\left\{W_{j}^{\prime} \cap W_{i}, \psi_{i} \phi_{j}, \Gamma_{j} \cap \Gamma_{i}, V_{j}, \mathbf{g}_{i, j}, \mathbf{G}_{i, j}\right\}
$$

where $\mathbf{g}_{i, j}=\mathbf{g}_{j}$. Thus the identity map

$$
\operatorname{id}:\left(W^{s, p}(\Gamma),\|\cdot\|_{s, p, \Gamma}^{1, \mathbf{g}}\right) \rightarrow\left(W^{s, p}(\Gamma),\|\cdot\| \|_{s, p, \Gamma}^{1}\right)
$$

is continuous. It follows the two norms, $\|\cdot\|_{s, p, \Gamma}^{1, \mathbf{g}}$ and $\|\cdot\|_{s, p, \Gamma}^{1}$, are equivalent by the open mapping theorem. In a similar way, the norms, $\|\cdot\|_{s, p, \Gamma}^{2, \mathbf{h}}$ and $\|\cdot\|_{s, p, \Gamma}^{2}$ are equivalent where

$$
\|u\|_{s, p, \Gamma}^{2} \equiv \sum_{j=1}^{l}\left\|\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)\right\|_{s, p, U_{i}}
$$

and

$$
\|u\|_{s, p, \Gamma}^{2, \mathbf{h}} \equiv \sum_{j, i}\left\|\mathbf{h}_{i}^{*}\left(u \phi_{j} \psi_{i}\right)\right\|_{s, p, U_{i}}=\sum_{j, i}\left\|\mathbf{h}_{i}^{*}\left(u \phi_{j} \psi_{i}\right)\right\|_{s, p, \mathbf{h}_{i}^{-1}\left(w_{i} \cap W_{j}^{\prime}\right)}
$$

But from the assumptions on $\mathbf{h}$ and $\mathbf{g}$, in particular the assumption that these are restrictions of functions which are defined on open subsets of $\mathbb{R}^{m}$ which have Lipschitz derivatives up to order $k$ along with their inverses, Theorem 45.4.4 implies, there exist constants $C_{i}$, independent of $u$ such that

$$
\left\|\mathbf{h}_{i}^{*}\left(u \phi_{j} \psi_{i}\right)\right\|_{s, p, \mathbf{h}_{i}^{-1}\left(W_{i} \cap W_{j}^{\prime}\right)} \leq C_{1}\left\|\mathbf{g}_{j}^{*}\left(u \phi_{j} \psi_{i}\right)\right\|_{s, p, \mathbf{g}_{j}^{-1}\left(W_{i} \cap W_{j}^{\prime}\right)}
$$

and

$$
\left\|\mathbf{g}_{j}^{*}\left(u \phi_{j} \psi_{i}\right)\right\|_{s, p, \mathbf{g}_{j}^{-1}\left(W_{i} \cap W_{j}^{\prime}\right)} \leq C_{2}\left\|\mathbf{h}_{i}^{*}\left(u \phi_{j} \psi_{i}\right)\right\|_{s, p, \mathbf{h}_{i}^{-1}\left(W_{i} \cap W_{j}^{\prime}\right)}
$$

Therefore, the two norms, $\|\cdot\|_{s, p, \Gamma}^{1, \mathbf{g}}$ and $\|\cdot\|_{s, p, \Gamma}^{2, \mathbf{h}}$ are equivalent. It follows that the norms, $\|\cdot\|_{s, p, \Gamma}^{2}$ and $\|\cdot\|_{s, p, \Gamma}^{1}$ are equivalent. This proves the following theorem.

Theorem 46.1.3 Let $\Gamma$ be described above. Then any two norms for $W^{s, p}(\Gamma)$ as in Definition 39.6.3 are equivalent.

### 46.2 The Trace On The Boundary Of An Open Set

Next is a generalization of earlier theorems about the loss of $\frac{1}{p}$ derivatives on the boundary.

## Definition 46.2.1 Define

$$
\mathbb{R}_{k}^{n-1} \equiv\left\{\mathbf{x} \in \mathbb{R}^{n}: x_{k}=0\right\}, \widehat{\mathbf{x}}_{k} \equiv\left(x_{1}, \cdots, x_{k-1}, 0, x_{k+1}, \cdots, x_{n}\right)
$$

An open set, $\Omega$ is $C^{m, 1}$ if there exist open sets, $W_{i}, i=0,1, \cdots, l$ such that

$$
\Omega=\cup_{i=0}^{l} W_{i}
$$

with $\overline{W_{0}} \subseteq \Omega$, open sets $U_{i} \subseteq \mathbb{R}_{k}^{n-1}$ for some $k$, and open intervals, $\left(a_{i}, b_{i}\right)$ containing 0 such that for $i \geq 1$,

$$
\begin{gathered}
\partial \Omega \cap W_{i}=\left\{\widehat{\mathbf{x}}_{k}+\phi_{i}\left(\widehat{\mathbf{x}}_{k}\right) \mathbf{e}_{k}: \widehat{\mathbf{x}}_{k} \in U_{i}\right\} \\
\Omega \cap W_{i}=\left\{\widehat{\mathbf{x}}_{k}+\left(\phi_{i}\left(\widehat{\mathbf{x}}_{k}\right)+x_{k}\right) \mathbf{e}_{k}:\left(\widehat{\mathbf{x}}_{k}, x_{k}\right) \in U_{i} \times I_{i}\right\},
\end{gathered}
$$

where $\phi_{i}$ is Lipschitz with partial derivatives up to order m also Lipschitz. Here $I_{i}=\left(a_{i}, 0\right)$ or $\left(0, b_{i}\right)$. The case of $\left(a_{i}, 0\right)$ is shown in the picture.

Assume $\Omega$ is $C^{m-1,1}$. Define

$$
\mathbf{h}_{i}\left(\widehat{\mathbf{x}}_{k}\right)=\widehat{\mathbf{x}}_{k}+\phi_{i}\left(\widehat{\mathbf{x}}_{k}\right) \mathbf{e}_{k}, \mathbf{H}_{i}(\mathbf{x}) \equiv \widehat{\mathbf{x}}_{k}+\left(\phi_{i}\left(\widehat{\mathbf{x}}_{k}\right)+x_{k}\right) \mathbf{e}_{k},
$$

and let $\psi_{i} \in C_{c}^{\infty}\left(W_{i}\right)$ with $\sum_{i=0}^{l} \psi_{i}(\mathbf{x})=1$ on $\bar{\Omega}$. Thus

$$
\left\{W_{i}, \psi_{i}, \partial \Omega \cap W_{i}, U_{i}, \mathbf{h}_{i}, \mathbf{H}_{i}\right\}_{i=1}^{l}
$$

satisfies all the conditions for defining $W^{s, p}(\partial \Omega)$ for $s \leq m$. Let $u \in C^{\infty}(\bar{\Omega})$ and let $\mathbf{h}_{i}$ be as just described. The trace, denoted by $\gamma$ is that operator which evaluates functions in $C^{\infty}(\bar{\Omega})$ on $\partial \Omega$. Thus for $u \in C^{\infty}(\bar{\Omega})$, and $\mathbf{y} \in \partial \Omega$,

$$
u(\mathbf{y})=\sum_{i=1}^{l}\left(u \psi_{i}\right)(\mathbf{y})
$$

and so using the notation to suppress the reference to $\mathbf{y}$,

$$
\gamma u=\sum_{i=1}^{l} \gamma\left(u \psi_{i}\right)
$$

It is necessary to show this is a continuous map. Letting $u \in W^{m, p}(\Omega)$, it follows from Theorem 45.4.3, and Theorem 38.0.14,

$$
\begin{gathered}
\|\gamma u\|_{m-\frac{1}{p}, p, \partial \Omega}=\sum_{i=1}^{l}\left\|\mathbf{h}_{i}^{*}\left(\gamma\left(\psi_{i} u\right)\right)\right\|_{m-\frac{1}{p}, p, U_{i}} \\
=\sum_{i=1}^{l}\left\|\mathbf{h}_{i}^{*} \gamma\left(\psi_{i} u\right)\right\|_{m-\frac{1}{p}, p, \mathbb{R}_{k}^{n-1}} \leq C \sum_{i=1}^{l}\left\|\mathbf{H}_{i}^{*}\left(\psi_{i} u\right)\right\|_{m, p, \mathbb{R}_{+}^{n}} \\
\leq C \sum_{i=1}^{l}\left\|\mathbf{H}_{i}^{*}\left(\psi_{i} u\right)\right\|_{m, p, U_{i} \times\left(a_{i}, 0\right)} \leq C \sum_{i=1}^{l}\left\|\left(\psi_{i} u\right)\right\|_{m, p, W_{i} \cap \Omega}
\end{gathered}
$$

$$
\leq C \sum_{i=1}^{l}\left\|\left(\psi_{i} u\right)\right\|_{m, p, \Omega} \leq C \sum_{i=1}^{l}\|u\|_{m, p, \Omega} \leq C l\|u\|_{m, p, \Omega}
$$

Now use the density of $C^{\infty}(\bar{\Omega})$ in $W^{m, p}(\Omega)$ to see that $\gamma$ extends to a continuous linear map defined on $W^{m, p}(\Omega)$ still called $\gamma$ such that for all $u \in W^{m, p}(\Omega)$,

$$
\begin{equation*}
\|\gamma u\|_{m-\frac{1}{p}, p, \partial \Omega} \leq C l\|u\|_{m, p, \Omega} . \tag{46.2.3}
\end{equation*}
$$

Also, it can be shown that $\gamma$ maps $W^{m, p}(\Omega)$ onto $W^{m-\frac{1}{p}}(\partial \Omega)$. Let $g \in W^{m-\frac{1}{p}}(\partial \Omega)$. By definition, this means

$$
\mathbf{h}_{i}^{*}\left(\psi_{i} g\right) \in W^{m-\frac{1}{p}}\left(U_{i}\right), \text { each } i
$$

and so, using a cutoff function, there exists $w_{i} \in W^{m, p}\left(U_{i} \times I_{i}\right)$ such that

$$
\gamma w_{i}=\mathbf{h}_{i}^{*}\left(\psi_{i} g\right)=\mathbf{h}_{i}^{*}\left(\gamma \psi_{i} g\right)
$$

Thus $\left(\mathbf{H}_{i}^{-1}\right)^{*} w_{i} \in W^{m p}\left(\Omega \cap W_{i}\right)$. Let

$$
w \equiv \sum_{i=1}^{l} \psi_{i}\left(\mathbf{H}_{i}^{-1}\right)^{*} w_{i} \in W^{m p}(\Omega)
$$

then

$$
\begin{aligned}
\gamma w & =\sum_{i} \gamma \psi_{j} \gamma\left(\mathbf{H}_{i}^{-1}\right)^{*} w_{i}=\sum_{i} \gamma \psi_{j}\left(\mathbf{H}_{i}^{-1}\right)^{*} \gamma w_{i} \\
& =\sum_{i} \gamma \psi_{j}\left(\mathbf{H}_{i}^{-1}\right)^{*} \mathbf{h}_{i}^{*}\left(\gamma \psi_{i} g\right)=g
\end{aligned}
$$

In addition to this, in the case where $m=1$, Lemma 45.2.1 implies there exists a linear map, $R$, from $W^{1-\frac{1}{p}, p}(\partial \Omega)$ to $W^{1, p}(\Omega)$ which has the property that $\gamma R g=g$ for every $g \in W^{1-\frac{1}{p}, p}(\partial \Omega)$. I show this now. Letting $g \in W^{1-\frac{1}{p}, p}(\partial \Omega)$,

$$
g=\sum_{i=1}^{l} \psi_{i} g .
$$

Then also,

$$
\mathbf{h}_{i}^{*}\left(\psi_{i} g\right) \in W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right)
$$

if extended to equal 0 off $U_{i}$. From Lemma 45.2.1, there exists an extension of this to $W^{1, p}\left(\mathbb{R}_{+}^{n}\right), R \mathbf{h}_{i}^{*}\left(\psi_{i} g\right)$. Without loss of generality, assume that

$$
R \mathbf{h}_{i}^{*}\left(\psi_{i} g\right) \in W^{1, p}\left(U_{i} \times\left(a_{i}, 0\right)\right) .
$$

If not so, multiply by a suitable cut off function in the definition of $R$. Then the extension is

$$
R g=\sum_{i=1}^{l}\left(\mathbf{H}_{i}^{-1}\right)^{*} R \mathbf{h}_{i}^{*}\left(\psi_{i} g\right) .
$$

This works because from the definition of $\gamma$ on $C^{\infty}(\bar{\Omega})$ and continuity of the map established above, $\gamma$ and $\left(\mathbf{H}_{i}^{-1}\right)^{*}$ commute and so

$$
\begin{aligned}
\gamma R g & \equiv \sum_{i=1}^{l} \gamma\left(\mathbf{H}_{i}^{-1}\right)^{*} R \mathbf{h}_{i}^{*}\left(\psi_{i} g\right) \\
& =\sum_{i=1}^{l}\left(\mathbf{H}_{i}^{-1}\right)^{*} \gamma R \mathbf{h}_{i}^{*}\left(\psi_{i} g\right) \\
& =\sum_{i=1}^{l}\left(\mathbf{H}_{i}^{-1}\right)^{*} \mathbf{h}_{i}^{*}\left(\psi_{i} g\right)=g .
\end{aligned}
$$

This proves the following theorem about the trace.
Theorem 46.2.2 Let $\Omega \in C^{m-1,1}$. Then there exists a constant, $C$ independent of $u \in$ $W^{m, p}(\Omega)$ and a continuous linear map, $\gamma: W^{m, p}(\Omega) \rightarrow W^{m-\frac{1}{p}, p}(\partial \Omega)$ such that 46.2.3 holds. This map satisfies $\gamma u(\mathbf{x})=u(\mathbf{x})$ for all $u \in C^{\infty}(\bar{\Omega})$ and $\gamma$ is onto. In the case where $m=1$, there exists a continuous linear map, $R: W^{1-\frac{1}{p}, p}(\partial \Omega) \rightarrow W^{1, p}(\Omega)$ which has the property that $\gamma R g=g$ for all $g \in W^{1-\frac{1}{p}, p}(\partial \Omega)$.

Of course more can be proved but this is all to be presented here.

## Part IV

## Multifunctions

## Chapter 47

## The Yankov von Neumann Aumann theorem

The Yankov von Neumann Aumann theorem deals with the projection of a product measurable set. It is a very difficult but interesting theorem. The material of this chapter is taken from [29], [30], [10], and [70]. We use the standard notation that for $\mathscr{S}$ and $\mathscr{F} \sigma$ algebras, $\mathscr{S} \times \mathscr{F}$ is the $\sigma$ algebra generated by the measurable rectangles, the product measure $\sigma$ algebra. The next result is fairly easy and the proof is left for the reader.
Lemma 47.0.1 Let $(X, d)$ be a metric space. Then if $d_{1}(x, y)=\frac{d(x, y)}{1+d(x, y)}$, it follows that $d_{1}$ is a metric on $X$ and the basis of open balls taken with respect to $d_{1}$ yields the same topology as the basis of open balls taken with respect to $d$.

Theorem 47.0.2 Let $\left(X_{i}, d_{i}\right)$ denote a complete metric space and let $X \equiv \prod_{i=1}^{\infty} X_{i}$. Then $X$ is also a complete metric space with the metric

$$
\rho(\mathbf{x}, \mathbf{y}) \equiv \sum_{i=1}^{\infty} 2^{-i} \frac{d_{i}\left(x_{i}, y_{i}\right)}{1+d_{i}\left(x_{i}, y_{i}\right)} .
$$

Also, if $X_{i}$ is separable for each $i$ then so is $X$.
Proof: It is clear from the above lemma that $\rho$ is a metric on $X$. We need to verify $X$ is complete with this metric. Let $\left\{\mathbf{x}^{n}\right\}$ be a Cauchy sequence in $X$. Then it is clear from the definition that $\left\{x_{i}^{n}\right\}$ is a Cauchy sequence for each $i$ and converges to $x_{i} \in X_{i}$. Therefore, letting $\varepsilon>0$ be given, we choose $N$ such that

$$
\sum_{k=N}^{\infty} 2^{-k}<\frac{\varepsilon}{2}
$$

we choose $M$ large enough that for $n>M$,

$$
2^{-i} \frac{d_{i}\left(x_{i}^{n}, x_{i}\right)}{1+d_{i}\left(x_{i}^{n}, x_{i}\right)}<\frac{\varepsilon}{2(N+1)}
$$

for all $i=1,2, \cdots, N$. Then letting $\mathbf{x}=\left\{x_{i}\right\}$,

$$
\rho\left(\mathbf{x}, \mathbf{x}^{n}\right) \leq \frac{\varepsilon N}{2(N+1)}+\sum_{k=N}^{\infty} 2^{-k}<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
$$

We need to verify that $X$ is separable. Let $D_{i}$ denote a countable dense set in $X_{i}, D_{i} \equiv$ $\left\{r_{k}^{i}\right\}_{k=1}^{\infty}$. Then let

$$
\mathscr{D}_{k} \equiv D_{1} \times \cdots \times D_{k} \times\left\{r_{1}^{k+1}\right\} \times\left\{r_{1}^{k+2}\right\} \times \cdots
$$

Thus $\mathscr{D}_{k}$ is a countable subset of $X$. Let $\mathscr{D} \equiv \cup_{k=1}^{\infty} \mathscr{D}_{k}$. Then $\mathscr{D}$ is countable and we can see $\mathscr{D}$ is dense in $X$ as follows. The projection of $\mathscr{D}_{k}$ onto the first $k$ entries is dense in
$\prod_{i=1}^{k} X_{i}$ and for $k$ large enough the remaining component's contribution to the metric, $\rho$ is very small. Therefore, obtaining $\mathbf{d} \in \mathscr{D}$ close to $\mathbf{x} \in X$ may be accomplished by finding $\mathbf{d} \in \mathscr{D}$ such that $\mathbf{d}$ is close to $\mathbf{x}$ in the first $k$ components for $k$ large enough. Note that we do not use $\prod_{k=1}^{\infty} D_{k}$ !

Definition 47.0.3 A complete separable metric space is called a polish space.
Theorem 47.0.4 Let $X$ be a polish space. Then there exists $f: \mathbb{N}^{\mathbb{N}} \rightarrow X$ which is onto and continuous. Here $\mathbb{N}^{\mathbb{N}} \equiv \prod_{i=1}^{\infty} \mathbb{N}$ and a metric is given according to the above theorem. Thus for $\mathbf{n}, \mathbf{m} \in \mathbb{N}^{\mathbb{N}}$,

$$
\rho(\mathbf{n}, \mathbf{m}) \equiv \sum_{i=1}^{\infty} 2^{-i} \frac{\left|n_{i}-m_{i}\right|}{1+\left|n_{i}-m_{i}\right|}
$$

Proof: Since $X$ is polish, there exists a countable covering of $X$ by closed sets having diameters no larger than $2^{-1},\{B(i)\}_{i=1}^{\infty}$. Each of these closed sets is also a polish space and so there exists a countable covering of $B(i)$ by a countable collection of closed sets, $\{B(i, j)\}_{j=1}^{\infty}$ each having diameter no larger than $2^{-2}$ where $B(i, j) \subseteq B(i) \neq \emptyset$ for all $j$. Continue this way. Thus

$$
B\left(n_{1}, n_{2}, \cdots, n_{m}\right)=\cup_{i=1}^{\infty} B\left(n_{1}, n_{2}, \cdots, n_{m}, i\right)
$$

and each of $B\left(n_{1}, n_{2}, \cdots, n_{m}, i\right)$ is a closed set contained in $B\left(n_{1}, n_{2}, \cdots, n_{m}\right)$ whose diameter is at most half of the diameter of $B\left(n_{1}, n_{2}, \cdots, n_{m}\right)$. Now we define our mapping from $\mathbb{N}^{\mathbb{N}}$ to $X$. If $\mathbf{n}=\left\{n_{k}\right\}_{k=1}^{\infty} \in \mathbb{N}^{\mathbb{N}}$, we let $f(\mathbf{n}) \equiv \cap_{m=1}^{\infty} B\left(n_{1}, n_{2}, \cdots, n_{m}\right)$. Since the diameters of these sets converge to 0 , there exists a unique point in this countable intersection and this is $f(\mathbf{n})$.

We need to verify $f$ is continuous. Let $\mathbf{n} \in \mathbb{N}^{\mathbb{N}}$ be given and suppose $\mathbf{m}$ is very close to $\mathbf{n}$. The only way this can occur is for $n_{k}$ to coincide with $m_{k}$ for many $k$. Therefore, both $f(\mathbf{n})$ and $f(\mathbf{m})$ must be contained in $B\left(n_{1}, n_{2}, \cdots, n_{m}\right)$ for some fairly large $m$. This implies, from the above construction that $f(\mathbf{m})$ is as close to $f(\mathbf{n})$ as $2^{-m}$, proving $f$ is continuous. To see that $f$ is onto, note that from the construction, if $x \in X$, then $x \in$ $B\left(n_{1}, n_{2}, \cdots, n_{m}\right)$ for some choice of $n_{1}, \cdots, n_{m}$ for each $m$. Note nothing is said about $f$ being one to one. It probably is not one to one.
Definition 47.0.5 We call a topological space $X$ a Suslin space if $X$ is a Hausdorff space and there exists a polish space, $Z$ and a continuous function $f$ which maps $Z$ onto $X$.

$$
Z \underset{\text { continuous }}{\substack{\text { onto }}} X
$$

These Suslin spaces are also called analytic sets in some contexts but we will use the term Suslin space in referring to them.
Corollary 47.0.6 $X$ is a Suslin space, if and only if there exists a continuous mapping from $\mathbb{N}^{\mathbb{N}}$ onto $X$.

Proof: We know there exists a polish space $Z$ and a continuous function, $h: Z \rightarrow X$ which is onto. By the above theorem there exists a continuous map, $g: \mathbb{N}^{\mathbb{N}} \rightarrow Z$ which is onto. Then $h \circ g$ is a continuous map from $\mathbb{N}^{\mathbb{N}}$ onto $X$. The "if" part of this theorem is accomplished by noting that $\mathbb{N}^{\mathbb{N}}$ is a polish space.

Lemma 47.0.7 Let $X$ be a Suslin space and suppose $X_{i}$ is a subspace of $X$ which is also a Suslin space. Then $\cup_{i=1}^{\infty} X_{i}$ and $\cap_{i=1}^{\infty} X_{i}$ are also Suslin spaces. Also every Borel set in $X$ is a Suslin space.

Proof: Let $f_{i}: Z_{i} \rightarrow X_{i}$ where $Z_{i}$ is a polish space and $f_{i}$ is continuous and onto. Without loss of generality we may assume the spaces $Z_{i}$ are disjoint because if not, we could replace $Z_{i}$ with $Z_{i} \times\{i\}$. Now we define a metric, $\rho$, for $Z \equiv \cup_{i=1}^{\infty} Z_{i}$ as follows.

$$
\begin{aligned}
& \rho(x, y) \equiv 1 \text { if } x \in Z_{i}, y \in Z_{k}, i \neq k \\
& \rho(x, y) \equiv \frac{d_{i}(x, y)}{1+d_{i}(x, y)} \text { if } x, y \in Z_{i} .
\end{aligned}
$$

Here $d_{i}$ is the metric on $Z_{i}$. It is easy to verify $\rho$ is a metric and that $(Z, \rho)$ is a polish space. Now we define $f: Z \rightarrow \cup_{i=1}^{\infty} X_{i}$ as follows. For $x \in Z_{i}, f(x) \equiv f_{i}(x)$. This is well defined because the $Z_{i}$ are disjoint. If $y$ is very close to $x$ it must be that $x$ and $y$ are in the same $Z_{i}$ otherwise this could not happen. Therefore, continuity of $f$ follows from continuity of $f_{i}$. This shows countable unions of Suslin subspaces of a Suslin space are Suslin spaces.

If $H \subseteq X$ is a closed subset, then, letting $f: Z \rightarrow X$ be onto and continuous, it follows $f: f^{-1}(H) \rightarrow H$ is onto and continuous. Since $f^{-1}(H)$ is closed, it follows $f^{-1}(H)$ is a polish space. Therefore, $H$ is a Suslin space.

Now we show countable intersections of Suslin spaces are Suslin. It is clear that $\theta$ : $\prod_{i=1}^{\infty} Z_{i} \rightarrow \prod_{i=1}^{\infty} X_{i}$ given by $\theta(\mathbf{z}) \equiv \mathbf{x}=\left\{x_{i}\right\}$ where $x_{i}=f_{i}\left(z_{i}\right)$ is continuous and onto, this with respect to the usual product topology. Note that $\prod_{i=1}^{\infty} Z_{i}$ is a polish space because of the assumption that each $Z_{i}$ is and the above considerations. Therefore, $\prod_{i=1}^{\infty} X_{i}$ is a Suslin space. Now let $P \equiv\left\{\mathbf{y} \in \prod_{i=1}^{\infty} f_{i}\left(Z_{i}\right): y_{i}=y_{j}\right.$ for all $\left.i, j\right\}$ (This is how you get it on the intersection. I guess this must be the case where each $X_{i} \subseteq X$ ). Then $P$ is a closed subspace of a Suslin space and so it is Suslin. Then we define $h: P \rightarrow \cap_{i=1}^{\infty} X_{i}$ by $h(\mathbf{y}) \equiv f_{i}\left(y_{i}\right)$. This shows $\cap_{i=1}^{\infty} X_{i}$ is Suslin because $h$ is continuous and onto. ( $h \circ \theta: \theta^{-1}(P) \rightarrow \cap_{i=1}^{\infty} X_{i}$ is continuous and $\theta^{-1}(P)$ being a closed subset of a polish space is polish.)

Next let $U$ be an open subset of $X$. Then $f^{-1}(U)$, being an open subset of a polish space, can be obtained as an increasing limit of closed sets, $K_{n}$. Therefore, $U=\cup_{n=1}^{\infty} f\left(K_{n}\right)$. Each $f\left(K_{n}\right)$ is a Suslin space because it is the continuous image of a polish space, $K_{n}$. Therefore, by the first part of the lemma, $U$ is a Suslin space. Now let

$$
\mathscr{F} \equiv\left\{E \subseteq X: \text { both } E^{C} \text { and } E \text { are Suslin }\right\} .
$$

We see that $\mathscr{F}$ is closed with respect to taking complements. The first part of this lemma shows $\mathscr{F}$ is closed with respect to countable unions. Therefore, $\mathscr{F}$ is a $\sigma$ algebra and so, since it contains the open sets, must contain the Borel sets.

It turns out that Suslin spaces tend to be measurable sets. In order to develop this idea, we need a technical lemma.

Lemma 47.0.8 Let $(\Omega, \mathscr{F}, \mu)$ be a measure space and denote by $\mu^{*}$ the outer measure generated by $\mu$. Thus

$$
\mu^{*}(S) \equiv \inf \{\mu(E): E \supseteq S, E \in \mathscr{F}\}
$$

Then $\mu^{*}$ is regular, meaning that for every $S$, there exists $E \in \mathscr{F}$ such that $E \supseteq S$ and $\mu(E)=\mu^{*}(S)$. If $S_{n} \uparrow S$, it follows that $\mu^{*}\left(S_{n}\right) \uparrow \mu^{*}(S)$. Also if $\mu(\Omega)<\infty$, then a set, $E$ is measurable if and only if

$$
\mu^{*}(\Omega) \geq \mu^{*}(E)+\mu^{*}(\Omega \backslash E)
$$

Proof: First we verify that $\mu^{*}$ is regular. If $\mu^{*}(S)=\infty$, let $E=\Omega$. Then $\mu^{*}(S)=\mu(E)$ and $E \supseteq S$. On the other hand, if $\mu^{*}(S)<\infty$, then we can obtain $E_{n} \in \mathscr{F}$ such that $\mu^{*}(S)+$ $\frac{1}{n} \geq \mu\left(E_{n}\right)$ and $E_{n} \supseteq S$. Now let $F_{n}=\cap_{i=1}^{n} E_{i}$. Then $F_{n} \supseteq S$ and so $\mu^{*}(S)+\frac{1}{n} \geq \mu\left(F_{n}\right) \geq$ $\mu^{*}(S)$. Therefore, letting $F=\cap_{k=1}^{\infty} F_{k} \in \mathscr{F}$ it follows $\mu(F)=\lim _{n \rightarrow \infty} \mu\left(F_{n}\right)=\mu^{*}(S)$.

Let $E_{n} \supseteq S_{n}$ be such that $E_{n} \in \mathscr{F}$ and $\mu\left(E_{n}\right)=\mu^{*}\left(S_{n}\right)$. Also let $E_{\infty} \supseteq S$ such that $\mu\left(E_{\infty}\right)=\mu^{*}(S)$ and $E_{\infty} \in \mathscr{F}$. Now consider $B_{n} \equiv \cup_{k=1}^{n} E_{k}$. We claim

$$
\begin{equation*}
\mu\left(B_{n}\right)=\mu\left(S_{n}\right) \tag{47.0.1}
\end{equation*}
$$

Here is why:

$$
\mu\left(E_{1} \backslash E_{2}\right)=\mu\left(E_{1}\right)-\mu\left(E_{1} \cap E_{2}\right)=\mu^{*}\left(S_{1}\right)-\mu^{*}\left(S_{1}\right)=0
$$

Therefore,

$$
\mu\left(B_{2}\right)=\mu\left(E_{1} \cup E_{2}\right)=\mu\left(E_{1} \backslash E_{2}\right)+\mu\left(E_{2}\right)=\mu\left(E_{2}\right)=\mu^{*}\left(S_{2}\right)
$$

Continuing in this way we see that 47.0 .1 holds. Now let $B_{n} \cap E_{\infty} \equiv C_{n}$. Then $C_{n} \uparrow C \equiv$ $\cup_{k=1}^{\infty} C_{n} \in \mathscr{F}$ and $\mu\left(C_{n}\right)=\mu^{*}\left(S_{n}\right)$. Since $S_{n} \uparrow S$ and each $C_{n} \supseteq S_{n}$, it follows $C \supseteq S$ and therefore,

$$
\mu^{*}(S) \leq \mu(C)=\lim _{n \rightarrow \infty} \mu\left(C_{n}\right)=\lim _{n \rightarrow \infty} \mu^{*}\left(S_{n}\right) \leq \mu^{*}(S)
$$

Now we verify the second claim of the lemma. It is clear the formula holds whenever $E$ is measurable. Suppose now that the formula holds. Let $S$ be an arbitrary set. We need to verify that

$$
\mu^{*}(S) \geq \mu^{*}(S \cap E)+\mu^{*}(S \backslash E)
$$

Let $F \supseteq S, F \in \mathscr{F}$, and $\mu(F)=\mu^{*}(S)$. Then since $\mu^{*}$ is subadditive,

$$
\begin{equation*}
\mu^{*}(\Omega \backslash F) \leq \mu^{*}(E \backslash F)+\mu^{*}\left(\Omega \cap E^{C} \cap F^{C}\right) \tag{47.0.2}
\end{equation*}
$$

Since $F$ is measurable,

$$
\begin{equation*}
\mu^{*}(E)=\mu^{*}(E \cap F)+\mu^{*}(E \backslash F) \tag{47.0.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\mu^{*}(\Omega \backslash E)=\mu^{*}(F \backslash E)+\mu^{*}\left(\Omega \cap E^{C} \cap F^{C}\right) \tag{47.0.4}
\end{equation*}
$$

and by the hypothesis,

$$
\begin{equation*}
\mu^{*}(\Omega) \geq \mu^{*}(E)+\mu^{*}(\Omega \backslash E) \tag{47.0.5}
\end{equation*}
$$

Therefore,

$$
\begin{aligned}
\mu(\Omega) & \geq \mu^{*}(E)+\mu^{*}(\Omega \backslash E) \\
& =\mu^{*}(E \cap F)+\mu^{*}(E \backslash F)+\mu^{*}(\Omega \backslash E) \\
& =\mu^{*}(E \cap F)+\mu^{*}(E \backslash F)+\mu^{*}(F \backslash E)+\mu^{*}\left(\Omega \cap E^{C} \cap F^{C}\right) \\
& \geq \mu^{*}(\Omega \backslash F)+\mu^{*}(F \backslash E)+\mu^{*}(E \cap F) \\
& \geq \mu^{*}(\Omega \backslash F)+\mu^{*}(F)=\mu(\Omega)
\end{aligned}
$$

showing that all the inequalities must be equal signs. Hence, referring to the top and fourth lines above,

$$
\mu(\Omega)=\mu^{*}(\Omega \backslash F)+\mu^{*}(F \backslash E)+\mu^{*}(E \cap F)
$$

Subtracting $\mu^{*}(\Omega \backslash F)=\mu(\Omega \backslash F)$ from both sides gives

$$
\mu^{*}(S)=\mu(F)=\mu^{*}(F \backslash E)+\mu^{*}(E \cap F) \geq \mu^{*}(S \backslash E)+\mu^{*}(E \cap S)
$$

This proves the lemma.
The next theorem is a major result. It states that the Suslin subsets are measurable under appropriate conditions. This is sort of interesting because something being a Suslin subset has to do with topology and this topological condition implies that the set is measurable.

Theorem 47.0.9 Let $\Omega$ be a metric space and let $(\Omega, \mathscr{F}, \mu)$ be a complete Borel measure space with $\mu(\Omega)<\infty$. Denote by $\mu^{*}$ the outer measure generated by $\mu$. Then if $A$ is a Suslin subset of $\Omega$, it follows that $A$ is $\mu^{*}$ measurable. Since the original measure space is complete, it follows that the completion produces nothing new and so in fact A is in $\mathscr{F}$. See Proposition 12.1.5.

Proof: We need to verify that

$$
\mu^{*}(\Omega) \geq \mu^{*}(A)+\mu^{*}(\Omega \backslash A)
$$

We know from Corollary 47.0.6, there exists a continuous map, $f: \mathbb{N}^{\mathbb{N}} \rightarrow A$ which is onto. Let

$$
E(k) \equiv\left\{\mathbf{n} \in \mathbb{N}^{\mathbb{N}}: n_{1} \leq k\right\}
$$

Then $E(k) \uparrow \mathbb{N}^{\mathbb{N}}$ and so from Lemma 47.0.8 we know $\mu^{*}(f(E(k))) \uparrow \mu^{*}(A)$. Therefore, there exists $m_{1}$ such that

$$
\mu^{*}\left(f\left(E\left(m_{1}\right)\right)\right)>\mu^{*}(A)-\frac{\varepsilon}{2} .
$$

Now $E(k)$ is clearly not compact but it is trying to be as far as the first component is concerned. Now we let

$$
E\left(m_{1}, k\right) \equiv\left\{\mathbf{n} \in \mathbb{N}^{\mathbb{N}}: n_{1} \leq m_{1} \text { and } n_{2} \leq k\right\}
$$

Thus $E\left(m_{1}, k\right) \uparrow E\left(m_{1}\right)$ and so we can pick $m_{2}$ such that

$$
\mu^{*}\left(f\left(E\left(m_{1}, m_{2}\right)\right)\right)>\mu^{*}\left(f\left(E\left(m_{1}\right)\right)\right)-\frac{\varepsilon}{2^{2}}
$$

We continue in this way obtaining a decreasing list of sets, $f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)\right)$, such that

$$
\mu^{*}\left(f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)\right)\right)>\mu^{*}\left(f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}\right)\right)\right)-\frac{\varepsilon}{2^{k}}
$$

Therefore,

$$
\mu^{*}\left(f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)\right)\right)-\mu^{*}(A)>\sum_{l=1}^{k}-\left(\frac{\varepsilon}{2^{l}}\right)>-\varepsilon
$$

Now define a closed set,

$$
C \equiv \cap_{k=1}^{\infty} \overline{f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)\right)}
$$

The sets $f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)\right)$ are decreasing as $k \rightarrow \infty$ and so

$$
\mu^{*}(C)=\lim _{k \rightarrow \infty} \mu^{*}\left(\overline{f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)\right)}\right) \geq \mu^{*}(A)-\varepsilon .
$$

We wish to verify that $C \subseteq A$. If we can do this we will be done because $C$, being a closed set, is measurable and so

$$
\mu^{*}(\Omega)=\mu^{*}(C)+\mu^{*}(\Omega \backslash C) \geq \mu^{*}(A)-\varepsilon+\mu^{*}(\Omega \backslash A)
$$

Since $\varepsilon$ is arbitrary, this will conclude the proof. Therefore, we only need to verify that $C \subseteq A$.

What we know is that each $f\left(E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)\right)$ is contained in $A$. We do not know their closures are contained in $A$. We let $\mathbf{m} \equiv\left\{m_{i}\right\}_{i=1}^{\infty}$ where the $m_{i}$ are defined above. Then letting

$$
K \equiv\left\{\mathbf{n} \in \mathbb{N}^{\mathbb{N}}: n_{i} \leq m_{i} \text { for all } i\right\}
$$

we see that $K$ is a closed, hence complete subset of $\mathbb{N}^{\mathbb{N}}$ which is also totally bounded due to the definition of the distance. Therefore, $K$ is compact and so $f(K)$ is also compact, hence closed due to the assumption that $\Omega$ is a Hausdorff space and we know that $f(K) \subseteq A$. We verify that $C=f(K)$. We know $f(K) \subseteq C$. Suppose therefore, $p \in C$. From the definition of $C$, we know there exists $\mathbf{r}^{k} \in E\left(m_{1}, m_{2}, \cdots, m_{k-1}, m_{k}\right)$ such that $d\left(f\left(\mathbf{r}^{k}\right), p\right)<\frac{1}{k}$. Denote by $\widetilde{\mathbf{r}^{k}}$ the element of $\mathbb{N}^{\mathbb{N}}$ which consists of modifying $\mathbf{r}^{k}$ by taking all components after the $k^{t h}$ equal to one. Thus $\widetilde{\mathbf{r}^{k}} \in K$. Now $\left\{\widetilde{\mathbf{r}^{k}}\right\}$ is in a compact set and so taking a subsequence we can have $\widetilde{\mathbf{r}^{k}} \rightarrow \mathbf{r} \in K$. But from the metric on $\mathbb{N}^{\mathbb{N}}$, it follows that $\rho\left(\widetilde{\mathbf{r}^{k}}, \mathbf{r}^{k}\right)<\frac{1}{2^{k-2}}$. Therefore, $\mathbf{r}^{k} \rightarrow \mathbf{r}$ also and so $f\left(\mathbf{r}^{k}\right) \rightarrow f(\mathbf{r})=p$. Therefore, $p \in f(K)$ and this proves the theorem.

Note we could have proved this under weaker assumptions. If we had assumed only that every point has a countable basis (first axiom of countability) and $\Omega$ is Hausdorff, the same argument would work. We will need the following definition.

Definition 47.0.10 Let $\mathscr{F}$ be a $\sigma$ algebra of sets from $\Omega$ and let $\mu$ denote a finite measure defined on $\mathscr{F}$. We let $\mathscr{F} \mu$ denote the completion of $\mathscr{F}$ with respect to $\mu$. Thus we let $\mu^{*}$ be the outer measure determined by $\mu$ and $\mathscr{F}_{\mu}$ will be the $\sigma$ algebra of $\mu^{*}$ measurable subsets of $\Omega$. We also define $\widehat{\mathscr{F}}$ by

$$
\widehat{\mathscr{F}} \equiv \cap\{\mathscr{F} \mu: \mu \text { is a finite measure defined on } \mathscr{F}\}
$$

Also, if $X$ is a topological space, we will denote by $B(X)$ the Borel sets of $X$.
With this notation, we can give the following simple corollary of Theorem 47.0.9. This is really quite amazing.

Corollary 47.0.11 Let $\Omega$ be a compact metric space and let $A$ be a Suslin subset of $\Omega$. Then $A \in \widehat{B(\Omega)}$.

Proof: Let $\mu$ be a finite measure defined on $B(\Omega)$. By Theorem 47.0.9 $A \in B(\Omega)_{\mu}$. Since this is true for every finite measure, $\mu$, it follows $A \in \widehat{B(\Omega)}$ as claimed. This proves the corollary.

We give another technical lemma about the completion of measure spaces.
Lemma 47.0.12 Let $\mu$ be a finite measure on a $\sigma$ algebra, $\Sigma$. Then $A \in \Sigma_{\mu}$ if and only if there exists $A_{1} \in \Sigma$ and $N_{1}$ such that $A=A_{1} \cup N_{1}$ where there exists $N \in \Sigma$ such that $\mu(N)=0$ and $N_{1} \subseteq N$.

Proof: Suppose first $A=A_{1} \cup N_{1}$ where these sets are as described. Let $S \in \mathscr{P}(\Omega)$ and let $\mu^{*}$ denote the outer measure determined by $\mu$. Then since $A_{1} \in \Sigma \subseteq \Sigma_{\mu}$

$$
\begin{aligned}
\mu^{*}(S) & \leq \mu^{*}(S \backslash A)+\mu^{*}(S \cap A) \\
& \leq \mu^{*}\left(S \backslash A_{1}\right)+\mu^{*}\left(S \cap A_{1}\right)+\mu^{*}\left(N_{1}\right) \\
& =\mu^{*}\left(S \backslash A_{1}\right)+\mu^{*}\left(S \cap A_{1}\right)=\mu^{*}(S)
\end{aligned}
$$

showing that $A \in \Sigma_{\mu}$.
Now suppose $A \in \Sigma_{\mu}$. Then there exists $B_{1} \supseteq A$ such that $\mu^{*}\left(B_{1}\right)=\mu^{*}(A)$, and $B_{1} \in \Sigma$. Also there exists $A_{1}^{C} \in \Sigma$ with $A_{1}^{C} \supseteq A^{C}$ and $\mu\left(A_{1}^{C}\right)=\mu^{*}\left(A^{C}\right)$. Then $A_{1} \subseteq A \subseteq B_{1}$

$$
A \subseteq A_{1} \cup\left(B_{1} \backslash A_{1}\right)
$$

Now

$$
\mu\left(A_{1}\right)+\mu^{*}\left(A^{C}\right)=\mu\left(A_{1}\right)+\mu\left(A_{1}^{C}\right)=\mu(\Omega)
$$

and so

$$
\begin{aligned}
\mu\left(B_{1} \backslash A_{1}\right) & =\mu^{*}\left(B_{1} \backslash A_{1}\right) \\
& =\mu^{*}\left(B_{1} \backslash A\right)+\mu^{*}\left(A \backslash A_{1}\right) \\
& =\mu^{*}\left(B_{1}\right)-\mu^{*}(A)+\mu^{*}(A)-\mu^{*}\left(A_{1}\right) \\
& =\mu^{*}(A)-\left(\mu(\Omega)-\mu^{*}\left(A^{C}\right)\right)=0
\end{aligned}
$$

because $A \in \Sigma_{\mu}$ implying $A=A_{1} \cup \overbrace{\left(B_{1} \backslash A_{1}\right) \cap A}^{N_{1}}$ and $N_{1} \subseteq N \equiv\left(B_{1} \backslash A_{1}\right) \in \Sigma$ with $\mu(N)=$ 0 . This proves the lemma.

Next we need another definition.
Definition 47.0.13 We say $(\Omega, \Sigma)$, where $\Sigma$ is a $\sigma$ algebra of subsets of $\Omega$, is separable if there exists a sequence $\left\{A_{n}\right\}_{n=1}^{\infty} \subseteq \Sigma$ such that $\sigma\left(\left\{A_{n}\right\}\right)=\Sigma$ and if $w \neq w^{\prime}$, then there exists $A \in \Sigma$ such that $\mathscr{X}_{A}(\omega) \neq \mathscr{X}_{A}\left(\omega^{\prime}\right)$. This last condition is referred to by saying $\left\{A_{n}\right\}$ separates the points of $\Omega$. Given two measure spaces, $(\Omega, \Sigma)$ and $\left(\Omega^{\prime}, \Sigma^{\prime}\right)$, we say they are isomorphic if there exists a function, $f: \Omega \rightarrow \Omega^{\prime}$ which is one to one and $f(E) \in \Sigma^{\prime}$ whenever $E \in \Sigma$ and $f^{-1}(F) \in \Sigma$ whenever $F \in \Sigma^{\prime}$.

The interesting thing about separable measure spaces is that they are isomorphic to a very simple sort of measure space in which topology plays a significant role.

Lemma 47.0.14 Let $(\Omega, \Sigma)$ be separable. Then there exists $E \in\{0,1\}^{\mathbb{N}}$ such that $(\Omega, \Sigma)$ and $(E, B(E))$ are isomorphic.

Proof: First we show $\left\{A_{n}\right\}$ separates the points. Here $\sigma\left(\left\{A_{n}\right\}\right)=\Sigma$. We already know $\Sigma$ separates the points but now we show the smaller set does so also. If this is not so, there exists $\omega, \omega_{1} \in \Omega$ such that for all $n, \mathscr{X}_{A_{n}}(\omega)=\mathscr{X}_{A_{n}}\left(\omega_{1}\right)$. Then let

$$
\mathscr{F} \equiv\left\{F \in \Sigma: \mathscr{X}_{F}(\omega)=\mathscr{X}_{F}\left(\omega_{1}\right)\right\}
$$

Thus $A_{n} \in \mathscr{F}$ for all $n$. It is also clear that $\mathscr{F}$ is a $\sigma$ algebra and so $\mathscr{F}=\Sigma$ contradicting the assumption that $\Sigma$ separates points. Now we define a function from $\Omega$ to $\{0,1\}^{\mathbb{N}}$ as follows.

$$
f(\omega) \equiv\left\{\mathscr{X}_{A_{n}}(\omega)\right\}_{n=1}^{\infty}
$$

We also let $E \equiv f(\Omega)$. Since the $\left\{A_{n}\right\}$ separate the points, we see that $f$ is one to one. A subbasis for the topology of $\{0,1\}^{\mathbb{N}}$ consists of sets of the form $\prod_{i=1}^{\infty} H_{i}$ where $H_{i}=\{0,1\}$ for all $i$ except one, when $i=j$ and $H_{j}$ equals either $\{0\}$ or $\{1\}$. Therefore,

$$
f^{-1}(\text { subbasic open set }) \in \Sigma
$$

because if $H_{j}$ is the exceptional set then this equals $A_{j}$ if $H_{j}=\{1\}$ and $A_{j}^{C}$ if $H_{j}=\{0\}$. Intersections of these subbasic sets with $E$ gives a countable subbasis for $E$ and so the inverse image of all sets in a countable subbasis for $E$ are in $\Sigma$, showing that $f^{-1}$ (open set) $\in \Sigma$. Now we consider $f\left(A_{n}\right)$.

$$
f\left(A_{n}\right) \equiv\left\{\left\{\lambda_{k}\right\}_{k=1}^{\infty}: \lambda_{n}=1\right\} \cap E,
$$

an open set in $E$. Hence $f\left(A_{n}\right) \in B(E)$. Now letting

$$
\mathscr{F} \equiv\{G \subseteq \Omega: f(G) \in B(E)\},
$$

we see that $\mathscr{F}$ is a $\sigma$ algebra which contains $\left\{A_{n}\right\}_{n=1}^{\infty}$ and so $\mathscr{F} \supseteq \sigma\left(\left\{A_{n}\right\}\right) \equiv \Sigma$. Thus $f(F) \in B(E)$ for all $A \in \Sigma$. This proves the lemma.

Lemma 47.0.15 Let $\phi:\left(\Omega_{1}, \Sigma_{1}\right) \rightarrow\left(\Omega_{2}, \Sigma_{2}\right)$ where $\phi^{-1}(U) \in \Sigma_{1}$ for all $U \in \Sigma_{2}$. Then if $F \in \widehat{\Sigma}_{2}$, it follows $\phi^{-1}(F) \in \widehat{\Sigma}_{1}$.

Proof: Let $\mu$ be a finite measure on $\Sigma_{1}$ and define a measure $\phi(\mu)$ on $\Sigma_{2}$ by the rule

$$
\phi(\mu)(F) \equiv \mu\left(\phi^{-1}(F)\right)
$$

Now let $A \in \Sigma_{2 \phi(\mu)}$. Then by Lemma 47.0.12, $A=A_{1} \cup N_{1}$ where there exists $N \in \Sigma_{2}$ with $\phi(\mu)(N)=0$ and $A_{1} \in \Sigma_{2}$. Therefore, from the definition of $\phi(\mu)$, we have $\mu\left(\phi^{-1}(N)\right)=$ 0 and therefore, $\phi^{-1}(A)=\phi^{-1}\left(A_{1}\right) \cup \phi^{-1}\left(N_{1}\right)$ where

$$
\phi^{-1}\left(N_{1}\right) \subseteq \phi^{-1}(N) \in \Sigma_{1}
$$

and $\mu\left(\phi^{-1}(N)\right)=0$. Therefore, $\phi^{-1}(A) \in \Sigma_{1 \mu}$ and so if $F \in \widehat{\Sigma}_{2}$, then
$F \in \cap\left\{\Sigma_{2 v}: v\right.$ is a finite measure on $\left.\Sigma_{2}\right\} \subseteq \cap\left\{\Sigma_{2 \phi(\mu)}: \mu\right.$ is a finite measure on $\left.\Sigma_{1}\right\}$,
and so $\phi^{-1}(F) \in \Sigma_{1 \mu}$. Since $\mu$ is arbitrary, this shows $\phi^{-1}(F) \in \widehat{\Sigma}_{1}$.
The next lemma is a special case of the Yankov von Neumann Aumann projection theorem. It contains the main idea of the proof of the more general theorem.

Definition 47.0.16 Let $(\Omega, \Sigma)$ be a measurable space and let $G \in \Sigma \times B(X)$ the product measurable sets resulting from the Borel sets $B(X)$ for $X$ a Suslan space. Then

$$
\operatorname{proj}_{\Omega}(G) \equiv\{\omega \in \Omega: \text { there exists } x \in X \text { with }(\omega, x) \in G\}
$$

What if you had $G=\cup\{(\omega \times A(\omega)): \omega \in \Omega\}$ where $A(\omega)$ is in $Y$ some polish space and $A(\omega)$ is, for example, a closed nonempty set? Then

$$
\operatorname{proj}_{\Omega}(G)=\{\omega \in \Omega: A(\omega) \cap X \neq \emptyset\}
$$

Of course, you might ask whether this particular $G$ is in $\Sigma \times B(X)$. For fixed $\omega$ the $\omega$ section is closed which is Borel. To say that $\operatorname{proj}_{\Omega}(G) \in \Sigma$ would be to say that each $y$ section is in $\Sigma$ so this $G$ is in $\Sigma \times B(X)$ exactly when $\operatorname{proj}_{\Omega}(G) \in \Sigma$. Later this will be defined as saying that $A$ is a measurable multifunction. It will be measurable when $X$ is open, strongly measurable when $X$ is closed.

Lemma 47.0.17 Let $(\Omega, \Sigma)$ be separable and let $X$ be a Suslin space. Let $G \in \Sigma \times B(X)$. (Recall $\Sigma \times B(X)$ is the $\sigma$ algebra of product measurable sets, the smallest $\sigma$ algebra containing the measurable rectangles.) Then

$$
\operatorname{proj}_{\Omega}(G) \in \widehat{\Sigma}
$$

Proof: Let $f:(\Omega, \Sigma) \rightarrow(E, B(E))$ be the isomorphism of Lemma 47.0.14. We have the following claim.

Claim: $f \times \mathrm{id}_{X}$ maps $\Sigma \times B(X)$ to $B(E) \times B(X)$.
Proof of the claim: First of all, assume $A \times B$ is a measurable rectangle where $A \in \Sigma$ and $B \in B(X)$. Then by the assumption that $f$ is an isomorphism, $f(A) \in B(E)$ and so

$$
f \times \operatorname{id}_{X}(A \times B) \in B(E) \times B(X) .
$$

Now let

$$
\mathscr{F} \equiv\left\{P \in \Sigma \times B(X): f \times \operatorname{id}_{X}(P) \in B(E) \times B(X)\right\} .
$$

Then we see that $\mathscr{F}$ is a $\sigma$ algebra and contains the elementary sets. ( $\mathscr{F}$ is closed with respect to complements because $f$ is one to one.) Therefore, $\mathscr{F}=\Sigma \times B(X)$ and this proves the claim.

Therefore, since $G \in \Sigma \times B(X)$, we see

$$
f \times \operatorname{id}_{X}(G) \in B(E) \times B(X) \subseteq B(E \times X) .
$$

The set inclusion follows from the observation that if $A \in B(E)$ and $B \in B(X)$ then $A \times B$ is in $B(E \times X)$ and the collection of sets in $B(E) \times B(X)$ which are in $B(E \times X)$ is a $\sigma$ algebra.

Therefore, there exists $D$, a Borel set in $E \times X$ such that $f \times \mathrm{id}_{X}(G)=D \cap(E \times X)$. Now from this it follows from Lemma 47.0.7 that $D$ is a Suslin space. Letting $Y$ be $\{0,1\}^{\mathbb{N}}$, it follows that $\operatorname{proj}_{Y}(D)$ is a Suslin space in $Y$. By Corollary 47.0.11, we see that $\operatorname{proj}_{Y}(D) \in$ $\widehat{B(Y)}$. Now

$$
\begin{gathered}
\operatorname{proj}_{\Omega}(G)=\{\omega \in \Omega \text { : there exists } x \in X \text { with }(\omega, x) \in G\} \\
=\left\{\omega \in \Omega: \text { there exists } x \in X \text { with }(f(\omega), x) \in f \times \operatorname{id}_{X}(G)\right\} \\
=f^{-1}(\{y \in Y: \text { there exists } x \in X \text { with }(y, x) \in D\}) \\
=f^{-1}\left(\operatorname{proj}_{Y}(D)\right)
\end{gathered}
$$

Now $\operatorname{proj}_{Y}(D) \in \widehat{B(Y)}$ and so Lemma 47.0.15 shows $f^{-1}\left(\operatorname{proj}_{Y}(D)\right) \in \widehat{\Sigma}$. This proves the lemma.

Now we are ready to prove the Yankov von Neumann Aumann projection theorem. First we must present another technical lemma.

Lemma 47.0.18 Let $X$ be a Hausdorff space and let $G \in \Sigma \times B(X)$ where $\Sigma$ is a $\sigma$ algebra of sets of $\Omega$. Then there exists $\Sigma_{0} \subseteq \Sigma$ a countably generated $\sigma$ algebra such that $G \in$ $\Sigma_{0} \times B(X)$.

Proof: First suppose $G$ is a measurable rectangle, $G=A \times B$ where $A \in \Sigma$ and $B \in$ $B(X)$. Letting $\Sigma_{0}$ be the finite $\sigma$ algebra, $\left\{\emptyset, A, A^{C}, \Omega\right\}$, we see that $G \in \Sigma_{0} \times B(X)$. Similarly, if $G$ equals an elementary set, then the conclusion of the lemma holds for $G$. Let

$$
\mathscr{F} \equiv\left\{H \in \Sigma \times B(X): H \in \Sigma_{0} \times B(X)\right\}
$$

for some countably generated $\sigma$ algebra, $\Sigma_{0}$. We just saw that $\mathscr{F}$ contains the elementary sets. If $H \in \mathscr{F}$, then $H^{C} \in \Sigma_{0} \times B(X)$ for the same $\Sigma_{0}$ and so $\mathscr{F}$ is closed with respect to complements. Now suppose $H_{n} \in \mathscr{F}$. Then for each $n$, there exists a countably generated $\sigma$ algebra, $\Sigma_{0 n}$ such that $H_{n} \in \Sigma_{0 n} \times B(X)$. Then $\cup_{n=1}^{\infty} H_{n} \in \sigma\left(\left\{\Sigma_{0 n} \times B(X)\right\}\right)$. We will be done when we show

$$
\sigma\left(\left\{\Sigma_{0 n} \times B(X)\right\}_{n=1}^{\infty}\right) \subseteq \sigma\left(\left\{\Sigma_{0 n}\right\}_{n=1}^{\infty}\right) \times B(X)
$$

because it is clear that $\sigma\left(\left\{\Sigma_{0 n}\right\}_{n=1}^{\infty}\right)$ is countably generated. We see that

$$
\sigma\left(\left\{\Sigma_{0 n} \times B(X)\right\}_{n=1}^{\infty}\right)
$$

is generated by sets of the form $A \times B$ where $A \in \Sigma_{0 n}$ and $B \in B(X)$. But each such set is also contained in $\sigma\left(\left\{\Sigma_{0 n}\right\}_{n=1}^{\infty}\right) \times B(X)$ and so the desired inclusion is obtained. Therefore, $\mathscr{F}$ is a $\sigma$ algebra and so since $\mathscr{F}$ was shown to contain the measurable rectangles, this verifies $\mathscr{F}=\Sigma \times B(X)$ and this proves the lemma.

Theorem 47.0.19 Let $(\Omega, \Sigma)$ be a measure space and let $G \in \widehat{\Sigma} \times B(X)$ where $X$ is a Suslin space. Then

$$
\operatorname{proj}_{\Omega}(G) \in \widehat{\Sigma}
$$

Proof: By the previous lemma, $G \in \Sigma_{0} \times B(X)$ where $\Sigma_{0}$ is countably generated. If $\left(\Omega, \Sigma_{0}\right)$ were separable, we could then apply Lemma 47.0.17 and be done. Unfortunately, we don't know $\Sigma_{0}$ separates the points of $\Omega$. Therefore, we define an equivalence class on the points of $\Omega$ as follows. We say $\omega \backsim \omega_{1}$ if and only if $\mathscr{X}_{A}(\omega)=\mathscr{X}_{A}\left(\omega_{1}\right)$ for all $A \in \Sigma_{0}$. Now the nice thing to notice about this equivalence relation is that if $\omega \in A \in \Sigma_{0}$, and if $\omega \backsim \omega_{1}$, then $1=\mathscr{X}_{A}(\omega)=\mathscr{X}_{A}\left(\omega_{1}\right)$ implying $\omega_{1} \in A$ also. Therefore, every set of $\Sigma_{0}$ is the union of equivalence classes. It follows that for $A \in \Sigma_{0}$, and $\pi$ the map given by $\pi \omega \equiv[\omega]$ where $[\omega]$ is the equivalence class determined by $\omega$,

$$
\pi(A) \cap \pi(\Omega \backslash A)=\emptyset
$$

Suppose now that $H_{n} \in \Sigma_{0} \times B(X)$. If $([\omega], x) \in \cap_{n=1}^{\infty} \pi \times \mathrm{id}_{X}\left(H_{n}\right)$, then for each $n$,

$$
([w], x)=\left(\pi w_{n}, x\right)
$$

for some $\left(\omega_{n}, x\right) \in H_{n}$. But this implies $\omega \backsim \omega_{n}$ and so from the above observation that the sets of $\Sigma_{0}$ are unions of equivalence classes, it follows that $(\omega, x) \in H_{n}$. Therefore, $(\omega, x) \in \cap_{n=1}^{\infty} H_{n}$ and so $([\omega], x)=\pi \times \operatorname{id}_{X}(\omega, x)$ where $(\omega, x) \in \cap_{n=1}^{\infty} H_{n}$. This shows that

$$
\pi \times \operatorname{id}_{X}\left(\cap_{n=1}^{\infty} H_{n}\right) \supseteq \cap_{n=1}^{\infty} \pi \times \operatorname{id}_{X}\left(H_{n}\right)
$$

In fact these two sets are equal because the other inclusion is obvious. We will denote by $\Omega_{1}$ the set of equivalence classes and $\Sigma_{1}$ will be the subsets, $S_{1}$, of $\Omega_{1}$ such that $S_{1}=$ $\left\{[\omega]: \omega \in S \in \Sigma_{0}\right\}$. Then $\left(\Omega_{1}, \Sigma_{1}\right)$ is clearly a measure space which is separable. Let

$$
\mathscr{F} \equiv\left\{H \in \Sigma_{0} \times B(X): \pi \times \operatorname{id}_{X}(H), \pi \times \operatorname{id}_{X}\left(H^{C}\right) \in \Sigma_{1} \times B(X)\right\}
$$

We see that the measurable rectangles, $A \times B$ where $A \in \Sigma_{0}$ and $B \in B(X)$ are in $\mathscr{F}$, that from the above observation on countable intersections, $\mathscr{F}$ is closed with respect to countable unions and closed with respect to complements. Therefore, $\mathscr{F}$ is a $\sigma$ algebra and so $\mathscr{F}=\Sigma_{0} \times B(X)$. By Lemma 47.0.14 $\left(\Omega_{1}, \Sigma_{1}\right)$ is isomorphic to $(E, B(E))$ where $E$ is a subspace of $\{0,1\}^{\mathbb{N}}$. Denoting the isomorphism by $h$, it follows as in Lemma 47.0.17 that $h \times \mathrm{id}_{X}$ maps $\Sigma_{1} \times B(X)$ to $B(E) \times B(X)$. Therefore, we see $f \equiv h \circ \pi$ is a mapping from $\Omega$ to $E$ which has the property that $f \times \operatorname{id}_{X}$ maps $\Sigma_{0} \times B(X)$ to $B(E) \times B(X)$. Now from the proof of Lemma 47.0 .17 starting with the claim, we see that $G \in \widehat{\Sigma}_{0}$. However, if $\mu$ is a finite measure on $\widehat{\Sigma}$, then $(\widehat{\Sigma})_{\mu}=\Sigma_{\mu}$ and so $\widehat{\Sigma}_{0} \subseteq \widehat{(\widehat{\Sigma})} \subseteq \widehat{\Sigma}$. This proves the theorem.

## Chapter 48

## Multifunctions and Their Measurability

### 48.1 The General Case

Let $X$ be a separable complete metric space and let $(\Omega, \mathscr{C}, \mu)$ be a set, a $\sigma$ algebra of subsets of $\Omega$, and a measure $\mu$ such that this is a complete $\sigma$ finite measure space. Also let $\Gamma: \Omega \rightarrow \mathscr{P}_{F}(X)$, the closed subsets of $X$.

Definition 48.1.1 We define $\Gamma^{-}(S) \equiv\{\omega \in \Omega: \Gamma(\omega) \cap S \neq \emptyset\}$
We will consider a theory of measurability of set valued functions. The following theorem is the main result in the subject. In this theorem the third condition is what we will refer to as measurable.

Theorem 48.1.2 The following are equivalent in case of a complete $\sigma$ finite measure space. However 3 and 4 are equivalent for any measurable space consisting only of a set $\Omega$ and $a \sigma$ algebra $\mathscr{C}$.

1. For all B a Borel set in $X, \Gamma^{-}(B) \in \mathscr{C}$.
2. For all $F$ closed in $X, \Gamma^{-}(F) \in \mathscr{C}$
3. For all $U$ open in $X, \Gamma^{-}(U) \in \mathscr{C}$
4. There exists a sequence, $\left\{\sigma_{n}\right\}$ of measurable functions satisfying $\sigma_{n}(\omega) \in \Gamma(\omega)$ such that for all $\omega \in \Omega$,

$$
\Gamma(\omega)=\overline{\left\{\sigma_{n}(\omega): n \in \mathbb{N}\right\}}
$$

These functions are called measurable selections.
5. For all $x \in X, \omega \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ is a measurable real valued function.
6. $\mathscr{G}(\Gamma) \equiv\{(\omega, x): x \in \Gamma(\omega)\} \subseteq \mathscr{C} \times B(X)$.

Proof: It is obvious that 1.) $\Rightarrow 2$.). To see that 2.) $\Rightarrow$ 3.) note that $\Gamma^{-}\left(\cup_{i=1}^{\infty} F_{i}\right)=$ $\cup_{i=1}^{\infty} \Gamma^{-}\left(F_{i}\right)$. Since any open set in $X$ can be obtained as a countable union of closed sets, this implies 2.) $\Rightarrow 3$.).

Now we verify that 3.) $\Rightarrow 4$.). For convenience, drop the assumption that $\Gamma(\omega)$ is closed in this part of the argument. It will just be set valued and satisfy the measurability condition. A measurable selection will be obtained in $\overline{\Gamma(\omega)}$. Let $\left\{x_{n}\right\}_{n=1}^{\infty}$ be a countable dense subset of $X$. For $\omega \in \Omega$, let $\psi_{1}(\omega)=x_{n}$ where $n$ is the smallest integer such that $\Gamma(\omega) \cap B\left(x_{n}, 1\right) \neq \emptyset$. Therefore, $\psi_{1}(\omega)$ has countably many values, $x_{n_{1}}, x_{n_{2}}, \cdots$ where $n_{1}<$ $n_{2}<\cdots$. Now

$$
\begin{gathered}
\left\{\omega: \psi_{1}=x_{n}\right\}= \\
\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 1\right) \neq \emptyset\right\} \cap\left[\Omega \backslash \cup_{k<n}\left\{\omega: \Gamma(\omega) \cap B\left(x_{k}, 1\right) \neq \emptyset\right\}\right] \in \mathscr{C} .
\end{gathered}
$$

Thus we see that $\psi_{1}$ is measurable and $\operatorname{dist}\left(\psi_{1}(\omega), \Gamma(\omega)\right)<1$. Let

$$
\Omega_{n} \equiv\left\{\omega \in \Omega: \psi_{1}(\omega)=x_{n}\right\}
$$

Then $\Omega_{n} \in \mathscr{C}$ and $\Omega_{n} \cap \Omega_{m}=\emptyset$ for $n \neq m$ and $\cup_{n=1}^{\infty} \Omega_{n}=\Omega$. Let

$$
D_{n} \equiv\left\{x_{k}: x_{k} \in B\left(x_{n}, 1\right)\right\}
$$

Now for each $n$, and $\omega \in \Omega_{n}$, let $\psi_{2}(\omega)=x_{k}$ where $k$ is the smallest index such that $x_{k} \in D_{n}$ and $B\left(x_{k}, \frac{1}{2}\right) \cap \Gamma(\omega) \neq \emptyset$. Thus dist $\left(\psi_{2}(\omega), \Gamma(\omega)\right)<\frac{1}{2}$ and

$$
d\left(\psi_{2}(\omega), \psi_{1}(\omega)\right)<1
$$

Continue this way obtaining $\psi_{k}$ a measurable function such that

$$
\operatorname{dist}\left(\psi_{k}(\omega), \Gamma(\omega)\right)<\frac{1}{2^{k-1}}, d\left(\psi_{k}(\omega), \psi_{k+1}(\omega)\right)<\frac{1}{2^{k-2}}
$$

Then for each $\omega,\left\{\psi_{k}(\omega)\right\}$ is a Cauchy sequence converging to a point, $\sigma(\omega) \in \overline{\Gamma(\omega)}$. This has shown that if $\Gamma$ is measurable, there exists a measurable selection, $\sigma(\omega) \in \overline{\Gamma(\omega)}$. Of course, if $\Gamma(\omega)$ is closed, then $\sigma(\omega) \in \Gamma(\omega)$. Note that this had nothing to do with the measure. It remains to show there exists a sequence of these measurable selections $\sigma_{n}$ such that the conclusion of 4.) holds. To do this we define for $\Gamma(\omega)$ closed and measurable,

$$
\Gamma_{n i}(\omega) \equiv\left\{\begin{array}{l}
\Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \text { if } \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \neq \emptyset \\
\Gamma(\omega) \text { otherwise }
\end{array}\right.
$$

Thus in the case of nonempty intersecton in the above cases,

$$
\Gamma(\omega) \cap \overline{B\left(x_{n}, 2^{-(i+1)}\right)} \subseteq \overline{\Gamma_{n i}(\omega)} \subseteq \Gamma(\omega) \cap \overline{B\left(x_{n}, 2^{-i}\right)}
$$

First we show that $\Gamma_{n i}$ is measurable. Let $U$ be open. Then

$$
\begin{gathered}
\left\{\omega: \Gamma_{n i}(\omega) \cap U \neq \emptyset\right\}=\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \cap U \neq \emptyset\right\} \cup \\
{\left[\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right)=\emptyset\right\} \cap\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}\right]} \\
=\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \cap U \neq \emptyset\right\} \cup \\
{\left[\left(\Omega \backslash\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \neq \emptyset\right\}\right) \cap\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}\right],}
\end{gathered}
$$

a measurable set. By what was just shown, there exists $\sigma_{n i}$, a measurable function such that $\sigma_{n i}(\omega) \in \overline{\Gamma_{n i}(\omega)} \subseteq \Gamma(\omega)$ for all $\omega \in \Omega$. If $x \in \Gamma(\omega)$, then

$$
x \in \overline{B\left(x_{n}, 2^{-(i+2)}\right)}
$$

whenever $x_{n}$ is close enough to $x$. Thus both $x, \sigma_{n(i+2)}(\omega)$ are in $B\left(x_{n}, 2^{-(i+2)}\right)$ and so $\left|\sigma_{n(i+1)}(\omega)-x\right|<2^{-i}$. It follows that condition 4.) holds. Note that this had nothing to do with the measure.

Now we verify that 4.) $\Rightarrow$ 3.). Suppose there exist measurable selections $\sigma_{n}(\omega) \in$ $\Gamma(\omega)$ satisfying condition 4 .). Let $U$ be open. Then

$$
\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}=\cup_{n=1}^{\infty} \sigma_{n}^{-1}(U) \in \mathscr{C} .
$$

Now we verify that 4.) $\Rightarrow$ 5.). Let $F(\omega) \equiv \operatorname{dist}(x, \Gamma(\omega))$. Then letting $U$ be an open set in $[0, \infty), F(\omega) \in U$ if and only if $d\left(x, \sigma_{n}(\omega)\right) \in U$ for some $\sigma_{n}(\omega)$. Let $h_{n}(\omega) \equiv$ $d\left(x, \sigma_{n}(\omega)\right)$. Then $h_{n}$ is measurable and $F^{-1}(U)=\cup_{n=1}^{\infty} h_{n}^{-1}(U) \in \mathscr{C}$. This shows that for all $x \in X, \omega \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ is measurable and this proves 5 .).

Now we verify that 5.$) \Rightarrow 4$.). We know $\operatorname{dist}(x, \Gamma(\cdot))$ is measurable and we show $\{\omega: \Gamma(\omega) \cap U \neq \emptyset\} \in \mathscr{C}$ whenever $U$ is open and then use 3.) $\Rightarrow 4$.). Since $X$ is separable, there exists $B\left(x_{i}, r_{i}\right)$ such that $U=\cup_{i=1}^{\infty} B\left(x_{i}, r_{i}\right)$. Then

$$
\begin{aligned}
\{\omega: \Gamma(\omega) \cap U \neq \emptyset\} & =\cup_{i=1}^{\infty}\left\{\omega: \Gamma(\omega) \cap B\left(x_{i}, r_{i}\right) \neq \emptyset\right\} \\
& =\cup_{i=1}^{\infty}\left\{\omega: \operatorname{dist}\left(x_{i}, \Gamma(\omega)\right)<r_{i}\right\} \in \mathscr{C} .
\end{aligned}
$$

Therefore, 5.) $\Rightarrow 4$.) as claimed.
Now we must prove 5.) $\Rightarrow 6$.). We note that $\omega \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ is measurable and $x \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ is continuous. Also, the graph of $\Gamma, \mathscr{G}(\Gamma)$ is given by

$$
\mathscr{G}(\Gamma)=\{(\omega, x): \operatorname{dist}(x, \Gamma(\omega))=0\} .
$$

We wish to show that $(\omega, x) \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ is product measurable because then $\mathscr{G}(\Gamma)$, being the inverse image of $\{0\}$ will be product measurable. Let $\left\{x_{k}\right\}$ be a countable dense set in $X$ and let

$$
\phi_{k}(\omega, x) \equiv \operatorname{dist}\left(x_{n}, \Gamma(\omega)\right)
$$

where $n$ is the first index such that $x \in B\left(x_{n}, 2^{-k}\right)$. Then $\phi_{k}(\omega, x) \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ due to the continuity of $x \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ and so we must argue that $\phi_{k}$ is product measurable. On

$$
E_{n} \equiv \Omega \times\left(B\left(x_{n}, 2^{-k}\right) \backslash \cup_{m<n} B\left(x_{m}, 2^{-k}\right)\right)
$$

$\phi_{k}(\omega, x)=\operatorname{dist}\left(x_{n}, \Gamma(\omega)\right)$. Thus, on this set, $\phi_{k}$ equals a measurable function of $\omega$ and does not depend on $x$ on $E_{n}$. It follows that there are measurable simple $\mathscr{C}$ measurable functions, $s_{m}(\omega)$ which increase pointwise to $\operatorname{dist}\left(x_{n}, \Gamma(\omega)\right)$ on $E_{n}$. Thus $s_{m}(\omega) \mathscr{X}_{E_{n}}(x)$ increases to $\phi_{k}(\omega, x)$ on $E_{n}$ showing that $\phi_{k} \mathscr{X}_{E_{n}}$ is product measurable with respect to $\mathscr{C} \times \sigma(\tau)$ since $E_{n}$ is a measurable rectangle with respect to $\mathscr{C}$ and $\sigma(\tau)$. Therefore, $\phi_{k}$ is product measurable and so $(\omega, x) \rightarrow \operatorname{dist}(x, \Gamma(\omega))$ is also product measurable.

It remains to prove 6 .) $\Rightarrow 1$.). This follows from Theorem 47.0.19.

$$
\begin{gathered}
\Gamma^{-}(B) \equiv\{\omega: \Gamma(\omega) \cap B \neq \emptyset\} \\
=\operatorname{proj}_{\Omega}(\mathscr{G}(\Gamma) \cap(\Omega \cap B))
\end{gathered}
$$

But from Theorem 47.0.19, $\operatorname{proj}_{\Omega}(\mathscr{G}(\Gamma) \cap(\Omega \cap B)) \in \hat{C} \subseteq \mathscr{C}_{\mu}=\mathscr{C}$.
The last part results from $(\Omega, \mathscr{C}, \mu)$ being a complete measure space. Note that without this assumption we could not draw the conclusion desired. This required consideration of the measure. The following theorem is like part of the above but without an assumption that $\Gamma(\omega)$ is closed.

Theorem 48.1.3 The following are equivalent for any measurable space consisting only of a set $\Omega$ and a $\sigma$ algebra $\mathscr{C}$. Here nothing is known about $\Gamma(\omega)$ other than that is $a$ nonempty set.

1. For all $U$ open in $X, \Gamma^{-}(U) \in \mathscr{C}$

$$
\Gamma^{-}(U) \equiv\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}
$$

2. There exists a sequence, $\left\{\sigma_{n}\right\}$ of measurable functions satisfying $\sigma_{n}(\omega) \in \Gamma(\omega)$ such that for all $\omega \in \Omega$,

$$
\overline{\Gamma(\omega)}=\overline{\left\{\sigma_{n}(\omega): n \in \mathbb{N}\right\}}
$$

These functions are called measurable selections.
Proof: First 1.) $\Rightarrow 2$.). A measurable selection will be obtained in $\overline{\Gamma(\omega)}$. Let $\left\{x_{n}\right\}_{n=1}^{\infty}$ be a countable dense subset of $X$. For $\omega \in \Omega$, let $\psi_{1}(\omega)=x_{n}$ where $n$ is the smallest integer such that $\Gamma(\omega) \cap B\left(x_{n}, 1\right) \neq \emptyset$. Therefore, $\psi_{1}(\omega)$ has countably many values, $x_{n_{1}}, x_{n_{2}}, \cdots$ where $n_{1}<n_{2}<\cdots$. Now

$$
\begin{gathered}
\left\{\omega: \psi_{1}=x_{n}\right\}= \\
\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 1\right) \neq \emptyset\right\} \cap\left[\Omega \backslash \cup_{k<n}\left\{\omega: \Gamma(\omega) \cap B\left(x_{k}, 1\right) \neq \emptyset\right\}\right] \in \mathscr{C} .
\end{gathered}
$$

Thus we see that $\psi_{1}$ is measurable and $\operatorname{dist}\left(\psi_{1}(\omega), \Gamma(\omega)\right)<1$. Let

$$
\Omega_{n} \equiv\left\{\omega \in \Omega: \psi_{1}(\omega)=x_{n}\right\}
$$

Then $\Omega_{n} \in \mathscr{C}$ and $\Omega_{n} \cap \Omega_{m}=\emptyset$ for $n \neq m$ and $\cup_{n=1}^{\infty} \Omega_{n}=\Omega$. Let

$$
D_{n} \equiv\left\{x_{k}: x_{k} \in B\left(x_{n}, 1\right)\right\}
$$

Now for each $n$, and $\omega \in \Omega_{n}$, let $\psi_{2}(\omega)=x_{k}$ where $k$ is the smallest index such that $x_{k} \in D_{n}$ and $B\left(x_{k}, \frac{1}{2}\right) \cap \Gamma(\omega) \neq \emptyset$. Thus dist $\left(\psi_{2}(\omega), \Gamma(\omega)\right)<\frac{1}{2}$ and

$$
d\left(\psi_{2}(\omega), \psi_{1}(\omega)\right)<1
$$

Continue this way obtaining $\psi_{k}$ a measurable function such that

$$
\operatorname{dist}\left(\psi_{k}(\omega), \Gamma(\omega)\right)<\frac{1}{2^{k-1}}, d\left(\psi_{k}(\omega), \psi_{k+1}(\omega)\right)<\frac{1}{2^{k-2}}
$$

Then for each $\omega,\left\{\psi_{k}(\omega)\right\}$ is a Cauchy sequence converging to a point, $\sigma(\omega) \in \overline{\Gamma(\omega)}$. This has shown that if $\Gamma$ is measurable, there exists a measurable selection, $\sigma(\omega) \in \overline{\Gamma(\omega)}$. Of course, if $\Gamma(\omega)$ is closed, then $\sigma(\omega) \in \Gamma(\omega)$. Note that this had nothing to do with a measure.

It remains to show there exists a sequence of these measurable selections $\sigma_{n}$ such that the conclusion of 2.) holds. To do this we define

$$
\Gamma_{n i}(\omega) \equiv\left\{\begin{array}{l}
\Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \text { if } \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \neq \emptyset \\
\Gamma(\omega) \text { otherwise }
\end{array}\right.
$$

First we show that $\Gamma_{n i}$ is measurable. Let $U$ be open. Then

$$
\left\{\omega: \Gamma_{n i}(\omega) \cap U \neq \emptyset\right\}=\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \cap U \neq \emptyset\right\} \cup
$$

$$
\begin{gathered}
{\left[\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right)=\emptyset\right\} \cap\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}\right]} \\
=\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \cap U \neq \emptyset\right\} \cup \\
{\left[\left(\Omega \backslash\left\{\omega: \Gamma(\omega) \cap B\left(x_{n}, 2^{-i}\right) \neq \emptyset\right\}\right) \cap\{\omega: \Gamma(\omega) \cap U \neq \emptyset\}\right],}
\end{gathered}
$$

a measurable set. By what was just shown, there exists $\sigma_{n i}$, a measurable function such that $\sigma_{n i}(\omega) \in \overline{\Gamma_{n i}(\omega)} \subseteq \overline{\Gamma(\omega)}$ for all $\omega \in \Omega$. If $x \in \overline{\Gamma(\omega)}$, then

$$
x \in B\left(x_{n}, 2^{-(i+2)}\right)
$$

whenever $x_{n}$ is close enough to $x$. Thus both $x, \sigma_{n(i+2)}(\omega)$ are in $B\left(x_{n}, 2^{-(i+2)}\right)$ and so $\left|\sigma_{n(i+1)}(\omega)-x\right|<2^{-i}$. It follows that condition 2.) holds. Note that this had nothing to do with a measure.

Now consider why 2.$) \Rightarrow$ 1.). We have $\left\{\sigma_{n}(\omega)\right\} \subseteq \Gamma(\omega)$ and $\sigma_{n}$ is measurable and $\overline{\cup_{n} \sigma_{n}(\omega)}$ equals $\overline{\Gamma(\omega)}$. Why is $\Gamma$ a measurable multifunction? Let $U$ be an open set

$$
\begin{aligned}
\Gamma^{-}(U) & \equiv\{\omega: \Gamma(\omega) \cap U \neq \emptyset\} \\
& =\{\omega: \overline{\Gamma(\omega)} \cap U \neq \emptyset\} \\
& =\cup_{n} \sigma_{n}^{-1}(U) \in \mathscr{C}
\end{aligned}
$$

For much more on multifunctions, you should see the book by Hu and Papageorgiou . The above proof follows the presentation in this book.

### 48.1.1 A Special Case Which Is Easier

The above is a pretty long and difficult argument to show that $\Gamma^{-}(U) \in \mathscr{C}$ for all $U$ open is equivalent to $\Gamma^{-}(F)$ for all $F$ closed. However, there is a special case for which this is much easier to show. Suppose $\Gamma(\omega)$ is not just closed but is also compact. Then as above, if $\Gamma^{-}(F) \in \mathscr{C}$ for all $F$ closed, then $\Gamma^{-}(U)=\cup_{n} \Gamma^{-}\left(F_{n}\right)$ where $F_{n}$ is an increasing sequence of closed sets whose union is $U$. This follows from the observation that

$$
\Gamma(\omega) \cap U=\cup_{n} \Gamma(\omega) \cap F_{n}
$$

and so to say the set on the left is nonempty is to say that at least one of the sets on the right is nonempty. Thus if $\Gamma^{-}(F) \in \mathscr{C}$ for all $F$ closed, then $\Gamma^{-}(U) \in \mathscr{C}$ for all $U$ open. This requires no special considerations.

Now suppose $\Gamma(\omega)$ is compact for every $\omega$ and that $\Gamma^{-}(U) \in \mathscr{C}$ for every $U$ open. Then let $F$ be a closed set and let $\left\{U_{n}\right\}$ be a decreasing sequence of open sets whose intersection equals $F$ such that also, for all $n, U_{n} \supseteq \overline{U_{n+1}}$. Then

$$
\Gamma(\omega) \cap F=\cap_{n} \Gamma(\omega) \cap U_{n}=\cap_{n} \Gamma(\omega) \cap \overline{U_{n}}
$$

Now because of compactness, the set on the left is nonempty if and only if each set on the right is also nonempty. Thus $\Gamma^{-}(F)=\cap_{n} \Gamma^{-}\left(U_{n}\right) \in \mathscr{C}$. Thus in this special case, it is much easier to see that these two conditions for measurability are equivalent. Note that there is no condition on measures or completeness or any such thing. This proves the following proposition.

Proposition 48.1.4 Let $X$ be a Polish space and let $\Gamma: X \rightarrow \mathscr{P}(X)$ have compact values. Then $\Gamma$ is measurable if and only if it is strongly measurable, the latter being the statement that $\Gamma^{-}(C)$ is measurable whenever $C$ is closed.

Let $\Gamma$ be strongly measurable. Let $\mathscr{G}$ be the sets $G$ such that $\Gamma^{-}(G)$ and $\Gamma^{-}\left(G^{C}\right)$ are both in $\mathscr{C}$. Then clearly $\mathscr{G}$ is closed with respect to complements. If $G \in \mathscr{G}$ is $G^{C}$ ? Is $\Gamma^{-}\left(G^{C}\right)$ and $\Gamma^{-}\left(\left(G^{C}\right)^{C}\right)$ in $\mathscr{C}$ ? I guess this is just the definition of what it means to be in $\mathscr{G}$. Also if you have $\left\{G_{i}\right\} \subseteq \mathscr{G}$, Then

$$
\Gamma^{-}\left(\cup_{i} G_{i}\right)=\cup_{i} \Gamma^{-}\left(G_{i}\right) \in \mathscr{C}
$$

and so $\mathscr{G}$ is closed with respect to countable unions. Hence $\mathscr{G}$ must contain the Borel sets because the strong measurability implies that the closed sets and hence open sets are in $\mathscr{G}$. Thus $\Gamma^{-}(G) \in \mathscr{C}$ whenever $G$ is Borel.

### 48.1.2 Other Measurability Considerations

Here are some general considerations about measurable multifunctions.
Lemma 48.1.5 Suppose $f: K(\omega) \times \Omega \rightarrow X, K \subseteq X$. Here $X$ is Polish space, separable complete metric space, and $(\Omega, \mathscr{F})$ is a measurable space. Also $\omega \rightarrow K(\omega)$ is a measurable multifunction as in Theorem 48.1.3. Also suppose $\omega \rightarrow f(x, \omega)$ is measurable and $x \rightarrow$ $f(x, \omega)$ is continuous. Also suppose that $\mathscr{K}(\omega) \equiv f(K(\omega), \omega)$. Then you can conclude that $\omega \rightarrow \mathscr{K}(\omega)$ is a measurable multifunction. If $\mathscr{K}(\omega)$ is compact, then it is also strongly measurable.

Proof: Let $\left\{x_{n}(\omega)\right\}$ be a countable dense subset of $K(\omega)$, each $x_{n}$ measurable. Then if $U$ is open,

$$
\{\omega: \mathscr{K}(\omega) \cap U \neq \emptyset\}=\cup_{n=1}^{\infty} f\left(x_{n}(\cdot), \cdot\right)^{-1}(U)
$$

and each of the sets in the union is measurable. The latter claim follows from the continuity of $f(\cdot, \omega)$. If $x(\omega)$ is measurable, then we can express it as the limit of simple functions $s_{n}$ for which $\omega \rightarrow f\left(s_{n}(\omega), \omega\right)$ is clearly measurable. Then $f(x(\omega), \omega)$ is the limit of $f\left(s_{n}(\omega), \omega\right)$. The reason for the equality is as follows. It is clear that the right side is contained in the left. Now if $\mathscr{K}(\omega) \cap U \neq \emptyset$, then by definition, $f(x, \omega) \in U$ for some $x \in K(\omega)$ but then by continuity, $f\left(x_{n}(\omega), \omega\right) \in U$ also for some $x_{n}(\omega)$ close to $x$. Thus the two sets are actually equal. Thus $\omega \rightarrow \mathscr{K}(\omega)$ is measurable. If $\mathscr{K}(\omega)$ has compact values it will be strongly measurable.

This lemma gives an easy example of a measurable multifunction having compact values. In fact this is the one of most interest in what follows. However, we also have the following general result. It gives the existence of a measurable $\varepsilon$ net. This is formulated in Banach space because it is convenient to add. It could also be formulated in Polish space with a little more difficulty. One just defines things a little differently.

Proposition 48.1.6 Let $\omega \rightarrow \mathscr{K}(\omega)$ be a measurable multifunction where $\mathscr{K}(\omega)$ is a pre compact set. Recall this means its closure is compact. Also, it must have an $\varepsilon$ net for
each $\varepsilon>0$. Then for each $\varepsilon>0$, there exists $N(\omega)$ and measurable functions $y_{j}, j=$ $1,2, \cdots, N(\omega), y_{j}(\omega) \in \mathscr{K}(\omega)$, such that

$$
\cup_{j=1}^{N} B\left(y_{j}(\omega), \varepsilon\right) \supseteq \mathscr{K}(\omega)
$$

for each $\omega$. Also $\omega \rightarrow N(\omega)$ is measurable.
Proof: Suppose that $\omega \rightarrow \mathscr{K}(\omega)$ is a measurable multifunction having compact values in $X$ a Banach space. Let $\left\{\sigma_{n}(\omega)\right\}$ be the measurable selections such that for each $\omega,\left\{\sigma_{n}(\omega)\right\}_{n=1}^{\infty}$ is dense in $\mathscr{K}(\omega)$. Let $y_{1}(\omega) \equiv \sigma_{1}(\omega)$. Now let $2(\omega)$ be the first index after 1 such that $\left\|\sigma_{2(\omega)}(\omega)-\sigma_{1}(\omega)\right\|>\frac{\varepsilon}{2}$. Thus $2(\omega)=k$ on the measurable set

$$
\left\{\omega \in \Omega:\left\|\sigma_{k}(\omega)-\sigma_{1}(\omega)\right\|>\frac{\varepsilon}{2}\right\} \cap\left\{\omega \in \Omega: \cap_{j=1}^{k-1}\left\|\sigma_{j}(\omega)-\sigma_{1}(\omega)\right\| \leq \frac{\varepsilon}{2}\right\}
$$

Suppose $1(\omega), 2(\omega), \cdots,(m-1)(\omega)$ have been chosen such that this is a strictly increasing sequence for each $\omega$, each is a measurable function, and for $i, j \leq m-1$,

$$
\left\|\sigma_{i(\omega)}(\omega)-\sigma_{j(\omega)}(\omega)\right\|>\frac{\varepsilon}{2}
$$

Each $\omega \rightarrow \sigma_{i(\omega)}(\omega)$ is measurable because it equals

$$
\sum_{k=1}^{\infty} \mathscr{X}_{[i(\omega)=k]}(\omega) \sigma_{k}(\omega)
$$

Then $m(\omega)$ will be the first index larger than $(m-1)(\omega)$ such that

$$
\left\|\sigma_{m(\omega)}(\omega)-\sigma_{j(\omega)}(\omega)\right\|>\frac{\varepsilon}{2}
$$

for all $j(\omega)<m(\omega)$. Thus $\omega \rightarrow m(\omega)$ is also measurable because it equals $k$ on the measurable set

$$
\begin{gathered}
\left(\cap\left\{\omega:\left\|\sigma_{k}(\omega)-\sigma_{j(\omega)}(\omega)\right\|>\frac{\varepsilon}{2}, j \leq m-1\right\}\right) \cap\{\omega:(m-1)(\omega)<k\} \\
\cap\left(\cup\left\{\omega:\left\|\sigma_{k-1}(\omega)-\sigma_{j(\omega)}(\omega)\right\| \leq \frac{\varepsilon}{2}, j \leq m-1\right\}\right)
\end{gathered}
$$

The top line says it does what is wanted and the second says it is the first after $(m-1)(\omega)$ which does so. Since $\mathscr{K}(\omega)$ is a pre compact set, it follows that the above measurable set will be empty for all $m(\omega)$ sufficiently large called $N(\omega)$, also a measurable function, and so the process ends. Let $y_{i}(\omega) \equiv \sigma_{i(\omega)}(\omega)$. Then this gives the desired measurable $\varepsilon$ net. The fact that

$$
\cup_{i=1}^{N(\omega)} B\left(y_{i}(\omega), \varepsilon\right) \supseteq \mathscr{K}(\omega)
$$

follows because if there exists $z \in \mathscr{K}(\omega) \backslash\left(\cup_{i=1}^{N(\omega)} B\left(y_{i}(\omega), \varepsilon\right)\right)$, then $B\left(z, \frac{\varepsilon}{2}\right)$ would have empty intersection with all of the balls $B\left(y_{i}(\omega), \frac{\varepsilon}{3}\right)$ and by density of the $\sigma_{i}(\omega)$ in $\mathscr{K}(\omega)$, there would be some $\sigma_{l}(\omega)$ contained in $B\left(z, \frac{\varepsilon}{3}\right)$ for arbitrarily large $l$ and so the process would not have ended as shown above.

### 48.2 Existence of Measurable Fixed Points

### 48.2.1 Simplices And Labeling

First define an $n$ simplex, denoted by $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$, to be the convex hull of the $n+1$ points, $\left\{\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right\}$ where $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are independent. Thus

$$
\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right] \equiv\left\{\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}: \sum_{i=0}^{n} t_{i}=1, t_{i} \geq 0\right\}
$$

Since $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ is independent, the $t_{i}$ are uniquely determined. If two of them are

$$
\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}=\sum_{i=0}^{n} s_{i} \mathbf{x}_{i}
$$

Then

$$
\sum_{i=0}^{n} t_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)=\sum_{i=0}^{n} s_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

so $t_{i}=s_{i}$ for $i \geq 1$. Since the $s_{i}$ and $t_{i}$ sum to 1 , it follows that also $s_{0}=t_{0}$. If $n \leq 2$, the simplex is a triangle, line segment, or point. If $n \leq 3$, it is a tetrahedron, triangle, line segment or point. To say that $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are independent is to say that $\left\{\mathbf{x}_{i}-\mathbf{x}_{r}\right\}_{i \neq r}$ are independent for each fixed $r$. Indeed, if $\mathbf{x}_{i}-\mathbf{x}_{r}=\sum_{j \neq i, r} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{r}\right)$, then you would have

$$
\mathbf{x}_{i}-\mathbf{x}_{0}+\mathbf{x}_{0}-\mathbf{x}_{r}=\sum_{j \neq i, r} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)+\left(\sum_{j \neq i, r} c_{j}\right) \mathbf{x}_{0}
$$

and it follows that $\mathbf{x}_{i}-\mathbf{x}_{0}$ is a linear combination of the $\mathbf{x}_{j}-\mathbf{x}_{0}$ for $j \neq i$, contrary to assumption.

A simplex $S$ can be triangulated. This means it is the union of smaller sub-simplices such that if $S_{1}, S_{2}$ are two simplices in the triangulation, with

$$
S_{1} \equiv\left[\mathbf{z}_{0}^{1}, \cdots, \mathbf{z}_{m}^{1}\right], S_{2} \equiv\left[\mathbf{z}_{0}^{2}, \cdots, \mathbf{z}_{p}^{2}\right]
$$

then

$$
S_{1} \cap S_{2}=\left[\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right]
$$

where $\left[\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right]$ is in the triangulation and

$$
\left\{\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right\}=\left\{\mathbf{z}_{0}^{1}, \cdots, \mathbf{z}_{m}^{1}\right\} \cap\left\{\mathbf{z}_{0}^{2}, \cdots, \mathbf{z}_{p}^{2}\right\}
$$

or else the two simplices do not intersect. Does there exist a triangulation in which all sub-simplices have diameter less than $\varepsilon$ ? This is obvious if $n \leq 2$. Supposing it to be true for $n-1$, is it also so for $n$ ? The barycenter $\mathbf{b}$ of a simplex $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ is just $\frac{1}{1+n} \sum_{i} \mathbf{x}_{i}$. This point is not in the convex hull of any of the faces, those simplices of the form $\left[\mathbf{x}_{0}, \cdots, \hat{\mathbf{x}}_{k}, \cdots, \mathbf{x}_{n}\right]$ where the hat indicates $\mathbf{x}_{k}$ has been left out. Thus $\left[\mathbf{x}_{0}, \cdots, \mathbf{b}, \cdots, \mathbf{x}_{n}\right]$ is a $n$ simplex also. Now in general, if you have an $n$ simplex $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$, its diameter is
the maximum of $\left|\mathbf{x}_{k}-\mathbf{x}_{l}\right|$ for all $k \neq l$. Consider $\left|\mathbf{b}-\mathbf{x}_{j}\right|$. It equals $\left|\sum_{i=0}^{n} \frac{1}{n+1}\left(\mathbf{x}_{i}-\mathbf{x}_{j}\right)\right|=$ $\left|\sum_{i \neq j} \frac{1}{n+1}\left(\mathbf{x}_{i}-\mathbf{x}_{j}\right)\right| \leq \frac{n}{n+1} \operatorname{diam}(S)$. Next consider the $k^{t h}$ face of $S\left[\mathbf{x}_{0}, \cdots, \hat{\mathbf{x}}_{k}, \cdots, \mathbf{x}_{n}\right]$. By induction, it has a triangulation into simplices which each have diameter no more than $\frac{n}{n+1} \operatorname{diam}(S)$. Let these $n-1$ simplices be denoted by $\left\{S_{1}^{k}, \cdots, S_{m_{k}}^{k}\right\}$. Then the simplices $\left\{\left[S_{i}^{k}, \mathbf{b}\right]\right\}_{i=1, k=1}^{m_{k}, n+1}$ are a triangulation of $S$ such that $\operatorname{diam}\left(\left[S_{i}^{k}, \mathbf{b}\right]\right) \leq \frac{n}{n+1} \operatorname{diam}(S)$. Do for $\left[S_{i}^{k}, \mathbf{b}\right]$ what was just done for $S$ obtaining a triangulation of $S$ as the union of what is obtained such that each simplex has diameter no more than $\left(\frac{n}{n+1}\right)^{2} \operatorname{diam}(S)$. Continuing this way shows the existence of the desired triangulation.

### 48.2.2 Labeling Vertices

Next is a way to label the vertices. Let $p_{0}, \cdots, p_{n}$ be the first $n+1$ prime numbers. All vertices of a simplex $S=\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ having $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ independent will be labeled with one of these primes. In particular, the vertex $\mathbf{x}_{k}$ will be labeled as $p_{k}$ if the simplex is $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$. The value of a simplex will be the product of its labels. Triangulate this $S$. Consider a 1 simplex coming from the original simplex $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$, label one end as $p_{k_{1}}$ and the other as $p_{k_{2}}$. Then label all other vertices of this triangulation which occur on $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$ either $p_{k_{1}}$ or $p_{k_{2}}$. Then obviously there will be an odd number of simplices in this triangulation having value $p_{k_{1}} p_{k_{2}}$, that is a $p_{k_{1}}$ at one end and a $p_{k_{2}}$ at the other. Suppose that the labeling has been done for all vertices of the triangulation which are on $\left[\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}\right]$,

$$
\left\{\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}\right\} \subseteq\left\{\mathbf{x}_{0}, \ldots \mathbf{x}_{n}\right\}
$$

any $k$ simplex for $k \leq n-1$, and there is an odd number of simplices from the triangulation having value equal to $\prod_{i=1}^{k+1} p_{j_{i}}$. Consider $\hat{S} \equiv\left[\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}, \mathbf{x}_{j_{k+2}}\right]$. Then by induction, there is an odd number of $k$ simplices on the $s^{t h}$ face $\left[\mathbf{x}_{j_{1}}, \ldots, \hat{\mathbf{x}}_{j_{s}}, \cdots, \mathbf{x}_{j_{k+1}}\right.$ ] having value $\prod_{i \neq s} p_{j_{i}}$. In particular the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ has an odd number of simplices with value $\prod_{i \leq k+1} p_{j_{i}}$. Now no simplex in any other face of $\hat{S}$ can have this value by uniqueness of prime factorization. Lable the "interior" vertices, those $\mathbf{u}$ having all $s_{i}>0$ in $\mathbf{u}=\sum_{i=1}^{k+2} s_{i} \mathbf{x}_{j_{i}}$, (These have not yet been labeled.) with any of the $p_{j_{1}}, \cdots, p_{j_{k+2}}$. Pick a simplex on the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ which has value $\prod_{i \leq k+1} p_{j_{i}}$ and cross this simplex into $\hat{S}$. Continue crossing simplices having value $\prod_{i \leq k+1} p_{j_{i}}$ which have not been crossed till the process ends. It must end because there are an odd number of these simplices having value $\prod_{i \leq k+1} p_{j_{i}}$. If the process leads to the outside of $\hat{S}$, then one can always enter it again because there are an odd number of simplices with value $\prod_{i \leq k+1} p_{j_{i}}$ available and you will have used up an even number. When the process ends, the value of the simplex must be $\prod_{i=1}^{k+2} p_{j_{i}}$ because it will have the additional label $p_{j_{k+2}}$ on a vertex since if not, there will be another way out of the simplex. This identifies a simplex in the triangulation with value $\prod_{i=1}^{k+2} p_{j_{i}}$. Then repeat the process with $\prod_{i \leq k+1} p_{j_{i}}$ valued simplices on $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ which have not been crossed. Repeating the process, entering from the outside, cannot deliver a $\prod_{i=1}^{k+2} p_{j_{i}}$ valued simplex encountered earlier. This is because you cross faces labeled $\prod_{i \leq k+1} p_{j_{i}}$. If the remaining vertex is labeled $p_{j_{i}}$ where $i \neq k+2$, then this yields exactly one other face to cross. There are two, the one with the first vertex $p_{j_{i}}$ and the next one with the new vertex labeled $p_{j_{i}}$ substituted for the first vertex having
this label. Thus there is either one route in to a simplex or two. Thus, starting at a simplex labeled $\prod_{i \leq k+1} p_{j_{i}}$ one can cross faces having this value till one is led to the $\prod_{i \leq k+1} p_{j_{i}}$ valued simplex on the selected face of $\hat{S}$. In other words, the process is one to one in selecting a $\prod_{i \leq k+1} p_{j_{i}}$ vertex from crossing such a vertex on the selected face of $\hat{S}$. Continue doing this, crossing a $\prod_{i \leq k+1} p_{j_{i}}$ simplex on the face of $\hat{S}$ which has not been crossed previously. This identifies an odd number of simplices having value $\prod_{i=1}^{k+2} p_{j_{i}}$. These are the ones which are "accessible" from the outside using this process. If there are any which are not accessible from outside, applying the same process starting inside one of these, leads to exactly one other inaccessible simplex with value $\prod_{i=1}^{k+2} p_{j_{i}}$. Hence these inaccessible simplices occur in pairs and so there are an odd number of simplices in the triangulation having value $\prod_{i=1}^{k+2} p_{j_{i}}$. We refer to this procedure of labeling as Sperner's lemma. The system of labeling is well defined thanks to the assumption that $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ is independent which implies that $\left\{\mathbf{x}_{k}-\mathbf{x}_{i}\right\}_{k \neq i}$ is also linearly independent. The following is a description of the system of labeling the vertices.

Lemma 48.2.1 Let $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ be an $n$ simplex with $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ independent, and let the first $n+1$ primes be $p_{0}, p_{1}, \cdots, p_{n}$. Label $\mathbf{x}_{k}$ as $p_{k}$ and consider a triangulation of this simplex. Labeling the vertices of this triangulation which occur on $\left[\mathbf{x}_{k_{1}}, \cdots, \mathbf{x}_{k_{s}}\right]$ with any of $p_{k_{1}}, \cdots, p_{k_{s}}$, beginning with all 1 simplices $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$ and then 2 simplices and so forth, there are an odd number of simplices $\left[\mathbf{y}_{k_{1}}, \cdots, \mathbf{y}_{k_{s}}\right]$ of the triangulation contained in $\left[\mathbf{x}_{k_{1}}, \cdots, \mathbf{x}_{k_{s}}\right]$ which have value $p_{k_{1}}, \cdots, p_{k_{s}}$. This for $s=1,2, \cdots, n$.

## Another way To Explain The Labeling

We now give a brief discussion of the system of labeling for Sperner's lemma from the point of view of counting numbers of faces rather than obtaining them with an algorithm. Let $p_{0}, \cdots, p_{n}$ be the first $n+1$ prime numbers. All vertices of a simplex $S=\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ having $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ independent will be labeled with one of these primes. In particular, the vertex $\mathbf{x}_{k}$ will be labeled as $p_{k}$. The value of a simplex will be the product of its labels. Triangulate this $S$. Consider a 1 simplex coming from the original simplex $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$, label one end as $p_{k_{1}}$ and the other as $p_{k_{2}}$. Then label all other vertices of this triangulation which occur on $\left[\mathbf{x}_{k_{1}}, \mathbf{x}_{k_{2}}\right]$ either $p_{k_{1}}$ or $p_{k_{2}}$. Then obviously there will be an odd number of simplices in this triangulation having value $p_{k_{1}} p_{k_{2}}$, that is a $p_{k_{1}}$ at one end and a $p_{k_{2}}$ at the other. Suppose that the labeling has been done for all vertices of the triangulation which are on $\left[\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}\right]$,

$$
\left\{\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}\right\} \subseteq\left\{\mathbf{x}_{0}, \ldots \mathbf{x}_{n}\right\}
$$

any $k$ simplex for $k \leq n-1$, and there is an odd number of simplices from the triangulation having value equal to $\prod_{i=1}^{k+1} p_{j_{i}}$. Consider $\hat{S} \equiv\left[\mathbf{x}_{j_{1}}, \ldots \mathbf{x}_{j_{k+1}}, \mathbf{x}_{j_{k+2}}\right]$. Then by induction, there is an odd number of $k$ simplices on the $s^{t h}$ face

$$
\left[\mathbf{x}_{j_{1}}, \ldots, \hat{\mathbf{x}}_{j_{s}}, \cdots, \mathbf{x}_{j_{k+1}}\right]
$$

having value $\prod_{i \neq s} p_{j_{i}}$. In particular the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ has an odd number of simplices with value $\prod_{i=1}^{k+1} p_{j_{i}}:=\hat{P}_{k}$. We want to argue that some simplex in the triangulation which is contained in $\hat{S}$ has value $\hat{P}_{k+1}:=\prod_{i=1}^{k+2} p_{j_{i}}$. Let $Q$ be the number of $k+1$
simplices from the triangulation contained in $\hat{S}$ which have two faces with value $\hat{P}_{k}$ (A $k+1$ simplex has either 1 or $2 \hat{P}_{k}$ faces.) and let $R$ be the number of $k+1$ simplices from the triangulation contained in $\hat{S}$ which have exactly one $\hat{P}_{k}$ face. These are the ones we want because they have value $\hat{P}_{k+1}$. Thus the number of faces having value $\hat{P}_{k}$ which is described here is $2 Q+R$. All interior $\hat{P}_{k}$ faces being counted twice by this number. Now we count the total number of $\hat{P}_{k}$ faces another way. There are $P$ of them on the face $\left[\mathbf{x}_{j_{1}}, \ldots, \mathbf{x}_{j_{k+1}}, \hat{\mathbf{x}}_{j_{k+2}}\right]$ and by induction, $P$ is odd. Then there are $O$ of them which are not on this face. These faces got counted twice. Therefore,

$$
2 Q+R=P+2 O
$$

and so, since $P$ is odd, so is $R$. Thus there is an odd number of $\hat{P}_{k+1}$ simplices in $\hat{S}$.
We refer to this procedure of labeling as Sperner's lemma. The system of labeling is well defined thanks to the assumption that $\left\{\mathbf{x}_{k}-\mathbf{x}_{0}\right\}_{k=1}^{n}$ is independent which implies that $\left\{\mathbf{x}_{k}-\mathbf{x}_{i}\right\}_{k \neq i}$ is also linearly independent. Sperner's lemma is now a consequence of this discussion.

### 48.2.3 Measurability Of Brouwer Fixed Points

First, here is a nice measurable selection theorem.
Lemma 48.2.2 Let $U$ be a separable reflexive Banach space. Suppose there is a sequence $\left\{u_{j}(\omega)\right\}_{j=1}^{\infty}$ in $U$, where each $\omega \rightarrow u_{j}(\omega)$ is measurable and for each $\omega$, $\sup _{i}\left\|u_{i}(\omega)\right\|<$ $\infty$. Then, there exists $u(\omega) \in U$ such that $\omega \rightarrow u(\omega)$ is measurable, and a subsequence $n(\omega)$, that depends on $\omega$, such that the weak limit

$$
\lim _{n(\omega) \rightarrow \infty} u_{n(\omega)}(\omega)=u(\omega)
$$

holds.
Proof: Let $\left\{z_{i}\right\}_{i=1}^{\infty}$ be a countable dense subset of $U^{\prime}$. Let $\mathbf{h}: U \rightarrow \prod_{i=1}^{\infty} \mathbb{R}$ be defined by

$$
\mathbf{h}(u)=\prod_{i=1}^{\infty}\left\langle z_{i}, u\right\rangle .
$$

Let $X=\prod_{i=1}^{\infty} \mathbb{R}$ with the product topology. Then, this is a Polish space with the metric defined as $d(\mathbf{x}, \mathbf{y})=\sum_{i=1}^{\infty} \frac{\left|x_{i}-y_{i}\right|}{1+\left|x_{i}-y_{i}\right|} 2^{-i}$. By compactness, for a fixed $\omega$,the $\mathbf{h}\left(u_{n}(\omega)\right)$ are contained in a compact subset of $X$. Next, define

$$
\Gamma_{n}(\omega)=\overline{\cup_{k \geq n} \mathbf{h}\left(u_{k}(\omega)\right)}
$$

which is a nonempty compact subset of $X$. Moreover, $\Gamma_{n}(\omega)$ is a measurable multifunction into $X$.

Next, we claim that $\omega \rightarrow \Gamma_{n}(\omega)$ is a measurable multifunction.
The proof of the claim is as follows. It is necessary to show that $\Gamma_{n}^{-}(O)$ defined as $\left\{\omega: \Gamma_{n}(\omega) \cap O \neq \emptyset\right\}$ is measurable whenever $O$ is open. It suffices to verify this for $O$ a
basic open set in the topology of $X$. Thus let $O=\prod_{i=1}^{\infty} O_{i}$ where each $O_{i}$ is a proper open subset of $\mathbb{R}$ only for $i \in\left\{j_{1}, \cdots, j_{m}\right\}$. Then,

$$
\Gamma_{n}^{-}(O)=\cup_{k \geq n} \cap_{r=1}^{m}\left\{\omega:\left\langle z_{j_{r}}, u_{k}(\omega)\right\rangle \in O_{j_{r}}\right\},
$$

which is a measurable set since $u_{k}$ is measurable.
Then, it follows that $\omega \rightarrow \Gamma_{n}(\omega)$ is strongly measurable because it has compact values in $X$, thanks to Tychonoff's theorem. Thus $\Gamma_{n}^{-}(H)=\left\{\omega: H \cap \Gamma_{n}(\omega) \neq \emptyset\right\}$ is measurable whenever $H$ is a closed set. Now, let $\Gamma(\omega)$ be defined as $\cap_{n} \Gamma_{n}(\omega)$ and then for $H$ closed,

$$
\Gamma^{-}(H)=\cap_{n} \Gamma_{n}^{-}(H)
$$

and each set in the intersection is measurable, so this shows that $\omega \rightarrow \Gamma(\omega)$ is also measurable. Therefore, it has a measurable selection $\mathbf{g}(\omega)$. It follows from the definition of $\Gamma(\omega)$ that there exists a subsequence $n(\omega)$ such that

$$
\mathbf{g}(\omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{h}\left(u_{n(\omega)}(\omega)\right) \quad \text { in } X
$$

In terms of components, we have

$$
g_{i}(\omega)=\lim _{n(\omega) \rightarrow \infty}\left\langle z_{i}, u_{n(\omega)}(\omega)\right\rangle
$$

Furthermore, there is a further subsequence, still denoted with $n(\omega)$, such that $u_{n(\omega)}(\omega) \rightarrow$ $u(\omega)$ weakly. This means that for each $i$,

$$
g_{i}(\omega)=\lim _{n(\omega) \rightarrow \infty}\left\langle z_{i}, u_{n(\omega)}(\omega)\right\rangle=\left\langle z_{i}, u(\omega)\right\rangle
$$

Thus, for each $z_{i}$ in a dense set, $\omega \rightarrow\left\langle z_{i}, u(\omega)\right\rangle$ is measurable. Since the $z_{i}$ are dense, this implies $\omega \rightarrow\langle z, u(\omega)\rangle$ is measurable for every $z \in U^{\prime}$ and so by the Pettis theorem, $\omega \rightarrow u(\omega)$ is measurable.

There is an easy version of this which follows from the same arguments.
Corollary 48.2.3 Let $K(\omega)$ be a compact subset of a separable metric space $X$ and suppose $\left\{u_{j}(\omega)\right\}_{j=1}^{\infty} \subseteq K(\omega)$ with each $\omega \rightarrow u_{j}(\omega)$ measurable into $X$. Then there exists $u(\omega) \in K(\omega)$ such that $\omega \rightarrow u(\omega)$ is measurable into $X$ and a subsequence $n(\omega)$ depending on $\omega$ such that $\lim _{n(\omega) \rightarrow \infty} u_{n(\omega)}(\omega)=u(\omega)$.

Proof: Define

$$
\Gamma_{n}(\omega)=\overline{\bigcup_{k \geq n} u_{k}(\omega)}
$$

This is a nonempty compact subset of $K(\omega) \subseteq X$. I claim that $\omega \rightarrow \Gamma_{n}(\omega)$ is a measurable multifunction into $X$. It is necessary to show that $\Gamma_{n}^{-}(O)$ defined as $\left\{\omega: \Gamma_{n}(\omega) \cap O \neq \emptyset\right\}$ is measurable whenever $O$ is open in $X$. For $\omega \in \Gamma_{n}^{-}(O)$ it means that some $u_{k}(\omega) \in O, k \geq n$. Thus $\Gamma_{n}^{-}(O)=\cup_{k \geq n} u_{k}^{-1}(O)$ and this is measurable by the assumption that each $u_{k}$ is. Since $\Gamma_{n}^{-}(\omega)$ is compact, it is also strongly measurable by Proposition 48.1.4, meaning that $\Gamma^{-}(H)$ is measurable whenever $H$ is closed. Now, let $\Gamma(\omega)$ be defined as

$$
\Gamma(\omega) \equiv \cap_{n} \Gamma_{n}(\omega)
$$

and then for $H$ closed,

$$
\Gamma^{-}(H)=\cap_{n} \Gamma_{n}^{-}(H)
$$

and each set in the intersection is measurable, so this shows that $\omega \rightarrow \Gamma(\omega)$ is also (strongly) measurable. Therefore, it has a measurable selection $u(\omega)$. It follows from the definition of $\Gamma(\omega)$ that there exists a subsequence $n(\omega)$ such that $u(\omega)=\lim _{n(\omega) \rightarrow \infty} u_{n(\omega)}(\omega)$.

Now we consider the case of fixed points for simplices.
Suppose $\mathbf{f}(\cdot, \omega): S \rightarrow S$ for $S$ a simplex. Then from the Brouwer fixed point theorem, there is a fixed point $\mathbf{x}(\omega)$ provided $\mathbf{f}(\cdot, \omega)$ is continuous. Can it be arranged to have $\omega \rightarrow \mathbf{x}(\omega)$ also measurable? In fact, it can, and this is shown here. In other words, if $P(\omega)$ are the fixed points of $f(\cdot, \omega)$, there exists a measurable selection in $P(\omega)$.
$S \equiv\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ is a simplex in $\mathbb{R}^{n}$. Assume $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are linearly independent. Thus a typical point of $S$ is of the form

$$
\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}
$$

where the $t_{i}$ are uniquely determined and the map $\mathbf{x} \rightarrow \mathbf{t}$ is continuous from $S$ to the compact set $\left\{\mathbf{t} \in \mathbb{R}^{n+1}: \sum t_{i}=1, t_{i} \geq 0\right\}$.

To see this, suppose $\mathbf{x}^{k} \rightarrow \mathbf{x}$ in $S$. Let $\mathbf{x}^{k} \equiv \sum_{i=0}^{n} t_{i}^{k} \mathbf{x}_{i}$ with $\mathbf{x}$ defined similarly with $t_{i}^{k}$ replaced with $t_{i}, \mathbf{x} \equiv \sum_{i=0}^{n} t_{i} \mathbf{x}_{i}$. Then

$$
\mathbf{x}^{k}-\mathbf{x}_{0}=\sum_{i=0}^{n} t_{i}^{k} \mathbf{x}_{i}-\sum_{i=0}^{n} t_{i}^{k} \mathbf{x}_{0}=\sum_{i=1}^{n} t_{i}^{k}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

Thus

$$
\mathbf{x}^{k}-\mathbf{x}_{0}=\sum_{i=1}^{n} t_{i}^{k}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right), \mathbf{x}-\mathbf{x}_{0}=\sum_{i=1}^{n} t_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

Say $t_{i}^{k}$ fails to converge to $t_{i}$ for all $i \geq 1$. Then there exists a subsequence, still denoted with superscript $k$ such that for each $i=1, \cdots, n$, it follows that $t_{i}^{k} \rightarrow s_{i}$ where $s_{i} \geq 0$ and some $s_{i} \neq t_{i}$. But then, taking a limit, it follows that

$$
\mathbf{x}-\mathbf{x}_{0}=\sum_{i=1}^{n} s_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)=\sum_{i=1}^{n} t_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

which contradicts independence of the $\mathbf{x}_{i}-\mathbf{x}_{0}$. It follows that for all $i \geq 1, t_{i}^{k} \rightarrow t_{i}$. Since they all sum to 1 , this implies that also $t_{0}^{k} \rightarrow t_{0}$. Thus the claim about continuity is verified.

Let $\mathbf{f}(\cdot, \omega): S \rightarrow S$ be continuous such that $\omega \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ is measurable. When doing $\mathbf{f}(\cdot, \omega)$ to a point $\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}$, one obtains another point of $S$ denoted as $\sum_{i=0}^{n} s_{i}(\omega) \mathbf{x}_{i}$. The coefficients $s_{i}$ must be measurable functions. This is because

$$
\omega \rightarrow \mathbf{f}(\mathbf{x}, \omega)=\sum_{i=0}^{n} s_{i}(\omega) \mathbf{x}_{i}
$$

and the left side is measurable so it follows the right is also. Now as noted above, the map which takes a point of $S$ to its coefficients is continuous and so each $s_{i}$ is measurable as a function of $\omega$. Note that if $\mathbf{x}$ is replaced with $\mathbf{x}(\omega)$, with $\omega \rightarrow \mathbf{x}(\omega)$ measurable, the same
conclusion can be drawn about the $s_{i}(\omega)$. This is because, thanks to the continuity of $\mathbf{f}$ in its first argument, the function on the left in the above is measurable.

Label $\mathbf{x}_{j}$ as $p_{j}$ where $p_{0}, \cdots, p_{n}$ are the first $n+1$ prime numbers. Thus the vertices of $S$ have been labeled. Next triangulate $S$ so that all simplices have diameter less than $\varepsilon$. If $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]$ is one of these small vertices, each is of the form $\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}$ where $t_{i} \geq 0$ and $\sum_{i} t_{i}=1$. Define $r_{k}(\omega) \equiv s_{k}(\omega) / t_{k}$ if $t_{k}>0$ and $\infty$ if $t_{k}=0$. Thus this is a measurable function.

$$
E_{k} \equiv \cap_{j \neq k}\left[\omega: r_{k}(\omega) \leq r_{j}(\omega)\right], F_{0} \equiv E_{0}, F_{1} \equiv E_{1} \backslash E_{0}, \cdots, F_{n} \equiv E_{n} \backslash \cup_{i=0}^{n-1} E_{i}
$$

Then $p\left(\mathbf{y}_{i}, \omega\right)$ will be the label placed on $\mathbf{y}_{i}$. It equals

$$
p\left(\mathbf{y}_{i}, \omega\right) \equiv \sum_{k=0}^{n} p_{k} \mathscr{X}_{F_{k}}(\omega)
$$

obviously a measurable function. Note also that this new method of labeling does not contradict the original labels placed on the vertices $\mathbf{x}_{i}$. This is because for $\mathbf{x}_{i}, t_{i}=1$ and all other $t_{j}=0$ so the only ratio that is finite will be $s_{i} / t_{i}$. All others are $\infty$ by definition. As for the vertices which are on the $k^{t h}$ face $\left[\mathbf{x}_{0}, \cdots, \hat{\mathbf{x}}_{k}, \cdots, \mathbf{x}_{n}\right]$, these will be labeled from the list $\left\{p_{0}, \cdots, \hat{p}_{k}, \cdots, p_{n}\right\}$ because $t_{k}=0$ for each of these and so $r_{k}(\omega)=\infty$. By the Sperner's lemma procedure described above, there are an odd number of simplices having value $\prod_{i \neq k} p_{i}$ on the $k^{\text {th }}$ face and an odd number of simplices in the triangulation of $S$ for which the product of the labels on their vertices equals $p_{0} p_{1} \cdots p_{n} \equiv P_{n}$. We call this the value of the simplex. Thus if $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]$ is one of these simplices, and $p\left(\mathbf{y}_{i}, \omega\right)$ is the label for $\mathbf{y}_{i}$, a measurable function of $\omega$,

$$
\prod_{i=0}^{n} p\left(\mathbf{y}_{i}, \omega\right)=\prod_{i=0}^{n} p_{i} \equiv P_{n}
$$

For $\omega \in F_{k}$, what is $r_{k}(\omega)$ ? Could it be larger than 1 ? $r_{k}(\omega)$ is certainly finite because at least some $t_{j} \neq 0$ since they sum to 1 . Thus, if $r_{k}(\omega)>1$, you would have $s_{k}(\omega)>t_{k}$. The $s_{j}$ sum to 1 and so some $s_{j}(\omega)<t_{j}$ since otherwise, the sum of the $t_{j}$ equalling 1 would require the sum of the $s_{j}$ to be larger than 1 . Hence $r_{k}(\omega)$ was not really the smallest so $\omega \notin F_{k}$. Thus $r_{k}(\omega) \leq 1$. Hence $s_{k}(\omega) \leq t_{k}$.

Let $\mathscr{S}$ denote those simplices whose value is $P_{n}$ for some $\omega$. In other words, if $\left\{\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right\}$ are the vertices of one of these simplices, and

$$
\mathbf{y}_{s}=\sum_{i=0}^{n} t_{i}^{S} \mathbf{x}_{i}
$$

then for some $\omega, r_{k_{s}}(\omega) \leq r_{j}(\omega)$ for all $j \neq k_{s}$ and $\left\{k_{0}, \cdots, k_{n}\right\}=\{0, \cdots, n\}$. There are finitely many of these simplices, so $\mathscr{S} \equiv\left\{S_{1}, \cdots, S_{m}\right\}$. Let $F_{1} \subseteq \Omega$ be defined by

$$
F_{1} \equiv\left\{\omega: \prod_{i=0}^{n} p\left(\mathbf{y}_{i}, \omega\right)=P_{n}\right\}:\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]=S_{1}
$$

If $F_{1}=\Omega$, then stop. If not, let

$$
F_{2} \equiv\left\{\omega \notin F_{1}: \prod_{i=0}^{n} p\left(\mathbf{y}_{i}, \omega\right)=P_{n}\right\}:\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]=S_{2}
$$

Continue this way obtaining disjoint measurable sets $F_{j}$ whose union is all of $\Omega$. The union is $\Omega$ because every $\omega$ is associated with at least one of the $S_{i}$. Now for $\omega \in F_{k}$ and $\left[\mathbf{y}_{0}, \cdots, \mathbf{y}_{n}\right]=S_{k}$, it follows that $\prod_{i=0}^{n} p\left(\mathbf{y}_{i}, \omega\right)=P_{n}$. For $\omega \in F_{k}$, let $\mathbf{b}(\omega)$ denote the barycenter of $S_{k}$. Thus $\omega \rightarrow \mathbf{b}(\omega)$ is a measurable function, being constant on a measurable set. Thus we let $\mathbf{b}(\omega)=\sum_{i=1}^{m} \mathscr{X}_{F_{i}}(\omega) \mathbf{b}_{i}$ where $\mathbf{b}_{i}$ is the barycenter of $S_{i}$.

Now do this for a sequence $\varepsilon_{k} \rightarrow 0$ where $\mathbf{b}_{k}(\omega)$ is a barycenter as above. By Lemma 48.2.2 there exists $\mathbf{x}(\omega)$ such that $\omega \rightarrow \mathbf{x}(\omega)$ is measurable and a sequence

$$
\left\{\mathbf{b}_{k(\omega)}\right\}_{k(\omega)=1}^{\infty}, \lim _{k(\omega) \rightarrow \infty} \mathbf{b}_{k(\omega)}(\omega)=\mathbf{x}(\omega)
$$

This $\mathbf{x}(\omega)$ is also a fixed point.
Consider this last claim. $\mathbf{x}(\omega)=\sum_{i=0}^{n} t_{i}(\omega) \mathbf{x}_{i}$ and after applying $\mathbf{f}(\cdot, \omega)$, the result is $\sum_{i=0}^{n} s_{i}(\omega) \mathbf{x}_{i}$. Then $\mathbf{b}_{k(\omega)} \in \sigma_{k}(\omega)$ where $\sigma_{k}(\omega)$ is a simplex having vertices

$$
\left\{\mathbf{y}_{0}^{k}(\omega), \cdots, \mathbf{y}_{n}^{k}(\omega)\right\}
$$

and the value of $\left[\mathbf{y}_{0}^{k}(\omega), \cdots, \mathbf{y}_{n}^{k}(\omega)\right]$ is $P_{n}$. Re ordering these if necessary, we can assume that the label for $\mathbf{y}_{i}^{k}(\omega)=p_{i}$ which implies that, as noted above,

$$
\frac{s_{i}(\omega)}{t_{i}(\omega)} \leq 1, s_{i}(\omega) \leq t_{i}(\omega)
$$

the $i^{\text {th }}$ coordinate of $\mathbf{f}\left(\mathbf{y}_{i}^{k}(\omega), \omega\right)$ with respect to the original vertices of $S$ decreases and each $i$ is represented for $i=\{0,1, \cdots, n\}$. Thus

$$
\mathbf{y}_{i}^{k}(\omega) \rightarrow \mathbf{x}(\omega)
$$

and so the $i^{t h}$ coordinate of $\mathbf{y}_{i}^{k}(\omega), t_{i}^{k}(\omega)$ must converge to $t_{i}(\omega)$. Hence if the $i^{t h}$ coordinate of $\mathbf{f}\left(\mathbf{y}_{i}^{k}(\omega), \omega\right)$ is denoted by $s_{i}^{k}(\omega)$,

$$
s_{i}^{k}(\omega) \leq t_{i}^{k}(\omega)
$$

By continuity of $\mathbf{f}$, it follows that $s_{i}^{k}(\omega) \rightarrow s_{i}(\omega)$. Thus the above inequality is preserved on taking $k \rightarrow \infty$ and so

$$
0 \leq s_{i}(\omega) \leq t_{i}(\omega)
$$

this for each $i$. But these $s_{i}$ add to 1 as do the $t_{i}$ and so in fact, $s_{i}(\omega)=t_{i}(\omega)$ for each $i$ and so $\mathbf{f}(\mathbf{x}(\omega), \omega)=\mathbf{x}(\omega)$. This proves the following theorem which gives the existence of a measurable fixed point.

Theorem 48.2.4 Let $S$ be a simplex $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ such that $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are independent. Also let $\mathbf{f}(\cdot, \omega): S \rightarrow S$ be continuous for each $\omega$ and $\omega \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ is measurable, meaning inverse images of sets open in $S$ are in $\mathscr{F}$ where $(\Omega, \mathscr{F})$ is a measurable space. Then there exists $\mathbf{x}(\omega) \in S$ such that $\omega \rightarrow \mathbf{x}(\omega)$ is measurable and $\mathbf{f}(\mathbf{x}(\omega), \omega)=\mathbf{x}(\omega)$.

Corollary 48.2.5 Let $K$ be a closed convex bounded subset of $\mathbb{R}^{n}$. Let $\mathbf{f}(\cdot, \omega): K \rightarrow K$ be continuous for each $\omega$ and $\omega \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ is measurable, meaning inverse images of sets open in $K$ are in $\mathscr{F}$ where $(\Omega, \mathscr{F})$ is a measurable space. Then there exists $\mathbf{x}(\omega) \in K$ such that $\omega \rightarrow \mathbf{x}(\omega)$ is measurable and $\mathbf{f}(\mathbf{x}(\omega), \omega)=\mathbf{x}(\omega)$.

Proof: Let $S$ be a large simplex containing $K$ and let $P$ be the projection map onto $K$. Consider $\mathbf{g}(\mathbf{x}, \omega) \equiv \mathbf{f}(P(\mathbf{x}), \omega)$. Then $\mathbf{g}$ satisfies the necessary conditions for Theorem 48.2.4 and so there exists $\mathbf{x}(\omega) \in S$ such that $\omega \rightarrow \mathbf{x}(\omega)$ is measurable and $\mathbf{g}(\mathbf{x}(\omega), \omega)=$ $\mathbf{x}(\omega)$. But this says $\mathbf{x}(\omega) \in K$ and so $\mathbf{g}(\mathbf{x}(\omega), \omega)=\mathbf{f}(\mathbf{x}(\omega), \omega)$.

## Much shorter proof

The above gives a proof of a measurable fixed point as part of a proof of the Brouwer fixed point theorem directly but it is a lot easier if you simply begin with the existence of the Brouwer fixed point and show it is measurable. We sent the above to be considered for publication and the referee pointed this out. I totally missed it because I had forgotten about the Kuratowski selection theorem. The functions $f: \Omega \times E \rightarrow \mathbb{R}$ in which $f(\cdot, \omega)$ is continuous are called Caratheodory functions.

Kuratowski [82] which is presented next. It is Theorem 11.1.11 in this book. I will give an alternate proof which comes from the measurable selection result of Corollary 48.2.3.

Theorem 48.2.6 Let $E$ be a compact metric space and let $(\Omega, \mathscr{F})$ be a measure space. Suppose $\psi: E \times \Omega \rightarrow \mathbb{R}$ has the property that $x \rightarrow \psi(x, \omega)$ is continuous and $\omega \rightarrow \psi(x, \omega)$ is measurable. Then there exists a measurable function, $f$ having values in $E$ such that

$$
\psi(f(\omega), \omega)=\max _{x \in E} \psi(x, \omega)
$$

Furthermore, $\omega \rightarrow \psi(f(\omega), \omega)$ is measurable.
Proof: Let $C=\left\{e_{i}\right\}_{i=1}^{\infty}$ be a countable dense subset of $E$. For example, take the union of $1 / 2^{n}$ nets for all $n$. Let $C_{n} \equiv\left\{e_{1}, \ldots, e_{n}\right\}$. Let $\omega \rightarrow f_{n}(\omega)$ be measurable and satisfy

$$
\psi\left(f_{n}(\omega), \omega\right)=\sup _{x \in C_{n}} \psi(x, \omega)
$$

This is easily done as follows. Let $B_{k} \equiv\left\{\omega: \psi\left(e_{k}, \omega\right) \geq \psi\left(e_{j}, \omega\right)\right.$ for all $\left.j \neq k\right\}$. Then let $A_{1} \equiv B_{1}$ and if $A_{1}, \ldots, A_{k}$ have been chosen, let $A_{k+1} \equiv B_{k+1} \backslash\left(\cup_{j=1}^{k} B_{k}\right)$. Thus each $A_{k}$ is measurable and you let $f_{n}(\omega) \equiv e_{k}$ for $\omega \in A_{k}$. Using Corollary 48.2.3, there is measurable $f(\omega)$ and a subsequence $n(\omega)$ such that $f_{n(\omega)}(\omega) \rightarrow f(\omega)$. Then by continuity, $\psi(f(\omega), \omega)=\lim _{n(\omega) \rightarrow \infty} \psi\left(f_{n(\omega)}(\omega), \omega\right)$ and this is an increasing sequence in this limit. Hence $\psi(f(\omega), \omega) \geq \sup _{x \in C_{n}} \psi(x, \omega)$ for each $n$ and so $\psi(f(\omega), \omega) \geq \sup _{x \in C} \psi(x, \omega)=$ $\sup _{x \in E} \psi(x, \omega)$. Since $f$ is measurable, it is the limit of a sequence $\left\{f_{n}(\omega)\right\}$ such that $f_{n}$ has finitely many values occuring on measurable sets, Theorem 11.3.10. Hence, by continuity, $\psi(f(\omega), \omega)=\lim _{n \rightarrow \infty} \psi\left(f_{n}(\omega), \omega\right)$ and since $\omega \rightarrow \psi\left(f_{n}(\omega), \omega\right)$ is measurable, so is $\psi(f(\omega), \omega)$.

One can generalize fairly easily. It is the same argument but carrying around more $\omega$.

Theorem 48.2.7 Let $E(\omega)$ be a compact metric space in a separable metric space $(X, d)$ and that $\omega \rightarrow E(\omega)$ is a measurable multifunction where $(\Omega, \mathscr{F})$ be a measure space. Suppose $\psi_{\omega}: E(\omega) \times \Omega \rightarrow \mathbb{R}$ has the property that $x \rightarrow \psi_{\omega}(x, \omega)$ is continuous and $\omega \rightarrow$ $\psi_{\omega}(x(\omega), \omega)$ is measurable if $x(\omega) \in E(\omega)$ and $\omega \rightarrow x(\omega)$ is measurable. Then there exists a measurable function, $f$ with $f(\omega) \in E(\omega)$ such that

$$
\psi_{\omega}(f(\omega), \omega)=\max _{x \in E(\omega)} \psi_{\omega}(x, \omega)
$$

Furthermore, $\omega \rightarrow \psi_{\omega}(f(\omega), \omega)$ is measurable.
Proof: Let $C(\omega)=\left\{e_{i}(\omega)\right\}_{i=1}^{\infty}$ be a countable dense subset of $E(\omega)$ with each $e_{i}(\omega)$ measurable. Since $\omega \rightarrow E(\omega)$ is measurable, such a countable dense subset exists. Let $C_{n}(\omega) \equiv\left\{e_{1}(\omega), \ldots, e_{n}(\omega)\right\}$. Let $\omega \rightarrow f_{n}(\omega)$ be measurable and satisfy

$$
\psi_{\omega}\left(f_{n}(\omega), \omega\right)=\sup _{x \in C_{n}} \psi(x, \omega)
$$

This is easily done as follows. Let

$$
B_{k} \equiv\left\{\omega: \psi_{\omega}\left(e_{k}(\omega), \omega\right) \geq \psi_{\omega}\left(e_{j}(\omega), \omega\right) \text { for all } j \neq k\right\}
$$

Then let $A_{1} \equiv B_{1}$ and if $A_{1}, \ldots, A_{k}$ have been chosen, let $A_{k+1} \equiv B_{k+1} \backslash\left(\cup_{j=1}^{k} B_{k}\right)$. Thus each $A_{k}$ is measurable and you let $f_{n}(\omega) \equiv e_{k}(\omega)$ for $\omega \in A_{k}$, so $f_{n}(\omega) \in E(\omega)$. Using Corollary 48.2.3, there is measurable $f(\omega)$ and a subsequence $n(\omega)$ such that $f_{n(\omega)}(\omega) \rightarrow f(\omega)$. Then by continuity,

$$
\psi_{\omega}(f(\omega), \omega)=\lim _{n(\omega) \rightarrow \infty} \psi_{\omega}\left(f_{n(\omega)}(\omega), \omega\right)
$$

and this is an increasing sequence in this limit. Hence

$$
\psi_{\omega}(f(\omega), \omega) \geq \sup _{x \in C_{n}(\omega)} \psi_{\omega}(x, \omega)
$$

for each $n$ and so

$$
\psi_{\omega}(f(\omega), \omega) \geq \sup _{x \in C(\omega)} \psi_{\omega}(x, \omega)=\sup _{x \in E(\omega)} \psi_{\omega}(x, \omega)
$$

Since $f$ is measurable, it is the limit of a sequence $\left\{f_{n}(\omega)\right\}$ such that $f_{n}$ has finitely many values on measurable sets, Theorem 11.3.10. We can assume each value of $f_{n}(\omega)$ is in $E(\omega)$. Indeed, repeat that theorem's proof applied to $C(\omega)$, letting $f_{n}(\omega)$ be the $e_{k}(\omega)$ in $C_{n}(\omega)$ closest to $f(\omega)$ as done there where this happens on a measurable set where in fact $e_{k}(\omega)$ is maximally close to $f(\omega)$ out of all $e_{i}(\omega), i \leq n$. Hence, by continuity, $\psi_{\omega}(f(\omega), \omega)=\lim _{n \rightarrow \infty} \psi_{\omega}\left(f_{n}(\omega), \omega\right)$ and since $\omega \rightarrow \psi_{\omega}\left(f_{n}(\omega), \omega\right)$ is measurable, so is $\psi_{\omega}(f(\omega), \omega)$.

Note the following: If you have the simpler situation where $\psi(x, \omega)$ defined on $X \times \Omega$ with $x \rightarrow \psi(x, \omega)$ continuous and $\omega \rightarrow \psi(x, \omega)$ measurable but $E(\omega)$ a compact measurable multifunction as above, then the conditions will hold because you would have
$\omega \rightarrow \psi(x(\omega), \omega)$ is measurable if $x(\omega)$ is. Indeed, $x(\omega)$ is the limit of a sequence $\left\{x_{n}(\omega)\right\}$ such that $x_{n}$ has finitely many values on measurable sets, Theorem 11.3.10. Hence, by continuity, $\psi(x(\omega), \omega)=\lim _{n \rightarrow \infty} \psi\left(x_{n}(\omega), \omega\right)$ and since $\omega \rightarrow \psi\left(x_{n}(\omega), \omega\right)$ is measurable, so is $\psi(x(\omega), \omega)$.

Now with the marvelous Kuratowski theorem, one gets the following interesting result on measurability of Brouwer fixed points.

Theorem 48.2.8 Let $K$ be a closed convex bounded subset of $\mathbb{R}^{n}$. Let $\mathbf{f}(\cdot, \omega): K \rightarrow K$ be continuous for each $\omega$ and $\omega \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ is measurable, meaning inverse images of sets open in $K$ are in $\mathscr{F}$ where $(\Omega, \mathscr{F})$ is a measurable space. Then there exists $\mathbf{x}(\omega) \in K$ such that $\omega \rightarrow \mathbf{x}(\omega)$ is measurable and $\mathbf{f}(\mathbf{x}(\omega), \omega)=\mathbf{x}(\omega)$.

Proof: Simply consider $E=K$ and $\psi(\mathbf{x}, \omega) \equiv-|\mathbf{x}-\mathbf{f}(\mathbf{x}, \omega)|$. It has a maximum $\mathbf{x}(\omega)$ for each $\omega$ thanks to continuity of $\mathbf{f}(\cdot, \omega)$. Thanks to the Brouwer fixed point theorem, this $\mathbf{x}(\omega)$ must be a fixed point. By the above Kuratowski theorem, one of these $\mathbf{x}(\omega)$ is measurable. Obviously, by continuity of $\mathbf{f}(\cdot, \omega), \omega \rightarrow \mathbf{f}(\mathbf{x}(\omega), \omega)$ is measurable.

You can also let $K$ be replaced with $K(\omega)$ where $\omega \rightarrow K(\omega)$ is measurable and each $K(\omega)$ is closed, bounded, and convex.

Corollary 48.2.9 Let $K(\omega)$ be a closed convex bounded subset of $\mathbb{R}^{n}$ and let $\omega \rightarrow K(\omega)$ be a measurable multifunction for $\omega \in \Omega$ with $(\Omega, \mathscr{F})$ a measurable space. Let $\mathbf{f}_{\omega}(\cdot, \omega)$ : $K(\omega) \rightarrow K(\omega)$ be continuous, $\omega \rightarrow \mathbf{f}_{\omega}(\mathbf{x}(\omega), \omega)$ is measurable whenever $\omega \rightarrow \mathbf{x}(\omega)$ is measurable and $\mathbf{x}(\omega) \in K(\omega)$. Then there exists a measurable fixed point

$$
\mathbf{x}(\omega), \mathbf{f}_{\omega}(\mathbf{x}(\omega), \omega)=\mathbf{x}(\omega)
$$

Proof: Consider $\psi_{\omega}(\mathbf{x}, \omega) \equiv-\left|\mathbf{f}_{\omega}(\mathbf{x}(\omega), \omega)-\mathbf{x}(\omega)\right|$. By the Brower fixed point theorem, the maximum for fixed $\omega$ is 0 . Therefore, there exists such a measurable $\omega \rightarrow \mathbf{x}(\omega)$, a fixed point, from Theorem 48.2.7.

You can show that for $K(\omega)$ a closed convex bounded subset of $\mathbb{R}^{n}$ which is also a measurable multifunction, then the projection map $\omega \rightarrow P(\omega) \mathbf{x}$ is measurable. Suppose $\mathbf{f}$ : $\mathbb{R}^{n} \times \Omega \rightarrow \mathbb{R}^{n}$ and you know that $\mathbf{x} \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ is continuous. Consider $\mathbf{f}(P(\omega) \mathbf{x}, \omega)$. Since $P(\omega)$ is a continuous map on $\mathbb{R}^{n}, \mathbf{x} \rightarrow \mathbf{f}(P(\omega) \mathbf{x}, \omega)$ is continuous. If $\mathbf{x}(\omega)$ is measurable with values in $K(\omega)$ so it is a pointwise limit of $\mathbf{x}_{n}(\omega)$ having finitely many values on measurable sets, then one can assume all these values of $\mathbf{x}_{n}(\omega)$ are in $K(\omega)$ since you could consider $P(\omega) \mathbf{x}_{n}(\omega) \rightarrow P(\omega) \mathbf{x}(\omega)=\mathbf{x}(\omega)$ and the measurability of $\omega \rightarrow P(\omega) \mathbf{x}$ implies $\omega \rightarrow P(\omega) \mathbf{x}_{n}(\omega)$ is measurable. Thus

$$
\mathbf{f}(\mathbf{x}(\omega), \omega)=\lim _{n \rightarrow \infty} \mathbf{f}\left(\mathbf{x}_{n}(\omega), \omega\right)
$$

and by assumption this last is measurable because it is a measurable function on each of several measurable sets. Thus from Corollary 48.2.9, there is a measurable fixed point $\mathbf{x}(\omega) \in K(\omega)$ for $\mathbf{f}$ so

$$
\mathbf{f}(P(\omega) \mathbf{x}(\omega), \omega)=\mathbf{f}(\mathbf{x}(\omega), \omega)=\mathbf{x}(\omega)
$$

This shows the following corollary.

Corollary 48.2.10 Let $K(\omega)$ be a closed convex bounded subset of $\mathbb{R}^{n}$ and let $\omega \rightarrow K(\omega)$ be a measurable multifunction for $\omega \in \Omega$ with $(\Omega, \mathscr{F})$ a measurable space. Let $\mathbf{f}(\cdot, \omega)$ : $K(\omega) \rightarrow K(\omega)$ and $\mathbf{x} \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ continuous on $\mathbb{R}^{n}$. Suppose also $\omega \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ is measurable for each fixed $\mathbf{x}$. Then there exists a measurable fixed point $\mathbf{x}(\omega), \mathbf{f}(\mathbf{x}(\omega), \omega)=$ $\mathbf{x}(\omega), \mathbf{x}(\omega) \in K(\omega)$.

### 48.2.4 Measurability Of Schauder Fixed Points

Now we consider the Schauder fixed point theorem. Let $\omega \rightarrow K(\omega)$ be a measurable multifunction having closed convex values. Here $K(\omega) \subseteq X$ a separable Banach space. Also assume

$$
\begin{gathered}
f(\cdot, \omega) \text { is continuous, } f(\cdot, \omega): K(\omega) \rightarrow K(\omega), \\
\omega \rightarrow f(x, \omega) \text { is measurable }
\end{gathered}
$$

Next we have the following approximation result.
Lemma 48.2.11 Let $f(\cdot, \omega)$ be as above and $f(K(\omega), \omega) \subseteq K(\omega)$ for $K(\omega)$ convex and closed and $\omega \rightarrow K(\omega)$ a measurable mutifunction. Suppose also that $\overline{f(K(\omega), \omega)}$ is a compact set. For each $r>0$ and $\omega$, there exists a finite set of points

$$
\left\{y_{1}(\omega), \cdots, y_{n(\omega)}(\omega)\right\} \subseteq \overline{f(K(\omega), \omega)}, \omega \rightarrow y_{i}(\omega) \text { measurable }
$$

and continuous functions $\psi_{i}(\cdot, \omega)$ defined on $\overline{f(K(\omega), \omega)}$ such that for $y \in f(K(\omega), \omega)$,

$$
\begin{gather*}
\sum_{i=1}^{n(\omega)} \psi_{i}(y, \omega)=1,  \tag{48.2.1}\\
\psi_{i}(y, \omega)=0 \text { if } y \notin B\left(y_{i}(\omega), r\right), \psi_{i}(y, \omega)>0 \text { if } y \in B\left(y_{i}(\omega), r\right)
\end{gather*}
$$

If

$$
\begin{equation*}
f_{r}(x, \omega) \equiv \sum_{i=1}^{n(\omega)} y_{i}(\omega) \psi_{i}(f(x, \omega), \omega) \tag{48.2.2}
\end{equation*}
$$

then whenever $x \in K(\omega)$,

$$
\left\|f(x, \omega)-f_{r}(x, \omega)\right\| \leq r .
$$

Proof: Using the compactness of $\overline{f(K(\omega), \omega)}$, Proposition 48.1.6 says there exist measurable functions $y_{i}(\omega)$

$$
\left\{y_{1}(\omega), \cdots, y_{n(\omega)}(\omega)\right\} \subseteq \overline{f(K(\omega), \omega)} \subseteq K(\omega)
$$

such that

$$
\left\{B\left(y_{i}(\omega), r\right)\right\}_{i=1}^{n}
$$

covers $\overline{f(K, \omega)}$. Let

$$
\phi_{i}(y, \omega) \equiv\left(r-\left\|y-y_{i}(\omega)\right\|\right)^{+}
$$

Thus $\phi_{i}$ is continuous in $y$ and measurable in $\omega$ for fixed $y$. Also $\phi_{i}(y, \omega)>0$ if $y \in$ $B\left(y_{i}(\omega), r\right)$ and $\phi_{i}(y, \omega)=0$ if $y \notin B\left(y_{i}(\omega), r\right)$. For $y \in \overline{f(K, \omega)}$, let

$$
\psi_{i}(y, \omega) \equiv \phi_{i}(y, \omega)\left(\sum_{j=1}^{n(\omega)} \phi_{j}(y, \omega)\right)^{-1}
$$

From the formula, $\omega \rightarrow \psi_{i}(y, \omega)$ is measurable. Also 48.2.1 is satisfied. Indeed the denominator is not zero because $y$ is in one of the $B\left(y_{i}(\omega), r\right)$. Thus it is obvious that the sum of these equals 1 on $f(K, \omega)$. Now let $f_{r}$ be given by 48.2 .2 for $x \in K(\omega)$. For such $x$,

$$
f(x, \omega)-f_{r}(x, \omega)=\sum_{i=1}^{n}\left(f(x, \omega)-y_{i}(\omega)\right) \psi_{i}(f(x, \omega), \omega)
$$

Thus

$$
\begin{aligned}
& f(x, \omega)- f_{r}(x, \omega)=\sum_{\left\{i: f(x) \in B\left(y_{i}(\omega), r\right)\right\}}\left(f(x, \omega)-y_{i}(\omega)\right) \psi_{i}(f(x, \omega), \omega) \\
&+\sum_{\left\{i: f(x, \omega) \notin B\left(y_{i}(\omega), r\right)\right\}}\left(f(x, \omega)-y_{i}(\omega)\right) \psi_{i}(f(x, \omega), \omega) \\
&=\sum_{\left\{i: f(x, \omega)-y_{i}(\omega) \in B(0, r)\right\}}\left(f(x, \omega)-y_{i}(\omega)\right) \psi_{i}(f(x, \omega), \omega)= \\
&\left\{\sum_{\left\{i: f(x, \omega)-y_{i}(\omega) \in B(0, r)\right\}}\left(f(x, \omega)-y_{i}(\omega)\right) \psi_{i}(f(x, \omega), \omega) \in B(0, r)\right.
\end{aligned}
$$

because $0 \in B(0, r), B(0, r)$ is convex, and 48.2.1. $f(x, \omega)-f_{r}(x, \omega)$ is a convex combination of vectors in $B(0, r)$.

We think of $f_{r}(\cdot, \omega)$ as an approximation to $f(\cdot, \omega)$. In fact it is uniformly within $r$ of $f(\cdot, \omega)$ on $K(\omega)$. The next lemma shows that this $f_{r}(\cdot, \omega)$ has a fixed point. This is the main result and comes from the Brouwer fixed point theorem in $\mathbb{R}^{n}$. It is an approximate fixed point.

Lemma 48.2.12 Let $\overline{f(K(\omega), \omega)}$ be compact. For each $r>0$, there exists $x_{r}(\omega) \in$ convex hull of $\overline{f(K(\omega), \omega)} \subseteq K(\omega)$ such that

$$
f_{r}\left(x_{r}(\omega), \omega\right)=x_{r}(\omega),\left\|f_{r}(x, \omega)-f(x, \omega)\right\|<r \text { for all } x \in K(\omega)
$$

and $\omega \rightarrow x_{r}(\omega)$ is measurable.
Proof: The upper limit in the sum of the above lemma $n(\omega)$ is a measurable function. One can partition the measure space according to the value of $n(\omega)$. This gives a countable set of disjoint measurable subsets $\left\{\Omega_{n}\right\}_{n=1}^{\infty}$ in the partition such that on the measurable set $\Omega_{n}, n(\omega)=n$. Specializing to the measurable space consisting of $\Omega_{n}$, we will assume here that $n(\omega)=n$ and show that there exists a measurable fixed point $x_{r}(\omega) \in K(\omega)$ for $\omega \in \Omega_{n}$. Then the result follows by letting $x_{r}(\omega)$ be that which has been obtained on $\Omega_{n}$.

Thus, from now on, simply denote as $n$ the upper limit and let $\omega \in \Omega_{n}$. If $f_{r}\left(x_{r}, \omega\right)=x_{r}$ and

$$
x_{r}=\sum_{i=1}^{n} a_{i} y_{i}(\omega)
$$

for $\sum_{i=1}^{n} a_{i}=1$ and the $y_{i}$ described in the above lemma, we need

$$
\begin{aligned}
f_{r}\left(x_{r}, \omega\right) & \equiv \sum_{i=1}^{n} y_{i}(\omega) \psi_{i}\left(f\left(x_{r}, \omega\right), \omega\right) \\
& =\sum_{j=1}^{n} y_{j}(\omega) \psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}, \omega\right), \omega\right)=\sum_{j=1}^{n} a_{j} y_{j}(\omega)=x_{r}
\end{aligned}
$$

Also, if this is satisfied, then we have the desired fixed point.
This will be satisfied if for each $j=1, \cdots, n$,

$$
\begin{equation*}
a_{j}=\psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}, \omega\right), \omega\right) \tag{48.2.3}
\end{equation*}
$$

so, let

$$
\Sigma_{n-1} \equiv\left\{\mathbf{a} \in \mathbb{R}^{n}: \sum_{i=1}^{n} a_{i}=1, a_{i} \geq 0\right\}
$$

and let $h(\cdot, \omega): \Sigma_{n-1} \rightarrow \Sigma_{n-1}$ be given by

$$
h(\mathbf{a}, \omega)_{j} \equiv \psi_{j}\left(f\left(\sum_{i=1}^{n} a_{i} y_{i}, \omega\right), \omega\right)
$$

Can we obtain a fixed point $\mathbf{a}(\omega)$ such that $\omega \rightarrow \mathbf{a}(\omega)$ is measurable? Since $h(\cdot, \omega)$ is a continuous function of $\mathbf{a}$ and $\omega \rightarrow h(\mathbf{x}, \omega)$ is measurable, such a measurable fixed point exists thanks to Theorem 48.2 .4 or the much easier Theorem 48.2.8 above. Then $x_{r}(\omega)=$ $\sum_{i=1}^{n} a_{i}(\omega) y_{i}(\omega)$ so $x_{r}$ is measurable.

The following is the Schauder fixed point theorem for measurable fixed points.
Theorem 48.2.13 Let $\omega \rightarrow K(\omega)$ be a measurable multifunction which has convex and closed values in a separable Banach space. Let $f(\cdot, \omega): K(\omega) \rightarrow K(\omega)$ be continuous and $\omega \rightarrow f(x, \omega)$ is measurable and $\overline{f(K(\omega), \omega)}$ is compact. Then $f(\cdot, \omega)$ has a fixed point $x(\omega)$ such that $\omega \rightarrow x(\omega)$ is measurable.

Proof: Recall that $f\left(x_{r}(\underline{\omega}), \omega\right)-f_{r}\left(x_{r}(\omega), \omega\right) \in B(0, r)$ and $f_{r}\left(x_{r}(\omega), \omega\right)=x_{r}(\omega)$ with $x_{r}(\omega) \in$ convex hull of $\overline{f(K(\omega), \omega)} \subseteq K(\omega)$. Here $x_{r}$ is measurable. By Lemma 48.2.2 there is a measurable function $x(\omega)$ which equals the weak $\lim _{r(\omega) \rightarrow 0} x_{r(\omega)}(\omega)$. However, since $\overline{f(K(\omega), \omega)}$ is compact, there is a subsequence still denoted with $r(\omega)$ such that $f\left(x_{r(\omega)}, \omega\right)$ converges strongly to some $x \in \overline{f(K(\omega), \omega)}$. It follows that

$$
f_{r(\omega)}\left(x_{r(\omega)}(\omega), \omega\right)
$$

also converges to $x$ strongly. But this equals $x_{r(\omega)}(\omega)$ which shows that $x_{r(\omega)}(\omega)$ converges strongly to the measurable $x(\omega)$. Therefore,

$$
\begin{aligned}
f(x(\omega), \omega) & =\lim _{r(\omega) \rightarrow 0} f\left(x_{r(\omega)}(\omega), \omega\right)=\lim _{r(\omega) \rightarrow 0} f_{r(\omega)}\left(x_{r(\omega)}(\omega), \omega\right) \\
& =\lim _{r(\omega) \rightarrow 0} x_{r(\omega)}(\omega)=x(\omega)
\end{aligned}
$$

As a special case of the above, here is a corollary which generalizes the earlier result on the Brouwer fixed point theorem.

Corollary 48.2.14 Let $(\Omega, \mathscr{F})$ be a measurable space and let $K(\omega)$ be a convex and compact set in $\mathbb{R}^{n}$ and $\omega \rightarrow K(\omega)$ is a measurable multifunction. Also let $\mathbf{f}(\cdot, \omega): K(\omega) \rightarrow$ $K(\omega)$ be continuous and for fixed $\mathbf{x} \in \mathbb{R}^{n}, \omega \rightarrow \mathbf{f}(\mathbf{x}, \omega)$ is measurable. Then there exists a fixed point $\mathbf{x}(\omega)$ for $\mathbf{f}(\cdot, \omega)$ such that $\omega \rightarrow \mathbf{x}(\omega)$ is measurable.

Note that in all of these considerations, there is no loss of generality in assuming $\mathbf{f}(\cdot, \omega)$ is defined on the whole space $X$ thanks to the theorem which says that a continuous function defined on a convex closed set can be extended to a continuous function defined on the whole space.

In the case of a single set, the following corollary is also obtained.
Corollary 48.2.15 Let $X$ be a Banach space and let $K$ be a compact convex subset. Let $f: K \times \Omega \rightarrow K$ satisfy

$$
\begin{aligned}
x & \rightarrow f(x, \omega) \text { is continous } \\
\omega & \rightarrow f(x, \omega) \text { is measurable }
\end{aligned}
$$

Then $f(\cdot, \omega)$ has a fixed point $x(\omega)$ such that $\omega \rightarrow x(\omega)$ is measurable.
Proof: The set $K$ has a countable dense subset $\left\{k_{i}\right\}$. You could consider $Y$ as the closure in $X$ of the span of these $k_{i}$. Thus $Y$ is a separable Banach space which contains $K$. Now apply the above result.

If $X$ is only a normed linear space, you could just consider its completion and apply the above result. Since $K$ is compact, it is automatically complete with respect to the norm on $X$.

What of the Schaefer fixed point theorem? Is there a measurable version of it? A map $h: X \rightarrow X$ for $X$ a Banach space is a compact map if it is continuous and it takes bounded sets to precompact sets. If you have such a compact map and it maps a closed ball to a closed ball, then it must have a fixed point by the Schauder theorem. If you have $h=f(\cdot, \omega)$ where $\omega \rightarrow f(x, \omega)$ is measurable, $x \rightarrow f(x, \omega)$ compact, then if $f(\cdot, \omega)$ maps a closed ball to a closed ball, it must have a measurable fixed point $x(\omega)$ by the above. Now the following is a version of the Schaefer fixed point theorem which can be used to get measurable fixed points.
Theorem 48.2.16 Let $f(\cdot, \omega): X \rightarrow X$ be a compact map (takes bounded sets to precompact sets and continuous) where $X$ is a Banach space. Also suppose that

$$
\sup \{z \in f(B(0, r), \omega)\} \leq C(r)
$$

independent of $\omega$. Here $\omega \rightarrow f(x, \omega)$ is measurable for each $x \in X$. Then either

1. There is a measurable fixed point $x(\omega)$ for $t f(\cdot, \omega)$ for all $t \in[0,1]$ or
2. For every $r>0$, there exists $\omega$ and $t \in(0,1)$ such that if $x$ satisfies $x=t f(x, \omega)$, then $\|x\|>r$.

Proof: Suppose that alternative 2 does not hold and yet alternative 1 also fails to hold. Since alternative 2 does not hold, there exists $M_{0}$ such that for all $\omega$, and for all $t \in(0,1)$, if $x=t f(x, \omega)$, then $\|x(\omega)\| \leq M_{0}$. If alternative 1 fails, then there is some $t$ with no measurable fixed point $x(\omega)$ for $t f(\cdot, \omega)$. So let $M>M_{0}$. By the measurable Schauder fixed point theorem, Theorem 48.2.13, there is measurable $x_{M}(\omega)$ such that

$$
x_{M}(\omega)=t\left(r_{M} f\left(x_{M}(\omega), \omega\right)\right), r_{M} y=y \text { if }\|y\| \leq M, r_{M} y=\frac{M y}{\|y\|} \text { if }\|y\|>M
$$

Thus $r_{M}$ is continuous and so $r_{M} f(\cdot, \omega)$ is continuous and compact. We must have

$$
\left\|f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)\right\|>M
$$

for some $\hat{\omega}$ and $r_{M} f\left(x_{M}(\hat{\omega}), \omega\right)=\frac{M f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)}{\left\|f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)\right\|}$ since if $\left\|f\left(x_{M}(\omega), \omega\right)\right\| \leq M$ for all $\omega$, then

$$
r_{M} f\left(x_{M}(\omega), \omega\right)=f\left(x_{M}(\omega), \omega\right)
$$

and there would be a measurable fixed point for this $t$. But then, for this $\hat{\omega}$

$$
x_{M}(\hat{\omega})=t\left(r_{M} f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)\right)=t \frac{M f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)}{\left\|f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)\right\|}=\hat{t} f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)
$$

From the hypotheses that 2 does not hold, $\left\|x_{M}(\hat{\omega})\right\| \leq M_{0}$. Thus $\left\|f\left(x_{M}(\hat{\omega}), \hat{\omega}\right)\right\|>M$. But this requires that $C\left(M_{0}\right)>M$ for all $M$ which is clearly impossible. Hence there is a measurable fixed point for $t f(\cdot, \omega)$ for all $t \in[0,1]$.

We will use this very interesting Shaefer theorem to give an easy to use criterion for showing the existence of measurable solutions to ordinary differential equations.

Lemma 48.2.17 Let $X \equiv C\left([0, T] ; \mathbb{R}^{n}\right)$ and let $\mathbf{f}(\cdot, \cdot, \omega):[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ where $\omega \in \Omega$ for $(\Omega, \mathscr{F})$ a measurable space and let $(t, \mathbf{x}) \rightarrow \mathbf{f}(t, \mathbf{x}, \omega)$ be continuous on $[0, T] \times \mathbb{R}^{n}$. Also suppose a uniform estimate of the form

$$
\begin{equation*}
\sup _{t \in[0, T],|\mathbf{x}| \leq r}|\mathbf{f}(t, \mathbf{x}, \omega)| \leq C(r) \text { independent of } \omega \tag{48.2.4}
\end{equation*}
$$

If $\mathbf{f}$ is $\mathscr{B}\left([0, T] \times \mathbb{R}^{n}\right) \times \mathscr{F}$ measurable and $\omega \rightarrow \mathbf{x}_{0}(\omega)$ is $\mathscr{F}$ measurable, then for $\mathbf{y} \in X$, define $F(\mathbf{y}, \omega) \in X$ by

$$
F(\mathbf{y}, \omega)(t) \equiv \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right) d s
$$

Then

$$
\omega \rightarrow F(\mathbf{y}, \omega)
$$

is measurable into $X$.

Proof: The space $X$ is separable and so by the Riesz representation theorem and the Pettis theorem, it suffices to verify that for $\mathbf{y} \in X$,

$$
\omega \rightarrow \int_{0}^{T} \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right) d s \cdot \sigma(t) d \mu(t)
$$

is measurable whenever $\sigma \in L^{\infty}([0, T], \mu)$ and $\mu$ is a finite Radon measure. By product measurability, there are simple functions $\mathbf{s}_{n}(t, \mathbf{x}, \omega)$ converging to $\mathbf{f}(t, \mathbf{x}, \omega)$ pointwise and we can have $\left|\mathbf{s}_{n}(t, \mathbf{x}, \omega)\right| \leq|\mathbf{f}(t, \mathbf{x}, \omega)|$ where

$$
\mathbf{s}_{n}(t, \mathbf{x}, \omega)=\sum_{i=1}^{m_{n}} c_{i} \mathscr{X}_{E_{i}^{n}}(t, \mathbf{x}, \omega), E_{i}^{n} \in \mathscr{B}\left([0, T] \times \mathbb{R}^{n}\right) \times \mathscr{F} .
$$

Therefore, for fixed $\omega,(t, \mathbf{x}) \rightarrow s_{n}\left(t, \mathbf{x}+\mathbf{x}_{0}(\omega), \omega\right)$ is Borel measurable and so

$$
t \rightarrow s_{n}\left(t, \mathbf{y}(t)+\mathbf{x}_{0}(\omega), \omega\right)
$$

is also Borel measurable so the above integral with $\mathbf{f}$ replaced with $\mathbf{s}_{n}$ surely makes sense. Then for $\mathbf{y} \in X$, you would have from dominated convergence theorem and assumed estimate 48.2.4,

$$
\begin{aligned}
& \int_{0}^{T} \int_{0}^{t} \mathbf{s}_{n}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right) d s \cdot \sigma(t) d \mu(t) \\
\rightarrow & \int_{0}^{T} \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right) d s \cdot \sigma(t) d \mu(t)
\end{aligned}
$$

and so the issue devolves to whether

$$
\begin{equation*}
\omega \rightarrow \int_{0}^{T} \int_{0}^{t} \mathbf{s}_{n}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right) d s \cdot \sigma(t) d \mu(t) \tag{48.2.5}
\end{equation*}
$$

is $\mathscr{F}$ measurable. Let $\mathscr{P}$ be the rectangles $B \times F$ where $B$ is Borel in $[0, T] \times \mathbb{R}^{n}$ and $F \in \mathscr{F}$. Let $\mathscr{G} \equiv$

$$
\left\{E \in \sigma(\mathscr{P}): \omega \rightarrow \int_{0}^{T} \int_{0}^{t} \mathscr{X}_{E}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right) d s \cdot \sigma(t) d \mu(t) \text { is } \mathscr{F} \text { measurable }\right\}
$$

the above condition holding for all $\sigma d \mu$. Obviously $\mathscr{G} \supseteq \mathscr{P}$. Indeed,

$$
\omega \rightarrow \mathscr{X}_{B}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega)\right) \mathscr{X}_{F}(\omega)=\mathscr{X}_{B \times F}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right)
$$

is measurable because $B$ is Borel and composition of Borel functions with a measurable function is measurable. It is also clear that $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. This follows from the monotone convergence theorem in the case of disjoint unions and from the observation that

$$
\mathscr{X}_{E}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right)+\mathscr{X}_{E^{C}}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right)=1
$$

in the case of complements. Hence, by Dynkin's lemma, $\mathscr{G}=\sigma(\mathscr{P})=\mathscr{B}\left([0, T] \times \mathbb{R}^{n}\right) \times$ $\mathscr{F}$. On consideration of components of $\mathbf{s}_{n}$, it follows that 48.2.5 is indeed measurable and this establishes the needed result.

There may be other conditions which will imply $\omega \rightarrow F(\mathbf{y}, \omega)$ is measurable into $X$ but an assumption of product measurability as above is fairly attractive. In particular, one could likely relax the estimate .

Now with this lemma, here is a very useable theorem related to measurable solutions to ordinary differential equations.

Theorem 48.2.18 Let $\mathbf{f}(\cdot, \cdot, \omega):[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be continuous and suppose

$$
\begin{equation*}
\omega \rightarrow F(\mathbf{y}, \omega) \tag{48.2.6}
\end{equation*}
$$

is measurable into $C\left([0, T] ; \mathbb{R}^{n}\right) \equiv X$ for

$$
F(\mathbf{y}, \omega)(t) \equiv \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}(\omega), \omega\right) d s
$$

Also suppose that

$$
\sup _{t \in[0, T],|\mathbf{x}| \leq r}|\mathbf{f}(t, \mathbf{x}, \omega)| \leq C(r) \text { independent of } \omega
$$

and suppose there exists $L>0$ such that for all $\omega$ and $\lambda \in(0,1)$, if

$$
\begin{equation*}
\mathbf{x}^{\prime}=\lambda \mathbf{f}(t, \mathbf{x}, \omega), \mathbf{x}(0, \omega)=\mathbf{x}_{0}(\omega), t \in[0, T] \tag{48.2.7}
\end{equation*}
$$

where $\mathbf{x}_{0}$ is bounded and measurable, then for all $t \in[0, T]$, then it follows that $\|\mathbf{x}\|<L$, the norm in $X \equiv C\left([0, T] ; \mathbb{R}^{n}\right)$. Then there exists a solution to

$$
\begin{equation*}
\mathbf{x}^{\prime}=\mathbf{f}(t, \mathbf{x}, \omega), \mathbf{x}(0, \omega)=\mathbf{x}_{0}(\omega) \tag{48.2.8}
\end{equation*}
$$

for $t \in[0, T]$ where $\omega \rightarrow \mathbf{x}(\cdot, \omega)$ is measurable into $X$. Thus $(t, \omega) \rightarrow \mathbf{x}(t, \omega)$ is product measurable.

Proof: Let $F(\cdot, \omega): X \rightarrow X$ where $X$ described above.

$$
F(\mathbf{y}, \omega)(t) \equiv \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}, \omega\right) d s
$$

$F$ is clearly continuous in the first variable and is assumed measurable in the second.
Let $B$ be a bounded set in $X$. Then by assumption $\left|\mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}, \omega\right)\right|$ is bounded for $s \in[0, T]$ if $\mathbf{y} \in B$. Say $\left|\mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}, \omega\right)\right| \leq C_{B}$. Hence $F(B, \omega)$ is bounded in $X$. Also, for $\mathbf{y} \in B, s<t$,

$$
|F(\mathbf{y}, \omega)(t)-F(\mathbf{y}, \omega)(s)| \leq\left|\int_{s}^{t} \mathbf{f}\left(s, \mathbf{y}(s)+\mathbf{x}_{0}, \omega\right) d s\right| \leq C_{B}|t-s|
$$

and so $F(B, \omega)$ is pre-compact by the Ascoli Arzela theorem. By the Schaefer fixed point theorem, there are two alternatives. Either there exist $\omega, \lambda$ resulting in arbitrarily large solutions $\mathbf{y}$ to

$$
\lambda F(\mathbf{y}, \omega)=\mathbf{y}
$$

or there is a fixed point for $\lambda F$ for all $\lambda \in[0,1]$. In the first case, there would be unbounded $\mathbf{y}_{\lambda, \omega}$ solving

$$
\mathbf{y}_{\lambda, \omega}(t)=\lambda \int_{0}^{t} \mathbf{f}\left(s, \mathbf{y}_{\lambda, \omega}(s)+\mathbf{x}_{0}, \omega\right) d s
$$

Then let $\mathbf{x}_{\lambda, \omega}(s) \equiv \mathbf{y}_{\lambda, \omega}(s)+\mathbf{x}_{0}$ and you get arbitrarily large $\left\|\mathbf{x}_{\lambda, \omega}\right\|$ for various $\omega$ and $\lambda \in(0,1)$. The above implies

$$
\mathbf{x}_{\lambda}(t)-\mathbf{x}_{0}=\lambda \int_{0}^{t} \mathbf{f}\left(s, \mathbf{x}_{\lambda}(s), \omega\right) d s
$$

so $\mathbf{x}_{\lambda}^{\prime}=\lambda \mathbf{f}\left(t, \mathbf{x}_{\lambda}, \omega\right), \mathbf{x}_{\lambda}(0, \omega)=\mathbf{x}_{0}(\omega)$ and these would be unbounded for $\lambda \in(0,1)$ contrary to the assumption that there exists an estimate for these valid for all $\lambda \in(0,1)$. Hence the first alternative must hold and hence there is $\mathbf{y}(\omega) \in X$ such that $\omega \rightarrow \mathbf{y}(\omega)$ measurable and

$$
F(\mathbf{y}(\omega), \omega)=\mathbf{y}(\omega)
$$

Then letting $\mathbf{x}(s, \omega) \equiv \mathbf{y}(s, \omega)+\mathbf{x}_{0}(\omega)$, it follows that

$$
\mathbf{x}(t, \omega)-\mathbf{x}_{0}(\omega)=\int_{0}^{t} \mathbf{f}(s, \mathbf{x}(s, \omega), \omega) d s
$$

and so $\mathbf{x}(\cdot, \omega)$ is a solution to the differential equation on $[0, T]$ which is measurable into $X$. In particular, one obtains that $(t, \omega) \rightarrow \mathbf{x}(t, \omega)$ is $\mathscr{B}(0, T) \times \mathscr{F}$ measurable where $\mathscr{F}$ is the $\sigma$ algebra of measurable sets.

### 48.3 A Set Valued Browder Lemma With Measurability

A simple application is a measurable version of the Browder lemma which is also valid for upper semicontinuous set valued maps. In what follows, we do not assume that $A(\cdot, \omega)$ is a set valued measurable multifunction, only that it has a measurable selection which is a weaker assumption. First is a general result on upper set valued maps $(u, \omega) \rightarrow A(u, \omega)$ where $u \rightarrow A(u, \omega)$ is upper semicontinuous and $\omega \rightarrow A(u, \omega)$ has a measurable selection.

Theorem 48.3.1 Let $V$ be a reflexive separable Banach space. Suppose $\omega \rightarrow A(u, \omega)$ has a measurable selection in $V^{\prime}$, for each $u \in V$ and $\omega \in \Omega$ the set $A(u, \omega)$ is closed and convex in $V^{\prime}$ and $u \rightarrow A(u, \omega)$ is bounded. Also, suppose $u \rightarrow A(u, \omega)$ is upper-semicontinuous from the strong topology of $V$ to the weak topology of $V^{\prime}$. That is, if $u_{n} \rightarrow u$ in $V$ strongly, then if $O$ is a weakly open set containing $A(u, \omega)$, it follows that $A\left(u_{n}, \omega\right) \in O$ for all $n$ large enough. Conclusion: Then, whenever $\omega \rightarrow u(\omega)$ is measurable into $V$ there is a measurable selection for $\omega \rightarrow A(u(\omega), \omega)$ into $V^{\prime}$.

Proof: Let $\omega \rightarrow u(\omega)$ be measurable into $V$, and let $u_{n}(\omega) \rightarrow u(\omega)$ in $V$ where $u_{n}$ is a simple function

$$
u_{n}(\omega)=\sum_{k=1}^{m_{n}} c_{k}^{n} \mathscr{X}_{E_{k}^{n}}(\omega), \text { the } E_{k}^{n} \text { disjoint, } \Omega=\cup_{k} E_{k}^{n}
$$

each $c_{k}^{n}$ being in $V$. We can assume that $\left\|u_{n}(\omega)\right\| \leq 2\|u(\omega)\|$ for all $\omega$. Then, by assumption, there is a measurable selection for $\omega \rightarrow A\left(c_{k}^{n}, \omega\right)$ denoted as $\omega \rightarrow y_{k}^{n}(\omega)$. Thus, $\omega \rightarrow y_{k}^{n}(\omega)$ is measurable into $V^{\prime}$ and $y_{k}^{n}(\omega) \in A\left(c_{k}^{n}, \omega\right)$ for all $\omega \in \Omega$. Consider now,

$$
y^{n}(\omega)=\sum_{k=1}^{m_{n}} y_{k}^{n}(\omega) \mathscr{X}_{E_{k}^{n}}(\omega)
$$

It is measurable and for $\omega \in E_{k}^{n}$ it equals $y_{k}^{n}(\omega) \in A\left(c_{k}^{n}, \omega\right)=A\left(u_{n}(\omega), \omega\right)$. Thus, $y^{n}$ is a measurable selection of $\omega \rightarrow A\left(u_{n}(\omega), \omega\right)$. By the assumption $A(\cdot, \omega)$ is bounded, for each $\omega$ these $y^{n}(\omega)$ lie in a bounded subset of $V^{\prime}$. The bound might depend on $\omega$ of course. It follows now from Lemma 48.2.2 that there is a subsequence $\left\{y^{n(\omega)}\right\}$ that converges weakly to $y(\omega)$, where $\omega \rightarrow y(\omega)$ is measurable. But,

$$
y^{n(\omega)}(\omega) \in A\left(u_{n(\omega)}(\omega), \omega\right)
$$

is a convex closed set for which $u \rightarrow A(u, \omega)$ is upper-semicontinuous and $u_{n(\omega)} \rightarrow u$, hence, $y(\omega) \in A(u(\omega), \omega)$. This is the claimed measurable selection.

The next lemma is about the projection map onto a set valued map whose values are closed convex sets.

Lemma 48.3.2 Let $\omega \rightarrow \mathscr{K}(\omega)$ be measurable into $\mathbb{R}^{n}$ where $\mathscr{K}(\omega)$ is closed and convex. Then $\omega \rightarrow P_{\mathscr{K}(\omega)} u(\omega)$ is also measurable into $\mathbb{R}^{n}$ if $\omega \rightarrow u(\omega)$ is measurable. Here $P_{\mathscr{K}(\omega)}$ is the projection map giving the closest point.

Proof: It follows from standard results on measurable multi-functions [70] also in Theorem 48.1.2 above that there is a countable collection $\left\{w_{n}(\omega)\right\}, \omega \rightarrow \underline{w_{n}(\omega) \text { being }}$ measurable and $w_{n}(\omega) \in \mathscr{K}(\omega)$ for each $\omega$ such that for each $\omega, \mathscr{K}(\omega)=\overline{\cup_{n} w_{n}(\omega)}$. Let

$$
d_{n}(\omega) \equiv \min \left\{\left\|u(\omega)-w_{k}(\omega)\right\|, k \leq n\right\}
$$

Let $u_{1}(\omega) \equiv w_{1}(\omega)$. Let

$$
u_{2}(\omega)=w_{1}(\omega)
$$

on the set

$$
\left\{\omega:\left\|u(\omega)-w_{1}(\omega)\right\|<\left\{\left\|u(\omega)-w_{2}(\omega)\right\|\right\}\right\}
$$

and

$$
u_{2}(\omega) \equiv w_{2}(\omega) \text { off the above set. }
$$

Thus $\left\|u_{2}(\omega)-u(\omega)\right\|=d_{2}$. Let

$$
\begin{aligned}
& u_{3}(\omega)=w_{1}(\omega) \text { on }\left\{\begin{array}{c}
\omega:\left\|u(\omega)-w_{1}(\omega)\right\| \\
<\left\|u(\omega)-w_{j}(\omega)\right\|, j=2,3
\end{array}\right\} \equiv S_{1} \\
& u_{3}(\omega)=w_{2}(\omega) \text { on } S_{1} \cap\left\{\begin{array}{c}
\omega:\left\|u(\omega)-w_{1}(\omega)\right\| \\
<\left\|u(\omega)-w_{j}(\omega)\right\|, j=3
\end{array}\right\} \\
& u_{3}(\omega)=w_{3}(\omega) \text { on the remainder of } \Omega
\end{aligned}
$$

Thus $\left\|u_{3}(\omega)-u(\omega)\right\|=d_{3}$. Continue this way, obtaining $u_{n}(\omega)$ such that

$$
\left\|u_{n}(\omega)-u(\omega)\right\|=d_{n}(\omega)
$$

and $u_{n}(\omega) \in \mathscr{K}(\omega)$ with $u_{n}$ measurable. Thus, in effect one picks the closest of all the $w_{k}(\omega)$ for $k \leq n$ as the value of $u_{n}(\omega)$ and $u_{n}$ is measurable and by density in $\mathscr{K}(\omega)$ of $\left\{w_{n}(\omega)\right\}$ for each $\omega,\left\{u_{n}(\omega)\right\}$ must be a minimizing sequence for

$$
\lambda(\omega) \equiv \inf \{\|u(\omega)-z\|: z \in \mathscr{K}(\omega)\}
$$

Then it follows that $u_{n}(\omega) \rightarrow P_{\mathscr{K}(\omega)} u(\omega)$ weakly in $\mathbb{R}^{n}$. Here is why: Suppose it fails to converge to $P_{\mathscr{K}(\omega)} u(\omega)$. Since it is minimizing, it is a bounded sequence. Thus there would be a subsequence, still denoted as $u_{n}(\omega)$ which converges to some $q(\omega) \neq P_{\mathscr{K}(\omega)} u(\omega)$. Then

$$
\lambda(\omega)=\lim _{n \rightarrow \infty}\left\|u(\omega)-u_{n}(\omega)\right\| \geq\|u(\omega)-q(\omega)\|
$$

because convex and lower semicontinuous is weakly lower semicontinuous. But this implies $q(\omega)=P_{\mathscr{K}(\omega)}(u(\omega))$ because the projection map is well defined thanks to strict convexity of the norm used. This is a contradiction. Hence $P_{\mathscr{K}(\omega)} u(\omega)=\lim _{n \rightarrow \infty} u_{n}(\omega)$ and so is a measurable function. It follows that $\omega \rightarrow P_{\mathscr{K}(\omega)}(u(\omega), \omega)$ is measurable into $\mathbb{R}^{n}$.

One way to prove the following Theorem in simpler cases is to use a measurable version of the Kakutani fixed point theorem. It is done this way in [99] without the dependence on $\omega$. See also [35] for a measurable version of this fixed point theorem. However, one can also prove it by a generalization of the proof Browder gave for a single valued case and this is summarized here. We want to include the case where $A$ is a sum of two set valued operators and this involves careful consideration of the details. Such a situation occurs when one considers operators which are a sum, one dependent on the boundary of a region, and the other from a partial differential inclusion. Also, we will need to consider finite dimensional subspaces which depend on $\omega$ which further complicates the considerations.

Theorem 48.3.3 Assumtions: Let $B(\cdot, \omega): V \rightarrow \mathscr{P}\left(V^{\prime}\right), C(\cdot, \omega): V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ for $V$ a separable Banach space. Suppose that $\omega \rightarrow B(x, \omega), \omega \rightarrow C(x, \omega)$ each has a measurable selection and $x \rightarrow B(x, \omega), x \rightarrow C(x, \omega)$ each is upper semicontinuous from strong to weak topologies. Also let $E(\omega)$ be an $n$ dimensional subspace of $V$ which has a basis $\left\{b_{1}(\omega), \cdots, b_{n}(\omega)\right\}$ each of which is a measurable function into $V$, and that $K(\omega) \subseteq E(\omega)$ where $K(\omega)$ is a measurable multifunction which has convex closed bounded values. Also let $y(\omega)$ be given, a measurable function into $V^{\prime}$. Conclusion: There exist measurable functions $w_{B}(\omega), w_{C}(\omega)$ and $x(\omega)$ with $w_{B}(\omega) \in B(x(\omega), \omega), w_{C}(\omega) \in C(x(\omega), \omega)$, and $x(\omega) \in K(\omega)$ such that for all $z \in K(\omega)$,

$$
\left\langle y(\omega)-\left(w_{B}(\omega)+w_{C}(\omega)\right), z-x(\omega)\right\rangle \leq 0
$$

Proof: The argument will refer to the following commutative diagram.

$$
\begin{array}{rll}
E(\omega)^{\prime} & \xrightarrow{\theta(\omega)^{*}} & \mathbb{R}^{n} \\
i(\omega)^{*} A(\cdot, \omega) \uparrow & & \uparrow \theta(\omega)^{*} i(\omega)^{*} A(\theta(\omega) \cdot, \omega) \\
E(\omega) & \stackrel{\theta(\omega)}{\leftarrow} & \mathbb{R}^{n}
\end{array}
$$

where $A(\cdot, \omega)$ will be either $B(\cdot, \omega)$ or $C(\cdot, \omega)$. Here $\theta(\omega) \mathbf{e}_{i} \equiv b_{i}(\omega)$ and extended linearly. Then it is clear that $\theta(\omega)$ maps measurable functions to measurable functions.

What of $\theta(\omega)^{-1}$ ? Is $\omega \rightarrow \theta(\omega)^{-1} h(\omega)$ measurable into $\mathbb{R}^{n}$ whenever $h$ is measurable into $V$ ? Let $h(\omega)$ have values in $E(\omega)$ and be measurable into $V$. Thus

$$
h(\omega)=\sum_{i} a_{i}(\omega) b_{i}(\omega)
$$

The question reduces to whether the $a_{i}$ are measurable. To see that these are measurable, consider first $\|h(\omega)\|<M$ for all $\omega$. Let $S_{r} \equiv\left\{\omega: \inf _{|\mathbf{a}|>r}\left\|\sum_{i} a_{i} b_{i}(\omega)\right\|>M\right\}$. Thus this is a measurable set. Also every $\omega$ is in some $S_{r}$ because if not, you could get a sequence $\left|\mathbf{a}^{r}\right| \rightarrow$ $\infty$ and yet $\left\|\sum_{i} a_{i}^{r} b_{i}(\omega)\right\| \leq M$. But then, dividing by $\left|\mathbf{a}^{r}\right|$ and taking a suitable subsequence, one can obtain $\sum_{i} a_{i} b_{i}(\omega)=0$ for some $|\mathbf{a}|=1$. Also the $S_{r}$ are increasing in $r$. Now for $\omega \in S_{r}$, define $\Phi(\mathbf{a}, \omega)=-\left\|\sum_{i} a_{i} b_{i}(\omega)-h(\omega)\right\|$ where we will let $|\mathbf{a}| \leq r+1$. Since $\left\{b_{i}(\omega)\right\}$ is a basis, there exists $\mathbf{a}(\omega)$ such that $\Phi(\mathbf{a}(\omega), \omega)=0$. This a must satisfy $|\mathbf{a}| \leq r+1$ because if not, then you would have $\left\|\sum_{i} a_{i} b_{i}(\omega)\right\| \geq M$ since $\omega \in S_{r}$. But $\left\|\sum_{i} a_{i} b_{i}(\omega)\right\|=\|h(\omega)\|<M$. Thus the maximum of $\mathbf{a} \rightarrow \Phi(\mathbf{a}, \omega)$ occurs on the compact set $|\mathbf{a}| \leq r+1$ and is 0 . By Kuratowski's theorem, we have $\omega \rightarrow \mathbf{a}(\omega)$ is measurable where $h(\omega)=\sum_{i} a_{i}(\omega) b_{i}(\omega)$ on $S_{r}$. Thus, since every $\omega$ is in some $S_{r}$, we must have $\omega \rightarrow a_{i}(\omega)$ is measurable in case $\|h(\omega)\| \leq M$ for all $\omega$. In the general case, let $\mathbf{a}^{m}(\omega)$ be the measurable function which goes with $h_{m}(\omega)$ where $h_{m}(\omega)$ is given by a truncation of $h$ so that $\left\|h_{m}(\omega)\right\| \leq m$. For each $\omega, h_{m}(\omega)$ is eventually smaller than $m$, so $h(\omega)=h_{m}(\omega)$. Thus if $a_{i}^{m}(\omega)$ go with $h_{m}(\omega)$, these are constant for all $m$ large enough. Thus letting $a_{i}(\omega) \equiv \lim _{m \rightarrow \infty} a_{i}^{m}(\omega), a_{i}$ is measurable and

$$
h(\omega)=\lim _{m \rightarrow \infty} h_{m}(\omega)=\lim _{m \rightarrow \infty} \sum_{i} a_{i}^{m}(\omega) b_{i}(\omega)=\sum_{i} a_{i}(\omega) b_{i}(\omega)
$$

and so the $a_{i}$ are indeed measurable. Thus the $\theta(\omega)^{-1} h(\omega)=\sum_{i} a_{i}(\omega) \mathbf{e}_{i}$ which shows that $\theta(\omega)^{-1}$ does map measurable functions to measurable functions. In particular,

$$
\theta(\omega)^{-1} K(\omega)
$$

is indeed a closed, bounded, convex, and measurable multifunction which can be seen by considering a sequence $\left\{k_{i}(\omega)\right\}_{i=1}^{\infty}$ of measurable functions dense in $K(\omega)$.

Define for $A=B$ or $C$,

$$
\begin{equation*}
\hat{A}(\cdot, \omega)=\theta(\omega)^{*} i(\omega)^{*} A(\theta(\omega) \cdot, \omega), \mathbf{y}(\omega)=\theta(\omega)^{*} i(\omega)^{*} y(\omega) \tag{48.3.9}
\end{equation*}
$$

We claim that $\omega \rightarrow \hat{A}(\mathbf{x}, \omega)$ has a measurable selection and for fixed $\omega$ this is upper semicontinuous in $\mathbf{x}$. The second condition for fixed $\omega$ is obvious. Consider the first. It was shown above that $\theta(\omega) \mathbf{x}$ is measurable into $V$. Thus, by Theorem 48.3.1, it follows that $\omega \rightarrow A(\theta(\omega) \mathbf{x}, \omega)$ has a measurable selection into $V^{\prime}$. Therefore, it suffices to show that if $z(\omega)$ is measurable into $V^{\prime}$ then $\theta(\omega)^{*} i(\omega)^{*} z(\omega)$ is measurable into $\mathbb{R}^{n}$. Let $\mathbf{w} \in \mathbb{R}^{n}$.

Then

$$
\begin{aligned}
\left(\theta(\omega)^{*} i(\omega)^{*} z(\omega), \mathbf{w}\right)_{\mathbb{R}^{n}} & \equiv\left\langle i(\omega)^{*} z(\omega), \theta(\omega) \mathbf{w}\right\rangle \\
& =\left\langle i(\omega)^{*} z(\omega), \sum_{i} w_{i} b_{i}(\omega)\right\rangle \\
& =\left\langle z(\omega), \sum_{i} w_{i} b_{i}(\omega)\right\rangle_{V^{\prime}, V}
\end{aligned}
$$

which is measurable. By the Pettis theorem, $\omega \rightarrow \theta(\omega)^{*} i(\omega)^{*} z(\omega)$ is measurable. Thus $\hat{A}(\cdot, \omega)$ has the properties claimed.

Now tile $\mathbb{R}^{n}$ with $n$ simplices, each having diameter less than $\varepsilon<1$, the set of simplices being locally finite. Define for $A=B$ or $C$ the single valued function $\hat{A}_{\varepsilon}$ on all of $\mathbb{R}^{n}$ by the following rule. If

$$
\mathbf{x} \in\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]
$$

so $\mathbf{x}=\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}, t_{i} \geq 0, \sum_{i} t_{i}=1$, then let $\hat{A}_{\varepsilon}\left(\mathbf{x}_{k}, \omega\right)$ be a measurable selection from $\hat{A}\left(\mathbf{x}_{k}, \omega\right)$ for each $\mathbf{x}_{k}$ a vertex of the simplex. However, we chose $\hat{A}_{\varepsilon}\left(\mathbf{x}_{k}, \omega\right)$ in the obvious way. It is $\theta(\omega)^{*} i(\omega)^{*} w_{k}^{\varepsilon B}(\omega)$ where $w_{k}^{\varepsilon B}(\omega)$ is a measurable selection of $B\left(\theta(\omega) \mathbf{x}_{k}, \omega\right)$, measurable into $V^{\prime}$ when $A=B$ and $\theta(\omega)^{*} i(\omega)^{*} w_{k}^{\varepsilon C}(\omega)$ where $w_{k}^{\varepsilon C}(\omega)$ is a measurable selection of $C\left(\theta(\omega) \mathbf{x}_{k}, \omega\right)$, measurable into $V^{\prime}$ when $A=C$. Then

$$
\begin{equation*}
\hat{B}_{\varepsilon}\left(\mathbf{x}_{k}, \omega\right)=\theta(\omega)^{*} i(\omega)^{*} w_{k}^{\varepsilon B}(\omega), \omega \rightarrow w_{k}^{\varepsilon B}(\omega) \text { measurable } \tag{48.3.10}
\end{equation*}
$$

with a similar definition holding for $\hat{C}_{\varepsilon}$.
Define single valued maps as follows. For $\mathbf{x}=\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}, \sum_{i} t_{i}=1, t_{i} \geq 0,\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$ in the tiling,

$$
\begin{gather*}
\hat{B}_{\varepsilon}(\mathbf{x}, \omega) \equiv \sum_{k=0}^{n} t_{k}\left(\hat{B}_{\varepsilon}\left(\mathbf{x}_{k}, \omega\right)\right), \hat{C}_{\varepsilon}(\mathbf{x}, \omega) \equiv \sum_{k=0}^{n} t_{k}\left(\hat{C}_{\varepsilon}\left(\mathbf{x}_{k}, \omega\right)\right) \\
\hat{A}_{\varepsilon}(\mathbf{x}, \omega) \equiv \hat{B}_{\varepsilon}(\mathbf{x}, \omega)+\hat{C}_{\varepsilon}(\mathbf{x}, \omega) \tag{48.3.11}
\end{gather*}
$$

Thus $\hat{A}_{\varepsilon}(\cdot, \omega)$ is a continuous map defined on $\mathbb{R}^{n}$ thanks to the local finiteness of the tiling, and $\omega \rightarrow \hat{A}_{\mathcal{E}}(\mathbf{x}, \omega)$ is measurable.

Let $P_{\theta(\omega)^{-1} K(\omega)}$ denote the projection onto the closed convex set $\theta(\omega)^{-1} K(\omega)$. This is a continuous mapping by Hilbert space considerations. Therefore,

$$
\mathbf{x} \rightarrow P_{\theta(\omega)^{-1} K(\omega)}\left(\mathbf{y}(\omega)-\hat{A}_{\mathcal{E}}(\mathbf{x}, \omega)+\mathbf{x}\right)
$$

is continuous and by Lemma 48.3.2, $\omega \rightarrow P_{\theta(\omega)^{-1} K(\omega)}\left(\mathbf{y}(\omega)-\hat{A}_{\varepsilon}(\mathbf{x}, \omega)+\mathbf{x}\right)$ is measurable, and for each $\omega$, this function of $\mathbf{x}$ maps into $\theta(\omega)^{-1} K(\omega)$. Therefore by Corollary 48.2.14, there exists a fixed point $\mathbf{x}_{\varepsilon}(\omega) \in \theta(\omega)^{-1} K(\omega)$ such that $\omega \rightarrow \mathbf{x}_{\varepsilon}(\omega)$ is measurable and

$$
P_{\theta(\omega)^{-1} K(\omega)}\left(\mathbf{y}(\omega)-\left(\hat{B}_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right)+\hat{C}_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right)\right)+\mathbf{x}_{\varepsilon}(\omega)\right)=\mathbf{x}_{\varepsilon}(\omega)
$$

This requires

$$
\begin{equation*}
\left(\mathbf{y}(\omega)-\left(\hat{B}_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right)+\hat{C}_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right)\right), \mathbf{z}-\mathbf{x}_{\varepsilon}(\omega)\right)_{\mathbb{R}^{n}} \leq 0 \tag{48.3.12}
\end{equation*}
$$

for all $\mathbf{z} \in \theta(\omega)^{-1} K(\omega)$. Note that this implies $\omega \rightarrow \hat{B}_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right), \hat{C}_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right)$ are measurable because of the continuity in first argument and measurability of $\omega \rightarrow \mathbf{x}_{\varepsilon}(\omega)$

We have

$$
\begin{equation*}
\mathbf{x}_{\varepsilon}(\omega)=\sum_{k=0}^{n} t_{k}^{\varepsilon}(\omega) \mathbf{x}_{k}^{\varepsilon}(\omega) \tag{48.3.13}
\end{equation*}
$$

where the $\mathbf{x}_{k}^{\varepsilon}(\omega)$ are vertices of the tiling corresponding to $\varepsilon$.
Claim: The vertices $\mathbf{x}_{k}^{\varepsilon}(\omega)$ and coordinates $t_{k}^{\varepsilon}(\omega)$ can be considered measurable.
Proof of claim: Let the simplices in the tiling be $\left\{\sigma_{k}\right\}_{k=1}^{\infty}$ and let the vertices of simplices in the tiling be $\left\{\mathbf{z}_{j}\right\}_{j=1}^{\infty}$. Say the vertices of $\sigma_{k}$ are $\left\{\mathbf{x}_{0}^{k}, \cdots, \mathbf{x}_{n}^{k}\right\}$ listed in the order of the given enumeraton of vertices of simplices in the tiling. Let $F_{k}$ and $E_{k}$ be defined as follows.

$$
F_{k} \equiv \mathbf{x}_{\varepsilon}^{-1}\left(\sigma_{k}\right), E_{1} \equiv F_{1}, \cdots, E_{k} \equiv F_{k} \backslash \cup_{i=1}^{k-1} F_{i}
$$

Then each $\omega$ is in exactly one of these measurable sets $E_{k}$ which partition $\Omega$. For $\omega \in$ $E_{k}, \mathbf{x}_{\varepsilon}(\omega) \in \sigma_{k}(\omega)$. Thus $\sigma_{k}(\omega)$ is the first simplex which contains $\mathbf{x}_{\varepsilon}(\omega)$ and the ordered vertices of this simplex are constant on the measurable set $E_{k}$. These vertices are determined this way on a measurable set $E_{k}$ and so they must be measurable $\mathbb{R}^{n}$ valued functions. Then $\omega \rightarrow t_{k}^{\varepsilon}(\omega)$ is also measurable because there is a continuous mapping to these scalars from $\mathbf{x}_{\varepsilon}(\omega)$ which was obtained measurable. This shows the claim.

Recall 48.3.10. Let $\mathbf{W}^{\varepsilon}(\omega)$ be defined as follows.

$$
\mathbf{W}^{\varepsilon}(\omega) \equiv\binom{t_{0}^{\varepsilon}(\omega), \cdots, t_{n}^{\varepsilon}(\omega), \mathbf{x}_{0}^{\varepsilon}(\omega), \cdots, \mathbf{x}_{n}^{\varepsilon}(\omega),}{\mathbf{x}_{\varepsilon}(\omega), w_{0}^{\varepsilon \varepsilon}(\omega), \cdots, w_{n}^{\varepsilon B}(\omega), w_{0}^{\varepsilon C}(\omega), \cdots, w_{n}^{\varepsilon C}(\omega)}
$$

This is in $\mathbb{R}^{2(n+1)} \times\left(V^{\prime}\right)^{2(n+1)}$. Then by Theorem 48.2.2, since $\mathbf{W}^{\varepsilon}(\omega)$ is bounded in a reflexive separable Banach space, there is a subsequence $\varepsilon(\omega) \rightarrow 0$ such that $\mathbf{W}^{\varepsilon(\omega)}(\omega) \rightarrow$ $\mathbf{W}(\omega)$ weakly and given by

$$
\mathbf{W}(\omega) \equiv\binom{t_{0}(\omega), \cdots, t_{n}(\omega), \mathbf{x}_{0}(\omega), \cdots, \mathbf{x}_{n}(\omega),}{\mathbf{x}(\omega), w_{0}^{B}(\omega), \cdots, w_{n}^{B}(\omega), w_{0}^{C}(\omega), \cdots, w_{n}^{C}(\omega)}
$$

where each of these components is measurable into the appropriate space. Of course, in the finite dimensional components, the convergence is strong because strong and weak convergence is the same in finite dimensions. Since the diameter of the simplex containing the fixed point $\mathbf{x}_{\varepsilon(\omega)}(\omega)$ converges to 0 , it follows that

$$
\lim _{\varepsilon(\omega) \rightarrow 0} \mathbf{x}_{k}^{\varepsilon(\omega)}(\omega)=\mathbf{x}(\omega)
$$

By upper semicontinuity, for $A=B, C$, it follows that $\hat{A}\left(\mathbf{x}_{k}^{\varepsilon(\omega)}(\omega), \omega\right) \subseteq \hat{A}(\mathbf{x}(\omega), \omega)+$ $B(\mathbf{0}, r)$ for all $\varepsilon(\omega)$ small enough. Since, by the construction,

$$
\hat{B}_{\varepsilon(\omega)}\left(\mathbf{x}_{k}^{\varepsilon(\omega)}(\omega), \omega\right)=\theta(\omega)^{*} i(\omega)^{*} w_{k}^{\varepsilon(\omega) B}(\omega) \in \hat{B}\left(\mathbf{x}_{k}^{\varepsilon(\omega)}(\omega), \omega\right)
$$

a similar statement for $\hat{C}$, it follows that $\hat{B}_{\varepsilon(\omega)}\left(\mathbf{x}_{k}^{\varepsilon(\omega)}(\omega), \omega\right)=\theta(\omega)^{*} i(\omega)^{*} w_{k}^{\varepsilon(\omega) B}(\omega)$ is within $r$ of the closed convex bounded set $\hat{B}(\mathbf{x}(\omega), \omega)$ whenever $\varepsilon(\omega)$ is small enough, similar for $\hat{C}$. Thus

$$
\theta(\omega)^{*} i(\omega)^{*} w_{k}^{B}(\omega) \in \hat{B}(\mathbf{x}(\omega), \omega)
$$

similar for $\hat{C}$. Since this last set is convex, it follows that

$$
\theta(\omega)^{*} i(\omega)^{*} \sum_{k} t_{k}(\omega) w_{k}^{B}(\omega) \in \hat{B}(\mathbf{x}(\omega), \omega)
$$

similar for $\hat{C}$.
Now recall 48.3 .9 and the inequality 48.3 .12 which imply that for $\mathbf{z} \in \theta(\omega)^{-1} K(\omega)$,

$$
\begin{align*}
& \left(\mathbf{y}(\omega)-\theta(\omega)^{*} i(\omega)^{*}\left(\sum_{k=0}^{n} t_{k}(\omega) w_{k}^{B}(\omega)+\sum_{k=0}^{n} t_{k}(\omega) w_{k}^{C}(\omega)\right), \mathbf{z}-\mathbf{x}(\omega)\right)  \tag{48.3.14}\\
& =\lim _{\varepsilon(\omega) \rightarrow 0}\left(\mathbf{y}(\omega)-\binom{\sum_{k=0}^{n} t_{k}^{\varepsilon(\omega)}(\omega) \theta(\omega)^{*} i(\omega)^{*} w_{k}^{\varepsilon(\omega) B}(\omega)}{+\sum_{k=0}^{n} t_{k}^{\varepsilon(\omega)}(\omega) \theta(\omega)^{*} i(\omega)^{*} w_{k}^{\varepsilon(\omega) C}(\omega)}, \mathbf{z}-\mathbf{x}_{\varepsilon(\omega)}(\omega)\right) \\
& =\lim _{\varepsilon(\omega) \rightarrow 0}\left(\mathbf{y}(\omega)-\binom{\sum_{k=0}^{n} t_{k}^{\varepsilon(\omega)}(\omega) \hat{B}_{\varepsilon(\omega)}\left(\mathbf{x}_{k}^{\varepsilon(\omega)}, \omega\right)}{+\sum_{k=0}^{n} t_{k}^{\varepsilon(\omega)}(\omega) \hat{C}_{\varepsilon(\omega)}\left(\mathbf{x}_{k}^{\varepsilon(\omega)}, \omega\right)}, \mathbf{z}-\mathbf{x}_{\varepsilon(\omega)}(\omega)\right)
\end{align*}
$$

Recall 48.3 .11 and 48.3 .13 which imply from the above conventions that the sum in the above equals $\hat{B}_{\varepsilon(\omega)}\left(\mathbf{x}_{\varepsilon(\omega)}, \omega\right)+\hat{C}_{\varepsilon(\omega)}\left(\mathbf{x}_{\varepsilon(\omega)}, \omega\right)$. Thus the above equals

$$
\lim _{\varepsilon(\omega) \rightarrow 0}\left(\mathbf{y}(\omega)-\left(\hat{B}_{\varepsilon(\omega)}\left(\mathbf{x}_{\varepsilon(\omega)}, \omega\right)+\hat{C}_{\varepsilon(\omega)}\left(\mathbf{x}_{\varepsilon(\omega)}, \omega\right)\right), \mathbf{z}-\mathbf{x}_{\varepsilon(\omega)}(\omega)\right) \leq 0
$$

Now $w_{k}^{\varepsilon(\omega) B}(\omega) \in B\left(\theta(\omega) \mathbf{x}_{k}^{\varepsilon(\omega)}(\omega), \omega\right)$ and the weak uppersemicontinuity must then imply that $w_{k}^{B}(\omega) \in B(\theta(\omega) \mathbf{x}(\omega), \omega)$, a similar statement holding for $C$. By convexity,

$$
w_{B}(\omega) \equiv \sum_{k=0}^{n} t_{k}(\omega) w_{k}^{B}(\omega) \in B(\theta(\omega) \mathbf{x}(\omega), \omega)
$$

similar for $C$. Then from 48.3.14,

$$
\begin{aligned}
& \left(\mathbf{y}(\omega)-\theta(\omega)^{*} i(\omega)^{*}\left(\sum_{k=0}^{n} t_{k}(\omega) w_{k}^{B}(\omega)+\sum_{k=0}^{n} t_{k}(\omega) w_{k}^{C}(\omega)\right), \mathbf{z}-\mathbf{x}(\omega)\right) \\
= & \left(\theta(\omega)^{*} i(\omega)^{*}\left(y(\omega)-\left(w_{B}(\omega)+w_{C}(\omega)\right)\right), \mathbf{z}-\mathbf{x}(\omega)\right) \leq 0
\end{aligned}
$$

It follows that if $x(\omega) \equiv \theta(\omega) \mathbf{x}(\omega)$,

$$
\left\langle y(\omega)-\left(w_{B}(\omega)+w_{C}(\omega)\right), \theta(\omega) \mathbf{z}-x(\omega)\right\rangle \leq 0
$$

each of $x(\omega)$,

$$
w_{B}(\omega), w_{C}(\omega)
$$

are measurable and $w_{B}(\omega) \in B(x(\omega), \omega), w_{C}(\omega) \in C(x(\omega), \omega)$. Since $\theta(\omega) \mathbf{z}$ is a generic element of $K(\omega)$, this proves the theorem.

Obviously one could have any finite sum of operators having the same properties as $B, C$ above and one could get a similar result.

### 48.4 A Measurable Kakutani Theorem

Recall the Kakutani theorem, Theorem 25.4.4.
Theorem 48.4.1 Let $K$ be a compact convex subset of $\mathbb{R}^{n}$ and let $A: K \rightarrow \mathscr{P}(K)$ such that $A \mathbf{x}$ is a closed convex subset of $K$ and $A$ is upper semicontinuous. Then there exists $\mathbf{x}$ such that $\mathbf{x} \in A \mathbf{x}$. This is the "fixed point".

Here is a measurable version of this theorem. It is just like the proof of the above Browder lemma.

Theorem 48.4.2 Let $K(\omega)$ be compact, convex, and $\omega \rightarrow K(\omega)$ a measurable multifunction. Let $A(\cdot, \omega): K(\omega) \rightarrow K(\omega)$ be upper semicontinuous, and let $\omega \rightarrow A(\mathbf{x}, \omega)$ have a measurable selection for each $\mathbf{x} \in \mathbb{R}^{n}$. Then there exists $\mathbf{x}(\omega) \in K(\omega) \cap A(K(\omega), \omega)$ such that $\omega \rightarrow \mathbf{x}(\omega)$ is measurable.

Proof: Tile $\mathbb{R}^{n}$ with $n$ simplices such that the collection is locally finite and each simplex has diameter less than $\varepsilon<1$. This collection of simplices is determined by a countable collection of vertices so there exists a one to one and onto map from $\mathbb{N}$ to the collection of vertices. By assumption, for each vertex $\mathbf{x}$, there exists $A_{\varepsilon}(\mathbf{x}, \omega) \in A\left(P_{K(\omega)} \mathbf{x}, \omega\right)$. By Lemma 48.3.2, $\omega \rightarrow P_{K(\omega)} \mathbf{x}$ is measurable and by Theorem 48.3.1, there is a measurable selection for $\omega \rightarrow A\left(P_{K(\omega)} \mathbf{x}, \omega\right)$ which is denoted as $A_{\varepsilon}(\mathbf{x}, \omega)$. By local finiteness, this function is continuous in $\mathbf{x}$ on the set of vertices. Define $A_{\varepsilon}$ on all of $\mathbb{R}^{n}$ by the following rule. If

$$
\mathbf{x} \in\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]
$$

so $\mathbf{x}=\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}$, then

$$
A_{\varepsilon}(\mathbf{x}, \omega) \equiv \sum_{k=0}^{n} t_{k} A_{\varepsilon}\left(\mathbf{x}_{k}, \omega\right)
$$

By local finiteness, this function satisfies $\omega \rightarrow A_{\mathcal{E}}(\mathbf{x}, \omega)$ is measurable and also $\mathbf{x} \rightarrow A_{\varepsilon}(\mathbf{x}, \varepsilon)$ is continuous. It also maps $\mathbb{R}^{n}$ to $K(\omega)$. By Corollary 48.2 .14 there is a measurable fixed point $\mathbf{x}_{\varepsilon}(\omega)$ satisfying $\mathbf{x}_{\varepsilon}(\omega) \in K(\omega)$ and $A_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right)=\mathbf{x}_{\varepsilon}(\omega)$.

Suppose $\mathbf{x}_{\varepsilon}(\omega) \in\left[\mathbf{x}_{0}^{\varepsilon}(\omega), \cdots, \mathbf{x}_{n}^{\varepsilon}(\omega)\right]$ so $\mathbf{x}_{\varepsilon}(\omega)=\sum_{k=0}^{n} t_{k}^{\varepsilon}(\omega) \mathbf{x}_{k}^{\varepsilon}(\omega)$.
claim: The vertices $\mathbf{x}_{k}^{\varepsilon}(\omega)$ can be considered measurable also as is $t_{k}^{\varepsilon}(\omega)$.
Proof of claim: Let the simplices in the tiling be $\left\{\sigma_{k}\right\}_{k=1}^{\infty}$ and let the vertices of simplices in the tiling be $\left\{\mathbf{z}_{j}\right\}_{j=1}^{\infty}$. Let

$$
F_{k}:=\mathbf{x}_{\varepsilon}^{-1}\left(\sigma_{k}\right), E_{1}:=F_{1}, \cdots, E_{k}:=F_{k} \backslash \cup_{i=1}^{k} F_{i}
$$

Then $\omega$ is in exactly one of these measurable sets $E_{k}$. These measurable sets partition $\Omega$. Let $\sigma_{k}(\omega)$ be the unique simplex for $\omega \in E_{k}$. Thus $\mathbf{x}_{\varepsilon}(\omega) \in \sigma_{k}(\omega)$ on the measurable set $E_{k}$. Its vertices, are $\mathbf{z}_{i_{0}}(\omega), \mathbf{z}_{i_{1}}(\omega), \cdots, \mathbf{z}_{i_{n}}(\omega)$. These are $\mathbf{x}_{0}^{\varepsilon}(\omega), \cdots, \mathbf{x}_{n}^{\varepsilon}(\omega)$ in order. They are determined in this way on a measurable set so they are measurable $\mathbb{R}^{n}$ valued functions. Then $\omega \rightarrow t_{k}^{\varepsilon}(\omega)$ is also measurable because there is a continuous mapping to these scalars from $\mathbf{x}_{\varepsilon}(\omega)$.

Then since $\mathbf{x}_{\varepsilon}(\omega)$ is contained in $K(\omega)$, a compact set, and the diameter of each simplex is less than 1 , it follows that $A_{\varepsilon}\left(\mathbf{x}_{k}^{\varepsilon}(\omega), \omega\right)$ is contained in

$$
A(\overline{K(\omega)+B(\mathbf{0}, 1)}, \omega)
$$

which is a compact set. Let $\mathbf{W}^{\varepsilon}(\omega) \in \mathbb{R}^{2 n+2 n^{2}}$ be defined as follows.

$$
\mathbf{W}^{\varepsilon}(\omega):=\binom{t_{1}^{\varepsilon}(\omega), \cdots, t_{n}^{\varepsilon}(\omega), \mathbf{x}_{0}^{\varepsilon}(\omega), \cdots, \mathbf{x}_{n}^{\varepsilon}(\omega), \mathbf{x}_{\varepsilon}(\omega),}{A_{\varepsilon}\left(\mathbf{x}_{1}^{\varepsilon}(\omega), \omega\right) \cdots A_{\varepsilon_{m}}\left(\mathbf{x}_{n}^{\varepsilon_{m}}(\omega), \omega\right)}
$$

Thus $\mathbf{W}^{\varepsilon}$ has values in a compact subset of $\mathbb{R}^{2 n+2 n^{2}}$ and is measurable. By Lemma 48.2.2 there exists a subsequence $\varepsilon(\omega) \rightarrow 0$ and a measurable function $\omega \rightarrow \mathbf{W}(\omega)$ such that

$$
\mathbf{W}^{\varepsilon(\omega)}(\omega) \rightarrow \mathbf{W}(\omega)=\binom{t_{1}(\omega), \cdots, t_{n}(\omega), \mathbf{x}_{0}(\omega), \cdots,}{\mathbf{x}_{n}(\omega), \mathbf{x}(\omega), \mathbf{y}_{1}(\omega), \cdots, \mathbf{y}_{n}(\omega)}
$$

as $\varepsilon(\omega) \rightarrow 0$. Recall also that

$$
A_{\varepsilon}\left(\mathbf{x}_{k}^{\varepsilon}(\omega), \omega\right) \subseteq A\left(P_{K(\omega)} \mathbf{x}_{k}^{\varepsilon}, \omega\right)
$$

Now

$$
\left|P_{K(\omega)} \mathbf{x}_{k}^{\varepsilon}(\omega)-\mathbf{x}_{\varepsilon}(\omega)\right|=\left|P_{K(\omega)} \mathbf{x}_{k}^{\varepsilon}(\omega)-P_{K(\omega)} \mathbf{x}_{\varepsilon}(\omega)\right| \leq\left|\mathbf{x}_{k}^{\varepsilon}-\mathbf{x}_{\varepsilon}\right|<\varepsilon
$$

Both $\mathbf{x}_{k}^{\varepsilon(\omega)}(\omega)$ and $\mathbf{x}_{\varepsilon(\omega)}(\omega)$ converge to $\mathbf{x}(\omega)$ and so the above shows that also,

$$
P_{K(\omega)} \mathbf{x}_{k}^{\varepsilon}(\omega) \rightarrow \mathbf{x}(\omega)
$$

Therefore,

$$
A_{\varepsilon(\omega)}\left(\mathbf{x}_{k}^{\varepsilon(\omega)}(\omega), \omega\right) \subseteq A(\mathbf{x}(\omega), \omega)+B(0, r)
$$

whenever $\varepsilon(\omega)$ is small enough. Since $A(\mathbf{x}(\omega), \omega)$ is closed, this implies

$$
\mathbf{y}_{k}(\omega) \in A(\mathbf{x}(\omega), \omega)
$$

Since $A(\mathbf{x}(\omega), \omega)$ is convex,

$$
\sum_{k=1}^{n} t_{k}(\omega) \mathbf{y}_{k}(\omega) \in A(\mathbf{x}(\omega), \omega)
$$

Also, from the construction,

$$
\mathbf{x}_{\varepsilon}(\omega)=A_{\varepsilon}\left(\mathbf{x}_{\varepsilon}(\omega), \omega\right) \equiv \sum_{k=0}^{n} t_{k}^{\varepsilon}(\omega) A_{\varepsilon}\left(\mathbf{x}_{k}^{\varepsilon}(\omega), \omega\right)
$$

so passing to the limit as $\varepsilon(\omega) \rightarrow 0$, we get

$$
\mathbf{x}(\omega)=\sum_{k=0}^{n} t_{k}(\omega) \mathbf{y}_{k}(\omega) \in A(\mathbf{x}(\omega), \omega)
$$

and this is the measurable fixed point.

### 48.5 Some Variational Inequalities

In the following, $V$ will be a reflexive separable Banach space. Following [99], here is a definition of a pseudomonotone operator. Actually, we will consider a slight generalization of the usual definition in 25.4.17 which involves an assumption that there exists a subsequence such that the liminf condition holds rather than use the original sequence.

Definition 48.5.1 Let $V$ be a reflexive Banach space. Then $A: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is pseudomonotone if the following conditions hold.
Au is closed, nonempty, convex.

If $F$ is a finite dimensional subspace of $V$, then if $u \in F$ and $W \supseteq A u$ for $W$ a weakly open set in $V^{\prime}$, then there exists $\delta>0$ such that

$$
\begin{equation*}
v \in B(u, \delta) \cap F \text { implies } A v \subseteq W \tag{48.5.16}
\end{equation*}
$$

If $u_{k} \rightharpoonup u$ and if $u_{k}^{*} \in A u_{k}$ is such that

$$
\limsup _{k \rightarrow \infty}\left\langle u_{k}^{*}, u_{k}-u\right\rangle \leq 0,
$$

Then there exists a subsequence still denoted with $k$ such that for all $v \in V$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim _{\inf _{k \rightarrow \infty}}\left\langle u_{k}^{*}, u_{k}-v\right\rangle \geq\left\langle u^{*}(v),(u-v)\right\rangle \tag{48.5.17}
\end{equation*}
$$

We say $A$ is coercive if

$$
\begin{equation*}
\lim _{\|v\| \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, v\right\rangle}{\|v\|}: z^{*} \in A v\right\}=\infty . \tag{48.5.18}
\end{equation*}
$$

If one assumes $A$ is bounded, then the weak upper semicontinuity condition 48.5.16 can be proved from the other conditions. It has been known for a long time that these operators are useful in the study of variational inequalities. In this section, we give a short example to show how one can obtain measurable solutions to variational inequalities from the measurable Browder lemma given above. This is the following theorem which gives a measurable version of old results of Brezis dating from the late 1960s. This will involve the following assumptions.

## 1. Measurability condition

For each $u \in V$, there is a measurable selection $z(\omega)$ such that

$$
z(\omega) \in A(u, \omega)
$$

## 2. Values of $A$

$A(\cdot, \omega): V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ has bounded, closed, nonempty, convex values. $A(\cdot, \omega)$ maps bounded sets to bounded sets.

## 3. Limit conditions

$$
\text { If } u_{n} \rightharpoonup u \text { and } \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0, z_{n} \in A\left(u_{n}, \omega\right)
$$

then for given $v$, there exists $z(v) \in A(u, \omega)$ such that

$$
\lim _{\inf _{k \rightarrow \infty}}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle
$$

Thus, for fixed $\omega, A(\cdot, \omega)$ is a set valued bounded pseudomonotone operator. Recall that the sum of two of these is also a set valued bounded pseudomonotone operator.

By Theorem 48.3.1 if $\omega \rightarrow u(\omega)$ is measurable, then $A(u(\omega), \omega)$ has a measurable selection. Also, the limit condition implies that $A(\cdot, \omega)$ is upper semicontinuous from the strong to the weak topology. The overall approach to the following theorem is well known. The new ingredients are Lemma 48.2.2 and Theorem 48.3.3 which are what allows us to obtain measurable solutions. First is a standard result on the sum of two pseudomonotone bounded operators. See Theorem 25.5.1 on Page 855.

Theorem 48.5.2 Say $A, B$ are set valued bounded pseudomonotone operators. Then their sum is also a set valued bounded pseudomonotone operator. Also, if $u_{n} \rightarrow u$ weakly, $z_{n} \rightarrow z$ weakly, $z_{n} \in A\left(u_{n}\right)$, and $w_{n} \rightarrow w$ weakly with $w_{n} \in B\left(u_{n}\right)$, then if

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0
$$

it follows that

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow w_{n}}\left\langle u_{n}-v\right\rangle \geq\langle z(v)+w(v), u-v\rangle, z(v) \in A(u), w(v) \in B(u)
$$

and $z \in A(u), w \in B(u)$.
Theorem 48.5.3 Let $V$ be a reflexive separable Banach space. Let $\omega \rightarrow K(\omega)$ be a measurable multifunction, $K(\omega)$ convex, closed, and bounded. Also for $A=B, C$ let $A(\cdot, \cdot)$ satisfy 1-3. Let $\omega \rightarrow f(\omega)$ be measurable with values in $V^{\prime}$. Then there exists measurable $\omega \rightarrow u(\omega) \in K(\omega)$ and $\omega \rightarrow w_{B}(\omega), \omega \rightarrow w_{C}(\omega)$ with $w_{B}(\omega) \in B(u(\omega), \omega), w_{C}(\omega) \in$ $C(u(\omega), \omega)$ such that

$$
\left\langle f(\omega)-\left(w_{B}(\omega)+w_{C}(\omega)\right), z-u(\omega)\right\rangle \leq 0
$$

for all $z \in K(\omega)$. If it is only known that $K(\omega)$ is closed and convex, the same conclusion can be obtained if it is also known that for some $z(\omega) \in K(\omega), B(\cdot, \omega)+C(\cdot, \omega)$ is coercive meaning

$$
\lim _{\|v\| \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, v-z\right\rangle}{\|v\|}: z^{*} \in B(v, \omega)+C(v, \omega)\right\}=\infty .
$$

Proof: Let $V_{n}=V_{n}(\omega)$ denote an increasing sequence of finite dimensional subspaces whose union is dense in $V$. Let $V_{n}(\omega)$ contain the first $n$ vectors of $\left\{d_{k}(\omega)\right\}_{k=1}^{\infty}$ where the closure of this sequence equals $K(\omega)$ for each $\omega$, each function being measurable. Let

$$
V_{n}(\omega)=\operatorname{span}\left(v_{1}, \cdots, v_{n}, d_{1}(\omega), \cdots, d_{n}(\omega)\right)
$$

where $\left\{v_{k}\right\}_{k=1}^{\infty}$ is dense in $V$. Also let

$$
\gamma_{n}(\omega)=\max \left\{\left\|d_{1}(\omega)\right\|, \cdots,\left\|d_{n}(\omega)\right\|,\left\|v_{1}\right\|, \cdots,\left\|v_{n}\right\|\right\}
$$

and $B_{n}(\omega)$ defined as $\overline{B\left(0, \gamma_{n}(\omega)\right)}$. Then let

$$
K_{n}(\omega)=V_{n} \cap K(\omega) \cap B_{n}(\omega) \neq \emptyset \text { so } \cup_{n} K_{n}(\omega) \text { dense in } K(\omega)
$$

Now each $K_{n}(\omega)$ is a set valued compact convex subset of $V_{n}(\omega)$ which is a measurable multifunction. It is a measurable multifunction because the linear combinations of the measurable functions $\left\{v_{1}, \cdots, v_{n}, d_{1}(\omega), \cdots, d_{n}(\omega)\right\}$ having a subset of the rational numbers as coefficients is a dense subset of $K_{n}(\omega)$. Then by Theorem 48.3.3, there exist measurable functions

$$
u_{n}(\omega) \in K_{n}(\omega), w_{n}^{B}(\omega) \in B\left(u_{n}(\omega), \omega\right), w_{n}^{C}(\omega) \in C\left(u_{n}(\omega), \omega\right)
$$

such that

$$
\begin{equation*}
\left\langle f(\omega)-\left(w_{n}^{B}(\omega)+w_{n}^{C}(\omega)\right), z-u_{n}(\omega)\right\rangle \leq 0 \tag{*}
\end{equation*}
$$

for all $z \in K_{n}(\omega)$.
Thus for all $w \in K_{n}(\omega)$,

$$
\left\langle w_{n}^{B}(\omega)+w_{n}^{C}(\omega), u_{n}(\omega)-w\right\rangle \leq\left\langle f(\omega), u_{n}(\omega)-w\right\rangle
$$

These $u_{n}(\omega)$ are bounded because $K(\omega)$ is a bounded set or in the other case, one can pick the special $z(\omega)$ in the definition for coercivity to obtain that these $u_{n}(\omega)$ are bounded. Thus, since $A(\cdot, \omega)$ is assumed to be bounded for $A=B, C$, each of $u_{n}(\omega), w_{n}^{B}(\omega), w_{n}^{C}(\omega)$ are bounded for each $\omega$.

By Lemma 48.2.2, there is a subsequence $n(\omega)$ such that

$$
\left(u_{n(\omega)}(\omega), w_{n(\omega)}^{B}(\omega), w_{n(\omega)}^{C}(\omega)\right)
$$

converges weakly to $\left(u(\omega), w_{B}(\omega), w_{C}(\omega)\right)$ in $V \times V^{\prime} \times V^{\prime}$ and

$$
\omega \rightarrow\left(u(\omega), w_{B}(\omega), w_{C}(\omega)\right)
$$

is measurable into $V \times V^{\prime} \times V^{\prime}$. It is now only a matter of verifying the desired variational inequality for each $\omega$.

By convexity, $u(\omega) \in K(\omega)$. Now for fixed $\omega$, let $\hat{u}_{n(\omega)} \rightarrow u(\omega)$ strongly in $V$ where $\hat{u}_{n(\omega)} \in K_{n}(\omega)$. Then

$$
\begin{gathered}
\quad \lim \sup _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-u(\omega)\right\rangle \\
=\lim \sup _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-\hat{u}_{n(\omega)}\right\rangle \\
\leq \lim \sup _{n(\omega) \rightarrow \infty}\left\langle f(\omega), u_{n(\omega)}(\omega)-\hat{u}_{n(\omega)}\right\rangle \leq 0 .
\end{gathered}
$$

By Theorem 48.5.2,

$$
w_{B}(\omega) \in B(u(\omega), \omega), w_{C}(\omega) \in C(u(\omega), \omega)
$$

Also, there is a subsequence, still denoted with $n(\omega)$ such that

$$
\begin{aligned}
& \lim \inf _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-u(\omega)\right\rangle \\
\geq & \langle w(u(\omega)), u(\omega)-u(\omega)\rangle=0
\end{aligned}
$$

for some $w(u(\omega)) \in B(u(\omega), \omega)+C(u(\omega), \omega)$ because the sum of pseudomonotone operators is pseudomonotone. Thus for this subsequence, since

$$
\begin{gathered}
\quad \lim \sup _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-u(\omega)\right\rangle \\
\leq \quad 0 \leq \lim \inf _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-u(\omega)\right\rangle,
\end{gathered}
$$

it follows that

$$
\lim _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-u(\omega)\right\rangle=0
$$

We will consider this subsequence or a further subsequence. Then since the limsup condition holds for this subsequence, there exists for any $v \in V$,

$$
w_{B}(v) \in B(u(\omega), \omega), w_{C}(v) \in C(u(\omega), \omega)
$$

such that

$$
\begin{aligned}
& \left\langle w_{B}(\omega)+w_{C}(\omega), u(\omega)-v\right\rangle \\
\geq & \lim _{\inf _{n(\omega) \rightarrow \infty}}\binom{\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-u(\omega)\right\rangle}{+\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u(\omega)-v\right\rangle} \\
= & \lim \inf _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-v\right\rangle \\
\geq & \left\langle w_{B}(v)+w_{C}(v), u(\omega)-v\right\rangle
\end{aligned}
$$

Finally, let $v \in K(\omega)$. Then it follows that there exists a sequence $\left\{\hat{v}_{n}\right\}$ such that $\hat{v}_{n} \in$ $K_{n}(\omega)$ which converges strongly to $v$. Thus

$$
\left\langle w_{n}^{B}(\omega)+w_{n}^{C}(\omega), u_{n}(\omega)-\hat{v}_{n}\right\rangle \leq\left\langle f(\omega), u_{n}(\omega)-\hat{v}_{n}\right\rangle
$$

Then

$$
\begin{gathered}
\left\langle w_{B}(\omega)+w_{C}(\omega), u(\omega)-v\right\rangle= \\
\lim \sup _{n(\omega) \rightarrow \infty}\left(\begin{array}{c}
\left\langle{ }^{(\omega)} \begin{array}{c}
\left.w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-u(\omega)\right\rangle \\
+\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u(\omega)-v\right\rangle
\end{array}\right)
\end{array}\right) .\left\{\begin{array}{c}
\end{array}\right)
\end{gathered}
$$

$$
\begin{aligned}
& =\lim \sup _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-v\right\rangle \\
& =\lim \sup _{n(\omega) \rightarrow \infty}\left\langle w_{n(\omega)}^{B}(\omega)+w_{n(\omega)}^{C}(\omega), u_{n(\omega)}(\omega)-\hat{v}_{n(\omega)}\right\rangle \\
& \leq \lim \sup _{n(\omega) \rightarrow \infty}\left\langle f(\omega), u_{n(\omega)}(\omega)-\hat{v}_{n(\omega)}\right\rangle=\langle f(\omega), u(\omega)-v\rangle
\end{aligned}
$$

Note that from standard results, in the case of coercivity and $V=K(\omega)$, the above shows that for $f$ measurable there is a measurable $u$ such that $f(\omega) \in B(u(\omega), \omega)+$ $C(u(\omega), \omega)$. Specifically, there are measurable functions

$$
w_{B}(\omega) \in B(u(\omega), \omega) \text { and } w_{C}(\omega) \in C(u(\omega), \omega)
$$

such that $f(\omega)=w_{C}(\omega)+w_{B}(\omega)$.
Example 48.5.4 We can let $\Omega=[0, T]$ and let the measurable sets be the Lebesgue measurable sets, $t \rightarrow f(t)$ measurable into $V^{\prime}$. Then for $A(\cdot, \cdot)$ satisfying $1-3$ the above theorem gives the solution $u, w(t), u(t) \in K(t)$ to variational inequalities of the form

$$
\langle f(t)-w(t), z-u(t)\rangle \leq 0, w(t) \in A(u(t), t)
$$

for all $z \in K(t)$ where $K(t)$ is a closed bounded convex subset of $V$ for $t \rightarrow K(t)$ a measurable multifunction. Here both $u$ and $w$ are measurable. If $u \rightarrow A(u, t)$ is coercive, this allows for $K(t)$ only closed and convex. If $A$ is the sum of $B, C$ and $u \rightarrow B(u, t)$ and $u \rightarrow C(u, t)$, these each satisfying the conditions $1-3, w(t)=w_{B}(t)+w_{C}(t)$ where both of these summands are measurable and $w_{B}(t) \in B(u(t), t), w_{C}(t) \in C(u(t), t)$. If suitable estimates hold, and $f \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ then one can conclude that $w \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)$ and $u \in L^{p}([0, T] ; V)$. This paper has resolved the only difficult issue which is existence of a measurable solution with no monotonicity or uniqueness assumptions on the problem for fixed $t$.

Example 48.5.5 We can let $\Omega$ be of the form $[0, T] \times \Omega$ where $(\Omega, \mathscr{F})$ is a measurable space. In this case, we could let the $\sigma$ algebra be $\mathscr{B} \times \mathscr{F}$ the product measurable sets and obtain product measurable solutions to the same variational inequalities.

Example 48.5.6 In the case of a filtration $\left\{\mathscr{F}_{t}\right\}$, one could let the $\sigma$ algebra consist of the progressively measurable sets and obtain the same conclusions. Thus the variational inequality would be of the form

$$
\langle f(t, \omega)-w(t, \omega), z-u(t, \omega)\rangle \leq 0, w(t, \omega) \in A(u(t, \omega), t, \omega), z \in K(t, \omega)
$$

This result is quite interesting because it is describing a situation where there is no uniqueness or monotonicity and all that is required are conditions of measurability on $f$. Also, one only needs to check the limit conditions on $u \rightarrow A(u, \omega)$ for fixed $\omega$ so all Sobolev embedding theorems are available. Nor is it necessary to assume that $\omega \rightarrow A(u, \omega)$ is a measurable multifunction as is often done. It suffices to check that it has a measurable selection. This is a strictly more general condition.

### 48.6 An Example

Let $\sigma(r, t)$ be a continuous function of $r$ which satisfies

$$
\begin{aligned}
r & \rightarrow \sigma(r, t) \text { is continuous, } t \rightarrow \sigma(r, t) \text { is measurable } \\
0 & <\delta(t) \leq \sigma(r, t) \leq 1 / \delta(t)
\end{aligned}
$$

There is no uniform lower bound needed for $\delta(t)$. Then we will let $V$ be a closed subspace of $H^{1}(\Omega)$ where $\Omega$ is a bounded open set with Lipschitz boundary.

$$
V \equiv\left\{u \in H^{1}(\omega): \gamma u=0 \text { on } \Sigma_{0}\right\}
$$

where $\alpha\left(\Sigma_{0}\right)>0$ for $\alpha$ the surface measure, $\Sigma_{0}$ a closed subset of $\partial \Omega$ and $\gamma$ is the trace map. Thus an equivalent norm for $V$ is

$$
\|u\|_{V}^{2}=\int_{\Omega}|\nabla u|^{2} d x
$$

Also let $H=L^{2}(\Omega)$ and let $H=H^{\prime}$ so that $V \subseteq H=H^{\prime} \subseteq V^{\prime}$. Then let $A(\cdot, t): V \rightarrow V^{\prime}$ be defined by

$$
\langle A(u, t), v\rangle \equiv \int_{\Omega} \sigma(u, t) \nabla u \cdot \nabla v
$$

Is this a bounded pseudomonotone map? It is clearly bounded thanks to the bounds on $\sigma$. Suppose then that $u_{n} \rightarrow u$ weakly in $V$ and

$$
\lim \sup _{n \rightarrow \infty}\left\langle A\left(u_{n}, t\right), u_{n}-u\right\rangle \leq 0
$$

Does the liminf condition hold? If not, then there exists a subsequence and $v \in V$ such that

$$
\lim _{n \rightarrow \infty}\left\langle A\left(u_{n}, t\right), u_{n}-v\right\rangle<\langle A(u, t), u-v\rangle
$$

By compactness, there is a further subsequence still denoted with $n$ such that $u_{n} \rightarrow u$ strongly in $L^{2}(\Omega)$ and pointwise. Consider

$$
\int_{\Omega} \sigma\left(u_{n}, t\right) \nabla u_{n} \cdot\left(\nabla u_{n}-\nabla v\right)
$$

Now by the dominated convergence theorem,

$$
\int_{\Omega}\left|\sigma\left(u_{n}, t\right)-\sigma(u, t)\right|^{2} \rightarrow 0
$$

and so in fact $\sigma\left(u_{n}, t\right) \nabla u_{n} \rightarrow \sigma(u, t) \nabla u$ weakly in $H^{3}$. Then

$$
\begin{aligned}
\int_{\Omega} \sigma\left(u_{n}, t\right) \nabla u_{n} \cdot\left(\nabla u_{n}-\nabla v\right)= & \int_{\Omega} \sigma\left(u_{n}, t\right) \nabla u_{n} \cdot\left(\nabla u_{n}-\nabla u\right) \\
& +\int_{\Omega} \sigma\left(u_{n}, t\right) \nabla u_{n} \cdot(\nabla u-\nabla v)
\end{aligned}
$$

$$
\geq \int_{\Omega} \sigma\left(u_{n}, t\right) \nabla u \cdot\left(\nabla u_{n}-\nabla u\right)+\int_{\Omega} \sigma\left(u_{n}, t\right) \nabla u_{n} \cdot(\nabla u-\nabla v)
$$

The second term in the above converges to $\int_{\Omega} \sigma(u, t) \nabla u \cdot(\nabla u-\nabla v)$.
Consider the first term after $\geq$. It equals

$$
\begin{equation*}
\int_{\Omega}\left(\sigma\left(u_{n}, t\right)-\sigma(u, t)\right) \nabla u \cdot\left(\nabla u_{n}-\nabla u\right)+\int_{\Omega} \sigma(u, t) \nabla u \cdot\left(\nabla u_{n}-\nabla u\right) \tag{*}
\end{equation*}
$$

The second of these terms converges to 0 because of weak convergence of $u_{n}$ to $u$. As to the first, if the measure of $E$ is small enough, then

$$
\left(\int_{E}|\nabla u|^{2}\right)^{1 / 2}<\delta
$$

By Egoroff's theorem, there is a set $E$ having measure this small such that off this set, $\sigma\left(u_{n}(x), t\right)-\sigma(u(x), t) \rightarrow 0$ uniformly for $x \notin E$. Thus an application of Holder's inequality shows that $\left|\int_{E^{C}}\left(\sigma\left(u_{n}, t\right)-\sigma(u, t)\right) \nabla u \cdot\left(\nabla u_{n}-\nabla u\right)\right| \leq \delta$ whenever $n$ is sufficiently large thanks to the weak convergence of $u_{n}$ to $u$ which implies that $\nabla u_{n}-\nabla u$ is bounded in $L^{2}(\Omega)^{3}$. As to the integral over $E$, the fact that $\sigma$ is bounded for fixed $t$ implies the existence of a constant $C$ independent of $n$ such that

$$
\left|\int_{\Omega}\left(\sigma\left(u_{n}, t\right)-\sigma(u, t)\right) \nabla u \mathscr{X}_{E} \cdot\left(\nabla u_{n}-\nabla u\right)\right| \leq C\left(\int_{E}|\nabla u|^{2}\right)^{1 / 2}<C \delta
$$

Thus the first term in * has absolute value no larger than $(C+1) \delta$ provided $n$ is sufficiently large. Since $\delta$ is arbitrary, the limit of this term is 0 . Thus,

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow} \sigma\left(u_{n}, t\right) \nabla u_{n} \cdot\left(\nabla u_{n}-\nabla v\right) \geq \int_{\Omega} \sigma(u, t) \nabla u \cdot(\nabla u-\nabla v)
$$

This is a contradiction. Thus the liminf condition must hold.
Next consider another operator. Let $\Sigma_{1}$ be $\partial \Omega \backslash \Sigma_{0}$ and has positive surface measure. Let $r \rightarrow a(r, t)$ be lower semicontinuous and $r \rightarrow b(r, t)$ be upper semicontinuous. Let $0<\delta(t) \leq a(r, t) \leq b(r, t) \leq \frac{1}{\delta(t)}$. Also let both of these functions be measurable in $t$. Now $\gamma: V \rightarrow L^{2}\left(\Sigma_{1}\right)$ and so $\gamma^{*}: L^{2}\left(\Sigma_{1}\right) \rightarrow V^{\prime}$ defined in the usual way. Then $z \in B(u, t)$ will mean $z=\gamma^{*} w$ for some $w \in L^{2}\left(\Sigma_{1}\right)$ with

$$
w(\mathbf{x}) \in[a(\gamma u(\mathbf{x}), t), b(\gamma u(\mathbf{x}), t)]
$$

for a.e. $\mathbf{x}$ such that

$$
\langle z, v\rangle=\int_{\Sigma_{1}} w(\mathbf{x}) \gamma v(\mathbf{x})
$$

Using Sobolev embedding theorems, if $u_{n} \rightarrow u$ weakly in $V$, then from the Sobolev embedding theorem $u_{n} \rightarrow u$ strongly in a suitable Sobolev space of fractional order such that the embedding of $V$ into this space is compact and the trace map is still continuous. Thus there is a subsequence such that $\gamma u_{n}(\mathbf{x}) \rightarrow \gamma u(\mathbf{x})$ pointwise a.e. and $w_{n} \rightarrow w$ in $L^{2}\left(\Sigma_{1}\right)$.

Then by the semicontinuity properties of $a, b$ we obtain from routine considerations that $w(\mathbf{x}) \in[a(\gamma u(\mathbf{x}), t), b(\gamma u(\mathbf{x}), t)]$ a.e. To see how you can do this, let

$$
E=\left\{\mathbf{x}: w(\mathbf{x}) \geq b(\gamma u(\mathbf{x}), t)+\frac{1}{k}\right\} .
$$

Then

$$
\begin{aligned}
\int_{\Sigma_{1}} \mathscr{X}_{E}(\mathbf{x})\left(-b\left(\gamma u_{n}(\mathbf{x}), t\right)\right) & \leq \int_{\Sigma_{1}} \mathscr{X}_{E}(\mathbf{x})\left(-w_{n}(\mathbf{x})\right) \rightarrow \int_{\Sigma_{1}} \mathscr{X}_{E}(\mathbf{x})(-w(\mathbf{x})) \\
& \leq \int_{\Sigma_{1}} \mathscr{X}_{E}(\mathbf{x})\left(-b(\gamma u(\mathbf{x}), t)-\frac{1}{k}\right)
\end{aligned}
$$

By lower semicontinuity of $-b(\cdot, t)$ and the boundedness assumption, we can use Fatou's lemma to take liminf of both sides and conclude that

$$
\int_{\Sigma_{1}} \mathscr{X}_{E}(\mathbf{x})(-b(\gamma u(\mathbf{x}), t)) \leq \int_{\Sigma_{1}} \mathscr{X}_{E}(\mathbf{x})\left(-b(\gamma u(\mathbf{x}), t)-\frac{1}{k}\right)
$$

an obvious contradiction unless $\alpha(E)=0$. Then taking the union of the exceptional sets for all $k$, it follows that $w(\mathbf{x}) \leq b(\gamma u(\mathbf{x}), t)$ a.e. The other side of the inequality can be shown similarly. Letting $z_{n} \in B\left(u_{n}, t\right)$ and $v \in V$, is it true that

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle \geq\left\langle z(v), u_{n}-v\right\rangle
$$

for some $z(v) \in B(u, t)$ ? Suppose not. Then from the above, there is a subsequence such that the limit equals the liminf but which has the inequality turned around for some $v$ and all $z \in B(u, t)$. Then from what was just shown, letting $w_{n}$ go with $z_{n}$, there is a further subsequence such that $w_{n} \rightarrow w$ weakly in $L^{2}\left(\Sigma_{1}\right)$ and and $\gamma u_{n} \rightarrow \gamma u$ strongly in $L^{2}\left(\Sigma_{1}\right)$ and

$$
w(\mathbf{x}) \in[a(\gamma u(\mathbf{x}), t), b(\gamma u(\mathbf{x}), t)] \text { a.e. } \mathbf{x}
$$

Then

$$
\int_{\Sigma_{1}} w_{n}(\mathbf{x})\left(\gamma u_{n}(\mathbf{x})-\gamma v(\mathbf{x})\right) \rightarrow \int_{\Sigma_{1}} w(\mathbf{x})(\gamma u(\mathbf{x})-\gamma v(\mathbf{x}))=\langle z, u-v\rangle
$$

where $w \in B(u, t)$ and $z=\gamma^{*} w$ so the liminf condition holds. Thus this second operator is pseudomonotone.

Do these have measurable selections? This is obvious. Letting $u \in V, t \rightarrow \gamma^{*} a(\gamma u(\mathbf{x}), t)$ is measurable into $V^{\prime}$ and is in $B(u, t)$. Similarly $t \rightarrow A(u, t)$ is measurable into $V^{\prime}$. Note that on the second operator, it was really only necessary to assume that there exists $t \rightarrow c(r, t)$ measurable with $c(r, t) \in[a(r, t), b(r, t)]$ and totally eliminate the assumption that either $a$ or $b$ is measurable in $t$.

Now let $t \rightarrow f(t)$ be measurable into $V^{\prime}$. Say

$$
\langle f(t), v\rangle=\int_{\Omega} h(t) v d x+\int_{\Sigma_{1}} \beta(t) v d \alpha
$$

and let $K(t) \subseteq V$ be a closed convex subset of $V$. There is obviously a coercivity condition holding for the sum of these two operators $A(u, t)+B(u, t)$ and so there exists $u(t) \in K(t)$ such that for all $v \in K(t)$

$$
\begin{equation*}
\langle f(t)-(A(u(t), t)+z(t)), v-u(t)\rangle \leq 0 \tag{*}
\end{equation*}
$$

where $t \rightarrow u(t)$ is measurable into $V, t \rightarrow z(t)$ measurable into $V^{\prime}, t \rightarrow A(u(t), t)$ measurable into $V^{\prime}$. Is $t \rightarrow w(t)$ measurable where $z(t)=\gamma^{*} w(t)$ ? Let $\phi \in V$. Then

$$
\langle z(t), \phi\rangle_{V^{\prime}, V}=(w(t), \gamma \phi)_{L^{2}\left(\Sigma_{1}\right)}
$$

and is given to be a measurable function of $t$. However, since $\Sigma_{1}$ is open, the image of the trace is dense in $L^{2}\left(\Sigma_{1}\right)$ and so by this density and Pettis theorem, $t \rightarrow w(t)$ must be measurable into $L^{2}\left(\Sigma_{1}\right)$. Thus the variational inequality $*$ is of the form

$$
\binom{(h(t), v-u(t))_{H}+(\beta(t)-w(t), \gamma v-\gamma u(t))_{L^{2}\left(\Sigma_{1}\right)}}{-(\sigma(u(t), t) \nabla u(t), \nabla v-\nabla u(t))_{H^{3}}} \leq 0
$$

for all $v \in K(t)$. If the inequality which gives coercivity were eliminated, we would still have the above if $K(t)$ were assumed bounded.

What equation is satisfied if $K(t)=V$ ? We would have

$$
\begin{gathered}
\int_{\Omega} \sigma(u(t), t) \nabla u(t) \cdot \nabla v d x+\int_{\Sigma_{1}} w(t) v d x=\int_{\Omega}\langle f(t), v\rangle d x \\
w(t) \in[a(\gamma u(t), t), b(\gamma u(t), t)]
\end{gathered}
$$

Then proceding formally, we obtain

$$
\begin{aligned}
& \int_{\Omega} \nabla \cdot(\sigma(u(t), t) \nabla u(t) v) d x-\int_{\Omega} \nabla \cdot(\sigma(u(t), t) \nabla u(t)) v+\int_{\Sigma_{1}} w(t) v d x \\
= & \int_{\Omega} h(t) v+\int_{\Sigma_{1}} \beta(t) v
\end{aligned}
$$

Then a formal application of the divergence theorem yields the boundary conditions

$$
\begin{aligned}
\sigma(u(t), t) \nabla u(t) \cdot \mathbf{n}+w(t) & =\beta(t) \text { on } \Sigma_{1} \\
u(t) & =0 \text { on } \Sigma_{0}
\end{aligned}
$$

where $w(t) \in[a(\gamma u(t), t), b(\gamma u(t), t)]$ along with the partial differential equation

$$
-\nabla \cdot(\sigma(u(t), t) \nabla u(t))=h(t)
$$

Note that if either $a(\cdot, t)$ or $b(\cdot, t)$ were continuous, there would have been no point in considering the second operator as a set valued map. One could simply replace the closed interval $[a(r, t), b(r, t)]$ with either $a(r, t)$ or $b(r, t)$ and obtain the desired solutions. Also note that nothing is needed about the integrability of either $t \rightarrow h(t)$ or $t \rightarrow \beta(t)$. The following lemma is convenient in considering the convex sets $K(t)$.

Lemma 48.6.1 Let $F$ be those points where $u=0$. Then for a.e. $\mathbf{x} \in F, \nabla u(\mathbf{x})=\mathbf{0}$. Here $u \in W^{1, p}(\Omega)$ and we assume $\partial \Omega$ has measure zero.

Proof: It suffices to consider $u=0$ on $F$ contained in the interior of $\Omega$. First I show that $u_{, x_{n}}=0$ a.e.

$$
\frac{u\left(t_{1}, \cdots, t_{n-1}, t_{n}\right)-u\left(t_{1}, \cdots, t_{n-1}, t_{n}-h\right)}{h}=\frac{1}{h} \int_{t_{n}-h}^{t_{n}} u,_{n}\left(t_{1}, \cdots, t_{n-1}, s\right) d s
$$

Then a.e. $t_{n}$ is a Lebesgue point of $u, x_{n}$ for $F_{\left(t_{1}, \cdots, t_{n-1}\right)}$ where $F_{\left(t_{1}, \cdots, t_{n-1}\right)}$ consists of those points of $F$ where $\left(t_{1}, \cdots, t_{n-1}\right)$ is fixed. Also let $t_{n}$ be a point of density of $F_{\left(t_{1}, \cdots, t_{n-1}\right)}$. Of course $m_{1}$ a.e. points of $F_{\left(t_{1}, \cdots, t_{n-1}\right)}$ are points of density. Therefore, there exists a sequence $h_{k} \rightarrow 0+$ such that $t_{n}-h_{k} \rightarrow t_{n}$ as $k \rightarrow \infty$ and $\left(t_{n}-h_{k}\right) \in F_{\left(t_{1}, \cdots, t_{n-1}\right)}$. Otherwise there would be some open set about $t_{n}$ which excludes points of $F_{\left(t_{1}, \cdots, t_{n-1}\right)}$ which would imply that $t_{n}$ is not actually a point of density. Then using the fundamental theorem of calculus, we get for such points which are points of $F_{\left(t_{1}, \cdots, t_{n-1}\right)}$ the fact that $u, x_{n}\left(t_{1}, \cdots, t_{n-1}, t_{n}\right)=0$. Thus for a.e. $t_{n} \in F_{\left(t_{1}, \cdots, t_{n-1}\right)}, u, x_{n}\left(t_{1}, \cdots, t_{n-1}, t_{n}\right)=0$. Thus $u, x_{n}\left(t_{1}, \cdots, t_{n-1}, t_{n}\right)=0$ for a.e. $t_{n}$ in $F_{\left(t_{1}, \cdots, t_{n-1}\right)}$. Similar reasoning holds for differentiation with respect to the other variables. Thus $\nabla u=\mathbf{0}$ a.e. on $F$.

Lemma 48.6.2 Let $V$ be a closed subset of $W^{1, p}(\Omega), p>1$ and let $k \in V$. Then $\max (k, u) \in$ $V$ and if $u_{n} \rightarrow u$ in $V$, then $\max \left(u_{n}, k\right) \rightarrow \max (u, k)$ in $V$.

Proof: We consider $\psi(r)=|r|, \psi_{\varepsilon}(r)=\sqrt{\varepsilon+r^{2}}$. Then for $\phi \in C_{c}^{\infty}(\Omega)$,

$$
\begin{aligned}
\int_{\Omega} \psi(u(\mathbf{x})) \phi,{x_{k}}_{k}(\mathbf{x}) & =\lim _{\varepsilon \rightarrow 0} \int_{\Omega} \psi_{\varepsilon}(u(\mathbf{x})) \phi, x_{k}(\mathbf{x}) \\
& =-\lim _{\varepsilon \rightarrow 0} \int_{\Omega} \frac{u(\mathbf{x})}{\sqrt{\varepsilon+u^{2}(\mathbf{x})}} u, x_{k}(\mathbf{x}) \phi(\mathbf{x}) \\
& =-\int_{\Omega} \xi(u(\mathbf{x})) u, x_{k}(\mathbf{x}) \phi(\mathbf{x})
\end{aligned}
$$

where $\xi(r)=1$ if $r>0,-1$ if $r<0$ and 0 if $r=0$. Thus $\psi(u), x_{k}=\xi(u(\mathbf{x})) u, x_{k}(\mathbf{x})$ a.e. and so $\psi \circ u$ is clearly in $W^{1, p}(\Omega)$. Of course $\max (u, k)=\frac{|k-u|+(k+u)}{2}$ so this shows that $\max (u, k)$ is in $W^{1, p}(\Omega)$.

Next suppose $u_{n} \rightarrow u$ in $W^{1, p}(\Omega)$. Does

$$
\xi\left(u_{n}\right) u_{n}, x_{k} \rightarrow \xi(u) u_{, x_{k}} ?
$$

Let $G=\{\mathbf{x}: u(\mathbf{x}) \neq 0\}$. A subsequence, still denoted by $u_{n}$ converges pointwise a.e . to $u$ and $u_{n}, x_{k} \rightarrow u, x_{k}$ pointwise a.e. Therefore, off a set of measure zero, $\xi\left(u_{n}(\mathbf{x})\right)=\xi(u(\mathbf{x}))$ for all $n$ large enough on $G$. Also,

$$
\begin{gather*}
\left(\int_{\Omega}\left|\xi\left(u_{n}\right) u_{n}, x_{k}-\xi(u) u_{, x_{k}}\right|^{p}\right)^{1 / p} \leq\left(\int_{\Omega}\left|\xi\left(u_{n}\right) u_{n, x_{k}}-\xi\left(u_{n}\right) u_{, x_{k}}\right|^{p}\right)^{1 / p} \\
+\left(\int_{\Omega}\left|\xi\left(u_{n}\right)-\xi(u)\right|^{p}\left|u, x_{k}\right|^{p}\right)^{1 / p} \tag{*}
\end{gather*}
$$

That second term on the right converges to 0 . It equals

$$
\left(\int_{G^{C}}\left|\xi\left(u_{n}\right)-\xi(u)\right|^{p}\left|u, x_{k}\right|^{p}+\int_{G}\left|\xi\left(u_{n}\right)-\xi(u)\right|^{p}\left|u, x_{k}\right|^{p}\right)^{1 / p}
$$

Now on $G^{C}, u, x_{k}(\mathbf{x})=0$ a.e. and so the first term in the parentheses is 0 . The second converges to 0 by the dominated convergence theorem. Then this shows that the second term in * converges to 0 . The first obviously converges to 0 from the convergence of $u_{n}, x_{k}$ to $u, x_{k}$. Now consider whether $\psi\left(u_{n}\right), x_{k}$ converges to $\psi(u), x_{k}$. Those functions $\psi\left(u_{n}\right), x_{k}$ are bounded in $L^{p}(\Omega)$ from the above description and so if it fails to converge to $\psi(u), x_{k}$ in $L^{p}$ a subsequence converges weakly to $\zeta \neq \psi(u),,_{k}$. But then, the above argument shows that a further subsequence does converge strongly to $\psi(u), x_{k}$ contrary to $\zeta \neq \psi(u), x_{k}$.

Now, from the description of the maximum of two functions given above, we obtain that $\max \left(u_{n}, k\right) \rightarrow \max (u, k)$ in $V$ provided $u_{n} \rightarrow u$ in $V$.

Consider $k \in C([0, T] ; V)$. Let

$$
K(t) \equiv\{u \in V: u(\mathbf{x}) \geq k(t, \mathbf{x}) \text { a.e. } \mathbf{x}\}
$$

This is clearly a convex subset of $V$. Is it closed and convex? Is $t \rightarrow K(t)$ a set valued measurable function?

Claim: $K(t)$ is closed and convex.
Proof: It is obvious it is convex. Suppose $u_{n} \rightarrow u$ in $V, u_{n} \in K(t)$. Then there is a subsequence, still denoted as $u_{n}$ such that $u_{n}(\mathbf{x}) \rightarrow u(\mathbf{x})$ a.e. Hence $K(t)$ is closed.

Claim: $t \rightarrow K(t)$ is a measurable multifunction.
Proof: Consider the subset of $C([0, T] ; V)$ defined by

$$
\{u \in C([0, T] ; V): \text { for a.e. } t, u(t, \mathbf{x}) \geq k(t, \mathbf{x}) \text { a.e. } \mathbf{x}\}
$$

This is a subset of the completely separable set $C([0, T] ; V)$ and so it is also separable. Let $\left\{d_{i}\right\}_{i=1}^{\infty}$ be a dense subset of $C([0, T] ; V)$. Then let $\left\{b_{i}\right\}_{i=1}^{\infty}$ be defined by $b_{i}(t, \mathbf{x}) \equiv$ $\max \left(k(t, \mathbf{x}), d_{i}(t, \mathbf{x})\right)$. Thus the functions $\mathbf{x} \rightarrow b_{i}(t, \mathbf{x})$ are each in $K(t)$ because of the above Lemma. They are also measurable into $V$ because $k, d_{i} \in C([0, T] ; V)$. Is $\left\{b_{i}(t, \cdot)\right\}_{i=1}^{\infty}$ dense in $K(t)$ ? Suppose $u \in K(t)$. Then $t \rightarrow v(t, \mathbf{x}) \equiv u(\mathbf{x})$ is in $C([0, T] ; V)$ and so there is a subsequence denoted by $d_{i}$ which converges pointwise to $u$ in $C([0, T] ; V)$. Therefore, we can get a subsequence such that by the above lemma, $\max \left(k(t, \cdot), d_{i}(t, \cdot)\right) \rightarrow u(\cdot)$ in $V$. Thus $\left\{b_{i}(t, \cdot)\right\}_{i=1}^{\infty}$ is dense in $K(t)$ and so $t \rightarrow K(t)$ is a measurable multifunction.

As an example, you could simply take $k$ to be the restriction to $\Omega \times[0, T]$ of a smooth function.

This is an example of an obstacle problem in which the obstacle changes in $t$ and there is no uniqueness even though there exists a measurable solution to the variational inequality for each $t$.

One could also replace $\sigma(u, t)$ with a graph having a jump as in the second of the two operators and get similar results by beginning with the above solutions and then using Lemma 48.2.2, and the arguments used in the second operator to pass to a limit.

The next section is an interesting result on the pseudomonotone condition for Nemytskii operators defined in this section.

### 48.7 Limit Conditions For Nemytskii Operators

This is about the following problem. You know

$$
u \rightarrow A(u, t)
$$

is pseudomonotone. You can also define $\hat{A}: \mathscr{V} \rightarrow \mathscr{V}^{\prime}$ by

$$
\hat{A}(u)(t) \equiv A(u(t), t) \text { a.e. }
$$

Then when can you obtain a useable limit condition for $\hat{A}$ ? I think the earliest solution to this problem was given in [17]. These ideas were extended to set valued maps in [18] and to another situation in [85].

Define $\mathscr{V} \equiv \mathscr{V}_{p}$ by

$$
\mathscr{V}=L^{p}([0, T] ; V), p>1
$$

where $V$ is a separable Banach space and $H$ is a Hilbert space such that

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

with each space dense in the following one. The measure space is chosen to be

$$
([0, T], \mathscr{B}([0, T]), m)
$$

where $m$ is the Lebesgue measure and $\mathscr{B}([0, T])$ consists of all the Borel sets, although one could use the $\sigma$ algebra of Lebesgue measurable sets as well. We denote by $\mathscr{V}_{p}$ or $\mathscr{V}$ the above space. If $U$ is a Banach space, $\mathscr{U}_{r}$ will denote $L^{r}([0, T], U)$.

We will assume the following measurability condition. For each $u \in \mathscr{V}$,

$$
\begin{equation*}
t \rightarrow A(u(t), t) \text { is a measurable multifunction } \tag{48.7.19}
\end{equation*}
$$

In the case when $A(\cdot, t)$ is single-valued, bounded and pseudomonotone, this measurability condition is satisfied and so it is measurable. Thus, this definition is a generalization of what would be expected for single-valued operators. We use the following lemma.

Lemma 48.7.1 Let $U$ be a separable reflexive Banach space. Suppose there is a sequence $\left\{u_{j}(\omega)\right\}_{j=1}^{\infty}$ in $U$, where each $\omega \rightarrow u_{j}(\omega)$ is measurable and for each $\omega, \sup _{i}\left\|u_{i}(\omega)\right\|<$ $\infty$. Then, there exists $u(\omega) \in U$ such that $\omega \rightarrow u(\omega)$ is measurable, and a subsequence $n(\omega)$, that depends on $\omega$, such that the weak limit

$$
\lim _{n(\omega) \rightarrow \infty} u_{n(\omega)}(\omega)=u(\omega)
$$

holds.
Proof. Let $\left\{z_{i}\right\}_{i=1}^{\infty}$ be a countable dense subset of $U^{\prime}$. Let $\mathbf{h}: U \rightarrow \prod_{i=1}^{\infty} \mathbb{R}$ be defined by

$$
\mathbf{h}(u)=\prod_{i=1}^{\infty}\left\langle z_{i}, u\right\rangle .
$$

Let $X=\prod_{i=1}^{\infty} \mathbb{R}$ with the product topology. Then, this is a Polish space with the metric defined as $d(\mathbf{x}, \mathbf{y})=\sum_{i=1}^{\infty} \frac{\left|x_{i}-y_{i}\right|}{1+\left|x_{i}-y_{i}\right|} 2^{-i}$. By compactness, for a fixed $\omega$, the $\mathbf{h}\left(u_{n}(\omega)\right)$ are contained in a compact subset of $X$. Next, define

$$
\Gamma_{n}(\omega)=\overline{\cup_{k \geq n} \mathbf{h}\left(u_{k}(\omega)\right)}
$$

which is a nonempty compact subset of $X$.
Next, we claim that $\omega \rightarrow \Gamma_{n}(\omega)$ is a measurable multifunction.
The proof of the claim is as follows. It is necessary to show that $\Gamma_{n}^{-}(O)$ defined as $\left\{\omega: \Gamma_{n}(\omega) \cap O \neq \emptyset\right\}$ is measurable whenever $O$ is open. It suffices to verify this for $O$ a basic open set in the topology of $X$. Thus let $O=\prod_{i=1}^{\infty} O_{i}$ where each $O_{i}$ is a proper open subset of $\mathbb{R}$ only for $i \in\left\{j_{1}, \cdots, j_{m}\right\}$. Then,

$$
\Gamma_{n}^{-}(O)=\cup_{k \geq n} \cap_{r=1}^{m}\left\{\omega:\left\langle z_{j_{r}}, u_{k}(\omega)\right\rangle \in O_{j_{r}}\right\}
$$

which is a measurable set since $u_{k}$ is measurable.
Then, it follows that $\omega \rightarrow \Gamma_{n}(\omega)$ is strongly measurable because it has compact values in $X$, thanks to Tychonoff's theorem. Thus $\Gamma_{n}^{-}(H)=\left\{\omega: H \cap \Gamma_{n}(\omega) \neq \emptyset\right\}$ is measurable whenever $H$ is a closed set. Now, let $\Gamma(\omega)$ be defined as $\cap_{n} \Gamma_{n}(\omega)$ and then for $H$ closed,

$$
\Gamma^{-}(H)=\cap_{n} \Gamma_{n}^{-}(H)
$$

and each set in the intersection is measurable, so this shows that $\omega \rightarrow \Gamma(\omega)$ is also measurable. Therefore, it has a measurable selection $\mathbf{g}(\omega)$. It follows from the definition of $\Gamma(\omega)$ that there exists a subsequence $n(\omega)$ such that

$$
\mathbf{g}(\omega)=\lim _{n(\omega) \rightarrow \infty} \mathbf{h}\left(u_{n(\omega)}(\omega)\right) \quad \text { in } X
$$

In terms of components, we have

$$
g_{i}(\omega)=\lim _{n(\omega) \rightarrow \infty}\left\langle z_{i}, u_{n(\omega)}(\omega)\right\rangle
$$

Furthermore, there is a further subsequence, still denoted with $n(\omega)$, such that $u_{n(\omega)}(\omega) \rightarrow$ $u(\omega)$ weakly. This means that for each $i$,

$$
g_{i}(\omega)=\lim _{n(\omega) \rightarrow \infty}\left\langle z_{i}, u_{n(\omega)}(\omega)\right\rangle=\left\langle z_{i}, u(\omega)\right\rangle
$$

Thus, for each $z_{i}$ in a dense set, $\omega \rightarrow\left\langle z_{i}, u(\omega)\right\rangle$ is measurable. Since the $z_{i}$ are dense, this implies $\omega \rightarrow\langle z, u(\omega)\rangle$ is measurable for every $z \in U^{\prime}$ and so by the Pettis theorem, $\omega \rightarrow u(\omega)$ is measurable.

Also is a definition.
Definition 48.7.2 Let $A(\cdot, t): V \rightarrow \mathscr{P}\left(V^{\prime}\right)$. Then, the Nemytskii operator associated with A,

$$
\hat{A}: L^{p}([0, T] ; V) \rightarrow \mathscr{P}\left(L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)\right)
$$

is given by

$$
z \in \hat{A}(u) \text { if and only if } z \in L^{p^{\prime}}\left([0, T] ; V^{\prime}\right) \text { and } z(t) \in A(u(t), t) \text { a.e. } t .
$$

## Growth and coercivity

The next three conditions on the operator $A$ are similar to the conditions proposed by Bian and Webb, [18] See also Berkovitz and Mustonen [17] which seems to be the paper where these ideas originated. These specific and reasonable conditions, together with a fourth one we add below, allow us to prove an appropriate limit condition that is based on the assumption that $u \rightarrow A(u, t)$ is a set-valued, bounded and pseudomonotone map from $V$ to $\mathscr{P}\left(V^{\prime}\right)$ and $t \rightarrow A(u, t)$ has a measurable selection.

Our aim is to provide reasonable conditions under which an assumption of pseudomonotonicity on $u \rightarrow A(u, t)$ transfers to a useable limit condition for the operator $\hat{A}$ defined on $\mathscr{V}=L^{p}([0, T] ; V)$.

It is obvious that $\hat{A} u$ is convex because this is true of $A(u, t)$. It is also closed. To see this, suppose $z_{n} \in \hat{A}(u)$. Then $z_{n}(t) \in A(u(t), t)$ for a.e.t. Taking the union of the exceptional sets, we can assume this inclusion holds off a single set of measure zero for all $n$. If you have $z_{n} \rightarrow w$ strongly in $\mathscr{V}^{\prime}$, then a subsequence converges pointwise a.e. Therefore, by upper semicontinuity of the pointwise operator $u \rightarrow A(u, t)$, it follows that $w(t) \in A(u(t), t)$ for a.e. $t$. Thus $\hat{A} u$ is convex and strongly closed.

We assume the following conditions on $A$.

1. $A(\cdot, t): V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is pseudomonotone and bounded: $A(u, t)$ is a closed convex set for each $t, u \rightarrow A(u, t)$ is bounded, and if

$$
\lim \sup _{n \rightarrow \infty}\left\langle A\left(u_{n}, t\right), u_{n}-u\right\rangle \leq 0
$$

then for any $v \in V$,

$$
\lim _{n \rightarrow \infty}\left\langle A\left(u_{n}, t\right), u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle \text { some } z(v) \in A(u, t)
$$

2. $A(\cdot, t)$ satisfies the estimates: There exists $b_{1} \geq 0$ and $b_{2} \geq 0$, such that

$$
\begin{equation*}
\|z\|_{V^{\prime}} \leq b_{1}\|u\|_{V}^{p-1}+b_{2}(t) \tag{48.7.20}
\end{equation*}
$$

for all $z \in A(u, t), b_{2}(\cdot) \in L^{p^{\prime}}([0, T])$.
3. There exist a positive constant $b_{3}$ and a nonnegative function $b_{4}$ that is $\mathscr{B}([0, T])$ measurable and also $b_{4}(\cdot) \in L^{1}([0, T])$, such that

$$
\begin{equation*}
\inf _{z \in A(u, t)}\langle z, u\rangle \geq b_{3}\|u\|_{V}^{p}-b_{4}(t)-\lambda|u|_{H}^{2} . \tag{48.7.21}
\end{equation*}
$$

4. The operators $t \rightarrow A(u(t), t)$ are measurable in the sense that

$$
t \rightarrow A(u(t), t)
$$

is a measurable multifunction with respect to $\mathscr{F}$ where $\mathscr{F}$ will be the $\sigma$ algebra of Lebesgue measurable sets whenever $t \rightarrow u(t)$ is in $\mathscr{V}_{p}$.
5. For $u \in \mathscr{V}_{p}$, we define $\hat{A}(u) \in \mathscr{P}\left(\mathscr{V}_{p}^{\prime}\right)$ as follows: $z \in \hat{A}(u)$ means that $z(t) \in$ $A(u(t), t)$ a.e. $t$. Thus this is the Nemytskii operator for $A(\cdot, t)$.

In the following theorem and in arguments which take place below, $U$ will be a Hilbert space dense in $V$ with the inclusion map compact. Such a Hilbert space always exists and is important in probability theory where $(i, U, V)$ is an abstract Wiener space. However, in most applications from partial differential equations, it suffices to take $U$ as a suitable Sobolev space.

Theorem 48.7.3 Suppose conditions 1 - 5 hold. Also, suppose

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}, \text { where } V \text { is dense in } H
$$

Then, the operator $\hat{A}$ satisfies the following.
Hypotheses:

$$
u_{n} \rightarrow u \text { weakly in } \mathscr{V}, \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0
$$

for $z_{n} \in \hat{A} u_{n}$, and there exists a set of zero measure $\Sigma$ such that for $t \notin \Sigma$, every subsequence of $\left\{u_{n}\right\}$ has a further subsequence, possibly depending on $t \notin \Sigma$ such that

$$
u_{n}(t) \rightarrow u(t) \text { weakly in } U^{\prime}
$$

where $U$ is a Banach space dense in $V$. In 3, if $\lambda>0$, then assume also that

$$
\begin{equation*}
\sup _{n} \sup _{t \in[0, T]}\left|u_{n}(t)\right|_{H}<\infty . \tag{48.7.22}
\end{equation*}
$$

Conclusion: If the above conditions hold, then for each $v \in \mathscr{V}$, there exists $z(v)$ with

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle z_{n}, u_{n}-v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\langle z(v), u-v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

where $z(v) \in \hat{A}(u)$. Furthermore, $\hat{A} u$ is a nonempty, closed and convex set in $\mathscr{V}^{\prime}$.
Proof: It was argued above that $\hat{A}(u)$ is closed and convex.
Enlarge the set of measure zero $\Sigma$, if needed, so that for each $n$,

$$
z_{n}(t) \in A\left(u_{n}(t), t\right)
$$

for each $t \notin \Sigma$.
Next, we claim that if $t \notin \Sigma$, then

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle \geq 0
$$

Proof of the claim: Let $t \notin \Sigma$ be fixed and suppose to the contrary that

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle<0 \tag{48.7.23}
\end{equation*}
$$

Then, there exists a subsequence $\left\{n_{k}\right\}$, which may depend on $t$, such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\langle z_{n_{k}}(t), u_{n_{k}}(t)-u(t)\right\rangle=\lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle<0 \tag{48.7.24}
\end{equation*}
$$

Now, condition 3 implies that for all $k$ large enough,

$$
\begin{gathered}
b_{3}\left\|u_{n_{k}}(t)\right\|_{V}^{p}-b_{4}(t)-\lambda\left|u_{n_{k}}(t)\right|_{H}^{2}<\left\|z_{n_{k}}(t)\right\|_{V^{\prime}}\|u(t)\|_{V} \\
\leq\left(b_{1}\left\|u_{n_{k}}(t)\right\|_{V}^{p-1}+b_{2}(t)\right)\|u(t)\|_{V}
\end{gathered}
$$

therefore, $\left\|u_{n_{k}}(t)\right\|_{V}$ and consequently $\left\|z_{n_{k}}(t)\right\|_{V^{\prime}}$ are bounded. This follows from 48.7.22 in case $\lambda>0$. Note that $\left\|z_{n_{k}}(t)\right\|_{V^{\prime}}$ is bounded independently of $n_{k}$ because of the assumption that $A(\cdot, t)$ is bounded and we just showed that $\left\|u_{n_{k}}(t)\right\|_{V}$ is bounded.

Taking a further subsequence if necessary, let $u_{n_{k}}(t) \rightarrow u(t)$ weakly in $U^{\prime}$ and $u_{n_{k}}(t) \rightarrow$ $\xi$ weakly in $V$. Thus, by density considerations, $\xi=u(t)$. Now, 48.7.24 and the limit conditions for pseudomonotone operators imply that the liminf condition holds.There exists $z_{\infty} \in A(u(t), t)$ such that

$$
\begin{aligned}
\liminf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t), u_{n_{k}}(t)-u(t)\right\rangle & \geq\left\langle z_{\infty}, u(t)-u(t)\right\rangle=0 \\
& >\lim _{k \rightarrow \infty}\left\langle z_{n_{k}}(t), u_{n_{k}}(t)-u(t)\right\rangle
\end{aligned}
$$

which is a contradiction. This completes the proof of the claim.
We continue with the proof of the theorem. It follows from this claim that for every $t \notin \Sigma$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle \geq 0 \tag{48.7.25}
\end{equation*}
$$

Also, it is assumed that

$$
\lim _{n \rightarrow \infty} \sup _{n \rightarrow}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}} \leq 0
$$

Then from the estimates,

$$
\int_{0}^{T}\left(b_{3}\left\|u_{n}(t)\right\|_{V}^{p}-b_{4}(t)-\lambda\left|u_{n}(t)\right|_{H}^{2}\right) d t \leq \int_{0}^{T}\|u(t)\|_{V}\left(\left\|u_{n}\right\|^{p-1} b_{1}+b_{2}\right) d t
$$

so it is routine to get $\left\|u_{n}\right\|_{\mathscr{V}}$ is bounded. This follows from the assumptions, in particular 48.7.22.

Now, the coercivity condition 3 shows that if $y \in L^{p}([0, T] ; V)$, then

$$
\begin{aligned}
\left\langle z_{n}(t), u_{n}(t)-y(t)\right\rangle \geq & b_{3}\left\|u_{n}(t)\right\|_{V}^{p}-b_{4}(t)-\lambda\left|u_{n}(t)\right|_{H}^{2} \\
& -\left(b_{1}\left\|u_{n}(t)\right\|^{p-1}+b_{2}(t)\right)\|y(t)\|_{V}
\end{aligned}
$$

Using $p-1=\frac{p}{p^{\prime}}$, where $\frac{1}{p}+\frac{1}{p^{\prime}}=1$, the right-hand side of this inequality equals

$$
b_{3}\left\|u_{n}(t)\right\|_{V}^{p}-b_{4}(t)-b_{1}\left\|u_{n}(t)\right\|^{p / p^{\prime}}\|y(t)\|_{V}-b_{2}(t)\|y(t)\|_{V}-\lambda\left|u_{n}(t)\right|_{H}^{2}
$$

the last term being bounded independent of $t, n$ by assumption. Thus there exists $c \in$ $L^{1}(0, T)$ and a positive constant $C$ such that

$$
\begin{equation*}
\left\langle z_{n}(t), u_{n}(t)-y(t)\right\rangle \geq-c(t)-C\|y(t)\|_{V}^{p} . \tag{48.7.26}
\end{equation*}
$$

Letting $y=u$, we use Fatou's lemma to write

$$
\begin{gathered}
{\lim \inf _{n \rightarrow \infty} \int_{0}^{T}\left(\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle+c(t)+C\|u(t)\|_{V}^{p}\right) d t \geq}_{\int_{0}^{T} \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle+\left(c(t)+C\|u(t)\|_{V}^{p}\right) d t} \begin{array}{c}
\geq \int_{0}^{T}\left(c(t)+C\|u(t)\|_{V}^{p}\right) d t
\end{array} .
\end{gathered}
$$

Here, we added the term $c(t)+C\|u(t)\|_{V}^{p}$ to make the integrand nonnegative in order to apply Fatou's lemma. Thus,

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \int_{0}^{T}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle d t \geq 0
$$

Consequently, using the claim in the last inequality,

$$
\begin{aligned}
0 & \geq \lim _{n \rightarrow \infty} \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
& \geq \lim _{n \rightarrow \infty} \inf _{0}^{T}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle d t \\
& =\lim _{n \rightarrow \infty} \inf _{n}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
& \geq \int_{0}^{T} \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle d t \geq 0
\end{aligned}
$$

hence, we find that

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0 \tag{48.7.27}
\end{equation*}
$$

We need to show that if $y$ is given in $\mathscr{V}$ then

$$
\left.\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\langle z(y), u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}, \quad z(y) \in \hat{A} u
$$

Suppose to the contrary that there exists $y$ such that

$$
\begin{equation*}
\eta=\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}<\langle z, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \tag{48.7.28}
\end{equation*}
$$

for all $z \in \hat{A} u$. Take a subsequence, denoted still with subscript $n$ such that

$$
\eta=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

Thus

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}<\langle z, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \tag{48.7.29}
\end{equation*}
$$

We will obtain a contradiction to this. In what follows we continue to use the subsequence just described which satisfies the above inequality.

The estimate 48.7.26 implies,

$$
\begin{equation*}
0 \leq\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{-} \leq c(t)+C\|u(t)\|_{V}^{p}, \tag{48.7.30}
\end{equation*}
$$

where $c$ is a function in $L^{1}(0, T)$. Thanks to (48.7.25),

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle \geq 0
$$

and, therefore, the following pointwise limit exists,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{-}=0
$$

and so we may apply the dominated convergence theorem using (48.7.30) and conclude

$$
\lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{-} d t=\int_{0}^{T} \lim _{n \rightarrow \infty}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{-} d t=0
$$

Now, it follows from (48.7.27) and the above equation, that

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{+} d t \\
= & \lim _{n \rightarrow \infty} \int_{0}^{T}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle+\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{-} d t \\
= & \lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0 .
\end{aligned}
$$

Therefore, both $\int_{0}^{T}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{+} d t$ and $\int_{0}^{T}\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle^{-} d t$ converge to 0, thus,

$$
\begin{align*}
\lim _{n \rightarrow \infty} \int_{0}^{T}\left|\left\langle z_{n}(t), u_{n}(t)-u(t)\right\rangle\right| d t & =0  \tag{48.7.31}\\
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} & =0
\end{align*}
$$

From the above, it follows that there exists a further subsequence $\left\{n_{k}\right\}$ not depending on $t$ such that

$$
\begin{equation*}
\left|\left\langle z_{n_{k}}(t), u_{n_{k}}(t)-u(t)\right\rangle\right| \rightarrow 0 \quad \text { a.e. } t . \tag{48.7.32}
\end{equation*}
$$

Therefore, by the pseudomonotone limit condition for $A$ there exists $w_{t} \in A(u(t), t)$ such that for a.e. $t$,

$$
\begin{aligned}
\alpha(t) & \equiv \lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t), u_{n_{k}}(t)-y(t)\right\rangle \\
& =\lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t), u(t)-y(t)\right\rangle \geq\left\langle w_{t}, u(t)-y(t)\right\rangle .
\end{aligned}
$$

Then on the exceptional set, let $\alpha(t) \equiv \infty$, and consider the set

$$
F(t) \equiv\{w \in A(u(t), t):\langle w, u(t)-y(t)\rangle \leq \alpha(t)\}
$$

which then satisfies $F(t) \neq \emptyset$. Now $F(t)$ is closed and convex in $V^{\prime}$.
Claim: $t \rightarrow F(t)$ has a measurable selection off a set of measure zero.
Proof of claim: Letting $B(0, C(t))$ contain $A(u(t), t)$, we can assume $t \rightarrow C(t)$ is measurable by using the estimates and the measurability of $u$. For $p \in \mathbb{N}$, let $S_{p} \equiv\{t: C(t)<p\}$. If it is shown that $F$ has a measurable selection on $S_{p}$, then it follows that it has a measurable selection. Thus in what follows, assume that $t \in S_{p}$.

Define

$$
G(t) \equiv\left\{w:\langle w, u(t)-y(t)\rangle<\alpha(t)+\frac{1}{n}, t \notin \Sigma\right\} \cap B(0, p)
$$

Thus, it was shown above that this $G(t) \neq \emptyset$. For $U$ open,

$$
\begin{equation*}
G^{-}(U) \equiv\left\{t \in S_{p}: \text { for some } w \in U \cap B(0, p),\langle w, u(t)-y(t)\rangle<\alpha(t)+\frac{1}{n}\right\} \tag{*}
\end{equation*}
$$

Let $\left\{w_{j}\right\}$ be a dense subset of $U \cap B(0, p)$. This is possible because $V^{\prime}$ is separable. The expression in $*$ equals

$$
\cup_{k=1}^{\infty}\left\{t \in S_{p}:\left\langle w_{k}, u(t)-y(t)\right\rangle<\alpha(t)+\frac{1}{n}\right\}
$$

which is measurable. Thus $G$ is a measurable multifunction.
Since $t \rightarrow G(t)$ is measurable, there is a sequence $\left\{w_{n}(t)\right\}$ of measurable functions such that $\overline{\cup_{n=1}^{\infty} w_{n}(t)}$ equals

$$
\overline{G(t)}=\left\{w:\langle w, u(t)-y(t)\rangle \leq \alpha(t)+\frac{1}{n}, t \notin \Sigma\right\} \cap \overline{B(0, p)}
$$

As shown above, there exists $w_{t}$ in $A(u(t), t)$ as well as $G(t)$. Thus there is a sequence of $w_{r}(t)$ converging to $w_{t}$. Since $t \rightarrow A(u(t), t)$ is a measurable multifunction, it has a countable subset of measurable functions $\left\{z_{m}(t)\right\}$ which is dense in $A(u(t), t)$. Let

$$
U_{k}(t) \equiv \cup_{m} B\left(z_{m}(t), \frac{1}{k}\right) \subseteq A(u(t), t)+B\left(0, \frac{2}{k}\right)
$$

Now define $A_{1 k}=\left\{t: w_{1}(t) \in U_{k}(t)\right\}$. Then let $A_{2 k}=\left\{t \notin A_{1 k}: w_{2}(t) \in U_{k}(t)\right\}$ and $A_{3 k}=\left\{t \notin \cup_{i=1}^{2} A_{i k}: w_{3}(t) \in U_{k}(t)\right\}$ and so forth. Any $t \in S_{p}$ must be contained in one of these $A_{r k}$ for some $r$ since if not so, there would not be a sequence $w_{r}(t)$ converging to $w_{t} \in A(u(t), t)$. These $A_{r p}$ partition $S_{p}$ and each is measurable since the $\left\{z_{k}(t)\right\}$ are measurable. Let

$$
\hat{w}_{k}(t) \equiv \sum_{r=1}^{\infty} \mathscr{X}_{A_{r k}}(t) w_{r}(t)
$$

Thus $\hat{w}_{k}(t)$ is in $U_{k}(t)$ for all $t \in S_{p}$ and equals exactly one of the $w_{m}(t) \in \overline{G(t)}$.
Also, by construction, the $\hat{w}_{k}(\cdot)$ are bounded in $L^{\infty}\left(S_{p} ; V^{\prime}\right)$. Therefore, there is a subsequence of these, still called $\hat{w}_{k}$ which converges weakly to a function $w$ in $L^{2}\left(S_{p} ; V^{\prime}\right)$. Thus $w$ is a weak limit point of $c o\left(\cup_{j=k}^{\infty} \hat{w}_{j}\right)$ for each $k$. Therefore, in the open ball
$B\left(w, \frac{1}{k}\right) \subseteq L^{2}\left(S_{p} ; V^{\prime}\right)$ with respect to the strong topology, there is a convex combination $\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}$ (the $c_{j k}$ add to 1 and only finitely many are nonzero). Since $\overline{G(t)}$ is convex and closed, this convex combination is in $\overline{G(t)}$. Off a set of measure zero, we can assume this convergence of $\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}$ as $k \rightarrow \infty$ happens pointwise for a suitable subsequence. However,

$$
\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}(t) \in U_{k}(t) \subseteq A(u(t), t)+B\left(0, \frac{2}{k}\right)
$$

Thus $w(t) \in A(u(t), t)$ a.e. $t$ because $A(u(t), t)$ is a closed set. Since $w$ is the pointwise limit of measurable functions off a set of measure zero, it can be assumed measurable and for a.e. $t, w(t) \in A(u(t), t) \cap \overline{G(t)}$. Now denote this measurable function $w_{n}$. Then

$$
w_{n}(t) \in A(u(t), t),\left\langle w_{n}(t), u(t)-y(t)\right\rangle \leq \alpha(t)+\frac{1}{n} \text { a.e. } t
$$

These $w_{n}(t)$ are bounded for each $t$ off a set of measure zero and so by Lemma 48.7.1, there is a measurable function $t \rightarrow z(t)$ and a subsequence $w_{n(t)}(t) \rightarrow z(t)$ weakly as $n(t) \rightarrow \infty$. Now $A(u(t), t)$ is closed and convex, hence weakly closed as well. Thus $z(t) \in A(u(t), t)$ and

$$
\begin{equation*}
\langle z(t), u(t)-y(t)\rangle \leq \alpha(t)=\lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t), u_{n_{k}}(t)-y(t)\right\rangle \tag{**}
\end{equation*}
$$

Therefore, $t \rightarrow F(t)$ has a measurable selection on $S_{p}$ excluding a set of measure zero, namely $z(t)$ which will be called $z_{p}(t)$ in what follows.

It follows that $F(t)$ has a measurable selection on $[0, T]$ other than a set of measure zero. To see this, enlarge $\Sigma$ to include the exceptional sets of measure zero in the above argument for each $p$. Then partition $[0, T] \backslash \Sigma$ as follows. For $p=1,2, \cdots$, consider $S_{p} \backslash$ $S_{p-1}, p=1,2, \cdots$ for $S_{0}$ defined as $\emptyset$. Then letting $z_{p}$ be the selection for $t \in S_{p}$, let $z(t)=$ $\sum_{p=1}^{\infty} z_{p}(t) \mathscr{X}_{S_{p} \backslash S_{p-1}}(t)$. The estimates imply $z \in \mathscr{V}^{\prime}$ and so $z \in \hat{A}(u)$.

From the estimates, there exists $h \in L^{1}(0, T)$ such that $\langle z(t), u(t)-y(t)\rangle \geq-|h(t)|$ Thus, from the above inequality,

$$
\begin{aligned}
& \|h\|_{L^{1}}+\langle z, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq \int_{0}^{T} \lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t), u_{n_{k}}(t)-y(t)\right\rangle+|h(t)| d t \\
& \leq \lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}, u_{n_{k}}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\|h\|_{L^{1}}=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\|h\|_{L^{1}}
\end{aligned}
$$

which contradicts 48.7.29.
This all works for progressively measurable operators. These are discussed more later in the material on probability. A filtration is $\left\{\mathscr{F}_{t}\right\}, t \in[0, T]$ where each $\mathscr{F}_{t}$ is a $\sigma$ algebra of sets in $\Omega$ usually a probability space and these are increasing in $t$. Then the progressively measurable sets $\mathscr{P}$ are $S \subseteq \Omega$ such that

$$
S \cap[0, t] \times \Omega \text { is } \mathscr{B}([0, t]) \times \mathscr{F}_{t} \text { measurable }
$$

You can verify that this is indeed a $\sigma$ algebra of sets in $[0, T] \times \Omega$. Now here is a generalization of the above which will work for this situation.

In what follows, $\mathscr{P}$ will be the $\sigma$ algebra of progressively measurable sets. Thus there is a filtration $\left\{\mathscr{F}_{t}\right\}$ and a set $S$ is $\mathscr{P}$ measurable means that

$$
(t, \omega) \rightarrow \mathscr{X}_{[0, t] \times \Omega}(t, \omega) \mathscr{X}_{S}(t, \omega) \text { is a } \mathscr{B}([0, t]) \times \mathscr{F}_{t}
$$

meaurable function.
We assume the following conditions on $A$.

1. $A(\cdot, t, \omega): V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is pseudomonotone and bounded: $A(u, t, \omega)$ is a closed convex set for each $(t, \omega), u \rightarrow A(u, t, \omega)$ is bounded, and if $u_{n} \rightarrow u$ weakly and

$$
\lim \sup _{n \rightarrow \infty}\left\langle A\left(u_{n}, t, \omega\right), u_{n}-u\right\rangle \leq 0
$$

then for any $v \in V$,

$$
\lim _{n \rightarrow \infty}\left\langle A\left(u_{n}, t, \omega\right), u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle \text { some } z(v) \in A(u, t, \omega)
$$

2. $A(\cdot, t, \omega)$ satisfies the estimates: There exists $b_{1} \geq 0$ and $b_{2} \geq 0$, such that

$$
\begin{equation*}
\|z\|_{V^{\prime}} \leq b_{1}\|u\|_{V}^{p-1}+b_{2}(t, \omega) \tag{48.7.33}
\end{equation*}
$$

for all $z \in A(u, t, \omega), b_{2}(\cdot, \cdot) \in L^{p^{\prime}}([0, T] \times \Omega)$.
3. There exist a positive constant $b_{3}$ and a nonnegative function $b_{4}$ that is $\mathscr{B}([0, T]) \times$ $\mathscr{F}_{T}$ measurable and also $b_{4}(\cdot, \cdot) \in L^{1}([0, T] \times \Omega)$, such that for some $\lambda \geq 0$,

$$
\begin{equation*}
\inf _{z \in A(u, t, \omega)}\langle z, u\rangle \geq b_{3}\|u\|_{V}^{p}-b_{4}(t, \omega)-\lambda|u|_{H}^{2} \tag{48.7.34}
\end{equation*}
$$

4. The mapping $(t, \omega) \rightarrow A(u(t, \omega), t, \omega)$ is measurable in the sense that

$$
(t, \omega) \rightarrow A(u(t, \omega), t, \omega)
$$

is a measurable multifunction with respect to $\mathscr{P}$ whenever $(t, \omega) \rightarrow u(t, \omega)$ is in $\mathscr{V} \equiv \mathscr{V}_{p} \equiv L^{p}([0, T] \times \Omega ; V, \mathscr{P})$.
5. For $u \in \mathscr{V}_{p}$, we define $\hat{A}(u) \in \mathscr{P}\left(\mathscr{V}_{p}^{\prime}\right)$ as follows: $z \in \hat{A}(u)$ means that $z(t, \omega) \in$ $A(u(t, \omega), t, \omega)$ a.e. $(t, \omega)$. Thus this is the Nemytskii operator for $A(\cdot, t, \omega)$.

In the following theorem and in arguments which take place below, $U$ will be a Hilbert space dense in $V$ with the inclusion map compact. Such a Hilbert space always exists and is important in probability theory where $(i, U, V)$ is an abstract Wiener space. However, in most applications from partial differential equations, it suffices to take $U$ as a suitable Sobolev space. Also for $S$ a set in $[0, T] \times \Omega, S_{\omega}$ will denote $\{t:(t, \omega) \in S\}$.

Theorem 48.7.4 Suppose conditions 1 - 5 hold. Also, suppose $U$ is a separable Hilbert space dense in $V$, a reflexive separable Banach space with the inclusion map compact and $V$ is dense in a Hilbert space $H$. Thus

$$
U \subseteq V \subseteq H=H^{\prime} \subseteq V^{\prime} \subseteq U^{\prime}
$$

Then, the operator $\hat{A}$ in the definition 5 satisfies the following.
Hypotheses:

$$
u_{n} \rightarrow u \text { weakly in } \mathscr{V}, \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \leq 0
$$

for $z_{n} \in \hat{A} u_{n}$. For each $\omega$, off a set of P measure zero $N$, every subsequence of $u_{n}(t, \omega)$ has a further subsequence, possibly depending on $t, \omega$ such that

$$
u_{n}(t, \omega) \rightarrow u(t, \omega) \text { weakly in } U^{\prime}
$$

Assume also that

$$
\begin{equation*}
\sup _{\omega \in \Omega \backslash N} \sup _{n} \sup _{t \in[0, T]} \lambda\left|u_{n}(t, \omega)\right|_{H}<\infty . \tag{48.7.35}
\end{equation*}
$$

Conclusion: If the above conditions hold, then there exists $z(v)$ with

$$
\lim _{n \rightarrow \infty} \inf _{n}\left\langle z_{n}, u_{n}-v\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\langle z(v), u-v\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

where $z(v) \in \hat{A}(u)$.
Proof: It was argued above that $\hat{A}(u)$ is closed and convex. Let $\Sigma$ have measure zero and for each $(t, \omega) \notin \Sigma, z_{n}(t, \omega) \in A\left(u_{n}(t, \omega), t, \omega\right)$ for each $n$. Now $\Sigma_{\omega}$ has measure zero for a.e. $\omega$ since otherwise $\Sigma$ would not have measure zero. These are the $\omega$ of interest in the following argument, and we can simply include the exceptional $\omega$ in the set of measure zero $N$ which is being ignored since it has measure zero.

First we claim that if $t \notin \Sigma_{\omega}$, then

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \geq 0
$$

Proof of the claim: Let $t \notin \Sigma_{\omega}$ be fixed and suppose to the contrary that

$$
\begin{equation*}
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle<0 \tag{48.7.36}
\end{equation*}
$$

Then, there exists a subsequence $\left\{n_{k}\right\}$, which may depend on $t, \omega$, such that

$$
\begin{align*}
& \lim _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-u(t, \omega)\right\rangle  \tag{48.7.37}\\
= & \lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle<0 . \tag{48.7.38}
\end{align*}
$$

Now, condition 3 implies that for all $k$ large enough,

$$
b_{3}\left\|\left.u_{n_{k}}(t, \omega)\right|_{V} ^{p}-b_{4}(t, \omega)-\lambda\left|u_{n_{k}}(t, \omega)\right|_{H}^{2}<\right\| z_{n_{k}}(t, \omega)\left\|_{V^{\prime}}\right\| u(t, \omega) \|_{V}
$$

$$
\leq\left(b_{1}\left\|u_{n_{k}}(t, \omega)\right\|_{V}^{p-1}+b_{2}(t, \omega)\right)\|u(t, \omega)\|_{V}
$$

therefore, $\left\|u_{n_{k}}(t, \omega)\right\|_{V}$ and consequently $\left\|z_{n_{k}}(t, \omega)\right\|_{V^{\prime}}$ are bounded. This follows from 48.7.35. Note that $\left|\mid z_{n_{k}}(t, \omega) \|_{V^{\prime}}\right.$ is bounded independently of $n_{k}$ because of the assumption that $A(\cdot, t, \omega)$ is bounded and we just showed that $\left\|u_{n_{k}}(t, \omega)\right\|_{V}$ is bounded.

Taking a further subsequence if necessary, let $u_{n_{k}}(t, \omega) \rightarrow u(t, \omega)$ weakly in $U^{\prime}$ and $u_{n_{k}}(t, \omega) \rightarrow \xi$ weakly in $V$. Thus, by density considerations, $\xi=u(t, \omega)$. Now, 48.7.37 and the limit conditions for pseudomonotone operators imply that the liminf condition holds.There exists $z_{\infty} \in A(u(t, \omega), t, \omega)$ such that

$$
\begin{aligned}
\lim _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-u(t, \omega)\right\rangle & \geq\left\langle z_{\infty}, u(t, \omega)-u(t, \omega)\right\rangle=0 \\
& >\lim _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-u(t, \omega)\right\rangle
\end{aligned}
$$

which is a contradiction. This completes the proof of the claim.
We continue with the proof of the theorem. It follows from this claim that for given $\omega$, every $t \notin \Sigma_{\omega}$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \geq 0 \tag{48.7.39}
\end{equation*}
$$

Also, it is assumed that

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}} \leq 0
$$

Then from the estimates,

$$
\begin{aligned}
& \int_{\Omega} \int_{0}^{T}\left(b_{3}\left\|u_{n}(t, \omega)\right\|_{V}^{p}-b_{4}(t, \omega)-\lambda\left|u_{n}(t, \omega)\right|_{H}^{2}\right) d t d P \\
\leq & \int_{\Omega} \int_{0}^{T}\|u(t, \omega)\|_{V}\left(\left\|u_{n}(t, \omega)\right\|^{p-1} b_{1}+b_{2}\right) d t d P
\end{aligned}
$$

so it is routine to get $\left\|u_{n}\right\|_{\mathscr{V}}$ is bounded. This follows from the assumptions, in particular 48.7.35.

Now, the coercivity condition 3 shows that if $y \in \mathscr{V}$, then

$$
\begin{aligned}
\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-y(t, \omega)\right\rangle \geq & b_{3}\left\|u_{n}(t, \omega)\right\|_{V}^{p}-b_{4}(t, \omega)-\lambda\left|u_{n}(t, \omega)\right|_{H}^{2} \\
& -\left(b_{1}\left\|u_{n}(t, \omega)\right\|^{p-1}+b_{2}(t, \omega)\right)\|y(t, \omega)\|_{V}
\end{aligned}
$$

Using $p-1=\frac{p}{p^{\prime}}$, where $\frac{1}{p}+\frac{1}{p^{\prime}}=1$, the right-hand side of this inequality equals

$$
\begin{aligned}
& b_{3}\left\|u_{n}(t, \omega)\right\|_{V}^{p}-b_{4}(t, \omega)-b_{1}\left\|u_{n}(t, \omega)\right\|^{p / p^{\prime}}\|y(t, \omega)\|_{V} \\
& -b_{2}(t, \omega)\|y(t, \omega)\|_{V}-\lambda\left|u_{n}(t, \omega)\right|_{H}^{2}
\end{aligned}
$$

the last term being bounded independent of $t, n$ by assumption. Thus there exists $c(\cdot, \cdot) \in$ $L^{1}([0, T] \times \Omega)$ and a positive constant $C$ such that

$$
\begin{equation*}
\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-y(t, \omega)\right\rangle \geq-c(t, \omega)-C\|y(t, \omega)\|_{V}^{p} \tag{48.7.40}
\end{equation*}
$$

Letting $y=u$, we use Fatou's lemma to write

$$
\begin{gathered}
{\lim \inf _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left(\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle+c(t, \omega)+C\|u(t, \omega)\|_{V}^{p}\right) d t d P \geq}_{\int_{\Omega} \int_{0}^{T} \lim \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle+\left(c(t, \omega)+C\|u(t, \omega)\|_{V}^{p}\right) d t d P} \begin{array}{c}
\geq \int_{\Omega} \int_{0}^{T}\left(c(t, \omega)+C\|u(t, \omega)\|_{V}^{p}\right) d t d P
\end{array} .
\end{gathered}
$$

Here, we added the term $c(t, \omega)+C\|u(t, \omega)\|_{V}^{p}$ to make the integrand nonnegative in order to apply Fatou's lemma. Thus,

$$
\lim \inf _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle d t d P \geq 0
$$

Consequently, using the claim in the last inequality,

$$
\begin{aligned}
0 & \geq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
& \geq \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle d t d P \\
& =\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
& \geq \int_{\Omega} \int_{0}^{T} \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle d t d P \geq 0
\end{aligned}
$$

hence, we find that

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0 \tag{48.7.41}
\end{equation*}
$$

We need to show that if $y$ is given in $\mathscr{V}$ then

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \geq\langle z(y), u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}, \quad z(y) \in \hat{A} u
$$

Suppose to the contrary that there exists $y$ such that

$$
\begin{equation*}
\eta=\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}<\langle z, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \tag{48.7.42}
\end{equation*}
$$

for all $z \in \hat{A} u$. Take a subsequence, denoted still with subscript $n$ such that

$$
\eta=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}
$$

Note that this subsequence does not depend on $(t, \omega)$. Thus

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}<\langle z, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \tag{48.7.43}
\end{equation*}
$$

We will obtain a contradiction to this. In what follows, we continue to use the subsequence just described which satisfies the above inequality.

The estimate 48.7.40 implies,

$$
\begin{equation*}
0 \leq\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} \leq c(t, \omega)+C\|u(t, \omega)\|_{V}^{p}, \tag{48.7.44}
\end{equation*}
$$

where $c$ is a function in $L^{1}(0, T)$. Thanks to (48.7.39),

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \geq 0, \text { a.e. }
$$

and, therefore, the following pointwise limit exists,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-}=0, \text { a.e. }
$$

and so we may apply the dominated convergence theorem using (48.7.44) and conclude

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P \\
= & \int_{\Omega} \int_{0}^{T} \lim _{n \rightarrow \infty}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P=0
\end{aligned}
$$

Now, it follows from (48.7.41) and the above equation, that

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{+} d t d P \\
= & \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle \\
& +\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P \\
= & \lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}=0 .
\end{aligned}
$$

Therefore, both

$$
\int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{+} d t d P
$$

and

$$
\int_{\Omega} \int_{0}^{T}\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle^{-} d t d P
$$

converge to 0 , thus,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left|\left\langle z_{n}(t, \omega), u_{n}(t, \omega)-u(t, \omega)\right\rangle\right| d t d P=0 \tag{48.7.45}
\end{equation*}
$$

From the above, it follows that there exists a further subsequence $\left\{n_{k}\right\}$ not depending on $t, \omega$ such that

$$
\begin{equation*}
\left|\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-u(t, \omega)\right\rangle\right| \rightarrow 0 \quad \text { a.e. }(t, \omega) . \tag{48.7.46}
\end{equation*}
$$

Therefore, by the pseudomonotone limit condition for $A$ there exists

$$
w_{t, \omega} \in A(u(t, \omega), t, \omega)
$$

such that for a.e. $(t, \omega)$

$$
\begin{aligned}
\alpha(t, \omega) & \equiv \lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-y(t, \omega)\right\rangle \\
& =\lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u(t, \omega)-y(t, \omega)\right\rangle \geq\left\langle w_{t, \omega}, u(t, \omega)-y(t, \omega)\right\rangle
\end{aligned}
$$

Then on the exceptional set, let $\alpha(t, \omega) \equiv \infty$, and consider the set

$$
F(t, \omega) \equiv\{w \in A(u(t, \omega), t, \omega):\langle w, u(t, \omega)-y(t, \omega)\rangle \leq \alpha(t, \omega)\}
$$

which then satisfies $F(t, \omega) \neq \emptyset$. Now $F(t, \omega)$ is closed and convex in $V^{\prime}$.
Claim : $(t, x) \rightarrow F(t, \omega)$ has a measurable selection off a set of measure zero.
Proof of claim: Letting $B(0, C(t, \omega))$ contain $A(u(t, \omega), t, \omega)$, we can assume

$$
(t, \omega) \rightarrow C(t, \omega)
$$

is $\mathscr{P}$ measurable by using the estimates and the measurability of $u$. For $\gamma \in \mathbb{N}$, let $S_{\gamma} \equiv$ $\{(t, \omega): C(t, \omega)<\gamma\}$. If it is shown that $F$ has a measurable selection on $S_{\gamma}$, then it follows that it has a measurable selection. Thus in what follows, assume that $(t, \omega) \in S_{\gamma}$.

Define

$$
G(t, \omega) \equiv\left\{w:\langle w, u(t, \omega)-y(t, \omega)\rangle<\alpha(t, \omega)+\frac{1}{n},(t, \omega) \notin \Sigma\right\} \cap B(0, \gamma)
$$

Thus, it was shown above that this $G(t, \omega) \neq \emptyset$ at least for large enough $\gamma$. For $U$ open,

$$
G^{-}(U) \equiv\left\{\begin{array}{c}
(t, \omega) \in S_{\gamma}: \text { for some } w \in U \cap B(0, \gamma)  \tag{*}\\
\langle w, u(t, \omega)-y(t, \omega)\rangle<\alpha(t, \omega)+\frac{1}{n}
\end{array}\right\}
$$

Let $\left\{w_{j}\right\}$ be a dense subset of $U \cap B(0, \gamma)$. This is possible because $V^{\prime}$ is separable. The expression in $*$ equals

$$
\cup_{k=1}^{\infty}\left\{(t, \omega) \in S_{\gamma}:\left\langle w_{k}, u(t, \omega)-y(t, \omega)\right\rangle<\alpha(t, \omega)+\frac{1}{n}\right\}
$$

which is measurable. Thus $G$ is a measurable multifunction.
Since $(t, \omega) \rightarrow \underline{G(t, \omega)}$ is measurable, there is a sequence $\left\{w_{n}(t, \omega)\right\}$ of measurable functions such that $\cup_{n=1}^{\infty} w_{n}(t, \omega)$ equals

$$
\overline{G(t, \omega)}=\left\{w:\langle w, u(t, \omega)-y(t, \omega)\rangle \leq \alpha(t, \omega)+\frac{1}{n}, t \notin \Sigma\right\} \cap \overline{B(0, \gamma)}
$$

As shown above, there exists $w_{t, \omega}$ in $A(u(t, \omega), t, \omega)$ as well as $G(t, \omega)$. Thus there is a sequence of $w_{r}(t, \omega)$ converging to $w_{t, \omega}$. Of course $r$ will need to depend on $t, \omega$. Since $(t, \omega) \rightarrow A(u(t, \omega), t, \omega)$ is a measurable multifunction, it has a countable subset of $\mathscr{P}$ measurable functions $\left\{z_{k}(t, \omega)\right\}$ which is dense in $A(u(t, \omega), t, \omega)$. Let

$$
U_{k}(t, \omega) \equiv \cup_{m} B\left(z_{m}(t, \omega), \frac{1}{k}\right) \subseteq A(u(t, \omega), t, \omega)+B\left(0, \frac{2}{k}\right)
$$

Now define $A_{1 k}=\left\{(t, \omega): w_{1}(t, \omega) \in U_{k}(t, \omega)\right\}$. Then let

$$
A_{2 k}=\left\{(t, \omega) \notin A_{1 k}: w_{2}(t, \omega) \in U_{k}(t, \omega)\right\}
$$

and

$$
A_{3 k}=\left\{(t, \omega) \notin \cup_{i=1}^{2} A_{i k}: w_{3}(t, \omega) \in U_{k}(t, \omega)\right\}
$$

and so forth. Any $(t, \omega) \in S_{\gamma}$ must be contained in one of these $A_{r k}$ for some $r$ since if not so, there would not be a sequence $w_{r}(t, \omega)$ converging to $w_{t, \omega} \in A(u(t, \omega), t, \omega)$. These $A_{r \gamma}$ partition $S_{\gamma}$ and each is measurable since the $\left\{z_{k}(t, \omega)\right\}$ are measurable. Let

$$
\hat{w}_{k}(t, \omega) \equiv \sum_{r=1}^{\infty} \mathscr{X}_{A_{r k}}(t, \omega) w_{r}(t, \omega)
$$

Thus $\hat{w}_{k}(t, \omega)$ is in $U_{k}(t, \omega)$ for all $(t, \omega) \in S_{\gamma}$ and equals exactly one of the $w_{m}(t, \omega) \in$ $\overline{G(t, \omega)}$.

Also, by construction, the $\hat{w}_{k}(\cdot, \cdot)$ are bounded in $L^{\infty}\left(S_{\gamma} ; V^{\prime}\right)$. Therefore, there is a subsequence of these, still called $\hat{w}_{k}$ which converges weakly to a function $w$ in $L^{2}\left(S_{\gamma} ; V^{\prime}\right)$. Thus $w$ is a weak limit point of $\operatorname{co}\left(\cup_{j=k}^{\infty} \hat{w}_{j}\right)$ for each $k$. Therefore, in the open ball $B\left(w, \frac{1}{k}\right) \subseteq L^{2}\left(S_{\gamma} ; V^{\prime}\right)$ with respect to the strong topology, there is a convex combination $\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}$ (the $c_{j k}$ add to 1 and only finitely many are nonzero). Since $\overline{G(t, \omega)}$ is convex and closed, this convex combination is in $\overline{G(t, \omega)}$. Off a set of $\mathscr{P}$ measure zero, we can assume this convergence of $\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}$ as $k \rightarrow \infty$ happens pointwise a.e. for a suitable subsequence. However,

$$
\sum_{j=k}^{\infty} c_{j k} \hat{w}_{j}(t, \omega) \in U_{k}(t, \omega) \subseteq A(u(t, \omega), t, \omega)+B\left(0, \frac{2}{k}\right)
$$

Thus $w(t, \omega) \in A(u(t, \omega), t, \omega)$ a.e. $(t, \omega)$ because $A(u(t, \omega), t, \omega)$ is a closed set. Since $w$ is the pointwise limit of measurable functions off a set of measure zero, it can be assumed measurable and for a.e. $(t, \omega), w(t, \omega) \in A(u(t, \omega), t, \omega) \cap \overline{G(t, \omega)}$. Now denote this measurable function $w_{n}$. Then

$$
w_{n}(t, \omega) \in A(u(t, \omega), t, \omega),\left\langle w_{n}(t, \omega), u(t, \omega)-y(t, \omega)\right\rangle \leq \alpha(t, \omega)+\frac{1}{n} \text { a.e. }(t, \omega)
$$

These $w_{n}(t, \omega)$ are bounded for each $(t, \omega)$ off a set of measure zero and so by Lemma 48.7.1, there is a $\mathscr{P}$ measurable function $(t, \omega) \rightarrow z(t, \omega)$ and a subsequence $w_{n(t, \omega)}(t, \omega) \rightarrow$ $z(t, \omega)$ weakly as $n(t, \omega) \rightarrow \infty$. Now $A(u(t, \omega), t, \omega)$ is closed and convex, and $w_{n(t, \omega)}(t, \omega)$ is in $A(u(t, \omega), t, \omega)$, and so $z(t, \omega) \in A(u(t, \omega), t, \omega)$ and

$$
\begin{equation*}
\langle z(t, \omega), u(t, \omega)-y(t, \omega)\rangle \leq \alpha(t, \omega)=\liminf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-y(t, \omega)\right\rangle \tag{**}
\end{equation*}
$$

Therefore, $t \rightarrow F(t, \omega)$ has a measurable selection on $S_{\gamma}$ excluding a set of measure zero, namely $z(t, \omega)$ which will be called $z_{\gamma}(t, \omega)$ in what follows.

Then $F(t, \omega)$ has a measurable selection on $[0, T] \times \Omega$ other than a set of measure zero. To see this, enlarge $\Sigma$ to include the exceptional sets of measure zero in the above
argument for each $\gamma$. Then partition $[0, T] \times \Omega \backslash \Sigma$ as follows. For $\gamma=1,2, \cdots$, consider $S_{\gamma} \backslash S_{\gamma-1}, \gamma=1,2, \cdots$ for $S_{0}$ defined as $\emptyset$. Then letting $z_{\gamma}$ be the selection for $(t, \omega) \in S_{\gamma}$, let $z(t, \omega)=\sum_{\gamma=1}^{\infty} z_{\gamma}(t, \omega) \mathscr{X}_{S_{\gamma} \backslash S_{\gamma-1}}(t, \omega)$. The estimates imply $z \in \mathscr{V}^{\prime}$ and so $z \in \hat{A}(u)$.

From the estimates, there exists $h \in L^{1}([0, T] \times \Omega)$ such that

$$
\langle z(t, \omega), u(t, \omega)-y(t, \omega)\rangle \geq-|h(t, \omega)|
$$

Thus, from the above inequality,

$$
\begin{gathered}
\|h\|_{L^{1}}+\langle z, u-y\rangle_{\mathscr{V}^{\prime}, \mathscr{V}} \\
\leq \int_{\Omega} \int_{0}^{T} \lim \inf _{k \rightarrow \infty}\left\langle z_{n_{k}}(t, \omega), u_{n_{k}}(t, \omega)-y(t, \omega)\right\rangle+|h(t, \omega)| d t d P \\
\leq \liminf _{k \rightarrow \infty}\left\langle z_{n_{k}}, u_{n_{k}}-y\right\rangle_{\mathscr{V}^{\prime}, \mathscr{V}}+\|h\|_{L^{1}} \\
=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-y\right\rangle_{\mathscr{V}^{1}, \mathscr{V}}+\|h\|_{L^{1}}
\end{gathered}
$$

which contradicts 48.7.42.
The difficulty with this, is that it is hard to get the hypotheses holding. If you have $u_{n} \rightarrow u$ weakly in $\mathscr{V}$, then how do you get $u_{n}(t, \omega) \rightarrow u(t, \omega)$ weakly in $U^{\prime}$, for a subsequence, this for each $\omega$ not in a set of measure zero? The weak convergence does not seem to give pointwise weak convergence of the sort you need. More precisely, the pointwise convergence you get, might not be the right thing because in $u_{n}$ it will be $u_{n(\omega)}$. This is the problem with this theorem. It seems correct but not very useful.

## Part V

## Complex Analysis

## Chapter 49

## The Complex Numbers

The reader is presumed familiar with the algebraic properties of complex numbers, including the operation of conjugation. Here a short review of the distance in $\mathbb{C}$ is presented.

The length of a complex number, referred to as the modulus of $z$ and denoted by $|z|$ is given by

$$
|z| \equiv\left(x^{2}+y^{2}\right)^{1 / 2}=(z \bar{z})^{1 / 2},
$$

Then $\mathbb{C}$ is a metric space with the distance between two complex numbers, $z$ and $w$ defined as

$$
d(z, w) \equiv|z-w|
$$

This metric on $\mathbb{C}$ is the same as the usual metric of $\mathbb{R}^{2}$. A sequence, $z_{n} \rightarrow z$ if and only if $x_{n} \rightarrow x$ in $\mathbb{R}$ and $y_{n} \rightarrow y$ in $\mathbb{R}$ where $z=x+i y$ and $z_{n}=x_{n}+i y_{n}$. For example if $z_{n}=\frac{n}{n+1}+i \frac{1}{n}$, then $z_{n} \rightarrow 1+0 i=1$.

Definition 49.0.1 A sequence of complex numbers, $\left\{z_{n}\right\}$ is a Cauchy sequence if for every $\varepsilon>0$ there exists $N$ such that $n, m>N$ implies $\left|z_{n}-z_{m}\right|<\varepsilon$.

This is the usual definition of Cauchy sequence. There are no new ideas here.
Proposition 49.0.2 The complex numbers with the norm just mentioned forms a complete normed linear space.

Proof: Let $\left\{z_{n}\right\}$ be a Cauchy sequence of complex numbers with $z_{n}=x_{n}+i y_{n}$. Then $\left\{x_{n}\right\}$ and $\left\{y_{n}\right\}$ are Cauchy sequences of real numbers and so they converge to real numbers, $x$ and $y$ respectively. Thus $z_{n}=x_{n}+i y_{n} \rightarrow x+i y . \mathbb{C}$ is a linear space with the field of scalars equal to $\mathbb{C}$. It only remains to verify that $|\mid$ satisfies the axioms of a norm which are:

$$
\begin{gathered}
|z+w| \leq|z|+|w| \\
|z| \geq 0 \text { for all } z \\
|z|=0 \text { if and only if } z=0 \\
|\alpha z|=|\alpha||z|
\end{gathered}
$$

The only one of these axioms of a norm which is not completely obvious is the first one, the triangle inequality. Let $z=x+i y$ and $w=u+i v$

$$
\begin{aligned}
|z+w|^{2} & =(z+w)(\bar{z}+\bar{w})=|z|^{2}+|w|^{2}+2 \operatorname{Re}(z \bar{w}) \\
& \leq|z|^{2}+|w|^{2}+2|(z \bar{w})|=(|z|+|w|)^{2}
\end{aligned}
$$

and this verifies the triangle inequality.
Definition 49.0.3 An infinite sum of complex numbers is defined as the limit of the sequence of partial sums. Thus,

$$
\sum_{k=1}^{\infty} a_{k} \equiv \lim _{n \rightarrow \infty} \sum_{k=1}^{n} a_{k}
$$

Just as in the case of sums of real numbers, an infinite sum converges if and only if the sequence of partial sums is a Cauchy sequence.

From now on, when $f$ is a function of a complex variable, it will be assumed that $f$ has values in $X$, a complex Banach space. Usually in complex analysis courses, $f$ has values in $\mathbb{C}$ but there are many important theorems which don't require this so I will leave it fairly general for a while. Later the functions will have values in $\mathbb{C}$. If you are only interested in this case, think $\mathbb{C}$ whenever you see $X$.

Definition 49.0.4 A sequence of functions of a complex variable, $\left\{f_{n}\right\}$ converges uniformly to a function, $g$ for $z \in S$ iffor every $\varepsilon>0$ there exists $N_{\varepsilon}$ such that if $n>N_{\varepsilon}$, then

$$
\left\|f_{n}(z)-g(z)\right\|<\varepsilon
$$

for all $z \in S$. The infinite sum $\sum_{k=1}^{\infty} f_{n}$ converges uniformly on $S$ if the partial sums converge uniformly on $S$. Here $\|\cdot\|$ refers to the norm in $X$, the Banach space in which $f$ has its values.

The following proposition is also a routine application of the above definition. Neither the definition nor this proposition say anything new.

Proposition 49.0.5 A sequence of functions, $\left\{f_{n}\right\}$ defined on a set $S$, converges uniformly to some function, $g$ if and only iffor all $\varepsilon>0$ there exists $N_{\varepsilon}$ such that whenever $m, n>N_{\varepsilon}$,

$$
\left\|f_{n}-f_{m}\right\|_{\infty}<\varepsilon
$$

Here $\|f\|_{\infty} \equiv \sup \{\|f(z)\|: z \in S\}$.
Just as in the case of functions of a real variable, one of the important theorems is the Weierstrass M test. Again, there is nothing new here. It is just a review of earlier material.

Theorem 49.0.6 Let $\left\{f_{n}\right\}$ be a sequence of complex valued functions defined on $S \subseteq \mathbb{C}$. Suppose there exists $M_{n}$ such that $\left\|f_{n}\right\|_{\infty}<M_{n}$ and $\sum M_{n}$ converges. Then $\sum f_{n}$ converges uniformly on $S$.

Proof: Let $z \in S$. Then letting $m<n$

$$
\left\|\sum_{k=1}^{n} f_{k}(z)-\sum_{k=1}^{m} f_{k}(z)\right\| \leq \sum_{k=m+1}^{n}\left\|f_{k}(z)\right\| \leq \sum_{k=m+1}^{\infty} M_{k}<\varepsilon
$$

whenever $m$ is large enough. Therefore, the sequence of partial sums is uniformly Cauchy on $S$ and therefore, converges uniformly to $\sum_{k=1}^{\infty} f_{k}(z)$ on $S$.

### 49.1 The Extended Complex Plane

The set of complex numbers has already been considered along with the topology of $\mathbb{C}$ which is nothing but the topology of $\mathbb{R}^{2}$. Thus, for $z_{n}=x_{n}+i y_{n}, z_{n} \rightarrow z \equiv x+i y$ if and only if $x_{n} \rightarrow x$ and $y_{n} \rightarrow y$. The norm in $\mathbb{C}$ is given by

$$
|x+i y| \equiv((x+i y)(x-i y))^{1 / 2}=\left(x^{2}+y^{2}\right)^{1 / 2}
$$

which is just the usual norm in $\mathbb{R}^{2}$ identifying $(x, y)$ with $x+i y$. Therefore, $\mathbb{C}$ is a complete metric space topologically like $\mathbb{R}^{2}$ and so the Heine Borel theorem that compact sets are those which are closed and bounded is valid. Thus, as far as topology is concerned, there is nothing new about $\mathbb{C}$.

The extended complex plane, denoted by $\widehat{\mathbb{C}}$, consists of the complex plane, $\mathbb{C}$ along with another point not in $\mathbb{C}$ known as $\infty$. For example, $\infty$ could be any point in $\mathbb{R}^{3}$ with nonzero third component. A sequence of complex numbers, $z_{n}$, converges to $\infty$ if, whenever $K$ is a compact set in $\mathbb{C}$, there exists a number, $N$ such that for all $n>N, z_{n} \notin K$. Since compact sets in $\mathbb{C}$ are closed and bounded, this is equivalent to saying that for all $R>0$, there exists $N$ such that if $n>N$, then $z_{n} \notin B(0, R)$ which is the same as saying $\lim _{n \rightarrow \infty}\left|z_{n}\right|=\infty$ where this last symbol has the same meaning as it does in calculus.

A geometric way of understanding this in terms of more familiar objects involves a concept known as the Riemann sphere.

Consider the unit sphere, $S^{2}$ given by $(z-1)^{2}+y^{2}+x^{2}=1$. Define a map from the complex plane to the surface of this sphere as follows. Extend a line from the point, $p$ in the complex plane to the point $(0,0,2)$ on the top of this sphere and let $\theta(p)$ denote the point of this sphere which the line intersects. Define $\theta(\infty) \equiv(0,0,2)$.

Then $\theta^{-1}$ is sometimes called sterographic projection. The mapping $\theta$ is clearly continuous because it takes converging sequences, to converging sequences. Furthermore, it is clear that $\theta^{-1}$ is also continuous. In terms of the extended complex plane, $\widehat{\mathbb{C}}$, a sequence, $z_{n}$ converges to $\infty$ if and only if $\theta z_{n}$ converges to $(0,0,2)$ and a sequence, $z_{n}$ converges to $z \in \mathbb{C}$ if and only if $\theta\left(z_{n}\right) \rightarrow \theta(z)$.

In fact this makes it easy to define a metric on $\widehat{\mathbb{C}}$.

Definition 49.1.1 Let $z, w \in \widehat{\mathbb{C}}$ including possibly $w=\infty$. Then let $d(x, w) \equiv|\theta(z)-\theta(w)|$ where this last distance is the usual distance measured in $\mathbb{R}^{3}$.

Theorem 49.1.2 $(\widehat{\mathbb{C}}, d)$ is a compact, hence complete metric space.

Proof: Suppose $\left\{z_{n}\right\}$ is a sequence in $\widehat{\mathbb{C}}$. This means $\left\{\theta\left(z_{n}\right)\right\}$ is a sequence in $S^{2}$ which is compact. Therefore, there exists a subsequence, $\left\{\theta z_{n_{k}}\right\}$ and a point, $z \in S^{2}$ such that $\theta z_{n_{k}} \rightarrow \theta z$ in $S^{2}$ which implies immediately that $d\left(z_{n_{k}}, z\right) \rightarrow 0$. A compact metric space must be complete.

### 49.2 Exercises

1. Prove the root test for series of complex numbers. If $a_{k} \in \mathbb{C}$ and $r \equiv \lim \sup _{n \rightarrow \infty}\left|a_{n}\right|^{1 / n}$ then

$$
\sum_{k=0}^{\infty} a_{k}\left\{\begin{array}{l}
\text { converges absolutely if } r<1 \\
\text { diverges if } r>1 \\
\text { test fails if } r=1
\end{array}\right.
$$

2. Does $\lim _{n \rightarrow \infty} n\left(\frac{2+i}{3}\right)^{n}$ exist? Tell why and find the limit if it does exist.
3. Let $A_{0}=0$ and let $A_{n} \equiv \sum_{k=1}^{n} a_{k}$ if $n>0$. Prove the partial summation formula,

$$
\sum_{k=p}^{q} a_{k} b_{k}=A_{q} b_{q}-A_{p-1} b_{p}+\sum_{k=p}^{q-1} A_{k}\left(b_{k}-b_{k+1}\right)
$$

Now using this formula, suppose $\left\{b_{n}\right\}$ is a sequence of real numbers which converges to 0 and is decreasing. Determine those values of $\omega$ such that $|\omega|=1$ and $\sum_{k=1}^{\infty} b_{k} \omega^{k}$ converges.
4. Let $f: U \subseteq \mathbb{C} \rightarrow \mathbb{C}$ be given by $f(x+i y)=u(x, y)+i v(x, y)$. Show $f$ is continuous on $U$ if and only if $u: U \rightarrow \mathbb{R}$ and $v: U \rightarrow \mathbb{R}$ are both continuous.

## Chapter 50

## Riemann Stieltjes Integrals

In the theory of functions of a complex variable, the most important results are those involving contour integration. I will base this on the notion of Riemann Stieltjes integrals as in [32], [95], and [65]. The Riemann Stieltjes integral is a generalization of the usual Riemann integral and requires the concept of a function of bounded variation.

Definition 50.0.1 Let $\gamma:[a, b] \rightarrow \mathbb{C}$ be a function. Then $\gamma$ is of bounded variation if

$$
\sup \left\{\sum_{i=1}^{n}\left|\gamma\left(t_{i}\right)-\gamma\left(t_{i-1}\right)\right|: a=t_{0}<\cdots<t_{n}=b\right\} \equiv V(\gamma,[a, b])<\infty
$$

where the sums are taken over all possible lists, $\left\{a=t_{0}<\cdots<t_{n}=b\right\}$. The set of points $\gamma([a, b])$ will also be denoted by $\gamma^{*}$.

The idea is that it makes sense to talk of the length of the curve $\gamma([a, b])$, defined as $V(\gamma,[a, b])$. For this reason, in the case that $\gamma$ is continuous, such an image of a bounded variation function is called a rectifiable curve.

Definition 50.0.2 Let $\gamma:[a, b] \rightarrow \mathbb{C}$ be of bounded variation and let $f: \gamma^{*} \rightarrow X$. Letting $\mathscr{P} \equiv\left\{t_{0}, \cdots, t_{n}\right\}$ where $a=t_{0}<t_{1}<\cdots<t_{n}=b$, define

$$
\|\mathscr{P}\| \equiv \max \left\{\left|t_{j}-t_{j-1}\right|: j=1, \cdots, n\right\}
$$

and the Riemann Steiltjes sum by

$$
S(\mathscr{P}) \equiv \sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)
$$

where $\tau_{j} \in\left[t_{j-1}, t_{j}\right]$. (Note this notation is a little sloppy because it does not identify the specific point, $\tau_{j}$ used. It is understood that this point is arbitrary.) Define $\int_{\gamma} f d \gamma$ as the unique number which satisfies the following condition. For all $\varepsilon>0$ there exists a $\delta>0$ such that if $\|\mathscr{P}\| \leq \delta$, then

$$
\left|\int_{\gamma} f d \gamma-S(\mathscr{P})\right|<\varepsilon
$$

Sometimes this is written as

$$
\int_{\gamma} f d \gamma \equiv \lim _{\|\mathscr{P}\| \rightarrow 0} S(\mathscr{P})
$$

The set of points in the curve, $\gamma([a, b])$ will be denoted sometimes by $\gamma^{*}$.
Then $\gamma^{*}$ is a set of points in $\mathbb{C}$ and as $t$ moves from $a$ to $b, \gamma(t)$ moves from $\gamma(a)$ to $\gamma(b)$. Thus $\gamma^{*}$ has a first point and a last point. If $\phi:[c, d] \rightarrow[a, b]$ is a continuous nondecreasing function, then $\gamma \circ \phi:[c, d] \rightarrow \mathbb{C}$ is also of bounded variation and yields the same set of points in $\mathbb{C}$ with the same first and last points.

Theorem 50.0.3 Let $\phi$ and $\gamma$ be as just described. Then assuming that

$$
\int_{\gamma} f d \gamma
$$

exists, so does

$$
\int_{\gamma \circ \phi} f d(\gamma \circ \phi)
$$

and

$$
\begin{equation*}
\int_{\gamma} f d \gamma=\int_{\gamma \circ \phi} f d(\gamma \circ \phi) \tag{50.0.1}
\end{equation*}
$$

Proof: There exists $\delta>0$ such that if $\mathscr{P}$ is a partition of $[a, b]$ such that $\|\mathscr{P}\|<\delta$, then

$$
\left|\int_{\gamma} f d \gamma-S(\mathscr{P})\right|<\varepsilon
$$

By continuity of $\phi$, there exists $\sigma>0$ such that if $\mathscr{Q}$ is a partition of $[c, d]$ with $\|\mathscr{Q}\|<$ $\sigma, \mathscr{Q}=\left\{s_{0}, \cdots, s_{n}\right\}$, then $\left|\phi\left(s_{j}\right)-\phi\left(s_{j-1}\right)\right|<\delta$. Thus letting $\mathscr{P}$ denote the points in $[a, b]$ given by $\phi\left(s_{j}\right)$ for $s_{j} \in \mathscr{Q}$, it follows that $\|\mathscr{P}\|<\delta$ and so

$$
\left|\int_{\gamma} f d \gamma-\sum_{j=1}^{n} f\left(\gamma\left(\phi\left(\tau_{j}\right)\right)\right)\left(\gamma\left(\phi\left(s_{j}\right)\right)-\gamma\left(\phi\left(s_{j-1}\right)\right)\right)\right|<\varepsilon
$$

where $\tau_{j} \in\left[s_{j-1}, s_{j}\right]$. Therefore, from the definition 50.0.1 holds and

$$
\int_{\gamma \circ \phi} f d(\gamma \circ \phi)
$$

exists.
This theorem shows that $\int_{\gamma} f d \gamma$ is independent of the particular $\gamma$ used in its computation to the extent that if $\phi$ is any nondecreasing continuous function from another interval, $[c, d]$, mapping to $[a, b]$, then the same value is obtained by replacing $\gamma$ with $\gamma \circ \phi$.

The fundamental result in this subject is the following theorem. We have in mind functions which have values in $\mathbb{C}$ but there is no change if the functions have values in any complete normed vector space.

Theorem 50.0.4 Let $f: \gamma^{*} \rightarrow X$ be continuous and let $\gamma:[a, b] \rightarrow \mathbb{C}$ be continuous and of bounded variation. Then $\int_{\gamma} f d \gamma$ exists. Also letting $\delta_{m}>0$ be such that $|t-s|<\delta_{m}$ implies $\|f(\gamma(t))-f(\gamma(s))\|<\frac{1}{m}$,

$$
\left|\int_{\gamma} f d \gamma-S(\mathscr{P})\right| \leq \frac{2 V(\gamma,[a, b])}{m}
$$

whenever $\|\mathscr{P}\|<\delta_{m}$.

Proof: The function, $f \circ \gamma$, is uniformly continuous because it is defined on a compact set. Therefore, there exists a decreasing sequence of positive numbers, $\left\{\boldsymbol{\delta}_{m}\right\}$ such that if $|s-t|<\delta_{m}$, then

$$
|f(\gamma(t))-f(\gamma(s))|<\frac{1}{m}
$$

Let

$$
F_{m} \equiv \overline{\left\{S(\mathscr{P}):\|\mathscr{P}\|<\delta_{m}\right\}} .
$$

Thus $F_{m}$ is a closed set. (The symbol, $S(\mathscr{P})$ in the above definition, means to include all sums corresponding to $\mathscr{P}$ for any choice of $\tau_{j}$.) It is shown that

$$
\begin{equation*}
\operatorname{diam}\left(F_{m}\right) \leq \frac{2 V(\gamma,[a, b])}{m} \tag{50.0.2}
\end{equation*}
$$

and then it will follow there exists a unique point, $I \in \cap_{m=1}^{\infty} F_{m}$. This is because $X$ is complete. It will then follow $I=\int_{\gamma} f(t) d \gamma(t)$. To verify 50.0 .2 , it suffices to verify that whenever $\mathscr{P}$ and $\mathscr{Q}$ are partitions satisfying $\|\mathscr{P}\|<\delta_{m}$ and $\|\mathscr{Q}\|<\delta_{m}$,

$$
\begin{equation*}
|S(\mathscr{P})-S(\mathscr{Q})| \leq \frac{2}{m} V(\gamma,[a, b]) \tag{50.0.3}
\end{equation*}
$$

Suppose $\|\mathscr{P}\|<\delta_{m}$ and $\mathscr{Q} \supseteq \mathscr{P}$. Then also $\|\mathscr{Q}\|<\delta_{m}$. To begin with, suppose that $\mathscr{P} \equiv\left\{t_{0}, \cdots, t_{p}, \cdots, t_{n}\right\}$ and $\mathscr{Q} \equiv\left\{t_{0}, \cdots, t_{p-1}, t^{*}, t_{p}, \cdots, t_{n}\right\}$. Thus $\mathscr{Q}$ contains only one more point than $\mathscr{P}$. Letting $S(\mathscr{Q})$ and $S(\mathscr{P})$ be Riemann Steiltjes sums,

$$
\begin{gathered}
S(\mathscr{Q}) \equiv \sum_{j=1}^{p-1} f\left(\gamma\left(\sigma_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)+f\left(\gamma\left(\sigma_{*}\right)\right)\left(\gamma\left(t^{*}\right)-\gamma\left(t_{p-1}\right)\right) \\
+f\left(\gamma\left(\sigma^{*}\right)\right)\left(\gamma\left(t_{p}\right)-\gamma\left(t^{*}\right)\right)+\sum_{j=p+1}^{n} f\left(\gamma\left(\sigma_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right) \\
S(\mathscr{P}) \equiv \sum_{j=1}^{p-1} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)+ \\
\overbrace{f\left(\gamma\left(\tau_{p}\right)\right)\left(\gamma\left(t^{*}\right)-\gamma\left(t_{p-1}\right)\right)+f\left(\gamma\left(\tau_{p}\right)\right)\left(\gamma\left(t_{p}\right)-\gamma\left(t^{*}\right)\right)}^{\left.=f\left(\tau_{p}\right)\right)\left(\gamma\left(t_{p}\right)-\gamma\left(t_{p-1}\right)\right)} \\
\quad+\sum_{j=p+1}^{n} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right) .
\end{gathered}
$$

Therefore,

$$
\begin{gather*}
|S(\mathscr{P})-S(\mathscr{Q})| \leq \sum_{j=1}^{p-1} \frac{1}{m}\left|\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right|+\frac{1}{m}\left|\gamma\left(t^{*}\right)-\gamma\left(t_{p-1}\right)\right|+ \\
\frac{1}{m}\left|\gamma\left(t_{p}\right)-\gamma\left(t^{*}\right)\right|+\sum_{j=p+1}^{n} \frac{1}{m}\left|\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right| \leq \frac{1}{m} V(\gamma,[a, b]) \tag{50.0.4}
\end{gather*}
$$

Clearly the extreme inequalities would be valid in 50.0 .4 if $\mathscr{Q}$ had more than one extra point. You simply do the above trick more than one time. Let $S(\mathscr{P})$ and $S(\mathscr{Q})$ be Riemann Steiltjes sums for which $\|\mathscr{P}\|$ and $\|\mathscr{Q}\|$ are less than $\delta_{m}$ and let $\mathscr{R} \equiv \mathscr{P} \cup \mathscr{Q}$. Then from what was just observed,

$$
|S(\mathscr{P})-S(\mathscr{Q})| \leq|S(\mathscr{P})-S(\mathscr{R})|+|S(\mathscr{R})-S(\mathscr{Q})| \leq \frac{2}{m} V(\gamma,[a, b])
$$

and this shows 50.0.3 which proves 50.0.2. Therefore, there exists a unique complex number, $I \in \cap_{m=1}^{\infty} F_{m}$ which satisfies the definition of $\int_{\gamma} f d \gamma$. This proves the theorem.

The following theorem follows easily from the above definitions and theorem.
Theorem 50.0.5 Let $f \in C\left(\gamma^{*}\right)$ and let $\gamma:[a, b] \rightarrow \mathbb{C}$ be of bounded variation and continuous. Let

$$
\begin{equation*}
M \geq \max \{\|f \circ \gamma(t)\|: t \in[a, b]\} \tag{50.0.5}
\end{equation*}
$$

Then

$$
\begin{equation*}
\left\|\int_{\gamma} f d \gamma\right\| \leq M V(\gamma,[a, b]) \tag{50.0.6}
\end{equation*}
$$

Also if $\left\{f_{n}\right\}$ is a sequence of functions of $C\left(\gamma^{*}\right)$ which is converging uniformly to the function, $f$ on $\gamma^{*}$, then

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{\gamma} f_{n} d \gamma=\int_{\gamma} f d \gamma \tag{50.0.7}
\end{equation*}
$$

Proof: Let 50.0.5 hold. From the proof of the above theorem, when $\|\mathscr{P}\|<\delta_{m}$,

$$
\left\|\int_{\gamma} f d \gamma-S(\mathscr{P})\right\| \leq \frac{2}{m} V(\gamma,[a, b])
$$

and so

$$
\begin{aligned}
& \left\|\int_{\gamma} f d \gamma\right\| \leq\|S(\mathscr{P})\|+\frac{2}{m} V(\gamma,[a, b]) \\
\leq & \sum_{j=1}^{n} M\left|\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right|+\frac{2}{m} V(\gamma,[a, b]) \\
\leq & M V(\gamma,[a, b])+\frac{2}{m} V(\gamma,[a, b])
\end{aligned}
$$

This proves 50.0 .6 since $m$ is arbitrary. To verify 50.0 .7 use the above inequality to write

$$
\begin{aligned}
\left\|\int_{\gamma} f d \gamma-\int_{\gamma} f_{n} d \gamma\right\|=\left\|\int_{\gamma}\left(f-f_{n}\right) d \gamma(t)\right\| \\
\leq \max \left\{\left\|f \circ \gamma(t)-f_{n} \circ \gamma(t)\right\|: t \in[a, b]\right\} V(\gamma,[a, b]) .
\end{aligned}
$$

Since the convergence is assumed to be uniform, this proves 50.0.7.
It turns out to be much easier to evaluate such integrals in the case where $\gamma$ is also $C^{1}([a, b])$. The following theorem about approximation will be very useful but first here is an easy lemma.

Lemma 50.0.6 Let $\gamma:[a, b] \rightarrow \mathbb{C}$ be in $C^{1}([a, b])$. Then $V(\gamma,[a, b])<\infty$ so $\gamma$ is of bounded variation.

Proof: This follows from the following

$$
\begin{aligned}
\sum_{j=1}^{n}\left|\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right| & =\sum_{j=1}^{n}\left|\int_{t_{j-1}}^{t_{j}} \gamma^{\prime}(s) d s\right| \\
& \leq \sum_{j=1}^{n} \int_{t_{j-1}}^{t_{j}}\left|\gamma^{\prime}(s)\right| d s \\
& \leq \sum_{j=1}^{n} \int_{t_{j-1}}^{t_{j}}\left\|\gamma^{\prime}\right\|_{\infty} d s \\
& =\left\|\gamma^{\prime}\right\|_{\infty}(b-a)
\end{aligned}
$$

Therefore it follows $V(\gamma,[a, b]) \leq\left\|\gamma^{\prime}\right\|_{\infty}(b-a)$. Here $\|\gamma\|_{\infty}=\max \{|\gamma(t)|: t \in[a, b]\}$.
Theorem 50.0.7 Let $\gamma:[a, b] \rightarrow \mathbb{C}$ be continuous and of bounded variation. Let $\Omega$ be an open set containing $\gamma^{*}$ and let $f: \Omega \times K \rightarrow X$ be continuous for $K$ a compact set in $\mathbb{C}$, and let $\varepsilon>0$ be given. Then there exists $\eta:[a, b] \rightarrow \mathbb{C}$ such that $\eta(a)=\gamma(a), \gamma(b)=\eta(b)$, $\eta \in C^{1}([a, b])$, and

$$
\begin{gather*}
\|\gamma-\eta\|<\varepsilon  \tag{50.0.8}\\
\left|\int_{\gamma} f(\cdot, z) d \gamma-\int_{\eta} f(\cdot, z) d \eta\right|<\varepsilon  \tag{50.0.9}\\
V(\eta,[a, b]) \leq V(\gamma,[a, b]) \tag{50.0.10}
\end{gather*}
$$

where $\|\gamma-\eta\| \equiv \max \{|\gamma(t)-\eta(t)|: t \in[a, b]\}$.
Proof: Extend $\gamma$ to be defined on all $\mathbb{R}$ according to $\gamma(t)=\gamma(a)$ if $t<a$ and $\gamma(t)=\gamma(b)$ if $t>b$. Now define

$$
\gamma_{h}(t) \equiv \frac{1}{2 h} \int_{-2 h+t+\frac{2 h}{(b-a)}(t-a)}^{t+\frac{2 h}{(b-a)}(t-a)} \gamma(s) d s
$$

where the integral is defined in the obvious way. That is,

$$
\int_{a}^{b} \alpha(t)+i \beta(t) d t \equiv \int_{a}^{b} \alpha(t) d t+i \int_{a}^{b} \beta(t) d t
$$

Therefore,

$$
\begin{aligned}
& \gamma_{h}(b)=\frac{1}{2 h} \int_{b}^{b+2 h} \gamma(s) d s=\gamma(b) \\
& \gamma_{h}(a)=\frac{1}{2 h} \int_{a-2 h}^{a} \gamma(s) d s=\gamma(a)
\end{aligned}
$$

Also, because of continuity of $\gamma$ and the fundamental theorem of calculus,

$$
\gamma_{h}^{\prime}(t)=\frac{1}{2 h}\left\{\gamma\left(t+\frac{2 h}{b-a}(t-a)\right)\left(1+\frac{2 h}{b-a}\right)-\right.
$$

$$
\left.\gamma\left(-2 h+t+\frac{2 h}{b-a}(t-a)\right)\left(1+\frac{2 h}{b-a}\right)\right\}
$$

and so $\gamma_{h} \in C^{1}([a, b])$. The following lemma is significant.
Lemma 50.0.8 $V\left(\gamma_{h},[a, b]\right) \leq V(\gamma,[a, b])$.
Proof: Let $a=t_{0}<t_{1}<\cdots<t_{n}=b$. Then using the definition of $\gamma_{h}$ and changing the variables to make all integrals over $[0,2 h]$,

$$
\begin{gathered}
\sum_{j=1}^{n}\left|\gamma_{h}\left(t_{j}\right)-\gamma_{h}\left(t_{j-1}\right)\right|= \\
\sum_{j=1}^{n} \left\lvert\, \frac{1}{2 h} \int_{0}^{2 h}\left[\gamma\left(s-2 h+t_{j}+\frac{2 h}{b-a}\left(t_{j}-a\right)\right)-\right.\right. \\
\left.\gamma\left(s-2 h+t_{j-1}+\frac{2 h}{b-a}\left(t_{j-1}-a\right)\right)\right] \mid \\
\leq \frac{1}{2 h} \int_{0}^{2 h} \sum_{j=1}^{n} \left\lvert\, \gamma\left(s-2 h+t_{j}+\frac{2 h}{b-a}\left(t_{j}-a\right)\right)-\right. \\
\left.\gamma\left(s-2 h+t_{j-1}+\frac{2 h}{b-a}\left(t_{j-1}-a\right)\right) \right\rvert\, d s
\end{gathered}
$$

For a given $s \in[0,2 h]$, the points, $s-2 h+t_{j}+\frac{2 h}{b-a}\left(t_{j}-a\right)$ for $j=1, \cdots, n$ form an increasing list of points in the interval $[a-2 h, b+2 h]$ and so the integrand is bounded above by $V(\gamma,[a-2 h, b+2 h])=V(\gamma,[a, b])$. It follows

$$
\sum_{j=1}^{n}\left|\gamma_{h}\left(t_{j}\right)-\gamma_{h}\left(t_{j-1}\right)\right| \leq V(\gamma,[a, b])
$$

which proves the lemma.
With this lemma the proof of the theorem can be completed without too much trouble. Let $H$ be an open set containing $\gamma^{*}$ such that $\bar{H}$ is a compact subset of $\Omega$. Let $0<\varepsilon<$ $\operatorname{dist}\left(\gamma^{*}, H^{C}\right)$. Then there exists $\delta_{1}$ such that if $h<\delta_{1}$, then for all $t$,

$$
\begin{align*}
\left|\gamma(t)-\gamma_{h}(t)\right| & \leq \frac{1}{2 h} \int_{-2 h+t+\frac{2 h}{(b-a)}(t-a)}^{t+\frac{2 h}{(b-a)}(t-a)}|\gamma(s)-\gamma(t)| d s \\
& <\frac{1}{2 h} \int_{-2 h+t+\frac{2 h}{(b-a)}(t-a)}^{t+\frac{2 h}{(b-a)}(t-a)} \varepsilon d s=\varepsilon \tag{50.0.11}
\end{align*}
$$

due to the uniform continuity of $\gamma$. This proves 50.0.8.
From 50.0.2 and the above lemma, there exists $\boldsymbol{\delta}_{2}$ such that if $\|\mathscr{P}\|<\boldsymbol{\delta}_{2}$, then for all $z \in K$,

$$
\left\|\int_{\gamma} f(\cdot, z) d \gamma(t)-S(\mathscr{P})\right\|<\frac{\varepsilon}{3},\left\|\int_{\gamma_{h}} f(\cdot, z) d \gamma_{h}(t)-S_{h}(\mathscr{P})\right\|<\frac{\varepsilon}{3}
$$

for all $h$. Here $S(\mathscr{P})$ is a Riemann Steiltjes sum of the form

$$
\sum_{i=1}^{n} f\left(\gamma\left(\tau_{i}\right), z\right)\left(\gamma\left(t_{i}\right)-\gamma\left(t_{i-1}\right)\right)
$$

and $S_{h}(\mathscr{P})$ is a similar Riemann Steiltjes sum taken with respect to $\gamma_{h}$ instead of $\gamma$. Because of 50.0.11 $\gamma_{h}(t)$ has values in $H \subseteq \Omega$. Therefore, fix the partition, $\mathscr{P}$, and choose $h$ small enough that in addition to this, the following inequality is valid for all $z \in K$.

$$
\left|S(\mathscr{P})-S_{h}(\mathscr{P})\right|<\frac{\varepsilon}{3}
$$

This is possible because of 50.0 .11 and the uniform continuity of $f$ on $\bar{H} \times K$. It follows

$$
\begin{gathered}
\left\|\int_{\gamma} f(\cdot, z) d \gamma(t)-\int_{\gamma_{h}} f(\cdot, z) d \gamma_{h}(t)\right\| \leq \\
\left\|\int_{\gamma} f(\cdot, z) d \gamma(t)-S(\mathscr{P})\right\|+\left\|S(\mathscr{P})-S_{h}(\mathscr{P})\right\| \\
\quad+\left\|S_{h}(\mathscr{P})-\int_{\gamma_{h}} f(\cdot, z) d \gamma_{h}(t)\right\|<\varepsilon
\end{gathered}
$$

Formula 50.0.10 follows from the lemma. This proves the theorem.
Of course the same result is obtained without the explicit dependence of $f$ on $z$.
This is a very useful theorem because if $\gamma$ is $C^{1}([a, b])$, it is easy to calculate $\int_{\gamma} f d \gamma$ and the above theorem allows a reduction to the case where $\gamma$ is $C^{1}$. The next theorem shows how easy it is to compute these integrals in the case where $\gamma$ is $C^{1}$. First note that if $f$ is continuous and $\gamma \in C^{1}([a, b])$, then by Lemma 50.0.6 and the fundamental existence theorem, Theorem 50.0.4, $\int_{\gamma} f d \gamma$ exists.

Theorem 50.0.9 If $f: \gamma^{*} \rightarrow X$ is continuous and $\gamma:[a, b] \rightarrow \mathbb{C}$ is in $C^{1}([a, b])$, then

$$
\begin{equation*}
\int_{\gamma} f d \gamma=\int_{a}^{b} f(\gamma(t)) \gamma^{\prime}(t) d t \tag{50.0.12}
\end{equation*}
$$

Proof: Let $\mathscr{P}$ be a partition of $[a, b], \mathscr{P}=\left\{t_{0}, \cdots, t_{n}\right\}$ and $\|\mathscr{P}\|$ is small enough that whenever $|t-s|<\|\mathscr{P}\|$,

$$
\begin{equation*}
|f(\gamma(t))-f(\gamma(s))|<\varepsilon \tag{50.0.13}
\end{equation*}
$$

and

$$
\left\|\int_{\gamma} f d \gamma-\sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)\right\|<\varepsilon
$$

Now

$$
\sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)=\int_{a}^{b} \sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right) \mathscr{X}_{\left[t_{j-1}, t_{j}\right]}(s) \gamma^{\prime}(s) d s
$$

where here

$$
\mathscr{X}_{[a, b]}(s) \equiv\left\{\begin{array}{l}
1 \text { if } s \in[p, q] \\
0 \text { if } s \notin[p, q]
\end{array} .\right.
$$

Also,

$$
\int_{a}^{b} f(\gamma(s)) \gamma^{\prime}(s) d s=\int_{a}^{b} \sum_{j=1}^{n} f(\gamma(s)) \mathscr{X}_{\left[t_{j-1}, t_{j}\right]}(s) \gamma^{\prime}(s) d s
$$

and thanks to 50.0.13,

$$
\left.\begin{aligned}
& \|\overbrace{\int_{a}^{b} \sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right) \mathscr{X}_{\left[t_{j-1}, t_{j}\right]}(s) \gamma(s) d s}^{=\sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)}-\overbrace{\int_{a}^{b} \sum_{j=1}^{n} f(\gamma(s)) \mathscr{X}_{\left[t_{j-1}, t_{j}\right]}(s) \gamma^{\prime}(s) d s}^{=\int_{a}^{b} f(\gamma(s)) \gamma^{\prime}(s) d s}\|
\end{aligned} \right\rvert\,
$$

It follows that

$$
\begin{aligned}
& \left\|\int_{\gamma} f d \gamma-\int_{a}^{b} f(\gamma(s)) \gamma^{\prime}(s) d s\right\| \leq\left\|\int_{\gamma} f d \gamma-\sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)\right\| \\
+ & \left\|\sum_{j=1}^{n} f\left(\gamma\left(\tau_{j}\right)\right)\left(\gamma\left(t_{j}\right)-\gamma\left(t_{j-1}\right)\right)-\int_{a}^{b} f(\gamma(s)) \gamma^{\prime}(s) d s\right\| \leq \varepsilon\left\|\gamma^{\prime}\right\|_{\infty}(b-a)+\varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this verifies 50.0.12.
Definition 50.0.10 Let $\Omega$ be an open subset of $\mathbb{C}$ and let $\gamma:[a, b] \rightarrow \Omega$ be a continuous function with bounded variation $f: \Omega \rightarrow X$ be a continuous function. Then the following notation is more customary.

$$
\int_{\gamma} f(z) d z \equiv \int_{\gamma} f d \gamma
$$

The expression, $\int_{\gamma} f(z) d z$, is called a contour integral and $\gamma$ is referred to as the contour. A function $f: \Omega \rightarrow X$ for $\Omega$ an open set in $\mathbb{C}$ has a primitive if there exists a function, $F$, the primitive, such that $F^{\prime}(z)=f(z)$. Thus $F$ is just an antiderivative. Also if $\gamma_{k}:\left[a_{k}, b_{k}\right] \rightarrow \mathbb{C}$ is continuous and of bounded variation, for $k=1, \cdots, m$ and $\gamma_{k}\left(b_{k}\right)=\gamma_{k+1}\left(a_{k}\right)$, define

$$
\begin{equation*}
\int_{\sum_{k=1}^{m} \gamma_{k}} f(z) d z \equiv \sum_{k=1}^{m} \int_{\gamma_{k}} f(z) d z \tag{50.0.14}
\end{equation*}
$$

In addition to this, for $\gamma:[a, b] \rightarrow \mathbb{C}$,
define $-\gamma:[a, b] \rightarrow \mathbb{C}$ by $-\gamma(t) \equiv \gamma(b+a-t)$. Thus $\gamma$ simply traces out the points of $\gamma^{*}$ in the opposite order.

The following lemma is useful and follows quickly from Theorem 50.0.3.
Lemma 50.0.11 In the above definition, there exists a continuous bounded variation function, $\gamma$ defined on some closed interval, $[c, d]$, such that $\gamma([c, d])=\cup_{k=1}^{m} \gamma_{k}\left(\left[a_{k}, b_{k}\right]\right)$ and $\gamma(c)=\gamma_{1}\left(a_{1}\right)$ while $\gamma(d)=\gamma_{m}\left(b_{m}\right)$. Furthermore,

$$
\int_{\gamma} f(z) d z=\sum_{k=1}^{m} \int_{\gamma_{k}} f(z) d z
$$

If $\gamma:[a, b] \rightarrow \mathbb{C}$ is of bounded variation and continuous, then

$$
\int_{\gamma} f(z) d z=-\int_{-\gamma} f(z) d z
$$

Re stating Theorem 50.0.7 with the new notation in the above definition,
Theorem 50.0.12 Let $K$ be a compact set in $\mathbb{C}$ and let $f: \Omega \times K \rightarrow X$ be continuous for $\Omega$ an open set in $\mathbb{C}$. Also let $\gamma:[a, b] \rightarrow \Omega$ be continuous with bounded variation. Then if $r>0$ is given, there exists $\eta:[a, b] \rightarrow \Omega$ such that $\eta(a)=\gamma(a), \eta(b)=\gamma(b), \eta$ is $C^{1}([a, b])$, and

$$
\left|\int_{\gamma} f(z, w) d z-\int_{\eta} f(z, w) d z\right|<r,\|\eta-\gamma\|<r
$$

It will be very important to consider which functions have primitives. It turns out, it is not enough for $f$ to be continuous in order to possess a primitive. This is in stark contrast to the situation for functions of a real variable in which the fundamental theorem of calculus will deliver a primitive for any continuous function. The reason for the interest in such functions is the following theorem and its corollary.

Theorem 50.0.13 Let $\gamma:[a, b] \rightarrow \mathbb{C}$ be continuous and of bounded variation. Also suppose $F^{\prime}(z)=f(z)$ for all $z \in \Omega$, an open set containing $\gamma^{*}$ and $f$ is continuous on $\Omega$. Then

$$
\int_{\gamma} f(z) d z=F(\gamma(b))-F(\gamma(a)) .
$$

Proof: By Theorem 50.0.12 there exists $\eta \in C^{1}([a, b])$ such that $\gamma(a)=\eta(a)$, and $\gamma(b)=\eta(b)$ such that

$$
\left\|\int_{\gamma} f(z) d z-\int_{\eta} f(z) d z\right\|<\varepsilon
$$

Then since $\eta$ is in $C^{1}([a, b])$,

$$
\begin{aligned}
\int_{\eta} f(z) d z & =\int_{a}^{b} f(\eta(t)) \eta^{\prime}(t) d t=\int_{a}^{b} \frac{d F(\eta(t))}{d t} d t \\
& =F(\eta(b))-F(\eta(a))=F(\gamma(b))-F(\gamma(a))
\end{aligned}
$$

Therefore,

$$
\left\|(F(\gamma(b))-F(\gamma(a)))-\int_{\gamma} f(z) d z\right\|<\varepsilon
$$

and since $\varepsilon>0$ is arbitrary, this proves the theorem.

Corollary 50.0.14 If $\gamma:[a, b] \rightarrow \mathbb{C}$ is continuous, has bounded variation, is a closed curve, $\gamma(a)=\gamma(b)$, and $\gamma^{*} \subseteq \Omega$ where $\Omega$ is an open set on which $F^{\prime}(z)=f(z)$, then

$$
\int_{\gamma} f(z) d z=0
$$

Another important result is a Fubini theorem for these contour integrals.
Theorem 50.0.15 Let $\gamma_{i}$ be continuous and bounded variation. Let $f$ be continuous on $\gamma_{1}^{*} \times \gamma_{2}^{*}$ having values in $X$ a complex complete normed linear space. Then

$$
\int_{\gamma_{1}} \int_{\gamma_{2}} f(z, w) d w d z=\int_{\gamma_{2}} \int_{\gamma_{1}} f(z, w) d z d w
$$

Proof: This follows quickly from the above lemma and the definition of the contour integral. Say $\gamma_{i}$ is defined on $\left[a_{i}, b_{i}\right]$. Let a partition of $\left[a_{1}, b_{1}\right]$ be denoted by $\left\{t_{0}, t_{1}, \cdots, t_{n}\right\}=$ $P_{1}$ and a partition of $\left[a_{2}, b_{2}\right]$ be denoted by $\left\{s_{0}, s_{1}, \cdots, s_{m}\right\}=P_{2}$.

$$
\begin{gathered}
\int_{\gamma_{1}} \int_{\gamma_{2}} f(z, w) d w d z=\sum_{i=1}^{n} \int_{\gamma_{1}\left(\left[t_{i-1}, t_{i}\right]\right)} \int_{\gamma_{2}} f(z, w) d w d z \\
=\sum_{i=1}^{n} \sum_{j=1}^{m} \int_{\gamma_{1}\left(\left[t_{i-1}, t_{i}\right]\right)} \int_{\gamma_{2}\left(\left[s_{j-1}, s_{j}\right]\right)} f(z, w) d w d z
\end{gathered}
$$

To save room, denote $\gamma_{1}\left(\left[t_{i-1}, t_{i}\right]\right)$ by $\gamma_{1 i}$ and $\gamma_{2}\left(\left[s_{j-1}, s_{j}\right]\right)$ by $\gamma_{2 j}$ Then if $\left\|P_{i}\right\|, i=1,2$ is small enough,

$$
\begin{gather*}
\left\|\int_{\gamma_{1 i}} \int_{\gamma_{2 j}} f(z, w) d w d z-\int_{\gamma_{1 i}} \int_{\gamma_{2 j}} f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) d w d z\right\| \\
=\left\|\int_{\gamma_{1 i}} \int_{\gamma_{2 j}}\left(f(z, w)-f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right)\right) d w d z\right\| \leq \\
\max \left(\left\|\int_{\gamma_{2 j}}\left(f(z, w)-f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right)\right) d w\right\|\right) V\left(\gamma_{1},\left[t_{i-1}, t_{i}\right]\right) \\
\leq \varepsilon V\left(\gamma_{2},\left[s_{j-1}, s_{j}\right]\right) V\left(\gamma_{1},\left[t_{i-1}, t_{i}\right]\right) \tag{50.0.15}
\end{gather*}
$$

Also from this theorem,

$$
\begin{gather*}
\left\|\int_{\gamma_{2 j}} \int_{\gamma_{1 i}} f(z, w) d z d w-\int_{\gamma_{2 j}} \int_{\gamma_{1 i}} f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) d z d w\right\| \\
\leq \max \left(\left\|\int_{\gamma_{1 i}}\left(f(z, w)-f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right)\right) d z\right\|\right) V\left(\gamma_{2},\left[s_{j-1}, s_{j}\right]\right) \\
\leq \varepsilon V\left(\gamma_{2},\left[s_{j-1}, s_{j}\right]\right) V\left(\gamma_{1},\left[t_{i-1}, t_{i}\right]\right) \tag{50.0.16}
\end{gather*}
$$

Now approximating with sums and using the definition, $\int_{\gamma_{1 i}} d z=\gamma_{1}\left(t_{j}\right)-\gamma_{1}\left(t_{j-1}\right)$ and so

$$
\begin{aligned}
& \int_{\gamma_{2 j}} \int_{\gamma_{1 i}} f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) d z d w=f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) \int_{\gamma_{2 j}} \int_{\gamma_{1 i}} d z d w \\
= & f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) \int_{\gamma_{1 i}} \int_{\gamma_{2 j}} d w d z=\int_{\gamma_{1 i}} \int_{\gamma_{2 j}} f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) d w d z(50.0 .17)
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
& \left\|\int_{\gamma_{1}} \int_{\gamma_{2}} f(z, w) d w d z-\int_{\gamma_{2}} \int_{\gamma_{1}} f(z, w) d z d w\right\| \leq \\
& \left\|\begin{array}{c}
\sum_{i=1}^{n} \sum_{j=1}^{m} \int_{\gamma_{1 i}} \int_{\gamma_{2 j}} f(z, w) d w d z \\
-\sum_{i=1}^{n} \sum_{j=1}^{m} \int_{\gamma_{1 i}} \int_{\gamma_{2 j}} f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) d w d z
\end{array}\right\| \\
& +\| \sum_{i=1}^{n} \sum_{j=1}^{m} \int_{\gamma_{1 i}} \int_{\gamma_{2 j}} f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) d w d z \\
& -\sum_{i=1}^{n} \sum_{j=1}^{m} \int_{\gamma_{2 j}} \int_{\gamma_{1 i}} f\left(\gamma_{1}\left(t_{i}\right), \gamma_{2}\left(s_{j}\right)\right) d z d w
\end{aligned} \| .
$$

From 50.0.17 the middle term is 0 . Thus, from the estimates 50.0.16 and 50.0.15,

$$
\begin{aligned}
& \left\|\int_{\gamma_{1}} \int_{\gamma_{2}} f(z, w) d w d z-\int_{\gamma_{2}} \int_{\gamma_{1}} f(z, w) d z d w\right\| \\
\leq & 2 \varepsilon V\left(\gamma_{2},\left[a_{2}, b_{2}\right]\right) V\left(\gamma_{1},\left[a_{1}, b_{1}\right]\right)
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, the two integrals are equal.

### 50.1 Exercises

1. Let $\gamma:[a, b] \rightarrow \mathbb{R}$ be increasing. Show $V(\gamma,[a, b])=\gamma(b)-\gamma(a)$.
2. Suppose $\gamma:[a, b] \rightarrow \mathbb{C}$ satisfies a Lipschitz condition, $|\gamma(t)-\gamma(s)| \leq K|s-t|$. Show $\gamma$ is of bounded variation and that $V(\gamma,[a, b]) \leq K|b-a|$.
3. $\gamma:\left[c_{0}, c_{m}\right] \rightarrow \mathbb{C}$ is piecewise smooth if there exist numbers, $c_{k}, k=1, \cdots, m$ such that $c_{0}<c_{1}<\cdots<c_{m-1}<c_{m}$ such that $\gamma$ is continuous and $\gamma:\left[c_{k}, c_{k+1}\right] \rightarrow \mathbb{C}$ is $C^{1}$. Show that such piecewise smooth functions are of bounded variation and give an estimate for $V\left(\gamma,\left[c_{0}, c_{m}\right]\right)$.
4. Let $\gamma:[0,2 \pi] \rightarrow \mathbb{C}$ be given by $\gamma(t)=r(\cos m t+i \sin m t)$ for $m$ an integer. Find $\int_{\gamma} \frac{d z}{z}$.
5. Show that if $\gamma:[a, b] \rightarrow \mathbb{C}$ then there exists an increasing function $h:[0,1] \rightarrow[a, b]$ such that $\gamma \circ h([0,1])=\gamma^{*}$.
6. Let $\gamma:[a, b] \rightarrow \mathbb{C}$ be an arbitrary continuous curve having bounded variation and let $f, g$ have continuous derivatives on some open set containing $\gamma^{*}$. Prove the usual integration by parts formula.

$$
\int_{\gamma} f g^{\prime} d z=f(\gamma(b)) g(\gamma(b))-f(\gamma(a)) g(\gamma(a))-\int_{\gamma} f^{\prime} g d z
$$

7. Let $f(z) \equiv|z|^{-(1 / 2)} e^{-i \frac{\theta}{2}}$ where $z=|z| e^{i \theta}$. This function is called the principle branch of $z^{-(1 / 2)}$. Find $\int_{\gamma} f(z) d z$ where $\gamma$ is the semicircle in the upper half plane which goes from $(1,0)$ to $(-1,0)$ in the counter clockwise direction. Next do the integral in which $\gamma$ goes in the clockwise direction along the semicircle in the lower half plane.
8. Prove an open set, $U$ is connected if and only if for every two points in $U$, there exists a $C^{1}$ curve having values in $U$ which joins them.
9. Let $\mathscr{P}, \mathscr{Q}$ be two partitions of $[a, b]$ with $\mathscr{P} \subseteq \mathscr{Q}$. Each of these partitions can be used to form an approximation to $V(\gamma,[a, b])$ as described above. Recall the total variation was the supremum of sums of a certain form determined by a partition. How is the sum associated with $\mathscr{P}$ related to the sum associated with $\mathscr{Q}$ ? Explain.
10. Consider the curve,

$$
\gamma(t)=\left\{\begin{array}{l}
t+i t^{2} \sin \left(\frac{1}{t}\right) \text { if } t \in(0,1] \\
0 \text { if } t=0
\end{array}\right.
$$

Is $\gamma$ a continuous curve having bounded variation? What if the $t^{2}$ is replaced with $t$ ? Is the resulting curve continuous? Is it a bounded variation curve?
11. Suppose $\gamma:[a, b] \rightarrow \mathbb{R}$ is given by $\gamma(t)=t$. What is $\int_{\gamma} f(t) d \gamma$ ? Explain.

## Chapter 51

## Fundamentals Of Complex Analysis

### 51.1 Analytic Functions

Definition 51.1.1 Let $\Omega$ be an open set in $\mathbb{C}$ and let $f: \Omega \rightarrow X$. Then $f$ is analytic on $\Omega$ if for every $z \in \Omega$,

$$
\lim _{h \rightarrow 0} \frac{f(z+h)-f(z)}{h} \equiv f^{\prime}(z)
$$

exists and is a continuous function of $z \in \Omega$. Here $h \in \mathbb{C}$.
Note that if $f$ is analytic, it must be the case that $f$ is continuous. It is more common to not include the requirement that $f^{\prime}$ is continuous but it is shown later that the continuity of $f^{\prime}$ follows.

What are some examples of analytic functions? In the case where $X=\mathbb{C}$, the simplest example is any polynomial. Thus

$$
p(z) \equiv \sum_{k=0}^{n} a_{k} z^{k}
$$

is an analytic function and

$$
p^{\prime}(z)=\sum_{k=1}^{n} a_{k} k z^{k-1}
$$

More generally, power series are analytic. This will be shown soon but first here is an important definition and a convergence theorem called the root test.

Definition 51.1.2 Let $\left\{a_{k}\right\}$ be a sequence in $X$. Then $\sum_{k=1}^{\infty} a_{k} \equiv \lim _{n \rightarrow \infty} \sum_{k=1}^{n} a_{k}$ whenever this limit exists. When the limit exists, the series is said to converge.

Theorem 51.1.3 Consider $\sum_{k=1}^{\infty} a_{k}$ and let $\rho \equiv \limsup _{k \rightarrow \infty}\left\|a_{k}\right\|^{1 / k}$. Then if $\rho<1$, the series converges absolutely and if $\rho>1$ the series diverges spectacularly in the sense that $\lim _{k \rightarrow \infty} a_{k} \neq 0$. If $\rho=1$ the test fails. Also $\sum_{k=1}^{\infty} a_{k}(z-a)^{k}$ converges on some disk $B(a, R)$. It converges absolutely if $|z-a|<R$ and uniformly on $B\left(a, r_{1}\right)$ whenever $r_{1}<R$. The function $f(z)=\sum_{k=1}^{\infty} a_{k}(z-a)^{k}$ is continuous on $B(a, R)$.

Proof: Suppose $\rho<1$. Then there exists $r \in(\rho, 1)$. Therefore, $\left\|a_{k}\right\| \leq r^{k}$ for all $k$ large enough and so by a comparison test, $\sum_{k}\left\|a_{k}\right\|$ converges because the partial sums are bounded above. Therefore, the partial sums of the original series form a Cauchy sequence in $X$ and so they also converge due to completeness of $X$.

Now suppose $\rho>1$. Then letting $\rho>r>1$, it follows $\left\|a_{k}\right\|^{1 / k} \geq r$ infinitely often. Thus $\left\|a_{k}\right\| \geq r^{k}$ infinitely often. Thus there exists a subsequence for which $\left\|a_{n_{k}}\right\|$ converges to $\infty$. Therefore, the series cannot converge.

Now consider $\sum_{k=1}^{\infty} a_{k}(z-a)^{k}$. This series converges absolutely if

$$
\limsup _{k \rightarrow \infty}\left\|a_{k}\right\|^{1 / k}|z-a|<1
$$

which is the same as saying $|z-a|<1 / \rho$ where $\rho \equiv \limsup _{k \rightarrow \infty}\left\|a_{k}\right\|^{1 / k}$. Let $R=1 / \rho$.
Now suppose $r_{1}<R$. Consider $|z-a| \leq r_{1}$. Then for such $z$,

$$
\left\|a_{k}\right\||z-a|^{k} \leq\left\|a_{k}\right\| r_{1}^{k}
$$

and

$$
\lim \sup _{k \rightarrow \infty}\left(\left\|a_{k}\right\| r_{1}^{k}\right)^{1 / k}=\lim \sup _{k \rightarrow \infty}\left\|a_{k}\right\|^{1 / k} r_{1}=\frac{r_{1}}{R}<1
$$

so $\sum_{k}\left\|a_{k}\right\| r_{1}^{k}$ converges. By the Weierstrass $M$ test, $\sum_{k=1}^{\infty} a_{k}(z-a)^{k}$ converges uniformly for $|z-a| \leq r_{1}$. Therefore, $f$ is continuous on $B(a, R)$ as claimed because it is the uniform limit of continuous functions, the partial sums of the infinite series.

What if $\rho=0$ ? In this case,

$$
\lim \sup _{k \rightarrow \infty}\left\|a_{k}\right\|^{1 / k}|z-a|=0 \cdot|z-a|=0
$$

and so $R=\infty$ and the series, $\sum\left\|a_{k}\right\||z-a|^{k}$ converges everywhere.
What if $\rho=\infty$ ? Then in this case, the series converges only at $z=a$ because if $z \neq a$,

$$
\limsup _{k \rightarrow \infty}\left\|a_{k}\right\|^{1 / k}|z-a|=\infty
$$

Theorem 51.1.4 Let $f(z) \equiv \sum_{k=1}^{\infty} a_{k}(z-a)^{k}$ be given in Theorem 51.1.3 where $R>0$. Then $f$ is analytic on $B(a, R)$. So are all its derivatives.

Proof: Consider $g(z)=\sum_{k=2}^{\infty} a_{k} k(z-a)^{k-1}$ on $B(a, R)$ where $R=\rho^{-1}$ as above. Let
$r_{1}<r<R$. Then letting $|z-a|<r_{1}$ and $h<r-r_{1}$,

$$
\begin{aligned}
& \| \frac{f(z+h)-f(z)}{h}-g(z)| | \\
\leq & \sum_{k=2}^{\infty}\left\|a_{k}\right\|\left|\frac{(z+h-a)^{k}-(z-a)^{k}}{h}-k(z-a)^{k-1}\right| \\
\leq & \sum_{k=2}^{\infty}\left\|a_{k}\right\|\left|\frac{1}{h}\left(\sum_{i=0}^{k}\binom{k}{i}(z-a)^{k-i} h^{i}-(z-a)^{k}\right)-k(z-a)^{k-1}\right| \\
= & \sum_{k=2}^{\infty}\left\|a_{k}\right\|\left|\frac{1}{h}\left(\sum_{i=1}^{k}\binom{k}{i}(z-a)^{k-i} h^{i}\right)-k(z-a)^{k-1}\right| \\
\leq & \sum_{k=2}^{\infty} \| a_{k}| |\left|\left(\sum_{i=2}^{k}\binom{k}{i}(z-a)^{k-i} h^{i-1}\right)\right| \\
\leq & |h| \sum_{k=2}^{\infty} \| a_{k}| |\left(\sum_{i=0}^{k-2}\binom{k}{i+2}|z-a|^{k-2-i}|h|^{i}\right) \\
= & |h| \sum_{k=2}^{\infty} \| a_{k}| |\left(\sum_{i=0}^{k-2}\binom{k-2}{i} \frac{k(k-1)}{(i+2)(i+1)}|z-a|^{k-2-i}|h|^{i}\right) \\
\leq & |h| \sum_{k=2}^{\infty} \| a_{k}| | \frac{k(k-1)}{2}\left(\sum_{i=0}^{k-2}\binom{k-2}{i}|z-a|^{k-2-i}|h|^{i}\right) \\
= & |h| \sum_{k=2}^{\infty}\left\|a_{k}\right\| \frac{k(k-1)}{2}(|z-a|+|h|)^{k-2}<|h| \sum_{k=2}^{\infty}\left\|a_{k}\right\| \frac{k(k-1)}{2} r^{k-2} .
\end{aligned}
$$

Then

$$
\limsup _{k \rightarrow \infty}\left(\left\|a_{k}\right\| \frac{k(k-1)}{2} r^{k-2}\right)^{1 / k}=\rho r<1
$$

and so

$$
\left\|\frac{f(z+h)-f(z)}{h}-g(z)\right\| \leq C|h| .
$$

therefore, $g(z)=f^{\prime}(z)$. Now by Theorem 51.1.3 it also follows that $f^{\prime}$ is continuous. Since $r_{1}<R$ was arbitrary, this shows that $f^{\prime}(z)$ is given by the differentiated series above for $|z-a|<R$. Now a repeat of the argument shows all the derivatives of $f$ exist and are continuous on $B(a, R)$.

### 51.1.1 Cauchy Riemann Equations

Next consider the very important Cauchy Riemann equations which give conditions under which complex valued functions of a complex variable are analytic.
Theorem 51.1.5 Let $\Omega$ be an open subset of $\mathbb{C}$ and let $f: \Omega \rightarrow \mathbb{C}$ be a function, such that for $z=x+i y \in \Omega$,

$$
f(z)=u(x, y)+i v(x, y) .
$$

Then $f$ is analytic if and only if $u, v$ are $C^{1}(\Omega)$ and

$$
\frac{\partial u}{\partial x}=\frac{\partial v}{\partial y}, \frac{\partial u}{\partial y}=-\frac{\partial v}{\partial x}
$$

## Furthermore,

$$
f^{\prime}(z)=\frac{\partial u}{\partial x}(x, y)+i \frac{\partial v}{\partial x}(x, y)
$$

Proof: Suppose $f$ is analytic first. Then letting $t \in \mathbb{R}$,

$$
\begin{gathered}
f^{\prime}(z)=\lim _{t \rightarrow 0} \frac{f(z+t)-f(z)}{t}= \\
\lim _{t \rightarrow 0}\left(\frac{u(x+t, y)+i v(x+t, y)}{t}-\frac{u(x, y)+i v(x, y)}{t}\right) \\
=\frac{\partial u(x, y)}{\partial x}+i \frac{\partial v(x, y)}{\partial x}
\end{gathered}
$$

But also

$$
\begin{gathered}
f^{\prime}(z)=\lim _{t \rightarrow 0} \frac{f(z+i t)-f(z)}{i t}= \\
\lim _{t \rightarrow 0}\left(\frac{u(x, y+t)+i v(x, y+t)}{i t}-\frac{u(x, y)+i v(x, y)}{i t}\right) \\
\frac{1}{i}\left(\frac{\partial u(x, y)}{\partial y}+i \frac{\partial v(x, y)}{\partial y}\right) \\
=\frac{\partial v(x, y)}{\partial y}-i \frac{\partial u(x, y)}{\partial y}
\end{gathered}
$$

This verifies the Cauchy Riemann equations. We are assuming that $z \rightarrow f^{\prime}(z)$ is continuous. Therefore, the partial derivatives of $u$ and $v$ are also continuous. To see this, note that from the formulas for $f^{\prime}(z)$ given above, and letting $z_{1}=x_{1}+i y_{1}$

$$
\left|\frac{\partial v(x, y)}{\partial y}-\frac{\partial v\left(x_{1}, y_{1}\right)}{\partial y}\right| \leq\left|f^{\prime}(z)-f^{\prime}\left(z_{1}\right)\right|
$$

showing that $(x, y) \rightarrow \frac{\partial v(x, y)}{\partial y}$ is continuous since $\left(x_{1}, y_{1}\right) \rightarrow(x, y)$ if and only if $z_{1} \rightarrow z$. The other cases are similar.

Now suppose the Cauchy Riemann equations hold and the functions, $u$ and $v$ are $C^{1}(\Omega)$. Then letting $h=h_{1}+i h_{2}$,

$$
\begin{gathered}
f(z+h)-f(z)=u\left(x+h_{1}, y+h_{2}\right) \\
+i v\left(x+h_{1}, y+h_{2}\right)-(u(x, y)+i v(x, y))
\end{gathered}
$$

We know $u$ and $v$ are both differentiable and so

$$
f(z+h)-f(z)=\frac{\partial u}{\partial x}(x, y) h_{1}+\frac{\partial u}{\partial y}(x, y) h_{2}+
$$

$$
i\left(\frac{\partial v}{\partial x}(x, y) h_{1}+\frac{\partial v}{\partial y}(x, y) h_{2}\right)+o(h) .
$$

Dividing by $h$ and using the Cauchy Riemann equations,

$$
\begin{gathered}
\frac{f(z+h)-f(z)}{h}=\frac{\frac{\partial u}{\partial x}(x, y) h_{1}+i \frac{\partial v}{\partial y}(x, y) h_{2}}{h}+ \\
\frac{i \frac{\partial v}{\partial x}(x, y) h_{1}+\frac{\partial u}{\partial y}(x, y) h_{2}}{h}+\frac{o(h)}{h} \\
=\frac{\partial u}{\partial x}(x, y) \frac{h_{1}+i h_{2}}{h}+i \frac{\partial v}{\partial x}(x, y) \frac{h_{1}+i h_{2}}{h}+\frac{o(h)}{h}
\end{gathered}
$$

Taking the limit as $h \rightarrow 0$,

$$
f^{\prime}(z)=\frac{\partial u}{\partial x}(x, y)+i \frac{\partial v}{\partial x}(x, y)
$$

It follows from this formula and the assumption that $u, v$ are $C^{1}(\Omega)$ that $f^{\prime}$ is continuous.
It is routine to verify that all the usual rules of derivatives hold for analytic functions. In particular, the product rule, the chain rule, and quotient rule.

### 51.1.2 An Important Example

An important example of an analytic function is $e^{z} \equiv \exp (z) \equiv e^{x}(\cos y+i \sin y)$ where $z=x+i y$. You can verify that this function satisfies the Cauchy Riemann equations and that all the partial derivatives are continuous. Also from the above discussion, $\left(e^{z}\right)^{\prime}=$ $e^{x} \cos (y)+i e^{x} \sin y=e^{z}$. Later I will show that $e^{z}$ is given by the usual power series. An important property of this function is that it can be used to parameterize the circle centered at $z_{0}$ having radius $r$.

Lemma 51.1.6 Let $\gamma$ denote the closed curve which is a circle of radius $r$ centered at $z_{0}$. Then a parameterization this curve is $\gamma(t)=z_{0}+r e^{i t}$ where $t \in[0,2 \pi]$.

Proof: $\left|\gamma(t)-z_{0}\right|^{2}=\left|r e^{i t} r e^{-i t}\right|=r^{2}$. Also, you can see from the definition of the sine and cosine that the point described in this way moves counter clockwise over this circle.

### 51.2 Exercises

1. Verify all the usual rules of differentiation including the product and chain rules.
2. Suppose $f$ and $f^{\prime}: U \rightarrow \mathbb{C}$ are analytic and $f(z)=u(x, y)+i v(x, y)$. Verify $u_{x x}+$ $u_{y y}=0$ and $v_{x x}+v_{y y}=0$. This partial differential equation satisfied by the real and imaginary parts of an analytic function is called Laplace's equation. We say these functions satisfying Laplace's equation are harmonic functions. If $u$ is a harmonic function defined on $B(0, r)$ show that $v(x, y) \equiv \int_{0}^{y} u_{x}(x, t) d t-\int_{0}^{x} u_{y}(t, 0) d t$ is such that $u+i v$ is analytic.
3. Let $f: U \rightarrow \mathbb{C}$ be analytic and $f(z)=u(x, y)+i v(x, y)$. Show $u, v$ and $u v$ are all harmonic although it can happen that $u^{2}$ is not. Recall that a function, $w$ is harmonic if $w_{x x}+w_{y y}=0$.
4. Define a function $f(z) \equiv \bar{z} \equiv x-i y$ where $z=x+i y$. Is $f$ analytic?
5. If $f(z)=u(x, y)+i v(x, y)$ and $f$ is analytic, verify that

$$
\operatorname{det}\left(\begin{array}{ll}
u_{x} & u_{y} \\
v_{x} & v_{y}
\end{array}\right)=\left|f^{\prime}(z)\right|^{2}
$$

6. Show that if $u(x, y)+i v(x, y)=f(z)$ is analytic, then $\nabla u \cdot \nabla v=0$. Recall

$$
\nabla u(x, y)=\left\langle u_{x}(x, y), u_{y}(x, y)\right\rangle .
$$

7. Show that every polynomial is analytic.
8. If $\gamma(t)=x(t)+i y(t)$ is a $C^{1}$ curve having values in $U$, an open set of $\mathbb{C}$, and if $f: U \rightarrow \mathbb{C}$ is analytic, we can consider $f \circ \gamma$, another $C^{1}$ curve having values in $\mathbb{C}$. Also, $\gamma^{\prime}(t)$ and $(f \circ \gamma)^{\prime}(t)$ are complex numbers so these can be considered as vectors in $\mathbb{R}^{2}$ as follows. The complex number, $x+i y$ corresponds to the vector, $\langle x, y\rangle$. Suppose that $\gamma$ and $\eta$ are two such $C^{1}$ curves having values in $U$ and that $\gamma\left(t_{0}\right)=\eta\left(s_{0}\right)=z$ and suppose that $f: U \rightarrow \mathbb{C}$ is analytic. Show that the angle between $(f \circ \gamma)^{\prime}\left(t_{0}\right)$ and $(f \circ \eta)^{\prime}\left(s_{0}\right)$ is the same as the angle between $\gamma^{\prime}\left(t_{0}\right)$ and $\eta^{\prime}\left(s_{0}\right)$ assuming that $f^{\prime}(z) \neq 0$. Thus analytic mappings preserve angles at points where the derivative is nonzero. Such mappings are called isogonal. . Hint: To make this easy to show, first observe that $\langle x, y\rangle \cdot\langle a, b\rangle=\frac{1}{2}(z \bar{w}+\bar{z} w)$ where $z=x+i y$ and $w=a+i b$.
9. Analytic functions are even better than what is described in Problem 8. In addition to preserving angles, they also preserve orientation. To verify this show that if $z=x+i y$ and $w=a+i b$ are two complex numbers, then $\langle x, y, 0\rangle$ and $\langle a, b, 0\rangle$ are two vectors in $\mathbb{R}^{3}$. Recall that the cross product, $\langle x, y, 0\rangle \times\langle a, b, 0\rangle$, yields a vector normal to the two given vectors such that the triple, $\langle x, y, 0\rangle,\langle a, b, 0\rangle$, and $\langle x, y, 0\rangle \times\langle a, b, 0\rangle$ satisfies the right hand rule and has magnitude equal to the product of the sine of the included angle times the product of the two norms of the vectors. In this case, the cross product either points in the direction of the positive $z$ axis or in the direction of the negative $z$ axis. Thus, either the vectors $\langle x, y, 0\rangle,\langle a, b, 0\rangle, \mathbf{k}$ form a right handed system or the vectors $\langle a, b, 0\rangle,\langle x, y, 0\rangle, \mathbf{k}$ form a right handed system. These are the two possible orientations. Show that in the situation of Problem 8 the orientation of $\gamma^{\prime}\left(t_{0}\right), \eta^{\prime}\left(s_{0}\right), \mathbf{k}$ is the same as the orientation of the vectors $(f \circ \gamma)^{\prime}\left(t_{0}\right),(f \circ \eta)^{\prime}\left(s_{0}\right), \mathbf{k}$. Such mappings are called conformal. If $f$ is analytic and $f^{\prime}(z) \neq 0$, then we know from this problem and the above that $f$ is a conformal map. Hint: You can do this by verifying that $(f \circ \gamma)^{\prime}\left(t_{0}\right) \times(f \circ \eta)^{\prime}\left(s_{0}\right)=$ $\left|f^{\prime}\left(\gamma\left(t_{0}\right)\right)\right|^{2} \gamma^{\prime}\left(t_{0}\right) \times \eta^{\prime}\left(s_{0}\right)$. To make the verification easier, you might first establish the following simple formula for the cross product where here $x+i y=z$ and $a+i b=w$.

$$
(x, y, 0) \times(a, b, 0)=\operatorname{Re}(z i \bar{w}) \mathbf{k}
$$

10. Write the Cauchy Riemann equations in terms of polar coordinates. Recall the polar coordinates are given by

$$
x=r \cos \theta, y=r \sin \theta
$$

This means, letting $u(x, y)=u(r, \theta), v(x, y)=v(r, \theta)$, write the Cauchy Riemann equations in terms of $r$ and $\theta$. You should eventually show the Cauchy Riemann equations are equivalent to

$$
\frac{\partial u}{\partial r}=\frac{1}{r} \frac{\partial v}{\partial \theta}, \frac{\partial v}{\partial r}=-\frac{1}{r} \frac{\partial u}{\partial \theta}
$$

11. Show that a real valued analytic function must be constant.

### 51.3 Cauchy's Formula For A Disk

The Cauchy integral formula is the most important theorem in complex analysis. It will be established for a disk in this chapter and later will be generalized to much more general situations but the version given here will suffice to prove many interesting theorems needed in the later development of the theory. The following are some advanced calculus results.

Lemma 51.3.1 Let $f:[a, b] \rightarrow \mathbb{C}$. Then $f^{\prime}(t)$ exists if and only if $\operatorname{Re} f^{\prime}(t)$ and $\operatorname{Im} f^{\prime}(t)$ exist. Furthermore,

$$
f^{\prime}(t)=\operatorname{Re} f^{\prime}(t)+i \operatorname{Im} f^{\prime}(t)
$$

Proof: The if part of the equivalence is obvious.
Now suppose $f^{\prime}(t)$ exists. Let both $t$ and $t+h$ be contained in $[a, b]$

$$
\left|\frac{\operatorname{Re} f(t+h)-\operatorname{Re} f(t)}{h}-\operatorname{Re}\left(f^{\prime}(t)\right)\right| \leq\left|\frac{f(t+h)-f(t)}{h}-f^{\prime}(t)\right|
$$

and this converges to zero as $h \rightarrow 0$. Therefore, $\operatorname{Re} f^{\prime}(t)=\operatorname{Re}\left(f^{\prime}(t)\right) . \operatorname{Similarly}, \operatorname{Im} f^{\prime}(t)=$ $\operatorname{Im}\left(f^{\prime}(t)\right)$.

Lemma 51.3.2 If $g:[a, b] \rightarrow \mathbb{C}$ and $g$ is continuous on $[a, b]$ and differentiable on $(a, b)$ with $g^{\prime}(t)=0$, then $g(t)$ is a constant.

Proof: From the above lemma, you can apply the mean value theorem to the real and imaginary parts of $g$.

Applying the above lemma to the components yields the following lemma.
Lemma 51.3.3 If $g:[a, b] \rightarrow \mathbb{C}^{n}=X$ and $g$ is continuous on $[a, b]$ and differentiable on $(a, b)$ with $g^{\prime}(t)=0$, then $g(t)$ is a constant.

If you want to have $X$ be a complex Banach space, the result is still true.
Lemma 51.3.4 If $g:[a, b] \rightarrow X$ and $g$ is continuous on $[a, b]$ and differentiable on $(a, b)$ with $g^{\prime}(t)=0$, then $g(t)$ is a constant.

Proof: Let $\Lambda \in X^{\prime}$. Then $\Lambda g:[a, b] \rightarrow \mathbb{C}$. Therefore, from Lemma 51.3.2, for each $\Lambda \in X^{\prime}, \Lambda g(s)=\Lambda g(t)$ and since $X^{\prime}$ separates the points, it follows $g(s)=g(t)$ so $g$ is constant.

Lemma 51.3.5 Let $\phi:[a, b] \times[c, d] \rightarrow \mathbb{R}$ be continuous and let

$$
\begin{equation*}
g(t) \equiv \int_{a}^{b} \phi(s, t) d s \tag{51.3.1}
\end{equation*}
$$

Then $g$ is continuous. If $\frac{\partial \phi}{\partial t}$ exists and is continuous on $[a, b] \times[c, d]$, then

$$
\begin{equation*}
g^{\prime}(t)=\int_{a}^{b} \frac{\partial \phi(s, t)}{\partial t} d s \tag{51.3.2}
\end{equation*}
$$

Proof: The first claim follows from the uniform continuity of $\phi$ on $[a, b] \times[c, d]$, which uniform continuity results from the set being compact. To establish 51.3.2, let $t$ and $t+h$ be contained in $[c, d]$ and form, using the mean value theorem,

$$
\begin{aligned}
\frac{g(t+h)-g(t)}{h} & =\frac{1}{h} \int_{a}^{b}[\phi(s, t+h)-\phi(s, t)] d s \\
& =\frac{1}{h} \int_{a}^{b} \frac{\partial \phi(s, t+\theta h)}{\partial t} h d s \\
& =\int_{a}^{b} \frac{\partial \phi(s, t+\theta h)}{\partial t} d s
\end{aligned}
$$

where $\theta$ may depend on $s$ but is some number between 0 and 1 . Then by the uniform continuity of $\frac{\partial \phi}{\partial t}$, it follows that 51.3.2 holds.

Corollary 51.3.6 Let $\phi:[a, b] \times[c, d] \rightarrow \mathbb{C}$ be continuous and let

$$
\begin{equation*}
g(t) \equiv \int_{a}^{b} \phi(s, t) d s \tag{51.3.3}
\end{equation*}
$$

Then $g$ is continuous. If $\frac{\partial \phi}{\partial t}$ exists and is continuous on $[a, b] \times[c, d]$, then

$$
\begin{equation*}
g^{\prime}(t)=\int_{a}^{b} \frac{\partial \phi(s, t)}{\partial t} d s \tag{51.3.4}
\end{equation*}
$$

Proof: Apply Lemma 51.3.5 to the real and imaginary parts of $\phi$.
Applying the above corollary to the components, you can also have the same result for $\phi$ having values in $\mathbb{C}^{n}$.

Corollary 51.3.7 Let $\phi:[a, b] \times[c, d] \rightarrow \mathbb{C}^{n}$ be continuous and let

$$
\begin{equation*}
g(t) \equiv \int_{a}^{b} \phi(s, t) d s \tag{51.3.5}
\end{equation*}
$$

Then $g$ is continuous. If $\frac{\partial \phi}{\partial t}$ exists and is continuous on $[a, b] \times[c, d]$, then

$$
\begin{equation*}
g^{\prime}(t)=\int_{a}^{b} \frac{\partial \phi(s, t)}{\partial t} d s \tag{51.3.6}
\end{equation*}
$$

If you want to consider $\phi$ having values in $X$, a complex Banach space a similar result holds.

Corollary 51.3.8 Let $\phi:[a, b] \times[c, d] \rightarrow X$ be continuous and let

$$
\begin{equation*}
g(t) \equiv \int_{a}^{b} \phi(s, t) d s \tag{51.3.7}
\end{equation*}
$$

Then $g$ is continuous. If $\frac{\partial \phi}{\partial t}$ exists and is continuous on $[a, b] \times[c, d]$, then

$$
\begin{equation*}
g^{\prime}(t)=\int_{a}^{b} \frac{\partial \phi(s, t)}{\partial t} d s \tag{51.3.8}
\end{equation*}
$$

Proof: Let $\Lambda \in X^{\prime}$. Then $\Lambda \phi:[a, b] \times[c, d] \rightarrow \mathbb{C}$ is continuous and $\frac{\partial \Lambda \phi}{\partial t}$ exists and is continuous on $[a, b] \times[c, d]$. Therefore, from 51.3.8,

$$
\Lambda\left(g^{\prime}(t)\right)=(\Lambda g)^{\prime}(t)=\int_{a}^{b} \frac{\partial \Lambda \phi(s, t)}{\partial t} d s=\Lambda \int_{a}^{b} \frac{\partial \phi(s, t)}{\partial t} d s
$$

and since $X^{\prime}$ separates the points, it follows 51.3.8 holds.
You can give a different proof of this.
Theorem 51.3.9 Let $\phi:[a, b] \times[c, d] \rightarrow X$ be continuous and suppose $\phi_{t}$ is continuous. Then

$$
\left(\int_{a}^{b} \phi(s, t) d s\right)_{, t}=\int_{a}^{b} \frac{\partial \phi}{\partial t}(s, t) d s
$$

Here $X$ is a complex Banach space.
Proof: Consider the following set $P$ which is where the ordered pair $(t, h)$ will be.

This is so that both $t$ and $t+h$ are in $[a, b]$. Then for such an ordered pair, consider

$$
\Delta(s, t, h) \equiv\left\{\begin{array}{l}
\frac{\phi(s, t+h)-\phi(s, t)}{h} \text { if } h \neq 0 \\
\phi_{t}(s, t) \text { if } h=0
\end{array}\right.
$$

Claim: $\Delta$ is continuous on the compact set $[a, b] \times P$.
Proof of claim: It is obvious unless $h=0$. Therefore, consider the point $(s, t, 0)$.

$$
\left\|\Delta\left(s^{\prime}, t^{\prime}, h\right)-\Delta(s, t, 0)\right\|=\left\|\frac{\phi\left(s^{\prime}, t^{\prime}+h\right)-\phi\left(s^{\prime}, t^{\prime}\right)}{h}-\phi_{t}(s, t)\right\|
$$

$$
=\left\|\frac{1}{h} \int_{t^{\prime}}^{t^{\prime}+h} \phi_{t}\left(s^{\prime}, r\right) d r-\phi_{t}(s, t)\right\| \leq \frac{1}{h} \int_{t^{\prime}}^{t^{\prime}+h}\left\|\phi_{t}\left(s^{\prime}, r\right)-\phi_{t}(s, t)\right\| d r<\varepsilon
$$

provided $\left|\left(s^{\prime}, t^{\prime}, h\right)-(s, t, 0)\right|$ is small enough, this by continuity of $\phi_{t}$. Therefore, $\Delta(s, t, h)$ is uniformly continuous.

$$
\begin{aligned}
\left\|\frac{1}{h}\left(\int_{a}^{b} \phi(s, t+h) d s-\int_{a}^{b} \phi(s, t) d s\right)-\int_{a}^{b} \phi_{t}(s, t) d s\right\| \\
\leq \int_{a}^{b}\left\|\frac{\phi(s, t+h)-\phi(s, t)}{h}-\phi_{t}(s, t)\right\| d s=\int_{a}^{b}\left\|\Delta(s, t, h)-\phi_{t}(s, t)\right\| d s
\end{aligned}
$$

Then by uniform continuity, if $h$ is small enough, the integrand on the right is smaller than $\varepsilon$.

The following is Cauchy's integral formula for a disk.
Theorem 51.3.10 Let $f: \Omega \rightarrow X$ be analytic on the open set, $\Omega$ and let

$$
\overline{B\left(z_{0}, r\right)} \subseteq \Omega
$$

Let $\gamma(t) \equiv z_{0}+r e^{i t}$ for $t \in[0,2 \pi]$. Then if $z \in B\left(z_{0}, r\right)$,

$$
\begin{equation*}
f(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z} d w \tag{51.3.9}
\end{equation*}
$$

Proof: Consider for $\alpha \in[0,1]$,

$$
g(\alpha) \equiv \int_{0}^{2 \pi} \frac{f\left(z+\alpha\left(z_{0}+r e^{i t}-z\right)\right)}{r e^{i t}+z_{0}-z} r i e^{i t} d t
$$

If $\alpha$ equals one, this reduces to the integral in 51.3.9. The idea is to show $g$ is a constant and that $g(0)=f(z) 2 \pi i$. First consider the claim about $g(0)$.

$$
\begin{aligned}
g(0) & =\left(\int_{0}^{2 \pi} \frac{r e^{i t}}{r e^{i t}+z_{0}-z} d t\right) i f(z) \\
& =i f(z)\left(\int_{0}^{2 \pi} \frac{1}{1-\frac{z-z_{0}}{r e^{i t}}} d t\right) \\
& =i f(z) \int_{0}^{2 \pi} \sum_{n=0}^{\infty} r^{-n} e^{-i n t}\left(z-z_{0}\right)^{n} d t
\end{aligned}
$$

because $\left|\frac{z-z_{0}}{r e^{i t}}\right|<1$. Since this sum converges uniformly you can interchange the sum and the integral to obtain

$$
\begin{aligned}
g(0) & =\text { if }(z) \sum_{n=0}^{\infty} r^{-n}\left(z-z_{0}\right)^{n} \int_{0}^{2 \pi} e^{-i n t} d t \\
& =2 \pi i f(z)
\end{aligned}
$$

because $\int_{0}^{2 \pi} e^{-i n t} d t=0$ if $n>0$.
Next consider the claim that $g$ is constant. By Corollary 51.3.7, for $\alpha \in(0,1)$,

$$
\begin{aligned}
g^{\prime}(\alpha) & =\int_{0}^{2 \pi} \frac{f^{\prime}\left(z+\alpha\left(z_{0}+r e^{i t}-z\right)\right)\left(r e^{i t}+z_{0}-z\right)}{r e^{i t}+z_{0}-z} r i e^{i t} d t \\
& =\int_{0}^{2 \pi} f^{\prime}\left(z+\alpha\left(z_{0}+r e^{i t}-z\right)\right) r i e^{i t} d t \\
& =\int_{0}^{2 \pi} \frac{d}{d t}\left(f\left(z+\alpha\left(z_{0}+r e^{i t}-z\right)\right) \frac{1}{\alpha}\right) d t \\
& =f\left(z+\alpha\left(z_{0}+r e^{i 2 \pi}-z\right)\right) \frac{1}{\alpha}-f\left(z+\alpha\left(z_{0}+r e^{0}-z\right)\right) \frac{1}{\alpha}=0
\end{aligned}
$$

Now $g$ is continuous on $[0,1]$ and $g^{\prime}(t)=0$ on $(0,1)$ so by Lemma 51.3.3, $g$ equals a constant. This constant can only be $g(0)=2 \pi i f(z)$. Thus,

$$
g(1)=\int_{\gamma} \frac{f(w)}{w-z} d w=g(0)=2 \pi i f(z)
$$

This proves the theorem.
This is a very significant theorem. A few applications are given next.

Theorem 51.3.11 Let $f: \Omega \rightarrow X$ be analytic where $\Omega$ is an open set in $\mathbb{C}$. Then $f$ has infinitely many derivatives on $\Omega$. Furthermore, for all $z \in B\left(z_{0}, r\right)$,

$$
\begin{equation*}
f^{(n)}(z)=\frac{n!}{2 \pi i} \int_{\gamma} \frac{f(w)}{(w-z)^{n+1}} d w \tag{51.3.10}
\end{equation*}
$$

where $\gamma(t) \equiv z_{0}+r e^{i t}, t \in[0,2 \pi]$ for $r$ small enough that $B\left(z_{0}, r\right) \subseteq \Omega$.
Proof: Let $z \in B\left(z_{0}, r\right) \subseteq \Omega$ and let $\overline{B\left(z_{0}, r\right)} \subseteq \Omega$. Then, letting $\gamma(t) \equiv z_{0}+r e^{i t}, t \in$ $[0,2 \pi]$, and $h$ small enough,

$$
f(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z} d w, f(z+h)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z-h} d w
$$

Now

$$
\frac{1}{w-z-h}-\frac{1}{w-z}=\frac{h}{(-w+z+h)(-w+z)}
$$

and so

$$
\begin{aligned}
\frac{f(z+h)-f(z)}{h} & =\frac{1}{2 \pi h i} \int_{\gamma} \frac{h f(w)}{(-w+z+h)(-w+z)} d w \\
& =\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{(-w+z+h)(-w+z)} d w
\end{aligned}
$$

Now for all $h$ sufficiently small, there exists a constant $C$ independent of such $h$ such that

$$
\begin{aligned}
& \left|\frac{1}{(-w+z+h)(-w+z)}-\frac{1}{(-w+z)(-w+z)}\right| \\
= & \left|\frac{h}{(w-z-h)(w-z)^{2}}\right| \leq C|h|
\end{aligned}
$$

and so, the integrand converges uniformly as $h \rightarrow 0$ to

$$
=\frac{f(w)}{(w-z)^{2}}
$$

Therefore, the limit as $h \rightarrow 0$ may be taken inside the integral to obtain

$$
f^{\prime}(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{(w-z)^{2}} d w
$$

Continuing in this way, yields 51.3.10.
This is a very remarkable result. It shows the existence of one continuous derivative implies the existence of all derivatives, in contrast to the theory of functions of a real variable. Actually, more than what is stated in the theorem was shown. The above proof establishes the following corollary.

Corollary 51.3.12 Suppose $f$ is continuous on $\partial B\left(z_{0}, r\right)$ and suppose that for all $z \in$ $B\left(z_{0}, r\right)$,

$$
f(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z} d w
$$

where $\gamma(t) \equiv z_{0}+r e^{i t}, t \in[0,2 \pi]$. Then $f$ is analytic on $B\left(z_{0}, r\right)$ and in fact has infinitely many derivatives on $B\left(z_{0}, r\right)$.

Another application is the following lemma.
Lemma 51.3.13 Let $\gamma(t)=z_{0}+r e^{i t}$, for $t \in[0,2 \pi]$, suppose $f_{n} \rightarrow f$ uniformly on $\overline{B\left(z_{0}, r\right)}$, and suppose

$$
\begin{equation*}
f_{n}(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f_{n}(w)}{w-z} d w \tag{51.3.11}
\end{equation*}
$$

for $z \in B\left(z_{0}, r\right)$. Then

$$
\begin{equation*}
f(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z} d w \tag{51.3.12}
\end{equation*}
$$

implying that $f$ is analytic on $B\left(z_{0}, r\right)$.
Proof: From 51.3.11 and the uniform convergence of $f_{n}$ to $f$ on $\gamma([0,2 \pi])$, the integrals in 51.3.11 converge to

$$
\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z} d w
$$

Therefore, the formula 51.3.12 follows.
Uniform convergence on a closed disk of the analytic functions implies the target function is also analytic. This is amazing. Think of the Weierstrass approximation theorem for polynomials. You can obtain a continuous nowhere differentiable function as the uniform limit of polynomials.

The conclusions of the following proposition have all been obtained earlier in Theorem 51.1.4 but they can be obtained more easily if you use the above theorem and lemmas.

Proposition 51.3.14 Let $\left\{a_{n}\right\}$ denote a sequence in $X$. Then there exists $R \in[0, \infty]$ such that

$$
\sum_{k=0}^{\infty} a_{k}\left(z-z_{0}\right)^{k}
$$

converges absolutely if $\left|z-z_{0}\right|<R$, diverges if $\left|z-z_{0}\right|>R$ and converges uniformly on $B\left(z_{0}, r\right)$ for all $r<R$. Furthermore, if $R>0$, the function,

$$
f(z) \equiv \sum_{k=0}^{\infty} a_{k}\left(z-z_{0}\right)^{k}
$$

is analytic on $B\left(z_{0}, R\right)$.
Proof: The assertions about absolute convergence are routine from the root test if

$$
R \equiv\left(\limsup _{n \rightarrow \infty}\left|a_{n}\right|^{1 / n}\right)^{-1}
$$

with $R=\infty$ if the quantity in parenthesis equals zero. The root test can be used to verify absolute convergence which then implies convergence by completeness of $X$.

The assertion about uniform convergence follows from the Weierstrass $M$ test and $M_{n} \equiv$ $\left|a_{n}\right| r^{n}$. ( $\sum_{n=0}^{\infty}\left|a_{n}\right| r^{n}<\infty$ by the root test). It only remains to verify the assertion about $f(z)$ being analytic in the case where $R>0$.

Let $0<r<R$ and define $f_{n}(z) \equiv \sum_{k=0}^{n} a_{k}\left(z-z_{0}\right)^{k}$. Then $f_{n}$ is a polynomial and so it is analytic. Thus, by the Cauchy integral formula above,

$$
f_{n}(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f_{n}(w)}{w-z} d w
$$

where $\gamma(t)=z_{0}+r e^{i t}$, for $t \in[0,2 \pi]$. By Lemma 51.3.13 and the first part of this proposition involving uniform convergence,

$$
f(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z} d w
$$

Therefore, $f$ is analytic on $B\left(z_{0}, r\right)$ by Corollary 51.3.12. Since $r<R$ is arbitrary, this shows $f$ is analytic on $B\left(z_{0}, R\right)$.

This proposition shows that all functions having values in $X$ which are given as power series are analytic on their circle of convergence, the set of complex numbers, $z$, such that $\left|z-z_{0}\right|<R$. In fact, every analytic function can be realized as a power series.

Theorem 51.3.15 If $f: \Omega \rightarrow X$ is analytic and if $B\left(z_{0}, r\right) \subseteq \Omega$, then

$$
\begin{equation*}
f(z)=\sum_{n=0}^{\infty} a_{n}\left(z-z_{0}\right)^{n} \tag{51.3.13}
\end{equation*}
$$

for all $\left|z-z_{0}\right|<r$. Furthermore,

$$
\begin{equation*}
a_{n}=\frac{f^{(n)}\left(z_{0}\right)}{n!} \tag{51.3.14}
\end{equation*}
$$

Proof: Consider $\left|z-z_{0}\right|<r$ and let $\gamma(t)=z_{0}+r e^{i t}, t \in[0,2 \pi]$. Then for $w \in \gamma([0,2 \pi])$,

$$
\left|\frac{z-z_{0}}{w-z_{0}}\right|<1
$$

and so, by the Cauchy integral formula,

$$
\begin{aligned}
f(z) & =\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{w-z} d w \\
& =\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{\left(w-z_{0}\right)\left(1-\frac{z-z_{0}}{w-z_{0}}\right)} d w \\
& =\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{\left(w-z_{0}\right)} \sum_{n=0}^{\infty}\left(\frac{z-z_{0}}{w-z_{0}}\right)^{n} d w .
\end{aligned}
$$

Since the series converges uniformly, you can interchange the integral and the sum to obtain

$$
\begin{aligned}
f(z) & =\sum_{n=0}^{\infty}\left(\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{\left(w-z_{0}\right)^{n+1}}\right)\left(z-z_{0}\right)^{n} \\
& \equiv \sum_{n=0}^{\infty} a_{n}\left(z-z_{0}\right)^{n}
\end{aligned}
$$

By Theorem 51.3.11, 51.3.14 holds.
Note that this also implies that if a function is analytic on an open set, then all of its derivatives are also analytic. This follows from Theorem 51.1.4 which says that a function given by a power series has all derivatives on the disk of convergence.

### 51.4 Exercises

1. Show that if $\left|e_{k}\right| \leq \varepsilon$, then $\left|\sum_{k=m}^{\infty} e_{k}\left(r^{k}-r^{k+1}\right)\right|<\varepsilon$ if $0 \leq r<1$. Hint: Let $|\theta|=1$ and verify that

$$
\theta \sum_{k=m}^{\infty} e_{k}\left(r^{k}-r^{k+1}\right)=\left|\sum_{k=m}^{\infty} e_{k}\left(r^{k}-r^{k+1}\right)\right|=\sum_{k=m}^{\infty} \operatorname{Re}\left(\theta e_{k}\right)\left(r^{k}-r^{k+1}\right)
$$

where $-\varepsilon<\operatorname{Re}\left(\theta e_{k}\right)<\varepsilon$.
2. Abel's theorem says that if $\sum_{n=0}^{\infty} a_{n}(z-a)^{n}$ has radius of convergence equal to 1 and if $A=\sum_{n=0}^{\infty} a_{n}$, then $\lim _{r \rightarrow 1-} \sum_{n=0}^{\infty} a_{n} r^{n}=A$. Hint: Show

$$
\sum_{k=0}^{\infty} a_{k} r^{k}=\sum_{k=0}^{\infty} A_{k}\left(r^{k}-r^{k+1}\right)
$$

where $A_{k}$ denotes the $k^{\text {th }}$ partial sum of $\sum a_{j}$. Thus

$$
\sum_{k=0}^{\infty} a_{k} r^{k}=\sum_{k=m+1}^{\infty} A_{k}\left(r^{k}-r^{k+1}\right)+\sum_{k=0}^{m} A_{k}\left(r^{k}-r^{k+1}\right)
$$

where $\left|A_{k}-A\right|<\varepsilon$ for all $k \geq m$. In the first sum, write $A_{k}=A+e_{k}$ and use Problem 1. Use this theorem to verify that $\arctan (1)=\sum_{k=0}^{\infty}(-1)^{k} \frac{1}{2 k+1}$.
3. Find the integrals using the Cauchy integral formula.
(a) $\int_{\gamma} \frac{\sin z}{z-i} d z$ where $\gamma(t)=2 e^{i t}: t \in[0,2 \pi]$.
(b) $\int_{\gamma} \frac{1}{z-a} d z$ where $\gamma(t)=a+r e^{i t}: t \in[0,2 \pi]$
(c) $\int_{\gamma} \frac{\cos z}{z^{2}} d z$ where $\gamma(t)=e^{i t}: t \in[0,2 \pi]$
(d) $\int_{\gamma} \frac{\log (z)}{z^{n}} d z$ where $\gamma(t)=1+\frac{1}{2} e^{i t}: t \in[0,2 \pi]$ and $n=0,1,2$. In this problem, $\log (z) \equiv \ln |z|+i \arg (z)$ where $\arg (z) \in(-\pi, \pi)$ and $z=|z| e^{i \arg (z)}$. Thus $e^{\log (z)}=z$ and $\log (z)^{\prime}=\frac{1}{z}$.
4. Let $\gamma(t)=4 e^{i t}: t \in[0,2 \pi]$ and find $\int_{\gamma} \frac{z^{2}+4}{z\left(z^{2}+1\right)} d z$.
5. Suppose $f(z)=\sum_{n=0}^{\infty} a_{n} z^{n}$ for all $|z|<R$. Show that then

$$
\frac{1}{2 \pi} \int_{0}^{2 \pi}\left|f\left(r e^{i \theta}\right)\right|^{2} d \theta=\sum_{n=0}^{\infty}\left|a_{n}\right|^{2} r^{2 n}
$$

for all $r \in[0, R)$. Hint: Let

$$
f_{n}(z) \equiv \sum_{k=0}^{n} a_{k} z^{k}
$$

show

$$
\frac{1}{2 \pi} \int_{0}^{2 \pi}\left|f_{n}\left(r e^{i \theta}\right)\right|^{2} d \theta=\sum_{k=0}^{n}\left|a_{k}\right|^{2} r^{2 k}
$$

and then take limits as $n \rightarrow \infty$ using uniform convergence.
6. The Cauchy integral formula, marvelous as it is, can actually be improved upon. The Cauchy integral formula involves representing $f$ by the values of $f$ on the boundary of the disk, $B(a, r)$. It is possible to represent $f$ by using only the values of $\operatorname{Re} f$ on the boundary. This leads to the Schwarz formula. Supply the details in the following outline.

Suppose $f$ is analytic on $|z|<R$ and

$$
\begin{equation*}
f(z)=\sum_{n=0}^{\infty} a_{n} z^{n} \tag{51.4.15}
\end{equation*}
$$

with the series converging uniformly on $|z|=R$. Then letting $|w|=R$,

$$
2 u(w)=f(w)+\overline{f(w)}
$$

and so

$$
\begin{equation*}
2 u(w)=\sum_{k=0}^{\infty} a_{k} w^{k}+\sum_{k=0}^{\infty} \overline{a_{k}}(\bar{w})^{k} \tag{51.4.16}
\end{equation*}
$$

Now letting $\gamma(t)=R e^{i t}, t \in[0,2 \pi]$

$$
\begin{aligned}
\int_{\gamma} \frac{2 u(w)}{w} d w & =\left(a_{0}+\overline{a_{0}}\right) \int_{\gamma} \frac{1}{w} d w \\
& =2 \pi i\left(a_{0}+\overline{a_{0}}\right)
\end{aligned}
$$

Thus, multiplying 51.4.16 by $w^{-1}$,

$$
\frac{1}{\pi i} \int_{\gamma} \frac{u(w)}{w} d w=a_{0}+\overline{a_{0}}
$$

Now multiply 51.4.16 by $w^{-(n+1)}$ and integrate again to obtain

$$
a_{n}=\frac{1}{\pi i} \int_{\gamma} \frac{u(w)}{w^{n+1}} d w
$$

Using these formulas for $a_{n}$ in 51.4.15, we can interchange the sum and the integral (Why can we do this?) to write the following for $|z|<R$.

$$
\begin{aligned}
f(z) & =\frac{1}{\pi i} \int_{\gamma} \frac{1}{z} \sum_{k=0}^{\infty}\left(\frac{z}{w}\right)^{k+1} u(w) d w-\overline{a_{0}} \\
& =\frac{1}{\pi i} \int_{\gamma} \frac{u(w)}{w-z} d w-\overline{a_{0}}
\end{aligned}
$$

which is the Schwarz formula. Now $\operatorname{Re} a_{0}=\frac{1}{2 \pi i} \int_{\gamma} \frac{u(w)}{w} d w$ and $\overline{a_{0}}=\operatorname{Re} a_{0}-i \operatorname{Im} a_{0}$. Therefore, we can also write the Schwarz formula as

$$
\begin{equation*}
f(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{u(w)(w+z)}{(w-z) w} d w+i \operatorname{Im} a_{0} \tag{51.4.17}
\end{equation*}
$$

7. Take the real parts of the second form of the Schwarz formula to derive the Poisson formula for a disk,

$$
\begin{equation*}
u\left(r e^{i \alpha}\right)=\frac{1}{2 \pi} \int_{0}^{2 \pi} \frac{u\left(R e^{i \theta}\right)\left(R^{2}-r^{2}\right)}{R^{2}+r^{2}-2 R r \cos (\theta-\alpha)} d \theta \tag{51.4.18}
\end{equation*}
$$

8. Suppose that $u(w)$ is a given real continuous function defined on $\partial B(0, R)$ and define $f(z)$ for $|z|<R$ by 51.4.17. Show that $f$, so defined is analytic. Explain why $u$ given in 51.4.18 is harmonic. Show that

$$
\lim _{r \rightarrow R_{-}} u\left(r e^{i \alpha}\right)=u\left(R e^{i \alpha}\right)
$$

Thus $u$ is a harmonic function which approaches a given function on the boundary and is therefore, a solution to the Dirichlet problem.
9. Suppose $f(z)=\sum_{k=0}^{\infty} a_{k}\left(z-z_{0}\right)^{k}$ for all $\left|z-z_{0}\right|<R$. Show that

$$
f^{\prime}(z)=\sum_{k=0}^{\infty} a_{k} k\left(z-z_{0}\right)^{k-1}
$$

for all $\left|z-z_{0}\right|<R$. Hint: Let $f_{n}(z)$ be a partial sum of $f$. Show that $f_{n}^{\prime}$ converges uniformly to some function, $g$ on $\left|z-z_{0}\right| \leq r$ for any $r<R$. Now use the Cauchy integral formula for a function and its derivative to identify $g$ with $f^{\prime}$.
10. Use Problem 9 to find the exact value of $\sum_{k=0}^{\infty} k^{2}\left(\frac{1}{3}\right)^{k}$.
11. Prove the binomial formula,

$$
(1+z)^{\alpha}=\sum_{n=0}^{\infty}\binom{\alpha}{n} z^{n}
$$

where

$$
\binom{\alpha}{n} \equiv \frac{\alpha \cdots(\alpha-n+1)}{n!}
$$

Can this be used to give a proof of the binomial formula,

$$
(a+b)^{n}=\sum_{k=0}^{n}\binom{n}{k} a^{n-k} b^{k} ?
$$

Explain.
12. Suppose $f$ is analytic on $B\left(z_{0}, r\right)$ and continuous on $\overline{B\left(z_{0}, r\right)}$ and $|f(z)| \leq M$ on $\overline{B\left(z_{0}, r\right)}$. Show that then $\left|f^{(n)}(a)\right| \leq \frac{M n!}{r^{n}}$.

### 51.5 Zeros Of An Analytic Function

In this section we give a very surprising property of analytic functions which is in stark contrast to what takes place for functions of a real variable.

Definition 51.5.1 A region is a connected open set.
It turns out the zeros of an analytic function which is not constant on some region cannot have a limit point. This is also a good time to define the order of a zero.

Definition 51.5.2 Suppose $f$ is an analytic function defined near a point, $\alpha$ where $f(\alpha)=$ 0 . Thus $\alpha$ is a zero of the function, $f$. The zero is of order $m$ if $f(z)=(z-\alpha)^{m} g(z)$ where $g$ is an analytic function which is not equal to zero at $\alpha$.

Theorem 51.5.3 Let $\Omega$ be a connected open set (region) and let $f: \Omega \rightarrow X$ be analytic. Then the following are equivalent.

1. $f(z)=0$ for all $z \in \Omega$
2. There exists $z_{0} \in \Omega$ such that $f^{(n)}\left(z_{0}\right)=0$ for all $n$.
3. There exists $z_{0} \in \Omega$ which is a limit point of the set,

$$
Z \equiv\{z \in \Omega: f(z)=0\}
$$

Proof: It is clear the first condition implies the second two. Suppose the third holds. Then for $z$ near $z_{0}$

$$
f(z)=\sum_{n=k}^{\infty} \frac{f^{(n)}\left(z_{0}\right)}{n!}\left(z-z_{0}\right)^{n}
$$

where $k \geq 1$ since $z_{0}$ is a zero of $f$. Suppose $k<\infty$. Then,

$$
f(z)=\left(z-z_{0}\right)^{k} g(z)
$$

where $g\left(z_{0}\right) \neq 0$. Letting $z_{n} \rightarrow z_{0}$ where $z_{n} \in Z, z_{n} \neq z_{0}$, it follows

$$
0=\left(z_{n}-z_{0}\right)^{k} g\left(z_{n}\right)
$$

which implies $g\left(z_{n}\right)=0$. Then by continuity of $g$, we see that $g\left(z_{0}\right)=0$ also, contrary to the choice of $k$. Therefore, $k$ cannot be less than $\infty$ and so $z_{0}$ is a point satisfying the second condition.

Now suppose the second condition and let

$$
S \equiv\left\{z \in \Omega: f^{(n)}(z)=0 \text { for all } n\right\}
$$

It is clear that $S$ is a closed set which by assumption is nonempty. However, this set is also open. To see this, let $z \in S$. Then for all $w$ close enough to $z$,

$$
f(w)=\sum_{k=0}^{\infty} \frac{f^{(k)}(z)}{k!}(w-z)^{k}=0
$$

Thus $f$ is identically equal to zero near $z \in S$. Therefore, all points near $z$ are contained in $S$ also, showing that $S$ is an open set. Now $\Omega=S \cup(\Omega \backslash S)$, the union of two disjoint open sets, $S$ being nonempty. It follows the other open set, $\Omega \backslash S$, must be empty because $\Omega$ is connected. Therefore, the first condition is verified. This proves the theorem. (See the following diagram.)

Note how radically different this is from the theory of functions of a real variable. Consider, for example the function

$$
f(x) \equiv\left\{\begin{array}{l}
x^{2} \sin \left(\frac{1}{x}\right) \text { if } x \neq 0 \\
0 \text { if } x=0
\end{array}\right.
$$

which has a derivative for all $x \in \mathbb{R}$ and for which 0 is a limit point of the set, $Z$, even though $f$ is not identically equal to zero.

Here is a very important application called Euler's formula. Recall that

$$
\begin{equation*}
e^{z} \equiv e^{x}(\cos (y)+i \sin (y)) \tag{51.5.19}
\end{equation*}
$$

Is it also true that $e^{z}=\sum_{k=0}^{\infty} \frac{z^{k}}{k!}$ ?
Theorem 51.5.4 (Euler's Formula) Let $z=x+i y$. Then

$$
e^{z}=\sum_{k=0}^{\infty} \frac{z^{k}}{k!}
$$

Proof: It was already observed that $e^{z}$ given by 51.5 .19 is analytic. So is $\exp (z) \equiv$ $\sum_{k=0}^{\infty} \frac{z^{k}}{k!}$. In fact the power series converges for all $z \in \mathbb{C}$. Furthermore the two functions, $e^{z}$ and $\exp (z)$ agree on the real line which is a set which contains a limit point. Therefore, they agree for all values of $z \in \mathbb{C}$.

This formula shows the famous two identities,

$$
e^{i \pi}=-1 \text { and } e^{2 \pi i}=1
$$

### 51.6 Liouville's Theorem

The following theorem pertains to functions which are analytic on all of $\mathbb{C}$, "entire" functions.

Definition 51.6.1 A function, $f: \mathbb{C} \rightarrow \mathbb{C}$ or more generally, $f: \mathbb{C} \rightarrow X$ is entire means it is analytic on $\mathbb{C}$.

Theorem 51.6.2 (Liouville's theorem) If $f$ is a bounded entire function having values in $X$, then $f$ is a constant.

Proof: Since $f$ is entire, pick any $z \in \mathbb{C}$ and write

$$
f^{\prime}(z)=\frac{1}{2 \pi i} \int_{\gamma_{R}} \frac{f(w)}{(w-z)^{2}} d w
$$

where $\gamma_{R}(t)=z+R e^{i t}$ for $t \in[0,2 \pi]$. Therefore,

$$
\left\|f^{\prime}(z)\right\| \leq C \frac{1}{R}
$$

where $C$ is some constant depending on the assumed bound on $f$. Since $R$ is arbitrary, let $R \rightarrow \infty$ to obtain $f^{\prime}(z)=0$ for any $z \in \mathbb{C}$. It follows from this that $f$ is constant for if $z_{j} j=1,2$ are two complex numbers, let $h(t)=f\left(z_{1}+t\left(z_{2}-z_{1}\right)\right)$ for $t \in[0,1]$. Then $h^{\prime}(t)=f^{\prime}\left(z_{1}+t\left(z_{2}-z_{1}\right)\right)\left(z_{2}-z_{1}\right)=0$. By Lemmas 51.3.2-51.3.4 $h$ is a constant on $[0,1]$ which implies $f\left(z_{1}\right)=f\left(z_{2}\right)$.

With Liouville's theorem it becomes possible to give an easy proof of the fundamental theorem of algebra. It is ironic that all the best proofs of this theorem in algebra come from the subjects of analysis or topology. Out of all the proofs that have been given of this very important theorem, the following one based on Liouville's theorem is the easiest.

Theorem 51.6.3 (Fundamental theorem of Algebra) Let

$$
p(z)=z^{n}+a_{n-1} z^{n-1}+\cdots+a_{1} z+a_{0}
$$

be a polynomial where $n \geq 1$ and each coefficient is a complex number. Then there exists $z_{0} \in \mathbb{C}$ such that $p\left(z_{0}\right)=0$.

Proof: Suppose not. Then $p(z)^{-1}$ is an entire function. Also

$$
|p(z)| \geq|z|^{n}-\left(\left|a_{n-1}\right||z|^{n-1}+\cdots+\left|a_{1}\right||z|+\left|a_{0}\right|\right)
$$

and so $\lim _{|z| \rightarrow \infty}|p(z)|=\infty$ which implies $\lim _{|z| \rightarrow \infty}\left|p(z)^{-1}\right|=0$. It follows that, since $p(z)^{-1}$ is bounded for $z$ in any bounded set, we must have that $p(z)^{-1}$ is a bounded entire function. But then it must be constant. However since $p(z)^{-1} \rightarrow 0$ as $|z| \rightarrow \infty$, this constant can only be 0 . However, $\frac{1}{p(z)}$ is never equal to zero. This proves the theorem.

### 51.7 The General Cauchy Integral Formula

### 51.7.1 The Cauchy Goursat Theorem

This section gives a fundamental theorem which is essential to the development which follows and is closely related to the question of when a function has a primitive. First of all, if you have two points in $\mathbb{C}, z_{1}$ and $z_{2}$, you can consider $\gamma(t) \equiv z_{1}+t\left(z_{2}-z_{1}\right)$ for $t \in[0,1]$ to obtain a continuous bounded variation curve from $z_{1}$ to $z_{2}$. More generally, if $z_{1}, \cdots, z_{m}$ are points in $\mathbb{C}$ you can obtain a continuous bounded variation curve from $z_{1}$ to $z_{m}$ which consists of first going from $z_{1}$ to $z_{2}$ and then from $z_{2}$ to $z_{3}$ and so on, till in the end one goes from $z_{m-1}$ to $z_{m}$. We denote this piecewise linear curve as $\gamma\left(z_{1}, \cdots, z_{m}\right)$. Now let $T$ be a triangle with vertices $z_{1}, z_{2}$ and $z_{3}$ encountered in the counter clockwise direction as shown.

Denote by $\int_{\partial T} f(z) d z$, the expression, $\int_{\gamma\left(z_{1}, z_{2}, z_{3}, z_{1}\right)} f(z) d z$. Consider the following picture.

By Lemma 50.0.11

$$
\begin{equation*}
\int_{\partial T} f(z) d z=\sum_{k=1}^{4} \int_{\partial T_{k}^{1}} f(z) d z \tag{51.7.20}
\end{equation*}
$$

On the "inside lines" the integrals cancel as claimed in Lemma 50.0.11 because there are two integrals going in opposite directions for each of these inside lines.

Theorem 51.7.1 (Cauchy Goursat) Let $f: \Omega \rightarrow X$ have the property that $f^{\prime}(z)$ exists for all $z \in \Omega$ and let $T$ be a triangle contained in $\Omega$. Then

$$
\int_{\partial T} f(w) d w=0
$$

Proof: Suppose not. Then

$$
\left\|\int_{\partial T} f(w) d w\right\|=\alpha \neq 0
$$

From 51.7.20 it follows

$$
\alpha \leq \sum_{k=1}^{4}\left\|\int_{\partial T_{k}^{1}} f(w) d w\right\|
$$

and so for at least one of these $T_{k}^{1}$, denoted from now on as $T_{1}$,

$$
\left\|\int_{\partial T_{1}} f(w) d w\right\| \geq \frac{\alpha}{4}
$$

Now let $T_{1}$ play the same role as $T$, subdivide as in the above picture, and obtain $T_{2}$ such that

$$
\left\|\int_{\partial T_{2}} f(w) d w\right\| \geq \frac{\alpha}{4^{2}}
$$

Continue in this way, obtaining a sequence of triangles,

$$
T_{k} \supseteq T_{k+1}, \operatorname{diam}\left(T_{k}\right) \leq \operatorname{diam}(T) 2^{-k}
$$

and

$$
\left\|\int_{\partial T_{k}} f(w) d w\right\| \geq \frac{\alpha}{4^{k}}
$$

Then let $z \in \cap_{k=1}^{\infty} T_{k}$ and note that by assumption, $f^{\prime}(z)$ exists. Therefore, for all $k$ large enough,

$$
\int_{\partial T_{k}} f(w) d w=\int_{\partial T_{k}} f(z)+f^{\prime}(z)(w-z)+g(w) d w
$$

where $\|g(w)\|<\varepsilon|w-z|$. Now observe that $w \rightarrow f(z)+f^{\prime}(z)(w-z)$ has a primitive, namely,

$$
F(w)=f(z) w+f^{\prime}(z)(w-z)^{2} / 2 .
$$

Therefore, by Corollary 50.0.14.

$$
\int_{\partial T_{k}} f(w) d w=\int_{\partial T_{k}} g(w) d w .
$$

From the definition, of the integral,

$$
\begin{aligned}
\frac{\alpha}{4^{k}} & \leq\left\|\int_{\partial T_{k}} g(w) d w\right\| \leq \varepsilon \operatorname{diam}\left(T_{k}\right)\left(\text { length of } \partial T_{k}\right) \\
& \leq \varepsilon 2^{-k}(\text { length of } T) \operatorname{diam}(T) 2^{-k}
\end{aligned}
$$

and so

$$
\alpha \leq \varepsilon(\text { length of } T) \operatorname{diam}(T)
$$

Since $\varepsilon$ is arbitrary, this shows $\alpha=0$, a contradiction. Thus $\int_{\partial T} f(w) d w=0$ as claimed. This fundamental result yields the following important theorem.

Theorem 51.7.2 (Morera ${ }^{1}$ ) Let $\Omega$ be an open set and let $f^{\prime}(z)$ exist for all $z \in \Omega$. Let $D \equiv \overline{B\left(z_{0}, r\right)} \subseteq \Omega$. Then there exists $\varepsilon>0$ such that $f$ has a primitive on $B\left(z_{0}, r+\varepsilon\right)$.

Proof: Choose $\varepsilon>0$ small enough that $B\left(z_{0}, r+\varepsilon\right) \subseteq \Omega$. Then for $w \in B\left(z_{0}, r+\varepsilon\right)$, define

$$
F(w) \equiv \int_{\gamma\left(z_{0}, w\right)} f(u) d u
$$

Then by the Cauchy Goursat theorem, and $w \in B\left(z_{0}, r+\varepsilon\right)$, it follows that for $|h|$ small enough,

$$
\begin{aligned}
& \frac{F(w+h)-F(w)}{h}=\frac{1}{h} \int_{\gamma(w, w+h)} f(u) d u \\
& =\frac{1}{h} \int_{0}^{1} f(w+t h) h d t=\int_{0}^{1} f(w+t h) d t
\end{aligned}
$$

which converges to $f(w)$ due to the continuity of $f$ at $w$. This proves the theorem.
The following is a slight generalization of the above theorem which is also referred to as Morera's theorem.

[^32]Corollary 51.7.3 Let $\Omega$ be an open set and suppose that whenever

$$
\gamma\left(z_{1}, z_{2}, z_{3}, z_{1}\right)
$$

is a closed curve bounding a triangle $T$, which is contained in $\Omega$, and $f$ is a continuous function defined on $\Omega$, it follows that

$$
\int_{\gamma\left(z_{1}, z_{2}, z_{3}, z_{1}\right)} f(z) d z=0
$$

then $f$ is analytic on $\Omega$.
Proof: As in the proof of Morera's theorem, let $\overline{B\left(z_{0}, r\right)} \subseteq \Omega$ and use the given condition to construct a primitive, $F$ for $f$ on $B\left(z_{0}, r\right)$. Then $F$ is analytic and so by Theorem 51.3.11, it follows that $F$ and hence $f$ have infinitely many derivatives, implying that $f$ is analytic on $B\left(z_{0}, r\right)$. Since $z_{0}$ is arbitrary, this shows $f$ is analytic on $\Omega$.

### 51.7.2 A Redundant Assumption

Earlier in the definition of analytic, it was assumed the derivative is continuous. This assumption is redundant.

Theorem 51.7.4 Let $\Omega$ be an open set in $\mathbb{C}$ and suppose $f: \Omega \rightarrow X$ has the property that $f^{\prime}(z)$ exists for each $z \in \Omega$. Then $f$ is analytic on $\Omega$.

Proof: Let $z_{0} \in \Omega$ and let $B\left(z_{0}, r\right) \subseteq \Omega$. By Morera's theorem $f$ has a primitive, $F$ on $B\left(z_{0}, r\right)$. It follows that $F$ is analytic because it has a derivative, $f$, and this derivative is continuous. Therefore, by Theorem 51.3.11 $F$ has infinitely many derivatives on $B\left(z_{0}, r\right)$ implying that $f$ also has infinitely many derivatives on $B\left(z_{0}, r\right)$. Thus $f$ is analytic as claimed.

It follows a function is analytic on an open set, $\Omega$ if and only if $f^{\prime}(z)$ exists for $z \in \Omega$. This is because it was just shown the derivative, if it exists, is automatically continuous.

The same proof used to prove Theorem 51.7.2 implies the following corollary.
Corollary 51.7.5 Let $\Omega$ be a convex open set and suppose that $f^{\prime}(z)$ exists for all $z \in \Omega$. Then $f$ has a primitive on $\Omega$.

Note that this implies that if $\Omega$ is a convex open set on which $f^{\prime}(z)$ exists and if $\gamma$ : $[a, b] \rightarrow \Omega$ is a closed, continuous curve having bounded variation, then letting $F$ be a primitive of $f$ Theorem 50.0.13 implies

$$
\int_{\gamma} f(z) d z=F(\gamma(b))-F(\gamma(a))=0
$$

Notice how different this is from the situation of a function of a real variable! It is possible for a function of a real variable to have a derivative everywhere and yet the derivative can be discontinuous. A simple example is the following.

$$
f(x) \equiv\left\{\begin{array}{l}
x^{2} \sin \left(\frac{1}{x}\right) \text { if } x \neq 0 \\
0 \text { if } x=0
\end{array} .\right.
$$

Then $f^{\prime}(x)$ exists for all $x \in \mathbb{R}$. Indeed, if $x \neq 0$, the derivative equals $2 x \sin \frac{1}{x}-\cos \frac{1}{x}$ which has no limit as $x \rightarrow 0$. However, from the definition of the derivative of a function of one variable, $f^{\prime}(0)=0$.

### 51.7.3 Classification Of Isolated Singularities

First some notation.
Definition 51.7.6 Let $B^{\prime}(a, r) \equiv\{z \in \mathbb{C}$ such that $0<|z-a|<r\}$. Thus this is the usual ball without the center. A function is said to have an isolated singularity at the point $a \in \mathbb{C}$ if $f$ is analytic on $B^{\prime}(a, r)$ for some $r>0$.

It turns out isolated singularities can be neatly classified into three types, removable singularities, poles, and essential singularities. The next theorem deals with the case of a removable singularity.
Definition 51.7.7 An isolated singularity of $f$ is said to be removable if there exists an analytic function, $g$ analytic at a and near a such that $f=g$ at all points near $a$.

Theorem 51.7.8 Let $f: B^{\prime}(a, r) \rightarrow X$ be analytic. Thus $f$ has an isolated singularity at $a$. Suppose also that

$$
\lim _{z \rightarrow a} f(z)(z-a)=0
$$

Then there exists a unique analytic function, $g: B(a, r) \rightarrow X$ such that $g=f$ on $B^{\prime}(a, r)$. Thus the singularity at a is removable.

Proof: Let $h(z) \equiv(z-a)^{2} f(z), h(a) \equiv 0$. Then $h$ is analytic on $B(a, r)$ because it is easy to see that $h^{\prime}(a)=0$. It follows $h$ is given by a power series,

$$
h(z)=\sum_{k=2}^{\infty} a_{k}(z-a)^{k}
$$

where $a_{0}=a_{1}=0$ because of the observation above that $h^{\prime}(a)=h(a)=0$. It follows that for $|z-a|>0$

$$
f(z)=\sum_{k=2}^{\infty} a_{k}(z-a)^{k-2} \equiv g(z)
$$

This proves the theorem.
What of the other case where the singularity is not removable? This situation is dealt with by the amazing Casorati Weierstrass theorem.

Theorem 51.7.9 (Casorati Weierstrass) Let a be an isolated singularity and suppose for some $r>0, f\left(B^{\prime}(a, r)\right)$ is not dense in $\mathbb{C}$. Then either a is a removable singularity or there exist finitely many $b_{1}, \cdots, b_{M}$ for some finite number, $M$ such that for $z$ near $a$,

$$
\begin{equation*}
f(z)=g(z)+\sum_{k=1}^{M} \frac{b_{k}}{(z-a)^{k}} \tag{51.7.21}
\end{equation*}
$$

where $g(z)$ is analytic near $a$.

Proof: Suppose $B\left(z_{0}, \boldsymbol{\delta}\right)$ has no points of $f\left(B^{\prime}(a, r)\right)$. If $f\left(B^{\prime}(a, r)\right)$ is not dense, then such a ball exists. Then for $z \in B^{\prime}(a, r),\left|f(z)-z_{0}\right| \geq \delta>0$. It follows from Theorem 51.7.8 that $\frac{1}{f(z)-z_{0}}$ has a removable singularity at $a$. Hence, there exists $h$ an analytic function such that for $z$ near $a$,

$$
\begin{equation*}
h(z)=\frac{1}{f(z)-z_{0}} . \tag{51.7.22}
\end{equation*}
$$

There are two cases. First suppose $h(a)=0$. Then $\sum_{k=1}^{\infty} a_{k}(z-a)^{k}=\frac{1}{f(z)-z_{0}}$ for $z$ near $a$. If all the $a_{k}=0$, this would be a contradiction because then the left side would equal zero for $z$ near $a$ but the right side could not equal zero. Therefore, there is a first $m$ such that $a_{m} \neq 0$. Hence there exists an analytic function, $k(z)$ which is not equal to zero in some ball, $B(a, \varepsilon)$ such that

$$
k(z)(z-a)^{m}=\frac{1}{f(z)-z_{0}}
$$

Hence, taking both sides to the -1 power,

$$
f(z)-z_{0}=\frac{1}{(z-a)^{m}} \sum_{k=0}^{\infty} b_{k}(z-a)^{k}
$$

and so 51.7.21 holds.
The other case is that $h(a) \neq 0$. In this case, raise both sides of 51.7.22 to the -1 power and obtain

$$
f(z)-z_{0}=h(z)^{-1}
$$

a function analytic near $a$. Therefore, the singularity is removable. This proves the theorem.
This theorem is the basis for the following definition which classifies isolated singularities.

Definition 51.7.10 Let a be an isolated singularity of a complex valued function, $f$. When 51.7.21 holds for $z$ near $a$, then $a$ is called a pole. The order of the pole in 51.7 .21 is $M$. If for every $r>0, f\left(B^{\prime}(a, r)\right)$ is dense in $\mathbb{C}$ then a is called an essential singularity.

In terms of the above definition, isolated singularities are either removable, a pole, or essential. There are no other possibilities.

Theorem 51.7.11 Suppose $f: \Omega \rightarrow \mathbb{C}$ has an isolated singularity at $a \in \Omega$. Then $a$ is $a$ pole if and only if

$$
\lim _{z \rightarrow a} d(f(z), \infty)=0
$$

in $\widehat{\mathbb{C}}$.
Proof: Suppose first $f$ has a pole at $a$. Then by definition, $f(z)=g(z)+\sum_{k=1}^{M} \frac{b_{k}}{(z-a)^{k}}$ for $z$ near $a$ where $g$ is analytic. Then

$$
\begin{aligned}
|f(z)| & \geq \frac{\left|b_{M}\right|}{|z-a|^{M}}-|g(z)|-\sum_{k=1}^{M-1} \frac{\left|b_{k}\right|}{|z-a|^{k}} \\
& =\frac{1}{|z-a|^{M}}\left(\left|b_{M}\right|-\left(|g(z)||z-a|^{M}+\sum_{k=1}^{M-1}\left|b_{k}\right||z-a|^{M-k}\right)\right)
\end{aligned}
$$

Now $\lim _{z \rightarrow a}\left(|g(z)||z-a|^{M}+\sum_{k=1}^{M-1}\left|b_{k}\right||z-a|^{M-k}\right)=0$ and so the above inequality proves $\lim _{z \rightarrow a}|f(z)|=\infty$. Referring to the diagram on Page 1597, you see this is the same as saying

$$
\lim _{z \rightarrow a}|\theta f(z)-(0,0,2)|=\lim _{z \rightarrow a}|\theta f(z)-\theta(\infty)|=\lim _{z \rightarrow a} d(f(z), \infty)=0
$$

Conversely, suppose $\lim _{z \rightarrow a} d(f(z), \infty)=0$. Then from the diagram on Page 1597, it follows $\lim _{z \rightarrow a}|f(z)|=\infty$ and in particular, $a$ cannot be either removable or an essential singularity by the Casorati Weierstrass theorem, Theorem 51.7.9. The only case remaining is that $a$ is a pole. This proves the theorem.

Definition 51.7.12 Let $f: \Omega \rightarrow \mathbb{C}$ where $\Omega$ is an open subset of $\mathbb{C}$. Then $f$ is called meromorphic if all singularities are isolated and are either poles or removable and this set of singularities has no limit point. It is convenient to regard meromorphic functions as having values in $\widehat{\mathbb{C}}$ where if $a$ is a pole, $f(a) \equiv \infty$. From now on, this will be assumed when $a$ meromorphic function is being considered.

The usefulness of the above convention about $f(a) \equiv \infty$ at a pole is made clear in the following theorem.

Theorem 51.7.13 Let $\Omega$ be an open subset of $\mathbb{C}$ and let $f: \Omega \rightarrow \widehat{\mathbb{C}}$ be meromorphic. Then $f$ is continuous with respect to the metric, $d$ on $\widehat{\mathbb{C}}$.

Proof: Let $z_{n} \rightarrow z$ where $z \in \Omega$. Then if $z$ is a pole, it follows from Theorem 51.7.11 that

$$
d\left(f\left(z_{n}\right), \infty\right) \equiv d\left(f\left(z_{n}\right), f(z)\right) \rightarrow 0
$$

If $z$ is not a pole, then $f\left(z_{n}\right) \rightarrow f(z)$ in $\mathbb{C}$ which implies

$$
\left|\theta\left(f\left(z_{n}\right)\right)-\theta(f(z))\right|=d\left(f\left(z_{n}\right), f(z)\right) \rightarrow 0
$$

Recall that $\theta$ is continuous on $\mathbb{C}$.

### 51.7.4 The Cauchy Integral Formula

This section presents the general version of the Cauchy integral formula valid for arbitrary closed rectifiable curves. The key idea in this development is the notion of the winding number. This is the number also called the index, defined in the following theorem. This winding number, along with the earlier results, especially Liouville's theorem, yields an extremely general Cauchy integral formula.

Definition 51.7.14 Let $\gamma:[a, b] \rightarrow \mathbb{C}$ and suppose $z \notin \gamma^{*}$. The winding number, $n(\gamma, z)$ is defined by

$$
n(\gamma, z) \equiv \frac{1}{2 \pi i} \int_{\gamma} \frac{d w}{w-z}
$$

The main interest is in the case where $\gamma$ is closed curve. However, the same notation will be used for any such curve.

Theorem 51.7.15 Let $\gamma:[a, b] \rightarrow \mathbb{C}$ be continuous and have bounded variation with $\gamma(a)=$ $\gamma(b)$. Also suppose that $z \notin \gamma^{*}$. Define

$$
\begin{equation*}
n(\gamma, z) \equiv \frac{1}{2 \pi i} \int_{\gamma} \frac{d w}{w-z} \tag{51.7.23}
\end{equation*}
$$

Then $n(\gamma, \cdot)$ is continuous and integer valued. Furthermore, there exists a sequence, $\eta_{k}$ : $[a, b] \rightarrow \mathbb{C}$ such that $\eta_{k}$ is $C^{1}([a, b])$,

$$
\left\|\eta_{k}-\gamma\right\|<\frac{1}{k}, \eta_{k}(a)=\eta_{k}(b)=\gamma(a)=\gamma(b)
$$

and $n\left(\eta_{k}, z\right)=n(\gamma, z)$ for all $k$ large enough. Also $n(\gamma, \cdot)$ is constant on every connected component of $\mathbb{C} \backslash \gamma^{*}$ and equals zero on the unbounded component of $\mathbb{C} \backslash \gamma^{*}$.

Proof: First consider the assertion about continuity.

$$
\begin{aligned}
\left|n(\gamma, z)-n\left(\gamma, z_{1}\right)\right| & \leq C\left|\int_{\gamma}\left(\frac{1}{w-z}-\frac{1}{w-z_{1}}\right) d w\right| \\
& \leq \widetilde{C}(\text { Length of } \gamma)\left|z_{1}-z\right|
\end{aligned}
$$

whenever $z_{1}$ is close enough to $z$. This proves the continuity assertion. Note this did not depend on $\gamma$ being closed.

Next it is shown that for a closed curve the winding number equals an integer. To do so, use Theorem 50.0.12 to obtain $\eta_{k}$, a function in $C^{1}([a, b])$ such that $z \notin \eta_{k}([a, b])$ for all $k$ large enough, $\eta_{k}(x)=\gamma(x)$ for $x=a, b$, and

$$
\left|\frac{1}{2 \pi i} \int_{\gamma} \frac{d w}{w-z}-\frac{1}{2 \pi i} \int_{\eta_{k}} \frac{d w}{w-z}\right|<\frac{1}{k},\left\|\eta_{k}-\gamma\right\|<\frac{1}{k}
$$

It is shown that each of $\frac{1}{2 \pi i} \int_{\eta_{k}} \frac{d w}{w-z}$ is an integer. To simplify the notation, write $\eta$ instead of $\eta_{k}$.

$$
\int_{\eta} \frac{d w}{w-z}=\int_{a}^{b} \frac{\eta^{\prime}(s) d s}{\eta(s)-z}
$$

Define

$$
\begin{equation*}
g(t) \equiv \int_{a}^{t} \frac{\eta^{\prime}(s) d s}{\eta(s)-z} \tag{51.7.24}
\end{equation*}
$$

Then

$$
\begin{aligned}
\left(e^{-g(t)}(\eta(t)-z)\right)^{\prime} & =e^{-g(t)} \eta^{\prime}(t)-e^{-g(t)} g^{\prime}(t)(\eta(t)-z) \\
& =e^{-g(t)} \eta^{\prime}(t)-e^{-g(t)} \eta^{\prime}(t)=0
\end{aligned}
$$

It follows that $e^{-g(t)}(\eta(t)-z)$ equals a constant. In particular, using the fact that $\eta(a)=$ $\eta(b)$,

$$
e^{-g(b)}(\eta(b)-z)=e^{-g(a)}(\eta(a)-z)=(\eta(a)-z)=(\eta(b)-z)
$$

and so $e^{-g(b)}=1$. This happens if and only if $-g(b)=2 m \pi i$ for some integer $m$. Therefore, 51.7.24 implies

$$
2 m \pi i=\int_{a}^{b} \frac{\eta^{\prime}(s) d s}{\eta(s)-z}=\int_{\eta} \frac{d w}{w-z}
$$

Therefore, $\frac{1}{2 \pi i} \int_{\eta_{k}} \frac{d w}{w-z}$ is a sequence of integers converging to $\frac{1}{2 \pi i} \int_{\gamma} \frac{d w}{w-z} \equiv n(\gamma, z)$ and so $n(\gamma, z)$ must also be an integer and $n\left(\eta_{k}, z\right)=n(\gamma, z)$ for all $k$ large enough.

Since $n(\gamma, \cdot)$ is continuous and integer valued, it follows from Corollary 7.13.11 on Page 172 that it must be constant on every connected component of $\mathbb{C} \backslash \gamma^{*}$. It is clear that $n(\gamma, z)$ equals zero on the unbounded component because from the formula,

$$
\lim _{z \rightarrow \infty}|n(\gamma, z)| \leq \lim _{z \rightarrow \infty} V(\gamma,[a, b])\left(\frac{1}{|z|-c}\right)
$$

where $c \geq \max \left\{|w|: w \in \gamma^{*}\right\}$. This proves the theorem.
Corollary 51.7.16 Suppose $\gamma:[a, b] \rightarrow \mathbb{C}$ is a continuous bounded variation curve and $n(\gamma, z)$ is an integer where $z \notin \gamma^{*}$. Then $\gamma(a)=\gamma(b)$. Also $z \rightarrow n(\gamma, z)$ for $z \notin \gamma^{*}$ is continuous.

Proof: Letting $\eta$ be a $C^{1}$ curve for which $\eta(a)=\gamma(a)$ and $\eta(b)=\gamma(b)$ and which is close enough to $\gamma$ that $n(\eta, z)=n(\gamma, z)$, the argument is similar to the above. Let

$$
\begin{equation*}
g(t) \equiv \int_{a}^{t} \frac{\eta^{\prime}(s) d s}{\eta(s)-z} \tag{51.7.25}
\end{equation*}
$$

Then

$$
\begin{aligned}
\left(e^{-g(t)}(\eta(t)-z)\right)^{\prime} & =e^{-g(t)} \eta^{\prime}(t)-e^{-g(t)} g^{\prime}(t)(\eta(t)-z) \\
& =e^{-g(t)} \eta^{\prime}(t)-e^{-g(t)} \eta^{\prime}(t)=0
\end{aligned}
$$

Hence

$$
\begin{equation*}
e^{-g(t)}(\eta(t)-z)=c \neq 0 \tag{51.7.26}
\end{equation*}
$$

By assumption

$$
g(b)=\int_{\eta} \frac{1}{w-z} d w=2 \pi i m
$$

for some integer, $m$. Therefore, from 51.7.26

$$
1=e^{2 \pi m i}=\frac{\eta(b)-z}{c}
$$

Thus $c=\eta(b)-z$ and letting $t=a$ in 51.7.26,

$$
1=\frac{\eta(a)-z}{\eta(b)-z}
$$

which shows $\eta(a)=\eta(b)$. This proves the corollary since the assertion about continuity was already observed.

It is a good idea to consider a simple case to get an idea of what the winding number is measuring. To do so, consider $\gamma:[a, b] \rightarrow \mathbb{C}$ such that $\gamma$ is continuous, closed and bounded variation. Suppose also that $\gamma$ is one to one on $(a, b)$. Such a curve is called a simple closed curve. It can be shown that such a simple closed curve divides the plane into exactly two components, an "inside" bounded component and an "outside" unbounded component. This is called the Jordan Curve theorem. This is a difficult theorem which requires some very hard topology such as homology theory or degree theory. It won't be used here beyond making reference to it. For now, it suffices to simply assume that $\gamma$ is such that this result holds. This will usually be obvious anyway. Also suppose that it is possible to change the parameter to be in $[0,2 \pi]$, in such a way that $\gamma(t)+\lambda\left(z+r e^{i t}-\gamma(t)\right)-z \neq 0$ for all $t \in[0,2 \pi]$ and $\lambda \in[0,1]$. (As $t$ goes from 0 to $2 \pi$ the point $\gamma(t)$ traces the curve $\gamma([0,2 \pi])$ in the counter clockwise direction.) Suppose $z \in D$, the inside of the simple closed curve and consider the curve $\delta(t)=z+r e^{i t}$ for $t \in[0,2 \pi]$ where $r$ is chosen small enough that $\overline{B(z, r)} \subseteq D$. Then it happens that $n(\delta, z)=n(\gamma, z)$.

Proposition 51.7.17 Under the above conditions,

$$
n(\delta, z)=n(\gamma, z)
$$

and $n(\delta, z)=1$.
Proof: By changing the parameter, assume that $[a, b]=[0,2 \pi]$. From Theorem 51.7.15 it suffices to assume also that $\gamma$ is $C^{1}$. Define $h_{\lambda}(t) \equiv \gamma(t)+\lambda\left(z+r e^{i t}-\gamma(t)\right)$ for $\lambda \in$ $[0,1]$. (This function is called a homotopy of the curves $\gamma$ and $\delta$.) Note that for each $\lambda \in$ $[0,1], t \rightarrow h_{\lambda}(t)$ is a closed $C^{1}$ curve. Also,

$$
\frac{1}{2 \pi i} \int_{h_{\lambda}} \frac{1}{w-z} d w=\frac{1}{2 \pi i} \int_{0}^{2 \pi} \frac{\gamma^{\prime}(t)+\lambda\left(r i e^{i t}-\gamma^{\prime}(t)\right)}{\gamma(t)+\lambda\left(z+r e^{i t}-\gamma(t)\right)-z} d t
$$

This number is an integer and it is routine to verify that it is a continuous function of $\lambda$. When $\lambda=0$ it equals $n(\gamma, z)$ and when $\lambda=1$ it equals $n(\boldsymbol{\delta}, z)$. Therefore, $n(\boldsymbol{\delta}, z)=n(\gamma, z)$. It only remains to compute $n(\boldsymbol{\delta}, z)$.

$$
n(\delta, z)=\frac{1}{2 \pi i} \int_{0}^{2 \pi} \frac{r i e^{i t}}{r e^{i t}} d t=1
$$

This proves the proposition.
Now if $\gamma$ was not one to one but caused the point, $\gamma(t)$ to travel around $\gamma^{*}$ twice, you could modify the above argument to have the parameter interval, $[0,4 \pi]$ and still find $n(\delta, z)=n(\gamma, z)$ only this time, $n(\delta, z)=2$. Thus the winding number is just what its name suggests. It measures the number of times the curve winds around the point. One might ask why bother with the winding number if this is all it does. The reason is that the notion of counting the number of times a curve winds around a point is rather vague. The winding number is precise. It is also the natural thing to consider in the general Cauchy integral formula presented below. Consider a situation typified by the following picture in which $\Omega$ is the open set between the dotted curves and $\gamma_{j}$ are closed rectifiable curves in $\Omega$.

The following theorem is the general Cauchy integral formula.
Definition 51.7.18 Let $\left\{\gamma_{k}\right\}_{k=1}^{n}$ be continuous oriented curves having bounded variation. Then this is called a cycle if whenever, $z \notin \cup_{k=1}^{n} \gamma_{k}^{*}, \sum_{k=1}^{n} n\left(\gamma_{k}, z\right)$ is an integer.

By Theorem 51.7.15 if each $\gamma_{k}$ is a closed curve, then $\left\{\gamma_{k}\right\}_{k=1}^{n}$ is a cycle.
Theorem 51.7.19 Let $\Omega$ be an open subset of the plane and let $f: \Omega \rightarrow X$ be analytic. If $\gamma_{k}:\left[a_{k}, b_{k}\right] \rightarrow \Omega, k=1, \cdots, m$ are continuous curves having bounded variation such that for all $z \notin \cup_{k=1}^{m} \gamma_{k}\left(\left[a_{k}, b_{k}\right]\right)$

$$
\sum_{k=1}^{m} n\left(\gamma_{k}, z\right) \text { equals an integer }
$$

and for all $z \notin \Omega$,

$$
\sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=0
$$

Then for all $z \in \Omega \backslash \cup_{k=1}^{m} \gamma_{k}\left(\left[a_{k}, b_{k}\right]\right)$,

$$
f(z) \sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=\sum_{k=1}^{m} \frac{1}{2 \pi i} \int_{\gamma_{k}} \frac{f(w)}{w-z} d w .
$$

Proof: Let $\phi$ be defined on $\Omega \times \Omega$ by

$$
\phi(z, w) \equiv\left\{\begin{array}{l}
\frac{f(w)-f(z)}{w-z} \text { if } w \neq z \\
f^{\prime}(z) \text { if } w=z
\end{array}\right.
$$

Then $\phi$ is analytic as a function of both $z$ and $w$ and is continuous in $\Omega \times \Omega$. Here is why: It is clear that $\frac{d}{d w} \phi(z, \cdot)(w)$ exists if $w \neq z$. It remains to consider whether $\frac{d}{d z} \phi(\cdot, z)(z)$ exists. One needs to consider

$$
\frac{\phi(z+h, z)-\phi(z, z)}{h}=\frac{\frac{f(z+h)-f(z)}{h}-f^{\prime}(z)}{h}
$$

We can write $f(z+h)$ as a power series in $h$ whenever $h$ is suitably small.

$$
\frac{\frac{f(z+h)-f(z)}{h}-f^{\prime}(z)}{h}=
$$

$$
\begin{aligned}
& =\frac{1}{h}\left(\frac{1}{h}\left(f^{\prime}(z) h+\frac{1}{2!} f^{\prime \prime}(z) h^{2}+\frac{1}{3!} f^{\prime \prime \prime}(z) h^{3}+\cdots\right)-f^{\prime}(z)\right) \\
& =\frac{1}{h}\left(\left(f^{\prime}(z)+\frac{1}{2!} f^{\prime \prime}(z) h+\frac{1}{3!} f^{\prime \prime \prime}(z) h^{2}+\cdots\right)-f^{\prime}(z)\right) \\
& =\frac{1}{2!} f^{\prime \prime}(z)+\frac{1}{3!} f^{\prime \prime \prime}(z) h+\text { higher order terms }
\end{aligned}
$$

Thus the limit of the difference quotient exists and is $\frac{1}{2!} f^{\prime \prime}(z)$.
Define

$$
h(z) \equiv \frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \phi(z, w) d w
$$

Is $h$ analytic on $\Omega$ ? To show this is the case, verify

$$
\int_{\partial T} h(z) d z=0
$$

for every triangle, $T$, contained in $\Omega$ and apply Corollary 51.7.3. This is an application of the Fubini theorem of Theorem 50.0.15. By Theorem 50.0.15,

$$
\int_{\partial T} \int_{\gamma_{k}} \phi(z, w) d w d z=\int_{\gamma_{k}} \overbrace{\int_{\partial T} \phi(z, w) d z}^{=0} d w=0
$$

because $\phi$ is analytic. By Corollary 51.7.3, $h$ is analytic on $\Omega$ as claimed.
Now let $H$ denote the set,

$$
\begin{aligned}
H & \equiv\left\{z \in \mathbb{C} \backslash \cup_{k=1}^{m} \gamma_{k}^{*}: \sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=0\right\} \\
& =\left\{z \in \mathbb{C} \backslash \cup_{k=1}^{m} \gamma_{k}^{*}: \sum_{k=1}^{m} n\left(\gamma_{k}, z\right) \in(-1 / 2,1 / 2)\right\}
\end{aligned}
$$

the second equality holding because it is given that the sum of these is integer valued. Thus $H$ is an open set because $z \rightarrow \sum_{k=1}^{m} n\left(\gamma_{k}, z\right)$ is continuous. This is obvious from the formula for $n\left(\gamma_{k}, z\right)$. Also, $\Omega \cup H=\mathbb{C}$ because by assumption, $\Omega^{C} \subseteq H$. Extend $h(z)$ to all of $\mathbb{C}$ as follows:

$$
g(z) \equiv\left\{\begin{array}{l}
h(z) \equiv \frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \phi(z, w) d w \text { if } z \in \Omega  \tag{51.7.27}\\
\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \frac{f(w)}{w-z} d w \text { if } z \in H
\end{array}\right.
$$

Why is $g(z)$ well defined? Then on $\Omega \cap H, z \notin \cup_{k=1}^{m} \gamma_{k}^{*}$ and so

$$
\begin{aligned}
g(z) & =\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \phi(z, w) d w=\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \frac{f(w)-f(z)}{w-z} d w \\
& =\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \frac{f(w)}{w-z} d w-\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \frac{f(z)}{w-z} d w \\
& =\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \frac{f(w)}{w-z} d w
\end{aligned}
$$

because $z \in H$. This shows $g(z)$ is well defined. Also, $g$ is analytic on $\Omega$ because it equals $h$ there. It is routine to verify that $g$ is analytic on $H$ also because of the second line of 51.7.27. (See discussion at the end if this is not clear. )

Therefore, $g$ is an entire function, meaning that it is analytic on all of $\mathbb{C}$.
Now note that $\sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=0$ for all $z$ contained in the unbounded component of $\mathbb{C} \backslash \cup_{k=1}^{m} \gamma_{k}^{*}$ which component contains $B(0, r)^{C}$ for $r$ large enough. It follows that for $|z|>r$, it must be the case that $z \in H$ and so for such $z$, the bottom description of $g(z)$ found in 51.7.27 is valid. Therefore, it follows

$$
\lim _{|z| \rightarrow \infty}\|g(z)\|=0
$$

and so $g$ is bounded and analytic on all of $\mathbb{C}$. By Liouville's theorem, $g$ is a constant. Hence, from the above equation, the constant can only equal zero.

For $z \in \Omega \backslash \cup_{k=1}^{m} \gamma_{k}^{*}$, since it was just shown that $h(z)=g(z)=0$ on $\Omega$

$$
\begin{aligned}
0=h(z)= & \frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \phi(z, w) d w=\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \frac{f(w)-f(z)}{w-z} d w= \\
& \frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} \frac{f(w)}{w-z} d w-f(z) \sum_{k=1}^{m} n\left(\gamma_{k}, z\right) .
\end{aligned}
$$

In case it is not obvious why $g$ is analytic on $H$, use the formula. It reduces to showing that

$$
z \rightarrow \int_{\gamma_{k}} \frac{f(w)}{w-z} d w
$$

is analytic. However, taking a difference quotient and simplifying a little, one obtains

$$
\frac{\int_{\gamma_{k}} \frac{f(w)}{w-(z+h)} d w-\int_{\gamma_{k}} \frac{f(w)}{w-z} d w}{h}=\int_{\gamma_{k}} \frac{f(w)}{(w-z)(w-(z+h))} d w
$$

considering only small $h$, the denominator is bounded below by some $\delta>0$ and also $f(w)$ is bounded on the compact set $\gamma_{k}^{*},|f(w)| \leq M$. Then for such small $h$,

$$
\begin{aligned}
& \left|\frac{f(w)}{(w-z)(w-(z+h))}-\frac{f(w)}{(w-z)^{2}}\right| \\
= & \left|\frac{1}{w-z}\left(\frac{1}{(w-(z+h))}-\frac{1}{(w-z)}\right) f(w)\right| \\
\leq & \left|\frac{1}{w-z}\right| \frac{1}{\delta} h M
\end{aligned}
$$

it follows that one obtains uniform convergence as $h \rightarrow 0$ of the integrand to $\frac{f(w)}{(w-z)^{2}}$ for any sequence $h \rightarrow 0$ and so the integral converges to

$$
\int_{\gamma_{k}} \frac{f(w)}{(w-z)^{2}} d w
$$

Corollary 51.7.20 Let $\Omega$ be an open set and let $\gamma_{k}:\left[a_{k}, b_{k}\right] \rightarrow \Omega, k=1, \cdots, m$, be closed, continuous and of bounded variation. Suppose also that $\sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=0$ for all $z \notin \Omega$. Then if $f: \Omega \rightarrow \mathbb{C}$ is analytic, $\sum_{k=1}^{m} \int_{\gamma_{k}} f(w) d w=0$.

Proof: This follows from Theorem 51.7.19 as follows. Let

$$
g(w)=f(w)(w-z)
$$

where $z \in \Omega \backslash \cup_{k=1}^{m} \gamma_{k}\left(\left[a_{k}, b_{k}\right]\right)$. Then by this theorem,

$$
\begin{gathered}
0=0 \sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=g(z) \sum_{k=1}^{m} n\left(\gamma_{k}, z\right)= \\
\sum_{k=1}^{m} \frac{1}{2 \pi i} \int_{\gamma_{k}} \frac{g(w)}{w-z} d w=\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} f(w) d w .
\end{gathered}
$$

Another simple corollary to the above theorem is Cauchy's theorem for a simply connected region.

Definition 51.7.21 An open set, $\Omega \subseteq \mathbb{C}$ is a region if it is open and connected. A region, $\Omega$ is simply connected if $\widehat{\mathbb{C}} \backslash \Omega$ is connected where $\widehat{\mathbb{C}}$ is the extended complex plane. In the future, the term simply connected open set will be an open set which is connected and $\widehat{\mathbb{C}}$ $\backslash \Omega$ is connected.

Corollary 51.7.22 Let $\gamma:[a, b] \rightarrow \Omega$ be a continuous closed curve of bounded variation where $\Omega$ is a simply connected region in $\mathbb{C}$ and let $f: \Omega \rightarrow X$ be analytic. Then

$$
\int_{\gamma} f(w) d w=0
$$

Proof: Let $D$ denote the unbounded component of $\widehat{\mathbb{C}} \backslash \gamma^{*}$. Thus $\infty \in \widehat{\mathbb{C}} \backslash \gamma^{*}$. Then the connected set, $\widehat{\mathbb{C}} \backslash \Omega$ is contained in $D$ since every point of $\widehat{\mathbb{C}} \backslash \Omega$ must be in some component of $\widehat{\mathbb{C}} \backslash \gamma^{*}$ and $\infty$ is contained in both $\widehat{\mathbb{C}} \backslash \Omega$ and $D$. Thus $D$ must be the component that contains $\widehat{\mathbb{C}} \backslash \Omega$. It follows that $n(\gamma, \cdot)$ must be constant on $\widehat{\mathbb{C}} \backslash \Omega$, its value being its value on $D$. However, for $z \in D, n(\gamma, z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{1}{w-z} d w$ and so $\lim _{|z| \rightarrow \infty} n(\gamma, z)=0$ showing $n(\gamma, z)=0$ on $D$. Therefore this verifies the hypothesis of Theorem 51.7.19. Let $z \in \Omega \cap D$ and define $g(w) \equiv f(w)(w-z)$. Thus $g$ is analytic on $\Omega$ and by Theorem 51.7.19,

$$
0=n(z, \gamma) g(z)=\frac{1}{2 \pi i} \int_{\gamma} \frac{g(w)}{w-z} d w=\frac{1}{2 \pi i} \int_{\gamma} f(w) d w
$$

This proves the corollary.
The following is a very significant result which will be used later.
Corollary 51.7.23 Suppose $\Omega$ is a simply connected open set and $f: \Omega \rightarrow X$ is analytic. Then $f$ has a primitive, $F$, on $\Omega$. Recall this means there exists $F$ such that $F^{\prime}(z)=f(z)$ for all $z \in \Omega$.

Proof: Pick a point, $z_{0} \in \Omega$ and let $V$ denote those points, $z$ of $\Omega$ for which there exists a curve, $\gamma:[a, b] \rightarrow \Omega$ such that $\gamma$ is continuous, of bounded variation, $\gamma(a)=z_{0}$, and $\gamma(b)=z$. Then it is easy to verify that $V$ is both open and closed in $\Omega$ and therefore, $V=\Omega$ because $\Omega$ is connected. Denote by $\gamma_{z_{0}, z}$ such a curve from $z_{0}$ to $z$ and define $F(z) \equiv$ $\int_{\gamma_{z_{0}, z}} f(w) d w$. Then $F$ is well defined because if $\gamma_{j}, j=1,2$ are two such curves, it follows from Corollary 51.7.22 that $\int_{\gamma_{1}} f(w) d w+\int_{-\gamma_{2}} f(w) d w=0$, implying that $\int_{\gamma_{1}} f(w) d w=$ $\int_{\gamma_{2}} f(w) d w$.Now this function, $F$ is a primitive because, thanks to Corollary 51.7.22

$$
(F(z+h)-F(z)) h^{-1}=\frac{1}{h} \int_{\gamma_{z, z+h}} f(w) d w=\frac{1}{h} \int_{0}^{1} f(z+t h) h d t
$$

and so, taking the limit as $h \rightarrow 0, F^{\prime}(z)=f(z)$.

### 51.7.5 An Example Of A Cycle

The next theorem deals with the existence of a cycle with nice properties. Basically, you go around the compact subset of an open set with suitable contours while staying in the open set. The method involves the following simple concept.

Definition 51.7.24 A tiling of $\mathbb{R}^{2}=\mathbb{C}$ is the union of infinitely many equally spaced vertical and horizontal lines. You can think of the small squares which result as tiles. To tile the plane or $\mathbb{R}^{2}=\mathbb{C}$ means to consider such a union of horizontal and vertical lines. It is like graph paper. See the picture below for a representation of part of a tiling of $\mathbb{C}$.

Theorem 51.7.25 Let $K$ be a compact subset of an open set, $\Omega$. Then there exist continuous, closed, bounded variation oriented curves $\left\{\Gamma_{j}\right\}_{j=1}^{m}$ for which $\Gamma_{j}^{*} \cap K=\emptyset$ for each $j$, $\Gamma_{j}^{*} \subseteq \Omega$, and for all $p \in K, \sum_{k=1}^{m} n\left(\Gamma_{k}, p\right)=1$ while for all $z \notin \Omega, \sum_{k=1}^{m} n\left(\Gamma_{k}, z\right)=0$.

Proof: Let $\delta=\operatorname{dist}\left(K, \Omega^{C}\right)$. Since $K$ is compact, $\delta>0$. Now tile the plane with squares, each of which has diameter less than $\delta / 2$.

Let $S$ denote the set of all the closed squares in this tiling which have nonempty intersection with $K$.Thus, all the squares of $S$ are contained in $\Omega$. First suppose $p$ is a point of $K$ which is in the interior of one of these squares in the tiling. Denote by $\partial S_{k}$ the boundary of $S_{k}$ one of the squares in $S$, oriented in the counter clockwise direction and $S_{m}$ denote the square of $S$ which contains the point, $p$ in its interior. Let the edges of the square, $S_{j}$ be $\left\{\gamma_{k}^{j}\right\}_{k=1}^{4}$. Thus a short computation shows $n\left(\partial S_{m}, p\right)=1$ but $n\left(\partial S_{j}, p\right)=0$ for all $j \neq m$. The reason for this is that for $z$ in $S_{j}$, the values $\left\{z-p: z \in S_{j}\right\}$ lie in an open square, $Q$ which is located at a positive distance from 0 . Then $\widehat{\mathbb{C}} \backslash Q$ is connected and $1 /(z-p)$ is analytic on $Q$. It follows from Corollary 51.7.23 that this function has a primitive on $Q$ and so

$$
\int_{\partial S_{j}} \frac{1}{z-p} d z=0
$$

Similarly, if $z \notin \Omega, n\left(\partial S_{j}, z\right)=0$. On the other hand, a direct computation will verify that $n\left(p, \partial S_{m}\right)=1$. Thus $1=\sum_{j, k} n\left(p, \gamma_{k}^{j}\right)=\sum_{S_{j} \in S} n\left(p, \partial S_{j}\right)$ and if $z \notin \Omega, 0=\sum_{j, k} n\left(z, \gamma_{k}^{j}\right)=$ $\sum_{S_{j} \in S} n\left(z, \partial S_{j}\right)$.

If $\gamma_{k}^{j *}$ coincides with $\gamma_{l}^{l *}$, then the contour integrals taken over this edge are taken in opposite directions and so the edge the two squares have in common can be deleted without changing $\sum_{j, k} n\left(z, \gamma_{k}^{j}\right)$ for any $z$ not on any of the lines in the tiling. For example, see the picture,

From the construction, if any of the $\gamma_{k}^{j *}$ contains a point of $K$ then this point is on one
of the four edges of $S_{j}$ and at this point, there is at least one edge of some $S_{l}$ which also contains this point. As just discussed, this shared edge can be deleted without changing $\sum_{k, j} n\left(z, \gamma_{k}^{j}\right)$. Delete the edges of the $S_{k}$ which intersect $K$ but not the endpoints of these edges. That is, delete the open edges. When this is done, delete all isolated points. Let the resulting oriented curves be denoted by $\left\{\gamma_{k}\right\}_{k=1}^{m}$. Note that you might have $\gamma_{k}^{*}=\gamma_{l}^{*}$. The construction is illustrated in the following picture.

Then as explained above, $\sum_{k=1}^{m} n\left(p, \gamma_{k}\right)=1$. It remains to prove the claim about the closed curves.

Each orientation on an edge corresponds to a direction of motion over that edge. Call such a motion over the edge a route. Initially, every vertex, (corner of a square in $S$ ) has the property there are the same number of routes to and from that vertex. When an open edge whose closure contains a point of $K$ is deleted, every vertex either remains unchanged as to the number of routes to and from that vertex or it loses both a route away and a route to. Thus the property of having the same number of routes to and from each vertex is preserved by deleting these open edges. The isolated points which result lose all routes to and from. It follows that upon removing the isolated points you can begin at any of the remaining vertices and follow the routes leading out from this and successive vertices according to orientation and eventually return to that end. Otherwise, there would be a vertex which would have only one route leading to it which does not happen. Now if you have used all the routes out of this vertex, pick another vertex and do the same process. Otherwise, pick an unused route out of the vertex and follow it to return. Continue this way till all routes are used exactly once, resulting in closed oriented curves, $\Gamma_{k}$. Then $\sum_{k} n\left(\Gamma_{k}, p\right)=\sum_{j} n\left(\gamma_{j}, p\right)=1$.

In case $p \in K$ is on some line of the tiling, it is not on any of the $\Gamma_{k}$ because $\Gamma_{k}^{*} \cap K=\emptyset$ and so the continuity of $z \rightarrow n\left(\Gamma_{k}, z\right)$ yields the desired result in this case also. This proves the lemma.

### 51.8 Exercises

1. If $U$ is simply connected, $f$ is analytic on $U$ and $f$ has no zeros in $U$, show there exists an analytic function, $F$, defined on $U$ such that $e^{F}=f$.
2. Let $f$ be defined and analytic near the point $a \in \mathbb{C}$. Show that then

$$
f(z)=\sum_{k=0}^{\infty} b_{k}(z-a)^{k}
$$

whenever $|z-a|<R$ where $R$ is the distance between $a$ and the nearest point where $f$ fails to have a derivative. The number $R$, is called the radius of convergence and the power series is said to be expanded about $a$.
3. Find the radius of convergence of the function $\frac{1}{1+z^{2}}$ expanded about $a=2$. Note there is nothing wrong with the function, $\frac{1}{1+x^{2}}$ when considered as a function of a real variable, $x$ for any value of $x$. However, if you insist on using power series, you find there is a limitation on the values of $x$ for which the power series converges due to the presence in the complex plane of a point, $i$, where the function fails to have a derivative.
4. Suppose $f$ is analytic on all of $\mathbb{C}$ and satisfies $|f(z)|<A+B|z|^{1 / 2}$. Show $f$ is constant.
5. What if you defined an open set, $U$ to be simply connected if $\mathbb{C} \backslash U$ is connected. Would it amount to the same thing? Hint: Consider the outside of $B(0,1)$.
6. Let $\gamma(t)=e^{i t}: t \in[0,2 \pi]$. Find $\int_{\gamma} \frac{1}{z^{n}} d z$ for $n=1,2, \cdots$.
7. Show $i \int_{0}^{2 \pi}(2 \cos \theta)^{2 n} d \theta=\int_{\gamma}\left(z+\frac{1}{z}\right)^{2 n}\left(\frac{1}{z}\right) d z$ where $\gamma(t)=e^{i t}: t \in[0,2 \pi]$. Then evaluate this integral using the binomial theorem and the previous problem.
8. Suppose that for some constants $a, b \neq 0, a, b \in \mathbb{R}, f(z+i b)=f(z)$ for all $z \in \mathbb{C}$ and $f(z+a)=f(z)$ for all $z \in \mathbb{C}$. If $f$ is analytic, show that $f$ must be constant. Can you generalize this? Hint: This uses Liouville's theorem.
9. Suppose $f(z)=u(x, y)+i v(x, y)$ is analytic for $z \in U$, an open set. Let $g(z)=$ $u^{*}(x, y)+i v^{*}(x, y)$ where

$$
\binom{u^{*}}{v^{*}}=Q\binom{u}{v}
$$

where $Q$ is a unitary matrix. That is $Q Q^{*}=Q^{*} Q=I$. When will $g$ be analytic?
10. Suppose $f$ is analytic on an open set, $U$, except for $\gamma^{*} \subset U$ where $\gamma$ is a one to one continuous function having bounded variation, but it is known that $f$ is continuous on $\gamma^{*}$. Show that in fact $f$ is analytic on $\gamma^{*}$ also. Hint: Pick a point on $\gamma^{*}$, say $\gamma\left(t_{0}\right)$ and suppose for now that $t_{0} \in(a, b)$. Pick $r>0$ such that $B=B\left(\gamma\left(t_{0}\right), r\right) \subseteq U$. Then show there exists $t_{1}<t_{0}$ and $t_{2}>t_{0}$ such that $\gamma\left(\left[t_{1}, t_{2}\right]\right) \subseteq \bar{B}$ and $\gamma\left(t_{i}\right) \notin B$. Thus $\gamma\left(\left[t_{1}, t_{2}\right]\right)$ is a path across $B$ going through the center of $B$ which divides $B$ into two open sets, $B_{1}$,
and $B_{2}$ along with $\gamma^{*}$. Let the boundary of $B_{k}$ consist of $\gamma\left(\left[t_{1}, t_{2}\right]\right)$ and a circular arc, $C_{k}$. Now letting $z \in B_{k}$, the line integral of $\frac{f(w)}{w-z}$ over $\gamma^{*}$ in two different directions cancels. Therefore, if $z \in B_{k}$, you can argue that $f(z)=\frac{1}{2 \pi i} \int_{C} \frac{f(w)}{w-z} d w$. By continuity, this continues to hold for $z \in \gamma\left(\left(t_{1}, t_{2}\right)\right)$. Therefore, $f$ must be analytic on $\gamma\left(\left(t_{1}, t_{1}\right)\right)$ also. This shows that $f$ must be analytic on $\gamma((a, b))$. To get the endpoints, simply extend $\gamma$ to have the same properties but defined on $[a-\varepsilon, b+\varepsilon]$ and repeat the above argument or else do this at the beginning and note that you get $[a, b] \subseteq(a-\varepsilon, b+\varepsilon)$.
11. Let $U$ be an open set contained in the upper half plane and suppose that there are finitely many line segments on the $x$ axis which are contained in the boundary of $U$. Now suppose that $f$ is defined, real, and continuous on these line segments and is defined and analytic on $U$. Now let $\widetilde{U}$ denote the reflection of $U$ across the $x$ axis. Show that it is possible to extend $f$ to a function, $g$ defined on all of

$$
W \equiv \widetilde{U} \cup U \cup\{\text { the line segments mentioned earlier }\}
$$

such that $g$ is analytic in $W$. Hint: For $z \in \widetilde{U}$, the reflection of $U$ across the $x$ axis, let $g(z) \equiv \overline{f(\bar{z})}$. Show that $g$ is analytic on $\widetilde{U} \cup U$ and continuous on the line segments. Then use Problem 10 or Morera's theorem to argue that $g$ is analytic on the line segments also. The result of this problem is know as the Schwarz reflection principle.
12. Show that rotations and translations of analytic functions yield analytic functions and use this observation to generalize the Schwarz reflection principle to situations in which the line segments are part of a line which is not the $x$ axis. Thus, give a version which involves reflection about an arbitrary line.

## Chapter 52

## The Open Mapping Theorem

### 52.1 A Local Representation

The open mapping theorem, is an even more surprising result than the theorem about the zeros of an analytic function. The following proof of this important theorem uses an interesting local representation of the analytic function.

Theorem 52.1.1 (Open mapping theorem) Let $\Omega$ be a region in $\mathbb{C}$ and suppose $f: \Omega \rightarrow \mathbb{C}$ is analytic. Then $f(\Omega)$ is either a point or a region. In the case where $f(\Omega)$ is a region, it follows that for each $z_{0} \in \Omega$, there exists an open set, $V$ containing $z_{0}$ and $m \in \mathbb{N}$ such that for all $z \in V$,

$$
\begin{equation*}
f(z)=f\left(z_{0}\right)+\phi(z)^{m} \tag{52.1.1}
\end{equation*}
$$

where $\phi: V \rightarrow B(0, \delta)$ is one to one, analytic and onto, $\phi\left(z_{0}\right)=0, \phi^{\prime}(z) \neq 0$ on $V$ and $\phi^{-1}$ analytic on $B(0, \delta)$. If $f$ is one to one then $m=1$ for each $z_{0}$ and $f^{-1}: f(\Omega) \rightarrow \Omega$ is analytic.

Proof: Suppose $f(\Omega)$ is not a point. Then if $z_{0} \in \Omega$ it follows there exists $r>0$ such that $f(z) \neq f\left(z_{0}\right)$ for all $z \in B\left(z_{0}, r\right) \backslash\left\{z_{0}\right\}$. Otherwise, $z_{0}$ would be a limit point of the set,

$$
\left\{z \in \Omega: f(z)-f\left(z_{0}\right)=0\right\}
$$

which would imply from Theorem 51.5 .3 that $f(z)=f\left(z_{0}\right)$ for all $z \in \Omega$. Therefore, making $r$ smaller if necessary and using the power series of $f$,

$$
f(z)=f\left(z_{0}\right)+\left(z-z_{0}\right)^{m} g(z)\left(\stackrel{?}{=}\left(\left(z-z_{0}\right) g(z)^{1 / m}\right)^{m}\right)
$$

for all $z \in B\left(z_{0}, r\right)$, where $g(z) \neq 0$ on $B\left(z_{0}, r\right)$. As implied in the above formula, one wonders if you can take the $m^{\text {th }}$ root of $g(z)$.
$\frac{g^{\prime}}{g}$ is an analytic function on $B\left(z_{0}, r\right)$ and so by Corollary 51.7.5 it has a primitive on $B\left(z_{0}, r\right), h$. Therefore by the product rule and the chain rule, $\left(g e^{-h}\right)^{\prime}=0$ and so there exists a constant, $C=e^{a+i b}$ such that on $B\left(z_{0}, r\right)$,

$$
g e^{-h}=e^{a+i b}
$$

Therefore,

$$
g(z)=e^{h(z)+a+i b}
$$

and so, modifying $h$ by adding in the constant, $a+i b, g(z)=e^{h(z)}$ where $h^{\prime}(z)=\frac{g^{\prime}(z)}{g(z)}$ on $B\left(z_{0}, r\right)$. Letting

$$
\phi(z)=\left(z-z_{0}\right) e^{\frac{h(z)}{m}}
$$

implies formula 52.1.1 is valid on $B\left(z_{0}, r\right)$. Now

$$
\phi^{\prime}\left(z_{0}\right)=e^{\frac{h\left(z_{0}\right)}{m}} \neq 0 .
$$

Shrinking $r$ if necessary you can assume $\phi^{\prime}(z) \neq 0$ on $B\left(z_{0}, r\right)$. Is there an open set $V$ contained in $B\left(z_{0}, r\right)$ such that $\phi$ maps $V$ onto $B(0, \delta)$ for some $\delta>0$ ?

Let $\phi(z)=u(x, y)+i v(x, y)$ where $z=x+i y$. Consider the mapping

$$
\binom{x}{y} \rightarrow\binom{u(x, y)}{v(x, y)}
$$

where $u, v$ are $C^{1}$ because $\phi$ is given to be analytic. The Jacobian of this map at $(x, y) \in$ $B\left(z_{0}, r\right)$ is

$$
\begin{gathered}
\left|\begin{array}{cc}
u_{x}(x, y) & u_{y}(x, y) \\
v_{x}(x, y) & v_{y}(x, y)
\end{array}\right|=\left|\begin{array}{cc}
u_{x}(x, y) & -v_{x}(x, y) \\
v_{x}(x, y) & u_{x}(x, y)
\end{array}\right| \\
=u_{x}(x, y)^{2}+v_{x}(x, y)^{2}=\left|\phi^{\prime}(z)\right|^{2} \neq 0
\end{gathered}
$$

This follows from a use of the Cauchy Riemann equations. Also

$$
\binom{u\left(x_{0}, y_{0}\right)}{v\left(x_{0}, y_{0}\right)}=\binom{0}{0}
$$

Therefore, by the inverse function theorem there exists an open set, $V$, containing $z_{0}$ and $\delta>0$ such that $(u, v)^{T}$ maps $V$ one to one onto $B(0, \delta)$. Thus $\phi$ is one to one onto $B(0, \delta)$ as claimed. Applying the same argument to other points, $z$ of $V$ and using the fact that $\phi^{\prime}(z) \neq 0$ at these points, it follows $\phi$ maps open sets to open sets. In other words, $\phi^{-1}$ is continuous.

It also follows that $\phi^{m}$ maps $V$ onto $B\left(0, \delta^{m}\right)$. Therefore, the formula 52.1.1 implies that $f$ maps the open set, $V$, containing $z_{0}$ to an open set. This shows $f(\Omega)$ is an open set because $z_{0}$ was arbitrary. It is connected because $f$ is continuous and $\Omega$ is connected. Thus $f(\Omega)$ is a region. It remains to verify that $\phi^{-1}$ is analytic on $B(0, \delta)$. Since $\phi^{-1}$ is continuous,

$$
\lim _{\phi\left(z_{1}\right) \rightarrow \phi(z)} \frac{\phi^{-1}\left(\phi\left(z_{1}\right)\right)-\phi^{-1}(\phi(z))}{\phi\left(z_{1}\right)-\phi(z)}=\lim _{z_{1} \rightarrow z} \frac{z_{1}-z}{\phi\left(z_{1}\right)-\phi(z)}=\frac{1}{\phi^{\prime}(z)}
$$

Therefore, $\phi^{-1}$ is analytic as claimed.
It only remains to verify the assertion about the case where $f$ is one to one. If $m>1$, then $e^{\frac{2 \pi i}{m}} \neq 1$ and so for $z_{1} \in V$,

$$
\begin{equation*}
e^{\frac{2 \pi i}{m}} \phi\left(z_{1}\right) \neq \phi\left(z_{1}\right) \tag{52.1.2}
\end{equation*}
$$

But $e^{\frac{2 \pi i}{m}} \phi\left(z_{1}\right) \in B(0, \delta)$ and so there exists $z_{2} \neq z_{1}$ (since $\phi$ is one to one) such that $\phi\left(z_{2}\right)=$ $e^{\frac{2 \pi i}{m}} \phi\left(z_{1}\right)$. But then

$$
\phi\left(z_{2}\right)^{m}=\left(e^{\frac{2 \pi i}{m}} \phi\left(z_{1}\right)\right)^{m}=\phi\left(z_{1}\right)^{m}
$$

implying $f\left(z_{2}\right)=f\left(z_{1}\right)$ contradicting the assumption that $f$ is one to one. Thus $m=1$ and $f^{\prime}(z)=\phi^{\prime}(z) \neq 0$ on $V$. Since $f$ maps open sets to open sets, it follows that $f^{-1}$ is
continuous and so

$$
\begin{aligned}
\left(f^{-1}\right)^{\prime}(f(z)) & =\lim _{f\left(z_{1}\right) \rightarrow f(z)} \frac{f^{-1}\left(f\left(z_{1}\right)\right)-f^{-1}(f(z))}{f\left(z_{1}\right)-f(z)} \\
& =\lim _{z_{1} \rightarrow z} \frac{z_{1}-z}{f\left(z_{1}\right)-f(z)}=\frac{1}{f^{\prime}(z)}
\end{aligned}
$$

This proves the theorem.
One does not have to look very far to find that this sort of thing does not hold for functions mapping $\mathbb{R}$ to $\mathbb{R}$. Take for example, the function $f(x)=x^{2}$. Then $f(\mathbb{R})$ is neither a point nor a region. In fact $f(\mathbb{R})$ fails to be open.

Corollary 52.1.2 Suppose in the situation of Theorem 52.1.1 $m>1$ for the local representation of $f$ given in this theorem. Then there exists $\delta>0$ such that if $w \in B\left(f\left(z_{0}\right), \delta\right)=$ $f(V)$ for $V$ an open set containing $z_{0}$, then $f^{-1}(w)$ consists of $m$ distinct points in $V$. ( $f$ is $m$ to one on $V$ )

Proof: Let $w \in B\left(f\left(z_{0}\right), \boldsymbol{\delta}\right)$. Then $w=f(\widehat{z})$ where $\widehat{z} \in V$. Thus $f(\widehat{z})=f\left(z_{0}\right)+\phi(\widehat{z})^{m}$. Consider the $m$ distinct numbers, $\left\{e^{\frac{2 k \pi i}{m}} \phi(\widehat{z})\right\}_{k=1}^{m}$. Then each of these numbers is in $B(0, \delta)$ and so since $\phi$ maps $V$ one to one onto $B(0, \delta)$, there are $m$ distinct numbers in $V,\left\{z_{k}\right\}_{k=1}^{m}$ such that $\phi\left(z_{k}\right)=e^{\frac{2 k \pi i}{m}} \phi(\widehat{z})$. Then

$$
\begin{aligned}
f\left(z_{k}\right) & =f\left(z_{0}\right)+\phi\left(z_{k}\right)^{m}=f\left(z_{0}\right)+\left(e^{\frac{2 k \pi i}{m}} \phi(\widehat{z})\right)^{m} \\
& =f\left(z_{0}\right)+e^{2 k \pi i} \phi(\widehat{z})^{m}=f\left(z_{0}\right)+\phi(\widehat{z})^{m}=f(\widehat{z})=w
\end{aligned}
$$

This proves the corollary.

### 52.2 Branches Of The Logarithm

The argument used in to prove the next theorem was used in the proof of the open mapping theorem. It is a very important result and deserves to be stated as a theorem.

Theorem 52.2.1 Let $\Omega$ be a simply connected region and suppose $f: \Omega \rightarrow \mathbb{C}$ is analytic and nonzero on $\Omega$. Then there exists an analytic function, $g$ such that $e^{g(z)}=f(z)$ for all $z \in \Omega$.

Proof: The function, $f^{\prime} / f$ is analytic on $\Omega$ and so by Corollary 51.7.23 there is a primitive for $f^{\prime} / f$, denoted as $g_{1}$. Then

$$
\left(e^{-g_{1}} f\right)^{\prime}=-\frac{f^{\prime}}{f} e^{-g_{1}} f+e^{-g_{1}} f^{\prime}=0
$$

and so since $\Omega$ is connected, it follows $e^{-g_{1}} f$ equals a constant, $e^{a+i b}$. Therefore, $f(z)=$ $e^{g_{1}(z)+a+i b}$. Define $g(z) \equiv g_{1}(z)+a+i b$.

The function, $g$ in the above theorem is called a branch of the logarithm of $f$ and is written as $\log (f(z))$.

Definition 52.2.2 Let $\rho$ be a ray starting at 0 . Thus $\rho$ is a straight line of infinite length extending in one direction with its initial point at 0 .

A special case of the above theorem is the following.

Theorem 52.2.3 Let $\rho$ be a ray starting at 0 . Then there exists an analytic function, $L(z)$ defined on $\mathbb{C} \backslash \rho$ such that

$$
e^{L(z)}=z .
$$

This function, L is called a branch of the logarithm. This branch of the logarithm satisfies the usual formula for logarithms, $L(z w)=L(z)+L(w)$ provided $z w \notin \rho$.

Proof: $\mathbb{C} \backslash \rho$ is a simply connected region because its complement with respect to $\widehat{\mathbb{C}}$ is connected. Furthermore, the function, $f(z)=z$ is not equal to zero on $\mathbb{C} \backslash \rho$. Therefore, by Theorem 52.2.1 there exists an analytic function $L(z)$ such that $e^{L(z)}=f(z)=z$. Now consider the problem of finding a description of $L(z)$. Each $z \in \mathbb{C} \backslash \rho$ can be written in a unique way in the form

$$
z=|z| e^{i \arg _{\theta}(z)}
$$

where $\arg _{\theta}(z)$ is the angle in $(\theta, \theta+2 \pi)$ associated with $z$. (You could of course have considered this to be the angle in $(\theta-2 \pi, \theta)$ associated with $z$ or in infinitely many other open intervals of length $2 \pi$. The description of the $\log$ is not unique.) Then letting $L(z)=$ $a+i b$

$$
z=|z| e^{i \arg _{\theta}(z)}=e^{L(z)}=e^{a} e^{i b}
$$

and so you can let $L(z)=\ln |z|+i \arg _{\theta}(z)$.
Does $L(z)$ satisfy the usual properties of the logarithm? That is, for $z, w \in \mathbb{C} \backslash \rho$, is $L(z w)=L(z)+L(w)$ ? This follows from the usual rules of exponents. You know $e^{z+w}=$ $e^{z} e^{w}$. (You can verify this directly or you can reduce to the case where $z, w$ are real. If $z$ is a fixed real number, then the equation holds for all real $w$. Therefore, it must also hold for all complex $w$ because the real line contains a limit point. Now for this fixed $w$, the equation holds for all $z$ real. Therefore, by similar reasoning, it holds for all complex z.)

Now suppose $z, w \in \mathbb{C} \backslash \rho$ and $z w \notin \rho$. Then

$$
e^{L(z w)}=z w, e^{L(z)+L(w)}=e^{L(z)} e^{L(w)}=z w
$$

and so $L(z w)=L(z)+L(w)$ as claimed. This proves the theorem.
In the case where the ray is the negative real axis, it is called the principal branch of the $\operatorname{logarithm}$. Thus $\arg (z)$ is a number between $-\pi$ and $\pi$.

Definition 52.2.4 Let $\log$ denote the branch of the logarithm which corresponds to the ray for $\theta=\pi$. That is, the ray is the negative real axis. Sometimes this is called the principal branch of the logarithm.

### 52.3 Maximum Modulus Theorem

Here is another very significant theorem known as the maximum modulus theorem which follows immediately from the open mapping theorem.

Theorem 52.3.1 (maximum modulus theorem) Let $\Omega$ be a bounded region and let $f: \Omega \rightarrow$ $\mathbb{C}$ be analytic and $f: \bar{\Omega} \rightarrow \mathbb{C}$ continuous. Then if $z \in \Omega$,

$$
\begin{equation*}
|f(z)| \leq \max \{|f(w)|: w \in \partial \Omega\} \tag{52.3.3}
\end{equation*}
$$

If equality is achieved for any $z \in \Omega$, then $f$ is a constant.
Proof: Suppose $f$ is not a constant. Then $f(\Omega)$ is a region and so if $z \in \Omega$, there exists $r>0$ such that $B(f(z), r) \subseteq f(\Omega)$. It follows there exists $z_{1} \in \Omega$ with $\left|f\left(z_{1}\right)\right|>|f(z)|$. Hence $\max \{|f(w)|: w \in \bar{\Omega}\}$ is not achieved at any interior point of $\Omega$. Therefore, the point at which the maximum is achieved must lie on the boundary of $\Omega$ and so

$$
\max \{|f(w)|: w \in \partial \Omega\}=\max \{|f(w)|: w \in \bar{\Omega}\}>|f(z)|
$$

for all $z \in \Omega$ or else $f$ is a constant. This proves the theorem.
You can remove the assumption that $\Omega$ is bounded and give a slightly different version.
Theorem 52.3.2 Let $f: \Omega \rightarrow \mathbb{C}$ be analytic on a region, $\Omega$ and suppose $\overline{B(a, r)} \subseteq \Omega$. Then

$$
|f(a)| \leq \max \left\{\left|f\left(a+r e^{i \theta}\right)\right|: \theta \in[0,2 \pi]\right\}
$$

Equality occurs for some $r>0$ and $a \in \Omega$ if and only if $f$ is constant in $\Omega$ hence equality occurs for all such $a, r$.

Proof: The claimed inequality holds by Theorem 52.3.1. Suppose equality in the above is achieved for some $\overline{B(a, r)} \subseteq \Omega$. Then by Theorem 52.3.1 $f$ is equal to a constant, $w$ on $B(a, r)$. Therefore, the function, $f(\cdot)-w$ has a zero set which has a limit point in $\Omega$ and so by Theorem 51.5.3 $f(z)=w$ for all $z \in \Omega$.

Conversely, if $f$ is constant, then the equality in the above inequality is achieved for all $\overline{B(a, r)} \subseteq \Omega$.

Next is yet another version of the maximum modulus principle which is in Conway [32]. Let $\Omega$ be an open set.

Definition 52.3.3 Define $\partial_{\infty} \Omega$ to equal $\partial \Omega$ in the case where $\Omega$ is bounded and $\partial \Omega \cup\{\infty\}$ in the case where $\Omega$ is not bounded.

Definition 52.3.4 Let $f$ be a complex valued function defined on a set $S \subseteq \mathbb{C}$ and let a be a limit point of $S$.

$$
\limsup |f(z)| \equiv \lim _{z \rightarrow 0}\left\{\sup |f(w)|: w \in B^{\prime}(a, r) \cap S\right\}
$$

The limit exists because $\left\{\sup |f(w)|: w \in B^{\prime}(a, r) \cap S\right\}$ is decreasing in $r$. In case $a=\infty$,

$$
\lim \sup _{z \rightarrow \infty}|f(z)| \equiv \lim _{r \rightarrow \infty}\{\sup |f(w)|:|w|>r, w \in S\}
$$

Note that if $\limsup _{z \rightarrow a}|f(z)| \leq M$ and $\delta>0$, then there exists $r>0$ such that if $z \in$ $B^{\prime}(a, r) \cap S$, then $|f(z)|<M+\delta$. If $a=\infty$, there exists $r>0$ such that if $|z|>r$ and $z \in S$, then $|f(z)|<M+\delta$.

Theorem 52.3.5 Let $\Omega$ be an open set in $\mathbb{C}$ and let $f: \Omega \rightarrow \mathbb{C}$ be analytic. Suppose also that for every $a \in \partial_{\infty} \Omega$,

$$
\limsup _{z \rightarrow a}|f(z)| \leq M<\infty
$$

Then in fact $|f(z)| \leq M$ for all $z \in \Omega$.
Proof: Let $\delta>0$ and let $H \equiv\{z \in \Omega:|f(z)|>M+\delta\}$. Suppose $H \neq \emptyset$. Then $H$ is an open subset of $\Omega$. I claim that $H$ is actually bounded. If $\Omega$ is bounded, there is nothing to show so assume $\Omega$ is unbounded. Then the condition involving the limsup implies there exists $r>0$ such that if $|z|>r$ and $z \in \Omega$, then $|f(z)| \leq M+\delta / 2$. It follows $H$ is contained in $\overline{B(0, r)}$ and so it is bounded. Now consider the components of $\Omega$. One of these components contains points from $H$. Let this component be denoted as $V$ and let $H_{V} \equiv H \cap V$. Thus $H_{V}$ is a bounded open subset of $V$. Let $U$ be a component of $H_{V}$. First suppose $\bar{U} \subseteq V$. In this case, it follows that on $\partial U,|f(z)|=M+\delta$ and so by Theorem 52.3.1 $|f(z)| \leq M+\delta$ for all $z \in U$ contradicting the definition of $H$. Next suppose $\partial U$ contains a point of $\partial V, a$. Then in this case, $a$ violates the condition on limsup. Either way you get a contradiction. Hence $H=\emptyset$ as claimed. Since $\delta>0$ is arbitrary, this shows $|f(z)| \leq M$.

### 52.4 Extensions Of Maximum Modulus Theorem

### 52.4.1 Phragmên Lindelöf Theorem

This theorem is an extension of Theorem 52.3.5. It uses a growth condition near the extended boundary to conclude that $f$ is bounded. I will present the version found in Conway [32]. It seems to be more of a method than an actual theorem. There are several versions of it.

Theorem 52.4.1 Let $\Omega$ be a simply connected region in $\mathbb{C}$ and suppose $f$ is analytic on $\Omega$. Also suppose there exists a function, $\phi$ which is nonzero and uniformly bounded on $\Omega$. Let $M$ be a positive number. Now suppose $\partial_{\infty} \Omega=A \cup B$ such that for every $a \in A$, $\limsup _{z \rightarrow a}|f(z)| \leq M$ and for every $b \in B$, and $\eta>0, \limsup _{z \rightarrow b}|f(z)||\phi(z)|^{\eta} \leq M$. Then $|f(z)| \leq M$ for all $z \in \Omega$.

Proof: By Theorem 52.2.1 there exists $\log (\phi(z))$ analytic on $\Omega$. Now define $g(z) \equiv$ $\exp (\eta \log (\phi(z)))$ so that $g(z)=\phi(z)^{\eta}$. Now also

$$
|g(z)|=|\exp (\eta \log (\phi(z)))|=|\exp (\eta \ln |\phi(z)|)|=|\phi(z)|^{\eta}
$$

Let $m \geq|\phi(z)|$ for all $z \in \Omega$. Define $F(z) \equiv f(z) g(z) m^{-\eta}$. Thus $F$ is analytic and for $b \in B$,

$$
\limsup \sup _{z \rightarrow b}|F(z)|=\lim \sup _{z \rightarrow b}|f(z)||\phi(z)|^{\eta} m^{-\eta} \leq M m^{-\eta}
$$

while for $a \in A$,

$$
\lim \sup _{z \rightarrow a}|F(z)| \leq M
$$

Therefore, for $\alpha \in \partial_{\infty} \Omega, \limsup _{z \rightarrow \alpha}|F(z)| \leq \max \left(M, M \eta^{-\eta}\right)$ and so by Theorem 52.3.5, $|f(z)| \leq\left(\frac{m^{\eta}}{|\phi(z)|^{\eta}}\right) \max \left(M, M \eta^{-\eta}\right)$. Now let $\eta \rightarrow 0$ to obtain $|f(z)| \leq M$.

In applications, it is often the case that $B=\{\infty\}$.
Now here is an interesting case of this theorem. It involves a particular form for $\Omega$, in this case $\Omega=\left\{z \in \mathbb{C}:|\arg (z)|<\frac{\pi}{2 a}\right\}$ where $a \geq \frac{1}{2}$.

Then $\partial \Omega$ equals the two slanted lines. Also on $\Omega$ you can define a $\operatorname{logarithm,\operatorname {log}(z)=}$ $\ln |z|+i \arg (z)$ where $\arg (z)$ is the angle associated with $z$ between $-\pi$ and $\pi$. Therefore, if $c$ is a real number you can define $z^{c}$ for such $z$ in the usual way:

$$
\begin{aligned}
z^{c} & \equiv \exp (c \log (z))=\exp (c[\ln |z|+i \arg (z)]) \\
& =|z|^{c} \exp (i c \arg (z))=|z|^{c}(\cos (c \arg (z))+i \sin (c \arg (z)))
\end{aligned}
$$

If $|c|<a$, then $|c \arg (z)|<\frac{\pi}{2}$ and so $\cos (c \arg (z))>0$. Therefore, for such $c$,

$$
\begin{aligned}
\left|\exp \left(-\left(z^{c}\right)\right)\right| & =\left|\exp \left(-|z|^{c}(\cos (c \arg (z))+i \sin (c \arg (z)))\right)\right| \\
& =\left|\exp \left(-|z|^{c}(\cos (c \arg (z)))\right)\right|
\end{aligned}
$$

which is bounded since $\cos (c \arg (z))>0$.
Corollary 52.4.2 Let $\Omega=\left\{z \in \mathbb{C}:|\arg (z)|<\frac{\pi}{2 a}\right\}$ where $a \geq \frac{1}{2}$ and suppose $f$ is analytic on $\Omega$ and satisfies $\limsup _{z \rightarrow a}|f(z)| \leq M$ on $\partial \Omega$ and suppose there are positive constants, $P, b$ where $b<a$ and

$$
|f(z)| \leq P \exp \left(|z|^{b}\right)
$$

for all $|z|$ large enough. Then $|f(z)| \leq M$ for all $z \in \Omega$.
Proof: Let $b<c<a$ and let $\phi(z) \equiv \exp \left(-\left(z^{c}\right)\right)$. Then as discussed above, $\phi(z) \neq 0$ on $\Omega$ and $|\phi(z)|$ is bounded on $\Omega$. Now

$$
\begin{gathered}
|\phi(z)|^{\eta}=\left|\exp \left(-|z|^{c} \eta(\cos (c \arg (z)))\right)\right| \\
\lim \sup _{z \rightarrow \infty}|f(z)||\phi(z)|^{\eta} \leq \lim \sup _{z \rightarrow \infty} \frac{P \exp \left(|z|^{b}\right)}{\left|\exp \left(|z|^{c} \eta(\cos (c \arg (z)))\right)\right|}=0 \leq M
\end{gathered}
$$

and so by Theorem 52.4.1 $|f(z)| \leq M$.
The following is another interesting case. This case is presented in Rudin [113]

Corollary 52.4.3 Let $\Omega$ be the open set consisting of $\{z \in \mathbb{C}: a<\operatorname{Re} z<b\}$ and suppose $f$ is analytic on $\Omega$, continuous on $\bar{\Omega}$, and bounded on $\Omega$. Suppose also that $f(z) \leq 1$ on the two lines $\operatorname{Re} z=a$ and $\operatorname{Re} z=b$. Then $|f(z)| \leq 1$ for all $z \in \Omega$.

Proof: This time let $\phi(z)=\frac{1}{1+z-a}$. Thus $|\phi(z)| \leq 1$ because $\operatorname{Re}(z-a)>0$ and $\phi(z) \neq 0$ for all $z \in \Omega$. Also, $\limsup _{z \rightarrow \infty}|\phi(z)|^{\eta}=0$ for every $\eta>0$. Therefore, if $a$ is a point of the sides of $\Omega, \limsup _{z \rightarrow a}|f(z)| \leq 1$ while $\limsup _{z \rightarrow \infty}|f(z)||\phi(z)|^{\eta}=0 \leq 1$ and so by Theorem 52.4.1, $|f(z)| \leq 1$ on $\Omega$.

This corollary yields an interesting conclusion.

Corollary 52.4.4 Let $\Omega$ be the open set consisting of $\{z \in \mathbb{C}: a<\operatorname{Re} z<b\}$ and suppose $f$ is analytic on $\Omega$, continuous on $\bar{\Omega}$, and bounded on $\Omega$. Define

$$
M(x) \equiv \sup \{|f(z)|: \operatorname{Re} z=x\}
$$

Then for $x \in(a, b)$.

$$
M(x) \leq M(a)^{\frac{b-x}{b-a}} M(b)^{\frac{x-a}{b-a}}
$$

Proof: Let $\varepsilon>0$ and define

$$
g(z) \equiv(M(a)+\varepsilon)^{\frac{b-z}{b-a}}(M(b)+\varepsilon)^{\frac{z-a}{b-a}}
$$

where for $M>0$ and $z \in \mathbb{C}, M^{z} \equiv \exp (z \ln (M))$. Thus $g \neq 0$ and so $f / g$ is analytic on $\Omega$ and continuous on $\bar{\Omega}$. Also on the left side,

$$
\left|\frac{f(a+i y)}{g(a+i y)}\right|=\left|\frac{f(a+i y)}{(M(a)+\varepsilon)^{\frac{b-a-i y}{b-a}}}\right|=\left|\frac{f(a+i y)}{(M(a)+\varepsilon)^{\frac{b-a}{b-a}}}\right| \leq 1
$$

while on the right side a similar computation shows $\left|\frac{f}{g}\right| \leq 1$ also. Therefore, by Corollary 52.4.3 $|f / g| \leq 1$ on $\Omega$. Therefore, letting $x+i y=z$,

$$
|f(z)| \leq\left|(M(a)+\varepsilon)^{\frac{b-z}{b-a}}(M(b)+\varepsilon)^{\frac{z-a}{b-a}}\right|=\left|(M(a)+\varepsilon)^{\frac{b-x}{b-a}}(M(b)+\varepsilon)^{\frac{x-a}{b-a}}\right|
$$

and so

$$
M(x) \leq(M(a)+\varepsilon)^{\frac{b-x}{b-a}}(M(b)+\varepsilon)^{\frac{x-a}{b-a}}
$$

Since $\varepsilon>0$ is arbitrary, it yields the conclusion of the corollary.
Another way of saying this is that $x \rightarrow \ln (M(x))$ is a convex function.
This corollary has an interesting application known as the Hadamard three circles theorem.

### 52.4.2 Hadamard Three Circles Theorem

Let $0<R_{1}<R_{2}$ and suppose $f$ is analytic on $\left\{z \in \mathbb{C}: R_{1}<|z|<R_{2}\right\}$. Then letting $R_{1}<$ $a<b<R_{2}$, note that $g(z) \equiv \exp (z)$ satisfies

$$
g:\{z \in \mathbb{C}: \ln a<\operatorname{Re} z<b\} \rightarrow\{z \in \mathbb{C}: a<|z|<b\}
$$

is onto and that in fact, $g$ maps the line $\ln r+i y$ onto the circle $r e^{i \theta}$. Now let $M(x)$ be defined as above and $m$ be defined by $m(r) \equiv \max _{\theta}\left|f\left(r e^{i \theta}\right)\right|$.Then for $a<r<b$, Corollary 52.4.4 implies

$$
\begin{aligned}
m(r) & =\sup _{y}\left|f\left(e^{\ln r+i y}\right)\right|=M(\ln r) \leq M(\ln a)^{\frac{\ln b-\ln r}{\ln b-\ln a}} M(\ln b)^{\frac{\ln r-\ln a}{\ln b-\ln a}} \\
& =m(a)^{\ln (b / r) / \ln (b / a)} m(b)^{\ln (r / a) / \ln (b / a)}
\end{aligned}
$$

and so $m(r)^{\ln (b / a)} \leq m(a)^{\ln (b / r)} m(b)^{\ln (r / a)}$. Taking logarithms, this yields

$$
\ln \left(\frac{b}{a}\right) \ln (m(r)) \leq \ln \left(\frac{b}{r}\right) \ln (m(a))+\ln \left(\frac{r}{a}\right) \ln (m(b))
$$

which says the same as $r \rightarrow \ln (m(r))$ is a convex function of $\ln r$.
The next example, also in Rudin [113] is very dramatic. An unbelievably weak assumption is made on the growth of the function and still you get a uniform bound in the conclusion.

Corollary 52.4.5 Let $\Omega=\left\{z \in \mathbb{C}:|\operatorname{Im}(z)|<\frac{\pi}{2}\right\}$. Suppose $f$ is analytic on $\Omega$, continuous on $\bar{\Omega}$, and there exist constants, $\alpha<1$ and $A<\infty$ such that

$$
|f(z)| \leq \exp (A \exp (\alpha|x|)) \text { for } z=x+i y
$$

and

$$
\left|f\left(x \pm i \frac{\pi}{2}\right)\right| \leq 1
$$

for all $x \in \mathbb{R}$. Then $|f(z)| \leq 1$ on $\Omega$.
Proof: This time let $\phi(z)=[\exp (A \exp (\beta z)) \exp (A \exp (-\beta z))]^{-1}$ where $\alpha<\beta<1$. Then $\phi(z) \neq 0$ on $\Omega$ and for $\eta>0$

$$
|\phi(z)|^{\eta}=\frac{1}{|\exp (\eta A \exp (\beta z)) \exp (\eta A \exp (-\beta z))|}
$$

Now

$$
\begin{aligned}
& \exp (\eta A \exp (\beta z)) \exp (\eta A \exp (-\beta z)) \\
= & \exp (\eta A(\exp (\beta z)+\exp (-\beta z))) \\
= & \exp \left[\eta A\left(\cos (\beta y)\left(e^{\beta x}+e^{-\beta x}\right)+i \sin (\beta y)\left(e^{\beta x}-e^{-\beta x}\right)\right)\right]
\end{aligned}
$$

and so

$$
|\phi(z)|^{\eta}=\frac{1}{\exp \left[\eta A\left(\cos (\beta y)\left(e^{\beta x}+e^{-\beta x}\right)\right)\right]}
$$

Now $\cos \beta y>0$ because $\beta<1$ and $|y|<\frac{\pi}{2}$. Therefore, $\limsup _{z \rightarrow \infty}|f(z)||\phi(z)|^{\eta} \leq 0 \leq 1$ and so by Theorem 52.4.1, $|f(z)| \leq 1$.

### 52.4.3 Schwarz's Lemma

This interesting lemma comes from the maximum modulus theorem. It will be used later as part of the proof of the Riemann mapping theorem.

Lemma 52.4.6 Suppose $F: B(0,1) \rightarrow B(0,1), F$ is analytic, and $F(0)=0$. Then for all $z \in B(0,1)$,

$$
\begin{equation*}
|F(z)| \leq|z| \tag{52.4.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|F^{\prime}(0)\right| \leq 1 \tag{52.4.5}
\end{equation*}
$$

If equality holds in 52.4 .5 then there exists $\lambda \in \mathbb{C}$ with $|\lambda|=1$ and

$$
\begin{equation*}
F(z)=\lambda z \tag{52.4.6}
\end{equation*}
$$

Proof: First note that by assumption, $F(z) / z$ has a removable singularity at 0 if its value at 0 is defined to be $F^{\prime}(0)$. By the maximum modulus theorem, if $|z|<r<1$,

$$
\left|\frac{F(z)}{z}\right| \leq \max _{t \in[0,2 \pi]} \frac{\left|F\left(r e^{i t}\right)\right|}{r} \leq \frac{1}{r}
$$

Then letting $r \rightarrow 1$,

$$
\left|\frac{F(z)}{z}\right| \leq 1
$$

this shows 52.4 .4 and it also verifies 52.4 .5 on taking the limit as $z \rightarrow 0$. If equality holds in 52.4.5, then $|F(z) / z|$ achieves a maximum at an interior point so $F(z) / z$ equals a constant, $\lambda$ by the maximum modulus theorem. Since $F(z)=\lambda z$, it follows $F^{\prime}(0)=\lambda$ and so $|\lambda|=1$.

Rudin [113] gives a memorable description of what this lemma says. It says that if an analytic function maps the unit ball to itself, keeping 0 fixed, then it must do one of two things, either be a rotation or move all points closer to 0 . (This second part follows in case $\left|F^{\prime}(0)\right|<1$ because in this case, you must have $|F(z)| \neq|z|$ and so by 52.4.4, $\left.|F(z)|<|z|\right)$

### 52.4.4 One To One Analytic Maps On The Unit Ball

The transformation in the next lemma is of fundamental importance.
Lemma 52.4.7 Let $\alpha \in B(0,1)$ and define

$$
\phi_{\alpha}(z) \equiv \frac{z-\alpha}{1-\bar{\alpha} z}
$$

Then $\phi_{\alpha}: B(0,1) \rightarrow B(0,1), \phi_{\alpha}: \partial B(0,1) \rightarrow \partial B(0,1)$, and is one to one and onto. Also $\phi_{-\alpha}=\phi_{\alpha}^{-1}$. Also

$$
\phi_{\alpha}^{\prime}(0)=1-|\alpha|^{2}, \phi^{\prime}(\alpha)=\frac{1}{1-|\alpha|^{2}}
$$

Proof: First of all, for $|z|<1 /|\alpha|$,

$$
\phi_{\alpha} \circ \phi_{-\alpha}(z) \equiv \frac{\left(\frac{z+\alpha}{1+\bar{\alpha} z}\right)-\alpha}{1-\bar{\alpha}\left(\frac{z+\alpha}{1+\bar{\alpha} z}\right)}=z
$$

after a few computations. If I show that $\phi_{\alpha}$ maps $B(0,1)$ to $B(0,1)$ for all $|\alpha|<1$, this will have shown that $\phi_{\alpha}$ is one to one and onto $B(0,1)$.

Consider $\left|\phi_{\alpha}\left(e^{i \theta}\right)\right|$. This yields

$$
\left|\frac{e^{i \theta}-\alpha}{1-\bar{\alpha} e^{i \theta}}\right|=\left|\frac{1-\alpha e^{-i \theta}}{1-\bar{\alpha} e^{i \theta}}\right|=1
$$

where the first equality is obtained by multiplying by $\left|e^{-i \theta}\right|=1$. Therefore, $\phi_{\alpha}$ maps $\partial B(0,1)$ one to one and onto $\partial B(0,1)$. Now notice that $\phi_{\alpha}$ is analytic on $B(0,1)$ because the only singularity, a pole is at $z=1 / \bar{\alpha}$. By the maximum modulus theorem, it follows

$$
\left|\phi_{\alpha}(z)\right|<1
$$

whenever $|z|<1$. The same is true of $\phi_{-\alpha}$.
It only remains to verify the assertions about the derivatives. Long division gives $\phi_{\alpha}(z)=(-\bar{\alpha})^{-1}+\left(\frac{-\alpha+(\bar{\alpha})^{-1}}{1-\bar{\alpha} z}\right)$ and so

$$
\begin{aligned}
\phi_{\alpha}^{\prime}(z) & =(-1)(1-\bar{\alpha} z)^{-2}\left(-\alpha+(\bar{\alpha})^{-1}\right)(-\bar{\alpha}) \\
& =\bar{\alpha}(1-\bar{\alpha} z)^{-2}\left(-\alpha+(\bar{\alpha})^{-1}\right) \\
& =(1-\bar{\alpha} z)^{-2}\left(-|\alpha|^{2}+1\right)
\end{aligned}
$$

Hence the two formulas follow. This proves the lemma.
One reason these mappings are so important is the following theorem.
Theorem 52.4.8 Suppose $f$ is an analytic function defined on $B(0,1)$ and $f$ maps $B(0,1)$ one to one and onto $B(0,1)$. Then there exists $\theta$ such that

$$
f(z)=e^{i \theta} \phi_{\alpha}(z)
$$

for some $\alpha \in B(0,1)$.
Proof: Let $f(\alpha)=0$. Then $h(z) \equiv f \circ \phi_{-\alpha}(z)$ maps $B(0,1)$ one to one and onto $B(0,1)$ and has the property that $h(0)=0$. Therefore, by the Schwarz lemma,

$$
|h(z)| \leq|z|
$$

but it is also the case that $h^{-1}(0)=0$ and $h^{-1}$ maps $B(0,1)$ to $B(0,1)$. Therefore, the same inequality holds for $h^{-1}$. Therefore,

$$
|z|=\left|h^{-1}(h(z))\right| \leq|h(z)|
$$

and so $|h(z)|=|z|$. By the Schwarz lemma again, $h(z) \equiv f\left(\phi_{-\alpha}(z)\right)=e^{i \theta} z$. Letting $z=$ $\phi_{\alpha}$, you get $f(z)=e^{i \theta} \phi_{\alpha}(z)$.

### 52.5 Exercises

1. Consider the function, $g(z)=\frac{z-i}{z+i}$. Show this is analytic on the upper half plane, $P+$ and maps the upper half plane one to one and onto $B(0,1)$. Hint: First show $g$ maps the real axis to $\partial B(0,1)$. This is really easy because you end up looking at a complex number divided by its conjugate. Thus $|g(z)|=1$ for $z$ on $\partial(P+)$. Now show that $\limsup _{z \rightarrow \infty}|g(z)|=1$. Then apply a version of the maximum modulus theorem. You might note that $g(z)=1+\frac{-2 i}{z+i}$. This will show $|g(z)| \leq 1$. Next pick $w \in B(0,1)$ and solve $g(z)=w$. You just have to show there exists a unique solution and its imaginary part is positive.
2. Does there exist an entire function $f$ which maps $\mathbb{C}$ onto the upper half plane?
3. Letting $g$ be the function of Problem 1 show that $\left(g^{-1}\right)^{\prime}(0)=2$. Also note that $g^{-1}(0)=i$. Now suppose $f$ is an analytic function defined on the upper half plane which has the property that $|f(z)| \leq 1$ and $f(i)=\beta$ where $|\beta|<1$. Find an upper bound to $\left|f^{\prime}(i)\right|$. Also find all functions, $f$ which satisfy the condition, $f(i)=$ $\beta,|f(z)| \leq 1$, and achieve this maximum value. Hint: You could consider the function, $h(z) \equiv \phi_{\beta} \circ f \circ g^{-1}(z)$ and check the conditions for the Schwarz lemma for this function, $h$.
4. This and the next two problems follow a presentation of an interesting topic in Rudin [113]. Let $\phi_{\alpha}$ be given in Lemma 52.4.7. Suppose $f$ is an analytic function defined on $B(0,1)$ which satisfies $|f(z)| \leq 1$. Suppose also there are $\alpha, \beta \in B(0,1)$ and it is required $f(\alpha)=\beta$. If $f$ is such a function, show that $\left|f^{\prime}(\alpha)\right| \leq \frac{1-|\beta|^{2}}{1-|\alpha|^{2}}$. Hint: To show this consider $g=\phi_{\beta} \circ f \circ \phi_{-\alpha}$. Show $g(0)=0$ and $|g(z)| \leq 1$ on $B(0,1)$. Now use Lemma 52.4.6.
5. In Problem 4 show there exists a function, $f$ analytic on $B(0,1)$ such that $f(\alpha)=$ $\beta,|f(z)| \leq 0$, and $\left|f^{\prime}(\alpha)\right|=\frac{1-|\beta|^{2}}{1-|\alpha|^{2}}$. Hint: You do this by choosing $g$ in the above problem such that equality holds in Lemma 52.4.6. Thus you need $g(z)=\lambda z$ where $|\lambda|=1$ and solve $g=\phi_{\beta} \circ f \circ \phi_{-\alpha}$ for $f$.
6. Suppose that $f: B(0,1) \rightarrow B(0,1)$ and that $f$ is analytic, one to one, and onto with $f(\alpha)=0$. Show there exists $\lambda,|\lambda|=1$ such that $f(z)=\lambda \phi_{\alpha}(z)$. This gives a different way to look at Theorem 52.4.8. Hint: Let $g=f^{-1}$. Then $g^{\prime}(0) f^{\prime}(\alpha)=1$. However, $f(\alpha)=0$ and $g(0)=\alpha$. From Problem 4 with $\beta=0$, you can conclude an inequality for $\left|f^{\prime}(\alpha)\right|$ and another one for $\left|g^{\prime}(0)\right|$. Then use the fact that the product of these two equals 1 which comes from the chain rule to conclude that equality must take place. Now use Problem 5 to obtain the form of $f$.
7. In Corollary 52.4 .5 show that it is essential that $\alpha<1$. That is, show there exists an example where the conclusion is not satisfied with a slightly weaker growth condition. Hint: Consider $\exp (\exp (z))$.
8. Suppose $\left\{f_{n}\right\}$ is a sequence of functions which are analytic on $\Omega$, a bounded region such that each $f_{n}$ is also continuous on $\bar{\Omega}$. Suppose that $\left\{f_{n}\right\}$ converges uniformly on
$\partial \Omega$. Show that then $\left\{f_{n}\right\}$ converges uniformly on $\bar{\Omega}$ and that the function to which the sequence converges is analytic on $\Omega$ and continuous on $\bar{\Omega}$.
9. Suppose $\Omega$ is a bounded region and there exists a point $z_{0} \in \Omega$ such that $\left|f\left(z_{0}\right)\right|=$ $\min \{|f(z)|: z \in \bar{\Omega}\}$. Can you conclude $f$ must equal a constant?
10. Suppose $f$ is continuous on $\overline{B(a, r)}$ and analytic on $B(a, r)$ and that $f$ is not constant. Suppose also $|f(z)|=C \neq 0$ for all $|z-a|=r$. Show that there exists $\alpha \in B(a, r)$ such that $f(\alpha)=0$. Hint: If not, consider $f / C$ and $C / f$. Both would be analytic on $B(a, r)$ and are equal to 1 on the boundary.
11. Suppose $f$ is analytic on $B(0,1)$ but for every $a \in \partial B(0,1), \lim _{z \rightarrow a}|f(z)|=\infty$. Show there exists a sequence, $\left\{z_{n}\right\} \subseteq B(0,1)$ such that $\lim _{n \rightarrow \infty}\left|z_{n}\right|=1$ and $f\left(z_{n}\right)=0$.

### 52.6 Counting Zeros

The above proof of the open mapping theorem relies on the very important inverse function theorem from real analysis. There are other approaches to this important theorem which do not rely on the big theorems from real analysis and are more oriented toward the use of the Cauchy integral formula and specialized techniques from complex analysis. One of these approaches is given next which involves the notion of "counting zeros". The next theorem is the one about counting zeros. It will also be used later in the proof of the Riemann mapping theorem.

Theorem 52.6.1 Let $\Omega$ be an open set in $\mathbb{C}$ and let $\gamma:[a, b] \rightarrow \Omega$ be closed, continuous, bounded variation, and $n(\gamma, z)=0$ for all $z \notin \Omega$. Suppose also that $f$ is analytic on $\Omega$ having zeros $a_{1}, \cdots, a_{m}$ where the zeros are repeated according to multiplicity, and suppose that none of these zeros are on $\gamma^{*}$. Then

$$
\frac{1}{2 \pi i} \int_{\gamma} \frac{f^{\prime}(z)}{f(z)} d z=\sum_{k=1}^{m} n\left(\gamma, a_{k}\right) .
$$

Proof: Let $f(z)=\prod_{j=1}^{m}\left(z-a_{j}\right) g(z)$ where $g(z) \neq 0$ on $\Omega$. Note that some of the $a_{j}$ could be repeated. Hence

$$
\frac{f^{\prime}(z)}{f(z)}=\sum_{j=1}^{m} \frac{1}{z-a_{j}}+\frac{g^{\prime}(z)}{g(z)}
$$

and so

$$
\frac{1}{2 \pi i} \int_{\gamma} \frac{f^{\prime}(z)}{f(z)} d z=\sum_{j=1}^{m} n\left(\gamma, a_{j}\right)+\frac{1}{2 \pi i} \int_{\gamma} \frac{g^{\prime}(z)}{g(z)} d z .
$$

But the function, $z \rightarrow \frac{g^{\prime}(z)}{g(z)}$ is analytic and so by Corollary 51.7.20, the last integral in the above expression equals 0 . Therefore, this proves the theorem.

The following picture is descriptive of the situation described in the next theorem.

Theorem 52.6.2 Let $\Omega$ be a region, let $\gamma:[a, b] \rightarrow \Omega$ be closed continuous, and bounded variation such that $n(\gamma, z)=0$ for all $z \notin \Omega$. Also suppose $f: \Omega \rightarrow \mathbb{C}$ is analytic and that $\alpha \notin$ $f\left(\gamma^{*}\right)$. Then $f \circ \gamma:[a, b] \rightarrow \mathbb{C}$ is continuous, closed, and bounded variation. Also suppose $\left\{a_{1}, \cdots, a_{m}\right\}=f^{-1}(\alpha)$ where these points are counted according to their multiplicities as zeros of the function $f-\alpha$ Then

$$
n(f \circ \gamma, \alpha)=\sum_{k=1}^{m} n\left(\gamma, a_{k}\right)
$$

Proof: It is clear that $f \circ \gamma$ is continuous. It only remains to verify that it is of bounded variation. Suppose first that $\gamma^{*} \subseteq B \subseteq \bar{B} \subseteq \Omega$ where $B$ is a ball. Then

$$
\begin{gathered}
|f(\gamma(t))-f(\gamma(s))|= \\
\leq\left|\int_{0}^{1} f^{\prime}(\gamma(s)+\lambda(\gamma(t)-\gamma(s)))(\gamma(t)-\gamma(s)) d \lambda\right| \\
\leq C|\gamma(t)-\gamma(s)|
\end{gathered}
$$

where $C \geq \max \left\{\left|f^{\prime}(z)\right|: z \in \bar{B}\right\}$. Hence, in this case,

$$
V(f \circ \gamma,[a, b]) \leq C V(\gamma,[a, b]) .
$$

Now let $\varepsilon$ denote the distance between $\gamma^{*}$ and $\mathbb{C} \backslash \Omega$. Since $\gamma^{*}$ is compact, $\varepsilon>0$. By uniform continuity there exists $\delta=\frac{b-a}{p}$ for $p$ a positive integer such that if $|s-t|<\delta$, then $|\gamma(s)-\gamma(t)|<\frac{\varepsilon}{2}$. Then

$$
\gamma([t, t+\delta]) \subseteq \overline{B\left(\gamma(t), \frac{\varepsilon}{2}\right)} \subseteq \Omega
$$

Let $C \geq \max \left\{\left|f^{\prime}(z)\right|: z \in \cup_{j=1}^{p} \overline{B\left(\gamma\left(t_{j}\right), \frac{\varepsilon}{2}\right)}\right\}$ where $t_{j} \equiv \frac{j}{p}(b-a)+a$. Then from what was just shown,

$$
\begin{aligned}
V(f \circ \gamma,[a, b]) & \leq \sum_{j=0}^{p-1} V\left(f \circ \gamma,\left[t_{j}, t_{j+1}\right]\right) \\
& \leq C \sum_{j=0}^{p-1} V\left(\gamma,\left[t_{j}, t_{j+1}\right]\right)<\infty
\end{aligned}
$$

showing that $f \circ \gamma$ is bounded variation as claimed. Now from Theorem 51.7.15 there exists $\eta \in C^{1}([a, b])$ such that

$$
\eta(a)=\gamma(a)=\gamma(b)=\eta(b), \eta([a, b]) \subseteq \Omega
$$

and

$$
\begin{equation*}
n\left(\eta, a_{k}\right)=n\left(\gamma, a_{k}\right), n(f \circ \gamma, \alpha)=n(f \circ \eta, \alpha) \tag{52.6.7}
\end{equation*}
$$

for $k=1, \cdots, m$. Then

$$
\begin{aligned}
& n(f \circ \gamma, \alpha)=n(f \circ \eta, \alpha) \\
= & \frac{1}{2 \pi i} \int_{f \circ \eta} \frac{d w}{w-\alpha} \\
= & \frac{1}{2 \pi i} \int_{a}^{b} \frac{f^{\prime}(\eta(t))}{f(\eta(t))-\alpha} \eta^{\prime}(t) d t \\
= & \frac{1}{2 \pi i} \int_{\eta} \frac{f^{\prime}(z)}{f(z)-\alpha} d z \\
= & \sum_{k=1}^{m} n\left(\eta, a_{k}\right)
\end{aligned}
$$

By Theorem 52.6.1. By 52.6.7, this equals $\sum_{k=1}^{m} n\left(\gamma, a_{k}\right)$ which proves the theorem.
The next theorem is incredible and is very interesting for its own sake. The following picture is descriptive of the situation of this theorem.

Theorem 52.6.3 Let $f: B(a, R) \rightarrow \mathbb{C}$ be analytic and let

$$
f(z)-\alpha=(z-a)^{m} g(z), \infty>m \geq 1
$$

where $g(z) \neq 0$ in $B(a, R) .(f(z)-\alpha$ has a zero of order $m$ at $z=a$.) Then there exist $\varepsilon, \delta>0$ with the property that for each $z$ satisfying $0<|z-\alpha|<\delta$, there exist points,

$$
\left\{a_{1}, \cdots, a_{m}\right\} \subseteq B(a, \varepsilon),
$$

such that

$$
f^{-1}(z) \cap B(a, \varepsilon)=\left\{a_{1}, \cdots, a_{m}\right\}
$$

and each $a_{k}$ is a zero of order 1 for the function $f(\cdot)-z$.
Proof: By Theorem 51.5.3 $f$ is not constant on $B(a, R)$ because it has a zero of order $m$. Therefore, using this theorem again, there exists $\varepsilon>0$ such that $\overline{B(a, 2 \varepsilon)} \subseteq B(a, R)$ and there are no solutions to the equation $f(z)-\alpha=0$ for $z \in \overline{B(a, 2 \varepsilon)}$ except $a$. Also assume $\varepsilon$ is small enough that for $0<|z-a| \leq 2 \varepsilon, f^{\prime}(z) \neq 0$. This can be done since otherwise, $a$
would be a limit point of a sequence of points, $z_{n}$, having $f^{\prime}\left(z_{n}\right)=0$ which would imply, by Theorem 51.5.3 that $f^{\prime}=0$ on $B(a, R)$, contradicting the assumption that $f-\alpha$ has a zero of order $m$ and is therefore not constant. Thus the situation is described by the following picture.

Now pick $\gamma(t)=a+\varepsilon e^{i t}, t \in[0,2 \pi]$. Then $\alpha \notin f\left(\gamma^{*}\right)$ so there exists $\delta>0$ with

$$
\begin{equation*}
B(\alpha, \delta) \cap f\left(\gamma^{*}\right)=\emptyset \tag{52.6.8}
\end{equation*}
$$

Therefore, $B(\alpha, \delta)$ is contained on one component of $\mathbb{C} \backslash f(\gamma([0,2 \pi]))$. Therefore,

$$
n(f \circ \gamma, \alpha)=n(f \circ \gamma, z)
$$

for all $z \in B(\alpha, \delta)$. Now consider $f$ restricted to $B(a, 2 \varepsilon)$. For $z \in B(\alpha, \delta), f^{-1}(z)$ must consist of a finite set of points because $f^{\prime}(w) \neq 0$ for all $w$ in $\overline{B(a, 2 \varepsilon)} \backslash\{a\}$ implying that the zeros of $f(\cdot)-z$ in $\overline{B(a, 2 \varepsilon)}$ have no limit point. Since $\overline{B(a, 2 \varepsilon)}$ is compact, this means there are only finitely many. By Theorem 52.6.2,

$$
\begin{equation*}
n(f \circ \gamma, z)=\sum_{k=1}^{p} n\left(\gamma, a_{k}\right) \tag{52.6.9}
\end{equation*}
$$

where $\left\{a_{1}, \cdots, a_{p}\right\}=f^{-1}(z)$. Each point, $a_{k}$ of $f^{-1}(z)$ is either inside the circle traced out by $\gamma$, yielding $n\left(\gamma, a_{k}\right)=1$, or it is outside this circle yielding $n\left(\gamma, a_{k}\right)=0$ because of 52.6.8. It follows the sum in 52.6 .9 reduces to the number of points of $f^{-1}(z)$ which are contained in $B(a, \varepsilon)$. Thus, letting those points in $f^{-1}(z)$ which are contained in $B(a, \varepsilon)$ be denoted by $\left\{a_{1}, \cdots, a_{r}\right\}$

$$
n(f \circ \gamma, \alpha)=n(f \circ \gamma, z)=r
$$

Also, by Theorem 52.6.1, $m=n(f \circ \gamma, \alpha)$ because $a$ is a zero of $f-\alpha$ of order $m$. Therefore, for $z \in B(\alpha, \delta)$

$$
m=n(f \circ \gamma, \alpha)=n(f \circ \gamma, z)=r
$$

It is required to show $r=m$, the order of the zero of $f-\alpha$. Therefore, $r=m$. Each of these $a_{k}$ is a zero of order 1 of the function $f(\cdot)-z$ because $f^{\prime}\left(a_{k}\right) \neq 0$. This proves the theorem.

This is a very fascinating result partly because it implies that for values of $f$ near a value, $\alpha$, at which $f(\cdot)-\alpha$ has a zero of order $m$ for $m>1$, the inverse image of these values includes at least $m$ points, not just one. Thus the topological properties of the inverse image changes radically. This theorem also shows that $f(B(a, \varepsilon)) \supseteq B(\alpha, \delta)$.

Theorem 52.6.4 (open mapping theorem) Let $\Omega$ be a region and $f: \Omega \rightarrow \mathbb{C}$ be analytic. Then $f(\Omega)$ is either a point or a region. If $f$ is one to one, then $f^{-1}: f(\Omega) \rightarrow \Omega$ is analytic.

Proof: If $f$ is not constant, then for every $\alpha \in f(\Omega)$, it follows from Theorem 51.5.3 that $f(\cdot)-\alpha$ has a zero of order $m<\infty$ and so from Theorem 52.6.3, for each $a \in \Omega$ there exist $\varepsilon, \delta>0$ such that $f(B(a, \varepsilon)) \supseteq B(\alpha, \delta)$ which clearly implies that $f$ maps open sets to open sets. Therefore, $f(\Omega)$ is open, connected because $f$ is continuous. If $f$ is one to one, Theorem 52.6.3 implies that for every $\alpha \in f(\Omega)$ the zero of $f(\cdot)-\alpha$ is of order 1. Otherwise, that theorem implies that for $z$ near $\alpha$, there are $m$ points which $f$ maps to $z$ contradicting the assumption that $f$ is one to one. Therefore, $f^{\prime}(z) \neq 0$ and since $f^{-1}$ is continuous, due to $f$ being an open map, it follows

$$
\begin{aligned}
\left(f^{-1}\right)^{\prime}(f(z)) & =\lim _{f\left(z_{1}\right) \rightarrow f(z)} \frac{f^{-1}\left(f\left(z_{1}\right)\right)-f^{-1}(f(z))}{f\left(z_{1}\right)-f(z)} \\
& =\lim _{z_{1} \rightarrow z} \frac{z_{1}-z}{f\left(z_{1}\right)-f(z)}=\frac{1}{f^{\prime}(z)}
\end{aligned}
$$

This proves the theorem.

### 52.7 An Application To Linear Algebra

Gerschgorin's theorem gives a convenient way to estimate eigenvalues of a matrix from easy to obtain information. For $A$ an $n \times n$ matrix, denote by $\sigma(A)$ the collection of all eigenvalues of $A$.

Theorem 52.7.1 Let A be an $n \times n$ matrix. Consider the $n$ Gerschgorin discs defined as

$$
D_{i} \equiv\left\{\lambda \in \mathbb{C}:\left|\lambda-a_{i i}\right| \leq \sum_{j \neq i}\left|a_{i j}\right|\right\} .
$$

Then every eigenvalue is contained in some Gerschgorin disc.
This theorem says to add up the absolute values of the entries of the $i^{t h}$ row which are off the main diagonal and form the disc centered at $a_{i i}$ having this radius. The union of these discs contains $\sigma(A)$.

Proof: Suppose $A \mathbf{x}=\lambda \mathbf{x}$ where $\mathbf{x} \neq \mathbf{0}$. Then for $A=\left(a_{i j}\right)$

$$
\sum_{j \neq i} a_{i j} x_{j}=\left(\lambda-a_{i i}\right) x_{i} .
$$

Therefore, if we pick $k$ such that $\left|x_{k}\right| \geq\left|x_{j}\right|$ for all $x_{j}$, it follows that $\left|x_{k}\right| \neq 0$ since $|\mathbf{x}| \neq 0$ and

$$
\left|x_{k}\right| \sum_{j \neq k}\left|a_{k j}\right| \geq \sum_{j \neq k}\left|a_{k j}\right|\left|x_{j}\right| \geq\left|\lambda-a_{k k}\right|\left|x_{k}\right| .
$$

Now dividing by $\left|x_{k}\right|$ we see that $\lambda$ is contained in the $k^{t h}$ Gerschgorin disc.

More can be said using the theory about counting zeros. To begin with the distance between two $n \times n$ matrices, $A=\left(a_{i j}\right)$ and $B=\left(b_{i j}\right)$ as follows.

$$
\|A-B\|^{2} \equiv \sum_{i j}\left|a_{i j}-b_{i j}\right|^{2}
$$

Thus two matrices are close if and only if their corresponding entries are close.
Let $A$ be an $n \times n$ matrix. Recall the eigenvalues of $A$ are given by the zeros of the polynomial, $p_{A}(z)=\operatorname{det}(z I-A)$ where $I$ is the $n \times n$ identity. Then small changes in $A$ will produce small changes in $p_{A}(z)$ and $p_{A}^{\prime}(z)$. Let $\gamma_{k}$ denote a very small closed circle which winds around $z_{k}$, one of the eigenvalues of $A$, in the counter clockwise direction so that $n\left(\gamma_{k}, z_{k}\right)=1$. This circle is to enclose only $z_{k}$ and is to have no other eigenvalue on it. Then apply Theorem 52.6.1. According to this theorem

$$
\frac{1}{2 \pi i} \int_{\gamma} \frac{p_{A}^{\prime}(z)}{p_{A}(z)} d z
$$

is always an integer equal to the multiplicity of $z_{k}$ as a root of $p_{A}(t)$. Therefore, small changes in $A$ result in no change to the above contour integral because it must be an integer and small changes in $A$ result in small changes in the integral. Therefore whenever every entry of the matrix $B$ is close enough to the corresponding entry of the matrix $A$, the two matrices have the same number of zeros inside $\gamma_{k}$ under the usual convention that zeros are to be counted according to multiplicity. By making the radius of the small circle equal to $\varepsilon$ where $\varepsilon$ is less than the minimum distance between any two distinct eigenvalues of $A$, this shows that if $B$ is close enough to $A$, every eigenvalue of $B$ is closer than $\varepsilon$ to some eigenvalue of $A$. The next theorem is about continuous dependence of eigenvalues.

Theorem 52.7.2 If $\lambda$ is an eigenvalue of $A$, then if $\|B-A\|$ is small enough, some eigenvalue of $B$ will be within $\varepsilon$ of $\lambda$.

Consider the situation that $A(t)$ is an $n \times n$ matrix and that $t \rightarrow A(t)$ is continuous for $t \in[0,1]$.

Lemma 52.7.3 Let $\lambda(t) \in \sigma(A(t))$ for $t<1$ and let $\Sigma_{t}=\cup_{s \geq t} \sigma(A(s))$. Also let $K_{t}$ be the connected component of $\lambda(t)$ in $\Sigma_{t}$. Then there exists $\eta>0$ such that $K_{t} \cap \sigma(A(s)) \neq \emptyset$ for all $s \in[t, t+\eta]$.

Proof: Denote by $D(\lambda(t), \delta)$ the disc centered at $\lambda(t)$ having radius $\delta>0$, with other occurrences of this notation being defined similarly. Thus

$$
D(\lambda(t), \delta) \equiv\{z \in \mathbb{C}:|\lambda(t)-z| \leq \delta\}
$$

Suppose $\delta>0$ is small enough that $\lambda(t)$ is the only element of $\sigma(A(t))$ contained in $D(\lambda(t), \delta)$ and that $p_{A(t)}$ has no zeroes on the boundary of this disc. Then by continuity, and the above discussion and theorem, there exists $\eta>0, t+\eta<1$, such that for $s \in[t, t+\eta], p_{A(s)}$ also has no zeroes on the boundary of this disc and that $A(s)$ has the
same number of eigenvalues, counted according to multiplicity, in the disc as $A(t)$. Thus $\sigma(A(s)) \cap D(\lambda(t), \delta) \neq \emptyset$ for all $s \in[t, t+\eta]$. Now let

$$
H=\bigcup_{s \in[t, t+\eta]} \sigma(A(s)) \cap D(\lambda(t), \delta) .
$$

I will show $H$ is connected. Suppose not. Then $H=P \cup Q$ where $P, Q$ are separated and $\lambda(t) \in P$. Let

$$
s_{0} \equiv \inf \{s: \lambda(s) \in Q \text { for some } \lambda(s) \in \sigma(A(s))\}
$$

There exists $\lambda\left(s_{0}\right) \in \sigma\left(A\left(s_{0}\right)\right) \cap D(\lambda(t), \delta)$. If $\lambda\left(s_{0}\right) \notin Q$, then from the above discussion there are

$$
\lambda(s) \in \sigma(A(s)) \cap Q
$$

for $s>s_{0}$ arbitrarily close to $\lambda\left(s_{0}\right)$. Therefore, $\lambda\left(s_{0}\right) \in Q$ which shows that $s_{0}>t$ because $\lambda(t)$ is the only element of $\sigma(A(t))$ in $D(\lambda(t), \delta)$ and $\lambda(t) \in P$. Now let $s_{n} \uparrow s_{0}$. Then $\lambda\left(s_{n}\right) \in P$ for any

$$
\lambda\left(s_{n}\right) \in \sigma\left(A\left(s_{n}\right)\right) \cap D(\lambda(t), \delta)
$$

and from the above discussion, for some choice of $s_{n} \rightarrow s_{0}, \lambda\left(s_{n}\right) \rightarrow \lambda\left(s_{0}\right)$ which contradicts $P$ and $Q$ separated and nonempty. Since $P$ is nonempty, this shows $Q=\emptyset$. Therefore, $H$ is connected as claimed. But $K_{t} \supseteq H$ and so $K_{t} \cap \sigma(A(s)) \neq \emptyset$ for all $s \in[t, t+\eta]$. This proves the lemma.

The following is the necessary theorem.
Theorem 52.7.4 Suppose $A(t)$ is an $n \times n$ matrix and that $t \rightarrow A(t)$ is continuous for $t \in[0,1]$. Let $\lambda(0) \in \sigma(A(0))$ and define $\Sigma \equiv \cup_{t \in[0,1]} \sigma(A(t))$. Let $K_{\lambda(0)}=K_{0}$ denote the connected component of $\lambda(0)$ in $\Sigma$. Then $K_{0} \cap \sigma(A(t)) \neq \emptyset$ for all $t \in[0,1]$.

Proof: Let $S \equiv\left\{t \in[0,1]: K_{0} \cap \sigma(A(s)) \neq \emptyset\right.$ for all $\left.s \in[0, t]\right\}$. Then $0 \in S$. Let $t_{0}=$ $\sup (S)$. Say $\sigma\left(A\left(t_{0}\right)\right)=\lambda_{1}\left(t_{0}\right), \cdots, \lambda_{r}\left(t_{0}\right)$. I claim at least one of these is a limit point of $K_{0}$ and consequently must be in $K_{0}$ which will show that $S$ has a last point. Why is this claim true? Let $s_{n} \uparrow t_{0}$ so $s_{n} \in S$. Now let the discs, $D\left(\lambda_{i}\left(t_{0}\right), \delta\right), i=1, \cdots, r$ be disjoint with $p_{A\left(t_{0}\right)}$ having no zeroes on $\gamma_{i}$ the boundary of $D\left(\lambda_{i}\left(t_{0}\right), \delta\right)$. Then for $n$ large enough it follows from Theorem 52.6 .1 and the discussion following it that $\sigma\left(A\left(s_{n}\right)\right)$ is contained in $\cup_{i=1}^{r} D\left(\lambda_{i}\left(t_{0}\right), \delta\right)$. Therefore, $K_{0} \cap\left(\sigma\left(A\left(t_{0}\right)\right)+D(0, \delta)\right) \neq \emptyset$ for all $\delta$ small enough. This requires at least one of the $\lambda_{i}\left(t_{0}\right)$ to be in $\overline{K_{0}}$. Therefore, $t_{0} \in S$ and $S$ has a last point.

Now by Lemma 52.7.3, if $t_{0}<1$, then $K_{0} \cup K_{t}$ would be a strictly larger connected set containing $\lambda(0)$. (The reason this would be strictly larger is that $K_{0} \cap \sigma(A(s))=\emptyset$ for some $s \in(t, t+\eta)$ while $K_{t} \cap \sigma(A(s)) \neq \emptyset$ for all $s \in[t, t+\eta]$.) Therefore, $t_{0}=1$ and this proves the theorem.

The following is an interesting corollary of the Gerschgorin theorem.
Corollary 52.7.5 Suppose one of the Gerschgorin discs, $D_{i}$ is disjoint from the union of the others. Then $D_{i}$ contains an eigenvalue of A. Also, if there are $n$ disjoint Gerschgorin discs, then each one contains an eigenvalue of $A$.

Proof: Denote by $A(t)$ the matrix $\left(a_{i j}^{t}\right)$ where if $i \neq j, a_{i j}^{t}=t a_{i j}$ and $a_{i i}^{t}=a_{i i}$. Thus to get $A(t)$ we multiply all non diagonal terms by $t$. Let $t \in[0,1]$. Then

$$
A(0)=\operatorname{diag}\left(a_{11}, \cdots, a_{n n}\right)
$$

and $A(1)=A$. Furthermore, the map, $t \rightarrow A(t)$ is continuous. Denote by $D_{j}^{t}$ the Gerschgorin disc obtained from the $j^{t h}$ row for the matrix, $A(t)$. Then it is clear that $D_{j}^{t} \subseteq D_{j}$ the $j^{t h}$ Gerschgorin disc for $A$. Then $a_{i i}$ is the eigenvalue for $A(0)$ which is contained in the disc, consisting of the single point $a_{i i}$ which is contained in $D_{i}$. Letting $K$ be the connected component in $\Sigma$ for $\Sigma$ defined in Theorem 52.7 .4 which is determined by $a_{i i}$, it follows by Gerschgorin's theorem that $K \cap \sigma(A(t)) \subseteq \cup_{j=1}^{n} D_{j}^{t} \subseteq \cup_{j=1}^{n} D_{j}=D_{i} \cup\left(\cup_{j \neq i} D_{j}\right)$ and also, since $K$ is connected, there are no points of $K$ in both $D_{i}$ and $\left(\cup_{j \neq i} D_{j}\right)$. Since at least one point of $K$ is in $D_{i},\left(a_{i i}\right)$ it follows all of $K$ must be contained in $D_{i}$. Now by Theorem 52.7.4 this shows there are points of $K \cap \sigma(A)$ in $D_{i}$. The last assertion follows immediately.

Actually, this can be improved slightly. It involves the following lemma.
Lemma 52.7.6 In the situation of Theorem 52.7.4 suppose $\lambda(0)=K_{0} \cap \sigma(A(0))$ and that $\lambda(0)$ is a simple root of the characteristic equation of $A(0)$. Then for all $t \in[0,1]$,

$$
\sigma(A(t)) \cap K_{0}=\lambda(t)
$$

where $\lambda(t)$ is a simple root of the characteristic equation of $A(t)$.
Proof: Let $S \equiv$

$$
\left\{t \in[0,1]: K_{0} \cap \sigma(A(s))=\lambda(s), \text { a simple eigenvalue for all } s \in[0, t]\right\}
$$

Then $0 \in S$ so it is nonempty. Let $t_{0}=\sup (S)$ and suppose $\lambda_{1} \neq \lambda_{2}$ are two elements of $\sigma\left(A\left(t_{0}\right)\right) \cap K_{0}$. Then choosing $\eta>0$ small enough, and letting $D_{i}$ be disjoint discs containing $\lambda_{i}$ respectively, similar arguments to those of Lemma 52.7.3 imply

$$
H_{i} \equiv \cup_{s \in\left[t_{0}-\eta, t_{0}\right]} \sigma(A(s)) \cap D_{i}
$$

is a connected and nonempty set for $i=1,2$ which would require that $H_{i} \subseteq K_{0}$. But then there would be two different eigenvalues of $A(s)$ contained in $K_{0}$, contrary to the definition of $t_{0}$. Therefore, there is at most one eigenvalue, $\lambda\left(t_{0}\right) \in K_{0} \cap \sigma\left(A\left(t_{0}\right)\right)$. The possibility that it could be a repeated root of the characteristic equation must be ruled out. Suppose then that $\lambda\left(t_{0}\right)$ is a repeated root of the characteristic equation. As before, choose a small disc, $D$ centered at $\lambda\left(t_{0}\right)$ and $\eta$ small enough that

$$
H \equiv \cup_{s \in\left[t_{0}-\eta, t_{0}\right]} \sigma(A(s)) \cap D
$$

is a nonempty connected set containing either multiple eigenvalues of $A(s)$ or else a single repeated root to the characteristic equation of $A(s)$. But since $H$ is connected and contains $\lambda\left(t_{0}\right)$ it must be contained in $K_{0}$ which contradicts the condition for $s \in S$ for all these $s \in\left[t_{0}-\eta, t_{0}\right]$. Therefore, $t_{0} \in S$ as hoped. If $t_{0}<1$, there exists a small disc centered at $\lambda\left(t_{0}\right)$ and $\eta>0$ such that for all $s \in\left[t_{0}, t_{0}+\eta\right], A(s)$ has only simple eigenvalues in
$D$ and the only eigenvalues of $A(s)$ which could be in $K_{0}$ are in $D$. (This last assertion follows from noting that $\lambda\left(t_{0}\right)$ is the only eigenvalue of $A\left(t_{0}\right)$ in $K_{0}$ and so the others are at a positive distance from $K_{0}$. For $s$ close enough to $t_{0}$, the eigenvalues of $A(s)$ are either close to these eigenvalues of $A\left(t_{0}\right)$ at a positive distance from $K_{0}$ or they are close to the eigenvalue, $\lambda\left(t_{0}\right)$ in which case it can be assumed they are in $D$.) But this shows that $t_{0}$ is not really an upper bound to $S$. Therefore, $t_{0}=1$ and the lemma is proved.

With this lemma, the conclusion of the above corollary can be improved.
Corollary 52.7.7 Suppose one of the Gerschgorin discs, $D_{i}$ is disjoint from the union of the others. Then $D_{i}$ contains exactly one eigenvalue of $A$ and this eigenvalue is a simple root to the characteristic polynomial of $A$.

Proof: In the proof of Corollary 52.7.5, first note that $a_{i i}$ is a simple root of $A(0)$ since otherwise the $i^{t h}$ Gerschgorin disc would not be disjoint from the others. Also, $K$, the connected component determined by $a_{i i}$ must be contained in $D_{i}$ because it is connected and by Gerschgorin's theorem above, $K \cap \sigma(A(t))$ must be contained in the union of the Gerschgorin discs. Since all the other eigenvalues of $A(0)$, the $a_{j j}$, are outside $D_{i}$, it follows that $K \cap \sigma(A(0))=a_{i i}$. Therefore, by Lemma 52.7.6, $K \cap \sigma(A(1))=K \cap \sigma(A)$ consists of a single simple eigenvalue. This proves the corollary.

Example 52.7.8 Consider the matrix,

$$
\left(\begin{array}{lll}
5 & 1 & 0 \\
1 & 1 & 1 \\
0 & 1 & 0
\end{array}\right)
$$

The Gerschgorin discs are $D(5,1), D(1,2)$, and $D(0,1)$. Then $D(5,1)$ is disjoint from the other discs. Therefore, there should be an eigenvalue in $D(5,1)$. The actual eigenvalues are not easy to find. They are the roots of the characteristic equation, $t^{3}-6 t^{2}+3 t+5=0$. The numerical values of these are $-.66966,1.4231$, and 5.24655 , verifying the predictions of Gerschgorin's theorem.

### 52.8 Exercises

1. Use Theorem 52.6.1 to give an alternate proof of the fundamental theorem of algebra. Hint: Take a contour of the form $\gamma_{r}=r e^{i t}$ where $t \in[0,2 \pi]$. Consider $\int_{\gamma_{r}} \frac{p^{\prime}(z)}{p(z)} d z$ and consider the limit as $r \rightarrow \infty$.
2. Let $M$ be an $n \times n$ matrix. Recall that the eigenvalues of $M$ are given by the zeros of the polynomial, $p_{M}(z)=\operatorname{det}(M-z I)$ where $I$ is the $n \times n$ identity. Formulate a theorem which describes how the eigenvalues depend on small changes in $M$. Hint: You could define a norm on the space of $n \times n$ matrices as $\|M\| \equiv \operatorname{tr}\left(M M^{*}\right)^{1 / 2}$ where $M^{*}$ is the conjugate transpose of $M$. Thus

$$
\|M\|=\left(\sum_{j, k}\left|M_{j k}\right|^{2}\right)^{1 / 2}
$$

Argue that small changes will produce small changes in $p_{M}(z)$. Then apply Theorem 52.6.1 using $\gamma_{k}$ a very small circle surrounding $z_{k}$, the $k^{t h}$ eigenvalue.
3. Suppose that two analytic functions defined on a region are equal on some set, $S$ which contains a limit point. (Recall $p$ is a limit point of $S$ if every open set which contains $p$, also contains infinitely many points of $S$. ) Show the two functions coincide. We defined $e^{z} \equiv e^{x}(\cos y+i \sin y)$ earlier and we showed that $e^{z}$, defined this way was analytic on $\mathbb{C}$. Is there any other way to define $e^{z}$ on all of $\mathbb{C}$ such that the function coincides with $e^{x}$ on the real axis?
4. You know various identities for real valued functions. For example $\cosh ^{2} x-\sinh ^{2} x=$ 1. If you define $\cosh z \equiv \frac{e^{z}+e^{-z}}{2}$ and $\sinh z \equiv \frac{e^{z}-e^{-z}}{2}$, does it follow that

$$
\cosh ^{2} z-\sinh ^{2} z=1
$$

for all $z \in \mathbb{C}$ ? What about

$$
\sin (z+w)=\sin z \cos w+\cos z \sin w ?
$$

Can you verify these sorts of identities just from your knowledge about what happens for real arguments?
5. Was it necessary that $U$ be a region in Theorem 51.5.3? Would the same conclusion hold if $U$ were only assumed to be an open set? Why? What about the open mapping theorem? Would it hold if $U$ were not a region?
6. Let $f: U \rightarrow \mathbb{C}$ be analytic and one to one. Show that $f^{\prime}(z) \neq 0$ for all $z \in U$. Does this hold for a function of a real variable?
7. We say a real valued function, $u$ is subharmonic if $u_{x x}+u_{y y} \geq 0$. Show that if $u$ is subharmonic on a bounded region, (open connected set) $U$, and continuous on $\bar{U}$ and $u \leq m$ on $\partial U$, then $u \leq m$ on $U$. Hint: If not, $u$ achieves its maximum at $\left(x_{0}, y_{0}\right) \in U$. Let $u\left(x_{0}, y_{0}\right)>m+\delta$ where $\delta>0$. Now consider $u_{\varepsilon}(x, y)=\varepsilon x^{2}+u(x, y)$ where $\varepsilon$ is small enough that $0<\varepsilon x^{2}<\delta$ for all $(x, y) \in U$. Show that $u_{\varepsilon}$ also achieves its maximum at some point of $U$ and that therefore, $u_{\varepsilon x x}+u_{\varepsilon y y} \leq 0$ at that point implying that $u_{x x}+u_{y y} \leq-\varepsilon$, a contradiction.
8. If $u$ is harmonic on some region, $U$, show that $u$ coincides locally with the real part of an analytic function and that therefore, $u$ has infinitely many derivatives on $U$. Hint: Consider the case where $0 \in U$. You can always reduce to this case by a suitable translation. Now let $B(0, r) \subseteq U$ and use the Schwarz formula to obtain an analytic function whose real part coincides with $u$ on $\partial B(0, r)$. Then use Problem 7.
9. Show the solution to the Dirichlet problem of Problem 8 on Page 1627 is unique. You need to formulate this precisely and then prove uniqueness.

## Chapter 53

## Residues

Definition 53.0.1 The residue of $f$ at an isolated singularity $\alpha$ which is a pole, written $\operatorname{res}(f, \alpha)$ is the coefficient of $(z-\alpha)^{-1}$ where

$$
f(z)=g(z)+\sum_{k=1}^{m} \frac{b_{k}}{(z-\alpha)^{k}} .
$$

Thus $\operatorname{res}(f, \alpha)=b_{1}$ in the above.
At this point, recall Corollary 51.7.20 which is stated here for convenience.
Corollary 53.0.2 Let $\Omega$ be an open set and let $\gamma_{k}:\left[a_{k}, b_{k}\right] \rightarrow \Omega, k=1, \cdots, m$, be closed, continuous and of bounded variation. Suppose also that

$$
\sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=0
$$

for all $z \notin \Omega$. Then if $f: \Omega \rightarrow \mathbb{C}$ is analytic,

$$
\sum_{k=1}^{m} \int_{\gamma_{k}} f(w) d w=0
$$

The following theorem is called the residue theorem. Note the resemblance to Corollary 51.7.20.

Theorem 53.0.3 Let $\Omega$ be an open set and let $\gamma_{k}:\left[a_{k}, b_{k}\right] \rightarrow \Omega, k=1, \cdots, m$, be closed, continuous and of bounded variation. Suppose also that

$$
\sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=0
$$

for all $z \notin \Omega$. Then if $f: \Omega \rightarrow \widehat{\mathbb{C}}$ is meromorphic such that no $\gamma_{k}^{*}$ contains any poles of $f$,

$$
\begin{equation*}
\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} f(w) d w=\sum_{\alpha \in A} \operatorname{res}(f, \alpha) \sum_{k=1}^{m} n\left(\gamma_{k}, \alpha\right) \tag{53.0.1}
\end{equation*}
$$

where here $A$ denotes the set of poles of $f$ in $\Omega$. The sum on the right is a finite sum.
Proof: First note that there are at most finitely many $\alpha$ which are not in the unbounded component of $\mathbb{C} \backslash \cup_{k=1}^{m} \gamma_{k}\left(\left[a_{k}, b_{k}\right]\right)$. Thus there exists a finite set, $\left\{\alpha_{1}, \cdots, \alpha_{N}\right\} \subseteq A$ such that these are the only possibilities for which $\sum_{k=1}^{n} n\left(\gamma_{k}, \alpha\right)$ might not equal zero. Therefore, 53.0.1 reduces to

$$
\frac{1}{2 \pi i} \sum_{k=1}^{m} \int_{\gamma_{k}} f(w) d w=\sum_{j=1}^{N} \operatorname{res}\left(f, \alpha_{j}\right) \sum_{k=1}^{n} n\left(\gamma_{k}, \alpha_{j}\right)
$$

and it is this last equation which is established. Near $\alpha_{j}$,

$$
f(z)=g_{j}(z)+\sum_{r=1}^{m_{j}} \frac{b_{r}^{j}}{\left(z-\alpha_{j}\right)^{r}} \equiv g_{j}(z)+Q_{j}(z)
$$

where $g_{j}$ is analytic at and near $\alpha_{j}$. Now define

$$
G(z) \equiv f(z)-\sum_{j=1}^{N} Q_{j}(z)
$$

It follows that $G(z)$ has a removable singularity at each $\alpha_{j}$. Therefore, by Corollary 51.7.20,

$$
0=\sum_{k=1}^{m} \int_{\gamma_{k}} G(z) d z=\sum_{k=1}^{m} \int_{\gamma_{k}} f(z) d z-\sum_{j=1}^{N} \sum_{k=1}^{m} \int_{\gamma_{k}} Q_{j}(z) d z
$$

Now

$$
\begin{aligned}
\sum_{k=1}^{m} \int_{\gamma_{k}} Q_{j}(z) d z & =\sum_{k=1}^{m} \int_{\gamma_{k}}\left(\frac{b_{1}^{j}}{\left(z-\alpha_{j}\right)}+\sum_{r=2}^{m_{j}} \frac{b_{r}^{j}}{\left(z-\alpha_{j}\right)^{r}}\right) d z \\
& =\sum_{k=1}^{m} \int_{\gamma_{k}} \frac{b_{1}^{j}}{\left(z-\alpha_{j}\right)} d z \equiv \sum_{k=1}^{m} n\left(\gamma_{k}, \alpha_{j}\right) \operatorname{res}\left(f, \alpha_{j}\right)(2 \pi i)
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
\sum_{k=1}^{m} \int_{\gamma_{k}} f(z) d z & =\sum_{j=1}^{N} \sum_{k=1}^{m} \int_{\gamma_{k}} Q_{j}(z) d z \\
& =\sum_{j=1}^{N} \sum_{k=1}^{m} n\left(\gamma_{k}, \alpha_{j}\right) \operatorname{res}\left(f, \alpha_{j}\right)(2 \pi i) \\
& =2 \pi i \sum_{j=1}^{N} \operatorname{res}\left(f, \alpha_{j}\right) \sum_{k=1}^{m} n\left(\gamma_{k}, \alpha_{j}\right) \\
& =(2 \pi i) \sum_{\alpha \in A} \operatorname{res}(f, \alpha) \sum_{k=1}^{m} n\left(\gamma_{k}, \alpha\right)
\end{aligned}
$$

which proves the theorem.
The following is an important example. This example can also be done by real variable methods and there are some who think that real variable methods are always to be preferred to complex variable methods. However, I will use the above theorem to work this example.

Example 53.0.4 Find $\lim _{R \rightarrow \infty} \int_{-R}^{R} \frac{\sin (x)}{x} d x$
Things are easier if you write it as

$$
\lim _{R \rightarrow \infty} \frac{1}{i}\left(\int_{-R}^{-R^{-1}} \frac{e^{i x}}{x} d x+\int_{R^{-1}}^{R} \frac{e^{i x}}{x} d x\right)
$$

This gives the same answer because $\cos (x) / x$ is odd. Consider the following contour in which the orientation involves counterclockwise motion exactly once around.

Denote by $\gamma_{R^{-1}}$ the little circle and $\gamma_{R}$ the big one. Then on the inside of this contour there are no singularities of $e^{i z} / z$ and it is contained in an open set with the property that the winding number with respect to this contour about any point not in the open set equals zero. By Theorem 51.7.22

$$
\begin{equation*}
\frac{1}{i}\left(\int_{-R}^{-R^{-1}} \frac{e^{i x}}{x} d x+\int_{\gamma_{R^{-1}}} \frac{e^{i z}}{z} d z+\int_{R^{-1}}^{R} \frac{e^{i x}}{x} d x+\int_{\gamma_{R}} \frac{e^{i z}}{z} d z\right)=0 \tag{53.0.2}
\end{equation*}
$$

Now

$$
\left|\int_{\gamma_{R}} \frac{e^{i z}}{z} d z\right|=\left|\int_{0}^{\pi} e^{R(i \cos \theta-\sin \theta)} i d \theta\right| \leq \int_{0}^{\pi} e^{-R \sin \theta} d \theta
$$

and this last integral converges to 0 by the dominated convergence theorem. Now consider the other circle. By the dominated convergence theorem again,

$$
\int_{\gamma_{R^{-1}}} \frac{e^{i z}}{z} d z=\int_{\pi}^{0} e^{R^{-1}(i \cos \theta-\sin \theta)} i d \theta \rightarrow-i \pi
$$

as $R \rightarrow \infty$. Then passing to the limit in 53.0.2,

$$
\begin{aligned}
& \lim _{R \rightarrow \infty} \int_{-R}^{R} \frac{\sin (x)}{x} d x \\
= & \lim _{R \rightarrow \infty} \frac{1}{i}\left(\int_{-R}^{-R^{-1}} \frac{e^{i x}}{x} d x+\int_{R^{-1}}^{R} \frac{e^{i x}}{x} d x\right) \\
= & \lim _{R \rightarrow \infty} \frac{1}{i}\left(-\int_{\gamma_{R^{-1}}} \frac{e^{i z}}{z} d z-\int_{\gamma_{R}} \frac{e^{i z}}{z} d z\right)=\frac{-1}{i}(-i \pi)=\pi .
\end{aligned}
$$

Example 53.0.5 Find $\lim _{R \rightarrow \infty} \int_{-R}^{R} e^{i x t} \frac{\sin x}{x} d x$. Note this is essentially finding the inverse Fourier transform of the function, $\sin (x) / x$.

This equals

$$
\begin{aligned}
& \lim _{R \rightarrow \infty} \int_{-R}^{R}(\cos (x t)+i \sin (x t)) \frac{\sin (x)}{x} d x \\
= & \lim _{R \rightarrow \infty} \int_{-R}^{R} \cos (x t) \frac{\sin (x)}{x} d x \\
= & \lim _{R \rightarrow \infty} \int_{-R}^{R} \cos (x t) \frac{\sin (x)}{x} d x \\
= & \lim _{R \rightarrow \infty} \frac{1}{2} \int_{-R}^{R} \frac{\sin (x(t+1))+\sin (x(1-t))}{x} d x
\end{aligned}
$$

Let $t \neq 1,-1$. Then changing variables yields

$$
\lim _{R \rightarrow \infty}\left(\frac{1}{2} \int_{-R(1+t)}^{R(1+t)} \frac{\sin (u)}{u} d u+\frac{1}{2} \int_{-R(1-t)}^{R(1-t)} \frac{\sin (u)}{u} d u\right)
$$

In case $|t|<1$ Example 53.0.4 implies this limit is $\pi$. However, if $t>1$ the limit equals 0 and this is also the case if $t<-1$. Summarizing,

$$
\lim _{R \rightarrow \infty} \int_{-R}^{R} e^{i x t} \frac{\sin x}{x} d x=\left\{\begin{array}{l}
\pi \text { if }|t|<1 \\
0 \text { if }|t|>1
\end{array}\right.
$$

### 53.1 Rouche's Theorem And The Argument Principle

### 53.1.1 Argument Principle

A simple closed curve is just one which is homeomorphic to the unit circle. The Jordan Curve theorem states that every simple closed curve in the plane divides the plane into exactly two connected components, one bounded and the other unbounded. This is a very hard theorem to prove. However, in most applications the conclusion is obvious. Nevertheless, to avoid using this big topological result and to attain some extra generality, I will state the following theorem in terms of the winding number to avoid using it. This theorem is called the argument principle. First recall that $f$ has a zero of order $m$ at $\alpha$ if $f(z)=g(z)(z-\alpha)^{m}$ where $g$ is an analytic function which is not equal to zero at $\alpha$. This is equivalent to having $f(z)=\sum_{k=m}^{\infty} a_{k}(z-\alpha)^{k}$ for $z$ near $\alpha$ where $a_{m} \neq 0$. Also recall that $f$ has a pole of order $m$ at $\alpha$ if for $z$ near $\alpha, f(z)$ is of the form

$$
\begin{equation*}
f(z)=h(z)+\sum_{k=1}^{m} \frac{b_{k}}{(z-\alpha)^{k}} \tag{53.1.3}
\end{equation*}
$$

where $b_{m} \neq 0$ and $h$ is a function analytic near $\alpha$.
Theorem 53.1.1 (argument principle) Let $f$ be meromorphic in $\Omega$. Also suppose $\gamma^{*}$ is a closed bounded variation curve containing none of the poles or zeros of $f$ with the property that for all $z \notin \Omega, n(\gamma, z)=0$ and for all $z \in \Omega, n(\gamma, z)$ either equals 0 or 1 . Now let $\left\{p_{1}, \cdots, p_{m}\right\}$ and $\left\{z_{1}, \cdots, z_{n}\right\}$ be respectively the poles and zeros for which the winding
number of $\gamma$ about these points equals 1 . Let $z_{k}$ be a zero of order $r_{k}$ and let $p_{k}$ be a pole of order $l_{k}$. Then

$$
\frac{1}{2 \pi i} \int_{\gamma} \frac{f^{\prime}(z)}{f(z)} d z=\sum_{k=1}^{n} r_{k}-\sum_{k=1}^{m} l_{k}
$$

Proof: This theorem follows from computing the residues of $f^{\prime} / f$ which has residues only at poles and zeros. I will do this now. First suppose $f$ has a pole of order $p$ at $\alpha$. Then $f$ has the form given in 53.1.3. Therefore,

$$
\begin{gathered}
\frac{f^{\prime}(z)}{f(z)}=\frac{h^{\prime}(z)-\sum_{k=1}^{p} \frac{k b_{k}}{(z-\alpha)^{k+1}}}{h(z)+\sum_{k=1}^{p} \frac{b_{k}}{(z-\alpha)^{k}}} \\
=\frac{h^{\prime}(z)(z-\alpha)^{p}-\sum_{k=1}^{p-1} k b_{k}(z-\alpha)^{-k-1+p}-\frac{p b_{p}}{(z-\alpha)}}{h(z)(z-\alpha)^{p}+\sum_{k=1}^{p-1} b_{k}(z-\alpha)^{p-k}+b_{p}} \\
=\frac{r(z)-\frac{p b_{p}}{(z-\alpha)}}{s(z)+b_{p}}
\end{gathered}
$$

where $s(\alpha)=0, \lim _{z \rightarrow \alpha}(z-\alpha) r(\alpha)=0$. It has a simple pole at $\alpha$ and so the residue is

$$
\operatorname{res}\left(\frac{f^{\prime}}{f}, \alpha\right)=\lim _{z \rightarrow \alpha}(z-\alpha) \frac{r(z)-\frac{p b_{p}}{(z-\alpha)}}{s(z)+b_{p}}=-p
$$

the order of the pole.
Next suppose $f$ has a zero of order $p$ at $\alpha$. Then

$$
\frac{f^{\prime}(z)}{f(z)}=\frac{k}{z-\alpha} \frac{\sum_{k=p}^{\infty} a_{k}(z-\alpha)^{k-1}}{\sum_{k=p}^{\infty} a_{k}(z-\alpha)^{k-1}}=\frac{k}{z-\alpha}
$$

and from this it is clear res $\left(f^{\prime} / f\right)=p$, the order of the zero. The conclusion of this theorem now follows from the residue theorem Theorem 53.0.3.

One can also generalize the theorem to the case where there are many closed curves involved. This is proved in the same way as the above.

Theorem 53.1.2 (argument principle) Let $f$ be meromorphic in $\Omega$ and let $\gamma_{k}:\left[a_{k}, b_{k}\right] \rightarrow \Omega$, $k=1, \cdots, m$, be closed, continuous and of bounded variation. Suppose also that

$$
\sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=0
$$

and for all $z \notin \Omega$ and for $z \in \Omega, \sum_{k=1}^{m} n\left(\gamma_{k}, z\right)$ either equals 0 or 1 . Now let $\left\{p_{1}, \cdots, p_{m}\right\}$ and $\left\{z_{1}, \cdots, z_{n}\right\}$ be respectively the poles and zeros for which the above sum of winding numbers equals 1. Let $z_{k}$ be a zero of order $r_{k}$ and let $p_{k}$ be a pole of order $l_{k}$. Then

$$
\frac{1}{2 \pi i} \int_{\gamma} \frac{f^{\prime}(z)}{f(z)} d z=\sum_{k=1}^{n} r_{k}-\sum_{k=1}^{m} l_{k}
$$

There is also a simple extension of this important principle which I found in [65].
Theorem 53.1.3 (argument principle) Let $f$ be meromorphic in $\Omega$. Also suppose $\gamma^{*}$ is a closed bounded variation curve with the property that for all $z \notin \Omega, n(\gamma, z)=0$ and for all $z \in \Omega, n(\gamma, z)$ either equals 0 or 1 . Now let $\left\{p_{1}, \cdots, p_{m}\right\}$ and $\left\{z_{1}, \cdots, z_{n}\right\}$ be respectively the poles and zeros for which the winding number of $\gamma$ about these points equals 1 listed according to multiplicity. Thus if there is a pole of order $m$ there will be this value repeated $m$ times in the list for the poles. Also let $g(z)$ be an analytic function. Then

$$
\frac{1}{2 \pi i} \int_{\gamma} g(z) \frac{f^{\prime}(z)}{f(z)} d z=\sum_{k=1}^{n} g\left(z_{k}\right)-\sum_{k=1}^{m} g\left(p_{k}\right)
$$

Proof: This theorem follows from computing the residues of $g\left(f^{\prime} / f\right)$. It has residues at poles and zeros. I will do this now. First suppose $f$ has a pole of order $m$ at $\alpha$. Then $f$ has the form given in 53.1.3. Therefore,

$$
\begin{aligned}
& g(z) \frac{f^{\prime}(z)}{f(z)} \\
= & \frac{g(z)\left(h^{\prime}(z)-\sum_{k=1}^{m} \frac{k b_{k}}{(z-\alpha)^{k+1}}\right)}{h(z)+\sum_{k=1}^{m} \frac{b_{k}}{(z-\alpha)^{k}}} \\
= & g(z) \frac{h^{\prime}(z)(z-\alpha)^{m}-\sum_{k=1}^{m-1} k b_{k}(z-\alpha)^{-k-1+m}-\frac{m b_{m}}{(z-\alpha)}}{h(z)(z-\alpha)^{m}+\sum_{k=1}^{m-1} b_{k}(z-\alpha)^{m-k}+b_{m}}
\end{aligned}
$$

From this, it is clear res $\left(g\left(f^{\prime} / f\right), \alpha\right)=-m g(\alpha)$, where $m$ is the order of the pole. Thus $\alpha$ would have been listed $m$ times in the list of poles. Hence the residue at this point is equivalent to adding $-g(\alpha) m$ times.

Next suppose $f$ has a zero of order $m$ at $\alpha$. Then

$$
g(z) \frac{f^{\prime}(z)}{f(z)}=g(z) \frac{\sum_{k=m}^{\infty} a_{k} k(z-\alpha)^{k-1}}{\sum_{k=m}^{\infty} a_{k}(z-\alpha)^{k}}=g(z) \frac{\sum_{k=m}^{\infty} a_{k} k(z-\alpha)^{k-1-m}}{\sum_{k=m}^{\infty} a_{k}(z-\alpha)^{k-m}}
$$

and from this it is clear res $\left(g\left(f^{\prime} / f\right)\right)=g(\alpha) m$, where $m$ is the order of the zero. The conclusion of this theorem now follows from the residue theorem, Theorem 53.0.3.

The way people usually apply these theorems is to suppose $\gamma^{*}$ is a simple closed bounded variation curve, often a circle. Thus it has an inside and an outside, the outside being the unbounded component of $\mathbb{C} \backslash \gamma^{*}$. The orientation of the curve is such that you go around it once in the counterclockwise direction. Then letting $r_{k}$ and $l_{k}$ be as described, the conclusion of the theorem follows. In applications, this is likely the way it will be.

### 53.1.2 Rouche's Theorem

With the argument principle, it is possible to prove Rouche's theorem. In the argument principle, denote by $Z_{f}$ the quantity $\sum_{k=1}^{m} r_{k}$ and by $P_{f}$ the quantity $\sum_{k=1}^{n} l_{k}$. Thus $Z_{f}$ is the
number of zeros of $f$ counted according to the order of the zero with a similar definition holding for $P_{f}$. Thus the conclusion of the argument principle is.

$$
\frac{1}{2 \pi i} \int_{\gamma} \frac{f^{\prime}(z)}{f(z)} d z=Z_{f}-P_{f}
$$

Rouche's theorem allows the comparison of $Z_{h}-P_{h}$ for $h=f, g$. It is a wonderful and amazing result.

Theorem 53.1.4 (Rouche's theorem)Let $f, g$ be meromorphic in an open set $\Omega$. Also suppose $\gamma^{*}$ is a closed bounded variation curve with the property that for all $z \notin \Omega, n(\gamma, z)=0$, no zeros or poles are on $\gamma^{*}$, and for all $z \in \Omega, n(\gamma, z)$ either equals 0 or 1. Let $Z_{f}$ and $P_{f}$ denote respectively the numbers of zeros and poles of $f$, which have the property that the winding number equals 1 , counted according to order, with $Z_{g}$ and $P_{g}$ being defined similarly. Also suppose that for $z \in \gamma^{*}$

$$
\begin{equation*}
|f(z)+g(z)|<|f(z)|+|g(z)| . \tag{53.1.4}
\end{equation*}
$$

Then

$$
Z_{f}-P_{f}=Z_{g}-P_{g}
$$

Proof: From the hypotheses,

$$
\left|1+\frac{f(z)}{g(z)}\right|<1+\left|\frac{f(z)}{g(z)}\right|
$$

which shows that for all $z \in \gamma^{*}$,

$$
\frac{f(z)}{g(z)} \in \mathbb{C} \backslash[0, \infty)
$$

Letting $l$ denote a branch of the logarithm defined on $\mathbb{C} \backslash[0, \infty)$, it follows that $l\left(\frac{f(z)}{g(z)}\right)$ is a primitive for the function,

$$
\frac{(f / g)^{\prime}}{(f / g)}=\frac{f^{\prime}}{f}-\frac{g^{\prime}}{g}
$$

Therefore, by the argument principle,

$$
\begin{aligned}
0 & =\frac{1}{2 \pi i} \int_{\gamma} \frac{(f / g)^{\prime}}{(f / g)} d z=\frac{1}{2 \pi i} \int_{\gamma}\left(\frac{f^{\prime}}{f}-\frac{g^{\prime}}{g}\right) d z \\
& =Z_{f}-P_{f}-\left(Z_{g}-P_{g}\right)
\end{aligned}
$$

This proves the theorem.
Often another condition other than 53.1.4 is used.
Corollary 53.1.5 In the situation of Theorem 53.1.4 change 53.1.4 to the condition,

$$
|f(z)-g(z)|<|f(z)|
$$

for $z \in \gamma^{*}$. Then the conclusion is the same.
Proof: The new condition implies $\left|1-\frac{g}{f}(z)\right|<\left|\frac{g(z)}{f(z)}\right|$ on $\gamma^{*}$. Therefore, $\frac{g(z)}{f(z)} \notin(-\infty, 0]$ and so you can do the same argument with a branch of the logarithm.

### 53.1.3 A Different Formulation

In [115] I found this modification for Rouche's theorem concerned with the counting of zeros of analytic functions. This is a very useful form of Rouche's theorem because it makes no mention of a contour.

Theorem 53.1.6 Let $\Omega$ be a bounded open set and suppose $f, g$ are continuous on $\bar{\Omega}$ and analytic on $\Omega$. Also suppose $|f(z)|<|g(z)|$ on $\partial \Omega$. Then $g$ and $f+g$ have the same number of zeros in $\Omega$ provided each zero is counted according to multiplicity.

Proof: Let $K=\{z \in \bar{\Omega}:|f(z)| \geq|g(z)|\}$. Then letting $\lambda \in[0,1]$, if $z \notin K$, then $|f(z)|<$ $|g(z)|$ and so

$$
0<|g(z)|-|f(z)| \leq|g(z)|-\lambda|f(z)| \leq|g(z)+\lambda f(z)|
$$

which shows that all zeros of $g+\lambda f$ are contained in $K$ which must be a compact subset of $\Omega$ due to the assumption that $|f(z)|<|g(z)|$ on $\partial \Omega$. By Theorem 51.7.25 on Page 1644 there exists a cycle, $\left\{\gamma_{k}\right\}_{k=1}^{n}$ such that $\cup_{k=1}^{n} \gamma_{k}^{*} \subseteq \Omega \backslash K, \sum_{k=1}^{n} n\left(\gamma_{k}, z\right)=1$ for every $z \in K$ and $\sum_{k=1}^{n} n\left(\gamma_{k}, z\right)=0$ for all $z \notin \Omega$. Then as above, it follows from the residue theorem or more directly, Theorem 53.1.2,

$$
\sum_{k=1}^{n} \frac{1}{2 \pi i} \int_{\gamma_{k}} \frac{\lambda f^{\prime}(z)+g^{\prime}(z)}{\lambda f(z)+g(z)} d z=\sum_{j=1}^{p} m_{j}
$$

where $m_{j}$ is the order of the $j^{\text {th }}$ zero of $\lambda f+g$ in $K$, hence in $\Omega$. However,

$$
\lambda \rightarrow \sum_{k=1}^{n} \frac{1}{2 \pi i} \int_{\gamma_{k}} \frac{\lambda f^{\prime}(z)+g^{\prime}(z)}{\lambda f(z)+g(z)} d z
$$

is integer valued and continuous so it gives the same value when $\lambda=0$ as when $\lambda=1$. When $\lambda=0$ this gives the number of zeros of $g$ in $\Omega$ and when $\lambda=1$ it is the number of zeros of $f+g$. This proves the theorem.

Here is another formulation of this theorem.
Corollary 53.1.7 Let $\Omega$ be a bounded open set and suppose $f, g$ are continuous on $\bar{\Omega}$ and analytic on $\Omega$. Also suppose $|f(z)-g(z)|<|g(z)|$ on $\partial \Omega$. Then $f$ and $g$ have the same number of zeros in $\Omega$ provided each zero is counted according to multiplicity.

Proof: You let $f-g$ play the role of $f$ in Theorem 53.1.6. Thus $f-g+g=f$ and $g$ have the same number of zeros. Alternatively, you can give a proof of this directly as follows.

Let $K=\{z \in \Omega:|f(z)-g(z)| \geq|g(z)|\}$. Then if $g(z)+\lambda(f(z)-g(z))=0$ it follows

$$
\begin{aligned}
0 & =|g(z)+\lambda(f(z)-g(z))| \geq|g(z)|-\lambda|f(z)-g(z)| \\
& \geq|g(z)|-|f(z)-g(z)|
\end{aligned}
$$

and so $z \in K$. Thus all zeros of $g(z)+\lambda(f(z)-g(z))$ are contained in $K$. By Theorem 51.7.25 on Page 1644 there exists a cycle, $\left\{\gamma_{k}\right\}_{k=1}^{n}$ such that $\cup_{k=1}^{n} \gamma_{k}^{*} \subseteq \Omega \backslash K, \sum_{k=1}^{n} n\left(\gamma_{k}, z\right)=$ 1 for every $z \in K$ and $\sum_{k=1}^{n} n\left(\gamma_{k}, z\right)=0$ for all $z \notin \Omega$. Then by Theorem 53.1.2,

$$
\sum_{k=1}^{n} \frac{1}{2 \pi i} \int_{\gamma_{k}} \frac{\lambda\left(f^{\prime}(z)-g^{\prime}(z)\right)+g^{\prime}(z)}{\lambda(f(z)-g(z))+g(z)} d z=\sum_{j=1}^{p} m_{j}
$$

where $m_{j}$ is the order of the $j^{\text {th }}$ zero of $\lambda(f-g)+g$ in $K$, hence in $\Omega$. The left side is continuous as a function of $\lambda$ and so the number of zeros of $g$ corresponding to $\lambda=0$ equals the number of zeros of $f$ corresponding to $\lambda=1$. This proves the corollary.

### 53.2 Singularities And The Laurent Series

### 53.2.1 What Is An Annulus?

In general, when you consider singularities, isolated or not, the fundamental tool is the Laurent series. This series is important for many other reasons also. In particular, it is fundamental to the spectral theory of various operators in functional analysis and is one way to obtain relationships between algebraic and analytical conditions essential in various convergence theorems. A Laurent series lives on an annulus. In all this $f$ has values in $X$ where $X$ is a complex Banach space. If you like, let $X=\mathbb{C}$.

Definition 53.2.1 Define ann $\left(a, R_{1}, R_{2}\right) \equiv\left\{z: R_{1}<|z-a|<R_{2}\right\}$.
Thus ann $(a, 0, R)$ would denote the punctured ball, $B(a, R) \backslash\{0\}$ and when $R_{1}>0$, the annulus looks like the following.

The annulus is the stuff between the two circles.
Here is an important lemma which is concerned with the situation described in the following picture.

Lemma 53.2.2 Let $\gamma_{r}(t) \equiv a+r e^{i t}$ for $t \in[0,2 \pi]$ and let $|z-a|<r$. Then $n\left(\gamma_{r}, z\right)=1$. If $|z-a|>r$, then $n\left(\gamma_{r}, z\right)=0$.

Proof: For the first claim, consider for $t \in[0,1]$,

$$
f(t) \equiv n\left(\gamma_{r}, a+t(z-a)\right)
$$

Then from properties of the winding number derived earlier, $f(t) \in \mathbb{Z}, f$ is continuous, and $f(0)=1$. Therefore, $f(t)=1$ for all $t \in[0,1]$. This proves the first claim because $f(1)=n\left(\gamma_{r}, z\right)$.

For the second claim,

$$
\begin{aligned}
n\left(\gamma_{r}, z\right) & =\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{1}{w-z} d w \\
& =\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{1}{w-a-(z-a)} d w \\
& =\frac{1}{2 \pi i} \frac{-1}{z-a} \int_{\gamma_{r}} \frac{1}{1-\left(\frac{w-a}{z-a}\right)} d w \\
& =\frac{-1}{2 \pi i(z-a)} \int_{\gamma_{r}} \sum_{k=0}^{\infty}\left(\frac{w-a}{z-a}\right)^{k} d w
\end{aligned}
$$

The series converges uniformly for $w \in \gamma_{r}$ because

$$
\left|\frac{w-a}{z-a}\right|=\frac{r}{r+c}
$$

for some $c>0$ due to the assumption that $|z-a|>r$. Therefore, the sum and the integral can be interchanged to give

$$
n\left(\gamma_{r}, z\right)=\frac{-1}{2 \pi i(z-a)} \sum_{k=0}^{\infty} \int_{\gamma_{r}}\left(\frac{w-a}{z-a}\right)^{k} d w=0
$$

because $w \rightarrow\left(\frac{w-a}{z-a}\right)^{k}$ has an antiderivative. This proves the lemma.
Now consider the following picture which pertains to the next lemma.

Lemma 53.2.3 Let $g$ be analytic on $\operatorname{ann}\left(a, R_{1}, R_{2}\right)$. Then if $\gamma_{r}(t) \equiv a+r e^{i t}$ for $t \in[0,2 \pi]$ and $r \in\left(R_{1}, R_{2}\right)$, then $\int_{\gamma_{r}} g(z) d z$ is independent of $r$.

Proof: Let $R_{1}<r_{1}<r_{2}<R_{2}$ and denote by $-\gamma_{r}(t)$ the curve, $-\gamma_{r}(t) \equiv a+r e^{i(2 \pi-t)}$ for $t \in[0,2 \pi]$. Then if $z \in \overline{B\left(a, R_{1}\right)}$, Lemma 53.2.2 implies both $n\left(\gamma_{r_{2}}, z\right)$ and $n\left(\gamma_{r_{1}}, z\right)=1$ and so

$$
n\left(-\gamma_{r_{1}}, z\right)+n\left(\gamma_{r_{2}}, z\right)=-1+1=0 .
$$

Also if $z \notin B\left(a, R_{2}\right)$, then Lemma 53.2.2 implies $n\left(\gamma_{r_{j}}, z\right)=0$ for $j=1,2$. Therefore, whenever $z \notin \operatorname{ann}\left(a, R_{1}, R_{2}\right)$, the sum of the winding numbers equals zero. Therefore, by Theorem 51.7.19 applied to the function, $f(w)=g(z)(w-z)$ and $z \in$ ann $\left(a, R_{1}, R_{2}\right) \backslash$ $\cup_{j=1}^{2} \gamma_{r_{j}}([0,2 \pi])$,

$$
\begin{gathered}
f(z)\left(n\left(\gamma_{r_{2}}, z\right)+n\left(-\gamma_{r_{1}}, z\right)\right)=0\left(n\left(\gamma_{r_{2}}, z\right)+n\left(-\gamma_{r_{1}}, z\right)\right)= \\
\frac{1}{2 \pi i} \int_{\gamma_{r_{2}}} \frac{g(w)(w-z)}{w-z} d w-\frac{1}{2 \pi i} \int_{\gamma_{r_{1}}} \frac{g(w)(w-z)}{w-z} d w \\
=\frac{1}{2 \pi i} \int_{\gamma_{r_{2}}} g(w) d w-\frac{1}{2 \pi i} \int_{\gamma_{r_{1}}} g(w) d w
\end{gathered}
$$

which proves the desired result.

### 53.2.2 The Laurent Series

The Laurent series is like a power series except it allows for negative exponents. First here is a definition of what is meant by the convergence of such a series.

Definition 53.2.4 $\sum_{n=-\infty}^{\infty} a_{n}(z-a)^{n}$ converges if both the series,

$$
\sum_{n=0}^{\infty} a_{n}(z-a)^{n} \text { and } \sum_{n=1}^{\infty} a_{-n}(z-a)^{-n}
$$

converge. When this is the case, the symbol, $\sum_{n=-\infty}^{\infty} a_{n}(z-a)^{n}$ is defined as

$$
\sum_{n=0}^{\infty} a_{n}(z-a)^{n}+\sum_{n=1}^{\infty} a_{-n}(z-a)^{-n}
$$

Lemma 53.2.5 Suppose

$$
f(z)=\sum_{n=-\infty}^{\infty} a_{n}(z-a)^{n}
$$

for all $|z-a| \in\left(R_{1}, R_{2}\right)$. Then both $\sum_{n=0}^{\infty} a_{n}(z-a)^{n}$ and $\sum_{n=1}^{\infty} a_{-n}(z-a)^{-n}$ converge absolutely and uniformly on $\left\{z: r_{1} \leq|z-a| \leq r_{2}\right\}$ for any $r_{1}<r_{2}$ satisfying $R_{1}<r_{1}<r_{2}<R_{2}$.

Proof: Let $R_{1}<|w-a|=r_{1}-\delta<r_{1}$. Then $\sum_{n=1}^{\infty} a_{-n}(w-a)^{-n}$ converges and so

$$
\lim _{n \rightarrow \infty}\left|a_{-n}\right||w-a|^{-n}=\lim _{n \rightarrow \infty}\left|a_{-n}\right|\left(r_{1}-\delta\right)^{-n}=0
$$

which implies that for all $n$ sufficiently large,

$$
\left|a_{-n}\right|\left(r_{1}-\delta\right)^{-n}<1
$$

Therefore,

$$
\sum_{n=1}^{\infty}\left|a_{-n}\right||z-a|^{-n}=\sum_{n=1}^{\infty}\left|a_{-n}\right|\left(r_{1}-\delta\right)^{-n}\left(r_{1}-\delta\right)^{n}|z-a|^{-n}
$$

Now for $|z-a| \geq r_{1}$,

$$
|z-a|^{-n} \leq \frac{1}{r_{1}^{n}}
$$

and so for all sufficiently large $n$

$$
\left|a_{-n}\right||z-a|^{-n} \leq \frac{\left(r_{1}-\delta\right)^{n}}{r_{1}^{n}}
$$

Therefore, by the Weierstrass $M$ test, the series, $\sum_{n=1}^{\infty} a_{-n}(z-a)^{-n}$ converges absolutely and uniformly on the set

$$
\left\{z \in \mathbb{C}:|z-a| \geq r_{1}\right\}
$$

Similar reasoning shows the series, $\sum_{n=0}^{\infty} a_{n}(z-a)^{n}$ converges uniformly on the set

$$
\left\{z \in \mathbb{C}:|z-a| \leq r_{2}\right\}
$$

This proves the Lemma.
Theorem 53.2.6 Let $f$ be analytic on ann $\left(a, R_{1}, R_{2}\right)$. Then there exist numbers, $a_{n} \in \mathbb{C}$ such that for all $z \in$ ann $\left(a, R_{1}, R_{2}\right)$,

$$
\begin{equation*}
f(z)=\sum_{n=-\infty}^{\infty} a_{n}(z-a)^{n} \tag{53.2.5}
\end{equation*}
$$

where the series converges absolutely and uniformly on $\overline{\operatorname{ann}\left(a, r_{1}, r_{2}\right)}$ whenever $R_{1}<r_{1}<$ $r_{2}<R_{2}$. Also

$$
\begin{equation*}
a_{n}=\frac{1}{2 \pi i} \int_{\gamma} \frac{f(w)}{(w-a)^{n+1}} d w \tag{53.2.6}
\end{equation*}
$$

where $\gamma(t)=a+r e^{i t}, t \in[0,2 \pi]$ for any $r \in\left(R_{1}, R_{2}\right)$. Furthermore the series is unique in the sense that if 53.2.5 holds for $z \in$ ann $\left(a, R_{1}, R_{2}\right)$, then $a_{n}$ is given in 53.2.6.

Proof: Let $R_{1}<r_{1}<r_{2}<R_{2}$ and define $\gamma_{1}(t) \equiv a+\left(r_{1}-\varepsilon\right) e^{i t}$ and $\gamma_{2}(t) \equiv a+$ $\left(r_{2}+\varepsilon\right) e^{i t}$ for $t \in[0,2 \pi]$ and $\varepsilon$ chosen small enough that $R_{1}<r_{1}-\varepsilon<r_{2}+\varepsilon<R_{2}$.

Then using Lemma 53.2.2, if $z \notin$ ann $\left(a, R_{1}, R_{2}\right)$ then

$$
n\left(-\gamma_{1}, z\right)+n\left(\gamma_{2}, z\right)=0
$$

and if $z \in \operatorname{ann}\left(a, r_{1}, r_{2}\right)$,

$$
n\left(-\gamma_{1}, z\right)+n\left(\gamma_{2}, z\right)=1
$$

Therefore, by Theorem 51.7.19, for $z \in$ ann $\left(a, r_{1}, r_{2}\right)$

$$
\begin{gather*}
f(z)=\frac{1}{2 \pi i}\left[\int_{-\gamma_{1}} \frac{f(w)}{w-z} d w+\int_{\gamma_{2}} \frac{f(w)}{w-z} d w\right] \\
=\frac{1}{2 \pi i}\left[\int_{\gamma_{1}} \frac{f(w)}{(z-a)\left[1-\frac{w-a}{z-a}\right]} d w+\int_{\gamma_{2}} \frac{f(w)}{(w-a)\left[1-\frac{z-a}{w-a}\right]} d w\right] \\
=\frac{1}{2 \pi i} \int_{\gamma_{2}} \frac{f(w)}{w-a} \sum_{n=0}^{\infty}\left(\frac{z-a}{w-a}\right)^{n} d w+ \\
\frac{1}{2 \pi i} \int_{\gamma_{1}} \frac{f(w)}{(z-a)} \sum_{n=0}^{\infty}\left(\frac{w-a}{z-a}\right)^{n} d w . \tag{53.2.7}
\end{gather*}
$$

From the formula 53.2.7, it follows that for $z \in \overline{\operatorname{ann}\left(a, r_{1}, r_{2}\right)}$, the terms in the first sum are bounded by an expression of the form $C\left(\frac{r_{2}}{r_{2}+\varepsilon}\right)^{n}$ while those in the second are bounded by one of the form $C\left(\frac{r_{1}-\varepsilon}{r_{1}}\right)^{n}$ and so by the Weierstrass M test, the convergence is uniform and so the integrals and the sums in the above formula may be interchanged and after renaming the variable of summation, this yields

$$
\begin{align*}
f(z)= & \sum_{n=0}^{\infty}\left(\frac{1}{2 \pi i} \int_{\gamma_{2}} \frac{f(w)}{(w-a)^{n+1}} d w\right)(z-a)^{n}+ \\
& \sum_{n=-\infty}^{-1}\left(\frac{1}{2 \pi i} \int_{\gamma_{1}} \frac{f(w)}{(w-a)^{n+1}}\right)(z-a)^{n} . \tag{53.2.8}
\end{align*}
$$

Therefore, by Lemma 53.2.3, for any $r \in\left(R_{1}, R_{2}\right)$,

$$
\begin{align*}
f(z)= & \sum_{n=0}^{\infty}\left(\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f(w)}{(w-a)^{n+1}} d w\right)(z-a)^{n}+ \\
& \sum_{n=-\infty}^{-1}\left(\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f(w)}{(w-a)^{n+1}}\right)(z-a)^{n} \tag{53.2.9}
\end{align*}
$$

and so

$$
f(z)=\sum_{n=-\infty}^{\infty}\left(\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f(w)}{(w-a)^{n+1}} d w\right)(z-a)^{n}
$$

where $r \in\left(R_{1}, R_{2}\right)$ is arbitrary. This proves the existence part of the theorem. It remains to characterize $a_{n}$.

If $f(z)=\sum_{n=-\infty}^{\infty} a_{n}(z-a)^{n}$ on ann $\left(a, R_{1}, R_{2}\right)$ let

$$
\begin{equation*}
f_{n}(z) \equiv \sum_{k=-n}^{n} a_{k}(z-a)^{k} \tag{53.2.10}
\end{equation*}
$$

This function is analytic in ann $\left(a, R_{1}, R_{2}\right)$ and so from the above argument,

$$
\begin{equation*}
f_{n}(z)=\sum_{k=-\infty}^{\infty}\left(\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f_{n}(w)}{(w-a)^{k+1}} d w\right)(z-a)^{k} \tag{53.2.11}
\end{equation*}
$$

Also if $k>n$ or if $k<-n$,

$$
\left(\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f_{n}(w)}{(w-a)^{k+1}} d w\right)=0
$$

and so

$$
f_{n}(z)=\sum_{k=-n}^{n}\left(\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f_{n}(w)}{(w-a)^{k+1}} d w\right)(z-a)^{k}
$$

which implies from 53.2.10 that for each $k \in[-n, n]$,

$$
\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f_{n}(w)}{(w-a)^{k+1}} d w=a_{k}
$$

However, from the uniform convergence of the series,

$$
\sum_{n=0}^{\infty} a_{n}(w-a)^{n}
$$

and

$$
\sum_{n=1}^{\infty} a_{-n}(w-a)^{-n}
$$

ensured by Lemma 53.2 .5 which allows the interchange of sums and integrals, if $k \in$
$[-n, n]$,

$$
\begin{aligned}
& \frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f(w)}{(w-a)^{k+1}} d w \\
= & \frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{\sum_{m=0}^{\infty} a_{m}(w-a)^{m}+\sum_{m=1}^{\infty} a_{-m}(w-a)^{-m}}{(w-a)^{k+1}} d w \\
= & \sum_{m=0}^{\infty} a_{m} \frac{1}{2 \pi i} \int_{\gamma_{r}}(w-a)^{m-(k+1)} d w \\
& +\sum_{m=1}^{\infty} a_{-m} \int_{\gamma_{r}}(w-a)^{-m-(k+1)} d w \\
= & \sum_{m=0}^{n} a_{m} \frac{1}{2 \pi i} \int_{\gamma_{r}}(w-a)^{m-(k+1)} d w \\
& +\sum_{m=1}^{n} a_{-m} \int_{\gamma_{r}}(w-a)^{-m-(k+1)} d w \\
= & \frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f_{n}(w)}{(w-a)^{k+1}} d w
\end{aligned}
$$

because if $l>n$ or $l<-n$,

$$
\int_{\gamma_{r}} \frac{a_{l}(w-a)^{l}}{(w-a)^{k+1}} d w=0
$$

for all $k \in[-n, n]$. Therefore,

$$
a_{k}=\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{f(w)}{(w-a)^{k+1}} d w
$$

and so this establishes uniqueness. This proves the theorem.

### 53.2.3 Contour Integrals And Evaluation Of Integrals

Here are some examples of hard integrals which can be evaluated by using residues. This will be done by integrating over various closed curves having bounded variation.

Example 53.2.7 The first example we consider is the following integral.

$$
\int_{-\infty}^{\infty} \frac{1}{1+x^{4}} d x
$$

One could imagine evaluating this integral by the method of partial fractions and it should work out by that method. However, we will consider the evaluation of this integral by the method of residues instead. To do so, consider the following picture.

Let $\gamma_{r}(t)=r e^{i t}, t \in[0, \pi]$ and let $\sigma_{r}(t)=t: t \in[-r, r]$. Thus $\gamma_{r}$ parameterizes the top curve and $\sigma_{r}$ parameterizes the straight line from $-r$ to $r$ along the $x$ axis. Denoting by $\Gamma_{r}$ the closed curve traced out by these two, we see from simple estimates that

$$
\lim _{r \rightarrow \infty} \int_{\gamma_{r}} \frac{1}{1+z^{4}} d z=0
$$

This follows from the following estimate.

$$
\left|\int_{\gamma_{r}} \frac{1}{1+z^{4}} d z\right| \leq \frac{1}{r^{4}-1} \pi r
$$

Therefore,

$$
\int_{-\infty}^{\infty} \frac{1}{1+x^{4}} d x=\lim _{r \rightarrow \infty} \int_{\Gamma_{r}} \frac{1}{1+z^{4}} d z
$$

We compute $\int_{\Gamma_{r}} \frac{1}{1+z^{4}} d z$ using the method of residues. The only residues of the integrand are located at points, $z$ where $1+z^{4}=0$. These points are

$$
\begin{aligned}
& z=-\frac{1}{2} \sqrt{2}-\frac{1}{2} i \sqrt{2}, z=\frac{1}{2} \sqrt{2}-\frac{1}{2} i \sqrt{2} \\
& z=\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}, z=-\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}
\end{aligned}
$$

and it is only the last two which are found in the inside of $\Gamma_{r}$. Therefore, we need to calculate the residues at these points. Clearly this function has a pole of order one at each of these points and so we may calculate the residue at $\alpha$ in this list by evaluating

$$
\lim _{z \rightarrow \alpha}(z-\alpha) \frac{1}{1+z^{4}}
$$

Thus

$$
\begin{aligned}
& \operatorname{Res}\left(f, \frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}\right) \\
= & \lim _{z \rightarrow \frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}}\left(z-\left(\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}\right)\right) \frac{1}{1+z^{4}} \\
= & -\frac{1}{8} \sqrt{2}-\frac{1}{8} i \sqrt{2}
\end{aligned}
$$

Similarly we may find the other residue in the same way

$$
\begin{aligned}
& \operatorname{Res}\left(f,-\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}\right) \\
= & \lim _{z \rightarrow-\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}}\left(z-\left(-\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}\right)\right) \frac{1}{1+z^{4}} \\
= & -\frac{1}{8} i \sqrt{2}+\frac{1}{8} \sqrt{2} .
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
\int_{\Gamma_{r}} \frac{1}{1+z^{4}} d z & =2 \pi i\left(-\frac{1}{8} i \sqrt{2}+\frac{1}{8} \sqrt{2}+\left(-\frac{1}{8} \sqrt{2}-\frac{1}{8} i \sqrt{2}\right)\right) \\
& =\frac{1}{2} \pi \sqrt{2}
\end{aligned}
$$

Thus, taking the limit we obtain $\frac{1}{2} \pi \sqrt{2}=\int_{-\infty}^{\infty} \frac{1}{1+x^{4}} d x$.
Obviously many different variations of this are possible. The main idea being that the integral over the semicircle converges to zero as $r \rightarrow \infty$.

Sometimes we don't blow up the curves and take limits. Sometimes the problem of interest reduces directly to a complex integral over a closed curve. Here is an example of this.

Example 53.2.8 The integral is

$$
\int_{0}^{\pi} \frac{\cos \theta}{2+\cos \theta} d \theta
$$

This integrand is even and so it equals

$$
\frac{1}{2} \int_{-\pi}^{\pi} \frac{\cos \theta}{2+\cos \theta} d \theta
$$

For $z$ on the unit circle, $z=e^{i \theta}, \bar{z}=\frac{1}{z}$ and therefore, $\cos \theta=\frac{1}{2}\left(z+\frac{1}{z}\right)$. Thus $d z=i e^{i \theta} d \theta$ and so $d \theta=\frac{d z}{i z}$. Note this is proceeding formally to get a complex integral which reduces to the one of interest. It follows that a complex integral which reduces to the one desired is

$$
\frac{1}{2 i} \int_{\gamma} \frac{\frac{1}{2}\left(z+\frac{1}{z}\right)}{2+\frac{1}{2}\left(z+\frac{1}{z}\right)} \frac{d z}{z}=\frac{1}{2 i} \int_{\gamma} \frac{z^{2}+1}{z\left(4 z+z^{2}+1\right)} d z
$$

where $\gamma$ is the unit circle. Now the integrand has poles of order 1 at those points where $z\left(4 z+z^{2}+1\right)=0$. These points are

$$
0,-2+\sqrt{3},-2-\sqrt{3}
$$

Only the first two are inside the unit circle. It is also clear the function has simple poles at these points. Therefore,

$$
\operatorname{Res}(f, 0)=\lim _{z \rightarrow 0} z\left(\frac{z^{2}+1}{z\left(4 z+z^{2}+1\right)}\right)=1
$$

$$
\begin{gathered}
\operatorname{Res}(f,-2+\sqrt{3})= \\
\lim _{z \rightarrow-2+\sqrt{3}}(z-(-2+\sqrt{3})) \frac{z^{2}+1}{z\left(4 z+z^{2}+1\right)}=-\frac{2}{3} \sqrt{3}
\end{gathered}
$$

It follows

$$
\begin{aligned}
\int_{0}^{\pi} \frac{\cos \theta}{2+\cos \theta} d \theta & =\frac{1}{2 i} \int_{\gamma} \frac{z^{2}+1}{z\left(4 z+z^{2}+1\right)} d z \\
& =\frac{1}{2 i} 2 \pi i\left(1-\frac{2}{3} \sqrt{3}\right) \\
& =\pi\left(1-\frac{2}{3} \sqrt{3}\right)
\end{aligned}
$$

Other rational functions of the trig functions will work out by this method also.
Sometimes you have to be clever about which version of an analytic function that reduces to a real function you should use. The following is such an example.

Example 53.2.9 The integral here is

$$
\int_{0}^{\infty} \frac{\ln x}{1+x^{4}} d x
$$

The same curve used in the integral involving $\frac{\sin x}{x}$ earlier will create problems with the $\log$ since the usual version of the log is not defined on the negative real axis. This does not need to be of concern however. Simply use another branch of the logarithm. Leave out the ray from 0 along the negative $y$ axis and use Theorem 52.2 .3 to define $L(z)$ on this set. Thus $L(z)=\ln |z|+i \arg _{1}(z)$ where $\arg _{1}(z)$ will be the angle, $\theta$, between $-\frac{\pi}{2}$ and $\frac{3 \pi}{2}$ such that $z=|z| e^{i \theta}$. Now the only singularities contained in this curve are

$$
\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2},-\frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}
$$

and the integrand, $f$ has simple poles at these points. Thus using the same procedure as in the other examples,

$$
\begin{gathered}
\operatorname{Res}\left(f, \frac{1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}\right)= \\
\frac{1}{32} \sqrt{2} \pi-\frac{1}{32} i \sqrt{2} \pi
\end{gathered}
$$

and

$$
\begin{gathered}
\operatorname{Res}\left(f, \frac{-1}{2} \sqrt{2}+\frac{1}{2} i \sqrt{2}\right)= \\
\frac{3}{32} \sqrt{2} \pi+\frac{3}{32} i \sqrt{2} \pi
\end{gathered}
$$

Consider the integral along the small semicircle of radius $r$. This reduces to

$$
\int_{\pi}^{0} \frac{\ln |r|+i t}{1+\left(r e^{i t}\right)^{4}}\left(r i e^{i t}\right) d t
$$

which clearly converges to zero as $r \rightarrow 0$ because $r \ln r \rightarrow 0$. Therefore, taking the limit as $r \rightarrow 0$,

$$
\begin{gathered}
\int_{\text {large semicircle }} \frac{L(z)}{1+z^{4}} d z+\lim _{r \rightarrow 0+} \int_{-R}^{-r} \frac{\ln (-t)+i \pi}{1+t^{4}} d t+ \\
\lim _{r \rightarrow 0+} \int_{r}^{R} \frac{\ln t}{1+t^{4}} d t=2 \pi i\left(\frac{3}{32} \sqrt{2} \pi+\frac{3}{32} i \sqrt{2} \pi+\frac{1}{32} \sqrt{2} \pi-\frac{1}{32} i \sqrt{2} \pi\right) .
\end{gathered}
$$

Observing that $\int_{\text {large semicircle }} \frac{L(z)}{1+z^{4}} d z \rightarrow 0$ as $R \rightarrow \infty$,

$$
e(R)+2 \lim _{r \rightarrow 0+} \int_{r}^{R} \frac{\ln t}{1+t^{4}} d t+i \pi \int_{-\infty}^{0} \frac{1}{1+t^{4}} d t=\left(-\frac{1}{8}+\frac{1}{4} i\right) \pi^{2} \sqrt{2}
$$

where $e(R) \rightarrow 0$ as $R \rightarrow \infty$. From an earlier example this becomes

$$
e(R)+2 \lim _{r \rightarrow 0+} \int_{r}^{R} \frac{\ln t}{1+t^{4}} d t+i \pi\left(\frac{\sqrt{2}}{4} \pi\right)=\left(-\frac{1}{8}+\frac{1}{4} i\right) \pi^{2} \sqrt{2}
$$

Now letting $r \rightarrow 0+$ and $R \rightarrow \infty$,

$$
\begin{aligned}
2 \int_{0}^{\infty} \frac{\ln t}{1+t^{4}} d t & =\left(-\frac{1}{8}+\frac{1}{4} i\right) \pi^{2} \sqrt{2}-i \pi\left(\frac{\sqrt{2}}{4} \pi\right) \\
& =-\frac{1}{8} \sqrt{2} \pi^{2}
\end{aligned}
$$

and so

$$
\int_{0}^{\infty} \frac{\ln t}{1+t^{4}} d t=-\frac{1}{16} \sqrt{2} \pi^{2}
$$

which is probably not the first thing you would thing of. You might try to imagine how this could be obtained using elementary techniques.

The next example illustrates the use of what is referred to as a branch cut. It includes many examples.

Example 53.2.10 Mellin transformations are of the form

$$
\int_{0}^{\infty} f(x) x^{\alpha} \frac{d x}{x}
$$

Sometimes it is possible to evaluate such a transform in terms of the constant, $\alpha$.
Assume $f$ is an analytic function except at isolated singularities, none of which are on $(0, \infty)$. Also assume that $f$ has the growth conditions,

$$
|f(z)| \leq \frac{C}{|z|^{b}}, b>\alpha
$$

for all large $|z|$ and assume that

$$
|f(z)| \leq \frac{C^{\prime}}{|z|^{b_{1}}}, b_{1}<\alpha
$$

for all $|z|$ sufficiently small. It turns out there exists an explicit formula for this Mellin transformation under these conditions. Consider the following contour.

In this contour the small semicircle in the center has radius $\varepsilon$ which will converge to 0 . Denote by $\gamma_{R}$ the large circular path which starts at the upper edge of the slot and continues to the lower edge. Denote by $\gamma_{\varepsilon}$ the small semicircular contour and denote by $\gamma_{\varepsilon R+}$ the straight part of the contour from 0 to $R$ which provides the top edge of the slot. Finally denote by $\gamma_{\varepsilon R-}$ the straight part of the contour from $R$ to 0 which provides the bottom edge of the slot. The interesting aspect of this problem is the definition of $f(z) z^{\alpha-1}$. Let

$$
z^{\alpha-1} \equiv e^{(\ln |z|+i \arg (z))(\alpha-1)}=e^{(\alpha-1) \log (z)}
$$

where $\arg (z)$ is the angle of $z$ in $(0,2 \pi)$. Thus you use a branch of the logarithm which is defined on $\mathbb{C} \backslash(0, \infty)$. Then it is routine to verify from the assumed estimates that

$$
\lim _{R \rightarrow \infty} \int_{\gamma_{R}} f(z) z^{\alpha-1} d z=0
$$

and

$$
\lim _{\varepsilon \rightarrow 0+} \int_{\gamma_{\varepsilon}} f(z) z^{\alpha-1} d z=0
$$

Also, it is routine to verify

$$
\lim _{\varepsilon \rightarrow 0+} \int_{\gamma_{\varepsilon R+}} f(z) z^{\alpha-1} d z=\int_{0}^{R} f(x) x^{\alpha-1} d x
$$

and

$$
\lim _{\varepsilon \rightarrow 0+} \int_{\gamma_{\varepsilon R-}} f(z) z^{\alpha-1} d z=-e^{i 2 \pi(\alpha-1)} \int_{0}^{R} f(x) x^{\alpha-1} d x
$$

Therefore, letting $\Sigma_{R}$ denote the sum of the residues of $f(z) z^{\alpha-1}$ which are contained in the disk of radius $R$ except for the possible residue at 0 ,

$$
e(R)+\left(1-e^{i 2 \pi(\alpha-1)}\right) \int_{0}^{R} f(x) x^{\alpha-1} d x=2 \pi i \Sigma_{R}
$$

where $e(R) \rightarrow 0$ as $R \rightarrow \infty$. Now letting $R \rightarrow \infty$,

$$
\lim _{R \rightarrow \infty} \int_{0}^{R} f(x) x^{\alpha-1} d x=\frac{2 \pi i}{1-e^{i 2 \pi(\alpha-1)}} \Sigma=\frac{\pi e^{-\pi i \alpha}}{\sin (\pi \alpha)} \Sigma
$$

where $\Sigma$ denotes the sum of all the residues of $f(z) z^{\alpha-1}$ except for the residue at 0 .
The next example is similar to the one on the Mellin transform. In fact it is a Mellin transform but is worked out independently of the above to emphasize a slightly more informal technique related to the contour.

Example 53.2.11 $\int_{0}^{\infty} \frac{x^{p-1}}{1+x} d x, p \in(0,1)$.
Since the exponent of $x$ in the numerator is larger than -1 . The integral does converge. However, the techniques of real analysis don't tell us what it converges to. The contour to be used is as follows: From $(\varepsilon, 0)$ to $(r, 0)$ along the $x$ axis and then from $(r, 0)$ to $(r, 0)$ counter clockwise along the circle of radius $r$, then from $(r, 0)$ to $(\varepsilon, 0)$ along the $x$ axis and from $(\varepsilon, 0)$ to $(\varepsilon, 0)$, clockwise along the circle of radius $\varepsilon$. You should draw a picture of this contour. The interesting thing about this is that $z^{p-1}$ cannot be defined all the way around 0 . Therefore, use a branch of $z^{p-1}$ corresponding to the branch of the logarithm obtained by deleting the positive $x$ axis. Thus

$$
z^{p-1}=e^{(\ln |z|+i A(z))(p-1)}
$$

where $z=|z| e^{i A(z)}$ and $A(z) \in(0,2 \pi)$. Along the integral which goes in the positive direction on the $x$ axis, let $A(z)=0$ while on the one which goes in the negative direction, take $A(z)=2 \pi$. This is the appropriate choice obtained by replacing the line from $(\varepsilon, 0)$ to $(r, 0)$ with two lines having a small gap joined by a circle of radius $\varepsilon$ and then taking a limit as the gap closes. You should verify that the two integrals taken along the circles of radius $\varepsilon$ and $r$ converge to 0 as $\varepsilon \rightarrow 0$ and as $r \rightarrow \infty$. Therefore, taking the limit,

$$
\int_{0}^{\infty} \frac{x^{p-1}}{1+x} d x+\int_{\infty}^{0} \frac{x^{p-1}}{1+x}\left(e^{2 \pi i(p-1)}\right) d x=2 \pi i \operatorname{Res}(f,-1)
$$

Calculating the residue of the integrand at -1 , and simplifying the above expression,

$$
\left(1-e^{2 \pi i(p-1)}\right) \int_{0}^{\infty} \frac{x^{p-1}}{1+x} d x=2 \pi i e^{(p-1) i \pi}
$$

Upon simplification

$$
\int_{0}^{\infty} \frac{x^{p-1}}{1+x} d x=\frac{\pi}{\sin p \pi}
$$

Example 53.2.12 The Fresnel integrals are

$$
\int_{0}^{\infty} \cos \left(x^{2}\right) d x, \int_{0}^{\infty} \sin \left(x^{2}\right) d x
$$

To evaluate these integrals consider $f(z)=e^{i z^{2}}$ on the curve which goes from the origin to the point $r$ on the $x$ axis and from this point to the point $r\left(\frac{1+i}{\sqrt{2}}\right)$ along a circle of radius $r$, and from there back to the origin as illustrated in the following picture.

Thus the curve to integrate over is shaped like a slice of pie. Denote by $\gamma_{r}$ the curved part. Since $f$ is analytic,

$$
\begin{aligned}
0 & =\int_{\gamma_{r}} e^{i z^{2}} d z+\int_{0}^{r} e^{i x^{2}} d x-\int_{0}^{r} e^{i\left(t\left(\frac{1+i}{\sqrt{2}}\right)\right)^{2}}\left(\frac{1+i}{\sqrt{2}}\right) d t \\
& =\int_{\gamma_{r}} e^{i z^{2}} d z+\int_{0}^{r} e^{i x^{2}} d x-\int_{0}^{r} e^{-t^{2}}\left(\frac{1+i}{\sqrt{2}}\right) d t \\
& =\int_{\gamma_{r}} e^{i z^{2}} d z+\int_{0}^{r} e^{i x^{2}} d x-\frac{\sqrt{\pi}}{2}\left(\frac{1+i}{\sqrt{2}}\right)+e(r)
\end{aligned}
$$

where $e(r) \rightarrow 0$ as $r \rightarrow \infty$. Here we used the fact that $\int_{0}^{\infty} e^{-t^{2}} d t=\frac{\sqrt{\pi}}{2}$. Now consider the first of these integrals.

$$
\begin{aligned}
& \left|\int_{\gamma_{r}} e^{i z^{2}} d z\right|
\end{aligned}=\left\lvert\, \int_{0}^{\frac{\pi}{4}} e^{i\left(r e^{i t}\right)^{2} r i e^{i t} d t \mid} \begin{aligned}
& \leq r \int_{0}^{\frac{\pi}{4}} e^{-r^{2} \sin 2 t} d t \\
&=\frac{r}{2} \int_{0}^{1} \frac{e^{-r^{2} u}}{\sqrt{1-u^{2}}} d u \\
& \leq \frac{r}{2} \int_{0}^{r^{-(3 / 2)}} \frac{1}{\sqrt{1-u^{2}}} d u+\frac{r}{2}\left(\int_{0}^{1} \frac{1}{\sqrt{1-u^{2}}}\right) e^{-\left(r^{1 / 2}\right)}
\end{aligned}\right.
$$

which converges to zero as $r \rightarrow \infty$. Therefore, taking the limit as $r \rightarrow \infty$,

$$
\frac{\sqrt{\pi}}{2}\left(\frac{1+i}{\sqrt{2}}\right)=\int_{0}^{\infty} e^{i x^{2}} d x
$$

and so

$$
\int_{0}^{\infty} \sin x^{2} d x=\frac{\sqrt{\pi}}{2 \sqrt{2}}=\int_{0}^{\infty} \cos x^{2} d x
$$

The following example is one of the most interesting. By an auspicious choice of the contour it is possible to obtain a very interesting formula for $\cot \pi z$ known as the MittagLeffler expansion of $\cot \pi z$.

Example 53.2.13 Let $\gamma_{N}$ be the contour which goes from $-N-\frac{1}{2}-N i$ horizontally to $N+\frac{1}{2}-N i$ and from there, vertically to $N+\frac{1}{2}+N i$ and then horizontally to $-N-\frac{1}{2}+N i$ and finally vertically to $-N-\frac{1}{2}-N i$. Thus the contour is a large rectangle and the direction of integration is in the counter clockwise direction. Consider the following integral.

$$
I_{N} \equiv \int_{\gamma_{N}} \frac{\pi \cos \pi z}{\sin \pi z\left(\alpha^{2}-z^{2}\right)} d z
$$

where $\alpha \in \mathbb{R}$ is not an integer. This will be used to verify the formula of Mittag Leffler,

$$
\begin{equation*}
\frac{1}{\alpha^{2}}+\sum_{n=1}^{\infty} \frac{2}{\alpha^{2}-n^{2}}=\frac{\pi \cot \pi \alpha}{\alpha} \tag{53.2.12}
\end{equation*}
$$

You should verify that $\cot \pi z$ is bounded on this contour and that therefore, $I_{N} \rightarrow 0$ as $N \rightarrow \infty$. Now you compute the residues of the integrand at $\pm \alpha$ and at $n$ where $|n|<$ $N+\frac{1}{2}$ for $n$ an integer. These are the only singularities of the integrand in this contour and therefore, you can evaluate $I_{N}$ by using these. It is left as an exercise to calculate these residues and find that the residue at $\pm \alpha$ is

$$
\frac{-\pi \cos \pi \alpha}{2 \alpha \sin \pi \alpha}
$$

while the residue at $n$ is

$$
\frac{1}{\alpha^{2}-n^{2}}
$$

Therefore,

$$
0=\lim _{N \rightarrow \infty} I_{N}=\lim _{N \rightarrow \infty} 2 \pi i\left[\sum_{n=-N}^{N} \frac{1}{\alpha^{2}-n^{2}}-\frac{\pi \cot \pi \alpha}{\alpha}\right]
$$

which establishes the following formula of Mittag Leffler.

$$
\lim _{N \rightarrow \infty} \sum_{n=-N}^{N} \frac{1}{\alpha^{2}-n^{2}}=\frac{\pi \cot \pi \alpha}{\alpha}
$$

Writing this in a slightly nicer form, yields 53.2.12.

### 53.3 Exercises

1. Example 53.2.7 found the integral of a rational function of a certain sort. The technique used in this example typically works for rational functions of the form $\frac{f(x)}{g(x)}$ where $\operatorname{deg}(g(x)) \geq \operatorname{deg} f(x)+2$ provided the rational function has no poles on the real axis. State and prove a theorem based on these observations.
2. Fill in the missing details of Example 53.2.13 about $I_{N} \rightarrow 0$. Note how important it was that the contour was chosen just right for this to happen. Also verify the claims about the residues.
3. Suppose $f$ has a pole of order $m$ at $z=a$. Define $g(z)$ by

$$
g(z)=(z-a)^{m} f(z) .
$$

Show

$$
\operatorname{Res}(f, a)=\frac{1}{(m-1)!} g^{(m-1)}(a)
$$

Hint: Use the Laurent series.
4. Give a proof of Theorem 53.1.1. Hint: Let $p$ be a pole. Show that near $p$, a pole of order $m$,

$$
\frac{f^{\prime}(z)}{f(z)}=\frac{-m+\sum_{k=1}^{\infty} b_{k}(z-p)^{k}}{(z-p)+\sum_{k=2}^{\infty} c_{k}(z-p)^{k}}
$$

Show that $\operatorname{Res}(f, p)=-m$. Carry out a similar procedure for the zeros.
5. Use Rouche's theorem to prove the fundamental theorem of algebra which says that if $p(z)=z^{n}+a_{n-1} z^{n-1} \cdots+a_{1} z+a_{0}$, then $p$ has $n$ zeros in $\mathbb{C}$. Hint: Let $q(z)=-z^{n}$ and let $\gamma$ be a large circle, $\gamma(t)=r e^{i t}$ for $r$ sufficiently large.
6. Consider the two polynomials $z^{5}+3 z^{2}-1$ and $z^{5}+3 z^{2}$. Show that on $|z|=1$, the conditions for Rouche's theorem hold. Now use Rouche's theorem to verify that $z^{5}+3 z^{2}-1$ must have two zeros in $|z|<1$.
7. Consider the polynomial, $z^{11}+7 z^{5}+3 z^{2}-17$. Use Rouche's theorem to find a bound on the zeros of this polynomial. In other words, find $r$ such that if $z$ is a zero of the polynomial, $|z|<r$. Try to make $r$ fairly small if possible.
8. Verify that $\int_{0}^{\infty} e^{-t^{2}} d t=\frac{\sqrt{\pi}}{2}$. Hint: Use polar coordinates.
9. Use the contour described in Example 53.2.7 to compute the exact values of the following improper integrals.
(a) $\int_{-\infty}^{\infty} \frac{x}{\left(x^{2}+4 x+13\right)^{2}} d x$
(b) $\int_{0}^{\infty} \frac{x^{2}}{\left(x^{2}+a^{2}\right)^{2}} d x$
(c) $\int_{-\infty}^{\infty} \frac{d x}{\left(x^{2}+a^{2}\right)\left(x^{2}+b^{2}\right)}, a, b>0$
10. Evaluate the following improper integrals.
(a) $\int_{0}^{\infty} \frac{\cos a x}{\left(x^{2}+b^{2}\right)^{2}} d x$
(b) $\int_{0}^{\infty} \frac{x \sin x}{\left(x^{2}+a^{2}\right)^{2}} d x$
11. Find the Cauchy principle value of the integral

$$
\int_{-\infty}^{\infty} \frac{\sin x}{\left(x^{2}+1\right)(x-1)} d x
$$

defined as

$$
\lim _{\varepsilon \rightarrow 0+}\left(\int_{-\infty}^{1-\varepsilon} \frac{\sin x}{\left(x^{2}+1\right)(x-1)} d x+\int_{1+\varepsilon}^{\infty} \frac{\sin x}{\left(x^{2}+1\right)(x-1)} d x\right)
$$

12. Find a formula for the integral $\int_{-\infty}^{\infty} \frac{d x}{\left(1+x^{2}\right)^{n+1}}$ where $n$ is a nonnegative integer.
13. Find $\int_{-\infty}^{\infty} \frac{\sin ^{2} x}{x^{2}} d x$.
14. If $m<n$ for $m$ and $n$ integers, show

$$
\int_{0}^{\infty} \frac{x^{2 m}}{1+x^{2 n}} d x=\frac{\pi}{2 n} \frac{1}{\sin \left(\frac{2 m+1}{2 n} \pi\right)}
$$

15. Find $\int_{-\infty}^{\infty} \frac{1}{\left(1+x^{4}\right)^{2}} d x$.
16. Find $\int_{0}^{\infty} \frac{\ln (x)}{1+x^{2}} d x=0$.
17. Suppose $f$ has an isolated singularity at $\alpha$. Show the singularity is essential if and only if the principal part of the Laurent series of $f$ has infinitely many terms. That is, show $f(z)=\sum_{k=0}^{\infty} a_{k}(z-\alpha)^{k}+\sum_{k=1}^{\infty} \frac{b_{k}}{(z-\alpha)^{k}}$ where infinitely many of the $b_{k}$ are nonzero.
18. Suppose $\Omega$ is a bounded open set and $f_{n}$ is analytic on $\Omega$ and continuous on $\bar{\Omega}$. Suppose also that $f_{n} \rightarrow f$ uniformly on $\bar{\Omega}$ and that $f \neq 0$ on $\partial \Omega$. Show that for all $n$ large enough, $f_{n}$ and $f$ have the same number of zeros on $\Omega$ provided the zeros are counted according to multiplicity.

## Functional Analysis Applications

### 54.1 The Spectral Radius

As a very important application of the theory of Laurent series, I will give a short description of the spectral radius. This is a fundamental result which must be understood in order to prove convergence of various important numerical methods such as the Gauss Seidel or Jacobi methods.

Definition 54.1.1 Let $X$ be a complex Banach space and let $A \in \mathscr{L}(X, X)$. Then

$$
r(A) \equiv\left\{\lambda \in \mathbb{C}:(\lambda I-A)^{-1} \in \mathscr{L}(X, X)\right\}
$$

This is called the resolvent set. The spectrum of $A$, denoted by $\sigma(A)$ is defined as all the complex numbers which are not in the resolvent set. Thus

$$
\sigma(A) \equiv \mathbb{C} \backslash r(A)
$$

Lemma 54.1.2 $\lambda \in r(A)$ if and only if $\lambda I-A$ is one to one and onto $X$. Also if $|\lambda|>||A||$, then $\lambda \in \sigma(A)$. If the Neumann series,

$$
\frac{1}{\lambda} \sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}
$$

converges, then

$$
\frac{1}{\lambda} \sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}=(\lambda I-A)^{-1}
$$

Proof: Note that to be in $r(A), \lambda I-A$ must be one to one and map $X$ onto $X$ since otherwise, $(\lambda I-A)^{-1} \notin \mathscr{L}(X, X)$.

By the open mapping theorem, if these two algebraic conditions hold, then $(\lambda I-A)^{-1}$ is continuous and so this proves the first part of the lemma. Now suppose $|\lambda|>||A||$. Consider the Neumann series

$$
\frac{1}{\lambda} \sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}
$$

By the root test, Theorem 51.1.3 on Page 1611 this series converges to an element of $\mathscr{L}(X, X)$ denoted here by $B$. Now suppose the series converges. Letting $B_{n} \equiv \frac{1}{\lambda} \sum_{k=0}^{n}\left(\frac{A}{\lambda}\right)^{k}$,

$$
\begin{aligned}
(\lambda I-A) B_{n} & =B_{n}(\lambda I-A)=\sum_{k=0}^{n}\left(\frac{A}{\lambda}\right)^{k}-\sum_{k=0}^{n}\left(\frac{A}{\lambda}\right)^{k+1} \\
& =I-\left(\frac{A}{\lambda}\right)^{n+1} \rightarrow I
\end{aligned}
$$

as $n \rightarrow \infty$ because the convergence of the series requires the $n^{\text {th }}$ term to converge to 0 . Therefore,

$$
(\lambda I-A) B=B(\lambda I-A)=I
$$

which shows $\lambda I-A$ is both one to one and onto and the Neumann series converges to $(\lambda I-A)^{-1}$. This proves the lemma.

This lemma also shows that $\sigma(A)$ is bounded. In fact, $\sigma(A)$ is closed.
Lemma 54.1.3 $r(A)$ is open. In fact, if $\lambda \in r(A)$ and $|\mu-\lambda|<\left\|(\lambda I-A)^{-1}\right\|^{-1}$, then $\mu \in r(A)$.

Proof: First note

$$
\begin{align*}
(\mu I-A) & =\left(I-(\lambda-\mu)(\lambda I-A)^{-1}\right)(\lambda I-A)  \tag{54.1.1}\\
& =(\lambda I-A)\left(I-(\lambda-\mu)(\lambda I-A)^{-1}\right) \tag{54.1.2}
\end{align*}
$$

Also from the assumption about $|\lambda-\mu|$,

$$
\left\|(\lambda-\mu)(\lambda I-A)^{-1}\right\| \leq|\lambda-\mu|\left\|(\lambda I-A)^{-1}\right\|<1
$$

and so by the root test,

$$
\sum_{k=0}^{\infty}\left((\lambda-\mu)(\lambda I-A)^{-1}\right)^{k}
$$

converges to an element of $\mathscr{L}(X, X)$. As in Lemma 54.1.2,

$$
\sum_{k=0}^{\infty}\left((\lambda-\mu)(\lambda I-A)^{-1}\right)^{k}=\left(I-(\lambda-\mu)(\lambda I-A)^{-1}\right)^{-1}
$$

Therefore, from 54.1.1,

$$
(\mu I-A)^{-1}=(\lambda I-A)^{-1}\left(I-(\lambda-\mu)(\lambda I-A)^{-1}\right)^{-1}
$$

This proves the lemma.
Corollary 54.1.4 $\sigma(A)$ is a compact set.
Proof: Lemma 54.1.2 shows $\sigma(A)$ is bounded and Lemma 54.1.3 shows it is closed.
Definition 54.1.5 The spectral radius, denoted by $\rho(A)$ is defined by

$$
\rho(A) \equiv \max \{|\lambda|: \lambda \in \sigma(A)\}
$$

Since $\sigma(A)$ is compact, this maximum exists. Note from Lemma 54.1.2, $\rho(A) \leq\|A\|$.
There is a simple formula for the spectral radius.

Lemma 54.1.6 If $|\lambda|>\rho(A)$, then the Neumann series,

$$
\frac{1}{\lambda} \sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}
$$

converges.
Proof: This follows directly from Theorem 53.2.6 on Page 1682 and the observation above that $\frac{1}{\lambda} \sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}=(\lambda I-A)^{-1}$ for all $|\lambda|>||A||$. Thus the analytic function, $\lambda \rightarrow$ $(\lambda I-A)^{-1}$ has a Laurent expansion on $|\lambda|>\rho(A)$ by Theorem 53.2.6 and it must coincide with $\frac{1}{\lambda} \sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}$ on $|\lambda|>\|A\|$ so the Laurent expansion of $\lambda \rightarrow(\lambda I-A)^{-1}$ must equal $\frac{1}{\lambda} \sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}$ on $|\lambda|>\rho(A)$. This proves the lemma.

The theorem on the spectral radius follows. It is due to Gelfand.
Theorem 54.1.7 $\rho(A)=\lim _{n \rightarrow \infty}\left\|A^{n}\right\|^{1 / n}$.
Proof: If

$$
|\lambda|<\lim \sup _{n \rightarrow \infty}\left\|A^{n}\right\|^{1 / n}
$$

then by the root test, the Neumann series does not converge and so by Lemma 54.1.6 $|\lambda| \leq \rho(A)$. Thus

$$
\rho(A) \geq \lim \sup _{n \rightarrow \infty}\left\|A^{n}\right\|^{1 / n}
$$

Now let $p$ be a positive integer. Then $\lambda \in \sigma(A)$ implies $\lambda^{p} \in \sigma\left(A^{p}\right)$ because

$$
\begin{aligned}
\lambda^{p} I-A^{p} & =(\lambda I-A)\left(\lambda^{p-1}+\lambda^{p-2} A+\cdots+A^{p-1}\right) \\
& =\left(\lambda^{p-1}+\lambda^{p-2} A+\cdots+A^{p-1}\right)(\lambda I-A)
\end{aligned}
$$

It follows from Lemma 54.1.2 applied to $A^{p}$ that for $\lambda \in \sigma(A),\left|\lambda^{p}\right| \leq\left|\left|A^{p}\right|\right|$ and so $|\lambda| \leq$ $\left\|A^{p}\right\|^{1 / p}$. Therefore, $\rho(A) \leq\left\|A^{p}\right\|^{1 / p}$ and since $p$ is arbitrary,

$$
\lim \inf _{p \rightarrow \infty}\left\|A^{p}\right\|^{1 / p} \geq \rho(A) \geq \lim \sup _{n \rightarrow \infty}\left\|A^{n}\right\|^{1 / n}
$$

This proves the theorem.

### 54.2 Analytic Semigroups

### 54.3 Sectorial Operators and Analytic Semigroups

In solving ordinary differential equations, the main result involves the fundamental matrix $\Phi(t)$ where $\Phi^{\prime}(t)=A \Phi(t), \Phi(0)=I$, or $\Phi^{\prime}(t)+A \Phi(t)=0, \Phi(0)=I$ and the variation of constants formula. Recall that $\Phi(t+s)=\Phi(t) \Phi(s)$. This idea generalizes to the situation where $A$ is a closed densely defined operator defined on $D(A) \subseteq X$, a Banach space under some conditions which are sufficiently general to include what was done above with $A$ an
$n \times n$ matrix as a special case. The identity $\Phi(t) \Phi(s)=\Phi(t+s)$ holds for any $t, s \in \mathbb{R}$ and so is called a group of transformations. However, in the more general case, the identity only holds for $t, s \geq 0$ which is why it is called a semigroup. In this more general setting, I will call it $S(t)$. I am mostly following the presentation in Henry [63] in this short introduction. In what follows $H$ will be a Banach space unless specified to be a Hilbert space. This new material differs in letting $A$ be only a closed densely defined operator. It might not be a bounded operator.

These semigroups are useful in considering various partial differential equations which can be considered just like they were ordinary differential equations in the form $u^{\prime}+A u=$ $f(u)$. The semigroups discussed here, when applied to actual examples, have the property of allowing one to begin with a very un-smooth initial condition, something in $H$, and making $S(t) x$ in $D(A)$ for all $t>0$. When applied to partial differential equations, this typically has the effect of making a solution $t \rightarrow S(t) x$ smoother for positive $t$ than the initial condition.

One can show that $\lambda \rightarrow(\lambda I-A)^{-1}$ is analytic on its so called resolvent set. This follows from two things, the resolvant identity

$$
(\lambda I-A)^{-1}(\mu I-A)^{-1}=(\mu-\lambda)^{-1}\left((\lambda I-A)^{-1}-(\mu I-A)^{-1}\right)
$$

which follows from an observation that $(\mu I-A),(\lambda I-A)$ are onto so the identity holds if and only if

$$
(\lambda I-A)^{-1}(\mu I-A)^{-1}(\mu I-A)=(\mu-\lambda)^{-1}\left((\lambda I-A)^{-1}-(\mu I-A)^{-1}\right)(\mu I-A)
$$

if and only if

$$
\begin{aligned}
(\lambda I-A)^{-1} & =(\mu-\lambda)^{-1}\left((\lambda I-A)^{-1}(\mu I-A)-I\right) \\
& =(\mu-\lambda)^{-1}\left((\lambda I-A)^{-1}((\mu-\lambda) I+(\lambda I-A))-I\right)
\end{aligned}
$$

if and only if

$$
\begin{aligned}
(\mu-\lambda)(\lambda I-A)^{-1} & =(\lambda I-A)^{-1}((\mu-\lambda) I+(\lambda I-A))-I \\
& =(\mu-\lambda)(\lambda I-A)^{-1}+I-I
\end{aligned}
$$

and an assumption that $\sup _{\lambda}\left\|(\lambda I-A)^{-1} x\right\|<\infty$ for all $\lambda$ near $\mu$ which by the Uniform boundedness theorem implies $\left\|(\lambda I-A)^{-1}\right\|$ is bounded for $\lambda$ near $\mu$.

Thus I will always assume this resolvent $\lambda \rightarrow(\lambda I-A)^{-1}$ is analytic for $\lambda$ on its resolvent set, where this function is analytic. As to the resolvent set, the following describes it in this case of sectorial operators.

Definition 54.3.1 Let $\phi<\pi / 2$ and for $a \in \mathbb{R}$, let $S_{a \phi}$ denote the sector in the complex plane

$$
\{z \in \mathbb{C} \backslash\{a\}:|\arg (z-a)| \leq \pi-\phi\}
$$

This sector is as shown below.

A closed, densely defined linear operator $A$ is called sectorial if for some sector as described above, it follows that for all $\lambda \in S_{a \phi}$,

$$
\begin{equation*}
(\lambda I-A)^{-1} \in \mathscr{L}(H, H) \tag{54.3.3}
\end{equation*}
$$

and for some $M$

$$
\begin{equation*}
\left\|(\lambda I-A)^{-1}\right\| \leq \frac{M}{|\lambda-a|} \tag{54.3.4}
\end{equation*}
$$

The following perturbation theorem is very useful for sectorial operators. I won't use it here, but in applications of this theory, it is useful. First note that for $\lambda \in S_{a \phi}$,

$$
\begin{equation*}
A(\lambda I-A)^{-1}=-I+\lambda(\lambda I-A)^{-1} \tag{54.3.5}
\end{equation*}
$$

Also, if $x \in D(A)$,

$$
\begin{equation*}
(\lambda-A)^{-1} A x=-x+\lambda(\lambda I-A)^{-1} x \tag{54.3.6}
\end{equation*}
$$

This follows from algebra and noting that $\lambda I-A$ maps $D(A)$ onto $H$ because $(\lambda I-A)^{-1} \in$ $\mathscr{L}(H, H)$. Thus the above is true if and only if $A=\left(-I+\lambda(\lambda I-A)^{-1}\right)(\lambda I-A)$ which is obviously true. 54.3.6 is similar. Thus from 54.3.5,

$$
\begin{equation*}
\left\|A(\lambda I-A)^{-1}\right\| \leq 1+|\lambda|\left\|(\lambda I-A)^{-1}\right\| \leq 1+|\lambda| \frac{M}{|\lambda-a|} \leq C \tag{54.3.7}
\end{equation*}
$$

for some constant $C$ whenever $|\lambda|$ is large enough and in $S_{a \phi}$.
Proposition 54.3.2 Suppose $A$ is a sectorial operator as defined above so it is a densely defined closed operator on $D(A) \subseteq H$ which satisfies

$$
\begin{equation*}
\left\|A(\lambda I-A)^{-1}\right\| \leq C \tag{54.3.8}
\end{equation*}
$$

whenever $|\lambda|, \lambda \in S_{a \phi}$, is sufficiently large and suppose $B$ is a densely defined closed operator such that $D(B) \supseteq D(A)$ and for all $x \in D(A)$,

$$
\begin{equation*}
\|B x\| \leq \varepsilon\|A x\|+K\|x\| \tag{54.3.9}
\end{equation*}
$$

where $\varepsilon C<1$. Then $A+B$ is also sectorial.

Proof: I need to consider $(\lambda I-(A+B))^{-1}$. This equals

$$
\begin{equation*}
\left(\left(I-B(\lambda I-A)^{-1}\right)(\lambda I-A)\right)^{-1} \tag{54.3.10}
\end{equation*}
$$

The issue is whether this makes any sense for all $\lambda \in S_{b \phi}$ for some $b \in \mathbb{R}$. Let $b>a$ be very large so that if $\lambda \in S_{b \phi}$, then 54.3.8 holds. Then from 54.3.9, it follows that for $\|x\| \leq 1$,

$$
\begin{aligned}
\left\|B(\lambda I-A)^{-1} x\right\| & \leq \varepsilon\left\|A(\lambda I-A)^{-1} x\right\|+K\left\|(\lambda I-A)^{-1} x\right\| \\
& \leq \varepsilon C+K /|\lambda-a|
\end{aligned}
$$

and so if $b$ is made sufficiently large and $\lambda \in S_{b \phi}$, then for all $\|x\| \leq 1$,

$$
\left\|B(\lambda I-A)^{-1} x\right\| \leq \varepsilon C+K /|\lambda-a|<r<1
$$

Therefore, for such $b$,

$$
\left(I-B(\lambda I-A)^{-1}\right)^{-1}=\sum_{k=0}^{\infty}\left(B(\lambda I-A)^{-1}\right)^{k}
$$

exists and so for such $b$, the expression in 54.3.10 makes sense and equals

$$
(\lambda I-A)^{-1}\left(I-B(\lambda I-A)^{-1}\right)^{-1}
$$

and furthermore,

$$
\left\|(\lambda I-A)^{-1}\left(I-B(\lambda I-A)^{-1}\right)^{-1}\right\| \leq \frac{M}{|\lambda-a|} \frac{1}{1-r} \leq \frac{M^{\prime}}{|\lambda-b|}
$$

by adjusting the constants because

$$
\frac{M}{|\lambda-a|} \frac{|\lambda-b|}{1-r}
$$

is bounded for $\lambda \in S_{b \phi}$.
In finite dimensions, this kind of thing just shown always holds. There you have $D(A)$ is the whole space typically and $B$ will satisfy such an inequality in 54.3.9. The following example shows that all the bounded operators are sectorial.

Example 54.3.3 If $A \in \mathscr{L}(H, H)$, then $A$ is sectorial.
The spectrum $\sigma(A)$ is bounded by $\|A\|$ and so there is clearly a sector of the above form contained in the resolvent set of $A$. As to the estimate 54.3.4, let $a$ be larger than $2\|A\|$ and let $S_{a \phi}$ be contained in the resolvent set. Then for $\lambda \in S_{a \phi},|\lambda|>2\|A\|$ and so

$$
\left\|(\lambda I-A)^{-1}\right\|=|\lambda|^{-1}\left\|\left(I-\frac{A}{\lambda}\right)^{-1}\right\| \leq|\lambda|^{-1}\left\|\sum_{k=0}^{\infty}\left(\frac{A}{\lambda}\right)^{k}\right\| \leq|\lambda|^{-1} 2
$$

Now for $\lambda \in S_{a \phi},\left|\frac{\lambda-a}{\lambda}\right| \leq M$ for some constant $M$ and so

$$
\left\|(\lambda I-A)^{-1}\right\| \leq \frac{2 M}{|\lambda-a|}
$$

Definition 54.3.4 Let $\varepsilon>0$ and for a sectorial operator as defined above, let the contour $\gamma_{\varepsilon, \phi}$ be as shown next where the orientation is also as shown by the arrow, a being the center of the small circle.

The little circle has radius $\varepsilon$ in the above contour but $\varepsilon$ is not necessarily small.
Definition 54.3.5 For $t \in S_{0(\phi+\pi / 2)}^{0}$ the open sector shown in the following picture,

define

$$
\begin{equation*}
S(t) \equiv \frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t}(\lambda I-A)^{-1} d \lambda \tag{54.3.11}
\end{equation*}
$$

where $\varepsilon$ is some positive number. Since the integrand is analytic, two different values for $\varepsilon$ give the same result in 54.3.11. The following picture shows $S_{0(\phi+\pi / 2)}^{0}$ and $S_{0 \phi}$. Note how the dotted line is at right angles to the solid line.

Also define $S(0) \equiv I$.
I need to move $A$ in and out of an integral.
Lemma 54.3.6 Let $f(\lambda), A f(y)$ be bounded and continuous on $\gamma_{\varepsilon, \phi}^{*}$ and have values in $D(A)$. Then $A \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} f(\lambda) d \lambda=\int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} A f(\lambda) d \lambda$ provided $t \in S_{0(\phi+\pi / 2)}^{0}$. Also, for large $R$, and $\Gamma_{R}$ the circle $a+R e^{i \theta}$ with $\theta \in[\pi-\phi, \pi+\phi], \lim _{R \rightarrow \infty} \int_{\Gamma_{R}} e^{\lambda t} f(\lambda) d \lambda=0$.

Proof: On one of the straight lines making up the contour, we have $\lambda=a+y w$ where $|w|=1, y \geq \varepsilon$. Then $e^{\lambda t}=e^{a t+y w t}=e^{a t} e^{y \mid t e^{i(\arg w+\arg t)}}=e^{a t} e^{y(\cos (\arg w+\arg t)+i \sin (\arg w+\arg t))}$. Now for $t \in S_{0(\phi+\pi / 2)}^{0}$,

$$
\arg w+\arg t>\frac{\pi}{2}
$$

and so $\cos (\arg w+\arg t)<0$. Therefore, $\left|e^{\lambda t}\right| \leq\left|e^{a t}\right| e^{-y|t| \delta_{t}}$ where $\delta_{t}>0$. Thus this part of the contour integral is of the form $\int_{\varepsilon}^{\infty} e^{a t+y t w} f(a+y w) w d y$ and

$$
\left\|\int_{R}^{\infty} e^{a t+y t w} f(a+y w) w d y\right\| \leq C\left|e^{a t}\right| \int_{R}^{\infty} e^{-y|t| \delta_{t}} d y<\eta
$$

if $R$ is large enough. Now consider $A \int_{\varepsilon}^{R} \overbrace{e^{a t+y t w} f(a+y w) w}^{g(y)} d y$. There is a sequence of Riemann sums converging to the integral, $\left\{S\left(g, P_{n}\right)\right\}$ as $\left\|P_{n}\right\| \rightarrow 0$ for $P_{n}$ a partition. Each of these sums is in the $D(A)$. Then

$$
S\left(g, P_{n}\right) \rightarrow \int_{\varepsilon}^{R} g(y) d y, A S\left(g, P_{n}\right)=S\left(A g, P_{n}\right) \rightarrow \int_{\varepsilon}^{R} A g(y) d y
$$

Since $A$ is a closed operator, $\int_{\varepsilon}^{R} g(y) d y \in D(A)$ and $A\left(\int_{\varepsilon}^{R} g(y) d y\right)=\int_{\varepsilon}^{R} A g(y) d y$. Now $\int_{\varepsilon}^{R} g(y) d y \in D(A)$ and $\lim _{R \rightarrow \infty} \int_{\varepsilon}^{R} g(y) d y=\int_{\varepsilon}^{\infty} g(y) d y$ while

$$
\lim _{R \rightarrow \infty} A \int_{\varepsilon}^{R} g(y) d y=\lim _{R \rightarrow \infty} \int_{\varepsilon}^{R} A g(y) d y=\int_{\varepsilon}^{\infty} A g(y) d y
$$

Since $A$ is closed, $\int_{\varepsilon}^{\infty} A g(y) d y=A \int_{\varepsilon}^{\infty} g(y) d y$ and $\int_{\varepsilon}^{\infty} g(y) d y \in D(A)$. The other straight line is similar. As to the circular part, it is easier because it is not an improper integral. The argument for taking $A$ on the inside is similar, approximating with Riemann sums and then passing to a limit.

It remains to consider the other claim. On the circle, $\lambda=a+\operatorname{Re}^{i \theta}$ so $d \lambda=\operatorname{Ri}^{i \theta} d \theta$ and

$$
\int_{\Gamma_{R}} e^{\lambda t} f(\lambda) d \lambda=\int_{\pi-\phi}^{\pi+\phi} e^{a t+|t| R(\cos (\theta+\arg t)+i \sin (\theta+\arg t))} f(\lambda) R i e^{i \theta} d \theta
$$

Now for $t \in S_{0(\phi+\pi / 2)}^{0}$ and $\theta$ as indicated, $\theta+\arg t>\frac{\pi}{2}$ and $\theta+\arg t<\frac{3 \pi}{2}$ and so the magnitude of the above integral is no more than an expresson of the form

$$
\left|e^{a t}\right| C \int_{\pi-\phi}^{\pi+\phi} e^{-|t| R \delta} R d \theta
$$

which clearly converges to 0 as $R \rightarrow \infty$.
Because of this lemma, I will move $A$ into and out of the integrals which occur in what follows. Also, it is possible to approximate contour integrals over $\gamma_{\varepsilon, \phi}$ with closed contours and use the Cauchy integral formula.

Next is consideration of the above definition along with estimates.

Lemma 54.3.7 The above definition is well defined for $t \in S_{0(\phi+\pi / 2)}^{0}$. Also there is a constant $M_{r}$ such that

$$
\|S(t)\| \leq M_{r} e^{a t}
$$

for every $t \in S_{0(\phi+\pi / 2)}^{0}$ such that $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right)$. If $S_{r}$ is the sector just described, $t$ such that $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right)$, then for any $x \in H$,

$$
\begin{equation*}
\lim _{t \rightarrow 0, t \in S_{r}} S(t) x=x \tag{54.3.12}
\end{equation*}
$$

Also, for $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right)$

$$
\begin{equation*}
\|A S(t)\| \leq M_{r}\left|e^{a t}\right| \frac{1}{|t|}+N_{r}\left|e^{a t}\right||a| \tag{54.3.13}
\end{equation*}
$$

Proof: In the definition of $S(t)$

$$
S(t) \equiv \frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t}(\lambda I-A)^{-1} d \lambda
$$

Since $S(t)$ does not depend on $\varepsilon$, we can take $\varepsilon=1 /|t|$. Then the circular part of the contour is $\lambda=a+\frac{1}{|t|} e^{i \theta}$. Then $e^{\lambda t}=e^{\left(a+\frac{1}{|t|} e^{i \theta}\right)\left(|t|\left(e^{i \arg t}\right)\right)}=e^{a t} e^{e^{i(\theta+\arg (t))}}$. Then on the circle which is part of $\gamma_{\varepsilon, \phi}$ the contour integral equals

$$
\frac{1}{2 \pi} \int_{\phi-\pi}^{\pi-\phi} e^{a t} e^{i(\theta+\arg (t))}\left(\left(a+\frac{1}{|t|} e^{i \theta}\right) I-A\right)^{-1} \frac{1}{|t|} e^{i \theta} d \theta
$$

Now

$$
\left|e^{e^{i(\theta+\arg (t))}}\right|=\left|e^{\cos (\theta+\arg t)+i \sin (\theta+\arg t)}\right| \leq e
$$

and by assumption, the norm of the integrand is no larger than $\frac{e e^{a t} M}{1 /|t|} \frac{1}{|t|}$ and so the norm of this integral is dominated by

$$
\frac{e e^{a t} M}{2 \pi} \int_{\phi-\pi}^{\pi-\phi} d \theta=\frac{e e^{a t} M}{2 \pi}(2 \pi-2 \phi) \leq e^{a t} M
$$

where $M$ is independent of $t$.
Now consider the part of the contour used to define $S(t)$ which is the top line segment. $\lambda=y w+a$ where $\arg (w)=\pi-\phi, y>1 /|t|$. This part of the contour integral equals

$$
\frac{1}{2 \pi i} \int_{1 /|t|}^{\infty} e^{(y w+a) t}((y w+a) I-A)^{-1} w d y
$$

Then from the resolvent estimate 54.3.4, the norm of this is dominated by

$$
e^{a t} \frac{1}{2 \pi i} \int_{1 /|t|}^{\infty} e^{y e^{i \arg w}\left(|t| e^{i \arg t}\right)} \frac{M}{y} d y=e^{a t} \frac{1}{2 \pi i} \int_{1 /|t|}^{\infty} e^{|t| y e^{i(\arg w+\arg t)}} \frac{M}{y} d y
$$

By assumption $|\arg (t)| \leq r<\left(\frac{\pi}{2}-\phi\right)$ and so

$$
\begin{gathered}
\arg (w)+\arg (t) \geq(\pi-\phi)-r=\frac{\pi}{2}+\left(\frac{\pi}{2}-\phi\right)-r \equiv \frac{\pi}{2}+\delta(r), \delta(r)>0 \\
e^{i(\arg w+\arg t)}=\cos (\arg w+\arg t)+i \sin (\arg w+\arg t), \text { so } \cos (\arg w+\arg t)<0
\end{gathered}
$$

It follows the integral dominated by an expression of the form

$$
\begin{aligned}
& e^{a t} \frac{1}{2 \pi} \int_{1 /|t|}^{\infty} \exp (-c(r)|t| y) \frac{M}{y} d y=e^{a t} \frac{1}{2 \pi} \int_{1}^{\infty} \exp (-c(r) x) \frac{M|t|}{x} \frac{1}{|t|} d x \\
= & e^{a t} \frac{1}{2 \pi} \int_{1}^{\infty} \exp (-c(r) x) \frac{M}{x} d x
\end{aligned}
$$

where $c(r)<0$ independent of $|\arg (t)| \leq r$. A similar estimate holds for the integral on the bottom segment. Thus for $|\arg (t)| \leq r,\|S(t)\|$ is bounded by $M e^{a t}$ for some constant $M$. In particular, $\|S(t)\| e^{-a t}$ is bounded for $t \in[0, \infty)$.

Now let $x \in D(A)$. From 54.3.6,

$$
\begin{equation*}
\frac{e^{\lambda t}}{\lambda}(\lambda-A)^{-1} A x+\frac{e^{\lambda t}}{\lambda} x=e^{\lambda t}(\lambda I-A)^{-1} x \tag{54.3.14}
\end{equation*}
$$

On the circular part of the contour, $\lambda=a+\frac{1}{|t|} e^{i \theta}$. Consider the first term on the left in the above equation. The contour integral is of the form

$$
\int_{\phi-\pi}^{\pi-\phi} e^{a t} e^{e^{i(\theta+\arg (t))}} \frac{1}{a+\frac{1}{|t|} e^{i \theta}}\left(\left(a+\frac{1}{|t|} e^{i \theta}\right) I-A\right)^{-1} A x \frac{i}{|t|} e^{i \theta} d \theta
$$

which is dominated by

$$
\begin{aligned}
e\left|e^{a t}\right| \int_{\phi-\pi}^{\pi-\phi} \frac{1}{\left|a+\frac{1}{|t|} e^{i \theta}\right|} \frac{M}{\left|\frac{1}{|t|} e^{i \theta}\right|}\|A x\| \frac{1}{|t|} & \leq e^{a t} \hat{M}\|A x\| \int_{\phi-\pi}^{\pi-\phi} \frac{|t|}{|a| t \mid+e^{i \theta \mid}} d \theta \\
& \leq e^{a t} \hat{M}\|A x\| \int_{\phi-\pi}^{\pi-\phi} \frac{|t|}{1-|a||t|} d \theta
\end{aligned}
$$

which converges to 0 as $t \rightarrow 0$. On the other part of the contour, $\lambda=y w+a$ where $\arg (w)=$ $\pi-\phi, y>1 /|t|$.

$$
\frac{e^{a t}}{2 \pi i} \int_{1 /|t|}^{\infty} e^{y w t} \frac{1}{y w+a}((y w+a) I-A)^{-1} w d y
$$

As above, $\arg (w)+\arg (t)>\frac{\pi}{2}+\delta(r), \delta(r)>0$ for $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right)$. Thus, as above, this integral is dominated by

$$
\frac{e^{a t}}{2 \pi} \int_{1 /|t|}^{\infty} e^{-y|t| c(r)} \frac{1}{|y w+a|} \frac{M}{|y|} d y=\frac{e^{a t}}{2 \pi} \int_{1}^{\infty} e^{-u c(r)} \frac{|t|}{|u w+a| t| |} \frac{M}{|u|} d u
$$

Which converges to 0 as $t \rightarrow 0$ in the sector $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right)$. Also note that for $t$ close to 0 , the contour contains 0 on the left. Similarly the integral over the other straight line converges to 0 as $t \rightarrow 0$ in that sector.

$$
S(t) x=\varepsilon(t)+\frac{1}{2 \pi i} \int_{\gamma_{1 /|t|, \phi}} \frac{e^{\lambda t}}{\lambda} x d \lambda, \lim _{t \rightarrow 0+} \varepsilon(t)=0
$$

Now approximate $\gamma_{1 /|t|, \phi}$ with a closed contour having a large circular arc of radius $R$ such that the resulting bounded contour $\Gamma_{R}$ has 0 on its inside and

$$
\left|\frac{1}{2 \pi i} \int_{\gamma_{1| | t \mid, \phi}} \frac{e^{\lambda t}}{\lambda} x d \lambda-\frac{1}{2 \pi i} \int_{\Gamma_{R}} \frac{e^{\lambda t}}{\lambda} x d \lambda\right|<\eta(R)
$$

By the Cauchy integral formula, this shows that

$$
S(t) x=\varepsilon(t)+\eta(R)+x, \quad \lim _{t \rightarrow 0+} \varepsilon(t)=0=\lim _{R \rightarrow \infty} \eta(R)
$$

So let $R \rightarrow \infty$ and obtain $S(t) x=\varepsilon(t)+x$ and now let $t \rightarrow 0$ to obtain $S(t) x \rightarrow x$. By the first part, $\|S(t)\|$ is bounded for small $t$ in that sector so it follows that for any $x \in H$,

$$
\begin{aligned}
\|S(t) x-x\| & \leq\|S(t) x-S(t) y\|+\|S(t) y-y\|+\|y-x\| \\
& \leq C\|x-y\|+\|S(t) y-y\|
\end{aligned}
$$

Choosing $\|x-y\|$ small enough for $y \in D(A)$, the above is no more than $\varepsilon / 2+\|S(t) y-y\|$ and the second term converges to 0 from what was just shown. Hence, for all $x \in H$,

$$
\lim _{t \rightarrow 0} S(t) x=x
$$

where $t$ is in the sector $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right)$.
Now for $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right), A S(t)=\frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} A(\lambda I-A)^{-1} d \lambda$. From 54.3.5 this is

$$
\frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t}\left(-I+\lambda(\lambda I-A)^{-1}\right) d \lambda
$$

As above, let $\varepsilon=1 /|t|$. On the circle, $\lambda=a+\frac{1}{|t|} e^{i \theta}$ and as above, this is

$$
\int_{\phi-\pi}^{\pi-\phi} e^{a t} e^{e^{i(\theta+\arg (t))}}\left(-I+\left(a+\frac{1}{|t|} e^{i \theta}\right)\left(\left(a+\frac{1}{|t|} e^{i \theta}\right) I-A\right)^{-1}\right) \frac{i}{|t|} e^{i \theta} d \theta
$$

As before, because of the choice of $t$, the above is dominated by

$$
\begin{aligned}
e\left|e^{a t}\right| \int_{\phi-\pi}^{\pi-\phi}\left(1+M \frac{\left|a+\frac{1}{|t|} e^{i \theta}\right|}{1 /|t|}\right) \frac{1}{|t|} d \theta & =e\left|e^{a t}\right| M \int_{\phi-\pi}^{\pi-\phi}\left(1+|a| t\left|+e^{i \theta}\right|\right) \frac{1}{|t|} d \theta \\
& =e\left|e^{a t}\right| M \int_{\phi-\pi}^{\pi-\phi}\left(\frac{1}{|t|}+\left|a+e^{i \theta} \frac{1}{|t|}\right|\right) d \theta \\
& \leq e\left|e^{a t} M\right| 2 \pi \frac{2}{|t|}+M e\left|e^{a t}\right||a| 2 \pi(54.3 .15)
\end{aligned}
$$

Now consider one of the straight lines. On either of these $\lambda=a+w y$ where $|w|=1$ and $y \geq 1 /|t|$. Then the contour integral is

$$
\frac{e^{a t}}{2 \pi i} \int_{1 /|t|}^{\infty} e^{y w t}\left(-I+(a+w y)((a+w y) I-A)^{-1}\right) w d y
$$

As earlier, the norm of this is dominated by $\frac{\left|e^{a t}\right|}{2 \pi} \int_{1 /|t|}^{\infty} e^{-y|t| c(r)}\left(1+M \frac{|a+w y|}{|w y|}\right) d y=$

$$
\begin{gathered}
=\frac{\left|e^{a t}\right|}{2 \pi} \int_{1}^{\infty} e^{-x c(r)}\left(1+M \frac{|a+w(x /|t|)|}{|w(x /|t|)|}\right) \frac{1}{|t|} d x \\
=\frac{\left|e^{a t}\right|}{2 \pi} \int_{1}^{\infty} e^{-x c(r)}\left(1+M \frac{|a| t|+w x|}{|x|}\right) \frac{1}{|t|} d x \leq \frac{\left|e^{a t}\right|}{2 \pi}\left(M_{r} \frac{1}{|t|}\right)+N_{r}|a| \frac{\left|e^{a t}\right|}{2 \pi}
\end{gathered}
$$

Combining this with 54.3 .15 and adjusting constants,

$$
\|A S(t)\| \leq M_{r}\left|e^{a t}\right| \frac{1}{|t|}+N_{r}\left|e^{a t}\right||a|
$$

Also note that if the contour is shifted to the right slightly, the integral over the shifted contour, $\gamma_{\varepsilon, \phi}^{\prime}$ coincides with the integral over $\gamma_{\varepsilon, \phi}$ thanks to the Cauchy integral formula and Lemma 54.3.6 which allows the approximation of the above integrals with one on a closed contour. The following is the main result.

Theorem 54.3.8 Let A be a sectorial operator as defined in Definition 54.3.1 for the sector $S_{a, \phi}$. Then there exists a semigroup $S(t)$ for $t \in|\arg z| \leq r<\left(\frac{\pi}{2}-\phi\right)$ which satisfies the following conditions.

1. Then $S(t)$ given above in 54.3 .11 is analytic for $t \in S_{0,(\phi+\pi / 2)}^{0}$.
2. For any $x \in H$ and $t \in S_{0,(\phi+\pi / 2)}^{0}$, then for $n$ a positive integer, $S^{(n)}(t) x=A^{n} S(t) x$
3. $S$ is a semigroup on the open sector, $S_{0,(\phi+\pi / 2)}^{0}$. That is, for all $t, s \in S_{0(\phi+\pi / 2)}^{0}$,

$$
S(t+s)=S(t) S(s)
$$

4. $\lim _{t \rightarrow 0, t \in S_{r}} S(t) x=x$ for all $x \in H$ where $|\arg t| \leq r<\left(\frac{\pi}{2}-\phi\right)$
5. For some constants $M, N$, ift is positive and real, $\|S(t)\| \leq M e^{a t},\|A S(t)\| \leq M e^{a t} \frac{1}{|t|}+$ $N\left|e^{a t}\right||a|$

Proof: Consider the first claim. This follows right away from the formula: $S(t) \equiv$ $\frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t}(\lambda I-A)^{-1} d \lambda$. One can differentiate under the integral sign using the dominated convergence theorem to obtain

$$
\begin{gathered}
S^{\prime}(t) \equiv \frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} \lambda e^{\lambda t}(\lambda I-A)^{-1} d \lambda=\frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t}\left(I+A(\lambda I-A)^{-1}\right) d \lambda \\
=\frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} A(\lambda I-A)^{-1} d \lambda
\end{gathered}
$$

because of Lemma 54.3.6 the Cauchy integral theorem, and approximating $\gamma_{\varepsilon, \phi}$ with closed contours.

Now from Lemma 54.3.6 one can take $A$ out of the integral and

$$
S^{\prime}(t)=A\left(\frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t}(\lambda I-A)^{-1} d \lambda\right)=A S(t)
$$

To get the bigher derivatives, note $S(t)$ has infinitely many derivatives due to $t$ being a complex variable. Therefore,

$$
S^{\prime \prime}(t)=\lim _{h \rightarrow 0} \frac{S^{\prime}(t+h)-S^{\prime}(t)}{h}=\lim _{h \rightarrow 0} A \frac{S(t+h)-S(t)}{h}
$$

and $\frac{S(t+h)-S(t)}{h} \rightarrow A S(t)$ and so since $A$ is closed, $A S(t) \in D(A)$ and the above becomes $A^{2} S(t)$. Continuing this way yields the claims 1.) and 2.). Note this also implies $S(t) x \in$ $D(A)$ for each $t \in S_{0(\phi+\pi / 2)}^{0}$ which says more than $S(t) x \in H$. In practice this has the effect of regularizing the solution to an initial value problem.

Next consider the semigroup property. Let $s, t \in S_{0,(\phi+\pi / 2)}^{0}$. As described above let $\gamma_{\varepsilon, \phi}^{\prime}$ denote the contour shifted slightly to the right. Then

$$
\begin{equation*}
S(t) S(s)=\left(\frac{1}{2 \pi i}\right)^{2} \int_{\gamma_{\varepsilon, \phi}} \int_{\gamma_{\varepsilon, \phi}^{\prime}} e^{\lambda t}(\lambda I-A)^{-1} e^{\mu s}(\mu I-A)^{-1} d \mu d \lambda \tag{54.3.16}
\end{equation*}
$$

Using the resolvent identity,

$$
(\lambda I-A)^{-1}(\mu I-A)^{-1}=(\mu-\lambda)^{-1}\left((\lambda I-A)^{-1}-(\mu I-A)^{-1}\right),
$$

then substituting this resolvent identity in 54.3.16, it equals

$$
\begin{gathered}
\left(\frac{1}{2 \pi i}\right)^{2} \int_{\gamma_{\varepsilon, \phi}} \int_{\gamma_{\varepsilon, \phi}^{\prime}} e^{\mu s} e^{\lambda t}\left((\mu-\lambda)^{-1}\left((\lambda I-A)^{-1}-(\mu I-A)^{-1}\right)\right) d \mu d \lambda \\
=-\left(\frac{1}{2 \pi i}\right)^{2} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} \int_{\gamma_{\varepsilon, \phi}^{\prime}} e^{\mu s}(\mu-\lambda)^{-1}(\mu I-A)^{-1} d \mu d \lambda \\
+\left(\frac{1}{2 \pi i}\right)^{2} \int_{\gamma_{\varepsilon, \phi}} \int_{\gamma_{\varepsilon, \phi}^{\prime}} e^{\mu s} e^{\lambda t}(\mu-\lambda)^{-1}(\lambda I-A)^{-1} d \mu d \lambda
\end{gathered}
$$

The order of integration can be interchanged because of the absolute convergence and Fubini's theorem. Then this reduces to

$$
\begin{aligned}
= & -\left(\frac{1}{2 \pi i}\right)^{2} \int_{\gamma_{\varepsilon, \phi}^{\prime}}(\mu I-A)^{-1} e^{\mu s} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t}(\mu-\lambda)^{-1} d \lambda d \mu \\
& +\left(\frac{1}{2 \pi i}\right)^{2} \int_{\gamma_{\varepsilon, \phi}}(\lambda I-A)^{-1} e^{\lambda t} \int_{\gamma_{\varepsilon, \phi}^{\prime}} e^{\mu s}(\mu-\lambda)^{-1} d \mu d \lambda
\end{aligned}
$$

Now the following diagram might help in drawing some interesting conclusions.

The first iterated integral equals 0 . This can be seen from the above picture. By Lemma 54.3.6, the inner integral taken over $\gamma_{\varepsilon, \phi}$ is essentially equal to the integral over the closed contour in the above picture provided the radius of the part of the large circle in the above closed contour is large enough. This closed contour integral equals 0 by the Cauchy integral theorem. The second iterated integral equals

$$
\frac{1}{2 \pi i} \int_{\gamma_{\varepsilon, \phi}}(\lambda I-A)^{-1} e^{\lambda t} e^{\lambda s} d \lambda=S(t+s)
$$

from the Cauchy integral formula. This verifies the semigroup identity.
4.) is done in Lemma 54.3 .7 which also includes 5.) when you let $t$ be positive and real.

### 54.3.1 The Numerical Range

In Hilbert space, there is a useful easy to check criterion which implies an operator is sectorial.

Definition 54.3.9 Let A be a closed densely defined operator $A: D(A) \rightarrow H$ for $H$ a Hilbert space. The numerical range is the following set.

$$
\{(A u, u): u \in D(A)\}
$$

Also recall the resolvent set, $r(A)$ consists of those $\lambda \in \mathbb{C}$ such that $(\lambda I-A)^{-1} \in \mathscr{L}(H, H)$. Thus, to be in this set $\lambda I-A$ is one to one and onto with continuous inverse.

Proposition 54.3.10 Suppose the numerical range of A, a closed densely defined operator $A: D(A) \rightarrow H$ for $H$ a Hilbert space is contained in the set

$$
\{z \in \mathbb{C}:|\arg (z)| \geq \pi-\phi\}
$$

where $0<\phi<\pi / 2$ and suppose $A^{-1} \in \mathscr{L}(H, H),(0 \in r(A))$. Then $A$ is sectorial with the sector $S_{0, \phi^{\prime}}$ where $\pi / 2>\phi^{\prime}>\phi$. Here $\arg (z)$ is the angle which is between $-\pi$ and $\pi$.

Proof: Here is a picture of the situation along with details used to motivate the proof.

In the picture the angle which is a little larger than $\phi$ is $\phi^{\prime}$. Let $\lambda$ be as shown with $|\arg \lambda| \leq \pi-\phi^{\prime}$. Then from the picture and trigonometry, if $u \in D(A)$,

$$
|\lambda| \sin \left(\phi^{\prime}-\phi\right)<\left|\lambda-\left(A \frac{u}{|u|}, \frac{u}{|u|}\right)\right|
$$

and so $|u||\lambda| \sin \left(\phi^{\prime}-\phi\right)<\left|\left(\lambda u-A u, \frac{u}{|u|}\right)\right| \leq\|(\lambda I-A) u\|$. Hence for all $\lambda$ such that $|\arg \lambda| \leq \pi-\phi^{\prime}$ and $u \in D(A)$,

$$
|u|<\left(\frac{1}{\sin \left(\phi^{\prime}-\phi\right)}\right) \frac{1}{|\lambda|}|(\lambda I-A) u| \equiv \frac{M}{|\lambda|}|(\lambda I-A) u|
$$

Thus $(\lambda I-A)$ is one to one on $S_{0, \phi^{\prime}}$ and if $\lambda \in r(A)$, then

$$
\left\|(\lambda I-A)^{-1}\right\|<\frac{M}{|\lambda|} .
$$

By assumption $0 \in r(A)$. Now if $|\mu|$ is small, $(\mu I-A)^{-1}$ must exist because it equals $\left(\left(\mu A^{-1}-I\right) A\right)^{-1}$ and for $|\mu|<\left\|A^{-1}\right\|,\left(\mu A^{-1}-I\right)^{-1} \in \mathscr{L}(H, H)$ since the infinite series

$$
\sum_{k=0}^{\infty}(-1)^{k}\left(\mu A^{-1}\right)^{k}
$$

converges and must equal to $\left(\mu A^{-1}-I\right)^{-1}$. Therefore, there exists $\mu \in S_{0, \phi^{\prime}}$ such that $\mu \neq 0$ and $\mu \in r(A)$. Also if $\mu \neq 0$ and $\mu \in S_{0, \phi^{\prime}}$, then if $|\lambda-\mu|<\frac{|\mu|}{M},(\lambda I-A)^{-1}$ must exist because

$$
(\lambda I-A)^{-1}=\left[\left((\lambda-\mu)(\mu I-A)^{-1}-I\right)(\mu I-A)\right]^{-1}
$$

where $\left((\lambda-\mu)(\mu I-A)^{-1}-I\right)^{-1}$ exists because

$$
\left\|(\lambda-\mu)(\mu I-A)^{-1}\right\|=|\lambda-\mu|\left\|(\mu I-A)^{-1}\right\|<\frac{|\mu|}{M} \cdot \frac{M}{|\mu|}=1
$$

It follows that if $S \equiv\left\{\lambda \in S_{0, \phi^{\prime}}: \lambda \in r(A)\right\}$, then $S$ is open in $S_{0, \phi}$. However, $S$ is also closed because if $\lambda=\lim _{n \rightarrow \infty} \lambda_{n}$ where $\lambda_{n} \in S$, then if $\lambda=0$, it is given $\lambda \in S$. If $\lambda \neq 0$, then for large enough $n,\left|\lambda-\lambda_{n}\right|<\frac{\left|\lambda_{n}\right|}{M}$ and so $\lambda \in S$. Since $S_{0, \phi^{\prime}}$ is connected, it follows $S=S_{0, \phi^{\prime}}$.

Corollary 54.3.11 If for some $a \in \mathbb{R}$, the numerical values of $-a I+A$ are in the set $\{\lambda:|\lambda| \geq \pi-\phi\}$ where $0<\phi<\pi / 2$, and $a \in r(A)$ then $A$ is sectorial.

Proof: By assumption, $0 \in r(-a I+A)$ and also from Proposition 54.3.10, for $\mu \in S_{0, \phi^{\prime}}$ where $\pi / 2>\phi^{\prime}>\phi$,

$$
((-a I+A)-\mu I)^{-1} \in \mathscr{L}(H, H),\left\|((-a I+A)-\mu I)^{-1}\right\| \leq \frac{M}{|\mu|}
$$

Therefore, for $\mu \in S_{0, \phi^{\prime}}, \mu+a \in r(A)$. Therefore, if $\lambda \in S_{a, \phi^{\prime}}, \lambda-a \in S_{0, \phi^{\prime}}$

$$
\left\|(A-\lambda I)^{-1}\right\|=\left\|(A-a I-(\lambda-a) I)^{-1}\right\| \leq \frac{M}{|\lambda-a|}
$$

### 54.3.2 An Interesting Example

In this section related to this example, for $V$ a Banach space, $V^{\prime}$ will denote the space of continuous conjugate linear functions defined on $V$. Usually the symbol has meant the space of continuous linear functions but here they will be conjugate linear. That is $f \in V^{\prime}$ means

$$
f(a x+b y)=\bar{a} f(x)+\bar{b} f(y)
$$

and $f$ is continuous.
Let $\Omega$ be a bounded open set in $\mathbb{R}^{n}$ and define

$$
V_{0} \equiv\left\{u \in C^{\infty}(\bar{\Omega}): u=0 \text { on } \Gamma\right\}
$$

where $\Gamma$ is some measurable subset of the boundary of $\Omega$ and $C^{\infty}(\bar{\Omega})$ denotes the restrictions of functions in $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ to $\Omega$. By Corollary 15.5.11 $V_{0}$ is dense in $L^{2}(\Omega)$. Now define the following for $u, v \in V_{0}$.

$$
A_{0} u(v) \equiv-a \int_{\Omega} u \bar{v} d x-\int_{\Omega} a(x) \nabla u \cdot \overline{\nabla v} d x
$$

where $a>0$ and $a(x) \geq 0$ is a $C^{1}(\bar{\Omega})$ function. Also define the following inner product on $V_{0}$.

$$
(u, v)_{1} \equiv \int_{\Omega}(a u \bar{v}+a(x) \nabla u \cdot \overline{\nabla v}) d x
$$

Let $\|\cdot\|_{1}$ denote the corresponding norm.
Of course $V_{0}$ is not a Banach space because it fails to be complete. $u \in V$ will mean that $u \in L^{2}(\Omega)$ and there exists a sequence $\left\{u_{n}\right\} \subseteq V_{0}$ such that

$$
\lim _{m, n \rightarrow \infty}\left\|u_{n}-u_{m}\right\|_{1}=0
$$

and

$$
\lim _{n \rightarrow \infty}\left|u_{n}-u\right|_{L^{2}(\Omega)}=0
$$

For $u \in V$, define $\nabla u$ to be that element of $L^{2}\left(\Omega ; \mathbb{C}^{n}, a(x) d m_{n}\right)$, the space of vector valued $L^{2}$ functions taken with respect to the measure $a(x) d m_{n}$ which satisfies

$$
\left|\nabla u-\nabla u_{n}\right|_{L^{2}\left(\Omega ; \mathbb{C}^{n}, a(x) d m_{n}\right)} \rightarrow 0 .
$$

Denote this space by $W$ for simplicity of notation.
Observation 54.3.12 $V$ is a Hilbert space with inner product given by

$$
(u, v)_{1} \equiv \int_{\Omega}(a u \bar{v}+a(x) \nabla u \cdot \overline{\nabla v}) d x
$$

Everything is obvious except completeness. Suppose then that $\left\{u_{n}\right\}$ is a Cauchy sequence in $V$. Then there exists a unique $u \in L^{2}(\Omega)$ such that $\left|u_{n}-u\right|_{L^{2}(\Omega)} \rightarrow 0$. Now let

$$
\left|w_{n}-u_{n}\right|_{L^{2}(\Omega)}+\left|\nabla w_{n}-\nabla u_{n}\right|_{W}<1 / 2^{n}
$$

It follows $\left\{\nabla w_{n}\right\}$ is also a Cauchy sequence in $W$ while $\left\{w_{n}\right\}$ is a Cauchy sequence in $L^{2}(\Omega)$ converging to $u$. Thus the thing to which $\nabla w_{n}$ converges in $W$ is the definition of $\nabla u$ and $u \in V$. Thus

$$
\begin{aligned}
\left\|u_{n}-u\right\|_{1} & \leq\left\|u_{n}-w_{n}\right\|_{1}+\left\|w_{n}-u\right\|_{1} \\
& <\frac{1}{2^{n}}+\left\|w_{n}-u\right\|_{1}
\end{aligned}
$$

and the last term converges to 0 . Hence $V$ is complete as claimed.
Then it is clear $V$ is a Hilbert space. The next observation is a simple one involving the Riesz map.

Definition 54.3.13 Let $V$ be a Hilbert space and let $V^{\prime}$ be the space of continuous conjugate linear functions defined on $V$. Then define $R: V \rightarrow V^{\prime}$ by

$$
R x(y) \equiv(x, y)
$$

This is called the Riesz map.
Lemma 54.3.14 The Riesz map is one to one and onto and linear.
Proof: It is obvious it is one to one and linear. The only challenge is to show it is onto. Let $z^{*} \in V^{\prime}$. If $z^{*}(V)=\{0\}$, then letting $z=0$, it follows $R z=z^{*}$. If $z^{*}(V) \neq 0$, then

$$
\operatorname{ker}\left(z^{*}\right) \equiv\left\{x \in V: z^{*}(x)=0\right\}
$$

is a closed subspace. It is closed because $z^{*}$ is continuous and it is just $z^{*-1}(0)$. Since $\operatorname{ker}\left(z^{*}\right)$ is not everything in $V$ there exists

$$
w \in \operatorname{ker}\left(z^{*}\right)^{\perp} \equiv\left\{x:(x, y)=0 \text { for all } y \in \operatorname{ker}\left(z^{*}\right)\right\}
$$

and $w \neq 0$. Then

$$
z^{*}\left(\overline{z^{*}(x)} w-\overline{z^{*}(w)} x\right)=z^{*}(x) z^{*}(w)-z^{*}(w) z^{*}(x)=0
$$

and so $\overline{z^{*}(x)} w-\overline{z^{*}(w)} x \in \operatorname{ker}\left(z^{*}\right)$. Therefore, for any $x \in V$,

$$
\begin{aligned}
& 0=\left(w, \overline{z^{*}(x)} w-\overline{z^{*}(w)} x\right) \\
& =z^{*}(x)(w, w)-z^{*}(w)(w, x)
\end{aligned}
$$

and so

$$
z^{*}(x)=\left(\frac{z^{*}(w)}{\|w\|^{2}}, x\right)
$$

so let $z=w /\|w\|^{2}$. Then $R z=z^{*}$ and so $R$ is onto. This proves the lemma.
Now for the $V$ described above,

$$
R u(v)=\int_{\Omega}(a u \bar{v}+a(x) \nabla u \cdot \overline{\nabla v}) d x
$$

Also, as noted above $V$ is dense in $H \equiv L^{2}(\Omega)$ and so if $H$ is identified with $H^{\prime}$, it follows

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

Let $A: D(A) \rightarrow H$ be given by

$$
D(A) \equiv\{u \in V: R u \in H\}
$$

and

$$
A \equiv-R
$$

on $D(A)$. Then the numerical range for $A$ is contained in $(-\infty,-a]$ and so $A$ is sectorial by Proposition 54.3.10 provided $A$ is closed and densely defined.

Why is $D(A)$ dense? It is because it contains $C_{c}^{\infty}(\Omega)$ which is dense in $L^{2}(\Omega)$. This follows from integration by parts which shows that for $u, v \in C_{c}^{\infty}(\Omega)$,

$$
\begin{aligned}
& -\int_{\Omega} a u \bar{v} d x-\int_{\Omega} a(x) \nabla u \cdot \overline{\nabla v} d x \\
= & -\int_{\Omega} a u \bar{v} d x+\int_{\Omega} \nabla \cdot(a(x) \nabla u) \bar{v} d x
\end{aligned}
$$

and since $C_{c}^{\infty}(\Omega)$ is dense in $H$,

$$
A u=-a u+\nabla \cdot(a(x) \nabla u) \in L^{2}(\Omega)=H
$$

Why is $A$ closed? If $u_{n} \in D(A)$ and $u_{n} \rightarrow u$ in $H$ while $A u_{n} \rightarrow \xi$ in $H$, then it follows from the definition that $R u_{n} \rightarrow-\xi$ and $\left\{u_{n}\right\}$ converges to $u$ in $V$ so for any $v \in V$,

$$
R u(v)=\lim _{n \rightarrow \infty} R u_{n}(v)=\lim _{n \rightarrow \infty}\left(R u_{n}, v\right)_{H}=(-\xi, v)_{H}
$$

which shows $R u=-\xi \in H$ and so $u \in D(A)$ and $A u=\xi$. Thus $A$ is closed. This completes the example.

Obviously you could follow identical reasoning to include many other examples of more complexity. What does it mean for $u \in D(A)$ ? It means that in a weak sense

$$
-a u+\nabla \cdot(a(x) \nabla u) \in H
$$

Since $A$ is sectorial for $S_{-a, \phi}$ for any $0<\phi<\pi / 2$, this has shown the existence of a weak solution to the partial differential equation along with appropriate boundary conditions,

$$
-a u+\nabla \cdot(a(x) \nabla u)=f, u \in V
$$

What are these appropriate boundary conditions? $u=0$ on $\Gamma$ is one. the other would be a variational boundary condition which comes from integration by parts. Letting $v \in V$, formally do the following using the divergence theorem.

$$
\begin{aligned}
& \quad(f, v)_{H}=\int_{\Omega}(-a u+\nabla \cdot(a(x) \nabla u)) v d x \\
& =\int_{\Omega}-a u v d x+\int_{\partial \Omega}(a(x) \nabla u v) \cdot n d s-\int_{\Omega} a(x) \nabla u(x) \cdot \nabla v(x) d x \\
& =(f, v)_{H}+\int_{\partial \Omega \backslash \Gamma}(a(x) \nabla u) \cdot n v d s
\end{aligned}
$$

and so the other boundary condition is

$$
a(x) \frac{\partial u}{\partial n}=0 \text { on } \partial \Omega \backslash \Gamma .
$$

To what extent this weak solution is really a classical solution depends on more technical considerations.

### 54.3.3 Fractional Powers Of Sectorial Operators

It will always be assumed in this section that $A$ is sectorial for the sector $S_{-a, \phi}$ where $a>0$. To begin with, here is a useful lemma which will be used in the presentation of these fractional powers.

Lemma 54.3.15 The following holds for $\alpha \in(0,1)$ and $\sigma<t$.

$$
\int_{\sigma}^{t}(t-s)^{\alpha-1}(s-\sigma)^{-\alpha} d s=\frac{\pi}{\sin (\pi \alpha)}
$$

In particular,

$$
\int_{0}^{1}(1-s)^{\alpha-1} s^{-\alpha} d s=\frac{\pi}{\sin (\pi \alpha)}
$$

Also for $\alpha, \beta>0$

$$
\Gamma(\alpha) \Gamma(\beta)=\left(\int_{0}^{1} x^{\alpha-1}(1-x)^{\beta-1} d x\right) \Gamma(\alpha+\beta)
$$

Proof: First change variables to get rid of the $\sigma$. Let $y=(t-\sigma)^{-1}(s-\sigma)$. Then the integral becomes

$$
\begin{aligned}
& \int_{0}^{1}(t-[(t-\sigma) y+\sigma])^{\alpha-1}(t-\sigma)^{-\alpha} y^{-\alpha}(t-\sigma) d y \\
= & \int_{0}^{1}((t-\sigma)(1-y))^{\alpha-1}(t-\sigma)^{-\alpha} y^{-\alpha}(t-\sigma) d y \\
= & \int_{0}^{1}(1-y)^{\alpha-1} y^{-\alpha} d y
\end{aligned}
$$

Next let $y=x^{2}$. The integral is

$$
2 \int_{0}^{1}\left(1-x^{2}\right)^{\alpha-1} x^{1-2 \alpha} d x
$$

Next let $x=\sin \theta$

$$
2 \int_{0}^{\frac{1}{2} \pi}(\cos (\theta))^{2 \alpha-1} \sin ^{(1-2 \alpha)}(\theta) d \theta=2 \int_{0}^{\frac{1}{2} \pi}\left(\frac{\cos (\theta)}{\sin (\theta)}\right)^{2 \alpha-1} d \theta
$$

Now change the variable again. Let $u=\cot (\theta)$. Then this yields

$$
2 \int_{0}^{\infty} \frac{u^{2 \alpha-1}}{1+u^{2}} d u
$$

This is fairly easy to evaluate using contour integrals. Consider the following contour called $\Gamma_{R}$ for large $R$. As $R \rightarrow \infty$, the integral over the little circle converges to 0 and so does the integral over the big circle. There is one singularity at $i$.

Thus

$$
\begin{aligned}
& \lim _{R \rightarrow \infty} \int_{\Gamma_{R}} \frac{e^{(\ln |z|+i \arg (z))(1-2 \alpha)}}{1+z^{2}} d z= \\
& =\quad(1+\cos (1-2 \alpha) \pi) \int_{0}^{\infty} \frac{u^{2 \alpha-1}}{1+u^{2}} d u \\
& \quad+i \sin ((1-2 \alpha) \pi) \int_{0}^{\infty} \frac{u^{2 \alpha-1}}{1+u^{2}} d u
\end{aligned}
$$

$$
=\pi\left(\cos \left(\frac{\pi}{2}(1-2 \alpha)\right)+i \sin \left(\frac{\pi}{2}(1-2 \alpha)\right)\right)
$$

Then equating the imaginary parts yields

$$
\sin ((1-2 \alpha) \pi) \int_{0}^{\infty} \frac{u^{2 \alpha-1}}{1+u^{2}} d u=\pi \sin \left(\frac{\pi}{2}(1-2 \alpha)\right)
$$

and so using the trig identities for the sum of two angles,

$$
\begin{aligned}
\int_{0}^{\infty} \frac{u^{2 \alpha-1}}{1+u^{2}} d u & =\frac{\pi\left(\sin \left(\frac{\pi}{2}(1-2 \alpha)\right)\right)}{2 \sin \left(\frac{\pi}{2}(1-2 \alpha)\right) \cos \left(\frac{\pi}{2}(1-2 \alpha)\right)} \\
& =\frac{\pi}{2 \cos \left(\frac{\pi}{2}(1-2 \alpha)\right)}=\frac{\pi}{2 \sin (\pi \alpha)}
\end{aligned}
$$

It remains to verify the last identity.

$$
\begin{aligned}
\Gamma(\alpha) \Gamma(\beta) & \equiv \int_{0}^{\infty} \int_{0}^{\infty} t^{\alpha-1} e^{-t} s^{\beta-1} e^{-s} d s d t \\
& =\int_{0}^{\infty} \int_{t}^{\infty} t^{\alpha-1} e^{-u}(u-t)^{\beta-1} d u d t \\
& =\int_{0}^{\infty} e^{-u} \int_{0}^{u} t^{\alpha-1}(u-t)^{\beta-1} d t d u \\
& =\int_{0}^{1} x^{\alpha-1}(1-x)^{\beta-1} d x \int_{0}^{\infty} e^{-u} u^{\alpha+\beta-1} d u \\
& =\left(\int_{0}^{1} x^{\alpha-1}(1-x)^{\beta-1} d x\right) \Gamma(\alpha+\beta)
\end{aligned}
$$

This proves the lemma.
If it is not stated otherwise, in all that follows $\alpha>0$.
Definition 54.3.16 Let A be a sectorial operator corresponding to the sector $S_{-a \phi}$ where $-a<0$. Then define for $\alpha>0$,

$$
(-A)^{-\alpha} \equiv \frac{1}{\Gamma(\alpha)} \int_{0}^{\infty} t^{\alpha-1} S(t) d t
$$

where $S(t)$ is the analytic semigroup generated by $A$ as in Corollary 54.3.8. Note that from the estimate, $\|S(t)\| \leq M e^{-a t}$ of this corollary, the integral is well defined and is in $\mathscr{L}(H, H)$.

Theorem 54.3.17 For $(-A)^{-\alpha}$ as defined in Definition 54.3.16

$$
\begin{equation*}
(-A)^{-\alpha}(-A)^{-\beta}=(-A)^{-(\alpha+\beta)} \tag{54.3.17}
\end{equation*}
$$

Also

$$
\begin{equation*}
(-A)^{-1}(-A)=I,(-A)(-A)^{-1}=I \tag{54.3.18}
\end{equation*}
$$

and $(-A)^{-\alpha}$ is one to one if $\alpha \geq 0$, defining $A^{0} \equiv I$.

If $\alpha<\beta$, then

$$
\begin{equation*}
(-A)^{-\beta}(H) \subseteq(-A)^{-\alpha}(H) \tag{54.3.19}
\end{equation*}
$$

If $\alpha \in(0,1)$, then

$$
\begin{equation*}
(-A)^{-\alpha}=\frac{\sin (\pi \alpha)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha}(\lambda I-A)^{-1} d \lambda \tag{54.3.20}
\end{equation*}
$$

Proof: Consider 54.3.17.

$$
(-A)^{-\alpha}(-A)^{-\beta} \equiv \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} \int_{0}^{\infty} t^{\alpha-1} s^{\beta-1} S(t+s) d s d t
$$

Changing variables and using Fubini's theorem which is justified because of the abolute convergence of the iterated integrals, which follows from Corollary 54.3.8, this becomes

$$
\begin{aligned}
& \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} \int_{t}^{\infty} t^{\alpha-1}(u-t)^{\beta-1} S(u) d u d t \\
= & \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} \int_{0}^{u} t^{\alpha-1}(u-t)^{\beta-1} S(u) d t d u \\
= & \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{\infty} S(u) \int_{0}^{1}(u x)^{\alpha-1}(u-u x)^{\beta-1} u d x d u \\
= & \frac{1}{\Gamma(\alpha) \Gamma(\beta)}\left(\int_{0}^{1} x^{\alpha-1}(1-x)^{\beta-1} d x\right) \int_{0}^{\infty} S(u) u^{\alpha+\beta-1} d u \\
= & \frac{1}{\Gamma(\alpha) \Gamma(\beta)}\left(\int_{0}^{1} x^{\alpha-1}(1-x)^{\beta-1} d x\right) \Gamma(\alpha+\beta)(-A)^{-(\alpha+\beta)} \\
= & (-A)^{-(\alpha+\beta)}
\end{aligned}
$$

This proves the first part of the theorem.
Consider 54.3.18. Since $A$ is a closed operator, and approximating the integral with an appropriate sequence of Riemann sums, $(-A)$ can be taken inside the integral and so

$$
\begin{aligned}
(-A) & \frac{1}{\Gamma(1)} \int_{0}^{\infty} t^{1-1} S(t) d t
\end{aligned}=\int_{0}^{\infty}(-A) S(t) d t t .
$$

Next let $x \in D(-A)$. Then

$$
\begin{aligned}
& \frac{1}{\Gamma(1)} \int_{0}^{\infty} t^{1-1} S(t) d t(-A) x=-\int_{0}^{\infty} S(t) A x d t \\
& =-\int_{0}^{\infty} A S(t) x d t=\int_{0}^{\infty}-\frac{d}{d t}(S(t)) d t=I x
\end{aligned}
$$

This shows that the integral in which $\alpha=1$ deserves to be called $A^{-1}$ so the definition is not bad notation. Also, by assumption, $A^{-1}$ is one to one. Thus

$$
(-A)^{-1}(-A)^{-1} x=0
$$

implies

$$
(-A)^{-1} x=0
$$

hence $x=0$ so that $(-A)^{-2}$ is also one to one. Similarly, $(-A)^{-m}$ is one to one for all positive integers $m$.

From what was just shown, if $(-A)^{-\alpha} x=0$ for $\alpha \in(0,1)$, then

$$
(-A)^{-1} x=(-A)^{-(1-\alpha)}(-A)^{-\alpha} x=0
$$

and so $x=0$. This shows $(-A)^{-\alpha}$ is one to one for all $\alpha \in[0,1]$ if is defined as $(-A)^{0} \equiv I$.
What about $\alpha>1$ ? For such $\alpha$, it is of the form $m+\beta$ where $\beta \in[0,1)$ and $m$ is a positive integer. Therefore, if

$$
(-A)^{-(m+\beta)} x=0
$$

then

$$
(-A)^{-\beta}\left((-A)^{-m}\right) x=0
$$

and so from what was just shown,

$$
\left((-A)^{-m}\right) x=0
$$

and now this implies $x=0$ so that $(-A)^{-\alpha}$ is one to one for all $\alpha \geq 0$.
Consider 54.3.19. It was shown above that

$$
(-A)^{-\alpha}(-A)^{-\beta}=(-A)^{-(\alpha+\beta)}
$$

Let $x=(-A)^{-(\alpha+\beta)} y$. Then

$$
x=(-A)^{-\alpha}(-A)^{-\beta} y \subseteq(-A)^{-\alpha}(-A)^{-\beta}(H) \subseteq(-A)^{-\alpha}(H)
$$

This proves 54.3.19. If $\alpha<\beta,(-A)^{-\beta}(H) \subseteq(-A)^{-\alpha}(H)$.
Now consider the problem of writing $(-A)^{-\alpha}$ for $\alpha \in(0,1)$ in terms of $A$, not mentioning $S(t)$. By Proposition 19.14.5,

$$
(\lambda I-A)^{-1} x=\int_{0}^{\infty} e^{-\lambda t} S(t) x d t
$$

Then

$$
\begin{aligned}
\int_{0}^{\infty} \lambda^{-\alpha}(\lambda I-A)^{-1} d \lambda & =\int_{0}^{\infty} \lambda^{-\alpha} \int_{0}^{\infty} e^{-\lambda t} S(t) d t d \lambda \\
& =\int_{0}^{\infty} S(t) \int_{0}^{\infty} \lambda^{-\alpha} e^{-\lambda t} d \lambda d t \\
& =\int_{0}^{\infty} S(t) \int_{0}^{\infty} \lambda^{\beta-1} e^{-\lambda t} d \lambda d t
\end{aligned}
$$

where $\beta \equiv 1-\alpha$. Then using Lemma 54.3.15, this equals

$$
\int_{0}^{\infty} S(t) \int_{0}^{\infty} \mu^{\beta-1} t^{1-\beta} e^{-\mu} t^{-1} d \mu d t=\int_{0}^{\infty} t^{-\beta} S(t) \int_{0}^{\infty} \mu^{\beta-1} e^{-\mu} d \mu d t
$$

$$
\begin{aligned}
& =\Gamma(1-\alpha) \int_{0}^{\infty} t^{\alpha-1} S(t) d t=\Gamma(\alpha) \Gamma(1-\alpha)(-A)^{-\alpha} \\
& =\left(\int_{0}^{1} x^{\alpha-1}(1-x)^{-\alpha} d x\right)(-A)^{-\alpha}=\frac{\pi}{\sin (\pi \alpha)}(-A)^{-\alpha}
\end{aligned}
$$

and so this gives the formula

$$
(-A)^{-\alpha}=\frac{\sin (\pi \alpha)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha}(\lambda I-A)^{-1} d \lambda
$$

This proves 54.3.20.
Definition 54.3.18 For $\alpha \geq 0$, define $(-A)^{\alpha}$ on $D\left((-A)^{\alpha}\right) \equiv(-A)^{-\alpha}(H)$ by

$$
(-A)^{\alpha} \equiv\left((-A)^{-\alpha}\right)^{-1}
$$

Note that if $\alpha, \beta>0$, then if $x \in D\left((-A)^{\alpha+\beta}\right)$,

$$
\begin{gather*}
(-A)^{\alpha+\beta} x=\left((-A)^{-(\alpha+\beta)}\right)^{-1} x= \\
\left((-A)^{-\alpha}(-A)^{-\beta}\right)^{-1} x=(-A)^{\beta}(-A)^{\alpha} x . \tag{54.3.21}
\end{gather*}
$$

Next let $\beta>\alpha>0$ and let $x \in D\left((-A)^{\beta}\right)$. Then from what was just shown,

$$
(-A)^{\alpha}(-A)^{\beta-\alpha} x=(-A)^{\beta} x
$$

and so

$$
(-A)^{\beta-\alpha} x=(-A)^{-\alpha}(-A)^{\beta} x
$$

If $x \in D\left((-A)^{\beta}\right)$, does it follow that $(-A)^{-\alpha} x \in D\left((-A)^{\beta}\right)$ ? Note $x=(-A)^{-\beta} y$ and so

$$
(-A)^{-\alpha} x=(-A)^{-\alpha}(-A)^{-\beta} y=(-A)^{-(\alpha+\beta)} y \in D\left((-A)^{\alpha+\beta}\right) .
$$

Therefore, from 54.3.21,

$$
(-A)^{\beta-\alpha} x=(-A)^{\beta-\alpha}(-A)^{\alpha}\left((-A)^{-\alpha} x\right)=(-A)^{\beta}(-A)^{-\alpha} x
$$

Theorem 54.3.19 The definition of $(-A)^{\alpha}$ is well defined and $(-A)^{\alpha}$ is densely defined and closed. Also for any $\alpha>0$,

$$
\begin{equation*}
\left\|(-A)^{\alpha} S(t)\right\| \leq \frac{C_{\alpha}}{\delta} \frac{1}{t^{\alpha}} e^{-\delta t} \tag{54.3.22}
\end{equation*}
$$

where $-\delta>-a$. Furthermore, $C_{\alpha}$ is bounded as $\alpha \rightarrow 0+$ and is bounded on compact intervals of $(0, \infty)$. Also for $\alpha \in(0,1)$ and $x \in D\left((-A)^{\alpha}\right)$,

$$
\begin{equation*}
\|(S(t)-I) x\| \leq \frac{C_{1-\alpha}}{\alpha \delta} t^{\alpha}\left\|(-A)^{\alpha} x\right\| \tag{54.3.23}
\end{equation*}
$$

There exists a constant $C$ independent of $\alpha \in[0,1)$ such that for $x \in D(A)$ and $\varepsilon>0$,

$$
\begin{equation*}
\left\|(-A)^{\alpha} x\right\| \leq \varepsilon\|(-A) x\|+C \varepsilon^{-\alpha /(1-\alpha)}\|x\| \tag{54.3.24}
\end{equation*}
$$

There exists a constant $C^{\prime}$ independent of $\alpha \in[0,1]$ such that for $x \in D(A)$,

$$
\begin{equation*}
\left\|(-A)^{\alpha} x\right\| \leq C^{\prime}\|(-A) x\|^{\alpha}\|x\|^{1-\alpha} \tag{54.3.25}
\end{equation*}
$$

The formula 54.3.25 is called an interpolation inequality.
Proof: It is obvious $(-A)^{\alpha}$ is densely defined because its domain is at least as large as $D(A)$ which was assumed to be dense. It is a closed operator because if $x_{n} \in D\left((-A)^{\alpha}\right)$ and

$$
x_{n} \rightarrow x,(-A)^{\alpha} x_{n} \rightarrow y
$$

then

$$
(-A)^{-\alpha} x_{n} \rightarrow(-A)^{-\alpha} x, x_{n}=(-A)^{-\alpha}(-A)^{\alpha} x_{n} \rightarrow(-A)^{-\alpha} y
$$

and so

$$
(-A)^{-\alpha} y=x
$$

showing $x \in D\left((-A)^{\alpha}\right)$ and $y=(-A)^{-\alpha} x$. Thus $(-A)^{\alpha}$ is closed and densely defined.
Let $-\delta>-a$ where the sector for $A$ was $S_{-a, \phi}, a>0$. Then recall from Corollary 54.3.8 there is a constant, $N$ such that

$$
\|(-A) S(t)\| \leq \frac{N}{t} e^{-\delta t}
$$

What about $\left\|(-A)^{\alpha} S(t)\right\|$ ? First note that for $\alpha \in[0,1)$ this at least makes sense because $S(t)$ maps into $D(A)$. For any $\alpha>0$,

$$
S(t)(-A)^{-\alpha}=(-A)^{-\alpha} S(t)
$$

follows from the definiton of $(-A)^{-\alpha}$. Therefore,

$$
\begin{equation*}
(-A)^{\alpha} S(t)(-A)^{-\alpha}=S(t) \tag{54.3.26}
\end{equation*}
$$

Note this implies that on $D\left((-A)^{\alpha}\right)$,

$$
(-A)^{\alpha} S(t)=S(t)(-A)^{\alpha}
$$

Also

$$
(-A)^{-1} S(t)=S(t)(-A)^{-1}=S(t)(-A)^{-\alpha}(-A)^{-(1-\alpha)}
$$

and so

$$
S(t)=(-A) S(t)(-A)^{-\alpha}(-A)^{-(1-\alpha)}
$$

From 54.3.26 it follows

$$
\begin{align*}
(-A)^{\alpha} S(t) & =(-A)(-A)^{\alpha} S(t)(-A)^{-\alpha}(-A)^{-(1-\alpha)} \\
& =(-A) S(t)(-A)^{-(1-\alpha)} \tag{54.3.27}
\end{align*}
$$

Then with this formula,

$$
\begin{aligned}
& \left\|(-A)^{\alpha} S(t)\right\|=\left\|(-A) S(t)(-A)^{-(1-\alpha)}\right\| \\
& =\left\|\frac{1}{\Gamma(1-\alpha)} \int_{0}^{\infty} s^{1-\alpha}(-A) S(t+s) d s\right\| \\
& \leq \frac{N}{\Gamma(1-\alpha)} \int_{0}^{\infty} \frac{s^{1-\alpha}}{(t+s)} e^{-\delta(s+t)} d s \\
& =\frac{N}{\Gamma(1-\alpha)} \int_{t}^{\infty} \frac{(u-t)^{1-\alpha}}{u} e^{-\delta u} d s \\
& \leq \frac{N}{\Gamma(1-\alpha)} \int_{t}^{\infty}\left(1-\frac{t}{u}\right)^{1-\alpha} \frac{1}{u^{\alpha}} e^{-\delta u} d s \\
& \leq \frac{N}{\Gamma(1-\alpha)} \frac{1}{t^{\alpha}} \int_{t}^{\infty} e^{-\delta u} d s=\frac{N}{\Gamma(1-\alpha) \delta} \frac{1}{t^{\alpha}} e^{-\delta t} \\
& \equiv \frac{C_{\alpha}}{\delta} \frac{1}{t^{\alpha}} e^{-\delta t} .
\end{aligned}
$$

this establishes the formula when $\alpha \in[0,1)$. Next suppose $\alpha=m$, a positive integer.

$$
\begin{aligned}
\left\|A^{m} S(t)\right\| & =\left\|A^{m} S\left(\frac{t}{m}\right)^{m}\right\| \\
& =\left\|\left(A S\left(\frac{t}{m}\right)\right)^{m}\right\| \leq \frac{N}{t^{m}} m^{m}
\end{aligned}
$$

This is why the above inequality holds.
If $\alpha, \beta>0$,

$$
\begin{aligned}
\left\|A^{\alpha+\beta} S(t)\right\| & =\left\|A^{\alpha+\beta} S\left(\frac{t}{2}\right) S\left(\frac{t}{2}\right)\right\| \\
& =\left\|A^{\alpha} S\left(\frac{t}{2}\right) A^{\beta} S\left(\frac{t}{2}\right)\right\| \\
& \leq \frac{C_{\alpha}}{t^{\alpha}} \frac{C_{\beta}}{t^{\beta}} e^{-2 \delta t}=\frac{C}{t^{\alpha+\beta}} e^{-\delta t}
\end{aligned}
$$

Suppose now that $\alpha>0$. Then

$$
\alpha=m+\beta
$$

where $\beta \in[0,1)$. Then from what was just shown,

$$
\left\|A^{m+\beta} S(t)\right\| \leq \frac{C}{t^{m+\beta}} e^{-\delta t}
$$

Next consider 54.3.23. First note that whenever $\alpha>0$,

$$
(-A)^{-\alpha} S(s)=S(s)(-A)^{-\alpha}
$$

and so on $D\left((-A)^{\alpha}\right)$,

$$
S(s)=(-A)^{\alpha} S(s)(-A)^{-\alpha}, S(s)(-A)^{\alpha}=(-A)^{\alpha} S(s)
$$

Now for $x \in D\left((-A)^{\alpha}\right)$,

$$
\begin{aligned}
\|(S(t)-I) x\| & =\left\|-\int_{0}^{t}(-A) S(s) x d s\right\| \\
& =\left\|-\int_{0}^{t}(-A)^{1-\alpha}(-A)^{\alpha} S(s) x d s\right\| \\
& =\left\|-\int_{0}^{t}(-A)^{1-\alpha} S(s)(-A)^{\alpha} x d s\right\| \\
& \leq \int_{0}^{t}\left\|(-A)^{1-\alpha} S(s)\right\| d s\left\|(-A)^{\alpha} x\right\| \\
\leq \int_{0}^{t} & \frac{C_{1-\alpha}}{\delta} \frac{1}{s^{1-\alpha}} e^{-\delta s} d s\left\|(-A)^{\alpha} x\right\| \\
& \leq \frac{C_{1-\alpha}}{\delta} \frac{1}{\alpha} t^{\alpha}\left\|(-A)^{\alpha} x\right\|
\end{aligned}
$$

and this shows 54.3.23.
Next consider 54.3.24. Let $x \in H$ and $\beta \in(0,1)$. Then

$$
\begin{gathered}
\left\|(-A)^{-\beta} x\right\|=\frac{1}{\Gamma(\beta)}\left\|\int_{0}^{\infty} t^{\beta-1} S(t) x d t\right\| \\
=\frac{1}{\Gamma(\beta)}\left\|\int_{0}^{\eta} t^{\beta-1} S(t) x d t+\int_{\eta}^{\infty} t^{\beta-1} S(t) x d t\right\| \\
\leq \frac{1}{\Gamma(\beta)} \int_{0}^{\eta} t^{\beta-1}\|S(t) x\| d t+\frac{1}{\Gamma(\beta)}\left\|\int_{\eta}^{\infty} t^{\beta-1} S(t) x d t\right\| \\
\leq \frac{C}{\Gamma(\beta)} \frac{\eta^{\beta}}{\beta}\|x\|+\frac{1}{\Gamma(\beta)}\left\|\int_{\eta}^{\infty} t^{\beta-1} S(t) x d t\right\| \\
\leq \frac{C}{\Gamma(\beta)} \frac{\eta^{\beta}}{\beta}\|x\|+ \\
\quad \frac{1}{\Gamma(\beta)}\left\|\eta^{\beta-1} S(\eta) A^{-1} x+(1-\beta) \int_{\eta}^{\infty} t^{\beta-2} S(t) A^{-1} x d t\right\| \\
\leq \frac{1}{\Gamma(\beta)}\left(\frac{C \eta^{\beta}}{\beta}\|x\|+\eta^{\beta-1}\left\|A^{-1} x\right\|+(1-\beta)\left\|A^{-1} x\right\| \int_{\eta}^{\infty} t^{\beta-2} d t\right) \\
=\frac{1}{\Gamma(\beta)}\left(\frac{C \eta^{\beta}}{\beta}\|x\|+2 \eta^{\beta-1}\left\|A^{-1} x\right\|\right) .
\end{gathered}
$$

Now let $\delta=C \eta^{\beta}$ so $\eta=C^{-1 / \beta} \delta^{1 / \beta}$ and $\eta^{\beta-1}=C^{\frac{1-\beta}{\beta}} \delta^{(\beta-1) / \beta}$. Thus for all $x \in H$,

$$
\left\|(-A)^{-\beta} x\right\| \leq \frac{1}{\Gamma(\beta)}\left(\frac{\delta}{\beta}\|x\|+2 C^{\frac{1-\beta}{\beta}} \delta^{(\beta-1) / \beta}\left\|A^{-1} x\right\|\right)
$$

Let $\varepsilon=\frac{\delta}{\beta \Gamma(\beta)}=\frac{\delta}{\Gamma(1+\beta)}$. Then the above is of the form

$$
\begin{aligned}
\left\|(-A)^{-\beta} x\right\| & \leq \varepsilon\|x\|+2 \frac{C^{\frac{1-\beta}{\beta}}}{\Gamma(\beta)}(\varepsilon \Gamma(1+\beta))^{(\beta-1) / \beta}\left\|A^{-1} x\right\| \\
& \leq \varepsilon\|x\|+2 C^{\frac{1-\beta}{\beta}}(\varepsilon \Gamma(1+\beta))^{(\beta-1) / \beta}\left\|A^{-1} x\right\|
\end{aligned}
$$

because $\Gamma$ is decreasing on $(0,1)$. I need to verify that for $\beta \in(0,1)$,

$$
\Gamma(1+\beta)^{(\beta-1) / \beta}
$$

is bounded. It is continuous on $(0,1]$ and so if I can show $\lim _{\beta \rightarrow 0+} \Gamma(1+\beta)^{(\beta-1) / \beta}$ exists, then it will follow the function is bounded. It suffices to show

$$
\lim _{\beta \rightarrow 0+} \frac{\beta-1}{\beta} \ln \Gamma(1+\beta)=-\lim _{\beta \rightarrow 0+} \frac{\ln \Gamma(1+\beta)}{\beta}
$$

exists. Consider this. By L'Hospital's rule and dominated convergence theorem, this is

$$
\begin{aligned}
\lim _{\beta \rightarrow 0+} \frac{\int_{0}^{\infty} \ln (t) t^{\beta} e^{-t} d t}{\Gamma(1+\beta)} & =\lim _{\beta \rightarrow 0+} \int_{0}^{\infty} \ln (t) t^{\beta} e^{-t} d t \\
& =\lim _{\beta \rightarrow 0+} \int_{0}^{\infty} \ln (t) e^{-t} d t
\end{aligned}
$$

Thus the function is bounded independent of $\beta \in(0,1)$. This shows there is a constant $C$ which is independent of $\beta \in(0,1)$ such that for any $x \in H$,

$$
\begin{equation*}
\left\|(-A)^{-\beta} x\right\| \leq \varepsilon\|x\|+C \varepsilon^{(\beta-1) / \beta}\left\|A^{-1} x\right\| \tag{54.3.28}
\end{equation*}
$$

Now let $y \in D(A)=D((-A))$ and let $x=(-A) y$. Then the above becomes

$$
\left\|(-A)^{-\beta}(-A) y\right\| \leq \varepsilon\|(-A) y\|+C \varepsilon^{(\beta-1) / \beta}\|y\|
$$

I claim that

$$
(-A)^{-\beta}(-A) y=(-A)^{1-\beta} y
$$

The reason for this is as follows.

$$
(-A)^{\beta}(-A)^{1-\beta} y=(-A) y
$$

and so the desired result follows from multiplying on the left by $(-A)^{-\beta}$. Hence

$$
\left\|(-A)^{1-\beta} y\right\| \leq \varepsilon\|(-A) y\|+C \varepsilon^{(\beta-1) / \beta}\|y\|
$$

Now let $1-\beta=\alpha$ and obtain

$$
\left\|(-A)^{\alpha} y\right\| \leq \varepsilon\|(-A) y\|+C \varepsilon^{-\alpha /(1-\alpha)}\|y\|
$$

This proves 54.3.24.
Finally choose $\varepsilon$ to minimize the right side of the above expression. Thus let

$$
\varepsilon=\left(\frac{\alpha\|y\| C}{\|(-A) y\|(1-\alpha)}\right)^{1-\alpha}
$$

Then the above expression becomes

$$
\begin{aligned}
&\left\|(-A)^{\alpha} y\right\| \leq\|(-A) y\|\left(\frac{\alpha\|y\| C}{\|(-A) y\|(1-\alpha)}\right)^{1-\alpha} \\
&+C\left(\left(\frac{\alpha\|y\| C}{\|(-A) y\|(1-\alpha)}\right)^{1-\alpha}\right)^{-\alpha /(1-\alpha)}\|y\| \\
&=\|(-A) y\|^{\alpha}\|y\|^{1-\alpha}\left(\frac{\alpha C}{(1-\alpha)}\right)^{1-\alpha} \\
& \quad+\|(-A) y\|^{\alpha}\|y\|^{1-\alpha}\left(\frac{\alpha C}{(1-\alpha)}\right)^{-\alpha} \\
&=\left(\left(\frac{\alpha C}{(1-\alpha)}\right)^{1-\alpha}+\left(\frac{\alpha C}{(1-\alpha)}\right)^{-\alpha}\right)\|(-A) y\|^{\alpha}\|y\|^{1-\alpha} \\
& \leq C^{\prime}\|(-A) y\|^{\alpha}\|y\|^{1-\alpha}
\end{aligned}
$$

where $C^{\prime}$ does not depend on $\alpha \in(0,1)$. To see such a constant exists, note

$$
\lim _{\alpha \rightarrow 1}\left(\frac{\alpha C}{(1-\alpha)}\right)^{1-\alpha}=1
$$

and

$$
\lim _{\alpha \rightarrow 1}\left(\frac{\alpha C}{(1-\alpha)}\right)^{-\alpha}=0
$$

while

$$
\lim _{\alpha \rightarrow 0}\left(\frac{\alpha C}{(1-\alpha)}\right)^{1-\alpha}=0, \lim _{\alpha \rightarrow 0}\left(\frac{\alpha C}{(1-\alpha)}\right)^{-\alpha}=1
$$

Of course $C^{\prime}$ depends on $C$ but as shown above, this did not depend on $\alpha \in(0,1)$. This proves 54.3.25.

The following corollary follows from the proof of the above theorem.
Corollary 54.3.20 Let $\alpha \in(0,1)$. Then for all $\varepsilon>0$, there exists a constant $C(\alpha, \varepsilon)$ such that

$$
\left\|(-A)^{-\alpha} x\right\| \leq \varepsilon\|x\|+C(\varepsilon, \alpha)\left\|(-A)^{-1} x\right\|
$$

Also if $A^{-1}$ is compact, then so is $(-A)^{-\alpha}$ for all $\alpha \in(0,1)$.

Proof: The first part is done in the above theorem. Let $S$ be a bounded set and let $\eta>0$. Then let $\varepsilon>0$ be small enough that for all $x \in S, \varepsilon\|x\|<\eta / 4$. Let $\left\{(-A)^{-1} x_{n}\right\}$ be a $\eta /(2+2 C(\varepsilon, \alpha))$ net for $(-A)^{-1}(S)$. Then if $(-A)^{-\alpha} x \in(-A)^{-\alpha} S$, there exists $x_{n}$ such that

$$
\left\|(-A)^{-1} x_{n}-(-A)^{-1} x\right\|<\frac{\eta}{2+2 C(\varepsilon, \alpha)}
$$

Then

$$
\begin{aligned}
\left\|(-A)^{-\alpha} x_{n}-(-A)^{-\alpha} x\right\| & \leq \varepsilon\left\|x_{n}-x\right\|+C(\varepsilon, \alpha)\left\|(-A)^{-1} x_{n}-(-A)^{-1} x\right\| \\
& <\frac{\eta}{2}+\frac{\eta}{2}=\eta
\end{aligned}
$$

showing $(-A)^{-\alpha}(S)$ has a $\eta$ net. Thus $(-A)^{-\alpha}$ is compact. This proves the corollary.
The next proposition gives a general interpolation inequality.
Proposition 54.3.21 Let $0<\alpha<\beta$ and let

$$
\gamma=\theta \beta+(1-\theta) \alpha, \theta \in(0,1)
$$

Then there exists a constant, $C$ such that for all $x \in D\left((-A)^{\beta}\right)$,

$$
\left\|(-A)^{\gamma} x\right\| \leq C\left\|(-A)^{\beta} x\right\|^{\theta}\left\|(-A)^{\alpha} x\right\|^{1-\theta}
$$

Proof: This is an exercise in using 54.3.22. Letting $x \in D\left((-A)^{\beta}\right)$,

$$
(-A)^{\gamma} x=(-A)^{\theta}(-A)^{-\theta}(-A)^{\gamma} x
$$

Therefore, letting $C$ denote a generic constant, it follows since $(-A)^{\theta}$ is closed,

$$
\begin{gathered}
\Gamma(\theta)\left\|(-A)^{\gamma} x\right\|=\left\|\int_{0}^{\infty} t^{\theta-1}(-A)^{\theta} S(t)(-A)^{\gamma} x d t\right\| \\
\leq \int_{0}^{\eta} t^{\theta-1}\left\|(-A)^{\theta}(-A)^{\gamma-\beta} S(t)(-A)^{\beta} x\right\| d t \\
+\int_{\eta}^{\infty} t^{\theta-1}\left\|(-A)^{\theta}(-A)^{\gamma-\alpha} S(t)(-A)^{\alpha} x\right\| d t \\
\leq C \int_{0}^{\eta} t^{\theta-1} t^{-\theta} t^{\beta-\gamma} d t\left\|(-A)^{\beta} x\right\|+C \int_{\eta}^{\infty} t^{\theta-1} t^{-\theta} t^{\alpha-\gamma} d t\left\|(-A)^{\alpha} x\right\| \\
=C\left(\frac{\eta^{\beta-\gamma}}{\beta-\gamma}\left\|(-A)^{\beta} x\right\|+\frac{\eta^{-(\gamma-\alpha)}}{\gamma-\alpha}\left\|(-A)^{\alpha} x\right\|\right)
\end{gathered}
$$

and now writing in what $\gamma$ is in terms of $\theta$ yields

$$
\Gamma(\theta)\left\|(-A)^{\gamma} x\right\| \leq C\left(\frac{1}{\beta-\alpha}\right)\left(\frac{\left(\eta^{\beta-\alpha}\right)^{1-\theta}}{(1-\theta)}\left\|(-A)^{\beta} x\right\|+\frac{\left(\eta^{\beta-\alpha}\right)^{-\theta}}{\theta}\left\|(-A)^{\alpha} x\right\|\right)
$$

Letting $\lambda=\eta^{\beta-\alpha}$, it follows

$$
\Gamma(\theta)\left\|(-A)^{\gamma} x\right\| \leq C\left(\frac{1}{\beta-\alpha}\right)\left(\frac{\lambda^{1-\theta}}{(1-\theta)}\left\|(-A)^{\beta} x\right\|+\frac{\lambda^{-\theta}}{\theta}\left\|(-A)^{\alpha} x\right\|\right)
$$

then let

$$
\lambda=\frac{\left\|(-A)^{\alpha} x\right\|}{\left\|(-A)^{\beta} x\right\|}
$$

which is obtained from minimizing the expression on the right in the above. then placing this in the inequality yields

$$
\begin{gathered}
\Gamma(\theta)\left\|(-A)^{\gamma} x\right\| \\
\leq C\left(\frac{1}{\beta-\alpha}\right)\left(\frac{\left(\frac{\left\|(-A)^{\alpha} x\right\|}{\left\|(-A)^{\beta} x\right\|}\right)^{1-\theta}}{(1-\theta)}\left\|(-A)^{\beta} x\right\|\right. \\
\left.+\frac{\left(\frac{\left\|(-A)^{\alpha} x\right\|}{\left\|(-A)^{\beta} x\right\|}\right)^{-\theta}}{\theta}\left\|(-A)^{\alpha} x\right\|\right) \\
=C\left(\frac{1}{\beta-\alpha}\right)\left(\frac{1}{(1-\theta)}+\frac{1}{\theta}\right)\left\|(-A)^{\alpha} x\right\|^{1-\theta}\left\|(-A)^{\beta} x\right\|^{\theta}
\end{gathered}
$$

and this proves the proposition.
Note that the constant is not bounded as $\theta \rightarrow 1$.
Here is another interesting result about compactness.

Proposition 54.3.22 Let $A$ be sectorial for $S_{-a, \phi}$ where $-a<0$. Then the following are equivalent.

1. $(-A)^{-\alpha}$ is compact for all $\alpha>0$.
2. $S(t)$ is compact for each $t>0$.

Proof: First suppose $(-A)^{-\alpha}$ is compact for all $\alpha>0$. Then

$$
\begin{aligned}
& \Gamma(\alpha)(-A)^{-\alpha}=\int_{0}^{t} s^{\alpha-1} S(s) d s+\int_{t}^{\infty} s^{\alpha-1} S(s) d s \\
&= \frac{t^{\alpha}}{\alpha} S(t)-\int_{0}^{t} \frac{s^{\alpha}}{\alpha} A S(s) d s+\left.s^{\alpha-1} S(s) A^{-1}\right|_{t} ^{\infty} \\
& \quad-(\alpha-1) \int_{t}^{\infty} s^{\alpha-2} S(s) A^{-1} d s
\end{aligned}
$$

Now

$$
\left\|\frac{s^{\alpha}}{\alpha} A S(s)\right\| \leq C \frac{s^{\alpha-1}}{\alpha}
$$

and so the second integral satisfies

$$
\begin{aligned}
& \left\|\int_{0}^{t} \frac{s^{\alpha}}{\alpha} A S(s) d s\right\| \leq C \frac{t^{\alpha}}{\alpha^{2}} \\
\Gamma(\alpha)(-A)^{-\alpha}= & O\left(\frac{t^{\alpha}}{\alpha^{2}}\right)+\frac{t^{\alpha}}{\alpha} S(t) \\
& -t^{\alpha-1} A^{-1} S(t)-(\alpha-1) \int_{t}^{\infty} s^{\alpha-2} S(s) d s A^{-1}
\end{aligned}
$$

It follows that for $t>0$, and $\varepsilon>0$ given,

$$
\begin{aligned}
S(t)= & \left(\frac{t^{\alpha}}{\alpha}-t^{\alpha-1}\right)^{-1}\left(\Gamma(\alpha)(-A)^{-\alpha}\right. \\
& \left.+(\alpha-1) \int_{t}^{\infty} s^{\alpha-2} S(s) d s A^{-1}+O\left(\frac{t^{\alpha}}{\alpha^{2}}\right)\right) \\
= & \left(\frac{t^{\alpha}}{\alpha}-t^{\alpha-1}\right)^{-1}\left(\Gamma(\alpha)(-A)^{-\alpha}\right. \\
& \left.+(\alpha-1) \int_{t}^{\infty} s^{\alpha-2} S(s) d s A^{-1}\right)+O\left(\frac{1}{\alpha}\right) \\
= & N_{\alpha}+O\left(\frac{1}{\alpha}\right)
\end{aligned}
$$

where $N_{\alpha}$ is a compact operator. Now let $B$ be a bounded set in $H,\|x\| \leq M$ for all $x \in B$ and let $\eta>0$ be given. Then choose $\alpha$ large enough that $\left\|O\left(\frac{1}{\alpha}\right)\right\|<\frac{\eta}{4+4 M}$. Then there exists a $\eta / 2$ net, $\left\{N_{\alpha} x_{n}\right\}_{n=1}^{N}$ for $N_{\alpha}(B)$. Then consider $\left\{S(t) x_{n}\right\}_{n=1}^{N}$. For $x \in B$, there exists $x_{n}$ such that $\left\|N_{\alpha} x_{n}-N_{\alpha} x\right\|<\eta / 2$. Then

$$
\begin{aligned}
\left\|S(t) x-S(t) x_{n}\right\| \leq & \left\|S(t) x-N_{\alpha} x\right\| \\
& +\left\|N_{\alpha} x-N_{\alpha} x_{n}\right\|+\left\|N_{\alpha} x_{n}-S(t) x_{n}\right\|
\end{aligned}
$$

$$
\leq \frac{\eta}{4+4 M} M+\frac{\eta}{2}+\frac{\eta}{4+4 M} M<\eta
$$

Thus $S(t)(B)$ has an $\eta$ net for every $\eta>0$ and so $S(t)$ is compact.
Next suppose $S(t)$ is compact for all $t>0$. Then

$$
(-A)^{-\alpha}=\frac{1}{\Gamma(\alpha)} \int_{0}^{\infty} t^{\alpha-1} S(t) d t
$$

and the integral is a limit in norm of Riemann sums of the form

$$
\sum_{k=1}^{m} t_{k}^{\alpha-1} S\left(t_{k}\right) \Delta t_{k}
$$

and each of these operators is compact. Since $(-A)^{-\alpha}$ is the limit in norm of compact operators, it must also be compact. This proves the proposition.

Here are some observations which are listed in the book by Henry [63]. Like the above proposition, these are exercises in this book.

Observation 54.3.23 For each $x \in H, t \rightarrow t A S(t)$ is continuous and $\lim _{t \rightarrow 0+} t A S(t) x=0$.
The reason for this is that if $x \in D(A)$, then

$$
t A S(t) x=|t S(t) A x| \rightarrow 0
$$

as $t \rightarrow 0$. Now suppose $y \in H$ is arbitrary. Then letting $x \in D(A)$,

$$
\begin{aligned}
|t A S(t) y| & \leq|t A S(t)(y-x)|+|t A S(t) x| \\
& \leq \varepsilon+|t A S(t) x|
\end{aligned}
$$

provided $x$ is close enough to $y$. The last term converges to 0 and so

$$
\lim _{\sup _{t \rightarrow 0+}}|t A S(t) y| \leq \varepsilon
$$

where $\varepsilon>0$ is arbitrary. Thus

$$
\lim _{t \rightarrow 0+}|t A S(t) y|=0
$$

Why is $t \rightarrow t A S(t) x$ continuous on $[0, T]$ ? This is true if $x \in D(A)$ because $t \rightarrow t S(t) A x$ is continuous. If $y \in H$ is arbitrary, let $x_{n}$ converge to $y$ in $H$ where $x_{n} \in D(A)$. Then

$$
\left|t A S(t) y-t A S(t) x_{n}\right| \leq C\left|y-x_{n}\right|
$$

and so the convergence is uniform. Thus $t \rightarrow t A S(t) y$ is continuous because it is the uniform limit of a sequence of continuous functions.

Observation 54.3.24 If $x \in H$ and $A$ is sectorial for $S_{-a, \phi},-a<0$, then for any $\alpha \in[0,1]$,

$$
\lim _{t \rightarrow 0+} t^{\alpha}\left\|(-A)^{\alpha} S(t) x\right\|=0
$$

This follows as above because you can verify this is true for $x \in D(A)$ and then use the fact shown above that

$$
t^{\alpha}\left\|(-A)^{\alpha} S(t)\right\| \leq C
$$

to extend it to $x$ arbitrary.

### 54.3.4 A Scale Of Banach Spaces

Next I will present an important and interesting theorem which can be used to prove equivalence of certain norms.

Theorem 54.3.25 Let $A, B$ be sectorial for $S_{-a, \phi}$ where $-a<0$ and suppose $D(A)=$ $D(B)$. Also suppose

$$
(A-B)(-A)^{-\alpha},(A-B)(-B)^{-\alpha}
$$

are both bounded on $D(A)$ for some $\alpha \in(0,1)$. Then for all $\beta \in[0,1]$,

$$
(-A)^{\beta}(-B)^{-\beta},(-B)^{\beta}(-A)^{-\beta}
$$

are both bounded on $D(A)=D(B)$. Also $D\left((-A)^{\beta}\right)=D\left((-B)^{\beta}\right)$.
Proof: First of all it is a good idea to verify $(A-B)(-A)^{-\alpha},(A-B)(-B)^{-\alpha}$ make sense on $D(A)$. If $x \in D(A)$, then why is $(-A)^{-\alpha} x \in D(A)$ ? Here is why. Since $x \in D(A)$,

$$
x=(-A)^{-1} y
$$

for some $y \in H$. Then

$$
(-A)^{-\alpha} x=(-A)^{-\alpha}(-A)^{-1} y=(-A)^{-1}(-A)^{-\alpha} y \in D(A)
$$

The case of $(A-B)(-B)^{-\alpha}$ is similar.
Next for $\beta \in(0,1)$ and $\lambda>0$, use 54.3.25 to write

$$
\begin{align*}
& \left\|(-A)^{\beta}(\lambda I-A)^{-1} x\right\| \\
\leq & C\left\|(-A)(\lambda I-A)^{-1} x\right\|^{\beta}\left\|(\lambda I-A)^{-1} x\right\|^{1-\beta} \\
\leq & C\left\|(-A)(\lambda I-A)^{-1}\right\|^{\beta}\left\|(\lambda I-A)^{-1}\right\|^{1-\beta}\|x\| \\
\leq & C\left\|I-\lambda(\lambda I-A)^{-1}\right\|^{\beta} \frac{M}{(\lambda+\delta)^{1-\beta}}\|x\| \\
\leq & C\left(1+\frac{\lambda}{(\lambda+\delta)}\right)^{\beta} \frac{M}{(\lambda+\delta)^{1-\beta}}\|x\| \equiv \frac{C}{(\lambda+\delta)^{1-\beta}}\|x\| \tag{54.3.29}
\end{align*}
$$

where $-a<-\delta<0$ where $C$ denotes a generic constant. Similarly, for all $\beta \in(0,1)$,

$$
\begin{equation*}
\left\|(-B)^{\beta}(\lambda I-B)^{-1} x\right\| \leq \frac{C}{(\lambda+\delta)^{1-\beta}}\|x\| \tag{54.3.30}
\end{equation*}
$$

Now from Theorem 54.3.17 and letting $\beta \in(0,1)$,

$$
(-B)^{-\beta}-(-A)^{-\beta}=\frac{\sin (\pi \beta)}{\pi} \int_{0}^{\infty} \lambda^{-\beta}\left((\lambda I-B)^{-1}-(\lambda I-A)^{-1}\right) d \lambda
$$

$$
\begin{equation*}
=\frac{\sin (\pi \beta)}{\pi} \int_{0}^{\infty} \lambda^{-\beta}(\lambda I-B)^{-1}(A-B)(\lambda I-A)^{-1} d \lambda . \tag{54.3.31}
\end{equation*}
$$

Therefore, letting $x \in D(A)$ and letting $C$ denote a generic constant which can be changed from line to line and using 54.3.29 and 54.3.30,

$$
\begin{aligned}
& \left\|x-(-B)^{\beta}(-A)^{-\beta} x\right\| \\
\leq & C \int_{0}^{\infty} \frac{1}{\lambda^{\beta}}\left\|(-B)^{\beta}(\lambda I-B)^{-1}(A-B)(\lambda I-A)^{-1} x\right\| d \lambda
\end{aligned}
$$

The reason $(-B)^{\beta}$ goes inside the integral is that it is a closed operator. Then the above

$$
\begin{aligned}
& \leq C \int_{0}^{\infty} \frac{1}{\lambda^{\beta}(\lambda+\delta)^{1-\beta}}\left\|(A-B)(-A)^{-\alpha}(-A)^{\alpha}(\lambda I-A)^{-1} x\right\| d \lambda \\
& \leq C \int_{0}^{\infty} \frac{1}{\lambda^{\beta}(\lambda+\delta)^{1-\beta}}\left\|(-A)^{\alpha}(\lambda I-A)^{-1} x\right\| d \lambda \\
& \leq C \int_{0}^{\infty} \frac{1}{\lambda^{\beta}(\lambda+\delta)^{1-\beta}} \frac{1}{(\lambda+\delta)^{1-\alpha}} d \lambda\|x\|=C\|x\| .
\end{aligned}
$$

It follows $(-B)^{\beta}(-A)^{-\beta}$ is bounded on $D(A)$.
Next reverse $A$ and $B$ in 54.3.31. This yields

$$
(-A)^{-\beta}-(-B)^{-\beta}=\frac{\sin (\pi \beta)}{\pi} \int_{0}^{\infty} \lambda^{-\beta}(\lambda I-A)^{-1}(B-A)(\lambda I-B)^{-1} d \lambda
$$

Letting $x \in D(A)$,

$$
\begin{align*}
& \left\|x-(-A)^{\beta}(-B)^{-\beta} x\right\| \\
\leq & C \int_{0}^{\infty} \lambda^{-\beta}\left\|(-A)^{\beta}(\lambda I-A)^{-1}(B-A)(\lambda I-B)^{-1} x\right\| d \lambda \\
\leq & C \int_{0}^{\infty} \frac{1}{\lambda^{\beta}(\lambda+\delta)^{1-\beta}}\left\|(B-A)(-B)^{-\alpha}(-B)^{\alpha}(\lambda I-B)^{-1} x\right\| d \lambda(54.3 .32) \\
\leq & C \int_{0}^{\infty} \frac{1}{\lambda^{\beta}(\lambda+\delta)^{1-\beta}(\lambda+\delta)^{1-\alpha}} d \lambda\|x\|=C\|x\| \tag{54.3.33}
\end{align*}
$$

This shows $(-A)^{\beta}(-B)^{-\beta}$ is bounded on $D(A)=D(B)$. Note the assertion these are bounded refers to the norm on $H$.

It remains to verify $D\left((-A)^{\beta}\right)=D\left((-B)^{\beta}\right)$. Since $D(A)$ is dense in $H$ there exists a unique $L(A, B) \in \mathscr{L}(H, H)$ such that $L(A, B)=(-A)^{\beta}(-B)^{-\beta}$ on $D(A)$. Let $L(B, A)$ be defined similarly as a continuous linear map which equals $(-B)^{\beta}(-A)^{-\beta}$ on $D(A)$. Then

$$
\begin{aligned}
& (-A)^{-\beta} L(A, B)=(-B)^{-\beta} \\
& (-B)^{-\beta} L(B, A)=(-A)^{-\beta}
\end{aligned}
$$

The first of these equations shows $D\left((-B)^{\beta}\right) \subseteq D\left((-A)^{\beta}\right)$ and the second turns the inclusion around. Thus they are equal as claimed.

Next consider the case where $\beta=1$. In this case

$$
(A-B) B^{-\alpha}
$$

is bounded on $D(A)$ and so

$$
(A-B) B^{-\alpha} B^{-1+\alpha}
$$

is also bounded on $D(A)$. But this equals

$$
(A-B) B^{-1}
$$

Thus $A B^{-1}$ is bounded on $D(A)$. Similarly you can show

$$
(B-A) A^{-1}
$$

is bounded which implies $B A^{-1}$ is bounded on $D(A)$. This proves the theorem.
Definition 54.3.26 Let $A$ be sectorial for the sector $S_{a, \phi}$. Let $b>a$ so that $A-b I$ is sectorial for $S_{-\delta, \phi}$ where $\delta=b-a$. Then for each $\alpha \in[0,1]$, define a norm on $D\left((b I-A)^{\alpha}\right) \equiv$ $H_{\alpha}$ by

$$
\|x\|_{\alpha} \equiv\left\|(b I-A)^{\alpha} x\right\|
$$

The $\left\{H_{\alpha}\right\}_{\alpha \in[0,1]}$ is called a scale of Banach spaces.
Proposition 54.3.27 The $H_{\alpha}$ above are Banach spaces and they decrease in $\alpha$. Furthermore, if $b_{i}>$ a for $i=1,2$ then the two norms associated with the $b_{i}$ are equivalent.

Proof: That the $H_{\alpha}$ are decreasing was shown above in Theorem 54.3.17. They are Banach spaces because $(b I-A)^{\alpha}$ is a closed mapping which is also one to one.

It only remains to verify the claim about the equivalence of the norms. Let $b_{2}>b_{1}>a$. Then if $\alpha \in(0,1)$,

$$
\begin{aligned}
& \left(\left(b_{1} I-A\right)-\left(b_{2} I-A\right)\right)\left(b_{2} I-A\right)^{-\alpha} \\
= & \left(b_{1}-b_{2}\right)\left(b_{2} I-A\right)^{-\alpha} \in \mathscr{L}(H, H)
\end{aligned}
$$

and so by Theorem 54.3.25, for each $\beta \in[0,1]$,

$$
D\left(\left(b_{1} I-A\right)^{\beta}\right)=D\left(\left(b_{2} I-A\right)^{\beta}\right)
$$

so the spaces, $H_{\beta}$ are the same for either choice of $b>a$. Also from this theorem,

$$
\left(b_{1} I-A\right)^{\beta}\left(b_{2} I-A\right)^{-\beta},\left(b_{2} I-A\right)^{\beta}\left(b_{1} I-A\right)^{-\beta}
$$

are both bounded on $D(A)$. Therefore, for $x \in H_{\beta}$

$$
\begin{aligned}
\left\|\left(b_{1} I-A\right)^{\beta} x\right\| & =\left\|\left(b_{1} I-A\right)^{\beta}\left(b_{2} I-A\right)^{-\beta}\left(b_{2} I-A\right)^{\beta} x\right\| \\
& \leq C\left\|\left(b_{2} I-A\right)^{\beta} x\right\|
\end{aligned}
$$

Similarly using the boundedness of $\left(b_{2} I-A\right)^{\beta}\left(b_{1} I-A\right)^{-\beta}$, it follows

$$
\left\|\left(b_{2} I-A\right)^{\beta} x\right\| \leq C^{\prime}\left\|\left(b_{1} I-A\right)^{\beta} x\right\|
$$

Thus showing the two norms are equivalent. This proves the proposition.

## Chapter 55

## Complex Mappings

### 55.1 Conformal Maps

If $\gamma(t)=x(t)+i y(t)$ is a $C^{1}$ curve having values in $U$, an open set of $\mathbb{C}$, and if $f: U \rightarrow \mathbb{C}$ is analytic, consider $f \circ \gamma$, another $C^{1}$ curve having values in $\mathbb{C}$. Also, $\gamma^{\prime}(t)$ and $(f \circ \gamma)^{\prime}(t)$ are complex numbers so these can be considered as vectors in $\mathbb{R}^{2}$ as follows. The complex number, $x+i y$ corresponds to the vector, $(x, y)$. Suppose that $\gamma$ and $\eta$ are two such $C^{1}$ curves having values in $U$ and that $\gamma\left(t_{0}\right)=\eta\left(s_{0}\right)=z$ and suppose that $f: U \rightarrow \mathbb{C}$ is analytic. What can be said about the angle between $(f \circ \gamma)^{\prime}\left(t_{0}\right)$ and $(f \circ \eta)^{\prime}\left(s_{0}\right)$ ? It turns out this angle is the same as the angle between $\gamma^{\prime}\left(t_{0}\right)$ and $\eta^{\prime}\left(s_{0}\right)$ assuming that $f^{\prime}(z) \neq 0$. To see this, note $(x, y) \cdot(a, b)=\frac{1}{2}(z \bar{w}+\bar{z} w)$ where $z=x+i y$ and $w=a+i b$. Therefore, letting $\theta$ be the cosine between the two vectors, $(f \circ \gamma)^{\prime}\left(t_{0}\right)$ and $(f \circ \eta)^{\prime}\left(s_{0}\right)$, it follows from calculus that

$$
\begin{aligned}
& \cos \theta \\
= & \frac{(f \circ \gamma)^{\prime}\left(t_{0}\right) \cdot(f \circ \eta)^{\prime}\left(s_{0}\right)}{\left|(f \circ \eta)^{\prime}\left(s_{0}\right)\right|\left|(f \circ \gamma)^{\prime}\left(t_{0}\right)\right|} \\
= & \frac{1}{2} \frac{f^{\prime}\left(\gamma\left(t_{0}\right)\right) \gamma^{\prime}\left(t_{0}\right) \overline{f^{\prime}\left(\eta\left(s_{0}\right)\right) \eta^{\prime}\left(s_{0}\right)}+\overline{f^{\prime}\left(\gamma\left(t_{0}\right)\right) \gamma^{\prime}\left(t_{0}\right)} f^{\prime}\left(\eta\left(s_{0}\right)\right) \eta^{\prime}\left(s_{0}\right)}{\left|f^{\prime}\left(\gamma\left(t_{0}\right)\right)\right|\left|f^{\prime}\left(\eta\left(s_{0}\right)\right)\right|} \\
= & \frac{1}{2} \frac{f^{\prime}(z) \overline{f^{\prime}(z)} \gamma^{\prime}\left(t_{0}\right) \overline{\eta^{\prime}\left(s_{0}\right)}+\overline{f^{\prime}(z)} f^{\prime}(z) \overline{\gamma^{\prime}\left(t_{0}\right)} \eta^{\prime}\left(s_{0}\right)}{\left|f^{\prime}(z)\right|\left|f^{\prime}(z)\right|} \\
= & \frac{1}{2} \frac{\gamma^{\prime}\left(t_{0}\right) \overline{\eta^{\prime}\left(s_{0}\right)}+\eta^{\prime}\left(s_{0}\right) \overline{\gamma^{\prime}\left(t_{0}\right)}}{1}
\end{aligned}
$$

which equals the angle between the vectors, $\gamma^{\prime}\left(t_{0}\right)$ and $\eta^{\prime}\left(t_{0}\right)$. Thus analytic mappings preserve angles at points where the derivative is nonzero. Such mappings are called isogonal.

Actually, they also preserve orientations. If $z=x+i y$ and $w=a+i b$ are two complex numbers, then $(x, y, 0)$ and $(a, b, 0)$ are two vectors in $\mathbb{R}^{3}$. Recall that the cross product, $(x, y, 0) \times(a, b, 0)$, yields a vector normal to the two given vectors such that the triple, $(x, y, 0),(a, b, 0)$, and $(x, y, 0) \times(a, b, 0)$ satisfies the right hand rule and has magnitude equal to the product of the sine of the included angle times the product of the two norms of the vectors. In this case, the cross product will produce a vector which is a multiple of $\mathbf{k}$, the unit vector in the direction of the $z$ axis. In fact, you can verify by computing both sides that, letting $z=x+i y$ and $w=a+i b$,

$$
(x, y, 0) \times(a, b, 0)=\operatorname{Re}(z i \bar{w}) \mathbf{k} .
$$

Therefore, in the above situation,

$$
\begin{aligned}
& (f \circ \gamma)^{\prime}\left(t_{0}\right) \times(f \circ \eta)^{\prime}\left(s_{0}\right) \\
= & \operatorname{Re}\left(f^{\prime}\left(\gamma\left(t_{0}\right)\right) \gamma\left(t_{0}\right) \overline{i f^{\prime}\left(\eta\left(s_{0}\right)\right) \eta^{\prime}\left(s_{0}\right)}\right) \mathbf{k} \\
= & \left|f^{\prime}(z)\right|^{2} \operatorname{Re}\left(\gamma^{\prime}\left(t_{0}\right) \overline{i \eta^{\prime}\left(s_{0}\right)}\right) \mathbf{k}
\end{aligned}
$$

which shows that the orientation of $\gamma^{\prime}\left(t_{0}\right), \eta^{\prime}\left(s_{0}\right)$ is the same as the orientation of

$$
(f \circ \gamma)^{\prime}\left(t_{0}\right),(f \circ \eta)^{\prime}\left(s_{0}\right)
$$

Mappings which preserve both orientation and angles are called conformal mappings and this has shown that analytic functions are conformal mappings if the derivative does not vanish.

### 55.2 Fractional Linear Transformations

### 55.2.1 Circles And Lines

These mappings map lines and circles to either lines or circles.
Definition 55.2.1 A fractional linear transformation is a function of the form

$$
\begin{equation*}
f(z)=\frac{a z+b}{c z+d} \tag{55.2.1}
\end{equation*}
$$

where $a d-b c \neq 0$.
Note that if $c=0$, this reduces to a linear transformation $(a / d) z+(b / d)$. Special cases of these are defined as follows.

$$
\begin{gathered}
\text { dilations: } z \rightarrow \delta z, \delta \neq 0, \text { inversions: } z \rightarrow \frac{1}{z} \\
\text { translations: } z \rightarrow z+\rho
\end{gathered}
$$

The next lemma is the key to understanding fractional linear transformations.
Lemma 55.2.2 The fractional linear transformation, 55.2.1 can be written as a finite composition of dilations, inversions, and translations.

Proof: Let

$$
S_{1}(z)=z+\frac{d}{c}, S_{2}(z)=\frac{1}{z}, S_{3}(z)=\frac{(b c-a d)}{c^{2}} z
$$

and

$$
S_{4}(z)=z+\frac{a}{c}
$$

in the case where $c \neq 0$. Then $f(z)$ given in 55.2.1 is of the form

$$
f(z)=S_{4} \circ S_{3} \circ S_{2} \circ S_{1}
$$

Here is why.

$$
S_{2}\left(S_{1}(z)\right)=S_{2}\left(z+\frac{d}{c}\right) \equiv \frac{1}{z+\frac{d}{c}}=\frac{c}{z c+d}
$$

Now consider

$$
S_{3}\left(\frac{c}{z c+d}\right) \equiv \frac{(b c-a d)}{c^{2}}\left(\frac{c}{z c+d}\right)=\frac{b c-a d}{c(z c+d)}
$$

Finally, consider

$$
S_{4}\left(\frac{b c-a d}{c(z c+d)}\right) \equiv \frac{b c-a d}{c(z c+d)}+\frac{a}{c}=\frac{b+a z}{z c+d}
$$

In case that $c=0, f(z)=\frac{a}{d} z+\frac{b}{d}$ which is a translation composed with a dilation. Because of the assumption that $a d-b c \neq 0$, it follows that since $c=0$, both $a$ and $d \neq 0$. This proves the lemma.

This lemma implies the following corollary.
Corollary 55.2.3 Fractional linear transformations map circles and lines to circles or lines.

Proof: It is obvious that dilations and translations map circles to circles and lines to lines. What of inversions? If inversions have this property, the above lemma implies a general fractional linear transformation has this property as well.

Note that all circles and lines may be put in the form

$$
\alpha\left(x^{2}+y^{2}\right)-2 a x-2 b y=r^{2}-\left(a^{2}+b^{2}\right)
$$

where $\alpha=1$ gives a circle centered at $(a, b)$ with radius $r$ and $\alpha=0$ gives a line. In terms of complex variables you may therefore consider all possible circles and lines in the form

$$
\begin{equation*}
\alpha z \bar{z}+\beta z+\bar{\beta} \bar{z}+\gamma=0 \tag{55.2.2}
\end{equation*}
$$

To see this let $\beta=\beta_{1}+i \beta_{2}$ where $\beta_{1} \equiv-a$ and $\beta_{2} \equiv b$. Note that even if $\alpha$ is not 0 or 1 the expression still corresponds to either a circle or a line because you can divide by $\alpha$ if $\alpha \neq 0$. Now I verify that replacing $z$ with $\frac{1}{z}$ results in an expression of the form in 55.2.2. Thus, let $w=\frac{1}{z}$ where $z$ satisfies 55.2.2. Then

$$
(\alpha+\beta \bar{w}+\bar{\beta} w+\gamma w \bar{w})=\frac{1}{z \bar{z}}(\alpha z \bar{z}+\beta z+\bar{\beta} \bar{z}+\gamma)=0
$$

and so $w$ also satisfies a relation like 55.2.2. One simply switches $\alpha$ with $\gamma$ and $\beta$ with $\bar{\beta}$. Note the situation is slightly different than with dilations and translations. In the case of an inversion, a circle becomes either a line or a circle and similarly, a line becomes either a circle or a line. This proves the corollary.

The next example is quite important.
Example 55.2.4 Consider the fractional linear transformation, $w=\frac{z-i}{z+i}$.
First consider what this mapping does to the points of the form $z=x+i 0$. Substituting into the expression for $w$,

$$
w=\frac{x-i}{x+i}=\frac{x^{2}-1-2 x i}{x^{2}+1}
$$

a point on the unit circle. Thus this transformation maps the real axis to the unit circle.
The upper half plane is composed of points of the form $x+i y$ where $y>0$. Substituting in to the transformation,

$$
w=\frac{x+i(y-1)}{x+i(y+1)}
$$

which is seen to be a point on the interior of the unit disk because $|y-1|<|y+1|$ which implies $|x+i(y+1)|>|x+i(y-1)|$. Therefore, this transformation maps the upper half plane to the interior of the unit disk.

One might wonder whether the mapping is one to one and onto. The mapping is clearly one to one because it has an inverse, $z=-i \frac{w+1}{w-1}$ for all $w$ in the interior of the unit disk. Also, a short computation verifies that $z$ so defined is in the upper half plane. Therefore, this transformation maps $\{z \in \mathbb{C}$ such that $\operatorname{Im} z>0\}$ one to one and onto the unit disk $\{z \in \mathbb{C}$ such that $|z|<1\}$.

A fancy way to do part of this is to use Theorem 52.3.5. $\lim \sup _{z \rightarrow a}\left|\frac{z-i}{z+i}\right| \leq 1$ whenever $a$ is the real axis or $\infty$. Therefore, $\left|\frac{z-i}{z+i}\right| \leq 1$. This is a little shorter.

### 55.2.2 Three Points To Three Points

There is a simple procedure for determining fractional linear transformations which map a given set of three points to another set of three points. The problem is as follows: There are three distinct points in the extended complex plane, $z_{1}, z_{2}$, and $z_{3}$ and it is desired to find a fractional linear transformation such that $z_{i} \rightarrow w_{i}$ for $i=1,2,3$ where here $w_{1}, w_{2}$, and $w_{3}$ are three distinct points in the extended complex plane. Then the procedure says that to find the desired fractional linear transformation solve the following equation for $w$.

$$
\frac{w-w_{1}}{w-w_{3}} \cdot \frac{w_{2}-w_{3}}{w_{2}-w_{1}}=\frac{z-z_{1}}{z-z_{3}} \cdot \frac{z_{2}-z_{3}}{z_{2}-z_{1}}
$$

The result will be a fractional linear transformation with the desired properties. If any of the points equals $\infty$, then the quotient containing this point should be adjusted.

Why should this procedure work? Here is a heuristic argument to indicate why you would expect this to happen rather than a rigorous proof. The reader may want to tighten the argument to give a proof. First suppose $z=z_{1}$. Then the right side equals zero and so the left side also must equal zero. However, this requires $w=w_{1}$. Next suppose $z=z_{2}$. Then the right side equals 1 . To get a 1 on the left, you need $w=w_{2}$. Finally suppose $z=z_{3}$. Then the right side involves division by 0 . To get the same bad behavior, on the left, you need $w=w_{3}$.

Example 55.2.5 Let $\operatorname{Im} \xi>0$ and consider the fractional linear transformation which takes $\xi$ to $0, \bar{\xi}$ to $\infty$ and 0 to $\xi / \bar{\xi}$, .

The equation for $w$ is

$$
\frac{w-0}{w-(\xi / \bar{\xi})}=\frac{z-\xi}{z-0} \cdot \frac{\bar{\xi}-0}{\bar{\xi}-\xi}
$$

After some computations,

$$
w=\frac{z-\xi}{z-\bar{\xi}}
$$

Note that this has the property that $\frac{x-\xi}{x-\bar{\xi}}$ is always a point on the unit circle because it is a complex number divided by its conjugate. Therefore, this fractional linear transformation
maps the real line to the unit circle. It also takes the point, $\xi$ to 0 and so it must map the upper half plane to the unit disk. You can verify the mapping is onto as well.

Example 55.2.6 Let $z_{1}=0, z_{2}=1$, and $z_{3}=2$ and let $w_{1}=0, w_{2}=i$, and $w_{3}=2 i$.

Then the equation to solve is

$$
\frac{w}{w-2 i} \cdot \frac{-i}{i}=\frac{z}{z-2} \cdot \frac{-1}{1}
$$

Solving this yields $w=i z$ which clearly works.

### 55.3 Riemann Mapping Theorem

From the open mapping theorem analytic functions map regions to other regions or else to single points. The Riemann mapping theorem states that for every simply connected region, $\Omega$ which is not equal to all of $\mathbb{C}$ there exists an analytic function, $f$ such that $f(\Omega)=B(0,1)$ and in addition to this, $f$ is one to one. The proof involves several ideas which have been developed up to now. The proof is based on the following important theorem, a case of Montel's theorem. Before, beginning, note that the Riemann mapping theorem is a classic example of a major existence theorem. In mathematics there are two sorts of questions, those related to whether something exists and those involving methods for finding it. The real questions are often related to questions of existence. There is a long and involved history for proofs of this theorem. The first proofs were based on the Dirichlet principle and turned out to be incorrect, thanks to Weierstrass who pointed out the errors. For more on the history of this theorem, see Hille [65].

The following theorem is really wonderful. It is about the existence of a subsequence having certain salubrious properties. It is this wonderful result which will give the existence of the mapping desired. The other parts of the argument are technical details to set things up and use this theorem.

### 55.3.1 Montel's Theorem

Theorem 55.3.1 Let $\Omega$ be an open set in $\mathbb{C}$ and let $\mathscr{F}$ denote a set of analytic functions mapping $\Omega$ to $B(0, M) \subseteq \mathbb{C}$. Then there exists a sequence of functions from $\mathscr{F},\left\{f_{n}\right\}_{n=1}^{\infty}$ and an analytic function, $f$ such that $f_{n}^{(k)}$ converges uniformly to $f^{(k)}$ on every compact subset of $\Omega$.

Proof: First note there exists a sequence of compact sets, $K_{n}$ such that $K_{n} \subseteq \operatorname{int} K_{n+1} \subseteq$ $\Omega$ for all $n$ where here int $K$ denotes the interior of the set $K$, the union of all open sets contained in $K$ and $\cup_{n=1}^{\infty} K_{n}=\Omega$. In fact, you can verify that $\overline{B(0, n)} \cap\left\{z \in \Omega: \operatorname{dist}\left(z, \Omega^{C}\right) \leq \frac{1}{n}\right\}$ works for $K_{n}$. Then there exist positive numbers, $\delta_{n}$ such that if $z \in K_{n}$, then $\overline{B\left(z, \delta_{n}\right)} \subseteq$ int $K_{n+1}$. Now denote by $\mathscr{F}_{n}$ the set of restrictions of functions of $\mathscr{F}$ to $K_{n}$. Then let $z \in K_{n}$
and let $\gamma(t) \equiv z+\delta_{n} e^{i t}, t \in[0,2 \pi]$. It follows that for $z_{1} \in B\left(z, \delta_{n}\right)$, and $f \in \mathscr{F}$,

$$
\begin{aligned}
\left|f(z)-f\left(z_{1}\right)\right| & =\left|\frac{1}{2 \pi i} \int_{\gamma} f(w)\left(\frac{1}{w-z}-\frac{1}{w-z_{1}}\right) d w\right| \\
& \leq \frac{1}{2 \pi}\left|\int_{\gamma} f(w) \frac{z-z_{1}}{(w-z)\left(w-z_{1}\right)} d w\right|
\end{aligned}
$$

Letting $\left|z_{1}-z\right|<\frac{\delta_{n}}{2}$,

$$
\begin{aligned}
\left|f(z)-f\left(z_{1}\right)\right| & \leq \frac{M}{2 \pi} 2 \pi \delta_{n} \frac{\left|z-z_{1}\right|}{\delta_{n}^{2} / 2} \\
& \leq 2 M \frac{\left|z-z_{1}\right|}{\delta_{n}}
\end{aligned}
$$

It follows that $\mathscr{F}_{n}$ is equicontinuous and uniformly bounded so by the Arzela Ascoli theorem there exists a sequence, $\left\{f_{n k}\right\}_{k=1}^{\infty} \subseteq \mathscr{F}$ which converges uniformly on $K_{n}$. Let $\left\{f_{1 k}\right\}_{k=1}^{\infty}$ converge uniformly on $K_{1}$. Then use the Arzela Ascoli theorem applied to this sequence to get a subsequence, denoted by $\left\{f_{2 k}\right\}_{k=1}^{\infty}$ which also converges uniformly on $K_{2}$. Continue in this way to obtain $\left\{f_{n k}\right\}_{k=1}^{\infty}$ which converges uniformly on $K_{1}, \cdots, K_{n}$. Now the sequence $\left\{f_{n n}\right\}_{n=m}^{\infty}$ is a subsequence of $\left\{f_{m k}\right\}_{k=1}^{\infty}$ and so it converges uniformly on $K_{m}$ for all $m$. Denoting $f_{n n}$ by $f_{n}$ for short, this is the sequence of functions promised by the theorem. It is clear $\left\{f_{n}\right\}_{n=1}^{\infty}$ converges uniformly on every compact subset of $\Omega$ because every such set is contained in $K_{m}$ for all $m$ large enough. Let $f(z)$ be the point to which $f_{n}(z)$ converges. Then $f$ is a continuous function defined on $\Omega$. Is $f$ is analytic? Yes it is by Lemma 51.3.13. Alternatively, you could let $T \subseteq \Omega$ be a triangle. Then

$$
\int_{\partial T} f(z) d z=\lim _{n \rightarrow \infty} \int_{\partial T} f_{n}(z) d z=0
$$

Therefore, by Morera's theorem, $f$ is analytic.
As for the uniform convergence of the derivatives of $f$, recall Theorem 51.7.25 about the existence of a cycle. Let $K$ be a compact subset of int $\left(K_{n}\right)$ and let $\left\{\gamma_{k}\right\}_{k=1}^{m}$ be closed oriented curves contained in

$$
\operatorname{int}\left(K_{n}\right) \backslash K
$$

such that $\sum_{k=1}^{m} n\left(\gamma_{k}, z\right)=1$ for every $z \in K$. Also let $\eta$ denote the distance between $\cup_{j} \gamma_{j}^{*}$ and $K$. Then for $z \in K$,

$$
\begin{aligned}
\left|f^{(k)}(z)-f_{n}^{(k)}(z)\right| & =\left|\frac{k!}{2 \pi i} \sum_{j=1}^{m} \int_{\gamma_{j}} \frac{f(w)-f_{n}(w)}{(w-z)^{k+1}} d w\right| \\
& \leq \frac{k!}{2 \pi}\left\|f_{k}-f\right\|_{K_{n}} \sum_{j=1}^{m}\left(\text { length of } \gamma_{k}\right) \frac{1}{\eta^{k+1}}
\end{aligned}
$$

where here $\left|\mid f_{k}-f \|_{K_{n}} \equiv \sup \left\{\left|f_{k}(z)-f(z)\right|: z \in K_{n}\right\}\right.$. Thus you get uniform convergence of the derivatives.

Since the family, $\mathscr{F}$ satisfies the conclusion of Theorem 55.3.1 it is known as a normal family of functions. More generally,

Definition 55.3.2 Let $\mathscr{F}$ denote a collection offunctions which are analytic on $\Omega$, a region. Then $\mathscr{F}$ is normal if every sequence contained in $\mathscr{F}$ has a subsequence which converges uniformly on compact subsets of $\Omega$.

The following result is about a certain class of fractional linear transformations. Recall Lemma 52.4.7 which is listed here for convenience.

Lemma 55.3.3 For $\alpha \in B(0,1)$, let

$$
\phi_{\alpha}(z) \equiv \frac{z-\alpha}{1-\bar{\alpha} z}
$$

Then $\phi_{\alpha}$ maps $B(0,1)$ one to one and onto $B(0,1), \phi_{\alpha}^{-1}=\phi_{-\alpha}$, and

$$
\phi_{\alpha}^{\prime}(\alpha)=\frac{1}{1-|\alpha|^{2}}
$$

The next lemma, known as Schwarz's lemma is interesting for its own sake but will also be an important part of the proof of the Riemann mapping theorem. It was stated and proved earlier but for convenience it is given again here.

Lemma 55.3.4 Suppose $F: B(0,1) \rightarrow B(0,1), F$ is analytic, and $F(0)=0$. Then for all $z \in B(0,1)$,

$$
\begin{equation*}
|F(z)| \leq|z| \tag{55.3.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|F^{\prime}(0)\right| \leq 1 \tag{55.3.4}
\end{equation*}
$$

If equality holds in 55.3 .4 then there exists $\lambda \in \mathbb{C}$ with $|\lambda|=1$ and

$$
\begin{equation*}
F(z)=\lambda z \tag{55.3.5}
\end{equation*}
$$

Proof: First note that by assumption, $F(z) / z$ has a removable singularity at 0 if its value at 0 is defined to be $F^{\prime}(0)$. By the maximum modulus theorem, if $|z|<r<1$,

$$
\left|\frac{F(z)}{z}\right| \leq \max _{t \in[0,2 \pi]} \frac{\left|F\left(r e^{i t}\right)\right|}{r} \leq \frac{1}{r}
$$

Then letting $r \rightarrow 1$,

$$
\left|\frac{F(z)}{z}\right| \leq 1
$$

this shows 55.3 .3 and it also verifies 55.3 .4 on taking the limit as $z \rightarrow 0$. If equality holds in 55.3.4, then $|F(z) / z|$ achieves a maximum at an interior point so $F(z) / z$ equals a constant, $\lambda$ by the maximum modulus theorem. Since $F(z)=\lambda z$, it follows $F^{\prime}(0)=\lambda$ and so $|\lambda|=1$. This proves the lemma.

Definition 55.3.5 A region, $\Omega$ has the square root property if whenever $f, \frac{1}{f}: \Omega \rightarrow \mathbb{C}$ are both analytic ${ }^{1}$, it follows there exists $\phi: \Omega \rightarrow \mathbb{C}$ such that $\phi$ is analytic and $f(z)=\phi^{2}(z)$.

The next theorem will turn out to be equivalent to the Riemann mapping theorem.

[^33]
### 55.3.2 Regions With Square Root Property

Theorem 55.3.6 Let $\Omega \neq \mathbb{C}$ for $\Omega$ a region and suppose $\Omega$ has the square root property. Then for $z_{0} \in \Omega$ there exists $h: \Omega \rightarrow B(0,1)$ such that $h$ is one to one, onto, analytic, and $h\left(z_{0}\right)=0$.

Proof: Define $\mathscr{F}$ to be the set of functions, $f$ such that $f: \Omega \rightarrow B(0,1)$ is one to one and analytic. The first task is to show $\mathscr{F}$ is nonempty. Then, using Montel's theorem it will be shown there is a function in $\mathscr{F}, h$, such that $\left|h^{\prime}\left(z_{0}\right)\right| \geq\left|\psi^{\prime}\left(z_{0}\right)\right|$ for all $\psi \in \mathscr{F}$. When this has been done it will be shown that $h$ is actually onto. This will prove the theorem.

Claim 1: $\mathscr{F}$ is nonempty.
Proof of Claim 1: Since $\Omega \neq \mathbb{C}$ it follows there exists $\xi \notin \Omega$. Then it follows $z-\xi$ and $\frac{1}{z-\xi}$ are both analytic on $\Omega$. Since $\Omega$ has the square root property, there exists an analytic function, $\phi: \Omega \rightarrow \mathbb{C}$ such that $\phi^{2}(z)=z-\xi$ for all $z \in \Omega, \phi(z)=\sqrt{z-\xi}$. Since $z-\xi$ is not constant, neither is $\phi$ and it follows from the open mapping theorem that $\phi(\Omega)$ is a region. Note also that $\phi$ is one to one because if $\phi\left(z_{1}\right)=\phi\left(z_{2}\right)$, then you can square both sides and conclude $z_{1}-\xi=z_{2}-\xi$ implying $z_{1}=z_{2}$.

Now pick $a \in \phi(\Omega)$. Thus $\sqrt{z_{a}-\xi}=a$. I claim there exists a positive lower bound to $|\sqrt{z-\xi}+a|$ for $z \in \Omega$. If not, there exists a sequence, $\left\{z_{n}\right\} \subseteq \Omega$ such that

$$
\sqrt{z_{n}-\xi}+a=\sqrt{z_{n}-\xi}+\sqrt{z_{a}-\xi} \equiv \varepsilon_{n} \rightarrow 0
$$

Then

$$
\begin{equation*}
\sqrt{z_{n}-\xi}=\left(\varepsilon_{n}-\sqrt{z_{a}-\xi}\right) \tag{55.3.6}
\end{equation*}
$$

and squaring both sides,

$$
z_{n}-\xi=\varepsilon_{n}^{2}+z_{a}-\xi-2 \varepsilon_{n} \sqrt{z_{a}-\xi}
$$

Consequently, $\left(z_{n}-z_{a}\right)=\varepsilon_{n}^{2}-2 \varepsilon_{n} \sqrt{z_{a}-\xi}$ which converges to 0 . Taking the limit in 55.3.6, it follows $2 \sqrt{z_{a}-\xi}=0$ and so $\xi=z_{a}$, a contradiction to $\xi \notin \Omega$. Choose $r>0$ such that for all $z \in \Omega,|\sqrt{z-\xi}+a|>r>0$. Then consider

$$
\begin{equation*}
\psi(z) \equiv \frac{r}{\sqrt{z-\xi}+a} . \tag{55.3.7}
\end{equation*}
$$

This is one to one, analytic, and maps $\Omega$ into $B(0,1)(|\sqrt{z-\xi}+a|>r)$. Thus $\mathscr{F}$ is not empty and this proves the claim.

Claim 2: Let $z_{0} \in \Omega$. There exists a finite positive real number, $\eta$, defined by

$$
\begin{equation*}
\eta \equiv \sup \left\{\left|\psi^{\prime}\left(z_{0}\right)\right|: \psi \in \mathscr{F}\right\} \tag{55.3.8}
\end{equation*}
$$

and an analytic function, $h \in \mathscr{F}$ such that $\left|h^{\prime}\left(z_{0}\right)\right|=\eta$. Furthermore, $h\left(z_{0}\right)=0$.
Proof of Claim 2: First you show $\eta<\infty$. Let $\gamma(t)=z_{0}+r e^{i t}$ for $t \in[0,2 \pi]$ and $r$ is small enough that $B\left(z_{0}, r\right) \subseteq \Omega$. Then for $\psi \in \mathscr{F}$, the Cauchy integral formula for the derivative implies

$$
\psi^{\prime}\left(z_{0}\right)=\frac{1}{2 \pi i} \int_{\gamma} \frac{\psi(w)}{\left(w-z_{0}\right)^{2}} d w
$$

and so $\left|\psi^{\prime}\left(z_{0}\right)\right| \leq(1 / 2 \pi) 2 \pi r\left(1 / r^{2}\right)=1 / r$. Therefore, $\eta<\infty$ as desired. For $\psi$ defined above in 55.3.7

$$
\psi^{\prime}\left(z_{0}\right)=\frac{-r \phi^{\prime}\left(z_{0}\right)}{\left(\phi\left(z_{0}\right)+a\right)^{2}}=\frac{-r(1 / 2)\left(\sqrt{z_{0}-\xi}\right)^{-1}}{\left(\phi\left(z_{0}\right)+a\right)^{2}} \neq 0
$$

Therefore, $\eta>0$. It remains to verify the existence of the function, $h$.
By Theorem 55.3.1, there exists a sequence, $\left\{\psi_{n}\right\}$, of functions in $\mathscr{F}$ and an analytic function, $h$, such that

$$
\begin{equation*}
\left|\psi_{n}^{\prime}\left(z_{0}\right)\right| \rightarrow \eta \tag{55.3.9}
\end{equation*}
$$

and

$$
\begin{equation*}
\psi_{n} \rightarrow h, \psi_{n}^{\prime} \rightarrow h^{\prime} \tag{55.3.10}
\end{equation*}
$$

uniformly on all compact subsets of $\Omega$. It follows

$$
\begin{equation*}
\left|h^{\prime}\left(z_{0}\right)\right|=\lim _{n \rightarrow \infty}\left|\psi_{n}^{\prime}\left(z_{0}\right)\right|=\eta \tag{55.3.11}
\end{equation*}
$$

and for all $z \in \Omega$,

$$
\begin{equation*}
|h(z)|=\lim _{n \rightarrow \infty}\left|\psi_{n}(z)\right| \leq 1 \tag{55.3.12}
\end{equation*}
$$

By 55.3.11, $h$ is not a constant. Therefore, in fact, $|h(z)|<1$ for all $z \in \Omega$ in 55.3 .12 by the open mapping theorem.

Next it must be shown that $h$ is one to one in order to conclude $h \in \mathscr{F}$. Pick $z_{1} \in \Omega$ and suppose $z_{2}$ is another point of $\Omega$. Since the zeros of $h-h\left(z_{1}\right)$ have no limit point, there exists a circular contour bounding a circle which contains $z_{2}$ but not $z_{1}$ such that $\gamma^{*}$ contains no zeros of $h-h\left(z_{1}\right)$.

Using the theorem on counting zeros, Theorem 52.6.1, and the fact that $\psi_{n}$ is one to one,

$$
\begin{aligned}
0 & =\lim _{n \rightarrow \infty} \frac{1}{2 \pi i} \int_{\gamma} \frac{\psi_{n}^{\prime}(w)}{\psi_{n}(w)-\psi_{n}\left(z_{1}\right)} d w \\
& =\frac{1}{2 \pi i} \int_{\gamma} \frac{h^{\prime}(w)}{h(w)-h\left(z_{1}\right)} d w
\end{aligned}
$$

which shows that $h-h\left(z_{1}\right)$ has no zeros in $B\left(z_{2}, r\right)$. In particular $z_{2}$ is not a zero of $h-$ $h\left(z_{1}\right)$. This shows that $h$ is one to one since $z_{2} \neq z_{1}$ was arbitrary. Therefore, $h \in \mathscr{F}$. It only remains to verify that $h\left(z_{0}\right)=0$.

If $h\left(z_{0}\right) \neq 0$,consider $\phi_{h\left(z_{0}\right)} \circ h$ where $\phi_{\alpha}$ is the fractional linear transformation defined in Lemma 55.3.3. By this lemma it follows $\phi_{h\left(z_{0}\right)} \circ h \in \mathscr{F}$. Now using the chain rule,

$$
\begin{aligned}
\left|\left(\phi_{h\left(z_{0}\right)} \circ h\right)^{\prime}\left(z_{0}\right)\right| & =\left|\phi_{h\left(z_{0}\right)}^{\prime}\left(h\left(z_{0}\right)\right)\right|\left|h^{\prime}\left(z_{0}\right)\right| \\
& =\left|\frac{1}{1-\left|h\left(z_{0}\right)\right|^{2}}\right|\left|h^{\prime}\left(z_{0}\right)\right| \\
& =\left|\frac{1}{1-\left|h\left(z_{0}\right)\right|^{2}}\right| \eta>\eta
\end{aligned}
$$

Contradicting the definition of $\eta$. This proves Claim 2.
Claim 3: The function, $h$ just obtained maps $\Omega$ onto $B(0,1)$.
Proof of Claim 3: To show $h$ is onto, use the fractional linear transformation of Lemma 55.3.3. Suppose $h$ is not onto. Then there exists $\alpha \in B(0,1) \backslash h(\Omega)$. Then $0 \neq \phi_{\alpha} \circ h(z)$ for all $z \in \Omega$ because

$$
\phi_{\alpha} \circ h(z)=\frac{h(z)-\alpha}{1-\bar{\alpha} h(z)}
$$

and it is assumed $\alpha \notin h(\Omega)$. Therefore, since $\Omega$ has the square root property, you can consider an analytic function $z \rightarrow \sqrt{\phi_{\alpha} \circ h(z)}$. This function is one to one because both $\phi_{\alpha}$ and $h$ are. Also, the values of this function are in $B(0,1)$ by Lemma 55.3.3 so it is in $\mathscr{F}$.

Now let

$$
\begin{equation*}
\psi \equiv \phi_{\sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)}} \circ \sqrt{\phi_{\alpha} \circ h} \tag{55.3.13}
\end{equation*}
$$

Thus

$$
\psi\left(z_{0}\right)=\phi \sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)} \circ \sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)}=0
$$

and $\psi$ is a one to one mapping of $\Omega$ into $B(0,1)$ so $\psi$ is also in $\mathscr{F}$. Therefore,

$$
\begin{equation*}
\left|\psi^{\prime}\left(z_{0}\right)\right| \leq \eta,\left|\left(\sqrt{\phi_{\alpha} \circ h}\right)^{\prime}\left(z_{0}\right)\right| \leq \eta \tag{55.3.14}
\end{equation*}
$$

Define $s(w) \equiv w^{2}$. Then using Lemma 55.3.3, in particular, the description of $\phi_{\alpha}^{-1}=\phi_{-\alpha}$, you can solve 55.3.13 for $h$ to obtain

$$
\begin{align*}
h(z) & =\phi_{-\alpha} \circ S \circ \phi_{-\sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)}} \circ \psi \\
& =(\overbrace{\left.\phi_{-\alpha} \circ S \circ \phi_{-\sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)}} \circ \psi\right)(z)}=F \\
& =(F \circ \psi)(z) \tag{55.3.15}
\end{align*}
$$

Now

$$
F(0)=\phi_{-\alpha} \circ s \circ \phi_{-\sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)}}(0)=\phi_{\alpha}^{-1}\left(\phi_{\alpha} \circ h\left(z_{0}\right)\right)=h\left(z_{0}\right)=0
$$

and $F$ maps $B(0,1)$ into $B(0,1)$. Also, $F$ is not one to one because it maps $B(0,1)$ to $B(0,1)$ and has $s$ in its definition. Thus there exists $z_{1} \in B(0,1)$ such that $\phi_{-\sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)}}\left(z_{1}\right)=$ $-\frac{1}{2}$ and another point $z_{2} \in B(0,1)$ such that $\phi_{-\sqrt{\phi_{\alpha} \circ h\left(z_{0}\right)}}\left(z_{2}\right)=\frac{1}{2}$. However, thanks to $s, F\left(z_{1}\right)=F\left(z_{2}\right)$.

Since $F(0)=h\left(z_{0}\right)=0$, you can apply the Schwarz lemma to $F$. Since $F$ is not one to one, it can't be true that $F(z)=\lambda z$ for $|\lambda|=1$ and so by the Schwarz lemma it must be the case that $\left|F^{\prime}(0)\right|<1$. But this implies from 55.3 .15 and 55.3.14 that

$$
\begin{aligned}
\eta & =\left|h^{\prime}\left(z_{0}\right)\right|=\left|F^{\prime}\left(\psi\left(z_{0}\right)\right)\right|\left|\psi^{\prime}\left(z_{0}\right)\right| \\
& =\left|F^{\prime}(0)\right|\left|\psi^{\prime}\left(z_{0}\right)\right|<\left|\psi^{\prime}\left(z_{0}\right)\right| \leq \eta
\end{aligned}
$$

a contradiction. This proves the theorem.
The following lemma yields the usual form of the Riemann mapping theorem.

Lemma 55.3.7 Let $\Omega$ be a simply connected region with $\Omega \neq \mathbb{C}$. Then $\Omega$ has the square root property.

Proof: Let $f$ and $\frac{1}{f}$ both be analytic on $\Omega$. Then $\frac{f^{\prime}}{f}$ is analytic on $\Omega$ so by Corollary 51.7.23, there exists $\widetilde{F}$, analytic on $\Omega$ such that $\widetilde{F}^{\prime}=\frac{f^{\prime}}{f}$ on $\Omega$. Then $\left(f e^{-\widetilde{F}}\right)^{\prime}=0$ and so $f(z)=C e^{\widetilde{F}}=e^{a+i b} e^{\widetilde{F}}$. Now let $F=\widetilde{F}+a+i b$. Then $F$ is still a primitive of $f^{\prime} / f$ and $f(z)=e^{F(z)}$. Now let $\phi(z) \equiv e^{\frac{1}{2} F(z)}$. Then $\phi$ is the desired square root and so $\Omega$ has the square root property.

Corollary 55.3.8 (Riemann mapping theorem) Let $\Omega$ be a simply connected region with $\Omega \neq \mathbb{C}$ and let $z_{0} \in \Omega$. Then there exists a function, $f: \Omega \rightarrow B(0,1)$ such that $f$ is one to one, analytic, and onto with $f\left(z_{0}\right)=0$. Furthermore, $f^{-1}$ is also analytic.

Proof: From Theorem 55.3.6 and Lemma 55.3.7 there exists a function, $f: \Omega \rightarrow B(0,1)$ which is one to one, onto, and analytic such that $f\left(z_{0}\right)=0$. The assertion that $f^{-1}$ is analytic follows from the open mapping theorem.

### 55.4 Analytic Continuation

### 55.4.1 Regular And Singular Points

Given a function which is analytic on some set, can you extend it to an analytic function defined on a larger set? Sometimes you can do this. It was done in the proof of the Cauchy integral formula. There are also reflection theorems like those discussed in the exercises starting with Problem 10 on Page 1647. Here I will give a systematic way of extending an analytic function to a larger set. I will emphasize simply connected regions. The subject of analytic continuation is much larger than the introduction given here. A good source for much more on this is found in Alfors [3]. The approach given here is suggested by Rudin [113] and avoids many of the standard technicalities.

Definition 55.4.1 Let $f$ be analytic on $B(a, r)$ and let $\beta \in \partial B(a, r)$. Then $\beta$ is called $a$ regular point of $f$ if there exists some $\delta>0$ and a function, $g$ analytic on $B(\beta, \delta)$ such that $g=f$ on $B(\beta, \delta) \cap B(a, r)$. Those points of $\partial B(a, r)$ which are not regular are called singular.

Theorem 55.4.2 Suppose $f$ is analytic on $B(a, r)$ and the power series

$$
f(z)=\sum_{k=0}^{\infty} a_{k}(z-a)^{k}
$$

has radius of convergence $r$. Then there exists a singular point on $\partial B(a, r)$.
Proof: If not, then for every $z \in \partial B(a, r)$ there exists $\delta_{z}>0$ and $g_{z}$ analytic on $B\left(z, \delta_{z}\right)$ such that $g_{z}=f$ on $B\left(z, \delta_{z}\right) \cap B(a, r)$. Since $\partial B(a, r)$ is compact, there exist $z_{1}, \cdots, z_{n}$, points in $\partial B(a, r)$ such that $\left\{B\left(z_{k}, \delta_{z_{k}}\right)\right\}_{k=1}^{n}$ covers $\partial B(a, r)$. Now define

$$
g(z) \equiv\left\{\begin{array}{l}
f(z) \text { if } z \in B(a, r) \\
g_{z_{k}}(z) \text { if } z \in B\left(z_{k}, \delta_{z_{k}}\right)
\end{array}\right.
$$

Is this well defined? If $z \in B\left(z_{i}, \delta_{z_{i}}\right) \cap B\left(z_{j}, \delta_{z_{j}}\right)$, is $g_{z_{i}}(z)=g_{z_{j}}(z)$ ? Consider the following picture representing this situation.

You see that if $z \in B\left(z_{i}, \delta_{z_{i}}\right) \cap B\left(z_{j}, \delta_{z_{j}}\right)$ then $I \equiv B\left(z_{i}, \delta_{z_{i}}\right) \cap B\left(z_{j}, \delta_{z_{j}}\right) \cap B(a, r)$ is a nonempty open set. Both $g_{z_{i}}$ and $g_{z_{j}}$ equal $f$ on $I$. Therefore, they must be equal on $B\left(z_{i}, \delta_{z_{i}}\right) \cap B\left(z_{j}, \delta_{z_{j}}\right)$ because $I$ has a limit point. Therefore, $g$ is well defined and analytic on an open set containing $\overline{B(a, r)}$. Since $g$ agrees with $f$ on $B(a, r)$, the power series for $g$ is the same as the power series for $f$ and converges on a ball which is larger than $B(a, r)$ contrary to the assumption that the radius of convergence of the above power series equals $r$. This proves the theorem.

### 55.4.2 Continuation Along A Curve

Next I will describe what is meant by continuation along a curve. The following definition is standard and is found in Rudin [113].

Definition 55.4.3 A function element is an ordered pair, $(f, D)$ where $D$ is an open ball and $f$ is analytic on $D$. $\left(f_{0}, D_{0}\right)$ and $\left(f_{1}, D_{1}\right)$ are direct continuations of each other if $D_{1} \cap D_{0} \neq \emptyset$ and $f_{0}=f_{1}$ on $D_{1} \cap D_{0}$. In this case I will write $\left(f_{0}, D_{0}\right) \sim\left(f_{1}, D_{1}\right)$. A chain is a finite sequence, of disks, $\left\{D_{0}, \cdots, D_{n}\right\}$ such that $D_{i-1} \cap D_{i} \neq \emptyset$. If $\left(f_{0}, D_{0}\right)$ is a given function element and there exist function elements, $\left(f_{i}, D_{i}\right)$ such that $\left\{D_{0}, \cdots, D_{n}\right\}$ is a chain and $\left(f_{j-1}, D_{j-1}\right) \sim\left(f_{j}, D_{j}\right)$ then $\left(f_{n}, D_{n}\right)$ is called the analytic continuation of $\left(f_{0}, D_{0}\right)$ along the chain $\left\{D_{0}, \cdots, D_{n}\right\}$. Now suppose $\gamma$ is an oriented curve with parameter interval $[a, b]$ and there exists a chain, $\left\{D_{0}, \cdots, D_{n}\right\}$ such that $\gamma^{*} \subseteq \cup_{k=1}^{n} D_{k}, \gamma(a)$ is the center of $D_{0}, \gamma(b)$ is the center of $D_{n}$, and there is an increasing list of numbers in $[a, b], a=$ $s_{0}<s_{1} \cdots<s_{n}=b$ such that $\gamma\left(\left[s_{i}, s_{i+1}\right]\right) \subseteq D_{i}$ and $\left(f_{n}, D_{n}\right)$ is an analytic continuation of $\left(f_{0}, D_{0}\right)$ along the chain. Then $\left(f_{n}, D_{n}\right)$ is called an analytic continuation of $\left(f_{0}, D_{0}\right)$ along the curve $\gamma$. ( $\gamma$ will always be a continuous curve. Nothing more is needed.)

In the above situation it does not follow that if $D_{n} \cap D_{0} \neq \emptyset$, that $f_{n}=f_{0}$ ! However, there are some cases where this will happen. This is the monodromy theorem which follows. This is as far as I will go on the subject of analytic continuation. For more on this subject including a development of the concept of Riemann surfaces, see Alfors [3].

Lemma 55.4.4 Suppose $(f, B(0, r))$ for $r<1$ is a function element and $(f, B(0, r))$ can be analytically continued along every curve in $B(0,1)$ that starts at 0 . Then there exists an analytic function, $g$ defined on $B(0,1)$ such that $g=f$ on $B(0, r)$.

Proof: Let

$$
\begin{aligned}
R= & \sup \left\{r_{1} \geq r \text { such that there exists } g_{r_{1}}\right. \\
& \text { analytic on } \left.B\left(0, r_{1}\right) \text { which agrees with } f \text { on } B(0, r) \cdot\right\}
\end{aligned}
$$

Define $g_{R}(z) \equiv g_{r_{1}}(z)$ where $|z|<r_{1}$. This is well defined because if you use $r_{1}$ and $r_{2}$, both $g_{r_{1}}$ and $g_{r_{2}}$ agree with $f$ on $B(0, r)$, a set with a limit point and so the two functions agree at every point in both $B\left(0, r_{1}\right)$ and $B\left(0, r_{2}\right)$. Thus $g_{R}$ is analytic on $B(0, R)$. If $R<1$, then by the assumption there are no singular points on $B(0, R)$ and so Theorem 55.4.2 implies the radius of convergence of the power series for $g_{R}$ is larger than $R$ contradicting the choice of $R$. Therefore, $R=1$ and this proves the lemma. Let $g=g_{R}$.

The following theorem is the main result in this subject, the monodromy theorem.
Theorem 55.4.5 Let $\Omega$ be a simply connected proper subset of $\mathbb{C}$ and suppose $(f, B(a, r))$ is a function element with $B(a, r) \subseteq \Omega$. Suppose also that this function element can be analytically continued along every curve through $a$. Then there exists $G$ analytic on $\Omega$ such that $G$ agrees with $f$ on $B(a, r)$.

Proof: By the Riemann mapping theorem, there exists $h: \Omega \rightarrow B(0,1)$ which is analytic, one to one and onto such that $f(a)=0$. Since $h$ is an open map, there exists $\delta>0$ such that

$$
B(0, \delta) \subseteq h(B(a, r))
$$

It follows $f \circ h^{-1}$ can be analytically continued along every curve through 0 . By Lemma 55.4.4 there exists $g$ analytic on $B(0,1)$ which agrees with $f \circ h^{-1}$ on $B(0, \delta)$. Define $G(z) \equiv g(h(z))$. For $z=h^{-1}(w)$, it follows $G\left(h^{-1}(w)\right)=g(w)$. If $w \in B(0, \delta)$, then $G\left(h^{-1}(w)\right)=f \circ h^{-1}(w)$ and so $G=f$ on $h^{-1}(B(0, \delta))$, an open set contained in $B(a, r)$. Therefore, $G=f$ on $B(a, r)$ because $h^{-1}(B(0, \delta))$ has a limit point. This proves the theorem.

Actually, you sometimes want to consider the case where $\Omega=\mathbb{C}$. This requires a small modification to obtain from the above theorem.

Corollary 55.4.6 Suppose $(f, B(a, r))$ is a function element with $B(a, r) \subseteq \mathbb{C}$. Suppose also that this function element can be analytically continued along every curve through $a$. Then there exists $G$ analytic on $\mathbb{C}$ such that $G$ agrees with $f$ on $B(a, r)$.

Proof: Let $\Omega_{1} \equiv\{z \in \mathbb{C}: a+i t: t>a\}$ and $\Omega_{2} \equiv\{z \in \mathbb{C}: a-i t: t>a\}$. Here is a picture of $\Omega_{1}$.

A picture of $\Omega_{2}$ is similar except the line extends down from the boundary of $B(a, r)$.
Thus $B(a, r) \subseteq \Omega_{i}$ and $\Omega_{i}$ is simply connected and proper. By Theorem 55.4.5 there exist analytic functions, $G_{i}$ analytic on $\Omega_{i}$ such that $G_{i}=f$ on $B(a, r)$. Thus $G_{1}=G_{2}$ on $B(a, r)$, a set with a limit point. Therefore, $G_{1}=G_{2}$ on $\Omega_{1} \cap \Omega_{2}$. Now let $G(z)=G_{i}(z)$ where $z \in \Omega_{i}$. This is well defined and analytic on $\mathbb{C}$. This proves the corollary.

### 55.5 The Picard Theorems

The Picard theorem says that if $f$ is an entire function and there are two complex numbers not contained in $f(\mathbb{C})$, then $f$ is constant. This is certainly one of the most amazing things which could be imagined. However, this is only the little Picard theorem. The big Picard theorem is even more incredible. This one asserts that to be non constant the entire function must take every value of $\mathbb{C}$ but two infinitely many times! I will begin with the little Picard theorem. The method of proof I will use is the one found in Saks and Zygmund [115], Conway [32] and Hille [65]. This is not the way Picard did it in 1879. That approach is very different and is presented at the end of the material on elliptic functions. This approach is much more recent dating it appears from around 1924.

Lemma 55.5.1 Let $f$ be analytic on a region containing $\overline{B(0, r)}$ and suppose

$$
\left|f^{\prime}(0)\right|=b>0, f(0)=0
$$

and $|f(z)| \leq M$ for all $z \in \overline{B(0, r)}$. Then $f(B(0, r)) \supseteq B\left(0, \frac{r^{2} b^{2}}{6 M}\right)$.

Proof: By assumption,

$$
\begin{equation*}
f(z)=\sum_{k=0}^{\infty} a_{k} z^{k},|z| \leq r \tag{55.5.16}
\end{equation*}
$$

Then by the Cauchy integral formula for the derivative,

$$
a_{k}=\frac{1}{2 \pi i} \int_{\partial B(0, r)} \frac{f(w)}{w^{k+1}} d w
$$

where the integral is in the counter clockwise direction. Therefore,

$$
\left|a_{k}\right| \leq \frac{1}{2 \pi} \int_{0}^{2 \pi} \frac{\left|f\left(r e^{i \theta}\right)\right|}{r^{k}} d \theta \leq \frac{M}{r^{k}}
$$

In particular, $b r \leq M$. Therefore, from 55.5.16

$$
\begin{aligned}
|f(z)| & \geq b|z|-\sum_{k=2}^{\infty} \frac{M}{r^{k}}|z|^{k}=b|z|-\frac{M\left(\frac{|z|}{r}\right)^{2}}{1-\frac{|z|}{r}} \\
& =b|z|-\frac{M|z|^{2}}{r^{2}-r|z|}
\end{aligned}
$$

Suppose $|z|=\frac{r^{2} b}{4 M}<r$. Then this is no larger than

$$
\frac{1}{4} b^{2} r^{2} \frac{3 M-b r}{M(4 M-b r)} \geq \frac{1}{4} b^{2} r^{2} \frac{3 M-M}{M(4 M-M)}=\frac{r^{2} b^{2}}{6 M}
$$

Let $|w|<\frac{r^{2} b}{4 M}$. Then for $|z|=\frac{r^{2} b}{4 M}$ and the above,

$$
|w|=|(f(z)-w)-f(z)|<\frac{r^{2} b}{4 M} \leq|f(z)|
$$

and so by Rouche's theorem, $z \rightarrow f(z)-w$ and $z \rightarrow f(z)$ have the same number of zeros in $B\left(0, \frac{r^{2} b}{4 M}\right)$. But $f$ has at least one zero in this ball and so this shows there exists at least one $z \in B\left(0, \frac{r^{2} b}{4 M}\right)$ such that $f(z)-w=0$. This proves the lemma.

### 55.5.1 Two Competing Lemmas

Lemma 55.5 .1 is a really nice lemma but there is something even better, Bloch's lemma. This lemma does not depend on the bound of $f$. Like the above two lemmas it is interesting for its own sake and in addition is the key to a fairly short proof of Picard's theorem. It features the number $\frac{1}{24}$. The best constant is not currently known.

Lemma 55.5.2 Let $f$ be analytic on an open set containing $\overline{B(0, R)}$ and suppose $\left|f^{\prime}(0)\right|>$ 0 . Then there exists $a \in B(0, R)$ such that

$$
f(B(0, R)) \supseteq B\left(f(a), \frac{\left|f^{\prime}(0)\right| R}{24}\right) .
$$

Proof: Let $K(\rho) \equiv \max \left\{\left|f^{\prime}(z)\right|:|z|=\rho\right\}$. For simplicity, let $C_{\rho} \equiv\{z:|z|=\rho\}$.
Claim: $K$ is continuous from the left.
Proof of claim: Let $z_{\rho} \in C_{\rho}$ such that $\left|f^{\prime}\left(z_{\rho}\right)\right|=K(\rho)$. Then by the maximum modulus theorem, if $\lambda \in(0,1)$,

$$
\left|f^{\prime}\left(\lambda z_{\rho}\right)\right| \leq K(\lambda \rho) \leq K(\rho)=\left|f^{\prime}\left(z_{\rho}\right)\right|
$$

Letting $\lambda \rightarrow 1$ yields the claim.
Let $\rho_{0}$ be the largest such that

$$
\left(R-\rho_{0}\right) K\left(\rho_{0}\right)=R\left|f^{\prime}(0)\right|
$$

(Note $(R-0) K(0)=R\left|f^{\prime}(0)\right|$.) Thus $\rho_{0}<R$ because $(R-R) K(R)=0$. Let $|a|=\rho_{0}$ such that $\left|f^{\prime}(a)\right|=K\left(\rho_{0}\right)$. Thus

$$
\begin{equation*}
\left|f^{\prime}(a)\right|\left(R-\rho_{0}\right)=\left|f^{\prime}(0)\right| R \tag{55.5.17}
\end{equation*}
$$

Now let $r=\frac{R-\rho_{0}}{2}$. From 55.5.17,

$$
\begin{equation*}
\left|f^{\prime}(a)\right| r=\frac{1}{2}\left|f^{\prime}(0)\right| R, B(a, r) \subseteq B\left(0, \rho_{0}+r\right) \subseteq B(0, R) \tag{55.5.18}
\end{equation*}
$$

Therefore, if $z \in B(a, r)$, it follows from the maximum modulus theorem and the definition of $\rho_{0}$ that

$$
\begin{align*}
\left|f^{\prime}(z)\right| & \leq K\left(\rho_{0}+r\right)<\frac{R\left|f^{\prime}(0)\right|}{R-\rho_{0}-r}=\frac{2 R\left|f^{\prime}(0)\right|}{R-\rho_{0}} \\
& =\frac{2 R\left|f^{\prime}(0)\right|}{2 r}=\frac{R\left|f^{\prime}(0)\right|}{r} \tag{55.5.19}
\end{align*}
$$

$\frac{\text { Let }}{B(0, r)} g(z)=f(a+z)-f(a)$ where $z \in B(0, r)$. Then $\left|g^{\prime}(0)\right|=\left|f^{\prime}(a)\right|>0$ and for $z \in$ $\overline{B(0, r)}$,

$$
|g(z)| \leq\left|\int_{\gamma(a, z)} g^{\prime}(w) d w\right| \leq|z-a| \frac{R\left|f^{\prime}(0)\right|}{r}=R\left|f^{\prime}(0)\right|
$$

By Lemma 55.5.1 and 55.5.18,

$$
\begin{aligned}
g(B(0, r)) & \supseteq B\left(0, \frac{r^{2}\left|f^{\prime}(a)\right|^{2}}{6 R\left|f^{\prime}(0)\right|}\right) \\
& =B\left(0, \frac{r^{2}\left(\frac{1}{2 r}\left|f^{\prime}(0)\right| R\right)^{2}}{6 R\left|f^{\prime}(0)\right|}\right)=B\left(0, \frac{\left|f^{\prime}(0)\right| R}{24}\right)
\end{aligned}
$$

Now $g(B(0, r))=f(B(a, r))-f(a)$ and so this implies

$$
f(B(0, R)) \supseteq f(B(a, r)) \supseteq B\left(f(a), \frac{\left|f^{\prime}(0)\right| R}{24}\right) .
$$

This proves the lemma.
Here is a slightly more general version which allows the center of the open set to be arbitrary.

Lemma 55.5.3 Let $f$ be analytic on an open set containing $\overline{B\left(z_{0}, R\right)}$ and suppose $\left|f^{\prime}\left(z_{0}\right)\right|>$ 0 . Then there exists $a \in B\left(z_{0}, R\right)$ such that

$$
f\left(B\left(z_{0}, R\right)\right) \supseteq B\left(f(a), \frac{\left|f^{\prime}\left(z_{0}\right)\right| R}{24}\right)
$$

Proof: You look at $g(z) \equiv f\left(z_{0}+z\right)-f\left(z_{0}\right)$ for $z \in B(0, R)$. Then $g^{\prime}(0)=f^{\prime}\left(z_{0}\right)$ and so by Lemma 55.5.2 there exists $a_{1} \in B(0, R)$ such that

$$
g(B(0, R)) \supseteq B\left(g\left(a_{1}\right), \frac{\left|f^{\prime}\left(z_{0}\right)\right| R}{24}\right)
$$

Now $g(B(0, R))=f\left(B\left(z_{0}, R\right)\right)-f\left(z_{0}\right)$ and $g\left(a_{1}\right)=f(a)-f\left(z_{0}\right)$ for some $a \in B\left(z_{0}, R\right)$ and so

$$
\begin{aligned}
f\left(B\left(z_{0}, R\right)\right)-f\left(z_{0}\right) & \supseteq B\left(g\left(a_{1}\right), \frac{\left|f^{\prime}\left(z_{0}\right)\right| R}{24}\right) \\
& =B\left(f(a)-f\left(z_{0}\right), \frac{\left|f^{\prime}\left(z_{0}\right)\right| R}{24}\right)
\end{aligned}
$$

which implies

$$
f\left(B\left(z_{0}, R\right)\right) \supseteq B\left(f(a), \frac{\left|f^{\prime}\left(z_{0}\right)\right| R}{24}\right)
$$

as claimed. This proves the lemma.
No attempt was made to find the best number to multiply by $R\left|f^{\prime}\left(z_{0}\right)\right|$. A discussion of this is given in Conway [32]. See also [65]. Much larger numbers than $1 / 24$ are available and there is a conjecture due to Alfors about the best value. The conjecture is that $1 / 24$ can be replaced with

$$
\frac{\Gamma\left(\frac{1}{3}\right) \Gamma\left(\frac{11}{12}\right)}{(1+\sqrt{3})^{1 / 2} \Gamma\left(\frac{1}{4}\right)} \approx .47186
$$

You can see there is quite a gap between the constant for which this lemma is proved above and what is thought to be the best constant.

Bloch's lemma above gives the existence of a ball of a certain size inside the image of a ball. By contrast the next lemma leads to conditions under which the values of a function do not contain a ball of certain radius. It concerns analytic functions which do not achieve the values 0 and 1 .

Lemma 55.5.4 Let $\mathscr{F}$ denote the set of functions, $f$ defined on $\Omega$, a simply connected region which do not achieve the values 0 and 1. Then for each such function, it is possible to define a function analytic on $\Omega, H(z)$ by the formula

$$
H(z) \equiv \log \left[\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right]
$$

There exists a constant $C$ independent of $f \in \mathscr{F}$ such that $H(\Omega)$ does not contain any ball of radius $C$.

Proof: Let $f \in \mathscr{F}$. Then since $f$ does not take the value 0 , there exists $g_{1}$ a primitive of $f^{\prime} / f$. Thus

$$
\frac{d}{d z}\left(e^{-g_{1}} f\right)=0
$$

so there exists $a, b$ such that $f(z) e^{-g_{1}(z)}=e^{a+b i}$. Letting $g(z)=g_{1}(z)+a+i b$, it follows $e^{g(z)}=f(z)$. Let $\log (f(z))=g(z)$. Then for $n \in \mathbb{Z}$, the integers,

$$
\frac{\log (f(z))}{2 \pi i}, \frac{\log (f(z))}{2 \pi i}-1 \neq n
$$

because if equality held, then $f(z)=1$ which does not happen. It follows $\frac{\log (f(z))}{2 \pi i}$ and $\frac{\log (f(z))}{2 \pi i}-1$ are never equal to zero. Therefore, using the same reasoning, you can define a logarithm of these two quantities and therefore, a square root. Hence there exists a function analytic on $\Omega$,

$$
\begin{equation*}
\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1} \tag{55.5.20}
\end{equation*}
$$

For $n$ a positive integer, this function cannot equal $\sqrt{n} \pm \sqrt{n-1}$ because if it did, then

$$
\begin{equation*}
\left(\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)=\sqrt{n} \pm \sqrt{n-1} \tag{55.5.21}
\end{equation*}
$$

and you could take reciprocals of both sides to obtain

$$
\begin{equation*}
\left(\sqrt{\frac{\log (f(z))}{2 \pi i}}+\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)=\sqrt{n} \mp \sqrt{n-1} \tag{55.5.22}
\end{equation*}
$$

Then adding 55.5.21 and 55.5.22

$$
2 \sqrt{\frac{\log (f(z))}{2 \pi i}}=2 \sqrt{n}
$$

which contradicts the above observation that $\frac{\log (f(z))}{2 \pi i}$ is not equal to an integer.
Also, the function of 55.5 .20 is never equal to zero. Therefore, you can define the logarithm of this function also. It follows

$$
H(z) \equiv \log \left(\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right) \neq \ln (\sqrt{n} \pm \sqrt{n-1})+2 m \pi i
$$

where $m$ is an arbitrary integer and $n$ is a positive integer. Now

$$
\lim _{n \rightarrow \infty} \ln (\sqrt{n}+\sqrt{n-1})=\infty
$$

and $\lim _{n \rightarrow \infty} \ln (\sqrt{n}-\sqrt{n-1})=-\infty$ and so $\mathbb{C}$ is covered by rectangles having vertices at points $\ln (\sqrt{n} \pm \sqrt{n-1})+2 m \pi i$ as described above. Each of these rectangles has height equal to $2 \pi$ and a short computation shows their widths are bounded. Therefore, there exists $C$ independent of $f \in \mathscr{F}$ such that $C$ is larger than the diameter of all these rectangles. Hence $H(\Omega)$ cannot contain any ball of radius larger than $C$.

### 55.5.2 The Little Picard Theorem

Now here is the little Picard theorem. It is easy to prove from the above.
Theorem 55.5.5 If $h$ is an entire function which omits two values then $h$ is a constant.
Proof: Suppose the two values omitted are $a$ and $b$ and that $h$ is not constant. Let $f(z)=(h(z)-a) /(b-a)$. Then $f$ omits the two values 0 and 1 . Let $H$ be defined in Lemma 55.5.4. Then $H(z)$ is clearly not of the form $a z+b$ because then it would have values equal to the vertices $\ln (\sqrt{n} \pm \sqrt{n-1})+2 m \pi i$ or else be constant neither of which happen if $h$ is not constant. Therefore, by Liouville's theorem, $H^{\prime}$ must be unbounded. Pick $\xi$ such that $\left|H^{\prime}(\xi)\right|>24 C$ where $C$ is such that $H(\mathbb{C})$ contains no balls of radius larger than $C$. But by Lemma 55.5.3 $H(B(\xi, 1))$ must contain a ball of radius $\frac{\left|H^{\prime}(\xi)\right|}{24}>\frac{24 C}{24}=C$, a contradiction. This proves Picard's theorem.

The following is another formulation of this theorem.
Corollary 55.5.6 If $f$ is a meromophic function defined on $\mathbb{C}$ which omits three distinct values, $a, b, c$, then $f$ is a constant.

Proof: Let $\phi(z) \equiv \frac{z-a}{z-c} \frac{b-c}{b-a}$. Then $\phi(c)=\infty, \phi(a)=0$, and $\phi(b)=1$. Now consider the function, $h=\phi \circ f$. Then $h$ misses the three points $\infty, 0$, and 1 . Since $h$ is meromorphic and does not have $\infty$ in its values, it must actually be analytic. Thus $h$ is an entire function which misses the two values 0 and 1 . Therefore, $h$ is constant by Theorem 55.5.5.

### 55.5.3 Schottky's Theorem

Lemma 55.5.7 Let $f$ be analytic on an open set containing $\overline{B(0, R)}$ and suppose that $f$ does not take on either of the two values 0 or 1 . Also suppose $|f(0)| \leq \beta$. Then letting $\theta \in(0,1)$, it follows

$$
|f(z)| \leq M(\beta, \theta)
$$

for all $z \in B(0, \theta R)$, where $M(\beta, \theta)$ is a function of only the two variables $\beta$, $\theta$. (In particular, there is no dependence on $R$.)

Proof: Consider the function, $H(z)$ used in Lemma 55.5.4 given by

$$
\begin{equation*}
H(z) \equiv \log \left(\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right) \tag{55.5.23}
\end{equation*}
$$

You notice there are two explicit uses of logarithms. Consider first the logarithm inside the radicals. Choose this logarithm such that

$$
\begin{equation*}
\log (f(0))=\ln |f(0)|+i \arg (f(0)), \arg (f(0)) \in(-\pi, \pi] . \tag{55.5.24}
\end{equation*}
$$

You can do this because

$$
e^{\log (f(0))}=f(0)=e^{\ln |f(0)|} e^{i \alpha}=e^{\ln |f(0)|+i \alpha}
$$

and by replacing $\alpha$ with $\alpha+2 m \pi$ for a suitable integer, $m$ it follows the above equation still holds. Therefore, you can assume 55.5.24. Similar reasoning applies to the logarithm on the outside of the parenthesis. It can be assumed $H(0)$ equals

$$
\begin{equation*}
\ln \left|\sqrt{\frac{\log (f(0))}{2 \pi i}}-\sqrt{\frac{\log (f(0))}{2 \pi i}-1}\right|+i \arg \left(\sqrt{\frac{\log (f(0))}{2 \pi i}}-\sqrt{\frac{\log (f(0))}{2 \pi i}-1}\right) \tag{55.5.25}
\end{equation*}
$$

where the imaginary part is no larger than $\pi$ in absolute value.
Now if $\xi \in B(0, R)$ is a point where $H^{\prime}(\xi) \neq 0$, then by Lemma 55.5.2

$$
H(B(\xi, R-|\xi|)) \supseteq B\left(H(a), \frac{\left|H^{\prime}(\xi)\right|(R-|\xi|)}{24}\right)
$$

where $a$ is some point in $B(\xi, R-|\xi|)$. But by Lemma 55.5.4 $H(B(\xi, R-|\xi|))$ contains no balls of radius $C$ where $C$ depended only on the maximum diameters of those rectangles having vertices $\ln (\sqrt{n} \pm \sqrt{n-1})+2 m \pi i$ for $n$ a positive integer and $m$ an integer. Therefore,

$$
\frac{\left|H^{\prime}(\xi)\right|(R-|\xi|)}{24}<C
$$

and consequently

$$
\left|H^{\prime}(\xi)\right|<\frac{24 C}{R-|\xi|}
$$

Even if $H^{\prime}(\xi)=0$, this inequality still holds. Therefore, if $z \in B(0, R)$ and $\gamma(0, z)$ is the straight segment from 0 to $z$,

$$
\begin{aligned}
|H(z)-H(0)| & =\left|\int_{\gamma(0, z)} H^{\prime}(w) d w\right|=\left|\int_{0}^{1} H^{\prime}(t z) z d t\right| \\
& \leq \int_{0}^{1}\left|H^{\prime}(t z) z\right| d t \leq \int_{0}^{1} \frac{24 C}{R-t|z|}|z| d t \\
& =24 C \ln \left(\frac{R}{R-|z|}\right)
\end{aligned}
$$

Therefore, for $z \in \partial B(0, \theta R)$,

$$
\begin{equation*}
|H(z)| \leq|H(0)|+24 C \ln \left(\frac{1}{1-\theta}\right) \tag{55.5.26}
\end{equation*}
$$

By the maximum modulus theorem, the above inequality holds for all $|z|<\theta R$ also.
Next I will use 55.5.23 to get an inequality for $|f(z)|$ in terms of $|H(z)|$. From 55.5.23,

$$
H(z)=\log \left(\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)
$$

and so

$$
\begin{aligned}
2 H(z) & =\log \left(\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)^{2} \\
-2 H(z) & =\log \left(\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)^{-2} \\
& =\log \left(\sqrt{\frac{\log (f(z))}{2 \pi i}}+\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)^{2}
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
& \left(\sqrt{\frac{\log (f(z))}{2 \pi i}}+\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)^{2} \\
& +\left(\sqrt{\frac{\log (f(z))}{2 \pi i}}-\sqrt{\frac{\log (f(z))}{2 \pi i}-1}\right)^{2} \\
= & \exp (2 H(z))+\exp (-2 H(z))
\end{aligned}
$$

and

$$
\left(\frac{\log (f(z))}{\pi i}-1\right)=\frac{1}{2}(\exp (2 H(z))+\exp (-2 H(z)))
$$

Thus

$$
\log (f(z))=\pi i+\frac{\pi i}{2}(\exp (2 H(z))+\exp (-2 H(z)))
$$

which shows

$$
\begin{aligned}
|f(z)| & =\left|\exp \left[\frac{\pi i}{2}(\exp (2 H(z))+\exp (-2 H(z)))\right]\right| \\
& \leq \exp \left|\frac{\pi i}{2}(\exp (2 H(z))+\exp (-2 H(z)))\right| \\
& \leq \exp \left|\frac{\pi}{2}(|\exp (2 H(z))|+|\exp (-2 H(z))|)\right| \\
& \leq \exp \left|\frac{\pi}{2}(\exp (2|H(z)|)+\exp (|-2 H(z)|))\right| \\
& =\exp (\pi \exp 2|H(z)|)
\end{aligned}
$$

Now from 55.5.26 this is dominated by

$$
\begin{align*}
& \exp \left(\pi \exp 2\left(|H(0)|+24 C \ln \left(\frac{1}{1-\theta}\right)\right)\right) \\
= & \exp \left(\pi \exp (2|H(0)|) \exp \left(48 C \ln \left(\frac{1}{1-\theta}\right)\right)\right) \tag{55.5.27}
\end{align*}
$$

Consider $\exp (2|H(0)|)$. I want to obtain an inequality for this which involves $\beta$. This is where I will use the convention about the logarithms discussed above. From 55.5.25,

$$
\begin{align*}
& 2|H(0)|=2\left|\log \left(\sqrt{\frac{\log (f(0))}{2 \pi i}}-\sqrt{\frac{\log (f(0))}{2 \pi i}-1}\right)\right| \\
\leq & 2\left(\left(\ln \left|\sqrt{\frac{\log (f(0))}{2 \pi i}}-\sqrt{\frac{\log (f(0))}{2 \pi i}-1}\right|\right)^{2}+\pi^{2}\right)^{1 / 2} \\
\leq & 2\left(\left|\ln \left(\left|\sqrt{\frac{\log (f(0))}{2 \pi i}}\right|+\left|\sqrt{\frac{\log (f(0))}{2 \pi i}-1}\right|\right)\right|^{2}+\pi^{2}\right)^{1 / 2} \\
\leq & 2\left|\ln \left(\left|\sqrt{\frac{\log (f(0))}{2 \pi i}}\right|+\left|\sqrt{\frac{\log (f(0))}{2 \pi i}-1}\right|\right)\right|+2 \pi \\
\leq & \ln \left(2\left(\left|\frac{\log (f(0))}{2 \pi i}\right|+\left|\frac{\log (f(0))}{2 \pi i}-1\right|\right)\right)+2 \pi \\
= & \ln \left(\left(\left|\frac{\log (f(0))}{\pi i}\right|+\left|\frac{\log (f(0))}{\pi i}-2\right|\right)\right)+2 \pi \tag{55.5.28}
\end{align*}
$$

Consider $\left|\frac{\log (f(0))}{\pi i}\right|$

$$
\frac{\log (f(0))}{\pi i}=-\frac{\ln |f(0)|}{\pi} i+\frac{\arg (f(0))}{\pi}
$$

and so

$$
\begin{aligned}
\left|\frac{\log (f(0))}{\pi i}\right| & =\left(\left|\frac{\ln |f(0)|}{\pi}\right|^{2}+\left(\frac{\arg (f(0))}{\pi}\right)^{2}\right)^{1 / 2} \\
& \leq\left(\left|\frac{\ln \beta}{\pi}\right|^{2}+\left(\frac{\pi}{\pi}\right)^{2}\right)^{1 / 2} \\
& =\left(\left|\frac{\ln \beta}{\pi}\right|^{2}+1\right)^{1 / 2}
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
\left|\frac{\log (f(0))}{\pi i}-2\right| & \leq\left(\left|\frac{\ln \beta}{\pi}\right|^{2}+(2+1)^{2}\right)^{1 / 2} \\
& =\left(\left|\frac{\ln \beta}{\pi}\right|^{2}+9\right)^{1 / 2}
\end{aligned}
$$

It follows from 55.5.28 that

$$
2|H(0)| \leq \ln \left(2\left(\left|\frac{\ln \beta}{\pi}\right|^{2}+9\right)^{1 / 2}\right)+2 \pi
$$

Hence from 55.5.27

$$
\begin{gathered}
|f(z)| \leq \\
\exp \left(\pi \exp \left(\ln \left(2\left(\left|\frac{\ln \beta}{\pi}\right|^{2}+9\right)^{1 / 2}\right)+2 \pi\right) \exp \left(48 C \ln \left(\frac{1}{1-\theta}\right)\right)\right)
\end{gathered}
$$

and so, letting $M(\beta, \theta)$ be given by the above expression on the right, the lemma is proved.
The following theorem will be referred to as Schottky's theorem. It looks just like the above lemma except it is only assumed that $f$ is analytic on $B(0, R)$ rather than on an open set containing $\overline{B(0, R)}$. Also, the case of an arbitrary center is included along with arbitrary points which are not attained as values of the function.
Theorem 55.5.8 Let $f$ be analytic on $B\left(z_{0}, R\right)$ and suppose that $f$ does not take on either of the two distinct values $a$ or $b$. Also suppose $\left|f\left(z_{0}\right)\right| \leq \beta$. Then letting $\theta \in(0,1)$, it follows

$$
|f(z)| \leq M(a, b, \beta, \theta)
$$

for all $z \in B\left(z_{0}, \theta R\right)$, where $M(a, b, \beta, \theta)$ is a function of only the variables $\beta, \theta, a, b$. (In particular, there is no dependence on $R$.)

Proof: First you can reduce to the case where the two values are 0 and 1 by considering

$$
h(z) \equiv \frac{f(z)-a}{b-a}
$$

If there exists an estimate of the desired sort for $h$, then there exists such an estimate for $f$. Of course here the function, $M$ would depend on $a$ and $b$. Therefore, there is no loss of generality in assuming the points which are missed are 0 and 1 .

Apply Lemma 55.5.7 to $B\left(0, R_{1}\right)$ for the function, $g(z) \equiv f\left(z_{0}+z\right)$ and $R_{1}<R$. Then if $\beta \geq\left|f\left(z_{0}\right)\right|=|g(0)|$, it follows $|g(z)|=\left|f\left(z_{0}+z\right)\right| \leq M(\beta, \theta)$ for every $z \in B\left(0, \theta R_{1}\right)$. Now let $\theta \in(0,1)$ and choose $R_{1}<R$ large enough that $\theta R=\theta_{1} R_{1}$ where $\theta_{1} \in(0,1)$. Then if $\left|z-z_{0}\right|<\theta R$, it follows

$$
|f(z)| \leq M\left(\beta, \theta_{1}\right)
$$

Now let $R_{1} \rightarrow R$ so $\theta_{1} \rightarrow \theta$.

### 55.5.4 A Brief Review

First recall the definition of the metric on $\widehat{\mathbb{C}}$. For convenience it is listed here again. Consider the unit sphere, $S^{2}$ given by $(z-1)^{2}+y^{2}+x^{2}=1$. Define a map from the complex plane to the surface of this sphere as follows. Extend a line from the point, $p$ in the complex plane to the point $(0,0,2)$ on the top of this sphere and let $\theta(p)$ denote the point of this sphere which the line intersects. Define $\theta(\infty) \equiv(0,0,2)$.

Then $\theta^{-1}$ is sometimes called sterographic projection. The mapping $\theta$ is clearly continuous because it takes converging sequences, to converging sequences. Furthermore, it is clear that $\theta^{-1}$ is also continuous. In terms of the extended complex plane, $\widehat{\mathbb{C}}$, a sequence, $z_{n}$ converges to $\infty$ if and only if $\theta z_{n}$ converges to $(0,0,2)$ and a sequence, $z_{n}$ converges to $z \in \mathbb{C}$ if and only if $\theta\left(z_{n}\right) \rightarrow \theta(z)$.

In fact this makes it easy to define a metric on $\widehat{\mathbb{C}}$.
Definition 55.5.9 Let $z, w \in \widehat{\mathbb{C}}$. Then let $d(x, y) \equiv|\theta(z)-\theta(w)|$ where this last distance is the usual distance measured in $\mathbb{R}^{3}$.

Theorem 55.5.10 $(\widehat{\mathbb{C}}, d)$ is a compact, hence complete metric space.
Proof: Suppose $\left\{z_{n}\right\}$ is a sequence in $\widehat{\mathbb{C}}$. This means $\left\{\theta\left(z_{n}\right)\right\}$ is a sequence in $S^{2}$ which is compact. Therefore, there exists a subsequence, $\left\{\theta z_{n_{k}}\right\}$ and a point, $z \in S^{2}$ such that $\theta z_{n_{k}} \rightarrow \theta z$ in $S^{2}$ which implies immediately that $d\left(z_{n_{k}}, z\right) \rightarrow 0$. A compact metric space must be complete.

Also recall the interesting fact that meromorphic functions are continuous with values in $\widehat{\mathbb{C}}$ which is reviewed here for convenience. It came from the theory of classification of isolated singularities.

Theorem 55.5.11 Let $\Omega$ be an open subset of $\mathbb{C}$ and let $f: \Omega \rightarrow \widehat{\mathbb{C}}$ be meromorphic. Then $f$ is continuous with respect to the metric, $d$ on $\widehat{\mathbb{C}}$.

Proof: Let $z_{n} \rightarrow z$ where $z \in \Omega$. Then if $z$ is a pole, it follows from Theorem 51.7.11 that

$$
d\left(f\left(z_{n}\right), \infty\right) \equiv d\left(f\left(z_{n}\right), f(z)\right) \rightarrow 0
$$

If $z$ is not a pole, then $f\left(z_{n}\right) \rightarrow f(z)$ in $\mathbb{C}$ which implies

$$
\left|\theta\left(f\left(z_{n}\right)\right)-\theta(f(z))\right|=d\left(f\left(z_{n}\right), f(z)\right) \rightarrow 0
$$

Recall that $\theta$ is continuous on $\mathbb{C}$.
The fundamental result behind all the theory about to be presented is the Ascoli Arzela theorem also listed here for convenience.

Definition 55.5.12 Let $(X, d)$ be a complete metric space. Then it is said to be locally compact if $\overline{B(x, r)}$ is compact for each $r>0$.

Thus if you have a locally compact metric space, then if $\left\{a_{n}\right\}$ is a bounded sequence, it must have a convergent subsequence.

Let $K$ be a compact subset of $\mathbb{R}^{n}$ and consider the continuous functions which have values in a locally compact metric space, $(X, d)$ where $d$ denotes the metric on $X$. Denote this space as $C(K, X)$.

Definition 55.5.13 For $f, g \in C(K, X)$, where $K$ is a compact subset of $\mathbb{R}^{n}$ and $X$ is a locally compact complete metric space define

$$
\rho_{K}(f, g) \equiv \sup \{d(f(\mathbf{x}), g(\mathbf{x})): \mathbf{x} \in K\}
$$

The Ascoli Arzela theorem, Theorem 7.8.4 is a major result which tells which subsets of $C(K, X)$ are sequentially compact.

Definition 55.5.14 Let $A \subseteq C(K, X)$ for $K$ a compact subset of $\mathbb{R}^{n}$. Then $A$ is said to be uniformly equicontinuous iffor every $\varepsilon>0$ there exists a $\delta>0$ such that whenever $\mathbf{x}, \mathbf{y} \in K$ with $|\mathbf{x}-\mathbf{y}|<\delta$ and $f \in A$,

$$
d(f(\mathbf{x}), f(\mathbf{y}))<\varepsilon
$$

The set, $A$ is said to be uniformly bounded if for some $M<\infty$, and $a \in X$,

$$
f(\mathbf{x}) \in B(a, M)
$$

for all $f \in A$ and $\mathbf{x} \in K$.
The Ascoli Arzela theorem follows.
Theorem 55.5.15 Suppose $K$ is a nonempty compact subset of $\mathbb{R}^{n}$ and $A \subseteq C(K, X)$, is uniformly bounded and uniformly equicontinuous where $X$ is a locally compact complete metric space. Then if $\left\{f_{k}\right\} \subseteq A$, there exists a function, $f \in C(K, X)$ and a subsequence, $f_{k_{l}}$ such that

$$
\lim _{l \rightarrow \infty} \rho_{K}\left(f_{k_{l}}, f\right)=0
$$

In the cases of interest here, $X=\widehat{\mathbb{C}}$ with the metric defined above.

### 55.5.5 Montel's Theorem

The following lemma is another version of Montel's theorem. It is this which will make possible a proof of the big Picard theorem.

Lemma 55.5.16 Let $\Omega$ be a region and let $\mathscr{F}$ be a set of functions analytic on $\Omega$ none of which achieve the two distinct values, $a$ and $b$. If $\left\{f_{n}\right\} \subseteq \mathscr{F}$ then one of the following hold: Either there exists a function, $f$ analytic on $\Omega$ and a subsequence, $\left\{f_{n_{k}}\right\}$ such that for any compact subset, $K$ of $\Omega$,

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \mid\left\|f_{n_{k}}-f\right\|_{K, \infty}=0 \tag{55.5.29}
\end{equation*}
$$

or there exists a subsequence $\left\{f_{n_{k}}\right\}$ such that for all compact subsets $K$,

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \rho_{K}\left(f_{n_{k}}, \infty\right)=0 \tag{55.5.30}
\end{equation*}
$$

Proof: Let $B\left(z_{0}, 2 R\right) \subseteq \Omega$. There are two cases to consider. The first case is that there exists a subsequence, $n_{k}$ such that $\left\{f_{n_{k}}\left(z_{0}\right)\right\}$ is bounded. The second case is that $\lim _{n \rightarrow \infty}\left|f_{n_{k}}\left(z_{0}\right)\right|=\infty$.

Consider the first case. By Theorem 55.5.8 $\left\{f_{n_{k}}(z)\right\}$ is uniformly bounded on $\overline{B\left(z_{0}, R\right)}$ because by this theorem, and letting $\theta=1 / 2$ applied to $B\left(z_{0}, 2 R\right)$, it follows $\left|f_{n_{k}}(z)\right| \leq$ $M\left(a, b, \frac{1}{2}, \beta\right)$ where $\beta$ is an upper bound to the numbers, $\left|f_{n_{k}}\left(z_{0}\right)\right|$. The Cauchy integral formula implies the existence of a uniform bound on the $\left\{f_{n_{k}}^{\prime}\right\}$ which implies the functions are equicontinuous and uniformly bounded. Therefore, by the Ascoli Arzela theorem there exists a further subsequence which converges uniformly on $\overline{B\left(z_{0}, R\right)}$ to a function, $f$ analytic on $B\left(z_{0}, R\right)$. Thus denoting this subsequence by $\left\{f_{n_{k}}\right\}$ to save on notation,

$$
\begin{equation*}
\lim _{k \rightarrow \infty}| | f_{n_{k}}-\left.f\right|_{\overline{B\left(z_{0}, R\right), \infty}}=0 \tag{55.5.31}
\end{equation*}
$$

Consider the second case. In this case, it follows $\left\{1 / f_{n}\left(z_{0}\right)\right\}$ is bounded on $\overline{B\left(z_{0}, R\right)}$ and so by the same argument just given $\left\{1 / f_{n}(z)\right\}$ is uniformly bounded on $\overline{B\left(z_{0}, R\right)}$. Therefore, a subsequence converges uniformly on $\overline{B\left(z_{0}, R\right)}$. But $\left\{1 / f_{n}(z)\right\}$ converges to 0 and so this requires that $\left\{1 / f_{n}(z)\right\}$ must converge uniformly to 0 . Therefore,

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \rho_{\overline{B\left(z_{0}, R\right)}}\left(f_{n_{k}}, \infty\right)=0 \tag{55.5.32}
\end{equation*}
$$

Now let $\left\{D_{k}\right\}$ denote a countable set of closed balls, $D_{k}=\overline{B\left(z_{k}, R_{k}\right)}$ such that

$$
B\left(z_{k}, 2 R_{k}\right) \subseteq \Omega
$$

and $\cup_{k=1}^{\infty} \operatorname{int}\left(D_{k}\right)=\Omega$. Using a Cantor diagonal process, there exists a subsequence, $\left\{f_{n_{k}}\right\}$ of $\left\{f_{n}\right\}$ such that for each $D_{j}$, one of the above two alternatives holds. That is, either

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|f_{n_{k}}-g_{j}\right\|_{D_{j}, \infty}=0 \tag{55.5.33}
\end{equation*}
$$

or,

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \rho_{D_{j}}\left(f_{n_{k}}, \infty\right) \tag{55.5.34}
\end{equation*}
$$

Let $A=\left\{\cup \operatorname{int}\left(D_{j}\right): 55.5 .33\right.$ holds $\}, B=\left\{\cup \operatorname{int}\left(D_{j}\right): 55.5 .34\right.$ holds $\}$. Note that the balls whose union is $A$ cannot intersect any of the balls whose union is $B$. Therefore, one of $A$ or $B$ must be empty since otherwise, $\Omega$ would not be connected.

If $K$ is any compact subset of $\Omega$, it follows $K$ must be a subset of some finite collection of the $D_{j}$. Therefore, one of the alternatives in the lemma must hold. That the limit function, $f$ must be analytic follows easily in the same way as the proof in Theorem 55.3.1 on Page 1739. You could also use Morera's theorem. This proves the lemma.

### 55.5.6 The Great Big Picard Theorem

The next theorem is the main result which the above lemmas lead to. It is the Big Picard theorem, also called the Great Picard theorem.Recall $B^{\prime}(a, r)$ is the deleted ball consisting of all the points of the ball except the center.

Theorem 55.5.17 Suppose $f$ has an isolated essential singularity at 0 . Then for every $R>0$, and $\beta \in \mathbb{C}, f^{-1}(\beta) \cap B^{\prime}(0, R)$ is an infinite set except for one possible exceptional $\beta$.

Proof: Suppose this is not true. Then there exists $R_{1}>0$ and two points, $\alpha$ and $\beta$ such that $f^{-1}(\beta) \cap B^{\prime}\left(0, R_{1}\right)$ and $f^{-1}(\alpha) \cap B^{\prime}\left(0, R_{1}\right)$ are both finite sets. Then shrinking $R_{1}$ and calling the result $R$, there exists $B(0, R)$ such that

$$
f^{-1}(\beta) \cap B^{\prime}(0, R)=\emptyset, f^{-1}(\alpha) \cap B^{\prime}(0, R)=\emptyset
$$

Now let $A_{0}$ denote the annulus $\left\{z \in \mathbb{C}: \frac{R}{2^{2}}<|z|<\frac{3 R}{2^{2}}\right\}$ and let $A_{n}$ denote the annulus $\left\{z \in \mathbb{C}: \frac{R}{2^{2+n}}<|z|<\frac{3 R}{2^{2+n}}\right\}$. The reason for the 3 is to insure that $A_{n} \cap A_{n+1} \neq \emptyset$. This follows from the observation that $3 R / 2^{2+1+n}>R / 2^{2+n}$. Now define a set of functions on $A_{0}$ as follows:

$$
f_{n}(z) \equiv f\left(\frac{z}{2^{n}}\right)
$$

By the choice of $R$, this set of functions missed the two points $\alpha$ and $\beta$. Therefore, by Lemma 55.5.16 there exists a subsequence such that one of the two options presented there holds.

First suppose $\lim _{k \rightarrow \infty}\left\|f_{n_{k}}-f\right\|_{K, \infty}=0$ for all $K$ a compact subset of $A_{0}$ and $f$ is analytic on $A_{0}$. In particular, this happens for $\gamma_{0}$ the circular contour having radius $R / 2$. Thus $f_{n_{k}}$ must be bounded on this contour. But this says the same thing as $f\left(z / 2^{n_{k}}\right)$ is bounded for $|z|=R / 2$, this holding for each $k=1,2, \cdots$. Thus there exists a constant, $M$ such that on each of a shrinking sequence of concentric circles whose radii converge to $0,|f(z)| \leq M$. By the maximum modulus theorem, $|f(z)| \leq M$ at every point between successive circles in this sequence. Therefore, $|f(z)| \leq M$ in $B^{\prime}(0, R)$ contradicting the Weierstrass Casorati theorem.

The other option which might hold from Lemma 55.5.16 is that $\lim _{k \rightarrow \infty} \rho_{K}\left(f_{n_{k}}, \infty\right)=0$ for all $K$ compact subset of $A_{0}$. Since $f$ has an essential singularity at 0 the zeros of $f$ in $B(0, R)$ are isolated. Therefore, for all $k$ large enough, $f_{n_{k}}$ has no zeros for $|z|<3 R / 2^{2}$. This is because the values of $f_{n_{k}}$ are the values of $f$ on $A_{n_{k}}$, a small anulus which avoids all the zeros of $f$ whenever $k$ is large enough. Only consider $k$ this large. Then use the above argument on the analytic functions $1 / f_{n_{k}}$. By the assumption that $\lim _{k \rightarrow \infty} \rho_{K}\left(f_{n_{k}}, \infty\right)=0$, it follows $\lim _{k \rightarrow \infty}\left\|1 / f_{n_{k}}-0\right\|_{K, \infty}=0$ and so as above, there exists a shrinking sequence of concentric circles whose radii converge to 0 and a constant, $M$ such that for $z$ on any of these circles, $|1 / f(z)| \leq M$. This implies that on some deleted ball, $B^{\prime}(0, r)$ where $r \leq R,|f(z)| \geq 1 / M$ which again violates the Weierstrass Casorati theorem. This proves the theorem.

As a simple corollary, here is what this remarkable theorem says about entire functions.

Corollary 55.5.18 Suppose $f$ is entire and nonconstant and not a polynomial. Then $f$ assumes every complex value infinitely many times with the possible exception of one.

Proof: Since $f$ is entire, $f(z)=\sum_{n=0}^{\infty} a_{n} z^{n}$. Define for $z \neq 0$,

$$
g(z) \equiv f\left(\frac{1}{z}\right)=\sum_{n=0}^{\infty} a_{n}\left(\frac{1}{z}\right)^{n}
$$

Thus 0 is an isolated essential singular point of $g$. By the big Picard theorem, Theorem 55.5.17 it follows $g$ takes every complex number but possibly one an infinite number of times. This proves the corollary.

Note the difference between this and the little Picard theorem which says that an entire function which is not constant must achieve every value but two.

### 55.6 Exercises

1. Prove that in Theorem 55.3.1 it suffices to assume $\mathscr{F}$ is uniformly bounded on each compact subset of $\Omega$.
2. Find conditions on $a, b, c, d$ such that the fractional linear transformation, $\frac{a z+b}{c z+d}$ maps the upper half plane onto the upper half plane.
3. Let $D$ be a simply connected region which is a proper subset of $\mathbb{C}$. Does there exist an entire function, $f$ which maps $\mathbb{C}$ onto $D$ ? Why or why not?
4. Verify the conclusion of Theorem 55.3.1 involving the higher order derivatives.
5. What if $\Omega=\mathbb{C}$ ? Does there exist an analytic function, $f$ mapping $\Omega$ one to one and onto $B(0,1)$ ? Explain why or why not. Was $\Omega \neq \mathbb{C}$ used in the proof of the Riemann mapping theorem?
6. Verify that $\left|\phi_{\alpha}(z)\right|=1$ if $|z|=1$. Apply the maximum modulus theorem to conclude that $\left|\phi_{\alpha}(z)\right| \leq 1$ for all $|z|<1$.
7. Suppose that $|f(z)| \leq 1$ for $|z|=1$ and $f(\alpha)=0$ for $|\alpha|<1$. Show that $|f(z)| \leq$ $\left|\phi_{\alpha}(z)\right|$ for all $z \in B(0,1)$. Hint: Consider $\frac{f(z)(1-\bar{\alpha} z)}{z-\alpha}$ which has a removable singularity at $\alpha$. Show the modulus of this function is bounded by 1 on $|z|=1$. Then apply the maximum modulus theorem.
8. Let $U$ and $V$ be open subsets of $\mathbb{C}$ and suppose $u: U \rightarrow \mathbb{R}$ is harmonic while $h$ is an analytic map which takes $V$ one to one onto $U$. Show that $u \circ h$ is harmonic on $V$.
9. Show that for a harmonic function, $u$ defined on $B(0, R)$, there exists an analytic function, $h=u+i v$ where

$$
v(x, y) \equiv \int_{0}^{y} u_{x}(x, t) d t-\int_{0}^{x} u_{y}(t, 0) d t
$$

10. Suppose $\Omega$ is a simply connected region and $u$ is a real valued function defined on $\Omega$ such that $u$ is harmonic. Show there exists an analytic function, $f$ such that $u=\operatorname{Re} f$. Show this is not true if $\Omega$ is not a simply connected region. Hint: You might use the Riemann mapping theorem and Problems 8 and 9. For the second part it might be good to try something like $u(x, y)=\ln \left(x^{2}+y^{2}\right)$ on the annulus $1<|z|<2$.
11. Show that $w=\frac{1+z}{1-z}$ maps $\{z \in \mathbb{C}: \operatorname{Im} z>0$ and $|z|<1\}$ to the first quadrant,

$$
\{z=x+i y: x, y>0\} .
$$

12. Let $f(z)=\frac{a z+b}{c z+d}$ and let $g(z)=\frac{a_{1} z+b_{1}}{c_{1} z+d_{1}}$. Show that $f \circ g(z)$ equals the quotient of two expressions, the numerator being the top entry in the vector

$$
\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\left(\begin{array}{ll}
a_{1} & b_{1} \\
c_{1} & d_{1}
\end{array}\right)\binom{z}{1}
$$

and the denominator being the bottom entry. Show that if you define

$$
\phi\left(\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\right) \equiv \frac{a z+b}{c z+d}
$$

then $\phi(A B)=\phi(A) \circ \phi(B)$. Find an easy way to find the inverse of $f(z)=\frac{a z+b}{c z+d}$ and give a condition on the $a, b, c, d$ which insures this function has an inverse.
13. The modular group ${ }^{2}$ is the set of fractional linear transformations, $\frac{a z+b}{c z+d}$ such that $a, b, c, d$ are integers and $a d-b c=1$. Using Problem 12 or brute force show this modular group is really a group with the group operation being composition. Also show the inverse of $\frac{a z+b}{c z+d}$ is $\frac{d z-b}{-c z+a}$.
14. Let $\Omega$ be a region and suppose $f$ is analytic on $\Omega$ and that the functions $f_{n}$ are also analytic on $\Omega$ and converge to $f$ uniformly on compact subsets of $\Omega$. Suppose $f$ is one to one. Can it be concluded that for an arbitrary compact set, $K \subseteq \Omega$ that $f_{n}$ is one to one for all $n$ large enough?
15. The Vitali theorem says that if $\Omega$ is a region and $\left\{f_{n}\right\}$ is a uniformly bounded sequence of functions which converges pointwise on a set, $S \subseteq \Omega$ which has a limit point in $\Omega$, then in fact, $\left\{f_{n}\right\}$ must converge uniformly on compact subsets of $\Omega$ to an analytic function. Prove this theorem. Hint: If the sequence fails to converge, show you can get two different subsequences converging uniformly on compact sets to different functions. Then argue these two functions coincide on $S$.
16. Does there exist a function analytic on $B(0,1)$ which maps $B(0,1)$ onto $B^{\prime}(0,1)$, the open unit ball in which 0 has been deleted?

[^34]
## Chapter 56

## Approximation By Rational Functions

### 56.1 Runge's Theorem

Consider the function, $\frac{1}{z}=f(z)$ for $z$ defined on $\Omega \equiv B(0,1) \backslash\{0\}=B^{\prime}(0,1)$. Clearly $f$ is analytic on $\Omega$. Suppose you could approximate $f$ uniformly by polynomials on ann $\left(0, \frac{1}{2}, \frac{3}{4}\right)$, a compact subset of $\Omega$. Then, there would exist a suitable polynomial $p(z)$, such that $\left|\frac{1}{2 \pi i} \int_{\gamma} f(z)-p(z) d z\right|<\frac{1}{10}$ where here $\gamma$ is a circle of radius $\frac{2}{3}$. However, this is impossible because $\frac{1}{2 \pi i} \int_{\gamma} f(z) d z=1$ while $\frac{1}{2 \pi i} \int_{\gamma} p(z) d z=0$. This shows you can't expect to be able to uniformly approximate analytic functions on compact sets using polynomials. This is just horrible! In real variables, you can approximate any continuous function on a compact set with a polynomial. However, that is just the way it is. It turns out that the ability to approximate an analytic function on $\Omega$ with polynomials is dependent on $\Omega$ being simply connected.

All these theorems work for $f$ having values in a complex Banach space. However, I will present them in the context of functions which have values in $\mathbb{C}$. The changes necessary to obtain the extra generality are very minor.

Definition 56.1.1 Approximation will be taken with respect to the following norm.

$$
\|f-g\|_{K, \infty} \equiv \sup \{\|f(z)-g(z)\|: z \in K\}
$$

### 56.1.1 Approximation With Rational Functions

It turns out you can approximate analytic functions by rational functions, quotients of polynomials. The resulting theorem is one of the most profound theorems in complex analysis. The basic idea is simple. The Riemann sums for the Cauchy integral formula are rational functions. The idea used to implement this observation is that if you have a compact subset, $K$ of an open set, $\Omega$ there exists a cycle composed of closed oriented curves $\left\{\gamma_{j}\right\}_{j=1}^{n}$ which are contained in $\Omega \backslash K$ such that for every $z \in K, \sum_{k=1}^{n} n\left(\gamma_{k}, z\right)=1$. One more ingredient is needed and this is a theorem which lets you keep the approximation but move the poles.

To begin with, consider the part about the cycle of closed oriented curves. Recall Theorem 51.7.25 which is stated for convenience.

Theorem 56.1.2 Let $K$ be a compact subset of an open set, $\Omega$. Then there exist continuous, closed, bounded variation oriented curves $\left\{\gamma_{j}\right\}_{j=1}^{m}$ for which $\gamma_{j}^{*} \cap K=\emptyset$ for each $j, \gamma_{j}^{*} \subseteq$ $\Omega$, and for all $p \in K$,

$$
\sum_{k=1}^{m} n\left(p, \gamma_{k}\right)=1
$$

and

$$
\sum_{k=1}^{m} n\left(z, \gamma_{k}\right)=0
$$

for all $z \notin \Omega$.

This theorem implies the following.
Theorem 56.1.3 Let $K \subseteq \Omega$ where $K$ is compact and $\Omega$ is open. Then there exist oriented closed curves, $\gamma_{k}$ such that $\gamma_{k}^{*} \cap K=\emptyset$ but $\gamma_{k}^{*} \subseteq \Omega$, such that for all $z \in K$,

$$
\begin{equation*}
f(z)=\frac{1}{2 \pi i} \sum_{k=1}^{p} \int_{\gamma_{k}} \frac{f(w)}{w-z} d w \tag{56.1.1}
\end{equation*}
$$

Proof: This follows from Theorem 51.7.25 and the Cauchy integral formula. As shown in the proof, you can assume the $\gamma_{k}$ are linear mappings but this is not important.

Next I will show how the Cauchy integral formula leads to approximation by rational functions, quotients of polynomials.

Lemma 56.1.4 Let $K$ be a compact subset of an open set, $\Omega$ and let $f$ be analytic on $\Omega$. Then there exists a rational function, $Q$ whose poles are not in $K$ such that

$$
\|Q-f\|_{K, \infty}<\varepsilon
$$

Proof: By Theorem 56.1.3 there are oriented curves, $\gamma_{k}$ described there such that for all $z \in K$,

$$
\begin{equation*}
f(z)=\frac{1}{2 \pi i} \sum_{k=1}^{p} \int_{\gamma_{k}} \frac{f(w)}{w-z} d w \tag{56.1.2}
\end{equation*}
$$

Defining $g(w, z) \equiv \frac{f(w)}{w-z}$ for $(w, z) \in \cup_{k=1}^{p} \gamma_{k}^{*} \times K$, it follows since the distance between $K$ and $\cup_{k} \gamma_{k}^{*}$ is positive that $g$ is uniformly continuous and so there exists a $\delta>0$ such that if $\|\mathscr{P}\|<\delta$, then for all $z \in K$,

$$
\left|f(z)-\frac{1}{2 \pi i} \sum_{k=1}^{p} \sum_{j=1}^{n} \frac{f\left(\gamma_{k}\left(\tau_{j}\right)\right)\left(\gamma_{k}\left(t_{i}\right)-\gamma_{k}\left(t_{i-1}\right)\right)}{\gamma_{k}\left(\tau_{j}\right)-z}\right|<\frac{\varepsilon}{2}
$$

The complicated expression is obtained by replacing each integral in 56.1 .2 with a Riemann sum. Simplifying the appearance of this, it follows there exists a rational function of the form

$$
R(z)=\sum_{k=1}^{M} \frac{A_{k}}{w_{k}-z}
$$

where the $w_{k}$ are elements of components of $\mathbb{C} \backslash K$ and $A_{k}$ are complex numbers or in the case where $f$ has values in $X$, these would be elements of $X$ such that

$$
\|R-f\|_{K, \infty}<\frac{\varepsilon}{2}
$$

This proves the lemma.

### 56.1.2 Moving The Poles And Keeping The Approximation

Lemma 56.1.4 is a nice lemma but needs refining. In this lemma, the Riemann sum handed you the poles. It is much better if you can pick the poles. The following theorem from advanced calculus, called Merten's theorem, will be used

### 56.1.3 Merten's Theorem.

Theorem 56.1.5 Suppose $\sum_{i=r}^{\infty} a_{i}$ and $\sum_{j=r}^{\infty} b_{j}$ both converge absolutely ${ }^{1}$. Then

$$
\left(\sum_{i=r}^{\infty} a_{i}\right)\left(\sum_{j=r}^{\infty} b_{j}\right)=\sum_{n=r}^{\infty} c_{n}
$$

where

$$
c_{n}=\sum_{k=r}^{n} a_{k} b_{n-k+r}
$$

Proof: Let $p_{n k}=1$ if $r \leq k \leq n$ and $p_{n k}=0$ if $k>n$. Then

$$
c_{n}=\sum_{k=r}^{\infty} p_{n k} a_{k} b_{n-k+r}
$$

Also,

$$
\begin{aligned}
\sum_{k=r}^{\infty} \sum_{n=r}^{\infty} p_{n k}\left|a_{k}\right|\left|b_{n-k+r}\right| & =\sum_{k=r}^{\infty}\left|a_{k}\right| \sum_{n=r}^{\infty} p_{n k}\left|b_{n-k+r}\right| \\
& =\sum_{k=r}^{\infty}\left|a_{k}\right| \sum_{n=k}^{\infty}\left|b_{n-k+r}\right| \\
& =\sum_{k=r}^{\infty}\left|a_{k}\right| \sum_{n=k}^{\infty}\left|b_{n-(k-r)}\right| \\
& =\sum_{k=r}^{\infty}\left|a_{k}\right| \sum_{m=r}^{\infty}\left|b_{m}\right|<\infty
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
\sum_{n=r}^{\infty} c_{n} & =\sum_{n=r}^{\infty} \sum_{k=r}^{n} a_{k} b_{n-k+r}=\sum_{n=r}^{\infty} \sum_{k=r}^{\infty} p_{n k} a_{k} b_{n-k+r} \\
& =\sum_{k=r}^{\infty} a_{k} \sum_{n=r}^{\infty} p_{n k} b_{n-k+r}=\sum_{k=r}^{\infty} a_{k} \sum_{n=k}^{\infty} b_{n-k+r} \\
& =\sum_{k=r}^{\infty} a_{k} \sum_{m=r}^{\infty} b_{m}
\end{aligned}
$$

and this proves the theorem.
It follows that $\sum_{n=r}^{\infty} c_{n}$ converges absolutely. Also, you can see by induction that you can multiply any number of absolutely convergent series together and obtain a series which is absolutely convergent. Next, here are some similar results related to Merten's theorem.

[^35]Lemma 56.1.6 Let $\sum_{n=0}^{\infty} a_{n}(z)$ and $\sum_{n=0}^{\infty} b_{n}(z)$ be two convergent series for $z \in K$ which satisfy the conditions of the Weierstrass $M$ test. Thus there exist positive constants, $A_{n}$ and $B_{n}$ such that $\left|a_{n}(z)\right| \leq A_{n},\left|b_{n}(z)\right| \leq B_{n}$ for all $z \in K$ and $\sum_{n=0}^{\infty} A_{n}<\infty, \sum_{n=0}^{\infty} B_{n}<\infty$. Then defining the Cauchy product,

$$
c_{n}(z) \equiv \sum_{k-0}^{n} a_{n-k}(z) b_{k}(z)
$$

it follows $\sum_{n=0}^{\infty} c_{n}(z)$ also converges absolutely and uniformly on $K$ because $c_{n}(z)$ satisfies the conditions of the Weierstrass $M$ test. Therefore,

$$
\begin{equation*}
\sum_{n=0}^{\infty} c_{n}(z)=\left(\sum_{k=0}^{\infty} a_{k}(z)\right)\left(\sum_{n=0}^{\infty} b_{n}(z)\right) \tag{56.1.3}
\end{equation*}
$$

Proof:

$$
\left|c_{n}(z)\right| \leq \sum_{k=0}^{n}\left|a_{n-k}(z)\right|\left|b_{k}(z)\right| \leq \sum_{k=0}^{n} A_{n-k} B_{k} .
$$

Also,

$$
\begin{aligned}
\sum_{n=0}^{\infty} \sum_{k=0}^{n} A_{n-k} B_{k} & =\sum_{k=0}^{\infty} \sum_{n=k}^{\infty} A_{n-k} B_{k} \\
& =\sum_{k=0}^{\infty} B_{k} \sum_{n=0}^{\infty} A_{n}<\infty
\end{aligned}
$$

The claim of 56.1.3 follows from Merten's theorem. This proves the lemma.
Corollary 56.1.7 Let $P$ be a polynomial and let $\sum_{n=0}^{\infty} a_{n}(z)$ converge uniformly and absolutely on $K$ such that the $a_{n}$ satisfy the conditions of the Weierstrass $M$ test. Then there exists a series for $P\left(\sum_{n=0}^{\infty} a_{n}(z)\right), \sum_{n=0}^{\infty} c_{n}(z)$, which also converges absolutely and uniformly for $z \in K$ because $c_{n}(z)$ also satisfies the conditions of the Weierstrass $M$ test.

The following picture is descriptive of the following lemma. This lemma says that if you have a rational function with one pole off a compact set, then you can approximate on the compact set with another rational function which has a different pole.

Lemma 56.1.8 Let $R$ be a rational function which has a pole only at $a \in V$, a component of $\mathbb{C} \backslash K$ where $K$ is a compact set. Suppose $b \in V$. Then for $\varepsilon>0$ given, there exists $a$ rational function, $Q$, having a pole only at $b$ such that

$$
\begin{equation*}
\|R-Q\|_{K, \infty}<\varepsilon \tag{56.1.4}
\end{equation*}
$$

If it happens that $V$ is unbounded, then there exists a polynomial, $P$ such that

$$
\begin{equation*}
\|R-P\|_{K, \infty}<\varepsilon \tag{56.1.5}
\end{equation*}
$$

Proof: Say that $b \in V$ satisfies $\mathscr{P}$ if for all $\varepsilon>0$ there exists a rational function, $Q_{b}$, having a pole only at $b$ such that

$$
\left\|R-Q_{b}\right\|_{K, \infty}<\varepsilon
$$

Now define a set,

$$
S \equiv\{b \in V: b \text { satisfies } \mathscr{P}\}
$$

Observe that $S \neq \emptyset$ because $a \in S$.
I claim $S$ is open. Suppose $b_{1} \in S$. Then there exists a $\delta>0$ such that

$$
\begin{equation*}
\left|\frac{b_{1}-b}{z-b}\right|<\frac{1}{2} \tag{56.1.6}
\end{equation*}
$$

for all $z \in K$ whenever $b \in B\left(b_{1}, \boldsymbol{\delta}\right)$. In fact, it suffices to take $\left|b-b_{1}\right|<\operatorname{dist}\left(b_{1}, K\right) / 4$ because then

$$
\begin{aligned}
\left|\frac{b_{1}-b}{z-b}\right| & <\left|\frac{\operatorname{dist}\left(b_{1}, K\right) / 4}{z-b}\right| \leq \frac{\operatorname{dist}\left(b_{1}, K\right) / 4}{\left|z-b_{1}\right|-\left|b_{1}-b\right|} \\
& \leq \frac{\operatorname{dist}\left(b_{1}, K\right) / 4}{\operatorname{dist}\left(b_{1}, K\right)-\operatorname{dist}\left(b_{1}, K\right) / 4} \leq \frac{1}{3}<\frac{1}{2}
\end{aligned}
$$

Since $b_{1}$ satisfies $\mathscr{P}$, there exists a rational function $Q_{b_{1}}$ with the desired properties. It is shown next that you can approximate $Q_{b_{1}}$ with $Q_{b}$ thus yielding an approximation to $R$ by the use of the triangle inequality,

$$
\left\|R-Q_{b_{1}}\right\|_{K, \infty}+\left\|Q_{b_{1}}-Q_{b}\right\|_{K, \infty} \geq\left\|R-Q_{b}\right\|_{K, \infty}
$$

Since $Q_{b_{1}}$ has poles only at $b_{1}$, it follows it is a sum of functions of the form $\frac{\alpha_{n}}{\left(z-b_{1}\right)^{n}}$. Therefore, it suffices to consider the terms of $Q_{b_{1}}$ or that $Q_{b_{1}}$ is of the special form

$$
Q_{b_{1}}(z)=\frac{1}{\left(z-b_{1}\right)^{n}}
$$

However,

$$
\frac{1}{\left(z-b_{1}\right)^{n}}=\frac{1}{(z-b)^{n}\left(1-\frac{b_{1}-b}{z-b}\right)^{n}}
$$

Now from the choice of $b_{1}$, the series

$$
\sum_{k=0}^{\infty}\left(\frac{b_{1}-b}{z-b}\right)^{k}=\frac{1}{\left(1-\frac{b_{1}-b}{z-b}\right)}
$$

converges absolutely independent of the choice of $z \in K$ because

$$
\left|\left(\frac{b_{1}-b}{z-b}\right)^{k}\right|<\frac{1}{2^{k}}
$$

By Corollary 56.1.7 the same is true of the series for $\frac{1}{\left(1-\frac{b_{1}-b}{z-b}\right)^{n}}$. Thus a suitable partial sum can be made uniformly on $K$ as close as desired to $\frac{1}{\left(z-b_{1}\right)^{n}}$. This shows that $b$ satisfies $\mathscr{P}$ whenever $b$ is close enough to $b_{1}$ verifying that $S$ is open.

Next it is shown $S$ is closed in $V$. Let $b_{n} \in S$ and suppose $b_{n} \rightarrow b \in V$. Then since $b_{n} \in S$, there exists a rational function, $Q_{b_{n}}$ such that

$$
\left\|Q_{b_{n}}-R\right\|_{K, \infty}<\frac{\varepsilon}{2}
$$

Then for all $n$ large enough,

$$
\frac{1}{2} \operatorname{dist}(b, K) \geq\left|b_{n}-b\right|
$$

and so for all $n$ large enough,

$$
\left|\frac{b-b_{n}}{z-b_{n}}\right|<\frac{1}{2}
$$

for all $z \in K$. Pick such a $b_{n}$. As before, it suffices to assume $Q_{b_{n}}$, is of the form $\frac{1}{\left(z-b_{n}\right)^{n}}$. Then

$$
Q_{b_{n}}(z)=\frac{1}{\left(z-b_{n}\right)^{n}}=\frac{1}{(z-b)^{n}\left(1-\frac{b_{n}-b}{z-b}\right)^{n}}
$$

and because of the estimate, there exists $M$ such that for all $z \in K$

$$
\begin{equation*}
\left|\frac{1}{\left(1-\frac{b_{n}-b}{z-b}\right)^{n}}-\sum_{k=0}^{M} a_{k}\left(\frac{b_{n}-b}{z-b}\right)^{k}\right|<\frac{\varepsilon(\operatorname{dist}(b, K))^{n}}{2} \tag{56.1.7}
\end{equation*}
$$

Therefore, for all $z \in K$

$$
\begin{aligned}
\left|Q_{b_{n}}(z)-\frac{1}{(z-b)^{n}} \sum_{k=0}^{M} a_{k}\left(\frac{b_{n}-b}{z-b}\right)^{k}\right| & = \\
\left|\frac{1}{(z-b)^{n}\left(1-\frac{b_{n}-b}{z-b}\right)^{n}}-\frac{1}{(z-b)^{n}} \sum_{k=0}^{M} a_{k}\left(\frac{b_{n}-b}{z-b}\right)^{k}\right| & \leq \\
\frac{\varepsilon(\operatorname{dist}(b, K))^{n}}{2} \frac{1}{\operatorname{dist}(b, K)^{n}} & =\frac{\varepsilon}{2}
\end{aligned}
$$

and so, letting $Q_{b}(z)=\frac{1}{(z-b)^{n}} \sum_{k=0}^{M} a_{k}\left(\frac{b_{n}-b}{z-b}\right)^{k}$,

$$
\begin{aligned}
\left\|R-Q_{b}\right\|_{K, \infty} & \leq\left\|R-Q_{b_{n}}\right\|_{K, \infty}+\left\|Q_{b_{n}}-Q_{b}\right\|_{K, \infty} \\
& <\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
\end{aligned}
$$

showing that $b \in S$. Since $S$ is both open and closed in $V$ it follows that, since $S \neq \emptyset, S=V$. Otherwise $V$ would fail to be connected.

It remains to consider the case where $V$ is unbounded. Pick $b \in V$ large enough that

$$
\begin{equation*}
\left|\frac{z}{b}\right|<\frac{1}{2} \tag{56.1.8}
\end{equation*}
$$

for all $z \in K$. From what was just shown, there exists a rational function, $Q_{b}$ having a pole only at $b$ such that $\left\|Q_{b}-R\right\|_{K, \infty}<\frac{\varepsilon}{2}$. It suffices to assume that $Q_{b}$ is of the form

$$
\begin{aligned}
Q_{b}(z) & =\frac{p(z)}{(z-b)^{n}}=p(z)(-1)^{n} \frac{1}{b^{n}} \frac{1}{\left(1-\frac{z}{b}\right)^{n}} \\
& =p(z)(-1)^{n} \frac{1}{b^{n}}\left(\sum_{k=0}^{\infty}\left(\frac{z}{b}\right)^{k}\right)^{n}
\end{aligned}
$$

Then by an application of Corollary 56.1.7 there exists a partial sum of the power series for $Q_{b}$ which is uniformly close to $Q_{b}$ on $K$. Therefore, you can approximate $Q_{b}$ and therefore also $R$ uniformly on $K$ by a polynomial consisting of a partial sum of the above infinite sum. This proves the theorem.

If $f$ is a polynomial, then $f$ has a pole at $\infty$. This will be discussed more later.

### 56.1.4 Runge's Theorem

Now what follows is the first form of Runge's theorem.
Theorem 56.1.9 Let $K$ be a compact subset of an open set, $\Omega$ and let $\left\{b_{j}\right\}$ be a set which consists of one point from each component of $\widehat{\mathbb{C}} \backslash K$. Let $f$ be analytic on $\Omega$. Then for each $\varepsilon>0$, there exists a rational function, $Q$ whose poles are all contained in the set, $\left\{b_{j}\right\}$ such that

$$
\begin{equation*}
\|Q-f\|_{K, \infty}<\varepsilon \tag{56.1.9}
\end{equation*}
$$

If $\widehat{\mathbb{C}} \backslash K$ has only one component, then $Q$ may be taken to be a polynomial.
Proof: By Lemma 56.1.4 there exists a rational function of the form

$$
R(z)=\sum_{k=1}^{M} \frac{A_{k}}{w_{k}-z}
$$

where the $w_{k}$ are elements of components of $\mathbb{C} \backslash K$ and $A_{k}$ are complex numbers such that

$$
\|R-f\|_{K, \infty}<\frac{\varepsilon}{2}
$$

Consider the rational function, $R_{k}(z) \equiv \frac{A_{k}}{w_{k}-z}$ where $w_{k} \in V_{j}$, one of the components of $\mathbb{C} \backslash K$, the given point of $V_{j}$ being $b_{j}$. By Lemma 56.1 .8 , there exists a function, $Q_{k}$ which is either a rational function having its only pole at $b_{j}$ or a polynomial, depending on whether $V_{j}$ is bounded such that

$$
\left\|R_{k}-Q_{k}\right\|_{K, \infty}<\frac{\varepsilon}{2 M}
$$

Letting $Q(z) \equiv \sum_{k=1}^{M} Q_{k}(z)$,

$$
\|R-Q\|_{K, \infty}<\frac{\varepsilon}{2}
$$

It follows

$$
\|f-Q\|_{K, \infty} \leq\|f-R\|_{K, \infty}+\|R-Q\|_{K, \infty}<\varepsilon .
$$

In the case of only one component of $\mathbb{C} \backslash K$, this component is the unbounded component and so you can take $Q$ to be a polynomial. This proves the theorem.

The next version of Runge's theorem concerns the case where the given points are contained in $\widehat{\mathbb{C}} \backslash \Omega$ for $\Omega$ an open set rather than a compact set. Note that here there could be uncountably many components of $\widehat{\mathbb{C}} \backslash \Omega$ because the components are no longer open sets. An easy example of this phenomenon in one dimension is where $\Omega=[0,1] \backslash P$ for $P$ the Cantor set. Then you can show that $\mathbb{R} \backslash \Omega$ has uncountably many components. Nevertheless, Runge's theorem will follow from Theorem 56.1.9 with the aid of the following interesting lemma.

Lemma 56.1.10 Let $\Omega$ be an open set in $\mathbb{C}$. Then there exists a sequence of compact sets, $\left\{K_{n}\right\}$ such that

$$
\begin{equation*}
\Omega=\cup_{k=1}^{\infty} K_{n}, \cdots, K_{n} \subseteq \operatorname{int} K_{n+1} \cdots \tag{56.1.10}
\end{equation*}
$$

and for any $K \subseteq \Omega$,

$$
\begin{equation*}
K \subseteq K_{n} \tag{56.1.11}
\end{equation*}
$$

for all $n$ sufficiently large, and every component of $\widehat{\mathbb{C}} \backslash K_{n}$ contains a component of $\widehat{\mathbb{C}} \backslash \Omega$.
Proof: Let

$$
V_{n} \equiv\{z:|z|>n\} \cup \bigcup_{z \notin \Omega} B\left(z, \frac{1}{n}\right)
$$

Thus $\{z:|z|>n\}$ contains the point, $\infty$. Now let

$$
K_{n} \equiv \widehat{\mathbb{C}} \backslash V_{n}=\mathbb{C} \backslash V_{n} \subseteq \Omega
$$

You should verify that 56.1 .10 and 56.1.11 hold. It remains to show that every component of $\widehat{\mathbb{C}} \backslash K_{n}$ contains a component of $\widehat{\mathbb{C}} \backslash \Omega$. Let $D$ be a component of $\widehat{\mathbb{C}} \backslash K_{n} \equiv V_{n}$.

If $\infty \notin D$, then $D$ contains no point of $\{z:|z|>n\}$ because this set is connected and $D$ is a component. (If it did contain a point of this set, it would have to contain the whole set.) Therefore, $D \subseteq \bigcup_{z \notin \Omega} B\left(z, \frac{1}{n}\right)$ and so $D$ contains some point of $B\left(z, \frac{1}{n}\right)$ for some $z \notin$ $\Omega$. Therefore, since this ball is connected, it follows $D$ must contain the whole ball and consequently $D$ contains some point of $\Omega^{C}$. (The point $z$ at the center of the ball will do.)

Since $D$ contains $z \notin \Omega$, it must contain the component, $H_{z}$, determined by this point. The reason for this is that

$$
H_{z} \subseteq \widehat{\mathbb{C}} \backslash \Omega \subseteq \widehat{\mathbb{C}} \backslash K_{n}
$$

and $H_{z}$ is connected. Therefore, $H_{z}$ can only have points in one component of $\widehat{\mathbb{C}} \backslash K_{n}$. Since it has a point in $D$, it must therefore, be totally contained in $D$. This verifies the desired condition in the case where $\infty \notin D$.

Now suppose that $\infty \in D . \infty \notin \Omega$ because $\Omega$ is given to be a set in $\mathbb{C}$. Letting $H_{\infty}$ denote the component of $\widehat{\mathbb{C}} \backslash \Omega$ determined by $\infty$, it follows both $D$ and $H_{\infty}$ contain $\infty$. Therefore, the connected set, $H_{\infty}$ cannot have any points in another component of $\widehat{\mathbb{C}} \backslash K_{n}$ and it is a set which is contained in $\widehat{\mathbb{C}} \backslash K_{n}$ so it must be contained in $D$. This proves the lemma.

The following picture is a very simple example of the sort of thing considered by Runge's theorem. The picture is of a region which has a couple of holes.

However, there could be many more holes than two. In fact, there could be infinitely many. Nor does it follow that the components of the complement of $\Omega$ need to have any interior points. Therefore, the picture is certainly not representative.

Theorem 56.1.11 (Runge) Let $\Omega$ be an open set, and let A be a set which has one point in each component of $\widehat{\mathbb{C}} \backslash \Omega$ and let $f$ be analytic on $\Omega$. Then there exists a sequence of rational functions, $\left\{R_{n}\right\}$ having poles only in $A$ such that $R_{n}$ converges uniformly to $f$ on compact subsets of $\Omega$.

Proof: Let $K_{n}$ be the compact sets of Lemma 56.1 .10 where each component of $\widehat{\mathbb{C}} \backslash K_{n}$ contains a component of $\widehat{\mathbb{C}} \backslash \Omega$. It follows each component of $\widehat{\mathbb{C}} \backslash K_{n}$ contains a point of $A$. Therefore, by Theorem 56.1.9 there exists $R_{n}$ a rational function with poles only in $A$ such that

$$
\left\|R_{n}-f\right\|_{K_{n}, \infty}<\frac{1}{n}
$$

It follows, since a given compact set, $K$ is a subset of $K_{n}$ for all $n$ large enough, that $R_{n} \rightarrow f$ uniformly on $K$. This proves the theorem.

Corollary 56.1.12 Let $\Omega$ be simply connected and $f$ analytic on $\Omega$. Then there exists $a$ sequence of polynomials, $\left\{p_{n}\right\}$ such that $p_{n} \rightarrow f$ uniformly on compact sets of $\Omega$.

Proof: By definition of what is meant by simply connected, $\widehat{\mathbb{C}} \backslash \Omega$ is connected and so there are no bounded components of $\widehat{\mathbb{C}} \backslash \Omega$. Therefore, in the proof of Theorem 56.1.11 when you use Theorem 56.1.9, you can always have $R_{n}$ be a polynomial by Lemma 56.1.8.

### 56.2 The Mittag-Leffler Theorem

### 56.2.1 A Proof From Runge's Theorem

This theorem is fairly easy to prove once you have Theorem 56.1.9. Given a set of complex numbers, does there exist a meromorphic function having its poles equal to this set of numbers? The Mittag-Leffler theorem provides a very satisfactory answer to this question. Actually, it says somewhat more. You can specify, not just the location of the pole but also the kind of singularity the meromorphic function is to have at that pole.

Theorem 56.2.1 Let $P \equiv\left\{z_{k}\right\}_{k=1}^{\infty}$ be a set of points in an open subset of $\mathbb{C}, \Omega$. Suppose also that $P \subseteq \Omega \subseteq \mathbb{C}$. For each $z_{k}$, denote by $S_{k}(z)$ a function of the form

$$
S_{k}(z)=\sum_{j=1}^{m_{k}} \frac{a_{j}^{k}}{\left(z-z_{k}\right)^{j}}
$$

Then there exists a meromorphic function, $Q$ defined on $\Omega$ such that the poles of $Q$ are the points, $\left\{z_{k}\right\}_{k=1}^{\infty}$ and the singular part of the Laurent expansion of $Q$ at $z_{k}$ equals $S_{k}(z)$. In other words, for $z$ near $z_{k}, Q(z)=g_{k}(z)+S_{k}(z)$ for some function, $g_{k}$ analytic near $z_{k}$.

Proof: Let $\left\{K_{n}\right\}$ denote the sequence of compact sets described in Lemma 56.1.10. Thus $\cup_{n=1}^{\infty} K_{n}=\Omega, K_{n} \subseteq \operatorname{int}\left(K_{n+1}\right) \subseteq K_{n+1} \cdots$, and the components of $\widehat{\mathbb{C}} \backslash K_{n}$ contain the components of $\widehat{\mathbb{C}} \backslash \Omega$. Renumbering if necessary, you can assume each $K_{n} \neq \emptyset$. Also let $K_{0}=\emptyset$. Let $P_{m} \equiv P \cap\left(K_{m} \backslash K_{m-1}\right)$ and consider the rational function, $R_{m}$ defined by

$$
R_{m}(z) \equiv \sum_{z_{k} \in K_{m} \backslash K_{m-1}} S_{k}(z)
$$

Since each $K_{m}$ is compact, it follows $P_{m}$ is finite and so the above really is a rational function. Now for $m>1$, this rational function is analytic on some open set containing $K_{m-1}$. There exists a set of points, $A$ one point in each component of $\widehat{\mathbb{C}} \backslash \Omega$. Consider $\widehat{\mathbb{C}} \backslash K_{m-1}$. Each of its components contains a component of $\widehat{\mathbb{C}} \backslash \Omega$ and so for each of these components of $\widehat{\mathbb{C}} \backslash K_{m-1}$, there exists a point of $A$ which is contained in it. Denote the resulting set of points by $A^{\prime}$. By Theorem 56.1.9 there exists a rational function, $Q_{m}$ whose poles are all contained in the set, $A^{\prime} \subseteq \Omega^{C}$ such that

$$
\left\|R_{m}-Q_{m}\right\|_{K_{m-1, \infty}}<\frac{1}{2^{m}}
$$

The meromorphic function is

$$
Q(z) \equiv R_{1}(z)+\sum_{k=2}^{\infty}\left(R_{k}(z)-Q_{k}(z)\right)
$$

It remains to verify this function works. First consider $K_{1}$. Then on $K_{1}$, the above sum converges uniformly. Furthermore, the terms of the sum are analytic in some open set containing $K_{1}$. Therefore, the infinite sum is analytic on this open set and so for $z \in K_{1}$

The function, $f$ is the sum of a rational function, $R_{1}$, having poles at $P_{1}$ with the specified singular terms and an analytic function. Therefore, $Q$ works on $K_{1}$. Now consider $K_{m}$ for $m>1$. Then

$$
Q(z)=R_{1}(z)+\sum_{k=2}^{m+1}\left(R_{k}(z)-Q_{k}(z)\right)+\sum_{k=m+2}^{\infty}\left(R_{k}(z)-Q_{k}(z)\right) .
$$

As before, the infinite sum converges uniformly on $K_{m+1}$ and hence on some open set, $O$ containing $K_{m}$. Therefore, this infinite sum equals a function which is analytic on $O$. Also,

$$
R_{1}(z)+\sum_{k=2}^{m+1}\left(R_{k}(z)-Q_{k}(z)\right)
$$

is a rational function having poles at $\cup_{k=1}^{m} P_{k}$ with the specified singularities because the poles of each $Q_{k}$ are not in $\Omega$. It follows this function is meromorphic because it is analytic except for the points in $P$. It also has the property of retaining the specified singular behavior.

### 56.2.2 A Direct Proof Without Runge's Theorem

There is a direct proof of this important theorem which is not dependent on Runge's theorem in the case where $\Omega=\mathbb{C}$. I think it is arguably easier to understand and the MittagLeffler theorem is very important so I will give this proof here.

Theorem 56.2.2 Let $P \equiv\left\{z_{k}\right\}_{k=1}^{\infty}$ be a set of points in $\mathbb{C}$ which satisfies $\lim _{n \rightarrow \infty}\left|z_{n}\right|=\infty$. For each $z_{k}$, denote by $S_{k}(z)$ a polynomial in $\frac{1}{z-z_{k}}$ which is of the form

$$
S_{k}(z)=\sum_{j=1}^{m_{k}} \frac{a_{j}^{k}}{\left(z-z_{k}\right)^{j}}
$$

Then there exists a meromorphic function, $Q$ defined on $\mathbb{C}$ such that the poles of $Q$ are the points, $\left\{z_{k}\right\}_{k=1}^{\infty}$ and the singular part of the Laurent expansion of $Q$ at $z_{k}$ equals $S_{k}(z)$. In other words, for $z$ near $z_{k}$,

$$
Q(z)=g_{k}(z)+S_{k}(z)
$$

for some function, $g_{k}$ analytic in some open set containing $z_{k}$.
Proof: First consider the case where none of the $z_{k}=0$. Letting

$$
K_{k} \equiv\left\{z:|z| \leq\left|z_{k}\right| / 2\right\}
$$

there exists a power series for $\frac{1}{z-z_{k}}$ which converges uniformly and absolutely on this set. Here is why:

$$
\frac{1}{z-z_{k}}=\left(\frac{-1}{1-\frac{z}{z_{k}}}\right) \frac{1}{z_{k}}=\frac{-1}{z_{k}} \sum_{l=0}^{\infty}\left(\frac{z}{z_{k}}\right)^{l}
$$

and the Weierstrass $M$ test can be applied because

$$
\left|\frac{z}{z_{k}}\right|<\frac{1}{2}
$$

on this set. Therefore, by Corollary 56.1.7, $S_{k}(z)$, being a polynomial in $\frac{1}{z-z_{k}}$, has a power series which converges uniformly to $S_{k}(z)$ on $K_{k}$. Therefore, there exists a polynomial, $P_{k}(z)$ such that

$$
\left\|P_{k}-S_{k}\right\|_{\overline{B\left(0,\left|z_{k}\right| / 2\right), \infty}}<\frac{1}{2^{k}}
$$

Let

$$
\begin{equation*}
Q(z) \equiv \sum_{k=1}^{\infty}\left(S_{k}(z)-P_{k}(z)\right) \tag{56.2.12}
\end{equation*}
$$

Consider $z \in K_{m}$ and let $N$ be large enough that if $k>N$, then $\left|z_{k}\right|>2|z|$

$$
Q(z)=\sum_{k=1}^{N}\left(S_{k}(z)-P_{k}(z)\right)+\sum_{k=N+1}^{\infty}\left(S_{k}(z)-P_{k}(z)\right) .
$$

On $K_{m}$, the second sum converges uniformly to a function analytic on int $\left(K_{m}\right)$ (interior of $K_{m}$ ) while the first is a rational function having poles at $z_{1}, \cdots, z_{N}$. Since any compact set is contained in $K_{m}$ for large enough $m$, this shows $Q(z)$ is meromorphic as claimed and has poles with the given singularities.

Now consider the case where the poles are at $\left\{z_{k}\right\}_{k=0}^{\infty}$ with $z_{0}=0$. Everything is similar in this case. Let

$$
Q(z) \equiv S_{0}(z)+\sum_{k=1}^{\infty}\left(S_{k}(z)-P_{k}(z)\right)
$$

The series converges uniformly on every compact set because of the assumption that

$$
\lim _{n \rightarrow \infty}\left|z_{n}\right|=\infty
$$

which implies that any compact set is contained in $K_{k}$ for $k$ large enough. Choose $N$ such that $z \in \operatorname{int}\left(K_{N}\right)$ and $z_{n} \notin K_{N}$ for all $n \geq N+1$. Then

$$
Q(z)=S_{0}(z)+\sum_{k=1}^{N}\left(S_{k}(z)-P_{k}(z)\right)+\sum_{k=N+1}^{\infty}\left(S_{k}(z)-P_{k}(z)\right)
$$

The last sum is analytic on $\operatorname{int}\left(K_{N}\right)$ because each function in the sum is analytic due to the fact that none of its poles are in $K_{N}$. Also, $S_{0}(z)+\sum_{k=1}^{N}\left(S_{k}(z)-P_{k}(z)\right)$ is a finite sum of rational functions so it is a rational function and $P_{k}$ is a polynomial so $z_{m}$ is a pole of this function with the correct singularity whenever $z_{m} \in \operatorname{int}\left(K_{N}\right)$.

### 56.2.3 Functions Meromorphic On $\widehat{\mathbb{C}}$

Sometimes it is useful to think of isolated singular points at $\infty$.

Definition 56.2.3 Suppose $f$ is analytic on $\{z \in \mathbb{C}:|z|>r\}$. Then $f$ is said to have a removable singularity at $\infty$ if the function, $g(z) \equiv f\left(\frac{1}{z}\right)$ has a removable singularity at 0 . $f$ is said to have a pole at $\infty$ if the function, $g(z)=f\left(\frac{1}{z}\right)$ has a pole at 0 . Then $f$ is said to be meromorphic on $\widehat{\mathbb{C}}$ if all its singularities are isolated and either poles or removable.

So what is $f$ like for these cases? First suppose $f$ has a removable singularity at $\infty$ $\left(f\left(\frac{1}{z}\right)=g(z)\right.$ has a removable singularity at 0 ). Then $z g(z)$ converges to 0 as $z \rightarrow 0$. It follows $g(z)$ must be analytic near 0 and so can be given as a power series. Thus $f(z)$ is of the form $f(z)=g\left(\frac{1}{z}\right)=\sum_{n=0}^{\infty} a_{n}\left(\frac{1}{z}\right)^{n}$. Next suppose $f$ has a pole at $\infty$. This means $g(z)$ has a pole at 0 so $g(z)$ is of the form $g(z)=\sum_{k=1}^{m} \frac{b_{k}}{z^{k}}+h(z)$ where $h(z)$ is analytic near 0 . Thus in the case of a pole at $\infty, f(z)$ is of the form $f(z)=g\left(\frac{1}{z}\right)=\sum_{k=1}^{m} b_{k} z^{k}+\sum_{n=0}^{\infty} a_{n}\left(\frac{1}{z}\right)^{n}$.

It turns out that the functions which are meromorphic on $\widehat{\mathbb{C}}$ are all rational functions. To see this, suppose $f$ is meromorphic on $\widehat{\mathbb{C}}$ and note that there exists $r>0$ such that $f(z)$ is analytic for $|z|>r$. This is required if $\infty$ is to be isolated. Therefore, there are only finitely many poles of $f$ for $|z| \leq r,\left\{a_{1}, \cdots, a_{m}\right\}$, because by assumption, these poles are isolated and this is a compact set. Let the singular part of $f$ at $a_{k}$ be denoted by $S_{k}(z)$. Then $f(z)-\sum_{k=1}^{m} S_{k}(z)$ is analytic on all of $\mathbb{C}$. Therefore, it is bounded on $|z| \leq r$. In one case, $f$ has a removable singularity at $\infty$. In this case, $f$ is bounded as $z \rightarrow \infty$ and $\sum_{k} S_{k}$ also converges to 0 as $z \rightarrow \infty$. Therefore, by Liouville's theorem, $f(z)-\sum_{k=1}^{m} S_{k}(z)$ equals a constant and so $f-\sum_{k} S_{k}$ is a constant. Thus $f$ is a rational function. In the other case that $f$ has a pole at $\infty, f(z)-\sum_{k=1}^{m} S_{k}(z)-\sum_{k=1}^{m} b_{k} z^{k}=\sum_{n=0}^{\infty} a_{n}\left(\frac{1}{z}\right)^{n}-\sum_{k=1}^{m} S_{k}(z)$. Now $f(z)-\sum_{k=1}^{m} S_{k}(z)-\sum_{k=1}^{m} b_{k} z^{k}$ is analytic on $\mathbb{C}$ and so is bounded on $|z| \leq r$. But now $\sum_{n=0}^{\infty} a_{n}\left(\frac{1}{z}\right)^{n}-\sum_{k=1}^{m} S_{k}(z)$ converges to 0 as $z \rightarrow \infty$ and so by Liouville's theorem, $f(z)-$ $\sum_{k=1}^{m} S_{k}(z)-\sum_{k=1}^{m} b_{k} z^{k}$ must equal a constant and again, $f(z)$ equals a rational function.

### 56.2.4 Great And Glorious Theorem, Simply Connected Regions

Here is given a laundry list of properties which are equivalent to an open set being simply connected. Recall Definition 51.7.21 on Page 1643 which said that an open set, $\Omega$ is simply connected means $\widehat{\mathbb{C}} \backslash \Omega$ is connected. Recall also that this is not the same thing at all as saying $\mathbb{C} \backslash \Omega$ is connected. Consider the outside of a disk for example. I will continue to use this definition for simply connected because it is the most convenient one for complex analysis. However, there are many other equivalent conditions. First here is an interesting lemma which is interesting for its own sake. Recall $n(p, \gamma)$ means the winding number of $\gamma$ about $p$. Now recall Theorem 51.7.25 implies the following lemma in which $B^{C}$ is playing the role of $\Omega$ in Theorem 51.7.25.

Lemma 56.2.4 Let $K$ be a compact subset of $B^{C}$, the complement of a closed set. Then there exist continuous, closed, bounded variation oriented curves $\left\{\Gamma_{j}\right\}_{j=1}^{m}$ for which $\Gamma_{j}^{*} \cap$ $K=\emptyset$ for each $j, \Gamma_{j}^{*} \subseteq \Omega$, and for all $p \in K$,

$$
\sum_{k=1}^{m} n\left(\Gamma_{k}, p\right)=1
$$

while for all $z \in B$

$$
\sum_{k=1}^{m} n\left(\Gamma_{k}, z\right)=0
$$

Definition 56.2.5 Let $\gamma$ be a closed curve in an open set, $\Omega, \gamma:[a, b] \rightarrow \Omega$. Then $\gamma$ is said to be homotopic to a point, $p$ in $\Omega$ if there exists a continuous function, $H:[0,1] \times[a, b] \rightarrow \Omega$ such that $H(0, t)=p, H(\alpha, a)=H(\alpha, b)$, and $H(1, t)=\gamma(t)$. This function, $H$ is called a homotopy.

Lemma 56.2.6 Suppose $\gamma$ is a closed continuous bounded variation curve in an open set, $\Omega$ which is homotopic to a point. Then if $a \notin \Omega$, it follows $n(a, \gamma)=0$.

Proof: Let $H$ be the homotopy described above. The problem with this is that it is not known that $H(\alpha, \cdot)$ is of bounded variation. There is no reason it should be. Therefore, it might not make sense to take the integral which defines the winding number. There are various ways around this. Extend $H$ as follows. $H(\alpha, t)=H(\alpha, a)$ for $t<a, H(\alpha, t)=$ $H(\alpha, b)$ for $t>b$. Let $\varepsilon>0$.

$$
H_{\varepsilon}(\alpha, t) \equiv \frac{1}{2 \varepsilon} \int_{-2 \varepsilon+t+\frac{2 \varepsilon}{(b-a)}(t-a)}^{t+\frac{2 \varepsilon}{(b-a)}(t-a)} H(\alpha, s) d s, H_{\varepsilon}(0, t)=p
$$

Thus $H_{\mathcal{E}}(\alpha, \cdot)$ is a closed curve which has bounded variation and when $\alpha=1$, this converges to $\gamma$ uniformly on $[a, b]$. Therefore, for $\varepsilon$ small enough, $n\left(a, H_{\varepsilon}(1, \cdot)\right)=n(a, \gamma)$ because they are both integers and as $\varepsilon \rightarrow 0, n\left(a, H_{\varepsilon}(1, \cdot)\right) \rightarrow n(a, \gamma)$. Also, $H_{\varepsilon}(\alpha, t) \rightarrow$ $H(\alpha, t)$ uniformly on $[0,1] \times[a, b]$ because of uniform continuity of $H$. Therefore, for small enough $\varepsilon$, you can also assume $H_{\mathcal{E}}(\alpha, t) \in \Omega$ for all $\alpha, t$. Now $\alpha \rightarrow n\left(a, H_{\mathcal{E}}(\alpha, \cdot)\right)$ is continuous. Hence it must be constant because the winding number is integer valued. But

$$
\lim _{\alpha \rightarrow 0} \frac{1}{2 \pi i} \int_{H_{\varepsilon}(\alpha, \cdot)} \frac{1}{z-a} d z=0
$$

because the length of $H_{\varepsilon}(\alpha, \cdot)$ converges to 0 and the integrand is bounded because $a \notin \Omega$. Therefore, the constant can only equal 0 . This proves the lemma.

Now it is time for the great and glorious theorem on simply connected regions. The following equivalence of properties is taken from Rudin [113]. There is a slightly different list in Conway [32] and a shorter list in Ash [7].

Theorem 56.2.7 The following are equivalent for an open set, $\Omega \neq \mathbb{C}$.

1. $\Omega$ is homeomorphic to the unit disk, $B(0,1)$.
2. Every closed curve contained in $\Omega$ is homotopic to a point in $\Omega$.
3. If $z \notin \Omega$, and if $\gamma$ is a closed bounded variation continuous curve in $\Omega$, then $n(\gamma, z)=$ 0 .
4. $\Omega$ is simply connected, ( $\widehat{\mathbb{C}} \backslash \Omega$ is connected and $\Omega$ is connected.)
5. Every function analytic on $\Omega$ can be uniformly approximated by polynomials on compact subsets.
6. For every $f$ analytic on $\Omega$ and every closed continuous bounded variation curve, $\gamma$,

$$
\int_{\gamma} f(z) d z=0
$$

7. Every function analytic on $\Omega$ has a primitive on $\Omega$.
8. If $f, 1 / f$ are both analytic on $\Omega$, then there exists an analytic, $g$ on $\Omega$ such that $f=\exp (g)$.
9. If $f, 1 / f$ are both analytic on $\Omega$, then there exists $\phi$ analytic on $\Omega$ such that $f=\phi^{2}$.

Proof: $1 \Rightarrow 2$. Assume 1 and let $\gamma$ be a closed curve in $\Omega$. Let $h$ be the homeomorphism, $h: B(0,1) \rightarrow \Omega$. Let $H(\alpha, t)=h\left(\alpha\left(h^{-1} \gamma(t)\right)\right)$. This works.
$2 \Rightarrow 3$ This is Lemma 56.2.6.
$3 \Rightarrow 4$. Suppose 3 but 4 fails to hold. Then if $\widehat{\mathbb{C}} \backslash \Omega$ is not connected, there exist disjoint nonempty sets, $A$ and $B$ such that $\bar{A} \cap B=A \cap \bar{B}=\emptyset$. It follows each of these sets must be closed because neither can have a limit point in $\Omega$ nor in the other. Also, one and only one of them contains $\infty$. Let this set be $B$. Thus $A$ is a closed set which must also be bounded. Otherwise, there would exist a sequence of points in $A,\left\{a_{n}\right\}$ such that $\lim _{n \rightarrow \infty} a_{n}=\infty$ which would contradict the requirement that no limit points of $A$ can be in $B$. Therefore, $A$ is a compact set contained in the open set, $B^{C} \equiv\{z \in \mathbb{C}: z \notin B\}$. Pick $p \in A$. By Lemma 56.2.4 there exist continuous bounded variation closed curves $\left\{\Gamma_{k}\right\}_{k=1}^{m}$ which are contained in $B^{C}$, do not intersect $A$ and such that

$$
1=\sum_{k=1}^{m} n\left(p, \Gamma_{k}\right)
$$

However, if these curves do not intersect $A$ and they also do not intersect $B$ then they must be all contained in $\Omega$. Since $p \notin \Omega$, it follows by 3 that for each $k, n\left(p, \Gamma_{k}\right)=0$, a contradiction.
$4 \Rightarrow 5$ This is Corollary 56.1.12 on Page 1773.
$5 \Rightarrow 6$ Every polynomial has a primitive and so the integral over any closed bounded variation curve of a polynomial equals 0 . Let $f$ be analytic on $\Omega$. Then let $\left\{f_{n}\right\}$ be a sequence of polynomials converging uniformly to $f$ on $\gamma^{*}$. Then

$$
0=\lim _{n \rightarrow \infty} \int_{\gamma} f_{n}(z) d z=\int_{\gamma} f(z) d z
$$

$6 \Rightarrow 7$ Pick $z_{0} \in \Omega$. Letting $\gamma\left(z_{0}, z\right)$ be a bounded variation continuous curve joining $z_{0}$ to $z$ in $\Omega$, you define a primitive for $f$ as follows.

$$
F(z)=\int_{\gamma\left(z_{0}, z\right)} f(w) d w
$$

This is well defined by 6 and is easily seen to be a primitive. You just write the difference quotient and take a limit using 6 .

$$
\begin{aligned}
\lim _{w \rightarrow 0} \frac{F(z+w)-F(z)}{w} & =\lim _{w \rightarrow 0} \frac{1}{w}\left(\int_{\gamma\left(z_{0}, z+w\right)} f(u) d u-\int_{\gamma\left(z_{0}, z\right)} f(u) d u\right) \\
& =\lim _{w \rightarrow 0} \frac{1}{w} \int_{\gamma(z, z+w)} f(u) d u \\
& =\lim _{w \rightarrow 0} \frac{1}{w} \int_{0}^{1} f(z+t w) w d t=f(z) .
\end{aligned}
$$

$7 \Rightarrow 8$ Suppose then that $f, 1 / f$ are both analytic. Then $f^{\prime} / f$ is analytic and so it has a primitive by 7 . Let this primitive be $g_{1}$. Then

$$
\begin{aligned}
\left(e^{-g_{1}} f\right)^{\prime} & =e^{-g_{1}}\left(-g_{1}^{\prime}\right) f+e^{-g_{1}} f^{\prime} \\
& =-e^{-g_{1}}\left(\frac{f^{\prime}}{f}\right) f+e^{-g_{1}} f^{\prime}=0 .
\end{aligned}
$$

Therefore, since $\Omega$ is connected, it follows $e^{-g_{1}} f$ must equal a constant. (Why?) Let the constant be $e^{a+i b i}$. Then $f(z)=e^{g_{1}(z)} e^{a+i b}$. Therefore, you let $g(z)=g_{1}(z)+a+i b$.
$8 \Rightarrow 9$ Suppose then that $f, 1 / f$ are both analytic on $\Omega$. Then by $8 f(z)=e^{g(z)}$. Let $\phi(z) \equiv e^{g(z) / 2}$.
$9 \Rightarrow 1$ There are two cases. First suppose $\Omega=\mathbb{C}$. This satisfies condition 9 because if $f, 1 / f$ are both analytic, then the same argument involved in $8 \Rightarrow 9$ gives the existence of a square root. A homeomorphism is $h(z) \equiv \frac{z}{\sqrt{1+|z|^{2}}}$. It obviously maps onto $B(0,1)$ and is continuous. To see it is $1-1$ consider the case of $z_{1}$ and $z_{2}$ having different arguments. Then $h\left(z_{1}\right) \neq h\left(z_{2}\right)$. If $z_{2}=t z_{1}$ for a positive $t \neq 1$, then it is also clear $h\left(z_{1}\right) \neq h\left(z_{2}\right)$. To show $h^{-1}$ is continuous, note that if you have an open set in $\mathbb{C}$ and a point in this open set, you can get a small open set containing this point by allowing the modulus and the argument to lie in some open interval. Reasoning this way, you can verify $h$ maps open sets to open sets. In the case where $\Omega \neq \mathbb{C}$, there exists a one to one analytic map which maps $\Omega$ onto $B(0,1)$ by the Riemann mapping theorem. This proves the theorem.

### 56.3 Exercises

1. Let $a \in \mathbb{C}$. Show there exists a sequence of polynomials, $\left\{p_{n}\right\}$ such that $p_{n}(a)=1$ but $p_{n}(z) \rightarrow 0$ for all $z \neq a$.
2. Let $l$ be a line in $\mathbb{C}$. Show there exists a sequence of polynomials $\left\{p_{n}\right\}$ such that $p_{n}(z) \rightarrow 1$ on one side of this line and $p_{n}(z) \rightarrow-1$ on the other side of the line. Hint: The complement of this line is simply connected.
3. Suppose $\Omega$ is a simply connected region, $f$ is analytic on $\Omega, f \neq 0$ on $\Omega$, and $n \in \mathbb{N}$. Show that there exists an analytic function, $g$ such that $g(z)^{n}=f(z)$ for all $z \in \Omega$. That is, you can take the $n^{\text {th }}$ root of $f(z)$. If $\Omega$ is a region which contains 0 , is it possible to find $g(z)$ such that $g$ is analytic on $\Omega$ and $g(z)^{2}=z$ ?
4. Suppose $\Omega$ is a region (connected open set) and $f$ is an analytic function defined on $\Omega$ such that $f(z) \neq 0$ for any $z \in \Omega$. Suppose also that for every positive integer, $n$ there exists an analytic function, $g_{n}$ defined on $\Omega$ such that $g_{n}^{n}(z)=f(z)$. Show that then it is possible to define an analytic function, $L$ on $f(\Omega)$ such that $e^{L(f(z))}=f(z)$ for all $z \in \Omega$.
5. You know that $\phi(z) \equiv \frac{z-i}{z+i}$ maps the upper half plane onto the unit ball. Its inverse, $\psi(z)=i \frac{1+z}{1-z}$ maps the unit ball onto the upper half plane. Also for $z$ in the upper half plane, you can define a square root as follows. If $z=|z| e^{i \theta}$ where $\theta \in(0, \pi)$, let $z^{1 / 2} \equiv|z|^{1 / 2} e^{i \theta / 2}$ so the square root maps the upper half plane to the first quadrant. Now consider

$$
\begin{equation*}
z \rightarrow \exp \left(-i \log \left[i\left(\frac{1+z}{1-z}\right)\right]^{1 / 2}\right) \tag{56.3.13}
\end{equation*}
$$

Show this is an analytic function which maps the unit ball onto an annulus. Is it possible to find a one to one analytic map which does this?

## Chapter 57

## Infinite Products

The Mittag-Leffler theorem gives existence of a meromorphic function which has specified singular part at various poles. It would be interesting to do something similar to zeros of an analytic function. That is, given the order of the zero at various points, does there exist an analytic function which has these points as zeros with the specified orders? You know that if you have the zeros of the polynomial, you can factor it. Can you do something similar with analytic functions which are just limits of polynomials? These questions involve the concept of an infinite product.

Definition 57.0.1 $\prod_{n=1}^{\infty}\left(1+u_{n}\right) \equiv \lim _{n \rightarrow \infty} \prod_{k=1}^{n}\left(1+u_{k}\right)$ whenever this limit exists. If $u_{n}=u_{n}(z)$ for $z \in H$, we say the infinite product converges uniformly on $H$ if the partial products, $\prod_{k=1}^{n}\left(1+u_{k}(z)\right)$ converge uniformly on $H$.

The main theorem is the following.
Theorem 57.0.2 Let $H \subseteq \mathbb{C}$ and suppose that $\sum_{n=1}^{\infty}\left|u_{n}(z)\right|$ converges uniformly on $H$ where $u_{n}(z)$ bounded on $H$. Then

$$
P(z) \equiv \prod_{n=1}^{\infty}\left(1+u_{n}(z)\right)
$$

converges uniformly on $H$. If $\left(n_{1}, n_{2}, \cdots\right)$ is any permutation of $(1,2, \cdots)$, then for all $z \in H$,

$$
P(z)=\prod_{k=1}^{\infty}\left(1+u_{n_{k}}(z)\right)
$$

and $P$ has a zero at $z_{0}$ if and only if $u_{n}\left(z_{0}\right)=-1$ for some $n$.
Proof: First a simple estimate:

$$
\begin{aligned}
& \prod_{k=m}^{n}\left(1+\left|u_{k}(z)\right|\right) \\
= & \exp \left(\ln \left(\prod_{k=m}^{n}\left(1+\left|u_{k}(z)\right|\right)\right)\right)=\exp \left(\sum_{k=m}^{n} \ln \left(1+\left|u_{k}(z)\right|\right)\right) \\
\leq & \exp \left(\sum_{k=m}^{\infty}\left|u_{k}(z)\right|\right)<e
\end{aligned}
$$

for all $z \in H$ provided $m$ is large enough. Since $\sum_{k=1}^{\infty}\left|u_{k}(z)\right|$ converges uniformly on $H$, $\left|u_{k}(z)\right|<\frac{1}{2}$ for all $z \in H$ provided $k$ is large enough. Thus you can take $\log \left(1+u_{k}(z)\right)$. Pick $N_{0}$ such that for $n>m \geq N_{0}$,

$$
\begin{equation*}
\left|u_{m}(z)\right|<\frac{1}{2}, \prod_{k=m}^{n}\left(1+\left|u_{k}(z)\right|\right)<e \tag{57.0.1}
\end{equation*}
$$

Now having picked $N_{0}$, the assumption the $u_{n}$ are bounded on $H$ implies there exists a constant, $C$, independent of $z \in H$ such that for all $z \in H$,

$$
\begin{equation*}
\prod_{k=1}^{N_{0}}\left(1+\left|u_{k}(z)\right|\right)<C \tag{57.0.2}
\end{equation*}
$$

Let $N_{0}<M<N$. Then

$$
\begin{aligned}
& \left|\prod_{k=1}^{N}\left(1+u_{k}(z)\right)-\prod_{k=1}^{M}\left(1+u_{k}(z)\right)\right| \\
\leq & \prod_{k=1}^{N_{0}}\left(1+\left|u_{k}(z)\right|\right)\left|\prod_{k=N_{0}+1}^{N}\left(1+u_{k}(z)\right)-\prod_{k=N_{0}+1}^{M}\left(1+u_{k}(z)\right)\right| \\
\leq & C\left|\prod_{k=N_{0}+1}^{N}\left(1+u_{k}(z)\right)-\prod_{k=N_{0}+1}^{M}\left(1+u_{k}(z)\right)\right| \\
\leq & C\left(\prod_{k=N_{0}+1}^{M}\left(1+\left|u_{k}(z)\right|\right)\right)\left|\prod_{k=M+1}^{N}\left(1+u_{k}(z)\right)-1\right| \\
\leq & C e\left|\prod_{k=M+1}^{N}\left(1+\left|u_{k}(z)\right|\right)-1\right|
\end{aligned}
$$

Since $1 \leq \prod_{k=M+1}^{N}\left(1+\left|u_{k}(z)\right|\right) \leq e$, it follows the term on the far right is dominated by

$$
\begin{aligned}
& C e^{2}\left|\ln \left(\prod_{k=M+1}^{N}\left(1+\left|u_{k}(z)\right|\right)\right)-\ln 1\right| \\
\leq & C e^{2} \sum_{k=M+1}^{N} \ln \left(1+\left|u_{k}(z)\right|\right) \\
\leq & C e^{2} \sum_{k=M+1}^{N}\left|u_{k}(z)\right|<\varepsilon
\end{aligned}
$$

uniformly in $z \in H$ provided $M$ is large enough. This follows from the simple observation that if $1<x<e$, then $x-1 \leq e(\ln x-\ln 1)$. Therefore, $\left\{\prod_{k=1}^{m}\left(1+u_{k}(z)\right)\right\}_{m=1}^{\infty}$ is uniformly Cauchy on $H$ and therefore, converges uniformly on $H$. Let $P(z)$ denote the function it converges to.

What about the permutations? Let $\left\{n_{1}, n_{2}, \cdots\right\}$ be a permutation of the indices. Let $\varepsilon>0$ be given and let $N_{0}$ be such that if $n>N_{0}$,

$$
\left|\prod_{k=1}^{n}\left(1+u_{k}(z)\right)-P(z)\right|<\varepsilon
$$

for all $z \in H$. Let $\{1,2, \cdots, n\} \subseteq\left\{n_{1}, n_{2}, \cdots, n_{p(n)}\right\}$ where $p(n)$ is an increasing sequence.

Then from 57.0.1 and 57.0.2,

$$
\begin{aligned}
& \left|P(z)-\prod_{k=1}^{p(n)}\left(1+u_{n_{k}}(z)\right)\right| \\
\leq & \left|P(z)-\prod_{k=1}^{n}\left(1+u_{k}(z)\right)\right|+\left|\prod_{k=1}^{n}\left(1+u_{k}(z)\right)-\prod_{k=1}^{p(n)}\left(1+u_{n_{k}}(z)\right)\right| \\
\leq & \varepsilon+\left|\prod_{k=1}^{n}\left(1+u_{k}(z)\right)-\prod_{k=1}^{p(n)}\left(1+u_{n_{k}}(z)\right)\right| \\
\leq & \varepsilon+\left|\prod_{k=1}^{n}\left(1+\left|u_{k}(z)\right|\right)\right|\left|1-\prod_{n_{k}>n}\left(1+u_{n_{k}}(z)\right)\right| \\
\leq & \varepsilon+\left|\prod_{k=1}^{N_{0}}\left(1+\left|u_{k}(z)\right|\right)\right|\left|\prod_{k=N_{0}+1}^{n}\left(1+\left|u_{k}(z)\right|\right)\right|\left|1-\prod_{n_{k}>n}\left(1+u_{n_{k}}(z)\right)\right| \\
\leq & \varepsilon+C e\left|\prod_{n_{k}>n}\left(1+\left|u_{n_{k}}(z)\right|\right)-1\right| \leq \varepsilon+C e\left|\prod_{k=n+1}^{M(p(n))}\left(1+\left|u_{n_{k}}(z)\right|\right)-1\right|
\end{aligned}
$$

where $M(p(n))$ is the largest index in the permuted list, $\left\{n_{1}, n_{2}, \cdots, n_{p(n)}\right\}$. then from 57.0.1, this last term is dominated by

$$
\begin{aligned}
& \varepsilon+C e^{2}\left|\ln \left(\prod_{k=n+1}^{M(p(n))}\left(1+\left|u_{n_{k}}(z)\right|\right)\right)-\ln 1\right| \\
\leq & \varepsilon+C e^{2} \sum_{k=n+1}^{\infty} \ln \left(1+\left|u_{n_{k}}\right|\right) \leq \varepsilon+C e^{2} \sum_{k=n+1}^{\infty}\left|u_{n_{k}}\right|<2 \varepsilon
\end{aligned}
$$

for all $n$ large enough uniformly in $z \in H$. Therefore, $\left|P(z)-\prod_{k=1}^{p(n)}\left(1+u_{n_{k}}(z)\right)\right|<2 \varepsilon$ whenever $n$ is large enough. This proves the part about the permutation.

It remains to verify the assertion about the points, $z_{0}$, where $P\left(z_{0}\right)=0$. Obviously, if $u_{n}\left(z_{0}\right)=-1$, then $P\left(z_{0}\right)=0$. Suppose then that $P\left(z_{0}\right)=0$ and $M>N_{0}$. Then

$$
\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)\right|=
$$

$$
\begin{aligned}
&\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)-\prod_{k=1}^{\infty}\left(1+u_{k}\left(z_{0}\right)\right)\right| \\
& \leq\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)\right|\left|1-\prod_{k=M+1}^{\infty}\left(1+u_{k}\left(z_{0}\right)\right)\right| \\
& \leq\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)\right|\left|\prod_{k=M+1}^{\infty}\left(1+\left|u_{k}\left(z_{0}\right)\right|\right)-1\right| \\
& \leq e\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)\right|\left|\ln \prod_{k=M+1}^{\infty}\left(1+\left|u_{k}\left(z_{0}\right)\right|\right)-\ln 1\right| \\
& \leq e\left(\sum_{k=M+1}^{\infty} \ln \left(1+\left|u_{k}(z)\right|\right)\right)\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)\right| \\
& \leq e \sum_{k=M+1}^{\infty}\left|u_{k}(z)\right|\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)\right| \\
& \leq \frac{1}{2}\left|\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)\right|
\end{aligned}
$$

whenever $M$ is large enough. Therefore, for such $M$,

$$
\prod_{k=1}^{M}\left(1+u_{k}\left(z_{0}\right)\right)=0
$$

and so $u_{k}\left(z_{0}\right)=-1$ for some $k \leq M$. This proves the theorem.

### 57.1 Analytic Function With Prescribed Zeros

Suppose you are given complex numbers, $\left\{z_{n}\right\}$ and you want to find an analytic function, $f$ such that these numbers are the zeros of $f$. How can you do it? The problem is easy if there are only finitely many of these zeros, $\left\{z_{1}, z_{2}, \cdots, z_{m}\right\}$. You just write $\left(z-z_{1}\right)\left(z-z_{2}\right) \cdots\left(z-z_{m}\right)$. Now if none of the $z_{k}=0$ you could also write it as

$$
\prod_{k=1}^{m}\left(1-\frac{z}{z_{k}}\right)
$$

and this might have a better chance of success in the case of infinitely many prescribed zeros. However, you would need to verify something like $\sum_{n=1}^{\infty}\left|\frac{z}{z_{n}}\right|<\infty$ which might not be so. The way around this is to adjust the product, making it $\prod_{k=1}^{\infty}\left(1-\frac{z}{z_{k}}\right) e^{g_{k}(z)}$ where $g_{k}(z)$ is some analytic function. Recall also that for $|x|<1, \ln \left((1-x)^{-1}\right)=\sum_{n=1}^{\infty} \frac{x^{n}}{n}$. If you had $x / x_{n}$ small and real, then $1=\left(1-x / x_{n}\right) \exp \left(\ln \left(\left(1-x / x_{n}\right)^{-1}\right)\right)$ and $\prod_{k=1}^{\infty} 1$ of course converges but loses all the information about zeros. However, this is why it is not
too unreasonable to consider factors of the form

$$
\left(1-\frac{z}{z_{k}}\right) e^{\sum_{k=1}^{p_{k}}\left(\frac{z}{z_{k}}\right)^{k} \frac{1}{k}}
$$

where $p_{k}$ is suitably chosen.
First here are some estimates.
Lemma 57.1.1 For $z \in \mathbb{C}$,

$$
\begin{equation*}
\left|e^{z}-1\right| \leq|z| e^{|z|} \tag{57.1.3}
\end{equation*}
$$

and if $|z| \leq 1 / 2$,

$$
\begin{equation*}
\left|\sum_{k=m}^{\infty} \frac{z^{k}}{k}\right| \leq \frac{1}{m} \frac{|z|^{m}}{1-|z|} \leq \frac{2}{m}|z|^{m} \leq \frac{1}{m} \frac{1}{2^{m-1}} \tag{57.1.4}
\end{equation*}
$$

Proof: Consider 57.1.3.

$$
\left|e^{z}-1\right|=\left|\sum_{k=1}^{\infty} \frac{z^{k}}{k!}\right| \leq \sum_{k=1}^{\infty} \frac{|z|^{k}}{k!}=e^{|z|}-1 \leq|z| e^{|z|}
$$

the last inequality holding by the mean value theorem. Now consider 57.1.4.

$$
\begin{aligned}
\left|\sum_{k=m}^{\infty} \frac{z^{k}}{k}\right| & \leq \sum_{k=m}^{\infty} \frac{|z|^{k}}{k} \leq \frac{1}{m} \sum_{k=m}^{\infty}|z|^{k} \\
& =\frac{1}{m} \frac{|z|^{m}}{1-|z|} \leq \frac{2}{m}|z|^{m} \leq \frac{1}{m} \frac{1}{2^{m-1}}
\end{aligned}
$$

This proves the lemma.
The functions, $E_{p}$ in the next definition are called the elementary factors.
Definition 57.1.2 Let $E_{0}(z) \equiv 1-z$ and for $p \geq 1$,

$$
E_{p}(z) \equiv(1-z) \exp \left(z+\frac{z^{2}}{2}+\cdots+\frac{z^{p}}{p}\right)
$$

In terms of this new symbol, here is another estimate. A sharper inequality is available in Rudin [113] but it is more difficult to obtain.

Corollary 57.1.3 For $E_{p}$ defined above and $|z| \leq 1 / 2$,

$$
\left|E_{p}(z)-1\right| \leq 3|z|^{p+1}
$$

Proof: From elementary calculus, $\ln (1-x)=-\sum_{n=1}^{\infty} \frac{x^{n}}{n}$ for all $|x|<1$. Therefore, for $|z|<1$,

$$
\log (1-z)=-\sum_{n=1}^{\infty} \frac{z^{n}}{n}, \log \left((1-z)^{-1}\right)=\sum_{n=1}^{\infty} \frac{z^{n}}{n}
$$

because the function $\log (1-z)$ and the analytic function, $-\sum_{n=1}^{\infty} \frac{z^{n}}{n}$ both are equal to $\ln (1-x)$ on the real line segment $(-1,1)$, a set which has a limit point. Therefore, using Lemma 57.1.1,

$$
\begin{aligned}
& \left|E_{p}(z)-1\right| \\
= & \left|(1-z) \exp \left(z+\frac{z^{2}}{2}+\cdots+\frac{z^{p}}{p}\right)-1\right| \\
= & \left|(1-z) \exp \left(\log \left((1-z)^{-1}\right)-\sum_{n=p+1}^{\infty} \frac{z^{n}}{n}\right)-1\right| \\
= & \left|\exp \left(-\sum_{n=p+1}^{\infty} \frac{z^{n}}{n}\right)-1\right| \\
\leq & \left|-\sum_{n=p+1}^{\infty} \frac{z^{n}}{n}\right| e^{\left|-\sum_{n=p+1}^{\infty} \frac{z^{n}}{n}\right|} \\
\leq & \frac{1}{p+1} \cdot 2 \cdot e^{1 /(p+1)}|z|^{p+1} \cdot \leq 3|z|^{p+1}
\end{aligned}
$$

This proves the corollary.
With this estimate, it is easy to prove the Weierstrass product formula.
Theorem 57.1.4 Let $\left\{z_{n}\right\}$ be a sequence of nonzero complex numbers which have no limit point in $\mathbb{C}$ and let $\left\{p_{n}\right\}$ be a sequence of nonnegative integers such that

$$
\begin{equation*}
\sum_{n=1}^{\infty}\left(\frac{R}{\left|z_{n}\right|}\right)^{p_{n}+1}<\infty \tag{57.1.5}
\end{equation*}
$$

for all $R \in \mathbb{R}$. Then

$$
P(z) \equiv \prod_{n=1}^{\infty} E_{p_{n}}\left(\frac{z}{z_{n}}\right)
$$

is analytic on $\mathbb{C}$ and has a zero at each point, $z_{n}$ and at no others. If $w$ occurs $m$ times in $\left\{z_{n}\right\}$, then $P$ has a zero of order $m$ at $w$.

Proof: Since $\left\{z_{n}\right\}$ has no limit point, it follows $\lim _{n \rightarrow \infty}\left|z_{n}\right|=\infty$. Therefore, if $p_{n}=$ $n-1$ the condition, 57.1.5 holds for this choice of $p_{n}$. Now by Theorem 57.0.2, the infinite product in this theorem will converge uniformly on $|z| \leq R$ if the same is true of the sum,

$$
\begin{equation*}
\sum_{n=1}^{\infty}\left|E_{p_{n}}\left(\frac{z}{z_{n}}\right)-1\right| . \tag{57.1.6}
\end{equation*}
$$

But by Corollary 57.1.3 the $n^{t h}$ term of this sum satisfies

$$
\left|E_{p_{n}}\left(\frac{z}{z_{n}}\right)-1\right| \leq 3\left|\frac{z}{z_{n}}\right|^{p_{n}+1}
$$

Since $\left|z_{n}\right| \rightarrow \infty$, there exists $N$ such that for $n>N,\left|z_{n}\right|>2 R$. Therefore, for $|z|<R$ and letting $0<a=\min \left\{\left|z_{n}\right|: n \leq N\right\}$,

$$
\begin{aligned}
& \sum_{n=1}^{\infty}\left|E_{p_{n}}\left(\frac{z}{z_{n}}\right)-1\right| \leq 3 \sum_{n=1}^{N}\left|\frac{R}{a}\right|^{p_{n}+1} \\
& +3 \sum_{n=N}^{\infty}\left(\frac{R}{2 R}\right)^{p_{n}+1}<\infty
\end{aligned}
$$

By the Weierstrass $M$ test, the series in 57.1 .6 converges uniformly for $|z|<R$ and so the same is true of the infinite product. It follows from Lemma 51.3.13 on Page 1622 that $P(z)$ is analytic on $|z|<R$ because it is a uniform limit of analytic functions.

Also by Theorem 57.0.2 the zeros of the analytic $P(z)$ are exactly the points, $\left\{z_{n}\right\}$, listed according to multiplicity. That is, if $z_{n}$ is a zero of order $m$, then if it is listed $m$ times in the formula for $P(z)$, then it is a zero of order $m$ for $P$. This proves the theorem.

The following corollary is an easy consequence and includes the case where there is a zero at 0 .

Corollary 57.1.5 Let $\left\{z_{n}\right\}$ be a sequence of nonzero complex numbers which have no limit point and let $\left\{p_{n}\right\}$ be a sequence of nonnegative integers such that

$$
\begin{equation*}
\sum_{n=1}^{\infty}\left(\frac{r}{\left|z_{n}\right|}\right)^{1+p_{n}}<\infty \tag{57.1.7}
\end{equation*}
$$

for all $r \in \mathbb{R}$. Then

$$
P(z) \equiv z^{m} \prod_{n=1}^{\infty} E_{p_{n}}\left(\frac{z}{z_{n}}\right)
$$

is analytic $\Omega$ and has a zero at each point, $z_{n}$ and at no others along with a zero of order $m$ at 0 . If $w$ occurs $m$ times in $\left\{z_{n}\right\}$, then $P$ has a zero of order $m$ at $w$.

The above theory can be generalized to include the case of an arbitrary open set. First, here is a lemma.

Lemma 57.1.6 Let $\Omega$ be an open set. Also let $\left\{z_{n}\right\}$ be a sequence of points in $\Omega$ which is bounded and which has no point repeated more than finitely many times such that $\left\{z_{n}\right\}$ has no limit point in $\Omega$. Then there exist $\left\{w_{n}\right\} \subseteq \partial \Omega$ such that $\lim _{n \rightarrow \infty}\left|z_{n}-w_{n}\right|=0$.

Proof: Since $\partial \Omega$ is closed, there exists $w_{n} \in \partial \Omega$ such that $\operatorname{dist}\left(z_{n}, \partial \Omega\right)=\left|z_{n}-w_{n}\right|$. Now if there is a subsequence, $\left\{z_{n_{k}}\right\}$ such that $\left|z_{n_{k}}-w_{n_{k}}\right| \geq \varepsilon$ for all $k$, then $\left\{z_{n_{k}}\right\}$ must possess a limit point because it is a bounded infinite set of points. However, this limit point can only be in $\Omega$ because $\left\{z_{n_{k}}\right\}$ is bounded away from $\partial \Omega$. This is a contradiction. Therefore, $\lim _{n \rightarrow \infty}\left|z_{n}-w_{n}\right|=0$. This proves the lemma.

Corollary 57.1.7 Let $\left\{z_{n}\right\}$ be a sequence of complex numbers contained in $\Omega$, an open subset of $\mathbb{C}$ which has no limit point in $\Omega$. Suppose each $z_{n}$ is repeated no more than finitely many times. Then there exists a function $f$ which is analytic on $\Omega$ whose zeros are exactly $\left\{z_{n}\right\}$. If $w \in\left\{z_{n}\right\}$ and $w$ is listed $m$ times, then $w$ is a zero of order $m$ of $f$.

Proof: There is nothing to prove if $\left\{z_{n}\right\}$ is finite. You just let $f(z)=\prod_{j=1}^{m}\left(z-z_{j}\right)$ where $\left\{z_{n}\right\}=\left\{z_{1}, \cdots, z_{m}\right\}$.

Pick $w \in \Omega \backslash\left\{z_{n}\right\}_{n=1}^{\infty}$ and let $h(z) \equiv \frac{1}{z-w}$. Since $w$ is not a limit point of $\left\{z_{n}\right\}$, there exists $r>0$ such that $B(w, r)$ contains no points of $\left\{z_{n}\right\}$. Let $\Omega_{1} \equiv \Omega \backslash\{w\}$. Now $h$ is not constant and so $h\left(\Omega_{1}\right)$ is an open set by the open mapping theorem. In fact, $h$ maps each component of $\Omega$ to a region. $\left|z_{n}-w\right|>r$ for all $z_{n}$ and so $\left|h\left(z_{n}\right)\right|<r^{-1}$. Thus the sequence, $\left\{h\left(z_{n}\right)\right\}$ is a bounded sequence in the open set $h\left(\Omega_{1}\right)$. It has no limit point in $h\left(\Omega_{1}\right)$ because this is true of $\left\{z_{n}\right\}$ and $\Omega_{1}$. By Lemma 57.1.6 there exist $w_{n} \in \partial\left(h\left(\Omega_{1}\right)\right)$ such that $\lim _{n \rightarrow \infty}\left|w_{n}-h\left(z_{n}\right)\right|=0$. Consider for $z \in \Omega_{1}$

$$
\begin{equation*}
f(z) \equiv \prod_{n=1}^{\infty} E_{n}\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right) . \tag{57.1.8}
\end{equation*}
$$

Letting $K$ be a compact subset of $\Omega_{1}, h(K)$ is a compact subset of $h\left(\Omega_{1}\right)$ and so if $z \in K$, then $\left|h(z)-w_{n}\right|$ is bounded below by a positive constant. Therefore, there exists $N$ large enough that for all $z \in K$ and $n \geq N$,

$$
\left|\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right|<\frac{1}{2}
$$

and so by Corollary 57.1.3, for all $z \in K$ and $n \geq N$,

$$
\begin{equation*}
\left|E_{n}\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right)-1\right| \leq 3\left(\frac{1}{2}\right)^{n} \tag{57.1.9}
\end{equation*}
$$

Therefore,

$$
\sum_{n=1}^{\infty}\left|E_{n}\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right)-1\right|
$$

converges uniformly for $z \in K$. This implies $\prod_{n=1}^{\infty} E_{n}\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right)$ also converges uniformly for $z \in K$ by Theorem 57.0.2. Since $K$ is arbitrary, this shows $f$ defined in 57.1.8 is analytic on $\Omega_{1}$.

Also if $z_{n}$ is listed $m$ times so it is a zero of multiplicity $m$ and $w_{n}$ is the point from $\partial\left(h\left(\Omega_{1}\right)\right)$ closest to $h\left(z_{n}\right)$, then there are $m$ factors in 57.1.8 which are of the form

$$
\begin{align*}
E_{n}\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right) & =\left(1-\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right) e^{g_{n}(z)} \\
& =\left(\frac{h(z)-h\left(z_{n}\right)}{h(z)-w_{n}}\right) e^{g_{n}(z)} \\
& =\frac{z_{n}-z}{(z-w)\left(z_{n}-w\right)}\left(\frac{1}{h(z)-w_{n}}\right) e^{g_{n}(z)} \\
& =\left(z-z_{n}\right) G_{n}(z) \tag{57.1.10}
\end{align*}
$$

where $G_{n}$ is an analytic function which is not zero at and near $z_{n}$. Therefore, $f$ has a zero of order $m$ at $z_{n}$. This proves the theorem except for the point, $w$ which has been left out
of $\Omega_{1}$. It is necessary to show $f$ is analytic at this point also and right now, $f$ is not even defined at $w$.

The $\left\{w_{n}\right\}$ are bounded because $\left\{h\left(z_{n}\right)\right\}$ is bounded and $\lim _{n \rightarrow \infty}\left|w_{n}-h\left(z_{n}\right)\right|=0$ which implies $\left|w_{n}-h\left(z_{n}\right)\right| \leq C$ for some constant, $C$. Therefore, there exists $\delta>0$ such that if $z \in B^{\prime}(w, \boldsymbol{\delta})$, then for all $n$,

$$
\left|\frac{h\left(z_{n}\right)-w}{\left(\frac{1}{z-w}\right)-w_{n}}\right|=\left|\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right|<\frac{1}{2}
$$

Thus 57.1.9 holds for all $z \in B^{\prime}(w, \boldsymbol{\delta})$ and $n$ so by Theorem 57.0.2, the infinite product in 57.1.8 converges uniformly on $B^{\prime}(w, \boldsymbol{\delta})$. This implies $f$ is bounded in $B^{\prime}(w, \boldsymbol{\delta})$ and so $w$ is a removable singularity and $f$ can be extended to $w$ such that the result is analytic. It only remains to verify $f(w) \neq 0$. After all, this would not do because it would be another zero other than those in the given list. By 57.1.10, a partial product is of the form

$$
\begin{equation*}
\prod_{n=1}^{N}\left(\frac{h(z)-h\left(z_{n}\right)}{h(z)-w_{n}}\right) e^{g_{n}(z)} \tag{57.1.11}
\end{equation*}
$$

where

$$
g_{n}(z) \equiv\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}+\frac{1}{2}\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right)^{2}+\cdots+\frac{1}{n}\left(\frac{h\left(z_{n}\right)-w_{n}}{h(z)-w_{n}}\right)^{n}\right)
$$

Each of the quotients in the definition of $g_{n}(z)$ converges to 0 as $z \rightarrow w$ and so the partial product of 57.1.11 converges to 1 as $z \rightarrow w$ because $\left(\frac{h(z)-h\left(z_{n}\right)}{h(z)-w_{n}}\right) \rightarrow 1$ as $z \rightarrow w$.

If $f(w)=0$, then if $z$ is close enough to $w$, it follows $|f(z)|<\frac{1}{2}$. Also, by the uniform convergence on $B^{\prime}(w, \boldsymbol{\delta})$, it follows that for some $N$, the partial product up to $N$ must also be less than $1 / 2$ in absolute value for all $z$ close enough to $w$ and as noted above, this does not occur because such partial products converge to 1 as $z \rightarrow w$. Hence $f(w) \neq 0$. This proves the corollary.

Recall the definition of a meromorphic function on Page 1636. It was a function which is analytic everywhere except at a countable set of isolated points at which the function has a pole. It is clear that the quotient of two analytic functions yields a meromorphic function but is this the only way it can happen?

Theorem 57.1.8 Suppose $Q$ is a meromorphic function on an open set, $\Omega$. Then there exist analytic functions on $\Omega, f(z)$ and $g(z)$ such that $Q(z)=f(z) / g(z)$ for all $z$ not in the set of poles of $Q$.

Proof: Let $Q$ have a pole of order $m(z)$ at $z$. Then by Corollary 57.1.7 there exists an analytic function, $g$ which has a zero of order $m(z)$ at every $z \in \Omega$. It follows $g Q$ has a removable singularity at the poles of $Q$. Therefore, there is an analytic function, $f$ such that $f(z)=g(z) Q(z)$. This proves the theorem.

Corollary 57.1.9 Suppose $\Omega$ is a region and $Q$ is a meromorphic function defined on $\Omega$ such that the set, $\{z \in \Omega: Q(z)=c\}$ has a limit point in $\Omega$. Then $Q(z)=c$ for all $z \in \Omega$.

Proof: From Theorem 57.1.8 there are analytic functions, $f, g$ such that $Q=\frac{f}{g}$. Therefore, the zero set of the function, $f(z)-c g(z)$ has a limit point in $\Omega$ and so $f(z)-c g(z)=0$ for all $z \in \Omega$. This proves the corollary.

### 57.2 Factoring A Given Analytic Function

The next theorem is the Weierstrass factorization theorem which can be used to factor a given analytic function $f$. If $f$ has a zero of order $m$ when $z=0$, then you could factor out a $z^{m}$ and from there consider the factorization of what remains when you have factored out the $z^{m}$. Therefore, the following is the main thing of interest.

Theorem 57.2.1 Let $f$ be analytic on $\mathbb{C}, f(0) \neq 0$, and let the zeros of $f$, be $\left\{z_{k}\right\}$, listed according to order. (Thus if $z$ is a zero of order $m$, it will be listed $m$ times in the list, $\left\{z_{k}\right\}$.) Choosing nonnegative integers, $p_{n}$ such that for all $r>0$,

$$
\sum_{n=1}^{\infty}\left(\frac{r}{\left|z_{n}\right|}\right)^{p_{n}+1}<\infty
$$

There exists an entire function, $g$ such that

$$
\begin{equation*}
f(z)=e^{g(z)} \prod_{n=1}^{\infty} E_{p_{n}}\left(\frac{z}{z_{n}}\right) \tag{57.2.12}
\end{equation*}
$$

Note that $e^{g(z)} \neq 0$ for any $z$ and this is the interesting thing about this function.
Proof: $\left\{z_{n}\right\}$ cannot have a limit point because if there were a limit point of this sequence, it would follow from Theorem 51.5.3 that $f(z)=0$ for all $z$, contradicting the hypothesis that $f(0) \neq 0$. Hence $\lim _{n \rightarrow \infty}\left|z_{n}\right|=\infty$ and so

$$
\sum_{n=1}^{\infty}\left(\frac{r}{\left|z_{n}\right|}\right)^{1+n-1}=\sum_{n=1}^{\infty}\left(\frac{r}{\left|z_{n}\right|}\right)^{n}<\infty
$$

by the root test. Therefore, by Theorem 57.1.4

$$
P(z)=\prod_{n=1}^{\infty} E_{p_{n}}\left(\frac{z}{z_{n}}\right)
$$

a function analytic on $\mathbb{C}$ by picking $p_{n}=n-1$ or perhaps some other choice. ( $p_{n}=n-1$ works but there might be another choice that would work.) Then $f / P$ has only removable singularities in $\mathbb{C}$ and no zeros thanks to Theorem 57.1.4. Thus, letting $h(z)=f(z) / P(z)$, Corollary 51.7.23 implies that $h^{\prime} / h$ has a primitive, $\widetilde{g}$. Then

$$
\left(h e^{-\widetilde{g}}\right)^{\prime}=0
$$

and so

$$
h(z)=e^{a+i b} e^{\widetilde{g}(z)}
$$

for some constants, $a, b$. Therefore, letting $g(z)=\widetilde{g}(z)+a+i b, h(z)=e^{g(z)}$ and thus 57.2.12 holds. This proves the theorem.

Corollary 57.2.2 Let $f$ be analytic on $\mathbb{C}$, $f$ has a zero of order $m$ at 0 , and let the other zeros of $f$ be $\left\{z_{k}\right\}$, listed according to order. (Thus if $z$ is a zero of order $l$, it will be listed $l$ times in the list, $\left\{z_{k}\right\}$.) Also let

$$
\begin{equation*}
\sum_{n=1}^{\infty}\left(\frac{r}{\left|z_{n}\right|}\right)^{1+p_{n}}<\infty \tag{57.2.13}
\end{equation*}
$$

for any choice of $r>0$. Then there exists an entire function, $g$ such that

$$
\begin{equation*}
f(z)=z^{m} e^{g(z)} \prod_{n=1}^{\infty} E_{p_{n}}\left(\frac{z}{z_{n}}\right) \tag{57.2.14}
\end{equation*}
$$

Proof: Since $f$ has a zero of order $m$ at 0 , it follows from Theorem 51.5.3 that $\left\{z_{k}\right\}$ cannot have a limit point in $\mathbb{C}$ and so you can apply Theorem 57.2.1 to the function, $f(z) / z^{m}$ which has a removable singularity at 0 . This proves the corollary.

### 57.2.1 Factoring Some Special Analytic Functions

Factoring a polynomial is in general a hard task. It is true it is easy to prove the factors exist but finding them is another matter. Corollary 57.2 .2 gives the existence of factors of a certain form but it does not tell how to find them. This should not be surprising. You can't expect things to get easier when you go from polynomials to analytic functions. Nevertheless, it is possible to factor some popular analytic functions. These factorizations are based on the following Mitag-Leffler expansions. By an auspicious choice of the contour and the method of residues it is possible to obtain a very interesting formula for $\cot \pi z$.

Example 57.2.3 Let $\gamma_{N}$ be the contour which goes from $-N-\frac{1}{2}-N i$ horizontally to $N+$ $\frac{1}{2}-N i$ and from there, vertically to $N+\frac{1}{2}+N i$ and then horizontally to $-N-\frac{1}{2}+N i$ and finally vertically to $-N-\frac{1}{2}-N i$. Thus the contour is a large rectangle and the direction of integration is in the counter clockwise direction. Consider the integral

$$
I_{N} \equiv \int_{\gamma_{N}} \frac{\pi \cos \pi z}{\sin \pi z\left(\alpha^{2}-z^{2}\right)} d z
$$

where $\alpha \in \mathbb{R}$ is not an integer. This will be used to verify the formula of Mittag-Leffler,

$$
\begin{equation*}
\frac{1}{\alpha}+\sum_{n=1}^{\infty} \frac{2 \alpha}{\alpha^{2}-n^{2}}=\pi \cot \pi \alpha \tag{57.2.15}
\end{equation*}
$$

First you show that $\cot \pi z$ is bounded on this contour. This is easy using the formula for $\cot (z)=\frac{e^{i z}+e^{-i z}}{e^{i z}-e^{-i z}}$. Therefore, $I_{N} \rightarrow 0$ as $N \rightarrow \infty$ because the integrand is of order $1 / N^{2}$ while the diameter of $\gamma_{N}$ is of order $N$. Next you compute the residues of the integrand at $\pm \alpha$ and at $n$ where $|n|<N+\frac{1}{2}$ for $n$ an integer. These are the only singularities of the integrand in this contour and therefore, using the residue theorem, you can evaluate $I_{N}$ by using these. You can calculate these residues and find that the residue at $\pm \alpha$ is
$\frac{-\pi \cos \pi \alpha}{2 \alpha \sin \pi \alpha}$
while the residue at $n$ is

$$
\frac{1}{\alpha^{2}-n^{2}}
$$

Therefore

$$
0=\lim _{N \rightarrow \infty} I_{N}=\lim _{N \rightarrow \infty} 2 \pi i\left[\sum_{n=-N}^{N} \frac{1}{\alpha^{2}-n^{2}}-\frac{\pi \cot \pi \alpha}{\alpha}\right]
$$

which establishes the following formula of Mittag Leffler.

$$
\lim _{N \rightarrow \infty} \sum_{n=-N}^{N} \frac{1}{\alpha^{2}-n^{2}}=\frac{\pi \cot \pi \alpha}{\alpha}
$$

Writing this in a slightly nicer form, you obtain 57.2.15.
This is a very interesting formula. This will be used to factor $\sin (\pi z)$. The zeros of this function are at the integers. Therefore, considering 57.2.13 you can pick $p_{n}=1$ in the Weierstrass factorization formula. Therefore, by Corollary 57.2.2 there exists an analytic function $g(z)$ such that

$$
\begin{equation*}
\sin (\pi z)=z e^{g(z)} \prod_{n=1}^{\infty}\left(1-\frac{z}{z_{n}}\right) e^{z / z_{n}} \tag{57.2.16}
\end{equation*}
$$

where the $z_{n}$ are the nonzero integers. Remember you can permute the factors in these products. Therefore, this can be written more conveniently as

$$
\sin (\pi z)=z e^{g(z)} \prod_{n=1}^{\infty}\left(1-\left(\frac{z}{n}\right)^{2}\right)
$$

and it is necessary to find $g(z)$. Differentiating both sides of 57.2.16

$$
\begin{aligned}
\pi \cos (\pi z)= & e^{g(z)} \prod_{n=1}^{\infty}\left(1-\left(\frac{z}{n}\right)^{2}\right)+z g^{\prime}(z) e^{g(z)} \prod_{n=1}^{\infty}\left(1-\left(\frac{z}{n}\right)^{2}\right) \\
& +z e^{g(z)} \sum_{n=1}^{\infty}-\left(\frac{2 z}{n^{2}}\right) \prod_{k \neq n}\left(1-\left(\frac{z}{k}\right)^{2}\right)
\end{aligned}
$$

Now divide both sides by $\sin (\pi z)$ to obtain

$$
\begin{aligned}
\pi \cot (\pi z) & =\frac{1}{z}+g^{\prime}(z)-\sum_{n=1}^{\infty} \frac{2 z / n^{2}}{\left(1-z^{2} / n^{2}\right)} \\
& =\frac{1}{z}+g^{\prime}(z)+\sum_{n=1}^{\infty} \frac{2 z}{z^{2}-n^{2}}
\end{aligned}
$$

By 57.2.15, this yields $g^{\prime}(z)=0$ for $z$ not an integer and so $g(z)=c$, a constant. So far this yields

$$
\sin (\pi z)=z e^{c} \prod_{n=1}^{\infty}\left(1-\left(\frac{z}{n}\right)^{2}\right)
$$

and it only remains to find $c$. Divide both sides by $\pi z$ and take a limit as $z \rightarrow 0$. Using the power series of $\sin (\pi z)$, this yields

$$
1=\frac{e^{c}}{\pi}
$$

and so $c=\ln \pi$. Therefore,

$$
\begin{equation*}
\sin (\pi z)=z \pi \prod_{n=1}^{\infty}\left(1-\left(\frac{z}{n}\right)^{2}\right) . \tag{57.2.17}
\end{equation*}
$$

Example 57.2.4 Find an interesting formula for $\tan (\pi z)$.
This is easy to obtain from the formula for $\cot (\pi z)$.

$$
\cot \left(\pi\left(z+\frac{1}{2}\right)\right)=-\tan \pi z
$$

for $z$ real and therefore, this formula holds for $z$ complex also. Therefore, for $z+\frac{1}{2}$ not an integer

$$
\pi \cot \left(\pi\left(z+\frac{1}{2}\right)\right)=\frac{2}{2 z+1}+\sum_{n=1}^{\infty} \frac{2 z+1}{\left(\frac{2 z+1}{2}\right)^{2}-n^{2}}
$$

### 57.3 The Existence Of An Analytic Function With Given Values

The Weierstrass product formula, Theorem 57.1.4, along with the Mittag-Leffler theorem, Theorem 56.2.1 can be used to obtain an analytic function which has given values on a countable set of points, having no limit point. This is clearly an amazing result and indicates how potent these theorems are. In fact, you can show that it isn't just the values of the function which may be specified at the points in this countable set of points but the derivatives up to any finite order.

Theorem 57.3.1 Let $P \equiv\left\{z_{k}\right\}_{k=1}^{\infty}$ be a set of points in $\mathbb{C}$, which has no limit point. For each $z_{k}$, consider

$$
\begin{equation*}
\sum_{j=0}^{m_{k}} a_{j}^{k}\left(z-z_{k}\right)^{j} \tag{57.3.18}
\end{equation*}
$$

Then there exists an analytic function defined on $\mathbb{C}$ such that the Taylor series of $f$ at $z_{k}$ has the first $m_{k}$ terms given by 57.3.18. ${ }^{1}$

Proof: By the Weierstrass product theorem, Theorem 57.1.4, there exists an analytic function, $f$ defined on all of $\Omega$ such that $f$ has a zero of order $m_{k}+1$ at $z_{k}$. Consider this $z_{k}$ Thus for $z$ near $z_{k}$,

$$
f(z)=\sum_{j=m_{k}+1}^{\infty} c_{j}\left(z-z_{k}\right)^{j}
$$

[^36]where $c_{m_{k}+1} \neq 0$. You choose $b_{1}, b_{2}, \cdots, b_{m_{k}+1}$ such that
$$
f(z)\left(\sum_{l=1}^{m_{k}+1} \frac{b_{l}}{\left(z-z_{k}\right)^{k}}\right)=\sum_{j=0}^{m_{k}} a_{j}^{k}\left(z-z_{k}\right)^{j}+\sum_{k=m_{k}+1}^{\infty} c_{j}^{k}\left(z-z_{k}\right)^{j} .
$$

Thus you need

$$
\sum_{l=1}^{m_{k}+1} \sum_{j=m_{k}+1}^{\infty} c_{j} b_{l}\left(z-z_{k}\right)^{j-l}=\sum_{r=0}^{m_{k}} a_{r}^{k}\left(z-z_{k}\right)^{r}+\text { Higher order terms }
$$

It follows you need to solve the following system of equations for $b_{1}, \cdots, b_{m_{k}+1}$.

$$
\begin{gathered}
c_{m_{k}+1} b_{m_{k}+1}=a_{0}^{k} \\
c_{m_{k}+2} b_{m_{k}+1}+c_{m_{k}+1} b_{m_{k}}=a_{1}^{k} \\
c_{m_{k}+3} b_{m_{k}+1}+c_{m_{k}+2} b_{m_{k}}+c_{m_{k}+1} b_{m_{k}-1}=a_{2}^{k} \\
\vdots \\
c_{m_{k}+m_{k}+1} b_{m_{k}+1}+c_{m_{k}+m_{k}} b_{m_{k}}+\cdots+c_{m_{k}+1} b_{1}=a_{m_{k}}^{k}
\end{gathered}
$$

Since $c_{m_{k}+1} \neq 0$, it follows there exists a unique solution to the above system. You first solve for $b_{m_{k}+1}$ in the top. Then, having found it, you go to the next and use $c_{m_{k}+1} \neq 0$ again to find $b_{m_{k}}$ and continue in this manner. Let $S_{k}(z)$ be determined in this manner for each $z_{k}$. By the Mittag-Leffler theorem, there exists a Meromorphic function, $g$ such that $g$ has exactly the singularities, $S_{k}(z)$. Therefore, $f(z) g(z)$ has removable singularities at each $z_{k}$ and for $z$ near $z_{k}$, the first $m_{k}$ terms of $f g$ are as prescribed. This proves the theorem.

Corollary 57.3.2 Let $P \equiv\left\{z_{k}\right\}_{k=1}^{\infty}$ be a set of points in $\Omega$, an open set such that $P$ has no limit points in $\Omega$. For each $z_{k}$, consider

$$
\begin{equation*}
\sum_{j=0}^{m_{k}} a_{j}^{k}\left(z-z_{k}\right)^{j} \tag{57.3.19}
\end{equation*}
$$

Then there exists an analytic function defined on $\Omega$ such that the Taylor series of $f$ at $z_{k}$ has the first $m_{k}$ terms given by 57.3.19.

Proof: The proof is identical to the above except you use the versions of the MittagLeffler theorem and Weierstrass product which pertain to open sets.

Definition 57.3.3 Denote by $H(\Omega)$ the analytic functions defined on $\Omega$, an open subset of $\mathbb{C}$. Then $H(\Omega)$ is a commutative ring ${ }^{2}$ with the usual operations of addition and multiplication. A set, $I \subseteq H(\Omega)$ is called a finitely generated ideal of the ring if $I$ is of the form

$$
\left\{\sum_{k=1}^{n} g_{k} f_{k}: f_{k} \in H(\Omega) \text { for } k=1,2, \cdots, n\right\}
$$

[^37]where $g_{1}, \cdots, g_{n}$ are given functions in $H(\Omega)$. This ideal is also denoted as $\left[g_{1}, \cdots, g_{n}\right]$ and is called the ideal generated by the functions, $\left\{g_{1}, \cdots, g_{n}\right\}$. Since there are finitely many of these functions it is called a finitely generated ideal. A principal ideal is one which is generated by a single function. An example of such a thing is $[1]=H(\Omega)$.

Then there is the following interesting theorem.
Theorem 57.3.4 Every finitely generated ideal in $H(\Omega)$ for $\Omega$ a connected open set (region) is a principal ideal.

Proof: Let $I=\left[g_{1}, \cdots, g_{n}\right]$ be a finitely generated ideal as described above. Then if any of the functions has no zeros, this ideal would consist of $H(\Omega)$ because then $g_{i}^{-1} \in H(\Omega)$ and so $1 \in I$. It follows all the functions have zeros. If any of the functions has a zero of infinite order, then the function equals zero on $\Omega$ because $\Omega$ is connected and can be deleted from the list. Similarly, if the zeros of any of these functions have a limit point in $\Omega$, then the function equals zero and can be deleted from the list. Thus, without loss of generality, all zeros are of finite order and there are no limit points of the zeros in $\Omega$. Let $m\left(g_{i}, z\right)$ denote the order of the zero of $g_{i}$ at $z$. If $g_{i}$ has no zero at $z$, then $m\left(g_{i}, z\right)=0$.

I claim that if no point of $\Omega$ is a zero of all the $g_{i}$, then the conclusion of the theorem is true and in fact $\left[g_{1}, \cdots, g_{n}\right]=[1]=H(\Omega)$. The claim is obvious if $n=1$ because this assumption that no point is a zero of all the functions implies $g \neq 0$ and so $g^{-1}$ is analytic. Hence $1 \in\left[g_{1}\right]$. Suppose it is true for $n-1$ and consider $\left[g_{1}, \cdots, g_{n}\right]$ where no point of $\Omega$ is a zero of all the $g_{i}$. Even though this may be true of $\left\{g_{1}, \cdots, g_{n}\right\}$, it may not be true of $\left\{g_{1}, \cdots, g_{n-1}\right\}$. By Corollary 57.1.7 there exists $\phi$, a function analytic on $\Omega$ such that $m(\phi, z)=\min \left\{m\left(g_{i}, z\right), i=1,2, \cdots, n-1\right\}$. Thus the functions $\left\{g_{1} / \phi, \cdots, g_{n-1} / \phi\right\}$.are all analytic. Could they all equal zero at some point, $z$ ? If so, pick $i$ where $m(\phi, z)=$ $m\left(g_{i}, z\right)$. Thus $g_{i} / \phi$ is not equal to zero at $z$ after all and so these functions are analytic there is no point of $\Omega$ which is a zero of all of them. By induction, $\left[g_{1} / \phi, \cdots, g_{n-1} / \phi\right]=H(\Omega)$. (Also there are no new zeros obtained in this way.)

Now this means there exist functions $f_{i} \in H(\Omega)$ such that

$$
\sum_{i=1}^{n} f_{i}\left(\frac{g_{i}}{\phi}\right)=1
$$

and so $\phi=\sum_{i=1}^{n} f_{i} g_{i}$. Therefore, $[\phi] \subseteq\left[g_{1}, \cdots, g_{n-1}\right]$. On the other hand, if $\sum_{k=1}^{n-1} h_{k} g_{k} \in$ [ $g_{1}, \cdots, g_{n-1}$ ] you could define $h \equiv \sum_{k=1}^{n-1} h_{k}\left(g_{k} / \phi\right)$, an analytic function with the property that $h \phi=\sum_{k=1}^{n-1} h_{k} g_{k}$ which shows $[\phi]=\left[g_{1}, \cdots, g_{n-1}\right]$. Therefore,

$$
\left[g_{1}, \cdots, g_{n}\right]=\left[\phi, g_{n}\right]
$$

Now $\phi$ has no zeros in common with $g_{n}$ because the zeros of $\phi$ are contained in the set of zeros for $g_{1}, \cdots, g_{n-1}$. Now consider a zero, $\alpha$ of $\phi$. It is not a zero of $g_{n}$ and so near $\alpha$, these functions have the form

$$
\phi(z)=\sum_{k=m}^{\infty} a_{k}(z-\alpha)^{k}, g_{n}(z)=\sum_{k=0}^{\infty} b_{k}(z-\alpha)^{k}, b_{0} \neq 0
$$

I want to determine coefficients for an analytic function, $h$ such that

$$
\begin{equation*}
m\left(1-h g_{n}, \alpha\right) \geq m(\phi, \alpha) \tag{57.3.20}
\end{equation*}
$$

Let

$$
h(z)=\sum_{k=0}^{\infty} c_{k}(z-\alpha)^{k}
$$

and the $c_{k}$ must be determined. Using Merten's theorem, the power series for $1-h g_{n}$ is of the form

$$
1-b_{0} c_{0}-\sum_{j=1}^{\infty}\left(\sum_{r=0}^{j} b_{j-r} c_{r}\right)(z-\alpha)^{j}
$$

First determine $c_{0}$ such that $1-c_{0} b_{0}=0$. This is no problem because $b_{0} \neq 0$. Next you need to get the coefficients of $(z-\alpha)$ to equal zero. This requires

$$
b_{1} c_{0}+b_{0} c_{1}=0
$$

Again, there is no problem because $b_{0} \neq 0$. In fact, $c_{1}=\left(-b_{1} c_{0} / b_{0}\right)$. Next consider the second order terms if $m \geq 2$.

$$
b_{2} c_{0}+b_{1} c_{1}+b_{0} c_{2}=0
$$

Again there is no problem in solving, this time for $c_{2}$ because $b_{0} \neq 0$. Continuing this way, you see that in every step, the $c_{k}$ which needs to be solved for is multiplied by $b_{0} \neq$ 0 . Therefore, by Corollary 57.1.7 there exists an analytic function, $h$ satisfying 57.3.20. Therefore, $\left(1-h g_{n}\right) / \phi$ has a removable singularity at every zero of $\phi$ and so may be considered an analytic function. Therefore,

$$
1=\frac{1-h g_{n}}{\phi} \phi+h g_{n} \in\left[\phi, g_{n}\right]=\left[g_{1} \cdots g_{n}\right]
$$

which shows $\left[g_{1} \cdots g_{n}\right]=H(\Omega)=[1]$. It follows the claim is established.
Now suppose $\left\{g_{1} \cdots g_{n}\right\}$ are just elements of $H(\Omega)$. As explained above, it can be assumed they all have zeros of finite order and the zeros have no limit point in $\Omega$ since if these occur, you can delete the function from the list. By Corollary 57.1.7 there exists $\phi \in H(\Omega)$ such that $m(\phi, z) \leq \min \left\{m\left(g_{i}, z\right): i=1, \cdots, n\right\}$. Then $g_{k} / \phi$ has a removable singularity at each zero of $g_{k}$ and so can be regarded as an analytic function. Also, as before, there is no point which is a zero of each $g_{k} / \phi$ and so by the first part of this argument, $\left[g_{1} / \phi \cdots g_{n} / \phi\right]=H(\Omega)$. As in the first part of the argument, this implies $\left[g_{1} \cdots g_{n}\right]=[\phi]$ which proves the theorem. $\left[g_{1} \cdots g_{n}\right]$ is a principal ideal as claimed.

The following corollary follows from the above theorem. You don't need to assume $\Omega$ is connected.

Corollary 57.3.5 Every finitely generated ideal in $H(\Omega)$ for $\Omega$ an open set is a principal ideal.

Proof: Let $\left[g_{1}, \cdots, g_{n}\right]$ be a finitely generated ideal in $H(\Omega)$. Let $\left\{U_{k}\right\}$ be the components of $\Omega$. Then applying the above to each component, there exists $h_{k} \in H\left(U_{k}\right)$ such that restricting each $g_{i}$ to $U_{k},\left[g_{1}, \cdots, g_{n}\right]=\left[h_{k}\right]$. Then let $h(z)=h_{k}(z)$ for $z \in U_{k}$. This is an analytic function which works.

### 57.4 Jensen's Formula

This interesting formula relates the zeros of an analytic function to an integral. The proof given here follows Alfors, [3]. First, here is a technical lemma.

## Lemma 57.4.1

$$
\int_{-\pi}^{\pi} \ln \left|1-e^{i \theta}\right| d \theta=0
$$

Proof: First note that the only problem with the integrand occurs when $\theta=0$. However, this is an integrable singularity so the integral will end up making sense. Letting $z=e^{i \theta}$, you could get the above integral as a limit as $\varepsilon \rightarrow 0$ of the following contour integral where $\gamma_{\varepsilon}$ is the contour shown in the following picture with the radius of the big circle equal to 1 and the radius of the little circle equal to $\varepsilon$..

$$
\int_{\gamma_{\varepsilon}} \frac{\ln |1-z|}{i z} d z
$$

On the indicated contour, $1-z$ lies in the half plane $\operatorname{Re} z>0$ and so $\log (1-z)=$ $\ln |1-z|+i \arg (1-z)$. The above integral equals

$$
\int_{\gamma_{\varepsilon}} \frac{\log (1-z)}{i z} d z-\int_{\gamma_{\varepsilon}} \frac{\arg (1-z)}{z} d z
$$

The first of these integrals equals zero because the integrand has a removable singularity at 0 . The second equals

$$
\begin{aligned}
& i \int_{-\pi}^{-\eta_{\varepsilon}} \arg \left(1-e^{i \theta}\right) d \theta+i \int_{\eta_{\varepsilon}}^{\pi} \arg \left(1-e^{i \theta}\right) d \theta \\
& +\varepsilon i \int_{-\frac{\pi}{2}-\lambda_{\varepsilon}}^{-\pi} \theta d \theta+\varepsilon i \int_{\pi}^{\frac{\pi}{2}-\lambda_{\varepsilon}} \theta d \theta
\end{aligned}
$$

where $\eta_{\varepsilon}, \lambda_{\varepsilon} \rightarrow 0$ as $\varepsilon \rightarrow 0$. The last two terms converge to 0 as $\varepsilon \rightarrow 0$ while the first two add to zero. To see this, change the variable in the first integral and then recall that when you multiply complex numbers you add the arguments. Thus you end up integrating $\arg$ (real valued function) which equals zero.

In this material on Jensen's equation, $\varepsilon$ will denote a small positive number. Its value is not important as long as it is positive. Therefore, it may change from place to place.

Now suppose $f$ is analytic on $B(0, r+\varepsilon)$, and $f$ has no zeros on $\overline{B(0, r)}$. Then you can define a branch of the logarithm which makes sense for complex numbers near $f(z)$. Thus $z \rightarrow \log (f(z))$ is analytic on $B(0, r+\varepsilon)$. Therefore, its real part, $u(x, y) \equiv \ln |f(x+i y)|$ must be harmonic. Consider the following lemma.

Lemma 57.4.2 Let u be harmonic on $B(0, r+\varepsilon)$. Then

$$
u(0)=\frac{1}{2 \pi} \int_{-\pi}^{\pi} u\left(r e^{i \theta}\right) d \theta
$$

Proof: For a harmonic function, $u$ defined on $B(0, r+\varepsilon)$, there exists an analytic function, $h=u+i v$ where

$$
v(x, y) \equiv \int_{0}^{y} u_{x}(x, t) d t-\int_{0}^{x} u_{y}(t, 0) d t
$$

By the Cauchy integral theorem,

$$
h(0)=\frac{1}{2 \pi i} \int_{\gamma_{r}} \frac{h(z)}{z} d z=\frac{1}{2 \pi} \int_{-\pi}^{\pi} h\left(r e^{i \theta}\right) d \theta
$$

Therefore, considering the real part of $h$,

$$
u(0)=\frac{1}{2 \pi} \int_{-\pi}^{\pi} u\left(r e^{i \theta}\right) d \theta
$$

This proves the lemma.
Now this shows the following corollary.
Corollary 57.4.3 Suppose $f$ is analytic on $B(0, r+\varepsilon)$ and has no zeros on $\overline{B(0, r)}$. Then

$$
\begin{equation*}
\ln |f(0)|=\frac{1}{2 \pi} \int_{-\pi}^{\pi} \ln \left|f\left(r e^{i \theta}\right)\right| \tag{57.4.21}
\end{equation*}
$$

What if $f$ has some zeros on $|z|=r$ but none on $B(0, r)$ ? It turns out 57.4.21 is still valid. Suppose the zeros are at $\left\{r e^{i \theta_{k}}\right\}_{k=1}^{m}$, listed according to multiplicity. Then let

$$
g(z)=\frac{f(z)}{\prod_{k=1}^{m}\left(z-r e^{i \theta_{k}}\right)}
$$

It follows $g$ is analytic on $B(0, r+\varepsilon)$ but has no zeros in $\overline{B(0, r)}$. Then 57.4.21 holds for $g$ in place of $f$. Thus

$$
\begin{aligned}
& \ln |f(0)|-\sum_{k=1}^{m} \ln |r| \\
= & \frac{1}{2 \pi} \int_{-\pi}^{\pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta-\frac{1}{2 \pi} \int_{-\pi}^{\pi} \sum_{k=1}^{m} \ln \left|r e^{i \theta}-r e^{i \theta_{k}}\right| d \theta \\
= & \frac{1}{2 \pi} \int_{-\pi}^{\pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta-\frac{1}{2 \pi} \int_{-\pi}^{\pi} \sum_{k=1}^{m} \ln \left|e^{i \theta}-e^{i \theta_{k}}\right| d \theta-\sum_{k=1}^{m} \ln |r| \\
= & \frac{1}{2 \pi} \int_{-\pi}^{\pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta-\frac{1}{2 \pi} \int_{-\pi}^{\pi} \sum_{k=1}^{m} \ln \left|e^{i \theta}-1\right| d \theta-\sum_{k=1}^{m} \ln |r|
\end{aligned}
$$

Therefore, 57.4.21 will continue to hold exactly when $\frac{1}{2 \pi} \int_{-\pi}^{\pi} \sum_{k=1}^{m} \ln \left|e^{i \theta}-1\right| d \theta=0$. But this is the content of Lemma 57.4.1. This proves the following lemma.

Lemma 57.4.4 Suppose $f$ is analytic on $B(0, r+\varepsilon)$ and has no zeros on $B(0, r)$. Then

$$
\begin{equation*}
\ln |f(0)|=\frac{1}{2 \pi} \int_{-\pi}^{\pi} \ln \left|f\left(r e^{i \theta}\right)\right| \tag{57.4.22}
\end{equation*}
$$

With this preparation, it is now not too hard to prove Jensen's formula. Suppose there are $n$ zeros of $f$ in $B(0, r),\left\{a_{k}\right\}_{k=1}^{n}$, listed according to multiplicity, none equal to zero. Let

$$
F(z) \equiv f(z) \prod_{i=1}^{n} \frac{r^{2}-\overline{a_{i}} z}{r\left(z-a_{i}\right)}
$$

Then $F$ is analytic on $B(0, r+\varepsilon)$ and has no zeros in $B(0, r)$. The reason for this is that $f(z) / \prod_{i=1}^{n} r\left(z-a_{i}\right)$ has no zeros there and $r^{2}-\overline{a_{i}} z$ cannot equal zero if $|z|<r$ because if this expression equals zero, then

$$
|z|=\frac{r^{2}}{\left|a_{i}\right|}>r
$$

The other interesting thing about $F(z)$ is that when $z=r e^{i \theta}$,

$$
\begin{aligned}
F\left(r e^{i \theta}\right) & =f\left(r e^{i \theta}\right) \prod_{i=1}^{n} \frac{r^{2}-\overline{a_{i}} r e^{i \theta}}{r\left(r e^{i \theta}-a_{i}\right)} \\
& =f\left(r e^{i \theta}\right) \prod_{i=1}^{n} \frac{r-\overline{a_{i}} e^{i \theta}}{\left(r e^{i \theta}-a_{i}\right)}=f\left(r e^{i \theta}\right) e^{i \theta} \prod_{i=1}^{n} \frac{r e^{-i \theta}-\overline{a_{i}}}{r e^{i \theta}-a_{i}}
\end{aligned}
$$

so $\left|F\left(r e^{i \theta}\right)\right|=\left|f\left(r e^{i \theta}\right)\right|$.
Theorem 57.4.5 Let $f$ be analytic on $B(0, r+\varepsilon)$ and suppose $f(0) \neq 0$. If the zeros of $f$ in $B(0, r)$ are $\left\{a_{k}\right\}_{k=1}^{n}$, listed according to multiplicity, then

$$
\ln |f(0)|=-\sum_{i=1}^{n} \ln \left(\frac{r}{\left|a_{i}\right|}\right)+\frac{1}{2 \pi} \int_{0}^{2 \pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta
$$

Proof: From the above discussion and Lemma 57.4.4,

$$
\ln |F(0)|=\frac{1}{2 \pi} \int_{-\pi}^{\pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta
$$

But $F(0)=f(0) \prod_{i=1}^{n} \frac{r}{a_{i}}$ and so $\ln |F(0)|=\ln |f(0)|+\sum_{i=1}^{n} \ln \left|\frac{r}{a_{i}}\right|$. Therefore,

$$
\ln |f(0)|=-\sum_{i=1}^{n} \ln \left|\frac{r}{a_{i}}\right|+\frac{1}{2 \pi} \int_{0}^{2 \pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta
$$

as claimed.
Written in terms of exponentials this is

$$
|f(0)| \prod_{k=1}^{n}\left|\frac{r}{a_{k}}\right|=\exp \left(\frac{1}{2 \pi} \int_{0}^{2 \pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta\right)
$$

### 57.5 Blaschke Products

The Blaschke ${ }^{3}$ product is a way to produce a function which is bounded and analytic on $B(0,1)$ which also has given zeros in $B(0,1)$. The interesting thing here is that there may be infinitely many of these zeros. Thus, unlike the above case of Jensen's inequality, the function is not analytic on $B(0,1)$. Recall for purposes of comparison, Liouville's theorem which says bounded entire functions are constant. The Blaschke product gives examples of bounded functions on $B(0,1)$ which are definitely not constant.

Theorem 57.5.1 Let $\left\{\alpha_{n}\right\}$ be a sequence of nonzero points in $B(0,1)$ with the property that

$$
\sum_{n=1}^{\infty}\left(1-\left|\alpha_{n}\right|\right)<\infty
$$

Then for $k \geq 0$, an integer

$$
B(z) \equiv z^{k} \prod_{k=1}^{\infty} \frac{\alpha_{n}-z}{1-\overline{\alpha_{n}} z} \frac{\left|\alpha_{n}\right|}{\alpha_{n}}
$$

is a bounded function which is analytic on $B(0,1)$ which has zeros only at 0 if $k>0$ and at the $\alpha_{n}$.

Proof: From Theorem 57.0.2 the above product will converge uniformly on $B(0, r)$ for $r<1$ to an analytic function if

$$
\sum_{k=1}^{\infty}\left|\frac{\alpha_{n}-z}{1-\overline{\alpha_{n}} z} \frac{\left|\alpha_{n}\right|}{\alpha_{n}}-1\right|
$$

converges uniformly on $B(0, r)$. But for $|z|<r$,

[^38]and so the assumption on the sum gives uniform convergence of the product on $B(0, r)$ to an analytic function. Since $r<1$ is arbitrary, this shows $B(z)$ is analytic on $B(0,1)$ and has the specified zeros because the only place the factors equal zero are at the $\alpha_{n}$ or 0 .

Now consider the factors in the product. The claim is that they are all no larger in absolute value than 1 . This is very easy to see from the maximum modulus theorem. Let $|\alpha|<1$ and $\phi(z)=\frac{\alpha-z}{1-\bar{\alpha} z}$. Then $\phi$ is analytic near $B(0,1)$ because its only pole is $1 / \bar{\alpha}$. Consider $z=e^{i \theta}$. Then

$$
\left|\phi\left(e^{i \theta}\right)\right|=\left|\frac{\alpha-e^{i \theta}}{1-\bar{\alpha} e^{i \theta}}\right|=\left|\frac{1-\alpha e^{-i \theta}}{1-\bar{\alpha} e^{i \theta}}\right|=1 .
$$

Thus the modulus of $\phi(z)$ equals 1 on $\partial B(0,1)$. Therefore, by the maximum modulus theorem, $|\phi(z)|<1$ if $|z|<1$. This proves the claim that the terms in the product are no larger than 1 and shows the function determined by the Blaschke product is bounded. This proves the theorem.

Note in the conditions for this theorem the one for the sum, $\sum_{n=1}^{\infty}\left(1-\left|\alpha_{n}\right|\right)<\infty$. The Blaschke product gives an analytic function, whose absolute value is bounded by 1 and which has the $\alpha_{n}$ as zeros. What if you had a bounded function, analytic on $B(0,1)$ which had zeros at $\left\{\alpha_{k}\right\}$ ? Could you conclude the condition on the sum? The answer is yes. In fact, you can get by with less than the assumption that $f$ is bounded but this will not be presented here. See Rudin [113]. This theorem is an exciting use of Jensen's equation.

Theorem 57.5.2 Suppose $f$ is an analytic function on $B(0,1), f(0) \neq 0$, and $|f(z)| \leq$ $M$ for all $z \in B(0,1)$. Suppose also that the zeros of $f$ are $\left\{\alpha_{k}\right\}_{k=1}^{\infty}$, listed according to multiplicity. Then $\sum_{k=1}^{\infty}\left(1-\left|\alpha_{k}\right|\right)<\infty$.

Proof: If there are only finitely many zeros, there is nothing to prove so assume there are infinitely many. Also let the zeros be listed such that $\left|\alpha_{n}\right| \leq\left|\alpha_{n+1}\right| \cdots$ Let $n(r)$ denote the number of zeros in $B(0, r)$. By Jensen's formula,

$$
\ln |f(0)|+\sum_{i=1}^{n(r)} \ln r-\ln \left|\alpha_{i}\right|=\frac{1}{2 \pi} \int_{0}^{2 \pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta \leq \ln (M)
$$

Therefore, by the mean value theorem,

$$
\sum_{i=1}^{n(r)} \frac{1}{r}\left(r-\left|\alpha_{i}\right|\right) \leq \sum_{i=1}^{n(r)} \ln r-\ln \left|\alpha_{i}\right| \leq \ln (M)-\ln |f(0)|
$$

As $r \rightarrow 1-, n(r) \rightarrow \infty$, and so an application of Fatous lemma yields

$$
\sum_{i=1}^{\infty}\left(1-\left|\alpha_{i}\right|\right) \leq \lim \inf _{r \rightarrow 1-} \sum_{i=1}^{n(r)} \frac{1}{r}\left(r-\left|\alpha_{i}\right|\right) \leq \ln (M)-\ln |f(0)|
$$

This proves the theorem.
You don't need the assumption that $f(0) \neq 0$.

Corollary 57.5.3 Suppose $f$ is an analytic function on $B(0,1)$ and $|f(z)| \leq M$ for all $z \in B(0,1)$. Suppose also that the nonzero zeros ${ }^{4}$ of $f$ are $\left\{\alpha_{k}\right\}_{k=1}^{\infty}$, listed according to multiplicity. Then $\sum_{k=1}^{\infty}\left(1-\left|\alpha_{k}\right|\right)<\infty$.

Proof: Suppose $f$ has a zero of order $m$ at 0 . Then consider the analytic function, $g(z) \equiv f(z) / z^{m}$ which has the same zeros except for 0 . The argument goes the same way except here you use $g$ instead of $f$ and only consider $r>r_{0}>0$. Thus from Jensen's equation,

$$
\begin{aligned}
& \ln |g(0)|+\sum_{i=1}^{n(r)} \ln r-\ln \left|\alpha_{i}\right| \\
= & \frac{1}{2 \pi} \int_{0}^{2 \pi} \ln \left|g\left(r e^{i \theta}\right)\right| d \theta \\
= & \frac{1}{2 \pi} \int_{0}^{2 \pi} \ln \left|f\left(r e^{i \theta}\right)\right| d \theta-\frac{1}{2 \pi} \int_{0}^{2 \pi} m \ln (r) \\
\leq & M+\frac{1}{2 \pi} \int_{0}^{2 \pi} m \ln \left(r^{-1}\right) \\
\leq & M+m \ln \left(\frac{1}{r_{0}}\right)
\end{aligned}
$$

Now the rest of the argument is the same.
An interesting restatement yields the following amazing result.
Corollary 57.5.4 Suppose $f$ is analytic and bounded on $B(0,1)$ having zeros $\left\{\alpha_{n}\right\}$. Then if $\sum_{k=1}^{\infty}\left(1-\left|\alpha_{n}\right|\right)=\infty$, it follows $f$ is identically equal to zero.

### 57.5.1 The Müntz-Szasz Theorem Again

Corollary 57.5.4 makes possible an easy proof of a remarkable theorem named above which yields a wonderful generalization of the Weierstrass approximation theorem. In what follows $b>0$. The Weierstrass approximation theorem states that linear combinations of $1, t, t^{2}, t^{3}, \cdots$ (polynomials) are dense in $C([0, b])$. Let $\lambda_{1}<\lambda_{2}<\lambda_{3}<\cdots$ be an increasing list of positive real numbers. This theorem tells when linear combinations of $1, t^{\lambda_{1}}, t^{\lambda_{2}}, \cdots$ are dense in $C([0, b])$. The proof which follows is like the one given in Rudin [113]. There is a much longer one in Cheney [33] which discusses more aspects of the subject. See also Page 533 where the version given in Cheney is presented. This other approach is much more elementary and does not depend in any way on the theory of functions of a complex variable. There are those of us who automatically prefer real variable techniques. Nevertheless, this proof by Rudin is a very nice and insightful application of the preceding material. Cheney refers to the theorem as the second Müntz theorem. I guess Szasz must also have been involved.

[^39]Theorem 57.5.5 Let $\lambda_{1}<\lambda_{2}<\lambda_{3}<\cdots$ be an increasing list of positive real numbers and let $a>0$. If

$$
\begin{equation*}
\sum_{n=1}^{\infty} \frac{1}{\lambda_{n}}=\infty \tag{57.5.23}
\end{equation*}
$$

then linear combinations of $1, t^{\lambda_{1}}, t^{\lambda_{2}}, \cdots$ are dense in $C([0, b])$.
Proof: Let $X$ denote the closure of linear combinations of $\left\{1, t^{\lambda_{1}}, t^{\lambda_{2}}, \cdots\right\}$ in $C([0, b])$. If $X \neq C([0, b])$, then letting $f \in C([0, b]) \backslash X$, define $\Lambda \in C([0, b])^{\prime}$ as follows. First let $\Lambda_{0}: X+\mathbb{C} f$ be given by $\Lambda_{0}(g+\alpha f)=\alpha\|f\|_{\infty}$. Then

$$
\begin{aligned}
\sup _{\|g+\alpha f\| \leq 1}\left|\Lambda_{0}(g+\alpha f)\right| & =\sup _{\|g+\alpha f\| \leq 1}|\alpha|\|f\|_{\infty} \\
& =\sup _{\|g / \alpha+f\| \leq \frac{1}{|\alpha|}}|\alpha|\|f\|_{\infty} \\
& =\sup _{\|g+f\| \leq \frac{1}{|\alpha|}}|\alpha|\|f\|_{\infty}
\end{aligned}
$$

Now $\operatorname{dist}(f, X)>0$ because $X$ is closed. Therefore, there exists a lower bound, $\eta>0$ to $\|g+f\|$ for $g \in X$. Therefore, the above is no larger than

$$
\sup _{|\alpha| \leq \frac{1}{\eta}}|\alpha|\|f\|_{\infty}=\left(\frac{1}{\eta}\right)\|f\|_{\infty}
$$

which shows that $\left\|\Lambda_{0}\right\| \leq\left(\frac{1}{\eta}\right)\|f\|_{\infty}$. By the Hahn Banach theorem $\Lambda_{0}$ can be extended to $\Lambda \in C([0, b])^{\prime}$ which has the property that $\Lambda(X)=0$ but $\Lambda(f)=\|f\| \neq 0$. By the Weierstrass approximation theorem, Theorem 9.1.7 or one of its cases, there exists a polynomial, $p$ such that $\Lambda(p) \neq 0$. Therefore, if it can be shown that whenever $\Lambda(X)=0$, it is the case that $\Lambda(p)=0$ for all polynomials, it must be the case that $X$ is dense in $C([0, b])$.

By the Riesz representation theorem the elements of $C([0, b])^{\prime}$ are complex measures. Suppose then that for $\mu$ a complex measure it follows that for all $t^{\lambda_{k}}$,

$$
\int_{[0, b]} t^{\lambda_{k}} d \mu=0
$$

I want to show that then

$$
\int_{[0, b]} t^{k} d \mu=0
$$

for all positive integers. It suffices to modify $\mu$ is necessary to have $\mu(\{0\})=0$ since this will not change any of the above integrals. Let $\mu_{1}(E)=\mu(E \cap(0, b])$ and use $\mu_{1}$. I will continue using the symbol, $\mu$.

For $\operatorname{Re}(z)>0$, define

$$
F(z) \equiv \int_{[0, b]} t^{z} d \mu=\int_{(0, b]} t^{z} d \mu
$$

The function $t^{z}=\exp (z \ln (t))$ is analytic. I claim that $F(z)$ is also analytic for $\operatorname{Re} z>0$. Apply Morera's theorem. Let $T$ be a triangle in $\operatorname{Re} z>0$. Then

$$
\int_{\partial T} F(z) d z=\int_{\partial T} \int_{(0, b]} e^{(z \ln (t))} \xi d|\mu| d z
$$

Now $\int_{\partial T}$ can be split into three integrals over intervals of $\mathbb{R}$ and so this integral is essentially a Lebesgue integral taken with respect to Lebesgue measure. Furthermore, $e^{(z \ln (t))}$ is a continuous function of the two variables and $\xi$ is a function of only the one variable, $t$. Thus the integrand is product measurable. The iterated integral is also absolutely integrable because $\left|e^{(z \ln (t))}\right| \leq e^{x \ln t} \leq e^{x \ln b}$ where $x+i y=z$ and $x$ is given to be positive. Thus the integrand is actually bounded. Therefore, you can apply Fubini's theorem and write

$$
\begin{aligned}
\int_{\partial T} F(z) d z & =\int_{\partial T} \int_{(0, b]} e^{(z \ln (t))} \xi d|\mu| d z \\
& =\int_{(0, b]} \xi \int_{\partial T} e^{(z \ln (t))} d z d|\mu|=0
\end{aligned}
$$

By Morera's theorem, $F$ is analytic on $\operatorname{Re} z>0$ which is given to have zeros at the $\lambda_{k}$.
Now let $\phi(z)=\frac{1+z}{1-z}$. Then $\phi$ maps $B(0,1)$ one to one onto $\operatorname{Re} z>0$. To see this let $0<r<1$.

$$
\phi\left(r e^{i \theta}\right)=\frac{1+r e^{i \theta}}{1-r e^{i \theta}}=\frac{1-r^{2}+i 2 r \sin \theta}{1+r^{2}-2 r \cos \theta}
$$

and so $\operatorname{Re} \phi\left(r e^{i \theta}\right)>0$. Now the inverse of $\phi$ is $\phi^{-1}(z)=\frac{z-1}{z+1}$. For $\operatorname{Re} z>0$,

$$
\left|\phi^{-1}(z)\right|^{2}=\frac{z-1}{z+1} \cdot \frac{\bar{z}-1}{\bar{z}+1}=\frac{|z|^{2}-2 \operatorname{Re} z+1}{|z|^{2}+2 \operatorname{Re} z+1}<1
$$

Consider $F \circ \phi$, an analytic function defined on $B(0,1)$. This function is given to have zeros at $z_{n}$ where $\phi\left(z_{n}\right)=\frac{1+z_{n}}{1-z_{n}}=\lambda_{n}$. This reduces to $z_{n}=\frac{-1+\lambda_{n}}{1+\lambda_{n}}$. Now

$$
1-\left|z_{n}\right| \geq \frac{c}{1+\lambda_{n}}
$$

for a positive constant, $c$. It is given that $\sum \frac{1}{\lambda_{n}}=\infty$. so it follows $\sum\left(1-\left|z_{n}\right|\right)=\infty$ also. Therefore, by Corollary 57.5.4, $F \circ \phi=0$. It follows $F=0$ also. In particular, $F(k)$ for $k$ a positive integer equals zero. This has shown that if $\Lambda \in C([0, b])^{\prime}$ and $\Lambda$ sends 1 and all the $t^{\lambda_{n}}$ to 0 , then $\Lambda$ sends 1 and all $t^{k}$ for $k$ a positive integer to zero. As explained above, $X$ is dense in $C((0, b])$.

The converse of this theorem is also true and is proved in Rudin [113].

### 57.6 Exercises

1. Suppose $f$ is an entire function with $f(0)=1$. Let

$$
M(r)=\max \{|f(z)|:|z|=r\}
$$

Use Jensen's equation to establish the following inequality.

$$
M(2 r) \geq 2^{n(r)}
$$

where $n(r)$ is the number of zeros of $f$ in $\overline{B(0, r)}$.
2. The version of the Blaschke product presented above is that found in most complex variable texts. However, there is another one in [89]. Instead of $\frac{\alpha_{n}-z}{1-\overline{\alpha_{n} z}} \frac{\left|\alpha_{n}\right|}{\alpha_{n}}$ you use

$$
\frac{\alpha_{n}-z}{\frac{1}{\overline{\alpha_{n}}}-z}
$$

Prove a version of Theorem 57.5.1 using this modification.
3. The Weierstrass approximation theorem holds for polynomials of $n$ variables on any compact subset of $\mathbb{R}^{n}$. Give a multidimensional version of the Müntz-Szasz theorem which will generalize the Weierstrass approximation theorem for $n$ dimensions. You might just pick a compact subset of $\mathbb{R}^{n}$ in which all components are positive. You have to do something like this because otherwise, $t^{\lambda}$ might not be defined.
4. Show $\cos (\pi z)=\prod_{k=1}^{\infty}\left(1-\frac{4 z^{2}}{(2 k-1)^{2}}\right)$.
5. Recall $\sin (\pi z)=z \pi \prod_{n=1}^{\infty}\left(1-\left(\frac{z}{n}\right)^{2}\right)$. Use this to derive Wallis product,

$$
\frac{\pi}{2}=\prod_{k=1}^{\infty} \frac{4 k^{2}}{(2 k-1)(2 k+1)}
$$

6. The order of an entire function, $f$ is defined as

$$
\inf \left\{a \geq 0:|f(z)| \leq e^{|z|^{a}} \text { for all large enough }|z|\right\}
$$

If no such $a$ exists, the function is said to be of infinite order. Show the order of an entire function is also equal to

$$
\lim \sup _{r \rightarrow \infty} \frac{\ln (\ln (M(r)))}{\ln (r)}
$$

where $M(r) \equiv \max \{|f(z)|:|z|=r\}$.
7. Suppose $\Omega$ is a simply connected region and let $f$ be meromorphic on $\Omega$. Suppose also that the set, $S \equiv\{z \in \Omega: f(z)=c\}$ has a limit point in $\Omega$. Can you conclude $f(z)=c$ for all $z \in \Omega$ ?
8. This and the next collection of problems are dealing with the gamma function. Show that

$$
\left|\left(1+\frac{z}{n}\right) e^{\frac{-z}{n}}-1\right| \leq \frac{C(z)}{n^{2}}
$$

and therefore,

$$
\sum_{n=1}^{\infty}\left|\left(1+\frac{z}{n}\right) e^{\frac{-z}{n}}-1\right|<\infty
$$

with the convergence uniform on compact sets.
9. $\uparrow$ Show $\prod_{n=1}^{\infty}\left(1+\frac{z}{n}\right) e^{\frac{-z}{n}}$ converges to an analytic function on $\mathbb{C}$ which has zeros only at the negative integers and that therefore,

$$
\prod_{n=1}^{\infty}\left(1+\frac{z}{n}\right)^{-1} e^{\frac{z}{n}}
$$

is a meromorphic function (Analytic except for poles) having simple poles at the negative integers.
10. $\uparrow$ Show there exists $\gamma$ such that if

$$
\Gamma(z) \equiv \frac{e^{-\gamma_{z}}}{z} \prod_{n=1}^{\infty}\left(1+\frac{z}{n}\right)^{-1} e^{\frac{z}{n}}
$$

then $\Gamma(1)=1$. Thus $\Gamma$ is a meromorphic function having simple poles at the negative integers. Hint: $\prod_{n=1}^{\infty}(1+n) e^{-1 / n}=c=e^{\gamma}$.
11. $\uparrow$ Now show that

$$
\gamma=\lim _{n \rightarrow \infty}\left[\sum_{k=1}^{n} \frac{1}{k}-\ln n\right]
$$

12. $\uparrow$ Justify the following argument leading to Gauss’s formula

$$
\begin{aligned}
& \Gamma(z)=\lim _{n \rightarrow \infty}\left(\prod_{k=1}^{n}\left(\frac{k}{k+z}\right) e^{\frac{z}{k}}\right) \frac{e^{-\gamma z}}{z} \\
= & \lim _{n \rightarrow \infty}\left(\frac{n!}{(1+z)(2+z) \cdots(n+z)} e^{z\left(\sum_{k=1}^{n} \frac{1}{k}\right)}\right) \frac{e^{-\gamma z}}{z} \\
= & \lim _{n \rightarrow \infty} \frac{n!}{(1+z)(2+z) \cdots(n+z)} e^{z\left(\sum_{k=1}^{n} \frac{1}{k}\right)} e^{-z\left[\sum_{k=1}^{n} \frac{1}{k}-\ln n\right]} \\
= & \lim _{n \rightarrow \infty} \frac{n!n^{z}}{(1+z)(2+z) \cdots(n+z)} .
\end{aligned}
$$

13. $\uparrow$ Verify from the Gauss formula above that $\Gamma(z+1)=\Gamma(z) z$ and that for $n$ a nonnegative integer, $\Gamma(n+1)=n!$.
14. $\uparrow$ The usual definition of the gamma function for positive $x$ is

$$
\Gamma_{1}(x) \equiv \int_{0}^{\infty} e^{-t} t^{x-1} d t
$$

Show $\left(1-\frac{t}{n}\right)^{n} \leq e^{-t}$ for $t \in[0, n]$. Then show

$$
\int_{0}^{n}\left(1-\frac{t}{n}\right)^{n} t^{x-1} d t=\frac{n!n^{x}}{x(x+1) \cdots(x+n)}
$$

Use the first part to conclude that

$$
\Gamma_{1}(x)=\lim _{n \rightarrow \infty} \frac{n!n^{x}}{x(x+1) \cdots(x+n)}=\Gamma(x)
$$

Hint: To show $\left(1-\frac{t}{n}\right)^{n} \leq e^{-t}$ for $t \in[0, n]$, verify this is equivalent to showing $(1-u)^{n} \leq e^{-n u}$ for $u \in[0,1]$.
15. $\uparrow$ Show $\Gamma(z)=\int_{0}^{\infty} e^{-t} t^{z-1} d t$. whenever $\operatorname{Re} z>0$. Hint: You have already shown that this is true for positive real numbers. Verify this formula for $\operatorname{Re} z>0$ yields an analytic function.
16. $\uparrow$ Show $\Gamma\left(\frac{1}{2}\right)=\sqrt{\pi}$. Then find $\Gamma\left(\frac{5}{2}\right)$.
17. Show that $\int_{-\infty}^{\infty} e^{\frac{-s^{2}}{2}} d s=\sqrt{2 \pi}$. Hint: Denote this integral by $I$ and observe that $I^{2}=\int_{\mathbb{R}^{2}} e^{-\left(x^{2}+y^{2}\right) / 2} d x d y$. Then change variables to polar coordinates, $x=r \cos (\theta)$, $y=r \sin \theta$.
18. $\uparrow$ Now that you know what the gamma function is, consider in the formula for $\Gamma(\alpha+1)$ the following change of variables. $t=\alpha+\alpha^{1 / 2} s$. Then in terms of the new variable, $s$, the formula for $\Gamma(\alpha+1)$ is

$$
\begin{aligned}
& e^{-\alpha} \alpha^{\alpha+\frac{1}{2}} \int_{-\sqrt{\alpha}}^{\infty} e^{-\sqrt{\alpha} s}\left(1+\frac{s}{\sqrt{\alpha}}\right)^{\alpha} d s \\
& =e^{-\alpha} \alpha^{\alpha+\frac{1}{2}} \int_{-\sqrt{\alpha}}^{\infty} e^{\alpha\left[\ln \left(1+\frac{s}{\sqrt{\alpha}}\right)-\frac{s}{\sqrt{\alpha}}\right]} d s
\end{aligned}
$$

Show the integrand converges to $e^{-\frac{s^{2}}{2}}$. Show that then

$$
\lim _{\alpha \rightarrow \infty} \frac{\Gamma(\alpha+1)}{e^{-\alpha} \alpha^{\alpha+(1 / 2)}}=\int_{-\infty}^{\infty} e^{\frac{-s^{2}}{2}} d s=\sqrt{2 \pi}
$$

Hint: You will need to obtain a dominating function for the integral so that you can use the dominated convergence theorem. You might try considering $s \in(-\sqrt{\alpha}, \sqrt{\alpha})$ first and consider something like $e^{1-\left(s^{2} / 4\right)}$ on this interval. Then look for another function for $s>\sqrt{\alpha}$. This formula is known as Stirling's formula.
19. This and the next several problems develop the zeta function and give a relation between the zeta and the gamma function. Define for $0<r<2 \pi$

$$
\begin{align*}
I_{r}(z) \equiv & \int_{0}^{2 \pi} \frac{e^{(z-1)(\ln r+i \theta)}}{e^{r e^{i \theta}}-1} i r e^{i \theta} d \theta+\int_{r}^{\infty} \frac{e^{(z-1)(\ln t+2 \pi i)}}{e^{t}-1} d t  \tag{57.6.24}\\
& +\int_{\infty}^{r} \frac{e^{(z-1) \ln t}}{e^{t}-1} d t
\end{align*}
$$

Show that $I_{r}$ is an entire function. The reason $0<r<2 \pi$ is that this prevents $e^{r e^{i \theta}}-1$ from equaling zero. The above is just a precise description of the contour integral, $\int_{\gamma} \frac{w^{z^{z-1}}}{e^{w}-1} d w$ where $\gamma$ is the contour shown below.

in which on the integrals along the real line, the argument is different in going from $r$ to $\infty$ than it is in going from $\infty$ to $r$. Now I have not defined such contour integrals over contours which have infinite length and so have chosen to simply write out explicitly what is involved. You have to work with these integrals given above anyway but the contour integral just mentioned is the motivation for them. Hint: You may want to use convergence theorems from real analysis if it makes this more convenient but you might not have to.
20. $\uparrow$ In the context of Problem 19 define for small $\delta>0$

$$
I_{r \delta}(z) \equiv \int_{\gamma_{r, \delta}} \frac{w^{z-1}}{e^{w}-1} d w
$$

where $\gamma_{r \delta}$ is shown below.

Show that $\lim _{\delta \rightarrow 0} I_{r \delta}(z)=I_{r}(z)$. Hint: Use the dominated convergence theorem if it makes this go easier. This is not a hard problem if you use these theorems but you can probably do it without them with more work.
21. $\uparrow$ In the context of Problem 20 show that for $r_{1}<r, I_{r \delta}(z)-I_{r_{1} \delta}(z)$ is a contour integral,

$$
\int_{\gamma_{r, r_{1}, \delta}} \frac{w^{z-1}}{e^{w}-1} d w
$$

where the oriented contour is shown below.

In this contour integral, $w^{z-1}$ denotes $e^{(z-1) \log (w)}$ where $\log (w)=\ln |w|+i \arg (w)$ for $\arg (w) \in(0,2 \pi)$. Explain why this integral equals zero. From Problem 20 it follows that $I_{r}=I_{r_{1}}$. Therefore, you can define an entire function, $I(z) \equiv I_{r}(z)$ for all $r$ positive but sufficiently small. Hint: Remember the Cauchy integral formula for analytic functions defined on simply connected regions. You could argue there is a simply connected region containing $\gamma_{r, r_{1}, \delta}$.
22. $\uparrow$ In case $\operatorname{Re} z>1$, you can get an interesting formula for $I(z)$ by taking the limit as $r \rightarrow 0$. Recall that

$$
\begin{align*}
I_{r}(z) \equiv & \int_{0}^{2 \pi} \frac{e^{(z-1)(\ln r+i \theta)}}{e^{r e^{i \theta}}-1} i r e^{i \theta} d \theta+\int_{r}^{\infty} \frac{e^{(z-1)(\ln t+2 \pi i)}}{e^{t}-1} d t  \tag{57.6.25}\\
& +\int_{\infty}^{r} \frac{e^{(z-1) \ln t}}{e^{t}-1} d t
\end{align*}
$$

and now it is desired to take a limit in the case where $\operatorname{Re} z>1$. Show the first integral above converges to 0 as $r \rightarrow 0$. Next argue the sum of the two last integrals converges to

$$
\left(e^{(z-1) 2 \pi i}-1\right) \int_{0}^{\infty} \frac{e^{(z-1) \ln (t)}}{e^{t}-1} d t
$$

Thus

$$
\begin{equation*}
I(z)=\left(e^{z 2 \pi i}-1\right) \int_{0}^{\infty} \frac{e^{(z-1) \ln (t)}}{e^{t}-1} d t \tag{57.6.26}
\end{equation*}
$$

when $\operatorname{Re} z>1$.
23. $\uparrow$ So what does all this have to do with the zeta function and the gamma function? The zeta function is defined for $\operatorname{Re} z>1$ by

$$
\sum_{n=1}^{\infty} \frac{1}{n^{z}} \equiv \zeta(z)
$$

By Problem 15, whenever $\operatorname{Re} z>0$,

$$
\Gamma(z)=\int_{0}^{\infty} e^{-t} t^{z-1} d t
$$

Change the variable and conclude

$$
\Gamma(z) \frac{1}{n^{z}}=\int_{0}^{\infty} e^{-n s} s^{z-1} d s
$$

Therefore, for $\operatorname{Re} z>1$,

$$
\zeta(z) \Gamma(z)=\sum_{n=1}^{\infty} \int_{0}^{\infty} e^{-n s} s^{z-1} d s
$$

Now show that you can interchange the order of the sum and the integral. This is possibly most easily done by using Fubini's theorem. Show that $\sum_{n=1}^{\infty} \int_{0}^{\infty}\left|e^{-n s} s^{z-1}\right| d s<$ $\infty$ and then use Fubini's theorem. I think you could do it other ways though. It is possible to do it without any reference to Lebesgue integration. Thus

$$
\begin{aligned}
\zeta(z) \Gamma(z) & =\int_{0}^{\infty} s^{z-1} \sum_{n=1}^{\infty} e^{-n s} d s \\
& =\int_{0}^{\infty} \frac{s^{z-1} e^{-s}}{1-e^{-s}} d s=\int_{0}^{\infty} \frac{s^{z-1}}{e^{s}-1} d s
\end{aligned}
$$

By 57.6.26,

$$
\begin{aligned}
I(z) & =\left(e^{z 2 \pi i}-1\right) \int_{0}^{\infty} \frac{e^{(z-1) \ln (t)}}{e^{t}-1} d t \\
& =\left(e^{z 2 \pi i}-1\right) \zeta(z) \Gamma(z) \\
& =\left(e^{2 \pi i z}-1\right) \zeta(z) \Gamma(z)
\end{aligned}
$$

whenever $\operatorname{Re} z>1$.
24. $\uparrow$ Now show there exists an entire function, $h(z)$ such that

$$
\zeta(z)=\frac{1}{z-1}+h(z)
$$

for $\operatorname{Re} z>1$. Conclude $\zeta(z)$ extends to a meromorphic function defined on all of $\mathbb{C}$ which has a simple pole at $z=1$, namely, the right side of the above formula. Hint: Use Problem 10 to observe that $\Gamma(z)$ is never equal to zero but has simple poles at every nonnegative integer. Then for $\operatorname{Re} z>1$,

$$
\zeta(z) \equiv \frac{I(z)}{\left(e^{2 \pi i z}-1\right) \Gamma(z)}
$$

By 57.6.26 $\zeta$ has no poles for $\operatorname{Re} z>1$. The right side of the above equation is defined for all $z$. There are no poles except possibly when $z$ is a nonnegative integer. However, these points are not poles either because of Problem 10 which states that $\Gamma$ has simple poles at these points thus cancelling the simple zeros of $\left(e^{2 \pi i z}-1\right)$. The
only remaining possibility for a pole for $\zeta$ is at $z=1$. Show it has a simple pole at this point. You can use the formula for $I(z)$

$$
\begin{align*}
I(z) \equiv & \int_{0}^{2 \pi} \frac{e^{(z-1)(\ln r+i \theta)}}{e^{r e^{i \theta}}-1} i r e^{i \theta} d \theta+\int_{r}^{\infty} \frac{e^{(z-1)(\ln t+2 \pi i)}}{e^{t}-1} d t  \tag{57.6.27}\\
& +\int_{\infty}^{r} \frac{e^{(z-1) \ln t}}{e^{t}-1} d t
\end{align*}
$$

Thus $I(1)$ is given by

$$
I(1) \equiv \int_{0}^{2 \pi} \frac{1}{e^{r e^{i \theta}}-1} i r e^{i \theta} d \theta+\int_{r}^{\infty} \frac{1}{e^{t}-1} d t+\int_{\infty}^{r} \frac{1}{e^{t}-1} d t
$$

$=\int_{\gamma_{r}} \frac{d w}{e^{w}-1}$ where $\gamma_{r}$ is the circle of radius $r$. This contour integral equals $2 \pi i$ by the residue theorem. Therefore,

$$
\frac{I(z)}{\left(e^{2 \pi i z}-1\right) \Gamma(z)}=\frac{1}{z-1}+h(z)
$$

where $h(z)$ is an entire function. People worry a lot about where the zeros of $\zeta$ are located. In particular, the zeros for $\operatorname{Re} z \in(0,1)$ are of special interest. The Riemann hypothesis says they are all on the line $\operatorname{Re} z=1 / 2$. This is a good problem for you to do next.
25. There is an important relation between prime numbers and the zeta function due to Euler. Let $\left\{p_{n}\right\}_{n=1}^{\infty}$ be the prime numbers. Then for $\operatorname{Re} z>1$,

$$
\prod_{n=1}^{\infty} \frac{1}{1-p_{n}^{-z}}=\zeta(z)
$$

To see this, consider a partial product.

$$
\prod_{n=1}^{N} \frac{1}{1-p_{n}^{-z}}=\prod_{n=1}^{N} \sum_{j_{n}=1}^{\infty}\left(\frac{1}{p_{n}^{z}}\right)^{j_{n}}
$$

Let $S_{N}$ denote all positive integers which use only $p_{1}, \cdots, p_{N}$ in their prime factorization. Then the above equals $\sum_{n \in S_{N}} \frac{1}{n^{2}}$. Letting $N \rightarrow \infty$ and using the fact that $\operatorname{Re} z>1$ so that the order in which you sum is not important (See Theorem 58.0.1 or recall advanced calculus. ) you obtain the desired equation. Show $\sum_{n=1}^{\infty} \frac{1}{p_{n}}=\infty$.

## Chapter 58

## Elliptic Functions

This chapter is to give a short introduction to elliptic functions. There is much more available. There are books written on elliptic functions. What I am presenting here follows Alfors [3] although the material is found in many books on complex analysis. Hille, [65] has a much more extensive treatment than what I will attempt here. There are also many references and historical notes available in the book by Hille. Another good source for more having much the same emphasis as what is presented here is in the book by Saks and Zygmund [115]. This is a very interesting subject because it has considerable overlap with algebra.

Before beginning, recall that an absolutely convergent series can be summed in any order and you always get the same answer. The easy way to see this is to think of the series as a Lebesgue integral with respect to counting measure and apply convergence theorems as needed. The following theorem provides the necessary results.

Theorem 58.0.1 Suppose $\sum_{n=1}^{\infty}\left|a_{n}\right|<\infty$ and let $\theta, \phi: \mathbb{N} \rightarrow \mathbb{N}$ be one to one and onto mappings. Then $\sum_{n=1}^{\infty} a_{\phi(n)}$ and $\sum_{n=1}^{\infty} a_{\theta(n)}$ both converge and the two sums are equal.

Proof: By the monotone convergence theorem,

$$
\sum_{n=1}^{\infty}\left|a_{n}\right|=\lim _{n \rightarrow \infty} \sum_{k=1}^{n}\left|a_{\phi(k)}\right|=\lim _{n \rightarrow \infty} \sum_{k=1}^{n}\left|a_{\theta(k)}\right|
$$

but these last two equal $\sum_{k=1}^{\infty}\left|a_{\phi(k)}\right|$ and $\sum_{k=1}^{\infty}\left|a_{\theta(k)}\right|$ respectively. Therefore, $\sum_{k=1}^{\infty} a_{\theta(k)}$ and $\sum_{k=1}^{\infty} a_{\phi(k)}$ exist ( $n \rightarrow a_{\theta(n)}$ is in $L^{1}$ with respect to counting measure.) It remains to show the two are equal. There exists $M$ such that if $n>M$ then

$$
\begin{gathered}
\sum_{k=n+1}^{\infty}\left|a_{\theta(k)}\right|<\varepsilon, \quad \sum_{k=n+1}^{\infty}\left|a_{\phi(k)}\right|<\varepsilon \\
\left|\sum_{k=1}^{\infty} a_{\phi(k)}-\sum_{k=1}^{n} a_{\phi(k)}\right|<\varepsilon,\left|\sum_{k=1}^{\infty} a_{\theta(k)}-\sum_{k=1}^{n} a_{\theta(k)}\right|<\varepsilon
\end{gathered}
$$

Pick such an $n$ denoted by $n_{1}$. Then pick $n_{2}>n_{1}>M$ such that

$$
\left\{\theta(1), \cdots, \theta\left(n_{1}\right)\right\} \subseteq\left\{\phi(1), \cdots, \phi\left(n_{2}\right)\right\}
$$

Then

$$
\sum_{k=1}^{n_{2}} a_{\phi(k)}=\sum_{k=1}^{n_{1}} a_{\theta(k)}+\sum_{\phi(k) \notin\left\{\theta(1), \cdots, \theta\left(n_{1}\right)\right\}} a_{\phi(k)}
$$

Therefore,

$$
\left|\sum_{k=1}^{n_{2}} a_{\phi(k)}-\sum_{k=1}^{n_{1}} a_{\theta(k)}\right|=\left|\sum_{\phi(k) \notin\left\{\theta(1), \cdots, \theta\left(n_{1}\right)\right\}, k \leq n_{2}} a_{\phi(k)}\right|
$$

Now all of these $\phi(k)$ in the last sum are contained in $\left\{\theta\left(n_{1}+1\right), \cdots\right\}$ and so the last sum above is dominated by

$$
\leq \sum_{k=n_{1}+1}^{\infty}\left|a_{\theta(k)}\right|<\varepsilon
$$

Therefore,

$$
\begin{aligned}
& \left|\sum_{k=1}^{\infty} a_{\phi(k)}-\sum_{k=1}^{\infty} a_{\theta(k)}\right| \leq \\
& +\left|\sum_{k=1}^{\infty} a_{\phi(k)}-\sum_{k=1}^{n_{2}} a_{\phi(k)}\right| \\
+ & \left|\sum_{k=1}^{n_{1}} a_{\theta(k)}-\sum_{k=1}^{n_{1}} a_{\theta(k)}\right| \\
\sum_{k=1}^{\infty} a_{\theta(k)} \mid< & \varepsilon+\varepsilon+\varepsilon=3 \varepsilon
\end{aligned}
$$

and since $\varepsilon$ is arbitrary, it follows $\sum_{k=1}^{\infty} a_{\phi(k)}=\sum_{k=1}^{\infty} a_{\theta(k)}$ as claimed. This proves the theorem.

### 58.1 Periodic Functions

Definition 58.1.1 A function defined on $\mathbb{C}$ is said to be periodic if there exists $w$ such that $f(z+w)=f(z)$ for all $z \in \mathbb{C}$. Denote by $M$ the set of all periods. Thus if $w_{1}, w_{2} \in M$ and $a, b \in \mathbb{Z}$, then $a w_{1}+b w_{2} \in M$. For this reason $M$ is called the module of periods. ${ }^{1}$ In all which follows it is assumed $f$ is meromorphic.

Theorem 58.1.2 Let $f$ be a meromorphic function and let $M$ be the module of periods. Then if $M$ has a limit point, then $f$ equals a constant. If this does not happen then either there exists $w_{1} \in M$ such that $\mathbb{Z} w_{1}=M$ or there exist $w_{1}, w_{2} \in M$ such that $M=$ $\left\{a w_{1}+b w_{2}: a, b \in \mathbb{Z}\right\}$ and $w_{1} / w_{2}$ is not real. Also if $\tau=w_{2} / w_{1}$,

$$
|\tau| \geq 1, \frac{-1}{2} \leq \operatorname{Re} \tau \leq \frac{1}{2}
$$

Proof: Suppose $f$ is meromorphic and $M$ has a limit point, $w_{0}$. By Theorem 57.1.8 on Page 1791 there exist analytic functions, $p, q$ such that $f(z)=\frac{p(z)}{q(z)}$. Now pick $z_{0}$ such that $z_{0}$ is not a pole of $f$. Then letting $w_{n} \rightarrow w_{0}$ where $\left\{w_{n}\right\} \subseteq M, f\left(z_{0}+w_{n}\right)=f\left(z_{0}\right)$. Therefore, $p\left(z_{0}+w_{n}\right)=f\left(z_{0}\right) q\left(z_{0}+w_{n}\right)$ and so the analytic function, $p(z)-f\left(z_{0}\right) q(z)$ has a zero set which has a limit point. Therefore, this function is identically equal to zero because of Theorem 51.5.3 on Page 1628. Thus $f$ equals a constant as claimed.

This has shown that if $f$ is not constant, then $M$ is discrete. Therefore, there exists $w_{1} \in M$ such that $\left|w_{1}\right|=\min \{|w|: w \in M\}$. Suppose first that every element of $M$ is a real multiple of $w_{1}$. Thus, if $w \in M$, it follows there exists a real number, $x$ such that $w=x w_{1}$. Then there exist positive integers, $k, k+1$ such that $k \leq x<k+1$. If $x>k$, then $w-k w_{1}=(x-k) w_{1}$ is a period having smaller absolute value than $\left|w_{1}\right|$ which would be a contradiction. Hence, $x=k$ and so $M=\mathbb{Z} w_{1}$.

[^40]Now suppose there exists $w_{2} \in M$ which is not a real multiple of $w_{1}$. You can let $w_{2}$ be the element of $M$ having this property which has smallest absolute value. Now let $w \in M$. Since $w_{1}$ and $w_{2}$ point in different directions, it follows $w=x w_{1}+y w_{2}$ for some real numbers, $x, y$. Let $|m-x| \leq \frac{1}{2}$ and $|n-y| \leq \frac{1}{2}$ where $m, n$ are integers. Therefore,

$$
w=m w_{1}+n w_{2}+(x-m) w_{1}+(y-n) w_{2}
$$

and so

$$
\begin{equation*}
w-m w_{1}-n w_{2}=(x-m) w_{1}+(y-n) w_{2} \tag{58.1.1}
\end{equation*}
$$

Now since $w_{2} / w_{1} \notin \mathbb{R}$,

$$
\begin{aligned}
\left|(x-m) w_{1}+(y-n) w_{2}\right| & <\left|(x-m) w_{1}\right|+\left|(y-n) w_{2}\right| \\
& =\frac{1}{2}\left|w_{1}\right|+\frac{1}{2}\left|w_{2}\right| .
\end{aligned}
$$

Therefore, from 58.1.1,

$$
\begin{aligned}
\left|w-m w_{1}-n w_{2}\right| & =\left|(x-m) w_{1}+(y-n) w_{2}\right| \\
& <\frac{1}{2}\left|w_{1}\right|+\frac{1}{2}\left|w_{2}\right| \leq\left|w_{2}\right|
\end{aligned}
$$

and so the period, $w-m w_{1}-n w_{2}$ cannot be a non real multiple of $w_{1}$ because $w_{2}$ is the one which has smallest absolute value and this period has smaller absolute value than $w_{2}$. Therefore, the ratio $w-m w_{1}-n w_{2} / w_{1}$ must be a real number, $x$. Thus

$$
w-m w_{1}-n w_{2}=x w_{1}
$$

Since $w_{1}$ has minimal absolute value of all periods, it follows $|x| \geq 1$. Let $k \leq x<k+1$ for some integer, $k$. If $x>k$, then

$$
w-m w_{1}-n w_{2}-k w_{1}=(x-k) w_{1}
$$

which would contradict the choice of $w_{1}$ as being the period having minimal absolute value because the expression on the left in the above is a period and it equals something which has absolute value less than $\left|w_{1}\right|$. Therefore, $x=k$ and $w$ is an integer linear combination of $w_{1}$ and $w_{2}$. It only remains to verify the claim about $\tau$.

From the construction, $\left|w_{1}\right| \leq\left|w_{2}\right|$ and $\left|w_{2}\right| \leq\left|w_{1}-w_{2}\right|,\left|w_{2}\right| \leq\left|w_{1}+w_{2}\right|$. Therefore,

$$
|\tau| \geq 1,|\tau| \leq|1-\tau|,|\tau| \leq|1+\tau|
$$

The last two of these inequalities imply $-1 / 2 \leq \operatorname{Re} \tau \leq 1 / 2$.
This proves the theorem.
Definition 58.1.3 For $f$ a meromorphic function which has the last of the above alternatives holding in which $M=\left\{a w_{1}+b w_{2}: a, b \in \mathbb{Z}\right\}$, the function, $f$ is called elliptic. This is also called doubly periodic.

Theorem 58.1.4 Suppose $f$ is an elliptic function which has no poles. Then $f$ is constant.

Proof: Since $f$ has no poles it is analytic. Now consider the parallelograms determined by the vertices, $m w_{1}+n w_{2}$ for $m, n \in \mathbb{Z}$. By periodicity of $f$ it must be bounded because its values are identical on each of these parallelograms. Therefore, it equals a constant by Liouville's theorem.

Definition 58.1.5 Define $P_{a}$ to be the parallelogram determined by the points

$$
\begin{aligned}
& a+m w_{1}+n w_{2}, a+(m+1) w_{1}+n w_{2}, a+m w_{1}+(n+1) w_{2}, \\
& a+(m+1) w_{1}+(n+1) w_{2}
\end{aligned}
$$

Such $P_{a}$ will be referred to as a period parallelogram. The sum of the orders of the poles in a period parallelogram which contains no poles or zeros of $f$ on its boundary is called the order of the function. This is well defined because of the periodic property of $f$.

Theorem 58.1.6 The sum of the residues of any elliptic function, $f$ equals zero on every $P_{a}$ if a is chosen so that there are no poles on $\partial P_{a}$.

Proof: Choose $a$ such that there are no poles of $f$ on the boundary of $P_{a}$. By periodicity,

$$
\int_{\partial P_{a}} f(z) d z=0
$$

because the integrals over opposite sides of the parallelogram cancel out because the values of $f$ are the same on these sides and the orientations are opposite. It follows from the residue theorem that the sum of the residues in $P_{a}$ equals 0 .

Theorem 58.1.7 Let $P_{a}$ be a period parallelogram for a nonconstant elliptic function, $f$ which has order equal to $m$. Then $f$ assumes every value in $f\left(P_{a}\right)$ exactly $m$ times.

Proof: Let $c \in f\left(P_{a}\right)$ and consider $P_{a^{\prime}}$ such that $f^{-1}(c) \cap P_{a^{\prime}}=f^{-1}(c) \cap P_{a}$ and $P_{a^{\prime}}$ contains the same poles and zeros of $f-c$ as $P_{a}$ but $P_{a^{\prime}}$ has no zeros of $f(z)-c$ or poles of $f$ on its boundary. Thus $f^{\prime}(z) /(f(z)-c)$ is also an elliptic function and so Theorem 58.1.6 applies. Consider

$$
\frac{1}{2 \pi i} \int_{\partial P_{a^{\prime}}} \frac{f^{\prime}(z)}{f(z)-c} d z
$$

By the argument principle, this equals $N_{z}-N_{p}$ where $N_{z}$ equals the number of zeros of $f(z)-c$ and $N_{p}$ equals the number of the poles of $f(z)$. From Theorem 58.1.6 this must equal zero because it is the sum of the residues of $f^{\prime} /(f-c)$ and so $N_{z}=N_{p}$. Now $N_{p}$ equals the number of poles in $P_{a}$ counted according to multiplicity.

There is an even better theorem than this one.

Theorem 58.1.8 Let $f$ be a non constant elliptic function with poles $p_{1}, \cdots, p_{m}$ and zeros, $z_{1}, \cdots, z_{m}$ in $P_{\alpha}$, listed according to multiplicity where $\partial P_{\alpha}$ contains no poles or zeros of $f$. Then $\sum_{k=1}^{m} z_{k}-\sum_{k=1}^{m} p_{k} \in M$, the module of periods.

Proof: You can assume $\partial P_{a}$ contains no poles or zeros of $f$ because if it did, then you could consider a slightly shifted period parallelogram, $P_{a^{\prime}}$ which contains no new zeros and poles but which has all the old ones but no poles or zeros on its boundary. By Theorem 53.1.3 on Page 1676

$$
\begin{equation*}
\frac{1}{2 \pi i} \int_{\partial P_{a}} z \frac{f^{\prime}(z)}{f(z)} d z=\sum_{k=1}^{m} z_{k}-\sum_{k=1}^{m} p_{k} . \tag{58.1.2}
\end{equation*}
$$

Denoting by $\gamma(z, w)$ the straight oriented line segment from $z$ to $w$,

$$
\begin{gathered}
\int_{\partial P_{a}} z \frac{f^{\prime}(z)}{f(z)} d z \\
=\int_{\gamma\left(a, a+w_{1}\right)} z \frac{f^{\prime}(z)}{f(z)} d z+\int_{\gamma\left(a+w_{1}+w_{2}, a+w_{2}\right)} z \frac{f^{\prime}(z)}{f(z)} d z \\
+\int_{\gamma\left(a+w_{1}, a+w_{2}+w_{1}\right)} z \frac{f^{\prime}(z)}{f(z)} d z+\int_{\gamma\left(a+w_{2}, a\right)} z \frac{f^{\prime}(z)}{f(z)} d z \\
=\int_{\gamma\left(a, a+w_{1}\right)}\left(z-\left(z+w_{2}\right)\right) \frac{f^{\prime}(z)}{f(z)} d z \\
\quad+\int_{\gamma\left(a, a+w_{2}\right)}\left(z-\left(z+w_{1}\right)\right) \frac{f^{\prime}(z)}{f(z)} d z
\end{gathered}
$$

Now near these line segments $\frac{f^{\prime}(z)}{f(z)}$ is analytic and so there exists a primitive, $g_{w_{i}}(z)$ on $\gamma\left(a, a+w_{i}\right)$ by Corollary 51.7.5 on Page 1633 which satisfies $e^{g_{w_{i}}(z)}=f(z)$. Therefore,

$$
=-w_{2}\left(g_{w_{1}}\left(a+w_{1}\right)-g_{w_{1}}(a)\right)-w_{1}\left(g_{w_{2}}\left(a+w_{2}\right)-g_{w_{2}}(a)\right) .
$$

Now by periodicity of $f$ it follows $f\left(a+w_{1}\right)=f(a)=f\left(a+w_{2}\right)$. Hence

$$
g_{w_{i}}\left(a+w_{1}\right)-g_{w_{i}}(a)=2 m \pi i
$$

for some integer, $m$ because

$$
e^{g_{w_{i}}\left(a+w_{i}\right)}-e^{g_{w_{i}}(a)}=f\left(a+w_{i}\right)-f(a)=0 .
$$

Therefore, from 58.1.2, there exist integers, $k, l$ such that

$$
\begin{aligned}
& \frac{1}{2 \pi i} \int_{\partial P_{a}} z \frac{f^{\prime}(z)}{f(z)} d z \\
= & \frac{1}{2 \pi i}\left[-w_{2}\left(g_{w_{1}}\left(a+w_{1}\right)-g_{w_{1}}(a)\right)-w_{1}\left(g_{w_{2}}\left(a+w_{2}\right)-g_{w_{2}}(a)\right)\right] \\
= & \frac{1}{2 \pi i}\left[-w_{2}(2 k \pi i)-w_{1}(2 l \pi i)\right] \\
= & -w_{2} k-w_{1} l \in M
\end{aligned}
$$

From 58.1.2 it follows

$$
\sum_{k=1}^{m} z_{k}-\sum_{k=1}^{m} p_{k} \in M
$$

This proves the theorem.
Hille says this relation is due to Liouville. There is also a simple corollary which follows from the above theorem applied to the elliptic function, $f(z)-c$.

Corollary 58.1.9 Let $f$ be a non constant elliptic function and suppose the function, $f(z)-$ $c$ has poles $p_{1}, \cdots, p_{m}$ and zeros, $z_{1}, \cdots, z_{m}$ on $P_{\alpha}$, listed according to multiplicity where $\partial P_{\alpha}$ contains no poles or zeros of $f(z)-c$. Then $\sum_{k=1}^{m} z_{k}-\sum_{k=1}^{m} p_{k} \in M$, the module of periods.

### 58.1.1 The Unimodular Transformations

Definition 58.1.10 Suppose $f$ is a nonconstant elliptic function and the module of periods is of the form $\left\{a w_{1}+b w_{2}\right\}$ where $a, b$ are integers and $w_{1} / w_{2}$ is not real. Then by analogy with linear algebra, $\left\{w_{1}, w_{2}\right\}$ is referred to as a basis. The unimodular transformations will refer to matrices of the form

$$
\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)
$$

where all entries are integers and

$$
a d-b c= \pm 1
$$

These linear transformations are also called the modular group.
The following is an interesting lemma which ties matrices with the fractional linear transformations.

Lemma 58.1.11 Define

$$
\phi\left(\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\right) \equiv \frac{a z+b}{c z+d}
$$

Then

$$
\begin{equation*}
\phi(A B)=\phi(A) \circ \phi(B), \tag{58.1.3}
\end{equation*}
$$

$\phi(A)(z)=z$ if and only if

$$
A=c I
$$

where $I$ is the identity matrix and $c \neq 0$. Also if $f(z)=\frac{a z+b}{c z+d}$, then $f^{-1}(z)$ exists if and only if $a d-c b \neq 0$. Furthermore it is easy to find $f^{-1}$.

Proof: The equation in 58.1.3 is just a simple computation. Now suppose $\phi(A)(z)=z$. Then letting $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$, this requires

$$
a z+b=z(c z+d)
$$

and so $a z+b=c z^{2}+d z$. Since this is to hold for all $z$ it follows $c=0=b$ and $a=d$. The other direction is obvious.

Consider the claim about the existence of an inverse. Let $a d-c b \neq 0$ for $f(z)=\frac{a z+b}{c z+d}$. Then

$$
f(z)=\phi\left(\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\right)
$$

It follows $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)^{-1}$ exists and equals $\frac{1}{a d-b c}\left(\begin{array}{cc}d & -b \\ -c & a\end{array}\right)$. Therefore,

$$
\begin{aligned}
z & =\phi(I)(z)=\phi\left(\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\left(\frac{1}{a d-b c}\left(\begin{array}{cc}
d & -b \\
-c & a
\end{array}\right)\right)\right)(z) \\
& =\phi\left(\left(\begin{array}{cc}
a & b \\
c & d
\end{array}\right)\right) \circ \phi\left(\left(\frac{1}{a d-b c}\left(\begin{array}{cc}
d & -b \\
-c & a
\end{array}\right)\right)\right)(z) \\
& =f \circ f^{-1}(z)
\end{aligned}
$$

which shows $f^{-1}$ exists and it is easy to find.
Next suppose $f^{-1}$ exists. I need to verify the condition $a d-c b \neq 0$. If $f^{-1}$ exists, then from the process used to find it, you see that it must be a fractional linear transformation. Letting $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ so $\phi(A)=f$, it follows there exists a matrix $B$ such that

$$
\phi(B A)(z)=\phi(B) \circ \phi(A)(z)=z .
$$

However, it was shown that this implies $B A$ is a nonzero multiple of $I$ which requires that $A^{-1}$ must exist. Hence the condition must hold.

Theorem 58.1.12 If $f$ is a nonconstant elliptic function with a basis $\left\{w_{1}, w_{2}\right\}$ for the module of periods, then $\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$ is another basis, if and only if there exists a unimodular transformation, $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)=A$ such that

$$
\binom{w_{1}^{\prime}}{w_{2}^{\prime}}=\left(\begin{array}{ll}
a & b  \tag{58.1.4}\\
c & d
\end{array}\right)\binom{w_{1}}{w_{2}}
$$

Proof: Since $\left\{w_{1}, w_{2}\right\}$ is a basis, there exist integers, $a, b, c, d$ such that 58.1.4 holds. It remains to show the transformation determined by the matrix is unimodular. Taking conjugates,

$$
\binom{\overline{w_{1}^{\prime}}}{\overline{w_{2}^{\prime}}}=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\binom{\overline{w_{1}}}{\overline{w_{2}}} .
$$

Therefore,

$$
\left(\begin{array}{ll}
w_{1}^{\prime} & \overline{w_{1}^{\prime}} \\
w_{2}^{\prime} & \overline{w_{2}^{\prime}}
\end{array}\right)=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\left(\begin{array}{ll}
w_{1} & \overline{w_{1}} \\
w_{2} & \overline{w_{2}}
\end{array}\right)
$$

Now since $\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$ is also given to be a basis, there exits another matrix having all integer entries, $\left(\begin{array}{ll}e & f \\ g & h\end{array}\right)$ such that

$$
\binom{\overline{w_{1}}}{\overline{w_{2}}}=\left(\begin{array}{ll}
e & f \\
g & h
\end{array}\right)\binom{\overline{w_{1}^{\prime}}}{\overline{w_{2}^{\prime}}}
$$

and

$$
\binom{w_{1}}{w_{2}}=\left(\begin{array}{ll}
e & f \\
g & h
\end{array}\right)\binom{w_{1}^{\prime}}{w_{2}^{\prime}}
$$

Therefore,

$$
\left(\begin{array}{ll}
w_{1}^{\prime} & \overline{w_{1}^{\prime}} \\
w_{2}^{\prime} & \overline{w_{2}^{\prime}}
\end{array}\right)=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\left(\begin{array}{ll}
e & f \\
g & h
\end{array}\right)\left(\begin{array}{ll}
w_{1}^{\prime} & \overline{w_{1}^{\prime}} \\
w_{2}^{\prime} & \overline{w_{2}^{\prime}}
\end{array}\right) .
$$

However, since $w_{1}^{\prime} / w_{2}^{\prime}$ is not real, it is routine to verify that

$$
\operatorname{det}\left(\begin{array}{ll}
w_{1}^{\prime} & \overline{w_{1}^{\prime}} \\
w_{2}^{\prime} & \overline{w_{2}^{\prime}}
\end{array}\right) \neq 0
$$

Therefore,

$$
\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right)=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\left(\begin{array}{ll}
e & f \\
g & h
\end{array}\right)
$$

and so $\operatorname{det}\left(\begin{array}{ll}a & b \\ c & d\end{array}\right) \operatorname{det}\left(\begin{array}{ll}e & f \\ g & h\end{array}\right)=1$. But the two matrices have all integer entries and so both determinants must equal either 1 or -1 .

Next suppose

$$
\binom{w_{1}^{\prime}}{w_{2}^{\prime}}=\left(\begin{array}{ll}
a & b  \tag{58.1.5}\\
c & d
\end{array}\right)\binom{w_{1}}{w_{2}}
$$

where $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ is unimodular. I need to verify that $\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$ is a basis. If $w \in M$, there exist integers, $m, n$ such that

$$
w=m w_{1}+n w_{2}=\left(\begin{array}{ll}
m & n
\end{array}\right)\binom{w_{1}}{w_{2}}
$$

From 58.1.5

$$
\pm\left(\begin{array}{cc}
d & -b \\
-c & a
\end{array}\right)\binom{w_{1}^{\prime}}{w_{2}^{\prime}}=\binom{w_{1}}{w_{2}}
$$

and so

$$
w= \pm\left(\begin{array}{cc}
m & n
\end{array}\right)\left(\begin{array}{cc}
d & -b \\
-c & a
\end{array}\right)\binom{w_{1}^{\prime}}{w_{2}^{\prime}}
$$

which is an integer linear combination of $\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$. It only remains to verify that $w_{1}^{\prime} / w_{2}^{\prime}$ is not real.

Claim: Let $w_{1}$ and $w_{2}$ be nonzero complex numbers. Then $w_{2} / w_{1}$ is not real if and only if

$$
w_{1} \overline{w_{2}}-\overline{w_{1}} w_{2}=\operatorname{det}\left(\begin{array}{ll}
w_{1} & \overline{w_{1}} \\
w_{2} & \overline{w_{2}}
\end{array}\right) \neq 0
$$

Proof of the claim: Let $\lambda=w_{2} / w_{1}$. Then

$$
w_{1} \overline{w_{2}}-\overline{w_{1}} w_{2}=\bar{\lambda} w_{1} \overline{w_{1}}-\overline{w_{1}} \lambda w_{1}=(\bar{\lambda}-\lambda)\left|w_{1}\right|^{2}
$$

Thus the ratio is not real if and only if $(\bar{\lambda}-\lambda) \neq 0$ if and only if $w_{1} \overline{w_{2}}-\overline{w_{1}} w_{2} \neq 0$.
Now to verify $w_{2}^{\prime} / w_{1}^{\prime}$ is not real,

$$
\begin{aligned}
& \operatorname{det}\left(\begin{array}{ll}
w_{1}^{\prime} & \overline{w_{1}^{\prime}} \\
w_{2}^{\prime} & \overline{w_{2}^{\prime}}
\end{array}\right) \\
= & \operatorname{det}\left(\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\left(\begin{array}{ll}
w_{1} & \overline{w_{1}} \\
w_{2} & \overline{w_{2}}
\end{array}\right)\right) \\
= & \pm \operatorname{det}\left(\begin{array}{ll}
w_{1} & \overline{w_{1}} \\
w_{2} & \overline{w_{2}}
\end{array}\right) \neq 0
\end{aligned}
$$

This proves the theorem.

### 58.1.2 The Search For An Elliptic Function

By Theorem 58.1.4 and 58.1.6 if you want to find a nonconstant elliptic function it must fail to be analytic and also have either no terms in its Laurent expansion which are of the form $b_{1}(z-a)^{-1}$ or else these terms must cancel out. It is simplest to look for a function which simply does not have them. Weierstrass looked for a function of the form

$$
\begin{equation*}
\wp(z) \equiv \frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right) \tag{58.1.6}
\end{equation*}
$$

where $w$ consists of all numbers of the form $a w_{1}+b w_{2}$ for $a, b$ integers. Sometimes people write this as $\wp\left(z, w_{1}, w_{2}\right)$ to emphasize its dependence on the periods, $w_{1}$ and $w_{2}$ but I won't do so. It is understood there exist these periods, which are given. This is a reasonable thing to try. Suppose you formally differentiate the right side. Never mind whether this is justified for now. This yields

$$
\wp^{\prime}(z)=\frac{-2}{z^{3}}-\sum_{w \neq 0} \frac{-2}{(z-w)^{3}}=\sum_{w} \frac{-2}{(z-w)^{3}}
$$

which is clearly periodic having both periods $w_{1}$ and $w_{2}$. Therefore, $\wp\left(z+w_{1}\right)-\wp(z)$ and $\wp\left(z+w_{2}\right)-\wp(z)$ are both constants, $c_{1}$ and $c_{2}$ respectively. The reason for this is that since $\wp^{\prime}$ is periodic with periods $w_{1}$ and $w_{2}$, it follows $\not \wp^{\prime}\left(z+w_{i}\right)-\not{ }^{\prime}(z)=0$ as long as $z$ is not a period. From 58.1.6 you can see right away that

$$
\wp(z)=\wp(-z)
$$

Indeed

$$
\begin{aligned}
\wp(-z) & =\frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(-z-w)^{2}}-\frac{1}{w^{2}}\right) \\
& =\frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(-z+w)^{2}}-\frac{1}{w^{2}}\right)=\wp(z) .
\end{aligned}
$$

and so

$$
\begin{aligned}
c_{1} & =\wp\left(-\frac{w_{1}}{2}+w_{1}\right)-\wp\left(-\frac{w_{1}}{2}\right) \\
& =\wp\left(\frac{w_{1}}{2}\right)-\wp\left(-\frac{w_{1}}{2}\right)=0
\end{aligned}
$$

which shows the constant for $\wp\left(z+w_{1}\right)-\wp(z)$ must equal zero. Similarly the constant for $\wp\left(z+w_{2}\right)-\wp(z)$ also equals zero. Thus $\wp$ is periodic having the two periods $w_{1}, w_{2}$.

Of course to justify this, you need to consider whether the series of 58.1.6 converges. Consider the terms of the series.

$$
\left|\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right|=|z|\left|\frac{2 w-z}{(z-w)^{2} w^{2}}\right|
$$

If $|w|>2|z|$, this can be estimated more. For such $w$,

$$
\begin{aligned}
& \left|\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right| \\
= & |z|\left|\frac{2 w-z}{(z-w)^{2} w^{2}}\right| \leq|z| \frac{(5 / 2)|w|}{|w|^{2}(|w|-|z|)^{2}} \\
\leq & |z| \frac{(5 / 2)|w|}{|w|^{2}((1 / 2)|w|)^{2}}=|z| \frac{10}{|w|^{3}} .
\end{aligned}
$$

It follows the series in 58.1 .6 converges uniformly and absolutely on every compact set, $K$ provided $\sum_{w \neq 0} \frac{1}{|w|^{3}}$ converges. This question is considered next.

Claim: There exists a positive number, $k$ such that for all pairs of integers, $m, n$, not both equal to zero,

$$
\frac{\left|m w_{1}+n w_{2}\right|}{|m|+|n|} \geq k>0
$$

Proof of claim: If not, there exists $m_{k}$ and $n_{k}$ such that

$$
\lim _{k \rightarrow \infty} \frac{m_{k}}{\left|m_{k}\right|+\left|n_{k}\right|} w_{1}+\frac{n_{k}}{\left|m_{k}\right|+\left|n_{k}\right|} w_{2}=0
$$

However, $\left(\frac{m_{k}}{\left|m_{k}\right|+\left|n_{k}\right|}, \frac{n_{k}}{\left|m_{k}\right|+\left|n_{k}\right|}\right)$ is a bounded sequence in $\mathbb{R}^{2}$ and so, taking a subsequence, still denoted by $k$, you can have

$$
\left(\frac{m_{k}}{\left|m_{k}\right|+\left|n_{k}\right|}, \frac{n_{k}}{\left|m_{k}\right|+\left|n_{k}\right|}\right) \rightarrow(x, y) \in \mathbb{R}^{2}
$$

and so there are real numbers, $x, y$ such that $x w_{1}+y w_{2}=0$ contrary to the assumption that $w_{2} / w_{1}$ is not equal to a real number. This proves the claim.

Now from the claim,

$$
\begin{aligned}
& \sum_{w \neq 0} \frac{1}{|w|^{3}} \\
= & \sum_{(m, n) \neq(0,0)} \frac{1}{\left|m w_{1}+n w_{2}\right|^{3}} \leq \sum_{(m, n) \neq(0,0)} \frac{1}{k^{3}(|m|+|n|)^{3}} \\
= & \frac{1}{k^{3}} \sum_{j=1}^{\infty} \sum_{|m|+|n|=j} \frac{1}{(|m|+|n|)^{3}}=\frac{1}{k^{3}} \sum_{j=1}^{\infty} \frac{4 j}{j^{3}}<\infty .
\end{aligned}
$$

Now consider the series in 58.1.6. Letting $z \in B(0, R)$,

$$
\begin{aligned}
\wp(z) \equiv & \frac{1}{z^{2}}+\sum_{w \neq 0,|w| \leq R}\left(\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right) \\
& +\sum_{w \neq 0,|w|>R}\left(\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right)
\end{aligned}
$$

and the last series converges uniformly on $B(0, R)$ to an analytic function. Thus $\wp$ is a meromorphic function and also the argument given above involving differentiation of the series termwise is valid. Thus $\wp$ is an elliptic function as claimed. This is called the Weierstrass $\wp$ function. This has proved the following theorem.

Theorem 58.1.13 The function $\wp$ defined above is an example of an elliptic function. On any compact set, $\wp ~ e q u a l s ~ a ~ r a t i o n a l ~ f u n c t i o n ~ a d d e d ~ t o ~ a ~ s e r i e s ~ w h i c h ~ i s ~ u n i f o r m l y ~ a n d ~$ absolutely convergent on the compact set.

### 58.1.3 The Differential Equation Satisfied By $\wp$

For $z$ not a pole,

$$
\wp^{\prime}(z)=\frac{-2}{z^{3}}-\sum_{w \neq 0} \frac{2}{(z-w)^{3}}
$$

Also since there are no poles of order 1 you can obtain a primitive for $\wp,-\zeta .{ }^{2}$ To do so, recall

$$
\wp(z) \equiv \frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right)
$$

where for $|z|<R$ this is the sum of a rational function with a uniformly convergent series. Therefore, you can take the integral along any path, $\gamma(0, z)$ from 0 to $z$ which misses the poles of $\wp$. By the uniform convergence of the above integral, you can interchange the sum with the integral and obtain

$$
\begin{equation*}
\zeta(z)=\frac{1}{z}+\sum_{w \neq 0} \frac{1}{z-w}+\frac{z}{w^{2}}+\frac{1}{w} \tag{58.1.7}
\end{equation*}
$$

[^41]This function is odd. Here is why.

$$
\zeta(-z)=\frac{1}{-z}+\sum_{w \neq 0} \frac{1}{-z-w}-\frac{z}{w^{2}}+\frac{1}{w}
$$

while

$$
\begin{aligned}
-\zeta(z) & =\frac{1}{-z}+\sum_{w \neq 0} \frac{-1}{z-w}-\frac{z}{w^{2}}-\frac{1}{w} \\
& =\frac{1}{-z}+\sum_{w \neq 0} \frac{-1}{z+w}-\frac{z}{w^{2}}+\frac{1}{w}
\end{aligned}
$$

Now consider 58.1.7. It will be used to find the Laurent expansion about the origin for $\zeta$ which will then be differentiated to obtain the Laurent expansion for $\wp$ at the origin. Since $w \neq 0$ and the interest is for $z$ near 0 so $|z|<|w|$,

$$
\begin{aligned}
\frac{1}{z-w}+\frac{z}{w^{2}}+\frac{1}{w} & =\frac{z}{w^{2}}+\frac{1}{w}-\frac{1}{w} \frac{1}{1-\frac{z}{w}} \\
& =\frac{z}{w^{2}}+\frac{1}{w}-\frac{1}{w} \sum_{k=0}^{\infty}\left(\frac{z}{w}\right)^{k} \\
& =-\frac{1}{w} \sum_{k=2}^{\infty}\left(\frac{z}{w}\right)^{k}
\end{aligned}
$$

From 58.1.7

$$
\begin{aligned}
\zeta(z) & =\frac{1}{z}+\sum_{w \neq 0}\left(-\sum_{k=2}^{\infty} \frac{z^{k}}{w^{k+1}}\right) \\
& =\frac{1}{z}-\sum_{k=2}^{\infty} \sum_{w \neq 0} \frac{z^{k}}{w^{k+1}}=\frac{1}{z}-\sum_{k=2}^{\infty} \sum_{w \neq 0} \frac{z^{2 k-1}}{w^{2 k}}
\end{aligned}
$$

because the sum over odd powers must be zero because for each $w \neq 0$, there exists $-w \neq 0$ such that the two terms $\frac{z^{2 k}}{w^{2 k+1}}$ and $\frac{z^{2 k}}{(-w)^{2 k+1}}$ cancel each other. Hence

$$
\zeta(z)=\frac{1}{z}-\sum_{k=2}^{\infty} G_{k} z^{2 k-1}
$$

where $G_{k}=\sum_{w \neq 0} \frac{1}{w^{2 k}}$. Now with this,

$$
\begin{aligned}
-\zeta^{\prime}(z) & =\wp(z)=\frac{1}{z^{2}}+\sum_{k=2}^{\infty} G_{k}(2 k-1) z^{2 k-2} \\
& =\frac{1}{z^{2}}+3 G_{2} z^{2}+5 G_{3} z^{4}+\cdots
\end{aligned}
$$

Therefore,

$$
\wp^{\prime}(z)=\frac{-2}{z^{3}}+6 G_{2} z+20 G_{3} z^{3}+\cdots
$$

$$
\begin{aligned}
\wp(z)^{2} & =\frac{4}{z^{6}}-\frac{24 G_{2}}{z^{2}}-80 G_{3}+\cdots \\
4 \wp(z)^{3} & =4\left(\frac{1}{z^{2}}+3 G_{2} z^{2}+5 G_{3} z^{4} \cdots\right)^{3} \\
& =\frac{4}{z^{6}}+\frac{36}{z^{2}} G_{2}+60 G_{3}+\cdots
\end{aligned}
$$

and finally

$$
60 G_{2} \wp(z)=\frac{60 G_{2}}{z^{2}}+0+\cdots
$$

where in the above, the positive powers of $z$ are not listed explicitly. Therefore,

$$
\wp^{\prime}(z)^{2}-4 \wp(z)^{3}+60 G_{2} \wp(z)+140 G_{3}=\sum_{n=1}^{\infty} a_{n} z^{n}
$$

In deriving the equation it was assumed $|z|<|w|$ for all $w=a w_{1}+b w_{2}$ where $a, b$ are integers not both zero. The left side of the above equation is periodic with respect to $w_{1}$ and $w_{2}$ where $w_{2} / w_{1}$ is not a real number. The only possible poles of the left side are at $0, w_{1}, w_{2}$, and $w_{1}+w_{2}$, the vertices of the parallelogram determined by $w_{1}$ and $w_{2}$. This follows from the original formula for $\wp(z)$. However, the above equation shows the left side has no pole at 0 . Since the left side is periodic with periods $w_{1}$ and $w_{2}$, it follows it has no pole at the other vertices of this parallelogram either. Therefore, the left side is periodic and has no poles. Consequently, it equals a constant by Theorem 58.1.4. But the right side of the above equation shows this constant is 0 because this side equals zero when $z=0$. Therefore, $\wp$ satisfies the differential equation,

$$
\wp^{\prime}(z)^{2}-4 \wp(z)^{3}+60 G_{2} \wp(z)+140 G_{3}=0
$$

It is traditional to define $60 G_{2} \equiv g_{2}$ and $140 G_{3} \equiv g_{3}$. Then in terms of these new quantities the differential equation is

$$
\wp^{\prime}(z)^{2}=4 \wp(z)^{3}-g_{2} \wp(z)-g_{3}
$$

Suppose $e_{1}, e_{2}$ and $e_{3}$ are zeros of the polynomial $4 w^{3}-g_{2} w-g_{3}=0$. Then the above equation can be written in the form

$$
\begin{equation*}
\wp(z)^{2}=4\left(\wp(z)-e_{1}\right)\left(\wp(z)-e_{2}\right)\left(\wp(z)-e_{3}\right) \tag{58.1.8}
\end{equation*}
$$

### 58.1.4 A Modular Function

The next task is to find the $e_{i}$ in 58.1.8. First recall that $\wp$ is an even function. That is $\wp(-z)=\wp(z)$. This follows from 58.1.6 which is listed here for convenience.

$$
\begin{equation*}
\wp(z) \equiv \frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right) \tag{58.1.9}
\end{equation*}
$$

Thus

$$
\begin{aligned}
\wp(-z) & =\frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(-z-w)^{2}}-\frac{1}{w^{2}}\right) \\
& =\frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(-z+w)^{2}}-\frac{1}{w^{2}}\right)=\wp(z)
\end{aligned}
$$

Therefore, $\wp\left(w_{1}-z\right)=\wp\left(z-w_{1}\right)=\wp(z)$ and so $-\wp^{\prime}\left(w_{1}-z\right)=\wp^{\prime}(z)$. Letting $z=$ $w_{1} / 2$, it follows $\wp^{\prime}\left(w_{1} / 2\right)=0$. Similarly, $\not \wp^{\prime}\left(w_{2} / 2\right)=0$ and $\wp^{\prime}\left(\left(w_{1}+w_{2}\right) / 2\right)=0$. Therefore, from 58.1.8

$$
0=4\left(\wp\left(w_{1} / 2\right)-e_{1}\right)\left(\wp\left(w_{1} / 2\right)-e_{2}\right)\left(\wp\left(w_{1} / 2\right)-e_{3}\right) .
$$

It follows one of the $e_{i}$ must equal $\wp\left(w_{1} / 2\right)$. Similarly, one of the $e_{i}$ must equal $\wp\left(w_{2} / 2\right)$ and one must equal $\wp\left(\left(w_{1}+w_{2}\right) / 2\right)$.

Lemma 58.1.14 The numbers, $\wp\left(w_{1} / 2\right), \wp\left(w_{2} / 2\right)$, and $\wp\left(\left(w_{1}+w_{2}\right) / 2\right)$ are distinct.
Proof: Choose $P_{a}$, a period parallelogram which contains the pole 0 , and the points $w_{1} / 2, w_{2} / 2$, and $\left(w_{1}+w_{2}\right) / 2$ but no other pole of $\wp(z)$. Also $\partial P_{a}^{*}$ does not contain any zeros of the elliptic function, $z \rightarrow \wp(z)-\wp\left(w_{1} / 2\right)$. This can be done by shifting $P_{0}$ slightly because the poles are only at the points $a w_{1}+b w_{2}$ for $a, b$ integers and the zeros of $\wp(z)-$ $\wp\left(w_{1} / 2\right)$ are discrete.

If $\wp\left(w_{2} / 2\right)=\wp\left(w_{1} / 2\right)$, then $\wp(z)-\wp\left(w_{1} / 2\right)$ has two zeros, $w_{2} / 2$ and $w_{1} / 2$ and since the pole at 0 is of order 2, this is the order of $\wp(z)-\wp\left(w_{1} / 2\right)$ on $P_{a}$ hence by Theorem 58.1.7 on Page 1818 these are the only zeros of this function on $P_{a}$. It follows by Corollary 58.1.9 on Page 1820 which says the sum of the zeros minus the sum of the poles is in $M$, $\frac{w_{1}}{2}+\frac{w_{2}}{2} \in M$. Thus there exist integers, $a, b$ such that

$$
\frac{w_{1}+w_{2}}{2}=a w_{1}+b w_{2}
$$

which implies $(2 a-1) w_{1}+(2 b-1) w_{2}=0$ contradicting $w_{2} / w_{1}$ not being real. Similar reasoning applies to the other pairs of points in $\left\{w_{1} / 2, w_{2} / 2,\left(w_{1}+w_{2}\right) / 2\right\}$. For example,
consider $\left(w_{1}+w_{2}\right) / 2$ and choose $P_{a}$ such that its boundary contains no zeros of the elliptic function, $z \rightarrow \wp(z)-\wp\left(\left(w_{1}+w_{2}\right) / 2\right)$ and $P_{a}$ contains no poles of $\wp$ on its interior other than 0 . Then if $\wp\left(w_{2} / 2\right)=\wp\left(\left(w_{1}+w_{2}\right) / 2\right)$, it follows from Theorem 58.1.7 on Page $1818 w_{2} / 2$ and $\left(w_{1}+w_{2}\right) / 2$ are the only two zeros of $\wp(z)-\wp\left(\left(w_{1}+w_{2}\right) / 2\right)$ on $P_{a}$ and by Corollary 58.1.9 on Page 1820

$$
\frac{w_{1}+w_{1}+w_{2}}{2}=a w_{1}+b w_{2} \in M
$$

for some integers $a, b$ which leads to the same contradiction as before about $w_{1} / w_{2}$ not being real. The other cases are similar. This proves the lemma.

Lemma 58.1.14 proves the $e_{i}$ are distinct. Number the $e_{i}$ such that

$$
e_{1}=\wp\left(w_{1} / 2\right), e_{2}=\wp\left(w_{2} / 2\right)
$$

and

$$
e_{3}=\wp\left(\left(w_{1}+w_{2}\right) / 2\right)
$$

To summarize, it has been shown that for complex numbers, $w_{1}$ and $w_{2}$ with $w_{2} / w_{1}$ not real, an elliptic function, $\wp$ has been defined. Denote this function as $\wp(z)=\wp\left(z, w_{1}, w_{2}\right)$. This in turn determined numbers, $e_{i}$ as described above. Thus these numbers depend on $w_{1}$ and $w_{2}$ and as described above,

$$
\begin{aligned}
& e_{1}\left(w_{1}, w_{2}\right)=\wp\left(\frac{w_{1}}{2}, w_{1}, w_{2}\right), e_{2}\left(w_{1}, w_{2}\right)=\wp\left(\frac{w_{2}}{2}, w_{1}, w_{2}\right) \\
& e_{3}\left(w_{1}, w_{2}\right)=\wp\left(\frac{w_{1}+w_{2}}{2}, w_{1}, w_{2}\right) .
\end{aligned}
$$

Therefore, using the formula for $\wp, 58.1 .9$,

$$
\wp(z) \equiv \frac{1}{z^{2}}+\sum_{w \neq 0}\left(\frac{1}{(z-w)^{2}}-\frac{1}{w^{2}}\right)
$$

you see that if the two periods $w_{1}$ and $w_{2}$ are replaced with $t w_{1}$ and $t w_{2}$ respectively, then

$$
e_{i}\left(t w_{1}, t w_{2}\right)=t^{-2} e_{i}\left(w_{1}, w_{2}\right)
$$

Let $\tau$ denote the complex number which equals the ratio, $w_{2} / w_{1}$ which was assumed in all this to not be real. Then

$$
e_{i}\left(w_{1}, w_{2}\right)=w_{1}^{-2} e_{i}(1, \tau)
$$

Now define the function, $\lambda(\tau)$

$$
\begin{equation*}
\lambda(\tau) \equiv \frac{e_{3}(1, \tau)-e_{2}(1, \tau)}{e_{1}(1, \tau)-e_{2}(1, \tau)}\left(=\frac{e_{3}\left(w_{1}, w_{2}\right)-e_{2}\left(w_{1}, w_{2}\right)}{e_{1}\left(w_{1}, w_{2}\right)-e_{2}\left(w_{1}, w_{2}\right)}\right) . \tag{58.1.10}
\end{equation*}
$$

This function is meromorphic for $\operatorname{Im} \tau>0$ or for $\operatorname{Im} \tau<0$. However, since the denominator is never equal to zero the function must actually be analytic on both the upper half plane and the lower half plane. It never is equal to 0 because $e_{3} \neq e_{2}$ and it never equals 1 because $e_{3} \neq e_{1}$. This is stated as an observation.

Observation 58.1.15 The function, $\lambda(\tau)$ is analytic for $\tau$ in the upper half plane and never assumes the values 0 and 1 .

This is a very interesting function. Consider what happens when

$$
\binom{w_{1}^{\prime}}{w_{2}^{\prime}}=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\binom{w_{1}}{w_{2}}
$$

and the matrix is unimodular. By Theorem 58.1.12 on Page $1821\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$ is just another basis for the same module of periods. Therefore, $\wp\left(z, w_{1}, w_{2}\right)=\wp\left(z, w_{1}^{\prime}, w_{2}^{\prime}\right)$ because both are defined as sums over the same values of $w$, just in different order which does not matter because of the absolute convergence of the sums on compact subsets of $\mathbb{C}$. Since $\wp$ is unchanged, it follows $\wp^{\prime}(z)$ is also unchanged and so the numbers, $e_{i}$ are also the same. However, they might be permuted in which case the function $\lambda(\tau)$ defined above would change. What would it take for $\lambda(\tau)$ to not change? In other words, for which unimodular transformations will $\lambda$ be left unchanged? This happens if and only if no permuting takes place for the $e_{i}$. This occurs if $\wp\left(\frac{w_{1}}{2}\right)=\wp\left(\frac{w_{1}^{\prime}}{2}\right)$ and $\wp\left(\frac{w_{2}}{2}\right)=\wp\left(\frac{w_{2}^{\prime}}{2}\right)$. If

$$
\frac{w_{1}^{\prime}}{2}-\frac{w_{1}}{2} \in M, \frac{w_{2}^{\prime}}{2}-\frac{w_{2}}{2} \in M
$$

then $\wp\left(\frac{w_{1}}{2}\right)=\wp\left(\frac{w_{1}^{\prime}}{2}\right)$ and so $e_{1}$ will be unchanged and similarly for $e_{2}$ and $e_{3}$. This occurs exactly when

$$
\frac{1}{2}\left((a-1) w_{1}+b w_{2}\right) \in M, \frac{1}{2}\left(c w_{1}+(d-1) w_{2}\right) \in M
$$

This happens if $a$ and $d$ are odd and if $b$ and $c$ are even. Of course the stylish way to say this is

$$
\begin{equation*}
a \equiv 1 \bmod 2, d \equiv 1 \bmod 2, b \equiv 0 \bmod 2, c \equiv 0 \bmod 2 \tag{58.1.11}
\end{equation*}
$$

This has shown that for unimodular transformations satisfying 58.1.11 $\lambda$ is unchanged. Letting $\tau$ be defined as above,

$$
\tau^{\prime}=\frac{w_{2}^{\prime}}{w_{1}^{\prime}} \equiv \frac{c w_{1}+d w_{2}}{a w_{1}+b w_{2}}=\frac{c+d \tau}{a+b \tau}
$$

Thus for unimodular transformations, $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ satisfying 58.1.11, or more succinctly,

$$
\left(\begin{array}{ll}
a & b  \tag{58.1.12}\\
c & d
\end{array}\right) \sim\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right) \bmod 2
$$

it follows that

$$
\begin{equation*}
\lambda\left(\frac{c+d \tau}{a+b \tau}\right)=\lambda(\tau) \tag{58.1.13}
\end{equation*}
$$

Furthermore, this is the only way this can happen.

Lemma 58.1.16 $\lambda(\tau)=\lambda\left(\tau^{\prime}\right)$ if and only if

$$
\tau^{\prime}=\frac{a \tau+b}{c \tau+d}
$$

where 58.1.12 holds.
Proof: It only remains to verify that if $\wp\left(w_{1}^{\prime} / 2\right)=\wp\left(w_{1} / 2\right)$ then it is necessary that

$$
\frac{w_{1}^{\prime}}{2}-\frac{w_{1}}{2} \in M
$$

with a similar requirement for $w_{2}$ and $w_{2}^{\prime}$. If $\frac{w_{1}^{\prime}}{2}-\frac{w_{1}}{2} \notin M$, then there exist integers, $m, n$ such that

$$
\frac{-w_{1}^{\prime}}{2}+m w_{1}+n w_{2}
$$

is in the interior of $P_{0}$, the period parallelogram whose vertices are $0, w_{1}, w_{1}+w_{2}$, and $w_{2}$. Therefore, it is possible to choose small $a$ such that $P_{a}$ contains the pole, $0, \frac{w_{1}}{2}$, and $\frac{-w_{1}^{\prime}}{2}+m w_{1}+n w_{2}$ but no other poles of $\wp$ and in addition, $\partial P_{a}^{*}$ contains no zeros of $z \rightarrow$ $\wp(z)-\wp\left(\frac{w_{1}}{2}\right)$. Then the order of this elliptic function is 2 . By assumption, and the fact that $\wp$ is even,

$$
\wp\left(\frac{-w_{1}^{\prime}}{2}+m w_{1}+n w_{2}\right)=\wp\left(\frac{-w_{1}^{\prime}}{2}\right)=\wp\left(\frac{w_{1}^{\prime}}{2}\right)=\wp\left(\frac{w_{1}}{2}\right) .
$$

It follows both $\frac{-w_{1}^{\prime}}{2}+m w_{1}+n w_{2}$ and $\frac{w_{1}}{2}$ are zeros of $\wp(z)-\wp\left(\frac{w_{1}}{2}\right)$ and so by Theorem 58.1.7 on Page 1818 these are the only two zeros of this function in $P_{a}$. Therefore, from Corollary 58.1.9 on Page 1820

$$
\frac{w_{1}}{2}-\frac{w_{1}^{\prime}}{2}+m w_{1}+n w_{2} \in M
$$

which shows $\frac{w_{1}}{2}-\frac{w_{1}^{\prime}}{2} \in M$. This completes the proof of the lemma.
Note the condition in the lemma is equivalent to the condition 58.1 .13 because you can relabel the coefficients. The message of either version is that the coefficient of $\tau$ in the numerator and denominator is odd while the constant in the numerator and denominator is even.

$$
\begin{array}{r}
\text { Next, }\left(\begin{array}{ll}
1 & 0 \\
2 & 1
\end{array}\right) \sim\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right) \bmod 2 \text { and therefore, } \\
 \tag{58.1.14}\\
\lambda\left(\frac{2+\tau}{1}\right)=\lambda(\tau+2)=\lambda(\tau) .
\end{array}
$$

Thus $\lambda$ is periodic of period 2.
Thus $\lambda$ leaves invariant a certain subgroup of the unimodular group. According to the next definition, $\lambda$ is an example of something called a modular function.

Definition 58.1.17 When an analytic or meromorphic function is invariant under a group of linear transformations, it is called an automorphic function. A function which is automorphic with respect to a subgroup of the modular group is called a modular function or an elliptic modular function.

Now consider what happens for some other unimodular matrices which are not congruent to the identity mod 2 . This will yield other functional equations for $\lambda$ in addition to the fact that $\lambda$ is periodic of period 2 . As before, these functional equations come about because $\wp$ is unchanged when you change the basis for $M$, the module of periods. In particular, consider the unimodular matrices

$$
\left(\begin{array}{ll}
1 & 0  \tag{58.1.15}\\
1 & 1
\end{array}\right),\left(\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right)
$$

Consider the first of these. Thus

$$
\binom{w_{1}^{\prime}}{w_{2}^{\prime}}=\binom{w_{1}}{w_{1}+w_{2}}
$$

Hence $\tau^{\prime}=w_{2}^{\prime} / w_{1}^{\prime}=\left(w_{1}+w_{2}\right) / w_{1}=1+\tau$. Then from the definition of $\lambda$,

$$
\left.\begin{array}{rl}
\lambda\left(\tau^{\prime}\right) & =\lambda(1+\tau) \\
& =\frac{\wp\left(\frac{w_{1}^{\prime}+w_{2}^{\prime}}{2}\right)-\wp\left(\frac{w_{2}^{\prime}}{2}\right)}{\wp\left(\frac{w_{1}^{\prime}}{2}\right)-\wp\left(\frac{w_{2}^{\prime}}{2}\right)} \\
& =\frac{\wp\left(\frac{w_{1}+w_{2}+w_{1}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)}{\wp\left(\frac{w_{1}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)} \\
& =\frac{\wp\left(\frac{w_{2}}{2}+w_{1}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)}{\wp\left(\frac{w_{1}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)} \\
& =\frac{\wp\left(\frac{w_{2}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)}{\wp\left(\frac{w_{1}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)} \\
& =-\frac{\wp\left(\frac{w_{1}+w_{2}}{2}\right)-\wp\left(\frac{w_{2}}{2}\right)}{\wp\left(\frac{w_{1}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)} \\
& =-\frac{\wp\left(\frac{w_{1}+w_{2}}{2}\right)-\wp\left(\frac{w_{2}}{2}\right)}{\wp\left(\frac{w_{1}}{2}\right)-\wp\left(\frac{w_{2}}{2}\right)+\wp\left(\frac{w_{2}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)} \\
& =-\frac{\wp\left(\frac{\wp\left(\frac{w_{1}+w_{2}}{2}\right)-\wp\left(\frac{w_{2}}{2}\right)}{\wp\left(\frac{w_{1}}{2}\right)-\wp\left(\frac{w_{2}}{2}\right)}\right)}{\wp\left(\frac{w_{2}}{2}\right)-\wp\left(\frac{w_{1}+w_{2}}{2}\right)} \\
\wp\left(\frac{w_{1}}{2}\right)-\wp\left(\frac{w_{2}}{2}\right)
\end{array}\right)
$$

Summarizing the important feature of the above,

$$
\begin{equation*}
\lambda(1+\tau)=\frac{\lambda(\tau)}{\lambda(\tau)-1} \tag{58.1.17}
\end{equation*}
$$

Next consider the other unimodular matrix in 58.1.15. In this case $w_{1}^{\prime}=w_{2}$ and $w_{2}^{\prime}=w_{1}$.

Therefore, $\tau^{\prime}=w_{2}^{\prime} / w_{1}^{\prime}=w_{1} / w_{2}=1 / \tau$. Then

$$
\begin{align*}
\lambda\left(\tau^{\prime}\right) & =\lambda(1 / \tau) \\
& =\frac{\wp\left(\frac{w_{1}^{\prime}+w_{2}^{\prime}}{2}\right)-\wp\left(\frac{w_{2}^{\prime}}{2}\right)}{\wp\left(\frac{w_{1}^{\prime}}{2}\right)-\wp\left(\frac{w_{2}^{\prime}}{2}\right)} \\
& =\frac{\wp\left(\frac{w_{1}+w_{2}}{2}\right)-\wp\left(\frac{w_{1}}{2}\right)}{\wp\left(\frac{w_{2}}{2}\right)-\wp\left(\frac{w_{1}}{2}\right)} \\
& =\frac{e_{3}-e_{1}}{e_{2}-e_{1}}=-\frac{e_{3}-e_{2}+e_{2}-e_{1}}{e_{1}-e_{2}} \\
& =-(\lambda(\tau)-1)=-\lambda(\tau)+1 . \tag{58.1.18}
\end{align*}
$$

You could try other unimodular matrices and attempt to find other functional equations if you like but this much will suffice here.

### 58.1.5 A Formula For $\lambda$

Recall the formula of Mittag-Leffler for $\cot (\pi \alpha)$ given in 57.2.15. For convenience, here it is.

$$
\frac{1}{\alpha}+\sum_{n=1}^{\infty} \frac{2 \alpha}{\alpha^{2}-n^{2}}=\pi \cot \pi \alpha
$$

As explained in the derivation of this formula it can also be written as

$$
\sum_{n=-\infty}^{\infty} \frac{\alpha}{\alpha^{2}-n^{2}}=\pi \cot \pi \alpha
$$

Differentiating both sides yields

$$
\begin{align*}
\pi^{2} \csc ^{2}(\pi \alpha) & =\sum_{n=-\infty}^{\infty} \frac{\alpha^{2}+n^{2}}{\left(\alpha^{2}-n^{2}\right)^{2}} \\
& =\sum_{n=-\infty}^{\infty} \frac{(\alpha+n)^{2}-2 \alpha n}{(\alpha+n)^{2}(\alpha-n)^{2}} \\
& =\sum_{n=-\infty}^{\infty} \frac{(\alpha+n)^{2}}{(\alpha+n)^{2}(\alpha-n)^{2}}-\overbrace{\sum_{n=-\infty}^{\infty} \frac{2 \alpha n}{\left(\alpha^{2}-n^{2}\right)^{2}}}^{=0} \\
& =\sum_{n=-\infty}^{\infty} \frac{1}{(\alpha-n)^{2}} \tag{58.1.19}
\end{align*}
$$

Now this formula can be used to obtain a formula for $\lambda(\tau)$. As pointed out above, $\lambda$ depends only on the ratio $w_{2} / w_{1}$ and so it suffices to take $w_{1}=1$ and $w_{2}=\tau$. Thus

$$
\begin{equation*}
\lambda(\tau)=\frac{\wp\left(\frac{1+\tau}{2}\right)-\wp\left(\frac{\tau}{2}\right)}{\wp\left(\frac{1}{2}\right)-\wp\left(\frac{\tau}{2}\right)} \tag{58.1.20}
\end{equation*}
$$

From the original formula for $\wp$,

$$
\begin{align*}
& \wp\left(\frac{1+\tau}{2}\right)-\wp\left(\frac{\tau}{2}\right) \\
= & \frac{1}{\left(\frac{1+\tau}{2}\right)^{2}}-\frac{1}{\left(\frac{\tau}{2}\right)^{2}}+\sum_{(k, m) \neq(0,0)} \frac{1}{\left(k-\frac{1}{2}+\left(m-\frac{1}{2}\right) \tau\right)^{2}}-\frac{1}{\left(k+\left(m-\frac{1}{2}\right) \tau\right)^{2}} \\
= & \sum_{(k, m) \in \mathbb{Z}^{2}} \frac{1}{\left(k-\frac{1}{2}+\left(m-\frac{1}{2}\right) \tau\right)^{2}}-\frac{1}{\left(k+\left(m-\frac{1}{2}\right) \tau\right)^{2}} \\
= & \sum_{(k, m) \in \mathbb{Z}^{2}} \frac{1}{\left(k-\frac{1}{2}+\left(m-\frac{1}{2}\right) \tau\right)^{2}}-\frac{1}{\left(k+\left(m-\frac{1}{2}\right) \tau\right)^{2}} \\
= & \sum_{(k, m) \in \mathbb{Z}^{2}} \frac{1}{\left(k-\frac{1}{2}+\left(-m-\frac{1}{2}\right) \tau\right)^{2}}-\frac{1}{\left(k+\left(-m-\frac{1}{2}\right) \tau\right)^{2}} \\
= & \sum_{(k, m) \in \mathbb{Z}^{2}} \frac{1}{\left(\frac{1}{2}+\left(m+\frac{1}{2}\right) \tau-k\right)^{2}}-\frac{1}{\left(\left(m+\frac{1}{2}\right) \tau-k\right)^{2}} . \tag{58.1.21}
\end{align*}
$$

Similarly,

$$
\begin{align*}
& \wp\left(\frac{1}{2}\right)-\wp\left(\frac{\tau}{2}\right) \\
= & \frac{1}{\left(\frac{1}{2}\right)^{2}}-\frac{1}{\left(\frac{\tau}{2}\right)^{2}}+\sum_{(k, m) \neq(0,0)} \frac{1}{\left(k-\frac{1}{2}+m \tau\right)^{2}}-\frac{1}{\left(k+\left(m-\frac{1}{2}\right) \tau\right)^{2}} \\
= & \sum_{(k, m) \in \mathbb{Z}^{2}} \frac{1}{\left(k-\frac{1}{2}+m \tau\right)^{2}}-\frac{1}{\left(k+\left(m-\frac{1}{2}\right) \tau\right)^{2}} \\
= & \sum_{(k, m) \in \mathbb{Z}^{2}} \frac{1}{\left(k-\frac{1}{2}-m \tau\right)^{2}}-\frac{1}{\left(k+\left(-m-\frac{1}{2}\right) \tau\right)^{2}} \\
= & \sum_{(k, m) \in \mathbb{Z}^{2}} \frac{1}{\left(\frac{1}{2}+m \tau-k\right)^{2}}-\frac{1}{\left(\left(m+\frac{1}{2}\right) \tau-k\right)^{2}} . \tag{58.1.22}
\end{align*}
$$

Now use 58.1.19 to sum these over $k$. This yields,

$$
\begin{aligned}
& \wp\left(\frac{1+\tau}{2}\right)-\wp\left(\frac{\tau}{2}\right) \\
= & \sum_{m} \frac{\pi^{2}}{\sin ^{2}\left(\pi\left(\frac{1}{2}+\left(m+\frac{1}{2}\right) \tau\right)\right)}-\frac{\pi^{2}}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)} \\
= & \sum_{m} \frac{\pi^{2}}{\cos ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}-\frac{\pi^{2}}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}
\end{aligned}
$$

and

$$
\begin{aligned}
\wp\left(\frac{1}{2}\right)-\wp\left(\frac{\tau}{2}\right) & =\sum_{m} \frac{\pi^{2}}{\sin ^{2}\left(\pi\left(\frac{1}{2}+m \tau\right)\right)}-\frac{\pi^{2}}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)} \\
& =\sum_{m} \frac{\pi^{2}}{\cos ^{2}(\pi m \tau)}-\frac{\pi^{2}}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}
\end{aligned}
$$

The following interesting formula for $\lambda$ results.

$$
\begin{equation*}
\lambda(\tau)=\frac{\sum_{m} \frac{1}{\cos ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}-\frac{1}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}}{\sum_{m} \frac{1}{\cos ^{2}(\pi m \tau)}-\frac{1}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}} \tag{58.1.23}
\end{equation*}
$$

From this it is obvious $\lambda(-\tau)=\lambda(\tau)$. Therefore, from 58.1.18,

$$
\begin{equation*}
-\lambda(\tau)+1=\lambda\left(\frac{1}{\tau}\right)=\lambda\left(\frac{-1}{\tau}\right) \tag{58.1.24}
\end{equation*}
$$

(It is good to recall that $\lambda$ has been defined for $\tau \notin \mathbb{R}$.)

### 58.1.6 Mapping Properties Of $\boldsymbol{\lambda}$

The two functional equations, 58.1.24 and 58.1.17 along with some other properties presented above are of fundamental importance. For convenience, they are summarized here in the following lemma.

Lemma 58.1.18 The following functional equations hold for $\lambda$.

$$
\begin{gather*}
\lambda(1+\tau)=\frac{\lambda(\tau)}{\lambda(\tau)-1}, 1=\lambda(\tau)+\lambda\left(\frac{-1}{\tau}\right)  \tag{58.1.25}\\
\lambda(\tau+2)=\lambda(\tau) \tag{58.1.26}
\end{gather*}
$$

$\lambda(z)=\lambda(w)$ if and only if there exists a unimodular matrix,

$$
\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \sim\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right) \bmod 2
$$

such that

$$
\begin{equation*}
w=\frac{a z+b}{c z+d} \tag{58.1.27}
\end{equation*}
$$

Consider the following picture.

In this picture, $l_{1}$ is the $y$ axis and $l_{2}$ is the line, $x=1$ while $C$ is the top half of the circle centered at $\left(\frac{1}{2}, 0\right)$ which has radius $1 / 2$. Note the above formula implies $\lambda$ has real values on $l_{1}$ which are between 0 and 1 . This is because 58.1 .23 implies

$$
\begin{align*}
\lambda(i b) & =\frac{\sum_{m} \frac{1}{\cos ^{2}\left(\pi\left(m+\frac{1}{2}\right) i b\right)}-\frac{1}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) i b\right)}}{\sum_{m} \frac{1}{\cos ^{2}(\pi m i b)}-\frac{1}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) i b\right)}} \\
& =\frac{\sum_{m} \frac{1}{\cosh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}+\frac{1}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}}{\sum_{m} \frac{1}{\cosh ^{2}(\pi m b)}+\frac{1}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}} \in(0,1) \tag{58.1.28}
\end{align*}
$$

This follows from the observation that

$$
\cos (i x)=\cosh (x), \sin (i x)=i \sinh (x)
$$

Thus it is clear from 58.1.28 that $\lim _{b \rightarrow 0+} \lambda(i b)=1$.
Next I need to consider the behavior of $\lambda(\tau)$ as $\operatorname{Im}(\tau) \rightarrow \infty$. From 58.1.23 listed here for convenience,

$$
\begin{equation*}
\lambda(\tau)=\frac{\sum_{m} \frac{1}{\cos ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}-\frac{1}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}}{\sum_{m} \frac{1}{\cos ^{2}(\pi m \tau)}-\frac{1}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}} \tag{58.1.29}
\end{equation*}
$$

it follows

$$
\begin{align*}
\lambda(\tau) & =\frac{\frac{1}{\cos ^{2}\left(\pi\left(-\frac{1}{2}\right) \tau\right)}-\frac{1}{\sin ^{2}\left(\pi\left(-\frac{1}{2}\right) \tau\right)}+\frac{1}{\cos ^{2}\left(\pi \frac{1}{2} \tau\right)}-\frac{1}{\sin ^{2}\left(\pi \frac{1}{2} \tau\right)}+A(\tau)}{1+B(\tau)} \\
& =\frac{\frac{2}{\cos ^{2}\left(\pi\left(\frac{1}{2}\right) \tau\right)}-\frac{2}{\sin ^{2}\left(\pi\left(\frac{1}{2}\right) \tau\right)}+A(\tau)}{1+B(\tau)} \tag{58.1.30}
\end{align*}
$$

Where $A(\tau), B(\tau) \rightarrow 0$ as $\operatorname{Im}(\tau) \rightarrow \infty$. I took out the $m=0$ term involving $1 / \cos ^{2}(\pi m \tau)$ in the denominator and the $m=-1$ and $m=0$ terms in the numerator of 58.1.29. In fact, $e^{-i \pi(a+i b)} A(a+i b), e^{-i \pi(a+i b)} B(a+i b)$ converge to zero uniformly in $a$ as $b \rightarrow \infty$.

Lemma 58.1.19 For $A, B$ defined in 58.1.30, $e^{-i \pi(a+i b)} C(a+i b) \rightarrow 0$ uniformly in a for $C=A, B$.

Proof: From 58.1.23,

$$
e^{-i \pi \tau} A(\tau)=\sum_{\substack{m \neq 0 \\ m \neq-1}} \frac{e^{-i \pi \tau}}{\cos ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}-\frac{e^{-i \pi \tau}}{\sin ^{2}\left(\pi\left(m+\frac{1}{2}\right) \tau\right)}
$$

Now let $\tau=a+i b$. Then letting $\alpha_{m}=\pi\left(m+\frac{1}{2}\right)$,

$$
\begin{aligned}
\cos \left(\alpha_{m} a+i \alpha_{m} b\right) & =\cos \left(\alpha_{m} a\right) \cosh \left(\alpha_{m} b\right)-i \sinh \left(\alpha_{m} b\right) \sin \left(\alpha_{m} a\right) \\
\sin \left(\alpha_{m} a+i \alpha_{m} b\right) & =\sin \left(\alpha_{m} a\right) \cosh \left(\alpha_{m} b\right)+i \cos \left(\alpha_{m} a\right) \sinh \left(\alpha_{m} b\right)
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
\left|\cos ^{2}\left(\alpha_{m} a+i \alpha_{m} b\right)\right| & =\cos ^{2}\left(\alpha_{m} a\right) \cosh ^{2}\left(\alpha_{m} b\right)+\sinh ^{2}\left(\alpha_{m} b\right) \sin ^{2}\left(\alpha_{m} a\right) \\
& \geq \sinh ^{2}\left(\alpha_{m} b\right)
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
\left|\sin ^{2}\left(\alpha_{m} a+i \alpha_{m} b\right)\right| & =\sin ^{2}\left(\alpha_{m} a\right) \cosh ^{2}\left(\alpha_{m} b\right)+\cos ^{2}\left(\alpha_{m} a\right) \sinh ^{2}\left(\alpha_{m} b\right) \\
& \geq \sinh ^{2}\left(\alpha_{m} b\right)
\end{aligned}
$$

It follows that for $\tau=a+i b$ and $b$ large

$$
\begin{aligned}
& \left|e^{-i \pi \tau} A(\tau)\right| \\
\leq & \sum_{\substack{m \neq 0 \\
m \neq-1}} \frac{2 e^{\pi b}}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)} \\
\leq & \sum_{m=1}^{\infty} \frac{2 e^{\pi b}}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}+\sum_{m=-\infty}^{-2} \frac{2 e^{\pi b}}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)} \\
= & 2 \sum_{m=1}^{\infty} \frac{2 e^{\pi b}}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}=4 \sum_{m=1}^{\infty} \frac{e^{\pi b}}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}
\end{aligned}
$$

Now a short computation shows

$$
\frac{\frac{e^{\pi b}}{\sinh ^{2}\left(\pi\left(m+1+\frac{1}{2}\right) b\right)}}{\frac{e^{\pi b}}{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}}=\frac{\sinh ^{2}\left(\pi\left(m+\frac{1}{2}\right) b\right)}{\sinh ^{2}\left(\pi\left(m+\frac{3}{2}\right) b\right)} \leq \frac{1}{e^{3 \pi b}}
$$

Therefore, for $\tau=a+i b$,

$$
\begin{aligned}
\left|e^{-i \pi \tau} A(\tau)\right| & \leq 4 \frac{e^{\pi b}}{\sinh \left(\frac{3 \pi b}{2}\right)} \sum_{m=1}^{\infty}\left(\frac{1}{e^{3 \pi b}}\right)^{m} \\
& \leq 4 \frac{e^{\pi b}}{\sinh \left(\frac{3 \pi b}{2}\right)} \frac{1 / e^{3 \pi b}}{1-\left(1 / e^{3 \pi b}\right)}
\end{aligned}
$$

which converges to zero as $b \rightarrow \infty$. Similar reasoning will establish the claim about $B(\tau)$. This proves the lemma.

Lemma 58.1.20 $\lim _{b \rightarrow \infty} \lambda(a+i b) e^{-i \pi(a+i b)}=16$ uniformly in $a \in \mathbb{R}$.
Proof: From 58.1.30 and Lemma 58.1.19, this lemma will be proved if it is shown

$$
\lim _{b \rightarrow \infty}\left(\frac{2}{\cos ^{2}\left(\pi\left(\frac{1}{2}\right)(a+i b)\right)}-\frac{2}{\sin ^{2}\left(\pi\left(\frac{1}{2}\right)(a+i b)\right)}\right) e^{-i \pi(a+i b)}=16
$$

uniformly in $a \in \mathbb{R}$. Let $\tau=a+i b$ to simplify the notation. Then the above expression equals

$$
\begin{aligned}
& \left(\frac{8}{\left(e^{i \frac{\pi}{2} \tau}+e^{-i \frac{\pi}{2} \tau}\right)^{2}}+\frac{8}{\left(e^{i \frac{\pi}{2} \tau}-e^{-i \frac{\pi}{2} \tau}\right)^{2}}\right) e^{-i \pi \tau} \\
= & \left(\frac{8 e^{i \pi \tau}}{\left(e^{i \pi \tau}+1\right)^{2}}+\frac{8 e^{i \pi \tau}}{\left(e^{i \pi \tau}-1\right)^{2}}\right) e^{-i \pi \tau} \\
= & \frac{8}{\left(e^{i \pi \tau}+1\right)^{2}}+\frac{8}{\left(e^{i \pi \tau}-1\right)^{2}} \\
= & 16 \frac{1+e^{2 \pi i \tau}}{\left(1-e^{2 \pi i \tau}\right)^{2}}
\end{aligned}
$$

Now

$$
\begin{aligned}
\left|\frac{1+e^{2 \pi i \tau}}{\left(1-e^{2 \pi i \tau}\right)^{2}}-1\right| & =\left|\frac{1+e^{2 \pi i \tau}}{\left(1-e^{2 \pi i \tau}\right)^{2}}-\frac{\left(1-e^{2 \pi i \tau}\right)^{2}}{\left(1-e^{2 \pi i \tau}\right)^{2}}\right| \\
& \leq \frac{\left|3 e^{2 \pi i \tau}-e^{4 \pi i \tau}\right|}{\left(1-e^{-2 \pi b}\right)^{2}} \leq \frac{3 e^{-2 \pi b}+e^{-4 \pi b}}{\left(1-e^{-2 \pi b}\right)^{2}}
\end{aligned}
$$

and this estimate proves the lemma.
Corollary 58.1.21 $\lim _{b \rightarrow \infty} \lambda(a+i b)=0$ uniformly in $a \in \mathbb{R}$. Also $\lambda(i b)$ for $b>0$ is real and is between 0 and $1, \lambda$ is real on the line, $l_{2}$ and on the curve, $C$ and $\lim _{b \rightarrow 0+} \lambda(1+i b)=$ $-\infty$.

Proof: From Lemma 58.1.20,

$$
\left|\lambda(a+i b) e^{-i \pi(a+i b)}-16\right|<1
$$

for all $a$ provided $b$ is large enough. Therefore, for such $b$,

$$
|\lambda(a+i b)| \leq 17 e^{-\pi b} .
$$

58.1.28 proves the assertion about $\lambda(-b i)$ real.

By the first part, $\lim _{b \rightarrow \infty}|\lambda(i b)|=0$. Now from 58.1.24

$$
\begin{equation*}
\lim _{b \rightarrow 0+} \lambda(i b)=\lim _{b \rightarrow 0+}\left(1-\lambda\left(\frac{-1}{i b}\right)\right)=\lim _{b \rightarrow 0+}\left(1-\lambda\left(\frac{i}{b}\right)\right)=1 \tag{58.1.31}
\end{equation*}
$$

by Corollary 58.1.21.
Next consider the behavior of $\lambda$ on line $l_{2}$ in the above picture. From 58.1.17 and 58.1.28,

$$
\lambda(1+i b)=\frac{\lambda(i b)}{\lambda(i b)-1}<0
$$

and so as $b \rightarrow 0+$ in the above, $\lambda(1+i b) \rightarrow-\infty$.
It is left as an exercise to show that the map $\tau \rightarrow 1-\frac{1}{\tau}$ maps $l_{2}$ onto the curve, $C$. Therefore, by 58.1.25, for $\tau \in l_{2}$,

$$
\begin{align*}
\lambda\left(1-\frac{1}{\tau}\right) & =\frac{\lambda\left(\frac{-1}{\tau}\right)}{\lambda\left(\frac{-1}{\tau}\right)-1}  \tag{58.1.32}\\
& =\frac{1-\lambda(\tau)}{(1-\lambda(\tau))-1}=\frac{\lambda(\tau)-1}{\lambda(\tau)} \in \mathbb{R} \tag{58.1.33}
\end{align*}
$$

It follows $\lambda$ is real on the boundary of $\Omega$ in the above picture. This proves the corollary.
Now, following Alfors [3], cut off $\Omega$ by considering the horizontal line segment, $z=$ $a+i b_{0}$ where $b_{0}$ is very large and positive and $a \in[0,1]$. Also cut $\Omega$ off by the images of this horizontal line, under the transformations $z=\frac{1}{\tau}$ and $z=1-\frac{1}{\tau}$. These are arcs of circles because the two transformations are fractional linear transformations. It is left as an exercise for you to verify these arcs are situated as shown in the following picture. The important thing to notice is that for $b_{0}$ large the points of these circles are close to the origin and $(1,0)$ respectively. The following picture is a summary of what has been obtained so far on the mapping by $\lambda$.

In the picture, the descriptions are of $\lambda$ acting on points of the indicated boundary of $\Omega$. Consider the oriented contour which results from $\lambda(z)$ as $z$ moves first up $l_{2}$ as indicated, then along the line $z=a+i b$ and then down $l_{1}$ and then along $C_{1}$ to $C$ and along $C$ till $C_{2}$ and then along $C_{2}$ to $l_{2}$. As indicated in the picture, this involves going from a large negative real number to a small negative real number and then over a smooth curve which stays small to a real positive number and from there to a real number near $1 . \lambda(z)$ stays
fairly near 1 on $C_{1}$ provided $b_{0}$ is large so that the circle, $C_{1}$ has very small radius. Then along $C, \lambda(z)$ is real until it hits $C_{2}$. What about the behavior of $\lambda$ on $C_{2}$ ? For $z \in C_{2}$, it follows from the definition of $C_{2}$ that $z=1-\frac{1}{\tau}$ where $\tau$ is on the line, $a+i b_{0}$. Therefore, by Lemma 58.1.20, 58.1.17, and 58.1.24

$$
\begin{aligned}
\lambda(z) & =\lambda\left(1-\frac{1}{\tau}\right)=\frac{\lambda\left(\frac{-1}{\tau}\right)}{\lambda\left(\frac{-1}{\tau}\right)-1}=\frac{\lambda\left(\frac{1}{\tau}\right)}{\lambda\left(\frac{1}{\tau}\right)-1} \\
& =\frac{1-\lambda(\tau)}{(1-\lambda(\tau))-1}=\frac{\lambda(\tau)-1}{\lambda(\tau)}=1-\frac{1}{\lambda(\tau)}
\end{aligned}
$$

which is approximately equal to

$$
1-\frac{1}{16 e^{i \pi\left(a+i b_{0}\right)}}=1-\frac{e^{\pi b_{0}} e^{-i a \pi}}{16}
$$

These points are essentially on a large half circle in the upper half plane which has radius approximately $\frac{e^{\pi b_{0}}}{16}$.

Now let $w \in \mathbb{C}$ with $\operatorname{Im}(w) \neq 0$. Then for $b_{0}$ large enough, the motion over the boundary of the truncated region indicated in the above picture results in $\lambda$ tracing out a large simple closed curve oriented in the counter clockwise direction which includes $w$ on its interior if $\operatorname{Im}(w)>0$ but which excludes $w$ if $\operatorname{Im}(w)<0$.

Theorem 58.1.22 Let $\Omega$ be the domain described above. Then $\lambda$ maps $\Omega$ one to one and onto the upper half plane of $\mathbb{C},\{z \in \mathbb{C}$ such that $\operatorname{Im}(z)>0\}$. Also, the line $\lambda\left(l_{1}\right)=$ $(0,1), \lambda\left(l_{2}\right)=(-\infty, 0)$, and $\lambda(C)=(1, \infty)$.

Proof: Let $\operatorname{Im}(w)>0$ and denote by $\gamma$ the oriented contour described above and illustrated in the above picture. Then the winding number of $\lambda \circ \gamma$ about $w$ equals 1. Thus

$$
\frac{1}{2 \pi i} \int_{\lambda \circ \gamma} \frac{1}{z-w} d z=1
$$

But, splitting the contour integrals into $l_{2}$, the top line, $l_{1}, C_{1}, C$, and $C_{2}$ and changing variables on each of these, yields

$$
1=\frac{1}{2 \pi i} \int_{\gamma} \frac{\lambda^{\prime}(z)}{\lambda(z)-w} d z
$$

and by the theorem on counting zeros, Theorem 52.6.1 on Page 1661 , the function, $z \rightarrow$ $\lambda(z)-w$ has exactly one zero inside the truncated $\Omega$. However, this shows this function has exactly one zero inside $\Omega$ because $b_{0}$ was arbitrary as long as it is sufficiently large. Since $w$ was an arbitrary element of the upper half plane, this verifies the first assertion of the theorem. The remaining claims follow from the above description of $\lambda$, in particular the estimate for $\lambda$ on $C_{2}$. This proves the theorem.

Note also that the argument in the above proof shows that if $\operatorname{Im}(w)<0$, then $w$ is not in $\lambda(\Omega)$. However, if you consider the reflection of $\Omega$ about the $y$ axis, then it will follow that $\lambda$ maps this set one to one onto the lower half plane. The argument will make significant use of Theorem 52.6.3 on Page 1663 which is stated here for convenience.

Theorem 58.1.23 Let $f: B(a, R) \rightarrow \mathbb{C}$ be analytic and let

$$
f(z)-\alpha=(z-a)^{m} g(z), \infty>m \geq 1
$$

where $g(z) \neq 0$ in $B(a, R) .(f(z)-\alpha$ has a zero of order $m$ at $z=a$.) Then there exist $\varepsilon, \delta>0$ with the property that for each z satisfying $0<|z-\alpha|<\delta$, there exist points,

$$
\left\{a_{1}, \cdots, a_{m}\right\} \subseteq B(a, \varepsilon)
$$

such that

$$
f^{-1}(z) \cap B(a, \varepsilon)=\left\{a_{1}, \cdots, a_{m}\right\}
$$

and each $a_{k}$ is a zero of order 1 for the function $f(\cdot)-z$.
Corollary 58.1.24 Let $\Omega$ be the region above. Consider the set of points, $Q=\bar{\Omega} \cup \Omega^{\prime} \backslash$ $\{0,1\}$ described by the following picture.

Then $\lambda(Q)=\mathbb{C} \backslash\{0,1\}$. Also $\lambda^{\prime}(z) \neq 0$ for every $z$ in $\cup_{k=-\infty}^{\infty}(Q+2 k) \equiv H$.
Proof: By Theorem 58.1.22, this will be proved if it can be shown that $\lambda\left(\Omega^{\prime}\right)=$ $\{z \in \mathbb{C}: \operatorname{Im}(z)<0\}$. Consider $\lambda_{1}$ defined on $\Omega^{\prime}$ by

$$
\lambda_{1}(x+i y) \equiv \overline{\lambda(-x+i y)}
$$

Claim: $\lambda_{1}$ is analytic.
Proof of the claim: You just verify the Cauchy Riemann equations. Letting $\lambda(x+i y)=$ $u(x, y)+i v(x, y)$,

$$
\begin{aligned}
\lambda_{1}(x+i y) & =u(-x, y)-i v(-x, y) \\
& \equiv u_{1}(x, y)+i v(x, y)
\end{aligned}
$$

Then $u_{1 x}(x, y)=-u_{x}(-x, y)$ and $v_{1 y}(x, y)=-v_{y}(-x, y)=-u_{x}(-x, y)$ since $\lambda$ is analytic. Thus $u_{1 x}=v_{1 y}$. Next, $u_{1 y}(x, y)=u_{y}(-x, y)$ and $v_{1 x}(x, y)=v_{x}(-x, y)=-u_{y}(-x, y)$ and so $u_{1 y}=-v_{x}$.

Now recall that on $l_{1}, \lambda$ takes real values. Therefore, $\lambda_{1}=\lambda$ on $l_{1}$, a set with a limit point. It follows $\lambda=\lambda_{1}$ on $\Omega^{\prime} \cup \Omega$. By Theorem 58.1.22 $\lambda$ maps $\Omega$ one to one onto the upper half plane. Therefore, from the definition of $\lambda_{1}=\lambda$, it follows $\lambda$ maps $\Omega^{\prime}$ one to one onto the lower half plane as claimed. This has shown that $\lambda$ is one to one on $\Omega \cup \Omega^{\prime}$. This also verifies from Theorem 52.6.3 on Page 1663 that $\lambda^{\prime} \neq 0$ on $\Omega \cup \Omega^{\prime}$.

Now consider the lines $l_{2}$ and $C$. If $\lambda^{\prime}(z)=0$ for $z \in l_{2}$, a contradiction can be obtained. Pick such a point. If $\lambda^{\prime}(z)=0$, then $z$ is a zero of order $m \geq 2$ of the function, $\lambda-\lambda(z)$. Then by Theorem 52.6 .3 there exist $\delta, \varepsilon>0$ such that if $w \in B(\lambda(z), \delta)$, then $\lambda^{-1}(w) \cap$ $B(z, \varepsilon)$ contains at least $m$ points.

In particular, for $z_{1} \in \Omega \cap B(z, \varepsilon)$ sufficiently close to $z, \lambda\left(z_{1}\right) \in B(\lambda(z), \delta)$ and so the function $\lambda-\lambda\left(z_{1}\right)$ has at least two distinct zeros. These zeros must be in $B(z, \varepsilon) \cap \Omega$ because $\lambda\left(z_{1}\right)$ has positive imaginary part and the points on $l_{2}$ are mapped by $\lambda$ to a real number while the points of $B(z, \varepsilon) \backslash \bar{\Omega}$ are mapped by $\lambda$ to the lower half plane thanks to the relation, $\lambda(z+2)=\lambda(z)$. This contradicts $\lambda$ one to one on $\Omega$. Therefore, $\lambda^{\prime} \neq 0$ on $l_{2}$. Consider $C$. Points on $C$ are of the form $1-\frac{1}{\tau}$ where $\tau \in l_{2}$. Therefore, using 58.1.33,

$$
\lambda\left(1-\frac{1}{\tau}\right)=\frac{\lambda(\tau)-1}{\lambda(\tau)}
$$

Taking the derivative of both sides,

$$
\lambda^{\prime}\left(1-\frac{1}{\tau}\right)\left(\frac{1}{\tau^{2}}\right)=\frac{\lambda^{\prime}(\tau)}{\lambda(\tau)^{2}} \neq 0
$$

Since $\lambda$ is periodic of period 2 it follows $\lambda^{\prime}(z) \neq 0$ for all $z \in \cup_{k=-\infty}^{\infty}(Q+2 k)$.
Lemma 58.1.25 If $\operatorname{Im}(\tau)>0$ then there exists a unimodular $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ such that

$$
\frac{c+d \tau}{a+b \tau}
$$

is contained in the interior of $Q$. In fact, $\left|\frac{c+d \tau}{a+b \tau}\right| \geq 1$ and

$$
-1 / 2 \leq \operatorname{Re}\left(\frac{c+d \tau}{a+b \tau}\right) \leq 1 / 2
$$

Proof: Letting a basis for the module of periods of $\wp$ be $\{1, \tau\}$, it follows from Theorem 58.1.2 on Page 1816 that there exists a basis for the same module of periods, $\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$ with the property that for $\tau^{\prime}=w_{2}^{\prime} / w_{1}^{\prime}$

$$
\left|\tau^{\prime}\right| \geq 1, \frac{-1}{2} \leq \operatorname{Re} \tau^{\prime} \leq \frac{1}{2}
$$

Since this is a basis for the same module of periods, there exists a unimodular matrix, $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ such that

$$
\binom{w_{1}^{\prime}}{w_{2}^{\prime}}=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\binom{1}{\tau} .
$$

Hence,

$$
\tau^{\prime}=\frac{w_{2}^{\prime}}{w_{1}^{\prime}}=\frac{c+d \tau}{a+b \tau}
$$

Thus $\tau^{\prime}$ is in the interior of $H$. In fact, it is on the interior of $\Omega^{\prime} \cup \Omega \equiv Q$.

### 58.1.7 A Short Review And Summary

With this lemma, it is easy to extend Corollary 58.1.24. First, a simple observation and review is a good idea. Recall that when you change the basis for the module of periods, the Weierstrass $\wp$ function does not change and so the set of $e_{i}$ used in defining $\lambda$ also do not change. Letting the new basis be $\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$, it was shown that

$$
\binom{w_{1}^{\prime}}{w_{2}^{\prime}}=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\binom{w_{1}}{w_{2}}
$$

for some unimodular transformation, $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$. Letting $\tau=w_{2} / w_{1}$ and $\tau^{\prime}=w_{2}^{\prime} / w_{1}^{\prime}$

$$
\tau^{\prime}=\frac{c+d \tau}{a+b \tau} \equiv \phi(\tau)
$$

Now as discussed earlier

$$
\begin{aligned}
\lambda\left(\tau^{\prime}\right) & =\lambda(\phi(\tau)) \equiv \frac{\wp\left(\frac{w_{1}^{\prime}+w_{2}^{\prime}}{2}\right)-\wp\left(\frac{w_{2}^{\prime}}{2}\right)}{\wp\left(\frac{w_{1}^{\prime}}{2}\right)-\wp\left(\frac{w_{2}^{\prime}}{2}\right)} \\
& =\frac{\wp\left(\frac{1+\tau^{\prime}}{2}\right)-\wp\left(\frac{\tau^{\prime}}{2}\right)}{\wp\left(\frac{1}{2}\right)-\wp\left(\frac{\tau^{\prime}}{2}\right)}
\end{aligned}
$$

These numbers in the above fraction must be the same as $\wp\left(\frac{1+\tau}{2}\right), \wp\left(\frac{\tau}{2}\right)$, and $\wp\left(\frac{1}{2}\right)$ but they might occur differently. This is because $\wp$ does not change and these numbers are the zeros of a polynomial having coefficients involving only numbers and $\wp(z)$. It could happen for example that $\wp\left(\frac{1+\tau^{\prime}}{2}\right)=\wp\left(\frac{\tau}{2}\right)$ in which case this would change the value of $\lambda$. In effect, you can keep track of all possibilities by simply permuting the $e_{i}$ in the formula for $\lambda(\tau)$ given by $\frac{e_{3}-e_{2}}{e_{1}-e_{2}}$. Thus consider the following permutation table.

| 1 | 2 | 3 |
| :--- | :--- | :--- |
| 2 | 3 | 1 |
| 3 | 1 | 2 |
| 2 | 1 | 3 |
| 1 | 3 | 2 |
| 3 | 2 | 1 |.

Corresponding to this list of 6 permutations, all possible formulas for $\lambda(\phi(\tau))$ can be obtained as follows. Letting $\tau^{\prime}=\phi(\tau)$ where $\phi$ is a unimodular matrix corresponding to a change of basis,

$$
\begin{gather*}
\lambda\left(\tau^{\prime}\right)=\frac{e_{3}-e_{2}}{e_{1}-e_{2}}=\lambda(\tau)  \tag{58.1.34}\\
\begin{aligned}
& \lambda\left(\tau^{\prime}\right)=\frac{e_{1}-e_{3}}{e_{2}-e_{3}}= \frac{e_{3}-e_{2}+e_{2}-e_{1}}{e_{3}-e_{2}}=1-\frac{1}{\lambda(\tau)}=\frac{\lambda(\tau)-1}{\lambda(\tau)} \\
& \lambda\left(\tau^{\prime}\right)= \frac{e_{2}-e_{1}}{e_{3}-e_{1}}=-\left[\frac{e_{3}-e_{2}-\left(e_{1}-e_{2}\right)}{e_{1}-e_{2}}\right]^{-1} \\
&=-[\lambda(\tau)-1]^{-1}=\frac{1}{1-\lambda(\tau)} \\
& \lambda\left(\tau^{\prime}\right)=\frac{e_{3}-e_{1}}{e_{2}-e_{1}}=-\left[\frac{e_{3}-e_{2}-\left(e_{1}-e_{2}\right)}{e_{1}-e_{2}}\right] \\
&=\frac{-[\lambda(\tau)-1]=1-\lambda(\tau)}{1\left(\tau^{\prime}\right)=\frac{e_{2}-e_{3}}{e_{1}-e_{3}}=\frac{e_{3}-e_{2}}{e_{3}-e_{2}-\left(e_{1}-e_{2}\right)}=\frac{1}{1-\frac{1}{\lambda(\tau)}}=\frac{\lambda(\tau)}{\lambda(\tau)-1}} \\
& \lambda\left(\tau^{\prime}\right)=\frac{e_{1}-e_{3}}{e_{3}-e_{2}}=\frac{1}{\lambda(\tau)}
\end{aligned} \tag{58.1.35}
\end{gather*}
$$

Corollary 58.1.26 $\lambda^{\prime}(\tau) \neq 0$ for all $\tau$ in the upper half plane, denoted by $P_{+}$.
Proof: Let $\tau \in P_{+}$. By Lemma 58.1.25 there exists $\phi$ a unimodular transformation and $\tau^{\prime}$ in the interior of $Q$ such that $\tau^{\prime}=\phi(\tau)$. Now from the definition of $\lambda$ in terms of the $e_{i}$, there is at worst a permutation of the $e_{i}$ and so it might be the case that $\lambda(\phi(\tau)) \neq \lambda(\tau)$ but it is the case that $\lambda(\phi(\tau))=\xi(\lambda(\tau))$ where $\xi^{\prime}(z) \neq 0$. Here $\xi$ is one of the functions determined by 58.1.34-58.1.39. (Since $\lambda(\tau) \notin\{0,1\}, \xi^{\prime}(\lambda(z)) \neq 0$. This follows from the above possibilities for $\xi$ listed above in $58.1 .34-58.1 .39$.) All the possibilities are $\xi(z)=$

$$
z, \frac{z-1}{z}, \frac{1}{1-z}, 1-z, \frac{z}{z-1}, \frac{1}{z}
$$

and these are the same as the possibilities for $\xi^{-1}$. Therefore,

$$
\lambda^{\prime}(\phi(\tau)) \phi^{\prime}(\tau)=\xi^{\prime}(\lambda(\tau)) \lambda^{\prime}(\tau)
$$

and so $\lambda^{\prime}(\tau) \neq 0$ as claimed.
Now I will present a lemma which is of major significance. It depends on the remarkable mapping properties of the modular function and the monodromy theorem from analytic continuation. A review of the monodromy theorem will be listed here for convenience. First recall the definition of the concept of function elements and analytic continuation.

Definition 58.1.27 A function element is an ordered pair, $(f, D)$ where $D$ is an open ball and $f$ is analytic on $D .\left(f_{0}, D_{0}\right)$ and $\left(f_{1}, D_{1}\right)$ are direct continuations of each other if $D_{1} \cap D_{0} \neq \emptyset$ and $f_{0}=f_{1}$ on $D_{1} \cap D_{0}$. In this case I will write $\left(f_{0}, D_{0}\right) \sim\left(f_{1}, D_{1}\right)$. A chain is a finite sequence, of disks, $\left\{D_{0}, \cdots, D_{n}\right\}$ such that $D_{i-1} \cap D_{i} \neq \emptyset$. If $\left(f_{0}, D_{0}\right)$ is a given function element and there exist function elements, $\left(f_{i}, D_{i}\right)$ such that $\left\{D_{0}, \cdots, D_{n}\right\}$ is a chain and $\left(f_{j-1}, D_{j-1}\right) \sim\left(f_{j}, D_{j}\right)$ then $\left(f_{n}, D_{n}\right)$ is called the analytic continuation of $\left(f_{0}, D_{0}\right)$ along the chain $\left\{D_{0}, \cdots, D_{n}\right\}$. Now suppose $\gamma$ is an oriented curve with parameter interval $[a, b]$ and there exists a chain, $\left\{D_{0}, \cdots, D_{n}\right\}$ such that $\gamma^{*} \subseteq \cup_{k=1}^{n} D_{k}, \gamma(a)$ is the center of $D_{0}, \gamma(b)$ is the center of $D_{n}$, and there is an increasing list of numbers in $[a, b], a=$ $s_{0}<s_{1} \cdots<s_{n}=b$ such that $\gamma\left(\left[s_{i}, s_{i+1}\right]\right) \subseteq D_{i}$ and $\left(f_{n}, D_{n}\right)$ is an analytic continuation of $\left(f_{0}, D_{0}\right)$ along the chain. Then $\left(f_{n}, D_{n}\right)$ is called an analytic continuation of $\left(f_{0}, D_{0}\right)$ along the curve $\gamma$. ( $\gamma$ will always be a continuous curve. Nothing more is needed. )

Then the main theorem is the monodromy theorem listed next, Theorem 55.4.5 and its corollary on Page 1747.

Theorem 58.1.28 Let $\Omega$ be a simply connected subset of $\mathbb{C}$ and suppose $(f, B(a, r))$ is a function element with $B(a, r) \subseteq \Omega$. Suppose also that this function element can be analytically continued along every curve through $a$. Then there exists $G$ analytic on $\Omega$ such that $G$ agrees with $f$ on $B(a, r)$.

Here is the lemma.
Lemma 58.1.29 Let $\lambda$ be the modular function defined on $P_{+}$the upper half plane. Let $V$ be a simply connected region in $\mathbb{C}$ and let $f: V \rightarrow \mathbb{C} \backslash\{0,1\}$ be analytic and nonconstant. Then there exists an analytic function, $g: V \rightarrow P_{+}$such that $\lambda \circ g=f$.

Proof: Let $a \in V$ and choose $r_{0}$ small enough that $f\left(B\left(a, r_{0}\right)\right)$ contains neither 0 nor 1 . You need only let $B\left(a, r_{0}\right) \subseteq V$. Now there exists a unique point in $Q, \tau_{0}$ such that $\lambda\left(\tau_{0}\right)=$ $f(a)$. By Corollary 58.1.24, $\lambda^{\prime}\left(\tau_{0}\right) \neq 0$ and so by the open mapping theorem, Theorem 52.6.3 on Page 1663, There exists $B\left(\tau_{0}, R_{0}\right) \subseteq P_{+}$such that $\lambda$ is one to one on $B\left(\tau_{0}, R_{0}\right)$ and has a continuous inverse. Then picking $r_{0}$ still smaller, it can be assumed $f\left(B\left(a, r_{0}\right)\right) \subseteq$ $\lambda\left(B\left(\tau_{0}, R_{0}\right)\right)$. Thus there exists a local inverse for $\lambda, \lambda_{0}^{-1}$ defined on $f\left(B\left(a, r_{0}\right)\right)$ having values in $B\left(\tau_{0}, R_{0}\right) \cap \lambda^{-1}\left(f\left(B\left(a, r_{0}\right)\right)\right)$. Then defining $g_{0} \equiv \lambda_{0}^{-1} \circ f,\left(g_{0}, B\left(a, r_{0}\right)\right)$ is a function element. I need to show this can be continued along every curve starting at $a$ in such a way that each function in each function element has values in $P_{+}$.

Let $\gamma:[\alpha, \beta] \rightarrow V$ be a continuous curve starting at $a,(\gamma(\alpha)=a)$ and suppose that if $t<T$ there exists a nonnegative integer $m$ and a function element $\left(g_{m}, B\left(\gamma(t), r_{m}\right)\right)$ which is an analytic continuation of $\left(g_{0}, B\left(a, r_{0}\right)\right)$ along $\gamma$ where $g_{m}(\gamma(t)) \in P_{+}$and each function in every function element for $j \leq m$ has values in $P_{+}$. Thus for some small $T>0$ this has been achieved.

Then consider $f(\gamma(T)) \in \mathbb{C} \backslash\{0,1\}$. As in the first part of the argument, there exists a unique $\tau_{T} \in Q$ such that $\lambda\left(\tau_{T}\right)=f(\gamma(T))$ and for $r$ small enough there is an analytic local inverse, $\lambda_{T}^{-1}$ between $f(B(\gamma(T), r))$ and $\lambda^{-1}(f(B(\gamma(T), r))) \cap B\left(\tau_{T}, R_{T}\right) \subseteq P_{+}$for some $R_{T}>0$. By the assumption that the analytic continuation can be carried out for $t<T$, there exists $\left\{t_{0}, \cdots, t_{m}=t\right\}$ and function elements $\left(g_{j}, B\left(\gamma\left(t_{j}\right), r_{j}\right)\right), j=0, \cdots, m$ as just described with $g_{j}\left(\gamma\left(t_{j}\right)\right) \in P_{+}, \lambda \circ g_{j}=f$ on $B\left(\gamma\left(t_{j}\right), r_{j}\right)$ such that for $t \in\left[t_{m}, T\right], \gamma(t) \in$ $B(\gamma(T), r)$. Let

$$
I=B\left(\gamma\left(t_{m}\right), r_{m}\right) \cap B(\gamma(T), r)
$$

Then since $\lambda_{T}^{-1}$ is a local inverse, it follows for all $z \in I$

$$
\lambda\left(g_{m}(z)\right)=f(z)=\lambda\left(\lambda_{T}^{-1} \circ f(z)\right)
$$

Pick $z_{0} \in I$. Then by Lemma 58.1.18 on Page 1836 there exists a unimodular mapping of the form

$$
\phi(z)=\frac{a z+b}{c z+d}
$$

where

$$
\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \sim\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right) \bmod 2
$$

such that

$$
g_{m}\left(z_{0}\right)=\phi\left(\lambda_{T}^{-1} \circ f\left(z_{0}\right)\right) .
$$

Since both $g_{m}\left(z_{0}\right)$ and $\phi\left(\lambda_{T}^{-1} \circ f\left(z_{0}\right)\right)$ are in the upper half plane, it follows $a d-c b=1$ and $\phi$ maps the upper half plane to the upper half plane. Note the pole of $\phi$ is real and all the sets being considered are contained in the upper half plane so $\phi$ is analytic where it needs to be.

Claim: For all $z \in I$,

$$
\begin{equation*}
g_{m}(z)=\phi \circ \lambda_{T}^{-1} \circ f(z) \tag{58.1.40}
\end{equation*}
$$

Proof: For $z=z_{0}$ the equation holds. Let

$$
A=\left\{z \in I: g_{m}(z)=\phi\left(\lambda_{T}^{-1} \circ f(z)\right)\right\} .
$$

Thus $z_{0} \in I$. If $z \in I$ and if $w$ is close enough to $z$, then $w \in I$ also and so both sides of 58.1.40 with $w$ in place of $z$ are in $\lambda_{m}^{-1}(f(I))$. But by construction, $\lambda$ is one to one on this set and since $\lambda$ is invariant with respect to $\phi$,

$$
\lambda\left(g_{m}(w)\right)=\lambda\left(\lambda_{T}^{-1} \circ f(w)\right)=\lambda\left(\phi \circ \lambda_{T}^{-1} \circ f(w)\right)
$$

and consequently, $w \in A$. This shows $A$ is open. But $A$ is also closed in $I$ because the functions are continuous. Therefore, $A=I$ and so 58.1.40 is obtained.

Letting $f(z) \in f(B(\gamma(T)), r)$,

$$
\lambda\left(\phi\left(\lambda_{T}^{-1}(f(z))\right)\right)=\lambda\left(\lambda_{T}^{-1}(f(z))\right)=f(z)
$$

and so $\phi \circ \lambda_{T}^{-1}$ is a local inverse for $\lambda$ on $\left.f(B(\gamma)), r\right)$. Let the new function element be $(\overbrace{\phi \circ \lambda_{T}^{-1} \circ f}^{g_{m+1}}, B(\gamma(T), r))$. This has shown the initial function element can be continued along every curve through $a$.

By the monodromy theorem, there exists $g$ analytic on $V$ such that $g$ has values in $P_{+}$ and $g=g_{0}$ on $B\left(a, r_{0}\right)$. By the construction, it also follows $\lambda \circ g=f$. This last claim is easy to see because $\lambda \circ g=f$ on $B\left(a, r_{0}\right)$, a set with a limit point so the equation holds for all $z \in V$. This proves the lemma.

### 58.2 The Picard Theorem Again

Having done all this work on the modular function which is important for its own sake, there is an easy proof of the Picard theorem. In fact, this is the way Picard did it in 1879. I will state it slightly differently since it is no trouble to do so, [65].

Theorem 58.2.1 Let $f$ be meromorphic on $\mathbb{C}$ and suppose $f$ misses three distinct points, $a, b, c$. Then $f$ is a constant function.

Proof: Let $\phi(z) \equiv \frac{z-a}{z-c} \frac{b-c}{b-a}$. Then $\phi(c)=\infty, \phi(a)=0$, and $\phi(b)=1$. Now consider the function, $h=\phi \circ f$. Then $h$ misses the three points $\infty, 0$, and 1 . Since $h$ is meromorphic and does not have $\infty$ in its values, it must actually be analytic. Thus $h$ is an entire function which misses the two values 0 and 1 . If $h$ is not constant, then by Lemma 58.1.29 there exists a function, $g$ analytic on $\mathbb{C}$ which has values in the upper half plane, $P_{+}$such that $\lambda \circ g=h$. However, $g$ must be a constant because there exists $\psi$ an analytic map on the upper half plane which maps the upper half plane to $B(0,1)$. You can use the Riemann mapping theorem or more simply, $\psi(z)=\frac{z-i}{z+i}$. Thus $\psi \circ g$ equals a constant by Liouville's theorem. Hence $g$ is a constant and so $h$ must also be a constant because $\lambda(g(z))=h(z)$. This proves $f$ is a constant also. This proves the theorem.

### 58.3 Exercises

1. Show the set of modular transformations is a group. Also show those modular transformations which are congruent mod 2 to the identity as described above is a subgroup.
2. Suppose $f$ is an elliptic function with period module $M$. If $\left\{w_{1}, w_{2}\right\}$ and $\left\{w_{1}^{\prime}, w_{2}^{\prime}\right\}$ are two bases, show that the resulting period parallelograms resulting from the two bases have the same area.
3. Given a module of periods with basis $\left\{w_{1}, w_{2}\right\}$ and letting a typical element of this module be denoted by $w$ as described above, consider the product

$$
\sigma(z) \equiv z \prod_{w \neq 0}\left(1-\frac{z}{w}\right) e^{(z / w)+\frac{1}{2}(z / w)^{2}} .
$$

Show this product converges uniformly on compact sets, is an entire function, and satisfies

$$
\sigma^{\prime}(z) / \sigma(z)=\zeta(z)
$$

where $\zeta(z)$ was defined above as a primitive of $\wp(z)$ and is given by

$$
\zeta(z)=\frac{1}{z}+\sum_{w \neq 0} \frac{1}{z-w}+\frac{z}{w^{2}}+\frac{1}{w}
$$

4. Show $\zeta\left(z+w_{i}\right)=\zeta(z)+\eta_{i}$ where $\eta_{i}$ is a constant.
5. Let $P_{a}$ be the parallelogram shown in the following picture.

Show that $\frac{1}{2 \pi i} \int_{\partial P_{a}} \zeta(z) d z=1$ where the contour is taken once around the parallelogram in the counter clockwise direction. Next evaluate this contour integral directly to obtain Legendre's relation,

$$
\eta_{1} w_{2}-\eta_{2} w_{1}=2 \pi i
$$

6. For $\sigma$ defined in Problem 3, 4 explain the following steps. For $j=1,2$

$$
\frac{\sigma^{\prime}\left(z+w_{j}\right)}{\sigma\left(z+w_{j}\right)}=\zeta\left(z+w_{j}\right)=\zeta(z)+\eta_{j}=\frac{\sigma^{\prime}(z)}{\sigma(z)}+\eta_{j}
$$

Therefore, there exists a constant, $C_{j}$ such that

$$
\sigma\left(z+w_{j}\right)=C_{j} \sigma(z) e^{\eta_{j} z}
$$

Next show $\sigma$ is an odd function, $(\sigma(-z)=-\sigma(z))$ and then let $z=-w_{j} / 2$ to find $C_{j}=-e^{\frac{\eta_{j} \omega_{j}}{2}}$ and so

$$
\begin{equation*}
\sigma\left(z+w_{j}\right)=-\sigma(z) e^{\eta_{j}\left(z+\frac{w_{j}}{2}\right)} \tag{58.3.41}
\end{equation*}
$$

7. Show any even elliptic function, $f$ with periods $w_{1}$ and $w_{2}$ for which 0 is neither a pole nor a zero can be expressed in the form

$$
f(0) \prod_{k=1}^{n} \frac{\wp(z)-\wp\left(a_{k}\right)}{\wp(z)-\wp\left(b_{k}\right)}
$$

where $C$ is some constant. Here $\wp$ is the Weierstrass function which comes from the two periods, $w_{1}$ and $w_{2}$. Hint: You might consider the above function in terms of the poles and zeros on a period parallelogram and recall that an entire function which is elliptic is a constant.
8. Suppose $f$ is any elliptic function with $\left\{w_{1}, w_{2}\right\}$ a basis for the module of periods. Using Theorem 58.1.8 and 58.3.41 show that there exists constants $a_{1}, \cdots, a_{n}$ and $b_{1}, \cdots, b_{n}$ such that for some constant $C$,

$$
f(z)=C \prod_{k=1}^{n} \frac{\sigma\left(z-a_{k}\right)}{\sigma\left(z-b_{k}\right)}
$$

Hint: You might try something like this: By Theorem 58.1.8, it follows that if $\left\{\alpha_{k}\right\}$ are the zeros and $\left\{b_{k}\right\}$ the poles in an appropriate period parallelogram, $\sum \alpha_{k}-\sum b_{k}$ equals a period. Replace $\alpha_{k}$ with $a_{k}$ such that $\sum a_{k}-\sum b_{k}=0$. Then use 58.3.41 to show that the given formula for $f$ is bi periodic. Anyway, you try to arrange things such that the given formula has the same poles as $f$. Remember an entire elliptic function equals a constant.
9. Show that the map $\tau \rightarrow 1-\frac{1}{\tau}$ maps $l_{2}$ onto the curve, $C$ in the above picture on the mapping properties of $\lambda$.
10. Modify the proof of Theorem 58.1.22 to show that $\lambda(\Omega) \cap\{z \in \mathbb{C}: \operatorname{Im}(z)<0\}=\emptyset$.

## Chapter 59

## Basic Probability

Caution: This material on probability and stochastic processes may be half baked in places. I have not yet rewritten it several times. This is not to say that nothing else is half baked. However, the probability is higher here.

### 59.1 Random Variables And Independence

Recall Lemma 14.2.3 on Page 388 which is stated here for convenience.
Lemma 59.1.1 Let $M$ be a metric space with the closed balls compact and suppose $\lambda$ is a measure defined on the Borel sets of $M$ which is finite on compact sets. Then there exists a unique Radon measure, $\bar{\lambda}$ which equals $\lambda$ on the Borel sets. In particular $\lambda$ must be both inner and outer regular on all Borel sets.

Also important is the following fundamental result which is called the Borel Cantelli lemma.

Lemma 59.1.2 Let $(\Omega, \mathscr{F}, \lambda)$ be a measure space and let $\left\{A_{i}\right\}$ be a sequence of measurable sets satisfying

$$
\sum_{i=1}^{\infty} \lambda\left(A_{i}\right)<\infty .
$$

Then letting $S$ denote the set of $\omega \in \Omega$ which are in infinitely many $A_{i}$, it follows $S$ is a measurable set and $\lambda(S)=0$.

Proof: $S=\cap_{k=1}^{\infty} \cup_{m=k}^{\infty} A_{m}$. Therefore, $S$ is measurable and also

$$
\lambda(S) \leq \lambda\left(\cup_{m=k}^{\infty} A_{m}\right) \leq \sum_{m=k}^{\infty} \lambda\left(A_{k}\right)
$$

and this converges to 0 as $k \rightarrow \infty$ because of the convergence of the series.
Here is another nice observation.
Proposition 59.1.3 Suppose $E_{i}$ is a separable Banach space. Then if $B_{i}$ is a Borel set of $E_{i}$, it follows $\prod_{i=1}^{n} B_{i}$ is a Borel set in $\prod_{i=1}^{n} E_{i}$.

Proof: An easy way to do this is to consider the projection maps.

$$
\pi_{i} \mathbf{x} \equiv x_{i}
$$

Then these projection maps are continuous. Hence for $U$ an open set,

$$
\pi_{i}^{-1}(U) \equiv \prod_{j=1}^{n} A_{j}, A_{j}=E_{j} \text { if } j \neq i \text { and } A_{i}=U
$$

Thus $\pi_{i}^{-1}$ (open) equals an open set. Let

$$
\mathscr{S} \equiv\left\{V \subseteq \mathbb{R}: \pi_{i}^{-1}(V) \text { is Borel }\right\}
$$

Then $\mathscr{S}$ contains all the open sets and is clearly a $\sigma$ algebra. Therefore, $\mathscr{S}$ contains the Borel sets. Let $B_{i}$ be a Borel set in $E_{i}$. Then

$$
\prod_{i=1}^{n} B_{i}=\cap_{i=1}^{n} \pi_{i}^{-1}\left(B_{i}\right)
$$

a finite intersection of Borel sets.
Definition 59.1.4 A probability space is a measure space, $(\Omega, \mathscr{F}, P)$ where $P$ is a measure satisfying $P(\Omega)=1$. A random vector (variable) is a measurable function, $\mathbf{X}: \Omega \rightarrow Z$ where $Z$ is some topological space. It is often the case that $Z$ will equal $\mathbb{R}^{p}$. Assume $Z$ is a separable Banach space. Define the following $\sigma$ algebra.

$$
\sigma(\mathbf{X}) \equiv\left\{\mathbf{X}^{-1}(E): E \text { is Borel in } Z\right\}
$$

Thus $\sigma(\mathbf{X}) \subseteq \mathscr{F}$. For $E$ a Borel set in $Z$ define

$$
\lambda_{\mathbf{X}}(E) \equiv P\left(\mathbf{X}^{-1}(E)\right)
$$

This is called the distribution of the random variable, $\mathbf{X}$. If

$$
\int_{\Omega}|\mathbf{X}(\omega)| d P<\infty
$$

then define

$$
E(\mathbf{X}) \equiv \int_{\Omega} \mathbf{X} d P
$$

where the integral is defined as the Bochner integral.
Recall the following fundamental result which was proved earlier but which I will give a short proof of now.

Proposition 59.1.5 Let $(\Omega, \mathscr{S}, \mu)$ be a measure space and let $\mathbf{X}: \Omega \rightarrow Z$ where $Z$ is a separable Banach space. Then $\mathbf{X}$ is strongly measurable if and only if $\mathbf{X}^{-1}(U) \in \mathscr{S}$ for all $U$ open in $Z$.

Proof: To begin with, let $D(a, r)$ be the closure of the open ball $B(a, r)$. By Lemma 21.1.6, there exists $\left\{f_{i}\right\} \subseteq B^{\prime}$, the unit ball in $Z^{\prime}$ such that

$$
\|z\|_{Z}=\sup _{i}\left\{\left|f_{i}(z)\right|\right\}
$$

Then

$$
\begin{gathered}
D(a, r)=\{z:\|a-z\| \leq r\}=\cap_{i}\left\{z:\left|f_{i}(z)-f_{i}(a)\right| \leq r\right\} \\
=\cap_{i} f_{i}^{-1}\left(\overline{B\left(f_{i}(a), r\right)}\right)
\end{gathered}
$$

It follows that

$$
\begin{aligned}
\mathbf{X}^{-1}(D(a, r)) & =\cap_{i} \mathbf{X}^{-1}\left(f_{i}^{-1}\left(\overline{B\left(f_{i}(a), r\right)}\right)\right) \\
& =\cap_{i}\left(f_{i} \circ \mathbf{X}\right)^{-1}\left(\overline{B\left(f_{i}(a), r\right)}\right)
\end{aligned}
$$

If $\mathbf{X}$ is strongly measurable, then it is weakly measurable and so each $f_{i} \circ \mathbf{X}$ is a real (complex) valued measurable function. Hence the expression on the right in the above is measurable. Now if $U$ is any open set in $Z$, then it is the countable union of such closed disks $U=\cup_{i} D_{i}$. Therefore, $\mathbf{X}^{-1}(U)=\cap_{i} \mathbf{X}^{-1}\left(D_{i}\right) \in \mathscr{S}$. It follows that strongly measurable implies inverse images of open sets are in $\mathscr{S}$.

Conversely, suppose $\mathbf{X}^{-1}(U) \in \mathscr{S}$ for every open $U$. Then for $f \in Z^{\prime}, f \circ \mathbf{X}$ is real valued and measurable. Therefore, $\mathbf{X}$ is weakly measurable. By the Pettis theorem, it follows that $f \circ \mathbf{X}$ is strongly measurable.

Proposition 59.1.6 If $\mathbf{X}: \Omega \rightarrow Z$ is measurable, then $\sigma(\mathbf{X})$ equals the smallest $\sigma$ algebra such that $\mathbf{X}$ is measurable with respect to it. Also if $X_{i}$ are random variables having values in separable Banach spaces $Z_{i}$, then $\sigma(\mathbf{X})=\sigma\left(X_{1}, \cdots, X_{n}\right)$ where $\mathbf{X}$ is the vector mapping $\Omega$ to $\prod_{i=1}^{n} Z_{i}$ and $\sigma\left(X_{1}, \cdots, X_{n}\right)$ is the smallest $\sigma$ algebra such that each $X_{i}$ is measurable with respect to it.

Proof: Let $\mathscr{G}$ denote the smallest $\sigma$ algebra such that $\mathbf{X}$ is measurable with respect to this $\sigma$ algebra. By definition $\mathbf{X}^{-1}$ (open) $\in \mathscr{G}$. Furthermore, the set of all $E$ such that $\mathbf{X}^{-1}(E) \in \mathscr{G}$ is a $\sigma$ algebra. Hence it includes all the Borel sets. Hence $\mathbf{X}^{-1}$ (Borel) $\in \mathscr{G}$ and so $\mathscr{G} \supseteq \sigma(\mathbf{X})$. However, $\sigma(\mathbf{X})$ defined above is a $\sigma$ algebra such that $\mathbf{X}$ is measurable with respect to $\sigma(\mathbf{X})$. Therefore, $\mathscr{G}=\sigma(\mathbf{X})$.

Letting $B_{i}$ be a Borel set in $Z_{i}, \prod_{i=1}^{n} B_{i}$ is a Borel set by Proposition 59.1.3 and so

$$
\mathbf{X}^{-1}\left(\prod_{i=1}^{n} B_{i}\right)=\cap_{i=1}^{n} X_{i}^{-1}\left(B_{i}\right) \in \sigma\left(X_{1}, \cdots, X_{n}\right)
$$

If $\mathscr{G}$ denotes the Borel sets $F \subseteq \prod_{i=1}^{n} Z_{i}$ such that $\mathbf{X}^{-1}(F) \in \sigma\left(X_{1}, \cdots, X_{n}\right)$, then $\mathscr{G}$ is clearly a $\sigma$ algebra which contains the open sets. Hence $\mathscr{G}=\mathscr{B}$ the Borel sets of $\prod_{i=1}^{n} Z_{i}$. This shows that $\sigma(\mathbf{X}) \subseteq \sigma\left(X_{1}, \cdots, X_{n}\right)$. Next we observe that $\sigma(\mathbf{X})$ is a $\sigma$ algebra with the property that each $X_{i}$ is measurable with respect to $\sigma(\mathbf{X})$. This follows from $X_{i}^{-1}\left(B_{i}\right)=$ $\mathbf{X}^{-1}\left(\prod_{j=1}^{n} A_{j}\right) \in \sigma(\mathbf{X})$, where each $A_{j}=Z_{j}$ except for $A_{i}=B_{i}$. Since $\sigma\left(X_{1}, \cdots, X_{n}\right)$ is defined as the smallest such $\sigma$ algebra, it follows that $\sigma(\mathbf{X}) \supseteq \sigma\left(X_{1}, \cdots, X_{n}\right)$.

For random variables having values in a separable Banach space or even more generally for a separable metric space, much can be said about regularity of $\lambda_{\mathbf{x}}$.

Definition 59.1.7 A measure, $\mu$ defined on $\mathscr{B}(E)$ will be called inner regular if for all $F \in \mathscr{B}(E)$,

$$
\mu(F)=\sup \{\mu(K): K \subseteq F \text { and } K \text { is closed }\}
$$

A measure, $\mu$ defined on $\mathscr{B}(E)$ will be called outer regular if for all $F \in \mathscr{B}(E)$,

$$
\mu(F)=\inf \{\mu(V): V \supseteq F \text { and } V \text { is open }\}
$$

When a measure is both inner and outer regular, it is called regular.
For probability measures, the above definition of regularity tends to come free. Note it is a little weaker than the usual definition of regularity because $K$ is only assumed to be closed, not compact.

Lemma 59.1.8 Let $\mu$ be a finite measure defined on $\mathscr{B}(E)$ where $E$ is a metric space. Then $\mu$ is regular.

Proof: First note every open set is the countable union of closed sets and every closed set is the countable intersection of open sets. Here is why. Let $V$ be an open set and let

$$
K_{k} \equiv\left\{x \in V: \operatorname{dist}\left(x, V^{C}\right) \geq 1 / k\right\}
$$

Then clearly the union of the $K_{k}$ equals $V$. Next, for $K$ closed let

$$
V_{k} \equiv\{x \in X: \operatorname{dist}(x, K)<1 / k\} .
$$

Clearly the intersection of the $V_{k}$ equals $K$. Therefore, letting $V$ denote an open set and $K$ a closed set,

$$
\begin{aligned}
& \mu(V)=\sup \{\mu(K): K \subseteq V \text { and } K \text { is closed }\} \\
& \mu(K)=\inf \{\mu(V): V \supseteq K \text { and } V \text { is open }\}
\end{aligned}
$$

Also since $V$ is open and $K$ is closed,

$$
\begin{aligned}
& \mu(V)=\inf \{\mu(U): U \supseteq V \text { and } U \text { is open }\} \\
& \mu(K)=\sup \{\mu(L): L \subseteq K \text { and } L \text { is closed }\}
\end{aligned}
$$

In words, $\mu$ is regular on open and closed sets. Let

$$
\mathscr{F} \equiv\{F \in \mathscr{B}(X) \text { such that } \mu \text { is regular on } F\}
$$

Then $\mathscr{F}$ contains the open sets and the closed sets.
Suppose $F \in \mathscr{F}$. Then there exists $V \supseteq F$ with $\mu(V \backslash F)<\varepsilon$. It follows $V^{C} \subseteq F^{C}$ and

$$
\mu\left(F^{C} \backslash V^{C}\right)=\mu(V \backslash F)<\varepsilon
$$

Thus $\mu$ is inner regular on $F^{C}$. Since $F \in \mathscr{F}$, there exists $K \subseteq F$ where $K$ is closed and $\mu(F \backslash K)<\varepsilon$. Then also $K^{C} \supseteq F^{C}$ and

$$
\mu\left(K^{C} \backslash F^{C}\right)=\mu(F \backslash K)<\varepsilon
$$

Thus if $F \in \mathscr{F}$ so is $F^{C}$.
Suppose now that $\left\{F_{i}\right\} \subseteq \mathscr{F}$, the $F_{i}$ being disjoint. Is $\cup F_{i} \in \mathscr{F}$ ? There exists $K_{i} \subseteq F_{i}$ such that $\mu\left(K_{i}\right)+\varepsilon / 2^{i}>\mu\left(F_{i}\right)$. Then

$$
\begin{aligned}
\mu\left(\cup_{i=1}^{\infty} F_{i}\right) & =\sum_{i=1}^{\infty} \mu\left(F_{i}\right) \leq \varepsilon+\sum_{i=1}^{\infty} \mu\left(K_{i}\right) \\
& <2 \varepsilon+\sum_{i=1}^{N} \mu\left(K_{i}\right)=2 \varepsilon+\mu\left(\cup_{i=1}^{N} K_{i}\right)
\end{aligned}
$$

provided $N$ is large enough. Thus it follows $\mu$ is inner regular on $\cup_{i=1}^{\infty} F_{i}$. Why is it outer regular? Let $V_{i} \supseteq F_{i}$ such that $\mu\left(F_{i}\right)+\varepsilon / 2^{i}>\mu\left(V_{i}\right)$ and

$$
\mu\left(\cup_{i=1}^{\infty} F_{i}\right)=\sum_{i=1}^{\infty} \mu\left(F_{i}\right)>-\varepsilon+\sum_{i=1}^{\infty} \mu\left(V_{i}\right) \geq-\varepsilon+\mu\left(\cup_{i=1}^{\infty} V_{i}\right)
$$

which shows $\mu$ is outer regular on $\cup_{i=1}^{\infty} F_{i}$. It follows $\mathscr{F}$ contains the $\pi$ system consisting of open sets and is closed with respect to countable disjoint unions and complements, and so by the Lemma on $\pi$ systems, Lemma 12.12.3, $\mathscr{F}$ contains $\sigma(\tau)$ where $\tau$ is the set of open sets. Hence $\mathscr{F}$ contains the Borel sets and is itself a subset of the Borel sets by definition. Therefore, $\mathscr{F}=\mathscr{B}(X)$.

One can say more if the metric space is complete and separable. In fact in this case the above definition of inner regularity can be shown to imply the usual one.

Lemma 59.1.9 Let $\mu$ be a finite measure on a $\sigma$ algebra containing $\mathscr{B}(X)$, the Borel sets of $X$, a separable complete metric space. Then if $C$ is a closed set,

$$
\mu(C)=\sup \{\mu(K): K \subseteq C \text { and } K \text { is compact. }\}
$$

It follows that for a finite measure on $\mathscr{B}(X)$ where $X$ is a Polish space, $\mu$ is inner regular in the sense that for all $F \in \mathscr{B}(X)$,

$$
\mu(F)=\sup \{\mu(K): K \subseteq F \text { and } K \text { is compact }\}
$$

Proof: Let $\left\{a_{k}\right\}$ be a countable dense subset of $C$. Thus $\cup_{k=1}^{\infty} B\left(a_{k}, \frac{1}{n}\right) \supseteq C$. Therefore, there exists $m_{n}$ such that

$$
\mu\left(C \backslash \cup_{k=1}^{m_{n}} B \overline{\left(a_{k}, \frac{1}{n}\right)}\right) \equiv \mu\left(C \backslash C_{n}\right)<\frac{\varepsilon}{2^{n}}
$$

Now let $K=C \cap\left(\cap_{n=1}^{\infty} C_{n}\right)$. Then $K$ is a subset of $C_{n}$ for each $n$ and so for each $\varepsilon>0$ there exists an $\varepsilon$ net for $K$ since $C_{n}$ has a $1 / n$ net, namely $a_{1}, \cdots, a_{m_{n}}$. Since $K$ is closed, it is complete and so it is also compact since it is complete and totally bounded, Theorem 7.6.5. Now

$$
\mu(C \backslash K) \leq \mu\left(\cup_{n=1}^{\infty}\left(C \backslash C_{n}\right)\right)<\sum_{n=1}^{\infty} \frac{\varepsilon}{2^{n}}=\varepsilon
$$

Thus $\mu(C)$ can be approximated by $\mu(K)$ for $K$ a compact subset of $C$. The last claim follows from Lemma 59.1.8.

Definition 59.1.10 A measurable function $\mathbf{X}:(\Omega, \mathscr{F}, \mu) \rightarrow Z$ a topological space is called a random variable when $\mu(\Omega)=1$. For such a random variable, one can define a distribution measure $\lambda_{\mathbf{x}}$ on the Borel sets of $Z$ as follows.

$$
\lambda_{\mathbf{x}}(G) \equiv \mu\left(\mathbf{X}^{-1}(G)\right)
$$

This is a well defined measure on the Borel sets of $Z$ because it makes sense for every $G$ open and $\mathscr{G} \equiv\left\{G \subseteq Z: \mathbf{X}^{-1}(G) \in \mathscr{F}\right\}$ is a $\sigma$ algebra which contains the open sets, hence the Borel sets. Such a measurable function is also called a random vector.

Corollary 59.1.11 Let $\mathbf{X}$ be a random variable (random vector) with values in a complete metric space, $Z$. Then $\lambda_{\mathbf{x}}$ is an inner and outer regular measure defined on $\mathscr{B}(Z)$.

Proposition 59.1.12 For $\mathbf{X}$ a random vector defined above, $\mathbf{X}$ having values in a complete separable metric space $Z$, then $\lambda_{\mathbf{x}}$ is inner and outer regular and Borel.

$$
(\Omega, P) \xrightarrow{\mathbf{x}}\left(Z, \lambda_{\mathbf{x}}\right) \xrightarrow{h} E
$$

If $h$ is Borel measurable and $h \in L^{1}\left(Z, \lambda_{\mathbf{x}} ; E\right)$ for $E$ a Banach space, then

$$
\begin{equation*}
\int_{\Omega} h(\mathbf{X}(\omega)) d P=\int_{Z} h(\mathbf{x}) d \lambda \mathbf{x} \tag{59.1.1}
\end{equation*}
$$

In the case where $Z=E$, a separable Banach space, if $\mathbf{X}$ is measurable then $\mathbf{X} \in$ $L^{1}(\Omega ; E)$ if and only if the identity map on $E$ is in $L^{1}(E ; \lambda \mathbf{x})$ and

$$
\begin{equation*}
\int_{\Omega} \mathbf{X}(\omega) d P=\int_{E} \mathbf{x} d \lambda \mathbf{X}(\mathbf{x}) \tag{59.1.2}
\end{equation*}
$$

Proof: The regularity claims are established above. It remains to verify 59.1.1.
Since $h \in L^{1}(Z, E)$, it follows there exists a sequence of simple functions $\left\{h_{n}\right\}$ such that

$$
h_{n}(\mathbf{x}) \rightarrow h(\mathbf{x}), \int_{Z}\left\|h_{m}-h_{n}\right\| d \lambda \mathbf{x} \rightarrow 0 \text { as } m, n \rightarrow \infty
$$

The first convergence above implies

$$
\begin{equation*}
h_{n} \circ \mathbf{X} \rightarrow h \circ \mathbf{X} \text { pointwise on } \Omega \tag{59.1.3}
\end{equation*}
$$

Then letting $h_{n}(\mathbf{x})=\sum_{k=1}^{m} \mathbf{x}_{k} \mathscr{X}_{E_{k}}(\mathbf{x})$, where the $E_{k}$ are disjoint and Borel, it follows easily that $h_{n} \circ \mathbf{X}$ is also a simple function of the form $h_{n} \circ \mathbf{X}(\omega)=\sum_{k=1}^{m} \mathbf{x}_{k} \mathscr{X}_{\mathbf{X}^{-1}\left(E_{k}\right)}(\omega)$ and by assumption $\mathbf{X}^{-1}\left(E_{k}\right) \in \mathscr{F}$. From the definition of the integral, it is easily seen

$$
\int h_{n} \circ \mathbf{X} d P=\int h_{n} d \lambda \mathbf{x}, \int\left\|h_{n}\right\| \circ \mathbf{X} d P=\int\left\|h_{n}\right\| d \lambda \mathbf{x}
$$

Also, $h_{n} \circ \mathbf{X}-h_{m} \circ \mathbf{X}$ is a simple function and so

$$
\begin{equation*}
\int\left\|h_{n} \circ \mathbf{X}-h_{m} \circ \mathbf{X}\right\| d P=\int\left\|h_{n}-h_{m}\right\| d \lambda_{\mathbf{x}} \tag{59.1.4}
\end{equation*}
$$

It follows from the definition of the Bochner integral and 59.1.3, and 59.1.4 that $h \circ \mathbf{X}$ is in $L^{1}(\Omega ; E)$ and

$$
\int h \circ \mathbf{X} d P=\lim _{n \rightarrow \infty} \int h_{n} \circ \mathbf{X} d P=\lim _{n \rightarrow \infty} \int h_{n} d \lambda_{\mathbf{x}}=\int h d \lambda_{\mathbf{x}}
$$

Finally consider the case that $E=Z$ and suppose $\mathbf{X} \in L^{1}(\Omega ; E)$. Then letting $h$ be the identity map on $E$, it follows $h$ is obviously separably valued and $h^{-1}(U) \in \mathscr{B}(E)$ for all $U$ open and so $h$ is measurable. Why is it in $L^{1}(E ; E)$ ?

$$
\begin{aligned}
\int_{E}\|h(\mathbf{x})\| d \lambda_{\mathbf{x}} & =\int_{0}^{\infty} \lambda_{\mathbf{x}}([\|h\|>t]) d t \equiv \int_{0}^{\infty} P(\mathbf{X} \in[\|\mathbf{x}\|>t]) d t \\
& \equiv \int_{0}^{\infty} P([\|\mathbf{X}\|>t]) d t=\int_{\Omega}\|\mathbf{X}\| d P<\infty
\end{aligned}
$$

Thus the identity map on $E$ is in $L^{1}\left(E ; \lambda_{\mathbf{X}}\right)$. Next suppose the identity map $h$ is in absolutely integrable, in $L^{1}\left(E ; \lambda_{\mathbf{x}}\right)$. Then $\mathbf{X}(\omega)=h \circ \mathbf{X}(\omega)$ and so from the first part, $\mathbf{X} \in L^{1}(\Omega ; E)$ and from 59.1.1, 59.1.2 follows.

### 59.2 Kolmogorov Extension Theorem For Polish Spaces

Let $M_{t}$ be a complete separable metric space. This is called a Polish space. I will denote a totally ordered index set, (Like $\mathbb{R})$ and the interest will be in building a measure on the product space, $\prod_{t \in I} M_{t}$. By the well ordering principle, you can always put an order on any index set so this order is no restriction, but we do not insist on a well order and in fact, index sets of great interest are $\mathbb{R}$ or $[0, \infty)$. Also for $X$ a topological space, $\mathscr{B}(X)$ will denote the Borel sets.

Notation 59.2.1 The symbol $J$ will denote a finite subset of $I, J=\left(t_{1}, \cdots, t_{n}\right)$, the $t_{i}$ taken in order. $\mathbf{E}_{J}$ will denote a set which has a set $E_{t}$ of $\mathscr{B}\left(M_{t}\right)$ in the $t^{t h}$ position for $t \in J$ and for $t \notin J$, the set in the $t^{\text {th }}$ position will be $M_{t} . \mathbf{K}_{J}$ will denote a set which has a compact set in the $t^{\text {th }}$ position for $t \in J$ and for $t \notin J$, the set in the $t^{\text {th }}$ position will be $M_{t}$. Also denote by $\mathscr{R}_{J}$ the sets $\mathbf{E}_{J}$ and $\mathscr{R}$ the union of the $\mathscr{R}_{J}$. Let $\mathscr{E}_{J}$ denote finite disjoint unions of sets of $\mathscr{R}_{J}$ and let $\mathscr{E}$ denote finite disjoint unions of sets of $\mathscr{R}$. Thus if $\mathbf{F}$ is a set of $\mathscr{E}$, there exists $J$ such that $\mathbf{F}$ is a finite disjoint union of sets of $\mathscr{R}_{J}$. For $\mathbf{F} \in \Omega$, denote by $\pi_{J}(\mathbf{F})$ the set $\prod_{t \in J} F_{t}$ where $\mathbf{F}=\prod_{t \in I} F_{t}$.

Lemma 59.2.2 The sets, $\mathscr{E}$, $\mathscr{E}_{J}$ defined above form an algebra of sets of $\prod_{t \in I} M_{t}$.
Proof: First consider $\mathscr{R}_{J}$. If $\mathbf{A}, \mathbf{B} \in \mathscr{R}_{J}$, then $\mathbf{A} \cap \mathbf{B} \in \mathscr{R}_{J}$ also. Is $\mathbf{A} \backslash \mathbf{B}$ a finite disjoint union of sets of $\mathscr{R}_{J}$ ? It suffices to verify that $\pi_{J}(\mathbf{A} \backslash \mathbf{B})$ is a finite disjoint union of $\pi_{J}\left(\mathscr{R}_{J}\right)$. Let $|J|$ denote the number of indices in $J$. If $|J|=1$, then it is obvious that $\pi_{J}(\mathbf{A} \backslash \mathbf{B})$ is a finite disjoint union of sets of $\pi_{J}\left(\mathscr{R}_{J}\right)$. In fact, letting $J=(t)$ and the $t^{t h}$ entry of $\mathbf{A}$ is $A$ and the $t^{\text {th }}$ entry of $\mathbf{B}$ is $B$, then the $t^{t h}$ entry of $\mathbf{A} \backslash \mathbf{B}$ is $A \backslash B$, a Borel set of $M_{t}$, a finite disjoint union of Borel sets of $M_{t}$.

Suppose then that for $\mathbf{A}, \mathbf{B}$ sets of $\mathscr{R}_{J}, \pi_{J}(\mathbf{A} \backslash \mathbf{B})$ is a finite disjoint union of sets of $\pi_{J}\left(\mathscr{R}_{J}\right)$ for $|J| \leq n$, and consider $J=\left(t_{1}, \cdots, t_{n}, t_{n+1}\right)$. Let the $t_{i}^{t h}$ entry of $\mathbf{A}$ and $\mathbf{B}$ be respectively $A_{i}$ and $B_{i}$. It follows that $\pi_{J}(\mathbf{A} \backslash \mathbf{B})$ has the following in the entries for $J$

$$
\left(A_{1} \times A_{2} \times \cdots \times A_{n} \times A_{n+1}\right) \backslash\left(B_{1} \times B_{2} \times \cdots \times B_{n} \times B_{n+1}\right)
$$

Letting $A$ represent $A_{1} \times A_{2} \times \cdots \times A_{n}$ and $B$ represent $B_{1} \times B_{2} \times \cdots \times B_{n}$, this is of the form

$$
A \times\left(A_{n+1} \backslash B_{n+1}\right) \cup(A \backslash B) \times\left(A_{n+1} \cap B_{n+1}\right)
$$

By induction, $(A \backslash B)$ is the finite disjoint union of sets of $\mathscr{R}_{\left(t_{1}, \cdots, t_{n}\right)}$. Therefore, the above is the finite disjoint union of sets of $\mathscr{R}_{J}$. It follows that $\mathscr{E}_{J}$ is an algebra.

Now suppose $\mathbf{A}, \mathbf{B} \in \mathscr{R}$. Then for some finite set $J$, both are in $\mathscr{R}_{J}$. Then from what was just shown,

$$
\mathbf{A} \backslash \mathbf{B} \in \mathscr{E}_{J} \subseteq \mathscr{E}, \mathbf{A} \cap \mathbf{B} \in \mathscr{R} .
$$

By Lemma 12.10.2 on Page 318 this shows $\mathscr{E}$ is an algebra.

With this preparation, here is the Kolmogorov extension theorem. In the statement and proof of the theorem, $F_{i}, G_{i}$, and $E_{i}$ will denote Borel sets. Any list of indices from $I$ will always be assumed to be taken in order. Thus, if $J \subseteq I$ and $J=\left(t_{1}, \cdots, t_{n}\right)$, it will always be assumed $t_{1}<t_{2}<\cdots<t_{n}$.

Theorem 59.2.3 For each finite set

$$
J=\left(t_{1}, \cdots, t_{n}\right) \subseteq I
$$

suppose there exists a Borel probability measure, $v_{J}=v_{t_{1} \cdots t_{n}}$ defined on the Borel sets of $\prod_{t \in J} M_{t}$ such that the following consistency condition holds. If

$$
\left(t_{1}, \cdots, t_{n}\right) \subseteq\left(s_{1}, \cdots, s_{p}\right)
$$

then

$$
\begin{equation*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=v_{s_{1} \cdots s_{p}}\left(G_{s_{1}} \times \cdots \times G_{s_{p}}\right) \tag{59.2.5}
\end{equation*}
$$

where if $s_{i}=t_{j}$, then $G_{s_{i}}=F_{t_{j}}$ and if $s_{i}$ is not equal to any of the indices, $t_{k}$, then $G_{s_{i}}=M_{s_{i}}$. Then for $\mathscr{E}$ defined in Definition 59.2.1, there exists a probability measure, $P$ and $a \sigma$ algebra $\mathscr{F}=\sigma(\mathscr{E})$ such that

$$
\left(\prod_{t \in I} M_{t}, P, \mathscr{F}\right)
$$

is a probability space. Also there exist measurable functions, $X_{s}: \prod_{t \in I} M_{t} \rightarrow M_{s}$ defined as

$$
X_{s} \mathbf{x} \equiv x_{s}
$$

for each $s \in I$ such that for each $\left(t_{1} \cdots t_{n}\right) \subseteq I$,

$$
\begin{gather*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=P\left(\left[X_{t_{1}} \in F_{t_{1}}\right] \cap \cdots \cap\left[X_{t_{n}} \in F_{t_{n}}\right]\right) \\
\quad=P\left(\left(X_{t_{1}}, \cdots, X_{t_{n}}\right) \in \prod_{j=1}^{n} F_{t_{j}}\right)=P\left(\prod_{t \in I} F_{t}\right) \tag{59.2.6}
\end{gather*}
$$

where $F_{t}=M_{t}$ for every $t \notin\left\{t_{1} \cdots t_{n}\right\}$ and $F_{t_{i}}$ is a Borel set. Also if $f$ is a nonnegative function of finitely many variables, $x_{t_{1}}, \cdots, x_{t_{n}}$, measurable with respect to $\mathscr{B}\left(\prod_{j=1}^{n} M_{t_{j}}\right)$, then $f$ is also measurable with respect to $\mathscr{F}$ and

$$
\begin{align*}
& \int_{M_{t_{1} \times \cdots \times M_{t_{n}}}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d v_{t_{1} \cdots t_{n}} \\
= & \int_{\prod_{t \in I} M_{t}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d P \tag{59.2.7}
\end{align*}
$$

Proof: Let $\mathscr{E}$ be the algebra of sets defined in Definition 14.4.1. I want to define a measure on $\mathscr{E}$. For $\mathbf{F} \in \mathscr{E}$, there exists $J$ such that $\mathbf{F}$ is the finite disjoint unions of sets of $\mathscr{R}_{J}$. Define

$$
P_{0}(\mathbf{F}) \equiv v_{J}\left(\pi_{J}(\mathbf{F})\right)
$$

Then $P_{0}$ is well defined because of the consistency condition on the measures $v_{J} . P_{0}$ is clearly finitely additive because the $v_{J}$ are measures and one can pick $J$ as large as desired to include all $t$ where there may be something other than $M_{t}$. Also, from the definition,

$$
P_{0}(\Omega) \equiv P_{0}\left(\prod_{t \in I} M_{t}\right)=v_{t_{1}}\left(M_{t_{1}}\right)=1
$$

Next I will show $P_{0}$ is a finite measure on $\mathscr{E}$. After this it is only a matter of using the Caratheodory extension theorem to get the existence of the desired probability measure $P$.

Claim: Suppose $\mathbf{E}^{n}$ is in $\mathscr{E}$ and suppose $\mathbf{E}^{n} \downarrow \emptyset$. Then $P_{0}\left(\mathbf{E}^{n}\right) \downarrow 0$.
Proof of the claim: If not, there exists a sequence such that although $\mathbf{E}^{n} \downarrow \emptyset, P_{0}\left(\mathbf{E}^{n}\right) \downarrow$ $\varepsilon>0$. Let $\mathbf{E}^{n} \in \mathscr{E}_{J_{n}}$. Thus it is a finite disjoint union of sets of $\mathscr{R}_{J_{n}}$. By regularity of the measures $v_{J}$, which follows from Lemmas 59.1.8 and 59.1.9, there exists a compact set $\mathbf{K}_{J_{n}} \subseteq \mathbf{E}^{n}$ such that

$$
v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{K}_{J_{n}}\right)\right)+\frac{\varepsilon}{2^{n+2}}>v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{E}^{n}\right)\right)
$$

Thus

$$
\begin{aligned}
P_{0}\left(\mathbf{K}_{J_{n}}\right)+\frac{\varepsilon}{2^{n+2}} & \equiv v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{K}_{J_{n}}\right)\right)+\frac{\varepsilon}{2^{n+2}} \\
& >v_{J_{n}}\left(\pi_{J_{n}}\left(\mathbf{E}^{n}\right)\right) \equiv P_{0}\left(\mathbf{E}^{n}\right)
\end{aligned}
$$

The interesting thing about these $\mathbf{K}_{J_{n}}$ is: they have the finite intersection property. Here is why.

$$
\begin{aligned}
\varepsilon & \leq P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+P_{0}\left(\mathbf{E}^{m} \backslash \cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right) \\
& \leq P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+P_{0}\left(\cup_{k=1}^{m} \mathbf{E}^{k} \backslash \mathbf{K}_{J_{k}}\right) \\
& <P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+\sum_{k=1}^{\infty} \frac{\varepsilon}{2^{k+2}}<P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)+\varepsilon / 2
\end{aligned}
$$

and so $P_{0}\left(\cap_{k=1}^{m} \mathbf{K}_{J_{k}}\right)>\varepsilon / 2$. In considering all the $\mathbf{E}^{n}$, there are countably many entries in the product space which have something other than $M_{t}$ in them. Say these are $\left\{t_{1}, t_{2}, \cdots\right\}$. Let $p_{t_{i}}$ be a point which is in the intersection of the $t_{i}$ components of the sets $\mathbf{K}_{J_{n}}$. The compact sets in the $t_{i}$ position must have the finite intersection property also because if not, the sets $\mathbf{K}_{J_{n}}$ can't have it. Thus there is such a point. As to the other positions, use the axiom of choice to pick something in each of these. Thus the intersection of these $\mathbf{K}_{J_{n}}$ contains a point which is contrary to $\mathbf{E}^{n} \downarrow \emptyset$ because these sets are contained in the $\mathbf{E}^{n}$.

With the claim, it follows $P_{0}$ is a measure on $\mathscr{E}$. Here is why: If $\mathbf{E}=\cup_{k=1}^{\infty} \mathbf{E}^{k}$ where $\mathbf{E}, \mathbf{E}^{k} \in \mathscr{E}$, then $\left(\mathbf{E} \backslash \cup_{k=1}^{n} \mathbf{E}_{k}\right) \downarrow \emptyset$ and so

$$
P_{0}\left(\cup_{k=1}^{n} \mathbf{E}_{k}\right) \rightarrow P_{0}(\mathbf{E}) .
$$

Hence if the $\mathbf{E}_{k}$ are disjoint, $P_{0}\left(\cup_{k=1}^{n} \mathbf{E}_{k}\right)=\sum_{k=1}^{n} P_{0}\left(\mathbf{E}_{k}\right) \rightarrow P_{0}(\mathbf{E})$. Thus for disjoint $\mathbf{E}_{k}$ having $\cup_{k} \mathbf{E}_{k}=\mathbf{E} \in \mathscr{E}$,

$$
P_{0}\left(\cup_{k=1}^{\infty} \mathbf{E}_{k}\right)=\sum_{k=1}^{\infty} P_{0}\left(\mathbf{E}_{k}\right)
$$

Now to conclude the proof, apply the Caratheodory extension theorem to obtain $P$ a probability measure which extends $P_{0}$ to a $\sigma$ algebra which contains $\sigma(\mathscr{E})$ the sigma algebra generated by $\mathscr{E}$ with $P=P_{0}$ on $\mathscr{E}$. Thus for $\mathbf{E}_{J} \in \mathscr{E}, P\left(\mathbf{E}_{J}\right)=P_{0}\left(\mathbf{E}_{J}\right)=v_{J}\left(P_{J} \mathbf{E}_{j}\right)$.

Next, let $\left(\prod_{t \in I} M_{t}, \mathscr{F}, P\right)$ be the probability space and for $\mathbf{x} \in \prod_{t \in I} M_{t}$ let $X_{t}(\mathbf{x})=x_{t}$, the $t^{t h}$ entry of $\mathbf{x}$. It follows $X_{t}$ is measurable (also continuous) because if $U$ is open in $M_{t}$, then $X_{t}^{-1}(U)$ has a $U$ in the $t^{t h}$ slot and $M_{s}$ everywhere else for $s \neq t$. Thus inverse images of open sets are measurable. Also, letting $J$ be a finite subset of $I$ and for $J=\left(t_{1}, \cdots, t_{n}\right)$, and $F_{t_{1}}, \cdots, F_{t_{n}}$ Borel sets in $M_{t_{1}} \cdots M_{t_{n}}$ respectively, it follows $\mathbf{F}_{J}$, where $\mathbf{F}_{J}$ has $F_{t_{i}}$ in the $t_{i}^{t h}$ entry, is in $\mathscr{E}$ and therefore,

$$
\begin{gathered}
P\left(\left[X_{t_{1}} \in F_{t_{1}}\right] \cap\left[X_{t_{2}} \in F_{t_{2}}\right] \cap \cdots \cap\left[X_{t_{n}} \in F_{t_{n}}\right]\right)= \\
P\left(\left[\left(X_{t_{1}}, X_{t_{2}}, \cdots, X_{t_{n}}\right) \in F_{t_{1}} \times \cdots \times F_{t_{n}}\right]\right)=P\left(\mathbf{F}_{J}\right)=P_{0}\left(\mathbf{F}_{J}\right) \\
=v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)
\end{gathered}
$$

Finally consider the claim about the integrals. Suppose $f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right)=\mathscr{X}_{F}$ where $F$ is a Borel set of $\prod_{t \in J} M_{t}$ where $J=\left(t_{1}, \cdots, t_{n}\right)$. To begin with suppose

$$
\begin{equation*}
F=F_{t_{1}} \times \cdots \times F_{t_{n}} \tag{59.2.8}
\end{equation*}
$$

where each $F_{t_{j}}$ is in $\mathscr{B}\left(M_{t_{j}}\right)$. Then

$$
\begin{align*}
\int_{M_{t_{1}} \times \cdots \times M_{t_{n}}} & \mathscr{X}_{F}\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d v_{t_{1} \cdots t_{n}}=v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right) \\
& =P\left(\prod_{t \in I} F_{t}\right)=\int_{\Omega} \mathscr{X}_{\Pi_{t \in I} F_{t}}(\mathbf{x}) d P \\
& =\int_{\Omega} \mathscr{X}_{F}\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d P \tag{59.2.9}
\end{align*}
$$

where $F_{t}=M_{t}$ if $t \notin J$. Let $\mathscr{K}$ denote sets, $F$ of the sort in 59.2.8. It is clearly a $\pi$ system. Now let $\mathscr{G}$ denote those sets $F$ in $\mathscr{B}\left(\prod_{t \in J} M_{t}\right)$ such that 59.2 .9 holds. Thus $\mathscr{G} \supseteq \mathscr{K}$. It is clear that $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. Hence $\mathscr{G} \supseteq \sigma(\mathscr{K})$ but $\sigma(\mathscr{K})=\mathscr{B}\left(\prod_{t \in J} M_{t}\right)$ because every open set in $\prod_{t \in J} M_{t}$ is the countable union of rectangles like 59.2.8 in which each $F_{t_{i}}$ is open. Therefore, 59.2.9 holds for every $F \in \mathscr{B}\left(\prod_{t \in J} M_{t}\right)$.

Passing to simple functions and then using the monotone convergence theorem yields the final claim of the theorem.

### 59.3 Independence

The concept of independence is probably the main idea which separates probability from analysis and causes some of us to struggle to understand what is going on.

Definition 59.3.1 Let $(\Omega, \mathscr{F}, P)$ be a probability space. The sets in $\mathscr{F}$ are called events. $A$ set of events, $\left\{A_{i}\right\}_{i \in I}$ is called independent if whenever $\left\{A_{i_{k}}\right\}_{k=1}^{m}$ is a finite subset

$$
P\left(\cap_{k=1}^{m} A_{i_{k}}\right)=\prod_{k=1}^{m} P\left(A_{i_{k}}\right)
$$

Each of these events defines a rather simple $\sigma$ algebra, $\left(A_{i}, A_{i}^{C}, \emptyset, \Omega\right)$ denoted by $\mathscr{F}_{i}$. Now the following lemma is interesting because it motivates a more general notion of independent $\sigma$ algebras.

Lemma 59.3.2 Suppose $B_{i} \in \mathscr{F}_{i}$ for $i \in I$. Then for any $m \in \mathbb{N}$

$$
P\left(\cap_{k=1}^{m} B_{i_{k}}\right)=\prod_{k=1}^{m} P\left(B_{i_{k}}\right)
$$

Proof: The proof is by induction on the number $l$ of the $B_{i_{k}}$ which are not equal to $A_{i_{k}}$. First suppose $l=0$. Then the above assertion is true by assumption. Suppose it is so for some $l$ and there are $l+1$ sets not equal to $A_{i_{k}}$. If any equals $\emptyset$ there is nothing to show. Both sides equal 0 . If any equals $\Omega$, there is also nothing to show. You can ignore that set in both sides and then you have by induction the two sides are equal because you have no more than $l$ sets different than $A_{i_{k}}$. The only remaining case is where some $B_{i_{k}}=A_{i_{k}}^{C}$. Say $B_{i_{m+1}}=A_{i_{m+1}}^{C}$ for simplicity.

$$
\begin{aligned}
& P\left(\cap_{k=1}^{m+1} B_{i_{k}}\right)=P\left(A_{i_{m+1}}^{C} \cap \cap_{k=1}^{m} B_{i_{k}}\right) \\
& =P\left(\cap_{k=1}^{m} B_{i_{k}}\right)-P\left(A_{i_{m+1}} \cap \cap_{k=1}^{m} B_{i_{k}}\right)
\end{aligned}
$$

Then by induction,

$$
\begin{aligned}
& =\prod_{k=1}^{m} P\left(B_{i_{k}}\right)-P\left(A_{i_{m+1}}\right) \prod_{k=1}^{m} P\left(B_{i_{k}}\right)=\prod_{k=1}^{m} P\left(B_{i_{k}}\right)\left(1-P\left(A_{i_{m+1}}\right)\right) \\
& =P\left(A_{i_{m+1}}^{C}\right) \prod_{k=1}^{m} P\left(B_{i_{k}}\right)=\prod_{k=1}^{m+1} P\left(B_{i_{k}}\right)
\end{aligned}
$$

thus proving it for $l+1$.
This motivates a more general notion of independence in terms of $\sigma$ algebras.
Definition 59.3.3 If $\left\{\mathscr{F}_{i}\right\}_{i \in I}$ is any set of $\sigma$ algebras contained in $\mathscr{F}$, they are said to be independent if whenever $A_{i_{k}} \in \mathscr{F}_{i_{k}}$ for $k=1,2, \cdots, m$, then

$$
P\left(\cap_{k=1}^{m} A_{i_{k}}\right)=\prod_{k=1}^{m} P\left(A_{i_{k}}\right) .
$$

A set of random variables $\left\{\mathbf{X}_{i}\right\}_{i \in I}$ is independent if the $\sigma$ algebras $\left\{\sigma\left(\mathbf{X}_{i}\right)\right\}_{i \in I}$ are independent $\sigma$ algebras. Here $\sigma(\mathbf{X})$ denotes the smallest $\sigma$ algebra such that $\mathbf{X}$ is measurable. Thus $\sigma(\mathbf{X})=\left\{\mathbf{X}^{-1}(U): U\right.$ is a Borel set $\}$. More generally, $\sigma\left(\mathbf{X}_{i}: i \in I\right)$ is the smallest $\sigma$ algebra such that each $\mathbf{X}_{i}$ is measurable.

Note that by Lemma 59.3.2 you can consider independent events in terms of independent $\sigma$ algebras. That is, a set of independent events can always be considered as events taken from a set of independent $\sigma$ algebras. This is a more general notion because here the $\sigma$ algebras might have infinitely many sets in them.

Lemma 59.3.4 Suppose the set of random variables, $\left\{\mathbf{X}_{i}\right\}_{i \in I}$ is independent. Also suppose $I_{1} \subseteq I$ and $j \notin I_{1}$. Then the $\sigma$ algebras $\sigma\left(\mathbf{X}_{i}: i \in I_{1}\right), \sigma\left(\mathbf{X}_{j}\right)$ are independent $\sigma$ algebras.

Proof: Let $B \in \sigma\left(\mathbf{X}_{j}\right)$. I want to show that for any $A \in \sigma\left(\mathbf{X}_{i}: i \in I_{1}\right)$, it follows that $P(A \cap B)=P(A) P(B)$. Let $\mathscr{K}$ consist of finite intersections of sets of the form $\mathbf{X}_{k}^{-1}\left(B_{k}\right)$ where $B_{k}$ is a Borel set and $k \in I_{1}$. Thus $\mathscr{K}$ is a $\pi$ system and $\sigma(\mathscr{K})=\sigma\left(\mathbf{X}_{i}: i \in I_{1}\right)$. Now if you have one of these sets of the form $A=\cap_{k=1}^{m} \mathbf{X}_{k}^{-1}\left(B_{k}\right)$ where without loss of generality, it can be assumed the $k$ are distinct since $\mathbf{X}_{k}^{-1}\left(B_{k}\right) \cap \mathbf{X}_{k}^{-1}\left(B_{k}^{\prime}\right)=\mathbf{X}_{k}^{-1}\left(B_{k} \cap B_{k}^{\prime}\right)$, then

$$
\begin{aligned}
P(A \cap B) & =P\left(\cap_{k=1}^{m} \mathbf{X}_{k}^{-1}\left(B_{k}\right) \cap B\right)=P(B) \prod_{k=1}^{m} P\left(\mathbf{X}_{k}^{-1}\left(B_{k}\right)\right) \\
& =P(B) P\left(\cap_{k=1}^{m} \mathbf{X}_{k}^{-1}\left(B_{k}\right)\right) .
\end{aligned}
$$

Thus $\mathscr{K}$ is contained in

$$
\mathscr{G} \equiv\left\{A \in \sigma\left(\mathbf{X}_{i}: i \in I_{1}\right): P(A \cap B)=P(A) P(B)\right\}
$$

Now $\mathscr{G}$ is closed with respect to complements and countable disjoint unions. Here is why: If each $A_{i} \in \mathscr{G}$ and the $A_{i}$ are disjoint,

$$
\begin{aligned}
P\left(\left(\cup_{i=1}^{\infty} A_{i}\right) \cap B\right) & =P\left(\cup_{i=1}^{\infty}\left(A_{i} \cap B\right)\right) \\
& =\sum_{i} P\left(A_{i} \cap B\right)=\sum_{i} P\left(A_{i}\right) P(B) \\
& =P(B) \sum_{i} P\left(A_{i}\right)=P(B) P\left(\cup_{i=1}^{\infty} A_{i}\right)
\end{aligned}
$$

If $A \in \mathscr{G}$,

$$
P\left(A^{C} \cap B\right)+P(A \cap B)=P(B)
$$

and so

$$
\begin{aligned}
P\left(A^{C} \cap B\right) & =P(B)-P(A \cap B) \\
& =P(B)-P(A) P(B) \\
& =P(B)(1-P(A))=P(B) P\left(A^{C}\right) .
\end{aligned}
$$

Therefore, from the lemma on $\pi$ systems, Lemma 12.12 .3 on Page 329 , it follows $\mathscr{G} \supseteq$ $\sigma(\mathscr{K})=\sigma\left(\mathbf{X}_{i}: i \in I_{1}\right)$.

Lemma 59.3.5 If $\left\{\mathbf{X}_{k}\right\}_{k=1}^{r}$ are independent random variables having values in $Z$ a separable metric space, and if $g_{k}$ is a Borel measurable function, then $\left\{g_{k}\left(\mathbf{X}_{k}\right)\right\}_{k=1}^{r}$ is also
independent. Furthermore, if the random variables have values in $\mathbb{R}$, and they are all bounded, then

$$
E\left(\prod_{i=1}^{r} X_{i}\right)=\prod_{i=1}^{r} E\left(X_{i}\right)
$$

More generally, the above formula holds if it is only known that each $X_{i} \in L^{1}(\Omega ; \mathbb{R})$ and

$$
\prod_{i=1}^{r} X_{i} \in L^{1}(\Omega ; \mathbb{R})
$$

Proof: First consider the claim about $\left\{g_{k}\left(\mathbf{X}_{k}\right)\right\}_{k=1}^{r}$. Letting $O$ be an open set in $Z$,

$$
\left(g_{k} \circ \mathbf{X}_{k}\right)^{-1}(O)=\mathbf{X}_{k}^{-1}\left(g_{k}^{-1}(O)\right)=\mathbf{X}_{k}^{-1}(\text { Borel set }) \in \sigma\left(\mathbf{X}_{k}\right) .
$$

It follows $\left(g_{k} \circ \mathbf{X}_{k}\right)^{-1}(E)$ is in $\sigma\left(\mathbf{X}_{k}\right)$ whenever $E$ is Borel because the sets whose inverse images are measurable includes the Borel sets. Thus $\sigma\left(g_{k} \circ \mathbf{X}_{k}\right) \subseteq \sigma\left(\mathbf{X}_{k}\right)$ and this proves the first part of the lemma.

Let $X_{1}=\sum_{i=1}^{m} c_{i} \mathscr{X}_{E_{i}}, X_{2}=\sum_{j=1}^{m} d_{j} \mathscr{X}_{F_{j}}$ where $P\left(E_{i} F_{j}\right)=P\left(E_{i}\right) P\left(F_{j}\right)$. Then

$$
\int X_{1} X_{2} d P=\sum_{i, j} d_{j} c_{i} P\left(E_{i}\right) P\left(F_{j}\right)=\left(\int X_{1} d P\right)\left(\int X_{2} d P\right)
$$

In general for $X_{1}, X_{2}$ independent, there exist sequences of bounded simple functions

$$
\left\{s_{n}\right\},\left\{t_{n}\right\}
$$

measurable with respect to $\sigma\left(X_{1}\right)$ and $\sigma\left(X_{2}\right)$ respectively such that $s_{n} \rightarrow X_{1}$ pointwise and $t_{n} \rightarrow X_{2}$ pointwise. Then from the above and the dominated convergence theorem,

$$
\begin{aligned}
\int X_{1} X_{2} d P & =\lim _{n \rightarrow \infty} \int s_{n} t_{n} d P=\lim _{n \rightarrow \infty}\left(\int s_{n} d P\right)\left(\int t_{n} d P\right) \\
& =\left(\int X_{1} d P\right)\left(\int X_{2} d P\right)
\end{aligned}
$$

Next suppose there are $m$ of these independent bounded random variables. Then $\prod_{i=2}^{m} X_{i} \in$ $\sigma\left(X_{2}, \cdots, X_{m}\right)$ and by Lemma 59.3.4 the two random variables $X_{1}$ and $\prod_{i=2}^{m} X_{i}$ are independent. Hence from the above and induction,

$$
\int \prod_{i=1}^{m} X_{i} d P=\int X_{1} \prod_{i=2}^{m} X_{i} d P=\int X_{1} d P \int \prod_{i=2}^{m} X_{i} d P=\prod_{i=1}^{m} \int X_{i} d P
$$

Now consider the last claim. Replace each $X_{i}$ with $X_{i}^{n}$ where this is just a truncation of the form

$$
X_{i}^{n} \equiv\left\{\begin{array}{c}
X_{i} \text { if }\left|X_{i}\right| \leq n \\
n \text { if } X_{i}>n \\
-n \text { if } X_{i}<n
\end{array}\right.
$$

Then by the first part

$$
E\left(\prod_{i=1}^{r} X_{i}^{n}\right)=\prod_{i=1}^{r} E\left(X_{i}^{n}\right)
$$

Now $\left|\prod_{i=1}^{r} X_{i}^{n}\right| \leq\left|\prod_{i=1}^{r} X_{i}\right| \in L^{1}$ and so by the dominated convergence theorem, you can pass to the limit in both sides to get the desired result.

Maybe this would be a good place to put a really interesting result known as the Doob Dynkin lemma. This amazing result is illustrated with the following diagram in which $\mathbf{X}=\left(X_{1}, \cdots, X_{m}\right)$. By Proposition 59.1.6 $\sigma(\mathbf{X})=\sigma\left(X_{1}, \cdots, X_{n}\right)$.

You start with $X$ and can write it as the composition $g \circ \mathbf{X}$ provided $X$ is $\sigma(\mathbf{X})$ measurable.
Lemma 59.3.6 Let $(\Omega, \mathscr{F})$ be a measure space and let $X_{i}: \Omega \rightarrow E_{i}$ where $E_{i}$ is a separable Banach space. Suppose also that $X: \Omega \rightarrow F$ where $F$ is a separable Banach space. Then $X$ is $\sigma\left(X_{1}, \cdots, X_{m}\right)$ measurable if and only if there exists a Borel measurable function $g: \prod_{i=1}^{m} E_{i} \rightarrow F$ such that $X=g\left(X_{1}, \cdots, X_{m}\right)$.

Proof: First suppose $X(\omega)=f \mathscr{X}_{W}(\omega)$ where $f \in F$ and $W \in \sigma\left(X_{1}, \cdots, X_{m}\right)$. Then by Proposition 59.1.6, $W$ is of the form $\left(X_{1}, \cdots, X_{m}\right)^{-1}(B) \equiv \mathbf{X}^{-1}(B)$ where $B$ is Borel in $\prod_{i=1}^{m} E_{i}$. Therefore,

$$
X(\omega)=f \mathscr{X}_{\mathbf{X}^{-1}(B)}(\omega)=f \mathscr{X}_{B}(\mathbf{X}(\omega))
$$

Now suppose $X$ is measurable with respect to $\sigma\left(X_{1}, \cdots, X_{m}\right)$. Then there exist simple functions

$$
X_{n}(\omega)=\sum_{k=1}^{m_{n}} f_{k} \mathscr{X}_{B_{k}}(\mathbf{X}(\omega)) \equiv g_{n}(\mathbf{X}(\omega))
$$

where the $B_{k}$ are Borel sets in $\prod_{i=1}^{m} E_{i}$, such that $X_{n}(\omega) \rightarrow X(\omega)$, each $g_{n}$ being Borel. Thus $g_{n}$ converges on $\mathbf{X}(\Omega)$. Furthermore, the set on which $g_{n}$ does converge is a Borel set equal to

$$
\cap_{n=1}^{\infty} \cup_{m=1}^{\infty} \cap_{p, q \geq m}\left[\left\|g_{p}-g_{q}\right\|<\frac{1}{n}\right]
$$

which contains $\mathbf{X}(\Omega)$. Therefore, modifying $g_{n}$ by multiplying it by the indicator function of this Borel set containing $\mathbf{X}(\Omega)$, we can conclude that $g_{n}$ converges to a Borel function $g$ and, passing to a limit in the above,

$$
X(\omega)=g(\mathbf{X}(\omega))
$$

Conversely, suppose $X(\omega)=g(\mathbf{X}(\omega))$. Why is $X \sigma(\mathbf{X})$ measurable?

$$
X^{-1}(\text { open })=\mathbf{X}^{-1}\left(g^{-1}(\text { open })\right)=\mathbf{X}^{-1}(\text { Borel }) \in \sigma(\mathbf{X})
$$

### 59.4 Banach Space Valued Random Variables

Recall that for $X$ a random variable, $\sigma(X)$ is the smallest $\sigma$ algebra containing all the sets of the form $X^{-1}(F)$ where $F$ is Borel. Since such sets, $X^{-1}(F)$ for $F$ Borel form a $\sigma$ algebra it follows $\sigma(X)=\left\{X^{-1}(F): F\right.$ is Borel $\}$.

Next consider the case where you have a set of $\sigma$ algebras. The following lemma is helpful when you try to verify such a set of $\sigma$ algebras is independent. It says you only need to check things on $\pi$ systems contained in the $\sigma$ algebras. This is really nice because it is much easier to consider the smaller $\pi$ systems than the whole $\sigma$ algebra.

Lemma 59.4.1 Suppose $\left\{\mathscr{F}_{i}\right\}_{i \in I}$ is a set of $\sigma$ algebras contained in $\mathscr{F}$ where $\mathscr{F}$ is a $\sigma$ algebra of sets of $\Omega$. Suppose that $\mathscr{K}_{i} \subseteq \mathscr{F}_{i}$ is a $\pi$ system and $\mathscr{F}_{i}=\sigma\left(\mathscr{K}_{i}\right)$. Suppose also that whenever $J$ is a finite subset of I and $A_{j} \in \mathscr{K}_{j}$ for $j \in J$, it follows

$$
P\left(\cap_{j \in J} A_{j}\right)=\prod_{j \in J} P\left(A_{j}\right) .
$$

Then $\left\{\mathscr{F}_{i}\right\}_{i \in I}$ is independent.
Proof: I need to verify that under the given conditions, if $\left\{j_{1}, j_{2}, \cdots, j_{n}\right\} \subseteq I$ and $A_{j_{k}} \subseteq$ $\mathscr{F}_{j_{k}}$, then

$$
P\left(\cap_{k=1}^{n} A_{j_{k}}\right)=\prod_{k=1}^{n} P\left(A_{j_{k}}\right) .
$$

By hypothesis, this is true if each $A_{j_{k}} \in \mathscr{K}_{j_{k}}$. Suppose it is true whenever there are at most $r-1 \geq 0$ of the $A_{j_{k}}$ which are not in $\mathscr{K}_{j_{k}}$. Consider

$$
\cap_{k=1}^{n} A_{j_{k}}
$$

where there are $r$ sets which are not in the corresponding $\mathscr{K}_{j_{k}}$. Without loss of generality, say there are at most $r-1$ sets in the first $n-1$ which are not in the corresponding $\mathscr{K}_{j_{k}}$.

Pick $\left(A_{j_{1}} \cdots, A_{j_{n-1}}\right)$ let

$$
\mathscr{G}_{\left(A_{j_{1}} \cdots A_{j_{n-1}}\right)} \equiv\left\{B \in \mathscr{F}_{j_{n}}: P\left(\cap_{k=1}^{n-1} A_{j_{k}} \cap B\right)=\prod_{k=1}^{n-1} P\left(A_{j_{k}}\right) P(B)\right\}
$$

I am going to show $\mathscr{G}_{\left(A_{j_{1}} \cdots A_{j_{n-1}}\right)}$ is closed with respect to complements and countable disjoint unions and then apply the Lemma on $\pi$ systems. By the induction hypothesis,

$$
\begin{aligned}
& \mathscr{K}_{j_{n}} \subseteq \mathscr{G}_{\left(A_{j_{1}} \cdots A_{j_{n-1}}\right)} . \text { If } B \in \mathscr{G}\left(A_{j_{1}} \cdots A_{j_{n-1}}\right) \\
& \prod_{k=1}^{n-1} P\left(A_{j_{k}}\right)=P\left(\cap_{k=1}^{n-1} A_{j_{k}}\right) \\
&=P\left(\left(\cap_{k=1}^{n-1} A_{j_{k}} \cap B^{C}\right) \cup\left(\cap_{k=1}^{n-1} A_{j_{k}} \cap B\right)\right) \\
&=P\left(\cap_{k=1}^{n-1} A_{j_{k}} \cap B^{C}\right)+P\left(\cap_{k=1}^{n-1} A_{j_{k}} \cap B\right) \\
&=P\left(\cap_{k=1}^{n-1} A_{j_{k}} \cap B^{C}\right)+\prod_{k=1}^{n-1} P\left(A_{j_{k}}\right) P(B)
\end{aligned}
$$

and so

$$
\begin{aligned}
P\left(\cap_{k=1}^{n-1} A_{j_{k}} \cap B^{C}\right) & =\prod_{k=1}^{n-1} P\left(A_{j_{k}}\right)(1-P(B)) \\
& =\prod_{k=1}^{n-1} P\left(A_{j_{k}}\right) P\left(B^{C}\right)
\end{aligned}
$$

showing if $B \in \mathscr{G}_{\left(A_{j_{1}} \cdots, A_{j_{n-1}}\right)}$, then so is $B^{C}$. It is clear that $\mathscr{G}_{\left(A_{j_{1}} \cdots, A_{j_{n-1}}\right)}$ is closed with respect to disjoint unions also. Here is why. If $\left\{B_{j}\right\}_{j=1}^{\infty}$ are disjoint sets in $\mathscr{G}_{\left(A_{j_{1}} \cdots A_{j_{n-1}}\right)}$,

$$
\begin{aligned}
P\left(\cup_{i=1}^{\infty} B_{i} \cap \cap_{k=1}^{n-1} A_{j_{k}}\right) & =\sum_{i=1}^{\infty} P\left(B_{i} \cap \cap_{k=1}^{n-1} A_{j_{k}}\right) \\
& =\sum_{i=1}^{\infty} P\left(B_{i}\right) \prod_{k=1}^{n-1} P\left(A_{j_{k}}\right) \\
& =\prod_{k=1}^{n-1} P\left(A_{j_{k}}\right) \sum_{i=1}^{\infty} P\left(B_{i}\right) \\
& =\prod_{k=1}^{n-1} P\left(A_{j_{k}}\right) P\left(\cup_{i=1}^{\infty} B_{i}\right)
\end{aligned}
$$

Therefore, by the $\pi$ system lemma, Lemma $12.12 .3^{\mathscr{G}}{\left(A_{j_{1} \cdots A_{j_{n-1}}}\right)}=\mathscr{F}_{j_{n}}$. This proves the induction step in going from $r-1$ to $r$.

What is a useful $\pi$ system for $\mathscr{B}(E)$, the Borel sets of $E$ where $E$ is a Banach space?
Recall the fundamental lemma used to prove the Pettis theorem. It was proved on Page 645.

Lemma 59.4.2 Let E be a separable real Banach space. Sets of the form

$$
\left\{x \in E: x_{i}^{*}(x) \leq \alpha_{i}, i=1,2, \cdots, m\right\}
$$

where $x_{i}^{*} \in D^{\prime}$, a dense subspace of the unit ball of $E^{\prime}$ and $\alpha_{i} \in[-\infty, \infty)$ are a $\pi$ system, and denoting this $\pi$ system by $\mathscr{K}$, it follows $\sigma(\mathscr{K})=\mathscr{B}(E)$. The sets of $\mathscr{K}$ are examples of cylindrical sets. The $D^{\prime}$ is that set for the proof of the Pettis theorem.

Proof: The sets described are obviously a $\pi$ system. I want to show $\sigma(\mathscr{K})$ contains the closed balls because then $\sigma(\mathscr{K})$ contains the open balls and hence the open sets and the result will follow. Let $D^{\prime}$ be described in Lemma 21.1.6. As pointed out earlier it can
be any dense subset of $B^{\prime}$. Then

$$
\begin{aligned}
& \{x \in E:\|x-a\| \leq r\} \\
= & \left\{x \in E: \sup _{f \in D^{\prime}}|f(x-a)| \leq r\right\} \\
= & \left\{x \in E: \sup _{f \in D^{\prime}}|f(x)-f(a)| \leq r\right\} \\
= & \cap_{f \in D^{\prime}}\{x \in E: f(a)-r \leq f(x) \leq f(a)+r\} \\
= & \cap_{f \in D^{\prime}}\{x \in E: f(x) \leq f(a)+r \text { and }(-f)(x) \leq r-f(a)\}
\end{aligned}
$$

which equals a countable intersection of sets of the given $\pi$ system. Therefore, every closed ball is contained in $\sigma(\mathscr{K})$. It follows easily that every open ball is also contained in $\sigma(\mathscr{K})$ because

$$
B(a, r)=\cup_{n=1}^{\infty} \overline{B\left(a, r-\frac{1}{n}\right)} .
$$

Since the Banach space is separable, it is completely separable and so every open set is the countable union of balls. This shows the open sets are in $\sigma(\mathscr{K})$ and so $\sigma(\mathscr{K}) \supseteq \mathscr{B}(E)$. However, all the sets in the $\pi$ system are closed hence Borel because they are inverse images of closed sets. Therefore, $\sigma(\mathscr{K}) \subseteq \mathscr{B}(E)$ and so $\sigma(\mathscr{K})=\mathscr{B}(E)$.

As mentioned above, we can replace $D^{\prime}$ in the above with $M$, any dense subset of $E^{\prime}$.
Observation 59.4.3 Denote by $C_{\alpha, n}$ the set $\left\{\beta \in \mathbb{R}^{n}: \beta_{i} \leq \alpha_{i}\right\}$. Also denote by $\mathbf{g}_{n}$ an element of $M^{n}$ with the understanding that $\mathbf{g}_{n}: E \rightarrow \mathbb{R}^{n}$ according to the rule

$$
\mathbf{g}_{n}(x) \equiv\left(g_{1}(x), \cdots, g_{n}(x)\right)
$$

Then the sets in the above lemma can be written as $\mathbf{g}_{n}^{-1}\left(C_{\alpha, n}\right)$. In other words, sets of the form $\mathbf{g}_{n}^{-1}\left(C_{\alpha, n}\right)$ form a $\pi$ system for $\mathscr{B}(E)$.

Next suppose you have some random variables having values in a separable Banach space, $E,\left\{X_{i}\right\}_{i \in I}$. How can you tell if they are independent? To show they are independent, you need to verify that

$$
P\left(\cap_{k=1}^{n} X_{i_{k}}^{-1}\left(F_{i_{k}}\right)\right)=\prod_{k=1}^{n} P\left(X_{i_{k}}^{-1}\left(F_{i_{k}}\right)\right)
$$

whenever the $F_{i_{k}}$ are Borel sets in $E$. It is desirable to find a way to do this easily.
Lemma 59.4.4 Let $\mathscr{K}$ be a $\pi$ system of sets of $E$, a separable real Banach space and let $(\Omega, \mathscr{F}, P)$ be a probability space and $X: \Omega \rightarrow E$ be a random variable. Then

$$
X^{-1}(\sigma(\mathscr{K}))=\sigma\left(X^{-1}(\mathscr{K})\right)
$$

Proof: First note that $X^{-1}(\sigma(\mathscr{K}))$ is a $\sigma$ algebra which contains $X^{-1}(\mathscr{K})$ and so it contains $\sigma\left(X^{-1}(\mathscr{K})\right)$. Thus

$$
X^{-1}(\sigma(\mathscr{K})) \supseteq \sigma\left(X^{-1}(\mathscr{K})\right)
$$

Now let

$$
\mathscr{G} \equiv\left\{A \in \sigma(\mathscr{K}): X^{-1}(A) \in \sigma\left(X^{-1}(\mathscr{K})\right)\right\}
$$

Then $\mathscr{G} \supseteq \mathscr{K}$. If $A \in \mathscr{G}$, then

$$
X^{-1}(A) \in \sigma\left(X^{-1}(\mathscr{K})\right)
$$

and so

$$
X^{-1}(A)^{C}=X^{-1}\left(A^{C}\right) \in \sigma\left(X^{-1}(\mathscr{K})\right)
$$

because $\sigma\left(X^{-1}(\mathscr{K})\right)$ is a $\sigma$ algebra. Hence $A^{C} \in \mathscr{G}$. Finally suppose $\left\{A_{i}\right\}$ is a sequence of disjoint sets of $\mathscr{G}$. Then

$$
X^{-1}\left(\cup_{i=1}^{\infty} A_{i}\right)=\cup_{i=1}^{\infty} X^{-1}\left(A_{i}\right) \in \sigma\left(X^{-1}(\mathscr{K})\right)
$$

again because $\sigma\left(X^{-1}(\mathscr{K})\right)$ is a $\sigma$ algebra. It follows from Lemma 12.12.3 on Page 329 that $\mathscr{G} \supseteq \sigma(\mathscr{K})$ and this shows that whenever

$$
A \in \sigma(\mathscr{K}), X^{-1}(A) \in \sigma\left(X^{-1}(\mathscr{K})\right)
$$

Thus $X^{-1}(\sigma(\mathscr{K})) \subseteq \sigma\left(X^{-1}(\mathscr{K})\right)$.
With this lemma, here is the desired result about independent random variables. Essentially, you can reduce to the case of random vectors having values in $\mathbb{R}^{n}$.

### 59.5 Reduction To Finite Dimensions

Let $E$ be a Banach space and let $\mathbf{g} \in\left(E^{\prime}\right)^{n}$. Then for $x \in E, \mathbf{g} \circ x$ is the vector in $\mathbb{F}^{n}$ which equals $\left(g_{1}(x), g_{2}(x), \cdots, g_{n}(x)\right)$.

Theorem 59.5.1 Let $X_{i}$ be a random variable having values in E a real separable Banach space. The random variables $\left\{X_{i}\right\}_{i \in I}$ are independent if whenever

$$
\left\{i_{1}, \cdots, i_{n}\right\} \subseteq I
$$

$m_{i_{1}}, \cdots, m_{i_{n}}$ are positive integers, and $\mathbf{g}_{m_{i_{1}}}, \cdots, \mathbf{g}_{m_{i_{n}}}$ are respectively in

$$
(M)^{m_{i_{1}}}, \cdots,(M)^{m_{i_{n}}}
$$

for $M$ a dense subspace of $E^{\prime},\left\{\mathbf{g}_{m_{i_{j}}} \circ X_{i_{j}}\right\}_{j=1}^{n}$ are independent random vectors having values in $\mathbb{R}^{m_{i_{1}}}, \cdots, \mathbb{R}^{m_{i n}}$ respectively.

Proof: It is necessary to show that the events $X_{i_{j}}^{-1}\left(B_{i_{j}}\right)$ are independent events whenever $B_{i_{j}}$ are Borel sets. By Lemma 59.4.1 and the above Lemma 59.4.2, it suffices to verify that the events

$$
X_{i_{j}}^{-1}\left(\mathbf{g}_{m_{i j}}^{-1}\left(C_{\tilde{\alpha}, m_{i j}}\right)\right)=\left(\mathbf{g}_{m_{i_{j}}} \circ X_{i_{j}}\right)^{-1}\left(C_{\tilde{\alpha}, m_{i j}}\right)
$$

are independent where $C_{\tilde{\alpha}, m_{i j}}$ are the cones described in Lemma 59.4.2. Thus

$$
\begin{aligned}
\tilde{\alpha} & =\left(\alpha_{k_{1}}, \cdots, \alpha_{k_{m}}\right) \\
C_{\tilde{\alpha}, m_{i_{j}}} & =\prod_{i=1}^{m_{i_{j}}}\left(-\infty, \alpha_{k_{i}}\right]
\end{aligned}
$$

But this condition is implied when the finite dimensional valued random vectors $\mathbf{g}_{m_{i j}} \circ X_{i_{j}}$ are independent.

The above assertion also goes the other way as you may want to show.

### 59.6 0, 1 Laws

I am following [120] for the proof of many of the following theorems. Recall the set of $\omega$ which are in infinitely many of the sets $\left\{A_{n}\right\}$ is

$$
\cap_{n=1}^{\infty} \cup_{m=n}^{\infty} A_{m} .
$$

This is because $\omega$ is in the above set if and only if for every $n$ there exists $m \geq n$ such that it is in $A_{m}$.

Theorem 59.6.1 Suppose $A_{n} \in \mathscr{F}_{n}$ where the $\sigma$ algebras $\left\{\mathscr{F}_{n}\right\}_{n=1}^{\infty}$ are independent. Suppose also that

$$
\sum_{k=1}^{\infty} P\left(A_{k}\right)=\infty
$$

Then

$$
P\left(\cap_{n=1}^{\infty} \cup_{m=n}^{\infty} A_{m}\right)=1
$$

Proof: It suffices to verify that

$$
P\left(\cup_{n=1}^{\infty} \cap_{m=n}^{\infty} A_{m}^{C}\right)=0
$$

which can be accomplished by showing

$$
P\left(\cap_{m=n}^{\infty} A_{m}^{C}\right)=0
$$

for each $n$. The sets $\left\{A_{k}^{C}\right\}$ satisfy $A_{k}^{C} \in \mathscr{F}_{k}$. Therefore, noting that $e^{-x} \geq 1-x$,

$$
\begin{aligned}
P\left(\cap_{m=n}^{\infty} A_{m}^{C}\right) & =\lim _{N \rightarrow \infty} P\left(\cap_{m=n}^{N} A_{m}^{C}\right)=\lim _{N \rightarrow \infty} \prod_{m=n}^{N} P\left(A_{m}^{C}\right) \\
& =\lim _{N \rightarrow \infty} \prod_{m=n}^{N}\left(1-P\left(A_{m}\right)\right) \leq \lim _{N \rightarrow \infty} \prod_{m=n}^{N} e^{-P\left(A_{m}\right)} \\
& =\lim _{N \rightarrow \infty} \exp \left(-\sum_{m=n}^{N} P\left(A_{m}\right)\right)=0
\end{aligned}
$$

The Kolmogorov zero one law follows next. It has to do with something called a tail event.

Definition 59.6.2 Let $\left\{\mathscr{F}_{n}\right\}$ be a sequence of $\sigma$ algebras. Then $\mathscr{T}_{n} \equiv \sigma\left(\cup_{k=n}^{\infty} \mathscr{F}_{k}\right)$ where this means the smallest $\sigma$ algebra which contains each $\mathscr{F}_{k}$ for $k \geq n$. Then a tail event is a set which is in the $\sigma$ algebra, $\mathscr{T} \equiv \cap_{n=1}^{\infty} \mathscr{T}_{n}$.

As usual, $(\Omega, \mathscr{F}, P)$ is the underlying probability space such that all $\sigma$ algebras are contained in $\mathscr{F}$.

Lemma 59.6.3 Suppose $\left\{\mathscr{F}_{n}\right\}_{n=1}^{\infty}$ are independent $\sigma$ algebras and suppose $A$ is a tail event and $A_{k_{i}} \in \mathscr{F}_{k_{i}}, i=1, \cdots, m$ are given sets. Then

$$
P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}} \cap A\right)=P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}}\right) P(A)
$$

Proof: Let $\mathscr{K}$ be the $\pi$ system consisting of finite intersections of the form

$$
B_{m_{1}} \cap B_{m_{2}} \cap \cdots \cap B_{m_{j}}
$$

where $m_{i} \in \mathscr{F}_{k_{i}}$ for $k_{i}>\max \left\{k_{1}, \cdots, k_{m}\right\} \equiv N$. Thus $\sigma(\mathscr{K})=\sigma\left(\cup_{i=N+1}^{\infty} \mathscr{F}_{i}\right)$. Now let

$$
\mathscr{G} \equiv\left\{B \in \sigma(\mathscr{K}): P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}} \cap B\right)=P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}}\right) P(B)\right\}
$$

Then clearly $\mathscr{K} \subseteq \mathscr{G}$. It is also true that $\mathscr{G}$ is closed with respect to complements and countable disjoint unions. By the lemma on $\pi$ systems, $\mathscr{G}=\sigma(\mathscr{K})=\sigma\left(\cup_{i=N+1}^{\infty} \mathscr{F}_{i}\right)$. Since $A$ is in $\sigma\left(\cup_{i=N+1}^{\infty} \mathscr{F}_{i}\right)$ due to the assumption that it is a tail event, it follows that

$$
P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}} \cap A\right)=P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}}\right) P(A)
$$

Theorem 59.6.4 Suppose the $\sigma$ algebras, $\left\{\mathscr{F}_{n}\right\}_{n=1}^{\infty}$ are independent and suppose $A$ is a tail event. Then $P(A)$ either equals 0 or 1 .

Proof: Let $A \in \mathscr{T}$. I want to show that $P(A)=P(A)^{2}$. Let $\mathscr{K}$ denote sets of the form $A_{k_{1}} \cap \cdots \cap A_{k_{m}}$ for some $m, A_{k_{j}} \in \mathscr{F}_{k_{j}}$ where each $k_{j}>n$. Thus $\mathscr{K}$ is a $\pi$ system and

$$
\sigma(\mathscr{K})=\sigma\left(\cup_{k=n+1}^{\infty} \mathscr{F}_{k}\right) \equiv \mathscr{T}_{n+1}
$$

Let

$$
\mathscr{G} \equiv\left\{B \in \mathscr{T}_{n+1} \equiv \sigma\left(\cup_{k=n+1}^{\infty} \mathscr{F}_{k}\right): P(A \cap B)=P(A) P(B)\right\}
$$

Thus $\mathscr{K} \subseteq \mathscr{G}$ because

$$
P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}} \cap A\right)=P\left(A_{k_{1}} \cap \cdots \cap A_{k_{m}}\right) P(A)
$$

by Lemma 59.6.3. However, $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. Here is why. If $B \in \mathscr{G}$,

$$
P\left(A \cap B^{C}\right)+P(A \cap B)=P(A)
$$

and so

$$
P\left(A \cap B^{C}\right)=P(A)-P(A \cap B)=P(A)(1-P(B))=P(A) P\left(B^{C}\right)
$$

and so $B^{C} \in \mathscr{G}$. If $\left\{B_{i}\right\}_{i=1}^{\infty}$ are disjoint sets in $\mathscr{G}$,

$$
\begin{aligned}
P\left(A \cap \cup_{k=1}^{\infty} B_{k}\right) & =\sum_{k=1}^{\infty} P\left(A \cap B_{k}\right)=P(A) \sum_{k=1}^{\infty} P\left(B_{k}\right) \\
& =P(A) P\left(\cup_{k=1}^{\infty} B_{k}\right)
\end{aligned}
$$

and so $\cup_{k=1}^{\infty} B_{k} \in \mathscr{G}$. Therefore by the Lemma on $\pi$ systems Lemma 12.12.3 on Page 329, it follows $\mathscr{G}=\sigma(\mathscr{K})=\sigma\left(\cup_{k=n+1}^{\infty} \mathscr{F}_{k}\right)$.

Thus for any $B \in \sigma\left(\cup_{k=n+1}^{\infty} \mathscr{F}_{k}\right)=\mathscr{T}_{n+1}, P(A \cap B)=P(A) P(B)$. However, $A$ is in all of these $\mathscr{T}_{n+1}$ and so $P(A \cap A)=P(A)=P(A)^{2}$ so $P(A)$ equals either 0 or 1 .

What sorts of things are tail events of independent $\sigma$ algebras?
Theorem 59.6.5 Let $\left\{\mathbf{X}_{k}\right\}$ be a sequence of independent random variables having values in $Z$ a Banach space. Then

$$
A \equiv\left\{\omega:\left\{\mathbf{X}_{k}(\omega)\right\} \text { converges }\right\}
$$

is a tail event of the independent $\sigma$ algebras $\left\{\sigma\left(\mathbf{X}_{k}\right)\right\}$. So is

$$
B \equiv\left\{\omega:\left\{\sum_{k=1}^{\infty} \mathbf{X}_{k}(\omega)\right\} \text { converges }\right\}
$$

Proof: Since $Z$ is complete, $A$ is the same as the set where $\left\{\mathbf{X}_{k}(\omega)\right\}$ is a Cauchy sequence. This set is

$$
\cap_{n=1}^{\infty} \cap_{p=1}^{\infty} \cup_{m=p}^{\infty} \cap_{l, k \geq m}\left\{\omega:\left\|\mathbf{X}_{k}(\omega)-\mathbf{X}_{l}(\omega)\right\|<1 / n\right\}
$$

Note that

$$
\cup_{m=p}^{\infty} \cap_{l, k \geq m}\left\{\omega:\left\|\mathbf{X}_{k}(\omega)-\mathbf{X}_{l}(\omega)\right\|<1 / n\right\} \in \sigma\left(\cup_{j=p}^{\infty} \sigma\left(\mathbf{X}_{j}\right)\right)
$$

for every $p$ is the set where ultimately any pair of $\mathbf{X}_{k}, \mathbf{X}_{l}$ are closer together than $1 / n$,

$$
\cap_{p=1}^{\infty} \cup_{m=p}^{\infty} \cap_{l, k \geq m}\left\{\omega:\left\|\mathbf{X}_{k}(\omega)-\mathbf{X}_{l}(\omega)\right\|<1 / n\right\}
$$

is a tail event. The set where $\left\{\mathbf{X}_{k}(\omega)\right\}$ is a Cauchy sequence is the intersection of all these and is therefore, also a tail event.

Now consider $B$. This set is the same as the set where the partial sums are Cauchy sequences. Let $\mathbf{S}_{n} \equiv \sum_{k=1}^{n} \mathbf{X}_{k}$. The set where the sum converges is then

$$
\cap_{n=1}^{\infty} \cap_{p=2}^{\infty} \cup_{m=p}^{\infty} \cap_{l, k \geq m}\left\{\omega:\left\|\mathbf{S}_{k}(\omega)-\mathbf{S}_{l}(\omega)\right\|<1 / n\right\}
$$

Say $k<l$ and consider for $m \geq p$

$$
\left\{\omega:\left\|\mathbf{S}_{k}(\omega)-\mathbf{S}_{l}(\omega)\right\|<1 / n, k \geq m\right\}
$$

This is the same as

$$
\left\{\omega:\left\|\sum_{j=k-1}^{l} \mathbf{X}_{j}(\omega)\right\|<1 / n, k \geq m\right\} \in \sigma\left(\cup_{j=p-1}^{\infty} \sigma\left(\mathbf{X}_{j}\right)\right)
$$

Thus

$$
\cup_{m=p}^{\infty} \cap_{l, k \geq m}\left\{\omega:\left\|\mathbf{S}_{k}(\omega)-\mathbf{S}_{l}(\omega)\right\|<1 / n\right\} \in \sigma\left(\cup_{j=p-1}^{\infty} \sigma\left(\mathbf{X}_{j}\right)\right)
$$

and so the intersection for all $p$ of these is a tail event. Then the intersection over all $n$ of these tail events is a tail event.

From this it can be concluded that if you have a sequence of independent random variables, $\left\{\mathbf{X}_{k}\right\}$ the set where it converges is either of probability 1 or probability 0 . A similar conclusion holds for the set where the infinite sum of these random variables converges. This is stated in the next corollary. This incredible assertion is the next corollary.

Corollary 59.6.6 Let $\left\{\mathbf{X}_{k}\right\}$ be a sequence of random variables having values in a Banach space. Then

$$
\lim _{n \rightarrow \infty} \mathbf{X}_{n}(\omega)
$$

either exists for a.e. $\omega$ or the convergence fails to take place for a.e. $\omega$. Also if

$$
A \equiv\left\{\omega: \sum_{k=1}^{\infty} \mathbf{X}_{k}(\omega) \text { converges }\right\}
$$

then $P(A)=0$ or 1 .

### 59.7 Kolmogorov's Inequality, Strong Law of Large Numbers

Kolmogorov's inequality is a very interesting inequality which depends on independence of a set of random vectors. The random vectors have values in $\mathbb{R}^{n}$ or more generally some real separable Hilbert space.

Lemma 59.7.1 If $\mathbf{Y}, \mathbf{X}$ are independent random variables having values in a real separable Hilbert space, $H$ with $E\left(|\mathbf{X}|^{2}\right), E\left(|\mathbf{Y}|^{2}\right)<\infty$, then

$$
\int_{\Omega}(\mathbf{X}, \mathbf{Y}) d P=\left(\int_{\Omega} \mathbf{X} d P, \int_{\Omega} \mathbf{Y} d P\right)
$$

Proof: Let $\left\{\mathbf{e}_{k}\right\}$ be a complete orthonormal basis. Thus

$$
\int_{\Omega}(\mathbf{X}, \mathbf{Y}) d P=\int_{\Omega} \sum_{k=1}^{\infty}\left(\mathbf{X}, \mathbf{e}_{k}\right)\left(\mathbf{Y}, \mathbf{e}_{k}\right) d P
$$

Now

$$
\int_{\Omega} \sum_{k=1}^{\infty}\left|\left(\mathbf{X}, \mathbf{e}_{k}\right)\left(\mathbf{Y}, \mathbf{e}_{k}\right)\right| d P \leq \int_{\Omega}\left(\sum_{k}\left|\left(\mathbf{X}, \mathbf{e}_{k}\right)\right|^{2}\right)^{1 / 2}\left(\sum_{k}\left|\left(\mathbf{Y}, \mathbf{e}_{k}\right)\right|^{2}\right)^{1 / 2} d P
$$

$$
=\int_{\Omega}|\mathbf{X}||\mathbf{Y}| d P \leq\left(\int_{\Omega}|\mathbf{X}|^{2} d P\right)^{1 / 2}\left(\int_{\Omega}|\mathbf{Y}|^{2} d P\right)^{1 / 2}<\infty
$$

and so by Fubini's theorem,

$$
\begin{gathered}
\int_{\Omega}(\mathbf{X}, \mathbf{Y}) d P=\int_{\Omega} \sum_{k=1}^{\infty}\left(\mathbf{X}, \mathbf{e}_{k}\right)\left(\mathbf{Y}, \mathbf{e}_{k}\right) d P=\sum_{k=1}^{\infty} \int_{\Omega}\left(\mathbf{X}, \mathbf{e}_{k}\right)\left(\mathbf{Y}, \mathbf{e}_{k}\right) d P \\
=\sum_{k=1}^{\infty} \int_{\Omega}\left(\mathbf{X}, \mathbf{e}_{k}\right) d P \int_{\Omega}\left(\mathbf{Y}, \mathbf{e}_{k}\right) d P=\sum_{k=1}^{\infty}\left(\int_{\Omega} \mathbf{X} d P, \mathbf{e}_{k}\right)\left(\int_{\Omega} \mathbf{Y} d P, \mathbf{e}_{k}\right) d P \\
=\left(\int_{\Omega} \mathbf{X} d P, \int_{\Omega} \mathbf{Y} d P\right)
\end{gathered}
$$

Now here is Kolmogorov's inequality.
Theorem 59.7.2 Suppose $\left\{\mathbf{X}_{k}\right\}_{k=1}^{n}$ are independent with $E\left(\left|\mathbf{X}_{k}\right|\right)<\infty, E\left(\mathbf{X}_{k}\right)=\mathbf{0}$. Then for any $\varepsilon>0$,

$$
P\left(\left[\max _{1 \leq k \leq n}\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right| \geq \varepsilon\right]\right) \leq \frac{1}{\varepsilon^{2}} \sum_{j=1}^{n} E\left(\left|\mathbf{X}_{k}\right|^{2}\right)
$$

Proof: Let

$$
A=\left[\max _{1 \leq k \leq n}\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right| \geq \varepsilon\right]
$$

Now let $A_{1} \equiv\left[\left|\mathbf{X}_{1}\right| \geq \boldsymbol{\varepsilon}\right]$ and if $A_{1}, \cdots, A_{m}$ have been chosen,

$$
A_{m+1} \equiv\left[\left|\sum_{j=1}^{m+1} \mathbf{X}_{j}\right| \geq \varepsilon\right] \cap \bigcap_{r=1}^{m}\left[\left|\sum_{j=1}^{r} \mathbf{X}_{j}\right|<\varepsilon\right]
$$

Thus the $A_{k}$ partition $A$ and $\omega \in A_{k}$ means

$$
\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right| \geq \varepsilon
$$

but this did not happen for $\left|\sum_{j=1}^{r} \mathbf{X}_{j}\right|$ for any $r<k$. Note also that $A_{k} \in \sigma\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{k}\right)$. Then from algebra,

$$
\begin{array}{r}
\left|\sum_{j=1}^{n} \mathbf{X}_{j}\right|^{2}=\left(\sum_{i=1}^{k} \mathbf{X}_{i}+\sum_{j=k+1}^{n} \mathbf{X}_{j}, \sum_{i=1}^{k} \mathbf{X}_{i}+\sum_{j=k+1}^{n} \mathbf{X}_{j}\right) \\
=\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right|^{2}+\sum_{i \leq k, j>k}\left(\mathbf{X}_{i}, \mathbf{X}_{j}\right)+\sum_{i \leq k, j>k}\left(\mathbf{X}_{j}, \mathbf{X}_{i}\right)+\sum_{i>k, j>k}\left(\mathbf{X}_{j}, \mathbf{X}_{i}\right)
\end{array}
$$

Written more succinctly,

$$
\left|\sum_{j=1}^{n} \mathbf{X}_{j}\right|^{2}=\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right|^{2}+\sum_{j>k \text { or } i>k}\left(\mathbf{X}_{i}, \mathbf{X}_{j}\right)
$$

Now multiply both sides by $\mathscr{X}_{A_{k}}$ and integrate. Suppose $i \leq k$ for one of the terms in the second sum. Then by Lemma 59.3.4 and $A_{k} \in \sigma\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{k}\right)$, the two random vectors $\mathscr{X}_{A_{k}} \mathbf{X}_{i}, \mathbf{X}_{j}$ are independent,

$$
\int_{\Omega} \mathscr{X}_{A_{k}}\left(\mathbf{X}_{i}, \mathbf{X}_{j}\right) d P=\left(\int_{\Omega} \mathscr{X}_{A_{k}} \mathbf{X}_{i} d P, \int_{\Omega} \mathbf{X}_{j} d P\right)=0
$$

the last equality holding because by assumption $E\left(\mathbf{X}_{j}\right)=\mathbf{0}$. Therefore, it can be assumed both $i, j$ are larger than $k$ and

$$
\begin{align*}
\int_{\Omega} \mathscr{X}_{A_{k}}\left|\sum_{j=1}^{n} \mathbf{X}_{j}\right|^{2} d P= & \int_{\Omega} \mathscr{X}_{A_{k}}\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right|^{2} d P \\
& +\sum_{j>k, i>k} \int_{\Omega} \mathscr{X}_{A_{k}}\left(\mathbf{X}_{i}, \mathbf{X}_{j}\right) d P \tag{59.7.10}
\end{align*}
$$

The last term on the right is interesting. Suppose $i>j$. The integral inside the sum is of the form

$$
\begin{equation*}
\int_{\Omega}\left(\mathbf{X}_{i}, \mathscr{X}_{A_{k}} \mathbf{X}_{j}\right) d P \tag{59.7.11}
\end{equation*}
$$

The second factor in the inner product is in

$$
\sigma\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{k}, \mathbf{X}_{j}\right)
$$

and $\mathbf{X}_{i}$ is not included in the list of random vectors. Thus by Lemma 59.3.4, the two random vectors $\mathbf{X}_{i}, \mathscr{X}_{A_{k}} \mathbf{X}_{j}$ are independent and so 59.7.11 reduces to

$$
\left(\int_{\Omega} \mathbf{X}_{i} d P, \int_{\Omega} \mathscr{X}_{A_{k}} \mathbf{X}_{j} d P\right)=\left(\mathbf{0}, \int_{\Omega} \mathscr{X}_{A_{k}} \mathbf{X}_{j} d P\right)=0
$$

A similar result holds if $j>i$. Thus the mixed terms in the last term of 59.7.10 are all equal to 0 . Hence 59.7.10 reduces to

$$
\begin{aligned}
\int_{\Omega} \mathscr{X}_{A_{k}}\left|\sum_{j=1}^{n} \mathbf{X}_{j}\right|^{2} d P= & \int_{\Omega} \mathscr{X}_{A_{k}}\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right|^{2} d P \\
& +\sum_{i>k} \int_{\Omega} \mathscr{X}_{A_{k}}\left|\mathbf{X}_{i}\right|^{2} d P
\end{aligned}
$$

and so

$$
\int_{\Omega} \mathscr{X}_{A_{k}}\left|\sum_{j=1}^{n} \mathbf{X}_{j}\right|^{2} d P \geq \int_{\Omega} \mathscr{X}_{A_{k}}\left|\sum_{j=1}^{k} \mathbf{X}_{j}\right|^{2} d P \geq \varepsilon^{2} P\left(A_{k}\right)
$$

Now, summing these yields

$$
\begin{gathered}
\varepsilon^{2} P(A) \leq \int_{\Omega} \mathscr{X}_{A}\left|\sum_{j=1}^{n} \mathbf{X}_{j}\right|^{2} d P \leq \int_{\Omega}\left|\sum_{j=1}^{n} \mathbf{X}_{j}\right|^{2} d P \\
=\sum_{i, j} \int_{\Omega}\left(\mathbf{X}_{i}, \mathbf{X}_{j}\right) d P
\end{gathered}
$$

By independence of the random vectors the mixed terms of the above sum equal zero and so it reduces to

$$
\sum_{i=1}^{n} \int_{\Omega}\left|\mathbf{X}_{i}\right|^{2} d P
$$

This theorem implies the following amazing result.
Theorem 59.7.3 Let $\left\{\mathbf{X}_{k}\right\}_{k=1}^{\infty}$ be independent random vectors having values in a separable real Hilbert space and suppose $E\left(\left|\mathbf{X}_{k}\right|\right)<\infty$ for each $k$ and $E\left(\mathbf{X}_{k}\right)=\mathbf{0}$. Suppose also that

$$
\sum_{j=1}^{\infty} E\left(\left|\mathbf{X}_{j}\right|^{2}\right)<\infty
$$

Then

$$
\sum_{j=1}^{\infty} \mathbf{X}_{j}
$$

converges a.e.
Proof: Let $\varepsilon>0$ be given. By Kolmogorov's inequality, Theorem 59.7.2, it follows that for $p \leq m<n$

$$
\begin{aligned}
P\left(\left[\max _{m \leq k \leq n}\left|\sum_{j=m}^{k} \mathbf{X}_{j}\right| \geq \varepsilon\right]\right) & \leq \frac{1}{\varepsilon^{2}} \sum_{j=p}^{n} E\left(\left|\mathbf{X}_{j}\right|^{2}\right) \\
& \leq \frac{1}{\varepsilon^{2}} \sum_{j=p}^{\infty} E\left(\left|\mathbf{X}_{j}\right|^{2}\right)
\end{aligned}
$$

Therefore, letting $n \rightarrow \infty$ it follows that for all $m, n$ such that $p \leq m \leq n$

$$
P\left(\left[\max _{p \leq m \leq n}\left|\sum_{j=m}^{n} \mathbf{X}_{j}\right| \geq \varepsilon\right]\right) \leq \frac{1}{\varepsilon^{2}} \sum_{j=p}^{\infty} E\left(\left|\mathbf{X}_{j}\right|^{2}\right)
$$

It follows from the assumption

$$
\sum_{j=1}^{\infty} E\left(\left|\mathbf{X}_{j}\right|^{2}\right)<\infty
$$

there exists a sequence, $\left\{p_{n}\right\}$ such that if $m \geq p_{n}$

$$
P\left(\left[\max _{k \geq m \geq p_{n}}\left|\sum_{j=m}^{k} \mathbf{X}_{j}\right| \geq 2^{-n}\right]\right) \leq 2^{-n}
$$

By the Borel Cantelli lemma, Lemma 59.1.2, there is a set of measure $0, N$ such that for $\omega \notin N, \omega$ is in only finitely many of the sets,

$$
\left[\max _{k \geq m \geq p_{n}}\left|\sum_{j=m}^{k} \mathbf{X}_{j}\right| \geq 2^{-n}\right]
$$

and so for $\omega \notin N$, it follows that for large enough $n$,

$$
\left[\max _{k \geq m \geq p_{n}}\left|\sum_{j=m}^{k} \mathbf{X}_{j}(\omega)\right|<2^{-n}\right]
$$

However, this says the partial sums $\left\{\sum_{j=1}^{k} \mathbf{X}_{j}(\omega)\right\}_{k=1}^{\infty}$ are a Cauchy sequence. Therefore, they converge.

With this amazing result, there is a simple proof of the strong law of large numbers. In the following lemma, $s_{k}$ and $a_{j}$ could have values in any normed linear space.

Lemma 59.7.4 Suppose $s_{k} \rightarrow s$. Then

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n} s_{k}=s
$$

Also if

$$
\sum_{j=1}^{\infty} \frac{a_{j}}{j}
$$

converges, then

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} a_{j}=0
$$

Proof: Consider the first part. Since $s_{k} \rightarrow s$, it follows there is some constant, $C$ such that $\left|s_{k}\right|<C$ for all $k$ and $|s|<C$ also. Choose $K$ so large that if $k \geq K$, then for $n>K$,

$$
\begin{gathered}
\left|s-s_{k}\right|<\varepsilon / 2 \\
\left|s-\frac{1}{n} \sum_{k=1}^{n} s_{k}\right| \leq \frac{1}{n} \sum_{k=1}^{n}\left|s_{k}-s\right| \\
=\frac{1}{n} \sum_{k=1}^{K}\left|s_{k}-s\right|+\frac{1}{n} \sum_{k=K}^{n}\left|s_{k}-s\right| \\
\leq \frac{2 C K}{n}+\frac{\varepsilon}{2} \frac{n-K}{n}<\frac{2 C K}{n}+\frac{\varepsilon}{2}
\end{gathered}
$$

Therefore, whenever $n$ is large enough,

$$
\left|s-\frac{1}{n} \sum_{k=1}^{n} s_{k}\right|<\varepsilon .
$$

Now consider the second claim. Let

$$
s_{k}=\sum_{j=1}^{k} \frac{a_{j}}{j}
$$

and $s=\lim _{k \rightarrow \infty} s_{k}$ Then by the first part,

$$
\begin{aligned}
s & =\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n} s_{k}=\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n} \sum_{j=1}^{k} \frac{a_{j}}{j} \\
& =\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} \frac{a_{j}}{j} \sum_{k=j}^{n} 1=\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} \frac{a_{j}}{j}(n-j) \\
& =\lim _{n \rightarrow \infty}\left(\sum_{j=1}^{n} \frac{a_{j}}{j}-\frac{1}{n} \sum_{j=1}^{n} a_{j}\right)=s-\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} a_{j}
\end{aligned}
$$

Now here is the strong law of large numbers.
Theorem 59.7.5 Suppose $\left\{\mathbf{X}_{k}\right\}$ are independent random variables and $E\left(\left|\mathbf{X}_{k}\right|\right)<\infty$ for each $k$ and $E\left(\mathbf{X}_{k}\right)=\mathbf{m}_{k}$. Suppose also

$$
\begin{equation*}
\sum_{j=1}^{\infty} \frac{1}{j^{2}} E\left(\left|\mathbf{X}_{j}-\mathbf{m}_{j}\right|^{2}\right)<\infty \tag{59.7.12}
\end{equation*}
$$

Then

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n}\left(\mathbf{X}_{j}-\mathbf{m}_{j}\right)=\mathbf{0}
$$

Proof: Consider the sum

$$
\sum_{j=1}^{\infty} \frac{\mathbf{X}_{j}-\mathbf{m}_{j}}{j}
$$

This sum converges a.e. because of 59.7.12 and Theorem 59.7.3 applied to the random vectors $\left\{\frac{\mathbf{x}_{j}-\mathbf{m}_{j}}{j}\right\}$. Therefore, from Lemma 59.7.4 it follows that for a.e. $\omega$,

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n}\left(\mathbf{X}_{j}(\omega)-\mathbf{m}_{j}\right)=\mathbf{0}
$$

The next corollary is often called the strong law of large numbers. It follows immediately from the above theorem.

Corollary 59.7.6 Suppose $\left\{\mathbf{X}_{j}\right\}_{j=1}^{\infty}$ are independent having mean $\mathbf{m}$ and variance equal to

$$
\sigma^{2} \equiv \int_{\Omega}\left|\mathbf{X}_{j}-\mathbf{m}\right|^{2} d P<\infty
$$

Then for a.e. $\omega \in \Omega$

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} \mathbf{X}_{j}(\omega)=\mathbf{m}
$$

### 59.8 The Characteristic Function

One of the most important tools in probability is the characteristic function. To begin with, assume the random variables have values in $\mathbb{R}^{p}$.

Definition 59.8.1 Let $\mathbf{X}$ be a random variable as above. The characteristic function is

$$
\phi_{\mathbf{X}}(\mathbf{t}) \equiv E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right) \equiv \int_{\Omega} e^{i \mathbf{t} \cdot \mathbf{X}(\omega)} d P=\int_{\mathbb{R} p} e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{X}
$$

the last equation holding by Proposition 59.1.12.
Recall the following fundamental lemma and definition, Lemma 32.3.4 on Page 1101.
Definition 59.8.2 For $T \in \mathscr{G}^{*}$, define $F T, F^{-1} T \in \mathscr{G}^{*}$ by

$$
F T(\phi) \equiv T(F \phi), F^{-1} T(\phi) \equiv T\left(F^{-1} \phi\right)
$$

Lemma 59.8.3 $F$ and $F^{-1}$ are both one to one, onto, and are inverses of each other.
The main result on characteristic functions is the following.
Theorem 59.8.4 Let $\mathbf{X}$ and $\mathbf{Y}$ be random vectors with values in $\mathbb{R}^{p}$ and suppose $E\left(e^{i \cdot \mathbf{X}}\right)$ $=E\left(e^{i \cdot \mathbf{t} \cdot \mathbf{Y}}\right)$ for all $\mathbf{t} \in \mathbb{R}^{p}$. Then $\lambda_{\mathbf{x}}=\lambda_{\mathbf{Y}}$.

Proof: For $\psi \in \mathscr{G}$, let $\lambda_{\mathbf{X}}(\psi) \equiv \int_{\mathbb{R}^{p}} \psi d \lambda_{\mathbf{X}}$ and $\lambda_{\mathbf{Y}}(\psi) \equiv \int_{\mathbb{R}^{p}} \psi d \lambda_{\mathbf{Y}}$. Thus both $\lambda_{\mathbf{X}}$ and $\lambda_{\mathbf{Y}}$ are in $\mathscr{G}^{*}$. Then letting $\psi \in \mathscr{G}$ and using Fubini's theorem,

$$
\begin{aligned}
\int_{\mathbb{R}^{p}} \int_{\mathbb{R}^{p}} e^{i \cdot \mathbf{y}} \psi(\mathbf{t}) d t d \lambda_{\mathbf{Y}} & =\int_{\mathbb{R}^{p}} \int_{\mathbb{R}^{p}} e^{i \cdot \mathbf{y}} d \lambda_{\mathbf{Y}} \psi(\mathbf{t}) d t \\
& =\int_{\mathbb{R}^{p}} E\left(e^{i \cdot \mathbf{Y}}\right) \psi(\mathbf{t}) d t \\
& =\int_{\mathbb{R}^{p}} E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right) \psi(\mathbf{t}) d t \\
& =\int_{\mathbb{R}^{p}} \int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda_{\mathbf{X}} \psi(\mathbf{t}) d t \\
& =\int_{\mathbb{R}^{p}} \int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} \psi(\mathbf{t}) d t d \lambda_{\mathbf{X}}
\end{aligned}
$$

Thus $\lambda_{\mathbf{Y}}\left(F^{-1} \psi\right)=\lambda_{\mathbf{X}}\left(F^{-1} \psi\right)$. Since $\psi \in \mathscr{G}$ is arbitrary and $F^{-1}$ is onto, this implies $\lambda_{\mathbf{X}}$ $=\lambda_{\mathbf{Y}}$ in $\mathscr{G}^{*}$. But $\mathscr{G}$ is dense in $C_{0}\left(\mathbb{R}^{p}\right)$ from the Stone Weierstrass theorem and so $\lambda_{\mathbf{X}}=\lambda_{\mathbf{Y}}$ as measures. Recall from real analysis the dual space of $C_{0}\left(\mathbb{R}^{n}\right)$ is the space of complex measures.

Alternatively, the above shows that since $F^{-1}$ is onto, for all $\psi \in \mathscr{G}$,

$$
\int_{\mathbb{R}^{p}} \psi d \lambda_{\mathbf{Y}}=\int_{\mathbb{R}^{p}} \psi d \lambda_{\mathbf{x}}
$$

and then, by a use of the Stone Weierstrass theorem, the above will hold for all $\psi \in C_{c}\left(\mathbb{R}^{n}\right)$ and now, by the Riesz representation theorem for positive linear functionals, the two measures are equal.

You can also give a version of this theorem in which reference is made only to the probability distribution measures.

Definition 59.8.5 For $\mu$ a probability measure on the Borel sets of $\mathbb{R}^{n}$,

$$
\phi_{\mu}(\mathbf{t}) \equiv \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu
$$

Theorem 59.8.6 Let $\mu$ and $v$ be probability measures on the Borel sets of $\mathbb{R}^{p}$ and suppose $\phi_{\mu}(\mathbf{t})=\phi_{v}(\mathbf{t})$. Then $\mu=v$.

Proof: The proof is identical to the above. Just replace $\lambda_{\mathbf{X}}$ with $\mu$ and $\lambda_{\mathbf{Y}}$ with $v$.

### 59.9 Conditional Probability

Here I will consider the concept of conditional probability depending on the theory of differentiation of general Radon measures. This leads to a different way of thinking about independence.

If $\mathbf{X}, \mathbf{Y}$ are two random vectors defined on a probability space having values in $\mathbb{R}^{p_{1}}$ and $\mathbb{R}^{p_{2}}$ respectively, and if $E$ is a Borel set in the appropriate space, then $(\mathbf{X}, \mathbf{Y})$ is a random vector with values in $\mathbb{R}^{p_{1}} \times \mathbb{R}^{p_{2}}$ and $\lambda_{(\mathbf{X}, \mathbf{Y})}\left(E \times \mathbb{R}^{p_{2}}\right)=\lambda_{\mathbf{X}}(E), \lambda_{(\mathbf{X}, \mathbf{Y})}\left(\mathbb{R}^{p_{1}} \times E\right)=\lambda_{\mathbf{Y}}(E)$. Thus, by Theorem 31.2.3 on Page 1085, there exist probability measures, denoted here by $\lambda_{\mathbf{X} \mid \mathbf{y}}$ and $\lambda_{\mathbf{Y} \mid \mathbf{x}}$, such that whenever $E$ is a Borel set in $\mathbb{R}^{p_{1}} \times \mathbb{R}^{p_{2}}$,

$$
\int_{\mathbb{R}^{p_{1} \times \mathbb{R}^{p_{2}}}} \mathscr{X}_{E} d \lambda_{(\mathbf{X}, \mathbf{Y})}=\int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \mathscr{X}_{E} d \lambda_{\mathbf{Y} \mid \mathbf{x}} d \lambda_{\mathbf{x}}
$$

and

$$
\int_{\mathbb{R}^{p_{1} \times \mathbb{R}^{p_{2}}}} \mathscr{X}_{E} d \lambda_{(\mathbf{X}, \mathbf{Y})}=\int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} \mathscr{X}_{E} d \lambda_{\mathbf{x} \mid \mathbf{y}} d \lambda_{\mathbf{Y}}
$$

Definition 59.9.1 Let $\mathbf{X}$ and $\mathbf{Y}$ be two random vectors defined on a probability space. The conditional probability measure of $\mathbf{Y}$ given $\mathbf{X}$ is the measure $\lambda_{\mathbf{Y} \mid \mathbf{x}}$ in the above. Similarly the conditional probability measure of $\mathbf{X}$ given $\mathbf{Y}$ is the measure $\lambda_{\mathbf{x | y}}^{\mathbf{y}}$.

More generally, one can use the theory of slicing measures to consider any finite list of random vectors, $\left\{\mathbf{X}_{i}\right\}$, defined on a probability space with $\mathbf{X}_{i} \in \mathbb{R}^{p_{i}}$, and write the following for $E$ a Borel set in $\prod_{i=1}^{n} \mathbb{R}^{p_{i}}$.

$$
\begin{gather*}
\int_{\mathbb{R}^{p_{1 \times \cdots}} \cdots \times \mathbb{R}^{p_{n}}} \mathscr{X}_{E} d \lambda_{\left(\mathbf{X}_{1}, \cdots, \mathbf{x}_{n}\right)}=\int_{\mathbb{R}^{p_{1}} \times \cdots \times \mathbb{R}^{p_{n-1}}} \int_{\mathbb{R}^{p_{n}}} \mathscr{X}_{E} d \lambda_{\mathbf{x}_{n} \mid\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-1}\right)} d \lambda_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-1}\right)} \\
=\int_{\mathbb{R}^{p_{1}} \times \cdots \times \mathbb{R}^{p_{n-2}}} \int_{\mathbb{R}^{p_{n-1}}} \int_{\mathbb{R}^{p_{n}}} \mathscr{X}_{E} d \lambda_{\mathbf{x}_{n} \mid\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-1}\right)} d \lambda_{\mathbf{x}_{n-1} \mid\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-2}\right)} d \lambda_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-2}\right)} \\
\vdots  \tag{59.9.13}\\
\int_{\mathbb{R}^{p_{1}}} \cdots \int_{\mathbb{R}^{p_{n}}} \mathscr{X}_{E} d \lambda_{\mathbf{x}_{n} \mid\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-1}\right)} d \lambda_{\mathbf{x}_{n-1} \mid\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-2}\right)} \cdots d \lambda_{\mathbf{x}_{2} \mid \mathbf{x}_{1}} d \lambda_{\mathbf{x}_{1}} .
\end{gather*}
$$

Obviously, this could have been done in any order in the iterated integrals by simply modifying the "given" variables, those occurring after the symbol |, to be those which have been integrated in an outer level of the iterated integral. For simplicity, write

$$
\lambda_{\mathbf{x}_{n} \mid\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n-1}\right)}=\lambda_{\mathbf{x}_{n} \mid \mathbf{x}_{1}, \cdots, \mathbf{x}_{n-1}}
$$

Definition 59.9.2 Let $\left\{\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right\}$ be random vectors defined on a probability space having values in $\mathbb{R}^{p_{1}}, \cdots, \mathbb{R}^{p_{n}}$ respectively. The random vectors are independent if for every $E$ a Borel set in $\mathbb{R}^{p_{1}} \times \cdots \times \mathbb{R}^{p_{n}}$,

$$
\begin{gather*}
\int_{\mathbb{R}^{p_{1 \times \cdots \times \mathbb{R}^{p_{n}}}}} \mathscr{X}_{E} d \lambda_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)} \\
=\int_{\mathbb{R}^{p_{1}}} \cdots \int_{\mathbb{R}^{p_{n}}} \mathscr{X}_{E} d \lambda \mathbf{x}_{n} d \lambda \mathbf{x}_{n-1} \cdots d \lambda_{\mathbf{x}_{2}} d \lambda \mathbf{x}_{1} \tag{59.9.14}
\end{gather*}
$$

and the iterated integration may be taken in any order. If $\mathscr{A}$ is any set of random vectors defined on a probability space, $\mathscr{A}$ is independent if any finite set of random vectors from $\mathscr{A}$ is independent.

Thus, the random vectors are independent exactly when the dependence on the givens in 59.9.13 can be dropped.

Does this amount to the same thing as discussed earlier? Suppose you have three random variables $\mathbf{X}, \mathbf{Y}, \mathbf{Z}$. Let $A=\mathbf{X}^{-1}(E), B=\mathbf{Y}^{-1}(F), C=\mathbf{Z}^{-1}(G)$ where $E, F, G$ are Borel sets. Thus these inverse images are typical sets in $\sigma(\mathbf{X}), \sigma(\mathbf{Y}), \sigma(\mathbf{Z})$ respectively. First suppose that the random variables are independent in the earlier sense. Then

$$
\begin{gathered}
P(A \cap B \cap C)=P(A) P(B) P(C) \\
=\int_{\mathbb{R}^{p_{1}}} \mathscr{X}_{E}(\mathbf{x}) d \lambda_{\mathbf{x}} \int_{\mathbb{R}^{p_{2}}} \mathscr{X}_{F}(\mathbf{y}) d \lambda_{\mathbf{Y}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z}} \\
=\int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z}} d \lambda_{\mathbf{Y}} d \lambda_{\mathbf{x}}
\end{gathered}
$$

Also

$$
\begin{aligned}
P & (A \cap B \cap C)=\int_{\mathbb{R}^{p_{1}} \times \mathbb{R}^{p_{2}} \times \mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{(\mathbf{X}, \mathbf{Y}, \mathbf{Z})} \\
& =\int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z} \mid \mathbf{x y}} d \lambda_{\mathbf{Y} \mid \mathbf{x}} d \lambda_{\mathbf{x}}
\end{aligned}
$$

Thus

$$
\begin{aligned}
& \int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z}} d \lambda_{\mathbf{Y}} d \lambda_{\mathbf{x}} \\
= & \int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z} \mid \mathbf{x y}} d \lambda_{\mathbf{Y} \mid \mathbf{x}} d \lambda_{\mathbf{x}}
\end{aligned}
$$

Now letting $G=\mathbb{R}^{p_{3}}$, it follows that

$$
\begin{aligned}
& \int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) d \lambda_{\mathbf{Y}} d \lambda_{\mathbf{x}} \\
= & \int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) d \lambda_{\mathbf{Y} \mid \mathbf{x}} d \lambda_{\mathbf{x}}
\end{aligned}
$$

By uniqueness of the slicing measures or an application of the Besikovitch differentiation theorem, it follows that for $\lambda_{\mathbf{x}}$ a.e. $\mathbf{x}$,

$$
\lambda_{\mathbf{Y}}=\lambda_{\mathbf{Y} \mid \mathbf{X}}
$$

Thus, using this in the above,

$$
\begin{aligned}
& \int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z}} d \lambda_{\mathbf{Y}} d \lambda_{\mathbf{x}} \\
= & \int_{\mathbb{R}^{p_{1}}} \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z} \mid \mathbf{x}} d \lambda_{\mathbf{Y}} d \lambda_{\mathbf{x}}
\end{aligned}
$$

and also it reduces to

$$
\begin{aligned}
& \int_{\mathbb{R}^{p_{1} \times \mathbb{R}^{p_{2}}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z}} d \lambda_{(\mathbf{X}, \mathbf{Y})} \\
= & \int_{\mathbb{R}^{p_{1} \times \mathbb{R}^{p_{2}}}} \int_{\mathbb{R}^{p_{3}}} \mathscr{X}_{E}(\mathbf{x}) \mathscr{X}_{F}(\mathbf{y}) \mathscr{X}_{G}(\mathbf{z}) d \lambda_{\mathbf{Z} \mid \mathbf{x y}} d \lambda_{(\mathbf{X}, \mathbf{Y})}
\end{aligned}
$$

Now by uniqueness of the slicing measures again, for $\lambda_{(\mathbf{X}, \mathbf{Y})}$ a.e. $(\mathbf{x}, \mathbf{y})$, it follows that

$$
\lambda_{\mathbf{Z}}=\lambda_{\mathbf{Z} \mid \mathbf{x y}}
$$

Similar conclusions hold for $\lambda_{\mathbf{X}}, \lambda_{\mathbf{Y}}$. In each case, off a set of measure zero the distribution measures equal the slicing measures.

Conversely, if the distribution measures equal the slicing measures off sets of measure zero as described above, then it is obvious that the random variables are independent. The same reasoning applies for any number of random variables.

Thus this gives a different and more analytical way to think of independence of finitely many random variables. Clearly, the argument given above will apply to any finite set of random variables.

Proposition 59.9.3 Equations 59.9.14 and 59.9.13 hold with $\mathscr{X}_{E}$ replaced by any nonnegative Borel measurable function and for any bounded continuous function or for any function in $L^{1}$.

Proof: The two equations hold for simple functions in place of $\mathscr{X}_{E}$ and so an application of the monotone convergence theorem applied to an increasing sequence of simple functions converging pointwise to a given nonnegative Borel measurable function yields the conclusion of the proposition in the case of the nonnegative Borel function. For a bounded continuous function or one in $L^{1}$, one can apply the result just established to the positive and negative parts of the real and imaginary parts of the function.

Lemma 59.9.4 Let $\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}$ be random vectors with values in $\mathbb{R}^{p_{1}}, \cdots, \mathbb{R}^{p_{n}}$ respectively and let $\mathbf{g}: \mathbb{R}^{p_{1}} \times \cdots \times \mathbb{R}^{p_{n}} \rightarrow \mathbb{R}^{k}$ be Borel measurable. Then $\mathbf{g}\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right)$ is a random vector with values in $\mathbb{R}^{k}$ and if $h: \mathbb{R}^{k} \rightarrow[0, \infty)$, then

$$
\begin{gather*}
\int_{\mathbb{R}^{k}} h(\mathbf{y}) d \lambda_{\mathbf{g}\left(\mathbf{X}_{1}, \cdots, \mathbf{x}_{n}\right)}(y)= \\
\int_{\mathbb{R}^{p_{1}} \times \cdots \times \mathbb{R}^{p_{n}}} h\left(\mathbf{g}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)\right) d \lambda_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right) .} \tag{59.9.15}
\end{gather*}
$$

If $\mathbf{X}_{i}$ is a random vector with values in $\mathbb{R}^{p_{i}}, i=1,2, \cdots$ and if $\mathbf{g}_{i}: \mathbb{R}^{p_{i}} \rightarrow \mathbb{R}^{k_{i}}$, where $\mathbf{g}_{i}$ is Borel measurable, then the random vectors $\mathbf{g}_{i}\left(\mathbf{X}_{i}\right)$ are also independent whenever the $\mathbf{X}_{i}$ are independent.

Proof: First let $E$ be a Borel set in $\mathbb{R}^{k}$. From the definition,

$$
\begin{aligned}
\lambda_{\mathbf{g}\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right)}(E) & =P\left(\mathbf{g}\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right) \in E\right) \\
= & P\left(\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right) \in \mathbf{g}^{-1}(E)\right)=\lambda_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)}\left(\mathbf{g}^{-1}(E)\right) \\
\int_{\mathbb{R}^{k}} \mathscr{X}_{E} d \lambda_{\mathbf{g}\left(\mathbf{X}_{1}, \cdots, \mathbf{x}_{n}\right)} & =\int_{\mathbb{R}^{p_{1 \times}} \cdots \times \mathbb{R}^{p_{n}}} \mathscr{X}_{\mathbf{g}^{-1}(E)} d \lambda_{\left(\mathbf{X}_{1}, \cdots, \mathbf{x}_{n}\right)} \\
& =\int_{\mathbb{R}^{p_{1 \times \cdots} \times \mathbb{R}^{p_{n}}}} \mathscr{X}_{E}\left(\mathbf{g}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)\right) d \lambda_{\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right)}
\end{aligned}
$$

This proves 59.9 .15 in the case when $h$ is $\mathscr{X}_{E}$. To prove it in the general case, approximate the nonnegative Borel measurable function with simple functions for which the formula is true, and use the monotone convergence theorem.

It remains to prove the last assertion that functions of independent random vectors are also independent random vectors. Let $E$ be a Borel set in $\mathbb{R}^{k_{1}} \times \cdots \times \mathbb{R}^{k_{n}}$. Then for

$$
\begin{gathered}
\pi_{i}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right) \equiv \mathbf{x}_{i}, \\
\int_{\mathbb{R}^{k_{1} \times \cdots \times \mathbb{R}^{k_{n}}}} \mathscr{X}_{E} d \lambda_{\left(\mathbf{g}_{1}\left(\mathbf{x}_{1}\right), \cdots, \mathbf{g}_{n}\left(\mathbf{x}_{n}\right)\right)} \\
\equiv \int_{\mathbb{R}^{p_{1}} \times \cdots \times \mathbb{R}^{p_{n}}} \mathscr{X}_{E} \circ\left(\mathbf{g}_{1} \circ \pi_{1}, \cdots, \mathbf{g}_{n} \circ \pi_{n}\right) d \lambda_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)} \\
=\int_{\mathbb{R}^{p_{1}}} \cdots \int_{\mathbb{R}^{p_{n}}} \mathscr{X}_{E} \circ\left(\mathbf{g}_{1} \circ \pi_{1}, \cdots, \mathbf{g}_{n} \circ \pi_{n}\right) d \lambda \mathbf{x}_{n} \cdots d \lambda_{\mathbf{x}_{1}} \\
=\int_{\mathbb{R}^{k_{1}}} \cdots \int_{\mathbb{R}^{k_{n}}} \mathscr{X}_{E} d \lambda_{\mathbf{g}_{n}\left(\mathbf{x}_{n}\right)} \cdots d \lambda_{\mathbf{g}_{1}\left(\mathbf{x}_{1}\right)}
\end{gathered}
$$

and this proves the last assertion.
Proposition 59.9.5 Let $v_{1}, \cdots, v_{n}$ be Radon probability measures defined on $\mathbb{R}^{p}$. Then there exists a probability space and independent random vectors $\left\{\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right\}$ defined on this probability space such that $\lambda_{\mathbf{x}_{i}}=v_{i}$.

Proof: Let $(\Omega, \mathscr{S}, P) \equiv\left(\left(\mathbb{R}^{p}\right)^{n}, \mathscr{S}_{1} \times \cdots \times \mathscr{S}_{n}, v_{1} \times \cdots \times v_{n}\right)$ where this is just the product $\sigma$ algebra and product measure which satisfies the following for measurable rectangles.

$$
\left(v_{1} \times \cdots \times v_{n}\right)\left(\prod_{i=1}^{n} E_{i}\right)=\prod_{i=1}^{n} v_{i}\left(E_{i}\right)
$$

Now let $\mathbf{X}_{i}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{i}, \cdots, \mathbf{x}_{n}\right)=\mathbf{x}_{i}$. Then from the definition, if $E$ is a Borel set in $\mathbb{R}^{p}$,

$$
\begin{gathered}
\lambda_{\mathbf{x}_{i}}(E) \equiv P\left\{\mathbf{X}_{i} \in E\right\} \\
=\left(v_{1} \times \cdots \times v_{n}\right)\left(\mathbb{R}^{p} \times \cdots \times E \times \cdots \times \mathbb{R}^{p}\right)=v_{i}(E) .
\end{gathered}
$$

Let $\mathscr{M}$ consist of all Borel sets of $\left(\mathbb{R}^{p}\right)^{n}$ such that

$$
\int_{\mathbb{R}^{p}} \cdots \int_{\mathbb{R}^{p}} \mathscr{X}_{E}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right) d \lambda_{\mathbf{x}_{1}} \cdots d \lambda_{\mathbf{x}_{n}}=\int_{\left(\mathbb{R}^{p}\right)^{n}} \mathscr{X}_{E} d \lambda_{\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)} .
$$

From what was just shown and the definition of $\left(v_{1} \times \cdots \times v_{n}\right)$ that $\mathscr{M}$ contains all sets of the form $\prod_{i=1}^{n} E_{i}$ where each $E_{i} \in$ Borel sets of $\mathbb{R}^{p}$. Therefore, $\mathscr{M}$ contains the algebra of all finite disjoint unions of such sets. It is also clear that $\mathscr{M}$ is a monotone class and so by the theorem on monotone classes, $\mathscr{M}$ equals the Borel sets. You could also note that $\mathscr{M}$ is closed with respect to complements and countable disjoint unions and apply Lemma 12.12.3. Therefore, the given random vectors are independent and this proves the proposition.

The following Lemma was proved earlier in a different way.
Lemma 59.9.6 If $\left\{X_{i}\right\}_{i=1}^{n}$ are independent random variables having values in $\mathbb{R}$,

$$
E\left(\prod_{i=1}^{n} X_{i}\right)=\prod_{i=1}^{n} E\left(X_{i}\right)
$$

Proof: By Lemma 59.9.4 and denoting by $P$ the product, $\prod_{i=1}^{n} X_{i}$,

$$
\begin{aligned}
E\left(\prod_{i=1}^{n} X_{i}\right) & =\int_{\mathbb{R}} z d \lambda_{P}(z)=\int_{\mathbb{R}^{n}} \prod_{i=1}^{n} x_{i} d \lambda_{\left(X_{1}, \cdots, X_{n}\right)} \\
& =\int_{\mathbb{R}} \cdots \int_{\mathbb{R}} \prod_{i=1}^{n} x_{i} d \lambda_{X_{1}} \cdots d \lambda_{X_{n}}=\prod_{i=1}^{n} E\left(X_{i}\right)
\end{aligned}
$$

### 59.10 Conditional Expectation

Definition 59.10.1 Let $\mathbf{X}$ and $\mathbf{Y}$ be random vectors having values in $\mathbb{F}^{p_{1}}$ and $\mathbb{F}^{p_{2}}$ respectively. Then if

$$
\int|\mathbf{x}| d \lambda_{\mathbf{x} \mid \mathbf{y}}(x)<\infty
$$

we define

$$
E(\mathbf{X} \mid \mathbf{y}) \equiv \int \mathbf{x} d \lambda \mathbf{X} \mid \mathbf{y}(x)
$$

Proposition 59.10.2 Suppose $\int_{\mathbb{F}^{p_{1}} \times \mathbb{F}^{p_{2}}}|\mathbf{x}| d \lambda_{(\mathbf{X}, \mathbf{Y})}(x)<\infty$. Then $E(\mathbf{X} \mid \mathbf{y})$ exists for $\lambda_{\mathbf{Y}}$ a.e. $\mathbf{y}$ and

$$
\int_{\mathbb{F}^{p_{2}}} E(\mathbf{X} \mid \mathbf{y}) d \lambda_{\mathbf{Y}}=\int_{\mathbb{F}^{p_{1}}} \mathbf{x} d \lambda_{\mathbf{X}}(x)=E(\mathbf{X})
$$

Proof: $\infty>\int_{\mathbb{F}^{p_{1}} \times \mathbb{F}^{p_{2}}}|\mathbf{x}| d \lambda_{(\mathbf{X}, \mathbf{Y})}=\int_{\mathbb{F}^{p_{2}}} \int_{\mathbb{F}^{p_{1}}}|\mathbf{x}| d \lambda_{\mathbf{X} \mid \mathbf{y}}(x) d \lambda_{\mathbf{Y}}(y)$ and so

$$
\int_{\mathbb{F}^{p_{1}}}|\mathbf{x}| d \lambda \mathbf{x} \mid \mathbf{y}(x)<\infty
$$

, $\lambda_{\mathbf{Y}}$ a.e. Now

$$
\int_{\mathbb{F}^{p_{2}}} E(\mathbf{X} \mid \mathbf{y}) d \lambda_{\mathbf{Y}}
$$

$$
\begin{aligned}
& =\int_{\mathbb{F}^{p_{2}}} \int_{\mathbb{F}^{p_{1}}} \mathbf{x} d \lambda_{\mathbf{X} \mid \mathbf{y}}(x) d \lambda_{\mathbf{Y}}(y)=\int_{\mathbb{F}^{p_{1 \times ~}} \mathbb{F}^{p_{2}}} \mathbf{x} d \lambda_{(\mathbf{X}, \mathbf{Y})} \\
& =\int_{\mathbb{F}^{p_{1}}} \int_{\mathbb{F}^{p_{2}}} \mathbf{x} d \lambda_{\mathbf{Y} \mid \mathbf{x}}(y) d \lambda_{\mathbf{X}}(x)=\int_{\mathbb{F}^{p_{2}}} \mathbf{x} d \lambda_{\mathbf{x}}(x)=E(\mathbf{X}) .
\end{aligned}
$$

Definition 59.10.3 Let $\left\{X_{n}\right\}$ be any sequence, finite or infinite, of random variables with values in $\mathbb{R}$ which are defined on some probability space, $(\Omega, \mathscr{S}, P)$. We say $\left\{X_{n}\right\}$ is a Martingale if

$$
E\left(X_{n} \mid x_{n-1}, \cdots, x_{1}\right)=x_{n-1}
$$

and we say $\left\{X_{n}\right\}$ is a submartingale if

$$
E\left(X_{n} \mid x_{n-1}, \cdots, x_{1}\right) \geq x_{n-1}
$$

Next we define what is meant by an upcrossing.
Definition 59.10.4 Let $\left\{x_{i}\right\}_{i=1}^{I}$ be any sequence of real numbers, $I \leq \infty$. Define an increasing sequence of integers $\left\{m_{k}\right\}$ as follows. $m_{1}$ is the first integer $\geq 1$ such that $x_{m_{1}} \leq a, m_{2}$ is the first integer larger than $m_{1}$ such that $x_{m_{2}} \geq b, m_{3}$ is the first integer larger than $m_{2}$ such that $x_{m_{3}} \leq a$, etc. Then each sequence, $\left\{x_{m_{2 k-1}}, \cdots, x_{m_{2 k}}\right\}$, is called an upcrossing of $[a, b]$.

Proposition 59.10.5 Let $\left\{X_{i}\right\}_{i=1}^{n}$ be a finite sequence of real random variables defined on $\Omega$ where $(\Omega, \mathscr{S}, P)$ is a probability space. Let $U_{[a, b]}(\omega)$ denote the number of upcrossings of $X_{i}(\omega)$ of the interval $[a, b]$. Then $U_{[a, b]}$ is a random variable.

Proof: Let $X_{0}(\omega) \equiv a+1$, let $Y_{0}(\omega) \equiv 0$, and let $Y_{k}(\omega)$ remain 0 for $k=0, \cdots, l$ until $X_{l}(\omega) \leq a$. When this happens (if ever), $Y_{l+1}(\omega) \equiv 1$. Then let $Y_{i}(\omega)$ remain 1 for $i=$ $l+1, \cdots, r$ until $X_{r}(\omega) \geq b$ when $Y_{r+1}(\omega) \equiv 0$. Let $Y_{k}(\omega)$ remain 0 for $k \geq r+1$ until $X_{k}(\omega) \leq a$ when $Y_{k}(\omega) \equiv 1$ and continue in this way. Thus the upcrossings of $X_{i}(\omega)$ are identified as unbroken strings of ones with a zero at each end, with the possible exception of the last string of ones which may be missing the zero at the upper end and may or may not be an upcrossing.

Note also that $Y_{0}$ is measurable because it is identically equal to 0 and that if $Y_{k}$ is measurable, then $Y_{k+1}$ is measurable because the only change in going from $k$ to $k+1$ is a change from 0 to 1 or from 1 to 0 on a measurable set determined by $X_{k}$. Now let

$$
Z_{k}(\omega)=\left\{\begin{array}{l}
1 \text { if } Y_{k}(\omega)=1 \text { and } Y_{k+1}(\omega)=0 \\
0 \text { otherwise }
\end{array}\right.
$$

if $k<n$ and

$$
Z_{n}(\omega)=\left\{\begin{array}{l}
1 \text { if } Y_{n}(\omega)=1 \text { and } X_{n}(\omega) \geq b \\
0 \text { otherwise }
\end{array}\right.
$$

Thus $Z_{k}(\omega)=1$ exactly when an upcrossing has been completed and each $Z_{i}$ is a random variable.

$$
U_{[a, b]}(\omega)=\sum_{k=1}^{n} Z_{k}(\omega)
$$

so $U_{[a, b]}$ is a random variable as claimed.
The following corollary collects some key observations found in the above construction.

Corollary 59.10.6 $U_{[a, b]}(\omega) \leq$ the number of unbroken strings of ones in the sequence, $\left\{Y_{k}(\omega)\right\}$ there being at most one unbroken string of ones which produces no upcrossing. Also

$$
\begin{equation*}
Y_{i}(\omega)=\psi_{i}\left(\left\{X_{j}(\omega)\right\}_{j=1}^{i-1}\right) \tag{59.10.16}
\end{equation*}
$$

where $\psi_{i}$ is some function of the past values of $X_{j}(\omega)$.
Lemma 59.10.7 (upcrossing lemma) Let $\left\{X_{i}\right\}_{i=1}^{n}$ be a submartingale and suppose

$$
E\left(\left|X_{n}\right|\right)<\infty .
$$

Then

$$
E\left(U_{[a, b]}\right) \leq \frac{E\left(\left|X_{n}\right|\right)+|a|}{b-a}
$$

Proof: Let $\phi(x) \equiv a+(x-a)^{+}$. Thus $\phi$ is a convex and increasing function.

$$
\begin{gathered}
\phi\left(X_{k+r}\right)-\phi\left(X_{k}\right)=\sum_{i=k+1}^{k+r} \phi\left(X_{i}\right)-\phi\left(X_{i-1}\right) \\
=\sum_{i=k+1}^{k+r}\left(\phi\left(X_{i}\right)-\phi\left(X_{i-1}\right)\right) Y_{i}+\sum_{i=k+1}^{k+r}\left(\phi\left(X_{i}\right)-\phi\left(X_{i-1}\right)\right)\left(1-Y_{i}\right) .
\end{gathered}
$$

The upcrossings of $\phi\left(X_{i}\right)$ are exactly the same as the upcrossings of $X_{i}$ and from Formula 59.10.16,

$$
\begin{gathered}
E\left(\sum_{i=k+1}^{k+r}\left(\phi\left(X_{i}\right)-\phi\left(X_{i-1}\right)\right)\left(1-Y_{i}\right)\right) \\
=\sum_{i=k+1}^{k+r} \int_{\mathbb{R}^{i}}\left(\phi\left(x_{i}\right)-\phi\left(x_{i-1}\right)\right)\left(1-\psi_{i}\left(\left\{x_{j}\right\}_{j=1}^{i-1}\right)\right) d \lambda_{\left(X_{1}, \cdots, X_{i}\right)} \\
=\sum_{i=k+1}^{k+r} \int_{\mathbb{R}^{i-1}} \int_{\mathbb{R}}\left(\phi\left(x_{i}\right)-\phi\left(x_{i-1}\right)\right) \\
\left(1-\psi_{i}\left(\left\{x_{j}\right\}_{j=1}^{i-1}\right)\right) d \lambda_{X_{i} \mid x_{1} \cdots x_{i-1}} d \lambda_{\left(X_{1}, \cdots, X_{i-1}\right)} \\
=\sum_{i=k+1}^{k+r} \int_{\mathbb{R}^{i-1}}\left(1-\psi_{i}\left(\left\{x_{j}\right\}_{j=1}^{i-1}\right)\right) . \\
\int_{\mathbb{R}}\left(\phi\left(x_{i}\right)-\phi\left(x_{i-1}\right)\right) d \lambda_{X_{i} \mid x_{1} \cdots x_{i-1}} d \lambda_{\left(X_{1}, \cdots, X_{i-1}\right)}
\end{gathered}
$$

By Jensen's inequality, Problem 10 of Chapter 15,

$$
\begin{gathered}
\geq \sum_{i=k+1}^{k+r} \int_{\mathbb{R}^{i-1}}\left(1-\psi_{i}\left(\left\{x_{j}\right\}_{j=1}^{i-1}\right)\right) \\
{\left[\phi\left(E\left(X_{i} \mid x_{1}, \cdots, x_{i-1}\right)\right)-\phi\left(x_{i-1}\right)\right] d \lambda_{\left(X_{1}, \cdots, X_{i-1}\right)}}
\end{gathered}
$$

$$
\geq \sum_{i=k+1}^{k+r} \int_{\mathbb{R}^{i-1}}\left(1-\psi_{i}\left(\left\{x_{j}\right\}_{j=1}^{i-1}\right)\right)\left[\phi\left(x_{i-1}\right)-\phi\left(x_{i-1}\right)\right] d \lambda_{\left(X_{1}, \cdots, X_{i-1}\right)}=0
$$

because of the assumption that our sequence of random variables is a submartingale and the observation that $\phi$ is both convex and increasing.

Now let the unbroken strings of ones for $\left\{Y_{i}(\omega)\right\}$ be

$$
\begin{equation*}
\left\{k_{1}, \cdots, k_{1}+r_{1}\right\},\left\{k_{2}, \cdots, k_{2}+r_{2}\right\}, \cdots,\left\{k_{m}, \cdots, k_{m}+r_{m}\right\} \tag{59.10.17}
\end{equation*}
$$

where $m=V(\omega) \equiv$ the number of unbroken strings of ones in the sequence $\left\{Y_{i}(\omega)\right\}$. By Corollary 59.10.6 $V(\omega) \geq U_{[a, b]}(\omega)$.

$$
\begin{gathered}
\phi\left(X_{n}(\omega)\right)-\phi\left(X_{1}(\omega)\right) \\
=\sum_{k=1}^{n}\left(\phi\left(X_{k}(\omega)\right)-\phi\left(X_{k-1}(\omega)\right)\right) Y_{k}(\omega) \\
+\sum_{k=1}^{n}\left(\phi\left(X_{k}(\omega)\right)-\phi\left(X_{k-1}(\omega)\right)\right)\left(1-Y_{k}(\omega)\right)
\end{gathered}
$$

Summing the first sum over the unbroken strings of ones (the terms in which $Y_{i}(\omega)=0$ contribute nothing), implies

$$
\begin{gather*}
\phi\left(X_{n}(\omega)\right)-\phi\left(X_{1}(\omega)\right) \\
\geq U_{[a, b]}(\omega)(b-a)+0+ \\
\sum_{k=1}^{n}\left(\phi\left(X_{k}(\omega)\right)-\phi\left(X_{k-1}(\omega)\right)\right)\left(1-Y_{k}(\omega)\right) \tag{59.10.18}
\end{gather*}
$$

where the zero on the right side results from a string of ones which does not produce an upcrossing. It is here that we use $\phi(x) \geq a$. Such a string begins with $\phi\left(X_{k}(\omega)\right)=a$ and results in an expression of the form $\phi\left(X_{k+m}(\omega)\right)-\phi\left(X_{k}(\omega)\right) \geq 0$ since $\phi\left(X_{k+m}(\omega)\right) \geq a$. If we had not replaced $X_{k}$ with $\phi\left(X_{k}\right)$, it would have been possible for $\phi\left(X_{k+m}(\omega)\right)$ to be less than $a$ and the zero in the above could have been a negative number.

Therefore from Formula 59.10.18,

$$
\begin{aligned}
(b-a) E\left(U_{[a, b]}\right) & \leq E\left(\phi\left(X_{n}\right)-\phi\left(X_{1}\right)\right) \leq E\left(\phi\left(X_{n}\right)-a\right) \\
& =E\left(\left(X_{n}-a\right)^{+}\right) \leq|a|+E\left(\left|X_{n}\right|\right)
\end{aligned}
$$

and this proves the lemma.
Theorem 59.10.8 (submartingale convergence theorem) Let $\left\{X_{i}\right\}_{i=1}^{\infty}$ be a submartingale with $K \equiv \sup \left\{E\left(\left|X_{n}\right|\right): n \geq 1\right\}<\infty$. Then there exists a random variable, $X_{\infty}$, such that $E\left(\left|X_{\infty}\right|\right) \leq K$ and $\lim _{n \rightarrow \infty} X_{n}(\omega)=X_{\infty}(\omega)$ a.e.

Proof: Let $a, b \in \mathbb{Q}$ and let $a<b$. Let $U_{[a, b]}^{n}(\omega)$ be the number of upcrossings of $\left\{X_{i}(\omega)\right\}_{i=1}^{n}$. Then let

$$
U_{[a, b]}(\omega) \equiv \lim _{n \rightarrow \infty} U_{[a, b]}^{n}(\omega)=\text { number of upcrossings of }\left\{X_{i}\right\}
$$

By the upcrossing lemma,

$$
E\left(U_{[a, b]}^{n}\right) \leq \frac{E\left(\left|X_{n}\right|\right)+|a|}{b-a} \leq \frac{K+|a|}{b-a}
$$

and so by the monotone convergence theorem,

$$
E\left(U_{[a, b]}\right) \leq \frac{K+|a|}{b-a}<\infty
$$

which shows $U_{[a, b]}(\omega)$ is finite a.e., for all $\omega \notin S_{[a, b]}$ where $P\left(S_{[a, b]}\right)=0$. Define

$$
S \equiv \cup\left\{S_{[a, b]}: a, b \in \mathbb{Q}, a<b\right\}
$$

Then $P(S)=0$ and if $\omega \notin S,\left\{X_{k}\right\}_{k=1}^{\infty}$ has only finitely many upcrossings of every interval having rational endpoints. Thus, for $\omega \notin S, \limsup _{k \rightarrow \infty} X_{k}(\omega)=\liminf _{k \rightarrow \infty} X_{k}(\omega)=$ $\lim _{k \rightarrow \infty} X_{k}(\omega) \equiv X_{\infty}(\omega)$. Letting $X_{\infty}(\omega)=0$ for $\omega \in S$, Fatou's lemma implies

$$
\int_{\Omega}\left|X_{\infty}\right| d P=\int_{\Omega} \lim \inf _{n \rightarrow \infty}\left|X_{n}\right| d P \leq \lim \inf _{n \rightarrow \infty} \int_{\Omega}\left|X_{n}\right| d P \leq K
$$

and so this proves the theorem.

### 59.11 Characteristic Functions, Independence

There is a way to tell if random vectors are independent by using their characteristic functions.

Proposition 59.11.1 If $\mathbf{X}_{i}$ is a random vector having values in $\mathbb{R}^{p_{i}}$, then the random vectors are independent if and only if

$$
E\left(e^{i P}\right)=\prod_{j=1}^{n} E\left(e^{i \mathbf{t}_{j} \cdot \mathbf{x}_{j}}\right)
$$

where $P \equiv \sum_{j=1}^{n} \mathbf{t}_{j} \cdot \mathbf{X}_{j}$ for $\mathbf{t}_{j} \in \mathbb{R}^{p_{j}}$.
The proof of this proposition will depend on the following lemma.
Lemma 59.11.2 Let $\mathbf{Y}$ be a random vector with values in $\mathbb{R}^{p}$ and let $f$ be bounded and measurable with respect to the Radon measure $\lambda_{\mathbf{Y}}$, and satisfy

$$
\int f(\mathbf{y}) e^{i t \cdot \mathbf{y}} d \lambda_{\mathbf{Y}}=0
$$

for all $\mathbf{t} \in \mathbb{R}^{p}$. Then $f(\mathbf{y})=0$ for $\lambda_{\mathbf{Y}}$ a.e. $\mathbf{y}$.
Proof: You could write the following for $\phi \in \mathscr{G}$

$$
\int \phi(\mathbf{t}) \int f(\mathbf{y}) e^{i t \cdot \mathbf{y}} d \lambda_{\mathbf{Y}} d t=0=\int f(\mathbf{y})\left(\int \phi(\mathbf{t}) e^{i \mathbf{t} \cdot \mathbf{y}} d t\right) d \lambda_{\mathbf{Y}}
$$

and now recall that the inverse Fourier transform maps $\mathscr{G}$ onto $\mathscr{G}$. Hence

$$
\int f(\mathbf{y}) \psi(\mathbf{y}) d \lambda_{\mathbf{Y}}=0
$$

for all $\psi \in \mathscr{G}$. Thus this is also so for every $\psi \in C_{0}^{\infty}\left(\mathbb{R}^{p}\right)$ by an obvious application of the Stone Weierstrass theorem. Let $\left\{\phi_{k}\right\}$ be a sequence of functions in $C_{c}^{\infty}\left(\mathbb{R}^{p}\right)$ which converges to

$$
\operatorname{sgn}(f) \equiv\left\{\begin{array}{l}
\bar{f} /|f| \text { if } f \neq 0 \\
0 \text { if } f=0
\end{array}\right.
$$

pointwise and in $L^{1}\left(\mathbb{R}^{p}, \lambda_{\mathbf{Y}}\right)$, each $\left|\phi_{k}\right| \leq 2$. Then for any $\psi \in C_{0}^{\infty}\left(\mathbb{R}^{p}\right)$,

$$
0=\int f(\mathbf{y}) \phi_{n}(\mathbf{y}) \psi(\mathbf{y}) d \lambda_{\mathbf{Y}} \rightarrow \int|f(\mathbf{y})| \psi(\mathbf{y}) d \lambda_{\mathbf{Y}}
$$

Also, the above holds for any $\psi \in C_{c}\left(\mathbb{R}^{p}\right)$ as can be seen by taking such a $\psi$ and convolving with a mollifier. By the Riesz representation theorem, $f(\mathbf{y})=0 \lambda_{\mathbf{Y}}$ a.e. (The measure $\mu(E) \equiv \int_{E}|f(\mathbf{y})| d \lambda_{\mathbf{Y}}$ equals 0 .)

Proof of the proposition: If the $\mathbf{X}_{j}$ are independent, the formula follows from Lemma 59.9.6 and Lemma 59.9.4.

Now suppose the formula holds. Thus

$$
\begin{gather*}
\prod_{j=1}^{n} E\left(e^{i \mathbf{t}_{j} \cdot \mathbf{x}_{j}}\right)= \\
\int_{\mathbb{R}^{p_{n}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i \mathbf{t}_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i \mathbf{t}_{n} \cdot \mathbf{x}_{n}} d \lambda_{\mathbf{x}_{1}} d \lambda_{\mathbf{x}_{2}} \cdots d \lambda_{\mathbf{x}_{n}}=E\left(e^{i P}\right) \\
=\int_{\mathbb{R}^{p_{n}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i \mathbf{t}_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i \mathbf{t}_{n} \cdot \mathbf{x}_{n}} d \lambda \lambda_{\mathbf{x}_{1} \mid \mathbf{x}_{2} \cdots \mathbf{x}_{n}} d \lambda_{\mathbf{x}_{2} \mid \mathbf{x}_{3} \cdots \mathbf{x}_{n}} \cdots d \lambda_{\mathbf{x}_{n}} \tag{59.11.19}
\end{gather*}
$$

Then from the above Lemma 59.11.2, the following equals 0 for $\lambda_{\mathbf{x}_{n}}$ a.e. $\mathbf{x}_{n}$.

$$
\begin{gathered}
\int_{\mathbb{R}^{p_{n-1}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i \mathbf{t}_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i \mathbf{t}_{n-1} \cdot \mathbf{x}_{n-1}} d \lambda \mathbf{x}_{1} d \lambda \mathbf{x}_{2} \cdots d \lambda \mathbf{x}_{n-1}- \\
\int_{\mathbb{R}^{p_{n-1}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i \mathbf{t}_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i \mathbf{t}_{n-1} \cdot \mathbf{x}_{n-1}} d \lambda \mathbf{x}_{1} \mid \mathbf{x}_{2} \ldots \mathbf{x}_{n} d \lambda \\
\mathbf{x}_{2} \mid \mathbf{x}_{3} \cdots \mathbf{x}_{n}
\end{gathered} \cdots d \lambda \lambda_{\mathbf{x}_{n-1} \mid \mathbf{x}_{n}} .
$$

Let $\mathbf{t}_{i}=\mathbf{0}$ for $i=1,2, \cdots, n-2$. Then this implies

$$
\int_{\mathbb{R}^{p_{n-1}}} e^{i \mathbf{t}_{n-1} \cdot \mathbf{x}_{n-1}} d \lambda \mathbf{x}_{n-1}=\int_{\mathbb{R}^{p_{n-1}}} e^{i \mathbf{t}_{n-1} \cdot \mathbf{x}_{n-1}} d \lambda_{\mathbf{x}_{n-1} \mid \mathbf{x}_{n}}
$$

By the fact that the characteristic function determines the distribution measure, Theorem 59.8.4, it follows that for these $\mathbf{x}_{n}$ off a set of $\lambda_{\mathbf{x}_{n}}$ measure zero, $\lambda_{\mathbf{x}_{n-1}}=\lambda \mathbf{x}_{n-1} \mid \mathbf{x}_{n}$. Returning to 59.11.19, one can replace $\lambda_{\mathbf{x}_{n-1} \mid \mathbf{x}_{n}}$ with $\lambda_{\mathbf{x}_{n-1}}$ to obtain

$$
\int_{\mathbb{R}^{p_{n}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i \mathbf{t}_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i \mathbf{t}_{n} \cdot \mathbf{x}_{n}} d \lambda \mathbf{x}_{1} d \lambda \mathbf{x}_{2} \cdots d \lambda \mathbf{x}_{n-1} d \lambda \mathbf{x}_{n}
$$

$$
=\int_{\mathbb{R} p_{n}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i i_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i t_{n} \cdot \mathbf{x}_{n}} d \lambda_{\mathbf{x}_{1} \mid \mathbf{x}_{2} \ldots \mathbf{x}_{n}} d \lambda_{\mathbf{x}_{2} \mid \mathbf{x}_{3} \cdots \mathbf{x}_{n}} \cdots d \lambda_{\mathbf{x}_{n-1}} d \lambda_{\mathbf{x}_{n}}
$$

Next let $\mathbf{t}_{n}=0$ and applying the above Lemma 59.11.2 again, this implies that for $\lambda_{\mathbf{x}_{n-1}}$ a.e. $\mathbf{x}_{n-1}$, the following equals 0 .

$$
\begin{gathered}
\int_{\mathbb{R}^{p_{n-2}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i \mathbf{t}_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i \mathbf{t}_{n-2} \cdot \mathbf{x}_{n-2}} d \lambda \mathbf{x}_{1} d \lambda \lambda_{\mathbf{x}_{2}} \cdots d \lambda \mathbf{x}_{n-2}- \\
\int_{\mathbb{R}^{p_{n-2}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} e^{i \mathbf{t}_{1} \cdot \mathbf{x}_{1}} e^{i \mathbf{t}_{2} \cdot \mathbf{x}_{2}} \cdots e^{i \mathbf{t}_{n-2} \cdot \mathbf{x}_{n-2}} d \lambda \lambda_{\mathbf{x}_{1} \mid \mathbf{x}_{2} \ldots \mathbf{x}_{n}} d \lambda \mathbf{x}_{2}\left|\mathbf{x}_{3} \cdots \mathbf{x}_{n} \cdots d \lambda \mathbf{x}_{n-2}\right| \mathbf{x}_{n} \mathbf{x}_{n-1}
\end{gathered}
$$

Let $\mathbf{t}_{i}=\mathbf{0}$ for $i=1,2, \cdots, n-3$. Then you obtain

$$
\int_{\mathbb{R}^{p_{n-2}}} e^{i \mathbf{t}_{n-2} \cdot \mathbf{x}_{n-2}} d \lambda \lambda_{\mathbf{x}_{n-2}}=\int_{\mathbb{R}^{p_{n-2}}} e^{i \mathbf{t}_{n-2} \cdot \mathbf{x}_{n-2}} d \lambda \mathbf{x}_{n-2} \mid \mathbf{x}_{n} \mathbf{x}_{n-1}
$$

and so $\lambda_{\mathbf{x}_{n-2}}=\lambda_{\mathbf{x}_{n-2} \mid \mathbf{x}_{n} \mathbf{x}_{n-1}}$ for $\mathbf{x}_{n-1}$ off a set of $\lambda_{\mathbf{x}_{n-1}}$ measure zero. Continuing this way, it follows that

$$
\lambda_{\mathbf{x}_{n-k}}=\lambda_{\mathbf{x}_{n-k} \mid \mathbf{x}_{n} \mathbf{x}_{n-1} \cdots \mathbf{x}_{n-k+1}}
$$

for $\mathbf{x}_{n-k+1}$ off a set of $\lambda_{\mathbf{x}_{n-k+1}}$ measure zero. Thus if $E$ is Borel in $\mathbb{R}^{p_{n-1}} \times \cdots \times \mathbb{R}^{p_{1}}$,

$$
\begin{gathered}
\int_{\mathbb{R}^{p_{n} \times \cdots \times \mathbb{R}^{p_{1}}}} \mathscr{X}_{E} d \lambda_{\left(\mathbf{x}_{1} \cdots \mathbf{x}_{n}\right)}= \\
\int_{\mathbb{R}^{p_{n}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} \mathscr{X}_{E} d \lambda_{\mathbf{x}_{1} \mid \mathbf{x}_{2} \cdots \mathbf{x}_{n}} d \lambda_{\mathbf{x}_{2} \mid \mathbf{x}_{3} \cdots \mathbf{x}_{n}} \cdots d \lambda_{\mathbf{x}_{n-1} \mid \mathbf{x}_{n}} d \lambda_{\mathbf{x}_{n}} \\
\int_{\mathbb{R}^{p_{n}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} \mathscr{X}_{E} d \lambda_{\mathbf{x}_{1} \mid \mathbf{x}_{2} \cdots \mathbf{x}_{n}} d \lambda_{\mathbf{x}_{2} \mid \mathbf{x}_{3} \cdots \mathbf{x}_{n}} \cdots d \lambda_{\mathbf{x}_{n-1}} d \lambda_{\mathbf{x}_{n}} \\
\vdots \\
=\int_{\mathbb{R}^{p_{n}}} \cdots \int_{\mathbb{R}^{p_{2}}} \int_{\mathbb{R}^{p_{1}}} \mathscr{X}_{E} d \lambda_{\mathbf{x}_{1}} d \lambda_{\mathbf{x}_{2}} \cdots d \lambda_{\mathbf{x}_{n}}
\end{gathered}
$$

One could achieve this iterated integral in any order by similar arguments to the above. By Definition 59.9.2 and the discussion which follows, this implies that the random variables $\mathbf{X}_{i}$ are independent.

Here is another proof of the Doob Dynkin lemma based on differentiation theory.
Lemma 59.11.3 Suppose $\mathbf{X}, \mathbf{Y}_{1}, \mathbf{Y}_{2}, \cdots, \mathbf{Y}_{k}$ are random vectors $\mathbf{X}$ having values in $\mathbb{R}^{n}$ and $\mathbf{Y}_{j}$ having values in $\mathbb{R}^{p_{j}}$ and

$$
\mathbf{X}, \mathbf{Y}_{j} \in L^{1}(\Omega)
$$

Suppose $\mathbf{X}$ is $\sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ measurable. Thus

$$
\left\{\mathbf{X}^{-1}(E): E \text { Borel }\right\} \subseteq\left\{\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)^{-1}(F): F \text { is Borel in } \prod_{j=1}^{k} \mathbb{R}^{p_{j}}\right\}
$$

Then there exists a Borel function, $\mathbf{g}: \prod_{j=1}^{k} \mathbb{R}^{p_{j}} \rightarrow \mathbb{R}^{n}$ such that

$$
\mathbf{X}=\mathbf{g}\left(\mathbf{Y}_{1}, \mathbf{Y}_{2}, \cdots, \mathbf{Y}_{k}\right)
$$

Proof: For the sake of brevity, denote by $\mathbf{Y}$ the vector $\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ and by $\mathbf{y}$ the vector $\left(\mathbf{y}_{1}, \cdots, \mathbf{y}_{k}\right)$ and let $\prod_{j=1}^{k} \mathbb{R}^{p_{j}} \equiv \mathbb{R}^{P}$. For $E$ a Borel set of $\mathbb{R}^{n}$,

$$
\begin{align*}
\int_{\mathbf{Y}^{-1}(E)} \mathbf{X} d P & =\int_{\mathbb{R}^{n} \times \mathbb{R}^{P}} \mathscr{X}_{\mathbb{R}^{n} \times E}(\mathbf{x}, \mathbf{y}) \mathbf{x} d \lambda_{(\mathbf{X}, \mathbf{Y})} \\
& =\int_{E} \int_{\mathbb{R}^{n}} \mathbf{x} d \lambda_{\mathbf{X} \mid \mathbf{y}} d \lambda_{\mathbf{Y}} \tag{59.11.20}
\end{align*}
$$

Consider the function

$$
\mathbf{y} \rightarrow \int_{\mathbb{R}^{n}} \mathbf{x} d \lambda_{\mathbf{x} \mid \mathbf{y}}
$$

Since $d \lambda_{\mathbf{Y}}$ is a Radon measure having inner and outer regularity, it follows the above function is equal to a Borel function for $\lambda_{\mathbf{Y}}$ a.e. $\mathbf{y}$. This function will be denoted by $\mathbf{g}$. Then from 59.11.20

$$
\begin{aligned}
\int_{\mathbf{Y}^{-1}(E)} \mathbf{X} d P & =\int_{E} \mathbf{g}(\mathbf{y}) d \lambda_{\mathbf{Y}}=\int_{\mathbb{R}^{P}} \mathscr{X}_{E}(\mathbf{y}) \mathbf{g}(\mathbf{y}) d \lambda_{\mathbf{Y}} \\
& =\int_{\Omega} \mathscr{X}_{E}(\mathbf{Y}(\omega)) \mathbf{g}(\mathbf{Y}(\omega)) d P \\
& =\int_{\mathbf{Y}^{-1}(E)} \mathbf{g}(\mathbf{Y}(\omega)) d P
\end{aligned}
$$

and since $\mathbf{Y}^{-1}(E)$ is an arbitrary element of $\sigma(\mathbf{Y})$, this shows that since $\mathbf{X}$ is $\sigma(\mathbf{Y})$ measurable,

$$
\mathbf{X}=\mathbf{g}(\mathbf{Y}) P \text { a.e. }
$$

What about the case where $\mathbf{X}$ is not necessarily measurable in $\sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ ?
Lemma 59.11.4 There exists a unique function $\mathbf{Z}(\omega)$ which satisfies

$$
\int_{F} \mathbf{X}(\omega) d P=\int_{F} \mathbf{Z}(\omega) d P
$$

for all $F \in \sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ such that $\mathbf{Z}$ is $\sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ measurable. It is denoted by

$$
E\left(\mathbf{X} \mid \sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)\right)
$$

Proof: It is like the above. Letting $E$ be a Borel set in $\mathbb{R}^{p}$,

$$
\begin{aligned}
\int_{\mathbf{Y}^{-1}(E)} \mathbf{X} d P & =\int_{\mathbb{R}^{n} \times \mathbb{R}^{P}} \mathscr{X}_{\mathbb{R}^{n} \times E}(\mathbf{x}, \mathbf{y}) \mathbf{x} d \lambda_{(\mathbf{X}, \mathbf{Y})} \\
& =\int_{E} \int_{\mathbb{R}^{n}} \mathbf{x} d \lambda_{\mathbf{X} \mid \mathbf{y}} d \lambda_{\mathbf{Y}}
\end{aligned}
$$

Now let $\mathbf{g}(\mathbf{y}) \equiv E\left(\mathbf{X} \mid \mathbf{y}_{1}, \cdots, \mathbf{y}_{k}\right)$ be a Borel representative of

$$
\int_{\mathbb{R}^{n}} \mathbf{x} d \lambda_{\mathbf{x} \mid \mathbf{y}}
$$

It follows $\omega \rightarrow \mathbf{g}(\mathbf{Y}(\omega))=E\left(\mathbf{X} \mid \mathbf{Y}_{1}(\omega), \cdots, \mathbf{Y}_{k}(\omega)\right)$ is $\sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ measurable because by definition $\omega \rightarrow \mathbf{Y}(\omega)$ is $\sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ measurable and a Borel measurable function composed with a measurable one is still measurable. It follows that for all $E$ Borel in $\mathbb{R}^{p}$,

$$
\begin{aligned}
& \int_{\mathbf{Y}^{-1}(E)} \mathbf{X} d P=\int_{E} E\left(\mathbf{X} \mid \mathbf{y}_{1}, \cdots, \mathbf{y}_{k}\right) d \lambda \mathbf{Y} \\
& =\int_{\mathbf{Y}^{-1}(E)} E\left(\mathbf{X} \mid \mathbf{Y}_{1}(\omega), \cdots, \mathbf{Y}_{k}(\omega)\right) d P
\end{aligned}
$$

and so $\mathbf{Z}(\omega)=E\left(\mathbf{X} \mid \mathbf{Y}_{1}(\omega), \cdots, \mathbf{Y}_{k}(\omega)\right)$ works because a generic set of $\sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$ is $\mathbf{Y}^{-1}(E)$ for $E$ a Borel set in $\mathbb{R}^{p}$. If both $\mathbf{Z}, \mathbf{Z}_{1}$ work, then for all $F \in \sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)$,

$$
\int_{F}\left(\mathbf{Z}-\mathbf{Z}_{1}\right) d P=0
$$

Since $F$ is arbitrary, some routine computations show $\mathbf{Z}=\mathbf{Z}_{1}$ a.e.
Observation 59.11.5 Note that a.e.

$$
E\left(\mathbf{X} \mid \mathbf{Y}_{1}(\omega), \cdots, \mathbf{Y}_{k}(\omega)\right)=E\left(\mathbf{X} \mid \sigma\left(\mathbf{Y}_{1}, \cdots, \mathbf{Y}_{k}\right)\right)
$$

where the one on the left is the expected value of $\mathbf{X}$ given values of $\mathbf{Y}_{j}(\omega)$. This one corresponds to the sort of thing we say in words. The one on the right is an abstract concept which is usually obtained using the Radon Nikodym theorem and its description is given in the lemma. This lemma shows that its meaning is really to take the expected value of $\mathbf{X}$ given values for the $\mathbf{Y}_{k}$.

### 59.12 Characteristic Functions For Measures

Recall the characteristic function for a random variable having values in $\mathbb{R}^{n}$. I will give a review of this to begin with. Then the concept will be generalized to random variables (vectors) which have values in a real separable Banach space.

Definition 59.12.1 Let $\mathbf{X}$ be a random variable. The characteristic function is

$$
\phi_{\mathbf{X}}(\mathbf{t}) \equiv E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right) \equiv \int_{\Omega} e^{i \mathbf{t} \cdot \mathbf{X}(\omega)} d P=\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda_{\mathbf{X}}
$$

the last equation holding by Proposition 59.1.12 on Page 1858.
Recall the following fundamental lemma and definition, Lemma 32.3.4 on Page 1101.
Definition 59.12.2 For $T \in \mathscr{G}^{*}$, define $F T, F^{-1} T \in \mathscr{G}^{*}$ by

$$
F T(\phi) \equiv T(F \phi), F^{-1} T(\phi) \equiv T\left(F^{-1} \phi\right)
$$

Lemma 59.12.3 $F$ and $F^{-1}$ are both one to one, onto, and are inverses of each other.
The main result on characteristic functions is the following in Theorem 59.8.4 on Page 1880 which is stated here for convenience.

Theorem 59.12.4 Let $\mathbf{X}$ and $\mathbf{Y}$ be random vectors with values in $\mathbb{R}^{p}$ and suppose $E\left(e^{i t \cdot \mathbf{X}}\right)$ $=E\left(e^{i \mathbf{t} \cdot \mathbf{Y}}\right)$ for all $\mathbf{t} \in \mathbb{R}^{p}$. Then $\lambda_{\mathbf{X}}=\lambda_{\mathbf{Y}}$.

I want to do something similar for random variables which have values in a separable real Banach space, $E$ instead of $\mathbb{R}^{p}$.

Corollary 59.12.5 Let $\mathscr{K}$ be a $\pi$ system of subsets of $\Omega$ and suppose two probability measures, $\mu$ and $v$ defined on $\sigma(\mathscr{K})$ are equal on $\mathscr{K}$. Then $\mu=v$.

Proof: This follows from the Lemma 12.12.3 on Page 329. Let

$$
\mathscr{G} \equiv\{E \in \sigma(\mathscr{K}): \mu(E)=v(E)\}
$$

Then $\mathscr{K} \subseteq \mathscr{G}$, since $\mu$ and $v$ are both probability measures, it follows that if $E \in \mathscr{G}$, then so is $E^{C}$. Since these are measures, if $\left\{A_{i}\right\}$ is a sequence of disjoint sets from $\mathscr{G}$ then

$$
\mu\left(\cup_{i=1}^{\infty} A_{i}\right)=\sum_{i} \mu\left(A_{i}\right)=\sum_{i} v\left(A_{i}\right)=v\left(\cup_{i=1}^{\infty} A\right)
$$

and so from Lemma 12.12.3, $\mathscr{G}=\sigma(\mathscr{K})$.
Next recall the following fundamental lemma used to prove Pettis' theorem. It is proved on Page 645 but is stated here for convenience.

Lemma 59.12.6 If $E$ is a separable Banach space with $B^{\prime}$ the closed unit ball in $E^{\prime}$, then there exists a sequence $\left\{f_{n}\right\}_{n=1}^{\infty} \equiv D^{\prime} \subseteq B^{\prime}$ with the property that for every $x \in E$,

$$
\|x\|=\sup _{f \in D^{\prime}}|f(x)|
$$

Definition 59.12.7 Let E be a separable real Banach space. A cylindrical set is one which is of the form

$$
\left\{x \in E: x_{i}^{*}(x) \in \Gamma_{i}, i=1,2, \cdots, m\right\}
$$

where here $x_{i}^{*} \in E^{\prime}$ and $\Gamma_{i}$ is a Borel set in $\mathbb{R}$.
It is obvious that $\emptyset$ is a cylindrical set and that the intersection of two cylindrical sets is another cylindrical set. Thus the cylindrical sets form a $\pi$ system. What is the smallest $\sigma$ algebra containing the cylindrical sets? It is the Borel sets of $E$. This is a special case of Lemma 59.4.2. Recall why this was. Letting $\left\{f_{n}\right\}_{n=1}^{\infty}=D^{\prime}$ be the sequence of Lemma 59.12.6 it follows that

$$
\begin{aligned}
& \{x \in E:| | x-a \| \leq \delta\} \\
= & \left\{x \in E: \sup _{f \in D^{\prime}}|f(x-a)| \leq \delta\right\} \\
= & \left\{x \in E: \sup _{f \in D^{\prime}}|f(x)-f(a)| \leq \delta\right\} \\
= & \cap_{n=1}^{\infty}\left\{x \in E: f_{n}(x) \in \overline{B\left(f_{n}(a), \delta\right)}\right\}
\end{aligned}
$$

which yields a countable intersection of cylindrical sets. It follows the smallest $\sigma$ algebra containing the cylindrical sets contains the closed balls and hence the open balls and consequently the open sets and so it contains the Borel sets. However, each cylindrical set is a Borel set and so in fact this $\sigma$ algebra equals $\mathscr{B}(E)$.

From Corollary 59.12.5 it follows that two probability measures which are equal on the cylindrical sets are equal on the Borel sets $\mathscr{B}(E)$.

Definition 59.12.8 Let $\mu$ be a probability measure on $\mathscr{B}(E)$ where $E$ is a real separable Banach space. Then for $x^{*} \in E^{\prime}$,

$$
\phi_{\mu}\left(x^{*}\right) \equiv \int_{E} e^{i x^{*}(x)} d \mu(x)
$$

$\phi_{\mu}$ is called the characteristic function for the measure $\mu$.
Note this is a little different than earlier when the symbol $\phi_{X}(\mathbf{t})$ was used and $X$ was a random variable. Here the focus is more on the measure than a random variable, $X$ such that $\mathscr{L}(X)=\mu$. It might appear this is a more general concept but in fact this is not the case. You could just consider the separable Banach space or Polish space with the Borel $\sigma$ algebra as your probabililty space and then consider the identity map as a random variable having the given measure as a distribution measure. Of course a major result is the one which says that the characteristic function determines the measures.

Theorem 59.12.9 Let $\mu$ and $v$ be two probability measures on $\mathscr{B}(E)$ where $E$ is a separable real Banach space. Suppose

$$
\phi_{\mu}\left(x^{*}\right)=\phi_{v}\left(x^{*}\right)
$$

for all $x^{*} \in E^{\prime}$. Then $\mu=v$.
Proof: It suffices to verify that $\mu(A)=v(A)$ for all $A \in \mathscr{K}$ where $\mathscr{K}$ is the set of cylindrical sets. Fix $\mathbf{g}_{n} \in\left(E^{\prime}\right)^{n}$. Thus the two measures are equal if for all such $\mathbf{g}_{n}, n \in \mathbb{N}$,

$$
\mu\left(\mathbf{g}_{n}^{-1}(B)\right)=v\left(\mathbf{g}_{n}^{-1}(B)\right)
$$

for $B$ a Borel set in $\mathbb{R}^{n}$. Of course, for such a choice of $\mathbf{g}_{n} \in\left(E^{\prime}\right)^{n}$, there are measures defined on the Borel sets of $\mathbb{R}^{n} \mu_{n}$ and $v_{n}$ which are given by

$$
\mu_{n}(B) \equiv \mu\left(\mathbf{g}_{n}^{-1}(B)\right), v_{n}(B) \equiv v\left(\mathbf{g}_{n}^{-1}(B)\right)
$$

and so it suffices to verify that these two measures are equal. So what are their characteristic functions? Note that $\mathbf{g}_{n}$ is a random variable taking $E$ to $\mathbb{R}^{n}$ and $\mu_{n}, v_{n}$ are just the probability distribution measures of this random variable. Therefore,

$$
\phi_{\mu_{n}}(\mathbf{t}) \equiv \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{s}} d \mu_{n}=\int_{E} e^{i \mathbf{t} \cdot \mathbf{g}_{n}(x)} d \mu
$$

Similarly,

$$
\phi_{v_{n}}(\mathbf{t}) \equiv \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{s}} d v_{n}=\int_{E} e^{i \mathbf{t} \cdot \mathbf{g}_{n}(x)} d v
$$

Now $\mathbf{t} \cdot \mathbf{g}_{n} \in E^{\prime}$ and so by assumption, the two ends of the above are equal. Hence $\phi_{\mu_{n}}(\mathbf{t})=$ $\phi_{v_{n}}(\mathbf{t})$ and so by Theorem 59.8.6, $\mu_{n}=v_{n}$ which, as shown above, implies $\mu=v$.

### 59.13 Characteristic Functions In Banach Space

I will consider the relation between the characteristic function and independence of random variables having values in a Banach space. Recall an earlier proposition which relates independence of random vectors with characteristic functions. It is proved starting on Page 1889.

Proposition 59.13.1 Let $\left\{\mathbf{X}_{k}\right\}_{k=1}^{n}$ be random vectors such that $\mathbf{X}_{k}$ has values in $\mathbb{R}^{p_{k}}$. Then the random vectors are independent if and only if

$$
E\left(e^{i P}\right)=\prod_{j=1}^{n} E\left(e^{i \boldsymbol{i t}_{j} \cdot \mathbf{x}_{j}}\right)
$$

where $P \equiv \sum_{j=1}^{n} \mathbf{t}_{j} \cdot \mathbf{X}_{j}$ for $\mathbf{t}_{j} \in \mathbb{R}^{p_{j}}$.
It turns out there is a generalization of the above proposition to the case where the random variables have values in a real separable Banach space. Before proving this recall an earlier theorem which had to do with reducing to the case where the random variables had values in $\mathbb{R}^{n}$, Theorem 59.5.1. It is restated here for convenience.

Theorem 59.13.2 The random variables $\left\{X_{i}\right\}_{i \in I}$ are independent if whenever

$$
\left\{i_{1}, \cdots, i_{n}\right\} \subseteq I
$$

$m_{i_{1}}, \cdots, m_{i_{n}}$ are positive integers, and $\mathbf{g}_{m_{i_{1}}}, \cdots, \mathbf{g}_{m_{i_{n}}}$ are in

$$
\left(E^{\prime}\right)^{m_{i_{1}}}, \cdots,\left(E^{\prime}\right)^{m_{i_{n}}}
$$

respectively, $\left\{\mathbf{g}_{m_{i_{j}}} \circ X_{i_{j}}\right\}_{j=1}^{n}$ are independent random vectors having values in

$$
\mathbb{R}^{m_{i_{1}}}, \cdots, \mathbb{R}^{m_{i_{n}}}
$$

respectively.
Now here is the theorem about independence and the characteristic functions.
Theorem 59.13.3 Let $\left\{X_{k}\right\}_{k=1}^{n}$ be random variables such that $X_{k}$ has values in $E_{k}$, a real separable Banach space. Then the random variables are independent if and only if

$$
E\left(e^{i P}\right)=\prod_{j=1}^{n} E\left(e^{i t_{j}^{*}\left(X_{j}\right)}\right)
$$

where $P \equiv \sum_{j=1}^{n} t_{j}^{*}\left(X_{j}\right)$ for $t_{j}^{*} \in E_{j}^{\prime}$.
Proof: If the random variables are independent, then so are the random variables, $t_{j}^{*}\left(X_{j}\right)$ and so the equation follows.

The interesting case is when the equation holds.

It suffices to consider only the case where each $E_{k}=E$. This is because you can consider each $X_{j}$ to have values in $\prod_{k=1}^{n} E_{k}$ by letting $X_{j}$ take its values in the $j^{\text {th }}$ component of the product and 0 in the other components. Can you draw the conclusion the random variables are independent? By Theorem 59.5.1, it suffices to show the random variables $\left\{\mathbf{g}_{m_{k}} \circ X_{k}\right\}_{k=1}^{n}$ are independent where $\mathbf{g}_{m_{k}}=\left(x_{1}^{*}, \cdots, x_{m_{k}}^{*}\right) \in\left(E^{\prime}\right)^{m_{k}}$. This happens if whenever $\mathbf{t}_{m_{k}} \in \mathbb{R}^{m_{k}}$ and

$$
P=\sum_{k=1}^{n} \mathbf{t}_{m_{k}} \cdot\left(\mathbf{g}_{m_{k}} \circ X_{k}\right)
$$

it follows

$$
\begin{equation*}
E\left(e^{i P}\right)=\prod_{k=1}^{n} E\left(e^{i \mathbf{t}_{m_{k}} \cdot\left(\mathbf{g}_{m_{k}} \circ X_{k}\right)}\right) \tag{59.13.21}
\end{equation*}
$$

However, the expression on the right in 59.13.21 equals

$$
\prod_{k=1}^{n} E\left(e^{i\left(\mathbf{t}_{m_{k}} \cdot \mathbf{g}_{m_{k}}\right) \circ X_{k}}\right)
$$

and $\mathbf{t}_{m_{k}} \cdot \mathbf{g}_{m_{k}} \equiv \sum_{j=1}^{m_{k}} t_{j} x_{j}^{*} \in E^{\prime}$. Also the expression on the left equals $E\left(e^{i \sum_{k=1}^{n} \mathbf{t}_{m_{k}} \cdot \mathbf{g}_{m_{k}} \circ X_{k}}\right)$ Therefore, by assumption, 59.13.21 holds.

There is an obvious corollary which is useful.
Corollary 59.13.4 Let $\left\{X_{k}\right\}_{k=1}^{n}$ be random variables such that $X_{k}$ has values in $E_{k}$, a real separable Banach space. Then the random variables are independent if and only if

$$
E\left(e^{i P}\right)=\prod_{j=1}^{n} E\left(e^{i i_{j}^{*}\left(X_{j}\right)}\right)
$$

where $P \equiv \sum_{j=1}^{n} t_{j}^{*}\left(X_{j}\right)$ for $t_{j}^{*} \in M_{j}$ where $M_{j}$ is a dense subset of $E_{j}^{\prime}$.
Proof: The easy direction follows from Theorem 59.13.3. Suppose then the above equation holds for all $t_{j}^{*} \in M_{j}$. Then let $t_{j}^{*} \in E^{\prime}$ and let $\left\{t_{n j}^{*}\right\}$ be a sequence in $M_{j}$ such that

$$
\lim _{n \rightarrow \infty} t_{n j}^{*}=t_{j}^{*} \text { in } E^{\prime}
$$

Then define

$$
P \equiv \sum_{j=1}^{n} t_{j}^{*} X_{j}, P_{n} \equiv \sum_{j=1}^{n} t_{n j}^{*} X_{j}
$$

It follows

$$
\begin{aligned}
E\left(e^{i P}\right) & =\lim _{n \rightarrow \infty} E\left(e^{i P_{n}}\right) \\
& =\lim _{n \rightarrow \infty} \prod_{j=1}^{n} E\left(e^{i t_{n j}^{*}\left(X_{j}\right)}\right) \\
& =\prod_{j=1}^{n} E\left(e^{i t_{j}^{*}\left(X_{j}\right)}\right) \square
\end{aligned}
$$

### 59.14 Convolution And Sums

Lemma 59.1.9 on Page 1857 makes possible a definition of convolution of two probability measures defined on $\mathscr{B}(E)$ where $E$ is a separable Banach space as well as some other interesting theorems which held earlier in the context of locally compact spaces. I will first show a little theorem about density of continuous functions in $L^{p}(E)$ and then define the convolution of two finite measures. First here is a simple technical lemma.

Lemma 59.14.1 Suppose $K$ is a compact subset of $U$ an open set in $E$ a metric space. Then there exists $\delta>0$ such that

$$
\operatorname{dist}(x, K)+\operatorname{dist}\left(x, U^{C}\right) \geq \delta \text { for all } x \in E
$$

Proof: For each $x \in K$, there exists a ball, $B\left(x, \delta_{x}\right)$ such that $B\left(x, 3 \delta_{x}\right) \subseteq U$. Finitely many of these balls cover $K$ because $K$ is compact, say $\left\{B\left(x_{i}, \delta_{x_{i}}\right)\right\}_{i=1}^{m}$. Let

$$
0<\delta<\min \left(\delta_{x_{i}}: i=1,2, \cdots, m\right)
$$

Now pick any $x \in K$. Then $x \in B\left(x_{i}, \delta_{x_{i}}\right)$ for some $x_{i}$ and so $B(x, \delta) \subseteq B\left(x_{i}, 2 \delta_{x_{i}}\right) \subseteq$ $U$. Therefore, for any $x \in K$, $\operatorname{dist}\left(x, U^{C}\right) \geq \delta$. If $x \in B\left(x_{i}, 2 \delta_{x_{i}}\right)$ for some $x_{i}$, it follows dist $\left(x, U^{C}\right) \geq \delta$ because then $B(x, \delta) \subseteq B\left(x_{i}, 3 \delta_{x_{i}}\right) \subseteq U$. If $x \notin B\left(x_{i}, 2 \delta_{x_{i}}\right)$ for any of the $x_{i}$, then $x \notin B(y, \delta)$ for any $y \in K$ because all these sets are contained in some $B\left(x_{i}, 2 \delta_{x_{i}}\right)$. Consequently dist $(x, K) \geq \delta$. This proves the lemma.

From this lemma, there is an easy corollary.
Corollary 59.14.2 Suppose $K$ is a compact subset of $U$, an open set in $E$ a metric space. Then there exists a uniformly continuous function $f$ defined on all of $E$, having values in $[0,1]$ such that $f(x)=0$ if $x \notin U$ and $f(x)=1$ if $x \in K$.

Proof: Consider

$$
f(x) \equiv \frac{\operatorname{dist}\left(x, U^{C}\right)}{\operatorname{dist}\left(x, U^{C}\right)+\operatorname{dist}(x, K)}
$$

Then some algebra yields

$$
\begin{gathered}
\left|f(x)-f\left(x^{\prime}\right)\right| \leq \\
\frac{1}{\delta}\left(\left|\operatorname{dist}\left(x, U^{C}\right)-\operatorname{dist}\left(x^{\prime}, U^{C}\right)\right|+\left|\operatorname{dist}(x, K)-\operatorname{dist}\left(x^{\prime}, K\right)\right|\right)
\end{gathered}
$$

where $\delta$ is the constant of Lemma 59.14.1. Now it is a general fact that

$$
\left|\operatorname{dist}(x, S)-\operatorname{dist}\left(x^{\prime}, S\right)\right| \leq d\left(x, x^{\prime}\right)
$$

Therefore,

$$
\left|f(x)-f\left(x^{\prime}\right)\right| \leq \frac{2}{\delta} d\left(x, x^{\prime}\right)
$$

and this proves the corollary.
Now suppose $\mu$ is a finite measure defined on the Borel sets of a separable Banach space, $E$. It was shown above that $\mu$ is inner and outer regular. Lemma 59.1.9 on Page 1857 shows that $\mu$ is inner regular in the usual sense with respect to compact sets. This makes possible the following theorem.

Theorem 59.14.3 Let $\mu$ be a finite measure on $\mathscr{B}(E)$ where $E$ is a separable Banach space and let $f \in L^{p}(E ; \mu)$. Then for any $\varepsilon>0$, there exists a uniformly continuous, bounded $g$ defined on $E$ such that

$$
\|f-g\|_{L^{p}(E)}<\varepsilon .
$$

Proof: As usual in such situations, it suffices to consider only $f \geq 0$. Then by Theorem 11.3.9 on Page 241 and an application of the monotone convergence theorem, there exists a simple measurable function,

$$
s(x) \equiv \sum_{k=1}^{m} c_{k} \mathscr{X}_{A_{k}}(x)
$$

such that $\|f-s\|_{L^{p}(E)}<\varepsilon / 2$. Now by regularity of $\mu$ there exist compact sets, $K_{k}$ and open sets, $V_{k}$ such that $2 \sum_{k=1}^{m}\left|c_{k}\right| \mu\left(V_{k} \backslash K\right)^{1 / p}<\varepsilon / 2$ and by Corollary 59.14.2 there exist uniformly continuous functions $g_{k}$ having values in $[0,1]$ such that $g_{k}=1$ on $K_{k}$ and 0 on $V_{k}^{C}$. Then consider

$$
g(x)=\sum_{k=1}^{m} c_{k} g_{k}(x) .
$$

This function is bounded and uniformly continuous. Furthermore,

$$
\begin{aligned}
\|s-g\|_{L^{p}(E)} & \leq\left(\int_{E}\left|\sum_{k=1}^{m} c_{k} \mathscr{X}_{A_{k}}(x)-\sum_{k=1}^{m} c_{k} g_{k}(x)\right|^{p} d \mu\right)^{1 / p} \\
& \leq\left(\int_{E}\left(\sum_{k=1}^{m}\left|c_{k}\right|\left|\mathscr{X}_{A_{k}}(x)-g_{k}(x)\right|\right)^{p}\right)^{1 / p} \\
& \leq \sum_{k=1}^{m}\left|c_{k}\right|\left(\int_{E}\left|\mathscr{X}_{A_{k}}(x)-g_{k}(x)\right|^{p} d \mu\right)^{1 / p} \\
& \leq \sum_{k=1}^{m}\left|c_{k}\right|\left(\int_{V_{k} \backslash K_{k}} 2^{p} d \mu\right)^{1 / p} \\
& =2 \sum_{k=1}^{m}\left|c_{k}\right| \mu\left(V_{k} \backslash K\right)^{1 / p}<\varepsilon / 2
\end{aligned}
$$

Therefore,

$$
\|f-g\|_{L^{p}} \leq\|f-s\|_{L^{p}}+\|s-g\|_{L^{p}}<\varepsilon / 2+\varepsilon / 2 .
$$

This proves the theorem.
Lemma 59.14.4 Let $A \in \mathscr{B}(E)$ where $\mu$ is a finite measure on $\mathscr{B}(E)$ for $E$ a separable Banach space. Also let $x_{i} \in E$ for $i=1,2, \cdots, m$. Then for $\mathbf{x} \in E^{m}$,

$$
\mathbf{x} \rightarrow \mu\left(A+\sum_{i=1}^{m} x_{i}\right), \mathbf{x} \rightarrow \mu\left(A-\sum_{i=1}^{m} x_{i}\right)
$$

are Borel measurable functions. Furthermore, the above functions are

$$
\mathscr{B}(E) \times \cdots \times \mathscr{B}(E)
$$

measurable where the above denotes the product measurable sets as described in Theorem 12.12.6 on Page 332.

Proof: First consider the case where $A=U$, an open set. Let

$$
\begin{equation*}
\mathbf{y} \in\left\{\mathbf{x} \in E^{m}: \mu\left(U+\sum_{i=1}^{m} x_{i}\right)>\alpha\right\} \tag{59.14.22}
\end{equation*}
$$

Then from Lemma 59.1.9 on Page 1857 there exists a compact set, $K \subseteq U+\sum_{i=1}^{m} y_{i}$ such that $\mu(K)>\alpha$. Then if $\mathbf{y}^{\prime}$ is close enough to $\mathbf{y}$, it follows $K \subseteq U+\sum_{i=1}^{m} y_{i}^{\prime}$ also. Therefore, for all $\mathbf{y}^{\prime}$ close enough to $\mathbf{y}$,

$$
\mu\left(U+\sum_{i=1}^{m} y_{i}^{\prime}\right) \geq \mu(K)>\alpha
$$

In other words the set described in 59.14 .22 is an open set and so $\mathbf{y} \rightarrow \mu\left(U+\sum_{i=1}^{m} y_{i}\right)$ is Borel measurable whenever $U$ is an open set in $E$.

Define a $\pi$ system, $\mathscr{K}$ to consist of all open sets in $E$. Then define $\mathscr{G}$ as

$$
\left\{A \in \sigma(\mathscr{K})=\mathscr{B}(E): \mathbf{y} \rightarrow \mu\left(A+\sum_{i=1}^{m} y_{i}\right) \text { is Borel measurable }\right\}
$$

I just showed $\mathscr{G} \supseteq \mathscr{K}$. Now suppose $A \in \mathscr{G}$. Then

$$
\mu\left(A^{C}+\sum_{i=1}^{m} y_{i}\right)=\mu(E)-\mu\left(A+\sum_{i=1}^{m} y_{i}\right)
$$

and so $A^{C} \in \mathscr{G}$ whenever $A \in \mathscr{G}$. Next suppose $\left\{A_{i}\right\}$ is a sequence of disjoint sets of $\mathscr{G}$. Then

$$
\begin{aligned}
\mu\left(\left(\cup_{i=1}^{\infty} A_{i}\right)+\sum_{j=1}^{m} y_{j}\right) & =\mu\left(\cup_{i=1}^{\infty}\left(A_{i}+\sum_{j=1}^{m} y_{j}\right)\right) \\
& =\sum_{i=1}^{\infty} \mu\left(A_{i}+\sum_{j=1}^{m} y_{j}\right)
\end{aligned}
$$

and so $\cup_{i=1}^{\infty} A_{i} \in \mathscr{G}$ because the above is the sum of Borel measurable functions. By the lemma on $\pi$ systems, Lemma 12.12.3 on Page 329, it follows $\mathscr{G}=\sigma(\mathscr{K})=\mathscr{B}(E)$. Similarly, $\mathbf{x} \rightarrow \mu\left(A-\sum_{j=1}^{m} x_{j}\right)$ is also Borel measurable whenever $A \in \mathscr{B}(E)$. Finally note that

$$
\mathscr{B}(E) \times \cdots \times \mathscr{B}(E)
$$

contains the open sets of $E^{m}$ because the separability of $E$ implies the existence of a countable basis for the topology of $E^{m}$ consisting of sets of the form $\prod_{i=1}^{m} U_{i}$ where the $U_{i}$ come from a countable basis for $E$. Since every open set is the countable union of sets like the above, each being a measurable box, the open sets are contained in

$$
\mathscr{B}(E) \times \cdots \times \mathscr{B}(E)
$$

which implies $\mathscr{B}\left(E^{m}\right) \subseteq \mathscr{B}(E) \times \cdots \times \mathscr{B}(E)$ also. This proves the lemma.
With this lemma, it is possible to define the convolution of two finite measures.
Definition 59.14.5 Let $\mu$ and $v$ be two finite measures on $\mathscr{B}(E)$, for $E$ a separable Banach space. Then define a new measure, $\mu * v$ on $\mathscr{B}(E)$ as follows

$$
\mu * v(A) \equiv \int_{E} v(A-x) d \mu(x)
$$

This is well defined because of Lemma 59.14.4 which says that $x \rightarrow v(A-x)$ is Borel measurable.

Here is an interesting theorem about convolutions. However, first here is a little lemma. The following picture is descriptive of the set described in the following lemma.

Lemma 59.14.6 For A a Borel set in E, a separable Banach space, define

$$
S_{A} \equiv\{(x, y) \in E \times E: x+y \in A\}
$$

Then $S_{A} \in \mathscr{B}(E) \times \mathscr{B}(E)$, the $\sigma$ algebra of product measurable sets, the smallest $\sigma$ algebra which contains all the sets of the form $A \times B$ where $A$ and $B$ are Borel.

Proof: Let $\mathscr{K}$ denote the open sets in $E$. Then $\mathscr{K}$ is a $\pi$ system. Let

$$
\mathscr{G} \equiv\left\{A \in \sigma(\mathscr{K})=\mathscr{B}(E): S_{A} \in \mathscr{B}(E) \times \mathscr{B}(E)\right\}
$$

Then $\mathscr{K} \subseteq \mathscr{G}$ because if $U \in \mathscr{K}$ then $S_{U}$ is an open set in $E \times E$ and all open sets are in $\mathscr{B}(E) \times \mathscr{B}(E)$ because a countable basis for the topology of $E \times E$ are sets of the form $B \times C$ where $B$ and $C$ come from a countable basis for $E$. Therefore, $\mathscr{K} \subseteq \mathscr{G}$. Now let
$A \in \mathscr{G}$. For $(x, y) \in E \times E$, either $x+y \in A$ or $x+y \notin A$. Hence $E \times E=S_{A} \cup S_{A C}$ which shows that if $A \in \mathscr{G}$ then so is $A^{C}$. Finally if $\left\{A_{i}\right\}$ is a sequence of disjoint sets of $\mathscr{G}$

$$
S_{\cup_{i=1}^{\infty} A_{i}}=\cup_{i=1}^{\infty} S_{A_{i}}
$$

and this shows that $\mathscr{G}$ is also closed with respect to countable unions of disjoint sets. Therefore, by the lemma on $\pi$ systems, Lemma 12.12 .3 on Page 329 it follows $\mathscr{G}=\sigma(\mathscr{K})=$ $\mathscr{B}(E)$. This proves the lemma.

Theorem 59.14.7 Let $\mu, v$, and $\lambda$ be finite measures on $\mathscr{B}(E)$ for $E$ a separable Banach space. Then

$$
\begin{align*}
\mu * v & =v * \mu  \tag{59.14.23}\\
(\mu * v) * \lambda & =\mu *(v * \lambda) \tag{59.14.24}
\end{align*}
$$

If $\mu$ is the distribution for an $E$ valued random variable, $X$ and if $v$ is the distribution for an $E$ valued random variable, $Y$, and $X$ and $Y$ are independent, then $\mu * v$ is the distribution for the random variable, $X+Y$. Also the characteristic function of a convolution equals the product of the characteristic functions.

Proof: First consider 59.14.23. Letting $A \in \mathscr{B}(E)$, the following computation holds from Fubini's theorem and Lemma 59.14.6

$$
\begin{aligned}
\mu * v(A) & \equiv \int_{E} v(A-x) d \mu(x)=\int_{E} \int_{E} \mathscr{X}_{S_{A}}(x, y) d v(y) d \mu(x) \\
& =\int_{E} \int_{E} \mathscr{X}_{S_{A}}(x, y) d \mu(x) d v(y)=v * \mu(A) .
\end{aligned}
$$

Next consider 59.14.24. Using 59.14.23 whenever convenient,

$$
\begin{aligned}
(\mu * v) * \lambda(A) & \equiv \int_{E}(\mu * v)(A-x) d \lambda(x) \\
& =\int_{E} \int_{E} v(A-x-y) d \mu(y) d \lambda(x)
\end{aligned}
$$

while

$$
\begin{aligned}
\mu *(v * \lambda)(A) & \equiv \int_{E}(v * \lambda)(A-y) d \mu(y) \\
& =\int_{E} \int_{E} v(A-y-x) d \lambda(x) d \mu(y) \\
& =\int_{E} \int_{E} v(A-y-x) d \mu(y) d \lambda(x)
\end{aligned}
$$

The necessary product measurability comes from Lemma 59.14.4.
Recall

$$
(\mu * v)(A) \equiv \int_{E} v(A-x) d \mu(x)
$$

Therefore, if $s$ is a simple function, $s(x)=\sum_{k=1}^{n} c_{k} \mathscr{X}_{A_{k}}(x)$,

$$
\begin{aligned}
\int_{E} s d(\mu * v) & =\sum_{k=1}^{n} c_{k} \int_{E} v\left(A_{k}-x\right) d \mu(x) \\
& =\int_{E} \sum_{k=1}^{n} c_{k} v\left(A_{k}-x\right) d \mu(x) \\
& =\int_{E} \sum_{k=1}^{n} c_{k} \mathscr{X}_{A_{k}-x}(y) d v(y) d \mu(x) \\
& =\int_{E} \int_{E} s(x+y) d v(y) d \mu(x)
\end{aligned}
$$

Approximating with simple functions it follows that whenever $f$ is bounded and measurable or nonnegative and measurable,

$$
\begin{equation*}
\int_{E} f d(\mu * v)=\int_{E} \int_{E} f(x+y) d v(y) d \mu(x) \tag{59.14.25}
\end{equation*}
$$

Therefore, letting $Z=X+Y$, and $\lambda$ the distribution of $Z$, it follows from independence of $X$ and $Y$ that for $t^{*} \in E^{\prime}$,

$$
\phi_{\lambda}\left(t^{*}\right) \equiv E\left(e^{i t^{*}(Z)}\right)=E\left(e^{i t^{*}(X+Y)}\right)=E\left(e^{i t^{*}(X)}\right) E\left(e^{i t^{*}(Y)}\right)
$$

But also, it follows from 59.14.25

$$
\begin{aligned}
\phi_{(\mu * v)}\left(t^{*}\right) & =\int_{E} e^{i t^{*}(z)} d(\mu * v)(z) \\
& =\int_{E} \int_{E} e^{i t^{*}(x+y)} d v(y) d \mu(x) \\
& =\int_{E} \int_{E} e^{i t^{*}(x)} e^{i t^{*}(y)} d v(y) d \mu(x) \\
& =\left(\int_{E} e^{i t^{*}(y)} d v(y)\right)\left(\int_{E} e^{i t^{*}(x)} d \mu(x)\right) \\
& =E\left(e^{i t^{*}(X)}\right) E\left(e^{i t^{*}(Y)}\right)
\end{aligned}
$$

Since $\phi_{\lambda}\left(t^{*}\right)=\phi_{(\mu * v)}\left(t^{*}\right)$, it follows $\lambda=\mu * v$.
Note the last part of this argument shows the characteristic function of a convolution equals the product of the characteristic functions. This proves the theorem.

### 59.15 The Convergence Of Sums

It turns out that when random variables have symmetric distributions, some remarkable things can be said about infinite sums of these random variables. Conditions are given here that enable one to conclude the convergence of the sequence of partial sums from the convergence of some subsequence of partial sums.

The following lemma is like an earlier result but is proved here for convenience.

Definition 59.15.1 Let $\mathbf{X}$ be a random variable. $\mathscr{L}(\mathbf{X})=\mu$ means $\lambda_{\mathbf{X}}=\mu$. This is called the law of $\mathbf{X}$. It is the same as saying the distribution measure of $\mathbf{X}$ is $\mu$.

Lemma 59.15.2 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $\mathbf{X}: \Omega \rightarrow E$ be a random variable, where $E$ is a real separable Banach space. Also let $\mathscr{L}(\mathbf{X})=\mu$, a probability measure defined on $\mathscr{B}(E)$, the Borel sets of $E$. Suppose $h: E \rightarrow \mathbb{R}$ is in $L^{1}(E ; \mu)$ or is nonnegative and Borel measurable. Then

$$
\int_{\Omega}(h \circ \mathbf{X}) d P=\int_{E} h(\mathbf{x}) d \mu .
$$

Proof: First suppose $A$ is a Borel set in $E$. Then

$$
\begin{aligned}
\int_{E} \mathscr{X}_{A}(\mathbf{x}) d \mu & \equiv \mu(A) \equiv P([\mathbf{X} \in A]) \\
\int_{\Omega}\left(\mathscr{X}_{A} \circ \mathbf{X}\right) d P & =\int_{\Omega} \mathscr{X}_{\mathbf{X}^{-1}(A)}(\omega) d P \equiv P\left(\mathbf{X}^{-1}(A)\right) \equiv P([\mathbf{X} \in A])
\end{aligned}
$$

Thus for nonnegative simple Borel measurable functions $s$, it follows

$$
\int_{\Omega}(s \circ \mathbf{X}) d P=\int_{E} s(\mathbf{x}) d \mu
$$

Now approximating with an increasing sequence of nonnegative simple functions and using the monotone convergence theorem, the desired formula holds for nonnegative Borel measurable functions $h$.

If $h$ is Borel measurable and in $L^{1}(E ; \mu)$, then you can consider the formula for the positive and negative parts and get the result in this case also. This proves the lemma.

Here is a simple definition and lemma about random variables whose distribution is symmetric.

Definition 59.15.3 Let $X$ be a random variable defined on a probability space, $(\Omega, \mathscr{F}, P)$ having values in a Banach space, $E$. Then it has a symmetric distribution if whenever $A$ is a Borel set,

$$
P([X \in A])=P([X \in-A])
$$

In terms of the distribution,

$$
\lambda_{X}=\lambda_{-X}
$$

It is good to observe that if $X, Y$ are independent random variables defined on a probability space, $(\Omega, \mathscr{F}, P)$ such that each has symmetric distribution, then $X+Y$ also has symmetric distribution. Here is why. Let $A$ be a Borel set in $E$. Then by Theorem 59.14.7 on Page 1902,

$$
\begin{aligned}
\lambda_{X+Y}(A) & =\int_{E} \lambda_{X}(A-z) d \lambda_{Y}(z) \\
& =\int_{E} \lambda_{-X}(A-z) d \lambda_{-Y}(z) \\
& =\lambda_{-(X+Y)}(A)=\lambda_{X+Y}(-A)
\end{aligned}
$$

By induction, it follows that if you have $n$ independent random variables each having symmetric distribution, then their sum has symmetric distribution.

Here is a simple lemma about random variables having symmetric distributions. It will depend on Lemma 59.15.2 on Page 1904.

Lemma 59.15.4 Let $\mathbf{X} \equiv\left(X_{1}, \cdots, X_{n}\right)$ and $Y$ be random variables defined on a probability space, $(\Omega, \mathscr{F}, P)$ such that $X_{i}, i=1,2, \cdots, n$ and $Y$ have values in $E$ a separable Banach space. Thus $\mathbf{X}$ has values in $E^{n}$. Suppose also that $\left\{X_{1}, \cdots, X_{n}, Y\right\}$ are independent and that $Y$ has symmetric distribution. Then if $A \in \mathscr{B}\left(E^{n}\right)$, it follows

$$
\begin{aligned}
& P\left([\mathbf{X} \in A] \cap\left[\left\|\sum_{i=1}^{n} X_{i}+Y\right\|<r\right]\right) \\
= & P\left([\mathbf{X} \in A] \cap\left[\left\|\sum_{i=1}^{n} X_{i}-Y\right\|<r\right]\right)
\end{aligned}
$$

You can also change the inequalities in the obvious way, $<$ to $\leq,>$ or $\geq$.
Proof: Denote by $\lambda_{\mathbf{X}}$ and $\lambda_{Y}$ the distribution measures for $\mathbf{X}$ and $Y$ respectively. Since the random variables are independent, the distribution for the random variable, $(\mathbf{X}, Y)$ mapping into $E^{n+1}$ is $\lambda_{\mathbf{x}} \times \lambda_{Y}$ where this denotes product measure. Since the Banach space is separable, the Borel sets are contained in the product measurable sets. Then by symmetry of the distribution of $Y$

$$
\begin{aligned}
& P\left([\mathbf{X} \in A] \cap\left[\left\|\sum_{i=1}^{n} X_{i}+Y\right\|<r\right]\right) \\
= & \int_{E^{n} \times E} \mathscr{X}_{A}(\mathbf{x}) \mathscr{X}_{B(0, r)}\left(\sum_{i=1}^{n} x_{i}+y\right) d\left(\lambda \mathbf{x} \times \lambda_{Y}\right)(\mathbf{x}, y) \\
= & \int_{E} \int_{E^{n}} \mathscr{X}_{A}(\mathbf{x}) \mathscr{X}_{B(0, r)}\left(\sum_{i=1}^{n} x_{i}+y\right) d \lambda_{\mathbf{x}} d \lambda_{Y} \\
= & \int_{E} \int_{E^{n}} \mathscr{X}_{A}(\mathbf{x}) \mathscr{X}_{B(0, r)}\left(\sum_{i=1}^{n} x_{i}+y\right) d \lambda_{\mathbf{x}} d \lambda_{-Y} \\
= & \int_{E^{n} \times E} \mathscr{X}_{A}(\mathbf{x}) \mathscr{X}_{B(0, r)}\left(\sum_{i=1}^{n} x_{i}+y\right) d\left(\lambda \mathbf{x} \times \lambda_{-Y}\right)(\mathbf{x}, y) \\
= & P\left([\mathbf{X} \in A] \cap\left[\left\|\sum_{i=1}^{n} X_{i}+(-Y)\right\|<r\right]\right)
\end{aligned}
$$

This proves the lemma. Other cases are similar.
Now here is a really interesting lemma.

Lemma 59.15.5 Let $E$ be a real separable Banach space. Assume $\xi_{1}, \cdots, \xi_{N}$ are independent random variables having values in $E$, a separable Banach space which have symmetric distributions. Also let $S_{k}=\sum_{i=1}^{k} \xi_{i}$. Then for any $r>0$,

$$
P\left(\left[\sup _{k \leq N}\left\|S_{k}\right\|>r\right]\right) \leq 2 P\left(\left[\left\|S_{N}\right\|>r\right]\right)
$$

Proof: First of all,

$$
\begin{gather*}
P\left(\left[\sup _{k \leq N}\left\|S_{k}\right\|>r\right]\right) \\
=P\left(\left[\sup _{k \leq N}\left\|S_{k}\right\|>r \text { and }\left\|S_{N}\right\|>r\right]\right) \\
+P\left(\left[\sup _{k \leq N-1}\left\|S_{k}\right\|>r \text { and }\left\|S_{N}\right\| \leq r\right]\right) \\
\leq P\left(\left[\left\|S_{N}\right\|>r\right]\right)+P\left(\left[\sup _{k \leq N-1}\left\|S_{k}\right\|>r \text { and }\left\|S_{N}\right\| \leq r\right]\right) \tag{59.15.26}
\end{gather*}
$$

I need to estimate the second of these terms. Let

$$
A_{1} \equiv\left[\left\|S_{1}\right\|>r\right], \cdots, A_{k} \equiv\left[\left\|S_{k}\right\|>r,\left\|S_{j}\right\| \leq r \text { for } j<k\right]
$$

Thus $A_{k}$ consists of those $\omega$ where $\left\|S_{k}(\omega)\right\|>r$ for the first time at $k$. Thus

$$
\left[\sup _{k \leq N-1}\left\|S_{k}\right\|>r \text { and }\left\|S_{N}\right\| \leq r\right]=\cup_{j=1}^{N-1} A_{j} \cap\left[\left\|S_{N}\right\| \leq r\right]
$$

and the sets in the above union are disjoint. Consider $A_{j} \cap\left[\left\|S_{N}\right\| \leq r\right]$. For $\omega$ in this set,

$$
\left\|S_{j}(\omega)\right\|>r,\left\|S_{i}(\omega)\right\| \leq r \text { if } i<j
$$

Since $\left\|S_{N}(\omega)\right\| \leq r$ in this set, it follows

$$
\left\|S_{N}(\omega)\right\|=\left\|S_{j}(\omega)+\sum_{i=j+1}^{N} \xi_{i}(\omega)\right\| \leq r
$$

Thus

$$
\begin{gather*}
P\left(A_{j} \cap\left[\left\|S_{N}\right\| \leq r\right]\right)  \tag{59.15.27}\\
=P\left(\cap_{i=1}^{j-1}\left[\left\|S_{i}\right\| \leq r\right] \cap\left[\left\|S_{j}\right\|>r\right] \cap\left[\left\|S_{j}+\sum_{i=j+1}^{N} \xi_{i}\right\| \leq r\right]\right) \tag{59.15.28}
\end{gather*}
$$

Now $\cap_{i=1}^{j-1}\left[\left\|S_{i}\right\| \leq r\right] \cap\left[\left\|S_{j}\right\|>r\right]$ is of the form

$$
\left[\left(\xi_{1}, \cdots, \xi_{j}\right) \in A\right]
$$

for some Borel set, $A$. Then letting $Y=\sum_{i=j+1}^{N} \xi_{i}$ in Lemma 59.15.4 and $X_{i}=\xi_{i}, 59.15 .28$ equals

$$
\begin{aligned}
& P\left(\cap_{i=1}^{j-1}\left[\left\|S_{i}\right\| \leq r\right] \cap\left[\left\|S_{j}\right\|>r\right] \cap\left[\left\|S_{j}-\sum_{i=j+1}^{N} \xi_{i}\right\| \leq r\right]\right) \\
= & P\left(\cap_{i=1}^{j-1}\left[\left\|S_{i}\right\| \leq r\right] \cap\left[\left\|S_{j}\right\|>r\right] \cap\left[\left\|S_{j}-\left(S_{N}-S_{j}\right)\right\| \leq r\right]\right) \\
= & P\left(\cap_{i=1}^{j-1}\left[\left\|S_{i}\right\| \leq r\right] \cap\left[\left\|S_{j}\right\|>r\right] \cap\left[\left\|2 S_{j}-S_{N}\right\| \leq r\right]\right)
\end{aligned}
$$

Now since $\left\|S_{j}(\omega)\right\|>r$,

$$
\begin{aligned}
{\left[\left\|2 S_{j}-S_{N}\right\| \leq r\right] } & \subseteq\left[2\left\|S_{j}\right\|-\left\|S_{N}\right\| \leq r\right] \\
& \subseteq\left[2 r-\left\|S_{N}\right\|<r\right] \\
& =\left[\left\|S_{N}\right\|>r\right]
\end{aligned}
$$

and so, referring to 59.15.27, this has shown

$$
\begin{aligned}
& \quad P\left(A_{j} \cap\left[\left\|S_{N}\right\| \leq r\right]\right) \\
& =P\left(\cap_{i=1}^{j-1}\left[| | S_{i} \| \leq r\right] \cap\left[\left\|S_{j}\right\|>r\right] \cap\left[\left\|2 S_{j}-S_{N}\right\| \leq r\right]\right) \\
& \leq P\left(\cap_{i=1}^{j-1}\left[\left\|S_{i}\right\| \leq r\right] \cap\left[\left\|S_{j}\right\|>r\right] \cap\left[\left\|S_{N}\right\|>r\right]\right) \\
& =P\left(A_{j} \cap\left[\left\|S_{N}\right\|>r\right]\right) .
\end{aligned}
$$

It follows that

$$
\begin{aligned}
& P\left(\left[\sup _{k \leq N-1}\left\|S_{k}\right\|>r \text { and }\left\|S_{N}\right\| \leq r\right]\right)=\sum_{i=1}^{N-1} P\left(A_{j} \cap\left[\left\|S_{N}\right\| \leq r\right]\right) \\
& \leq \sum_{i=1}^{N-1} P\left(A_{j} \cap\left[\left\|S_{N}\right\|>r\right]\right) \leq P\left(\left[\left\|S_{N}\right\|>r\right]\right)
\end{aligned}
$$

and using 59.15.26, this proves the lemma.
This interesting lemma will now be used to prove the following which concludes a sequence of partial sums converges given a subsequence of the sequence of partial sums converges.

Lemma 59.15.6 Let $\left\{\zeta_{k}\right\}$ be a sequence of independent random variables having values in a separable real Banach space, $E$ whose distributions are symmetric. Letting $S_{k} \equiv \sum_{i=1}^{k} \zeta_{i}$, suppose $\left\{S_{n_{k}}\right\}$ converges a.e. Also suppose that for every $m>n_{k}$,

$$
\begin{equation*}
P\left(\left[\left|\mid S_{m}-S_{n_{k}} \|_{E}>2^{-k}\right]\right)<2^{-k}\right. \tag{59.15.29}
\end{equation*}
$$

Then in fact,

$$
\begin{equation*}
S_{k}(\omega) \rightarrow S(\omega) \text { a.e. } \omega \tag{59.15.30}
\end{equation*}
$$

and off a set of measure zero, the convergence of $S_{k}$ to $S$ is uniform.
Proof: Let $n_{k} \leq l \leq m$. Then by Lemma 59.15.5

$$
P\left(\left[\sup _{n_{k}<l \leq m}\left\|S_{l}-S_{n_{k}}\right\|>2^{-k}\right]\right) \leq 2 P\left(\left[\| S_{m}-S_{n_{k}}| |>2^{-k}\right]\right)
$$

In using this lemma, you could renumber the $\zeta_{i}$ so that the sum

$$
\sum_{j=n_{k}+1}^{l} \zeta_{j}
$$

corresponds to

$$
\sum_{j=1}^{l-n_{k}} \xi_{j}
$$

where $\xi_{j}=\zeta_{j+n_{k}}$.
Then using 59.15.29,

$$
P\left(\left[\sup _{n_{k}<l \leq m}\left\|S_{l}-S_{n_{k}}\right\|>2^{-k}\right]\right) \leq 2 P\left(\left[\left\|S_{m}-S_{n_{k}}\right\|>2^{-k}\right]\right)<2^{-(k-1)}
$$

If $S_{l}(\omega)$ fails to converge then $\omega$ must be in infinitely many of the sets,

$$
\left[\sup _{n_{k}<l} \|\left|S_{l}-S_{n_{k}}\right| \mid>2^{-k}\right]
$$

each of which has measure no more than $2^{-(k-1)}$. Thus $\omega$ must be in a set of measure zero. This proves the lemma.

### 59.16 The Multivariate Normal Distribution

Definition 59.16.1 A random vector, $\mathbf{X}$, with values in $\mathbb{R}^{p}$ has a multivariate normal distribution written as $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ if for all Borel $E \subseteq \mathbb{R}^{p}$,

$$
\lambda_{\mathbf{x}}(E)=\int_{\mathbb{R}^{p}} \mathscr{X}_{E}(\mathbf{x}) \frac{1}{(2 \pi)^{p / 2} \operatorname{det}(\Sigma)^{1 / 2}} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x
$$

for $\mu$ a given vector and $\Sigma$ a given positive definite symmetric matrix.
Theorem 59.16.2 For $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma), \mathbf{m}=E(\mathbf{X})$ and

$$
\Sigma=E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right) .
$$

Proof: Let $R$ be an orthogonal transformation such that

$$
R \Sigma R^{*}=D=\operatorname{diag}\left(\sigma_{1}^{2}, \cdots, \sigma_{p}^{2}\right)
$$

Changing the variable by $\mathbf{x}-\mathbf{m}=R^{*} \mathbf{y}$,

$$
\begin{aligned}
E(\mathbf{X}) & \equiv \int_{\mathbb{R}^{p}} \mathbf{x} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x\left(\frac{1}{(2 \pi)^{p / 2} \operatorname{det}(\Sigma)^{1 / 2}}\right) \\
& =\int_{\mathbb{R}^{p}}\left(R^{*} \mathbf{y}+\mathbf{m}\right) e^{-\frac{1}{2} \mathbf{y}^{*} D^{-1} \mathbf{y}} d y\left(\frac{1}{(2 \pi)^{p / 2} \prod_{i=1}^{p} \sigma_{i}}\right) \\
& =\mathbf{m} \int_{\mathbb{R}^{p}} e^{-\frac{1}{2} \mathbf{y}^{*} D^{-1} \mathbf{y}} d y\left(\frac{1}{(2 \pi)^{p / 2} \prod_{i=1}^{p} \sigma_{i}}\right)=\mathbf{m}
\end{aligned}
$$

by Fubini's theorem and the easy to establish formula

$$
\frac{1}{\sqrt{2 \pi} \sigma} \int_{\mathbb{R}} e^{-\frac{y^{2}}{2 \sigma^{2}}} d y=1
$$

Next let $M \equiv E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right)$. Thus, changing the variable as above by $\mathbf{x}-\mathbf{m}=$ $R^{*} \mathbf{y}$

$$
\begin{aligned}
M & =\int_{\mathbb{R}^{p}}(\mathbf{x}-\mathbf{m})(\mathbf{x}-\mathbf{m})^{*} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x\left(\frac{1}{(2 \pi)^{p / 2} \operatorname{det}(\Sigma)^{1 / 2}}\right) \\
& =R^{*} \int_{\mathbb{R}^{p}} \mathbf{y y}^{*} e^{-\frac{1}{2} \mathbf{y}^{*} D^{-1} \mathbf{y}} d y\left(\frac{1}{(2 \pi)^{p / 2} \prod_{i=1}^{p} \sigma_{i}}\right) R
\end{aligned}
$$

Therefore,

$$
\left(R M R^{*}\right)_{i j}=\int_{\mathbb{R}^{p}} y_{i} y_{j} e^{-\frac{1}{2} \mathbf{y}^{*} D^{-1} \mathbf{y}} d y\left(\frac{1}{(2 \pi)^{p / 2} \prod_{i=1}^{p} \sigma_{i}}\right)=0
$$

so; $R M R^{*}$ is a diagonal matrix.

$$
\left(R M R^{*}\right)_{i i}=\int_{\mathbb{R}^{p}} y_{i}^{2} e^{-\frac{1}{2} \mathbf{y}^{*} D^{-1} \mathbf{y}} d y\left(\frac{1}{(2 \pi)^{p / 2} \prod_{i=1}^{p} \sigma_{i}}\right)
$$

Using Fubini's theorem and the easy to establish equations,

$$
\frac{1}{\sqrt{2 \pi} \sigma} \int_{\mathbb{R}} e^{-\frac{y^{2}}{2 \sigma^{2}}} d y=1, \frac{1}{\sqrt{2 \pi} \sigma} \int_{\mathbb{R}} y^{2} e^{-\frac{y^{2}}{2 \sigma^{2}}} d y=\sigma^{2}
$$

it follows $\left(R M R^{*}\right)_{i i}=\sigma_{i}^{2}$. Hence $R M R^{*}=D$ and so $M=R^{*} D R=\Sigma$.
Theorem 59.16.3 Suppose $\mathbf{X}_{1} \sim N_{p}\left(\mathbf{m}_{1}, \Sigma_{1}\right), \mathbf{X}_{2} \sim N_{p}\left(\mathbf{m}_{2}, \Sigma_{2}\right)$ and the two random vectors are independent. Then

$$
\begin{equation*}
\mathbf{X}_{1}+\mathbf{X}_{2} \sim N_{p}\left(\mathbf{m}_{1}+\mathbf{m}_{2}, \Sigma_{1}+\Sigma_{2}\right) \tag{59.16.31}
\end{equation*}
$$

Also, if $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ then $-\mathbf{X} \sim N_{p}(-\mathbf{m}, \Sigma)$. Furthermore, if $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ then

$$
\begin{equation*}
E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right)=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}} \tag{59.16.32}
\end{equation*}
$$

Also if $a$ is a constant and $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ then $a \mathbf{X} \sim N_{p}\left(a \mathbf{m}, a^{2} \Sigma\right)$.
Proof: Consider $E\left(e^{i t \cdot \mathbf{X}}\right)$ for $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$.

$$
E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right) \equiv \frac{1}{(2 \pi)^{p / 2}(\operatorname{det} \Sigma)^{1 / 2}} \int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} e^{-\frac{1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x
$$

Let $R$ be an orthogonal transformation such that

$$
R \Sigma R^{*}=D=\operatorname{diag}\left(\sigma_{1}^{2}, \cdots, \sigma_{p}^{2}\right)
$$

Then let $R(\mathbf{x}-\mathbf{m})=\mathbf{y}$. Then

$$
E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right)=\frac{1}{(2 \pi)^{p / 2} \prod_{i=1}^{p} \sigma_{i}} \int_{\mathbb{R} p} e^{i \mathbf{t} \cdot\left(R^{*} \mathbf{y}+\mathbf{m}\right)} e^{-\frac{1}{2} \mathbf{y}^{*} D^{-1} \mathbf{y}} d y
$$

Therefore

$$
E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right)=\frac{1}{(2 \pi)^{p / 2} \prod_{i=1}^{p} \sigma_{i}} \int_{\mathbb{R}^{p}} e^{i \mathbf{s} \cdot(\mathbf{y}+R \mathbf{m})} e^{-\frac{1}{2} \mathbf{y}^{*} D^{-1} \mathbf{y}} d y
$$

where $\mathbf{s}=R \mathbf{t}$. This equals

$$
\begin{gathered}
e^{i \mathbf{t} \cdot \mathbf{m}} \prod_{i=1}^{p}\left(\int_{\mathbb{R}} e^{i s_{i} y_{i}} e^{-\frac{1}{2 \sigma_{i}^{2}} y_{i}^{2}} d y_{i}\right) \frac{1}{\sqrt{2 \pi} \sigma_{i}} \\
=e^{i \mathbf{t} \cdot \mathbf{m}} \prod_{i=1}^{p}\left(\int_{\mathbb{R}} e^{i s_{i} \sigma_{i} u} e^{-\frac{1}{2} u^{2}} d u\right) \frac{1}{\sqrt{2 \pi}} \\
=e^{i \mathbf{t} \cdot \mathbf{m}} \prod_{i=1}^{p} e^{-\frac{1}{2} s_{i}^{2} \sigma_{i}^{2}} \frac{1}{\sqrt{2 \pi}} \int_{\mathbb{R}} e^{-\frac{1}{2}\left(u-i s_{i} \sigma_{i}\right)^{2}} d u \\
=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \sum_{i=1}^{p} s_{i}^{2} \sigma_{i}^{2}}=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}
\end{gathered}
$$

This proves 59.16.32.
Since $\mathbf{X}_{1}$ and $\mathbf{X}_{2}$ are independent, $e^{i t \cdot \mathbf{X}_{1}}$ and $e^{i \mathbf{t} \cdot \mathbf{X}_{2}}$ are also independent. Hence

$$
E\left(e^{i \boldsymbol{t} \cdot \mathbf{X}_{1}+\mathbf{X}_{2}}\right)=E\left(e^{i \mathbf{t} \cdot \mathbf{X}_{1}}\right) E\left(e^{i \boldsymbol{t} \cdot \mathbf{X}_{2}}\right)
$$

Thus,

$$
\begin{aligned}
E\left(e^{i \mathbf{t} \cdot \mathbf{X}_{1}+\mathbf{X}_{2}}\right) & =E\left(e^{i \mathbf{t} \cdot \mathbf{X}_{1}}\right) E\left(e^{i \mathbf{t} \cdot \mathbf{X}_{2}}\right) \\
& =e^{i \mathbf{t} \cdot \mathbf{m}_{1}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma_{1} \mathbf{t}} e^{i \mathbf{t} \cdot \mathbf{m}_{2}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma_{2} \mathbf{t}} \\
& =e^{i \mathbf{t} \cdot\left(\mathbf{m}_{1}+\mathbf{m}_{2}\right)} e^{-\frac{1}{2} \mathbf{t}^{*}\left(\Sigma_{1}+\Sigma_{2}\right) \mathbf{t}}
\end{aligned}
$$

which is the characteristic function of a random vector distributed as

$$
N_{p}\left(\mathbf{m}_{1}+\mathbf{m}_{2}, \Sigma_{1}+\Sigma_{2}\right)
$$

Now it follows that $\mathbf{X}_{1}+\mathbf{X}_{2} \sim N_{p}\left(\mathbf{m}_{1}+\mathbf{m}_{2}, \Sigma_{1}+\Sigma_{2}\right)$ by Theorem 59.8.4. This proves 59.16.31.

The assertion about $-\mathbf{X}$ is also easy to see because

$$
\begin{aligned}
E\left(e^{i \mathbf{t} \cdot(-\mathbf{X})}\right) & =E\left(e^{i(-\mathbf{t}) \cdot \mathbf{x}}\right) \\
& =\frac{1}{(2 \pi)^{p / 2}(\operatorname{det} \Sigma)^{1 / 2}} \int_{\mathbb{R}^{p}} e^{i(-\mathbf{t}) \cdot \mathbf{x}} e^{-\frac{1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x \\
& =\frac{1}{(2 \pi)^{p / 2}(\operatorname{det} \Sigma)^{1 / 2}} \int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} e^{-\frac{1}{2}(\mathbf{x}+\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}+\mathbf{m})} d x
\end{aligned}
$$

which is the characteristic function of a random variable which is $N(-\mathbf{m}, \Sigma)$. Theorem 59.8.4 again implies $-\mathbf{X} \sim N(-\mathbf{m}, \Sigma)$. Finally consider the last claim. You apply what is known about $\mathbf{X}$ with $\mathbf{t}$ replaced with $a \mathbf{t}$ and then massage things. This gives the characteristic function for $a \mathbf{X}$ is given by

$$
E(\exp (i \mathbf{t} \cdot a \mathbf{X}))=\exp (i \mathbf{t} \cdot a \mathbf{m}) \exp \left(-\frac{1}{2} \mathbf{t}^{*} \Sigma a^{2} \mathbf{t}\right)
$$

which is the characteristic function of a normal random vector having mean $a \mathbf{m}$ and covariance $a^{2} \Sigma$. This proves the theorem.

Following [103] a random vector has a generalized normal distribution if its characteristic function is given as

$$
\begin{equation*}
e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}} \tag{59.16.33}
\end{equation*}
$$

where $\Sigma$ is symmetric and has nonnegative eigenvalues. For a random real valued variable, $\mathbf{m}$ is scalar and so is $\Sigma$ so the characteristic function of such a generalized normally distributed random variable is

$$
\begin{equation*}
e^{i t \mu} e^{-\frac{1}{2} t^{2} \sigma^{2}} \tag{59.16.34}
\end{equation*}
$$

These generalized normal distributions do not require $\Sigma$ to be invertible, only that the eigenvalues be nonnegative. In one dimension this would correspond the characteristic function of a dirac measure having point mass 1 at $\mu$. In higher dimensions, it could be a mixture of such things with more familiar things. I won't try very hard to distinguish between generalized normal distributions and normal distributions in which the covariance matrix has all positive eigenvalues.

Here are some other interesting results about normal distributions found in [103]. The next theorem has to do with the question whether a random vector is normally distributed in the above generalized sense.

Theorem 59.16.4 Let $\mathbf{X}=\left(X_{1}, \cdots, X_{p}\right)$ where each $X_{i}$ is a real valued random variable. Then $\mathbf{X}$ is normally distributed in the above generalized sense if and only if every linear combination, $\sum_{j=1}^{p} a_{i} X_{i}$ is normally distributed. In this case the mean of $\mathbf{X}$ is

$$
\mathbf{m}=\left(E\left(X_{1}\right), \cdots, E\left(X_{p}\right)\right)
$$

and the covariance matrix for $\mathbf{X}$ is

$$
\Sigma_{j k}=E\left(\left(X_{j}-m_{j}\right)\left(X_{k}-m_{k}\right)^{*}\right)
$$

Proof: Suppose first $\mathbf{X}$ is normally distributed. Then its characteristic function is of the form

$$
\phi_{\mathbf{X}}(\mathbf{t})=E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right)=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}
$$

Then letting $\mathbf{a}=\left(a_{1}, \cdots, a_{p}\right)$

$$
E\left(e^{i t \sum_{j=1}^{p} a_{i} X_{i}}\right)=E\left(e^{i t \mathbf{a} \cdot \mathbf{X}}\right)=e^{i t \mathbf{a} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{a}^{*} \Sigma \mathbf{a} t^{2}}
$$

which is the characteristic function of a normally distributed random variable with mean $\mathbf{a} \cdot \mathbf{m}$ and variance $\sigma^{2}=\mathbf{a}^{*} \Sigma \mathbf{a}$. This proves half of the theorem. If $\mathbf{X}$ is normally distributed, then every linear combination is normally distributed.

Next suppose $\sum_{j=1}^{p} a_{j} X_{j}=\mathbf{a} \cdot \mathbf{X}$ is normally distributed with mean $\mu$ and variance $\sigma^{2}$ so that its characteristic function is given in 59.16.34. I will now relate $\mu$ and $\sigma^{2}$ to various quantities involving the $X_{j}$. Letting $m_{j}=E\left(X_{j}\right), \mathbf{m}=\left(m_{1}, \cdots, m_{p}\right)^{*}$

$$
\begin{aligned}
\mu & =\sum_{j=1}^{p} a_{j} E\left(X_{j}\right)=\sum_{j=1}^{p} a_{j} m_{j}, \sigma^{2}=E\left(\left(\sum_{j=1}^{p} a_{j} X_{j}-\sum_{j=1}^{p} a_{j} m_{j}\right)^{2}\right) \\
& =E\left(\left(\sum_{j=1}^{p} a_{j}\left(X_{j}-m_{j}\right)\right)^{2}\right)=\sum_{j, k} a_{j} a_{k} E\left(\left(X_{j}-m_{j}\right)\left(X_{k}-m_{k}\right)\right)
\end{aligned}
$$

It follows the mean of the normally distributed random variable, $\mathbf{a} \cdot \mathbf{X}$ is

$$
\mu=\sum_{j} a_{j} m_{j}=\mathbf{a} \cdot \mathbf{m}
$$

and its variance is

$$
\sigma^{2}=\mathbf{a}^{*} E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right) \mathbf{a}
$$

Therefore,

$$
\begin{gathered}
E\left(e^{i t \mathbf{t} \cdot \mathbf{X}}\right)=e^{i t \mu} e^{-\frac{1}{2} t^{2} \sigma^{2}} \\
=e^{i t \mathbf{a} \cdot \mathbf{m}} e^{-\frac{1}{2} t^{2} \mathbf{a}^{*} E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right) \mathbf{a}}
\end{gathered}
$$

Then letting $\mathbf{s}=t \mathbf{a}$ this shows

$$
\begin{aligned}
E\left(e^{i s \cdot \mathbf{X}}\right) & =e^{i \mathbf{s} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{s}^{*} E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right) \mathbf{s}} \\
& =e^{i \mathbf{s} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{s}^{*} \Sigma \mathbf{s}}
\end{aligned}
$$

which is the characteristic function of a normally distributed random variable with $\mathbf{m}$ given above and $\Sigma$ given by

$$
\Sigma_{j k}=E\left(\left(X_{j}-m_{j}\right)\left(X_{k}-m_{k}\right)\right)
$$

By assumption, a is completely arbitrary and so it follows that $\mathbf{s}$ is also. Hence, $\mathbf{X}$ is normally distributed as claimed.

Corollary 59.16.5 Let $\mathbf{X}=\left(X_{1}, \cdots, X_{p}\right), \mathbf{Y}=\left(Y_{1}, \cdots, Y_{p}\right)$ where each $X_{i}, Y_{i}$ is a real valued random variable. Suppose also that for every $\mathbf{a} \in \mathbb{R}^{p}, \mathbf{a} \cdot \mathbf{X}$ and $\mathbf{a} \cdot \mathbf{Y}$ are both normally distributed with the same mean and variance. Then $\mathbf{X}$ and $\mathbf{Y}$ are both multivariate normal random vectors with the same mean and variance.

Proof: In the Proof of Theorem 59.16.4 the proof implies that the characteristic functions of $\mathbf{a} \cdot \mathbf{X}$ and $\mathbf{a} \cdot \mathbf{Y}$ are both of the form

$$
e^{i t m} e^{-\frac{1}{2} \sigma^{2} t^{2}}
$$

Then as in the proof of that theorem, it must be the case that

$$
m=\sum_{j=1}^{p} a_{j} m_{j}
$$

where $E\left(X_{i}\right)=m_{i}=E\left(Y_{i}\right)$ and

$$
\begin{aligned}
\sigma^{2} & =\mathbf{a}^{*} E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right) \mathbf{a} \\
& =\mathbf{a}^{*} E\left((\mathbf{Y}-\mathbf{m})(\mathbf{Y}-\mathbf{m})^{*}\right) \mathbf{a}
\end{aligned}
$$

and this last equation must hold for every $\mathbf{a}$. Therefore,

$$
E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right)=E\left((\mathbf{Y}-\mathbf{m})(\mathbf{Y}-\mathbf{m})^{*}\right) \equiv \Sigma
$$

and so the characteristic function of both $\mathbf{X}$ and $\mathbf{Y}$ is $e^{i s \cdot m} e^{-\frac{1}{2} s^{*} \Sigma s}$ as in the proof of Theorem 59.16.4.

Theorem 59.16.6 Suppose $\mathbf{X}=\left(X_{1}, \cdots, X_{p}\right)$ is normally distributed with mean $\mathbf{m}$ and covariance $\Sigma$. Then if $X_{1}$ is uncorrelated with any of the $X_{i}$, meaning

$$
E\left(\left(X_{1}-m_{1}\right)\left(X_{j}-m_{j}\right)\right)=0 \text { for } j>1
$$

then $X_{1}$ and $\left(X_{2}, \cdots, X_{p}\right)$ are both normally distributed and the two random vectors are independent. Here $m_{j} \equiv E\left(X_{j}\right)$. More generally, if the covariance matrix is a diagonal matrix, the random variables, $\left\{X_{1}, \cdots, X_{p}\right\}$ are independent.

Proof: From Theorem 59.16.2

$$
\Sigma=E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right) .
$$

Then by assumption,

$$
\Sigma=\left(\begin{array}{cc}
\sigma_{1}^{2} & \mathbf{0}  \tag{59.16.35}\\
\mathbf{0} & \Sigma_{p-1}
\end{array}\right)
$$

I need to verify that if $E \in \sigma\left(X_{1}\right)$ and $F \in \sigma\left(X_{2}, \cdots, X_{p}\right)$, then

$$
P(E \cap F)=P(E) P(F) .
$$

Let $E=X_{1}^{-1}(A)$ and

$$
F=\left(X_{2}, \cdots, X_{p}\right)^{-1}(B)
$$

where $A$ and $B$ are Borel sets in $\mathbb{R}$ and $\mathbb{R}^{p-1}$ respectively. Thus I need to verify that

$$
\begin{array}{r}
P\left(\left[\left(X_{1},\left(X_{2}, \cdots, X_{p}\right)\right) \in(A, B)\right]\right)= \\
\mu_{\left(X_{1},\left(X_{2}, \cdots, X_{p}\right)\right)}(A \times B)=\mu_{X_{1}}(A) \mu_{\left(X_{2}, \cdots, X_{p}\right)}(B) . \tag{59.16.36}
\end{array}
$$

Using 59.16.35, Fubini's theorem, and definitions,

$$
\begin{gathered}
\mu_{\left(X_{1},\left(X_{2}, \cdots, X_{p}\right)\right)}(A \times B)= \\
\int_{\mathbb{R}^{p}} \mathscr{X}_{A \times B}(\mathbf{x}) \frac{1}{(2 \pi)^{p / 2} \operatorname{det}(\Sigma)^{1 / 2}} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x \\
=\int_{\mathbb{R}} \mathscr{X}_{A}\left(x_{1}\right) \int_{\mathbb{R}^{p-1}} \mathscr{X}_{B}\left(X_{2}, \cdots, X_{p}\right) . \\
\frac{1}{(2 \pi)^{(p-1) / 2} \sqrt{2 \pi}\left(\sigma_{1}^{2}\right)^{1 / 2} \operatorname{det}\left(\Sigma_{p-1}\right)^{1 / 2}} e^{\frac{-\left(x_{1}-m_{1}\right)^{2}}{2 \sigma_{1}^{2}}} . \\
e^{\frac{-1}{2}\left(\mathbf{x}^{\prime}-\mathbf{m}^{\prime}\right)^{*} \Sigma_{p-1}^{-1}\left(\mathbf{x}^{\prime}-\mathbf{m}^{\prime}\right)} d x^{\prime} d x_{1}
\end{gathered}
$$

where $\mathbf{x}^{\prime}=\left(x_{2}, \cdots, x_{p}\right)$ and $\mathbf{m}^{\prime}=\left(m_{2}, \cdots, m_{p}\right)$. Now this equals

$$
\begin{align*}
& \int_{\mathbb{R}} \mathscr{X}_{A}\left(x_{1}\right) \frac{1}{\sqrt{2 \pi \sigma_{1}^{2}}} e^{\frac{-\left(x_{1}-m_{1}\right)^{2}}{2 \sigma_{1}^{2}}} \int_{B} \frac{1}{(2 \pi)^{(p-1) / 2} \operatorname{det}\left(\Sigma_{p-1}\right)^{1 / 2}}  \tag{59.16.37}\\
& e^{\frac{-1}{2}\left(\mathbf{x}^{\prime}-\mathbf{m}^{\prime}\right)^{*} \Sigma_{p-1}^{-1}\left(\mathbf{x}^{\prime}-\mathbf{m}^{\prime}\right)} d x^{\prime} d x \tag{59.16.38}
\end{align*}
$$

In case $B=\mathbb{R}^{p-1}$, the inside integral equals 1 and

$$
\begin{aligned}
\mu_{X_{1}}(A) & =\mu_{\left(X_{1},\left(X_{2}, \cdots, X_{p}\right)\right)}\left(A \times \mathbb{R}^{p-1}\right) \\
& =\int_{\mathbb{R}} \mathscr{X}_{A}\left(x_{1}\right) \frac{1}{\sqrt{2 \pi \sigma_{1}^{2}}} e^{\frac{-\left(x_{1}-m_{1}\right)^{2}}{2 \sigma_{1}^{2}}} d x_{1}
\end{aligned}
$$

which shows $X_{1}$ is normally distributed as claimed. Similarly, letting $A=\mathbb{R}$,

$$
\begin{aligned}
& \mu_{\left(X_{2}, \cdots, X_{p}\right)}(B) \\
= & \mu_{\left(X_{1},\left(X_{2}, \cdots, X_{p}\right)\right)}(\mathbb{R} \times B) \\
= & \int_{B} \frac{1}{(2 \pi)^{(p-1) / 2} \operatorname{det}\left(\Sigma_{p-1}\right)^{1 / 2}} e^{\frac{-1}{2}\left(\mathbf{x}^{\prime}-\mathbf{m}^{\prime}\right)^{*} \Sigma_{p-1}^{-1}\left(\mathbf{x}^{\prime}-\mathbf{m}^{\prime}\right)} d x^{\prime}
\end{aligned}
$$

and $\left(X_{2}, \cdots, X_{p}\right)$ is also normally distributed with mean $\mathbf{m}^{\prime}$ and covariance $\Sigma_{p-1}$. Now from 59.16.37, 59.16 .36 follows. In case the covariance matrix is diagonal, the above reasoning extends in an obvious way to prove the random variables, $\left\{X_{1}, \cdots, X_{p}\right\}$ are independent.

However, another way to prove this is to use Proposition 59.11.1 on Page 1889 and consider the characteristic function. Let $E\left(X_{j}\right)=m_{j}$ and

$$
P=\sum_{j=1}^{p} t_{j} X_{j}
$$

Then since $\mathbf{X}$ is normally distributed and the covariance is a diagonal,

$$
\begin{align*}
D & \equiv\left(\begin{array}{ccc}
\sigma_{1}^{2} & & 0 \\
& \ddots & \\
0 & & \sigma_{p}^{2}
\end{array}\right) \\
E\left(e^{i P}\right) & =E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right)=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}} \\
& =\exp \left(\sum_{j=1}^{p} i t_{j} m_{j}-\frac{1}{2} t_{j}^{2} \sigma_{j}^{2}\right)  \tag{59.16.39}\\
& =\prod_{j=1}^{p} \exp \left(i t_{j} m_{j}-\frac{1}{2} t_{j}^{2} \sigma_{j}^{2}\right)
\end{align*}
$$

Also,

$$
\begin{aligned}
E\left(e^{i t_{j} X_{j}}\right) & =E\left(\exp \left(i t_{j} X_{j}+\sum_{k \neq j} i 0 X_{k}\right)\right) \\
& =\exp \left(i t_{j} m_{j}-\frac{1}{2} t_{j}^{2} \sigma_{j}^{2}\right)
\end{aligned}
$$

With 59.16.39, this shows

$$
E\left(e^{i P}\right)=\prod_{j=1}^{p} E\left(e^{i t_{j} X_{j}}\right)
$$

which shows by Proposition 59.11.1 that the random variables,

$$
\left\{X_{1}, \cdots, X_{p}\right\}
$$

are independent.

### 59.17 Use Of Characteristic Functions To Find Moments

Let $X$ be a random variable with characteristic function

$$
\phi_{X}(t) \equiv E(\exp (i t X))
$$

Then this can be used to find moments of the random variable assuming they exist. The $k^{t h}$ moment is defined as

$$
E\left(X^{k}\right)
$$

This can be done by using the dominated convergence theorem to differentiate the characteristic function with respect to $t$ and then plugging in $t=0$. For example,

$$
\phi_{X}^{\prime}(t)=E(i X \exp (i t X))
$$

and now plugging in $t=0$ you get $i E(X)$. Doing another differentiation you obtain

$$
\phi_{X}^{\prime \prime}(t)=E\left(-X^{2} \exp (i t X)\right)
$$

and plugging in $t=0$ you get $-E\left(X^{2}\right)$ and so forth.
An important case is where $X$ is normally distributed with mean 0 and variance $\sigma^{2}$. In this case, as shown above, the characteristic function is

$$
e^{-\frac{1}{2} t^{2} \sigma^{2}}
$$

Also all moments exist when $X$ is normally distributed. So what are these moments?

$$
D_{t}\left(e^{-\frac{1}{2} t^{2} \sigma^{2}}\right)=-t \sigma^{2} e^{-\frac{1}{2} t^{2} \sigma^{2}}
$$

and plugging in $t=0$ you find the mean equals 0 as expected.

$$
D_{t}\left(-t \sigma^{2} e^{-\frac{1}{2} t^{2} \sigma^{2}}\right)=-\sigma^{2} e^{-\frac{1}{2} t^{2} \sigma^{2}}+t^{2} \sigma^{4} e^{-\frac{1}{2} t^{2} \sigma^{2}}
$$

and plugging in $t=0$ you find the second moment is $\sigma^{2}$. Then do it again.

$$
D_{t}\left(-\sigma^{2} e^{-\frac{1}{2} t^{2} \sigma^{2}}+t^{2} \sigma^{4} e^{-\frac{1}{2} t^{2} \sigma^{2}}\right)=3 \sigma^{4} t e^{-\frac{1}{2} t^{2} \sigma^{2}}-t^{3} \sigma^{6} e^{-\frac{1}{2} t^{2} \sigma^{2}}
$$

Then $E\left(X^{3}\right)=0$.

$$
\begin{aligned}
& D_{t}\left(3 \sigma^{4} t e^{-\frac{1}{2} t^{2} \sigma^{2}}-t^{3} \sigma^{6} e^{-\frac{1}{2} t^{2} \sigma^{2}}\right) \\
= & 3 \sigma^{4} e^{-\frac{1}{2} t^{2} \sigma^{2}}-6 \sigma^{6} t^{2} e^{-\frac{1}{2} t^{2} \sigma^{2}}+t^{4} \sigma^{8} e^{-\frac{1}{2} t^{2} \sigma^{2}}
\end{aligned}
$$

and so $E\left(X^{4}\right)=3 \sigma^{4}$. By now you can see the pattern. If you continue this way, you find the odd moments are all 0 and

$$
\begin{equation*}
E\left(X^{2 m}\right)=C_{m}\left(\sigma^{2}\right)^{m} \tag{59.17.40}
\end{equation*}
$$

This is an important observation.

### 59.18 The Central Limit Theorem

The central limit theorem is one of the most marvelous theorems in mathematics. It can be proved through the use of characteristic functions. Recall for $\mathbf{x} \in \mathbb{R}^{p}$,

$$
\|\mathbf{x}\|_{\infty} \equiv \max \left\{\left|x_{j}\right|, j=1, \cdots, p\right\} .
$$

Also recall the definition of the distribution function for a random vector, $\mathbf{X}$.

$$
F_{\mathbf{X}}(\mathbf{x}) \equiv P\left(X_{j} \leq x_{j}, j=1, \cdots, p\right)
$$

Definition 59.18.1 Let $\left\{\mathbf{X}_{n}\right\}$ be random vectors with values in $\mathbb{R}^{p}$. Then $\left\{\lambda_{\mathbf{x}_{n}}\right\}_{n=1}^{\infty}$ is called "tight" if for all $\varepsilon>0$ there exists a compact set, $K_{\mathcal{\varepsilon}}$ such that

$$
\lambda_{\mathbf{x}_{n}}\left(\left[\mathbf{x} \notin K_{\mathcal{\varepsilon}}\right]\right)<\boldsymbol{\varepsilon}
$$

for all $\lambda_{\mathbf{x}_{n}}$. Similarly, if $\left\{\mu_{n}\right\}$ is a sequence of probability measures defined on the Borel sets of $\mathbb{R}^{p}$, then this sequence is "tight" if for each $\varepsilon>0$ there exists a compact set, $K_{\mathcal{E}}$ such that

$$
\mu_{n}\left(\left[\mathbf{x} \notin K_{\varepsilon}\right]\right)<\varepsilon
$$

for all $\mu_{n}$.
Lemma 59.18.2 If $\left\{\mathbf{X}_{n}\right\}$ is a sequence of random vectors with values in $\mathbb{R}^{p}$ such that

$$
\lim _{n \rightarrow \infty} \phi_{\mathbf{X}_{n}}(\mathbf{t})=\psi(\mathbf{t})
$$

for all $\mathbf{t}$, where $\psi(\mathbf{0})=1$ and $\psi$ is continuous at $\mathbf{0}$, then $\left\{\lambda_{\mathbf{x}_{n}}\right\}_{n=1}^{\infty}$ is tight.
Proof: Let $\mathbf{e}_{j}$ be the $j^{t h}$ standard unit basis vector.

$$
\begin{aligned}
& \left|\frac{1}{u} \int_{-u}^{u}\left(1-\phi_{\mathbf{X}_{n}}\left(t \mathbf{e}_{j}\right)\right) d t\right| \\
= & \left|\frac{1}{u} \int_{-u}^{u}\left(1-\int_{\mathbb{R}^{p}} e^{i t x_{j}} d \lambda \mathbf{x}_{n}\right) d t\right| \\
= & \left|\frac{1}{u} \int_{-u}^{u}\left(\int_{\mathbb{R}^{p}}\left(1-e^{i t x_{j}}\right) d \lambda \mathbf{x}_{n}\right) d t\right| \\
= & \left|\int_{\mathbb{R}^{p}} \frac{1}{u} \int_{-u}^{u}\left(1-e^{i t x_{j}}\right) d t d \lambda_{\mathbf{x}_{n}}(x)\right| \\
= & \left|2 \int_{\mathbb{R}^{p}}\left(1-\frac{\sin \left(u x_{j}\right)}{u x_{j}}\right) d \lambda \mathbf{x}_{n}(x)\right| \\
\geq & 2 \int_{\left[\left|x_{j}\right| \geq \frac{2}{u}\right]}\left(1-\frac{1}{\left|u x_{j}\right|}\right) d \lambda \mathbf{x}_{n}(x)
\end{aligned}
$$

$$
\begin{gathered}
\geq 2 \int_{\left[\left|x_{j}\right| \geq \frac{2}{u}\right]}\left(1-\frac{1}{|u|(2 / u)}\right) d \lambda \mathbf{x}_{n}(x) \\
\quad=\int_{\left[\left|x_{j}\right| \geq \frac{2}{u}\right]} 1 d \lambda_{\mathbf{x}_{n}}(x) \\
\quad=\lambda_{\mathbf{x}_{n}}\left(\left[\mathbf{x}:\left|x_{j}\right| \geq \frac{2}{u}\right]\right) .
\end{gathered}
$$

If $\varepsilon>0$ is given, there exists $r>0$ such that if $u \leq r$,

$$
\frac{1}{u} \int_{-u}^{u}\left(1-\psi\left(t \mathbf{e}_{j}\right)\right) d t<\varepsilon / p
$$

for all $j=1, \cdots, p$ and so, by the dominated convergence theorem, the same is true with $\phi_{\mathbf{X}_{n}}$ in place of $\psi$ provided $n$ is large enough, say $n \geq N(u)$. Thus, if $u \leq r$, and $n \geq N(u)$,

$$
\lambda \mathbf{x}_{n}\left(\left[\mathbf{x}:\left|x_{j}\right| \geq \frac{2}{u}\right]\right)<\varepsilon / p
$$

for all $j \in\{1, \cdots, p\}$. It follows that for $u \leq r$ and $n \geq N(u)$,

$$
\lambda_{\mathbf{x}_{n}}\left(\left[\mathbf{x}:\|\mathbf{x}\|_{\infty} \geq \frac{2}{u}\right]\right)<\varepsilon
$$

because

$$
\left[\mathbf{x}:\|\mathbf{x}\|_{\infty} \geq \frac{2}{u}\right] \subseteq \cup_{j=1}^{p}\left[\mathbf{x}:\left|x_{j}\right| \geq \frac{2}{u}\right]
$$

This proves the lemma because there are only finitely many measures, $\lambda_{\mathbf{x}_{n}}$ for $n<N(u)$ and the compact set can be enlarged finitely many times to obtain a single compact set, $K_{\varepsilon}$ such that for all $n, \lambda_{\mathbf{x}_{n}}\left(\left[\mathbf{x} \notin K_{\varepsilon}\right]\right)<\varepsilon$. This proves the lemma.
Lemma 59.18.3 If $\phi_{\mathbf{X}_{n}}(\mathbf{t}) \rightarrow \phi_{\mathbf{X}}(\mathbf{t})$ for all $\mathbf{t}$, then whenever $\psi \in \mathfrak{S}$,

$$
\lambda_{\mathbf{x}_{n}}(\psi) \equiv \int_{\mathbb{R}^{p}} \psi(\mathbf{y}) d \lambda_{\mathbf{x}_{n}}(y) \rightarrow \int_{\mathbb{R}^{p}} \psi(\mathbf{y}) d \lambda_{\mathbf{X}}(y) \equiv \lambda_{\mathbf{X}}(\psi)
$$

as $n \rightarrow \infty$.
Proof: Recall that if $\mathbf{X}$ is any random vector, its characteristic function is given by

$$
\phi_{\mathbf{X}}(\mathbf{y}) \equiv \int_{\mathbb{R}^{p}} e^{i \mathbf{y} \cdot \mathbf{x}} d \lambda_{\mathbf{X}}(x)
$$

Also remember the inverse Fourier transform. Letting $\psi \in \mathfrak{S}$, the Schwartz class,

$$
\begin{aligned}
F^{-1}\left(\lambda_{\mathbf{x}}\right)(\psi) & \equiv \lambda_{\mathbf{x}}\left(F^{-1} \psi\right) \equiv \int_{\mathbb{R}^{p}} F^{-1} \psi d \lambda_{\mathbf{x}} \\
& =\frac{1}{(2 \pi)^{p / 2}} \int_{\mathbb{R}^{p}} \int_{\mathbb{R}^{p}} e^{i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) d x d \lambda_{\mathbf{x}}(y) \\
& =\frac{1}{(2 \pi)^{p / 2}} \int_{\mathbb{R}^{p}} \psi(\mathbf{x}) \int_{\mathbb{R}^{p}} e^{i \mathbf{y} \cdot \mathbf{x}} d \lambda_{\mathbf{x}}(y) d x \\
& =\frac{1}{(2 \pi)^{p / 2}} \int_{\mathbb{R}^{p}} \psi(\mathbf{x}) \phi_{\mathbf{X}}(\mathbf{x}) d x
\end{aligned}
$$

and so, considered as elements of $\mathfrak{S}^{*}$,

$$
F^{-1}\left(\lambda_{\mathbf{x}}\right)=\phi_{\mathbf{X}}(\cdot)(2 \pi)^{-(p / 2)} \in L^{\infty}
$$

By the dominated convergence theorem

$$
\begin{aligned}
(2 \pi)^{p / 2} F^{-1}\left(\lambda_{\mathbf{x}_{n}}\right)(\psi) & \equiv \int_{\mathbb{R}^{p}} \phi_{\mathbf{X}_{n}}(\mathbf{t}) \psi(\mathbf{t}) d t \\
& \rightarrow \int_{\mathbb{R}^{p}} \phi_{\mathbf{X}}(\mathbf{t}) \psi(\mathbf{t}) d t \\
& =(2 \pi)^{p / 2} F^{-1}(\lambda \mathbf{x})(\psi)
\end{aligned}
$$

whenever $\psi \in \mathfrak{S}$. Thus

$$
\begin{aligned}
\lambda_{\mathbf{x}_{n}}(\psi) & =F F^{-1} \lambda_{\mathbf{x}_{n}}(\psi) \equiv F^{-1} \lambda_{\mathbf{x}_{n}}(F \psi) \rightarrow F^{-1} \lambda_{\mathbf{X}}(F \psi) \\
& \equiv F^{-1} F \lambda_{\mathbf{x}}(\psi)=\lambda_{\mathbf{X}}(\psi)
\end{aligned}
$$

This proves the lemma.
Lemma 59.18.4 If $\phi_{\mathbf{X}_{n}}(\mathbf{t}) \rightarrow \phi_{\mathbf{X}}(\mathbf{t})$, then if $\psi$ is any bounded uniformly continuous function,

$$
\lim _{n \rightarrow \infty} \int_{\mathbb{R}^{p}} \psi d \lambda \mathbf{x}_{n}=\int_{\mathbb{R}^{p}} \psi d \lambda \mathbf{x}
$$

Proof: Let $\varepsilon>0$ be given, let $\psi$ be a bounded function in $C^{\infty}\left(\mathbb{R}^{p}\right)$. Now let $\eta \in C_{c}^{\infty}\left(Q_{r}\right)$ where $Q_{r} \equiv[-r, r]^{p}$ satisfy the additional requirement that $\eta=1$ on $Q_{r / 2}$ and $\eta(\mathbf{x}) \in[0,1]$ for all $\mathbf{x}$. By Lemma 59.18.2 the set, $\left\{\lambda_{\mathbf{x}_{n}}\right\}_{n=1}^{\infty}$, is tight and so if $\varepsilon>0$ is given, there exists $r$ sufficiently large such that for all $n$,

$$
\int_{\left[\mathbf{x} \notin Q_{r / 2}\right]}|1-\eta||\psi| d \lambda \mathbf{x}_{n}<\frac{\varepsilon}{3}
$$

and

$$
\int_{\left[\mathbf{x} \notin \varrho_{r / 2}\right]}|1-\eta||\psi| d \lambda \mathbf{x}<\frac{\varepsilon}{3} .
$$

Thus,

$$
\begin{gathered}
\left|\int_{\mathbb{R}^{p}} \psi d \lambda_{\mathbf{x}_{n}}-\int_{\mathbb{R}^{p}} \psi d \lambda\right| \leq\left|\int_{\mathbb{R}^{p}} \psi d \lambda_{\mathbf{x}_{n}}-\int_{\mathbb{R}^{p}} \psi \eta d \lambda \mathbf{x}_{n}\right|+ \\
\left|\int_{\mathbb{R}^{p}} \psi \eta d \lambda_{\mathbf{x}_{n}}-\int_{\mathbb{R}^{p}} \psi \eta d \lambda_{\mathbf{x}}\right|+\left|\int_{\mathbb{R}^{p}} \psi \eta d \lambda_{\mathbf{x}}-\int_{\mathbb{R}^{p}} \psi d \lambda \mathbf{x}\right| \\
\leq \frac{2 \varepsilon}{3}+\left|\int_{\mathbb{R}^{p}} \psi \eta d \lambda_{\mathbf{x}_{n}}-\int_{\mathbb{R}^{p}} \psi \eta d \lambda \mathbf{x}\right|<\varepsilon
\end{gathered}
$$

whenever $n$ is large enough by Lemma 59.18 .3 because $\psi \eta \in \mathfrak{S}$. This establishes the conclusion of the lemma in the case where $\psi$ is also infinitely differentiable. To consider the general case, let $\psi$ only be uniformly continuous and let $\psi_{k}=\psi * \phi_{k}$ where $\phi_{k}$ is a mollifier whose support is in $(-(1 / k),(1 / k))^{p}$. Then $\psi_{k}$ converges uniformly to $\psi$ and so the desired conclusion follows for $\psi$ after a routine estimate. This proves the lemma.

Definition 59.18.5 Let $\mu$ be a Radon measure on $\mathbb{R}^{p}$. A Borel set, $A$, is a $\mu$ continuity set if $\mu(\partial A)=0$ where $\partial A \equiv \bar{A} \backslash \operatorname{int}(A)$ and int denotes the interior.

The main result is the following continuity theorem. More can be said about the equivalence of various criteria [19].

Theorem 59.18.6 If $\phi_{\mathbf{X}_{n}}(\mathbf{t}) \rightarrow \phi_{\mathbf{X}}(\mathbf{t})$ then $\lambda_{\mathbf{X}_{n}}(A) \rightarrow \lambda_{\mathbf{X}}(A)$ whenever $A$ is a $\lambda_{\mathbf{X}}$ continuity set.

Proof: First suppose $K$ is a closed set and let

$$
\psi_{k}(\mathbf{x}) \equiv(1-k \operatorname{dist}(\mathbf{x}, K))^{+}
$$

Thus, since $K$ is closed $\lim _{k \rightarrow \infty} \psi_{k}(\mathbf{x})=\mathscr{X}_{K}(\mathbf{x})$. Choose $k$ large enough that

$$
\int_{\mathbb{R}^{p}} \psi_{k} d \lambda_{\mathbf{x}} \leq \lambda_{\mathbf{x}}(K)+\varepsilon
$$

Then by Lemma 59.18.4, applied to the bounded uniformly continuous function $\psi_{k}$,

$$
\lim \sup _{n \rightarrow \infty} \lambda_{\mathbf{x}_{n}}(K) \leq \lim \sup _{n \rightarrow \infty} \int \psi_{k} d \lambda_{\mathbf{x}_{n}}=\int \psi_{k} d \lambda_{\mathbf{x}} \leq \lambda_{\mathbf{x}}(K)+\varepsilon
$$

Since $\varepsilon$ is arbitrary, this shows

$$
\lim \sup _{n \rightarrow \infty} \lambda_{\mathbf{x}_{n}}(K) \leq \lambda_{\mathbf{x}}(K)
$$

for all $K$ closed.
Next suppose $V$ is open and let

$$
\psi_{k}(\mathbf{x})=1-\left(1-k \operatorname{dist}\left(\mathbf{x}, \mathbf{V}^{C}\right)\right)^{+}
$$

Thus $\psi_{k}(\mathbf{x}) \in[0,1], \psi_{k}=1$ if $\operatorname{dist}\left(\mathbf{x}, V^{C}\right) \geq 1 / k$, and $\psi_{k}=0$ on $V^{C}$. Since $V$ is open, it follows

$$
\lim _{k \rightarrow \infty} \psi_{k}(\mathbf{x})=\mathscr{X}_{V}(\mathbf{x})
$$

Choose $k$ large enough that

$$
\int \psi_{k} d \lambda_{\mathbf{x}} \geq \lambda_{\mathbf{x}}(V)-\varepsilon
$$

Then by Lemma 59.18.4,

$$
\begin{gathered}
{\lim \inf _{n \rightarrow \infty}}^{\lambda_{\mathbf{x}_{n}}(V) \geq \lim _{\inf _{n \rightarrow \infty}} \int \psi_{k}(\mathbf{x}) d \lambda_{\mathbf{x}_{n}}=} \\
=\int \psi_{k}(\mathbf{x}) d \lambda_{\mathbf{x}} \geq \lambda_{\mathbf{x}}(V)-\varepsilon
\end{gathered}
$$

and since $\varepsilon$ is arbitrary,

$$
\lim _{n \rightarrow \infty} \inf _{\mathbf{x}_{n}}(V) \geq \lambda_{\mathbf{x}}(V)
$$

Now let $\lambda_{\mathbf{x}}(\partial A)=0$ for $A$ a Borel set.

$$
\begin{aligned}
\lambda_{\mathbf{X}}(\operatorname{int}(A)) & \leq \lim \inf _{n \rightarrow \infty} \lambda_{\mathbf{x}_{n}}(\operatorname{int}(A)) \leq \lim \inf _{n \rightarrow \infty} \lambda_{\mathbf{x}_{n}}(A) \leq \\
\lim \sup _{n \rightarrow \infty} \lambda_{\mathbf{x}_{n}}(A) & \leq \lim \sup _{n \rightarrow \infty} \lambda_{\mathbf{x}_{n}}(\bar{A}) \leq \lambda_{\mathbf{x}}(\bar{A})
\end{aligned}
$$

But $\lambda_{\mathbf{X}}(\operatorname{int}(A))=\lambda_{\mathbf{X}}(\bar{A})$ by assumption and so $\lim _{n \rightarrow \infty} \lambda_{\mathbf{x}_{n}}(A)=\lambda_{\mathbf{X}}(A)$ as claimed. This proves the theorem.

As an application of this theorem the following is a version of the central limit theorem in the situation in which the limit distribution is multivariate normal. It concerns a sequence of random vectors, $\left\{\mathbf{X}_{k}\right\}_{k=1}^{\infty}$, which are identically distributed, have finite mean $\mathbf{m}$, and satisfy

$$
\begin{equation*}
E\left(\left|\mathbf{X}_{k}\right|^{2}\right)<\infty \tag{59.18.41}
\end{equation*}
$$

Definition 59.18.7 For $\mathbf{X}$ a random vector with values in $\mathbb{R}^{p}$, let

$$
F_{\mathbf{X}}(\mathbf{x}) \equiv P\left(\left\{X_{j} \leq x_{j} \text { for each } j=1,2, \ldots, p\right\}\right)
$$

Theorem 59.18.8 Let $\left\{\mathbf{X}_{k}\right\}_{k=1}^{\infty}$ be random vectors satisfying 59.18.41, which are independent and identically distributed with mean $\mathbf{m}$ and positive definite covariance $\mathbf{\square} \equiv$ $E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right)$. Let

$$
\begin{equation*}
\mathbf{Z}_{n} \equiv \sum_{j=1}^{n} \frac{\mathbf{X}_{j}-\mathbf{m}}{\sqrt{n}} \tag{59.18.42}
\end{equation*}
$$

Then for $\mathbf{Z} \sim N_{p}(\mathbf{0}, \llbracket)$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} F_{\mathbf{Z}_{n}}(\mathbf{x})=F_{\mathbf{Z}}(\mathbf{x}) \tag{59.18.43}
\end{equation*}
$$

for all $\mathbf{x}$.
Proof: The characteristic function of $\mathbf{Z}_{n}$ is given by

$$
\phi_{\mathbf{Z}_{n}}(\mathbf{t})=E\left(e^{i \mathbf{t} \cdot \sum_{j=1}^{n} \frac{\mathbf{x}_{j}-\mathbf{m}}{\sqrt{n}}}\right)=\prod_{j=1}^{n} E\left(e^{i \mathbf{t} \cdot\left(\frac{\mathbf{x}_{j}-\mathbf{m}}{\sqrt{n}}\right)}\right) .
$$

By Taylor's theorem applied to real and imaginary parts of $e^{i x}$, it follows

$$
e^{i x}=1+i x-f(x) \frac{x^{2}}{2}
$$

where $|f(x)|<2$ and

$$
\lim _{x \rightarrow 0} f(x)=1
$$

Denoting $\mathbf{X}_{j}$ as $\mathbf{X}$, this implies

$$
e^{i \mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)}=1+i \mathbf{i} \cdot \frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}-f\left(\mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)\right) \frac{(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}}{2 n}
$$

Thus

$$
\begin{aligned}
& e^{i \mathbf{t} \cdot\left(\frac{\mathbf{x}-\mathbf{m}}{\sqrt{n}}\right)}=1+i \mathbf{t} \cdot \frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}-\frac{(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}}{2 n} \\
& +\left(1-f\left(\mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)\right)\right) \frac{(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}}{2 n}
\end{aligned}
$$

Thus

$$
\begin{gather*}
\phi_{\mathbf{Z}_{n}}(\mathbf{t})=\prod_{j=1}^{n}\left[1-E\left(\frac{(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}}{2 n}\right)\right. \\
\left.+E\left(\left(1-f\left(\mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)\right)\right) \frac{(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}}{2 n}\right)\right] \\
=\prod_{j=1}^{n}\left[1-\frac{1}{2 n} \mathbf{t}^{*} \Sigma \mathbf{t}+\right. \\
\left.\frac{1}{2 n} E\left(\left(1-f\left(\mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)\right)\right)(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}\right)\right] . \tag{59.18.44}
\end{gather*}
$$

(Note $(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}=\mathbf{t}^{*}(\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*} \mathbf{t}$.) Now here is a simple inequality for complex numbers whose moduli are no larger than one. I will give a proof of this at the end. It follows easily by induction.

$$
\begin{equation*}
\left|z_{1} \cdots z_{n}-w_{1} \cdots w_{n}\right| \leq \sum_{k=1}^{n}\left|z_{k}-w_{k}\right| \tag{59.18.45}
\end{equation*}
$$

Also for each $\mathbf{t}$, and all $n$ large enough,

$$
\left|\frac{1}{2 n} E\left(\left(1-f\left(\mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)\right)\right)(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}\right)\right|<1
$$

Applying 59.18.45 to 59.18.44,

$$
\begin{aligned}
\phi_{\mathbf{Z}_{n}}(\mathbf{t}) & =\left(\prod_{j=1}^{n}\left(1-\frac{1}{2 n} \mathbf{t}^{*} \Sigma \mathbf{t}\right)\right)+e_{n} \\
& =\left(1-\frac{1}{2 n} \mathbf{t}^{*} \Sigma \mathbf{t}\right)^{n}+e_{n}
\end{aligned}
$$

where

$$
\begin{aligned}
\left|e_{n}\right| & \leq \sum_{j=1}^{n}\left|\frac{1}{2 n} E\left(\left(1-f\left(\mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)\right)\right)(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}\right)\right| \\
& =\frac{1}{2}\left|E\left(\left(1-f\left(\mathbf{t} \cdot\left(\frac{\mathbf{X}-\mathbf{m}}{\sqrt{n}}\right)\right)\right)(\mathbf{t} \cdot(\mathbf{X}-\mathbf{m}))^{2}\right)\right|
\end{aligned}
$$

which converges to 0 as $n \rightarrow \infty$ by the Dominated Convergence theorem. Therefore,

$$
\lim _{n \rightarrow \infty}\left|\phi_{\mathbf{Z}_{n}}(\mathbf{t})-\left(1-\frac{\mathbf{t}^{*} \Sigma \mathbf{t}}{2 n}\right)^{n}\right|=0
$$

and so

$$
\lim _{n \rightarrow \infty} \phi_{\mathbf{Z}_{n}}(\mathbf{t})=e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}=\phi_{\mathbf{Z}}(\mathbf{t})
$$

where $\mathbf{Z} \sim N_{p}(\mathbf{0}, \boldsymbol{\square})$. Therefore, $F_{\mathbf{Z}_{n}}(\mathbf{x}) \rightarrow F_{\mathbf{Z}}(\mathbf{x})$ for all $\mathbf{x}$ because $R_{\mathbf{x}} \equiv \prod_{k=1}^{p}\left(-\infty, x_{k}\right]$ is a set of $\lambda_{\mathbf{Z}}$ continuity due to the assumption that $\lambda_{\mathbf{Z}} \ll m_{p}$ which is implied by $\mathbf{Z} \sim N_{p}(\mathbf{0}, \boldsymbol{\square})$. This proves the theorem.

Here is the proof of the little inequality used above. The inequality is obviously true if $n=1$. Assume it is true for $n$. Then since all the numbers have absolute value no larger than one,

$$
\begin{aligned}
& \left|\prod_{i=1}^{n+1} z_{i}-\prod_{i=1}^{n+1} w_{i}\right| \leq\left|\prod_{i=1}^{n+1} z_{i}-z_{n+1} \prod_{i=1}^{n} w_{i}\right| \\
& \quad+\left|z_{n+1} \prod_{i=1}^{n} w_{i}-\prod_{i=1}^{n+1} w_{i}\right| \\
& \leq\left|\prod_{i=1}^{n} z_{i}-\prod_{i=1}^{n} w_{i}\right|+\left|z_{n+1}-w_{n+1}\right| \\
& \leq \sum_{k=1}^{n+1}\left|z_{k}-w_{k}\right|
\end{aligned}
$$

by induction.
Suppose $\mathbf{X}$ is a random vector with covariance $\Sigma$ and mean $\mathbf{m}$, and suppose also that $\Sigma^{-1}$ exists. Consider $\Sigma^{-(1 / 2)}(\mathbf{X}-\mathbf{m}) \equiv \mathbf{Y}$. Then $E(\mathbf{Y})=0$ and

$$
\begin{aligned}
E\left(\mathbf{Y} \mathbf{Y}^{*}\right) & =E\left(\Sigma^{-(1 / 2)}(\mathbf{X}-\mathbf{m})\left(\mathbf{X}^{*}-\mathbf{m}\right) \Sigma^{-(1 / 2)}\right) \\
& =\Sigma^{-(1 / 2)} E\left((\mathbf{X}-\mathbf{m})\left(\mathbf{X}^{*}-\mathbf{m}\right)\right) \Sigma^{-(1 / 2)}=I
\end{aligned}
$$

Thus $\mathbf{Y}$ has zero mean and covariance $I$. This implies the following corollary to Theorem 59.18.8.

Corollary 59.18.9 Let independent identically distributed random variables,

$$
\left\{\mathbf{X}_{j}\right\}_{j=1}^{\infty}
$$

have mean $\mathbf{m}$ and positive definite covariance $\llbracket$ where $\mathbf{■}^{-1}$ exists. Then if

$$
\mathbf{Z}_{n} \equiv \sum_{j=1}^{n} \mathbf{m}^{-(1 / 2)} \frac{\left(\mathbf{X}_{j}-\mathbf{m}\right)}{\sqrt{n}}
$$

it follows that for $\mathbf{Z} \sim N_{p}(\mathbf{0}, I)$,

$$
F_{\mathbf{Z}_{n}}(\mathbf{x}) \rightarrow F_{\mathbf{Z}}(\mathbf{x})
$$

for all $\mathbf{x}$.

### 59.19 Characteristic Functions, Prokhorov Theorem

Recall one can define the characteristic function of a probability measure. In a sense it is more natural.

Definition 59.19.1 Let $\mu$ be a probability measure defined on the Borel sets of $\mathbb{R}^{p}$. Then

$$
\phi_{\mu}(\mathbf{t}) \equiv \int_{\mathbb{R}^{p}} e^{i t \cdot \mathbf{x}} d \mu
$$

Also $\left\{\mu_{n}\right\}_{n=1}^{\infty}$ is called "tight" if for all $\varepsilon>0$ there exists a compact set, $K_{\varepsilon}$ such that

$$
\mu_{n}\left(\left[\mathbf{x} \notin K_{\varepsilon}\right]\right)<\varepsilon
$$

for all $\mu_{n}$.
Then there is a version of Lemma 59.18.2 whose proof is identical to the proof of that lemma.

Lemma 59.19.2 If $\left\{\mu_{n}\right\}$ is a sequence of Borel probability measures defined on the Borel sets of $\mathbb{R}^{p}$ such that

$$
\lim _{n \rightarrow \infty} \phi_{\mu_{n}}(\mathbf{t})=\psi(\mathbf{t})
$$

for all $\mathbf{t}$, where $\psi(\mathbf{0})=1$ and $\psi$ is continuous at $\mathbf{0}$, then $\left\{\mu_{n}\right\}_{n=1}^{\infty}$ is tight.
Proof: Let $\mathbf{e}_{j}$ be the $j^{t h}$ standard unit basis vector. Letting $\mathbf{t}=t \mathbf{e}_{j}$ in the definition,

$$
\begin{align*}
& \left|\frac{1}{u} \int_{-u}^{u}\left(1-\phi_{\mu_{n}}\left(t \mathbf{e}_{j}\right)\right) d t\right|  \tag{59.19.46}\\
= & \left|\frac{1}{u} \int_{-u}^{u}\left(1-\int_{\mathbb{R}^{p}} e^{i t x_{j}} d \mu_{n}(x)\right) d t\right| \\
= & \left|\frac{1}{u} \int_{-u}^{u}\left(\int_{\mathbb{R}^{p}}\left(1-e^{i t x_{j}}\right) d \mu_{n}(x)\right) d t\right| \\
= & \left|\int_{\mathbb{R}^{p}} \frac{1}{u} \int_{-u}^{u}\left(1-e^{i t x_{j}}\right) d t d \mu_{n}(x)\right| \\
= & \left|2 \int_{\mathbb{R}^{p}}\left(1-\frac{\sin \left(u x_{j}\right)}{u x_{j}}\right) d \mu_{n}(x)\right| \\
\geq & 2 \int_{\left[\left|x_{j}\right| \geq \frac{2}{u}\right]}\left(1-\frac{1}{\left|u x_{j}\right|}\right) d \mu_{n}(x) \\
\geq & 2 \int_{\left[\left|x_{j}\right| \geq \frac{2}{u}\right]}\left(1-\frac{1}{|u|(2 / u)}\right) d \mu_{n}(x)
\end{align*}
$$

$$
\begin{aligned}
& =\int_{\left[\left|x_{j}\right| \geq \frac{2}{u}\right]} 1 d \mu_{n}(x) \\
& =\mu_{n}\left(\left[\mathbf{x}:\left|x_{j}\right| \geq \frac{2}{u}\right]\right)
\end{aligned}
$$

If $\varepsilon>0$ is given, there exists $r>0$ such that if $u \leq r$,

$$
\frac{1}{u} \int_{-u}^{u}\left(1-\psi\left(t \mathbf{e}_{j}\right)\right) d t<\varepsilon / p
$$

for all $j=1, \cdots, p$ and so, by the dominated convergence theorem, the same is true with $\phi_{\mu_{n}}$ in place of $\psi$ provided $n$ is large enough, say $n \geq N(u)$. Thus, from 59.19.46, if $u \leq r$, and $n \geq N(u)$,

$$
\mu_{n}\left(\left[\mathbf{x}:\left|x_{j}\right| \geq \frac{2}{u}\right]\right)<\varepsilon / p
$$

for all $j \in\{1, \cdots, p\}$. It follows that for $u \leq r$ and $n \geq N(u)$,

$$
\mu_{n}\left(\left[\mathbf{x}:\|\mathbf{x}\|_{\infty} \geq \frac{2}{u}\right]\right)<\varepsilon .
$$

because

$$
\left[\mathbf{x}:\|\mathbf{x}\|_{\infty} \geq \frac{2}{u}\right] \subseteq \cup_{j=1}^{p}\left[\mathbf{x}:\left|x_{j}\right| \geq \frac{2}{u}\right]
$$

This proves the lemma because there are only finitely many measures, $\mu_{n}$ for $n<N(u)$ and the compact set can be enlarged finitely many times to obtain a single compact set, $K_{\mathcal{\varepsilon}}$ such that for all $n, \mu_{n}\left(\left[\mathbf{x} \notin K_{\varepsilon}\right]\right)<\varepsilon$.

As before, there are simple modifications of Lemmas 59.18.3 and 59.18.4. The first of these is as follows.

Lemma 59.19.3 If $\phi_{\mu_{n}}(\mathbf{t}) \rightarrow \phi_{\mu}(\mathbf{t})$ for all $\mathbf{t}$, then whenever $\psi \in \mathfrak{S}$, the Schwartz class,

$$
\mu_{n}(\psi) \equiv \int_{\mathbb{R}^{p}} \psi(\mathbf{y}) d \mu_{n}(y) \rightarrow \int_{\mathbb{R}^{p}} \psi(\mathbf{y}) d \mu(y) \equiv \mu(\psi)
$$

as $n \rightarrow \infty$.
Proof: By definition,

$$
\phi_{\mu}(\mathbf{y}) \equiv \int_{\mathbb{R}^{p}} e^{i \mathbf{y} \cdot \mathbf{x}} d \mu(x)
$$

Also remember the inverse Fourier transform. Letting $\psi \in \mathfrak{S}$, the Schwartz class,

$$
\begin{aligned}
F^{-1}(\mu)(\psi) & \equiv \mu\left(F^{-1} \psi\right) \equiv \int_{\mathbb{R}^{p}} F^{-1} \psi d \mu \\
& =\frac{1}{(2 \pi)^{p / 2}} \int_{\mathbb{R}^{p}} \int_{\mathbb{R}^{p}} e^{i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) d x d \mu(y) \\
& =\frac{1}{(2 \pi)^{p / 2}} \int_{\mathbb{R}^{p}} \psi(\mathbf{x}) \int_{\mathbb{R}^{p}} e^{i \mathbf{y} \cdot \mathbf{x}} d \mu(y) d x \\
& =\frac{1}{(2 \pi)^{p / 2}} \int_{\mathbb{R}^{p}} \psi(\mathbf{x}) \phi_{\mu}(\mathbf{x}) d x
\end{aligned}
$$

and so, considered as elements of $\mathfrak{S}^{*}$,

$$
F^{-1}(\mu)=\phi_{\mu}(\cdot)(2 \pi)^{-(p / 2)} \in L^{\infty}
$$

By the dominated convergence theorem

$$
\begin{aligned}
(2 \pi)^{p / 2} F^{-1}\left(\mu_{n}\right)(\psi) & \equiv \int_{\mathbb{R}^{p}} \phi_{\mu_{n}}(\mathbf{t}) \psi(\mathbf{t}) d t \\
& \rightarrow \int_{\mathbb{R}^{p}} \phi_{\mu}(\mathbf{t}) \psi(\mathbf{t}) d t \\
& =(2 \pi)^{p / 2} F^{-1}(\mu)(\psi)
\end{aligned}
$$

whenever $\psi \in \mathfrak{S}$. Thus

$$
\begin{aligned}
\mu_{n}(\psi) & =F F^{-1} \mu_{n}(\psi) \equiv F^{-1} \mu_{n}(F \psi) \rightarrow F^{-1} \mu(F \psi) \\
& \equiv F^{-1} F \mu(\psi)=\mu(\psi)
\end{aligned}
$$

The version of Lemma 59.18.4 is the following.
Lemma 59.19.4 If $\phi_{\mu_{n}}(\mathbf{t}) \rightarrow \phi_{\mu}(\mathbf{t})$ where $\left\{\mu_{n}\right\}$ and $\mu$ are probability measures defined on the Borel sets of $\mathbb{R}^{p}$, then if $\psi$ is any bounded uniformly continuous function,

$$
\lim _{n \rightarrow \infty} \int_{\mathbb{R}^{p}} \psi d \mu_{n}=\int_{\mathbb{R}^{p}} \psi d \mu
$$

Proof: Let $\varepsilon>0$ be given, let $\psi$ be a bounded function in $C^{\infty}\left(\mathbb{R}^{p}\right)$. Now let $\eta \in$ $C_{c}^{\infty}\left(Q_{r}\right)$ where $Q_{r} \equiv[-r, r]^{p}$ satisfy the additional requirement that $\eta=1$ on $Q_{r / 2}$ and $\eta(\mathbf{x}) \in[0,1]$ for all $\mathbf{x}$. By Lemma 59.19.2 the set, $\left\{\mu_{n}\right\}_{n=1}^{\infty}$, is tight and so if $\varepsilon>0$ is given, there exists $r$ sufficiently large such that for all $n$,

$$
\int_{\left[\mathbf{x} \notin Q_{r / 2}\right]}|1-\eta||\psi| d \mu_{n}<\frac{\varepsilon}{3}
$$

and

$$
\int_{\left[\mathbf{x} \notin Q_{r / 2}\right]}|1-\eta||\psi| d \mu<\frac{\varepsilon}{3}
$$

Thus,

$$
\begin{gathered}
\left|\int_{\mathbb{R}^{p}} \psi d \mu_{n}-\int_{\mathbb{R}^{p}} \psi d \mu\right| \leq\left|\int_{\mathbb{R}^{p}} \psi d \mu_{n}-\int_{\mathbb{R}^{p}} \psi \eta d \mu_{n}\right|+ \\
\left|\int_{\mathbb{R}^{p}} \psi \eta d \mu_{n}-\int_{\mathbb{R}^{p}} \psi \eta d \mu\right|+\left|\int_{\mathbb{R}^{p}} \psi \eta d \mu-\int_{\mathbb{R}^{p}} \psi d \mu\right| \\
\leq \frac{2 \varepsilon}{3}+\left|\int_{\mathbb{R}^{p}} \psi \eta d \mu_{n}-\int_{\mathbb{R}^{p}} \psi \eta d \mu\right|<\varepsilon
\end{gathered}
$$

whenever $n$ is large enough by Lemma 59.19 .3 because $\psi \eta \in \mathfrak{S}$. This establishes the conclusion of the lemma in the case where $\psi$ is also infinitely differentiable. To consider the general case, let $\psi$ only be uniformly continuous and let $\psi_{k}=\psi * \phi_{k}$ where $\phi_{k}$ is a
mollifier whose support is in $(-(1 / k),(1 / k))^{p}$. Then $\psi_{k}$ converges uniformly to $\psi$ and so the desired conclusion follows for $\psi$ after a routine estimate.

The next theorem is really important. It gives the existence of a measure based on an assumption that a set of measures is tight. The next theorem is Prokhorov's theorem about a tight set of measures. Recall that $\Lambda$ is tight means that for every $\varepsilon>0$ there exists $K$ compact such that $\mu\left(K^{C}\right)<\varepsilon$ for all $\mu \in \Lambda$.

Theorem 59.19.5 Let $\Lambda=\left\{\mu_{n}\right\}_{n=1}^{\infty}$ be a sequence of probability measures defined on the Borel sets of $\mathbb{R}^{p}$. If $\Lambda$ is tight then there exists a probability measure, $\lambda$ and a subsequence of $\left\{\mu_{n}\right\}_{n=1}^{\infty}$, still denoted by $\left\{\mu_{n}\right\}_{n=1}^{\infty}$ such that whenever $\phi$ is a continuous bounded complex valued function defined on $E$,

$$
\lim _{n \rightarrow \infty} \int \phi d \mu_{n}=\int \phi d \lambda
$$

Proof: By tightness, there exists an increasing sequence of compact sets, $\left\{K_{n}\right\}$ such that

$$
\mu\left(K_{n}\right)>1-\frac{1}{n}
$$

for all $\mu \in \Lambda$. Now letting $\mu \in \Lambda$ and $\phi \in C\left(K_{n}\right)$ such that $\|\phi\|_{\infty} \leq 1$, it follows

$$
\left|\int_{K_{n}} \phi d \mu\right| \leq \mu\left(K_{n}\right) \leq 1
$$

and so the restrictions of the measures of $\Lambda$ to $K_{n}$ are contained in the unit ball of $C\left(K_{n}\right)^{\prime}$. Recall from the Riesz representation theorem, the dual space of $C\left(K_{n}\right)$ is a space of complex Borel measures. Theorem 17.5 .5 on Page 462 implies the unit ball of $C\left(K_{n}\right)^{\prime}$ is weak * sequentially compact. This follows from the observation that $C\left(K_{n}\right)$ is separable which follows easily from the Weierstrass approximation theorem. Thus the unit ball in $C\left(K_{n}\right)^{\prime}$ is actually metrizable by Theorem 17.5.5 on Page 462. Therefore, there exists a subsequence of $\Lambda,\left\{\mu_{1 k}\right\}$ such that their restrictions to $K_{1}$ converge weak $*$ to a measure, $\lambda_{1} \in C\left(K_{1}\right)^{\prime}$. That is, for every $\phi \in C\left(K_{1}\right)$,

$$
\lim _{k \rightarrow \infty} \int_{K_{1}} \phi d \mu_{1 k}=\int_{K_{1}} \phi d \lambda_{1}
$$

By the same reasoning, there exists a further subsequence $\left\{\mu_{2 k}\right\}$ such that the restrictions of these measures to $K_{2}$ converge weak $*$ to a measure $\lambda_{2} \in C\left(K_{2}\right)^{\prime}$ etc. Continuing this way,

$$
\begin{gathered}
\mu_{11}, \mu_{12}, \mu_{13}, \cdots \rightarrow \text { Weak } * \text { in } C\left(K_{1}\right)^{\prime} \\
\mu_{21}, \mu_{22}, \mu_{23}, \cdots \rightarrow \text { Weak } * \text { in } C\left(K_{2}\right)^{\prime} \\
\mu_{31}, \mu_{32}, \mu_{33}, \cdots \rightarrow \text { Weak } * \text { in } C\left(K_{3}\right)^{\prime} \\
\vdots
\end{gathered}
$$

Here the $j^{t h}$ sequence is a subsequence of the $(j-1)^{t h}$. Let $\lambda_{n}$ denote the measure in $C\left(K_{n}\right)^{\prime}$ to which the sequence $\left\{\mu_{n k}\right\}_{k=1}^{\infty}$ converges weak $*$. Let $\left\{\mu_{n}\right\} \equiv\left\{\mu_{n n}\right\}$, the diagonal sequence. Thus this sequence is ultimately a subsequence of every one of the above sequences and so $\mu_{n}$ converges weak $*$ in $C\left(K_{m}\right)^{\prime}$ to $\lambda_{m}$ for each $m$.

Claim: For $p>n$, the restriction of $\lambda_{p}$ to the Borel sets of $K_{n}$ equals $\lambda_{n}$.
Proof of claim: Let $H$ be a compact subset of $K_{n}$. Then there are sets, $V_{l}$ open in $K_{n}$ which are decreasing and whose intersection equals $H$. This follows because this is a metric space. Then let $H \prec \phi_{l} \prec V_{l}$. It follows

$$
\begin{aligned}
\lambda_{n}\left(V_{l}\right) & \geq \int_{K_{n}} \phi_{l} d \lambda_{n}=\lim _{k \rightarrow \infty} \int_{K_{n}} \phi_{l} d \mu_{k} \\
& =\lim _{k \rightarrow \infty} \int_{K_{p}} \phi_{l} d \mu_{k}=\int_{K_{p}} \phi_{l} d \lambda_{p} \geq \lambda_{p}(H) .
\end{aligned}
$$

Now considering the ends of this inequality, let $l \rightarrow \infty$ and pass to the limit to conclude

$$
\lambda_{n}(H) \geq \lambda_{p}(H)
$$

Similarly,

$$
\begin{aligned}
\lambda_{n}(H) & \leq \int_{K_{n}} \phi_{l} d \lambda_{n}=\lim _{k \rightarrow \infty} \int_{K_{n}} \phi_{l} d \mu_{k} \\
& =\lim _{k \rightarrow \infty} \int_{K_{p}} \phi_{l} d \mu_{k}=\int_{K_{p}} \phi_{l} d \lambda_{p} \leq \lambda_{p}\left(V_{l}\right) .
\end{aligned}
$$

Then passing to the limit as $l \rightarrow \infty$, it follows

$$
\lambda_{n}(H) \leq \lambda_{p}(H)
$$

Thus the restriction of $\lambda_{p},\left.\lambda_{p}\right|_{K_{n}}$ to the compact sets of $K_{n}$ equals $\lambda_{n}$. Then by inner regularity it follows the two measures, $\left.\lambda_{p}\right|_{K_{n}}$, and $\lambda_{n}$ are equal on all Borel sets of $K_{n}$. Recall that for finite measures on the Borel sets of separable metric spaces, regularity is obtained for free.

It is fairly routine to exploit regularity of the measures to verify that $\lambda_{m}(F) \geq 0$ for all $F$ a Borel subset of $K_{m}$. (Whenever $\phi \geq 0, \int_{K_{m}} \phi d \lambda_{m} \geq 0$ because $\int_{K_{m}} \phi d \mu_{k} \geq 0$. Now you can approximate $\mathscr{X}_{F}$ with a suitable nonnegative $\phi$ using regularity of the measure.) Also, letting $\phi \equiv 1$,

$$
\begin{equation*}
1 \geq \lambda_{m}\left(K_{m}\right) \geq 1-\frac{1}{m} \tag{59.19.47}
\end{equation*}
$$

Define for $F$ a Borel set,

$$
\lambda(F) \equiv \lim _{n \rightarrow \infty} \lambda_{n}\left(F \cap K_{n}\right)
$$

The limit exists because the sequence on the right is increasing due to the above observation that $\lambda_{n}=\lambda_{m}$ on the Borel subsets of $K_{m}$ whenever $n>m$. Thus for $n>m$

$$
\lambda_{n}\left(F \cap K_{n}\right) \geq \lambda_{n}\left(F \cap K_{m}\right)=\lambda_{m}\left(F \cap K_{m}\right)
$$

Now let $\left\{F_{k}\right\}$ be a sequence of disjoint Borel sets. Then

$$
\begin{aligned}
\lambda\left(\cup_{k=1}^{\infty} F_{k}\right) & \equiv \lim _{n \rightarrow \infty} \lambda_{n}\left(\cup_{k=1}^{\infty} F_{k} \cap K_{n}\right)=\lim _{n \rightarrow \infty} \lambda_{n}\left(\cup_{k=1}^{\infty}\left(F_{k} \cap K_{n}\right)\right) \\
& =\lim _{n \rightarrow \infty} \sum_{k=1}^{\infty} \lambda_{n}\left(F_{k} \cap K_{n}\right)=\sum_{k=1}^{\infty} \lambda\left(F_{k}\right)
\end{aligned}
$$

the last equation holding by the monotone convergence theorem.
It remains to verify

$$
\lim _{k \rightarrow \infty} \int \phi d \mu_{k}=\int \phi d \lambda
$$

for every $\phi$ bounded and continuous. This is where tightness is used again. Suppose $\|\phi\|_{\infty}<M$. Then as noted above,

$$
\lambda_{n}\left(K_{n}\right)=\lambda\left(K_{n}\right)
$$

because for $p>n, \lambda_{p}\left(K_{n}\right)=\lambda_{n}\left(K_{n}\right)$ and so letting $p \rightarrow \infty$, the above is obtained. Also, from 59.19.47,

$$
\begin{aligned}
\lambda\left(K_{n}^{C}\right) & =\lim _{p \rightarrow \infty} \lambda_{p}\left(K_{n}^{C} \cap K_{p}\right) \\
& \leq \lim _{p \rightarrow \infty}\left(\lambda_{p}\left(K_{p}\right)-\lambda_{p}\left(K_{n}\right)\right) \\
& \leq \lim _{p \rightarrow \infty}\left(\lambda_{p}\left(K_{p}\right)-\lambda_{n}\left(K_{n}\right)\right) \\
& \leq \lim \sup _{p \rightarrow \infty}\left(1-\left(1-\frac{1}{n}\right)\right)=\frac{1}{n}
\end{aligned}
$$

Consequently,

$$
\begin{aligned}
\mid \int \phi d \mu_{k} & -\int \phi d \lambda\left|\leq\left|\int_{K_{n}^{C}} \phi d \mu_{k}+\int_{K_{n}} \phi d \mu_{k}-\left(\int_{K_{n}} \phi d \lambda+\int_{K_{n}^{C}} \phi d \lambda\right)\right|\right. \\
& \leq\left|\int_{K_{n}} \phi d \mu_{k}-\int_{K_{n}} \phi d \lambda_{n}\right|+\left|\int_{K_{n}^{C}} \phi d \mu_{k}-\int_{K_{n}^{C}} \phi d \lambda\right| \\
& \leq\left|\int_{K_{n}} \phi d \mu_{k}-\int_{K_{n}} \phi d \lambda_{n}\right|+\left|\int_{K_{n}^{C}} \phi d \mu_{k}\right|+\left|\int_{K_{n}^{C}} \phi d \lambda\right| \\
& \leq\left|\int_{K_{n}} \phi d \mu_{k}-\int_{K_{n}} \phi d \lambda_{n}\right|+\frac{M}{n}+\frac{M}{n}
\end{aligned}
$$

First let $n$ be so large that $2 M / n<\varepsilon / 2$ and then pick $k$ large enough that the above expression is less than $\varepsilon$.

Definition 59.19.6 Let $\mu,\left\{\mu_{n}\right\}$ be probability measures defined on the Borel sets of $\mathbb{R}^{p}$ and let the sequence of probability measures, $\left\{\mu_{n}\right\}$ satisfy

$$
\lim _{n \rightarrow \infty} \int \phi d \mu_{n}=\int \phi d \mu
$$

for every $\phi$ a bounded continuous function. Then $\mu_{n}$ is said to converge weakly to $\mu$.
With the above, it is possible to prove the following amazing theorem of Levy.

Theorem 59.19.7 Suppose $\left\{\mu_{n}\right\}$ is a sequence of probability measures defined on the Borel sets of $\mathbb{R}^{p}$ and let $\left\{\phi_{\mu_{n}}\right\}$ denote the corresponding sequence of characteristic functions. If there exists $\psi$ which is continuous at $\mathbf{0}, \psi(\mathbf{0})=1$, and for all $\mathbf{t}$,

$$
\phi_{\mu_{n}}(\mathbf{t}) \rightarrow \psi(\mathbf{t})
$$

then there exists a probability measure, $\lambda$ defined on the Borel sets of $\mathbb{R}^{p}$ and

$$
\phi_{\lambda}(\mathbf{t})=\psi(\mathbf{t}) .
$$

That is, $\psi$ is a characteristic function of a probability measure. Also, $\left\{\mu_{n}\right\}$ converges weakly to $\lambda$.

Proof: By Lemma 59.19.2 $\left\{\mu_{n}\right\}$ is tight. Therefore, there exists a subsequence $\left\{\mu_{n_{k}}\right\}$ converging weakly to a probability measure, $\lambda$. In particular,

$$
\begin{aligned}
\phi_{\lambda}(\mathbf{t}) & =\int e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda(x)=\lim _{n \rightarrow \infty} \int e^{i \mathbf{t} \cdot \mathbf{x}} d \mu_{n_{k}}(x) \\
& =\lim _{n \rightarrow \infty} \phi_{\mu_{n_{k}}}(\mathbf{t})=\psi(\mathbf{t})
\end{aligned}
$$

The last claim follows from this and Lemma 59.19.4.
Note how it was only necessary to assume $\psi(\mathbf{0})=1$ and $\psi$ is continuous at $\mathbf{0}$ in order to conclude that $\psi$ is a characteristic function. Thus you find that $|\psi(\mathbf{t})| \leq 1$ for free. This helps to see why Prokhorov's and Levy's theorems are so amazing.

### 59.20 Generalized Multivariate Normal

In this section is a further explanation of generalized multivariable normal random variables. Recall that these have characteristic function equal to $e^{i \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}$ where $\Sigma \geq 0, \Sigma=$ $\Sigma^{*}$. The new detail is the case that $\operatorname{det}(\Sigma)=0$.

Definition 59.20.1 A random vector, $\mathbf{X}$, with values in $\mathbb{R}^{p}$ has a multivariate normal distribution written as

$$
\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)
$$

if for all Borel $E \subseteq \mathbb{R}^{p}$, the distribution measure is given by

$$
\lambda_{\mathbf{x}}(E)=\int_{\mathbb{R}^{p}} \mathscr{X}_{E}(\mathbf{x}) \frac{1}{(2 \pi)^{p / 2} \operatorname{det}(\Sigma)^{1 / 2}} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x
$$

for $\mathbf{m}$ a given vector and $\Sigma$ a given positive definite symmetric matrix. Recall also that the characteristic function of this random variable is

$$
\begin{equation*}
E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right)=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}} \tag{59.20.48}
\end{equation*}
$$

So what if $\operatorname{det}(\Sigma)=0$ ? Is there a probability measure having characteristic equation

$$
e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}} ?
$$

Let $\Sigma_{n} \rightarrow \Sigma$ in the Frobenius norm, $\operatorname{det}\left(\Sigma_{n}\right)>0$. That is the $i j^{t h}$ components converge. Let $\mathbf{X}_{n}$ be the random variable which is associated with $\mathbf{m}$ and $\Sigma_{n}$. Thus for $\phi \in C_{0}\left(\mathbb{R}^{p}\right)$,

$$
\left|\lambda \mathbf{x}_{n}(\phi)\right| \equiv\left|\int_{\mathbb{R}^{p}} \phi(\mathbf{x}) \frac{1}{(2 \pi)^{p / 2} \operatorname{det}\left(\Sigma_{n}\right)^{1 / 2}} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma_{n}^{-1}(\mathbf{x}-\mathbf{m})} d x\right| \leq\|\phi\|_{C_{0}\left(\mathbb{R}^{p}\right)}
$$

Thus these $\lambda_{\mathbf{X}_{n}}$ are bounded in the weak $*$ topology of $C_{0}\left(\mathbb{R}^{p}\right)^{\prime}$ which is the space of signed measures. By the separability of $C_{0}\left(\mathbb{R}^{p}\right)$ and the Banach Alaoglu theorem and the Riesz representation theorem for $C_{0}\left(\mathbb{R}^{p}\right)^{\prime}$, there is a subsequence still denoted as $\lambda_{\mathbf{x}_{n}}$ which converges weak $*$ to a finite measure $\mu$. Is $\mu$ a probability measure? Is the characteristic function of this measure $e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}$.

Note that $E\left(e^{i \mathbf{t} \cdot \mathbf{X}_{n}}\right)=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \dot{\Sigma}_{n} \mathbf{t}} \rightarrow e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}$ and this last function of $\mathbf{t}$ is continuous at $\mathbf{0}$. Therefore, by Lemma 59.18.2, these measures $\lambda_{\mathbf{x}_{n}}$ are also tight. Let $\varepsilon>0$ be given. Then there is a compact set $K_{\mathcal{\varepsilon}}$ such that $\lambda \mathbf{x}_{n}\left(\mathbf{x} \notin K_{\varepsilon}\right)<\varepsilon$. Now let $\phi=1$ on $K_{\mathcal{\varepsilon}}$ and $\phi \in C_{c}\left(\mathbb{R}^{p}\right), \phi \geq 0, \phi(\mathbf{x}) \in[0,1]$. Then

$$
(1-\varepsilon) \leq \int_{\mathbb{R}^{p}} \phi d \lambda_{\mathbf{x}_{n}} \rightarrow \int_{\mathbb{R}^{p}} \phi d \mu \leq \mu\left(\mathbb{R}^{p}\right)
$$

and so, since $\varepsilon$ is arbitrary, this shows that $\mu\left(\mathbb{R}^{p}\right) \geq 1$. However, $\mu\left(\mathbb{R}^{p}\right) \leq 1$ because

$$
\mu\left(\mathbb{R}^{n}\right) \leq \int_{\mathbb{R}^{p}} \psi d \mu+\varepsilon \leq \int_{\mathbb{R}^{p}} \psi d \lambda \mathbf{x}_{n}+2 \varepsilon \leq 1+2 \varepsilon
$$

for suitable $\psi \in C_{c}\left(\mathbb{R}^{p}\right)$ having values in $[0,1]$ and $n$. Thus $\mu$ is indeed a probability measure.

Now what of its characteristic function?

$$
\begin{equation*}
e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}=\lim _{n \rightarrow \infty} e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma_{n} \mathbf{t}}=\lim _{n \rightarrow \infty} \int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}(x) \tag{59.20.49}
\end{equation*}
$$

Is this equal to

$$
\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu(x) ?
$$

Using tightness again,

$$
\begin{gathered}
\left|\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu(x)-\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}(x)\right| \leq\left|\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu(x)-\int_{\mathbb{R}^{p}} \psi e^{i \cdot \mathbf{x}} d \mu(x)\right| \\
+\left|\int_{\mathbb{R}^{p}} \psi e^{i \boldsymbol{t} \cdot \mathbf{x}} d \mu(x)-\int_{\mathbb{R}^{p}} \psi e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}(x)\right|+\left|\int_{\mathbb{R}^{p}} \psi e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}(x)-\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}(x)\right| \\
\leq \varepsilon+\left|\int_{\mathbb{R}^{p}} \psi e^{i \mathbf{t} \cdot \mathbf{x}} d \mu(x)-\int_{\mathbb{R}^{p}} \psi e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}(x)\right|+\varepsilon
\end{gathered}
$$

for a suitable choice of $\psi \in C_{c}\left(\mathbb{R}^{p}\right)$ having values in $[0,1]$. The middle term is less than $\varepsilon$ if $n$ large enough thanks to the weak $*$ convergence of $\lambda \mathbf{x}_{n}$ to $\mu$. Hence the last limit in 59.20.49 equals $\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \mathbf{x}} d \mu(x)$ as hoped. Letting $\mathbf{X}$ be a random variable having $\mu$ as its distribution measure, (You could take $\Omega=\mathbb{R}^{p}$ and the measurable sets the Borel sets.) what about $E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right)$ ? Is it equal to $\Sigma$ ? What about the question whether $\mathbf{X} \in L^{q}\left(\Omega ; \mathbb{R}^{p}\right)$ for all $q>1$ ? This is clearly true for the case where $\Sigma^{-1}$ exists, but what of the case where $\operatorname{det}(\Sigma)=0$ ?

For simplicity, say $\mathbf{m}=\mathbf{0}$.

$$
\begin{gathered}
\int_{\Omega}|\mathbf{X}|^{q} d P=\int_{0}^{\infty} P\left(|\mathbf{X}|^{q}>\lambda\right) d \lambda=\int_{0}^{\infty} \mu\left(|\mathbf{x}|^{q}>\lambda\right) d \lambda \\
\leq \int_{0}^{\infty} \mu\left(|\mathbf{x}|^{q}>\lambda\right) d \lambda \leq \int_{0}^{\infty} \int_{\mathbb{R}^{p}}\left(1-\psi_{\lambda}\right) d \mu d \lambda
\end{gathered}
$$

where $\psi_{\lambda}=1$ on $B\left(\mathbf{0}, \frac{1}{2} \lambda^{1 / q}\right)$ is nonnegative, and is in $C_{c}\left(B\left(\mathbf{0}, \lambda^{1 / q}\right)\right)$. Now from the above, $\mu\left(\mathbb{R}^{p}\right)=\lambda_{\mathbf{x}_{n}}\left(\mathbb{R}^{p}\right)=1$ and so the inside integral satisfies

$$
\begin{equation*}
\int_{\mathbb{R}^{p}}\left(1-\psi_{\lambda}\right) d \mu=\lim _{n \rightarrow \infty} \int_{\mathbb{R}^{p}}\left(1-\psi_{\lambda}\right) d \lambda \mathbf{x}_{n} \tag{59.20.50}
\end{equation*}
$$

because

$$
\int_{\mathbb{R}^{p}} d \mu=\int_{\mathbb{R}^{p}} d \lambda_{\mathbf{x}_{n}}=1
$$

and as to the other terms, the weak $*$ convergence gives

$$
\int_{\mathbb{R}^{p}} \psi_{\lambda} d \mu=\lim _{n \rightarrow \infty} \int_{\mathbb{R}^{p}} \psi_{\lambda} d \lambda \mathbf{x}_{n}
$$

Each of these integrals in 59.20 .50 is no larger than 1. Hence from Fatou's lemma,

$$
\int_{\Omega}|\mathbf{X}|^{q} d P \leq \int_{0}^{\infty} \int_{\mathbb{R}^{p}}\left(1-\psi_{\lambda}\right) d \mu d \lambda \leq \lim \inf _{n \rightarrow \infty} \int_{0}^{\infty} \int_{\mathbb{R}^{p}}\left(1-\psi_{\lambda}\right) d \lambda \mathbf{x}_{n} d \lambda
$$

Is this on the right finite? It is dominated by

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \int_{0}^{\infty} \lambda_{\mathbf{x}_{n}}\left(|\mathbf{x}|^{q}>\frac{1}{2^{q}} \lambda\right) d \lambda & =\lim _{n \rightarrow \infty} 2^{q} \int_{0}^{\infty} \lambda_{\mathbf{x}_{n}}\left(|\mathbf{x}|^{q}>\delta\right) d \delta \\
& =\liminf _{n \rightarrow \infty} 2^{q} E\left(\left|\mathbf{X}_{n}\right|^{q}\right)
\end{aligned}
$$

So is a subsequence of $\left\{E\left(\left|\mathbf{X}_{n}\right|^{q}\right)\right\}$ bounded? It equals

$$
\int_{\mathbb{R}^{p}}|\mathbf{x}|^{q} \frac{1}{(2 \pi)^{p / 2} \operatorname{det}\left(\Sigma_{n}\right)^{1 / 2}} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma_{n}^{-1}(\mathbf{x}-\mathbf{m})} d x
$$

and for $q$ an even integer, this moment can be computed using the characteristic function.

$$
e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma_{n} \mathbf{t}}=\int_{\mathbb{R}^{p}} e^{i \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}
$$

Also, it suffices to consider $E\left(X_{k}^{q}\right)$. Differentiate both sides. Using the repeated index summation convention,

$$
e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}\left(-\Sigma_{n k j} t_{j}\right)=\int_{\mathbb{R}^{p}} i x_{k} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu
$$

Now differentiate again.

$$
e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}\left(-\Sigma_{n k j} t_{j}\right)\left(-\Sigma_{n k j} t_{j}\right)+\left(-\Sigma_{n k k}\right)=-\int_{\mathbb{R}^{p}} x_{k}^{2} e^{i \mathbf{t} \cdot \mathbf{x}} d \lambda \mathbf{x}_{n}
$$

Next let $\mathbf{t}=\mathbf{0}$ to conclude that $E\left(X_{n k}^{2}\right)=\Sigma_{n k k}$. Of course you can continue differentiating as long as desired and obtain $E\left(X_{n k}^{2 m}\right)$ is equal to some polynomial formula involving $\Sigma_{n k k}$ and these are given to converge to $\Sigma_{k k}$. Therefore, for any $q>1,\left\{E\left(\left|\mathbf{X}_{n}\right|^{q}\right)\right\}$ is bounded and so from the above,

$$
\int_{\Omega}|\mathbf{X}|^{q} d P \leq \lim \inf _{n \rightarrow \infty} 2^{q} E\left(\left|\mathbf{X}_{n}\right|^{q}\right)<\infty
$$

So yes, $\mathbf{X}$ is indeed in $L^{q}\left(\Omega, \mathbb{R}^{p}\right)$ for every $q$. What about the covariance?
From the definition of the characteristic function,

$$
e^{-\frac{1}{2} *^{*} \Sigma \mathbf{t}}=\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu
$$

and so taking the derivative with respect to $t_{k}$ of both sides,

$$
e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}\left(-\Sigma_{k j} t_{j}\right)=\int_{\mathbb{R}^{p}} i x_{k} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu
$$

Now differentiate with respect to $t_{l}$ on both sides.

$$
\begin{aligned}
& e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}\left(-\Sigma_{l i} t_{i}\right)\left(-\Sigma_{k j} t_{j}\right)+e^{-\frac{1}{2} *^{*} \Sigma \mathbf{t}}\left(-\Sigma_{k l}\right) \\
= & \int_{\mathbb{R}^{p}} i x_{k}\left(i x_{l}\right) e^{i \mathbf{t} \cdot \mathbf{x}} d \mu=-\int_{\mathbb{R}^{p}} x_{k} x_{l} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu
\end{aligned}
$$

Now let $\mathbf{t}=\mathbf{0}$ to obtain

$$
\Sigma_{k l}=\int_{\mathbb{R}^{p}} x_{k} x_{l} e^{i t \cdot \mathbf{x}} d \mu=E\left(X_{k} X_{l}\right)
$$

If $\mathbf{m} \neq \mathbf{0}$, the same kind of argument holds with a little more details. This proves the following theorem.

Theorem 59.20.2 Let $\Sigma$ be nonnegative and self adjoint $p \times p$ matrix. Then there exists $a$ random variable $\mathbf{X}$ whose distribution measure $\lambda_{\mathbf{X}}$ has characteristic function

$$
e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}
$$

Also

$$
E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right)=\Sigma
$$

that is

$$
E\left((X-m)_{i}(X-m)_{j}\right)=\Sigma_{i j}
$$

This is generalized normally distributed random variable.

There is an interesting corollary to this theorem.
Corollary 59.20.3 Let $H$ be a real Hilbert space. There exist random variables $W$ (h) for $h \in H$ such that each is normally distributed with mean 0 and for every $h, g,(W(h), W(g))$ is normally distributed and

$$
E(W(h) W(g))=(h, g)_{H}
$$

Furthermore, if $\left\{e_{i}\right\}$ is an orthogonal set of vectors of $H$, then $\left\{W\left(e_{i}\right)\right\}$ are independent random variables. Also for any finite set $\left\{f_{1}, f_{2}, \cdots, f_{n}\right\}$,

$$
\left(W\left(f_{1}\right), W\left(f_{2}\right), \cdots, W\left(f_{n}\right)\right)
$$

is normally distributed.
Proof: Let $\mu_{h_{1} \cdots h_{m}}$ be a multivariate normal distribution with covariance $\Sigma_{i j}=\left(h_{i}, h_{j}\right)$ and mean 0 . Thus the characteristic function of this measure is

$$
e^{-\frac{1}{2} t^{*} \Sigma \mathbf{t}}
$$

Now suppose $\mu_{k_{1} \cdots k_{n}}$ is another such measure where for simplicity,

$$
\left\{h_{1} \cdots h_{m}, k_{m+1} \cdots k_{n}\right\}=\left\{k_{1} \cdots k_{n}\right\}
$$

Let $v$ be a measure on $\mathscr{B}\left(\mathbb{R}^{m}\right)$ which is given by

$$
v(E) \equiv \mu_{k_{1} \cdots k_{n}}\left(E \times \mathbb{R}^{n-m}\right)
$$

Then does it follow that $v=\mu_{h_{1} \cdots h_{m}}$ ? If so, then the Kolmogorov consistency condition will hold for these measures $\mu_{h_{1} \ldots h_{m}}$. To determine whether this is so, take the characteristic function of $v$. Let $\Sigma_{1}$ be the $n \times n$ matrix which comes from the $\left\{k_{1} \cdots k_{n}\right\}$ and let $\Sigma_{2}$ be the one which comes from the $\left\{h_{1} \cdots h_{m}\right\}$.

$$
\begin{aligned}
\int_{\mathbb{R}^{m}} e^{i \mathbf{t} \cdot \mathbf{x}} d v(x) & \equiv \int_{\mathbb{R}^{n-m}} \int_{\mathbb{R}^{m}} e^{i(\mathbf{t}, \mathbf{0}) \cdot(\mathbf{x}, \mathbf{y})} d \mu_{k_{1} \cdots k_{n}}(x, y) \\
& =e^{-\frac{1}{2}\left(\mathbf{t}^{*}, \mathbf{0}^{*}\right) \Sigma_{1}(\mathbf{t}, \mathbf{0})}=e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma_{2} \mathbf{t}}
\end{aligned}
$$

which is the characteristic function for $\mu_{h_{1} \cdots h_{m}}$. Therefore, these two measures are the same and the Kolmogorov consistency condition holds. It follows that there exists a measure $\mu$ defined on the Borel sets of $\prod_{h \in H} \mathbb{R}$ which extends all of these measures. This argument also shows that if a random vector $\mathbf{X}$ has characteristic function $e^{-\frac{1}{2} t^{*} \Sigma \mathbf{t}}$, then if $X_{k}$ is one of its components, then the characteristic function of $X_{k}$ is $e^{-\frac{1}{2} t^{2}\left|h_{k}\right|^{2}}$ so this scalar valued random variable has mean zero and variance $\left|h_{k}\right|^{2}$. Then if $\omega \in \prod_{h \in H} \mathbb{R}$

$$
W(h)(\omega) \equiv \pi_{h}(\omega)
$$

where $\pi_{h}$ denotes the projection onto position $h$ in this product. Also define

$$
\left(W\left(f_{1}\right), W\left(f_{2}\right), \cdots, W\left(f_{n}\right)\right) \equiv \pi_{f_{1} \cdots f_{n}}(\omega)
$$

Then this is a random variable whose covariance matrix is just $\Sigma_{i j}=\left(f_{i}, f_{j}\right)_{H}$ and whose characteristic equation is $e^{-\frac{1}{2} t^{*} \Sigma t}$ so this verifies that

$$
\left(W\left(f_{1}\right), W\left(f_{2}\right), \cdots, W\left(f_{n}\right)\right)
$$

is normally distributed with covariance $\Sigma$. If you have two of them, $W(g), W(h)$, then $E(W(h) W(g))=(h, g)_{H}$. This follows from what was just shown that $(W(f), W(g))$ is normally distributed and so the covariance will be

$$
\left(\begin{array}{cc}
|f|^{2} & (f, g) \\
(f, g) & |g|^{2}
\end{array}\right)=\left(\begin{array}{cc}
E\left(W(f)^{2}\right) & E(W(f) W(g)) \\
E(W(f) W(g)) & E\left(W(g)^{2}\right)
\end{array}\right)
$$

Finally consider the claim about independence. Any finite subset of $\left\{W\left(e_{i}\right)\right\}$ is generalized normal with the covariance matrix being a diagonal. Therefore, writing in terms of the distribution measures, this diagonal matrix allows the iterated integrals to be split apart and it follows that

$$
E\left(\exp \left(i \sum_{k=1}^{m} t_{k} W\left(e_{k}\right)\right)\right)=\prod_{k=1}^{m} \exp \left(i t_{k} W\left(e_{k}\right)\right)
$$

and so this follows from Proposition 59.11.1. Note that in this case, the covariance matrix will not have zero determinant.

### 59.21 Positive Definite Functions, Bochner's Theorem

First here is a nice little lemma about matrices.
Lemma 59.21.1 Suppose $M$ is an $n \times n$ matrix. Suppose also that

$$
\alpha^{*} M \alpha=0
$$

for all $\alpha \in \mathbb{C}^{n}$. Then $M=0$.
Proof: Suppose $\lambda$ is an eigenvalue for $M$ and let $\alpha$ be an associated eigenvector.

$$
0=\alpha^{*} M \alpha=\alpha^{*} \lambda \alpha=\lambda \alpha^{*} \alpha=\lambda|\alpha|^{2}
$$

and so all the eigenvalues of $M$ equal zero. By Schur's theorem there is a unitary matrix $U$ such that

$$
M=U\left(\begin{array}{ccc}
0 & & *_{1}  \tag{59.21.51}\\
& \ddots & \\
0 & & 0
\end{array}\right) U^{*}
$$

where the matrix in the middle has zeros down the main diagonal and zeros below the main diagonal. Thus

$$
M^{*}=U\left(\begin{array}{ccc}
0 & & 0 \\
& \ddots & \\
*_{2} & & 0
\end{array}\right) U^{*}
$$

where $M^{*}$ has zeros down the main diagonal and zeros above the main diagonal. Also taking the adjoint of the given equation for $M$, it follows that for all $\alpha$,

$$
\alpha^{*} M^{*} \alpha=0
$$

Therefore, $M+M^{*}$ is Hermitian and has the property that

$$
\alpha^{*}\left(M+M^{*}\right) \alpha=0
$$

Thus $M+M^{*}=0$ because it is unitarily similar to a diagonal matrix and the above equation can only hold for all $\alpha$ if $M+M^{*}$ has all zero eigenvalues which implies the diagonal matrix has zeros down the main diagonal. Therefore, from the formulas for $M, M^{*}$,

$$
0=U\left(\left(\begin{array}{ccc}
0 & & 0 \\
& \ddots & \\
*_{2} & & 0
\end{array}\right)+\left(\begin{array}{ccc}
0 & & *_{1} \\
& \ddots & \\
0 & & 0
\end{array}\right)\right) U^{*}
$$

and so the sum of the two matrices in the middle must also equal 0 . Hence the entries of the matrix in the middle in 59.21 .51 are all equal to zero. Thus $M=0$ as claimed.

Definition 59.21.2 A Borel measurable function, $f: \mathbb{R}^{n} \rightarrow \mathbb{C}$ is called positive definite if whenever $\left\{\mathbf{t}_{\mathbf{k}}\right\}_{k=1}^{p} \subseteq \mathbb{R}^{n}, \alpha \in \mathbb{C}^{p}$

$$
\begin{equation*}
\sum_{k, j} f\left(\mathbf{t}_{j}-\mathbf{t}_{k}\right) \alpha_{j} \overline{\alpha_{k}} \geq 0 \tag{59.21.52}
\end{equation*}
$$

The first thing to notice about a positive definite function is the following which implies these functions are automatically bounded.

Lemma 59.21.3 If $f$ is positive definite then whenever $\left\{\mathbf{t}_{k}\right\}_{k=1}^{p}$ are $p$ points in $\mathbb{R}^{n}$,

$$
\left|f\left(\mathbf{t}_{j}-\mathbf{t}_{k}\right)\right| \leq f(\mathbf{0})
$$

In particular, for all $\mathbf{t},|f(\mathbf{t})| \leq f(\mathbf{0})$.
Proof: Let $F$ be the $p \times p$ matrix such that

$$
F_{k j}=f\left(\mathbf{t}_{j}-\mathbf{t}_{k}\right)
$$

Then 59.21 .52 is of the form

$$
\begin{equation*}
\alpha^{*} F \alpha=(F \alpha, \alpha) \geq 0 \tag{59.21.53}
\end{equation*}
$$

where this is the inner product in $\mathbb{C}^{p}$. Letting $[\alpha, \beta] \equiv(F \alpha, \beta) \equiv \beta^{*} F \alpha$, it is obvious that $[\alpha, \beta]$ satisfies

$$
[\alpha, \alpha] \geq 0,[a \alpha+b \beta, \gamma]=a[\alpha, \gamma]+b[\beta, \gamma]
$$

I claim it also satisfies

$$
[\alpha, \beta]=\overline{[\beta, \alpha]}
$$

To verify this last claim, note that since $\alpha^{*} F \alpha$ is real,

$$
\alpha^{*} F^{*} \alpha=\alpha^{*} F \alpha \geq \mathbf{0}
$$

and so for all $\alpha \in \mathbb{C}^{p}$,

$$
\alpha^{*}\left(F^{*}-F\right) \alpha=0
$$

which from Lemma 59.21.1 implies $F^{*}=F$. Hence $F$ is self adjoint and it follows

$$
[\alpha, \beta] \equiv \beta^{*} F \alpha=\beta^{*} F^{*} \alpha=\alpha^{T} F^{* T} \bar{\beta}=\overline{\alpha^{*} F \beta}=\overline{[\beta, \alpha]} .
$$

Therefore, the Cauchy Schwarz inequality holds for $[\cdot, \cdot]$ and it follows

$$
|[\alpha, \beta]|=|(F \alpha, \beta)| \leq(F \alpha, \alpha)^{1 / 2}(F \beta, \beta)^{1 / 2}
$$

Letting $\alpha=\mathbf{e}_{k}$ and $\beta=\mathbf{e}_{j}$, it follows $F_{s s} \geq 0$ for all $s$ and

$$
\left|F_{k j}\right| \leq F_{k k}^{1 / 2} F_{j j}^{1 / 2}
$$

which says nothing more than

$$
\left|f\left(\mathbf{t}_{j}-\mathbf{t}_{k}\right)\right| \leq f(0)^{1 / 2} f(0)^{1 / 2}=f(0)
$$

This proves the lemma.
With this information, here is another useful lemma involving positive definite functions. It is interesting because it looks like the formula which defines what it means for the function to be positive definite.

Lemma 59.21.4 Let $f$ be a positive definite function as defined above and let $\mu$ be a finite Borel measure. Then

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{x}-\mathbf{y}) d \mu(x) d \mu(y) \geq 0 \tag{59.21.54}
\end{equation*}
$$

If $\mu$ also has the property that it is symmetric, $\mu(F)=\mu(-F)$ for all $F$ Borel, then

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} f(\mathbf{x}) d(\mu * \mu)(x) \geq 0 \tag{59.21.55}
\end{equation*}
$$

Proof: By definition if $\left\{t_{j}\right\}_{j=1}^{p} \subseteq \mathbb{R}^{n}$, and letting $\alpha=(1, \cdots, 1)^{T} \in \mathbb{R}^{n}$,

$$
\sum_{j, k} f\left(\mathbf{t}_{j}-\mathbf{t}_{k}\right) \geq 0
$$

Therefore, integrating over each of the variables,

$$
0 \leq \sum_{j=1}^{p} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f\left(\mathbf{t}_{j}-\mathbf{t}_{j}\right) d \mu\left(t_{j}\right) d \mu\left(t_{j}\right)+\sum_{j \neq k} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f\left(\mathbf{t}_{j}-\mathbf{t}_{k}\right) d \mu\left(t_{j}\right) d \mu\left(t_{k}\right)
$$

and so

$$
0 \leq f(0) \mu\left(\mathbb{R}^{n}\right)^{2} p+p(p-1) \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{x}-\mathbf{y}) d \mu(x) d \mu(y)
$$

Dividing both sides by $p(p-1)$ and letting $p \rightarrow \infty$, it follows

$$
0 \leq \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{x}-\mathbf{y}) d \mu(x) d \mu(y)
$$

which shows 59.21.54.
To verify 59.21.55, use 59.14.25.

$$
\int_{\mathbb{R}^{n}} f d(\mu * \mu)=\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{x}+\mathbf{y}) d \mu(x) d \mu(y)
$$

and since $\mu$ is symmetric, this equals

$$
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{x}-\mathbf{y}) d \mu(x) d \mu(y) \geq 0
$$

by the first part of the lemma. This proves the lemma.
Lemma 59.21.5 Let $\mu_{t}$ be the measure defined on $\mathscr{B}\left(\mathbb{R}^{n}\right)$ by

$$
\mu_{t}(F) \equiv \int_{F} \frac{1}{(\sqrt{2 \pi t})^{n}} e^{-\frac{1}{2 t}|\mathbf{x}|^{2}} d x
$$

for $t>0$. Then $\mu_{t} * \mu_{t}=\mu_{2 t}$ and each $\mu_{t}$ is a probability measure.
Proof: By Theorem 59.14.7,

$$
\phi_{\mu_{t} * \mu_{t}}(\mathbf{s})=\phi_{\mu_{t}}(\mathbf{s}) \phi_{\mu_{t}}(\mathbf{s})=\left(e^{-\frac{1}{2} t|\mathbf{s}|^{2}}\right)^{2}=e^{-\frac{1}{2}(2 t)|\mathbf{s}|^{2}}=\phi_{\mu_{2 t}}(\mathbf{s})
$$

Each $\mu_{t}$ is a probability measure because it is the distribution of a normally distributed random variable of mean $\mathbf{0}$ and covariance $t I$.

Now let $\mu$ be a probability measure on $\mathscr{B}\left(\mathbb{R}^{n}\right)$.

$$
\phi_{\mu}(\mathbf{t}) \equiv \int e^{i \cdot \mathbf{t} \cdot \mathbf{y}} d \mu(y)
$$

and so by the dominated convergence theorem, $\phi_{\mu}$ is continuous and also $\phi_{\mu}(\mathbf{0})=1$. I claim $\phi_{\mu}$ is also positive definite. Let $\alpha \in \mathbb{C}^{p}$ and $\left\{\mathbf{t}_{k}\right\}_{k=1}^{p}$ a sequence of points of $\mathbb{R}^{n}$. Then

$$
\begin{gathered}
\sum_{k, j} \phi_{\mu}\left(\mathbf{t}_{k}-\mathbf{t}_{j}\right) \alpha_{k} \overline{\alpha_{j}}=\sum_{k, j} \int e^{i \mathbf{t}_{k} \cdot \mathbf{y}} \alpha_{k} e^{-i \mathbf{t}_{j} \cdot \mathbf{y}} \overline{\alpha_{j}} d \mu(y) \\
=\int \sum_{k, j} e^{i \boldsymbol{t}_{k} \cdot \mathbf{y}} \alpha_{k} e^{i_{j} \cdot \mathbf{y}} \alpha_{j} d \mu(y) .
\end{gathered}
$$

Now let $\beta(\mathbf{y}) \equiv\left(e^{i \mathbf{t}_{1} \cdot \mathbf{y}} \alpha_{1}, \cdots, e^{i \mathbf{t}_{p} \cdot \mathbf{y}} \alpha_{p}\right)^{T}$. Then the above equals

$$
\int(1, \cdots, 1) \beta(\mathbf{y}) \beta^{*}(\mathbf{y})\left(\begin{array}{c}
1 \\
\vdots \\
1
\end{array}\right) d \mu
$$

The integrand is of the form

$$
\overline{\left(\beta^{*}\left(\begin{array}{c}
1 \\
\vdots \\
1
\end{array}\right)\right)}\left(\beta^{*}\left(\begin{array}{c}
1 \\
\vdots \\
1
\end{array}\right)\right) \geq 0
$$

because it is just a complex number times its conjugate.
Thus every characteristic function is continuous, equals 1 at $\mathbf{0}$, and is positive definite. Bochner's theorem goes the other direction.

To begin with, suppose $\mu$ is a finite measure on $\mathscr{B}\left(\mathbb{R}^{n}\right)$. Then for $\mathfrak{S}$ the Schwartz class, $\mu$ can be considered to be in the space of linear transformations defined on $\mathfrak{S}$, $\mathfrak{S}^{*}$ as follows.

$$
\mu(f) \equiv \int f d \mu
$$

Recall $F^{-1}(\mu)$ is defined as

$$
\begin{aligned}
& F^{-1}(\mu)(f) \equiv \mu\left(F^{-1} f\right)=\int_{\mathbb{R}^{n}} F^{-1} f d \mu \\
& \quad=\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} e^{i \mathbf{x} \cdot \mathbf{y}} f(\mathbf{y}) d y d \mu \\
& \quad=\int_{\mathbb{R}^{n}}\left(\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} e^{i \mathbf{x} \cdot \mathbf{y}} d \mu\right) f(\mathbf{y}) d y
\end{aligned}
$$

and so $F^{-1}(\mu)$ is the bounded continuous function

$$
\mathbf{y} \rightarrow \frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} e^{i \mathbf{x} \cdot \mathbf{y}} d \mu
$$

Now the following lemma has the main ideas for Bochner's theorem.
Lemma 59.21.6 Suppose $\psi(\mathbf{t})$ is positive definite, $\mathbf{t} \rightarrow \psi(\mathbf{t})$ is in $L^{1}\left(\mathbb{R}^{n}, m_{n}\right)$ where $m_{n}$ is Lebesgue measure, $\psi(\mathbf{0})=1$, and $\psi$ is continuous at $\mathbf{0}$. Then there exists a unique probability measure, $\mu$ defined on the Borel sets of $\mathbb{R}^{n}$ such that

$$
\phi_{\mu}(\mathbf{t})=\psi(\mathbf{t})
$$

Proof: If the conclusion is true, then

$$
\psi(\mathbf{t})=\int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu(x)=(2 \pi)^{n / 2} F^{-1}(\mu)(\mathbf{t})
$$

Recall that $\mu \in \mathfrak{S}^{*}$, the algebraic dual of $\mathfrak{S}$. Therefore, in $\mathfrak{S}^{*}$,

$$
\frac{1}{(2 \pi)^{n / 2}} F(\psi)=\mu
$$

That is, for all $f \in \mathfrak{S}$,

$$
\begin{align*}
\int_{\mathbb{R}^{n}} f(\mathbf{y}) d \mu(y) & =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} F(\psi)(\mathbf{y}) f(\mathbf{y}) d y \\
& =\frac{1}{(2 \pi)^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{y})\left(\int_{\mathbb{R}^{n}} e^{-i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) d x\right) d y \tag{59.21.56}
\end{align*}
$$

I will show

$$
f \rightarrow \frac{1}{(2 \pi)^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{y})\left(\int_{\mathbb{R}^{n}} e^{-i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) d x\right) d y
$$

is a positive linear functional and then it will follow from 59.21 .56 that $\mu$ is unique. Thus it is needed to show the inside integral in 59.21.56 is nonnegative. First note that the integrand is a positive definite function of $\mathbf{x}$ for each fixed $\mathbf{y}$. This follows from

$$
\begin{aligned}
& \sum_{k, j} e^{-i \mathbf{y} \cdot\left(\mathbf{x}_{k}-\mathbf{x}_{j}\right)} \psi\left(\mathbf{x}_{k}-\mathbf{x}_{j}\right) \alpha_{k} \overline{\alpha_{j}} \\
= & \sum_{k, j} \psi\left(\mathbf{x}_{k}-\mathbf{x}_{j}\right)\left(e^{-i \mathbf{y} \cdot\left(\mathbf{x}_{k}\right)} \alpha_{k}\right) \overline{e^{-i \mathbf{y} \cdot\left(\mathbf{x}_{j}\right)} \alpha_{j}} \geq 0 .
\end{aligned}
$$

Let $t>0$ and

$$
h_{2 t}(\mathbf{x}) \equiv \frac{1}{(4 \pi t)^{1 / 2}} e^{-\frac{1}{4 t}|\mathbf{x}|^{2}}
$$

Then by dominated convergence theorem,

$$
\int_{\mathbb{R}^{n}} e^{-i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) d x=\lim _{t \rightarrow \infty} \int_{\mathbb{R}^{n}} e^{-i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) h_{2 t}(\mathbf{x}) d x
$$

Letting $d \eta_{2 t}=h_{2 t}(\mathbf{x}) d x$, it follows from Lemma 59.21.5 $\eta_{2 t}=\eta_{t} * \eta_{t}$ and since these are symmetric measures, it follows from Lemma 59.21.4 the above equals

$$
\lim _{t \rightarrow \infty} \int_{\mathbb{R}^{n}} e^{-i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) d\left(\eta_{t} * \eta_{t}\right) \geq 0
$$

Thus the above functional is a positive linear functional and so there exists a unique Radon measure, $\mu$ satisfying

$$
\begin{aligned}
\int_{\mathbb{R}^{n}} f(\mathbf{y}) d \mu(y) & =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} F(\psi)(\mathbf{y}) f(\mathbf{y}) d y \\
& =\frac{1}{(2 \pi)^{n}} \int_{\mathbb{R}^{n}} f(\mathbf{y})\left(\int_{\mathbb{R}^{n}} e^{-i \mathbf{y} \cdot \mathbf{x}} \psi(\mathbf{x}) d x\right) d y \\
& =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \psi(\mathbf{x})\left(\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} f(\mathbf{y}) e^{-i \mathbf{y} \cdot \mathbf{x}} d y\right) d x
\end{aligned}
$$

for all $f \in C_{c}\left(\mathbb{R}^{n}\right)$. Thus from the dominated convergence theorem, the above holds for all $f \in \mathfrak{S}$ also. Hence for all $f \in \mathfrak{S}$ and considering $\mu$ as an element of $\mathfrak{S}^{*}$,

$$
\begin{aligned}
F^{-1} \mu(F f) & =\mu(f)=\int_{\mathbb{R}^{n}} f(\mathbf{y}) d \mu(y) \\
& =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \psi(\mathbf{x}) F(f)(\mathbf{x}) d x \\
& =\frac{1}{(2 \pi)^{n / 2}} F(\psi)(f) \equiv \frac{1}{(2 \pi)^{n / 2}} \psi(F f) .
\end{aligned}
$$

It follows that in $\mathfrak{S}^{*}$,

$$
\psi=(2 \pi)^{n / 2} F^{-1} \mu
$$

Thus

$$
\psi(\mathbf{t})=\int_{\mathbb{R}^{n}} e^{i t \cdot x} d \mu
$$

in $L^{1}$. Since the right side is continuous and the left is given continuous at $\mathbf{t}=\mathbf{0}$ and equal to 1 there, it follows

$$
1=\psi(\mathbf{0})=\int_{\mathbb{R}^{n}} e^{i \boldsymbol{0} \cdot \mathbf{x}} d \mu=\mu\left(\mathbb{R}^{n}\right)
$$

and so $\mu$ is a probability measure as claimed. This proves the lemma.
The following is Bochner's theorem.
Theorem 59.21.7 Let $\psi$ be positive definite, continuous at $\mathbf{0}$, and $\psi(\mathbf{0})=1$. Then there exists a unique Radon probability measure $\mu$ such that $\psi=\phi_{\mu}$.

Proof: If $\psi \in L^{1}\left(\mathbb{R}^{n}, m_{n}\right)$, then the result follows from Lemma 59.21.6. By Lemma 59.21.3 $\psi$ is bounded. Consider

$$
\psi_{t}(\mathbf{x}) \equiv \psi(\mathbf{x}) \frac{1}{(2 \pi t)^{n / 2}} e^{-\frac{1}{2 t}|\mathbf{x}|^{2}}
$$

Then $\psi_{t}(\mathbf{0})=1, \mathbf{x} \rightarrow \psi_{t}(\mathbf{x})$ is continuous at $\mathbf{0}$, and $\psi_{t} \in L^{1}\left(\mathbb{R}^{n}, m_{n}\right)$. Therefore, by Lemma 59.21.6 there exists a unique Radon probability measure $\mu_{t}$ such that

$$
\psi_{t}(\mathbf{x})=\int_{\mathbb{R}^{n}} e^{i \mathbf{x} \cdot \mathbf{y}} d \mu_{t}(y)=\phi_{\mu_{t}}(\mathbf{x})
$$

Now letting $t \rightarrow \infty$,

$$
\lim _{t \rightarrow \infty} \psi_{t}(\mathbf{x})=\lim _{t \rightarrow \infty} \phi_{\mu_{t}}(\mathbf{x})=\psi(\mathbf{x})
$$

By Levy's theorem, Theorem 59.19.7 it follows there exists $\mu$, a probability measure on $\mathscr{B}\left(\mathbb{R}^{n}\right)$ such that $\psi(\mathbf{x})=\phi_{\mu}(\mathbf{x})$. The measure is unique because the characteristic functions are uniquely determined by the measure. This proves the theorem.

## Chapter 60

## Conditional, Martingales

### 60.1 Conditional Expectation

From Observation 59.11 .5 on Page 1893, it was shown that the conditional expectation of a random variable $\mathbf{X}$ given some others really is just what the words suggest. Given $\omega \in \Omega$, it results in a value for the "other" random variables and then you essentially take the expectation of $\mathbf{X}$ given this information which yields the value of the conditional expectation of $\mathbf{X}$ given the other random variables. It was also shown in Lemma 59.11.4 that this gives the same result as finding a $\sigma\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right)$ measurable function $\mathbf{Z}$ such that for all $F \in \sigma\left(\mathbf{X}_{1}, \cdots, \mathbf{X}_{n}\right)$,

$$
\int_{F} \mathbf{X} d P=\int_{F} \mathbf{Z} d P
$$

This was done for a particular type of $\sigma$ algebra but there is no need to be this specialized. The following is the general version of conditional expectation given a $\sigma$ algebra. It makes perfect sense to ask for the conditional expectation given a $\sigma$ algebra and this is what will be done from now on.

Definition 60.1.1 Let $(\Omega, \mathscr{M}, P)$ be a probability space and let $\mathscr{S} \subseteq \mathscr{F}$ be two $\sigma$ algebras contained in $\mathscr{M}$. Let $f$ be $\mathscr{F}$ measurable and in $L^{1}(\Omega)$. Then $E(f \mid \mathscr{S})$, called the conditional expectation of $f$ with respect to $\mathscr{S}$ is defined as follows:

$$
E(f \mid \mathscr{S}) \text { is } \mathscr{S} \text { measurable }
$$

For all $E \in \mathscr{S}$,

$$
\int_{E} E(f \mid \mathscr{S}) d P=\int_{E} f d P
$$

Lemma 60.1.2 The above is well defined. Also, if $\mathscr{S} \subseteq \mathscr{F}$ then

$$
\begin{equation*}
E(X \mid \mathscr{S})=E(E(X \mid \mathscr{F}) \mid \mathscr{S}) \tag{60.1.1}
\end{equation*}
$$

If $Z$ is bounded and measurable in $\mathscr{S}$ then

$$
\begin{equation*}
Z E(X \mid \mathscr{S})=E(Z X \mid \mathscr{S}) \tag{60.1.2}
\end{equation*}
$$

Proof: Let a finite measure on $\mathscr{S}, \mu$ be given by

$$
\mu(E) \equiv \int_{E} f d P
$$

Then $\mu \ll P$ and so by the Radon Nikodym theorem, there exists a unique $\mathscr{S}$ measurable function, $E(f \mid \mathscr{S})$ such that

$$
\int_{E} f d P \equiv \mu(E)=\int_{E} E(f \mid \mathscr{S}) d P
$$

for all $E \in \mathscr{S}$.

Let $F \in \mathscr{S}$. Then

$$
\begin{aligned}
\int_{F} E(E(X \mid \mathscr{F}) \mid \mathscr{S}) d P & \equiv \int_{F} E(X \mid \mathscr{F}) d P \\
& \equiv \int_{F} X d P \equiv \int_{F} E(X \mid \mathscr{S}) d P
\end{aligned}
$$

and so, by uniqueness, $E(E(X \mid \mathscr{F}) \mid \mathscr{S})=E(X \mid \mathscr{S})$. This shows 60.1.1.
To establish 60.1.2, note that if $Z=\mathscr{X}_{F}$ where $F \in \mathscr{S}$,

$$
\int \mathscr{X}_{F} E(X \mid \mathscr{S}) d P=\int \mathscr{X}_{F} X d P=\int E\left(\mathscr{X}_{F} X \mid \mathscr{S}\right) d P
$$

which shows 60.1 .2 in the case where $Z$ is the indicator function of a set in $\mathscr{S}$. It follows this also holds for simple functions. Let $\left\{s_{n}\right\}$ be a sequence of simple functions which converges uniformly to $Z$ and let $F \in \mathscr{S}$. Then by what was just shown,

$$
\int_{F} s_{n} E(X \mid \mathscr{S}) d P=\int_{F} s_{n} X d P=\int_{F} E\left(s_{n} X \mid \mathscr{S}\right) d P
$$

Now

$$
\begin{aligned}
& \left|\int_{F} E\left(s_{n} X \mid \mathscr{S}\right) d P-\int_{F} E(Z X \mid \mathscr{S}) d P\right| \\
\leq & \int_{F}\left|s_{n} X-Z X\right| d P=\int_{F}\left|s_{n}-Z\right||X| d P
\end{aligned}
$$

which converges to 0 by the dominated convergence theorem. Then passing to the limit using the dominated convergence theorem, yields

$$
\int_{F} Z E(X \mid \mathscr{S}) d P=\int_{F} Z X d P \equiv \int_{F} E(Z X \mid \mathscr{S}) d P
$$

Since this holds for every $F \in \mathscr{S}$, this shows 60.1.2.
The next major result is a generalization of Jensen's inequality whose proof depends on the following lemma about convex functions.

Lemma 60.1.3 Let $\phi$ be a convex real valued function defined on an interval I. Then for each $x \in I$, there exists $a_{x}$ such that for all $t \in I$,

$$
\phi(t) \geq a_{x}(t-x)+\phi(x) .
$$

Also $\phi$ is continuous on I.
Proof: Let $x \in I$ and let $t>x$. Then by convexity of $\phi$,

$$
\begin{gathered}
\frac{\phi(x+\lambda(t-x))-\phi(x)}{\lambda(t-x)} \leq \frac{\phi(x)(1-\lambda)+\lambda \phi(t)-\phi(x)}{\lambda(t-x)} \\
=\frac{\phi(t)-\phi(x)}{t-x}
\end{gathered}
$$

Therefore $t \rightarrow \frac{\phi(t)-\phi(x)}{t-x}$ is increasing if $t>x$. If $t<x$

$$
\begin{gathered}
\frac{\phi(x+\lambda(t-x))-\phi(x)}{\lambda(t-x)} \geq \frac{\phi(x)(1-\lambda)+\lambda \phi(t)-\phi(x)}{\lambda(t-x)} \\
=\frac{\phi(t)-\phi(x)}{t-x}
\end{gathered}
$$

and so $t \rightarrow \frac{\phi(t)-\phi(x)}{t-x}$ is increasing for $t \neq x$. Let

$$
a_{x} \equiv \inf \left\{\frac{\phi(t)-\phi(x)}{t-x}: t>x\right\}
$$

Then if $t_{1}<x$, and $t>x$,

$$
\frac{\phi\left(t_{1}\right)-\phi(x)}{t_{1}-x} \leq a_{x} \leq \frac{\phi(t)-\phi(x)}{t-x}
$$

Thus for all $t \in I$,

$$
\begin{equation*}
\phi(t) \geq a_{x}(t-x)+\phi(x) \tag{60.1.3}
\end{equation*}
$$

The continuity of $\phi$ follows easily from this and the observation that convexity simply says that the graph of $\phi$ lies below the line segment joining two points on its graph. Thus, we have the following picture which clearly implies continuity.

Lemma 60.1.4 Let I be an open interval on $\mathbb{R}$ and let $\phi$ be a convex function defined on $I$. Then there exists a sequence $\left\{\left(a_{n}, b_{n}\right)\right\}$ such that

$$
\phi(t)=\sup \left\{a_{n} t+b_{n}, n=1, \cdots\right\}
$$

Proof: Let $a_{x}$ be as defined in the above lemma. Let

$$
\psi(x) \equiv \sup \left\{a_{r}(x-r)+\phi(r): r \in \mathbb{Q} \cap I\right\}
$$

Thus if $r_{1} \in \mathbb{Q}$,

$$
\psi\left(r_{1}\right) \equiv \sup \left\{a_{r}\left(r_{1}-r\right)+\phi(r): r \in \mathbb{Q} \cap I\right\} \geq \phi\left(r_{1}\right)
$$

Then $\psi$ is convex on $I$ so $\psi$ is continuous. Therefore, $\psi(t) \geq \phi(t)$ for all $t \in I$. By 60.1.3,

$$
\psi(t) \geq \phi(t) \geq \sup \left\{a_{r}(t-r)+\phi(r), r \in \mathbb{Q} \cap I\right\} \equiv \psi(t)
$$

Thus $\psi(t)=\phi(t)$. Let $\mathbb{Q} \cap I=\left\{r_{n}\right\}, a_{n}=a_{r_{n}}$ and $b_{n}=-a_{r_{n}} r_{n}+\phi\left(r_{n}\right)$.

Lemma 60.1.5 If $X \leq Y$, then $E(X \mid \mathscr{S}) \leq E(Y \mid \mathscr{S})$ a.e. Also

$$
X \rightarrow E(X \mid \mathscr{S})
$$

is linear.
Proof: Let $A \in \mathscr{S}$.

$$
\begin{aligned}
& \int_{A} E(X \mid \mathscr{S}) d P \equiv \int_{A} X d P \\
\leq & \int_{A} Y d P \equiv \int_{A} E(Y \mid \mathscr{S}) d P
\end{aligned}
$$

Hence $E(X \mid \mathscr{S}) \leq E(Y \mid \mathscr{S})$ a.e. as claimed. It is obvious $X \rightarrow E(X \mid \mathscr{S})$ is linear.
Theorem 60.1.6 (Jensen's inequality)Let $X(\omega) \in I$ and let $\phi: I \rightarrow \mathbb{R}$ be convex. Suppose

$$
E(|X|), E(|\phi(X)|)<\infty
$$

Then

$$
\phi(E(X \mid \mathscr{S})) \leq E(\phi(X) \mid \mathscr{S})
$$

Proof: Let $\phi(x)=\sup \left\{a_{n} x+b_{n}\right\}$. Letting $A \in \mathscr{S}$,

$$
\frac{1}{P(A)} \int_{A} E(X \mid \mathscr{S}) d P=\frac{1}{P(A)} \int_{A} X d P \in I \text { a.e. }
$$

whenever $P(A) \neq 0$. Hence $E(X \mid \mathscr{S})(\omega) \in I$ a.e. and so it makes sense to consider $\phi(E(X \mid \mathscr{S}))$. Now

$$
a_{n} E(X \mid \mathscr{S})+b_{n}=E\left(a_{n} X+b_{n} \mid \mathscr{S}\right) \leq E(\phi(X) \mid \mathscr{S})
$$

Thus

$$
\begin{gathered}
\sup \left\{a_{n} E(X \mid \mathscr{S})+b_{n}\right\} \\
=\phi(E(X \mid \mathscr{S})) \leq E(\phi(X) \mid \mathscr{S}) \text { a.e. }
\end{gathered}
$$

### 60.2 Discrete Martingales

Definition 60.2.1 Let $\mathscr{S}_{k}$ be an increasing sequence of $\sigma$ algebras which are subsets of $\mathscr{S}$ and $X_{k}$ be a sequence of real-valued random variables with $E\left(\left|X_{k}\right|\right)<\infty$ such that $X_{k}$ is $\mathscr{S}_{k}$ measurable. Then this sequence is called a martingale if

$$
E\left(X_{k+1} \mid \mathscr{S}_{k}\right)=X_{k},
$$

a submartingale if

$$
E\left(X_{k+1} \mid \mathscr{S}_{k}\right) \geq X_{k},
$$

and a supermartingale if

$$
E\left(X_{k+1} \mid \mathscr{S}_{k}\right) \leq X_{k} .
$$

Saying that $X_{k}$ is $\mathscr{S}_{k}$ measurable is referred to by saying $\left\{X_{k}\right\}$ is adapted to $\mathscr{S}_{k}$.

Note that if $\left\{X_{k}\right\}$ is a martingale, then $\left\{\left|X_{k}\right|\right\}$ is a submartingale and that if $\left\{X_{k}\right\}$ is a submartingale and $\phi$ is convex and increasing, then $\left\{\phi\left(X_{k}\right)\right\}$ is a submartingale.

An upcrossing occurs when a sequence goes from $a$ up to $b$. Thus it crosses the interval, $[a, b]$ in the up direction, hence upcrossing. More precisely,

Definition 60.2.2 Let $\left\{x_{i}\right\}_{i=1}^{I}$ be any sequence of real numbers, $I \leq \infty$. Define an increasing sequence of integers $\left\{m_{k}\right\}$ as follows. $m_{1}$ is the first integer $\geq 1$ such that $x_{m_{1}} \leq a, m_{2}$ is the first integer larger than $m_{1}$ such that $x_{m_{2}} \geq b, m_{3}$ is the first integer larger than $m_{2}$ such that $x_{m_{3}} \leq a$, etc. Then each sequence, $\left\{x_{m_{2 k-1}}, \cdots, x_{m_{2 k}}\right\}$, is called an upcrossing of $[a, b]$.

Here is a picture of an upcrossing.

Proposition 60.2.3 Let $\left\{X_{i}\right\}_{i=1}^{n}$ be a finite sequence of real random variables defined on $\Omega$ where $(\Omega, \mathscr{S}, P)$ is a probability space. Let $U_{[a, b]}(\omega)$ denote the number of upcrossings of $X_{i}(\omega)$ of the interval $[a, b]$. Then $U_{[a, b]}$ is a random variable.

Proof: Let $X_{0}(\omega) \equiv a+1$, let $Y_{0}(\omega) \equiv 0$, and let $Y_{k}(\omega)$ remain 0 for $k=0, \cdots, l$ until $X_{l}(\omega) \leq a$. When this happens (if ever), $Y_{l+1}(\omega) \equiv 1$. Then let $Y_{i}(\omega)$ remain 1 for $i=l+1, \cdots, r$ until $X_{r}(\omega) \geq b$ when $Y_{r+1}(\omega) \equiv 0$. Let $Y_{k}(\omega)$ remain 0 for $k \geq r+1$ until $X_{k}(\omega) \leq a$ when $Y_{k}(\omega) \equiv 1$ and continue in this way. Thus the upcrossings of $X_{i}(\omega)$ are identified as unbroken strings of ones for $Y_{k}$ with a zero at each end, with the possible exception of the last string of ones which may be missing the zero at the upper end and may or may not be an upcrossing.

Note also that $Y_{0}$ is measurable because it is identically equal to 0 and that if $Y_{k}$ is measurable, then $Y_{k+1}$ is measurable because the only change in going from $k$ to $k+1$ is a change from 0 to 1 or from 1 to 0 on a measurable set determined by $X_{k}$. In particular,

$$
Y_{k+1}^{-1}(1)=\left(\left[Y_{k}=1\right] \cap\left[X_{k}<b\right]\right) \cup\left(\left[Y_{k}=0\right] \cap\left[X_{k} \leq a\right]\right)
$$

This set is in $\mathscr{S}$ by induction. Of course, $Y_{k+1}^{-1}(0)$ is just the complement of this set. Thus $Y_{k+1}$ is $\mathscr{S}$ measurable since 0,1 are the only two values possible. Now let

$$
Z_{k}(\omega)=\left\{\begin{array}{l}
1 \text { if } Y_{k}(\omega)=1 \text { and } Y_{k+1}(\omega)=0 \\
0 \text { otherwise }
\end{array}\right.
$$

if $k<n$ and

$$
Z_{n}(\omega)=\left\{\begin{array}{l}
1 \text { if } Y_{n}(\omega)=1 \text { and } X_{n}(\omega) \geq b \\
0 \text { otherwise }
\end{array}\right.
$$

Thus $Z_{k}(\omega)=1$ exactly when an upcrossing has been completed and each $Z_{i}$ is a random variable.

$$
U_{[a, b]}(\omega)=\sum_{k=1}^{n} Z_{k}(\omega)
$$

so $U_{[a, b]}$ is a random variable as claimed.
The following corollary collects some key observations found in the above construction.
Corollary 60.2.4 $U_{[a, b]}(\omega) \leq$ the number of unbroken strings of ones in the sequence, $\left\{Y_{k}(\omega)\right\}$ there being at most one unbroken string of ones which produces no upcrossing. Also

$$
\begin{equation*}
Y_{i}(\omega)=\psi_{i}\left(\left\{X_{j}(\omega)\right\}_{j=1}^{i-1}\right) \tag{60.2.4}
\end{equation*}
$$

where $\psi_{i}$ is some function of the past values of $X_{j}(\omega)$.
Lemma 60.2.5 Let $\phi$ be a convex and increasing function and suppose

$$
\left\{\left(X_{n}, \mathscr{S}_{n}\right)\right\}
$$

is a submartingale. Then if $E\left(\left|\phi\left(X_{n}\right)\right|\right)<\infty$, it follows

$$
\left\{\left(\phi\left(X_{n}\right), \mathscr{S}_{n}\right)\right\}
$$

is also a submartingale.
Proof: It is given that $E\left(X_{n+1}, \mathscr{S}_{n}\right) \geq X_{n}$ and so

$$
\phi\left(X_{n}\right) \leq \phi\left(E\left(X_{n+1} \mid \mathscr{S}_{n}\right)\right) \leq E\left(\phi\left(X_{n+1}\right) \mid \mathscr{S}_{n}\right)
$$

by Jensen's inequality.
The following is called the upcrossing lemma.

### 60.2.1 Upcrossings

Lemma 60.2.6 (upcrossing lemma) Let $\left\{\left(X_{i}, \mathscr{S}_{i}\right)\right\}_{i=1}^{n}$ be a submartingale and let $U_{[a, b]}(\omega)$ be the number of upcrossings of $[a, b]$. Then

$$
E\left(U_{[a, b]}\right) \leq \frac{E\left(\left|X_{n}\right|\right)+|a|}{b-a}
$$

Proof: Let $\phi(x) \equiv a+(x-a)^{+}$so that $\phi$ is an increasing convex function always at least as large as $a$. By Lemma 60.2.5 it follows that $\left\{\left(\phi\left(X_{k}\right), \mathscr{S}_{k}\right)\right\}$ is also a submartingale.

$$
\begin{gathered}
\phi\left(X_{k+r}\right)-\phi\left(X_{k}\right)=\sum_{i=k+1}^{k+r} \phi\left(X_{i}\right)-\phi\left(X_{i-1}\right) \\
=\sum_{i=k+1}^{k+r}\left(\phi\left(X_{i}\right)-\phi\left(X_{i-1}\right)\right) Y_{i}+\sum_{i=k+1}^{k+r}\left(\phi\left(X_{i}\right)-\phi\left(X_{i-1}\right)\right)\left(1-Y_{i}\right) .
\end{gathered}
$$

Observe that $Y_{i}$ is $\mathscr{S}_{i-1}$ measurable from its construction in Proposition 60.2.3, $Y_{i}$ depending only on $X_{j}$ for $j<i$.

Now let the unbroken strings of ones for $\left\{Y_{i}(\omega)\right\}$ be

$$
\begin{equation*}
\left\{k_{1}, \cdots, k_{1}+r_{1}\right\},\left\{k_{2}, \cdots, k_{2}+r_{2}\right\}, \cdots,\left\{k_{m}, \cdots, k_{m}+r_{m}\right\} \tag{60.2.5}
\end{equation*}
$$

where $m=V(\omega) \equiv$ the number of unbroken strings of ones in the sequence $\left\{Y_{i}(\omega)\right\}$. By Corollary 60.2.4 $V(\omega) \geq U_{[a, b]}(\omega)$.

$$
\begin{gathered}
\phi\left(X_{n}(\omega)\right)-\phi\left(X_{1}(\omega)\right) \\
=\sum_{k=1}^{n}\left(\phi\left(X_{k}(\omega)\right)-\phi\left(X_{k-1}(\omega)\right)\right) Y_{k}(\omega) \\
+\sum_{k=1}^{n}\left(\phi\left(X_{k}(\omega)\right)-\phi\left(X_{k-1}(\omega)\right)\right)\left(1-Y_{k}(\omega)\right) .
\end{gathered}
$$

The first sum in the above reduces to summing over the unbroken strings of ones because the terms in which $Y_{i}(\omega)=0$ contribute nothing. Therefore,

$$
\begin{gather*}
\phi\left(X_{n}(\omega)\right)-\phi\left(X_{1}(\omega)\right) \\
\geq U_{[a, b]}(\omega)(b-a)+0+ \\
\sum_{k=1}^{n}\left(\phi\left(X_{k}(\omega)\right)-\phi\left(X_{k-1}(\omega)\right)\right)\left(1-Y_{k}(\omega)\right) \tag{60.2.6}
\end{gather*}
$$

where the zero on the right side results from a string of ones which does not produce an upcrossing. It is here that it is important that $\phi(x) \geq a$. Such a string begins with $\phi\left(X_{k}(\omega)\right)=a$ and results in an expression of the form $\phi\left(X_{k+m}(\omega)\right)-\phi\left(X_{k}(\omega)\right) \geq 0$ since $\phi\left(X_{k+m}(\omega)\right) \geq a$. If $X_{k}$ had not been replaced with $\phi\left(X_{k}\right)$, it would have been possible for $\phi\left(X_{k+m}(\omega)\right)$ to be less than $a$ and the zero in the above could have been a negative number This would have been inconvenient.

Next take the expected value of both sides in 60.2.6. This results in

$$
\begin{aligned}
E\left(\phi\left(X_{n}\right)-\phi\left(X_{1}\right)\right) \geq & (b-a) E\left(U_{[a, b]}\right) \\
& +E\left(\sum_{k=1}^{n}\left(\phi\left(X_{k}\right)-\phi\left(X_{k-1}\right)\right)\left(1-Y_{k}\right)\right) \\
\geq & (b-a) E\left(U_{[a, b]}\right)
\end{aligned}
$$

The reason for the last inequality where the term at the end was dropped is

$$
\begin{gathered}
E\left(\left(\phi\left(X_{k}\right)-\phi\left(X_{k-1}\right)\right)\left(1-Y_{k}\right)\right) \\
=E\left(E\left(\left(\phi\left(X_{k}\right)-\phi\left(X_{k-1}\right)\right)\left(1-Y_{k}\right) \mid \mathscr{F}_{k-1}\right)\right) \\
=E\left(\left(1-Y_{k}\right) E\left(\phi\left(X_{k}\right) \mid \mathscr{F}_{k-1}\right)-\left(1-Y_{k}\right) E\left(\phi\left(X_{k-1}\right) \mid \mathscr{F}_{k-1}\right)\right) \\
\geq E\left(\left(1-Y_{k}\right)\left(\phi\left(X_{k-1}\right)-\phi\left(X_{k-1}\right)\right)\right)=0 .
\end{gathered}
$$

Recall that $Y_{k}$ is $\mathscr{S}_{k-1}$ measurable and that $\left(\phi\left(X_{k}\right), \mathscr{S}_{k}\right)$ is a submartingale.
The reason for this lemma is to prove the amazing submartingale convergence theorem.

### 60.2.2 The Submartingale Convergence Theorem

Theorem 60.2.7 (submartingale convergence theorem) Let

$$
\left\{\left(X_{i}, \mathscr{S}_{i}\right)\right\}_{i=1}^{\infty}
$$

be a submartingale with $K \equiv \sup E\left(\left|X_{n}\right|\right)<\infty$. Then there exists a random variable, $X$, such that $E(|X|) \leq K$ and

$$
\lim _{n \rightarrow \infty} X_{n}(\omega)=X(\omega) \text { a.e. }
$$

Proof: Let $a, b \in \mathbb{Q}$ and let $a<b$. Let $U_{[a, b]}^{n}(\omega)$ be the number of upcrossings of $\left\{X_{i}(\omega)\right\}_{i=1}^{n}$. Then let

$$
U_{[a, b]}(\omega) \equiv \lim _{n \rightarrow \infty} U_{[a, b]}^{n}(\omega)=\text { number of upcrossings of }\left\{X_{i}\right\}
$$

By the upcrossing lemma,

$$
E\left(U_{[a, b]}^{n}\right) \leq \frac{E\left(\left|X_{n}\right|\right)+|a|}{b-a} \leq \frac{K+|a|}{b-a}
$$

and so by the monotone convergence theorem,

$$
E\left(U_{[a, b]}\right) \leq \frac{K+|a|}{b-a}<\infty
$$

which shows $U_{[a, b]}(\omega)$ is finite a.e., for all $\omega \notin S_{[a, b]}$ where $P\left(S_{[a, b]}\right)=0$. Define

$$
S \equiv \cup\left\{S_{[a, b]}: a, b \in \mathbb{Q}, a<b\right\} .
$$

Then $P(S)=0$ and if $\omega \notin S,\left\{X_{k}\right\}_{k=1}^{\infty}$ has only finitely many upcrossings of every interval having rational endpoints. For such $\omega$ it cannot be the case that

$$
\lim \sup _{k \rightarrow \infty} X_{k}(\omega)>\lim \inf _{k \rightarrow \infty} X_{k}(\omega)
$$

because then you could pick rational $a, b$ such that $[a, b]$ is between the limsup and the liminf and there would be infinitely many upcrossings of $[a, b]$. Thus, for $\omega \notin S$,

$$
\begin{aligned}
\limsup _{k \rightarrow \infty} X_{k}(\omega) & =\lim _{k \rightarrow \infty} \inf _{k}(\omega) \\
& =\lim _{k \rightarrow \infty} X_{k}(\omega) \equiv X_{\infty}(\omega) .
\end{aligned}
$$

Letting $X_{\infty}(\omega) \equiv 0$ for $\omega \in S$, Fatou's lemma implies

$$
\int_{\Omega}\left|X_{\infty}\right| d P=\int_{\Omega} \lim \inf _{n \rightarrow \infty}\left|X_{n}\right| d P \leq \lim \inf _{n \rightarrow \infty} \int_{\Omega}\left|X_{n}\right| d P \leq K
$$

### 60.2.3 Doob Submartingale Estimate

Another very interesting result about submartingales is the Doob submartingale estimate.
Theorem 60.2.8 Let $\left\{\left(X_{i}, \mathscr{S}_{i}\right)\right\}_{i=1}^{\infty}$ be a submartingale. Then for $\lambda>0$,

$$
P\left(\left[\max _{1 \leq k \leq n} X_{k} \geq \lambda\right]\right) \leq \frac{1}{\lambda} \int_{\Omega} X_{n}^{+} d P
$$

Proof: Let

$$
\begin{aligned}
A_{1} & \equiv\left[X_{1} \geq \lambda\right], A_{2} \equiv\left[X_{2} \geq \lambda\right] \backslash A_{1}, \\
\cdots, A_{k} & \equiv\left[X_{k} \geq \lambda\right] \backslash\left(\cup_{i=1}^{k-1} A_{i}\right) \cdots
\end{aligned}
$$

Thus each $A_{k}$ is $\mathscr{S}_{k}$ measurable, the $A_{k}$ are disjoint, and their union equals

$$
\left[\max _{1 \leq k \leq n} X_{k} \geq \lambda\right]
$$

Therefore from the definition of a submartingale and Jensen's inequality,

$$
\begin{aligned}
P\left(\left[\max _{1 \leq k \leq n} X_{k} \geq \lambda\right]\right) & =\sum_{k=1}^{n} P\left(A_{k}\right) \leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_{k}} X_{k} d P \\
& \leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_{k}} E\left(X_{n} \mid \mathscr{S}_{k}\right) d P \\
& \leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_{k}} E\left(X_{n} \mid \mathscr{S}_{k}\right)^{+} d P \\
& \leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_{k}} E\left(X_{n}^{+} \mid \mathscr{S}_{k}\right) d P \\
& =\frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_{k}} X_{n}^{+} d P \leq \frac{1}{\lambda} \int_{\Omega} X_{n}^{+} d P .
\end{aligned}
$$

### 60.3 Optional Sampling And Stopping Times

### 60.3.1 Stopping Times And Their Properties Overview

I will give a brief overview of the main ideas about stopping times first and then repeat them in what follows. I think that these things are so important that it is good to have a short synopsis of what to expect. I think that the optional sampling theorem of Doob is amazing. That is why it gets repeated quite a bit. It is one of those theorems that you read and when you get to the end, having followed the argument, you sit back and feel amazed at what you just went through. You ask yourself if it is really true or whether you made some mistake. At least this is how it effects me.

First it is necessary to define the notion of a stopping time. If you have an increasing sequence of $\sigma$ algebras $\left\{\mathscr{F}_{n}\right\}$ and a process $\left\{X_{n}\right\}$ such that $X_{n}$ is $\mathscr{F}_{n}$ measurable, the idea
of a stopping time $T$ is that $T$ is a measurable function and for such a process $\left\{X_{n}\right\}, \omega \rightarrow$ $X_{n \wedge T(\omega)}(\omega)$ is also $\mathscr{F}_{n}$ measurable. In other words, by stopping with this stopping time, we preserve the $\mathscr{F}_{n}$ measurability. We want to have

$$
X_{n \wedge T}^{-1}(O) \in \mathscr{F}_{n}
$$

where $O$ is an open set in some metric space where $X_{n}$ has its values.

$$
X_{n \wedge T}^{-1}(O)=[T \leq n] \cap\left[\omega: X_{T(\omega)}(\omega) \in O\right] \cup[T>n] \cap\left[\omega: X_{n}(\omega) \in O\right]
$$

Now

$$
[T \leq n] \cap\left[\omega: X_{T(\omega)}(\omega) \in O\right]=\cup_{k=1}^{n}[T=k] \cap\left[X_{k} \in O\right]
$$

To have this in $\mathscr{F}_{n}$, we should have $[T=k] \in \mathscr{F}_{k}$. That is $[T \leq k] \in \mathscr{F}_{k}$. Now once this is done, $[T>n]=[T \leq n]^{C} \in \mathscr{F}_{n}$ also. This motivates the following definition and shows that the requirement that $[T \leq n] \in \mathscr{F}_{n}$ implies that $\omega \rightarrow X_{n \wedge T(\omega)}(\omega)$ is $\mathscr{F}_{n}$ measurable if this is true of $X_{n}$.

Definition 60.3.1 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $\left\{\mathscr{F}_{n}\right\}_{n=1}^{\infty}$ be an increasing sequence of $\sigma$ algebras each contained in $\mathscr{F}$. A stopping time is a measurable function, $T$ which maps $\Omega$ to $\mathbb{N}$,

$$
T^{-1}(A) \in \mathscr{F} \text { for all } A \in \mathscr{P}(\mathbb{N})
$$

such that for all $n \in \mathbb{N}$,

$$
[T \leq n] \in \mathscr{F}_{n}
$$

Note this is equivalent to saying

$$
[T=n] \in \mathscr{F}_{n}
$$

because

$$
[T=n]=[T \leq n] \backslash[T \leq n-1]
$$

For $T$ a stopping time define $\mathscr{F}_{T}$ as follows.

$$
\mathscr{F}_{T} \equiv\left\{A \in \mathscr{F}: A \cap[T \leq n] \in \mathscr{F}_{n} \text { for all } n \in \mathbb{N}\right\}
$$

These sets in $\mathscr{F}_{T}$ are referred to as "prior" to $T$.
Of course $T$ has values $i$, a countable well ordered set of numbers, $i \leq i+1$. Then we have the following about the relation with stopping times and conditional expectations.

Lemma 60.3.2 Let $X$ be in $L^{1}(\Omega)$. Then $\mathscr{F}_{T} \cap[T=i]=\mathscr{F}_{i} \cap[T=i]$ and $E\left(X \mid \mathscr{F}_{T}\right)=$ $E\left(X \mid \mathscr{F}_{i}\right)$ a.e. on the set $[T=i]$. Also if $A \in \mathscr{F}_{T}$, then $A \cap[T=i] \in \mathscr{F}_{i} \cap \mathscr{F}_{T}$. Also $\mathscr{F}_{T} \cap$ $[T \leq i]=\mathscr{F}_{i} \cap[T \leq i]$ and $E\left(X \mid \mathscr{F}_{T}\right)=E\left(X \mid \mathscr{F}_{i}\right)$ a.e. on the set $[T \leq i]$.

## Proof: Let

1. Typical set in $\mathscr{F}_{T} \cap[T=i]$ is $A \cap[T=i]$ where $A \in \mathscr{F}_{T}$. Thus $A \cap[T=i]=B \in \mathscr{F}_{i}$ so $A \cap[T=i]=A \cap[T=i] \cap[T=i]=B \cap[T=i] \in \mathscr{F}_{i} \cap[T=i]$.
2. Typical set in $\mathscr{F}_{i} \cap[T=i]$ is $A \cap[T=i]$ where $A \in \mathscr{F}_{i}$. Then $A \cap[T=i] \cap[T=j] \in$ $\mathscr{F}_{j}$ for all $j$. If $j \neq i$, you get $\emptyset$ and if $j=i$, you get $A \cap[T=i] \in \mathscr{F}_{i}=\mathscr{F}_{j}$ so $A \cap[T=i]=B \in \mathscr{F}_{T}$ and so $A \cap[T=i] \cap[T=i]=B \cap[T=i] \in \mathscr{F}_{T} \cap[T=i]$.

Now let $A \in \mathscr{F}_{T}$. Then

$$
\int_{A \cap[T=i]} E\left(X \mid \mathscr{F}_{i}\right) d P=\int_{A \cap[T=i]} X d P \equiv \int_{A \cap[T=i]} E\left(X \mid \mathscr{F}_{T}\right) d P
$$

because the set $A \cap[T=i] \in \mathscr{F}_{i}$ and is also in $\mathscr{F}_{T}$. A typical set in $\mathscr{F}_{T} \cap[T=i]=\mathscr{F}_{i} \cap$ $[T=i]$ is of this form which was just shown above and so, since this holds for all sets in $\mathscr{F}_{T} \cap[T=i]=\mathscr{F}_{i} \cap[T=i]$, it must be the case that $E\left(X \mid \mathscr{F}_{i}\right)=E\left(X \mid \mathscr{F}_{T}\right)$ a.e. on $[T=i]$. The last claim is obvious from this. Indeed, if $A \in \mathscr{F}_{T} \cap[T \leq i]$, then it is of the form

$$
A=B \cap \cup_{k \leq i}[T=k]=\cup_{k \leq i} B \cap[T=k]
$$

and each set in the union is in $\mathscr{F}_{i} \cap[T \leq i]$. For the other direction, if $A \in \mathscr{F}_{i} \cap[T \leq i]$ then

$$
A=\cup_{k \leq i} B \cap[T=k], B \in \mathscr{F}_{i}
$$

and each set in the union is in $\mathscr{F}_{T} \cap[T \leq i]$. Now note that if $A \in \mathscr{F}_{T}$, then $A \cap[T \leq i] \in \mathscr{F}_{i}$ by definition and $A \cap[T \leq i] \cap[T \leq j] \in \mathscr{F}_{j} \subseteq \mathscr{F}_{i}$ if $j \leq i$ wile if $j>i$, this set is equal to $A \cap[T \leq i]$ which is in $\mathscr{F}_{i}$ and so the same argument above gives the result that $E\left(X \mid \mathscr{F}_{T}\right)=$ $E\left(X \mid \mathscr{F}_{i}\right)$ a.e. on the set $[T \leq i]$.

One of the big results is the optional sampling theorem. Suppose $X_{n}$ is a martingale. In particular, each $X_{n} \in L^{1}(\Omega)$ and $E\left(X_{n} \mid \mathscr{F}_{k}\right)=X_{k}$ whenever $k \leq n$. We can assume $X_{n}$ has values in some separable Banach space. Then $\left\|X_{n}\right\|$ is a submartingale because if $k \leq n$, then if $A \in \mathscr{F}_{k}$,

$$
\int_{A} E\left(\left\|X_{n}\right\| \mid \mathscr{F}_{k}\right) d P \geq \int_{A}\left\|E\left(X_{n} \mid \mathscr{F}_{k}\right)\right\| d P=\int_{A}\left\|X_{k}\right\| d P
$$

Now suppose we have two stopping times $\tau$ and $\sigma$ and $\tau$ is bounded meaning it has values in $\{1,2, \cdots, n\}$. The optional sampling theorem says the following. Here $M$ is a martingale.

$$
M(\sigma \wedge \tau)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Furthermore, it all makes sense. First of all, why does it make sense? We need to verify that $M(\tau)$ is integrable.

$$
\begin{aligned}
\int\|M(\tau)\| & =\sum_{k=1}^{n} \int_{[\tau=k]}\|M(k)\|=\sum_{k=1}^{n} \int_{[\tau=k]}\left\|E\left(M(n) \mid \mathscr{F}_{k}\right)\right\| \\
& \leq \sum_{k=1}^{n} \int_{[\tau=k]} E\left(\|M(n)\| \mid \mathscr{F}_{k}\right) \leq \sum_{k=1}^{n} \int E\left(\|M(n)\| \mid \mathscr{F}_{k}\right) \\
& =\sum_{k=1}^{n} E(\|M(n)\|)<\infty
\end{aligned}
$$

Similarly, $M(\sigma \wedge \tau)$ is integrable. Now let $A \in \mathscr{F} \sigma$. Then using Lemma 60.3.2 as needed,

$$
\begin{aligned}
\int_{A} M(\sigma \wedge \tau) & =\sum_{i=1}^{n} \int_{A \cap[\tau=i]} M(\sigma \wedge i)=\sum_{i=1}^{n} \sum_{j=1}^{\infty} \int_{A \cap[\tau=i] \cap[\sigma=j]} M(j \wedge i) \\
& =\sum_{i=1}^{n} \sum_{j=1}^{\infty} \int_{A \cap[\tau=i] \cap[\sigma=j]} E\left(M(i) \mid \mathscr{F}_{j}\right)
\end{aligned}
$$

There are two cases here. If $j \leq i$ it is the martingale definition. If $j>i$ the third term has integrand equal to $M(i)$ which is $\mathscr{F}_{j}$ measurable so the formula is still valid. Then the above equals

$$
\begin{gathered}
\sum_{i=1}^{n} \sum_{j=1}^{\infty} \int_{A \cap[\tau=i] \cap[\sigma=j]} E\left(M(i) \mid \mathscr{F}_{\sigma}\right)=\sum_{j=1}^{\infty} \sum_{i=1}^{n} \int_{A \cap[\tau=i] \cap[\sigma=j]} E\left(M(i) \mid \mathscr{F}_{\sigma}\right) \\
=\sum_{j=1}^{\infty} \int_{A \cap[\sigma=j]} E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)=\int_{A} E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)
\end{gathered}
$$

Since $A$ is an arbitrary element of $\mathscr{F}_{\sigma}$, this shows the optional sampling theorem that $M(\sigma \wedge \tau)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)$.

Proposition 60.3.3 Let $M$ be a martingale having values in some separable Banach space. Let $\tau$ be a bounded stopping time and let $\sigma$ be another stopping time. Then everything makes sense in the following formula and

$$
M(\sigma \wedge \tau)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right) \text { a.e. }
$$

### 60.4 Stopping Times

The following lemma is fundamental to understand.
Lemma 60.4.1 In the situation of Definition 60.3.1, if $S \leq T$ for two stopping times, $S$ and $T$, then $\mathscr{F}_{S} \subseteq \mathscr{F}_{T}$. Also $\mathscr{F}_{T}$ is a $\sigma$ algebra.

Proof: Let $A \in \mathscr{F}_{S}$. Then this means

$$
A \cap[S \leq n] \in \mathscr{F}_{n} \text { for all } n
$$

Then I claim that

$$
\begin{equation*}
A \cap[T \leq n]=\cup_{i=1}^{n}(A \cap[S \leq i]) \cap[T \leq n] \tag{60.4.7}
\end{equation*}
$$

Suppose $\omega$ is in the set on the left. Then if $T(\omega)<n$, it is clearly in the set on the right. If $T(\omega)=n$, then $\omega \in[S \leq i]$ for some $i \leq n$ and it is also in $[T \leq n]$. Thus the set on the left is contained in the set on the right. Next suppose $\omega$ is in the set on the right. Then $\omega \in[T \leq n]$ and it only remains to verify $\omega \in A$. However, $\omega \in A \cap[S \leq i]$ for some $i$ and so $\omega \in A$ also.

Now from 60.4.7 it follows $A \cap[T \leq n] \in \mathscr{F}_{n}$ because

$$
A \cap[S \leq i] \in \mathscr{F}_{i} \subseteq \mathscr{F}_{n}
$$

and $[T \leq n] \in \mathscr{F}_{n}$ because $T$ is a stopping time. Since $n$ is arbitrary, this shows $\mathscr{F}_{S} \subseteq \mathscr{F}_{T}$. It remains to verify $\mathscr{F}_{T}$ is a $\sigma$ algebra. Suppose $\left\{A_{i}\right\}$ is a sequence of sets in $\mathscr{F}_{T}$. Then I need to show that $\left(\cup_{i=1}^{\infty} A_{i}\right) \cap[T \leq j] \in \mathscr{F}_{j}$ for all $j$.

$$
\cup_{i=1}^{\infty} A_{i} \cap[T \leq j]=\cup_{i=1}^{\infty}\left(A_{i} \cap[T \leq j]\right)
$$

Now each $\left(A_{i} \cap[T \leq j]\right)$ is in $\mathscr{F}_{j}$ and so the countable union of these sets is also in $\mathscr{F}_{j}$. Next suppose $A \in \mathscr{F}_{T}$. I need to verify $A^{C} \cap[T \leq j] \in \mathscr{F}_{j}$ for all $j$. However, $[T \leq j] \in \mathscr{F}_{j}$ and $\Omega \in \mathscr{F}_{j}$ so $\Omega \in \mathscr{F}_{T}$. Thus

$$
\Omega \cap[T \leq j]=(A \cap[T \leq j]) \cup\left(A^{C} \cap[T \leq j]\right)
$$

and so

$$
\left(A^{C} \cap[T \leq j]\right)=\Omega \cap[T \leq j] \backslash(A \cap[T \leq j]) \in \mathscr{F}_{j} .
$$

This proves the lemma.
Lemma 60.4.2 Let $T$ be a stopping time and let $\left\{X_{n}\right\}$ be a sequence of random variables such that $X_{n}$ is $\mathscr{F}_{n}$ measurable. Then $X_{T}(\omega) \equiv X_{T(\omega)}(\omega)$ is also a random variable and it is measurable with respect to $\mathscr{F}_{T}$.

Proof: I assume the $X_{n}$ have values in some topological space and each is measurable because the inverse image of an open set is in $\mathscr{F}_{n}$. I need to show $X_{T}^{-1}(U) \cap[T \leq n] \in \mathscr{F}_{n}$ for all $n$ whenever $U$ is open.

$$
X_{T}^{-1}(U)=\cup_{i=1}^{\infty} X_{i}^{-1}(U) \cap[T=i]
$$

It follows $X_{T}^{-1}(U) \in \mathscr{F}$. Furthermore,

$$
\begin{aligned}
X_{T}^{-1}(U) \cap[T \leq n] & =\cup_{i=1}^{\infty} X_{i}^{-1}(U) \cap[T=i] \cap[T \leq n] \\
& =\cup_{i=1}^{n} X_{i}^{-1}(U) \cap[T=i] \cap[T \leq n] \\
& =\cup_{i=1}^{n} \overbrace{X_{i}^{-1}(U) \cap[T=i]}^{\text {in } \mathscr{F}_{i}} \in \mathscr{F}_{n}
\end{aligned}
$$

and so $X_{T}$ is $\mathscr{F}_{T}$ is measurable as claimed. This proves the lemma.
Lemma 60.4.3 Let $S \leq T$ be two stopping times such that $T$ is bounded above and let $\left\{X_{n}\right\}$ be a submartingale (martingale) adapted to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{n}\right\}$. Then

$$
E\left(X_{T} \mid \mathscr{F}_{S}\right) \geq X_{S}
$$

in the case where $\left\{X_{n}\right\}$ is a submartingale and

$$
E\left(X_{T} \mid \mathscr{F}_{S}\right)=X_{S}
$$

in the case where $\left\{X_{n}\right\}$ is a martingale.

Proof: I will prove the case where $\left\{X_{n}\right\}$ is a submartingale and note the other case will only involve replacing $\geq$ with $=$. First recall that from Lemma 60.4.1 $\mathscr{F}_{S} \subseteq \mathscr{F}_{T}$. Also let $m$ be an upper bound for $T$. Then it follows from this that

$$
E\left(\left|X_{T}\right|\right)=\sum_{i=1}^{m} \int_{[T=i]}\left|X_{i}\right| d P<\infty
$$

with a similar formula holding for $E\left(\left|X_{S}\right|\right)$. Thus it makes sense to speak of $E\left(X_{T} \mid \mathscr{F}_{S}\right)$.
I need to show that if $B \in \mathscr{F}_{S}$, so that $B \cap[S \leq n] \in \mathscr{F}_{n}$ for all $n$, then

$$
\begin{equation*}
\int_{B} X_{T} d P \equiv \int_{B} E\left(X_{T} \mid \mathscr{F}_{S}\right) d P \geq \int_{B} X_{S} d P \tag{60.4.8}
\end{equation*}
$$

It suffices to do this for $B$ of the special form

$$
B=A \cap[S=i]
$$

because if this is done, then the result follows from summing over all possible values of $S$. Note that if $B=A \cap[S=m]$, then $X_{T}=X_{S}=X_{m}$ and there is nothing to prove in 60.4.8 so it can be assumed $i \leq m-1$. Then let $B$ be of this form.

$$
\begin{aligned}
& \int_{A \cap[S=i]} X_{T} d P=\sum_{j=i}^{m} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P \\
= & \sum_{j=i}^{m-1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \geq m]} X_{m} d P
\end{aligned}
$$

And so

$$
\begin{align*}
\int_{A \cap[S=i]} & X_{T} d P=\sum_{j=i}^{m-1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \geq m]} X_{m} d P  \tag{60.4.9}\\
& =\sum_{j=i}^{m-1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \leq m-1]^{C}} X_{m} d P \\
& \geq \sum_{j=i}^{m-1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \leq m-1]^{C}} X_{m-1} d P \\
& =\sum_{j=i}^{m-1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T>m-1]} X_{m-1} d P
\end{align*}
$$

provided $m-1 \geq i$ because $\left\{X_{n}\right\}$ is a submartingale and

$$
A \cap[S=i] \cap[T \leq m-1]^{C} \in \mathscr{F}_{m-1}
$$

Now combine the top term of the sum with the term on the right to obtain

$$
=\sum_{j=i}^{m-2} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \geq m-1]} X_{m-1} d P
$$

which is exactly the same form as 60.4 .9 except $m$ is replaced with $m-1$. Now repeat this process till you get the following inequality

$$
\int_{A \cap[S=i]} X_{T} d P \geq \sum_{j=i}^{i+1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \geq i+2]} X_{i+2} d P
$$

The right hand side equals

$$
\begin{gathered}
\sum_{j=i}^{i+1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \leq i+1]^{C}} X_{i+2} d P \\
\geq \sum_{j=i}^{i+1} \int_{A \cap[S=i] \cap[T=j]} X_{T} d P+\int_{A \cap[S=i] \cap[T \leq i+1]^{C}} X_{i+1} d P \\
=\int_{A \cap[S=i] \cap[T=i]} X_{T} d P+\int_{A \cap[S=i] \cap[T=i+1]} X_{T} d P+\int_{A \cap[S=i] \cap[T \leq i+1]^{C}} X_{i+1} d P \\
=\int_{A \cap[S=i] \cap[T=i]} X_{i} d P+\int_{A \cap[S=i] \cap[T=i+1]} X_{i+1} d P+\int_{A \cap[S=i] \cap[T>i+1]} X_{i+1} d P \\
=\int_{A \cap[S=i] \cap[T=i]} X_{i} d P+\int_{A \cap[S=i] \cap[T \geq i+1]} X_{i+1} d P \\
=\int_{A \cap[S=i] \cap[T=i]} X_{i} d P+\int_{A \cap[S=i] \cap[T \leq i]^{C}} X_{i+1} d P \\
= \\
\int_{A \cap[S=i] \cap[T=i]} X_{i} d P+\int_{A \cap[S=i] \cap[T \leq i]^{C}} X_{i} d P \\
= \\
\int_{A \cap[S=i] \cap[T=i] \cap[T \geq i]} X_{i} d P+\int_{A \cap[S=i] \cap[T>i]} X_{i} d P=\int_{A \cap[S=i]} X_{i} d P=\int_{A \cap[S=i]} X_{S} d P
\end{gathered}
$$

In the case where $\left\{X_{n}\right\}$ is a martingale, you replace every occurance of $\geq$ in the above argument with $=$. This proves the lemma.

This lemma is called the optional sampling theorem. Another version of this theorem is the case where you have an increasing sequence of stopping times, $\left\{T_{n}\right\}_{n=1}^{\infty}$. Thus if $\left\{X_{n}\right\}$ is a sequence of random variables each $\mathscr{F}_{n}$ measurable, the sequence $\left\{X_{T_{n}}\right\}$ is also a sequence of random variables such that $X_{T_{n}}$ is measurable with respect to $\mathscr{F}_{T_{n}}$ where $\mathscr{F}_{T_{n}}$ is an increasing sequence of $\sigma$ fields. In the case where $X_{n}$ is a submartingale (martingale) it is reasonable to ask whether $\left\{X_{T_{n}}\right\}$ is also a submartingale (martingale). The optional sampling theorem says this is often the case.

Theorem 60.4.4 Let $\left\{T_{n}\right\}$ be an increasing bounded sequence of stopping times and let $\left\{X_{n}\right\}$ be a submartingale (martingale) adapted to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{n}\right\}$. Then $\left\{X_{T_{n}}\right\}$ is a submartingale (martingale) adapted to the increasing sequence of $\sigma$ algebras $\left\{\mathscr{F}_{T_{n}}\right\}$.

Proof: This follows from Lemma 60.4.3
Example 60.4.5 Let $\left\{X_{n}\right\}$ be a sequence of real random variables such that $X_{n}$ is $\mathscr{F}_{n}$ measurable and let A be a Borel subset of $\mathbb{R}$. Let $T(\omega)$ denote the first time $X_{n}(\omega)$ is in $A$. Then $T$ is a stopping time. It is called the first hitting time.

To see this is a stopping time,

$$
[T \leq l]=\cup_{i=1}^{l} X_{i}^{-1}(A) \in \mathscr{F}_{l} .
$$

### 60.5 Optional Stopping Times And Martingales

### 60.5.1 Stopping Times And Their Properties

The purpose of this section is to consider a special optional sampling theorem for martingales which is superior to the one presented earlier. I have presented a different treatment of the fundamental properties of stopping times also. See Kallenberg [77] for more.

Definition 60.5.1 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $\left\{\mathscr{F}_{n}\right\}_{n=1}^{\infty}$ be an increasing sequence of $\sigma$ algebras each contained in $\mathscr{F}$. A stopping time is a measurable function, $\tau$ which maps $\Omega$ to $\mathbb{N}$,

$$
\tau^{-1}(A) \in \mathscr{F} \text { for all } A \in \mathscr{P}(\mathbb{N})
$$

such that for all $n \in \mathbb{N}$,

$$
[\tau \leq n] \in \mathscr{F}_{n}
$$

Note this is equivalent to saying

$$
[\tau=n] \in \mathscr{F}_{n}
$$

because

$$
[\tau=n]=[\tau \leq n] \backslash[\tau \leq n-1] .
$$

For $\tau$ a stopping time define $\mathscr{F}_{\tau}$ as follows.

$$
\mathscr{F}_{\tau} \equiv\left\{A \in \mathscr{F}: A \cap[\tau \leq n] \in \mathscr{F}_{n} \text { for all } n \in \mathbb{N}\right\}
$$

These sets in $\mathscr{F}_{\tau}$ are referred to as "prior" to $\tau$.
First note that for $\tau$ a stopping time, $\mathscr{F}_{\tau}$ is a $\sigma$ algebra. This is in the next proposition.
Proposition 60.5.2 For $\tau$ a stopping time, $\mathscr{F}_{\tau}$ is a $\sigma$ algebra and if $Y(k)$ is $\mathscr{F}_{k}$ measurable for all $k$, then

$$
\omega \rightarrow Y(\tau(\omega))
$$

is $\mathscr{F}_{\tau}$ measurable.
Proof: Let $A_{n} \in \mathscr{F}_{\tau}$. I need to show $\cup_{n} A_{n} \in \mathscr{F}_{\tau}$. In other words, I need to show that

$$
\cup_{n} A_{n} \cap[\tau \leq k] \in \mathscr{F}_{k}
$$

The left side equals

$$
\cup_{n}\left(A_{n} \cap[\tau \leq k]\right)
$$

which is a countable union of sets of $\mathscr{F}_{k}$ and so $\mathscr{F}_{\tau}$ is closed with respect to countable unions. Next suppose $A \in \mathscr{F} \tau$.

$$
\left(A^{C} \cap[\tau \leq k]\right) \cup(A \cap[\tau \leq k])=\Omega \cap[\tau \leq k]
$$

and $\Omega \cap[\tau \leq k] \in \mathscr{F}_{k}$. Therefore, so is $A^{C} \cap[\tau \leq k]$. It remains to verify the last claim. It suffices to verify that $[Y(\tau) \leq a] \in \mathscr{F}_{\tau}$. Is $[Y(\tau) \leq a] \cap[\tau \leq l] \in \mathscr{F}_{l}$ ?

$$
[Y(\tau) \leq a]=\cup_{k}[\tau=k] \cap[Y(k) \leq a]
$$

Thus

$$
[Y(\tau) \leq a] \cap[\tau \leq l]=\cup_{k}[\tau=k] \cap[Y(k) \leq a] \cap[\tau \leq l]
$$

Consider a term in the union. If $l \geq k$ the term reduces to $[\tau=k] \cap[Y(k) \leq a] \in \mathscr{F}_{k}$ while if $l<k$, this term reduces to $\emptyset$, also a set of $\mathscr{F}_{k}$. Therefore, $Y(\tau)$ must be $\mathscr{F}_{\tau}$ measurable. This proves the proposition.

The following lemma contains the fundamental properties of stopping times.
Lemma 60.5.3 In the situation of Definition 60.5.1, let $\sigma, \tau$ be two stopping times. Then

1. $\tau$ is $\mathscr{F}_{\tau}$ measurable
2. $\mathscr{F}_{\sigma} \cap[\sigma \leq \tau] \subseteq \mathscr{F}_{\sigma \wedge \tau}=\mathscr{F}_{\sigma} \cap \mathscr{F}_{\tau}$
3. $\mathscr{F}_{\tau}=\mathscr{F}_{k}$ on $[\tau=k]$ for all $k$. That is if $A \in \mathscr{F}_{k}$, then $A \cap[\tau=k] \in \mathscr{F}_{\tau}$ and if $A \in \mathscr{F}_{\tau}$, then $A \cap[\tau=k] \in \mathscr{F}_{k}$. Also if $A \in \mathscr{F}_{\tau}$,

$$
\int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{\tau}\right) d P=\int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{k}\right) d P
$$

and

$$
E\left(Y \mid \mathscr{F}_{\tau}\right)=E\left(Y \mid \mathscr{F}_{k}\right) \text { a.e. }
$$

$$
\text { on }[\tau=k] \text {. }
$$

Proof: Consider the first claim. I need to show that $[\tau \leq a] \cap[\tau \leq k] \in \mathscr{F}_{k}$ for every $k$. However, this is easy if $a \geq k$ because the left side is then $[\tau \leq k]$ which is given to be in $\mathscr{F}_{k}$ since $\tau$ is a stopping time. If $a<k$, it is also easy because then the left side is $[\tau \leq a] \in \mathscr{F}_{[a]}$ where $[a]$ is the greatest integer less than or equal to $a$.

Next consider the second claim. Let $A \in \mathscr{F} \sigma$. I want to show first that

$$
\begin{equation*}
A \cap[\sigma \leq \tau] \in \mathscr{F}_{\tau} \tag{60.5.10}
\end{equation*}
$$

In other words, I want to show

$$
A \cap[\sigma \leq \tau] \cap[\tau \leq k] \in \mathscr{F}_{k}
$$

for all $k$. This will be done if I can show

$$
A \cap[\sigma \leq j] \cap[\tau \leq k] \in \mathscr{F}_{k}
$$

for each $j \leq k$ because

$$
\cup_{j \leq k} A \cap[\sigma \leq j] \cap[\tau \leq k]=A \cap[\sigma \leq \tau] \cap[\tau \leq k]
$$

However, since $A \in \mathscr{F}_{\sigma}$, it follows $A \cap[\sigma \leq j] \in \mathscr{F}_{j} \subseteq \mathscr{F}_{k}$ for each $j \leq k$ and $[\tau \leq k] \in \mathscr{F}_{k}$ and so this has shown what I wanted to show, $A \cap[\sigma \leq \tau] \in \mathscr{F} \tau$.

Now replace the stopping time, $\tau$ with the stopping time $\tau \wedge \sigma$ in what was just shown. Note

$$
[\tau \wedge \sigma \leq n]=[\tau \leq n] \cup[\sigma \leq n] \in \mathscr{F}_{n}
$$

so $\tau \wedge \sigma$ really is a stopping time. This yields

$$
A \cap[\sigma \leq \tau \wedge \sigma] \in \mathscr{F}_{\tau \wedge \sigma}
$$

However the left side equals $A \cap[\sigma \leq \tau]$. Thus

$$
A \cap[\sigma \leq \tau] \in \mathscr{F}_{\tau \wedge \sigma}
$$

This has shown the first part of 2.), $\mathscr{F}_{\sigma} \cap[\sigma \leq \tau] \subseteq \mathscr{F}_{\tau \wedge \sigma}$. Now 60.5 .10 implies if $A \in$ $\mathscr{F}_{\sigma \wedge \tau}$,

$$
A=A \cap \overbrace{[\sigma \wedge \tau \leq \tau]}^{\text {all of } \Omega} \in \mathscr{F}_{\tau}
$$

and so $\mathscr{F}_{\sigma \wedge \tau} \subseteq \mathscr{F}_{\tau}$. Similarly, $\mathscr{F}_{\sigma \wedge \tau} \subseteq \mathscr{F}_{\sigma}$ which shows

$$
\mathscr{F}_{\sigma \wedge \tau} \subseteq \mathscr{F}_{\tau} \cap \mathscr{F}_{\sigma}
$$

Next let $A \in \mathscr{F}_{\tau} \cap \mathscr{F}_{\sigma}$. Then is it in $\mathscr{F}_{\sigma \wedge \tau}$ ? Is $A \cap[\sigma \wedge \tau \leq k] \in \mathscr{F}_{k}$ ? Of course this is so because

$$
\begin{aligned}
& A \cap[\sigma \wedge \tau \leq k]=A \cap([\sigma \leq k] \cup[\tau \leq k]) \\
& \quad=(A \cap[\sigma \leq k]) \cup(A \cap[\tau \leq k]) \in \mathscr{F}_{k}
\end{aligned}
$$

since both $\sigma, \tau$ are stopping times. This proves part 2.$)$.
Now consider part 3.). Note that $[\tau=k]$ is in both $\mathscr{F}_{k}$ and $\mathscr{F}_{\tau}$. This is because $\tau$ is a stopping time so it is in $\mathscr{F}_{k}$. Why is it in $\mathscr{F}_{\tau}$ ? Is $[\tau=k] \cap[\tau \leq j] \in \mathscr{F}_{j}$ for all $j$ ? If $j<k$, then the intersection is $\emptyset \in \mathscr{F}_{j}$. If $j \geq k$, then the intersection reduces to $[\tau=k]$ and this is in $\mathscr{F}_{k} \subseteq \mathscr{F}_{j}$ so yes, $[\tau=k]$ is in both $\mathscr{F}_{k}$ and $\mathscr{F}_{\tau}$.

Let $A \in \mathscr{F}_{k}$. I need to show

$$
\mathscr{F}_{\tau} \cap[\tau=k]=\mathscr{F}_{k} \cap[\tau=k]
$$

where $\mathscr{G} \cap[\tau=k]$ means all sets of the form $A \cap[\tau=k]$ where $A \in \mathscr{G}$. Let $A \in \mathscr{F} \tau$. Then

$$
A \cap[\tau=k]=(A \cap[\tau \leq k]) \backslash(A \cap[\tau \leq k-1]) \in \mathscr{F}_{k}
$$

Therefore, there exists $B \in \mathscr{F}_{k}$ such that $B=A \cap[\tau=k]$ and so

$$
B \cap[\tau=k]=A \cap[\tau=k]
$$

which shows $\mathscr{F}_{\tau} \cap[\tau=k] \subseteq \mathscr{F}_{k} \cap[\tau=k]$. Now let $A \in \mathscr{F}_{k}$ so that

$$
A \cap[\tau=k] \in \mathscr{F}_{k} \cap[\tau=k]
$$

Then

$$
A \cap[\tau=k] \cap[\tau \leq j] \in \mathscr{F}_{j}
$$

because in case $j<k$, the set on the left is $\emptyset$ and if $j \geq k$ it reduces to $A \cap[\tau=k]$ and both $A$ and $[\tau=k]$ are in $\mathscr{F}_{k} \subseteq \mathscr{F}_{j}$. Therefore, the two $\sigma$ algebras of subsets of $[\tau=k]$,

$$
\mathscr{F}_{\tau} \cap[\tau=k], \mathscr{F}_{k} \cap[\tau=k]
$$

are equal. Thus for $A$ in either $\mathscr{F}_{\tau}$ or $\mathscr{F}_{k}, A \cap[\tau=k]$ is a set of both $\mathscr{F}_{\tau}$ and $\mathscr{F}_{k}$ because if $A \in \mathscr{F}_{k}$, then from the above, there exists $B \in \mathscr{F}_{\tau}$ such that

$$
A \cap[\tau=k]=B \cap[\tau=k] \in \mathscr{F}_{\tau}
$$

with similar reasoning holding if $A \in \mathscr{F}_{\tau}$. In other words, if $g$ is $\mathscr{F}_{\tau}$ or $\mathscr{F}_{k}$ measurable, then the restriction of $g$ to $[\tau=k]$ is measurable with respect to $\mathscr{F}_{\tau} \cap[\tau=k]$ and $\mathscr{F}_{k} \cap[\tau=k]$. Let $Y$ be an arbitrary random variable in $L^{1}(\Omega, \mathscr{F})$. It follows

$$
\begin{aligned}
\int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{\tau}\right) d P & \equiv \int_{A \cap[\tau=k]} Y d P \\
& \equiv \int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{k}\right) d P
\end{aligned}
$$

Since this holds for an arbitrary set in $\mathscr{F}_{\tau} \cap[\tau=k]=\mathscr{F}_{k} \cap[\tau=k]$, it follows

$$
E\left(Y \mid \mathscr{F}_{\tau}\right)=E\left(Y \mid \mathscr{F}_{k}\right) \text { a.e. on }[\tau=k]
$$

This proves the third claim and the Lemma.
With this lemma, here is a major theorem, the optional sampling theorem of Doob. This one is special for martingales.

Theorem 60.5.4 Let $\{M(k)\}$ be a real valued martingale with respect to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{k}\right\}$ and let $\sigma, \tau$ be two stopping times such that $\tau$ is bounded. Then $M(\tau)$ defined as

$$
\omega \rightarrow M(\tau(\omega))
$$

is integrable and

$$
M(\sigma \wedge \tau)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Proof: By Proposition 62.6.3 $M(\tau)$ is $\mathscr{F}_{\tau}$ measurable.
Next note that since $\tau$ is bounded by some $l$,

$$
\int_{\Omega}\|M(\tau(\omega))\| d P \leq \sum_{i=1}^{l} \int_{[\tau=i]}\|M(i)\| d P<\infty .
$$

This proves the first assertion and makes possible the consideration of conditional expectation.

Let $l \geq \tau$ as described above. Then for $k \leq l$, by Lemma 62.6.4,

$$
\mathscr{F}_{k} \cap[\tau=k]=\mathscr{F}_{\tau} \cap[\tau=k] \equiv \mathscr{G}
$$

implying that if $g$ is either $\mathscr{F}_{k}$ measurable or $\mathscr{F}_{\tau}$ measurable, then its restriction to $[\tau=k]$ is $\mathscr{G}$ measurable and so if $A \in \mathscr{F}_{k} \cap[\tau=k]=\mathscr{F}_{\tau} \cap[\tau=k]$,

$$
\begin{aligned}
\int_{A} E\left(M(l) \mid \mathscr{F}_{\tau}\right) d P & \equiv \int_{A} M(l) d P \\
& =\int_{A} E\left(M(l) \mid \mathscr{F}_{k}\right) d P \\
& =\int_{A} M(k) d P \\
& =\int_{A} M(\tau) d P(\text { on } A, \tau=k)
\end{aligned}
$$

Therefore, since $A$ was arbitrary,

$$
E\left(M(l) \mid \mathscr{F}_{\tau}\right)=M(\tau) \text { a.e. }
$$

on $[\tau=k]$ for every $k \leq l$. It follows

$$
\begin{equation*}
E\left(M(l) \mid \mathscr{F}_{\tau}\right)=M(\tau) \text { a.e. } \tag{60.5.11}
\end{equation*}
$$

since it is true on each $[\tau=k]$ for all $k \leq l$.
Now consider $E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)$ on the set $[\sigma=i] \cap[\tau=j]$. By Lemma 62.6.4, on this set,

$$
E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)=E\left(M(\tau) \mid \mathscr{F}_{i}\right)=E\left(E\left(M(l) \mid \mathscr{F}_{\tau}\right) \mid \mathscr{F}_{i}\right)=E\left(E\left(M(l) \mid \mathscr{F}_{j}\right) \mid \mathscr{F}_{i}\right)
$$

If $j \leq i$, this reduces to

$$
E\left(M(l) \mid \mathscr{F}_{j}\right)=M(j)=M(\sigma \wedge \tau)
$$

If $j>i$, this reduces to

$$
E\left(M(l) \mid \mathscr{F}_{i}\right)=M(i)=M(\sigma \wedge \tau)
$$

and since this exhausts all possibilities for values of $\sigma$ and $\tau$, it follows

$$
E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)=M(\sigma \wedge \tau) \text { a.e. }
$$

This is a really amazing theorem. Note it says $M(\sigma \wedge \tau)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)$. I would have expected something involving $E(M(\tau) \mid \mathscr{F} \sigma \wedge \tau)$ on the right.

What about submartingales? Recall $\{X(k)\}_{k=1}^{\infty}$ is a submartingale if

$$
E\left(X(k+1) \mid \mathscr{F}_{k}\right) \geq X(k)
$$

where the $\mathscr{F}_{k}$ are an increasing sequence of $\sigma$ algebras in the usual way. The following is a very interesting result.

Lemma 60.5.5 Let $\{X(k)\}_{k=0}^{\infty}$ be a submartingale adapted to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{k}\right\}$. Then there exists a unique increasing process $\{A(k)\}_{k=0}^{\infty}$ such that $A(0)=0$ and $A(k+1)$ is $\mathscr{F}_{k}$ measurable for all $k$ and a martingale, $\{M(k)\}_{k=0}^{\infty}$ such that

$$
X(k)=A(k)+M(k)
$$

Furthermore, for $\tau$ a stopping time, $A(\tau)$ is $\mathscr{F}_{\tau}$ measurable.
Proof: Define $\sum_{k=0}^{-1} \neq 0$. First consider the uniqueness assertion. Suppose $A$ is a process which does what is supposed to do.

$$
\begin{aligned}
& \sum_{k=0}^{n-1} E\left(X(k+1)-X(k) \mid \mathscr{F}_{k}\right)=\sum_{k=0}^{n-1} E\left(A(k+1)-A(k) \mid \mathscr{F}_{k}\right) \\
& +\sum_{k=0}^{n-1} E\left(M(k+1)-M(k) \mid \mathscr{F}_{k}\right)
\end{aligned}
$$

Then since $\{M(k)\}$ is a martingale,

$$
\sum_{k=0}^{n-1} E\left(X(k+1)-X(k) \mid \mathscr{F}_{k}\right)=\sum_{k=0}^{n-1} A(k+1)-A(k)=A(n)
$$

This shows uniqueness and gives a formula for $A(n)$ assuming it exists. It is only a matter of verifying this does work. Define

$$
A(n) \equiv \sum_{k=0}^{n-1} E\left(X(k+1)-X(k) \mid \mathscr{F}_{k}\right), A(0)=0
$$

Then $A$ is increasing because from the definition,

$$
A(n+1)-A(n)=E\left(X(n+1)-X(n) \mid \mathscr{F}_{n}\right) \geq 0
$$

Also from the definition above, $A(n)$ is $\mathscr{F}_{n-1}$ measurable, consider

$$
\{X(k)-A(k)\} .
$$

Why is this a martingale?

$$
\begin{aligned}
& E\left(X(k+1)-A(k+1) \mid \mathscr{F}_{k}\right) \\
= & E\left(X(k+1) \mid \mathscr{F}_{k}\right)-A(k+1) \\
= & E\left(X(k+1) \mid \mathscr{F}_{k}\right)-\sum_{j=0}^{k} E\left(X(j+1)-X(j) \mid \mathscr{F}_{j}\right) \\
= & E\left(X(k+1) \mid \mathscr{F}_{k}\right)-E\left(X(k+1)-X(k) \mid \mathscr{F}_{k}\right) \\
& -\sum_{j=0}^{k-1} E\left(X(j+1)-X(j) \mid \mathscr{F}_{j}\right) \\
= & X(k)-\sum_{j=0}^{k-1} E\left(X(j+1)-X(j) \mid \mathscr{F}_{j}\right)=X(k)-A(k)
\end{aligned}
$$

Let $M(k) \equiv X(k)-A(k) . A(\tau)$ is $\mathscr{F}_{\tau}$ measurable by Proposition 62.6.3.
Note the nonnegative integers could be replaced with any finite set or ordered countable set of numbers with no change in the conclusions of this lemma or the above optional sampling theorem.

Next consider the case of a submartingale.

Theorem 60.5.6 Let $\{X(k)\}$ be a submartingale with respect to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{k}\right\}$ and let $\sigma, \tau$ be two stopping times such that $\tau$ is bounded. Then $X(\tau)$ defined as

$$
\omega \rightarrow X(\tau(\omega))
$$

is integrable and

$$
X(\sigma \wedge \tau) \leq E\left(X(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Proof: The claim about $X(\tau)$ being integrable is the same as in Theorem 62.6.5. If $\tau \leq l$,

$$
E(|X(\tau(\omega))|)=\sum_{i=1}^{l} \int_{[\tau=i]}|X(i)| d P<\infty
$$

By Lemma 60.5 .5 there is a martingale, $\{M(k)\}$ and an increasing process $\{A(k)\}$ such that $A(k+1)$ is $\mathscr{F}_{k}$ measurable such that

$$
X(k)=M(k)+A(k) .
$$

Then using Theorem 62.6 .5 on the martingale and the fact $A$ is increasing

$$
\begin{aligned}
E\left(X(\tau) \mid \mathscr{F}_{\sigma}\right) & =E\left(M(\tau)+A(\tau) \mid \mathscr{F}_{\sigma}\right)=M(\tau \wedge \sigma)+E\left(A(\tau) \mid \mathscr{F}_{\sigma}\right) \\
& \geq M(\tau \wedge \sigma)+E\left(A(\tau \wedge \sigma) \mid \mathscr{F}_{\sigma}\right) \\
& =M(\tau \wedge \sigma)+A(\tau \wedge \sigma)=X(\tau \wedge \sigma)
\end{aligned}
$$

because in the above, it follows from Lemma $60.5 .5, A(\tau \wedge \sigma)$ is $\mathscr{F}_{\tau \wedge \sigma}$ measurable and from Lemma 62.6.4,

$$
\mathscr{F}_{\tau \wedge \sigma}=\mathscr{F}_{\tau} \cap \mathscr{F}_{\sigma} \subseteq \mathscr{F}_{\sigma}
$$

and so

$$
E\left(A(\tau \wedge \sigma) \mid \mathscr{F}_{\sigma}\right)=A(\tau \wedge \sigma)
$$

### 60.6 Submartingale Convergence Theorem

### 60.6.1 Upcrossings

Let $\{X(k)\}$ be an adapted stochastic process, $k=0,1,2, \cdots, M$ adapted to the increasing $\sigma$ algebras $\mathscr{F}_{k}$. Also let $[a, b]$ be an interval. An upcrossing occurs when $X(k)<a$ and you have $X(k+l)>b$ while $X(r)<b$ for all $r \in[k, k+l-1]$. In order to understand
upcrossings, consider the following:

$$
\begin{aligned}
& \tau_{0} \equiv \min (\inf \{k: X(k) \leq a\}, M), \\
& \tau_{1} \equiv \min \left(\inf \left\{k:\left(X\left(k \vee \tau_{0}\right)-X\left(\tau_{0}\right)\right)_{+} \geq b-a\right\}, M\right), \\
& \tau_{2} \equiv \min \left(\inf \left\{k:\left(X\left(\tau_{1}\right)-X\left(k \vee \tau_{1}\right)\right)_{+} \geq b-a\right\}, M\right), \\
& \tau_{3} \equiv \min \left(\inf \left\{k:\left(X\left(k \vee \tau_{2}\right)-X\left(\tau_{2}\right)\right)_{+} \geq b-a\right\}, M\right), \\
& \tau_{4} \equiv \min \left(\inf \left\{k:\left(X\left(\tau_{3}\right)-X\left(k \vee \tau_{3}\right)\right)_{+} \geq b-a\right\}, M\right), \\
& \vdots
\end{aligned}
$$

As usual, $\inf (\emptyset) \equiv \infty$. Are the above stopping times? If $\alpha \geq 0$, and $\tau$ is a stopping time, is $k \rightarrow(X(\tau)-X(k \vee \tau))_{+}$adapted?

$$
\left[(X(\tau)-X(k \vee \tau))_{+}>\alpha\right]=\left[(X(\tau)-X(k))_{+}>\alpha\right] \cap[\tau \leq k]
$$

Now

$$
\left[(X(\tau)-X(k))_{+}>\alpha\right] \cap[\tau \leq k]=\cup_{i=0}^{k}\left[(X(i)-X(k))_{+}>\alpha\right] \cap[\tau \leq k] \in \mathscr{F}_{k}
$$

If $\alpha<0$, then $\left[\left(X\left(\tau_{1}\right)-X\left(k \vee \tau_{1}\right)\right)_{+}>\alpha\right]=\Omega$ and so $k \rightarrow(X(\tau)-X(k \vee \tau))_{+}$is adapted. Similarly $k \rightarrow(X(k \vee \tau)-X(\tau))_{+}$is adapted. Therefore, all those $\tau_{k}$ are stopping times.

Now consider the following random variable for odd $M, 2 n+1=M$

$$
U_{M}^{[a, b]} \equiv \lim _{\varepsilon \rightarrow 0} \sum_{k=0}^{n} \frac{X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)}{\varepsilon+X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)} \leq \frac{1}{b-a} \sum_{k=0}^{n} X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)
$$

Now suppose $\{X(k)\}$ is a nonnegative submartingale. Then since $E\left(X(2 \tau) \mid \mathscr{F}_{2 \tau-1}\right) \geq$ $X\left(\tau_{2 k-1}\right)$

$$
E\left(\sum_{k=1}^{n} X\left(\tau_{2 k}\right)-X\left(\tau_{2 k-1}\right)\right) \geq 0
$$

Hence

$$
\begin{gathered}
E\left(U_{M}^{[a, b]}\right) \leq \frac{1}{b-a} \sum_{k=0}^{n} E\left(X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)\right) \\
\leq \frac{1}{b-a} \sum_{k=0}^{n} E\left(X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)\right)+\frac{1}{b-a} \sum_{k=1}^{n} E\left(X\left(\tau_{2 k}\right)-X\left(\tau_{2 k-1}\right)\right) \\
=\frac{1}{b-a} \sum_{k=0}^{n} E\left(X\left(\tau_{k}\right)-X\left(\tau_{k-1}\right)\right) \leq \frac{1}{b-a} E\left(X\left(\tau_{k}\right)\right)
\end{gathered}
$$

Now by the optional sampling theorem $X(0), X\left(\tau_{k}\right), X(M)$ is a submartingale. Therefore, the above is no larger than

$$
\frac{1}{b-a} E(|X(M)|)
$$

Now note that $U_{M}^{[a, b]}$ is at least as large as the number of upcrossings of $\{X(k)\}$ for $k \leq M$. This is because every time an upcrossing occurs, it will follow that $X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)>0$
and so a one will occur in the above sum which defines $U_{M}^{[a, b]}$. However, this might be larger than the number of upcrossings. The above discussion has proved the following upcrossing lemma.

Lemma 60.6.1 Let $\{X(k)\}$ be a nonnegative submartingale. Let

$$
U_{M}^{[a, b]} \equiv \lim _{\varepsilon \rightarrow 0} \sum_{k=0}^{n} \frac{X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)}{\varepsilon+X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)}, 2 n+1=M
$$

Then

$$
E\left(U_{M}^{[a, b]}\right) \leq \frac{1}{b-a} E(X(M))
$$

Suppose that there exists a constant $C \geq E(X(M))$ for all $M$. That is, $\{X(k)\}$ is bounded in $L^{1}(\Omega)$. Then letting

$$
U^{[a, b]} \equiv \lim _{M \rightarrow \infty} U_{M}^{[a, b]}
$$

it follows that

$$
E\left(U^{[a, b]}\right) \leq C \frac{1}{b-a}
$$

The second half follows from the first part and the monotone convergence theorem.
Now with this estimate, it is easy to prove the submartingale convergence theorem.
Theorem 60.6.2 Let $\{X(k)\}$ be a submartingale which is bounded in $L^{1}(\Omega)$,

$$
\|X(k)\|_{L^{1}(\Omega)} \leq C
$$

Then there is a set of measure zero $N$ such that for $\omega \notin N, \lim _{k \rightarrow \infty} X(k)(\omega)$ exists. If $X(\omega)=\lim _{k \rightarrow \infty} X(k)(\omega)$, then $X \in L^{1}(\Omega)$.

Proof: Let $a<b$ and consider the submartingale $(X(k)-a)_{+}$. Let $U^{[0, b-a]}$ be the random variable of the above lemma which is associated with this submartingale. Thus

$$
E\left(U^{[0, b-a]}\right) \leq \frac{C}{b-a}
$$

It follows that $U^{[0, b-a]}$ is finite for a.e. $\omega$. As noted above, $U^{[0, b-a]}$ is an upper bound to the number of upcrossings of $(X(k)-a)_{+}$and each of these corresponds to an upcrossing of $[a, b]$ by $X(k)$. Thus for all $\omega \notin N_{a, b}$ where $P\left(N_{a, b}\right)=0$, it follows that

$$
U^{[0, b-a]}<\infty .
$$

If $\lim _{k \rightarrow \infty} X(k)(\omega)$ fails to exist, then there exists $a<b$ both rational such that

$$
\lim _{k \rightarrow \infty} \sup _{k \rightarrow \infty} X(k)>b>a>\lim _{\inf _{k \rightarrow \infty}} X(k)
$$

Thus $\omega \in N_{a, b}$ because there are infinitely many upcrossings of $[a, b]$. Let

$$
N=\cup\left\{N_{a, b}: a, b \in \mathbb{Q}\right\}
$$

Then for $\omega \notin N$, the limit just discussed must exist. Letting $X(\omega)=\lim _{k \rightarrow \infty} X(k)(\omega)$ for $\omega \notin N$ and letting $X(\omega)=0$ on $N$, it follows from Fatou's lemma that $X$ is in $L^{1}(\Omega)$.

### 60.6.2 Maximal Inequalities

Next I will show that stopping times and the optional sampling theorem, Lemma 60.4.3, can be used to establish maximal inequalities for submartingales very easily.

Lemma 60.6.3 Let $\{X(k)\}$ be real valued and adapted to the increasing sequence of $\sigma$ algebras $\left\{\mathscr{F}_{k}\right\}$. Let

$$
T(\omega) \equiv \inf \{k: X(k) \geq \lambda\}
$$

Then $T$ is a stopping time. Similarly,

$$
T(\omega) \equiv \inf \{k: X(k) \leq \lambda\}
$$

is a stopping time.
Proof: Is $[T \leq p] \in \mathscr{F}_{p}$ for all $p$ ?

$$
[T=p]=\overbrace{\cap_{i=1}^{p-1}[X(i)<\lambda]}^{\in \mathscr{F}_{p-1}} \cap \overbrace{[X(p) \geq \lambda]}^{\in \mathscr{F}_{p}}
$$

Therefore,

$$
[T \leq p]=\cup_{i=1}^{p}[T=i] \in \mathscr{F}_{p}
$$

Theorem 60.6.4 Let $\left\{X_{k}\right\}$ be a real valued submartingale with respect to the $\sigma$ algebras $\left\{\mathscr{F}_{k}\right\}$. Then for $\lambda>0$

$$
\begin{gather*}
\lambda P\left(\left[\max _{1 \leq k \leq n} X_{k} \geq \lambda\right]\right) \leq E\left(X_{n}^{+}\right),  \tag{60.6.12}\\
\lambda P\left(\left[\min _{1 \leq k \leq n} X_{k} \leq-\lambda\right]\right) \leq E\left(\left|X_{n}\right|+\left|X_{1}\right|\right),  \tag{60.6.13}\\
\lambda P\left(\left[\max _{1 \leq k \leq n}\left|X_{k}\right| \geq \lambda\right]\right) \leq 2 E\left(\left|X_{n}\right|+\left|X_{1}\right|\right) . \tag{60.6.14}
\end{gather*}
$$

Proof: Let $T(\omega)$ be the first time $X_{k}(\omega)$ is $\geq \lambda$ or if this does not happen for $k \leq n$, then $T(\omega) \equiv n$. Thus

$$
T(\omega) \equiv \min \left(\min \left\{k: X_{k}(\omega) \geq \lambda\right\}, n\right)
$$

Note

$$
[T>k]=\cap_{i=1}^{k}\left[X_{i}<\lambda\right] \in \mathscr{F}_{k}
$$

and so the complement, $[T \leq k]$ is also in $\mathscr{F}_{k}$ which shows $T$ is indeed a stopping time.
Then $1, T(\omega), n$ are stopping times, $1 \leq T(\omega) \leq n$. Therefore, from the optional sampling theorem, Lemma 60.4.3, $X_{1}, X_{T}, X_{n}$ is a submartingale. It follows

$$
\begin{aligned}
E\left(X_{n}\right) & \geq E\left(X_{T}\right)=\int_{\left[\max _{k} X_{k} \geq \lambda\right]} X_{T} d P+\int_{\left[\max _{k} X_{k}<\lambda\right]} X_{T} d P \\
& =\int_{\left[\max _{k} X_{k} \geq \lambda\right]} X_{T} d P+\int_{\left[\max _{k} X_{k}<\lambda\right]} X_{n} d P
\end{aligned}
$$

and so, subtracting the last term on the right from both sides,

$$
\begin{aligned}
E\left(X_{n}^{+}\right) & \geq \int_{\left[\max _{k} X_{k} \geq \lambda\right]} X_{n} d P=\int_{\left[\max _{k} X_{k} \geq \lambda\right]} X_{T} d P \\
& \geq \lambda P\left(\left[\max _{k} X_{k} \geq \lambda\right]\right)
\end{aligned}
$$

because $X_{T}(\omega) \geq \lambda$ on $\left[\max _{k} X_{k} \geq \lambda\right]$ from the definition of $T$. This establishes 60.6.12.
Next let $T(\omega)$ be the first time $X_{k}(\omega)$ is $\leq-\lambda$ or if this does not happen for $k \leq n$, then $T(\omega) \equiv n$. Then this is a stopping time by similar reasoning and $1 \leq T(\omega) \leq n$ are stopping times and so by the optional stopping theorem, $X_{1}, X_{T}, X_{n}$ is a submartingale. Therefore, on

$$
\left[\min _{k} X_{k} \leq-\lambda\right], X_{T}(\omega) \leq-\lambda
$$

and $E\left(X_{T} \mid \mathscr{F}_{1}\right) \geq X_{1}$ and so

$$
E\left(X_{1}\right) \leq E\left(E\left(X_{T} \mid \mathscr{F}_{1}\right)\right)=E\left(X_{T}\right)
$$

which implies

$$
\begin{aligned}
E\left(X_{1}\right) & \leq E\left(X_{T}\right)=\int_{\left[\min _{k} X_{k} \leq-\lambda\right]} X_{T} d P+\int_{\left[\min _{k} X_{k}>-\lambda\right]} X_{T} d P \\
& =\int_{\left[\min _{k} X_{k} \leq-\lambda\right]} X_{T} d P+\int_{\left[\min _{k} X_{k}>-\lambda\right]} X_{n} d P
\end{aligned}
$$

and so

$$
\begin{aligned}
E\left(X_{1}\right)-\int_{\left[\min _{k} X_{k}>-\lambda\right]} X_{n} d P & \leq \int_{\left[\min _{k} X_{k} \leq-\lambda\right]} X_{T} d P \\
& \leq-\lambda P\left(\left[\min _{k} X_{k} \leq-\lambda\right]\right)
\end{aligned}
$$

which implies

$$
\begin{aligned}
\lambda P\left(\left[\min _{k} X_{k} \leq-\lambda\right]\right) & \leq \int_{\left[\min _{k} X_{k}>-\lambda\right]} X_{n} d P-E\left(X_{1}\right) \\
& \leq \int_{\Omega}\left(\left|X_{n}\right|+\left|X_{1}\right|\right) d P
\end{aligned}
$$

and this proves 60.6.13.
The last estimate follows from these. Here is why.

$$
\left[\max _{1 \leq k \leq n}\left|X_{k}\right| \geq \lambda\right] \subseteq\left[\max _{1 \leq k \leq n} X_{k} \geq \lambda\right] \cup\left[\min _{1 \leq k \leq n} X_{k} \leq-\lambda\right]
$$

and so

$$
\lambda P\left(\left[\max _{1 \leq k \leq n}\left|X_{k}\right| \geq \lambda\right]\right) \leq \lambda P\left(\left[\max _{1 \leq k \leq n} X_{k} \geq \lambda\right] \cup\left[\min _{1 \leq k \leq n} X_{k} \leq-\lambda\right]\right)
$$

$$
\begin{gathered}
\leq \lambda P\left(\left[\max _{1 \leq k \leq n} X_{k} \geq \lambda\right]\right)+\lambda P\left(\left[\min _{1 \leq k \leq n} X_{k} \leq-\lambda\right]\right) \\
\leq 2 E\left(\left|X_{1}\right|+\left|X_{n}\right|\right)
\end{gathered}
$$

and this proves the last estimate.

### 60.6.3 The Upcrossing Estimate

A very interesting example of stopping times is next. It has to do with upcrossings. First here is a lemma.

Lemma 60.6.5 Let $\left\{\mathscr{F}_{k}\right\}$ be an increasing sequence of $\sigma$ algebras and let $\{X(k)\}$ be adapted to this sequence. Suppose that $X(k)$ has all values in $[a, b]$ and suppose $\sigma$ is a stopping time with the property that $X(\sigma)=a$. Let $\tau(\omega)$ be the first $k>\sigma$ such that $X(k)=b$. If no such $k$ exists, then $\tau \equiv \infty$. Then $\tau$ is a stopping time. Also, you can switch $a, b$ in the above and obtain the same conclusion that $\tau$ is a stopping time.

Proof: Let $I$ be an interval and consider $X(k \vee \sigma)$. Is $k \rightarrow X(k \vee \sigma)$ adapted? Let $I$ be an interval. Is

$$
A \equiv X(k \vee \sigma)^{-1}(I) \in \mathscr{F}_{k} ?
$$

We know that this set is in $\mathscr{F}_{k \vee \sigma}$.

$$
A=A \cap[\sigma \leq k] \cup\left(X(k \vee \sigma)^{-1}(I) \cap[\sigma>k]\right)
$$

Consider the second set in $\boldsymbol{\phi}$. There are two cases, $a \in I$ and $a \notin I$. First suppose $a \notin I$. Then if $\omega \in[\sigma>k]$, it follows that $X(k \vee \sigma)=X(\sigma)=a$. Therefore, in this case, the set on the right in $\boldsymbol{\phi}$ is empty and the empty set is in $\mathscr{F}_{k}$. Next suppose $a \in I$. Then for $\omega \in[\sigma>k]$,

$$
X(k \vee \sigma(\omega))=X(\sigma(\omega))=a \in I
$$

and so each $\omega \in[\sigma>k]$ is in the set $X(k \vee \sigma)^{-1}(I)$ and so, in this case, the set on the right equals

$$
[\sigma>k] \in \mathscr{F}_{k}
$$

Now consider the first set in $\boldsymbol{\varphi}$,

$$
A \cap[\sigma \leq k]=A \cap[\sigma \vee k \leq k] \in \mathscr{F}_{k}
$$

by the definition of what it means for the set $A$ to be in $\mathscr{F}_{k \vee \sigma}$. The argument proceeds in the same way when you switch $a, b$.

Definition 60.6.6 Let $\left\{X_{k}\right\}$ be a sequence of random variables adapted to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{k}\right\}$. Let $[a, b]$ be an interval. An upcrossing is a sequence $X_{n}(\omega), \cdots, X_{n+p}(\omega)$ such that $X_{n}(\omega) \leq a, X_{n+i}(\omega)<b$ for $i<p$, and $X_{n+p}(\omega) \geq b$.

Example 60.6.7 Let $\left\{\mathscr{F}_{n}\right\}$ be an increasing sequence of $\sigma$ algebras contained in $\mathscr{F}$ where $(\Omega, \mathscr{F}, P)$ is a probability space and let $\left\{X_{n}\right\}$ be a sequence of real valued random variables such that $X_{n}$ is $\mathscr{F}_{n}$ measurable. Also let $a<b$. Define

$$
\begin{gathered}
T_{0} \equiv \inf \{n: X(n) \leq a\} \\
T_{1} \equiv \inf \left\{n>T_{0}: X(n) \geq b\right\} \\
T_{2} \equiv \inf \left\{n>T_{1}: X(n) \leq a\right\} \\
\vdots \\
T_{2 k-1} \equiv \inf \left\{n>T_{2 k-2}: X(n) \geq b\right\} \\
T_{2 k} \equiv \inf \left\{n>T_{2 k-1}: X(n) \leq a\right\}
\end{gathered}
$$

If $X_{n}(\omega)$ is never in the desired interval for any $n>T_{j}(\omega)$, then define $T_{j+1}(\omega) \equiv \infty$. Then this is an increasing sequence of stopping times.

It happens that the above gives an increasing sequence of stopping times.
Lemma 60.6.8 The above example gives an increasing sequence of stopping times.
Proof: You could consider the modified random variables

$$
Y(k) \equiv(X(k) \vee a) \wedge b
$$

Then these new random variables stay in $[a, b]$ and if you replace $X(n)$ in the above with $Y(n)$, you get the same sequence of stopping times. Now apply Lemma 60.6.5.

Now there is an interesting application of these stopping times to the concept of upcrossings. Let $\left\{X_{n}\right\}$ be a submartingale such that $X_{n}$ is $\mathscr{F}_{n}$ measurable and let $a<b$. Assume $X_{0}(\omega) \leq a$. The function, $x \rightarrow(x-a)^{+}$is increasing and convex so $\left\{\left(X_{n}-a\right)^{+}\right\}$ is also a submartingale. Furthermore, $\left\{X_{n}\right\}$ goes from $\leq a$ to $\geq b$ if and only if $\left\{\left(X_{n}-a\right)^{+}\right\}$ goes from 0 to $\geq b-a$. That is, a subsequence of the form $Y_{n}(\omega), Y_{n+1}(\omega), \cdots, Y_{n+r}(\omega)$ for $Y$ equal to either $X$ or $(X-a)^{+}$starts out below $a(0)$ and ends up above $b(b-a)$. Such a sequence is called an upcrossing of $[a, b]$. The idea is to estimate the expected number of upcrossings for $n \leq N$. For the stopping times defined in Example 60.6.7, let $T_{k}^{\prime} \equiv \min \left(T_{k}, N\right)$. Thus $T_{k}^{\prime}$, a continuous function of the stopping time, is also a stopping time which is bounded. Moreover, $T_{k}^{\prime} \leq T_{k+1}^{\prime}$. Now pick $n$ such that $2 n>N$. Then for each $\omega \in \Omega$

$$
\left(X_{N}(\omega)-a\right)^{+}-\left(X_{0}(\omega)-a\right)^{+}
$$

must equal the sum of all successive terms of the form

$$
\left(\left(X_{T_{k+1}^{\prime}}(\omega)-a\right)^{+}-\left(X_{T_{k}^{\prime}}(\omega)-a\right)^{+}\right)
$$

for $k=1,2, \cdots, 2 n$. This is because $\left\{T_{k}^{\prime}(\omega)\right\}$ is a strictly increasing sequence which starts with 0 due to the assumption $X_{0}(\omega) \leq a$ and ends with $N<2 n$. Therefore,

$$
\left(X_{N}-a\right)^{+}-\left(X_{0}-a\right)^{+}=\sum_{k=1}^{2 n}\left(X_{T_{k}^{\prime}}-a\right)^{+}-\left(X_{T_{k-1}^{\prime}}-a\right)^{+}
$$

$$
=\overbrace{\sum_{k=0}^{n-1}\left(\left(X_{T_{2 k+1}^{\prime}}-a\right)^{+}-\left(X_{T_{2 k}^{\prime}}-a\right)^{+}\right)}^{\text {odds - evens }}+\overbrace{\sum_{k=1}^{n}\left(\left(X_{T_{2 k}^{\prime}}-a\right)^{+}-\left(X_{T_{2 k-1}^{\prime}}-a\right)^{+}\right)}^{\text {evens - odds }} .
$$

Now denote by $U_{[a, b]}^{N}$ the number of upcrossings. When $T_{k}^{\prime}$ is such that $k$ is odd, $\left(X_{T_{k}^{\prime}}-a\right)^{+}$ is above $b-a$ and when $k$ is even, it equals 0 . Therefore, in the first sum $X_{T_{2 k+1}^{\prime}}-X_{T_{2 k}^{\prime}} \geq$ $b-a$ and there are $U_{[a, b]}^{N}$ terms which are nonzero in this sum. (Note this might not be $n$ because many of the terms in the sum could be 0 due to the definition of $T_{k}^{\prime}$.) Hence

$$
\begin{gather*}
\left(X_{N}-a\right)^{+}-\left(X_{0}-a\right)^{+}=\left(X_{N}-a\right)^{+} \\
\geq(b-a) U_{[a, b]}^{N}+\sum_{k=1}^{n}\left(\left(X_{T_{2 k}^{\prime}}-a\right)^{+}-\left(X_{T_{2 k-1}^{\prime}}-a\right)^{+}\right) . \tag{60.6.15}
\end{gather*}
$$

Now $U_{[a, b]}^{N}$ is a random variable. To see this, let $Z_{k}(\omega)=1$ if $T_{2 k+1}^{\prime}>T_{2 k}^{\prime}$ and 0 otherwise. Thus $U_{[a, b]}^{N}(\omega)=\sum_{k=0}^{n-1} Z_{k}(\omega)$. Therefore, it makes sense to take the expected value of both sides of 60.6.15. By the optional sampling theorem, $\left\{\left(X_{T_{k}^{\prime}}-a\right)^{+}\right\}$is a submartingale and so

$$
\begin{gathered}
E\left(\left(X_{T_{2 k}^{\prime}}-a\right)^{+}-\left(X_{T_{2 k-1}^{\prime}}-a\right)^{+}\right) \\
=\int_{\Omega} E\left(\left(X_{T_{2 k}^{\prime}}-a\right)^{+} \mid \mathscr{F}_{T_{2 k-1}^{\prime}}\right) d P-\int_{\Omega}\left(X_{T_{2 k-1}^{\prime}}-a\right)^{+} d P \geq 0 .
\end{gathered}
$$

Therefore,

$$
\begin{equation*}
E\left(\left(X_{N}-a\right)^{+}\right) \geq(b-a) E\left(U_{[a, b]}^{N}\right) \tag{60.6.16}
\end{equation*}
$$

This proves most of the following fundamental upcrossing estimate.

Theorem 60.6.9 Let $\left\{X_{n}\right\}$ be a real valued submartingale such that $X_{n}$ is $\mathscr{F}_{n}$ measurable. Then letting $U_{[a, b]}^{N}$ denote the upcrossings of $\left\{X_{n}\right\}$ from a to $b$ for $n \leq N$,

$$
E\left(U_{[a, b]}^{N}\right) \leq \frac{1}{b-a} E\left(\left(X_{N}-a\right)^{+}\right)
$$

Proof: The estimate 60.6 .16 was based on the assumption that $X_{0}(\omega) \leq a$. If this is not so, modify $X_{0}$. Change it to $\min \left(X_{0}, a\right)$. Then the inequality holds for the modified submartingale which has at least as many upcrossings. Therefore, the inequality remains.

Note this theorem holds if the submartingale starts at the index 1 rather than 0 . Just adjust the argument.

### 60.7 The Submartingale Convergence Theorem

With this estimate it is now possible to prove the amazing submartingale convergence theorem.

Theorem 60.7.1 Let $\left\{X_{n}\right\}$ be a real valued submartingale such that

$$
E\left(\left|X_{n}\right|\right)<M
$$

for all $n$. Then there exists $X \in L^{1}(\Omega, \mathscr{F})$ such that $X_{n}(\omega)$ converges to $X(\omega)$ a.e. $\omega$ and $X \in L^{1}(\Omega)$.

Proof: Let $a<b$ be two rational numbers. From Theorem 60.6 .9 it follows that for all $N$,

$$
\begin{aligned}
\int_{\Omega} U_{[a, b]}^{N} d P & \leq \frac{1}{b-a} E\left(\left(X_{N}-a\right)^{+}\right) \\
& \leq \frac{1}{b-a}\left(E\left(\left|X_{N}\right|\right)+|a|\right) \leq \frac{M+|a|}{b-a}
\end{aligned}
$$

Therefore, letting $N \rightarrow \infty$, it follows that for a.e. $\omega$, there are only finitely many upcrossings of $[a, b]$. Denote by $S_{[a, b]}$ the exceptional set. Then letting $S \equiv \cup_{a, b \in \mathbb{Q}} S_{[a, b]}$, it follows that $P(S)=0$ and for $\omega \notin S,\left\{X_{n}(\omega)\right\}$ is a Cauchy sequence because if

$$
\lim \sup _{n \rightarrow \infty} X_{n}(\omega)>\lim \inf _{n \rightarrow \infty} X_{n}(\omega)
$$

then you can pick $\liminf _{n \rightarrow \infty} X_{n}(\omega)<a<b<\limsup \sin _{n \rightarrow \infty} X_{n}(\omega)$ with $a, b$ rational and conclude $\omega \in S_{[a, b]}$.

Let $X(\omega)=\lim _{n \rightarrow \infty} X_{n}(\omega)$ if $\omega \notin S$ and let $X(\omega)=0$ if $\omega \in S$. Then it only remains to verify $X \in L^{1}(\Omega)$. Since $X$ is the pointwise limit of measurable functions, it follows $X$ is measurable. By Fatou's lemma,

$$
\int_{\Omega}|X(\omega)| d P \leq \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left|X_{n}(\omega)\right| d P
$$

Thus $X \in L^{1}(\Omega)$. This proves the theorem.
As a simple application, here is an easy proof of a nice theorem about convergence of sums of independent random variables.

Theorem 60.7.2 Let $\left\{X_{k}\right\}$ be a sequence of independent real valued random variables such that $E\left(\left|X_{k}\right|\right)<\infty, E\left(X_{k}\right)=0$, and

$$
\sum_{k=1}^{\infty} E\left(X_{k}^{2}\right)<\infty
$$

Then $\sum_{k=1}^{\infty} X_{k}$ converges a.e.

Proof: Let $\mathscr{F}_{n} \equiv \sigma\left(X_{1}, \cdots, X_{n}\right)$. Consider $S_{n} \equiv \sum_{k=1}^{n} X_{k}$.

$$
E\left(S_{n+1} \mid \mathscr{F}_{n}\right)=S_{n}+E\left(X_{n+1} \mid \mathscr{F}_{n}\right) .
$$

Letting $A \in \mathscr{F}_{n}$ it follows from independence that

$$
\begin{aligned}
\int_{A} E\left(X_{n+1} \mid \mathscr{F}_{n}\right) d P & \equiv \int_{A} X_{n+1} d P \\
& =\int_{\Omega} \mathscr{X}_{A} X_{n+1} d P \\
& =P(A) \int_{\Omega} X_{n+1} d P=0
\end{aligned}
$$

and so $E\left(X_{n+1} \mid \mathscr{F}_{n}\right)=0$. Therefore, $\left\{S_{n}\right\}$ is a martingale. Now using independence again,

$$
E\left(\left|S_{n}\right|\right) \leq E\left(\left|S_{n}^{2}\right|\right)=\sum_{k=1}^{n} E\left(X_{k}^{2}\right) \leq \sum_{k=1}^{\infty} E\left(X_{k}^{2}\right)<\infty
$$

and so $\left\{S_{n}\right\}$ is an $L^{1}$ bounded martingale. Therefore, it converges a.e. and this proves the theorem.

Corollary 60.7.3 Let $\left\{X_{k}\right\}$ be a sequence of independent real valued random variables such that $E\left(\left|X_{k}\right|\right)<\infty, E\left(X_{k}\right)=m_{k}$, and

$$
\sum_{k=1}^{\infty} E\left(\left|X_{k}-m_{k}\right|^{2}\right)<\infty .
$$

Then $\sum_{k=1}^{\infty}\left(X_{k}-m_{k}\right)$ converges a.e.
This can be extended to the case where the random variables have values in a separable Hilbert space.

Theorem 60.7.4 Let $\left\{X_{k}\right\}$ be a sequence of independent $H$ valued random variables where $H$ is a real separable Hilbert space such that $E\left(\left|X_{k}\right|_{H}\right)<\infty, E\left(X_{k}\right)=0$, and

$$
\sum_{k=1}^{\infty} E\left(\left|X_{k}\right|_{H}^{2}\right)<\infty
$$

Then $\sum_{k=1}^{\infty} X_{k}$ converges a.e.
Proof: Let $\left\{e_{k}\right\}$ be an orthonormal basis for $H$. Then $\left\{\left(X_{n}, e_{k}\right)_{H}\right\}_{n=1}^{\infty}$ are real valued, independent, and their mean equals 0 . Also

$$
\sum_{n=1}^{\infty} E\left(\left|\left(X_{n}, e_{k}\right)_{H}^{2}\right|\right) \leq \sum_{n=1}^{\infty} E\left(\left|X_{n}\right|_{H}^{2}\right)<\infty
$$

and so from Theorem 60.7.2, the series,

$$
\sum_{n=1}^{\infty}\left(X_{n}, e_{k}\right)_{H}
$$

converges a.e. Therefore, there exists a set of measure zero such that for $\omega$ not in this set, $\sum_{n}\left(X_{n}(\omega), e_{k}\right)_{H}$ converges for each $k$. For $\omega$ not in this exceptional set, define

$$
Y_{k}(\omega) \equiv \sum_{n=1}^{\infty}\left(X_{n}(\omega), e_{k}\right)_{H}
$$

Next define

$$
\begin{equation*}
S(\omega) \equiv \sum_{k=1}^{\infty} Y_{k}(\omega) e_{k} \tag{60.7.17}
\end{equation*}
$$

Of course it is not clear this even makes sense. I need to show $\sum_{k=1}^{\infty}\left|Y_{k}(\omega)\right|^{2}<\infty$. Using the independence of the $X_{n}$

$$
\begin{aligned}
E\left(\left|Y_{k}\right|^{2}\right) & =E\left(\left(\sum_{n=1}^{\infty}\left(X_{n}, e_{k}\right)_{H}\right)^{2}\right) \\
& =E\left(\left(\sum_{n=1}^{\infty} \sum_{m=1}^{\infty}\left(X_{n}, e_{k}\right)_{H}\left(X_{m}, e_{k}\right)_{H}\right)\right) \\
& \leq \lim _{N \rightarrow \infty} E\left(\left(\sum_{n=1}^{N} \sum_{m=1}^{N}\left(X_{n}, e_{k}\right)_{H}\left(X_{m}, e_{k}\right)_{H}\right)\right) \\
& =\liminf _{N \rightarrow \infty} E\left(\sum_{n=1}^{N}\left(X_{n}, e_{k}\right)_{H}^{2}\right) \\
& =\sum_{n=1}^{\infty} E\left(\left(X_{n}, e_{k}\right)_{H}^{2}\right)
\end{aligned}
$$

Hence from the above,

$$
E\left(\sum_{k}\left|Y_{k}\right|^{2}\right)=\sum_{k} E\left(\left|Y_{k}\right|^{2}\right) \leq \sum_{k} \sum_{n} E\left(\left(X_{n}, e_{k}\right)_{H}^{2}\right)
$$

and by the monotone convergence theorem or Fubini's theorem,

$$
\begin{align*}
& =E\left(\sum_{k} \sum_{n}\left(X_{n}, e_{k}\right)_{H}^{2}\right)=E\left(\sum_{n} \sum_{k}\left(X_{n}, e_{k}\right)_{H}^{2}\right) \\
& =E\left(\sum_{n}\left|X_{n}\right|_{H}^{2}\right)=\sum_{n} E\left(\left|X_{n}\right|_{H}^{2}\right)<\infty \tag{60.7.18}
\end{align*}
$$

Therefore, for $\omega$ off a set of measure zero, and for

$$
\begin{gathered}
Y_{k}(\omega) \equiv \sum_{n=1}^{\infty}\left(X_{n}(\omega), e_{k}\right)_{H} \\
\sum_{k}\left|Y_{k}(\omega)\right|^{2}<\infty
\end{gathered}
$$

and also for these $\omega$,

$$
\sum_{n} \sum_{k}\left(X_{n}(\omega), e_{k}\right)_{H}^{2}<\infty .
$$

It follows from the estimate 60.7 .18 that for $\omega$ not on a suitable set of measure zero, $S(\omega)$ defined by 60.7.17,

$$
S(\omega) \equiv \sum_{k=1}^{\infty} Y_{k}(\omega) e_{k}
$$

makes sense. Thus for these $\omega$

$$
\begin{aligned}
S(\omega) & =\sum_{l}\left(S(\omega), e_{l}\right) e_{l}=\sum_{l} Y_{l}(\omega) e_{l} \equiv \sum_{l} \sum_{n}\left(X_{n}(\omega), e_{l}\right)_{H} e_{l} \\
& =\sum_{n} \sum_{l}\left(X_{n}(\omega), e_{l}\right) e_{l}=\sum_{n} X_{n}(\omega)
\end{aligned}
$$

This proves the theorem.
Now with this theorem, here is a strong law of large numbers.
Theorem 60.7.5 Suppose $\left\{\mathbf{X}_{k}\right\}$ are independent random variables and $E\left(\left|\mathbf{X}_{k}\right|\right)<\infty$ for each $k$ and $E\left(\mathbf{X}_{k}\right)=\mathbf{m}_{k}$. Suppose also

$$
\begin{equation*}
\sum_{j=1}^{\infty} \frac{1}{j^{2}} E\left(\left|\mathbf{X}_{j}-\mathbf{m}_{j}\right|^{2}\right)<\infty \tag{60.7.19}
\end{equation*}
$$

Then

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n}\left(\mathbf{X}_{j}-\mathbf{m}_{j}\right)=\mathbf{0} \text { a.e. }
$$

Proof: Consider the sum

$$
\sum_{j=1}^{\infty} \frac{\mathbf{X}_{j}-\mathbf{m}_{j}}{j}
$$

This sum converges a.e. because of 60.7.19 and Theorem 60.7.4 applied to the random vectors $\left\{\frac{\mathbf{x}_{j}-\mathbf{m}_{j}}{j}\right\}$. Therefore, from Lemma 59.7.4 it follows that for a.e. $\omega$,

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n}\left(\mathbf{X}_{j}(\omega)-\mathbf{m}_{j}\right)=\mathbf{0}
$$

This proves the theorem.
The next corollary is often called the strong law of large numbers. It follows immediately from the above theorem.

Corollary 60.7.6 Suppose $\left\{\mathbf{X}_{j}\right\}_{j=1}^{\infty}$ are independent random vectors, $\lambda_{\mathbf{x}_{i}}=\lambda_{\mathbf{x}_{j}}$ for all $i, j$ having mean $\mathbf{m}$ and variance equal to

$$
\sigma^{2} \equiv \int_{\Omega}\left|\mathbf{X}_{j}-\mathbf{m}\right|^{2} d P<\infty
$$

Then for a.e. $\omega \in \Omega$

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} \mathbf{X}_{j}(\omega)=\mathbf{m}
$$

### 60.8 A Reverse Submartingale Convergence Theorem

Definition 60.8.1 Let $\left\{X_{n}\right\}_{n=0}^{\infty}$ be a sequence of real random variables such that $E\left(\left|X_{n}\right|\right)<$ $\infty$ for all $n$ and let $\left\{\mathscr{F}_{n}\right\}$ be a sequence of $\sigma$ algebras such that $\mathscr{F}_{n} \supseteq \mathscr{F}_{n+1}$ for all $n$. Then $\left\{X_{n}\right\}$ is called a reverse submartingale if for all $n$,

$$
E\left(X_{n} \mid \mathscr{F}_{n+1}\right) \geq X_{n+1}
$$

Note it is just like a submartingale only the indices are going the other way. Here is an interesting lemma. This lemma gives uniform integrability for a reverse submartingale.

Lemma 60.8.2 Suppose $E\left(\left|X_{n}\right|\right)<\infty$ for all $n, X_{n}$ is $\mathscr{F}_{n}$ measurable, $\mathscr{F}_{n+1} \subseteq \mathscr{F}_{n}$ for all $n \in \mathbb{N}$, and there exist $X_{\infty} \mathscr{F}_{\infty}$ measurable such that $\mathscr{F}_{\infty} \subseteq \mathscr{F}_{n}$ for all $n$ and $X_{0} \mathscr{F}_{0}$ measurable such that $\mathscr{F}_{0} \supseteq \mathscr{F}_{n}$ for all $n$ such that for all $n \in\{0,1, \cdots\}$,

$$
E\left(X_{n} \mid \mathscr{F}_{n+1}\right) \geq X_{n+1}, E\left(X_{n} \mid \mathscr{F}_{\infty}\right) \geq X_{\infty}
$$

where $E\left(\left|X_{\infty}\right|\right)<\infty$. Then $\left\{X_{n}: n \in \mathbb{N}\right\}$ is uniformly integrable.
Proof:

$$
E\left(X_{n+1}\right) \leq E\left(E\left(X_{n} \mid \mathscr{F}_{n+1}\right)\right)=E\left(X_{n}\right)
$$

Therefore, the sequence $\left\{E\left(X_{n}\right)\right\}$ is a decreasing sequence bounded below by $E\left(X_{\infty}\right)$ so it has a limit. I am going to show the functions are equiintegrable. Let $k$ be large enough that

$$
\begin{equation*}
\left|E\left(X_{k}\right)-\lim _{m \rightarrow \infty} E\left(X_{m}\right)\right|<\varepsilon \tag{60.8.20}
\end{equation*}
$$

and suppose $n>k$. Then if $\lambda>0$,

$$
\begin{aligned}
& \int_{\left[\left|X_{n}\right| \geq \lambda\right]}\left|X_{n}\right| d P=\int_{\left[X_{n} \geq \lambda\right]} X_{n} d P+\int_{\left[X_{n} \leq-\lambda\right]}\left(-X_{n}\right) d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{n} d P+\int_{\Omega}\left(-X_{n}\right) d P-\int_{\left[-X_{n}<\lambda\right]}\left(-X_{n}\right) d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{n} d P-\int_{\Omega} X_{n} d P+\int_{\left[-X_{n}<\lambda\right]} X_{n} d P
\end{aligned}
$$

From 60.8.20,

$$
\leq \int_{\left[X_{n} \geq \lambda\right]} X_{n} d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[-X_{n}<\lambda\right]} X_{n} d P
$$

By assumption,

$$
E\left(X_{k} \mid \mathscr{F}_{n}\right) \geq X_{n}
$$

and so the above

$$
\begin{aligned}
& \leq \int_{\left[X_{n} \geq \lambda\right]} E\left(X_{k} \mid \mathscr{F}_{n}\right) d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[-X_{n}<\lambda\right]} E\left(X_{k} \mid \mathscr{F}_{n}\right) d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[-X_{n}<\lambda\right]} X_{k} d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[X_{n}>-\lambda\right]} X_{k} d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P+\left(\int_{\Omega}\left(-X_{k}\right) d P-\int_{\left[X_{n}>-\lambda\right]}\left(-X_{k}\right) d P\right)+\varepsilon \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P+\int_{\left[X_{n} \leq-\lambda\right]}\left(-X_{k}\right) d P+\varepsilon=\int_{\left[\left|X_{n}\right| \geq \lambda\right]}\left|X_{k}\right| d P+\varepsilon
\end{aligned}
$$

Applying the maximal inequality for submartingales, Theorem 60.6.4,

$$
P\left(\left[\max \left\{\left|X_{j}\right|: j=n, \cdots, 1\right\} \geq \lambda\right]\right) \leq \frac{1}{\lambda}\left(E\left(\left|X_{0}\right|\right)+E\left(\left|X_{\infty}\right|\right)\right) \leq \frac{C}{\lambda}
$$

and taking sup for all $n$,

$$
P\left(\left[\sup \left\{\left|X_{j}\right|\right\} \geq \lambda\right]\right) \leq \frac{C}{\lambda}
$$

It follows since the single function, $X_{k}$ is equiintegrable that for all $\lambda$ large enough,

$$
\int_{\left[\left|X_{n}\right| \geq \lambda\right]}\left|X_{n}\right| d P \leq 2 \varepsilon
$$

and since $\varepsilon$ is arbitrary, this shows $\left\{X_{n}\right\}$ for $n>k$ is equiintegrable. Since there are only finitely many $X_{j}$ for $j \leq k$, this shows $\left\{X_{n}\right\}$ is equiintegrable. Hence $\left\{X_{n}\right\}$ is uniformly integrable. This proves the lemma.

Now with this lemma and the upcrossing lemma it is easy to prove an important convergence theorem.

Theorem 60.8.3 Let $\left\{X_{n}, \mathscr{F}_{n}\right\}_{n=0}^{\infty}$ be a backwards submartingale as described above and suppose $\sup _{n \geq 0} E\left(\left|X_{n}\right|\right)<\infty$. Then $\left\{X_{n}\right\}$ converges a.e. and in $L^{1}(\Omega)$ to a function, $X_{\infty}$.

Proof: By the upcrossing lemma applied to the submartingale $\left\{X_{k}\right\}_{k=0}^{N}$, the number of upcrossings (Downcrossings is probably a better term. They are upcrossings as $n$ gets smaller.) of the interval $[a, b]$ satisfies the inequality

$$
E\left(U_{[a, b]}^{N}\right) \leq \frac{1}{b-a} E\left(\left(X_{0}-a\right)^{+}\right)
$$

Letting $N \rightarrow \infty$, it follows the expected number of upcrossings, $E\left(U_{[a, b]}\right)$ is bounded. Therefore, there exists a set of measure $0 N_{a b}$ such that if $\omega \notin N_{a b}, U_{[a, b]}(\omega)<\infty$. Let $N=\cup\left\{N_{a b}: a, b \in \mathbb{Q}\right\}$. Then for $\omega \notin N$,

$$
\lim \sup _{n \rightarrow \infty} X_{n}(\omega)=\lim \inf _{n \rightarrow \infty} X_{n}(\omega)
$$

because if inequality holds, then letting

$$
\lim \inf _{n \rightarrow \infty} X_{n}(\omega)<a<b<\lim \sup _{n \rightarrow \infty} X_{n}(\omega)
$$

it would follow $U_{[a, b]}(\omega)=\infty$, contrary to $\omega \notin N_{a b}$.
Let $X_{\infty}(\omega) \equiv \lim _{n \rightarrow \infty} X_{n}(\omega)$. Then by Fatou's lemma,

$$
\int_{\Omega}\left|X_{\infty}(\omega)\right| d P \leq \lim \inf _{n \rightarrow \infty} \int_{\Omega}\left|X_{n}\right| d P<\infty
$$

and so $X_{\infty}$ is in $L^{1}(\Omega)$. By the Vitali convergence theorem and Lemma 62.7 .16 which shows $\left\{\left|X_{n}\right|\right\}$ is uniformly integrable, it follows

$$
\lim _{n \rightarrow \infty} \int_{\Omega}\left|X_{\infty}(\omega)-X_{n}(\omega)\right| d P=0
$$

This proves the theorem.

### 60.9 Strong Law Of Large Numbers

There is a version of the strong law of large numbers which does not depend on the random variables having finite variance. First are some preparatory lemmas. The approach followed here is from Ash [7].

Lemma 60.9.1 Let $\left\{X_{n}\right\}$ be a sequence of independent random variables with $E\left(\left|X_{k}\right|\right)<\infty$ for all $k$ and let $S_{n} \equiv \sum_{k=1}^{n} X_{k}$. Then for $k \leq n$,

$$
E\left(X_{k} \mid \sigma\left(S_{n}\right)\right)=E\left(X_{k} \mid \sigma\left(S_{n}, \mathbf{Y}\right)\right) \text { a.e. }
$$

where $\mathbf{Y}=\left(X_{n+1}, X_{n+2}, \cdots\right) \in \mathbb{R}^{\mathbb{N}}$. Also for $k \leq n$ as above,

$$
\sigma\left(S_{n}, \mathbf{Y}\right)=\sigma\left(S_{n}, S_{n+1}, \cdots\right)
$$

Proof: Note that $\mathbb{R}^{\mathbb{N}}$ with the usual product topology has a countable basis. Here it is. Let $\mathscr{B}_{N}$ denote sets of the form $\prod_{i=1}^{\infty} D_{i}$ where for $i \leq N, D_{i} \in \mathscr{B}$, a countable basis for $\mathbb{R}$ and for $i>N, D_{i}=\mathbb{R}$. Then $\mathscr{B}_{N}$ is countable and so is $\mathscr{D} \equiv \cup_{N=1}^{\infty} \mathscr{B}_{N}$. From the definition of the product topology, this is a countable basis for the product topology.

Let $V \in \mathscr{D}$ and $U$ be an open set of $\mathbb{R}$. Then if $A \in\left(S_{n}, \mathbf{Y}\right)^{-1}(U \times V)$, by independence of the $\left\{X_{n}\right\}$,

$$
\begin{gathered}
\int_{\left(S_{n}, \mathbf{Y}\right)^{-1}(U \times V)} E\left(X_{k} \mid \sigma\left(S_{n}, \mathbf{Y}\right)\right) d P \equiv \int_{\left(S_{n}, \mathbf{Y}\right)^{-1}(U \times V)} X_{k} d P \\
=\int_{\Omega} \mathscr{X}_{S_{n}^{-1}(U)}(\omega) \mathscr{X}_{\mathbf{Y}^{-1}(V)}(\omega) X_{k} d P=P\left(\mathbf{Y}^{-1}(V)\right) \int_{\Omega} \mathscr{X}_{S_{n}^{-1}(U)}(\omega) X_{k} d P \\
=P\left(\mathbf{Y}^{-1}(V)\right) \int_{S_{n}^{-1}(U)} E\left(X_{k} \mid \sigma\left(S_{n}\right)\right) d P .
\end{gathered}
$$

Now by independence again, $\left\{S_{n}, X_{n+1}, X_{n+2}, \cdots\right\}$ are independent and so the above equals

$$
\int_{S_{n}^{-1}(U)} \mathscr{X}_{\mathbf{Y}^{-1}(V)} E\left(X_{k} \mid \sigma\left(S_{n}\right)\right) d P=\int_{\left(S_{n}, \mathbf{Y}\right)^{-1}(U \times V)} E\left(X_{k} \mid \sigma\left(S_{n}\right)\right) d P
$$

Letting

$$
\begin{gathered}
\mathscr{S} \equiv\left\{A \in \mathscr{B}\left(\mathbb{R} \times \mathbb{R}^{\mathbb{N}}\right): \int_{\left(S_{n}, \mathbf{Y}\right)^{-1}(A)} E\left(X_{k} \mid \sigma\left(S_{n}\right)\right) d P\right. \\
\left.=\int_{\left(S_{n}, \mathbf{Y}\right)^{-1}(A)} E\left(X_{k} \mid \sigma\left(S_{n}, \mathbf{Y}\right)\right) d P\right\}
\end{gathered}
$$

the above has shown this is true for all $A$ in a countable basis. Therefore, it is true for all $A$ open in $\mathbb{R} \times \mathbb{R}^{\mathbb{N}}$. Finally, it is clear that $\mathscr{S}$ is a $\sigma$ algebra which shows the above holds for all $A$ Borel in $\mathbb{R} \times \mathbb{R}^{\mathbb{N}}$. Thus, for all $B \in \sigma\left(S_{n}, \mathbf{Y}\right)$,

$$
\int_{B} E\left(X_{k} \mid \sigma\left(S_{n}\right)\right) d P=\int_{B} E\left(X_{k} \mid \sigma\left(S_{n}, \mathbf{Y}\right)\right) d P
$$

and thus $E\left(X_{k} \mid \sigma\left(S_{n}\right)\right)=E\left(X_{k} \mid \sigma\left(S_{n}, \mathbf{Y}\right)\right)$ a.e.
It only remains to prove the last assertion. For $k>0$,

$$
X_{n+k}=S_{n+k}-S_{n+k-1}
$$

Thus

$$
\begin{aligned}
\sigma\left(S_{n}, \mathbf{Y}\right) & =\sigma\left(S_{n}, X_{n+1}, \cdots\right) \\
& =\sigma\left(S_{n},\left(S_{n+1}-S_{n}\right),\left(S_{n+2}-S_{n+1}\right), \cdots\right) \\
& \subseteq \sigma\left(S_{n}, S_{n+1}, \cdots\right)
\end{aligned}
$$

On the other hand,

$$
\begin{aligned}
\sigma\left(S_{n}, S_{n+1}, \cdots\right) & =\sigma\left(S_{n}, X_{n+1}+S_{n}, X_{n+2}+X_{n+1}+S_{n}, \cdots\right) \\
& \subseteq \sigma\left(S_{n}, X_{n+1}, X_{n+2}, \cdots\right)
\end{aligned}
$$

To see this, note that for an open set, and hence for a Borel set, $B$,

$$
\left(S_{n}+\sum_{k=n+1}^{m} X_{k}\right)^{-1}(B)=\left(S_{n}, X_{n+1}, \cdots, X_{m}\right)^{-1}\left(B^{\prime}\right)
$$

for some $B^{\prime} \in \mathbb{R}^{m+1}$. Thus $\left(S_{n}+\sum_{k=n+1}^{m} X_{k}\right)^{-1}(B)$ for $B$ a Borel set is contained in

$$
\sigma\left(S_{n}, X_{n+1}, X_{n+2}, \cdots\right)
$$

Similar considerations apply to the other inclusion stated earlier. This proves the lemma.
Lemma 60.9.2 Let $\left\{X_{k}\right\}$ be a sequence of independent identically distributed random variables such that $E\left(\left|X_{k}\right|\right)<\infty$. Then letting $S_{n}=\sum_{k=1}^{n} X_{k}$, it follows that for $k \leq n$

$$
E\left(X_{k} \mid \sigma\left(S_{n}, S_{n+1}, \cdots\right)\right)=E\left(X_{k} \mid \sigma\left(S_{n}\right)\right)=\frac{S_{n}}{n}
$$

Proof: It was shown in Lemma 60.9.1 the first equality holds. It remains to show the second. Letting $A=S_{n}^{-1}(B)$ where $B$ is Borel, it follows there exists $B^{\prime} \subseteq \mathbb{R}^{n}$ a Borel set such that

$$
S_{n}^{-1}(B)=\left(X_{1}, \cdots, X_{n}\right)^{-1}\left(B^{\prime}\right)
$$

Then

$$
\begin{gathered}
\int_{A} E\left(X_{k} \mid \sigma\left(S_{n}\right)\right) d P=\int_{S_{n}^{-1}(B)} X_{k} d P \\
=\int_{\left(X_{1}, \cdots, X_{n}\right)^{-1}\left(B^{\prime}\right)} X_{k} d P=\int_{\left(X_{1}, \cdots, X_{n}\right)^{-1}\left(B^{\prime}\right)} x_{k} d \lambda_{\left(X_{1}, \cdots, X_{n}\right)} \\
=\int \cdots \int \mathscr{X}_{\left(X_{1}, \cdots, X_{n}\right)^{-1}\left(B^{\prime}\right)}(\mathbf{x}) x_{k} d \lambda_{X_{1}} d \lambda_{X_{2}} \cdots d \lambda_{X_{n}} \\
=\int \cdots \int \mathscr{X}_{\left(X_{1}, \cdots, X_{n}\right)^{-1}\left(B^{\prime}\right)}(\mathbf{x}) x_{l} d \lambda_{X_{1}} d \lambda_{X_{2}} \cdots d \lambda_{X_{n}} \\
=\int_{A} E\left(X_{l} \mid \sigma\left(S_{n}\right)\right) d P
\end{gathered}
$$

and so since $A \in \sigma\left(S_{n}\right)$ is arbitrary,

$$
E\left(X_{l} \mid \sigma\left(S_{n}\right)\right)=E\left(X_{k} \mid \sigma\left(S_{n}\right)\right)
$$

for each $k, l \leq n$. Therefore,

$$
S_{n}=E\left(S_{n} \mid \sigma\left(S_{n}\right)\right)=\sum_{j=1}^{n} E\left(X_{j} \mid \sigma\left(S_{n}\right)\right)=n E\left(X_{k} \mid \sigma\left(S_{n}\right)\right) \text { a.e. }
$$

and so

$$
E\left(X_{k} \mid \sigma\left(S_{n}\right)\right)=\frac{S_{n}}{n} \text { a.e. }
$$

as claimed. This proves the lemma.
With this preparation, here is the strong law of large numbers for identically distributed random variables.

Theorem 60.9.3 Let $\left\{X_{k}\right\}$ be a sequence of independent identically distributed random variables such that $E\left(\left|X_{k}\right|\right)<\infty$ for all $k$. Letting $m=E\left(X_{k}\right)$,

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n} X_{k}(\omega)=m \text { a.e. }
$$

and convergence also takes place in $L^{1}(\Omega)$.
Proof: Consider the reverse submartingale $\left\{E\left(X_{1} \mid \sigma\left(S_{n}, S_{n+1}, \cdots\right)\right)\right\}$. By Theorem 60.8.3, this converges a.e. and in $L^{1}(\Omega)$ to a random variable, $X_{\infty}$. However, from Lemma 60.9.2, $E\left(X_{1} \mid \sigma\left(S_{n}, S_{n+1}, \cdots\right)\right)=S_{n} / n$. Therefore, $S_{n} / n$ converges a.e. and in $L^{1}(\Omega)$ to $X_{\infty}$. I need to argue that $X_{\infty}$ is constant and also that it equals $m$. For $a \in \mathbb{R}$ let

$$
E_{a} \equiv\left[X_{\infty} \geq a\right]
$$

For $a$ small enough, $P\left(E_{a}\right) \neq 0$. Then since $E_{a}$ is a tail event for the independent random variables, $\left\{X_{k}\right\}$ it follows from the Kolmogorov zero one law, Theorem 59.6.4, that $P\left(E_{a}\right)=1$. Let $b \equiv \sup \left\{a: P\left(E_{a}\right)=1\right\}$. The sets, $E_{a}$ are decreasing as $a$ increases. Let $\left\{a_{n}\right\}$ be a strictly increasing sequence converging to $b$. Then

$$
\left[X_{\infty} \geq b\right]=\cap_{n}\left[X_{\infty} \geq a_{n}\right]
$$

and so

$$
1=P\left(E_{b}\right)=\lim _{n \rightarrow \infty} P\left(E_{a_{n}}\right)
$$

On the other hand, if $c>b$, then $P\left(E_{c}\right)<1$ and so $P\left(E_{c}\right)=0$. Hence $P([X=b])=1$. It remains to show $b=m$. This is easy because by the $L^{1}$ convergence,

$$
b=\int_{\Omega} X_{\infty} d P=\lim _{n \rightarrow \infty} \int_{\Omega} \frac{S_{n}}{n} d P=\lim _{n \rightarrow \infty} m=m
$$

This proves the theorem.

## Chapter 61

## Probability In Infinite Dimensions

### 61.1 Conditional Expectation In Banach Spaces

Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $X \in L^{1}(\Omega ; \mathbb{R})$. Also let $\mathscr{G} \subseteq \mathscr{F}$ where $\mathscr{G}$ is also a $\sigma$ algebra. Then the usual conditional expectation is defined by

$$
\int_{A} X d P=\int_{A} E(X \mid \mathscr{G}) d P
$$

where $E(X \mid \mathscr{G})$ is $\mathscr{G}$ measurable and $A \in \mathscr{G}$ is arbitrary. Recall this is an application of the Radon Nikodym theorem. Also recall $E(X \mid \mathscr{G})$ is unique up to a set of measure zero.

I want to do something like this here. Denote by $L^{1}(\Omega ; E, \mathscr{G})$ those functions in $L^{1}(\Omega ; E)$ which are measurable with respect to $\mathscr{G}$.

Theorem 61.1.1 Let $E$ be a separable Banach space and let $X \in L^{1}(\Omega ; E, \mathscr{F})$ where $X$ is measurable with respect to $\mathscr{F}$ and let $\mathscr{G}$ be a $\sigma$ algebra which is contained in $\mathscr{F}$. Then there exists a unique $Z \in L^{1}(\Omega ; E, \mathscr{G})$ such that for all $A \in \mathscr{G}$,

$$
\int_{A} X d P=\int_{A} Z d P
$$

Denoting this $Z$ as $E(X \mid \mathscr{G})$, it follows

$$
\|E(X \mid \mathscr{G})\| \leq E(\|X\| \mid \mathscr{G}) .
$$

Proof: First consider uniqueness. Suppose $Z^{\prime}$ is another in $L^{1}(\Omega ; E, \mathscr{G})$ which works. Consider a dense subset of $E\left\{a_{n}\right\}_{n=1}^{\infty}$. Then the balls $\left\{B\left(a_{n}, \frac{\left\|a_{n}\right\|}{4}\right)\right\}_{n=1}^{\infty}$ must cover $E \backslash$ $\{\boldsymbol{0}\}$. Here is why. If $y \neq 0$, pick $a_{n} \in B\left(y, \frac{\|y\|}{5}\right)$.

Then $\left\|a_{n}\right\| \geq 4\|y\| / 5$ and so $\left\|a_{n}-y\right\|<\|y\| / 5$. Thus

$$
y \in B\left(a_{n},\|y\| / 5\right) \subseteq B\left(a_{n}, \frac{\left\|a_{n}\right\|}{4}\right)
$$

Now suppose $Z$ is $\mathscr{G}$ measurable and

$$
\int_{A} Z d P=0
$$

for all $A \in \mathscr{G}$. The letting $A \equiv Z^{-1}\left(B\left(a_{n}, \frac{\left\|a_{n}\right\|}{4}\right)\right)$ it follows

$$
0=\int_{A} Z-a_{n}+a_{n} d P
$$

and so

$$
\begin{aligned}
& \left\|a_{n}\right\| P(A)=\left\|\int_{A} a_{n} d P\right\|=\left\|\int_{A}\left(a_{n}-Z\right) d P\right\| \\
& \leq \int_{Z^{-1}\left(B\left(a_{n}, \frac{\left\|a_{n}\right\|}{4}\right)\right)}\left\|a_{n}-Z\right\| d P \leq \frac{\left\|a_{n}\right\|}{4} P(A)
\end{aligned}
$$

which is a contradiction unless $P(A)=0$. Therefore, letting

$$
N \equiv \cup_{n=1}^{\infty} Z^{-1}\left(B\left(a_{n}, \frac{\left\|a_{n}\right\|}{4}\right)\right)=Z^{-1}(E \backslash\{0\})
$$

it follows $N$ has measure zero and so $Z=0$ a.e. This proves uniqueness because if $Z, Z^{\prime}$ both hold, then from the above argument, $Z-Z^{\prime}=0$ a.e.

Next I will show $Z$ exists. To do this recall Theorem 21.2.4 on Page 652 which is stated below for convenience.

Theorem 61.1.2 An E valued function, $X$, is Bochner integrable if and only if $X$ is strongly measurable and

$$
\begin{equation*}
\int_{\Omega}\|X(\omega)\| d P<\infty \tag{61.1.1}
\end{equation*}
$$

In this case there exists a sequence of simple functions $\left\{X_{n}\right\}$ satisfying

$$
\begin{equation*}
\int_{\Omega}\left\|X_{n}(\omega)-X_{m}(\omega)\right\| d P \rightarrow 0 \text { as } m, n \rightarrow \infty \tag{61.1.2}
\end{equation*}
$$

$X_{n}(\omega)$ converging pointwise to $X(\omega)$,

$$
\begin{equation*}
\left\|X_{n}(\omega)\right\| \leq 2\|X(\omega)\| \tag{61.1.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{\Omega}\left\|X(\omega)-X_{n}(\omega)\right\| d P=0 \tag{61.1.4}
\end{equation*}
$$

Now let $\left\{X_{n}\right\}$ be the simple functions just defined and let

$$
X_{n}(\omega)=\sum_{k=1}^{m} x_{k} \mathscr{X}_{F_{k}}(\omega)
$$

where $F_{k} \in \mathscr{F}$, the $F_{k}$ being disjoint. Then define

$$
Z_{n} \equiv \sum_{k=1}^{m} x_{k} E\left(\mathscr{X}_{F_{k}} \mid \mathscr{G}\right)
$$

Thus, if $A \in \mathscr{G}$,

$$
\begin{align*}
\int_{A} Z_{n} d P & =\sum_{k=1}^{m} x_{k} \int_{A} E\left(\mathscr{X}_{F_{k}} \mid \mathscr{G}\right) d P \\
& =\sum_{k=1}^{m} x_{k} \int_{A} \mathscr{X}_{F_{k}} d P \\
& =\sum_{k=1}^{m} x_{k} P\left(F_{k} \cap A\right)=\int_{A} X_{n} d P \tag{61.1.5}
\end{align*}
$$

Then since $E\left(\mathscr{X}_{F_{k}} \mid \mathscr{G}\right) \geq 0$,

$$
\left\|Z_{n}\right\| \leq \sum_{k=1}^{m}\left\|x_{k}\right\| E\left(\mathscr{X}_{F_{k}} \mid \mathscr{G}\right)
$$

Thus if $A \in \mathscr{G}$,

$$
\begin{align*}
E\left(\left\|Z_{n}\right\| \mathscr{X}_{A}\right) & \leq E\left(\sum_{k=1}^{m}\left\|x_{k}\right\| \mathscr{X}_{A} E\left(\mathscr{X}_{F_{k}} \mid \mathscr{G}\right)\right)=\sum_{k=1}^{m}\left\|x_{k}\right\| \int_{A} E\left(\mathscr{X}_{F_{k}} \mid \mathscr{G}\right) d P \\
& =\sum_{k=1}^{m}\left\|x_{k}\right\| \int_{A} \mathscr{X}_{F_{k}} d P=E\left(\mathscr{X}_{A}\left\|X_{n}\right\|\right) \tag{61.1.6}
\end{align*}
$$

Note the use of $\leq$ in the first step in the above. Although the $F_{k}$ are disjoint, all that is known about $E\left(\mathscr{X}_{F_{k}} \mid \mathscr{G}\right)$ is that it is nonnegative. Similarly,

$$
E\left(\left\|Z_{n}-Z_{m}\right\|\right) \leq E\left(\left\|X_{n}-X_{m}\right\|\right)
$$

and this last term converges to 0 as $n, m \rightarrow \infty$ by the properties of the $X_{n}$. Therefore, $\left\{Z_{n}\right\}$ is a Cauchy sequence in $L^{1}(\Omega ; E ; \mathscr{G})$. It follows it converges to some $Z$ in $L^{1}(\Omega ; E, \mathscr{G})$. Then letting $A \in \mathscr{G}$, and using 61.1.5,

$$
\begin{aligned}
\int_{A} Z d P & =\int \mathscr{X}_{A} Z d P=\lim _{n \rightarrow \infty} \int \mathscr{X}_{A} Z_{n} d P=\lim _{n \rightarrow \infty} \int_{A} Z_{n} d P \\
& =\lim _{n \rightarrow \infty} \int_{A} X_{n} d P=\int_{A} X d P .
\end{aligned}
$$

Then define $Z \equiv E(X \mid \mathscr{G})$.
It remains to verify $\|E(X \mid \mathscr{G})\| \equiv\|Z\| \leq E(\|X\| \mid \mathscr{G})$. This follows because, from the above,

$$
\left\|Z_{n}\right\| \rightarrow\|Z\|,\left\|X_{n}\right\| \rightarrow\|X\| \text { in } L^{1}(\Omega)
$$

and so if $A \in \mathscr{G}$, then from 61.1.6,

$$
\frac{1}{P(A)} \int_{A}\left\|Z_{n}\right\| d P \leq \frac{1}{P(A)} \int_{A}\left\|X_{n}\right\| d P
$$

and so, passing to the limit,

$$
\frac{1}{P(A)} \int_{A}\|Z\| d P \leq \frac{1}{P(A)} \int_{A}\|X\| d P=\frac{1}{P(A)} \int_{A} E(\|X\| \mid \mathscr{G}) d P
$$

Since $A$ is arbitrary, this shows that

$$
\|E(X \mid \mathscr{G})\| \equiv\|Z\| \leq E(\|X\| \mid \mathscr{G}) .
$$

In the case where $E$ is reflexive, one could also use Corollary 21.7.6 on Page 681 to get the above result. You would define a vector measure on $\mathscr{G}$,

$$
v(F) \equiv \int_{F} X d P
$$

and then you would use the fact that reflexive separable Banach spaces have the Radon Nikodym property to obtain $Z \in L^{1}(\Omega ; E, \mathscr{G})$ such that

$$
v(F)=\int_{F} X d P=\int_{F} Z d P
$$

The function, $Z$ whose existence and uniqueness is guaranteed by Theorem 61.1.2 is called $E(X \mid \mathscr{G})$.

### 61.2 Probability Measures And Tightness

Here and in what remains, $\mathscr{B}(E)$ will denote the Borel sets of $E$ where $E$ is a topological space, usually at least a Banach space. Because of the fact that probability measures are finite, you can use a simpler definition of what it means for a measure to be regular. Recall that there were two ingredients, inner regularity which said that the measure of a set is the supremum of the measures of compact subsets and outer regularity which says that the measure of a set is the infimum of the measures of the open sets which contain the given set. Here the definition will be similar but instead of using compact sets, closed sets are substituted. Thus the following definition is a little different than the earlier one. I will show, however, that in many interesting cases, this definition of regularity is actually the same as the earlier one.

Definition 61.2.1 A measure, $\mu$ defined on $\mathscr{B}(E)$ will be called inner regular if for all $F \in \mathscr{B}(E)$,

$$
\mu(F)=\sup \{\mu(K): K \subseteq F \text { and } K \text { is closed }\}
$$

A measure, $\mu$ defined on $\mathscr{B}(E)$ will be called outer regular iffor all $F \in \mathscr{B}(E)$,

$$
\mu(F)=\inf \{\mu(V): V \supseteq F \text { and } V \text { is open }\}
$$

When a measure is both inner and outer regular, it is called regular.
For probability measures, regularity tends to come free.

Lemma 61.2.2 Let $\mu$ be a finite measure defined on $\mathscr{B}(E)$ where $E$ is a metric space. Then $\mu$ is regular.

Proof: First note every open set is the countable union of closed sets and every closed set is the countable intersection of open sets. Here is why. Let $V$ be an open set and let

$$
K_{k} \equiv\left\{x \in V: \operatorname{dist}\left(x, V^{C}\right) \geq 1 / k\right\}
$$

Then clearly the union of the $K_{k}$ equals $V$. Next, for $K$ closed let

$$
V_{k} \equiv\{x \in E: \operatorname{dist}(x, K)<1 / k\}
$$

Clearly the intersection of the $V_{k}$ equals $K$. Therefore, letting $V$ denote an open set and $K$ a closed set,

$$
\begin{aligned}
& \mu(V)=\sup \{\mu(K): K \subseteq V \text { and } K \text { is closed }\} \\
& \mu(K)=\inf \{\mu(V): V \supseteq K \text { and } V \text { is open }\}
\end{aligned}
$$

Also since $V$ is open and $K$ is closed,

$$
\begin{aligned}
& \mu(V)=\inf \{\mu(U): U \supseteq V \text { and } V \text { is open }\} \\
& \mu(K)=\sup \{\mu(L): L \subseteq K \text { and } L \text { is closed }\}
\end{aligned}
$$

In words, $\mu$ is regular on open and closed sets. Let

$$
\mathscr{F} \equiv\{F \in \mathscr{B}(E) \text { such that } \mu \text { is regular on } F\} .
$$

Then $\mathscr{F}$ contains the open sets. I want to show $\mathscr{F}$ is a $\sigma$ algebra and then it will follow $\mathscr{F}=\mathscr{B}(E)$.

First I will show $\mathscr{F}$ is closed with respect to complements. Let $F \in \mathscr{F}$. Then since $\mu$ is finite and $F$ is inner regular, there exists $K \subseteq F$ such that $\mu(F \backslash K)<\varepsilon$. But $K^{C} \backslash F^{C}=F \backslash K$ and so $\mu\left(K^{C} \backslash F^{C}\right)<\varepsilon$ showning that $F^{C}$ is outer regular. I have just approximated the measure of $F^{C}$ with the measure of $K^{C}$, an open set containing $F^{C}$. A similar argument works to show $F^{C}$ is inner regular. You start with $V \supseteq F$ such that $\mu(V \backslash F)<\varepsilon$, note $F^{C} \backslash V^{C}=V \backslash F$, and then conclude $\mu\left(F^{C} \backslash V^{C}\right)<\varepsilon$, thus approximating $F^{C}$ with the closed subset, $V^{C}$.

Next I will show $\mathscr{F}$ is closed with respect to taking countable unions. Let $\left\{F_{k}\right\}$ be a sequence of sets in $\mathscr{F}$. Then $\mu$ is inner regular on each of these so there exist $\left\{K_{k}\right\}$ such that $K_{k} \subseteq F_{k}$ and $\mu\left(F_{k} \backslash K_{k}\right)<\varepsilon / 2^{k+1}$. First choose $m$ large enough that

$$
\mu\left(\left(\cup_{k=1}^{\infty} F_{k}\right) \backslash\left(\cup_{k=1}^{m} F_{k}\right)\right)<\frac{\varepsilon}{2}
$$

Then

$$
\mu\left(\left(\cup_{k=1}^{m} F_{k}\right) \backslash\left(\cup_{k=1}^{m} K_{k}\right)\right) \leq \sum_{k=1}^{m} \frac{\varepsilon}{2^{k+1}}<\frac{\varepsilon}{2}
$$

and so

$$
\begin{aligned}
\mu\left(\left(\cup_{k=1}^{\infty} F_{k}\right) \backslash\left(\cup_{k=1}^{m} K_{k}\right)\right) \leq & \mu\left(\left(\cup_{k=1}^{\infty} F_{k}\right) \backslash\left(\cup_{k=1}^{m} F_{k}\right)\right) \\
& +\mu\left(\left(\cup_{k=1}^{m} F_{k}\right) \backslash\left(\cup_{k=1}^{m} K_{k}\right)\right) \\
< & \frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
\end{aligned}
$$

showing $\mu$ is inner regular on $\cup_{k=1}^{\infty} F_{k}$. Since $\mu$ is outer regular on $F_{k}$, there exists $V_{k}$ such that $\mu\left(V_{k} \backslash F_{k}\right)<\varepsilon / 2^{k}$. Then

$$
\begin{aligned}
\mu\left(\left(\cup_{k=1}^{\infty} V_{k}\right) \backslash\left(\cup_{k=1}^{\infty} F_{k}\right)\right) & \leq \sum_{k=1}^{\infty} \mu\left(V_{k} \backslash F_{k}\right) \\
& <\sum_{k=1}^{\infty} \frac{\varepsilon}{2^{k}}=\varepsilon
\end{aligned}
$$

and this shows $\mu$ is outer regular on $\cup_{k=1}^{\infty} F_{k}$ and this proves the lemma.
Lemma 61.2.3 Let $\mu$ be a finite measure on $\mathscr{B}(E)$, the Borel sets of $E$, a separable complete metric space. Then if $C$ is a closed set,

$$
\mu(C)=\sup \{\mu(K): K \subseteq C \text { and } K \text { is compact. }\}
$$

Proof: Let $\left\{a_{k}\right\}$ be a countable dense subset of $C$. Thus $\cup_{k=1}^{\infty} B\left(a_{k}, \frac{1}{n}\right) \supseteq C$. Therefore, there exists $m_{n}$ such that

$$
\mu\left(C \backslash \cup_{k=1}^{m_{n}} \overline{B\left(a_{k}, \frac{1}{n}\right)}\right) \equiv \mu\left(C \backslash C_{n}\right)<\frac{\varepsilon}{2^{n}}
$$

Now let $K=C \cap\left(\cap_{n=1}^{\infty} C_{n}\right)$. Then $K$ is a subset of $C_{n}$ for each $n$ and so for each $\varepsilon>0$ there exists an $\varepsilon$ net for $K$ since $C_{n}$ has a $1 / n$ net, namely $a_{1}, \cdots, a_{m_{n}}$. Since $K$ is closed, it is complete and so it is also compact. Now

$$
\mu(C \backslash K)=\mu\left(\cup_{n=1}^{\infty}\left(C \backslash C_{n}\right)\right)<\sum_{n=1}^{\infty} \frac{\varepsilon}{2^{n}}=\varepsilon
$$

Thus $\mu(C)$ can be approximated by $\mu(K)$ for $K$ a compact subset of $C$. This proves the lemma.

This shows that for a finite measure on the Borel sets of a separable metric space, the above definition of regular coincides with the earlier one.

### 61.3 Tight Measures

Now here is a definition of what it means for a set of measures to be tight.
Definition 61.3.1 Let $\Lambda$ be a set of probability measures defined on the Borel sets of a topological space. Then $\Lambda$ is "tight" if for all $\varepsilon>0$ there exists a compact set, $K_{\varepsilon}$ such that

$$
\mu\left(\left[x \notin K_{\varepsilon}\right]\right)<\varepsilon
$$

for all $\mu \in \Lambda$.
Lemma 61.2 .3 implies a single probability measure on the Borel sets of a separable metric space is tight. The proof of that lemma generalizes slightly to give a simple criterion for a set of measures to be tight.

Lemma 61.3.2 Let E be a separable complete metric space and let $\Lambda$ be a set of Borel probability measures. Then $\Lambda$ is tight if and only iffor every $\varepsilon>0$ and $r>0$ there exists $a$ finite collection of balls, $\left\{B\left(a_{i}, r\right)\right\}_{i=1}^{m}$ such that

$$
\mu\left(\cup_{i=1}^{m} \overline{B\left(a_{i}, r\right)}\right)>1-\varepsilon
$$

for every $\mu \in \Lambda$.
Proof: If $\Lambda$ is tight, then there exists a compact set, $K_{\varepsilon}$ such that

$$
\mu\left(K_{\varepsilon}\right)>1-\varepsilon
$$

for all $\mu \in \Lambda$. Then consider the open cover, $\left\{B(x, r): x \in K_{\varepsilon}\right\}$. Finitely many of these cover $K_{\varepsilon}$ and this yields the above condition.

Now suppose the above condition and let

$$
C_{n} \equiv \cup_{i=1}^{m_{n}} \overline{B\left(a_{i}^{n}, 1 / n\right)}
$$

satisfy $\mu\left(C_{n}\right)>1-\varepsilon / 2^{n}$ for all $\mu \in \Lambda$. Then let $K_{\varepsilon} \equiv \cap_{n=1}^{\infty} C_{n}$. This set $K_{\varepsilon}$ is a compact set because it is a closed subset of a complete metric space and is therefore complete, and it is also totally bounded by construction. For $\mu \in \Lambda$,

$$
\mu\left(K_{\varepsilon}^{C}\right)=\mu\left(\cup_{n} C_{n}^{C}\right) \leq \sum_{n} \mu\left(C_{n}^{C}\right)<\sum_{n} \frac{\varepsilon}{2^{n}}=\varepsilon
$$

Therefore, $\Lambda$ is tight.
Prokhorov's theorem is an important result which also involves tightness. In order to give a proof of this important theorem, it is necessary to consider some simple results from topology which are interesting for their own sake.

Theorem 61.3.3 Let $H$ be a compact metric space. Then there exists a compact subset of $[0,1], K$ and a continuous function, $\theta$ which maps $K$ onto $H$.

Proof: Without loss of generality, it can be assumed $H$ is an infinite set since otherwise the conclusion is trivial. You could pick finitely many points of $[0,1]$ for $K$.

Since $H$ is compact, it is totally bounded. Therefore, there exists a 1 net for $H\left\{h_{i}\right\}_{i=1}^{m_{1}}$. Letting $H_{i}^{1} \equiv \overline{B\left(h_{i}, 1\right)}$, it follows $H_{i}^{1}$ is also a compact metric space and so there exists a $1 / 2$ net for each $H_{i}^{1},\left\{h_{j}^{i}\right\}_{j=1}^{m_{i}}$. Then taking the intersection of $\bar{B}\left(h_{j}^{i}, \frac{1}{2}\right)$ with $H_{i}^{1}$ to obtain sets denoted by $H_{j}^{2}$ and continuing this way, one can obtain compact subsets of $H,\left\{H_{k}^{i}\right\}$ which satisfies: each $H_{j}^{i}$ is contained in some $H_{k}^{i-1}$, each $H_{j}^{i}$ is compact with diameter less than $i^{-1}$, each $H_{j}^{i}$ is the union of sets of the form $H_{k}^{i+1}$ which are contained in it. Denoting by $\left\{H_{j}^{i}\right\}_{j=1}^{m_{i}}$ those sets corresponding to a superscript of $i$, it can also be assumed $m_{i}<m_{i+1}$. If this is not so, simply add in another point to the $i^{-1}$ net. Now let $\left\{I_{j}^{i}\right\}_{j=1}^{m_{i}}$ be disjoint closed intervals in $[0,1]$ each of length no longer than $2^{-m_{i}}$ which have the property that
$I_{j}^{i}$ is contained in $I_{k}^{i-1}$ for some $k$. Letting $K_{i} \equiv \cup_{j=1}^{m_{i}} I_{j}^{i}$, it follows $K_{i}$ is a sequence of nested compact sets. Let $K=\cap_{i=1}^{\infty} K_{i}$. Then each $x \in K$ is the intersection of a unique sequence of these closed intervals, $\left\{I_{j_{k}}^{k}\right\}_{k=1}^{\infty}$. Define $\theta x \equiv \cap_{k=1}^{\infty} H_{j_{k}}^{k}$. Since the diameters of the $H_{j}^{i}$ converge to 0 as $i \rightarrow \infty$, this function is well defined. It is continuous because if $x_{n} \rightarrow x$, then ultimately $x_{n}$ and $x$ are both in $I_{j_{k}}^{k}$, the $k^{t h}$ closed interval in the sequence whose intersection is $x$. Hence, $d\left(\theta x_{n}, \theta x\right) \leq \operatorname{diameter}\left(H_{j_{k}}^{k}\right) \leq 1 / k$. To see the map is onto, let $h \in H$. Then from the construction, there exists a sequence $\left\{H_{j_{k}}^{k}\right\}_{k=1}^{\infty}$ of the above sets whose intersection equals $h$. Then $\theta\left(\cap_{i=1}^{\infty} I_{j_{k}}^{k}\right)=h$.

Note $\theta$ is maybe not one to one.
As an important corollary, it follows that the continuous functions defined on any compact metric space is separable.

Corollary 61.3.4 Let $H$ be a compact metric space and let $C(H)$ denote the continuous functions defined on $H$ with the usual norm,

$$
\|f\|_{\infty} \equiv \max \{|f(x)|: x \in H\}
$$

Then $C(H)$ is separable.
Proof: The proof is by contradiction. Suppose $C(H)$ is not separable. Let $\mathscr{H}_{k}$ denote a maximal collection of functions of $C(H)$ with the property that if $f, g \in \mathscr{H}_{k}$, then $\|f-g\|_{\infty} \geq 1 / k$. The existence of such a maximal collection of functions is a consequence of a simple use of the Hausdorff maximality theorem. Then $\cup_{k=1}^{\infty} \mathscr{H}_{k}$ is dense. Therefore, it cannot be countable by the assumption that $C(H)$ is not separable. It follows that for some $k, \mathscr{H}_{k}$ is uncountable. Now by Theorem 61.3.3 there exists a continuous function, $\theta$ defined on a compact subset, $K$ of $[0,1]$ which maps $K$ onto $H$. Now consider the functions defined on $K$

$$
\mathscr{G}_{k} \equiv\left\{f \circ \theta: f \in \mathscr{H}_{k}\right\}
$$

Then $\mathscr{G}_{k}$ is an uncountable set of continuous functions defined on $K$ with the property that the distance between any two of them is at least as large as $1 / k$. This contradicts separability of $C(K)$ which follows from the Weierstrass approximation theorem in which the separable countable set of functions is the restrictions of polynomials that involve only rational coefficients.

Now here is Prokhorov's theorem.

Theorem 61.3.5 Let $\Lambda=\left\{\mu_{n}\right\}_{n=1}^{\infty}$ be a sequence of probability measures defined on $\mathscr{B}(E)$ where $E$ is a separable complete metric space. If $\Lambda$ is tight then there exists a probability measure, $\lambda$ and a subsequence of $\left\{\mu_{n}\right\}_{n=1}^{\infty}$, still denoted by $\left\{\mu_{n}\right\}_{n=1}^{\infty}$ such that whenever $\phi$ is a continuous bounded complex valued function defined on $E$,

$$
\lim _{n \rightarrow \infty} \int \phi d \mu_{n}=\int \phi d \lambda
$$

Proof: By tightness, there exists an increasing sequence of compact sets, $\left\{K_{n}\right\}$ such that

$$
\mu\left(K_{n}\right)>1-\frac{1}{n}
$$

for all $\mu \in \Lambda$. Now letting $\mu \in \Lambda$ and $\phi \in C\left(K_{n}\right)$ such that $\|\phi\|_{\infty} \leq 1$, it follows

$$
\left|\int_{K_{n}} \phi d \mu\right| \leq \mu\left(K_{n}\right) \leq 1
$$

and so the restrictions of the measures of $\Lambda$ to $K_{n}$ are contained in the unit ball of $C\left(K_{n}\right)^{\prime}$. Recall from the Riesz representation theorem, the dual space of $C\left(K_{n}\right)$ is a space of complex Borel measures. Theorem 17.5.5 on Page 462 implies the unit ball of $C\left(K_{n}\right)^{\prime}$ is weak * sequentially compact. This follows from the observation that $C\left(K_{n}\right)$ is separable which is proved in Corollary 61.3.4 and leads to the fact that the unit ball in $C\left(K_{n}\right)^{\prime}$ is actually metrizable by Theorem 17.5.5 on Page 462. Therefore, there exists a subsequence of $\Lambda$, $\left\{\mu_{1 k}\right\}$ such that their restrictions to $K_{1}$ converge weak $*$ to a measure, $\lambda_{1} \in C\left(K_{1}\right)^{\prime}$. That is, for every $\phi \in C\left(K_{1}\right)$,

$$
\lim _{k \rightarrow \infty} \int_{K_{1}} \phi d \mu_{1 k}=\int_{K_{1}} \phi d \lambda_{1}
$$

By the same reasoning, there exists a further subsequence $\left\{\mu_{2 k}\right\}$ such that the restrictions of these measures to $K_{2}$ converge weak $*$ to a measure $\lambda_{2} \in C\left(K_{2}\right)^{\prime}$ etc. Continuing this way,

$$
\begin{aligned}
& \mu_{11}, \mu_{12}, \mu_{13}, \cdots \rightarrow \text { Weak } * \operatorname{in} C\left(K_{1}\right)^{\prime} \\
& \mu_{21}, \mu_{22}, \mu_{23}, \cdots \rightarrow \text { Weak } * \operatorname{in} C\left(K_{2}\right)^{\prime} \\
& \mu_{31}, \mu_{32}, \mu_{33}, \cdots \rightarrow \text { Weak } * \text { in } C\left(K_{3}\right)^{\prime}
\end{aligned}
$$

Here the $j^{t h}$ sequence is a subsequence of the $(j-1)^{t h}$. Let $\lambda_{n}$ denote the measure in $C\left(K_{n}\right)^{\prime}$ to which the sequence $\left\{\mu_{n k}\right\}_{k=1}^{\infty}$ converges weak*. Let $\left\{\mu_{n}\right\} \equiv\left\{\mu_{n n}\right\}$, the diagonal sequence. Thus this sequence is ultimately a subsequence of every one of the above sequences and so $\mu_{n}$ converges weak* in $C\left(K_{m}\right)^{\prime}$ to $\lambda_{m}$ for each $m$. Note that this is all happening on different sets so there is no contradiction with something converging to two different things.

Claim: For $p>n$, the restriction of $\lambda_{p}$ to the Borel sets of $K_{n}$ equals $\lambda_{n}$.
Proof of claim: Let $H$ be a compact subset of $K_{n}$. Then there are sets, $V_{l}$ open in $K_{n}$ which are decreasing and whose intersection equals $H$. This follows because this is a metric space. Then let $H \prec \phi_{l} \prec V_{l}$. It follows

$$
\begin{aligned}
\lambda_{n}\left(V_{l}\right) & \geq \int_{K_{n}} \phi_{l} d \lambda_{n}=\lim _{k \rightarrow \infty} \int_{K_{n}} \phi_{l} d \mu_{k} \\
& =\lim _{k \rightarrow \infty} \int_{K_{p}} \phi_{l} d \mu_{k}=\int_{K_{p}} \phi_{l} d \lambda_{p} \geq \lambda_{p}(H) .
\end{aligned}
$$

Now considering the ends of this inequality, let $l \rightarrow \infty$ and pass to the limit to conclude

$$
\lambda_{n}(H) \geq \lambda_{p}(H)
$$

Similarly,

$$
\begin{aligned}
\lambda_{n}(H) & \leq \int_{K_{n}} \phi_{l} d \lambda_{n}=\lim _{k \rightarrow \infty} \int_{K_{n}} \phi_{l} d \mu_{k} \\
& =\lim _{k \rightarrow \infty} \int_{K_{p}} \phi_{l} d \mu_{k}=\int_{K_{p}} \phi_{l} d \lambda_{p} \leq \lambda_{p}\left(V_{l}\right) .
\end{aligned}
$$

Then passing to the limit as $l \rightarrow \infty$, it follows

$$
\lambda_{n}(H) \leq \lambda_{p}(H)
$$

Thus the restriction of $\lambda_{p},\left.\lambda_{p}\right|_{K_{n}}$ to the compact sets of $K_{n}$ equals $\lambda_{n}$. Then by inner regularity it follows the two measures, $\left.\lambda_{p}\right|_{K_{n}}$, and $\lambda_{n}$ are equal on all Borel sets of $K_{n}$. Recall that for finite measures on separable metric spaces, regularity is obtained for free.

It is fairly routine to exploit regularity of the measures to verify that $\lambda_{m}(F) \geq 0$ for all $F$ a Borel subset of $K_{m}$. Note that $\phi \rightarrow \int_{K_{n}} \phi d \lambda_{n}$ is a positive linear functional and so $\lambda_{n} \geq 0$. Also, letting $\phi \equiv 1$,

$$
\begin{equation*}
1 \geq \lambda_{m}\left(K_{m}\right) \geq 1-\frac{1}{m} \tag{61.3.7}
\end{equation*}
$$

Define for $F$ a Borel set,

$$
\lambda(F) \equiv \lim _{n \rightarrow \infty} \lambda_{n}\left(F \cap K_{n}\right)
$$

The limit exists because the sequence on the right is increasing due to the above observation that $\lambda_{n}=\lambda_{m}$ on the Borel subsets of $K_{m}$ whenever $n>m$. Thus for $n>m$

$$
\lambda_{n}\left(F \cap K_{n}\right) \geq \lambda_{n}\left(F \cap K_{m}\right)=\lambda_{m}\left(F \cap K_{m}\right)
$$

Now let $\left\{F_{k}\right\}$ be a sequence of disjoint Borel sets. Then

$$
\begin{aligned}
\lambda\left(\cup_{k=1}^{\infty} F_{k}\right) & \equiv \lim _{n \rightarrow \infty} \lambda_{n}\left(\cup_{k=1}^{\infty} F_{k} \cap K_{n}\right)=\lim _{n \rightarrow \infty} \lambda_{n}\left(\cup_{k=1}^{\infty}\left(F_{k} \cap K_{n}\right)\right) \\
& =\lim _{n \rightarrow \infty} \sum_{k=1}^{\infty} \lambda_{n}\left(F_{k} \cap K_{n}\right)=\sum_{k=1}^{\infty} \lambda\left(F_{k}\right)
\end{aligned}
$$

the last equation holding by the monotone convergence theorem.
It remains to verify

$$
\lim _{k \rightarrow \infty} \int \phi d \mu_{k}=\int \phi d \lambda
$$

for every $\phi$ bounded and continuous. This is where tightness is used again. Then as noted above,

$$
\lambda_{n}\left(K_{n}\right)=\lambda\left(K_{n}\right)
$$

because for $p>n, \lambda_{p}\left(K_{n}\right)=\lambda_{n}\left(K_{n}\right)$ and so letting $p \rightarrow \infty$, the above is obtained. Also,
from 61.3.7,

$$
\begin{aligned}
\lambda\left(K_{n}^{C}\right) & =\lim _{p \rightarrow \infty} \lambda_{p}\left(K_{n}^{C} \cap K_{p}\right) \\
& \leq \lim _{p \rightarrow \infty}\left(\lambda_{p}\left(K_{p}\right)-\lambda_{p}\left(K_{n}\right)\right) \\
& \leq \lim _{p \rightarrow \infty}\left(\lambda_{p}\left(K_{p}\right)-\lambda_{n}\left(K_{n}\right)\right) \\
& \leq \lim _{p \rightarrow \infty}\left(1-\left(1-\frac{1}{n}\right)\right)=\frac{1}{n}
\end{aligned}
$$

Suppose $\|\phi\|_{\infty}<M$. Then

$$
\begin{aligned}
\mid \int \phi d \mu_{k} & -\int \phi d \lambda\left|\leq\left|\int_{K_{n}^{C}} \phi d \mu_{k}+\int_{K_{n}} \phi d \mu_{k}-\left(\int_{K_{n}} \phi d \lambda+\int_{K_{n}^{C}} \phi d \lambda\right)\right|\right. \\
& \leq\left|\int_{K_{n}} \phi d \mu_{k}-\int_{K_{n}} \phi d \lambda_{n}\right|+\left|\int_{K_{n}^{C}} \phi d \mu_{k}-\int_{K_{n}^{C}} \phi d \lambda\right| \\
& \leq\left|\int_{K_{n}} \phi d \mu_{k}-\int_{K_{n}} \phi d \lambda_{n}\right|+\left|\int_{K_{n}^{C}} \phi d \mu_{k}\right|+\left|\int_{K_{n}^{C}} \phi d \lambda\right| \\
& \leq\left|\int_{K_{n}} \phi d \mu_{k}-\int_{K_{n}} \phi d \lambda_{n}\right|+\frac{M}{n}+\frac{M}{n}
\end{aligned}
$$

First let $n$ be so large that $2 M / n<\varepsilon / 2$ and then pick $k$ large enough that the above expression is less than $\varepsilon$.

Definition 61.3.6 Let $E$ be a complete separable metric space and let $\mu$ and the sequence of probability measures, $\left\{\mu_{n}\right\}$ defined on $\mathscr{B}(E)$ satisfy

$$
\lim _{n \rightarrow \infty} \int \phi d \mu_{n}=\int \phi d \mu
$$

for every $\phi$ a bounded continuous function. Then $\mu_{n}$ is said to converge weakly to $\mu$.

### 61.4 A Major Existence And Convergence Theorem

Here is an interesting lemma about weak convergence.
Lemma 61.4.1 Let $\mu_{n}$ converge weakly to $\mu$ and let $U$ be an open set with $\mu(\partial U)=0$. Then

$$
\lim _{n \rightarrow \infty} \mu_{n}(U)=\mu(U)
$$

Proof: Let $\left\{\psi_{k}\right\}$ be a sequence of bounded continuous functions which decrease to $\mathscr{X}_{\bar{U}}$. Also let $\left\{\phi_{k}\right\}$ be a sequence of bounded continuous functions which increase to $\mathscr{X}_{U}$. For example, you could let

$$
\begin{aligned}
\psi_{k}(x) & \equiv(1-k \operatorname{dist}(x, U))^{+} \\
\phi_{k}(x) & \equiv 1-\left(1-k \operatorname{dist}\left(x, U^{C}\right)\right)^{+}
\end{aligned}
$$

Let $\varepsilon>0$ be given. Then since $\mu(\partial U)=0$, the dominated convergence theorem implies there exists $\psi=\psi_{k}$ and $\phi=\phi_{k}$ such that

$$
\varepsilon>\int \psi d \mu-\int \phi d \mu
$$

Next use the weak convergence to pick $N$ large enough that if $n \geq N$,

$$
\int \psi d \mu_{n} \leq \int \psi d \mu+\varepsilon, \int \phi d \mu_{n} \geq \int \phi d \mu-\varepsilon .
$$

Therefore, for $n$ this large,

$$
\mu(U), \mu_{n}(U) \in\left[\int \phi d \mu-\varepsilon, \int \psi d \mu+\varepsilon\right]
$$

and so

$$
\left|\mu(U)-\mu_{n}(U)\right|<3 \varepsilon
$$

since $\varepsilon$ is arbitrary, this proves the lemma.
Definition 61.4.2 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $X: \Omega \rightarrow E$ be a random variable where here $E$ is some topological space. Then one can define a probability measure, $\lambda_{X}$ on $\mathscr{B}(E)$ as follows:

$$
\lambda_{X}(F) \equiv P([X \in F])
$$

More generally, if $\mu$ is a probability measure on $\mathscr{B}(E)$, and $X$ is a random variable defined on a probability space, $\mathscr{L}(X)=\mu$ means

$$
\mu(F) \equiv P([X \in F])
$$

The following amazing theorem is due to Skorokhod. It starts with a measure, $\mu$ on $\mathscr{B}(E)$ and produces a random variable, $X$ for which $\mathscr{L}(X)=\mu$. It also has something to say about the convergence of a sequence of such random variables.

Theorem 61.4.3 Let $E$ be a separable complete metric space and let $\left\{\mu_{n}\right\}$ be a sequence of Borel probability measures defined on $\mathscr{B}(E)$ such that $\mu_{n}$ converges weakly to $\mu$ another probability measure on $\mathscr{B}(E)$. Then there exist random variables, $X_{n}, X$ defined on the probability space, $([0,1), \mathscr{B}([0,1)), m)$ where $m$ is one dimensional Lebesgue measure such that

$$
\begin{equation*}
\mathscr{L}(X)=\mu, \mathscr{L}\left(X_{n}\right)=\mu_{n} \tag{61.4.8}
\end{equation*}
$$

each random variable, $X, X_{n}$ is continuous off a set of measure zero, and

$$
X_{n}(\omega) \rightarrow X(\omega) \text { ma.e. }
$$

Proof: Let $\left\{a_{k}\right\}$ be a countable dense subset of $E$.

## Construction of sets in $E$

First I will describe a construction. Letting $C \in \mathscr{B}(E)$ and $r>0$,

$$
\begin{aligned}
C_{1}^{r} & \equiv C \cap B\left(a_{1}, r\right), C_{2}^{r} \equiv B\left(a_{2}, r\right) \cap C \backslash C_{1}^{r}, \cdots, \\
C_{n}^{r} & \equiv B\left(a_{n}, r\right) \cap C \backslash\left(\cup_{k=1}^{n-1} C_{k}^{r}\right) .
\end{aligned}
$$

Thus the sets, $C_{k}^{r}$ for $k=1,2, \cdots$ are disjoint Borel sets whose union is all of $C$. Of course many may be empty.

$$
C_{n\left(\text { index of the }\left\{a_{k}\right\} \text { it is close to }\right)}^{r(\text { size })}
$$

Now let $C=E$, the whole metric space. Also let $\left\{r_{k}\right\}$ be a decreasing sequence of positive numbers which converges to 0 . Let

$$
A_{k} \equiv E_{k}^{r_{1}}, k=1,2, \cdots
$$

Thus $\left\{A_{k}\right\}$ is a sequence of Borel sets, $A_{k} \subseteq B\left(a_{k}, r_{1}\right)$, and the union of the $A_{k}$ equals $E$. For $\left(i_{1}, \cdots, i_{m}\right) \in \mathbb{N}^{m}$, suppose $A_{i_{1}, \cdots, i_{m}}$ has been defined. Then for $k \in \mathbb{N}$,

$$
A_{i_{1}, \cdots, i_{m} k} \equiv\left(A_{i_{1}, \cdots, i_{m}}\right)_{k}^{r_{m+1}}
$$

Thus $A_{i_{1}, \cdots, i_{m} k} \subseteq B\left(a_{k}, r_{m+1}\right)$, is a Borel set, and

$$
\begin{equation*}
\cup_{k=1}^{\infty} A_{i_{1}, \cdots, i_{m} k}=A_{i_{1}, \cdots, i_{m}} \tag{61.4.9}
\end{equation*}
$$

Also note that $A_{i_{1}, \cdots, i_{m}}$ could be empty. This is because $A_{i_{1}, \cdots, i_{m} k} \subseteq B\left(a_{k}, r_{m+1}\right)$ but $A_{i_{1}, \cdots, i_{m}} \subseteq$ $B\left(a_{i_{m}}, r_{m}\right)$ which might have empty intersection with $B\left(a_{k}, r_{m+1}\right)$. Applying 61.4.9 repeatedly,

$$
E=\cup_{i_{1}} \cdots \cup_{i_{m}} A_{i_{1}, \cdots, i_{m}}
$$

and also, the construction shows the Borel sets, $A_{i_{1}, \cdots, i_{m}}$ are disjoint. Note that to get $A_{i_{1}, \cdots, i_{m} k}$, you do to $A_{i_{1}, \cdots, i_{m}}$ what was done for $E$ but you consider smaller sized pieces.

## Construction of intervals depending on the measure

Next I will construct intervals, $I_{i_{1}, \cdots, i_{n}}^{V}$ in $[0,1)$ corresponding to these $A_{i_{1}, \cdots, i_{n}}$. In what follows, $v=\mu_{n}$ or $\mu$. These intervals will depend on the measure chosen as indicated in the notation.

$$
I_{1}^{v} \equiv\left[0, v\left(A_{1}\right)\right), \cdots, I_{j}^{v} \equiv\left[\sum_{k=1}^{j-1} v\left(A_{k}\right), \sum_{k=1}^{j} v\left(A_{k}\right)\right)
$$

for $j=1,2, \cdots$. Note these are disjoint intervals whose union is $[0,1)$. Also note

$$
m\left(I_{j}^{V}\right)=v\left(A_{j}\right)
$$

The endpoints of these intervals as well as their lengths depend on the measures of the sets $A_{k}$. Now supposing $I_{i_{1}, \cdots, i_{m}}^{v}=[\alpha, \beta)$ where $\beta-\alpha=v\left(A_{i_{1} \cdots, i_{m}}\right)$, define

$$
I_{i_{1} \cdots, i_{m}, j}^{v} \equiv\left[\alpha+\sum_{k=1}^{j-1} v\left(A_{i_{1} \cdots, i_{m}, k}\right), \alpha+\sum_{k=1}^{j} v\left(A_{i_{1} \cdots, i_{m}, k}\right)\right)
$$

Thus $m\left(I_{i_{1} \cdots, i_{m}, j}^{v}\right)=v\left(A_{i_{1} \cdots, i_{m}, j}\right)$ and

$$
v\left(A_{i_{1} \cdots, i_{m}}\right)=\sum_{k=1}^{\infty} v\left(A_{i_{1} \cdots, i_{m}, k}\right)=\sum_{k=1}^{\infty} m\left(I_{i_{1} \cdots, i_{m}, k}^{v}\right)=\beta-\alpha
$$

the intervals, $I_{i_{1} \cdots, i_{m}, j}^{v}$ being disjoint and

$$
I_{i_{1} \cdots, i_{m}}^{V}=\cup_{j=1}^{\infty} I_{i_{1} \cdots, i_{m}, j}^{V}
$$

These intervals satisfy the same inclusion properties as the sets $\left\{A_{i_{1}, \cdots, i_{m}}\right\}$. They are just on $[0,1)$ rather than on $E$. The intervals $I_{i_{1} \cdots, i_{m} k}^{V}$ correspond to the sets $A_{i_{1} \cdots, i_{m}, k}$ and in fact the Lebesgue measure of the interval is the same as $v\left(A_{i_{1} \cdots, i_{m}, k}\right)$.

## Choosing the sequence $\left\{r_{k}\right\}$ in an auspicious manner

There are at most countably many positive numbers, $r$ such that for $v=\mu_{n}$ or $\mu$,

$$
v\left(\partial B\left(a_{i}, r\right)\right)>0
$$

This is because $v$ is a finite measure. Taking the countable union of these countable sets, there are only countably many $r$ such that $v\left(\partial B\left(a_{i}, r\right)\right)>0$ for some $a_{i}$. Let the sequence avoid all these bad values of $r$. Thus for

$$
F \equiv \cup_{m=1}^{\infty} \cup_{k=1}^{\infty} \partial B\left(a_{k}, r_{m}\right)
$$

and $v=\mu$ or $\mu_{n}, v(F)=0$. Here the $r_{m}$ are all good values such that for all $k, m, \partial B\left(a_{k}, r_{m}\right)$ has $\mu$ measure zero and $\mu_{n}$ measure zero.

Claim 1: $\partial A_{i_{1}, \cdots, i_{k}} \subseteq F$. This really follows from the construction. However, the details follow.

Proof of claim: Suppose $C$ is a Borel set for which $\partial C \subseteq F$. I need to show $\partial C_{k}^{r_{i}} \in F$. First consider $k=1$. Then $C_{1}^{r_{i}} \equiv B\left(a_{1}, r_{i}\right) \cap C$. If $x \in \partial C_{1}^{r_{i}}$, then $B(x, \delta)$ contains points of $B\left(a_{1}, r_{i}\right) \cap C$ and points of $B\left(a_{1}, r_{i}\right)^{C} \cup C^{C}$ for every $\delta>0$. First suppose $x \in B\left(a_{1}, r_{i}\right)$. Then a small enough neighborhood of $x$ has no points of $B\left(a_{1}, r_{i}\right)^{C}$ and so every $B(x, \delta)$ has points of $C$ and points of $C^{C}$ so that $x \in \partial C \subseteq F$ by assumption. If $x \in \partial C_{1}^{r_{i}}$, then it can't happen that $\left\|x-a_{1}\right\|>r_{i}$ because then there would be a neighborhood of $x$ having no points of $C_{1}^{r_{i}}$. The only other case to consider is that $\left\|x-a_{i}\right\|=r_{i}$ but this says $x \in F$. Now assume $\partial C_{j}^{r_{i}} \subseteq F$ for $j \leq k-1$ and consider $\partial C_{k}^{r_{i}}$.

$$
\begin{align*}
C_{k}^{r_{i}} & \equiv B\left(a_{k}, r_{i}\right) \cap C \backslash \cup_{j=1}^{k-1} C_{j}^{r_{i}} \\
& =B\left(a_{k}, r_{i}\right) \cap C \cap\left(\cap_{j=1}^{k-1}\left(C_{j}^{r_{i}}\right)^{C}\right) \tag{61.4.10}
\end{align*}
$$

Consider $x \in \partial C_{k}^{r_{i}}$. If $x \in \operatorname{int}\left(B\left(a_{k}, r_{i}\right) \cap C\right)($ int $\equiv$ interior $)$ then a small enough ball about $x$ contains no points of $\left(B\left(a_{k}, r_{i}\right) \cap C\right)^{C}$ and so every ball about $x$ must contain points of

$$
\left(\cap_{j=1}^{k-1}\left(C_{j}^{r_{i}}\right)^{C}\right)^{C}=\cup_{j=1}^{k-1} C_{j}^{r_{i}}
$$

Since there are only finitely many sets in the union, there exists $s \leq k-1$ such that every ball about $x$ contains points of $C_{s}^{r_{i}}$ but from 61.4.10, every ball about $x$ contains points of $\left(C_{s}^{r_{i}}\right)^{C}$ which implies $x \in \partial C_{s}^{r_{i}} \subseteq F$ by induction. It is not possible that $d\left(x, a_{k}\right)>r_{i}$ and yet have $x$ in $\partial C_{k}^{r_{i}}$. This follows from the description in 61.4.10. If $d\left(x, a_{k}\right)=r_{i}$ then by definition, $x \in F$. The only other case to consider is that $x \notin \operatorname{int}\left(B\left(a_{k}, r_{i}\right) \cap C\right)$ but $x \in B\left(a_{k}, r_{i}\right)$. From 61.4.10, every ball about $x$ contains points of $C$. However, since $x \in B\left(a_{k}, r_{i}\right)$, a small enough ball is contained in $B\left(a_{k}, r_{i}\right)$. Therefore, every ball about $x$ must also contain points of $C^{C}$ since otherwise, $x \in \operatorname{int}\left(B\left(a_{k}, r_{i}\right) \cap C\right)$. Thus $x \in \partial C \subseteq F$ by assumption. Now apply what was just shown to the case where $C=E$, the whole space. In this case, $\partial E \subseteq F$ because $\partial E=\emptyset$. Then keep applying what was just shown to the $A_{i_{1}, \cdots, i_{n}}$. This proves the claim.

From the claim, $v\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{n}}\right)\right)=v\left(A_{i_{1}, \cdots, i_{n}}\right)$ whenever $v=\mu$ or $\mu_{n}$. This is because that in $A_{i_{1}, \cdots, i_{n}}$ which is not in $\operatorname{int}\left(A_{i_{1}, \cdots, i_{n}}\right)$ is in $F$ which has measure zero.

## Some functions on $[0,1)$

By the axiom of choice, there exists $x_{i_{1}, \cdots, i_{m}} \in \operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)$ whenever

$$
\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right) \neq \emptyset
$$

For $v=\mu_{n}$ or $\mu$, define the following functions. For $\omega \in I_{i_{1}, \cdots, i_{m}}^{v}$

$$
Z_{m}^{v}(\omega) \equiv x_{i_{1}, \cdots, i_{m}}
$$

This defines the functions, $Z_{m}^{\mu_{n}}$ and $Z_{m}^{\mu}$. Note these functions have the same values but on slightly different intervals. Here is an important claim.

Claim 2 (Limit on $\mu_{n}$ ): For a.e. $\omega \in[0,1), \lim _{n \rightarrow \infty} Z_{m}^{\mu_{n}}(\omega)=Z_{m}^{\mu}(\omega)$.
Proof of the claim: This follows from the weak convergence of $\mu_{n}$ to $\mu$ and Lemma 61.4.1. This lemma implies $\mu_{n}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right) \rightarrow \mu\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right)$. Thus by the construction described above, $\mu_{n}\left(A_{i_{1}, \cdots, i_{m}}\right) \rightarrow \mu\left(A_{i_{1}}, \cdots, i_{m}\right)$ because of claim 1 and the construction of $F$ in which it is always a set of measure zero. It follows that if $\omega \in \operatorname{int}\left(I_{i_{1}, \cdots, i_{m}}^{\mu}\right)$, then for all $n$ large enough, $\omega \in \operatorname{int}\left(I_{i_{1}, \cdots, i_{m}}^{\mu_{n}}\right)$ and so $Z_{m}^{\mu_{n}}(\omega)=Z_{m}^{\mu}(\omega)$. Note this convergence is very far from being uniform.

Claim 3 (Limit on size of sets, fixed measure): For $v=\mu_{n}$ or $\mu,\left\{Z_{m}^{v}\right\}_{m=1}^{\infty}$ is uniformly Cauchy independent of $v$.

Proof of the claim: For $\omega \in I_{i_{1}, \cdots, i_{m}}^{V}$, then by the construction,

$$
\omega \in I_{i_{1}, \cdots, i_{m}, i_{m+1} \cdots, i_{n}}^{V}
$$

for some $i_{m+1} \cdots, i_{n}$. Therefore, $Z_{m}^{v}(\omega)$ and $Z_{n}^{v}(\omega)$ are both contained in $A_{i_{1}, \cdots, i_{m}}$ which is contained in $B\left(a_{i_{m}}, r_{m}\right)$. Since $\omega \in[0,1)$ was arbitrary, and $r_{m} \rightarrow 0$, it follows these functions are uniformly Cauchy as claimed.

Let $X^{\nu}(\omega)=\lim _{m \rightarrow \infty} Z_{m}^{\nu}(\omega)$. Since each $Z_{m}^{V}$ is continuous off a set of measure zero, it follows from the uniform convergence that $X^{v}$ is also continuous off a set of measure zero.

Claim 4: For a.e. $\omega$,

$$
\lim _{n \rightarrow \infty} X^{\mu_{n}}(\omega)=X^{\mu}(\omega)
$$

Proof of the claim: From Claim 3 and letting $\varepsilon>0$ be given, there exists $m$ large enough that for all $n$,

$$
\sup _{\omega} d\left(Z_{m}^{\mu_{n}}(\omega), X^{\mu_{n}}(\omega)\right)<\varepsilon / 3, \sup _{\omega} d\left(Z_{m}^{\mu}(\omega), X^{\mu}(\omega)\right)<\varepsilon / 3 .
$$

for $\omega$ off a set of measure zero. Now pick $\omega \in[0,1)$ such that $\omega$ is not equal to any of the end points of any of the intervals, $\left\{I_{i_{1}, \cdots, i_{m}}^{v}\right\}$, this countable set of endpoints, a set of Lebesgue measure zero. Then by Claim 2, there exists $N$ such that if $n \geq N$, then $d\left(Z_{m}^{\mu_{n}}(\omega), Z_{m}^{\mu}(\omega)\right)<\varepsilon / 3$. Therefore, for such $n$ and this $\omega$,

$$
\begin{aligned}
d\left(X^{\mu_{n}}(\omega), X^{\mu}(\omega)\right) \leq & d\left(X^{\mu_{n}}(\omega), Z_{m}^{\mu_{n}}(\omega)\right)+d\left(Z_{m}^{\mu_{n}}(\omega), Z_{m}^{\mu}(\omega)\right) \\
& +d\left(Z_{m}^{\mu}(\omega), X^{\mu}(\omega)\right) \\
< & \varepsilon / 3+\varepsilon / 3+\varepsilon / 3=\varepsilon
\end{aligned}
$$

This proves the claim.

$$
\text { Showing } \mathscr{L}\left(X^{v}\right)=v
$$

This has mostly proved the theorem except for the claim that $\mathscr{L}\left(X^{v}\right)=v$ for $v=$ $\mu_{n}$ and $\mu$. To do this, I will first show $m\left(\left(X^{v}\right)^{-1}\left(\partial A_{i_{1}, \cdots, i_{m}}\right)\right)=0$. By the construction, $v\left(\partial A_{i_{1}, \cdots, i_{m}}\right)=0$. Let $\varepsilon>0$ be given and let $\delta>0$ be small enough that

$$
H_{\delta} \equiv\left\{x \in E: \operatorname{dist}\left(x, \partial A_{i_{1}, \cdots, i_{m}}\right) \leq \delta\right\}
$$

is a set of measure less than $\varepsilon / 2$. Denote by $\mathscr{G}_{k}$ the sets of the form $A_{i_{1}, \cdots, i_{k}}$ where $\left(i_{1}, \cdots, i_{k}\right) \in \mathbb{N}^{k}$. Recall also that corresponding to $A_{i_{1}, \cdots, i_{k}}$ is an interval, $I_{i_{1}, \cdots, i_{k}}^{v}$ having length equal to $v\left(A_{i_{1}, \cdots, i_{k}}\right)$. Denote by $\mathscr{B}_{k}$ those sets of $\mathscr{G}_{k}$ which have nonempty intersection with $H_{\delta}$ and let the corresponding intervals be denoted by $\mathscr{I}_{k}^{v}$. If $\omega \notin \cup \mathscr{I}_{k}^{v}$, then from the construction, $Z_{p}^{v}(\omega)$ is at a distance of at least $\delta$ from $\partial A_{i_{1}, \cdots, i_{m}}$ for all $p \geq k$. (If $Z_{k}^{v}(\omega)$ were in some set of $\mathscr{B}_{k}$, this would require $\omega$ to be in the corresponding $I_{k}^{v}$ and it is assumed this does not happen. Then for any $p>k, Z_{p}^{v}(\omega)$ cannot be in any set of $\mathscr{G}_{p}$ which intersects $H_{\delta}$ either. If it did, you would need to have $\omega \notin \cup \mathscr{I}_{p}^{v}$ but all of these intervals are inside the intervals $\mathscr{I}_{k}^{V}$.) Passing to the limit as $p \rightarrow \infty$, it follows $X^{v}(\omega) \notin \partial A_{i_{1}, \cdots, i_{m}}$. Therefore,

$$
\left(X^{v}\right)^{-1}\left(\partial A_{i_{1}, \cdots, i_{m}}\right) \subseteq \cup \mathscr{I}_{k}^{v}
$$

Recall that $A_{i_{1}, \cdots, i_{k}} \subseteq B\left(a_{i_{k}}, r_{k}\right)$ and the $r_{k} \rightarrow 0$. Therefore, if $k$ is large enough,

$$
v\left(\cup \mathscr{B}_{k}\right)<\varepsilon
$$

because $\cup \mathscr{B}_{k}$ approximates $H_{\delta}$ closely (In fact, $\cap_{k=1}^{\infty}\left(\cup \mathscr{B}_{k}\right)=H_{\delta}$.). Therefore,

$$
\begin{aligned}
m\left(\left(X^{v}\right)^{-1}\left(\partial A_{i_{1}, \cdots, i_{m}}\right)\right) & \leq m\left(\cup \mathscr{I}_{k}^{v}\right) \\
& =\sum_{I_{i_{1}, \cdots, i_{k}}^{v} \in \mathscr{I}_{k}^{v}} m\left(I_{i_{1}, \cdots, i_{k}}^{v}\right) \\
& =\sum_{A_{i_{1}, \cdots, i_{k} \in \mathscr{B}_{k}} v\left(A_{i_{1}, \cdots, i_{k}}\right)}=v\left(\cup \mathscr{B}_{k}\right)<\varepsilon .
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this shows $m\left(\left(X^{v}\right)^{-1}\left(\partial A_{i_{1}, \cdots, i_{m}}\right)\right)=0$.
If $\omega \in I_{i_{1}, \cdots, i_{m}}^{V}$, then from the construction, $Z_{p}^{V}(\omega) \in \operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)$ for all $p \geq k$. Therefore, taking a limit, as $p \rightarrow \infty$,

$$
X^{V}(\omega) \in \operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right) \cup \partial A_{i_{1}, \cdots, i_{m}}
$$

and so

$$
I_{i_{1}, \cdots, i_{m}}^{V} \subseteq\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right) \cup \partial A_{i_{1}, \cdots, i_{m}}\right)
$$

but also, if $X^{v}(\omega) \in \operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)$, then $Z_{p}^{v}(\omega) \in \operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)$ for all $p$ large enough and so

$$
\begin{aligned}
& \left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right) \\
\subseteq & I_{i_{1}, \cdots, i_{m}}^{v} \subseteq\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right) \cup \partial A_{i_{1}, \cdots, i_{m}}\right)
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
& m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}}, \cdots, i_{m}\right)\right)\right) \\
\leq & m\left(I_{i_{1}, \cdots, i_{m}}^{V}\right) \\
\leq & m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right)\right)+m\left(\left(X^{v}\right)^{-1}\left(\partial A_{i_{1}, \cdots, i_{m}}\right)\right) \\
= & m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right)\right)
\end{aligned}
$$

which shows

$$
\begin{equation*}
m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right)\right)=m\left(I_{i_{1}, \cdots, i_{m}}^{v}\right)=v\left(A_{i_{1}, \cdots, i_{m}}\right) \tag{61.4.11}
\end{equation*}
$$

Also

$$
\begin{aligned}
& m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right)\right) \\
\leq & m\left(\left(X^{v}\right)^{-1}\left(A_{i_{1}, \cdots, i_{m}}\right)\right) \\
\leq & m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right) \cup \partial A_{i_{1}, \cdots, i_{m}}\right)\right) \\
= & m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right)\right)
\end{aligned}
$$

Hence from 61.4.11,

$$
\begin{gather*}
v\left(A_{i_{1}, \cdots, i_{m}}\right)=m\left(\left(X^{v}\right)^{-1}\left(\operatorname{int}\left(A_{i_{1}, \cdots, i_{m}}\right)\right)\right) \\
=m\left(\left(X^{v}\right)^{-1}\left(A_{i_{1}, \cdots, i_{m}}\right)\right) \tag{61.4.12}
\end{gather*}
$$

Now let $U$ be an open set in $E$. Then letting

$$
H_{k}=\left\{x \in U: \operatorname{dist}\left(x, U^{C}\right) \geq r_{k}\right\}
$$

it follows

$$
\cup_{k} H_{k}=U
$$

Next consider the sets of $\mathscr{G}_{k}$ which have nonempty intersection with $H_{k}, \mathscr{H}_{k}$. Then $H_{k}$ is covered by $\mathscr{H}_{k}$ and every set of $\mathscr{H}_{k}$ is contained in $U$, the sets of $\mathscr{H}_{k}$ also being disjoint. Then from 61.4.12,

$$
\begin{aligned}
m\left(\left(X^{v}\right)^{-1}\left(\cup \mathscr{H}_{k}\right)\right) & =\sum_{A \in \mathscr{H}_{k}} m\left(\left(X^{v}\right)^{-1}(A)\right) \\
& =\sum_{A \in \mathscr{H}_{k}} v(A)=v\left(\cup \mathscr{H}_{k}\right)
\end{aligned}
$$

Therefore, letting $k \rightarrow \infty$ and passing to the limit in the above,

$$
m\left(\left(X^{v}\right)^{-1}(U)\right)=v(U)
$$

Since this holds for every open set, it is routine to verify using regularity that it holds for every Borel set and so $\mathscr{L}\left(X^{v}\right)=v$ as claimed.

### 61.5 Bochner's Theorem In Infinite Dimensions

Let $X$ be a real vector space and let $X^{*}$ denote the space of real valued linear mappings defined on $X$. Then you can consider each $x \in X$ as a linear transformation defined on $X^{*}$ by the convention $x^{*} \rightarrow x^{*}(x)$. Now let $\Lambda$ be a Hamel basis. For a description of what one of these is, see Page 2726. It is just the usual notion of a basis. Thus every vector of $X$ is a finite linear combination of vectors of $\Lambda$ in a unique way.

Now consider $\mathbb{R}^{\Lambda}$ the space of all mappings from $\Lambda$ to $\mathbb{R}$. In different notation, this is of the form

$$
\mathbb{R}^{\Lambda} \equiv \prod_{y \in \Lambda} \mathbb{R}
$$

Since $\Lambda$ is a Hamel basis, there exists a one to one and onto mapping, $\theta: X^{*} \rightarrow \mathbb{R}^{\Lambda}$ defined as

$$
\boldsymbol{\theta}\left(x^{*}\right) \equiv \prod_{y \in \Lambda} x^{*}(y)
$$

Now denote by $\sigma(X)$ the smallest $\sigma$ algebra of sets of $X^{*}$ such that each $x$ is measurable with respect to this $\sigma$ algebra. Thus

$$
\left\{x^{*}: x^{*}(x) \in B\right\} \in \sigma(X)
$$

whenever $B$ is a Borel set in $\mathbb{R}$.
Let $\mathscr{E}$ denote the algebra of disjoint unions of sets of $\mathbb{R}^{\Lambda}$ of the form

$$
\prod_{y \in \Lambda} A_{y}
$$

where $A_{y}=\mathbb{R}$ except for finitely many $y$.

Lemma 61.5.1 Let $\mathscr{A}$ denote sets of the form

$$
\left\{x^{*}: \theta\left(x^{*}\right) \in U\right\}
$$

where $U \in \mathscr{E}$. Then $\mathscr{A}$ is an algebra and $\sigma(\mathscr{A})=\sigma(X)$. Also

$$
\left\{\theta^{-1}(U): U \in \sigma(\mathscr{E})\right\}=\sigma(X)
$$

Proof: Since $\mathscr{E}$ is an algebra it is clear $\mathscr{A}$ is also an algebra. Also, $\mathscr{A} \subseteq \sigma(X)$ because you could let $U$ have only one $A_{y}$ not equal to $\mathbb{R}$ and all the others equal to $\mathbb{R}$ and then

$$
\left\{x^{*}: \theta\left(x^{*}\right) \in U\right\}=\left\{x^{*}: y\left(x^{*}\right) \equiv x^{*}(y) \in A_{y}\right\} \in \sigma(X) .
$$

Therefore, $\sigma(\mathscr{A}) \subseteq \sigma(X)$. I need to verify that for an arbitrary $x$, it is measurable with respect to $\sigma(\mathscr{A})$. However, this is true because if $x$ is arbitrary, it is a linear combination of $\left\{y_{1}, \cdots, y_{n}\right\}$, some finite set of functions in $\Lambda$ and so, $x$ being a linear combination of measurable functions implies it is itself measurable.

By definition, $\theta^{-1}(U)$ is in $\mathscr{A}$ whenever $U \in \mathscr{E}$. Now let $\mathscr{G}$ denote those sets, $U$ in $\sigma(\mathscr{E})$ such that $\theta^{-1}(U) \in \sigma(\mathscr{A})$. Then $\mathscr{G}$ is a $\sigma$ algebra which contains $\mathscr{E}$ and so $\mathscr{G} \supseteq \sigma(\mathscr{E}) \supseteq \mathscr{G}$. This proves the last claim. This proves the lemma.

Definition 61.5.2 Let $\psi: X \rightarrow \mathbb{C}$. Then $\psi$ is said to be pseudo continuous if whenever $\left\{x_{1}, \cdots, x_{n}\right\}$ is a finite subset of $X$ and $\mathbf{a}=\left(a_{1}, \cdots, a_{n}\right) \in \mathbb{R}^{n}$,

$$
\mathbf{a} \rightarrow \psi\left(\sum_{k=1}^{n} a_{k} x_{k}\right)
$$

is continuous. $\psi$ is said to be positive definite if

$$
\sum_{j, k} \psi\left(x_{k}-x_{j}\right) \alpha_{k} \overline{\alpha_{j}} \geq 0
$$

$\psi$ is said to be a characteristic function if there exists a probability measure, $\mu$ defined on $\sigma(X)$ such that

$$
\psi(x)=\int_{X^{*}} e^{i x^{*}(x)} d \mu\left(x^{*}\right)
$$

Note that $x^{*} \rightarrow e^{i x^{*}(x)}$ is $\sigma(X)$ measurable.
Using Kolmogorov's extension theorem on Page 59.2.3, there exists a generalization of Bochner's theorem found in [125]. For convenience, here is Kolmogorov's theorem.

Theorem 61.5.3 (Kolmogorov extension theorem) For each finite set

$$
J=\left(t_{1}, \cdots, t_{n}\right) \subseteq I
$$

suppose there exists a Borel probability measure, $v_{J}=v_{t_{1} \cdots t_{n}}$ defined on the Borel sets of $\prod_{t \in J} M_{t}$ for $M_{t}=\mathbb{R}^{n_{t}}$ for $n_{t}$ an integer, such that the following consistency condition holds. If

$$
\left(t_{1}, \cdots, t_{n}\right) \subseteq\left(s_{1}, \cdots, s_{p}\right)
$$

then

$$
\begin{equation*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=v_{s_{1} \cdots s_{p}}\left(G_{s_{1}} \times \cdots \times G_{s_{p}}\right) \tag{61.5.13}
\end{equation*}
$$

where if $s_{i}=t_{j}$, then $G_{s_{i}}=F_{t_{j}}$ and if $s_{i}$ is not equal to any of the indices, $t_{k}$, then $G_{s_{i}}=M_{s_{i}}$. Then for $\mathscr{E}$ defined as in Definition 14.4.1, adjusted so that $\pm \infty$ never appears as any endpoint of any interval, there exists a probability measure, $P$ and a $\sigma$ algebra $\mathscr{F}=\sigma(\mathscr{E})$ such that

$$
\left(\prod_{t \in I} M_{t}, P, \mathscr{F}\right)
$$

is a probability space. Also there exist measurable functions, $X_{s}: \prod_{t \in I} M_{t} \rightarrow M_{s}$ defined as

$$
X_{S} \mathbf{x} \equiv x_{s}
$$

for each $s \in I$ such that for each $\left(t_{1} \cdots t_{n}\right) \subseteq I$,

$$
\begin{gather*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=P\left(\left[X_{t_{1}} \in F_{t_{1}}\right] \cap \cdots \cap\left[X_{t_{n}} \in F_{t_{n}}\right]\right) \\
\quad=P\left(\left(X_{t_{1}}, \cdots, X_{t_{n}}\right) \in \prod_{j=1}^{n} F_{t_{j}}\right)=P\left(\prod_{t \in I} F_{t}\right) \tag{61.5.14}
\end{gather*}
$$

where $F_{t}=M_{t}$ for every $t \notin\left\{t_{1} \cdots t_{n}\right\}$ and $F_{t_{i}}$ is a Borel set. Also if $f$ is a nonnegative function of finitely many variables, $x_{t_{1}}, \cdots, x_{t_{n}}$, measurable with respect to $\mathscr{B}\left(\prod_{j=1}^{n} M_{t_{j}}\right)$, then $f$ is also measurable with respect to $\mathscr{F}$ and

$$
\begin{align*}
& \int_{M_{t_{1} \times \cdots \times M_{t_{n}}}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d v_{t_{1} \cdots t_{n}} \\
= & \int_{\prod_{t \in I} M_{t}} f\left(x_{t_{1}}, \cdots, x_{t_{n}}\right) d P \tag{61.5.15}
\end{align*}
$$

Theorem 61.5.4 Let $X$ be a real vector space and let $X^{*}$ be the space of linear functionals defined on $X$. Also let $\psi: X \rightarrow \mathbb{C}$. Then $\psi$ is a characteristic function if and only if $\psi(0)=1$ and $\psi$ is pseudo continuous at 0 .

Proof: Suppose first $\psi$ is a characteristic function as just described. I need to show it is positive definite and pseudo continuous. It is obvious $\psi(0)=1$ in this case. Also

$$
\psi\left(\sum_{k} a_{k} x_{k}\right)=\int_{X^{*}} \exp \left(i x^{*}\left(\sum_{k} a_{k} x_{k}\right)\right) d \mu\left(x^{*}\right)
$$

and this is obviously a continuous function of a by the dominated convergence theorem. It only remains to verify the function is positive definite. However,

$$
\sum_{k, j} \exp \left(i x^{*}\left(x_{k}-x_{j}\right)\right) \alpha_{k} \overline{\alpha_{j}}=\sum_{k, j} e^{i x^{*}\left(x_{k}\right)} \alpha_{k} \overline{e^{i x^{*}\left(x_{j}\right)} \alpha_{j}} \geq 0
$$

as in the earlier discussion of what it means to be positive definite given on Page 1938.

Next suppose the conditions hold. Define for $\mathbf{t} \in \mathbb{R}^{n}$ and $\left\{y_{1}, \cdots, y_{n}\right\} \subseteq \Lambda$

$$
\psi_{\left\{y_{1}, \cdots, y_{n}\right\}}(\mathbf{t}) \equiv \psi\left(\sum_{j=1}^{n} t_{j} y_{j}\right) .
$$

Then $\psi_{\left\{y_{1}, \cdots, y_{n}\right\}}$ is continuous at $\mathbf{0}$, equals 1 there, and is positive definite. It follows from Bochner's theorem, Theorem 59.21 .7 on Page 1941 there exists a measure $\mu_{\left\{y_{1}, \cdots, y_{n}\right\}}$ defined on the Borel sets of $\mathbb{R}^{n}$ such that

$$
\begin{equation*}
\psi\left(\sum_{j=1}^{n} t_{j} y_{j}\right)=\psi_{\left\{y_{1}, \cdots, y_{n}\right\}}(\mathbf{t})=\int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu_{\left\{y_{1}, \cdots, y_{n}\right\}}(x) \tag{61.5.16}
\end{equation*}
$$

Thus if $\left\{y_{1}, \cdots, y_{n}, y_{n+1}, \cdots, y_{p}\right\} \subseteq \Lambda$,

$$
\begin{aligned}
\psi\left(\sum_{j=1}^{n} t_{j} y_{j}+\sum_{j=1}^{p-n} s_{j} y_{j+n}\right) & =\psi_{\left\{y_{1}, \cdots, y_{p}\right\}}(\mathbf{t}, \mathbf{s}) \\
& =\int_{\mathbb{R}^{p-n}} e^{i \mathbf{s} \cdot \mathbf{x}} \int_{\mathbb{R}^{n}} e^{i \cdot \mathbf{x}} d \mu_{\left\{y_{1}, \cdots, y_{p}\right\}}(x)
\end{aligned}
$$

I need to verify the measures are consistent to use Kolmogorov's theorem. Specifically, I need to show

$$
\mu_{\left\{y_{1}, \cdots, y_{p}\right\}}\left(A \times \mathbb{R}^{p-n}\right)=\mu_{\left\{y_{1}, \cdots, y_{n}\right\}}(A)
$$

Letting

$$
\lambda(A)=\mu_{\left\{y_{1}, \cdots, y_{p}\right\}}\left(A \times \mathbb{R}^{p-n}\right)
$$

it follows

$$
\begin{aligned}
\int_{\mathbb{R}^{n}} e^{i \cdot \mathbf{x}} d \lambda & =\int_{\mathbb{R}^{p-n}} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu_{\left\{y_{1}, \cdots, y_{p}\right\}}(x) \\
& =\int_{\mathbb{R}^{p-n}} e^{i \mathbf{0} \cdot \mathbf{x}} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu_{\left\{y_{1}, \cdots, y_{p}\right\}}(x) \\
& =\psi\left(\sum_{j=1}^{n} t_{j} y_{j}+\sum_{j=1}^{p-n} 0 y_{j+n}\right) \\
& =\psi\left(\sum_{j=1}^{n} t_{j} y_{j}\right) \\
& =\int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} d \mu_{\left\{y_{1}, \cdots, y_{n}\right\}}(x)
\end{aligned}
$$

and so, by uniqueness of characteristic functions,

$$
\lambda=\mu_{\left\{y_{1}, \cdots, y_{n}\right\}}
$$

which verifies the necessary consistency condition for Kolmogorov's theorem.

It follows there exists a probability measure $\mu$ defined on $\sigma(\mathscr{E})$ and random variables, $X_{y}$ for each $y \in \Lambda$ such that whenever $\left\{y_{1}, \cdots, y_{p}\right\} \subseteq \Lambda$,

$$
\mu_{\left\{y_{1}, \cdots, y_{p}\right\}}\left(A_{y_{1}} \times \cdots \times A_{y_{n}}\right)=\mu\left(\prod_{y \in \Lambda} A_{y}\right)
$$

where $A_{y}=\mathbb{R}$ whenever $y \notin\left\{y_{1}, \cdots, y_{p}\right\}$. This defines a measure on $\sigma(\mathscr{E})$ which consists of sets of $\mathbb{R}^{\Lambda}$.

By Lemma 61.5 .1 it follows $\left\{\theta^{-1}(U): U \in \sigma(\mathscr{E})\right\}=\sigma(\mathscr{A})$ which equals $\sigma(X)$. Define $v$ on $\sigma(X)$ by

$$
v(F) \equiv \mu(\theta F)
$$

Thus $v$ is a measure because $\mu$ is and $\theta$ is one to one.
I need to check whether $v$ works. Let $x=\sum_{k=1}^{m} t_{k} y_{k}$ and let a typical element of $\mathbb{R}^{\Lambda}$ be denoted by $\mathbf{z}$. Then by Kolmogorov's theorem above,

$$
\begin{gathered}
\int_{X^{*}} \exp \left(i x^{*}\left(\sum_{k=1}^{m} t_{k} y_{k}\right)\right) d v=\int_{X^{*}} \exp \left(i\left(\sum_{k=1}^{m} t_{k} x^{*}\left(y_{k}\right)\right)\right) d v \\
=\int_{X^{*}} \exp \left(i\left(\sum_{k=1}^{m} t_{k} \pi_{y_{k}}\left(\theta x^{*}\right)\right)\right) d v=\int_{\mathbb{R}^{\Lambda}} \exp \left(i\left(\sum_{k=1}^{m} t_{k} \pi_{y_{k}} \mathbf{z}\right)\right) d \mu \\
=\int_{\mathbb{R}^{m}} \exp (i(\mathbf{t} \cdot \mathbf{x})) d \mu_{\left\{y_{1}, \cdots, y_{m}\right\}}(x)=\psi\left(\sum_{k=1}^{m} t_{k} y_{k}\right)
\end{gathered}
$$

where the last equality comes from 61.5.16. Since $\Lambda$ is a Hamel basis, it follows that for every $x \in X$,

$$
\psi(x)=\int_{X^{*}} \exp \left(i x^{*}(x)\right) d \nu
$$

This proves the theorem.

### 61.6 The Multivariate Normal Distribution

Here I give a review of the main theorems and definitions about multivariate normal random variables. Recall that for a random vector (variable), $\mathbf{X}$ having values in $\mathbb{R}^{p}, \lambda_{\mathbf{X}}$ is the law of $\mathbf{X}$ defined by

$$
P([\mathbf{X} \in E])=\lambda_{\mathbf{X}}(E)
$$

for all $E$ a Borel set in $\mathbb{R}^{p}$. In different notaion, $\mathscr{L}(\mathbf{X})=\lambda_{\mathbf{x}}$. Then the following definitions and theorems are proved and presented starting on Page 1908

Definition 61.6.1 A random vector, $\mathbf{X}$, with values in $\mathbb{R}^{p}$ has a multivariate normal distribution written as $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ if for all Borel $E \subseteq \mathbb{R}^{p}$,

$$
\lambda_{\mathbf{x}}(E)=\int_{\mathbb{R}^{p}} \mathscr{X}_{E}(\mathbf{x}) \frac{1}{(2 \pi)^{p / 2} \operatorname{det}(\Sigma)^{1 / 2}} e^{\frac{-1}{2}(\mathbf{x}-\mathbf{m})^{*} \Sigma^{-1}(\mathbf{x}-\mathbf{m})} d x
$$

for $\mu$ a given vector and $\Sigma$ a given positive definite symmetric matrix.

Theorem 61.6.2 For $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma), \mathbf{m}=E(\mathbf{X})$ and

$$
\Sigma=E\left((\mathbf{X}-\mathbf{m})(\mathbf{X}-\mathbf{m})^{*}\right) .
$$

Theorem 61.6.3 Suppose $\mathbf{X}_{1} \sim N_{p}\left(\mathbf{m}_{1}, \Sigma_{1}\right), \mathbf{X}_{2} \sim N_{p}\left(\mathbf{m}_{2}, \Sigma_{2}\right)$ and the two random vectors are independent. Then

$$
\begin{equation*}
\mathbf{X}_{1}+\mathbf{X}_{2} \sim N_{p}\left(\mathbf{m}_{1}+\mathbf{m}_{2}, \Sigma_{1}+\Sigma_{2}\right) \tag{61.6.17}
\end{equation*}
$$

Also, if $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ then $-\mathbf{X} \sim N_{p}(-\mathbf{m}, \Sigma)$. Furthermore, if $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ then

$$
\begin{equation*}
E\left(e^{i \mathbf{t} \cdot \mathbf{X}}\right)=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}} \tag{61.6.18}
\end{equation*}
$$

Also if $a$ is a constant and $\mathbf{X} \sim N_{p}(\mathbf{m}, \Sigma)$ then $a \mathbf{X} \sim N_{p}\left(a \mathbf{m}, a^{2} \Sigma\right)$.
Following [103] a random vector has a generalized normal distribution if its characteristic function is given as

$$
\begin{equation*}
e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}} \tag{61.6.19}
\end{equation*}
$$

where $\Sigma$ is symmetric and has nonnegative eigenvalues. For a random real valued variable, $\mathbf{m}$ is scalar and so is $\Sigma$ so the characteristic function of such a generalized normally distributed random variable is

$$
\begin{equation*}
e^{i t m} e^{-\frac{1}{2} t^{2} \sigma^{2}} \tag{61.6.20}
\end{equation*}
$$

These generalized normal distributions do not require $\Sigma$ to be invertible, only that the eigenvalues be nonnegative. In one dimension this would correspond the characteristic function of a dirac measure having point mass 1 at $m$. In higher dimensions, it could be a mixture of such things with more familiar things. I will often not bother to distinguish between generalized normal and normal distributions.

Here are some other interesting results about normal distributions found in [103]. The next theorem has to do with the question whether a random vector is normally distributed in the above generalized sense. It is proved on Page 1911.

Theorem 61.6.4 Let $\mathbf{X}=\left(X_{1}, \cdots, X_{p}\right)$ where each $X_{i}$ is a real valued random variable. Then $\mathbf{X}$ is normally distributed in the above generalized sense if and only if every linear combination, $\sum_{j=1}^{p} a_{i} X_{i}$ is normally distributed. In this case the mean of $\mathbf{X}$ is

$$
\mathbf{m}=\left(E\left(X_{1}\right), \cdots, E\left(X_{p}\right)\right)
$$

and the covariance matrix for $\mathbf{X}$ is

$$
\Sigma_{j k}=E\left(\left(X_{j}-m_{j}\right)\left(X_{k}-m_{k}\right)\right)
$$

where $m_{j}=E\left(X_{j}\right)$.
Also proved there is the interesting corollary listed next.
Corollary 61.6.5 Let $\mathbf{X}=\left(X_{1}, \cdots, X_{p}\right), \mathbf{Y}=\left(Y_{1}, \cdots, Y_{p}\right)$ where each $X_{i}, Y_{i}$ is a real valued random variable. Suppose also that for every $\mathbf{a} \in \mathbb{R}^{p}, \mathbf{a} \cdot \mathbf{X}$ and $\mathbf{a} \cdot \mathbf{Y}$ are both normally distributed with the same mean and variance. Then $\mathbf{X}$ and $\mathbf{Y}$ are both multivariate normal random vectors with the same mean and variance.

Theorem 61.6.6 Suppose $\mathbf{X}=\left(X_{1}, \cdots, X_{p}\right)$ is normally distributed with mean $\mathbf{m}$ and covariance $\Sigma$. Then if $X_{1}$ is uncorrelated with any of the $X_{i}$,

$$
E\left(\left(X_{1}-m_{1}\right)\left(X_{j}-m_{j}\right)\right)=0 \text { for } j>1
$$

then $X_{1}$ and $\left(X_{2}, \cdots, X_{p}\right)$ are both normally distributed and the two random vectors are independent. Here $m_{j} \equiv E\left(X_{j}\right)$.

Next I will consider the question of existence of independent random variables having a given law.

Lemma 61.6.7 Let $\mu$ be a probability measure on $\mathscr{B}(E)$, the Borel subsets of a separable real Banach space. Then there exists a probability space $(\Omega, \mathscr{F}, P)$ and two independent random variables, $X, Y$ mapping $\Omega$ to $E$ such that $\mathscr{L}(X)=\mathscr{L}(Y)=\mu$.

Proof: First note that if $A, B$ are Borel sets of $E$ then $A \times B$ is a Borel set in $E \times E$ where the norm on $E \times E$ is given by

$$
\|(x, y)\| \equiv \max (\|x\|,\|y\|)
$$

This can be proved by letting $A$ be open and considering

$$
\mathscr{G} \equiv\{B \in \mathscr{B}(E): A \times B \in \mathscr{B}(A \times B)\}
$$

Show $\mathscr{G}$ is a $\sigma$ algebra and it contains the open sets. Therefore, this will show $A \times B$ is in $\mathscr{B}(A \times B)$ whenever $A$ is open and $B$ is Borel. Next repeat a similar argument to show that this is true whenever either set is Borel. Since $E$ is separable, it is completely separable and so is $E \times E$. Thus every open set in $E \times E$ is the union of balls from a countable set. However, these balls are of the form $B_{1} \times B_{2}$ where $B_{i}$ is a ball in $E$. Now let

$$
\mathscr{K} \equiv\{A \times B: A, B \text { are Borel }\}
$$

Then $\mathscr{K} \subseteq \mathscr{B}(E \times E)$ as was just shown and also every open set from $E \times E$ is in $\sigma(\mathscr{K})$. It follows $\sigma(\mathscr{K})$ equals the $\sigma$ algebra of product measurable sets, $\mathscr{B}(E) \times \mathscr{B}(E)$ and you can consider the product measure, $\mu \times \mu$. By Skorokhod's theorem, Theorem 61.4.3, there exists $(X, Y)$ a random variable with values in $E \times E$ and a probability space, $(\Omega, \mathscr{F}, P)$ such that $\mathscr{L}((X, Y))=\mu \times \mu$. Then for $A, B$ Borel sets in $E$

$$
P(X \in A, Y \in B)=(\mu \times \mu)(A \times B)=\mu(A) \mu(B)
$$

Also, $P(X \in A)=P(X \in A, Y \in E)=\mu(A)$ and similarly, $P(Y \in B)=\mu(B)$ showing $\mathscr{L}(X)=\mathscr{L}(Y)=\mu$ and $X, Y$ are independent.

Now here is an interesting theorem in [36].
Theorem 61.6.8 Suppose $v$ is a probability measure on the Borel sets of $\mathbb{R}$ and suppose that $\xi$ and $\zeta$ are independent random variables such that $\mathscr{L}(\xi)=\mathscr{L}(\zeta)=v$ and whenever $\alpha^{2}+\beta^{2}=1$ it follows $\mathscr{L}(\alpha \xi+\beta \zeta)=v$. Then

$$
\mathscr{L}(\xi)=N\left(0, \sigma^{2}\right)
$$

for some $\sigma \geq 0$. Also if $\mathscr{L}(\xi)=\mathscr{L}(\zeta)=N\left(0, \sigma^{2}\right)$ where $\xi, \zeta$ are independent, then if $\alpha^{2}+\beta^{2}=1$, it follows $\mathscr{L}(\alpha \xi+\beta \zeta)=N\left(0, \sigma^{2}\right)$.

Proof: Let $\xi, \zeta$ be independent random variables with $\mathscr{L}(\xi)=\mathscr{L}(\zeta)=v$ and whenever $\alpha^{2}+\beta^{2}=1$ it follows $\mathscr{L}(\alpha \xi+\beta \zeta)=v$.

By independence of $\xi$ and $\zeta$,

$$
\begin{aligned}
\phi_{v}(t) & \equiv \phi_{\alpha \xi+\alpha \zeta}(t) \\
& =E\left(e^{i t(\alpha \xi+\beta \zeta)}\right) \\
& =E\left(e^{i t \alpha \xi}\right) E\left(e^{i t \beta \zeta}\right) \\
& =\phi_{\xi}(\alpha t) \phi_{\zeta}(\beta t) \\
& \equiv \phi_{v}(\alpha t) \phi_{v}(\beta t)
\end{aligned}
$$

In simpler terms and suppressing the subscript,

$$
\begin{equation*}
\phi(t)=\phi(\cos (\theta) t) \phi(\sin (\theta) t) \tag{61.6.21}
\end{equation*}
$$

Since $v$ is a probability measure, $\phi(0)=1$. Also, letting $\theta=\pi / 4$, this yields

$$
\begin{equation*}
\phi(t)=\phi\left(\frac{\sqrt{2}}{2} t\right)^{2} \tag{61.6.22}
\end{equation*}
$$

and so if $\phi$ has real values, then $\phi(t) \geq 0$.
Next I will show $\phi$ is real. To do this, it follows from the definition of $\phi_{v}$,

$$
\phi_{v}(-t) \equiv \int_{\mathbb{R}} e^{-i t x} d v=\overline{\int_{\mathbb{R}} e^{i t x} d v}=\overline{\phi_{v}(t)}
$$

Then letting $\theta=\pi$,

$$
\phi(t)=\phi(-t) \cdot \phi(0)=\phi(-t)=\overline{\phi(t)}
$$

showing $\phi$ has real values. It is positive near 0 because $\phi(0)=1$ and $\phi$ is a continuous function of $t$ thanks to the dominated convergence theorem. However, this and $61.6 .22 \mathrm{im}-$ plies it is positive everywhere. Here is why. If not, let $t_{m}$ be the smallest positive value of $t$ where $\phi(t)=0$. Then $t_{m}>0$ by continuity. Now from 61.6.22, an immediate contradiction results. Therefore, $\phi(t)>0$ for all $t>0$. Similar reasoning yields the same conclusion for $t<0$.

Next note that $\phi(t)=\phi(-t)$ also implies $\phi$ depends only on $|t|$ because it takes the same value for $t$ as for $-t$. More simply, $\phi$ depends only on $t^{2}$. Thus one can define a new function of the form $\phi(t)=f\left(t^{2}\right)$ and 61.6.21 implies the following for $\alpha \in[0,1]$.

$$
f\left(t^{2}\right)=f\left(\alpha^{2} t^{2}\right) f\left(\left(1-\alpha^{2}\right) t^{2}\right)
$$

Taking $\ln$ of both sides, one obtains the following.

$$
\ln f\left(t^{2}\right)=\ln f\left(\alpha^{2} t^{2}\right)+\ln f\left(\left(1-\alpha^{2}\right) t^{2}\right)
$$

Now let $x, y \geq 0$. Then choose $t$ such that $t^{2}=x+y$. Then for some $\alpha \in[0,1], x=\alpha^{2} t^{2}$ and so $y=t^{2}\left(1-\alpha^{2}\right)$. Thus for $x, y \geq 0$,

$$
\ln f(x+y)=\ln f(x)+\ln f(y) .
$$

Hence $\ln f(x)=k x$ and so $\ln f\left(t^{2}\right)=k t^{2}$ and so $\phi(t)=f\left(t^{2}\right)=e^{k t^{2}}$ for all $t$. The constant, $k$ must be nonpositive because $\phi(t)$ is bounded due to its definition. Therefore, the characteristic function of $v$ is

$$
\phi_{v}(t)=e^{-\frac{1}{2} t^{2} \sigma^{2}}
$$

for some $\sigma \geq 0$. That is, $v$ is the law of a generalized normal random variable.
Note the other direction of the implication is obvious. If $\xi, \zeta \sim N(0, \sigma)$ and they are independent, then if $\alpha^{2}+\beta^{2}=1$, it follows

$$
\alpha \xi+\beta \zeta \sim N\left(0, \sigma^{2}\right)
$$

because

$$
\begin{aligned}
E\left(e^{i t(\alpha \xi+\beta \zeta)}\right) & =E\left(e^{i t \alpha \xi}\right) E\left(e^{i t \beta \zeta}\right) \\
& =e^{-\frac{1}{2}(\alpha t)^{2} \sigma^{2}} e^{-\frac{1}{2}(\beta t)^{2} \sigma^{2}} \\
& =e^{-\frac{1}{2} t^{2} \sigma^{2}}
\end{aligned}
$$

the characteristic function for a random variable which is $N(0, \sigma)$. This proves the theorem.
The next theorem is a useful gimmick for showing certain random variables are independent in the context of normal distributions.

Theorem 61.6.9 Let $\mathbf{X}$ and $\mathbf{Y}$ be random vectors having values in $\mathbb{R}^{p}$ and $\mathbb{R}^{q}$ respectively. Suppose also that $(\mathbf{X}, \mathbf{Y})$ is multivariate normally distributed and

$$
E\left((\mathbf{X}-E(\mathbf{X}))(\mathbf{Y}-E(\mathbf{Y}))^{*}\right)=\mathbf{0}
$$

Then $\mathbf{X}$ and $\mathbf{Y}$ are independent random vectors.
Proof: Let $\mathbf{Z}=(\mathbf{X}, \mathbf{Y}), m=p+q$. Then by hypothesis, the characteristic function of $\mathbf{Z}$ is of the form

$$
E\left(e^{i \mathbf{t} \cdot \mathbf{Z}}\right)=e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} i \mathbf{t}^{*} \Sigma \mathbf{t}}
$$

where $\mathbf{m}=\left(\mathbf{m}_{\mathbf{X}}, \mathbf{m}_{\mathbf{Y}}\right)=E(\mathbf{Z})=E(\mathbf{X}, \mathbf{Y})$ and

$$
\begin{aligned}
\Sigma & =\left(\begin{array}{cc}
E\left((\mathbf{X}-E(\mathbf{X}))(\mathbf{X}-E(\mathbf{X}))^{*}\right) & \mathbf{0} \\
& E\left((\mathbf{Y}-E(\mathbf{Y}))(\mathbf{Y}-E(\mathbf{Y}))^{*}\right)
\end{array}\right) \\
& \equiv\left(\begin{array}{cc}
\Sigma_{\mathbf{X}} & \mathbf{0} \\
\mathbf{0} & \Sigma_{\mathbf{Y}}
\end{array}\right)
\end{aligned}
$$

Therefore, letting $\mathbf{t}=(\mathbf{u}, \mathbf{v})$ where $\mathbf{u} \in \mathbb{R}^{p}$ and $\mathbf{v} \in \mathbb{R}^{q}$

$$
\begin{align*}
E\left(e^{i \mathbf{t} \cdot \mathbf{Z}}\right) & =E\left(e^{i(\mathbf{u}, \mathbf{v}) \cdot(\mathbf{X}, \mathbf{Y})}\right)=E\left(e^{i(\mathbf{u} \cdot \mathbf{X}+\mathbf{v} \cdot \mathbf{Y})}\right) \\
& =e^{i \mathbf{u} \cdot \mathbf{m}_{\mathbf{X}}} e^{-\frac{1}{2} \mathbf{u}^{*} \Sigma_{\mathbf{X}} \mathbf{u} e^{i \mathbf{v} \cdot \mathbf{m}_{\mathbf{Y}}} e^{-\frac{1}{2} \mathbf{v}^{*} \Sigma_{\mathbf{Y}} \mathbf{v}}} \\
& =E\left(e^{i \mathbf{u} \cdot \mathbf{X}}\right) E\left(e^{i \mathbf{v} \cdot \mathbf{Y}}\right) \tag{61.6.23}
\end{align*}
$$

Where the last equality needs to be justified. When this is done it will follow from Proposition 59.11.1 on Page 1889 which is proved on Page 1889 that $\mathbf{X}$ and $\mathbf{Y}$ are independent. Thus all that remains is to verify

$$
E\left(e^{i \mathbf{u} \cdot \mathbf{X}}\right)=e^{i \mathbf{u} \cdot \mathbf{m}_{\mathbf{X}}} e^{-\frac{1}{2} \mathbf{u}^{*} \Sigma_{\mathbf{X}} \mathbf{u}}, E\left(e^{i \mathbf{v} \cdot \mathbf{Y}}\right)=e^{i \mathbf{v} \cdot \mathbf{m}_{\mathbf{Y}}} e^{-\frac{1}{2} \mathbf{v}^{*} \Sigma_{\mathbf{Y}} \mathbf{v}}
$$

However, this follows from 61.6.23. To get the first formula, let $\mathbf{v}=\mathbf{0}$. To get the second, let $\mathbf{u}=\mathbf{0}$. This proves the Theorem.

Note that to verify the conclusion of this theorem, it suffices to show

$$
E\left(X_{i}-E\left(X_{i}\right)\left(Y_{j}-E\left(Y_{j}\right)\right)\right)=0
$$

### 61.7 Gaussian Measures

### 61.7.1 Definitions And Basic Properties

First suppose $\mathbf{X}$ is a random vector having values in $\mathbb{R}^{n}$ and its distribution function is $N(\mathbf{m}, \Sigma)$ where $\mathbf{m}$ is the mean and $\Sigma$ is the covariance. Then the characteristic function of $\mathbf{X}$ or equivalently, the characteristic function of its distribution is

$$
e^{i \mathbf{t} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{t}^{*} \Sigma \mathbf{t}}
$$

What is the distribution of $\mathbf{a} \cdot \mathbf{X}$ where $\mathbf{a} \in \mathbb{R}^{n}$ ? In other words, if you take a linear functional and do it to $\mathbf{X}$ to get a scalar valued random variable, what is the distribution of this scalar valued random variable? Let $Y=\mathbf{a} \cdot \mathbf{X}$. Then

$$
E\left(e^{i t Y}\right)=E\left(e^{i t \mathbf{a} \cdot \mathbf{X}}\right)
$$

which from the above formula is

$$
e^{i \mathbf{a} \cdot \mathbf{m} t} e^{-\frac{1}{2} \mathbf{a}^{*} \sum \mathbf{a} t^{2}}
$$

which is the characteristic function of a random variable whose distribution is the normal distribution $N\left(\mathbf{a} \cdot \mathbf{m}, \mathbf{a}^{*} \Sigma \mathbf{a}\right)$. In other words, it is normally distributed having mean equal to $\mathbf{a} \cdot \mathbf{m}$ and variance equal to $\mathbf{a}^{*} \Sigma \mathbf{a}$. Obviously such a concept generalizes to a Banach space in place of $\mathbb{R}^{n}$ and this motivates the following definition.

Definition 61.7.1 Let $E$ be a real separable Banach space. A probability measure, $\mu$ defined on $\mathscr{B}(E)$ is called a Gaussian measure if for every $h \in E^{\prime}$, the law of h considered as a random variable defined on the probability space, $(E, \mathscr{B}(E), \mu)$ is normal. That is, for $A \subseteq \mathbb{R}$ a Borel set,

$$
\lambda_{h}(A) \equiv \mu\left(h^{-1}(A)\right)
$$

is given by

$$
\int_{A} \frac{1}{\sqrt{2 \pi} \sigma} e^{-\frac{1}{2 \sigma^{2}}(x-m)^{2}} d x
$$

for some $\sigma$ and m. A Gaussian measure is called symmetric if $m$ is always equal to 0 .

There is another definition of symmetric. First here are a few simple conventions. For $f \in E^{\prime}, x \rightarrow f(x)$ is normally distributed. In particular,

$$
\int_{E}|f(x)| d \mu<\infty
$$

and so it makes sense to define

$$
m_{\mu}(f) \equiv \int_{E} f(x) d \mu
$$

Thus $m_{\mu}(f)$ is the mean of the random variable $x \rightarrow f(x)$. It is obvious that $f \rightarrow m_{\mu}(f)$ is linear. Also define the variance $\sigma^{2}(f)$ by

$$
\sigma^{2}(f) \equiv \int_{E}\left(f(x)-m_{\mu}(f)\right)^{2} d \mu
$$

This is finite because $x \rightarrow f(x)$ is normally distributed. The following lemma gives such an equivalent condition for $\mu$ to be symmetric.

Lemma 61.7.2 Let $\mu$ be a Gaussian measure defined on $\mathscr{B}(E)$. Then $\mu(F)=\mu(-F)$ for all $F$ Borel if and only if $m_{\mu}(f)=0$ for all $f \in E^{\prime}$. Such a Gaussian measure is called symmetric.

Proof: Suppose first $m_{\mu}(f)=0$ for all $f \in E^{\prime}$. Let

$$
G \equiv f_{1}^{-1}\left(F_{1}\right) \cap f_{2}^{-1}\left(F_{2}\right) \cap \cdots \cap f_{m}^{-1}\left(F_{m}\right)
$$

where $F_{i}$ is a Borel set of $\mathbb{R}$ and each $f_{i} \in E^{\prime}$. Since every linear combination of the $f_{i}$ is in $E^{\prime}$, every such linear combination is normally distributed and so $\mathbf{f} \equiv\left(f_{1}, \cdots, f_{m}\right)$ is multivariate normal. That is, $\lambda_{\mathbf{f}}$ the distribution measure, is multivariate normal. Since each $m_{\mu}(f)=0$, it follows

$$
\begin{equation*}
\mu(G)=\lambda_{\mathbf{f}}\left(\prod_{i=1}^{m} F_{i}\right)=\lambda_{\mathbf{f}}\left(\prod_{i=1}^{m}-F_{i}\right)=\mu(-G) \tag{61.7.24}
\end{equation*}
$$

By Lemma 21.1.6 on Page 645 there exists a countable subset, $D \equiv\left\{f_{k}\right\}_{k=1}^{\infty}$ of the closed unit ball such that for every $x \in E$,

$$
\|x\|=\sup _{f \in D}|f(x)|
$$

Therefore, letting $D(a, r)$ denote the closed ball centered at $a$ having radius $r$, it follows

$$
D(a, r)=\cap_{k=1}^{\infty} f_{k}^{-1}\left(D\left(f_{k}(a), r\right)\right)
$$

Let

$$
D_{n}(a, r)=\cap_{k=1}^{n} f_{k}^{-1}\left(D\left(f_{k}(a), r\right)\right)
$$

Then by 61.7.24

$$
\mu\left(D_{n}(a, r)\right)=\mu\left(-D_{n}(a, r)\right)
$$

and letting $n \rightarrow \infty$, it follows

$$
\mu(D(a, r))=\mu(-D(a, r))
$$

Therefore the same is true with $D(a, r)$ replaced with an open ball. Now consider

$$
D\left(a, r_{1}\right) \cap D\left(b, r_{2}\right)=\cap_{k=1}^{\infty} f_{k}^{-1}\left(D\left(f_{k}(a), r_{1}\right)\right) \cap \cap_{k=1}^{\infty} f_{k}^{-1}\left(D\left(f_{k}(b), r_{2}\right)\right)
$$

The intersection of these two closed balls is the intersection of sets of the form

$$
\cap_{k=1}^{n} f_{k}^{-1}\left(D\left(f_{k}(a), r_{1}\right)\right) \cap \cap_{k=1}^{n} f_{k}^{-1}\left(D\left(f_{k}(b), r_{2}\right)\right)
$$

to which 61.7.24 applies. Therefore, by continuing this way it follows that if $G$ is any finite intersection of closed balls,

$$
\mu(G)=\mu(-G)
$$

Let $\mathscr{K}$ denote the set of finite intersections of closed balls, a $\pi$ system. Thus for $G \in \mathscr{K}$ the above holds. Now let

$$
\mathscr{G} \equiv\{F \in \sigma(\mathscr{K}): \mu(F)=\mu(-F)\}
$$

Thus $\mathscr{G}$ contains $\mathscr{K}$ and it is clearly closed with respect to complements and countable disjoint unions. By the $\pi$ system lemma, $\mathscr{G} \supseteq \sigma(\mathscr{K})$ but $\sigma(\mathscr{K})$ clearly contains the open sets since every open ball is the countable union of closed disks and every open set is the countable union of open balls. Therefore, $\mu(G)=\mu(-G)$ for all Borel $G$.

Conversely suppose $\mu(G)=\mu(-G)$ for all $G$ Borel. If for some $f \in E^{\prime}, m_{\mu}(f) \neq 0$, then

$$
\begin{aligned}
\mu\left(f^{-1}(0, \infty)\right) & \equiv \lambda_{f}(0, \infty) \neq \lambda_{f}(-\infty, 0) \\
& \equiv \mu\left(f^{-1}(-\infty, 0)\right)=\mu\left(-f^{-1}(0, \infty)\right)
\end{aligned}
$$

a contradiction. This proves the lemma.
Lemma 61.7.3 Let $\mu=\mathscr{L}(X)$ where $X$ is a random variable defined on a probability space, $(\Omega, \mathscr{F}, P)$ which has values in $E$, a Banach space. Suppose also that for all $\phi \in$ $E^{\prime}, \phi \circ X$ is normally distributed. Then $\mu$ is a Gaussian measure. Conversely, suppose $\mu$ is a Gaussian measure on $\mathscr{B}(E)$ and $X$ is a random variable having values in $E$ such that $\mathscr{L}(X)=\mu$. Then for every $h \in E^{\prime}, h \circ X$ is normally distributed.

Proof: First suppose $\mu$ is a Gaussian measure and $X$ is a random variable such that $\mathscr{L}(X)=\mu$. Then if $F$ is a Borel set in $\mathbb{R}$, and $h \in E^{\prime}$

$$
\begin{aligned}
P\left((h \circ X)^{-1}(F)\right) & =P\left(X^{-1}\left(h^{-1}(F)\right)\right) \\
& =\mu\left(h^{-1}(F)\right) \\
& =\frac{1}{\sqrt{2 \pi} \sigma} \int_{F} e^{-\frac{|x-m|^{2}}{2 \sigma^{2}}} d x
\end{aligned}
$$

for some $m$ and $\sigma^{2}$ showing that $h \circ X$ is normally distributed.
Next suppose $h \circ X$ is normally distributed whenever $h \in E^{\prime}$ and $\mathscr{L}(X)=\mu$. Then letting $F$ be a Borel set in $\mathbb{R}$, I need to verify

$$
\mu\left(h^{-1}(F)\right)=\frac{1}{\sqrt{2 \pi} \sigma} \int_{F} e^{-\frac{|x-m|^{2}}{2 \sigma^{2}}} d x .
$$

However, this is easy because

$$
\begin{aligned}
\mu\left(h^{-1}(F)\right) & =P\left(X^{-1}\left(h^{-1}(F)\right)\right) \\
& =P\left((h \circ X)^{-1}(F)\right)
\end{aligned}
$$

which is given to equal

$$
\frac{1}{\sqrt{2 \pi} \sigma} \int_{F} e^{-\frac{|x-m|^{2}}{2 \sigma^{2}}} d x
$$

for some $m$ and $\sigma^{2}$. This proves the lemma.
Here is another important observation. Suppose $X$ is as just described, a random variable having values in $E$ such that $\mathscr{L}(X)=\mu$ and suppose $h_{1}, \cdots, h_{n}$ are each in $E^{\prime}$. Then for scalars, $t_{1}, \cdots, t_{n}$,

$$
\begin{aligned}
& t_{1} h_{1} \circ X+\cdots+t_{n} h_{n} \circ X \\
= & \left(t_{1} h_{1}+\cdots+t_{n} h_{n}\right) \circ X
\end{aligned}
$$

and this last is assumed to be normally distributed because $\left(t_{1} h_{1}+\cdots+t_{n} h_{n}\right) \in E^{\prime}$. Therefore, by Theorem 61.6.4

$$
\left(h_{1} \circ X, \cdots, h_{n} \circ X\right)
$$

is distributed as a multivariate normal.
Obviously there exist examples of Gaussian measures defined on $E$, a Banach space. Here is why. Let $\xi$ be a random variable defined on a probability space, $(\Omega, \mathscr{F}, P)$ which is normally distributed with mean 0 and variance $\sigma^{2}$. Then let $X(\omega) \equiv \xi(\omega) e$ where $e \in E$. Then let $\mu \equiv \mathscr{L}(X)$. For $A$ a Borel set of $\mathbb{R}$ and $h \in E^{\prime}$,

$$
\begin{aligned}
\mu([h(x) \in A]) & \equiv P([X(\omega) \in[x: h(x) \in A]]) \\
& =P([h \circ X \in A])=P([\xi(\omega) h(e) \in A]) \\
& =\frac{1}{|h(e)| \sigma \sqrt{2 \pi}} \int_{A} e^{-\frac{1}{2|h(e)|^{2} \sigma^{2}} x^{2}} d x
\end{aligned}
$$

because $h(e) \xi$ is a random variable which has variance $|h(e)|^{2} \sigma^{2}$ and mean 0 . Thus $\mu$ is indeed a Gaussian measure. Similarly, one can consider finite sums of the form

$$
\sum_{i=1}^{n} \xi_{i}(\omega) e_{i}
$$

where the $\xi_{i}$ are independent normal random variables having mean 0 for convenience. However, this is a rather trivial case.

### 61.7.2 Fernique's Theorem

The following is an interesting lemma.
Lemma 61.7.4 Suppose $\mu$ is a symmetric Gaussian measure on the real separable Banach space, $E$. Then there exists a probability space, $(\Omega, \mathscr{F}, P)$ and independent random variables, $X$ and $Y$ mapping $\Omega$ to $E$ such that $\mathscr{L}(X)=\mathscr{L}(Y)=\mu$. Also, the two random variables,

$$
\frac{1}{\sqrt{2}}(X-Y), \frac{1}{\sqrt{2}}(X+Y)
$$

are independent and

$$
\mathscr{L}\left(\frac{1}{\sqrt{2}}(X-Y)\right)=\mathscr{L}\left(\frac{1}{\sqrt{2}}(X+Y)\right)=\mu
$$

Proof: Letting $X^{\prime} \equiv \frac{1}{\sqrt{2}}(X+Y)$ and $Y^{\prime} \equiv \frac{1}{\sqrt{2}}(X-Y)$, it follows from Theorem 59.13.2 on Page 1896, that $X^{\prime}$ and $Y^{\prime}$ are independent if whenever $h_{1}, \cdots, h_{m} \in E^{\prime}$ and $g_{1}, \cdots, g_{k} \in$ $E^{\prime}$, the two random vectors,

$$
\left(h_{1} \circ X^{\prime}, \cdots, h_{m} \circ X^{\prime}\right) \text { and }\left(g_{1} \circ Y^{\prime}, \cdots, g_{k} \circ Y^{\prime}\right)
$$

are independent. Now consider linear combinations

$$
\sum_{j=1}^{m} t_{j} h_{j} \circ X^{\prime}+\sum_{i=1}^{k} s_{i} g_{i} \circ Y^{\prime}
$$

This equals

$$
\begin{array}{r}
\frac{1}{\sqrt{2}} \sum_{j=1}^{m} t_{j} h_{j}(X)+\frac{1}{\sqrt{2}} \sum_{j=1}^{m} t_{j} h_{j}(Y) \\
+\frac{1}{\sqrt{2}} \sum_{i=1}^{k} s_{i} g_{i}(X)-\frac{1}{\sqrt{2}} \sum_{i=1}^{k} s_{i} g_{i}(Y) \\
= \\
\quad \frac{1}{\sqrt{2}}\left(\sum_{j=1}^{m} t_{j} h_{j}+\sum_{i=1}^{k} s_{i} g_{i}\right)(X) \\
\quad+\frac{1}{\sqrt{2}}\left(\sum_{j=1}^{m} t_{j} h_{j}-\sum_{i=1}^{k} s_{i} g_{i}\right)(Y)
\end{array}
$$

and this is the sum of two independent normally distributed random variables so it is also normally distributed. Therefore, by Theorem 61.6.4

$$
\left(h_{1} \circ X^{\prime}, \cdots, h_{m} \circ X^{\prime}, g_{1} \circ Y^{\prime}, \cdots, g_{k} \circ Y^{\prime}\right)
$$

is a random variable with multivariate normal distribution and by Theorem 61.6.9 the two random vectors

$$
\left(h_{1} \circ X^{\prime}, \cdots, h_{m} \circ X^{\prime}\right) \text { and }\left(g_{1} \circ Y^{\prime}, \cdots, g_{k} \circ Y^{\prime}\right)
$$

are independent if

$$
E\left(\left(h_{i} \circ X^{\prime}\right)\left(g_{j} \circ Y^{\prime}\right)\right)=0
$$

for all $i, j$. This is what I will show next.

$$
\begin{align*}
& E\left(\left(h_{i} \circ X^{\prime}\right)\left(g_{j} \circ Y^{\prime}\right)\right) \\
= & \frac{1}{4} E\left(\left(h_{i}(X)+h_{i}(Y)\right)\left(g_{j}(X)-g_{j}(Y)\right)\right) \\
= & \frac{1}{4} E\left(h_{i}(X) g_{j}(X)\right)-\frac{1}{4} E\left(h_{i}(X) g_{j}(Y)\right) \\
& +\frac{1}{4} E\left(h_{i}(Y) g_{j}(X)\right)-\frac{1}{4} E\left(h_{i}(Y) g_{j}(Y)\right) \tag{61.7.25}
\end{align*}
$$

Now from the above observation after the definition of Gaussian measure $h_{i}(X) g_{j}(X)$ and $h_{i}(Y) g_{j}(Y)$ are both in $L^{1}$ because each term in each product is normally distributed. Therefore, by Lemma 59.15.2,

$$
\begin{aligned}
E\left(h_{i}(X) g_{j}(X)\right) & =\int_{\Omega} h_{i}(Y) g_{j}(Y) d P \\
& =\int_{E} h_{i}(y) g_{j}(y) d \mu \\
& =\int_{\Omega} h_{i}(X) g_{j}(X) d P \\
& =E\left(h_{i}(Y) g_{j}(Y)\right)
\end{aligned}
$$

and so 61.7.25 reduces to

$$
\frac{1}{4}\left(E\left(h_{i}(Y) g_{j}(X)-h_{i}(X) g_{j}(Y)\right)\right)=0
$$

because $h_{i}(X)$ and $g_{j}(Y)$ are independent due to the assumption that $X$ and $Y$ are independent. Thus

$$
E\left(h_{i}(X) g_{j}(Y)\right)=E\left(h_{i}(X)\right) E\left(g_{j}(Y)\right)=0
$$

due to the assumption that $\mu$ is symmetric which implies the mean of these random variables equals 0 . The other term works out similarly. This has proved the independence of the random variables, $X^{\prime}$ and $Y^{\prime}$.

Next consider the claim they have the same law and it equals $\mu$. To do this, I will use Theorem 59.12.9 on Page 1895. Thus I need to show

$$
\begin{equation*}
E\left(e^{i h\left(X^{\prime}\right)}\right)=E\left(e^{i h\left(Y^{\prime}\right)}\right)=E\left(e^{i h(X)}\right) \tag{61.7.26}
\end{equation*}
$$

for all $h \in E^{\prime}$. Pick such an $h$. Then $h \circ X$ is normally distributed and has mean 0 . Therefore, for some $\sigma$,

$$
E\left(e^{i t h \circ X}\right)=e^{-\frac{1}{2} t^{2} \sigma^{2}}
$$

Now since $X$ and $Y$ are independent,

$$
\begin{aligned}
E\left(e^{i t h o X^{\prime}}\right) & =E\left(e^{i t h\left(\frac{1}{\sqrt{2}}\right)(X+Y)}\right) \\
& =E\left(e^{i t h\left(\frac{1}{\sqrt{2}}\right) X}\right) E\left(e^{i t h\left(\frac{1}{\sqrt{2}}\right) Y}\right)
\end{aligned}
$$

the product of two characteristic functions of two random variables, $\frac{1}{\sqrt{2}} X$ and $\frac{1}{\sqrt{2}} Y$. The variance of these two random variables which are normally distributed with zero mean is $\frac{1}{2} \sigma^{2}$ and so

$$
E\left(e^{i t h \circ X^{\prime}}\right)=e^{-\frac{1}{2}\left(\frac{1}{2} \sigma^{2}\right)} e^{-\frac{1}{2}\left(\frac{1}{2} \sigma^{2}\right)}=e^{-\frac{1}{2} \sigma^{2}}=E\left(e^{i t h \circ X}\right)
$$

Similar reasoning shows $E\left(e^{i t h \circ Y^{\prime}}\right)=E\left(e^{i t h \circ Y}\right)=E\left(e^{i t h \circ X}\right)$. Letting $t=1$, this yields 61.7.26. This proves the lemma.

With this preparation, here is an incredible theorem due to Fernique.
Theorem 61.7.5 Let $\mu$ be a symmetric Gaussian measure on $\mathscr{B}(E)$ where $E$ is a real separable Banach space. Then for $\lambda$ sufficiently small and positive,

$$
\int_{E} e^{\lambda\|x\|^{2}} d \mu<\infty
$$

More specifically, if $\lambda$ and $r$ are chosen such that

$$
\ln \left(\frac{\mu([x:||x||>r])}{\mu(\overline{B(0, r)})}\right)+25 \lambda r^{2}<-1
$$

then

$$
\int_{E} e^{\lambda\|x\|^{2}} d \mu \leq \exp \left(\lambda r^{2}\right)+\frac{e^{2}}{e^{2}-1}
$$

Proof: Let $X, Y$ be independent random variables having values in $E$ such that $\mathscr{L}(X)=$ $\mathscr{L}(Y)=\mu$. Then by Lemma 61.7.4

$$
\frac{1}{\sqrt{2}}(X-Y), \frac{1}{\sqrt{2}}(X+Y)
$$

are also independent and have the same law. Now let $0 \leq s \leq t$ and use independence of the above random variables along with the fact they have the same law as $X$ and $Y$ to obtain

$$
\begin{aligned}
& P(\|X\| \leq s,\|Y\|>t)=P(\|X\| \leq s) P(\|Y\|>t) \\
= & P\left(\left\|\frac{1}{\sqrt{2}}(X-Y)\right\| \leq s\right) P\left(\left\|\frac{1}{\sqrt{2}}(X+Y)\right\|>t\right) \\
= & P\left(\left\|\frac{1}{\sqrt{2}}(X-Y)\right\| \leq s,\left\|\frac{1}{\sqrt{2}}(X+Y)\right\|>t\right) \\
\leq & P\left(\frac{1}{\sqrt{2}}\left|\|X\|-\|Y \mid\| \leq s, \frac{1}{\sqrt{2}}(\|X\|+\|Y\|)>t\right) .\right.
\end{aligned}
$$

Now consider the following picture in which the region, $R$ represents the points, $(\|X\|,\|Y\|)$ such that

$$
\frac{1}{\sqrt{2}}|\|X\|-\|Y\|| \leq s \text { and } \frac{1}{\sqrt{2}}(\|X\|+\|Y\|)>t
$$

Therefore, continuing with the chain of inequalities above,

$$
\begin{aligned}
& P(\|X\| \leq s) P(\|Y\|>t) \\
\leq & P\left(\|X\|>\frac{t-s}{\sqrt{2}},\|Y\|>\frac{t-s}{\sqrt{2}}\right) \\
= & P\left(\|X\|>\frac{t-s}{\sqrt{2}}\right)^{2} .
\end{aligned}
$$

Since $X, Y$ have the same law, this can be written as

$$
P(\|X\|>t) \leq \frac{P\left(\|X\|>\frac{t-s}{\sqrt{2}}\right)^{2}}{P(\|X\| \leq s)}
$$

Now define a sequence as follows. $t_{0} \equiv r>0$ and $t_{n+1} \equiv r+\sqrt{2} t_{n}$. Also, in the above inequality, let $s \equiv r$ and then it follows

$$
\begin{aligned}
P\left(\|X\|>t_{n+1}\right) & \leq \frac{P\left(\|X\|>\frac{t_{n+1}-r}{\sqrt{2}}\right)^{2}}{P(\|X\| \leq r)} \\
& =\frac{P\left(\|X\|>t_{n}\right)^{2}}{P(\|X\| \leq r)}
\end{aligned}
$$

Let

$$
\alpha_{n}(r) \equiv \frac{P\left(\|X\|>t_{n}\right)}{P(\|X\| \leq r)}
$$

Then it follows

$$
\alpha_{n+1}(r) \leq \alpha_{n}(r)^{2}, \alpha_{0}(r)=\frac{P(\|X\|>r)}{P(\|X\| \leq r)}
$$

Consequently, $\alpha_{n}(r) \leq \alpha_{0}(r)^{2^{n}}$ and also

$$
\begin{align*}
P\left(\|X\|>t_{n}\right) & =\alpha_{n}(r) P(\|X\| \leq r) \\
& \leq P(\|X\| \leq r) \alpha_{0}(r)^{2^{n}} \\
& =P(\|X\| \leq r) e^{\ln \left(\alpha_{0}(r)\right) 2^{n}} \tag{61.7.27}
\end{align*}
$$

Now using the distribution function technique and letting $\lambda>0$,

$$
\begin{align*}
\int_{E} e^{\lambda\|x\|^{2}} d \mu & =\int_{0}^{\infty} \mu\left(\left[e^{\lambda\|x\|^{2}}>t\right]\right) d t \\
& =1+\int_{1}^{\infty} \mu\left(\left[e^{\lambda\|x\|^{2}}>t\right]\right) d t \\
& =1+\int_{1}^{\infty} P\left(\left[e^{\lambda\|X\|^{2}}>t\right]\right) d t \tag{61.7.28}
\end{align*}
$$

From 61.7.27,

$$
P\left(\left[\exp \left(\lambda\|X\|^{2}\right)>\exp \left(\lambda t_{n}^{2}\right)\right]\right) \leq P([\|X\| \leq r]) e^{\ln \left(\alpha_{0}(r)\right) 2^{n}}
$$

Now split the above improper integral into intervals, $\left(\exp \left(\lambda t_{n}^{2}\right), \exp \left(\lambda t_{n+1}^{2}\right)\right)$ for $n=$ $0,1, \cdots$ and note that $P\left(\left[e^{\lambda\|X\|^{2}}>t\right]\right)$ is decreasing in $t$. Then from 61.7.28,

$$
\begin{aligned}
& \int_{E} e^{\lambda\|x\|^{2}} d \mu \leq \exp \left(\lambda r^{2}\right)+\sum_{n=0}^{\infty} \int_{\exp \left(\lambda t_{n}^{2}\right)}^{\exp \left(\lambda t_{n+1}^{2}\right)} P\left(\left[e^{\lambda\|X\|^{2}}>t\right]\right) d t \\
\leq & \exp \left(\lambda r^{2}\right)+\sum_{n=0}^{\infty} P\left(\left[e^{\lambda\|X\|^{2}}>\exp \left(\lambda t_{n}^{2}\right)\right]\right)\left(\exp \left(\lambda t_{n+1}^{2}\right)-\exp \left(\lambda t_{n}^{2}\right)\right) \\
\leq & \exp \left(\lambda r^{2}\right)+\sum_{n=0}^{\infty} P([\|X\| \leq r]) e^{\ln \left(\alpha_{0}(r)\right) 2^{n}} \exp \left(\lambda t_{n+1}^{2}\right) \\
\leq & \exp \left(\lambda r^{2}\right)+\sum_{n=0}^{\infty} e^{\ln \left(\alpha_{0}(r)\right) 2^{n}} \exp \left(\lambda t_{n+1}^{2}\right)
\end{aligned}
$$

It remains to estimate $t_{n+1}$. From the description of the $t_{n}$,

$$
t_{n}=\left(\sum_{k=0}^{n}(\sqrt{2})^{k}\right) r=r \frac{(\sqrt{2})^{n+1}-1}{\sqrt{2}-1} \leq \frac{\sqrt{2}}{\sqrt{2}-1} r(\sqrt{2})^{n}
$$

and so

$$
t_{n+1} \leq 5 r(\sqrt{2})^{n}
$$

Therefore,

$$
\int_{E} e^{\lambda\|x\|^{2}} d \mu \leq \exp \left(\lambda r^{2}\right)+\sum_{n=0}^{\infty} e^{\ln \left(\alpha_{0}(r)\right) 2^{n}+\lambda 25 r^{2} 2^{n}}
$$

Now first pick $r$ large enough that $\ln \left(\alpha_{0}(r)\right)<-2$ and then let $\lambda$ be small enough that $25 \lambda r^{2}<1$ or some such scheme and you obtain $\ln \left(\alpha_{0}(r)\right)+\lambda 25 r^{2}<-1$. Then for this choice of $r$ and $\lambda$, or for any other choice which makes $\ln \left(\alpha_{0}(r)\right)+\lambda 25 r^{2}<-1$,

$$
\begin{aligned}
\int_{E} e^{\lambda\|x\|^{2}} d \mu & \leq \exp \left(\lambda r^{2}\right)+\sum_{n=0}^{\infty} e^{-2^{n}} \\
& \leq \exp \left(\lambda r^{2}\right)+\sum_{n=0}^{\infty} e^{-2 n} \\
& =\exp \left(\lambda r^{2}\right)+\frac{e^{2}}{e^{2}-1}
\end{aligned}
$$

This proves the theorem.

### 61.8 Gaussian Measures For A Separable Hilbert Space

First recall the Kolmogorov extension theorem, Theorem 59.2.3 on Page 1860 which is stated here for convenience. In this theorem, $I$ is an ordered index set, possibly infinite, even uncountable.

Theorem 61.8.1 (Kolmogorov extension theorem) For each finite set

$$
J=\left(t_{1}, \cdots, t_{n}\right) \subseteq I
$$

suppose there exists a Borel probability measure, $v_{J}=v_{t_{1} \cdots t_{n}}$ defined on the Borel sets of $\prod_{t \in J} M_{t}$ where $M_{t}=\mathbb{R}^{n_{t}}$ such that if

$$
\left(t_{1}, \cdots, t_{n}\right) \subseteq\left(s_{1}, \cdots, s_{p}\right)
$$

then

$$
\begin{equation*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=v_{s_{1} \cdots s_{p}}\left(G_{s_{1}} \times \cdots \times G_{s_{p}}\right) \tag{61.8.29}
\end{equation*}
$$

where if $s_{i}=t_{j}$, then $G_{s_{i}}=F_{t_{j}}$ and if $s_{i}$ is not equal to any of the indices, $t_{k}$, then $G_{s_{i}}=M_{s_{i}}$. Then there exists a probability space, $(\Omega, P, \mathscr{F})$ and measurable functions, $X_{t}: \Omega \rightarrow M_{t}$ for each $t \in I$ such that for each $\left(t_{1} \cdots t_{n}\right) \subseteq I$,

$$
\begin{equation*}
v_{t_{1} \cdots t_{n}}\left(F_{t_{1}} \times \cdots \times F_{t_{n}}\right)=P\left(\left[X_{t_{1}} \in F_{t_{1}}\right] \cap \cdots \cap\left[X_{t_{n}} \in F_{t_{n}}\right]\right) . \tag{61.8.30}
\end{equation*}
$$

Lemma 61.8.2 There exists a sequence, $\left\{\xi_{k}\right\}_{k=1}^{\infty}$ of random variables such that

$$
\mathscr{L}\left(\xi_{k}\right)=N(0,1)
$$

and $\left\{\xi_{k}\right\}_{k=1}^{\infty}$ is independent.
Proof: Let $i_{1}<i_{2} \cdots<i_{n}$ be positive integers and define

$$
\mu_{i_{1} \cdots i_{n}}\left(F_{1} \times \cdots \times F_{n}\right) \equiv \frac{1}{(\sqrt{2 \pi})^{n}} \int_{F_{1} \times \cdots \times F_{n}} e^{-|\mathbf{x}|^{2} / 2} d x
$$

Then for the index set equal to $\mathbb{N}$ the measures satisfy the necessary consistency condition for the Kolmogorov theorem above. Therefore, there exists a probability space, $(\Omega, P, \mathscr{F})$ and measurable functions, $\xi_{k}: \Omega \rightarrow \mathbb{R}$ such that

$$
\begin{aligned}
& P\left(\left[\xi_{i_{1}} \in F_{i_{1}}\right] \cap\left[\xi_{i_{2}} \in F_{i_{2}}\right] \cdots \cap\left[\xi_{i_{n}} \in F_{i_{n}}\right]\right) \\
= & \mu_{i_{1} \cdots i_{n}}\left(F_{1} \times \cdots \times F_{n}\right) \\
= & P\left(\left[\xi_{i_{1}} \in F_{i_{1}}\right]\right) \cdots P\left(\left[\xi_{i_{n}} \in F_{i_{n}}\right]\right)
\end{aligned}
$$

which shows the random variables are independent as well as normal with mean 0 and variance 1 . This proves the Lemma.

A random variable $X$ defined on a probability space $(\Omega, \mathscr{F}, P)$ is called Gaussian if

$$
P([X \in A])=\frac{1}{\sqrt{2 \pi \sigma(v)^{2}}} \int_{A} e^{-\frac{1}{2 \sigma(v)^{2}}(x-m(v))^{2}} d x
$$

for all $A$ a Borel set in $\mathbb{R}$. Therefore, for the probability space $(X, \mathscr{B}(X), \mu)$ it is natural to say $\mu$ is a Gaussian measure if every $x^{*}$ in the dual space $X^{\prime}$ is a Gaussian random variable. That is, normally distributed.

Definition 61.8.3 Let $\mu$ be a measure defined on $\mathscr{B}(X)$, the Borel sets of $X$, a separable Banach space. It is called a Gaussian measure if each of the functions in the dual space $X^{\prime}$ is normally distributed. As a special case, when $X=U$ a separable real Hilberts space, $\mu$ is called a Gaussian measure if for each $v \in U$, the function $u \rightarrow(u, v)_{U}$ is normally distributed. That is, denoting this random variable as $v^{\prime}$, it follows for $A$ a Borel set in $\mathbb{R}$

$$
\lambda_{v^{\prime}}(A) \equiv \mu\left(\left[u: v^{\prime}(u) \in A\right]\right)=\frac{1}{\sqrt{2 \pi \sigma(v)^{2}}} \int_{A} e^{-\frac{1}{2 \sigma(v)^{2}}(x-m(v))^{2}} d x
$$

in case $\sigma(v)>0$. In case $\sigma(v)=0$

$$
\lambda_{v^{\prime}} \equiv \delta_{m(v)}
$$

In other words, the random variables $v^{\prime}$ for $v \in U$ are all normally distributed on the probability space $(U, \mathscr{B}(U), \mu)$.

Also recall the definition of the characteristic function of a measure.
Definition 61.8.4 The Borel sets in a topological space $X$ will be denoted by $\mathscr{B}(X)$. For a Borel probability measure $\mu$ defined on $\mathscr{B}(U)$ for $U$ a real separable Hilbert space, define its characteristic function as follows.

$$
\begin{equation*}
\phi_{\mu}(u) \equiv \widehat{\mu}(u) \equiv \int_{U} e^{i(u, v)} d \mu(v) \tag{61.8.31}
\end{equation*}
$$

More generally, if $\mu$ is a probability measure defined on $\mathscr{B}(X)$ where $X$ is a separable Banach space, then the characteristic function is defined as

$$
\phi_{\mu}\left(x^{*}\right)=\widehat{\mu}\left(x^{*}\right) \equiv \int_{U} e^{i x^{*}(x)} d \mu(x)
$$

One can tell whether $\mu$ is a Gaussian measure by looking at its characteristic function. In fact you can show the following theorem. One part of this theorem is that if $\mu$ is Gaussian, then $m$ and $\sigma^{2}$ have a certain form.

Theorem 61.8.5 A measure $\mu$ on $\mathscr{B}(U)$ is Gaussian if and only if there exists $m \in U$ and $Q \in \mathscr{L}(U)$ such that $Q$ is nonnegative symmetric with finite trace,

$$
\sum_{k}\left(Q e_{k}, e_{k}\right)<\infty
$$

for a complete orthonormal basis for $U$, and

$$
\begin{equation*}
\phi_{\mu}(u)=\widehat{\mu}(u)=e^{i(m, u)-\frac{1}{2}(Q u, u)} \tag{61.8.32}
\end{equation*}
$$

In this case $\mu$ is called $N(m, Q)$ where $m$ is the mean and $Q$ is called the covariance. The measure $\mu$ is uniquely determined by $m$ and $Q$. Also for all $h, g \in U$

$$
\begin{gather*}
\int(x, h)_{U} d \mu(x)=(m, h)_{U}  \tag{61.8.33}\\
\int((x, h)-(m, h))((x, g)-(m, g)) d \mu(x)=(Q h, g)  \tag{61.8.34}\\
\int\|x-m\|_{U}^{2} d \mu(x)=\operatorname{trace}(Q) \tag{61.8.35}
\end{gather*}
$$

Proof: First of all suppose 61.8 .32 holds. Why is $\mu$ Gaussian? Consider the random variable $u^{\prime}$ defined by $u^{\prime}(v) \equiv(v, u)$. Why is $\lambda_{u^{\prime}}$ a Gaussian measure on $\mathbb{R}$ ? By the definition in 61.8.31,

$$
\begin{aligned}
\int_{U} e^{i t u^{\prime}(v)} d \mu(v) & \equiv \int_{U} e^{i t(v, u)} d \mu(v)=\int_{\mathbb{R}} e^{i x} d \lambda_{u^{\prime}}(x) \\
& =\int_{U} e^{i(v, t u)} d \mu(v)=e^{i t(m, u)-\frac{1}{2} t^{2}(Q u, u)}
\end{aligned}
$$

and this is the characteristic equation for a random variable having mean $(m, u)$ and variance $(Q u, u)$. In case $(Q u, u)=0$, you get $e^{i t(m, u)}$ which is the characteristic function for a random variable having distribution $\boldsymbol{\delta}_{(m, u)}$. Thus if 61.8 .32 holds, then $u^{\prime}$ is normally distributed as desired. Thus $\mu$ is Gaussian by definition.

The next task is to suppose $\mu$ is Gaussian and show the existence of $m, Q$ which have the desired properties. This involves the following lemma.
Lemma 61.8.6 Let $U$ be a real separable Hilbert space and let $\mu$ be a probability measure defined on $\mathscr{B}(U)$. Suppose for some positive integer, $k$

$$
\int_{U}|(x, z)|^{k} d \mu(x)<\infty
$$

for all $z \in U$. Then the transformation,

$$
\begin{equation*}
\left(h_{1}, \cdots, h_{k}\right) \rightarrow \int_{U}\left(h_{1}, x\right) \cdots\left(h_{k}, x\right) d \mu(x) \tag{61.8.36}
\end{equation*}
$$

is a continuous $k$-linear form.

Proof: I need to show that for each $\mathbf{h} \in U^{k}$, the integral in 61.8.36 exists. From this it is obvious it is $k$ - linear, meaning linear in each argument. Then it is shown it is continuous.

First note

$$
\left|\left(h_{1}, x\right) \cdots\left(h_{k}, x\right)\right| \leq\left|\left(h_{1}, x\right)\right|^{k}+\cdots+\left|\left(h_{k}, x\right)\right|^{k}
$$

This follows from observing that one of $\left|\left(h_{j}, x\right)\right|$ is largest. Then the left side is smaller than $\left|\left(h_{j}, x\right)\right|^{k}$. Therefore, the above inequality is valid. This inequality shows the integral in 61.8.36 makes sense.

I need to establish an estimate of the form

$$
\int_{U}|(x, h)|^{k} d \mu(x)<C<\infty
$$

for every $h \in U$ such that $\|h\|$ is small enough.
Let

$$
U_{n} \equiv\left\{z \in U: \int_{U}|(x, z)|^{k} d \mu(x) \leq n\right\}
$$

Then by assumption $U=\cup_{n=1}^{\infty} U_{n}$ and it is also clear from Fatou's lemma that each $U_{n}$ is closed. Therefore, by the Bair category theorem, at least one of these $U_{n_{0}}$ contains an open ball, $B\left(z_{0}, r\right)$. Then letting $|y|<r$,

$$
\int_{U}\left|\left(x, z_{0}+y\right)\right|^{k} d \mu(x), \int_{U}\left|\left(x, z_{0}\right)\right|^{k} d \mu(x) \leq n_{0}
$$

and so for such $y$,

$$
\begin{aligned}
\int_{U}|(x, y)|^{k} d \mu & =\int_{U}\left|\left(x, z_{0}+y\right)-\left(x, z_{0}\right)\right|^{k} d \mu \\
& \leq \int_{U} 2^{k}\left|\left(x, z_{0}+y\right)\right|^{k}+2^{k}\left|\left(x, z_{0}\right)\right|^{k} d \mu(x) \\
& \leq 2^{k}\left(n_{0}+n_{0}\right)=2^{k+1} n_{0} .
\end{aligned}
$$

It follows that for arbitrary nonzero $y \in U$

$$
\int_{U}\left|\left(x, \frac{(r / 2) y}{\|y\|}\right)\right|^{k} d \mu \leq 2^{k+1} n_{0}
$$

and so

$$
\int_{U}|(x, y)|^{k} d \mu \leq\left(2^{k+2} / r\right) n_{0}\|y\|^{k} \equiv C\|y\|^{k}
$$

Thus by Holder's inequality,

$$
\begin{aligned}
\int_{U}\left|\left(h_{1}, x\right) \cdots\left(h_{k}, x\right)\right| d \mu(x) & \leq \prod_{j=1}^{k}\left(\int_{U}\left|\left(h_{j}, x\right)\right|^{k} d \mu(x)\right)^{1 / k} \\
& \leq C \prod_{j=1}^{k} \| h_{j}| |
\end{aligned}
$$

This proves the lemma.
Now continue with the proof of the theorem. I need to identify $m$ and $Q$. It is assumed $\mu$ is Gaussian. Recall this means $h^{\prime}$ is normally distributed for each $h \in U$. Then using

$$
\begin{gathered}
|x| \leq|x-m(h)|+|m(h)| \\
\int_{U}\left|(x, h)_{U}\right| d \mu(x)=\int_{\mathbb{R}}|x| d \lambda_{h^{\prime}}(x) \\
=\frac{1}{\sqrt{2 \pi \sigma^{2}(h)}} \int_{\mathbb{R}}|x| e^{-\frac{1}{2 \sigma^{2}}(x-m(h))^{2}} d x \\
\leq \frac{1}{\sqrt{2 \pi \sigma^{2}(h)}} \int_{\mathbb{R}}|x-m(h)| e^{-\frac{1}{2 \sigma^{2}}(x-m(h))^{2}} d x \\
+|m(h)|
\end{gathered}
$$

Then using the Cauchy Schwarz inequality, with respect to the probability measure

$$
\begin{gathered}
\frac{1}{\sqrt{2 \pi \sigma^{2}(h)}} e^{-\frac{1}{2 \sigma^{2}}(x-m(h))^{2}} d x \\
\leq \frac{1}{\sqrt{2 \pi \sigma^{2}(h)}}\left(\int_{\mathbb{R}}|x-m(h)|^{2} e^{-\frac{1}{2 \sigma^{2}}(x-m(h))^{2}} d x\right)^{1 / 2}+|m(h)|<\infty
\end{gathered}
$$

Thus by Lemma 61.8.6

$$
h \rightarrow \int_{U}(x, h) d \mu(x)
$$

is a continuous linear transformation and so by the Riesz representation theorem, there exists a unique $m \in U$ such that

$$
(h, m)_{U}=\int_{U}(h, x) d \mu(x)
$$

Also the above says $(h, m)$ is the mean of the random variable $x \rightarrow(x, h)$ so in the above,

$$
m(h)=(h, m)_{U}
$$

Next it is necessary to find $Q$. To do this let $Q$ be given by 61.8.34. Thus

$$
\begin{aligned}
(Q h, g) & \equiv \int_{U}((x, h)-(m, h))((x, g)-(m, g)) d \mu(x) \\
& =\int_{U}(x-m, h)(x-m, g) d \mu(x)
\end{aligned}
$$

It is clear $Q$ is linear and the above is a bilinear form (The integral makes sense because of the assumption that $h^{\prime}, g^{\prime}$ are normally distributed.) but is it continuous? Does $(Q h, h)=$ $\sigma^{2}(h)$ ?

First, the above equals

$$
\begin{align*}
& \int_{U}(x, h)(x-m, g) d \mu-\int_{U}(m, h)(x-m, g) d \mu(x) \\
= & \int_{U}(x, h)(x-m, g) d \mu \tag{61.8.37}
\end{align*}
$$

because from the first part,

$$
\int_{U}(x-m, g) d \mu(x)=\int_{U}(x, g) d \mu(x)-(m, g)_{U}=0
$$

Now by the first part, the term in 61.8.37 is

$$
\begin{aligned}
& \int_{U}(x, h)(x, g) d \mu(x)-(m, g) \int_{U}(x, h) d \mu(x) \\
= & \int_{U}(x, h)(x, g) d \mu(x)-(m, g)(m, h) .
\end{aligned}
$$

Thus

$$
|(Q h, g)| \leq \int_{U}|(x, h)(x, g)| d \mu(x)+\|m\|^{2}\|h\|\|g\|
$$

and since the random variables $h^{\prime}$ and $g^{\prime}$ given by $x \rightarrow(x, h)$ and $x \rightarrow(x, g)$ respectively are given to be normally distributed with variance $\sigma^{2}(h)$ and $\sigma^{2}(g)$ respectively, the above integral is finite. Also for all $h$,

$$
\int_{U}|(x, h)|^{2} d \mu(x)<\infty
$$

because the random variable $h^{\prime}$ is given to be normally distributed. Therefore from Lemma 61.8.6, there exists some constant $C$ such that

$$
|(Q h, g)| \leq C\|h\|\|g\|
$$

which shows $Q$ is continuous as desired.
Why is $\sigma^{2}(h)=(Q h, h)$ ? This follows because from the above

$$
\begin{aligned}
&(Q h, h) \equiv \int_{U}(h, x-m)^{2} d \mu(x) \\
&=\int_{U}((x, h)-(h, m))^{2} d \mu(x)=\int_{\mathbb{R}}(t-(h, m))^{2} d \lambda_{h^{\prime}}(t) \\
&=\frac{1}{\sqrt{2 \pi \sigma^{2}(h)}} \int_{\mathbb{R}}(t-(h, m))^{2} e^{-\frac{1}{2 \sigma^{2}(h)}(t-(h, m))^{2}} d t=\sigma^{2}(h)
\end{aligned}
$$

from a standard result for the normal distribution function which follows from an easy change of variables argument.

Why must $Q$ have finite trace? For $h \in U$, it follows from the above that $h^{\prime}$ is normally distributed with mean $(h, m)$ and variance $(Q h, h)$. Therefore, the characteristic function of $h^{\prime}$ is known. In fact

$$
\int_{U} e^{i t(x, h)} d \mu(x)=e^{i t(h, m)} e^{-\frac{1}{2} t^{2}(Q h, h)}
$$

Thus also

$$
\int_{U} e^{i t(x-m, h)} d \mu(x)=e^{-\frac{1}{2} t^{2}(Q h, h)}
$$

and letting $t=1$ this yields

$$
\int_{U} e^{i(x-m, h)} d \mu(x)=e^{-\frac{1}{2}(Q h, h)}
$$

From this it follows

$$
\int_{U}\left(1-e^{i(x-m, h)}\right) d \mu=1-e^{-\frac{1}{2}(Q h, h)}
$$

and since the right side is real, this implies

$$
\int_{U}(1-\cos (x-m, h)) d \mu(x)=1-e^{-\frac{1}{2}(Q h, h)}
$$

Thus

$$
\begin{aligned}
1-e^{-\frac{1}{2}(Q h, h)} \leq & \int_{[\|x-m\| \leq c]}(1-\cos (x-m, h)) d \mu(x) \\
& +2 \int_{[\|x-m\|>c]} d \mu(x)
\end{aligned}
$$

Now it is routine to show

$$
1-\cos t \leq \frac{1}{2} t^{2}
$$

and so

$$
\begin{aligned}
1-e^{-\frac{1}{2}(Q h, h)} \leq & \frac{1}{2} \int_{[\|x-m\| \leq c]}|(x-m, h)|^{2} d \mu(x) \\
& +2 \mu([\|x-m\|>c])
\end{aligned}
$$

Pick $c$ large enough that the last term is smaller than $1 / 8$. This can be done because the sets decrease to $\emptyset$ as $c \rightarrow \infty$ and $\mu$ is given to be a finite measure. Then with this choice of $c$,

$$
\begin{equation*}
\frac{7}{8}-\frac{1}{2} \int_{[| | x-m \| \leq c]}|(x-m, h)|^{2} d \mu(x) \leq e^{-\frac{1}{2}(Q h, h)} \tag{61.8.38}
\end{equation*}
$$

For each $h$ the integral in the above is finite. In fact

$$
\int_{[\|x-m\| \leq c]}|(x-m, h)|^{2} d \mu(x) \leq c^{2}\|h\|^{2}
$$

Let

$$
\left(Q_{c} h, h_{1}\right) \equiv \int_{[\|x-m\| \leq c]}(x-m, h)\left(x-m, h_{1}\right) d \mu(x)
$$

and let $A$ denote those $h \in U$ such that

$$
\left(Q_{c} h, h\right)<1
$$

Then from 61.8.38 it follows that for $h \in A$,

$$
\frac{3}{8}=\frac{7}{8}-\frac{1}{2} \leq \frac{7}{8}-\frac{1}{2}\left(Q_{c} h, h\right) \leq e^{-\frac{1}{2}(Q h, h)}
$$

Therefore, for such $h$,

$$
\frac{8}{3} \geq e^{\frac{1}{2}(Q h, h)} \geq 1+\frac{1}{2}(Q h, h)
$$

and so for $h \in A$,

$$
(Q h, h) \leq\left(\frac{8}{3}-1\right) 2=\frac{10}{3}
$$

Now let $h$ be arbitrary. Then for each $\varepsilon>0$

$$
\frac{h}{\varepsilon+\sqrt{\left(Q_{c} h, h\right)}} \in A
$$

and so

$$
\left(Q\left(\frac{h}{\varepsilon+\sqrt{\left(Q_{c} h, h\right)}}\right), \frac{h}{\varepsilon+\sqrt{\left(Q_{c} h, h\right)}}\right) \leq \frac{10}{3}
$$

which implies

$$
(Q h, h) \leq \frac{10}{3}\left(\varepsilon+\sqrt{\left(Q_{c} h, h\right)}\right)^{2}
$$

Since $\varepsilon$ is arbitrary,

$$
\begin{equation*}
(Q h, h) \leq \frac{10}{3}\left(Q_{c} h, h\right) \tag{61.8.39}
\end{equation*}
$$

However, $Q_{c}$ has finite trace. To see this, let $\left\{e_{k}\right\}$ be an orthonormal basis in $U$. Then

$$
\begin{gathered}
\sum_{k}\left(Q_{c} e_{k}, e_{k}\right)=\sum_{k} \int_{[\|x-m\| \leq c]}\left|\left(x-m, e_{k}\right)\right|^{2} d \mu(x) \\
=\int_{[\|x-m\| \leq c]} \sum_{k}\left|\left(x-m, e_{k}\right)\right|^{2} d \mu(x)=\int_{[\|x-m\| \leq c]}\|x-m\|^{2} d \mu(x) \leq c^{2}
\end{gathered}
$$

It follows from 61.8.39 $Q$ that $Q$ must also have finite trace.
That $\mu$ is uniquely determined by $m$ and $Q$ follows from Theorem 59.12.9. This proves the theorem.

Suppose you have a given $Q$ having finite trace and $m \in U$. Does there exist a Gaussian measure on $\mathscr{B}(U)$ having these as the covariance and mean respectively?

Proposition 61.8.7 Let $U$ be a real separable Hilbert space and let $m \in U$ and $Q$ be a positive, symmetric operator defined on $U$ which has finite trace. Then there exists a Gaussian measure with mean $m$ and covariance $Q$.

Proof: By Lemma 61.8.2 which comes from Kolmogorov's extension theorem, there exists a probability space $(\Omega, \mathscr{F}, P)$ and a sequence $\left\{\xi_{i}\right\}$ of independent random variables which are normally distributed with mean 0 and variance 1 . Then let

$$
X(\omega) \equiv m+\sum_{j=1}^{\infty} \sqrt{\lambda_{j}} \xi_{j}(\omega) e_{j}
$$

where the $\left\{e_{j}\right\}$ are the eigenvectors of $Q$ such that $Q e_{j}=\lambda_{j} e_{j}$. The series in the above converges in $L^{2}(\Omega ; U)$ because

$$
\left\|\sum_{j=m}^{n} \sqrt{\lambda_{j}} \xi_{j} e_{j}\right\|_{L^{2}(\Omega ; U)}^{2}=\int_{\Omega} \sum_{j=m}^{n} \lambda_{j} \xi_{j}^{2}(\omega) d P=\sum_{j=m}^{n} \lambda_{j}
$$

and so the partial sums form a Cauchy sequence in $L^{2}(\Omega ; U)$.
Now if $h \in U$, I need to show that $\omega \rightarrow(X(\omega), h)$ is normally distributed. From this it will follow that $\mathscr{L}(X)$ is Gaussian. A subsequence

$$
\left\{m+\sum_{j=1}^{n_{k}} \sqrt{\lambda_{j}} \xi_{j}(\omega) e_{j}\right\} \equiv\left\{S_{n_{k}}(\omega)\right\}
$$

of the above sequence converges pointwise a.e. to $X$.

$$
\begin{aligned}
& E(\exp (i t(X, h))) \\
= & \lim _{k \rightarrow \infty} E\left(\exp \left(i t\left(S_{n_{k}}, h\right)\right)\right) \\
= & \exp (i t(m, h)) \lim _{k \rightarrow \infty} E\left(\exp \left(i t \sum_{j=1}^{n_{k}} \sqrt{\lambda_{j}} \xi_{j}(\omega)\left(e_{j}, h\right)\right)\right)
\end{aligned}
$$

Since the $\xi_{j}$ are independent,

$$
\begin{gather*}
=\exp (i t(m, h)) \lim _{k \rightarrow \infty} \prod_{j=1}^{n_{k}} E\left(\exp \left(i t \sqrt{\lambda_{j}}\left(e_{j}, h\right)\right) \xi_{j}\right) \\
=\exp (i t(m, h)) \lim _{k \rightarrow \infty} \prod_{j=1}^{n_{k}} e^{-\frac{1}{2} t^{2} \lambda_{j}\left(e_{j}, h\right)^{2}} \\
=\exp (i t(m, h)) \lim _{k \rightarrow \infty} \exp \left(-\frac{1}{2} t^{2} \sum_{j=1}^{n_{k}} \lambda_{j}\left(e_{j}, h\right)^{2}\right) . \tag{61.8.40}
\end{gather*}
$$

Now

$$
\begin{aligned}
(Q h, h) & =\left(Q \sum_{k=1}^{\infty}\left(e_{k}, h\right) e_{k}, \sum_{j=1}^{\infty}\left(e_{j}, h\right) e_{j}\right) \\
& =\left(\sum_{k=1}^{\infty}\left(e_{k}, h\right) \lambda_{k} e_{k}, \sum_{j=1}^{\infty}\left(e_{j}, h\right) e_{j}\right) \\
& =\sum_{j=1}^{\infty} \lambda_{j}\left(e_{j}, h\right)^{2}
\end{aligned}
$$

and so, passing to the limit in 61.8 .40 yields

$$
\begin{equation*}
\exp (i t(m, h)) \exp \left(-\frac{1}{2} t^{2}(Q h, h)\right) \tag{61.8.41}
\end{equation*}
$$

which implies that $\omega \rightarrow(X(\omega), h)$ is normally distributed with mean $(m, h)$ and variance $(Q h, h)$.

Now let $\mu=\mathscr{L}(X)$. That is, for all $B \in \mathscr{B}(U)$,

$$
\mu(B) \equiv P([X \in B])
$$

In particular, $B$ could be the cylindrical set

$$
B \equiv[x:(x, h) \in A]
$$

for $A$ a Borel set in $\mathbb{R}$. Then by definition, if $h \in U$, and $A$ is a Borel set in $\mathbb{R}$,

$$
\begin{aligned}
\mu(B) & =\mu([x:(x, h) \in A]) \equiv P(\{\omega:(X(\omega), h) \in A\}) \\
& =\int_{A} \frac{1}{\sqrt{2 \pi(Q h, h)}} e^{-\frac{(t-(m, h))^{2}}{2(Q h, h)}} d t
\end{aligned}
$$

and so $x \rightarrow(x, h)$ is normally distributed. Therefore by definition, $\mu$ is a Gaussian measure.
Letting $t=1$ in 61.8.41 it follows

$$
\int_{U} e^{i(x, h)} d \mu(x)=\int_{\Omega} e^{i(X(\omega), h)} d P=\exp (i(m, h)) \exp \left(-\frac{1}{2}(Q h, h)\right)
$$

which is the characteristic function of a Gaussian measure on $U$ having covariance $Q$ and mean $m$. This proves the proposition.

### 61.9 Abstract Wiener Spaces

This material follows [21], [71] and [58]. More can be found on this subject in these references. Here $H$ will be a separable real Hilbert space.

Definition 61.9.1 Cylinder sets in $H$ are of the form

$$
\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F\right\}
$$

where $F \in \mathscr{B}\left(\mathbb{R}^{n}\right)$, the Borel sets of $\mathbb{R}^{n}$ and $\left\{e_{k}\right\}$ are given vectors in $H$. Denote this collection of cylinder sets as $\mathscr{C}$.

Proposition 61.9.2 The cylinder sets form an algebra of sets.
Proof: First note the complement of a cylinder set is a cylinder set.

$$
\begin{aligned}
& \left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F\right\}^{C} \\
= & \left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F^{C}\right\} .
\end{aligned}
$$

Now consider the intersection of two of these cylinder sets. Let the cylinder sets be

$$
\begin{aligned}
& \left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in E\right\}, \\
& \left\{x \in H:\left(\left(x, f_{1}\right), \cdots,\left(x, f_{m}\right)\right) \in F\right\}
\end{aligned}
$$

The first of these equals

$$
\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right),\left(x, f_{1}\right), \cdots,\left(x, f_{m}\right)\right) \in E \times \mathbb{R}^{m}\right\}
$$

and the second equals

$$
\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right),\left(x, f_{1}\right), \cdots,\left(x, f_{m}\right)\right) \in \mathbb{R}^{n} \times F\right\}
$$

Therefore, their intersection equals

$$
\begin{aligned}
& \left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right),\left(x, f_{1}\right), \cdots,\left(x, f_{m}\right)\right)\right. \\
& \left.\in E \times \mathbb{R}^{m} \cap \mathbb{R}^{n} \times F\right\}
\end{aligned}
$$

a cylinder set.
Now it is clear the whole of $H$ and $\emptyset$ are cylinder sets given by

$$
\{x \in H:(e, x) \in \mathbb{R}\},\{x \in H:(e, x) \in \emptyset\}
$$

respectively and so if $C_{1}, C_{2}$ are two cylinder sets,

$$
C_{1} \backslash C_{2} \equiv C_{1} \cap C_{2}^{C}
$$

which was just shown to be a cylinder set. Hence

$$
C_{1} \cup C_{2}=\left(C_{1}^{C} \cap C_{2}^{C}\right)^{C}
$$

a cylinder set. This proves the proposition.
It is good to have a more geometrical description of cylinder sets. Letting $A$ be a cylinder set as just described, let $P$ denote the orthogonal projection onto span $\left(e_{1}, \cdots, e_{n}\right)$. Also let $\alpha: P H \rightarrow \mathbb{R}^{n}$ be given by

$$
\alpha(x) \equiv\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right)
$$

This is continuous but might not be one to one if the $e_{i}$ are not a basis for example. Then consider $\alpha^{-1}(F)$, those $x \in P H$ such that

$$
\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F .
$$

For any $x \in H$,

$$
\left((I-P) x, e_{k}\right)=0
$$

for each $k$ and so

$$
\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right)=\left(\left(P x, e_{1}\right), \cdots,\left(P x, e_{n}\right)\right) \in F
$$

Thus $P x \in \alpha^{-1}(F)$, which is a Borel set of $P H$ and

$$
x=P x+(I-P) x
$$

so the cylinder set is contained in

$$
\alpha^{-1}(F)+(P H)^{\perp}
$$

which is of the form

$$
(\text { Borel set of } P H)+(P H)^{\perp}
$$

On the other hand, consider a set of the form

$$
G+(P H)^{\perp}
$$

where $G$ is a Borel set in $P H$. There is a basis for $P H$ consisting of a subset of $\left\{e_{1} \cdots, e_{n}\right\}$. For simplicity, suppose it is $\left\{e_{1} \cdots, e_{k}\right\}$. Then let $\alpha_{1}: P H \rightarrow \mathbb{R}^{k}$ be given by

$$
\alpha_{1}(x) \equiv\left(\left(x, e_{1}\right), \cdots,\left(x, e_{k}\right)\right)
$$

Thus $\alpha$ is a homeomorphism of $P H$ and $\mathbb{R}^{k}$ so $\alpha_{1}(G)$ is a Borel set of $\mathbb{R}^{k}$. Now

$$
\alpha^{-1}\left(\alpha_{1}(G) \times \mathbb{R}^{n-k}\right)=G
$$

and $\alpha_{1}(G) \times \mathbb{R}^{n-k}$ is a Borel set of $\mathbb{R}^{n}$. This has proved the following important Proposition illustrated by the following picture.

Proposition 61.9.3 The cylinder sets are sets of the form

$$
B+M^{\perp}
$$

where $M$ is a finite dimensional subspace and B is a Borel subset of M. Furthermore, the collection of cylinder sets is an algebra.

Lemma 61.9.4 $\sigma(\mathscr{C})$, the smallest $\sigma$ algebra containing $\mathscr{C}$, contains the Borel sets of $H, \mathscr{B}(H)$.

Proof: It follows from the definition of these cylinder sets that if $f_{i}(x) \equiv\left(x, e_{i}\right)$, so that $f_{i} \in H^{\prime}$, then with respect to $\sigma(\mathscr{C})$, each $f_{i}$ is measurable. It follows that every linear combination of the $f_{i}$ is also measurable with respect to $\sigma(\mathscr{C})$. However, this set of linear
combinations is dense in $H^{\prime}$ and so the conclusion of the lemma follows from Lemma 59.4.2 on Page 1868. This proves the lemma.

Also note that the mapping

$$
x \rightarrow\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right)
$$

is a $\sigma(\mathscr{C})$ measurable map. Restricting it to span $\left(e_{1}, \cdots, e_{n}\right)$, it is Borel measurable. Next is a definition of a Gaussian measure defined on $\mathscr{C}$. While this is what it is called, it is a fake measure in general because it cannot be extended to a countably additive measure on $\sigma(\mathscr{C})$. This will be shown below.

Definition 61.9.5 Let $Q \in \mathscr{L}(H, H)$ be self adjoint and satisfy

$$
(Q x, x)>0
$$

for all $x \in H, x \neq 0$. Define $v$ on the cylinder sets, $\mathscr{C}$ by the following rule. For $\left\{e_{k}\right\}_{k=1}^{n}$ an orthonormal set in $H$,

$$
\begin{aligned}
& v\left(\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F\right\}\right) \\
\equiv & \frac{1}{(2 \pi)^{n / 2}\left(\operatorname{det}\left(\theta^{*} Q \theta\right)\right)^{1 / 2}} \int_{F} e^{-\frac{1}{2} *^{*} \theta^{*} Q^{-1} \theta \mathbf{t}} d t .
\end{aligned}
$$

where here

$$
\theta \mathbf{t} \equiv \sum_{i=1}^{n} t_{i} e_{i} .
$$

Note that the cylinder set is of the form

$$
\theta F+\operatorname{span}\left(e_{1}, \cdots, e_{n}\right)^{\perp} .
$$

Thus if $B+M^{\perp}$ is a typical cylinder set, choose an orthonormal basis for $M,\left\{e_{k}\right\}_{k=1}^{n}$ and do the above definition with $F=\theta^{-1} B$.

To see this last claim which is like what was done earlier, let

$$
\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F
$$

Then $\theta\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right)=\sum_{i}\left(x, e_{i}\right) e_{i}=P x$ and so

$$
\begin{aligned}
x & =x-P x+P x=x-P x+\theta\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \\
& \in \theta F+\operatorname{span}\left(e_{1}, \cdots, e_{n}\right)^{\perp}
\end{aligned}
$$

Thus

$$
\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F\right\} \subseteq \theta F+\operatorname{span}\left(e_{1}, \cdots, e_{n}\right)^{\perp}
$$

To see the other inclusion, if $\mathbf{t} \in F$ and $y \in \operatorname{span}\left(e_{1}, \cdots, e_{n}\right)^{\perp}$, then if $x=\theta \mathbf{t}$, it follows

$$
t_{i}=\left(x, e_{i}\right)
$$

and so $\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F$. But $\left(y, e_{k}\right)=0$ for all $k$ and so $x+y$ is in

$$
\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F\right\}
$$

Lemma 61.9.6 The above definition is well defined.
Proof: Let $\left\{f_{k}\right\}$ be another orthonormal set such that for $F, G$ Borel sets in $\mathbb{R}^{n}$,

$$
\begin{aligned}
& A=\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in F\right\} \\
= & \left\{x \in H:\left(\left(x, f_{1}\right), \cdots,\left(x, f_{n}\right)\right) \in G\right\}
\end{aligned}
$$

I need to verify $\boldsymbol{v}(A)$ is the same using either $\left\{f_{k}\right\}$ or $\left\{e_{k}\right\}$. Let $\mathbf{a} \in G$. Then

$$
x \equiv \sum_{i=1}^{n} a_{i} f_{i} \in A
$$

because $\left(x, f_{k}\right)=a_{k}$. Therefore, for this $x$ it is also true that $\left(\left(x, e_{1}\right), \cdots\left(x, e_{n}\right)\right) \in F$. In other words for $\mathbf{a} \in G$,

$$
\left(\sum_{i=1}^{n}\left(e_{1}, f_{i}\right) a_{i}, \cdots, \sum_{i=1}^{n}\left(e_{n}, f_{i}\right) a_{i}\right) \in F
$$

Let $L \in \mathscr{L}\left(\mathbb{R}^{n}, \mathbb{R}^{n}\right)$ be defined by

$$
L \mathbf{a} \equiv \sum_{i} L_{j i} a_{i}, L_{j i} \equiv\left(e_{j}, f_{i}\right)
$$

Since the $\left\{e_{j}\right\}$ and $\left\{f_{k}\right\}$ are orthonormal, this mapping is unitary. Also this has shown that

$$
L G \subseteq F
$$

Similarly

$$
L^{*} F \subseteq G
$$

where $L^{*}$ has the $i j^{t h}$ entry $L_{i j}^{*}=\left(f_{i}, e_{j}\right)$ as above and $L^{*}$ is the inverse of $L$ because $L$ is unitary. Thus

$$
F=L\left(L^{*}(F)\right) \subseteq L(G) \subseteq F
$$

showing that $L G=F$ and $L^{*} F=G$.
Now let $\theta_{e} \mathbf{t} \equiv \sum_{i} t_{i} e_{i}$ with $\theta_{f}$ defined similarly. Then the definition of $v(A)$ corresponding to $\left\{e_{i}\right\}$ is

$$
v(A) \equiv \frac{1}{(2 \pi)^{n / 2}\left(\operatorname{det}\left(\theta_{e}^{*} Q \theta_{e}\right)\right)^{1 / 2}} \int_{F} e^{-\frac{1}{2} \mathbf{t}^{*} \theta_{e}^{*} Q^{-1} \theta_{e} \mathbf{t}} d t
$$

Now change the variables letting $\mathbf{t}=L \mathbf{s}$ where $\mathbf{s} \in G$.
From the definition,

$$
\begin{gathered}
\theta_{e} L \mathbf{s}=\sum_{j} \sum_{i}\left(e_{j}, f_{i}\right) s_{i} e_{j} \\
=\sum_{j}\left(e_{j}, \sum_{i} f_{i} s_{i}\right) e_{j}=\sum_{j}\left(e_{j}, \theta_{f} \mathbf{s}\right) e_{j}
\end{gathered}
$$

and so

$$
L \mathbf{s}=\left(\left(e_{1}, \theta_{f} \mathbf{s}\right), \cdots,\left(e_{n}, \theta_{f} \mathbf{s}\right)\right)=\theta_{e}^{*} \theta_{f} \mathbf{s}
$$

where from the definition,

$$
\begin{aligned}
\left(\theta_{e}^{*} \theta_{e} \mathbf{s}, \mathbf{t}\right) & =\sum_{i} t_{i}\left(\sum_{j} s_{j} e_{j}, e_{i}\right) \\
& =\sum_{i} t_{i} s_{i}=(\mathbf{s}, \mathbf{t})
\end{aligned}
$$

and so $\theta_{e}^{*} \theta_{e}$ is the identity on $\mathbb{R}^{n}$ and similar reasoning yields $\theta_{e} \theta_{e}^{*}$ is the identity on $\theta_{e}\left(\mathbb{R}^{n}\right)$. Then using the change of variables formula and the fact $|\operatorname{det}(L)|=1$,

$$
\begin{aligned}
& \frac{1}{(2 \pi)^{n / 2}\left(\operatorname{det}\left(\theta_{e}^{*} Q \theta_{e}\right)\right)^{1 / 2}} \int_{F} e^{-\frac{1}{2} \mathbf{t}^{*} \theta_{e}^{*} Q^{-1} \theta_{e} \mathbf{t}} d t \\
= & \frac{1}{(2 \pi)^{n / 2}\left(\operatorname{det}\left(\theta_{e}^{*} Q \theta_{e}\right)\right)^{1 / 2}} \int_{G} e^{-\frac{1}{2} s^{*} L^{*} \theta_{e}^{*} Q^{-1} \theta_{e} L s} d s \\
= & \frac{1}{(2 \pi)^{n / 2}\left(\operatorname{det}\left(\theta_{f}^{*} Q \theta_{f}\right)\right)^{1 / 2}} \int_{G} e^{-\frac{1}{2} s^{*} \theta_{f}^{*} \theta_{e} \theta_{e}^{*} Q^{-1} \theta_{e} \theta_{e}^{*} \theta_{f} \mathbf{s}} d s \\
= & \frac{1}{(2 \pi)^{n / 2}\left(\operatorname{det}\left(\theta_{f}^{*} Q \theta_{f}\right)\right)^{1 / 2}} \int_{G} e^{-\frac{1}{2} s^{*} \theta_{f}^{*} Q^{-1} \theta_{f} \mathbf{s}} d s
\end{aligned}
$$

where part of the justification is as follows.

$$
\begin{aligned}
& \operatorname{det}\left(\theta_{f}^{*} Q \theta_{f}\right)=\operatorname{det}\left(\theta_{f}^{*} \theta_{e} \theta_{e}^{*} Q \theta_{e} \theta_{e}^{*} \theta_{f}\right) \\
& \quad=\operatorname{det}\left(\theta_{f}^{*} \theta_{e}\right) \operatorname{det}\left(\theta_{e}^{*} Q \theta_{e}\right) \operatorname{det}\left(\theta_{e}^{*} \theta_{f}\right) \\
& =\operatorname{det}\left(\theta_{e}^{*} Q \theta_{e}\right)
\end{aligned}
$$

because

$$
\operatorname{det}\left(\theta_{f}^{*} \boldsymbol{\theta}_{e}\right) \operatorname{det}\left(\theta_{e}^{*} \theta_{f}\right)=\operatorname{det}\left(\theta_{f}^{*} \theta_{e} \theta_{e}^{*} \theta_{f}\right)=\operatorname{det}\left(\theta_{f}^{*} \theta_{f}\right)=1
$$

This proves the lemma.
It would be natural to try to extend $v$ to the $\sigma$ algebra determined by $\mathscr{C}$ and obtain a measure defined on this $\sigma$ algebra. However, this is always impossible in the case where $Q=I$.

Proposition 61.9.7 For $Q=I$, v cannot be extended to a measure defined on $\sigma(\mathscr{C})$ whenever $H$ is infinite dimensional.

Proof: Let $\left\{e_{n}\right\}$ be a complete orthonormal set of vectors in $H$. Then first note that $H$ is a cylinder set.

$$
H=\left\{x \in H:\left(x, e_{1}\right) \in \mathbb{R}\right\}
$$

and so

$$
v(H)=\frac{1}{\sqrt{2 \pi}} \int_{\mathbb{R}} e^{-\frac{1}{2} t^{2}} d t=1
$$

However, $H$ is also equal to the countable union of the sets,

$$
A_{n} \equiv\left\{x \in H:\left(\left(x, e_{1}\right)_{H}, \cdots,\left(x, e_{a_{n}}\right)_{H}\right) \in B(\mathbf{0}, n)\right\}
$$

where $a_{n} \rightarrow \infty$.

$$
\begin{aligned}
v\left(A_{n}\right) & \equiv \frac{1}{(\sqrt{2 \pi})^{a_{n}}} \int_{B(\mathbf{0}, n)} e^{-\frac{1}{2}|\mathbf{t}|^{2}} d t \\
& \leq \frac{1}{(\sqrt{2 \pi})^{a_{n}}} \int_{-n}^{n} \cdots \int_{-n}^{n} e^{-|\mathbf{t}|^{2} / 2} d t_{1} \cdots d t_{a_{n}} \\
& =\left(\frac{\int_{-n}^{n} e^{-x^{2} / 2} d x}{\sqrt{2 \pi}}\right)^{a_{n}}
\end{aligned}
$$

Now pick $a_{n}$ so large that the above is smaller than $1 / 2^{n+1}$. This can be done because for no matter what choice of $n$,

$$
\frac{\int_{-n}^{n} e^{-x^{2} / 2} d x}{\sqrt{2 \pi}}<1
$$

Then

$$
\sum_{n=1}^{\infty} v\left(A_{n}\right) \leq \sum_{n=1}^{\infty} \frac{1}{2^{n+1}}=\frac{1}{2}
$$

This proves the proposition and shows something else must be done to get a countably additive measure from $v$.

However, let $\mu(C) \equiv v_{M}(C)$ where $C$ is a cylinder set of the form $C=B+M^{\perp}$ for $M$ a finite dimensional subspace.

Proposition 61.9.8 $\mu$ is finitely additive on $\mathscr{C}$ the algebra of cylinder sets.
Proof: Let

$$
\begin{aligned}
A & \equiv\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right)\right) \in E\right\} \\
B & \equiv\left\{x \in H:\left(\left(x, f_{1}\right), \cdots,\left(x, f_{m}\right)\right) \in F\right\}
\end{aligned}
$$

be two disjoint cylinder sets. Then writing them differently as was done earlier they are

$$
\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right),\left(x, f_{1}\right), \cdots,\left(x, f_{m}\right)\right) \in E \times \mathbb{R}^{m}\right\}
$$

and

$$
\left\{x \in H:\left(\left(x, e_{1}\right), \cdots,\left(x, e_{n}\right),\left(x, f_{1}\right), \cdots,\left(x, f_{m}\right)\right) \in \mathbb{R}^{n} \times F\right\}
$$

respectively. Hence the two sets $E \times \mathbb{R}^{m}, \mathbb{R}^{n} \times F$ must be disjoint. Then the definition yields $\mu(A \cup B)=\mu(A)+\mu(B)$. This proves the proposition.

Definition 61.9.9 Let $H$ be a separable Hilbert space and let $\|\cdot\|$ be a norm defined on $H$ which has the following property. Whenever $\left\{e_{n}\right\}$ is an orthonormal sequence of vectors in $H$ and $\mathscr{F}\left(\left\{e_{n}\right\}\right)$ consists of the set of all orthogonal projections onto the span of finitely
many of the $e_{k}$ the following condition holds. For every $\varepsilon>0$ there exists $P_{\varepsilon} \in \mathscr{F}\left(\left\{e_{n}\right\}\right)$ such that if $P \in \mathscr{F}\left(\left\{e_{n}\right\}\right)$ and $P P_{\varepsilon}=0$, then

$$
v(\{x \in H:\|P x\|>\varepsilon\})<\varepsilon .
$$

Then $\|\cdot\|$ is called Gross measurable.
The following lemma is a fundamental result about Gross measurable norms. It is about the continuity of $\|\cdot\|$. It is obvious that with respect to the topology determined by $\|\cdot\|$ that $x \rightarrow\|x\|$ is continuous. However, it would be interesting if this were the case with respect to the topology determined by the norm on $H,|\cdot|$. This lemma shows this is the case and so the funny condition above implies $x \rightarrow\|x\|$ is a continuous, hence Borel measurable function.

Lemma 61.9.10 Let $\|\cdot\|$ be Gross measurable. Then there exists $c>0$ such that

$$
\|x\| \leq c|x|
$$

for all $x \in H$. Furthermore, the above definition is well defined.
Proof: First it is important to consider the question whether the above definition is well defined. To do this note that on $P H$, the two norms are equivalent because $P H$ is a finite dimensional space. Let $G=\{y \in P H:\|y\|>\varepsilon\}$ so $G$ is an open set in $P H$. Then

$$
\{x \in H:\|P x\|>\varepsilon\}
$$

equals

$$
\{x \in H: P x \in G\}
$$

which equals a set of the form

$$
\left\{x \in H:\left(\left(x, e_{i_{1}}\right)_{H}, \cdots,\left(x, e_{i_{m}}\right)_{H}\right) \in G^{\prime}\right\}
$$

for $G^{\prime}$ an open set in $\mathbb{R}^{m}$ and so everything makes sense in the above definition.
Now it is necessary to verify $\|\cdot\| \leq c|\cdot|$. If it is not so, there exists $e_{1}$ such that

$$
\left\|e_{1}\right\| \geq 1,\left|e_{1}\right|=1
$$

Suppose $\left\{e_{k}\right\}_{k=1}^{n}$ have been chosen such that each is a unit vector in $H$ and $\left\|e_{k}\right\| \geq k$. Then considering span $\left(e_{1}, \cdots, e_{n}\right)^{\perp}$ if for every $x \in \operatorname{span}\left(e_{1}, \cdots, e_{n}\right)^{\perp},\|x\| \leq c|x|$, then if $z \in H$ is arbitrary, $z=x+y$ where $y \in \operatorname{span}\left(e_{1}, \cdots, e_{n}\right)$ and so since the two norms are equivalent on a finite dimensional subspace, there exists $c^{\prime}$ corresponding to $\operatorname{span}\left(e_{1}, \cdots, e_{n}\right)$ such that

$$
\begin{aligned}
\|z\|^{2} & \leq(\|x\|+\|y\|)^{2} \leq 2\|x\|^{2}+2\|y\|^{2} \\
& \leq 2 c^{2}|x|^{2}+2 c^{\prime}|y|^{2} \\
& \leq\left(2 c^{2}+2 c^{\prime 2}\right)\left(|x|^{2}+|y|^{2}\right) \\
& =\left(2 c^{2}+2 c^{\prime 2}\right)|z|^{2}
\end{aligned}
$$

and the lemma is proved. Therefore it can be assumed, there exists

$$
e_{n+1} \in \operatorname{span}\left(e_{1}, \cdots, e_{n}\right)^{\perp}
$$

such that $\left|e_{n+1}\right|=1$ and $\left\|e_{n+1}\right\| \geq n+1$.
This constructs an orthonormal set of vectors, $\left\{e_{k}\right\}$. Letting $0<\varepsilon<\frac{1}{2}$, it follows since $\|\cdot\|$ is measurable, there exists $P_{\varepsilon} \in \mathscr{F}\left(\left\{e_{n}\right\}\right)$ such that if $P P_{\varepsilon}=0$ where $P \in \mathscr{F}\left(\left\{e_{n}\right\}\right)$, then

$$
v(\{x \in H:\|P x\|>\varepsilon\})<\varepsilon .
$$

Say $P_{\varepsilon}$ is the projection onto the span of finitely many of the $e_{k}$, the last one being $e_{N}$. Then for $n>N$ and $P_{n}$ the projection onto $e_{n}$, it follows $P_{\varepsilon} P_{n}=0$ and from the definition of $v$,

$$
\begin{aligned}
\varepsilon & >v\left(\left\{x \in H:\left|\left|P_{n} x\right|\right|>\varepsilon\right\}\right) \\
& =v\left(\left\{x \in H:\left|\left(x, e_{n}\right)\right|\left\|e_{n+1}\right\|>\varepsilon\right\}\right) \\
& =v\left(\left\{x \in H:\left|\left(x, e_{n}\right)\right|>\varepsilon /\left\|e_{n+1}\right\|\right\}\right) \\
& \geq v\left(\left\{x \in H:\left|\left(x, e_{n}\right)\right|>\varepsilon /(n+1)\right\}\right) \\
& >\frac{1}{\sqrt{2 \pi}} \int_{\varepsilon /(n+1)}^{\infty} e^{-x^{2} / 2} d x
\end{aligned}
$$

which yields a contradiction for all $n$ large enough. This proves the lemma.
What are examples of Gross measurable norms defined on a separable Hilbert space, $H$ ? The following lemma gives an important example.

Lemma 61.9.11 Let $H$ be a separable Hilbert space and let $A \in \mathscr{L}_{2}(H, H)$, a Hilbert Schmidt operator. Thus A is a continuous linear operator with the property that for any orthonormal set, $\left\{e_{k}\right\}$,

$$
\sum_{k=1}^{\infty}\left|A e_{k}\right|^{2}<\infty .
$$

Then define ||•\| by

$$
\| x| | \equiv|A x|_{H}
$$

Then if $\|\cdot\|$ is a norm, it is measurable ${ }^{1}$.
Proof: Let $\left\{e_{k}\right\}$ be an orthonormal sequence. Let $P_{n}$ denote the orthogonal projection onto span $\left(e_{1}, \cdots, e_{n}\right)$. Let $\varepsilon>0$ be given. Since $A$ is a Hilbert Schmidt operator, there exists $N$ such that

$$
\sum_{k=N}^{\infty}\left|A e_{k}\right|^{2}<\alpha
$$

where $\alpha$ is chosen very small. In fact, $\alpha$ is chosen such that $\alpha<\varepsilon^{2} / r^{2}$ where $r$ is sufficiently large that

$$
\begin{equation*}
\frac{2}{\sqrt{2 \pi}} \int_{r}^{\infty} e^{-t^{2} / 2} d t<\varepsilon \tag{61.9.42}
\end{equation*}
$$

[^42]Let $P$ denote an orthogonal projection in $\mathscr{F}\left(\left\{e_{k}\right\}\right)$ such that $P P_{N}=0$. Thus $P$ is the projection on to span $\left(e_{i_{1}}, \cdots, e_{i_{m}}\right)$ where each $i_{k}>N$. Then

$$
\begin{aligned}
& v(\{x \in H:||P x||>\varepsilon\}) \\
= & v(\{x \in H:|A P x|>\varepsilon\})
\end{aligned}
$$

Now $P x=\sum_{j=1}^{m}\left(x, e_{i_{j}}\right) e_{i_{j}}$ and the above reduces to

$$
\begin{aligned}
& v\left(\left\{x \in H:\left|\sum_{j=1}^{m}\left(x, e_{i_{j}}\right) A e_{i_{j}}\right|>\varepsilon\right\}\right) \leq \\
& v\left(\left\{x \in H:\left(\sum_{j=1}^{m}\left|\left(x, e_{i_{j}}\right)\right|^{2}\right)^{1 / 2}\left(\sum_{j=1}^{m}\left|A e_{i_{j}}\right|^{2}\right)^{1 / 2}>\varepsilon\right\}\right) \\
\leq & v\left(\left\{x \in H:\left(\sum_{j=1}^{m}\left|\left(x, e_{i_{j}}\right)\right|^{2}\right)^{1 / 2} \alpha^{1 / 2}>\varepsilon\right\}\right) \\
= & v\left(\left\{x \in H:\left(\sum_{j=1}^{m}\left|\left(x, e_{i_{j}}\right)\right|^{2}\right)^{1 / 2}>\frac{\varepsilon}{\alpha^{1 / 2}}\right\}\right) \\
= & v\left(\left\{x \in H:\left(\left(x, e_{i_{1}}\right), \cdots,\left(x, e_{i_{m}}\right)\right) \in B\left(\mathbf{0}, \frac{\varepsilon}{\alpha^{1 / 2}}\right)^{C}\right\}\right) \\
\leq & v\left(\left\{x \in H: \max \left\{\left|\left(x, e_{i_{j}}\right)\right|\right\}>\frac{\varepsilon}{\sqrt{m} \alpha^{1 / 2}}\right\}\right)
\end{aligned}
$$

This is no larger than

$$
\begin{gathered}
\frac{1}{(\sqrt{2 \pi})^{m}} \int_{\left|t_{1}\right|>\frac{\varepsilon}{\sqrt{m} \sqrt{\alpha}}} \int_{\left|t_{2}\right|>\frac{\varepsilon}{\sqrt{m} \sqrt{\alpha}}} \cdots \int_{\left|t_{m}\right|>\frac{\varepsilon}{\sqrt{m} \sqrt{\alpha}}} e^{-|t|^{2} / 2} d t_{m} \cdots d t_{1} \\
=\left(\frac{2 \int_{\varepsilon /\left(\sqrt{m} \alpha^{1 / 2}\right)} e^{-t^{2} / 2 d t}}{\sqrt{2 \pi}}\right)^{m}
\end{gathered}
$$

which by Jensen's inequality is no larger than

$$
\begin{aligned}
\frac{2 \int_{\varepsilon /\left(\sqrt{m} \alpha^{1 / 2}\right)}^{\infty} e^{-m t^{2} / 2} d t}{\sqrt{2 \pi}} & =\frac{2 \frac{1}{\sqrt{m}} \int_{\varepsilon /\left(\alpha^{1 / 2}\right)}^{\infty} e^{-t^{2} / 2} d t}{\sqrt{2 \pi}} \\
& \leq \frac{2 \int_{\varepsilon /(\varepsilon / r)}^{\infty} e^{-t^{2} / 2} d t}{\sqrt{2 \pi}} \\
& =\frac{2 \int_{r}^{\infty} e^{-t^{2} / 2} d t}{\sqrt{2 \pi}}<\varepsilon
\end{aligned}
$$

By 61.9.42. This proves the lemma.

Definition 61.9.12 A triple, $(i, H, B)$ is called an abstract Wiener space if $B$ is a separable Banach space and $H$ is a separable Hilbert space such that $H$ is dense and continuously embedded in $B$ and the norm $\|\cdot\|$ on $B$ is Gross measurable.

Next consider a weaker norm for $H$ which comes from the inner product

$$
(x, y)_{E} \equiv \sum_{k=1}^{\infty} \frac{1}{k^{2}}\left(x, e_{k}\right)_{H}\left(y, e_{k}\right)_{H}
$$

Then let $E$ be the completion of $H$ with respect to this new norm. Thus $\left\{k e_{k}\right\}$ is a complete orthonormal basis for $E$. This follows from the density of $H$ in $E$ along with the obvious observation that in the above inner product, $\left\{k e_{k}\right\}$ is an orthonormal set of vectors.

Lemma 61.9.13 There exists a countably additive Gaussian measure, $\lambda$ defined on $\mathscr{B}(E)$. This measure is the law of the random variable,

$$
X(\omega) \equiv \sum_{k=1}^{\infty} \xi_{k}(\omega) e_{k}
$$

where $\left\{\xi_{k}\right\}$ denotes a sequence of independent normally distributed random variables having mean 0 and variance 1, the series converging pointwise a.e. in E. Also

$$
k^{2}\left(X(\omega), e_{k}\right)_{E}=\xi_{k}(\omega) \text { a.e. }
$$

Proof: Observe that $\sum_{k=1}^{\infty} \frac{1}{k^{2}}\left(k e_{k}\right) \otimes\left(k e_{k}\right)$ is a nuclear operator on the Hilbert space, $E$. Letting $\left\{\xi_{k}\right\}$ be a sequence of independent random variables each normally distributed with mean 0 and variance 1 , that

$$
\begin{equation*}
X(\omega) \equiv \sum_{k=1}^{\infty} \frac{1}{k} \xi_{k}(\omega) k e_{k}=\sum_{k=1}^{\infty} \xi_{k}(\omega) e_{k} \tag{61.9.43}
\end{equation*}
$$

is a random variable with values in $E$ and $\mathscr{L}(X)$ is a Gaussian measure on $\mathscr{B}(E)$, the series converging pointwise a.e. in $E$. Let $\lambda$ be the name of this Gaussian measure and denote the probability space on which the $\xi_{k}$ are defined as $(\Omega, \mathscr{F}, P)$. Thus for $F \in \mathscr{B}(E)$,

$$
\lambda(F) \equiv P(\{\omega \in \Omega: X(\omega) \in F\})
$$

Finally, denoting by $X_{N}$, the partial sum,

$$
X_{N}(\omega) \equiv \sum_{k=1}^{N} \xi_{k}(\omega) e_{k}
$$

the definition of $(\cdot, \cdot)_{E}$ on $H$ and a simple computation yields

$$
\begin{align*}
\xi_{k}(\omega) & =\lim _{N \rightarrow \infty} k^{2}\left(X_{N}(\omega), e_{k}\right)_{E} \\
& =k^{2}\left(X(\omega), e_{k}\right)_{E} \tag{61.9.44}
\end{align*}
$$

One can pass to the limit because $X_{N}(\omega)$ converges to $X(\omega)$ in $E$. This proves the lemma.

Theorem 61.9.14 Let $(i, H, B)$ be an abstract Wiener space. Then there exists a Gaussian measure on the Borel sets of $B$.

Proof: Let $E$ be defined above as the completion of $H$ with respect to that weaker norm. Then from Lemma 61.9.13 and $X(\omega)$ given above in 61.9.43,

$$
k^{2}\left(X(\omega), e_{k}\right)_{E}=\xi_{k}(\omega) \text { a.e. } \omega
$$

Let $\left\{e_{n}\right\}$ be a complete orthonormal set for $H$. There exists an increasing sequence of projections, $\left\{Q_{n}\right\} \subseteq \mathscr{F}\left(\left\{e_{n}\right\}\right)$ such that $Q_{n} x \rightarrow x$ in $H$ for each $x \in H$. Say $Q_{n}$ is the orthogonal projection onto span $\left(e_{1}, \cdots, e_{p_{n}}\right)$. Then since $\|\cdot\|$ is measurable, these can be chosen such that if $Q$ is the orthogonal projection onto span $\left(e_{1}, \cdots, e_{k}\right)$ for some $k>p_{n}$ then

$$
v\left(\left\{x:\left\|Q x-Q_{n} x\right\|>2^{-n}\right\}\right)<2^{-n}
$$

In particular,

$$
v\left(\left\{x:\left\|Q_{n} x-Q_{m} x\right\|>2^{-m}\right\}\right)<2^{-m}
$$

whenever $n \geq m$.
I would like to consider the infinite series,

$$
S(\omega) \equiv \sum_{k=1}^{\infty} k^{2}\left(X(\omega), e_{k}\right)_{E} e_{k} \in B
$$

converging in $B$ but of course this might make no sense because the series might not converge. It was shown above that the series converges in $E$ but it has not been shown to converge in $B$.

Suppose the series did converge a.e. Then let $f \in B^{\prime}$ and consider the random variable $f \circ S$ which maps $\Omega$ to $\mathbb{R}$. I would like to verify this is normally distributed. First note that the following finite sum is weakly measurable and separably valued so it is strongly measurable with values in $B$.

$$
S_{p_{n}}(\omega) \equiv \sum_{k=1}^{p_{n}} k^{2}\left(X(\omega), e_{k}\right)_{E} e_{k}
$$

Since $f \in B^{\prime}$ which is a subset of $H^{\prime}$ due to the assumption that $H$ is dense in $B$, there exists a unique $v \in H$ such that $f(x)=(x, v)$ for all $x \in H$. Then from the above sum,

$$
f\left(S_{p_{n}}(\omega)\right)=\left(S_{p_{n}}(\omega), v\right)=\sum_{k=1}^{p_{n}} k^{2}\left(X(\omega), e_{k}\right)_{E}\left(e_{k}, v\right)
$$

which by Lemma 61.9.13 equals

$$
\sum_{k=1}^{p_{n}}\left(e_{k}, v\right)_{H} \xi_{k}(\omega)
$$

a finite linear combination of the independent $N(0,1)$ random variables, $\xi_{k}(\omega)$. Then it follows

$$
\omega \rightarrow f\left(S_{p_{n}}(\omega)\right)
$$

is also normally distributed and has mean 0 and variance equal to

$$
\sum_{k=1}^{p_{n}}\left(e_{k}, v\right)_{H}^{2}
$$

Then it seems reasonable to suppose

$$
\begin{align*}
E\left(e^{i t f \circ S}\right) & =\lim _{n \rightarrow \infty} E\left(e^{i t f \circ S_{p_{n}}}\right) \\
& =\lim _{n \rightarrow \infty} e^{-t^{2} \sum_{k=1}^{p_{n}}\left(e_{k}, v\right)_{H}^{2}} \\
& =e^{-t^{2} \sum_{k=1}^{\infty}\left(e_{k}, v\right)_{H}^{2}} \\
& =e^{-t^{2}|v|_{H}^{2}} \tag{61.9.45}
\end{align*}
$$

the characteristic function of a random variable which is $N\left(0,|v|_{H}^{2}\right)$. Thus at least formally, this would imply for all $f \in B^{\prime}, f \circ S$ is normally distributed and so if $\mu=\mathscr{L}(S)$, then by Lemma 61.7.3 it follows $\mu$ is a Gaussian measure.

What is missing to make the above a proof? First of all, there is the issue of the sum. Next there is the problem of passing to the limit in the little argument above in which the characteristic function is used.

First consider the sum. Note that $Q_{n} X(\omega) \in H$. Then for any $n>p_{m}$,

$$
\begin{align*}
& P\left(\left\{\omega \in \Omega:\left\|S_{n}(\omega)-S_{p_{m}}(\omega)\right\|>2^{-m}\right\}\right) \\
= & P\left(\left\{\omega \in \Omega:\left\|\sum_{k=p_{m}+1}^{n} k^{2}\left(X(\omega), e_{k}\right)_{E} e_{k}\right\|>2^{-m}\right\}\right) \\
= & P\left(\left\{\omega \in \Omega:\left\|\sum_{k=p_{m}+1}^{n} \xi_{k}(\omega) e_{k}\right\|>2^{-m}\right\}\right) \tag{61.9.46}
\end{align*}
$$

Let $Q$ be the orthogonal projection onto span $\left(e_{1}, \cdots, e_{n}\right)$. Define

$$
F \equiv\left\{x \in\left(Q-Q_{m}\right) H:\|x\|>2^{-m}\right\}
$$

Then continuing the chain of equalities ending with 61.9.46,

$$
\begin{aligned}
& =P\left(\left\{\omega \in \Omega: \sum_{k=p_{m}+1}^{n} \xi_{k}(\omega) e_{k} \in F\right\}\right) \\
= & P\left(\left\{\omega \in \Omega:\left(\xi_{n}(\omega), \cdots, \xi_{p_{m}+1}(\omega)\right) \in F^{\prime}\right\}\right) \\
= & v\left(\left\{x \in H:\left(\left(x, e_{n}\right)_{H}, \cdots,\left(x, e_{p_{m}+1}\right)_{H}\right) \in F^{\prime}\right\}\right) \\
= & v\left(\left\{x \in H: Q(x)-Q_{m}(x) \in F\right\}\right) \\
= & v\left(\left\{x \in H:\left\|Q(x)-Q_{m}(x)\right\|>2^{-m}\right\}\right)<2^{-m} .
\end{aligned}
$$

This has shown that

$$
\begin{equation*}
P\left(\left\{\omega \in \Omega: \| S_{n}(\omega)-S_{p_{m}}(\omega)| |>2^{-m}\right\}\right)<2^{-m} \tag{61.9.47}
\end{equation*}
$$

for all $n>p_{m}$. In particular, the above is true if $n=p_{n}$ for $n>m$.
If $\left\{S_{p_{n}}(\omega)\right\}$ fails to converge, then $\omega$ must be contained in the set,

$$
\begin{equation*}
A \equiv \cap_{m=1}^{\infty} \cup_{n=m}^{\infty}\left\{\omega \in \Omega:\left\|S_{p_{n}}(\omega)-S_{p_{m}}(\omega)\right\|>2^{-m}\right\} \tag{61.9.48}
\end{equation*}
$$

because if $\omega$ is in the complement of this set,

$$
\cup_{m=1}^{\infty} \cap_{n=m}^{\infty}\left\{\omega \in \Omega:| | S_{p_{n}}(\omega)-S_{p_{m}}(\omega) \| \leq 2^{-m}\right\}
$$

it follows $\left\{S_{p_{n}}(\omega)\right\}_{n=1}^{\infty}$ is a Cauchy sequence and so it must converge. However, the set in 61.9.48 is a set of measure 0 because of 61.9.47 and the observation that for all $m$,

$$
\begin{aligned}
P(A) & \leq \sum_{n=m}^{\infty} P\left(\left\{\omega \in \Omega:\left\|S_{p_{n}}(\omega)-S_{p_{m}}(\omega)\right\|>2^{-m}\right\}\right) \\
& \leq \sum_{n=m}^{\infty} \frac{1}{2^{m}}
\end{aligned}
$$

Thus the subsequence $\left\{S_{p_{n}}\right\}$ of the sequence of partial sums of the above series does converge pointwise in $B$ and so the dominated convergence theorem also verifies that the computations involving the characteristic function in 61.9.45 are correct.

The random variable obtained as the limit of the partial sums, $\left\{S_{p_{n}}(\omega)\right\}$ described above is strongly measurable because each $S_{p_{n}}(\omega)$ is strongly measurable due to each of these being weakly measurable and separably valued. Thus the measure given as the law of $S$ defined as

$$
S(\omega) \equiv \lim _{n \rightarrow \infty} S_{p_{n}}(\omega)
$$

is defined on the Borel sets of $B$.This proves the theorem.
Also, there is an important observation from the proof which I will state as the following corollary.

Corollary 61.9.15 Let $(i, H, B)$ be an abstract Wiener space. Then there exists a Gaussian measure on the Borel sets of B. This Gaussian measure equals $\mathscr{L}(S)$ where $S(\omega)$ is the a.e. limit of a subsequence of the sequence of partial sums,

$$
S_{p_{n}}(\omega) \equiv \sum_{k=1}^{p_{n}} \xi_{k}(\omega) e_{k}
$$

for $\left\{\xi_{k}\right\}$ a sequence of independent random variables which are normal with mean 0 and variance 1 which are defined on a probability space, $(\Omega, \mathscr{F}, P)$. Furthermore, for any $k>p_{n}$,

$$
P\left(\left\{\omega \in \Omega:\left\|S_{k}(\omega)-S_{p_{n}}(\omega)\right\|>2^{-n}\right\}\right)<2^{-n}
$$

### 61.10 White Noise

In an abstract Wiener space as discussed above there is a Gaussian measure, $\mu$ defined on the Borel sets of $B$. This measure is the law of a random variable having values in $B$ which is the limit of a subsequence of a sequence of partial sums. I will show here that the sequence of partial sums also converges pointwise a.e.

Now with this preparation, here is the theorem about white noise.
Theorem 61.10.1 Let $(i, H, B)$ be an abstract Wiener space and $\left\{e_{k}\right\}$ is a complete orthonormal sequence in $H$. Then there exists a Gaussian measure on the Borel sets of B. This Gaussian measure equals $\mathscr{L}(S)$ where $S(\omega)$ is the a.e. limit of the sequence of partial sums,

$$
S_{n}(\omega) \equiv \sum_{k=1}^{n} \xi_{k}(\omega) e_{k}
$$

for $\left\{\xi_{k}\right\}$ a sequence of independent random variables which are normal with mean 0 and variance 1, defined on a probability space, $(\Omega, \mathscr{F}, P)$

Proof: By Corollary 61.9 .15 there is a subsequence, $\left\{S_{p_{n}}\right\}$ of these partial sums which converge pointwise a.e. to $S(\omega)$. However, this corollary also states that

$$
P\left(\left\{\omega \in \Omega:\left\|S_{k}(\omega)-S_{p_{n}}(\omega)\right\|>2^{-n}\right\}\right)<2^{-n}
$$

whenever $k>p_{n}$ and so by Lemma 59.15.6 the original sequence of partial sums also converges uniformly of a set of measure zero. The reason this lemma applies is that $\xi_{k}(\omega) e_{k}$ has symmetric distribution. This proves the theorem.

### 61.11 Existence Of Abstract Wiener Spaces

It turns out that if $E$ is a separable Banach space, then it is the top third of an abstract Wiener space. This is what will be shown in this section. Therefore, it follows from the above that there exists a Gaussian measure on $E$ which is the law of an a.e. convergent series as discussed above. First recall Lemma 17.4.2 on Page 458.

Lemma 61.11.1 Let $E$ be a separable Banach space. Then there exists an increasing sequence of subspaces, $\left\{F_{n}\right\}$ such that $\operatorname{dim}\left(F_{n+1}\right)-\operatorname{dim}\left(F_{n}\right) \leq 1$ and equals 1 for all $n$ if the dimension of $E$ is infinite. Also $\cup_{n=1}^{\infty} F_{n}$ is dense in $E$.

Lemma 61.11.2 Let $E$ be a separable Banach space. Then there exists a sequence $\left\{e_{n}\right\}$ of points of $E$ such that whenever $|\beta| \leq 1$ for $\beta \in \mathbb{F}^{n}$,

$$
\sum_{k=1}^{n} \beta_{k} e_{k} \in B(0,1)
$$

the unit ball in $E$.

Proof: By Lemma 61.11.1, let $\left\{z_{1}, \cdots, z_{n}\right\}$ be a basis for $F_{n}$ where $\cup_{n=1}^{\infty} F_{n}$ is dense in $E$. Then let $\alpha_{1}$ be such that $e_{1} \equiv \alpha_{1} z_{1} \in B(0,1)$. Thus $\beta_{1} e_{1} \in B(0,1)$ whenever $\left|\beta_{1}\right| \leq 1$. Suppose $\alpha_{i}$ has been chosen for $i=1,2, \cdots, n$ such that for all $\beta \in D_{n} \equiv\left\{\alpha \in \mathbb{F}^{n}:|\alpha| \leq 1\right\}$, it follows

$$
\sum_{k=1}^{n} \beta_{k} \alpha_{k} z_{k} \in B(0,1)
$$

Then

$$
C_{n} \equiv\left\{\sum_{k=1}^{n} \beta_{k} \alpha_{k} z_{k}: \beta \in D_{n}\right\}
$$

is a compact subset of $B(0,1)$ and so it is at a positive distance from the complement of $B(0,1), \delta$. Now let $0<\alpha_{n+1}<\delta /\left\|z_{n+1}\right\|$. Then for $\beta \in D_{n+1}$,

$$
\sum_{k=1}^{n} \beta_{k} \alpha_{k} z_{k} \in C_{n}
$$

and so

$$
\begin{aligned}
\left\|\sum_{k=1}^{n+1} \beta_{k} \alpha_{k} z_{k}-\sum_{k=1}^{n} \beta_{k} \alpha_{k} z_{k}\right\| & =\left\|\beta_{n+1} \alpha_{n+1} z_{n+1}\right\| \\
& <\left\|\alpha_{n+1} z_{n+1}\right\|<\delta
\end{aligned}
$$

which shows

$$
\sum_{k=1}^{n+1} \beta_{k} \alpha_{k} z_{k} \in B(0,1)
$$

This proves the lemma. Let $e_{k} \equiv \alpha_{k} z_{k}$.
Now the main result is the following. It says that any separable Banach space is the upper third of some abstract Wiener space.

Theorem 61.11.3 Let $E$ be a real separable Banach space with norm $\|\cdot\|$. Then there exists a separable Hilbert space, $H$ such that $H$ is dense in $E$ and the inclusion map is continuous. Furthermore, if $v$ is the Gaussian measure defined earlier on the cylinder sets of $H,\|\cdot\|$ is Gross measurable.

Proof: Let $\left\{e_{k}\right\}$ be the points of $E$ described in Lemma 61.11.2. Then let $H_{0}$ denote the subspace of all finite linear combinations of the $\left\{e_{k}\right\}$. It follows $H_{0}$ is dense in $E$. Next decree that $\left\{e_{k}\right\}$ is an orthonormal basis for $H_{0}$. Thus for

$$
\begin{gathered}
\sum_{k=1}^{n} c_{k} e_{k}, \sum_{j=1}^{n} d_{j} e_{k} \in H_{0}, \\
\left(\sum_{k=1}^{n} c_{k} e_{k}, \sum_{j=1}^{n} d_{j} e_{j}\right)_{H_{0}} \equiv \sum_{k=1}^{n} c_{k} d_{k}
\end{gathered}
$$

this being well defined because the $\left\{e_{k}\right\}$ are independent. Let the norm on $H_{0}$ be denoted by $|\cdot|_{H_{0}}$. Let $H_{1}$ be the completion of $H_{0}$ with respect to this norm.

I want to show that $|\cdot|_{H_{0}}$ is stronger than $\|\cdot\|$. Suppose then that

$$
\left|\sum_{k=1}^{n} \beta_{k} e_{k}\right|_{H_{0}} \leq 1
$$

It follows then from the definition of $|\cdot|_{H_{0}}$ that

$$
\left|\sum_{k=1}^{n} \beta_{k} e_{k}\right|_{H_{0}}^{2}=\sum_{k=1}^{n} \beta_{k}^{2} \leq 1
$$

and so from the construction of the $e_{k}$, it follows that

$$
\left\|\sum_{k=1}^{n} \beta_{k} e_{k}\right\|<1
$$

Stated more simply, this has just shown that if $h \in H_{0}$ then since $\left|h /|h|_{H_{0}}\right|_{H_{0}} \leq 1$, it follows that

$$
\|h\| /|h|_{H_{0}}<1
$$

and so

$$
\left|\left|h \|<|h|_{H_{0}}\right.\right.
$$

It follows that the completion of $H_{0}$ must lie in $E$ because this shows that every Cauchy sequence in $H_{0}$ is a Cauchy sequence in $E$. Thus $H_{1}$ embedds continuously into $E$ and is dense in $E$. Denote its norm by $|\cdot|_{H_{1}}$.

Now consider the nuclear operator,

$$
A=\sum_{k=1}^{\infty} \lambda_{k} e_{k} \otimes e_{k}
$$

where each $\lambda_{k}>0$ and $\sum_{k} \lambda_{k}<\infty$. This operator is clearly one to one. Also it is clear the operator is Hilbert Schmidt because $\sum_{k} \lambda_{k}^{2}<\infty$. Let

$$
H \equiv A H_{1}
$$

and for $x \in H$, define

$$
|x|_{H} \equiv\left|A^{-1} x\right|_{H_{1}}
$$

Since each $e_{k}$ is in $H$ it follows that $H$ is dense in $E$. Note also that $H \subseteq H_{1}$ because $A$ maps $H_{1}$ to $H_{1}$.

$$
A x \equiv \sum_{k=1}^{\infty} \lambda_{k}\left(x, e_{k}\right) e_{k}
$$

and the series converges in $H_{1}$ because

$$
\sum_{k=1}^{\infty} \lambda_{k}\left|\left(x, e_{k}\right)\right| \leq\left(\sum_{k=1}^{\infty} \lambda_{k}^{2}\right)^{1 / 2}\left(\sum_{k=1}^{\infty}\left|\left(x, e_{k}\right)\right|^{2}\right)^{1 / 2}<\infty
$$

Also $H$ is a Hilbert space with inner product given by

$$
(x, y)_{H} \equiv\left(A^{-1} x, A^{-1} y\right)_{H_{1}}
$$

$H$ is complete because if $\left\{x_{n}\right\}$ is a Cauchy sequence in $H$, this is the same as $\left\{A^{-1} x_{n}\right\}$ being a Cauchy sequence in $H_{1}$ which implies $A^{-1} x_{n} \rightarrow y$ for some $y \in H_{1}$. Then it follows $x_{n}=A\left(A^{-1} x_{n}\right) \rightarrow A y$ in $H$.

For $x \in H \subseteq H_{1}$,

$$
\|x\| \leq|x|_{H_{1}}=\left|A A^{-1} x\right|_{H_{1}} \leq\|A\|\left|A^{-1} x\right|_{H_{1}} \equiv\|A\||x|_{H}
$$

and so the embedding of $H$ into $E$ is continuous. Why is $\|\cdot\|$ a measurable norm on $H$ ? Note first that for $x \in H \subseteq H_{1}$,

$$
\begin{equation*}
|A x|_{H} \equiv\left|A^{-1} A x\right|_{H_{1}}=|x|_{H_{1}} \geq \|\left. x\right|_{E} \tag{61.11.49}
\end{equation*}
$$

Therefore, if it can be shown $A$ is a Hilbert Schmidt operator on $H$, the desired measurability will follow from Lemma 61.9.11 on Page 2035.

Claim: $A$ is a Hilbert Schmidt operator on $H$.
Proof of the claim: From the definition of the inner product in $H$, it follows an orthonormal basis for $H$ is $\left\{\lambda_{k} e_{k}\right\}$. This is because

$$
\left(\lambda_{k} e_{k}, \lambda_{j} e_{j}\right)_{H} \equiv\left(\lambda_{k} A^{-1} e_{k}, \lambda_{j} A^{-1} e_{j}\right)_{H_{1}}=\left(e_{k}, e_{j}\right)_{H_{1}}=\delta_{j k} .
$$

To show that $A$ is Hilbert Schmidt, it suffices to show that

$$
\sum_{k}\left|A\left(\lambda_{k} e_{k}\right)\right|_{H}^{2}<\infty
$$

because this is the definition of an operator being Hilbert Schmidt. However, the above equals

$$
\sum_{k}\left|A^{-1} A\left(\lambda_{k} e_{k}\right)\right|_{H_{1}}^{2}=\sum_{k} \lambda_{k}^{2}<\infty .
$$

This proves the claim.
Now consider 61.11.49. By Lemma 61.9.11, it follows the norm $\|x\|^{\prime} \equiv|A x|_{H}$ is Gross measurable on $H$. Therefore, $\|\cdot\|_{E}$ is also Gross measurable because it is smaller. This proves the theorem.

Using Theorem 61.11.3 and Theorem 61.10.1 this proves most of the following important corollary.

Corollary 61.11.4 Let E be any real separable Banach space. Then there exists a sequence, $\left\{e_{k}\right\} \subseteq E$ such that for any $\left\{\xi_{k}\right\}$ a sequence of independent random variables such that $\mathscr{L}\left(\xi_{k}\right)=N(0,1)$, it follows

$$
X(\omega) \equiv \sum_{k=1}^{\infty} \xi_{k}(\omega) e_{k}
$$

converges a.e. and its law is a Gaussian measure defined on $\mathscr{B}(E)$. Furthermore, $\left\|e_{k}\right\|_{E} \leq$ $\lambda_{k}$ where $\sum_{k} \lambda_{k}<\infty$.

Proof: From the proof of Theorem 61.11.3 a basis for $H$ is $\left\{\lambda_{k} e_{k}\right\}$. Therefore, by Theorem 61.10.1, if $\left\{\xi_{k}\right\}$ is a sequence of independent $N(0,1)$ random variables, then $\sum_{k=1}^{\infty} \xi_{k}(\omega) \lambda_{k} e_{k}$ converges $a . e$. to a random variable whose law is Gaussian. Also from the proof of Theorem 61.10.1, each $e_{k}$ in that proof has the property that $\left\|e_{k}\right\| \leq 1$ because if $\left\|e_{k}\right\|>1$, then you could consider $\beta \equiv(0,0, \cdots, 1)$ and from the construction of the $e_{k}$, you would need $1 e_{k} \in B(0,1)$ which is a contradiction. Thus $\left\|\lambda_{k} e_{k}\right\| \leq \lambda_{k}$ and changing the notation, replacing $\lambda_{k} e_{k}$ with $e_{k}$, this proves the corollary.

## Chapter 62

## Stochastic Processes

### 62.1 Fundamental Definitions And Properties

Here $E$ will be a separable Banach space and $\mathscr{B}(E)$ will be the Borel sets of $E$. Let $(\Omega, \mathscr{F}, P)$ be a probability space and $I$ will be an interval of $\mathbb{R}$. A set of $E$ valued random variables, one for each $t \in I,\{X(t): t \in I\}$ is called a stochastic process. Thus for each $t$, $X(t)$ is a measurable function of $\omega \in \Omega$. Set $X(t, \omega) \equiv X(t)(\omega)$. Functions $t \rightarrow X(t, \omega)$ are called trajectories. Thus there is a trajectory for each $\omega \in \Omega$. A stochastic process, $Y$ is called a version or a modification of a stochastic process, $X$ if for all $t \in I$,

$$
X(t, \omega)=Y(t, \omega) \text { a.e. } \omega
$$

There are several descriptions of stochastic processes.

1. $X$ is measurable if $X(\cdot, \cdot): I \times \Omega \rightarrow E$ is $B(I) \times \mathscr{F}$ measurable. Note that a stochastic process, $X$ is not necessarily measurable.
2. $X$ is stochastically continuous at $t_{0} \in I$ means: for all $\varepsilon>0$ and $\delta>0$ there exists $\rho>0$ such that

$$
P\left(\left[\left|\mid X(t)-X\left(t_{0}\right) \| \geq \varepsilon\right]\right) \leq \delta \text { whenever }\left|t-t_{0}\right|<\rho, t \in I\right.
$$

Note the above condition says that for each $\varepsilon>0$,

$$
\lim _{t \rightarrow t_{0}} P\left(\left[\left\|X(t)-X\left(t_{0}\right)\right\| \geq \varepsilon\right]\right)=0
$$

3. $X$ is stochastically continuous if it is stochastically continuous at every $t \in I$.
4. $X$ is stochastically uniformly continuous if for every $\varepsilon, \delta>0$ there exists $\rho>0$ such that whenever $s, t \in I$ with $|s-t|<\rho$, it follows

$$
P([\|X(t)-X(s)\| \geq \varepsilon]) \leq \delta
$$

5. $X$ is mean square continuous at $t_{0} \in I$ if

$$
\lim _{t \rightarrow t_{0}} E\left(\left\|X(t)-X\left(t_{0}\right)\right\|^{2}\right) \equiv \lim _{t \rightarrow t_{0}} \int_{\Omega}\left\|X(t)(\omega)-X\left(t_{0}\right)(\omega)\right\|^{2} d P=0
$$

6. $X$ is mean square continuous in $I$ if it is mean square continuous at every point of $I$.
7. $X$ is continuous with probability 1 or continuous if $t \rightarrow X(t, \omega)$ is continuous for all $\omega$ outside some set of measure 0 .
8. $X$ is Hölder continuous if $t \rightarrow X(t, \omega)$ is Hölder continuous for a.e. $\omega$.

Lemma 62.1.1 A stochastically continuous process on $[a, b] \equiv I$ is uniformly stochastically continuous on $[a, b] \equiv I$.

Proof: If this is not so, there exists $\varepsilon, \delta>0$ and points of $I, s_{n}, t_{n}$ such that even though

$$
\begin{gather*}
\left|t_{n}-s_{n}\right|<\frac{1}{n} \\
P\left(\left[\left|\left|X\left(s_{n}\right)-X\left(t_{n}\right)\right|\right| \geq \varepsilon\right]\right)>\delta . \tag{62.1.1}
\end{gather*}
$$

Taking a subsequence, still denoted by $s_{n}$ and $t_{n}$ there exists $t \in I$ such that the above hold and

$$
\lim _{n \rightarrow \infty} s_{n}=\lim _{n \rightarrow \infty} t_{n}=t
$$

Then

$$
\begin{aligned}
& P\left(\left[\left\|X\left(s_{n}\right)-X\left(t_{n}\right)\right\| \geq \varepsilon\right]\right) \\
\leq & P\left(\left[\left\|X\left(s_{n}\right)-X(t)\right\| \geq \varepsilon / 2\right]\right)+P\left(\left[\left\|X(t)-X\left(t_{n}\right)\right\| \geq \varepsilon / 2\right]\right)
\end{aligned}
$$

But the sum of the last two terms converges to 0 as $n \rightarrow \infty$ by stochastic continuity of $X$ at $t$, violating 62.1.1 for all $n$ large enough. This proves the lemma.

For a stochastically continuous process defined on a closed and bounded interval, there always exists a measurable version. This is significant because then you can do things with product measure and iterated integrals.

Proposition 62.1.2 Let $X$ be a stochastically continuous process defined on a closed interval, $I \equiv[a, b]$. Then there exists a measurable version of $X$.

Proof: By Lemma 62.1.1 $X$ is uniformly stochastically continuous and so there exists a sequence of positive numbers, $\left\{\rho_{n}\right\}$ such that if $|s-t|<\rho_{n}$, then

$$
\begin{equation*}
P\left(\left[\|X(t)-X(s)\| \geq \frac{1}{2^{n}}\right]\right) \leq \frac{1}{2^{n}} \tag{62.1.2}
\end{equation*}
$$

Then let $\left\{t_{0}^{n}, t_{1}^{n}, \cdots, t_{m_{n}}^{n}\right\}$ be a partition of $[a, b]$ in which $\left|t_{i}^{n}-t_{i-1}^{n}\right|<\rho_{n}$. Now define $X_{n}$ as follows:

$$
\begin{aligned}
X_{n}(t) & \equiv \sum_{i=1}^{m_{n}} X\left(t_{i-1}^{n}\right) \mathscr{X}_{\left[t_{i-1}^{n}, t_{i}^{n}\right)}(t) \\
X_{n}(b) & \equiv X(b)
\end{aligned}
$$

Then $X_{n}$ is obviously $B(I) \times \mathscr{F}$ measurable because it is the sum of functions which are. Consider the set, $A$ on which $\left\{X_{n}(t, \omega)\right\}$ is a Cauchy sequence. This set is of the form

$$
A=\cap_{n=1}^{\infty} \cup_{m=1}^{\infty} \cap_{p, q \geq m}\left[\left\|X_{p}-X_{q}\right\|<\frac{1}{n}\right]
$$

and so it is a $B(I) \times \mathscr{F}$ measurable set. Now define

$$
Y(t, \omega) \equiv\left\{\begin{array}{l}
\lim _{n \rightarrow \infty} X_{n}(t, \omega) \text { if }(t, \omega) \in A \\
0 \text { if }(t, \omega) \notin A
\end{array}\right.
$$

I claim $Y(t, \omega)=X(t, \omega)$ for a.e. $\omega$. To see this, consider 62.1.2. From the construction of $X_{n}$, it follows that for each $t$,

$$
P\left(\left[\left\|X_{n}(t)-X(t)\right\| \geq \frac{1}{2^{n}}\right]\right) \leq \frac{1}{2^{n}}
$$

Also, for a fixed $t$, if $X_{n}(t, \omega)$ fails to converge to $X(t, \omega)$, then $\omega$ must be in infinitely many of the sets,

$$
B_{n} \equiv\left[\left\|X_{n}(t)-X(t)\right\| \geq \frac{1}{2^{n}}\right]
$$

which is a set of measure zero by the Borel Cantelli lemma. Recall why this is so.

$$
P\left(\cap_{k=1}^{\infty} \cup_{n=k}^{\infty} B_{n}\right) \leq \sum_{n=k}^{\infty} P\left(B_{n}\right)<\frac{1}{2^{k-1}}
$$

Therefore, for each $t,(t, \omega) \in A$ for a.e. $\omega$. Hence $X(t)=Y(t)$ a.e. and so $Y$ is a measurable version of $X$.

Lemma 62.1.3 Let $D$ be a dense subset of an interval, $I=[0, T]$ and suppose $X: D \rightarrow E$ satisfies

$$
\left\|X(d)-X\left(d^{\prime}\right)\right\| \leq C\left|d-d^{\prime}\right|^{\gamma}
$$

for all $d^{\prime}, d \in D$. Then $X$ extends uniquely to a continuous $Y$ defined on $[0, T]$ such that

$$
\left\|Y(t)-Y\left(t^{\prime}\right)\right\| \leq C\left|t-t^{\prime}\right|^{\gamma}
$$

Proof: Let $t \in I$ and let $d_{k} \rightarrow t$ where $d_{k} \in D$. Then $\left\{X\left(d_{k}\right)\right\}$ is a Cauchy sequence because $\left\|X\left(d_{k}\right)-X\left(d_{m}\right)\right\| \leq C\left|d_{k}-d_{m}\right|^{\gamma}$. Therefore, $X\left(d_{k}\right)$ converges. The thing it converges to will be called $Y(t)$. Note this is well defined, giving $X(t)$ if $t \in D$. Also, if $d_{k} \rightarrow t$ and $d_{k}^{\prime} \rightarrow t$, then $\left|\left|X\left(d_{k}\right)-X\left(d_{k}^{\prime}\right) \| \leq C\right| d_{k}-d_{k}^{\prime}\right|^{\gamma}$ and so $X\left(d_{k}\right)$ and $X\left(d_{k}^{\prime}\right)$ converge to the same thing. Therefore, it makes sense to define $Y(t) \equiv \lim _{d \rightarrow t} X(d)$. It only remains to verify the estimate. But letting $|d-t|$ and $\left|d^{\prime}-t^{\prime}\right|$ be small enough,

$$
\begin{aligned}
\left\|Y(t)-Y\left(t^{\prime}\right)\right\| & =\left\|X(d)-X\left(d^{\prime}\right)\right\|+\varepsilon \\
& \leq C\left|d^{\prime}-d\right|+\varepsilon \leq C\left|t-t^{\prime}\right|+2 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this proves the existence part of the lemma. Uniqueness follows from observing that $Y(t)$ must equal $\lim _{d \rightarrow t} X(d)$. This proves the lemma.

### 62.2 Kolmogorov Čentsov Continuity Theorem

Lemma 62.2.1 Let $r_{j}^{m}$ denote $j\left(\frac{T}{2^{m}}\right)$ where $j \in\left\{0,1, \cdots, 2^{m}\right\}$. Also let $D_{m}=\left\{r_{j}^{m}\right\}_{j=1}^{2^{m}}$ and $D=\cup_{m=1}^{\infty} D_{m}$. Suppose $X(t)$ satisfies

$$
\begin{equation*}
\left\|X\left(r_{j+1}^{k}\right)-X\left(r_{j}^{k}\right)\right\| \leq 2^{-\gamma k} \tag{62.2.3}
\end{equation*}
$$

for all $k \geq M$. Then if $d, d^{\prime} \in D_{m}$ for $m>n \geq M$ such that $\left|d-d^{\prime}\right| \leq T 2^{-n}$, then

$$
\left\|X\left(d^{\prime}\right)-X(d)\right\| \leq 2 \sum_{j=n+1}^{m} 2^{-\gamma j}
$$

Also, there exists a constant $C$ depending on $M$ such that for all $d, d^{\prime} \in D$,

$$
\left\|X(d)-X\left(d^{\prime}\right)\right\| \leq C\left|d-d^{\prime}\right|^{\gamma}
$$

Proof: Suppose $d^{\prime}<d$. Suppose first $m=n+1$. Then $d=(k+1) T 2^{-(n+1)}$ and $d^{\prime}=$ $k T 2^{-(n+1)}$. Then from 62.2.3

$$
\left\|X\left(d^{\prime}\right)-X(d)\right\| \leq 2^{-\gamma(n+1)} \leq 2 \sum_{j=n+1}^{n+1} 2^{-\gamma j}
$$

Suppose the claim is true for some $m>n$ and let $d, d^{\prime} \in D_{m+1}$ with $\left|d-d^{\prime}\right|<T 2^{-n}$. If there is no point of $D_{m}$ between these, then $d^{\prime}, d$ are adjacent points either in $D_{m}$ or in $D_{m+1}$. Consequently,

$$
\left\|X\left(d^{\prime}\right)-X(d)\right\| \leq 2^{-\gamma m}<2 \sum_{j=n+1}^{m+1} 2^{-\gamma j}
$$

Assume therefore, there exist points of $D_{m}$ between $d^{\prime}$ and $d$. Let $d^{\prime} \leq d_{1}^{\prime} \leq d_{1} \leq d$ where $d_{1}, d_{1}^{\prime}$ are in $D_{m}$ and $d_{1}^{\prime}$ is the smallest element of $D_{m}$ which is at least as large as $d^{\prime}$ and $d_{1}$ is the largest element of $D_{m}$ which is no larger than $d$. Then $\left|d^{\prime}-d_{1}^{\prime}\right| \leq T 2^{-(m+1)}$ and $\left|d_{1}-d\right| \leq T 2^{-(m+1)}$ while all of these points are in $D_{m+1}$ which contains $D_{m}$. Therefore, from 62.2.3 and induction,

$$
\begin{align*}
& \left\|X\left(d^{\prime}\right)-X(d)\right\| \\
\leq & \left\|X\left(d^{\prime}\right)-X\left(d_{1}^{\prime}\right)\right\|+\left\|X\left(d_{1}^{\prime}\right)-X\left(d_{1}\right)\right\| \\
& +\left\|X\left(d_{1}\right)-X(d)\right\| \\
\leq & 2 \times 2^{-\gamma(m+1)}+2 \sum_{j=n+1}^{m} 2^{-\gamma j}=2 \sum_{j=n+1}^{m+1} 2^{-\gamma j} \\
\leq & 2\left(\frac{2^{-\gamma(n+1)}}{1-2^{-\gamma}}\right)=\left(\frac{2 T^{-\gamma}}{1-2^{-\gamma}}\right)\left(T 2^{-(n+1)}\right)^{\gamma} \tag{62.2.4}
\end{align*}
$$

It follows the above holds for any $d, d^{\prime} \in D$ such that $\left|d-d^{\prime}\right| \leq T 2^{-n}$ because they are both in some $D_{m}$ for $m>n$.

Consider the last claim. Let $d, d^{\prime} \in D,\left|d-d^{\prime}\right| \leq T 2^{-M}$. Then $d, d^{\prime}$ are both in some $D_{m}$ for $m>M$. The number $\left|d-d^{\prime}\right|$ satisfies

$$
T 2^{-(n+1)}<\left|d-d^{\prime}\right| \leq T 2^{-n}
$$

for large enough $n \geq M$. Just pick the first $n$ such that $T 2^{-(n+1)}<\left|d-d^{\prime}\right|$. Then from 62.2.4,

$$
\begin{aligned}
\left\|X\left(d^{\prime}\right)-X(d)\right\| & \leq\left(\frac{2 T^{-\gamma}}{1-2^{-\gamma}}\right)\left(T 2^{-(n+1)}\right)^{\gamma} \\
& \leq\left(\frac{2 T^{-\gamma}}{1-2^{-\gamma}}\right)\left(\left|d-d^{\prime}\right|\right)^{\gamma}
\end{aligned}
$$

Now $[0, T]$ is covered by $2^{M}$ intervals of length $T 2^{-M}$ and so for any pair $d, d^{\prime} \in D$,

$$
\left\|X(d)-X\left(d^{\prime}\right)\right\| \leq C\left|d-d^{\prime}\right|^{\gamma}
$$

where $C$ is a suitable constant depending on $2^{M}$.
For $\gamma \leq 1$, you can show, using convexity arguments, that it suffices to have $C=$ $\left(\frac{2 T^{-\gamma}}{1-2^{-\gamma}}\right)^{1 / \gamma}\left(2^{M}\right)^{1-\gamma}$. Of course the case where $\gamma>1$ is not interesting because it would result in $X$ being a constant.

The following is the amazing Kolmogorov Čentsov continuity theorem [78].
Theorem 62.2.2 Suppose $X$ is a stochastic process on $[0, T]$. Suppose also that there exists a constant, $C$ and positive numbers, $\alpha, \beta$ such that

$$
\begin{equation*}
E\left(\|X(t)-X(s)\|^{\alpha}\right) \leq C|t-s|^{1+\beta} \tag{62.2.5}
\end{equation*}
$$

Then there exists a stochastic process $Y$ such that for a.e. $\omega, t \rightarrow Y(t)(\omega)$ is Hölder continuous with exponent $\gamma<\frac{\beta}{\alpha}$ and for each $t, P([\|X(t)-Y(t)\|>0])=0$. (Y is a version of $X$.)

Proof: Let $r_{j}^{m}$ denote $j\left(\frac{T}{2^{m}}\right)$ where $j \in\left\{0,1, \cdots, 2^{m}\right\}$. Also let $D_{m}=\left\{r_{j}^{m}\right\}_{j=1}^{2^{m}}$ and $D=\cup_{m=1}^{\infty} D_{m}$. Consider the set,

$$
[\|X(t)-X(s)\|>\delta]
$$

By 62.2.5,

$$
\begin{align*}
P([\|X(t)-X(s)\|>\delta]) \delta^{\alpha} & \leq \int_{[\|X(t)-X(s)\|>\delta]}\|X(t)-X(s)\|^{\alpha} d P \\
& \leq C|t-s|^{1+\beta} \tag{62.2.6}
\end{align*}
$$

Letting $t=r_{j+1}^{k}, s=r_{j}^{k}$, and $\delta=2^{-\gamma k}$ where

$$
\gamma \in\left(0, \frac{\beta}{\alpha}\right)
$$

this yields

$$
P\left(\left[\left\|X\left(r_{j+1}^{k}\right)-X\left(r_{j}^{k}\right)\right\|>2^{-\gamma k}\right]\right) \leq C 2^{\alpha \gamma k}\left(T 2^{-k}\right)^{1+\beta}
$$

$$
=C T^{1+\beta} 2^{k(\alpha \gamma-(1+\beta))}
$$

There are $2^{k}$ of these differences and so letting

$$
N_{k}=\cup_{j=1}^{2^{k}}\left[\left\|X\left(r_{j+1}^{k}\right)-X\left(r_{j}^{k}\right)\right\|>2^{-\gamma k}\right]
$$

it follows

$$
P\left(N_{k}\right) \leq C 2^{\alpha \gamma k}\left(T 2^{-k}\right)^{1+\beta} 2^{k}=C 2^{k(\alpha \gamma-\beta)} T^{1+\beta}
$$

Since $\gamma<\beta / \alpha$,

$$
\sum_{k=1}^{\infty} P\left(N_{k}\right) \leq C T^{1+\beta} \sum_{k=1}^{\infty} 2^{k(\alpha \gamma-\beta)}<\infty
$$

and so by the Borel Cantelli lemma, Lemma 59.1.2, there exists a set of measure zero $N$, such that if $\omega \notin N$, then $\omega$ is in only finitely many $N_{k}$. In other words, for $\omega \notin N$, there exists $M(\omega)$ such that if $k \geq M(\omega)$, then for each $j$,

$$
\begin{equation*}
\left\|X\left(r_{j+1}^{k}\right)(\omega)-X\left(r_{j}^{k}\right)(\omega)\right\| \leq 2^{-\gamma k} \tag{62.2.7}
\end{equation*}
$$

It follows from Lemma 62.2 .1 that $t \rightarrow X(t)(\omega)$ is Holder continuous on $D$ with Holder exponent $\gamma$. Note the constant is a measurable function of $\omega$, depending on how many measurable $N_{k}$ which contain $\omega$.

By Lemma 62.1.3, one can define $Y(t)(\omega)$ to be the unique function which extends $d \rightarrow X(d)(\omega)$ off $D$ for $\omega \notin N$ and let $Y(t)(\omega)=0$ if $\omega \in N$. Thus by Lemma 62.1.3 $t \rightarrow Y(t)(\omega)$ is Holder continuous. Also, $\omega \rightarrow Y(t)(\omega)$ is measurable because it is the pointwise limit of measurable functions

$$
\begin{equation*}
Y(t)(\omega)=\lim _{d \rightarrow t} X(d)(\omega) \mathscr{X}_{N^{C}}(\omega) \tag{62.2.8}
\end{equation*}
$$

It remains to verify the claim that $Y(t)(\omega)=X(t)(\omega)$ a.e.

$$
\mathscr{X}_{[\| Y(t)-X(t)| |>\varepsilon] \cap N^{C}}(\omega) \leq \lim _{d \rightarrow t} \mathscr{X}_{[\|X(d)-X(t)\|>\varepsilon] \cap N^{C}}(\omega)
$$

because if $\omega \in N$ both sides are 0 and if $\omega \in N^{C}$ then the above limit in 62.2 .8 holds and so if $\|Y(t)(\omega)-X(t)(\omega)\|>\varepsilon$, the same is true of $\|X(d)(\omega)-X(t)(\omega)\|$ whenever $d$ is close enough to $t$ and so by Fatou's lemma,

$$
\begin{aligned}
P([\|Y(t)-X(t)\|>\varepsilon]) & =\int \mathscr{X}_{[\|Y(t)-X(t)\|>\varepsilon] \cap N^{C}}(\omega) d P \\
& \leq \int \liminf _{d \rightarrow t} \mathscr{X}_{[\|X(d)-X(t)\|>\varepsilon]}(\omega) d P \\
& \leq \liminf _{d \rightarrow t} \int \mathscr{X}_{[\|X(d)-X(t)\|>\varepsilon]}(\omega) d P \\
& \leq \liminf _{d \rightarrow t} P\left(\left[\|X(d)-X(t)\|^{\alpha}>\varepsilon^{\alpha}\right]\right) \\
& \leq \liminf _{d \rightarrow t} \varepsilon^{-\alpha} \int_{\left[\|X(d)-X(t)\|^{\alpha}>\varepsilon^{\alpha}\right]}\|X(d)-X(t)\|^{\alpha} d P \\
& \leq \liminf _{d \rightarrow t} \frac{C}{\varepsilon^{\alpha}}|d-t|^{1+\beta}=0 .
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
& P([\|Y(t)-X(t)\|>0]) \\
= & P\left(\cup_{k=1}^{\infty}\left[\|Y(t)-X(t)\|>\frac{1}{k}\right]\right) \\
\leq & \sum_{k=1}^{\infty} P\left(\left[\|Y(t)-X(t)\|>\frac{1}{k}\right]\right)=0 .
\end{aligned}
$$

A few observations are interesting. In the proof, the following inequality was obtained.

$$
\begin{aligned}
\left\|X\left(d^{\prime}\right)(\omega)-X(d)(\omega)\right\| & \leq \frac{2}{T^{\gamma}\left(1-2^{-\gamma}\right)}\left(T 2^{-(n+1)}\right)^{\gamma} \\
& \leq \frac{2}{T^{\gamma}\left(1-2^{-\gamma}\right)}\left(\left|d-d^{\prime}\right|\right)^{\gamma}
\end{aligned}
$$

which was so for any $d^{\prime}, d \in D$ with $\left|d^{\prime}-d\right|<T 2^{-(M(\omega)+1)}$. Thus the Holder continuous version of $X$ will satisfy

$$
\|Y(t)(\omega)-Y(s)(\omega)\| \leq \frac{2}{T^{\gamma}\left(1-2^{-\gamma}\right)}(|t-s|)^{\gamma}
$$

provided $|t-s|<T 2^{-(M(\omega)+1)}$. Does this translate into an inequality of the form

$$
\|Y(t)(\omega)-Y(s)(\omega)\| \leq \frac{2}{T^{\gamma}\left(1-2^{-\gamma}\right)}(|t-s|)^{\gamma}
$$

for any pair of points $t, s \in[0, T]$ ? It seems it does not for any $\gamma<1$ although it does yield

$$
\|Y(t)(\omega)-Y(s)(\omega)\| \leq C(|t-s|)^{\gamma}
$$

where $C$ depends on the number of intervals having length less than $T 2^{-(M(\omega)+1)}$ which it takes to cover $[0, T]$. First note that if $\gamma>1$, then the Holder continuity will imply $t \rightarrow$ $Y(t)(\omega)$ is a constant. Therefore, the only case of interest is $\gamma<1$. Let $s, t$ be any pair of points and let $s=x_{0}<\cdots<x_{n}=t$ where $\left|x_{i}-x_{i-1}\right|<T 2^{-(M(\omega)+1)}$. Then

$$
\begin{align*}
\| Y(t)(\omega)- & Y(s)(\omega)\left\|\leq \sum_{i=1}^{n}\right\| Y\left(x_{i}\right)(\omega)-Y\left(x_{i-1}\right)(\omega) \| \\
& \leq \frac{2}{T^{\gamma}\left(1-2^{-\gamma}\right)} \sum_{i=1}^{n}\left(\left|x_{i}-x_{i-1}\right|\right)^{\gamma} \tag{62.2.9}
\end{align*}
$$

How does this compare to

$$
\left(\sum_{i=1}^{n}\left|x_{i}-x_{i-1}\right|\right)^{\gamma}=|t-s|^{\gamma_{?}}
$$

This last expression is smaller than the right side of 62.2 .9 for any $\gamma<1$. Thus for $\gamma<1$, the constant in the conclusion of the theorem depends on both $T$ and $\omega \notin N$.

In the case where $\alpha \geq 1$, here is another proof of this theorem. It is based on the one in the book by Stroock [121].

Theorem 62.2.3 Suppose $X$ is a stochastic process on $[0, T]$ having values in the Banach space $E$. Suppose also that there exists a constant, $C$ and positive numbers $\alpha, \beta, \alpha \geq 1$, such that

$$
\begin{equation*}
E\left(\|X(t)-X(s)\|^{\alpha}\right) \leq C|t-s|^{1+\beta} \tag{62.2.10}
\end{equation*}
$$

Then there exists a stochastic process $Y$ such that for a.e. $\omega, t \rightarrow Y(t)(\omega)$ is Hölder continuous with exponent $\gamma<\frac{\beta}{\alpha}$ and for each $t, P([\|X(t)-Y(t)\|>0])=0$. $(Y$ is a version of X.) Also

$$
E\left(\sup _{0 \leq s<t \leq T} \frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right) \leq C
$$

where $C$ depends on $\alpha, \beta, T, \gamma$.
Proof: The proof considers piecewise linear approximations of $X$ which are automatically continuous. These are shown to converge to $Y$ in $L^{\alpha}(\Omega ; C([0, T], E))$ so it follows that $Y$ must be continuous for a.e. $\omega$. Finally, it is shown that $Y$ is a version of $X$ and is Holder continuous. In the proof, I will use $C$ to denote a constant which depends on the quantities $\gamma, \alpha, \beta, T$. Let $\left\{t_{k}^{n}\right\}_{k=0}^{2^{n}}$ be a uniform partition of the interval $[0, T]$ so that $t_{k+1}^{n}-t_{k}^{n}=T 2^{-n}$. Now let

$$
M_{n} \equiv \max _{k \leq 2^{n}}\left\|X\left(t_{k}^{n}\right)-X\left(t_{k-1}^{n}\right)\right\|
$$

Then it follows that

$$
M_{n}^{\alpha} \leq \sum_{k=1}^{2^{n}}\left\|X\left(t_{k}^{n}\right)-X\left(t_{k-1}^{n}\right)\right\|^{\alpha}
$$

and so

$$
\begin{equation*}
E\left(M_{n}^{\alpha}\right) \leq \sum_{k=1}^{2^{n}} C\left(T 2^{-n}\right)^{1+\beta}=C 2^{n} 2^{-n(1+\beta)}=C 2^{-n \beta} \tag{62.2.11}
\end{equation*}
$$

Next denote by $X_{n}$ the piecewise linear function which results from the values of $X$ at the points $t_{k}^{n}$. Consider the following picture which illustrates a part of the graphs of $X_{n}$ and $X_{n+1}$.

Then

$$
\max _{t \in[0, T]}\left\|X_{n+1}(t)-X_{n}(t)\right\| \leq \max _{1 \leq k \leq 2^{n+1}}\left\|X\left(t_{2 k-1}^{n+1}\right)-\frac{X\left(t_{k}^{n}\right)+X\left(t_{k-1}^{n}\right)}{2}\right\|
$$

$$
\leq \max _{k \leq 2^{n+1}}\left(\frac{1}{2}\left\|X\left(t_{2 k-1}^{n+1}\right)-X\left(t_{2 k}^{n+1}\right)\right\|+\frac{1}{2}\left\|X\left(t_{2 k-1}^{n+1}\right)-X\left(t_{2 k-2}^{n+1}\right)\right\|\right) \leq M_{n+1}
$$

Denote by $\|\cdot\|_{\infty}$ the usual norm in $C([0, T], E)$,

$$
\max _{t \in[0, T]}\|Z(t)\| \equiv\|Z\|_{\infty}
$$

Then from what was just established,

$$
E\left(\left\|X_{n+1}-X_{n}\right\|_{\infty}^{\alpha}\right)=\int_{\Omega}\left\|X_{n+1}-X_{n}\right\|_{\infty}^{\alpha} d P \leq E\left(M_{n+1}^{\alpha}\right)=C 2^{-n \beta}
$$

which shows that

$$
\left\|X_{n+1}-X_{n}\right\|_{L^{\alpha}(\Omega ; C([0, T], E))}=\left(\int_{\Omega}\left\|X_{n+1}-X_{n}\right\|_{\infty}^{\alpha} d P\right)^{1 / \alpha} \leq C\left(2^{(\beta / \alpha)}\right)^{-n}
$$

Also, for $m>n$, it follows from the assumption that $\alpha \geq 1$,

$$
\begin{gather*}
\left\|X_{m}-X_{n}\right\|_{L^{\alpha}(\Omega ; C([0, T], E))} \leq \\
\sum_{k=n}^{\infty} C\left(2^{(\beta / \alpha)}\right)^{-k} \leq C \frac{\left(2^{(\beta / \alpha)}\right)^{-n}}{1-2^{(-\beta / \alpha)}}=C\left(2^{(\beta / \alpha)}\right)^{-n} \tag{62.2.12}
\end{gather*}
$$

Thus $\left\{X_{n}\right\}$ is a Cauchy sequence in $L^{\alpha}(\Omega ; C([0, T], E))$ and so it converges to some $Y$ in this space, a subsequence converging pointwise. Then from Fatou's lemma,

$$
\begin{equation*}
\left\|Y-X_{n}\right\|_{L^{\alpha}(\Omega ; C([0, T], E))} \leq C\left(2^{(\beta / \alpha)}\right)^{-n} \tag{62.2.13}
\end{equation*}
$$

Also, for a.e. $\omega, t \rightarrow Y(t)$ is in $C([0, T], E)$. It remains to verify that $Y(t)=X(t)$ a.e.
From the construction, it follows that for any $n$ and $m \geq n$

$$
Y\left(t_{k}^{n}\right)=X_{m}\left(t_{k}^{n}\right)=X\left(t_{k}^{n}\right)
$$

Thus

$$
\begin{aligned}
\|Y(t)-X(t)\| & \leq\left\|Y(t)-Y\left(t_{k}^{n}\right)\right\|+\left\|Y\left(t_{k}^{n}\right)-X(t)\right\| \\
& =\left\|Y(t)-Y\left(t_{k}^{n}\right)\right\|+\left\|X\left(t_{k}^{n}\right)-X(t)\right\|
\end{aligned}
$$

Now from the hypotheses of the theorem,

$$
P\left(\left\|X\left(t_{k}^{n}\right)-X(t)\right\|^{\alpha}>\varepsilon\right) \leq \frac{1}{\varepsilon} E\left(\left\|X\left(t_{k}^{n}\right)-X(t)\right\|^{\alpha}\right) \leq \frac{C}{\varepsilon}\left|t_{k}^{n}-t\right|^{1+\beta}
$$

Thus, there exists a sequence of mesh points $\left\{s_{n}\right\}$ converging to $t$ such that

$$
P\left(\left\|X\left(s_{n}\right)-X(t)\right\|^{\alpha}>2^{-n}\right) \leq 2^{-n}
$$

Then by the Borel Cantelli lemma, there is a set of measure zero $N$ such that for $\omega \notin N$,

$$
\left\|X\left(s_{n}\right)-X(t)\right\|^{\alpha} \leq 2^{-n}
$$

for all $n$ large enough. Then

$$
\|Y(t)-X(t)\| \leq\left\|Y(t)-Y\left(s_{n}\right)\right\|+\left\|X\left(s_{n}\right)-X(t)\right\|
$$

which shows that, by continuity of $Y$, for $\omega$ not in an exceptional set of measure zero, $\|Y(t)-X(t)\|=0$.

It remains to verify the assertion about Holder continuity of $Y$. Let $0 \leq s<t \leq T$. Then for some $n$,

$$
\begin{equation*}
2^{-(n+1)} T \leq t-s \leq 2^{-n} T \tag{62.2.14}
\end{equation*}
$$

Thus

$$
\begin{align*}
\|Y(t)-Y(s)\| & \leq\left\|Y(t)-X_{n}(t)\right\|+\left\|X_{n}(t)-X_{n}(s)\right\|+\left\|X_{n}(s)-Y(s)\right\| \\
& \leq 2 \sup _{\tau \in[0, T]}\left\|Y(\tau)-X_{n}(\tau)\right\|+\left\|X_{n}(t)-X_{n}(s)\right\| \tag{62.2.15}
\end{align*}
$$

Now

$$
\frac{\left\|X_{n}(t)-X_{n}(s)\right\|}{t-s} \leq \frac{\left\|X_{n}(t)-X_{n}(s)\right\|}{2^{-(n+1)} T}
$$

From 62.2 .14 a picture like the following must hold.

| - |  |  |  | + |
| :---: | :---: | :---: | :---: | :---: |
| $t_{k-1}^{n+1}$ | $s$ | $t_{k}^{n+1}$ | $t$ | $t_{k+1}^{n+1}$ |

Therefore, from the above,

$$
\begin{aligned}
\frac{\left\|X_{n}(t)-X_{n}(s)\right\|}{t-s} & \leq \frac{\left\|X\left(t_{k-1}^{n+1}\right)-X\left(t_{k}^{n+1}\right)\right\|+\left\|X\left(t_{k+1}^{n+1}\right)-X\left(t_{k}^{n+1}\right)\right\|}{2^{-(n+1)} T} \\
& \leq C 2^{n} M_{n+1}
\end{aligned}
$$

It follows from 62.2.15,

$$
\|Y(t)-Y(s)\| \leq 2\left\|Y-X_{n}\right\|_{\infty}+C 2^{n} M_{n+1}(t-s)
$$

Next, letting $\gamma<\beta / \alpha$, and using 62.2.14,

$$
\begin{aligned}
\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}} & \leq 2\left(T^{-1} 2^{n+1}\right)^{\gamma}\left\|Y-X_{n}\right\|_{\infty}+C 2^{n}\left(2^{-n}\right)^{1-\gamma} M_{n+1} \\
& =C 2^{n \gamma}\left(\left\|Y-X_{n}\right\|_{\infty}+M_{n+1}\right)
\end{aligned}
$$

The above holds for any $s, t$ satisfying 62.2.14. Then

$$
\sup \left\{\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}, 0 \leq s<t \leq T,|t-s| \in\left[2^{-(n+1)} T, 2^{-n} T\right]\right\}
$$

$$
\leq C 2^{n \gamma}\left(\left\|Y-X_{n}\right\|_{\infty}+M_{n+1}\right)
$$

Denote by $P_{n}$ the ordered pairs $(s, t)$ satisfying the above condition that

$$
\begin{gathered}
0 \leq s<t \leq T,|t-s| \in\left[2^{-(n+1)} T, 2^{-n} T\right] \\
\sup _{(s, t) \in P_{n}} \frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}} \leq C 2^{n \gamma}\left(\left\|Y-X_{n}\right\|_{\infty}+M_{n+1}\right)
\end{gathered}
$$

Thus for a.e. $\omega$, and for all $n$,

$$
\left(\sup _{(s, t) \in P_{n}} \frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha} \leq C \sum_{k=0}^{\infty} 2^{k \alpha \gamma}\left(\left\|Y-X_{k}\right\|_{\infty}^{\alpha}+M_{k+1}^{\alpha}\right)
$$

Note that $n$ is arbitrary. Hence

$$
\begin{gathered}
\sup _{0 \leq s<t \leq T}\left(\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha} \leq \\
\sup _{n} \sup _{(s, t) \in P_{n}}\left(\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha} \leq \sup _{n}\left(\sup _{(s, t) \in P_{n}} \frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha} \\
\leq \sum_{k=0}^{\infty} C 2^{k \alpha \gamma}\left(\left\|Y-X_{k}\right\|_{\infty}^{\alpha}+M_{k+1}^{\alpha}\right)
\end{gathered}
$$

By continuity of $Y$, the result on the left is unchanged if the ordered pairs are restricted to lie in $\mathbb{Q} \cap[0, T] \times \mathbb{Q} \cap[0, T]$, a countable set. Thus the left side is measurable. It follows from 62.2.11 and 62.2.13 which say

$$
\left\|Y-X_{k}\right\|_{L^{\alpha}(\Omega ; C([0, T], E))} \leq C\left(2^{(\beta / \alpha)}\right)^{-k}, E\left(M_{k}^{\alpha}\right) \leq C 2^{-k \beta}
$$

that

$$
E\left(\sup _{0 \leq s<t \leq T}\left(\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha}\right) \leq \sum_{k=0}^{\infty} C 2^{k \alpha \gamma} 2^{-\beta k} \equiv C<\infty
$$

because $\alpha \gamma-\beta<0$. By continuity of $Y$, there are no measurability concerns in taking the above expectation. Note that this implies, since $\alpha \geq 1$,

$$
E\left(\sup _{0 \leq s<t \leq T} \frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right) \leq\left(E\left(\sup _{0 \leq s<t \leq T}\left(\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha}\right)\right)^{1 / \alpha} \leq C^{1 / \alpha} \equiv C
$$

Now

$$
P\left(\sup _{0 \leq s<t \leq T}\left(\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha}>2^{\alpha k}\right) \leq \frac{1}{2^{\alpha k}} C
$$

and so there exists a set of measure zero $N$ such that for $\omega \notin N$,

$$
\sup _{0 \leq s<t \leq T}\left(\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}}\right)^{\alpha} \leq 2^{\alpha k}
$$

for all $k$ large enough. Pick such a $k$, depending on $\omega \notin N$. Then for any $s, t$,

$$
\frac{\|Y(t)-Y(s)\|}{(t-s)^{\gamma}} \leq 2^{k}
$$

and so, this has shown that for $\omega \notin N$,

$$
\|Y(t)-Y(s)\| \leq C(\omega)(t-s)^{\gamma}
$$

Note that if $X(t)$ is known to be continuous off a set of measure zero, then the piecewise linear approximations converge to $X(t)$ in $C([0, T], E)$ off this set of measure zero. Therefore, it must be that off a set of measure zero, $Y(t)=X(t)$ and so in fact $X(t)$ is Holder continuous off a set of measure zero and the condition on expectation also must hold, that is

$$
E\left(\sup _{0 \leq s<t \leq T} \frac{\|X(t)-X(s)\|}{(t-s)^{\gamma}}\right) \leq C
$$

### 62.3 Filtrations

Instead of having a sequence of $\sigma$ algebras, one can consider an increasing collection of $\sigma$ algebras indexed by $t \in \mathbb{R}$. This is called a filtration.

Definition 62.3.1 Let $X$ be a stochastic process defined on an interval, $I=[0, T]$ or $[0, \infty)$. Suppose the probability space, $(\Omega, \mathscr{F}, P)$ has an increasing family of $\sigma$ algebras, $\left\{\mathscr{F}_{t}\right\}$. This is called a filtration. If for arbitrary $t \in I$ the random variable $X(t)$ is $\mathscr{F}_{t}$ measurable, then $X$ is said to be adapted to the filtration $\left\{\mathscr{F}_{t}\right\}$. Denote by $\mathscr{F}_{t+}$ the intersection of all $\mathscr{F}_{s}$ for $s>t$. The filtration is normal if

1. $\mathscr{F}_{0}$ contains all $A \in \mathscr{F}$ such that $P(A)=0$
2. $\mathscr{F}_{t}=\mathscr{F}_{t+}$ for all $t \in I$.
$X$ is called progressively measurable if for every $t \in I$, the mapping

$$
(s, \omega) \in[0, t] \times \Omega, \quad(s, \omega) \rightarrow X(s, \omega)
$$

is $B([0, t]) \times \mathscr{F}_{t}$ measurable.
Thus $X$ is progressively measurable means

$$
(s, \omega) \rightarrow \mathscr{X}_{[0, t]}(s) X(s, \omega)
$$

is $B([0, t]) \times \mathscr{F}_{t}$ measurable. As an example of a normal filtration, here is an example.
Example 62.3.2 For example, you could have a stochastic process, $X(t)$ and you could define

$$
\mathscr{G}_{t} \equiv \overline{\sigma(X(s): s \leq t)}
$$

the completion of the smallest $\sigma$ algebra such that each $X(s)$ is measurable for all $s \leq t$. This gives an example of a filtration to which $X(t)$ is adapted which satisfies 1. More generally, suppose $X(t)$ is adapted to a filtration, $\mathscr{G}_{t}$. Define

$$
\mathscr{F}_{t} \equiv \cap_{s>t} \mathscr{G}_{s}
$$

Then

$$
\mathscr{F}_{t+} \equiv \cap_{s>t} \mathscr{F}_{s}=\cap_{s>t} \cap_{r>s} \mathscr{G}_{r}=\cap_{s>t} \mathscr{F}_{s} \equiv \mathscr{F}_{t} .
$$

and each $X(t)$ is measurable with respect to $\mathscr{F}_{t}$. Thus there is no harm in assuming a stochastic process adapted to a filtration can be modified so the filtration is normal. Also note that $\mathscr{F}_{t}$ defined this way will be complete so if $A \in \mathscr{F}_{t}$ has $P(A)=0$ and if $B \subseteq A$, then $B \in \mathscr{F}_{t}$ also. This is because this relation between the sets and the probability of $A$ being zero, holds for this pair of sets when considered as elements of each $\mathscr{G}_{s}$ for $s>t$. Hence $B \in \mathscr{G}_{s}$ for each $s>t$ and is therefore one of the sets in $\mathscr{F}_{t}$.

What is the description of a progressively measurable set?

It means that for $Q$ progressively measurable, $Q \cap[0, t] \times \Omega$ as shown in the above picture is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable. It is like saying a little more descriptively that the function is progressively product measurable.

I shall generally assume the filtration is normal.
Observation 62.3.3 If $X$ is progressively measurable, then it is adapted. Furthermore the progressively measurable sets, those $E \cap[0, T] \times \Omega$ for which $\mathscr{X}_{E}$ is progressively measurable form a $\sigma$ algebra.

To see why this is, consider $X$ progressively measurable and fix $t$. Then $(s, \omega) \rightarrow$ $X(s, \omega)$ for $(s, \omega) \in[0, t] \times \Omega$ is given to be $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable, the ordinary product measure and so fixing any $s \in[0, t]$, it follows the resulting function of $\omega$ is $\mathscr{F}_{t}$ measurable. In particular, this is true upon fixing $s=t$. Thus $\omega \rightarrow X(t, \omega)$ is $\mathscr{F}_{t}$ measurable and so $X(t)$ is adapted.

A set $E \subseteq[0, T] \times \Omega$ is progressively measurable means that $\mathscr{X}_{E}$ is progressively measurable. That is $\mathscr{X}_{E}$ restricted to $[0, t] \times \Omega$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable. In other words, $E$ is progressively measurable if

$$
E \cap([0, t] \times \Omega) \in \mathscr{B}([0, t]) \times \mathscr{F}_{t} .
$$

If $E_{i}$ is progressively measurable, does it follow that $E \equiv \cup_{i=1}^{\infty} E_{i}$ is also progressively measurable? Yes.

$$
E \cap([0, t] \times \Omega)=\cup_{i=1}^{\infty} E_{i} \cap([0, t] \times \Omega) \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}
$$

because each set in the union is in $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$. If $E$ is progressively measurable, is $E^{C}$ ?

$$
E^{C} \cap([0, t] \times \Omega) \cup \overbrace{(E \cap([0, t] \times \Omega))}^{\in \mathscr{B}([0, t]) \times \mathscr{F}_{t}}=\overbrace{[0, t] \times \Omega}^{\in \mathscr{B}([0, t]) \times \mathscr{F}_{t}}
$$

and so $E^{C} \cap([0, t] \times \Omega) \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}$. Thus the progressively measurable sets are a $\sigma$ algebra.

Another observation of interest is in the following lemma.
Lemma 62.3.4 Suppose $Q$ is in $\mathscr{B}([0, a]) \times \mathscr{F}_{r}$. Then if $b \geq a$ and $t \geq r$, then $Q$ is also in $\mathscr{B}([0, b]) \times \mathscr{F}_{t}$.

Proof: Consider a measurable rectangle $A \times B$ where $A \in \mathscr{B}([0, a])$ and $B \in \mathscr{F}_{r}$. Is it true that $A \times B \in \mathscr{B}([0, b]) \times \mathscr{F}_{t}$ ? This reduces to the question whether $A \in \mathscr{B}([0, b])$. If $A$ is an interval, it is clear that $A \in \mathscr{B}([0, b])$. Consider the $\pi$ system of intervals and let $\mathscr{G}$ denote those Borel sets $A \in \mathscr{B}([0, a])$ such that $A \in \mathscr{B}([0, b])$. If $A \in \mathscr{G}$, then $[0, b] \backslash A \in \mathscr{B}([0, b])$ by assumption (the difference of Borel sets is surely Borel). However, this set equals

$$
([0, a] \backslash A) \cup(a, b]
$$

and so

$$
[0, b]=([0, a] \backslash A) \cup(a, b] \cup A
$$

The set on the left is in $\mathscr{B}([0, b])$ and the sets on the right are disjoint and two of them are also in $\mathscr{B}([0, b])$. Therefore, the third, $([0, a] \backslash A)$ is in $\mathscr{B}([0, b])$. It is obvious that $\mathscr{G}$ is closed with respect to countable disjoint unions. Therefore, by Lemma 12.12.3, Dynkin's lemma, $\mathscr{G} \supseteq \sigma$ (Intervals) $=\mathscr{B}([0, a])$.

Therefore, such a measurable rectangle $A \times B$ where $A \in \mathscr{B}([0, a])$ and $B \in \mathscr{F}_{r}$ is in $\mathscr{B}([0, b]) \times \mathscr{F}_{t}$ and in fact it is a measurable rectangle in $\mathscr{B}([0, b]) \times \mathscr{F}_{t}$. Now let $\mathscr{K}$ denote all these measurable rectangles $A \times B$ where $A \in \mathscr{B}([0, a])$ and $B \in \mathscr{F} r$. Let $\mathscr{G}$ (new $\mathscr{G})$ denote those sets $Q$ of $\mathscr{B}([0, a]) \times \mathscr{F}_{r}$ which are in $\mathscr{B}([0, b]) \times \mathscr{F}_{t}$. Then if $Q \in \mathscr{G}$,

$$
Q \cup([0, a] \times \Omega \backslash Q) \cup(a, b] \times \Omega=[a, b] \times \Omega
$$

Then the sets are disjoint and all but $[0, a] \times \Omega \backslash Q$ are in $\mathscr{B}([0, b]) \times \mathscr{F}_{t}$. Therefore, this one is also in $\mathscr{B}([0, b]) \times \mathscr{F}_{t}$. If $Q_{i} \in \mathscr{G}$ and the $Q_{i}$ are disjoint, then $\cup_{i} Q_{i}$ is also in $\mathscr{B}([0, b]) \times$ $\mathscr{F}_{t}$ and so $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. Hence $\mathscr{G} \supseteq \sigma(\mathscr{K})=\mathscr{B}([0, a]) \times \mathscr{F}_{r}$ which shows

$$
\mathscr{B}([0, a]) \times \mathscr{F}_{r} \subseteq \mathscr{B}([0, b]) \times \mathscr{F}_{t}
$$

A significant observation is the following which states that the integral of a progressively measurable function is progressively measurable.

Proposition 62.3.5 Suppose $X:[0, T] \times \Omega \rightarrow E$ where $E$ is a separable Banach space. Also suppose that $X(\cdot, \omega) \in L^{1}([0, T], E)$ for each $\omega$. Here $\mathscr{F}_{t}$ is a filtration and with respect to this filtration, $X$ is progressively measurable. Then

$$
(t, \omega) \rightarrow \int_{0}^{t} X(s, \omega) d s
$$

is also progressively measurable.

Proof: Suppose $Q \in[0, T] \times \Omega$ is progressively measurable. This means for each $t$,

$$
Q \cap[0, t] \times \Omega \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}
$$

What about

$$
(s, \omega) \in[0, t] \times \Omega,(s, \omega) \rightarrow \int_{0}^{s} \mathscr{X}_{Q} d r ?
$$

Is that function on the right $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable? We know that $Q \cap[0, s] \times \Omega$ is $\mathscr{B}([0, s]) \times \mathscr{F}_{s}$ measurable and hence $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable. When you integrate a product measurable function, you do get one which is product measurable. Therefore, this function must be $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable. This shows that $(t, \omega) \rightarrow \int_{0}^{t} \mathscr{X}_{Q}(s, \omega) d s$ is progressively measurable. Here is a claim which was just used.

Claim: If $Q$ is $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable, then $(s, \omega) \rightarrow \int_{0}^{s} \mathscr{X}_{Q} d r$ is also $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable.

Proof of claim: First consider $A \times B$ where $A \in \mathscr{B}([0, t])$ and $B \in \mathscr{F}_{t}$. Then

$$
\int_{0}^{s} \mathscr{X}_{A \times B} d r=\int_{0}^{s} \mathscr{X}_{A} \mathscr{X}_{B} d r=\mathscr{X}_{B}(\omega) \int_{0}^{s} \mathscr{X}_{A}(s) d r
$$

This is clearly $\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ measurable. It is the product of a continuous function of $s$ with the indicator function of a set in $\mathscr{F}_{t}$. Now let

$$
\mathscr{G} \equiv\left\{Q \in \mathscr{B}([0, t]) \times \mathscr{F}_{t}:(s, \omega) \rightarrow \int_{0}^{s} \mathscr{X}_{Q}(r, \omega) d r \text { is } \mathscr{B}([0, t]) \times \mathscr{F}_{t} \text { measurable }\right\}
$$

Then it was just shown that $\mathscr{G}$ contains the measurable rectangles. It is also clear that $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. Therefore, $\mathscr{G} \supseteq$ $\sigma\left(\mathscr{K}_{t}\right)=\mathscr{B}([0, t]) \times \mathscr{F}_{t}$ where $\mathscr{K}_{t}$ denotes the measurable rectangles $A \times B$ where $B \in \overline{\mathscr{F}}_{t}$ and $A \in \mathscr{B}([0, t])=\mathscr{B}([0, T]) \cap[0, t]$. This proves the claim.

Thus if $Q$ is progressively measurable, it follows that $(s, \omega) \rightarrow \int_{0}^{s} \mathscr{X}_{Q}(r, \omega) d r \equiv f(s, \omega)$ is progressively measurable because for $(s, \omega) \in[0, t] \times \Omega,(s, \omega) \rightarrow f(s, \omega)$ is $\mathscr{B}([0, t]) \times$ $\mathscr{F}_{t}$ measurable. This is what was to be proved in this special case.

Now consider the conclusion of the proposition. By considering the positive and negative parts of $\phi(X)$ for $\phi \in E^{\prime}$, and using Pettis theorem, it suffices to consider the case where $X \geq 0$. Then there exists an increasing sequence of progressively measurable simple functions $\left\{X_{n}\right\}$ converging pointwise to $X$. From what was just shown,

$$
(t, \omega) \rightarrow \int_{0}^{t} X_{n} d s
$$

is progressively measurable. Hence, by the monotone convergence theorem, $(t, \omega) \rightarrow$ $\int_{0}^{t} X d s$ is also progressively measurable.

What else can you do to something which is progressively measurable and obtain something which is progressively measurable? It turns out that shifts in time can preserve progressive measurability. Let $\mathscr{F}_{t}$ be a filtration on $[0, T]$ and extend the filtration to be equal to $\mathscr{F}_{0}$ and $\mathscr{F}_{T}$ for $t<0$ and $t>T$, respectively. Recall the following definition of progressively measurable sets.

Definition 62.3.6 Denote by $\mathscr{P}$ those sets $Q$ in $\mathscr{F}_{T} \times \mathscr{B}([0, T])$ such that for $t \in[-\infty, T]$

$$
\Omega \times(-\infty, t] \cap Q \in \mathscr{F}_{t} \times \mathscr{B}((-\infty, t])
$$

Lemma 62.3.7 Define $Q+h$ as

$$
Q+h \equiv\{(t+h, \omega):(t, \omega) \in Q\}
$$

Then if $Q \in \mathscr{P}$, it follows that $Q+h \in \mathscr{P}$.
Proof: This is most easily seen through the use of the following diagram. In this diagram, $Q$ is in $\mathscr{P}$ so it is progressively measurable.

By definition, $S$ in the picture is $\mathscr{B}((-\infty, t-h]) \times \mathscr{F}_{t-h}$ measurable. Hence $S+h \equiv$ $Q+h \cap \Omega \times(-\infty, t]$ is $\mathscr{B}((-\infty, t]) \times \mathscr{F}_{t-h}$ measurable. To see this, note that if $B \times A \in$ $\mathscr{B}((-\infty, t-h]) \times \mathscr{F}_{t-h}$, then translating it by $h$ gives a set in $\mathscr{B}((-\infty, t]) \times \mathscr{F}_{t-h}$. Then if $\mathscr{G}$ consists of sets $S$ in $\mathscr{B}((-\infty, t-h]) \times \mathscr{F}_{t-h}$ for which $S+h$ is in $\mathscr{B}((-\infty, t]) \times \mathscr{F}_{t-h}$, $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. Thus, $\mathscr{G}$ equals $\mathscr{B}((-\infty, t-h]) \times \mathscr{F}_{t-h}$. In particular, it contains the set $S$ just described.

Now for $h>0$,

$$
\tau_{h} f(t) \equiv\left\{\begin{array}{l}
f(t-h) \text { if } t \geq h \\
0 \text { if } t<h
\end{array}\right.
$$

Lemma 62.3.8 Let $Q \in \mathscr{P}$. Then $\tau_{h} \mathscr{X}_{Q}$ is $\mathscr{P}$ measurable.
Proof: If $\tau_{h} \mathscr{X}_{Q}(t, \omega)=1$, then you need to have $(t-h, \omega) \in Q$ and so $(t, \omega) \in Q+h$. Thus

$$
\tau_{h} \mathscr{X}_{Q}=\mathscr{X}_{Q+h}
$$

which is $\mathscr{P}$ measurable since $Q \in \mathscr{P}$. In general,

$$
\tau_{h} \mathscr{X}_{Q}=\mathscr{X}_{[h, T] \times \Omega} \mathscr{X}_{Q+h},
$$

which is $\mathscr{P}$ measurable.
This lemma implies the following.
Lemma 62.3.9 Let $f(t, \omega)$ have values in a separable Banach space and suppose $f$ is $\mathscr{P}$ measurable. Then $\tau_{h} f$ is $\mathscr{P}$ measurable.

Proof: Taking values in a separable Banach space and being $\mathscr{P}$ measurable, $f$ is the pointwise limit of $\mathscr{P}$ measurable simple functions. If $s_{n}$ is one of these, then from the above lemmas, $\tau_{h} s_{n}$ is $\mathscr{P}$ measurable. Then, letting $n \rightarrow \infty$, it follows that $\tau_{h} f$ is $\mathscr{P}$ measurable.

The following is similar to Proposition 62.1.2. It shows that under pretty weak conditions, an adapted process has a progressively measurable adapted version.

Proposition 62.3.10 Let $X$ be a stochastically continuous adapted process for a normal filtration defined on a closed interval, $I \equiv[0, T]$. Then $X$ has a progressively measurable adapted version.

Proof: By Lemma 62.1.1 $X$ is uniformly stochastically continuous and so there exists a sequence of positive numbers, $\left\{\rho_{n}\right\}$ such that if $|s-t|<\rho_{n}$, then

$$
\begin{equation*}
P\left(\left[\|X(t)-X(s)\| \geq \frac{1}{2^{n}}\right]\right) \leq \frac{1}{2^{n}} \tag{62.3.16}
\end{equation*}
$$

Then let $\left\{t_{0}^{n}, t_{1}^{n}, \cdots, t_{m_{n}}^{n}\right\}$ be a partition of $[0, T]$ in which $\left|t_{i}^{n}-t_{i-1}^{n}\right|<\rho_{n}$. Now define $X_{n}$ as follows:

$$
\begin{aligned}
X_{n}(t)(\omega) & \equiv \sum_{i=1}^{m_{n}} X\left(t_{i-1}^{n}\right)(\omega) \mathscr{X}_{\left[t_{i-1}^{n}, t_{i}^{n}\right)}(t) \\
X_{n}(T) & \equiv X(T)
\end{aligned}
$$

Then $(s, \omega) \rightarrow X_{n}(s, \omega)$ for $(s, \omega) \in[0, t] \times \Omega$ is obviously $B([0, t]) \times \mathscr{F}_{t}$ measurable. Consider the set, $A$ on which $\left\{X_{n}(t, \omega)\right\}$ is a Cauchy sequence. This set is of the form

$$
A=\cap_{n=1}^{\infty} \cup_{m=1}^{\infty} \cap_{p, q \geq m}\left[\left\|X_{p}-X_{q}\right\|<\frac{1}{n}\right]
$$

and so it is a $B(I) \times \mathscr{F}$ measurable set and $A \cap[0, t] \times \Omega$ is $B([0, t]) \times \mathscr{F}_{t}$ measurable for each $t \leq T$ because each $X_{q}$ in the above has the property that its restriction to $[0, t] \times \Omega$ is $B([0, t]) \times \mathscr{F}_{t}$ measurable. Now define

$$
Y(t, \omega) \equiv\left\{\begin{array}{l}
\lim _{n \rightarrow \infty} X_{n}(t, \omega) \text { if }(t, \omega) \in A \\
0 \text { if }(t, \omega) \notin A
\end{array}\right.
$$

I claim that for each $t, Y(t, \omega)=X(t, \omega)$ for a.e. $\omega$. To see this, consider 62.3.16. From the construction of $X_{n}$, it follows that for each $t$,

$$
P\left(\left[\left\|X_{n}(t)-X(t)\right\| \geq \frac{1}{2^{n}}\right]\right) \leq \frac{1}{2^{n}}
$$

Also, for a fixed $t$, if $X_{n}(t, \omega)$ fails to converge to $X(t, \omega)$, then $\omega$ must be in infinitely many of the sets,

$$
B_{n} \equiv\left[\left\|X_{n}(t)-X(t)\right\| \geq \frac{1}{2^{n}}\right]
$$

which is a set of measure zero by the Borel Cantelli lemma. Recall why this is so.

$$
P\left(\cap_{k=1}^{\infty} \cup_{n=k}^{\infty} B_{n}\right) \leq \sum_{n=k}^{\infty} P\left(B_{n}\right)<\frac{1}{2^{k-1}}
$$

Therefore, for each $t,(t, \omega) \in A$ for a.e. $\omega$. Hence $X(t)=Y(t)$ a.e. and so $Y$ is a measurable version of $X . Y$ is adapted because the filtration is normal and hence $\mathscr{F}_{t}$ contains all sets of measure zero. Therefore, $Y(t)$ differs from $X(t)$ on a set which is $\mathscr{F}_{t}$ measurable.

There is a more specialized situation in which the measurability of a stochastic process automatically implies it is adapted. Furthermore, this can be defined easily in terms of a $\pi$ system of sets.

Definition 62.3.11 Let $\mathscr{F}_{t}$ be a filtration on $(\Omega, \mathscr{F}, P)$ and denote by $\mathscr{P}_{\infty}$ the smallest $\sigma$ algebra of sets of $[0, \infty) \times \Omega$ containing the sets

$$
(s, t] \times F, F \in \mathscr{F}_{s} \quad\{0\} \times F, F \in \mathscr{F}_{0} .
$$

This is called the predictable $\sigma$ algebra. and the sets in this $\sigma$ algebra are called the predictable sets. Denote by $\mathscr{P}_{T}$ the intersection of $\mathscr{P}_{\infty}$ to $[0, T] \times \Omega$. A stochastic process $X$ which maps either $[0, T] \times \Omega$ or $[0, \infty) \times \Omega$ to $E$, a separable real Banach space is called predictable if for every Borel set $A \in \mathscr{B}(E)$, it follows $X^{-1}(A) \in \mathscr{P}_{T}$ or $\mathscr{P}_{\infty}$.

This is a lot like product measure except one of the $\sigma$ algebras is changing.
Proposition 62.3.12 Let $\mathscr{F}_{t}$ be a filtration as above and let $X$ be a predictable stochastic process. Then $X$ is $\mathscr{F}_{t}$ adapted.

Proof: Let $s_{0}>0$ and define

$$
\mathscr{G}_{s_{0}} \equiv\left\{S \in \mathscr{P}_{\infty}: S_{s_{0}} \in \mathscr{F}_{s_{0}}\right\}
$$

where

$$
S_{s_{0}} \equiv\left\{\omega \in \Omega:\left(s_{0}, \omega\right) \in S\right\}
$$

It is clear $\mathscr{G}_{s_{0}}$ is a $\sigma$ algebra. The next step is to show $\mathscr{G}_{s_{0}}$ contains the sets

$$
\begin{equation*}
(s, t] \times F, F \in \mathscr{F}_{s} \tag{62.3.17}
\end{equation*}
$$

and

$$
\begin{equation*}
\{0\} \times F, F \in \mathscr{F}_{0} . \tag{62.3.18}
\end{equation*}
$$

It is clear $\{0\} \times F$ is contained in $\mathscr{G}_{s_{0}}$ because $(\{0\} \times F)_{s_{0}}=\emptyset \in \mathscr{F}_{s_{0}}$. Similarly, if $s \geq s_{0}$ or if $s, t<s_{0}$ then $((s, t] \times F)_{s_{0}}=\emptyset \in \mathscr{F}_{s_{0}}$. The only case left is for $s<s_{0}$ and $t \geq s_{0}$. In this case, letting $A_{s} \in \mathscr{F}_{s},\left((s, t] \times A_{s}\right)_{s_{0}}=A_{s} \in \mathscr{F}_{s} \subseteq \mathscr{F}_{s_{0}}$. Therefore, $\mathscr{G}_{s_{0}}$ contains all the sets of the form given in 62.3.17 and 62.3 .18 and so since $\mathscr{P}_{\infty}$ is the smallest $\sigma$ algebra containing these sets, it follows $\mathscr{P}_{\infty}=\mathscr{G}_{s_{0}}$. The case where $s_{0}=0$ is entirely similar but shorter.

Therefore, if $X$ is predictable, letting $A \in \mathscr{B}(E), X^{-1}(A) \in \mathscr{P}_{\infty}$ or $\mathscr{P}_{T}$ and so

$$
\left(X^{-1}(A)\right)_{s} \equiv\{\omega \in \Omega: X(s, \omega) \in A\}=X(s)^{-1}(A) \in \mathscr{F}_{s}
$$

showing $X(t)$ is $\mathscr{F}_{t}$ adapted. This proves the proposition.
Another way to see this is to recall the progressively measurable functions are adapted. Then show the predictable sets are progressively measurable.

Proposition 62.3.13 Let $\mathscr{P}$ denote the predictable $\sigma$ algebra and let $\mathscr{R}$ denote the progressively measurable $\sigma$ algebra. Then $\mathscr{P} \subseteq \mathscr{R}$.

Proof: Let $\mathscr{G}$ denote those sets of $\mathscr{P}$ such that they are also in $\mathscr{R}$. Then $\mathscr{G}$ clearly contains the $\pi$ system of sets $\{0\} \times A, A \in \mathscr{F}_{0}$, and $(s, t] \times A, A \in \mathscr{F}_{s}$. Furthermore, $\mathscr{G}$ is closed with respect to countable disjoint unions and complements. It follows $\mathscr{G}$ contains the $\sigma$ algebra generated by this $\pi$ systems which is $\mathscr{P}$. This proves the proposition.

Proposition 62.3.14 Let $X(t)$ be a stochastic process having values in $E$ a complete metric space and let it be $\mathscr{F}_{t}$ adapted and left continuous. Then it is predictable. Also, if $X(t)$ is stochastically continuous and adapted on $[0, T]$, then it has a predictable version.

Proof:Define $I_{m, k} \equiv\left((k-1) 2^{-m} T, k 2^{-m} T\right]$ if $k \geq 1$ and $I_{m, 0}=\{0\}$ if $k=1$. Then define

$$
\begin{aligned}
X_{m}(t) \equiv & \sum_{k=1}^{2^{m}} X\left(T(k-1) 2^{-m}\right) \mathscr{X}_{\left((k-1) 2^{-m} T, k 2^{-m} T\right]}(t) \\
& +X(0) \mathscr{X}_{[0,0]}(t)
\end{aligned}
$$

Here the sum means that $X_{m}(t)$ has value $X\left(T(k-1) 2^{-m}\right)$ on the interval

$$
\left((k-1) 2^{-m} T, k 2^{-m} T\right] .
$$

Thus $X_{m}$ is predictable because each term in the sum is. Thus

$$
\begin{aligned}
& X_{m}^{-1}(U)=\cup_{k=1}^{2^{m}}\left(X\left(T(k-1) 2^{-m}\right) \mathscr{X}_{\left((k-1) 2^{-m} T, k 2^{-m} T\right]}\right)^{-1}(U) \\
& =\cup_{k=1}^{2^{m}}\left((k-1) 2^{-m} T, k 2^{-m} T\right] \times\left(X\left(T(k-1) 2^{-m}\right)\right)^{-1}(U),
\end{aligned}
$$

a finite union of predictable sets. Since $X$ is left continuous,

$$
X(t, \omega)=\lim _{m \rightarrow \infty} X_{m}(t, \omega)
$$

and so $X$ is predictable.
Next consider the other claim. Since $X$ is stochastically continuous on $[0, T]$, it is uniformly stochastically continuous on this interval by Lemma 62.1.1. Therefore, there exists a sequence of partitions of $[0, T]$, the $m^{t h}$ being

$$
0=t_{m, 0}<t_{m, 1}<\cdots<t_{m, n(m)}=T
$$

such that for $X_{m}$ defined as above, then for each $t$

$$
\begin{equation*}
P\left(\left[d\left(X_{m}(t), X(t)\right) \geq 2^{-m}\right]\right) \leq 2^{-m} \tag{62.3.19}
\end{equation*}
$$

Then as above, $X_{m}$ is predictable. Let $A$ denote those points of $\mathscr{P}_{T}$ at which $X_{m}(t, \omega)$ converges. Thus $A$ is a predictable set because it is just the set where $X_{m}(t, \omega)$ is a Cauchy sequence. Now define the predictable function $Y$

$$
Y(t, \omega) \equiv\left\{\begin{array}{l}
\lim _{m \rightarrow \infty} X_{m}(t, \omega) \text { if }(t, \omega) \in A \\
0 \text { if }(t, \omega) \notin A
\end{array}\right.
$$

From 62.3 .19 it follows from the Borel Cantelli lemma that for fixed $t$, the set of $\omega$ which are in infinitely many of the sets,

$$
\left[d\left(X_{m}(t), X(t)\right) \geq 2^{-m}\right]
$$

has measure zero. Therefore, for each $t$, there exists a set of measure zero, $N(t)$ such that for $\omega \notin N(t)$ and all $m$ large enough

$$
d\left(X_{m}(t, \omega), X(t, \omega)\right)<2^{-m}
$$

Hence for $\omega \notin N(t),(t, \omega) \in A$ and so $X_{m}(t, \omega) \rightarrow Y(t, \omega)$ which shows

$$
d(Y(t, \omega), X(t, \omega))=0 \text { if } \omega \notin N(t) .
$$

The predictable version of $X(t)$ is $Y(t)$.
Here is a summary of what has been shown above.

> adapted and left continuous
> $\Downarrow$
> predictable
> $\Downarrow$
> progressively measurable
> $\Downarrow$
> adapted

Also
stochastically continuous and adapted $\Longrightarrow$ progressively measurable version

### 62.4 Martingales

Definition 62.4.1 Let $X$ be a stochastic process defined on an interval, I with values in a separable Banach space, $E$. It is called integrable if $E(\|X(t)\|)<\infty$ for each $t \in I$. Also let $\mathscr{F}_{t}$ be a filtration. An integrable and adapted stochastic process $X$ is called a martingale if for $s \leq t$

$$
E\left(X(t) \mid \mathscr{F}_{s}\right)=X(s) P \text { a.e. } \omega .
$$

Recalling the definition of conditional expectation this says that for $F \in \mathscr{F}_{s}$

$$
\int_{F} X(t) d P=\int_{F} E\left(X(t) \mid \mathscr{F}_{s}\right) d P=\int_{F} X(s) d P
$$

for all $F \in \mathscr{F}_{s}$. A real valued stochastic process is called a submartingale if whenever $s \leq t$,

$$
E\left(X(t) \mid \mathscr{F}_{s}\right) \geq X(s) \text { a.e. }
$$

and a supermartingale if

$$
E\left(X(t) \mid \mathscr{F}_{s}\right) \leq X(s) \text { a.e. }
$$

Example 62.4.2 Let $\mathscr{F}_{t}$ be a filtration and let $Z$ be in $L^{1}\left(\Omega, \mathscr{F}_{T}, P\right)$. Then let $X(t)=$ $E\left(Z \mid \mathscr{F}_{t}\right)$.

This works because for $s<t, E\left(X(t) \mid \mathscr{F}_{s}\right)=E\left(E\left(Z \mid \mathscr{F}_{t}\right) \mid \mathscr{F}_{s}\right)=E\left(Z \mid \mathscr{F}_{s}\right)=X(s)$.
Proposition 62.4.3 The following statements hold for a stochastic process defined on the product $[0, T] \times \Omega$ having values in a real separable Banach space, $E$.

1. If $X(t)$ is a martingale then $\|X(t)\|, t \in[0, T]$ is a submartingale.
2. If $g$ is an increasing convex function from $[0, \infty)$ to $[0, \infty)$ and $E(g(\|X(t)\|))<\infty$ for all $t \in[0, T]$ then then $g(\|X(t)\|), t \in[0, T]$ is a submartingale.

Proof:Let $s \leq t$

$$
\begin{aligned}
\|X(s)\| & =\left\|E\left(X(s)-X(t) \mid \mathscr{F}_{s}\right)+E\left(X(t) \mid \mathscr{F}_{s}\right)\right\| \\
& \leq \overbrace{\left\|E\left(X(s)-X(t) \mid \mathscr{F}_{s}\right)\right\|}^{=0 \text { a.e. }}+\left\|E\left(X(t) \mid \mathscr{F}_{s}\right)\right\| \\
& \leq\left\|E\left(X(t) \mid \mathscr{F}_{s}\right)\right\| .
\end{aligned}
$$

Now by Theorem 61.1.1 on Page 1983

$$
\left\|E\left(X(t) \mid \mathscr{F}_{s}\right)\right\| \leq E\left(\|X(t)\| \mid \mathscr{F}_{s}\right) .
$$

Thus $\|X(s)\| \leq E\left(\|X(t)\| \mid \mathscr{F}_{s}\right)$ which shows $\|X\|$ is a submartingale as claimed.
Consider the second claim. Recall Jensen's inequality for submartingales, Theorem 60.1.6 on Page 1946. From the first part

$$
\|X(s)\| \leq E\left(\|X(t)\| \mathscr{F}_{s}\right) \text { a.e. }
$$

and so from Jensen's inequality,

$$
g(\|X(s)\|) \leq g\left(E\left(\|X(t)\| \mid \mathscr{F}_{s}\right)\right) \leq E\left(g(\|X(t)\|) \mid \mathscr{F}_{s}\right) \text { a.e. }
$$

showing that $g(\|X(t)\|)$ is also a submartingale. This proves the proposition.

### 62.5 Some Maximal Estimates

Martingales and submartingales have some very interesting maximal estimates. I will present some of these here. The proofs are fairly general and do not require the filtration to be normal.

Lemma 62.5.1 Let $\left\{\mathscr{F}_{t}\right\}$ be a filtration and let $\{X(t)\}$ be a nonnegative valued submartingale for $t \in[S, T]$. Then for $\lambda>0$ and any $p \geq 1$, if $A_{t}$ is a $\mathscr{F}_{t}$ measurable subset of $[X(t) \geq \lambda]$, then

$$
P\left(A_{t}\right) \leq \frac{1}{\lambda^{p}} \int_{A_{t}} X(T)^{p} d P
$$

Proof: From Jensen's inequality,

$$
\begin{aligned}
\lambda^{p} P\left(A_{t}\right) & \leq \int_{A_{t}} X(t)^{p} d P \leq \int_{A_{t}} E\left(X(T) \mid \mathscr{F}_{t}\right)^{p} d P \\
& \leq \int_{A_{t}} E\left(X(T)^{p} \mid \mathscr{F}_{t}\right) d P=\int_{A_{t}} X(T)^{p} d P
\end{aligned}
$$

and this proves the lemma.
The following theorem is the main result.
Theorem 62.5.2 Let $\left\{\mathscr{F}_{t}\right\}$ be a filtration and let $\{X(t)\}$ be a nonnegative valued right continuous ${ }^{1}$ submartingale for $t \in[S, T]$. Then for all $\lambda>0$ and $p \geq 1$, for

$$
\begin{gathered}
X^{*} \equiv \sup _{t \in[S, T]} X(t), \\
P\left(\left[X^{*} \geq \lambda\right]\right) \leq \frac{1}{\lambda^{p}} \int_{\Omega} \mathscr{X}_{\left[X^{*} \geq \lambda\right]} X(T)^{p} d P
\end{gathered}
$$

In the case that $p>1$, it is also true that

$$
E\left(\left(X^{*}\right)^{p}\right) \leq\left(\frac{p}{p-1}\right) E\left(X(T)^{p}\right)^{1 / p}\left(E\left(\left(X^{*}\right)^{p}\right)\right)^{1 / p^{\prime}}
$$

Also there are no measurability issues related to the above $\sup _{t \in[S, T]} X(t) \equiv X^{*}$
Proof: Let $S \leq t_{0}^{m}<t_{1}^{m}<\cdots<t_{N_{m}}^{m}=T$ where $t_{j+1}^{m}-t_{j}^{m}=(T-S) 2^{-m}$. First consider $m=1$.

$$
\begin{gathered}
A_{t_{0}^{1}} \equiv\left\{\omega \in \Omega: X\left(t_{0}^{1}\right)(\omega) \geq \lambda\right\}, A_{t_{1}^{1}} \equiv\left\{\omega \in \Omega: X\left(t_{1}^{1}\right)(\omega) \geq \lambda\right\} \backslash A_{t_{0}^{1}} \\
A_{t_{2}^{1}} \equiv\left\{\omega \in \Omega: X\left(t_{2}^{1}\right)(\omega) \geq \lambda\right\} \backslash\left(A_{t_{0}^{1}} \cup A_{t_{0}^{1}}\right)
\end{gathered}
$$

Do this type of construction for $m=2,3,4, \cdots$ yielding disjoint sets, $\left\{A_{t_{j}^{m}}\right\}_{j=0}^{2^{m}}$ whose union equals

$$
\cup_{t \in D_{m}}[X(t) \geq \lambda]
$$

where $D_{m}=\left\{t_{j}^{m}\right\}_{j=0}^{2^{m}}$. Thus $D_{m} \subseteq D_{m+1}$. Then also, $D \equiv \cup_{m=1}^{\infty} D_{m}$ is dense and countable. From Lemma 62.5.1,

$$
\begin{aligned}
P\left(\cup_{t \in D_{m}}[X(t) \geq \lambda]\right) & =P\left(\sup _{t \in D_{m}} X(t) \geq \lambda\right)=\sum_{j=0}^{2^{m}} P\left(A_{t_{j}^{m}}\right) \\
& \leq \frac{1}{\lambda^{p}} \sum_{j=0}^{2^{m}} \int_{A_{t_{j}^{m}}} \mathscr{X}_{\left[\sup _{t \in D_{m}} X(t) \geq \lambda\right]} X(T)^{p} d P \\
& \leq \frac{1}{\lambda^{p}} \int_{\Omega} \mathscr{X}_{\left[\sup _{t \in D} X(t) \geq \lambda\right]} X(T)^{p} d P .
\end{aligned}
$$

${ }^{1} t \rightarrow M(t)(\omega)$ is continuous from the right for a.e. $\omega$.

Let $m \rightarrow \infty$ in the above to obtain

$$
\begin{equation*}
P\left(\cup_{t \in D}[X(t) \geq \lambda]\right)=P\left(\left[\sup _{t \in D} X(t) \geq \lambda\right]\right) \leq \frac{1}{\lambda^{p}} \int_{\Omega} \mathscr{X}_{\left[\sup _{t \in D} X(t) \geq \lambda\right]} X(T)^{p} d P \tag{62.5.20}
\end{equation*}
$$

From now on, assume that for a.e. $\omega \in \Omega, t \rightarrow X(t)(\omega)$ is right continuous. Then with this assumption, the following claim holds.

$$
\sup _{t \in[S, T]} X(t) \equiv X^{*}=\sup _{t \in D} X(t)
$$

which verifies that $X^{*}$ is measurable. Then from 62.5.20,

$$
\begin{aligned}
P\left(\left[X^{*} \geq \lambda\right]\right) & =P\left(\left[\sup _{t \in D} X(t) \geq \lambda\right]\right) \\
& \leq \frac{1}{\lambda^{p}} \int_{\Omega} \mathscr{X}_{\left[\sup _{t \in D} X(t) \geq \lambda\right]} X(T)^{p} d P \\
& =\frac{1}{\lambda^{p}} \int_{\Omega} \mathscr{X}_{\left[X^{*} \geq \lambda\right]} X(T)^{p} d P
\end{aligned}
$$

Now consider the other inequality. Using the distribution function technique and the above estimate obtained in the first part,

$$
\begin{aligned}
& E\left(\left(X^{*}\right)^{p}\right)=\int_{0}^{\infty} p \alpha^{p-1} P\left(\left[X^{*}>\alpha\right]\right) d \alpha \\
& \leq \int_{0}^{\infty} p \alpha^{p-1} P\left(\left[X^{*} \geq \alpha\right]\right) d \alpha \\
& \leq \int_{0}^{\infty} p \alpha^{p-1} \frac{1}{\alpha} \int_{\Omega} \mathscr{X}_{\left[X^{*} \geq \alpha\right]} X(T) d P d \alpha \\
& =p \int_{\Omega} \int_{0}^{X^{*}} \alpha^{p-2} d \alpha X(T) d P \\
& =\frac{p}{p-1} \int_{\Omega}\left(X^{*}\right)^{p-1} X(T) d P \\
& \leq \frac{p}{p-1}\left(\int_{\Omega}\left(X^{*}\right)^{p}\right)^{1 / p^{\prime}}\left(\int_{\Omega} X(T)^{p}\right)^{1 / p} \\
& =\frac{p}{p-1} E\left(X(T)^{p}\right)^{1 / p} E\left(\left(X^{*}\right)^{p}\right)^{1 / p^{\prime}} . \square
\end{aligned}
$$

Of course it would be nice to divide both sides by $E\left(\left(X^{*}\right)^{p}\right)^{1 / p^{\prime}}$ but we don't know that this is finite. One can use a stopped submartingale which will have $X(t)$ bounded, divide, and then let the stopping time increase to $\infty$. However, this is discussed later.

With Theorem 62.5.2, here is an important maximal estimate for martingales having values in $E$, a real separable Banach space.

Theorem 62.5.3 Let $X(t)$ for $t \in I=[0, T]$ be an $E$ valued right continuous martingale with respect to a filtration, $\mathscr{F}_{t}$. Then for $p \geq 1$,

$$
\begin{equation*}
P\left(\left[\sup _{t \in I}\|X(t)\| \geq \lambda\right]\right) \leq \frac{1}{\lambda^{p}} E\left(\|X(T)\|^{p}\right) \tag{62.5.21}
\end{equation*}
$$

If $p>1$,

$$
\begin{equation*}
E\left(\left(\sup _{t \in[S, T]}\|X(t)\|\right)^{p}\right) \leq\left(\frac{p}{p-1}\right) E\left(\|X(T)\|^{p}\right)^{1 / p} E\left(\left(\sup _{t \in[S, T]}\|X(t)\|\right)^{p}\right)^{1 / p^{\prime}} \tag{62.5.22}
\end{equation*}
$$

Proof: By Proposition 62.4.3 $\|X(t)\|, t \in I$ is a submartingale and so from Theorem 62.5.2, it follows 62.5.21 and 62.5.22 hold.

Definition 62.5.4 Let $K$ be a set of functions of $L^{1}(\Omega, \mathscr{F}, P)$. Then $K$ is called equi integrable if

$$
\limsup _{\lambda \rightarrow \infty} \int_{f \in K} \int_{[|f| \geq \lambda]}|f| d P=0
$$

Recall that from Corollary 20.9.6 on Page 640 such an equi integrable set of functions is weakly sequentially precompact in $L^{1}(\Omega, \mathscr{F}, P)$ in the sense that if $\left\{f_{n}\right\} \subseteq K$, there exists a subsequence, $\left\{f_{n_{k}}\right\}$ and a function, $f \in L^{1}(\Omega, \mathscr{F}, P)$ such that for all $g \in L^{1}(\Omega, \mathscr{F}, P)^{\prime}$,

$$
g\left(f_{n_{k}}\right) \rightarrow g(f)
$$

### 62.6 Optional Sampling Theorems

### 62.6.1 Stopping Times And Their Properties

The optional sampling theorem is very useful in the study of martingales and submartingales as will be shown.

First it is necessary to define the notion of a stopping time.
Definition 62.6.1 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $\left\{\mathscr{F}_{n}\right\}_{n=1}^{\infty}$ be an increasing sequence of $\sigma$ algebras each contained in $\mathscr{F}$, called a discrete filtration. A stopping time is a measurable function, $\tau$ which maps $\Omega$ to $\mathbb{N}$,

$$
\tau^{-1}(A) \in \mathscr{F} \text { for all } A \in \mathscr{P}(\mathbb{N})
$$

such that for all $n \in \mathbb{N}$,

$$
[\tau \leq n] \in \mathscr{F}_{n}
$$

Note this is equivalent to saying

$$
[\tau=n] \in \mathscr{F}_{n}
$$

because

$$
[\tau=n]=[\tau \leq n] \backslash[\tau \leq n-1] .
$$

For $\tau$ a stopping time define $\mathscr{F}_{\tau}$ as follows.

$$
\mathscr{F}_{\tau} \equiv\left\{A \in \mathscr{F}: A \cap[\tau \leq n] \in \mathscr{F}_{n} \text { for all } n \in \mathbb{N}\right\}
$$

These sets in $\mathscr{F}_{\tau}$ are referred to as "prior" to $\tau$.
The most important example of a stopping time is the first hitting time.
Example 62.6.2 The first hitting time of an adapted process $X(n)$ of a Borel set $G$ is a stopping time. This is defined as

$$
\tau \equiv \min \{k: X(k) \in G\}
$$

To see this, note that

$$
[\tau=n]=\cap_{k<n}\left[X(k) \in G^{C}\right] \cap[X(n) \in G] \in \mathscr{F}_{n}
$$

Proposition 62.6.3 For $\tau$ a stopping time, $\mathscr{F}_{\tau}$ is a $\sigma$ algebra and if $Y(k)$ is $\mathscr{F}_{k}$ measurable for all $k, Y(k)$ having values in a separable Banach space $E$, then

$$
\omega \rightarrow Y(\tau(\omega))
$$

is $\mathscr{F}_{\tau}$ measurable.
Proof: Let $A_{n} \in \mathscr{F}_{\tau}$. I need to show $\cup_{n} A_{n} \in \mathscr{F}_{\tau}$. In other words, I need to show that

$$
\cup_{n} A_{n} \cap[\tau \leq k] \in \mathscr{F}_{k}
$$

The left side equals

$$
\cup_{n}\left(A_{n} \cap[\tau \leq k]\right)
$$

which is a countable union of sets of $\mathscr{F}_{k}$ and so $\mathscr{F}_{\tau}$ is closed with respect to countable unions. Next suppose $A \in \mathscr{F} \tau$.

$$
\left(A^{C} \cap[\tau \leq k]\right) \cup(A \cap[\tau \leq k])=\Omega \cap[\tau \leq k]
$$

and $\Omega \cap[\tau \leq k] \in \mathscr{F}_{k}$. Therefore, so is $A^{C} \cap[\tau \leq k]$.
It remains to verify the last claim. Let $B$ be an open set in $E$. Is

$$
[Y(\tau) \in B] \in \mathscr{F}_{\tau} ?
$$

Is

$$
[Y(\tau) \in B] \cap[\tau \leq k] \in \mathscr{F}_{k} \text { for all } k ?
$$

This equals

$$
\cup_{i=1}^{k}[Y(\tau) \in B] \cap[\tau=i]=\cup_{i=1}^{k}[Y(i) \in B] \cap[\tau=i] \in \mathscr{F}_{k}
$$

Therefore, $Y(\tau)$ must be $\mathscr{F}_{\tau}$ measurable.
The following lemma contains the fundamental properties of stopping times for discrete filtrations.

Lemma 62.6.4 In the situation of Definition 62.6.1, let $\sigma, \tau$ be two stopping times. Then

1. $\tau$ is $\mathscr{F}_{\tau}$ measurable
2. $\mathscr{F}_{\sigma} \cap[\sigma \leq \tau] \subseteq \mathscr{F}_{\sigma \wedge \tau}=\mathscr{F}_{\sigma} \cap \mathscr{F}_{\tau}$
3. $\mathscr{F}_{\tau}=\mathscr{F}_{k}$ on $[\tau=k]$ for all $k$. That is if $A \in \mathscr{F}_{k}$, then $A \cap[\tau=k] \in \mathscr{F}_{\tau}$ and if $A \in \mathscr{F}_{\tau}$, then $A \cap[\tau=k] \in \mathscr{F}_{k}$. In other words, the two $\sigma$ algebras

$$
[\tau=k] \cap \mathscr{F}_{\tau},[\tau=k] \cap \mathscr{F}_{k}
$$

are equal. Letting $\mathscr{G}$ denote this $\sigma$ algebra, if $g$ is either $\mathscr{F}_{\tau}$ or $\mathscr{F}_{k}$ measurable then its restriction to $[\tau=k]$ is $\mathscr{G}$ measurable. Also if $A \in \mathscr{F}_{\tau}$, and $Y \in L^{1}(\Omega ; E)$,

$$
\int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{\tau}\right) d P=\int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{k}\right) d P
$$

and

$$
E\left(Y \mid \mathscr{F}_{\tau}\right)=E\left(Y \mid \mathscr{F}_{k}\right) \text { a.e. }
$$

on $[\tau=k]$.
Proof: Consider the first claim. $[\tau \leq l] \cap[\tau \leq m]=[\tau \leq\lfloor l\rfloor \wedge m] \in \mathscr{F}_{[l] \wedge m} \subseteq \mathscr{F}_{m}$ and so $\tau$ is $\mathscr{F} \tau$ measurable. Here $\lfloor l\rfloor$ is the greatest integer less than or equal to $l$. Next note that $\sigma \wedge \tau$ is a stopping time because

$$
[\sigma \wedge \tau \leq k]=[\sigma \leq k] \cup[\tau \leq k] \in \mathscr{F}_{k}
$$

Next consider the second claim. Let $A \in \mathscr{F} \sigma$. I want to show

$$
\begin{equation*}
A \cap[\sigma \leq \tau] \in \mathscr{F} \tau \wedge \sigma \tag{62.6.23}
\end{equation*}
$$

In other words, I want to show

$$
\begin{equation*}
A \cap[\sigma \leq \tau] \cap[\tau \wedge \sigma \leq k] \in \mathscr{F}_{k} \tag{62.6.24}
\end{equation*}
$$

for all $k$. However, the set on the left equals

$$
\begin{aligned}
& A \cap[\sigma \leq \tau] \cap[\sigma \leq k] \\
= & \cup_{j=1}^{k} A \cap[\sigma=j] \cap[\tau \geq j] \cap[\sigma \leq k] \\
= & \cup_{j=1}^{k} A \cap[\sigma=j] \cap[\tau \leq j-1]^{C} \cap[\sigma \leq k] \in \mathscr{F}_{k}
\end{aligned}
$$

Now let $A \in \mathscr{F}_{\sigma \wedge \tau}$. I want to show it is in both $\mathscr{F}_{\tau}$ and $\mathscr{F}_{\sigma}$. To show it is in $\mathscr{F}_{\tau}$ I need to show that

$$
A \cap[\tau \leq k] \in \mathscr{F}_{k}
$$

for all $k$. However,

$$
A \cap[\tau=k]=\cup_{i=1}^{\infty} A \cap[\sigma=i] \cap[\tau=k]
$$

$$
\begin{aligned}
& =\cup_{i=1}^{k-1} \overbrace{A \cap[\sigma \wedge \tau=i]}^{\in \mathscr{F}_{i}} \cap \overbrace{[\tau=k]}^{\in \mathscr{F}_{k}} \cup \cup_{i=k}^{\infty} A \cap[\sigma=i] \cap[\tau=k] \\
& =\cup_{i=1}^{k-1} \overbrace{A \cap[\sigma \wedge \tau=i]}^{\in \mathscr{F}_{i}} \cap \overbrace{[\tau=k]}^{\in \mathscr{F}_{k}} \cup \overbrace{A \cap[\sigma \wedge \tau=k]}^{\in \mathscr{F}_{k}} \cap\left[\begin{array}{c}
\in=k]
\end{array}\right.
\end{aligned}
$$

and so this is in $\mathscr{F}_{k}$. Thus $A \cap[\tau \leq k] \in \mathscr{F}_{k}$ being the finite union of sets which are. Similarly $A \cap[\sigma \leq k] \in \mathscr{F}_{k}$ for all $k$ and so $A \in \mathscr{F}_{\tau} \cap \mathscr{F}_{\sigma}$.

Next let $A \in \mathscr{F}_{\tau} \cap \mathscr{F}_{\sigma}$. Then is it in $\mathscr{F}_{\sigma \wedge \tau}$ ? Is $A \cap[\sigma \wedge \tau \leq k] \in \mathscr{F}_{k}$ ? Of course this is so because

$$
\begin{aligned}
& A \cap[\sigma \wedge \tau \leq k]=A \cap([\sigma \leq k] \cup[\tau \leq k]) \\
& \quad=(A \cap[\sigma \leq k]) \cup(A \cap[\tau \leq k]) \in \mathscr{F}_{k}
\end{aligned}
$$

since both $\sigma, \tau$ are stopping times. This proves part 2.).
Now consider part 3.). Note that $[\tau=k]$ is in both $\mathscr{F}_{k}$ and $\mathscr{F}_{\tau}$. First consider the claim it is in $\mathscr{F}_{\tau}$.

$$
[\tau=k] \cap[\tau \leq l]=\emptyset \text { if } l<k
$$

which is in $\mathscr{F}_{l}$. If $l \geq k$, it reduces to $[\tau=k] \in \mathscr{F}_{k} \subseteq \mathscr{F}_{l}$ so it is in $\mathscr{F}_{\tau} .[\tau=k]$ is obviously in $\mathscr{F}_{k}$.

I need to show

$$
\mathscr{F}_{\tau} \cap[\tau=k]=\mathscr{F}_{k} \cap[\tau=k]
$$

where $\mathscr{H} \cap[\tau=k]$ means all sets of the form $A \cap[\tau=k]$ where $A \in \mathscr{H}$. Let $A \in \mathscr{F} \tau$. Then

$$
A \cap[\tau=k]=(A \cap[\tau \leq k]) \backslash(A \cap[\tau \leq k-1]) \in \mathscr{F}_{k}
$$

Therefore, there exists $B \in \mathscr{F}_{k}$ such that $B=A \cap[\tau=k]$ and so

$$
B \cap[\tau=k]=A \cap[\tau=k]
$$

which shows $\mathscr{F}_{\tau} \cap[\tau=k] \subseteq \mathscr{F}_{k} \cap[\tau=k]$. Now let $A \in \mathscr{F}_{k}$ so that

$$
A \cap[\tau=k] \in \mathscr{F}_{k} \cap[\tau=k]
$$

Then

$$
A \cap[\tau=k] \cap[\tau \leq j] \in \mathscr{F}_{j}
$$

because in case $j<k$, the set on the left is $\emptyset$ and if $j \geq k$ it reduces to $A \cap[\tau=k]$ and both $A$ and $[\tau=k]$ are in $\mathscr{F}_{k} \subseteq \mathscr{F}_{j}$. Thus $A \cap[\tau=k]=B \in \mathscr{F}_{\tau}$ and so

$$
A \cap[\tau=k]=B \cap[\tau=k] \in \mathscr{F}_{\tau} \cap[\tau=k] .
$$

Therefore, the two $\sigma$ algebras of subsets of $[\tau=k]$,

$$
\mathscr{F}_{\tau} \cap[\tau=k], \mathscr{F}_{k} \cap[\tau=k]
$$

are equal. Thus for $A$ in either $\mathscr{F}_{\tau}$ or $\mathscr{F}_{k}, A \cap[\tau=k]$ is a set of both $\mathscr{F}_{\tau}$ and $\mathscr{F}_{k}$ because if $A \in \mathscr{F}_{k}$, then from the above, there exists $B \in \mathscr{F}_{\tau}$ such that

$$
A \cap[\tau=k]=B \cap \overbrace{[\tau=k]}^{\in \mathscr{F}_{\tau} \cap \mathscr{F}_{k}} \in \mathscr{F}_{\tau}
$$

with similar reasoning holding if $A \in \mathscr{F}_{\tau}$. In other words, if $g$ is $\mathscr{F}_{\tau}$ or $\mathscr{F}_{k}$ measurable, then the restriction of $g$ to $[\tau=k]$ is measurable with respect to $\mathscr{F}_{\tau} \cap[\tau=k]$ and $\mathscr{F}_{k} \cap[\tau=k]$. Let $Y$ be an arbitrary random variable in $L^{1}(\Omega, \mathscr{F})$. It follows, since $A \cap[\tau=k]$ is in both $\mathscr{F}_{\tau}$ and $\mathscr{F}_{k}$,

$$
\begin{aligned}
\int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{\tau}\right) d P & \equiv \int_{A \cap[\tau=k]} Y d P \\
& \equiv \int_{A \cap[\tau=k]} E\left(Y \mid \mathscr{F}_{k}\right) d P
\end{aligned}
$$

Since this holds for an arbitrary set in $\mathscr{F}_{\tau} \cap[\tau=k]=\mathscr{F}_{k} \cap[\tau=k]$, it follows

$$
E\left(Y \mid \mathscr{F}_{\tau}\right)=E\left(Y \mid \mathscr{F}_{k}\right) \text { a.e. on }[\tau=k]
$$

The assertion that

$$
E\left(Y \mid \mathscr{F}_{\tau}\right)=E\left(Y \mid \mathscr{F}_{k}\right) \text { a.e. }
$$

on $[\tau=k]$ and that a function $g$ which is $\mathscr{F}_{\tau}$ or $\mathscr{F}_{k}$ measurable when restricted to $[\tau=k]$ is $\mathscr{G}$ measurable for

$$
\mathscr{G}=[\tau=k] \cap \mathscr{F}_{\tau}=[\tau=k] \cap \mathscr{F}_{k}
$$

is the main result in the above lemma and this fact leads to the amazing Doob optional sampling theorem below. Also note that if $Y(k)$ is any process defined on the positive integers $k$, then by definition, $Y(k)(\omega)=Y(\tau(\omega))(\omega)$ on the set $[\tau=k]$ because $\tau$ is constant on this set.

### 62.6.2 Doob Optional Sampling Theorem

With this lemma, here is a major theorem, the optional sampling theorem of Doob. This one is for martingales having values in a Banach space. To begin with, consider the case of a martingale defined on a countable set.

Theorem 62.6.5 Let $\{M(k)\}$ be a martingale having values in E a separable real Banach space with respect to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{k}\right\}$ and let $\sigma, \tau$ be two stopping times such that $\tau$ is bounded. Then $M(\tau)$ defined as

$$
\omega \rightarrow M(\tau(\omega))
$$

is integrable and

$$
M(\sigma \wedge \tau)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Proof: By Proposition 62.6.3 $M(\tau)$ is $\mathscr{F}_{\tau}$ measurable.
Next note that since $\tau$ is bounded by some $l$,

$$
\int_{\Omega}\|M(\tau(\omega))\| d P \leq \sum_{i=1}^{l} \int_{[\tau=i]}\|M(i)\| d P<\infty .
$$

This proves the first assertion and makes possible the consideration of conditional expectation.

Let $l \geq \tau$ as described above. Then for $k \leq l$, by Lemma 62.6.4,

$$
\mathscr{F}_{k} \cap[\tau=k]=\mathscr{F}_{\tau} \cap[\tau=k] \equiv \mathscr{G}
$$

implying that if $g$ is either $\mathscr{F}_{k}$ measurable or $\mathscr{F}_{\tau}$ measurable, then its restriction to $[\tau=k]$ is $\mathscr{G}$ measurable and so if $A \in \mathscr{F}_{k} \cap[\tau=k]=\mathscr{F}_{\tau} \cap[\tau=k]$,

$$
\begin{aligned}
\int_{A} E\left(M(l) \mid \mathscr{F}_{\tau}\right) d P & \equiv \int_{A} M(l) d P \\
& =\int_{A} E\left(M(l) \mid \mathscr{F}_{k}\right) d P \\
& =\int_{A} M(k) d P \\
& =\int_{A} M(\tau) d P(\text { on } A, \tau=k)
\end{aligned}
$$

Therefore, since $A$ was arbitrary,

$$
E\left(M(l) \mid \mathscr{F}_{\tau}\right)=M(\tau) \text { a.e. }
$$

on $[\tau=k]$ for every $k \leq l$. It follows

$$
E\left(M(l) \mid \mathscr{F}_{\tau}\right)=M(\tau) \text { a.e. }
$$

since it is true on each $[\tau=k]$ for all $k \leq l$.
Now consider $E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)$ on the set $[\sigma=i] \cap[\tau=j]$. By Lemma 62.6.4, on this set,

$$
E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)=E\left(M(\tau) \mid \mathscr{F}_{i}\right)=E\left(E\left(M(l) \mid \mathscr{F}_{\tau}\right) \mid \mathscr{F}_{i}\right)=E\left(E\left(M(l) \mid \mathscr{F}_{j}\right) \mid \mathscr{F}_{i}\right)
$$

If $j \leq i$, this reduces to

$$
E\left(M(l) \mid \mathscr{F}_{j}\right)=M(j)=M(\sigma \wedge \tau)
$$

If $j>i$, this reduces to

$$
E\left(M(l) \mid \mathscr{F}_{i}\right)=M(i)=M(\sigma \wedge \tau)
$$

and since this exhausts all possibilities for values of $\sigma$ and $\tau$, it follows

$$
E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)=M(\sigma \wedge \tau) \text { a.e. }
$$

You can also give a version of the above to submartingales. This requires the following very interesting decomposition of a submartingale into the sum of an increasing stochastic process and a martingale.

Theorem 62.6.6 Let $\left\{X_{n}\right\}$ be a submartingale. Then there exists a unique stochastic process, $\left\{A_{n}\right\}$ and martingale, $\left\{M_{n}\right\}$ such that

1. $A_{n}(\omega) \leq A_{n+1}(\omega), A_{1}(\omega)=0$,
2. $A_{n}$ is $\mathscr{F}_{n-1}$ adapted for all $n \geq 1$ where $\mathscr{F}_{0} \equiv \mathscr{F}_{1}$.
and also $X_{n}=M_{n}+A_{n}$.
Proof: Let $A_{1} \equiv 0$ and define

$$
A_{n} \equiv \sum_{k=2}^{n} E\left(X_{k}-X_{k-1} \mid \mathscr{F}_{k-1}\right) .
$$

It follows $A_{n}$ is $\mathscr{F}_{n-1}$ measurable. Since $\left\{X_{k}\right\}$ is a submartingale, $A_{n}$ is increasing because

$$
\begin{equation*}
A_{n+1}-A_{n}=E\left(X_{n+1}-X_{n} \mid \mathscr{F}_{n}\right) \geq 0 \tag{62.6.25}
\end{equation*}
$$

It is a submartingale because

$$
\begin{aligned}
E\left(A_{n} \mid \mathscr{F}_{n-1}\right) & =E\left(\sum_{k=2}^{n} E\left(X_{k}-X_{k-1} \mid \mathscr{F}_{k-1}\right) \mid \mathscr{F}_{n-1}\right) \\
& =\sum_{k=2}^{n} E\left(X_{k}-X_{k-1} \mid \mathscr{F}_{k-1}\right) \equiv A_{n} \geq A_{n-1}
\end{aligned}
$$

Now let $M_{n}$ be defined by

$$
X_{n}=M_{n}+A_{n} .
$$

Then from 62.6.25,

$$
\begin{aligned}
& E\left(M_{n+1} \mid \mathscr{F}_{n}\right)=E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(A_{n+1} \mid \mathscr{F}_{n}\right) \\
= & E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(A_{n+1}-A_{n} \mid \mathscr{F}_{n}\right)-A_{n} \\
= & E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(E\left(X_{n+1}-X_{n} \mid \mathscr{F}_{n}\right) \mid \mathscr{F}_{n}\right)-A_{n} \\
= & E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(X_{n+1}-X_{n} \mid \mathscr{F}_{n}\right)-A_{n} \\
= & E\left(X_{n} \mid \mathscr{F}_{n}\right)-A_{n} \\
= & X_{n}-A_{n} \equiv M_{n}
\end{aligned}
$$

This proves the existence part.
It remains to verify uniqueness. Suppose then that

$$
X_{n}=M_{n}+A_{n}=M_{n}^{\prime}+A_{n}^{\prime}
$$

where $\left\{A_{n}\right\}$ and $\left\{A_{n}^{\prime}\right\}$ both satisfy the conditions of the theorem and $\left\{M_{n}\right\}$ and $\left\{M_{n}^{\prime}\right\}$ are both martingales. Then

$$
M_{n}-M_{n}^{\prime}=A_{n}^{\prime}-A_{n}
$$

and so, since $A_{n}^{\prime}-A_{n}$ is $\mathscr{F}_{n-1}$ measurable and $\left\{M_{n}-M_{n}^{\prime}\right\}$ is a martingale,

$$
\begin{aligned}
M_{n-1}-M_{n-1}^{\prime} & =E\left(M_{n}-M_{n}^{\prime} \mid \mathscr{F}_{n-1}\right) \\
& =E\left(A_{n}^{\prime}-A_{n} \mid \mathscr{F}_{n-1}\right) \\
& =A_{n}^{\prime}-A_{n}=M_{n}-M_{n}^{\prime} .
\end{aligned}
$$

Continuing this way shows $M_{n}-M_{n}^{\prime}$ is a constant. However, since $A_{1}^{\prime}-A_{1}=0=M_{1}-M_{1}^{\prime}$, it follows $M_{n}=M_{n}^{\prime}$ and this proves uniqueness.

Now here is a version of the optional sampling theorem for submartingales.

Theorem 62.6.7 Let $\{X(k)\}$ be a real valued submartingale with respect to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{k}\right\}$ and let $\sigma \leq \tau$ be two stopping times such that $\tau$ is bounded. Then $M(\tau)$ defined as

$$
\omega \rightarrow X(\tau(\omega))
$$

is integrable and

$$
X(\sigma) \leq E\left(X(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Without assuming $\sigma \leq \tau$, one can write

$$
X(\sigma \wedge \tau) \leq E\left(X(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Proof: That $\omega \rightarrow X(\tau(\omega))$ is integrable follows right away as in the optional sampling theorem for martingales. You just consider the finitely many values of $\tau$.

Use Theorem 62.6.6 above to write

$$
X(n)=M(n)+A(n)
$$

where $M$ is a martingale and $A$ is increasing with $A(n)$ being $\mathscr{F}_{n-1}$ measurable and $A(0)=$ 0 as discussed in Theorem 62.6.6. Then

$$
E\left(X(\tau) \mid \mathscr{F}_{\tau}\right)=E\left(M(\tau)+A(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Now since $A$ is increasing, you can use the optional sampling theorem for martingales, Theorem 62.6.5 to conclude that, since $\mathscr{F}_{\sigma \wedge \tau} \subseteq \mathscr{F}_{\sigma}$ and $A(\sigma \wedge \tau)$ is $\mathscr{F}_{\sigma \wedge \tau}$ measurable,

$$
\begin{aligned}
& \geq E\left(M(\tau)+A(\sigma \wedge \tau) \mid \mathscr{F}_{\sigma}\right)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)+A(\sigma \wedge \tau) \\
& =M(\sigma \wedge \tau)+A(\sigma \wedge \tau)=X(\sigma \wedge \tau) .
\end{aligned}
$$

In summary, the main results for stopping times for discrete filtrations are the following definitions and theorems.

$$
[\tau \leq m] \in \mathscr{F}_{m}
$$

$$
\begin{gathered}
A \in \mathscr{F}_{\tau} \text { means } A \cap[\tau \leq m] \in \mathscr{F}_{m} \text { for any } m \\
X \text { adapted implies } X(\tau) \text { is } \mathscr{F}_{\tau} \text { measurable } \\
\mathscr{F}_{\sigma \wedge \tau}=\mathscr{F}_{\sigma} \cap \mathscr{F}_{\tau} \\
{[\tau=k] \cap \mathscr{F}_{k}=[\tau=k] \cap \mathscr{F}_{\tau}}
\end{gathered}
$$

This last theorem implies the following amazing result. From these fundamental properties, we obtain the optional sampling theorem for martingales and submartingales.

$$
E\left(Y \mid \mathscr{F}_{\tau}\right)=E\left(Y \mid \mathscr{F}_{k}\right) \text { a.e. on }[\tau=k]
$$

### 62.7 Doob Optional Sampling Continuous Case

### 62.7.1 Stopping Times

Let $X(t)$ be a stochastic process adapted to a filtration $\left\{\mathscr{F}_{t}\right\}$ for $t \in[0, T]$. We will assume two things. The stochastic process is right continuous and the filtration is normal.

Definition 62.7.1 A normal filtration is one which satisfies the following :

1. $\mathscr{F}_{0}$ contains all $A \in \mathscr{F}$ such that $P(A)=0$. Here $\mathscr{F}$ is the $\sigma$ algebra which contains all $\mathscr{F}_{t}$.
2. $\mathscr{F}_{t}=\mathscr{F}_{t+}$ for all $t \in I$ where $\mathscr{F}_{t+} \equiv \cap_{s>t} \mathscr{F}_{s}$.

For an $\mathscr{F}$ measurable $[0, \infty)$ valued function $\tau$ to be a stopping time, we want to have the stopped process $X^{\tau}$ defined by $X^{\tau}(t)(\omega) \equiv X(t \wedge \tau(\omega))(\omega)$ to be adapted whenever $X$ is right continuous and adapted. Thus a stopping time is a measurable function which can be used to stop the process while retaining the property of being adapted. We want to find a simple criterion which will ensure that this happens.

Let $X(t)$ be adapted. Let $O$ be an open set in some metric space where $X$ has its values. This could probably be generalized. Then we need to have

$$
X^{\tau}(t)^{-1}(O) \in \mathscr{F}_{t}
$$

Thus we need to have

$$
[\tau \leq t] \cap\left[X(\tau)^{-1}(O)\right] \cup[\tau>t] \cap\left[X(t)^{-1}(O)\right] \in \mathscr{F}_{t}
$$

How does this happen? Consider $\tau_{k}(\omega) \equiv \sum_{n=0}^{\infty} \mathscr{X}_{\tau^{-1}\left(\left(n 2^{-k},(n+1) 2^{-k}\right]\right)}(\omega)(n+1) 2^{-k}$. Thus for each $\omega, \tau_{k}(\omega) \downarrow \tau(\omega)$. Since $X$ is right continuous for each $\omega$, it follows that, since $O$ is open,

$$
\begin{gathered}
{[\tau \leq t] \cap\left[X(\tau)^{-1}(O)\right]=[\tau \leq t] \cap\left(\cup_{m} \cap_{k \geq m}\left[X\left(\tau_{k}\right)^{-1}(O)\right]\right)} \\
=\cup_{m} \cap_{k \geq m} \cup_{n=0}^{\infty} \tau^{-1}\left(\left(n 2^{-k},(n+1) 2^{-k} \wedge t\right]\right) \cap\left[X\left((n+1) 2^{-k}\right)^{-1}(O)\right]
\end{gathered}
$$

the last union being a disjoint union. Now

$$
\tau^{-1}\left(\left(n 2^{-k},(n+1) 2^{-k} \wedge t\right]\right) \cap\left[X\left((n+1) 2^{-k}\right)^{-1}(O)\right]
$$

is a set of $\mathscr{F}_{(n+1) 2^{-k}}$ intersected with $\left[\tau \in\left(n 2^{-k},(n+1) 2^{-k}\right]\right] \cap[\tau \in(0, t]]$. If we assume $[\tau \leq t] \in \mathscr{F}_{t}$, for all $t$, then this shows that the above expression is a set of $\mathscr{F}_{t+2^{-k}}$. Since this is true for each $k$, and the filtration is normal, this implies $[\tau \leq t] \cap\left[X(\tau)^{-1}(O)\right] \in \mathscr{F}_{t}$. Also with this assumption, $[\tau>t]=[\tau \leq t]^{C} \in \mathscr{F}_{t}$ and so we get $X^{\tau}(t)^{-1}(O) \in \mathscr{F}_{t}$. This is why we define stopping times this way. It is so that when you have a right continuous adapted process, then the stopped process is also adapted.

Definition 62.7.2 $\tau$ an $\mathscr{F}$ measurable function is a stopping time if $[\tau \leq t] \in \mathscr{F}_{t}$.
What follows will be more discussion of this simple idea of preserving the process of being adapted when the process is stopped.

Then the above discussion shows the following proposition.
Proposition 62.7.3 Let $\left\{\mathscr{F}_{t}\right\}$ be a normal filtration and let $X(t)$ be a right continuous process adapted to $\left\{\mathscr{F}_{t}\right\}$. Then if $\tau$ is a stopping time, it follows that the stopped process $X^{\tau}$ defined by $X^{\tau}(t) \equiv X(\tau \wedge t)$ is also adapted.

Definition 62.7.4 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $\mathscr{F}_{t}$ be a filtration. A measurable function, $\tau: \Omega \rightarrow[0, \infty]$ is called a stopping time if

$$
[\tau \leq t] \in \mathscr{F}_{t}
$$

for all $t \geq 0$. Associated with a stopping time is the $\sigma$ algebra, $\mathscr{F} \tau$ defined by

$$
\mathscr{F}_{\tau} \equiv\left\{A \in \mathscr{F}: A \cap[\tau \leq t] \in \mathscr{F}_{t} \text { for all } t\right\} .
$$

These sets are also called those "prior" to $\tau$.
Note that $\mathscr{F}_{\tau}$ is obviously closed with respect to countable unions. If $A \in \mathscr{F} \tau$, then

$$
A^{C} \cap[\tau \leq t]=[\tau \leq t] \backslash(A \cap[\tau \leq t]) \in \mathscr{F}_{t}
$$

Thus $\mathscr{F}_{\tau}$ is a $\sigma$ algebra.
Proposition 62.7.5 Let B be an open subset of topological space $E$ and let $X(t)$ be a right continuous $\mathscr{F}_{t}$ adapted stochastic process such that $\mathscr{F}_{t}$ is normal. Then define

$$
\tau(\omega) \equiv \inf \{t>0: X(t)(\omega) \in B\}
$$

This is called the first hitting time. Then $\tau$ is a stopping time. If $X(t)$ is continuous and adapted to $\mathscr{F}_{t}$, a normal filtration, then if $H$ is a nonempty closed set such that $H=\cap_{n=1}^{\infty} B_{n}$ for $B_{n}$ open, $B_{n} \supseteq B_{n+1}$,

$$
\tau(\omega) \equiv \inf \{t>0: X(t)(\omega) \in H\}
$$

is also a stopping time.
Proof: Consider the first claim. $\omega \in[\tau=a]$ implies that for each $n \in \mathbb{N}$, there exists $t \in\left[a, a+\frac{1}{n}\right]$ such that $X(t) \in B$. Also for $t<a$, you would need $X(t) \notin B$. By right continuity, this is the same as saying that $X(d) \notin B$ for all rational $d<a$. (If $t<a$, you could let $d_{n} \downarrow t$ where $X\left(d_{n}\right) \in B^{C}$, a closed set. Then it follows that $X(t)$ is also in the closed set $B^{C}$.) Thus, aside from a set of measure zero, for each $m \in \mathbb{N}$,

$$
[\tau=a]=\left(\cap_{n=m}^{\infty} \cup_{t \in\left[a, a+\frac{1}{n}\right]}[X(t) \in B]\right) \cap\left(\cap_{t \in[0, a)}\left[X(t) \in B^{C}\right]\right)
$$

Since $X(t)$ is right continuous, this is the same as

$$
\left(\cap_{n=m}^{\infty} \cup_{d \in \mathbb{Q} \cap\left[a, a+\frac{1}{n}\right]}[X(d) \in B]\right) \cap\left(\cap_{d \in \mathbb{Q} \cap[0, a)}\left[X(d) \in B^{C}\right]\right) \in \mathscr{F}_{a+\frac{1}{m}}
$$

Thus, since the filtration is normal,

$$
[\tau=a] \in \cap_{m=1}^{\infty} \mathscr{F}_{a+\frac{1}{m}}=\mathscr{F}_{a+}=\mathscr{F}_{a}
$$

Now what of $[\tau<a]$ ? This is equivalent to saying that $X(t) \in B$ for some $t<a$. Since $X$ is right continuous, this is the same as saying that $X(t) \in B$ for some $t \in \mathbb{Q}, t<a$. Thus

$$
[\tau<a]=\cup_{d \in \mathbb{Q}, d<a}[X(d) \in B] \in \mathscr{F}_{a}
$$

It follows that $[\tau \leq a]=[\tau<a] \cup[\tau=a] \in \mathscr{F}_{a}$.
Now consider the claim involving the additional assumption that $X(t)$ is continuous and it is desired to hit a closed set $H=\cap_{n=1}^{\infty} B_{n}$ where $B_{n}$ is open, $B_{n} \supseteq B_{n+1}$. (Note that if the topological space is a metric space, this is always possible so this is not a big restriction.) Then let $\tau_{n}$ be the first hitting time of $B_{n}$ by $X(t)$. Then it can be shown that

$$
[\tau \leq a]=\cap_{n}\left[\tau_{n} \leq a\right] \in \mathscr{F}_{a}
$$

To show this, first note that $\omega \in[\tau \leq a]$ if and only if there exists $t \leq a$ such that $X(t)(\omega) \in$ $H$. This follows from continuity and the fact that $H$ is closed. Thus $\tau_{n} \leq a$ for all $n$ because for some $t \leq a, X(t) \in H \subseteq B_{n}$ for all $n$. Next suppose $\omega \in\left[\tau_{n} \leq a\right]$ for all $n$. Then for $\delta_{n} \downarrow 0$, there exists $t_{n} \in\left[0, a+\delta_{n}\right]$ such that $X\left(t_{n}\right)(\omega) \in B_{n}$. It follows there is a subsequence, still denoted by $t_{n}$ such that $t_{n} \rightarrow t \in[0, a]$. By continuity of $X$, it must be the case that $X(t)(\omega) \in H$ and so $\omega \in[\tau \leq a]$. This shows the above formula. Now by the first part, each $\left[\tau_{n} \leq a\right] \in \mathscr{F}_{a}$ and so $[\tau \leq a] \in \mathscr{F}_{a}$ also.

Another useful result for real valued stochastic process is the following.
Proposition 62.7.6 Let $X(t)$ be a real valued stochastic process which is $\mathscr{F}_{t}$ adapted for a normal filtration $\mathscr{F}_{t}$, with the property that off a set of measure zero in $\Omega, t \rightarrow X(t)$ is lower semicontinuous. Then

$$
\tau \equiv \inf \{t: X(t)>\alpha\}
$$

is a stopping time.
Proof: As above, for each $m>0$,

$$
[\tau=a]=\left(\cap_{n=m}^{\infty} \cup_{t \in\left[a, a+\frac{1}{n}\right]}[X(t)>\alpha]\right) \cap\left(\cap_{t \in[0, a)}[X(t) \leq \alpha]\right)
$$

Now

$$
\cap_{t \in[0, a)}[X(t) \leq \alpha] \subseteq \cap_{t \in[0, a), t \in \mathbb{Q}}[X(t) \leq \alpha]
$$

If $\omega$ is in the right side, then for arbitrary $t<a$, let $t_{n} \downarrow t$ where $t_{n} \in \mathbb{Q}$ and $t<a$. Then $X(t) \leq \liminf _{n \rightarrow \infty} X\left(t_{n}\right) \leq \alpha$ and so $\omega$ is in the left side also. Thus

$$
\cap_{t \in[0, a)}[X(t) \leq \alpha]=\cap_{t \in[0, a), t \in \mathbb{Q}}[X(t) \leq \alpha]
$$

$$
\cup_{t \in\left[a, a+\frac{1}{n}\right]}[X(t)>\alpha] \supseteq \cup_{t \in\left[a, a+\frac{1}{n}\right], t \in \mathbb{Q}}[X(t)>\alpha]
$$

If $\omega$ is in the left side, then for some $t$ in the given interval, $X(t)>\alpha$. If for all $s \in$ $\left[a, a+\frac{1}{n}\right] \cap \mathbb{Q}$ you have $X(s) \leq \alpha$, then you could take $s_{n} \rightarrow t$ where $X\left(s_{n}\right) \leq \alpha$ and conclude from lower semicontinuity that $X(t) \leq \alpha$ also. Thus there is some rational $s$ where $X(s)>\alpha$ and so the two sides are equal. Hence,

$$
[\tau=a]=\left(\cap_{n=m}^{\infty} \cup_{t \in\left[a, a+\frac{1}{n}\right], t \in \mathbb{Q}}[X(t)>\alpha]\right) \cap\left(\cap_{t \in[0, a), t \in \mathbb{Q}}[X(t) \leq \alpha]\right)
$$

The first set on the right is in $\mathscr{F}_{a+(1 / m)}$ and so is the next set on the right. Hence $[\tau=a] \in$ $\cap_{m} \mathscr{F}_{a+(1 / m)}=\mathscr{F}_{a}$. To be a stopping time, one needs $[\tau \leq a] \in \mathscr{F}_{a}$. What of $[\tau<a]$ ? This equals $\cup_{t \in[0, a)}[X(t)>\alpha]=\cup_{t \in[0, a) \cap \mathbb{Q}}[X(t)>\alpha] \in \mathscr{F}_{a}$, the equality following from lower semicontinuity. Thus $[\tau \leq a]=[\tau=a] \cup[\tau<a] \in \mathscr{F} a$.

Thus there do exist stopping times, the first hitting time above being an example. When dealing with continuous stopping times on a normal filtration, one uses the following discrete stopping times

$$
\tau_{n} \equiv \sum_{k=1}^{\infty} \mathscr{X}_{\left[\tau \in\left(t_{k}^{n}, t_{k+1}^{n}\right]\right]_{k+1}} t_{k}^{n}
$$

where here $\left|t_{k}^{n}-t_{k+1}^{n}\right|=r_{n}$ for all $k$ where $r_{n} \rightarrow 0$. Then here is an important lemma.
Lemma 62.7.7 $\tau_{n}$ is a stopping time $\left(\left[\tau_{n} \leq t\right] \in \mathscr{F}_{t}\right.$.) Also the inclusion $\mathscr{F}_{\tau} \subseteq \mathscr{F}_{\tau_{n}}$ holds and for each $\omega, \tau_{n}(\omega) \downarrow \tau(\omega)$.

Proof: Say $t \in\left(t_{k-1}^{n}, t_{k}^{n}\right]$. Then $\left[\tau_{n} \leq t\right]=\left[\tau \leq t_{k-1}^{n}\right]$ if $t<t_{k}^{n}$ and it equals $\left[\tau \leq t_{k}^{n}\right]$ if $t=t_{k}^{n}$. Either way $\left[\tau_{n} \leq t\right] \in \mathscr{F}_{t}$ so it is a stopping time. Also from the definition, it follows that $\tau_{n} \geq \tau$ and $\left|\tau_{n}(\omega)-\tau(\omega)\right| \leq r_{n}$ which is given to converge to 0 . Now suppose $A \in \mathscr{F}_{\tau}$ and say $t \in\left(t_{k-1}^{n}, t_{k}^{n}\right]$ as above. Then

$$
A \cap\left[\tau_{n} \leq t\right]=A \cap\left[\tau \leq t_{k-1}^{n}\right] \in \mathscr{F}_{t_{k-1}^{n}}^{n} \subseteq \mathscr{F}_{t} \text { if } t<t_{k}^{n}
$$

and

$$
A \cap\left[\tau_{n} \leq t\right]=A \cap\left[\tau \leq t_{k}^{n}\right] \in \mathscr{F}_{t_{k}^{n}}^{n}=\mathscr{F}_{t} \text { if } t=t_{k}^{n}
$$

Thus $\mathscr{F} \tau \subseteq \mathscr{F}_{\tau_{n}}$ as claimed.
Next is the claim that if $X(t)$ is adapted to $\mathscr{F}_{t}$, then $X(\tau)$ is adapted to $\mathscr{F}_{\tau}$ just like the discrete case.

Proposition 62.7.8 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $\sigma \leq \tau$ be two stopping times with respect to a filtration, $\mathscr{F}_{\text {f }}$. Then $\mathscr{F}_{\sigma} \subseteq \mathscr{F}_{\tau}$. If $X(t)$ is a right continuous stochastic process adapted to a normal filtration $\mathscr{F}_{t}$ and $\tau$ is a stopping time, $\omega \rightarrow X(\tau(\omega))$ is $\mathscr{F}_{\tau}$ measurable.

Proof: Let $A \in \mathscr{F}_{\sigma}$. Then $A \cap[\sigma \leq t] \in \mathscr{F}_{t}$ for all $t \geq 0$. Since $\sigma \leq \tau$,

$$
A \cap[\tau \leq t]=\overbrace{A \cap[\sigma \leq t]}^{\in \mathscr{F}_{t}} \cap[\tau \leq t] \in \mathscr{F}_{t}
$$

Thus $A \in \mathscr{F}_{\tau}$ and so $\mathscr{F}_{\sigma} \subseteq \mathscr{F}_{\tau}$.
Consider the following approximation of $\tau$ in which $t_{k}^{n}=k 2^{-n}$.

$$
\left.\tau_{n} \equiv \sum_{k=1}^{\infty} \mathscr{X}_{\left[\tau \in\left(t_{k}^{n}, t_{k+1}^{n}\right]\right.}\right]_{k+1}^{n}
$$

Thus $\tau_{n} \downarrow \tau$. Consider for $U$ an open set, $X\left(\tau_{n}\right)^{-1}(U) \cap\left[\tau_{n}<t\right]$. Say $t \in\left(t_{k}^{n}, t_{k+1}^{n}\right]$. Then from the above definition of $\tau_{n}$,

$$
\left[\tau_{n}<t\right]=\left[\tau \leq t_{k}^{n}\right] \in \mathscr{F}_{t}^{n} \subseteq \mathscr{F}_{t}
$$

It follows that

$$
X\left(\tau_{n}\right)^{-1}(U) \cap\left[\tau_{n}<t\right]=\cup_{j=1}^{k} X\left(t_{j}^{n}\right)^{-1}(U) \cap\left[\begin{array}{c}
\in \mathscr{F}_{t}^{n} \\
\tau_{j}^{n} \\
=t_{j}^{n}
\end{array}\right]
$$

and so this set is in $\mathscr{F}_{t_{k}^{n}} \subseteq \mathscr{F}_{t}$. The reason $\left[\tau_{n}=t_{j}^{n}\right] \in \mathscr{F}_{t_{j}^{n}}$ is that it equals $\left[\tau \in\left(t_{j-1}^{n}, t_{j}^{n}\right]\right] \in$ $\mathscr{F}_{t_{j}^{n}}$ by assumption that $\tau$ is a stopping time.

By right continuity of $X$, it follows that

$$
X(\tau)^{-1}(U) \cap[\tau<t]=\cup_{m=1}^{\infty} \cap_{n \geq m} X\left(\tau_{n}\right)^{-1}(U) \cap\left[\tau_{n}<t\right] \in \mathscr{F}_{t}
$$

It follows that for every $m$,

$$
X(\tau)^{-1}(U) \cap[\tau \leq t]=\cap_{n=m}^{\infty} X(\tau)^{-1}(U) \cap\left[\tau<t+\frac{1}{n}\right] \in \mathscr{F}_{t+\frac{1}{m}}
$$

Since the filtration is normal, it follows that

$$
X(\tau)^{-1}(U) \cap[\tau \leq t] \in \mathscr{F}_{t+}=\mathscr{F}_{t} .
$$

Now consider an increasing family of stopping times, $\tau(t)(\omega \rightarrow \tau(t)(\omega))$. It turns out this is a submartingale.

Example 62.7.9 Let $\{\tau(t)\}$ be an increasing family of stopping times. Then $\tau(t)$ is adapted to the $\sigma$ algebras $\mathscr{F}_{\tau(t)}$ and $\{\tau(t)\}$ is a submartingale adapted to these $\sigma$ algebras.

First I need to show that a stopping time, $\tau$ is $\mathscr{F} \tau$ measurable. Consider $[\tau \leq s]$. Is this in $\mathscr{F}_{\tau}$ ? Is $[\tau \leq s] \cap[\tau \leq r] \in \mathscr{F}_{r}$ for each $r$ ? This is obviously so if $s \leq r$ because the intersection reduces to $[\tau \leq s] \in \mathscr{F}_{s} \subseteq \mathscr{F}_{r}$. On the other hand, if $s>r$ then the intersection reduces to $[\tau \leq r] \in \mathscr{F}_{r}$ and so it is clear that $\tau$ is $\mathscr{F}_{\tau}$ measurable. It remains to verify it is a submartingale.

Let $s<t$ and let $A \in \mathscr{F}_{\tau(s)}$

$$
\int_{A} E(\tau(t) \mid \mathscr{F} \tau(s)) d P \equiv \int_{A} \tau(t) d P \geq \int_{A} \tau(s) d P
$$

and this shows $E\left(\tau(t) \mid \mathscr{F}_{\tau(s)}\right) \geq \tau(s)$.
Now here is an important example. First note that for $\tau$ a stopping time, so is $t \vee \tau$. Here is why.

$$
[t \vee \tau \leq s]=[t \leq s] \cap[\tau \leq s] \in \mathscr{F}_{s}
$$

Example 62.7.10 Let $\tau$ be a stopping time and let $X$ be continuous and adapted to the filtration $\mathscr{F}_{t}$. Then for $a>0$, define $\sigma$ as

$$
\sigma(\omega) \equiv \inf \{t>\tau(\omega):\|X(t)(\omega)-X(\tau(\omega))\|=a\}
$$

Then $\sigma$ is also a stopping time.
To see this is so, let

$$
Y(t)(\omega)=\|X(t \vee \tau)(\omega)-X(\tau(\omega))\|
$$

Then $Y(t)$ is $\mathscr{F}_{t \vee \tau}$ measurable. It is desired to show that $Y$ is $\mathscr{F}_{t}$ adapted. Hence if $U$ is open in $\mathbb{R}$, then

$$
Y(t)^{-1}(U)=\left(Y(t)^{-1}(U) \cap[\tau \leq t]\right) \cup\left(Y(t)^{-1}(U) \cap[\tau>t]\right)
$$

The second set in the above union on the right equals either $\emptyset$ or $[\tau>t]$ depending on whether $0 \in U$. If $\tau>t$, then $Y(t)=0$ and so the second set equals $[\tau>t]$ if $0 \in U$. If $0 \notin U$, then the second set equals $\emptyset$. Thus the second set above is in $\mathscr{F}_{t}$. It is necessary to show the first set is also in $\mathscr{F}_{t}$. The first set equals

$$
Y(t)^{-1}(U) \cap[\tau \leq t]=Y(t)^{-1}(U) \cap[\tau \vee t \leq t]
$$

because $[\tau \vee t \leq t]=[\tau \leq t]$. However, $Y(t)^{-1}(U) \in \mathscr{F}_{t \vee \tau}$ and so the set on the right in the above is in $\mathscr{F}_{t}$. Therefore, $Y(t)$ is adapted. Then $\sigma$ is just the first hitting time for $Y(t)$ to equal the closed set $a$. Therefore, $\sigma$ is a stopping time by Proposition 62.7.5.

### 62.7.2 The Optional Sampling Theorem Continuous Case

Next I want a version of the Doob optional sampling theorem which applies to martingales defined on $[0, L], L \leq \infty$. First recall Theorem 61.1.2 part of which is stated as the following lemma.

Lemma 62.7.11 Let $f \in L^{1}(\Omega ; E, \mathscr{F})$ where $E$ is a separable Banach space. Then if $\mathscr{G}$ is a $\sigma$ algebra $\mathscr{G} \subseteq \mathscr{F}$,

$$
\|E(f \mid \mathscr{G})\| \leq E(\|f\| \mid \mathscr{G})
$$

Here is a lemma which is the main idea for the proofs of the optional sampling theorem for the continuous case.

Lemma 62.7.12 Let $X(t)$ be a right continuous nonnegative submartingale such that the filtration $\left\{\mathscr{F}_{t}\right\}$ is normal. Recall this includes

$$
\mathscr{F}_{t}=\cap_{s>t} \mathscr{F}_{s}
$$

Also let $\tau$ be a stopping time with values in $[0, T]$. Let $\mathscr{P}_{n}=\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}+1}$ be a sequence of partitions of $[0, T]$ which have the property that

$$
\mathscr{P}_{n} \subseteq \mathscr{P}_{n+1}, \lim _{n \rightarrow \infty}\left\|\mathscr{P}_{n}\right\|=0
$$

where

$$
\left\|\mathscr{P}_{n}\right\| \equiv \sup \left\{\left|t_{k}^{n}-t_{k+1}^{n}\right|: k=1,2, \cdots, m_{n}\right\}
$$

Then let

$$
\tau_{n}(\omega) \equiv \sum_{k=0}^{m_{n}} t_{k+1}^{n} \mathscr{X}_{\tau^{-1}\left(\left(t_{k}^{n}, t_{k+1}^{n}\right]\right)}(\omega)
$$

It follows that $\tau_{n}$ is a stopping time and also the functions $\left|X\left(\tau_{n}\right)\right|$ are uniformly integrable. Furthermore, $|X(\tau)|$ is integrable.

Proof: First of all, say $t \in\left(t_{k}^{n}, t_{k+1}^{n}\right]$. If $t<t_{k+1}^{n}$, then

$$
\left[\tau_{n} \leq t\right]=\left[\tau \leq t_{k}^{n}\right] \in \mathscr{F}_{t_{k}^{n}} \subseteq \mathscr{F}_{t}
$$

and if $t=t_{k+1}^{n}$, then

$$
\left[\tau_{n} \leq t_{k+1}^{n}\right]=\left[\tau \leq t_{k+1}^{n}\right] \in \mathscr{F}_{k+1}^{n}=\mathscr{F}_{t}
$$

and so $\tau_{n}$ is a stopping time. It follows from Proposition 62.7 .8 that $X\left(\tau_{n}\right)$ is $\mathscr{F}_{\tau_{n}}$ measurable.

Now from Lemma 60.4.3 or Theorem 62.6.7, $X(0), X\left(\tau_{n}\right), X(T)$ is a submartingale. Then

$$
\begin{aligned}
\int_{\left[X\left(\tau_{n}\right) \geq \lambda\right]} X\left(\tau_{n}\right) d P & \leq \int_{\left[X\left(\tau_{n}\right) \geq \lambda\right]} E\left(X(T) \mid \mathscr{F}_{\tau_{n}}\right) d P \\
& =\int_{\Omega} E\left(\mathscr{X}_{\left[X\left(\tau_{n}\right) \geq \lambda\right]} X(T) \mid \mathscr{F}_{\tau_{n}}\right) d P \\
& =\int_{\left[X\left(\tau_{n}\right) \geq \lambda\right]} X(T) d P
\end{aligned}
$$

From maximal estimates, for example Theorem 60.2.8,

$$
P\left(\left[X\left(\tau_{n}\right) \geq \lambda\right]\right) \leq \frac{1}{\lambda} \int_{\Omega} X(T)^{+} d P=\frac{1}{\lambda} \int_{\Omega} X(T) d P
$$

and now it follows from the above that the random variables $X\left(\tau_{n}\right)$ are equiintegrable. Recall this means that

$$
\lim _{\lambda \rightarrow \infty} \sup _{n} \int_{\left[X\left(\tau_{n}\right) \geq \lambda\right]} X\left(\tau_{n}\right) d P=0
$$

Hence they are uniformly integrable.
To verify that $|X(\tau)|$ is integrable, note that by right continuity, $X\left(\tau_{n}\right) \rightarrow X(\tau)$ pointwise. Apply the Vitali convergence theorem to obtain

$$
\int_{\Omega}|X(\tau)| d P=\lim _{n \rightarrow \infty} \int_{\Omega}\left|X\left(\tau_{n}\right)\right| d P \leq \int_{\Omega} X(T) d P<\infty
$$

In fact, you do not need to assume $X$ is nonnegative.

Lemma 62.7.13 Let $X(t)$ be a right continuous submartingale such that the filtration $\left\{\mathscr{F}_{t}\right\}$ is normal. Recall this includes

$$
\mathscr{F}_{t}=\cap_{s>t} \mathscr{F}_{s}
$$

Also let $\tau$ be a stopping time with values in $[0, T]$. Let $\mathscr{P}_{n}=\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}+1}$ be a sequence of partitions of $[0, T]$ which have the property that

$$
\mathscr{P}_{n} \subseteq \mathscr{P}_{n+1}, \lim _{n \rightarrow \infty}\left\|\mathscr{P}_{n}\right\|=0
$$

where

$$
\left\|\mathscr{P}_{n}\right\| \equiv \sup \left\{\left|t_{k}^{n}-t_{k+1}^{n}\right|: k=1,2, \cdots, m_{n}\right\}
$$

Then let

$$
\tau_{n}(\omega) \equiv \sum_{k=0}^{m_{n}} t_{k+1}^{n} \mathscr{X}_{\tau^{-1}\left(\left(t_{k}^{n}, t_{k+1}^{n}\right]\right)}(\omega)
$$

It follows that $\tau_{n}$ is a stopping time and also the functions $\left|X\left(\tau_{n}\right)\right|$ are uniformly integrable. Furthermore, $|X(\tau)|$ is integrable.

Proof: It was shown above that $\tau_{n}$ is a stopping time. Also, $t_{k}^{n} \rightarrow X\left(t_{k}^{n}\right)$ is a discrete submartingale. Then by Theorem 62.6 .6 there is a martingale $t_{k}^{n} \rightarrow M\left(t_{k}^{n}\right)$ and an increasing submartingale $t_{k}^{n} \rightarrow A\left(t_{k}^{n}\right)$ such that $A \geq 0$ and is increasing

$$
X\left(t_{k}^{n}\right)=M\left(t_{k}^{n}\right)+A\left(t_{k}^{n}\right)
$$

You define $A\left(t_{0}^{m}\right) \equiv 0$ and for $n \geq 1$,

$$
A\left(t_{n}^{m}\right) \equiv \sum_{k=1}^{n} E\left(X\left(t_{k}^{m}\right)-X\left(t_{k-1}^{m}\right) \mid \mathscr{F}_{t_{k-1}^{m}}^{m}\right)
$$

and repeat the arguments in that theorem. You know that $A(0), A\left(\tau_{n}\right), A(T)$ is a submartingale by the optional sampling theorem given earlier, Theorem 62.6.7, and so

$$
P\left(A\left(\tau_{n}\right)>\lambda\right) \leq \frac{1}{\lambda} \int_{\left[A\left(\tau_{n}\right)>\lambda\right]} A\left(\tau_{n}\right) d P \leq \frac{1}{\lambda} \int_{\left[A\left(\tau_{n}\right)>\lambda\right]} A(T) d P \leq \frac{\|A(T)\|_{L^{1}}}{\lambda}
$$

It also follows from the definition of $A$ that

$$
\|A(T)\|_{L^{1}}=\int_{\Omega} X(T)-X(0) d P<\infty
$$

Hence

$$
\lim _{\lambda \rightarrow \infty} \int_{\left[A\left(\tau_{n}\right)>\lambda\right]} A\left(\tau_{n}\right) d P \leq \lim _{\lambda \rightarrow \infty} \int_{\left[A\left(\tau_{n}\right)>\lambda\right]} A(T) d P=0
$$

Because $P\left(A\left(\tau_{n}\right)>\lambda\right) \rightarrow 0$ and a single function in $L^{1}$ is uniformly integrable. Thus these functions $A\left(\tau_{n}\right)$ are equi-integrable. Hence they are uniformly integrable. Now $t_{k}^{n} \rightarrow$ $\left|M\left(t_{k}^{n}\right)\right|$ is also a nonnegative submartingale. Thus

$$
|M(0)|,\left|M\left(\tau_{n}\right)\right|,|M(T)|
$$

is a submartingale by the optional sampling theorem for discrete submartingales given earlier. Therefore,

$$
P\left(\left|M\left(\tau_{n}\right)\right|>\lambda\right) \leq \frac{1}{\lambda} \int_{\left[\left|M\left(\tau_{n}\right)\right|>\lambda\right]}\left|M\left(\tau_{n}\right)\right| d P \leq \frac{1}{\lambda} \int_{\left[\left|M\left(\tau_{n}\right)\right|>\lambda\right]}|M(T)| d P \leq \frac{\|M(T)\|_{L^{1}}}{\lambda}
$$

Of course $\|M(T)\|_{L^{1}}$ is finite because it is dominated by

$$
\int_{\Omega} A(T)+|X(T)| d P<\infty
$$

Hence

$$
\lim _{\lambda \rightarrow \infty} \sup _{n} \int_{\left[\left|M\left(\tau_{n}\right)\right|>\lambda\right]}\left|M\left(\tau_{n}\right)\right| d P \leq \lim _{\lambda \rightarrow \infty} \sup _{n} \int_{\left[\left|M\left(\tau_{n}\right)\right|>\lambda\right]}|M(T)| d P=0
$$

because a single function in $L^{1}$ is uniformly integrable and the above estimate shows that $P\left(\left[\left|M\left(\tau_{n}\right)\right|>\lambda\right]\right) \rightarrow 0$ uniformly in $n$. Thus, in fact $X\left(\tau_{n}\right)$ must be uniformly integrable since it is the sum of two which are.

Theorem 62.7.14 Let $\{M(t)\}$ be a right continuous martingale having values in E a separable real Banach space with respect to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{t}\right\}$ which is assumed to be a normal filtration satisfying,

$$
\mathscr{F}_{t}=\cap_{s>t} \mathscr{F}_{s}
$$

for $t \in[0, L], L \leq \infty$ and let $\sigma, \tau$ be two stopping times with $\tau$ bounded. Then $M(\tau)$ defined as

$$
\omega \rightarrow M(\tau(\omega))
$$

is integrable and

$$
M(\sigma \wedge \tau)=E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Proof: Since $M(t)$ is a martingale, $\|M(t)\|$ is a submartingale. Let

$$
\tau_{n}(\omega) \equiv \sum_{k=0}^{\infty} 2^{-n}(k+1) T \mathscr{X}_{\tau^{-1}\left(\left(k 2^{-n} T,(k+1) T 2^{-n}\right]\right)}(\omega)
$$

By Lemma 62.7.13, $\tau_{n}$ is a stopping time and the functions $\left\|M\left(\tau_{n}\right)\right\|$ are uniformly integrable. Also $\|M(\tau)\|$ is integrable. Similarly $\left\|M\left(\tau_{n} \wedge \sigma_{n}\right)\right\|$ are uniformly integrable where $\sigma_{n}$ is defined similarly to $\tau_{n}$.

Consider the main claim now. Letting $\sigma, \tau$ be stopping times with $\tau$ bounded, it follows that for $\sigma_{n}$ and $\tau_{n}$ as above, it follows from Theorem 62.6.5

$$
M\left(\sigma_{n} \wedge \tau_{n}\right)=E\left(M\left(\tau_{n}\right) \mid \mathscr{F}_{\sigma_{n}}\right)
$$

Thus, taking $A \in \mathscr{F}_{\sigma}$ and recalling $\sigma \leq \sigma_{n}$ so that by Proposition 62.7.8, $\mathscr{F}_{\sigma} \subseteq \mathscr{F}_{\sigma_{n}}$,

$$
\int_{A} M\left(\sigma_{n} \wedge \tau_{n}\right) d P=\int_{A} E\left(M\left(\tau_{n}\right) \mid \mathscr{F}_{\sigma_{n}}\right) d P=\int_{A} M\left(\tau_{n}\right) d P
$$

Now passing to a limit as $n \rightarrow \infty$, the Vitali convergence theorem, Theorem 11.5.3 on Page 257 and the right continuity of $M$ implies one can pass to the limit in the above and conclude

$$
\int_{A} M(\sigma \wedge \tau) d P=\int_{A} M(\tau) d P
$$

By Proposition 62.7.8, $M(\sigma \wedge \tau)$ is $\mathscr{F}_{\sigma \wedge \tau} \subseteq \mathscr{F}_{\sigma}$ measurable showing

$$
E\left(M(\tau) \mid \mathscr{F}_{\sigma}\right)=M(\sigma \wedge \tau)
$$

A similar theorem is available for submartingales defined on $[0, L], L \leq \infty$.
Theorem 62.7.15 Let $\{X(t)\}$ be a right continuous submartingale with respect to the increasing sequence of $\sigma$ algebras, $\left\{\mathscr{F}_{t}\right\}$ which is assumed to be a normal filtration,

$$
\mathscr{F}_{t}=\cap_{s>t} \mathscr{F}_{s}
$$

for $t \in[0, L], L \leq \infty$ and let $\sigma, \tau$ be two stopping times with $\tau$ bounded. Then $X(\tau)$ defined as

$$
\omega \rightarrow X(\tau(\omega))
$$

is integrable and

$$
X(\sigma \wedge \tau) \leq E\left(X(\tau) \mid \mathscr{F}_{\sigma}\right)
$$

Proof: Let

$$
\tau_{n}(\omega) \equiv \sum_{k \geq 0} 2^{-n}(k+1) T \mathscr{X}_{\tau^{-1}\left(\left(k 2^{-n} T,(k+1) T 2^{-n}\right]\right)}(\omega)
$$

Then by Lemma 62.7.13 $\tau_{n}$ is a stopping time, the functions $\left|X\left(\tau_{n}\right)\right|$ are uniformly integrable, and $|X(\tau)|$ is also integrable. For $\sigma_{n}$ defined similarly to $\tau_{n}$, it also follows $\left|X\left(\tau_{n} \wedge \sigma_{n}\right)\right|$ are uniformly integrable.

Let $A \in \mathscr{F}_{\sigma}$. Since $\sigma \leq \sigma_{n}$, it follows that $\mathscr{F}_{\sigma} \subseteq \mathscr{F}_{\sigma_{n}}$. By the discrete optional sampling theorem for submartingales, Theorem 62.6.7,

$$
X\left(\sigma_{n} \wedge \tau_{n}\right) \leq E\left(X\left(\tau_{n}\right) \mid \mathscr{F}_{\sigma_{n}}\right)
$$

and so

$$
\int_{A} X\left(\sigma_{n} \wedge \tau_{n}\right) d P \leq \int_{A} E\left(X\left(\tau_{n}\right) \mid \mathscr{F}_{\sigma_{n}}\right) d P=\int_{A} X\left(\tau_{n}\right) d P
$$

and now taking $\lim _{n \rightarrow \infty}$ of both sides and using the Vitali convergence theorem along with the right continuity of $X$, it follows

$$
\int_{A} X(\sigma \wedge \tau) d P \leq \int_{A} X(\tau) d P \equiv \int_{A} E\left(X(\tau) \mid \mathscr{F}_{\sigma}\right) d P
$$

By Proposition 62.7.8, $\mathscr{F}_{\sigma \wedge \tau} \subseteq \mathscr{F}_{\sigma}$, and so since $A \in \mathscr{F} \sigma$ was arbitrary,

$$
E\left(X(\tau) \mid \mathscr{F}_{\sigma}\right) \geq X(\sigma \wedge \tau) \text { a.e. }
$$

Note that a function defined on a countable ordered set such as the integers or equally spaced points is right continuous.

Here is an interesting lemma.

Lemma 62.7.16 Suppose $E\left(\left|X_{n}\right|\right)<\infty$ for all $n, X_{n}$ is $\mathscr{F}_{n}$ measurable, $\mathscr{F}_{n+1} \subseteq \mathscr{F}_{n}$ for all $n \in \mathbb{N}$, and there exist $X_{\infty} \mathscr{F}_{\infty}$ measurable such that $\mathscr{F}_{\infty} \subseteq \mathscr{F}_{n}$ for all $n$ and $X_{0} \mathscr{F}_{0}$ measurable such that $\mathscr{F}_{0} \supseteq \mathscr{F}_{n}$ for all $n$ such that for all $n \in\{0,1, \cdots\}$,

$$
E\left(X_{n} \mid \mathscr{F}_{n+1}\right) \geq X_{n+1}, E\left(X_{n} \mid \mathscr{F}_{\infty}\right) \geq X_{\infty}
$$

Then $\left\{X_{n}: n \in \mathbb{N}\right\}$ is uniformly integrable.
Proof:

$$
E\left(X_{n+1}\right) \leq E\left(E\left(X_{n} \mid \mathscr{F}_{n+1}\right)\right)=E\left(X_{n}\right)
$$

Therefore, the sequence $E\left(X_{n}\right)$ is a decreasing sequence bounded below by $E\left(X_{\infty}\right)$ so it has a limit. Let $k$ be large enough that

$$
\begin{equation*}
\left|E\left(X_{k}\right)-\lim _{m \rightarrow \infty} E\left(X_{m}\right)\right|<\varepsilon \tag{62.7.26}
\end{equation*}
$$

and suppose $n>k$. Then if $\lambda>0$,

$$
\begin{aligned}
& \int_{\left[\left|X_{n}\right| \geq \lambda\right]}\left|X_{n}\right| d P=\int_{\left[X_{n} \geq \lambda\right]} X_{n} d P+\int_{\left[X_{n} \leq-\lambda\right]}\left(-X_{n}\right) d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{n} d P+\int_{\Omega}\left(-X_{n}\right) d P-\int_{\left[-X_{n}<\lambda\right]}\left(-X_{n}\right) d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{n} d P-\int_{\Omega} X_{n} d P+\int_{\left[-X_{n}<\lambda\right]} X_{n} d P
\end{aligned}
$$

From 62.7.26,

$$
\leq \int_{\left[X_{n} \geq \lambda\right]} X_{n} d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[-X_{n}<\lambda\right]} X_{n} d P
$$

By assumption,

$$
E\left(X_{k} \mid \mathscr{F}_{n}\right) \geq X_{n}
$$

and so

$$
\begin{aligned}
& \leq \int_{\left[X_{n} \geq \lambda\right]} E\left(X_{k} \mid \mathscr{F}_{n}\right) d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[-X_{n}<\lambda\right]} E\left(X_{k} \mid \mathscr{F}_{n}\right) d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[-X_{n}<\lambda\right]} X_{k} d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P-\int_{\Omega} X_{k} d P+\varepsilon+\int_{\left[X_{n}>-\lambda\right]} X_{k} d P \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P+\left(\int_{\Omega}\left(-X_{k}\right) d P-\int_{\left[X_{n}>-\lambda\right]}\left(-X_{k}\right) d P\right)+\varepsilon \\
& =\int_{\left[X_{n} \geq \lambda\right]} X_{k} d P+\int_{\left[X_{n} \leq-\lambda\right]}\left(-X_{k}\right) d P+\varepsilon=\int_{\left[\left|X_{n}\right| \geq \lambda\right]}\left|X_{k}\right| d P+\varepsilon
\end{aligned}
$$

Applying the maximal inequality for submartingales, Theorem 60.6.4,

$$
P\left(\max \left\{\left|X_{j}\right|: j=n, \cdots, 1\right\} \geq \lambda\right) \leq \frac{1}{\lambda}\left(E\left(\left|X_{0}\right|\right)+E\left(\left|X_{\infty}\right|\right)\right) \leq \frac{C}{\lambda}
$$

and taking sup for all $n$,

$$
P\left(\sup \left\{\left|X_{j}\right|\right\} \geq \lambda\right) \leq \frac{C}{\lambda}
$$

It follows that for all $\lambda$ large enough,

$$
\int_{\left[\left|X_{n}\right| \geq \lambda\right]}\left|X_{n}\right| d P \leq 2 \varepsilon
$$

and since $\varepsilon$ is arbitrary, this shows $\left\{X_{n}\right\}$ for $n>k$ is equiintegrable. Since there are only finitely many $X_{j}$ for $j \leq k$, this shows $\left\{X_{n}\right\}$ is equiintegrable. Hence $\left\{X_{n}\right\}$ is uniformly integrable.

### 62.8 Right Continuity Of Submartingales

The following theorem is an attempt to consider the question of right continuity. It turns out that you can always assume right continuity of a submartingale by going to a suitable version and this theorem is a first step in this direction.

Theorem 62.8.1 Let $\{X(t)\}$ be a real valued submartingale adapted to the filtration $\mathscr{F}_{t}$. Then there exists a set of measure zero $N, P(N)=0$, such that if $\omega \notin N$ then,

$$
\lim _{r \rightarrow t+, r \in \mathbb{Q}} X(r, \omega), \lim _{r \rightarrow t-, r \in \mathbb{Q}} X(r, \omega)
$$

both exist. There also exists a set of measure zero $N$ such that for $\mathbb{Q}^{+}$the nonnegative rationals and $\omega \notin N$,

$$
\sup _{t \in \mathbb{Q}^{+} \cap[0, M]}|X(t, \omega)|<\infty
$$

is bounded for each $M \in \mathbb{N}$. $\mathbb{Q}$ can be replaced with any countable dense subset of $\mathbb{R}$.
Proof: Let $\left\{r_{k}\right\}_{k=1}^{\infty}$ be an enumeration of the nonnegative rationals. Let $t>0$ be given. Then let $\left\{s_{1}, s_{2}, \cdots, s_{n}\right\}$ be such that these are in order and $\left\{s_{2}, \cdots, s_{n-1}\right\}$ are the first $n-2$ rationals less than $t$ listed in order and $s_{1}=0$ while $s_{n}=t$. Then let $Y_{k} \equiv X\left(s_{k}\right)$. It follows $\left\{Y_{k}\right\}$ is a submartingale and so from the maximal inequality in Theorem 60.6.4,

$$
\begin{aligned}
P\left(\left[\max _{1 \leq k \leq n}\left|Y_{k}\right| \geq 2^{m}\right]\right) & \leq \frac{1}{2^{m}}\left(2 E\left(\left|Y_{n}\right|+\left|Y_{1}\right|\right)\right) \\
& =2^{-m}(2 E(|X(t)|+|X(0)|))
\end{aligned}
$$

Then letting $n \rightarrow \infty$, it follows upon letting $C_{t}=2 E(|X(t)|+|X(0)|)$,

$$
P\left(\left[\sup _{r \in \mathbb{Q}^{+} \cap[0, t]}|X(r)| \geq 2^{m}\right]\right) \leq 2^{-m} C_{t}
$$

By the Borel Cantelli lemma, there exists a set of measure $0, N_{t}$ such that for $\omega \notin N_{t}, \omega$ is contained in only finitely many of the sets

$$
\left[\sup _{r \in \mathbb{Q}^{+} \cap[0, t]}|X(r)| \geq 2^{m}\right]
$$

which shows that for $\omega \notin N_{t}, \sup _{r \in \mathbb{Q}^{+} \cap[0, t]}|X(r)|$ is bounded. Now let $N=\cup_{j=1}^{\infty} N_{j}$. This proves the second claim.

Next consider the first claim. By the upcrossing estimate, Theorem 60.6.9 or Lemma 60.2.6, and letting $a<b$ and $U_{[a, b]}^{n}[c, d]$ the upcrossings of $Y_{k}$ from $a$ to $b$ on $[c, d]$ for $d \leq t$ and $c \geq 0$,

$$
\begin{aligned}
E\left(U_{[a, b]}^{n}[0, t]\right) & \leq \frac{1}{b-a} E\left(\left(Y_{n}-a\right)^{+}\right) \\
& =\frac{1}{b-a} E\left((X(t)-a)^{+}\right)
\end{aligned}
$$

Hence

$$
\begin{equation*}
P\left(\left[U_{[a, b]}^{n}[0, t] \geq M\right]\right) \leq \frac{1}{M}\left(\frac{1}{b-a} E\left((X(t)-a)^{+}\right)\right) \tag{62.8.27}
\end{equation*}
$$

Suppose for some $s<t$,

$$
\begin{equation*}
\lim \sup _{r \rightarrow s+, r \in \mathbb{Q}} X(r, \omega)>b>a>\lim \inf _{r \rightarrow s+, r \in \mathbb{Q}} X(r, \omega) \tag{62.8.28}
\end{equation*}
$$

If this is so, then in $(s, t) \cap \mathbb{Q}$ there must be infinitely many values of $r \in \mathbb{Q}$ such that $X(r, \omega) \geq b$ as well as infinitely many values of $r \in \mathbb{Q}$ such that $X(r, \omega) \leq a$. Note this involves the consideration of a limit from one side. Thus, since it is a limit from one side only, there are an arbitrarily large number of upcrossings between $s$ and $t$. Therefore, letting $M$ be a large positive number, it follows that for all $n$ sufficiently large,

$$
U_{[a, b]}^{n}[0, t](\omega) \geq M
$$

which implies

$$
\omega \in\left[U_{[a, b]}^{n}[0, t] \geq M\right]
$$

which from 62.8 .27 is a set of measure no more than

$$
\frac{1}{M}\left(\frac{1}{b-a} E\left((X(t)-a)^{+}\right)\right)
$$

This has shown that the set of $\omega$ such that for some $s \in[0, t) 62.8 .28$ holds is contained in the set

$$
N_{[a, b]} \equiv \cap_{M=1}^{\infty} \cup_{n=1}^{\infty}\left[U_{[a, b]}^{n}[0, t] \geq M\right]
$$

Now the sets,

$$
\left[U_{[a, b]}^{n}[0, t] \geq M\right]
$$

are increasing in $n$ and each has measure less than

$$
\frac{1}{M}\left(\frac{1}{b-a} E\left((X(t)-a)^{+}\right)\right)
$$

and so

$$
P\left(\cup_{n=1}^{\infty}\left[U_{[a, b]}^{n}[0, t] \geq M\right]\right) \leq \frac{1}{M}\left(\frac{1}{b-a} E\left((X(t)-a)^{+}\right)\right)
$$

which shows that

$$
P\left(N_{[a, b]}\right) \leq \frac{1}{M}\left(\frac{1}{b-a} E\left((X(t)-a)^{+}\right)\right)
$$

for every $M$ and therefore, $P\left(N_{[a, b]}\right)=0$.
Therefore, corresponding to $a<b$, there exists a set of measure $0, N_{[a, b]}$ such that for $\omega \notin N_{[a, b]} 62.8 .28$ is not true for any $s \in[0, t)$. Let $N \equiv \cup_{a, b \in \mathbb{Q}} N_{[a, b]}$, a set of measure 0 with the property that if $\omega \notin N$, then 62.8 .28 fails to hold for any pair of rational numbers, $a<b$ for any $s \in[0, t)$. Thus for $\omega \notin N$,

$$
\lim _{r \rightarrow s+, r \in \mathbb{Q}} X(r, \omega)
$$

exists for all $s \in[0, t)$. Similar reasoning applies to show the existence of the limit

$$
\lim _{r \rightarrow s-, r \in \mathbb{Q}} X(r, \omega) .
$$

for all $s \in(0, t]$ whenever $\omega$ is outside of a set of measure zero. Of course, this exceptional set depends on $t$. However, if this exceptional set is denoted as $N_{t}$, one could consider $N \equiv \cup_{n=1}^{\infty} N_{n}$. It is obvious there is no change if $\mathbb{Q}$ is replaced with any countable dense subset. This proves the theorem.

Of course the above theorem does not say the left and right limits are equal, just that they exist in some way for $\omega$ not in some set of measure zero. Also it has not been shown that $\lim _{r \rightarrow s+, r \in \mathbb{Q}} X(r, \omega)=X(r, \omega)$ for a.e. $\omega$.

Corollary 62.8.2 In the situation of Theorem 62.8.1, let $s>0$ and let $D_{1}$ and $D_{2}$ be two countable dense subsets of $\mathbb{R}$. Then

$$
\begin{aligned}
\lim _{r \rightarrow s-, r \in D_{1}} X(r, \omega) & =\lim _{r \rightarrow s-, r \in D_{2}} X(r, \omega) \text { a.e. } \omega \\
\lim _{r \rightarrow s+, r \in D_{1}} X(r, \omega) & =\lim _{r \rightarrow s+, r \in D_{2}} X(r, \omega) \text { a.e. } \omega
\end{aligned}
$$

Proof: Let $\left\{r_{n}^{i}\right\}$ be an increasing sequence from $D_{i}$ converging to $s$ and let $N$ be the exceptional set corresponding to the countable dense set $D_{1} \cup D_{2}$. Then for $\omega \notin N$, and $i=1,2$,

$$
\lim _{r \rightarrow s-, r \in D_{1} \cup D_{2}} X(r, \omega)=\lim _{n \rightarrow \infty} X\left(r_{n}^{i}, \omega\right)=\lim _{r \rightarrow s-, r \in D_{i}} X(r, \omega)
$$

The other claim is similar. This proves the corollary.
Now here is an impressive lemma about submartingales and uniform integrability.
Lemma 62.8.3 Let $X(t)$ be a submartingale adapted to a filtration $\mathscr{F}_{t}$. Let $\left\{r_{k}\right\} \subseteq[s, t)$ be a decreasing sequence converging to $s$. Then $\left\{X\left(r_{j}\right)\right\}_{j=1}^{\infty}$ is uniformly integrable.

Proof: First I will show the sequence is equiintegrable. I need to show that for all $\varepsilon>0$ there exists $\lambda$ large enough that for all $n$

$$
\int_{\left[\left|X\left(r_{n}\right)\right| \geq \lambda\right]}\left|X\left(r_{n}\right)\right| d P<\varepsilon
$$

Let $\varepsilon>0$ be given. Since $\{X(r)\}_{r>0}$ is a submartingale, $E\left(X\left(r_{n}\right)\right)$ is a decreasing sequence bounded below by $E(X(s))$. This is because for $r_{n}<r_{k}$,

$$
E\left(X\left(r_{n}\right)\right) \leq E\left(E\left(X\left(r_{k}\right) \mid \mathscr{F}_{n}\right)\right)=E\left(X\left(r_{k}\right)\right)
$$

Pick $k$ such that

$$
\begin{aligned}
& E\left(X\left(r_{k}\right)\right)-\lim _{n \rightarrow \infty} E\left(X\left(r_{n}\right)\right) \\
= & \left|E\left(X\left(r_{k}\right)\right)-\lim _{n \rightarrow \infty} E\left(X\left(r_{n}\right)\right)\right|<\varepsilon / 2
\end{aligned}
$$

Then for $n>k$,

$$
\begin{align*}
& \int_{\left[\left|X\left(r_{n}\right)\right| \geq \lambda\right]}\left|X\left(r_{n}\right)\right| d P=\int_{\left[X\left(r_{n}\right) \geq \lambda\right]} X\left(r_{n}\right) d P+\int_{\left[X\left(r_{n}\right) \leq-\lambda\right]}-X\left(r_{n}\right) d P \\
& =\int_{\left[X\left(r_{n}\right) \geq \lambda\right]} X\left(r_{n}\right) d P+\int_{\left[X\left(r_{n}\right)>-\lambda\right]} X\left(r_{n}\right) d P-\int_{\Omega} X\left(r_{n}\right) d P \\
& \leq \int_{\left[X\left(r_{n}\right) \geq \lambda\right]} X\left(r_{n}\right) d P+\int_{\left[X\left(r_{n}\right)>-\lambda\right]} E\left(X\left(r_{k}\right) \mid \mathscr{F}_{n}\right) d P-\int_{\Omega} X\left(r_{n}\right) d P \\
& \leq \int_{\left[X\left(r_{n}\right) \geq \lambda\right]} X\left(r_{k}\right) d P+\int_{\left[X\left(r_{n}\right)>-\lambda\right]} X\left(r_{k}\right) d P-\int_{\Omega} X\left(r_{k}\right) d P+\varepsilon / 2 \\
& =\int_{\left[X\left(r_{n}\right) \geq \lambda\right]} X\left(r_{k}\right) d P+\int_{\left[X\left(r_{n}\right) \leq-\lambda\right]}\left(-X\left(r_{k}\right)\right) d P+\varepsilon / 2 \\
& =\int_{\left[\left|X\left(r_{n}\right)\right| \geq \lambda\right]}\left|X\left(r_{k}\right)\right| d P+\varepsilon / 2 \\
& \leq \int_{\left[\sup \left\{|X(r)| \geq \lambda: r \in\left\{r_{j}\right\}_{j=1}^{\infty}\right\}\right]}\left|X\left(r_{k}\right)\right| d P+\varepsilon / 2 \tag{62.8.29}
\end{align*}
$$

From maximal inequalities of Theorem 60.6.4

$$
P\left(\left[\sup _{r \in\left\{r_{n}, r_{n-1}, \cdots, r_{1}\right\}}|X(r)| \geq \lambda\right]\right) \leq \frac{2 E(|X(t)|+|X(0)|)}{\lambda} \equiv \frac{C}{\lambda}
$$

and so, letting $n \rightarrow \infty$,

$$
P\left(\left[\sup _{r \in\left\{r_{n}\right\}_{n=1}^{\infty}}|X(r)| \geq \lambda\right]\right) \leq \frac{C}{\lambda}
$$

It follows that for $\lambda$ sufficiently large the first term in 62.8 .29 is smaller than $\varepsilon / 2$ because $k$ is fixed. Now this shows there is a choice of $\lambda$ such that for all $n>k$,

$$
\int_{\left[\left|X\left(r_{n}\right)\right| \geq \lambda\right]}\left|X\left(r_{n}\right)\right| d P<\varepsilon
$$

There are only finitely many $r_{n}$ for $n \leq k$ and by choosing $\lambda$ sufficiently large the above formula can be made to hold for these also, thus showing $\left\{X\left(r_{n}\right)\right\}$ is equi integrable.

Now this implies the sequence of random variables is uniformly integrable as well. Let $\varepsilon>0$ be given and choose $\lambda$ large enough that for all $n$,

$$
\int_{\left[\left|X\left(r_{n}\right)\right| \geq \lambda\right]}\left|X\left(r_{n}\right)\right| d P<\varepsilon / 2
$$

Then let $A$ be a measurable set.

$$
\begin{aligned}
\int_{A}\left|X\left(r_{n}\right)\right| d P & =\int_{A \cap\left[\left|X\left(r_{n}\right)\right| \geq \lambda\right]}\left|X\left(r_{n}\right)\right| d P+\int_{A \cap\left[\left|X\left(r_{n}\right)\right|<\lambda\right]}\left|X\left(r_{n}\right)\right| d P \\
& <\varepsilon / 2+\int_{A \cap\left[\left|X\left(r_{n}\right)\right|<\lambda\right]}\left|X\left(r_{n}\right)\right| d P \leq \frac{\varepsilon}{2}+\lambda P(A)
\end{aligned}
$$

and now you see that if $P(A)$ is sufficiently small then for all $n$,

$$
\int_{A}\left|X\left(r_{n}\right)\right| d P<\varepsilon
$$

which shows the set of functions is uniformly integrable as claimed. This proves the lemma.
You can often consider a submartingale to be right continuous. This is the importance of the following theorem.

Theorem 62.8.4 Let $\{X(t)\}$ be a submartingale adapted to a normal filtration $\mathscr{F}_{t}$. There exists a right continuous submartingale having left limits, $\{Y(t)\}$ such that $Y(t)=X(t)$ a.e. for every $t \in \mathbb{Q}^{+}$. Furthermore $\{X(t)\}$ has a right continuous left limits version if and only if

$$
t \rightarrow E(X(t))
$$

is right continuous. More generally, $Y(t)=X(t)$ a.e. at every point where the above function is right continuous.

Proof: From Theorem 62.8.1, there exists a set of measure zero, $N$ such that for $\omega \notin N$, left and right limits of the following form exist.

$$
\lim _{r \rightarrow t+, r \in \mathbb{Q}} X(r, \omega), \lim _{r \rightarrow t-, r \in \mathbb{Q}} X(r, \omega) .
$$

Then define for each $t$ and $\omega \notin N$,

$$
Y(t, \omega) \equiv \lim _{r \rightarrow t+, r \in \mathbb{Q}} X(r, \omega) .
$$

and for $\omega \in N$,

$$
Y(t, \omega) \equiv 0
$$

Thus $Y(t)(\omega)=X(t)(\omega)$ a.e. for $t \in \mathbb{Q}^{+}$. For each $\omega \notin N$, there exists $\delta>0$ such that if $r \in \mathbb{Q}, t<r<t+2 \delta$, then

$$
|Y(t, \omega)-X(r, \omega)|<\varepsilon / 2
$$

Now suppose $s \in(t, t+\boldsymbol{\delta})$. Then there exists $\delta_{1}<\boldsymbol{\delta}$ such that if $s<r<s+\delta_{1}$ then

$$
|Y(s, \omega)-X(r, \omega)|<\varepsilon / 2
$$

pick $r \in \mathbb{Q} \cap(s, t+\boldsymbol{\delta})$. Then both of the above two inequalities hold and so it follows

$$
\begin{aligned}
|Y(t, \omega)-Y(s, \omega)| & <|Y(t, \omega)-X(r, \omega)|+|X(r, \omega)-Y(s, \omega)| \\
& <\varepsilon / 2+\varepsilon / 2=\varepsilon
\end{aligned}
$$

Therefore, $t \rightarrow Y(t, \omega)$ is right continuous as claimed.
From the definition of $Y(t, \omega)$, it follows $\omega \rightarrow Y(t, \omega)$ is measurable in $\mathscr{F}_{t+}$ because it is the limit of a sequence, $X\left(r_{n}, \omega\right) \mathscr{X}_{N^{C}}$ where $r_{n} \rightarrow t+$. Now each $X\left(r_{n}, \cdot\right)$ is $\mathscr{F}_{r_{n}}$ measurable and so $Y(t, \cdot)$ is $\mathscr{F}_{r_{n}}$ measurable also for each $r_{n}$. Thus $Y(t, \cdot)$ is $\mathscr{F}_{t+}$ measurable. Since the filtration is normal, $\mathscr{F}_{t}=\mathscr{F}_{t+}$ and it follows $Y(t, \cdot)$ is $\mathscr{F}_{t}$ measurable. Why is $Y(t, \cdot) \in L^{1}(\Omega)$ ?

From Lemma 62.8.3, the collection $\left\{X\left(r_{n}\right)\right\}$ is uniformly integrable. Therefore, from the Vitali convergence theorem, Theorem 11.5.3 on Page 257,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{\Omega}\left|Y(s)-X\left(r_{n}\right)\right| d P=0 \tag{62.8.30}
\end{equation*}
$$

and $Y(s) \in L^{1}(\Omega)$.
It remains to verify $\{Y(s)\}$ is a submartingale. For $s<t$, is it true that

$$
E\left(Y(t) \mid \mathscr{F}_{s}\right) \geq Y(s) ?
$$

Fix $A \in \mathscr{F}_{s}$. From the above construction, there exists $w \in \mathbb{Q}$ and $w \geq t$ such that

$$
\int_{A} Y(t) d P \geq \int_{A} X(w) d P-\varepsilon
$$

Then also, there exists $r \in \mathbb{Q} \cap(s, t)$ such that

$$
\int_{A} X(r) d P \geq \int_{A} Y(s) d P-\varepsilon
$$

Now

$$
\begin{aligned}
\int_{A} E\left(Y(t) \mid \mathscr{F}_{s}\right) d P & =\int_{A} Y(t) d P \geq \int_{A} X(w) d P-\varepsilon \\
& =\int_{A} E\left(X(w) \mid \mathscr{F}_{r}\right) d P-\varepsilon \\
& \geq \int_{A} X(r) d P-\varepsilon \geq \int_{A} Y(s) d P-2 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows

$$
\int_{A} E\left(Y(t) \mid \mathscr{F}_{s}\right) d P \geq \int_{A} Y(s) d P
$$

for any $A \in \mathscr{F}_{s}$ and so this verifies since $A$ is arbitrary that

$$
E\left(Y(t) \mid \mathscr{F}_{s}\right) \geq Y(s)
$$

so $Y$ is a submartingale.
By Theorem 62.8.1 there exists a set of measure $0, N$ such that the left limits of $Y(r, \omega)$ exist through rational numbers if $\omega \notin N$.

Is $\{Y(t)\}$ a version of $\{X(t)\}$ ? This is where the assumption $t \rightarrow E(X(t))$ is continuous is used. We know $E\left(X\left(r_{n}\right) \mid \mathscr{F}_{s}\right) \geq X(s)$ and also for $A \in \mathscr{F}_{s}$

$$
\int_{A} X\left(r_{n}\right) d P=\int_{A} E\left(X\left(r_{n}\right) \mid \mathscr{F}_{s}\right) d P \geq \int_{A} X(s) d P
$$

Hence taking a limit yields

$$
\int_{A} Y(s) d P \geq \int_{A} X(s) d P
$$

and since $A$ is arbitrary, $Y(s) \geq X(s)$. Now since $t \rightarrow E(X(t))$ is continuous,

$$
\begin{aligned}
\int_{\Omega}|Y(s)-X(s)| d P & =E(Y(s))-E(X(s)) \\
& =\lim _{n \rightarrow \infty}\left(E\left(X\left(r_{n}\right)\right)-E\left(X\left(r_{n}\right)\right)\right)=0
\end{aligned}
$$

It only remains to verify the only way $X(t)$ has a right continuous version is for $t \rightarrow E(X(t))$ to be continuous. Suppose then that $\{X(t)\}$ has a right continuous version, $\{Y(t)\}$. Letting $r_{n} \downarrow s$, Lemma 62.8.3 implies $\left\{Y\left(r_{n}\right)\right\}$ is uniformly integrable. Also $Y(s)(\omega)=\lim _{n \rightarrow \infty} Y\left(r_{n}\right)(\omega)$ a.e. and so by the Vitali convergence theorem,

$$
\lim _{n \rightarrow \infty} \int_{\Omega}\left|X\left(r_{n}\right)-X(s)\right| d P=\lim _{n \rightarrow \infty} \int_{\Omega}\left|Y\left(r_{n}\right)-Y(s)\right| d P=0
$$

This proves the theorem.
Note that the condition $t \rightarrow E(X(t))$ being continuous holds for any martingale. Therefore, every martingale has a right continuous version. The condition that $t \rightarrow E(X(t))$ is right continuous is not a very stringent assumption. For $\{X(t)\}$ a submartingale, this is an increasing function. Therefore, the only points where the condition might not hold comprise a countable set.

### 62.9 Some Maximal Inequalities

As in the case of discrete martingales and submartingales, there are maximal inequalities available.

Lemma 62.9.1 Let $X$ be right continuous and adapted such that the given filtration is complete in the sense that $\mathscr{F}_{0}$ contains all sets $A$ of $\mathscr{F}$ such that $P(A)=0$. Then there exists a set of measure zero $N$ and a $\mathscr{F} \times \mathscr{B}(\mathbb{R})$ measurable function $Y$ such that if $\omega \notin N$, then $Y(t)(\omega)=X(t)(\omega)$. Also, if $f$ is $\mathscr{F}$ measurable and nonnegative then $(\lambda, \omega) \rightarrow \mathscr{X}_{[f>\lambda]}$ is $\mathscr{F} \times \mathscr{B}(\mathbb{R})$ measurable.

Proof: Let $\left\{t_{0}^{n}, t_{1}^{n}, \cdots, t_{m_{n}}^{n}\right\}$ be a partition of $[0, T]$ in which $\left|t_{i}^{n}-t_{i-1}^{n}\right|<\rho_{n}$ where $\rho_{n} \rightarrow 0$. Now define $X_{n}$ as follows:

$$
\begin{aligned}
X_{n}(t)(\omega) & \equiv \sum_{i=1}^{m_{n}} X\left(t_{i}^{n}\right)(\omega) \mathscr{X}_{\left(t_{i-1}^{n}, t_{i}^{n}\right]}(t) \\
X_{n}(0) & \equiv X(0)
\end{aligned}
$$

then each $X_{n}$ is obviously product measurable because it is the sum of functions which are. By right continuity, $X_{n}$ converges pointwise to $X$ for $\omega \notin N$ where $N$ is a set of measure zero and so if $Y(t)(\omega) \equiv X(t)(\omega)$ for all $\omega \notin N$ and $Y(t)(\omega)=0$ for all $\omega \in N$, this is the desired product measurable function.

To see the last claim, let $s$ be a nonnegative simple function, $s(\omega)=\sum_{k=1}^{n} c_{k} \mathscr{X}_{E_{k}}(\omega)$ where the $c_{k}$ are strictly increasing in $k$. Also let $F_{k}=\cup_{i=k}^{n} E_{i}$. Then

$$
\mathscr{X}_{[s>\lambda]}=\sum_{k=1}^{n} \mathscr{X}_{\left[c_{k-1}, c_{k}\right)}(\lambda) \mathscr{X}_{F_{k}}(\omega)
$$

which is clearly product measurable. For arbitrary $f \geq 0$ and measurable, there is an increasing sequence of simple functions $s_{n}$ converging pointwise to $f$. Therefore,

$$
\lim _{n \rightarrow \infty} \mathscr{X}_{\left[s_{n}>\lambda\right]}=\mathscr{X}_{[f>\lambda]}
$$

and so $\mathscr{X}_{[f>\lambda]}$ is product measurable.
Definition 62.9.2 Let $X(t)$ be a right continuous submartingale for $t \in I$ and let $\left\{\tau_{n}\right\}$ be a sequence of stopping times such that $\lim _{n \rightarrow \infty} \tau_{n}=\infty$. Then $X^{\tau_{n}}$ is called the stopped submartingale and it is defined by

$$
X^{\tau_{n}}(t) \equiv X\left(t \wedge \tau_{n}\right)
$$

Proposition 62.9.3 The stopped submartingale just defined is a submartingale.
Proof: By the optional sampling theorem for submartingales, Theorem 62.7.15, it follows that for $s<t$,

$$
\begin{aligned}
E\left(X^{\tau_{n}}(t) \mid \mathscr{F}_{s}\right) & \equiv E\left(X\left(t \wedge \tau_{n}\right) \mid \mathscr{F}_{s}\right) \geq X\left(t \wedge \tau_{n} \wedge s\right) \\
& =X\left(\tau_{n} \wedge s\right) \equiv X^{\tau_{n}}(s)
\end{aligned}
$$

Theorem 62.9.4 Let $\{X(t)\}$ be a right continuous nonnegative submartingale adapted to the normal filtration $\mathscr{F}_{t}$ for $t \in[0, T]$. Let $p \geq 1$. Define

$$
X^{*}(t) \equiv \sup \{X(s): 0<s<t\}, X^{*}(0) \equiv 0
$$

Then for $\lambda>0$, if $X(t)^{p}$ is in $L^{1}(\Omega)$ for each $t$,

$$
\begin{equation*}
P\left(\left[X^{*}(T)>\lambda\right]\right) \leq \frac{1}{\lambda^{p}} \int \mathscr{X}_{\left[X^{*}(T)>\lambda\right]} X(T)^{p} d P \tag{62.9.31}
\end{equation*}
$$

If $X(t)$ is continuous, the above inequality holds without this assumption. In case $p>1$, and $X(t)$ continuous, then for each $t \leq T$,

$$
\begin{equation*}
\left(\int_{\Omega}\left|X^{*}(t)\right|^{p} d P\right)^{1 / p} \leq \frac{p}{p-1}\left(\int_{\Omega} X(T)^{p} d P\right)^{1 / p} \tag{62.9.32}
\end{equation*}
$$

Proof: The first inequality follows from Theorem 62.5.2. However, it can also be obtained a different way using stopping times.

Define the stopping time

$$
\tau \equiv \inf \{t>0: X(t)>\lambda\} \wedge T
$$

(The infimum over an empty set will equal $\infty$.) This is a stopping time by 62.7 .5 because it is just a continuous function of the first hitting time of an open set. Also from the definition of $X^{*}$ in which the supremum is taken over an open interval,

$$
[\tau<t]=\left[X^{*}(t)>\lambda\right]
$$

Note this also shows $X^{*}(t)$ is $\mathscr{F}_{t}$ measurable. Then it follows that $X^{p}(t)$ is also a submartingale since $r^{p}$ is increasing and convex. By the optional sampling theorem, the sequence given by $X(0)^{p}, X(\tau)^{p}, X(T)^{p}$ is a submartingale. Also $[\tau<T] \in \mathscr{F} \tau$ and so

$$
\int_{[\tau<T]} X(\tau)^{p} d P \leq \int_{[\tau<T]} E\left(X(T)^{p} \mid \mathscr{F}_{\tau}\right) d P=\int_{[\tau<T]} X(T)^{p} d P
$$

By right continuity, on $[\tau<T], X(\tau) \geq \lambda$. Therefore,

$$
\begin{aligned}
\lambda^{p} P\left(\left[X^{*}(T)>\lambda\right]\right) & =\lambda^{p} P([\tau<T]) \\
& \leq \int_{[\tau<T]} X(\tau)^{p} d P \leq \int_{\left[X^{*}(T)>\lambda\right]} X(T)^{p} d P
\end{aligned}
$$

Next suppose $X(t)$ is continuous and let $\left\{\tau_{n}\right\}$ be a localizing sequence,

$$
\tau_{n} \equiv \inf \{t: X(t)>n\}
$$

Then by continuity, $X^{\tau_{n}}$ is bounded because $X\left(\tau_{n} \wedge t\right) \leq n$, and so from what was just shown,

$$
\lambda^{p} P\left(\left[\left(X^{\tau_{n}}\right)^{*}(T)>\lambda\right]\right) \leq \int_{\left[\left(X^{\tau_{n}}\right)^{*}(T)>\lambda\right]}\left(X^{\tau_{n}}\right)(T)^{p} d P
$$

Then $\left(X^{\tau_{n}}\right)(T)$ is increasing as $\tau_{n} \rightarrow \infty$ so the result follows from the monotone convergence theorem. This proves the first part.

Let $X^{\tau_{n}}$ be as just defined. Thus it is a bounded submartingale. To save on notation, the $X$ in the following argument is really $X^{\tau_{n}}$. This is done so that all the integrals are finite. If $p>1$, then from the first part using the case of $p=1$,

$$
\int_{\Omega}\left|X^{*}(t)\right|^{p} d P \leq \int_{\Omega}\left|X^{*}(T)\right|^{p} d P=\int_{0}^{\infty} p \lambda^{p-1} \overbrace{P\left(\left[X^{*}(T)>\lambda\right]\right)}^{\leq \frac{1}{\lambda} \int \mathscr{X}_{\left[X^{*}(T)>\lambda\right]} X(T) d P} d \lambda
$$

$$
\begin{aligned}
& \leq p \int_{0}^{\infty} \lambda^{p-1} \frac{1}{\lambda} \int \mathscr{X}_{\left[X^{*}(T)>\lambda\right]} X(T) d P d \lambda \\
& =p \int_{\Omega} X(T) \int_{0}^{X^{*}(T)} \lambda^{p-2} d \lambda d P \\
& =p \int_{\Omega} X(T) \frac{X^{*}(T)^{p-1}}{p-1} d P \\
& \leq \frac{p}{p-1}\left(\int_{\Omega} X^{*}(T)^{p} d P\right)^{1 / p^{\prime}}\left(\int_{\Omega} X(T)^{p} d P\right)^{1 / p}
\end{aligned}
$$

Now divide both sides by $\left(\int_{\Omega} X^{*}(T)^{p} d P\right)^{1 / p^{\prime}}$. Substituting $X^{\tau_{n}}$ for $X$

$$
\left(\int_{\Omega}\left|X^{\tau_{n} *}(t)\right|^{p} d P\right)^{1 / p} \leq\left(\int_{\Omega} X^{\tau_{n} *}(T)^{p} d P\right)^{1 / p} \leq \frac{p}{p-1}\left(\int_{\Omega} X^{\tau_{n}}(T)^{p} d P\right)^{1 / p}
$$

Now let $n \rightarrow \infty$ and use the monotone convergence theorem to obtain the inequality of the theorem. This establishes 62.9.32. The use of Fubini's theorem follows from Lemma 62.9.1.

Here is another sort of maximal inequality in which $X(t)$ is not assumed nonnegative.
Theorem 62.9.5 Let $\{X(t)\}$ be a right continuous submartingale adapted to the normal filtration $\mathscr{F}_{t}$ for $t \in[0, T]$ and $X^{*}(t)$ defined as in Theorem 62.9.4

$$
\begin{gather*}
X^{*}(t) \equiv \sup \{X(s): 0<s<t\}, X^{*}(0) \equiv 0 \\
P\left(\left[X^{*}(T)>\lambda\right]\right) \leq \frac{1}{\lambda} E(|X(T)|) \tag{62.9.33}
\end{gather*}
$$

For $t>0$, let

$$
X_{*}(t)=\inf \{X(s): s<t\}
$$

Then

$$
\begin{equation*}
P\left(\left[X_{*}(T)<-\lambda\right]\right) \leq \frac{1}{\lambda} E(|X(T)|+|X(0)|) \tag{62.9.34}
\end{equation*}
$$

Also

$$
\begin{align*}
& P([\sup \{|X(s)|: s<T\}>\lambda]) \\
& \quad \leq \frac{2}{\lambda} E(|X(T)|+|X(0)|) \tag{62.9.35}
\end{align*}
$$

Proof: The function $f(r)=r^{+} \equiv \frac{1}{2}(|r|+r)$ is convex and increasing. Therefore, $X^{+}(t)$ is also a submartingale but this one is nonnegative. Also

$$
\left[X^{*}(T)>\lambda\right]=\left[\left(X^{+}\right)^{*}(T)>\lambda\right]
$$

and so from Theorem 62.9.4,

$$
P\left(\left[X^{*}(T)>\lambda\right]\right)=P\left(\left[\left(X^{+}\right)^{*}(T)>\lambda\right]\right) \leq \frac{1}{\lambda} E\left(X^{+}(T)\right) \leq \frac{1}{\lambda} E(|X(T)|) .
$$

Next let

$$
\tau=\min (\inf \{t: X(t)<-\lambda\}, T)
$$

then as before, $X(0), X(\tau), X(T)$ is a submartingale and so

$$
\int_{[\tau<T]} X(\tau) d P+\int_{[\tau=T]} X(\tau) d P=\int_{\Omega} X(\tau) d P \geq \int_{\Omega} X(0) d P
$$

Now for $\omega \in[\tau<T], X(t)(\omega)<-\lambda$ for some $t<T$ and so by right continuity, $X(\tau)(\omega) \leq$ $-\lambda$. therefore,

$$
-\lambda \int_{[\tau<T]} d P \geq-\int_{[\tau=T]} X(T) d P+\int_{\Omega} X(0) d P
$$

If $X_{*}(T)<-\lambda$, then from the definition given above, there exists $t<T$ such that $X(t)<$ $-\lambda$ and so $\tau<T$. If $\tau<T$, then by definition, there exists $t<T$ such that $X(t)<-\lambda$ and so $X_{*}(T)<-\lambda$. Hence $[\tau<T]=\left[X_{*}(T)<-\lambda\right]$. It follows that

$$
\begin{aligned}
P\left(\left[X_{*}(T)<-\lambda\right]\right) & =P([\tau<T]) \\
& \leq \frac{1}{\lambda} \int_{[\tau=T]} X(T) d P-\frac{1}{\lambda} \int_{\Omega} X(0) d P \\
& \leq \frac{1}{\lambda} E(|X(T)|+|X(0)|)
\end{aligned}
$$

and this proves 62.9.34.
Finally, combining the above two inequalities,

$$
\begin{gathered}
P([\sup \{|X(s)|: s<T\}>\lambda]) \\
=P\left(\left[X_{*}(T)<-\lambda\right]\right)+P\left(\left[X^{*}(T)>\lambda\right]\right) \\
\leq \frac{2}{\lambda} E(|X(T)|+|X(0)|) .
\end{gathered}
$$

### 62.10 Continuous Submartingale Convergence Theorem

In this section, $\{Y(t)\}$ will be a continuous submartingale and $a<b$. Let

$$
X(t) \equiv(Y(t)-a)_{+}+a
$$

so $X(0) \geq a$. Then $X$ is also a submartingale. It is an increasing convex function of one. If $Y(t)$ has an upcrossing of $[a, b]$, then $X(t)$ starts off at $a$ and ends up at least as large as $b$. If $X(t)$ has an upcrossing of $[a, b]$ then it must start off at $a$ since it cannot be smaller and it ends up at least as large as $b$. Thus we can count the upcrossings of $Y(t)$ by considering the upcrossings of $X(t)$.

The next task is to consider an upcrossing estimate as was done before for discrete submartingales.

$$
\begin{aligned}
\tau_{0} & \equiv \min (\inf \{t>0: X(t)=a\}, M), \\
\tau_{1} & \equiv \min \left(\inf \left\{t>0:\left(X\left(t \vee \tau_{0}\right)-X\left(\tau_{0}\right)\right)_{+}=b-a\right\}, M\right), \\
\tau_{2} & \equiv \min \left(\inf \left\{t>0:\left(X\left(\tau_{1}\right)-X\left(t \vee \tau_{1}\right)\right)_{+}=b-a\right\}, M\right), \\
\tau_{3} & \equiv \min \left(\inf \left\{t>0:\left(X\left(t \vee \tau_{2}\right)-X\left(\tau_{2}\right)\right)_{+}=b-a\right\}, M\right), \\
\tau_{4} & \equiv \min \left(\inf \left\{t>0:\left(X\left(\tau_{3}\right)-X\left(t \vee \tau_{3}\right)\right)_{+}=b-a\right\}, M\right),
\end{aligned}
$$

If $X(t)$ is never $a$, then $\tau_{0}=M$ and there are no upcrossings. It is obvious $\tau_{1} \geq \tau_{0}$ since otherwise, the inequality could not hold. Thus the evens have $X\left(\tau_{2 k}\right)=a$ and $X\left(\tau_{2 k+1}\right)=$ $b$.

Lemma 62.10.1 The above $\tau_{i}$ are stopping times for $t \in[0, M]$.
Proof: It is obvious that $\tau_{0}$ is a stopping time because it is the minimum of $M$ and the first hitting time of a closed set by a continuous adapted process. Consider a stopping time $\eta \leq M$ and let

$$
\sigma \equiv \inf \left\{t>0:(X(t \vee \eta)-X(\eta))_{+}=b-a\right\}
$$

I claim that $t \rightarrow X(t \vee \eta)-X(\eta)$ is adapted to $\mathscr{F}_{t}$. Suppose $\alpha \geq 0$ and consider

$$
\begin{equation*}
\left[(X(t \vee \eta)-X(\eta))_{+}>\alpha\right] \tag{62.10.36}
\end{equation*}
$$

The above set equals

$$
\left(\left[(X(t \vee \eta)-X(\eta))_{+}>\alpha\right] \cap[\eta \leq t]\right) \cap\left(\left[(X(t \vee \eta)-X(\eta))_{+}>\alpha\right] \cap[\eta>t]\right)
$$

Consider the second of the above two sets. Since $\alpha \geq 0$, this set is $\emptyset$. This is because for $\eta>t, X(t \vee \eta)-X(\eta)=0$. Now consider the first. It equals

$$
\left[(X(t \vee \eta)-X(\eta))_{+}>\alpha\right] \cap[\eta \vee t \leq t]
$$

a set of $\mathscr{F}_{t \vee \eta}$ intersected with $[\eta \vee t \leq t]$ and so it is in $\mathscr{F}_{t}$ from properties of stopping times.

If $\alpha<0$, then 62.10 .36 reduces to $\Omega$, also in $\mathscr{F}_{t}$. Therefore, by Proposition 62.7.5, $\sigma$ is a stopping time because it is the first hitting time of a closed set of a continuous adapted process. It follows that $\sigma \wedge M$ is also a stopping time. Similarly $t \rightarrow X(\eta)-X(t \vee \eta)$ is adapted and

$$
\sigma \equiv \inf \left\{t>0:(X(\eta)-X(t \vee \eta))_{+}=b-a\right\}
$$

is also a stopping time from the same reasoning. It follows that the $\tau_{i}$ defined above are all stopping times.

Note that in the above, if $\eta=M$, then $\sigma=M$ also. Thus in the definition of the $\tau_{i}$, if any $\tau_{i}=M$, it follows that also $\tau_{i+1}=M$ and so there is no change in the stopping times. Also note that these stopping times $\tau_{i}$ are increasing as $i$ increases.

Let

$$
U_{[a, b]}^{n M} \equiv \lim _{\varepsilon \rightarrow 0} \sum_{k=0}^{n} \frac{X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)}{\varepsilon+X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)}
$$

Note that if an upcrossing occurs after $\tau_{2 k}$ on $[0, M]$, then $\tau_{2 k+1}>\tau_{2 k}$ because there exists $t$ such that

$$
\left(X\left(t \vee \tau_{2 k}\right)-X\left(\tau_{2 k}\right)\right)_{+}=b-a
$$

However, you could have $\tau_{2 k+1}>\tau_{2 k}$ without an upcrossing occuring. This happens when $\tau_{2 k}<M$ and $\tau_{2 k+1}=M$ which may mean that $X(t)$ never again climbs to $b$. You break the sum into those terms where $X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)=b-a$ and those where this is less than $b-a$. Suppose for a fixed $\omega$, the terms where the difference is $b-a$ are for $k \leq m$. Then there might be a last term for which $X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)<b-a$ because it fails to complete the up crossing. There is only one of these at $k=m+1$. Then the above sum is

$$
\begin{aligned}
& \leq \frac{1}{b-a} \sum_{k=0}^{m} X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)+\frac{X(M)-a}{\varepsilon+X(M)-a} \\
& \leq \frac{1}{b-a} \sum_{k=0}^{n} X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)+\frac{X(M)-a}{\varepsilon+X(M)-a} \\
& \leq \frac{1}{b-a} \sum_{k=0}^{n} X\left(\tau_{2 k+1}\right)-X\left(\tau_{2 k}\right)+1
\end{aligned}
$$

Then $U_{[a, b]}^{n M}$ is clearly a random variable which is at least as large as the number of upcrossings occurring for $t \leq M$ using only $2 n+1$ of the stopping times. From the optional sampling theorem,

$$
\begin{aligned}
E\left(X\left(\tau_{2 k}\right)\right)-E\left(X\left(\tau_{2 k-1}\right)\right) & =\int_{\Omega} X\left(\tau_{2 k}\right)-X\left(\tau_{2 k-1}\right) d P \\
& =\int_{\Omega} E\left(X\left(\tau_{2 k}\right) \mid \mathscr{F}_{2 k-1}\right)-X\left(\tau_{2 k-1}\right) d P \\
& \geq \int_{\Omega} X\left(\tau_{2 k-1}\right)-X\left(\tau_{2 k-1}\right) d P=0
\end{aligned}
$$

Note that, $X\left(\tau_{2 k}\right)=a$ while $X\left(\tau_{2 k-1}\right)=b$ so the above may seem surprising. However, the two stopping times can both equal $M$ so this is actually possible. For example, it could happen that $X(t)=a$ for all $t \in[0, M]$.

Next, take the expectation of both sides,

$$
\begin{gathered}
E\left(U_{[a, b]}^{n M}\right) \leq \frac{1}{b-a} \sum_{k=0}^{n} E\left(X\left(\tau_{2 k+1}\right)\right)-E\left(X\left(\tau_{2 k}\right)\right)+1 \\
\leq \frac{1}{b-a} \sum_{k=0}^{n} E\left(X\left(\tau_{2 k+1}\right)\right)-E\left(X\left(\tau_{2 k}\right)\right)+\frac{1}{b-a} \sum_{k=1}^{n} E\left(X\left(\tau_{2 k}\right)\right)-E\left(X\left(\tau_{2 k-1}\right)\right)+1 \\
=\frac{1}{b-a}\left(E\left(X\left(\tau_{1}\right)\right)-E\left(X\left(\tau_{0}\right)\right)\right)+\frac{1}{b-a} \sum_{k=1}^{n} E\left(X\left(\tau_{2 k+1}\right)\right)-E\left(X\left(\tau_{2 k-1}\right)\right)+1
\end{gathered}
$$

$$
\begin{aligned}
& \leq \frac{1}{b-a}\left(E\left(X\left(\tau_{2 n+1}\right)\right)-E\left(X\left(\tau_{0}\right)\right)\right)+1 \\
& \leq \frac{1}{b-a}(E(X(M))-a)+1
\end{aligned}
$$

which does not depend on $n$. The last inequality follows because $0 \leq \tau_{2 n+1} \leq M$ and $X(t)$ is a submartingale. Let $n \rightarrow \infty$ to obtain

$$
E\left(U_{[a, b]}^{M}\right) \leq \frac{1}{b-a}(E(X(M))-a)+1
$$

where $U_{[a, b]}^{M}$ is an upper bound to the number of upcrossings of $\{X(t)\}$ on $[0, M]$. This proves the following interesting upcrossing estimate.

Lemma 62.10.2 Let $\{Y(t)\}$ be a continuous submartingale adapted to a normal filtration $\mathscr{F}_{t}$ for $t \in[0, M]$. Then if $U_{[a, b]}^{M}$ is defined as the above upper bound to the number of upcrossings of $\{Y(t)\}$ for $t \in[0, M]$, then this is a random variable and

$$
\begin{aligned}
E\left(U_{[a, b]}^{M}\right) & \leq \frac{1}{b-a}\left(E(Y(M)-a)_{+}+a-a\right)+1 \\
& =\frac{1}{b-a} E|Y(M)|+\frac{1}{b-a}|a|+1
\end{aligned}
$$

With this it is easy to prove a continuous submartingale convergence theorem.
Theorem 62.10.3 Let $\{X(t)\}$ be a continuous submartingale adapted to a normal filtration such that

$$
\sup _{t}\{E(|X(t)|)\}=C<\infty
$$

Then there exists $X_{\infty} \in L^{1}(\Omega)$ such that

$$
\lim _{t \rightarrow \infty} X(t)(\omega)=X_{\infty}(\omega) \text { a.e. } \omega
$$

Proof: Let $U_{[a, b]}$ be defined by

$$
U_{[a, b]}=\lim _{M \rightarrow \infty} U_{[a, b]}^{M} .
$$

Thus the random variable $U_{[a, b]}$ is an upper bound for the number of upcrossings. From Lemma 62.10.2 and the assumption of this theorem, there exists a constant $C$ independent of $M$ such that

$$
E\left(U_{[a, b]}^{M}\right) \leq \frac{C}{b-a}+1
$$

Letting $M \rightarrow \infty$, it follows from monotone convergence theorem that

$$
E\left(U_{[a, b]}\right) \leq \frac{C}{b-a}+1
$$

also. Therefore, there exists a set of measure $0 N_{a b}$ such that if $\omega \notin N_{a b}$, then $U_{[a, b]}(\omega)<\infty$. That is, there are only finitely many upcrossings. Now let

$$
N=\cup\left\{N_{a b}: a, b \in \mathbb{Q}\right\} .
$$

It follows that for $\omega \notin N$, it cannot happen that

$$
\lim \sup _{t \rightarrow \infty} X(t)(\omega)-\lim \inf _{t \rightarrow \infty} X(t)(\omega)>0
$$

because if this expression is positive, there would be arbitrarily large values of $t$ where $X(t)(\omega)>b$ and arbitrarily large values of $t$ where $X(t)(\omega)<a$ where $a, b$ are rational numbers chosen such that

$$
\lim \sup _{t \rightarrow \infty} X(t)(\omega)>b>a>\lim _{\inf _{t \rightarrow \infty}} X(t)(\omega)
$$

Thus there would be infinitely many upcrossings which is not allowed for $\omega \notin N$. Therefore, the limit $\lim _{t \rightarrow \infty} X(t)(\omega)$ exists for a.e. $\omega$. Let $X_{\infty}(\omega)$ equal this limit for $\omega \notin N$ and let $X_{\infty}(\omega)=0$ for $\omega \in N$. Then $X_{\infty}$ is measurable and by Fatou's lemma,

$$
\int_{\Omega}\left|X_{\infty}(\omega)\right| d P \leq \lim \inf _{n \rightarrow \infty} \int_{\Omega}|X(n)(\omega)| d P<C
$$

Now here is an interesting result due to Doob.
Theorem 62.10.4 Let $\{M(t)\}$ be a continuous real martingale adapted to the normal filtration $\mathscr{F}_{t}$. Then the following are equivalent.

1. The random variables $M(t)$ are equiintegrable.
2. There exists $M(\infty) \in L^{1}(\Omega)$ such that $\lim _{t \rightarrow \infty}\|M(\infty)-M(t)\|_{L^{1}(\Omega)}=0$.

In this case, $M(t)=E\left(M(\infty) \mid \mathscr{F}_{t}\right)$ and convergence also takes place pointwise.
Proof: Suppose the equiintegrable condition. Then there exists $\lambda$ large enough that for all $t$,

$$
\int_{[|M(t)| \geq \lambda]}|M(t)| d t<1
$$

It follows that for all $t$,

$$
\begin{aligned}
\int_{\Omega}|M(t)| d P & =\int_{[|M(t)| \geq \lambda]}|M(t)| d P+\int_{[|M(t)|<\lambda]}|M(t)| d P \\
& \leq 1+\lambda
\end{aligned}
$$

Since the martingale is bounded in $L^{1}$, by Theorem 62.10 .3 there exists $M(\infty) \in L^{1}(\Omega)$ such that $\lim _{t \rightarrow \infty} M(t)(\omega)=M(\infty)(\omega)$ pointwise a.e. By the assumption $\{M(t)\}$ are equiintegrable, it follows these functions are uniformly integrable. Letting $\delta>0$ be such that if $P(E)<\delta$, then

$$
\int_{E}|M(t)| d P<\frac{\varepsilon}{5}
$$

and $t_{n} \rightarrow \infty$, Egoroff's theorem implies that there exists a set $E$ of measure less than $\delta$ such that on $E^{C}$, the convergence of the $M\left(t_{n}\right)$ is uniform. Thus

$$
\begin{aligned}
\int_{\Omega}\left|M\left(t_{m}\right)-M\left(t_{n}\right)\right| d P & =\int_{E}\left|M\left(t_{m}\right)-M\left(t_{n}\right)\right| d P+\int_{E^{C}}\left|M\left(t_{m}\right)-M\left(t_{n}\right)\right| d P \\
& \leq \frac{2 \varepsilon}{5}+\int_{E^{C}}\left|M\left(t_{m}\right)-M\left(t_{n}\right)\right| d P<\varepsilon
\end{aligned}
$$

whenever $m, n$ are large enough. Therefore, the sequence $\left\{M\left(t_{n}\right)\right\}$ is Cauchy in $L^{1}(\Omega)$ which implies it converges to something in $L^{1}(\Omega)$ which must equal $M(\infty)$ a.e.

Next suppose there is a function $M(\infty)$ to which $M(t)$ converges in $L^{1}(\Omega)$. Then for $t$ fixed and $A \in \mathscr{F}_{t}$, then as $s \rightarrow \infty, s>t$

$$
\begin{aligned}
\int_{A} M(t) d P & =\int_{A} E\left(M(s) \mid \mathscr{F}_{t}\right) d P \equiv \int_{A} M(s) d P \\
& \rightarrow \int_{A} M(\infty) d P=\int_{A} E\left(M(\infty) \mid \mathscr{F}_{t}\right)
\end{aligned}
$$

which shows $E\left(M(\infty) \mid \mathscr{F}_{t}\right)=M(t)$ a.e. since $A \in \mathscr{F}_{t}$ is arbitrary. By Lemma 62.7.11,

$$
\begin{align*}
\int_{[|M(t)| \geq \lambda]}|M(t)| d P & =\int_{[|M(t)| \geq \lambda]}\left|E\left(M(\infty) \mid \mathscr{F}_{t}\right)\right| d P \\
& \leq \int_{[|M(t)| \geq \lambda]} E\left(|M(\infty)| \mid \mathscr{F}_{t}\right) d P \\
& =\int_{[|M(t)| \geq \lambda]}|M(\infty)| d P \tag{62.10.37}
\end{align*}
$$

Now from this,

$$
\begin{aligned}
\lambda P([|M(t)| \geq \lambda]) & \leq \int_{[|M(t)| \geq \lambda]}|M(t)| d P \leq \int_{\Omega}\left|E\left(M(\infty) \mid \mathscr{F}_{t}\right)\right| d P \\
& \leq \int_{\Omega} E\left(|M(\infty)| \mid \mathscr{F}_{t}\right) d P=\int_{\Omega}|M(\infty)| d P
\end{aligned}
$$

and so

$$
P([|M(t)| \geq \lambda]) \leq \frac{C}{\lambda}
$$

From 62.10.37, this shows $\{M(t)\}$ is uniformly integrable because this is true of the single function $|M(\infty)|$. By the submartingale convergence theorem, the convergence to $M(\infty)$ also takes place pointwise.

### 62.11 Hitting This Before That

Let $\{M(t)\}$ be a real valued martingale for $t \in[0, T]$ where $T \leq \infty$ and $M(0)=0$. In case $T=\infty$, assume the conditions of Theorem 62.10 .4 are satisfied. Thus there exists $M(\infty)$ and the $M(t)$ are equiintegrable. With the Doob optional sampling theorem it is possible to estimate the probability that $M(t)$ hits $a$ before it hits $b$ where $a<0<b$. There is no loss
of generality in assuming $T=\infty$ since if it is less than $\infty$, you could just let $M(t) \equiv M(T)$ for all $t>T$. In this case, the equiintegrability of the $M(t)$ follows because for $t<T$,

$$
\begin{aligned}
\int_{[|M(t)|>\lambda]}|M(t)| d P & =\int_{[|M(t)|>\lambda]}\left|E\left(M(T) \mid \mathscr{F}_{t}\right)\right| d P \\
& \leq \int_{[|M(t)|>\lambda]}|M(T)| d P
\end{aligned}
$$

and from Theorem 62.9.5,

$$
P(|M(t)|>\lambda) \leq P\left(\left[M^{*}(t)>\lambda\right]\right) \leq \frac{1}{\lambda} \int_{\Omega}|M(T)| d P
$$

Definition 62.11.1 Let $M$ be a process adapted to the filtration $\mathscr{F}_{t}$ and let $\tau$ be a stopping time. Then $M^{\tau}$, called the stopped process is defined by

$$
M^{\tau}(t) \equiv M(\tau \wedge t)
$$

With this definition, here is a simple lemma.
Lemma 62.11.2 Let $M$ be a right continuous martingale adapted to the normal filtration $\mathscr{F}_{t}$ and let $\tau$ be a stopping time. Then $M^{\tau}$ is also a martingale adapted to the filtration $\mathscr{F}_{t}$.

Proof:Let $s<t$. By the Doob optional sampling theorem,

$$
E\left(M^{\tau}(t) \mid \mathscr{F}_{s}\right) \equiv E\left(M(\tau \wedge t) \mid \mathscr{F}_{s}\right)=M(\tau \wedge t \wedge s)=M^{\tau}(s)
$$

Theorem 62.11.3 Let $\{M(t)\}$ be a continuous real valued martingale adapted to the normal filtration $\mathscr{F}_{t}$ and let

$$
M^{*} \equiv \sup \{|M(t)|: t \geq 0\}
$$

and $M(0)=0$. Letting

$$
\tau_{x} \equiv \inf \{t>0: M(t)=x\}
$$

Then if $a<0<b$ the following inequalities hold.

$$
(b-a) P\left(\left[\tau_{b} \leq \tau_{a}\right]\right) \geq-a P\left(\left[M^{*}>0\right]\right) \geq(b-a) P\left(\left[\tau_{b}<\tau_{a}\right]\right)
$$

and

$$
(b-a) P\left(\left[\tau_{a}<\tau_{b}\right]\right) \leq b P\left(\left[M^{*}>0\right]\right) \leq(b-a) P\left(\left[\tau_{a} \leq \tau_{b}\right]\right)
$$

In words, $P\left(\left[\tau_{b} \leq \tau_{a}\right]\right)$ is the probability that $M(t)$ hits $b$ no later than when it hits $a$. (Note that if $\tau_{a}=\infty=\tau_{b}$ then you would have $\left[\tau_{a}=\tau_{b}\right]$.)

Proof: For $x \in \mathbb{R}$, define

$$
\tau_{x} \equiv \inf \{t \in \mathbb{R} \text { such that } M(t)=x\}
$$

with the usual convention that $\inf (\emptyset)=\infty$. Let $a<0<b$ and let

$$
\tau=\tau_{a} \wedge \tau_{b}
$$

Then the following claim will be important.
Claim: $E(M(\tau))=0$.
Proof of the claim: Let $t>0$. Then by the Doob optional sampling theorem,

$$
\begin{align*}
E(M(\tau \wedge t)) & =E\left(E\left(M(t) \mid \mathscr{F}_{\tau}\right)\right)=E(M(t))  \tag{62.11.38}\\
& =E\left(E\left(M(t) \mid \mathscr{F}_{0}\right)\right)=E(M(0))=0 \tag{62.11.39}
\end{align*}
$$

Observe the martingale $M^{\tau}$ must be bounded because it is stopped when $M(t)$ equals either $a$ or $b$. There are two cases according to whether $\tau=\infty$. If $\tau=\infty$, then $M(t)$ never hits $a$ or $b$ so $M(t)$ has values between $a$ and $b$. In this case $M^{\tau}(t)=M(t) \in[a, b]$. On the other hand, you could have $\tau<\infty$. Then in this case $M^{\tau}(t)$ is eventually equal to either $a$ or $b$ depending on which it hits first. In either case, the martingale $M^{\tau}$ is bounded and by the martingale convergence theorem, Theorem 62.10.3, there exists $M^{\tau}(\infty)$ such that

$$
\lim _{t \rightarrow \infty} M^{\tau}(t)(\omega)=M^{\tau}(\infty)(\omega)=M(\tau)(\omega)
$$

and since the $M^{\tau}(t)$ are bounded, the dominated convergence theorem implies

$$
E(M(\tau))=\lim _{t \rightarrow \infty} E(M(\tau \wedge t))=0
$$

This proves the claim.
Recall

$$
M^{*}(\omega) \equiv \sup \{|M(t)(\omega)|: t \in[0, \infty]\}
$$

Also note that $\left[\tau_{a}=\tau_{b}\right]=[\tau=\infty]$. Now from the claim,

$$
\begin{align*}
0= & E(M(\tau))=\int_{\left[\tau_{a}<\tau_{b}\right]} M(\tau) d P \\
& +\int_{\left[\tau_{b}<\tau_{a}\right]} M(\tau) d P+\int_{\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]} M(\infty) d P  \tag{62.11.40}\\
& +\int_{\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}=0\right]} M(\infty) d P
\end{align*}
$$

The last term equals 0 . By continuity, $M(\tau)$ is either equal to $a$ or $b$ depending on whether $\tau_{a}<\tau_{b}$ or $\tau_{b}<\tau_{a}$. Thus

$$
\begin{gather*}
0=E(M(\tau))=a P\left(\left[\tau_{a}<\tau_{b}\right]\right) \\
+b P\left(\left[\tau_{b}<\tau_{a}\right]\right)+\int_{\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]} M(\infty) d P \tag{62.11.41}
\end{gather*}
$$

Consider this last term. By the definition, $\left[\tau_{a}=\tau_{b}\right]$ corresponds to $M(t)$ never hitting either $a$ or $b$. Since $M(0)=0$, this can only happen if $M(t)$ has values in $[a, b]$. Therefore, this last term satisfies

$$
\begin{align*}
& a P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right) \\
& \leq \int_{\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]} M(\infty) d P \\
& \leq b P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right) \tag{62.11.42}
\end{align*}
$$

It follows

$$
\begin{gather*}
a P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a P\left(\left[\tau_{a}<\tau_{b}\right]\right)+b P\left(\left[\tau_{b}<\tau_{a}\right]\right) \leq \\
0 \leq b P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a P\left(\left[\tau_{a}<\tau_{b}\right]\right)+b P\left(\left[\tau_{b}<\tau_{a}\right]\right) \tag{62.11.43}
\end{gather*}
$$

Note that $\left[\tau_{b}<\tau_{a}\right],\left[\tau_{a}<\tau_{b}\right] \subseteq\left[M^{*}>0\right]$ and so

$$
\begin{equation*}
\left[\tau_{b}<\tau_{a}\right] \cup\left[\tau_{a}<\tau_{b}\right] \cup\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)=\left[M^{*}>0\right] \tag{62.11.44}
\end{equation*}
$$

The following diagram may help in keeping track of the various substitutions.

| $\left[M^{*}>0\right]$ |  |  |
| :--- | :--- | :--- |
| $\left[\tau_{a}<\tau_{b}\right]$ | $\left[\tau_{b}<\tau_{a}\right]$ | $\left[\tau_{b}=\tau_{a}\right] \cap\left[M^{*}>0\right]$ |

## Left side of 62.11.43

From 62.11.44, this yields on substituting for $P\left(\left[\tau_{a}<\tau_{b}\right]\right)$

$$
\begin{aligned}
0 \geq & a P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a\left[P\left(\left[M^{*}>0\right]\right)-P\left(\left[\tau_{a} \geq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)\right] \\
& +b P\left(\left[\tau_{b}<\tau_{a}\right]\right)
\end{aligned}
$$

and so since $\left[\tau_{a} \neq \tau_{b}\right] \subseteq\left[M^{*}>0\right]$,

$$
\begin{gather*}
0 \geq a\left[P\left(\left[M^{*}>0\right]\right)-P\left(\left[\tau_{a}>\tau_{b}\right]\right)\right]+b P\left(\left[\tau_{b}<\tau_{a}\right]\right) \\
-a P\left(\left[M^{*}>0\right]\right) \geq(b-a) P\left(\left[\tau_{b}<\tau_{a}\right]\right) \tag{62.11.45}
\end{gather*}
$$

Next use 62.11.44 to substitute for $P\left(\left[\tau_{b}<\tau_{a}\right]\right)$

$$
\begin{gathered}
0 \geq a P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a P\left(\left[\tau_{a}<\tau_{b}\right]\right)+b P\left(\left[\tau_{b}<\tau_{a}\right]\right) \\
=\quad a P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a P\left(\left[\tau_{a}<\tau_{b}\right]\right) \\
\\
+b\left[P\left(\left[M^{*}>0\right]\right)-P\left(\left[\tau_{a} \leq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)\right] \\
=a P\left(\left[\tau_{a} \leq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)+b\left[P\left(\left[M^{*}>0\right]\right)-P\left(\left[\tau_{a} \leq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)\right]
\end{gathered}
$$

and so

$$
\begin{equation*}
(b-a) P\left(\left[\tau_{a} \leq \tau_{b}\right]\right) \geq b P\left(\left[M^{*}>0\right]\right) \tag{62.11.46}
\end{equation*}
$$

## Right side of 62.11.43

From 62.11.44, used to substitute for $P\left(\left[\tau_{a}<\tau_{b}\right]\right)$ this yields

$$
\begin{aligned}
& 0 \leq b P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a P\left(\left[\tau_{a}<\tau_{b}\right]\right)+b P\left(\left[\tau_{b}<\tau_{a}\right]\right) \\
= & b P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a\left[P\left(\left[M^{*}>0\right]\right)-P\left(\left[\tau_{a} \geq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)\right] \\
& +b P\left(\left[\tau_{b}<\tau_{a}\right]\right)
\end{aligned}
$$

$$
=b P\left(\left[\tau_{a} \geq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a\left[P\left(\left[M^{*}>0\right]\right)-P\left(\left[\tau_{a} \geq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)\right]
$$

and so

$$
\begin{equation*}
(b-a) P\left(\left[\tau_{a} \geq \tau_{b}\right]\right) \geq-a P\left(\left[M^{*}>0\right]\right) \tag{62.11.47}
\end{equation*}
$$

Next use 62.11 .44 to substitute for the term $P\left(\left[\tau_{b}<\tau_{a}\right]\right)$ and write

$$
\begin{gathered}
0 \leq b P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a P\left(\left[\tau_{a}<\tau_{b}\right]\right)+b P\left(\left[\tau_{b}<\tau_{a}\right]\right) \\
=\quad b P\left(\left[\tau_{a}=\tau_{b}\right] \cap\left[M^{*}>0\right]\right)+a P\left(\left[\tau_{a}<\tau_{b}\right]\right) \\
+b\left[P\left(\left[M^{*}>0\right]\right)-P\left(\left[\tau_{a} \leq \tau_{b}\right] \cap\left[M^{*}>0\right]\right)\right] \\
=a P\left(\left[\tau_{a}<\tau_{b}\right]\right)+b P\left(\left[M^{*}>0\right]\right)-b P\left(\left[\tau_{a}<\tau_{b}\right] \cap\left[M^{*}>0\right]\right) \\
=a P\left(\left[\tau_{a}<\tau_{b}\right]\right)+b P\left(\left[M^{*}>0\right]\right)-b P\left(\left[\tau_{a}<\tau_{b}\right]\right)
\end{gathered}
$$

and so

$$
\begin{equation*}
(b-a) P\left(\left[\tau_{a}<\tau_{b}\right]\right) \leq b P\left(\left[M^{*}>0\right]\right) \tag{62.11.48}
\end{equation*}
$$

Now the boxed in formulas in 62.11.45-62.11.48 yield the conclusion of the theorem. This proves the theorem.

Note $P\left(\left[\tau_{a}<\tau_{b}\right]\right)$ means $M(t)$ hits $a$ before it hits $b$ with other occurrences of similar expressions being defined similarly.

### 62.12 The Space $\mathscr{M}_{T}^{p}(E)$

Here $p \geq 1$.
Definition 62.12.1 Let $M$ be an $E$ valued martingale. Then $M \in \mathscr{M}_{T}^{p}(E)$ if $t \rightarrow M(t)(\omega)$ is continuous for a.e. $\omega$ and

$$
E\left(\sup _{t \in[0, T]}\|M(t)\|^{p}\right)<\infty
$$

Here $E$ is a separable Banach space.
Proposition 62.12.2 Define a norm on $\mathscr{M}_{T}^{p}(E)$ by

$$
\|M\|_{\mathscr{M}_{T}^{p}(E)} \equiv E\left(\sup _{t \in[0, T]}\|M(t)\|^{p}\right)^{1 / p}
$$

Then with this norm, $\mathscr{M}_{T}^{p}(E)$ is a Banach space.
Proof: First it is good to observe that $\sup _{t \in[0, T]}\|M(t)\|^{p}$ is measurable. This follows because of the continuity of $t \rightarrow M(t)$. Let $D$ be a dense countable set in $[0, T]$. Then by continuity,

$$
\sup _{t \in[0, T]}\|M(t)\|^{p}=\sup _{t \in D}\|M(t)\|^{p}
$$

and the expression on the right is measurable because $D$ is countable.
Next it is necessary to show this is a norm. It is clear that

$$
\|M\|_{\mathscr{M}_{T}^{p}(E)} \geq 0
$$

and equals 0 only if

$$
0=E\left(\sup _{t \in[0, T]}\|M(t)\|^{p}\right)
$$

which requires $M(t)=0$ for all $t$ for $\omega$ off a set of measure zero so that $M=0$. It is also clear that

$$
\|\alpha M\|_{\mathscr{M}_{T}^{p}(E)}=|\alpha|\|M\|_{\mathscr{M}_{T}^{p}(E)}
$$

It remains to check the triangle inequality. Let $M, N \in \mathscr{M}_{T}^{p}(E)$.

$$
\begin{aligned}
& \|M+N\|_{\mathscr{M}_{T}^{p}(E)} \equiv E\left(\sup _{t \in[0, T]}\|M(t)+N(t)\|^{p}\right)^{1 / p} \\
\leq & E\left(\sup _{t \in[0, T]}(\|M(t)\|+\|N(t)\|)^{p}\right)^{1 / p} \\
\leq & E\left(\left(\sup _{t \in[0, T]}\|M(t)\|+\sup _{t \in[0, T]}\|N(t)\|\right)^{p}\right)^{1 / p} \\
\equiv & \left(\int_{\Omega}\left(\sup _{t \in[0, T]}\|M(t)\|+\sup _{t \in[0, T]}\|N(t)\|\right)^{p} d P\right)^{1 / p} \\
\leq & \left(\int_{\Omega}\left(\sup _{t \in[0, T]}\|M(t)\|\right)^{p} d P\right)^{1 / p}+\left(\int_{\Omega}\left(\sup _{t \in[0, T]}\|N(t)\|\right)^{p} d P\right)^{1 / p} \\
\equiv & \|M\|\left\|_{\mathscr{M}_{T}^{p}(E)}+\right\| N \|_{\mathscr{M}_{T}^{p}(E)}
\end{aligned}
$$

Next consider the claim that $\mathscr{M}_{T}^{p}(E)$ is a Banach space. Let $\left\{M_{n}\right\}$ be a Cauchy sequence. Then

$$
\begin{equation*}
E\left(\sup _{t \in[0, T]}\left\|M_{n}(t)-M_{m}(t)\right\|^{p}\right) \rightarrow 0 \tag{62.12.49}
\end{equation*}
$$

as $m, n \rightarrow \infty$. From continuity,

$$
\sup _{t \in[0, T]}\left\|M_{n}(t)-M_{m}(t)\right\|=\sup _{t \in(0, T)}\left\|M_{n}(t)-M_{m}(t)\right\|
$$

Then from theorem 62.5.3 or 62.9.4,

$$
P\left(\sup _{t \in[0, T]}\left\|M_{n}(t)-M_{m}(t)\right\|>\lambda\right) \leq \frac{1}{\lambda^{p}} E\left(\left\|M_{n}(T)-M_{m}(T)\right\|^{p}\right)
$$

Therefore, one can extract a subsequence $\left\{M_{n_{k}}\right\}$ such that

$$
P\left(\sup _{t \in[0, T]}\left\|M_{n_{k}}(t)-M_{n_{k+1}}(t)\right\|>2^{-k}\right) \leq 2^{-k}
$$

By the Borel Cantelli lemma, it follows $\left\{M_{n_{k}}(t)(\omega)\right\}$ converges uniformly on $[0, T]$ for a.e. $\omega$. Denote by $M(t)(\omega)$ the thing to which it converges, a continuous process because of the uniform convergence. Also, because it is the pointwise limit off a set of measure zero, $\omega \rightarrow M(t)(\omega)$ is $\mathscr{F}_{t}$ measurable. Also, from 62.12.49 and Fatou's lemma

$$
\begin{aligned}
& \int_{\Omega} \sup _{t \in[0, T]}\left\|M_{n}(t)-M(t)\right\|^{p} d P \\
\leq & \lim \inf _{k \rightarrow \infty} \int_{\Omega_{t \in[0, T]}} \sup _{t}\left\|M_{n}(t)-M_{n_{k}}(t)\right\|^{p} d P \leq \varepsilon
\end{aligned}
$$

whenever $n$ is large enough, this from the assumption that $\left\{M_{n}\right\}$ is Cauchy. Thus

$$
\lim _{n \rightarrow \infty} E\left(\sup _{t \in[0, T]}\left\|M_{n}(t)-M(t)\right\|^{p}\right)=0
$$

and so for each $t, M_{n}(t) \rightarrow M(t)$ in $L^{p}(\Omega)$. This also shows that for large, $n$

$$
\begin{aligned}
& E\left(\sup _{t \in[0, T]}\|M(t)\|^{p}\right) \leq E\left(\sup _{t \in[0, T]}\left(\left\|M(t)-M_{n}(t)\right\|+\left\|M_{n}(t)\right\|\right)^{p}\right) \\
& \quad \leq 2^{p-1} E\left(\sup _{t \in[0, T]}\left\|M(t)-M_{n}(t)\right\|^{p}+\sup _{t \in[0, T]}\left(\left\|M_{n}(t)\right\|\right)^{p}\right)<\infty
\end{aligned}
$$

It only remains to verify $M$ is a martingale. Let $s \leq t$ and let $B \in \mathscr{F}_{s}$. For each $s, M_{n}(s) \rightarrow$ $M(s)$ in $L^{p}(\Omega)$. Then from the above, $\omega \rightarrow M(s)(\omega)$ is $\mathscr{F}_{s}$ measurable. Then it follows that

$$
\begin{aligned}
\int_{B} M(s) d P & =\lim _{n \rightarrow \infty} \int_{B} M_{n}(s) d P=\lim _{n \rightarrow \infty} \int_{B} E\left(M_{n}(t) \mid \mathscr{F}_{s}\right) d P \\
& =\lim _{n \rightarrow \infty} \int_{B} M_{n}(t) d P=\int_{B} M(t) d P
\end{aligned}
$$

and so by definition, $E\left(M(t) \mid \mathscr{F}_{s}\right)=M(s)$ which shows $M$ is a martingale.
Proposition 62.12.3 The functions $M(t)$ for each $M \in \mathscr{M}_{T}^{p}(E)$ are equi integrable.
Proof: This follows because

$$
\begin{equation*}
\int_{[\|M(t)\| \geq \lambda]}\|M(t)\|^{p} d P \leq \int_{\left[\sup _{t \in[0, T]}| | M(t) \| \geq \lambda\right]}\left(\sup _{t \in[0, T]}\|M(t)\|^{p}\right) d P \tag{62.12.50}
\end{equation*}
$$

which converges to 0 due to the definition of $\mathscr{M}_{T}^{p}(E)$ which requires that

$$
\sup _{t \in[0, T]}\|M(t)\|^{p} \in L^{1}(\Omega, \mathscr{F}, P)
$$

Since the sets $\left[\sup _{t \in[0, T]}\|M(t)\| \geq \lambda\right]$ decrease to $\emptyset$ as $\lambda \rightarrow \infty$, the dominated convergence theorem implies the integral on the right in 62.12 .50 converges to 0 .

## Chapter 63

## The Quadratic Variation Of A Martingale

### 63.1 How To Recognize A Martingale

The main ideas are most easily understood in the special case where it is assumed the martingale is bounded. Then one can extend to more general situations using a localizing sequence of stopping times.

Let $\{M(t)\}$ be a continuous martingale having values in a separable Hilbert space. The idea is to consider the submartingale, $\left\{\|M(t)\|^{2}\right\}$ and write it as the sum of a martingale and a submartingale. An important part of the argument is the following lemma which gives a checkable criterion for a stochastic process to be a martingale.

Lemma 63.1.1 Let $\{X(t)\}$ be a stochastic process adapted to the filtration $\left\{\mathscr{F}_{t}\right\}$ for $t \geq 0$. Then it is a martingale for the given filtration if for every stopping time $\sigma$ it follows

$$
E(X(t))=E(X(\sigma))
$$

In fact, it suffices to check this on stopping times which have two values.
Proof: Let $s<t$ and $A \in \mathscr{F}_{s}$. Define a stopping time

$$
\sigma(\omega) \equiv s \mathscr{X}_{A}(\omega)+t \mathscr{X}_{A^{C}}(\omega)
$$

This is a stopping time because $[\sigma \leq l]=\Omega$ if $l \geq t$. Also $[\sigma \leq l]=A \in \mathscr{F}_{s}$ if $l \in[s, t)$ and $[\sigma \leq l]=\emptyset$ if $l<s$. Then by assumption,

$$
\int_{A} X(t) d P+\int_{A^{C}} X(t) d P=
$$

$$
\overbrace{\int X(t) d P=\int X(\sigma) d P}^{\text {by assumption }}=\int_{A} X(s) d P+\int_{A^{C}} X(t) d P
$$

Therefore,

$$
\int_{A} X(t) d P=\int_{A} X(s) d P
$$

and since $X(s)$ is $\mathscr{F}_{s}$ measurable, it follows $E\left(X(t) \mid \mathscr{F}_{s}\right)=X(s)$ a.e. and this shows $\{X(t)\}$ is a martingale.

Note that if $t \in[0, T]$, it suffices to check the expectation condition for stopping times which have two values no larger than $T$.

The following lemma will be useful.
Lemma 63.1.2 Suppose $X_{n} \rightarrow X$ in $L^{1}(\Omega, \mathscr{F}, P ; E)$ where $E$ is a separable Banach space. Then letting $\mathscr{G}$ be a $\sigma$ algebra contained in $\mathscr{F}$,

$$
E\left(X_{n} \mid \mathscr{G}\right) \rightarrow E(X \mid \mathscr{G})
$$

in $L^{1}(\Omega)$.

Proof: This follows from the definitions and Theorem 61.1.1 on Page 1983.

$$
\begin{aligned}
\int_{\Omega}\left\|E(X \mid \mathscr{G})-E\left(X_{n} \mid \mathscr{G}\right)\right\| d P & =\int_{\Omega}\left\|E\left(X_{n}-X \mid \mathscr{G}\right)\right\| d P \\
& \leq \int_{\Omega} E\left(\left\|X_{n}-X\right\| \mid \mathscr{G}\right) d P \\
& =\int_{\Omega}\left\|X_{n}-X\right\| d P \square
\end{aligned}
$$

Corollary 63.1.3 Let $X, Y$ be in $L^{2}(\Omega, \mathscr{F}, P ; H)$ where $H$ is a separable Hilbert space and let $X$ be $\mathscr{G}$ measurable where $\mathscr{G} \subseteq \mathscr{F}$. Then

$$
E((X, Y) \mid \mathscr{G})=(X, E(Y \mid \mathscr{G})) \text { a.e. }
$$

Proof: First let $X=a \mathscr{X}_{B}$ where $B \in \mathscr{G}$. Then for $A \in \mathscr{G}$,

$$
\begin{aligned}
\int_{A} E\left(\left(a \mathscr{X}_{B}, Y\right) \mid \mathscr{G}\right) d P & =\int_{A} \mathscr{X}_{B} E((a, Y) \mid \mathscr{G}) d P=\int_{A} \mathscr{X}_{B}(a, Y) d P \\
& =\int_{A \cap B}(a, Y) d P=\left(a, \int_{A \cap \mathscr{B}} Y d P\right) \\
\int_{A}\left(a \mathscr{X}_{B}, E(Y \mid \mathscr{G})\right) d P & =\int_{A} \mathscr{X}_{B}(a, E(Y \mid \mathscr{G})) d P \\
& =\left(a, \int_{A} \mathscr{X}_{B} E(Y \mid \mathscr{G}) d P\right)=\left(a, \int_{A \cap \mathscr{B}} Y d P\right)
\end{aligned}
$$

It follows that the formula holds for $X$ simple.
Therefore, letting $X_{n}$ be a sequence of $\mathscr{G}$ measurable simple functions converging pointwise to $X$ and also in $L^{2}(\Omega)$,

$$
E\left(\left(X_{n}, Y\right) \mid \mathscr{G}\right)=\left(X_{n}, E(Y \mid \mathscr{G})\right)
$$

Now the desired formula holds from Lemma 63.1.2.
The following is related to something called a martingale transform. It is a lot like what will happen later with the Ito integral.

Proposition 63.1.4 Let $\left\{\tau_{k}\right\}$ be an increasing sequence of stopping times for the normal filtration $\left\{\mathscr{F}_{t}\right\}$ such that

$$
\lim _{k \rightarrow \infty} \tau_{k}=\infty, \tau_{0}=0
$$

Also let $\xi_{k}$ be $\mathscr{F}_{\tau_{k}}$ measurable with values in $H$, a separable Hilbert space and let $M(t)$ be a right continuous martingale adapted to the normal filtration $\mathscr{F}_{t}$ which has the property that $M(t) \in L^{2}(\Omega ; H)$ for all $t, M(0)=0$. Then if $\left|\xi_{k}\right| \leq C$,

$$
\begin{gather*}
E\left(\left(\sum_{k \geq 0}\left(\xi_{k},\left(M\left(\tau_{k+1} \wedge t\right)-M\left(\tau_{k} \wedge t\right)\right)\right)\right)^{2}\right) \\
\leq C^{2} E\left(\|M(t)\|^{2}\right) \tag{63.1.1}
\end{gather*}
$$

Proof: First of all, the sum converges because eventually $\tau_{k} \wedge t=t$. Therefore, for large enough $k, M\left(\tau_{k+1} \wedge t\right)-M\left(\tau_{k} \wedge t\right) \equiv \Delta M_{k}=0$. Consider first the finite sum, $k \leq q$.

$$
\begin{equation*}
E\left(\left(\sum_{k=0}^{q}\left(\xi_{k}, \Delta M_{k}\right)\right)^{2}\right) \tag{63.1.2}
\end{equation*}
$$

When the sum is multiplied out, you get mixed terms. Consider one of these mixed terms, $j<k$

$$
E\left(\left(\xi_{k}, \Delta M_{k}\right)\left(\xi_{j}, \Delta M_{j}\right)\right)
$$

Using Corollary 63.1.3 and Doob's optional sampling theorem, Theorem 60.5.4, this equals

$$
\begin{gathered}
E\left(E\left(\left(\xi_{k}, \Delta M_{k}\right)\left(\xi_{j}, \Delta M_{j}\right) \mid \mathscr{F}_{\tau_{k}}\right)\right)=E\left(\left(\xi_{j}, \Delta M_{j}\right) E\left(\left(\xi_{k}, \Delta M_{k}\right) \mid \mathscr{F}_{\tau_{k}}\right)\right) \\
=E\left(\left(\xi_{j}, \Delta M_{j}\right)\left(\xi_{k}, E\left(M\left(\tau_{k+1} \wedge t\right)-M\left(\tau_{k} \wedge t\right) \mid \mathscr{F}_{\tau_{k}}\right)\right)\right)=E\left(\left(\xi_{j}, \Delta M_{j}\right)\left(\xi_{k}, 0\right)\right)=0
\end{gathered}
$$

Note that in using the optional sampling theorem, the stopping time $\tau_{k+1} \wedge t$ is bounded.
Therefore, the only terms which survive in 63.1.2 are the non mixed terms and so this expression reduces to

$$
\begin{align*}
& \sum_{k=0}^{q} E\left(\xi_{k}, \Delta M_{k}\right)^{2} \leq C^{2} \sum_{k=0}^{q} E\left(\left\|\Delta M_{k}\right\|^{2}\right) \\
= & C^{2} \sum_{k=0}^{q} E\left(\left\|M\left(\tau_{k+1} \wedge t\right)-M\left(\tau_{k} \wedge t\right)\right\|^{2}\right) \\
= & C^{2} \sum_{k=0}^{q} E\left(\left\|M\left(\tau_{k+1} \wedge t\right)\right\|^{2}\right)+E\left(\left\|M\left(\tau_{k} \wedge t\right)\right\|^{2}\right) \\
& -2 E\left(\left(M\left(\tau_{k} \wedge t\right), M\left(\tau_{k+1} \wedge t\right)\right)\right) \tag{63.1.3}
\end{align*}
$$

Consider the term $E\left(\left(M\left(\tau_{k} \wedge t\right), M\left(\tau_{k+1} \wedge t\right)\right)\right)$. By Doob's optional sampling theorem for martingales and Corollary 63.1.3 again, this equals

$$
\begin{aligned}
& E\left(E\left(\left(M\left(\tau_{k} \wedge t\right), M\left(\tau_{k+1} \wedge t\right)\right) \mid \mathscr{F}_{\tau_{k}}\right)\right) \\
= & E\left(\left(M\left(\tau_{k} \wedge t\right), E\left(M\left(\tau_{k+1} \wedge t\right) \mid \mathscr{F} \tau_{k}\right)\right)\right) \\
= & E\left(\left(M\left(\tau_{k} \wedge t\right), M\left(\tau_{k+1} \wedge t \wedge \tau_{k}\right)\right)\right) \\
= & E\left(\left\|M\left(\tau_{k} \wedge t\right)\right\|^{2}\right)
\end{aligned}
$$

It follows 63.1.3 equals

$$
C^{2} \sum_{k=0}^{q} E\left(\left\|M\left(\tau_{k+1} \wedge t\right)\right\|^{2}\right)-E\left(\left\|M\left(\tau_{k} \wedge t\right)\right\|^{2}\right) \leq C^{2} E\left(\|M(t)\|^{2}\right)
$$

Then from Fatou's lemma,

$$
\begin{aligned}
& E\left(\left(\sum_{k \geq 0}\left(\xi_{k},\left(M\left(\tau_{k+1} \wedge t\right)-M\left(\tau_{k} \wedge t\right)\right)\right)\right)^{2}\right) \leq \\
& \lim _{q \rightarrow \infty} \inf E\left(\left(\sum_{k=0}^{q}\left(\xi_{k},\left(M\left(\tau_{k+1} \wedge t\right)-M\left(\tau_{k} \wedge t\right)\right)\right)\right)^{2}\right) \\
\leq & C^{2} E\left(\|M(t)\|^{2}\right) \square
\end{aligned}
$$

Now here is an interesting lemma which will be used to prove uniqueness in the main result.

Lemma 63.1.5 Let $\mathscr{F}_{t}$ be a normal filtration and let $A(t), B(t)$ be adapted to $\mathscr{F}_{t}$, continuous, and increasing with $A(0)=B(0)=0$ and suppose $A(t)-B(t)$ is a martingale. Then $A(t)-B(t)=0$ for all $t$.

Proof: I shall show $A(l)=B(l)$ where $l$ is arbitrary. Let $M(t)$ be the name of the martingale. Define a stopping time

$$
\begin{aligned}
\tau \equiv & \inf \{t>0:|M(t)|>C\} \wedge l \wedge \inf \{t>0: A(t)>C\} \\
& \wedge \inf \{t>0: B(t)>C\}
\end{aligned}
$$

where $\inf (\emptyset) \equiv \infty$ and denote the stopped martingale

$$
M^{\tau}(t) \equiv M(t \wedge \tau)
$$

Then I claim this is also a martingale with respect to the filtration $\mathscr{F}_{t}$ because by Doob's optional sampling theorem for martingales, if $s<t$,

$$
E\left(M^{\tau}(t) \mid \mathscr{F}_{s}\right) \equiv E\left(M(\tau \wedge t) \mid \mathscr{F}_{s}\right)=M(\tau \wedge t \wedge s)=M(\tau \wedge s)=M^{\tau}(s)
$$

Note the bounded stopping time is $\tau \wedge t$ and the other one is $\sigma=s$ in this theorem. Then $M^{\tau}$ is a continuous martingale which is also uniformly bounded. It equals $A^{\tau}-B^{\tau}$. The stopping time ensures $A^{\tau}$ and $B^{\tau}$ are uniformly bounded by $C$. Thus all of $\left|M^{\tau}(t)\right|, B^{\tau}(t), A^{\tau}(t)$ are bounded by $C$ on $[0, l]$. Now let $\mathscr{P}_{n} \equiv\left\{t_{k}\right\}_{k=1}^{n}$ be a uniform partition of $[0, l]$ and let $M^{\tau}\left(\mathscr{P}_{n}\right)$ denote

$$
M^{\tau}\left(\mathscr{P}_{n}\right) \equiv \max \left\{\left|M^{\tau}\left(t_{i+1}\right)-M^{\tau}\left(t_{i}\right)\right|\right\}_{i=1}^{n}
$$

Then

$$
E\left(M^{\tau}(l)^{2}\right)=E\left(\left(\sum_{k=0}^{n-1} M^{\tau}\left(t_{k+1}\right)-M^{\tau}\left(t_{k}\right)\right)^{2}\right)
$$

Now consider a mixed term in the sum where $j<k$.

$$
E\left(\left(M^{\tau}\left(t_{k+1}\right)-M^{\tau}\left(t_{k}\right)\right)\left(M^{\tau}\left(t_{j+1}\right)-M^{\tau}\left(t_{j}\right)\right)\right)
$$

$$
\begin{aligned}
& =E\left(E\left(\left(M^{\tau}\left(t_{k+1}\right)-M^{\tau}\left(t_{k}\right)\right)\left(M^{\tau}\left(t_{j+1}\right)-M^{\tau}\left(t_{j}\right)\right) \mid \mathscr{F}_{t_{k}}\right)\right) \\
& =E\left(\left(M^{\tau}\left(t_{j+1}\right)-M^{\tau}\left(t_{j}\right)\right) E\left(\left(M^{\tau}\left(t_{k+1}\right)-M^{\tau}\left(t_{k}\right)\right) \mid \mathscr{F}_{t_{k}}\right)\right) \\
& =E\left(\left(M^{\tau}\left(t_{j+1}\right)-M^{\tau}\left(t_{j}\right)\right)\left(M^{\tau}\left(t_{k}\right)-M^{\tau}\left(t_{k}\right)\right)\right)=0
\end{aligned}
$$

It follows

$$
\begin{aligned}
& E\left(M^{\tau}(l)^{2}\right)=E\left(\sum_{k=0}^{n-1}\left(M^{\tau}\left(t_{k+1}\right)-M^{\tau}\left(t_{k}\right)\right)^{2}\right) \\
& \leq E\left(\sum_{k=0}^{n-1} M^{\tau}\left(\mathscr{P}_{n}\right)\left|M^{\tau}\left(t_{k+1}\right)-M^{\tau}\left(t_{k}\right)\right|\right) \\
& \leq E\left(\sum_{k=0}^{n-1} M^{\tau}\left(\mathscr{P}_{n}\right)\left(\left|A^{\tau}\left(t_{k+1}\right)-A^{\tau}\left(t_{k}\right)\right|+\left|B^{\tau}\left(t_{k+1}\right)-B^{\tau}\left(t_{k}\right)\right|\right)\right) \\
& \leq E\left(M^{\tau}\left(\mathscr{P}_{n}\right) \sum_{k=0}^{n-1}\left(\left|A^{\tau}\left(t_{k+1}\right)-A^{\tau}\left(t_{k}\right)\right|+\left|B^{\tau}\left(t_{k+1}\right)-B^{\tau}\left(t_{k}\right)\right|\right)\right) \\
& \leq E\left(M^{\tau}\left(\mathscr{P}_{n}\right) 2 C\right)
\end{aligned}
$$

the last step holding because $A$ and $B$ are increasing. Now letting $n \rightarrow \infty$, the right side converges to 0 by the dominated convergence theorem and the observation that for a.e. $\omega$,

$$
\lim _{n \rightarrow \infty} M^{\tau}\left(\mathscr{P}_{n}\right)(\omega)=0
$$

because of continuity of $M$. Thus for $\tau=\tau_{C}$ given above,

$$
M\left(l \wedge \tau_{C}\right)=0 \text { a.e. }
$$

Now let $C \in \mathbb{N}$ and let $N_{C}$ be the exceptional set off which $M\left(l \wedge \tau_{C}\right)=0$. Then letting $N_{l}$ denote the union of all these exceptional sets for $C \in \mathbb{N}$, it is also a set of measure zero and for $\omega$ not in this set, $M\left(l \wedge \tau_{C}\right)=0$ for all $C$. Since the martingale is continuous, it follows for each such $\omega$, eventually $\tau_{C}>l$ and so $M(l)=0$. Thus for $\omega \notin N_{l}$,

$$
M(l)(\omega)=0
$$

Now let $N=\cup_{l \in \mathbb{Q} \cap[0, \infty)} N_{l}$. Then for $\omega \notin N, M(l)(\omega)=0$ for all $l \in \mathbb{Q} \cap[0, \infty)$ and so by continuity, this is true for all positive $l$.

Note this shows a continuous martingale is not of bounded variation unless it is a constant.

### 63.2 The Quadratic Variation

This section is on the quadratic variation of a martingale. Actually, you can also consider the quadratic variation of a local martingale which is more general. Therefore, this concept is defined first. We will generally assume $M(0)=0$ since there is no real loss of generality in doing so. One can simply subtract $M(0)$ otherwise.

Definition 63.2.1 Let $\{M(t)\}$ be adapted to the normal filtration $\mathscr{F}_{t}$ for $t>0$. Then $\{M(t)\}$ is a local martingale (submartingale) if there exist stopping times $\tau_{n}$ increasing to infinity such that for each $n$, the process $M^{\tau_{n}}(t) \equiv M\left(t \wedge \tau_{n}\right)$ is a martingale (submartingale) with respect to the given filtration. The sequence of stopping times is called a localizing sequence. The martingale $M^{\tau_{n}}$ is called the stopped martingale. Exactly the same convention applies to a localized submartingale.

Proposition 63.2.2 If $M(t)$ is a continuous local martingale (submartingale) for a normal filtration as above, $M(0)=0$, then there exists a localizing sequence $\tau_{n}$ such that for each $n$ the stopped martingale(submartingale) $M^{\tau_{n}}$ is uniformly bounded. Also if $M$ is a martingale, then $M^{\tau}$ is also a martingale (submartingale). If $\tau_{n}$ is an increasing sequence of stopping times such that $\lim _{n \rightarrow \infty} \tau_{n}=\infty$, and for each $\tau_{n}$ and real valued stopping time $\delta$, there exists a function $X$ of $\tau_{n} \wedge \delta$ such that $X\left(\tau_{n} \wedge \boldsymbol{\delta}\right)$ is $\mathscr{F}_{\tau_{n} \wedge \delta}$ measurable, then $\lim _{n \rightarrow \infty} X\left(\tau_{n} \wedge \boldsymbol{\delta}\right) \equiv X(\boldsymbol{\delta})$ exists for each $\omega$ and $X(\boldsymbol{\delta})$ is $\mathscr{F}_{\delta}$ measurable.

Proof: First consider the claim about $M^{\tau}$ being a martingale (submartingale) when $M$ is. By optional sampling theorem,

$$
E\left(M^{\tau}(t) \mid \mathscr{F}_{s}\right)=E\left(M(\tau \wedge t) \mid \mathscr{F}_{s}\right)=M(\tau \wedge t \wedge s)=M^{\tau}(s)
$$

The case where $M$ is a submartingale is similar.
Next suppose $\sigma_{n}$ is a localizing sequence for the local martingale(submartingale) $M$. Then define

$$
\eta_{n} \equiv \inf \{t>0:\|M(t)\|>n\}
$$

Therefore, by continuity of $M,\left\|M\left(\eta_{n}\right)\right\| \leq n$. Now consider $\tau_{n} \equiv \eta_{n} \wedge \sigma_{n}$. This is an increasing sequence of stopping times. By continuity of $M$, it must be the case that $\eta_{n} \rightarrow \infty$. Hence $\sigma_{n} \wedge \eta_{n} \rightarrow \infty$.

Finally, consider the last claim. Pick $\omega$. Then $X\left(\tau_{n}(\omega) \wedge \delta(\omega)\right)(\omega)$ is eventually constant as $n \rightarrow \infty$ because for all $n$ large enough, $\tau_{n}(\omega)>\delta(\omega)$ and so this sequence of functions converges pointwise. That which it converges to, denoted by $X(\delta)$, is $\mathscr{F}_{\delta}$ measurable because each function $\omega \rightarrow X\left(\tau_{n}(\omega) \wedge \delta(\omega)\right)(\omega)$ is $\mathscr{F}_{\delta \wedge \tau_{n}} \subseteq \mathscr{F}_{\delta}$ measurable.

One can also give a generalization of Lemma 63.1.5 to conclude a local martingale must be constant or else they must fail to be of bounded variation.

Corollary 63.2.3 Let $\mathscr{F}_{t}$ be a normal filtration and let $A(t), B(t)$ be adapted to $\mathscr{F}_{t}$, continuous, and increasing with $A(0)=B(0)=0$ and suppose $A(t)-B(t) \equiv M(t)$ is a local martingale. Then $M(t)=A(t)-B(t)=0$ a.e. for all $t$.

Proof: Let $\left\{\tau_{n}\right\}$ be a localizing sequence for $M$. For given $n$, consider the martingale,

$$
M^{\tau_{n}}(t)=A^{\tau_{n}}(t)-B^{\tau_{n}}(t)
$$

Then from Lemma 63.1.5, it follows $M^{\tau_{n}}(t)=0$ for all $t$ for all $\omega \notin N_{n}$, a set of measure 0 . Let $N=\cup_{n} N_{n}$. Then for $\omega \notin N, M\left(\tau_{n}(\omega) \wedge t\right)(\omega)=0$. Let $n \rightarrow \infty$ to conclude that $M(t)(\omega)=0$. Therefore, $M(t)(\omega)=0$ for all $t$.

Recall Example 62.7.10 on Page 2083. For convenience, here is a version of what it says.

Lemma 63.2.4 Let $X(t)$ be continuous and adapted to a normal filtration $\mathscr{F}_{t}$ and let $\eta$ be a stopping time. Then if $K$ is a closed set,

$$
\tau \equiv \inf \{t>\eta: X(t) \in K\}
$$

is also a stopping time.
Proof: First consider $Y(t)=X(t \vee \eta)-X(\eta)$. I claim that $Y(t)$ is adapted to $\mathscr{F}_{t}$. Consider $U$ and open set and $[Y(t) \in U]$. Is it in $\mathscr{F}_{t}$ ? We know it is in $\mathscr{F}_{t \vee \eta}$. It equals

$$
([Y(t) \in U] \cap[\eta \leq t]) \cup([Y(t) \in U] \cap[\eta>t])
$$

Consider the second of these sets. It equals

$$
([X(\eta)-X(\eta) \in U] \cap[\eta>t])
$$

If $0 \in U$, then it reduces to $[\eta>t] \in \mathscr{F}_{t}$. If $0 \notin U$, then it reduces to $\emptyset$ still in $\mathscr{F}_{t}$. Next consider the first set. It equals

$$
\begin{aligned}
& {[X(t \vee \eta)-X(\eta) \in U] \cap[\eta \leq t] } \\
= & {[X(t \vee \eta)-X(\eta) \in U] \cap[t \vee \eta \leq t] \in \mathscr{F}_{t} }
\end{aligned}
$$

from the definition of $\mathscr{F}_{t \vee \eta}$. (You know that $[X(t \vee \eta)-X(\eta) \in U] \in \mathscr{F}_{t \vee \eta}$ and so when this is intersected with $[t \vee \eta \leq t]$ one obtains a set in $\mathscr{F}_{t}$. This is what it means to be in $\mathscr{F}_{t \vee \eta}$.) Now $\tau$ is just the first hitting time of $Y(t)$ of the closed set.

Proposition 63.2.5 Let $M(t)$ be a continuous local martingale for $t \in[0, T]$ having values in $H$ a separable Hilbert space adapted to the normal filtration $\left\{\mathscr{F}_{t}\right\}$ such that $M(0)=0$. Then there exists a unique continuous, increasing, nonnegative, local submartingale $[M](t)$ called the quadratic variation such that

$$
\|M(t)\|^{2}-[M](t)
$$

is a real local martingale and $[M](0)=0$. Here $t \in[0, T]$. If $\delta$ is any stopping time

$$
\left[M^{\delta}\right]=[M]^{\delta}
$$

Proof: First it is necessary to define some stopping times. Define stopping times $\tau_{0}^{n} \equiv \eta_{0}^{n} \equiv 0$.

$$
\begin{aligned}
\eta_{k+1}^{n} & \equiv \inf \left\{s>\eta_{k}^{n}:\left\|M(s)-M\left(\eta_{k}^{n}\right)\right\|=2^{-n}\right\} \\
\tau_{k}^{n} & \equiv \eta_{k}^{n} \wedge T
\end{aligned}
$$

where $\inf \emptyset \equiv \infty$. These are stopping times by Example 62.7.10 on Page 2083. See also Lemma 63.2.4. Then for $t>0$ and $\delta$ any stopping time, and fixed $\omega$, for some $k$,

$$
t \wedge \delta \in I_{k}(\omega), I_{0}(\omega) \equiv\left[\tau_{0}^{n}(\omega), \tau_{1}^{n}(\omega)\right], I_{k}(\omega) \equiv\left(\tau_{k}^{n}(\omega), \tau_{k+1}^{n}(\omega)\right] \text { some } k
$$

Here is why. The sequence $\left\{\tau_{k}^{n}(\omega)\right\}_{k=1}^{\infty}$ eventually equals $T$ for all $n$ sufficiently large. This is because if it did not, it would converge, being bounded above by $T$ and then by continuity of $M,\left\{M\left(\tau_{k}^{n}(\omega)\right)\right\}_{k=1}^{\infty}$ would be a Cauchy sequence contrary to the requirement that

$$
\begin{aligned}
& \left\|M\left(\tau_{k+1}^{n}(\omega)\right)-M\left(\tau_{k}^{n}(\omega)\right)\right\| \\
= & \left\|M\left(\eta_{k+1}^{n}(\omega)\right)-M\left(\eta_{k}^{n}(\omega)\right)\right\|=2^{-n} .
\end{aligned}
$$

Note that if $\delta$ is any stopping time, then

$$
\begin{aligned}
& \left\|M\left(t \wedge \delta \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \delta \wedge \tau_{k}^{n}\right)\right\| \\
= & \left\|M^{\delta}\left(t \wedge \tau_{k+1}^{n}\right)-M^{\delta}\left(t \wedge \tau_{k}^{n}\right)\right\| \leq 2^{-n}
\end{aligned}
$$

You can see this is the case by considering the cases, $t \wedge \delta \geq \tau_{k+1}^{n}, t \wedge \delta \in\left[\tau_{k}^{n}, \tau_{k+1}^{n}\right)$, and $t \wedge \delta<\tau_{k}^{n}$. It is only this approximation property and the fact that the $\tau_{k}^{n}$ partition $[0, T]$ which is important in the following argument.

Now let $\alpha_{n}$ be a localizing sequence such that $M^{\alpha_{n}}$ is bounded as in Proposition 63.2.2. Thus $M^{\alpha_{n}}(t) \in L^{2}(\Omega)$ and this is all that is needed. In what follows, let $\delta$ be a stopping time and denote $M^{\alpha_{p} \wedge \delta}$ by $M$ to save notation. Thus $M$ will be uniformly bounded and from the definition of the stopping times $\tau_{k}^{n}$, for $t \in[0, T]$,

$$
\begin{equation*}
M(t) \equiv \sum_{k \geq 0} M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right) \tag{63.2.4}
\end{equation*}
$$

and the terms of the series are eventually 0 , as soon as $\eta_{k}^{n}=\infty$.
Therefore,

$$
\|M(t)\|^{2}=\left\|\sum_{k \geq 0} M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right\|^{2}
$$

Then this equals

$$
\begin{gather*}
=\sum_{k \geq 0}\left\|M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right\|^{2} \\
+\sum_{j \neq k}\left(\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right),\left(M\left(t \wedge \tau_{j+1}^{n}\right)-M\left(t \wedge \tau_{j}^{n}\right)\right)\right) \tag{63.2.5}
\end{gather*}
$$

Consider the second sum. It equals

$$
\begin{aligned}
& 2 \sum_{k \geq 0} \sum_{j=0}^{k-1}\left(\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right),\left(M\left(t \wedge \tau_{j+1}^{n}\right)-M\left(t \wedge \tau_{j}^{n}\right)\right)\right) \\
= & 2 \sum_{k \geq 0}\left(\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right), \sum_{j=0}^{k-1}\left(M\left(t \wedge \tau_{j+1}^{n}\right)-M\left(t \wedge \tau_{j}^{n}\right)\right)\right) \\
= & 2 \sum_{k \geq 0}\left(\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right), M\left(t \wedge \tau_{k}^{n}\right)\right)
\end{aligned}
$$

This last sum equals $P_{n}(t)$ defined as

$$
\begin{equation*}
2 \sum_{k \geq 0}\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right) \equiv P_{n}(t) \tag{63.2.6}
\end{equation*}
$$

This is because in the $k^{t h}$ term, if $t \geq \tau_{k}^{n}$, then it reduces to

$$
\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right)
$$

while if $t<\tau_{k}^{n}$, then the term reduces to 0 which is also the same as

$$
\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right)
$$

This is a finite sum because eventually, for large enough $k, \tau_{k}^{n}=T$. However the number of nonzero terms depends on $\omega$. This is not a good thing. However, a little more can be said. In fact the sum also converges in $L^{2}(\Omega)$. Say $\|M(t, \omega)\| \leq C$.

$$
\begin{align*}
& E\left(\left(\sum_{k \geq p}^{q}\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right)\right)^{2}\right) \\
= & \sum_{k \geq p}^{q} E\left(\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right)^{2}\right)+\text { mixed terms } \tag{63.2.7}
\end{align*}
$$

Consider one of these mixed terms for $j<k$.

$$
\begin{aligned}
& E((M\left(\tau_{j}^{n}\right),(\overbrace{M\left(t \wedge \tau_{j+1}^{n}\right)-M\left(t \wedge \tau_{j}^{n}\right)}^{\Delta_{j}})) \\
& (M\left(\tau_{k}^{n}\right),(\overbrace{M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)}^{\Delta_{k}})))
\end{aligned}
$$

Then it equals

$$
\begin{aligned}
& E\left(E\left(\left(M\left(\tau_{j}^{n}\right), \Delta_{j}\right)\left(M\left(\tau_{j}^{n}\right), \Delta_{k}\right) \mid \mathscr{F}_{\tau_{k}}\right)\right) \\
= & E\left(\left(M\left(\tau_{j}^{n}\right), \Delta_{j}\right) E\left(\left(M\left(\tau_{j}^{n}\right), \Delta_{k}\right) \mid \mathscr{F}_{\tau_{k}}\right)\right) \\
= & E\left(\left(M\left(\tau_{j}^{n}\right), \Delta_{j}\right)\left(M\left(\tau_{j}^{n}\right), E\left(\Delta_{k} \mid \mathscr{F}_{\tau_{k}}\right)\right)\right)=0
\end{aligned}
$$

Now since the mixed terms equal 0 , it follows from 63.2.7, that expression is dominated by

$$
C^{2} \sum_{k \geq p}^{q} E\left(\left\|M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right\|^{2}\right)
$$

Using a similar manipulation to what was just done to show the mixed terms equal 0 , this equals

$$
\begin{aligned}
& C^{2} \sum_{k=p}^{q} E\left(\left\|M\left(t \wedge \tau_{k+1}^{n}\right)\right\|^{2}\right)-E\left(\left\|M\left(t \wedge \tau_{k}^{n}\right)\right\|^{2}\right) \\
\leq & C^{2} E\left(\left\|M\left(t \wedge \tau_{q+1}^{n}\right)\right\|^{2}-\left\|M\left(t \wedge \tau_{p}^{n}\right)\right\|^{2}\right)
\end{aligned}
$$

The integrand converges to 0 as $p, q \rightarrow \infty$ and the uniform bound on $M$ allows a use of the dominated convergence theorem. Thus the partial sums of the series of 63.2 .6 converge in $L^{2}(\Omega)$ as claimed.

By adding in the values of $\left\{\tau_{k}^{n+1}\right\} P_{n}(t)$ can be written in the form

$$
2 \sum_{k \geq 0}\left(M\left(\tau_{k}^{n+1 \prime}\right),\left(M\left(t \wedge \tau_{k+1}^{n+1}\right)-M\left(t \wedge \tau_{k}^{n+1}\right)\right)\right)
$$

where $\tau_{k}^{n+1 \prime}$ has some repeats. From the construction,

$$
\left\|M\left(\tau_{k}^{n+1 \prime}\right)-M\left(\tau_{k}^{n+1}\right)\right\| \leq 2^{-(n+1)}
$$

Thus

$$
P_{n}(t)-P_{n+1}(t)=2 \sum_{k \geq 0}\left(M\left(\tau_{k}^{n+1 \prime}\right)-M\left(\tau_{k}^{n+1}\right),\left(M\left(t \wedge \tau_{k+1}^{n+1}\right)-M\left(t \wedge \tau_{k}^{n+1}\right)\right)\right)
$$

and so from Proposition 63.1.4 applied to $\xi_{k} \equiv M\left(\tau_{k}^{n+1 \prime}\right)-M\left(\tau_{k}^{n+1}\right)$,

$$
\begin{equation*}
E\left(\left\|P_{n}(t)-P_{n+1}(t)\right\|^{2}\right) \leq\left(2^{-2 n} E\left(\|M(t)\|^{2}\right)\right) \tag{63.2.8}
\end{equation*}
$$

Now $t \rightarrow P_{n}(t)$ is continuous because it is a finite sum of continuous functions. It is also the case that $\left\{P_{n}(t)\right\}$ is a martingale. To see this use Lemma 63.1.1. Let $\sigma$ be a stopping time having two values. Then using Corollary 63.1.3 and the Doob optional sampling theorem, Theorem 62.7.14

$$
\begin{aligned}
& E\left(\sum_{k=0}^{q}\left(M\left(\tau_{k}^{n}\right),\left(M\left(\sigma \wedge \tau_{k+1}^{n}\right)-M\left(\sigma \wedge \tau_{k}^{n}\right)\right)\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(M\left(\tau_{k}^{n}\right),\left(M\left(\sigma \wedge \tau_{k+1}^{n}\right)-M\left(\sigma \wedge \tau_{k}^{n}\right)\right)\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(E\left(M\left(\tau_{k}^{n}\right),\left(M\left(\sigma \wedge \tau_{k+1}^{n}\right)-M\left(\sigma \wedge \tau_{k}^{n}\right)\right)\right) \mid \mathscr{F}_{\tau_{k}^{n}}\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(M\left(\tau_{k}^{n}\right), E\left(M\left(\sigma \wedge \tau_{k+1}^{n}\right)-M\left(\sigma \wedge \tau_{k}^{n}\right)\right) \mid \mathscr{F}_{\tau_{k}^{n}}\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(M\left(\tau_{k}^{n}\right), E\left(M\left(\sigma \wedge \tau_{k+1}^{n} \wedge \tau_{k}^{n}\right)-M\left(\sigma \wedge \tau_{k}^{n}\right)\right)\right)\right)=0
\end{aligned}
$$

Note the Doob theorem applies because $\sigma \wedge \tau_{k+1}^{n}$ is a bounded stopping time due to the fact $\sigma$ has only two values. Similarly

$$
\begin{aligned}
& E\left(\sum_{k=0}^{q}\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(E\left(M\left(\tau_{k}^{n}\right),\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right) \mid \mathscr{F}_{\tau_{k}^{n}}\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(M\left(\tau_{k}^{n}\right), E\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right) \mid \mathscr{F}_{\tau_{k}^{n}}\right)\right) \\
= & \sum_{k=0}^{q} E\left(\left(M\left(\tau_{k}^{n}\right), E\left(M\left(t \wedge \tau_{k+1}^{n} \wedge \tau_{k}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right)\right)\right)=0
\end{aligned}
$$

It follows each partial sum for $P_{n}(t)$ is a martingale. As shown above, these partial sums converge in $L^{2}(\Omega)$ and so it follows that $P_{n}(t)$ is also a martingale. Note the Doob theorem applies because $t \wedge \tau_{k+1}^{n}$ is a bounded stopping time.

I want to argue that $P_{n}$ is a Cauchy sequence in $\mathscr{M}_{T}^{2}(\mathbb{R})$. By Theorem 62.9.4 and continuity of $P_{n}$

$$
E\left(\left(\sup _{t \leq T}\left|P_{n}(t)-P_{n+1}(t)\right|\right)^{2}\right)^{1 / 2} \leq 2 E\left(\left|P_{n}(T)-P_{n+1}(T)\right|^{2}\right)^{1 / 2}
$$

By 63.2.8,

$$
\leq 2^{-n} E\left(\|M(T)\|^{2}\right)^{1 / 2}
$$

which shows $\left\{P_{n}\right\}$ is indeed a Cauchy sequence in $\mathscr{M}_{T}^{2}(\mathbb{R})$.
Therefore, by Proposition 62.12.2, there exists $\{N(t)\} \in \mathscr{M}_{T}^{2}(\mathbb{R})$ such that $P_{n} \rightarrow N$ in $\mathscr{M}_{T}^{2}(H)$. That is

$$
\lim _{n \rightarrow \infty} E\left(\sup _{t \in[0, T]}\left|P_{n}(t)-N(t)\right|^{2}\right)^{1 / 2}=0
$$

Since $\{N(t)\} \in \mathscr{M}_{T}^{2}(\mathbb{R})$, it is a continuous martingale and $N(t) \in L^{2}(\Omega)$, and $N(0)=0$ because this is true of each $P_{n}(0)$. From the above 63.2.5,

$$
\begin{equation*}
\|M(t)\|^{2}=Q_{n}(t)+P_{n}(t) \tag{63.2.9}
\end{equation*}
$$

where

$$
Q_{n}(t)=\sum_{k \geq 0}\left\|M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right\|^{2}
$$

and $P_{n}(t)$ is a martingale. Then from 63.2.9, $Q_{n}(t)$ is a submartingale and converges for each $t$ to something, denoted as $[M](t)$ in $L^{1}(\Omega)$ uniformly in $t \in[0, T]$. This is because $P_{n}(t)$ converges uniformly on $[0, T]$ to $N(t)$ in $L^{2}(\Omega)$ and $\|M(t)\|^{2}$ does not depend on $n$. Then also $[M]$ is a submartingale which equals 0 at 0 because this is true of $Q_{n}$ and because if $A \in \mathscr{F}_{s}$ where $s<t$,

$$
\begin{gathered}
\int_{A} E\left([M](t) \mid \mathscr{F}_{s}\right) d P \equiv \int_{A}[M](t) d P=\lim _{n \rightarrow \infty} \int_{A}\left(\|M(t)\|^{2}-P_{n}(t)\right) d P \\
=\lim _{n \rightarrow \infty} \int_{A} E\left(\|M(t)\|^{2}-P_{n}(t) \mid \mathscr{F}_{s}\right) d P \geq \lim _{n \rightarrow \infty} \inf _{A}\|M(s)\|^{2}-P_{n}(s) d P \\
=\lim _{n \rightarrow \infty} \inf _{A} Q_{n}(s) d P=\int_{A}[M](s) d P .
\end{gathered}
$$

Note that $Q_{n}(t)$ is increasing because as $t$ increases, the definition allows for the possibility of more nonzero terms in the sum. Therefore, $[M](t)$ is also increasing in $t$. The function $t \rightarrow[M](t)$ is continuous because $\|M(t)\|^{2}=[M](t)+N(t)$ and $t \rightarrow N(t)$ is continuous as is $t \rightarrow\|M(t)\|^{2}$. That is, off a set of measure zero, these are both continuous functions of $t$ and so the same is true of $[M]$.

Now put back in $M^{\alpha_{p} \wedge \delta}$ in place of $M$. From the above, this has shown

$$
\left\|M^{\alpha_{p} \wedge \delta}(t)\right\|^{2}=\left[M^{\alpha_{p} \wedge \delta}\right](t)+N_{p}(t)
$$

where $N_{p}$ is a martingale and

$$
\begin{array}{r}
{\left[M^{\alpha_{p} \wedge \delta}\right](t)=\lim _{n \rightarrow \infty} \sum_{k \geq 0}\left\|M^{\alpha_{p} \wedge \delta}\left(t \wedge \tau_{k+1}^{n}\right)-M^{\alpha_{p} \wedge \delta}\left(t \wedge \tau_{k}^{n}\right)\right\|^{2}} \\
=\lim _{n \rightarrow \infty} \sum_{k \geq 0}\left\|M\left(t \wedge \tau_{k+1}^{n} \wedge \alpha_{p} \wedge \delta\right)-M\left(t \wedge \tau_{k}^{n} \wedge \alpha_{p} \wedge \delta\right)\right\|^{2} \text { in } L^{1}(\Omega), \tag{63.2.10}
\end{array}
$$

the convergence being uniform on $[0, T]$. The above formula shows that $\left[M^{\alpha_{p} \wedge \delta}\right](t)$ is a $\mathscr{F}_{t \wedge \delta \wedge \alpha_{p}}$ measurable random variable which depends on $t \wedge \delta \wedge \alpha_{p}$. (Note that $t \wedge \delta$ is a real valued stopping time even if $\delta=\infty$.) Therefore, by Proposition 63.2.2, there exists a random variable, denoted as $\left[M^{\delta}\right](t)$ which is the pointwise limit as $p \rightarrow \infty$ of these random variables which is $\mathscr{F}_{t \wedge \delta}$ measurable because, for a given $\omega$, when $\alpha_{p}$ becomes larger than $t$, the sum in 63.2.10 loses its dependence on $p$. Thus from pointwise convergence in 63.2.10,

$$
\left[M^{\delta}\right](t) \equiv \lim _{n \rightarrow \infty} \sum_{k \geq 0}\left\|M\left(t \wedge \delta \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \delta \wedge \tau_{k}^{n}\right)\right\|^{2}
$$

In case $\delta=\infty$, the above gives an $\mathscr{F}_{t}$ measurable random variable denoted by $[M](t)$ such that

$$
[M](t) \equiv \lim _{n \rightarrow \infty} \sum_{k \geq 0}\left\|M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right\|^{2}
$$

Now stopping with the stopping time $\delta$, this shows that

$$
\left[M^{\delta}\right](t) \equiv \lim _{n \rightarrow \infty} \sum_{k \geq 0}\left\|M\left(t \wedge \delta \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \delta \wedge \tau_{k}^{n}\right)\right\|^{2}=[M]^{\delta}(t)
$$

That is, the quadratic variation of the stopped local martingale makes sense a.e. and equals the stopped quadratic variation of the local martingale.

This has now shown that

$$
\begin{aligned}
\left\|M^{\alpha_{n}}(t)\right\|^{2}-[M]^{\alpha_{n}}(t) & =\left\|M^{\alpha_{n}}(t)\right\|^{2}-\left[M^{\alpha_{n}}\right](t) \\
& =N_{n}(t), N_{n}(t) \text { a martingale }
\end{aligned}
$$

and both of the random variables on the left converge pointwise as $n \rightarrow \infty$ to a function which is $\mathscr{F}_{t}$ measurable. Hence so does $N_{n}(t)$. Of course $N_{n}(t)$ is likewise a function of $\alpha_{n} \wedge t$ and so by Proposition 63.2.2 again, it converges pointwise to a $\mathscr{F}_{t}$ measurable function called $N(t)$ and $N(t)$ is a continuous local martingale.

It remains to consider the claim about the uniqueness. Suppose then there are two which work, $[M]$, and $[M]_{1}$. Then $[M]-[M]_{1}$ equals a local martingale $G$ which is 0 when $t=0$. Thus the uniqueness assertion follows from Corollary 63.2.3.

Here is a corollary which tells how to manipulate stopping times. It is contained in the above proposition, but it is worth emphasizing it from a different point of view.

Corollary 63.2.6 In the situation of Proposition 63.2 .5 let $\tau$ be a stopping time. Then

$$
\left[M^{\tau}\right]=[M]^{\tau} .
$$

Proof:

$$
[M]^{\tau}(t)+N_{1}(t)=\left(\|M\|^{2}\right)^{\tau}(t)=\left\|M^{\tau}\right\|^{2}(t)=\left[M^{\tau}\right](t)+N_{2}(t)
$$

where $N_{i}$ is a local martingale. Therefore,

$$
[M]^{\tau}(t)-\left[M^{\tau}\right](t)=N_{2}(t)-N_{1}(t),
$$

a local martingale. Therefore, by Corollary 63.2.3, this shows $[M]^{\tau}(t)-\left[M^{\tau}\right](t)=0$.

### 63.3 The Covariation

Definition 63.3.1 The covariation of two continuous $H$ valued local martingales for $H$ a separable Hilbert space $M, N, M(0)=0=N(0)$, is defined as follows.

$$
[M, N] \equiv \frac{1}{4}([M+N]-[M-N])
$$

Lemma 63.3.2 The following hold for the covariation.

$$
\begin{aligned}
& {[M]=[M, M] } \\
& {[M, N]=} \text { local martingale }+\frac{1}{4}\left(\|M+N\|^{2}-\|M-N\|^{2}\right) \\
&=(M, N)+\text { local martingale. }
\end{aligned}
$$

Proof: From the definition of covariation,

$$
\begin{gathered}
{[M]=\|M\|^{2}-\mathscr{N}_{1}} \\
{[M, M]=\frac{1}{4}([M+M]-[M-M])=\frac{1}{4}\left(\|M+M\|^{2}-\mathscr{N}_{2}\right)} \\
=\|M\|^{2}-\frac{1}{4} \mathscr{N}_{2}
\end{gathered}
$$

where $\mathscr{N}_{i}$ is a local martingale. Thus $[M]-[M, M]$ is equal to the difference of two increasing continuous adapted processes and it also equals a local martingale. By Corollary 63.2 .3 , this process must equal 0 . Now consider the second claim.

$$
\begin{aligned}
{[M, N] } & =\frac{1}{4}([M+N]-[M-N])=\frac{1}{4}\left(\|M+N\|^{2}-\|M-N\|^{2}+\mathscr{N}\right) \\
& =(M, N)+\frac{1}{4} \mathscr{N}
\end{aligned}
$$

where $\mathscr{N}$ is a local martingale.
Corollary 63.3.3 Let $M, N$ be two continuous local martingales, $M(0)=N(0)=0$, as in Proposition 63.2.5. Then $[M, N]$ is of bounded variation and

$$
(M, N)_{H}-[M, N]
$$

is a local martingale. Also for $\tau$ a stopping time,

$$
[M, N]^{\tau}=\left[M^{\tau}, N^{\tau}\right]=\left[M^{\tau}, N\right]=\left[M, N^{\tau}\right] .
$$

In addition to this,

$$
\left[M-M^{\tau}\right]=[M]-\left[M^{\tau}\right] \leq[M]
$$

and also

$$
(M, N) \rightarrow[M, N]
$$

is bilinear and symmetric.
Proof: Since $[M, N]$ is the difference of increasing functions, it is of bounded variation.

$$
\begin{aligned}
(M, N)_{H}-[M, N]= & \overbrace{\frac{1}{4}\left(\|M+N\|^{2}-\|M-N\|^{2}\right)}^{(M, N)_{H}} \\
& \overbrace{-\frac{1}{4}([M+N]-[M-N])}^{[M, N]}
\end{aligned}
$$

which equals a local martingale from the definition of $[M+N]$ and $[M-N]$. It remains to verify the claim about the stopping time. Using Corollary 63.2.6

$$
[M, N]^{\tau}=\frac{1}{4}([M+N]-[M-N])^{\tau}
$$

$$
\begin{aligned}
& =\frac{1}{4}\left([M+N]^{\tau}-[M-N]^{\tau}\right) \\
& =\frac{1}{4}\left(\left[M^{\tau}+N^{\tau}\right]-\left[M^{\tau}-N^{\tau}\right]\right) \equiv\left[M^{\tau}, N^{\tau}\right] .
\end{aligned}
$$

The really interesting part is the next equality. This will involve Corollary 63.2.3.

$$
\begin{gather*}
{[M, N]^{\tau}-\left[M^{\tau}, N\right]=\left[M^{\tau}, N^{\tau}\right]-\left[M^{\tau}, N\right]} \\
\equiv \frac{1}{4}\left(\left[M^{\tau}+N^{\tau}\right]-\left[M^{\tau}-N^{\tau}\right]\right)-\frac{1}{4}\left(\left[M^{\tau}+N\right]-\left[M^{\tau}-N\right]\right) \\
=\frac{1}{4}\left(\left[M^{\tau}+N^{\tau}\right]+\left[M^{\tau}-N\right]\right)-\frac{1}{4}\left(\left[M^{\tau}+N\right]+\left[M^{\tau}-N^{\tau}\right]\right), \tag{63.3.11}
\end{gather*}
$$

the difference of two increasing adapted processes. Also, this equals

$$
\text { local martingale }-\left(M^{\tau}, N\right)+\left(M^{\tau}, N^{\tau}\right)
$$

Claim: $\left(M^{\tau}, N\right)-\left(M^{\tau}, N^{\tau}\right)=\left(M^{\tau}, N-N^{\tau}\right)$ is a local martingale. Let $\sigma_{n}$ be a localizing sequence for both $M$ and $M$. Such a localizing sequence is of the form $\tau_{n}^{M} \wedge \tau_{n}^{N}$ where these are localizing sequences for the indicated local submartingale. Then obviously,

$$
\left(-\left(M^{\tau}, N\right)+\left(M^{\tau}, N^{\tau}\right)\right)^{\sigma_{n}}=-\left(M^{\sigma_{n} \wedge \tau}, N^{\sigma_{n}}\right)+\left(M^{\sigma_{n} \wedge \tau}, N^{\sigma_{n} \wedge \tau}\right)
$$

where $N^{\sigma_{n}}$ and $M^{\sigma_{n}}$ are martingales. To save notation, denote these by $M$ and $N$ respectively. Now use Lemma 63.1.1. Let $\sigma$ be a stopping time with two values.

$$
E\left(\left(M^{\tau}(\sigma), N(\sigma)-N^{\tau}(\sigma)\right)\right)=E\left(E\left(\left(M^{\tau}(\sigma), N(\sigma)-N^{\tau}(\sigma)\right) \mid \mathscr{F}_{\tau}\right)\right)
$$

Now $M^{\tau}(\sigma)$ is $M(\sigma \wedge \tau)$ which is $\mathscr{F}_{\tau}$ measurable and so by the Doob optional sampling theorem,

$$
\begin{gathered}
=E\left(M^{\tau}(\sigma), E\left(N(\sigma)-N^{\tau}(\sigma) \mid \mathscr{F}_{\tau}\right)\right) \\
=E\left(M^{\tau}(\sigma), N(\sigma \wedge \tau)-N(\tau \wedge \sigma)\right)=0
\end{gathered}
$$

while

$$
E\left(\left(M^{\tau}(t), N(t)-N^{\tau}(t)\right)\right)=E\left(E\left(\left(M^{\tau}(t), N(t)-N^{\tau}(t)\right) \mid \mathscr{F}_{\tau}\right)\right)
$$

Since $M^{\tau}(t)$ is $\mathscr{F}_{\tau}$ measurable,

$$
\begin{aligned}
& =E\left(\left(M^{\tau}(t), E\left(N(t)-N^{\tau}(t) \mid \mathscr{F}_{\tau}\right)\right)\right) \\
& =E\left(\left(M^{\tau}(t), E(N(t \wedge \tau)-N(t \wedge \tau))\right)\right)=0
\end{aligned}
$$

This shows the claim is true.
Now from 63.3.11 and Corollary 63.3.3,

$$
[M, N]^{\tau}-\left[M^{\tau}, N\right]=0 .
$$

Similarly

$$
[M, N]^{\tau}-\left[M, N^{\tau}\right]=0
$$

Now consider the next claim that $\left[M-M^{\tau}\right]=[M]-\left[M^{\tau}\right]$. From the definition, it follows

$$
\begin{aligned}
& {\left[M-M^{\tau}\right]-\left([M]+\left[M^{\tau}\right]-2\left[M, M^{\tau}\right]\right) } \\
= & \left\|M-M^{\tau}\right\|^{2}-\left(\|M\|^{2}+\left\|M^{\tau}\right\|^{2}-2\left(M, M^{\tau}\right)\right)+\text { local martingale } \\
= & \text { local martingale. }
\end{aligned}
$$

By the first part of the corollary which ensures $\left[M, M^{\tau}\right]$ is of bounded variation, the left side is the difference of two increasing adapted processes and so by Corollary 63.2.3 again, the left side equals 0 . Thus from the above,

$$
\begin{aligned}
{\left[M-M^{\tau}\right] } & =[M]+\left[M^{\tau}\right]-2\left[M, M^{\tau}\right] \\
& =[M]+\left[M^{\tau}\right]-2\left[M^{\tau}, M^{\tau}\right] \\
& =[M]+\left[M^{\tau}\right]-2\left[M^{\tau}\right] \\
& =[M]-\left[M^{\tau}\right] \leq[M]
\end{aligned}
$$

Finally consider the claim that $[M, N]$ is bilinear. From the definition, letting $M_{1}, M_{2}, N$ be $H$ valued local martingales,

$$
\begin{aligned}
\left(a M_{1}+b M_{2}, N\right)_{H} & =\left[a M_{1}+b M_{2}, N\right]+\text { local martingale } \\
a\left(M_{1}, N\right)+b\left(M_{2}, N\right)_{H} & =a\left[M_{1}, N\right]+b\left[M_{2}, N\right]+\text { local martingale }
\end{aligned}
$$

Hence

$$
\left[a M_{1}+b M_{2}, N\right]-\left(a\left[M_{1}, N\right]+b\left[M_{2}, N\right]\right)=\text { local martingale. }
$$

The left side can be written as the difference of two increasing functions thanks to $[M, N]$ of bounded variation and so by Lemma 63.1.5 it equals $0 .[M, N]$ is obviously symmetric from the definition.

### 63.4 The Burkholder Davis Gundy Inequality

Define

$$
M^{*}(\omega) \equiv \sup \{\|M(t)(\omega)\|: t \in[0, T]\}
$$

The Burkholder Davis Gundy inequality is an amazing inequality which involves $M^{*}$ and $[M](T)$.

Before presenting this, here is the good lambda inequality, Theorem 12.7.1 on Page 299 listed here for convenience.

Theorem 63.4.1 Let $(\Omega, \mathscr{F}, \mu)$ be a finite measure space and let $F$ be a continuous increasing function defined on $[0, \infty)$ such that $F(0)=0$. Suppose also that for all $\alpha>1$, there exists a constant $C_{\alpha}$ such that for all $x \in[0, \infty)$,

$$
F(\alpha x) \leq C_{\alpha} F(x)
$$

Also suppose $f, g$ are nonnegative measurable functions and there exists $\beta>1,0<r \leq 1$, such that for all $\lambda>0$ and $1>\delta>0$,

$$
\begin{equation*}
\mu([f>\beta \lambda] \cap[g \leq r \delta \lambda]) \leq \phi(\delta) \mu([f>\lambda]) \tag{63.4.12}
\end{equation*}
$$

where $\lim _{\delta \rightarrow 0+} \phi(\delta)=0$ and $\phi$ is increasing. Under these conditions, there exists a constant $C$ depending only on $\beta, \phi, r$ such that

$$
\int_{\Omega} F(f(\omega)) d \mu(\omega) \leq C \int_{\Omega} F(g(\omega)) d \mu(\omega)
$$

The proof of this important inequality also will depend on the hitting this before that theorem which is listed next for convenience.

Theorem 63.4.2 Let $\{M(t)\}$ be a continuous real valued martingale adapted to the normal filtration $\mathscr{F}_{t}$ and let

$$
\begin{aligned}
& M^{*} \equiv \sup \{|M(t)|: t \geq 0\} \\
& \tau_{x} \equiv \inf \{t>0: M(t)=x\}
\end{aligned}
$$

and $M(0)=0$. Letting

Then if $a<0<b$ the following inequalities hold.

$$
(b-a) P\left(\left[\tau_{b} \leq \tau_{a}\right]\right) \geq-a P\left(\left[M^{*}>0\right]\right) \geq(b-a) P\left(\left[\tau_{b}<\tau_{a}\right]\right)
$$

and

$$
(b-a) P\left(\left[\tau_{a}<\tau_{b}\right]\right) \leq b P\left(\left[M^{*}>0\right]\right) \leq(b-a) P\left(\left[\tau_{a} \leq \tau_{b}\right]\right)
$$

In words, $P\left(\left[\tau_{b} \leq \tau_{a}\right]\right)$ is the probability that $M(t)$ hits $b$ no later than when it hits $a$. (Note that if $\tau_{a}=\infty=\tau_{b}$ then you would have $\left[\tau_{a}=\tau_{b}\right]$.)

Then the Burkholder Davis Gundy inequality is as follows. Generalizations will be presented later.

Theorem 63.4.3 Let $\{M(t)\}$ be a continuous $H$ valued martingale which is uniformly bounded, $M(0)=0$, where $H$ is a separable Hilbert space and $t \in[0, T]$. Then if $F$ is a function of the sort described in the good lambda inequality above, there are constants, $C$ and $c$ independent of such martingales $M$ such that

$$
c \int_{\Omega} F\left(([M](T))^{1 / 2}\right) d P \leq \int_{\Omega} F\left(M^{*}\right) d P \leq C \int_{\Omega} F\left(([M](T))^{1 / 2}\right) d P
$$

where

$$
M^{*}(\omega) \equiv \sup \{\|M(t)(\omega)\|: t \in[0, T]\}
$$

Proof: Using Corollary 63.3.3, let

$$
\begin{aligned}
N(t) & \equiv\left\|M(t)-M^{\tau}(t)\right\|^{2}-\left[M-M^{\tau}\right](t) \\
& =\left\|M(t)-M^{\tau}(t)\right\|^{2}-[M](t)+[M]^{\tau}(t)
\end{aligned}
$$

where

$$
\tau \equiv \inf \{t \in[0, T]:\|M(t)\|>\lambda\}
$$

Thus $N$ is a martingale and $N(0)=0$. In fact $N(t)=0$ as long as $t \leq \tau$. As usual $\inf (\emptyset) \equiv \infty$. Note

$$
[\tau<\infty]=\left[M^{*}>\lambda\right] \supseteq\left[N^{*}>0\right] .
$$

This is because to say $\tau<\infty$ is to say there exists $t<T$ such that $\|M(t)\|>\lambda$ which is the same as saying $M^{*}>\lambda$. Thus the first two sets are equal. If $\tau=\infty$, then from the formula for $N(t)$ above, $N(t)=0$ for all $t \in[0, T]$ and so it can't happen that $N^{*}>0$. Thus the third set is contained in $[\tau<\infty]$ as claimed.

Let $\beta>2$ and let $\delta \in(0,1)$. Then

$$
\beta-1>1>\delta>0
$$

Consider the following which is set up to use the good lambda inequality.

$$
S_{r} \equiv\left[M^{*}>\beta \lambda\right] \cap\left[([M](T))^{1 / 2} \leq r \delta \lambda\right]
$$

where $0<r<1$.It is shown that $S_{r}$ corresponds to hitting "this before that" and there is an estimate for this which involves $P\left(\left[N^{*}>0\right]\right)$ which is bounded above by $P\left(\left[M^{*}>\lambda\right]\right)$ as discussed above. This will satisfy the hypotheses of the good lambda inequality.

Claim: For $\omega \in S_{r}, N(t)$ hits $\lambda^{2}\left(1-\delta^{2}\right)$.
Proof of claim: For $\omega \in S_{r}$, there exists a $t<T$ such that $\|M(t)\|>\beta \lambda$ and so using Corollary 63.3.3,

$$
\begin{aligned}
N(t) & \geq\|M(t)\|-\left\|M^{\tau}(t)\right\| \|^{2}-\left[M-M^{\tau}\right](t) \geq|\beta \lambda-\lambda|^{2}-[M](t) \\
& \geq(\beta-1)^{2} \lambda^{2}-\delta^{2} \lambda^{2}
\end{aligned}
$$

which shows that $N(t)$ hits $(\beta-1)^{2} \lambda^{2}-\delta^{2} \lambda^{2}$ for $\omega \in S_{r}$. By the intermediate value theorem, it also hits $\lambda^{2}\left(1-\delta^{2}\right)$. This proves the claim.

Claim: $N(t)(\omega)$ never hits $-\delta^{2} \lambda^{2}$ for $\omega \in S_{r}$.
Proof of claim: Suppose $t$ is the first time $N(t)$ reaches $-\delta^{2} \lambda^{2}$. Then $t>\tau$ and so

$$
\begin{aligned}
N(t) & =-\delta^{2} \lambda^{2} \geq\| \| M(t) \|-\left.\lambda\right|^{2}-[M](t)+\left[M^{\tau}\right](t) \\
& \geq-r^{2} \lambda^{2} \delta^{2}
\end{aligned}
$$

a contradiction since $r<1$. This proves the claim.
Therefore, for all $\omega \in S_{r}, N(t)(\omega)$ reaches $\lambda^{2}\left(1-\delta^{2}\right)$ before it reaches $-\delta^{2} \lambda^{2}$. It follows

$$
P\left(S_{r}\right) \leq P\left(N(t) \text { reaches } \lambda^{2}\left(1-\delta^{2}\right) \text { before }-\delta^{2} \lambda^{2}\right)
$$

and because of Theorem 62.11 .3 this is no larger than

$$
P\left(\left[N^{*}>0\right]\right) \frac{\delta^{2} \lambda^{2}}{\lambda^{2}\left(1-\delta^{2}\right)-\left(-\delta^{2} \lambda^{2}\right)}=P\left(\left[N^{*}>0\right]\right) \delta^{2} \leq \delta^{2} P\left(\left[M^{*}>\lambda\right]\right)
$$

Thus

$$
P\left(\left[M^{*}>\beta \lambda\right] \cap\left[([M](T))^{1 / 2} \leq r \delta \lambda\right]\right) \leq P\left(\left[M^{*}>\lambda\right]\right) \delta^{2}
$$

By the good lambda inequality,

$$
\int_{\Omega} F\left(M^{*}\right) d P \leq C \int_{\Omega} F\left(([M](T))^{1 / 2}\right) d P
$$

which is one half the inequality.
Now consider the other half. This time define the stopping time $\tau$ by

$$
\tau \equiv \inf \left\{t \in[0, T]:([M](t))^{1 / 2}>\lambda\right\}
$$

and let

$$
S_{r} \equiv\left[([M](T))^{1 / 2}>\beta \lambda\right] \cap\left[2 M^{*} \leq r \delta \lambda\right]
$$

Then there exists $t<T$ such that $[M](t)>\beta^{2} \lambda^{2}$. This time, let

$$
N(t) \equiv[M](t)-\left[M^{\tau}\right](t)-\left\|M(t)-M^{\tau}(t)\right\|^{2}
$$

This is still a martingale since by Corollary 63.3.3

$$
[M](t)-\left[M^{\tau}\right](t)=\left[M-M^{\tau}\right](t)
$$

Claim: $N(t)(\omega)$ hits $\lambda^{2}\left(1-\delta^{2}\right)$ for some $t<T$ for $\omega \in S_{r}$.
Proof of claim: Fix such a $\omega \in S_{r}$. Let $t<T$ be such that $[M](t)>\beta^{2} \lambda^{2}$. Then $t>\tau$ and so for that $\omega$,

$$
\begin{aligned}
N(t) & >\beta^{2} \lambda^{2}-\lambda^{2}-\|M(t)-M(\tau)\|^{2} \\
& \geq(\beta-1)^{2} \lambda^{2}-(\|M(t)\|+\|M(\tau)\|)^{2} \\
& \geq(\beta-1)^{2} \lambda^{2}-r^{2} \delta^{2} \lambda^{2} \geq \lambda^{2}-\delta^{2} \lambda^{2}
\end{aligned}
$$

By the intermediate value theorem, it hits $\lambda^{2}\left(1-\delta^{2}\right)$. This proves the claim.
Claim: $N(t)(\omega)$ never hits $-\delta^{2} \lambda^{2}$ for $\omega \in S_{r}$.
Proof of claim: By Corollary 63.3.3, if it did at $t$, then $t>\tau$ because $N(t)=0$ for $t \leq \tau$, and so

$$
\begin{aligned}
0 & \leq[M](t)-\left[M^{\tau}\right](t)=\|M(t)-M(\tau)\|^{2}-\delta^{2} \lambda^{2} \\
& \leq(\|M(t)\|+\|M(\tau)\|)^{2}-\delta^{2} \lambda^{2} \leq r^{2} \delta^{2} \lambda^{2}-\delta^{2} \lambda^{2}<0
\end{aligned}
$$

a contradiction. This proves the claim.
It follows that for each $r \in(0,1)$,

$$
P\left(S_{r}\right) \leq P\left(N(t) \text { hits } \lambda^{2}\left(1-\delta^{2}\right) \text { before }-\delta^{2} \lambda^{2}\right)
$$

By Theorem 62.11.3 this is no larger than

$$
\begin{aligned}
& P\left(\left[N^{*}>0\right]\right) \frac{\delta^{2} \lambda^{2}}{\lambda^{2}\left(1-\delta^{2}\right)+\delta^{2} \lambda^{2}}=P\left(\left[N^{*}>0\right]\right) \delta^{2} \\
& \quad \leq P([\tau<\infty]) \delta^{2}=P\left(\left[([M](T))^{1 / 2}>\lambda\right]\right) \delta^{2}
\end{aligned}
$$

Now by the good lambda inequality, there is a constant $k$ independent of $M$ such that

$$
\int_{\Omega} F\left(([M](T))^{1 / 2}\right) d P \leq k \int_{\Omega} F\left(2 M^{*}\right) d P \leq k C_{2} \int_{\Omega} F\left(M^{*}\right) d P
$$

by the assumptions about $F$. Therefore, combining this result with the first part,

$$
\begin{aligned}
\left(k C_{2}\right)^{-1} \int_{\Omega} F\left(([M](T))^{1 / 2}\right) d P & \leq \int_{\Omega} F\left(M^{*}\right) d P \\
& \leq C \int_{\Omega} F\left(([M](T))^{1 / 2}\right) d P
\end{aligned}
$$

Of course, everything holds for local martingales in place of martingales.
Theorem 63.4.4 Let $\{M(t)\}$ be a continuous $H$ valued local martingale, $M(0)=0$, where $H$ is a separable Hilbert space and $t \in[0, T]$. Then if $F$ is a function of the sort described in the good lambda inequality, that is,

$$
F(0)=0, F \text { continuous, } F \text { increasing, }
$$

$$
F(\alpha x) \leq c_{\alpha} F(x)
$$

there are constants, $C$ and $c$ independent of such local martingales $M$ such that

$$
c \int_{\Omega} F\left([M](T)^{1 / 2}\right) d P \leq \int_{\Omega} F\left(M^{*}\right) d P \leq C \int_{\Omega} F\left([M](T)^{1 / 2}\right) d P
$$

where

$$
M^{*}(\omega) \equiv \sup \{\|M(t)(\omega)\|: t \in[0, T]\}
$$

Proof: Let $\left\{\tau_{n}\right\}$ be an increasing localizing sequence for $M$ such that $M^{\tau_{n}}$ is uniformly bounded. Such a localizing sequence exists from Proposition 63.2.2. Then from Theorem 63.4.3 there exist constants $c, C$ independent of $\tau_{n}$ such that

$$
\begin{aligned}
c \int_{\Omega} F\left(\left[M^{\tau_{n}}\right](T)^{1 / 2}\right) d P & \leq \int_{\Omega} F\left(\left(M^{\tau_{n}}\right)^{*}\right) d P \\
& \leq C \int_{\Omega} F\left(\left[M^{\tau_{n}}\right](T)^{1 / 2}\right) d P
\end{aligned}
$$

By Corollary 63.3.3, this implies

$$
\begin{aligned}
c \int_{\Omega} F\left(\left([M]^{\tau_{n}}\right)(T)^{1 / 2}\right) d P & \leq \int_{\Omega} F\left(\left(M^{\tau_{n}}\right)^{*}\right) d P \\
& \leq C \int_{\Omega} F\left(\left([M]^{\tau_{n}}\right)(T)^{1 / 2}\right) d P
\end{aligned}
$$

and now note that $\left([M]^{\tau_{n}}\right)(T)^{1 / 2}$ and $\left(M^{\tau_{n}}\right)^{*}$ increase in $n$ to $[M](T)^{1 / 2}$ and $M^{*}$ respectively. Then the result follows from the monotone convergence theorem.

Here is a corollary [108].
Corollary 63.4.5 Let $\{M(t)\}$ be a continuous $H$ valued local martingale and let $\varepsilon, \delta \in$ $(0, \infty)$. Then there is a constant $C$, independent of $\varepsilon, \delta$ such that

$$
P([\overbrace{\sup _{t \in[0, T]}\|M(t)\|}^{M^{*}(T)} \geq \varepsilon]) \leq \frac{C}{\varepsilon} E\left([M]^{1 / 2}(T) \wedge \delta\right)+P\left([M]^{1 / 2}(T)>\delta\right)
$$

Proof: Let the stopping time $\tau$ be defined by

$$
\tau \equiv \inf \left\{t>0:[M]^{1 / 2}(t)>\delta\right\}
$$

Then

$$
P\left(\left[M^{*} \geq \varepsilon\right]\right)=P\left(\left[M^{*} \geq \varepsilon\right] \cap[\tau=\infty]\right)+P\left(\left[M^{*} \geq \varepsilon\right] \cap[\tau<\infty]\right)
$$

On the set where $[\tau=\infty], M^{\tau}=M$ and so $P\left(\left[M^{*} \geq \varepsilon\right]\right) \leq$

$$
\leq \frac{1}{\varepsilon} \int_{\Omega}\left(M^{\tau}\right)^{*} d P+P\left(\left[M^{*} \geq \varepsilon\right] \cap\left[[M]^{1 / 2}(T)>\delta\right]\right)
$$

By Theorem 63.4.4 and Corollary 63.3.3,

$$
\begin{aligned}
\leq & \frac{C}{\varepsilon} \int_{\Omega}\left[M^{\tau}\right]^{1 / 2}(T) d P+P\left(\left[M^{*} \geq \varepsilon\right] \cap\left[[M]^{1 / 2}(T)>\delta\right]\right) \\
= & \frac{C}{\varepsilon} \int_{\Omega}\left([M]^{\tau}\right)^{1 / 2}(T) d P+P\left(\left[M^{*} \geq \varepsilon\right] \cap\left[[M]^{1 / 2}(T)>\delta\right]\right) \\
\leq & \frac{C}{\varepsilon} \int_{\Omega}[M]^{1 / 2}(T) \wedge \delta d P+P\left(\left[M^{*} \geq \varepsilon\right] \cap\left[[M]^{1 / 2}(T)>\delta\right]\right) \\
& \leq \frac{C}{\varepsilon} \int_{\Omega}[M]^{1 / 2}(T) \wedge \delta d P+P\left(\left[[M]^{1 / 2}(T)>\delta\right]\right)
\end{aligned}
$$

The Burkholder Davis Gundy inequality along with the properties of the covariation implies the following amazing proposition.

Proposition 63.4.6 The space $M_{T}^{2}(H)$ is a Hilbert space. Here $H$ is a separable Hilbert space.

Proof: We already know from Proposition 62.12 .2 that this space is a Banach space. It is only necessary to exhibit an equivalent norm which makes it a Hilbert space. However, you can let $F(\lambda)=\lambda^{2}$ in the Burkholder Davis Gundy theorem and obtain for $M \in M_{T}^{2}(H)$, the two norms

$$
\left(\int_{\Omega}[M](T) d P\right)^{1 / 2}=\left(\int_{\Omega}[M, M](T) d P\right)^{1 / 2}
$$

and

$$
\left(\int_{\Omega}\left(M^{*}\right)^{2} d P\right)^{1 / 2}
$$

are equivalent. The first comes from an inner product since from Corollary 63.3.3, $[\cdot, \cdot]$ is bilinear and symmetric and nonnegative. If $[M, M](T)=[M](T)=0$ in $L^{1}(\Omega)$, then from the Burkholder Davis Gundy inequality, $M^{*}=0$ in $L^{2}(\Omega)$ and so $M=0$. Hence

$$
\int_{\Omega}[M, N](T) d P
$$

is an inner product which yields the equivalent norm.
Example 63.4.7 An example of a real martingale is the Wiener process, $W(t)$. It has the property that whenever $t_{1}<t_{2}<\cdots<t_{n}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent and whenever $s<t, W(t)-W(s)$ is normally distributed with mean 0 and variance $(t-s)$. For the Wiener process, we let

$$
\mathscr{F}_{t} \equiv \cap_{u>t} \overline{\sigma(W(s)-W(r): r<s \leq u)}
$$

and it is with respect to this normal filtration that $W$ is a continuous martingale. What is the quadratic variation of such a process?

The quadratic variation of the Wiener process is just $t$. This is because if $A \in \mathscr{F}_{s}, s<t$,

$$
\begin{gathered}
E\left(\mathscr{X}_{A}\left(|W(t)|^{2}-t\right)\right)= \\
E\left(\mathscr{X}_{A}\left(|W(t)-W(s)|^{2}+|W(s)|^{2}+2(W(s), W(t)-W(s))-(t-s+s)\right)\right)
\end{gathered}
$$

Now

$$
E\left(\mathscr{X}_{A}(2(W(s), W(t)-W(s)))\right)=P(A) E(2 W(s)) E(W(t)-W(s))=0
$$

by the independence of the increments. Thus the above reduces to

$$
\begin{aligned}
& E\left(\mathscr{X}_{A}\left(|W(t)-W(s)|^{2}+|W(s)|^{2}-(t-s+s)\right)\right) \\
= & E\left(\mathscr{X}_{A}\left(|W(t)-W(s)|^{2}-(t-s)\right)\right)+E\left(\mathscr{X}_{A}\left(|W(s)|^{2}-s\right)\right) \\
= & P(A) E\left(|W(t)-W(s)|^{2}-(t-s)\right)+E\left(\mathscr{X}_{A}\left(|W(s)|^{2}-s\right)\right) \\
= & E\left(\mathscr{X}_{A}\left(|W(s)|^{2}-s\right)\right)
\end{aligned}
$$

and so $E\left(|W(t)|^{2}-t \mid \mathscr{F}_{s}\right)=|W(s)|^{2}-s$ showing that $t \rightarrow|W(t)|^{2}-t$ is a martingale. Hence, by uniqueness, $[W](t)=t$.

### 63.5 The Quadratic Variation And Stochastic Integration

Let $\mathscr{F}_{t}$ be a normal filtration and let $\{M(t)\}$ be a continuous local martingale adapted to $\mathscr{F}_{t}$ having values in $U$ a separable real Hilbert space.

Definition 63.5.1 Let $\mathscr{F}_{t}$ be a normal filtration and let

$$
f(t) \equiv \sum_{k=0}^{n-1} f_{k} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t)
$$

where $\left\{t_{k}\right\}_{k=0}^{n}$ is a partition of $[0, T]$ and each $f_{k}$ is $\mathscr{F}_{t_{k}}$ measurable, $f_{k} M^{*} \in L^{2}(\Omega)$ where

$$
M^{*}(\omega) \equiv \sup _{t \in[0, T]}\|M(t)(\omega)\|
$$

Such a function is called an elementary function. Also let $\{M(t)\}$ be a local martingale adapted to $\mathscr{F}_{t}$ which has values in a separable real Hilbert space $U$ such that $M(0)=0$. For such an elementary real valued function define

$$
\int_{0}^{t} f d M \equiv \sum_{k=0}^{n-1} f_{k}\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)
$$

Then with this definition, here is a wonderful lemma.
Lemma 63.5.2 For $f$ an elementary function as above, $\left\{\int_{0}^{t} f d M\right\}$ is a continuous local martingale and

$$
\begin{equation*}
E\left(\left\|\int_{0}^{t} f d M\right\|_{U}^{2}\right)=\int_{\Omega} \int_{0}^{t} f(s)^{2} d[M](s) d P \tag{63.5.13}
\end{equation*}
$$

If $N$ is another continuous local martingale adapted to $\mathscr{F}_{t}$ and both $f, g$ are elementary functions such that for each $k$,

$$
f_{k} M^{*}, g_{k} N^{*} \in L^{2}(\Omega),
$$

then

$$
\begin{equation*}
E\left(\left(\int_{0}^{t} f d M, \int_{0}^{t} g d N\right)_{U}\right)=\int_{\Omega} \int_{0}^{t} f g d[M, N] \tag{63.5.14}
\end{equation*}
$$

and both sides make sense.
Proof: Let $\left\{\tau_{l}\right\}$ be a localizing sequence for $M$ such that $M^{\tau_{l}}$ is a bounded martingale. Then from the definition, for each $\omega$

$$
\int_{0}^{t} f d M=\lim _{l \rightarrow \infty} \int_{0}^{t} f d M^{\tau_{l}}=\lim _{l \rightarrow \infty}\left(\int_{0}^{t} f d M\right)^{\tau_{l}}
$$

and it is clear that $\left\{\int_{0}^{t} f d M^{\tau_{l}}\right\}$ is a martingale because it is just the sum of some martingales. Thus $\left\{\tau_{l}\right\}$ is a localizing sequence for $\int_{0}^{t} f d M$. It is also clear $\int_{0}^{t} f d M$ is continuous because it is a finite sum of continuous random variables.

Next consider the formula which is really a version of the Ito isometry. There is no loss of generality in assuming the mesh points are the same for the two elementary functions because if not, one can simply add in points to make this happen. It suffices to consider 63.5.14 because the other formula is a special case. To begin with, let $\left\{\tau_{l}\right\}$ be a localizing sequence which makes both $M^{\tau_{l}}$ and $N^{\tau_{l}}$ into bounded martingales. Consider the stopped process.

$$
\begin{aligned}
& E\left(\left(\int_{0}^{t} f d M^{\tau_{l}}, \int_{0}^{t} g d N^{\tau_{l}}\right)_{U}\right) \\
= & E\left(\left(\sum_{k=0}^{n-1} f_{k}\left(M^{\tau_{l}}\left(t \wedge t_{k+1}\right)-M^{\tau_{l}}\left(t \wedge t_{k}\right)\right)\right.\right. \\
& \left.\left.\sum_{k=0}^{n-1} g_{k}\left(N^{\tau_{l}}\left(t \wedge t_{k+1}\right)-N^{\tau_{l}}\left(t \wedge t_{k}\right)\right)\right)\right)
\end{aligned}
$$

To save on notation, write $M^{\tau_{l}}\left(t \wedge t_{k+1}\right)-M^{\tau_{l}}\left(t \wedge t_{k}\right) \equiv \Delta M_{k}(t)$, similar for $\Delta N_{k}$. Thus

$$
\Delta M_{k}=M^{\tau_{l} \wedge t_{k+1}}-M^{\tau_{l} \wedge t_{k}},
$$

similar for $\Delta N_{k}$. Then the above equals

$$
E\left(\sum_{k=0}^{n-1}\left(f_{k} \Delta M_{k}, \sum_{k=0}^{n-1} g_{k} \Delta N_{k}\right)\right)=E\left(\sum_{k, j} f_{k} g_{j}\left(\Delta M_{k}, \Delta N_{j}\right)\right)
$$

Now consider one of the mixed terms with $j<k$.

$$
\begin{gathered}
E\left(\left(f_{k} \Delta M_{k}, g_{j} \Delta N_{j}\right)\right)=E\left(E\left(\left(f_{k} \Delta M_{k}, g_{j} \Delta N_{j}\right) \mid \mathscr{F}_{t_{k}}\right)\right) \\
=E\left(g_{j} \Delta N_{j}, f_{k} E\left(\Delta M_{k} \mid \mathscr{F}_{t_{k}}\right)\right)=0
\end{gathered}
$$

since $E\left(\Delta M_{k} \mid \mathscr{F}_{t_{k}}\right)=E\left(\left(M^{\tau_{l}}\left(t \wedge t_{k+1}\right)-M^{\tau_{l}}\left(t \wedge t_{k}\right)\right) \mid \mathscr{F}_{t_{k}}\right)=0$ by the Doob optional sampling theorem. Thus

$$
\begin{gather*}
E\left(\left(\int_{0}^{t} f d M^{\tau_{l}}, \int_{0}^{t} g d N^{\tau_{l}}\right)_{U}\right)=  \tag{63.5.15}\\
=\sum_{k=0}^{n-1} E\left(f_{k} g_{k}\left(\Delta M_{k}, \Delta N_{k}\right)\right)=\sum_{k=0}^{n-1} E\left(f_{k} g_{k}\left(\left[\Delta M_{k}, \Delta N_{k}\right]+\mathscr{N}_{k}\right)\right) \tag{63.5.16}
\end{gather*}
$$

where $\mathscr{N}_{k}$ is a martingale such that $\mathscr{N}_{k}(t)=0$ for all $t \leq t_{k}$. This is because the martingale $\left(N^{\tau_{l}}\right)^{t_{k+1}}-\left(N^{\tau_{l}}\right)^{t_{k}}=\Delta N_{k}$ equals 0 for such $t$; and so $E\left(\mathscr{N}_{k}(t)\right)=0$. Thus $f_{k} g_{k} \mathscr{N}_{k}$ is a martingale which equals zero when $t=0$. Therefore, its expectation also equals 0 . Consequently the above reduces to

$$
\sum_{k=0}^{n-1} E\left(f_{k} g_{k}\left[\Delta M_{k}, \Delta N_{k}\right]\right) .
$$

At this point, recall the definition of the covariation. The above equals

$$
\frac{1}{4} \sum_{k=0}^{n-1} E\left(f_{k} g_{k}\left(\left[\Delta M_{k}+\Delta N_{k}\right]-\left[\Delta M_{k}-\Delta N_{k}\right]\right)\right)
$$

Rewriting this yields

$$
\begin{aligned}
= & \frac{1}{4} \sum_{k=0}^{n-1} E\left(f _ { k } g _ { k } \left(\left[\left(M^{\tau_{l}}\right)^{t_{k+1}}+\left(N^{\tau_{l}}\right)^{t_{k+1}}-\left(\left(M^{\tau_{l}}\right)^{t_{k}}+\left(N^{\tau_{l}}\right)^{t_{k}}\right)\right]\right.\right. \\
& \left.\left.-\left[\left(M^{\tau_{l}}\right)^{t_{k+1}}-\left(N^{\tau_{l}}\right)^{t_{k+1}}-\left(\left(M^{\tau_{l}}\right)^{t_{k}}-\left(N^{\tau_{l}}\right)^{t_{k}}\right)\right]\right)\right)
\end{aligned}
$$

To save on notation, denote

$$
\begin{aligned}
\left(M^{\tau_{l}}\right)^{t_{k+1}}+\left(N^{\tau_{l}}\right)^{t_{k+1}}-\left(\left(M^{\tau_{l}}\right)^{t_{k}}+\left(N^{\tau_{l}}\right)^{t_{k}}\right) & \equiv \Delta_{k}\left(M^{\tau_{l}}+N^{\tau_{l}}\right) \\
\left(M^{\tau_{l}}\right)^{t_{k+1}}-\left(N^{\tau_{l}}\right)^{t_{k+1}}-\left(\left(M^{\tau_{l}}\right)^{t_{k}}-\left(N^{\tau_{l}}\right)^{t_{k}}\right) & \equiv \Delta_{k}\left(M^{\tau_{l}}-N^{\tau_{l}}\right)
\end{aligned}
$$

Thus the above equals

$$
\frac{1}{4} \sum_{k=0}^{n-1} E\left(f_{k} g_{k}\left(\left[\Delta_{k}\left(M^{\tau_{l}}+N^{\tau_{l}}\right)\right]-\left[\Delta_{k}\left(M^{\tau_{l}}-N^{\tau_{l}}\right)\right]\right)\right)
$$

Now from Corollary 63.3.3,

$$
=\frac{1}{4} \sum_{k=0}^{n-1} E\left(f_{k} g_{k}\left(\left[\Delta_{k}(M+N)\right]^{\tau_{l}}-\left[\Delta_{k}(M-N)\right]^{\tau_{l}}\right)\right)
$$

Letting $l \rightarrow \infty$, this reduces to

$$
\begin{aligned}
& =\frac{1}{4} \sum_{k=0}^{n-1} E\left(f_{k} g_{k}\left(\left[\Delta_{k}(M+N)\right]-\left[\Delta_{k}(M-N)\right]\right)\right) \\
& =\frac{1}{4}\left(\int_{\Omega} \int_{0}^{t} f g(d[M+N]-d[M-N])\right) \\
& =\int_{\Omega} \int_{0}^{t} f g d[M, N]
\end{aligned}
$$

Now consider the left side of 63.5.16.

$$
\begin{aligned}
& E\left(\left(\int_{0}^{t} f d M^{\tau_{l}}, \int_{0}^{t} g d N^{\tau_{l}}\right)_{U}\right) \\
\equiv & \int_{\Omega} \sum_{k, j} f_{k} g_{j}\left(\left(M^{\tau_{l}}\left(t \wedge t_{k+1}\right)-M^{\tau_{l}}\left(t \wedge t_{k}\right)\right)\right. \\
& \left.\left(N^{\tau_{l}}\left(t \wedge t_{j+1}\right)-N^{\tau_{l}}\left(t \wedge t_{j}\right)\right)\right) d P
\end{aligned}
$$

Then for each $\omega$, the integrand converges as $l \rightarrow \infty$ to

$$
\sum_{k, j} f_{k} g_{j}\left(\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right),\left(N\left(t \wedge t_{j+1}\right)-N\left(t \wedge t_{j}\right)\right)\right)
$$

But also you can do a sloppy estimate which will allow the use of the dominated convergence theorem.

$$
\begin{gathered}
\left\|\sum_{k, j} f_{k} g_{j}\left(M^{\tau_{l}}\left(t \wedge t_{k+1}\right)-M^{\tau_{l}}\left(t \wedge t_{k}\right)\right),\left(N^{\tau_{l}}\left(t \wedge t_{j+1}\right)-N^{\tau_{l}}\left(t \wedge t_{j}\right)\right)\right\| \\
\leq \sum_{k, j}\left|f_{k}\right|\left|g_{j}\right| 4 M^{*} N^{*} \in L^{1}(\Omega)
\end{gathered}
$$

by assumption. Thus the left side of 63.5 .16 converges as $l \rightarrow \infty$ to

$$
\begin{aligned}
\int_{\Omega} \sum_{k, j} f_{k} g_{j}((M(t & \left.\left.\left.\wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right),\left(N\left(t \wedge t_{j+1}\right)-N\left(t \wedge t_{j}\right)\right)\right) d P \\
& =\int_{\Omega}\left(\int_{0}^{t} f d M, \int_{0}^{t} g d N\right)_{U} d P \square
\end{aligned}
$$

Note for each $\omega$, the inside integral in 63.5 .13 is just a Stieltjes integral taken with respect to the increasing integrating function $[M]$.

Of course, with this estimate it is obvious how to extend the integral to a larger class of functions.

Definition 63.5.3 Let $v(\omega)$ denote the Radon measure representing the functional

$$
\Lambda(\omega)(g) \equiv \int_{0}^{T} g d[M](t)(\omega)
$$

$(t \rightarrow[M](t)(\omega)$ is a continuous increasing function and $v(\omega)$ is the measure representing the Stieltjes integral, one for each $\omega$.) Then let $\mathscr{G}_{M}$ denote functions $f(s, \omega)$ which are the limit of such elementary functions in the space $L^{2}\left(\Omega ; L^{2}([0, T], v(\cdot))\right)$, the norm of such functions being

$$
\|f\|_{\mathscr{G}}^{2} \equiv \int_{\Omega} \int_{0}^{T} f(s)^{2} d[M](s) d P
$$

For $f \in \mathscr{G}$ just defined,

$$
\int_{0}^{t} f d M \equiv \lim _{n \rightarrow \infty} \int_{0}^{t} f_{n} d M
$$

where $\left\{f_{n}\right\}$ is a sequence of elementary functions converging to $f$ in

$$
L^{2}\left(\Omega ; L^{2}([0, T], v(\cdot))\right)
$$

Now here is an interesting lemma.

Lemma 63.5.4 Let $M$, $N$ be continuous local martingales, $M(0)=N(0)=0$ having values in a separable Hilbert space, $U$. Then

$$
\begin{gather*}
{[M+N]^{1 / 2} \leq\left([M]^{1 / 2}+[N]^{1 / 2}\right)}  \tag{63.5.17}\\
{[M+N] \leq 2([M]+[N])} \tag{63.5.18}
\end{gather*}
$$

Also, letting $v_{M+N}$ denote the measure obtained from the increasing function $[M+N]$ and $v_{N}, v_{M}$ defined similarly,

$$
\begin{equation*}
v_{M+N} \leq 2\left(v_{M}+v_{N}\right) \tag{63.5.19}
\end{equation*}
$$

on all Borel sets.
Proof: Since $(M, N) \rightarrow[M, N]$ is bilinear and satisfies

$$
\begin{aligned}
{[M, N] } & =[N, M] \\
{\left[a M+b M_{1}, N\right] } & =a[M, N]+b\left[M_{1}, N\right] \\
{[M, M] } & \geq 0
\end{aligned}
$$

which follows from Corollary 63.3.3, the usual Cauchy Schwarz inequality holds and so

$$
|[M, N]| \leq[M]^{1 / 2}[N]^{1 / 2}
$$

Thus

$$
\begin{aligned}
{[M+N] } & \equiv[M+N, M+N]=[M, M]+[N, N]+2[M, N] \\
& \leq[M]+[N]+2[M]^{1 / 2}[N]^{1 / 2}=\left([M]^{1 / 2}+[N]^{1 / 2}\right)^{2}
\end{aligned}
$$

This proves 63.5.17. Now square both sides. Then the right side is no larger than

$$
2([M]+[N])
$$

and this shows 63.5.18.
Now consider the claim about the measures. It was just shown that

$$
\left[(M+N)-(M+N)^{s}\right] \leq 2\left(\left[M-M^{s}\right]+\left[N-N^{s}\right]\right)
$$

and from Corollary 63.3.3 this implies that for $t>s$

$$
\begin{aligned}
& {[M+N](t)-[M+N](s \wedge t) } \\
&= {[M+N](t)-[M+N]^{s}(t) } \\
&= {\left[M+N-\left(M^{s}+N^{s}\right)\right](t) } \\
&= {\left[M-M^{s}+\left(N-N^{s}\right)\right](t) } \\
& \leq 2\left[M-M^{s}\right](t)+2\left[N-N^{s}\right](t) \\
& \leq 2([M](t)-[M](s))+2([N](t)-[N](s))
\end{aligned}
$$

Thus

$$
v_{M+N}([s, t]) \leq 2\left(v_{M}([s, t])+v_{N}([s, t])\right)
$$

By regularity of the measures, this continues to hold with any Borel set $F$ in place of $[s, t]$.

Theorem 63.5.5 The integral is well defined and has a continuous version which is a local martingale. Furthermore it satisfies the Ito isometry,

$$
E\left(\left\|\int_{0}^{t} f d M\right\|_{U}^{2}\right)=\int_{\Omega} \int_{0}^{t} f(s)^{2} d[M](s) d P
$$

Let the norm on $\mathscr{G}_{N} \cap \mathscr{G}_{M}$ be the maximum of the norms on $\mathscr{G}_{N}$ and $\mathscr{G}_{M}$ and denote by $\mathscr{E}_{N}$ and $\mathscr{E}_{M}$ the elementary functions corresponding to the martingales $N$ and $M$ respectively. Define $\mathscr{G}_{N M}$ as the closure in $\mathscr{G}_{N} \cap \mathscr{G}_{M}$ of $\mathscr{E}_{N} \cap \mathscr{E}_{M}$. Then for $f, g \in \mathscr{G}_{N M}$,

$$
\begin{equation*}
E\left(\left(\int_{0}^{t} f d M, \int_{0}^{t} g d N\right)\right)=\int_{\Omega} \int_{0}^{t} f g d[M, N] \tag{63.5.20}
\end{equation*}
$$

Proof: It is clear the definition is well defined because if $\left\{f_{n}\right\}$ and $\left\{g_{n}\right\}$ are two sequences of elementary functions converging to $f$ in $L^{2}\left(\Omega ; L^{2}([0, T], v(\cdot))\right)$ and if $\int_{0}^{1 t} f d M$ is the integral which comes from $\left\{g_{n}\right\}$,

$$
\begin{aligned}
& \int_{\Omega}\left\|\int_{0}^{1 t} f d M-\int_{0}^{t} f d M\right\|^{2} d P \\
= & \lim _{n \rightarrow \infty} \int_{\Omega}\left\|\int_{0}^{t} g_{n} d M-\int_{0}^{t} f_{n} d M\right\|^{2} d P \\
\leq & \lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left\|g_{n}-f_{n}\right\|^{2} d v d P=0 .
\end{aligned}
$$

Consider the claim the integral has a continuous version. Recall Theorem 62.9.4, part of which is listed here for convenience.

Theorem 63.5.6 Let $\{X(t)\}$ be a right continuous nonnegative submartingale adapted to the normal filtration $\mathscr{F}_{t}$ for $t \in[0, T]$. Let $p \geq 1$. Define

$$
X^{*}(t) \equiv \sup \{X(s): 0<s<t\}, X^{*}(0) \equiv 0
$$

Then for $\lambda>0$

$$
\begin{equation*}
P\left(\left[X^{*}(T)>\lambda\right]\right) \leq \frac{1}{\lambda^{p}} \int_{\Omega} X(T)^{p} d P \tag{63.5.21}
\end{equation*}
$$

Let $\left\{f_{n}\right\}$ be a sequence of elementary functions converging to $f$ in

$$
L^{2}\left(\Omega ; L^{2}([0, T], v(\cdot))\right) .
$$

Then letting

$$
\begin{aligned}
X_{n, m}^{\tau_{l}}(t) & =\left\|\int_{0}^{t}\left(f_{n}-f_{m}\right) d M^{\tau_{l}}\right\|_{U} \\
X_{n, m}(t) & =\left\|\int_{0}^{t}\left(f_{n}-f_{m}\right) d M\right\|_{U} \\
& =\left\|\int_{0}^{t} f_{n} d M-\int_{0}^{t} f_{m} d M\right\| \|_{U}
\end{aligned}
$$

It follows $X_{n, m}^{\tau_{l}}$ is a continuous nonnegative submartingale and from Theorem 62.9.4 just listed,

$$
\begin{aligned}
& P\left(\left[X_{n, m}^{\tau_{l} *}(T)>\lambda\right]\right) \leq \frac{1}{\lambda^{2}} \int_{\Omega} X_{n, m}^{\tau_{l}}(T)^{2} d P \\
& \quad \leq \frac{1}{\lambda^{2}} \int_{\Omega} \int_{0}^{T}\left|f_{n}-f_{m}\right|^{2} d\left[M^{\tau_{l}}\right] d P \\
& \quad \leq \frac{1}{\lambda^{2}} \int_{\Omega} \int_{0}^{T}\left|f_{n}-f_{m}\right|^{2} d[M] d P
\end{aligned}
$$

Letting $l \rightarrow \infty$,

$$
P\left(\left[X_{n, m}^{*}(T)>\lambda\right]\right) \leq \frac{1}{\lambda^{2}} \int_{\Omega} \int_{0}^{T}\left|f_{n}-f_{m}\right|^{2} d[M] d P
$$

Therefore, there exists a subsequence, still denoted by $\left\{f_{n}\right\}$ such that

$$
P\left(\left[X_{n, n+1}^{*}(T)>2^{-n}\right]\right)<2^{-n}
$$

Then by the Borel Cantelli lemma, the $\omega$ in infinitely many of the sets

$$
\left[X_{n, n+1}^{*}(T)>2^{-n}\right]
$$

has measure 0 . Denoting this exceptional set as $N$, it follows that for $\omega \notin N$, there exists $n(\omega)$ such that for $n>n(\omega)$,

$$
\sup _{t \in[0, T]}| | \int_{0}^{t} f_{n} d M-\int_{0}^{t} f_{n+1} d M \| \leq 2^{-n}
$$

and this implies uniform convergence of $\left\{\int_{0}^{t} f_{n} d M\right\}$. Letting

$$
G(t)=\lim _{n \rightarrow \infty} \int_{0}^{t} f_{n} d M
$$

for $\omega \notin N$ and $G(t)=0$ for $\omega \in N$, it follows that for each $t$, the continuous adapted process $G(t)$ equals $\int_{0}^{t} f d M$ a.e. Thus $\left\{\int_{0}^{t} f d M\right\}$ has a continuous version.

It suffices to verify 63.5.20. Let $\left\{f_{n}\right\}$ and $\left\{g_{n}\right\}$ be sequences of elementary functions converging to $f$ and $g$ in $\mathscr{G}_{M} \cap \mathscr{G}_{N}$. By Lemma 63.5.2,

$$
E\left(\left(\int_{0}^{t} f_{n} d M, \int_{0}^{t} g_{n} d N\right)_{U}\right)=\int_{\Omega} \int_{0}^{t} f_{n} g_{n} d[M, N]
$$

Then by the Holder inequality and the above definition,

$$
\lim _{n \rightarrow \infty} E\left(\left(\int_{0}^{t} f_{n} d M, \int_{0}^{t} g_{n} d N\right)_{U}\right)=E\left(\left(\int_{0}^{t} f d M, \int_{0}^{t} g d N\right)_{U}\right)
$$

Consider the right side which equals

$$
\frac{1}{4} \int_{\Omega} \int_{0}^{t} f_{n} g_{n} d[M+N] d P-\frac{1}{4} \int_{\Omega} \int_{0}^{t} f_{n} g_{n} d[M-N] d P
$$

Now from Lemma 63.5.4,

$$
\begin{aligned}
& \left|\int_{\Omega} \int_{0}^{t} f_{n} g_{n} d[M+N] d P-\int_{\Omega} \int_{0}^{t} f g d[M+N] d P\right| \\
= & \left|\int_{\Omega} \int_{0}^{t} f_{n} g_{n} d v_{M+N} d P-\int_{\Omega} \int_{0}^{t} f g d v_{M+N} d P\right| \\
\leq 2 & \left(\int_{\Omega} \int_{0}^{t}\left|f_{n} g_{n}-f g\right| d v_{M} d P+\int_{\Omega} \int_{0}^{t}\left|f_{n} g_{n}-f g\right| d v_{N} d P\right)
\end{aligned}
$$

and by the choice of the $f_{n}$ and $g_{n}$, these both converge to 0 . Similar considerations apply to

$$
\left|\int_{\Omega} \int_{0}^{t} f_{n} g_{n} d[M-N] d P-\int_{\Omega} \int_{0}^{t} f g d[M-N] d P\right|
$$

and show

$$
\lim _{n \rightarrow \infty} \int_{\Omega} \int_{0}^{t} f_{n} g_{n} d[M, N]=\int_{\Omega} \int_{0}^{t} f g d[M, N]
$$

### 63.6 Another Limit For Quadratic Variation

The problem to consider first is to define an integral

$$
\int_{0}^{t} f d M
$$

where $f$ has values in $H^{\prime}$ and $M$ is a continuous martingale having values in $H$. For the sake of simplicity assume $M(0)=0$. The process of definition is the same as before. First consider an elementary function

$$
\begin{equation*}
f(t) \equiv \sum_{k=0}^{m-1} f_{k} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t) \tag{63.6.22}
\end{equation*}
$$

where $f_{k}$ is measurable into $H^{\prime}$ with respect to $\mathscr{F}_{t_{k}}$. Then define

$$
\begin{equation*}
\int_{0}^{t} f d M \equiv \sum_{k=0}^{m-1} f_{k}\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right) \in \mathbb{R} \tag{63.6.23}
\end{equation*}
$$

Lemma 63.6.1 The $k^{\text {th }}$ term in the above sum is a martingale and the integral is also a martingale.

Proof: Let $\sigma$ be a stopping time with two values. Then

$$
\begin{aligned}
& E\left(f_{k}\left(M\left(\sigma \wedge t_{k+1}\right)-M\left(\sigma \wedge t_{k}\right)\right)\right) \\
= & E\left(E\left(f_{k}\left(M\left(\sigma \wedge t_{k+1}\right)-M\left(\sigma \wedge t_{k}\right)\right) \mid \mathscr{F}_{t_{k}}\right)\right) \\
= & E\left(f_{k} E\left(\left(M\left(\sigma \wedge t_{k+1}\right)-M\left(\sigma \wedge t_{k}\right)\right) \mid \mathscr{F}_{t_{k}}\right)\right)=0
\end{aligned}
$$

and it works the same with $\sigma$ replaced with $t$. Hence by the lemma about recognizing martingales, Lemma 63.1.1, each term is a martingale and so it follows that the integral $\int_{0}^{t} f d M$ is also a martingale.

Note also that, since $M$ is continuous, this is a continuous martingale.
As before, it is important to estimate this.

$$
E\left(\left|\int_{0}^{t} f d M\right|^{2}\right) \leq ?
$$

Consider a mixed term. For $j<k$, it follows from measurability considerations that

$$
\begin{gathered}
E\left(\left(f_{k}\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)\right)\left(f_{j}\left(M\left(t \wedge t_{j+1}\right)-M\left(t \wedge t_{j}\right)\right)\right)\right) \\
=E\left(E\left[\left(f_{k}\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)\right)\left(f_{j}\left(M\left(t \wedge t_{j+1}\right)-M\left(t \wedge t_{j}\right)\right)\right) \mid \mathscr{F}_{t_{k}}\right]\right) \\
=E\left(\left(f_{j}\left(M\left(t \wedge t_{j+1}\right)-M\left(t \wedge t_{j}\right)\right)\right) f_{k} E\left[\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right) \mid \mathscr{F}_{t_{k}}\right]\right)=0
\end{gathered}
$$

Therefore,

$$
\begin{gathered}
E\left(\left|\int_{0}^{t} f d M\right|^{2}\right)=E\left(\sum_{k=0}^{m-1}\left|f_{k}\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)\right|^{2}\right) \\
\leq E\left(\sum_{k=0}^{m-1}\left\|f_{k}\right\|^{2}\left|M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right|^{2}\right) \\
=E\left(\sum_{k=0}^{m-1}\left\|f_{k}\right\|^{2}\left(\left[M^{t_{k+1}}-M^{t_{k}}\right](t)+N_{k}(t)\right)\right) \\
=E\left(\sum_{k=0}^{m-1}\left\|f_{k}\right\|^{2}\left(\left[M^{t_{k+1}}\right](t)-\left[M^{t_{k}}\right](t)+N_{k}(t)\right)\right) \\
=E\left(\sum_{k=0}^{m-1}\left\|f_{k}\right\|^{2}\left([M]\left(t \wedge t_{k+1}\right)-[M]\left(t \wedge t_{k}\right)+N_{k}(t)\right)\right) \\
=E\left(\sum_{k=0}^{m-1}\left\|f_{k}\right\|^{2}\left([M]\left(t \wedge t_{k+1}\right)-[M]\left(t \wedge t_{k}\right)\right)\right)
\end{gathered}
$$

where $N_{k}$ is a martingale which equals 0 for $t \leq t_{k}$. The above equals

$$
E\left(\int_{0}^{t}\|f\|^{2} d[M]\right) \equiv E\left(\int_{0}^{t}\|f\|^{2} d v\right)
$$

the integral inside being the ordinary Lebesgue Stieltjes integral for the step function where $v$ is the measure determined by the positive linear functional

$$
\Lambda g=\int_{0}^{T} g d[M]
$$

where the integral on the right is the ordinary Stieltjes integral. Thus, the following inequality is obtained.

$$
\begin{equation*}
E\left(\left|\int_{0}^{t} f d M\right|^{2}\right) \leq E\left(\int_{0}^{t}\|f\|^{2} d[M],\right) \tag{63.6.24}
\end{equation*}
$$

Now what would it take for

$$
\begin{equation*}
E\left(\left|\int_{0}^{t} f d M\right|^{2}\right) \tag{63.6.25}
\end{equation*}
$$

to be well defined? A convenient condition would be to insist that each $\left\|f_{k}\right\| M^{*}$ is in $L^{2}(\Omega)$ where

$$
M^{*}(\omega) \equiv \sup _{t \in[0, T]}|M(t)(\omega)|_{H}
$$

Is this condition also sufficient for the above integral 63.6 .25 to be finite? From the above, that integral equals

$$
\begin{gathered}
E\left(\sum_{k=0}^{m-1}\left\|f_{k}\right\|^{2}\left|M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right|^{2}\right) \\
\leq E\left(4 \sum_{k=0}^{m-1}\left\|f_{k}\right\|^{2}\left(M^{*}\right)^{2}\right)
\end{gathered}
$$

Thus the condition that for each $k,\left\|f_{k}\right\| M^{*} \in L^{2}(\Omega)$ is sufficient for all of the above to consist of real numbers and be well defined.

Definition 63.6.2 A function $f$ is called an elementary function if it is a step function of the form given in 63.6 .22 where each $f_{k}$ is $\mathscr{F}_{t_{k}}$ measurable and for each $k,\left\|f_{k}\right\| M^{*} \in L^{2}(\Omega)$. Define $\mathscr{G}_{M}$ to be the collection of functions $f$ having values in $H^{\prime}$ which have the property that there exists a sequence of elementary functions $\left\{f_{n}\right\}$ with $f_{n} \rightarrow f$ in the space

$$
L^{2}\left(\Omega ; L^{2}([0, T], v)\right)
$$

Then picking such an approximating sequence,

$$
\int_{0}^{t} f d M \equiv \lim _{n \rightarrow \infty} \int_{0}^{t} f_{n} d M
$$

the convergence happening in $L^{2}(\Omega)$.

The inequality 63.6 .24 shows that this definition is well defined. So what are the properties of the integral just defined? Each $\int_{0}^{t} f_{n} d M$ is a continuous martingale because it is the sum of continuous martingales. Since convergence happens in $L^{2}(\Omega)$, it follows that $\int_{0}^{t} f d M$ is also a martingale. Is it continuous? By the maximal inequality Theorem 62.9.4, it follows that

$$
\left.\left.\left.\begin{array}{c}
P\left(\left[\sup _{t \in[0, T]} \mid \int_{0}^{t} f_{m} d M\right.\right.
\end{array}-\int_{0}^{t} f_{n} d M \right\rvert\,>\lambda\right]\right) \leq \frac{1}{\lambda^{2}} E\left(\left|\int_{0}^{T}\left(f_{m}-f_{n}\right) d M\right|^{2}\right)
$$

and it follows that there exists a subsequence, still called $n$ such that for all $p$ positive,

$$
P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} f_{n+p} d M-\int_{0}^{t} f_{n} d M\right|>\frac{1}{n}\right]\right)<2^{-n}
$$

By the Borel Cantelli lemma, there exists a set of measure zero $N$ such that for $\omega \notin N$, $\left\{\int_{0}^{t} f_{n} d M\right\}$ is a Cauchy sequence. Thus, what it converges to is continuous in $t$ for each $\omega \notin N$ and for each $t$, it equals $\int_{0}^{t} f d M$ a.e. Hence we can regard $\int_{0}^{t} f d M$ as this continuous version.

What is an example of such a function in $\mathscr{G}_{M}$ ?
Lemma 63.6.3 Let $R: H \rightarrow H^{\prime}$ be the Riesz map.

$$
\langle R f, g\rangle \equiv(f, g)_{H}
$$

Also suppose $M$ is a uniformly bounded continuous martingale with values in $H$. Then $R M \in \mathscr{G}_{M}$.

Proof: I need to exhibit an approximating sequence of elementary functions as described above. Consider

$$
M_{n}(t) \equiv \sum_{i=0}^{m_{n}-1} M\left(t_{i}\right) \mathscr{X}_{\left[t_{i}^{n}, t_{i+1}^{n}\right]}(t)
$$

Then clearly $R M_{n}\left(t_{i}\right) M^{*} \in L^{\infty}(\Omega)$ and so in particular it is in $L^{2}(\Omega)$. Here

$$
\lim _{n \rightarrow \infty} \max \left\{\left|t_{i}^{n}-t_{i+1}^{n}\right|, i=0, \cdots, m_{n}\right\}=0
$$

Say $M^{*}(\omega) \leq C$. Furthermore, I claim that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} E\left(\int_{0}^{T}\left\|R M_{n}-R M\right\|^{2} d[M]\right)=0 \tag{63.6.26}
\end{equation*}
$$

This requires a little proof. Recall the description of $[M](t)$. It was as follows. You considered

$$
P_{n}(t) \equiv 2 \sum_{k \geq 0}\left(\left(M\left(t \wedge \tau_{k+1}^{n}\right)-M\left(t \wedge \tau_{k}^{n}\right)\right), M\left(t \wedge \tau_{k}^{n}\right)\right)
$$

where the stopping times were defined such that $\tau_{k+1}^{n}$ is the first time $t>\tau_{k}^{n}$ such that $\left|M(t)-M\left(\tau_{k}^{n}\right)\right|^{2}=2^{-n}$ and $\tau_{0}^{n}=0$. Recall that $\lim _{k \rightarrow \infty} \tau_{k}^{n}=\infty$ or $T$ in the way it was formulated earlier. Then it was shown that $P_{n}(t)$ converged to a martingale $P(t)$ in $L^{1}(\Omega)$. Then by the usual procedure using the Borel Cantelli lemma, a subsequence converges to $P(t)$ uniformly off a set of measure zero. It is easy to estimate $P_{n}(t)$.

$$
\left|P_{n}(t)\right| \leq \sum_{k \geq 0}\left|M\left(t \wedge \tau_{k+1}^{n}\right)\right|^{2}-\left|M\left(t \wedge \tau_{k}^{n}\right)\right|^{2}=|M(t)|^{2} \leq M^{*}
$$

This follows from the observation that

$$
\left(M\left(t \wedge \tau_{k+1}^{n}\right), M\left(t \wedge \tau_{k}^{n}\right)\right) \leq \frac{1}{2}\left(\left|M\left(t \wedge \tau_{k+1}^{n}\right)\right|^{2}+\left|M\left(t \wedge \tau_{k}^{n}\right)\right|^{2}\right)
$$

Then it follows that $\sup _{t \in[0, T]}|P(t)(\omega)| \leq M^{*}(\omega) \leq C$ for a.e. $\omega$. The quadratic variation $[M]$ was defined as

$$
|M(t)|^{2}=P(t)+[M](t)
$$

Thus $[M](t) \leq 2\left(M^{*}\right)^{2}$. Now consider the above limit in 63.6.26. From the assumption that $M$ is uniformly bounded,

$$
\int_{0}^{T}\left\|R M_{n}-R M\right\|^{2} d[M] \leq \int_{0}^{T} 4 C^{2} d[M]=4 C^{2}[M](T) \leq 4 C^{2}\left(2 C^{2}\right)<\infty
$$

Also, by the continuity of the martingale, for each $\omega$,

$$
\lim _{n \rightarrow \infty}\left\|R M_{n}-R M\right\|^{2}=0
$$

By the dominated convergence theorem, and the fact that the integrand is bounded,

$$
\lim _{n \rightarrow \infty} \int_{0}^{T}\left\|R M_{n}-R M\right\|^{2} d[M]=0
$$

Then from the above estimate and the dominated convergence theorem again, 63.6.26 follows. Thus $R M \in \mathscr{G}_{M}$.

From the above lemma, it makes sense to speak of

$$
\int_{0}^{t}(R M) d M
$$

and this is a continuous martingale having values in $\mathbb{R}$. Also from the above argument, if $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}$ is a sequence of partitions such that

$$
\lim _{n \rightarrow \infty} \max \left\{\left|t_{i}^{n}-t_{i+1}^{n}\right|, i=0, \cdots, m_{n}\right\}=0
$$

then it follows that

$$
\sum_{i=0}^{m_{n}-1} R M\left(t_{i}\right)\left(M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right) \rightarrow \int_{0}^{t}(R M) d M
$$

in $L^{2}(\Omega)$, this for each $t \in[0, T]$.
Now here is the main result.

Theorem 63.6.4 Let $H$ be a Hilbert space and suppose $\left(M, \mathscr{F}_{t}\right), t \in[0, T]$ is a uniformly bounded continuous martingale with values in $H$. Also let $\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}}$ be a sequence of partitions satisfying

$$
\lim _{n \rightarrow \infty} \max \left\{\left|t_{i}^{n}-t_{i+1}^{n}\right|, i=0, \cdots, m_{n}\right\}=0,\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}} \subseteq\left\{t_{k}^{n+1}\right\}_{k=1}^{m_{n+1}}
$$

Then

$$
[M](t)=\lim _{n \rightarrow \infty} \sum_{k=0}^{m_{n}-1}\left|M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right|_{H}^{2}
$$

the limit taking place in $L^{2}(\Omega)$. In case $M$ is just a continuous local martingale, the above limit happens in probability.

Proof: First suppose $M$ is uniformly bounded.

$$
\begin{gathered}
\sum_{k=0}^{m_{n}-1}\left|M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right|_{H}^{2} \\
=\sum_{k=0}^{m_{n}-1}\left|M\left(t \wedge t_{k+1}^{n}\right)\right|^{2}-\left|M\left(t \wedge t_{k}^{n}\right)\right|^{2}-2 \sum_{k=0}^{m_{n}-1}\left(M\left(t \wedge t_{k}^{n}\right), M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right) \\
=|M(t)|_{H}^{2}-2 \sum_{k=0}^{m_{n}-1}\left(M\left(t \wedge t_{k}^{n}\right), M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right) \\
=|M(t)|_{H}^{2}-2 \sum_{k=0}^{m_{n}-1} R M\left(t \wedge t_{k}^{n}\right)\left(M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right) \\
=|M(t)|_{H}^{2}-2 \sum_{k=0}^{m_{n}-1} R M\left(t_{k}^{n}\right)\left(M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right)
\end{gathered}
$$

Then by Lemma 63.6.3, the right side converges to

$$
|M(t)|_{H}^{2}-2 \int_{0}^{t}(R M) d M
$$

Therefore, in $L^{2}(\Omega)$,

$$
\lim _{n \rightarrow \infty} \sum_{k=0}^{m_{n}-1}\left|M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right|_{H}^{2}+2 \int_{0}^{t}(R M) d M=|M(t)|_{H}^{2}
$$

That term on the left involving the limit is increasing and equal to 0 when $t=0$. Therefore, it must equal $[M](t)$.

Next suppose $M$ is only a continuous local martingale. By Proposition 63.2.2 there exists an increasing localizing sequence $\left\{\tau_{k}\right\}$ such that $M^{\tau_{k}}$ is a uniformly bounded martingale. Then

$$
P\left(\cup_{k=1}^{\infty}\left[\tau_{k}=\infty\right]\right)=1
$$

To save notation, let

$$
Q_{n}(t) \equiv \sum_{k=0}^{m_{n}-1}\left|M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right|_{H}^{2}
$$

Let $\eta, \varepsilon>0$ be given. Then there exists $k$ large enough that $P\left(\left[\tau_{k}=\infty\right]\right)>1-\eta / 2$. This is because the sets $\left[\tau_{k}=\infty\right]$ increase to $\Omega$ other than a set of measure zero. Then,

$$
\left[\left|Q_{n}^{\tau_{k}}-[M]^{\tau_{k}}(t)\right|>\varepsilon\right] \cap\left[\tau_{k}=\infty\right]=\left[\left|Q_{n}-[M](t)\right|>\varepsilon\right] \cap\left[\tau_{k}=\infty\right]
$$

Thus

$$
\begin{aligned}
& P\left(\left[\left|Q_{n}-[M](t)\right|>\varepsilon\right]\right) \leq P\left(\left[\left|Q_{n}-[M](t)\right|>\varepsilon\right] \cap\left[\tau_{k}=\infty\right]\right) \\
&+P\left(\left[\tau_{k}<\infty\right]\right) \\
& \leq P\left(\left[\left|Q_{n}^{\tau_{k}}-[M]^{\tau_{k}}(t)\right|>\varepsilon\right]\right)+\eta / 2
\end{aligned}
$$

From the first part, the convergence in probability of $Q_{n}^{\tau_{k}}(t)$ to $[M]^{\tau_{k}}(t)$ follows from the convergence in $L^{2}(\Omega)$ and so if $n$ is large enough, the right side of the above inequality is less than $\eta / 2+\eta / 2=\eta$. Since $\eta$ was arbitrary, this proves convergence in probability.

### 63.7 Doob Meyer Decomposition

This section is on the Doob Meyer decomposition which is a way of starting with a submartingale and writing it as the sum of a martingale and an increasing adapted stochastic process of a certain form. This is more general than what was done above with the submartingales $\|M(t)\|^{2}$ for $M(t) \in \mathscr{M}_{T}^{2}(H)$ where $M$ is a continuous martingale. There are two forms for this theorem, one for discrete martingales and one for martingales defined on an interval of the real line which is much harder. According to [74], this material is found in [78] however, I am following [74] for the continuous version of this theorem.

Theorem 63.7.1 Let $\left\{X_{n}\right\}$ be a submartingale. Then there exists a unique stochastic process, $\left\{A_{n}\right\}$ and martingale, $\left\{M_{n}\right\}$ such that

1. $A_{n}(\omega) \leq A_{n+1}(\omega), A_{1}(\omega)=0$,
2. $A_{n}$ is $\mathscr{F}_{n-1}$ adapted for all $n \geq 1$ where $\mathscr{F}_{0} \equiv \mathscr{F}_{1}$.
and also $X_{n}=M_{n}+A_{n}$.
Proof: Let $A_{1} \equiv 0$ and define

$$
A_{n} \equiv \sum_{k=2}^{n} E\left(X_{k}-X_{k-1} \mid \mathscr{F}_{k-1}\right)
$$

It follows $A_{n}$ is $\mathscr{F}_{n-1}$ measurable. Since $\left\{X_{k}\right\}$ is a submartingale, $A_{n}$ is increasing because

$$
\begin{equation*}
A_{n+1}-A_{n}=E\left(X_{n+1}-X_{n} \mid \mathscr{F}_{n}\right) \geq 0 \tag{63.7.27}
\end{equation*}
$$

It is a submartingale because

$$
E\left(A_{n} \mid \mathscr{F}_{n-1}\right)=A_{n} \geq A_{n-1}
$$

Now let $M_{n}$ be defined by

$$
X_{n}=M_{n}+A_{n}
$$

Then from 63.7.27,

$$
\begin{aligned}
& E\left(M_{n+1} \mid \mathscr{F}_{n}\right)=E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(A_{n+1} \mid \mathscr{F}_{n}\right) \\
= & E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(A_{n+1}-A_{n} \mid \mathscr{F}_{n}\right)-A_{n} \\
= & E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(E\left(X_{n+1}-X_{n} \mid \mathscr{F}_{n}\right) \mid \mathscr{F}_{n}\right)-A_{n} \\
= & E\left(X_{n+1} \mid \mathscr{F}_{n}\right)-E\left(X_{n+1}-X_{n} \mid \mathscr{F}_{n}\right)-A_{n} \\
= & E\left(X_{n} \mid \mathscr{F}_{n}\right)-A_{n} \\
= & X_{n}-A_{n} \equiv M_{n}
\end{aligned}
$$

This proves the existence part.
It remains to verify uniqueness. Suppose then that

$$
X_{n}=M_{n}+A_{n}=M_{n}^{\prime}+A_{n}^{\prime}
$$

where $\left\{A_{n}\right\}$ and $\left\{A_{n}^{\prime}\right\}$ both satisfy the conditions of the theorem and $\left\{M_{n}\right\}$ and $\left\{M_{n}^{\prime}\right\}$ are both martingales. Then

$$
M_{n}-M_{n}^{\prime}=A_{n}^{\prime}-A_{n}
$$

and so, since $A_{n}^{\prime}-A_{n}$ is $\mathscr{F}_{n-1}$ measurable and $\left\{M_{n}-M_{n}^{\prime}\right\}$ is a martingale,

$$
\begin{aligned}
M_{n-1}-M_{n-1}^{\prime} & =E\left(M_{n}-M_{n}^{\prime} \mid \mathscr{F}_{n-1}\right) \\
& =E\left(A_{n}^{\prime}-A_{n} \mid \mathscr{F}_{n-1}\right) \\
& =A_{n}^{\prime}-A_{n}=M_{n}-M_{n}^{\prime} .
\end{aligned}
$$

Continuing this way shows $M_{n}-M_{n}^{\prime}$ is a constant. However, since $A_{1}^{\prime}-A_{1}=0=M_{1}-M_{1}^{\prime}$, it follows $M_{n}=M_{n}^{\prime}$ and this proves uniqueness. This proves the theorem.

Definition 63.7.2 A stochastic process, $\left\{A_{n}\right\}$ which satisfies the conditions of Theorem 63.7.1,

$$
A_{n}(\omega) \leq A_{n+1}(\omega)
$$

and

$$
A_{n} \text { is } \mathscr{F}_{n-1} \text { adapted for all } n \geq 1
$$

where $\mathscr{F}_{0} \equiv \mathscr{F}_{1}$ is said to be natural.
The Doob Meyer theorem needs to be extended to continuous submartingales and this will require another description of what it means for a stochastic process to be natural. To get an idea of what this condition should be, here is a lemma.

Lemma 63.7.3 Let a stochastic process, $\left\{A_{n}\right\}$ be natural. Then for every martingale, $\left\{M_{n}\right\}$,

$$
E\left(M_{n} A_{n}\right)=E\left(\sum_{j=1}^{n-1} M_{j}\left(A_{j+1}-A_{j}\right)\right)
$$

Proof: Start with the right side.

$$
\begin{aligned}
E\left(\sum_{j=1}^{n-1} M_{j}\left(A_{j+1}-A_{j}\right)\right) & =E\left(\sum_{j=2}^{n} M_{j-1} A_{j}-\sum_{j=1}^{n-1} M_{j} A_{j}\right) \\
& =E\left(\sum_{j=2}^{n-1} A_{j}\left(M_{j-1}-M_{j}\right)\right)+E\left(M_{n-1} A_{n}\right)
\end{aligned}
$$

Then the first term equals zero because since $A_{j}$ is $\mathscr{F}_{j-1}$ measurable,

$$
\begin{aligned}
\int_{\Omega} A_{j} M_{j-1} d P-\int_{\Omega} A_{j} M_{j} & =\int_{\Omega} A_{j} E\left(M_{j} \mid \mathscr{F}_{j-1}\right) d P-\int_{\Omega} A_{j} M_{j} d P \\
& =\int_{\Omega} E\left(A_{j} M_{j} \mid \mathscr{F}_{j-1}\right) d P-\int_{\Omega} A_{j} M_{j} d P \\
& =\int_{\Omega} A_{j} M_{j} d P-\int_{\Omega} A_{j} M_{j} d P=0
\end{aligned}
$$

The last term equals

$$
\begin{aligned}
\int_{\Omega} M_{n-1} A_{n} d P & =\int_{\Omega} E\left(M_{n} \mid \mathscr{F}_{n-1}\right) A_{n} d P \\
& =\int_{\Omega} E\left(M_{n} A_{n} \mid \mathscr{F}_{n-1}\right) d P=E\left(M_{n} A_{n}\right)
\end{aligned}
$$

This proves the lemma.
Definition 63.7.4 Let A be an increasing function defined on $\mathbb{R}$. By Theorem 4.3.4 on Page 50 there exists a positive linear functional, $L$ defined on $C_{c}(\mathbb{R})$ given by

$$
L f \equiv \int_{a}^{b} f d A \text { where } \operatorname{spt}(f) \subseteq[a, b]
$$

where the integral is just the Riemann Stieltjes integral. Then by the Riesz representation theorem, Theorem 12.3.2 on Page 288, there exists a unique Radon measure, $\mu$ which extends this functional, as described in the Riesz representation theorem. Then for $B$ a measurable set, I will write either

$$
\int_{B} f d \mu \text { or } \int_{B} f d A
$$

to denote the Lebesgue integral,

$$
\int \mathscr{X}_{B} f d \mu
$$

Lemma 63.7.5 Let $f$ be right continuous. Then $f$ is Borel measurable. Also, if the limit from the left exists, then $f_{-}(x) \equiv f(x)_{-} \equiv \lim _{y \rightarrow x-} f(y)$ is also Borel measurable. If $A$ is an increasing right continuous function and $f$ is right continuous and $f_{-}$, the left limit function exists, then if $f$ is bounded, on $[a, b]$, and if

$$
\left\{x_{0}^{p}, \cdots, x_{n_{p}}^{p}\right\}_{p=1}^{\infty}
$$

is a sequence of partitions of $[a, b]$ such that

$$
\begin{equation*}
\lim _{p \rightarrow \infty} \max \left\{\left|x_{k}^{p}-x_{k-1}^{p}\right|: k=1,2, \cdots, n_{p}\right\}=0 \tag{63.7.28}
\end{equation*}
$$

then

$$
\begin{equation*}
\int_{(a, b]} f_{-} d A=\lim _{p \rightarrow \infty} \sum_{k=1}^{n_{p}} f\left(x_{k-1}^{p}\right)\left(A\left(x_{k}^{p}\right)-A\left(x_{k-1}^{p}\right)\right) \tag{63.7.29}
\end{equation*}
$$

More generally, let

$$
D \equiv \cup_{p=1}^{\infty}\left\{x_{0}^{p}, \cdots, x_{n_{p}}^{p}\right\}_{p=1}^{\infty}
$$

and

$$
f_{-}(t)=\lim _{s \rightarrow t-, s \in D} f(s)
$$

Then 63.7.29 holds.
Proof: For $x \in f^{-1}((a, \infty))$, denote by $I_{x}$ the union of all intervals containing $x$ such that $f(y)$ is larger than $a$ for all $y$ in the interval. Since $f$ is right continuous, each $I_{x}$ has positive length. Now if $I_{x}$ and $I_{y}$ are two of these intervals, then either they must have empty intersection or they are the same interval. Thus $f^{-1}((a, \infty))$ is of the form $\cup_{x \in f^{-1}((a, \infty))} I_{x}$ and there can only be countably many distinct intervals because each has positive length and $\mathbb{R}$ is separable. Hence $f^{-1}((a, \infty))$ equals the countable union of intervals and is therefore, Borel measurable. Now

$$
f_{-}(x)=\lim _{n \rightarrow \infty} f\left(x-r_{n}\right) \equiv \lim _{n \rightarrow \infty} f_{r_{n}}(x)
$$

where $r_{n}$ is a decreasing sequence converging to 0 . Now each $f_{r_{n}}$ is Borel measurable by the first part of the proof because it is right continuous and so it follows the same is true of $f_{-}$.

Finally consider the claim about the integral. Since $A$ is right continuous, a simple argument involving the dominated convergence theorem and approximating $(c, d]$ with a piecewise linear continuous function nonzero only on $(c, d+h)$ which approximates $\mathscr{X}_{(c, d]}$ will show that for $\mu$ the measure of Definition 63.7.4

$$
\mu((c, d])=A(d)-A(c) .
$$

Therefore, the sum in 63.7.29 is of the form

$$
\sum_{k=1}^{n_{p}} f\left(x_{k-1}^{p}\right) \mu\left(\left(x_{k-1}, x_{k}\right]\right)=\int_{(a, b]} \sum_{k=1}^{n_{p}} f\left(x_{k-1}^{p}\right) \mathscr{X}_{\left(x_{k-1}, x_{k}\right]} d \mu
$$

and by 63.7.28

$$
\lim _{p \rightarrow \infty} \sum_{k=1}^{n_{p}} f\left(x_{k-1}^{p}\right) \mathscr{X}_{\left(x_{k-1}, x_{k}\right]}(x)=f_{-}(x)
$$

for each $x \in(a, b]$. Therefore, since $f$ is bounded, 63.7.29 follows from the dominated convergence theorem. The last claim follows the same way. This proves the lemma.

Definition 63.7.6 An increasing stochastic process, $\{A(t)\}$ which is right continuous is said to be natural if $A(0)=0$ and whenever $\{\xi(t)\}$ is a bounded right continuous martingale,

$$
\begin{equation*}
E(A(t) \xi(t))=E\left(\int_{(0, t]} \xi_{-}(s) d A(s)\right) \tag{63.7.30}
\end{equation*}
$$

Here

$$
\xi_{-}(s, \omega) \equiv \lim _{r \rightarrow s-, r \in D} \xi(r, \omega)
$$

a.e. where $D$ is a countable dense subset of $[0, t]$. By Corollary 62.8.2 the right side of 63.7.30 is not dependent on the choice of $D$ since if $\xi_{-}$is computed using two different dense subsets, the two random variables are equal a.e.

Some discussion is in order for this definition. Pick $\omega \in \Omega$. Then since $A$ is right continuous, the function $t \rightarrow A(t, \omega)$ is increasing and right continuous. Therefore, one can do the Lebesgue Stieltjes integral defined in Definition 63.7.4 for each $\omega$ whenever $f$ is Borel measurable and bounded. Now it is assumed $\{\xi(t)\}$ is bounded and right continuous. By Lemma 63.7.5 $\xi_{-}(t) \equiv \lim _{r \rightarrow t-, r \in D} \xi(r)$ is measurable and by this lemma,

$$
\int_{(0, t]} \xi_{-}(s) d A(s)=\lim _{p \rightarrow \infty} \sum_{k=1}^{n_{p}} \xi\left(t_{k-1}^{p}\right)\left(A\left(t_{k}^{p}\right)-A\left(t_{k-1}^{p}\right)\right)
$$

where $\left\{t_{k}^{p}\right\}_{k=1}^{n_{p}}$ is a sequence of partitions of $[0, t]$ such that

$$
\begin{equation*}
\lim _{p \rightarrow \infty} \max \left\{\left|t_{k}^{p}-t_{k-1}^{p}\right|: k=1,2, \cdots, n_{p}\right\}=0 \tag{63.7.31}
\end{equation*}
$$

and $D \equiv \cup_{p=1}^{\infty} \cup_{k=1}^{n_{p}}\left\{t_{k}^{p}\right\}_{k=1}^{n_{p}}$.
Also, if $t \rightarrow A(t, \omega)$ is right continuous, hence Borel measurable, then for $\xi(t)$ the above bounded right continuous martingale, it follows it makes sense to write

$$
\int_{(0, t]} \xi(s) d A(s)
$$

Consider the right sum,

$$
\sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right)\left(A\left(t_{k}^{p}\right)-A\left(t_{k-1}^{p}\right)\right)
$$

This equals

$$
\int_{(0, t]} \sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right) \mathscr{X}_{\left(t_{k-1}^{p}, t_{k}^{p}\right]}(s) d A(s)
$$

and by right continuity, it follows

$$
\lim _{p \rightarrow \infty} \sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right) \mathscr{X}_{\left(t_{k-1}^{p}, t_{k}^{p}\right]}(s)=\xi(s)
$$

and so the dominated convergence theorem applies and it follows

$$
\lim _{p \rightarrow \infty} \sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right)\left(A\left(t_{k}^{p}\right)-A\left(t_{k-1}^{p}\right)\right)=\int_{(0, t]} \xi(s) d A(s)
$$

where this is a random variable. Thus

$$
\begin{equation*}
E\left(\int_{(0, t]} \xi(s) d A(s)\right)=\int_{\Omega}\left(\lim _{p \rightarrow \infty} \int_{(0, t]} \sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right) \mathscr{X}_{\left(t_{k-1}^{p}, t_{k}^{p}\right]}(s) d A(s)\right) d P \tag{63.7.32}
\end{equation*}
$$

Now as mentioned above,

$$
\int_{(0, t]} \sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right) \mathscr{X}_{\left(t_{k-1}^{p}, t_{k}^{p}\right]}(s) d A(s)=\sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right)\left(A\left(t_{k}^{p}\right)-A\left(t_{k-1}^{p}\right)\right)
$$

and since $A$ is increasing, this is bounded above by an expression of the form $C A(t)$, a function in $L^{1}$. Therefore, by the dominated convergence theorem, 63.7.32 reduces to

$$
\begin{align*}
& \lim _{p \rightarrow \infty} \int_{\Omega} \int_{(0, t]} \sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right) \mathscr{X}_{\left(t_{k-1}^{p}, t_{k}^{p}\right]}(s) d A(s) d P \\
= & \lim _{p \rightarrow \infty} \int_{\Omega} \sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right)\left(A\left(t_{k}^{p}\right)-A\left(t_{k-1}^{p}\right)\right) d P \\
= & \lim _{p \rightarrow \infty} \int_{\Omega}\left(\sum_{k=1}^{n_{p}} \xi\left(t_{k}^{p}\right) A\left(t_{k}^{p}\right)-\sum_{k=0}^{n_{p}-1} \xi\left(t_{k+1}^{p}\right) A\left(t_{k}^{p}\right)\right) d P \\
= & \lim _{p \rightarrow \infty} \sum_{k=1}^{n_{p}-1} \int_{\Omega}\left(\xi\left(t_{k}^{p}\right)-\xi\left(t_{k+1}^{p}\right)\right) A\left(t_{k}^{p}\right) d P+\int_{\Omega} \xi(t) A(t) d P . \tag{63.7.33}
\end{align*}
$$

Since $\xi$ is a martingale,

$$
\begin{aligned}
\int_{\Omega} \xi\left(t_{k+1}^{p}\right) A\left(t_{k}^{p}\right) d P & =\int_{\Omega} E\left(\xi\left(t_{k+1}^{p}\right) A\left(t_{k}^{p}\right) \mid \mathscr{F}_{t_{k}^{p}}\right) d P \\
& =\int_{\Omega} A\left(t_{k}^{p}\right) E\left(\xi\left(t_{k+1}^{p}\right) \mid \mathscr{F}_{t_{k}^{p}}\right) d P \\
& =\int_{\Omega} A\left(t_{k}^{p}\right) \xi\left(t_{k}^{p}\right) d P
\end{aligned}
$$

and so in 63.7.33 the term with the sum equals 0 and it reduces to

$$
E(\xi(t) A(t))
$$

This is sufficiently interesting to state as a lemma.

Lemma 63.7.7 Let A be an increasing adapted stochastic process which is right continuous. Also let $\xi(t)$ be a bounded right continuous martingale. Then

$$
E(\xi(t) A(t))=E\left(\int_{(0, t]} \xi(s) d A(s)\right)
$$

and $A$ is natural, if and only if for all such bounded right continuous martingales,

$$
E(\xi(t) A(t))=E\left(\int_{(0, t]} \xi(s) d A(s)\right)=E\left(\int_{(0, t]} \xi_{-}(s) d A(s)\right)
$$

Lemma 63.7.8 Let $(\Omega, \mathscr{F}, P)$ be a probability space and let $\mathscr{G}$ be a $\sigma$ algebra contained in $\mathscr{F}$. Suppose also that $\left\{f_{n}\right\}$ is a sequence in $L^{1}(\Omega)$ which converges weakly to $f$ in $L^{1}(\Omega)$. That is, for every $h \in L^{\infty}(\Omega)$,

$$
\int_{\Omega} f_{n} h d P \rightarrow \int_{\Omega} f h d P
$$

Then $E\left(f_{n} \mid \mathscr{G}\right)$ converges weakly in $L^{1}(\Omega)$ to $E(f \mid \mathscr{G})$.

Proof:First note that if $h \in L^{\infty}(\Omega, \mathscr{F})$, then $E(h \mid \mathscr{G}) \in L^{\infty}(\Omega, \mathscr{G})$ because if $A \in \mathscr{G}$,

$$
\int_{A}|E(h \mid \mathscr{G})| d P \leq \int_{A} E(|h| \mid \mathscr{G}) d P=\int_{A}|h| d P
$$

and so if $A=\left[|E(h \mid \mathscr{G})|>\|h\|_{\infty}\right]$, then if $P(A)>0$,

$$
\|h\|_{\infty} P(A)<\int_{A}|E(h \mid \mathscr{G})| d P \leq \int_{A}|h| d P \leq\|h\|_{\infty} P(A)
$$

a contradiction. Hence $P(A)=0$ and so $E(h \mid \mathscr{G}) \in L^{\infty}(\Omega, \mathscr{G})$ as claimed. Let $h \in L^{\infty}(\Omega, \mathscr{G})$.

$$
\begin{aligned}
\int_{\Omega} E\left(f_{n} \mid \mathscr{G}\right) h d P & =\int_{\Omega} E\left(E\left(f_{n} \mid \mathscr{G}\right) h \mid \mathscr{G}\right) d P \\
& =\int_{\Omega} E\left(f_{n} \mid \mathscr{G}\right) E(h \mid \mathscr{G}) d P \\
& =\int_{\Omega} E\left(f_{n} E(h \mid \mathscr{G}) \mid \mathscr{G}\right) d P \\
& =\int_{\Omega} f_{n} E(h \mid \mathscr{G}) d P
\end{aligned}
$$

and so

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \int_{\Omega} E\left(f_{n} \mid \mathscr{G}\right) h d P & =\lim _{n \rightarrow \infty} \int_{\Omega} f_{n} E(h \mid \mathscr{G}) d P \\
& =\int_{\Omega} f E(h \mid \mathscr{G}) d P \\
& =\int_{\Omega} E(f E(h \mid \mathscr{G}) \mid \mathscr{G}) d P \\
& =\int_{\Omega} E(h \mid \mathscr{G}) E(f \mid \mathscr{G}) d P \\
& =\int_{\Omega} E(E(f \mid \mathscr{G}) h \mid \mathscr{G}) d P \\
& =\int_{\Omega} E(f \mid \mathscr{G}) h d P
\end{aligned}
$$

and this proves the lemma.
Next suppose $\{X(t)\}$ is a real submartingale and suppose $X(t)=M(t)+A(t)$ where $A(t)$ is an increasing stochastic process adapted to $\mathscr{F}_{t}$ such that $A(0)=0$ and $\{M(t)\}$ is a martingale adapted to $\mathscr{F}_{t}$. Also let $T$ be a stopping time bounded above by $a$. Then by the optional sampling theorem, and the observation that $\{|M(t)|\}$ is a submartingale

$$
\begin{aligned}
& \int_{[|X(T)| \geq \lambda]}|X(T)| d P \\
\leq & \int_{[|X(T)| \geq \lambda]}|M(T)| d P+\int_{[|X(T)| \geq \lambda]} A(T) d P \\
\leq & \int_{[|X(T)| \geq \lambda]} E\left(|M(a)| \mid \mathscr{F}_{T}\right) d P+\int_{[|X(T)| \geq \lambda]} E\left(A(a) \mid \mathscr{F}_{T}\right) d P \\
\leq & \int_{[|X(T)| \geq \lambda]}|M(a)| d P+\int_{[|X(T)| \geq \lambda]} A(a) d P
\end{aligned}
$$

Now by Theorem 60.6.4,

$$
P\left(\left[\left|X_{T}\right| \geq \lambda\right]\right) \leq \frac{2}{\lambda} E(|X(0)|+|X(a)|)
$$

and so $P([|X(T)| \geq \lambda]) \rightarrow 0$ uniformly for $T$ a stopping time bounded by $a$ as $\lambda \rightarrow \infty$ and so this shows equi integrability of $\{X(T)\}$ because $A(t, \omega) \geq 0$.

This motivates the following definition.
Definition 63.7.9 A stochastic process, $\{X(t)\}$ is called DL if for all $a>0$, the set of random variables, $\{X(T)\}$ for $T$ a stopping time bounded by a is equi integrable.

Example 63.7.10 Let $\{M(t)\}$ be a continuous martingale. Then $\{M(t)\}$ is of class DL.
To show this, let $a>0$ be given and let $T$ be a stopping time bounded by $a$. Then by the optional sampling theorem, $M(0), M(T), M(a)$ is a martingale and so

$$
E\left(M(a) \mid \mathscr{F}_{T}\right)=M(T)
$$

and so by Jensen's inequality, $|M(T)| \leq E\left(|M(a)| \mid \mathscr{F}_{T}\right)$. Therefore,

$$
\begin{align*}
\int_{[|M(T)| \geq \lambda]}|M(T)| d P & \leq \int_{[|M(T)| \geq \lambda]} E\left(|M(a)| \mid \mathscr{F}_{T}\right) d P \\
& =\int_{[|M(T)| \geq \lambda]}|M(a)| d P \tag{63.7.34}
\end{align*}
$$

Now by Theorem 62.5.3,

$$
P([|M(T)| \geq \lambda]) \leq \frac{1}{\lambda} E(|M(a)|)
$$

and so since a given $L^{1}$ function is uniformly integrable, there exists $\delta$ such that if $P(A)<\delta$ then

$$
\int_{A}|M(a)| d P<\varepsilon
$$

Now choose $\lambda$ large enough that

$$
\frac{1}{\lambda} E(|M(a)|)<\delta
$$

Then for such $\lambda$, it follows from 63.7.34 that for any stopping time bounded by $a$,

$$
\int_{[|M(T)| \geq \lambda]}|M(T)| d P<\varepsilon
$$

This shows $M$ is $D L$.
Example 63.7.11 Let $\{X(t)\}$ be a nonnegative submartingale with $t \rightarrow E(X(t))$ right continuous so $\{X(t)\}$ can be considered right continuous. Then $\{X(t)\}$ is $D L$.

To show this, let $T$ be a stopping time bounded by $a>0$. Then by the optional sampling theorem,

$$
\int_{[X(T) \geq \lambda]} X(T) d P \leq \int_{[X(T) \geq \lambda]} X(a) d P
$$

and now by Theorem 60.6.4 on Page 1967

$$
P([X(T) \geq \lambda]) \leq \frac{1}{\lambda} E\left(X_{a}^{+}\right)
$$

Thus if $\varepsilon>0$ is given, there exists $\lambda$ large enough that for any stopping time, $T \leq a$,

$$
\int_{[X(T) \geq \lambda]} X(T) d P \leq \varepsilon
$$

Thus the submartingale is $D L$.
Now with this preparation, here is the Doob Meyer decomposition.

Theorem 63.7.12 Let $\{X(t)\}$ be a submartingale of class $D L$. Then there exists a martingale, $\{M(t)\}$ and an increasing submartingale, $\{A(t)\}$ such that for each $t$,

$$
X(t)=M(t)+A(t)
$$

If $\{A(t)\}$ is chosen to be natural and $A(0)=0$, then with this condition, $\{M(t)\}$ and $\{A(t)\}$ are unique.

Proof: First I will show uniqueness. Suppose then that

$$
X(t)=M(t)+A(t)=M^{\prime}(t)+A^{\prime}(t)
$$

where $M, M^{\prime}$ and $A, A^{\prime}$ satisfy the given conditions. Let $t>0$ and consider $s \in[0, t]$. Then

$$
A(s)-A^{\prime}(s)=M^{\prime}(s)-M(s)
$$

Since $A, A^{\prime}$ are natural, it follows that for $\xi(t)$ a right continuous bounded martingale,

$$
\begin{aligned}
& E\left(\xi(t)\left(A(t)-A^{\prime}(t)\right)\right)=E\left(\int_{(0, t]} \xi_{-}(s) d A(s)\right)-E\left(\int_{(0, t]} \xi_{-}(s) d A^{\prime}(s)\right) \\
& =E\left(\lim _{n \rightarrow \infty} \sum_{k=1}^{m_{n}} \xi\left(t_{k-1}^{n}\right)\left(A\left(t_{k}^{n}\right)-A\left(t_{k-1}^{n}\right)\right)-\sum_{k=1}^{m_{n}} \xi\left(t_{k-1}^{n}\right)\left(A^{\prime}\left(t_{k}^{n}\right)-A^{\prime}\left(t_{k-1}^{n}\right)\right)\right)
\end{aligned}
$$

where $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}$ is a sequence of partitions of $[0, t]$ such that these are equally spaced points, $\lim _{n \rightarrow \infty} t_{k+1}^{n}-t_{k}^{n}=0$, and $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}} \subseteq\left\{t_{k}^{n+1}\right\}_{k=0}^{m_{n+1}}$. Then since $A(t)$ and $A^{\prime}(t)$ are increasing, the absolute value of each sum is bounded above by an expression of the form

$$
C A(t) \text { or } C A^{\prime}(t)
$$

and so the dominated convergence theorem can be applied to get the above expression to equal

$$
\lim _{n \rightarrow \infty} E\left(\sum_{k=1}^{m_{n}} \xi\left(t_{k-1}^{n}\right)\left(A\left(t_{k}^{n}\right)-A\left(t_{k-1}^{n}\right)\right)-\sum_{k=1}^{m_{n}} \xi\left(t_{k-1}^{n}\right)\left(A^{\prime}\left(t_{k}^{n}\right)-A^{\prime}\left(t_{k-1}^{n}\right)\right)\right)
$$

Now using $X=A+M$ and $X=A^{\prime}+M^{\prime}$

$$
=\lim _{n \rightarrow \infty} E\left(\sum_{k=1}^{m_{n}} \xi\left(t_{k-1}^{n}\right)\left(M\left(t_{k}^{n}\right)-M\left(t_{k-1}^{n}\right)\right)-\sum_{k=1}^{m_{n}} \xi\left(t_{k-1}^{n}\right)\left(M^{\prime}\left(t_{k}^{n}\right)-M^{\prime}\left(t_{k-1}^{n}\right)\right)\right) .
$$

Both terms in the above equal 0 . Here is why.

$$
\begin{aligned}
E\left(\xi\left(t_{k-1}^{n}\right) M\left(t_{k}^{n}\right)\right) & =E\left(E\left(\xi\left(t_{k-1}^{n}\right) M\left(t_{k}^{n}\right) \mid \mathscr{F}_{t_{k-1}^{n}}^{n}\right)\right) \\
& =E\left(\xi\left(t_{k-1}^{n}\right) E\left(M\left(t_{k}^{n}\right) \mid \mathscr{F}_{t_{k-1}^{n}}^{n}\right)\right) \\
& =E\left(\xi\left(t_{k-1}^{n}\right) M\left(t_{k-1}^{n}\right)\right) .
\end{aligned}
$$

Thus the expected value of the first sum equals 0 . Similarly, the expected value of the second sum equals 0 . Hence this has shown that for any bounded right continuous martingale, $\{\xi(s)\}$ and $t>0$,

$$
E\left(\xi(t)\left(A(t)-A^{\prime}(t)\right)\right)=0 .
$$

Now let $\xi$ be a bounded random variable and let $\xi(t)$ be a right continuous version of the martingale $E\left(\xi \mid \mathscr{F}_{t}\right)$. Then

$$
\begin{aligned}
0 & =E\left(E\left(\xi \mid \mathscr{F}_{t}\right)\left(A(t)-A^{\prime}(t)\right)\right)=E\left(E\left(\xi\left(A(t)-A^{\prime}(t)\right) \mid \mathscr{F}_{t}\right)\right) \\
& =E\left(\xi\left(A(t)-A^{\prime}(t)\right)\right)
\end{aligned}
$$

and since $\xi$ is arbitrary, it follows that $A(t)=A^{\prime}(t)$ a.e. which proves uniqueness.
Because of the uniqueness assertion, it suffices to prove the theorem on an arbitrary interval, $[0, a]$.

Without loss of generality, it can be assumed $X(0)=0$ since otherwise, you could simply consider $X(t)-X(0)$ in its place and then at the end, add $X(0)$ to $M(t)$. Let $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}$ be a sequence of partitions of $[0, a]$ such that these are equally spaced points, $\lim _{n \rightarrow \infty} t_{k+1}^{n}-$ $t_{k}^{n}=0$, and $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}} \subseteq\left\{t_{k}^{n+1}\right\}_{k=0}^{m_{n+1}}$. Then consider the submartingale, $\left\{X\left(t_{k}^{n}\right)\right\}_{k=0}^{m_{n}}$. Theorem 63.7.1 implies there exists a unique martingale, and increasing submartingale,

$$
\left\{M\left(t_{k}^{n}\right)\right\}_{k=0}^{m_{n}} \text { and }\left\{A\left(t_{k}^{n}\right)\right\}_{k=0}^{m_{n}}
$$

respectively such that $M(0)=0=A(0)$,

$$
X\left(t_{k}^{n}\right)=M^{n}\left(t_{k}^{n}\right)+A^{n}\left(t_{k}^{n}\right)
$$

and $A^{n}\left(t_{k}^{n}\right)$ is $\mathscr{F}_{k-1}^{n}$ measurable. Recall how these were defined.

$$
\begin{gathered}
A^{n}\left(t_{k}^{n}\right)=\sum_{j=1}^{k} E\left(X\left(t_{j}^{n}\right)-X\left(t_{j-1}^{n}\right) \mid \mathscr{F}_{j-1}^{n}\right), A^{n}(0)=0 \\
M^{n}\left(t_{k}^{n}\right)=X\left(t_{k}^{n}\right)-A^{n}\left(t_{k}^{n}\right)
\end{gathered}
$$

I want to show that $\left\{A^{n}(a)\right\}$ is equi integrable. From this there will be a weakly convergent subsequence and nice things will happen. Define $T^{n}(\omega)$ to equal $t_{j-1}^{n}$ where $t_{j}^{n}$ is the first time where $A^{n}\left(t_{j}^{n}, \omega\right) \geq \lambda$ or $T^{n}(\omega)=a$ if this never happens. I want to say that $T^{n}$ is a stopping time and so I need to verify that $\left[T^{n} \leq t_{j}^{n}\right] \in \mathscr{F}_{t_{j}^{n}}$ for each $j$. If $\omega \in\left[T^{n} \leq t_{j}^{n}\right]$, then this means the first time, $t_{k}^{n}$, where $A^{n}\left(t_{k}^{n}, \omega\right) \geq \lambda$ is such that $t_{k}^{n} \leq t_{j+1}^{n}$. Since $A_{k}^{n}$ is increasing in $k$,

$$
\begin{aligned}
{\left[T^{n} \leq t_{j}^{n}\right] } & =\cup_{k=0}^{j+1}\left[A^{n}\left(t_{k}^{n}\right) \geq \lambda\right] \\
& =\left[A^{n}\left(t_{j+1}^{n}\right) \geq \lambda\right] \in \mathscr{F}_{t_{j}^{n}}
\end{aligned}
$$

Note $T^{n}$ only has the values $t_{k}^{n}$. Thus for $t \in\left[t_{j-1}^{n}, t_{j}^{n}\right)$,

$$
\left[T^{n} \leq t\right]=\left[T^{n} \leq t_{j-1}^{n}\right] \in \mathscr{F}_{t_{j-1}^{n}}^{n} \subseteq \mathscr{F}_{t}
$$

Thus $T^{n}$ is one of those stopping times bounded by $a$. Since $\{X(t)\}$ is $D L$, this shows $\left\{X\left(T^{n}\right)\right\}$ is equi integrable. Now from the definition of $T^{n}$, it follows

$$
A^{n}\left(T^{n}\right) \leq \lambda
$$

Recall $T^{n}(\omega)=t_{j-1}^{n}$ where $t_{j}^{n}$ is the first time where $A^{n}\left(t_{j}^{n}, \omega\right) \geq \lambda$ or $T^{n}(\omega)=a$ if this never happens. Thus $T^{n}$ is such that it is before $A^{n}$ gets larger than $\lambda$. Thus,

$$
\begin{gathered}
\int_{\left[A^{n}(a) \geq 2 \lambda\right]} \frac{1}{2} A^{n}(a) d P \leq \int_{\left[A^{n}(a) \geq 2 \lambda\right]}\left(A^{n}(a)-\lambda\right) d P \\
\leq \int_{\left[A^{n}(a) \geq 2 \lambda\right]}\left(A^{n}(a)-A^{n}\left(T^{n}\right)\right) d P \\
\leq \int_{\Omega}\left(A^{n}(a)-A^{n}\left(T^{n}\right)\right) d P \\
=\int_{\Omega}\left(X(a)-M^{n}(a)-\left(X\left(T^{n}\right)\right)-M^{n}\left(T^{n}\right)\right) d P \\
=\int_{\Omega}\left(X(a)-X\left(T^{n}\right)\right) d P
\end{gathered}
$$

Because by the discrete optional sampling theorem,

$$
\int_{\Omega}\left(M^{n}(a)-M^{n}\left(T^{n}\right)\right) d P=0
$$

Remember $\left\{M^{n}\left(t_{k}^{n}\right)\right\}_{k=0}^{m_{n}}$ was a martingale.

$$
\begin{aligned}
\int_{\Omega}\left(X(a)-X\left(T^{n}\right)\right) d P= & \int_{\left[A^{n}(a) \geq \lambda\right]}\left(X(a)-X\left(T^{n}\right)\right) d P \\
& +\int_{\left[A^{n}(a)<\lambda\right]}\left(X(a)-X\left(T^{n}\right)\right) d P .
\end{aligned}
$$

The second of the integrals on the right is such that for $\omega$ in this set, $T^{n}(\omega)=a$ and so the second integral equals 0 . Hence from the above,

$$
\int_{\left[A^{n}(a) \geq 2 \lambda\right]} \frac{1}{2} A^{n}(a) d P \leq \int_{\left[A^{n}(a) \geq \lambda\right]}\left(X(a)-X\left(T^{n}\right)\right) d P
$$

and since $\{X(t)\}$ is $D L$, this shows $\left\{A^{n}(a)\right\}_{n=1}^{\infty}$ is equi integrable.
By Corollary 20.9.6 on Page 640 there exists a subsequence $\left\{A^{n_{k}}(a)\right\}_{k=1}^{\infty}$ which converges weakly in $L^{1}(\Omega)$ to $A(a)$. By Lemma 63.7 .8 it also follows that $E\left(A^{n_{k}}(a) \mid \mathscr{F}_{t}\right)$ converges weakly to $E\left(A(a) \mid \mathscr{F}_{t}\right)$ in $L^{1}(\Omega)$. Now define

$$
M(t) \equiv E\left(X(a)-A(a) \mid \mathscr{F}_{t}\right)
$$

Thus it is obvious from properties of conditional expectation that $\{M(t)\}$ is a martingale adapted to $\mathscr{F}_{t}$ and without loss of generality, it is a right continuous version. Let

$$
A(t) \equiv X(t)-M(t)
$$

Then since $\{X(t)\}$ is a submartingale, it follows $\{A(t)\}$ is also a submartingale.
It remains to show several things. First, it is necessary to show $A(t)$ is increasing in $t$ and $A(0)=0$. To see this, let $s<t, s, t \in \cup_{n=1}^{\infty} \cup_{k=0}^{m_{n}} t_{k}^{n}$. Then letting $n$ large enough both $s, t$ are in $\cup_{k=0}^{m_{n}} t_{k}^{n}$. Only consider such $n$. Let $t=t_{k(t)}^{n}, s=t_{k(s)}^{n}$ and let $h \in L^{\infty}(\Omega), h \geq 0$. Then

$$
\begin{array}{r}
\int_{\Omega}(A(t)-A(s)) h d P=\int_{\Omega}(X(t)-M(t)-(X(s)-M(s))) h d P \\
\int_{\Omega}\left(X(t)-E\left(X(a)-A(a) \mid \mathscr{F}_{t}\right)-\left(X(s)-E\left(X(a)-A(a) \mid \mathscr{F}_{s}\right)\right)\right) h d P \tag{63.7.35}
\end{array}
$$

Now by Lemma 63.7.8, the following weak limit holds.

$$
\begin{aligned}
E\left(X(a)-A(a) \mid \mathscr{F}_{t}\right) & =\lim _{k \rightarrow \infty} E(\overbrace{X(a)-A^{n_{k}}(a)}^{M^{n_{k}}(a)} \mathscr{F}_{t}) \\
& =\lim _{k \rightarrow \infty} M^{n_{k}}(t)
\end{aligned}
$$

A similar formula holds for $s$ in place of $t$. Then the expression in 63.7.35 equals

$$
\begin{aligned}
& =\lim _{k \rightarrow \infty} \int_{\Omega}\left(X(t)-M^{n_{k}}(t)-\left(X(s)-M^{n_{k}}(s)\right)\right) h d P \\
& =\lim _{k \rightarrow \infty} \int_{\Omega}\left(A^{n_{k}}(t)-A^{n_{k}}(s)\right) h d P \geq 0
\end{aligned}
$$

Since $h \geq 0$ is arbitrary, this shows $A(t)-A(s) \geq 0$ a.e. Not requiring $h \geq 0$, the above argument also shows that for $s, t \in \cup_{n=1}^{\infty} \cup_{k=0}^{m_{n}} t_{k}^{n}$,

$$
\begin{equation*}
A(t)-A(s)=\text { weak } \lim _{p \rightarrow \infty} A^{n_{p}}(t)-A^{n_{p}}(s) \tag{63.7.36}
\end{equation*}
$$

Now consider the claim that $A(0)=0$. Recall

$$
A(0) \equiv X(0)-E\left(X(a)-A(a) \mid \mathscr{F}_{0}\right)=-E\left(X(a)-A(a) \mid \mathscr{F}_{0}\right)
$$

and so

$$
\begin{aligned}
A(0) & =\lim _{k \rightarrow \infty}-E\left(X(a)-A^{n_{k}}(a) \mid \mathscr{F}_{0}\right) \\
& =\lim _{k \rightarrow \infty}-E\left(M^{n_{k}}(a) \mid \mathscr{F}_{0}\right)=\lim _{k \rightarrow \infty}-M^{n_{k}}(0)=0 .
\end{aligned}
$$

This proves the theorem except for the claim that $A(t)$ is natural. Let $\xi(t)$ be a bounded right continuous martingale. I need to consider

$$
E\left(\int_{(0, t]} \xi_{-}(s) d A(s)\right)
$$

and show it equals $\xi(t) A(t)$. First consider the case $t=a$. By Lemma 63.7.5,

$$
\begin{equation*}
E\left(\int_{(0, a]} \xi_{-}(s) d A(s)\right) \equiv E\left(\lim _{k \rightarrow \infty} \sum_{j=1}^{m_{n_{k}}} \xi\left(t_{j-1}^{n_{k}}\right)\left(A\left(t_{j}^{n_{k}}\right)-A\left(t_{j-1}^{n_{k}}\right)\right)\right) \tag{63.7.37}
\end{equation*}
$$

Since $\xi$ is bounded, you can take the limit outside. This follows from the dominated convergence theorem and the fact, shown above that $A$ is increasing and nonnegative. Here is why.

$$
0 \leq\left|\xi\left(t_{j-1}^{n_{k}}\right)\right| A\left(t_{j}^{n_{k}}\right) \leq A(a) C
$$

where $C$ is a constant larger than the values of $\xi$. Thus the above equals

$$
\begin{gather*}
\lim _{k \rightarrow \infty} E\left(\sum_{j=1}^{m_{n_{k}}} \xi\left(t_{j-1}^{n_{k}}\right)\left(A\left(t_{j}^{n_{k}}\right)-A\left(t_{j-1}^{n_{k}}\right)\right)\right) \\
=\lim _{k \rightarrow \infty} E\left(\sum_{j=1}^{m_{n_{k}}} \xi\left(t_{j-1}^{n_{k}}\right)\left(X\left(t_{j}^{n_{k}}\right)-M\left(t_{j}^{n_{k}}\right)-\left(X\left(t_{j-1}^{n_{k}}\right)-M\left(t_{j-1}^{n_{k}}\right)\right)\right)\right) \\
=\lim _{k \rightarrow \infty} E\left(\sum_{j=1}^{m_{n_{k}}} \xi\left(t_{j-1}^{n_{k}}\right)\left(X\left(t_{j}^{n_{k}}\right)-X\left(t_{j-1}^{n_{k}}\right)\right)\right) \tag{63.7.38}
\end{gather*}
$$

because

$$
\begin{aligned}
E\left(\xi\left(t_{j-1}^{n_{k}}\right) M\left(t_{j}^{n_{k}}\right)\right) & =E\left(E\left(\xi\left(t_{j-1}^{n_{k}}\right) M\left(t_{j}^{n_{k}}\right) \mid \mathscr{F}_{t_{j-1}^{n_{k}}}\right)\right) \\
& =E\left(\xi\left(t_{j-1}^{n_{k}}\right) E\left(M\left(t_{j}^{n_{k}}\right) \mid \mathscr{F}_{t_{j-1}^{n_{k}}}\right)\right) \\
& =E\left(\xi\left(t_{j-1}^{n_{k}}\right) M\left(t_{j-1}^{n_{k}}\right)\right)
\end{aligned}
$$

since $M$ is a martingale. Now by a similar trick, this time using that $\left\{M^{n_{k}}\left(t_{j}^{n_{k}}\right)\right\}_{j=0}^{m_{n_{k}}}$ is a martingale, 63.7.38 equals

$$
\begin{equation*}
\lim _{k \rightarrow \infty} E\left(\sum_{j=1}^{m_{n_{k}}} \xi\left(t_{j-1}^{n_{k}}\right)\left(A^{n_{k}}\left(t_{j}^{n_{k}}\right)-A^{n_{k}}\left(t_{j-1}^{n_{k}}\right)\right)\right) \tag{63.7.39}
\end{equation*}
$$

and now recall that $A^{n_{k}}\left(t_{j}^{n_{k}}\right)$ is $\mathscr{F}_{t_{j-1}}^{n_{k}}$ measurable. This will now be used to change the subscript of $t_{j-1}^{n_{k}}$ in $\xi\left(t_{j-1}^{n_{k}}\right)$ to a $j$. 63.7.39 equals

$$
\begin{aligned}
& =\lim _{k \rightarrow \infty} \sum_{j=1}^{m_{n_{k}}} E\left(E\left(\xi\left(t_{j}^{n_{k}}\right) \mid \mathscr{F}_{t_{j-1}^{n_{k}}}\right)\left(A^{n_{k}}\left(t_{j}^{n_{k}}\right)-A^{n_{k}}\left(t_{j-1}^{n_{k}}\right)\right)\right) \\
& =\lim _{k \rightarrow \infty} \sum_{j=1}^{m_{n_{k}}} E\left(E\left(\xi\left(t_{j}^{n_{k}}\right)\left(A^{n_{k}}\left(t_{j}^{n_{k}}\right)-A^{n_{k}}\left(t_{j-1}^{n_{k}}\right)\right) \mid \mathscr{F}_{t_{j-1}^{n_{k}}}\right)\right) \\
& =\lim _{k \rightarrow \infty} \sum_{j=1}^{m_{n_{k}}} E\left(\xi\left(t_{j}^{n_{k}}\right)\left(A^{n_{k}}\left(t_{j}^{n_{k}}\right)-A^{n_{k}}\left(t_{j-1}^{n_{k}}\right)\right)\right) \\
& =\lim _{k \rightarrow \infty} E\left(\sum_{j=1}^{m_{n_{k}}} \xi\left(t_{j}^{n_{k}}\right)\left(A^{n_{k}}\left(t_{j}^{n_{k}}\right)-A^{n_{k}}\left(t_{j-1}^{n_{k}}\right)\right)\right)
\end{aligned}
$$

From this all that remains is to write the above as

$$
\begin{aligned}
& \lim _{k \rightarrow \infty} E\left(\sum_{j=1}^{m_{n_{k}}} \xi\left(t_{j}^{n_{k}}\right) A^{n_{k}}\left(t_{j}^{n_{k}}\right)-\sum_{j=0}^{m_{n_{k}}-1} \xi\left(t_{j+1}^{n_{k}}\right) A^{n_{k}}\left(t_{j}^{n_{k}}\right)\right) \\
= & \lim _{k \rightarrow \infty}\left(E\left(\xi(a) A^{n_{k}}(a)\right)+E\left(\sum_{j=1}^{m_{n_{k}-1}}\left(\xi\left(t_{j}^{n_{k}}\right)-\xi\left(t_{j+1}^{n_{k}}\right)\right) A^{n_{k}}\left(t_{j}^{n_{k}}\right)\right)\right)
\end{aligned}
$$

Now using the fact $\xi$ is a martingale, this last term equals 0 . Here is why.

$$
\begin{aligned}
E\left(\xi\left(t_{j+1}^{n_{k}}\right) A^{n_{k}}\left(t_{j}^{n_{k}}\right)\right) & =E\left(E\left(\xi\left(t_{j+1}^{n_{k}}\right) A^{n_{k}}\left(t_{j}^{n_{k}}\right) \mid \mathscr{F}_{t_{j}^{n_{k}}}\right)\right) \\
& =E\left(A^{n_{k}}\left(t_{j}^{n_{k}}\right) E\left(\xi\left(t_{j+1}^{n_{k}}\right) \mid \mathscr{F}_{t_{j}^{n_{k}}}\right) \mid \mathscr{F}_{t_{j}^{n_{k}}}\right) \\
& =E\left(A^{n_{k}}\left(t_{j}^{n_{k}}\right) \xi\left(t_{j}^{n_{k}}\right) \mid \mathscr{F}_{t_{j}^{n_{k}}}\right)
\end{aligned}
$$

The first term converges to $E(\xi(a) A(a))$ because this was how $A(a)$ was obtained, as a weak limit in $L^{1}(\Omega)$ of $A^{n_{k}}(a)$. Also by Lemma 63.7.7,

$$
E(\xi(a) A(a))=E\left(\int_{(0, a]} \xi(s) d A(s)\right)
$$

From 63.7.37 this has now shown that

$$
E(\xi(a) A(a))=E\left(\int_{(0, a]} \xi_{-}(s) d A(s)\right)
$$

To get the desired result on $(0, t]$, apply what was just shown to a "stopped martingale",

$$
\begin{gathered}
\xi^{t}(s) \equiv \begin{cases}\xi(s) \text { if } s \leq t \\
\xi(t) \text { if } s>t\end{cases} \\
E\left(\int_{(0, t]} \xi(s) d A(s)\right)+(A(a)-A(t)) E(\xi(t)) \\
=E\left(\int_{(0, a]} \xi^{t}(s) d A(s)\right)
\end{gathered}
$$

From what was shown above,

$$
\begin{aligned}
& =E\left(\int_{(0, a]} \xi_{-}^{t}(s) d A(s)\right) \\
& =E\left(\int_{(0, t]} \xi_{-}(s) d A(s)+\int_{(t, a]} \xi(t) s A(s)\right) \\
& =E\left(\int_{(0, t]} \xi_{-}(s) d A(s)\right)+(A(a)-A(t)) E(\xi(t))
\end{aligned}
$$

and so

$$
E\left(\int_{(0, t]} \xi(s) d A(s)\right)=E\left(\int_{(0, t]} \xi_{-}(s) d A(s)\right)
$$

which shows $A$ is natural by Lemma 63.7.7. This proves the theorem.
There is another interesting variation of the above theorem. It involves the following definition.

Definition 63.7.13 A submartingale, $\{X(t)\}$ is said to be $D$ if

$$
\left\{X_{T}: T<\infty \text { is a stopping time }\right\}
$$

is equi integrable.
In this case, you can consider partitions of the entire positive real line and the martingales, $\left\{M\left(t_{k}^{n}\right)\right\}_{k=0}^{\infty}$ and $\left\{A\left(t_{k}^{n}\right)\right\}_{k=0}^{\infty}$ as before. This time you don't stop at $m_{n}$. By the submartingale convergence theorem, you can argue there exists $A_{\infty}^{n}=\lim _{k \rightarrow \infty} A\left(t_{k}^{n}\right)$. Then repeat the above argument using $A_{\infty}^{n}$ in place of $A^{n}(a)$. This time you get $\{A(t)\}$ equi integrable. Thus the following corollary is obtained.

Corollary 63.7.14 Let $\{X(t)\}$ be a right continuous submartingale of class $D$. Then there exists a right continuous martingale, $\{M(t)\}$ and a right continuous increasing submartingale, $\{A(t)\}$ such that for each $t$,

$$
X(t)=M(t)+A(t)
$$

If $\{A(t)\}$ is chosen to be natural and $A(0)=0$, then with this condition, $\{M(t)\}$ and $\{A(t)\}$ are unique. Furthermore $\{M(t)\}$ and $\{A(t)\}$ are equi integrable on $[0, \infty)$.

In the above theorem, $\{X(t)\}$ was a submartingale and so it has a right continuous version. What if $\{X(t)\}$ is actually continuous? Can one conclude that $A(t)$ and $M(t)$ are also continuous? The answer is yes.

Theorem 63.7.15 Let $\{X(t)\}$ be a right continuous submartingale of class DL. Then there exists a right continuous martingale, $\{M(t)\}$ and a right continuous increasing submartingale, $\{A(t)\}$ such that for each $t$,

$$
X(t)=M(t)+A(t) .
$$

If $\{A(t)\}$ is chosen to be natural and $A(0)=0$, then with this condition, $\{M(t)\}$ and $\{A(t)\}$ are unique. Also, if $\{X(t)\}$ is continuous, $(t \rightarrow X(t, \omega)$ is continuous for a.e. $\omega)$ then the same is true of $\{A(t)\}$ and $\{M(t)\}$.

Proof: The first part is done above. Let $\{X(t)\}$ be continuous. As before, let $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}$ be a sequence of partitions of $[0, a]$ such that these are equally spaced points, $\lim _{n \rightarrow \infty} t_{k+1}^{n}-$ $t_{k}^{n}=0$, and $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}} \subseteq\left\{t_{k}^{n+1}\right\}_{k=0}^{m_{n+1}}$ where here $a>0$ is an arbitrary positive number and let $\lambda>0$ be an arbitrary positive number. Define

$$
\xi^{n}(t) \equiv E\left(\min \left(\lambda, A\left(t_{j}^{n}\right)\right) \mid \mathscr{F}_{t}\right) \text { for } t_{j-1}^{n}<t \leq t_{j}^{n}
$$

Thus on $\left(t_{j-1}^{n}, t_{j}^{n}\right] \xi^{n}(t)$ is a bounded martingale. Assuming we are dealing with a right continuous version of this martingale so there are no measurability questions, it follows since $A$ is natural,

$$
E\left(\int_{\left(t_{j-1}^{n}, t_{j}^{n}\right]} \xi^{n}(s) d A(s)\right)=E\left(\int_{\left(t_{j-1}^{n}, t_{j}^{n}\right]} \xi_{-}^{n}(s) d A(s)\right)
$$

where here

$$
\xi_{-}^{n}(s, \omega) \equiv \lim _{r \rightarrow s-, r \in D} \xi^{n}(s, \omega) \text { a.e. }
$$

for $D \equiv \cup_{n=1}^{\infty} \cup_{k=1}^{m_{n}}\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}$. Thus, adding these up for all the intervals, $\left(t_{j-1}^{n}, t_{j}^{n}\right]$ yields

$$
E\left(\int_{(0, a]} \xi^{n}(s) d A(s)\right)=E\left(\int_{(0, a]} \xi_{-}^{n}(s) d A(s)\right)
$$

I want to show that for a.e. $\omega, \xi^{n_{k}}(t, \omega)$ converges uniformly to

$$
\min (\lambda, A(t, \omega)) \equiv \lambda \wedge A(t, \omega)
$$

on $(0, a]$. From this it will follow

$$
E\left(\int_{(0, a]} \lambda \wedge A(s, \omega) d A(s)\right)=E\left(\int_{(0, a]} \lambda \wedge A_{-}(s, \omega) d A(s)\right)
$$

Now since $s \rightarrow A(s, \omega)$ is increasing, there is no problem in writing $A_{-}(s, \omega)$ and the above equation will suffice to show with simple considerations that for a.e. $\omega, s \rightarrow A(s, \omega)$ is left continuous. Since $\{A(s)\}$ is a submartingale already, it has a right continuous version which we are using in the above. Thus for a.e. $\omega$ it must be the case that $s \rightarrow A(s, \omega)$ is continuous. Let $t \in\left(t_{j-1}^{n}, t_{j}^{n}\right.$ ]. Then since $\lambda \wedge A(t)$ is $\mathscr{F}_{t}$ measurable,

$$
\xi^{n}(t)-\lambda \wedge A(t) \equiv E\left(\lambda \wedge A\left(t_{j}^{n}\right)-\lambda \wedge A(t) \mid \mathscr{F}_{t}\right) \geq 0
$$

because $A(t)$ is increasing.
Now define a stopping time, $T^{n}(\varepsilon)$ for $\varepsilon>0$ by letting $T^{n}(\varepsilon)$ be the infimum of all $t \in[0, a]$ with the property that

$$
\xi^{n}(t)-\lambda \wedge A(t)>\varepsilon
$$

or if this does not happen, then $T^{n}(\varepsilon)=a$. Thus

$$
T^{n}(\varepsilon)(\omega)=a \wedge \inf \left\{t \in[0, a]: \xi^{n}(t, \omega)-\lambda \wedge A(t, \omega)>\varepsilon\right\}
$$

I need to verify $T^{n}(\varepsilon)$ really is a stopping time. Letting $s<a$, it follows that if $\omega \in$ $\left[T^{n}(\varepsilon) \leq s\right]$, then for each $N$, there exists $t \in\left[s, s+\frac{1}{N}\right)$ such that $\xi^{n}(t, \omega)-\lambda \wedge A(t, \omega)>\varepsilon$. Then by right continuity it follows there exists $r \in D \cap\left[s, s+\frac{1}{N}\right)$ such that

$$
\xi^{n}(r, \omega)-\lambda \wedge A(r, \omega)>\varepsilon
$$

Thus

$$
\left[T^{n}(\varepsilon) \leq s\right]=\cap_{N=1}^{\infty} \cup_{r \in D \cap\left[s, s+\frac{1}{N}\right)}\left[\xi^{n}(r, \omega)-\lambda \wedge A(r, \omega)>\varepsilon\right]
$$

and each $\cup_{r \in D \cap\left[s, s+\frac{1}{N}\right)}\left[\xi^{n}(r, \omega)-\lambda \wedge A(r, \omega)>\varepsilon\right] \in \mathscr{F}_{s+1 / N}$ and so

$$
\left[T^{n}(\varepsilon) \leq s\right] \in \cap_{r \in D, r \geq s} \mathscr{F}_{r}=\mathscr{F}_{s+}=\mathscr{F}_{s}
$$

due to the assumption that the filtration is normal. What if $s \geq a$ ? Then from the definition, $\left[T^{n}(\varepsilon) \leq a\right]=\Omega \in \mathscr{F}_{a}$. Thus this really is a stopping time.

Now let $B_{j} \equiv\left[t_{j-1}^{n}<T^{n}(\varepsilon) \leq t_{j}^{n}\right]$. Note that $T^{n}(\varepsilon) \wedge t_{j}^{n}$ is also a stopping time.

$$
\begin{gathered}
\int_{\Omega} \xi_{T^{n}(\varepsilon)}^{n} d P=\sum_{j=1}^{m_{n}} \int_{B_{j}} \xi_{T^{n}(\varepsilon)}^{n} d P=\sum_{j=1}^{m_{n}} \int_{B_{j}} \xi_{T^{n}(\varepsilon) \wedge t_{j}^{n}}^{n} d P \\
=\sum_{j=1}^{m_{n}} \int_{B_{j}} E\left(\xi_{T^{n}(\varepsilon) \wedge t_{j}^{n}}^{n} \mid \mathscr{F}_{T^{n}(\varepsilon) \wedge t_{j}^{n}}\right) d P
\end{gathered}
$$

This is because $B_{j} \in \mathscr{F}_{T^{n}(\varepsilon) \wedge t_{j}^{n}}$. Thus from the definition, the above equals

$$
\begin{align*}
& =\sum_{j=1}^{m_{n}} \int_{B_{j}} E\left(E\left(\lambda \wedge A\left(t_{j}^{n}\right) \mid \mathscr{F}_{T^{n}(\varepsilon) \wedge t_{j}^{n}}\right) \mid \mathscr{F}_{T^{n}(\varepsilon) \wedge t_{j}^{n}}\right) d P \\
& =\sum_{j=1}^{m_{n}} \int_{B_{j}} E\left(\lambda \wedge A\left(t_{j}^{n}\right) \mid \mathscr{F}_{T^{n}(\varepsilon) \wedge t_{j}^{n}}\right) d P \\
& =\sum_{j=1}^{m_{n}} \int_{B_{j}} \lambda \wedge A\left(t_{j}^{n}\right) d P=\int_{\Omega} \lambda \wedge A\left(\left\lceil T^{n}(\varepsilon)\right\rceil\right) d P \tag{63.7.40}
\end{align*}
$$

where on $\left(t_{j-1}^{n}, t_{j}^{n}\right],\left\lceil T^{n}(\varepsilon)\right\rceil \equiv t_{j}^{n}$. Now $\left\lceil T^{n}(\varepsilon)\right\rceil$ is also a bounded stopping time. Here is why. Suppose $s \in\left(t_{j-1}^{n}, t_{j}^{n}\right]$. Then

$$
\left[\left\lceil T^{n}(\varepsilon)\right] \leq s\right]=\left[T^{n}(\varepsilon) \leq t_{j-1}^{n}\right] \in \mathscr{F}_{t_{j-1}^{n}} \subseteq \mathscr{F}_{s}
$$

Now let

$$
Q_{n} \equiv \sup _{t \in[0, a]}\left|\xi^{n}(t)-\lambda \wedge A(t)\right|
$$

Then first note that

$$
\left[Q_{n}>\varepsilon\right]=\left[\sup _{t \in[0, a)}\left|\xi^{n}(t)-\lambda \wedge A(t)\right|>\varepsilon\right]
$$

because $Q_{n}(a)=0$ follows from the definition of $\xi^{n}(t)$ as

$$
E\left(\lambda \wedge A\left(t_{j}^{n}\right) \mid \mathscr{F}_{t}\right) \text { for } t_{j-1}^{n}<t \leq t_{j}^{n}
$$

and so

$$
\xi^{n}(a)=E\left(\lambda \wedge A(a) \mid \mathscr{F}_{a}\right)=\lambda \wedge A(a) .
$$

Thus it suffices to take the supremum over the half open interval, $[0, a)$. It follows

$$
\left[Q_{n}>\varepsilon\right]=\left[T^{n}(\varepsilon)<a\right]
$$

By right continuity,

$$
\xi^{n}\left(T^{n}(\varepsilon)\right)-\lambda \wedge A\left(T^{n}(\varepsilon)\right) \geq \varepsilon
$$

on $\left[Q_{n}>\varepsilon\right]$.

$$
\begin{aligned}
\varepsilon P\left(\left[Q_{n}>\varepsilon\right]\right) & =\varepsilon P\left(\left[T^{n}(\varepsilon)<a\right]\right) \\
& \leq \int_{\left[Q_{n}>\varepsilon\right]}\left(\xi^{n}\left(T^{n}(\varepsilon)\right)-\lambda \wedge A\left(T^{n}(\varepsilon)\right)\right) d P \\
& \leq \int_{\Omega}\left(\xi^{n}\left(T^{n}(\varepsilon)\right)-\lambda \wedge A\left(T^{n}(\varepsilon)\right)\right) d P
\end{aligned}
$$

Therefore, from 63.7.40,

$$
\begin{align*}
P\left(\left[Q_{n}>\varepsilon\right]\right) & \leq \frac{1}{\varepsilon} \int_{\Omega}\left(\lambda \wedge A\left(\left\lceil T^{n}(\varepsilon)\right\rceil\right)-\lambda \wedge A\left(T^{n}(\varepsilon)\right)\right) d P \\
& \leq \frac{1}{\varepsilon} \int_{\Omega}\left(A\left(\left\lceil T^{n}(\varepsilon)\right\rceil\right)-A\left(T^{n}(\varepsilon)\right)\right) d P \tag{63.7.41}
\end{align*}
$$

By optional sampling theorem,

$$
E\left(M\left(T^{n}(\varepsilon)\right)\right)=E(M(0))=0
$$

and also

$$
E\left(M\left(\left\lceil T^{n}(\varepsilon)\right\rceil\right)\right)=E(M(0))=0 .
$$

Therefore, 63.7.41 reduces to

$$
P\left(\left[Q_{n}>\varepsilon\right]\right) \leq \frac{1}{\varepsilon} \int_{\Omega}\left(X\left(\left\lceil T^{n}(\varepsilon)\right\rceil\right)-X\left(T^{n}(\varepsilon)\right)\right) d P
$$

By the assumption that $\{X(t)\}$ is $D L$, it follows the functions in the above integrand are equi integrable and so since $\lim _{n \rightarrow \infty} X\left(\left\lceil T^{n}(\varepsilon)\right\rceil\right)-X\left(T^{n}(\varepsilon)\right)=0$, the above integral converges to 0 as $n \rightarrow \infty$ by Vitali's convergence theorem, Theorem 11.5.3 on Page 257. It follows that there is a subsequence, $n_{k}$ such that

$$
P\left(\left[Q_{n_{k}}>2^{-k}\right]\right) \leq 2^{-k}
$$

and so from the definition of $Q_{n}$,

$$
\lim _{k \rightarrow \infty} \sup _{t \in[0, a]}\left|\xi^{n_{k}}(t)-\lambda \wedge A(t)\right|
$$

giving uniform convergence. Now recall that

$$
E\left(\int_{(0, a]} \xi^{n_{k}}(s) d A(s)\right)=E\left(\int_{(0, a]} \xi_{-}^{n_{k}}(s) d A(s)\right)
$$

and so passing to the limit as $k \rightarrow \infty$ with the uniform convergence yields

$$
E\left(\int_{(0, a]} \lambda \wedge A(s) d A(s)\right)=E\left(\int_{(0, a]} \lambda \wedge A_{-}(s) d A(s)\right)
$$

Now let $\lambda \rightarrow \infty$. Then from the monotone convergence theorem,

$$
E\left(\int_{(0, a]} A(s) d A(s)\right)=E\left(\int_{(0, a]} A_{-}(s) d A(s)\right)
$$

and so for a.e. $\omega$,

$$
\int_{(0, a]}\left(A(s)-A_{-}(s)\right) d A(s)=0
$$

Thus letting the measure associated with this Lebesgue integral be denoted by $\mu$,

$$
A(s)-A_{-}(s)=0 \mu \text { a.e. }
$$

Suppose then that $A(s)-A_{-}(s)>0$. Then $\mu(\{s\})=0=A(s)-A(s-)$, a contradiction. Hence $A(s)-A_{-}(s)=0$ for all $s$. It is already the case that $s \rightarrow A(s)$ is right continuous. Therefore, this proves the theorem.

Example 63.7.16 Suppose $\{M(t)\}$ is a continuous martingale. Assume

$$
\sup _{t \in[0, a]}\|M(t)\|_{L^{2}(\Omega)}<\infty
$$

Then $\{\|M(t)\|\}$ is a submartingale and so is $\left\{\|M(t)\|^{2}\right\}$. By Example 63.7.11, this is DL. Then there exists a unique Doob Meyer decomposition,

$$
\|M(t)\|^{2}=Y(t)+\langle\|M(t)\|\rangle
$$

where $Y(t)$ is a martingale and $\{\langle\|M(t)\|\rangle\}$ is a submartingale which is continuous, natural, increasing and equal to 0 when $t=0$. This submartingale is called the quadratic variation.

### 63.8 Levy's Theorem

This remarkable theorem has to do with when a martingale is a Wiener process. The proof I am giving here follows [44].

Definition 63.8.1 Let $W(t)$ be a stochastic process which has the properties that whenever $t_{1}<t_{2}<\cdots<t_{m}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent and whenever $s<t$, it follows $W(t)-W(s)$ is normally distributed with variance $t-s$ and mean 0 . Also $t \rightarrow W(t)$ is Holder continuous with every exponent $\gamma<1 / 2$ and $W(0)=0$. This is called a Wiener process.

First here is a lemma.

Lemma 63.8.2 Let $\{X(t)\}$ be a real martingale adapted to the filtration $\mathscr{F}_{t}$ for $t \in[a, b]$ some interval such that for all $t \in[a, b], E\left(X(t)^{2}\right)<\infty$. Then $\left\{X(t)^{2}-t\right\}$ is also a martingale if and only if whenever $s<t$,

$$
E\left((X(t)-X(s))^{2} \mid \mathscr{F}_{s}\right)=t-s
$$

Proof: Suppose first $\left\{X(t)^{2}-t\right\}$ is a real martingale. Then since $\{X(t)\}$ is a martingale,

$$
\begin{aligned}
E((X(t) & \left.-X(s))^{2} \mid \mathscr{F}_{s}\right)=E\left(X(t)^{2}-2 X(t) X(s)+X(s)^{2} \mid \mathscr{F}_{s}\right) \\
& =E\left(X(t)^{2} \mid \mathscr{F}_{s}\right)-2 E\left(X(t) X(s) \mid \mathscr{F}_{s}\right)+X(s)^{2} \\
& =E\left(X(t)^{2} \mid \mathscr{F}_{s}\right)-2 X(s) E\left(X(t) \mid \mathscr{F}_{s}\right)+X(s)^{2} \\
& =E\left(X(t)^{2} \mid \mathscr{F}_{s}\right)-2 X(s)^{2}+X(s)^{2} \\
& =E\left(X(t)^{2}-t \mid \mathscr{F}_{s}\right)+t-X(s)^{2} \\
& =X(s)^{2}-s+t-X(s)^{2}=t-s
\end{aligned}
$$

Next suppose $E\left((X(t)-X(s))^{2} \mid \mathscr{F}_{s}\right)=t-s$. Then since $\{X(t)\}$ is a martingale,

$$
\begin{aligned}
t-s & =E\left(X(t)^{2}-X(s)^{2} \mid \mathscr{F}_{s}\right) \\
& =E\left(X(t)^{2}-t \mid \mathscr{F}_{s}\right)+t-X(s)^{2}
\end{aligned}
$$

and so

$$
0=E\left(X(t)^{2}-t \mid \mathscr{F}_{s}\right)-\left(X(s)^{2}-s\right)
$$

which proves the converse.
Theorem 63.8.3 Suppose $\{X(t)\}$ is a real stochastic process which satisfies all the conditions of a real Wiener process except the requirement that it be continuous. Then both $\{X(t)\}$ and $\left\{X(t)^{2}-t\right\}$ are martingales.

Proof: First define the filtration to be

$$
\mathscr{F}_{t} \equiv \sigma(X(s)-X(r): r \leq s \leq t) .
$$

Claim: If $A \in \mathscr{F}_{s}$, then

$$
\int_{\Omega} \mathscr{X}_{A}(X(t)-X(s)) d P=P(A) \int_{\Omega}(X(t)-X(s)) d P
$$

Proof of claim: Let $\mathscr{G}$ denote those sets of $\mathscr{F}_{s}$ for which the above formula holds. Then it is clear that $\mathscr{G}$ is closed with respect to countable unions of disjoint sets and
complements. Let $\mathscr{K}$ denote those sets which are finite intersections of sets of the form $(X(u)-X(r))^{-1}(B)$ where $B$ is a Borel set and $r \leq u \leq s$. Say a set, $A$ of $\mathscr{K}$ is of the form

$$
\cap_{i=1}^{m}\left(X\left(u_{i}\right)-X\left(r_{i}\right)\right)^{-1}\left(B_{i}\right)
$$

Then since disjoint increments are independent, linear combinations of the random variables, $X\left(u_{i}\right)-X\left(r_{i}\right)$ are normally distributed. Consequently,

$$
\left(X\left(u_{1}\right)-X\left(r_{1}\right), \cdots, X\left(u_{m}\right)-X\left(r_{m}\right), X(t)-X(s)\right)
$$

is multivariate normal. The covariance matrix is of the form

$$
\left(\begin{array}{cc}
A & 0 \\
0 & t-s
\end{array}\right)
$$

and so the random vector, $\left(X\left(u_{1}\right)-X\left(r_{1}\right), \cdots, X\left(u_{m}\right)-X\left(r_{m}\right)\right)$ and the random variable $X(t)-X(s)$ are independent. Consequently, $\mathscr{X}_{A}$ is independent of $X(t)-X(s)$ for any $A \in \mathscr{K}$. Then by the lemma on $\pi$ systems, Lemma 12.12.3 on Page $329, \mathscr{F} s \supseteq \mathscr{G} \supseteq$ $\sigma(\mathscr{K})=\mathscr{F}_{s}$. This proves the claim.

Thus

$$
\begin{aligned}
\int_{A}(X(t)-X(s)) d P & =\int_{\Omega}(X(t)-X(s)) \mathscr{X}_{A} d P \\
& =P(A) \int_{\Omega}(X(t)-X(s)) d P=0
\end{aligned}
$$

which shows that since $A \in \mathscr{F}_{s}$ was arbitrary,

$$
E\left(X(t) \mid \mathscr{F}_{s}\right)=X(s)
$$

and $\{X(t)\}$ is a martingale.
Now consider whether $\left\{X(t)^{2}-t\right\}$ is a martingale. By assumption,

$$
\mathscr{L}(X(t)-X(s))=\mathscr{L}(X(t-s))=N(0, t-s)
$$

Then for $A \in \mathscr{F}_{s}$, the independence of $\mathscr{X}_{A}$ and $X(t)-X(s)$ shows

$$
\begin{aligned}
\int_{A} E\left((X(t)-X(s))^{2} \mid \mathscr{F}_{s}\right) d P & =\int_{A}(X(t)-X(s))^{2} d P \\
& =P(A)(t-s)=\int_{A}(t-s) d P
\end{aligned}
$$

and since $A \in \mathscr{F}_{s}$ is arbitrary,

$$
E\left((X(t)-X(s))^{2} \mid \mathscr{F}_{s}\right)=t-s
$$

and so the result follows from Lemma 63.8.2. This proves the theorem.
The next lemma is the main result from which Levy's theorem will be established.

Lemma 63.8.4 Let $\{X(t)\}$ be a real continuous martingale adapted to the filtration $\mathscr{F}_{t}$ for $t \in[a, b]$ some interval such that for all $t \in[a, b], E\left(X(t)^{2}\right)<\infty$. Suppose also that $\left\{X(t)^{2}-t\right\}$ is a martingale. Then for $\lambda$ real,

$$
E\left(e^{i \lambda X(b)}\right)=E\left(e^{i \lambda X(a)}\right) e^{-(b-a) \frac{\lambda^{2}}{2}}
$$

Proof: Let $\lambda \in[-p, p]$ where for most of the proof, $p$ is fixed but arbitrary. Let $\left\{t_{k}^{n}\right\}_{k=0}^{2^{n}}$ be uniform partitions such that $t_{k}^{n}-t_{k-1}^{n}=\delta_{n} \equiv(b-a) / 2^{n}$. Now for $\varepsilon>0$ define a stopping time $\tau_{\varepsilon, n}$ to be the first time, $t$ such that there exist $s_{1}, s_{2} \in[a, t]$ with $\left|s_{1}-s_{2}\right|<\boldsymbol{\delta}_{n}$ but

$$
\left|X\left(s_{1}\right)-X\left(s_{2}\right)\right|=\varepsilon
$$

If no such time exists, then $\tau_{\varepsilon, n} \equiv b$.
Then $\tau_{\varepsilon, n}$ really is a stopping time because from continuity of $X(t)$ and denoting by $r, r_{1}$ elements of $\mathbb{Q}$, then

$$
\left[\tau_{\varepsilon, n}>t\right]=\bigcup_{m=1}^{\infty} \bigcap_{0 \leq r_{1}, r_{2} \leq t,\left|r_{1}-r_{2}\right| \leq \delta_{n}}\left[\left|X\left(r_{1}\right)-X\left(r_{2}\right)\right| \leq \varepsilon-\frac{1}{m}\right] \in \mathscr{F}_{t}
$$

because to be in $\left[\tau_{\varepsilon, n}>t\right]$ it means that by $t$ the absolute value of the differences must always be less than $\varepsilon$. Hence $\left[\tau_{\varepsilon, n} \leq t\right]=\Omega \backslash\left[\tau_{\varepsilon, n}>t\right] \in \mathscr{F}_{t}$.

Now consider $\left[\tau_{\varepsilon, n}=b\right]$ for various $n$. By continuity, it follows that for each $\omega \in \Omega$,

$$
\tau_{\varepsilon, n}(\omega)=b
$$

for all $n$ large enough. Thus

$$
\emptyset=\cap_{n=1}^{\infty}\left[\tau_{\varepsilon, n}<b\right]
$$

the sets in the intersection decreasing. Thus there exists $n(\varepsilon)$ such that

$$
\begin{equation*}
P\left(\left[\tau_{\varepsilon, n(\varepsilon)}<b\right]\right)<\varepsilon . \tag{63.8.42}
\end{equation*}
$$

Denote $\tau_{\varepsilon, n(\varepsilon)}$ as $\tau_{\varepsilon}$ for short and it will always be assumed that $n(\varepsilon)$ is at least this large and that $\lim _{\varepsilon \rightarrow 0+} n(\varepsilon)=\infty$. In addition to this, $n(\varepsilon)$ will also be large enough that

$$
1-\frac{\lambda^{2}}{2} \delta_{n(\varepsilon)}>0
$$

for all $\lambda \in[-p, p]$. To save on notation, $t_{j}$ will take the place of $t_{j}^{n}$. Then consider the stopping times $\tau_{\varepsilon} \wedge t_{j}$ for $j=0,1, \cdots, 2^{n(\varepsilon)}$.

Let $y_{j} \equiv X\left(\tau_{\varepsilon} \wedge t_{j}\right)-X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)$, it follows from the definition of the stopping time that

$$
\begin{equation*}
\left|y_{j}\right| \leq \varepsilon \tag{63.8.43}
\end{equation*}
$$

because both $\tau_{\varepsilon} \wedge t_{j}$ and $\tau_{\varepsilon} \wedge t_{j-1}$ are less than $\tau_{\varepsilon}$ and closer together than $\delta_{n(\varepsilon)}$ and so if $\left|y_{j}\right|>\varepsilon$, then $\tau_{\varepsilon} \leq t_{j}, t_{j-1}$ and so $y_{j}$ would need to equal 0 .

By the optional stopping theorem, $\left\{X\left(\tau_{\varepsilon} \wedge t_{j}\right)\right\}_{j}$ is a martingale as is also

$$
\left\{X\left(\tau_{\varepsilon} \wedge t_{j}\right)-\tau_{\varepsilon} \wedge t_{j}\right\}_{j}
$$

Thus for $A \in \mathscr{F} \tau_{\varepsilon} \wedge t_{j-1}$,

$$
\begin{gathered}
\int_{A} E\left(y_{j}^{2} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) d P=\int_{A} E\left(\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right)-X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)\right)^{2} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) d P \\
=\int_{A} E\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right)^{2} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right)+X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2} \\
-2 X\left(\tau_{\varepsilon} \wedge t_{j-1}\right) E\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right) \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) d P \\
=\int_{A} E\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right)^{2}-\tau_{\varepsilon} \wedge t_{j} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) d P+\int_{A} E\left(\tau_{\varepsilon} \wedge t_{j} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) d P \\
+\int_{A} X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2} d P-2 \int_{A} X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2} d P \\
=\int_{A} X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2} d P-\int_{A} \tau_{\varepsilon} \wedge t_{j-1} d P+\int_{A} E\left(\tau_{\varepsilon} \wedge t_{j} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) d P \\
+\int_{A} X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2} d P-2 \int_{A} X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2} d P \\
=\int_{A} E\left(\tau_{\varepsilon} \wedge t_{j} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) d P-\int_{A} \tau_{\varepsilon} \wedge t_{j-1} d P \\
=\int_{A}\left(\tau_{\varepsilon} \wedge t_{j}-\tau_{\varepsilon} \wedge t_{j-1}\right) d P \leq \int_{A} t_{j}-t_{j-1} d P
\end{gathered}
$$

Thus, since $A$ is arbitrary,

$$
\begin{gather*}
\sigma_{j}^{2} \equiv \int_{A} E\left(y_{j}^{2} \mid \mathscr{F}_{\varepsilon} \wedge t_{j-1}\right) d P= \\
E\left(\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right)-X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)\right)^{2} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right) \leq t_{j}-t_{j-1}=\delta_{n(\varepsilon)} \tag{63.8.44}
\end{gather*}
$$

Also,

$$
\begin{equation*}
E\left(y_{j} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right)=E\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right)-X\left(\tau_{\varepsilon} \wedge t_{j-1}\right) \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right)=0 \tag{63.8.45}
\end{equation*}
$$

Now it is time to find $E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j}\right)}\right)$.

$$
\begin{align*}
& E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j}\right)}\right)=E\left(e^{i \lambda\left(X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)+y_{j}\right)}\right) \\
& =E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} E\left(e^{\left.i \lambda y_{j} \mid \mathscr{F}_{\tau_{\varepsilon} \wedge t_{j-1}}\right)}\right)\right. \tag{63.8.46}
\end{align*}
$$

Now let $o(1)$ denote any quantity which converges to 0 as $\varepsilon \rightarrow 0$ for all $\lambda \in[-p, p]$ and $O(1)$ is a quantity which is bounded as $\varepsilon \rightarrow 0$. Then from 63.8.45 and 63.8.46 you can consider the power series for $e^{i \lambda y_{j}}$ which converges uniformly due to 63.8 .43 and write 63.8.46 as

$$
E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)}\left(1-\frac{\lambda^{2}}{2} \sigma_{j}^{2}(1+o(1))\right)\right)
$$

then noting that from 63.8 .44 which shows $\sigma_{j}^{2}$ is $o(1)$,it is routine to verify

$$
1-\frac{\lambda^{2}}{2} \sigma_{j}^{2}(1+o(1))=e^{-\frac{\lambda^{2}}{2} \sigma_{j}^{2}(1+o(1))}
$$

Now this shows

$$
E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j}\right)}\right)=E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{-\frac{\lambda^{2}}{2} \sigma_{j}^{2}(1+o(1))}\right)
$$

Recall that $\sigma_{j}^{2} \leq \delta_{n}=t_{j}-t_{j-1}$. Consider

$$
\begin{gathered}
\left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j}\right)}\right)-E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{-\frac{\lambda^{2}}{2} \delta_{n}}\right)\right| \\
=\left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{-\frac{\lambda^{2}}{2} \sigma_{j}^{2}(1+o(1))}\right)-E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{-\frac{\lambda^{2}}{2} \delta_{n}}\right)\right| \\
=\left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)}\left(e^{-\frac{\lambda^{2}}{2} \sigma_{j}^{2}(1+o(1))}-e^{-\frac{\lambda^{2}}{2} \delta_{n}}\right)\right)\right| \\
=\left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{-\frac{\lambda^{2}}{2} \delta_{n}}\left(e^{-\frac{\lambda^{2}}{2} \sigma_{j}^{2}(1+o(1))+\frac{\lambda^{2}}{2} \delta_{n}}-1\right)\right)\right| \\
\leq E\left(\left|e^{\frac{\lambda^{2}}{2}\left(\delta_{n}-\sigma_{j}^{2}\right)+\sigma_{j}^{2} o(1)}-1\right|\right)
\end{gathered}
$$

Everything in the exponent is $o(1)$ and so the above expression is bounded by

$$
\begin{align*}
& O(1) E\left(\left|\frac{\lambda^{2}}{2}\left(\delta_{n}-\sigma_{j}^{2}\right)+\sigma_{j}^{2} o(1)\right|\right) \\
\leq & O(1) E\left(\left(\delta_{n}-\sigma_{j}^{2}\right)+\delta_{n}|o(1)|\right) \\
= & O(1)\left[\delta_{n}-E\left(y_{j}^{2}\right)+\delta_{n} o(1)\right] \tag{63.8.47}
\end{align*}
$$

Therefore,

$$
\begin{aligned}
& \left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j}\right)}\right)-E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{-\frac{\lambda^{2}}{2} \delta_{n}}\right)\right| \\
\leq & O(1)\left[\delta_{n}-E\left(y_{j}^{2}\right)+\delta_{n} o(1)\right]
\end{aligned}
$$

and so it also follows

$$
\begin{aligned}
& \left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j}\right)}\right) e^{\frac{\lambda^{2}}{2} t_{j}}-E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{\frac{\lambda^{2}}{2} t_{j-1}}\right)\right| \\
\leq & O(1)\left[\delta_{n}-E\left(y_{j}^{2}\right)+\delta_{n} o(1)\right]
\end{aligned}
$$

Now also remember

$$
y_{j}=X\left(\tau_{\varepsilon} \wedge t_{j}\right)-X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)
$$

and that $\left\{X\left(\tau_{\varepsilon} \wedge t_{j}\right)\right\}_{j}$ is a martingale. Therefore it is routine to show,

$$
E\left(y_{j}^{2}\right)=E\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right)^{2}\right)-E\left(X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2}\right)
$$

and so

$$
\begin{aligned}
& \left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j}\right)}\right) e^{\frac{\lambda^{2}}{2} t_{j}}-E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)} e^{\frac{\lambda^{2}}{2} t_{j-1}}\right)\right| \\
\leq & O(1)\left[\delta_{n}-\left(E\left(X\left(\tau_{\varepsilon} \wedge t_{j}\right)^{2}\right)-E\left(X\left(\tau_{\varepsilon} \wedge t_{j-1}\right)^{2}\right)\right)+\delta_{n} o(1)\right]
\end{aligned}
$$

and so, summing over all $j=1, \cdots, 2^{n(\varepsilon)}$,

$$
\begin{align*}
& \left|E\left(e^{i \lambda X\left(\tau_{\varepsilon} \wedge b\right)}\right) e^{\frac{\lambda^{2}}{2} b}-E\left(e^{i \lambda X(a)} e^{\frac{\lambda^{2}}{2} a}\right)\right| \\
\leq & O(1)\left((1+o(1))(b-a)-\left(E\left(X\left(\tau_{\varepsilon} \wedge b\right)^{2}\right)-E\left(X(a)^{2}\right)\right)\right) . \tag{63.8.48}
\end{align*}
$$

Now recall 63.8.42 which said

$$
P\left(\left[\tau_{\varepsilon}<b\right]\right)<\varepsilon
$$

Let $\varepsilon_{k} \equiv 2^{-k}$ and then by the Borel Cantelli lemma,

$$
X\left(\tau_{\varepsilon} \wedge b\right) \rightarrow X(b)
$$

a.e. since if $\omega$ is such that convergence does not take place, $\omega$ must be in infinitely many of the sets, $\left[\tau_{\varepsilon_{k}}<b\right]$, a set of measure 0 . Also since $\left\{X\left(\tau_{\varepsilon} \wedge t_{j}\right)\right\}_{j}$ is a martingale, it follows from optional sampling theorem that $\left\{X(a)^{2}, X\left(\tau_{\varepsilon} \wedge b\right)^{2}, X(b)^{2}\right\}$ is a submartingale and so

$$
\int_{\left[X\left(\tau_{\varepsilon} \wedge b\right)^{2} \geq \alpha\right]} X\left(\tau_{\varepsilon} \wedge b\right)^{2} d P \leq \int_{\left[X\left(\tau_{\varepsilon} \wedge b\right)^{2} \geq \alpha\right]} X(b)^{2} d P
$$

and also from the maximal inequalities, Theorem 60.6.4 on Page 1967 it follows

$$
P\left(\left[X\left(\tau_{\varepsilon} \wedge b\right)^{2} \geq \alpha\right]\right) \leq \frac{1}{\alpha} E\left(X(b)^{2}\right)
$$

and so the functions, $\left\{X\left(\tau_{\varepsilon_{k}} \wedge b\right)^{2}\right\}_{\varepsilon_{k}}$ are uniformly integrable which implies by the Vitali convergence theorem, Theorem 11.5.3 on Page 257, that you can pass to the limit as $\varepsilon_{k} \rightarrow 0$
in the inequality, 63.8.48 and conclude

$$
\begin{aligned}
& \left|E\left(e^{i \lambda X(b)}\right) e^{\frac{\lambda^{2}}{2} b}-E\left(e^{i \lambda X(a)} e^{\frac{\lambda^{2}}{2} a}\right)\right| \\
\leq & O(1)\left((b-a)-\left(E\left(X(b)^{2}\right)-E\left(X(a)^{2}\right)\right)\right)=0
\end{aligned}
$$

Therefore,

$$
E\left(e^{i \lambda X(b)}\right)=E\left(e^{i \lambda X(a)}\right) e^{-\frac{\lambda^{2}}{2}(b-a)}
$$

This proves the lemma because $p$ was arbitrary.
Now from this lemma, it is not hard to establish Levy's theorem.
Theorem 63.8.5 Let $\{X(t)\}$ be a real continuous martingale adapted to the filtration $\mathscr{F}_{t}$ for $t \in[0, a]$ some interval such that for all $t \in[0, a], E\left(X(t)^{2}\right)<\infty$. Suppose also that $\left\{X(t)^{2}-t\right\}$ is a martingale. Then for $s<t, X(t)-X(s)$ is normally distributed with mean 0 and variance $t-s$. Also if $0 \leq t_{0}<t_{1}<\cdots<t_{m} \leq b$, then the increments $\left\{X\left(t_{j}\right)-X\left(t_{j-1}\right)\right\}$ are independent.

Proof: Let the $t_{j}$ be as described above and consider the interval $\left[t_{m-1}, t_{m}\right]$ in place of [ $a, b]$ in Lemma 63.8.4. Also let $\lambda_{k}$ for $k=1,2, \cdots, m$ be given. For $t \in\left[t_{m-1}, t_{m}\right]$, and $\lambda_{m} \neq 0$,

$$
Z_{\lambda_{m}}(t)=\frac{1}{\lambda_{m}} \sum_{j=1}^{m-1} \lambda_{j}\left(X\left(t_{j}\right)-X\left(t_{j-1}\right)\right)+\left(X(t)-X\left(t_{m-1}\right)\right)
$$

Then it is clear that $\left\{Z_{\lambda_{m}}(t)\right\}$ is a martingale on $\left[t_{m-1}, t_{m}\right]$. What is possibly less clear is that $\left\{Z_{\lambda_{m}}(t)^{2}-t\right\}$ is also a martingale. Note that $Z_{\lambda_{m}}(t)=X(t)+Y$ where $Y$ is measurable in $\mathscr{F}_{t_{m-1}}$. Therefore, for $s<t, s \in\left[t_{m-1}, t_{m}\right]$,

$$
\begin{gathered}
E\left(Z_{\lambda_{m}}(t)^{2}-t \mid \mathscr{F}_{s}\right)=E\left(X(t)^{2}+2 X(t) Y+Y^{2}-t \mid \mathscr{F}_{s}\right) \\
=X(s)^{2}-s+2 E\left(X(t) Y \mid \mathscr{F}_{s}\right)+Y^{2} \\
=X(s)^{2}-s+2 Y X(s)+Y^{2}=Z_{\lambda_{m}}(s)^{2}-s
\end{gathered}
$$

and so Lemma 63.8.4 can be applied to conclude

$$
E\left(e^{i \lambda Z_{\lambda_{m}}\left(t_{m}\right)}\right)=E\left(e^{i \lambda Z_{\lambda_{m}}\left(t_{m-1}\right)}\right) e^{-\frac{\lambda^{2}}{2}\left(t_{m}-t_{m-1}\right)}
$$

Now letting $\lambda=\lambda_{m}$,

$$
E\left(e^{i \sum_{j=1}^{m} \lambda_{j}\left(X\left(t_{j}\right)-X\left(t_{j-1}\right)\right)}\right)=E\left(e^{i \sum_{j=1}^{m-1} \lambda_{j}\left(X\left(t_{j}\right)-X\left(t_{j-1}\right)\right)}\right) e^{-\frac{\lambda_{m}^{2}}{2}\left(t_{m}-t_{m-1}\right)}
$$

By continuity, this equation continues to hold for $\lambda_{m}=0$. Then iterate this, using a similar argument on the first factor of the right side to eventually obtain

$$
E\left(e^{i \sum_{j=1}^{m} \lambda_{j}\left(X\left(t_{j}\right)-X\left(t_{j-1}\right)\right)}\right)=\prod_{j=1}^{m} e^{-\frac{\lambda_{j}^{2}}{2}\left(t_{j}-t_{j-1}\right)}
$$

Then letting all but one $\lambda_{j}$ equal zero, this shows the increment, $X\left(t_{j}\right)-X\left(t_{j-1}\right)$ is a random variable which is normally distributed having variance $t_{j}-t_{j-1}$ and mean 0 . The above formula also shows from Proposition 59.11.1 on Page 1889 that the increments are independent. This proves the theorem.

## Chapter 64

## Wiener Processes

A real valued random variable $X$ is normally distributed with mean 0 and variance $\sigma^{2}$ if

$$
P(X \in A)=\frac{1}{\sqrt{2 \pi} \sigma} \int_{A} e^{-\frac{1}{2} \frac{x^{2}}{\sigma^{2}}} d x
$$

Consider the characteristic function. By definition it is

$$
\phi_{X}(\lambda) \equiv \int_{\mathbb{R}} e^{i \lambda x} d \lambda_{X}(x)
$$

where $\lambda_{X}$ is the distribution measure for this random variable. Thus the characteristic function of this random variable is

$$
\frac{1}{\sqrt{2 \pi} \sigma} \int_{-\infty}^{\infty} e^{i \lambda x} e^{-\frac{1}{2 \sigma^{2}} x^{2}} d x
$$

One can then show through routine arguments that this equals $\exp \left(-\frac{1}{2} \sigma \lambda^{2}\right)$.

### 64.1 Real Wiener Processes

Here is the definition of a Wiener process.
Definition 64.1.1 Let $W(t)$ be a stochastic process which has the properties that whenever $t_{1}<t_{2}<\cdots<t_{m}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent and whenever $s<t$, it follows $W(t)-W(s)$ is normally distributed with variance $t-s$ and mean 0 . Also $t \rightarrow W(t)$ is Holder continuous with every exponent $\gamma<1 / 2$ and $W(0)=0$. This is called a Wiener process.

Do Wiener processes exist? Yes, they do. First here is a simple lemma which has really been done before. It depends on the Kolmogorov extension theorem, Theorem 59.2.3 on Page 1860.

Lemma 64.1.2 There exists a sequence, $\left\{\xi_{k}\right\}_{k=1}^{\infty}$ of random variables such that

$$
\mathscr{L}\left(\xi_{k}\right)=N(0,1)
$$

and $\left\{\xi_{k}\right\}_{k=1}^{\infty}$ is independent.
Proof: Let $i_{1}<i_{2} \cdots<i_{n}$ be positive integers and define

$$
\mu_{i_{1} \cdots i_{n}}\left(F_{1} \times \cdots \times F_{n}\right) \equiv \frac{1}{(\sqrt{2 \pi})^{n}} \int_{F_{1} \times \cdots \times F_{n}} e^{-|\mathbf{x}|^{2} / 2} d x
$$

Then for the index set equal to $\mathbb{N}$ the measures satisfy the necessary consistency condition for the Kolmogorov theorem. Therefore, there exists a probability space, $(\Omega, P, \mathscr{F})$ and
measurable functions, $\xi_{k}: \Omega \rightarrow \mathbb{R}$ such that

$$
\begin{aligned}
& P\left(\left[\xi_{i_{1}} \in F_{i_{1}}\right] \cap\left[\xi_{i_{2}} \in F_{i_{2}}\right] \cdots \cap\left[\xi_{i_{n}} \in F_{i_{n}}\right]\right) \\
= & \mu_{i_{1} \cdots i_{n}}\left(F_{1} \times \cdots \times F_{n}\right) \\
= & P\left(\left[\xi_{i_{1}} \in F_{i_{1}}\right]\right) \cdots P\left(\left[\xi_{i_{n}} \in F_{i_{n}}\right]\right)
\end{aligned}
$$

which shows the random variables are independent as well as normal with mean 0 and variance 1 .

Recall that the sum of independent normal random variables is normal. The Wiener process is just an infinite weighted sum of the above independent normal random variables, the weights depending on $t$. Therefore, if the sum converges, it is not too surprising that the result will be normally distributed and the variance will depend on $t$. This is the idea behind the following theorem.

Theorem 64.1.3 There exists a real Wiener process as defined in Definition 64.1.1. Furthermore, the distribution of $W(t)-W(s)$ is the same as the distribution of $W(t-s)$ and $W$ is Holder continuous with exponent $\gamma$ for any $\gamma<1 / 2$. Also for each $\alpha>1$,

$$
E\left(|W(t)-W(s)|^{\alpha}\right) \leq C_{\alpha}|t-s|^{\alpha / 2} E\left(|W(1)|^{\alpha}\right)
$$

Proof: Let $\left\{g_{m}\right\}_{m=1}^{\infty}$ be a complete orthonormal set in $L^{2}(0, \infty)$. Thus, if $f \in L^{2}(0, \infty)$,

$$
f=\sum_{i=1}^{\infty}\left(f, g_{i}\right)_{L^{2}} g_{i}
$$

The Wiener process is defined as

$$
W(t, \omega) \equiv \sum_{i=1}^{\infty}\left(\mathscr{X}_{(0, t)}, g_{i}\right)_{L^{2}} \xi_{i}(\omega)
$$

where the random variables, $\left\{\xi_{i}\right\}$ are as described in Lemma 64.1.2. The series converges in $L^{2}(\Omega)$ where $(\Omega, \mathscr{F}, P)$ is the probability space on which the random variables, $\xi_{i}$ are defined. This will first be shown. Note first that from the independence of the $\xi_{i}$,

$$
\int_{\Omega} \xi_{i} \xi_{j} d P=0
$$

Therefore,

$$
\begin{aligned}
\int_{\Omega}\left|\sum_{i=m}^{n}\left(\mathscr{X}_{(0, t)}, g_{i}\right)_{L^{2}} \xi_{i}(\omega)\right|^{2} d P & =\sum_{i=m}^{n}\left(\mathscr{X}_{(0, t)}, g_{i}\right)_{L^{2}}^{2} \int_{\Omega}\left|\xi_{i}\right|^{2} d P \\
& =\sum_{i=m}^{n}\left(\mathscr{X}_{(0, t)}, g_{i}\right)_{L^{2}}^{2}
\end{aligned}
$$

which converges to 0 as $m, n \rightarrow \infty$. Thus the partial sums are a Cauchy sequence in $L^{2}(\Omega, P)$.

It just remains to verify this definition satisfies the desired conditions. First I will show that $\omega \rightarrow W(t, \omega)$ is normally distributed with mean 0 and variance $t$. That it should be normally distributed is not surprising since it is just a sum of independent random variables which are this way. Selecting a suitable subsequence, $\left\{n_{k}\right\}$ it can be assumed

$$
W(t, \omega)=\lim _{k \rightarrow \infty} \sum_{i=1}^{n_{k}}\left(\mathscr{X}_{(0, t)}, g_{i}\right)_{L^{2}} \xi_{i}(\omega) \text { a.e. }
$$

and so from the dominated convergence theorem and the independence of the $\xi_{i}$,

$$
\begin{aligned}
E(\exp (i \lambda W(t))) & =\lim _{k \rightarrow \infty} E\left(\exp \left(i \lambda \sum_{j=1}^{n_{k}}\left(\mathscr{X}_{(0, t)}, g_{j}\right)_{L^{2}} \xi_{j}(\omega)\right)\right) \\
& =\lim _{k \rightarrow \infty} E\left(\prod_{j=1}^{n_{k}} \exp \left(i \lambda\left(\mathscr{X}_{(0, t)}, g_{j}\right)_{L^{2}} \xi_{j}(\omega)\right)\right) \\
& =\lim _{k \rightarrow \infty} \prod_{j=1}^{n_{k}} E\left(\exp \left(i \lambda\left(\mathscr{X}_{(0, t)}, g_{j}\right)_{L^{2}} \xi_{j}(\omega)\right)\right) \\
& =\lim _{k \rightarrow \infty} \prod_{j=1}^{n_{k}} e^{-\frac{1}{2} \lambda^{2}\left(\mathscr{X}_{\left.(0, t), g_{j}\right)_{L^{2}}^{2}}^{2}\right.} \\
& =\lim _{k \rightarrow \infty} \exp \left(\sum_{j=1}^{n_{k}}-\frac{1}{2} \lambda^{2}\left(\mathscr{X}_{(0, t)}, g_{j}\right)_{L^{2}}^{2}\right) \\
& =\exp \left(-\frac{1}{2} \lambda^{2}\left\|\mathscr{X}_{(0, t)}\right\|_{L^{2}}^{2}\right)=\exp \left(-\frac{1}{2} \lambda^{2} t\right)
\end{aligned}
$$

the characteristic function of a normally distributed random variable having variance $t$ and mean 0 .

It is clear $W(0)=0$. It remains to verify the increments are independent. To do this, consider

$$
\begin{equation*}
E(\exp (i[\lambda(W(t)-W(s))+\mu(W(s)-W(r))])) \tag{64.1.1}
\end{equation*}
$$

Is this equal to

$$
\begin{equation*}
E(\exp (i[\lambda(W(t)-W(s))])) E(\exp (i[\mu(W(s)-W(r))])) ? \tag{64.1.2}
\end{equation*}
$$

Letting $n_{k} \rightarrow \infty$ such that convergence happens pointwise for each function of interest, and using the independence of the $\xi_{i}$, and the dominated convergence theorem as needed,

$$
\begin{aligned}
& E\left(\exp \left(i\left[\sum_{i=1}^{\infty} \lambda\left(\mathscr{X}_{(s, t)}, g_{i}\right)_{L^{2}} \xi_{i}+\sum_{i=1}^{\infty} \mu\left(\mathscr{X}_{(r, s)}, g_{i}\right)_{L^{2}} \xi_{i}\right]\right)\right) \\
= & \lim _{k \rightarrow \infty} E\left(\exp \left(i\left[\sum_{j=1}^{n_{k}}\left(\lambda\left(\mathscr{X}_{(s, t)}, g_{j}\right)_{L^{2}}+\mu\left(\mathscr{X}_{(r, s)}, g_{j}\right)_{L^{2}}\right) \xi_{j}\right]\right)\right)
\end{aligned}
$$

$$
\begin{gathered}
=\lim _{k \rightarrow \infty} E\left(\prod_{j=1}^{n_{k}} \exp \left(i\left(\lambda\left(\mathscr{X}_{(s, t)}, g_{j}\right)_{L^{2}}+\mu\left(\mathscr{X}_{(r, s)}, g_{j}\right)_{L^{2}}\right) \xi_{j}\right)\right) \\
=\lim _{k \rightarrow \infty} \prod_{j=1}^{n_{k}} E\left(\exp \left(i\left(\lambda\left(\mathscr{X}_{(s, t)}, g_{j}\right)_{L^{2}}+\mu\left(\mathscr{X}_{(r, s)}, g_{j}\right)_{L^{2}}\right) \xi_{j}\right)\right) \\
=\lim _{k \rightarrow \infty} \prod_{j=1}^{n_{k}} \exp \left(-\frac{1}{2}\left(\lambda \mathscr{X}_{(s, t)}+\mu \mathscr{X}_{(r, s)}, g_{j}\right)_{L^{2}}^{2}\right) \\
=\lim _{k \rightarrow \infty} \exp \left(-\frac{1}{2} \sum_{j=1}^{n_{k}}\left(\lambda \mathscr{X}_{(s, t)}+\mu \mathscr{X}_{(r, s)}, g_{j}\right)_{L^{2}}^{2}\right) \\
=\exp \left(-\frac{1}{2} \sum_{j=1}^{\infty}\left(\lambda \mathscr{X}_{(s, t)}+\mu \mathscr{X}_{(r, s)}, g_{j}\right)_{L^{2}}^{2}\right)=\exp \left(-\frac{1}{2}\left\|\lambda \mathscr{X}_{(s, t)}+\mu \mathscr{X}_{(r, s)}\right\|_{L^{2}}^{2}\right) \\
=\exp \left(-\frac{1}{2}\left[\lambda^{2}\left\|\mathscr{X}_{(s, t)}\right\|_{L^{2}}^{2}+\mu^{2}\left\|\mathscr{X}_{(r, s)}\right\|_{L^{2}}^{2}\right]\right)
\end{gathered}
$$

because the functions $\lambda \mathscr{X}_{(s, t)}, \mu \mathscr{X}_{(r, s)}$ are orthogonal. Then this equals

$$
\begin{gathered}
=\exp \left(-\frac{1}{2}\left[\lambda^{2}(t-s)+\mu^{2}(s-r)\right]\right) \\
=\exp \left(-\frac{1}{2}(t-s) \lambda^{2}\right) \exp \left(-\frac{1}{2}(s-r) \mu^{2}\right)
\end{gathered}
$$

which equals 64.1.2 and this shows the increments are independent. Obviously, this same argument shows this holds for any finite set of disjoint increments.

From the definition, if $t>s$

$$
W(t-s)=\sum_{k=1}^{\infty}\left(\mathscr{X}_{(0, t-s)}, g_{k}\right)_{L^{2}} \xi_{k}
$$

while

$$
W(t)-W(s)=\sum_{k=1}^{\infty}\left(\mathscr{X}_{(s, t)}, g_{k}\right)_{L^{2}} \xi_{k} .
$$

Then the same argument given above involving the characteristic function to show $W(t)$ is normally distributed shows both of these random variables are normally distributed with mean 0 and variance $t-s$ because they have the same characteristic function.

For example, ignoring the limit questions and proceding formally,

$$
\begin{aligned}
E(\exp (i \lambda(W(t)-W(s)))) & =E\left(\exp \left(i \lambda\left(\sum_{k=1}^{\infty}\left(\mathscr{X}_{(s, t)}, g_{k}\right)_{L^{2}} \xi_{k}\right)\right)\right) \\
& =E\left(\prod_{k=1}^{\infty} \exp \left(i \lambda\left(\mathscr{X}_{(s, t)}, g_{k}\right)_{L^{2}} \xi_{k}\right)\right) \\
& =\prod_{k=1}^{\infty} E\left(\exp \left(i \lambda\left(\mathscr{X}_{(s, t)}, g_{k}\right)_{L^{2}} \xi_{k}\right)\right) \\
& =\prod_{k=1}^{\infty} e^{-\frac{1}{2} \lambda^{2}\left(\mathscr{X}_{(s, t)}, g_{k}\right)_{L^{2}}^{2}} \\
& =\exp \left(-\frac{1}{2} \lambda^{2} \sum_{k=1}^{\infty}\left(\mathscr{X}_{(s, t)}, g_{k}\right)_{L^{2}}^{2}\right) \\
& =\exp \left(-\frac{1}{2} \lambda^{2}(t-s)\right)
\end{aligned}
$$

which is the characteristic function of a random variable having mean 0 and variance $t-s$.
Finally note the distribution of $W(t-s)$ is the same as the distribution of

$$
W(1)(t-s)^{1 / 2}=\sum_{k=1}^{\infty}\left(\mathscr{X}_{(0,1)}, g_{k}\right)_{L^{2}} \xi_{k}(t-s)^{1 / 2}
$$

because the characteristic function of this last random variable is the same as the characteristic function of $W(t-s)$ which is $e^{-\frac{1}{2} \lambda^{2}(t-s)}$ which follows from a simple computation. Since $W(1)$ is a normally distrubuted random variable with mean 0 and variance 1 ,

$$
E\left(\exp \left(i \lambda W(1)(t-s)^{1 / 2}\right)\right)=e^{-\frac{1}{2} \lambda^{2}(t-s)}
$$

which is the same as the characteristic function of $W(t-s)$.
Hence for any positive $\alpha$,

$$
\begin{align*}
E\left(|W(t)-W(s)|^{\alpha}\right) & =E\left(|W(t-s)|^{\alpha}\right) \\
& =E\left(\left|(t-s)^{1 / 2} W(1)\right|^{\alpha}\right) \\
& =|t-s|^{\alpha / 2} E\left(|W(1)|^{\alpha}\right) \tag{64.1.3}
\end{align*}
$$

It follows from Theorem 62.2.2 that $W(t)$ is Holder continuous with exponent $\gamma$ where $\gamma$ is any positive number less than $\beta / \alpha$ where $\alpha / 2=1+\beta$. Thus $\gamma$ is any constant less than

$$
\frac{\frac{\alpha}{2}-1}{\alpha}=\frac{1}{2} \frac{\alpha-2}{\alpha}
$$

Thus $\gamma$ is any constant less than $\frac{1}{2}$.
The proof of the theorem, which only depended on $\left\{\xi_{i}\right\}_{i=1}^{\infty}$ being independent random variables each normal with mean 0 and variance 1 , implies the following corollary.

Corollary 64.1.4 Let $\left\{\xi_{i}\right\}_{i=1}^{\infty}$ be independent random variables each normal with mean 0 and variance 1. Then

$$
W(t, \omega) \equiv \sum_{i=1}^{\infty}\left(\mathscr{X}_{[0, t]}, g_{i}\right)_{L^{2}} \xi_{i}(\omega)
$$

is a real Wiener process. Furthermore, the distribution of $W(t)-W(s)$ is the same as the distribution of $W(t-s)$ and $W$ is Holder continuous with exponent $\gamma$ for any $\gamma<1 / 2$. Also for each $\alpha>1$,

$$
E\left(|W(t)-W(s)|^{\alpha}\right) \leq C_{\alpha}|t-s|^{\alpha / 2} E\left(|W(1)|^{\alpha}\right)
$$

### 64.2 Nowhere Differentiability of Wiener Processes

If $W(t)$ is a Wiener process, it turns out that $t \rightarrow W(t, \omega)$ is nowhere differentiable for a.e. $\omega$. This fact is based on the independence of the increments and the fact that these increments are normally distributed.

First note that $W(t)-W(s)$ has the same distribution as $(t-s)^{1 / 2} W(1)$. This is because they have the same characteristic function. Next it follows that because of the independence of the increments and what was just noted that,

$$
\begin{align*}
& P\left(\cap_{r=1}^{5}[|W(t+r \delta)-W(t+(r-1) \boldsymbol{\delta})| \leq K \boldsymbol{\delta}]\right) \\
= & \prod_{r=1}^{5} P([|W(t+r \delta)-W(t+(r-1) \delta)| \leq K \boldsymbol{\delta}]) \\
= & \prod_{r=1}^{5} P\left(\left[\left|\delta^{1 / 2} W(1)\right| \leq K \delta\right]\right)=\left(\frac{1}{\sqrt{2 \pi}} \int_{-K \sqrt{\delta}}^{K \sqrt{\delta}} e^{-\frac{1}{2} t^{2}} d t\right)^{5} \\
\leq & C \delta^{5 / 2} \tag{64.2.4}
\end{align*}
$$

With this observation, here is the proof which follows [120] and according to this reference is due to Payley, Wiener and Zygmund and the proof is like one given by Dvoretsky, Erdös and Kakutani.

Theorem 64.2.1 Let $W(t)$ be a Wiener process. Then there exists a set of measure $0, N$ such that for all $\omega \notin N$,

$$
t \rightarrow W(t, \omega)
$$

is nowhere differentiable.
Proof: Let $[0, a]$ be an interval. If for some $\omega, t \rightarrow W(t, \omega)$ is differentiable at some $s$, then for some $n, p>0$,

$$
\left|\frac{W(t, \omega)-W(s, \omega)}{t-s}\right| \leq p
$$

whenever $|t-s|<5 a 2^{-n} \equiv 5 \delta_{n}$. Define $C_{n p}$ by

$$
\begin{equation*}
\left\{\omega: \text { for some } s \in[0, a),\left|\frac{W(t, \omega)-W(s, \omega)}{t-s}\right| \leq p \text { if }|t-s| \leq 5 \delta_{n}\right\} \tag{64.2.5}
\end{equation*}
$$

Thus $\cup_{n, p \in \mathbb{N}} C_{n p}$ contains the set of $\omega$ such that $t \rightarrow W(t, \omega)$ is differentiable for some $s \in[0, a)$.

Now define uniform partitions of $[0, a),\left\{t_{k}^{n}\right\}_{k=0}^{2^{n}}$ such that

$$
\left|t_{k}^{n}-t_{k-1}^{n}\right|=a 2^{-n} \equiv \delta_{n}
$$

Let

$$
D_{n p} \equiv \cup_{i=0}^{2^{n}-1}\left(\cap_{r=1}^{5}\left[\left|W\left(t_{i}^{n}+r \delta_{n}\right)-W\left(t_{i}^{n}+(r-1) \delta_{n}\right)\right| \leq 10 p \delta_{n}\right]\right)
$$

If $\omega \in C_{n p}$, then for some $s \in[0, a)$, the condition of 64.2 .5 holds. Suppose $k$ is the number such that $s \in\left[t_{k-1}^{n}, t_{k}^{n}\right)$. Then for $r \in\{1,2,3,4,5\}$,

$$
\begin{gathered}
\left|W\left(t_{k-1}^{n}+r \delta_{n}, \omega\right)-W\left(t_{k-1}^{n}+(r-1) \delta_{n}, \omega\right)\right| \\
\leq\left|W\left(t_{k-1}^{n}+r \delta_{n}, \omega\right)-W(s, \omega)\right|+\left|W(s, \omega)-W\left(t_{k-1}^{n}+(r-1) \delta_{n}, \omega\right)\right| \\
\leq 5 p \delta_{n}+5 p \delta_{n}=10 p \delta_{n}
\end{gathered}
$$

Thus $C_{n p} \subseteq D_{n p}$. Now from 64.2.4,

$$
\begin{equation*}
P\left(D_{n p}\right) \leq 2^{n} C \delta_{n}^{5 / 2}=C a^{5 / 2} 2^{n}\left(2^{-n}\right)^{5 / 2}=C(\sqrt{a})^{5} 2^{-\frac{3}{2} n} \tag{64.2.6}
\end{equation*}
$$

Let

$$
C_{p}=\cup_{n=1}^{\infty} \cap_{k=n}^{\infty} C_{k p} \subseteq \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} D_{k p} .
$$

It was just shown in 64.2 .6 that $P\left(\cap_{k=n}^{\infty} D_{k p}\right)=0$ and so $C_{p}$ has measure 0 . Thus $\cup_{p=1}^{\infty} C_{p}$, the set of points, $\omega$ where $t \rightarrow W(t, \omega)$ could have a derivative has measure 0 . Taking the union of the exceptional sets corresponding to intervals $[0, n)$ for $n \in \mathbb{N}$, this proves the theorem.

This theorem on nowhere differentiability is very important because it shows it is doubtful one can define an integral $\int f(s) d W(s)$ by simply fixing $\omega$ and then doing some sort of Stieltjes integral in time. The reason for this is that the nowhere differentiability of $W$ implies it is also not of bounded variation on any interval since if it were, it would equal the difference of two increasing functions and would therefore have a derivative at a.e. point.

I have presented the theorem on nowhere differentiability for one dimensional Wiener processes but the same proof holds with minor modifications if you have defined the Wiener process in $\mathbb{R}^{n}$ or you could simply consider the components and apply the above result.

### 64.3 Wiener Processes In Separable Banach Space

Here is an important lemma on which the existence of Wiener processes will be based.
Lemma 64.3.1 There exists a sequence of real Wiener processes, $\left\{\psi_{k}(t)\right\}_{k=1}^{\infty}$ which have the following properties. Let $t_{0}<t_{1}<\cdots<t_{n}$ be an arbitrary sequence. Then the random variables

$$
\begin{equation*}
\left\{\psi_{k}\left(t_{q}\right)-\psi_{k}\left(t_{q-1}\right):(q, k) \in(1,2, \cdots, n) \times\left(k_{1}, \cdots, k_{m}\right)\right\} \tag{64.3.7}
\end{equation*}
$$

are independent. Also each $\psi_{k}$ is Holder continuous with exponent $\gamma$ for any $\gamma<1 / 2$ and for each $m \in \mathbb{N}$ there exists a constant $C_{m}$ independent of $k$ such that

$$
\begin{equation*}
\int_{\Omega}\left|\psi_{k}(t)-\psi_{k}(s)\right|^{2 m} d P \leq C_{m}|t-s|^{m} \tag{64.3.8}
\end{equation*}
$$

Proof: First, there exists a sequence $\left\{\xi_{i j}\right\}_{(i, j) \in \mathbb{N} \times \mathbb{N}}$ such that the $\left\{\xi_{i j}\right\}$ are independent and each normally distributed with mean 0 and variance 1 . This follows from Lemma 64.1.2. Let $\left\{\xi_{i}\right\}_{i=1}^{\infty}$ be independent and normally distributed with mean 0 and variance 1. (Let $\theta$ be a one to one and onto map from $\mathbb{N}$ to $\mathbb{N} \times \mathbb{N}$. Then define $\xi_{i j} \equiv \xi_{\theta^{-1}(i, j)}$.)

Let

$$
\begin{equation*}
\psi_{k}(t)=\sum_{j=1}^{\infty}\left(\mathscr{X}_{[0, t]}, g_{j}\right)_{L^{2}} \xi_{k j} \tag{64.3.9}
\end{equation*}
$$

where $\left\{g_{j}\right\}$ is a orthonormal basis for $L^{2}(0, \infty)$. By Corollary 64.1.4, this defines a real Wiener process satisfying 64.3.8. It remains to show that the random variables

$$
\begin{equation*}
\psi_{k_{r}}\left(t_{q}\right)-\psi_{k_{r}}\left(t_{q-1}\right) \tag{64.3.10}
\end{equation*}
$$

are independent.
Let

$$
P=\sum_{q=1}^{n} \sum_{r=1}^{m} s_{q r}\left(\psi_{k_{r}}\left(t_{q}\right)-\psi_{k_{r}}\left(t_{q-1}\right)\right)
$$

and consider $E\left(e^{i P}\right)$. I want to use Proposition 59.11.1 on Page 1889. To do this I need to show $E\left(e^{i P}\right)$ equals

$$
\prod_{q=1}^{n} \prod_{r=1}^{m} E\left(\exp \left(i s_{q r}\left(\psi_{k_{r}}\left(t_{q}\right)-\psi_{k_{r}}\left(t_{q-1}\right)\right)\right)\right)
$$

Using 64.3.9, $E\left(e^{i P}\right)$ equals

$$
\begin{aligned}
& E\left(\exp \left(i \sum_{q=1}^{n} \sum_{r=1}^{m} s_{q r} \sum_{j=1}^{\infty}\left(\mathscr{X}_{\left[t_{q-1}, t_{q}\right]}, g_{j}\right)_{L^{2}} \xi_{k_{r} j}\right)\right) \\
= & \lim _{N \rightarrow \infty} E\left(\exp \left(i \sum_{q=1}^{n} \sum_{r=1}^{m} s_{q r} \sum_{j=1}^{N}\left(\mathscr{X}_{\left[t_{q-1}, t_{q}\right]}, g_{j}\right)_{L^{2}} \xi_{k_{r} j}\right)\right)
\end{aligned}
$$

Now the $\xi_{k_{r} j}$ are independent by construction. Therefore, the above equals

$$
\begin{aligned}
= & \lim _{N \rightarrow \infty} \prod_{q=1}^{n} \prod_{r=1}^{m} \prod_{j=1}^{N} E\left(\exp \left(i s_{q r}\left(\mathscr{X}_{\left[t_{q-1}, t_{q}\right]}, g_{j}\right)_{L^{2}} \xi_{k_{r} j}\right)\right) \\
& =\lim _{N \rightarrow \infty} \prod_{q=1}^{n} \prod_{r=1}^{m} \prod_{j=1}^{N} \exp \left(-\frac{1}{2} s_{q r}^{2}\left(\mathscr{X}_{\left[t_{q-1}, t_{q}\right]}, g_{j}\right)_{L^{2}}^{2}\right) \\
& =\prod_{q=1}^{n} \prod_{r=1}^{m} \lim _{N \rightarrow \infty} \exp \left(-\frac{1}{2} s_{q r}^{2} \sum_{j=1}^{N}\left(\mathscr{X}_{\left[t_{q-1}, t_{q}\right]}, g_{j}\right)_{L^{2}}^{2}\right) \\
& =\prod_{q=1}^{n} \prod_{r=1}^{m} \exp \left(-\frac{1}{2} s_{q r}^{2}\left(t_{q}-t_{q-1}\right)\right)
\end{aligned}
$$

$$
=\prod_{q=1}^{n} \prod_{r=1}^{m} E\left(\exp \left(i s_{q r}\left(\psi_{k_{r}}\left(t_{q}\right)-\psi_{k_{r}}\left(t_{q-1}\right)\right)\right)\right)
$$

because $\psi_{k_{r}}\left(t_{q}\right)-\psi_{k_{r}}\left(t_{q-1}\right)$ is normally distributed with variance $t_{q}-t_{q-1}$ and mean 0 . By Proposition 59.11.1 on Page 1889, it follows the random variables of 64.3.10 are independent. Note that as a special case, this also shows the random variables, $\left\{\psi_{k}(t)\right\}_{k=1}^{\infty}$ are independent due to the fact $\psi_{k}(0)=0$.

Recall Corollary 61.11 .4 which is stated here for convenience.

Corollary 64.3.2 Let $E$ be any real separable Banach space. Then there exists a sequence, $\left\{e_{k}\right\} \subseteq E$ such that for any $\left\{\xi_{k}\right\}$ a sequence of independent random variables such that $\mathscr{L}\left(\xi_{k}\right)=N(0,1)$, it follows

$$
X(\omega) \equiv \sum_{k=1}^{\infty} \xi_{k}(\omega) e_{k}
$$

converges a.e. and its law is a Gaussian measure defined on $\mathscr{B}(E)$. Furthermore, $\left\|e_{k}\right\|_{E} \leq$ $\lambda_{k}$ where $\sum_{k} \lambda_{k}<\infty$.

Now let $\left\{\psi_{k}(t)\right\}$ be the sequence of Wiener processes described in Lemma 64.3.1. Then define a process with values in $E$ by

$$
\begin{equation*}
W(t) \equiv \sum_{k=1}^{\infty} \psi_{k}(t) e_{k} \tag{64.3.11}
\end{equation*}
$$

Then $\psi_{k}(t) / \sqrt{t}$ is $N(0,1)$ and so by Corollary 61.11.4 the law of

$$
W(t) / \sqrt{t}=\sum_{k=1}^{\infty}\left(\psi_{k}(t) / \sqrt{t}\right) e_{k}
$$

is a Gaussian measure. Therefore, the same is true of $W(t)$. Similar reasoning applies to the increments, $W(t)-W(s)$ to conclude the law of each of these is Gaussian. Consider the question whether the increments are independent. Let $0 \leq t_{0}<t_{1}<\cdots<t_{m}$ and let $\phi_{j} \in E^{\prime}$. Then by the dominated convergence theorem and the properties of the $\left\{\psi_{k}\right\}$,

$$
\begin{aligned}
& E\left(\exp \left(i \sum_{j=1}^{m} \phi_{j}\left(W\left(t_{j}\right)-W\left(t_{j-1}\right)\right)\right)\right) \\
= & E\left(\exp \left(i \sum_{j=1}^{m}\left(\sum_{k=1}^{\infty}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right)\right) \\
= & E\left(\prod_{j=1}^{m} \exp \left(i \sum_{k=1}^{\infty}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right)
\end{aligned}
$$

$$
\begin{aligned}
& =\lim _{n \rightarrow \infty} E\left(\prod_{j=1}^{m} \exp \left(i \sum_{k=1}^{n}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right) \\
& =\lim _{n \rightarrow \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} E\left(\exp \left(i\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right) \\
& =\lim _{n \rightarrow \infty} \prod_{j=1}^{m} E\left(\exp \left(i \sum_{k=1}^{n}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right) \\
& =\lim _{n \rightarrow \infty} E\left(\prod_{j=1}^{m} \exp \left(i \sum_{k=1}^{n}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right) \\
& =\lim _{n \rightarrow \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} E\left(\exp \left(i\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right) \\
& =\lim _{n \rightarrow \infty} \prod_{j=1}^{m} E\left(\exp \left(i \sum_{k=1}^{n}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right) \\
& =\prod_{j=1}^{m} E\left(\exp \left(i \sum_{k=1}^{\infty}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) \phi_{j}\left(e_{k}\right)\right)\right) \\
& =\prod_{j=1}^{m} E\left(\exp \left(i \phi_{j}\left(\sum_{k=1}^{\infty}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right) e_{k}\right)\right)\right) \\
& =\prod_{j=1}^{m} E\left(\exp \left(i \phi_{j}\left(W\left(t_{j}\right)-W\left(t_{j-1}\right)\right)\right)\right)
\end{aligned}
$$

which shows by Theorem 59.13.3 on Page 1896 that the random vectors,

$$
\left\{W\left(t_{j}\right)-W\left(t_{j-1}\right)\right\}_{j=1}^{m}
$$

are independent.
It is also routine to verify using properties of the $\psi_{k}$ and characteristic functions that $\mathscr{L}(W(t)-W(s))=\mathscr{L}(W(t-s))$. To see this, let $\phi \in E^{\prime}$

$$
\begin{gathered}
E(\exp (i \phi(W(t)-W(s)))) \\
=E\left(\left(\exp \left(i \phi \sum_{k=1}^{\infty}\left(\psi_{k}(t)-\psi_{k}(s)\right) e_{k}\right)\right)\right) \\
=\lim _{n \rightarrow \infty} E\left(\left(\exp \left(i \phi \sum_{k=1}^{n}\left(\psi_{k}(t)-\psi_{k}(s)\right) e_{k}\right)\right)\right)
\end{gathered}
$$

$$
\begin{aligned}
& =\lim _{n \rightarrow \infty} \prod_{k=1}^{n} E\left(\exp \left(i \phi\left(e_{k}\right)\left(\psi_{k}(t)-\psi_{k}(s)\right)\right)\right) \\
& =\lim _{n \rightarrow \infty} \prod_{k=1}^{n} E\left(\exp \left(-\frac{1}{2} \phi\left(e_{k}\right)^{2}(t-s)\right)\right) \\
& =\lim _{n \rightarrow \infty} E\left(\exp \sum_{k=1}^{n}\left(-\frac{1}{2} \phi\left(e_{k}\right)^{2}(t-s)\right)\right)
\end{aligned}
$$

which is the same as the result for

$$
E(\exp (i \phi(W(t-s))))
$$

and

$$
E(\exp (i \phi(\sqrt{t-s} W(1)))) .
$$

This has proved the following lemma.
Lemma 64.3.3 Let $E$ be a real separable Banach space. Then there exists an $E$ valued stochastic process, $W(t)$ such that $\mathscr{L}(W(t))$ and $\mathscr{L}(W(t)-W(s))$ are Gaussian measures and the increments, $\{W(t)-W(s)\}$ are independent. Furthermore, the increment $W(t)-W(s)$ has the same distribution as $W(t-s)$ and $W(t)$ has the same distribution as $\sqrt{t} W(1)$.

Now I want to consider the question of Holder continuity of the functions, $t \rightarrow W(t, \omega)$.

$$
\begin{aligned}
\int_{\Omega}\|W(t)-W(s)\|^{\alpha} d P & =\int_{E}\|x\|^{\alpha} d \mu_{W(t)-W(s)} \\
& =\int_{E}\|x\|^{\alpha} d \mu_{W(t-s)}=\int_{E}\|x\|^{\alpha} d \mu_{\sqrt{t-s} W(1)} \\
& =\int_{\Omega}\|\sqrt{t-s} W(1)\|^{\alpha} d P \\
& =|t-s|^{\alpha / 2} \int_{\Omega}\|W(1)\|^{\alpha} d P=C_{\alpha}|t-s|^{\alpha / 2}
\end{aligned}
$$

by Fernique's theorem, Theorem 61.7.5. From the Kolmogorov Čentsov theorem, Theorem 62.2.2, it follows $\{W(t)\}$ is Holder continuous with exponent $\gamma<\left(\frac{\alpha}{2}-1\right) / \alpha$.

This completes the proof of the following theorem.
Theorem 64.3.4 Let $E$ be a separable real Banach space. Then there exists a stochastic process, $\{W(t)\}$ such that the distribution of $W(t)$ and every increment, $W(t)-W(s)$ is Gaussian. Furthermore, the increments corresponding to disjoint intervals are independent, $\mathscr{L}(W(t)-W(s))=\mathscr{L}(W(t-s))=\mathscr{L}(\sqrt{t-s} W(1))$. Also for a.e. $\omega, t \rightarrow W(t, \omega)$ is Holder continuous with exponent $\gamma<1 / 2$.

### 64.4 Independent Increments and Martingales

Here is an interesting lemma.

Lemma 64.4.1 Let $\left(W(t), \mathscr{F}_{t}\right)$ be a stochastic process which has independent increments having values in E a real separable Banach space. Let

$$
A \in \mathscr{F}_{s} \equiv \sigma(W(u)-W(r): 0 \leq r<u \leq s)
$$

Suppose $g(W(t)-W(s)) \in L^{1}(\Omega ; E)$. Then the following formula holds.

$$
\begin{equation*}
\int_{\Omega} \mathscr{X}_{A} g(W(t)-W(s)) d P=P(A) \int_{\Omega} g(W(t)-W(s)) d P \tag{64.4.12}
\end{equation*}
$$

Proof: Let $\mathscr{G}$ denote the set, of all $A \in \mathscr{F}_{s}$ such that 64.4.12 holds. Then it is obvious $\mathscr{G}$ is closed with respect to complements and countable disjoint unions. Let $\mathscr{K}$ denote those sets which are finite intersections of the form

$$
A=\cap_{i=1}^{m} A_{i}
$$

where each $A_{i}$ is in a set of $\sigma\left(W\left(u_{i}\right)-W\left(r_{i}\right)\right)$ for some $0 \leq r_{i}<u_{i} \leq s$. For such $A$, it follows

$$
A \in \sigma\left(W\left(u_{i}\right)-W\left(r_{i}\right), i=1, \cdots, m\right)
$$

Now consider the random vector having values in $E^{m+1}$,

$$
\left(W\left(u_{1}\right)-W\left(r_{1}\right), \cdots, W\left(u_{m}\right)-W\left(r_{m}\right), g(W(t)-W(s))\right)
$$

Let $\mathbf{t}^{*} \in\left(E^{\prime}\right)^{m}$ and $s^{*} \in E^{\prime}$.

$$
\mathbf{t}^{*} \cdot\left(W\left(u_{1}\right)-W\left(r_{1}\right), \cdots, W\left(u_{m}\right)-W\left(r_{m}\right)\right)
$$

can be written in the form $\mathbf{g}^{*} \cdot\left(W\left(\tau_{1}\right)-W\left(\eta_{1}\right), \cdots, W\left(\tau_{l}\right)-W\left(\eta_{l}\right)\right)$ where the intervals, $\left(\eta_{j}, \tau_{j}\right)$ are disjoint and each $\tau_{j} \leq s$. For example, suppose you have

$$
a(W(2)-W(1))+b(W(2)-W(0))+c(W(3)-W(1))
$$

where obviously the increments are not disjoint. Then you would write the above expression as

$$
\begin{aligned}
& a(W(2)-W(1))+b(W(2)-W(1))+b(W(1)-W(0)) \\
& +c(W(3)-W(2))+c(W(2)-W(1))
\end{aligned}
$$

and then you would collect the terms to obtain

$$
b(W(1)-W(0))+(a+b+c)(W(2)-W(1))+c(W(3)-W(2))
$$

and now these increments are disjoint.
Therefore, by independence of the increments,

$$
\begin{aligned}
& E\left(\exp i\left(\mathbf{t}^{*} \cdot\left(W\left(u_{1}\right)-W\left(r_{1}\right), \cdots, W\left(u_{m}\right)-W\left(r_{m}\right)\right)+s^{*}(g(W(t)-W(s)))\right)\right) \\
= & E\left(\exp i\left(\mathbf{g}^{*} \cdot\left(W\left(\tau_{1}\right)-W\left(\eta_{1}\right), \cdots, W\left(\tau_{l}\right)-W\left(\eta_{l}\right)\right)+s^{*}(g(W(t)-W(s)))\right)\right)
\end{aligned}
$$

$$
\begin{gathered}
=\prod_{j=1}^{l} E\left(\exp \left(i g_{j}\left(W\left(\tau_{j}\right)-W\left(\eta_{j}\right)\right)\right)\right) E\left(\exp \left(i s^{*}(g(W(t)-W(s)))\right)\right) \\
=E\left(\exp \left(i\left(\mathbf{t}^{*} \cdot\left(W\left(u_{1}\right)-W\left(r_{1}\right), \cdots, W\left(u_{m}\right)-W\left(r_{m}\right)\right)\right)\right)\right) . \\
E\left(\exp \left(i s^{*}(g(W(t)-W(s)))\right) .\right.
\end{gathered}
$$

By Theorem 59.13.3, it follows the vector $\left(W\left(u_{1}\right)-W\left(r_{1}\right), \cdots, W\left(u_{m}\right)-W\left(r_{m}\right)\right)$ is independent of the random variable $g(W(t)-W(s))$ which shows that for $A \in \mathscr{K}, \mathscr{X}_{A}$, measurable in $\sigma\left(W\left(u_{1}\right)-W\left(r_{1}\right), \cdots, W\left(u_{m}\right)-W\left(r_{m}\right)\right)$ is independent of $g(W(t)-W(s))$. Therefore,

$$
\begin{aligned}
\int_{\Omega} \mathscr{X}_{A} g(W(t)-W(s)) d P & =\int_{\Omega} \mathscr{X}_{A} d P \int_{\Omega} g(W(t)-W(s)) d P \\
& =P(A) \int_{\Omega} g(W(t)-W(s)) d P
\end{aligned}
$$

Thus $\mathscr{K} \subseteq \mathscr{G}$ and so by the lemma on $\pi$ systems, Lemma 12.12.3 on Page 329 , it follows $\mathscr{G} \supseteq \sigma(\mathscr{K}) \supseteq \mathscr{F}_{s} \supseteq \mathscr{G}$.

Lemma 64.4.2 Let $\{W(t)\}$ be a stochastic process having values in a separable Banach space which has the property that if $t_{1}<t_{2} \cdots<t_{n}$, then the increments,

$$
\left\{W\left(t_{k}\right)-W\left(t_{k-1}\right)\right\}
$$

are independent and integrable and $E(W(t)-W(s))=0$. Suppose also that $W(t)$ is right continuous, meaning that for $\omega$ off a set of measure zero, $t \rightarrow W(t)(\omega)$ is right continuous. Also suppose that for some $q>1$

$$
\|W(t)-W(s)\|_{L^{q}(\Omega)}
$$

is bounded independent of $s \leq t$. Then $\{W(t)\}$ is also a martingale with respect to the normal filtration defined by

$$
\mathscr{F}_{s} \equiv \cap_{t>s} \overline{\sigma(W(u)-W(r): 0 \leq r<u \leq t)}
$$

where this denotes the intersection of the completions of the $\sigma$ algebras

$$
\sigma(W(u)-W(r): 0 \leq r<u \leq t)
$$

Also, in the same situation but without the assumption that $E(W(t)-W(s))=0$, if $t>s$ and $A \in \mathscr{F}_{s}$ it follows that if $g$ is a continuous function such that

$$
\begin{equation*}
\|g(W(t)-W(s))\|_{L^{q}(\Omega)} \tag{64.4.13}
\end{equation*}
$$

is bounded independent of $s \leq t$ for some $q>1$ then for $t>s$,

$$
\begin{equation*}
\int_{\Omega} \mathscr{X}_{A} g(W(t)-W(s)) d P=P(A) \int_{\Omega} g(W(t)-W(s)) d P . \tag{64.4.14}
\end{equation*}
$$

Proof: Consider first the claim, 64.4.14. To begin with I show that if $A \in \mathscr{F}_{s}$ then for all $\varepsilon$ small enough that $t>s+\varepsilon,{ }^{1}$

$$
\begin{equation*}
\int_{\Omega} \mathscr{X}_{A} g(W(t)-W(s+\varepsilon)) d P=P(A) \int_{\Omega} g(W(t)-W(s+\varepsilon)) d P \tag{64.4.15}
\end{equation*}
$$

This will happen if $\mathscr{X}_{A}$ and $g(W(t)-W(s+\varepsilon))$ are independent. First note that from the definition

$$
A \in \overline{\sigma(W(u)-W(r): 0 \leq r<u \leq s+\varepsilon)}
$$

and so from the process of completion of a measure space, there exists

$$
B \in \sigma(W(u)-W(r): 0 \leq r<u \leq s+\varepsilon)
$$

such that $B \supseteq A$ and $P(B \backslash A)=0$. Therefore, letting $\phi \in E^{\prime}$,

$$
\begin{gathered}
E\left(\exp \left(i t \mathscr{X}_{A}+i \phi(g(W(t)-W(s+\varepsilon)))\right)\right) \\
=E\left(\exp \left(i t \mathscr{X}_{B}+i \phi(g(W(t)-W(s+\varepsilon)))\right)\right) \\
=E\left(\exp \left(i t \mathscr{X}_{B}\right)\right) E(\exp (i \phi(g(W(t)-W(s+\varepsilon)))))
\end{gathered}
$$

because $\mathscr{X}_{\boldsymbol{B}}$ is independent of $g(W(t)-W(s+\varepsilon))$ by Lemma 64.4.1 above. Then the above equals

$$
=E\left(\exp \left(i t \mathscr{X}_{A}\right)\right) E(\exp (i \phi(g(W(t)-W(s+\varepsilon)))))
$$

Now by Theorem 59.13.3, 64.4 .15 follows. Next pass to the limit in both sides of 64.4.15 as $\varepsilon \rightarrow 0$. One can do this because of 64.4 .13 which implies the functions in the integrands are uniformly integrable and Vitali's convergence theorem, Theorem 21.5.7. This yields 64.4.14.

Now consider the part about the stochastic process being a martingale. Let $g$ be the identity map. If $A \in \mathscr{F}_{s}$, the above implies

$$
\begin{aligned}
\int_{A} E\left(W(t) \mid \mathscr{F}_{s}\right) d P & =\int_{A} W(t) d P=\int_{A}(W(t)-W(s)) d P+\int_{A} W(s) d P \\
& =P(A) \int_{\Omega}(W(t)-W(s)) d P+\int_{A} W(s) d P=\int_{A} W(s) d P
\end{aligned}
$$

and so since $A$ is arbitrary, $E\left(W(t) \mid \mathscr{F}_{s}\right)=W(s)$.
Note this implies immediately from Lemma 63.1.5 that Wiener process is not of bounded variation on any interval. This is because this lemma implies if it were of bounded variation, then it would be constant which is not the case due to

$$
\mathscr{L}(W(t)-W(s))=\mathscr{L}(W(t-s))=\mathscr{L}(\sqrt{t-s} W(1)) .
$$

Here is an interesting theorem about approximation.

[^43]Theorem 64.4.3 Let $\{W(t)\}$ be a Wiener process having values in a separable Banach space as described in Theorem 64.3.4. There exists a set of measure $0, N$ such that for $\omega \notin N$, the sum in 64.3 .11 converges uniformly to $W(t, \omega)$ on any interval, $[0, T]$. That is, for each $\omega$ not in a set of measure zero, the partial sums of the sum in that formula converge uniformly to $t \rightarrow W(t, \omega)$ on $[0, T]$.

Proof: By Lemma 64.4.2 the independence of the increments imply

$$
\sum_{k=m}^{n} \psi_{k}(t) e_{k}
$$

is a martingale and so by Theorem 62.5.3,

$$
P\left(\left[\sup _{t \in[0, T]}\left\|\sum_{k=m}^{n} \psi_{k}(t) e_{k}\right\| \geq \alpha\right]\right) \leq \frac{1}{\alpha} \int_{\Omega}\left\|\sum_{k=m}^{n} \psi_{k}(T) e_{k}\right\| d P
$$

From Corollary 64.3.2

$$
\begin{aligned}
\int_{\Omega}\left\|\sum_{k=m}^{n} \psi_{k}(T) e_{k}\right\| d P & \leq \sum_{k=m}^{n} \int_{\Omega}\left|\psi_{k}(T)\right| d P \lambda_{k} \\
& \leq \sum_{k=m}^{n} \lambda_{k}
\end{aligned}
$$

which shows that there exists a subsequence, $m_{l}$ such that whenever $n>m_{l}$,

$$
P\left(\left[\sup _{t \in[0, T]}\left\|\sum_{k=m_{l}}^{n} \psi_{k}(t) e_{k}\right\| \geq 2^{-k}\right]\right) \leq 2^{-k}
$$

Recall Lemma 59.15.6 stated below for convenience.
Lemma 64.4.4 Let $\left\{\zeta_{k}\right\}$ be a sequence of random variables having values in a separable real Banach space, $E$ whose distributions are symmetric. Letting $S_{k} \equiv \sum_{i=1}^{k} \zeta_{i}$, suppose $\left\{S_{n_{k}}\right\}$ converges a.e. Also suppose that for every $m>n_{k}$,

$$
\begin{equation*}
P\left(\left[\left|\mid S_{m}-S_{n_{k}} \|_{E}>2^{-k}\right]\right)<2^{-k}\right. \tag{64.4.16}
\end{equation*}
$$

Then in fact,

$$
\begin{equation*}
S_{k}(\omega) \rightarrow S(\omega) \text { a.e. } \omega \tag{64.4.17}
\end{equation*}
$$

Apply this lemma to the situation in which the Banach space, $E$ is $C([0, T] ; E)$ and $\zeta_{k}=\psi_{k} e_{k}$. Then you can conclude uniform convergence of the partial sums,

$$
\sum_{k=1}^{m} \psi_{k}(t) e_{k}
$$

This proves the theorem.

Why is $C([0, T] ; E)$ separable? You can assume without loss of generality that the interval is $[0,1]$ and consider the Bernstein polynomials

$$
p_{n}(t) \equiv \sum_{k=0}^{n}\binom{n}{k} f\left(\frac{k}{n}\right) t^{k}(1-t)^{n-k}
$$

These converge uniformly to $f$ Now look at all polynomials of the form

$$
\sum_{k=0}^{n} a_{k} t^{k}\left(1-t^{k}\right)
$$

where the $a_{k}$ is one of the countable dense set and $n \in \mathbb{N}$. Each Bernstein polynomial uniformly close to one of these and also uniformly close to $f$. Hence polynomials of this sort are countable and dense in $C([0, T] ; E)$.

### 64.5 Hilbert Space Valued Wiener Processes

Next I will consider the case of Hilbert space valued Wiener processes. This will include the case of $\mathbb{R}^{n}$ valued Wiener processes. I will present this material independent of the more general case of $E$ valued Wiener processes.

Definition 64.5.1 Let $W(t)$ be a stochastic process with values in $H$, a real separable Hilbert space which has the properties that $t \rightarrow W(t, \omega)$ is continuous, whenever $t_{1}<$ $t_{2}<\cdots<t_{m}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent, $W(0)=0$, and whenever $s<t$,

$$
\mathscr{L}(W(t)-W(s))=N(0,(t-s) Q)
$$

which means that whenever $h \in H$,

$$
\mathscr{L}((h, W(t)-W(s)))=N(0,(t-s)(Q h, h))
$$

Also

$$
E\left(\left(h_{1}, W(t)-W(s)\right)\left(h_{2}, W(t)-W(s)\right)\right)=\left(Q h_{1}, h_{2}\right)(t-s) .
$$

Here $Q$ is a nonnegative trace class operator. Recall this means

$$
Q=\sum_{i=1}^{\infty} \lambda_{i} e_{i} \otimes e_{i}
$$

where $\left\{e_{i}\right\}$ is a complete orthonormal basis, $\lambda_{i} \geq 0$, and

$$
\sum_{i=1}^{\infty} \lambda_{i}<\infty
$$

Such a stochastic process is called a $Q$ Wiener process. In the case where these have values in $\mathbb{R}^{n}$ tQ ends up being the covariance matrix of $W(t)$.

Note the characteristic function of a $Q$ Wiener process is

$$
\begin{equation*}
E\left(e^{i(h, W(t))}\right)=e^{-\frac{1}{2} t^{2}(Q h, h)} \tag{64.5.18}
\end{equation*}
$$

Note that by Theorem 61.8.5 if you simply say that the distribution measure of $W(t)$ is Gaussian, then it follows there exists a trace class operator $Q_{t}$ and $m_{t} \in H$ such that this measure is $N\left(m_{t}, Q_{t}\right)$. Thus for $W(t)$ a Wiener process, $Q_{t}=t Q$ and $m_{t}=0$. In addition, the increments are independent so this is much more specific than the earlier definition of a Gaussian measure.

What is a $Q$ Wiener process if the Hilbert space is $\mathbb{R}^{n}$ ? In particular, what is $Q$ ? It is given that

$$
\mathscr{L}((h, W(t)-W(s)))=N(0,(t-s)(Q h, h))
$$

In this case everything is a vector in $\mathbb{R}^{n}$ and so for $h \in \mathbb{R}^{n}$,

$$
E\left(e^{i \lambda(h, W(t)-W(s))}\right)=e^{-\frac{1}{2} \lambda^{2}(t-s)(Q h, h)}
$$

In particular, letting $\lambda=1$ this shows $W(t)-W(s)$ is normally distributed with covariance $(t-s) Q$ because its characteristic function is $e^{-\frac{1}{2} h^{*}(t-s) Q h}$.

With this and definition, one can describe Hilbert space valued Wiener processes in a fairly general setting.

Theorem 64.5.2 Let $U$ be a real separable Hilbert space and let $J: U_{0} \rightarrow U$ be a Hilbert Schmidt operator where $U_{0}$ is a real separable Hilbert space. Then let $\left\{g_{k}\right\}$ be a complete orthonormal basis for $U_{0}$ and define for $t \in[0, T]$

$$
W(t) \equiv \sum_{k=1}^{\infty} \psi_{k}(t) J g_{k}
$$

Then $W(t)$ is a $Q$ Wiener process for $Q=J J^{*}$ as in Definition 64.5.1. Furthermore, the distribution of $W(t)-W(s)$ is the same as the distribution of $W(t-s)$, and $W$ is Holder continuous with exponent $\gamma$ for any $\gamma<1 / 2$. There also is a subsequence denoted by $N$ such that the convergence of the series

$$
\sum_{k=1}^{N} \psi_{k}(t) J g_{k}
$$

is uniform for all $\omega$ not in some set of measure zero.
Proof: First it is necessary to show the series converges in $L^{2}(\Omega ; U)$ for each $t$. For convenience I will consider the series for $W(t)-W(s)$. (Always, it is assumed $t>s$.) Then since $\psi_{k}(t)-\psi_{k}(s)$ is normal with mean 0 and variance $(t-s)$ and $\psi_{k}(t)-\psi_{k}(s)$ and $\psi_{l}(t)-\psi_{l}(s)$ are independent,

$$
\begin{aligned}
& \int_{\Omega}\left|\sum_{k=m}^{n}\left(\psi_{k}(t)-\psi_{k}(s)\right) J g_{k}\right|_{U}^{2} d P \\
= & \int_{\Omega_{k, l=m}} \sum_{k}^{n}\left(\left(\psi_{k}(t)-\psi_{k}(s)\right) J g_{k},\left(\psi_{l}(t)-\psi_{l}(s)\right) J g_{l}\right)
\end{aligned}
$$

$$
=(t-s) \sum_{k=m}^{n}\left(J g_{k}, J g_{k}\right)=(t-s) \sum_{k=m}^{n}\left\|J g_{k}\right\|_{U}^{2}
$$

which converges to 0 as $m, n \rightarrow \infty$ thanks to the assumption that $J$ is Hilbert Schmidt. It follows the above sum converges in $L^{2}(\Omega ; U)$. Now letting $m<n$, it follows by the maximal estimate, Theorem 62.5.3, and the above

$$
\begin{aligned}
& P\left(\left[\sup _{t \in[0, T]}\left|\sum_{k=1}^{m} \psi_{k}(t) J g_{k}-\sum_{k=1}^{n} \psi_{k}(t) J g_{k}\right|_{U} \geq \lambda\right]\right) \\
& \leq \frac{1}{\lambda^{2}} E\left(\left|\sum_{k=m+1}^{n} \psi_{k}(T) J g_{k}\right|_{U}^{2}\right) \leq \frac{1}{\lambda^{2}} T \sum_{k=m}^{n}\left\|J g_{k}\right\|_{U}^{2}
\end{aligned}
$$

and so there exists a subsequence $n_{l}$ such that for all $p \geq 0$,

$$
P\left(\left[\sup _{t \in[0, T]}\left|\sum_{k=1}^{n_{l}} \psi_{k}(t) J g_{k}-\sum_{k=1}^{n_{l}+p} \psi_{k}(t) J g_{k}\right|_{U} \geq 2^{-l}\right]\right)<2^{-l}
$$

Therefore, by Borel Cantelli lemma, there is a set of measure zero such that for $\omega$ not in this set,

$$
\lim _{l \rightarrow \infty} \sum_{k=1}^{n_{l}} \psi_{k}(t) J g_{k}=\sum_{k=1}^{\infty} \psi_{k}(t) J g_{k}
$$

is uniform on $[0, T]$. From now on denote this subsequence by $N$ to save on notation.
I need to consider the characteristic function of $(h, W(t)-W(s))_{U}$ for $h \in U$. Then

$$
\begin{gathered}
E\left(\exp \left(\operatorname{ir}(h,(W(t)-W(s)))_{U}\right)\right) \\
=\lim _{N \rightarrow \infty} E\left(\exp \left(\operatorname{ir}\left(\sum_{j=1}^{N}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h, J g_{j}\right)\right)\right)\right) \\
=\lim _{N \rightarrow \infty} E\left(\prod_{j=1}^{N} e^{i r\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h, J g_{j}\right)}\right)
\end{gathered}
$$

Since the random variables $\psi_{j}(t)-\psi_{j}(s)$ are independent,

$$
=\lim _{N \rightarrow \infty} \prod_{j=1}^{N} E\left(e^{i r\left(h, J g_{j}\right)\left(\psi_{j}(t)-\psi_{j}(s)\right)}\right)
$$

Since $\psi_{j}(t)-\psi_{j}(s)$ is a Gaussian random variable having mean 0 and variance $(t-s)$, the above equals

$$
=\lim _{N \rightarrow \infty} \prod_{j=1}^{N} e^{-\frac{1}{2} r^{2}\left(h, J g_{j}\right)^{2}(t-s)}
$$

$$
\begin{align*}
& =\lim _{N \rightarrow \infty} \exp \left(\sum_{j=1}^{N}-\frac{1}{2} r^{2}\left(h, J g_{j}\right)^{2}(t-s)\right) \\
& =\exp \left(-\frac{1}{2} r^{2}(t-s) \sum_{j=1}^{\infty}\left(h, J g_{j}\right)_{U}^{2}\right) \\
& =\exp \left(-\frac{1}{2} r^{2}(t-s) \sum_{j=1}^{\infty}\left(J^{*} h, g_{j}\right)_{U_{0}}^{2}\right) \\
& =\exp \left(-\frac{1}{2} r^{2}(t-s)\left\|J^{*} h\right\|_{U_{0}}^{2}\right)=\exp \left(-\frac{1}{2} r^{2}(t-s)\left(J J^{*} h, h\right)_{U}\right) \\
& =\exp \left(-\frac{1}{2} r^{2}(t-s)(Q h, h)_{U}\right) \tag{64.5.19}
\end{align*}
$$

which shows $(h, W(t)-W(s))_{U}$ is normally distributed with mean 0 and variance

$$
(t-s)(Q h, h)
$$

where $Q \equiv J J^{*}$. It is obvious from the definition that $W(0)=0$. Note that $Q$ is of trace class because if $\left\{e_{k}\right\}$ is an orthonormal basis for $U$,

$$
\begin{aligned}
\sum_{k}\left(Q e_{k}, e_{k}\right)_{U} & =\sum_{k}\left\|J^{*} e_{k}\right\|_{U_{0}}^{2}=\sum_{k} \sum_{l}\left(J^{*} e_{k}, g_{l}\right)_{U_{0}}^{2} \\
& =\sum_{l} \sum_{k}\left(e_{k}, J g_{l}\right)_{U}^{2}=\sum_{l}\left\|J g_{l}\right\|_{U}^{2}<\infty
\end{aligned}
$$

To find the covariance, consider

$$
E\left(\left(h_{1}, W(t)-W(s)\right)\left(h_{2}, W(t)-W(s)\right)\right)
$$

This equals

$$
E\left(\sum_{k=1}^{\infty}\left(\psi_{k}(t)-\psi_{k}(s)\right)\left(h_{1}, J g_{k}\right) \sum_{j=1}^{\infty}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h_{2}, J g_{j}\right)\right)
$$

Since the series converge in $L^{2}(\Omega ; U)$, the independence of the $\psi_{k}(t)-\psi_{k}(s)$ implies the above equals

$$
\begin{aligned}
=\lim _{n \rightarrow \infty} E\left(\sum_{k=1}^{n}\right. & \left.\left(\psi_{k}(t)-\psi_{k}(s)\right)\left(h_{1}, J g_{k}\right) \sum_{j=1}^{n}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h_{2}, J g_{j}\right)\right) \\
& =\lim _{n \rightarrow \infty}(t-s) \sum_{k=1}^{n}\left(h_{1}, J g_{k}\right)\left(h_{2}, J g_{k}\right) \\
& =\lim _{n \rightarrow \infty}(t-s) \sum_{k=1}^{n}\left(J^{*} h_{1}, g_{k}\right)_{U_{0}}\left(J^{*} h_{2}, g_{k}\right)_{U_{0}} \\
& =(t-s) \sum_{k=1}^{\infty}\left(J^{*} h_{1}, g_{k}\right)_{U_{0}}\left(J^{*} h_{2}, g_{k}\right)_{U_{0}} \\
= & (t-s)\left(J^{*} h_{1}, J^{*} h_{2}\right)=(t-s)\left(Q h_{1}, h_{2}\right)
\end{aligned}
$$

Next consider the claim that the increments are independent. Let $W^{N}(t)$ be given by the appropriate partial sum and let $\left\{h_{j}\right\}_{j=1}^{m}$ be a finite list of vectors of $U$. Then from the independence properties of $\psi_{j}$ explained above,

$$
\begin{aligned}
& E\left(\exp \sum_{j=1}^{m} i\left(h_{j}, W^{N}\left(t_{j}\right)-W^{N}\left(t_{j-1}\right)\right)_{U}\right) \\
& E\left(\exp \sum_{j=1}^{m} i\left(h_{j}, \sum_{k=1}^{N} J g_{k}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right)_{U}\right) \\
= & E\left(\exp \sum_{j=1}^{m} \sum_{k=1}^{N} i\left(h_{j}, J g_{k}\right)_{U}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right) \\
= & E\left(\prod_{j, k} \exp \left(i\left(h_{j}, J g_{k}\right)_{U}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right)\right) \\
= & \prod_{j, k} E\left(\exp \left(i\left(h_{j}, J g_{k}\right)_{U}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right)\right)
\end{aligned}
$$

This can be done because of the independence of the random variables

$$
\left\{\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right\}_{j, k}
$$

Thus the above equals

$$
\begin{aligned}
& \prod_{j, k} \exp \left(-\frac{1}{2}\left(h_{j}, J g_{k}\right)_{U}^{2}\left(t_{j}-t_{j-1}\right)\right) \\
= & \prod_{j=1}^{m} \exp \left(-\frac{1}{2} \sum_{k=1}^{N}\left(h_{j}, J g_{k}\right)_{U}^{2}\left(t_{j}-t_{j-1}\right)\right)
\end{aligned}
$$

because $\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)$ is normally distributed having variance $t_{j}-t_{j-1}$. Now letting
$N \rightarrow \infty$, this implies

$$
\begin{align*}
& E\left(\exp \sum_{j=1}^{m} i\left(h_{j}, W\left(t_{j}\right)-W\left(t_{j-1}\right)\right)_{U}\right) \\
= & \prod_{j=1}^{m} \exp \left(-\frac{1}{2} \sum_{k=1}^{\infty}\left(h_{j}, J g_{k}\right)_{U}^{2}\left(t_{j}-t_{j-1}\right)\right) \\
= & \prod_{j=1}^{m} \exp \left(-\frac{1}{2}\left(t_{j}-t_{j-1}\right) \sum_{k=1}^{\infty}\left(J^{*} h_{j}, g_{k}\right)_{U_{0}}^{2}\right) \\
= & \prod_{j=1}^{m} \exp \left(-\frac{1}{2}\left(t_{j}-t_{j-1}\right)\left\|J^{*} h_{j}\right\|_{U_{0}}^{2}\right) \\
= & \prod_{j=1}^{m} \exp \left(-\frac{1}{2}\left(t_{j}-t_{j-1}\right)\left(Q h_{j}, h_{j}\right)_{U}\right) \\
= & \prod_{j=1}^{m} \exp \left(i\left(h_{j}, W\left(t_{j}\right)-W\left(t_{j-1}\right)\right)_{U}\right) \tag{64.5.20}
\end{align*}
$$

from 64.5.19, letting $r=1$. By Theorem 59.13.3 on Page 1896, this shows the increments are independent.

It remains to verify the Holder continuity. Recall

$$
W(t)=\sum_{k=1}^{\infty} J g_{k} \psi_{k}(t)
$$

where $\psi_{k}$ is a real Wiener process.
Next consider the claim about Holder continuity. It was shown above that

$$
E\left(\exp \left(\operatorname{ir}(h,(W(t)-W(s)))_{U}\right)\right)=\exp \left(-\frac{1}{2} r^{2}(t-s)(Q h, h)_{U}\right)
$$

Therefore, taking a derivative with respect to $r$ two times yields

$$
\begin{aligned}
& E\left(\left(-(h,(W(t)-W(s)))_{U}^{2}\right) \exp \left(\operatorname{ir}(h,(W(t)-W(s)))_{U}\right)\right) \\
= & -(t-s)(Q h, h) \exp \left(-\frac{1}{2} r^{2}(t-s)(Q h, h)_{U}\right)+ \\
& r^{2}(t-s)^{2}(Q h, h)_{U}^{2} \exp \left(-\frac{1}{2} r^{2}(t-s)(Q h, h)_{U}\right)
\end{aligned}
$$

Now plug in $r=0$ to obtain

$$
E\left((h,(W(t)-W(s)))_{U}^{2}\right)=(t-s)(Q h, h)
$$

Similarly, taking 4 derivatives, it follows that an expression of the following form holds.

$$
E\left((h,(W(t)-W(s)))_{U}^{4}\right)=C_{2}(Q h, h)^{2}(t-s)^{2}
$$

and in general,

$$
E\left((h,(W(t)-W(s)))_{U}^{2 m}\right)=C_{m}(Q h, h)^{m}(t-s)^{m}
$$

Now it follows from Minkowsky's inequality applied to the two integrals $\sum_{i=1}^{\infty}$ and $\int_{\Omega}$ that

$$
\begin{aligned}
{\left[E\left(|W(t)-W(s)|^{2 m}\right)\right]^{1 / m} } & =\left[E\left(\left(\sum_{k=1}^{\infty}\left(e_{k}, W(t)-W(s)\right)^{2}\right)^{m}\right)\right]^{1 / m} \\
& \leq \sum_{k=1}^{\infty}\left[E\left(\left(e_{k}, W(t)-W(s)\right)^{2 m}\right)\right]^{1 / m} \\
& =\sum_{k=1}^{\infty}\left[C_{m}\left(Q e_{k}, e_{k}\right)^{m}(t-s)^{m}\right]^{1 / m} \\
& =C_{m}^{1 / m}|t-s|\left(\sum_{k=1}^{\infty}\left(Q e_{k}, e_{k}\right)\right) \equiv C_{m}^{\prime}|t-s|
\end{aligned}
$$

Hence there exists a constant $C_{m}$ such that

$$
E\left(|W(t)-W(s)|^{2 m}\right) \leq C_{m}|t-s|^{m}
$$

By the Kolmogorov Čentsov Theorem, Theorem 62.2.2, it follows that off a set of measure $0, t \rightarrow W(t, \omega)$ is Holder continuous with exponent $\gamma$ such that

$$
\gamma<\frac{m-1}{2 m}, m>2 .
$$

Finally, from 64.5 .19 with $r=1$,

$$
E\left(\exp i(h, W(t)-W(s))_{U}\right)=\exp \left(-\frac{1}{2}(t-s)(Q h, h)\right)
$$

which is the same as $E\left(\exp i(h, W(t-s))_{U}\right)$ due to the fact $W(0)=0$.
The above has shown that $W(t)$ satisfies the conditions of Lemma 64.4.2 and so it is a martingale with respect to the filtration given there. What is its quadratic variation?

$$
E\left(\|W(t)\|^{2}\right)=\sum_{k=1}^{\infty} E\left(\left(W(t), e_{k}\right)\left(W(t), e_{k}\right)\right)=\sum_{k=1}^{\infty}\left(Q e_{k}, e_{k}\right) t=\operatorname{trace}(Q) t
$$

Is it the case that $[W](t)=\operatorname{trace}(Q) t$ ? Let the filtration be as in Lemma 64.4.2 and let $A \in \mathscr{F}_{s}$. Then using the result of that lemma,

$$
\begin{gathered}
\int_{A}\left(\|W(t)\|^{2}-t \operatorname{trace}(Q) \mid \mathscr{F}_{s}\right) d P \\
=\quad \int_{A}\left(\|W(t)-W(s)\|^{2}+2(W(t), W(s))-\|W(s)\|^{2}\right. \\
\left.-(t-s) \operatorname{trace} Q-\operatorname{trace} Q s \mid \mathscr{F}_{s}\right) d P
\end{gathered}
$$

$$
\begin{aligned}
= & P(A) \int_{\Omega}\|W(t)-W(s)\|^{2}-(t-s) \operatorname{trace} Q d P \\
& \quad+\int_{A}\left(2(W(t), W(s))-\|W(s)\|^{2}-\operatorname{trace}(Q) s \mid \mathscr{F}_{s}\right) d P \\
= & \int_{A} 2\left(W(s), E\left(W(t) \mid \mathscr{F}_{s}\right)\right) d P-\int_{A}\|W(s)\|^{2} d P-\int_{A} s \operatorname{trace} Q d P \\
= & \int_{A}\left(\|W(s)\|^{2}-s \operatorname{trace} Q\right) d P
\end{aligned}
$$

and this shows that the quadratic variation $[W](t)=t$ trace $(Q)$ by uniqueness of the quadratic variation.

Now suppose you start with a nonnegative trace class operator $Q$. Then in this case also one can define a $Q$ Wiener process. It is possible to get this theorem from Theorem 64.5.2 but this will not be done here.

Theorem 64.5.3 Let $U$ be a real separable Hilbert space and let $Q$ be a nonnegative trace class operator defined on $U$. Then there exists a $Q$ Wiener process as defined in Definition 64.5.1. Furthermore, the distribution of $W(t)-W(s)$ is the same as the distribution of $W(t-s)$ and $W$ is Holder continuous with exponent $\gamma$ for any $\gamma<1 / 2$.

Proof: One can obtain this theorem as a corollary of Theorem 64.5.2 but this will not be done here.

Let

$$
Q=\sum_{i=1}^{\infty} \lambda_{i} e_{i} \otimes e_{i}
$$

where $\left\{e_{i}\right\}$ is a complete orthonormal set and $\lambda_{i} \geq 0$ and $\sum \lambda_{i}<\infty$. Now the definition of the $Q$ Wiener process is

$$
\begin{equation*}
W(t) \equiv \sum_{k=1}^{\infty} \sqrt{\lambda_{k}} e_{k} \psi_{k}(t) \tag{64.5.21}
\end{equation*}
$$

where $\left\{\psi_{k}(t)\right\}$ are the real Wiener processes defined in Lemma 64.3.1.
Now consider 64.5.21. From this formula, if $s<t$

$$
\begin{equation*}
W(t)-W(s)=\sum_{k=1}^{\infty} \sqrt{\lambda_{k}} e_{k}\left(\psi_{k}(t)-\psi_{k}(s)\right) \tag{64.5.22}
\end{equation*}
$$

First it is necessary to show this sum converges. Since $\psi_{j}(t)$ is a Wiener process,

$$
\begin{aligned}
& \int_{\Omega}\left|\sum_{j=m}^{n} \sqrt{\lambda_{j}}\left(\psi_{j}(t)-\psi_{j}(s)\right) e_{j}\right|_{U}^{2} d P \\
= & \int_{\Omega} \sum_{j=m}^{n} \lambda_{j}\left(\psi_{j}(t)-\psi_{j}(s)\right)^{2} d P \\
= & (t-s) \sum_{j=m}^{n} \lambda_{j}
\end{aligned}
$$

and this converges to 0 as $m, n \rightarrow \infty$ because it was given that

$$
\sum_{j=1}^{\infty} \lambda_{j}<\infty
$$

so the series in 64.5 .22 converges in $L^{2}(\Omega ; U)$.
Therefore, there exists a subsequence

$$
\left\{\sum_{k=1}^{N} \sqrt{\lambda_{k}} e_{k}\left(\psi_{k}(t)-\psi_{k}(s)\right)\right\}
$$

which converges pointwise a.e. to $W(t)-W(s)$ as well as in $L^{2}(\Omega ; U)$ as $N \rightarrow \infty$. Then letting $h \in U$,

$$
\begin{equation*}
(h, W(t)-W(s))_{U}=\sum_{k=1}^{\infty} \sqrt{\lambda_{k}}\left(\psi_{k}(t)-\psi_{k}(s)\right)\left(h, e_{k}\right) \tag{64.5.23}
\end{equation*}
$$

Then by the dominated convergence theorem,

$$
\begin{gathered}
E\left(\exp \left(\operatorname{ir}(h,(W(t)-W(s)))_{U}\right)\right) \\
=\lim _{N \rightarrow \infty} E\left(\exp \left(i r\left(\sum_{j=1}^{N} \sqrt{\lambda_{j}}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h, e_{j}\right)\right)\right)\right) \\
=\lim _{N \rightarrow \infty} E\left(\prod_{j=1}^{N} e^{i r \sqrt{\lambda_{j}}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h, e_{j}\right)}\right)
\end{gathered}
$$

Since the random variables $\psi_{j}(t)-\psi_{j}(s)$ are independent,

$$
=\lim _{N \rightarrow \infty} \prod_{j=1}^{N} E\left(e^{i r \sqrt{\lambda_{j}}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h, e_{j}\right)}\right)
$$

Since $\psi_{j}(t)$ is a real Wiener process,

$$
\begin{align*}
& =\lim _{N \rightarrow \infty} \prod_{j=1}^{N} e^{-\frac{1}{2} r^{2} \lambda_{j}(t-s)\left(h, e_{j}\right)^{2}} \\
= & \lim _{N \rightarrow \infty} \exp \left(\sum_{j=1}^{N}-\frac{1}{2} r^{2} \lambda_{j}(t-s)\left(h, e_{j}\right)^{2}\right) \\
= & \exp \left(-\frac{1}{2} r^{2}(t-s) \sum_{j=1}^{\infty} \lambda_{j}\left(h, e_{j}\right)^{2}\right) \\
= & \exp \left(-\frac{1}{2} r^{2}(t-s)(Q h, h)\right) \tag{64.5.24}
\end{align*}
$$

Thus $(h, W(t)-W(s))$ is normally distributed with mean 0 and variance $(t-s)(Q h, h)$. It is obvious from the definition that $W(0)=0$. Also to find the covariance, consider

$$
E\left(\left(h_{1}, W(t)-W(s)\right)\left(h_{2}, W(t)-W(s)\right)\right)
$$

and use 64.5 .23 to obtain this is equal to

$$
\begin{gathered}
E\left(\sum_{k=1}^{\infty} \sqrt{\lambda_{k}}\left(\psi_{k}(t)-\psi_{k}(s)\right)\left(h_{1}, e_{k}\right) \sum_{j=1}^{\infty} \sqrt{\lambda_{j}}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h_{2}, e_{j}\right)\right) \\
=\lim _{n \rightarrow \infty} E\left(\sum_{k=1}^{n} \sqrt{\lambda_{k}}\left(\psi_{k}(t)-\psi_{k}(s)\right)\left(h_{1}, e_{k}\right) \sum_{j=1}^{n} \sqrt{\lambda_{j}}\left(\psi_{j}(t)-\psi_{j}(s)\right)\left(h_{2}, e_{j}\right)\right) \\
=\lim _{n \rightarrow \infty}(t-s) \sum_{k=1}^{n} \lambda_{k}\left(h_{1}, e_{k}\right)\left(h_{2}, e_{j}\right)=(t-s)\left(Q h_{1}, h_{2}\right)
\end{gathered}
$$

(Recall $\left.Q \equiv \sum_{k} \lambda_{k} e_{k} \otimes e_{k}.\right)$
Next I show the increments are independent. Let $N$ be the subsequence defined above and let $W^{N}(t)$ be given by the appropriate partial sum and let $\left\{h_{j}\right\}_{j=1}^{m}$ be a finite list of vectors of $U$. Then from the independence properties of $\psi_{j}$ explained above,

$$
\begin{aligned}
& E\left(\exp \sum_{j=1}^{m} i\left(h_{j}, W^{N}\left(t_{j}\right)-W^{N}\left(t_{j-1}\right)\right)_{U}\right) \\
& E\left(\exp \sum_{j=1}^{m} i\left(h_{j}, \sum_{k=1}^{N} \sqrt{\lambda_{k}} e_{k}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right)_{U}\right) \\
= & E\left(\exp \sum_{j=1}^{m} \sum_{k=1}^{N} i \sqrt{\lambda_{k}}\left(h_{j}, e_{k}\right)_{U}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right) \\
= & E\left(\prod_{j, k} \exp \left(i \sqrt{\lambda_{k}}\left(h_{j}, e_{k}\right)_{U}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right)\right) \\
= & \prod_{j, k} E\left(\exp \left(i \sqrt{\lambda_{k}}\left(h_{j}, e_{k}\right)_{U}\left(\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right)\right)\right)
\end{aligned}
$$

This can be done because of the independence of the random variables

$$
\left\{\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)\right\}_{j, k}
$$

Thus the above equals

$$
=\prod_{j=1}^{m} \exp \left(-\frac{1}{2} \sum_{k=1}^{N} \lambda_{k}\left(h_{j}, e_{k}\right)_{U}^{2}\left(t_{j}-t_{j-1}\right)\right)
$$

because $\psi_{k}\left(t_{j}\right)-\psi_{k}\left(t_{j-1}\right)$ is normally distributed having variance $t_{j}-t_{j-1}$ and mean 0 . Now letting $N \rightarrow \infty$, this implies

$$
\begin{align*}
& E\left(\exp \sum_{j=1}^{m} i\left(h_{j}, W\left(t_{j}\right)-W\left(t_{j-1}\right)\right)_{U}\right) \\
= & \prod_{j=1}^{m} \exp \left(-\frac{1}{2}\left(t_{j}-t_{j-1}\right) \sum_{k=1}^{\infty} \lambda_{k}\left(h_{j}, e_{k}\right)_{U}^{2}\right) \\
= & \prod_{j=1}^{m} \exp \left(-\frac{1}{2}\left(t_{j}-t_{j-1}\right)(Q h, h)_{U}\right) \\
= & \prod_{j=1}^{m} \exp \left(i\left(h_{j}, W\left(t_{j}\right)-W\left(t_{j-1}\right)\right)_{U}\right) \tag{64.5.25}
\end{align*}
$$

because of the fact shown above that $(h, W(t)-W(s))$ is normally distributed with mean 0 and variance $(t-s)(Q h, h)$. By Theorem 59.13.3 on Page 1896, this shows the increments are independent.

Next consider the continuity assertion. Recall

$$
W(t)=\sum_{k=1}^{\infty} \sqrt{\lambda_{k}} e_{k} \psi_{k}(t)
$$

where $\psi_{k}$ is a real Wiener process. Therefore, letting $2 m>2, m \in \mathbb{N}$ and using 64.1.3 for $\psi_{k}$ and Jensen's inequality along with Lemma 64.3.1,

$$
\begin{align*}
E\left(|W(t)-W(s)|^{2 m}\right) & =E\left(\left|\sum_{k=1}^{\infty} \sqrt{\lambda_{k}} e_{k}\left(\psi_{k}(t)-\psi_{k}(s)\right)\right|^{2 m}\right) \\
& =E\left(\left(\sum_{k=1}^{\infty} \lambda_{k}\left|\psi_{k}(t)-\psi_{k}(s)\right|^{2}\right)^{m}\right) \\
& \leq E\left(\left(\sum_{k=1}^{\infty} \lambda_{k}\right)^{m-1} \sum_{k=1}^{\infty} \lambda_{k}\left|\psi_{k}(t)-\psi_{k}(s)\right|^{2 m}\right) \\
& \leq C_{m} \sum_{k=1}^{\infty} \lambda_{k} E\left(\left|\psi_{k}(t)-\psi_{k}(s)\right|^{2 m}\right)  \tag{64.5.26}\\
& \leq C_{m}|t-s|^{m} \tag{64.5.27}
\end{align*}
$$

By the Kolmogorov Čentsov Theorem, Theorem 62.2.2, it follows that off a set of measure $0, t \rightarrow W(t, \omega)$ is Holder continuous with exponent $\gamma$ such that

$$
\gamma<\frac{m-1}{2 m}
$$

Finally, from 64.5.24 taking $r=1$,

$$
E\left(\exp i(h, W(t)-W(s))_{U}\right)=\exp \left(-\frac{1}{2}(t-s)(Q h, h)\right)
$$

which is the same as $E\left(\exp i(h, W(t-s))_{U}\right)$ due to the fact $W(0)=0$. This proves the theorem.

The above shows there exists $Q$ Wiener processes in any separable Hilbert space. Next I will show the way described above is the only way it can happen.

Theorem 64.5.4 Suppose $\{W(t)\}$ is a $Q$ Wiener process in $U$, a real separable Hilbert space. Then letting

$$
Q=\sum_{k=1}^{\infty} \lambda_{k} e_{k} \otimes e_{k}
$$

where the $\left\{e_{k}\right\}$ are orthonormal, $\lambda_{k} \geq 0$, and $\sum_{k=1}^{\infty} \lambda_{k}<\infty$, it follows

$$
\begin{equation*}
W(t)=\sum_{k=1}^{\infty} \sqrt{\lambda_{k}} \psi_{k}(t) e_{k} \tag{64.5.28}
\end{equation*}
$$

where

$$
\psi_{k}(t) \equiv\left\{\begin{array}{l}
\frac{1}{\sqrt{\lambda_{k}}}\left(W(t), e_{k}\right)_{U} \text { if } \lambda_{k} \neq 0 \\
0 \text { if } \lambda_{k}=0
\end{array}\right.
$$

then $\left\{\psi_{k}(t)\right\}$ is a Wiener process and for $t_{0}<t_{1}<\cdots<t_{n}$ the random variables

$$
\left\{\psi_{k}\left(t_{q}\right)-\psi_{k}\left(t_{q-1}\right):(q, k) \in(1,2, \cdots, n) \times\left(k_{1}, \cdots, k_{m}\right)\right\}
$$

are independent. Furthermore, the sum in 64.5 .28 converges uniformly for a.e. $\omega$ on any closed interval, $[0, T]$.

Proof: First of all, the fact that $W(t)$ has values in $U$ and that $\left\{e_{k}\right\}$ is an orthonormal basis implies the sum in 64.5 .28 converges for each $\omega$. Consider

$$
E\left(\exp \left(i r \psi_{k}(t)\right)\right)=E\left(\exp \left(\operatorname{ir} \frac{1}{\sqrt{\lambda_{k}}}\left(W(t), e_{k}\right)_{U}\right)\right)
$$

Since $W(t)$ is given to be a $Q$ Wiener process, $\left(W(t), e_{k}\right)_{U}$ is normally distributed with mean 0 and variance $t(Q h, h)$. Therefore, the above equals

$$
=e^{-\frac{1}{2} r^{2} \frac{1}{\lambda_{k}} t\left(Q e_{k}, e_{k}\right)}=e^{-\frac{1}{2} r^{2} \frac{1}{\lambda_{k}} t \lambda_{k}}=e^{-\frac{1}{2} r^{2} t}
$$

the characteristic function for a random variable which is $N(0, t)$. The independence of the increments for a given $\psi_{k}(t)$ follows right away from the independence of the increments of $W(t)$ and the distribution of the increments being $N(0,(t-s))$ follows similarly to the above.

For $t_{1}<t_{2}<\cdots<t_{n}$, why are the random variables,

$$
\begin{equation*}
\left\{\left(W\left(t_{q}\right), e_{k}\right)_{U}-\left(W\left(t_{q-1}\right), e_{k}\right)_{U}:(q, k) \in(1,2, \cdots, n) \times\left(k_{1}, \cdots, k_{m}\right)\right\} \tag{64.5.29}
\end{equation*}
$$

independent? Let

$$
P=\sum_{q=1}^{n} \sum_{j=1}^{m} s_{q j}\left(\left(W\left(t_{q}\right), e_{k_{j}}\right)_{U}-\left(W\left(t_{q-1}\right), e_{k_{j}}\right)_{U}\right)
$$

and consider $E\left(e^{i P}\right)$. This equals

$$
\begin{gather*}
e^{i P}=E\left(\exp \left(i \sum_{q=1}^{n} \sum_{j=1}^{m} s_{q j}\left(\left(W\left(t_{q}\right), e_{k_{j}}\right)_{U}-\left(W\left(t_{q-1}\right), e_{k_{j}}\right)_{U}\right)\right)\right)  \tag{64.5.30}\\
=E\left(\exp \left(i \sum_{q=1}^{n}\left(\left(W\left(t_{q}\right), \sum_{j=1}^{m} s_{q j} e_{k_{j}}\right)_{U}-\left(W\left(t_{q-1}\right), \sum_{j=1}^{m} s_{q j} e_{k_{j}}\right)_{U}\right)\right)\right) \\
=E\left(\prod_{q=1}^{n} \exp \left(i\left(W\left(t_{q}\right)-W\left(t_{q-1}\right), \sum_{j=1}^{m} s_{q j} e_{k_{j}}\right)_{U}\right)\right)
\end{gather*}
$$

Now recall that by assumption the increments $W(t)-W(s)$ are independent. Therefore, the above equals

$$
\prod_{q=1}^{n} E\left(\exp \left(i\left(W\left(t_{q}\right)-W\left(t_{q-1}\right), \sum_{j=1}^{m} s_{q j} e_{k_{j}}\right)_{U}\right)\right)
$$

Recall that by assumption $(W(t)-W(s), h)_{U}$ is normally distributed with variance given by the expresson $(t-s)(Q h, h)$ and mean 0 . Therefore, the above equals

$$
\begin{gather*}
\prod_{q=1}^{n} \exp \left(-\frac{1}{2}\left(t_{q}-t_{q-1}\right)\left(Q \sum_{j=1}^{m} s_{q j} e_{k_{j}}, \sum_{j=1}^{m} s_{q j} e_{k_{j}}\right)\right) \\
=\prod_{q=1}^{n} \exp \left(-\frac{1}{2}\left(t_{q}-t_{q-1}\right) \sum_{j=1}^{m} s_{q j}^{2} \lambda_{k_{j}}\right) \\
\quad \exp \left(-\frac{1}{2} \sum_{q=1}^{n} \sum_{j=1}^{m}\left(t_{q}-t_{q-1}\right) s_{q j}^{2} \lambda_{k_{j}}\right) \tag{64.5.31}
\end{gather*}
$$

Also

$$
\begin{array}{r}
\prod_{q=1}^{n} \prod_{j=1}^{n} E\left(\exp \left(i s_{q j}\left(\left(W\left(t_{q}\right), e_{k_{j}}\right)_{U}-\left(W\left(t_{q-1}\right), e_{k_{j}}\right)_{U}\right)\right)\right)  \tag{64.5.32}\\
=\prod_{q=1}^{n} \prod_{j=1}^{n} E\left(\exp \left(i s_{q j}\left(\left(W\left(t_{q}\right)-W\left(t_{q-1}\right), e_{k_{j}}\right)_{U}\right)\right)\right) \\
=\prod_{q=1}^{n} \prod_{j=1}^{n} \exp \left(-\frac{1}{2}\left(t_{q}-t_{q-1}\right) s_{q j}^{2}\left(Q e_{k_{j}}, e_{k_{j}}\right)\right) \\
=\prod_{q=1}^{n} \prod_{j=1}^{n} \exp \left(-\frac{1}{2}\left(t_{q}-t_{q-1}\right) s_{q j}^{2} \lambda_{k_{j}}\right) \\
=\exp \left(-\frac{1}{2} \sum_{q=1}^{n} \sum_{j=1}^{m}\left(t_{q}-t_{q-1}\right) s_{q j}^{2} \lambda_{k_{j}}\right)
\end{array}
$$

Therefore, $e^{i P}$ equals the expression in 64.5.32 because both equal the expression in 64.5.31 and it follows from Proposition 59.11.1 on Page 1889 that the random variables of 64.5.29 are independent.

What about the claim of uniform convergence? By the independence of the increments, it follows from Lemma 64.4.2 that $\{W(t)\}$ is a martingale and each real valued function, $\left(W(t), e_{k}\right)_{U}$ is also a martingale. Therefore, Theorem 62.5.3 can be applied to conclude

$$
\begin{aligned}
& P\left(\left[\sup _{t \in[0, T]}\left|\sum_{k=m}^{n}\left(W(t), e_{k}\right)_{U} e_{k}\right| \geq \alpha\right]\right) \leq \frac{1}{\alpha} \int_{\Omega}\left|\sum_{k=m}^{n}\left(W(T), e_{k}\right)_{U} e_{k}\right| d P \\
& \quad \leq \frac{1}{\alpha} \int_{\Omega}\left|\sum_{k=m}^{n}\left(W(T), e_{k}\right)_{U} e_{k}\right|^{2} d P=\frac{1}{\alpha} \sum_{k=m}^{n} \int_{\Omega}\left(W(T), e_{k}\right)_{U}^{2} d P \\
& \quad=\frac{1}{\alpha} \sum_{k=m}^{n}\left(Q e_{k}, e_{k}\right) T=\frac{T}{\alpha} \sum_{k=m}^{n} \lambda_{k} \leq \frac{T}{\alpha} \sum_{k=m}^{\infty} \lambda_{k}
\end{aligned}
$$

Since $\sum_{k=1}^{\infty} \lambda_{k}<\infty$, there exists a sequence, $\left\{m_{l}\right\}$ such that if $n>m_{l}$

$$
P\left(\left[\sup _{t \in[0, T]}\left|\sum_{k=m_{l}}^{n}\left(W(t), e_{k}\right)_{U} e_{k}\right|>2^{-k}\right]\right)<2^{-k}
$$

and so by the Borel Cantelli lemma, off a set of measure 0 the partial sums

$$
\left\{\sum_{k=1}^{m_{l}}\left(W(t), e_{k}\right)_{U} e_{k}\right\}
$$

converge uniformly on $[0, T]$. This is very interesting but more can be said. In fact the original partial sums converge.

Recall Lemma 59.15.6 stated below for convenience.
Lemma 64.5.5 Let $\left\{\zeta_{k}\right\}$ be a sequence of random variables having values in a separable real Banach space, $E$ whose distributions are symmetric. Letting $S_{k} \equiv \sum_{i=1}^{k} \zeta_{i}$, suppose $\left\{S_{n_{k}}\right\}$ converges a.e. Also suppose that for every $m>n_{k}$,

$$
\begin{equation*}
P\left(\left[\left\|S_{m}-S_{n_{k}}\right\|_{E}>2^{-k}\right]\right)<2^{-k} \tag{64.5.33}
\end{equation*}
$$

Then in fact,

$$
\begin{equation*}
S_{k}(\omega) \rightarrow S(\omega) \text { a.e. } \omega \tag{64.5.34}
\end{equation*}
$$

Apply this lemma to the situation in which the Banach space, $E$ is $C([0, T] ; U)$. Then you can conclude uniform convergence of the partial sums,

$$
\sum_{k=1}^{m}\left(W(t), e_{k}\right)_{U} e_{k}
$$

This proves the theorem.

### 64.6 Wiener Processes, Another Approach

### 64.6.1 Lots Of Independent Normally Distributed Random Variables

You can use the Kolmogorov extension theorem to prove the following corollary. It is Corollary 59.20.3 on Page 1934.

Corollary 64.6.1 Let $H$ be a real Hilbert space. Then there exist real valued random variables $W(h)$ for $h \in H$ such that each is normally distributed with mean 0 and for every $h, g,(W(f), W(g))$ is normally distributed and

$$
E(W(h) W(g))=(h, g)_{H}
$$

Furthermore, if $\left\{e_{i}\right\}$ is an orthogonal set of vectors of $H$, then $\left\{W\left(e_{i}\right)\right\}$ are independent random variables. Also for any finite set $\left\{f_{1}, f_{2}, \cdots, f_{n}\right\}$,

$$
\left(W\left(f_{1}\right), W\left(f_{2}\right), \cdots, W\left(f_{n}\right)\right)
$$

is normally distributed.
Corollary 64.6.2 The map $h \rightarrow W(h)$ is linear. Also, $\{W(h): h \in H\}$ is a closed subspace of $L^{2}(\Omega, \mathscr{F}, P)$ where $\mathscr{F}=\sigma(W(h): h \in H)$.

Proof: This follows from the above description.

$$
\begin{gathered}
E\left([W(g+h)-(W(g)+W(h))]^{2}\right)=E\left(W(g+h)^{2}\right) \\
+E\left((W(g)+W(h))^{2}\right)-2 E(W(g+h)(W(g)+W(h))) \\
=|g+h|^{2}+|g|^{2}+|h|^{2}+2(g, h)-2(g+h, g)-2(g+h, h) \\
=|g|^{2}+|h|^{2}+2(g, h)++2(g, h)+|g|^{2} \\
+|h|^{2}-2|g|^{2}-2(g, h)-2(g, h)-2|h|^{2}=0
\end{gathered}
$$

Hence $W(h+g)=W(g)+W(h)$.

$$
\begin{gathered}
E\left((W(\alpha f)-\alpha W(f))^{2}\right)=E\left(W(\alpha f)^{2}\right)+E\left(\alpha^{2} W(f)^{2}\right)-2 E(W(\alpha f) \alpha W(f)) \\
=\alpha^{2}|f|^{2}+\alpha^{2}|f|^{2}-2 \alpha(\alpha f, f)=0
\end{gathered}
$$

Why is $\{W(h): h \in H\}$ a subspace? This is obvious because $W$ is linear. Why is it closed? Say $W\left(h_{n}\right) \rightarrow f \in L^{2}(\Omega)$. This requires that $\left\{h_{n}\right\}$ is a Cauchy sequence. Thus $h_{n} \rightarrow h$ and so

$$
\begin{aligned}
E\left(|f-W(h)|^{2}\right) & \leq 2\left[\lim _{n \rightarrow \infty} E\left(\left|f-W\left(h_{n}\right)\right|^{2}\right)+E\left(\left|W\left(h_{n}\right)-W(h)\right|^{2}\right)\right] \\
& =2 \lim _{n \rightarrow \infty} E\left(\left|W\left(h_{n}\right)-W(h)\right|^{2}\right)=2 \lim _{n \rightarrow \infty}\left|h_{n}-h\right|_{H}^{2}=0
\end{aligned}
$$

and so $f=W(h)$ showing that this is indeed a closed subspace.
Next is a technical lemma which will be of considerable use.

Lemma 64.6.3 Let $X \geq 0$ and measurable. Also define a finite measure on $\mathscr{B}\left(\mathbb{R}^{p}\right)$

$$
v(B) \equiv \int_{\Omega} X \mathscr{X}_{B}(\mathbf{Y}) d P
$$

Then let $f: \mathbb{R}^{p} \rightarrow[0, \infty)$ be Borel measurable. Then

$$
\int_{\Omega} f(\mathbf{Y}) X d P=\int_{\mathbb{R}^{p}} f(\mathbf{y}) d v(y)
$$

where here $\mathbf{Y}$ is a given measurable function with values in $\mathbb{R}^{p}$. Formally, $X d P=d v$.
Note that $\mathbf{Y}$ is given and $X$ is just some random variable which here has nonnegative values. Of course similar things will work without this stipulation.

Proof: First say $X=\mathscr{X}_{D}$ and replace $f(\mathbf{Y})$ with $\mathscr{X}_{\mathbf{Y}^{-1}(B)}$. Then

$$
\begin{aligned}
\int_{\Omega} \mathscr{X}_{D} & \mathscr{X}_{\mathbf{Y}^{-1}(B)} d P=P\left(D \cap \mathbf{Y}^{-1}(B)\right) \\
\int_{\mathbb{R}^{p}} \mathscr{X}_{B}(\mathbf{y}) d v(y) & \equiv v(B) \equiv \int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{B}(\mathbf{Y}) d P \\
& =\int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{\mathbf{Y}^{-1}(B)} d P=P\left(D \cap \mathbf{Y}^{-1}(B)\right)
\end{aligned}
$$

Thus

$$
\int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{\mathbf{Y}^{-1}(B)} d P=\int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{B}(\mathbf{Y}) d P=\int_{\mathbb{R}^{p}} \mathscr{X}_{B}(\mathbf{y}) d v(y)
$$

Now let $s_{n}(\mathbf{y}) \uparrow f(\mathbf{y})$, and let $s_{n}(\mathbf{y})=\sum_{k=1}^{m} c_{k} \mathscr{X}_{B_{k}}(\mathbf{y})$ where $B_{k}$ is a Borel set. Then

$$
\begin{gathered}
\int_{\mathbb{R}^{p}} s_{n}(\mathbf{y}) d v(y)=\int_{\mathbb{R}^{p}} \sum_{k=1}^{m} c_{k} \mathscr{X}_{B_{k}}(\mathbf{y}) d v(\mathbf{y})=\sum_{k=1}^{m} c_{k} \int_{\mathbb{R}^{p}} \mathscr{X}_{B_{k}}(\mathbf{y}) d v(\mathbf{y}) \\
=\sum_{k=1}^{m} c_{k} P\left(D \cap \mathbf{Y}^{-1}\left(B_{k}\right)\right) \\
\int_{\Omega} s_{n}(\mathbf{Y}) \mathscr{X}_{D} d P=\sum_{k=1}^{m} c_{k} \int_{\Omega} \mathscr{X}_{D} \mathscr{X}_{B_{k}}(\mathbf{Y}) d P=\sum_{k=1}^{m} c_{k} P\left(D \cap \mathbf{Y}^{-1}\left(B_{k}\right)\right)
\end{gathered}
$$

which is the same thing. Therefore,

$$
\int_{\Omega} s_{n}(\mathbf{Y}) \mathscr{X}_{D} d P=\int_{\mathbb{R}^{p}} s_{n}(\mathbf{y}) d v(y)
$$

Now pass to a limit using the monotone convergence theorem to obtain

$$
\int_{\Omega} f(\mathbf{Y}) \mathscr{X}_{D} d P=\int_{\mathbb{R}^{p}} f(\mathbf{y}) d v(y)
$$

Next replace $\mathscr{X}_{D}$ with $\sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}} \equiv s_{n}(\omega)$, a simple function.

$$
\int_{\Omega} f(\mathbf{Y}) \sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}} d P=\sum_{k=1}^{m} d_{k} \int_{\Omega} f(\mathbf{Y}) \mathscr{X}_{D_{k}} d P
$$

$$
=\sum_{k=1}^{m} d_{k} \int_{\mathbb{R}^{p}} f(\mathbf{Y}) d v_{k}
$$

where $v_{k}(B) \equiv \int_{\Omega} \mathscr{X}_{D_{k}} \mathscr{X}_{B}(\mathbf{Y}) d P$. Now let

$$
v_{n}(B) \equiv \int_{\Omega} \sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}} \mathscr{X}_{B}(\mathbf{Y})=\int_{\Omega} s_{n} \mathscr{X}_{B}(\mathbf{Y}) d P
$$

It is indexed with $n$ thanks to $s_{n}$. Then

$$
v_{n}(B)=\sum_{k=1}^{m} d_{k} \int_{\Omega} \mathscr{X}_{D_{k}} \mathscr{X}_{B}(\mathbf{Y}) d P=\sum_{k=1}^{m} d_{k} v_{k}(B)
$$

Hence

$$
\begin{aligned}
\int_{\Omega} f(\mathbf{Y}) s_{n} d P & =\int_{\Omega} f(\mathbf{Y}) \sum_{k=1}^{m} d_{k} \mathscr{X}_{D_{k}} d P=\sum_{k=1}^{m} d_{k} \int_{\mathbb{R}^{p}} f(\mathbf{y}) d v_{k} \\
& =\int_{\mathbb{R}^{p}} f(\mathbf{y}) \sum_{k=1}^{m} d_{k} d v_{k}=\int_{\mathbb{R}^{p}} f(\mathbf{y}) d v_{n}
\end{aligned}
$$

$\left(s_{n} d P=d v_{n}\right.$ so to speak.) Then let $s_{n}(\omega) \uparrow X(\omega)$. Clearly $v_{n} \ll v$ and so by the Radon Nikodym theorem $d v_{n}=h_{n} d v$ where $h_{n} \uparrow$. It follows from the monotone convergence theorem that one can pass to a limit in the above and obtain

$$
\int_{\Omega} f(\mathbf{Y}) X d P=\int_{\mathbb{R}^{p}} f(\mathbf{y}) d v
$$

The interest here is to let $f(\mathbf{Y}) \equiv e^{\lambda \cdot \mathbf{Y}}$ so $f(\mathbf{y})=e^{\lambda \cdot \mathbf{y}}$. To remember this, $X d P=d \nu$ in a sort of sloppy way then the above formula holds.

Lemma 64.6.4 Each $e^{W(h)}$ is in $L^{p}(\Omega)$ for every $h \in H$ and for every $p \geq 1$. In fact,

$$
\int_{\Omega}\left(e^{W(h)}\right)^{p} d P=\int_{\Omega} e^{W(p h)} d P=e^{\frac{1}{2}|p h|_{H}^{2}}
$$

In addition to this,

$$
\sum_{k=0}^{n} \frac{W(h)^{k}}{k!} \rightarrow e^{W(h)} \text { in } L^{p}(\Omega, \mathscr{F}, P), p>1
$$

Proof: It suffices to verify this for all positive integers $p$. Let $p$ be such an integer. Note that from the linearity of $W,\left(e^{W(h)}\right)^{p}=e^{p W(h)}=e^{W(p h)}$ and so it suffices to verify that for each $h \in H, e^{W(h)}$ is in $L^{1}(\Omega)$. From Lemma 64.6.3,

$$
\int_{\Omega} e^{W(h)} d P=\int_{\mathbb{R}} e^{y} d v(y)
$$

where $v(B) \equiv \int_{\Omega} \mathscr{X}_{B}(W(h)) d P=\int_{\mathbb{R}} \mathscr{X}_{B}(y) d v(y)$. In using this lemma, $\mathbf{Y}=W(h), X=$ 1. Thus

$$
\int_{\Omega} e^{W(h)} d P=\int_{0}^{\infty} v\left(e^{y}>\lambda\right) d \lambda=\int_{0}^{\infty} \frac{1}{\sqrt{2 \pi}|h|} \int_{[y>\ln (\lambda)]} e^{-\frac{1}{2} \frac{y^{2}}{|h|^{2}}} d y d \lambda, u=\ln (\lambda)
$$

$$
\begin{aligned}
& =\frac{1}{\sqrt{2 \pi}|h|} \int_{-\infty}^{\infty} e^{u} \int_{u}^{\infty} e^{-\frac{1}{2} \frac{y^{2}}{|h|^{2}}} d y d u=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} \int_{u /|h|}^{\infty} e^{u} e^{-\frac{1}{2} v^{2}} d v d u \\
& \quad=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} \int_{-\infty}^{|h| v} e^{u} e^{-\frac{1}{2} v^{2}} d u d v=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} e^{-\frac{1}{2} v^{2}} e^{|h| v} d v \\
& \quad=\frac{1}{\sqrt{2 \pi}} \sqrt{2} \sqrt{\pi} e^{|h|^{2} / 2}=e^{\frac{1}{2}|h|^{2}}<\infty
\end{aligned}
$$

If $h=0, W(h)$ would be 0 because by the construction, $E\left(W(0)^{2}\right)=(0,0)_{H}=0$. Then

$$
\int_{\Omega} e^{W(h)} d P=\int_{\Omega} e^{0} d P=1
$$

Consider the last claim. It is enough to assume $p$ is an integer.

$$
\begin{aligned}
\left|\sum_{k=0}^{n} \frac{W(h)^{k}}{k!}-e^{W(h)}\right| & =\left|\sum_{k=n+1}^{\infty} \frac{W(h)^{k}}{k!}\right|=\left|W(h)^{n+1}\right|\left|\sum_{k=0}^{\infty} \frac{W(h)^{k}}{(n+1+k)!}\right| \\
& =\left|W(h)^{n+1}\right|\left|\sum_{k=0}^{\infty} \frac{W(h)^{k}}{k!} \frac{k!}{(n+1+k)!}\right| \\
& \leq\left|W(h)^{n+1}\right| \frac{1}{(n+1)!}\left|\sum_{k=0}^{\infty} \frac{W(h)^{k}}{k!}\right|=\left|\frac{W(h)^{n+1}}{(n+1)!}\right| e^{W(h)}
\end{aligned}
$$

This converges to 0 for each $\omega$ because it says nothing more than that the $n^{t h}$ term of a convergent sequence converges to 0 .

$$
\begin{gathered}
\int_{\Omega}\left(\left|\frac{W(h)^{n+1}}{(n+1)!}\right| e^{W(h)}\right)^{2 p} d P=\int_{\Omega}\left(\frac{W(h)^{n+1}}{(n+1)!}\right)^{2 p}\left(e^{W(h)}\right)^{2 p} d P \\
=\left(\frac{1}{(n+1)!}\right)^{2 p} \frac{1}{\sqrt{2 \pi}|h|} \int_{\mathbb{R}} e^{-\frac{1}{2} \frac{x^{2}}{|h|^{2}}} e^{2 p x} x^{2 p(n+1)} d x \\
=\left(\frac{1}{(n+1)!}\right)^{2 p} \frac{1}{\sqrt{2 \pi}|h|} e^{2 p|h|^{2}} \int_{\mathbb{R}} e^{-\frac{1}{2|h|^{2}}\left(x-2 p|h|^{2}\right)^{2}} x^{2 p(n+1)} d x \\
\leq\left(\frac{1}{(n+1)!}\right)^{2 p} \frac{2^{2 p(n+1)}}{\sqrt{2 \pi}|h|} e^{2 p|h|^{2}} \int_{\mathbb{R}} e^{-\frac{1}{2|h|^{2}}\left(x-2 p|h|^{2}\right)^{2}}\left(x-2 p|h|^{2}\right)^{2 p(n+1)} d x \\
+\left(\frac{1}{(n+1)!}\right)^{2 p} \frac{2^{2 p(n+1)}}{\sqrt{2 \pi}|h|} e^{2 p|h|^{2}} \int_{\mathbb{R}} e^{-\frac{1}{2|h|^{2}}\left(x-2 p|h|^{2}\right)^{2}}\left(2 p|h|^{2}\right)^{2 p(n+1)} d x
\end{gathered}
$$

The second term clearly converges to 0 as $n \rightarrow \infty$. Consider the first term. To simplify, let $t=\frac{x-2 p|h|}{|h|}$. Then this term reduces to

$$
\begin{aligned}
& \left(\frac{1}{(n+1)!}\right)^{2 p} \frac{2^{2 p(n+1)}|h|^{2 p(n+1)}|h|}{\sqrt{2 \pi}} e^{2 p|h|^{2}} \int_{\mathbb{R}} e^{-t^{2}} t^{2 p(n+1)} d t \\
= & 2\left(\frac{1}{(n+1)!}\right)^{2 p} \frac{2^{2 p(n+1)}|h|^{2 p(n+1)}|h|}{\sqrt{2 \pi}} e^{2 p|h|^{2}} \int_{0}^{\infty} e^{-t^{2}} t^{2 p(n+1)} d t
\end{aligned}
$$

Now let $t^{2}=u$. Then this becomes

$$
\begin{aligned}
& 2\left(\frac{1}{(n+1)!}\right)^{2 p} \frac{2^{2 p(n+1)}|h|^{2 p(n+1)}|h|}{\sqrt{2 \pi}} e^{2 p|h|^{2}} \int_{0}^{\infty} e^{-u} u^{p(n+1)} u^{-(1 / 2)} \frac{1}{2} d u \\
= & \left(\frac{1}{(n+1)!}\right)^{2 p} \frac{2^{2 p(n+1)}|h|^{2 p(n+1)}|h|}{\sqrt{2 \pi}} e^{2 p|h|^{2}} \int_{0}^{\infty} e^{-u} u^{p+n p-\frac{1}{2}} d u \\
\leq & C(h)(2|h|)^{2 p(n+1)} \frac{1}{(n+1)!} \frac{1}{((n+1)!)^{2 p-1}} \Gamma\left(p(n+1)-\frac{1}{2}\right) \\
= & C(h) \frac{(2|h|)^{2 p(n+1)}}{(n+1)!} \frac{\Gamma\left(p(n+1)-\frac{1}{2}\right)}{((n+1)!)^{2 p-1}} \\
\leq & C(h) \frac{\left(2^{2}|h|^{2}\right)^{p(n+1)}}{(n+1)!} \frac{\Gamma\left(p(n+1)-\frac{1}{2}\right)}{((n+1)!)^{2 p-1}} \\
= & C(h) \frac{\left(2^{2}|h|^{2}\right)^{p(n+1)}}{(n+1)!} \frac{(p(n+1))!}{((n+1)!)^{2 p-1}}
\end{aligned}
$$

this converges to 0 as $n \rightarrow \infty$. This is obvious for $\frac{\left(2^{2}|h|^{2}\right)^{p(n+1)}}{(n+1)!}$. Consider $\frac{(p(n+1))!}{((n+1)!)^{2 p-1}}$. By the ratio test, $\sum_{n} \frac{(p(n+1))!}{((n+1)!)^{2 p-1}}<\infty$ so this also converges to 0 . The details of this ratio test argument are as follows. The ratio, after simplifying is

$$
\overbrace{\frac{(p n+2 p)(p n+2 p-1) \cdots(p n+p+1)}{(n+2)^{2 p-1}}}^{p \text { factors }} \leq \frac{p^{p}(n+p)^{p}}{(n+2)^{2 p-1}}
$$

which clearly converges to 0 since $2 p-1>p$ since $p$ is an integer larger than 1 .
Therefore, $\left\{\left|\frac{W(h)^{n+1}}{(n+1)!}\right| e^{W(h)}\right\}_{n=1}^{\infty}$ is bounded in $L^{2 p}(\Omega)$. Then

$$
\int_{\Omega}\left|\sum_{k=0}^{n} \frac{W(h)^{k}}{k!}-e^{W(h)}\right|^{p} d P \rightarrow 0
$$

because the integrand is bounded by $\left(\left|\frac{W(h)^{n+1}}{(n+1)!}\right| e^{W(h)}\right)^{p}$ and it was just shown that these functions are bounded in $L^{2}(\Omega)$. Therefore, the claimed convergence follows from the Vitali convergence theorem.

The following lemma shows that the functions $e^{W(h)}$ are dense in $L^{p}(\Omega)$ for every $p>1$.
Lemma 64.6.5 Let $\mathscr{F}$ be the $\sigma$ algebra determined by the random variables $W(h)$. If $X \in L^{p}(\Omega, \mathscr{F}, P), p>1$ and $\int_{\Omega} X e^{W(h)} d P=0$ for every $h \in H$, then $X=0$.

Proof: Let $h_{1}, \cdots, h_{p}$ be given. Then for $t_{i} \in \mathbb{R}$,

$$
\sum_{i} t_{i} h_{i} \in H
$$

and so since $W$ is linear,

$$
\int_{\Omega} X e^{\mathbf{t} \cdot \mathbf{W}(\mathbf{h})} d P=0, \mathbf{W}(\mathbf{h}) \equiv\left(W\left(h_{1}\right), \cdots, W\left(h_{p}\right)\right)
$$

Now by Lemma 64.6.3,

$$
\int_{\Omega} X^{+} e^{\mathbf{t} \cdot\left(W\left(h_{1}\right), \cdots, W\left(h_{p}\right)\right)} d P=\int_{\mathbb{R}^{p}} e^{\mathbf{t} \cdot \mathbf{y}} d v_{+}(y)
$$

where $v_{+}(B)=E\left(X^{+} \mathscr{X}_{B}(\mathbf{W}(\mathbf{h}))\right)$. From Lemma 64.6.4, this function of $\mathbf{t}$ is finite for all $\mathbf{t} \in \mathbb{R}^{p}$. Similarly,

$$
\int_{\Omega} X^{-} e^{\mathbf{t} \cdot\left(W\left(h_{1}\right), \cdots, W\left(h_{p}\right)\right)} d P=\int_{\mathbb{R}^{p}} e^{\mathbf{t} \cdot \mathbf{y}} d v_{-}(y)
$$

where $v_{-}(B)=E\left(X^{-} \mathscr{X}_{B}(\mathbf{W}(\mathbf{h}))\right)$. Thus for $v$ equal to the signed measure $v \equiv v_{+}-v_{-}$,

$$
f(\mathbf{t}) \equiv \int_{\mathbb{R}^{p}} e^{\mathbf{t} \cdot \mathbf{y}} d v(y)=0
$$

for $\mathbf{t} \in \mathbb{R}^{p}$. Also

$$
\int_{\Omega} X^{+} e^{i \mathbf{t} \cdot(\mathbf{W}(\mathbf{h}))} d P=\int_{\mathbb{R}^{p}} e^{i \mathbf{t} \cdot \mathbf{y}} d v_{+}(y)
$$

with a similar formula holding for $X^{-}$. Thus

$$
f(\mathbf{t}) \equiv \int_{\mathbb{R}^{p}} e^{\mathbf{t} \cdot \mathbf{y}} d v(y) \in \mathbb{C}
$$

is well defined for all $\mathbf{t} \in \mathbb{C}^{p}$. Consider

$$
\int_{\mathbb{R}^{p}} e^{\mathbf{t} \cdot \mathbf{y}} d v_{+}(y)
$$

Is this function analytic in each $t_{k}$ ? Take a difference quotient. It equals for $h \in \mathbb{C}$,

$$
\int_{\Omega} X^{+} \frac{\left(e^{\left(\mathbf{t}+h \mathbf{e}_{k}\right) \cdot(\mathbf{W}(\mathbf{h}))}-e^{\mathbf{t} \cdot(\mathbf{W}(\mathbf{h}))}\right)}{h} d P=\int_{\Omega} X^{+} e^{\mathbf{t} \cdot \mathbf{W}(\mathbf{h})} \frac{\left(e^{h \mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h}))}-1\right)}{h} d P
$$

In case $\mathbf{e}_{k} \cdot \mathbf{W}(\mathbf{h})=0$ there is nothing to show. Assume then that this is not 0 . Then this equals

$$
\int_{\Omega} X^{+} \mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h})) e^{\mathbf{t} \cdot \mathbf{W}(\mathbf{h})} \frac{\left(e^{h \mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h}))}-1\right)}{h\left(\mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h}))\right)} d P
$$

Now

$$
\left|\frac{e^{z}-1}{z}\right|=\left|\frac{1}{z} \sum_{k=1}^{\infty} \frac{z^{k}}{k!}\right| \leq \sum_{k=0}^{\infty} \leq\left|e^{z}\right|
$$

and so the integrand is dominated by

$$
\begin{aligned}
\left|X^{+} \mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h})) e^{\mathbf{t} \cdot \mathbf{W}(\mathbf{h})} \frac{\left(e^{h \mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h}))}-1\right)}{h\left(\mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h}))\right)}\right| & \leq X^{+}\left|\mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h})) e^{\mathbf{t} \cdot \mathbf{W}(\mathbf{h})} e^{h\left(\mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h}))\right)}\right| \\
& =X^{+}\left|\mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h})) e^{\left(\mathbf{t}+h \mathbf{e}_{k}\right) \cdot \mathbf{W}(\mathbf{h})}\right|
\end{aligned}
$$

From Lemma 64.6 .4 which says that $e^{W(h)}$ is in $L^{q}(\Omega)$ for each $q>1$, this is in particular true for $q=m p$ where $m$ is an arbitrary positive integer satisfying

$$
p>\frac{m+1}{m}
$$

Then the integrand is of the form $f g_{h}$ where $f \in L^{p}$ and $g_{h}$ is bounded in $L^{m p}$. Therefore,

$$
\alpha \equiv(p m) /(m+1)>1
$$

and

$$
\int_{\Omega}\left|f g_{h}\right|^{\alpha} d P=\int_{\Omega}|f|^{\alpha}\left|g_{h}\right|^{\alpha} d P \leq\left(\int_{\Omega}|f|^{p} d P\right)^{m /(m+1)}\left(\int_{\Omega}\left|g_{h}\right|^{p m} d P\right)^{1 /(m+1)}
$$

which is bounded. By the Vitali convergence theorem,

$$
\lim _{h \rightarrow 0} \int_{\Omega} X^{+} \frac{\left(e^{\left(\mathbf{t}+h \mathbf{e}_{k}\right) \cdot(\mathbf{W}(\mathbf{h}))}-e^{\mathbf{t} \cdot(\mathbf{W}(\mathbf{h}))}\right)}{h} d P=\int_{\Omega} X^{+} \mathbf{e}_{k} \cdot(\mathbf{W}(\mathbf{h})) e^{\mathbf{t} \cdot \mathbf{W}(\mathbf{h})} d P
$$

and so this function of $t_{k}$ is analytic. Similarly one can do the same thing for the integral involving $X^{-}$. Thus

$$
0=\int_{\mathbb{R}^{p}} e^{\boldsymbol{t} \cdot \mathbf{y}} d v(y)
$$

whenever $t_{j} \in \mathbb{R}$ for all $j$ and $t_{1} \rightarrow \int_{\mathbb{R}^{p}} e^{\mathbf{t} \cdot \mathbf{y}} d \boldsymbol{v}(y)$ is analytic on $\mathbb{C}$. Thus this analytic function of $t_{1}$ is zero for all $t_{1} \in \mathbb{C}$ since it is zero on a set which has a limit point, and in particular

$$
\int_{\mathbb{R}^{p}} e^{i t_{1} y_{1}+t_{2} y_{2}+\cdots+t_{p} y_{p}} d v(y)=0
$$

where each $t_{j}$ is real. Now repeat the argument with respect to $t_{2}$ and conclude that

$$
\int_{\mathbb{R}^{p}} e^{i t_{1} y_{1}+i t_{2} y_{2}+\cdots+t_{p} y_{p}} d v(y)=0
$$

and continue this way to conclude that

$$
0=\int_{\mathbb{R}^{p}} e^{i \cdot \mathbf{y}} d v(y)
$$

which shows that the inverse Fourier transform of $v$ is 0 . Thus $v=0$. To see this, let $\psi \in \mathfrak{S}$, the Schwartz class. Then neglecting troublesome constants in the Fourier transform,

$$
0=\int_{\mathbb{R}^{p}} \psi(\mathbf{t}) \int_{\mathbb{R}^{p}} e^{i t \cdot \mathbf{y}} d v(y) d t=\int_{\mathbb{R}^{p}} \int_{\mathbb{R}^{p}} \psi(\mathbf{t}) e^{i \mathbf{t} \cdot \mathbf{y}} d t d v(y)=v\left(F^{-1} \psi\right)
$$

Now $F^{-1}$ maps $\mathfrak{S}$ onto $\mathfrak{S}$ and so this reduces to

$$
\int_{\mathbb{R}^{p}} \psi d v=0
$$

for all $\psi \in \mathfrak{S}$. By density of $\mathfrak{S}$ in $C_{0}\left(\mathbb{R}^{p}\right)$, it follows that the above holds for all $\psi \in C_{0}\left(\mathbb{R}^{p}\right)$ and so $v=0$.

It follows that for every $B$ Borel and for every such description of $\mathbf{W}(\mathbf{h})$.

$$
0=\int_{\Omega} X \mathscr{X}_{B}(\mathbf{W}(\mathbf{h})) d P=\int_{\Omega} X \mathscr{X}_{\mathbf{W}(\mathbf{h})^{-1}(B)} d P
$$

Let $\mathscr{K}$ be sets of the form $\mathbf{W}(\mathbf{h})^{-1}(B)$ where $B$ is of the form $B_{1} \times \cdots \times B_{p}, B_{i}$ open, this for some $p$. Then this is clearly a $\pi$ system because the intersection of any two of them is another one and

$$
\emptyset, \Omega=\mathbf{W}(\mathbf{h})^{-1}\left(\mathbb{R}^{p}\right)
$$

are both in $\mathscr{K}$. Also $\sigma(\mathscr{K})=\mathscr{F}$. Let $\mathscr{G}$ be those sets $F$ of $\mathscr{F}$ such that

$$
\begin{equation*}
0=\int_{\Omega} X \mathscr{X}_{F} d P \tag{64.6.35}
\end{equation*}
$$

This is true for $F \in \mathscr{K}$. Now it is clear that $\mathscr{G}$ is closed with respect to complements and countable disjoint unions. It is closed with respect to complements because

$$
\int_{\Omega} X \mathscr{X}_{F^{C}} d P=\int_{\Omega} X\left(1-\mathscr{X}_{F}\right) d P=\int_{\Omega} X d P-\int_{\Omega} X \mathscr{X}_{F} d P=0
$$

By Dynkin's lemma, $\mathscr{G}=\mathscr{F}$ and so 64.6 .35 holds for all $F \in \mathscr{F}$ which requires $X=0$.

### 64.6.2 The Wiener Processes

Recall the definition of the Wiener process.
Definition 64.6.6 Let $W(t)$ be a stochastic process which has the properties that whenever $t_{1}<t_{2}<\cdots<t_{m}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent and whenever $s<t$, it follows $W(t)-W(s)$ is normally distributed with variance $t-s$ and mean 0 . Also $t \rightarrow W(t)$ is Holder continuous with every exponent $\gamma<1 / 2, W(0)=0$. This is called a Wiener process.

Now in the definition of $W$ above, you begin with a Hilbert space $H$. There exists a probability space $(\Omega, \widehat{\mathscr{F}}, P)$ and a linear mapping $W$ such that

$$
E(W(f) W(g))=(f, g)
$$

and $\left(W\left(f_{1}\right), W\left(f_{2}\right), \cdots, W\left(f_{n}\right)\right)$ is normally distributed with mean $\mathbf{0}$. Next define $\mathscr{F}=$ $\sigma(W(h): h \in H)$.

Consider the special example where $H=L^{2}(0, \infty ; \mathbb{R})$, real valued functions which are square integrable with respect to Lebesgue measure. Note that for each $t \in[0, \infty), \mathscr{X}_{[0, t)} \in$ $H$. Let

$$
W(t) \equiv W\left(\mathscr{X}_{(0, t)}\right)
$$

Then from definition, if $t_{1}<t_{2}<\cdots<t_{m}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent. This is because, due to the linearity of $W$, each of these equals

$$
W\left(\mathscr{X}_{\left(0, t_{i}\right)}-\mathscr{X}_{\left(0, t_{i-1}\right)}\right)=W\left(\mathscr{X}_{\left(t_{i-1}, t_{i}\right)}\right)
$$

and from Corollary 64.6.1, the random vector $\left(W\left(\mathscr{X}_{\left(t_{1}, t_{2}\right)}\right), \cdots, W\left(\mathscr{X}_{\left(t_{m}, t_{m-1}\right)}\right)\right)$ is normally distributed with covariance equal to a diagonal matrix. Also

$$
E\left(W(t)^{2}\right)=E\left(W\left(\mathscr{X}_{(0, t)}\right)^{2}\right)=\int_{0}^{\infty} \mathscr{X}_{(0, t)}^{2} d s=t
$$

More generally,

$$
\begin{gathered}
W(t)-W(s)=W\left(\mathscr{X}_{(0, t)}\right)-W\left(\mathscr{X}_{(0, s)}\right)=W\left(\mathscr{X}_{(s, t)}\right) \\
W(t-s)=W\left(\mathscr{X}_{(0, t-s)}\right)
\end{gathered}
$$

so both $W(t)-W(s)$ and $W(t-s)$ are normally distrubuted with mean 0 and variance $t-s$. What about the Holder continuity? The characteristic function of $W(t)-W(s)$ is

$$
E\left(e^{i \lambda(W(t-s))}\right)=e^{\frac{1}{2} \lambda^{2}|t-s|}
$$

Consider a few derivatives of the right side with respect to $\lambda$ and then let $\lambda=0$. This will yield $E\left((W(t)-W(s))^{n}\right)$ for $n=1,2,3,4$.

$$
0,|s-t|, 0,3|s-t|^{2}
$$

You see the pattern. By induction, you can show that $E\left((W(t)-W(s))^{2 m}\right)=C_{m}|t-s|^{m}$. By the Kolmogorov Centsov theorem, Theorem 62.2.3,

$$
E\left(\sup _{0 \leq s<t \leq T} \frac{\|W(t)-W(s)\|}{(t-s)^{\gamma}}\right) \leq C_{m}
$$

whenever $\gamma<\beta / \alpha=\frac{m-1}{2 m}$. Thus the above is true whenever $\gamma<1 / 2$. It follows that there exists a set of measure zero off which $t \rightarrow W(t)$ is Holder continuous with exponent $\gamma<$ 1/2.

Thus this gives a construction of the real Wiener process. Now consider the normal filtration

$$
\mathscr{F}_{s} \equiv \cap_{t>s} \overline{\sigma(W(u)-W(r): 0 \leq r<u \leq t)}
$$

By Lemma 64.4.2, $\{W(t)\}$ is a martingale with respect to this filtration, because of the independence of the increments.

You could also take an arbitrary $f \in L^{2}(0, \infty)$ and consider $W(t) \equiv W\left(\mathscr{X}_{(0, t)} f\right)$. You could consider this as an integral and write it in the notation

$$
W(t) \equiv \int_{0}^{t} f d W \equiv W\left(f \mathscr{X}_{(0, t)}\right)
$$

Then from the construction,

$$
E\left(\left(\int_{0}^{t} f d W\right)^{2}\right)=E\left(W\left(f \mathscr{X}_{(0, t)}\right)^{2}\right)=\int_{0}^{T} f^{2} \mathscr{X}_{(0, t)} d s=\int_{0}^{t}|f|^{2} d s=E\left(\int_{0}^{t}|f|^{2} d s\right)
$$

because $f$ does not depend on $\omega$. This of course is formally the Ito isometry.

### 64.6.3 $Q$ Wiener Processes In Hilbert Space

Now let $U$ be a real separable Hilbert space. Let an orthonormal basis for $U$ be $\left\{g_{i}\right\}$. Now let $L^{2}(0, \infty, U)$ be $H$ in the above construction. For $h, g \in L^{2}(0, \infty, U)$.

$$
E(W(h) W(g))=(h, g)_{L^{2}(0, \infty, U)} \equiv(h, g)_{H}
$$

Here each $W(g)$ will be a real valued normal random variable, the variance of $W(g)$ is $|g|_{L^{2}(0, \infty, U)}^{2}$ and its mean is 0 , every vector $\left(W\left(h_{1}\right), \cdots, W\left(h_{n}\right)\right)$ being generalized multivariate normal. Let

$$
\psi_{k}(t)=W\left(\mathscr{X}_{(0, t)} g_{k}\right)
$$

Then this is a real valued random variable. Disjoint increments are obviously independent in the same way as before. Also

$$
\begin{equation*}
E\left(\psi_{k}(t) \psi_{j}(s)\right)=E\left(W\left(\mathscr{X}_{(0, t)} g_{k}\right) W\left(\mathscr{X}_{(0, s)} g_{j}\right)\right) \equiv \int_{0}^{\infty} \mathscr{X}_{(0, t \wedge s)}\left(g_{k}, g_{j}\right)_{U} d t=0 \tag{64.6.36}
\end{equation*}
$$

if $j \neq k$. Thus the random variables $\psi_{k}(t)$ and $\psi_{j}(s)$ are independent. This is because, from the construction, $\left(\psi_{k}(t), \psi_{j}(s)\right)$ is normally distributed and the covariance is a diagonal matrix. Also

$$
\begin{gathered}
\psi_{k}(t)-\psi_{k}(s)=W\left(\mathscr{X}_{(0, t)} J g_{k}\right)-W\left(\mathscr{X}_{(0, s)} J g_{k}\right)=W\left(\mathscr{X}_{(s, t)} J g_{k}\right) \\
\psi_{k}(t-s) \equiv W\left(\mathscr{X}_{(0, t-s)} J g_{k}\right)
\end{gathered}
$$

so $\psi_{k}(t-s)$ has the same mean, 0 and variance, $|t-s|$, as $\psi_{k}(t)-\psi_{s}(s)$. Thus these have the same distribution because both are normally distributed.

Now let $J$ be a Hilbert Schmidt map from $U$ to $H$. Then consider

$$
\begin{equation*}
W(t)=\sum_{k} \psi_{k}(t) J g_{k} . \tag{64.6.37}
\end{equation*}
$$

This has values in $H$. It is shown below that the series converges in $L^{2}(\Omega ; H)$. Recall the definition of a $Q$ Wiener process.

Definition 64.6.7 Let $W(t)$ be a stochastic process with values in $H$, a real separable Hilbert space which has the properties that $t \rightarrow W(t, \omega)$ is continuous, whenever $t_{1}<$ $t_{2}<\cdots<t_{m}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent, $W(0)=0$, and whenever $s<t$,

$$
\mathscr{L}(W(t)-W(s))=N(0,(t-s) Q)
$$

which means that whenever $h \in H$,

$$
\mathscr{L}((h, W(t)-W(s)))=N(0,(t-s)(Q h, h))
$$

Also

$$
E\left(\left(h_{1}, W(t)-W(s)\right)\left(h_{2}, W(t)-W(s)\right)\right)=\left(Q h_{1}, h_{2}\right)(t-s) .
$$

Here $Q$ is a nonnegative trace class operator. Recall this means

$$
Q=\sum_{i=1}^{\infty} \lambda_{i} e_{i} \otimes e_{i}
$$

where $\left\{e_{i}\right\}$ is a complete orthonormal basis, $\lambda_{i} \geq 0$, and

$$
\sum_{i=1}^{\infty} \lambda_{i}<\infty
$$

Such a stochastic process is called a $Q$ Wiener process. In the case where these have values in $\mathbb{R}^{n}$, tQ ends up being the covariance matrix of $W(t)$.

Proposition 64.6.8 The process defined in 64.6 .37 is a $Q$ Wiener process in $H$ where $Q=$ $J J^{*}$.

Proof: First, why does the sum converge? Consider the sum for an increment in time. Let $t_{i-1}=0$ to obtain the convergence of the sum for a given $t$. Consider the difference of two partial sums.

$$
\begin{aligned}
& E\left(\sum_{k, l=m}^{n}\left(\psi_{k}\left(t_{i}\right)-\psi_{k}\left(t_{i-1}\right)\right) J g_{k},\left(\psi_{l}\left(t_{i}\right)-\psi_{l}\left(t_{i-1}\right)\right) J g_{k}\right) \\
= & E\left(\sum_{k, l=m}^{n}\left(J^{*} J g_{k}, g_{l}\right)\left(\psi_{k}\left(t_{i}\right)-\psi_{k}\left(t_{i-1}\right)\right)\left(\psi_{l}\left(t_{i}\right)-\psi_{l}\left(t_{i-1}\right)\right)\right) \\
= & \sum_{k, l=m}^{n}\left(J^{*} J g_{k}, g_{l}\right) E\left(\left(\psi_{k}\left(t_{i}\right)-\psi_{k}\left(t_{i-1}\right)\right)\left(\psi_{l}\left(t_{i}\right)-\psi_{l}\left(t_{i-1}\right)\right)\right) \\
= & \sum_{k=m}^{n}\left(J^{*} J g_{k}, g_{k}\right) E\left(\psi_{k}\left(t_{i}\right)-\psi_{k}\left(t_{i-1}\right)^{2}\right)=\sum_{k=m}^{n}\left(J^{*} J g_{k}, g_{k}\right)\left(t_{i}-t_{i-1}\right) \\
= & \sum_{k=m}^{n}\left|J g_{k}\right|_{H}^{2}\left(t_{i}-t_{i-1}\right)
\end{aligned}
$$

and this converges to 0 as $m, n \rightarrow \infty$ since $J$ is Hilbert Schmidt. Thus the sum converges in $L^{2}(\Omega, H)$. Why are the disjoint increments independent?

Let $\lambda_{k} \in H$. Consider $t_{0}<t_{1}<\cdots<t_{n}$.

$$
\begin{equation*}
E\left(\exp i \sum_{k=1}^{n}\left(\lambda_{k}, W\left(t_{k}\right)-W\left(t_{k-1}\right)\right)\right)=\prod_{k=1}^{n} E\left(\exp \left(i\left(\lambda_{k}, W\left(t_{k}\right)-W\left(t_{k-1}\right)\right)\right)\right) ? \tag{64.6.38}
\end{equation*}
$$

Start with the left. There are finitely many increments concerned and so it can be assumed that for each $k$ one can have $m \rightarrow \infty$ such that the partial sums up to $m$ in the definition of $W\left(t_{k}\right)-W\left(t_{k-1}\right)$ converge pointwise a.e. Thus

$$
\begin{aligned}
& E\left(\exp i \sum_{k=1}^{n}\left(\lambda_{k}, W\left(t_{k}\right)-W\left(t_{k-1}\right)\right)\right) \\
= & \lim _{m \rightarrow \infty} E\left(\exp i \sum_{k=1}^{n}\left(\lambda_{k}, \sum_{j=1}^{m}\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right) \\
= & \lim _{m \rightarrow \infty} E\left(\exp \sum_{k=1}^{n} \sum_{j=1}^{m} i\left(\lambda_{k},\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right) \\
= & \lim _{m \rightarrow \infty} E\left(\prod_{j=1}^{m} \exp \left(\sum_{k=1}^{n} i\left(\lambda_{k},\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right)\right)
\end{aligned}
$$

Now from 64.6.36, $\left\{\sum_{k=1}^{n} i\left(\lambda_{k},\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right\}_{j=1}^{m}$ are independent. Hence the above equals

$$
\begin{aligned}
& =\lim _{m \rightarrow \infty} \prod_{j=1}^{m} E\left(\exp \left(\sum_{k=1}^{n} i\left(\lambda_{k},\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right)\right) \\
& =\lim _{m \rightarrow \infty} \prod_{j=1}^{m} E\left(\prod_{k=1}^{n} \exp \left(i\left(\lambda_{k},\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right)\right)
\end{aligned}
$$

Now from independence of the increments for the $\psi_{j}$, this equals

$$
\begin{align*}
& =\lim _{m \rightarrow \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} E\left(\exp \left(i\left(\lambda_{k},\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right)\right) \\
= & \lim _{m \rightarrow \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} E\left(\exp \left(i\left(\lambda_{k}, J g_{j}\right)\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right)\right)\right) \\
= & \lim _{m \rightarrow \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} e^{-\frac{1}{2}\left(\lambda_{k}, J g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)}=\lim _{m \rightarrow \infty} \prod_{j=1}^{m} e^{-\frac{1}{2} \sum_{k=1}^{n}\left(\lambda_{k}, J g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)} \\
= & \lim _{m \rightarrow \infty} \exp \left(-\frac{1}{2} \sum_{j=1}^{m} \sum_{k=1}^{n}\left(\lambda_{k}, J g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)\right) \\
= & \exp \left(-\frac{1}{2} \sum_{k=1}^{n} \sum_{j=1}^{\infty}\left(J^{*} \lambda_{k}, g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)\right) \tag{64.6.39}
\end{align*}
$$

What is the right side of 64.6 .38 .

$$
\begin{aligned}
& \prod_{k=1}^{n} E\left(\exp \left(i\left(\lambda_{k}, W\left(t_{k}\right)-W\left(t_{k-1}\right)\right)\right)\right) \\
= & \prod_{k=1}^{n} E\left[\exp \left(i\left(\lambda_{k}, \sum_{j=1}^{\infty}\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right)\right] \\
= & \lim _{m \rightarrow \infty} \prod_{k=1}^{n} E\left[\exp \left(i\left(\lambda_{k}, \sum_{j=1}^{m}\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right) J g_{j}\right)\right)\right] \\
= & \lim _{m \rightarrow \infty} \prod_{k=1}^{n} E\left[\exp \left(i \sum_{j=1}^{m}\left(J g_{j}, \lambda_{k}\right)\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right)\right)\right] \\
= & \lim _{m \rightarrow \infty} \prod_{k=1}^{n} E\left(\prod_{j=1}^{m} i\left(J^{*} \lambda_{k}, g_{j}\right)\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right)\right)
\end{aligned}
$$

and by independence, 64.6.36,

$$
\begin{aligned}
& =\lim _{m \rightarrow \infty} \prod_{k=1}^{n} \prod_{j=1}^{m} E\left[i\left(J^{*} \lambda_{k}, g_{j}\right)\left(\psi_{j}\left(t_{k}\right)-\psi_{j}\left(t_{k-1}\right)\right)\right] \\
& =\lim _{m \rightarrow \infty} \prod_{k=1}^{n} \prod_{j=1}^{m} e^{-\frac{1}{2}\left(J^{*} \lambda_{k}, g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)}=\lim _{m \rightarrow \infty} \prod_{k=1}^{n} \exp \left(-\frac{1}{2} \sum_{j=1}^{m}\left(J^{*} \lambda_{k}, g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)\right) \\
& =\prod_{k=1}^{n} \exp \left(-\frac{1}{2} \sum_{j=1}^{\infty}\left(J^{*} \lambda_{k}, g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)\right) \\
& =\exp \left(-\frac{1}{2} \sum_{k=1}^{n} \sum_{j=1}^{\infty}\left(J^{*} \lambda_{k}, g_{j}\right)^{2}\left(t_{k}-t_{k-1}\right)\right)
\end{aligned}
$$

which is exactly the same thing as 64.6 .39 . Thus the disjoint increments are independent.
You could also do something like the following. Let $W_{m}(t)$ denote the partial sum for $W(t)$ and since there are only finitely many increments, we can assume the partial sums converge a.e. Then we need to consider the random variables

$$
\left\{\left(W_{m}\left(t_{k}\right)-W_{m}\left(t_{k-1}\right)\right)\right\}_{k=1}^{m}=\left\{\left(\sum_{i=1}^{m}\left(\psi_{i}\left(t_{k}\right)-\psi_{i}\left(t_{k-1}\right)\right) J g_{i}\right)\right\}_{k=1}^{m}
$$

Then for any $h \in H$, you could consider

$$
\left\{\left(\sum_{i=1}^{m}\left(\psi_{i}\left(t_{k}\right)-\psi_{i}\left(t_{k-1}\right)\right)\left(J g_{i}, h\right)_{H}\right)\right\}_{k=1}^{m}
$$

and the vector whose $k^{t h}$ component is $\sum_{i=1}^{m}\left(\psi_{i}\left(t_{k}\right)-\psi_{i}\left(t_{k-1}\right)\right)\left(J g_{i}, h\right)_{H}$ for $k=1,2, \cdots, n$ is normally distributed and the covariance is a diagonal matrix. Hence these are independent random variables as hoped. Now you can pass to a limit as $m \rightarrow \infty$. Since this is true
for any $h \in H$ that the random variables $\left(W\left(t_{k}\right)-W\left(t_{k-1}\right), h\right)_{H}$ are independent, it follows that the random variables $W\left(t_{k}\right)-W\left(t_{k-1}\right)$ are also.

What of the Holder continuity? In the above computation for independence, as a special case, for $\lambda \in H$,

$$
\begin{equation*}
E(\exp i(\lambda, W(t)-W(s)))=\exp \left(-\frac{1}{2}\left|J^{*} \lambda\right|_{U}^{2}(t-s)\right) \tag{64.6.40}
\end{equation*}
$$

In particular, replacing $\lambda$ with $\lambda r$ for $r$ real,

$$
E(\exp \operatorname{ir}(\lambda, W(t)-W(s)))=\exp \left(-\frac{1}{2} r^{2}\left|J^{*} \lambda\right|_{U}^{2}(t-s)\right)
$$

Now we differentiate with respect to $r$ and then take $r=0$ as before to obtain finally that

$$
E\left((\lambda, W(t)-W(s))^{2 m}\right) \leq C_{m}\left|J^{*} \lambda\right|^{2 m}|t-s|^{m}=C_{m}(Q \lambda, \lambda)^{m}|t-s|^{m}
$$

Then letting $\left\{h_{k}\right\}$ be an orthonormal basis for $H$, and using the above inequality with Minkowski’s inequalitiy,

$$
\begin{aligned}
& \left(E\left(|W(t)-W(s)|^{2 m}\right)\right)^{1 / m}=\left(E\left(\left[\sum_{k=1}^{\infty}\left(W(t)-W(s), h_{k}\right)^{2}\right]^{m}\right)\right)^{1 / m} \\
& \leq \sum_{k=1}^{\infty}\left[E\left(\left(W(t)-W(s), h_{k}\right)^{2 m}\right)\right]^{1 / m} \leq \sum_{k=1}^{\infty}\left(C_{m}(t-s)^{m}\left|J^{*} h_{k}\right|_{U}^{2 m}\right)^{1 / m} \\
& =C_{m}^{1 / m}|t-s| \sum_{k=1}^{\infty}\left|J^{*} h_{k}\right|_{U}^{2}=C_{m}^{1 / m}|t-s| \sum_{k=1}^{\infty} \sum_{j=1}^{\infty}\left(J^{*} h_{k}, g_{j}\right)^{2} \\
& =C_{m}^{1 / m}|t-s| \sum_{j=1}^{\infty} \sum_{k=1}^{\infty}\left(h_{k}, J g_{j}\right)^{2}=|t-s| C_{m}^{1 / m} \sum_{j=1}^{\infty}\left|J g_{j}\right|_{H}^{2}
\end{aligned}
$$

and since $J$ is Hilbert Schmidt, modifying the constant yields

$$
E\left(|W(t)-W(s)|^{2 m}\right) \leq C_{m}|t-s|^{m}
$$

By the Kolmogorov Centsov theorem, Theorem 62.2.3,

$$
E\left(\sup _{0 \leq s<t \leq T} \frac{\|W(t)-W(s)\|}{(t-s)^{\gamma}}\right) \leq C_{m}
$$

whenever $\gamma<\beta / \alpha=\frac{m-1}{2 m}$. Thus the above is true whenever $\gamma<1 / 2$. Hence off a set of measure zero, $t \rightarrow W(t)$ is Holder continuous.

What of the covariance condition? From 64.6.40, letting $f, g$ be two elements of $H$,

$$
E(\exp i(\alpha f+\beta g, W(t)-W(s)))=\exp \left(-\frac{1}{2}(Q(\alpha f+\beta g), \alpha f+\beta g)(t-s)\right)
$$

Differentiate with respect to $\alpha$

$$
\begin{aligned}
& E(i(f, W(t)-W(s)) \exp i(\alpha f+\beta g, W(t)-W(s))) \\
= & -[\alpha(Q f, f)+(Q f, \beta g)](t-s) \exp \left(-\frac{1}{2}(Q(\alpha f+\beta g), \alpha f+\beta g)(t-s)\right)
\end{aligned}
$$

Let $\alpha=0$.

$$
\begin{aligned}
& E(i(f, W(t)-W(s)) \exp i(\beta g, W(t)-W(s))) \\
= & -[(Q f, \beta g)](t-s) \exp \left(-\frac{1}{2}(Q(\beta g), \beta g)(t-s)\right)
\end{aligned}
$$

Now differentiate with respect to $\beta$

$$
\begin{gathered}
E(-(f, W(t)-W(s))(g, W(t)-W(s)) \exp i(\beta g, W(t)-W(s))) \\
=-[(Q f, g)](t-s) \exp \left(-\frac{1}{2}(Q(\beta g), \beta g)(t-s)\right)+-[(Q f, \beta g)](t-s)(\text { something })
\end{gathered}
$$

Now let $\beta=0$.

$$
E((f, W(t)-W(s))(g, W(t)-W(s)))=(Q f, g)(t-s)
$$

Finally, $Q=J J^{*}$. It is self adjoint and nonnegative and so there is a complete orthonormal basis $\left\{e_{i}\right\}$ such that $Q e_{i}=\lambda_{i} e_{i}$. Then $\lambda_{i}=\left(Q e_{i}, e_{i}\right)_{H}$ and so

$$
\sum_{i} \lambda_{i}=\sum_{i}\left(Q e_{i}, e_{i}\right)=\sum_{i}\left|J^{*} e_{i}\right|_{U}^{2}<\infty
$$

because $J$ and hence $J^{*}$ are both Hilbert Schmidt operators.
Recall the notion of the Hilbert space $L U$ in Definition 19.2.1.
What if you have a given $Q \in \mathscr{L}(H, H)$ which is trace class, $Q=Q^{*}$, and nonnegative. Does there exist a $Q$ Wiener process of the sort just described? It appears this amounts to obtaining a Hilbert Schmidt map $J$ from some Hilbert space $U$ to $H$ such that $Q=J J^{*}$.

Since $Q$ is trace class and is self adjoint, it follows that there is an orthonormal basis $\left\{e_{i}\right\}, Q e_{i}=\lambda_{i} e_{i}$, where $\lambda_{i}$ is positive for $i \leq L$ or positive for all $i$. Then

$$
Q^{1 / 2}=\sum_{i=1}^{L} \sqrt{\lambda_{i}} e_{i} \otimes e_{i}
$$

and

$$
Q^{1 / 2} e_{i}=\sqrt{\lambda_{i}} e_{i}
$$

Then also on $Q^{1 / 2} H$,

$$
\left(Q^{1 / 2} e_{i}, Q^{1 / 2} e_{j}\right)_{Q^{1 / 2} H} \equiv\left(e_{i}, e_{j}\right)_{H}
$$

and so an orthonormal basis in $Q^{1 / 2} H$ is $\left\{\sqrt{\lambda_{i}} e_{i}\right\}_{i=1}^{L}$. Then define $J: Q^{1 / 2} H \rightarrow H$

$$
J x \equiv \sum_{k=1}^{L}\left(x, \sqrt{\lambda_{k}} e_{k}\right)_{Q^{1 / 2} H} \sqrt{\lambda_{k}} e_{k}
$$

It follows from the above that

$$
J e_{j}=\sum_{k=1}^{L} \frac{1}{\sqrt{\lambda_{j}}} \overbrace{\left(\sqrt{\lambda_{j}} e_{j}, \sqrt{\lambda_{k}} e_{k}\right)_{Q^{1 / 2} H}}^{\delta_{i j}} \sqrt{\lambda_{k}} e_{k}=e_{j}
$$

Then

$$
\begin{aligned}
\sum_{i=1}^{L}\left|J \sqrt{\lambda_{i}} e_{i}\right|_{H}^{2} & =\sum_{i=1}^{L}\left|\sum_{k=1}^{L}\left(\sqrt{\lambda_{i}} e_{i}, \sqrt{\lambda_{k}} e_{k}\right)_{Q^{1 / 2} H} \sqrt{\lambda_{k}} e_{k}\right|_{H}^{2} \\
& =\sum_{i=1}^{L}\left|\sqrt{\lambda_{i}} e_{i}\right|_{H}^{2}=\sum_{i=1}^{L} \lambda_{i}<\infty
\end{aligned}
$$

Thus it is clear that $J$ is Hilbert Schmidt. Is $J J^{*}=Q$ ? For $y \in Q^{1 / 2} H, x \in H$,

$$
\begin{aligned}
\left(J^{*} x, y\right)_{Q^{1 / 2} H} & \equiv(x, J(y))_{H}=\left(x, \sum_{k=1}^{L}\left(y, \sqrt{\lambda_{k}} e_{k}\right)_{Q^{1 / 2} H} \sqrt{\lambda_{k}} e_{k}\right)_{H} \\
& =\sum_{k=1}^{L}\left(x, \sqrt{\lambda_{k}} e_{k}\right)_{H}\left(y, \sqrt{\lambda_{k}} e_{k}\right)_{Q^{1 / 2} H}
\end{aligned}
$$

Thus for $y \in H, x \in H$,

$$
\begin{aligned}
\left(J^{*} x, J^{*} y\right)_{Q^{1 / 2} H} & =\sum_{k=1}^{L}\left(x, \sqrt{\lambda_{k}} e_{k}\right)_{H}\left(J^{*} y, \sqrt{\lambda_{k}} e_{k}\right)_{Q^{1 / 2} H} \\
& \equiv \sum_{k=1}^{L}\left(x, \sqrt{\lambda_{k}} e_{k}\right)_{H}\left(y, \sqrt{\lambda_{k}} J e_{k}\right)_{H} \\
& =\sum_{k=1}^{L} \lambda_{k}\left(x, e_{k}\right)_{H}\left(y, e_{k}\right)_{H}=(Q x, y)
\end{aligned}
$$

and so $\left(J J^{*} x, y\right)=(Q x, y)$ showing that $J J^{*}=Q$. This shows the following.
Proposition 64.6.9 Let $Q \in \mathscr{L}(H, H)$ where $H$ is a real separable Hilbert space and $(Q x, x) \geq 0$ and is trace class. Then there exists a one to one Hilbert Schmidt map J : $Q^{1 / 2} H \rightarrow H$ such that $J J^{*}=Q$. Then the $Q$ Wiener process is $W(t)=\sum_{k=1}^{\infty} \psi_{k}(t) J g_{k}$ where $\left\{g_{k}\right\}$ is a complete orthonormal basis for the Hilbert space $Q^{1 / 2} H$.

Note that in case $H$ is $\mathbb{R}^{p}$ and $Q$ is any symmetric $p \times p$ matrix, having nonnegative eigenvalues, this is automatically trace class and so the above conclusion holds. In particular, the covariance condition says in this case that

$$
\begin{aligned}
& E\left(\left(\mathbf{e}_{i}, \mathbf{W}(t)-\mathbf{W}(s)\right)\left(\mathbf{e}_{j}, \mathbf{W}(t)-\mathbf{W}(s)\right)\right) \\
= & E\left(\left(W_{i}(t)-W_{i}(s)\right)\left(W_{j}(t)-W_{j}(s)\right)\right)=\left(Q e_{i}, e_{j}\right)=Q_{i j}
\end{aligned}
$$

This is a $p$ dimensional Wiener process.

### 64.6.4 Levy's Theorem In Hilbert Space

Recall the concept of quadratic variation. Let $W(t)$ be a $Q$ Wiener process. Does it follow $\{W(t)\} \in \mathscr{M}_{T}^{2}(H)$ ? The Wiener process is continuous. Furthermore,

$$
E\left(|W(t)|_{H}^{2}\right)<\infty
$$

for each $t \in[0, T]$. Since $\{W(t)\}$ is a martingale, Theorem 62.5.3 can be applied to conclude

$$
E\left(|W(t)|_{H}^{2}\right)^{1 / 2} \leq E\left(\left(\sup _{t \in[0, T]}|W(t)|\right)^{2}\right)^{1 / 2} \leq 2 E\left(|W(T)|_{H}^{2}\right)^{1 / 2}
$$

and so $\{W(t)\} \in \mathscr{M}_{T}^{2}(H)$. Therefore, by the Doob Meyer decomposition, Theorem 63.7.15, there exists an increasing natural process, $A(t)$ and a martingale, $Y(t)$ such that

$$
|W(t)|_{H}^{2}=Y(t)+A(t)
$$

What is $A(t)$ ? Consider the process

$$
|W(t)|^{2}
$$

From Theorem 64.5.4 this equals

$$
\sum_{k=1}^{\infty} \lambda_{k} \psi_{k}(t)^{2}
$$

where $\psi_{k}(t)$ is a one dimensional Wiener process and

$$
Q=\sum_{k=1}^{\infty} \lambda_{k} e_{k} \otimes e_{k}, \sum_{k=1}^{\infty} \lambda_{k}<\infty .
$$

By Lemma 64.4.2, $\{W(t)\}$ is a martingale. Therefore, for $s<t$ and $A \in \mathscr{F}_{s}$, it follows since $\mathscr{X}_{A}$ is independent of $W(t)-W(s)$ as in the proof of Lemma 64.4.2 that the following holds.

$$
\begin{gathered}
\int_{A} E\left(|W(t)|^{2} \mid \mathscr{F}_{s}\right)-|W(s)|^{2} d P \\
=\int_{A} E\left(|W(t)|^{2}+|W(s)|^{2}-2 W(t) \cdot W(s) \mid \mathscr{F}_{s}\right) d P \\
=\int_{A} E\left(|W(t)-W(s)|^{2} \mid \mathscr{F}_{s}\right) d P=\int_{A}|W(t)-W(s)|^{2} d P \\
=P(A) \int_{\Omega}|W(t)-W(s)|^{2} d P \\
=P(A) \sum_{k=1}^{\infty} \lambda_{k} E\left(\left(\psi_{k}(t)-\psi_{k}(s)\right)^{2}\right) \\
=P(A)(t-s) \sum_{k=1}^{\infty} \lambda_{k}=P(A)(t-s) \operatorname{tr}(Q) .
\end{gathered}
$$

Therefore,

$$
\int_{A} E\left(|W(t)|^{2}-t \operatorname{tr}(Q) \mid \mathscr{F}_{s}\right)-\left(|W(s)|^{2}-s \operatorname{tr}(Q)\right) d P=0
$$

and since $A \in \mathscr{F}_{s}$ is arbitrary, this shows $\left\{|W(t)|^{2}-t \operatorname{tr}(Q)\right\}$ is a martingale. Hence the Doob Meyer decomposition for $|W(t)|^{2}$ is

$$
|W(t)|^{2}=Y(t)+t \operatorname{tr}(Q)
$$

where $Y(t)$ is a martingale.
There is a generalization of Levy's theorem to Hilbert space valued Wiener processes.
Theorem 64.6.10 Let $\{W(t)\} \in \mathscr{M}_{T}^{2}(H), E(W(t))=0$, where $H$ is a real separable Hilbert space. Then for $Q$ a nonnegative symmetric trace class operator, $\{W(t)\}$ is a $Q$ Wiener process if and only if both $\{W(t)\}$ and $\left\{(W(t), h)^{2}-t(Q h, h)\right\}$ are martingales for every $h \in H$.

Proof: First suppose $\{W(t)\}$ is a $Q$ Wiener process. Then defining the filtration to be

$$
\mathscr{F}_{t} \equiv \sigma(W(s)-W(u): u \leq s \leq t)
$$

it follows from Lemma 64.4.2 that $\{W(t)\}$ is a martingale. Consider

$$
\left\{(W(t), h)^{2}-t(Q h, h)\right\} .
$$

Let $A \in \mathscr{F}_{s}$ where $s \leq t$. Then using the fact $\{W(t)\}$ is a martingale,

$$
\begin{gathered}
\int_{A} E\left((W(t)-W(s), h)^{2} \mid \mathscr{F}_{s}\right) d P \\
=\int_{A} E\left((W(t), h)^{2}+(W(s), h)^{2}-2(W(t), h)(W(s), h) \mid \mathscr{F}_{s}\right) d P \\
=\int_{A} E\left((W(t), h)^{2} \mid \mathscr{F}_{s}\right)+(W(s), h)^{2}-E\left(2(W(t), h)(W(s), h) \mid \mathscr{F}_{s}\right) d P \\
=\int_{A} E\left((W(t), h)^{2} \mid \mathscr{F}_{s}\right) d P+\int_{A}(W(s), h)^{2} d P \\
-\int_{A}(W(s), h) E\left(2(W(t), h) \mid \mathscr{F}_{s}\right) d P \\
=\int_{A} E\left((W(t), h)^{2} \mid \mathscr{F}_{s}\right) d P-\int_{A}(W(s), h)^{2} d P .
\end{gathered}
$$

Also since $\mathscr{X}_{A}$ is independent of $(W(t)-W(s), h)^{2}$ as in the proof of Lemma 64.4.2, and $\{W(t)\}$ is a $Q$ Wiener process,

$$
\begin{aligned}
& \int_{A} E\left((W(t)-W(s), h)^{2} \mid \mathscr{F}_{s}\right) d P \\
= & \int_{A}(W(t)-W(s), h)^{2} d P \\
= & P(A) \int_{\Omega}(W(t)-W(s), h)^{2} d P \\
= & P(A)(t-s)(Q h, h)
\end{aligned}
$$

Thus, this has shown that for all $A \in \mathscr{F}_{s}$,

$$
\begin{aligned}
& \int_{A} E\left((W(t), h)^{2} \mid \mathscr{F}_{s}\right) d P-\int_{A}(W(s), h)^{2} d P \\
= & P(A)(t-s)(Q h, h)=\int_{A}(t-s)(Q h, h) d P
\end{aligned}
$$

and since $A \in \mathscr{F}_{s}$ is arbitrary, this proves

$$
E\left((W(t), h)^{2}-t(Q h, h) \mid \mathscr{F}_{s}\right)=(W(s), h)^{2}-s(Q h, h)
$$

This proves one half of the theorem.
Next suppose both $\{W(t)\}$ and $\left\{(W(t), h)^{2}-t(Q h, h)\right\}$ are martingales for any $h \in H$. It follows that both $\{(W(t), h)\}$ and $\left\{(W(t), h)^{2}-t(Q h, h)\right\}$ are martingales also. Therefore, by Levy's theorem, Theorem 63.8.5, $\{(W(t), h)\}$ is a Wiener process with the property that its variance at $t$ equals $(Q h, h) t$ instead of $t$. Thus the time increments are normal and independent. I need to verify that $\{W(t)\}$ is a $Q$ Wiener process. One of the things which needs to be shown is that

$$
\begin{equation*}
E\left(\left(W(t)-W(s), h_{1}\right)\left(W(t)-W(s), h_{2}\right)\right)=\left(Q h_{1}, h_{2}\right)(t-s) . \tag{64.6.41}
\end{equation*}
$$

I have just shown

$$
\begin{equation*}
E\left((W(t)-W(s), h)^{2}\right)=(t-s)(Q h, h) \tag{64.6.42}
\end{equation*}
$$

which follows from Levy's theorem which concludes $\{(W(t), h)\}$ is a Wiener process. Therefore,

$$
\begin{aligned}
& E\left(\left(W(t)-W(s), h_{1}+h_{2}\right)\left(W(t)-W(s), h_{2}+h_{1}\right)\right) \\
= & \left(Q\left(h_{1}+h_{2}\right),\left(h_{1}+h_{2}\right)\right)(t-s)
\end{aligned}
$$

Now using 64.6.42, it follows from this that

$$
E\left(\left(W(t)-W(s), h_{1}\right)\left(W(t)-W(s), h_{2}\right)\right)=\left(Q h_{1}, h_{2}\right)(t-s)
$$

which shows 64.6.41. This completes the proof.

## Chapter 65

## Stochastic Integration

### 65.1 Integrals Of Elementary Processes

Stochastic integration starts with a $Q$ Wiener process having values in a separable Hilbert space $U$. Thus it satisfies the following definition.

Definition 65.1.1 Let $W(t)$ be a stochastic process with values in $U$, a real separable Hilbert space which has the properties that $t \rightarrow W(t, \omega)$ is continuous. Whenever $t_{1}<$ $t_{2}<\cdots<t_{m}$, the increments $\left\{W\left(t_{i}\right)-W\left(t_{i-1}\right)\right\}$ are independent, $W(0)=0$, and whenever $s<t$,

$$
\mathscr{L}(W(t)-W(s))=N(0,(t-s) Q)
$$

which means that whenever $h \in H$,

$$
\mathscr{L}((h, W(t)-W(s)))=N(0,(t-s)(Q h, h))
$$

Also

$$
E\left(\left(h_{1}, W(t)-W(s)\right)\left(h_{2}, W(t)-W(s)\right)\right)=\left(Q h_{1}, h_{2}\right)(t-s) .
$$

Here $Q$ is a nonnegative trace class operator. Recall this means

$$
Q=\sum_{i=1}^{\infty} \lambda_{i} e_{i} \otimes e_{i}
$$

where $\left\{e_{i}\right\}$ is a complete orthonormal basis, $\lambda_{i} \geq 0$, and

$$
\sum_{i=1}^{\infty} \lambda_{i}<\infty
$$

Such a stochastic process is called a $Q$ Wiener process.
Recall that such Wiener processes are always of the form

$$
\sum_{k=1}^{\infty} \psi_{k}(t) J g_{k}
$$

where $J$ is a Hilbert Schmidt operator from a suitable space $U_{0}$ to $U$ and the $\psi_{k}$ are real independent Wiener processes described earlier. This follows from Theorem 64.5.4 where you let $U_{0} \subseteq U$ be such that for $J$ the inclusion map, $J e_{k}=\sqrt{\lambda_{k}} e_{k}$ for $Q=\sum_{k} \lambda_{k} e_{k} \otimes e_{k}$, the $e_{k}$ an orthonormal set in $U$. Thus

$$
\begin{aligned}
(Q x, y) & =\left(\sum_{k} \lambda_{k} e_{k}\left(x, e_{k}\right), y\right)=\sum_{k}\left(x, \sqrt{\lambda_{k}} e_{k}\right)\left(y, \sqrt{\lambda_{k}} e_{k}\right) \\
& =\sum_{k}\left(x, J e_{k}\right)\left(y, J e_{k}\right)=\sum_{k}\left(J^{*} x, e_{k}\right)\left(J^{*} y, e_{k}\right)=\left(J^{*} x, J^{*} y\right)=\left(J J^{*} x, y\right)
\end{aligned}
$$

so it follows that $Q=J J^{*}$. Of course in finite dimensions, there is no issue because the identity map is Hilbert Schmidt.

Recall the definition of $\mathscr{L}_{2}(U, H) \equiv \mathscr{L}_{2}$ the space of Hilbert Schmidt operators. $\Psi \in$ $\mathscr{L}_{2}(U, H)$ means $\Psi$ has the property that for some (equivalently all) orthonormal basis of $U\left\{e_{k}\right\}$, it follows

$$
\sum_{k=1}^{\infty}\left\|\Psi\left(e_{k}\right)\right\|^{2}<\infty
$$

and the inner product for two of these, $\Psi, \Phi$ is given by

$$
(\Psi, \Phi)_{\mathscr{L}_{2}} \equiv \sum_{k}\left(\Psi\left(e_{k}\right), \Phi\left(e_{k}\right)\right)
$$

Then for such a Hilbert Schmidt operator, the norm in $\mathscr{L}_{2}$ is given by

$$
\left(\sum_{k=1}^{\infty}\left\|\Psi\left(e_{k}\right)\right\|^{2}\right)^{1 / 2} \equiv\|\Psi\|_{\mathscr{L}_{2}}
$$

Note this is the same as

$$
\begin{equation*}
\left(\sum_{k=1}^{\infty} \sum_{j=1}^{\infty}\left(\Psi\left(e_{k}\right), f_{j}\right)^{2}\right)^{1 / 2} \tag{65.1.1}
\end{equation*}
$$

where $\left\{f_{j}\right\}$ is an orthonormal basis for $H$. This is the analog of the Frobenius norm for matrices obtained as

$$
\operatorname{trace}\left(M M^{*}\right)^{1 / 2}=\left(\sum_{i}\left(M M^{*}\right)_{i i}\right)^{1 / 2}=\left(\sum_{i, j} M_{i j}^{2}\right)^{1 / 2}
$$

Also 65.1 .1 shows right away that if $\Psi \in \mathscr{L}_{2}(U, H)$, then

$$
\begin{aligned}
\|\Psi\|_{\mathscr{L}_{2}(U, H)}^{2} & =\sum_{k=1}^{\infty} \sum_{j=1}^{\infty}\left(\Psi e_{k}, f_{j}\right)_{H}^{2} \\
& =\sum_{k=1}^{\infty} \sum_{j=1}^{\infty}\left(e_{k}, \Psi^{*} f_{j}\right)_{U}^{2}=\left\|\Psi^{*}\right\|_{\mathscr{L}_{2}(H, U)}^{2}
\end{aligned}
$$

and that $\Psi$ and $\Psi^{*}$ are Hilbert Schmidt together.
The filtration will continue to be denoted by $\mathscr{F}_{t}$. It will be defined as the following normal filtration in which

$$
\overline{\sigma(W(s)-W(r): 0 \leq r<s \leq u)}
$$

is the completion of $\sigma(W(s)-W(r): 0 \leq r<s \leq u)$.

$$
\begin{equation*}
\mathscr{F}_{t} \equiv \cap_{u>t} \overline{\sigma(W(s)-W(r): 0 \leq r<s \leq u)} \tag{65.1.2}
\end{equation*}
$$

and $\sigma(W(s)-W(r): 0 \leq r<s \leq u)$ denotes the $\sigma$ algebra of all sets of the form

$$
(W(s)-W(r))^{-1}(\text { Borel })
$$

where $0 \leq r<s \leq u$.

Definition 65.1.2 Let $\Phi(t) \in \mathscr{L}(U, H)$ be constant on each interval, $\left(t_{m}, t_{m+1}\right]$ determined by a partition of $[a, T], 0 \leq a=t_{0}<t_{1} \cdots<t_{n}=T$. Then $\Phi(t)$ is said to be elementary if also $\Phi\left(t_{m}\right)$ is $\mathscr{F}_{t_{m}}$ measurable and $\Phi\left(t_{m}\right)$ equals a sum of the form

$$
\Phi\left(t_{m}\right)(\omega)=\sum_{j=1}^{m} \Phi_{j} \mathscr{X}_{A_{j}}
$$

where $\Phi_{j} \in \mathscr{L}(U, H), A_{j} \in \mathscr{F}_{t_{m}}$. What does the measurability assertion mean? It means that if $O$ is an open (Borel) set in the topological space $\mathscr{L}(U, H), \Phi\left(t_{m}\right)^{-1}(O) \in \mathscr{F}_{t_{m}}$. Thus an elementary function is of the form

$$
\Phi(t)=\sum_{k=0}^{n-1} \Phi\left(t_{k}\right) \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t)
$$

Then for $\Phi$ elementary, the stochastic integral is defined by

$$
\int_{a}^{t} \Phi(s) d W(s) \equiv \sum_{k=0}^{n-1} \Phi\left(t_{k}\right)\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right)
$$

It is also sometimes denoted by $\Phi \cdot W(t)$.
The above definition is the same as saying that for $t \in\left(t_{m}, t_{m+1}\right]$,

$$
\begin{align*}
\int_{a}^{t} \Phi(s) d W(s)= & \sum_{k=0}^{m-1} \Phi\left(t_{k}\right)\left(W\left(t_{k+1}\right)-W\left(t_{k}\right)\right) \\
& +\Phi\left(t_{m}\right)\left(W(t)-W\left(t_{m}\right)\right) \tag{65.1.3}
\end{align*}
$$

The following lemma will be useful.
Lemma 65.1.3 Let $f, g \in L^{2}(\Omega ; H)$ and suppose $g$ is $\mathscr{G}$ measurable and $f$ is $\mathscr{F}$ measurable where $\mathscr{F} \supseteq \mathscr{G}$. Then

$$
E\left((f, g)_{H} \mid \mathscr{G}\right)=(E(f \mid \mathscr{G}), g)_{H} \text { a.e. }
$$

Similarly if $\Phi$ is $\mathscr{G}$ measurable as a map into $\mathscr{L}(U, H)$ with

$$
\int_{\Omega}\|\Phi\|^{2} d P<\infty
$$

and $f$ is $\mathscr{F}$ measurable as a map into $U$ such that $f \in L^{2}(\Omega ; H)$, then

$$
E(\Phi f \mid \mathscr{G})=\Phi E(f \mid \mathscr{G})
$$

Proof: Let $A \in \mathscr{G}$. Let $\left\{g_{n}\right\}$ be a sequence of simple functions, measurable with respect to $\mathscr{G}$,

$$
g_{n}(\omega) \equiv \sum_{k=1}^{m_{n}} a_{k}^{n} \mathscr{X}_{E_{k}^{n}}(\omega)
$$

which converges in $L^{2}(\Omega ; H)$ and pointwise to $g$.Then

$$
\begin{gathered}
\int_{A}(E(f \mid \mathscr{G}), g)_{H} d P=\lim _{n \rightarrow \infty} \int_{A}\left(E(f \mid \mathscr{G}), g_{n}\right)_{H} d P \\
=\lim _{n \rightarrow \infty} \int_{A} \sum_{k=1}^{m_{n}}\left(E(f \mid \mathscr{G}), a_{k}^{n} \mathscr{X}_{E_{k}^{n}}\right)_{H} d P=\lim _{n \rightarrow \infty} \int_{A} \sum_{k=1}^{m_{n}} E\left(\left(f, a_{k}^{n}\right)_{H} \mid \mathscr{G}\right) \mathscr{X}_{E_{k}^{n}} d P \\
=\lim _{n \rightarrow \infty} \int_{A} \sum_{k=1}^{m_{n}} E\left(\left(f, a_{k}^{n} \mathscr{X}_{E_{k}^{n}}\right)_{H} \mid \mathscr{G}\right) d P=\lim _{n \rightarrow \infty} \int_{A} E\left(\left(f, \sum_{k=1}^{m_{n}} a_{k}^{n} \mathscr{X}_{E_{k}^{n}}\right)_{H} \mid \mathscr{G}\right) d P \\
=\lim _{n \rightarrow \infty} \int_{A} E\left(\left(f, g_{n}\right)_{H} \mid \mathscr{G}\right) d P=\lim _{n \rightarrow \infty} \int_{A}\left(f, g_{n}\right)_{H} d P=\int_{A}(f, g)_{H} d P
\end{gathered}
$$

which shows

$$
(E(f \mid \mathscr{G}), g)_{H}=E\left((f, g)_{H} \mid \mathscr{G}\right)
$$

as claimed.
Consider the other claim. Let

$$
\Phi_{n}(\omega)=\sum_{k=1}^{m_{n}} \Phi_{k}^{n} \mathscr{X}_{E_{k}^{n}}(\omega), E_{k}^{n} \in \mathscr{G}
$$

where $\Phi_{k}^{n} \in \mathscr{L}(U, H)$ be such that $\Phi_{n}$ converges to $\Phi$ pointwise in $\mathscr{L}(U, H)$ and also

$$
\int_{\Omega}\left\|\Phi_{n}-\Phi\right\|^{2} d P \rightarrow 0
$$

Then letting $A \in \mathscr{G}$ and using Corollary 21.2.6 as needed,

$$
\begin{aligned}
& \int_{A} \Phi E(f \mid \mathscr{G}) d P \\
= & \lim _{n \rightarrow \infty} \int_{A} \Phi_{n} E(f \mid \mathscr{G}) d P=\lim _{n \rightarrow \infty} \int_{A} \sum_{k=1}^{m_{n}} \Phi_{k}^{n} E(f \mid \mathscr{G}) \mathscr{X}_{E_{k}^{n}} d P \\
= & \lim _{n \rightarrow \infty} \sum_{k=1}^{m_{n}} \Phi_{k}^{n} \int_{A} E(f \mid \mathscr{G}) \mathscr{X}_{E_{k}^{n}} d P=\lim _{n \rightarrow \infty} \sum_{k=1}^{m_{n}} \Phi_{k}^{n} \int_{A} E\left(\mathscr{X}_{E_{k}^{n}} f \mid \mathscr{G}\right) d P \\
= & \lim _{n \rightarrow \infty} \sum_{k=1}^{m_{n}} \Phi_{k}^{n} \int_{A} \mathscr{X}_{E_{k}^{n}} f d P=\lim _{n \rightarrow \infty} \int_{A} \sum_{k=1}^{m_{n}} \Phi_{k}^{n} \mathscr{X}_{E_{k}^{n}} f d P \\
= & \lim _{n \rightarrow \infty} \int_{A} \Phi_{n} f d P=\lim _{n \rightarrow \infty} \int_{A} \Phi f d P \equiv \int_{A} E(\Phi f \mid \mathscr{G}) d P
\end{aligned}
$$

Since $A \in \mathscr{G}$ is arbitrary, this proves the lemma.
Lemma 65.1.4 Let $J: U_{0} \rightarrow U$ be a Hilbert Schmidt operator and let $W(t)$ be the resulting Wiener process

$$
W(t)=\sum_{k=1}^{\infty} \psi_{k}(t) J g_{k}
$$

where $\left\{g_{k}\right\}$ is an orthonormal basis for $U_{0}$. Let $f \in H$. Then considering one of the terms of the integral defined above,

$$
\begin{aligned}
& E\left(\left(\Phi\left(t_{k}\right)\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right), f\right)^{2}\right) \\
= & E\left(\left(\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right), \Phi\left(t_{k}\right)^{*} f\right)^{2}\right) \\
= & \left(t \wedge t_{k+1}-t \wedge t_{k}\right) E\left(\left\|J^{*} \Phi\left(t_{k}\right)^{*} f\right\|_{U_{0}}^{2}\right) .
\end{aligned}
$$

Proof: For simplicity, write $\Delta W_{k}(t)$ for $W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)$ and $\Delta_{k}(t)=\left(t \wedge t_{k+1}\right)-$ $\left(t \wedge t_{k}\right)$. If $\Phi\left(t_{k}\right)$ were a constant, then the result would follow right away from the fact that $W(t)$ is a Wiener process. Therefore, suppose for disjoint $E_{i}$,

$$
\Phi\left(t_{k}\right)(\omega)=\sum_{i=1}^{m} \Phi_{i} \mathscr{X}_{E_{i}}(\omega)
$$

where $\Phi_{i} \in \mathscr{L}(U, H)$ and $E_{i} \in \mathscr{F}_{t}$. Then, since the $E_{i}$ are disjoint,

$$
\begin{gathered}
E\left(\left(\Phi\left(t_{k}\right)\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right), f\right)^{2}\right) \\
=\sum_{i=1}^{m} E\left(\left(\left(\Delta_{k} W(t)\right), \Phi_{i}^{*} f \mathscr{X}_{E_{i}}\right)^{2}\right)=\sum_{i=1}^{m} \int_{\Omega}\left(\mathscr{X}_{E_{i}}\left(\left(\Delta_{k} W(t)\right), \Phi_{i}^{*} f\right)^{2}\right) d P
\end{gathered}
$$

Each $E_{i}$ is $\mathscr{F}_{t_{k}}$ measurable. By Lemma 64.4.2, and the properties of the Wiener process, this equals

$$
\sum_{i=1}^{m} P\left(E_{i}\right) \int_{\Omega}\left(\left(\left(\Delta_{k} W(t)\right), \Phi_{i}^{*} f\right)^{2}\right) d P=\sum_{i=1}^{m} P\left(E_{i}\right) \Delta_{k} t\left(Q \Phi_{i}^{*} f, \Phi_{i}^{*} f\right)_{U}
$$

where $Q=J J^{*}$. Then the above reduces to

$$
\left(t \wedge t_{k+1}-t \wedge t_{k}\right) E\left(\left\|J^{*} \Phi\left(t_{k}\right)^{*} f\right\|_{U_{0}}^{2}\right)
$$

Now here is a major result on the integral of elementary functions. The last assertion in the following proposition is called the Ito isometry.

Proposition 65.1.5 Let $\Phi(t)$ be an elementary process as defined in Definition 65.1.2 and let $W(t)$ be a Wiener process.

$$
W(t)=\sum_{k=1}^{\infty} \psi_{k}(t) J g_{k}
$$

where $J: U_{0} \rightarrow U$ is Hilbert Schmidt and the $\psi_{k}$ are real independent Wiener processes as described above.

$$
\underset{\left\{g_{k}\right\}}{U_{0}} \xrightarrow{J} \underset{W(t)}{U} \xrightarrow{\Phi} H
$$

Then $\int_{a}^{t} \Phi(s) d W$ is a continuous square integrable $H$ valued martingale with respect to the $\sigma$ algebras of 65.1.2 on $[0, T]$ and

$$
E\left(\left|\int_{a}^{t} \Phi(s) d W\right|_{H}^{2}\right)=\int_{a}^{t} E\left(\|\Phi \circ J\|_{\mathscr{L}_{2}\left(U_{0}, H\right)}^{2}\right) d s
$$

Proof: Start with the left side. Denote by $\Delta_{k} W(t) \equiv W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)$. Then

$$
E\left(\left|\int_{a}^{t} \Phi(s) d W\right|_{H}^{2}\right)=E\left(\left|\sum_{k=0}^{n-1} \Phi\left(t_{k}\right) \Delta_{k} W(t)\right|_{H}^{2}\right)
$$

Consider a mixed term for $j<k$. Using Lemma 65.1.3 and the fact that $W(t)$ is a martingale,

$$
\begin{aligned}
& E\left(\left(\Phi\left(t_{k}\right) \Delta_{k} W(t), \Phi\left(t_{j}\right) \Delta_{j} W(t)\right)_{H}\right) \\
= & E\left(E\left(\left(\Phi\left(t_{k}\right) \Delta_{k} W(t), \Phi\left(t_{j}\right) \Delta_{j} W(t)\right)_{H}\right) \mid \mathscr{F}_{t_{k}}\right) \\
= & E\left(\left(\Phi\left(t_{j}\right) \Delta_{j} W(t), E\left(\Phi\left(t_{k}\right) \Delta_{k} W(t) \mid \mathscr{F}_{t_{k}}\right)\right)\right) \\
= & E\left(\left(\Phi\left(t_{j}\right) \Delta_{j} W(t), \Phi\left(t_{k}\right) E\left(\Delta_{k} W(t) \mid \mathscr{F}_{t_{k}}\right)\right)\right) \\
= & E\left(\left(\Phi\left(t_{j}\right) \Delta_{j} W(t), \Phi\left(t_{k}\right) 0\right)\right)=0 .
\end{aligned}
$$

Therefore, from Lemma 65.1.4, and letting $\left\{f_{j}\right\}$ be an orthonormal basis for $H$, it follows that since the mixed terms disappeared,

$$
\begin{gathered}
E\left(\left|\int_{a}^{t} \Phi(s) d W\right|_{H}^{2}\right)=\sum_{k=0}^{n-1} E\left(\left(\Phi\left(t_{k}\right) \Delta_{k} W(t), \Phi\left(t_{k}\right) \Delta_{k} W(t)\right)\right) \\
=\sum_{k=0}^{n-1} E\left(\sum_{j=1}^{\infty}\left(\Phi\left(t_{k}\right) \Delta_{k} W(t), f_{j}\right)^{2}\right)=\sum_{k=0}^{n-1} \sum_{j=1}^{\infty} E\left(\left(\Phi\left(t_{k}\right) \Delta_{k} W(t), f_{j}\right)^{2}\right) \\
=\sum_{k=0}^{n-1} \sum_{j=1}^{\infty}\left(t \wedge t_{k+1}-t \wedge t_{k}\right) E\left(\left\|J^{*} \Phi\left(t_{k}\right)^{*} f_{j}\right\|_{U_{0}}^{2}\right) \\
=\sum_{k=0}^{n-1}\left(t \wedge t_{k+1}-t \wedge t_{k}\right) E\left(\left\|J^{*} \Phi\left(t_{k}\right)^{*}\right\|_{\mathscr{L}_{2}\left(H, U_{0}\right)}^{2}\right) \\
=\sum_{k=0}^{n-1}\left(t \wedge t_{k+1}-t \wedge t_{k}\right) E\left(\left\|\Phi\left(t_{k}\right) J\right\|_{\mathscr{L}_{2}\left(U_{0}, H\right)}^{2}\right) \\
=\int_{a}^{t} E\left(\|\Phi \circ J\|_{\mathscr{L}_{2}\left(U_{0}, H\right)}^{2}\right) d s
\end{gathered}
$$

It is obvious that $\int_{a}^{t} \Phi(s) d W$ is a continuous square integrable martingale from the definition, because it is just a finite sum of such things.

Of course this is a version of the Ito isometry. The presence of the $J$ is troublesome but it is hidden in the definition of $W$ on the left side of the conclusion of the proposition. In finite dimensions one could just let $J=I$ and this fussy detail would not be there to cause confusion. The next task is to generalize the above integral to a more general class of functions and obtain a process which is not explicitly dependent on $J$.

### 65.2 Different Definition Of Elementary Functions

What if elementary functions had been defined in terms of $\mathscr{X}_{\left[t_{k}, t_{k+1}\right)}$ ? That is, what if the elementary functions had been of the form

$$
\Phi(t)=\sum_{k=0}^{n-1} \Phi\left(t_{k}\right) \mathscr{X}_{\left[t_{k}, t_{k+1}\right)}(t) ?
$$

Would anything change? If you go over the arguments given, it is clear that nothing would change at all. Furthermore, this elementary function equals the one described above off a finite set of mesh points so the convergence properties in $L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$, which will be important in what follows are exactly the same. Thus it does not matter whether we give elementary functions in this form or in the form described above. However, some arguments given later about localization depend on it being in the earlier form.

### 65.3 Approximating With Elementary Functions

Here is a really surprising result about approximating with step functions which is due to Doob. See [78] which is where I found this lemma. This is based on continuity of translation in the $L^{p}(\mathbb{R} ; E)$.

Lemma 65.3.1 Let $\Phi:[0, T] \times \Omega \rightarrow E$, be $\mathscr{B}([0, T]) \times \mathscr{F}$ measurable and suppose

$$
\Phi \in K \equiv L^{p}([0, T] \times \Omega ; E), p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
\Phi_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t) \\
\Phi_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t)
\end{aligned}
$$

both converge to $\Phi$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

Also, each $\Phi\left(t_{j}^{k}\right), \Phi\left(t_{j-1}^{k}\right)$ is in $L^{p}(\Omega ; E)$. One can also assume that $\Phi(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$
\left|t_{j}^{k}-t_{j-1}^{k}\right|=2^{-n_{k}}
$$

except for the case where $j=1$ or $j=m_{n_{k}}$ when this is so, you could have $\left|t_{j}^{k}-t_{j-1}^{k}\right|<2^{-n_{k}}$.

Note that it would make no difference in terms of the conclusion of this lemma if you defined

$$
\Phi_{k}^{l}(t) \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t)
$$

because the modified function equals the one given above off a countable subset of $[0, T]$, the union of the mesh points. One could change $\Phi_{k}^{r}$ similarly with no change in the conclusion.

Proof: For $t \in \mathbb{R}$ let $\gamma_{n}(t) \equiv k / 2^{n}, \delta_{n}(t) \equiv(k+1) / 2^{n}$, where $t \in\left(k / 2^{n},(k+1) / 2^{n}\right]$, and $2^{-n}<T / 4$. Also suppose $\Phi$ is defined to equal 0 on $[0, T]^{C} \times \Omega$. There exists a set of measure zero $N$ such that for $\omega \notin N, t \rightarrow\|\Phi(t, \omega)\|$ is in $L^{p}(\mathbb{R})$. Therefore by continuity of translation, as $n \rightarrow \infty$ it follows that for $\omega \notin N$, and $t \in[0, T]$,

$$
\int_{\mathbb{R}}\left\|\Phi\left(\gamma_{n}(t)+s\right)-\Phi(t+s)\right\|_{E}^{p} d s \rightarrow 0
$$

The above is dominated by

$$
\begin{aligned}
& \int_{\mathbb{R}} 2^{p-1}\left(\|\Phi(s)\|^{p}+\|\Phi(s)\|^{p}\right) \mathscr{X}_{[-2 T, 2 T]}(s) d s \\
= & \int_{-2 T}^{2 T} 2^{p-1}\left(\|\Phi(s)\|^{p}+\|\Phi(s)\|^{p}\right) d s<\infty
\end{aligned}
$$

Consider

$$
\int_{\Omega} \int_{-2 T}^{2 T}\left(\int_{\mathbb{R}}\left\|\Phi\left(\gamma_{n}(t)+s\right)-\Phi(t+s)\right\|_{E}^{p} d s\right) d t d P
$$

By the dominated convergence theorem, this converges to 0 as $n \rightarrow \infty$. This is because the integrand with respect to $\omega$ is dominated by

$$
\int_{-2 T}^{2 T}\left(\int_{\mathbb{R}} 2^{p-1}\left(\|\Phi(s)\|^{p}+\|\Phi(s)\|^{p}\right) \mathscr{X}_{[-2 T, 2 T]}(s) d s\right) d t
$$

and this is in $L^{1}(\Omega)$ by assumption that $\Phi \in K$. Now Fubini. This yields

$$
\int_{\Omega} \int_{\mathbb{R}} \int_{-2 T}^{2 T}\left\|\Phi\left(\gamma_{n}(t)+s\right)-\Phi(t+s)\right\|_{E}^{p} d t d s d P
$$

Change the variables on the inside.

$$
\int_{\Omega} \int_{\mathbb{R}} \int_{-2 T+s}^{2 T+s}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s d P
$$

Now by definition, $\Phi(t)$ vanishes if $t \notin[0, T]$, thus the above reduces to

$$
\begin{aligned}
& \int_{\Omega} \int_{\mathbb{R}} \int_{0}^{T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s d P \\
& +\int_{\Omega} \int_{\mathbb{R}} \int_{-2 T+s}^{2 T+s} \mathscr{X}_{[0, T]^{c}}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)\right\|_{E}^{p} d t d s d P
\end{aligned}
$$

$$
\begin{aligned}
= & \int_{\Omega} \int_{\mathbb{R}} \int_{0}^{T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s d P \\
& +\int_{\Omega} \int_{\mathbb{R}} \int_{-2 T+s}^{2 T+s} \mathscr{X}_{[0, T]}{ }^{C}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s d P
\end{aligned}
$$

Also by definition, $\gamma_{n}(t-s)+s$ is within $2^{-n}$ of $t$ and so the integrand in the integral on the right equals 0 unless $t \in\left[-2^{-n}-T, T+2^{-n}\right] \subseteq[-2 T, 2 T]$. Thus the above reduces to

$$
\int_{\Omega} \int_{\mathbb{R}} \int_{-2 T}^{2 T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s d P
$$

Now Fubini again.

$$
\int_{\mathbb{R}} \int_{\Omega} \int_{-2 T}^{2 T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d P d s
$$

This converges to 0 as $n \rightarrow \infty$ as was shown above. Therefore,

$$
\int_{0}^{T} \int_{\Omega} \int_{0}^{T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d P d s
$$

also converges to 0 as $n \rightarrow \infty$. The only problem is that $\gamma_{n}(t-s)+s \geq t-2^{-n}$ and so $\gamma_{n}(t-s)+s$ could be less than 0 for $t \in\left[0,2^{-n}\right]$. Since this is an interval whose measure converges to 0 it follows

$$
\int_{0}^{T} \int_{\Omega} \int_{0}^{T}\left\|\Phi\left(\left(\gamma_{n}(t-s)+s\right)^{+}\right)-\Phi(t)\right\|_{E}^{p} d t d P d s
$$

converges to 0 as $n \rightarrow \infty$. Let

$$
m_{n}(s)=\int_{\Omega} \int_{0}^{T}\left\|\Phi\left(\left(\gamma_{n}(t-s)+s\right)^{+}\right)-\Phi(t)\right\|_{E}^{p} d t d P
$$

Then letting $\mu$ denote Lebesgue measure,

$$
\mu\left(\left[m_{n}(s)>\lambda\right]\right) \leq \frac{1}{\lambda} \int_{0}^{T} m_{n}(s) d s
$$

It follows there exists a subsequence $n_{k}$ such that

$$
\mu\left(\left[m_{n_{k}}(s)>\frac{1}{k}\right]\right)<2^{-k}
$$

Hence by the Borel Cantelli lemma, there exists a set of measure zero $N$ such that for $s \notin N$,

$$
m_{n_{k}}(s) \leq 1 / k
$$

for all $k$ sufficiently large. Pick such an $s$. Then consider $t \rightarrow \Phi\left(\left(\gamma_{n_{k}}(t-s)+s\right)^{+}\right)$. For $n_{k}, t \rightarrow\left(\gamma_{n_{k}}(t-s)+s\right)^{+}$has jumps at points of the form $0, s+l 2^{-n_{k}}$ where $l$ is an integer.

Thus $\mathscr{P}_{n_{k}}$ consists of points of $[0, T]$ which are of this form and these partitions are nested. Define $\Phi_{k}^{l}(0) \equiv 0, \Phi_{k}^{l}(t) \equiv \Phi\left(\left(\gamma_{n_{k}}(t-s)+s\right)^{+}\right)$. Now suppose $N_{1}$ is a set of measure zero. Can $s$ be chosen such that all jumps for all partitions occur off $N_{1}$ ? Let $(a, b)$ be an interval contained in $[0, T]$. Let $S_{j}$ be the points of $(a, b)$ which are translations of the measure zero set $N_{1}$ by $t_{j}^{l}$ for some $j$. Thus $S_{j}$ has measure 0 . Now pick $s \in(a, b) \backslash \cup_{j} S_{j}$.

It will be assumed that all these mesh points miss the set of all $t$ such that $\omega \rightarrow \Phi(t, \omega)$ is not in $L^{p}(\Omega ; E)$. To get the other sequence of step functions, the right step functions, just use a similar argument with $\delta_{n}$ in place of $\gamma_{n}$. Just apply the argument to a subsequence of $n_{k}$ so that the same $s$ can hold for both.

The following proposition says that elementary functions can be used to approximate progressively measurable functions under certain conditions.

Proposition 65.3.2 Let $\Phi \in L^{p}([0, T] \times \Omega, E)$, $p \geq 1$, be progressively measurable. Then there exists a sequence of elementary functions which converges to $\Phi$ in

$$
L^{p}([0, T] \times \Omega, E) .
$$

These elementary functions have values in $E_{0}$, a dense subset of $E$. If $\varepsilon_{n} \rightarrow 0$, and

$$
\Phi_{n}(t)=\sum_{k=1}^{m_{n}} \Psi_{k}^{n} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t)
$$

$\Psi_{k}^{n}$ having values in $E_{0}$, it can be assumed that

$$
\begin{equation*}
\sum_{k=1}^{m_{n}}\left\|\Psi_{k}^{n}-\Phi\left(t_{k}\right)\right\|_{L^{p}(\Omega ; E)}<\varepsilon_{n} \tag{65.3.4}
\end{equation*}
$$

Proof: By Lemma 65.3.1 there exists a sequence of step functions

$$
\Phi_{k}^{l}(t)=\sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t)
$$

which converges to $\Phi$ in $L^{p}([0, T] \times \Omega, E)$ where at the left endpoint $\Phi(0)$ can be modified as described above. Now each $\Phi\left(t_{j-1}^{k}\right)$ is in $L^{p}(\Omega, E)$ and is $\mathscr{F}\left(t_{j-1}^{k}\right)$ measurable and so it can be approximated as closely as desired in $L^{p}(\Omega)$ with a simple function

$$
s\left(t_{j-1}^{k}\right) \equiv \sum_{i=1}^{m_{k}} c_{i}^{j} \mathscr{X}_{F_{i}}(\omega), F_{i} \in \mathscr{F}\left(t_{j-1}^{k}\right)
$$

Furthermore, by density of $E_{0}$ in $E$, it can be assumed each $c_{i}^{j} \in E_{0}$ and the condition 65.3.4 holds. Replacing each $\Phi\left(t_{j-1}^{k}\right)$ with $s\left(t_{j-1}^{k}\right)$, the result is an elementary function which approximates $\Phi_{k}^{l}$.

Of course everything in the above holds with obvious modifications replacing $[0, T]$ with $[a, T]$ where $a<T$.

Here is another interesting proposition about the time integral being adapted.

Proposition 65.3.3 Suppose $f \geq 0$ is progressively measureable and $\mathscr{F}_{t}$ is a filtration. Then

$$
\omega \rightarrow \int_{a}^{t} f(s, \omega) d s
$$

is $\mathscr{F}_{t}$ adapted.
Proof: This follows right away from the fact $f$ is $\mathscr{B}([a, t]) \times \mathscr{F}_{t}$ measurable. This is just product measure and so the integral from $a$ to $t$ is $\mathscr{F}_{t}$ measurable. See also Proposition 62.3.5.

### 65.4 Some Hilbert Space Theory

Recall the following definition which makes $L U$ into a Hilbert space where $L \in \mathscr{L}(U, H)$.
Definition 65.4.1 Let $L \in \mathscr{L}(U, H)$, the bounded linear maps from $U$ to $H$ for $U, H$ Hilbert spaces. For $y \in L(U)$, let $L^{-1} y$ denote the unique vector in

$$
\{x: L x=y\} \equiv M_{y}
$$

which is closest in $U$ to 0 .

Note this is a good definition because $\{x: L x=y\}$ is closed thanks to the continuity of $L$ and it is obviously convex. Thus Theorem 19.1.8 applies. With this definition define an inner product on $L(U)$ as follows. For $y, z \in L(U)$,

$$
(y, z)_{L(U)} \equiv\left(L^{-1} y, L^{-1} z\right)_{U}
$$

Thus it is obvious that $L^{-1}: L U \rightarrow U$ is continuous. The notation is abominable because $L^{-1}(y)$ is the normal notation for $M_{y}$.

With this definition, here is one of the main results. It is Theorem 19.2.3 proved earlier.
Theorem 65.4.2 Let $U, H$ be Hilbert spaces and let $L \in \mathscr{L}(U, H)$. Then Definition 65.4.1 makes $L(U)$ into a Hilbert space. Also $L: U \rightarrow L(U)$ is continuous and $L^{-1}: L(U) \rightarrow U$ is continuous. Furthermore there is a constant $C$ independent of $x \in U$ such that

$$
\begin{equation*}
\|L\|_{\mathscr{L}(U, H)}\|L x\|_{L(U)} \geq\|L x\|_{H} \tag{65.4.5}
\end{equation*}
$$

If $U$ is separable, so is $L(U)$. Also $\left(L^{-1}(y), x\right)=0$ for all $x \in \operatorname{ker}(L)$, and $L^{-1}: L(U) \rightarrow U$ is linear. Also, in case that $L$ is one to one, both $L$ and $L^{-1}$ preserve norms.

Let $U$ be a separable Hilbert space and let $Q$ be a positive self adjoint operator. Then consider

$$
J: Q^{1 / 2} U \rightarrow U_{1}
$$

a one to one Hilbert Schmidt operator, where $U_{1}$ is a separable real Hilbert space. First of all, there is the obvious question whether there are any examples.

Lemma 65.4.3 Let $A \in \mathscr{L}(U, U)$ be a bounded linear transformation defined on $U$ a separable real Hilbert space. There exists a one to one Hilbert Schmidt operator $J$ : $A U \rightarrow U_{1}$ where $U_{1}$ is a separable real Hilbert space. In fact you can take $U_{1}=U$.

Proof: Let $\alpha_{k}>0$ and $\sum_{k=1}^{\infty} \alpha_{k}^{2}<\infty$. Then let $\left\{g_{k}\right\}_{k=1}^{L}$ be an orthonormal basis for $A U$, the inner product and norm given in Definition 65.4.1 above, and let

$$
J x \equiv \sum_{k=1}^{L}\left(x, g_{k}\right)_{A U} \alpha_{k} g_{k}
$$

Then it is clear that $J \in \mathscr{L}(A U, U)$. This is because,

$$
\begin{aligned}
\|J x\|_{U} & \leq \sum_{k=1}^{L}\left|\left(x, g_{k}\right)_{A U}\right| \alpha_{k}| | g_{k} \|_{U} \\
& \leq C \sum_{k=1}^{L}\left|\left(x, g_{k}\right)_{A U}\right| \alpha_{k} \mid \overbrace{g_{k} \|_{A U}}^{=1} \\
& \leq C\left(\sum_{k=1}^{L}\left|\left(x, g_{k}\right)_{A U}\right|^{2}\right)^{1 / 2}\left(\sum_{k=1}^{L} \alpha_{k}^{2}\right)^{1 / 2} \\
& =C\left(\sum_{k=1}^{L} \alpha_{k}^{2}\right)^{1 / 2}\|x\|_{A U}
\end{aligned}
$$

Also, from the definition, $J g_{j}=\alpha_{j} g_{j}$. Say $g_{j}=A f_{j}$ where $f_{j} \in U$ and $1=\left\|g_{j}\right\|_{A U}=$ $\left\|f_{j}\right\|_{U}$. Since $A$ is continuous,

$$
\left\|g_{j}\right\|_{U}=\left\|A f_{j}\right\|_{U} \leq\|A\|\left\|f_{j}\right\|_{U}=\|A\|\left\|g_{j}\right\|_{A U}=\|A\| \equiv C^{1 / 2}
$$

Thus

$$
\sum_{j=1}^{L}\left\|J g_{j}\right\|_{U}^{2}=\sum_{j=1}^{L} \alpha_{j}^{2}\left\|g_{j}\right\|_{U}^{2} \leq C \sum_{j=1}^{L} \alpha_{j}^{2}<\infty
$$

and so $J$ is also a Hilbert Schmidt operator which maps $A U$ to $U$. It is clear that $J$ is one to one because each $\alpha_{k}>0$. If $A U$ is finite dimensional, $L<\infty$ and so the above sum is finite.

Definition 65.4.4 Let $U_{1}, U, H$ be real separable Hilbert spaces and let $Q$ be a nonnegative self adjoint operator, $Q \in \mathscr{L}(U, U)$. Let $Q^{1 / 2} U$ be the Hilbert space described in Definition 65.4.1. Let $J$ be a one to one Hilbert Schmidt map from $Q^{1 / 2} U$ to $U_{1}$.

$$
U_{1} \stackrel{J}{\leftarrow} Q^{1 / 2} U \xrightarrow{\Phi} H
$$

Then denote by $\mathscr{L}\left(U_{1}, H\right)_{0}$ the space of restrictions of elements of $\mathscr{L}\left(U_{1}, H\right)$ to the Hilbert space $J Q^{1 / 2} U \subseteq U_{1}$.

Here is a diagram to keep this straight.

Lemma 65.4.5 In the context of the above definition, $\mathscr{L}\left(U_{1}, H\right)_{0}$ is dense in

$$
\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)
$$

the Hilbert Schmidt operators from $J Q^{1 / 2} U$ to $H$. That is, if $f \in \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)$, there exists

$$
g \in \mathscr{L}\left(U_{1}, H\right)_{0},\|g-f\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}<\varepsilon
$$

Proof: The operator $J J^{*} \equiv Q_{1}: U_{1} \rightarrow U_{1}$ is self adjoint and nonnegative. It is also compact because $J$ is Hilbert Schmidt. Therefore, by Theorem 21.3.9 on Page 663,

$$
Q_{1}=\sum_{k=1}^{L} \lambda_{k} e_{k} \otimes e_{k}
$$

where the $\lambda_{k}$ are decreasing and positive, the $\left\{e_{k}\right\}$ are an orthonormal basis for $U_{1}$, and $\lambda_{L}$ is the last positive $\lambda_{j}$. (This is a lot like the singular value matrix in linear algebra.) Thus also

$$
Q_{1} e_{k}=\lambda_{k} e_{k}
$$

If the $\lambda_{k}$ are all positive, then $L \equiv \infty$. Then for $k \leq L$ if $L<\infty, k<\infty$ otherwise,

$$
\left(\frac{J^{*} e_{k}}{\sqrt{\lambda_{k}}}, \frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}\right)_{Q^{1 / 2}(U)}=\left(\frac{J J^{*} e_{k}}{\sqrt{\lambda_{k}}}, \frac{e_{j}}{\sqrt{\lambda_{j}}}\right)_{U_{1}}=\left(\frac{\lambda_{k} e_{k}}{\sqrt{\lambda_{k}}}, \frac{e_{j}}{\sqrt{\lambda_{j}}}\right)_{U_{1}}=\frac{\sqrt{\lambda_{k}}}{\sqrt{\lambda_{j}}} \delta_{k j}=\delta_{j k}
$$

Now in case $L<\infty, J\left(Q^{1 / 2}(U)\right) \subseteq \operatorname{span}\left(e_{1}, \cdots, e_{L}\right)$. Here is why. First note that $Q_{1}$ is one to one on span $\left(e_{1}, \cdots, e_{L}\right)$ and maps this space onto itself because $Q_{1}$ maps $e_{k}$ to a nonzero multiple of $e_{k}$. Hence its restriction to this subspace has an inverse which does the same. It also maps all of $U_{1}$ to span $\left(e_{1}, \cdots, e_{L}\right)$. This follows from the definition of $Q_{1}$ given in the above sum. For $x \in Q^{1 / 2}(U), J x \in U_{1}$ and so

$$
J J^{*} J x=Q_{1}(J x) \in \operatorname{span}\left(e_{1}, \cdots, e_{L}\right)
$$

Hence $J x \in Q_{1}^{-1}\left(\operatorname{span}\left(e_{1}, \cdots, e_{L}\right)\right) \in \operatorname{span}\left(e_{1}, \cdots, e_{L}\right)$. Recall that $J$ is one to one so there is only one element of $J^{-1} x$.

Then for $x \in Q^{1 / 2} U$,

$$
\begin{aligned}
& \sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j} \otimes_{Q^{1 / 2} U} \frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}(x)=\sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j}\left(\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{Q^{1 / 2}(U)} \\
= & \sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j}\left(\frac{e_{j}}{\sqrt{\lambda_{j}}}, J x\right)_{U_{1}}=\sum_{j=1}^{L} e_{j}\left(e_{j}, J x\right)_{U_{1}} \\
= & \sum_{j=1}^{\infty} e_{j}\left(e_{j}, J x\right)_{U_{1}}=J x .\left(J\left(Q^{1 / 2}(U)\right) \subseteq \operatorname{span}\left(e_{1}, \cdots, e_{L}\right) \text { if } L<\infty\right)
\end{aligned}
$$

Thus,

$$
J=\sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j} \otimes_{Q^{1 / 2} U} \frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}
$$

It follows that an orthonormal basis in $J Q^{1 / 2} U$ is $\left\{\frac{J J^{*} e_{j}}{\sqrt{\lambda_{j}}}\right\}_{j=1}^{L}$. This is because an orthonormal basis for $Q^{1 / 2} U$ is $\left\{\frac{J^{*} e_{k}}{\sqrt{\lambda_{k}}}\right\}$. Since $J$ is one to one, it preserves norms between $Q^{1 / 2} U$ and $J Q^{1 / 2} U$. Let $\Phi \in \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)$. Then by the discussion of Hilbert Schmidt operators given earlier, in particular the demonstration that these operators are compact,

$$
\Phi=\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \phi_{i j} f_{i} \otimes_{J Q^{1 / 2} U} \frac{J J^{*} e_{j}}{\sqrt{\lambda_{j}}}
$$

where $\left\{f_{i}\right\}$ is an orthonormal basis for $H$. In fact, $\left\{f_{i} \otimes \frac{J J^{*} e_{j}}{\sqrt{\lambda_{j}}}\right\}_{i, j}$ is an orthonormal basis for $\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)$ and $\sum_{i} \sum_{j} \phi_{i j}^{2}<\infty$, the $\phi_{i j}$ being the Fourier coefficients of $\Phi$. Then consider

$$
\begin{equation*}
\Phi_{n}=\sum_{i=1}^{n} \sum_{j=1}^{n} \phi_{i j} f_{i} \otimes_{J Q^{1 / 2} U} \frac{J J^{*} e_{j}}{\sqrt{\lambda_{j}}} \tag{65.4.6}
\end{equation*}
$$

Consider one of the finitely many operators in this sum. For $x \in J Q^{1 / 2} U$, since $J$ preserves norms,

$$
\begin{gathered}
f_{i} \otimes_{J Q^{1 / 2} U} \frac{J J^{*} e_{j}}{\sqrt{\lambda_{j}}}(x) \equiv f_{i}\left(\frac{J J^{*} e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{J Q^{1 / 2} U}=f_{i}\left(\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}, J^{-1} x\right)_{Q^{1 / 2} U} \\
=f_{i}\left(\frac{e_{j}}{\sqrt{\lambda_{j}}}, J J^{-1} x\right)_{U_{1}}=f_{i}\left(\frac{e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{U_{1}} \equiv \Lambda_{i j}(x)
\end{gathered}
$$

Recall how, since $J$ is one to one, it preserves norms and inner products. Now $\Lambda_{i j}$ makes sense from the above formula for all $x \in U_{1}$ and is also a continuous linear map from $U_{1}$ to
$H$ because

$$
\left\|f_{i}\left(\frac{e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{U_{1}}\right\|_{H} \leq\left\|f_{i}\right\|_{H} \frac{1}{\sqrt{\lambda_{j}}}\|x\|_{U_{1}}
$$

Thus each term in the finite sum of 65.4.6 is in $\mathscr{L}\left(U_{1}, H\right)_{0}$ and this proves the lemma.
It is interesting to note that $Q_{1}^{1 / 2} U_{1}=J\left(Q^{1 / 2}(U)\right)$.

$$
\sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j}\left(\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{Q^{1 / 2}(U)}=J x
$$

and $\left\{\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}\right\}$ are an orthonormal set in $Q^{1 / 2}(U)$. Therefore, the sum of the squares of $\left(\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{Q^{1 / 2}(U)}$ is finite. Hence you can define $y \in U_{1}$ by

$$
y \equiv \sum_{j=1}^{L}\left(\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{Q^{1 / 2}(U)} e_{j}
$$

Also

$$
\begin{aligned}
\sum_{i=1}^{L} \sqrt{\lambda_{i}} e_{i} \otimes e_{i}(y) & =\sum_{i=1}^{L} \sqrt{\lambda_{i}} e_{i}\left(\frac{J^{*} e_{i}}{\sqrt{\lambda_{i}}}, x\right)_{Q^{1 / 2}(U)} \\
& =\sum_{i=1}^{L} e_{i}\left(e_{i}, J x\right)_{U_{1}}=J x
\end{aligned}
$$

Now you can show that $Q_{1}^{1 / 2}=\sum_{i=1}^{L} \sqrt{\lambda_{i}} e_{i} \otimes e_{i}$. You do this by showing that it works and commutes with every operator which commutes with $Q_{1}$. Thus $J x=Q_{1}^{1 / 2} y$. This shows that $J\left(Q^{1 / 2}(U)\right) \subseteq Q_{1}^{1 / 2}\left(U_{1}\right)$. However, you can also turn the inclusion around. Thus if you start with $y \in U_{1}$ and form

$$
Q_{1}^{1 / 2} y=\sum_{i=1}^{L} \sqrt{\lambda_{i}} e_{i} \otimes e_{i}(y)=\sum_{i=1}^{L} \sqrt{\lambda_{i}} e_{i}\left(y, e_{i}\right)
$$

then the $\left(y, e_{i}\right)_{U_{1}}^{2}$ has a finite sum because the $\left\{e_{i}\right\}$ are orthonormal. Thus you can form

$$
x \equiv \sum_{i=1}^{L}\left(y, e_{i}\right)_{U_{1}} \frac{J^{*} e_{i}}{\sqrt{\lambda_{i}}} \in Q^{1 / 2}(U)
$$

Then since the $\left\{\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}\right\}$ are orthonormal,

$$
\begin{aligned}
J(x) & =\sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j}\left(\frac{J^{*} e_{j}}{\sqrt{\lambda_{j}}}, x\right)_{Q^{1 / 2}(U)}=\sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j}\left(y, e_{j}\right)_{U_{1}} \\
& =\sum_{j=1}^{L} \sqrt{\lambda_{j}} e_{j} \otimes e_{j}(y)=Q_{1}^{1 / 2}(y)
\end{aligned}
$$

It follows that $Q_{1}^{1 / 2}\left(U_{1}\right) \subseteq J\left(Q^{1 / 2}(U)\right)$.
One can also show that $W(t) \equiv \sum_{k=1}^{L} \psi_{k}(t) J g_{k}$ where the $\psi_{k}(t)$ are the real Wiener processes described earlier and $\left\{g_{k}\right\}$ is an orthonormal basis for $Q^{1 / 2}(U)$, is a $Q_{1}$ Wiener process. To see this, recall the above definition of a Wiener process in terms of Hilbert Schmidt operators, the convergence happening in $U_{1}$ in this case. Then by independence of the $\psi_{j}$,

$$
\begin{aligned}
& \quad E\left(\left(h, \sum_{k=1}^{L} \psi_{k}(t-s) J g_{k}\right)\left(l, \sum_{j=1}^{L} \psi_{j}(t-s) J g_{j}\right)\right) \\
& =E\left(\sum_{k}\left(h, J g_{k}\right)\left(l, J g_{j}\right) \psi_{k}(t-s) \psi_{j}(t-s)\right) \\
& =\sum_{k}\left(h, J g_{k}\right)\left(l, J g_{k}\right) E\left(\psi_{k}^{2}(t-s)\right)=(t-s) \sum_{k}\left(h, J g_{k}\right)\left(l, J g_{k}\right) \\
& =(t-s) \sum_{k}\left(J^{*} h, g_{k}\right)_{Q^{1 / 2}(U)}\left(J^{*} l, g_{k}\right)_{Q^{1 / 2}(U)}=(t-s)\left(J^{*} h, J^{*} l\right)_{Q^{1 / 2}(U)} \\
& =(t-s)\left(J J^{*} h, l\right)_{U_{1}} \equiv(t-s)\left(Q_{1} h, l\right)_{U_{1}}
\end{aligned}
$$

### 65.5 The General Integral

It is time to generalize the integral. The following diagram illustrates the ingredients of the next lemma.

$$
\begin{array}{ccc}
W(t) \in U_{1} \stackrel{J}{\leftarrow} Q^{1 / 2} U & \xrightarrow{\Phi} H \\
& & \\
& \\
\supseteq J & \\
& \downarrow & Q^{1 / 2} U \\
& \underset{1-1}{J} & Q^{1 / 2} U \\
\Phi_{n} & \searrow & \\
& & \\
& & \\
& &
\end{array}
$$

Lemma 65.5.1 Let $\Phi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and suppose also that $\Phi$ is progressively measurable with respect to the usual filtration associated with the Wiener process

$$
W(t)=\sum_{k=1}^{L} \psi_{k}(t) J g_{k}
$$

which has values in $U_{1}$ for $U_{1}$ a separable real Hilbert space such that $J: Q^{1 / 2} U \rightarrow U_{1}$ is Hilbert Schmidt and one to one, $\left\{g_{k}\right\}$ an orthonormal basis in $Q^{1 / 2} U$. Then letting $J^{-1}: J Q^{1 / 2} U \rightarrow Q^{1 / 2} U$ be the map described in Definition 65.4.1, it follows that

$$
\Phi \circ J^{-1} \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right) .
$$

Also there exists a sequence of elementary functions $\left\{\Phi_{n}\right\}$ having values in $\mathscr{L}\left(U_{1}, H\right)_{0}$ which converges to $\Phi \circ J^{-1}$ in $L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$.

Proof: First, why is $\Phi \circ J^{-1} \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$ ? This follows from the observation that $A$ is Hilbert Schmidt if and only if $A^{*}$ is Hilbert Schmidt. In fact, the Hilbert Schmidt norms of $A$ and $A^{*}$ are the same. Now since $\Phi$ is Hilbert Schmidt, it follows that $\Phi^{*}$ is and since $J^{-1}$ is continuous, it follows $\left(J^{-1}\right)^{*} \Phi^{*}=\left(\Phi \circ J^{-1}\right)^{*}$ is Hilbert Schmidt. Also letting $\mathscr{L}_{2}$ be the appropriate space of Hilbert Schmidt operators,

$$
\left\|\left(J^{-1}\right)^{*}\right\|\|\Phi\|_{\mathscr{L}_{2}}=\left\|\left(J^{-1}\right)^{*}\right\|\left\|\Phi^{*}\right\|_{\mathscr{L}_{2}} \geq\left\|\left(\Phi \circ J^{-1}\right)^{*}\right\|_{\mathscr{L}_{2}}=\left\|\Phi \circ J^{-1}\right\|_{\mathscr{L}_{2}}
$$

Thus $\Phi \circ J^{-1}$ has values in $\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)$. This also shows that

$$
\Phi \circ J^{-1} \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)
$$

Since $\Phi$ is given to be progressively measurable, so is $\Phi \circ J^{-1}$. Therefore, the existence of the desired sequence of elementary functions follows from Proposition 65.3.2 and Lemma 65.4.5.

Definition 65.5.2 Let $\Phi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and be progressively measurable where $Q$ is a self adjoint nonnegative operator defined on $U$. Let $J: Q^{1 / 2} U \rightarrow U_{1}$ be Hilbert Schmidt. Then the stochastic integral

$$
\begin{equation*}
\int_{a}^{t} \Phi d W \tag{65.5.7}
\end{equation*}
$$

is defined as

$$
\lim _{n \rightarrow \infty} \int_{a}^{t} \Phi_{n} d W \text { in } L^{2}(\Omega ; H)
$$

where $W(t)$ is a Wiener process

$$
\sum_{k=1}^{\infty} \psi_{k}(t) J g_{k},\left\{g_{k}\right\} \text { orthonormal basis in } Q^{1 / 2} U
$$

and $\Phi_{n}$ is an elementary function which has values in $\mathscr{L}\left(U_{1}, H\right)$ and converges to $\Phi \circ J^{-1}$ in

$$
L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)
$$

such a sequence exists by Lemma 65.4.5 and Proposition 65.3.2.

It is necessary to show that this is well defined and does not depend on the choice of $U_{1}$ and $J$.

Theorem 65.5.3 The stochastic integral 65.5 .7 is well defined. It also is a continuous martingale and does not depend on the choice of $J$ and $U_{1}$. Furthermore,

$$
E\left(\left|\int_{a}^{t} \Phi(s) d W\right|_{H}^{2}\right)=\int_{a}^{t} E\left(\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s
$$

Proof: First of all, it is obvious that it is well defined in the sense that the same stochastic process is obtained from two different sequences of elementary functions. This follows from the isometry of Proposition 65.1 .5 with $U_{1}$ in place of $U$ and $Q^{1 / 2} U$ in place of $U_{0}$. Thus if $\left\{\Psi_{n}\right\}$ and $\left\{\Phi_{n}\right\}$ are two sequences of elementary functions converging to $\Phi \circ J^{-1}$ in $L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$,

$$
\begin{equation*}
E\left(\left|\int_{a}^{T}\left(\Phi_{n}(s)-\Psi_{n}(s)\right) d W\right|_{H}^{2}\right)=\int_{a}^{T} E\left(\left\|\left(\Phi_{n}-\Psi_{n}\right) \circ J\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \tag{65.5.8}
\end{equation*}
$$

Now for $\Phi \in \mathscr{L}_{2}\left(U_{1}, H\right)$ and $\left\{g_{k}\right\}$ an orthonormal basis for $Q^{1 / 2} U$,

$$
\|\Phi \circ J\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} \equiv \sum_{k=1}^{\infty}\left|\Phi\left(J\left(g_{k}\right)\right)\right|_{H}^{2}=\|\Phi\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}^{2}
$$

because, by definition, $\left\{J g_{k}\right\}$ is an orthonormal basis in $J Q^{1 / 2} U$. Hence 65.5 .8 reduces to

$$
\int_{a}^{T} E\left(\left\|\left(\Phi_{n}-\Psi_{n}\right)\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}^{2}\right) d s
$$

which is given to converge to 0 . This reasoning also shows that the sequence $\left\{\int_{a}^{t} \Phi_{n} d W\right\}$ is indeed a Cauchy sequence in $L^{2}(\Omega, H)$.

Why is $\int_{a}^{t} \Phi d W$ a continuous martingale? The integrals $\int_{a}^{t} \Phi_{n} d W$ are martingales and so, by the maximal estimate of Theorem 62.5.3,

$$
\begin{gather*}
P\left(\left[\sup _{t \in[a, T]}\left|\int_{a}^{t} \Phi_{n} d W-\int_{a}^{t} \Phi_{m} d W\right|_{H} \geq \lambda\right]\right) \leq \frac{1}{\lambda^{2}} E\left(\left|\int_{a}^{T}\left(\Phi_{n}-\Phi_{m}\right) d W\right|^{2}\right) \\
=\frac{1}{\lambda^{2}} \int_{a}^{T} E\left(\left\|\left(\Phi_{n}-\Phi_{m}\right) \circ J\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right) d s \\
=\frac{1}{\lambda^{2}} \int_{a}^{T} E\left(\left\|\left(\Phi_{n}-\Phi_{m}\right)\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}^{2}\right) d s \tag{65.5.9}
\end{gather*}
$$

which is given to converge to 0 as $m, n \rightarrow \infty$. Therefore, there exists a subsequence $\left\{n_{k}\right\}$ such that

$$
P\left(\left[\sup _{t \in[a, T]}\left|\int_{a}^{t} \Phi_{n_{k}} d W-\int_{a}^{t} \Phi_{n_{k+1}} d W\right|_{H} \geq 2^{-k}\right]\right) \leq 2^{-k}
$$

Consequently, by the Borel Cantelli lemma, there is a set of measure zero $N$ such that if $\omega \notin$ $N$, then the convergence of $\int_{a}^{t} \Phi_{n_{k}} d W$ to $\int_{a}^{t} \Phi d W$ is uniform on $[a, T]$. Hence $t \rightarrow \int_{a}^{t} \Phi d W$ is continuous as claimed.

Why is it a martingale? Let $s<t$ and $A \in \mathscr{F}_{s}$. Then

$$
\begin{aligned}
\int_{A}\left(\int_{a}^{t} \Phi d W\right) d P & =\lim _{n \rightarrow \infty} \int_{A}\left(\int_{a}^{t} \Phi_{n} d W\right) d P=\lim _{n \rightarrow \infty} \int_{A} E\left(\left(\int_{a}^{t} \Phi_{n} d W\right) \mid \mathscr{F}_{s}\right) d P \\
= & \lim _{n \rightarrow \infty} \int_{A}\left(\int_{a}^{s} \Phi_{n} d W\right) d P=\int_{A}\left(\int_{a}^{s} \Phi d W\right) d P
\end{aligned}
$$

Hence this is a martingale as claimed.
It remains to verify that the stochastic process does not depend on $J$ and $U_{1}$. Let the approximating sequence of elementary functions be

$$
\Phi_{n}(t)=\sum_{j=0}^{m_{n}} f_{j}^{n} \mathscr{X}_{\left[t_{j}^{n}, t_{j+1}^{n}\right]}(t)
$$

where $f_{j}^{n}$ is $\mathscr{F}_{t_{j}^{n}}$ measurable and has finitely many values in $\mathscr{L}\left(U_{1}, H\right)_{0}$, the restrictions of things in $\mathscr{L}\left(U_{1}, H\right)$ to $J Q^{1 / 2} U$. These are the elementary functions which converge to $\Phi \circ J^{-1}$. Also let the partitions be such that

$$
\begin{equation*}
\Phi^{n} \circ J^{-1} \equiv \sum_{j=0}^{m_{n}} \Phi\left(t_{j}^{n}\right) \circ J^{-1} \mathscr{X}_{\left(t_{j}^{n}, t_{j+1}^{n}\right]} \tag{65.5.10}
\end{equation*}
$$

converges to $\Phi \circ J^{-1}$ in $L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2}(U), H\right)\right)$. Then by definition,

$$
\begin{aligned}
& \int_{a}^{t} \Phi_{n} d W=\sum_{j=0}^{m_{n}} f_{j}^{n}\left(W\left(t \wedge t_{j+1}^{n}\right)-W\left(t \wedge t_{j}^{n}\right)\right) \\
& =\sum_{j=0}^{m_{n}} f_{j}^{n} \sum_{k=1}^{\infty}\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right) J g_{k}
\end{aligned}
$$

where $\left\{g_{k}\right\}$ is an orthonormal basis for $Q^{1 / 2} U$. The infinite sum converges in $L^{2}\left(\Omega ; U_{1}\right)$ and $f_{j}^{n}$ is continuous on $U_{1}$. Therefore, $f_{j}^{n}$ can go inside the infinite sum, and this last expression equals

$$
\begin{equation*}
=\sum_{j=0}^{m_{n}} \sum_{k=1}^{\infty}\left(\psi_{k}\left(t \wedge t_{k+1}\right)-\psi_{k}\left(t \wedge t_{k}\right)\right) f_{j}^{n} J g_{k}, \tag{65.5.11}
\end{equation*}
$$

the infinite sum converging in $L^{2}(\Omega, H)$.
Now consider the left sum 65.5.10. Since $\Phi\left(t_{j}^{n}\right) \in \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$, it follows that the sum

$$
\begin{align*}
& \sum_{k=1}^{\infty}\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right) \Phi\left(t_{j}^{n}\right) g_{k} \\
= & \sum_{k=1}^{\infty}\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right) \Phi\left(t_{j}^{n}\right) \circ J^{-1}\left(J g_{k}\right) \tag{65.5.12}
\end{align*}
$$

must converge in $L^{2}(\Omega, H)$. Lets review why this is.

Diversion The reason the series converges goes as follows. Estimate

$$
E\left(\left|\sum_{k=p}^{q}\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right) \Phi\left(t_{j}^{n}\right) g_{k}\right|_{H}^{2}\right)
$$

First consider the mixed terms. Let $\Delta \psi_{k}=\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)$. For $l<k$,

$$
\begin{aligned}
& E\left(\left(\Delta \psi_{k} \Phi\left(t_{j}^{n}\right) g_{k}, \Delta \psi_{l} \Phi\left(t_{j}^{n}\right) g_{l}\right)\right) \\
= & E\left(\Delta \psi_{k} \Delta \psi_{l}\left(\Phi\left(t_{j}^{n}\right) g_{k}, \Phi\left(t_{j}^{n}\right) g_{l}\right)\right)
\end{aligned}
$$

Now by independence, this equals

$$
\begin{aligned}
& E\left(\Delta \psi_{k} \Delta \psi_{l}\right) E\left(\left(\Phi\left(t_{j}^{n}\right) g_{k}, \Phi\left(t_{j}^{n}\right) g_{l}\right)\right) \\
= & E\left(\Delta \psi_{k}\right) E\left(\Delta \psi_{l}\right) E\left(\left(\Phi\left(t_{j}^{n}\right) g_{k}, \Phi\left(t_{j}^{n}\right) g_{l}\right)\right)=0
\end{aligned}
$$

Thus you only need to consider the non mixed terms, and the thing you want to estimate is of the form

$$
\sum_{k=p}^{q} E\left(\left|\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right) \Phi\left(t_{j}^{n}\right) g_{k}\right|^{2}\right)
$$

Now by independence again, this equals

$$
\begin{aligned}
& \sum_{k=p}^{q} E\left(\left(\Delta \psi_{k} \Phi\left(t_{j}^{n}\right) g_{k}, \Delta \psi_{k} \Phi\left(t_{j}^{n}\right) g_{k}\right)\right) \\
= & \sum_{k=p}^{q} E\left(\Delta \psi_{k}^{2}\left(\Phi\left(t_{j}^{n}\right) g_{k}, \Phi\left(t_{j}^{n}\right) g_{k}\right)\right) \\
= & \sum_{k=p}^{q} E\left(\Delta \psi_{k}^{2}\right) E\left(\Phi\left(t_{j}^{n}\right) g_{k}, \Phi\left(t_{j}^{n}\right) g_{k}\right) \\
= & \left(\left(t \wedge t_{j+1}^{n}\right)-\left(t \wedge t_{j}^{n}\right)\right) \sum_{k=p}^{q} E\left(\left|\Phi\left(t_{j}^{n}\right) g_{k}\right|_{H}^{2}\right)
\end{aligned}
$$

and this sum is just a part of the convergent infinite sum for

$$
\int_{\Omega}\left\|\Phi\left(t_{j}^{n}\right)\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d P<\infty
$$

Therefore, this converges to 0 as $p, q \rightarrow \infty$ and so the sum converges in $L^{2}(\Omega, H)$ as claimed.

End of diversion
The $J$ and the $J^{-1}$ cancel in 65.5 .12 because $J$ is one to one. It follows that 65.5.11 equals

$$
\sum_{j=0}^{m_{n}} \sum_{k=1}^{\infty}\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right) \Phi\left(t_{j}^{n}\right) g_{k}+
$$

$$
\sum_{j=0}^{m_{n}} \sum_{k=1}^{\infty}\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right)\left(\left(f_{j}^{n}-\Phi\left(t_{j}^{n}\right) \circ J^{-1}\right)\left(J g_{k}\right)\right)
$$

The first expression does not depend on $J$ or $U_{1}$. I need only argue that the second expression converges to 0 as $n \rightarrow \infty$. The infinite sum converges in $L^{2}(\Omega ; H)$ and also, as in the above diversion, the independence of the $\psi_{k}$ implies that

$$
\begin{aligned}
& E\left(\left|\sum_{j=0}^{m_{n}} \sum_{k=1}^{\infty}\left(\psi_{k}\left(t \wedge t_{j+1}^{n}\right)-\psi_{k}\left(t \wedge t_{j}^{n}\right)\right)\left(\left(f_{j}^{n}-\Phi\left(t_{j}^{n}\right) \circ J^{-1}\right)\left(J g_{k}\right)\right)\right|_{H}^{2}\right) \\
& \quad=\sum_{j=0}^{m_{n}}\left(t \wedge t_{j+1}^{n}-t \wedge t_{j}^{n}\right) \sum_{k=1}^{\infty} E\left(\left|\left(f_{j}^{n}-\Phi\left(t_{j}^{n}\right) \circ J^{-1}\right)\left(J g_{k}\right)\right|_{H}^{2}\right) \\
& \quad=\sum_{j=0}^{m_{n}}\left(t \wedge t_{j+1}^{n}-t \wedge t_{j}^{n}\right) E\left(\left\|f_{j}^{n}-\Phi\left(t_{j}^{n}\right) \circ J^{-1}\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}^{2}\right) \\
& \quad=\int_{a}^{t} E\left(\left\|\Phi_{n}-\Phi^{n} \circ J^{-1}\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}^{2}\right) d s
\end{aligned}
$$

which is given to converge to 0 since both converge to $\Phi \circ J^{-1}$. Consequently, the stochastic integral defined above does not depend on $J$ or $U_{1}$.

It is interesting to note that in the above definition, the approximate problems do appear to depend on $J$ and $U_{1}$ but the limiting stochastic process does not. Since it is the case that the stochastic integral is independent of $U_{1}$ and $J$, it can only be dependent on $Q^{1 / 2} U$ and $U$, and so we refer to $W(t)$ as a cylindrical process on $U$. By Lemma 65.4.3 you can take $U_{1}=U$ and so you can consider the finite sums defining the Wiener process to be in $U$ itself. From the proof of this lemma, you can even have $J$ being the identity on the span of the first $n$ vectors in the orthonormal basis for $Q^{1 / 2} U$. The case where $Q$ is trace class follows in the next section. In this case, $W$ is an actual $Q$ Wiener process on $U$.

The following corollary follows right away from the above theorem.
Corollary 65.5.4 Let $\Phi, \Psi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and suppose they are both progressively measurable. Then

$$
E\left(\left(\int_{a}^{t} \Phi d W, \int_{a}^{t} \Psi d W\right)_{H}\right)=E\left(\int_{a}^{t}(\Phi, \Psi)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d s\right)
$$

Also if $L$ is in $L^{\infty}(\Omega, \mathscr{L}(H, H))$ and is $\mathscr{F}_{a}$ measurable, then

$$
\begin{equation*}
L \int_{a}^{t} \Phi d W=\int_{a}^{t} L \Phi d W \tag{65.5.13}
\end{equation*}
$$

and

$$
\begin{equation*}
E\left(\left(L \int_{a}^{t} \Phi d W, \int_{a}^{t} \Psi d W\right)_{H}\right)=E\left(\int_{a}^{t}(L \Phi, \Psi)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d s\right) \tag{65.5.14}
\end{equation*}
$$

Proof: First note that

$$
\left(\int_{a}^{t} \Phi d W, \int_{a}^{t} \Psi d W\right)_{H}=\frac{1}{4}\left[\left|\int_{a}^{t}(\Phi+\Psi) d W\right|_{H}^{2}-\left|\int_{a}^{t}(\Phi-\Psi) d W\right|_{H}^{2}\right]
$$

and so from the above theorem,

$$
\begin{gathered}
E\left(\left(\int_{a}^{t} \Phi d W, \int_{a}^{t} \Psi d W\right)_{H}\right)= \\
=E\left(\frac{1}{4}\left[\left|\int_{a}^{t}(\Phi+\Psi) d W\right|_{H}^{2}-\left|\int_{a}^{t}(\Phi-\Psi) d W\right|_{H}^{2}\right]\right) \\
\frac{1}{4} E\left(\int_{a}^{t}\|\Phi+\Psi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s\right)+\frac{1}{4} E\left(\int_{a}^{t}\|\Phi-\Psi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s\right) \\
=E\left(\int_{a}^{t} \frac{1}{4}\left[\|\Phi+\Psi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}+\|\Phi-\Psi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2}\right] d s\right) \\
=E\left(\int_{a}^{t}(\Phi, \Psi)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d s\right)
\end{gathered}
$$

Now consider the last claim. First suppose $L=l \mathscr{X}_{A}$ where $A \in \mathscr{F}_{a}$, and $l \in \mathscr{L}(H, H)$. Also suppose $\Phi$ is an elementary function

$$
\Phi=\sum_{i=0}^{n} \psi_{i} \mathscr{X}_{\left(s_{i}, s_{i+1}\right]}
$$

Then

$$
\begin{aligned}
L \int_{a}^{t} \Phi d W & =l \mathscr{X}_{A} \sum_{i=0}^{n} \psi_{i}\left(W\left(t \wedge s_{i+1}\right)-W\left(t \wedge s_{i}\right)\right) \\
& =\sum_{i=0}^{n} l \mathscr{X}_{A} \psi_{i}\left(W\left(t \wedge s_{i+1}\right)-W\left(t \wedge s_{i}\right)\right)
\end{aligned}
$$

Thus 65.5.13 also holds for $L$ a simple function which is $\mathscr{F}_{a}$ measurable. For general $L \in L^{\infty}(\Omega, \mathscr{L}(H, H))$, approximating with a sequence of such simple functions $L_{n}$ yields

$$
L \int_{a}^{t} \Phi d W=\lim _{n \rightarrow \infty} L_{n} \int_{a}^{t} \Phi d W=\lim _{n \rightarrow \infty} \int_{a}^{t} L_{n} \Phi d W=\int_{a}^{t} L \Phi d W
$$

because $L_{n} \Phi \rightarrow L \Phi$ in $L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Now what about general $\Phi$ ? Let $\left\{\Phi_{n}\right\}$ be elementary functions converging to $\Phi \circ J^{-1}$ in $L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$. Then by definition of the integral,

$$
L \int_{a}^{t} \Phi d W=\lim _{n \rightarrow \infty} L \int_{a}^{t} \Phi_{n} d W=\lim _{n \rightarrow \infty} \int_{a}^{t} L \Phi_{n} d W=\int_{a}^{t} L \Phi d W
$$

The remaining claim now follows from the first part of the proof.
The above has discussed the integral of $\Phi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. An obvious case to consider is when

$$
\Phi=\sum_{k=0}^{n-1} \Phi_{k} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t)
$$

and $\Phi_{k} \in L^{2}\left(\Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ with $\Phi_{k}$ measurable with respect to $\mathscr{F}_{t_{k}}$. What is $\int_{0}^{t} \Phi d W$ ? First note that $\Phi_{k} \circ J^{-1} \in L^{2}\left(\Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$. Let

$$
\lim _{m \rightarrow \infty} \Phi_{k}^{m} \rightarrow \Phi_{k} \circ J^{-1}
$$

in $L^{2}\left(\Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$ where $\Phi_{k}^{m}$ is $\mathscr{F}_{t_{k}}$ measurable and is a simple function having values in $\mathscr{L}\left(U_{1}, H\right)$. Thus

$$
\Phi_{m} \equiv \sum_{k=0}^{n-1} \Phi_{k}^{m} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t)
$$

is an elementary function and it converges to $\Phi \circ J^{-1}$ in $L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$. It follows that

$$
\begin{aligned}
\int_{a}^{t} \Phi d W & \equiv \lim _{m \rightarrow \infty} \int_{a}^{t} \Phi_{m} d W \equiv \lim _{m \rightarrow \infty} \sum_{k=0}^{n-1} \Phi_{k}^{m}\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right) \\
& =\sum_{k=0}^{n-1} \Phi_{k} \circ J^{-1}\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right)
\end{aligned}
$$

Note again how it appears to depend on $J$ but really doesn't because there is a $J$ in the definition of $W$.

### 65.6 The Case That $Q$ Is Trace Class

In this special case, you have a $Q$ Wiener process with values in $U$ and still you have

$$
\Phi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)
$$

with $\Phi$ progressively measurable. The difference here is that in fact, $Q$ is trace class.

$$
Q=\sum_{i=1}^{L} \lambda_{i} e_{i} \otimes e_{i}
$$

where $\lambda_{i}>0, \sum_{i} \lambda_{i}<\infty$, and the $e_{i}$ form an orthonormal set of vectors. $L$ is either a positive integer or $\infty$. Then let $U_{0}=Q^{1 / 2} U$. Then $Q^{1 / 2}=\sum_{i=1}^{L} \sqrt{\lambda_{i}} e_{i} \otimes e_{i}$ because this works, and the square root is unique. Hence $Q^{1 / 2} e_{i}=\sqrt{\lambda_{i}} e_{i}$ and so an orthonormal basis for $U_{0}=Q^{1 / 2} U$ is $\left\{\sqrt{\lambda_{i}} e_{i}\right\}_{i=1}^{L}$. Now consider $J=\sum_{i=1}^{L} \sqrt{\lambda_{i}}\left(e_{i} \otimes \sqrt{\lambda_{i}} e_{i}\right), J: U_{0} \rightarrow U$, where the tensor product is defined in the usual way,

$$
u \otimes v(w) \equiv u(w, v)_{U_{0}}
$$

Then $J^{*}=\sum_{i=1}^{L} \sqrt{\lambda_{i}}\left(\sqrt{\lambda_{i}} e_{i} \otimes e_{i}\right)$ and $J J^{*}=\sum_{i=1}^{L} \lambda_{i} e_{i} \otimes e_{i}=Q$. Also, $J$ is a Hilbert Schmidt map into $U$ from $U_{0}$.

$$
\sum_{i=1}^{L}\left\|J\left(\sqrt{\lambda_{i}} e_{i}\right)\right\|_{U}^{2}=\sum_{i=1}^{L}\left\|\sqrt{\lambda_{i}} e_{i}\right\|_{U}^{2}=\sum_{i=1}^{L} \lambda_{i}<\infty
$$

and so $J$ is a Hilbert Schmidt mapping. In addition to this, from the construction, the span of $\left\{e_{i}\right\}_{i=1}^{L}$ is dense in $U_{0}$ and $J e_{i}=e_{i}$ because

$$
J e_{k}=\sum_{i=1}^{L} \sqrt{\lambda_{i}}\left(e_{i} \otimes \sqrt{\lambda_{i}} e_{i}\right)\left(e_{k}\right)=e_{k} \sqrt{\lambda_{k}}\left(e_{k}, \sqrt{\lambda_{k}} e_{k}\right)_{U_{0}}=e_{k}
$$

so in fact $J$ is just the injection map of $U_{0}$ into $U$. Hence $J^{-1}$ must also be the identity map. Now we can let $U_{1}=U$ with $J$ the injection map. Thus, in this case, the elementary functions $\Phi_{n}$ simply converge to $\Phi$ in

$$
L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J U_{0}, H\right)\right)
$$

Note that $\left\|J \sqrt{\lambda_{i}} e_{i}\right\|_{U}=\sqrt{\lambda_{i}}$ whereas $\left\|\sqrt{\lambda_{i}} e_{i}\right\|_{Q^{1 / 2} U}=1$, and so $J$ definitely does not preserve norms. That is, the norm in $U_{0}$ is not the same as the norm in $U$. Then everything else is the same. In particular

$$
E\left(\left|\int_{a}^{t} \Phi d W\right|_{H}^{2}\right)=\int_{a}^{t} E\left(\|\Phi\|_{\mathscr{L}_{2}\left(U_{0}, H\right)}^{2}\right) d s
$$

### 65.7 A Short Comment On Measurability

It will also be important to consider the composition of functions. The following is the main result. With the explanation of progressively measurable given, it says the composition of progressively measurable functions is progressively measurable.

Proposition 65.7.1 Let $A:[a, T] \times V \times \Omega \rightarrow U$ where $V, U$ are topological spaces and suppose $A$ satisfies its restriction to $[a, t] \times V \times \Omega$ is $\mathscr{B}([a, t]) \times \mathscr{B}(V) \times \mathscr{F}_{t}$ measurable . This will be referred to as $A$ is progressively measurable. Then if $X:[a, T] \times \Omega \rightarrow V$ is progressively measurable, then so is the map

$$
(t, \omega) \rightarrow A(t, X(t, \omega), \omega)
$$

Proof: Consider the restriction of this map to $\left[a, t_{0}\right] \times \Omega$. For such $(t, \omega)$, to say

$$
A(t, X(t, \omega), \omega) \in O
$$

for $O$ a Borel set in $U$ is to say that

$$
X(t, \omega) \in\left\{v:(t, v, \omega) \in A^{-1}(O), t \leq t_{0}\right\} \equiv A^{-1}(O)_{t \omega}
$$

Consider the set

$$
\left\{(t, \omega) \in\left[a, t_{0}\right] \times \Omega: X(t, \omega) \in A^{-1}(O)_{t \omega}\right\}
$$

Is this in $\mathscr{B}\left(\left[a, t_{0}\right]\right) \times \mathscr{F}_{t_{0}}$ ? This is what needs to be checked. Since $A$ is progressively measurable,

$$
A^{-1}(O) \cap\left[a, t_{0}\right] \times V \times \Omega \in \mathscr{B}\left(\left[a, t_{0}\right]\right) \times \mathscr{B}(V) \times \mathscr{F}_{t_{0}} \equiv \mathscr{P}_{t_{0}}
$$

because $A^{-1}(O)$ is a progressively measurable set. So let

$$
\mathscr{G} \equiv\left\{S \in \mathscr{P}_{t_{0}}:\left\{(t, \omega) \in\left[a, t_{0}\right] \times \Omega: X(t, \omega) \in S_{t \omega}\right\} \in \mathscr{B}\left(\left[a, t_{0}\right]\right) \times \mathscr{F}_{t_{0}}\right\}
$$

It is clear that $\mathscr{G}$ contains the $\pi$ system composed of sets of the form $I \times B \times W$ where $I$ is an interval in $\left[a, t_{0}\right], B$ is Borel, and $W \in \mathscr{F}_{t_{0}}$. This is because for $S$ of this form, $S_{t \omega}=B$ or $\emptyset$. Thus if not empty,

$$
\begin{aligned}
& \left\{(t, \omega) \in\left[a, t_{0}\right] \times \Omega: X(t, \omega) \in S_{t \omega}\right\} \\
= & X^{-1}(B) \cap\left[0, t_{0}\right] \times \Omega \in \mathscr{B}\left(\left[a, t_{0}\right]\right) \times \mathscr{F}_{t_{0}}
\end{aligned}
$$

because $X$ is given to be progressively measurable. Now if $S \in \mathscr{G}$, what about $S^{C}$ ? You have $\left(S^{C}\right)_{t \omega}=\left(S_{t \omega}\right)^{C}$ thus

$$
\begin{aligned}
& \left\{(t, \omega) \in\left[a, t_{0}\right] \times \Omega: X(t, \omega) \in\left(S^{C}\right)_{t \omega}\right\} \\
= & \left\{(t, \omega) \in\left[a, t_{0}\right] \times \Omega: X(t, \omega) \in\left(S_{t \omega}\right)^{C}\right\}
\end{aligned}
$$

which is the complement with respect to $\left[a, t_{0}\right] \times \Omega$ of a set in $\mathscr{B}\left(\left[a, t_{0}\right]\right) \times \mathscr{F}_{t_{0}}$. Therefore, $\mathscr{G}$ is closed with respect to complements. It is clearly closed with respect to countable disjoint unions. It follows, $\mathscr{G}=\mathscr{P}_{t_{0}}$. Thus

$$
\left\{(t, \omega) \in\left[a, t_{0}\right] \times \Omega: X(t, \omega) \in S_{t \omega}\right\} \in \mathscr{B}\left(\left[a, t_{0}\right]\right) \times \mathscr{F}_{t_{0}}
$$

where $S=A^{-1}(O) \cap\left[a, t_{0}\right] \times V \times \Omega$. In other words,

$$
\left\{(t, \omega), t \leq t_{0}: A(t, X(t, \omega), \omega) \in O\right\} \in \mathscr{B}\left(\left[0, t_{0}\right]\right) \times \mathscr{F}_{t_{0}}
$$

and so $(t, \omega) \rightarrow A(t, X(t, \omega), \omega)$ is progressively measurable.

### 65.8 Localization For Elementary Functions

It is desirable to extend everything to stochastically square integrable functions. This will involve localization using a suitable stopping time. First it is necessary to understand localization for elementary functions. As above, we are in the situation described by the following diagram.

$$
\begin{aligned}
& U \\
& \begin{array}{l}
\downarrow Q^{1 / 2} \\
Q^{1 / 2} U
\end{array} \\
& \Phi_{n} \searrow \\
& \downarrow \Phi
\end{aligned}
$$

The elementary functions $\left\{\Phi_{n}\right\}$ have values in $\mathscr{L}\left(U_{1}, H\right)_{0}$ meaning they are restrictions of functions in $\mathscr{L}\left(U_{1}, H\right)$ to $J Q^{1 / 2} U$ and converge to $\Phi \circ J^{-1}$ in

$$
L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)
$$

where $\Phi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ is given. Let

$$
\Phi(t) \equiv \sum_{k=0}^{n-1} \Phi\left(t_{k}\right) \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t)
$$

be an elementary function. In particular, let $\Phi\left(t_{k}\right)$ be $\mathscr{F}_{t_{k}}$ measurable as a map into $\mathscr{L}\left(U_{1}, H\right)$, and has finitely many values. As just mentioned, the topic of interest is the elementary functions $\Phi_{n}$ in the above diagram. Thus $\Phi$ will be one of these elementary functions.

Let $\tau$ be a stopping time having values from the set of mesh points $\left\{t_{k}\right\}$ for the elementary function. Then from the definition of the integral for elementary functions,

$$
\int_{a}^{t \wedge \tau} \Phi d W \equiv \sum_{k=0}^{n-1} \Phi\left(t_{k}\right)\left(W\left(t \wedge \tau \wedge t_{k+1}\right)-W\left(t \wedge \tau \wedge t_{k}\right)\right)
$$

If $\omega$ is such that $\tau(\omega)=t_{j}$, then to get something nonzero, you must have $t_{j}>t_{k}$ so $k \leq j-1$. Thus the above on the right reduces to

$$
\sum_{k=0}^{j-1} \Phi\left(t_{k}\right)\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right)
$$

It clearly is 0 if $j=0$. Define $\sum_{k=0}^{-1} \equiv 0$. Thus the integral equals

$$
\sum_{j=0}^{n} \mathscr{X}_{\left[\tau=t_{j}\right]} \sum_{k=0}^{j-1} \Phi\left(t_{k}\right)\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right)
$$

Interchanging the order of summation, $k \leq j-1$ so $j \geq k+1$ and this equals

$$
\begin{aligned}
& \sum_{k=0}^{n-1} \sum_{j=k+1}^{n} \mathscr{X}_{\left[\tau=t_{j}\right]} \Phi\left(t_{k}\right)\left(W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right) \\
&= \sum_{k=0}^{n-1} \overbrace{\mathscr{X}_{\left[\tau>t_{k}\right.} \text { measurable }} \Phi\left(t_{k}\right) \\
& \mathscr{F}_{k} \\
&\left.W\left(t \wedge t_{k+1}\right)-W\left(t \wedge t_{k}\right)\right)
\end{aligned}
$$

Therefore

$$
\begin{equation*}
\int_{a}^{t \wedge \tau} \Phi d W=\int_{a}^{t} \sum_{k=0}^{t-1} \mathscr{X}_{\left[\tau>t_{k}\right]} \Phi\left(t_{k}\right) \mathscr{X}_{\left(t_{k}, t_{k+1}\right]} d W \tag{65.8.15}
\end{equation*}
$$

Now observe

$$
\begin{align*}
\mathscr{X}_{[a, \tau]}(t) \Phi(t) & =\sum_{k=0}^{n-1} \mathscr{X}_{[a, \tau]}(t) \Phi\left(t_{k}\right) \mathscr{X}_{\left[t_{k}, t_{k+1}\right]}(t) \\
& =\sum_{k=0}^{n-1} \mathscr{X}_{[\tau \geq t]} \Phi\left(t_{k}\right) \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t) \\
& =\sum_{k=0}^{n-1} \mathscr{X}_{\left[\tau>t_{k}\right]} \Phi\left(t_{k}\right) \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t) \tag{65.8.16}
\end{align*}
$$

The last step occurs because of the following reasoning. The $k^{t h}$ term of the sum in the middle expression above equals $\Phi\left(t_{k}\right)$ if and only if $t>t_{k}$ and $\tau \geq t$. If the two conditions do not hold, then the $k^{t h}$ term equals 0 . As to the third line, if $\tau>t_{k}$ and $t \in\left(t_{k}, t_{k+1}\right]$, then $\tau \geq t_{k+1} \geq t$ which is the same as the situation in the second line. The term equals $\Phi\left(t_{k}\right)$. Note that $\mathscr{X}_{\left[\tau>t_{k}\right]}(\omega)$ is $\mathscr{F}_{t_{k}}$ measurable, because $\left[\tau>t_{k}\right]$ is the complement of $\left[\tau \leq t_{k}\right]$. Therefore, this is an elementary function. Thus, from 65.8.15-65.8.16, $\mathscr{X}_{[a, \tau]}(t) \Phi(t)$ is an elementary function and

$$
\int_{a}^{t \wedge \tau} \Phi d W=\int_{a}^{t} \sum_{k=0}^{t-1} \mathscr{X}_{\left[\tau>t_{k}\right]} \Phi\left(t_{k}\right) \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t) d W=\int_{a}^{t} \mathscr{X}_{[a, \tau]}(t) \Phi(t) d W
$$

From Proposition 65.1.5, if you have $\Phi, \Psi$ two of these elementary functions

$$
\begin{gather*}
E\left(\left\|\int_{a}^{t} \mathscr{X}_{[a, \tau]}(t) \Phi(t) d W-\int_{a}^{t} \mathscr{X}_{[a, \tau]}(t) \Psi(t) d W\right\|_{H}^{2}\right)= \\
\quad \int_{a}^{t} \int_{\Omega} \mathscr{X}_{[a, \tau]}(t)\|(\Phi(s)-\Psi(s)) \circ J\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d P d s \\
\leq \int_{a}^{t} \int_{\Omega}\|(\Phi(s)-\Psi(s)) \circ J\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d P d s \tag{65.8.17}
\end{gather*}
$$

### 65.9 Localization In General

Next, what about the general case where $\Phi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and is progressively measurable? Is it the case that for an arbitrary stopping time $\tau$,

$$
\int_{a}^{t \wedge \tau} \Phi d W=\int_{a}^{t} \mathscr{X}_{[a, \tau]} \Phi d W ?
$$

This is the sort of thing which would be expected for an ordinary Stieltjes integral which of course this isn't. Let

$$
L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)=K
$$

From Doob's result Proposition 65.3.2 and Lemma 65.3.1, there exists a sequence of elementary functions $\left\{\Phi_{k}\right\}$

$$
\Phi_{k}(t)=\sum_{j=0}^{m_{k}-1} \Phi\left(t_{j}^{k}\right) \mathscr{X}_{\left(t_{j}^{k}, t_{j+1}^{k}\right]}(t)
$$

which converges to $\Phi \circ J^{-1}$ in $K$ where also the lengths of the sub intervals converge uniformly to 0 as $k \rightarrow \infty$.

Now let $\tau$ be an arbitrary stopping time. The partition points corresponding to $\Phi_{k}$ are $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$. Let $\tau_{k}=t_{j+1}^{k}$ on $\tau^{-1}\left(t_{j}^{k}, t_{j+1}^{k}\right]$. Then $\tau_{k}$ is a stopping time because

$$
\left[\tau_{k} \leq t\right] \in \mathscr{F}_{t}
$$

Here is why. If $t \in\left(t_{j}^{k}, t_{j+1}^{k}\right]$, then if $t=t_{j+1}^{k}$, it would follow that $\tau_{k}(\omega) \leq t$ would be the same as saying $\omega \in\left[\tau \leq t_{j+1}^{k}\right]=[\tau \leq t] \in \mathscr{F}_{t}$. On the other hand, if $t<t_{j+1}^{k}$, then $\left[\tau_{k} \leq t\right]=\left[\tau \leq t_{j}^{k}\right] \in \mathscr{F}_{t_{j}^{k}} \subseteq \mathscr{F}_{t}$ because $\tau_{k}$ can only take the values $t_{j}^{k}$.

Consider $\mathscr{X}_{\left[a, \tau_{k}\right]} \Phi_{k}$. It is given that $\Phi_{k} \rightarrow \Phi \circ J^{-1}$ in $K$. Does it follow that $\mathscr{X}_{\left[a, \tau_{k}\right]} \Phi_{k} \rightarrow$ $\mathscr{X}_{[a, \tau]} \Phi \circ J^{-1}$ in $K$ ? Consider first the indicator function. Let $\tau(\omega) \in\left(t_{j}^{k}, t_{j+1}^{k}\right]$. Fixing $t$, if $\mathscr{X}_{[a, \tau]}(t)=1$, then also $\mathscr{X}_{\left[a, \tau_{k}\right]}(t)=1$ because $\tau_{k} \geq \tau$. Therefore, in this case

$$
\lim _{k \rightarrow \infty} \mathscr{X}_{\left[a, \tau_{k}\right]}(t)=\mathscr{X}_{[a, \tau]}(t) .
$$

Next suppose $\mathscr{X}_{[a, \tau]}(t)=0$ so that $\tau(\omega)<t$. Since the intervals defined by the partition points have lengths which converge to 0 , it follows that for all $k$ large enough, $\tau_{k}(\omega)<t$ also and so $\mathscr{X}_{\left[a, \tau_{k}\right]}(t)=0$. Therefore,

$$
\lim _{k \rightarrow \infty} \mathscr{X}_{\left[a, \tau_{k}(\omega)\right]}(t)=\mathscr{X}_{[a, \tau(\omega)]}(t) .
$$

It follows that $\mathscr{X}_{\left[a, \tau_{k}\right]} \Phi_{k} \rightarrow \mathscr{X}_{[a, \tau]} \Phi \circ J^{-1}$ in $K$. Now from 65.8.16, the function $\mathscr{X}_{\left[a, \tau_{k}\right]} \Phi_{k}$ is progressively measurable. Therefore, the same is true of $\mathscr{X}_{[a, \tau]} \Phi \circ J^{-1}$.

From the proof of Theorem 65.5.3, the part depending on maximal estimates and the fact that $\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{k}\right]} \Phi_{k} d W$ is a continuous martingale, there is a set of measure zero $N$, such that off this set, a suitable subsequence satisfies

$$
\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{k}\right]} \Phi_{k} d W \rightarrow \int_{a}^{t} \mathscr{X}_{[a, \tau]} \Phi d W
$$

uniformly on $[a, T]$. But also, since $\Phi_{k} \rightarrow \Phi \circ J^{-1}$ in $K$, a suitable subsequence satisfies,

$$
\int_{a}^{t} \Phi_{k} d W \rightarrow \int_{a}^{t} \Phi d W
$$

uniformly on $[a, T]$ a.e. $\omega$. In particular, $\int_{a}^{t \wedge \tau_{k}} \Phi_{k} d W \rightarrow \int_{a}^{t \wedge \tau} \Phi d W$. Therefore,

$$
\begin{aligned}
\int_{a}^{t} \mathscr{X}_{[a, \tau]} \Phi d W & =\lim _{k \rightarrow \infty} \int_{a}^{t} \mathscr{X}_{\left[a, \tau_{k}\right]} \Phi_{k} d W \\
& =\lim _{k \rightarrow \infty} \int_{a}^{t \wedge \tau_{k}} \Phi_{k} d W \\
& =\int_{a}^{t \wedge \tau} \Phi d W
\end{aligned}
$$

This has proved the following major localization lemma. This is a marvelous result. It says that the stochastic integral acts algebraically like an ordinary Stieltjes integral, one for each $\omega$ off a set of measure zero.

Lemma 65.9.1 Let $\Phi$ be progressively measurable and in

$$
L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)
$$

Let $W(t)$ be a cylindrical Wiener process as described above. Then for $\tau$ a stopping time, $\mathscr{X}_{[a, \tau]} \Phi$ is progressively measurable, in $K$, and

$$
\int_{a}^{t \wedge \tau} \Phi d W=\int_{a}^{t} \mathscr{X}_{[a, \tau]} \Phi d W
$$

### 65.10 The Stochastic Integral As A Local Martingale

With Lemma 65.9.1, it becomes possible to define the stochastic integral on functions which are only stochastically square integrable.

Definition 65.10.1 $\Phi$ is stochastically square integrable in $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ if $\Phi$ is progressively measurable and

$$
P\left(\left[\int_{a}^{T}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s<\infty\right]\right)=1
$$

Thus equivalently, there exists $N$ such that $P(N)=0$ and for $\omega \notin N$,

$$
\int_{a}^{T}\|\Phi(s, \omega)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s<\infty
$$

Lemma 65.10.2 Suppose $\Phi$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ progressively measurable and

$$
P\left(\left[\int_{a}^{T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s<\infty\right]\right)=1 .
$$

Define

$$
\tau_{n}(\omega) \equiv \inf \left\{t \in[a, T]: \int_{a}^{t}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s \geq n\right\}
$$

By convention, let $\inf \emptyset=\infty$. Then $\tau_{n}$ is a stopping time. Furthermore, $\tau_{n}$ has the following properties.

1. $\left\{\tau_{n}\right\}$ is an increasing sequence and for $\omega$ outside a set of measure zero $N$, for every $t \in[a, T]$ there exists $n$ such that $\tau_{n}(\omega)>t$. (It is a localizing sequence of stopping times.)
2. For each $n, \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi$ is progressively measurable and

$$
E\left(\int_{a}^{T}\left\|\mathscr{X}_{\left[a, \tau_{n}\right]} \Phi\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t\right)<\infty
$$

Proof: It follows from Proposition 62.7.5 that $\tau_{n}$ is a stopping time because it is the first hitting time of a closed set by an adapted continuous process.

It remains to verify the two claims. There exists a set of measure $0, N$ such that for $\omega \notin N$

$$
\int_{a}^{T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t<\infty
$$

Therefore, for such $\omega$, there exists $n$ large enough that

$$
\int_{a}^{t}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s<n
$$

and so $\tau_{n}(\omega) \geq t$. Now consider the second claim.

$$
\begin{aligned}
& E\left(\int_{a}^{T}\left\|\mathscr{X}_{\left[a, \tau_{n}\right]} \Phi\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t\right) \\
= & E\left(\int_{a}^{\tau_{n}(\omega) \wedge T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t\right) \leq E(n)=n .
\end{aligned}
$$

With this lemma, it is possible to give the following definition.
Definition 65.10.3 Suppose $\Phi$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ progressively measurable and

$$
\begin{equation*}
P\left(\left[\int_{a}^{T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s<\infty\right]\right)=1 \tag{65.10.18}
\end{equation*}
$$

More generally, suppose there exists a localizing sequence of stopping times $\tau_{n}$ having the two properties of Lemma 65.10.2. Then for all $\omega$ not in the exceptional set $N$.

$$
\int_{a}^{t} \Phi d W \equiv \lim _{n \rightarrow \infty} \int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W
$$

Lemma 65.10.4 The above definition is well defined. For all $\omega$ not in a set of measure zero,

$$
\int_{a}^{t} \Phi d W(\omega) \equiv \lim _{n \rightarrow \infty} \int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W(\omega)
$$

the function on the right being constant for all n large enough for a given $\omega$. The random variable $\int_{a}^{t} \Phi d W$ is also $\mathscr{F}_{t}$ adapted.

Proof: Let $\left\{\tau_{n}\right\}$ be a sequence of stopping times as described in 1 and 2 of Lemma 65.10.2. Such a sequence exists by Lemma 65.10.2. It makes sense to define the random variable

$$
\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W
$$

Now what if both $\tau_{m}$ and $\tau_{n}$ are at least as large as $t$ for some $\omega$ ? Do the two random variables coincide at that value of $\omega$ ? Say $m>n$ so that $\tau_{m}(\omega) \geq \tau_{n}(\omega)>t$. For the given $\omega$,

$$
\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{m}\right]} \Phi d W=\int_{a}^{t \wedge \tau_{m}} \mathscr{X}_{\left[a, \tau_{m}\right]} \Phi d W
$$

For the particular $\omega$ of interest,

$$
=\int_{a}^{t \wedge \tau_{n}} \mathscr{X}_{\left[a, \tau_{m}\right]} \Phi d W
$$

and this equals

$$
=\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \mathscr{X}_{\left[a, \tau_{m}\right]} \Phi d W=\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W
$$

for all $\omega$, in particular for the given $\omega$. Therefore, for the particular $\omega$ of interest,

$$
\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W=\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{m}\right]} \Phi d W
$$

Thus the limit exists because for all $n$ large enough, the integral is eventually constant. Then $\int_{a}^{t} \Phi d W$ is $\mathscr{F}_{t}$ adapted because for $U$ an open set in $H$,

$$
\left(\int_{a}^{t} \Phi d W\right)^{-1}(U)=\cup_{n=1}^{\infty}\left(\left(\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W\right)^{-1}(U) \cap\left[\tau_{n}>t\right]\right) \in \mathscr{F}_{t}
$$

The next lemma says that even when $\int_{a}^{t} \Phi(s) d W(s)$ is only a local martingale relative to a suitable localizing sequence, it is still the case that

$$
\int_{a}^{t \wedge \sigma} \Phi d W=\int_{a}^{t} \mathscr{X}_{[a, \sigma]} \Phi d W
$$

Lemma 65.10.5 Let $\Phi$ be progressively measurable and suppose there exists the localizing sequence described above. Then if $\sigma$ is a stopping time,

$$
\int_{a}^{t \wedge \sigma} \Phi d W(s)=\int_{a}^{t} \mathscr{X}_{[a, \sigma]} \Phi d W(s)
$$

Proof: Let $\left\{\tau_{n}\right\}$ be the localizing sequence described above for which, when the local martingale is stopped, it results in a martingale, (satisfying 1 and 2 on Page 2253). Then by definition,

$$
\begin{aligned}
\int_{a}^{t \wedge \sigma} \Phi d W(s) & \equiv \lim _{n \rightarrow \infty} \int_{a}^{t \wedge \tau_{n} \wedge \sigma} \Phi d W(s) \\
& =\lim _{n \rightarrow \infty} \int_{a}^{t \wedge \tau_{n}} \mathscr{X}_{[a, \sigma]} \Phi d W(s)=\int_{a}^{t} \mathscr{X}_{[a, \sigma]} \Phi d W(s)
\end{aligned}
$$

since $t \wedge \tau_{n}=t$ for all $n$ large enough.

### 65.11 The Quadratic Variation Of The Stochastic Integral

An important corollary of Lemma 65.9.1 concerns the quadratic variation of $\int_{a}^{t} \Phi d W$. It is convenient here to use the notation $\int_{a}^{t} \Phi d W \equiv \Phi \cdot W(t)$. Recall this is a local submartingale $[\Phi \cdot W]$ such that

$$
\|\Phi \cdot W(t)\|_{H}^{2}=[\Phi \cdot W](t)+N(t)
$$

where $N$ is a local martingale. Recall the quadratic variation is unique so that if it acts like the quadratic variation, then it is the quadratic variation. Recall also why this was so. If you have a local martingale equal to the difference of increasing adapted processes which equals 0 when $t=0$, then the local martingale was equal to 0 . Of course you can substitute $a$ for 0 .

Corollary 65.11.1 Suppose $\Phi$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ progressively measurable and has the localizing sequence with the two properties in Lemma 65.10.2. Then the quadratic variation, $[\Phi \cdot W]$ is given by the formula

$$
[\Phi \cdot W](t)=\int_{a}^{t}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s
$$

Proof: By the above discussion, $\int_{a}^{t} \Phi d W$ is a local martingale. Let $\left\{\tau_{n}\right\}$ be a localizing sequence for which the stopped local martingale is a martingale and $\Phi \mathscr{X}_{\left[a, \tau_{n}\right]}$ is in $L^{2}\left([a, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Also let $\sigma$ be a stopping time with two values no larger than $T$. Then from Lemma 65.10.5,

$$
\begin{gathered}
E\left(\left|\int_{a}^{\tau_{n} \wedge \sigma} \Phi d W\right|_{H}^{2}-\int_{a}^{\tau_{n} \wedge \sigma}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s\right) \\
E\left(\left|\int_{a}^{T \wedge \tau_{n} \wedge \sigma} \Phi d W\right|_{H}^{2}-\int_{a}^{T \wedge \tau_{n} \wedge \sigma}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s\right) \\
=E\left(\left|\int_{a}^{T} \mathscr{X}_{\left[a, \tau_{n}\right]} \mathscr{X}_{[0, \sigma]} \Phi d W\right|_{H}^{2}-\int_{a}^{T} \mathscr{X}_{\left[a, \tau_{n}\right]} \mathscr{X}_{[0, \sigma]}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s\right) \\
= \\
E\left(\int_{a}^{T}\left\|\mathscr{X}_{\left[a, \tau_{n}\right]} \mathscr{X}_{[0, \sigma]} \Phi\right\|_{\mathscr{L}_{2}}^{2} d t\right)-E\left(\int_{a}^{T}\left\|\mathscr{X}_{\left[a, \tau_{n}\right]} \mathscr{X}_{[0, \sigma]} \Phi(s)\right\|_{\mathscr{L}_{2}}^{2} d s\right)=0
\end{gathered}
$$

thanks to the Ito isometry. There is also no change in letting $\sigma=t$. You still get 0 . It follows from Lemma 63.1.1, the lemma about recognizing a martingale when you see one, that

$$
t \rightarrow\left|\int_{a}^{t \wedge \tau_{n}} \Phi d W\right|_{H}^{2}-\int_{a}^{t \wedge \tau_{n}}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s
$$

is a martingale. Therefore,

$$
\left|\int_{a}^{t} \Phi d W\right|_{H}^{2}-\int_{a}^{t}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s
$$

is a local martingale and so, by uniqueness of the quadratic variation,

$$
[\Phi \cdot W](t)=\int_{a}^{t}\|\Phi(s)\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s
$$

Here is an interesting little lemma which seems to be true.

Lemma 65.11.2 Let $\Phi, \Phi_{n}$ all be in $L^{2}\left([0, T], \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ off some set of measure zero. These are all progressively measurable. Thus there are all stochastically square integrable.

$$
P\left(\int_{0}^{T}\|\Phi\|^{2} d s\right)=1
$$

Suppose also that for each $\omega \notin N$, the exceptional set,

$$
\int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} d t \rightarrow 0
$$

Then there exists a set of measure zero, still denoted as $N$ and a subsequence, still denoted as $n$ such that for each $\omega \notin N$,

$$
\lim _{n \rightarrow \infty} \int_{0}^{T} \Phi_{n} d W=\int_{0}^{T} \Phi d W
$$

Proof: Define stopping times

$$
\tau_{n p} \equiv \inf \left\{t \in[0, T]: \int_{0}^{t}\left\|\Phi_{n}\right\|^{2} d s>p\right\}
$$

Let $\tau_{p}$ be similar but defined with reference to $\Phi$. Then by Ito isometry,

$$
\begin{align*}
& E\left(\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n} d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W\right|^{2}\right) \\
= & E\left(\int_{0}^{T}\left\|\mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n}-\mathscr{X}_{\left[0, \tau_{p}\right]} \Phi\right\|_{\mathscr{L}_{2}}^{2} d t\right) \tag{65.11.19}
\end{align*}
$$

The integrand in the right side is bounded by $2 p^{2}$. Also this integrand converges to 0 for each $\omega$ as $n \rightarrow \infty$. This is shown next.

$$
\begin{aligned}
& \int_{0}^{T}\left\|\mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n}-\mathscr{X}_{\left[0, \tau_{p}\right]} \Phi\right\|_{\mathscr{L}_{2}}^{2} d t \\
\leq & 2 \int_{0}^{T}\left(\left\|\mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n}-\mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi\right\|_{\mathscr{L}_{2}}^{2}+\left\|\mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi-\mathscr{X}_{\left[0, \tau_{p}\right]} \Phi\right\|_{\mathscr{L}_{2}}^{2}\right) d t \\
\leq & 2 \int_{0}^{T}\left\|\Phi_{n}-\Phi\right\|_{\mathscr{L}_{2}}^{2} d t+2 \int_{0}^{T}\left|\mathscr{X}_{\left[0, \tau_{n p}\right]}(t)-\mathscr{X}_{\left[0, \tau_{p}\right]}(t)\right|^{2}\|\Phi\|_{\mathscr{L}_{2}}^{2} d t
\end{aligned}
$$

The first converges to 0 by assumption. Problem is, it does not look like this second integral converges to 0 . We do know that $\int_{0}^{t}\left\|\Phi_{n}\right\|^{2} d s \rightarrow \int_{0}^{t}\|\Phi\|^{2} d s$ uniformly so $\tau_{n p} \rightarrow \tau_{p}$ is likely. However, this does not imply $\mathscr{X}_{\left[0, \tau_{n p}\right]} \rightarrow \mathscr{X}_{\left[0, \tau_{p}\right]}$. However, it would converge in $L^{2}(0, T)$ and so there is a subsequence such that convergence takes place a.e. $t$. Then restricting to this subsequence, the second integral converges to 0 . Actually, it may be easier than this. $\mathscr{X}_{\left[0, \tau_{p}\right]}$ has a single point of discontinuity and convergence takes place at every other point. Thus it appears that the integrand in 65.11 .19 converges to 0 for each $\omega$. Thus, by dominated convergence theorem the whole expectation converges to 0 .

Now consider

$$
\begin{aligned}
& P\left(\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n} d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W\right|^{2}>\lambda\right) \\
\leq & \frac{E\left(\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n} d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W\right|^{2}\right)}{\lambda}
\end{aligned}
$$

and so, there exists a subsequence, still denoted as $n$ such that

$$
P\left(\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n} d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W\right|^{2}>\frac{1}{n}\right)<2^{-k}
$$

It follows that $N$ can be enlarged so that for $\omega \notin N_{p}$

$$
\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n} d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W\right|^{2} \leq \frac{1}{n}
$$

for all $n$ large enough. Now obtain a succession of subsequences for $p=1,2, \cdots$, each a subsequence of the preceeding one such that the above convergence takes place and let $N$ include $\cup_{p} N_{p}$. Then for $\omega \notin N$, and letting $n$ denote the diagonal sequence, it follows that for all $p$,

$$
\lim _{n \rightarrow \infty}\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n} d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W\right|=0
$$

For $\omega \notin N$, there is a $p$ such that $\tau_{p}=\infty$. Then this means $\int_{0}^{T}\|\Phi\|^{2} d s<p$. It follows that the same is true for $\Phi_{n}$ for all $n$ large enough. Hence $\tau_{n p}=\infty$ also. Thus, for large enough $n$,

$$
\left|\int_{0}^{T} \Phi_{n} d W-\int_{0}^{T} \Phi d W\right|=\left|\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{n p}\right]} \Phi_{n} d W-\int_{0}^{T} \mathscr{X}_{\left[0, \tau_{p}\right]} \Phi d W\right|
$$

and the latter was just shown to converge to 0 .

### 65.12 The Holder Continuity Of The Integral

Let $\Phi \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Then you can consider the stochastic integral as described above and it yields a continuous function off a set of measure zero. What if $\Phi \in L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ ? Can you say more? The short answer is yes. You obtain a Holder condition in addition to continuity. This is a consequence of the Burkolder Davis Gundy inequality and Corollary 65.11 .1 above. Let $\alpha>2$. Let $\|\Phi\|_{\infty}$ denote the norm in $L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. By the Burkholder Davis Gundy inequality,

$$
\begin{gathered}
\int_{\Omega}\left(\left|\int_{s}^{t} \Phi d W\right|\right)^{\alpha} d P \leq \\
\int_{\Omega}\left(\sup _{r \in[s, t]}\left|\int_{s}^{r} \Phi d W\right|\right)^{\alpha} d P \leq C \int_{\Omega}\left(\int_{s}^{t}\|\Phi\|^{2} d \tau\right)^{\alpha / 2} d P
\end{gathered}
$$

$$
\leq C\|\Phi\|_{\infty}^{\alpha} \int_{\Omega}\left(\int_{s}^{t} d \tau\right)^{\alpha / 2} d P=C\|\Phi\|_{\infty}^{\alpha}|t-s|^{\alpha / 2}
$$

By the Kolmogorov Čentsov theorem, Theorem 62.2.2, this shows that $t \rightarrow \int_{0}^{t} \Phi d W$ is Holder continuous with exponent

$$
\gamma<\frac{(\alpha / 2)-1}{\alpha}=\frac{1}{2}-\frac{1}{\alpha}
$$

Since $\alpha>2$ is arbitrary, this shows that for any $\gamma<1 / 2$, the stochastic integral is Holder continuous with exponent $\gamma$. This is exactly the same kind of continuity possessed by the Wiener process.

Theorem 65.12.1 Suppose $\Phi \in L^{\infty}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and is progressively measurable. Then if $\gamma<1 / 2$, there exists a set of measure zero such that off this set,

$$
t \rightarrow \int_{0}^{t} \Phi d W
$$

is Holder continuous with exponent $\gamma$.

### 65.13 Taking Out A Linear Transformation

When is

$$
L \int_{a}^{T} \Phi d W=\int_{a}^{T} L \Phi d W ?
$$

It is assumed $L \in \mathscr{L}\left(H, H_{1}\right)$ where $H_{1}$ is another separable real Hilbert space. First of all, here is a lemma which shows $\int_{a}^{t} L \Phi d W$ at least makes sense.

Proposition 65.13.1 Suppose $\Phi$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$ progressively measurable and

$$
P\left(\left[\int_{a}^{T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d s<\infty\right]\right)=1 .
$$

Then the same is true of $L \Phi$. Furthermore, for each $t \in[a, T]$

$$
\int_{a}^{t} L \Phi d W=L \int_{a}^{t} \Phi d W
$$

Proof: First note that if $\Phi \in \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)$, then $L \Phi \in \mathscr{L}_{2}\left(Q^{1 / 2} U, H_{1}\right)$ and that the map $\Phi \rightarrow L \Phi$ is continuous. It follows $L \Phi$ is $\mathscr{L}_{2}\left(Q^{1 / 2} U, H_{1}\right)$ progressively measurable. All that remains is to check the appropriate integral.

$$
\int_{a}^{T}\|L \Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H_{1}\right)}^{2} d t \leq \int_{a}^{T}\|L\|^{2}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t
$$

and so this proves $L \Phi$ satisfies the same conditions as $\Phi$, being stochastically square integrable.

It follows one can consider

$$
\int_{a}^{T} L \Phi d W
$$

Assume to begin with that $\Phi \in L^{2}\left([a, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Next recall the situation in which the definition of the integral is considered.

$$
\begin{array}{ccc} 
& & \\
& & \\
& & \\
& \\
Q^{1 / 2} U & \stackrel{J}{\leftarrow} & Q^{1 / 2} \\
& & Q^{1 / 2} U \\
\Phi_{n} & \searrow & \\
& & \downarrow \\
& & H
\end{array}
$$

Letting $\left\{\Phi_{n}\right\}$ be an approximating sequence of elementary functions satisfying

$$
E\left(\int_{a}^{T}\left\|\Phi_{n}-\Phi \circ J^{-1}\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}^{2} d t\right) \rightarrow 0
$$

it is also the case that

$$
E\left(\int_{a}^{T}\left\|L \Phi_{n}-L \Phi \circ J^{-1}\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H_{1}\right)}^{2} d t\right) \rightarrow 0
$$

By the definition of the integral, for each $t$

$$
\begin{aligned}
\int_{a}^{t} L \Phi d W & =\lim _{n \rightarrow \infty} \int_{a}^{t} L \Phi_{n} d W=\lim _{n \rightarrow \infty} L \int_{a}^{t} \Phi_{n} d W \\
& =L \lim _{n \rightarrow \infty} \int_{a}^{t} \Phi_{n} d W=L \int_{a}^{t} \Phi d W
\end{aligned}
$$

The second equality is obvious for elementary functions.
Now consider the case where $\Phi$ is only stochastically square integrable so that all is known is that

$$
P\left(\left[\int_{a}^{T}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t<\infty\right]\right)=1 .
$$

Then define $\tau_{n}$ as above

$$
\tau_{n} \equiv \inf \left\{t: \int_{a}^{t}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t \geq n\right\}
$$

This sequence of stopping times works for $L \Phi$ also. Recall there were two conditions the sequence of stopping times needed to satisfy. The first is obvious. Here is why the second holds.

$$
\begin{aligned}
\int_{a}^{T}\left\|\mathscr{X}_{\left[a, \tau_{n}\right]} L \Phi\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H_{1}\right)}^{2} d t & \leq\|L\|^{2} \int_{a}^{T}\left\|\mathscr{X}_{\left[a, \tau_{n}\right]} \Phi\right\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t \\
& =\|L\|^{2} \int_{a}^{\tau_{n}}\|\Phi\|_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)}^{2} d t \leq\|L\|^{2} n
\end{aligned}
$$

Then let $t$ be given and pick $n$ such that $\tau_{n}(\omega) \geq t$. Then from the first part, for that $\omega$,

$$
\begin{aligned}
L \int_{a}^{t} \Phi d W & \equiv L \int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W \\
& =\int_{a}^{t} L \mathscr{X}_{\left[a, \tau_{n}\right]} \Phi d W \\
& =\int_{a}^{t} \mathscr{X}_{\left[a, \tau_{n}\right]} L \Phi d W \equiv \int_{a}^{t} L \Phi d W
\end{aligned}
$$

### 65.14 A Technical Integration By Parts Result

Let $Z \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ where this has reference to the usual diagram

$$
\begin{array}{cccc} 
& & & \\
U_{1} & \supseteq J Q^{1 / 2} U & \stackrel{J}{亡} & \downarrow \\
& & Q^{1 / 2} & Q^{1 / 2} \\
& \Phi_{n} \searrow & & \downarrow \\
& & & \\
& &
\end{array}
$$

Also suppose $X \in L^{2}([0, T] \times \Omega, H)$, both $X$ and $Z$ being progressively measurable. Let $\left\{t_{j}^{n}\right\}_{j=1}^{m_{n}}$ denote a sequence of partitions of the sort discussed earlier where

$$
X_{n}(t) \equiv \sum_{j=0}^{m_{n}-1} X\left(t_{j}^{n}\right) \mathscr{X}_{\left[t_{j}^{n}, t_{j+1}^{n}\right)}(t)
$$

converges to $X$ in $L^{2}([0, T] \times \Omega, H)$. Thus $X_{n}(t)$ is right continuous. Let

$$
\tau_{p}^{n}=\inf \left\{t:\left|X_{n}(t)\right|_{H}>p\right\}
$$

This is the first hitting time of a right continuous adapted process so it is a stopping time. Also there exists a set of measure zero $N$ such that for $\omega \notin N$, then given $t$,

$$
\tau_{p}^{n} \geq t
$$

if $p$ is large enough because of the assumption on $X$. Here is why. There exists a set of measure $0 N$ such that if $\omega \notin N$, then

$$
\int_{0}^{T}\left|X_{n}(t)\right|_{H}^{2} d t=\sum_{j=0}^{m_{n}-1}\left|X\left(t_{k}^{n}\right)\right|_{H}^{2}\left(t_{j+1}^{n}-t_{j}^{n}\right)<\infty
$$

It follows that there exists an upper bound, depending on $\omega$ which dominates each of the values $\left|X\left(t_{k}^{n}\right)\right|_{H}^{2}$. Then if $p$ is larger than this upper bound, $\tau_{p}^{n}=\infty>t$.

Next consider the expression

$$
\begin{equation*}
\sum_{j=0}^{m-1}\left(\int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z(u) d W, X\left(t_{j}^{n}\right)\right)_{H} \tag{65.14.20}
\end{equation*}
$$

This expression is a function of $\omega$.
I want to write this in the form of a stochastic integral. To begin with, consider one of the terms. For simplicity of notation, consider

$$
\left(\int_{a}^{b} Z(u) d W, X(a)\right)_{H}
$$

where $Z \in L^{2}\left([a, b] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and $X(a) \in L^{2}(\Omega, H)$. Also assume the function of $\omega,|X(a)|_{H}$, is bounded. There is an Ito integral involved in the above. Let $Z_{n}$ be a sequence of elementary functions defined on $[a, b]$ which converges to $Z \circ J^{-1}$ in $L^{2}\left([a, b] \times \Omega, \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$. Then by the definition of the integral,

$$
\left\|\int_{a}^{t} Z(u) d W-\int_{a}^{t} Z_{n}(u) d W\right\|_{L^{2}(\Omega, H)} \rightarrow 0
$$

Also, by the use of a maximal inequality and the fact that the two integrals above are martingales, there is a subsequence, still called $n$ and a set of measure zero $N$ such that for $\omega \notin N$, the convergence

$$
\int_{a}^{t} Z_{n}(u) d W(\omega) \rightarrow \int_{a}^{t} Z(u) d W(\omega)
$$

is uniform for $t \in[a, b]$. Therefore, for such $\omega$,

$$
\left(\int_{a}^{t} Z(u) d W, X(a)\right)_{H}=\lim _{n \rightarrow \infty}\left(\int_{a}^{t} Z_{n}(u) d W, X(a)\right)_{H}
$$

Say $\left.Z_{n}(u)=\sum_{k=0}^{m_{n}-1} Z_{k}^{n} \mathscr{X}_{\left[t_{k}^{n}, t_{k+1}^{n}\right.}\right)(u)$ where $Z_{k}^{n}$ has finitely many values in $\mathscr{L}\left(U_{1}, H\right)_{0}$, the restrictions of $\mathscr{L}\left(U_{1}, H\right)$ to $J Q^{1 / 2} U$. Then the inner product in the above formula on the right is of the form

$$
\begin{aligned}
& \sum_{k=0}^{m_{n}-1}\left(Z_{k}^{n}\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right), X(a)\right)_{H} \\
= & \sum_{k=0}^{m_{n}-1}\left(\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right),\left(Z_{k}^{n}\right)^{*} X(a)\right)_{U_{1}} \\
= & \sum_{k=0}^{m_{n}-1} \mathscr{R}\left(\left(Z_{k}^{n}\right)^{*} X(a)\right)\left(W\left(t \wedge t_{k+1}^{n}\right)-W\left(t \wedge t_{k}^{n}\right)\right) \\
\equiv & \int_{a}^{t} \mathscr{R}\left(Z_{n}^{*} X(a)\right) d W
\end{aligned}
$$

where $\mathscr{R}$ is the Riesz map from $U_{1}$ to $U_{1}^{\prime}$. Note that $\mathscr{R}\left(Z_{n}^{*} X(a)\right)$ has values in

$$
\mathscr{L}\left(U_{1}, \mathbb{R}\right)_{0} \subseteq \mathscr{L}_{2}\left(J Q^{1 / 2} U, \mathbb{R}\right)
$$

Now let $\left\{g_{i}\right\}$ be an orthonormal basis for $Q^{1 / 2} U$, so it follows that $\left\{J g_{i}\right\}$ is an orthonormal basis for $J Q^{1 / 2} U$. Then

$$
\begin{gathered}
\sum_{i}\left|\mathscr{R}\left(Z_{n}^{*} X(a)-\left(Z \circ J^{-1}\right)^{*} X(a)\right)\left(J g_{i}\right)\right|^{2} \\
\equiv \sum_{i}\left|\left(Z_{n}^{*} X(a)-\left(Z \circ J^{-1}\right)^{*} X(a), J g_{i}\right)_{U_{1}}\right|^{2}=\sum_{i}\left|\left(X(a),\left(Z_{n}-Z \circ J^{-1}\right) J g_{i}\right)_{H}\right|^{2} \\
\leq \sum_{i}|X(a)|_{H}^{2}\left|\left(Z_{n}-Z \circ J^{-1}\right) J g_{i}\right|_{H}^{2}=|X(a)|_{H}^{2}\left\|Z_{n}-Z \circ J^{-1}\right\|_{\mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)}^{2}
\end{gathered}
$$

When integrated over $[a, b] \times \Omega$, it is given that this converges to 0 . This has shown that

$$
\mathscr{R}\left(Z_{n}^{*} X(a)\right) \rightarrow \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*} X(a)\right)
$$

in $\mathscr{L}_{2}\left(J Q^{1 / 2} U, \mathbb{R}\right)$. In other words

$$
\mathscr{R}\left(Z_{n}^{*} X(a)\right) \rightarrow\left(\mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*} X(a)\right) \circ J\right) \circ J^{-1}
$$

It follows that

$$
\left(\int_{a}^{t} Z(u) d W, X(a)\right)_{H}=\int_{a}^{t} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*} X(a)\right) \circ J d W
$$

From localization,

$$
\begin{aligned}
\left(\int_{a \wedge \tau_{p}^{n}}^{b \wedge \tau_{p}^{n}} Z(u) d W, X(a)\right)_{H} & =\left(\int_{a}^{b} \mathscr{X}_{\left[0, \tau_{p}^{n}\right]} Z(u) d W, X(a)\right)_{H} \\
& =\int_{a}^{b} \mathscr{X}_{\left[0, \tau_{p}^{n}\right]} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*} X(a)\right) \circ J d W \\
& =\int_{a \wedge \tau_{p}^{n}}^{b \wedge \tau_{p}^{n}} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*} X(a)\right) \circ J d W
\end{aligned}
$$

Then it follows that, using the stopping time,

$$
\begin{gathered}
\sum_{j=0}^{m-1}\left(\int_{t_{j}^{n} \wedge \tau_{p}^{n} \wedge t}^{t_{j+1}^{n} \wedge \tau_{\wedge}^{n} \wedge t} Z(u) d W, X\left(t_{j}^{n}\right)\right)_{H}=\sum_{j=0}^{m-1} \int_{t_{j}^{n} \wedge \tau_{p}^{n} \wedge t}^{t_{j+1}^{n} \wedge \tau_{p}^{n} \wedge t} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*} X_{n}\left(t_{j}^{n}\right)\right) \circ J d W \\
=\int_{0}^{t_{m}^{n} \wedge \tau_{p}^{n} \wedge t} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}\left(X_{n}^{l}\right)\right) \circ J d W
\end{gathered}
$$

where $X_{n}^{l}$ is the step function

$$
X_{n}^{l}(t) \equiv \sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left[t_{k}^{n}, t_{k+1}^{n}\right)}(t)
$$

By localization, this is

$$
\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}^{n}\right]} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}\left(X_{n}^{l}\right)\right) \circ J d W
$$

If $\omega$ is not in a suitable set of measure zero, then $\tau_{p}^{n}(\omega) \geq t$ provided $p$ is large enough. Thus, for such $\omega$, if $p$ is large enough,

$$
\begin{aligned}
\sum_{j=0}^{m_{n}-1}\left(\int_{t_{j}^{n} \wedge \tau_{p}^{n} \wedge t}^{t_{j+1}^{n} \wedge \tau_{p}^{n} \wedge t} Z(u) d W, X\left(t_{j}^{n}\right)\right)_{H} & =\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{p}^{n}\right]} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}\left(X_{n}^{l}\right)\right) \circ J d W \\
& =\int_{0}^{t} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}\left(X_{n}^{l}\right)\right) \circ J d W
\end{aligned}
$$

This shows that the expression is a local martingale. Also note that the expression on the left does not depend on $J$ or $U_{1}$ so the same must be true of the expression on the right although it does not look that way. This has proved the following important theorem.

Theorem 65.14.1 Let $Z \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and let $X \in L^{2}([0, T] \times \Omega, H)$, both $X, Z$ progressively measurable. Also let $\left\{t_{j}^{n}\right\}_{j=1}^{m_{n}}$ be a sequence of partitions of $[0, T]$ such that each $X\left(t_{j}^{n}\right)$ is in $L^{2}(\Omega, H)$. Then

$$
\begin{equation*}
\sum_{j=0}^{m-1}\left(\int_{t_{j}^{n} \wedge t}^{t_{j+1}^{n} \wedge t} Z(u) d W, X\left(t_{j}^{n}\right)\right)_{H} \tag{65.14.21}
\end{equation*}
$$

is a stochastic integral of the form

$$
\int_{0}^{t} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}\left(X_{n}^{l}\right)\right) \circ J d W
$$

where $\left\{\tau_{p}^{n}\right\}_{p=1}^{\infty}$ is a localizing sequence used to define the above integral whose integrand is only stochastically square integrable. Here $X_{n}^{l}$ is the step function defined by

$$
X_{n}^{l}(t) \equiv \sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left[t_{k}^{n}, t_{k+1}^{n}\right)}(t)
$$

In particular, 65.14 .21 is a local martingale.
Of course it would be very interesting to see what happens in the case where $X_{n}^{l} \rightarrow X$ in $L^{2}([0, T] \times \Omega, H)$. Is it the case that convergence to

$$
\begin{equation*}
\int_{0}^{t} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}(X)\right) \circ J d W \tag{65.14.22}
\end{equation*}
$$

happens in some sense? Also, does the above stochastic integral even make sense? First of all, consider the question whether it makes sense. It would be nice to define a stopping time

$$
\tau_{n} \equiv \inf \left\{t:|X(t)|_{H}>n\right\}
$$

because then $\mathscr{X}_{\left[0, \tau_{n}\right]} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}(X)\right) \circ J$ would end up being integrable in the right way and you could define the stochastic integral provided $\tau_{n}>t$ whenever $n$ is large enough. However, this is problematic because $t \rightarrow X(t)$ is not known to be continuous. Therefore, some other condition must be assumed.

Lemma 65.14.2 Suppose $t \rightarrow X(t)$ is weakly continuous into $H$ for a.e. $\omega$, and that $X$ is adapted. Then the $\tau_{n}$ described above is a stopping time.

Proof: Let $B \equiv\{x \in H:|x|>n\}$. Then the complement of $B$ is a closed convex set. It follows that $B^{C}$ is also weakly closed. Hence $B$ must be weakly open. Now $t \rightarrow X(t)$ is adapted as a function mapping into the topological space consisting of $H$ with the weak topology because it is in fact adapted into the strong topolgy. Therefore, the above $\tau_{n}$ is just the first hitting time of an open set by a continuous process so $\tau_{n}$ is a stopping time by Proposition 62.7.5. Also, by the assumption that $t \rightarrow X(t)$ is weakly continuous, it follows that $X(t)$ for $t \in[0, T]$ is weakly bounded. Hence, for each $\omega$ off a set of measure zero, $|X(t)|$ is bounded for $t \in[0, T]$. This follows from the uniform boundedness theorem. It follows that $\tau_{n}=\infty$ for $n$ large enough.

Hence the weak continuity of $t \rightarrow X(t)$ suffices to define the stochastic integral in 65.14.22. It remains to verify some sort of convergence in the case that

$$
\lim _{n \rightarrow \infty}\left[\max _{j \leq m_{n}-1}\left(t_{j+1}^{n}-t_{j}^{n}\right)\right]=0
$$

Lemma 65.14.3 Let $X(s)-X_{k}^{l}(s) \equiv \Delta_{k}(s)$. Here $Z \in L^{2}\left([0, T] \times \Omega, \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and let $X \in L^{2}([0, T] \times \Omega, H)$ with both $X$ and $Z$ progressively measurable, $t \rightarrow X(t)$ being weakly continuous into $H$,

$$
\lim _{k \rightarrow \infty}\left\|X-X_{k}^{l}\right\|_{L^{2}([0, T] \times \Omega, H)}=0
$$

Then the integral

$$
\int_{0}^{t} \mathscr{R}\left(\left(Z \circ J^{-1}\right)^{*}(X)\right) \circ J d W
$$

exists as a local martingale and the following limit occurs for a suitable subsequence, still called $k$.

$$
\begin{equation*}
\lim _{k \rightarrow \infty} P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon\right]\right)=0 \tag{65.14.23}
\end{equation*}
$$

That is,

$$
\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(X(s)-X_{k}^{l}(s)\right)\right) \circ J d W(s)\right|
$$

converges to 0 in probability.
Proof: Let $k$ denote a subsequence for which $X_{k}^{l}$ also converges pointwise to $X$.

The existence of the integral follows from Lemma 65.14.2. From the assumption of weak continuity, $\sup _{t \in[0, T]}|X(t)| \leq C(\omega)$ for a.e. $\omega$. For the first part of the argument, assume $C$ does not depend on $\omega$ off a set of measure zero. Let

$$
M(t) \equiv \int_{0}^{t} Z d W
$$

Let $\left\{e_{k}\right\}$ be an orthonormal basis for $H$ and let $P_{n}$ be the orthogonal projection onto $\operatorname{span}\left(e_{1}, \cdots, e_{n}\right)$. For each $e_{i}$

$$
\lim _{k \rightarrow \infty}\left|\left(X(s)-X_{k}^{l}(s), e_{i}\right)\right|=0
$$

and so, by weak continuity,

$$
\lim _{k \rightarrow \infty} P_{n}\left(X(s)-X_{k}^{l}(s)\right)=0 \text { for a.e. } \omega
$$

Then

$$
\lim _{k \rightarrow \infty} \int_{\Omega} \int_{0}^{T}\left|P_{n}\left(X(s)-X_{k}^{l}(s)\right)\right|^{2}\|Z(s)\|_{\mathscr{L}_{2}}^{2} d s d P=0
$$

because you can apply the dominated convergence theorem with respect to the measure $\|Z(s)\|_{\mathscr{L}_{2}}^{2} d s d P$.

Therefore,

$$
\begin{equation*}
\lim _{k \rightarrow \infty} P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} P_{n} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon / 2\right]\right)=0 \tag{65.14.24}
\end{equation*}
$$

Here is why. By the Burkholder Davis Gundy theorem, Theorem 63.4.4 and Corollary 65.11.1 which describes the quadratic variation of the stochastic integral,

$$
\begin{aligned}
& \int_{\Omega}\left(\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} P_{n} \Delta_{k}(s)\right) d W(s)\right|\right) d P \\
& \leq C \int_{\Omega}\left(\int_{0}^{T}\left|P_{n}\left(X(s)-X_{k}^{l}(s)\right)\right|^{2}\|Z(s)\|_{\mathscr{L}_{2}}^{2} d s\right)^{1 / 2} d P
\end{aligned}
$$

Consider the following two probabilities.

$$
\begin{align*}
& P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(I-P_{n}\right) X(s)\right) \circ J d W(s)\right| \geq \varepsilon / 2\right]\right)  \tag{65.14.25}\\
& P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(I-P_{n}\right) X_{k}^{l}(s)\right) \circ J d W(s)\right| \geq \varepsilon / 2\right]\right) \tag{65.14.26}
\end{align*}
$$

By Corollary 63.4.5 which depends on the Burkholder Davis Gundy inequality and Corollary 65.11 .1 which describes the quadratic variation of the stochastic integral, 65.14.25
is dominated by

$$
\begin{align*}
& \frac{C}{\varepsilon} E\left(\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)^{1 / 2} \wedge \delta\right) \\
&+P\left(\left[\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)^{1 / 2}>\delta\right]\right) \\
& \leq \frac{C \delta}{\varepsilon}+P\left(\left[\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)^{1 / 2}>\delta\right]\right) \tag{65.14.27}
\end{align*}
$$

Let $\eta>0$ be given. Then let $\delta$ be small enough that the first term is less than $\eta$. Fix such a $\delta$.

Consider the second of the above terms.

$$
\begin{aligned}
& P\left(\left[\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)^{1 / 2}>\delta\right]\right) \\
\leq & \frac{1}{\delta}\left(E\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)\right)^{1 / 2}
\end{aligned}
$$

and this converges to 0 because $\left(I-P_{n}\right) X(s)$ is assumed to be bounded and converges to 0 . Next consider 65.14.26. By similar reasoning, we end up with having to estimate

$$
\frac{1}{\delta}\left(E\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X_{k}^{l}(s)\right|^{2} d s\right)\right)^{1 / 2}
$$

But this is dominated by

$$
\begin{aligned}
& \frac{2}{\delta}\left(E\left(\int_{0}^{T}\|Z(s)\|^{2}\left|X_{k}^{l}(s)-X(s)\right|^{2} d s\right)\right)^{1 / 2} \\
& +\frac{2}{\delta}\left(E\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)\right)^{1 / 2}
\end{aligned}
$$

The first term is no larger than $\eta$ provided $k$ is large enough, independent of $n$ thanks to the pointwise convergence and the assumption that $X$ is bounded. Thus, there exists $K$ such that if $k>K$, then the term in 65.14 .26 is dominated by

$$
2 \eta+\frac{2}{\delta}\left(E\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)\right)^{1 / 2}
$$

It follows that for $k>K$, the sum of 65.14 .25 and 65.14 .26 is dominated by

$$
3 \eta+\frac{3}{\delta}\left(E\left(\int_{0}^{T}\|Z(s)\|^{2}\left|\left(I-P_{n}\right) X(s)\right|^{2} d s\right)\right)^{1 / 2}
$$

This is then no larger than $4 \eta$ provided $n$ is large enough. Pick such an $n$. Then for all $k>K$, this has shown that

$$
\begin{aligned}
& P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon\right]\right) \\
& \leq P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} P_{n} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon / 2\right]\right)+ \\
& P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*}\left(I-P_{n}\right) \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon / 2\right]\right) \\
& \leq P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} P_{n} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon / 2\right]\right)+4 \eta
\end{aligned}
$$

By 65.14 .24 this whole thing is less than $5 \eta$ provided $k$ is large enough. This has proved that under the assumption that $X$ is bounded uniformly off a set of measure zero,

$$
\lim _{k \rightarrow \infty} P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon\right]\right)=0
$$

This is what was desired to show. It remains to remove the extra assumption that $X$ is bounded.

Now to finish the argument, define the stopping time

$$
\tau_{m} \equiv \inf \left\{t>0:|X(t)|_{H}>m\right\}
$$

As observed in Lemma 65.14.2, this is a valid stopping time. Also define $\Delta_{k}^{\tau_{m}} \equiv X^{\tau_{m}}-$ $\left(X_{k}^{l}\right)^{\tau_{m}}$. Using this stopping time on $X$ and $X_{k}^{l}$ does not affect the pointwise convergence to 0 as $k \rightarrow \infty$ of $\Delta_{k}^{\tau_{m}}$ on which the above argument depends.

Consider

$$
A_{k \varepsilon} \equiv\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \Delta_{k}(s)\right) \circ J d W(s)\right| \geq \varepsilon\right]
$$

Then

$$
P\left(A_{k \varepsilon} \cap\left[\tau_{m}=\infty\right]\right) \leq P\left(\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \mathscr{R}\left(\left(Z(s) \circ J^{-1}\right)^{*} \Delta_{k}^{\tau_{m}}(s)\right) \circ J d W(s)\right| \geq \varepsilon\right]\right)
$$

which converges to 0 as $k \rightarrow \infty$ by the first part of the argument. This is because $\left|X^{\tau_{m}}\right|$ and $\left|\left(X_{k}^{l}\right)^{\tau_{m}}\right|$ are both bounded by $m$ and the same pointwise convergence condition still holds. Now

$$
A_{k \varepsilon}=\cup_{m=1}^{\infty} A_{k \varepsilon} \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)
$$

Thus

$$
\begin{equation*}
P\left(A_{k \varepsilon}\right)=\sum_{m=1}^{\infty} P\left(A_{k \varepsilon} \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)\right) \tag{65.14.28}
\end{equation*}
$$

Also

$$
P\left(A_{k \varepsilon} \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)\right) \leq P\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)
$$

which is summable because these are disjoint sets. Hence one can apply the dominated convergence theorem in 65.14.28 and conclude

$$
\lim _{k \rightarrow \infty} P\left(A_{k \varepsilon}\right)=\sum_{m=1}^{\infty} \lim _{k \rightarrow \infty} P\left(A_{k \varepsilon} \cap\left(\left[\tau_{m}=\infty\right] \backslash\left[\tau_{m-1}<\infty\right]\right)\right)=0 \square
$$

## Chapter 66

## The Integral $\int_{0}^{t}(Y, d M)_{H}$

First the integral is defined for elementary functions.
Definition 66.0.1 Let an elementary function be one which is of the form

$$
\sum_{i=0}^{m-1} Y_{i} \mathscr{X}_{\left(t_{i}, t_{i+1}\right]}(t)
$$

where $Y_{i}$ is $\mathscr{F}_{t_{i}}$ measurable with values in $H$ a separable real Hilbert space for $0=t_{0}<$ $t_{1}<\cdots<t_{m}=T$.

Definition 66.0.2 Now let $M$ be a $H$ valued continuous local martingale, $M(0)=0$. Then for $Y$ a simple function as above,

$$
\int_{0}^{t}(Y, d M) \equiv \sum_{i=0}^{m-1}\left(Y_{i}, M\left(t \wedge t_{i+1}\right)-M\left(t \wedge t_{i}\right)\right)_{H}
$$

Assumption 66.0.3 We will always assume that $d[M]$ is absolutely continuous with respect to Lebesgue measure. Thus $d[M]=k d t$ where $k \geq 0$ and is in $L^{1}([0, T] \times \Omega)$. This is done to avoid technical questions related to whether $t \rightarrow \int_{0}^{t} d[M]$ is continuous and also to make it easier to get examples of a certain class of functions.

This includes the usual stochastic integral $M(t)=\int_{0}^{t} \Phi d W$ where $[M](t)=\int_{0}^{t}\|\Phi\|_{\mathscr{L}_{2}}^{2} d s$ so $d[M]=\|\Phi\|^{2} d t$.

Next is to consider how this relates to stopping times which have values in the $\left\{t_{i}\right\}$. Let $\tau$ be a stopping time which takes the values $\left\{t_{i}\right\}_{i=0}^{m}$. Then

$$
\begin{equation*}
\int_{0}^{t \wedge \tau}(Y, d M) \equiv \sum_{i=0}^{m-1}\left(Y_{i}, M\left(t \wedge t_{i+1} \wedge \tau\right)-M\left(t \wedge t_{i} \wedge \tau\right)\right)_{H} \tag{66.0.1}
\end{equation*}
$$

Now consider $\mathscr{X}_{[0, \tau]} Y$. Is it also an elementary function?

$$
\mathscr{X}_{[0, \tau]} Y=\sum_{i=0}^{m-1} \mathscr{X}_{[0, \tau]}(t) Y_{i} \mathscr{X}_{\left(t_{i}, t_{i+1}\right]}(t)
$$

To get the $i^{t h}$ term to be non zero, you must have $\tau \geq t$ and $t \in\left(t_{i}, t_{i+1}\right]$. Thus it must be the case that $\tau>t_{i}$. Also, if $\tau>t_{i}$ and $t \in\left(t_{i}, t_{i+1}\right]$, then $\tau \geq t_{i+1}$ because $\tau$ has only the values $t_{i}$. Hence also $\tau \geq t$. Thus the above sum reduces to

$$
\sum_{i=0}^{m-1} \mathscr{X}_{\left[\tau>t_{i}\right]}(\omega) Y_{i} \mathscr{X}_{\left(t_{i}, t_{i+1}\right]}(t)
$$

This shows that $\mathscr{X}_{[0, \tau]} Y$ is of the right sort, the sum of $\mathscr{F}_{t_{i}}$ measurable functions times $\mathscr{X}_{\left(t_{i}, t_{i+1}\right]}(t)$. Thus from the definition of this funny integral,

$$
\begin{equation*}
\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M\right) \equiv \sum_{i=0}^{m-1}(\overbrace{\mathscr{X}_{\left[\tau>t_{i}\right]}(\omega) Y_{i}}^{\mathscr{F}_{i}}, M\left(t \wedge t_{i+1}\right)-M\left(t \wedge t_{i}\right))_{H} \tag{66.0.2}
\end{equation*}
$$

Are the right sides of 66.0.1 and 66.0.2 equal?
Begin with the right side of 66.0 .1 and consider $\tau=t_{j}$. Then to get something nonzero in the terms of the sum in 66.0.1, you would need to have $t_{j} \geq t_{i+1}$. Otherwise, $t_{j} \leq t_{i}$ and the difference involving $M$ would give 0 . Hence, for such $\omega$ you would need to have the sum in 66.0.1 equal to

$$
\sum_{i=0}^{j-1}\left(Y_{i}, M\left(t \wedge t_{i+1}\right)-M\left(t \wedge t_{i}\right)\right)_{H}
$$

Thus this sum in 66.0.1 equals

$$
\sum_{j=0}^{m} \mathscr{X}_{\left[\tau=t_{j}\right]} \sum_{i=0}^{j-1}\left(Y_{i}, M\left(t \wedge t_{i+1}\right)-M\left(t \wedge t_{i}\right)\right)_{H}
$$

Of course when $j=0$ the term in the sum in 66.0.1 equals 0 so there is no harm in defining $\sum_{i=0}^{-1} \equiv 0$. Then from the sum, you have $i \leq j-1$ and so when you interchange the order, you get that $\int_{0}^{t \wedge \tau}(Y, d M)=$

$$
\begin{aligned}
& \sum_{i=0}^{m-1} \sum_{j=i+1}^{m} \mathscr{X}_{\left[\tau=t_{j}\right]}\left(Y_{i}, M\left(t \wedge t_{i+1}\right)-M\left(t \wedge t_{i}\right)\right)_{H} \\
& =\sum_{i=0}^{m-1}\left(\mathscr{X}_{\left[\tau>t_{i}\right]}(\omega) Y_{i}, M\left(t \wedge t_{i+1}\right)-M\left(t \wedge t_{i}\right)\right)_{H}
\end{aligned}
$$

Thus the right side of 66.0.1 equals the right side of 66.0.2.

$$
\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M\right)=\sum_{i=0}^{m-1}\left(\mathscr{X}_{\left[\tau>t_{i}\right]}(\omega) Y_{i}, M\left(t \wedge t_{i+1}\right)-M\left(t \wedge t_{i}\right)\right)=\int_{0}^{t \wedge \tau}(Y, d M)
$$

This has proved the first part of the following lemma.
Lemma 66.0.4 For an elementary function $Y$, and a stopping time $\tau$ having values in the $\left\{t_{i}\right\}$, the points of discontinuity of $Y$, it follows that $\mathscr{X}_{[0, \tau]} Y$ is also an elementary function and

$$
\int_{0}^{t \wedge \tau}(Y, d M)=\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M\right)=\int_{0}^{t}\left(Y, d M^{\tau}\right)
$$

Proof: Consider the second equal sign. By definition,

$$
\begin{aligned}
\int_{0}^{t \wedge \tau}(Y, d M) & =\sum_{i=0}^{m-1}\left(Y_{i}, M\left(t \wedge t_{i+1} \wedge \tau\right)-M\left(t \wedge t_{i} \wedge \tau\right)\right)_{H} \\
& =\sum_{i=0}^{m-1}\left(Y_{i}, M^{\tau}\left(t \wedge t_{i+1}\right)-M^{\tau}\left(t \wedge t_{i}\right)\right)_{H} \equiv \int_{0}^{t}\left(Y, d M^{\tau}\right)
\end{aligned}
$$

Next is another lemma about these integrals of elementary functions. First recall the following definition

$$
M^{*} \equiv \sup \{\|M(t)\|: t \in[0, T]\}
$$

Lemma 66.0.5 Let $M$ be a local martingale on $[0, T]$ where $M(0)=0$ and $M$ is continuous. Let $0<r<s<T$ and consider $\left(Y,\left(M^{\tau_{p} s}-M^{\tau_{p} r}\right)(t)\right)$ where $Y\left(M^{\tau_{p}}\right)^{*} \in L^{2}(\Omega)$ and $Y$ is $\mathscr{F}_{r}$ measurable and $\tau_{p}$ is a localizing sequence of stopping times for which $M^{\tau_{p}}$ is a $L^{2}$ martingale. Then this is a martingale on $[0, T]$ which equals 0 at $t=0$ and

$$
\begin{aligned}
{\left[\left(Y,\left(M^{\tau_{p} s}-M^{\tau_{p} r}\right)\right)\right](t) } & \leq\|Y\|^{2}\left[M^{\tau_{p} s}-M^{\tau_{p} r}\right](t) \\
& =\|Y\|^{2}\left(\left[M^{\tau_{p}}\right]^{s}(t)-\left[M^{\tau_{p}}\right]^{r}(t)\right) \\
& =\|Y\|^{2}\left(\left[M^{\tau_{p}}\right](t \wedge s)-\left[M^{\tau_{p}}\right](t \wedge r)\right)
\end{aligned}
$$

It follows that for $Y$ an elementary function where each $Y_{i}\left(M^{\tau_{p}}\right)^{*}$ is in $L^{2}(\Omega)$,

$$
\int_{0}^{t}(Y, d M)
$$

is a local martingale.
Proof: To save notation, $M$ is written in place of $M^{\tau_{p}}$. It is clear that $\left(Y,\left(M^{s}-M^{r}\right)(t)\right)=$ 0 if $t \leq r$. Is it a martingale?

$$
\begin{aligned}
E\left(\left(Y,\left(M^{s}-M^{r}\right)(t)\right)\right) & =E\left(E\left(\left(Y,\left(M^{s}-M^{r}\right)(t)\right) \mid \mathscr{F}_{r}\right)\right) \\
& =E\left(\left(Y, E\left((M(s \wedge t)-M(r \wedge t)) \mid \mathscr{F}_{r}\right)\right)\right)=0
\end{aligned}
$$

because $M$ is a martingale. Now let $\sigma$ be a bounded stopping time with two values. Then using the optional sampling theorem where needed,

$$
\begin{aligned}
E\left(\left(Y,\left(M^{s}-M^{r}\right)(\sigma)\right)\right) & =E\left(E\left(\left(Y,\left(M^{s}-M^{r}\right)(\sigma)\right) \mid \mathscr{F}_{r}\right)\right) \\
& =E\left(\left(Y, E\left((M(s \wedge \sigma)-M(r \wedge \sigma)) \mid \mathscr{F}_{r}\right)\right)\right) \\
& =E((Y, M(s \wedge \sigma \wedge r)-M(r \wedge \sigma))) \\
& =E((Y, M(\sigma \wedge r)-M(r \wedge \sigma)))=0
\end{aligned}
$$

It follows that this is indeed a martingale as claimed.
By the definition of the quadratic variation,

$$
\begin{gathered}
\left|\left(Y,\left(M^{s}-M^{r}\right)(t)\right)\right|^{2} \leq\|Y\|^{2}\left\|\left(M^{s}-M^{r}\right)(t)\right\|^{2} \\
=\|Y\|^{2}\left[\left(M^{s}-M^{r}\right)\right](t)+\|Y\|^{2} \hat{N}(t)
\end{gathered}
$$

where $\hat{N}(t)$ is a martingale. It equals 0 if $t \leq r$. By similar reasoning to the above, $\|Y\|^{2} \hat{N}(t)$ is a martingale. To see this,

$$
\begin{aligned}
E\left(\|Y\|^{2} \hat{N}(\sigma)\right) & =E\left(E\left(\|Y\|^{2} \hat{N}(\sigma) \mid \mathscr{F}_{r}\right)\right) \\
& =E\left(\|Y\|^{2} E\left(\hat{N}(\sigma) \mid \mathscr{F}_{r}\right)\right) \\
& =E\left(\|Y\|^{2} N(\sigma \wedge r)\right)=0
\end{aligned}
$$

One also sees that $E\left(\|Y\|^{2} \hat{N}(t)\right)=0$.

Now it follows from Corollary 63.3.3 that

$$
\left[\left(M^{s}-M^{r}\right)\right]=\left[M^{s}\right]-\left[M^{r}\right]=[M]^{s}-[M]^{r}
$$

Hence

$$
\left[\left(Y,\left(M^{s}-M^{r}\right)\right)\right](t) \leq\|Y\|^{2}\left[M^{s}-M^{r}\right](t)=\|Y\|^{2}\left([M]^{s}(t)-[M]^{r}(t)\right)
$$

as claimed.
The last claim is easy. Let $\tau_{p}$ be a localizing sequence for which $M^{\tau_{p}}$ is a martingale. Then

$$
\begin{aligned}
\int_{0}^{t \wedge \tau_{p}}(Y, d M) & \equiv \sum_{i=0}^{m-1}\left(Y_{i}, M\left(t \wedge t_{i+1} \wedge \tau_{p}\right)-M\left(t \wedge t_{i} \wedge \tau_{p}\right)\right)_{H} \\
& =\sum_{i=0}^{m-1}\left(Y_{i}, M^{\tau_{p}}\left(t \wedge t_{i+1}\right)-M^{\tau_{p}}\left(t \wedge t_{i}\right)\right)_{H}
\end{aligned}
$$

a finite sum of martingales.
Note that this is just a definition and did not use the above localization lemma. In particular, $\tau_{p}$ is not restricted to having only the partition points as values.

Next one needs to generalize past the elementary functions.
Continue writing $M$ in place of $M^{\tau_{p}}$ in what follows. Consider an elementary function

$$
Y \equiv \sum_{k=0}^{m_{n}-1} Y_{k} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t)
$$

where $Y_{k} M^{*} \in L^{2}(\Omega)$. Consider

$$
\begin{equation*}
\int_{0}^{t}(Y, d M) \equiv \sum_{k=0}^{m_{n}-1}\left(Y_{k}, M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right) \tag{66.0.3}
\end{equation*}
$$

Then it is routine to verify that

$$
\begin{gather*}
E\left(\left(\sum_{k=0}^{m_{n}-1}\left(Y_{k}, M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)_{H}\right)^{2}\right) \\
=\sum_{k=0}^{m_{n}-1} E\left(\left(Y_{k}, M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)_{H}^{2}\right) \tag{66.0.4}
\end{gather*}
$$

This is because the mixed terms all vanish. This follows from the following reasoning. Let $t_{j}<t_{k}$

$$
\begin{gathered}
E\left(\left(Y_{k}, M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)_{H}\left(Y_{j}, M\left(t \wedge t_{j+1}\right)-M\left(t \wedge t_{j+1}\right)\right)_{H}\right) \\
=E\left(E\left(\left(Y_{k}, \Delta_{k} M(t)\right)_{H}\left(Y_{j}, \Delta_{j} M(t)\right)_{H} \mid \mathscr{F}_{t_{k}}\right)\right)
\end{gathered}
$$

$$
\begin{gathered}
=E\left(\left(Y_{j}, \Delta_{j} M(t)\right)_{H} E\left(\left(Y_{k}, \Delta_{k} M(t)\right)_{H} \mid \mathscr{F}_{t_{k}}\right)\right) \\
=E\left(\left(Y_{j}, \Delta_{j} M(t)\right)_{H}\left(Y_{k}, E\left(\Delta_{k} M(t) \mid \mathscr{F}_{t_{k}}\right)\right)_{H}\right) \\
\quad=E\left(\left(Y_{j}, \Delta_{j} M(t)\right)_{H}\left(Y_{k}, 0\right)_{H}\right)=0
\end{gathered}
$$

Now

$$
\sum_{k=0}^{m_{n}-1} E\left(\left(Y_{k}, M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)_{H}^{2}\right)=\sum_{k=0}^{m_{n}-1} E\left(\left(Y_{k},\left(M^{t_{k+1}}-M^{t_{k}}\right)(t)\right)_{H}^{2}\right)
$$

It follows from 66.0.4

$$
\begin{gathered}
E\left(\left(\sum_{k=0}^{m_{n}-1}\left(Y_{k}, M\left(t \wedge t_{k+1}\right)-M\left(t \wedge t_{k}\right)\right)_{H}\right)^{2}\right)=\sum_{k=0}^{m_{n}-1} E\left(\left(Y_{k},\left(M^{t_{k+1}}-M^{t_{k}}\right)(t)\right)_{H}^{2}\right) \\
=\sum_{k=0}^{m_{n}-1} E\left(\left[\left(Y_{k},\left(M^{t_{k+1}}-M^{t_{k}}\right)(t)\right)\right]+N_{k}(t)\right)
\end{gathered}
$$

where $N_{k}$ is a martingale equal to 0 for $t \leq t_{k}$. Then this equals

$$
\sum_{k=0}^{m_{n}-1} E\left(\left[\left(Y_{k},\left(M^{t_{k+1}}-M^{t_{k}}\right)(t)\right)\right]\right)
$$

From Lemma 66.0.5

$$
\begin{align*}
& \leq E\left(\sum_{k=0}^{m_{n}-1}\left\|Y_{k}\right\|_{H}^{2}\left([M]^{t_{k+1}}(t)-[M]^{t_{k}}(t)\right)\right) \\
= & E\left(\sum_{k=0}^{m_{n}-1}\left\|Y_{k}\right\|_{H}^{2}\left([M]\left(t_{k+1}^{n} \wedge t\right)-[M]\left(t_{k}^{n} \wedge t\right)\right)\right)  \tag{66.0.5}\\
= & E\left(\int_{0}^{t}\|Y\|_{H}^{2} d\left[M^{\tau_{p}}\right]\right)=E\left(\int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}}\right)
\end{align*}
$$

Note that everything makes sense because it is assumed that $\left\|Y_{k}\right\| M^{*} \in L^{2}(\Omega)$. This proves the following lemma.

Lemma 66.0.6 Let $\|Y(t)\|\left(M^{\tau_{p}}\right)^{*} \in L^{2}(\Omega)$ for each $t$, where $Y$ is an elementary function and let $\tau_{p}$ be a stopping time for which $M^{\tau_{p}}$ is a $L^{2}$ martingale. Then

$$
E\left(\left|\int_{0}^{t}\left(Y, d M^{\tau_{p}}\right)\right|^{2}\right) \leq E\left(\int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}}\right)
$$

The condition that $\|Y(t)\|\left(M^{\tau_{p}}\right)^{*} \in L^{2}(\Omega)$ ensures that

$$
E\left(\left(Y_{k}, M^{\tau_{p}}\left(t \wedge t_{k+1}\right)-M^{\tau_{p}}\left(t \wedge t_{k+1}\right)\right)_{H}^{2}\right)
$$

always is finite.

Definition 66.0.7 Let $\mathscr{G}$ denote those functions $Y$ which are adapted and have the property that for each $p$,

$$
\lim _{n \rightarrow \infty} E\left(\int_{0}^{T}\left\|Y-Y^{n}\right\|_{H}^{2} d[M]^{\tau_{p}}\right)=0
$$

for some sequence $Y^{n}$ of elementary functions for which $\left\|Y^{n}(t)\right\| M^{*} \in L^{2}(\Omega)$ for each $t$. Here $d[M]^{\tau_{p}}$ signifies the Lebesgue Stieltjes measure determined by the increasing function $t \rightarrow\left[M^{\tau_{p}}\right](t)$. Let $M^{\tau_{p}}$ be an $L^{2}$ martingale. Recall that $\tau_{p}$ is just a localizing sequence for the local martingale $M$.

It is not known whether this increasing function is absolutely continuous.
Definition 66.0.8 Let $Y \in \mathscr{G}$. Then

$$
\int_{0}^{t}\left(Y, d M^{\tau_{p}}\right) \equiv \lim _{n \rightarrow \infty} \int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right) \text { in } L^{2}(\Omega)
$$

For example, suppose $Y$ is a bounded continuous process having values in $H$. Then you could look at the left step functions

$$
Y^{n}(t) \equiv \sum_{i=0}^{m_{n}-1} Y\left(t_{i}\right) \mathscr{X}_{\left[t_{i}, t_{i+1}\right)}(t)
$$

The $Y^{n}$ would converge to $Y$ pointwise on $[0, T]$ for each $\omega$ and these $Y^{n}$ are bounded. In fact, in this case, these converge uniformly to $Y$ on $[0, T]$. Thus this is an example of the situation in the above definition. In this case, the integrand would be bounded by $C$ for some $C$ and

$$
E\left(\int_{0}^{T} C d[M]^{\tau_{p}}\right)=E\left([M]^{\tau_{p}}(T)\right)=E\left(\left\|M^{\tau_{p}}(T)\right\|^{2}\right)<\infty
$$

by assumption. Hence, by the dominated convergence theorem,

$$
\lim _{n \rightarrow \infty} E\left(\int_{0}^{T}\left\|Y-Y^{n}\right\|_{H}^{2} d[M]^{\tau_{p}}\right)=0
$$

What if $[M]^{\tau_{p}}$ were bounded and absolutely continuous with respect to Lebesgue measure? This could be the case if you had $\tau_{p}$ a stopping time of the form

$$
\tau_{p}=\inf \{t:[M](t)>p\}
$$

Then if $Y \in L^{2}([0, T] \times \Omega, H)$, and progressively measurable there are left step functions which converge to $Y$ in $L^{2}([0, T] \times \Omega, H)$. Say $d\left[M^{\tau_{p}}\right]=k(t, \omega) d m$ where $k$ is bounded. Then

$$
E\left(\int_{0}^{T}\left\|Y-Y^{n}\right\|_{H}^{2} d[M]^{\tau_{p}}\right)=E\left(\int_{0}^{T}\left\|Y-Y^{n}\right\|_{H}^{2} k d t\right) \rightarrow 0
$$

Lemma 66.0.9 The above definition is well defined. Also, $\int_{0}^{t}\left(Y, d M^{\tau_{p}}\right)$ is a continuous martingale. The inequality

$$
E\left(\left|\int_{0}^{t}\left(Y, d M^{\tau_{p}}\right)\right|^{2}\right) \leq E\left(\int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}}\right)
$$

is also valid. For any sequence of elementary functions $\left\{Y^{n}\right\},\left\|Y^{n}(t)\right\| M^{*} \in L^{2}(\Omega)$,

$$
\left\|Y^{n}-Y\right\|_{L^{2}\left(\Omega ; L^{2}\left([0, T] ; H, d\left[M^{\left.\left.\left.\tau_{p}\right]\right)\right)}\right.\right.\right.} \rightarrow 0
$$

there exists a subsequence, still denoted as $\left\{Y^{n}\right\}$ of elementary functions for which

$$
\int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right)
$$

converges uniformly to $\int_{0}^{t}\left(Y, d M^{\tau_{p}}\right)$ on $[0, T]$ for $\omega$ off some set of measure zero.
Proof: First of all, why does the limit even exist? From Lemma 66.0.6,

$$
E\left(\left|\int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right)-\int_{0}^{t}\left(Y^{m}, d M^{\tau_{p}}\right)\right|^{2}\right) \leq E\left(\int_{0}^{T}\left\|Y^{n}-Y^{m}\right\|_{H}^{2} d[M]^{\tau_{p}}\right)
$$

which converges to 0 as $n, m \rightarrow \infty$ by definition of $Y \in \mathscr{G}$. This also shows that the definition is well defined and that the same thing is obtained from any other sequence converging to $Y$. $\left\{\int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right)\right\}$ is a Cauchy sequence in $L^{2}(\Omega)$. Hence it converges to something $N(t) \in L^{2}(\Omega)$. This is a martingale because if $A \in \mathscr{F}_{s}, s<t$

$$
\begin{aligned}
\int_{A} N(t) d P & =\lim _{n \rightarrow \infty} \int_{A} \int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right) d P \\
& =\lim _{n \rightarrow \infty} \int_{A} \int_{0}^{s}\left(Y^{n}, d M^{\tau_{p}}\right) d P=\int_{A} N(s) d P
\end{aligned}
$$

Since $A$ is arbitrary, this shows that $E\left(N(t) \mid \mathscr{F}_{s}\right)=N(s)$. Then

$$
N(t) \equiv \int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right)
$$

In fact, this has a continuous version off a set of measure zero.
These are martingales and so actually, by maximal theorems,

$$
\begin{gathered}
P\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right)-\int_{0}^{t}\left(Y^{m}, d M^{\tau_{p}}\right)\right|^{2}>\lambda\right) \\
\leq \frac{1}{\lambda} E\left(\left|\int_{0}^{T}\left(Y^{n}, d M^{\tau_{p}}\right)-\int_{0}^{T}\left(Y^{m}, d M^{\tau_{p}}\right)\right|^{2}\right) \\
\leq \frac{1}{\lambda} E\left(\int_{0}^{T}\left\|Y^{n}-Y^{m}\right\|_{H}^{2} d[M]^{\tau_{p}}\right)
\end{gathered}
$$

which converges to 0 . Thus there is a subsequence still denoted with index $k$ such that

$$
P\left(\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Y^{k}, d M^{\tau_{p}}\right)-\int_{0}^{t}\left(Y^{k+1}, d M^{\tau_{p}}\right)\right|^{2}>2^{-k}\right)<2^{-k}
$$

and so there exists a set of measure zero $N$ such that for $\omega \notin N$,

$$
\sup _{t \in[0, T]}\left|\int_{0}^{t}\left(Y^{k}, d M^{\tau_{p}}\right)-\int_{0}^{t}\left(Y^{k+1}, d M^{\tau_{p}}\right)\right|^{2} \leq 2^{-k}
$$

for all $k$ large enough and so for this subsequence, the convergence is uniform. Hence $t \rightarrow \int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right)$ has a continuous version obtained from the uniform limit of these.

Finally,

$$
\begin{aligned}
E\left(\left|\int_{0}^{t}\left(Y, d M^{\tau_{p}}\right)\right|^{2}\right) & =\lim _{n \rightarrow \infty} E\left(\left|\int_{0}^{t}\left(Y^{n}, d M^{\tau_{p}}\right)\right|^{2}\right) \\
& \leq \lim _{n \rightarrow \infty} E\left(\int_{0}^{t}\left\|Y^{n}\right\|_{H}^{2} d[M]^{\tau_{p}}\right)=E\left(\int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}}\right)
\end{aligned}
$$

What is the quadratic variation of the martingale in the above lemma? I am not going to give it exactly but it is easy to give an estimate for it. Recall the following result. It is Theorem 63.6.4.

Theorem 66.0.10 Let $H$ be a Hilbert space and suppose $\left(M, \mathscr{F}_{t}\right), t \in[0, T]$ is a uniformly bounded continuous martingale with values in $H$. Also let $\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}}$ be a sequence of partitions satisfying

$$
\lim _{n \rightarrow \infty} \max \left\{\left|t_{i}^{n}-t_{i+1}^{n}\right|, i=0, \cdots, m_{n}\right\}=0,\left\{t_{k}^{n}\right\}_{k=1}^{m_{n}} \subseteq\left\{t_{k}^{n+1}\right\}_{k=1}^{m_{n+1}}
$$

Then

$$
[M](t)=\lim _{n \rightarrow \infty} \sum_{k=0}^{m_{n}-1}\left|M\left(t \wedge t_{k+1}^{n}\right)-M\left(t \wedge t_{k}^{n}\right)\right|_{H}^{2}
$$

the limit taking place in $L^{2}(\Omega)$. In case $M$ is just a continuous local martingale, the above limit happens in probability.

In the above Lemma, you would find the quadratic variation according to this theorem as follows.

$$
\left[\int_{0}^{(\cdot)}\left(Y, d M^{\tau_{p}}\right)\right](t)=\lim _{n \rightarrow \infty} \sum_{k=0}^{m_{n}-1}\left|\int_{t \wedge t_{k}^{n}}^{t \wedge t_{k+1}^{n}}\left(Y, d M^{\tau_{p}}\right)\right|_{H}^{2}
$$

where the limit is in probability. Thus

$$
\left.\lim _{n \rightarrow \infty} P\left(| | \int_{0}^{(\cdot)}\left(Y, d M^{\tau_{p}}\right)\right](t)-\sum_{k=0}^{m_{n}-1}\left|\int_{t \wedge t_{k}^{n}}^{t \wedge t_{k+1}^{n}}\left(Y, d M^{\tau_{p}}\right)\right|^{2} \mid \geq \varepsilon\right)=0
$$

Then you can obtain from this and the usual appeal to the Borel Cantelli lemma a set of measure zero $N_{t}$ and a subsequence still denoted with $n$ satisfying that for all $\omega \notin N_{t}$ and $n$ large enough,

$$
\left.\left|\left[\int_{0}^{(\cdot)}\left(Y, d M^{\tau_{p}}\right)\right](t)-\sum_{k=0}^{m_{n}-1}\right| \int_{t \wedge t_{k}^{n}}^{t \wedge t_{k+1}^{n}}\left(Y, d M^{\tau_{p}}\right)\right|^{2} \left\lvert\, \leq \frac{1}{n}\right.
$$

Hence

$$
\begin{gathered}
{\left[\int_{0}^{(\cdot)}\left(Y, d M^{\tau_{p}}\right)\right](t) \leq \frac{1}{n}+\sum_{k=0}^{m_{n}-1} \int_{t \wedge t_{k}^{n}}^{t \wedge t_{k+1}^{n}}\|Y\|_{H}^{2} d[M]^{\tau_{p}}} \\
=\frac{1}{n}+\int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}}
\end{gathered}
$$

Then for that $t$, you have on taking a limit as $n \rightarrow \infty$,

$$
\left[\int_{0}^{(\cdot)}\left(Y, d M^{\tau_{p}}\right)\right](t) \leq \int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}}
$$

Now take the union of $N_{t}$ for $t \in \mathbb{Q} \cap[0, T]$. Denote this as $N$. Then if $\omega \notin N$, the above shows that for such $t$,

$$
\left[\int_{0}^{(\cdot)}\left(Y, d M^{\tau_{p}}\right)\right](t) \leq \int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}}
$$

But both sides are continuous in $t$ and so this inequality holds for all $t \in[0, T]$. Thus the following corollary is obtained.

Corollary 66.0.11 Let $M$ be a continuous local martingale and $\tau_{p}$ a localizing sequence which makes $M^{\tau_{p}}$ an $L^{2}$ martingale and assume that $Y \in \mathscr{G}$. Then the quadratic variation of this martingale satisfies

$$
\left[\int_{0}^{(\cdot)}\left(Y, d M^{\tau_{p}}\right)\right](t) \leq \int_{0}^{t}\|Y\|_{H}^{2} d[M]^{\tau_{p}} \leq \int_{0}^{t}\|Y\|_{H}^{2} d[M]
$$

for $\omega$ off a set of measure zero.
Does the localization stuff hold for an arbitrary stopping time? Let $\left\{t_{i}^{k}\right\}$ denote the $k^{t h}$ partition of a sequence of nested partitions whose maximum length between successive points converges to 0 . Let $\tau$ be a stopping time and let $\tau_{k}=t_{j+1}^{k}$ on $\tau^{-1}\left(t_{j}^{k}, t_{j+1}^{k}\right]$. Then $\tau_{k}$ is a stopping time because

$$
\left[\tau_{k} \leq t\right] \in \mathscr{F}_{t}
$$

Here is why. If $t \in\left(t_{j}^{k}, t_{j+1}^{k}\right]$, then if $t=t_{j+1}^{k}$, it would follow that $\tau_{k}(\omega) \leq t$ would be the same as saying $\omega \in\left[\tau \leq t_{j+1}^{k}\right]=[\tau \leq t] \in \mathscr{F}_{t}$. On the other hand, if $t<t_{j+1}^{k}$, then $\left[\tau_{k} \leq t\right]=\left[\tau \leq t_{j}^{k}\right] \in \mathscr{F}_{t_{j}^{k}} \subseteq \mathscr{F}_{t}$ because $\tau_{k}$ can only take the values $t_{j}^{k}$.

Let $Y$ be one of those elementary functions which is in $\mathscr{G},\|Y(t)\| M^{*} \in L^{2}(\Omega)$.

$$
Y(t)=\sum_{i=0}^{m_{k}-1} Y_{i} \mathscr{X}_{\left(t_{i}^{k}, t_{i+1}^{k}\right]}(t)
$$

and consider $\mathscr{X}_{\left[0, \tau_{k}\right]} Y$. Here $Y$ will be always the same for the different partitions. It is just that some of the $Y_{i}$ will be repeated on smaller and smaller intervals. Does it follow that $\mathscr{X}_{\left[0, \tau_{k}\right]} Y \rightarrow \mathscr{X}_{[0, \tau]} Y$ for each fixed $\omega$ ? This depends only on the indicator function. Let $\tau(\omega) \in\left(t_{j}^{k}, t_{j+1}^{k}\right]$. Fixing $t$, if $\mathscr{X}_{[0, \tau]}(t)=1$, then also $\mathscr{X}_{\left[0, \tau_{k}\right]}(t)=1$ because $\tau_{k} \geq \tau$. Therefore, in this case $\lim _{k \rightarrow \infty} \mathscr{X}_{\left[0, \tau_{k}\right]}(t)=\mathscr{X}_{[0, \tau]}(t)$. Next suppose $\mathscr{X}_{[0, \tau]}(t)=0$ so that $\tau(\omega)<t$. Since the intervals defined by the partition points have lengths which converge to 0 , it follows that for all $k$ large enough, $\tau_{k}(\omega)<t$ also and so $\mathscr{X}_{\left[0, \tau_{k}\right]}(t)=0$. Therefore,

$$
\lim _{k \rightarrow \infty} \mathscr{X}_{\left[0, \tau_{k}(\omega)\right]}(t)=\mathscr{X}_{[0, \tau(\omega)]}(t) .
$$

It follows that $\mathscr{X}_{\left[0, \tau_{k}\right]} Y \rightarrow \mathscr{X}_{[0, \tau]} Y$. Also it is clear from the dominated convergence theorem,

$$
\left\|\mathscr{X}_{\left[0, \tau_{k}\right]} Y-\mathscr{X}_{[0, \tau]} Y\right\|_{H}^{2} \leq 4\|Y\|_{H}^{2}
$$

that

$$
\lim _{k \rightarrow \infty} E\left(\int_{0}^{T}\left\|\mathscr{X}_{\left[0, \tau_{k}\right]} Y-\mathscr{X}_{[0, \tau]} Y\right\|_{H}^{2} d\left[M^{\tau_{p}}\right]\right)=0
$$

Thus $\mathscr{X}_{[0, \tau]} Y \in \mathscr{G}$. By Lemma 66.0.9, there is a subsequence, still denoted as $\mathscr{X}_{\left[0, \tau_{k}\right]} Y$ such that off a set of measure zero,

$$
\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{k}\right]} Y, d M^{\tau_{p}}\right) \rightarrow \int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)
$$

uniformly on $[0, T]$. Therefore, from the localization for elementary functions and this uniform convergence,

$$
\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)=\lim _{n \rightarrow \infty} \int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{n}\right]} Y, d M^{\tau_{p}}\right)=\lim _{n \rightarrow \infty} \int_{0}^{t \wedge \tau_{n}}\left(Y, d M^{\tau_{p}}\right)=\int_{0}^{t \wedge \tau}\left(Y, d M^{\tau_{p}}\right)
$$

This proves most of the following lemma.
Lemma 66.0.12 Let $Y$ be an elementary function. Then if $\tau$ is any stopping time, then off a set of measure zero,

$$
\int_{0}^{t \wedge \tau}\left(Y, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(Y, d M^{\tau \wedge \tau_{p}}\right)
$$

Proof: It remains to prove the second equation.

$$
\begin{aligned}
\int_{0}^{t \wedge \tau}\left(Y, d M^{\tau_{p}}\right) & \equiv \sum_{i=0}^{m-1}\left(Y_{i}, M^{\tau_{p}}\left(t \wedge t_{i+1} \wedge \tau\right)-M^{\tau_{p}}\left(t \wedge t_{i} \wedge \tau\right)\right) \\
& \equiv \sum_{i=0}^{m-1}\left(Y_{i}, M^{\tau \wedge \tau_{p}}\left(t \wedge t_{i+1}\right)-M^{\tau_{p}}\left(t \wedge t_{i}\right)\right) \\
& \equiv \int_{0}^{t}\left(Y, d M^{\tau \wedge \tau_{p}}\right) \square
\end{aligned}
$$

Lemma 66.0.13 Let $Y \in \mathscr{G}$. Then for any stopping time $\tau$,

$$
\int_{0}^{t \wedge \tau}\left(Y, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(Y, d M^{\tau \wedge \tau_{p}}\right)
$$

for $\omega$ off some set of measure zero.
Proof: From Lemma 66.0.9, there exists a sequence of elementary functions $Y^{n}$ such that $t \rightarrow \int_{0}^{t}\left(Y^{n}, d M\right)$ converges uniformly to $t \rightarrow \int_{0}^{t}\left(Y, d M^{\tau_{p}}\right)$ on $[0, T]$ for each $\omega \notin N$, a set of measure zero. Then

$$
\begin{aligned}
\int_{0}^{t \wedge \tau}\left(Y, d M^{\tau_{p}}\right) & =\lim _{n \rightarrow \infty} \int_{0}^{t \wedge \tau}\left(Y^{n}, d M^{\tau_{p}}\right) \\
& =\lim _{n \rightarrow \infty} \int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y^{n}, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)
\end{aligned}
$$

The last claim needs a little clarification. As shown in the above discussion proving Lemma 66.0.12, while $\mathscr{X}_{[0, \tau]} Y^{n}$ is no longer obviously an elementary function due to the fact that $\tau$ has values which are not partition points, it is still the limit of a sequence of elementary functions $\mathscr{X}_{\left[0, \tau_{k}\right]} Y^{n}$ and so the integral makes sense. Then from the inequality of Lemma 66.0.9,

$$
E\left(\left|\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y^{n}, d M^{\tau_{p}}\right)-\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)\right|^{2}\right) \leq E\left(\int_{0}^{T}\left\|Y^{n}-Y\right\|_{H}^{2} d[M]^{\tau_{p}}\right)
$$

and so by the same Borel Canteli argument of that lemma, there is a further subsequence for which the convergence is uniform off a set of measure zero as $n \rightarrow \infty$. (Actually, the same subsequence as in the first part of the argument works.) Therefore, the conclusion follows.

What of the second equation? Let $\left\{Y^{n}\right\}$ be as above where uniform convergence takes place for the stochastic integrals. Then from Lemma 66.0.12

$$
\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y^{n}, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(Y^{n}, d M^{\tau \wedge \tau_{p}}\right)
$$

Hence

$$
E\left(\left|\int_{0}^{t}\left(Y^{n}, d M^{\tau \wedge \tau_{p}}\right)-\int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)\right|^{2}\right) \leq E\left(\int_{0}^{T}\left\|Y^{n}-Y\right\|_{H}^{2} d[M]^{\tau_{p}}\right)
$$

Now by the usual application of the Borel Canelli lemma, there is a subsequence and a set of measure zero off which $\int_{0}^{t}\left(Y^{n}, d M^{\tau \wedge \tau_{p}}\right)$ converges uniformly to $\int_{0}^{t}\left(Y, d M^{\tau \wedge \tau_{p}}\right)$ on $[0, T]$ and as $n \rightarrow \infty$, and also

$$
\int_{0}^{t}\left(Y^{n}, d M^{\tau \wedge \tau_{p}}\right) \rightarrow \int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)
$$

uniformly on $t \in[0, T]$. Then from the above,

$$
\int_{0}^{t}\left(Y^{n}, d M^{\tau \wedge \tau_{p}}\right) \rightarrow \int_{0}^{t}\left(\mathscr{X}_{[0, \tau]} Y, d M^{\tau_{p}}\right)=\int_{0}^{t \wedge \tau}\left(Y, d M^{\tau_{p}}\right)
$$

uniformly. Thus $\int_{0}^{t}\left(Y, d M^{\tau \wedge \tau_{p}}\right)=\int_{0}^{t \wedge \tau}\left(Y, d M^{\tau_{p}}\right)$.

Definition 66.0.14 Let $\tau_{p}$ be an increasing sequence of stopping times for which

$$
\lim _{p \rightarrow \infty} \tau_{p}=\infty
$$

and such that $M^{\tau_{p}}$ is a $L^{2}$ martingale and $\mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$. Then the definition of $\int_{0}^{t}(Y, d M)$ is as follows. For each $\omega$,

$$
\int_{0}^{t}(Y, d M) \equiv \lim _{p \rightarrow \infty} \int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right)
$$

In fact, this is well defined.
Theorem 66.0.15 The above definition is well defined. Also this makes $\int_{0}^{t}(Y, d M)$ a local martingale. In particular,

$$
\int_{0}^{t \wedge \tau_{p}}(Y, d M)=\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right)
$$

In addition to this, if $\sigma$ is any stopping time,

$$
\int_{0}^{t \wedge \sigma}(Y, d M)=\int_{0}^{t}\left(\mathscr{X}_{[0, \sigma]} Y, d M\right)
$$

In this last formula, $\mathscr{X}_{[0, \sigma]} \mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$. In addition, the following estimate holds for the quadratic variation.

$$
\left[\int_{0}^{(\cdot)}(Y, d M)\right](t) \leq \int_{0}^{t}\|Y\|^{2} d[M]
$$

Proof: Suppose for some $\omega, t<\tau_{p}<\tau_{q}$. Let $\omega$ be such that both $\tau_{p}, \tau_{q}$ are larger than $t$. Then for all $\omega$, and $\tau$ a stopping time,

$$
\int_{0}^{t \wedge \tau}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{q}}\right)=\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d\left(\left(M^{\tau_{q}}\right)^{\tau}\right)\right)
$$

In particular, for the given $\omega$,

$$
\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d\left(M^{\tau_{q}}\right)^{\tau_{q}}\right)=\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{q}}\right)=\int_{0}^{t \wedge \tau_{q}}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{q}}\right)
$$

For the particular $\omega$, this equals

$$
\int_{0}^{t \wedge \tau_{p}}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{q}}\right)
$$

Now for all $\omega$ including the particular one, this equals

$$
\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d\left(\left(M^{\tau_{q}}\right)^{\tau_{p}}\right)\right)=\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{p}}\right)
$$

For the $\omega$ of interest, this is

$$
\int_{0}^{t \wedge \tau_{p}}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{p}}\right)
$$

and for all $\omega$, including the one of interest, the above equals

$$
\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} \mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right)
$$

thus for this particular $\omega$, you get the same for both $p$ and $q$. Thus the definition is well defined because for a given $\omega, \int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right)$ is constant for all $p$ large enough.

Next consider the claim about this process being a local martingale. Is

$$
\int_{0}^{t \wedge \tau_{p}}(Y, d M)
$$

is a martingale? From the definition,

$$
\begin{gather*}
\int_{0}^{t \wedge \tau_{p}}(Y, d M)=\lim _{q \rightarrow \infty} \int_{0}^{t \wedge \tau_{p}}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{q}}\right) \\
=\lim _{q \rightarrow \infty} \int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d\left(M^{\tau_{q}}\right)^{\tau_{p}}\right)=\lim _{q \rightarrow \infty} \int_{0}^{t \wedge \tau_{p}}\left(\mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{p}}\right) \\
=\lim _{q \rightarrow \infty} \int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} \mathscr{X}_{\left[0, \tau_{q}\right]} Y, d M^{\tau_{p}}\right)=\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right) \tag{66.0.6}
\end{gather*}
$$

which is known to be a martingale since $\mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$. This is what it means to be a local martingale. You localize and get a martingale.

Next consider the claim about an arbitrary stopping time. Why is $\mathscr{X}_{[0, \sigma]} \mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$ ? This is part of a more general question. Suppose $\hat{Y} \in \mathscr{G}$. Then why is $\mathscr{X}_{[0, \sigma]} \hat{Y} \in \mathscr{G}$. It suffices to show this. Let $\left\{Y^{n}\right\}$ be the sequence of elementary functions which converge to $\hat{Y}$ as in the definition. Also let $\sigma_{n}$ be the stopping time with discreet values which equals $t_{k+1}^{n}$ when $\sigma \in\left(t_{k}^{n}, t_{k+1}^{n}\right],\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}$ being the partition associated with $Y^{n}$. Then, as explained earlier, $\mathscr{X}_{\left[0, \sigma_{n}\right]} Y^{n}$ is an acceptable elementary function and also

$$
\begin{gathered}
\left\{E\left(\int_{0}^{T}\left\|\mathscr{X}_{\left[0, \sigma_{n}\right]} Y^{n}-\mathscr{X}_{[0, \sigma]} \hat{Y}\right\|^{2} d[M]\right)\right\}^{1 / 2} \\
\leq \\
+\left\{E\left(\int_{0}^{T}\left\|\mathscr{X}_{\left[0, \sigma_{n}\right]} Y^{n}-\mathscr{X}_{\left[0, \sigma_{n}\right]} \hat{Y}\right\|^{2} d[M]\right)\right\}^{1 / 2} \\
\leq\left\{E\left(\int_{0}^{T}\left\|\mathscr{X}_{\left[\sigma, \sigma_{n}\right]} \hat{Y}\right\|^{2} d[M]\right)\right\}^{1 / 2} \\
\left.=\left\{Y_{0}^{n}-\hat{Y} \|^{2} d[M]\right)\right\}^{1 / 2}+\left\{E\left(\int_{0}^{T}\left\|\mathscr{X}_{\left[\sigma, \sigma_{n}\right]} \hat{Y}\right\|^{2} d[M]\right)\right\}^{1 / 2}
\end{gathered}
$$

which converges to 0 from the definition of $\hat{Y} \in \mathscr{G}$ and the dominated convergence theorem. Thus $\mathscr{X}_{[0, \sigma]} \hat{Y} \in \mathscr{G}$.

From the above definition, for each $\omega$ off a suitable set of measure zero, from Lemma 66.0.13,

$$
\begin{aligned}
\int_{0}^{t \wedge \sigma}(Y, d M) & \equiv \lim _{p \rightarrow \infty} \int_{0}^{t \wedge \sigma}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right) \\
& =\lim _{p \rightarrow \infty} \int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} \mathscr{X}_{[0, \sigma]} Y, d M^{\tau_{p}}\right) \equiv \int_{0}^{t}\left(\mathscr{X}_{[0, \sigma]} Y, d M\right)
\end{aligned}
$$

Finally, consider the claim about the quadratic variation. Using 66.0.6,

$$
\begin{gathered}
{\left[\left(\int_{0}^{(\cdot)}(Y, d M)\right)\right]^{\tau_{p}}(t)=\left[\left(\int_{0}^{(\cdot)}(Y, d M)\right)^{\tau_{p}}\right](t)=\left[\int_{0}^{(\cdot)}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right)\right](t)} \\
\leq \int_{0}^{t}\left\|\mathscr{X}_{\left[0, \tau_{p}\right]} Y\right\|^{2} d[M]^{\tau_{p}} \leq \int_{0}^{t}\|Y\|^{2} d[M]
\end{gathered}
$$

Now letting $\tau_{p} \rightarrow \infty$,

$$
\left[\left(\int_{0}^{(\cdot)}(Y, d M)\right)\right](t) \leq \int_{0}^{t}\|Y\|^{2} d[M]
$$

Next is the case in which $Y$ is continuous in $t$ but not necessarily bounded nor assumed to be in any kind of $L^{2}$ space either.

Definition 66.0.16 Let $Y$ be continuous in $t$ and adapted. Let $M$ be a continuous local martingale $M(0)=0$. Then the definition of a local martingale $\int_{0}^{t}(Y, d M)$ is as follows. Let $\tau_{p}$ be an increasing sequence of stopping times for which $[M]^{\tau_{p}},\left\|M^{\tau_{p}}\right\|,\left\|\mathscr{X}_{\left[0, \tau_{p}\right]} Y\right\|$ are all bounded by $p$. Then

$$
\int_{0}^{t}(Y, d M) \equiv \lim _{p \rightarrow \infty} \int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right)
$$

Then it is clear that $\mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$. Therefore, the above Theorem yields the following corollary.
Corollary 66.0.17 The above definition is well defined. Also this makes $\int_{0}^{t}(Y, d M)$ a local martingale. In particular,

$$
\int_{0}^{t \wedge \tau_{p}}(Y, d M)=\int_{0}^{t}\left(\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right)
$$

In addition to this, if $\sigma$ is any stopping time,

$$
\int_{0}^{t \wedge \sigma}(Y, d M)=\int_{0}^{t}\left(\mathscr{X}_{[0, \sigma]} Y, d M\right)
$$

In this last formula, $\mathscr{X}_{[0, \sigma]} Y$ has the same properties as $Y$, being the pointwise limit on $[0, T]$ of a bounded seuqence of elementary functions for each $\omega$. In addition to this, there is an estimate for the quadratic variation

$$
\left[\int_{0}^{(\cdot)}(Y, d M)\right](t) \leq \int_{0}^{t}\|Y\|^{2} d[M]
$$

Of course there is no change in anything if $M$ has its values in a Hilbert space $W$ while $Y$ has its values in its dual space. Then one defines $\int_{0}^{t}\langle Y, d M\rangle_{W^{\prime}, W}$ by analogy to the above for $Y$ an elementary function, step function which is adapted.

We use the following definition.
Definition 66.0.18 Let $\tau_{p}$ be an increasing sequence of stopping times for which $M^{\tau_{p}}$ is a $L^{2}$ martingale. If $M$ is already an $L^{2}$ martingale, simply let $\tau_{p} \equiv \infty$. Let $\mathscr{G}$ denote those functions $Y$ which are adapted and for which there is a sequence of elementary functions $\left\{Y^{n}\right\}$ satisfying $\left\|Y^{n}(t)\right\|_{W^{\prime}} M^{*} \in L^{2}(\Omega)$ for each $t$ with

$$
\lim _{n \rightarrow \infty} E\left(\int_{0}^{T}\left\|Y-Y^{n}\right\|_{W^{\prime}}^{2} d[M]^{\tau_{p}}\right)=0
$$

for each $\tau_{p}$.
Then exactly the same arguments given above yield the following simple generalizations.

Definition 66.0.19 Let $Y \in \mathscr{G}$. Then

$$
\int_{0}^{t}\left\langle Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W} \equiv \lim _{n \rightarrow \infty} \int_{0}^{t}\left\langle Y^{n}, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W} \text { in } L^{2}(\Omega)
$$

Lemma 66.0.20 The above definition is well defined. Also, $\int_{0}^{t}\left\langle Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}$ is a continuous martingale. The inequality

$$
E\left(\left|\int_{0}^{t}\left\langle Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}\right|^{2}\right) \leq E\left(\int_{0}^{t}\|Y\|_{W^{\prime}}^{2} d[M]^{\tau_{p}}\right)
$$

is also valid. For any sequence of elementary functions $\left\{Y^{n}\right\},\left\|Y^{n}(t)\right\|_{W^{\prime}} M^{*} \in L^{2}(\Omega)$,

$$
\left\|Y^{n}-Y\right\|_{L^{2}\left(\Omega ; L^{2}\left([0, T] ; W^{\prime}, d\left[M^{\tau_{p}}\right]\right)\right)} \rightarrow 0
$$

there exists a subsequence, still denoted as $\left\{Y^{n}\right\}$ of elementary functions for which

$$
\int_{0}^{t}\left\langle Y^{n}, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}
$$

converges uniformly to $\int_{0}^{t}\left\langle Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}$ on $[0, T]$ for $\omega$ off some set of measure zero. In addition, the quadratic variation satisfies the following inequality.

$$
\left[\int_{0}^{(\cdot)}\left\langle Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}\right](t) \leq \int_{0}^{t}\|Y\|_{W^{\prime}}^{2} d[M]^{\tau_{p}} \leq \int_{0}^{t}\|Y\|_{W^{\prime}}^{2} d[M]
$$

As before, you can consider the case where you only know $\mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$. This yields a local martingale as before.

Definition 66.0.21 Let $\tau_{p}$ be an increasing sequence of stopping times for which

$$
\lim _{p \rightarrow \infty} \tau_{p}=\infty
$$

and such that $M^{\tau_{p}}$ is a martingale and $\mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$. Then the definition of $\int_{0}^{t}\langle Y, d M\rangle_{W^{\prime}, W}$ is as follows. For each $\omega$ off a set of measure zero,

$$
\int_{0}^{t}\langle Y, d M\rangle_{W^{\prime}, W} \equiv \lim _{p \rightarrow \infty} \int_{0}^{t}\left\langle\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}
$$

where $\int_{0}^{t}\left\langle\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}$ is a martingale.
In fact, this is well defined.
Theorem 66.0.22 The above definition is well defined. Also this makes $\int_{0}^{t}\langle Y, d M\rangle_{W^{\prime}, W} a$ local martingale. In particular,

$$
\int_{0}^{t \wedge \tau_{p}}\langle Y, d M\rangle_{W^{\prime}, W}=\int_{0}^{t}\left\langle\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}
$$

In addition to this, if $\sigma$ is any stopping time,

$$
\int_{0}^{t \wedge \sigma}\langle Y, d M\rangle_{W^{\prime}, W}=\int_{0}^{t}\left\langle\mathscr{X}_{[0, \sigma]} Y, d M\right\rangle_{W^{\prime}, W}
$$

In this last formula, $\mathscr{X}_{[0, \sigma]} \mathscr{X}_{\left[0, \tau_{p}\right]} Y \in \mathscr{G}$. In addition, the following estimate holds for the quadratic variation.

$$
\left[\int_{0}^{(\cdot)}\langle Y, d M\rangle_{W^{\prime}, W}\right](t) \leq \int_{0}^{t}\|Y\|_{W^{\prime}}^{2} d[M]
$$

Note that from Definition 66.0.21 it is also true that

$$
\int_{0}^{t}\langle Y, d M\rangle_{W^{\prime}, W} \equiv \lim _{p \rightarrow \infty} \int_{0}^{t}\left\langle\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}
$$

in probability. In addition, since $\tau_{p} \rightarrow \infty$, it follows that for each $\omega$, eventually $\tau_{p}>T$. Therefore, $t \rightarrow \int_{0}^{t}\langle Y, d M\rangle_{W^{\prime}, W}$ is continuous, being equal to $\int_{0}^{t}\left\langle\mathscr{X}_{\left[0, \tau_{p}\right]} Y, d M^{\tau_{p}}\right\rangle_{W^{\prime}, W}$ for that $\omega$.

## Chapter 67

## The Easy Ito Formula

First recall 64.5 .26 where it is shown that for every $\alpha$

$$
E\left(|W(t)-W(s)|^{\alpha}\right) \leq C_{\alpha}|t-s|^{\alpha / 2}
$$

and so by Kolmogorov Čentsov continuity theorem

$$
\begin{equation*}
|W(t)-W(s)| \leq C_{\gamma}|t-s|^{\gamma} \tag{67.0.1}
\end{equation*}
$$

for every $\gamma<1 / 2$.

### 67.1 The Situation

The idea is as follows. You have a sufficiently smooth function $F:[0, T] \times H \rightarrow \mathbb{R}$ where $H$ is a separable Hilbert space. You also have the random variable

$$
X(t)=X_{0}+\int_{0}^{t} \phi(s) d s+\int_{0}^{t} \Phi d W
$$

where $\Phi$ is progressively measurable and in $L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ where $Q: U \rightarrow$ $U$ is a positive self adjoint operator. Also assume $X_{0}$ is $\mathscr{F}_{0}$ measurable with values in $H$. Recall the descriptive diagram.

\[

\]

Here the Wiener process is in $U_{1}$ and the filtration with respect to which $\Phi$ is progressively measurable is the usual filtration determined by this Wiener process. Then the Ito formula is about writing the random variable $F(t, X(t))$ in terms of various integrals and derivatives of $F$.

### 67.2 Assumptions And A Lemma

Assume $F:[0, T] \times H \times \Omega \rightarrow \mathbb{R}^{1}$ has continuous partial derivatives $F_{t}, F_{X}$, and $F_{X X}$ which are uniformly continuous and bounded on bounded subsets of $[0, T] \times H$ independent of $\omega \in \Omega$. Also assume $F_{X X}$ is uniformly bounded and that $F_{X X X}$ exists. Let $\phi:[0, T] \times \Omega \rightarrow H$ be progressively measurable and Bochner integrable for each $\omega$. Assume $\Phi$ is progressively measurable, and is in $L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$.

Now here is the important lemma which makes the Ito formula possible.

Lemma 67.2.1 Suppose $\eta_{j}$ are real random variables $E\left(\eta_{j}^{2}\right)<\infty$, such that $\eta_{k}$ is measurable with respect to $\mathscr{G}_{j}$ for all $j>k$ where $\left\{\mathscr{G}_{k}\right\}$ is increasing. Then

$$
\begin{align*}
& E\left(\left[\sum_{k=0}^{m-1} \eta_{k}-\sum_{k=0}^{m-1} E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right]^{2}\right)  \tag{67.2.2}\\
& \quad=E\left(\sum_{k=0}^{m-1} \eta_{k}^{2}-E\left(\eta_{k} \mid \mathscr{G}_{k}\right)^{2}\right)
\end{align*}
$$

Proof: First consider a mixed term $i<k$.

$$
E\left(\left(\eta_{i}-E\left(\eta_{i} \mid \mathscr{G}_{i}\right)\right)\left(\eta_{k}-E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right)\right)
$$

This equals

$$
\begin{gathered}
E\left(\eta_{i} \eta_{k}\right)-E\left(\eta_{i} E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right)-E\left(\eta_{k} E\left(\eta_{i} \mid \mathscr{G}_{i}\right)\right)+E\left(E\left(\eta_{i} \mid \mathscr{G}_{i}\right) E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right) \\
=E\left(\eta_{i} \eta_{k}\right)-E\left(E\left(\eta_{i} \eta_{k} \mid \mathscr{G}_{k}\right)\right)-E\left(\eta_{k} E\left(\eta_{i} \mid \mathscr{G}_{i}\right)\right)+E\left(E\left(\eta_{k} E\left(\eta_{i} \mid \mathscr{G}_{i}\right) \mid \mathscr{G}_{k}\right)\right) \\
=E\left(\eta_{i} \eta_{k}\right)-E\left(E\left(\eta_{i} \eta_{k} \mid \mathscr{G}_{k}\right)\right)-E\left(\eta_{k} E\left(\eta_{i} \mid \mathscr{G}_{i}\right)\right)+E\left(\eta_{k} E\left(\eta_{i} \mid \mathscr{G}_{i}\right)\right) \\
=E\left(\eta_{i} \eta_{k}\right)-E\left(\eta_{i} \eta_{k}\right)-E\left(\eta_{k} E\left(\eta_{i} \mid \mathscr{G}_{i}\right)\right)+E\left(\eta_{k} E\left(\eta_{i} \mid \mathscr{G}_{i}\right)\right)=0
\end{gathered}
$$

Thus 67.2.2 equals

$$
\sum_{k=0}^{m-1} E\left(\left(\eta_{k}-E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right)^{2}\right)
$$

which equals

$$
\begin{aligned}
& \sum_{k=0}^{m-1} E\left(\eta_{k}^{2}\right)-2 E\left(\eta_{k} E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right)+E\left(E\left(\eta_{k} \mid \mathscr{G}_{k}\right)^{2}\right) \\
= & \sum_{k=0}^{m-1} E\left(\eta_{k}^{2}\right)-2 E\left(E\left(\eta_{k} E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right) \mid \mathscr{G}_{k}\right)+E\left(E\left(\eta_{k} \mid \mathscr{G}_{k}\right)^{2}\right) \\
= & \sum_{k=0}^{m-1} E\left(\eta_{k}^{2}\right)-2 E\left(E\left(\eta_{k} \mid \mathscr{G}_{k}\right) E\left(\eta_{k} \mid \mathscr{G}_{k}\right)\right)+E\left(E\left(\eta_{k} \mid \mathscr{G}_{k}\right)^{2}\right) \\
= & \sum_{k=0}^{m-1} E\left(\eta_{k}^{2}\right)-2 E\left(E\left(\eta_{k} \mid \mathscr{G}_{k}\right)^{2}\right)+E\left(E\left(\eta_{k} \mid \mathscr{G}_{k}\right)^{2}\right) \\
= & \sum_{k=0}^{m-1} E\left(\eta_{k}^{2}\right)-E\left(E\left(\eta_{k} \mid \mathscr{G}_{k}\right)^{2}\right)
\end{aligned}
$$

### 67.3 A Special Case

To make it simpler, first consider the situation in which $\Phi=\Phi_{0}$ where $\Phi_{0}$ is $\mathscr{F}_{0}$ measurable and has finitely many values in $\mathscr{L}\left(U_{1}, H\right)$, and $\phi=\phi_{0}$ where $\phi_{0}$ is $\mathscr{F}_{0}$ measurable and a simple function with values in $H$. Thus

$$
X(t)=X_{0}+\int_{0}^{t} \phi_{0} d s+\int_{0}^{t} \Phi_{0} d W
$$

Now let $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}$ denote the $n^{\text {th }}$ partition of $[0, T]$, referred to as $\mathscr{P}_{n}$ such that

$$
\lim _{n \rightarrow \infty}\left(\max \left\{\left|t_{k}^{n}-t_{k-1}^{n}\right|, k=0,1,2, \cdots, m_{n}\right\}\right) \equiv \lim _{n \rightarrow \infty}\left\|\mathscr{P}_{n}\right\|=0
$$

The superscript $n$ will be suppressed to save notation. Then

$$
\begin{aligned}
F(T, X(T))- & F\left(0, X_{0}\right)=\sum_{k=0}^{m_{n}-1}\left(F\left(t_{k+1}, X\left(t_{k+1}\right)\right)-F\left(t_{k}, X\left(t_{k}\right)\right)\right) \\
= & \sum_{k=0}^{m_{n}-1}\left(F\left(t_{k+1}, X\left(t_{k+1}\right)\right)-F\left(t_{k}, X\left(t_{k+1}\right)\right)\right) \\
& +\sum_{k=0}^{m_{n}-1}\left(F\left(t_{k}, X\left(t_{k+1}\right)\right)-F\left(t_{k}, X\left(t_{k}\right)\right)\right)
\end{aligned}
$$

This equals

$$
\begin{gather*}
\sum_{k=0}^{m_{n}-1} F_{t}\left(t_{k}, X\left(t_{k+1}\right)\right)\left(t_{k+1}-t_{k}\right)+o\left(\left|t_{k+1}-t_{k}\right|\right)  \tag{67.3.3}\\
+\sum_{k=0}^{m_{n}-1} F_{X}\left(t_{k}, X\left(t_{k}\right)\right)\left(X\left(t_{k+1}\right)-X\left(t_{k}\right)\right)  \tag{67.3.4}\\
+\frac{1}{2} \sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right)\left(X\left(t_{k+1}\right)-X\left(t_{k}\right)\right),\left(X\left(t_{k+1}\right)-X\left(t_{k}\right)\right)\right)_{H}  \tag{67.3.5}\\
+\sum_{k=0}^{m_{n}-1} O\left(\left|X\left(t_{k+1}\right)-X\left(t_{k}\right)\right|_{H}^{3}\right) \tag{67.3.6}
\end{gather*}
$$

Recall

$$
X(t)=X_{0}+\int_{0}^{t} \phi_{0} d s+\int_{0}^{t} \Phi_{0} d W
$$

From the properties of the Wiener process in 67.0.1, the term in 67.3 .6 converges to 0 as $n \rightarrow \infty$ since these properties of the Wiener process imply $X$ is Holder continuous with exponent $2 / 5$.

Now consider the term of 67.3.5. All terms converge to 0 except

$$
\begin{equation*}
\frac{1}{2} \sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W, \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W\right)_{H} \tag{67.3.7}
\end{equation*}
$$

Consider one of the terms in 67.3.7. Let $A \in \mathscr{F}_{t_{k}}$.By Corollary 65.5.4,

$$
\begin{aligned}
& \int_{A} \frac{1}{2}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W, \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W\right)_{H} d P \\
= & \int_{A} \frac{1}{2}\left(\int_{t_{k}}^{t_{k+1}} F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0} d W, \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W\right)_{H} d P
\end{aligned}
$$

By independence,

$$
=P(A) \frac{1}{2} \int_{\Omega}\left(\int_{t_{k}}^{t_{k+1}} F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0} d W, \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W\right)_{H} d P
$$

By the Ito isometry results presented earlier,

$$
\begin{aligned}
& =\int_{\Omega} \mathscr{X}_{A} \frac{1}{2} \int_{t_{k}}^{t_{k+1}}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}} d s d P \\
& =\int_{A} \frac{1}{2} \int_{\int_{t_{k}} t_{k+1}}^{t_{k}}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}}
\end{aligned} d s d P \text { measurable } \quad \begin{aligned}
& =\int_{A} \frac{1}{2}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}}\left(t_{k+1}-t_{k}\right) d P
\end{aligned}
$$

Since $A \in \mathscr{F}_{t_{k}}$ was arbitrary,

$$
\begin{aligned}
& E\left(\left.\frac{1}{2}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W, \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W\right)_{H} \right\rvert\, \mathscr{F}_{t_{k}}\right) \\
= & \frac{1}{2}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}}\left(t_{k+1}-t_{k}\right)
\end{aligned}
$$

From what was just shown, and Lemma 67.2.1,

$$
\begin{align*}
& E\left(\left[\frac{1}{2} \sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0} \Delta W\left(t_{k}\right), \Phi_{0} \Delta W\left(t_{k}\right)\right)_{H}-\right.\right. \\
& \left.\left.\sum_{k=0}^{m_{n}-1} \frac{1}{2}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}}\left(t_{k+1}-t_{k}\right)\right]^{2}\right)  \tag{67.3.8}\\
& =\frac{1}{4} E\left(\sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0} \Delta W\left(t_{k}\right), \Phi_{0} \Delta W\left(t_{k}\right)\right)_{H}^{2}\right. \\
& \left.\quad-\sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}}^{2}\left(t_{k+1}-t_{k}\right)^{2}\right)
\end{align*}
$$

Now $F_{X X}$ is bounded and so there exists a constant $M$ independent of $k$ and $n$,

$$
M \geq\left\|\Phi_{0}^{*} F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}\right\|,\left|\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}}\right|
$$

Hence the above is dominated by

$$
\begin{aligned}
& \leq \frac{1}{4} M^{2} \sum_{k=0}^{m_{n}-1} E\left\|\Delta W\left(t_{k}\right)\right\|_{U_{1}}^{4}+\frac{1}{4} M^{2} \sum_{k=0}^{m_{n}-1}\left(t_{k+1}-t_{k}\right)^{2} \\
& \leq \frac{M^{2}}{4}\left(\sum_{k=0}^{m_{n}-1}\left(C_{4}+1\right)\left(t_{k+1}-t_{k}\right)^{2}\right)
\end{aligned}
$$

which converges to 0 as $n \rightarrow \infty$. Then from 67.3.8, and referring to 67.3.5,

$$
\begin{gather*}
\lim _{n \rightarrow \infty} \frac{1}{2} \sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right)\left(X\left(t_{k+1}\right)-X\left(t_{k}\right)\right),\left(X\left(t_{k+1}\right)-X\left(t_{k}\right)\right)\right)_{H}  \tag{67.3.9}\\
=\lim _{n \rightarrow \infty} \frac{1}{2} \sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W, \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W\right)_{H} \\
=\lim _{n \rightarrow \infty} \frac{1}{2} \sum_{k=0}^{m_{n}-1}\left(F_{X X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}}\left(t_{k+1}-t_{k}\right)
\end{gather*}
$$

if this last limit exists in $L^{2}(\Omega)$. However, since $F_{X X}$ is bounded, this limit certainly exists for a.e. $\omega$ and equals

$$
=\frac{1}{2} \int_{0}^{T}\left(F_{X X}(t, X(t)) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}} d t
$$

The limit also exists in $L^{2}(\Omega)$ obviously, since $F_{X X}$ is assumed bounded. Therefore, a subsequence of 67.3.9, still denoted as $n$ must converge for a.e. $\omega$ to the above integral as $n \rightarrow \infty$.

Next consider 67.3.4.

$$
\begin{gather*}
\sum_{k=0}^{m_{n}-1} F_{X}\left(t_{k}, X\left(t_{k}\right)\right)\left(X\left(t_{k+1}\right)-X\left(t_{k}\right)\right)=\sum_{k=0}^{m_{n}-1} F_{X}\left(t_{k}, X\left(t_{k}\right)\right)\left(\int_{t_{k}}^{t_{k+1}} \phi_{0} d s\right) \\
+\sum_{k=0}^{m_{n}-1} F_{X}\left(t_{k}, X\left(t_{k}\right)\right) \int_{t_{k}}^{t_{k+1}} \Phi_{0} d W \tag{67.3.10}
\end{gather*}
$$

Consider the second of these in 67.3.10. From Corollary 65.5.4, it equals

$$
\begin{aligned}
& \sum_{k=0}^{m_{n}-1} \int_{t_{k}}^{t_{k+1}} F_{X}\left(t_{k}, X\left(t_{k}\right)\right) \Phi_{0} d W \\
= & \int_{0}^{T}\left(\sum_{k=0}^{m_{n}-1} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t) F_{X}\left(t_{k}, X\left(t_{k}\right)\right)\right) \Phi_{0} d W
\end{aligned}
$$

which converges as $n \rightarrow \infty$ to

$$
\int_{0}^{T} F_{X}(t, X(t)) \Phi_{0} d W
$$

because

$$
\lim _{n \rightarrow \infty}\left(\sum_{k=0}^{m_{n}-1} \mathscr{X}_{\left(t_{k}, t_{k+1}\right]}(t) F_{X}\left(t_{k}, X\left(t_{k}\right)\right)\right) \Phi_{0}=F_{X}(t, X(t)) \Phi_{0}
$$

in $L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$. Next consider the first on the right in 67.3.10. It equals

$$
\sum_{k=0}^{m_{n}-1}\left(F_{X}\left(t_{k}, X\left(t_{k}\right)\right) \phi_{0}\left(t_{k+1}-t_{k}\right)\right)
$$

and converges to

$$
\int_{0}^{T} F_{X}(t, X(t)) \phi_{0} d t
$$

Finally, it is obviously the case that 67.3 .3 converges to

$$
\int_{0}^{T} F_{t}(t, X(t)) d t
$$

This has shown

$$
\begin{gathered}
F(T, X(T))=F\left(0, X_{0}\right)+\int_{0}^{T} F_{t}(t, X(t))+F_{X}(t, X(t)) \phi_{0} d t \\
+\int_{0}^{T} F_{X}(t, X(t)) \Phi_{0} d W+\frac{1}{2} \int_{0}^{T}\left(F_{X X}(t, X(t)) \Phi_{0}, \Phi_{0}\right)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d t
\end{gathered}
$$

when

$$
X(t)=X_{0}+\int_{0}^{t} \phi_{0} d s+\int_{0}^{t} \Phi_{0} d W
$$

$\phi_{0}, \Phi_{0} \mathscr{F}_{0}$ measurable as described above. This is the first version of the Ito formula.

### 67.4 The Case Of Elementary Functions

Of course there was nothing special about the interval $[0, T]$. It follows that for $[a, b] \subseteq$ $[0, T], \Phi_{a} \in \mathscr{L}\left(U_{1}, U\right)$ and $\mathscr{F}_{a}$ measurable, having finitely many values, $\phi_{a}$ a simple function which is $\mathscr{F}_{a}$ measurable,

$$
\begin{gathered}
X(t)=X(a)+\int_{a}^{t} \phi_{a} d t+\int_{a}^{t} \Phi_{a} d W \\
F(b, X(b))=F(a, X(a))+\int_{a}^{b}\left(F_{t}(t, X(t))+F_{X}(t, X(t)) \phi_{a}\right) d t \\
+\int_{a}^{b} F_{X}(t, X(t)) \Phi_{a} d W+\frac{1}{2} \int_{a}^{b}\left(F_{X X}(t, X(t)) \Phi_{a}, \Phi_{a}\right)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d t .
\end{gathered}
$$

Therefore, if $\Phi$ is any elementary function, being a sum of functions like $\Phi_{a} \mathscr{X}_{(a, b]}$, and $\phi$ a similar sort of elementary fuction with

$$
X(t)=X_{0}+\int_{0}^{t} \phi d s+\int_{0}^{t} \Phi d W
$$

then

$$
\begin{array}{r}
F(T, X(T))=F\left(0, X_{0}\right)+\int_{0}^{T} F_{t}(t, X(t))+F_{X}(t, X(t)) \phi(t) d t \\
+\int_{0}^{T} F_{X}(t, X(t)) \Phi d W+\frac{1}{2} \int_{0}^{T}\left(F_{X X}(t, X(t)) \Phi, \Phi\right)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d t \tag{67.4.11}
\end{array}
$$

This has proved the following lemma.
Lemma 67.4.1 Let $\Phi, \phi$ be elementary functions as described and let

$$
X(t)=X_{0}+\int_{0}^{t} \phi(s) d s+\int_{0}^{t} \Phi d W
$$

Then 67.4.11 holds.

### 67.5 The Integrable Case

Now let $\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right), \phi \in L^{1}([0, T] \times \Omega ; H)$ and be progressively measurable. Let $\phi$ be as above, and let

$$
\begin{equation*}
X(t)=X_{0}+\int_{0}^{t} \phi(t) d t+\int_{0}^{t} \Phi d W \tag{67.5.12}
\end{equation*}
$$

Suppose also the additional condition that for some $M$,

$$
|X(t, \omega)|<M \text { for all }(t, \omega) \in[0, T] \times N^{C}, P(N)=0
$$

Does it follow that 67.4.11 holds?
There exists a sequence of elementary functions $\left\{\Phi_{n}\right\}$ converging to $\Phi \circ J^{-1}$ in

$$
L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)
$$

Similarly let $\left\{\phi_{n}\right\}$ converge to $\phi$ in $L^{1}([0, T] \times \Omega ; H)$ where $\phi_{n}$ is also an elementary function, $\left|\phi_{n}\right| \leq|\phi|$ at the mesh points. You could use that theorem about approximating with left and right step functions if desired, Lemma 65.3.1. Let

$$
X_{n}(t)=X_{0}+\int_{0}^{t} \phi_{n}(s) d s+\int_{0}^{t} \Phi_{n} d W
$$

Also let $\tau_{n}$ be the stopping times

$$
\tau_{n} \equiv \inf \left\{t>0:\left|X_{n}(t)\right|>M\right\}
$$

Since $X_{n}$ is continuous, this is a well defined stopping time. Thus

$$
X_{n}^{\tau_{n}}(t)=X_{0}+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} \phi_{n}(t) d t+\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n} d W
$$

and as noted in the discussion of localization for elementary functions, $\mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n}$ is an elementary function.

Claim: $\lim _{n \rightarrow \infty} \mathscr{X}_{\left[0, \tau_{n}\right]}=1$.
Proof of claim: From maximal estimates as in the construction of the stochastic integral and the Borel Cantelli lemma, it follows that there exists a subsequence still denoted by $n$ and a set of measure zero $N$ such that for $\omega \notin N_{1}$,

$$
\int_{0}^{t} \Phi_{n} d W \rightarrow \int_{0}^{t} \Phi d W
$$

uniformly on $[0, T]$. Also one can show that off a set of measure zero, there is a subsequence still called $n$ such that $\int_{0}^{t} \phi_{n}(s) d s \rightarrow \int_{0}^{t} \phi(s) d s$ uniformly on $[0, T]$. Here is why.

$$
E\left(\left|\int_{0}^{t} \phi_{n}(s) d s-\int_{0}^{t} \phi(s) d s\right|\right) \leq \int_{\Omega} \int_{0}^{T}\left|\phi_{n}-\phi\right| d t d P
$$

which is given to converge to 0 . Thus

$$
\begin{gathered}
P\left(\max _{t \in[0, T]}\left|\int_{0}^{t} \phi_{n}(s) d s-\int_{0}^{t} \phi(s) d s\right|>\lambda\right) \leq P\left(\int_{0}^{T}\left|\phi_{n}(s)-\phi(s)\right| d s>\lambda\right) \\
\leq \frac{1}{\lambda} \int_{\left[\int_{0}^{T}\left|\phi_{n}(s)-\phi(s)\right| d s>\lambda\right]} \int_{0}^{T}\left|\phi_{n}(s)-\phi(s)\right| d s d P \\
\leq \frac{1}{\lambda} \int_{\Omega} \int_{0}^{T}\left|\phi_{n}(s)-\phi(s)\right| d s d P
\end{gathered}
$$

Thus

$$
P\left(\max _{t \in[0, T]}\left|\int_{0}^{t} \phi_{n}(s) d s-\int_{0}^{t} \phi(s) d s\right|>2^{-k}\right) \leq 2^{k} \int_{\Omega} \int_{0}^{T}\left|\phi_{n}(s)-\phi(s)\right| d s d P
$$

If $n>n_{k}$, the right side is less than $2^{-k}$. Use $\phi_{n_{k}}$. Then there exists a set of measure zero $N_{2}$ such that for $\omega \notin N_{2}$,

$$
\left|\int_{0}^{t} \phi_{n}(s) d s-\int_{0}^{t} \phi(s) d s\right| \rightarrow 0
$$

uniformly. Hence, you can take a couple of subsequences and assert that there exists a subsequence still called $n$ and a set of measure zero $N$ such that $X_{n}(t) \rightarrow X(t)$ uniformly on $[0, T]$ for each $\omega \notin N$. Since $|X(t, \omega)|<M$, it follows that for each $\omega \notin N$, when $n$ is large enough, $\tau_{n}=\infty$ and this proves the claim.

From the claim, it follows that $\mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n} \rightarrow \Phi \circ J^{-1}$ in $L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and $\mathscr{X}_{\left[0, \tau_{n}\right]} \phi_{n} \rightarrow \phi$ in $L^{1}([0, T] \times \Omega ; \mathscr{H})$. Thus you can replace $\Phi_{n}$ in the above with $\mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n}$ and $\phi_{n}$ with $\mathscr{X}_{\left[0, \tau_{n}\right]} \phi_{n}$. Thus there exists a subsequence, still called $n$ and a set of measure zero $N$ such that for $\omega \notin N$,

$$
\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n} d W \rightarrow \int_{0}^{t} \Phi d W
$$

uniformly and

$$
\int_{0}^{t} \mathscr{X}_{\left[0, \tau_{n}\right]} \phi_{n} d s \rightarrow \int_{0}^{t} \phi d s
$$

uniformly. Hence also $X_{n}^{\tau_{n}}(t) \rightarrow X(t)$ uniformly on $[0, T]$ whenever $\omega \notin N$. Of course $\left|X_{n}^{\tau_{n}}(t)\right|_{H}$ has the advantage of being bounded by $M$.

From the above,

$$
\begin{gathered}
F\left(T, X_{n}^{\tau_{n}}(T)\right)=F\left(0, X_{0}\right)+\int_{0}^{T} F_{t}\left(t, X_{n}^{\tau_{n}}(t)\right)+F_{X}\left(t, X_{n}^{\tau_{n}}(t)\right) \mathscr{X}_{\left[0, \tau_{n}\right]} \phi_{n}(t) d t \\
+\int_{0}^{T} F_{X}\left(t, X_{n}^{\tau_{n}}(t)\right) \Phi_{n} d W+\frac{1}{2} \int_{0}^{T}\left(F_{X X}\left(t, X_{n}^{\tau_{n}}(t)\right) \mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n}, \mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n}\right)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d t
\end{gathered}
$$

Then it is obvious that one can pass to the limit in each of the non stochastic integrals in the above. It is necessary to consider the other one.

From the above claim, $\mathscr{X}_{\left[0, \tau_{n}\right]} \Phi_{n} \rightarrow \Phi \circ J^{-1}$ in $L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(J Q^{1 / 2} U, H\right)\right)$ and also, from the stopping times $\tau_{n}, F_{X}\left(t, X_{n}^{\tau_{n}}(t)\right)$ is bounded and converges to $F_{X}(t, X(t))$. Hence the dominated convergence theorem applies, and letting $n \rightarrow \infty$, the following is obtained for a.e. $\omega$

$$
\begin{array}{r}
F(T, X(T))=F\left(0, X_{0}\right)+\int_{0}^{T} F_{t}(t, X(t))+F_{X}(t, X(t)) \phi(t) d t \\
+\int_{0}^{T} F_{X}(t, X(t)) \Phi d W+\frac{1}{2} \int_{0}^{T}\left(F_{X X}(t, X(t)) \Phi, \Phi\right)_{\mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)} d t \tag{67.5.13}
\end{array}
$$

This is the Ito formula in case that $\Phi \in L^{2}\left([0, T] \times \Omega ; \mathscr{L}_{2}\left(Q^{1 / 2} U, H\right)\right)$ and $|X|$ is bounded above by $M$.

It is easy to remove this assumption on $|X|$. Let $X$ be given in 67.5.12. Let $\tau_{n}$ be the stopping time

$$
\tau_{n} \equiv \inf \{t>0:|X|>n\}
$$
