-\frac{1}{2}\left\langle B u_{0 n}-B u_{0 m}, u_{0 n}-u_{0 m}\right\rangle \\
& +\delta \int_{0}^{t}\left\|u_{n}-u_{m}\right\|_{U}^{\alpha} d s \\
& \leq \lambda \int_{0}^{t}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s) d s \\
& \quad+\frac{1}{2} \int_{0}^{t}\left\langle B\left(\Phi_{n}-\Phi_{m}\right), \Phi_{n}-\Phi_{m}\right\rangle_{\mathscr{L}_{2}} d s+M_{m n}(t)
\end{aligned}
$$

Also the last term is a martingale whose quadratic variation satisfies

$$
\begin{gathered}
{\left[M_{m n}\right](t) \leq C \int_{0}^{t}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}^{2}\left\|B\left(u_{n}-u_{m}\right)\right\|_{W^{\prime}}^{2} d s} \\
\leq C \int_{0}^{t}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}^{2}\left\langle B u_{n}-B u_{m}, u_{n}-u_{m}\right\rangle d s
\end{gathered}
$$

Then from Gronwall's inequality, and adjusting the constants,

$$
\begin{aligned}
& \left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(t)+\int_{0}^{t}\left\|u_{n}-u_{m}\right\|_{U}^{\alpha} d s \\
\leq & C\left(u_{0 n}-u_{0 m}, \Phi_{n}-\Phi_{m}\right)+C(T) M_{m n}^{*}(t)
\end{aligned}
$$

where the expectation of the first constant on the right converges to 0 as $m, n \rightarrow \infty$. Here

$$
M_{n m}^{*}(t)=\sup _{s \in[0, t]}\left|M_{n m}(t)\right|
$$

Since $M^{*}$ is increasing, this implies that after adjusting constants,

$$
\begin{aligned}
& \sup _{s \in[0, t]}\left(\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)+\int_{0}^{t}\left\|u_{n}-u_{m}\right\|_{U}^{\alpha} d s\right) \\
\leq & C\left(u_{0 n}-u_{0 m}, \Phi_{n}-\Phi_{m}\right)+C(T) M_{m n}^{*}(t)
\end{aligned}
$$

Then taking expectations and using the Burkholder Davis Gundy inequality,

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left(\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)+\int_{0}^{t}\left\|u_{n}-u_{m}\right\|_{U}^{\alpha} d s\right)\right) \\
\leq C\left(u_{0 n}-u_{0 m}, \Phi_{n}-\Phi_{m}\right)+ \\
C(T) \int_{\Omega}\left(\int_{0}^{t}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}^{2}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle d s\right)^{1 / 2} d P \\
\leq C_{n, m}+2 C \int_{\Omega_{s \in[0, t]} \sup \left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle^{1 / 2}(s)} \begin{array}{c}
\left(\int_{0}^{t}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}^{2}\right)^{1 / 2} d P
\end{array} .
\end{gathered}
$$

Then adjusting the constants,

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left(\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)+\int_{0}^{t}\left\|u_{n}-u_{m}\right\|_{U}^{\alpha} d s\right)\right) \\
\quad \leq C_{n, m}+C \int_{\Omega} \int_{0}^{T}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}^{2} d t d P \equiv C_{n, m}
\end{gathered}
$$

where $C_{n, m} \rightarrow 0$ as $n, m \rightarrow \infty$. In particular, it is true for $t=T$

$$
E\left(\sup _{s \in[0, T]}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)+\int_{0}^{T}\left\|u_{n}-u_{m}\right\|_{U}^{\alpha} d s\right) \leq C_{n, m}
$$

Then

$$
P\left(\sup _{s \in[0, T]}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)+\int_{0}^{T}\left\|u_{n}-u_{m}\right\|_{U}^{\alpha} d s \geq \lambda\right) \leq \frac{C_{n, m}}{\lambda}
$$

Now take a subsequence such that if $m>n_{k}, C_{n_{k}, m}<4^{-k}$. Then the above inequality implies that

$$
P\binom{\sup _{s \in[0, T]}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)}{+\int_{0}^{T}\left\|u_{n_{k}}-u_{n_{k+1}}\right\|_{U}^{\alpha} d s \geq 2^{-k}} \leq \frac{4^{-k}}{2^{-k}}=2^{-k}
$$

and so, by the Borel Cantelli lemma, there is a set of measure zero $N$ including all earlier exceptional sets of measure zero such that for $\omega \notin N$,

$$
\sup _{s \in[0, T]}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)+\int_{0}^{T}\left\|u_{n_{k}}-u_{n_{k+1}}\right\|_{U}^{\alpha} d s<2^{-k}
$$

for all $k$ large enough. We will denote this new subsequence by $\left\{u_{n}\right\}$. Thus for such $\omega$, it follows that $\left\{B u_{n}\right\}$ is a Cauchy sequence in $C\left(N_{\omega}^{C}, W^{\prime}\right)$ for $N_{\omega}$ an exceptional set of measure zero where $B\left(u_{n}-u_{m}\right)(t) \neq B\left(u_{n}(t)-u_{m}(t)\right)$ and also $\left\{u_{n}\right\}$ is a Cauchy sequence in $L^{\alpha}(0, T, U)$. It follows

$$
\begin{align*}
& B u_{n} \rightarrow z \text { strongly in } C\left(N_{\omega}^{C}, W^{\prime}\right) \text { with uniform norm }  \tag{76.4.28}\\
& \lim _{m, n \rightarrow \infty} \sup _{s \in[0, T]}\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(s)=0 \tag{76.4.29}
\end{align*}
$$

There exists $u \in L^{\alpha}(0, T, U)$ such that for $\omega \notin N$,

$$
\begin{equation*}
\left\|u_{n}-u\right\|_{L^{\alpha}(0, T, U)} \rightarrow 0, u_{n}(t, \omega) \rightarrow u(t, \omega) \text { for a.e.t in } U \tag{76.4.30}
\end{equation*}
$$

Of course a technical issue is the fact that $B$ is a degenerate operator which might not be invertible. In the above limit, we do not know that $z=B u$ for some $u$. We resolve this issue by obtaining pointwise estimates for a given $\omega$ and then pass to a limit. After this, a time integration will give the desired result. There are easier ways to do this if $B$ is not degenerate.

From now on, this or a subsequence of this one will be the sequence of interest. Return to 76.4.27 and use the Ito formula again. Thus using the estimates,

$$
\begin{aligned}
& \frac{1}{2}\left\langle B u_{n}, u_{n}\right\rangle(t)-\frac{1}{2}\left\langle B u_{0 n}, u_{0 n}\right\rangle+\delta \int_{0}^{t}\left\|u_{n}\right\|_{V}^{p} d s-\lambda \int_{0}^{t}\left\langle B u_{n}, u_{n}\right\rangle d s \\
= & \frac{1}{2} \int_{0}^{t}\left\langle B \Phi_{n}, \Phi_{n}\right\rangle d s+\int_{0}^{t} c(s, \omega) d s+\int_{0}^{t}\left\langle f, u_{n}\right\rangle d s+M_{n}(t)
\end{aligned}
$$

where $M_{n}(t)$ is a local martingale whose quadratic variation satisfies

$$
\left[M_{n}\right](t) \leq C \int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2}\left\|B u_{n}\right\|_{W}^{2} d s
$$

Then adjusting the constants,

$$
\left\langle B u_{n}, u_{n}\right\rangle(t)+\int_{0}^{t}\left\|u_{n}\right\|_{V}^{p} d s \leq C\left(u_{0 n}, \Phi_{n}, f, c\right)+C M_{n}^{*}(t)
$$

where the expectation of the first constant on the right is no larger than a constant $C$ which is independent of $n$. Since the right term is increasing in $t$,

$$
\begin{equation*}
\sup _{s \in[0, t]}\left\langle B u_{n}, u_{n}\right\rangle(s)+\int_{0}^{t}\left\|u_{n}\right\|_{V}^{p} d s \leq C\left(u_{0 n}, \Phi_{n}, f, c\right)+C M_{n}^{*}(t) \tag{76.4.31}
\end{equation*}
$$

Now using the Burkholder Davis Gundy inequality as before and taking the expectation,

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left\langle B u_{n}, u_{n}\right\rangle(s)\right)+E \int_{0}^{t}\left\|u_{n}\right\|_{V}^{p} d s \\
\leq C+C \int_{\Omega}\left(\int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2}\left\|B u_{n}\right\|_{W}^{2} d s\right)^{1 / 2} d P \\
\leq C+C \int_{\Omega}\left(\int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2}\left\langle B u_{n}, u_{n}\right\rangle d s\right)^{1 / 2} d P \\
\leq C+C \int_{\Omega_{s \in[0, t]}} \sup \left\langle B u_{n}, u_{n}\right\rangle^{1 / 2}(s)\left(\int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2} d s\right)^{1 / 2} d P
\end{gathered}
$$

Then adjusting the constants and using the approximation properties of $\Phi_{n}$ given above, there is a constant $C$ independent of $n, t \leq T$ such that

$$
E\left(\sup _{s \in[0, t]}\left\langle B u_{n}, u_{n}\right\rangle(s)\right)+E \int_{0}^{t}\left\|u_{n}\right\|_{V}^{p} d s \leq C
$$

In particular

$$
\begin{equation*}
E\left(\sup _{s \in[0, T]}\left\langle B u_{n}, u_{n}\right\rangle(s)\right)+E \int_{0}^{T}\left\|u_{n}\right\|_{V}^{p} d s \leq C \tag{76.4.32}
\end{equation*}
$$

Next use monotonicity to obtain

$$
\begin{aligned}
\frac{1}{2}\left\langle B u_{r}-B u_{q}, u_{r}-u_{q}\right\rangle(t) \leq & \frac{1}{2} \int_{0}^{t}\left(\left(\Phi_{r}-\Phi_{q}\right) \circ J^{-1}\right)^{*} B\left(u_{r}-u_{q}\right) \circ J d W \\
& +C_{\lambda} \int_{0}^{t}\left\langle B u_{r}-B u_{q}, u_{r}-u_{q}\right\rangle d s+\int_{0}^{t}\left\|\Phi_{r}-\Phi_{q}\right\|^{2} d s
\end{aligned}
$$

and so, from Gronwall's inequality, there is a constant $C$ which is independent of $r, q$ such that

$$
\left\langle B u_{r}-B u_{q}, u_{r}-u_{q}\right\rangle(t) \leq C M_{r q}(t) \leq C M_{r q}^{*}(T)+C \int_{0}^{t}\left\|\Phi_{r}-\Phi_{q}\right\|^{2} d s
$$

where $M_{r q}$ refers to that local martingale on the right. Thus also

$$
\begin{equation*}
\sup _{t \in[0, T]}\left\langle B u_{r}-B u_{q}, u_{r}-u_{q}\right\rangle(t) \leq C M_{r q}(t) \leq C M_{r q}^{*}(T)+C \int_{0}^{T}\left\|\Phi_{r}-\Phi_{q}\right\|^{2} d s \tag{76.4.33}
\end{equation*}
$$

Taking the expectation and using the Burkholder Davis Gundy inequality again, and similar estimates to the above, using appropriate stopping times as needed, we obtain

$$
E\left(\sup _{t \in[0, T]}\left\langle B u_{r}-B u_{q}, u_{r}-u_{q}\right\rangle(t)\right) \leq C \int_{\Omega} \int_{0}^{T}\left\|\Phi_{r}-\Phi_{q}\right\|^{2} d t d P
$$

Now the right side converges to 0 as $r, q \rightarrow \infty$ and so there is a subsequence, denoted with the index $k$ such that if $p>k$,

$$
\begin{equation*}
E\left(\sup _{t \in[0, T]}\left\langle B u_{k}-B u_{p}, u_{k}-u_{p}\right\rangle(t)\right) \leq \frac{1}{2^{k}} \tag{76.4.34}
\end{equation*}
$$

Then consider the earlier local martingales. One of these is of the form

$$
M_{k}=\int_{0}^{t}\left(\Phi_{k} \circ J^{-1}\right)^{*} B u_{k} \circ J d W
$$

Then by the Burkholder Davis Gundy inequality and modifying constants as appropriate,

$$
\begin{gathered}
E\left(\left(M_{k}-M_{k+1}\right)^{*}\right) \\
\leq \quad C \int_{\Omega}\left(\int_{0}^{T}\left\|\left(\Phi_{k} \circ J^{-1}\right)^{*} B u_{k}-\left(\Phi_{k+1} \circ J^{-1}\right)^{*} B u_{k+1}\right\|^{2} d t\right)^{1 / 2} d P \\
\leq C \int_{\Omega}\binom{\int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2}\left\langle B u_{k}, u_{k}\right\rangle}{+\left\|\Phi_{k+1}\right\|^{2}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle d t}^{1 / 2} d P \\
\leq \quad C \int_{\Omega}\left(\int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2}\left\langle B u_{k}, u_{k}\right\rangle d t\right)^{1 / 2} \\
\quad+C \int_{\Omega}\left(\int_{0}^{T}\left\|\Phi_{k+1}\right\|^{2}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle d t\right)^{1 / 2} d P \\
\leq C \int_{\Omega} \sup _{t}\left\langle B u_{k}, u_{k}\right\rangle^{1 / 2}\left(\int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2} d t\right)^{1 / 2} d P \\
+C \int_{\Omega} \sup _{t}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle^{1 / 2}\left(\int_{0}^{T}\left\|\Phi_{k+1}\right\|^{2} d t\right)^{1 / 2} d P \\
\leq C\left(\int_{\Omega} \sup _{t}\left\langle B u_{k}, u_{k}\right\rangle d P\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2} d t d P\right)^{1 / 2} \\
+C\left(\int_{\Omega} \sup _{t}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle d P\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{k+1}\right\|^{2} d t d P\right)^{1 / 2}
\end{gathered}
$$

From the above inequalities, after adjusting the constants, the above is no larger than an expression of the form $C\left(\frac{1}{2}\right)^{k / 2}$ which is a summable sequence. Then

$$
\sum_{k} \int_{\Omega} \sup _{t \in[0, T]}\left|M_{k}(t)-M_{k+1}(t)\right| d P<\infty
$$

Then $\left\{M_{k}\right\}$ is a Cauchy sequence in $M_{T}^{1}$ and so there is a continuous martingale $M$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} E\left(\sup _{t}\left|M_{k}(t)-M(t)\right|\right)=0 \tag{76.4.35}
\end{equation*}
$$

Taking a further subsequence if needed, one can also have

$$
P\left(\sup _{t}\left|M_{k}(t)-M(t)\right|>\frac{1}{k}\right) \leq \frac{1}{2^{k}}
$$

and so by the Borel Cantelli lemma, there is a set of measure zero such that off this set, $\sup _{t}\left|M_{k}(t)-M(t)\right|$ converges to 0 . Hence for such $\omega, M_{k}^{*}(T)$ is bounded independent of $k$. Thus for $\omega$ off a set of measure zero, 76.4.31 implies that for such $\omega$,

$$
\sup _{s \in[0, T]}\left\langle B u_{r}, u_{r}\right\rangle(s)+\int_{0}^{T}\left\|u_{r}(s)\right\|_{V}^{p} d s \leq C(\omega)
$$

where $C(\omega)$ does not depend on the index $r$, this for the subsequence just described which will be the sequence of interest in what follows. Using the boundedness assumption for $A$, one also obtains an estimate of the form

$$
\begin{equation*}
\sup _{s \in[0, T]}\left\langle B u_{r}, u_{r}\right\rangle(s)+\int_{0}^{T}\left\|u_{r}(s)\right\|_{V}^{p} d s+\int_{0}^{T}\left\|z_{r}\right\|_{V^{\prime}}^{p^{\prime}} \leq C(\omega) \tag{76.4.36}
\end{equation*}
$$

Lemma 76.4.2 There is a subsequence, still indexed by $n$ and a set of measure zero $N$, containing all the preceding sets of measure zero such that for $\omega \notin N$,

$$
\sup _{s \in[0, T]}\left\langle B u_{n}, u_{n}\right\rangle(s)+\int_{0}^{T}\left\|u_{n}\right\|_{V}^{p} d s \leq C(\omega)<\infty
$$

From the theory of the stochastic integral, there is a further subsequence of the above such that

$$
\int_{0}^{t} \Phi_{n} d W \rightarrow \int_{0}^{t} \Phi d W \text { strongly in } C([0, T], W)
$$

for all $\omega$ off a set of measure zero. Enlarge the exceptional set $N$ and only use subsequences of this one so that both the above estimate in the lemma and the above convergence hold for $\omega \notin N$. Recall the integral equation solved.

$$
\begin{equation*}
B u_{n}(t)-B u_{0 n}+\int_{0}^{t} A\left(s, u_{n}, \omega\right) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi_{n} d W \tag{76.4.37}
\end{equation*}
$$

Thus

$$
\left(B u_{n}-B \int_{0}^{(\cdot)} \Phi_{n} d W-B u_{0 n}\right)^{\prime}+A u_{n}=f
$$

Then for $\omega \notin N$, a subsequence of the one for which the above lemma holds, still denoted as $\left\{u_{n}\right\}$ yields the following convergences,

$$
\begin{gather*}
u_{n} \rightarrow u \text { weakly in } \mathscr{V}_{\omega}  \tag{76.4.38}\\
A u_{n} \rightharpoonup \xi \text { weakly in } \mathscr{V}_{\omega}^{\prime}  \tag{76.4.39}\\
\left(B u_{n}-B \int_{0}^{(\cdot)} \Phi_{n} d W-B u_{0 n}\right)^{\prime} \rightharpoonup \zeta \text { weakly in } \mathscr{V}_{\omega}^{\prime} \tag{76.4.40}
\end{gather*}
$$

By the earlier convergence 76.4.30, this $u$ is the same as the one in 76.4.30.
Consider $\zeta$. Let $\psi$ be infinitely differentiable and equal to 0 near $T$ and let $g \in V$. Then since $B u_{n}(0)=B u_{0 n}$,

$$
\begin{gathered}
\int_{0}^{T}\langle\zeta, \psi g\rangle d t=\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle\left(B u_{n}-B \int_{0}^{(\cdot)} \Phi_{n} d W-B u_{0 n}\right)^{\prime}, \psi g\right\rangle d t \\
=-\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle\left(B u_{n}-B \int_{0}^{(\cdot)} \Phi_{n} d W-B u_{0 n}\right), \psi^{\prime} g\right\rangle d t \\
\quad=-\int_{0}^{T}\left\langle\psi^{\prime} B g,\left(u-\int_{0}^{(\cdot)} \Phi d W-u_{0}\right)\right\rangle d t \\
\quad=-\int_{0}^{T}\left\langle B\left(u-\int_{0}^{(\cdot)} \Phi d W-u_{0}\right), \psi^{\prime} g\right\rangle d t
\end{gathered}
$$

which shows that

$$
\zeta=\left(B\left(u-\int_{0}^{(\cdot)} \Phi d W-u_{0}\right)\right)^{\prime}
$$

in the sense of $V^{\prime}$ valued distributions. Also from the above,

$$
\begin{aligned}
\int_{0}^{T}\langle\zeta, \psi g\rangle d t= & \left\langle B u(0)-B u_{0}, \psi(0) g\right\rangle \\
& +\int_{0}^{T}\left\langle\left(B u-B \int_{0}^{(\cdot)} \Phi d W-B u_{0}\right), \psi^{\prime} g\right\rangle d t \\
= & \left\langle B u(0)-B u_{0}, \psi(0) g\right\rangle+\int_{0}^{T}\langle\zeta, \psi g\rangle d t
\end{aligned}
$$

Hence $B(u(0, \omega))=B u_{0}$. Thus this has shown that

$$
\left(B\left(u-\int_{0}^{(\cdot)} \Phi d W-u_{0}\right)\right)^{\prime}+\xi(\cdot, \omega)=f(\cdot, \omega) \text { in } \mathscr{V}_{\omega}^{\prime}, B u(0)=B u_{0}
$$

Thus integrating this, we get

$$
\begin{equation*}
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} \xi(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi d W \tag{76.4.41}
\end{equation*}
$$

Lemma 76.4.3 The above sequence does not depend on $\omega \notin N$. In fact, it is not necessary to take a further subsequence.

Proof: In fact, it is not necessary to take a subsequence to get the convergences 76.4.38 - 76.4.40. This is because of the pointwise convergence of 76.4.30 and Lemma 76.4.1. If the original sequence did not converge, then there would be two subsequences converging weakly to two different functions in $\mathscr{V}_{\omega} v, w$ which is impossible because of 76.4.30 and this lemma since it would require $v(t)=w(t)$ a.e.

The question at this point is whether $u$ is progressively measurable. From the assumed estimates, the Ito formula, and 76.4.27, the same kind of estimates used earlier show that there exists an estimate of the form

$$
\left\|u_{n}\right\|_{\mathscr{V}} \leq C
$$

Therefore, there exists a further subsequence such that

$$
u_{n} \rightarrow \bar{u} \text { weakly in } \mathscr{V}
$$

It follows from Lemma 76.3.4 that off an enlarged exceptional set of measure zero, still denoted as $N$,

$$
\bar{u}(\cdot, \omega)=u(\cdot, \omega) \text { in } \mathscr{V}_{\omega}
$$

Hence we can assume that $u$ is progressively measurable into $V$. It follows that $B u$ is progressively measurable into $W^{\prime}$.

Thus also

$$
(t, \omega) \rightarrow \int_{0}^{t} \xi(s, \omega) d s
$$

is progressively measurable into $V^{\prime}$.
Of course the next task is to identify $\xi$. This is always a problem even in the non stochastic case. Here it is especially difficult because in order to identify $\xi$ we need to use the implicit Ito formula which only holds if $\xi$ is sufficiently measurable. However, we have obtained $\xi$ as a weak limit for fixed $\omega$. Therefore, this is a significant issue. In stochastic evolution problems where $B=I$ this is not as difficult because one gets $\xi$ as a weak limit in $\mathscr{V}$ and then $\xi$ is progressively measurable. We cannot do it this way and still get the best results in which there is a solution to the integral equation which holds for all $t$ off a set of measure zero because of the degenerate nature of the operator $B$. However, $\xi$ is only an equivalence class of functions. We show in the next lemma that there exists a representative of this equivalence class for each $\omega$ off an exceptional set of measure zero such that the resulting $\xi$ is progressively measurable. This will enable us to use the implicit Ito formula and indentify $\xi$.

The following lemma will allow the use of the Ito formula and eventually identify $\xi$.
Lemma 76.4.4 Enlarging the exceptional set, one can assume that $\xi$ is also progressively measurable. In fact, if

$$
\xi_{n} \equiv \int_{t-(1 / n)}^{t} \xi d s
$$

is known to be progressively measurable, $\xi(t, \omega) \equiv 0$ for $t<0$, then there exists a set of measure zero $N$ such that for $\omega \notin N, \xi(t, \omega)=\bar{\xi}(t, \omega)$ for all $t$ off a set of measure zero and $\bar{\xi}$ is progressively measurable.

Proof: Define

$$
\xi_{n} \equiv n \int_{t-(1 / n)}^{t} \xi d s
$$

where $\xi$ is defined to be zero for $t \leq 0$. Then by what was just shown, this is progressively measurable. Also, standard approximate identity arguments verify that for each $\omega, \xi_{n} \rightarrow$
$\xi$ in $\mathscr{V}_{\omega}$. Next note that the set where $\xi_{n}$ is not a Cauchy sequence is a progressively measurable set. It equals

$$
\cup_{n} \cap_{m} \cup_{k, l \geq m}\left[(t, \omega):\left\|\xi_{l}(t, \omega)-\xi_{k}(t, \omega)\right\|>\frac{1}{n}\right] \equiv S
$$

Now for $p>0$

$$
\lim _{m \rightarrow \infty} P\left(\sup _{p>0}\left\|\xi_{m+p}-\xi_{m}\right\|_{\mathscr{V}_{\omega}}>\varepsilon\right)=0
$$

This is because of the convergence of $\xi_{n}$ to $\xi$ in $\mathscr{V}_{\omega}$. Therefore, there is a subsequence still called $\xi_{n}$ such that

$$
P\left(\sup _{p>0}\left\|\xi_{n+p}-\xi_{n}\right\|_{\mathscr{V}_{\omega}}>2^{-n}\right)<2^{-n}
$$

and so there is an enlarged set of measure zero, still denoted as $N$ such that all of the above considerations hold for $\omega \notin N$ and also for $\omega \notin N$,

$$
\sup _{p>0}\left\|\xi_{n+p}-\xi_{n}\right\|_{\mathscr{V}_{\omega}} \leq 2^{-n}
$$

for all $n$ large enough. Now let $S$ defined above, correspond to this particular subsequence. Let $S(\omega)$ be those $t$ such that $(t, \omega) \in S$. Then $S(\omega)$ is a set of measure zero for each $\omega \notin N$ because the above inequality implies that $t \rightarrow \xi_{n}(t, \omega)$ is a Cauchy sequence off a set of measure zero which by definition is $S(\omega)$. Then consider $\left\{\xi_{n}(t, \omega) \mathscr{X}_{S^{C}}(t, \omega)\right\}$. For each $\omega$ off $N$, this converges for all $t$. Thus it converges pointwise to a function $\bar{\xi}$ which must be progressively measurable. However, $t \rightarrow \bar{\xi}(t, \omega)$ must also equal $t \rightarrow \xi(t, \omega)$ in $\mathscr{V}_{\omega}$ by the above construction. Therefore, we can assume without loss of generality that $\xi$ is itself progressively measurable.

From the weak convergence of $u_{n}$ to $u$ in $\mathscr{V}_{\omega}$,

$$
B u_{n} \rightarrow B u \text { weakly in } \mathscr{V}_{\omega}^{\prime}
$$

and so

$$
(\lambda B+A(\omega)) u_{n} \rightarrow \lambda B u+\xi \text { weakly in } \mathscr{V}_{\omega}^{\prime}
$$

Now the above convergences and the integral equation imply that off the exceptional set $N$, for each $t$

$$
B u_{n}(t) \rightarrow B u(t) \text { weakly in } V^{\prime}
$$

From a generalization of standard theorems in Hilbert space, stated in Lemma 76.2.1 there exist vectors $\left\{e_{i}\right\} \subseteq V$ such that

$$
\left\langle B u_{n}(t), u_{n}(t)\right\rangle=\sum_{i=1}^{\infty}\left|\left\langle B u_{n}(t), e_{i}\right\rangle\right|^{2}
$$

Hence

$$
\lim \inf _{n \rightarrow \infty}\left\langle B u_{n}(t), u_{n}(t)\right\rangle \geq \sum_{i=1}^{\infty} \lim \inf _{n \rightarrow \infty}\left|\left\langle B u_{n}(t), e_{i}\right\rangle\right|^{2}
$$

$$
\begin{equation*}
=\sum_{i=1}^{\infty}\left|\left\langle B u(t), e_{i}\right\rangle\right|^{2}=\langle B u(t), u(t)\rangle \tag{76.4.42}
\end{equation*}
$$

Thus the above inequalities and formulas hold for a.e. $t$.
Return to the equation 76.4.41. Define the stopping time

$$
\tau_{p} \equiv \inf \left\{t \in[0, T]:\langle B u, u\rangle(t)+\int_{0}^{t}\|\xi\|_{V^{\prime}}^{p^{\prime}} d s>p\right\}
$$

From 76.4.28 and the fact that $\xi \in \mathscr{V}_{\omega}^{\prime}$, it follows that $\tau_{p}=\infty$ for all $p$ large enough. Then stop the equation using this stopping time.

$$
\begin{aligned}
& B u^{\tau_{p}}(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]} \xi^{\tau_{p}}(s, \omega) d s \\
= & \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]} f(s, \omega) d s+B \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W
\end{aligned}
$$

From the implicit Ito formula Theorem 76.2.3, for a.e. $t$,

$$
\begin{aligned}
& \frac{1}{2}\left\langle B u^{\tau_{p}}(t), u^{\tau_{p}}(t)\right\rangle-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}\left\langle\xi^{\tau_{p}}, u^{\tau_{p}}\right\rangle d s \\
= & \frac{1}{2} \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}\langle B \Phi, \Phi\rangle d s \\
+ & \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}\left\langle f, u^{\tau_{p}}\right\rangle d s+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi \circ J^{-1}\right)^{*} B u^{\tau_{p}} \circ J d W
\end{aligned}
$$

Then letting $p \rightarrow \infty$ this yields the following formula for a.e. $t$

$$
\begin{align*}
& \frac{1}{2}\langle B u(t), u(t)\rangle-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\langle\lambda B u+\xi, u\rangle d s=\frac{1}{2} \int_{0}^{t}\langle B \Phi, \Phi\rangle d s \\
& \quad+\int_{0}^{t}\langle f, u\rangle d s+\int_{0}^{t}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W+\int_{0}^{t}\langle\lambda B u, u\rangle d s \tag{76.4.43}
\end{align*}
$$

Lemma 76.4.5 It is true that

$$
\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle B u_{n}, u_{n}\right\rangle d t=\int_{0}^{T}\langle B u, u\rangle d t
$$

Proof: From 76.4.28 $B u_{n} \rightarrow z$ strongly in $C\left(N_{\omega}^{C}, W^{\prime}\right)$. But also, for each $t, B u_{n}(t) \rightarrow$ $B u(t)$ weakly in $V^{\prime}$ and so $z(t)=B u(t)$. This strong convergence in $C\left(N_{\omega}^{C}, W^{\prime}\right)$ along with the uniform norm with the weak convergence of $u_{n}$ to $u$ in $\mathscr{V}_{\omega}$ is sufficient to obtain the above limit.

You might think that

$$
\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \rightarrow \int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
$$

but this is not entirely clear. It will be true in the case that in 76.4.26, $\alpha=2$ and $U=W$ and this is shown later. However, it is not clearly true here unless it is also the case that $\Phi \in L^{2}\left(\Omega, L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right)$.

Lemma 76.4.6 If $\Phi \in L^{2}\left(\Omega, L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right)$ then

$$
\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \rightarrow \int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
$$

Proof:

$$
\begin{gather*}
E\left(\left|\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W\right|\right) \\
\leq E\left(\left|\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u_{n} \circ J d W\right|\right) \\
+E\left(\left|\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u_{n} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W\right|\right) \\
\leq \\
\quad \int_{\Omega}\left(\left(\int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2}\left\langle B u_{n}, u_{n}\right\rangle\right)^{1 / 2}\right) d P  \tag{76.4.44}\\
\\
\quad+\int_{\Omega}\left(\int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2}\left\langle B u_{n}-B u, u_{n}-u\right\rangle d t\right)^{1 / 2} d P
\end{gather*}
$$

Consider that second term. It is no larger than

$$
\begin{aligned}
& \int_{\Omega}\|\Phi\|_{L^{\infty}\left([0, T], \mathscr{L}_{2}\right)}\left(\int_{0}^{T}\left\langle B u_{n}-B u, u_{n}-u\right\rangle d t\right)^{1 / 2} d P \\
\leq & \left(\int_{\Omega}\|\Phi\|_{L^{\infty}\left([0, T], \mathscr{L}_{2}\right)}^{2}\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\langle B u_{n}-B u, u_{n}-u\right\rangle d t d P\right)^{1 / 2}
\end{aligned}
$$

Now consider the following. Letting the $e_{i}$ be the special vectors of Lemma 34.4.2, it follows,

$$
\begin{aligned}
\int_{\Omega} \int_{0}^{T} & \left\langle B u_{n}-B u, u_{n}-u\right\rangle d t d P=\int_{\Omega} \int_{0}^{T} \sum_{i=1}^{\infty}\left\langle B u_{n}-B u, e_{i}\right\rangle^{2} d t d P \\
& =\int_{\Omega} \int_{0}^{T} \sum_{i=1}^{\infty} \lim _{p \rightarrow \infty} \inf _{p \rightarrow \infty}\left\langle B u_{n}-B u_{p}, e_{i}\right\rangle^{2} d t d P \\
& \leq \lim _{p \rightarrow \infty} \inf _{\Omega} \int_{\Omega} \int_{0}^{T} \sum_{i=1}^{\infty}\left\langle B u_{n}-B u_{p}, e_{i}\right\rangle^{2} d t d P \\
& =\lim _{p \rightarrow \infty} \inf _{\Omega} \int_{0}^{T}\left\langle B u_{n}-B u_{p}, u_{n}-u_{p}\right\rangle d t d P \leq \frac{T}{2^{n}}
\end{aligned}
$$

The last inequality follows from 76.4.34. Therefore, the second term in 76.4.44 is no larger than $\left(C(T, \Phi) / 2^{n}\right)^{1 / 2}$ which converges to 0 as $n \rightarrow \infty$. Now consider the first term in 76.4.44.

$$
\int_{\Omega}\left(\left(\int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2}\left\langle B u_{n}, u_{n}\right\rangle\right)^{1 / 2}\right) d P
$$

$$
\begin{aligned}
& \leq \int_{\Omega_{t \in[0, T]} \sup _{t}\left\langle B u_{n}, u_{n}\right\rangle^{1 / 2}(t)\left(\left(\int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} d t\right)^{1 / 2}\right) d P}^{\leq\left(\int_{\Omega_{t \in[0, T]}} \sup _{t]}\left\langle B u_{n}, u_{n}\right\rangle(t)\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} d t\right)^{1 / 2}}
\end{aligned}
$$

From 76.4.32

$$
\leq C\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} d t\right)^{1 / 2}
$$

which converges to 0 .
Return now to the equation solved by $u_{n}$ in 76.4.37. Apply the Ito formula to this one. This yields for a.e. $t$,

$$
\begin{align*}
\frac{1}{2}\left\langle B u_{n}(t), u_{n}(t)\right\rangle & -\frac{1}{2}\left\langle B u_{0 n}, u_{0 n}\right\rangle+\int_{0}^{t}\left\langle A(\omega) u_{n}, u_{n}\right\rangle d s=\frac{1}{2} \int_{0}^{t}\left\langle B \Phi_{n}, \Phi_{n}\right\rangle d s \\
& +\int_{0}^{t}\left\langle f, u_{n}\right\rangle d s+\int_{0}^{t}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \tag{76.4.45}
\end{align*}
$$

Assume without loss of generality that $T$ is not in the exceptional set. If not, consider all $T^{\prime}$ close to $T$ such that $T^{\prime}$ is not in the exceptional set.

$$
\begin{gathered}
\int_{0}^{T}\left\langle(\lambda B+A(\omega)) u_{n}, u_{n}\right\rangle d s \\
=\frac{1}{2}\left\langle B u_{0 n}, u_{0 n}\right\rangle-\frac{1}{2}\left\langle B u_{n}(T), u_{n}(T)\right\rangle+\int_{0}^{T}\left\langle f, u_{n}\right\rangle d s \\
+\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W+\frac{1}{2} \int_{0}^{T}\left\langle B \Phi_{n}, \Phi_{n}\right\rangle d s+\int_{0}^{T}\left\langle\lambda B u_{n}, u_{n}\right\rangle d s
\end{gathered}
$$

Now it follows from 76.4.42 applied to $t=T$ and the above lemma that

$$
\begin{gathered}
\lim \sup _{n \rightarrow \infty} \int_{0}^{T}\left\langle(\lambda B+A(\omega)) u_{n}, u_{n}\right\rangle d s \\
\leq \frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle-\frac{1}{2}\langle B u(T), u(T)\rangle+\int_{0}^{T}\langle f, u\rangle d s \\
+\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W+\frac{1}{2} \int_{0}^{T}\langle B \Phi, \Phi\rangle d s+\int_{0}^{T}\langle\lambda B u, u\rangle d s
\end{gathered}
$$

and from 76.4.43, the expression on the right equals $\int_{0}^{T}\langle\lambda B u+\xi, u\rangle d s$. Hence

$$
\lim \sup _{n \rightarrow \infty} \int_{0}^{T}\left\langle(\lambda B+A(\omega)) u_{n}, u_{n}\right\rangle d s \leq \int_{0}^{T}\langle\lambda B u+\xi, u\rangle d s
$$

Then since $\lambda B+A(\omega)$ is monotone and hemicontinuous, it is type $M$ and so this requires $A(\omega) u=\xi$.

Hence we obtain

$$
B u(t)-B u_{0}(\omega)+\int_{0}^{t} A(\omega)(u) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi d W
$$

This is a solution for a given $\omega \notin N$. Also, a stopping time argument like the above and the coercivity estimates for $A$ along with the implicit Ito formula show that $u \in \mathscr{V}$. This yields the existence part of the following existence and uniqueness theorem.

Theorem 76.4.7 Suppose $\mathscr{V} \equiv L^{p}([0, T] \times \Omega, V)$ where $p \geq 2$,with the $\sigma$ algebra of progressively measurable sets and $\mathscr{V}_{\omega}=L^{p}([0, T], V)$.

$$
\begin{aligned}
\Phi & \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right) \cap L^{2}\left(\Omega, L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right), \\
f & \in \quad \mathscr{V}^{\prime} \equiv L^{p^{\prime}}\left([0, T] \times \Omega, V^{\prime}\right)
\end{aligned}
$$

and both are progressively measurable. Suppose that

$$
\lambda B+A(\omega): \mathscr{V}_{\omega} \rightarrow \mathscr{V}_{\omega}^{\prime}, \lambda B+A: \mathscr{V} \rightarrow \mathscr{V}^{\prime}
$$

are monotone hemicontinuous and bounded where

$$
A(\omega) u(t) \equiv A(t, u(t), \omega)
$$

and $(t, u, \omega) \rightarrow A(t, u, \omega)$ is progressively measurable. Also suppose for $p \geq 2$, the coercivity, and the boundedness conditions

$$
\begin{equation*}
\lambda\langle B u, u\rangle+\langle A(t, u, \omega), u\rangle_{V} \geq \delta\|u\|_{V}^{p}-c(t, \omega) \tag{76.4.46}
\end{equation*}
$$

where $c \in L^{1}([0, T] \times \Omega)$ for all $\lambda$ large enough. Also,

$$
\begin{equation*}
\|A(t, u, \omega)\|_{V^{\prime}} \leq k\|u\|_{V}^{p-1}+c^{1 / p^{\prime}}(t, \omega) \tag{76.4.47}
\end{equation*}
$$

also suppose the monotonicity condition for all $\lambda$ large enough.

$$
\begin{equation*}
\langle(\lambda B+A(\omega))(u)-(\lambda B+A(\omega))(v), u-v\rangle \geq \delta\|u-v\|_{U}^{\alpha} \tag{76.4.48}
\end{equation*}
$$

Then if $u_{0} \in L^{2}(\Omega, W)$ with $u_{0} \mathscr{F}_{0}$ measurable, there exists a unique solution $u(\cdot, \omega) \in \mathscr{V}_{\omega}$ with $u \in \mathscr{V}\left(L^{p}([0, T] \times \Omega, V)\right.$ and progressively measurable) such that for $\omega$ off a set of measure zero,

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u(s, \omega), \omega) d s=\int_{0}^{t} f d s+B \int_{0}^{t} \Phi d W
$$

It is also assumed that $V$ is a reflexive separable real Banach space.
Proof: The uniqueness assertion follows easily from the monotonicity condition.
Now we remove the assumption that $\Phi \in L^{2}\left(\Omega, L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right)$. Everything is the same except for the need for a different argument to show that

$$
\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \rightarrow \int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
$$

In this case we assume

$$
\langle(\lambda B+A(\omega))(u)-(\lambda B+A(\omega))(v), u-v\rangle \geq \delta\|u-v\|_{W}^{2}
$$

Then repeating the above argument with this change yields set of measure zero, still denoted as $N$ such that for $\omega \notin N$

$$
\begin{equation*}
\int_{0}^{T}\left\|u_{n}-u_{n+1}\right\|_{W}^{2} d s \leq 2^{-n} \tag{76.4.49}
\end{equation*}
$$

for all $n$ large enough. Hence for such $\omega, u_{n}(\cdot, \omega)$ is Cauchy in $L^{2}([0, T], W)$ and in fact $u_{n}(t, \omega)$ is a Cauchy sequence in $W$. Thus $\left\{u_{n}(\cdot, \omega)\right\}$ converges in $L^{2}([0, T], W)$ to $u(\cdot, \omega) \in L^{2}([0, T], W)$ and by the above considerations involving continuous dependence of $V$ into $W$, it follows that $u(\cdot, \omega)$ will be the same as the $u$ from the above convergences. Now this convergence implies that in addition, for a.e. $t$,

$$
\begin{gather*}
\lim _{n \rightarrow \infty}\left\langle B u_{n}(t, \omega)-B u(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle=0  \tag{76.4.50}\\
\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle B u_{n}(t, \omega)-B u(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle d t=0
\end{gather*}
$$

What is known from 76.4.35 is that for

$$
M_{n}(t)=\int_{0}^{t}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W
$$

there is a continuous martingale $M \in M_{T}^{1}$ such that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} E\left(\sup _{t \in[0, T]}\left|M_{n}(t)-M(t)\right|\right)=0 \tag{76.4.51}
\end{equation*}
$$

Define a stopping time

$$
\tau_{p} \equiv \inf \left\{t:\langle B u, u\rangle(t)+\sup _{n}\left\langle B u_{n}, u_{n}\right\rangle(t)>p\right\}
$$

This is a good enough stopping time because the function used to define it as a hitting time is lower semicontinuous.

Lemma 76.4.8 $\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \rightarrow \int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W$ in probability. Also there is a futher subsequence and set of measure zero such that off this set,

$$
\lim _{n \rightarrow \infty}\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W-\int_{0}^{t}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W\right|\right)=0 .
$$

In particular, what is needed here is valid,

$$
\lim _{n \rightarrow \infty} \int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W=\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
$$

Proof: Let $\varepsilon>0$. Then define

$$
A_{n}=\left\{\omega:\left|\int_{0}^{T}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W\right|>\varepsilon\right\}
$$

Then

$$
A_{n}=\cup_{p=1}^{\infty} A_{n} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right),\left[\tau_{0}<\infty\right] \equiv \emptyset
$$

the sets in the union being disjoint. Then $A \cap\left(\left[\tau_{p}=\infty\right]\right) \subseteq$

$$
\left\{\omega:\left|\begin{array}{c}
\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \\
-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
\end{array}\right|>\varepsilon\right\}
$$

Then as before,

$$
\begin{align*}
& E\left(\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W\right|\right) \\
& \leq \int_{\Omega}\left(\left(\int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} \mathscr{X}_{\left[0, \tau_{p}\right]}\left\langle B u_{n}, u_{n}\right\rangle\right)^{1 / 2}\right) d P \\
&+\int_{\Omega}\left(\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\|\Phi\|_{\mathscr{L}_{2}}^{2}\left\langle B u_{n}-B u, u_{n}-u\right\rangle d t\right)^{1 / 2} d P \tag{76.4.52}
\end{align*}
$$

Consider the second term. It is no larger than

$$
\left(\int_{\Omega} \int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\|\Phi\|_{\mathscr{L}_{2}}^{2}\left\langle B u_{n}-B u, u_{n}-u\right\rangle d t d P\right)^{1 / 2}
$$

Now $t \rightarrow\left\langle B u_{n}, u_{n}\right\rangle$ is continuous and so $\mathscr{X}_{\left[0, \tau_{p}\right]}\left\langle B u_{n}, u_{n}\right\rangle(t) \leq p$. If not, then you would have $\left\langle B u_{n}, u_{n}\right\rangle(t)>p$ for some $t \leq \tau_{p}$ and so, by continuity, there would be $s<t \leq \tau_{p}$ for which $\left\langle B u_{n}, u_{n}\right\rangle(s)>p$ contrary to the definition of $\tau_{p}$. Then $\mathscr{X}_{\left[0, \tau_{p}\right]}\left\langle B u_{n}-B u, u_{n}-u\right\rangle$ is bounded a.e. and also converges to 0 for a.e. $t \leq \tau_{p}$ as $n \rightarrow \infty$. Therefore, off a set of measure zero, including the set where $t \rightarrow\|\Phi\|_{\mathscr{L}_{2}}^{2}$ is not in $L^{1}$, the double integral converges to 0 by the dominated convergence theorem. As to the first integral in 76.4.52, it is dominated by

$$
\begin{aligned}
& \int_{\Omega} \mathscr{X}_{\left[0, \tau_{p}\right]} \sup _{t \in\left[0, \tau_{p}\right]}\left\langle B u_{n}, u_{n}\right\rangle^{1 / 2}(t)\left(\int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2}\right)^{1 / 2} d P \\
\leq & \left(\int_{\Omega_{t \in[0, T]}} \sup \left\langle B u_{n}, u_{n}\right\rangle d P\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} d t d P\right)^{1 / 2}
\end{aligned}
$$

From the estimate 76.4.32,

$$
\leq C\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} d t d P\right)^{1 / 2}
$$

for a constant $C$ independent of $n$. Therefore,

$$
\lim _{n \rightarrow \infty} E\left(\left|\begin{array}{l}
\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \\
-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
\end{array}\right|\right)=0
$$

Hence

$$
P\left(A_{n} \cap\left[\tau_{p}=\infty\right]\right) \leq \frac{1}{\varepsilon} E\left(\left|\begin{array}{l}
\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \\
-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
\end{array}\right|\right)
$$

and so

$$
\lim _{n \rightarrow \infty} P\left(A_{n} \cap\left[\tau_{p}=\infty\right]\right)=0
$$

Then

$$
P\left(A_{n}\right)=\sum_{p=1}^{\infty} P\left(A_{n} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right)
$$

and so from the dominated convergence theorem,

$$
\lim _{n \rightarrow \infty} P\left(A_{n}\right)=\sum_{p=1}^{\infty} \lim _{n \rightarrow \infty} P\left(A_{n} \cap\left(\left[\tau_{p}=\infty\right] \backslash\left[\tau_{p-1}<\infty\right]\right)\right)=\sum_{p} 0=0 .
$$

There was nothing special about $T$. The same argument holds for all $t$ and so $M(t)$ mentioned above has been identified as $\int_{0}^{t}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W$. Then from 76.4.51

$$
\lim _{n \rightarrow \infty} E\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W-\int_{0}^{t}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W\right|\right)=0
$$

It follows from the usual Borel Cantelli argument that there is a set of measure zero and a further subsequence such that off this set, all the above convergences happen and also

$$
\int_{0}^{t}\left(\Phi_{n} \circ J^{-1}\right)^{*} B u_{n} \circ J d W \rightarrow \int_{0}^{t}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
$$

uniformly on $[0, T]$.
The rest of the argument is identical. This yields the following theorem.
Theorem 76.4.9 Suppose $\mathscr{V} \equiv L^{p}([0, T] \times \Omega, V)$ where $p \geq 2$, with the $\sigma$ algebra of progressively measurable sets and $\mathscr{V}_{\omega}=L^{p}([0, T], V)$.

$$
\begin{aligned}
\Phi & \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right) \\
f & \in \quad \mathscr{V}^{\prime} \equiv L^{p^{\prime}}\left([0, T] \times \Omega, V^{\prime}\right)
\end{aligned}
$$

and both are progressively measurable. Suppose that

$$
\lambda B+A(\omega): \mathscr{V}_{\omega} \rightarrow \mathscr{V}_{\omega}^{\prime}, \lambda B+A: \mathscr{V} \rightarrow \mathscr{V}^{\prime}
$$

are monotone hemicontinuous and bounded where

$$
A(\omega) u(t) \equiv A(t, u(t), \omega)
$$

and $(t, u, \omega) \rightarrow A(t, u, \omega)$ is progressively measurable. Also suppose for $p \geq 2$, the coercivity, and the boundedness conditions

$$
\begin{equation*}
\lambda\langle B u, u\rangle+\langle A(t, u, \omega), u\rangle_{V} \geq \delta\|u\|_{V}^{p}-c(t, \omega) \tag{76.4.53}
\end{equation*}
$$

where $c \in L^{1}([0, T] \times \Omega)$ for all $\lambda$ large enough. Also,

$$
\begin{equation*}
\|A(t, u, \omega)\|_{V^{\prime}} \leq k\|u\|_{V}^{p-1}+c^{1 / p^{\prime}}(t, \omega) \tag{76.4.54}
\end{equation*}
$$

also suppose the monotonicity condition for all $\lambda$ large enough.

$$
\begin{equation*}
\langle(\lambda B+A(\omega))(u)-(\lambda B+A(\omega))(v), u-v\rangle \geq \delta\|u-v\|_{W}^{2} \tag{76.4.55}
\end{equation*}
$$

Then if $u_{0} \in L^{2}(\Omega, W)$ with $u_{0} \mathscr{F}_{0}$ measurable, there exists a unique solution $u(\cdot, \omega) \in \mathscr{V}_{\omega}$ with $u \in \mathscr{V}\left(L^{p}([0, T] \times \Omega, V)\right.$ and progressively measurable) such that for $\omega$ off a set of measure zero,

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u(s, \omega), \omega) d s=\int_{0}^{t} f d s+B \int_{0}^{t} \Phi d W
$$

It is also assumed that $V$ is a reflexive separable real Banach space.

### 76.5 Replacing $\Phi$ With $\sigma(u)$

It is not hard to include the case where $\Phi$ is replaced with a function $\sigma(u)$. We make the following assumptions. For each $r>0$ there exists $\lambda$ large enough that

$$
\langle\lambda B(u)+A(u)-(\lambda B(\hat{u})+A(\hat{u})), u-\hat{u}\rangle \geq r\|u-\hat{u}\|_{W}^{2}
$$

Note that in the case where $B=I$ and there is a conventional Gelfand triple, $V, H, V^{\prime}$, this kind of condition is obvious if $\lambda I+A$ is monotone for some $\lambda$. Thus this is not an unreasonable assumption to make although it is stronger than some of the assumptions used above with the integral given by $\int_{0}^{t} \Phi d W$.

As to $\sigma$ we make the following assumptions.

$$
\begin{gathered}
(t, u, \omega) \in[0, T] \times W \times \Omega \rightarrow \sigma(t, u, \omega) \text { is progressively measurable into } W \\
\|\sigma(t, u, \omega)\|_{W} \leq C+C\|u\|_{W} \\
\|\sigma(t, u, \omega)-\sigma(t, \hat{u}, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \leq K\|u-\hat{u}\|_{W}
\end{gathered}
$$

That is, it has linear growth and is Lipschitz.
Let $\lambda$ correspond to $r$ where $r-\|B\| K^{2}>4$. Also let $T$ be such that

$$
\hat{C} e^{\lambda T} K^{2}<3
$$

where $\hat{C}$ is a constant used in the Burkholder Davis Gundy inequality. This is a restriction on the size of $K$. Thus we only give a solution if $K$ is small enough. Later, this will be removed in the most interesting case. This will give a local solution valid for a fixed $T>0$ and then the global solution can be obtained by applying this result on the succession of intervals $[0, T],[T, 2 T],[3 T, 4 T]$, and so forth.

From Theorem 76.4.9, if $w \in \mathscr{W}$, there exists a unique solution $u$ to

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u(s, \omega), \omega) d s=\int_{0}^{t} f d s+B \int_{0}^{t} \sigma(w) d W
$$

holding in the sense described there. Let $u_{i}$ result from $w_{i}$. Then from the implicit Ito formula and the above monotonicity estimate,

$$
\begin{aligned}
& \frac{1}{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t)+r \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s \\
&-\lambda \int_{0}^{t}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s \\
&-\int_{0}^{t}\left\langle B \sigma\left(u_{1}\right)-B \sigma\left(u_{2}\right), \sigma\left(u_{1}\right)-\sigma\left(u_{2}\right)\right\rangle_{\mathscr{L}_{2}} d s \leq M^{*}(t)
\end{aligned}
$$

where the right side is of the form $\sup _{s \in[0, t]}|M(s)|$ where $M(t)$ is a local martingale having quadratic variation dominated by

$$
\begin{equation*}
C \int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|^{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s \tag{76.5.56}
\end{equation*}
$$

Therefore, since $M^{*}$ is increasing in $t$, it follows from the Lipschitz condition on $\sigma$ that

$$
\begin{aligned}
& \frac{1}{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t)+r \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s \\
& -\lambda \int_{0}^{t}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s-\|B\| K^{2} \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s \leq M^{*}(t)
\end{aligned}
$$

Thus, from the assumption about $r$,

$$
\begin{aligned}
& \sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)+4 \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s \\
\leq & \lambda \int_{0}^{t}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s+2 M^{*}(t)
\end{aligned}
$$

Then applying Gronwall's inequality,

$$
\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)+4 \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s \leq 2 e^{\lambda T} M^{*}(t)
$$

Now take expectations and use the Burkholder Davis Gundy inequality. The expectation of the right side is then dominated by

$$
2 \hat{C} e^{\lambda T} \int_{\Omega}\left(\int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|_{\mathscr{L}_{2}}^{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s\right)^{1 / 2} d P
$$

$$
\begin{gathered}
\leq\left[\begin{array}{c}
\int_{\Omega} \sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle^{1 / 2} . \\
2 \hat{C} e^{\lambda T}\left(\int_{0}^{t} K^{2}\left\|w_{1}-w_{2}\right\|_{W}^{2} d t\right)^{1 / 2} d P
\end{array}\right] \\
\leq E\left(\frac{1}{2} \sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)\right) \\
+\hat{C} e^{\lambda T} E\left(\int_{0}^{t} K^{2}\left\|w_{1}-w_{2}\right\|_{W}^{2} d t\right)
\end{gathered}
$$

It follows that, after adjusting constants as needed, one gets an inequality of the following form.

$$
\begin{aligned}
& \frac{1}{2} E\left(\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)\right)+4 \int_{\Omega} \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s d P \\
\leq & \hat{C} e^{\lambda T} E\left(\int_{0}^{t} K^{2}\left\|w_{1}-w_{2}\right\|_{W}^{2} d t\right)
\end{aligned}
$$

This holds for every $t \leq T$ and so, from the estimate on the size of $T$, it follows that

$$
\int_{0}^{T} \int_{\Omega}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s d P \leq \frac{3}{4} \int_{0}^{T} \int_{\Omega}\left\|w_{1}-w_{2}\right\|_{W}^{2} d t d P
$$

Therefore, there is a unique fixed point to this mapping which takes $w \in \mathscr{W}$ to $u$ the solution to the integral equation. We denote it as $u$. Thus $u$ is progressively measurable and for $\omega$ off a set of measure zero, we have a solution to the integral equation

$$
\begin{aligned}
& B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u(s, \omega), \omega) d s \\
= & \int_{0}^{t} f d s+B \int_{0}^{t} \sigma(u) d W, t \in[0, T]
\end{aligned}
$$

Now the same argument can be repeated for the succession of intervals mentioned above. However, you need to be careful that at $T$, you have $B u(T, \omega)=B(u(T, \omega))$ for $\omega$ off a set of measure zero. If this is not so, you locate $T^{\prime}$ close to $T$ for which it is so as in Lemma 73.3.1 and use this $T^{\prime}$ instead, but these are mainly technical issues. This proves the following existence and uniqueness theorem.

Theorem 76.5.1 Suppose $f \in \mathscr{V}^{\prime}$ is progressively measurable and that

$$
(t, \omega) \rightarrow \sigma(t, \omega, u(t, \omega))
$$

is progressively measurable whenever u is. Suppose that

$$
\lambda B+A(\omega): \mathscr{V}_{\omega} \rightarrow \mathscr{V}_{\omega}^{\prime}, \lambda B+A: \mathscr{V} \rightarrow \mathscr{V}^{\prime}
$$

are monotone hemicontinuous and bounded where

$$
A(\omega) u(t) \equiv A(t, u(t), \omega)
$$

and $(t, u, \omega) \rightarrow A(t, u, \omega)$ is progressively measurable. Also suppose for $p \geq 2$, the coercivity, and the boundedness conditions

$$
\begin{equation*}
\lambda\langle B u, u\rangle+\langle A(t, u, \omega), u\rangle_{V} \geq \delta\|u\|_{V}^{p}-c(t, \omega) \tag{76.5.57}
\end{equation*}
$$

for all $\lambda$ large enough.

$$
\begin{equation*}
\|A(t, u, \omega)\|_{V^{\prime}} \leq k\|u\|_{V}^{p-1}+c^{1 / p^{\prime}}(t, \omega) \tag{76.5.58}
\end{equation*}
$$

where $c \in L^{1}([0, T] \times \Omega)$. Also suppose the monotonicity condition that for all $r>0$ there exists $\lambda$ such that

$$
\langle(\lambda B+A(\omega))(u)-(\lambda B+A(\omega))(v), u-v\rangle \geq r\|u-v\|_{W}^{2}
$$

Also suppose that

$$
\begin{gathered}
(t, u, \omega) \in[0, T] \times W \times \Omega \rightarrow \sigma(t, u, \omega) \text { is progressively measurable into } W \\
\|\sigma(t, u, \omega)\|_{W} \leq C+C\|u\|_{W} \\
\|\sigma(t, u, \omega)-\sigma(t, \hat{u}, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \leq K\|u-\hat{u}\|_{W}
\end{gathered}
$$

Then if $u_{0} \in L^{2}(\Omega, W)$ with $u_{0} \mathscr{F}_{0}$ measurable, there exists a unique solution $u(\cdot, \omega) \in \mathscr{V}_{\omega}$ with $u \in \mathscr{V}\left(L^{p}([0, T] \times \Omega, V)\right.$ and progressively measurable) such that for $\omega$ off a set of measure zero,

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u(s, \omega), \omega) d s=\int_{0}^{t} f d s+B \int_{0}^{t} \sigma(u) d W
$$

In case $B$ is the Riesz map, you do not have to make any assumption on the size of $K$. Thus

$$
\langle B u, u\rangle=\|u\|_{W}^{2}
$$

The case of most interest is the usual one where $V \subseteq W=W^{\prime} \subseteq V^{\prime}$, the case of a Gelfand triple in which $B$ is the identity. As to $\sigma$, the assumption is made that

$$
\begin{gathered}
\|\sigma(t, \omega, u)\|_{W} \leq C+C\|u\|_{W} \\
\left\|\sigma\left(t, \omega, u_{1}\right)-\sigma\left(t, \omega, u_{2}\right)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \leq K\left\|u_{1}-u_{2}\right\|_{W}
\end{gathered}
$$

Of course it is also assumed that whenever $u$ has values in $W$ and is progressively measurable, $(t, \omega) \rightarrow \sigma(t, \omega, u(t, \omega))$ is also progressively measurable into $\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)$.

Letting $w_{i} \in L^{2}([0, T] \times \Omega, W)$ each $w_{i}$ being progressively measurable, the above assumptions imply that there exists a solution $u_{i}$ to the integral equation

$$
B u_{i}(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A\left(u_{i}\right) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \sigma\left(w_{i}\right) d W
$$

here we write $\sigma\left(w_{i}\right)$ for short instead of $\sigma\left(t, \omega, w_{i}\right)$. First, consider

$$
w \in L^{2}([0, T] \times \Omega, W) \cap L^{\infty}\left([0, T], L^{2}(\Omega, W)\right)
$$

and let $u$ be the solution which results from placing $w$ in $\sigma$. Then from the estimates,

$$
\begin{gathered}
\langle B u, u\rangle(t)-\left\langle B u_{0}, u_{0}\right\rangle+\delta \int_{0}^{t}\|u\|_{V}^{p} d s=2 \int_{0}^{t}\langle f, u\rangle d s+C\left(b_{3}, b_{4}, b_{5}\right) \\
+\lambda \int_{0}^{t}\langle B u, u\rangle d s+\int_{0}^{t}\langle B \sigma(w), \sigma(w)\rangle_{\mathscr{L}_{2}} d s+2 M^{*}(t) \\
\leq 2 \int_{0}^{t}\langle f, u\rangle d s+C\left(b_{3}, b_{4}, b_{5}\right)+\lambda \int_{0}^{t}\langle B u, u\rangle d s+\int_{0}^{t}\left(C+C\|w\|_{W}^{2}\right) d s+2 M^{*}(t)
\end{gathered}
$$

where $M^{*}(t)=\sup _{s \in[0, t]}|M(s)|$ and the quadratic variation of $M$ is no larger than

$$
\int_{0}^{t}\|\sigma(w)\|^{2}\langle B(u), u\rangle d s
$$

Then using Gronwall's inequality, one obtains an inequality of the form

$$
\sup _{s \in[0, T]}\langle B u, u\rangle(s) \leq C+C\left(M^{*}(t)+\int_{0}^{t}\|w\|_{W}^{2} d s\right)
$$

where $C=C\left(u_{0}, f, \delta, \lambda, b_{3}, b_{4}, b_{5}, T\right)$ and is integrable. Then take expectation. By Burkholder Davis Gundy inequality and adjusting constants as needed,

$$
\begin{aligned}
& E\left(\sup _{s \in[0, T]}\langle B u, u\rangle(s)\right) \\
\leq & C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P+C \int_{\Omega}\left(\int_{0}^{T}\|\sigma(w)\|^{2}\langle B(u), u\rangle d s\right)^{1 / 2} d P \\
\leq & C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P+C \int_{\Omega} \sup _{s \in[0, T]}\langle B u, u\rangle^{1 / 2}(s)\left(\int_{0}^{T}\|\sigma(w)\|^{2} d s\right)^{1 / 2} d P \\
\leq & C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P+\frac{1}{2} E\left(\sup _{s \in[0, T]}\langle B u, u\rangle(s)\right)+C \int_{\Omega} \int_{0}^{T}\left(C+C\|w\|_{W}^{2}\right)
\end{aligned}
$$

Thus

$$
E(\langle B u, u\rangle(t)) \leq E\left(\sup _{s \in[0, T]}\langle B u, u\rangle(s)\right) \leq C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P
$$

and so

$$
\|u\|_{L^{\infty}\left([0, T], L^{2}(\Omega, W)\right)}^{2} \leq C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P
$$

which implies $u \in L^{\infty}\left([0, T], L^{2}(\Omega, W)\right)$ and is progressively measurable.
Using the monotonicity assumption, there is a suitable $\lambda$ such that

$$
\begin{aligned}
& \frac{1}{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t)+r \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s \\
& -\lambda \int_{0}^{t}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s
\end{aligned}
$$

$$
-\int_{0}^{t}\left\langle B \sigma\left(u_{1}\right)-B \sigma\left(u_{2}\right), \sigma\left(u_{1}\right)-\sigma\left(u_{2}\right)\right\rangle_{\mathscr{L}_{2}} d s \leq M^{*}(t)
$$

where the right side is of the form $\sup _{s \in[0, t]}|M(s)|$ where $M(t)$ is a local martingale having quadratic variation dominated by

$$
\begin{equation*}
C \int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|^{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s \tag{76.5.59}
\end{equation*}
$$

Then by assumption and using Gronwall's inequality, there is a constant $C=C(\lambda, K, T)$ such that

$$
\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t) \leq C M^{*}(t)
$$

Then also, since $M^{*}$ is increasing,

$$
\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s) \leq C M^{*}(t)
$$

Taking expectations and from the Burkholder Davis Gundy inequality,

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)\right) \\
\leq C \int_{\Omega}\left(\int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|^{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle\right)^{1 / 2} d P \\
\leq C \int_{\Omega} \sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle^{1 / 2}(s)\left(\int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|^{2}\right)^{1 / 2} d P
\end{gathered}
$$

Then it follows after adjusting constants that there exists an inequality of the form

$$
E\left(\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)\right) \leq C E\left(\int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|_{\mathscr{L}_{2}}^{2} d s\right)
$$

Hence

$$
E\left(\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t)\right) \leq C K^{2} E\left(\int_{0}^{t}\left\|w_{1}-w_{2}\right\|_{W}^{2} d s\right)
$$

Thus, for each $t \leq T$

$$
\int_{\Omega}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t) d P \leq C K^{2} E\left(\int_{0}^{t}\left\|w_{1}-w_{2}\right\|_{W}^{2} d s\right)
$$

one can consider the map $\psi(w) \equiv u$ as described above. Then the above inequality implies

$$
\begin{aligned}
& E\left(\left\langle B\left(\psi^{n} w_{1}-\psi^{n} w_{2}\right), \psi^{n} w_{1}-\psi^{n} w_{2}\right\rangle(t)\right) \\
\leq & C K^{2} E\left(\int_{0}^{t}\left\|\psi^{n-1} w_{1}-\psi^{n-1} w_{2}\right\|_{W}^{2} d t_{1}\right)
\end{aligned}
$$

$$
\begin{gathered}
=C K^{2} E\left(\int_{0}^{t}\left\langle B\left(\psi^{n-1} w_{1}-\psi^{n-1} w_{2}\right), \psi^{n-1} w_{1}-\psi^{n-1} w_{2}\right\rangle\left(t_{1}\right) d t_{1}\right) \\
\leq\left(C K^{2}\right)^{2} E\left(\int_{0}^{t} \int_{0}^{t_{1}}\left\langle B\left(\psi^{n-2} w_{1}-\psi^{n-2} w_{2}\right), \psi^{n-2} w_{1}-\psi^{n-2} w_{2}\right\rangle\left(t_{2}\right) d t_{2} d t_{1}\right) \\
\cdots \leq\left(C K^{2}\right)^{n} E\left(\int_{0}^{t} \int_{0}^{t_{1}} \cdots \int_{0}^{t_{n-1}}\left\langle B\left(w_{1}-w_{2}\right), w_{1}-w_{2}\right\rangle\left(t_{n}\right) d t_{n} \cdots d t_{2} d t_{1}\right) \\
=\left(C K^{2}\right)^{n} \int_{0}^{t} \int_{0}^{t_{1}} \cdots \int_{0}^{t_{n-1}} E\left(\left\langle B\left(w_{1}-w_{2}\right), w_{1}-w_{2}\right\rangle\left(t_{n}\right)\right) d t_{n} \cdots d t_{2} d t_{1} \\
\leq\left(C K^{2}\right)^{n} \sup _{t} E\left(\left\langle B\left(w_{1}-w_{2}\right), w_{1}-w_{2}\right\rangle(t)\right) \frac{T^{n}}{n!}<\frac{1}{2}\left\|w_{1}-w_{2}\right\|_{L^{\infty}\left([0, T], L^{2}(\Omega, W)\right)}^{2}
\end{gathered}
$$

provided $n$ is sufficiently large. It follows that

$$
\left\|\psi^{n} w_{1}-\psi^{n} w_{2}\right\|_{L^{\infty}\left([0, T], L^{2}(\Omega, W)\right)}^{2} \leq \frac{1}{2}\left\|w_{1}-w_{2}\right\|_{L^{\infty}\left([0, T], L^{2}(\Omega, W)\right)}^{2}
$$

for all $n$ sufficiently large. Hence, if one begins with

$$
w \in L^{\infty}\left([0, T], L^{2}(\Omega, W)\right) \cap L^{2}([0, T] \times \Omega, W),
$$

the sequence of iterates $\left\{\psi^{n} w\right\}_{n=1}^{\infty}$ converges to a fixed point $u$ in $L^{\infty}\left([0, T], L^{2}(\Omega, W)\right)$. This $u$ is automatically in $L^{2}([0, T] \times \Omega, W)$ and is progressively measurable since each of the iterates is progressively measurable. This proves the following theorem.
Theorem 76.5.2 Suppose $f \in \mathscr{V}^{\prime}$ is progressively measurable and that $(t, \omega) \rightarrow \sigma(t, u, \omega)$ is progressively measurable whenever u is. Suppose that $B: W \rightarrow W^{\prime}$ is a Riesz map.

$$
\lambda B+A(\omega): \mathscr{V}_{\omega} \rightarrow \mathscr{V}_{\omega}^{\prime}, \lambda B+A: \mathscr{V} \rightarrow \mathscr{V}^{\prime}
$$

are monotone hemicontinuous and bounded where

$$
A(\omega) u(t) \equiv A(t, u(t), \omega)
$$

and $(t, u, \omega) \rightarrow A(t, u, \omega)$ is progressively measurable. Also suppose for $p \geq 2$, the coercivity, and the boundedness conditions

$$
\begin{equation*}
\lambda\langle B u, u\rangle+\langle A(t, u, \omega), u\rangle_{V} \geq \delta\|u\|_{V}^{p}-c(t, \omega) \tag{76.5.60}
\end{equation*}
$$

for all $\lambda$ large enough.

$$
\begin{equation*}
\|A(t, u, \omega)\|_{V^{\prime}} \leq k\|u\|_{V}^{p-1}+c^{1 / p^{\prime}}(t, \omega) \tag{76.5.61}
\end{equation*}
$$

where $c \in L^{1}([0, T] \times \Omega)$. Also suppose that

$$
\begin{gathered}
\|\sigma(t, u, \omega)\|_{W} \leq C+C\|u\|_{W} \\
\|\sigma(t, u, \omega)-\sigma(t, \hat{u}, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \leq K\|u-\hat{u}\|_{W}
\end{gathered}
$$

Then if $u_{0} \in L^{2}(\Omega, W)$ with $u_{0} \mathscr{F}_{0}$ measurable, there exists a unique solution $u(\cdot, \omega) \in \mathscr{V}_{\omega}$ with $u \in \mathscr{V}\left(L^{p}([0, T] \times \Omega, V)\right.$ and progressively measurable) such that for $\omega$ off a set of measure zero,

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} A(s, u(s, \omega), \omega) d s=\int_{0}^{t} f d s+B \int_{0}^{t} \sigma(u) d W
$$

### 76.6 Examples

Here we give some examples. The first is a standard example, the porous media equation, which is discussed well in [116]. For stochastic versions of this example, see [108]. The generalization to stochastic equations does not require the theory developed here. We will show, however, that it can be considered in terms of the theory of this paper without much difficulty using an approach proposed in [23]. These examples involve operators which are not monotone, in the usual way but they can be transformed into equations which do fit the above theory.

Example 76.6.1 The stochastic porous media equation is

$$
u_{t}-\Delta\left(u|u|^{p-2}\right)=f, u(0)=u_{0}, u=0 \text { on } \partial U
$$

where here $U$ is a bounded open set in $\mathbb{R}^{n}, n \leq 3$ having Lipschitz boundary. One can consider a stochastic version of this as a solution to the following integral equation

$$
\begin{equation*}
u(t)-u_{0}+\int_{0}^{t}(-\Delta)\left(u|u|^{p-2}\right) d s=\int_{0}^{t} \Phi d W+\int_{0}^{t} f d s \tag{76.6.62}
\end{equation*}
$$

where here

$$
\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right) \cap L^{2}\left(\Omega, L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)\right)
$$

$H=L^{2}(U)$ and the equation holds in the manner described above in $H^{-1}(U)$. Assume $p \geq 2$ and $f \in L^{2}((0, T) \times \Omega, H)$.

One can consider this as an implicit integral equation of the form

$$
\begin{equation*}
(-\Delta)^{-1} u(t)-(-\Delta)^{-1} u_{0}+\int_{0}^{t} u|u|^{p-2} d s=(-\Delta)^{-1} \int_{0}^{t} \Phi d W+(-\Delta)^{-1} \int_{0}^{t} f d s \tag{76.6.63}
\end{equation*}
$$

where $-\Delta$ is the Riesz map of $H_{0}^{1}(U)$ to $H^{-1}(U)$. Then we can also consider $(-\Delta)^{-1}$ as a map from $L^{2}(U)$ to $L^{2}(U)$ as follows.

$$
(-\Delta)^{-1} f=u \text { where }-\Delta u=f, u=0 \text { on } \partial U
$$

Thus we let $W=L^{2}(U)=H$ and $V=L^{p}(U)$. Let $B \equiv(-\Delta)^{-1}$ on $L^{2}(U)$ as just described. Let $A(u)=u|u|^{p-2}$. It is obvious that the necessary coercivity condition holds. In addition, there is a strong monotonicity condition which holds. Therefore, if $u_{0} \in L^{2}\left(\Omega, L^{2}(U)\right)$ and $\mathscr{F}_{0}$ measurable, Theorem 76.4.7 applies and we can conclude that there exists a unique solution to the integral equation 76.6 .63 in the sense described in this theorem. Here $u \in$ $L^{p}\left([0, T] \times \Omega, L^{p}(U)\right)$ and is progressively measurable, the integral equation holding for all $t$ for $\omega$ off a set of measure zero. Since $A$ satisfies for some $\delta>0$ an inequality of the form

$$
\langle A u-A v, u-v\rangle \geq \delta\|u-v\|_{L^{p}(U)}^{p}
$$

it follows easily from the above methods that the solution is also unique. In fact, this follows right away from Theorem 76.4.7 because $\left\langle-\Delta^{-1} u, u\right\rangle=\|u\|_{H^{-1}}^{2}$.

Also note that from the integral equation,

$$
(-\Delta)^{-1}\left(u(t)-u_{0}-\int_{0}^{t} \Phi d W\right)+\int_{0}^{t} u|u|^{p-2} d s=(-\Delta)^{-1} \int_{0}^{t} f d s
$$

and so, since $(-\Delta)$ is the Riesz map on $H_{0}^{1}(U)$, the integral equation above shows that off a set of measure zero,
$\int_{0}^{t} u|u|^{p-2} d s=(-\Delta)^{-1}\left(\int_{0}^{t} f d s-\left(u(t)-u_{0}-\int_{0}^{t} \Phi d W\right)\right) \in L^{2}\left(0, T, H_{0}^{1}(U) \cap H^{2}(U)\right)$
by elliptic regularity results. Without that stochastic integral, one could assert that $|u|^{\frac{p-2}{2}} u \in$ $L^{2}\left(0, T, H_{0}^{1}(U)\right)$. This is shown in [23]. However, it appears that no such condition can be obtained here because of the nowhere differentiability of the stochastic integral, even if more is assumed on $u_{0}$ and $\Phi$.

Also in this reference is a treatment of the Stefan problem. The Stefan problem involves a partial differential equation

$$
u_{t}-\sum_{i} \frac{\partial}{\partial x_{i}}\left(k(u) \frac{\partial u}{\partial x_{i}}\right)=f, \text { on } U \times[0, T] \equiv Q
$$

for $(x, t) \notin S$ where $u$ is the temperature and $k(u)$ has a jump at $\sigma$ and $S$ is given by $u(x, t)=$ $\sigma$. It is assumed that $0<k_{1} \leq k(r) \leq k_{2}<\infty$ for all $r \in \mathbb{R}$. For example, its graph could be of the form

On $S$ there is a jump condition which is assumed to hold. Namely

$$
b n_{t}-\left(k(u+) u_{, i}(+)-k(u-) u_{, i}(-)\right) n_{i}=0
$$

where the sum is taken over repeated indices and $b>0 . u(+)$ is the "limit" as $\left(x^{\prime}, t^{\prime}\right) \rightarrow$ $(x, t) \in S$ where $\left(x^{\prime}, t^{\prime}\right) \in S_{+}, u(-)$ defined similarly. Also $\mathbf{n}$ will denote the unit normal which goes from $S_{+} \equiv\{(x, t): u(x, t)>\sigma\}$ toward $S_{-} \equiv\{(x, t): u(x, t)<\sigma\}$.

$$
\mathbf{n}=\left(n_{t}, n_{x_{1}}, \cdots, n_{x_{n}}\right)
$$

In addition, there is an initial condition and boundary conditions

$$
u(x, 0)=u_{0}(x) \notin S, u(x, t)=0 \text { on } \partial U
$$

The idea is to obtain a variational formulation of this thing. To do this, let $K(r) \equiv \int_{0}^{r} k(s) d s$. Thus in the case of the above picture, the graph of $K(r)$ would look like

Now let $\beta(t)$ be a function which satisfies

$$
\beta^{\prime}(t)=\frac{1}{k\left(K^{-1}(t)\right)} \text { for } t \neq \tau \equiv K(\sigma)
$$

and it has a jump equal to $b$ at $\tau$.

Let $v=K(u)$. Then for $u \neq \sigma$, equivalently $v \neq \tau$,

$$
v_{t}=K^{\prime}(u) u_{t}=k\left(K^{-1}(v)\right) u_{t}
$$

and so

$$
u_{t}=\frac{1}{k\left(K^{-1}(v)\right)} v_{t}=\frac{d}{d t}(\beta(v))
$$

Also,

$$
v_{, i}=K^{\prime}(u) u_{, i}=k(u) u_{, i}
$$

and so

$$
u_{, i}=\frac{1}{k(u)} v_{, i}
$$

Hence

$$
\left(k(u) u_{, i}\right)_{, i}=\left(k(u) \frac{1}{k(u)} v_{, i}\right)_{, i}=\Delta v
$$

Thus, off the set $S$,

$$
\beta(v)_{t}-\Delta v=f
$$

Now let $\phi \in L^{2}\left(0, T, H_{0}^{1}(U)\right)$ with $\phi(x, T)=0$. Then assume $S$ is sufficiently smooth that things like divergence theorem apply. Also note that $u=\sigma$ is the same as $v=\tau$.

$$
\begin{aligned}
& \int_{Q}\left(\beta(v)_{t}-\Delta v\right) \phi=\int_{S_{+}}\left(\beta(v)_{t}-\Delta v\right) \phi+\int_{S_{-}}\left(\beta(v)_{t}-\Delta v\right) \phi \\
&= \int_{S_{+}}(\beta(v) \phi)_{t}-\beta(v) \phi_{t}-\left(v_{, i} \phi\right)_{, i}+v_{, i} \phi_{, i} \\
&+\int_{S_{-}}(\beta(v) \phi)_{t}-\beta(v) \phi_{t}-\left(v_{, i} \phi\right)_{, i}+v_{, i} \phi_{, i}
\end{aligned}
$$

Now using the divergence theorem, and continuing these formal manipulations, the above reduces to

$$
\begin{aligned}
& \int_{S} \beta(v(+)) \phi n_{t}-\left(v_{, i}(+) \phi\right) n_{i}+\int_{S_{+}}-\beta(v) \phi_{t}+v_{, i} \phi_{, i}-\int_{U \cap S_{+}} \beta(v(x, 0)) \phi(x, 0) \\
+ & \int_{S}-\beta(v(-)) \phi n_{t}+\left(v_{, i}(-) \phi\right) n_{i}+\int_{S_{-}}-\beta(v) \phi_{t}+v_{, i} \phi_{, i}-\int_{U \cap S_{-}} \beta(v(x, 0)) \phi(x, 0)
\end{aligned}
$$

Combining the two integrals over $S$ yields

$$
\int_{S}\left(b n_{t}-\left(v_{, i}(+)-v_{, i}(-)\right) n_{i}\right) \phi=\int_{S}\left(b n_{t}-\left(k(u) u_{, i}(+)-k(u) u_{, i}(-)\right) n_{i}\right) \phi=0
$$

by assumption. Therefore, including $f$, we obtain

$$
\int_{Q}-\beta(v) \phi_{t}+v_{, i} \phi_{, i}-\int_{U} \beta(v(x, 0)) \phi(x, 0)=\int_{Q} f \phi
$$

which implies, using the initial condition

$$
\int_{U} \beta\left(v_{0}\right) \phi(x, 0)+\int_{Q}\left((\beta(v))^{\prime} \phi+v_{, i} \phi_{, i}\right)-\int_{U} \beta(v(x, 0)) \phi(x, 0)=\int_{Q} f \phi
$$

Regard $\beta$ as a maximal monotone graph and let $\alpha(t) \equiv \beta^{-1}(t)$. Thus $\alpha$ is single valued. It just has a horizontal place corresponding to the jump in $\beta$. Then let $w=\beta(v)$ so that $v=\alpha(w)$.

Then in terms of $w$, the above equals

$$
\int_{U} w_{0} \phi(x, 0)+\int_{Q}\left(w^{\prime} \phi+\alpha(w)_{, i} \phi_{, i}\right)-\int_{U} w(x, 0) \phi(x, 0)=\int_{Q} f \phi
$$

and so this simplifies to

$$
w^{\prime}-\Delta(\alpha(w))=f, w(0)=w_{0}
$$

where $\alpha$ maps onto $\mathbb{R}$ and is monotone and satisfies

$$
\begin{aligned}
\left(\alpha\left(r_{1}\right)-\alpha\left(r_{2}\right)\right)\left(r_{1}-r_{2}\right) & \geq 0,|\alpha(r)| \leq m|r| \\
\left|\alpha\left(r_{1}\right)-\alpha\left(r_{2}\right)\right| & \leq m\left|r_{1}-r_{2}\right|, \alpha(r) r \geq \delta|r|^{2}
\end{aligned}
$$

for some $\delta, m>0$. Then $K^{-1}(\alpha(w))=u$ where $u$ is the original dependent variable. Obviously, the original function $k$ could have had more than one jump and you would handle it the same way by defining $\beta$ to be like $K^{-1}$ except for having appropriate jumps at the values of $K(u)$ corresponding to the jumps in $k$. This explains the following example.

Example 76.6.2 It can be shown that the Stefan problem can be reduced to the consideration of an equation of the form

$$
w_{t}-\Delta(\alpha(w))=f, w(0)=w_{0}
$$

where $\alpha: L^{2}\left(0, T, L^{2}(U)\right) \rightarrow L^{2}\left(0, T, L^{2}(U)\right)$ is monotone hemicontinuous and coercive, $\alpha$ being a single valued function. Here $f$ is the same which occurred in the original partial differential equation

$$
u_{t}-\sum_{i} \frac{\partial}{\partial x_{i}}\left(k(u) \frac{\partial u}{\partial x_{i}}\right)=f
$$

Thus a stochastic Stefan problem could be considered in the form

$$
\left(-\Delta^{-1}\right) w(t)-(-\Delta)^{-1} w_{0}+\int_{0}^{t} \alpha(w) d s=\left(-\Delta^{-1}\right) \int_{0}^{t} f d s+\left(-\Delta^{-1}\right) \int_{0}^{t} \Phi d W
$$

This example can be included in the above general theory because

$$
\left(\left(-\Delta^{-1}\right) u-\left(-\Delta^{-1}\right) v, u-v\right) \geq\|u-v\|_{V^{\prime}}^{2}, V^{\prime} \equiv H^{-1}, V=H_{0}^{1}(U)
$$

This is seen as follows. $V, L^{2}(U), V^{\prime}$ is a Gelfand triple. Then $-\Delta$ is the Riesz map $R$ from $H_{0}^{1}(U)$ to $H^{-1}(U)$. then you have

$$
\left(y, R^{-1} y\right)_{L^{2}(U)}=\left\langle R R^{-1} y, R^{-1} y\right\rangle_{V^{\prime}, V}=\left\|R^{-1} y\right\|_{V}^{2}=\|y\|_{V^{\prime}}^{2}
$$

Next we give a simple example which is a singular and degenerate equation. This is a model problem which illustrates how the theory can be used. This problem is mixed parabolic and stochastic and nonlinear elliptic. It is a singular equation because the coefficient $b$ can be unbounded. The existence of a solution is easy to obtain from the above theory but it does not follow readily from other methods. If $p=2$ it is an abstract version of stochastic heat equation which could model a material in which the density becomes vanishingly small in some regions and very large in other regions.

Example 76.6.3 Suppose $U$ is a bounded open set in $\mathbb{R}^{3}$ and $b(\mathbf{x}) \geq 0, b \in L^{p}(U), p \geq 4$ for simplicity. Consider the degenerate stochastic initial boundary value problem

$$
\begin{aligned}
b(\cdot) u(t, \cdot)-b(\cdot) u_{0}(\cdot)-\int_{0}^{t} \nabla \cdot\left(|\nabla u|^{p-2} \nabla u\right) & =b \int_{0}^{t} \Phi d W \\
u & =0 \text { on } \partial U
\end{aligned}
$$

where $\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)$ for $W=H_{0}^{1}(U)$.
To consider this equation and initial condition, it suffices to let $W=H_{0}^{1}(U), V=$ $W_{0}^{1, p}(U)$,

$$
\begin{aligned}
A & : \quad V \rightarrow V^{\prime},\langle A u, v\rangle=\int_{U}|\nabla u|^{p-2} \nabla u \cdot \nabla v d x \\
B & : \quad W \rightarrow W^{\prime},\langle B u, v\rangle=\int_{U} b(x) u(x) v(x) d x
\end{aligned}
$$

Then by the Sobolev embedding theorem, $B$ is obviously self adjoint, bounded and nonnegative. This follows from a short computation:

$$
\begin{aligned}
& \left|\int_{U} b(x) u(x) v(x) d x\right| \leq\|v\|_{L^{4}(U)}\left(\int_{U}|b(x)|^{4 / 3}|u(x)|^{4 / 3} d x\right)^{3 / 4} \\
& \leq\|v\|_{H_{0}^{1}(U)}\left(\left(\int|b(x)|^{4} d x\right)^{1 / 3}\left(\int\left(|u(x)|^{4 / 3}\right)^{3 / 2}\right)^{2 / 3}\right)^{3 / 4} \\
& =\|v\|_{H_{0}^{1}(U)}\|b\|_{L^{4}(U)}\|u\|_{L^{2}(U)} \leq\|b\|_{L^{4}}\|u\|_{H_{0}^{1}}\|v\|_{H_{0}^{1}}
\end{aligned}
$$

Also for some $\delta>0$

$$
\langle A u-A v, u-v\rangle \geq \delta\|u-v\|_{V}^{p}
$$

The nonlinear operator is obviously monotone and hemicontinuous. As for $u_{0}$, it is only necessary to assume $u_{0} \in L^{2}(\Omega, W)$ and $\mathscr{F}_{0}$ measurable. Then Theorem 76.4.7 gives the existence of a solution in the sense that for a.e. $\omega$ the integral equation holds for all $t$. Note that $b$ can be unbounded and may also vanish. Thus the equation can degenerate to the case of a non stochastic nonlinear elliptic equation.

The existence theorems can easily be extended to include the situation where $\Phi$ is replaced with a function of the unknown function $u$. This is done by splitting the time interval into small sub intervals of length $h$ and retarding the function in the stochastic integral, like a standard proof of the Peano existence theorem. Then the Ito formula is applied to obtain estimates and a limit is taken.

Other examples of the usefulness of this theory will result when one considers stochastic versions of systems of partial differential equations in which there is a nonlinear coupling between a parabolic equation and a nonlinear elliptic equation. These kinds of problems occur, for example as quasistatic damage problems in which the damage parameter satisfies a parabolic equation and the balance of momentum is a nonlinear elliptic equation and the two equations are coupled in a nonlinear way.

### 76.7 Other Examples, Inclusions

The above general result can also be used as a starting point for evolution inclusions or other situations where one does not have hemicontinuous operators. Assume here that

$$
\Phi \in L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)
$$

We will use the following simple observation. Let $\alpha>2$. Let $\|\Phi\|_{\infty}$ denote the norm in $L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. By the Burkholder Davis Gundy inequality,

$$
\begin{gathered}
\int_{\Omega}\left(\left|\int_{s}^{t} \Phi d W\right|\right)^{\alpha} d P \leq \\
\int_{\Omega}\left(\sup _{r \in[s, t]}\left|\int_{s}^{r} \Phi d W\right|\right)^{\alpha} d P \leq C \int_{\Omega}\left(\int_{s}^{t}\|\Phi\|^{2} d \tau\right)^{\alpha / 2} d P \\
\leq C\|\Phi\|_{\infty}^{\alpha} \int_{\Omega}\left(\int_{s}^{t} d \tau\right)^{\alpha / 2} d P=C\|\Phi\|_{\infty}^{\alpha}|t-s|^{\alpha / 2}
\end{gathered}
$$

By the Kolmogorov Čentsov theorem, this shows that $t \rightarrow \int_{0}^{t} \Phi d W$ is Holder continuous with exponent

$$
\gamma<\frac{(\alpha / 2)-1}{\alpha}=\frac{1}{2}-\frac{1}{\alpha}
$$

Since $\alpha>2$ is arbitrary, this shows that for any $\gamma<1 / 2$, the stochastic integral is Holder continuous with exponent $\gamma$. This is exactly the same kind of continuity possessed by the Wiener process. We state this as the following lemma.

Lemma 76.7.1 Let $\Phi \in L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ then for any $\gamma<1 / 2$, the stochastic integral $\int_{0}^{t} \Phi d W$ is Holder continuous with exponent $\gamma$.

To begin with, we consider a stochastic inclusion. Suppose, in the context of Theorem 76.4.7, that $V$ is a closed subspace of $W^{\sigma, p}(U), \sigma>1$ which contains $C_{c}^{\infty}(U)$ where $U$ is an open bounded set in $\mathbb{R}^{n}$, different than the Hilbert space $U$. (In case the matrix $A$ which follows equals 0 , it suffices to take $\sigma \geq 1$.) Let

$$
\sum_{i, j} a_{i, j}(\mathbf{x}) \xi_{i} \xi_{j} \geq 0, a_{i j}=a_{j i}
$$

where the $a_{i, j} \in C^{1}(\bar{U})$. Denoting by $A$ the matrix whose $i j^{t h}$ entry is $a_{i j}$, let

$$
W \equiv\left\{u \in L^{2}(U):\left(u, \quad A^{1 / 2} \nabla u\right) \in L^{2}(U)^{n+1}\right\}
$$

with a norm given by

$$
\|u\|_{W} \equiv\left(\int_{U}\left(u v+\sum_{i, j} a_{i j}(\mathbf{x}) \partial_{i} u \partial_{j} v\right) d x\right)^{1 / 2}
$$

$B: W \rightarrow W^{\prime}$ be given by

$$
\langle B u, v\rangle \equiv \int_{U}\left(u v+\sum_{i, j} a_{i j}(\mathbf{x}) \partial_{i} u \partial_{j} v\right) d x
$$

so that $B$ is the Riesz map for this space. The case where the $a_{i j}$ could vanish is allowed. Thus $B$ is a positive self adjoint operator and is therefore, included in the above discussion. In this example, it will be significant that $B$ is one to one and does not vanish.

This operator maps onto $L^{2}(U)$ because of basic considerations concerning maximal monotone operators. This is because

$$
\langle D u, v\rangle \equiv \int_{U} \sum_{i, j} a_{i j}(\mathbf{x}) \partial_{i} u \partial_{j} v d x
$$

can be obtained as a subgradient of a convex lower semicontinuous and proper functional defined on $L^{2}(U)$. Therefore, the operator is maximal monotone on $L^{2}(U)$ which means that $I+D$ is onto. The domain of $D$ consists of all $u \in L^{2}(U)$ such that

$$
D u=-\sum_{i, j} \partial_{j}\left(a_{i j}(\mathbf{x}) \partial_{i} u\right) \in L^{2}(U)
$$

along with suitable boundary conditions determined by the choice of $V$. It follows that if $u+D u=B u=f \in H=L^{2}(U)$, then

$$
u-\sum_{i, j} \partial_{j}\left(a_{i j} \partial_{i} u\right)=f
$$

Therefore,

$$
\begin{gathered}
\|u\|_{L^{2}(U)}^{2}+\int_{U} \sum_{i, j} a_{i j}(\mathbf{x}) \partial_{i} u \partial_{j} u=\|u\|_{W}^{2}= \\
=(f, u) \leq\|f\|_{L^{2}(U)}\|u\|_{L^{2}(U)} \leq\|f\|_{L^{2}(U)}\|u\|_{W}
\end{gathered}
$$

which shows that the map $B^{-1}: H=L^{2}(U) \rightarrow W$ is continuous.
Next suppose that $\Phi \in L^{\infty}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Then by continuity of the mapping $B^{-1}$, it follows that $\Psi \equiv B^{-1} \Phi$ satisfies $\Psi \in L^{\infty}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)$. Thus $\Phi=B \Psi$. In addition to this, to simplify the presentation, assume in addition that

$$
\begin{gathered}
\langle A(t, u, \omega)-A(t, v, \omega), u-v\rangle \geq \delta^{2}\|u-v\|_{V}^{p} \\
\langle A(t, u, \omega), u\rangle \geq \delta^{2}\|u\|_{V}^{p}
\end{gathered}
$$

Also assume the uniqueness condition of Lemma 76.3.16 is satisfied. Consider the following graph.

There is a monotone Lipschitz function $J_{n}$ which is approximating a function with the indicated jump. For a convex function $\phi$, we denote by $\partial \phi$ its subgradient. Thus for $y \in \partial \phi(x)$

$$
(y, u) \leq \phi(x+u)-\phi(x) .
$$

Denote the Lipschitz function as $J_{n}$ and the maximal monotone graph which it is approximating as $J$. Thus $J$ denotes the ordered pairs $(x, y)$ which are of the form $(0, y)$ for $|y| \leq 1$ along with ordered pairs $(x, 1), x>0$ and ordered pairs $(x,-1)$ for $x<0$. The graph of $J$ is illustrated in the above picture and is a maximal monotone graph. Thus $J=\partial \phi$ where $\phi(r)=|r|$. As illustrated in the graph, $J_{n}$ is piecewise linear.

Let $\phi_{n}(r) \equiv \int_{0}^{r} J_{n}(s) d s$. It follows easily that $\phi_{n}(r) \rightarrow \phi(r)$ uniformly on $\mathbb{R}$. Also let $h \geq 0$ be progressively measurable and uniformly bounded by $M$ and let $u_{0} \in L^{2}(\Omega, W), u_{0}$ $\mathscr{F}_{0}$ measurable. Then from the above theorems, there exists a unique solution to the integral equation

$$
B u_{n}(t)-B u_{0}+\int_{0}^{t} A\left(s, u_{n}, \omega\right) d s+\int_{0}^{t} h(s, \omega) J_{n}\left(u_{n}\right) d s=B \int_{0}^{t} \Psi d W
$$

the last term equaling $\int_{0}^{t} \Phi d W$. The integral equation holds off a set of measure zero and is progressively measurable.

Then from the Ito formula, one obtains, using the monotonicity of $J_{n}$ an estimate in which $C$ does not depend on $n$

$$
\frac{1}{2} E\left\langle B u_{n}(t), u_{n}(t)\right\rangle-\frac{1}{2} E\left\langle B u_{0}, u_{0}\right\rangle+E \int_{0}^{t}\left\langle A u_{n}, u_{n}\right\rangle_{V} d s \leq C
$$

In particular, this holds for $n=1$. Therefore, adjusting the constant, it follows that

$$
\int_{\Omega}\left\langle B u_{1}(t), u_{1}(t)\right\rangle+\int_{\Omega} \int_{0}^{T}\left\|u_{1}\right\|_{V}^{p} d t d s \leq C
$$

Consequently, there exists a set of measure zero $N$ such that for $\omega \notin N$,

$$
\begin{equation*}
\left\langle B u_{1}(t), u_{1}(t)\right\rangle+\int_{0}^{T}\left\|u_{1}\right\|_{V}^{p} d t \leq C(\omega) \tag{76.7.64}
\end{equation*}
$$

From the integral equation, it follows that, enlarging $N$ by including countably many sets of measure zero, for $\omega \notin N$

$$
\begin{gathered}
B u_{n}(t)-B u_{1}(t)+\int_{0}^{t} A\left(s, u_{n}, \omega\right)-A\left(s, u_{1}, \omega\right) d s \\
\quad+\int_{0}^{t} h(s, \omega) J_{n}\left(u_{n}\right)-h(s, \omega) J_{1}\left(u_{1}\right) d s=0
\end{gathered}
$$

Now it is certainly true that $\left|J_{n}\left(u_{n}\right)-J_{1}\left(u_{n}\right)\right| \leq 2$. Thus

$$
\begin{gathered}
\int_{0}^{t}\left\langle h(s, \omega) J_{n}\left(u_{n}\right)-h(s, \omega) J_{1}\left(u_{1}\right), u_{n}-u_{1}\right\rangle d s \\
=\int_{0}^{t}\left\langle h(s, \omega) J_{n}\left(u_{n}\right)-h(s, \omega) J_{1}\left(u_{n}\right), u_{n}-u_{1}\right\rangle d s \\
+\int_{0}^{t}\left\langle h(s, \omega)\left(J_{1}\left(u_{n}\right)-J_{1}\left(u_{1}\right)\right), u_{n}-u_{1}\right\rangle d s \\
\geq-2 M \int_{0}^{t}\left|u_{n}-u_{1}\right| d s
\end{gathered}
$$

Therefore, from the Ito formula and for $\omega \notin N$,

$$
\begin{aligned}
& \frac{1}{2}\left\langle B u_{n}(t)-B u_{1}(t), u_{n}(t)-u_{1}(t)\right\rangle+\delta^{2} \int_{0}^{t}\left\|u_{n}-u_{1}\right\|_{V}^{p} d s \\
\leq & \int_{0}^{t} 2 M\left|u_{n}-u_{1}\right| d s \leq\left(2+\frac{1}{2} \int_{0}^{t}\left|u_{n}-u_{1}\right|^{2} d s\right) M \\
\leq & \left(2+\frac{1}{2} \int_{0}^{t}\left\langle B u_{n}-B u_{1}, u_{n}-u_{1}\right\rangle d s\right) M
\end{aligned}
$$

where $M$ is an upper bound to $h$. Then by Gronwall's inequality

$$
\frac{1}{2}\left\langle B u_{n}(t)-B u_{1}(t), u_{n}(t)-u_{1}(t)\right\rangle \leq 2 M e^{M T}
$$

Hence

$$
\frac{1}{2}\left\langle B u_{n}(t)-B u_{1}(t), u_{n}(t)-u_{1}(t)\right\rangle+\delta^{2} \int_{0}^{t}\left\|u_{n}-u_{1}\right\|_{V}^{p} d s \leq 2 M+T M 2 e^{T M}
$$

It follows from 76.7.64 that for all $\omega \notin N$ and adjusting the constant,

$$
\begin{equation*}
\left\langle B u_{n}(t), u_{n}(t)\right\rangle+\int_{0}^{T}\left\|u_{n}\right\|_{V}^{p} d s \leq C(\omega) \tag{76.7.65}
\end{equation*}
$$

for all $n$, where $C(\omega)$ depends only on $\omega$.
For $\omega \notin N$, the above estimate implies there exists a further subsequence, still called $n$ such that

$$
\begin{gathered}
B u_{n} \rightarrow B u \text { weak } * \text { in } L^{\infty}\left(0, T, W^{\prime}\right) \\
u_{n} \rightarrow u \text { weak } * \operatorname{in} L^{\infty}(0, T, H) \\
u_{n} \rightarrow u \text { weakly in } \mathscr{V}_{\omega}
\end{gathered}
$$

From the integral equation solved and the assumption that $A$ is bounded, it can also be assumed that

$$
\begin{gather*}
\left(B\left(u_{n}-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime} \rightarrow\left(B\left(u-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime} \text { weakly in } \mathscr{V}_{\omega}^{\prime}  \tag{76.7.66}\\
B u(0)=B u_{0} \\
A u_{n} \rightarrow \xi \text { weakly in } \mathscr{V}_{\omega}^{\prime}
\end{gather*}
$$

It is known that $u_{n}$ is bounded in $\mathscr{V}_{\omega}$. Also it is known that $\left(B\left(u_{n}-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime}$ is bounded in $\mathscr{V}_{\omega}^{\prime}$. Therefore, $B\left(u_{n}-\int_{0}^{(\cdot)} \Psi d W\right)$ satisfies a Holder condition into $V^{\prime}$. Since $\Psi$ is in $L^{\infty}, \int_{0}^{(\cdot)} \Psi d W$ satisfies a Holder condition, and so $B u_{n}$ satisfies a Holder condition into $V^{\prime}$ while $B u_{n}$ is bounded in $\mathscr{W}_{\omega}^{\prime}$. By compactness of the embedding of $V$ into $W$, it follows that $W^{\prime}$ embeds compactly into $V^{\prime}$. This is sufficient to conclude that $\left\{B u_{n}\right\}$ is precompact in $\mathscr{W}_{\omega}^{\prime}$. The proof is similar to one given by Lions. [91] page 57. See Theorem 69.5.6. Since $B$ is the Riesz map, this implies that $\left\{u_{n}\right\}$ is precompact in $\mathscr{W}_{\omega}$ and hence in $\mathscr{H}_{\omega}$.

Therefore, one can take a further subsequence and conclude that

$$
u_{n} \rightarrow u \text { strongly in } \mathscr{H}_{\omega} \equiv L^{2}\left([0, T], L^{2}(U)\right)
$$

Therefore, a further subsequence, still denoted by $n$ satisfies

$$
u_{n}(t) \rightarrow u(t) \text { in } L^{2}(U) \text { for a.e. } t
$$

We can also assume that

$$
J_{n}\left(u_{n}\right) \rightarrow \zeta \text { weak } * \operatorname{in} L^{\infty}\left(0, T, L^{\infty}(U)\right)
$$

From the integral equation solved,

$$
\begin{align*}
& \left\langle\left(B\left(u_{n}-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime}, u_{n}-u\right\rangle_{V_{\omega}} \\
& +\left\langle A\left(t, u_{n}\right)+h(t, \omega) J_{n}\left(u_{n}\right), u_{n}-u\right\rangle=0 \tag{76.7.67}
\end{align*}
$$

We claim that

$$
\int_{0}^{t}\left\langle\left(B\left(u_{n}-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime}-\left(B\left(u-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime}, u_{n}-u\right\rangle d s \geq 0
$$

The difficulty is that $\int_{0}^{(\cdot)} \Psi d W$ is only in $W$. To see that the conclusion is so, note that it is clear from a computation that

$$
\int_{0}^{t}\left\langle\begin{array}{c}
\frac{1-\tau(h)}{h}\left(B u_{n}-B \int_{0}^{(\cdot)} \Psi d W\right)  \tag{76.7.68}\\
-\frac{1-\tau(h)}{h}\left(B u-B \int_{0}^{(\cdot)} \Psi d W\right), u_{n}-u
\end{array}\right\rangle d s \geq 0
$$

Claim: The above is indeed nonnegative.
Proof: Denote by $q(t)$ the stochastic integral, $u_{n}$ as $u$ and $u$ as $v$ to save notation. Then the left side of the above equals

$$
\begin{aligned}
& \frac{1}{h} \int_{0}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& -\frac{1}{h} \int_{h}^{t}\langle B(u(s-h)-q(s-h))-B(v(s-h)-q(s-h)), u(s)-v(s)\rangle d s \\
& \geq \frac{1}{h} \int_{0}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& -\frac{1}{2 h} \int_{h}^{t}\left\langle\begin{array}{c}
B(u(s-h)-q(s-h))-B(v(s-h)-q(s-h)), \\
(u(s-h)-v(s-h))
\end{array}\right\rangle d s \\
& -\frac{1}{2 h} \int_{h}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& \geq \frac{1}{h} \int_{0}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& -\frac{1}{2 h} \int_{0}^{t-h}\langle B(u(s)-q(s))-B(v(s)-q(s)),(u(s)-v(s))\rangle d s \\
& -\frac{1}{2 h} \int_{h}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& =\frac{1}{h} \int_{t-h}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& +\frac{1}{h} \int_{0}^{t-h}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& -\frac{1}{2 h} \int_{0}^{t-h}\langle B(u-q)-B(v-q),(u-v)\rangle d s \\
& -\frac{1}{2 h} \int_{h}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s
\end{aligned}
$$

$$
\begin{aligned}
= & \frac{1}{h} \int_{t-h}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& +\frac{1}{2 h} \int_{0}^{t-h}\langle B(u-q)-B(v-q),(u-v)\rangle d s \\
& -\frac{1}{2 h} \int_{h}^{t-h}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& -\frac{1}{2 h} \int_{t-h}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
= & \frac{1}{2 h} \int_{t-h}^{t}\langle B(u-q)-B(v-q), u-v\rangle d s \\
& +\frac{1}{2 h} \int_{0}^{h}\langle B(u-q)-B(v-q),(u-v)\rangle d s
\end{aligned}
$$

which is nonnegative as can be seen by replacing $u-v$ with $(u-q)-(v-q)$ and using monotonicity of $B$.

Now pass to a limit in 76.7.68 as $h \rightarrow 0$ to get the desired inequality. Therefore, from 76.7.67,

$$
\lim \sup _{n \rightarrow \infty} \int_{0}^{T}\left\langle A\left(t, u_{n}\right)+h(t, \omega) J_{n}\left(u_{n}\right), u_{n}-u\right\rangle d t \leq 0
$$

From the above strong convergence, the left side equals

$$
\lim \sup _{n \rightarrow \infty} \int_{0}^{T}\left\langle A\left(t, u_{n}\right), u_{n}-u\right\rangle d t \leq 0
$$

It follows that for all $v \in \mathscr{V}_{\omega}$,

$$
\begin{aligned}
& \int_{0}^{T}\langle A(t, u), u-v\rangle d t \\
\leq & \lim _{n \rightarrow \infty} \inf _{n} \int_{0}^{T}\left\langle A\left(t, u_{n}\right), u_{n}-v\right\rangle d t \\
= & \lim \sup _{n \rightarrow \infty}\left[\int_{0}^{T}\left\langle A\left(t, u_{n}\right), u_{n}-u\right\rangle d t+\int_{0}^{T}\left\langle A\left(t, u_{n}\right), u-v\right\rangle d t\right] \\
\leq & \int_{0}^{T}\langle\xi, u-v\rangle d t
\end{aligned}
$$

Since $v$ is arbitrary, $A(\cdot, u)=\xi \in \mathscr{V}_{\omega}^{\prime}$. Passing to the limit in the integral equation yields

$$
B u(t)-B u_{0}+\int_{0}^{t} A(s, u) d s+\int_{0}^{t} h(s, \omega) \zeta(s, \omega) d s=\int_{0}^{t} \Phi d W
$$

What is $h(s, \omega) \zeta(s, \omega)$ ?

$$
\int_{0}^{T}\left\langle h(s, \omega) J_{n}\left(u_{n}(s)\right), v(s)-u_{n}(s)\right\rangle d s \leq \int_{0}^{T} h(s, \omega)\left(\phi_{n}(v)-\phi_{n}\left(u_{n}\right)\right) d s
$$

Passing to the limit and using the strong convergence described above along with the uniform convergence of $\phi_{n}$ to $\phi$,

$$
\int_{0}^{T}(h(s, \omega) \zeta(s), v(s)-u(s))_{H} d s \leq \int_{0}^{T} h(s, \omega)(\phi(v(s))-\phi(u(s))) d s
$$

Hence,

$$
\int_{0}^{T}(h(s, \omega) \phi(v(s))-h(s, \omega) \phi(u(s)))-(h(s, \omega) \zeta(s), v(s)-u(s))_{H} d s \geq 0
$$

for any choice of $v \in \mathscr{H}_{\omega}$. It follows that for a.e. $s, h(s, \omega) \zeta(s) \in \partial_{v}(h(s, \omega) \phi(u(s)))$.
This has shown that for each $\omega \notin N$, there exists a solution to the integral equation

$$
\begin{equation*}
B u(t)-B u_{0}+\int_{0}^{t} A(s, u) d s+\int_{0}^{t} h(s, \omega) \zeta(s, \omega) d s=\int_{0}^{t} \Phi d W \tag{76.7.69}
\end{equation*}
$$

where for a.e. $s, h(s, \omega) \zeta(s, \omega) \in \partial_{v}(h(s, \omega) \phi(u(s)))$. Suppose you have two such solutions $\left(u_{1}, \zeta_{1}\right)$ and $\left(u_{2}, \zeta_{2}\right)$. Then

$$
B u_{1}(t)-B u_{2}(t)+\int_{0}^{t} A\left(s, u_{1}\right)-A\left(s, u_{2}\right) d s+\int_{0}^{t} h(s, \omega)\left(\zeta_{1}(s, \omega)-\zeta_{2}(s, \omega)\right) d s=0
$$

Then from monotonicity of the subgradient it follows that $u_{1}=u_{2}$. Then the two integral equations yield that for a.e. $t$

$$
\begin{aligned}
& \left(B\left(u_{1}-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime}(t)+A\left(s, u_{1}(t)\right)+h(t, \omega) \zeta_{1}(t, \omega)= \\
= & \left(B\left(u_{2}-\int_{0}^{(\cdot)} \Psi d W\right)\right)^{\prime}(t)+A\left(s, u_{2}(t)\right)+h(t, \omega) \zeta_{2}(t, \omega)=0
\end{aligned}
$$

Therefore, for a.e. $t, h(t, \omega) \zeta_{1}(t, \omega)=h(t, \omega) \zeta_{2}(t, \omega)$. Thus the solution to the integral equation for each $\omega$ off a set of measure zero is unique.

At this point it is not clear that $(t, \omega) \rightarrow u(t, \omega)$ is progressively measurable. We claim that for $\omega \notin N$ it is not necessary to take a subsequence in the above. This is because the above argument shows that if $u_{n}$ fails to converge weakly, then there would exist two subsequences converging weakly to two different solutions to the integral equation which would contradict uniqueness.

Therefore, for $\omega \notin N, u_{n}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $\mathscr{V}_{\omega}$ for a single sequence. Using the estimate 76.3.24 it also follows that for a further subsequence still denoted as $u_{n}$,

$$
u_{n} \rightharpoonup \bar{u} \text { in } L^{p}([0, T] \times \Omega ; V)
$$

where the measurable sets are just the product measurable sets $\mathscr{B}([0, T]) \times \mathscr{F}_{T}$. By Lemma 76.3.4 for $\omega$ off a set of measure zero, $u(\cdot, \omega)=\bar{u}(\cdot, \omega)$ in $\mathscr{V}_{\omega}$ where $\bar{u}$ is progressively measurable. It follows that in all of the above, we could substitute $\bar{u}$ for $u$ at least for $\omega$ off a single set of measure zero. Thus $u$ can be assumed progressively measurable. The above argument along with technical details related to exponential shift considerations proves the following theorem.

Theorem 76.7.2 In the situation of Corollary 76.4.9 where $V$ is a closed subspace of $W^{\sigma, p}(U), \sigma>1$ and $W$ is as described above for $U$ a bounded open set, $u_{0} \in L^{2}(\Omega, W), u_{0}$ $\mathscr{F}_{0}$ measurable. Suppose $\lambda I+A(t, u, \omega)$ satisfies

$$
\langle\lambda I+A(t, u, \omega)-(\lambda I+A(t, v, \omega)), u-v\rangle \geq \delta^{2}\|u-v\|_{V}^{p}
$$

for all $\lambda$ large enough. Also assume $\Phi \in L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ with $\Phi=B \Psi$ where

$$
\Psi \in L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)
$$

and progressively measurable. Then there exists a unique solution to the integral equation

$$
\begin{equation*}
B u(t)-B u_{0}+\int_{0}^{t} A(s, u) d s+\int_{0}^{t} h(s, \omega) \zeta(s, \omega) d s=\int_{0}^{t} \Phi d W \tag{76.7.70}
\end{equation*}
$$

where for a.e. $s, h(s, \omega) \zeta(s, \omega) \in \partial_{u}(h(s, \omega) \phi(u(s)))$ where $\phi(r) \equiv|r|$. The symbol $\partial_{u}$ is the subgradient of $\phi(u)$. Written in terms of inclusions, there exists a set of measure zero such that off this set,

$$
\begin{aligned}
\left(B\left(u-\int_{0}^{(\cdot)} \Phi d W\right)\right)^{\prime}+A(t, u) & \in \partial_{u}(h(t, \omega) \phi(u(s))) \text { a.e. } t \\
u(0) & =u_{0}
\end{aligned}
$$

Note that one can replace

$$
\Phi \in L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)
$$

with $\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ along with an assumption that $t \rightarrow \Phi(t, \omega)$ is continuous. This can be done by defining a stopping time

$$
\tau_{n} \equiv \inf \{t:\|\Phi(t)\|>n\}
$$

Then from the above example, there exists a solution to the integral equation off a set of measure zero

$$
B u_{n}(t)-B u_{0}+\int_{0}^{t} A\left(s, u_{n}\right) d s+\int_{0}^{t} h(s, \omega) \zeta_{n}(s, \omega) d s=\int_{0}^{t \wedge \tau_{n}} \Phi d W
$$

Since $\Phi$ is a continuous process, $\tau_{n}=\infty$ for all $n$ large enough. Hence, one can replace the above with the desired integral equation. Of course the size of $n$ depends on $\omega$, but we can define

$$
u(t, \omega)=\lim _{n \rightarrow \infty} u_{n}(t, \omega)
$$

because by uniqueness which comes from monotonicity, if for a particular $\omega$, both $n, k$ are sufficiently large, then $u_{n}=u_{k}$. Thus $u$ is progressively measurable and is the desired solution.

Next we show that the above theory can also be used as a starting point for some second order in time problems. Consider a beam which has a point mass of mass $m$ attached to
one end. Suppose for sake of illustration that the left end is clamped, $u(0, t)=u_{x}(0, t)=0$, while the right end which has the attached mass is free to move, $u_{x}(1, t)=0$, and the beam occupies the interval $[0,1]$ in material coordinates. Then the stress is $\sigma=-u_{x x x}$ and balance of momentum is

$$
u_{t t}=\sigma_{x}+f
$$

where $f$ is a body force. Thus, letting

$$
w \in V \equiv\left\{w \in H^{2}(0,1): w(0)=w_{x}(0)=0, w_{x}(1)=0\right\}
$$

be a test function,

$$
\begin{aligned}
\int_{0}^{1} u_{t t} w d x & =\left.\sigma w\right|_{0} ^{1}+\int_{0}^{1}(-\sigma) w_{x} d x+\int_{0}^{1} f w d x \\
& =-m u_{t t}(1, t) w(1, t)+\int_{0}^{1} u_{x x x} w_{x} d x+\int_{0}^{1} f w d x
\end{aligned}
$$

Doing another integration by parts and using the boundary conditions, it follows that an appropriate variational formulation for this problem is

$$
\int_{0}^{1} u_{t t} w d x+m \gamma_{1} u_{t t} \gamma_{1} w+\int_{0}^{1} u_{x x} w_{x x} d x=\int_{0}^{1} f w d x
$$

where here $\gamma_{1}$ is the trace map on the right end.
Letting

$$
u(t)=u_{0}+\int_{0}^{t} v(s) d s
$$

where $u(0, t)=u_{0}$, we can write the above variational equation in the form

$$
(B v)^{\prime}+A u=f, B v(0)=B v_{0}
$$

where we assume that $v_{0} \in W$ where $W$ is the closure of $V$ in $H^{1}(0,1)$ and the operators are given by

$$
\begin{aligned}
& B: \quad W \rightarrow W^{\prime},\langle B u, w\rangle \equiv \int_{0}^{1} u w d x+m \gamma_{1} u \gamma_{1} w \\
& A: \quad V \rightarrow V^{\prime},\langle A u, w\rangle \equiv \int_{0}^{1} u_{x x} w_{x x} d x
\end{aligned}
$$

Thus in terms of an integral equation, this would be of the form

$$
B v(t)-B v_{0}+\int_{0}^{t} A(u) d s=\int_{0}^{t} f d s
$$

This suggests a stochastic version of the form

$$
B v(t)-B v_{0}+\int_{0}^{t} A(u) d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W
$$

where $\Phi \in L^{\infty}\left((0, T) \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ for $H=L^{2}(0,1)$. As in the previous example, simple considerations involving maximal monotone operators imply that there exists $\Psi \in$ $L^{\infty}\left((0, T) \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)$ such that $\Phi=B \Psi$. We also assume that $f \in \mathscr{V}^{\prime}$ and $u_{0}, v_{0}$ are in $L^{2}(\Omega, V)$ and $L^{2}(\Omega, W)$ respectively, both being $\mathscr{F}_{0}$ measurable. The above equation does not fit the general theory developed earlier because it is second order in time and is a stochastic version of a hyperbolic equation rather than a parabolic one. We consider it using a parabolic regularization which can be studied with the above general theory along with a simple fixed point argument.

Consider the approximate problem which is to find a solution to

$$
\begin{equation*}
B v(t)-B v_{0}+\varepsilon \int_{0}^{t} A v d s+\int_{0}^{t} A(u) d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W \tag{76.7.71}
\end{equation*}
$$

where $u$ is given above as an integral of $v$. First we argue that there exists a unique solution to the above integral equation and then we pass to a limit as $\varepsilon \rightarrow 0$. Let $u \in \mathscr{V}$ be given.

From Corollary 76.4.9 there exists a unique solution $v$ to 76.7.71. Now suppose $u_{1}, u_{2}$ are two given in $\mathscr{V}$ and denote by $v_{i}$ the corresponding $v$ which solves the above. Then from the Ito formula or standard considerations,

$$
\begin{aligned}
& \frac{1}{2} E\left\langle B\left(v_{1}(t)-v_{2}(t)\right), v_{1}(t)-v_{2}(t)\right\rangle+\varepsilon E \int_{0}^{t}\left\|v_{1}-v_{2}\right\|_{V}^{2} d s \\
\leq & \frac{\varepsilon}{2} E \int_{0}^{t}\left\|v_{1}-v_{2}\right\|_{V}^{2} d s+C_{\varepsilon} E \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{V}^{2} d s
\end{aligned}
$$

Now define a mapping $\theta$ from $\mathscr{V}$ to $\mathscr{V}$ as follows. Begin with $v$ then obtain

$$
\begin{equation*}
u(t) \equiv u_{0}+\int_{0}^{t} v(s) d s \tag{76.7.72}
\end{equation*}
$$

Use this $u$ in 76.7.71. Then $\theta v$ is the solution to 76.7 .71 which corresponds to $u$. Then the above inequality shows that

$$
\begin{gathered}
\int_{0}^{t} \int_{\Omega}\left\|\theta v_{1}(s)-\theta v_{2}(s)\right\|^{2} d P d s \leq \frac{C_{\varepsilon}}{\varepsilon} \int_{0}^{t} \int_{\Omega}\left\|u_{1}-u_{2}\right\|_{V}^{2} d P d s \\
\leq \frac{C_{\varepsilon}}{\varepsilon} C_{T} \int_{0}^{t} \int_{0}^{s} \int_{\Omega}\left\|v_{1}(r)-v_{2}(r)\right\|_{V}^{2} d P d r d s
\end{gathered}
$$

It follows that a high enough power of $\theta$ is a contraction map on $L^{2}\left(0, T, L^{2}(\Omega, V)\right)$ and so there exists a unique fixed point. This yields a unique solution to the above approximate problem 76.7.71 in which $u, v$ are related by 76.7.72.

Next we let $\varepsilon \rightarrow 0$. Index the above solution with $\varepsilon$. By the Ito formula again,

$$
\begin{gathered}
\frac{1}{2} E\left\langle B v_{\varepsilon}(t), v_{\varepsilon}(t)\right\rangle-\frac{1}{2} E\left\langle B v_{0}, v_{0}\right\rangle+\varepsilon \int_{0}^{t} E\left\|v_{\varepsilon}\right\|_{V}^{2} d s \\
\quad+\frac{1}{2} E\left\|u_{\varepsilon}(t)\right\|_{V}^{2}-\frac{1}{2} E\left\|u_{0}\right\|_{V}^{2}=\int_{0}^{t} E\left\langle f, v_{\varepsilon}\right\rangle d s
\end{gathered}
$$

Then one can obtain an estimate and pass to a limit as $\varepsilon \rightarrow 0$ obtaining the following convergences.

$$
\begin{gathered}
\varepsilon v_{\varepsilon} \rightarrow 0 \text { strongly in } \mathscr{V} \\
B v_{\varepsilon} \rightarrow B v \text { weak } * \operatorname{in} L^{\infty}\left(0, T, L^{2}\left(\Omega, W^{\prime}\right)\right) \\
u_{\varepsilon}(t) \rightarrow u(t) \text { weak } * \text { in } L^{\infty}\left(0, T, L^{2}(\Omega, V)\right)
\end{gathered}
$$

Then one can simply pass to a limit in the approximate integral equation and obtain, thanks to linearity considerations, that

$$
\begin{equation*}
B v(t)-B v_{0}+\int_{0}^{t} A(u) d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W, u(t)=u_{0}+\int_{0}^{t} v(s) d s \tag{76.7.73}
\end{equation*}
$$

the equation holding in $\mathscr{V}^{\prime}$. Thus for a.e. $\omega$, the above holds for a.e. $t$. It is possible to work harder and have the equation holding for all $t$. This involves using the other form of the Ito formula, estimating for a fixed $\omega$ as done above and then arguing that by uniqueness one can use a single subsequence which works independent of $\omega$.

Example 76.7.3 Let $u_{0} \in L^{2}(\Omega, V)$ where $V$ is described above and let $v_{0} \in L^{2}(\Omega, W)$ for $W$ described above. Let both of these initial conditions be progressively measurable. Also let $f \in \mathscr{V}^{\prime}$ and $\Phi \in L^{\infty}\left((0, T) \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Then there exists a unique solution to the the integral equation 76.7 .73 which can be written in the form

$$
B u_{t}(t)-B v_{0}+\int_{0}^{t} A\left(u_{0}+\int_{0}^{t} u_{t}(r) d r\right) d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W
$$

Note that a more standard model involves no point mass at the tip of the beam. This would be done the same way but it would not require the generalized Ito formula presented earlier. A more standard version would work.

One can find many other examples where this generalized Ito formula is a useful tool to study various kinds of stochastic partial differential equations. We have presented five examples above in which it was helpful to have the extra generality.

## Chapter 77

## Stochastic Inclusions

### 77.1 The General Context

The situation is as follows. There are spaces $V \subseteq W$ where $V, W$ are reflexive separable Banach spaces. It is assumed that $V$ is dense in $W$. Define the space for $p>1$

$$
\mathscr{V} \equiv L^{p}([0, T] ; V)
$$

where in each case, the $\sigma$ algebra of measurable sets will be $\mathscr{B}([0, T])$ the Borel measurable sets. Thus, from the Riesz representation theorem,

$$
\mathscr{V}^{\prime}=L^{p^{\prime}}\left([0, T] ; V^{\prime}\right),
$$

We also assume $(\Omega, \mathscr{F}, P)$ is a complete probability space. That is, if $P(E)=0$ and $F \subseteq E$, then $F \in \mathscr{F}$. Also

$$
V \subseteq W, \quad W^{\prime} \subseteq V^{\prime}
$$

$B(\omega)$ will be a linear operator, $B(\omega): W \rightarrow W^{\prime}$ which satisfies

1. $\langle B(\omega) x, y\rangle=\langle B(\omega) y, x\rangle$
2. $\langle B(\omega) x, x\rangle \geq 0$ and equals 0 if and only if $x=0$.
3. $\omega \rightarrow B(\omega)$ is a measurable $\mathscr{L}\left(W, W^{\prime}\right)$ valued function.

In the above formulae, $\langle\cdot, \cdot\rangle$ denotes the duality pairing of the Banach space $W$, with its dual space. We will use this notation in the present paper, the exact specification of which Banach space being determined by the context in which this notation occurs.

For example, you could simply take $W=H=H^{\prime}$ and $B$ the identity and consider a standard Gelfand triple where $H$ is a Hilbert space and $B$ equal to the identity. An interesting feature is the requirement that $B(\omega)$ be one to one. It would be interesting to include the case of degenerate $B$, but $B$ one to one includes the case of most interest just mentioned. Also a more general set of assumptions will allow the inclusion of this case of degenerate $B(\omega)$ also.

We assume always that the norm on the various reflexive Banach spaces is strictly convex.

### 77.2 Some Fundamental Theorems

The following fundamental result will be very useful. It says essentially that if $(B u)^{\prime} \in$ $L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ and $u \in L^{p}(0, T ; V)$ then the map $u \rightarrow B u(t)$ is continuous as a map from

$$
X \equiv\left\{u \in L^{p}([0, T] ; V):(B u)^{\prime} \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)\right\}
$$

having norm equal to

$$
\|u\|_{X} \equiv\|u\|_{L^{p}(0, T, V)}+\left\|(B u)^{\prime}\right\|_{L^{p^{\prime}}\left(0, T ; V^{\prime}\right)}
$$

to $W^{\prime}$. There is also a convenient integration by parts formula, Theorem 34.4.3. For convenience, the dependence of $B$ on $\omega$ is often suppressed. This is not a problem because the entire approach will be to consider the situation for fixed $\omega$.

Theorem 77.2.1 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, and let $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ and

$$
\begin{equation*}
B u(t)=B u_{0}+\int_{0}^{t} Y(s) d s \text { in } V^{\prime}, u_{0} \in W, B u(t)=B(u(t)) \text { for a.e. } t \tag{77.2.1}
\end{equation*}
$$

Thus $Y=(B u)^{\prime}$ as a weak derivative in the sense of $V^{\prime}$ valued distributions. It is known that $u \in L^{p}(0, T, V)$ for $p>1$. Then $t \rightarrow B u(t)$ is continuous into $W^{\prime}$ for $t$ off a set of measure zero $N$ and also there exists a continuous function $t \rightarrow\langle B u, u\rangle(t)$ such that for all $t \notin N,\langle B u, u\rangle(t)=\langle B(u(t)), u(t)\rangle, B u(t)=B(u(t))$, and for all $t$,

$$
\frac{1}{2}\langle B u, u\rangle(t)=\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\langle Y(s), u(s)\rangle d s
$$

Note that the formula 77.2 .1 shows that $B u_{0}=B u(0)$. Also it shows that $t \rightarrow\langle B u, u\rangle(t)$ is continuous. To emphasize this a little more, $B u$ is the name of a function. $B u(t)=$ $B(u(t))$ for a.e. $t$ and $t \rightarrow B u(t)$ is continuous into $V^{\prime}$ on $[0, T]$ because of the integral equation.

Theorem 77.2.2 In the above corollary, the map $u \rightarrow B u(t)$ is continuous as a map from $X$ to $V^{\prime}$. Also if $Y$ denotes those $f \in L^{p}([0, T] ; V)$ for which $f^{\prime} \in L^{p}([0, T] ; V)$, so that $f$ has a representative such that $f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s$, then if $\|f\|_{Y} \equiv\|f\|_{L^{p}([0, T] ; V)}+$ $\left\|f^{\prime}\right\|_{L^{p}([0, T] ; V)}$ the map $f \rightarrow f(t)$ is continuous.

Proof: First, why is $u \rightarrow B u(0)$ continuous? Say $u, v \in X$ and say $p \geq 2$ first.

$$
B u(t)-B v(t)=B u(0)-B v(0)+\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s
$$

and so,

$$
\begin{gathered}
\left(\int_{0}^{T}\|B u(0)-B v(0)\|_{V^{\prime}}^{p^{\prime}} d t\right)^{1 / p^{\prime}} \leq\left(\int_{0}^{T}\|B u(t)-B v(t)\|_{V^{\prime}}^{p^{\prime}} d t\right)^{1 / p^{\prime}} \\
+\left(\int_{0}^{T}\left\|\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s\right\|^{p^{\prime}} d t\right)^{1 / p^{\prime}}
\end{gathered}
$$

and so

$$
\begin{gathered}
\|B u(0)-B v(0)\|_{V^{\prime}} T^{1 / p^{\prime}} \leq \\
\left(\|B\|\|u-v\|_{L^{p^{\prime}}([0, T] ; V)}+T^{1 / p^{\prime}}\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)}\right) \\
\leq C(\|B\|, T)\|u-v\|_{X}
\end{gathered}
$$

Thus $u \rightarrow B u(0)$ is continuous into $V^{\prime}$. If $p<2$, then you do something similar.

$$
\begin{gathered}
\left(\int_{0}^{T}\|B u(0)-B v(0)\|_{V^{\prime}}^{p} d t\right)^{1 / p} \leq\left(\int_{0}^{T}\|B u(t)-B v(t)\|_{V^{\prime}}^{p} d t\right)^{1 / p} \\
+\left(\int_{0}^{T}\left\|\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s\right\|^{p} d t\right)^{1 / p} \\
\|B u(0)-B v(0)\|_{V^{\prime}} T^{1 / p} \leq\|B\|\|u-v\|_{L^{p}}+C(T)\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)} \\
\leq C(\|B\|, T)\|u-v\|_{X}
\end{gathered}
$$

However, one could just as easily have done this for an arbitrary $s<T$ by repeating the argument for

$$
B u(t)=B u(s)+\int_{s}^{t}(B u)^{\prime}(r) d r
$$

Thus this mapping is certainly continuous into $V^{\prime}$. The last assertion is similar.
Also of use will be the following generalization of the Ascoli Arzela theorem. [117], Theorem 69.5.4.

Theorem 77.2.3 Let $q>1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$
\left\{u \text { such that }\|u(t)\|_{E} \leq R \text { for all } t \in[a, b], \text { and }\|u(s)-u(t)\|_{X} \leq R|t-s|^{1 / q}\right\}
$$

Thus $S$ is bounded in $L^{\infty}(0, T, E)$ and in addition, the functions are uniformly Holder continuous into $X$. Then $S \subseteq C([a, b] ; W)$ and if $\left\{u_{n}\right\} \subseteq S$, there exists a subsequence, $\left\{u_{n_{k}}\right\}$ which converges to a function $u \in C([a, b] ; W)$ in the following way.

$$
\lim _{k \rightarrow \infty}\left\|u_{n_{k}}-u\right\|_{\infty, W}=0
$$

Next is a major measurable selection theorem which forms an essential part of showing the existence of measurable solutions. See Theorem 70.2.1. The following is not dependent on there being a measure but in the applications there is typically a probability measure and often a set of measure zero which occurs in a natural way so an exceptional set of measure zero is included in the statement of the theorem but it has absolutely nothing to do with a set of measure zero as will be seen by just letting the exceptional set be $\emptyset$.

Theorem 77.2.4 Let $V$ be a reflexive separable Banach space with dual $V^{\prime}$, and let $p, p^{\prime}$ be such that $p>1$ and $\frac{1}{p}+\frac{1}{p^{\prime}}=1$. Let the functions $t \rightarrow u_{n}(t, \omega)$, for $n \in \mathbb{N}$, be in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ and $(t, \omega) \rightarrow u_{n}(t, \omega)$ be $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable into $V^{\prime}$. Suppose there is a set of measure zero $N \subseteq \Omega$ such that if $\omega \notin N$, then

$$
\sup _{t \in[0, T]}\left\|u_{n}(t, \omega)\right\|_{V^{\prime}} \leq C(\omega),
$$

for all $n$. Also, suppose for each $\omega \notin N$, each subsequence of $\left\{u_{n}\right\}$ has a further subsequence that converges weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ to $v(\cdot, \omega) \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ such that the function $t \rightarrow v(t, \omega)$ is weakly continuous into $V^{\prime}$.

Then, there exists a product measurable function $u$ such that $t \rightarrow u(t, \omega)$ is weakly continuous into $V^{\prime}$ and for each $\omega \notin N$, a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$.

We prove the theorem in steps given below. Let $X=\prod_{k=1}^{\infty} C([0, T])$ and note that when it is equipped with the product topology, then one can consider $X$ as a metric space using the metric

$$
d(\mathbf{f}, \mathbf{g}) \equiv \sum_{k=1}^{\infty} 2^{-k} \frac{\left\|f_{k}-g_{k}\right\|}{1+\left\|f_{k}-g_{k}\right\|}
$$

where $\mathbf{f}=\left(f_{1}, f_{2}, \ldots\right), \mathbf{g}=\left(g_{1}, g_{2}, \ldots\right) \in X$, and the norm is the maximum norm in $C([0, T])$. With this metric, $X$ is complete and separable.

Lemma 77.2.5 Let $\left\{\mathbf{f}_{n}\right\}$ be a sequence in $X$ and suppose that each one of the components $f_{n k}$ is bounded by $C=C(k)$ in $C^{0,1}([0, T])$. Then, there exists a subsequence $\left\{\mathbf{f}_{n_{j}}\right\}$ that converges to some $\mathbf{f} \in X$ as $n_{j} \rightarrow \infty$. Thus, $\left\{\mathbf{f}_{n}\right\}$ is pre-compact in $X$.

Proof: By the Ascoli-Arzelà theorem, there exists a subsequence $\left\{\mathbf{f}_{n_{1}}\right\}$ such that the sequence of the first components $f_{n_{1} 1}$ converges in $C([0, T])$. Then, taking a subsequence, one can obtain $\left\{n_{2}\right\}$ a subsequence of $\left\{n_{1}\right\}$ such that both the first and second components of $\mathbf{f}_{n_{2}}$ converge. Continuing in this way one obtains a sequence of subsequences, each a subsequence of the previous one such that $\mathbf{f}_{n_{j}}$ has the first $j$ components converging to functions in $C([0, T])$. Therefore, the diagonal subsequence has the property that it has every component converging to a function in $C([0, T])$. The resulting function is $\mathbf{f} \in$ $\prod_{k} C([0, T])$.

Now, for $m \in \mathbb{N}$ and $\phi \in V$, define $l_{m}(t) \equiv \max (0, t-(1 / m))$ and

$$
\psi_{m, \phi}: L^{p^{\prime}}\left([0, T] ; V^{\prime}\right) \rightarrow C([0, T])
$$

by

$$
\psi_{m, \phi} u(t) \equiv \int_{0}^{T}\left\langle m \phi \mathscr{X}_{\left[l_{m}(t), t\right]}(s), u(s)\right\rangle_{V} d s=m \int_{l_{m}(t)}^{t}\langle\phi, u(s)\rangle_{V} d s
$$

Here, $\mathscr{X}_{\left[l_{m}(t), t\right]}(\cdot)$ is the indicator function of the interval $\left[l_{m}(t), t\right]$ and $\langle\cdot, \cdot\rangle_{V}=\langle\cdot, \cdot\rangle_{V}$ is the duality pairing between $V$ and $V^{\prime}$.

Let $\mathscr{D}=\left\{\phi_{r}\right\}_{r=1}^{\infty}$ denote a countable dense subset of $V$. Then the pairs $(\phi, m)$ for $\phi \in \mathscr{D}$ and $m \in \mathbb{N}$ form a countable set. Let $\left(m_{k}, \phi_{r_{k}}\right)$ denote an enumeration of the pairs $(m, \phi) \in \mathbb{N} \times \mathscr{D}$. To simplify the notation, we set

$$
f_{k}(u)(t) \equiv \psi_{m_{k}, \phi_{r_{k}}}(u)(t)=m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u(s)\right\rangle_{V} d s
$$

For fixed $\omega \notin N$ and $k$, the functions $\left\{t \rightarrow f_{k}\left(u_{j}(\cdot, \omega)\right)(t)\right\}_{j}$ are uniformly bounded and equicontinuous because they are in $C^{0,1}([0, T])$. Indeed, we have for $\omega \notin N$,

$$
\left|f_{k}\left(u_{j}(\cdot, \omega)\right)(t)\right|=\left|m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V} d s\right| \leq C(\omega)\left\|\phi_{r_{k}}\right\|_{V}
$$

and for $t \leq t^{\prime}$

$$
\begin{aligned}
& \left|f_{k}\left(u_{j}(\cdot, \omega)\right)(t)-f_{k}\left(u_{j}(\cdot, \omega)\right)\left(t^{\prime}\right)\right| \\
\leq & \left|m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V} d s-m_{k} \int_{l_{m_{k}}\left(t^{\prime}\right)}^{t^{\prime}}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V} d s\right| \\
\leq & 2 m_{k}\left|t^{\prime}-t\right| C(\omega)\left\|\phi_{r_{k}}\right\|_{V^{\prime}}
\end{aligned}
$$

By Lemma 77.2.5, the set of functions $\left\{\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right\}_{j=n}^{\infty}$ is pre-compact in $X=$ $\prod_{k} C([0, T])$. We now define a set valued map $\Gamma^{n}: \Omega \rightarrow X$ by

$$
\Gamma^{n}(\omega) \equiv \overline{\cup_{j \geq n}\left\{\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right\}}
$$

where the closure is taken in $X$. Then $\Gamma^{n}(\omega)$ is the closure of a pre-compact set in $X$ and so $\Gamma^{n}(\omega)$ is compact in $X$. From the definition, a function $\mathbf{f}$ is in $\Gamma^{n}(\omega)$ if and only if $d\left(\mathbf{f}, \mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(w_{l}\right)\right) \rightarrow 0$ as $l \rightarrow \infty$, where each $w_{l}$ is one of the $u_{j}(\cdot, \omega)$ for $j \geq n$. In the topology on $X$, this happens iff for every $k$,

$$
f_{k}(t)=\lim _{l \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) w_{l}(s, \omega)\right\rangle_{V} d s
$$

where the limit is the uniform limit in $t$.
Lemma 77.2.6 The mapping $\omega \rightarrow \Gamma^{n}(\omega)$ is an $\mathscr{F}$ measurable set-valued map with values in $X$. If $\sigma$ is a measurable selection, then for each $t, \omega \rightarrow \sigma(t, \omega)$ is $\mathscr{F}$ measurable and $(t, \omega) \rightarrow \sigma(t, \omega)$ is $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable.

We note that if $\sigma$ is a measurable selection then $\sigma(\omega) \in \Gamma^{n}(\omega)$, so $\sigma=\sigma(\cdot, \omega)$ is a continuous function. To have $\sigma$ measurable would mean that $\sigma_{k}^{-1}($ open $) \in \mathscr{F}$, where the open set is in $C([0, T])$.

Proof: Let $O$ be a basic open set in $X$. Then $O=\prod_{k=1}^{\infty} O_{k}$, where $O_{k}$ is a proper open set of $C([0, T])$ only for $k \in\left\{k_{1}, \cdots, k_{r}\right\}$. Thus there is a proper open set in these positions and in every other position the open set is the whole space $C([0, T])$. We need to show that

$$
\Gamma^{n-}(O) \equiv\left\{\omega: \Gamma^{n}(\omega) \cap O \neq \emptyset\right\} \in \mathscr{F}
$$

Now, $\Gamma^{n-}(O)=\cap_{i=1}^{r}\left\{\omega: \Gamma^{n}(\omega)_{k_{i}} \cap O_{k_{i}} \neq \emptyset\right\}$, so we consider whether

$$
\begin{equation*}
\left\{\omega: \Gamma^{n}(\omega)_{k_{i}} \cap O_{k_{i}} \neq \emptyset\right\} \in \mathscr{F} . \tag{77.2.2}
\end{equation*}
$$

From the definition of $\Gamma^{n}(\omega)$, this is equivalent to the condition that

$$
f_{k_{i}}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)=\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)\right)_{k_{i}} \in O_{k_{i}}
$$

for some $j \geq n$, and so the set in 77.2.2 is of the form

$$
\cup_{j=n}^{\infty}\left\{\omega:\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)\right)_{k_{i}} \in O_{k_{i}}\right\} .
$$

Now $\omega \rightarrow\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)\right)_{k_{i}}$ is $\mathscr{F}$ measurable into $C([0, T])$ and so the above set is in $\mathscr{F}$. To see this, let $g \in C([0, T])$ and consider the inverse image of the ball with radius $r$ and center $g$,

$$
B(g, r)=\left\{\omega:\left\|\left(\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}}-g\right\|_{C([0, T])}<r\right\} .
$$

By continuity considerations,

$$
\begin{aligned}
& \left\|\left(\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}}-g\right\|_{C([0, T])} \\
= & \sup _{t \in \mathbb{Q} \cap[0, T]}\left|\left(\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(t, \omega)\right)\right)_{k_{i}}-g(t)\right|,
\end{aligned}
$$

which is the sup over countably many $\mathscr{F}$ measurable functions. Thus, it is $\mathscr{F}$ measurable. Since every open set is the countable union of such balls, it follows that the claim about $\mathscr{F}$ measurability is valid. Hence, $\Gamma^{n-}(O)$ is $\mathscr{F}$ measurable whenever $O$ is a basic open set.

Now, $X$ is a separable metric space and so every open set is a countable union of these basic sets. Let $U \subseteq X$ be open with $U=\cup_{l=1}^{\infty} O_{l}$ where $O_{l}$ is a basic open set as above. Then,

$$
\Gamma^{n-}(U)=\cup_{l=1}^{\infty} \Gamma^{n-}\left(O_{l}\right) \in \mathscr{F} .
$$

The existence of a measurable selection follows from the standard theory of measurable multi-functions [10, 70] see [70] starting on Page 141 for all the necessay stuff on measurable multifunctions or Section 48. If $\sigma$ is one of these measurable selections, the evaluation at $t$ is $\mathscr{F}$ measurable. Thus, $\omega \rightarrow \sigma(t, \omega)$ is $\mathscr{F}$ measurable with values in $\mathbb{R}^{\infty}$. Also, $t \rightarrow \sigma(t, \omega)$ is continuous, and so it follows that in fact $\sigma$ is product measurable as claimed.

Definition 77.2.7 Let $\Gamma(\omega) \equiv \cap_{n=1}^{\infty} \Gamma^{n}(\omega)$.
Lemma 77.2.8 $\Gamma$ is a nonempty $\mathscr{F}$ measurable set-valued function with values in compact subsets of $X$. There exists a measurable selection $\gamma$ such that $(t, \omega) \rightarrow \gamma(t, \omega)$ is $\mathscr{P}$ measurable. Also, for each $\omega$, there exists a subsequence, $u_{n(\omega)}(\cdot, \omega)$ such that for each $k$,

$$
\begin{aligned}
\gamma_{k}(t, \omega) & =\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(t, \omega)\right)_{k} \\
& =\lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(s, \omega)\right\rangle_{V} d s .
\end{aligned}
$$

Proof: From the definition of $\Gamma(\omega)=\cap_{n=1}^{\infty} \Gamma^{n}(\omega)$ it follows that $\omega \rightarrow \Gamma(\omega)$ is a compact set-valued map in $X$ and is nonempty because each $\Gamma^{n}(\omega)$ is nonempty and compact, and the $\Gamma^{n}(\omega)$ are nested. We next show that $\omega \rightarrow \Gamma(\omega)$ is $\mathscr{F}$ measurable. Indeed, each $\Gamma^{n}$ is compact valued and $\mathscr{F}$ measurable so, if $F$ is closed,

$$
\Gamma(\omega) \cap F=\cap_{n=1}^{\infty} \Gamma^{n}(\omega) \cap F
$$

and the left-hand side is not empty if and only if each $\Gamma^{n}(\omega) \cap F \neq \emptyset$. Thus, for $F$ closed,

$$
\{\omega: \Gamma(\omega) \cap F \neq \emptyset\}=\cap_{n}\left\{\omega: \Gamma^{n}(\omega) \cap F \neq \emptyset\right\}
$$

and so

$$
\Gamma^{-}(F)=\cap_{n} \Gamma^{n-}(F) \in \mathscr{F}
$$

The last claim follows from the theory of multi-functions, see, e.g., [10, 70] or Section 48. See Proposition 48.1.4. The fact that $\Gamma^{n}(\omega)$ is compact, $\Gamma^{n}$ is measurable and $\Gamma^{n-}(U) \in$ $\mathscr{F}$, for $U$ open, imply the strong measurability of $\Gamma^{n}[10,70]$ see also Section 48 , and also that $\Gamma^{n-}(F) \in \mathscr{F}$. Thus, $\omega \rightarrow \Gamma(\omega)$ is a nonempty compact valued in $X$ and $\mathscr{F}$ measurable. We are using the theorem which says that when $\Gamma$ has compact values, then one can conclude that strong measurability and measurability coincide. This is why we can say that $\Gamma^{n-}(F) \in \mathscr{F}$.

The standard theory [10, 70], Section 48, also guarantees the existence of an $\mathscr{F}$ measurable selection $\omega \rightarrow \gamma(\omega)$ with $\gamma(\omega) \in \Gamma(\omega)$, for each $\omega$, and also that $t \rightarrow \gamma_{k}(t, \omega)$ (the $k^{t h}$ component of $\gamma$ ) is continuous. Next, we consider the product measurability of $\gamma_{k}$. We know that $\omega \rightarrow \gamma_{k}(\omega)$ is $\mathscr{F}$ measurable into $C([0, T])$ and since pointwise evaluation is continuous, $\omega \rightarrow \gamma_{k}(t, \omega)$ is $\mathscr{F}$ measurable. (This is nothing more than a case of the general result that a continuous function of a measurable function is measurable.) Then, since $t \rightarrow \gamma_{k}(t, \omega)$ is continuous, it follows that $\gamma_{k}$ is a $\mathscr{P}$ measurable real valued function and that $\gamma$ is a $\mathscr{P}$ measurable $\mathbb{R}^{\infty}$ valued function. Since $\gamma(\omega) \in \Gamma(\omega)$, it follows that for each $n, \gamma(\omega) \in \Gamma^{n}(\omega)$. Therefore, there exists $j_{n} \geq n$ such that for each $\omega$,

$$
d\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j_{n}}(\cdot, \omega)\right), \gamma(\omega)\right)<2^{-n}
$$

Therefore, for a suitable subsequence $\left\{u_{n(\omega)}(\cdot, \omega)\right\}$, we have

$$
\gamma(\omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(\cdot, \omega)\right),
$$

for each $\omega$. In particular, for each $k$

$$
\begin{gather*}
\gamma_{k}(t, \omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(t, \omega)\right)_{k} \\
=\lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(s, \omega)\right\rangle_{V} d s \tag{77.2.3}
\end{gather*}
$$

for each $t$.
Note that it is not clear that $(t, \omega) \rightarrow \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(t, \omega)\right)$ is $\mathscr{P}$ measurable, although $(t, \omega) \rightarrow \gamma(t, \omega)$ is $\mathscr{P}$ measurable.

Now here is the proof of the theorem.
Proof of Theorem 77.2.4 By assumption, there exists a further subsequence, still denoted by $n(\omega)$, such that, in addition to 77.2.3, the weak limit

$$
\lim _{n(\omega) \rightarrow \infty} \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(\cdot, \omega)=u(\cdot, \omega)
$$

exists in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ such that $t \rightarrow u(t, \omega)$ is weakly continuous into $V^{\prime}$. Then, 77.2.3 also holds for this further subsequence and in addition,

$$
\begin{aligned}
& m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u(s, \omega)\right\rangle_{V} d s \\
= & \lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(s, \omega)\right\rangle_{V} d s \\
= & \gamma_{k}(t, \omega) .
\end{aligned}
$$

Letting $\phi \in \mathscr{D}$ be given, there exists a subsequence, denoted by $k$, such that $m_{k} \rightarrow \infty$ and $\phi_{r_{k}}=\phi$. Recall $\left(m_{k}, \phi_{r_{k}}\right)$ denoted an enumeration of the pairs $(m, \phi) \in \mathbb{N} \times \mathscr{D}$. Then, passing to the limit and using the assumed continuity of $s \rightarrow u(s, \omega)$, the left-hand side of this equality converges to $\langle\phi, u(s, \omega)\rangle_{V}$ and so the right-hand side, $\gamma_{k}(t, \omega)$, must also converge and for each $\omega$. Since the right-hand side is a product measurable function of $(t, \omega)$, it follows that the pointwise limit is also product measurable. Hence, $(t, \omega) \rightarrow$ $\langle\phi, u(t, \omega)\rangle_{V}$ is product measurable for each $\phi \in \mathscr{D}$. Since $\mathscr{D}$ is a dense set, it follows that $(t, \omega) \rightarrow\langle\phi, u(t, \omega)\rangle_{V}$ is $\mathscr{P}$ measurable for all $\phi \in V$ and so by the Pettis theorem, [127], $(t, \omega) \rightarrow u(t, \omega)$ is $\mathscr{P}$ measurable into $V^{\prime}$.

Actually, one can say more about the measurability of the approximating sequence and in fact, we can obtain one for which $\omega \rightarrow u_{n(\omega)}(t, \omega)$ is also $\mathscr{F}$ measurable.

Lemma 77.2.9 Suppose that $u_{n(\omega)} \rightarrow u$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$, where $u$ is product measurable, and $\left\{u_{n(\omega)}\right\}$ is a subsequence of $\left\{u_{n}\right\}$, such that there exists a set of measure zero $N \subseteq \Omega$ and

$$
\sup _{t \in[0, T]}\left\|u_{n}(t, \omega)\right\|_{V^{\prime}}<C(\omega), \text { for } \omega \notin N
$$

Then, there exists a subsequence of $\left\{u_{n}\right\}$, denoted as $\left\{u_{k(\omega)}\right\}$, such that $u_{k(\omega)} \rightarrow u$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right), \omega \rightarrow k(\omega)$ is $\mathscr{F}$ measurable, and $\omega \rightarrow u_{k(\omega)}(t, \omega)$ is also $\mathscr{F}$ measurable, for each $\omega \notin N$.

Proof: Assume that $f, g \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ and let $\left\{\phi_{k}\right\}$ be a countable dense subset of $L^{p}([0, T] ; V)$. Then, a bounded set in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ with the weak topology can be considered a complete metric space using the metric

$$
d(f, g) \equiv \sum_{j=1}^{\infty} 2^{-j} \frac{\left|\left\langle\phi_{k}, f-g\right\rangle\right|}{1+\left|\left\langle\phi_{k}, f-g\right\rangle\right|}
$$

Now, let $k(\omega)$ be the first index of $\left\{u_{n}\right\}$ that is at least as large as $k$ and such that

$$
d\left(\mathscr{X}_{N^{C}}(\omega) u_{k(\omega)}, u\right) \leq 2^{-k}
$$

Such an index exists because there exists a convergent sequence $\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}$ that converge weakly to $u$. In fact,

$$
\{\omega: k(\omega)=l\}=\left\{\omega: d\left(u_{l}, u\right) \leq 2^{-k}\right\} \cap \cap_{j=1}^{l-1}\left\{\omega: d\left(u_{j}, u\right)>2^{-k}\right\}
$$

Since $u$ is product measurable and each $u_{l}$ is also product measurable, these are all measurable sets with respect to $\mathscr{F}$ and so $\omega \rightarrow k(\omega)$ is $\mathscr{F}$ measurable. Now, we have that $\mathscr{X}_{N^{C}}(\omega) u_{k(\omega)} \rightarrow u$ weakly in $L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$, for each $\omega$, and each function is $\mathscr{F}$ measurable because

$$
u_{k(\omega)}(t, \omega)=\sum_{j=1}^{\infty} \mathscr{X}_{[k(\omega)=j]} u_{j}(t, \omega),
$$

and every term in the sum is $\mathscr{F}$ measurable.
Theorem 77.2.4 can be generalized in a very nice way. It is a better result because you don't need to assume anything so strong as to have the functions bounded. One does not need any assumption that the limit is weakly continuous into $V^{\prime}$. You can also have the functions take values in either $V$ or $V^{\prime}$. The following is not dependent on there being a measure but in the applications there is typically a probability measure and often a set of measure zero which occurs in a natural way so an exceptional set of measure zero is included in the statement of the theorem.

Theorem 77.2.10 Let $V$ be a reflexive separable Banach space with dual $V^{\prime}$, and let $p, p^{\prime}$ be such that $p>1$ and $\frac{1}{p}+\frac{1}{p^{\prime}}=1$. Let the functions $t \rightarrow u_{n}(t, \omega)$, for $n \in \mathbb{N}$, be in $L^{p}([0, T] ; V) \equiv \mathscr{V}$ and $(t, \omega) \rightarrow u_{n}(t, \omega)$ be $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable into V. Suppose there is a set of measure zero $N \subseteq \Omega$ such that if $\omega \notin N$, then

$$
\left\|u_{n}(\cdot, \omega)\right\|_{\mathscr{V}} \leq C(\omega)
$$

for all $n$. (Thus, by weak compactness, for each $\omega$, each subsequence of $\left\{u_{n}\right\}$ has a further subsequence that converges weakly in $\mathscr{V}$ to $v(\cdot, \omega) \in \mathscr{V}$. (v not known to be $\mathscr{P}$ measurable))

Then, there exists a product measurable function $u$ such that $t \rightarrow u(t, \omega)$ is in $\mathscr{V}$ and for each $\omega \notin N$, a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $\mathscr{V}$.

We prove the theorem in steps given below. Let $X=\prod_{k=1}^{\infty} C([0, T])$ and note that when it is equipped with the product topology, then one can consider $X$ as a metric space using the metric

$$
d(\mathbf{f}, \mathbf{g}) \equiv \sum_{k=1}^{\infty} 2^{-k} \frac{\left\|f_{k}-g_{k}\right\|}{1+\left\|f_{k}-g_{k}\right\|}
$$

where $\mathbf{f}=\left(f_{1}, f_{2}, \ldots\right), \mathbf{g}=\left(g_{1}, g_{2}, \ldots\right) \in X$, and the norm is the maximum norm in $C([0, T])$. With this metric, $X$ is complete and separable.

Lemma 77.2.11 Let $\left\{\mathbf{f}_{n}\right\}$ be a sequence in $X$ and suppose that each one of the components $f_{n k}$ is bounded by $C=C(k)$ in $C^{0,\left(1 / p^{\prime}\right)}([0, T])$. Then, there exists a subsequence $\left\{\mathbf{f}_{n_{j}}\right\}$ that converges to some $\mathbf{f} \in X$ as $n_{j} \rightarrow \infty$. Thus, $\left\{\mathbf{f}_{n}\right\}$ is pre-compact in $X$.

Proof: This follows right away from Tychonoff's theorem and the compactness of the embedding of the Holder space into $C([0,1])$.

Now, for $m \in \mathbb{N}$ and $\phi \in V^{\prime}$, define $l_{m}(t) \equiv \max (0, t-(1 / m))$ and $\psi_{m, \phi}: \mathscr{V} \rightarrow C([0, T])$ by

$$
\psi_{m, \phi} u(t) \equiv \int_{0}^{T}\left\langle m \phi \mathscr{X}_{\left[l_{m}(t), t\right]}(s), u(s)\right\rangle_{V} d s=m \int_{l_{m}(t)}^{t}\langle\phi, u(s)\rangle_{V} d s
$$

Here, $\mathscr{X}_{\left[l_{m}(t), t\right]}(\cdot)$ is the characteristic function of the interval $\left[l_{m}(t), t\right]$ and $\langle\cdot, \cdot\rangle_{V}=\langle\cdot, \cdot\rangle_{V}$ is the duality pairing between $V$ and $V^{\prime}$.

Let $\mathscr{D}=\left\{\phi_{r}\right\}_{r=1}^{\infty}$ denote a countable subset of $V^{\prime}$. Then the pairs $(\phi, m)$ for $\phi \in \mathscr{D}$ and $m \in \mathbb{N}$ form a countable set. Let $\left(m_{k}, \phi_{r_{k}}\right)$ denote an enumeration of the pairs $(m, \phi) \in$ $\mathbb{N} \times \mathscr{D}$. To simplify the notation, we set

$$
f_{k}(u)(t) \equiv \psi_{m_{k}, \phi_{r_{k}}}(u)(t)=m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u(s)\right\rangle_{V} d s
$$

For fixed $\omega \notin N$ and $k$, the functions $\left\{t \rightarrow f_{k}\left(u_{j}(\cdot, \omega)\right)(t)\right\}_{j}$ are uniformly bounded and equicontinuous because they are in $C^{0,1 / p^{\prime}}([0, T])$. Indeed, we have for $\omega \notin N$,

$$
\begin{aligned}
\left|f_{k}\left(u_{j}(\cdot, \omega)\right)(t)\right| & =\left|m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V} d s\right| \\
& \leq m\left\|\phi_{r_{k}}\right\| T^{1 / p^{\prime}}\left|\int_{0}^{T}\left\|u_{j}(s, \omega)\right\|_{V}^{p} d s\right|^{1 / p} \leq C(\omega) m\left\|\phi_{r_{k}}\right\|_{V^{\prime}} T^{1 / p^{\prime}}
\end{aligned}
$$

and for $t \leq t^{\prime}$

$$
\begin{aligned}
& \left|f_{k}\left(u_{j}(\cdot, \omega)\right)(t)-f_{k}\left(u_{j}(\cdot, \omega)\right)\left(t^{\prime}\right)\right| \\
\leq & \left|m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V} d s-m_{k} \int_{l_{m_{k}}\left(t^{\prime}\right)}^{t^{\prime}}\left\langle\phi_{r_{k}}, u_{j}(s, \omega)\right\rangle_{V} d s\right| \\
\leq & 2 m_{k}\left|t^{\prime}-t\right|^{1 / p^{\prime}} C(\omega)\left\|\phi_{r_{k}}\right\|_{V^{\prime}} .
\end{aligned}
$$

By Lemma 77.2.11, the set of functions $\left\{\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right\}_{j=n}^{\infty}$ is pre-compact in $X=$ $\prod_{k} C([0, T])$. We now define a set valued map $\Gamma^{n}: \Omega \rightarrow X$ by

$$
\Gamma^{n}(\omega) \equiv \overline{\cup_{j \geq n}\left\{\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right\}}
$$

where the closure is taken in $X$. Then $\Gamma^{n}(\omega)$ is the closure of a pre-compact set in $X$ and so $\Gamma^{n}(\omega)$ is compact in $X$. From the definition, a function $\mathbf{f}$ is in $\Gamma^{n}(\omega)$ if and only if $d\left(\mathbf{f}, \mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(w_{l}\right)\right) \rightarrow 0$ as $l \rightarrow \infty$, where each $w_{l}$ is one of the $u_{j}(\cdot, \omega)$ for $j \geq n$. In the topology on $X$, this happens iff for every $k$,

$$
f_{k}(t)=\lim _{l \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) w_{l}(s, \omega)\right\rangle_{V} d s
$$

where the limit is the uniform limit in $t$.

Lemma 77.2.12 The mapping $\omega \rightarrow \Gamma^{n}(\omega)$ is an $\mathscr{F}$ measurable set-valued map with values in $X$. If $\sigma$ is a measurable selection, then for each $t, \omega \rightarrow \sigma(t, \omega)$ is $\mathscr{F}$ measurable and $(t, \omega) \rightarrow \sigma(t, \omega)$ is $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable.

We note that if $\sigma$ is a measurable selection then $\sigma(\omega) \in \Gamma^{n}(\omega)$, so $\sigma=\sigma(\cdot, \omega)$ is a continuous function. To have $\sigma$ measurable would mean that $\sigma_{k}^{-1}($ open $) \in \mathscr{F}$, where the open set is in $C([0, T])$.

Proof: Let $O$ be a basic open set in $X$. Then $O=\prod_{k=1}^{\infty} O_{k}$, where $O_{k}$ is a proper open set of $C([0, T])$ only for $k \in\left\{k_{1}, \cdots, k_{r}\right\}$. Thus there is a proper open set in these positions and in every other position the open set is the whole space $C([0, T])$. We need to show that

$$
\Gamma^{n-}(O) \equiv\left\{\omega: \Gamma^{n}(\omega) \cap O \neq \emptyset\right\} \in \mathscr{F}
$$

Now, $\Gamma^{n-}(O)=\cap_{i=1}^{r}\left\{\omega: \Gamma^{n}(\omega)_{k_{i}} \cap O_{k_{i}} \neq \emptyset\right\}$, so we consider whether

$$
\begin{equation*}
\left\{\omega: \Gamma^{n}(\omega)_{k_{i}} \cap O_{k_{i}} \neq \emptyset\right\} \in \mathscr{F} . \tag{77.2.4}
\end{equation*}
$$

From the definition of $\Gamma^{n}(\omega)$, this is equivalent to the condition that

$$
f_{k_{i}}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)=\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)\right)_{k_{i}} \in O_{k_{i}}
$$

for some $j \geq n$, and so the set in 77.2.4 is of the form

$$
\cup_{j=n}^{\infty}\left\{\omega:\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)\right)_{k_{i}} \in O_{k_{i}}\right\} .
$$

Now $\omega \rightarrow\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j}(\cdot, \omega)\right)\right)_{k_{i}}$ is $\mathscr{F}$ measurable into $C([0, T])$ and so the above set is in $\mathscr{F}$. To see this, let $g \in C([0, T])$ and consider the inverse image of the ball with radius $r$ and center $g$,

$$
B(g, r)=\left\{\omega:\left\|\left(\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}}-g\right\|_{C([0, T])}<r\right\} .
$$

By continuity considerations,

$$
\begin{aligned}
& \left\|\left(\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(\cdot, \omega)\right)\right)_{k_{i}}-g\right\|_{C([0, T])} \\
= & \sup _{t \in \mathbb{Q} \cap[0, T]}\left|\left(\mathscr{X}_{N^{C}}(\omega) \mathbf{f}\left(u_{j}(t, \omega)\right)\right)_{k_{i}}-g(t)\right|,
\end{aligned}
$$

which is the sup over countably many $\mathscr{F}$ measurable functions. Thus, it is $\mathscr{F}$ measurable. Since every open set is the countable union of such balls, it follows that the claim about $\mathscr{F}$ measurability is valid. Hence, $\Gamma^{n-}(O)$ is $\mathscr{F}$ measurable whenever $O$ is a basic open set.

Now, $X$ is a separable metric space and so every open set is a countable union of these basic sets. Let $U \subseteq X$ be open with $U=\cup_{l=1}^{\infty} O_{l}$ where $O_{l}$ is a basic open set as above. Then,

$$
\Gamma^{n-}(U)=\cup_{l=1}^{\infty} \Gamma^{n-}\left(O_{l}\right) \in \mathscr{F} .
$$

The existence of a measurable selection follows from the standard theory of measurable multi-functions [10, 70] see [70] starting on Page 141 for all the necessary stuff on measurable multifunctions or Section 48. If $\sigma$ is one of these measurable selections, the evaluation at $t$ is $\mathscr{F}$ measurable. Thus, $\omega \rightarrow \sigma(t, \omega)$ is $\mathscr{F}$ measurable with values in $\mathbb{R}^{\infty}$. Also, $t \rightarrow \sigma(t, \omega)$ is continuous, and so it follows that in fact $\sigma$ is product measurable as claimed.

Definition 77.2.13 Let $\Gamma(\omega) \equiv \cap_{n=1}^{\infty} \Gamma^{n}(\omega)$.
Lemma 77.2.14 $\Gamma$ is a nonempty $\mathscr{F}$ measurable set-valued function with values in compact subsets of $X$. There exists a measurable selection $\gamma$ such that $(t, \omega) \rightarrow \gamma(t, \omega)$ is $\mathscr{P}$ measurable. Also, for each $\omega$, there exists a subsequence, $u_{n(\omega)}(\cdot, \omega)$ such that for each $k$,

$$
\begin{aligned}
\gamma_{k}(t, \omega) & =\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(t, \omega)\right)_{k} \\
& =\lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(s, \omega)\right\rangle_{V} d s .
\end{aligned}
$$

Proof: From the definition of $\Gamma(\omega)=\cap_{n=1}^{\infty} \Gamma^{n}(\omega)$ it follows that $\omega \rightarrow \Gamma(\omega)$ is a compact set-valued map in $X$ and is nonempty because each $\Gamma^{n}(\omega)$ is nonempty and compact, and the $\Gamma^{n}(\omega)$ are nested. We next show that $\omega \rightarrow \Gamma(\omega)$ is $\mathscr{F}$ measurable. Indeed, each $\Gamma^{n}$ is compact valued and $\mathscr{F}$ measurable so, if $F$ is closed,

$$
\Gamma(\omega) \cap F=\cap_{n=1}^{\infty} \Gamma^{n}(\omega) \cap F
$$

and the left-hand side is not empty if and only if each $\Gamma^{n}(\omega) \cap F \neq \emptyset$. Thus, for $F$ closed,

$$
\{\omega: \Gamma(\omega) \cap F \neq \emptyset\}=\cap_{n}\left\{\omega: \Gamma^{n}(\omega) \cap F \neq \emptyset\right\}
$$

and so

$$
\Gamma^{-}(F)=\cap_{n} \Gamma^{n-}(F) \in \mathscr{F} .
$$

The last claim follows from the theory of multi-functions, see, e.g., [10, 70] or Section 48. The fact that $\Gamma^{n}(\omega)$ is compact, $\Gamma^{n}$ is measurable and $\Gamma^{n-}(U) \in \mathscr{F}$, for $U$ open, imply the strong measurability of $\Gamma^{n}[10,70]$ see also Section 48, and also that $\Gamma^{n-}(F) \in \mathscr{F}$. Thus, $\omega \rightarrow \Gamma(\omega)$ is nonempty compact valued in $X$ and $\mathscr{F}$ measurable. We are using the theorem which says that when $\Gamma$ has compact values, then one can conclude that strong measurability and measurability coincide. See Proposition 48.1.4. This is why we can say that $\Gamma^{n-}(F) \in \mathscr{F}$.

The standard theory [10, 70], Section 48, also guarantees the existence of an $\mathscr{F}$ measurable selection $\omega \rightarrow \gamma(\omega)$ with $\gamma(\omega) \in \Gamma(\omega)$, for each $\omega$, and also that $t \rightarrow \gamma_{k}(t, \omega)$ (the $k^{\text {th }}$ component of $\gamma$ ) is continuous. Next, we consider the product measurability of $\gamma_{k}$. We know that $\omega \rightarrow \gamma_{k}(\omega)$ is $\mathscr{F}$ measurable into $C([0, T])$ and since pointwise evaluation is continuous, $\omega \rightarrow \gamma_{k}(t, \omega)$ is $\mathscr{F}$ measurable. (This is nothing more than a case of the general result that a continuous function of a measurable function is measurable.) Then, since $t \rightarrow \gamma_{k}(t, \omega)$ is continuous, it follows that $\gamma_{k}$ is a $\mathscr{P}$ measurable real valued function
and that $\gamma$ is a $\mathscr{P}$ measurable $\mathbb{R}^{\infty}$ valued function. Since $\gamma(\omega) \in \Gamma(\omega)$, it follows that for each $n, \gamma(\omega) \in \Gamma^{n}(\omega)$. Therefore, there exists $j_{n} \geq n$ such that for each $\omega$,

$$
d\left(\mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{j_{n}}(\cdot, \omega)\right), \gamma(\omega)\right)<2^{-n}
$$

Therefore, for a suitable subsequence $\left\{u_{n(\omega)}(\cdot, \omega)\right\}$, we have

$$
\gamma(\omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(\cdot, \omega)\right),
$$

for each $\omega$. In particular, for each $k$

$$
\begin{gather*}
\gamma_{k}(t, \omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(t, \omega)\right)_{k} \\
=\lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(s, \omega)\right\rangle_{V} d s \tag{77.2.5}
\end{gather*}
$$

for each $t$.
Note that it is not clear that $(t, \omega) \rightarrow \mathbf{f}\left(\mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(t, \omega)\right)$ is $\mathscr{P}$ measurable, although $(t, \omega) \rightarrow \gamma(t, \omega)$ is $\mathscr{P}$ measurable.

Now here is the proof of the theorem.
Proof of Theorem 77.2.10 By assumption, there exists a further subsequence, still denoted by $n(\omega)$, such that, the weak limit

$$
\lim _{n(\omega) \rightarrow \infty} \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(\cdot, \omega)=v(\cdot, \omega)
$$

exists in $\mathscr{V}$. Then,

$$
\begin{aligned}
& m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, v(s, \omega)\right\rangle_{V} d s \\
= & \lim _{n(\omega) \rightarrow \infty} m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{r_{k}}, \mathscr{X}_{N^{C}}(\omega) u_{n(\omega)}(s, \omega)\right\rangle_{V} d s \\
= & \gamma_{k}(t, \omega), \text { product measurable } .
\end{aligned}
$$

Letting $\phi \in \mathscr{D}$ be given, there exists a subsequence, denoted by $k$, such that $m_{k} \rightarrow \infty$ and $\phi_{r_{k}}=\phi$. Recall $\left(m_{k}, \phi_{r_{k}}\right)$ denoted an enumeration of the pairs $(m, \phi) \in \mathbb{N} \times \mathscr{D}$. For a given $\phi \in \mathscr{D}$ denote this sequence by $m_{\phi}$. Thus we have measurability of

$$
(t, \omega) \rightarrow m_{\phi} \int_{l_{m_{\phi}}(t)}^{t}\langle\phi, v(s, \omega)\rangle_{V} d s
$$

for each $\phi \in \mathscr{D}$.
Now we will be a little more careful about the countable set $\mathscr{D}$. Iterate the following. Let $\phi_{1} \neq 0$. Let $\mathscr{F}$ denote linearly independent subsets of $V^{\prime}$ which contain $\phi_{1}$ such that the elements are further apart than $1 / 5$. Let $\mathscr{C}$ denote a maximal chain. Thus $\cup \mathscr{C}$ is also in $\mathscr{F}$. If $W:=\overline{\operatorname{span} \cup \mathscr{C}}$ fails to be all of $V^{\prime}$, then there would exist $\psi \notin W$ such that the distance of
$\psi$ to the closed subspace $W$ is at least $1 / 5$. Now $\mathscr{C}, \cup\{\mathscr{C} \cup\{\psi\}\}$ would violate maximality of $\mathscr{C}$. Hence $W=V^{\prime}$. Now it follows that $\mathscr{C}$ must be countable since otherwise, $V^{\prime}$ would fail to be separable. Let $M$ be the rational linear combinations of $\mathscr{D}$. It must be dense in $V^{\prime}$. Note that linear combinations of the $\phi_{i}$ are uniquely determined because none is a linear combination of the others. Now define a linear mapping on $M$ which makes sense for $(t, \omega)$ on a certain set.

Definition 77.2.15 Let $E$ be those points $(t, \omega)$ such that the following limit exists for each $\phi \in \mathscr{D}$

$$
\Lambda(t, \omega) \phi \equiv \lim _{m_{\phi} \rightarrow \infty} m_{\phi} \int_{l_{m_{\phi}}(t)}^{t}\langle\phi, v(s, \omega)\rangle d s
$$

The set of points where the limit of measurable functions exists is always measurable so $E$ is a measurable set. Extend this mapping linearly. That is, for $\psi \in M, \psi \equiv \sum_{i} a_{i} \phi_{i}$,

$$
\Lambda(t, \omega) \psi \equiv \sum_{i} a_{i} \Lambda(t, \omega) \phi_{i}=\sum_{i} a_{i}\left(\lim _{m_{\phi_{i}} \rightarrow \infty} m_{\phi_{i}} \int_{l_{m_{\phi_{i}}}(t)}^{t}\left\langle\phi_{i}, v(s, \omega)\right\rangle d s\right)
$$

Thus $(t, \omega) \rightarrow \Lambda(t, \omega) \psi$ is product measurable, being the sum of limits of product measurable functions. Let $G$ denote those $(t, \omega)$ in $E$ such that there exists a constant $C(t, \omega)$ such that for all $\psi \in M$,

$$
|\Lambda(t, \omega) \psi| \leq C(t, \omega)\|\psi\|
$$

Lemma 77.2.16 G is product measurable.
Proof: This follows from the formula

$$
E \cap G^{C}=\cap_{n} \cup_{\psi \in M}\{(t, \omega) \in E:|\Lambda(t, \omega) \psi|>n\|\psi\|\}
$$

which is clearly product measurable because $(t, \omega) \rightarrow \Lambda(t, \omega) \psi$ is. Thus, since $E$ is measurable, it follows that $E \cap G=G$ is also.

For $(t, \omega) \in G, \Lambda(t, \omega)$ has a unique extension to all of $V$, the dual space of $V^{\prime}$, still denoted as $\Lambda(t, \omega)$. By the Riesz representation theorem, for $(t, \omega) \in G$, there exists $u(t, \omega) \in V$,

$$
\Lambda(t, \omega) \psi=\langle\psi, u(t, \omega)\rangle_{V^{\prime}, V}
$$

Thus $(t, \omega) \rightarrow \mathscr{X}_{G}(t, \omega) u(t, \omega)$ is product measurable by the Pettis theorem. Let $u=0$ off $G$. We know $G$ is product measurable. For each $\omega,\{t:(t, \omega) \in G\}$ has full measure. This involves the fundamental theorem of calclulus.

Fix $\omega$. By the fundamental theorem of calculus,

$$
\lim _{m \rightarrow \infty} m \int_{l_{m}(t)}^{t} v(s, \omega) d s=v(t, \omega) \text { in } V
$$

for a.e. $t$ say for all $t \notin N(\omega) \subseteq[0, T]$. Of course we do not know that $\omega \rightarrow v(t, \omega)$ is measurable. However, the existence of this limit for $t \notin N(\omega)$ implies that for every $\phi \in V^{\prime}$,

$$
\lim _{m \rightarrow \infty}\left|m \int_{l_{m}(t)}^{t}\langle\phi, v(s, \omega)\rangle d s\right| \leq C(t, \omega)\|\phi\|
$$

for some $C(t, \omega)$. Here $m$ does not depend on $\phi$. Thus, in particular, this holds for a subsequence and so for each $t \notin N(\omega),(t, \omega) \in G$ because for each $\phi \in \mathscr{D}$,

$$
\lim _{m_{\phi} \rightarrow \infty} m_{\phi} \int_{l_{m_{\phi}}(t)}^{t}\langle\phi, v(s, \omega)\rangle d s \text { exists and satisfies the above inequality. }
$$

Hence, for all $\psi \in M$,

$$
\Lambda(t, \omega) \psi=\langle\psi, u(t, \omega)\rangle_{V^{\prime}, V}
$$

where $u$ is product measurable.
Also, for $t \notin N(\omega)$ and $\phi \in \mathscr{D}$,

$$
\langle\phi, u(t, \omega)\rangle_{V^{\prime}, V}=\Lambda(t, \omega) \phi \equiv \lim _{m_{\phi} \rightarrow \infty} m_{\phi} \int_{l_{m_{\phi}}(t)}^{t}\langle\phi, v(s, \omega)\rangle d s=\langle\phi, v(t, \omega)\rangle_{V^{\prime}, V}
$$

therefore, for all $\phi \in M$

$$
\langle\phi, u(t, \omega)\rangle_{V^{\prime}, V}=\langle\phi, v(t, \omega)\rangle_{V^{\prime}, V}
$$

and hence $u(t, \omega)=v(t, \omega)$. Thus, for each $\omega$, the product measurable function $u$ satisfies $u(t, \omega)=v(t, \omega)$ for a.e. $t$. Hence $u(\cdot, \omega)=v(\cdot, \omega)$ in $\mathscr{V}$.

Of course a similar theorem will hold with essentially the identical proof if the functions take values in $V^{\prime}$.

One can also combine the two theorems to obtain a useful result for limits of functions in $\mathscr{V}^{\prime}$ and $\mathscr{V}$. You just let

$$
X=\prod_{k=1}^{\infty} C([0, T]) \times C([0, T])
$$

and let $\left\{\phi_{k}\right\}$ be a dense subset of $V^{\prime}$ while $\left\{\eta_{k}\right\}$ is a dense subset of $V$. Then the mappings are given by

$$
\psi_{m, \phi} u(t)=m \int_{l_{m}(t)}^{t}\langle\phi, u(s)\rangle_{V^{\prime}, V} d s, \psi_{m, \eta} y(t)=m \int_{l_{m}(t)}^{t}\langle\eta, y(s)\rangle_{V, V^{\prime}} d s
$$

and one considers for each $\phi_{k}, \eta_{k}$,

$$
\left(m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\phi_{k}, u(s)\right\rangle_{V^{\prime}, V} d s, m_{k} \int_{l_{m_{k}}(t)}^{t}\left\langle\eta_{k}, y(s)\right\rangle_{V, V^{\prime}} d s\right)
$$

This time you need to use an enumeration of $\mathbb{N} \times V^{\prime} \times V$ and in the last step, you must use a subsequence still denoted with $k$ such that $m_{k} \rightarrow \infty$ but $\phi_{k}=\phi$ and $\eta_{k}=\eta$ for $\phi, \eta$ two given elements of $V^{\prime}$ and $V$ respectively. Then repeating the above argument, one obtains the following generalization.

Theorem 77.2.17 Let $V$ be a reflexive separable Banach space with dual $V^{\prime}$, and let $p, p^{\prime}$ be such that $p>1$ and $\frac{1}{p}+\frac{1}{p^{\prime}}=1$. Let the functions $t \rightarrow u_{n}(t, \omega)$, for $n \in \mathbb{N}$, be in $L^{p}([0, T] ; V) \equiv \mathscr{V}$ and $(t, \omega) \rightarrow u_{n}(t, \omega)$ be $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable into $V$. Also
let the functions $t \rightarrow y_{n}(t, \omega)$ be in $\mathscr{V}^{\prime}$ and $(t, \omega) \rightarrow y_{n}(t, \omega)$ is $\mathscr{P}$ measurable into $V^{\prime}$. Suppose there is a set of measure zero $N \subseteq \Omega$ such that if $\omega \notin N$, then

$$
\sup _{t \in[0, T]}\left\|y_{n}(t, \omega)\right\|_{V^{\prime}}+\left\|u_{n}(\cdot, \omega)\right\|_{\mathscr{V}} \leq C(\omega)
$$

for all $n$. (Thus, by weak compactness, for each $\omega$, each subsequence of $\left\{u_{n}\right\}$ has a further subsequence that converges weakly in $\mathscr{V}$ to $v(\cdot, \omega) \in \mathscr{V}$. (v not known to be $\mathscr{P}$ measurable)) Suppose that each subsequence of $\left\{y_{n}(\cdot, \omega)\right\}$ has a subsequence which converges weakly in $\mathscr{V}^{\prime}$ to $z(\cdot, \omega) \in \mathscr{V}^{\prime}$ such that the function $t \rightarrow z(t, \omega)$ is weakly continuous into $V^{\prime}$.

Then, there exist product measurable functions $u, y$ such that $t \rightarrow u(t, \omega)$ is in $\mathscr{V}, t \rightarrow$ $y(t, \omega)$ is weakly continuous into $V^{\prime}$ and for each $\omega \notin N$, a subsequence of $\mathbb{N}$ denoted by $\{n(\omega)\}$ such that $u_{n(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $\mathscr{V}$ and $y_{n(\omega)}(\cdot, \omega)$ converges weakly to $y(\cdot, \omega)$ in $\mathscr{V}^{\prime}$.

Note that the conclusion of the proposition holds if $p=1$ and $\mathscr{V}=L^{1}([0, T], V)$.
Here is something else about being measurable into $\mathscr{V}$ or $\mathscr{V}^{\prime}$. Such functions have representatives which are product measurable.

Lemma 77.2.18 Let $f(\cdot, \omega) \in \mathscr{V}^{\prime}$. Then if $\omega \rightarrow f(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$, it follows that for each $\omega$, there exists a representative $\hat{f}(\cdot, \omega) \in \mathscr{V}^{\prime}, \hat{f}(\cdot, \omega)=f(\cdot, \omega)$ in $\mathscr{V}^{\prime}$ such that $(t, \omega) \rightarrow \hat{f}(t, \omega)$ is product measurable. If $f(\cdot, \omega) \in \mathscr{V}^{\prime}$ and $(t, \omega) \rightarrow f(t, \omega)$ is product measurable, then $\omega \rightarrow f(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$. The same holds replacing $\mathscr{V}^{\prime}$ with $\mathscr{V}$.

Proof: If a function $f$ is measurable into $\mathscr{V}^{\prime}$, then there exist simple functions $f_{n}$

$$
\lim _{n \rightarrow \infty}\left\|f_{n}(\omega)-f(\omega)\right\|_{\mathscr{V}^{\prime}}=0,\left\|f_{n}(\omega)\right\| \leq 2\|f(\omega)\|_{\mathscr{V}^{\prime}} \equiv C(\omega)
$$

Now one of these simple functions is of the form $\sum_{i=1}^{M} c_{i} \mathscr{X}_{E_{i}}(\omega)$ where $c_{i} \in \mathscr{V}^{\prime}$. Therefore, there is no loss of generality in assuming that $c_{i}(t)=\sum_{j=1}^{N} d_{j}^{i} \mathscr{X}_{F_{j}}(t)$ where $d_{j}^{i} \in V^{\prime}$. Hence we can assume each $f_{n}$ is product measurable into $\mathscr{B}\left(V^{\prime}\right) \times \mathscr{F}$. Then by Theorem 77.2.10, there exists $\hat{f}(\cdot, \omega) \in \mathscr{V}^{\prime}$ such that $\hat{f}$ is product measurable and a subsequence $f_{n(\omega)}$ converging weakly in $\mathscr{V}^{\prime}$ to $\hat{f}(\cdot, \omega)$ for each $\omega$. Thus $f_{n(\omega)}(\omega) \rightarrow f(\omega)$ strongly in $\mathscr{V}^{\prime}$ and $f_{n(\omega)}(\omega) \rightarrow \hat{f}(\omega)$ weakly in $\mathscr{V}^{\prime}$. Therefore, $\hat{f}(\omega)=f(\omega)$ in $\mathscr{V}^{\prime}$ and so it can be assumed that if $f$ is measurable into $\mathscr{V}^{\prime}$ then for each $\omega$, it has a representative $\hat{f}(\omega)$ such that $(t, \omega) \rightarrow \hat{f}(t, \omega)$ is product measurable.

If $f$ is product measurable into $V^{\prime}$ and each $f(\cdot, \omega) \in \mathscr{V}^{\prime}$, does it follow that $f$ is measurable into $\mathscr{V}^{\prime}$ ? By measurability, $f(t, \omega)=\lim _{n \rightarrow \infty} \sum_{i=1}^{m_{n}} c_{i}^{n} \mathscr{X}_{E_{i}^{n}}(t, \omega)=\lim _{n \rightarrow \infty} f_{n}(t, \omega)$ where $E_{i}^{n}$ is product measurable and we can assume $\left\|f_{n}(t, \omega)\right\|_{V^{\prime}} \leq 2\|f(t, \omega)\|$. Then by product measurability, $\omega \rightarrow f_{n}(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$ because if $g \in \mathscr{V}$ then

$$
\omega \rightarrow\left\langle f_{n}(\cdot, \omega), g\right\rangle
$$

is of the form

$$
\omega \rightarrow \sum_{i=1}^{m_{n}} \int_{0}^{T}\left\langle c_{i}^{n} \mathscr{X}_{E_{i}^{n}}(t, \omega), g(t)\right\rangle d t \text { which is } \omega \rightarrow \sum_{i=1}^{m_{n}} \int_{0}^{T}\left\langle c_{i}^{n}, g(t)\right\rangle \mathscr{X}_{E_{i}^{n}}(t, \omega) d t
$$

and this is $\mathscr{F}$ measurable since $E_{i}^{n}$ is product measurable. Thus, it is measurable into $\mathscr{V}^{\prime}$ as desired and

$$
\langle f(\cdot, \omega), g\rangle=\lim _{n \rightarrow \infty}\left\langle f_{n}(\cdot, \omega), g\right\rangle, \omega \rightarrow\left\langle f_{n}(\cdot, \omega), g\right\rangle \text { is } \mathscr{F} \text { measurable. }
$$

By the Pettis theorem, $\omega \rightarrow\langle f(\cdot, \omega), g\rangle$ is measurable into $\mathscr{V}^{\prime}$. Obviously, the conclusion is the same for these two conditions if $\mathscr{V}^{\prime}$ is replaced with $\mathscr{V}$.

The following theorem is also useful. It is really a generalization of the familiar Gram Schmidt process. It is Lemma 34.4.2.

Theorem 77.2.19 Suppose $V, W$ are separable Banach spaces, such that $V$ is dense in $W$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle, B \neq 0
$$

Then there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
$$

and also

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i},
$$

the series converging in $W^{\prime}$. In case $B=B(\omega)$ where $\omega \rightarrow B(\omega)$ is measurable into $\mathscr{L}\left(W, W^{\prime}\right)$, these vectors $e_{i}$ will also depend on $\omega$ and will be measurable functions of $\omega$.

### 77.3 Preliminary Results

We use the following well known theorem [91]. It is Theorem 34.7.6.
Theorem 77.3.1 Let $E \subseteq F \subseteq G$ where the injection map is continuous from $F$ to $G$ and compact from $E$ to $F$. Let $p \geq 1$, let $q>1$, and define

$$
\begin{gathered}
S \equiv\left\{u \in L^{p}([a, b], E): \text { for some } C,\|u(t)-u(s)\|_{G} \leq C|t-s|^{1 / q}\right. \\
\text { and } \left.\|u\|_{L^{p}([a, b], E)} \leq R\right\} .
\end{gathered}
$$

Thus $S$ is bounded in $L^{p}([a, b], E)$ and Holder continuous into $G$. Then $S$ is precompact in $L^{p}([a, b], F)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b], F)$.

We recall the following theorem which is proved in [99] and earlier, Theorem 25.5.2 for what will suffice here.

Theorem 77.3.2 If $A$ and $B$ are pseudo monotone and bounded then $A+B$ is also pseudo monotone and bounded.

Also the following result, found in [91] is well known.
Theorem 77.3.3 If a single valued map, $A: X \rightarrow X^{\prime}$ is monotone, hemicontinuous, and bounded, then $A$ is pseudo monotone. Furthermore, the duality map, $J^{-1}: X \rightarrow X^{\prime}$ which satisfies $\left\langle J^{-1} f, f\right\rangle=\|f\|^{2},\left\|J^{-1} f\right\|_{X}=\|f\|_{X}$ is strictly monotone hemicontinuous and bounded. So is the duality map $F: X \rightarrow X^{\prime}$ which satisfies $\|F f\|_{X^{\prime}}=\|f\|_{X}^{p-1},\langle F f, f\rangle=$ $\|f\|_{X}^{p}$ for $p>1$.

The following fundamental result will be of use in what follows. There is somewhat more in this than will be needed. In this paper, $B$ is a possibly degenerate operator satisfying only the following:

$$
\begin{equation*}
B \in \mathscr{L}\left(W, W^{\prime}\right),\langle B u, u\rangle \geq 0,\langle B u, v\rangle=\langle B v, u\rangle \tag{77.3.6}
\end{equation*}
$$

where here $V \subseteq W$ and $V$ is dense in $W$. In the case where $B=B(\omega)$, we will assume for the sake of simplicity that

$$
B(\omega)=k(\omega) B, k(\omega) \geq 0, k \text { being } \mathscr{F} \text { measurable }
$$

Allowing $B$ to depend on $\omega$ introduces some technical considerations so if there is no interest in this, simply assume $B$ is independent of $\omega$. This includes all cases of most interest.

Lemma 77.3.4 Suppose $V, W$ are separable Banach spaces such that $V$ is dense in $W$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle, B \neq 0 .
$$

Then there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
$$

and also

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

the series converging in $W^{\prime}$. If $B=B(\omega)$ and $B$ is $\mathscr{F}$ measurable into $\mathscr{L}\left(W, W^{\prime}\right)$ and if the $e_{i}=e_{i}(\omega)$ are as described above, then these $e_{i}$ are measurable into $V$. If $t \rightarrow B(t, \omega)$ is $C^{1}\left([0, T], \mathscr{L}\left(W, W^{\prime}\right)\right)$ and iffor each $w \in W$,

$$
\left\langle B^{\prime}(t, \omega) w, w\right\rangle \leq k_{w, \omega}(t)\langle B(t, \omega) w, w\rangle
$$

Where $k_{w, \omega} \in L^{1}([0, T])$, then the vectors $e_{i}(t)$ can be chosen to also be right continuous functions of $t$.

The following has to do with the values of $B u$ and gives an integration by parts formula.
Corollary 77.3.5 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ is nonnegative and self adjoint. Also suppose $t \rightarrow B(u(t))$ has a weak derivative $(B u)^{\prime} \in$ $L^{p^{\prime}}\left(0, T, V^{\prime}\right)$ for $u \in L^{p}(0, T, V)$. Then there is a continuous function denoted as $t \rightarrow B u(t)$ which equals $B(u(t))$ a.e. $t$. Say for $t \notin N$. Suppose $B u(0)=B u_{0}, u_{0} \in W$. Then

$$
\begin{equation*}
B u(t)=B u_{0}+\int_{0}^{t}(B u)^{\prime}(s) d s \text { in } V^{\prime} \tag{77.3.7}
\end{equation*}
$$

Then $t \rightarrow B u(t)$ is in $C\left(N^{C}, W^{\prime}\right)$ and also for such $t$,

$$
\frac{1}{2}\langle B u(t), u(t)\rangle=\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s
$$

There exists a continuous function $t \rightarrow\langle B u, u\rangle(t)$ which equals the right side of the above for all $t$ and equals $\langle B(u(t)), u(t)\rangle$ off $N$. This also satisfies

$$
\sup _{t \in[0, T]}\langle B u, u\rangle(t) \leq C\left(\left\|(B u)^{\prime}\right\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)},\|u\|_{L^{p}(0, T, V)}\right)
$$

This also makes it easy to verify continuity of pointwise evaluation of $B u$. Let $L u=$ $(B u)^{\prime}$.

$$
\begin{gather*}
u \in D(L) \equiv X \equiv\left\{u \in L^{p}(0, T, V): L u \equiv(B u)^{\prime} \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)\right\} \\
\|u\|_{X} \equiv \max \left(\|u\|_{L^{p}(0, T, V)},\|L u\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)}\right) \tag{77.3.8}
\end{gather*}
$$

Since $L$ is closed, this $X$ is a Banach space.
Then the following theorem is obtained.
Theorem 77.3.6 $\operatorname{Say}(B u)^{\prime} \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)$ so

$$
B u(t)=B u(0)+\int_{0}^{t}(B u)^{\prime}(s) d s \text { in } V^{\prime}
$$

the map $u \rightarrow B u(t)$ is continuous as a map from $X$ to $V^{\prime}$. Also, if $Y$ denotes those $f \in$ $L^{p}([0, T], V)$ for which $f^{\prime} \in L^{p}([0, T], V)$, so that $f$ has a representative such that $f(t)=$ $f(0)+\int_{0}^{t} f^{\prime}(s) d s$, then if $\|f\|_{Y} \equiv\|f\|_{L^{p}([0, T], V)}+\left\|f^{\prime}\right\|_{L^{p}([0, T], V)}$, the map $f \rightarrow f(t)$ is continuous.

Also one can obtain the following for $p>1$.
Proposition 77.3.7 Let

$$
X=\left\{u \in L^{p}(0, T, V) \equiv \mathscr{V}: L u \equiv(B u)^{\prime} \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)\right\}
$$

where $V$ is a reflexive Banach space. Let a norm on $X$ be given by

$$
\|u\|_{X} \equiv \max \left(\|u\|_{\mathscr{V}},\|L u\|_{\mathscr{V}^{\prime}}\right)
$$

Then there is a continuous function $t \rightarrow\langle B u, v\rangle(t)$ such that

$$
\langle B u, v\rangle(t)=\langle B(u(t)), v(t)\rangle
$$

a.e. $t$ such that

$$
\sup _{t \in[0, T]}|\langle B u, v\rangle(t)| \leq C\|u\|_{X}\|v\|_{X}
$$

and if $K: X \rightarrow X^{\prime}$

$$
\langle K u, v\rangle \equiv \int_{0}^{T}\langle L u, v\rangle d s+\langle B u, v\rangle(0)
$$

Then $K$ is continuous and linear and

$$
\langle K u, u\rangle=\frac{1}{2}[\langle B u, u\rangle(T)+\langle B u, u\rangle(0)]
$$

If $u \in X$ and $B u(0)=0$ then there exists a sequence $\left\{u_{n}\right\}$ such that $\left\|u_{n}-u\right\|_{X} \rightarrow 0$ but $u_{n}(t)=0$ for all $t$ close to 0 .

### 77.4 Measurable Approximate Solutions

The main result in this section is the following theorem. Its proof follows a method due to Brezis and Lions [91] adapted to the case considered here where the operator is set valued. In this theorem, we let $F: V \rightarrow V^{\prime}$ be the duality map $\langle F u, u\rangle=\|u\|^{p},\|F u\|=\|u\|^{p-1}$ for $p>1$.

As above, $L u=(B u)^{\prime}$. In addition to this, define $\Lambda$ to be the restriction of $L$ to those $u \in X$ which have $B u(0)=0$. Thus

$$
D(\Lambda)=\{u \in X: B u(0)=0\}
$$

Then one can show that $\Lambda^{*}$ is monotone. It is not hard to see that this should be the case. Let $v \in D\left(\Lambda^{*}\right)$ and suppose it is smooth. Then

$$
\int_{0}^{T}\langle\Lambda u, v\rangle d t=\langle B u(T), v(T)\rangle-\int_{0}^{T}\left\langle B u, v^{\prime}\right\rangle d t
$$

and so, if $\left|\int_{0}^{T}\langle\Lambda u, v\rangle d t\right| \leq C\|u\|_{\mathscr{V}}$, then we need to have $v(T)=0$ and $\Lambda^{*} v=-B v^{\prime}$. Now it is just a matter of doing the computations to verify that

$$
\left\langle\Lambda^{*} v, v\right\rangle \geq 0
$$

Lemma 77.4.1 Let $K$ and L be as in Proposition 77.3.7. Then for each $f \in \mathscr{V}^{\prime}$ and $u_{0} \in W$, there exists a unique $u \in X$ such that

$$
\begin{equation*}
\langle K u, v\rangle+F u=\langle f, v\rangle+\left\langle B v(0), u_{0}\right\rangle \tag{77.4.9}
\end{equation*}
$$

for all $v \in X$. Also, the mapping which takes $\left(f, u_{0}\right)$ to this solution is demicontinuous in the sense that if $f_{n} \rightarrow f$ strongly in $\mathscr{V}^{\prime}$ and $u_{0 n} \rightarrow u_{0}$ in $W$, then $u_{n} \rightarrow u$ weakly in $\mathscr{V}$.

Proof: Let $J^{-1}$ be the duality map mentioned above and define $H_{\varepsilon}: X \rightarrow X^{\prime}$ by

$$
\left\langle H_{\varepsilon}(u), v\right\rangle=\varepsilon\left\langle L v, J^{-1} L u\right\rangle+\langle F u, v\rangle+\langle K u, v\rangle
$$

for all $v \in X$. Then $H_{\varepsilon}$ is pseudo monotone because it is monotone, bounded, and hemicontinuous. This follows from Theorem 77.3.2, and 77.3.3. It is also easy to see that $H_{\varepsilon}$ is coercive.

$$
\frac{\left\langle H_{\varepsilon}(u), u\right\rangle}{\|u\|_{X}}=\varepsilon \frac{\|L u\|_{\mathscr{V}^{\prime}}^{2}}{\|u\|_{X}}+\frac{\|u\|_{\mathscr{V}}^{p}}{\|u\|_{X}}+\frac{1}{2}[\langle B u(T), u(T)\rangle+\langle B u, u\rangle(0)] \frac{1}{\|u\|_{X}}
$$

If not, then there is $\left\|u_{n}\right\|_{X} \rightarrow \infty$ but for some $M$,

$$
\varepsilon \frac{\left\|L u_{n}\right\|_{\mathscr{V}^{\prime}}^{2}}{\left\|u_{n}\right\|_{X}}+\frac{\left\|u_{n}\right\|_{\mathscr{V}}^{p}}{\left\|u_{n}\right\|_{X}}+\frac{1}{2}\left[\left\langle B u_{n}(T), u_{n}(T)\right\rangle+\left\langle B u_{n}, u_{n}\right\rangle(0)\right] \frac{1}{\left\|u_{n}\right\|_{X}} \leq M
$$

Then one of $\left\|u_{n}\right\|_{\mathscr{V}}$ or $\left\|L u_{n}\right\|_{\mathscr{V}^{\prime}}$ is unbounded. Either way, a contradiction is obtained. Thus $H_{\varepsilon}$ is coercive bounded, and pseudomonotone. It follows that it maps onto $X^{\prime}$.

There exists $u_{\varepsilon} \in X$ such that for all $v \in X$,

$$
\begin{equation*}
\varepsilon\left\langle L v, J^{-1} L u_{\varepsilon}\right\rangle+\left\langle F u_{\varepsilon}, v\right\rangle+\left\langle K u_{\varepsilon}, v\right\rangle=\langle f, v\rangle+\left\langle B v(0), u_{0}\right\rangle . \tag{77.4.10}
\end{equation*}
$$

In 77.4.10, let $v=u_{\varepsilon}$. Using the inequality,

$$
\begin{aligned}
\left|\left\langle B v(0), u_{0}\right\rangle\right| & \leq\langle B v, v\rangle^{1 / 2}(0)\left\langle B u_{0}, u_{0}\right\rangle^{1 / 2} \\
& \leq \frac{1}{2}\langle B v, v\rangle(0)+\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle
\end{aligned}
$$

it follows that

$$
\begin{aligned}
& \left\langle F u_{\mathcal{E}}, u_{\varepsilon}\right\rangle+\frac{1}{2}\left[\left\langle B u_{\mathcal{E}}, u_{\varepsilon}\right\rangle(T)+\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(0)\right] \\
\leq & \|f\|_{\mathscr{V}^{\prime}}\left\|u_{\varepsilon}\right\|_{\mathscr{V}}+\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(0)+\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle
\end{aligned}
$$

Thus

$$
\left\|u_{\mathcal{E}}\right\|_{\mathscr{V}}^{p}+\frac{1}{2}\left\langle B u_{\mathcal{E}}, u_{\varepsilon}\right\rangle(T) \leq \frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\|f\|_{\mathscr{V}}\left\|u_{\mathcal{E}}\right\|_{\mathscr{V}}
$$

which implies that there exists a constant $C$ independent of $\varepsilon$ such that

$$
\begin{equation*}
\left\|u_{\mathcal{E}}\right\|_{\mathscr{V}} \leq C . \tag{77.4.11}
\end{equation*}
$$

Now let $v \in D(\Lambda)$. Thus $v \in X$ and $B v(0)=0$ so the last term of 77.4.10 equals 0 . The term, $\left\langle B u_{\varepsilon}, v\right\rangle(0)$ found in the definition of $\left\langle K u_{\varepsilon}, v\right\rangle$ also equals 0 . This follows from

$$
\left\langle B u_{\varepsilon}, v\right\rangle(0)=\lim _{n \rightarrow \infty}\left\langle B u_{\varepsilon}, v_{n}\right\rangle(0)=0 .
$$

where $v_{n}=0$ near 0 and converges to $v$ in $X$ by Proposition 77.3.7. Therefore, for $v \in D(\Lambda)$, a dense subset of $\mathscr{V}$,

$$
\varepsilon\left\langle\Lambda v, J^{-1} L u_{\varepsilon}\right\rangle+\left\langle F u_{\varepsilon}, v\right\rangle+\left\langle L u_{\mathcal{\varepsilon}}, v\right\rangle=\langle f, v\rangle .
$$

It follows that $J^{-1} L u_{\mathcal{\varepsilon}} \in D\left(\Lambda^{*}\right)$ and so for all $v \in D(\Lambda)$,

$$
\begin{equation*}
\varepsilon\left\langle\Lambda^{*} J^{-1} L u_{\varepsilon}, v\right\rangle+\left\langle F u_{\varepsilon}, v\right\rangle+\left\langle L u_{\varepsilon}, v\right\rangle=\langle f, v\rangle . \tag{77.4.12}
\end{equation*}
$$

Since $D(\Lambda)$ is dense in $\mathscr{V}$, this equation holds for all $v \in \mathscr{V}$ and so in particular, it holds for $v=J^{-1} L u_{\varepsilon}$. Therefore,

$$
\begin{equation*}
-\left\|F u_{\mathcal{E}}\right\|_{\mathscr{V}^{\prime}}\left\|L u_{\mathcal{E}}\right\|_{\mathscr{V}^{\prime}}+\left\|L u_{\mathcal{E}}\right\|_{\mathscr{V}^{\prime}}^{2} \leq\|f\|_{\mathscr{V}^{\prime}}\left\|L u_{\mathcal{E}}\right\|_{\mathscr{V}^{\prime}} \tag{77.4.13}
\end{equation*}
$$

It follows from 77.4.13, 77.4.11 that $\left\|L u_{\mathcal{E}}\right\|_{\mathscr{V}^{\prime}}$ is bounded independent of $\varepsilon$. Therefore, there exists a sequence $\varepsilon \rightarrow 0$ such that

$$
\begin{gather*}
u_{\varepsilon} \rightharpoonup u \text { in } \mathscr{V},  \tag{77.4.14}\\
K u_{\varepsilon} \rightharpoonup K u \text { in } X^{\prime},  \tag{77.4.15}\\
F u_{\varepsilon} \rightharpoonup u^{*} \text { in } \mathscr{V}^{\prime},  \tag{77.4.16}\\
B u_{\varepsilon}(0) \rightharpoonup B u(0) \text { in } W^{\prime} . \tag{77.4.17}
\end{gather*}
$$

In 77.4.10 replace $v$ with $u_{\varepsilon}-u$. Using $J^{-1}$ is monotone,

$$
\begin{gather*}
\varepsilon\left\langle L u_{\varepsilon}-L u, J^{-1} L u\right\rangle+\left\langle F u_{\varepsilon}+K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle \\
\leq\left\langle f, u_{\varepsilon}-u\right\rangle+\left\langle B\left(u_{\varepsilon}-u\right)(0), u_{0}\right\rangle \tag{77.4.18}
\end{gather*}
$$

Formula 77.4.17 applied to the last term of 77.4.18 implies

$$
\begin{equation*}
\lim \sup _{\varepsilon \rightarrow 0}\left\langle F u_{\varepsilon}+K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle \leq 0 \tag{77.4.19}
\end{equation*}
$$

By pseudomonotonicity,

$$
\lim _{\varepsilon \rightarrow 0} \inf _{\varepsilon \rightarrow 0}\left\langle F u_{\varepsilon}+K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle \geq\langle F u+K u, u-u\rangle=0
$$

so $\lim _{\varepsilon \rightarrow 0}\left\langle F u_{\varepsilon}+K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle=0$ and so

$$
\begin{gathered}
\left\langle u^{*}+K u, u-v\right\rangle \\
\lim _{\varepsilon \rightarrow 0} \inf _{\varepsilon \rightarrow 0}\left(\left\langle F u_{\varepsilon}+K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle+\left\langle F u_{\varepsilon}+K u_{\varepsilon}, u-v\right\rangle\right)= \\
\lim _{\varepsilon \rightarrow 0} \inf _{\varepsilon \rightarrow 0}\left\langle F u_{\varepsilon}+K u_{\varepsilon}, u_{\varepsilon}-v\right\rangle \geq\langle F u+K u, u-v\rangle
\end{gathered}
$$

and so $u^{*}=F u$ and from 77.4.10,

$$
\begin{equation*}
\langle K u, v\rangle+\langle F u, v\rangle=\langle f, v\rangle+\left\langle B v(0), u_{0}\right\rangle \tag{77.4.20}
\end{equation*}
$$

Thus for every $v \in X$,

$$
\int_{0}^{T}\left\langle(B u)^{\prime}, v\right\rangle d s+\langle B u, v\rangle(0)+\int_{0}^{T}\langle F u, v\rangle d s=\int_{0}^{T}\langle f, v\rangle d s+\left\langle B v(0), u_{0}\right\rangle
$$

So let $v$ be smooth and equal to 0 except for $t \in[0, \delta]$ and equals $v_{0}$ at 0 . Then as $\delta \rightarrow 0$, the integrals become increasingly small and so

$$
\left\langle B u(0), v_{0}\right\rangle=\left\langle B v_{0}, u_{0}\right\rangle=\left\langle B u_{0}, v_{0}\right\rangle
$$

and since $v_{0}$ is arbitrary in $V$, then it follows that $B u(0)=B u_{0}$. Thus this has provided a solution $u$ to the system

$$
(B u)^{\prime}+F u=f, B u(0)=B u_{0}, u \in X
$$

It remains to consider the assertion about continuity. First note that the solution to the above initial value problem is unique due to the strict monotonicity of $F$. In fact, if there are two solutions, $u, w$, then

$$
\frac{1}{2}\|B u(t)-B w(t)\|_{W}^{2}+\int_{0}^{t}\langle F u-F w, u-w\rangle d s=0
$$

and so, in particular, $\langle F u-F w, u-w\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0$ which implies $u=w$ in $\mathscr{V}$.
Let $u$ be the solution which goes with $\left(f, u_{0}\right)$ and let $u_{n}$ denote the solution which goes with $\left(f_{n}, u_{0 n}\right)$ where it is assumed that $f_{n} \rightarrow f$ in $\mathscr{V}^{\prime}$ and $u_{0 n} \rightarrow u_{0}$ in $W$. It is desired to show that $u_{n} \rightarrow u$ weakly in $\mathscr{V}$. First note that the $u_{n}$ are bounded in $\mathscr{V}$ because

$$
\frac{1}{2}\left\langle B u_{n}, u_{n}\right\rangle(T)-\frac{1}{2}\left\langle B u_{0 n}, u_{0 n}\right\rangle+\int_{0}^{T}\left\|u_{n}\right\|_{V}^{p} d s=\int_{0}^{T}\left\langle f_{n}, u_{n}\right\rangle d s \leq\left\|f_{n}\right\|_{\mathscr{V}^{\prime}}\left\|u_{n}\right\|_{\mathscr{V}}
$$

and this clearly implies that $\left\|u_{n}\right\|_{\mathscr{V}}$ is indeed bounded. Thus if this sequence fails to converge weakly to $u$, it must be the case that there is a subsequence, still denoted as $u_{n}$ which converges weakly to $w \neq u$ in $\mathscr{V}$. Then by the fact that $F$ is bounded, there is an estimate of the form

$$
\left\|u_{n}\right\|_{\mathscr{V}}+\left\|L u_{n}\right\|_{\mathscr{V}^{\prime}} \leq C
$$

Thus, a further subsequence satisfies

$$
\begin{aligned}
u_{n} & \rightarrow w \text { weakly in } \mathscr{V} \\
L u_{n} & \rightarrow L w \text { weakly in } \mathscr{V}^{\prime} \\
F u_{n} & \rightarrow \xi \text { weakly in } \mathscr{V}^{\prime}
\end{aligned}
$$

then

$$
\begin{aligned}
& \int_{0}^{T}\left\langle\left(B\left(u_{n}-w\right)\right)^{\prime}, u_{n}-w\right\rangle d t \\
= & \frac{1}{2}\left\langle B\left(u_{n}-w\right),\left(u_{n}-w\right)\right\rangle(T)-\frac{1}{2}\left\langle B\left(u_{n}-w\right),\left(u_{n}-w\right)\right\rangle(0) \\
\geq & -\frac{1}{2}\left\langle B\left(u_{n}-w\right),\left(u_{n}-w\right)\right\rangle(0)=-\frac{1}{2}\left\langle B\left(u_{n 0}-u_{0}\right), u_{n 0}-u_{0}\right\rangle
\end{aligned}
$$

It follows

$$
\left\langle L w, u_{n}-w\right\rangle_{\mathscr{V}}+\left\langle F u_{n}, u_{n}-w\right\rangle_{\mathscr{V}}-\frac{1}{2}\left\langle B\left(u_{n 0}-u_{0}\right), u_{n 0}-u_{0}\right\rangle \leq\left\langle f_{n}, u_{n}-w\right\rangle
$$

and so $\lim \sup _{n \rightarrow \infty}\left\langle F u_{n}, u_{n}-w\right\rangle \leq 0$. Then as before, $\xi=F w$ and one obtains

$$
(B w)^{\prime}+F w=f, \quad B w(0)=B u_{0}, w \in X
$$

contradicting uniqueness. Hence $u_{n} \rightarrow u$ weakly as claimed.
Now suppose $(\Omega, \mathscr{F})$ is a measurable space and $B=B(\omega)$ and is measurable into $\mathscr{L}\left(W, W^{\prime}\right)$ and $f:[0, T] \times \Omega \rightarrow V^{\prime}$ is product measurable, $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable where $\mathscr{B}([0, T])$ denotes the Borel sets. Also, it is assumed that for each $\omega, f(\cdot, \omega) \in \mathscr{V}^{\prime}$. The following lemma ties together these ideas. It is Lemma 77.2.18 proved above. It is stated here for convenience.

Lemma 77.4.2 Let $f(\cdot, \omega) \in \mathscr{V}^{\prime}$. Then if $\omega \rightarrow f(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$, it follows that for each $\omega$, there exists a representative $\hat{f}(\cdot, \omega) \in \mathscr{V}^{\prime}, \hat{f}(\cdot, \omega)=f(\cdot, \omega)$ in $\mathscr{V}^{\prime}$ such that $(t, \omega) \rightarrow \hat{f}(t, \omega)$ is product measurable. If $f(\cdot, \omega) \in \mathscr{V}^{\prime}$ and $(t, \omega) \rightarrow f(t, \omega)$ is product measurable, then $\omega \rightarrow f(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$. The same holds replacing $\mathscr{V}^{\prime}$ with $\mathscr{V}$.

Now consider the initial value problem

$$
\begin{align*}
(B(\omega) u(\cdot, \omega))^{\prime}+F u(\cdot, \omega) & =f(\cdot, \omega), \\
B(\omega) u(0, \omega) & =B(\omega) u_{0}(\omega), u(\cdot, \omega) \in X \tag{77.4.21}
\end{align*}
$$

where we also assume $u_{0}$ is $\mathscr{F}$ measurable into $W$. From Lemma 77.4.2,

$$
\omega \rightarrow\left(f(\cdot, \omega), u_{0}(\omega)\right)
$$

is measurable into $\mathscr{V}^{\prime} \times W$. That is,

$$
\left(f, u_{0}\right)^{-1}(U)=\left\{\omega:\left(f(\cdot, \omega), u_{0}(\omega)\right) \in U\right\} \in \mathscr{F}
$$

for $U$ an open set in $\mathscr{V}^{\prime} \times W$. From Lemma 77.4.1, the map $\Phi_{\omega}$ which takes $\left(f, u_{0}\right)$ to the solution $u$ is demicontinuous. We desire to argue that $u$ is measurable into $\mathscr{V}$. In doing so, it is easiest to assume that $B$ does not depend on $\omega$. However, the dependence on $\omega$ can be included using the approximation assumption for $B(\omega)$ mentioned earlier.

Letting $f_{n}(\cdot, \omega) \rightarrow f(\cdot, \omega)$ where $f_{n}$ is a simple function and $u_{0 n}(\omega) \rightarrow u_{0}(\omega)$ where $u_{0 n}$ is also a simple function, it follows that

$$
\Phi_{\omega}\left(f_{n}(\cdot, \omega), u_{0 n}(\omega)\right) \rightarrow \Phi_{\omega}\left(f(\cdot, \omega), u_{0}(\omega)\right)=u
$$

weakly. Here $\Phi_{\omega}$ would be a continuous function of $\mathscr{V}^{\prime} \times W$.
Lemma 77.4.3 Suppose $f(\cdot, \omega) \in \mathscr{V}^{\prime}$ for each $\omega$ and that $(t, \omega) \rightarrow f(t, \omega)$ is product measurable into $V^{\prime}$. Also $u_{0}$ is $\mathscr{F}$ measurable into $W$ and

$$
B(\omega)=k(\omega) B, k(\omega) \geq 0, k \text { measurable }
$$

Then for each $\omega \in \Omega$, there exists a unique solution $u(\cdot, \omega)$ in $\mathscr{V}$ satisfying

$$
\begin{aligned}
(B(\omega) u(\cdot, \omega))^{\prime}+F u(\cdot, \omega) & =f(\cdot, \omega), \\
B(\omega) u(0, \omega) & =B(\omega) u_{0}(\omega), u(\cdot, \omega) \in X
\end{aligned}
$$

This solution has a representative which satisfies $(t, \omega) \rightarrow u(t, \omega)$ is product measurable into $V$.

Proof: Let $B_{n}(\omega) \equiv k_{n}(\omega) B$ where $\left\{k_{n}(\omega)\right\}$ is an increasing sequence of simple functions converging pointwise to $k(\omega)$. Replace $B(\omega)$ with $B_{n}(\omega)$. Then define

$$
\left\langle K_{n} u, v\right\rangle \equiv \int_{0}^{T}\left\langle L_{n} u, v\right\rangle d s+\langle B u, v\rangle(0)
$$

where $L_{n}$ is defined as

$$
L_{n} u=\left(B_{n}(\omega) u\right)^{\prime}
$$

for $B_{n}$ having values in $\mathscr{L}\left(W, W^{\prime}\right)$ such that $B_{n}(\omega) \rightarrow B(\omega)$ and each of these is self adjoint and nonnegative. Let $u_{n}$ be the solution to the above initial value problem

$$
\left\langle K_{n} u_{n}, v\right\rangle+F u_{n}=\left\langle f_{n}, v\right\rangle+\left\langle B v(0), u_{0 n}\right\rangle
$$

in which $u_{0 n}$ and $f_{n}$ are simple functions converging to $u_{0}$ and $f$ in $W$ and $\mathscr{V}^{\prime}$ respectively for each $\omega$. Thus these have constant values in $\mathscr{V}^{\prime}$ or $W$ on finitely many measurable subsets of $\Omega$. Since $B_{n}$ is constant on measurable sets, it follows that $u_{n}(\cdot, \omega)$ is also a constant element of $\mathscr{V}$ on each of finitely many measurable sets. Hence $u_{n}(\cdot, \omega)$ is measurable into $\mathscr{V}$. Then fixing $\omega$, and letting $v=u_{n}$,

$$
\frac{1}{2}\left[\left\langle B u_{n}, u_{n}\right\rangle(T)+\left\langle B u_{n}, u_{n}\right\rangle(0)\right]+\int_{0}^{T}\left\|u_{n}\right\|_{V}^{p} d s=\int_{0}^{T}\left\langle f_{n}, u_{n}\right\rangle d s+\left\langle B v(0), u_{0 n}\right\rangle
$$

Thus, since $F$ is bounded, one obtains an inequality of the form

$$
\left\|u_{n}\right\|_{\mathscr{V}}+\left\|\left(B_{n}(\omega) u_{n}\right)^{\prime}\right\|_{\mathscr{V}^{\prime}} \leq C
$$

Then there is a subsequence such that

$$
\begin{aligned}
& u_{n} \rightarrow u \text { weakly in } \mathscr{V} \\
& B_{n}(\omega) u_{n} \rightarrow B(\omega) u \text { weak } * \text { in } L^{\infty}\left([0, T] ; V^{\prime}\right) \\
& B_{n}(\omega) u_{n} \rightarrow B(\omega) u \text { weakly in } \mathscr{V}^{\prime} \\
& F u_{n} \rightarrow \xi \text { weakly in } \mathscr{V}^{\prime} \\
&\left(B_{n}(\omega) u_{n}\right)^{\prime} \rightarrow(B(\omega) u)^{\prime} \text { weakly in } \mathscr{V}^{\prime}
\end{aligned}
$$

Also, suppressing the dependence on $\omega$,

$$
\left(B_{n} u_{n}\right)(t)=B_{n} u_{0 n}+\int_{0}^{t}\left(B_{n} u\right)^{\prime}(s) d s
$$

and so in fact,

$$
\left(B_{n} u_{n}\right)(t) \rightarrow(B u)(t) \text { in } V^{\prime} \text { for each } t
$$

Also,

$$
\begin{aligned}
\left\langle\left(B_{n} u_{n}\right)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle F u_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} & =\left\langle f_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
\left\langle k_{n}(\omega)\left(B u_{n}\right)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle F u_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} & =\left\langle f_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
\end{aligned}
$$

Thus, by monotonicity,

$$
\begin{gathered}
\left\langle k_{n}(\omega)\left(B u_{n}\right)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\left\langle k(\omega)\left(B u_{n}\right)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
+\left\langle\left(k_{n}(\omega)-k(\omega)\right)\left(B u_{n}\right)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
\geq\left\langle k(\omega)(B u)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle\left(k_{n}(\omega)-k(\omega)\right)\left(B u_{n}\right)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
\end{gathered}
$$

The last term in the above expression converges to 0 due to the convergence of $k_{n}(\omega)$ to $k(\omega)$. Thus

$$
\left\langle(B(\omega) u)^{\prime}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle F u_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq\left\langle f_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

and so

$$
\limsup _{n \rightarrow \infty}\left\langle F u_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0
$$

Then as before, one can conclude that $F u=\xi$. Then passing to the limit gives the desired solution to the equation, this for each $\omega$. However, by uniqueness, it follows that if $\bar{u}$ is the solution to the evolution equation of Lemma 77.4.1, then for each $\omega, u=\bar{u}$ in $\mathscr{V}$. Also this $u$ just obtained is measurable into $\mathscr{V}$ thanks to the Pettis theorem. Therefore, $\bar{u}$ can be modified on a set of measure zero for each fixed $\omega$ to equal $u$ a function measurable into $\mathscr{V}$. Hence there exists a solution to the evolution equation of this lemma $u$ which is measurable into $\mathscr{V}$. By the Lemma 77.4.2, it follows that there is a representative for $u$ which is product measurable into $V$.

### 77.5 The Main Result

The main result is an existence theorem for product measurable solutions to the system

$$
\begin{align*}
(B(\omega) u(\cdot, \omega))^{\prime}+u^{*}(\cdot, \omega) & =f(\cdot, \omega) \text { in } \mathscr{V}^{\prime} \\
B(\omega) u(0, \omega) & =B(\omega) u_{0}(\omega) \tag{77.5.22}
\end{align*}
$$

where $u^{*}(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$. It is Theorem 77.5.6 below. First are some assumptions.
Here $I$ will denote a subinterval of $[0, T]$, of the form $I=[0, \hat{T}], \hat{T} \leq T$, and $\mathscr{V}_{I} \equiv$ $L^{p}(I, V)$ with similar things defined analogously. We assume only that $p>1$.

Definition 77.5.1 For $X$ a reflexive Banach space, we say $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ is pseudomonotone and bounded if the following hold.

1. The set $A u$ is nonempty, closed and convex for all $u \in X$. A takes bounded sets to bounded sets.
2. If $u_{i} \rightarrow u$ weakly in $X$ and $u_{i}^{*} \in A u_{i}$ is such that

$$
\begin{equation*}
\lim \sup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle \leq 0 \tag{77.5.23}
\end{equation*}
$$

then, for each $v \in X$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \inf _{i \rightarrow}\left\langle u_{i}^{*}, u_{i}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle \tag{77.5.24}
\end{equation*}
$$

Now suppose the following for the operator $A(\cdot, \omega) . A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{V}_{I}^{\prime}$ for each $I$ a subinterval of $[0, T]$ and

$$
\begin{equation*}
A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{P}\left(\mathscr{V}_{I}^{\prime}\right) \text { is bounded, } \tag{77.5.25}
\end{equation*}
$$

If, for $u \in \mathscr{V}$,

$$
u^{*} \mathscr{X}_{[0, \hat{T}]} \in A\left(u \mathscr{X}_{[0, \hat{T}]}, \omega\right)
$$

for each $\hat{T}$ in an increasing sequence converging to $T$, then

$$
\begin{equation*}
u^{*} \in A(u, \omega) \tag{77.5.26}
\end{equation*}
$$

For some $\hat{p} \geq p$, assume the specific estimate

$$
\begin{equation*}
\sup \left\{\left\|u^{*}\right\|_{\mathscr{V}_{I}^{\prime}}: u^{*} \in A(u, \omega)\right\} \leq a(\omega)+b(\omega)\|u\|_{\mathscr{V}_{I}}^{\hat{p}-1} \tag{77.5.27}
\end{equation*}
$$

where $a(\omega), b(\omega)$ are nonnegative. Note that the growth could be quadratic in case $p=2$. Also assume the coercivity condition:

$$
\begin{equation*}
\left.\left.\lim _{\substack{\|u\|_{\mathscr{V}} \rightarrow \infty \\ u \in X_{r}}} \frac{\inf \left\{2\left\langle u^{*}, u\right\rangle_{\mathscr{V}}, \mathscr{V}\right.}{}+\langle B u, u\rangle(T): u^{*} \in A(u, \omega)\right\}\right) \tag{77.5.28}
\end{equation*}
$$

or alternatively the following specific estimate valid for each $t \leq T$ and for some $\lambda(\omega) \geq 0$,

$$
\begin{equation*}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d t: u^{*} \in A(u, \omega)\right) \geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \tag{77.5.29}
\end{equation*}
$$

where $m(\omega)$ is some nonnegative constant, $\delta(\omega)>0$. Note that the estimate is a coercivity condition on $\lambda B+A$ rather than on $A$ but is more specific than 77.5.28.

Let $U$ be a Banach space dense in $V$ and that if $u_{i} \rightharpoonup u$ in $\mathscr{V}_{I}$ and $u_{i}^{*} \in A\left(u_{i}\right)$ with $u_{i}^{*} \rightharpoonup u^{*}$ in $\mathscr{V}_{I}^{\prime}$ and $\left(B u_{i}\right)^{\prime} \rightharpoonup(B u)^{\prime}$ in $\mathscr{U}_{r I}^{\prime}$, $\rightharpoonup$ denoting weak convergence, then if

$$
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \leq 0
$$

it follows that for all $v \in \mathscr{V}_{I}$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \geq\left\langle u^{*}(v), u-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \tag{77.5.30}
\end{equation*}
$$

where $r>\max (\hat{p}, 2)$, and we replace $p$ with $r$ and $I$ an arbitrary subinterval of the form $[0, \hat{T}], \hat{T}<T$, for $[0, T]$, and $U$ for $V$ where indicated. Here

$$
\mathscr{U}_{r I} \equiv L^{r}(I ; U)
$$

Note that we are not assuming $A$ is pseudomonotone, just that it satisfies a similar limit condition. Typically, this limit condition holds because of a use of the compact embedding of theorem 77.3.1 or similar result and it does not matter whether $U$ is a small subset of $V$ as long as it is dense in $V$.

Here is an alternate limit condition. Let $U$ be a Banach space dense in $V$ and that if $u_{i} \rightharpoonup u$ in $\mathscr{V}_{I}$ and $u_{i}^{*} \in A\left(u_{i}\right)$ with $u_{i}^{*} \rightharpoonup u^{*}$ in $\mathscr{V}_{I}^{\prime}$ and $t \rightarrow B u_{i}(t)$ is continuous and

$$
\begin{equation*}
\sup _{i} \sup _{t \neq s} \frac{\left\|B u_{i}(t)-B u_{i}(s)\right\|_{U^{\prime}}}{|t-s|^{\alpha}} \leq C \tag{77.5.31}
\end{equation*}
$$

then if

$$
\begin{equation*}
\lim \sup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \leq 0 \tag{77.5.32}
\end{equation*}
$$

it follows that for all $v \in \mathscr{V}_{I}$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle_{\mathscr{Y}_{I}^{\prime}, \mathscr{V}_{I}} \geq\left\langle u^{*}(v), u-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \tag{77.5.33}
\end{equation*}
$$

This alternate condition is implied by 77.5 .30 but the conditions under which either condition holds are likely to depend on some sort of compactness which will be useable for either limit condition. Technically if you assume this alternate condition, you are assuming more, but I don't have any examples to show that it would be actually assuming more.

For $\omega \rightarrow u(\cdot, \omega)$ measurable into $\mathscr{V}$,

$$
\begin{equation*}
\omega \rightarrow A(u(\cdot, \omega), \omega) \text { has a measurable selection into } \mathscr{V}^{\prime} \tag{77.5.34}
\end{equation*}
$$

This last condition means there is a function $\omega \rightarrow u^{*}(\omega)$ which is measurable into $\mathscr{V}^{\prime}$ such that $u^{*}(\omega) \in A(u(\cdot, \omega), \omega)$. This is assured to take place if the following standard measurability condition is satisfied for all $O$ open in $\mathscr{V}^{\prime}$ :

$$
\begin{equation*}
\{\omega: A(u(\cdot, \omega), \omega) \cap O \neq \emptyset\} \in \mathscr{F} \tag{77.5.35}
\end{equation*}
$$

See for example [70], [10]. Our assumption is implied by this one but they are not equivalent. Thus what is considered here generalizes an assumption that $\omega \rightarrow A(u(\cdot, \omega), \omega)$ is set valued measurable.

Note that this condition would hold if $u \rightarrow A(t, u, \omega)$ is bounded and pseudomonotone as a single valued map from $V$ to $V^{\prime}$ and $(t, \omega) \rightarrow A(t, u, \omega)$ is product measurable into $V^{\prime}$. One would use the demicontinuity of $u \rightarrow A(\cdot, u, \omega)$ which comes from the pseudo monotone and bounded assumption and consider a sequence of simple functions $u_{n}(t, \omega) \rightarrow u(t, \omega)$ in $V$ for $u$ measurable, each $u(\cdot, \omega)$ being in $\mathscr{V}$, Then the measurability of $A\left(t, u_{n}, \omega\right)$ would attach to $A(t, u, \omega)$ in the limit. More generally, here is a useful lemma. It is about preserving the existence of a measurable representative under the assumption that the values are closed and convex.

Lemma 77.5.2 Suppose $\omega \rightarrow A(u, \omega)$ has a measurable selection in $\mathscr{V}^{\prime}$ for u a given element of $\mathscr{V}$ not dependent on $\omega$ and for each $\omega, A(u, \omega)$ is a closed bounded, convex set in $\mathscr{V}^{\prime}$. Also suppose $u \rightarrow A(u, \omega)$ is upper semicontinuous from the strong topology of $\mathscr{V}$ to the weak topology of $\mathscr{V}^{\prime}$. That is, if $u_{n} \rightarrow u$ in $\mathscr{V}$ strongly, then if $O$ is a weakly open set containing $A(u, \omega)$, it follows that $A\left(u_{n}, \omega\right) \in O$ for all n large enough. Then whenever $u$ is measurable into $\mathscr{V}$, it follows that there is a measurable selection for $\omega \rightarrow A(u(\omega), \omega)$ into $\mathscr{V}^{\prime}$.

Proof: Let $\omega \rightarrow u(\omega)$ be measurable into $\mathscr{V}$ and let $u_{n}(\omega) \rightarrow u(\omega)$ in $\mathscr{V}$ where $u_{n}$ is a simple function

$$
u_{n}(\omega)=\sum_{k=1}^{m_{n}} c_{k}^{n} \mathscr{X}_{E_{k}^{n}}(\omega), \text { the } E_{k}^{n} \text { disjoint, } \Omega=\cup_{k} E_{k}^{n}
$$

each $c_{k}^{n}$ being in $\mathscr{V}$. Then by assumption, there is a measurable selection for $\omega \rightarrow A\left(c_{k}^{n}, \omega\right)$ denoted as $\omega \rightarrow y_{k}^{n}(\omega)$. Thus $\omega \rightarrow y_{k}^{n}(\omega)$ is measurable into $\mathscr{V}^{\prime}$ and $y_{k}^{n}(\omega) \in A\left(c_{k}^{n}, \omega\right)$ for all $\omega \in \Omega$. Then consider

$$
y^{n}(\omega)=\sum_{k=1}^{m_{n}} y_{k}^{n}(\omega) \mathscr{X}_{E_{k}^{n}}(\omega)
$$

It is measurable and for $\omega \in E_{k}^{n}$ it equals $y_{k}^{n}(\omega) \in A\left(c_{k}^{n}, \omega\right)=A\left(u_{n}(\omega), \omega\right)$. Thus $y^{n}$ is a measurable selection of $\omega \rightarrow A\left(u_{n}(\omega), \omega\right)$. By the estimates, for each $\omega$ these $y^{n}(\omega)$ lie in a bounded subset of $\mathscr{V}^{\prime}$. The bound might depend on $\omega$ of course. By Theorem 77.2.10 and Lemma 77.4.2 there is a measurable into $\mathscr{V}^{\prime}$ function $\omega \rightarrow y(\omega)$ and a subsequence for each $\omega, y^{n(\omega)}(\omega)$ such that $y^{n(\omega)}(\omega) \rightarrow y(\omega)$ weakly in $\mathscr{V}^{\prime}$. By the Pettis theorem, $y$ is measurable into $\mathscr{V}^{\prime}$. Where is $y(\omega)$ ? If $y(\omega) \notin A(u(\omega), \omega)$, then there would exist $z(\omega) \in \mathscr{V}$ such that $\langle y(\omega), z\rangle>r>\langle w, z\rangle$ for all $w \in A(u(\omega), \omega)$. Let $O=$ $\left\{w \in \mathscr{V}^{\prime}\right.$ such that $\left.r>\langle w, z\rangle\right\}$. Then $O$ contains $A(u(\omega), \omega)$ and is a weakly open set. It follows from the upper semicontinuity assumption that $y^{n(\omega)}(\omega) \in O$ for all $n(\omega)$ large enough. Thus $r>\left\langle y^{n(\omega)}(\omega), z\right\rangle$. But by weak convergence,

$$
\langle y(\omega), z\rangle>r \geq \lim _{n(\omega) \rightarrow \infty}\left\langle y^{n(\omega)}(\omega), z\right\rangle=\langle y(\omega), z\rangle
$$

contradicting $y(\omega) \notin A(u(\omega), \omega)$. Hence $y(\omega) \in A(u(\omega), \omega)$ and $\omega \rightarrow y(\omega)$ is a measurable selection.

In fact, this is just a special case of a general result in the next theorem. It says essentially that having a measurable selection is preserved when going from constant to measurable functions. In this theorem, $V$ is a reflexive separable Banach space. This is difficult to show for measurable multifunctions. It is Theorem 48.3.1 and was proved earlier. A proof is given here also.

Theorem 77.5.3 Suppose $\omega \rightarrow A(u, \omega)$ has a measurable selection in $V^{\prime}$ for u a given element of $V$ not dependent on $\omega$ and for each $\omega, A(u, \omega)$ is a closed, convex set in $V^{\prime}$ and $A(\cdot, \omega)$ is bounded. Also suppose $u \rightarrow A(u, \omega)$ is upper semicontinuous from the strong topology of $V$ to the weak topology of $V^{\prime}$. That is, if $u_{n} \rightarrow u$ in $V$ strongly, then if $O$ is a weakly open set containing $A(u, \omega)$, it follows that $A\left(u_{n}, \omega\right) \in O$ for all $n$ large enough. Conclusion: whenever $\omega \rightarrow u(\omega)$ is measurable into $V$, it follows that there is a measurable selection for $\omega \rightarrow A(u(\omega), \omega)$ into $V^{\prime}$.

Proof: Let $\omega \rightarrow u(\omega)$ be measurable into $V$ and let $u_{n}(\omega) \rightarrow u(\omega)$ in $V$ where $u_{n}$ is a simple function

$$
u_{n}(\omega)=\sum_{k=1}^{m_{n}} c_{k}^{n} \mathscr{X}_{E_{k}^{n}}(\omega), \text { the } E_{k}^{n} \text { disjoint, } \Omega=\cup_{k} E_{k}^{n}
$$

each $c_{k}^{n}$ being in $V$. We can assume that $\left\|u_{n}(\omega)\right\| \leq 2\|u(\omega)\|$ for all $\omega$. Then by assumption, there is a measurable selection for $\omega \rightarrow A\left(c_{k}^{n}, \omega\right)$ denoted as $\omega \rightarrow y_{k}^{n}(\omega)$. Thus $\omega \rightarrow y_{k}^{n}(\omega)$ is measurable into $V^{\prime}$ and $y_{k}^{n}(\omega) \in A\left(c_{k}^{n}, \omega\right)$ for all $\omega \in \Omega$. Then consider

$$
y^{n}(\omega)=\sum_{k=1}^{m_{n}} y_{k}^{n}(\omega) \mathscr{X}_{E_{k}^{n}}(\omega)
$$

It is measurable and for $\omega \in E_{k}^{n}$ it equals $y_{k}^{n}(\omega) \in A\left(c_{k}^{n}, \omega\right)=A\left(u_{n}(\omega), \omega\right)$. Thus $y^{n}$ is a measurable selection of $\omega \rightarrow A\left(u_{n}(\omega), \omega\right)$. By the estimates, for each $\omega$ these $y^{n}(\omega)$ lie in a bounded subset of $V^{\prime}$. The bound might depend on $\omega$ of course.

Now let $\left\{z_{i}\right\}$ be a countable dense subset of $V$. Then let $X \equiv \prod_{i=1}^{\infty} \mathbb{R}$. It is a Polish space. Let

$$
\begin{gathered}
\mathbf{f}\left(y^{j}\right)(\omega) \equiv \prod_{i=1}^{\infty}\left\langle y^{j}(\omega), z_{i}\right\rangle \\
\Gamma_{n}(\omega) \equiv \overline{\cup_{k \geq n} \mathbf{f}\left(y^{k}\right)(\omega)},
\end{gathered}
$$

the closure taken in $X$. Now $y^{k}(\omega) \in A\left(u_{k}(\omega), \omega\right)$ and so by assumption, since $\left\|u_{k}(\omega)\right\| \leq$ $2\|u(\omega)\|$ it is bounded in $V^{\prime}$, this for each $\omega$.

Thus the components of $\mathbf{f}\left(y^{j}\right)(\omega)$ lie in a compact subset of $\mathbb{R}$, this for each $\omega$. It follows from Tychanoff's theorem that $\Gamma_{n}(\omega)$ is a compact subset of the Polish space $X$.

Claim: $\Gamma_{n}$ is measurable into $X$.
Proof of claim: It is necessary to show that $\Gamma_{n}^{-}(U) \equiv\left\{\omega: \Gamma_{n}(U) \cap U \neq \emptyset\right\}$ is measurable whenever $U$ is open. It suffices to verify this for $U$ a basic open set in the topology of $X$. Thus let $U=\prod_{i=1}^{\infty} O_{i}$ where $O_{i}$ is a proper open subset of $\mathbb{R}$ only for $i \in\left\{j_{1}, \cdots, j_{n}\right\}$. Then

$$
\Gamma_{n}^{-}(U)=\cup_{j \geq n} \cap_{r=1}^{n}\left\{\omega:\left\langle y^{j}(\omega), z_{j_{r}}\right\rangle \in O_{j_{r}}\right\}
$$

which is a measurable set thanks to $y^{j}$ being measurable.
In addition to this, $\Gamma_{n}(\omega)$ is compact, as explained above. Therefore, $\Gamma_{n}$ is also strongly measurable meaning $\Gamma_{n}^{-}(F)$ is measurable for all $F$ closed. Now let $\Gamma(\omega) \equiv \cap_{n=1}^{\infty} \Gamma_{n}(\omega)$. It is a nonempty closed subset of $X$ and if $F$ is closed in $X$,

$$
\Gamma^{-}(F)=\cap_{n=1}^{\infty} \Gamma_{n}^{-}(F)
$$

a measurable set since each $\Gamma_{n}^{-}(F)$ is measurable. Thus $\Gamma$ is a measurable multifunction and so it has a measurable selection $\omega \rightarrow \mathbf{z}(\omega)$. Thus by definition, for each $i, z_{i}(\omega)=$ $\lim _{n(\omega) \rightarrow \infty}\left\langle y^{n(\omega)}(\omega), z_{i}\right\rangle$ for some subsequence indexed by $n(\omega)$. The sequence given as $\left\{y^{n(\omega)}(\omega)\right\}$ is bounded in $V^{\prime}$ and so there is a subsequence still denoted as $\left\{y^{n(\omega)}\right\}$ which converges weakly to $y(\omega)$. Thus $z_{i}(\omega)=\left\langle y(\omega), z_{i}\right\rangle$ for each $i$. Since $\omega \rightarrow z_{i}(\omega)$ is measurable, it follows from density of the $\left\{z_{i}\right\}$ that $y$ is weakly, hence strongly measurable, this by the Pettis theorem. Now $y(\omega)=\lim _{n(\omega) \rightarrow \infty} y^{n(\omega)}(\omega)$. But

$$
y^{n(\omega)}(\omega) \in A\left(u_{n(\omega)}(\omega), \omega\right)
$$

which is a convex closed set for which $u \rightarrow A(u, \omega)$ is upper semicontinuous and $u_{n(\omega)} \rightarrow u$ so in fact, $y(\omega) \in A(u(\omega), \omega)$. This is the claimed measurable selection.

Note that we are not assuming that $\omega \rightarrow A(u, \omega)$ is measurable, only that it has a measurable selection and of course the upper semicontinuity and that the values are closed and convex. Also note that $\omega \rightarrow \Gamma(\omega)$ is measurable so there is a dense subset of measurable functions $\left\{\mathbf{z}_{k}(\omega)\right\}$ each being measurable into $X$. However, we don't know much about $\Gamma(\omega)$ other than it is measurable into $X$.

Also $\mathscr{V}$ could be replaced with $L^{p}(I, V)$ where $I$ is any interval and nothing changes.
The condition leading to 77.5 .26 will typically be satisfied. For example, suppose $u^{*} \in$ $A(u, \omega)$ means that

$$
u^{*}(t) \in A\left(t, u(t), \int_{0}^{t} u(s) d s, \omega\right)
$$

for a.e. $t$. where $A$ has values in $\mathscr{P}\left(V^{\prime}\right)$. Then to say that $u^{*} \mathscr{X}_{[0, \hat{Y}]} \in A\left(u \mathscr{X}_{[0, \hat{T}]}, \omega\right)$ for each $\hat{T}$ in an increasing sequence converging to $T$ would imply the above holding for a.e. $t$. While the above is the typical situation one would expect to see, the following proposition is also interesting.

Proposition 77.5.4 Suppose $A(\cdot, \omega): \mathscr{V} \rightarrow \mathscr{P}\left(\mathscr{V}^{\prime}\right)$ is upper semicontinuous as a map from the strong topology of $\mathscr{V}$ to the weak topology of $\mathscr{V}^{\prime}$ and has closed convex values. Then if

$$
u^{*} \mathscr{X}_{[0, \hat{T}]} \in A\left(u \mathscr{X}_{[0, \hat{T}]}, \omega\right)
$$

for each $\hat{T}$ in an increasing sequence converging to $T$, then

$$
\begin{equation*}
u^{*} \in A(u, \omega) \tag{77.5.36}
\end{equation*}
$$

Proof: Let $\hat{T}_{n} \uparrow T$ such that $u^{*} \mathscr{X}_{\left[0, \hat{T}_{n}\right]} \in A\left(u \mathscr{X}_{\left[0, \hat{T}_{n}\right]}, \omega\right)$. Then if $u^{*} \notin A(u, \omega)$, there exists $z \in \mathscr{V}$ such that

$$
\left\langle u^{*}, z\right\rangle>r>\left\langle w^{*}, z\right\rangle
$$

for all $w^{*} \in A(u, \omega)$. Now $u^{*} \mathscr{X}_{\left[0, \hat{T}_{n}\right]} \rightarrow u^{*}$ in $\mathscr{V}^{\prime}$ and $u \mathscr{X}_{\left[0, \hat{T}_{n}\right]} \rightarrow u$ in $\mathscr{V}$. Letting $O$ be the weakly open set, $\left\{z^{*}:\left\langle z^{*}, z\right\rangle<r\right\}$, it follows that this $O$ is a weakly open set which contains $A(u, \omega)$. Hence, by upper semicontinuity, $\left\langle u^{*} \mathscr{X}_{\left[0, \hat{T}_{n}\right]}, z\right\rangle<r$ for all $n$ large enough. Hence, passing to a limit, one obtains $\left\langle u^{*}, z\right\rangle>r \geq\left\langle u^{*}, z\right\rangle$, a contradiction. Thus $u^{*} \in A(u, \omega)$.

Let $r>\max (\hat{p}, 2)$. Recall that $\hat{p} \geq p$ and the growth had to do with $\hat{p}$. Let $\mathscr{U}$ and $\mathscr{U}_{I}$ be defined by analogy with $\mathscr{V}$ and $\mathscr{V}_{I}$ where $\mathscr{U} \equiv L^{r}([0, T], U)$. Here $U$ is a Hilbert space which is dense in $V$ and embedds compactly into $V,\|u\|_{U} \geq\|u\|_{V}$. Also let $F: U \rightarrow U^{\prime}$ be the duality map for $r$. Thus

$$
\|F u\|_{U^{\prime}}=\|u\|_{U}^{r-1},\langle F u, u\rangle=\|u\|_{U}^{r}
$$

Also define the following notation for small positive $h$.

$$
\tau_{h} g(t) \equiv\left\{\begin{array}{l}
g(t-h) \text { if } t>h \\
0 \text { if } t \leq h
\end{array}\right.
$$

Let $\omega \rightarrow u_{0}(\omega)$ be $\mathscr{F}$ measurable into $W$. Also let $\omega \rightarrow f(\cdot, \omega)$ be $\mathscr{F}$ measurable into $\mathscr{V}^{\prime}, \omega \rightarrow B(\omega)$ measurable into $\mathscr{L}\left(W, W^{\prime}\right)$. Now let $u_{h}$ for $h>0$ and small, be the unique solution to the initial value problem

$$
\begin{align*}
\left(B(\omega) u_{h}(\cdot, \omega)\right)^{\prime}+\varepsilon F u_{h}(\cdot, \omega) & =f(\cdot, \omega)-u_{h}^{*}(\cdot, \omega) \text { in } \mathscr{U}^{\prime},  \tag{77.5.37}\\
B u_{h}(0, \omega) & =B u_{0}(\omega)
\end{align*}
$$

where $u_{h}^{*} \in A\left(\tau_{h} u, \omega\right)$ is a $\mathscr{F}$ measurable selection into $\mathscr{V}^{\prime}$. Since $F$ is monotone bounded and hemicontinuous, there is no problem with it being pseudomonotone from $X_{r I}$ to $X_{r I}^{\prime}$. Such a solution exists on $[0, h]$ by the above reasoning. Let this solution be denoted by $u_{1}$. Then use it to define a solution to the evolution equation on $[0,2 h]$ called $u_{2}$. By uniqueness, these coincide on $[0, h]$. Then use $u_{2}$ to extend to a solution on $[0,3 h]$ called $u_{3}$. Then $u_{3}=u_{2}$ on $[0,2 h]$. Continue this way to obtain a solution valid on $[0, T]$. By Lemma 77.4.3, this solution may be assumed to be measurable into $\mathscr{U}^{\prime}$. One gets this by using the lemma on a succession of intervals $[0, h],[0,2 h]$, and so forth.

Now acting on $u_{h}$ and suppressing the dependence on $\omega$ in most places, it follows from the assumed estimates (Note how the assumption on growth was used here.) that

$$
\begin{align*}
& \frac{1}{2}\left\langle B u_{h}, u_{h}\right\rangle(T)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\varepsilon \int_{0}^{T}\left\|u_{h}\right\|_{U}^{r} d s \\
& \leq\left(\int_{0}^{T}\|f\|_{V^{\prime}}^{p^{\prime}} d s\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|u_{h}\right\|_{V}^{p}\right)^{1 / p} \\
&+\int_{0}^{T}\left(a+b\left\|\tau_{h} u_{h}\right\|_{V}^{\hat{p}-1}\right)\left\|u_{h}\right\|_{V} d s \\
& \leq\|f\|_{V^{\prime}}^{\hat{p}^{\prime}}+\left\|u_{h}\right\|_{\mathscr{V}}^{\hat{p}}+\left\|u_{h}\right\|_{\mathscr{V}}^{\hat{p}}+a T^{1 / \hat{p}^{\prime}}+b\left\|u_{h}\right\|_{\mathscr{V}}^{\hat{p}} \tag{77.5.38}
\end{align*}
$$

which is of the form

$$
\leq C\left(\|f\|_{\mathscr{V}^{\prime}}^{\hat{p}^{\prime}}, a(\omega) T\right)+(2+b)\left\|u_{h}\right\|_{\mathscr{V}}^{\hat{p}}
$$

Now here is where it is good that $\hat{p}<r$.

$$
\begin{aligned}
\left\|u_{h}\right\|_{\mathscr{V}}^{\hat{p}} \leq & \int_{0}^{T} \frac{1}{\delta} \delta\left\|u_{h}\right\|_{U}^{\hat{p}} d s \\
& \leq\left(\int_{0}^{T} \delta^{r / \hat{p}}\left\|u_{h}\right\|_{U}^{r} d s\right)^{\hat{p} / r}\left(\int_{0}^{T} \frac{1}{\delta^{r /(r-\hat{p})}} 1^{r / r-\hat{p}}\right)^{(r-\hat{p}) / r} \\
& \leq \frac{1}{\delta^{r /(r-\hat{p})}} \frac{T^{(r-\hat{p}) / r}}{r}(r-\hat{p})+\frac{\hat{p} \delta^{r / \hat{p}}\left\|u_{h}\right\|_{\mathscr{U}}^{r}}{r}
\end{aligned}
$$

Thus this has shown

$$
\begin{aligned}
& \frac{1}{2}\left\langle B u_{h}, u_{h}\right\rangle(T)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\varepsilon\left\|u_{h}\right\|_{\mathscr{U}}^{r} \\
\leq & C\left(\|f\|_{\mathscr{V}^{\prime}}^{\hat{p}^{\prime}}, a(\omega) T\right)+\frac{1}{\delta^{r /(r-\hat{p})}} \frac{T^{(r-\hat{p}) / r}}{r}(r-\hat{p})+\frac{\hat{p} \delta^{r / \hat{p}}\left\|u_{h}\right\|_{\mathscr{U}}^{r}}{r}
\end{aligned}
$$

Then for $\delta$ small enough, depending on $\varepsilon$,

$$
\frac{\hat{p}}{r} \delta^{r / \hat{p}}<\frac{\varepsilon}{2}
$$

And so the inequality ending at 77.5 .38 yields

$$
\left\langle B u_{h}, u_{h}\right\rangle(T)+\varepsilon\left\|u_{h}\right\|_{\mathscr{U}}^{r} \leq C\left(\|f\|_{\mathscr{V}^{\prime}}^{\hat{p}^{\prime}},(a(\omega)+1) T, \varepsilon\right)+\left\langle B u_{0}, u_{0}\right\rangle
$$

From 77.5.37 and the boundedness of the various operators, $\left(B(\omega) u_{h}(\cdot, \omega)\right)^{\prime}$ is bounded in $\mathscr{U}^{\prime}$. Thus, summarizing these estimates yields the following for fixed $\varepsilon$

$$
\begin{equation*}
\left\|\left(B(\omega) u_{h}(\cdot, \omega)\right)^{\prime}\right\|_{\mathscr{U}^{\prime}}+\left\|u_{h}\right\|_{\mathscr{U}}+\left\|u_{h}^{*}\right\|_{\mathscr{V}^{\prime}} \leq C \tag{77.5.39}
\end{equation*}
$$

where $C$ does not depend on $h$ although it does depend on $\varepsilon$ and of course on $\omega$. Then one can get a subsequence, still denoted with $h$ such that as $h \rightarrow 0$,

$$
\begin{gather*}
u_{h} \rightarrow u \text { weakly in } \mathscr{U}  \tag{77.5.40}\\
\tau_{h} u_{h} \rightarrow u \text { weakly in } \mathscr{U}  \tag{77.5.41}\\
\left(B(\omega) u_{h}(\cdot, \omega)\right)^{\prime} \rightarrow(B(\omega) u)^{\prime} \text { weakly in } \mathscr{U}^{\prime}  \tag{77.5.42}\\
u_{h} \rightarrow u \text { strongly in } \mathscr{V}  \tag{77.5.43}\\
u_{h}^{*} \rightarrow u^{*} \text { weakly in } \mathscr{V}^{\prime}  \tag{77.5.44}\\
F u_{h} \rightarrow \xi \in \mathscr{U}^{\prime}  \tag{77.5.45}\\
B u(0, \omega)=B u_{0}(\omega) \tag{77.5.46}
\end{gather*}
$$

The fourth of these comes from a use of Theorem 77.3.1. We need to argue that $u^{*} \in$ $A(u, \omega)$. From the equation and initial conditions of 77.5.37, it follows from monotonicity conditions and the observation that $\mathscr{V}^{\prime}$ is contained in $\mathscr{U}^{\prime}$ that

$$
\begin{gathered}
\left\langle\left(B(\omega) u_{h}(\cdot, \omega)\right)^{\prime}, u_{h}-u\right\rangle+\left\langle\varepsilon F u_{h}(\cdot, \omega), u_{h}-u\right\rangle \\
+\left\langle u_{h}^{*}(\cdot, \omega), u_{h}-u\right\rangle=\left\langle f(\cdot, \omega), u_{h}-u\right\rangle
\end{gathered}
$$

and so

$$
\begin{gathered}
\left\langle(B(\omega) u(\cdot, \omega))^{\prime}, u_{h}-u\right\rangle+\left\langle\varepsilon F u_{h}(\cdot, \omega), u_{h}-u\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}} \\
+\left\langle u_{h}^{*}(\cdot, \omega), u_{h}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq\left\langle f(\cdot, \omega), u_{h}-u\right\rangle
\end{gathered}
$$

by the strong convergence of 77.5 .43 , it follows that the third term converges to 0 as $h \rightarrow 0$. This is because the estimate 77.5 .27 implies that the $u_{h}^{*}$ are bounded, and then the strong convergence gives the desired result. Hence

$$
\limsup _{h \rightarrow 0}\left\langle\varepsilon F u_{h}(\cdot, \omega), u_{h}-u\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}} \leq 0
$$

and since $F$ is monotone and hemicontinuous, it follows that in fact,

$$
\lim _{h \rightarrow 0}\left\langle\varepsilon F u_{h}(\cdot, \omega), u_{h}-u\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}}=0
$$

so for $v \in \mathscr{U}$ arbitrary,

$$
\begin{aligned}
\langle\varepsilon \xi, u-v\rangle= & \lim \inf _{h \rightarrow 0}\left(\left\langle\varepsilon F u_{h}(\cdot, \omega), u-u_{h}\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}}+\left\langle\varepsilon F u_{h}(\cdot, \omega), u_{h}-v\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}}\right) \\
& =\lim _{h \rightarrow 0}\left\langle\varepsilon F u_{h}(\cdot, \omega), u_{h}-v\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}} \geq\langle\varepsilon F u, u-v\rangle
\end{aligned}
$$

and so, since $v$ is an arbitrary element of $\mathscr{U}$, it follows that $\xi=F(u)$.
Now consider the other term involving $u_{h}^{*}$. Recall that $u_{h}^{*} \in A\left(\tau_{h} u_{h}, \omega\right)$.

$$
\begin{aligned}
\left\|\tau_{h} u_{h}-u_{h}\right\|_{\mathscr{V}} & \leq\left\|\tau_{h} u_{h}-\tau_{h} u\right\|_{\mathscr{V}}+\left\|\tau_{h} u-u\right\|_{\mathscr{V}} \\
& \leq\left\|u_{h}-u\right\|_{\mathscr{V}}+\left\|\tau_{h} u-u\right\|_{\mathscr{V}}
\end{aligned}
$$

and both of these on the right converge to 0 thanks to continuity of translation and 77.5.43. Therefore,

$$
\lim _{h \rightarrow 0}\left\langle u_{h}^{*}(\cdot, \omega), \tau_{h} u_{h}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0
$$

It follows that

$$
\begin{aligned}
\left\langle u^{*}, u-v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} & =\lim \inf _{h \rightarrow 0}\left(\left\langle u_{h}^{*}(\cdot, \omega), u-\tau_{h} u_{h}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle u_{h}^{*}(\cdot, \omega), \tau_{h} u_{h}-v\right\rangle\right) \\
& \geq \lim \inf _{h \rightarrow 0}\left\langle u_{h}^{*}(\cdot, \omega), \tau_{h} u_{h}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle
\end{aligned}
$$

where $u^{*}(v) \in A(u, \omega)$. Then it follows that $u^{*} \in A(u, \omega)$ because if not, then by separation theorems, there would exist $v$ such that

$$
\left\langle u^{*}, u-v\right\rangle_{V^{\prime}, \mathscr{V}}<\left\langle w^{*}, u-v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

for all $w^{*} \in A(u, \omega)$ which contradicts the above inequality. Thus, passing to the limit in 77.5.37,

$$
\begin{align*}
(B(\omega) u(\cdot, \omega))^{\prime}+\varepsilon F u(\cdot, \omega)+u^{*} & =f(\cdot, \omega) \text { in } \mathscr{U}^{\prime},  \tag{77.5.47}\\
B u(0, \omega) & =B u_{0}(\omega)
\end{align*}
$$

Here $u^{*} \in A(u, \omega)$. Of course nothing is known about the measurability of $u^{*}, u$. All that has been obtained in the above is a solution for each fixed $\omega$. However, each of the functions $u_{h}, u_{h}^{*}$ is measurable. Also we have the estimate 77.5.39. By Theorem 77.2.10, there are functions $\hat{u}(\cdot, \omega), \hat{u}^{*}(\cdot, \omega)$ and a subsequence with subscript $h(\omega)$ such that the following weak convergences in $\mathscr{V}$ and $\mathscr{V}^{\prime}$ take place

$$
u_{h(\omega)}(\cdot, \omega) \rightharpoonup \hat{u}(\cdot, \omega), u_{h(\omega)}^{*}(\cdot, \omega) \rightharpoonup \hat{u}^{*}(\cdot, \omega)
$$

such that the functions $(t, \omega) \rightarrow \hat{u}(t, \omega),(t, \omega) \rightarrow \hat{u}^{*}(t, \omega)$ are product measurable into $V$ and $V^{\prime}$ respectively. The above argument shows that for each $\omega$, there is a further subsequence, still denoted with subscript $h(\omega)$ such that $u_{h(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $\mathscr{V}$ and $u_{h(\omega)}^{*}(\cdot, \omega) \rightarrow u^{*}(\cdot, \omega)$ weakly in $\mathscr{V}^{\prime}$ such that $\left(u(\cdot, \omega), u^{*}(\cdot, \omega)\right)$ is a solution to the evolution equation for each $\omega$. By uniqueness of limits, $u(\cdot, \omega)=\hat{u}(\cdot, \omega)$, similar for $\hat{u}^{*}$. Thus this solution which is defined for each $\omega$ has a representative for each $\omega$ such that the resulting functions of $t, \omega$ are product measurable into $V, V^{\prime}$ respectively. This proves the following lemma.

Lemma 77.5.5 For each $\varepsilon>0$ there exists a solution to

$$
\begin{align*}
(B(\omega) u(\cdot, \omega))^{\prime}+\varepsilon F u(\cdot, \omega)+u^{*}(\cdot, \omega) & =f(\cdot, \omega) \text { in } \mathscr{U}^{\prime},  \tag{77.5.48}\\
B u(0, \omega) & =B u_{0}(\omega) \\
u^{*}(\cdot, \omega) & \in A(u(\cdot, \omega), \omega) \tag{77.5.49}
\end{align*}
$$

this solution satisfies $(t, \omega) \rightarrow u(t, \omega)$ is product measurable into $V$. Also $(t, \omega) \rightarrow u^{*}(t, \omega)$, and $(t, \omega) \rightarrow B(\omega) u(t, \omega)$ are product measurable into $V^{\prime}$ and $W^{\prime}$ respectively.

Next it is desired to remove the regularizing term $\varepsilon F u$. This will involve another use of Theorem 77.2.10. Denote by $u_{\varepsilon}$ the solution to the above lemma. Then act on $u_{\varepsilon}$ on both sides. This yields

$$
\begin{gather*}
\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(T)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\varepsilon \int_{0}^{T}\left\langle F u_{\varepsilon}, u_{\varepsilon}\right\rangle d s \\
\quad+\int_{0}^{T}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle d s=\int_{0}^{T}\left\langle f, u_{\varepsilon}\right\rangle d s \tag{77.5.50}
\end{gather*}
$$

Then by the coercivity assumption,

$$
\lim _{\substack{\|u\|_{\mathscr{V}} \rightarrow \infty \\ u \in X_{r}}} \frac{\inf \left\{2\left\langle u^{*}, u\right\rangle+\langle B u, u\rangle(T): u^{*} \in A(u, \omega)\right\}}{\|u\|_{\mathscr{V}}}=\infty
$$

it follows that

$$
\begin{equation*}
\varepsilon\left\langle F u_{\varepsilon}, u_{\varepsilon}\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}}+\left\|u_{\varepsilon}\right\|_{\mathscr{V}} \leq C\left(u_{0}, f\right) \tag{77.5.51}
\end{equation*}
$$

where the constant on the right does not depend on $\varepsilon$. Then

$$
\varepsilon F u_{\varepsilon} \rightarrow 0 \text { strongly in } \mathscr{U}^{\prime}
$$

this follows because from properties of the duality map,

$$
\begin{aligned}
\left\langle\varepsilon F u_{\varepsilon}, v\right\rangle & \leq \varepsilon\left\langle F u_{\varepsilon}, u_{\varepsilon}\right\rangle^{1 / r^{\prime}}\langle F v, v\rangle^{1 / r} \\
& =\varepsilon^{1 / r^{\prime}}\left\langle F u_{\mathcal{E}}, u_{\mathcal{E}}\right\rangle^{1 / r^{\prime}} \varepsilon^{1 / r}\|v\|_{\mathscr{U}} \leq C \varepsilon^{1 / r}\|v\|_{\mathscr{U}}
\end{aligned}
$$

Then since $A$ is bounded, there is a constant $C$ independent of $\varepsilon$ such that

$$
\begin{equation*}
\left\|u_{\varepsilon}^{*}\right\|_{\mathscr{V}^{\prime}}+\left\|\left(B u_{\varepsilon}\right)^{\prime}\right\|_{\mathscr{U}^{\prime}}+\left\|u_{\varepsilon}\right\|_{\mathscr{V}} \leq C \tag{77.5.52}
\end{equation*}
$$

It follows there is a subsequence, still denoted with $\varepsilon$ such that

$$
\begin{align*}
u_{\varepsilon}^{*} & \rightarrow u^{*} \text { weakly in } \mathscr{V}^{\prime}  \tag{77.5.53}\\
\left(B u_{\varepsilon}\right)^{\prime} & \rightarrow(B u)^{\prime} \text { weakly in } \mathscr{U}^{\prime},  \tag{77.5.54}\\
u_{\varepsilon} & \rightarrow u \text { weakly in } \mathscr{V} . \tag{77.5.55}
\end{align*}
$$

Also

$$
\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(T)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle+\varepsilon\left\langle F u_{\varepsilon}, u_{\varepsilon}\right\rangle=\left\langle f, u_{\varepsilon}\right\rangle
$$

Assume $T$ is such that

$$
\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(T)=\left\langle B\left(u_{\varepsilon}(T)\right), u_{\varepsilon}(T)\right\rangle, B u_{\varepsilon}(T)=B\left(u_{\varepsilon}(T)\right)
$$

for all $\varepsilon$ in the sequence converging to 0 and also

$$
B u(T)=B(u(T)),\langle B u, u\rangle(T)=\langle B(u(T)), u(T)\rangle
$$

If not, carry out the argument for $\hat{T}$ close to $T$ for which this condition does hold. We have the integral equation

$$
B u_{\varepsilon}(t)-B u_{0}+\int_{0}^{t} u_{\varepsilon}^{*} d s+\int_{0}^{t} \varepsilon F u_{\varepsilon} d s=\int_{0}^{t} f d s
$$

and so $B u_{\varepsilon}(t)$ converges to $B u(t)$ in $U^{\prime}$ weakly. This follows right away from the convergence of $\left(B u_{\varepsilon}\right)^{\prime}$ in the above. Also from the above equation,

$$
B u(t)-B u_{0}+\int_{0}^{t} u^{*} d s=\int_{0}^{t} f d s
$$

Thus

$$
\begin{aligned}
B u(0) & =B u_{0} \\
(B u)^{\prime}+u^{*} & =f \text { in } \mathscr{U}^{\prime}
\end{aligned}
$$

Since $\mathscr{V}^{\prime} \subseteq \mathscr{U}^{\prime}$,

$$
\frac{1}{2}\langle B u, u\rangle(t)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\left\langle u^{*}, u\right\rangle_{V^{\prime}, V} d s=\int_{0}^{t}\langle f, u\rangle d s
$$

Also

$$
\begin{gather*}
\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(t)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\left\langle u_{\mathcal{\varepsilon}}^{*}, u_{\varepsilon}\right\rangle_{V^{\prime}, V} d s \\
\quad+\int_{0}^{t}\left\langle\varepsilon F u_{\varepsilon}, u_{\varepsilon}\right\rangle d s=\int_{0}^{t}\left\langle f, u_{\varepsilon}\right\rangle d s \tag{77.5.56}
\end{gather*}
$$

Now let $\left\{e_{i}\right\}$ be the vectors of Lemma 77.3.4 where these are in $U$. Thus

$$
\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(T)=\sum_{i=1}^{\infty}\left\langle B\left(u_{\varepsilon}(T)\right), e_{i}\right\rangle^{2}
$$

Hence, by Fatou's lemma,

$$
\begin{aligned}
\liminf _{\varepsilon \rightarrow 0}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(T) & =\lim \inf _{\varepsilon \rightarrow 0} \sum_{i=1}^{\infty}\left\langle B\left(u_{\varepsilon}(T)\right), e_{i}\right\rangle^{2} \\
& \geq \sum_{i=1}^{\infty} \lim \inf _{\varepsilon \rightarrow 0}\left\langle B\left(u_{\varepsilon}(T)\right), e_{i}\right\rangle^{2} \\
& =\sum_{i=1}^{\infty} \liminf _{\varepsilon \rightarrow 0}\left\langle B u_{\varepsilon}(T), e_{i}\right\rangle^{2} \\
& =\sum_{i=1}^{\infty}\left\langle B u(T), e_{i}\right\rangle^{2} \\
& =\langle B(u(T)), u(T)\rangle=\langle B u, u\rangle(T)
\end{aligned}
$$

From 77.5.56, letting $t=T$,

$$
\begin{aligned}
\limsup _{\varepsilon \rightarrow 0}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} & \leq \limsup _{\varepsilon \rightarrow 0}\left(\left\langle f, u_{\varepsilon}\right\rangle+\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle-\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(T)\right) \\
& \leq\langle f, u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle-\frac{1}{2}\langle B u, u\rangle(T)=\left\langle u^{*}, u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
\end{aligned}
$$

It follows that

$$
\limsup _{\varepsilon \rightarrow 0}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq\left\langle u^{*}, u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}-\left\langle u^{*}, u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0
$$

and so

$$
\liminf _{\varepsilon \rightarrow 0}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle
$$

for any $v \in \mathscr{V}$ where $u^{*}(v) \in A(u, \omega)$. In particular for $v=u$. Hence

$$
\liminf _{\varepsilon \rightarrow 0}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \geq\left\langle u^{*}(v), u-u\right\rangle=0 \geq \lim \sup _{\varepsilon \rightarrow 0}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle
$$

showing that $\lim _{\varepsilon \rightarrow 0}\left\langle u_{\varepsilon}^{*}, u_{\mathcal{E}}-u\right\rangle=0$. Thus

$$
\begin{aligned}
\left\langle u^{*}, u-v\right\rangle & \geq \lim \inf _{\varepsilon \rightarrow 0}\left(\left\langle u_{\varepsilon}^{*}, u-u_{\varepsilon}\right\rangle+\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-v\right\rangle\right) \\
& =\lim \inf _{\varepsilon \rightarrow 0}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle
\end{aligned}
$$

This implies $u^{*} \in A(u, \omega)$ because if not, then by separation theorems, there exists $v \in \mathscr{V}$ such that for all $w^{*} \in A(u, \omega)$,

$$
\left\langle u^{*}, u-v\right\rangle<\left\langle w^{*}, u-v\right\rangle
$$

contrary to what was shown above. Thus this obtains

$$
B u(t)-B u_{0}+\int_{0}^{t} u^{*} d s=\int_{0}^{t} f d s
$$

where $u^{*} \in A(u, \omega)$. In case $B u_{\varepsilon}(T) \neq B\left(u_{\varepsilon}(T)\right)$, you do the same argument for $\hat{T}<T$ where $B u_{\varepsilon}(\hat{T})=B\left(u_{\varepsilon}(\hat{T})\right)$ for all $\varepsilon$ and for $u$. Then the above argument shows that $u^{*} \mathscr{X}_{[0, \hat{T}]} \in A\left(\mathscr{X}_{[0, \hat{T}]} u, \omega\right)$. This being true for every such $\hat{T}<T$ implies that it holds on $[0, T]$ and shows part of the following theorem which is the main result.

Theorem 77.5.6 Let the conditions on A hold 77.5.25-77.5.28, 77.5.30-77.5.34. Also let $B$ satisfy 77.3.6 and assume, if it depends on $\omega$, it is of the form

$$
B(\omega)=k(\omega) B, k(\omega) \geq 0, k \text { measurable }
$$

Let $u_{0}$ be $\mathscr{F}$ measurable into $W$, and let $f$ be product measurable into $V^{\prime}, f(\cdot, \omega) \in \mathscr{V}^{\prime}$. Then there exists a solution to the following evolution inclusion

$$
\begin{align*}
(B(\omega) u(\cdot, \omega))^{\prime}+u^{*}(\cdot, \omega) & =f(\cdot, \omega) \text { in } \mathscr{V}^{\prime} \\
B(\omega) u(0, \omega) & =B(\omega) u_{0}(\omega) \tag{77.5.57}
\end{align*}
$$

where $u^{*}(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$. In addition to this, $(t, \omega) \rightarrow u(t, \omega)$ is product measurable into $V$ and $(t, \omega) \rightarrow u^{*}(t, \omega)$ is product measurable into $V^{\prime}$.

In place of the coercivity condition 77.5 .28 assume the coercivity condition involving both $B$ and $A$ given in 77.5.29. Then

$$
\begin{align*}
(B(\omega) u(\cdot, \omega))^{\prime}+u^{*}(\cdot, \omega) & =f(\cdot, \omega) \text { in } \mathscr{U}^{\prime}  \tag{77.5.58}\\
B(\omega) u(0, \omega) & =B(\omega) u_{0}(\omega) \tag{77.5.59}
\end{align*}
$$

Thus the following holds in $V^{\prime}$

$$
\begin{aligned}
(B(\omega) u(\cdot, \omega))(t)-B(\omega) u_{0}(\omega)+\int_{0}^{t} u^{*}(\cdot, \omega) d s & =\int_{0}^{t} f(s, \omega) d s \\
(B u)^{\prime} & \in \mathscr{V}^{\prime}
\end{aligned}
$$

Proof of Theorem 77.5.6: First consider the claim about replacing the coercivity condition. Returning to 77.5.50, one obtains by integrating up to $t$ and adding $\lambda \int_{0}^{t}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle d s$ to both sides,

$$
\begin{gather*}
\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(t)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\varepsilon \int_{0}^{t}\left\langle F u_{\varepsilon}, u_{\varepsilon}\right\rangle d s \\
+\int_{0}^{t}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle d s+\lambda \int_{0}^{t}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle d s=\int_{0}^{t}\left\langle f, u_{\varepsilon}\right\rangle d s+\lambda \int_{0}^{t}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle d s \tag{77.5.60}
\end{gather*}
$$

Then from the estimate 77.5.29,

$$
\begin{array}{r}
\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(t)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\varepsilon \int_{0}^{t}\left\langle F u_{\varepsilon}, u_{\varepsilon}\right\rangle d s \\
+\delta(\omega) \int_{0}^{t}\left\|u_{\varepsilon}\right\|_{V}^{p} d s-m(\omega)=\int_{0}^{t}\left\langle f, u_{\varepsilon}\right\rangle d s+\lambda \int_{0}^{t}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle d s \tag{77.5.61}
\end{array}
$$

From this, it is a routine use of Gronwall's inequality to obtain the estimate

$$
\begin{equation*}
\varepsilon\left\langle F u_{\mathcal{E}}, u_{\varepsilon}\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}}+\left\|u_{\varepsilon}\right\|_{\mathscr{V}} \leq C\left(u_{0}, f, \lambda, \omega\right) \tag{77.5.62}
\end{equation*}
$$

Then the rest of the argument is the same. You obtain the following in $U^{\prime}$.

$$
B(\omega) u(t, \omega)-B(\omega) u_{0}(\omega)+\int_{0}^{t} u^{*}(\cdot, \omega) d s=\int_{0}^{t} f(s, \omega) d s
$$

Since all terms but the first are in $V^{\prime}$, the equation holds in $V^{\prime}$. Also, the equation in 77.5.58 shows that $(B(\omega) u(\cdot, \omega))^{\prime} \in \mathscr{V}^{\prime}$.

It only remains to show that there is a product measurable solution. The above argument has shown that there exists a solution for each $\omega$. This is another application of Theorem 77.2.10. For the sequence defined in the convergences 77.5.53-77.5.55, there is an estimate 77.5.52. Therefore, the conditions of this theorem hold and there exists a subsequence denoted with $\varepsilon(\omega)$ such that

$$
\begin{aligned}
& u_{\mathcal{E}(\omega)}(\cdot, \omega) \quad \rightarrow \hat{u}(\cdot, \omega) \text { weakly in } \mathscr{V} \\
& u_{\varepsilon(\omega)}^{*}(\cdot, \omega) \quad \rightarrow \quad \hat{u}^{*}(\cdot, \omega) \text { weakly in } \mathscr{V}^{\prime}
\end{aligned}
$$

where the $\hat{u}$ and $\hat{u}^{*}$ are product measurable. Now the above argument shows that for each $\omega$ there exists a further subsequence, still denoted with $\varepsilon(\omega)$ such that convergence to a solution to the evolution inclusion is obtained $\left(u(\cdot, \omega), u^{*}(\cdot, \omega)\right)$. Then by uniqueness of limits, $\hat{u}(\cdot, \omega)=u(\cdot, \omega)$ in $\mathscr{V}$, similar for $u^{*}$ and $\hat{u}^{*}$. Hence there is a solution to the above evolution problem which satisfies the claimed product measurability.

One can give a very interesting generalization of the above theorem.
Theorem 77.5.7 In the context of Theorem 77.5.6, let $q(t, \omega)$ be a product measurable function into $V$ such that $t \rightarrow q(t, \omega)$ is continuous, $q(0, \omega)=0$.

Then, there exists a solution $u$ of the integral equation

$$
B u(t, \omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)+B q(t, \omega)
$$

where $(t, \omega) \rightarrow u(t, \omega)$ is product measurable. Moreover, for each $\omega, B u(t, \omega)=B(u(t, \omega))$ for a.e. $t$ and $z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$ for a.e. $t, z$ is product measurable into $V^{\prime}$. Also, for each $a \in[0, T]$,

$$
B u(t, \omega)+\int_{a}^{t} z(s, \omega) d s=\int_{a}^{t} f(s, \omega) d s+B u(a, \omega)+B q(t, \omega)-B q(a, \omega)
$$

Proof: Define a stopping time

$$
\tau_{r} \equiv \inf \{t:|q(t, \omega)|>r\}
$$

Then this is the first hitting time of an open set by a continuous random variable and so it is a valid stopping time. Then for each $r$, let

$$
A_{r}(\omega, w) \equiv A\left(\omega, w+q^{\tau_{r}}(\cdot, \omega)\right)
$$

where the notation means $q^{\tau_{r}}(t) \equiv q\left(t \wedge \tau_{r}\right)$. Then, since $q^{\tau_{r}}$ is uniformly bounded, all of the necessary estimates and measurability for the solution to the above corollary hold for $A_{r}$ replacing $A$. Therefore, there exists a solution $w_{r}$ to the inclusion

$$
\left(B w_{r}\right)^{\prime}(\cdot, \omega)+A_{r}\left(w_{r}(\cdot, \omega), \omega\right) \ni f(\cdot, \omega), B w_{r}(0, \omega)=B u_{0}(\omega)
$$

Now for fixed $\omega, q^{\tau_{r}}(t, \omega)$ does not change for all $r$ large enough. This is because it is a continuous function of $t$ and so is bounded on the interval $[0, T]$. Thus, for $r$ large enough and fixed $\omega, q^{\tau_{r}}(t, \omega)=q(t, \omega)$. Thus, we obtain

$$
\begin{equation*}
\left\langle B w_{r}(t, \omega), w_{r}(t, \omega)\right\rangle+\int_{0}^{t}\left\|w_{r}(s, \omega)\right\|_{V}^{p} d s \leq C(\omega) \tag{77.5.63}
\end{equation*}
$$

Now, as before one can pass to a limit involving a subsequence, as $r \rightarrow \infty$ and obtain a solution to the integral equation

$$
B w(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s
$$

where $z(s, \omega) \in A(s, \omega, w(s, \omega)+q(s, \omega))$ for a.e. $s$ and $z$ is product measurable. Then an application of Theorem 77.2.10 shows that there exists a solution $w$ to this integral equation for each $\omega$ which also has $(t, \omega) \rightarrow w(t, \omega)$ product measurable and $(t, \omega) \rightarrow$ $z(t, \omega)$ product measurable. Now just let $u(t, \omega)=w(t, \omega)+q(t, \omega)$.

The last claim follows from letting $t=a$ in the top equation and then subtracting this from the top equation with $t>a$.

### 77.6 Variational Inequalities

We have some good theorems above in the context of 77.5.25-77.5.28, 77.5.30-77.5.34 and $B$ satisfies 77.3.6 and assume, if it depends on $\omega$, it is of the form

$$
B(\omega)=k(\omega) B, k(\omega) \geq 0, k \text { measurable }
$$

Now this will be used to consider variational inequalities.
Let $\mathscr{K}$ be a closed convex subset of $\mathscr{V}$ containing 0 . Let $P: \mathscr{V} \rightarrow \mathscr{V}^{\prime}$ be an operator of penalization. Thus $P=0$ on $\mathscr{K}$ and is monotone and demicontinuous and nonzero off $\mathscr{K}$.

$$
P u=F\left(u-\operatorname{proj}_{\mathscr{K}}(u)\right)
$$

where $F$ is the duality map such that $\langle F u, u\rangle=\|u\|^{2},\|F u\|=\|u\|$. Then $A(\cdot, \omega)+n P$ satisfies the conditions for Theorem 77.5.6 assuming $A(\cdot, \omega)$ satisfies the conditions of this theorem. Then by Theorem 77.5.6, there exists a solution $u_{n}$ such that $(t, \omega) \rightarrow$ $u_{n}(t, \omega),(t, \omega) \rightarrow u_{n}^{*}(t, \omega)$ are product measurable, and for each $\omega$,

$$
\begin{align*}
\left(B u_{n}\right)^{\prime}+u_{n}^{*}(\cdot, \omega)+n P\left(u_{n}(\cdot, \omega)\right) & =f(\cdot, \omega) \text { in } \mathscr{V}^{\prime} \\
B u_{n}(0, \omega) & =0 \tag{77.6.64}
\end{align*}
$$

Here $B$ is as described in that theorem. Using $0 \in \mathscr{K}$ and monotonicity of $P$, the estimates for $A$ lead to an estimate of the form

$$
\left\|u_{n}(\cdot, \omega)\right\|_{\mathscr{V}}+\left\|u_{n}^{*}(\cdot, \omega)\right\|_{\mathscr{V}^{\prime}} \leq C(\omega)
$$

Then there is a subsequence

$$
u_{n} \rightarrow u \text { weakly in } \mathscr{V}
$$

$$
\begin{gathered}
u_{n}^{*} \rightarrow u^{*} \text { weakly in } \mathscr{V}^{\prime} \\
P u_{n} \rightarrow \xi \text { weakly in } \mathscr{V}^{\prime}
\end{gathered}
$$

Let $\Lambda$ denote those $v \in \mathscr{V}$ such that $(B v)^{\prime} \in \mathscr{V}^{\prime}$ and $B v(0)=0$. Then for $v \in \Lambda$,

$$
\left\langle\left(B u_{n}\right)^{\prime}, u_{n}-v\right\rangle+\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-v\right\rangle+n\left\langle P\left(u_{n}(\cdot, \omega)\right), u_{n}-v\right\rangle=\left\langle f(\cdot, \omega), u_{n}-v\right\rangle
$$

Thus by monotonicity considerations,

$$
\begin{equation*}
\left\langle(B v)^{\prime}, u_{n}-v\right\rangle+\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-v\right\rangle+n\left\langle P\left(u_{n}(\cdot, \omega)\right), u_{n}-v\right\rangle \leq\left\langle f(\cdot, \omega), u_{n}-v\right\rangle \tag{*}
\end{equation*}
$$

It follows that

$$
\begin{aligned}
\lim \sup _{n \rightarrow \infty}\left\langle P\left(u_{n}(\cdot, \omega)\right), u_{n}-v\right\rangle & \leq 0 \\
\lim \sup _{n \rightarrow \infty}\left\langle P\left(u_{n}(\cdot, \omega)\right), u_{n}-u\right\rangle & \leq\langle-\xi, u-v\rangle
\end{aligned}
$$

Now, since $\Lambda$ is dense, $v$ can be chosen as close as desired to $u$ and hence

$$
\lim \sup _{n \rightarrow \infty}\left\langle P\left(u_{n}(\cdot, \omega)\right), u_{n}-u\right\rangle \leq 0
$$

Since $P$ is monotone, in fact the limit exists in the above. Therefore, for any $v \in \Lambda$ and $*$,

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left(\left\langle P\left(u_{n}(\cdot, \omega)\right), u_{n}-v\right\rangle\right) \geq\langle P u, u-v\rangle
$$

and so

$$
\langle P u, u-v\rangle \leq 0
$$

for all $v \in \Lambda$. It follows that $P u=0$ and so $u \in \mathscr{K}$.
Now for $v \in \Lambda \cap \mathscr{K}$, monotonicity considerations imply

$$
\left\langle(B v)^{\prime}, u_{n}-v\right\rangle+\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle+\left\langle u_{n}^{*}(\cdot, \omega), u-v\right\rangle \leq\left\langle f(\cdot, \omega), u_{n}-v\right\rangle
$$

Then

$$
\begin{equation*}
\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle \leq\left\langle f(\cdot, \omega), u_{n}-v\right\rangle-\left\langle(B v)^{\prime}, u_{n}-v\right\rangle-\left\langle u_{n}^{*}(\cdot, \omega), u-v\right\rangle \tag{77.6.65}
\end{equation*}
$$

Then

$$
\lim _{n \rightarrow \infty}\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle \leq\langle f(\cdot, \omega), u-v\rangle+\left\langle(B v)^{\prime}, v-u\right\rangle+\left\langle u^{*}(\cdot, \omega), v-u\right\rangle
$$

We assume the existence of a regularizing sequence. If $u \in \mathscr{K}$ there exists $u_{i} \rightarrow u$ weakly in $\mathscr{V}$ such that

$$
\limsup _{i \rightarrow \infty}\left\langle\left(B u_{i}\right)^{\prime}, u_{i}-u\right\rangle_{\mathscr{V}} \leq 0
$$

In the above inequality, let $v=u_{i}$

$$
\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle \leq\left\langle f(\cdot, \omega), u-u_{i}\right\rangle+\left\langle\left(B u_{i}\right)^{\prime}, u_{i}-u\right\rangle+\left\langle u^{*}(\cdot, \omega), u_{i}-u\right\rangle
$$

Then take limsup $\sin _{i \rightarrow 0}$ of both sides to obtain

$$
\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle \leq 0
$$

Now assume the usual limit condition holds for $A(\cdot, \omega)$. In practice, this typically means $A(\cdot, \omega)$ will be single valued, monotone and hemicontinuous because there is no control on the time derivative. However, we will go ahead and assume just that the limit condition holds. This would also take place if $A(\cdot, \omega)$ were defined on $\mathscr{V}$ and maximal monotone, for example. Then for every $v \in \mathscr{V}$,

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle
$$

where $u^{*}(v) \in A(u, \omega)$. In particular, this holds for $v=u$ and so

$$
\lim \inf _{n \rightarrow \infty}\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle \geq 0 \geq \lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle
$$

showing the the limit exists. Then

$$
\begin{aligned}
\left\langle u^{*}(v), u-v\right\rangle & \leq \lim _{n \rightarrow \infty}\left(\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-v\right\rangle\right) \\
& =\lim _{n \rightarrow \infty}\left(\left\langle u_{n}^{*}(\cdot, \omega), u_{n}-u\right\rangle+\left\langle u_{n}^{*}(\cdot, \omega), u-v\right\rangle\right) \\
& =\left\langle u^{*}, u-v\right\rangle
\end{aligned}
$$

and since this is true for all $v \in \mathscr{V}$ it follows that $u^{*} \in A(u(\cdot, \omega), \omega)$ since otherwise, separation theorems would give a contradiction. If $u^{*}$ were not in $A(u(\cdot, \omega), \omega)$ there would exist $v$ such that for all $z^{*} \in A(u, \omega)$,

$$
\left\langle z^{*}, u-v\right\rangle>\left\langle u^{*}, u-v\right\rangle
$$

contrary to the above. Therefore, in 77.6 .65 we can take the limit of both sides and conclude that for every $v \in \mathscr{K}$ such that $(B v)^{\prime} \in \mathscr{V}^{\prime}, B v(0)=0$,

$$
\left\langle(B v)^{\prime}, u-v\right\rangle+\left\langle u^{*}, u-v\right\rangle \leq\langle f(\cdot, \omega), u-v\rangle
$$

where $u^{*} \in A(u, \omega)$
This has proved the first part of the following theorem which gives measurable solutions to a variational inequality.

Theorem 77.6.1 Suppose $A(\cdot, \omega)$ is monotone hemicontinuous bounded and single valued and coercive as a map from $\mathscr{V}$ to $\mathscr{V}^{\prime}$. Suppose also that for $\omega \rightarrow u(\omega)$ measurable into $\mathscr{V}$, it follows that $\omega \rightarrow A(u(\omega), \omega)$ is measurable into $\mathscr{V}^{\prime}$. Let $\mathscr{K}$ be a closed convex subset of $\mathscr{V}$ containing 0 and let $B \in \mathscr{L}\left(W, W^{\prime}\right)$ be self adjoint and nonnegative as above. Let there be a regularizing sequence $\left\{u_{i}\right\}$ for each $u \in \mathscr{K}$ satisfying $B u_{i}(0)=0,\left(B u_{i}\right)^{\prime} \in \mathscr{V}^{\prime}, u_{i} \in \mathscr{K}$,

$$
\lim \sup _{i \rightarrow \infty}\left\langle\left(B u_{i}\right)^{\prime}, u_{i}-u\right\rangle \leq 0
$$

Then for each $\omega$, there exists a solution to

$$
\left\langle(B v)^{\prime}, u-v\right\rangle+\langle A(u(\cdot, \omega), \omega), u(\cdot, \omega)-v\rangle \leq\langle f(\cdot, \omega), u-v\rangle
$$

valid for all $v \in \mathscr{K}$ such that $(B v)^{\prime} \in \mathscr{V}^{\prime}, B v(0)=0$, and $(t, \omega) \rightarrow u(t, \omega)$, is $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable.

Proof: This follows from Theorem 77.2.10. This is because there is an estimate of the right sort for the measurable functions $u_{n}(\cdot, \omega)$ and $u_{n}^{*}(\cdot, \omega)$ and the above argument which shows that a subsequence has a convergent subsequence which converges appropriately to a solution.

You can have $\mathscr{K}=\mathscr{K}(\omega)$. There would be absolutely no change in the above theorem. You just need to have the operator of penalization satisfy $\omega \rightarrow P(u(\omega), \omega)=$ $F\left(u(\omega)-\operatorname{proj}_{\mathscr{K}(\omega)} u(\omega)\right)$ is measurable into $\mathscr{V}^{\prime}$ provided $\omega \rightarrow u(\omega)$ is measurable into $\mathscr{V}$. What are the conditions on the set valued $\omega \rightarrow \mathscr{K}(\omega)$ which will cause this to take place?

Lemma 77.6.2 Let $\omega \rightarrow \mathscr{K}(\omega)$ be measurable into $\mathscr{V}$. Then $\omega \rightarrow \operatorname{proj}_{\mathscr{K}(\omega)} u(\omega)$ is also measurable into $\mathscr{V}$ if $\omega \rightarrow u(\omega)$ is measurable.

Proof: It follows from standard results on measurable multi-functions [70] that there is a countable collection $\left\{w_{n}(\omega)\right\}, \omega \rightarrow w_{n}(\omega)$ being measurable and $w_{n}(\omega) \in \mathscr{K}(\omega)$ for each $\omega$ such that for each $\omega, \mathscr{K}(\omega)=\overline{\cup_{n} w_{n}(\omega)}$. Let

$$
d_{n}(\omega) \equiv \min \left\{\left\|u(\omega)-w_{k}(\omega)\right\|, k \leq n\right\}
$$

Let $u_{1}(\omega) \equiv w_{1}(\omega)$. Let

$$
u_{2}(\omega)=w_{1}(\omega)
$$

on the set

$$
\left\{\omega:\left\|u(\omega)-w_{1}(\omega)\right\|<\left\{\left\|u(\omega)-w_{2}(\omega)\right\|\right\}\right\}
$$

and

$$
u_{2}(\omega) \equiv w_{2}(\omega) \text { off the above set. }
$$

Thus $\left\|u_{2}(\omega)-u(\omega)\right\|=d_{2}$. Let

$$
\begin{aligned}
& u_{3}(\omega)=w_{1}(\omega) \text { on }\left\{\begin{array}{c}
\omega:\left\|u(\omega)-w_{1}(\omega)\right\| \\
<\left\|u(\omega)-w_{j}(\omega)\right\|, j=2,3
\end{array}\right\} \equiv S_{1} \\
& u_{3}(\omega)=w_{2}(\omega) \text { on } S_{1} \cap\left\{\begin{array}{c}
\omega:\left\|u(\omega)-w_{1}(\omega)\right\| \\
<\left\|u(\omega)-w_{j}(\omega)\right\|, j=3
\end{array}\right\} \\
& u_{3}(\omega)=w_{3}(\omega) \text { on the remainder of } \Omega
\end{aligned}
$$

Thus $\left\|u_{3}(\omega)-u(\omega)\right\|=d_{3}$. Continue this way, obtaining $u_{n}(\omega)$ such that

$$
\left\|u_{n}(\omega)-u(\omega)\right\|=d_{n}(\omega)
$$

and $u_{n}(\omega) \in \mathscr{K}(\omega)$ with $u_{n}$ measurable. Thus, in effect one picks the closest of all the $w_{k}(\omega)$ for $k \leq n$ as the value of $u_{n}(\omega)$ and $u_{n}$ is measurable and by density in $\mathscr{K}(\omega)$ of $\left\{w_{n}(\omega)\right\}$ for each $\omega,\left\{u_{n}(\omega)\right\}$ must be a minimizing sequence for

$$
\lambda(\omega) \equiv \inf \{\|u(\omega)-z\|: z \in \mathscr{K}(\omega)\}
$$

Then it follows that $u_{n}(\omega) \rightarrow \operatorname{proj}_{\mathscr{K}(\omega)} u(\omega)$ weakly in $\mathscr{V}$. Here is why: Suppose it fails to converge to $\operatorname{proj}_{\mathscr{K}(\omega)} u(\omega)$. Since it is minimizing, it is a bounded sequence. Thus
there would be a subsequence, still denoted as $u_{n}(\omega)$ which converges to some $q(\omega) \neq$ $\operatorname{proj}_{\mathscr{K}(\omega)} u(\omega)$. Then

$$
\lambda(\omega)=\lim _{n \rightarrow \infty}\left\|u(\omega)-u_{n}(\omega)\right\| \geq\|u(\omega)-q(\omega)\|
$$

because convex and lower semicontinuous is weakly lower semicontinuous. But this implies $q(\omega)=\operatorname{proj}_{\mathscr{K}(\omega)}(u(\omega))$ because the projection map is well defined thanks to strict convexity of the norm used. This is a contradiction. Hence $\operatorname{proj}_{\mathscr{K}(\omega)} u(\omega)=\lim _{n \rightarrow \infty} u_{n}(\omega)$ and so is a measurable function. It follows that $\omega \rightarrow P(u(\omega), \omega)$ is measurable into $\mathscr{V}$.

The following corollary is now immediate.
Corollary 77.6.3 Suppose $A(\cdot, \omega)$ is monotone hemicontinuous bounded, single valued, and coercive as a map from $\mathscr{V}$ to $\mathscr{V}^{\prime}$. Suppose also that for $\omega \rightarrow u(\omega)$ measurable into $\mathscr{V}$, it follows that $\omega \rightarrow A(u(\omega), \omega)$ is measurable into $\mathscr{V}^{\prime}$. Let $\mathscr{K}(\omega)$ be a closed convex subset of $\mathscr{V}$ containing 0 and $\omega \rightarrow \mathscr{K}(\omega)$ is a set valued measurable multifunction. Let $B \in$ $\mathscr{L}\left(W, W^{\prime}\right)$ be self adjoint and nonnegative as above. Let there be a regularizing sequence $\left\{u_{i}\right\}$ for each $u \in \mathscr{K}$ satisfying $B u_{i}(0)=0,\left(B u_{i}\right)^{\prime} \in \mathscr{V}^{\prime}, u_{i} \in \mathscr{K}$,

$$
\lim \sup _{i \rightarrow \infty}\left\langle\left(B u_{i}\right)^{\prime}, u_{i}-u\right\rangle \leq 0
$$

Then for each $\omega$, there exists a solution to

$$
\left\langle(B v)^{\prime}, u-v\right\rangle+\langle A(u(\cdot, \omega), \omega), u(\cdot, \omega)-v\rangle \leq\langle f(\cdot, \omega), u(\cdot, \omega)-v\rangle
$$

valid for all $v \in \mathscr{K}(\omega)$ with $(B v)^{\prime} \in \mathscr{V}^{\prime}, B v(0)=0$, and $(t, \omega) \rightarrow u(t, \omega)$, is $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable.

Proof: The proof is identical to the above. One obtains a measurable solution to 77.6.64 in which $P$ is replaced with $P(\cdot, \omega)$. Then one proceeds in exactly the same steps as before and finally uses Theorem 77.2.10 to obtain the measurability of a solution to the variational inequality.

What does it mean for $u(\omega) \in \mathscr{K}(\omega)$ for each $\omega$ ? It means that there is a sequence of the $w_{n}\left\{w_{n(\omega)}\right\}$ such that each $w_{n}$ is measurable into $\mathscr{V}$ implying that for each $\omega$ there is a representative $t \rightarrow w_{n}(t, \omega)$ such that the resulting $(t, \omega) \rightarrow w_{n}(t, \omega)$ is product measurable and $\left\|u(\cdot, \omega)-w_{n(\omega)}(\cdot, \omega)\right\|_{\mathscr{V}} \rightarrow 0$. Thus there is no reason to think that $(t, \omega) \rightarrow u(t, \omega)$ is product measurable. The message of the above corollary says that nevertheless, there is a measurable solution to the variational inequality.

### 77.7 Progressively Measurable Solutions

In the context of uniqueness of the evolution initial value problem for fixed $\omega$, one can prove theorems about progressively measurable solutions fairly easily. First is a definition of the term progressively measurable.
Definition 77.7.1 Let $\mathscr{F}_{t}$ be an increasing in $t$ set of $\sigma$ algebras of sets of $\mathscr{F}$. Thus each $\mathscr{F}_{t}$ is a $\sigma$ algebra and if $s \leq t$, then $\mathscr{F}_{s} \leq \mathscr{F}_{t}$. This set of $\sigma$ algebras is called a filtration. A set $S \subseteq[0, T] \times \Omega$ is called progressively measurable iffor every $t \in[0, T]$,

$$
S \cap[0, t] \times \Omega \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}
$$

Denote by $\mathscr{P}$ the progressively measurable sets. This is a $\sigma$ algebra of subsets of $[0, T] \times \Omega$. A function $g$ is progressively measurable if $\mathscr{X}_{[0, t]} g$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable for each $t$.

Let $A$ satisfy the bounded condition 77.5.25, the condition on subintervals 77.5.26, the specific boundedness estimate 77.5 .27 , the specific coercivity estimate involving $B$ and $A$ in 77.5.29, and the limit condition 77.5.30. In place of the condition on the existence of a measurable selection 77.5.34, we will assume the following condition.

Condition 77.7.2 For each $t \leq T$, if $\omega \rightarrow u(\cdot, \omega)$ is $\mathscr{F}_{t}$ measurable into $\mathscr{V}_{[0, t]}$, then there exists a $\mathscr{F}_{t}$ measurable selection of $A(u(\cdot, \omega), \omega)$ into $\mathscr{V}_{[0, t]}^{\prime}$.

Note that $u(\cdot, \omega)$ is in $\mathscr{V}_{[0, t]}$ so $u(t, \omega) \in V$.
In this section, we assume that $\omega \rightarrow B(\omega)$ is $\mathscr{F}_{0}$ measurable into $\mathscr{L}\left(W, W^{\prime}\right)$. For convenience, here are the conditions used on $A$.

For the operator $A(\cdot, \omega) \cdot A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{V}_{I}^{\prime}$ for each $I$ a subinterval of $[0, T], I=[0, \hat{T}]$ and

$$
\begin{equation*}
A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{P}\left(\mathscr{V}_{I}^{\prime}\right) \text { is bounded, } \tag{77.7.66}
\end{equation*}
$$

If, for $u \in \mathscr{V}$,

$$
u^{*} \mathscr{X}_{[0, \hat{T}]} \in A\left(u \mathscr{X}_{[0, \hat{T}]}, \omega\right)
$$

for each $\hat{T}$ in an increasing sequence converging to $T$, then

$$
\begin{equation*}
u^{*} \in A(u, \omega) \tag{77.7.67}
\end{equation*}
$$

For some $\hat{p} \geq p$, assume the specific estimate

$$
\begin{equation*}
\sup \left\{\left\|u^{*}\right\|_{\mathscr{V}_{I}^{\prime}}: u^{*} \in A(u, \omega)\right\} \leq a(\omega)+b(\omega)\|u\|_{\mathscr{V}_{I}}^{\hat{p}-1} \tag{77.7.68}
\end{equation*}
$$

where $a(\omega), b(\omega)$ are nonnegative. Note that the growth could be quadratic in case $p=2$. This really just says there is polynomial growth. Also assume the coercivity condition:

$$
\begin{equation*}
\lim _{\substack{\|u\|_{\mathscr{V}} \rightarrow \infty \\ u \in X_{r}}} \frac{\inf \left\{2\left\langle u^{*}, u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\langle B u, u\rangle(T): u^{*} \in A(u, \omega)\right\}}{\|u\|_{\mathscr{V}}}=\infty, \tag{77.7.69}
\end{equation*}
$$

or alternatively the following specific estimate valid for each $t \leq T$ and for some $\lambda(\omega) \geq 0$,

$$
\begin{equation*}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d t: u^{*} \in A(u, \omega)\right) \geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \tag{77.7.70}
\end{equation*}
$$

where $m(\omega)$ is some nonnegative constant, $\delta(\omega)>0$. Note that the estimate is a coercivity condition on $\lambda B+A$ rather than on $A$ but is more specific than 77.5.28.

Let $U$ be a Banach space dense in $V$ and that if $u_{i} \rightharpoonup u$ in $\mathscr{V}_{I}$ and $u_{i}^{*} \in A\left(u_{i}\right)$ with $u_{i}^{*} \rightharpoonup u^{*}$ in $\mathscr{V}_{I}^{\prime}$ and $\left(B u_{i}\right)^{\prime} \rightharpoonup(B u)^{\prime}$ in $\mathscr{U}_{r I}^{\prime}$, $\rightharpoonup$ denoting weak convergence, then if

$$
\lim \sup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{y}_{I}} \leq 0
$$

it follows that for all $v \in \mathscr{V}_{I}$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \geq\left\langle u^{*}(v), u-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \tag{77.7.71}
\end{equation*}
$$

where $r>\max (\hat{p}, 2)$, and we replace $p$ with $r$ and $I$ an arbitrary subinterval of the form $[0, \hat{T}], \hat{T}<T$, for $[0, T]$, and $U$ for $V$ where indicated. Here

$$
\mathscr{U}_{r I} \equiv L^{r}(I ; U)
$$

The theorem to be shown is the following.
Theorem 77.7.3 Assume the above conditions, 77.7.66, 77.7.67, 77.7.68, 77.7.70, 77.7.71, and the Condition 77.7.2. Let $u_{0}$ be $\mathscr{F}_{0}$ measurable and $\omega \rightarrow B(\omega)$ also $\mathscr{F}_{0}$ measurable and $(t, \omega) \rightarrow \mathscr{X}_{[0, t]}(t) f(t, \omega)$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ product measurable into $V^{\prime}$ for each $t$. Also assume that for each $\omega$, there is at most one solution to the evolution equation

$$
\begin{aligned}
(B(\omega) u(\cdot, \omega))(t)-B(\omega) u_{0}(\omega)+\int_{0}^{t} u^{*}(\cdot, \omega) d s & =\int_{0}^{t} f(s, \omega) d s \\
u^{*}(\cdot, \omega) & \in A(u(\cdot, \omega), \omega)
\end{aligned}
$$

for $t \in[0, \hat{T}]$ for each $\hat{T} \leq T$. Then there exists a unique solution $\left(u(\cdot, \omega), u^{*}(\cdot, \omega)\right)$ in $\mathscr{V} \times \mathscr{V}^{\prime}$ to the above integral equation for each $\omega$. This solution satisfies $(t, \omega) \rightarrow$ $\left(u(t, \omega), u^{*}(t, \omega)\right)$ is progressively measurable into $V \times V^{\prime}$.

Proof: Let $\mathscr{T}$ denote subsets of $(0, T]$ which contain $T$ such that for $S \in \mathscr{T}$, there exists a solution $u_{S}$ for each $\omega$ to the above integral equation on $[0, T]$ such that $(t, \omega) \rightarrow$ $\mathscr{X}_{[0, s]}(t) u_{S}(t, \omega)$ is $\mathscr{B}([0, s]) \times \mathscr{F}_{s}$ measurable for each $s \in S$. Then $\{T\} \in \mathscr{T}$. If $S, S^{\prime}$ are in $\mathscr{T}$, then $S \leq S^{\prime}$ will mean that $S \subseteq S^{\prime}$ and also $u_{S}(t, \omega)=u_{S^{\prime}}(t, \omega)$ in $V$ for all $t \in S$, similar for $u_{S}^{*}$ and $u_{S^{\prime}}^{*}$. Note that equality must hold in $\mathscr{V}$ by uniqueness. Now let $\mathscr{C}$ denote a maximal chain. Is $\cup \mathscr{C} \equiv S_{\infty}$ all of $(0, T]$ ? What is $u_{S_{\infty}}$ ? Define $u_{S_{\infty}}(t, \omega)$ the common value of $u_{S}(t, \omega)$ for all $S$ in $\mathscr{C}$, which contain $t \in S_{\infty}$. If $s \in S_{\infty}$, then it is in some $S \in \mathscr{C}$ and so the product measurability condition holds for this $s$. Thus $S_{\infty}$ is a maximal element of the partially ordered set. Is $S_{\infty}$ all of $(0, T]$ ? Suppose $\hat{s} \notin S_{\infty}, T>\hat{s}>0$.

From Theorem 77.5.6 there exists a solution to the integral equation on $[0, \hat{s}]$ called $u_{1}$ such that $(t, \omega) \rightarrow u_{1}(t, \omega)$ is $\mathscr{B}([0, \hat{s}]) \times \mathscr{F}_{\hat{s}}$ measurable, similar for $u_{1}^{*}$. By the same theorem, there is a solution on $[0, T], u_{2}$ which is $\mathscr{B}([0, T]) \times \mathscr{F}_{T}$ measurable. Now by uniqueness, $u_{2}(\cdot, \omega)=u_{1}(\cdot, \omega)$ in $\mathscr{V}_{[0, \hat{s}]}$, similar for $u_{i}^{*}$. Therefore, no harm is done in redefining $u_{2}$ on $[0, \hat{s}]$ so that $u_{2}(t, \omega)=u_{1}(t, \omega)$ for all $t \in[0, \hat{s}]$, similar for $u^{*}$. Denote these functions as $\hat{u}, \hat{u}^{*}$. By uniqueness, $u_{S_{\infty}}(\cdot, \omega)=\hat{u}(\cdot, \omega)$ in $L^{p}([0, \hat{s}], V)$. Thus no harm is done by re-defining $\hat{u}(s, \omega)$ to equal $u_{S_{\infty}}(s, \omega)$ for $s<\hat{s}$ and $\hat{u}(\hat{s}, \omega)$ at $\hat{s}$. As to $s>\hat{s}$ also re define $\hat{u}(s, \omega) \equiv u_{S_{\infty}}(s, \omega)$ for such $s$. By uniqueness, the two are equal in $\mathscr{V}_{[\hat{s}, T]}$ and so no change occurs in the solution of the integral equation. Now $S_{\infty}$ was not maximal after all. $S_{\infty} \cup\{\hat{s}\}$ is larger. This contradiction shows that in fact, $S_{\infty}=(0, T]$.

Theorem 77.7.4 Assume the above conditions, 77.7.66, 77.7.67, 77.7.68, 77.7.70, 77.7.71, and the Condition 77.7.2. Let $u_{0}$ be $\mathscr{F}_{0}$ measurable and $\omega \rightarrow B(\omega)$ also $\mathscr{F}_{0}$ measurable and $(t, \omega) \rightarrow \mathscr{X}_{[0, t]}(t) f(t, \omega)$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ product measurable into $V^{\prime}$ for each $t$.

$$
B(\omega)=k(\omega) B, k(\omega) \geq 0, k \text { measurable }
$$

Also let $t \rightarrow q(t, \omega)$ be continuous and $q$ is progressively measurable into $V$. Suppose there is at most one solution to

$$
\begin{equation*}
B u(t, \omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)+B q(t, \omega) \tag{77.7.72}
\end{equation*}
$$

for each $\omega$. Then the solution $u$ to the above integral equation is progressively measurable and so is $z$. Moreover, for each $\omega$, both $B u(t, \omega)=B(u(t, \omega))$ a.e. $t$ and $z(\cdot, \omega) \in$ $A(u(\cdot, \omega), \omega)$. Also, for each $a \in[0, T]$,

$$
B u(t, \omega)+\int_{a}^{t} z(s, \omega) d s=\int_{a}^{t} f(s, \omega) d s+B u(a, \omega)+B q(t, \omega)-B q(a, \omega)
$$

Proof: By Theorem 77.5 .7 there exists a solution to 77.7 .72 which is $\mathscr{B}([0, T]) \times \mathscr{F}_{T}$ measurable. Now, as in the proof of Theorem 77.5 .7 one can define a new operator

$$
A_{r}(w, \omega) \equiv A\left(\omega, w+q^{\tau_{r}}(\cdot, \omega)\right)
$$

where $\tau_{r}$ is the stopping time defined there. Then, since $q$ is progressively measurable, the progressively measurable condition is satisfied for this new operator. Hence by Theorem 77.7.3 there exists a unique solution $w_{r}$ which is progressively measurable to the integral equation

$$
B w_{r}(t, \omega)+\int_{0}^{t} z_{r}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)
$$

where $z_{r}(\cdot, \omega) \in A_{r}(w(\cdot, \omega), \omega)$. Then as in Theorem 77.7.3 you can let $r \rightarrow \infty$ and eventually $q^{\tau_{r}}(\cdot, \omega)=q(\cdot, \omega)$. Then, passing to a limit, it follows that for a given $\omega$, there is a solution to

$$
\begin{aligned}
B w(t, \omega)+\int_{0}^{t} z(s, \omega) d s & =\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega) \\
z(\cdot, \omega) & \in A(w(\cdot, \omega)+q(\cdot, \omega), \omega)
\end{aligned}
$$

which is progressively measurable because $w(\cdot, \omega)=\lim _{r \rightarrow \infty} w_{r}(\cdot, \omega)$ in $\mathscr{V}$ each $w_{r}$ being progressively measurable. Note how uniqueness for fixed $\omega$ is important in this argument. Recall that

$$
\tau_{r} \equiv \inf \{t:|q(t, \omega)|>r\}
$$

By continuity, eventually, for a given $\omega, \tau_{r}=\infty$ and so no further change takes place in $q^{\tau_{r}}(\cdot, \omega)$ for that $\omega$. By uniqueness, the same is true of the solution $w_{r}(\cdot, \omega)$ and so pointwise convergence takes place for the $w_{r}$. Without uniqueness holding, this becomes very unclear. Thus for each $\hat{T}<T, \omega \rightarrow w(\cdot, \omega)$ is measurable into $\mathscr{V}[0, \hat{T}]$. Then by Lemma 77.4.2, $w$ has a representative in $\mathscr{V}$ for each $\omega$ such that the resulting function satisfies $(t, \omega) \rightarrow \mathscr{X}_{[0, \hat{T}]}(t) w(t, \omega)$ is $\mathscr{B}([0, \hat{T}]) \times \mathscr{F}_{\hat{T}}$ measurable into $V$. Thus one can assume that $w$ is progressively measurable. Now as in Theorem 77.5.7, Define $u=w+q$.

The last claim follows from letting $t=a$ in the top equation and then subtracting this from the top equation with $t>a$.

### 77.8 Adding A Quasi-bounded Operator

Recall the following conditions for the various operators.

## Bounded and coercive conditions

$A(\cdot, \omega) \cdot A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{V}_{I}^{\prime}$ for each $I$ a subinterval of $[0, T] I=[0, \hat{T}], \hat{T} \leq T$

$$
\begin{equation*}
A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{P}\left(\mathscr{V}_{I}^{\prime}\right) \text { is bounded, } \tag{77.8.73}
\end{equation*}
$$

If, for $u \in \mathscr{V}$,

$$
u^{*} \mathscr{X}_{[0, \hat{T}]} \in A\left(u \mathscr{X}_{[0, \hat{T}]}, \omega\right)
$$

for each $\hat{T}$ in an increasing sequence converging to $T$, then

$$
\begin{equation*}
u^{*} \in A(u, \omega) \tag{77.8.74}
\end{equation*}
$$

Assume the specific estimate

$$
\begin{equation*}
\sup \left\{\left\|u^{*}\right\|_{\mathscr{V}_{I}^{\prime}}: u^{*} \in A(u, \omega)\right\} \leq a(\omega)+b(\omega)\|u\|_{\mathscr{V}_{I}}^{p-1} \tag{77.8.75}
\end{equation*}
$$

where $a(\omega), b(\omega)$ are nonnegative. Also assume the following coercivity estimate valid for each $t \leq T$ and for some $\lambda(\omega) \geq 0$,

$$
\begin{equation*}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d t: u^{*} \in A(u, \omega)\right) \geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \tag{77.8.76}
\end{equation*}
$$

where $m(\omega)$ is some nonnegative constant, $\delta(\omega)>0$.

## Limit condition

Let $U$ be a Banach space dense in $V$ and that if $u_{i} \rightharpoonup u$ in $\mathscr{V}_{I}$ and $u_{i}^{*} \in A\left(u_{i}\right)$ with $u_{i}^{*} \rightharpoonup u^{*}$ in $\mathscr{V}_{I}^{\prime}$ and $\left(B u_{i}\right)^{\prime} \rightharpoonup(B u)^{\prime}$ in $\mathscr{U}_{r I}^{\prime}$, $\rightharpoonup$ denoting weak convergence, then if

$$
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle_{\mathscr{Y}_{I}^{\prime}, \mathscr{y}_{I}} \leq 0
$$

it follows that for all $v \in \mathscr{V}_{I}$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \geq\left\langle u^{*}(v), u-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \tag{77.8.77}
\end{equation*}
$$

where $r>\max (p, 2)$, and we replace $p$ with $r$ and $I$ an arbitrary subinterval of the form $[0, \hat{T}], \hat{T}<T$, for $[0, T]$, and $U$ for $V$ where indicated. Here

$$
\mathscr{U}_{r I} \equiv L^{r}(I ; U)
$$

Typically, $U$ is compactly embedded in $V$.

## Measurability condition

For $\omega \rightarrow u(\cdot, \omega)$ measurable into $\mathscr{V}$,

$$
\begin{equation*}
\omega \rightarrow A(u(\cdot, \omega), \omega) \text { has a measurable selection into } \mathscr{V}^{\prime} \tag{77.8.78}
\end{equation*}
$$

This last condition means there is a function $\omega \rightarrow u^{*}(\omega)$ which is measurable into $\mathscr{V}^{\prime}$ such that $u^{*}(\omega) \in A(u(\cdot, \omega), \omega)$.

As for the operator $B$ it is either independent of $\omega$ and is a nonnegative self adjoint operator mapping $W$ to $W^{\prime}$ or else it is of the form $k(\omega) B$ where $k \geq 0$ and is measurable.

We will assume here that $p>1$. Then the following main result was obtained above. It is Theorem 77.5.7.

Theorem 77.8.1 If 77.8.73-77.8.78 and $B$ as described above,let $q(t, \omega)$ be a product measurable function into $V$ such that $t \rightarrow q(t, \omega)$ is continuous, $q(0, \omega)=0$.

Then, there exists a solution $u$ of the integral equation

$$
B u(t, \omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)+B q(t, \omega)
$$

where $(t, \omega) \rightarrow u(t, \omega)$ is measurable. Moreover, for each $\omega, B u(t, \omega)=B(u(t, \omega))$ for a.e. $t$ and $z(\cdot, \omega) \in A(\omega, u(\cdot, \omega))$ for a.e. $t$. Also, for each $a \in[0, T]$,

$$
B u(t, \omega)+\int_{a}^{t} z(s, \omega) d s=\int_{a}^{t} f(s, \omega) d s+B u(a, \omega)+B q(t, \omega)-B q(a, \omega)
$$

The idea here is to show that everything works as well if a suitable unbounded maximal monotone operator is added in. The result is interesting but not as interesting as it might be. This is because the maximal monotone operator must be quasi bounded. Still it is interesting to note that the above holds for some unbounded operators. This has been pointed out in the case where there are no stochastic effects in a recent paper [54]. This generalizes this result by considering the measurability of solutions and allowing for possibly degenerate leading operator $B$.

To begin with assume $q=0$.
Now let $G: D(G) \subseteq \mathscr{V} \rightarrow \mathscr{P}\left(\mathscr{V}^{\prime}\right)$ be maximal monotone. Also assume that $0 \in D(G)$. Then you have

$$
\left\langle u^{*}, u\right\rangle \geq\left\langle g^{*}, u\right\rangle \text { if } u^{*} \in G u
$$

for every $g^{*} \in G(0)$. Hence

$$
\begin{equation*}
\left\langle u^{*}, u\right\rangle \geq-|G(0)|\|u\|_{\mathscr{V}} \text { if } u^{*} \in G u \tag{77.8.79}
\end{equation*}
$$

where $|G(0)| \equiv \inf \left\{\left\|y^{*}\right\|_{\mathscr{V}^{\prime}}: y^{*} \in G(0)\right\}$.
There is a standard way of approximating $G$ with bounded demicontinuous operators which is reviewed next. It is all in Barbu [13]. See Section 25.7.4. Since $G$ is maximal monotone,

$$
0 \in F\left(x_{\mu}-x\right)+\mu^{p-1} G\left(x_{\mu}\right)
$$

where $F$ is a duality map for $p$, the one used in the above theorem. Barbu uses only $p=2$ but it works just as well for arbitrary $p>1$ with the minor modifications used here. To see
this, you consider $\hat{G}(y) \equiv G(x+y)$. Then $\hat{G}$ is also maximal monotone and so there exists a solution to

$$
0 \in F(\hat{x})+\mu^{p-1} \hat{G}(\hat{x})=F(\hat{x})+\mu^{p-1} G(x+\hat{x})
$$

Now let $x_{\mu}=x+\hat{x}$ so $\hat{x}=x_{\mu}-x$. Hence

$$
0 \in F\left(x_{\mu}-x\right)+\mu^{p-1} G x_{\mu}
$$

The symbol $\lim \sup _{n, n \rightarrow \infty} a_{m n}$ means $\lim _{N \rightarrow \infty}\left(\sup _{m \geq N, n \geq N} a_{m n}\right)$.
Lemma 77.8.2 Suppose $\limsup \lim _{n \rightarrow \infty} a_{m n} \leq 0$. Then $\limsup \lim _{m \rightarrow \infty}\left(\limsup _{n \rightarrow \infty} a_{m n}\right) \leq 0$.
Proof: Suppose the first inequality. Then for $\varepsilon>0$, there exists $N$ such that if $n, m$ are both as large as $N$, then $a_{m n} \leq \varepsilon$. Thus $\sup _{n \geq N} a_{m n} \leq \varepsilon$ provided $m \geq N$ also. Hence for such $m$,

$$
\lim _{n \rightarrow \infty}\left(\sup _{n \geq N} a_{m n}\right) \leq \varepsilon
$$

for each $m \geq N$. It follows $\limsup _{m \rightarrow \infty}\left(\limsup _{n \rightarrow \infty} a_{m n}\right) \leq \varepsilon$. Since $\varepsilon$ is arbitrary, this proves the lemma.

Then here is a simple observation.
Lemma 77.8.3 Let $G: D(G) \subseteq X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ where $X$ is a Banach space be maximal monotone and let $v_{n} \in G u_{n}$ and

$$
u_{n} \rightarrow u, v_{n} \rightarrow v \text { weakly. }
$$

Also suppose that

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle \leq 0
$$

or

$$
\limsup _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle \leq 0
$$

Then $[u, v] \in \mathscr{G}(G)$ and $\left\langle v_{n}, u_{n}\right\rangle \rightarrow\langle v, u\rangle$.
Proof: By monotonicity,

$$
\begin{aligned}
0 & \geq \lim \sup _{m, n \rightarrow \infty}\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle \\
& \geq \lim _{m, n \rightarrow \infty}\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle \geq 0
\end{aligned}
$$

and so

$$
\lim _{m, n \rightarrow \infty}\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle=0
$$

Suppose then that $\left\langle v_{n}, u_{n}\right\rangle$ fails to converge to $\langle v, u\rangle$. Then there is a subsequence, still denoted with subscript $n$ such that $\left\langle v_{n}, u_{n}\right\rangle \rightarrow \mu \neq\langle v, u\rangle$. Let $\varepsilon>0$. Then there exists $M$ such that if $n, m>M$, then

$$
\left|\left\langle v_{n}, u_{n}\right\rangle-\mu\right|<\varepsilon,\left|\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle\right|<\varepsilon
$$

Then if $m, n>M$,

$$
\left|\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle\right|=\left|\left\langle v_{n}, u_{n}\right\rangle+\left\langle v_{m}, u_{m}\right\rangle-\left\langle v_{n}, u_{m}\right\rangle-\left\langle v_{m}, u_{n}\right\rangle\right|<\varepsilon
$$

Hence it is also true that

$$
\left|\left\langle v_{n}, u_{n}\right\rangle+\left\langle v_{m}, u_{m}\right\rangle-\left\langle v_{n}, u_{m}\right\rangle-\left\langle v_{m}, u_{n}\right\rangle\right| \leq\left|2 \mu-\left(\left\langle v_{n}, u_{m}\right\rangle+\left\langle v_{m}, u_{n}\right\rangle\right)\right|<3 \varepsilon
$$

Now take a limit first with respect to $n$ and then with respect to $m$ to obtain

$$
|2 \mu-(\langle v, u\rangle+\langle v, u\rangle)|<3 \varepsilon
$$

Since $\varepsilon$ is arbitrary, $\mu=\langle v, u\rangle$ after all. Hence the claim that $\left\langle v_{n}, u_{m}\right\rangle \rightarrow\langle v, u\rangle$ is verified. Next suppose $[x, y] \in \mathscr{G}(G)$ and consider

$$
\begin{aligned}
& \langle v-y, u-x\rangle=\langle v, u\rangle-\langle v, x\rangle-\langle y, u\rangle+\langle y, x\rangle \\
& =\lim _{n \rightarrow \infty}\left(\left\langle v_{n}, u_{n}\right\rangle-\left\langle v_{n}, x\right\rangle-\left\langle y, u_{n}\right\rangle+\langle y, x\rangle\right) \\
& =\lim _{n \rightarrow \infty}\left\langle v_{n}-y, u_{n}-x\right\rangle \geq 0
\end{aligned}
$$

and since $[x, y]$ is arbitrary, it follows that $v \in G u$.
Next suppose $\lim \sup _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle \leq 0$. It is not known that $[u, v] \in \mathscr{G}(G)$.

$$
\begin{aligned}
\lim \sup _{n \rightarrow \infty}\left[\left\langle v_{n}, u_{n}\right\rangle-\left\langle v, u_{n}\right\rangle-\left\langle v_{n}, u\right\rangle+\langle v, u\rangle\right] & \leq 0 \\
\lim \sup _{n \rightarrow \infty}\left\langle v_{n}, u_{n}\right\rangle-\langle v, u\rangle & \leq 0
\end{aligned}
$$

Thus $\lim \sup _{n \rightarrow \infty}\left\langle v_{n}, u_{n}\right\rangle \leq\langle v, u\rangle$. Now let $[x, y] \in \mathscr{G}(G)$

$$
\begin{aligned}
& \langle v-y, u-x\rangle=\langle v, u\rangle-\langle v, x\rangle-\langle y, u\rangle+\langle y, x\rangle \\
& \geq \lim \sup _{n \rightarrow \infty}\left[\left\langle v_{n}, u_{n}\right\rangle-\left\langle v_{n}, x\right\rangle-\left\langle y, u_{n}\right\rangle+\langle y, x\rangle\right] \\
& \geq \lim _{n \rightarrow \infty}\left[\left\langle v_{n}-y, u_{n}-x\right\rangle\right] \geq 0
\end{aligned}
$$

Hence $[u, v] \in \mathscr{G}(G)$. Now

$$
\lim \sup _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle \leq 0 \leq \lim _{n \rightarrow \infty} \inf _{n}\left\langle v_{n}-v, u_{n}-u\right\rangle
$$

the second coming from monotonicity and the fact that $v \in G u$. Therefore,

$$
\lim _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle=0
$$

which shows that $\lim _{n \rightarrow \infty}\left\langle v_{n}, u_{n}\right\rangle=\langle v, u\rangle$.
Similar reasoning implies

Lemma 77.8.4 Suppose $A$ is a set valued operator, $A: X \rightarrow \mathscr{P}(X)$ and $u_{n}^{*} \in A u_{n}$. Suppose also that $u_{n} \rightarrow u$ weakly and $u_{n}^{*} \rightarrow u^{*}$ weakly. Suppose also that

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle u_{n}^{*}-u_{m}^{*}, u_{n}-u_{m}\right\rangle \leq 0
$$

Then one can conclude that

$$
\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}-u\right\rangle \leq 0
$$

Proof: It is assumed that

$$
\lim \sup _{m, n \rightarrow \infty}\left(\left\langle u_{n}^{*}, u_{n}\right\rangle+\left\langle u_{m}^{*}, u_{m}\right\rangle-\left(\left\langle u_{n}^{*}, u_{m}\right\rangle+\left\langle u_{m}^{*}, u_{n}\right\rangle\right)\right) \leq 0
$$

Then is it the case that $\limsup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}\right\rangle \leq\left\langle u^{*}, u\right\rangle$ ? Let $\mu$ equal $\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}\right\rangle$. Then in the above, it implies

$$
\left(2 \mu-\left(\left\langle u_{n}^{*}, u_{m}\right\rangle+\left\langle u_{m}^{*}, u_{n}\right\rangle\right)\right)<\varepsilon
$$

whenever $m, n$ large enough. Thus taking $\limsup _{n \rightarrow \infty} \limsup _{m \rightarrow \infty}$ of the above, you get

$$
\left(2 \mu-\left(\left\langle u^{*}, u\right\rangle+\left\langle u^{*}, u\right\rangle\right)\right)<\varepsilon
$$

Thus you at least need $\mu \leq\left\langle u^{*}, u\right\rangle$. That is, $\limsup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}\right\rangle \leq\left\langle u^{*}, u\right\rangle$. Hence

$$
\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}-u\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}\right\rangle-\left\langle u^{*}, u\right\rangle \leq\left\langle u^{*}, u\right\rangle-\left\langle u^{*}, u\right\rangle=0
$$

Definition 77.8.5 Let $x_{\mu}$ just defined be denoted by $J_{\mu} x$ and define also

$$
G_{\mu}(x) \equiv-\mu^{-(p-1)} F\left(x_{\mu}-x\right)
$$

This $x_{\mu}$ is defined as follows.

$$
0 \in F\left(x_{\mu}-x\right)+\mu^{p-1} G x_{\mu}
$$

Later, we will write $J_{\mu}$ u for $u_{\mu}$. Thus

$$
0=F\left(J_{\mu} u-u\right)+\mu^{p-1} z_{\mu}, z_{\mu} \in G\left(J_{\mu} u\right)
$$

Also from this definition,

$$
G_{\mu}(u)=-\mu^{-(p-1)} F\left(J_{\mu} u-u\right)=z_{\mu} \in G\left(J_{\mu} u\right)
$$

Then there are some things which can be said about these operators.
Theorem 77.8.6 The following hold. Here $V$ is a reflexive Banach space with strictly convex norm. $G: D(G) \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is maximal monotone. Then

1. $J_{\mu}$ and $G_{\mu}$ are bounded single valued operators defined on $V$. Bounded means they take bounded sets to bounded sets. Also $G_{\mu}$ is a monotone operator.
2. $G_{\mu}, J_{\mu}$ are demicontinuous. That is, strongly convergent sequences are mapped to weakly convergent sequences.
3. For every

$$
x \in D(G),\left\|G_{\mu}(x)\right\| \leq|G x| \equiv \inf \left\{\left\|y^{*}\right\|: y^{*} \in G x\right\}
$$

For every $x \in \overline{\operatorname{conv}(D(G))}$, it follows that $\lim _{\mu \rightarrow 0} J_{\mu}(x)=x$. The new symbol means the closure of the convex hull. It is the closure of the set of all convex combinations of points of $D(G)$.

Then $A(\cdot, \omega)+G_{\mu}$ will be bounded and have the same limit properties as $A(\cdot, \omega)$. As to measurability, $G$ and hence $G_{\mu}$ do not depend on $\omega$ and so the measurability condition will hold.

What about the estimates? We need to consider the estimates. Recall what these were:

$$
\begin{equation*}
\sup \left\{\left\|u^{*}\right\|_{\mathscr{V}_{I}^{\prime}}: u^{*} \in A(u, \omega)\right\} \leq a(\omega)+b(\omega)\|u\|_{\mathscr{V}_{I}}^{p-1} \tag{77.8.80}
\end{equation*}
$$

where $a(\omega), b(\omega)$ are nonnegative. Also assume the following coercivity estimate valid for each $t \leq T$ and for some $\lambda(\omega) \geq 0$,

$$
\begin{equation*}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d t: u^{*} \in A(u, \omega)\right) \geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \tag{77.8.81}
\end{equation*}
$$

where $m(\omega)$ is some nonnegative constant, $\delta(\omega)>0$.
The coercivity is not too bad. This is because $G_{\mu}$ is monotone and $0 \in D(G)$. Therefore,

$$
\left\langle G_{\mu} u, u\right\rangle=\left\langle G_{\mu} u-G_{\mu}(0), u\right\rangle \geq 0
$$

so

$$
\left\langle G_{\mu} u, u\right\rangle \geq-|G(0)|\|u\| \geq \frac{\delta(\omega)}{2}\|u\|^{p}-\hat{m}(\omega)
$$

so the coercivity condition 77.8 .81 will end up holding for $A+G_{\mu}$. However, more needs to be considered for the growth condition.

From the definition of $u_{\mu}$, there exists $z_{\mu} \in G u_{\mu}$

$$
0=F\left(u_{\mu}-u\right)+\mu^{p-1} z_{\mu}
$$

Then from the choice of $F$, it is also the duality map from $\mathscr{V}$ to $\mathscr{V}^{\prime}$ corresponding to $p>2$.

$$
\begin{aligned}
& 0=\left\langle F\left(u_{\mu}-u\right), u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\mu^{p-1}\left\langle z_{\mu}, u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
& \geq\left\langle F\left(u_{\mu}-u\right), u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}-\mu^{p-1}|G(0)|\left\|u_{\mu}\right\|_{\mathscr{V}} \\
&=\left\|u_{\mu}-u\right\|_{\mathscr{V}}^{p}+\left\langle F\left(u_{\mu}-u\right), u\right\rangle-\mu|G(0)|\left\|u_{\mu}\right\| \\
& \geq\left\|u_{\mu}-u\right\|^{p}-\left\|u_{\mu}-u\right\|^{p-1}\|u\|-\mu|G(0)|\left\|u_{\mu}\right\| \\
& \geq \frac{1}{p}\left\|u_{\mu}-u\right\|^{p}-\frac{1}{p}\|u\|^{p}-\mu|G(0)|\left\|u_{\mu}\right\|
\end{aligned}
$$

Thus

$$
0 \geq\left|\left\|u_{\mu}\right\|-\|u\|\right|^{p}-\|u\|^{p}-p \mu|G(0)|\left\|u_{\mu}\right\|
$$

This requires that there is some constant $C$ such that $\left\|u_{\mu}\right\| \leq C\|u\|+C$. The details follow.
Let $a=\left\|u_{\mu}\right\|, b=\|u\|$. Then they are both positive and

$$
0 \geq|a-b|^{p}-b^{p}-\alpha a
$$

where $\alpha=p \mu|G(0)|$. Want to say $a \leq C b+C$ for some $C$. This is the conclusion of the following lemma.

Lemma 77.8.7 Suppose $0 \geq|a-b|^{p}-b^{p}-\alpha a$ for $a, b \geq 0$ and $\alpha>0$. Then there exists a constant $C$ such that

$$
a \leq C b+C
$$

Proof: If $b \geq a$, then there is nothing to show. Therefore, it suffices to show that the desired inequality holds for $a>b$. Thus from now on, $a>b$.

$$
0 \geq(a-b)^{p}-b^{p}-\alpha a
$$

Suppose $a>n b+n$. Let $x=b / a$. Then for $x \in[0,1]$,

$$
\begin{aligned}
0 & \geq(1-x)^{p}-x^{p}-\alpha \frac{1}{a^{p-1}} \\
& \geq(1-x)^{p}-x^{p}-\alpha \frac{1}{(n b+n)^{p-1}} \\
& \geq(1-x)^{p}-x^{p}-\alpha \frac{1}{(n)^{p-1}}
\end{aligned}
$$

Now for all $n$ large enough, the right side is a decreasing function of $x$ which is positive at $x=0$ and negative at $x=1$. Thus $x$ corresponds to the place where this function is negative. Taking a limit as $n \rightarrow \infty$, it follows that we must have

$$
x \geq \delta, \delta \in(0,1)
$$

It is where $(1-x)^{p}-x^{p}=0$. Thus $x=\frac{b}{a} \geq \delta$. Then, since $a>n b+n$,

$$
\frac{1}{\delta} b \geq a>n b+n
$$

Now this is a contradiction when $n$ is taken increasingly large. Hence, for large enough $n, a \leq n b+n$.

It follows that $\left\|u_{\mu}\right\| \leq C\|u\|+C$ for some $C$. Hence,

$$
\begin{aligned}
\left\|G_{\mu} u\right\| & \leq \frac{1}{\mu^{p-1}}\left\|u_{\mu}-u\right\|^{p-1} \leq \frac{1}{\mu^{p-1}}\left(\left\|u_{\mu}\right\|+\|u\|\right)^{p-1} \\
& \leq \frac{2^{p-2}}{\mu^{p-1}}\left(\left\|u_{\mu}\right\|^{p-1}+\|u\|^{p-1}\right)
\end{aligned}
$$

$$
\begin{aligned}
& \leq \frac{2^{p-2}}{\mu^{p-1}}\left((C\|u\|+C)^{p-1}+\|u\|^{p-1}\right) \\
& \leq \frac{2^{p-2}}{\mu^{p-1}}\left(2^{p-2}\left(C^{p-1}\|u\|^{p-1}+C^{p-1}\right)+\|u\|^{p-1}\right) \\
& \leq C_{\mu}\|u\|^{p-1}+C_{\mu}
\end{aligned}
$$

This is the case that $p \geq 2$. The case that $p>1$ but $p<2$ is easier. In this case,

$$
\frac{1}{\mu^{p-1}}\left(\left\|u_{\mu}\right\|+\|u\|\right)^{p-1} \leq \frac{1}{\mu^{p-1}}\left(\left\|u_{\mu}\right\|^{p-1}+\|u\|^{p-1}\right)
$$

A similar inequality holds. Thus the necessary growth condition is obtained for $G_{\mu}$ and consequently, the necessary growth condition remains valid for $G_{\mu}+A$. It was noted earlier that the coercivity estimate continues to hold.

It follows that there exists a solution to the integral equation

$$
B u(t, \omega)+\int_{0}^{t} z(s, \omega) d s+\int_{0}^{t} G_{\mu}(u(s, \omega)) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)
$$

where $z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$ which has the measurability described above. That is, both $u$ and $z$ are product measurable. Then acting on $u \mathscr{X}_{[0, t]}$ and using the estimates valid for $\lambda$ large enough, one can get an estimate of the form

$$
\begin{equation*}
\frac{1}{2}\langle B u, u\rangle(t)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\|u(s)\|_{V}^{p} d s+\int_{0}^{t}\left\langle G_{\mu} u, u\right\rangle d s \leq \lambda \int_{0}^{t}\langle B u, u\rangle d s+C(f) \tag{77.8.82}
\end{equation*}
$$

Now $G_{\mu}$ is monotone and so,

$$
\left\langle G_{\mu} u, u\right\rangle=\left\langle G_{\mu} u-G_{\mu} 0, u\right\rangle+\left\langle G_{\mu}(0), u\right\rangle \geq\left\langle G_{\mu}(0), u\right\rangle \geq-|G(0)|\|u\|
$$

It follows easily from standard manipulations and 77.8 .82 that $\|u\|_{\mathscr{V}}$ is bounded independent of $\mu$. That is, there is a constant $C$ independent of $\mu$ such that

$$
\begin{equation*}
\|u\|_{\mathscr{V}} \leq C \tag{77.8.83}
\end{equation*}
$$

The details follow. The above inequality 77.8.82 implies that by acting on $u \mathscr{X}_{[0, t]}$,

$$
\frac{1}{2}\langle B u, u\rangle(t)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\|u(s)\|_{V}^{p} d s-\int_{0}^{t}|G(0)|\|u\|_{V} d s \leq \lambda \int_{0}^{t}\langle B u, u\rangle d s+C(f)
$$

Then by Gronwall's inequality and adjusting constants,

$$
\begin{equation*}
\langle B u, u\rangle(t)+\int_{0}^{t}\|u(s)\|_{V}^{p} d s \leq C\left(u_{0}, f, \lambda\right)+C(\lambda) \int_{0}^{t}|G(0)|\|u\|_{V} d s \tag{77.8.84}
\end{equation*}
$$

so it is clear that there is an inequality of the form

$$
\sup _{t \in[0, T]}\langle B u, u\rangle(t)+\int_{0}^{T}\|u(s)\|_{V}^{p} d s \leq C\left(u_{0}, f, \lambda\right)
$$

Then returning to 77.8.82, all terms are bounded except $\int_{0}^{t}\left\langle G_{\mu} u, u\right\rangle d s$, so this term must also be bounded for $t=T$ also. Thus

$$
\left|\int_{0}^{T}\left\langle G_{\mu} u, u\right\rangle d t\right| \leq C
$$

where $C$ is independent of $\mu$. We denote by $u_{\mu}$ the solution to the above equation.
Here is the definition of quasi-bounded.
Definition 77.8.8 A set valued operator $G$ is quasi-bounded if whenever $x \in D(G)$ and $x^{*} \in G x$ are such that

$$
\left|\left\langle x^{*}, x\right\rangle\right|,\|x\| \leq M
$$

it follows that $\left\|x^{*}\right\| \leq K_{M}$. Bounded would mean that if $\|x\| \leq M$, then $\left\|x^{*}\right\| \leq K_{M}$. Here you only know this if there is another condition.

Assumption 77.8.9 $G: D(G) \rightarrow \mathscr{P}\left(\mathscr{V}^{\prime}\right)$ is quasi-bounded and maximal monotone.
By Proposition 25.7.23 an example of a quasi-bounded operator is a maximal monotone operator $G$ for which $0 \in \operatorname{int}(D(G))$.

Now $G_{\mu} u_{\mu} \in G J_{\mu} u_{\mu}$ as noted above. Therefore, there exists $g_{\mu} \in G\left(J_{\mu} u_{\mu}\right)$ such that

$$
\begin{gather*}
C \geq\left\langle G_{\mu} u_{\mu}, u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\left\langle g_{\mu}, u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\left\langle g_{\mu}, J_{\mu} u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle g_{\mu}, u_{\mu}-J_{\mu} u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}  \tag{77.8.85}\\
\geq-|G(0)|\left\|J_{\mu} u_{\mu}\right\|_{\mathscr{V}}+\left\langle-\frac{1}{\mu^{p-1}} F\left(J_{\mu} u_{\mu}-u_{\mu}\right), u_{\mu}-J_{\mu} u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
\quad \geq-|G(0)|\left\|J_{\mu} u_{\mu}\right\|_{\mathscr{V}}+\frac{1}{\mu^{p-1}}\left\|J_{\mu} u_{\mu}-u_{\mu}\right\|_{\mathscr{V}}^{p} \tag{77.8.86}
\end{gather*}
$$

Thus the fact that $\left\|u_{\mu}\right\|$ is bounded independent of $\mu$ implies that $\left\|J_{\mu} u_{\mu}\right\|$ is also bounded and that in fact $\left\|u_{\mu}-J_{\mu} u_{\mu}\right\|_{\mathscr{V}} \rightarrow 0$ as $\mu \rightarrow 0$. This follows from consideration of the last line of the above formula. Note also that

$$
\begin{equation*}
\left\langle g_{\mu}, u_{\mu}-J_{\mu} u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\frac{1}{\mu^{p-1}}\left\|J_{\mu} u_{\mu}-u_{\mu}\right\|_{\mathscr{V}}^{p} \text { is bounded. } \tag{77.8.87}
\end{equation*}
$$

Then from 77.8.85, it follows that $\left\langle g_{\mu}, J_{\mu} u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}$ is bounded. By the assumption that $G$ is quasi-bounded, $g_{\mu}$ must also be bounded.

Then we have shown

$$
\begin{equation*}
B u_{\mu}(t, \omega)+\int_{0}^{t} z_{\mu}(s, \omega) d s+\int_{0}^{t} g_{\mu}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega) \tag{77.8.88}
\end{equation*}
$$

where

$$
\begin{equation*}
\left\|g_{\mu}\right\|_{\mathscr{V}^{\prime}}+\left\|z_{\mu}\right\|_{\mathscr{V}^{\prime}}+\sup _{t \in[0, T]}\left\langle B u_{\mu}, u_{\mu}\right\rangle(t)+\left\|J_{\mu} u_{\mu}\right\|_{\mathscr{V}}+\left\|u_{\mu}\right\|_{\mathscr{V}}+\left\|\left(B u_{\mu}\right)^{\prime}\right\|_{\mathscr{V}^{\prime}} \leq C \tag{77.8.89}
\end{equation*}
$$

The last term in the sum being bounded follows from the integral equation and the fundamental theorem of calculus along with the boundedness $f, g_{\mu}, z_{\mu}$. In addition to this, the estimate 77.8.86 implies

$$
\begin{equation*}
\lim _{\mu \rightarrow 0}\left\|J_{\mu} u_{\mu}-u_{\mu}\right\|_{\mathscr{V}}=0 \tag{77.8.90}
\end{equation*}
$$

There is a subsequence, $\mu \rightarrow 0$ still denoted as $\mu$ such that

$$
\begin{gather*}
g_{\mu} \rightarrow g \text { weakly in } \mathscr{V}^{\prime}  \tag{77.8.91}\\
z_{\mu} \rightarrow z \text { weakly in } \mathscr{V}^{\prime}  \tag{77.8.92}\\
u_{\mu} \rightarrow u \text { weakly in } \mathscr{V}  \tag{77.8.93}\\
J_{\mu} u_{\mu} \rightarrow u \text { weakly in } \mathscr{V}  \tag{77.8.94}\\
\left(B u_{\mu}\right)^{\prime} \rightarrow(B u)^{\prime} \text { weakly in } \mathscr{V}^{\prime}  \tag{77.8.95}\\
B u_{\mu}(t) \rightarrow B u(t) \text { weakly in } V^{\prime} \tag{77.8.96}
\end{gather*}
$$

Now consider two of these for $\mu$ and $\nu$. Subtract and act on $u_{\mu}-u_{\nu}$. Then one obtains

$$
\left\langle B u_{\mu}-B u_{v}, u_{\mu}-u_{v}\right\rangle(t)+\int_{0}^{t}\left\langle z_{\mu}-z_{v}, u_{\mu}-u_{v}\right\rangle+\int_{0}^{t}\left\langle g_{\mu}-g_{v}, u_{\mu}-v_{v}\right\rangle=0
$$

Consider that last term for $t=T$. It equals

$$
\begin{aligned}
\int_{0}^{T}\left\langle G_{\mu} u_{\mu}-\right. & \left.G_{v} u_{v}, u_{\mu}-u_{v}\right\rangle=\overbrace{\int_{0}^{T}\left\langle G_{\mu} u_{\mu}-G_{v} u_{v}, J_{\mu} u_{\mu}-J_{v} u_{v}\right\rangle}^{\geq 0} \\
& +\int_{0}^{T}\left\langle g_{\mu}-g_{v}, u_{\mu}-J_{\mu} u_{\mu}-\left(u_{v}-J_{v} u_{v}\right)\right\rangle \\
& =\int_{0}^{T}\left\langle g_{\mu}-g_{v}, J_{\mu} u_{\mu}-J_{v} u_{v}\right\rangle+\varepsilon(\mu, v)
\end{aligned}
$$

where

$$
\begin{gathered}
|\varepsilon(\mu, v)| \leq\left(\int_{0}^{T}\left(\left\|g_{\mu}\right\|+\left\|g_{v}\right\|\right)^{p^{\prime}}\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left(\left\|u_{\mu}-J_{\mu} u_{\mu}\right\|+\left\|u_{v}-J_{v} u_{V}\right\|\right)^{p}\right)^{1 / p} \\
\leq 2 C\left(\left\|u_{\mu}-J_{\mu} u_{\mu}\right\|_{\mathscr{V}}+\left\|u_{v}-J_{v} u_{v}\right\|_{\mathscr{V}}\right)
\end{gathered}
$$

Adjusting constants and using 77.8.87,

$$
\leq C\left(\mu^{(1-(1 / p))}+v^{(1-(1 / p))}\right)
$$

Thus

$$
\int_{0}^{T}\left\langle G_{\mu} u_{\mu}-G_{v} u_{v}, u_{\mu}-u_{v}\right\rangle=\int_{0}^{T}\left\langle g_{\mu}-g_{v}, J_{\mu} u_{\mu}-J_{v} u_{v}\right\rangle+\varepsilon(\mu, v)
$$

where $\lim _{\mu, v \rightarrow 0} \varepsilon(\mu, v)=0$. It follows from 77.8.97

$$
\begin{aligned}
& \lim \sup _{\mu, v \rightarrow 0}\left(\int_{0}^{T}\left\langle z_{\mu}-z_{v}, u_{\mu}-u_{v}\right\rangle d s+\varepsilon(\mu, v)\right) \\
= & \lim \sup _{\mu, v \rightarrow 0}\left(\int_{0}^{T}\left\langle z_{\mu}-z_{v}, u_{\mu}-u_{v}\right\rangle d s\right) \leq 0
\end{aligned}
$$

From Lemma 77.8.4,

$$
\limsup _{\mu \rightarrow 0}\left\langle z_{\mu}, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0
$$

By the limit condition for $A(\cdot, \omega)$, for each $v \in \mathscr{V}$, there exists $z(v) \in A u$ such that

$$
\begin{aligned}
\lim _{\mu \rightarrow 0} \inf _{\mu}\left\langle z_{\mu}, u_{\mu}-v\right\rangle & =\lim _{\mu \rightarrow 0}\left(\left\langle z_{\mu}, u_{\mu}-u\right\rangle+\left\langle z_{\mu}, u-v\right\rangle\right) \\
& =\langle z, u-v\rangle \geq\langle z(v), u-v\rangle
\end{aligned}
$$

Since $A(u, \omega)$ is convex and closed, separation theorems imply that $z \in A u$. Return to the equation solved.

$$
\left(B u_{\mu}\right)^{\prime}+z_{\mu}+g_{\mu}=f
$$

Then act on $u_{\mu}-u$ and use monotonicity arguments to write

$$
\begin{equation*}
\left\langle(B u)^{\prime}, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle z_{\mu}, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle g_{\mu}, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq\left\langle f, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \tag{77.8.98}
\end{equation*}
$$

Then it was shown above that

$$
0 \geq \lim \sup _{\mu \rightarrow 0}\left\langle z_{\mu}, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq \lim \inf _{\mu \rightarrow 0}\left\langle z_{\mu}, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\langle z(u), u-u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0
$$

and so, from 77.8.98,

$$
\lim _{\mu \rightarrow 0}\left\langle g_{\mu}, u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\lim _{\mu \rightarrow 0}\left\langle g_{\mu}, J_{\mu} u_{\mu}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0
$$

and so

$$
\lim _{\mu \rightarrow 0}\left\langle g_{\mu}, J_{\mu} u_{\mu}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\langle g, u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

Now let $[a, b] \in \mathscr{G}(G)$. Then

$$
\langle b-g, a-u\rangle=\lim _{\mu \rightarrow 0}\left\langle b-g_{\mu}, a-J_{\mu} u_{\mu}\right\rangle \geq 0
$$

because $g_{\mu} \in G\left(J_{\mu} u_{\mu}\right)$. Since $G$ is maximal monotone, it follows that $[u, g] \in \mathscr{G}(G)$.
This has shown that for each $\omega$ fixed, and every sequence of solutions to the integral equation $\left\{u_{\mu}\right\}$, each function $\left\{B u_{\mu}\right\}$ being product measurable by Theorem 77.5.7, there exists a subsequence which converges to a solution $u$ to the integral equation. In particular, $t \rightarrow B u(t)$ is weakly continuous into $V^{\prime}$. Then by the fundamental measurable selection theorem, Theorem 77.2.10, there exists a product measurable function $\bar{u}(t, \omega)$ with values in $V$ weakly continuous in $t$ and a sequence depending on $\omega,\left\{u_{\mu(\omega)}\right\}$ such that for each
$\omega, \lim _{\mu(\omega) \rightarrow 0} u_{\mu(\omega)}(\cdot, \omega)=\bar{u}(\cdot, \omega)$ weakly in $\mathscr{V}$. However, from the above argument, for each $\omega$, there is a further subsequence, still denoted with subscript $\mu(\omega)$ such that in $\mathscr{V}^{\prime}$,

$$
\lim _{\mu(\omega) \rightarrow 0} u_{\mu(\omega)}(\cdot, \omega)=u(\cdot, \omega)
$$

where $u$ is a solution to the integral equation. Since $u(\cdot, \omega)=\bar{u}(\cdot, \omega)$ in $\mathscr{V}$ it follows that these must be equal a.e. and hence $(t, \omega) \rightarrow u(t, \omega)$ is product measurable. This proves the following theorem.

Theorem 77.8.10 Suppose 77.8.73-77.8.78 and B as described above and $u_{0}$ is $\mathscr{F}$ measurable. Also let $G: D(G) \subseteq V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ be maximal monotone and quasi-bounded.

Then, there exists a solution $u$ of the integral equation

$$
B u(t, \omega)+\int_{0}^{t} z(s, \omega) d s+\int_{0}^{t} g(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega),
$$

where $(t, \omega) \rightarrow u(t, \omega)$ is product measurable $(t, \omega) \rightarrow z(t, \omega)$ also. Moreover, for each $\omega, B u(t, \omega)=B(u(t, \omega))$ a.e. $t$ and $z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$, and $g(\cdot, \omega) \in G(u(\cdot, \omega))$ for each $\omega$.

Note that in the case of most interest where you have a Gelfand triple and $B$ is the identity, the fundamental theorem of calculus implies easily that $\omega \rightarrow z(s, \omega)+g(s, \omega)$ is measurable for a.e. $s$. One can also generalize to the following in which a measurable $q(t, \omega)$ is added.

Corollary 77.8.11 Suppose 77.8.73-77.8.78 and $B$ as described above and $u_{0}$ is $\mathscr{F}$ measurable. Also let $G: D(G) \subseteq V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ be maximal monotone and quasi-bounded. Let $(t, \omega) \rightarrow q(t, \omega)$ be product measurable into $V$ and let $t \rightarrow q(t, \omega)$ be continuous, $q(0, \omega)=0$. Then, there exists a solution $u$ of the integral equation

$$
B u(t, \omega)+\int_{0}^{t} z(s, \omega) d s+\int_{0}^{t} g(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)+B q(t, \omega)
$$

where $(t, \omega) \rightarrow u(t, \omega),(t, \omega) \rightarrow z(t, \omega), g(t, \omega)$ are product measurable. Moreover, for each $\omega, B u(t, \omega)=B(u(t, \omega))$ a.e. $t$ and $z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$ for a.e. $t$, and $g(\cdot, \omega) \in$ $G(u(\cdot, \omega))$ for each $\omega$.

Proof: Define a stopping time

$$
\tau_{n}(\omega) \equiv \inf \{t: q(t, \omega)>n\}
$$

Then let $\tilde{A}(\cdot, \omega) \equiv A\left(q^{\tau_{n}}(\cdot, \omega)+w, \omega\right)$. Then $\tilde{A}$ satisfies the same properties as $A$ and so there exists a solution to the integral equation

$$
B w_{n}(t, \omega)+\int_{0}^{t} z_{n}(s, \omega) d s+\int_{0}^{t} g_{n}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)
$$

where $w_{n}, z_{n}, g_{n}$ are product measurable, $z_{n}(\cdot, \omega) \in \tilde{A}\left(w_{n}(\cdot, \omega), \omega\right)$ a.e. $t$. By continuity of $t \rightarrow q(t, \omega), \tau_{n}=\infty$ for all $n$ sufficiently large and so $q(t, \omega)=q^{\tau_{n}}(t, \omega)$. As before,
for each $\omega$, one obtains the convergences 77.8.91-77.8.96 as $n \rightarrow \infty$. As before, for each $\omega, z(\cdot, \omega) \in \tilde{A}(w(\cdot, \omega), \omega)$ a.e. where $t \rightarrow w(t, \omega)$ is the function to which $w_{n}(\cdot, \omega)$ converges weakly. Note that the estimates allowing this to happen are dependent on $\omega$. However, one can apply Theorem 77.2.10 as before and obtain a solution to

$$
B w(t, \omega)+\int_{0}^{t} z(s, \omega) d s+\int_{0}^{t} g(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)
$$

such that $w, z, g$ are product measurable into $V$ or $V^{\prime}$ and,$z(\cdot, \omega) \in \tilde{A}(w(\cdot, \omega), \omega)$. Now let $u(t, \omega)=w(t, \omega)+q(t, \omega)$ to obtain the existence of the desired solution in the corollary.

## Chapter 78

## A Different Approach

### 78.1 Summary Of The Problem

The situation is as follows. There are spaces $V \subseteq W$ where $V, W$ are reflexive separable Banach spaces. It is assumed that $V$ is dense in $W$. Define the space for $p>1$

$$
\mathscr{V} \equiv L^{p}([0, T] ; V)
$$

where in each case, the $\sigma$ algebra of measurable sets will be $\mathscr{B}([0, T])$ the Borel measurable sets. Thus, from the Riesz representation theorem,

$$
\mathscr{V}^{\prime}=L^{p^{\prime}}\left([0, T] ; V^{\prime}\right),
$$

We also assume $(\Omega, \mathscr{F})$ is a measurable space. No measure is needed. Also

$$
V \subseteq W, \quad W^{\prime} \subseteq V^{\prime}, V \text { dense in } W
$$

$B(t)$ will be a linear operator, $B(t): W \rightarrow W^{\prime}$ which satisfies

1. $\langle B(t) x, y\rangle=\langle B(t) y, x\rangle$
2. $\langle B(t) x, x\rangle \geq 0$
3. $B \in C^{1}\left([0, T] ; \mathscr{L}\left(W, W^{\prime}\right)\right)$ so in particular, the time derivative is bounded.

In the above formulae, $\langle\cdot, \cdot\rangle$ denotes the duality pairing of the Banach space $W$, with its dual space. We will use this notation in the present paper, the exact specification of which Banach space being determined, by the context in which this notation occurs.

For example, you could simply take $W=H=H^{\prime}$ and $B$ the identity and consider a standard Gelfand triple where $H$ is a Hilbert space and $B$ equal to the identity.

The product measurable sets are those in the smallest $\sigma$ algebra which contains the measurable rectangles $B \times A$ where $B \in \mathscr{B}([0, T]), A \in \mathscr{F}$. The paper is about the existence of product measurable solutions to the system

$$
\begin{align*}
(B u(\cdot, \omega))^{\prime}+u^{*}(\cdot, \omega) & =f(\cdot, \omega) \text { in } \mathscr{V}^{\prime} \\
B u(0, \omega) & =B u_{0}(\omega)  \tag{78.1.1}\\
u^{*}(\cdot, \omega) & \in A(u(\cdot, \omega), \omega) . \tag{78.1.2}
\end{align*}
$$

The evolution inclusion is well understood for fixed $\omega$. However, we will show the existence of a solution $u, u^{*}$ such that $(t, \omega) \rightarrow u(t, \omega)$ and $(t, \omega) \rightarrow u^{*}(t, \omega)$ are product measurable in this solution. Essentially, we show the existence of a measurable selection in the set of solutions. There are no assumptions made on the measurable space. It is just a set with a $\sigma$ algebra of subsets. Essentially this involves showing that the usual limit processes preserve measurability in some sense. The main theorems in this paper are essentially measurable selection theorems for the set of solutions to these implicit inclusions.

To begin with, we will assume $p \geq 2$. The reason for this is that we want to consider

$$
\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d t
$$

and this won't make sense unless $p \geq 2$. However, this restriction is not necessary if $B$ is a constant operator, as we show in the succeeding section.

### 78.1.1 General Assumptions On $A$

The case $A(u, \omega)$ for $u \in \mathscr{V}$ given by $A(u, \omega)(t)=A(u(t), \omega)$ is included as a special case. In addition to this commonly used situation, we are including the case where $A(u, \omega)(t)$ depends on past values of $u(s)$ for $s \leq t$. This makes our theory useful in situations where the problem is second order in $t$. The following definition is the standard one [99].

Definition 78.1.1 For $X$ a reflexive Banach space, we say $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ is pseudomonotone and bounded if the following hold.

1. The set $A u$ is nonempty, closed and convex for all $u \in X$. A takes bounded sets to bounded sets.
2. If $u_{i} \rightarrow u$ weakly in $X$ and $u_{i}^{*} \in A u_{i}$ is such that

$$
\begin{equation*}
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle \leq 0 \tag{78.1.3}
\end{equation*}
$$

then, for each $v \in X$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle \tag{78.1.4}
\end{equation*}
$$

We will assume in this section in which $B$ is time dependent that $p \geq 2$. The specific assumptions on $A(\cdot, \omega)$ are described next.

- growth estimate

Assume the specific estimate

$$
\begin{equation*}
\sup \left\{\left\|u^{*}\right\|_{\mathscr{V}^{\prime}}: u^{*} \in A(u, \omega)\right\} \leq a(\omega)+b(\omega)\|u\|_{\mathscr{V}}^{\hat{p}-1} \tag{78.1.5}
\end{equation*}
$$

where $a(\omega), b(\omega)$ are nonnegative and $\hat{p} \geq p$.

## - coercivity estimate

Also assume the coercivity condition: valid for each $t \leq T$,

$$
\begin{gather*}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle d s: u^{*} \in A(u, \omega)\right) \\
+\frac{1}{2} \int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d s \geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \tag{78.1.6}
\end{gather*}
$$

where $m(\omega)$ is some nonnegative constant, $\delta(\omega)>0$. In fact, it is often enough to assume the left side is given by

$$
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d s: u^{*} \in A(u, \omega)\right)
$$

for some $\lambda(\omega)$ by using a suitable exponential shift argument and changing the dependent variable. We will sometimes denote weak convergence by $\rightharpoonup$.

## - limit condition

If $u_{i} \rightharpoonup u$ in $\mathscr{V}$ and $\left(B u_{i}\right)^{\prime} \rightharpoonup(B u)^{\prime}$ in $\mathscr{V}^{\prime}, u_{i}^{*} \in A\left(u_{i}\right), \rightharpoonup$ denoting weak convergence, then if

$$
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0
$$

it follows that for all $v \in \mathscr{V}$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \inf _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\left\langle u^{*}(v), u-v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \tag{78.1.7}
\end{equation*}
$$

## - measurability condition

For $\omega \rightarrow u(\cdot, \omega)$ measurable into $\mathscr{V}$,

$$
\begin{equation*}
\omega \rightarrow A(u(\cdot, \omega), \omega) \text { has a measurable selection into } \mathscr{V}^{\prime} \tag{78.1.8}
\end{equation*}
$$

This last condition means there is a function $\omega \rightarrow u^{*}(\omega)$ which is measurable into $\mathscr{V}^{\prime}$ such that $u^{*}(\omega) \in A(u(\cdot, \omega), \omega)$. This is assured to take place if the following standard measurability condition is satisfied for all $O$ open in $\mathscr{V}^{\prime}$ :

$$
\begin{equation*}
\{\omega: A(u(\cdot, \omega), \omega) \cap O \neq \emptyset\} \in \mathscr{F} \tag{78.1.9}
\end{equation*}
$$

See for example [70], [10] or the chapter on measurable multifunctions Chapter 48. Our assumption is implied by this one but they are not equivalent. Thus what is considered here is more general than an assumption that $\omega \rightarrow A(u(\cdot, \omega), \omega)$ is set valued measurable.

Note that this condition would hold if $u \rightarrow A(t, u, \omega)$ is bounded and pseudomonotone as a single valued map from $V$ to $V^{\prime}$ and $(t, \omega) \rightarrow A(t, u, \omega)$ is product measurable into $V^{\prime}$ for each $u$. One would use the demicontinuity of $u \rightarrow A(t, u, \omega)$ which comes from a pseudo monotone and bounded assumption and consider a sequence of simple functions $u_{n}(t, \omega) \rightarrow u(t, \omega)$ in $V$ for $u$ measurable, each $u_{n}(\cdot, \omega)$ being in $\mathscr{V}$, Then the measurability of $A\left(t, u_{n}, \omega\right)$ would attach to $A(t, u, \omega)$ in the limit. In the situation where $A(\cdot, \omega)$ satisfies a suitable upper semicontinuity condition, it is enough to assume only that $\omega \rightarrow A(u, \omega)$ has a measurable selection for each $u \in V$. This is a straightforward exercise in approximating with simple functions and then using upper semicontinuity instead of continuity.

We assume always that the norm on the various reflexive Banach spaces is strictly convex.

### 78.1.2 Preliminary Results

We use the following well known theorem [91]. It is stated here for the situation in which a Holder condition is given rather than a bound on weak derivatives. See Theorem 34.7.6 on Page 1219.

Theorem 78.1.2 Let $E \subseteq F \subseteq G$ where the injection map is continuous from $F$ to $G$ and compact from $E$ to $F$. Let $p \geq 1$, let $q>1$, and define

$$
\begin{gathered}
S \equiv\left\{u \in L^{p}([a, b], E): \text { for some } C,\|u(t)-u(s)\|_{G} \leq C|t-s|^{1 / q}\right. \\
\text { and } \left.\|u\|_{L^{p}([a, b], E)} \leq R\right\}
\end{gathered}
$$

Thus $S$ is bounded in $L^{p}([a, b], E)$ and Holder continuous into $G$. Then $S$ is precompact in $L^{p}([a, b], F)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b], F)$. The same conclusion can be drawn if it is known instead of the Holder condition that $\left\|u^{\prime}\right\|_{L^{1}([a, b] ; X)}$ is bounded.

Next are some measurable selection theorems which form an essential part of showing the existence of measurable solutions. They are not dependent on there being a measure but in the applications of most interest to us, there is typically a probability measure. First is a basic selection theorem for a set of limits. See Lemma 48.2.2 on Page 1541.

Theorem 78.1.3 Let $U$ be a separable reflexive Banach space. Suppose there is a sequence $\left\{u_{j}(\omega)\right\}_{j=1}^{\infty}$ in $U$, where $\omega \rightarrow u_{j}(\omega)$ is measurable and for each $\omega$,

$$
\sup _{j}\left\|u_{j}(\omega)\right\|_{U}<\infty
$$

Then there exists a function $\omega \rightarrow u(\omega)$ with values in $U$ such that $\omega \rightarrow u(\omega)$ is measurable, and a subsequence $n(\omega)$, depending on $\omega$, such that

$$
\lim _{n(\omega) \rightarrow \infty} u_{n(\omega)}(\omega)=u(\omega) \text { weakly in } U
$$

Next is a specialization to the situation where the Banach space is a function space. The proof is in [88]. This gives a result on product measurability. It is Theorem 77.2.10 on Page 2601.

Theorem 78.1.4 Let $V$ be a reflexive separable Banach space with dual $V^{\prime}$, and let $p, p^{\prime}$ be such that $p>1$ and $\frac{1}{p}+\frac{1}{p^{\prime}}=1$. Let the functions $t \rightarrow u_{n}(t, \omega)$, for $n \in \mathbb{N}$, be in $L^{p}([0, T] ; V) \equiv \mathscr{V}$ and $(t, \omega) \rightarrow u_{n}(t, \omega)$ be $\mathscr{B}([0, T]) \times \mathscr{F} \equiv \mathscr{P}$ measurable into $V$. Suppose

$$
\left\|u_{n}(\cdot, \omega)\right\|_{\mathscr{V}} \leq C(\omega)
$$

for all $n$. (Thus, by weak compactness, for each $\omega$, each subsequence of $\left\{u_{n}\right\}$ has a further subsequence that converges weakly in $\mathscr{V}$ to $v(\cdot, \omega) \in \mathscr{V} .(v$ not known to be $\mathscr{P}$ measurable))

Then, there exists a product measurable function $u$ such that $t \rightarrow u(t, \omega)$ is in $\mathscr{V}$ and for each $\omega$ a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)}(\cdot, \omega) \rightarrow u(\cdot, \omega)$ weakly in $\mathscr{V}$.

Next is what it means to be measurable into $\mathscr{V}$ or $\mathscr{V}^{\prime}$. Such functions have representatives which are product measurable.

Lemma 78.1.5 Let $f(\cdot, \omega) \in \mathscr{V}^{\prime}$. Then if $\omega \rightarrow f(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$, it follows that for each $\omega$, there exists a representative $\hat{f}(\cdot, \omega) \in \mathscr{V}^{\prime}, \hat{f}(\cdot, \omega)=f(\cdot, \omega)$ in $\mathscr{V}^{\prime}$ such that $(t, \omega) \rightarrow \hat{f}(t, \omega)$ is product measurable. If $f(\cdot, \omega) \in \mathscr{V}^{\prime}$ and $(t, \omega) \rightarrow f(t, \omega)$ is product measurable, then $\omega \rightarrow f(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$. The same holds replacing $\mathscr{V}^{\prime}$ with $\mathscr{V}$.

Proof: If a function $f$ is measurable into $\mathscr{V}^{\prime}$, then there exist simple functions $f_{n}$

$$
\lim _{n \rightarrow \infty}\left\|f_{n}(\omega)-f(\omega)\right\|_{\mathscr{V}^{\prime}}=0,\left\|f_{n}(\omega)\right\| \leq 2\|f(\omega)\|_{\mathscr{V}^{\prime}} \equiv C(\omega)
$$

Now one of these simple functions is of the form $\sum_{i=1}^{M} c_{i} \mathscr{X}_{E_{i}}(\omega)$ where $c_{i} \in \mathscr{V}^{\prime}$. Therefore, there is no loss of generality in assuming that

$$
c_{i}(t)=\sum_{j=1}^{N} d_{j}^{i} \mathscr{X}_{F_{j}}(t)
$$

where $d_{j}^{i} \in V^{\prime}$. Hence we can assume each $f_{n}$ is product measurable into $\mathscr{B}\left(V^{\prime}\right) \times \mathscr{F}$. Then by Theorem 78.1.4, there exists $\hat{f}(\cdot, \omega) \in \mathscr{V}^{\prime}$ such that $\hat{f}$ is product measurable and a subsequence $f_{n(\omega)}$ converging weakly in $\mathscr{V}^{\prime}$ to $\hat{f}(\cdot, \omega)$ for each $\omega$. Thus $f_{n(\omega)}(\omega) \rightarrow f(\omega)$ strongly in $\mathscr{V}^{\prime}$ and $f_{n(\omega)}(\omega) \rightarrow \hat{f}(\omega)$ weakly in $\mathscr{V}^{\prime}$. Therefore, $\hat{f}(\omega)=f(\omega)$ in $\mathscr{V}^{\prime}$ and so it can be assumed that if $f$ is measurable into $\mathscr{V}^{\prime}$ then for each $\omega$, it has a representative $\hat{f}(\omega)$ such that $(t, \omega) \rightarrow \hat{f}(t, \omega)$ is product measurable.

If $f$ is product measurable into $V^{\prime}$ and each $f(\cdot, \omega) \in \mathscr{V}^{\prime}$, does it follow that $f$ is measurable into $\mathscr{V}^{\prime}$ ? By measurability, $f(t, \omega)=\lim _{n \rightarrow \infty} \sum_{i=1}^{m_{n}} c_{i}^{n} \mathscr{X}_{E_{i}^{n}}(t, \omega)=\lim _{n \rightarrow \infty} f_{n}(t, \omega)$ where $E_{i}^{n}$ is product measurable and we can assume $\left\|f_{n}(t, \omega)\right\|_{V^{\prime}} \leq 2\|f(t, \omega)\|$. Then by product measurability, $\omega \rightarrow f_{n}(\cdot, \omega)$ is measurable into $\mathscr{V}^{\prime}$ because if $g \in \mathscr{V}$ then

$$
\omega \rightarrow\left\langle f_{n}(\cdot, \omega), g\right\rangle
$$

is of the form

$$
\omega \rightarrow \sum_{i=1}^{m_{n}} \int_{0}^{T}\left\langle c_{i}^{n} \mathscr{X}_{E_{i}^{n}}(t, \omega), g(t)\right\rangle d t \text { which is } \omega \rightarrow \sum_{i=1}^{m_{n}} \int_{0}^{T}\left\langle c_{i}^{n}, g(t)\right\rangle \mathscr{X}_{E_{i}^{n}}(t, \omega) d t
$$

and this is $\mathscr{F}$ measurable since $E_{i}^{n}$ is product measurable. Thus, it is measurable into $\mathscr{V}^{\prime}$ as desired and

$$
\langle f(\cdot, \omega), g\rangle=\lim _{n \rightarrow \infty}\left\langle f_{n}(\cdot, \omega), g\right\rangle, \omega \rightarrow\left\langle f_{n}(\cdot, \omega), g\right\rangle \text { is } \mathscr{F} \text { measurable. }
$$

By the Pettis theorem, $\omega \rightarrow\langle f(\cdot, \omega), g\rangle$ is measurable into $\mathscr{V}^{\prime}$. Obviously, the conclusion is the same for these two conditions if $\mathscr{V}^{\prime}$ is replaced with $\mathscr{V}$.

The following theorem is also useful. It is really a generalization of the familiar Gram Schmidt process. See Lemma 34.4.2 on Page 1179.

Theorem 78.1.6 Suppose $V, W$ are separable Banach spaces, such that $V$ is dense in $W$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle, B \neq 0
$$

Then there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
$$

and also

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

the series converging in $W^{\prime}$. In case $B=B(\omega)$ where $\omega \rightarrow B(\omega)$ is measurable into $\mathscr{L}\left(W, W^{\prime}\right)$, these vectors $e_{i}$ will also depend on $\omega$ and will be measurable functions of $\omega$. In particular, we could let $\omega=t$ with the Lebesgue measurable sets.

The following result, found in [91] is well known. See Section 25.2 on Page 832.
Theorem 78.1.7 If a single valued map, $A: X \rightarrow X^{\prime}$ is monotone, hemicontinuous, and bounded, then $A$ is pseudo monotone. Furthermore, the duality map, $J^{-1}: X \rightarrow X^{\prime}$ which satisfies $\left\langle J^{-1} f, f\right\rangle=\|f\|^{2},\left\|J^{-1} f\right\|_{X}=\|f\|_{X}$ is strictly monotone hemicontinuous and bounded. So is the duality map $F: X \rightarrow X^{\prime}$ which satisfies $\|F f\|_{X^{\prime}}=\|f\|_{X}^{p-1},\langle F f, f\rangle=$ $\|f\|_{X}^{p}$ for $p>1$.

The following fundamental result will be of use in what follows. There is somewhat more in this than will be needed. $B$ is a possibly degenerate operator satisfying only the following:

$$
\begin{equation*}
B \in \mathscr{L}\left(W, W^{\prime}\right),\langle B u, u\rangle \geq 0,\langle B u, v\rangle=\langle B v, u\rangle \tag{78.1.10}
\end{equation*}
$$

where here $V \subseteq W$ and $V$ is dense in $W$.
Also one can obtain the following for $p \geq 2$. It is an integration by parts formula. See Theorem 34.6.4 on Page 1211.

Proposition 78.1.8 Let $p \geq 2$ in what follows. For $u, v \in X$, the following hold. If $B$ is time independent, then it is not necessary to assume $p \geq 2$. It is enough to assume $p>1$.

1. $t \rightarrow\langle B(t) u(t), v(t)\rangle_{W^{\prime}, W}$ equals an absolutely continuous function a.e., denoted by $\langle B u, v\rangle(\cdot)$.
2. $\langle L u(t), u(t)\rangle=\frac{1}{2}\left[\langle B u, u\rangle^{\prime}(t)+\left\langle B^{\prime}(t) u(t), u(t)\right\rangle\right]$ a.e. $t$
3. $|\langle B u, v\rangle(t)| \leq C\|u\|_{X}\|v\|_{X}$ for some $C>0$ and for all $t \in[0, T]$.
4. $t \rightarrow B(t) u(t)$ equals a function in $C\left(0, T ; W^{\prime}\right)$ a.e., denoted by $B u(\cdot)$.
5. $\sup \left\{\|B u(t)\|_{W^{\prime}}, t \in[0, T]\right\} \leq C\|u\|_{X}$ for some $C>0$.

If $K: X \rightarrow X^{\prime}$ is given by

$$
\langle K u, v\rangle_{X^{\prime}, X} \equiv \int_{0}^{T}\langle L u(t), v(t)\rangle d t+\langle B u, v\rangle(0),
$$

then
6. $K$ is linear, continuous and weakly continuous.
7. $\langle K u, u\rangle=\frac{1}{2}[\langle B u, u\rangle(T)+\langle B u, u\rangle(0)]+\frac{1}{2} \int_{0}^{T}\left\langle B^{\prime}(t) u(t), u(t)\right\rangle d t$.
8. If $B u(0)=0$, for $u \in X$, there exists $u_{n} \rightarrow u$ in $X$ such that $u_{n}(t)$ is 0 near 0 . A similar conclusion could be deduced at $T$ if $B u(T)=0$.

Fussing with $p \geq 2$ is necessary only because of the consideration of

$$
\int_{0}^{T}\left\langle B^{\prime}(t) u(t), u(t)\right\rangle d t
$$

If $p<2$, this term might not make sense. The last assertion about approximation makes possible the following corollary.

Corollary 78.1.9 If $B u(0)=0$ for $u \in X$, then $\langle B u, u\rangle(0)=0$. The converse is also true. An analogous result will hold with 0 replaced with $T$.

Proof: Let $u_{n} \rightarrow u$ in $X$ with $u_{n}(t)=0$ for all $t$ close enough to 0 . For $t$ off a set of measure zero consisting of the union of sets of measure zero corresponding to $u_{n}$ and $u$,

$$
\begin{gathered}
\left\langle B u_{n}, u_{n}\right\rangle(t)=\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle,\langle B u, u\rangle(t)=\langle B(t) u(t), u(t)\rangle, \\
\left\langle B\left(u-u_{n}\right), u\right\rangle(t)=\left\langle B(t)\left(u(t)-u_{n}(t)\right), u(t)\right\rangle \\
\left\langle B u_{n}, u-u_{n}\right\rangle(t)=\left\langle B(t) u_{n}(t), u(t)-u_{n}(t)\right\rangle
\end{gathered}
$$

Then, considering such $t$,

$$
\begin{aligned}
\langle B(t) u(t), u(t)\rangle-\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle= & \left\langle B(t)\left(u(t)-u_{n}(t)\right), u(t)\right\rangle \\
& +\left\langle B(t) u_{n}(t), u(t)-u_{n}(t)\right\rangle
\end{aligned}
$$

Hence from Theorem 78.1.8,

$$
\left|\langle B(t) u(t), u(t)\rangle-\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle\right| \leq C\left\|u-u_{n}\right\|_{X}\left(\|u\|_{X}+\left\|u_{n}\right\|_{X}\right)
$$

Thus if $n$ is sufficiently large,

$$
\left|\langle B(t) u(t), u(t)\rangle-\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle\right|<\varepsilon
$$

So let $n$ be fixed and this large and now let $t_{k} \rightarrow 0$ to obtain

$$
\left\langle B\left(t_{k}\right) u_{n}\left(t_{k}\right), u_{n}\left(t_{k}\right)\right\rangle=0
$$

for $k$ large enough. Hence

$$
\langle B u, u\rangle(0)=\lim _{k \rightarrow \infty}\left\langle B\left(t_{k}\right) u\left(t_{k}\right), u\left(t_{k}\right)\right\rangle<\varepsilon
$$

Since $\varepsilon$ is arbitrary, $\langle B u, u\rangle(0)=0$.
Next suppose $\langle B u, u\rangle(0)=0$. Then letting $v \in X$, with $v$ smooth,

$$
\langle B u(0), v(0)\rangle=\langle B u, v\rangle(0)=\langle B u, u\rangle^{1 / 2}(0)\langle B v, v\rangle^{1 / 2}(0)=0
$$

and it follows that $B u(0)=0$.
Note also that this shows that if $(B v)^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ as well as $(B u)^{\prime}$, then there is a continuous function

$$
t \rightarrow\langle B(u+v), u+v\rangle(t)
$$

which equals $\langle B(u(t)+v(t)), u(t)+v(t)\rangle$ for $a . e . t$ and so, defining

$$
\langle B u, v\rangle(t) \equiv(\langle B u, u\rangle(t)+\langle B v, v\rangle(t)-\langle B(u+v), u+v\rangle(t)) \frac{1}{2}
$$

It follows that $t \rightarrow\langle B u, v\rangle(t)$ is continuous and equals $\langle B(u(t)), v(t)\rangle$ a.e. $t$.
This also makes it easy to verify continuity of pointwise evaluation of $B u$.
Let $L u=(B u)^{\prime}$.

$$
\begin{gather*}
u \in D(L) \equiv X \equiv\left\{u \in L^{p}(0, T, V): L u \equiv(B u)^{\prime} \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)\right\} \\
\|u\|_{X} \equiv \max \left(\|u\|_{L^{p}(0, T, V)},\|L u\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)}\right) \tag{78.1.11}
\end{gather*}
$$

Since $L$ is closed, this $X$ is a Banach space. To see that $L$ is closed, suppose $u_{n} \rightarrow u$ in $\mathscr{V}$ and $\left(B u_{n}\right)^{\prime} \rightarrow \xi$ in $\mathscr{V}^{\prime}$. Is $\xi=(B u)^{\prime}$ ? Letting $\phi \in C_{c}^{\infty}([0, T])$ and $v \in V$,

$$
\begin{equation*}
\int_{0}^{T}\langle\xi, \phi v\rangle_{V^{\prime}, V}=\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle\left(B u_{n}\right)^{\prime}, \phi v\right\rangle=\lim _{n \rightarrow \infty}-\int_{0}^{T}\left\langle B u_{n}, \phi^{\prime} v\right\rangle \tag{78.1.12}
\end{equation*}
$$

We can take a subsequence, still denoted with $n$ such that $u_{n}(t) \rightarrow u(t)$ pointwise a.e. Also

$$
\int_{0}^{T}\left|\left\langle B u_{n}, \phi^{\prime} v\right\rangle\right|^{p} \leq \int_{0}^{T}\left\|u_{n}\right\|_{V}^{p} d t C\left(\phi^{\prime}, v\right)
$$

and these terms on the right are uniformly bounded by the assumption that $u_{n}$ is bounded in $\mathscr{V}$. Therefore, by the Vitali convergence theorem, and using the subsequence just described, we can pass to the limit in 78.1.12.

$$
\left\langle\int_{0}^{T} \xi \phi d t, v\right\rangle=\left\langle-\int_{0}^{T}(B u) \phi^{\prime} d t, v\right\rangle
$$

Since $v$ is arbitrary, this shows that

$$
\int_{0}^{T} \xi \phi d t=-\int_{0}^{T}(B u) \phi^{\prime} d t \text { in } V^{\prime}
$$

and so $\xi=(B u)^{\prime}$ because this is what is meant by $(B u)^{\prime}$. Hence $L$ is indeed closed and $X$ is a Banach space. It is also a reflexive Banach space because it is isometric to a closed subspace of the reflexive Banach space $\mathscr{V} \times \mathscr{V}^{\prime}$. Also, the following is useful. See Theorem 34.4.7 on Page 1193.

Theorem 78.1.10 If $Y$ denotes those $f \in L^{p}([0, T] ; V)$ for which $f^{\prime} \in L^{p}([0, T] ; V)$, so that $f$ has a representative such that $f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d$ s a.e. $t$, then if $\|f\|_{Y} \equiv$ $\|f\|_{L^{p}([0, T] ; V)}+\left\|f^{\prime}\right\|_{L^{p}([0, T] ; V)}$ the map $f \rightarrow f(t)$ is continuous in the sense that $\|f(t)\| \leq$ $C\left(\|f\|_{Y}\right)$.

We also have the following general theory about existence of measurable solutions to elliptic problems. First are conditions which a nonlinear set valued map should satisfy. In what follows, $X$ denotes a reflexive separable Banach space with dual $X^{\prime},(\Omega, \mathscr{F})$ is a measurable space, and $A(\cdot, \omega): X \rightarrow \mathscr{P}\left(X^{\prime}\right)$, for $\omega \in \Omega$, denotes a set valued operator. We make the following assumptions on such an operator:

- $H_{1}$ Measurability condition. For each $u \in X$, there is a measurable selection $z(\omega)$ such that

$$
z(\omega) \in \mathscr{A}(u, \omega)
$$

- $H_{2}$ Values of $\mathscr{A}$. $\mathscr{A}(\cdot, \omega): X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ has bounded, closed, nonempty, and convex values. $A(\cdot, \omega)$ maps bounded sets to bounded sets.
- $H_{3}$ Limit conditions, $\mathscr{A}(\cdot, \omega)$ is pseudomonotone:

$$
\text { If } u_{n} \rightharpoonup u \text { and } \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0, \text { for } z_{n} \in \mathscr{A}\left(u_{n}, \omega\right),
$$

then for each $v$, there exists $z(v) \in \mathscr{A}(u, \omega)$ such that

$$
\lim _{k \rightarrow \infty} \inf _{k}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle
$$

In our use of the above, the space $X$ will be a space of functions defined on $[0, T]$ to be described more later.

We note that for a fixed $\omega$, the operator $A(\cdot, \omega)$ described earlier is set-valued, bounded and pseudomonotone as a map from $X$ to $\mathscr{P}(X)$. Moreover, the sum of two of such operators is set-valued, bounded and pseudomonotone, Theorem 48.5.2 below. The limit condition $H_{3}$ implies that $A(\cdot, \omega)$ is upper-semicontinuous from the strong topology to the weak topology. This can be used to show that when $\omega \rightarrow u(\omega)$ is measurable, then $A(u(\omega), \omega)$ has a measurable selection assuming only that $\omega \rightarrow A(u, \omega)$ has a measurable selection for fixed $u \in X$. Here is a well known result on the sum of pseudomonotone operators. See Theorem 25.5.1 on Page 855.

Theorem 78.1.11 Assume that A and B are set-valued, bounded and pseudomonotone operators. Then, their sum is also a set-valued, bounded and pseudomonotone operator. Moreover, if $u_{n} \rightarrow u$ weakly, $z_{n} \rightarrow z, z_{n} \in A\left(u_{n}\right), w_{n} \rightarrow w$ weakly with $w_{n} \in A\left(u_{n}\right)$, and

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0
$$

then,

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-v\right\rangle \geq\langle z(v)+w(v), u-v\rangle
$$

for $z(v) \in A(u), w(v) \in B(u)$ and in fact, $z \in A(u)$ and $w \in B(u)$.
We now state our result on measurable solutions to general elliptic variational inequalities that may contain sums of set-valued, bounded and pseudomonotone operators. Then the following is proved in [2]. See Theorem 48.5.3 on Page 1566.

Theorem 78.1.12 Let $\omega \rightarrow K(\omega)$ be a measurable set-valued function, where $K(\omega) \subset V$ is convex, closed and bounded. Let the operators $A(\cdot, \cdot)$ and $B(\cdot, \cdot)$ satisfy assumptions $H_{1}-H_{3}$. Finally, let $\omega \rightarrow f(\omega)$ be measurable with values in $V^{\prime}$.

Then, there exists a measurable function $\omega \rightarrow u(\omega) \in K(\omega)$ such that $\omega \rightarrow w^{A}(\omega)$, and $\omega \rightarrow w^{B}(\omega)$ with $w^{A}(\omega) \in A(u(\omega), \omega)$ and $w^{B}(\omega) \in B(u(\omega), \omega)$, and

$$
\left\langle f(\omega)-\left(w^{A}(\omega)+w^{B}(\omega)\right), z-u(\omega)\right\rangle \leq 0
$$

for all $z \in K(\omega)$.
If it is only known that $K(\omega)$ is closed and convex, the same conclusion holds true if it is also known that for some $z(\omega) \in K(\omega), A(\cdot, \omega)+B(\cdot, \omega)$ is coercive, that is

$$
\lim _{\|v\| \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, v-z\right\rangle}{\|v\|}: z^{*} \in(A(v, \omega)+B(v, \omega))\right\}=\infty .
$$

Instead of two operators, one could have the sum of finitely many with the same conclusions.

### 78.2 Measurable Solutions To Evolution Inclusions

The main result in this section is Theorem 78.2.2 below. It gives an existence theorem for many evolution inclusions. We are assuming that $A(\cdot, \omega): \mathscr{V} \rightarrow \mathscr{P}\left(\mathscr{V}^{\prime}\right)$ satisfies some conditions presented earlier: These are 78.1.1-78.1.1. Then we can regard $A(\cdot, \omega)$ as a set valued pseudomonotone map from $X$ to $\mathscr{P}\left(X^{\prime}\right)$. It is clear that $A(u, \omega)$ is a closed convex set in $X^{\prime}$ because if $z_{n}^{*} \rightarrow z^{*}$ in $X^{\prime}, z_{n}^{*} \in A(u, \omega)$, then $z^{*} \in A(u, \omega)$ because a subsequence, still denoted as $z_{n}^{*}$ converges weakly to some $w^{*} \in A(u, \omega)$ in $V^{\prime}$. Since $X$ is dense in $\mathscr{V}$, this requires $w^{*}=z^{*}$. The necessary limit conditions for pseudomonotone are nothing more than the assumed conditions in 78.1.1. Also, we will assume in this section that $p \geq 2$. This restriction is necessary because of the desire to consider time dependent $B$ and the assumption 78.1 .6 which involves a term $\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle$ which might not make sense if $p$ were only larger than 1 . If $B$ were not time dependent, this assumption would not be necessary and the argument given here would continue to be valid. We essentially show this is the case in the following section in which we also consider a more general coercivity condition than 78.1.1, but one can see that there is no change in the argument and it is in fact simpler if we assume $B$ is constant.

As above, $5, K: X \rightarrow X^{\prime}$ can be defined as

$$
\langle K u, v\rangle \equiv \int_{0}^{T}\langle L u, v\rangle d s+\langle B u, v\rangle(0)
$$

Note that from Proposition 78.1.8, if $v \in X$ and $B v(0)=0$, then

$$
\begin{equation*}
\langle K u, v\rangle=\int_{0}^{T}\langle L u, v\rangle d s \tag{78.2.13}
\end{equation*}
$$

This is because, from the Cauchy Schwarz inequality and continuity of $\langle B u, u\rangle(\cdot)$,

$$
\langle B u, v\rangle(0) \leq\langle B u, u\rangle^{1 / 2}(0)\langle B v, v\rangle^{1 / 2}(0)
$$

and if $B v(0)=0$, then from Corollary 78.1.9, $\langle B v, v\rangle^{1 / 2}(0)=0$. From the above Proposition 78.1.8, this operator $K$ is hemicontinuous and bounded and monotone as a map from $X$ to $X^{\prime}$. Thus $K+A(\cdot, \omega)$ is a set valued pseudomonotone map for which we can apply Theorem 78.1.12 and obtain existence theorems for measurable solutions to variational inequalities right away, but we want to obtain solutions to an evolution equation in which $K(\omega)=V$ and the above theorem does not apply because the sum of these two operators is not coercive. Therefore, we consider another operator which, when added, will result in coercivity. Let $J: \mathscr{V} \rightarrow \mathscr{V}^{\prime}$ be the duality map for 2 . Thus $\|J u\|_{\mathscr{V}^{\prime}}=\|u\|_{\mathscr{V}}$ and $\langle J u, u\rangle=\|u\|_{\mathscr{V}}^{2}$. Then $J^{-1}: \mathscr{V}^{\prime} \rightarrow \mathscr{V}$ also satisfies $\left\langle f, J^{-1} f\right\rangle=\|f\|_{V^{\prime}}^{2}$.

The main result in this section is based on methods due to Brezis [22] and Lions [91] adapted to the case considered here where the operator is set valued, and we consider measurability. We define the operator $M: X \rightarrow X^{\prime}$ by

$$
\langle M u, v\rangle \equiv\left\langle L v, J^{-1} L u\right\rangle_{V^{\prime}, \mathscr{V}} \text { where as above, } L u=(B u)^{\prime} .
$$

Then let $f$ be measurable into $\mathscr{V}^{\prime}$. Thus, in particular, $f(\omega) \in \mathscr{V}^{\prime}$ for each $\omega$. Consider the approximate problem and a solution $u_{\varepsilon}$ to

$$
\begin{equation*}
\varepsilon M u_{\varepsilon}(\omega)+K u_{\varepsilon}(\omega)+w_{\varepsilon}^{*}(\omega)=f(\omega)+g(\omega), w_{\varepsilon}^{*}(\omega) \in A\left(u_{\varepsilon}(\omega), \omega\right) \tag{78.2.14}
\end{equation*}
$$

Where $g(\omega) \in X^{\prime}$ is given by

$$
\langle g(\omega), v\rangle \equiv\left\langle B v(0), u_{0}(\omega)\right\rangle
$$

where $u_{0}(\omega)$ is a given function measurable into $W$. Now for $u \in X$, we let

$$
\mathscr{A}(u, \omega)=\varepsilon M u+K u+A(u, \omega)
$$

Then by the assumptions on $A(\cdot, \omega)$, there is $u^{*}(\omega)$ for which $\omega \rightarrow u^{*}(\omega)$ is measurable into $\mathscr{V}^{\prime}$, hence measurable into $X^{\prime}$. Therefore, $\omega \rightarrow \mathscr{A}(u, \omega)$ has a measurable selection, namely $\varepsilon M u+K u+u^{*}(\omega)$ and so condition 78.1.2 is verified.

By Theorem 78.1.12, a solution to 78.2.14 will exist with both $u_{\varepsilon}$ and $w_{\varepsilon}^{*}$ measurable if we can argue that the sum of the operators $\varepsilon M+K+A(\cdot, \omega)$ is coercive, since this is the sum of pseudomonotone operators. From 78.1.1

$$
\inf \left(\int_{0}^{T}\left\langle u^{*}, u\right\rangle d s: u^{*} \in A(u, \omega)\right)+\frac{1}{2} \int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle \geq \delta(\omega) \int_{0}^{T}\|u\|_{V}^{p} d s-m(\omega)
$$

and so routine considerations show that $\varepsilon M+K+A(\cdot, \omega)$ does indeed satisfy a suitable coercivity estimate for each positive $\varepsilon$. Thus we have the following existence theorem for approximate solutions.

Lemma 78.2.1 Let $f$ be measurable into $\mathscr{V}^{\prime}$ and let A satisfy the conditions 78.1.1-78.1.1. Then for $K$ and $M$ defined as above, it follows there exist measurable $u_{\varepsilon}$ and $w_{\varepsilon}^{*}$ satisfying 78.2.14.

Note this implies that, suppressing dependence on $\omega$,

$$
\left\langle B u_{\varepsilon}, v\right\rangle(0)=\left\langle B v(0), u_{0}\right\rangle
$$

for all $v \in X$. Thus, letting $v$ be a smooth function with values in $V$

$$
\left\langle B u_{\varepsilon}(0), v(0)\right\rangle=\left\langle B u_{0}, v(0)\right\rangle
$$

Since $V$ is dense in $W$, this requires $B u_{\varepsilon}(0)=B u_{0}$.
Now define $\Lambda$ to be the restriction of $L$ to those $u \in X$ which have $B u(0)=0$. Thus by Corollary 78.1.9,

$$
D(\Lambda)=\{u \in X: B u(0)=0\}=\{u \in X:\langle B u, u\rangle(0)=0\}
$$

and if $v \in D(\Lambda), u \in X$, then as noted earlier,

$$
\langle K u, v\rangle=\int_{0}^{T}\langle L u, v\rangle d s
$$

Also, one can show an estimate for $\Lambda^{*}$.
You can define $D(T) \equiv\left\{u \in \mathscr{V}: u^{\prime} \in \mathscr{V}, u(T)=0\right\}$ and let $T u=-B u^{\prime}$. Then

$$
\begin{aligned}
\langle T u, u\rangle & =-\int_{0}^{T}\left\langle B u^{\prime}, u\right\rangle=-\left.\langle B u, u\rangle\right|_{0} ^{T}+\int_{0}^{T}\left\langle(B u)^{\prime}, u\right\rangle \\
& =\langle B u, u\rangle(0)+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle+\int_{0}^{T}\left\langle B u^{\prime}, u\right\rangle
\end{aligned}
$$

and so we obtain

$$
\begin{equation*}
2\langle T u, u\rangle \geq \int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle \tag{78.2.15}
\end{equation*}
$$

Then one shows that $T^{*}=\Lambda$ and that the graph of $\Lambda^{*}$ is the closure of the graph of $T$ thus showing that $\Lambda^{*}$ also satisfies an inequality like 78.2 .15 for $u \in D\left(\Lambda^{*}\right)$.

From 78.2.14,

$$
\begin{aligned}
& \varepsilon\left\langle L v, J^{-1} L u_{\varepsilon}\right\rangle_{V^{\prime}, \mathscr{V}}+\left\langle K u_{\varepsilon}(\omega), v\right\rangle_{X^{\prime}, X}+\left\langle w_{\varepsilon}^{*}(\omega), v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
= & \langle f(\omega), v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\langle g(\omega), v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
\end{aligned}
$$

If we restrict to $v \in D(\Lambda)$ so $B v(0)=0$, then it reduces to

$$
\varepsilon\left\langle\Lambda v, J^{-1} L u_{\varepsilon}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle L u_{\varepsilon}(\omega), v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\left\langle w_{\varepsilon}^{*}(\omega), v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\langle f(\omega), v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

and so $J^{-1} L u_{\varepsilon} \in D\left(\Lambda^{*}\right)$. Thus, since $D(\Lambda)$ is dense in $\mathscr{V}$, it follows that

$$
\varepsilon \Lambda^{*} J^{-1} L u_{\varepsilon}+L u_{\varepsilon}+w_{\varepsilon}^{*}=f \text { in } \mathscr{V}^{\prime}
$$

Then act on $J^{-1} L u_{\varepsilon}$ on both sides in the above. This yields for some $C$ dependent on $B^{\prime}$ an inequality of the following form.

$$
\begin{equation*}
-\varepsilon C\left\|L u_{\varepsilon}\right\|^{2}+\left\|L u_{\varepsilon}\right\|^{2}+\left\langle w_{\varepsilon}^{*}, J^{-1} L u_{\varepsilon}\right\rangle \leq\left\langle f, J^{-1} L u_{\varepsilon}\right\rangle \tag{78.2.16}
\end{equation*}
$$

Also, acting on both sides of 78.2 .14 with $u_{\varepsilon}$ and using the formula for $\langle K u, u\rangle$,

$$
\begin{aligned}
& \varepsilon\left\langle L u_{\varepsilon}, J^{-1} L u_{\varepsilon}\right\rangle+\frac{1}{2}\left[\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(T)+\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(0)\right] \\
&+\frac{1}{2} \int_{0}^{T}\left\langle B^{\prime}(t) u_{\varepsilon}(t), u_{\varepsilon}(t)\right\rangle d t+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle_{V^{\prime}, \mathscr{V}}=\left\langle f, u_{\varepsilon}\right\rangle+\left\langle B u_{\varepsilon}(0), u_{0}(\omega)\right\rangle \\
&=\left\langle f, u_{\varepsilon}\right\rangle+\left\langle B u_{0}(\omega), u_{0}(\omega)\right\rangle
\end{aligned}
$$

It follows easily from the coercivity condition 78.1 .6 that $u_{\varepsilon}$ is bounded in $\mathscr{V}$ and consequently $w_{\varepsilon}^{*}$ is bounded in $\mathscr{V}^{\prime}$, this from the growth estimate 78.1.1. Now from 78.2.16, it also follows that $\left\|L u_{\mathcal{\varepsilon}}\right\|_{\mathscr{V}^{\prime}}$ is bounded for small $\varepsilon$. Thus

$$
\left\|L u_{\varepsilon}(\omega)\right\|_{\mathscr{V}^{\prime}}+\left\|u_{\varepsilon}(\omega)\right\|_{\mathscr{V}}+\left\|w_{\varepsilon}^{*}(\omega)\right\|_{\mathscr{V}^{\prime}} \leq C(\omega)<\infty
$$

$C(\omega)$ independent of small $\varepsilon$. By Theorem 78.1.3, there is a subsequence $\varepsilon(\omega) \rightarrow 0$ such that

$$
\begin{gather*}
\left(L u_{\varepsilon(\omega)}(\omega), u_{\varepsilon(\omega)}(\omega), w_{\varepsilon(\omega)}^{*}(\omega), B u_{\mathcal{E}(\omega)}(\omega)(0)\right) \rightarrow \\
(L u(\omega), u(\omega), \xi(\omega), B u(\omega)(0)) \tag{78.2.17}
\end{gather*}
$$

in $\mathscr{V}^{\prime} \times \mathscr{V} \times \mathscr{V}^{\prime} \times V^{\prime}$ weakly and $\omega \rightarrow(L u(\omega), u(\omega), \xi(\omega))$ is measurable into $\mathscr{V}^{\prime} \times \mathscr{V} \times$ $\mathscr{V}^{\prime}$. It follows that $B u(\omega)(0)=B u_{0}(\omega)$ because each $B u_{\varepsilon(\omega)}(\omega)(0)=B u_{0}(\omega)$. Note that this also shows that $K u_{\varepsilon} \rightharpoonup K u$ in $X^{\prime}$. Thus, suppressing the dependence on $\omega$, use 78.2.14 to act on $u_{\varepsilon}-u$ and obtain

$$
\varepsilon\left\langle L u_{\varepsilon}-L u, J^{-1} L u_{\varepsilon}\right\rangle+\left\langle K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle=\left\langle f, u_{\varepsilon}-u\right\rangle+\left\langle g, u_{\varepsilon}-u\right\rangle
$$

Using monotonicity of $J^{-1}$,

$$
\varepsilon\left\langle L u_{\varepsilon}-L u, J^{-1} L u\right\rangle+\left\langle K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq\left\langle f, u_{\varepsilon}-u\right\rangle+\left\langle g, u_{\varepsilon}-u\right\rangle
$$

Now $\left(B u_{\varepsilon}-B u\right)(0)=0$. Therefore, $u_{\varepsilon}-u \in D(\Lambda)$ and so

$$
\varepsilon\left\langle\Lambda^{*} J^{-1} L u, u_{\varepsilon}-u\right\rangle+\left\langle K u_{\varepsilon}, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq\left\langle f, u_{\varepsilon}-u\right\rangle+\left\langle g, u_{\varepsilon}-u\right\rangle
$$

Recall that $K$ is monotone, bounded and hemicontinuous. In fact, it is monotone and linear. Hence, $K+A$ is pseudomonotone. Then from the above,

$$
\limsup _{\varepsilon \rightarrow 0}\left\langle K u_{\varepsilon}+w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq 0
$$

Now these weak convergences in 78.2.17 include the weak convergence of $u_{\varepsilon}$ to $u$ in $X$. Thus, since $K+A(\cdot, \omega)$ is pseudomonotone as a map from $X$ to $\mathscr{P}\left(X^{\prime}\right)$, for every $v \in X$, there exists $w^{*}(v) \in K(u)+A(u, \omega)$ such that

$$
\lim _{\varepsilon \rightarrow 0}\left\langle K u_{\varepsilon}+w_{\varepsilon}^{*}, u_{\varepsilon}-v\right\rangle \geq\left\langle w^{*}(v), u-v\right\rangle
$$

In particular, this holds if $v=u$ which shows that

$$
\lim _{\varepsilon \rightarrow 0}\left\langle K\left(u_{\varepsilon}\right)+w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle=0
$$

It follows then that for $v \in X$,

$$
\begin{aligned}
\langle\xi+K u, u-v\rangle & =\lim _{\varepsilon \rightarrow 0}\left\langle w_{\varepsilon}^{*}+K u_{\varepsilon}, u-v\right\rangle \\
& =\lim _{\varepsilon \rightarrow 0}\left[\left\langle w_{\varepsilon}^{*}+K u_{\varepsilon}, u-u_{\varepsilon}\right\rangle+\left\langle w_{\varepsilon}^{*}+K u_{\varepsilon}, u_{\varepsilon}-v\right\rangle\right] \\
& \geq \lim _{\varepsilon \rightarrow 0}\left\langle w_{\varepsilon}^{*}+K u_{\varepsilon}, u_{\varepsilon}-v\right\rangle \geq\left\langle w^{*}(v), u-v\right\rangle
\end{aligned}
$$

Since $v$ is arbitrary, separation theorems imply that

$$
\xi(\omega)+K u(\omega) \equiv w^{*}(\omega)+K u(\omega) \in A(u(\omega), \omega)+K u(\omega)
$$

Then passing to the limit in 78.2 .14 , we have

$$
\begin{gather*}
K u(\omega)+w^{*}(\omega)=f(\omega)+g(\omega) \text { in } X^{\prime}, \\
w^{*}(\omega) \in A(u(\omega), \omega), B u(\omega)(0)=B u_{0}(\omega) \tag{78.2.18}
\end{gather*}
$$

and $L u, w^{*}, u$ are all measurable into the appropriate spaces. This implies for each $v \in X$,

$$
\int_{0}^{T}\langle L u, v\rangle+\langle B u, v\rangle(0)+\int_{0}^{T}\left\langle w^{*}, v\right\rangle=\int_{0}^{T}\langle f, v\rangle+\left\langle B v(0), u_{0}\right\rangle
$$

In particular, letting $v=u$,

$$
\begin{aligned}
\int_{0}^{T}\langle L u, u\rangle+\langle B u, u\rangle(0)+\int_{0}^{T}\left\langle w^{*}, u\right\rangle & =\int_{0}^{T}\langle f, v\rangle+\left\langle B u(0), u_{0}\right\rangle \\
& =\int_{0}^{T}\langle f, v\rangle+\left\langle B u_{0}, u_{0}\right\rangle
\end{aligned}
$$

Thanks to 78.2.18, this shows that $\langle B u, u\rangle(0)=\left\langle B u_{0}, u_{0}\right\rangle$. Also it follows from Theorem 78.1.8.

This has proved the following theorem.
Theorem 78.2.2 Let $p \geq 2$ and let A satisfy 78.1.1-78.1.1 and let $f$ be measurable into $\mathscr{V}^{\prime}$ and let $u_{0}$ be measurable into $W$. Then there exists a solution to 78.2 .18 such that $L u, w^{*}, u$ are all measurable. We also have for $u$ this solution that for fixed $\omega,\left\langle B u_{0}, u_{0}\right\rangle=\langle B u, u\rangle(0)$.

We also have the following corollary which gives measurable solutions to periodic problems. Of course there is no uniqueness for such periodic problems so this is another place where our theory is applicable. In this corollary, we assume for the sake of simplicity that $B(t)=B$ a constant. Thus, it is not necessary to assume $p \geq 2$ in the following corollary.

Corollary 78.2.3 Let A satisfy 78.1.1-78.1.1, $p>1$, and let $f$ be measurable into $\mathscr{V}^{\prime}$. Then there exists a solution to

$$
\begin{aligned}
L u(\omega)+w^{*}(\omega) & =f(\omega), B u(0, \omega)=B u(T, \omega), \\
w^{*}(\omega) & \in A(u(\omega), \omega)
\end{aligned}
$$

such that $L u, w^{*}, u$ are all measurable.
Proof: Define $\Lambda$ as the restriction of $L$ to the space $\{u \in D(L): B u(0)=B u(T)\}$. This enables periodic conditions. Let

$$
D(T) \equiv\left\{v \in \mathscr{V}: v^{\prime} \in \mathscr{V} \text { and } v(T)=v(0)\right\}, T v=-B v^{\prime}
$$

Then consider $T^{*}$. If $u \in D(\Lambda), v \in D(T)$,

$$
-\int_{0}^{T}\left\langle B v^{\prime}, u\right\rangle=-\left.\langle B u, v\rangle\right|_{0} ^{T}+\int_{0}^{T}\left\langle(B u)^{\prime}, v\right\rangle
$$

and so, since the boundary term vanishes, this shows that $D(\Lambda) \subseteq D\left(T^{*}\right)$ and that $T^{*}=\Lambda$ on $D(\Lambda)$.

Next let $u \in D\left(T^{*}\right)$. By definition, this means that

$$
\begin{equation*}
|\langle T v, u\rangle| \leq C_{u}\|v\|_{\mathscr{V}} \tag{*}
\end{equation*}
$$

So let $v \in C_{c}^{\infty}([0, T] ; V)$.

$$
\langle T v, u\rangle=-\int_{0}^{T}\left\langle B v^{\prime}, u\right\rangle=-\int_{0}^{T}\left\langle B u, v^{\prime}\right\rangle
$$

From the Riesz representation theorem, there exists a unique $(B u)^{\prime}$ such that the above equals $\int_{0}^{T}\left\langle(B u)^{\prime}, v\right\rangle$ and by density of $C_{c}^{\infty}([0, T] ; V)$ this shows $T^{*} u=(B u)^{\prime}=L u$. Thus $T^{*}=L$ on $D\left(T^{*}\right)$ and in particular $(B u)^{\prime} \in \mathscr{V}^{\prime}$. It remains to consider the boundary conditions. For $u \in D\left(T^{*}\right)$ and $v \in D(T)$,

$$
\langle T v, u\rangle=-\int_{0}^{T}\left\langle B v^{\prime}, u\right\rangle=-\left.\langle B u, v\rangle\right|_{0} ^{T}+\int_{0}^{T}\left\langle(B u)^{\prime}, v\right\rangle
$$

The boundary term is of the form

$$
\langle B u(0)-B u(T), v(0)\rangle
$$

If $*$ is to hold for all $v \in D(T)$ we must have $B u(0)=B u(T)$. If the difference is $\xi \neq 0$, you would need to have

$$
|\langle\xi, v(0)\rangle| \leq C_{u}\|v\|_{\mathscr{V}}
$$

for all $v \in D(T)$. So pick $v \in D(T)$ such that $|\langle\xi, v(0)\rangle|=\delta>0$ and consider a piecewise linear function $\psi_{n}$ which is one at 0 and $T$ but zero on $[1 / n, T-(1 / n)]$. Then if $v_{n}=\psi_{n} v$, the left side is $\delta$ for all $n$ but the right converges to 0 .

This shows that $D\left(T^{*}\right)=D(\Lambda)$ and $T^{*}=\Lambda$. Now it follows that $T^{* *}=\Lambda^{*}$ and so $\Lambda^{*}$ is monotone because $T$ is and the graph of $\Lambda^{*}$ is the closure of the graph of $T$. Indeed,

$$
\int_{0}^{T}\left\langle-B v^{\prime}, v\right\rangle=\int_{0}^{T}\left\langle B v^{\prime}, v\right\rangle
$$

so $\langle T v, v\rangle=0$. The same is true of $\Lambda^{*}$.
Now in this case we let $X$ be the same as before. Then we consider the approximate problem for $u_{\varepsilon}$ given by

$$
\begin{aligned}
& \varepsilon\left\langle L v, J^{-1}\left(L u_{\varepsilon}\right)\right\rangle+\left\langle L u_{\varepsilon}(\omega), v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+ \\
& \frac{1}{2}\langle B u, v\rangle(0)-\frac{1}{2}\langle B u, v\rangle(T)+\left\langle w_{\varepsilon}^{*}(\omega), v\right\rangle \\
&=\langle f(\omega), v\rangle, w_{\varepsilon}^{*}(\omega) \in A\left(u_{\varepsilon}(\omega), \omega\right)
\end{aligned}
$$

Then using monotonicity of $\Lambda^{*}$ and $\Lambda$ as before, one obtains the existence of a measurable solution. To see that the necessary monotonicity holds, note that

$$
\langle L u, u\rangle_{V^{\prime}, V}+\frac{1}{2}\langle B u, u\rangle(0)-\frac{1}{2}\langle B u, u\rangle(T)=0
$$

This follows from 5 and 7. Indeed, these imply that

$$
\langle L u, u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\langle B u, u\rangle(0)=\frac{1}{2}[\langle B u, u\rangle(T)+\langle B u, u\rangle(0)]
$$

and so the above follows. The rest of the argument is similar to that used to prove Theorem 78.2.2. At the end you will obtain that

$$
\frac{1}{2}\langle B u, v\rangle(0)-\frac{1}{2}\langle B u, v\rangle(T)=0
$$

which will require that $B u(T)=B u(0)$ since $v$ is arbitrary.

### 78.3 Relaxed Coercivity Condition

This section is devoted to proving Theorem 78.3.2 below. It includes a more general coercivity condition and uses a slightly modified limit condition. Also, it removes the restriction that $p \geq 2$, which was made because of the terms involving $B^{\prime}$. However, we will specialize to the case where $B$ does not depend on $t$. It seems that this will be necessary because if one is required to consider $\left\langle B^{\prime} u, u\right\rangle$ then this won't make sense unless $p \geq 2$. In what follows $p>1$.

Let $U$ be dense in $V$ with the embedding compact, $U$ being a separable reflexive Banach space. It is always possible to get such a space, (In fact, it can be assumed a Hilbert space.) but in applications of most interest to us, it can be obtained by Sobolev embedding theorems. We will let $r>\max (2, p)$ and $\mathscr{U}_{r}=L^{r}([0, T] ; U)$. Also, for $I=[0, \hat{T}], \hat{T}<$ $T$, we will denote as $\mathscr{V}_{I}$ the space $L^{p}(I ; V)$ with a similar usage of this notation in other
situations. If $u \in \mathscr{V}$, then we will always consider $u \in \mathscr{V}_{I}$ also by simply considering its restriction to $I$. With this convention, it is clear that if $u$ is measurable into $\mathscr{V}$ then it is also measurable into $\mathscr{V}_{I}$.

Then the modified conditions on $A: \mathscr{V}_{I} \rightarrow \mathscr{P}\left(\mathscr{V}_{I}^{\prime}\right)$ are as follows for $A(u, \omega)$ a convex closed set in $\mathscr{V}_{I}^{\prime}$ whenever $u \in \mathscr{V}_{I}$.

## - growth estimate

Assume the specific estimate for $u \in \mathscr{V}_{I}$.

$$
\begin{equation*}
\sup \left\{\left\|u^{*}\right\|_{\mathscr{V}_{I}^{\prime}}: u^{*} \in A(u, \omega)\right\} \leq a(\omega)+b(\omega)\|u\|_{\mathscr{Y}_{I}}^{\hat{p}-1} \tag{78.3.19}
\end{equation*}
$$

where $a(\omega), b(\omega)$ are nonnegative, $\hat{p} \geq p$.

## - coercivity estimate

Also assume the coercivity condition: valid for each $t \leq T$ and for some $\lambda(\omega) \geq 0$,

$$
\begin{gather*}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d s: u^{*} \in A(u, \omega)\right) \\
\geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \tag{78.3.20}
\end{gather*}
$$

where $m(\omega)$ is some nonnegative constant for fixed $\omega$, and $\delta(\omega)>0$. No uniformity in $\omega$ is necessary.

## - Limit conditions

Let $U$ be a Banach space dense and compact in $V$ and that if $u_{i} \rightharpoonup u$ in $\mathscr{V}_{I}$ and $u_{i}^{*} \in A\left(u_{i}, \omega\right)$ with $\left(B u_{n}\right)^{\prime} \rightarrow(B u)^{\prime}$ weakly in $\mathscr{U}_{r I}^{\prime}$, then if

$$
\begin{equation*}
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \leq 0 \tag{78.3.21}
\end{equation*}
$$

it follows that for all $v \in \mathscr{V}_{I}$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \geq\left\langle u^{*}(v), u-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \tag{78.3.22}
\end{equation*}
$$

You typically obtain this kind of thing from Theorem 78.1.2 applied to lower order terms along with some sort of compactness of the embedding of $V$ into $W$.

## - measurability condition

For $\omega \rightarrow u(\cdot, \omega)$ measurable into $\mathscr{V}$,

$$
\begin{equation*}
\omega \rightarrow A\left(\mathscr{X}_{I} u(\cdot, \omega), \omega\right) \text { has a measurable selection into } \mathscr{V}_{I}^{\prime} \tag{78.3.23}
\end{equation*}
$$

This condition means there is a function $\omega \rightarrow u^{*}(\omega)$ which is measurable into $\mathscr{V}_{I}^{\prime}$ such that $u^{*}(\omega) \in A\left(\mathscr{X}_{I} u(\cdot, \omega), \omega\right)$. This is assured to take place if the following standard measurability condition is satisfied for all $O$ open in $\mathscr{V}_{I}^{\prime}$ :

$$
\begin{equation*}
\left\{\omega: A\left(\mathscr{X}_{I} u(\cdot, \omega), \omega\right) \cap O \neq \emptyset\right\} \in \mathscr{F} \tag{78.3.24}
\end{equation*}
$$

A sufficient condition for this condition is that $\omega \rightarrow A(u(\cdot, \omega), \omega)$ has a measurable selection into $\mathscr{V}^{\prime}$ for any $\omega \rightarrow u(\cdot, \omega)$ measurable into $\mathscr{V}$ and if $u^{*} \in A(u(\cdot, \omega), \omega)$, then $\mathscr{X}_{I} u^{*} \in A\left(\mathscr{X}_{I} u(\cdot, \omega), \omega\right)$, and this is typical of what we will always consider, in which the values of $u^{*}$ are dependent on the earlier values of $u$ only.

Let $F$ be the duality map for $r>\max (\hat{p}, 2)$. Thus

$$
\langle F u, u\rangle=\|u\|^{r}, \quad\|F u\|=\|u\|^{r-1}
$$

and is a demicontinuous map. Let $X$ be those $u \in \mathscr{U}_{r}$ such that $(B u)^{\prime} \in \mathscr{U}_{r}^{\prime}$ with a convenient norm given by $\max \left(\|u\|_{\mathscr{U}_{r}},\left\|(B u)^{\prime}\right\|_{\mathscr{U}_{r}^{\prime}}\right)$. Then if we let $\mathscr{U}_{r I}$ play the role of $\mathscr{V}_{I}$ in Theorem 78.2.2, we obtain the following lemma as a corollary of this theorem.

Lemma 78.3.1 Let A satisfy 78.3-78.3 and let $f$ be measurable into $\mathscr{V}^{\prime}$ and let $u_{0}$ be measurable into $W$. Then for $\varepsilon>0$, there exists a solution to

$$
\begin{equation*}
L u+\varepsilon F u+u^{*}=f, B u(0, \omega)=B u_{0}(\omega) \tag{78.3.25}
\end{equation*}
$$

such that $L u, u^{*}, u$ are all measurable into $\mathscr{U}_{r}^{\prime}, \mathscr{U}_{r}^{\prime}$, and $\mathscr{U}_{r}$ respectively, $u^{*}(\omega) \in A(u, \omega)$. In other terms, for $v \in X=\left\{u \in \mathscr{U}_{r}: L u \in \mathscr{U}_{r}^{\prime}\right\}$

$$
\begin{gather*}
\int_{0}^{T}\langle L u, v\rangle+\varepsilon \int_{0}^{T}\langle F u, v\rangle+\int_{0}^{T}\left\langle u^{*}, v\right\rangle+ \\
\langle B u, v\rangle(0)=\int_{0}^{T}\langle f, v\rangle+\left\langle B v(0), u_{0}\right\rangle \tag{78.3.26}
\end{gather*}
$$

Proof: Using easy estimates and the definition that $r>\max (\hat{p}, 2), \hat{p} \geq p$, (Recall that $\hat{p}$ determined the polynomial growth of $\left\|u^{*}\right\|_{\mathscr{V}^{\prime}}$ where $\left.u^{*} \in A(u, \omega)\right)$ it is routine to show that the earlier coercivity condition holds for $\varepsilon F+A(\cdot, \omega)$. Indeed, we have the following from the above assumptions.

$$
\begin{gathered}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d s: u^{*} \in A(u, \omega)\right) \\
\geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega)
\end{gathered}
$$

Thus,

$$
\begin{gathered}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle: u^{*} \in A(u, \omega)\right) \geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s \\
-C_{B} \lambda(\omega) \int_{0}^{t} \eta\left(\frac{1}{\eta}\right)\|u\|_{V}^{2}-m(\omega)
\end{gathered}
$$

Then the right side is no smaller than

$$
\begin{aligned}
& -C_{B} \lambda(\omega) \int_{0}^{t}\left(\frac{1}{\eta}\right) \eta\|u\|_{V}^{2}-m(\omega) \\
\geq & -C_{B,} \lambda(\omega) \eta^{r / 2} \int_{0}^{t}\|u\|_{U}^{r}-C_{B} \lambda(\omega) T\left(\frac{1}{\eta}\right)^{r /(r-2)}-m(\omega)
\end{aligned}
$$

Then picking $\eta$ small enough, we obtain $C_{B} \lambda(\omega) \eta^{r / 2}<\varepsilon / 2$.
Both operators $\varepsilon F$ and $A(\cdot, \omega)$ are pseudomonotone as maps from $X$ to $\mathscr{P}\left(X^{\prime}\right)$ where $X$ is defined in terms of $\mathscr{U}_{r I}$ as before. Therefore, the existence of the measurable solution is obtained.

Denoting with $u_{\varepsilon}$ the above solution, suppose $L u_{\varepsilon} \rightarrow L u$ weakly in $\mathscr{U}_{r}^{\prime}$ with $L u=$ $(B u)^{\prime} \in \mathscr{V}^{\prime}$ and $u_{\varepsilon} \rightarrow u$ weakly in $\mathscr{V}$ and $u_{\varepsilon}^{*} \rightarrow u^{*}$ in $\mathscr{V}^{\prime}, \varepsilon F u_{\varepsilon} \rightarrow 0$ strongly in $\mathscr{U}_{r}^{\prime}$. Thus, passing to the limit in 78.3 .25 we obtain $L u \in \mathscr{V}^{\prime}$ because it equals something in $\mathscr{V}^{\prime}$. We will show this below by an argument that $\varepsilon F u_{\varepsilon} \rightarrow 0$ strongly in $\mathscr{U}_{r}^{\prime}$.

Written differently, the $u_{\varepsilon}$ satisfy the following for all $v \in X$.

$$
\begin{gather*}
\int_{0}^{T}\left\langle L u_{\mathcal{\varepsilon}}, v\right\rangle+\left\langle B u_{\varepsilon}, v\right\rangle(0)+\int_{0}^{T}\left\langle u_{\varepsilon}^{*}, v\right\rangle \\
+\varepsilon \int_{0}^{T}\left\langle F u_{\mathcal{\varepsilon}}, u_{\varepsilon}\right\rangle=\int_{0}^{T}\langle f, v\rangle+\left\langle B v(0), u_{0}\right\rangle \tag{78.3.27}
\end{gather*}
$$

and

$$
B u_{\varepsilon}(t)=B u_{0}+\int_{0}^{t} L u_{\varepsilon}(s) d s
$$

The weak convergence of $L u_{\varepsilon}$ implies that $B u_{\varepsilon}(t) \rightarrow B u(t)$ in $U^{\prime}$. Thus

$$
B u(t)=B u_{0}+\int_{0}^{t} L u(s) d s
$$

and so $B u(0)=B u_{0}$. We will show that there exist suitable subsequences such that the kind of convergence just described will hold.

Using the equation to act on $u$ in 78.3 .25 or in 78.3 .27 , we obtain from the assumed coercivity condition the following for fixed $\omega$,

$$
\begin{align*}
& \frac{1}{2}\langle B u, u\rangle(t)-\frac{1}{2}\langle B u, u\rangle(0)+\varepsilon \int_{0}^{t}\|u\|_{U}^{r} d s+\delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \\
\leq & \lambda(\omega) \int_{0}^{t}\langle B u, u\rangle(s) d s+\int_{0}^{t}\langle f, u\rangle(s) d s \tag{78.3.28}
\end{align*}
$$

From Gronwall's inequality, one obtains an estimate of the form

$$
\langle B u, u\rangle(t)+\varepsilon \int_{0}^{T}\|u\|_{U}^{r} d s+\int_{0}^{T}\|u\|_{V}^{p} d s \leq C(f, \omega)
$$

where the constant depends only on the indicated quantities. It follows from this and the definition of the duality map $F$ that if $u_{\varepsilon}$ is the solution to Lemma 78.3.1, then $\varepsilon F u_{\varepsilon} \rightarrow 0$ strongly in $\mathscr{U}_{r}^{\prime}$. Also, the estimates for $A$ and the above estimate implies that $L u_{\varepsilon}$ is bounded in $\mathscr{U}_{r}^{\prime}$. Thus we have an inequality of the form

$$
\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(t)+\varepsilon \int_{0}^{T}\left\|u_{\mathcal{E}}\right\|_{U}^{r} d s+\left\|u_{\mathcal{E}}\right\|_{\mathscr{V}}^{p}+\left\|L u_{\mathcal{E}}\right\|_{\mathscr{U}_{r}^{\prime}}+\left\|u_{\mathcal{\varepsilon}}^{*}\right\|_{\mathscr{V}^{\prime}} \leq C(f, \omega)
$$

Of course each of these $u_{\mathcal{\varepsilon}}, u_{\varepsilon}^{*}$ are measurable into $\mathscr{V}$ and $\mathscr{U}^{\prime}$ respectively. By density considerations, $u_{\varepsilon}^{*}$ is also measurable into $\mathscr{V}^{\prime}$. It follows from Theorem 78.1.3 that there
exists $\left(u, u^{*}\right)$ which is measurable into $\mathscr{V} \times \mathscr{V}^{\prime}$ and a sequence with $\varepsilon(\omega)$ such that as $\varepsilon(\omega) \rightarrow 0,\left(u_{\varepsilon(\omega)}(\omega), u_{\varepsilon(\omega)}^{*}(\omega)\right) \rightarrow\left(u(\omega), u^{*}(\omega)\right)$ in $\mathscr{V} \times \mathscr{V}^{\prime}$. Then, taking a further subsequence, we can obtain the following convergences for fixed $\omega$.

$$
\begin{aligned}
u_{\varepsilon(\omega)}(\omega) & \rightarrow u(\omega) \text { weakly in } \mathscr{V} \\
u_{\varepsilon(\omega)}^{*}(\omega) & \rightarrow u^{*}(\omega) \text { weakly in } \mathscr{V}^{\prime} \\
L u_{\varepsilon(\omega)} & \rightarrow L u \text { weakly in } \mathscr{U}_{r}^{\prime}
\end{aligned}
$$

These convergences continue to hold for $\mathscr{V}$ and $\mathscr{U}_{r}^{\prime}$ replaced with $\mathscr{V}_{I}$ and $\mathscr{U}_{r I}^{\prime}$ and we simply consider the restrictions of the functions to $I$. The problem here is that we do not know that $u$ is in $\mathscr{U}_{r}$. This is why it is necessary to take a little different approach.

Letting $\sigma>0$, there exists $\hat{T}(\omega)>T-\sigma$ such that for each $\varepsilon(\omega)$ in that sequence,

$$
\left\langle B u_{\varepsilon(\omega)}, u_{\varepsilon(\omega)}\right\rangle(\hat{T})=\left\langle B\left(u_{\varepsilon(\omega)}(\hat{T})\right), u_{\varepsilon(\omega)}(\hat{T})\right\rangle, B u_{\varepsilon}(\hat{T})=B\left(u_{\varepsilon}(\hat{T})\right)
$$

for all $\varepsilon(\omega)$ in the sequence converging to 0 and also

$$
B u(\hat{T})=B(u(\hat{T})),\langle B u, u\rangle(\hat{T})=\langle B(u(\hat{T})), u(\hat{T})\rangle
$$

Now let $\left\{e_{i}\right\}$ be the vectors of Theorem 78.1.6 where these are in $U$. Thus for $\hat{T}$,

$$
\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(\hat{T})=\left\langle B u_{\varepsilon}(\hat{T}), u_{\varepsilon}(\hat{T})\right\rangle=\sum_{i=1}^{\infty}\left\langle B\left(u_{\varepsilon}(\hat{T})\right), e_{i}\right\rangle^{2}
$$

Hence, by Fatou's lemma,

$$
\begin{align*}
\liminf _{\varepsilon \rightarrow 0}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(\hat{T}) & =\lim \inf _{\varepsilon \rightarrow 0} \sum_{i=1}^{\infty}\left\langle B\left(u_{\varepsilon}(\hat{T})\right), e_{i}\right\rangle^{2} \\
& \geq \sum_{i=1}^{\infty} \liminf _{\varepsilon \rightarrow 0}\left\langle B\left(u_{\varepsilon}(\hat{T})\right), e_{i}\right\rangle^{2} \\
& =\sum_{i=1}^{\infty} \liminf _{\varepsilon \rightarrow 0}\left\langle B u_{\varepsilon}(\hat{T}), e_{i}\right\rangle^{2} \\
& =\sum_{i=1}^{\infty}\left\langle B u(\hat{T}), e_{i}\right\rangle^{2} \\
& =\langle B(u(\hat{T})), u(\hat{T})\rangle=\langle B u, u\rangle(\hat{T}) \tag{78.3.29}
\end{align*}
$$

Then by 78.3.25, we can obtain

$$
\begin{gather*}
\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(\hat{T})-\frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(0)+ \\
\int_{0}^{\hat{T}} \varepsilon\left\langle F u_{\varepsilon}, u_{\varepsilon}\right\rangle d t+\int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle=\int_{0}^{\hat{T}}\left\langle f, u_{\varepsilon}\right\rangle \tag{78.3.30}
\end{gather*}
$$

From what was shown above, $\left\langle B u_{\varepsilon}, u_{\mathcal{E}}\right\rangle(0)=\left\langle B u_{0}, u_{0}\right\rangle$. Now passing to the limit as $\varepsilon \rightarrow 0$,

$$
L u+u^{*}=f
$$

in $\mathscr{U}_{r}^{\prime}$. But every term is in $\mathscr{V}^{\prime}$ except the first and so it is also in $\mathscr{V}^{\prime}$. Also, we know that $\left\langle B u_{\mathcal{E}}, u_{\varepsilon}\right\rangle(0)=\left\langle B u_{0}, u_{0}\right\rangle$ and by Theorem 78.1.8, $\langle B u, u\rangle(0)=\left\langle B u_{0}, u_{0}\right\rangle$ also. Then the integration by parts formula yields

$$
\frac{1}{2}\langle B u, u\rangle(\hat{T})-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{\hat{T}}\left\langle u^{*}, u\right\rangle d t=\int_{0}^{\hat{T}}\langle f, u\rangle d t
$$

which shows

$$
\int_{0}^{\hat{T}}\left\langle u^{*}, u\right\rangle d t=\int_{0}^{\hat{T}}\langle f, u\rangle d t-\frac{1}{2}\langle B u, u\rangle(\hat{T})+\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle
$$

Then from 78.3.30 and the lower semicontinuity shown in 78.3.29, it follows that

$$
\begin{aligned}
\limsup _{\varepsilon \rightarrow 0} \int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle & \leq \int_{0}^{\hat{T}}\langle f, u\rangle d t+\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle-\lim _{\varepsilon \rightarrow 0} \inf _{2} \frac{1}{2}\left\langle B u_{\varepsilon}, u_{\varepsilon}\right\rangle(\hat{T}) \\
& \leq \int_{0}^{\hat{T}}\langle f, u\rangle d t+\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle-\frac{1}{2}\langle B u, u\rangle(\hat{T})=\int_{0}^{\hat{T}}\left\langle u^{*}, u\right\rangle d t
\end{aligned}
$$

Thus we have $u_{\varepsilon} \rightarrow u$ weakly in $\mathscr{V}_{I}$ and $\left(B u_{\varepsilon}\right)^{\prime} \rightarrow(B u)^{\prime}$ weakly in $\mathscr{U}_{r I}^{\prime}$,

$$
\lim \sup _{\varepsilon \rightarrow 0} \int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq \int_{0}^{\hat{T}}\left\langle u^{*}, u\right\rangle-\int_{0}^{\hat{T}}\left\langle u^{*}, u\right\rangle=0
$$

Therefore, by the limit condition 78.3, for any $v \in \mathscr{V}$

$$
\lim _{\varepsilon \rightarrow 0} \inf _{0} \int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-v\right\rangle \geq \int_{0}^{\hat{T}}\left\langle u^{*}(v), u-v\right\rangle, \text { some } u^{*}(v) \in A(u, \omega)
$$

In particular, this holds for $u$ and so, in fact, $\int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle$ converges to 0 . Therefore,

$$
\begin{aligned}
\int_{0}^{\hat{T}}\left\langle u^{*}, u-v\right\rangle & =\lim _{\varepsilon \rightarrow 0} \int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u-v\right\rangle \\
& \geq \lim _{\varepsilon \rightarrow 0} \inf _{\varepsilon \rightarrow 0}\left(\int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u-u_{\varepsilon}\right\rangle+\int_{0}^{\hat{T}}\left\langle u_{\varepsilon}^{*}, u_{\varepsilon}-v\right\rangle\right) \\
& \geq \int_{0}^{\hat{T}}\left\langle u^{*}(v), u-v\right\rangle, \text { some } u^{*}(v) \in A(u, \omega)
\end{aligned}
$$

since $v$ is arbitrary, this shows from separation theorems that $u^{*}(\omega) \in A(u(\omega), \omega)$ in $\mathscr{V}_{[0, \hat{T}]}^{\prime}$.
This has proved the following theorem in which a more general coercivity condition is used.

Theorem 78.3.2 Suppose the conditions on A,78.3-78.3. Also let $u_{0}$ be measurable into $W$ and $f$ measurable into $\mathscr{V}^{\prime}$. Let $B \in \mathscr{L}\left(W, W^{\prime}\right)$ be nonnegative and self adjoint as described above. Let $\sigma>0$ be small. Then there exist functions $u, u^{*}$ measurable into $\mathscr{V}_{[0, T-\sigma]} \times \mathscr{V}_{[0, T-\sigma]}^{\prime}$ such that $u^{*}(\omega) \in A\left(\mathscr{X}_{[0, T-\sigma]} u(\omega), \omega\right)$ for each $\omega$ and for $t \leq T-\sigma$, for each $\omega$,

$$
B u(t)-B u_{0}+\int_{0}^{t} u^{*}(s) d s=\int_{0}^{t} f(s) d s
$$

Note that if for a given $\omega$ there is a unique solution to the evolution equation, then we can obtain the solution on $(0, T)$. However, $\sigma$ was totally arbitrary so it seems like there is not much difference between the above and the obtimum solution. However, one could also index the above solutions relative to $\sigma$, take an appropriate extension of each on $(T-\sigma, T)$ and get similar estimates and pass to a limit as above as $\sigma \rightarrow 0$ and thereby obtain a measurable solution valid on $(0, T)$. This time, it will be clear that $L u, L u_{\sigma}$ are both in $\mathscr{V}^{\prime}$ so a monotonicity condition will hold for $L$ without the delicate argument given above which caused a smaller interval to be considered. Thus the following corollary will hold if enough additional details are considered. The issue does not seem sufficiently significant to justify the consideration of these details.

Corollary 78.3.3 In the situation of Theorem 78.3.2 there exists the same kind of measurable solution valid on $(0, T)$. This time, $u^{*}, u$ are measurable into $\mathscr{V}$ and $\mathscr{V}^{\prime}$ respectively.

One can give a very interesting generalization of Theorem 78.3.2.
Theorem 78.3.4 In the context of Theorem 78.3.2, let $q(t, \omega)$ be a product measurable function into $V$ such that $t \rightarrow q(t, \omega)$ is continuous, $q(0, \omega)=0$.

Then for each small $\sigma$, there exists a solution $u$ of the integral equation

$$
B u(t, \omega)+\int_{0}^{t} u^{*}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)+B q(t, \omega), t \leq T-\sigma
$$

where $(t, \omega) \rightarrow u(t, \omega)$ is product measurable. Moreover, for each $\omega, B u(t, \omega)=B(u(t, \omega))$ for a.e. $t$ and $u^{*}(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$ for a.e. $t, u^{*}$ is product measurable into $V^{\prime}$. Also, for each $a \in[0, T-\sigma]$,

$$
B u(t, \omega)+\int_{a}^{t} u^{*}(s, \omega) d s=\int_{a}^{t} f(s, \omega) d s+B u(a, \omega)+B q(t, \omega)-B q(a, \omega)
$$

Proof: Define a stopping time

$$
\tau_{r}(\omega) \equiv \inf \{t:|q(t, \omega)|>r\}
$$

Then this is the first hitting time of an open set by a continuous random variable and so it is a valid stopping time. Then for each $r$, let

$$
A_{r}(\omega, w) \equiv A\left(\omega, w+q^{\tau_{r}}(\cdot, \omega)\right)
$$

where the notation means $q^{\tau_{r}}(t) \equiv q\left(t \wedge \tau_{r}\right)$. Then, since $q^{\tau_{r}}$ is uniformly bounded, all of the necessary estimates and measurability for the solution to the above corollary hold for $A_{r}$ replacing $A$. Therefore, there exists a solution $w_{r}$ to the inclusion

$$
\left(B w_{r}\right)^{\prime}(\cdot, \omega)+A_{r}\left(w_{r}(\cdot, \omega), \omega\right) \ni f(\cdot, \omega), B w_{r}(0, \omega)=B u_{0}(\omega), t \in[0, T-\sigma / 2]
$$

Now for fixed $\omega, q^{\tau_{r}}(t, \omega)$ does not change for all $r$ large enough. This is because it is a continuous function of $t$ and so is bounded on the interval [ $0, T-\sigma / 2]$. Thus, for $r$ large enough and fixed $\omega, q^{\tau_{r}}(t, \omega)=q(t, \omega)$. Thus, we obtain

$$
\begin{equation*}
\left\langle B w_{r}(t, \omega), w_{r}(t, \omega)\right\rangle+\int_{0}^{t}\left\|w_{r}(s, \omega)\right\|_{V}^{p} d s \leq C(\omega) \tag{78.3.31}
\end{equation*}
$$

Now, as before in the proof of Theorem 78.3.2 one can pass to a limit involving a subsequence, as $r(\omega) \rightarrow \infty$ and obtain a solution to the integral equation

$$
B w(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} u^{*}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s, t \in[0, T-\sigma]
$$

where $u^{*}(\omega) \in A(w(s, \omega)+q(s, \omega), \omega)$ and $u^{*}, w$ are measurable into $\mathscr{V}_{[0, T-\sigma]}^{\prime}$. Now let $u(t, \omega)=w(t, \omega)+q(t, \omega)$.

The last claim follows from letting $t=a$ in the top equation and then subtracting this from the top equation with $t>a$.

### 78.4 Progressively Measurable Solutions

In the context of uniqueness of the evolution initial value problem for fixed $\omega$, one can prove theorems about progressively measurable solutions fairly easily.

First is a definition of the term progressively measurable.
Definition 78.4.1 Let $\mathscr{F}_{t}$ be an increasing in $t$ set of $\sigma$ algebras of sets of $\Omega$ where $(\Omega, \mathscr{F})$ is a measurable space. Thus each $\mathscr{F}_{t}$ is a $\sigma$ algebra and if $s \leq t$, then $\mathscr{F}_{s} \leq \mathscr{F}_{t}$. This set of $\sigma$ algebras is called a filtration. A set $S \subseteq[0, T] \times \Omega$ is called progressively measurable if for every $t \in[0, T]$,

$$
S \cap[0, t] \times \Omega \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}
$$

Denote by $\mathscr{P}$ the progressively measurable sets. This is a $\sigma$ algebra of subsets of $[0, T] \times \Omega$. A function $g$ is progressively measurable if $\mathscr{X}_{[0, t]} g$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable for each $t$.

Let $A$ satisfy the conditions 78.3-78.3 but the last condition will be modified as follows.

Condition 78.4.2 For each $t \leq T$, if $\omega \rightarrow u(\cdot, \omega)$ is $\mathscr{F}_{t}$ measurable into $\mathscr{V}_{[0, t]}$, then there exists a $\mathscr{F}_{t}$ measurable selection of $A\left(\mathscr{X}_{[0, t]} u(\cdot, \omega), \omega\right)$ into $\mathscr{V}_{[0, t]}^{\prime}$.

Note that $u(\cdot, \omega)$ is in $\mathscr{V}_{[0, t]}$ so $u(t, \omega) \in V$.
The theorem to be shown is the following.

Theorem 78.4.3 Assume the above conditions, 78.3-78.3, and 78.4.2. Let $u_{0}$ be $\mathscr{F}_{0}$ measurable and $(t, \omega) \rightarrow \mathscr{X}_{[0, t]}(t) f(t, \omega)$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ product measurable into $V^{\prime}$ for each $t$. Also assume that for each $\omega$, there is at most one solution $\left(u, u^{*}\right)$ to the evolution equation

$$
\begin{align*}
B u(\omega)(t)-B u_{0}(\omega)+\int_{0}^{t} u^{*}(\cdot, \omega) d s & =\int_{0}^{t} f(s, \omega) d s  \tag{78.4.32}\\
u^{*}(\cdot, \omega) & \in A(u(\cdot, \omega), \omega)
\end{align*}
$$

for $t \in[0, T]$. Then there exists a unique solution $\left(u(\cdot, \omega), u^{*}(\cdot, \omega)\right)$ in $\mathscr{V}_{[0, T]} \times \mathscr{V}_{[0, T]}^{\prime}$ to the above integral equation for each $\omega, t \in(0, T)$. This solution satisfies

$$
(t, \omega) \rightarrow\left(u(t, \omega), u^{*}(t, \omega)\right)
$$

is progressively measurable into $V \times V^{\prime}$.
Proof: First note that Theorem 78.3.2 there exists a solution on $[0, T-\sigma]$ for each small $\sigma>0$. Then by uniqueness, there exists a solution on $(0, T)$. Let $\mathscr{T}$ denote subsets of $(0, T-\sigma]$ which contain $T-\sigma$ such that for $S \in \mathscr{T}$, there exists a solution $u_{S}$ for each $\omega$ to the above integral equation on $[0, T-\sigma]$ such that $(t, \omega) \rightarrow \mathscr{X}_{[0, s]}(t) u_{S}(t, \omega)$ is $\mathscr{B}([0, s]) \times$ $\mathscr{F}_{s}$ measurable for each $s \in S$. Then $\{T-\sigma\} \in \mathscr{T}$. If $S, S^{\prime}$ are in $\mathscr{T}$, then $S \leq S^{\prime}$ will mean that $S \subseteq S^{\prime}$ and also $u_{S}(t, \omega)=u_{S^{\prime}}(t, \omega)$ in $V$ for all $t \in S$, similar for $u_{S}^{*}$ and $u_{S^{\prime}}^{*}$. Note how we are considering a particular representative of a function in $\mathscr{V}_{[0, T-\sigma]}$ and $\mathscr{V}_{[0, T-\sigma]}^{\prime}$ because of the pointwise condition. Now let $\mathscr{C}$ denote a maximal chain. Is $\cup \mathscr{C} \equiv S_{\infty}$ all of $(0, T-\sigma]$ ? What is $u_{S_{\infty}}$ ? Define $u_{S_{\infty}}(t, \omega)$ the common value of $u_{S}(t, \omega)$ for all $S$ in $\mathscr{C}$, which contain $t \in S_{\infty}$. If $s \in S_{\infty}$, then it is in some $S \in \mathscr{C}$ and so the product measurability condition holds for this $s$. Thus $S_{\infty}$ is a maximal element of the partially ordered set. Is $S_{\infty}$ all of $(0, T-\sigma]$ ? Suppose $\hat{s} \notin S_{\infty}, T-\sigma>\hat{s}>0$.

From Theorem 78.3.2 there exists a solution to the integral equation 78.4.32 on $[0, \hat{s}]$ called $u_{1}$ such that $(t, \omega) \rightarrow u_{1}(t, \omega)$ is $\mathscr{B}([0, \hat{s}]) \times \mathscr{F}_{\hat{s}}$ measurable, similar for $u_{1}^{*}$. By the same theorem, there is a solution on $[0, T-\sigma], u_{2}$ which is $\mathscr{B}([0, T-\sigma]) \times \mathscr{F}_{[0, T-\sigma]}$ measurable. Now by uniqueness, $u_{2}(\cdot, \omega)=u_{1}(\cdot, \omega)$ in $\mathscr{V}_{[0, \hat{s}]}$, similar for $u_{i}^{*}$. Therefore, no harm is done in re-defining $u_{2}, u_{2}^{*}$ on $[0, \hat{s}]$ so that $u_{2}(t, \omega)=u_{1}(t, \omega)$, for all $t \in[0, \hat{s}]$, similar for $u^{*}$. Denote these functions as $\hat{u}, \hat{u}^{*}$. By uniqueness, $u_{S_{\infty}}(\cdot, \omega)=\hat{u}(\cdot, \omega)$ in $L^{p}([0, \hat{s}], V)$. Thus no harm is done by re-defining $\hat{u}(s, \omega)$ to equal $u_{S_{\infty}}(s, \omega)$ for $s<\hat{s}$ and $u_{1}(\hat{s}, \omega)$ at $\hat{s}$. As to $s>\hat{s}$ also re define $\hat{u}(s, \omega) \equiv u_{S_{\infty}}(s, \omega)$ for such $s$. By uniqueness, the two are equal in $\mathscr{V}_{[\hat{s}, T-\sigma]}$ and so no change occurs in the solution of the integral equation. Now $S_{\infty}$ was not maximal after all. $S_{\infty} \cup\{\hat{s}\}$ is larger. This contradiction shows that in fact, $S_{\infty}=(0, T-\sigma]$. Thus there exists a unique progressively measurable solution to 78.4.32 on $[0, T-\sigma]$ for each small $\sigma$. Thus we can simply use uniqueness to conclude the existence of a unique progressively measurable solution on $[0, T)$.
Theorem 78.4.4 Assume the above conditions, 78.3-78.3, and 78.4.2. Let $u_{0}$ be $\mathscr{F}_{0}$ measurable and $(t, \omega) \rightarrow \mathscr{X}_{[0, t]}(t) f(t, \omega)$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ product measurable into $V^{\prime}$ for each $t \in[0, T-\sigma]$. Also let $t \rightarrow q(t, \omega)$ be continuous and $q$ is progressively measurable into $V$. Suppose there is at most one solution to

$$
\begin{equation*}
B u(t, \omega)+\int_{0}^{t} u^{*}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)+B q(t, \omega) \tag{78.4.33}
\end{equation*}
$$

for each $\omega$. Then the solution $u$ to the above integral equation is progressively measurable and so is $u^{*}$. Moreover, for each $\omega, u^{*}(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$. Also, for each $a \in[0, T]$,

$$
B u(\omega)(t)+\int_{a}^{t} u^{*}(s, \omega) d s=\int_{a}^{t} f(s, \omega) d s+B u(\omega)(a)+B q(t, \omega)-B q(a, \omega)
$$

Proof: By Theorem 78.3.4 there exists a solution to 78.4 .33 which is $\mathscr{B}([0, T-\sigma]) \times$ $\mathscr{F}_{T-\sigma}$ measurable. Since this is true for all $\sigma>0$, there exists a unique $\mathscr{B}([0, \hat{T}]) \times \mathscr{F}_{\hat{T}}$ measurable solution for each $\hat{T}<T$. Now, as in the proof of Theorem 78.3.4 one can define a new operator

$$
A_{r}(w, \omega) \equiv A\left(\omega, w+q^{\tau_{r}}(\cdot, \omega)\right)
$$

where $\tau_{r}$ is the stopping time defined there. Then, since $q$ is progressively measurable, the progressively measurable condition is satisfied for this new operator. Hence by Theorem 78.4.3 there exists a unique solution $w$ which is progressively measurable to the integral equation

$$
B w_{r}(t, \omega)+\int_{0}^{t} u_{r}^{*}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)
$$

where $u_{r}^{*}(\cdot, \omega) \in A_{r}(w(\cdot, \omega), \omega)$. Then you can let $r \rightarrow \infty$ and eventually $q^{\tau_{r}}(\cdot, \omega)=$ $q(\cdot, \omega)$. Thus there is a solution to

$$
\begin{aligned}
B w(t, \omega)+\int_{0}^{t} u^{*}(s, \omega) d s & =\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega) \\
u^{*}(\cdot, \omega) & \in A(w(\cdot, \omega)+B q(\cdot, \omega), \omega)
\end{aligned}
$$

which is progressively measurable because $w(\cdot, \omega)=\lim _{r \rightarrow \infty} w_{r}(\cdot, \omega)$ in $\mathscr{V}$ each $w_{r}$ being progressively measurable. Uniqueness is needed in passing to the limit. Thus for each $\hat{T}<T, \omega \rightarrow w(\cdot, \omega)$ is measurable into $\mathscr{V}_{[0, \hat{T}]}$. Then by Lemma 78.1.5, $w$ has a representative in $\mathscr{V}_{[0, \hat{T}]}$ for each $\omega$ such that the resulting function satisfies $(t, \omega) \rightarrow \mathscr{X}_{[0, \hat{T}]}(t) w(t, \omega)$ is $\mathscr{B}([0, \hat{T}]) \times \mathscr{F}_{\hat{T}}$ measurable into $V$. Thus one can assume that $w$ is progressively measurable. Now as in Theorem 78.3.4, Define $u=w+q$. It follows by uniqueness that there exists a unique progressively measurable solution to 78.4 .33 on $(0, T)$.

The last claim follows from letting $t=a$ in the top equation and then subtracting this from the top equation with $t>a$.

## Chapter 79

## Including Stochastic Integrals

### 79.1 The Case of Uniqueness

You can include stochastic integrals in the above formulation. In this section and from now on, we will assume that $W$ is a Hilbert space because the stochastic integrals featured here will have values in $W$ and the version of the stochastic integral to be considered here will be the Ito integral. Here is a brief review of this integral.

Let $U$ be a separable real Hilbert space and let $Q: U \rightarrow U$ be self adjoint and nonnegative. Also $H$ will be a separable real Hilbert space. $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ will denote the Hilbert Schmidt operators which map $Q^{1 / 2} U$ to $H$. Here $Q^{1 / 2} U$ is the Hilbert space which has an inner product given by

$$
(y, z) \equiv\left(Q^{-1 / 2} y, Q^{-1 / 2} z\right)
$$

where $Q^{-1 / 2} y$ denotes $x$ such that $Q^{1 / 2} x=y$ and out of all such $x$, this is the one which has the smallest norm. It is like the Moore Penrose inverse in linear algebra. Then one can define a stochastic integral

$$
\int_{0}^{t} \Phi d W
$$

where $\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ where here $\Phi$ is progressively measurable with respect to the filtration $\mathscr{F}_{t}$. This filtration will be

$$
\mathscr{F}_{t}=\overline{\cap_{p>t} \sigma(W(r)-W(s): 0 \leq s \leq r \leq p)}
$$

The horizontal line indicates completion. The symbol

$$
\sigma(W(r)-W(s): 0 \leq s \leq r \leq p)
$$

indicates the smallest $\sigma$ algebra for which all those increments are measurable. Here $W(t)$ is a Wiener process which has values in $U_{1}$, some other Hilbert space, maybe $H$. There is a Hilbert Schmidt operator $J \in \mathscr{L}_{2}\left(Q^{1 / 2} U, U_{1}\right)$ such that $W(t)=\sum_{i=1}^{\infty} \psi_{i}(t) J e_{i}$ where here the $\psi_{i}$ are independent real Wiener processes. You could take $U, U_{1}$ to both be $H$. This is following [108]. Then the stochastic integral has the following properties.

1. $\int_{0}^{t} \Phi d W$ is a martingale with respect to $\mathscr{F}_{t}$ with values in $H$, equal to 0 when $t=0$.
2. One has the Ito isometry

$$
E\left(\left\|\int_{0}^{t} \Phi d W\right\|_{H}^{2}\right)=\int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s
$$

3. One can localize as follows. For $\tau$ a stopping time,

$$
\int_{0}^{t \wedge \tau} \Phi d W=\int_{0}^{t} \mathscr{X}_{[0, \tau]} \Phi d W
$$

4. One can also generalize to the case where $\Phi$ is only progressively measurable and instead of being in $L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$, you have only that

$$
P\left(\int_{0}^{T}\|\Phi(t)\|_{\mathscr{L}_{2}}^{2} d t<\infty\right)=1
$$

This is done by using an appropriate sequence of stopping times called a localizing sequence. More generally a local martingale is a stochastic process $M(t)$ adapted to the filtration for which there is a locallizing sequence of stopping times $\left\{\tau_{n}\right\}$ such that $\lim _{n \rightarrow \infty} \tau_{n}=\infty$ and $M^{\tau_{n}}$ is a martingale. Local martingales will occur in the estimates which are encountered in what follows.
5. Denoting by $M(t)$ the stochastic integral, $M(t)=\int_{0}^{t} \Phi d W$, the quadratic variation is given by

$$
[M](t)=\int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s
$$

6. We will also need a part of the Burkholder Davis Gundy inequality [77], Theorem 63.4.4 which in terms of this stochastic integral is of the form

$$
\int_{\Omega} M^{*} d P \leq C E\left(\left(\int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s\right)^{1 / 2}\right), C \text { some constant }
$$

where $M(t)$ is the above stochastic integral and

$$
M^{*} \equiv \sup \left\{\|M(t)\|_{H}: t \in[0, T]\right\}
$$

Now let $\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)$. Let an orthonormal basis for $Q^{1 / 2} U$ be $\left\{g_{i}\right\}$ and an orthonormal basis for $W$ be $\left\{f_{i}\right\}$. Then $\left\{f_{i} \otimes g_{i}\right\}$ is an orthonormal basis for $\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)$. Hence,

$$
\Phi=\sum_{i} \sum_{j} \Phi_{i j} f_{i} \otimes g_{j}
$$

where $f_{i} \otimes g_{j}(y) \equiv\left(g_{j}, y\right)_{Q^{1 / 2} U} f_{i}$. Let $E$ be a separable real Hilbert space which is dense in $V$. Then without loss of generality, one can assume that the orthonormal basis for $W$ are all vectors in $E$. Thus the orthogonal projection of $\Phi$ onto the closed subspace

$$
\operatorname{span}\left(\left\{f_{i} \otimes g_{i}\right\}, i, j \leq n\right)
$$

given by

$$
\Phi_{n} \equiv \sum_{i=1}^{n} \sum_{j=1}^{n} \Phi_{i j} f_{i} \otimes g_{j}
$$

Then $\Phi_{n} \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, E\right)\right)$ and also

$$
\lim _{n \rightarrow \infty}\left\|\Phi_{n}-\Phi\right\|_{L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)}=0
$$

and $\int_{0}^{t} \Phi_{n} d W$ is continuous and progressively measurable into $E$ hence into $V$. We can take a subsequence such that $\left\|\Phi_{n}-\Phi\right\|_{L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)}<2^{-n}$ and this will be assumed whenever convenient.

Note that if $P_{n}$ is the orthogonal projection onto $\operatorname{span}\left(f_{1}, \cdots, f_{n}\right)$, then

$$
\begin{aligned}
\left|P_{n} \Phi(y)\right|_{W} & =\left|P_{n} \sum_{i} \sum_{j} \Phi_{i j} f_{i} \otimes g_{j}(y)\right|_{W} \\
& =\left|P_{n} \sum_{i} \sum_{j} \Phi_{i j} f_{i}\left(y, g_{j}\right)\right|_{W} \\
& =\left|\sum_{i=1}^{n} \sum_{j} \Phi_{i j} f_{i}\left(y, g_{j}\right)\right|_{W} \\
& \geq\left|\sum_{i=1}^{n} \sum_{j=1}^{n} \Phi_{i j} f_{i}\left(y, g_{j}\right)\right|_{W}=\left|\Phi_{n}(y)\right|_{W}
\end{aligned}
$$

Thus

$$
\left|\int_{s}^{t} \Phi_{n} d W\right|_{W} \leq\left|\int_{s}^{t} P_{n} \Phi d W\right|_{W}=\left|P_{n} \int_{s}^{t} \Phi d W\right|_{W} \leq\left|\int_{S}^{t} \Phi d W\right|_{W}
$$

The following corollary will be useful.
Corollary 79.1.1 Let $\Phi_{n}$ be as described above. Then

$$
\left\|\Phi_{n}(t, \omega)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \leq\|\Phi(t, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}
$$

where $\left\|\Phi_{n}(t, \omega)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \uparrow\|\Phi(t, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}$

$$
\Phi \in L^{\alpha}\left(\Omega ; L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right) \cap L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)
$$

where $\alpha>2$. Then off a set of measure zero, the stochastic integrals $\int_{0}^{t} \Phi_{n} d W$ satisfy

$$
\sup _{n} \sup _{t \neq s} \frac{\left\|\int_{s}^{t} \Phi_{n} d W\right\|}{|t-s|^{\gamma}}<C(\omega), \gamma<1 / 2, \gamma=\frac{(\alpha / 2)-1}{\alpha}
$$

Proof: Let, $\alpha>2$. As explained above, $\left|\int_{s}^{r} \Phi_{n} d W\right| \leq\left|\int_{s}^{r} \Phi d W\right|$. Thus by the Burkholder Davis Gundy inequality,

$$
\begin{aligned}
& \sup _{n}\left|\int_{s}^{r} \Phi_{n} d W\right| \leq\left|\int_{s}^{r} \Phi d W\right| \\
& \int_{\Omega}\left(\left|\int_{s}^{t} \Phi d W\right|\right)^{\alpha} d P \leq C \int_{\Omega}\left(\int_{S}^{t}\|\Phi\|^{2} d \tau\right)^{\alpha / 2} d P \\
& \leq C \int_{\Omega}\|\Phi\|_{L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)}^{\alpha}|t-s|^{\alpha / 2} \\
& \leq C\|\Phi\|_{L^{\alpha}\left(\Omega ; L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right)|t-s|^{\alpha / 2}}^{\alpha} \\
& \equiv C|t-s|^{\alpha / 2}
\end{aligned}
$$

Then by the Kolmogorov Čentsov theorem, for $\gamma$ as given,

$$
E\left(\sup _{0 \leq s<t \leq T} \sup _{n} \frac{\left|\int_{s}^{t} \Phi_{n} d W\right|}{(t-s)^{\gamma}}\right) \leq E\left(\sup _{0 \leq s<t \leq T} \frac{\left|\int_{s}^{t} \Phi d W\right|}{(t-s)^{\gamma}}\right) \leq C
$$

where $\gamma<\beta / \alpha$ where, $\beta+1=\alpha / 2$. Thus for $\gamma<\frac{(\alpha / 2)-1}{\alpha}$,

$$
\sup _{n} \sup _{0 \leq s<t \leq T} \frac{\left|\int_{s}^{t} \Phi_{n} d W\right|}{(t-s)^{\gamma}} \leq C(\omega)
$$

for all $\omega$ off a set of measure zero.
Recall the following conditions for the various operators.

## Bounded and coercive conditions

$A(\cdot, \omega) \cdot A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{V}_{I}^{\prime}$ for each $I$ a subinterval of $[0, T] I=[0, \hat{T}], \hat{T} \leq T$

$$
\begin{equation*}
A(\cdot, \omega): \mathscr{V}_{I} \rightarrow \mathscr{P}\left(\mathscr{V}_{I}^{\prime}\right) \text { is bounded, } \tag{79.1.1}
\end{equation*}
$$

If, for $u \in \mathscr{V}$,

$$
u^{*} \mathscr{X}_{[0, \hat{T}]} \in A\left(u \mathscr{X}_{[0, \hat{T}]}, \omega\right)
$$

for each $\hat{T}$ in an increasing sequence converging to $T$, then

$$
\begin{equation*}
u^{*} \in A(u, \omega) \tag{79.1.2}
\end{equation*}
$$

Assume the specific estimate

$$
\begin{equation*}
\sup \left\{\left\|u^{*}\right\|_{\mathscr{V}_{I}^{\prime}}: u^{*} \in A(u, \omega)\right\} \leq a(\omega)+b(\omega)\|u\|_{\mathscr{V}_{I}}^{p-1} \tag{79.1.3}
\end{equation*}
$$

where $a(\omega), b(\omega)$ are nonnegative. Note that here we use $p$ and not $\hat{p} \geq p$ as done earlier. It is likely that this could be generalized by introduction of a suitable regularizing duality map multiplied by $\varepsilon$ and letting $\varepsilon \rightarrow 0$. You would do everything here adding in $\varepsilon F$ where $F$ is the duality map $F: U \rightarrow U^{\prime}$ for $r$ where $r>\hat{p} \geq p$ and keep it in the definition of $A$. Here $U$ is a Hilbert space embedded compactly into $V$ and dense in $V$. Then you would let $\varepsilon \rightarrow 0$ and observe that $\varepsilon F u_{\varepsilon} \rightarrow 0$ in $\mathscr{U}_{r}^{\prime}$. Also assume the following coercivity estimate valid for each $t \leq T$ and for some $\lambda(\omega) \geq 0$,

$$
\begin{equation*}
\inf \left(\int_{0}^{t}\left\langle u^{*}, u\right\rangle+\lambda(\omega)\langle B u, u\rangle d t: u^{*} \in A(u, \omega)\right) \geq \delta(\omega) \int_{0}^{t}\|u\|_{V}^{p} d s-m(\omega) \tag{79.1.4}
\end{equation*}
$$

where $m(\omega)$ is some nonnegative constant, $\delta(\omega)>0$.

## Monotonicity

It will also be assumed that $\lambda(\omega) B+A$ is monotone in the sense that

$$
\int_{0}^{t}\left\langle\lambda(\omega) B u+u^{*}-\lambda(\omega) B v+v^{*}, u-v\right\rangle d s \geq 0
$$

for a suitable choice of $\lambda(\omega)$ whenever $u^{*} \in A(u, \omega), v^{*} \in A(v, \omega)$.

## Limit condition

Let $U$ be a Banach space dense in $V$ and that if $u_{i} \rightharpoonup u$ in $\mathscr{V}_{I}$ and $u_{i}^{*} \in A\left(u_{i}\right)$ with $u_{i}^{*} \rightharpoonup u^{*}$ in $\mathscr{V}_{I}^{\prime}$ and $t \rightarrow B u_{i}(t)$ is continuous and

$$
\begin{equation*}
\sup _{i} \sup _{t \neq s} \frac{\left\|B u_{i}(t)-B u_{i}(s)\right\|_{U^{\prime}}}{|t-s|^{\alpha}} \leq C \tag{79.1.5}
\end{equation*}
$$

then if

$$
\begin{equation*}
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \leq 0 \tag{79.1.6}
\end{equation*}
$$

it follows that for all $v \in \mathscr{V}_{I}$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \geq\left\langle u^{*}(v), u-v\right\rangle_{\mathscr{V}_{I}^{\prime}, \mathscr{V}_{I}} \tag{79.1.7}
\end{equation*}
$$

As to $B(\omega)$, it is $k(\omega) B$ where $B \in \mathscr{L}\left(W, W^{\prime}\right)$ and is self adjoint and nonnegative where $k$ is $\mathscr{F}_{0}$ measurable.

## Progressively measurable condition

Condition 79.1.2 For each $t \leq T$, if $\omega \rightarrow u(\cdot, \omega)$ is $\mathscr{F}_{t}$ measurable into $\mathscr{V}_{[0, t]}$, then there exists a $\mathscr{F}_{t}$ measurable selection of $A(u(\cdot, \omega), \omega)$ into $\mathscr{V}_{[0, t]}^{\prime}$.

Then there is a theorem. It was Theorem 77.7 .4 which gave existence and uniqueness of progressively measurable solutions $u$ to the integral equation.

Theorem 79.1.3 Assume the above conditions, 79.1.1-, 79.1.7 along with the progressive measurability condition 79.1.2. Let $u_{0}$ be $\mathscr{F}_{0}$ measurable and $\omega \rightarrow B(\omega)$ also $\mathscr{F}_{0}$ measurable and $(t, \omega) \rightarrow \mathscr{X}_{[0, t]}(t) f(t, \omega)$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ product measurable into $V^{\prime}$ for each $t$.

$$
B(\omega)=k(\omega) B, k(\omega) \geq 0, k \text { measurable }
$$

Also let $t \rightarrow q(t, \omega)$ be continuous and $q$ is progressively measurable into $V$. Suppose there is at most one solution to

$$
\begin{equation*}
B u(t, \omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B u_{0}(\omega)+B q(t, \omega), \tag{79.1.8}
\end{equation*}
$$

for each $\omega$. Then the solution to the above integral equation u is progressively measurable. Moreover, for each $\omega$, both $B u(t, \omega)=B(u(t, \omega))$ for a.e. $t$ and $z(t, \omega) \in A(u(t, \omega), \omega)$ for a.e. t. Also, for each $a \in[0, T]$,

$$
B u(t, \omega)+\int_{a}^{t} z(s, \omega) d s=\int_{a}^{t} f(s, \omega) d s+B u(a, \omega)+B q(t, \omega)-B q(a, \omega)
$$

Letting $q(t)=\int_{0}^{t} \Phi_{n} d W$ defined above with the filtration also being the one obtained from the Wiener process, this implies the following theorem. The $\sigma$ algebra of progressively measurable sets will be denoted by $\mathscr{P}$.

Theorem 79.1.4 Assume the above conditions, 79.1.1-, 79.1.7 along with the progressive measurability condition 79.1.2. Also assume there is at most one solution to 79.1.8 where

$$
q(t, \cdot) \equiv \int_{0}^{t} \Phi_{n} d W
$$

Then there exists a $\mathscr{P}$ measurable $u_{n}$ such that also $z_{n}$ is progressively measurable

$$
B u_{n}(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} z_{n}(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi_{n} d W
$$

where for each $\omega, z_{n}(\cdot, \omega) \in A\left(u_{n}(\cdot, \omega), \omega\right)$. The function $B u_{n}(t, \omega)=B\left(u_{n}(t, \omega)\right)$ for a.e. $t$.

This gives an existence theorem for the inclusion of a stochastic integral. However, it is desired to get a similar result for $\Phi$ rather than $\Phi_{n}$. Next is the Ito formula which is useable because of the progressive measurability of $u_{n}, z_{n}$. This formula applies to the following situation.

Situation 79.1.5 Let $X$ have values in $V$ and satisfy the following

$$
\begin{equation*}
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s+B \int_{0}^{t} Z(s) d W(s) \tag{79.1.9}
\end{equation*}
$$

$X_{0} \in L^{2}(\Omega ; W)$ and is $\mathscr{F}_{0}$ measurable, where $Z$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)$ progressively measurable and

$$
\|Z\|_{L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)}<\infty .
$$

This is what is needed to define the stochastic integral in the above formula.
Assume $X, Y$ satisfy

$$
B X, Y \in K^{\prime} \equiv L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)
$$

the $\sigma$ algebra of measurable sets defining $K^{\prime}$ will be the progressively measurable sets. Here $1 / p^{\prime}+1 / p=1, p>1$.

Also the sense in which the equation holds is as follows. For a.e. $\omega$, the equation holds in $V^{\prime}$ for all $t \in[0, T]$. Thus we are considering a particular representative $X$ of $K$ for which this happens. Also it is only assumed that $B X(t)=B(X(t))$ for a.e. $t$. Thus $B X$ is the name of a function having values in $V^{\prime}$ for which $B X(t)=B(X(t))$ for a.e. $t$, all $t \notin N_{\omega}$ a set of measure zero. Assume that $X$ is progressively measurable also and $X \in L^{p}([0, T] \times \Omega, V)$.

Then in the above situation, we obtain the following integration by parts formula which is called the Ito formula. This particular version is presented in Theorem 73.7.2 and is a generalization of work of Krylov. A proof of the case of a Gelfand triple in which $B=I$ is in [108].

Theorem 79.1.6 In Situation 79.1.5, for $\omega$ off a set of measure zero, for every $t \in N_{\omega}^{C}$, the measure of $N_{\omega}$ equalling 0 ,

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t} 2\langle Y(s), X(s)\rangle d s+ \\
\int_{0}^{t}\langle B Z, Z\rangle_{\mathscr{L}_{2}} d s+2 M(t) \tag{79.1.10}
\end{gather*}
$$

where $M(t)$ is a stochastic integral and a local martingale equal to 0 when $t=0$. Also, there exists a unique continuous, progressively measurable function denoted as $\langle B X, X\rangle$ such that it equals $\langle B X(t), X(t)\rangle$ for a.e. $t$ and $\langle B X, X\rangle(t)$ equals the right side of the above for all $t$. In addition to this,

$$
\begin{gather*}
E(\langle B X, X\rangle(t))= \\
E\left(\left\langle B X_{0}, X_{0}\right\rangle\right)+E\left(\int_{0}^{t}\left(2\langle Y(s), X(s)\rangle+\langle B Z, Z\rangle_{\mathscr{L}_{2}}\right) d s\right) \tag{79.1.11}
\end{gather*}
$$

Also the quadratic variation of $M(t)$ in 79.1.10 is dominated by

$$
\begin{equation*}
C \int_{0}^{t}\|Z\|_{\mathscr{L}_{2}}^{2}\|B X\|_{W^{\prime}}^{2} d s \tag{79.1.12}
\end{equation*}
$$

for a suitable constant $C$. Also $t \rightarrow B X(t)$ is continuous with values in $W^{\prime}$ for $t \in N_{\omega}^{C}$. In fact, this martingale can be written as

$$
\int_{0}^{t}\left(Z \circ J^{-1}\right)^{*} B X \circ J d W
$$

That ugly integral displayed above can be written in the form

$$
\int_{0}^{t}\langle B X, d N\rangle
$$

where $N(t)=\int_{0}^{t} Z(s) d W$.
Now we consider the meaning of the symbol $\langle B Z, Z\rangle_{\mathscr{L}_{2}}$. You begin with a complete orthonormal set $\left\{g_{k}\right\}$ in $Q^{1 / 2} U$. Then to say that $Z$ has values in $\mathscr{L}_{2}\left(Q^{1 / 2} U ; W\right)$ is to say that $\sum_{j} \sum_{i}\left(Z\left(g_{i}\right), e_{j}\right)^{2}=\sum_{i}\left\|Z\left(g_{i}\right)\right\|_{W}^{2}<\infty$ where $\left\{e_{j}\right\}$ is an orthonormal basis in $W$. You can let it be the one used earlier where each is actually in $V$ or even in $E$. Then the symbol means

$$
\left(R^{-1} B Z, Z\right)_{\mathscr{L}_{2}}
$$

where $R$ is the Riesz map from the Hilbert space $W$ to its dual space. Thus it equals

$$
\sum_{i}\left(R^{-1} B Z\left(g_{i}\right), Z\left(g_{i}\right)\right)_{W}=\sum_{i}\left\langle B Z\left(g_{i}\right), Z\left(g_{i}\right)\right\rangle
$$

so it is seen to be nonnegative.

Now apply this Ito formula to Theorem 79.1.4 in which we make the assumptions there on $\left\|u_{0}\right\| \in L^{2}(\Omega)$ and that $f \in L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)$ where the $\sigma$ algebra is $\mathscr{P}$ the progressively measurable $\sigma$ algebra, and

$$
\Phi \in L^{2}\left(\Omega, L^{2}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right)
$$

which implies the same is true of $\Phi_{n}$. This yields, from the assumed estimates, an expression of the form where $\delta>0$ is a suitable constant.

$$
\begin{align*}
& \frac{1}{2}\left\langle B u_{n}, u_{n}\right\rangle(t)-\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\delta \int_{0}^{t}\left\|u_{n}(s)\right\|_{V}^{p} d s \\
\leq & \lambda \int_{0}^{t}\left\langle B u_{n}, u_{n}\right\rangle(s) d s+\int_{0}^{t}\left\langle f, u_{n}\right\rangle_{V^{\prime}, V} d s+\int_{0}^{t} c(s, \omega) d s \\
& +\int_{0}^{t}\left\langle B \Phi_{n}, \Phi_{n}\right\rangle_{\mathscr{L}_{2}} d s+M_{n}(t) \tag{79.1.13}
\end{align*}
$$

where $c \in L^{1}([0, T] \times \Omega)$. Then taking expectations or using that part of the Ito formula,

$$
\begin{aligned}
& \frac{1}{2} E\left(\left\langle B u_{n}, u_{n}\right\rangle(t)\right)+\delta E\left(\int_{0}^{T}\left\|u_{n}(s)\right\|_{V}^{p} d s\right) \\
\leq & \lambda \int_{0}^{t} E\left(\left\langle B u_{n}, u_{n}\right\rangle(s)\right) d s+\int_{0}^{t} E\left(\left\langle f, u_{n}\right\rangle_{V^{\prime}, V}\right) d s+C\left(\Phi, u_{0}\right)
\end{aligned}
$$

Then by Gronwall's inequality and some simple manipulations,

$$
E\left(\left\langle B u_{n}, u_{n}\right\rangle(t)\right)+E\left(\int_{0}^{T}\left\|u_{n}(s)\right\|_{V}^{p} d s\right) \leq C\left(T, f, u_{0}, \Phi\right)
$$

Then using obvious estimates and Gronwall's inequality in 79.1.13, this yields an inequality of the form

$$
\left\langle B u_{n}, u_{n}\right\rangle(t)-\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\left\|u_{n}(s)\right\|_{V}^{p} d s \leq C(f, \lambda, c)+\|B\| \int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2} d s+M_{n}^{*}(t)
$$

where the random variable $C(f, \lambda, c)$ is nonnegative and is integrable. Now $t \rightarrow M_{n}^{*}(t)$ is increasing as is the integral on the right. Hence it follows that, modifying the constants,

$$
\begin{gather*}
\sup _{s \in[0, t]}\left\langle B u_{n}, u_{n}\right\rangle(s)+\int_{0}^{t}\left\|u_{n}(s)\right\|_{V}^{p} d s \\
\leq C\left(f, \lambda, c, u_{0}\right)+2\|B\| \int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2} d s+2 M_{n}^{*}(t) \tag{79.1.14}
\end{gather*}
$$

Next take the expectation of both sides and use the Burkholder Davis Gundy inequality along with the description of the quadratic variation of the martingale $M_{n}(t)$. This yields

$$
\begin{aligned}
& E\left(\sup _{s \in[0, t]}\left\langle B u_{n}, u_{n}\right\rangle(s)\right)+E\left(\int_{0}^{t}\left\|u_{n}(s)\right\|_{V}^{p} d s\right) \\
\leq & C+2\|B\| E\left(\int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2} d s\right)
\end{aligned}
$$

$$
+C \int_{\Omega}\left(\int_{0}^{t}\left\|B u_{n}\right\|_{W}^{2}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2} d s\right)^{1 / 2} d P
$$

Now $\|B w\|=\sup _{\|v\| \leq 1}\langle B w, v\rangle \leq\langle B w, w\rangle^{1 / 2}$. Also $\int_{0}^{t}\left\|\Phi_{n}\right\|_{\mathscr{L}_{2}}^{2} d s \leq \int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s$ and so the above inequality implies

$$
\begin{aligned}
& E\left(\sup _{s \in[0, t]}\left\langle B u_{n}, u_{n}\right\rangle(s)\right)+E\left(\int_{0}^{t}\left\|u_{n}(s)\right\|_{V}^{p} d s\right) \\
\leq & C(f, \lambda, c, \Phi)+C \int_{\Omega} \sup _{s \in[0, t]}\left\langle B u_{n}, u_{n}\right\rangle^{1 / 2}(s)\left(\int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2}\right)^{1 / 2} d P
\end{aligned}
$$

Then adjusting the constants yields

$$
\begin{gather*}
\frac{1}{2} E\left(\sup _{s \in[0, T]}\left\langle B u_{n}, u_{n}\right\rangle(s)\right)+E\left(\int_{0}^{T}\left\|u_{n}(s)\right\|_{V}^{p} d s\right) \\
\leq C+C \int_{\Omega} \int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2} d t d P \equiv C \tag{79.1.15}
\end{gather*}
$$

If needed, you could use a stopping time to be sure that $E\left(\sup _{s \in[0, T]}\left\langle B u_{n}, u_{n}\right\rangle(s)\right)<\infty$ and then let it converge to $\infty$.

From the integral equation,

$$
B u_{n}(t)-B u_{m}(t)+\int_{0}^{t} z_{n}-z_{m} d s=B \int_{0}^{t}\left(\Phi_{n}-\Phi_{m}\right) d W
$$

Then using the monotonicity assumption and the Ito formula,

$$
\begin{gathered}
\frac{1}{2}\left\langle B u_{n}-B u_{m}, u_{n}-u_{m}\right\rangle(t) \leq \lambda \int_{0}^{t}\left\langle B u_{n}-B u_{m}, u_{n}-u_{m}\right\rangle d s s \\
+\int_{0}^{t}\left\langle B\left(\Phi_{n}-\Phi_{m}\right), \Phi_{n}-\Phi_{m}\right\rangle d+\int_{0}^{t}\left(\left(\Phi_{n}-\Phi_{m}\right) \circ J^{-1}\right)^{*} B\left(u_{n}-u_{m}\right) \circ J d W
\end{gathered}
$$

and so, from Gronwall's inequality, there is a constant $C$ which is independent of $m, n$ such that

$$
\left\langle B u_{n}-B u_{m}, u_{n}-u_{m}\right\rangle(t) \leq C M_{n m}(t) \leq C M_{n m}^{*}(T)+C \int_{0}^{t}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}}^{2} d s
$$

where $M_{n m}$ refers to that local martingale on the right. Thus also

$$
\begin{equation*}
\sup _{t \in[0, T]}\left\langle B u_{n}-B u_{m}, u_{n}-u_{m}\right\rangle(t) \leq C M_{n m}(t) \leq C M_{n m}^{*}(T)+C \int_{0}^{T}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}}^{2} d s \tag{79.1.16}
\end{equation*}
$$

Taking the expectation and using the Burkholder Davis Gundy inequality again in a similar manner to the above,

$$
E\left(\sup _{t \in[0, T]}\left\langle B u_{n}-B u_{m}, u_{n}-u_{m}\right\rangle(t)\right) \leq C \int_{\Omega} \int_{0}^{T}\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}}^{2} d t d P
$$

Now the right side converges to 0 as $m, n \rightarrow \infty$ and so there is a subsequence, denoted with the index $k$ such that whenever $m>k$,

$$
E\left(\sup _{t \in[0, T]}\left\langle B u_{k}-B u_{m}, u_{k}-u_{m}\right\rangle(t)\right) \leq \frac{1}{2^{k}}
$$

Note how this implies

$$
\begin{equation*}
\int_{\Omega} \int_{0}^{T}\left\langle B u_{k}-B u_{m}, u_{k}-u_{m}\right\rangle d t d P \leq \frac{T}{2^{k}} \tag{79.1.17}
\end{equation*}
$$

Then consider the martingales $M_{k}(t)$ considered earlier. One of these is of the form

$$
M_{k}=\int_{0}^{t}\left(\Phi_{k} \circ J^{-1}\right)^{*} B u_{k} \circ J d W
$$

Then by the Burkholder Davis Gundy inequality and modifying constants as appropriate,

$$
\begin{gathered}
E\left(\left(M_{k}-M_{k+1}\right)^{*}\right) \\
\leq C \int_{\Omega}\left(\int_{0}^{T}\left\|\left(\Phi_{k} \circ J^{-1}\right)^{*} B u_{k}-\left(\Phi_{k+1} \circ J^{-1}\right)^{*} B u_{k+1}\right\|^{2} d t\right)^{1 / 2} d P \\
\leq C \int_{\Omega}\binom{\int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2}\left\langle B u_{k}, u_{k}\right\rangle}{+\left\|\Phi_{k+1}\right\|^{2}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle d t}^{1 / 2} d P \\
\leq \quad C \int_{\Omega}\left(\int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2}\left\langle B u_{k}, u_{k}\right\rangle d t\right)^{1 / 2} \\
\quad+C \int_{\Omega}\left(\int_{0}^{T}\left\|\Phi_{k+1}\right\|^{2}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle d t\right)^{1 / 2} d P \\
\leq C \int_{\Omega} \sup _{t}\left\langle B u_{k}, u_{k}\right\rangle^{1 / 2}\left(\int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2} d t\right)^{1 / 2} d P \\
+C \int_{\Omega} \sup _{t}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle^{1 / 2}\left(\int_{0}^{T}\left\|\Phi_{k+1}\right\|^{2} d t\right)^{1 / 2} d P \\
\leq C\left(\int_{\Omega} \sup _{t}\left\langle B u_{k}, u_{k}\right\rangle d P\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{k}-\Phi_{k+1}\right\|^{2} d t d P\right)^{1 / 2} \\
+C\left(\int_{\Omega} \sup _{t}\left\langle B u_{k}-B u_{k+1}, u_{k}-u_{k+1}\right\rangle d P\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{k+1}\right\|^{2} d t d P\right)^{1 / 2}
\end{gathered}
$$

From the above inequality, 79.1.15 and after adjusting the constants, the above is no larger than an expression of the form $C\left(\frac{1}{2}\right)^{k / 2}$ which is a summable sequence. Then

$$
\sum_{k} \int_{\Omega_{t \in[0, T]}} \sup _{t}\left|M_{k}(t)-M_{k+1}(t)\right| d P<\infty
$$

Thus $\left\{M_{k}\right\}$ is a Cauchy sequence in $M_{T}^{1}$ and so there is a continuous martingale $M$ such that

$$
\lim _{k \rightarrow \infty} E\left(\sup _{t}\left|M_{k}(t)-M(t)\right|\right)=0
$$

Taking a further subsequence if needed, one can also have

$$
P\left(\sup _{t}\left|M_{k}(t)-M(t)\right|>\frac{1}{k}\right) \leq \frac{1}{2^{k}}
$$

and so by the Borel Cantelli lemma, there is a set of measure zero such that off this set, $\sup _{t}\left|M_{k}(t)-M(t)\right|$ converges to 0 . Hence for such $\omega, M_{k}^{*}(T)$ is bounded independent of $k$. Thus for $\omega$ off a set of measure zero, 79.1.14 implies that for such $\omega$,

$$
\sup _{s \in[0, T]}\left\langle B u_{r}, u_{r}\right\rangle(s)+\int_{0}^{T}\left\|u_{r}(s)\right\|_{V}^{p} d s \leq C(\omega)
$$

where $C(\omega)$ does not depend on the index $r$, this for the subsequence just described which will be the sequence of interest in what follows. Using the boundedness assumption for $A$, one also obtains an estimate of the form

$$
\begin{equation*}
\sup _{s \in[0, T]}\left\langle B u_{r}, u_{r}\right\rangle(s)+\int_{0}^{T}\left\|u_{r}(s)\right\|_{V}^{p} d s+\int_{0}^{T}\left\|z_{r}\right\|_{V^{\prime}}^{p^{\prime}} \leq C(\omega) \tag{79.1.18}
\end{equation*}
$$

The idea here is to take weak limits converging to a function $u$ and then identify $z(\cdot, \omega)$ as being in $A(u, \omega)$ but this will involve a difficulty. It will require a use of the above Ito formula and this will need $u$ to be progressively measurable. By uniqueness, it would seem that this could be concluded by arguing that one does not need to take a subsequence due to uniqueness but the problem is that we won't know the limit of the sequence is a solution unless we use the Ito formula. This is why we make the extra assumption that for $z_{i}(\cdot, \omega) \in A\left(u_{i}, \omega\right)$ and for all $\lambda$ large enough,

$$
\begin{equation*}
\left\langle\lambda B u_{1}(t)+z_{1}(t)-\left(\lambda B u_{2}(t)+z_{2}(t)\right), u_{1}(t)-u_{2}(t)\right\rangle \geq \delta\left\|u_{1}(t)-u_{2}(t)\right\|_{\hat{V}}^{\alpha}, \alpha \geq 1 \tag{79.1.19}
\end{equation*}
$$

where here $\hat{V}$ will be a Banach space such that $V$ is dense in $\hat{V}$ and the embedding is continuous. As mentioned, this is not surprising in the case of most interest where there is a Gelfand triple and $B=I$ and $A$ is defined pointwise with no memory terms involving time integrals. Then using the integral equation for $r=p, q, p<q$ along with the conclusion of the Ito formula above,

$$
\begin{aligned}
& E\left(\left\langle B\left(u_{n}-u_{m}\right), u_{n}-u_{m}\right\rangle(t)\right)+E\left(\int_{0}^{t}\left\|u_{n}-u_{m}\right\|_{\hat{V}}^{\alpha} d s\right) \\
\leq & E\left(\int_{0}^{t}\|B\|\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}}^{2} d s\right) \equiv e(m, n)
\end{aligned}
$$

Hence, the right side converges to 0 as $m, n \rightarrow \infty$ from the dominated convergence theorem. In particular,

$$
\begin{equation*}
E\left(\int_{0}^{T}\left\|u_{n}-u_{m}\right\|_{\hat{V}}^{\alpha} d s\right) \leq E\left(\int_{0}^{T}\|B\|\left\|\Phi_{n}-\Phi_{m}\right\|_{\mathscr{L}_{2}}^{2} d s\right) \equiv e(m, n) \tag{79.1.20}
\end{equation*}
$$

Then also

$$
P\left(\int_{0}^{T}\left\|u_{n}-u_{m}\right\|_{\hat{V}}^{\alpha} d s>\lambda\right) \leq \frac{e(m, n)}{\lambda}
$$

and so there exists a subsequence, denoted by $r$ such that

$$
P\left(\int_{0}^{T}\left\|u_{r}-u_{r+1}\right\|_{\hat{V}}^{\alpha} d s \leq 2^{-r}\right)<2^{-r}
$$

Thus, by the Borel Cantelli lemma, there is a further enlarged set of measure zero, still denoted as $N$ such that for $\omega \notin N$

$$
\int_{0}^{T}\left\|u_{r}-u_{r+1}\right\|_{\hat{V}}^{\alpha} d s \leq 2^{-r}
$$

for all $r$ large enough. Hence, by the usual proof of completeness, for these $\omega$,

$$
\left\{u_{r}(\cdot, \omega)\right\}
$$

is Cauchy in $L^{\alpha}([0, T], \hat{V})$ and also $u_{r}(t, \omega)$ converges to some $u(t, \omega)$ pointwise in $\hat{V}$ for a.e. $t$. In addition, from 79.1.20 these functions are a Cauchy sequence in $L^{\alpha}([0, T] \times \Omega ; \hat{V})$ with respect to the $\sigma$ algebra of progressively measurable sets. Thus from Lemma 76.3.4, it can be assumed that for $\omega$ off the set of measure zero, $(t, \omega) \rightarrow u(t, \omega)$ is progressively measurable. From now on, this will be the sequence or a further subsequence. For $\omega \notin N$, a set of measure zero and 79.1.18, there is a further subsequence for which the following convergences occur as $r \rightarrow \infty$.

$$
\begin{align*}
& u_{r} \rightarrow u \text { weakly in } \mathscr{V}  \tag{79.1.21}\\
& B\left(u_{r}\right) \rightarrow B(u) \text { weakly in } \mathscr{V}^{\prime}  \tag{79.1.22}\\
& z_{r} \rightarrow z \text { weakly in } \mathscr{V}^{\prime}  \tag{79.1.23}\\
&\left(B\left(u_{r}-\int_{0}^{(\cdot)} \Phi_{r} d W\right)\right)^{\prime} \rightarrow\left(B\left(u-\int_{0}^{(\cdot)} \Phi d W\right)\right)^{\prime} \text { weakly in } \mathscr{V}^{\prime}  \tag{79.1.24}\\
& \int_{0}^{(\cdot)} \Phi_{r} d W \rightarrow \int_{0}^{(\cdot)} \Phi d W \text { uniformly in } C([0, T] ; W)  \tag{79.1.25}\\
& B u_{r}(t) \rightarrow B u(t) \text { weakly in } V^{\prime}  \tag{79.1.26}\\
& B u(0)=B u_{0}  \tag{79.1.27}\\
& B u(t)=B(u(t)) \text { a.e. } t \tag{79.1.28}
\end{align*}
$$

In addition to this, we can choose the subsequence such that

$$
\begin{equation*}
\sup _{r} \sup _{t \neq s} \frac{\left\|\int_{s}^{t} \Phi_{r} d W\right\|}{|t-s|^{\gamma}}<C(\omega)<\infty \tag{79.1.29}
\end{equation*}
$$

This is thanks to Corollary 79.1.1. The boundedness of the operator $A$, in particular the given estimates, imply that $z_{r}$ is bounded in $L^{p^{\prime}}\left([0, T] \times \Omega, V^{\prime}\right)$. Thus a subsequence can be obtained which yields weak convergence of $z_{r}$ in $L^{p^{\prime}}\left([0, T] \times \Omega, V^{\prime}\right)$ and then Lemma
76.3.4 may be applied to conclude that off a set of measure zero, $z$ is progressively measurable.

The claim 79.1.26 and 79.1.27 follow from the continuity of the evaluation map defined on $X$, Theorem 77.2.2. The claim in 79.1.28 follows from 79.1.22 and the convergence 79.1.26. To see this, let $\psi \in C_{c}^{\infty}(0, T)$.

$$
\begin{aligned}
\int_{0}^{T} B u(t) \psi(t) d t & =\lim _{r \rightarrow \infty} \int_{0}^{T} B u_{r}(t) \psi(t) d t \\
& =\lim _{r \rightarrow \infty} \int_{0}^{T} B\left(u_{r}(t)\right) \psi(t) d t=\int_{0}^{T} B(u(t)) \psi(t) d t
\end{aligned}
$$

Since this is true for all such $\psi$, it follows that $B u(t)=B(u(t))$ for a.e. $t$. Passing to a limit in the integral equation yields the following for $\omega$ off a set of measure zero,

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi_{n} d W
$$

In the following claim, assume $\Phi \in L^{\alpha}\left(\Omega, L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right), \alpha>2$
Claim: $\lim _{r \rightarrow \infty} \int_{0}^{T}\left(\Phi_{r} \circ J^{-1}\right)^{*} B u_{r} \circ J d W=\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W$ off a set of measure zero.

Proof of claim:

$$
\begin{aligned}
& E\left(\left|\int_{0}^{T}\left(\Phi_{r} \circ J^{-1}\right)^{*} B u_{r} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W\right|\right) \\
\leq & E\left(\left|\int_{0}^{T}\left(\Phi_{r} \circ J^{-1}\right)^{*} B u_{r} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u_{r} \circ J d W\right|\right) \\
& +E\left(\left|\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u_{r} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W\right|\right)
\end{aligned}
$$

Then, by the Burkholder Davis Gundy inequality,

$$
\begin{gathered}
\leq \int_{\Omega}\left(\int_{0}^{T}\left\|\Phi_{r}-\Phi\right\|^{2}\left\langle B u_{r}, u_{r}\right\rangle\right)^{1 / 2} d P \\
+\int_{\Omega}\left(\int_{0}^{T}\|\Phi\|^{2}\left\langle B u_{r}-B u, u_{r}-u\right\rangle\right)^{1 / 2} d P \\
\leq \int_{\Omega} \sup _{t}\left\langle B u_{r}(t), u_{r}(t)\right\rangle^{1 / 2}\left(\int_{0}^{T}\left\|\Phi_{r}-\Phi\right\|^{2} d t\right)^{1 / 2} d P \\
+\int_{\Omega}\left\|\Phi_{n}\right\|_{L^{\infty}\left([0, T], \mathscr{L}_{2}\right)}\left(\int_{0}^{T}\left\langle B u_{r}-B u, u_{r}-u\right\rangle\right)^{1 / 2} d P \\
\leq\left(\int_{\Omega} \sup _{t}\left\langle B u_{r}(t), u_{r}(t)\right\rangle d P\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{r}-\Phi\right\|^{2} d t\right)^{1 / 2}
\end{gathered}
$$

$$
\begin{equation*}
+\left(\int_{\Omega}\left\|\Phi_{n}\right\|_{L^{\infty}\left([0, T], \mathscr{L}_{2}\right)}^{2}\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\langle B u_{r}-B u, u_{r}-u\right\rangle d t d P\right)^{1 / 2} \tag{79.1.30}
\end{equation*}
$$

Letting the $e_{i}$ be the special vectors of Theorem 77.2.19,

$$
\begin{aligned}
& \int_{\Omega} \int_{0}^{T}\left\langle B u_{r}-B u, u_{r}-u\right\rangle d t d P=\int_{\Omega} \int_{0}^{T} \sum_{i}\left\langle B u_{r}-B u, e_{i}\right\rangle^{2} d t d P \\
&=\int_{\Omega} \int_{0}^{T} \sum_{i} \lim _{p \rightarrow \infty} \inf _{p}\left\langle B u_{r}-B u_{p}, e_{i}\right\rangle^{2} d t d P \\
& \quad \leq \lim \inf _{p \rightarrow \infty} \int_{\Omega} \int_{0}^{T} \sum_{i}\left\langle B u_{r}-B u_{p}, e_{i}\right\rangle^{2} d t d P \\
&= \liminf _{p \rightarrow \infty} \int_{\Omega} \int_{0}^{T} \sum_{i}\left\langle B u_{r}-B u_{p}, e_{i}\right\rangle^{2} d t d P \\
&=\lim _{p \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle B u_{r}-B u_{p}, u_{r}-u_{p}\right\rangle d t d P
\end{aligned}
$$

Now by 79.1.17, the last expression is no larger than $T / 2^{r}$ and so

$$
\int_{\Omega} \int_{0}^{T}\left\langle B u_{r}-B u, u_{r}-u\right\rangle d t d P \leq \frac{T}{2^{r}}
$$

Then, from 79.1.30,

$$
\begin{gathered}
E\left(\left|\int_{0}^{T}\left(\Phi_{r} \circ J^{-1}\right)^{*} B u_{r} \circ J d W-\int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W\right|\right) \\
\leq\left(\int_{\Omega} \sup _{t}\left\langle B u_{r}(t), u_{r}(t)\right\rangle d P\right)^{1 / 2}\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{r}-\Phi\right\|^{2} d t\right)^{1 / 2}+C\left(\frac{T}{2^{r}}\right)^{1 / 2} \\
\leq C\left(\int_{\Omega} \int_{0}^{T}\left\|\Phi_{r}-\Phi\right\|^{2} d t\right)^{1 / 2}+C\left(\frac{T}{2^{r}}\right)^{1 / 2}<C 2^{-r}+C\left(\frac{T}{2^{r}}\right)^{1 / 2}
\end{gathered}
$$

which clearly converges to 0 as $r \rightarrow \infty$. Since the right side is summable, one obtains also pointwise convergence. This proves the claim.

From the above considerations using the space $\hat{V}$, it follows that this $u$ is the same as the one just obtained in the sense that for $\omega$ off $N$, the two are equal for a.e. $t$. Thus we take $u$ to be this common function. Hence there is a set of measure zero such that $(t, \omega) \rightarrow \mathscr{X}_{N^{C}} u(t, \omega)$ is progressively measurable in the above convergences. Also, this shows that we are taking $u \in L^{p}([0, T] \times \Omega ; V)$. From the measurability of $u_{r}, u$, we can obtain a dense countable subset $\left\{t_{k}\right\}$ and an enlarged set of measure zero $N$ such that for $\omega \notin N, B u\left(t_{k}, \omega\right)=B\left(u\left(t_{k}, \omega\right)\right)$ and $B u_{r}\left(t_{k}, \omega\right)=B\left(u_{r}\left(t_{k}, \omega\right)\right)$ for all $t_{k}$ and $r$. This uses the same argument as in Lemma 73.3.1.

It remains to verify that $z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$. It follows from the above considerations that the Ito formula above can be used at will. Assume that for a given $\omega \notin$
$N, B u(T, \omega)=B(u(T, \omega))$, similar for $B u_{r}$. If not, just do the following argument for all $T^{\prime}$ close to $T$, letting $T^{\prime}$ be in the dense subset just described. Then from the integral equation solved, and letting $\left\{e_{i}\right\}$ be the special set described in Theorem 77.2.19 and suppressing the dependence on $\omega$,

$$
\begin{aligned}
& \sum_{i=1}^{\infty}\left\langle B u_{r}(T), e_{i}\right\rangle^{2}-\sum_{i=1}^{\infty}\left\langle B u_{0}, e_{i}\right\rangle+2 \int_{0}^{T}\left\langle z_{r}, u_{r}\right\rangle d s \\
= & 2 \int_{0}^{T}\left\langle f, u_{r}\right\rangle d s+2 \int_{0}^{T}\left(\Phi_{r} \circ J^{-1}\right)^{*} B u_{r} \circ J d W
\end{aligned}
$$

Thus also

$$
\begin{align*}
& 2 \int_{0}^{T}\left\langle z_{r}, u_{r}\right\rangle d s=-\sum_{i=1}^{\infty}\left\langle B u_{r}(T), e_{i}\right\rangle^{2}+\sum_{i=1}^{\infty}\left\langle B u_{0}, e_{i}\right\rangle \\
& +2 \int_{0}^{T}\left\langle f, u_{r}\right\rangle d s+2 \int_{0}^{T}\left(\Phi_{r} \circ J^{-1}\right)^{*} B u_{r} \circ J d W \tag{79.1.31}
\end{align*}
$$

A similar formula to 79.1 .31 holds for $u$. Thus

$$
\begin{aligned}
& 2 \int_{0}^{T}\langle z, u\rangle d s=-\sum_{i=1}^{\infty}\left\langle B u(T), e_{i}\right\rangle^{2}+\sum_{i=1}^{\infty}\left\langle B u_{0}, e_{i}\right\rangle \\
& +2 \int_{0}^{T}\langle f, u\rangle d s+2 \int_{0}^{T}\left(\Phi \circ J^{-1}\right)^{*} B u \circ J d W
\end{aligned}
$$

It follows from 79.1.25 and the other convergences that

$$
\lim \sup _{r \rightarrow \infty} \int_{0}^{T}\left\langle z_{r}, u_{r}\right\rangle d s \leq \int_{0}^{T}\langle z, u\rangle d s
$$

Hence

$$
\lim \sup _{r \rightarrow \infty}\left\langle z_{r}, u_{r}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0
$$

Now from the limit condition, for any $v \in \mathscr{V}$, there exists a $z(v) \in A(u(\cdot, \omega), \omega)$ such that

$$
\begin{aligned}
\langle z, u-v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} & \geq \lim _{r \rightarrow \infty}\left(\left\langle z_{r}, u_{r}-u\right\rangle+\left\langle z_{r}, u-v\right\rangle\right) \\
& \geq \lim _{r \rightarrow \infty} \inf _{r \rightarrow}\left\langle z_{r}, u_{r}-v\right\rangle \geq\langle z(v), u-v\rangle
\end{aligned}
$$

The reason the limit condition applies is the estimate 79.1.29 and the convergence 79.1.24 which shows that

$$
B\left(u_{r}-\int_{0}^{(\cdot)} \Phi_{r} d W\right)
$$

satisfy a Holder condition into $V^{\prime}$. Then the estimate 79.1.29 implies that the $B \int_{0}^{(\cdot)} \Phi_{r} d W$ are bounded in a Holder norm and so the same is true of the $B u_{r}$. Thus the situation of the limit condition 79.1.7 is obtained. Then it follows from separation theorems and the fact that $A(u(\cdot, \omega), \omega)$ is closed and convex that $z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$. This has proved the following Theorem.

Theorem 79.1.7 Assume the above conditions, 79.1.1-, 79.1.7 along with the progressive measurability condition 79.1.2. Also assume there is at most one solution to 79.1.8 where

$$
q(t, \cdot) \equiv \int_{0}^{t} \Phi d W
$$

Then there exists a $\mathscr{P}$ measurable u such that also z is progressively measurable

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \Phi d W
$$

where for each $\omega, z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$. The function $B u(t, \omega)=B(u(t, \omega))$ for a.e. $t$. Here

$$
\Phi \in L^{\alpha}\left(\Omega ; L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right) \cap L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right), \alpha>2
$$

and $u_{0} \in L^{2}(\Omega, W), f \in L^{p^{\prime}}\left([0, T] \times \Omega ; V^{\prime}\right)$.
The following corollary comes right away from the above and uniqueness for fixed $\omega$.
Corollary 79.1.8 In the situation of Theorem 79.1.7, change the conditions on $\Phi$. Instead of letting

$$
\Phi \in L^{\alpha}\left(\Omega ; L^{\infty}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)\right) \cap L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)
$$

assume that $\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)\right)$ and that $t \rightarrow \Phi(t, \omega)$ is continuous into $\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)$. Then there exists a unique solution to the integral equation of Theorem 79.1.7.

Proof: Let $\tau_{m}=\inf \left\{t:\|\Phi(t, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)}>m\right\}$. Then $\Phi^{\tau_{m}}$ is uniformly bounded above by $m$ and $\lim _{m \rightarrow \infty} \tau_{m}=\infty$. Hence $\Phi^{\tau_{m}}$ is in the necessary space for the conclusion of Theorem 79.1.7 to hold. Letting $m \rightarrow \infty$ and using uniqueness, one finds a solution to the integral equation.

### 79.2 Replacing $\Phi$ With $\sigma(u)$

One can replace $\Phi$ with $\sigma(u)$ provided $B$ maps $W$ one to one onto $W^{\prime}$. This includes the most common case of a Gelfand triple in which $B=I$ and $V \subseteq H=H^{\prime} \subseteq V^{\prime}$. We also need to assume that $A$ is defined pointwise as described below rather than possibly having memory terms involved.

Theorem 79.2.1 In the situation of Theorem 79.1.7, suppose 1-79.4.2 and progressive measurability condition 79.1.2 but A defined pointwise,

$$
A(u, \omega)(t)=A(u(t, \omega), t, \omega)
$$

and suppose $f$ is progressively measurable and is in $L^{p^{\prime}}\left(\Omega ; L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)\right)$. Assume

$$
\langle B u, u\rangle \geq \delta\|u\|_{W}^{2}
$$

so that an equivalent norm on $W$ is $\langle B u, u\rangle^{1 / 2}$. Assume the monotonicity assumption: for $z_{i} \in A\left(u_{i}, \omega\right)$,

$$
\begin{equation*}
\left\langle\lambda B u_{1}+z_{1}-\left(\lambda B u_{2}+z_{2}\right), u_{1}-u_{2}\right\rangle \geq \delta\left\|u_{1}-u_{2}\right\|_{W}^{2} \tag{79.2.32}
\end{equation*}
$$

for all $\lambda$ large enough. Suppose $\sigma(t, \omega, u) \in \mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)$ and has the growth properties

$$
\begin{gather*}
\|\sigma(t, \omega, u)\|_{W} \leq C+C\|u\|_{W} \\
\left\|\sigma\left(t, \omega, u_{1}\right)-\sigma\left(t, \omega, u_{2}\right)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, W\right)} \leq K\left\|u_{1}-u_{2}\right\|_{W} \tag{79.2.33}
\end{gather*}
$$

and $(t, \omega) \rightarrow \sigma(t, \omega, u(t, \omega))$ is progressively measurable whenever $(t, \omega) \rightarrow u(t, \omega)$ is. Then there exists a unique solution $u$ to the integral equation

$$
B u(t)-B u_{0}+\int_{0}^{t} z d s=\int_{0}^{t} f d s+B \int_{0}^{t} \sigma(s, \cdot, u) d W
$$

The case of most interest is the usual one where $V \subseteq W=W^{\prime} \subseteq V^{\prime}$, the case of a Gelfand triple in which $B$ is the identity. We also are assuming that $A$ does not have memory terms. We obtain $(t, \omega) \rightarrow \sigma(t, \omega, u(t, \omega))$ progressively measurable if $(t, \omega) \rightarrow \sigma(t, \omega, u)$ is progressively measurable for each $u \in W$ thanks to continuity in $u$ which comes from 79.2.33.

Proof: For given $w \in L^{2}(\Omega, C([0, T], W))$ each $w$ being progressively measurable, define $u=\psi(w)$ as the solution to the integral equation

$$
B u(t, \omega)-B u_{0}(\omega)+\int_{0}^{t} z(s, \omega) d s=\int_{0}^{t} f(s, \omega) d s+B \int_{0}^{t} \sigma(w) d W
$$

which exists by above assumptions and Corollary 79.1.8. Here we write $\sigma(w)$ for short instead of $\sigma(t, \omega, w)$. From Theorem 73.7.2, $\langle B u, u\rangle$ is continuous hence bounded and so $B u$ is in $L^{\infty}\left([0, T], W^{\prime}\right)$ which implies $u \in L^{\infty}([0, T], W)$. Since $B u$ is essentially bounded in $W^{\prime}$ and equals a continuous function in $V^{\prime}$, it follows from density considerations that $B u_{i}$ can be re defined on a set of meausure zero to be weakly continuous into $W^{\prime}$ hence weakly continuous into $V^{\prime}$. This re definition must yield the integral equation because all other terms than $B u$ are continuous. However, this implies that if we let $u(t)=B^{-1}(B u)(t)$, then $u$ is weakly continuous into $W$. By continuity of $\|u\|^{2} \equiv\langle B u, u\rangle$, this shows that in fact, $u$ is continuous into $W$ thanks to the uniform continuity of the Hilbert space norm. Thus $u(\cdot, \omega) \in C([0, T], W)$.

Then from the estimates,

$$
\begin{array}{r}
\langle B u, u\rangle(t)-\left\langle B u_{0}, u_{0}\right\rangle+\delta \int_{0}^{t}\|u\|_{V}^{p} d s=2 \int_{0}^{t}\langle f, u\rangle d s+C\left(b_{3}, b_{4}, b_{5}\right) \\
+\lambda \int_{0}^{t}\langle B u, u\rangle d s+\int_{0}^{t}\langle B \sigma(w), \sigma(w)\rangle_{\mathscr{L}_{2}} d s+2 M^{*}(t) \\
\leq 2 \int_{0}^{t}\langle f, u\rangle d s+C\left(b_{3}, b_{4}, b_{5}\right)+\lambda \int_{0}^{t}\langle B u, u\rangle d s+\int_{0}^{t}\left(C+C\|w\|_{W}^{2}\right) d s+2 M^{*}(t)
\end{array}
$$

where $M^{*}(t)=\sup _{s \in[0, t]}|M(s)|$ and the quadratic variation of $M$ is no larger than

$$
\int_{0}^{t}\|\sigma(w)\|^{2}\langle B u, u\rangle d s
$$

Then using Gronwall's inequality, one obtains an inequality of the form

$$
\sup _{s \in[0, t]}\langle B u, u\rangle(s) \leq C+C\left(M^{*}(t)+\int_{0}^{t}\|w\|_{W}^{2} d s\right)
$$

where $C=C\left(u_{0}, f, \delta, \lambda, b_{3}, b_{4}, b_{5}, T\right)$ and is integrable. Then take expectation. By Burkholder Davis Gundy inequality and adjusting constants as needed,

$$
\begin{aligned}
& E\left(\sup _{s \in[0, T]}\langle B u, u\rangle(s)\right) \\
\leq & C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P+C \int_{\Omega}\left(\int_{0}^{T}\|\sigma(w)\|^{2}\langle B(u), u\rangle d s\right)^{1 / 2} d P \\
\leq & C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P+C \int_{\Omega} \sup _{s \in[0, T]}\langle B u, u\rangle^{1 / 2}(s)\left(\int_{0}^{T}\|\sigma(w)\|^{2} d s\right)^{1 / 2} d P \\
\leq & C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P+\frac{1}{2} E\left(\sup _{s \in[0, T]}\langle B u, u\rangle(s)\right)+C \int_{\Omega} \int_{0}^{T}\left(C+C\|w\|_{W}^{2}\right)
\end{aligned}
$$

Thus

$$
E(\langle B u, u\rangle(t)) \leq E\left(\sup _{s \in[0, T]}\langle B u, u\rangle(s)\right) \leq C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P
$$

and so

$$
\|u\|_{L^{2}(\Omega, C([0, T] ; W))}^{2} \leq C+C \int_{\Omega} \int_{0}^{T}\|w\|_{W}^{2} d s d P
$$

which implies $u \in L^{2}(\Omega, C([0, T] ; W))$ and is progressively measurable.
Using the monotonicity assumption, there is a suitable $\lambda$ such that

$$
\begin{aligned}
& \frac{1}{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t)+r \int_{0}^{t}\left\|u_{1}-u_{2}\right\|_{W}^{2} d s \\
&-\lambda \int_{0}^{t}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s \\
&-\int_{0}^{t}\left\langle B \sigma\left(u_{1}\right)-B \sigma\left(u_{2}\right), \sigma\left(u_{1}\right)-\sigma\left(u_{2}\right)\right\rangle_{\mathscr{L}_{2}} d s \leq M^{*}(t)
\end{aligned}
$$

where the right side is of the form $\sup _{s \in[0, t]}|M(s)|$ where $M(t)$ is a local martingale having quadratic variation dominated by

$$
\begin{equation*}
C \int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|^{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle d s \tag{79.2.34}
\end{equation*}
$$

Then by assumption and using Gronwall's inequality, there is a constant $C=C(\lambda, K, T)$ such that

$$
\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(t) \leq C M^{*}(t)
$$

Then also, since $M^{*}$ is increasing,

$$
\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s) \leq C M^{*}(t)
$$

Taking expectations and from the Burkholder Davis Gundy inequality,

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)\right) \\
\leq C \int_{\Omega}\left(\int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|^{2}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle\right)^{1 / 2} d P \\
\leq C \int_{\Omega} \sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle^{1 / 2}(s)\left(\int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|^{2}\right)^{1 / 2} d P
\end{gathered}
$$

Then it follows after adjusting constants that there exists an inequality of the form

$$
E\left(\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)\right) \leq C E\left(\int_{0}^{t}\left\|\sigma\left(w_{1}\right)-\sigma\left(w_{2}\right)\right\|_{\mathscr{L}_{2}}^{2} d s\right)
$$

Hence

$$
\begin{gathered}
E\left(\sup _{s \in[0, t]}\left\langle B\left(u_{1}-u_{2}\right), u_{1}-u_{2}\right\rangle(s)\right) \leq C K^{2} E\left(\int_{0}^{t}\left\|w_{1}-w_{2}\right\|_{W}^{2} d s\right) \\
E\left(\sup _{s \in[0, t]}\left\|u_{1}(s)-u_{2}(s)\right\|_{W}^{2}\right) \leq C K^{2} E\left(\int_{0}^{t} \sup _{\tau \in[0, s]}\left\|w_{1}(\tau)-w_{2}(\tau)\right\|_{W}^{2} d \tau\right)
\end{gathered}
$$

You can iterate this inequality and obtain for $\psi\left(w_{i}\right)$ defined as $u_{i}$ in the above, the following inequality.

$$
\begin{aligned}
& E\left(\sup _{s \in[0, t]}\left\|\psi^{n} w_{1}-\psi^{n} w_{2}\right\|_{W}^{2}(s)\right) \\
\leq & \left(C K^{2}\right)^{n} E\left(\int_{0}^{t} \int_{0}^{t_{1}} \cdots \int_{0}^{t_{n-1}} \sup _{t_{n} \in\left[0, t_{n-1}\right]}\left\|w_{1}\left(t_{n}\right)-w_{2}\left(t_{n}\right)\right\|_{W}^{2} d t_{n} \cdots d t_{2} d t_{1}\right)
\end{aligned}
$$

Then, letting $t=T$,

$$
\begin{aligned}
E\left(\sup _{s \in[0, T]}\left\|\psi^{n} w_{1}-\psi^{n} w_{2}\right\|_{W}^{2}(s)\right) & \leq E\left(\sup _{t \in[0, T]}\left\|w_{1}(t)-w_{2}(t)\right\|^{2}\right) \frac{T^{n}}{n!} \\
& \leq \frac{1}{2} E\left(\sup _{t \in[0, T]}\left\|w_{1}-w_{2}\right\|_{W}^{2}(t)\right)
\end{aligned}
$$

provided $n$ is large enough and so $\psi$ has a high enough power a contraction map. Hence, if one begins with $w \in L^{2}(\Omega, C([0, T] ; W))$, the sequence of iterates $\left\{\psi^{n} w\right\}_{n=1}^{\infty}$ must converge to some fixed point $u$ in $L^{2}(\Omega, C([0, T], W))$. This $u$ is progressively measurable since each of the iterates is progressively measurable. This fixed point is the solution to the integral equation.

### 79.3 An Example

A model for a nonlinear beam is the Gao beam in which the transverse vibrations satisfy an equation of the form

$$
w_{t t}+w_{x x x x}+\alpha w_{t x x x x}+\left(1-w_{x}^{2}\right) w_{x x}=f
$$

To this, we can add boundary conditions and initial conditions

$$
\begin{aligned}
w(t, 0) & =w_{x}(t, 0)=w(t, 1)=w_{x}(t, 1)=0 \\
w(0, x) & =w_{0}(x), w_{t}(0, x)=v_{0}(x) \\
w_{0} & \in H_{0}^{2}((0,1))=V, v_{0} \in L^{2}((0,1))=H
\end{aligned}
$$

Also let $W$ be the closure of $V$ in $H^{1}((0,1))$ so $W=H_{0}^{1}((0,1))$. Let $H$ denote $L^{2}((0,1))$. These conditions correspond to a clamped beam. An equivalent norm on $V$ is $\|u\|_{V}=$ $\left|u_{x x}\right|_{H}$. Our theory allows us to include coefficient functions which are progressively measurable but in the interest of simplicity, this technical complication will be omitted. Also, it will follow that there is a pointwise estimate for $w_{x}(t, x)$ thanks to Sobolev embedding theorems and routine arguments involving the term $w_{x x x x}$. Therefore, in the case of a deterministic Gao beam, there is no loss of generality in replacing $w_{x}^{2}$ with $q\left(w_{x}\right)$ where $q$ is a bounded and Lipschitz continuous truncation of $r \rightarrow r^{2}$. To begin with, we make this approximation. Let $Q^{\prime}(r)=q(r)$ and $Q(0)=0$. Thus $Q$ will have linear growth for $|r|$ large and is an odd function. Define operators $L, N$ mapping $V$ to $V^{\prime}$.

$$
\langle L w, u\rangle=\int_{0}^{1} w_{x x} u_{x x} d x,\langle N w, u\rangle=\int_{0}^{1}\left(Q\left(w_{x}\right)-w_{x}\right) u_{x} d x
$$

Then in terms of these operators, and writing in terms of the velocity $v$, we obtain the following abstract formulation.

$$
v^{\prime}+\alpha L v+L w+N w=f \in \mathscr{V}^{\prime}, w(t)=w_{0}+\int_{0}^{t} v d s, v(0)=v_{0}
$$

In terms of an integral equation, this would be

$$
\begin{align*}
v(t)-v_{0}+\alpha \int_{0}^{t} L v(s) d s+\int_{0}^{t} L w d s+\int_{0}^{t} N w d s & =\int_{0}^{t} f d s \\
w(t) & =w_{0}+\int_{0}^{t} v d s \tag{79.3.35}
\end{align*}
$$

Then the abstract version of a stochastic equation is

$$
\begin{align*}
v(t)-v_{0}+\alpha \int_{0}^{t} L v(s) d s+\int_{0}^{t} L w d s+\int_{0}^{t} N w d s & =\int_{0}^{t} f d s+\int_{0}^{t} \sigma(v) d(W 9.3 .36) \\
w(t) & =w_{0}+\int_{0}^{t} v d s \tag{79.3.37}
\end{align*}
$$

where $\sigma$ will be of the form given in Theorem 79.2.1. To show existence of a solution to the above, note that by Theorem 79.2.1, if $w \in L^{2}(\Omega, C([0, T] ; V))$ with $w$ progressively measurable, then there exists a unique solution $v$ to the above integral equation 79.3.36. Let $\psi(w)(t)=w_{0}+\int_{0}^{t} v d s$. Suppose now you have $w_{i} \in L^{2}(\Omega, C([0, T] ; V))$ with $v_{i}$ being the solution corresponding to the fixed $w_{i}$. Then

$$
\begin{gathered}
v_{1}(t)-v_{2}(t)+\alpha \int_{0}^{t} L\left(v_{1}-v_{2}\right)(s) d s+\int_{0}^{t} L\left(w_{1}-w_{2}\right) d s \\
\quad+\int_{0}^{t}\left(N w_{1}-N w_{2}\right) d s=\int_{0}^{t}\left(\sigma\left(v_{1}\right)-\sigma_{2}\left(v_{2}\right)\right) d W
\end{gathered}
$$

From the Ito formula,

$$
\begin{gathered}
\left|v_{1}-v_{2}\right|_{H}^{2}+2 \alpha \int_{0}^{t}\left\|v_{1}-v_{2}\right\|_{V}^{2} d s+\int_{0}^{t}\left\langle\int_{0}^{s} L\left(w_{1}-w_{2}\right) d \tau, v_{1}(s)-v_{2}(s)\right\rangle d s+ \\
\int_{0}^{t}\left\langle\int_{0}^{s} N\left(w_{1}\right)-N\left(w_{2}\right) d \tau, v_{1}(s)-v_{2}(s)\right\rangle d s=2 \int_{0}^{t}\left\|\sigma\left(v_{1}\right)-\sigma_{2}\left(v_{2}\right)\right\|_{\mathscr{L}_{2}}^{2} d s+M(t)
\end{gathered}
$$

where the quadratic variation of $M(t)$ is

$$
\int_{0}^{t}\left\|\sigma\left(v_{1}\right)-\sigma_{2}\left(v_{2}\right)\right\|_{\mathscr{L}_{2}}^{2}\left|v_{1}-v_{2}\right|_{H}^{2} d s
$$

Using the estimates and the Lipschitz condition on $Q$, and letting $C$ be a generic constant depending on the subscripts, routine manipulations yield an inequality of the form

$$
\begin{aligned}
& \left|v_{1}-v_{2}\right|_{H}^{2}+2 \alpha \int_{0}^{t}\left\|v_{1}-v_{2}\right\|_{V}^{2} d s \leq \varepsilon \int_{0}^{t}\left\|v_{1}(s)-v_{2}(s)\right\|_{V}^{2} d s \\
& \quad+C_{\varepsilon} \int_{0}^{t} \int_{0}^{s}\left\|w_{1}-w_{2}\right\|_{V}^{2} d \tau d s+C \int_{0}^{t}\left|v_{1}-v_{2}\right|_{H}^{2} d s+M^{*}(t)
\end{aligned}
$$

Letting $\varepsilon \leq \alpha$, and modifying the constants as needed, Gronwall's inequality yields an inequality of the form

$$
\left|v_{1}-v_{2}\right|_{H}^{2}+\alpha \int_{0}^{t}\left\|v_{1}-v_{2}\right\|_{V}^{2} d s \leq C_{\alpha, T} \int_{0}^{t} \int_{0}^{s}\left\|w_{1}-w_{2}\right\|_{V}^{2} d \tau d s+C_{\alpha, T} M^{*}(t)
$$

Modifying the constants again if necessary, one obtains

$$
\sup _{s \in[0, t]}\left|v_{1}-v_{2}\right|_{H}^{2}(s)+\alpha \int_{0}^{t}\left\|v_{1}-v_{2}\right\|_{V}^{2} d s \leq C_{\alpha, T} \int_{0}^{t} \int_{0}^{s}\left\|w_{1}-w_{2}\right\|_{V}^{2} d \tau d s+C_{\alpha, T} M^{*}(t)
$$

and now, by the Burkholder Davis Gundy inequality,

$$
E\left(\sup _{s \in[0, t]}\left|v_{1}-v_{2}\right|_{H}^{2}(s)\right)+\alpha \int_{0}^{t} E\left(\left\|v_{1}-v_{2}\right\|_{V}^{2}\right) d s \leq
$$

$$
\begin{aligned}
& C_{\alpha, T} \int_{0}^{t} \int_{0}^{s} E\left(\left\|w_{1}-w_{2}\right\|_{V}^{2}\right) d \tau d s \\
& +C_{\alpha, T} \int_{\Omega}\left(\int_{0}^{t}\left\|\sigma\left(v_{1}\right)-\sigma_{2}\left(v_{2}\right)\right\|_{\mathscr{L}_{2}}^{2}\left|v_{1}-v_{2}\right|_{W}^{2} d s\right)^{1 / 2} d P
\end{aligned}
$$

Then the usual manipulations and the Lipschitz condition on $\sigma$ yields an inequality of the form

$$
\begin{gathered}
\frac{1}{2} E\left(\sup _{s \in[0, t]}\left|v_{1}-v_{2}\right|_{H}^{2}(s)\right)+\alpha \int_{0}^{t} E\left(\left\|v_{1}-v_{2}\right\|_{V}^{2}\right) d s \leq \\
\quad C_{\alpha, T} \int_{0}^{t} \int_{0}^{s} E\left(\left\|w_{1}-w_{2}\right\|_{V}^{2}\right) d \tau d s \\
\quad+C_{\alpha, T} \int_{0}^{t} E\left(\sup _{\tau \in[0, s]}\left|v_{1}-v_{2}\right|_{H}^{2}(\tau)\right) d s
\end{gathered}
$$

Thus, Gronwall's inequality yields

$$
\begin{gather*}
E\left(\sup _{s \in[0, t]}\left|v_{1}-v_{2}\right|_{H}^{2}(s)\right)+\int_{0}^{t} E\left(\left\|v_{1}-v_{2}\right\|_{V}^{2}\right) d s \\
\quad \leq C_{\alpha, T} \int_{0}^{t} \int_{0}^{s} E\left(\left\|w_{1}-w_{2}\right\|_{V}^{2}\right) d \tau d s \tag{79.3.38}
\end{gather*}
$$

Now $\psi\left(w_{i}\right)$ is defined as $w_{0}+\int_{0}^{t} v_{i} d s$ and so $\psi\left(w_{i}\right)$ is in $C([0, T] ; V)$ and from the above,

$$
\left\|\psi\left(w_{1}\right)(s)-\psi\left(w_{2}\right)(s)\right\|_{V}^{2} \leq C_{T} \int_{0}^{s}\left\|v_{1}(\tau)-v_{2}(\tau)\right\|_{V}^{2} d \tau
$$

and so

$$
\begin{aligned}
\sup _{s \in[0, t]}\left\|\psi\left(w_{1}\right)(s)-\psi\left(w_{2}\right)(s)\right\|_{V}^{2} & =\left\|\psi\left(w_{1}\right)-\psi\left(w_{2}\right)\right\|_{C([0, t] ; V)}^{2} \\
& \leq C_{T} \int_{0}^{t}\left\|v_{1}(s)-v_{2}(s)\right\|_{V}^{2} d s
\end{aligned}
$$

Using 79.3.38,

$$
\begin{gathered}
E\left(\left\|\psi\left(w_{1}\right)-\psi\left(w_{2}\right)\right\|_{C([0, t] ; V)}^{2}\right) \leq C_{T} \int_{0}^{t} E\left(\left\|v_{1}(s)-v_{2}(s)\right\|_{V}^{2}\right) d s \\
\leq C_{\alpha, T} \int_{0}^{t} \int_{0}^{s} E\left(\left\|w_{1}-w_{2}\right\|_{V}^{2}\right) d \tau d s \leq C_{\alpha, T} \int_{0}^{t} E\left(\left\|w_{1}-w_{2}\right\|_{C([0, s] ; V)}^{2}\right) d s
\end{gathered}
$$

Iterating this inequality shows that for all $n$ large enough,

$$
\left\|\psi^{n}\left(w_{1}\right)-\psi^{n}\left(w_{2}\right)\right\|_{C([0, t] ; V)}^{2} \leq \frac{1}{2}\left\|w_{1}-w_{2}\right\|_{C([0, t] ; V)}^{2}
$$

Letting $t=T$, it follows that $\psi$ has a unique progressively measurable fixed point in $L^{2}(\Omega ; C([0, T] ; V))$. The fixed point is the limit of the sequence $\left\{\psi^{n} w\right\}$ and each function in the sequence is progressively measurable. This is the unique solution to the integral equation.

This is interesting because it is an example of a stochastic equation which is second order in time. If one were to include a point mass on the beam at $x_{0}$, then this would lead to an evolution equation of the form

$$
B v(t)-v_{0}+\alpha \int_{0}^{t} L v(s) d s+\int_{0}^{t} L w d s+\int_{0}^{t} N w d s=\int_{0}^{t} f d s+B \int_{0}^{t} \sigma(v) d W
$$

where $B=I+P$ with $\langle P u, v\rangle=u\left(x_{0}\right) v\left(x_{0}\right)$. If this were done, you would need to adjust $W$ so that $B$ is the Riesz map from $W$ to $W^{\prime}$. You would use the same kind of fixed point argument that was just given. If you wished to consider quasistatic motion of the nonlinear beam in which the acceleration term $w_{t t}$ were neglected, this would involve letting $W=$ $V$ and your operator $B$ in Theorem 79.2 .1 would be given by $\langle B w, u\rangle=\int_{0}^{1} w_{x x} u_{x x}$. Thus Theorem 79.2.1 gives a way to study second order in time equations, and implicit equations in which the leading coefficient involves a self adjoint operator $B$. Without the assumption that $B$ is one to one, we can give an even more general theorem in case $\sigma$ does not depend on the solution, Corollary 79.1.8. This one allows the time differentiated term to even vanish so the differential inclusion could be degenerate. Many other examples are available. One has only to consider set valued problems, for example.

Next we consider the elimination of the truncation function. As mentioned, this is easy for a deterministic equation but not so much for the situation here. Begin with 79.3.3679.3.37 and use the Ito formula. Then

$$
\begin{gathered}
|v(t)|_{H}^{2}+2 \alpha \int_{0}^{t}\|v\|_{V}^{2} d s+2 \int_{0}^{t}\langle L w, v\rangle d s \\
+2 \int_{0}^{t}\langle N w, v\rangle d s-\int_{0}^{t}\|\sigma(v)\|^{2} d s=2 \int_{0}^{t}\langle f, v\rangle d s+M(t)
\end{gathered}
$$

where $M(t)$ is a martingale whose total variation satisfies

$$
[M](t)=\int_{0}^{t}\|\sigma(v)\|^{2}|v|_{H}^{2} d s
$$

Then, using estimates and simple manipulations, for $M^{*}(t) \equiv \sup _{s \leq t}|M(s)|$,

$$
\begin{gathered}
\frac{1}{2}|v(t)|_{H}^{2}+2 \alpha \int_{0}^{t}\|v\|_{V}^{2} d s+\|w(t)\|_{V}^{2}+2 \int_{0}^{t} \int_{0}^{1}\left(Q\left(w_{x}\right)-w_{x}\right) v_{x} d x d s \\
\leq \int_{0}^{t}\left(C+C|v|_{H}^{2}\right) d s+C\left(f, w_{0}, \omega\right)+M^{*}(t)
\end{gathered}
$$

Now let $\Psi^{\prime}=Q$ so that $\Psi(r) \geq 0$ and is quadratic for large $|r|$. Then the above implies

$$
\frac{1}{2}|v(t)|_{H}^{2}+2 \alpha \int_{0}^{t}\|v\|_{V}^{2} d s+\|w(t)\|_{V}^{2}+\int_{0}^{1} \Psi\left(w_{x}\right)-\left|w_{x}(t)\right|^{2} d x
$$

$$
\leq \int_{0}^{t}\left(C+C|v|_{H}^{2}\right) d s+C\left(f, w_{0}, \omega\right)+M^{*}(t)
$$

Using compactness of the embedding of $V$ into $W$, we can simplify this to an inequality of the following form where this involves modifying the constants $C$.

$$
\begin{aligned}
& \frac{1}{2}|v(t)|_{H}^{2}+2 \alpha \int_{0}^{t}\|v\|_{V}^{2} d s+\frac{1}{2}\|w(t)\|_{V}^{2} \\
\leq & \int_{0}^{t}\left(C+C|v|_{H}^{2}\right) d s+C\left(f, w_{0}, \omega\right)+M^{*}(t)
\end{aligned}
$$

Then, since the functions on the right are increasing in $t$, we can modify the constants again and obtain an inequality of the form

$$
\begin{aligned}
& \sup _{s \leq t}|v(s)|_{H}^{2}+\sup _{s \leq t}\|w(t)\|_{V}^{2}+\alpha \int_{0}^{t}\|v\|_{V}^{2} d s \\
\leq & \int_{0}^{t}\left(C+C|v|_{H}^{2}\right) d s+C\left(f, w_{0}, \omega\right)+C M^{*}(t)
\end{aligned}
$$

Take expectations using the Burkholder Davis Gundy inequality and estimates for $\sigma$ and obtain

$$
\begin{gathered}
E\left(\sup _{s \leq t}|v(s)|_{H}^{2}\right)+E\left(\sup _{s \leq t}\|w(t)\|_{V}^{2}\right)+E\left(\alpha \int_{0}^{t}\|v\|_{V}^{2} d s\right) \\
\leq \int_{0}^{t} E\left(C+C\left(\sup _{\tau \leq s}|v(\tau)|_{H}^{2}\right)\right) d s \\
+C\left(f, w_{0}\right)+C \int_{\Omega}\left(\int_{0}^{t}\left(\left(C+C|v|_{H}\right)^{2} \sup _{\tau \leq s}|v(\tau)|_{H}^{2}\right)\right)^{1 / 2} d P \\
\leq \int_{0}^{t} E\left(C+C\left(\sup _{\tau \leq s}|v(\tau)|_{H}^{2}\right)\right) d s+C\left(f, w_{0}\right) \\
\quad+C \int_{\Omega} \sup _{\tau \leq t}|v(\tau)|_{H}\left(\int_{0}^{t}\left(C+C|v|_{H}^{2}\right)\right)^{1 / 2} d P
\end{gathered}
$$

Using Cauchy Schwarz inequality one can simplify the above to

$$
\begin{aligned}
& E\left(\sup _{s \leq t}|v(s)|_{H}^{2}\right)+E\left(\sup _{s \leq t}\|w(t)\|_{V}^{2}\right)+E\left(\alpha \int_{0}^{t}\|v\|_{V}^{2} d s\right) \\
\leq & C\left(f, w_{0}, T\right)+C \int_{0}^{t} E\left(\sup _{\tau \leq s}|v(\tau)|_{H}^{2}\right) d s
\end{aligned}
$$

Then Gronwall's inequality implies

$$
\begin{equation*}
E\left(\sup _{s \leq t}|v(s)|_{H}^{2}\right)+E\left(\sup _{s \leq t}\|w(t)\|_{V}^{2}\right)+E\left(\alpha \int_{0}^{t}\|v\|_{V}^{2} d s\right) \leq C\left(f, w_{0}, T\right) \tag{79.3.39}
\end{equation*}
$$

Thus, letting $t=T$,

$$
\begin{equation*}
E\left(\|v\|_{C([0, T] ; H)}^{2}\right)+E\left(\|w\|_{C([0, T] ; V)}^{2}\right)+E\left(\alpha \int_{0}^{T}\|v\|_{V}^{2} d s\right) \leq C\left(f, w_{0}, T\right) \tag{79.3.40}
\end{equation*}
$$

Now let $w_{n}, v_{n}$ correspond in the above to $q_{n}$ where $q_{n}(r)=r^{2}$ for $|r| \leq 2^{n}$ and $q_{n}(r)=$ $4^{n}$ for $|r| \geq 2^{n}$. Let $N_{n}$ be the operator resulting from $q_{n}$ and let $N$ be the operator defined by

$$
\langle N w, u\rangle \equiv \int_{0}^{1}\left(\frac{w_{x}^{3}}{3}-w_{x}\right) u_{x} d x
$$

By embedding theorems, $\left\|w_{n x}\right\|_{C([0,1])} \leq C\left\|w_{x x}\right\|_{V}$. We define stopping times.

$$
\tau_{n}(\omega) \equiv \inf \left\{t \in[0, T]: C\left\|w_{n x x}(\cdot, \omega)\right\|_{C([0, t])}>2^{n}\right\}
$$

$\inf (\emptyset)$ defined as $\infty$. Then

$$
\begin{aligned}
& v_{n}^{\tau_{n}}(t)-v_{0}+\alpha \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s) L v_{n}(s) d s+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s) L w_{n} d s \\
+ & \int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s) N_{n} w_{n} d s=\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s) f d s+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]}(s) \sigma(v) d W
\end{aligned}
$$

Does $\lim _{n \rightarrow \infty} \tau_{n}=\infty$ ? If not so for some $\omega$, then there is a subsequence still denoted with $n$ such that for all $n, \tau_{n}(\omega) \leq T$. This implies

$$
C^{2}\left\|w_{n x x}(\cdot, \omega)\right\|_{C([0, T])}^{2}>4^{n}
$$

but the set of $\omega$ for which the above holds has measure no more than $C^{2} C\left(f, w_{0}, T\right) / 4^{n}$ thanks to 79.3 .40 and so there is a further subsequence and a set of measure zero such that for $\omega$ not in this set, eventually, for all $n$ large enough,

$$
C\left\|w_{n x x}(\cdot, \omega)\right\|_{C([0, T])} \leq 2^{n}
$$

which requires $\tau_{n}=\infty$, contrary to the construction of this subsequence. Thus $\tau_{n}$ converges to $\infty$ off a set of measure zero. Using uniqueness, define $v=v_{n}$ whenever $\tau_{n}=\infty$ and $w=$ $w_{n}$ whenever $\tau_{n}=\infty$. Then from the embedding theorem mentioned above, $w_{x}(t, \omega)^{2}=$ $q_{n}\left(w_{x}(t, \omega)\right)$ and so

$$
\begin{align*}
& v(t)-v_{0}+\alpha \int_{0}^{t} L v(s) d s+\int_{0}^{t} L w d s \\
& +\int_{0}^{t} N w d s=\int_{0}^{t} f d s+\int_{0}^{t} \sigma(v) d W \tag{79.3.41}
\end{align*}
$$

where

$$
\langle N w, u\rangle=\int_{0}^{1}\left(\left(\frac{w_{x}^{3}}{3}\right)-w_{x}\right) u_{x} d x
$$

Of course it would be very interesting in this example to see if you can pass to a limit as $\alpha \rightarrow 0$. We do this in the non probabilistic version of this problem quite easily, but whether it can be done in the stochastic equations considered here is not clear.

### 79.4 Stochastic Inclusions Without Uniqueness ??

We will consider strong solutions to the integral equation

$$
u(t)-u_{0}+\int_{0}^{t} z d s=\int_{0}^{t} f+\int_{0}^{t} \Phi d W
$$

where $z(t, \omega) \in A(u(t, \omega), t, \omega)$ in a situation where there is not necessarily uniqueness for the integral equation for fixed $\omega$. Uniqueness usually comes from monotonicity considerations. I am trying to eliminate these and replace with a monotonicity condition which comes from including $\varepsilon F$ for $F$ a duality map.

### 79.4.1 Estimates

In what follows $[0, T]$ will be a finite interval with no restriction on the size of $T$.
Definition 79.4.1 Recall a filtration is $\left\{\mathscr{F}_{t}\right\}, t \in[0, T]$ where each $\mathscr{F}_{t}$ is a $\sigma$ algebra of sets in $\Omega$ a probability space and these are increasing in $t$. Then the progressively measurable sets $\mathscr{P}$ are $S \subseteq \Omega$ such that

$$
S \cap[0, t] \times \Omega \text { is } \mathscr{B}([0, t]) \times \mathscr{F}_{t} \text { measurable }
$$

You can verify that this is indeed a $\sigma$ algebra of sets in $[0, T] \times \Omega$. Here $\mathscr{B}([0, t])$ is the $\sigma$ algebra of Borel measurable sets on $[0, t]$. We could have used $\mathscr{B}([0, T]) \times \mathscr{F}_{t}$ instead of $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ in the above because a set is in $\mathscr{B}([0, t])$ if and only if it is the intersection of a Borel set of $[0, T]$ with $[0, t]$. We will always assume that each $\mathscr{F}_{t}$ contains all the sets of measure zero of $\mathscr{F}_{T}$.

We will assume all Banach spaces are separable in what follows.
We will assume $U \subseteq V \subseteq H=H^{\prime} \subseteq V^{\prime} \subseteq U^{\prime}$ where the inclusion map of $V$ into the Hilbert space $H$ is compact and $V$ is dense in $H$ and $U$ is a Banach space which is dense and compact in $V$. One can always obtain such a space. In fact one can always have $U$ be a Hilbert space. In practice this is most easily seen from Sobolev embedding theorems but the existence of this space follows from general abstract considerations.

Then for $p>1$, define

$$
\mathscr{V} \equiv L^{p}([0, T] \times \Omega ; V), \mathscr{U} \equiv L^{r}([0, T] \times \Omega ; V), r \geq \max (2, p)
$$

It follows that the dual space $\mathscr{V}^{\prime}$ can be identified in the usual way as $L^{p^{\prime}}([0, T] \times \Omega ; V)$. Similarly $\mathscr{H}$ will be defined as $L^{2}([0, T] \times \Omega ; H)$. In each instance the relevant $\sigma$ algebra will be the progressively measurable sets. A set $A \subseteq \Omega \times[0, T]$ is progressively measurable if

$$
A \cap[0, t] \times \Omega \in \mathscr{F}_{t} \times \mathscr{B}([0, t])
$$

where $\mathscr{B}([0, t])$ denotes the Borel sets of $[0, t]$, equivalently the intersections of a Borel set of $[0, T]$ with $[0, t]$.

Also define $\mathscr{V}_{\omega}$ as $L^{p}([0, T] ; V)$ where the subscript $\omega$ indicates that $\omega$ is fixed. Let $\mathscr{H}_{\omega}$ and $\mathscr{U}_{\omega}$ be defined similarly. We will assume the following on $A: V \times[0, T] \times \Omega \rightarrow \mathscr{P}\left(V^{\prime}\right)$.

1. $A(\cdot, t, \omega): V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is pseudomonotone and bounded: $A(u, t, \omega)$ is a closed convex set for each $(t, \omega), u \rightarrow A(u, t, \omega)$ is bounded, and if $u_{n} \rightarrow u$ weakly and

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0, z_{n} \in A\left(u_{n}, t, \omega\right)
$$

then for any $v \in V$,

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle \text { some } z(v) \in A(u, t, \omega)
$$

2. $A(\cdot, t, \omega)$ satisfies the estimates: There exists $b_{1} \geq 0$ and $b_{2} \geq 0$, such that

$$
\begin{equation*}
\|z\|_{V^{\prime}} \leq b_{1}\|u\|_{V}^{p-1}+b_{2}(t, \omega) \tag{79.4.42}
\end{equation*}
$$

for all $z \in A(u, t, \omega), b_{2}(\cdot, \cdot) \in L^{p^{\prime}}([0, T] \times \Omega)$.
3. There exists a positive constant $b_{3}$ and a nonnegative function $b_{4}$ that is $\mathscr{B}([0, T]) \times$ $\mathscr{F}_{T}$ measurable and also $b_{4}(\cdot, \cdot) \in L^{1}([0, T] \times \Omega)$, such that for some $\lambda \geq 0$,

$$
\begin{equation*}
\inf _{z \in A(u, t, \omega)}\langle z, u\rangle \geq b_{3}\|u\|_{V}^{p}-b_{4}(t, \omega)-\lambda|u|_{H}^{2} \tag{79.4.43}
\end{equation*}
$$

One can often reduce to the case that $\lambda=0$ by using an exponential shift argument.
4. The mapping $(t, \omega) \rightarrow A(u(t, \omega), t, \omega)$ is measurable in the sense that

$$
(t, \omega) \rightarrow A(u(t, \omega), t, \omega)
$$

is a progressively measurable multifunction with respect to $\mathscr{P}$ whenever $(t, \omega) \rightarrow$ $u(t, \omega)$ is in $\mathscr{V} \equiv \mathscr{V}_{p} \equiv L^{p}([0, T] \times \Omega ; V, \mathscr{P})$.

As mentioned one can often reduce to the case where $\lambda=0$ in 3 . Indeed, let $A(u, t, \omega)$ be single valued for the sake of simplicity. Let

$$
w=e^{-\lambda t} u
$$

where $u$ satisfies

$$
u(t)-u_{0}+\frac{1}{n} \int_{0}^{t} F u d s+\int_{0}^{t} A(u, t, \omega) d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W
$$

Then this amounts to

$$
\left(u-\int_{0}^{(\cdot)} \Phi d W\right)^{\prime}+\frac{1}{n} F u+A(u, t, \omega)=f, u(0)=u_{0}
$$

In terms of $w$, this is

$$
\left(e^{\lambda(\cdot)} w-e^{\lambda(\cdot)} \int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W\right)^{\prime}+\frac{1}{n} F\left(e^{\lambda(\cdot)} w\right)+A\left(e^{\lambda(\cdot)} w, t, \omega\right)=f, u(0)=u_{0}
$$

and this reduces to

$$
\begin{gathered}
\lambda e^{\lambda(\cdot)}\left(w-\int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W\right)+e^{\lambda(\cdot)}\left(w-\int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W\right)^{\prime} \\
+\frac{1}{n} F\left(e^{\lambda(\cdot)} w\right)+A\left(e^{\lambda(\cdot)} w, t, \omega\right)=f
\end{gathered}
$$

and this reduces to

$$
\begin{gathered}
\lambda\left(w-\int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W\right)+\left(w-\int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W\right)^{\prime} \\
+e^{-\lambda(\cdot)} \frac{1}{n} F\left(e^{\lambda(\cdot)} w\right)+e^{-\lambda(\cdot)} A\left(e^{\lambda(\cdot)} w, t, \omega\right)=e^{-\lambda(\cdot)} f, w(0)=u_{0}
\end{gathered}
$$

which implies

$$
\begin{aligned}
& \left(w-\int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W\right)^{\prime}+\lambda w+e^{-\lambda(\cdot)} \frac{1}{n} F\left(e^{\lambda(\cdot)} w\right) \\
+e^{-\lambda(\cdot)} A\left(e^{\lambda(\cdot)} w, t, \omega\right)= & \lambda \int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W+e^{-\lambda(\cdot)} f, w(0)=u_{0}
\end{aligned}
$$

which is equivalent to

$$
w(t)+\int_{0}^{t} e^{-\lambda(\cdot)} \frac{1}{n} F\left(e^{\lambda(\cdot)} w\right) d s+\int_{0}^{t} \lambda w+e^{-\lambda(\cdot)} A\left(e^{\lambda s} w(s), s, \omega\right) d s=\int_{0}^{t} \hat{f}(s) d s
$$

where $\hat{f}(\cdot)=e^{-\lambda(\cdot)} f+\lambda \int_{0}^{(\cdot)} e^{-\lambda(\cdot)} \Phi d W$. You can consider $\tilde{A}(w, t, \omega) \equiv e^{-\lambda t} A\left(e^{\lambda t} w, t, \omega\right)$. This satisfies similar conditions to $A$. If $F$ were a linear Riesz map, then you would get the same type of problem but with $\lambda=0$ for $\lambda$ large enough. It may work in other cases also.

Definition 79.4.2 Let A be given above. Then $z \in \hat{A}(u)$ means that for $u \in \mathscr{V}, z(t, \omega) \in$ $A(u(t, \omega), t, \omega)$ for a.e. $(t, \omega), z \in V^{\prime}$

Thus $\hat{A}: \mathscr{V} \rightarrow \mathscr{P}\left(\mathscr{V}^{\prime}\right)$. Now let $F$ be the duality map from $U$ to $U^{\prime}$ which satisfies

$$
\langle F u, u\rangle=\|u\|_{U}^{r},\|F u\|=\|u\|^{r-1}, r \geq \max (2, p)
$$

Thus $r$ is at least 2 . We assume that $u_{0} \in L^{2}(\Omega ; H)$ and is $\mathscr{F}_{0}$ measurable and for each $n$ there exist $\left(u_{n}, z_{n}\right)$ a progressively measurable solution to the integral equation

$$
\begin{equation*}
u_{n}(t)-u_{0}+\frac{1}{n} \int_{0}^{t} F u_{n} d s+\int_{0}^{t} z_{n} d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W, z_{n} \in \hat{A}\left(u_{n}\right), f \in \mathscr{V} p^{\prime} \tag{79.4.44}
\end{equation*}
$$

in $\mathscr{U}_{\omega}{ }^{\prime}$. This would be the case if $\lambda I+\frac{1}{n} F+A$ were monotone for large enough $\lambda$. Such theorems are now well known and versions of them are in [108]. The message here is about going from the solution to the regularized problem to one which is missing the $F$ term for which $A$ might not be monotone. Therefore, we assume the existence of such a
progressively measurable solution $(u, z)$ to 79.4 .44. Is it possible that without the $\frac{1}{n} F$ it might never happen that $\lambda I+A$ is monotone and yet still have appropriate estimates for $A$ ? I don't have any examples right now. Thus it is not clear that this gives anything new.

The other consideration is a usable limit condition on Nemytskii operators, $\hat{A}$ described in the following lemma. Probably the earliest solution to this problem was given in [17]. These ideas were extended to set valued maps in [18] and to implicit evolution inclusions in [85]. Here the nonlinear operators will depend not just on $t$ but also on $\omega$ where $\omega \in \Omega$ for $(\Omega, \mathscr{F}, P)$ a probability space.

Lemma 79.4.3 Let A be as described above in 1-4. Then for $u \in \mathscr{V}, \hat{A}(u)$ is a closed and convex and bounded subset of $\mathscr{V}^{\prime}$.

Proof: It is clear that $\hat{A}(u)$ is convex. Indeed, if $z, w$ are in this set, and $\lambda \in[0,1]$, then $(\lambda z+(1-\lambda) w)(t, \omega) \in A(u(t, \omega), t, \omega)$ for $(t, \omega)$ off the union of the two exceptional sets corresponding to $z, w$. Now let $\left\{z_{n}\right\}$ be a sequence in $\hat{A}(u)$ which converges to $z$ in $\mathscr{V}^{\prime}$. Then pass to a subsequence which converges pointwise a.e. Let an exceptional set be the union of the exceptional sets for each $z_{n}$. Thus, off some set of measure zero $\Sigma$, $z_{n}(t, \omega) \in A(u(t, \omega), t, \omega)$ and we have $z_{n}(t, \omega) \rightarrow z(t, \omega)$ for $(t, \omega)$ off this exceptional set of measure zero. Now the fact that $A(u, t, \omega)$ is closed for $u \in V$ shows that $z(t, \omega) \in$ $A(u(t, \omega), t, \omega)$.

Definition 79.4.4 For $S$ a set in $[0, T] \times \Omega, S_{\omega}$ will denote $\{t:(t, \omega) \in S\}$.

### 79.4.2 A Limit Theorem

We will make use of the following fundamental measurable selection lemma. It is proved in [87]. We will use this lemma in the context where the measurable space is $(\Omega \times[0, T], \mathscr{P})$ where $\mathscr{P}$ is the $\sigma$ algebra of progressively measurable sets.

Lemma 79.4.5 Let $\Omega$ be a set and let $\mathscr{F}$ be a $\sigma$ algebra of subsets of $\Omega$. Let $U$ be a separable reflexive Banach space. Suppose there is a sequence $\left\{u_{j}(\omega)\right\}_{j=1}^{\infty}$ in $U$, where each $\omega \rightarrow u_{j}(\omega)$ is measurable and for each $\omega, \sup _{i}\left\|u_{i}(\omega)\right\|<\infty$. Then, there exists $u(\omega) \in U$ such that $\omega \rightarrow u(\omega)$ is measurable into $U$, and a subsequence $n(\omega)$, that depends on $\omega$, such that the weak limit

$$
\lim _{n(\omega) \rightarrow \infty} u_{n(\omega)}(\omega)=u(\omega)
$$

holds.
Next we derive some considerations of solutions to 79.4.44. From the Ito formula in 79.4.44,

$$
\begin{gather*}
\frac{1}{2}\left|u_{n}(t)\right|_{H}^{2}-\frac{1}{2}\left|u_{0}\right|_{H}^{2}+\frac{1}{n} \int_{0}^{t}\left\langle F u_{n}, u_{n}\right\rangle d s+\int_{0}^{t}\left\langle z_{n}, u_{n}\right\rangle d s \\
\quad-\frac{1}{2} \int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s=\int_{0}^{t}\left\langle f, u_{n}\right\rangle d s+M_{n}(t) \tag{79.4.45}
\end{gather*}
$$

where $M_{n}(t)$ is a local martingale whose quadratic variation is

$$
\left[M_{n}\right](t) \leq C \int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2}\left|u_{n}\right|_{H}^{2} d s
$$

Then estimates give $\left\|\frac{1}{n}\left\langle F u_{n}, u_{n}\right\rangle\right\|_{\mathscr{U}^{\prime}}$ bounded as well as

$$
\begin{equation*}
\left\|u_{n}\right\|_{\mathscr{V}},\left\|z_{n}\right\|_{\mathscr{V}^{\prime}} \tag{79.4.46}
\end{equation*}
$$

One takes expectation of 79.4.45 using an appropriate localizing sequence of stopping times if necessary. It follows that there is a subsequence, still denoted with $n$ such that

$$
\begin{align*}
u_{n} & \rightarrow u \text { weakly in } \mathscr{V}  \tag{79.4.47}\\
z_{n} & \rightarrow z \text { weakly in } \mathscr{V}^{\prime} \\
\frac{1}{n} F u_{n} & \rightarrow 0 \text { strongly in } \mathscr{U}^{\prime}
\end{align*}
$$

The last convergence follows from the following argument.

$$
\begin{aligned}
& \int_{0}^{T} \int_{\Omega} \frac{1}{n}\left\langle F u_{n}, w\right\rangle d P d t \\
\leq & \int_{0}^{T} \int_{\Omega} \frac{1}{n^{1 / r^{\prime}}}\left\langle F u_{n}, u_{n}\right\rangle^{1 / r^{\prime}} \frac{1}{n^{1 / r}}\langle F w, w\rangle^{1 / r} d P d t \\
\leq & \left(\int_{0}^{T} \int_{\Omega} \frac{1}{n}\left\langle F u_{n}, u_{n}\right\rangle d P d t\right)^{1 / r^{\prime}}\left(\int_{0}^{T} \int_{\Omega} \frac{1}{n}\|w\|^{r} d P d t\right)^{1 / r} \\
\leq & C \frac{1}{n^{1 / r}}\|w\|_{\mathscr{U}}
\end{aligned}
$$

and so

$$
\left\|\frac{1}{n} F u_{n}\right\|_{\mathscr{U}^{\prime}} \leq \frac{C}{n^{1 / r}}
$$

Recall

$$
\begin{aligned}
& u_{n}(t)-u_{0}+\frac{1}{n} \int_{0}^{t} F u_{n} d s+\int_{0}^{t} z_{n} d s \\
= & \int_{0}^{t} f d s+\int_{0}^{t} \Phi d W, z_{n} \in \hat{A}\left(u_{n}\right)
\end{aligned}
$$

Then if $\phi \in \mathscr{U}$,

$$
\begin{gathered}
\left\langle\frac{1}{n} \int_{0}^{(\cdot)} F u_{n} d s+\int_{0}^{(\cdot)} z_{n} d s, \phi\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}} \\
=\int_{\Omega} \int_{0}^{T}\left\langle\left(\frac{1}{n} \int_{0}^{r} F u_{n} d s+\int_{0}^{r} z_{n} d s\right), \phi(r, \omega)\right\rangle_{U^{\prime}, U} d r d P
\end{gathered}
$$

Then the above equals

$$
\int_{\Omega} \int_{0}^{T} \frac{1}{n} \int_{0}^{r}\left\langle F u_{n}(s, \omega), \phi(r, \omega)\right\rangle d s d r d P+\int_{0}^{r}\left\langle z_{n}(s, \omega), \phi(r, \omega)\right\rangle d s d r d P
$$

$$
\begin{aligned}
= & \int_{\Omega} \int_{0}^{T} \int_{s}^{T}\left\langle\frac{1}{n} F u_{n}(s, \omega), \phi(r, \omega)\right\rangle d r d s d P \\
& +\int_{\Omega} \int_{0}^{T} \int_{s}^{T}\left\langle z_{n}(s, \omega), \phi(r, \omega)\right\rangle d r d s d P \\
= & \int_{\Omega} \int_{0}^{T}\left\langle\frac{1}{n} F u_{n}(s, \omega), \int_{s}^{T} \phi(r, \omega) d r\right\rangle d s d P \\
& +\int_{\Omega} \int_{0}^{T}\left\langle z_{n}(s, \omega), \int_{s}^{T} \phi(r, \omega) d r\right\rangle d s d P
\end{aligned}
$$

Now $(s, \omega) \rightarrow \int_{s}^{T} \phi(r, \omega) d r$ is also in $\mathscr{U}$ and so the above weak convergences and estimates yield that in the limit, this becomes

$$
\begin{aligned}
& \int_{\Omega} \int_{0}^{T}\left\langle z(s, \omega), \int_{s}^{T} \phi(r, \omega) d r\right\rangle_{U^{\prime}, U} d s d P \\
= & \int_{\Omega} \int_{0}^{T}\left\langle\int_{0}^{r} z d s, \phi(r, \omega)\right\rangle_{U^{\prime}, U} d r d P
\end{aligned}
$$

Thus $u_{n}$ must converge in $\mathscr{U}^{\prime}$ to

$$
u_{0}-\int_{0}^{(\cdot)} z d s+\int_{0}^{(\cdot)} f d s+\int_{0}^{(\cdot)} \Phi d W
$$

Therefore, when passing to a limit, one obtains from 79.4.44

$$
\begin{equation*}
u(\cdot)-u_{0}+\int_{0}^{(\cdot)} z d s=\int_{0}^{(\cdot)} f d s+\int_{0}^{(\cdot)} \Phi d W \text { in } \mathscr{U}_{\omega}^{\prime} \text { for a.e. } \omega \tag{79.4.48}
\end{equation*}
$$

All functions are continuous except the first so we define it so that the above holds pointwise in $t$. Thus, with 79.4.44, off a set of measure zero,

$$
\begin{align*}
u_{n}(t)-u_{0}+\frac{1}{n} \int_{0}^{t} F u_{n} d s+\int_{0}^{t} z_{n} d s & =\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W \\
u(t)-u_{0}+\int_{0}^{t} z d s & =\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W \tag{79.4.49}
\end{align*}
$$

Note that these are now equations which hold for each $t$ for $\omega$ off a set of measure zero. Then it follows that for a.e. $\omega$

$$
\begin{gather*}
\left\|u_{n}(t)+\int_{0}^{t} z_{n} d s-\left(u(t)+\int_{0}^{t} z d s\right)\right\|_{U^{\prime}} \\
=\left\|\frac{1}{n} \int_{0}^{t} F u_{n} d s\right\|_{U^{\prime}} \leq \int_{0}^{T} \frac{1}{n}\left\|F u_{n}\right\| d s \tag{79.4.50}
\end{gather*}
$$

Let $n_{k}>k$ be the first index such that if $l \geq n_{k}$, then

$$
\int_{\Omega} \int_{0}^{T} \frac{1}{l}\left\|F u_{l}\right\| d s d P<4^{-k}
$$

Then

$$
\begin{gathered}
P\left(\omega: \sup _{t \in[0, T]}\left\|u_{n_{k}}(t)+\int_{0}^{t} z_{n_{k}} d s-\left(u(t)+\int_{0}^{t} z d s\right)\right\|_{U^{\prime}}>2^{-k}\right) \\
\leq 2^{k} \int_{\Omega} \int_{0}^{T} \frac{1}{n_{k}}\left\|F u_{n_{k}}\right\| d s d P<2^{-k}
\end{gathered}
$$

Therefore there is a subsequence still denoted with $n$ such that

$$
P\left(\omega: \sup _{t \in[0, T]}\left\|u_{n}(t)+\int_{0}^{t} z_{n} d s-\left(u(t)+\int_{0}^{t} z d s\right)\right\|_{U^{\prime}}>2^{-n}\right) \leq 2^{-n}
$$

It follows that there is a set of measure zero $N$ such that if $\omega \notin N$, then $\omega$ is in only finitely many of the above sets. That is, for $\omega \notin N$,

$$
\sup _{t \in[0, T]}\left\|u_{n}(t, \omega)+\int_{0}^{t} z_{n}(s, \omega) d s-\left(u(t, \omega)+\int_{0}^{t} z(s, \omega) d s\right)\right\|_{U^{\prime}}<2^{-n}
$$

for all $n$ large enough.
Lemma 79.4.6 There is a set of measure zero $N$, an enlargement of the earlier set such that for $\omega \notin N$, and a suitable subsequence, still denoted with n, such that

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left(u_{n}(t, \omega)+\int_{0}^{t} z_{n}(s, \omega) d s\right)=u(t, \omega)+\int_{0}^{t} z(s, \omega) d s \text { in } U^{\prime} \tag{79.4.51}
\end{equation*}
$$

for each $t \in[0, T]$. In addition to this, for $\omega \notin N$,

$$
\begin{equation*}
\left\|u_{n}(t, \omega)-u_{0}(\omega)+\int_{0}^{t}\left(z_{n}(s, \omega)-f(s, \omega)\right) d s-\int_{0}^{t} \Phi d W\right\|_{U^{\prime}} \rightarrow 0 \tag{79.4.52}
\end{equation*}
$$

Proof: The formula 79.4 .51 follows from the above discussion. The second claim follows from the first and the equation satisfied by $u$ 79.4.49.

In the situation of 79.4.44, can we conclude that for the subsequence of Lemma 79.4.6,

$$
\begin{equation*}
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{U}^{\prime}, \mathscr{U}} \leq 0 ? \tag{79.4.53}
\end{equation*}
$$

Let $\left\{e_{k}\right\}$ be a complete orthonormal set in $H$, dense in $H$, with each vector in $U$. Thus

$$
\begin{equation*}
u_{n}(t, \omega)=\sum_{k}\left(u_{n}(t, \omega), e_{k}\right)_{H} e_{k},\left|u_{n}(t, \omega)\right|^{2}=\sum_{k}\left(u_{n}(t, \omega), e_{k}\right)^{2} \tag{79.4.54}
\end{equation*}
$$

The following claim is the key idea which will yield 79.4.53.
Claim: $\liminf _{n \rightarrow \infty}\left(u_{n}(t, \omega), e_{k}\right)^{2} \geq\left(u(t, \omega), e_{k}\right)^{2}$ for a.e. $(t, \omega)$.
Proof of claim: Let $B_{\varepsilon}$ be those $(t, \omega)$ such that

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left(u_{n}(t, \omega), e_{k}\right)^{2} \leq\left(u(t, \omega), e_{k}\right)^{2}-\varepsilon
$$

and consider $I(w) \equiv \int_{B_{\varepsilon}}\left(w(t, \omega), e_{k}\right)^{2} d(P \times m)$, the measure being product measure. Then $I$ is clearly convex and strongly lower semicontinuous on

$$
\mathscr{H} \equiv L^{2}(\Omega \times[0, T] ; H)
$$

To see that this is strongly lower semicontinuous, suppose $w_{n} \rightarrow w$ in $\mathscr{H}$ but

$$
\lim _{n \rightarrow \infty} \inf _{n} I\left(w_{n}\right)<I(w)
$$

Then take a subsequence, still denoted with $n$ such that the liminf equals lim. Then take a further subsequence, still denoted with $n$ such that $w_{n}(t, \omega) \rightarrow w(t, \omega)$ for a.e. $(t, \omega)$. Then by Fatou's lemma,

$$
I(w) \leq \lim \inf _{n \rightarrow \infty} I\left(w_{n}\right)<I(\omega)
$$

a contradiction. Thus $I$ is strongly lower semicontinuous as claimed. By convexity, it is also weakly lower semicontinuous. Hence by the weak convergence of $u_{n}$ to $u$ 79.4.47,

$$
\begin{gathered}
\lim \inf _{n \rightarrow \infty} \int_{B_{\varepsilon}}\left(u_{n}(t, \omega), e_{k}\right)^{2} d(P \times m) \geq \int_{B_{\varepsilon}}\left(u(t, \omega), e_{k}\right)^{2} d(P \times m) \\
\quad \geq \int_{B_{\varepsilon}} \lim _{n \rightarrow \infty}\left(u_{n}(t, \omega), e_{k}\right)^{2} d(P \times m)+\varepsilon(P \times m)\left(B_{\varepsilon}\right)
\end{gathered}
$$

Thus $(P \times m)\left(B_{\varepsilon}\right)=0$. Since this is so for each $\varepsilon>0$, it must be the case that the claimed inequality is satisfied off a set of measure zero. Let $\Sigma$ denote this progressively measurable set of product measure zero.

Let

$$
\begin{aligned}
& M_{\varepsilon} \equiv\left\{t:(t, \omega) \in \Sigma \text { for } \omega \text { in a set of measure larger than } \varepsilon, N_{\varepsilon}\right\} \\
& \qquad M_{\varepsilon} \equiv\left\{t: \int_{\Omega} \mathscr{X}_{\Sigma}(t, \omega) d P>\varepsilon\right\}
\end{aligned}
$$

If this set has positive measure, then

$$
m\left(M_{\varepsilon}\right) \varepsilon \leq \int_{M_{\varepsilon}} \int_{\Omega} \mathscr{X}_{\Sigma}(t, \omega) d P d t \leq(P \times m)(\Sigma)=0 .
$$

Thus each $M_{\varepsilon}$ has measure zero and so, taking the union of $M_{\varepsilon}$ for $\varepsilon$ a sequence converging to 0 , it follows that for $t \notin M$, defined as $\cup_{\varepsilon} M_{\varepsilon},(t, \omega)$ is in $\Sigma$ only for $\omega$ in a set of measure $\leq \varepsilon$ for each $\varepsilon$. Thus for $t \notin M,(t, \omega)$ is in $\Sigma$ only for $\omega$ in a set of measure zero. Letting $t \notin M$, it follows from 79.4.54 that for a.e. $\omega$

$$
\begin{aligned}
\lim _{n \rightarrow \infty}\left|u_{n}(t, \omega)\right|^{2} & =\lim _{n \rightarrow \infty} \inf _{k}\left(u_{n}(t, \omega), e_{k}\right)^{2} \\
& \geq \sum_{k} \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left(u_{n}(t, \omega), e_{k}\right)^{2} \\
& \geq \sum_{k}\left(u(t, \omega), e_{k}\right)^{2}=|u(t, \omega)|_{H}^{2}
\end{aligned}
$$

Therefore, from Fatou's lemma, for such $t$,

$$
\lim \inf _{n \rightarrow \infty} \int_{\Omega}\left|u_{n}(t, \omega)\right|^{2} d P \geq \int_{\Omega} \lim \inf _{n \rightarrow \infty}\left|u_{n}(t, \omega)\right|^{2} d P \geq \int_{\Omega}|u(t, \omega)|_{H}^{2} d P
$$

This has proved the following fundamental result.

Lemma 79.4.7 There exists a set $M \subseteq[0, T]$ having measure zero such that for $t \notin M$,

$$
\lim \inf _{n \rightarrow \infty} \int_{\Omega}\left|u_{n}(t, \omega)\right|^{2} d P \geq \int_{\Omega}|u(t, \omega)|_{H}^{2} d P
$$

We will always assume $T \notin M$ because otherwise, we could complete the argument with $\hat{T} \notin M$ arbitrarily close to $T$ and then draw the desired conclusions or settle for drawing the desired conclusions with $[0, \hat{T}]$ replacing $[0, T]$ where $\hat{T}$ is a fixed number as close to $T$ as desired. Note that the inequality is only strengthened by going to a subsequence.

Then from the Ito formula and 79.4.44,

$$
\begin{gather*}
\frac{1}{2}\left|u_{n}(T)\right|_{H}^{2}-\frac{1}{2}\left|u_{0}\right|_{H}^{2}+\frac{1}{n} \int_{0}^{T}\left\langle F u_{n}, u_{n}\right\rangle d s+\int_{0}^{T}\left\langle z_{n}, u_{n}\right\rangle d s \\
\quad-\frac{1}{2} \int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s=\int_{0}^{T}\left\langle f, u_{n}\right\rangle d s+M_{n}(T) \tag{79.4.55}
\end{gather*}
$$

where $M_{n}(t)$ is a local martingale, $M(0)=0$. Therefore,

$$
\begin{gathered}
\int_{\Omega} \int_{0}^{T}\left\langle z_{n}, u_{n}\right\rangle d s d P \leq \\
\int_{\Omega} \int_{0}^{T}\left\langle f, u_{n}\right\rangle d s d P-\frac{1}{2} \int_{\Omega}\left(\left|u_{n}(T)\right|_{H}^{2}\right) d P+\frac{1}{2} \int_{\Omega}\left(\left|u_{0}\right|^{2}\right) d P \\
+\frac{1}{2} \int_{\Omega} \int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s d P+\overbrace{\int_{\Omega} M_{n}(T) d P}^{=0}
\end{gathered}
$$

To make more precise, one would use a localizing sequence of stopping times for the local martingale, take expectations and then pass to a limit, but the end result will be as above. Then taking limsup $\sin _{n \rightarrow \infty}$ of both sides and using Lemma 79.4.7,

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} \sup _{\Omega} \int_{0}^{T}\left\langle z_{n}, u_{n}\right\rangle d s d P \\
\leq & \int_{\Omega} \int_{0}^{T}\langle f, u\rangle d s d P-\frac{1}{2} \lim _{n \rightarrow \infty} \inf _{\Omega}\left|u_{n}(T)\right|_{H}^{2} d P \\
& +\frac{1}{2} \int_{\Omega}\left(\left|u_{0}\right|^{2}\right) d P+\frac{1}{2} \int_{\Omega} \int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s d P \\
\leq & \int_{\Omega} \int_{0}^{T}\langle f, u\rangle d s d P+\frac{1}{2} \int_{\Omega}\left(\left|u_{0}\right|^{2}\right) d P \\
& +\frac{1}{2} \int_{\Omega} \int_{0}^{T}| | \Phi \|_{\mathscr{L}_{2}}^{2} d s d P-\frac{1}{2} \int_{\Omega}|u(T)|_{H}^{2} d P
\end{aligned}
$$

On the other hand, from 79.4.48 and the Ito formula,

$$
\begin{aligned}
\langle z, u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}= & \int_{\Omega} \int_{0}^{T}\langle f, u\rangle d s d P+\frac{1}{2} \int_{\Omega}\left(\left|u_{0}\right|^{2}\right) d P \\
& +\frac{1}{2} \int_{\Omega} \int_{0}^{T}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s d P-\frac{1}{2} \int_{\Omega}|u(T)|_{H}^{2} d P
\end{aligned}
$$

and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq\langle z, u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

Now it follows that

$$
\begin{equation*}
\limsup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq\langle z, u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}-\langle z, u\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0 \tag{79.4.56}
\end{equation*}
$$

Thus in the situation of 79.4.44, we get 79.4.56. We state this as the following lemma.
Lemma 79.4.8 Suppose $u_{n}, z_{n}$ are progressively measurable, $z_{n} \in \hat{A}\left(u_{n}\right)$, and

$$
u_{n}(t)-u_{0}+\frac{1}{n} \int_{0}^{t} F u_{n} d s+\int_{0}^{t} z_{n} d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W
$$

Then there is a subsequence, still denoted with $n$ such that 79.4 .56 holds.
Now the following is the main limit lemma which is a statement about this subsequence satisfying 79.4.56. This lemma gives a useable limit condition for the Nemytskii operators.
Lemma 79.4.9 Suppose conditions 1-79.4.2 hold. Also, suppose $U$ is a separable Banach space dense in $V$, a reflexive separable Banach space and $V$ is dense in a Hilbert space $H$ identified with its dual space. Thus

$$
U \subseteq V \subseteq H=H^{\prime} \subseteq V^{\prime} \subseteq U^{\prime}
$$

Hypotheses: For $f \in \mathscr{V}^{\prime}$

$$
\begin{gather*}
u_{n}(t)-u_{0}+\frac{1}{n} \int_{0}^{t} F u_{n} d s+\int_{0}^{t} z_{n} d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W \text { in } U^{\prime}  \tag{**}\\
u_{n} \text { and } z_{n} \text { are } \mathscr{P} \text { measurable } \\
u_{n} \rightarrow u \text { weakly in } \mathscr{V}, z_{n} \rightarrow z \text { weakly in } \mathscr{U}^{\prime} \\
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0, \tag{*}
\end{gather*}
$$

Note that from the above discussion, * follows ** from taking a suitable subsequence. Assume also that for some set of measure zero $N$, if $\omega \notin N$,

$$
\begin{equation*}
\sup _{t \in[0, T]} \lambda\left|u_{n}(t, \omega)\right|_{H}^{2} \leq C(\omega), C(\cdot) \in L^{1}(\Omega) \tag{79.4.57}
\end{equation*}
$$

(Since we are assuming that $\lambda=0$ in 3, this condition is automatic, but if you did have 79.4.57 for $\lambda>0$, then the following argument will show how to use it.)

Conclusion: If the above conditions hold, then there exists a further subsequence, still denoted with $n$ such that for any $v \in \mathscr{V}$, there exists $z(v) \in \hat{A}(u)$ with

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\langle z(v), u-v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

Also $z \in \hat{A}(u)$ and $u, z$ are progressively measurable and

$$
u(t)-u_{0}+\int_{0}^{t} z d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W \text { in } V^{\prime}
$$

for all $\omega$ off a set of measure zero.

Proof: In the following argument, $N$ will be a set of measure zero containing the one of Lemma 79.4.6 and the sequence will always be a subsequence of the subsequence of that lemma. Recall that from Lemma 79.4.6, that for $\omega \notin N$,

$$
\left\|\begin{array}{c}
u_{n}(t, \omega)-u_{0}(\omega)  \tag{79.4.58}\\
+\int_{0}^{t}\left(z_{n}(s, \omega)-f(s, \omega)\right) d s-\int_{0}^{t} \Phi d W
\end{array}\right\|_{U^{\prime}} \rightarrow 0
$$

for this sequence which does not depend on $\omega$ or $t$. From now on, this or a further subsequence will be meant.

From the hypothesis,

$$
\begin{equation*}
u_{n} \rightarrow u \text { weakly in } \mathscr{V}, z_{n} \rightarrow z \text { weakly in } \mathscr{V}^{\prime} \tag{79.4.59}
\end{equation*}
$$

Thus

$$
\begin{equation*}
u(t)-u_{0}+\int_{0}^{t} z d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W \text { for a.e. } \omega \tag{79.4.60}
\end{equation*}
$$

and so

$$
\begin{equation*}
\left\|u(t)-u_{0}+\int_{0}^{t} z d s-\left(\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W\right)\right\|_{U^{\prime}}=0 \tag{79.4.61}
\end{equation*}
$$

Note that in these weak convergences 79.4.59, we can assume the $\sigma$ algebra is just $\mathscr{B}([0, T]) \times \mathscr{F}_{T}$ because the progressive measurability will be preserved in the limit due to the Pettis theorem and the progressive measurability of each $u_{n}, z_{n}$. However, we could also let the $\sigma$ algebra be $\mathscr{P}$ the progressively measurable sets just as well.

Claim: There is a set of measure zero $N$, including the one obtained so far such that for $\omega \notin N$

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \geq 0
$$

for a.e. $t$. The exceptional set, denoted as $M_{\omega}$ includes those $t$ for which some $z_{n}(t, \omega) \notin$ $A\left(u_{n}(t, \omega), t, \omega\right)$.

Let $\omega \notin N$ and $t \notin M_{\omega}$. First take a subsequence such that liminf = lim. Then suppose that

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle<0
$$

Then from the estimates, one can obtain that for a suitable subsequence, $u_{n}(t, \omega) \rightarrow$ $\psi(t, \omega)$ weakly in $V$. Note, $n=n(t, \omega)$. Here is why: From the above inequality, there exists a subsequence $\left\{n_{k}\right\}$, which may depend on $t, \omega$, such that

$$
\begin{align*}
& \lim _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-u(t, \omega)\right\rangle  \tag{79.4.62}\\
= & \lim _{n \rightarrow \infty} \inf _{n}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle<0 . \tag{79.4.63}
\end{align*}
$$

Now, condition 3 implies that for all $k$ large enough,

$$
\begin{align*}
& b_{3}\left\|u_{n_{k}}(t, \omega)\right\|_{V}^{p}-b_{4}(t, \omega)-\lambda\left|u_{n_{k}}(t, \omega)\right|_{H}^{2} \\
< & \left\|z_{n_{k}}(t, \omega)\right\|_{V^{\prime}}\|u(t, \omega)\|_{V} \\
\leq & \left(b_{1}\left\|u_{n_{k}}(t, \omega)\right\|_{V}^{p-1}+b_{2}(t, \omega)\right)\|u(t, \omega)\|_{V} \tag{79.4.64}
\end{align*}
$$

it follows from 79.4.57 that $\left\|u_{n_{k}}(t, \omega)\right\|_{V}$ and consequently $\left\|z_{n_{k}}(t, \omega)\right\|_{V^{\prime}}$ are bounded. Thus, denoting this subsequence with $n$, there is a further subsequence for which $u_{n}(t, \omega) \rightarrow$ $\psi(t, \omega)$ weakly in $V$ which was what was claimed.

But also, it follows from Lemma 79.4.6 that for $\omega \notin N$,

$$
\left\|u_{n}(t, \omega)-u_{0}(\omega)+\int_{0}^{t}\left(z_{n}(s, \omega)-f(s, \omega)\right) d s-\int_{0}^{t} \Phi d W\right\|_{U^{\prime}} \rightarrow 0
$$

where $n$ doesn't depend on $(t, \omega)$.
By convexity, Lemma 79.4.6, and weak semicontinuity considerations, it must be the case that

$$
\begin{aligned}
& \left\|\psi(t, \omega)-u_{0}(\omega)+\int_{0}^{t}(z(s, \omega)-f(s, \omega)) d s-\int_{0}^{t} \Phi d W\right\|_{U^{\prime}} \\
\leq & \lim _{n \rightarrow \infty}\left\|+\int_{0}^{t}\left(z_{n}(s, \omega)-f(s, \omega)\right) d s-\int_{0}^{t} \Phi d W\right\|_{U^{\prime}}=0
\end{aligned}
$$

Here $n=n(t, \omega)$ is a subsequence. But of course, this requires $\psi(t, \omega)=u(t, \omega)$ in $U^{\prime}$ thanks to 79.4 .60 and so in fact, $u_{n}(t, \omega) \rightarrow u(t, \omega)$ weakly.

Now, 79.4.62 and the limit conditions for pseudomonotone operators imply that the liminf condition holds. There exists $z_{\infty} \in A(u(t, \omega), t, \omega)$ such that

$$
\begin{aligned}
& \lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \\
\geq & \left\langle z_{\infty}, u(t, \omega)-u(t, \omega)\right\rangle=0 \\
> & \lim _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-u(t, \omega)\right\rangle \\
= & \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle
\end{aligned}
$$

which is a contradiction. This completes the proof of the claim.
It follows from this claim that for given $\omega$ off a set of measure zero and $t \notin M_{\omega}$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \geq 0 \tag{79.4.65}
\end{equation*}
$$

Also, it is assumed that

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0
$$

This continues holding for subsequences. From the estimates,

$$
\begin{aligned}
& \int_{\Omega} \int_{0}^{T}\left(b_{3}\left\|u_{n}(t, \omega)\right\|_{V}^{p}-b_{4}(t, \omega)-\lambda\left|u_{n}(t, \omega)\right|_{H}^{2}\right) d t d P \\
\leq & \int_{\Omega} \int_{0}^{T}\|u(t, \omega)\|_{V}\left(\left\|u_{n}(t, \omega)\right\|_{V}^{p-1} b_{1}+b_{2}\right) d t d P
\end{aligned}
$$

so it is routine to get $\left\|u_{n}\right\|_{\mathscr{V}}$ is bounded. This follows from the assumptions, in particular 79.4.57.

Now, the coercivity condition 3 shows that if $y \in \mathscr{V}$, then

$$
\begin{aligned}
\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-y(t, \omega)\right\rangle \geq & b_{3}\left\|u_{n}(t, \omega)\right\|_{V}^{p}-b_{4}(t, \omega)-\lambda\left|u_{n}(t, \omega)\right|_{H}^{2} \\
& -\left(b_{1}\left\|u_{n}(t, \omega)\right\|^{p-1}+b_{2}(t, \omega)\right)\|y(t, \omega)\|_{V}
\end{aligned}
$$

Using $p-1=\frac{p}{p^{\prime}}$, where $\frac{1}{p}+\frac{1}{p^{\prime}}=1$, the right-hand side of this inequality equals

$$
\begin{aligned}
& b_{3}\left\|u_{n}(t, \omega)\right\|_{V}^{p}-b_{4}(t, \omega)-b_{1}\left\|u_{n}(t, \omega)\right\|^{p / p^{\prime}}\|y(t, \omega)\|_{V} \\
& -b_{2}(t, \omega)\|y(t, \omega)\|_{V}-\lambda\left|u_{n}(t, \omega)\right|_{H}^{2}
\end{aligned}
$$

the last term being bounded by a function in $L^{1}([0, T] \times \Omega)$ by assumption. Thus there exists $c_{y}(\cdot, \cdot) \in L^{1}([0, T] \times \Omega)$ and a positive constant $C$ such that

$$
\begin{equation*}
\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-y(t, \omega)\right\rangle \geq-c_{y}(t, \omega)-C\|y(t, \omega)\|_{V}^{p} . \tag{79.4.66}
\end{equation*}
$$

Letting $y=u$, we use Fatou's lemma to write

$$
\begin{gathered}
{\lim \inf _{n \rightarrow \infty}}^{\int_{\Omega}} \int_{0}^{T}\left(\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle+c_{u}(t, \omega)+C\|u(t, \omega)\|_{V}^{p}\right) d t d P \geq \\
\int_{\Omega} \int_{0}^{T} \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle+\left(c_{u}(t, \omega)+C\|u(t, \omega)\|_{V}^{p}\right) d t d P \\
\geq \int_{\Omega} \int_{0}^{T}\left(c_{u}(t, \omega)+C\|u(t, \omega)\|_{V}^{p}\right) d t d P
\end{gathered}
$$

Here, we added the term $c_{u}(t, \omega)+C\|u(t, \omega)\|_{V}^{p}$ to make the integrand nonnegative in order to apply Fatou's lemma. Thus,

$$
\lim \inf _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle d t d P \geq 0
$$

Consequently, using the claim in the last inequality,

$$
\begin{aligned}
0 & \geq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
& \geq \lim _{n \rightarrow \infty} \inf _{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle d t d P \\
& \geq \int_{\Omega} \int_{0}^{T} \lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle d t d P \geq 0
\end{aligned}
$$

hence, we find that

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0 \tag{79.4.67}
\end{equation*}
$$

We need to show that if $y$ is given in $\mathscr{V}$ then

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\langle z(y), u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}, \quad z(y) \in \hat{A} u
$$

Suppose to the contrary that there exists $y$ such that

$$
\begin{equation*}
\eta=\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}<\langle\tilde{z}, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \tag{79.4.68}
\end{equation*}
$$

for all $\tilde{z} \in \hat{A} u$. Take a subsequence, denoted still with subscript $n$ such that

$$
\eta=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

Note that this subsequence does not depend on $(t, \omega)$. Thus

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}<\langle\tilde{z}, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \text { for all } \tilde{z} \in \hat{A} u \tag{79.4.69}
\end{equation*}
$$

We will obtain a contradiction to this. In what follows, we continue to use the subsequence just described which satisfies the above inequality 79.4.69.

The estimate 79.4.66 implies,

$$
\begin{equation*}
0 \leq\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} \leq c(t, \omega)+C\|u(t, \omega)\|_{V}^{p} \tag{79.4.70}
\end{equation*}
$$

where $c$ is a function in $L^{1}([0, T] \times \Omega)$. Thanks to 79.4.65,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \geq 0, \text { a.e. }
$$

and, therefore, the following pointwise limit exists,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-}=0, \text { a.e. }
$$

and so we may apply the dominated convergence theorem using 79.4.70 and conclude

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P \\
= & \int_{\Omega} \int_{0}^{T} \lim _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P=0
\end{aligned}
$$

Now, it follows from 79.4.67 and the above equation, that

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{+} d t d P \\
= & \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \\
& +\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P \\
= & \lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0 .
\end{aligned}
$$

Therefore, both

$$
\int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{+} d t d P
$$

and

$$
\int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P
$$

converge to 0 , thus,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left|\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle\right| d t d P=0 \tag{79.4.71}
\end{equation*}
$$

From the above, it follows that there exists a further subsequence $\left\{n_{k}\right\}$ not depending on $t, \omega$ such that

$$
\begin{equation*}
\left|\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-u(t, \omega)\right\rangle\right| \rightarrow 0 \quad \text { a.e. }(t, \omega) . \tag{79.4.72}
\end{equation*}
$$

By the pseudomonotone limit condition for $A$ there exists $w_{t, \omega} \in A(u(t, \omega), t, \omega)$ such that for a.e. $(t, \omega)$

$$
\begin{aligned}
\alpha(t, \omega) & \equiv \lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-y(t, \omega)\right\rangle \\
& =\lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u(t, \omega)-y(t, \omega)\right\rangle \geq\left\langle w_{t, \omega}, u(t, \omega)-y(t, \omega)\right\rangle
\end{aligned}
$$

Note that $u$ is progressively measurable and if $A(\cdot, t, \omega)$ were single valued, this would give a contradiction at this point. We continue with the case where $A$ is set valued. This case will make use of the measurable selection in Lemma 79.4.5.

On the exceptional set, let $\alpha(t, \omega) \equiv \infty$, and consider the set

$$
F(t, \omega) \equiv\{w \in A(u(t, \omega), t, \omega):\langle w, u(t, \omega)-y(t, \omega)\rangle \leq \alpha(t, \omega)\}
$$

which then satisfies $F(t, \omega) \neq \emptyset$. Now $F(t, \omega)$ is closed and convex in $V^{\prime}$.
We will let $\Sigma$ be a progressively measurable set of measure zero which includes

$$
N \times[0, T] \cup\left\{(t, \omega): \omega \notin N^{C}, t \in M_{\omega}\right\}
$$

Claim $*:(t, x) \rightarrow F(t, \omega)$ has a $\mathscr{P}$ measurable selection off a set of measure zero.
Proof of claim: Letting $B(0, C(t, \omega))$ contain $A(u(t, \omega), t, \omega)$, we can assume $(t, \omega) \rightarrow$ $C(t, \omega)$ is $\mathscr{P}$ measurable by using the estimates and the measurability of $u$. For $\gamma \in \mathbb{N}$, let $S_{\gamma} \equiv\{(t, \omega): C(t, \omega)<\gamma\}$. If it is shown that $F$ has a measurable selection on $S_{\gamma}$, then it follows that it has a measurable selection. Thus in what follows, assume that $(t, \omega) \in S_{\gamma}$.

Define for $(t, \omega) \in S_{\gamma}$

$$
G(t, \omega) \equiv\left\{w:\langle w, u(t, \omega)-y(t, \omega)\rangle<\alpha(t, \omega)+\frac{1}{n},(t, \omega) \in \Sigma^{C} \cap S_{\gamma}\right\} \cap B(0, \gamma)
$$

Thus, it was shown above that this $G(t, \omega) \neq \emptyset$ at least for large enough $\gamma$ that $S_{\gamma} \neq \emptyset$. For $U$ open, $G^{-}(U)$ is defined by

$$
G^{-}(U) \equiv\left\{\begin{array}{c}
(t, \omega) \in S_{\gamma}: \text { for some } w \in U \cap B(0, \gamma)  \tag{*}\\
\langle w, u(t, \omega)-y(t, \omega)\rangle<\alpha(t, \omega)+\frac{1}{n}
\end{array}\right\}
$$

Let $\left\{w_{j}\right\}$ be a dense subset of $U \cap B(0, \gamma)$. This is possible because $V^{\prime}$ is separable. The expression in $*$ equals

$$
\cup_{k=1}^{\infty}\left\{(t, \omega) \in S_{\gamma}:\left\langle w_{k}, u(t, \omega)-y(t, \omega)\right\rangle<\alpha(t, \omega)+\frac{1}{n}\right\}
$$

which is $\mathscr{P}$ measurable. Thus $G$ is a measurable multifunction.
Since $(t, \omega) \rightarrow G(t, \omega)$ is measurable, there is a sequence $\left\{w_{n}(t, \omega)\right\}$ of measurable functions such that $\overline{\cup_{n=1}^{\infty} w_{n}(t, \omega)}$ equals

$$
\overline{G(t, \omega)}=\left\{w:\langle w, u(t, \omega)-y(t, \omega)\rangle \leq \alpha(t, \omega)+\frac{1}{n},(t, \omega) \notin \Sigma\right\} \cap \overline{B(0, \gamma)}
$$

As shown above, there exists $w_{t, \omega}$ in $A(u(t, \omega), t, \omega)$ as well as $G(t, \omega)$. Thus there is a sequence of $w_{r}(t, \omega)$ converging to $w_{t, \omega}$. Of course $r$ will need to depend on $t, \omega$. Since $(t, \omega) \rightarrow A(u(t, \omega), t, \omega)$ is a $\mathscr{P}$ measurable multifunction, it has a countable subset of $\mathscr{P}$ measurable functions $\left\{z_{k}(t, \omega)\right\}$ which is dense in $A(u(t, \omega), t, \omega)$. Let $U_{k}$ be defined as

$$
U_{k}(t, \omega) \equiv \cup_{m} B\left(z_{m}(t, \omega), \frac{1}{k}\right) \subseteq A(u(t, \omega), t, \omega)+B\left(0, \frac{2}{k}\right)
$$

Now define $A_{1 k}=\left\{(t, \omega): w_{1}(t, \omega) \in U_{k}(t, \omega)\right\}$. Then let

$$
A_{2 k}=\left\{(t, \omega) \notin A_{1 k}: w_{2}(t, \omega) \in U_{k}(t, \omega)\right\}
$$

and

$$
A_{3 k}=\left\{(t, \omega) \notin \cup_{i=1}^{2} A_{i k}: w_{3}(t, \omega) \in U_{k}(t, \omega)\right\}
$$

and so forth. Any $(t, \omega) \in S_{\gamma}$ must be contained in one of these $A_{r k}$ for some $r$ since if not so, there would not be a sequence $w_{r}(t, \omega)$ converging to $w_{t, \omega} \in A(u(t, \omega), t, \omega)$. These $A_{r k}$ partition $S_{\gamma} \backslash \Sigma$ and each is measurable since the $\left\{z_{k}(t, \omega)\right\}$ are measurable. Let

$$
\hat{w}_{k}(t, \omega) \equiv \sum_{r=1}^{\infty} \mathscr{X}_{A_{r k}}(t, \omega) w_{r}(t, \omega)
$$

Thus $\hat{w}_{k}(t, \omega)$ is in $U_{k}(t, \omega)$ for all $(t, \omega) \in S_{\gamma}$ and equals exactly one of the $w_{m}(t, \omega) \in$ $\overline{G(t, \omega)}$.

Also, by construction, the $\hat{w}_{k}(\cdot, \cdot)$ are bounded in $L^{\infty}\left(S_{\gamma} ; V^{\prime}\right)$. Therefore, there is a subsequence of these, still called $\hat{w}_{k}$ which converges weakly to a function $w$ in $L^{2}\left(S_{\gamma} ; V^{\prime}\right)$. Thus $w$ is a weak limit point of $\operatorname{co}\left(\cup_{j=k}^{\infty} \hat{w}_{j}\right)$ for each $k$. Therefore, in the open ball $B\left(w, \frac{1}{k}\right) \subseteq L^{2}\left(S_{\gamma} ; V^{\prime}\right)$ with respect to the strong topology, there is a convex combination $\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}$ (the $c_{j k}$ add to 1 and only finitely many are nonzero) which converges strongly in $L^{2}\left(S_{\gamma} ; V^{\prime}\right)$. Since $\overline{G(t, \omega)}$ is convex and closed, this convex combination is in $\overline{G(t, \omega)}$. Off a set of $\mathscr{P}$ measure zero, we can assume this convergence of $\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}$ as $k \rightarrow \infty$ happens pointwise a.e. for a suitable subsequence. However,

$$
\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}(t, \omega) \in U_{k}(t, \omega) \subseteq A(u(t, \omega), t, \omega)+B\left(0, \frac{2}{k}\right)
$$

Thus $w(t, \omega) \in A(u(t, \omega), t, \omega)$ a.e. $(t, \omega)$ because $A(u(t, \omega), t, \omega)$ is a closed set. Since $w$ is the pointwise limit of measurable functions off a set of measure zero, it can be assumed measurable and for a.e. $(t, \omega), w(t, \omega) \in A(u(t, \omega), t, \omega) \cap \overline{G(t, \omega)}$. Now denote this measurable function $w_{n}$. Then

$$
w_{n}(t, \omega) \in A(u(t, \omega), t, \omega),\left\langle w_{n}(t, \omega), u(t, \omega)-y(t, \omega)\right\rangle \leq \alpha(t, \omega)+\frac{1}{n} \text { a.e. }(t, \omega)
$$

These $w_{n}(t, \omega)$ are bounded for each $(t, \omega)$ off a set of measure zero and so by Lemma 79.4.5, there is a $\mathscr{P}$ measurable function $(t, \omega) \rightarrow \hat{z}(t, \omega)$ and a subsequence $w_{n(t, \omega)}(t, \omega) \rightarrow$ $\hat{z}(t, \omega)$ weakly as $n(t, \omega) \rightarrow \infty$. Now $A(u(t, \omega), t, \omega)$ is closed and convex, and $w_{n(t, \omega)}(t, \omega)$ is in $A(u(t, \omega), t, \omega)$, and so $\hat{z}(t, \omega) \in A(u(t, \omega), t, \omega)$ and

$$
\begin{equation*}
\langle\hat{z}(t, \omega), u(t, \omega)-y(t, \omega)\rangle \leq \alpha(t, \omega)=\lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-y(t, \omega)\right\rangle \tag{**}
\end{equation*}
$$

Therefore, $t \rightarrow F(t, \omega)$ has a measurable selection on $S_{\gamma}$ excluding a set of measure zero, namely $\hat{z}(t, \omega)$ which will be called $\hat{z}_{\gamma}(t, \omega)$ in what follows.

Then $F(t, \omega)$ has a measurable selection on $[0, T] \times \Omega$ other than a set of measure zero. To see this, enlarge $\Sigma$ to include the exceptional sets of measure zero in the above argument for each $\gamma$. Then partition $[0, T] \times \Omega \backslash \Sigma$ as follows. For $\gamma=1,2, \cdots$, consider $S_{\gamma} \backslash S_{\gamma-1}, \gamma=1,2, \cdots$ for $S_{0}$ defined as $\emptyset$. Then letting $\hat{z}_{\gamma}$ be the selection for $(t, \omega) \in S_{\gamma}$, let $\tilde{z}(t, \omega)=\sum_{\gamma=1}^{\infty} \hat{z}_{\gamma}(t, \omega) \mathscr{X}_{S_{\gamma} \backslash S_{\gamma-1}}(t, \omega)$. The estimates imply $\tilde{z} \in \mathscr{V}^{\prime}$ and so $\tilde{z} \in \hat{A}(u)$.

From the estimates, there exists $h \in L^{1}([0, T] \times \Omega)$ such that

$$
\langle\tilde{z}(t, \omega), u(t, \omega)-y(t, \omega)\rangle \geq-|h(t, \omega)|
$$

Thus, from the above inequality,

$$
\begin{aligned}
& \|h\|_{L^{1}}+\langle\tilde{z}, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
& \leq \int_{\Omega} \int_{0}^{T} \lim _{k \rightarrow \infty} \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-y(t, \omega)\right\rangle+|h(t, \omega)| d t d P \\
& \leq \lim _{k \rightarrow \infty} \inf \left\langle z_{n_{k}}, u_{n_{k}}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\|h\|_{L^{1}} \\
& \quad=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\|h\|_{L^{1}}
\end{aligned}
$$

which contradicts 79.4.69.
Finally, why is $z \in \hat{A}(u)$ ? We have shown that $(t, \omega) \rightarrow F(t, \omega)$ has a measurable selection. Thus, there exists for any $y \in \mathscr{V}, \tilde{z}(y) \in \hat{A}(u)$ such that for a.e. $(t, \omega)$,

$$
\langle\tilde{z}(y)(t, \omega), u(t, \omega)-y(t, \omega)\rangle \leq \lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u(t, \omega)-y(t, \omega)\right\rangle
$$

Using the same trick involving the estimates and Fatou's lemma, there exists $\tilde{z}$ depending on $y$ such that $\tilde{z}(y) \in \hat{A}(u)$ and

$$
\langle\tilde{z}(y), u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq \lim _{k \rightarrow \infty} \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}, u-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=\langle z, u-y\rangle
$$

It follows that since $y$ is arbitrary, it must be the case that $z \in \hat{A}(u)$ thanks to separation theorems and the fact that $\hat{A}(u)$ is convex and closed.

An examination of the above proof yields the following corollary.
Corollary 79.4.10 Replace $\frac{1}{n} F u_{n}$ with $e_{n}$ where $e_{n}$ is progressively measurable and

$$
\left\|e_{n}\right\|_{\mathscr{U}^{\prime}} \rightarrow 0,\left\|e_{n}(\cdot, \omega)\right\|_{\mathscr{U}_{\omega}^{\prime}} \rightarrow 0
$$

where the second convergence happens for each $\omega$ off a set of measure zero and keep the other assumptions the same. Then the same conclusion is obtained.

### 79.4.3 The Main Theorem

We first consider an easier problem and then obtain the result by taking limits. Let $U$ be a Banach space that is compactly embedded and dense in $V$. Also, let $F: U \rightarrow U^{\prime}$ be the duality map

$$
\langle F u, u\rangle=\|u\|_{U}^{r}, \quad\|F u\|_{U^{\prime}}=\|u\|_{U}^{r-1}
$$

where $r>\max (2, p)$. Such a Banach space always exists and is important in probability theory where $(i, U, V)$ is an abstract Wiener space but you can also get it in most applications to partial differential equations from Sobolev embedding theorems. Then the above has proved the following main theorem.

Theorem 79.4.11 Suppose 1-79.4.2 with $\lambda=0$, and suppose $f$ is progressively measurable and is in $L^{p^{\prime}}\left(\Omega ; L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)\right)$. Also let $F$ be the duality map for $r \geq \max (2, p)$ which maps $U$ to $U^{\prime}$ for $U$ a separable Banach space contained and dense in $V$. Let

$$
\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} H, H\right)\right) \cap L^{2}\left(\Omega ; L^{\infty}\left([0, T] ; \mathscr{L}_{2}\left(Q^{1 / 2} H, H\right)\right)\right)
$$

Also suppose that for each $n \in \mathbb{N}$, there is a progressively measurable $u_{n}, z_{n}$ such that

$$
u_{n}(t)-u_{0}+\frac{1}{n} \int_{0}^{t} F u_{n} d s+\int_{0}^{t} z_{n} d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W, z_{n} \in \hat{A}\left(u_{n}\right)
$$

Then there exists a solution $u, z$ to the inclusion

$$
u(t)-u_{0}+\int_{0}^{t} z d s=\int_{0}^{t} f d s+\int_{0}^{t} \Phi d W, z \in \hat{A}(u) \text { in } \mathscr{U}_{\omega}^{\prime}
$$

where both $u, z$ are progressively measurable. If $U$ is compact in $V$ and if for every $\varepsilon>0$ there exists $\mu_{\varepsilon} \geq 0$ such that $u \rightarrow \mu_{\varepsilon} u+\varepsilon F u+A u$ is strictly monotone as a map from $U$ to $U^{\prime}$, then the above hypothesis is satisfied.

The reason for assuming $\lambda=0$ is that it is hard to show 79.4.57 otherwise. As noted, it may be possible to reduce to this case using an exponential shift argument. Other than that, it appears you almost have to have $A+\mu I$ monotone for suitable $\mu$ which would end up yielding uniqueness. This is because in order to get the necessary estimates, you would need to have a Cauchy sequence for certain martingales in $M_{T}^{2}$ an appropriate space of continuous martingales. This will end up requiring an assumption of monotonicity. If $\Phi=0$ then of course there would be no problem. Right now, I don't have good examples.

The significant thing about this is that there may be no uniqueness of solutions to the evolution inclusion for fixed $\omega$ but there exists a progressively measurable solution. The case where $\Phi$ is replaced by $\sigma(u)$ is currently unsolved as far as I know unless one has uniqueness of the evolution inclusion for fixed $\omega$. It may well be possible to do something on this in case $\sigma$ is Lipschitz continuous. I don't know yet. If $\sigma$ is only continuous, I am pretty sure this will not be possible because there are examples where strong solutions do not exist. It should be possible to consider

$$
B u(t)-B u_{0}+\int_{0}^{t} z d s=\int_{0}^{t} f d s+B \int_{0}^{t} \Phi d W
$$

where $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ being self adjoint and one to one by using a more technical Ito formula. However, this has not been done. A non probabilitic version is in [85]. I don't know how to resolve the problem in which $B$ is only nonnegative. Good results are certainly available in the non probabilistic setting without the stochastic integral. Some were presented earlier.

## Appendix A

## The Hausdorff Maximal Theorem

First is a review of the definition of a partially ordered set.
Definition A.0.1 A nonempty set $\mathscr{F}$ is called a partially ordered set if it has a partial order denoted by $\prec$. This means it satisfies the following. If $x \prec y$ and $y \prec z$, then $x \prec z$. Also $x \prec x$. It is like $\subseteq$ on the set of all subsets of a given set. It is not the case that given two elements of $\mathscr{F}$ that they are related. In other words, you cannot conclude that either $x \prec y$ or $y \prec x$. A chain, denoted by $\mathscr{C} \subseteq \mathscr{F}$ has the property that it is totally ordered meaning that if $x, y \in \mathscr{C}$, either $x \prec y$ or $y \prec x$. A maximal chain is a chain $\mathscr{C}$ which has the property that there is no strictly larger chain. In other words, if $x \in \mathscr{F} \backslash \cup \mathscr{C}$, then $\mathscr{C} \cup\{x\}$ is no longer a chain so $x$ fails to be related to something in $\mathscr{C}$.

Here is the Hausdorff maximal theorem. The proof is a proof by contradiction. We assume there is no maximal chain and then show this cannot happen. The axiom of choice is used in choosing the $x_{\mathscr{C}}$ right at the beginning of the argument.

Theorem A.0.2 Let $\mathscr{F}$ be a nonempty partially ordered set with order $\prec$. Then there exists a maximal chain.

Proof: Suppose no chain is maximal. Then, from the axiom of choice, for each chain $\mathscr{C}$ there exists $x_{\mathscr{C}} \in \mathscr{F} \backslash \cup \mathscr{C}$ such that $\mathscr{C} \cup\left\{x_{\mathscr{C}}\right\}$ is a chain. For $\mathscr{C}$ a chain, let $\theta \mathscr{C}$ denote $\mathscr{C} \cup\left\{x_{\mathscr{C}}\right\}$. Thus for $\mathscr{C}$ a chain, $\theta \mathscr{C}$ is a larger chain which has exactly one more element of $\mathscr{F}$. Since $\mathscr{F} \neq \emptyset$, pick $x_{0} \in \mathscr{F}$. Note that $\left\{x_{0}\right\}$ is a chain. Let $\mathscr{X}$ be the set of all chains $\mathscr{C}$ such that $x_{0} \in \cup \mathscr{C}$. Thus $\mathscr{X}$ contains $\left\{x_{0}\right\}$. Call two chains comparable if one is a subset of the other. Then summarizing,

1. $x_{0} \in \cup \mathscr{C}$ for all $\mathscr{C} \in \mathscr{X}$.
2. $\left\{x_{0}\right\} \in \mathscr{X}$
3. If $\mathscr{C} \in \mathscr{X}$ then $\theta \mathscr{C} \in \mathscr{X}$.
4. If $\mathscr{S} \subseteq \mathscr{X}$ is nonempty and every pair of chains in $\mathscr{S}$ is comparable, then $\cup \mathscr{S}$ is also a chain in $\mathscr{X}$.

A subset $\mathscr{Y}$ of $\mathscr{X}$ will be called a "tower" if $\mathscr{Y}$ satisfies 1.) - 4.). Let $\mathscr{Y}_{0}$ be the intersection of all towers. Then $\mathscr{Y}_{0}$ is also a tower, the smallest one. Then the next claim might seem to be so because if not, $\mathscr{Y}_{0}$ would not be the smallest tower.

Claim 1: If $\mathscr{C}_{0} \in \mathscr{Y}_{0}$ is comparable to every chain $\mathscr{C} \in \mathscr{Y}_{0}$, then if $\mathscr{C}_{0} \subsetneq \mathscr{C}$, it must be the case that $\theta \mathscr{C}_{0} \subseteq \mathscr{C}$. In other words, $x_{\mathscr{C}_{0}} \in \mathscr{C}$. The symbol $\subsetneq$ indicates proper subset.

This is done by considering a set $\mathscr{B} \subseteq \mathscr{Y}_{0}$ consisting of $\mathscr{D}$ which acts like $\mathscr{C}$ in the above and showing that it actually equals $\mathscr{\mathscr { Y }}_{0}$ because it is a tower.

Proof of Claim 1: Consider $\mathscr{B} \equiv\left\{\mathscr{D} \in \mathscr{Y}_{0}: \mathscr{D} \subseteq \mathscr{C}_{0}\right.$ or $\left.x_{\mathscr{C}_{0}} \in \cup \mathscr{D}\right\}$. Let $\mathscr{Y}_{1} \equiv \mathscr{Y}_{0} \cap \mathscr{B}$. I want to argue that $\mathscr{Y}_{1}$ is a tower. By definition all chains of $\mathscr{Y}_{1}$ contain $x_{0}$ in their unions. If $\mathscr{D} \in \mathscr{Y}_{1}$, is $\boldsymbol{\theta} \mathscr{D} \in \mathscr{Y}_{1}$ ?

If $\mathscr{S}$ is a nonempty subset of $\mathscr{Y}_{1}$ is $\mathscr{D} \equiv \cup \mathscr{S} \in \mathscr{Y}_{1} ? \mathscr{D}$ is in $\mathscr{Y}_{0}$ and so it is comparable to $\mathscr{C}_{0}$. If $\mathscr{D} \subseteq \mathscr{C}_{0}$, then it is in $\mathscr{B}$. Otherwise $\mathscr{D} \supseteq \mathscr{C}_{0}$ and in this case, why is $\mathscr{D}$ in $\mathscr{B}$ ? Why is $x_{\mathscr{C}_{0}} \in \cup \mathscr{D}$ ? The chains of $\mathscr{S}$ are in $\mathscr{B}$ so one of them, called $\tilde{C}$ must properly contain $\mathscr{C}_{0}$ and so $x_{\mathscr{C}_{0}} \in \cup \tilde{\mathscr{C}} \subseteq \cup \mathscr{D}$. Therefore, $\mathscr{D} \in \mathscr{B} \cap \mathscr{Y}_{0}=\mathscr{Y}_{1}$. Two cases remain to show that $\mathscr{Y}_{1}$ satisfies 3.).
case 1: $\mathscr{D} \supseteq \mathscr{C}_{0}$. Then $x_{\mathscr{C}_{0}} \in \cup \mathscr{D}$ and so $x_{\mathscr{C}_{0}} \in \cup \theta \mathscr{D}$ so $\theta \mathscr{D} \in \mathscr{Y}_{1}$.
case 2: $\mathscr{D} \subseteq \mathscr{C}_{0}$. Then $\theta \mathscr{D} \in \mathscr{T}_{0}$ by definition of $\mathscr{Y}_{0}$ and if $\theta \mathscr{D} \supseteq \mathscr{C}_{0}$, it follows that $\mathscr{D} \subseteq \mathscr{C}_{0} \varsubsetneqq \mathscr{D} \cup\left\{x_{\mathscr{D}}\right\}$. If $x \in \mathscr{C}_{0} \backslash \mathscr{D}$ then $x=x_{\mathscr{D}}$. This is where having $\theta \mathscr{C}$ contain exactly one more element of $\mathscr{F}$ is used. But then

$$
\mathscr{C}_{0} \varsubsetneqq \mathscr{D} \cup\left\{x_{\mathscr{D}}\right\} \subseteq \mathscr{C}_{0} \cup\left\{x_{\mathscr{D}}\right\}=\mathscr{C}_{0}
$$

the last equality coming because $x_{\mathscr{D}} \in \mathscr{C}_{0}$. The above is nonsense, and so $\mathscr{C}_{0}=\mathscr{D}$ so $x_{\mathscr{D}}=x_{\mathscr{C}_{0}} \in \cup \theta \mathscr{C}_{0}=\cup \theta \mathscr{D}$ and so $\theta \mathscr{D} \in \mathscr{Y}_{1}$. If $\theta \mathscr{D} \subseteq \mathscr{C}_{0}$ then right away $\theta \mathscr{D} \in \mathscr{B}$. Thus $\mathscr{B}=\mathscr{Y}_{0}$ because $\mathscr{Y}_{1}$ cannot be smaller than $\mathscr{Y}_{0}$. In particular, if $\mathscr{D} \supseteq \mathscr{C}_{0}$, then $x_{\mathscr{C}_{0}} \in \cup \mathscr{D}$ or in other words, $\theta \mathscr{C}_{0} \subseteq \mathscr{D}$.

Claim 2: Any two chains in $\mathscr{Y}_{0}$ are comparable so if $\mathscr{C} \subsetneq \mathscr{D}$, then $\theta \mathscr{C} \subseteq \mathscr{D}$.
Proof of Claim 2: Let $\mathscr{Y}_{1}$ consist of all chains of $\mathscr{Y}_{0}$ which are comparable to every chain of $\mathscr{Y}_{0}$. (Like $\mathscr{C}_{0}$ above.) I want to show that $\mathscr{Y}_{1}$ is a tower. Let $\mathscr{C} \in \mathscr{Y}_{1}$ and $\mathscr{D} \in \mathscr{Y}_{0}$. Since $\mathscr{C}$ is comparable to all chains in $\mathscr{Y}_{0}$, either $\mathscr{C} \subsetneq \mathscr{D}$ or $\mathscr{C} \supseteq \mathscr{D}$. I need to show that $\theta \mathscr{C}$ is comparable with $\mathscr{D}$. The second case is obvious so consider the first that $\mathscr{C} \subsetneq \mathscr{D}$. By Claim $1, \boldsymbol{\theta} \mathscr{C} \subseteq \mathscr{D}$. Since $\mathscr{D}$ is arbitrary, this shows that $\mathscr{Y}_{1}$ is a tower. Hence $\mathscr{Y}_{1}=\mathscr{Y}_{0}$ because $\mathscr{Y}_{0}$ is as small as possible. It follows that every two chains in $\mathscr{Y}_{0}$ are comparable and so if $\mathscr{C} \subsetneq \mathscr{D}$, then $\theta \mathscr{C} \subseteq \mathscr{D}$.

Since every pair of chains in $\mathscr{Y}_{0}$ are comparable and $\mathscr{Y}_{0}$ is a tower, it follows that $\cup \mathscr{Y}_{0} \in \mathscr{Y}_{0}$ so $\cup \mathscr{Y}_{0}$ is a chain. However, $\theta \cup \mathscr{Y}_{0}$ is a chain which properly contains $\cup \mathscr{Y}_{0}$ and since $\mathscr{Y}_{0}$ is a tower, $\theta \cup \mathscr{Y}_{0} \in \mathscr{Y}_{0}$. Thus $\cup\left(\theta \cup \mathscr{Y}_{0}\right) \supseteq \cup\left(\cup \mathscr{Y}_{0}\right) \supseteq \cup\left(\theta \cup \mathscr{Y}_{0}\right)$ which is a contradiction. Therefore, for some chain $\mathscr{C}$ it is impossible to obtain the $x_{C}$ described above and so, this $\mathscr{C}$ is a maximal chain.

If $X$ is a nonempty set,$\leq$ is an order on $X$ if

$$
x \leq x
$$

and if $x, y \in X$, then

$$
\text { either } x \leq y \text { or } y \leq x
$$

and

$$
\text { if } x \leq y \text { and } y \leq z \text { then } x \leq z
$$

$\leq$ is a well order and say that $(X, \leq)$ is a well-ordered set if every nonempty subset of $X$ has a smallest element. More precisely, if $S \neq \emptyset$ and $S \subseteq X$ then there exists an $x \in S$ such that $x \leq y$ for all $y \in S$. A familiar example of a well-ordered set is the natural numbers.

Lemma A.0.3 The Hausdorff maximal principle implies every nonempty set can be wellordered.

Proof: Let $X$ be a nonempty set and let $a \in X$. Then $\{a\}$ is a well-ordered subset of $X$. Let

$$
\mathscr{F}=\{S \subseteq X: \text { there exists a well order for } S\}
$$

Thus $\mathscr{F} \neq \emptyset$. For $S_{1}, S_{2} \in \mathscr{F}$, define $S_{1} \prec S_{2}$ if $S_{1} \subseteq S_{2}$ and there exists a well order for $S_{2}$, $\leq_{2}$ such that

$$
\left(S_{2}, \leq_{2}\right) \text { is well-ordered }
$$

and if

$$
y \in S_{2} \backslash S_{1} \text { then } x \leq_{2} y \text { for all } x \in S_{1},
$$

and if $\leq_{1}$ is the well order of $S_{1}$ then the two orders are consistent on $S_{1}$. Then observe that $\prec$ is a partial order on $\mathscr{F}$. By the Hausdorff maximal principle, let $\mathscr{C}$ be a maximal chain in $\mathscr{F}$ and let

$$
X_{\infty} \equiv \cup \mathscr{C}
$$

Define an order, $\leq$, on $X_{\infty}$ as follows. If $x, y$ are elements of $X_{\infty}$, pick $S \in \mathscr{C}$ such that $x, y$ are both in $S$. Then if $\leq_{S}$ is the order on $S$, let $x \leq y$ if and only if $x \leq_{S} y$. This definition is well defined because of the definition of the order, $\prec$. Now let $U$ be any nonempty subset of $X_{\infty}$. Then $S \cap U \neq \emptyset$ for some $S \in \mathscr{C}$. Because of the definition of $\leq$, if $y \in S_{2} \backslash S_{1}, S_{i} \in \mathscr{C}$, then $x \leq y$ for all $x \in S_{1}$. Thus, if $y \in X_{\infty} \backslash S$ then $x \leq y$ for all $x \in S$ and so the smallest element of $S \cap U$ exists and is the smallest element in $U$. Therefore $X_{\infty}$ is well-ordered. Now suppose there exists $z \in X \backslash X_{\infty}$. Define the following order, $\leq_{1}$, on $X_{\infty} \cup\{z\}$.

$$
\begin{gathered}
x \leq_{1} y \text { if and only if } x \leq y \text { whenever } x, y \in X_{\infty} \\
\qquad x \leq_{1} z \text { whenever } x \in X_{\infty} .
\end{gathered}
$$

Then let

$$
\widetilde{\mathscr{C}}=\left\{S \in \mathscr{C} \text { or } X_{\infty} \cup\{z\}\right\}
$$

Then $\tilde{\mathscr{C}}$ is a strictly larger chain than $\mathscr{C}$ contradicting maximality of $\mathscr{C}$. Thus $X \backslash X_{\infty}=\emptyset$ and this shows $X$ is well-ordered by $\leq$. This proves the lemma.

With these two lemmas the main result follows.
Theorem A.0. 4 The following are equivalent.

## The axiom of choice

## The Hausdorff maximal principle

The well-ordering principle.
Proof: It only remains to prove that the well-ordering principle implies the axiom of choice. Let $I$ be a nonempty set and let $X_{i}$ be a nonempty set for each $i \in I$. Let $X=\cup\left\{X_{i}\right.$ : $i \in I\}$ and well order $X$. Let $f(i)$ be the smallest element of $X_{i}$. Then

$$
f \in \prod_{i \in I} X_{i} .
$$

## A. 1 The Hamel Basis

A Hamel basis is nothing more than the correct generalization of the notion of a basis for a finite dimensional vector space to vector spaces which are possibly not of finite dimension.

Definition A.1.1 Let $X$ be a vector space. A Hamel basis is a subset of $X, \Lambda$ such that every vector of $X$ can be written as a finite linear combination of vectors of $\Lambda$ and the vectors of $\Lambda$ are linearly independent in the sense that if $\left\{x_{1}, \cdots, x_{n}\right\} \subseteq \Lambda$ and

$$
\sum_{k=1}^{n} c_{k} x_{k}=0
$$

then each $c_{k}=0$.
The main result is the following theorem.
Theorem A.1.2 Let $X$ be a nonzero vector space. Then it has a Hamel basis.
Proof: Let $x_{1} \in X$ and $x_{1} \neq 0$. Let $\mathscr{F}$ denote the collection of subsets of $X, \Lambda$ containing $x_{1}$ with the property that the vectors of $\Lambda$ are linearly independent as described in Definition A.1.1 partially ordered by set inclusion. By the Hausdorff maximal theorem, there exists a maximal chain, $\mathscr{C}$ Let $\Lambda=\cup \mathscr{C}$. Since $\mathscr{C}$ is a chain, it follows that if $\left\{x_{1}, \cdots, x_{n}\right\} \subseteq \mathscr{C}$ then there exists a single $\Lambda^{\prime} \in \mathbb{C}$ containing all these vectors. Therefore, if

$$
\sum_{k=1}^{n} c_{k} x_{k}=0
$$

it follows each $c_{k}=0$. Thus the vectors of $\Lambda$ are linearly independent. Is every vector of $X$ a finite linear combination of vectors of $\Lambda$ ?

Suppose not. Then there exists $z$ which is not equal to a finite linear combination of vectors of $\Lambda$. Consider $\Lambda \cup\{z\}$. If

$$
c z+\sum_{k=1}^{m} c_{k} x_{k}=0
$$

where the $x_{k}$ are vectors of $\Lambda$, then if $c \neq 0$ this contradicts the condition that $z$ is not a finite linear combination of vectors of $\Lambda$. Therefore, $c=0$ and now all the $c_{k}$ must equal zero because it was just shown $\Lambda$ is linearly independent. It follows $\mathscr{C} \cup\{\Lambda \cup\{z\}\}$ is a strictly larger chain than $\mathscr{C}$ and this is a contradiction. Therefore, $\Lambda$ is a Hamel basis as claimed. This proves the theorem.

## A. 2 Exercises

1. Zorn's lemma states that in a nonempty partially ordered set, if every chain has an upper bound, there exists a maximal element, $x$ in the partially ordered set. $x$ is maximal, means that if $x \prec y$, it follows $y=x$. Show Zorn's lemma is equivalent to the Hausdorff maximal theorem.
2. Show that if $Y, Y_{1}$ are two Hamel bases of $X$, then there exists a one to one and onto map from $Y$ to $Y_{1}$. Thus any two Hamel bases are of the same size.
3. $\uparrow$ Using the Baire category theorem of the chapter on Banach spaces show that any Hamel basis of a Banach space is either finite or uncountable.
4. $\uparrow$ Consider the vector space of all polynomials defined on $[0,1]$. Does there exist a norm, $\|\cdot\|$ defined on these polynomials such that with this norm, the vector space of polynomials becomes a Banach space (complete normed vector space)?

[^0]:    ${ }^{1}$ Archimedes 287-212 B.C. found areas of curved regions by stuffing them with simple shapes which he knew the area of and taking a limit. He also made fundamental contributions to physics. The story is told about how he determined that a gold smith had cheated the king by giving him a crown which was not solid gold as had been claimed. He did this by finding the amount of water displaced by the crown and comparing with the amount of water it should have displaced if it had been solid gold.

[^1]:    ${ }^{2}$ This theorem is why Newton and Liebnitz are credited with inventing calculus. The integral had been around for thousands of years and the derivative was by their time well known. However the connection between these two ideas had not been fully made although Newton's predecessor, Isaac Barrow had made some progress in this direction.

[^2]:    ${ }^{3}$ Of course it was proved that if $f$ is continuous on a closed interval, $[a, b]$, then $f \in R([a, b])$ but this is a hard theorem using the difficult result about uniform continuity.

[^3]:    ${ }^{1}$ This is the plural form of basis. We could say basiss but it would involve an inordinate amount of hissing as in "The sixth shiek's sixth sheep is sick". This is the reason that bases is used instead of basiss.

[^4]:    ${ }^{3}$ A special case was first proved by Hamilton in 1853. The general case was announced by Cayley some time later and a proof was given by Frobenius in 1878.

[^5]:    ${ }^{1}$ To a mathematician, the statment: Whenever a pig is born with wings it can fly must be taken as true. We do not consider biological or aerodynamic considerations in such statements. There is no such thing as a winged pig and therefore, all winged pigs must be superb flyers since there can be no example of one which is not. On the other hand we would also consider the statement: Whenever a pig is born with wings it can't possibly fly, as equally true. The point is, you can say anything you want about the elements of the empty set and no one can gainsay your statement. Therefore, such statements are considered as true by default. You may say this is a very strange way of thinking about truth and ultimately this is because mathematics is not about truth. It is more about consistency and logic.

[^6]:    ${ }^{1}$ This is the plural form of basis. We could say basiss but it would involve an inordinate amount of hissing as in "The sixth shiek's sixth sheep is sick". This is the reason that bases is used instead of basiss.

[^7]:    ${ }^{1}$ Note the difference between this picture and the one usually drawn in calculus courses where the little rectangles are upright rather than on their sides. This illustrates a fundamental philosophical difference between the Riemann and the Lebesgue integrals. With the Riemann integral intervals are measured. With the Lebesgue integral, it is inverse images of intervals which are measured.

[^8]:    ${ }^{2}$ The negative part of the real number $x$ is defined to be $x^{-} \equiv \frac{1}{2}(|x|-x)$. Thus $|x|=x^{+}+x^{-}$and $x=x^{+}-x^{-}$.

[^9]:    ${ }^{3}$ Note that, since $g$ is allowed to have the value $\infty$, it is not known that $g \in L^{1}(\Omega)$.

[^10]:    ${ }^{1} 1$ Kings 17, 2 Kings 4, Mathew 14, and Mathew 15 all contain such descriptions. The stuff involved was either oil, bread, flour or fish. In mathematics such things have also been done with sets. In the book by Bruckner Bruckner and Thompson there is an interesting discussion of the Banach Tarski paradox which says it is possible to divide a ball in $\mathbb{R}^{3}$ into five disjoint pieces and assemble the pieces to form two disjoint balls of the same size as the first. The details can be found in: The Banach Tarski Paradox by Wagon, Cambridge University press. 1985. It is known that all such examples must involve the axiom of choice.

[^11]:    ${ }^{3}$ Set of all subsets of $Z$

[^12]:    ${ }^{4}$ In 1940 it was shown by Godel that the continuum hypothesis cannot be disproved. In 1963 it was shown by Cohen that the continuum hypothesis cannot be proved. These assertions are based on the axiom of choice and the Zermelo Frankel axioms of set theory. This topic is far outside the scope of this book and this is only a hopefully interesting historical observation.

[^13]:    ${ }^{1}$ Actually it is only a function of the first but this is not important in what follows.

[^14]:    ${ }^{1}$ Set of all subsets of $Z$

[^15]:    ${ }^{1}$ These spaces are named after Stefan Banach, 1892-1945. Banach spaces are the basic item of study in the subject of functional analysis and will be considered later in this book.

    There is a recent biography of Banach, R. Katuża, The Life of Stefan Banach, (A. Kostant and W. Woyczyński, translators and editors) Birkhauser, Boston (1996). More information on Banach can also be found in a recent short article written by Douglas Henderson who is in the department of chemistry and biochemistry at BYU.

    Banach was born in Austria, worked in Poland and died in the Ukraine but never moved. This is because borders kept changing. There is a rumor that he died in a German concentration camp which is apparently not true. It seems he died after the war of lung cancer.

    He was an interesting character. He hated taking examinations so much that he did not receive his undergraduate university degree. Nevertheless, he did become a professor of mathematics due to his important research. He and some friends would meet in a cafe called the Scottish cafe where they wrote on the marble table tops until Banach's wife supplied them with a notebook which became the "Scotish notebook" and was eventually published.

[^16]:    ${ }^{1}$ Actually, all this works in much more general settings than this.

[^17]:    ${ }^{1}$ As proved above, the assumption that $|\lambda|(\Omega)<\infty$ is redundant.

[^18]:    ${ }^{2}$ Recall this is automatic for a complex measure.

[^19]:    ${ }^{1}$ Note that this follows from the assumed separability of $X, Y$ because the graph is a subset of the separable space $X \times Y$

[^20]:    ${ }^{1}$ René Gateaux was one of the many young French men killed in world war I. This derivative is named after him, but it developed naturally from ideas used in the calculus of variations which were due to Euler and Lagrange back in the 1700 's.

[^21]:    ${ }^{2}$ In Hilbert space, the existence of this projection map is obvious and it is assumed that it exists here.

[^22]:    ${ }^{1}$ It is known that if the space is reflexive, then there is an equivalent norm which is strictly convex. However, in most examples, this strict convexity is obvious.

[^23]:    ${ }^{1}$ In this example, you only know that $f^{\prime}$ exists a.e.

[^24]:    ${ }^{1}$ The definition applies with no change to a general topological space in place of $\mathbb{R}^{n}$.

[^25]:    ${ }^{1}$ The definition applies with no change to a general topological space in place of $\mathbb{R}^{n}$.

[^26]:    ${ }^{2}$ If each $\psi_{U}$ were only continuous, one could conclude $f$ is continuous. Here the main interest is differentiable.

[^27]:    ${ }^{3}$ This means $V$ is the intersection of an open set with $\Gamma$. Equivalently, it means that $V$ is an open set in the traditional way regarding $\Gamma$ as a metric space with the metric it inherits from $\mathbb{R}^{m}$.

[^28]:    ${ }^{1}$ You could also let the norm be given by $\|u\|_{m, p} \equiv \sum_{|\alpha| \leq m}\left\|D^{\alpha} u\right\|_{p}$ or $\|u\|_{m, p} \equiv \max \left\{\left\|D^{\alpha} u\right\|_{p}:|\alpha| \leq m\right\}$ because all norms are equivalent on $\mathbb{R}^{p}$ where $p$ is the number of multi indices no larger than $m$. This is used whenever convenient.

[^29]:    ${ }^{2}$ This is never a problem in $\mathbb{R}^{n}$. In fact, every open covering has a locally finite subcovering in $\mathbb{R}^{n}$ or more generally in any metric space due to Stone's theorem. These are issues best left to you in case you are interested. I am usually interested in bounded sets, $U$, and for these, there is a finite covering.

[^30]:    ${ }^{3}$ This means that $\operatorname{spt}(u) \subseteq B \times(a, b)$ and $u \in C^{1}\left(\overline{V^{-}}\right)$.

[^31]:    ${ }^{1}$ Vector addition is continuous is the property which is used here.

[^32]:    ${ }^{1}$ Giancinto Morera 1856-1909. This theorem or one like it dates from around 1886

[^33]:    ${ }^{1}$ This implies $f$ has no zero on $\Omega$.

[^34]:    ${ }^{2}$ This is the terminology used in Rudin's book Real and Complex Analysis.

[^35]:    ${ }^{1}$ Actually, it is only necessary to assume one of the series converges and the other converges absolutely. This is known as Merten's theorem and may be read in the 1974 book by Apostol listed in the bibliography.

[^36]:    ${ }^{1}$ This says you can specify the first $m_{k}$ derivatives of the function at the point $z_{k}$.

[^37]:    ${ }^{2}$ It is not a field because you can't divide two analytic functions and get another one.

[^38]:    ${ }^{3}$ Wilhelm Blaschke, 1915

[^39]:    ${ }^{4}$ This is a fun thing to say: nonzero zeros.

[^40]:    ${ }^{1}$ A module is like a vector space except instead of a field of scalars, you have a ring of scalars.

[^41]:    ${ }^{2}$ I don't know why it is traditional to refer to this antiderivative as $-\zeta$ rather than $\zeta$ but I am following the convention. I think it is to minimize the number of minus signs in the next expression.

[^42]:    ${ }^{1}$ If it is only a seminorm, it satisfies the same conditions.

[^43]:    ${ }^{1}$ Note how the $\sigma$ algebra $\mathscr{F}_{s}$ are defined, as the intersection of completions of $\sigma$ algebras corresponding to $t$ strictly larger than $s$.

[^44]:    ${ }^{1}$ It is known that if the space is reflexive, then there is an equivalent norm which is strictly convex. However, in most examples, this strict convexity is obvious.
