Theorem 23.4.6 (Brouwer fixed point) Let $B=\overline{B(\mathbf{0}, r)} \subseteq \mathbb{R}^{p}$ and let $\mathbf{f}: B \rightarrow B$ be continuous. Then there exists a point $\mathbf{x} \in B$, such that $\mathbf{f}(\mathbf{x})=\mathbf{x}$.

Proof: Assume there is no fixed point. Consider $\mathbf{h}(\mathbf{x}, t) \equiv t \mathbf{f}(\mathbf{x})-\mathbf{x}$ for $t \in[0,1]$. Then for $\|\mathbf{x}\|=r$,

$$
\mathbf{0} \notin t \mathbf{f}(\mathbf{x})-\mathbf{x}, t \in[0,1]
$$

By homotopy invariance,

$$
t \rightarrow d(t \mathbf{f}-I, B, \mathbf{0})
$$

is constant. But when $t=0$, this is $d(-I, B, \mathbf{0})=(-1)^{n} \neq 0$. Hence $d(\mathbf{f}-I, B, \mathbf{0}) \neq 0$ so there exists $\mathbf{x}$ such that $\mathbf{f}(\mathbf{x})-\mathbf{x}=\mathbf{0}$.

You can use standard stuff from Hilbert space to get this the fixed point theorem for a compact convex set. Let $K$ be a closed bounded convex set and let $\mathbf{f}: K \rightarrow K$ be continuous. Let $P$ be the projection map onto $K$ as in Problem 3 on Page 194. Then $P$ is continuous because $|P \mathbf{x}-P \mathbf{y}| \leq|\mathbf{x}-\mathbf{y}|$. Recall why this is. From the characterization of the projection $\operatorname{map} P,(\mathbf{x}-P \mathbf{x}, \mathbf{y}-P \mathbf{x}) \leq 0$ for all $\mathbf{y} \in K$. Therefore,

$$
(\mathbf{x}-P \mathbf{x}, P \mathbf{y}-P \mathbf{x}) \leq 0,(\mathbf{y}-P \mathbf{y}, P \mathbf{x}-P \mathbf{y}) \leq 0 \text { so }(\mathbf{y}-P \mathbf{y}, P \mathbf{y}-P \mathbf{x}) \geq 0
$$

Hence, subtracting the first from the last,

$$
(\mathbf{y}-P \mathbf{y}-(\mathbf{x}-P \mathbf{x}), P \mathbf{y}-P \mathbf{x}) \geq 0
$$

consequently,

$$
|\mathbf{x}-\mathbf{y}||P \mathbf{y}-P \mathbf{x}| \geq(\mathbf{y}-\mathbf{x}, P \mathbf{y}-P \mathbf{x}) \geq|P \mathbf{y}-P \mathbf{x}|^{2}
$$

and so $|P \mathbf{y}-P \mathbf{x}| \leq|\mathbf{y}-\mathbf{x}|$ as claimed.
Now let $r$ be so large that $K \subseteq B(\mathbf{0}, r)$. Then consider $\mathbf{f} \circ P$. This map takes $\overline{B(\mathbf{0}, r)} \rightarrow$ $\overline{B(\mathbf{0}, r)}$. In fact it maps $\overline{B(\mathbf{0}, r)}$ to $K$. Therefore, being the composition of continuous functions, it is continuous and so has a fixed point in $\overline{B(\mathbf{0}, r)}$ denoted as $\mathbf{x}$. Hence $\mathbf{f}(P(\mathbf{x}))=$ $\mathbf{x}$. Now, since $\mathbf{f}$ maps into $K$, it follows that $\mathbf{x} \in K$. Hence $P \mathbf{x}=\mathbf{x}$ and so $\mathbf{f}(\mathbf{x})=\mathbf{x}$. This has proved the following general Brouwer fixed point theorem.

Theorem 23.4.7 Let $\mathbf{f}: K \rightarrow K$ be continuous where $K$ is compact and convex and nonempty, $K \subseteq \mathbb{R}^{p}$. Then $\mathbf{f}$ has a fixed point.

Definition 23.4.8 $\mathbf{f}$ is a retract of $\overline{B(\mathbf{0}, r)}$ onto $\partial B(0, r)$ if $\mathbf{f}$ is continuous,

$$
\mathbf{f}(\overline{B(\mathbf{0}, r)}) \subseteq \partial B(\mathbf{0}, r)
$$

and $\mathbf{f}(\mathbf{x})=\mathbf{x}$ for all $\mathbf{x} \in \partial B(\mathbf{0}, r)$.

Theorem 23.4.9 There does not exist a retract of $\overline{B(\mathbf{0}, r)}$ onto its boundary, $\partial B(\mathbf{0}, r)$.
Proof: Suppose $\mathbf{f}$ were such a retract. Then for all $\mathbf{x} \in \partial B(\mathbf{0}, r), \mathbf{f}(\mathbf{x})=\mathbf{x}$ and so from the properties of the degree, the one which says if two functions agree on $\partial \Omega$, then they have the same degree,

$$
1=d(I, B(\mathbf{0}, r), \mathbf{0})=d(\mathbf{f}, B(\mathbf{0}, r), \mathbf{0})
$$

which is clearly impossible because $\mathbf{f}^{-1}(\mathbf{0})=\emptyset$ which implies $d(\mathbf{f}, B(\mathbf{0}, r), \mathbf{0})=0$.
You should now use this theorem to give another proof of the Brouwer fixed point theorem.

The proofs of the next two theorems make use of the Tietze extension theorem, Theorem 7.10.7.

Theorem 23.4.10 Let $\Omega$ be a symmetric open set in $\mathbb{R}^{p}$ such that $\mathbf{0} \in \Omega$ and let $\mathbf{f}: \partial \Omega \rightarrow V$ be continuous where $V$ is an $m$ dimensional subspace of $\mathbb{R}^{p}, m<p$. Then $\mathbf{f}(-\mathbf{x})=\mathbf{f}(\mathbf{x})$ for some $\mathbf{x} \in \partial \Omega$.

Proof: Suppose not. Using the Tietze extension theorem on components of the function, extend $\mathbf{f}$ to all of $\mathbb{R}^{p}, \mathbf{f}(\bar{\Omega}) \subseteq V$. (Here the extended function is also denoted by $\mathbf{f}$.) Let $\mathbf{g}(\mathbf{x})=\mathbf{f}(\mathbf{x})-\mathbf{f}(-\mathbf{x})$. Then $\mathbf{0} \notin \mathbf{g}(\partial \Omega)$ and so for some $r>0, B(\mathbf{0}, r) \subseteq \mathbb{R}^{p} \backslash \mathbf{g}(\partial \Omega)$. For $\mathbf{z} \in B(\mathbf{0}, r)$,

$$
d(\mathbf{g}, \Omega, \mathbf{z})=d(\mathbf{g}, \Omega, \mathbf{0}) \neq 0
$$

because $B(\mathbf{0}, r)$ is contained in a component of $\mathbb{R}^{p} \backslash \mathbf{g}(\partial \Omega)$ and Borsuk's theorem implies that $d(\mathbf{g}, \Omega, \mathbf{0}) \neq 0$ since $\mathbf{g}$ is odd. Hence

$$
V \supseteq \mathbf{g}(\Omega) \supseteq B(\mathbf{0}, r)
$$

and this is a contradiction because $V$ is $m$ dimensional.
This theorem is called the Borsuk Ulam theorem. Note that it implies there exist two points on opposite sides of the surface of the earth which have the same atmospheric pressure and temperature, assuming the earth is symmetric and that pressure and temperature are continuous functions. The next theorem is an amusing result which is like combing hair. It gives the existence of a "cowlick".
Theorem 23.4.11 Let $n$ be odd and let $\Omega$ be an open bounded set in $\mathbb{R}^{p}$ with $\mathbf{0} \in \Omega$. Suppose $\mathbf{f}: \partial \Omega \rightarrow \mathbb{R}^{p} \backslash\{\mathbf{0}\}$ is continuous. Then for some $\mathbf{x} \in \partial \Omega$ and $\lambda \neq 0, \mathbf{f}(\mathbf{x})=\lambda \mathbf{x}$.

Proof: Using the Tietze extension theorem, extend $\mathbf{f}$ to all of $\mathbb{R}^{p}$. Also denote the extended function by $\mathbf{f}$. Suppose for all $\mathbf{x} \in \partial \Omega, \mathbf{f}(\mathbf{x}) \neq \lambda \mathbf{x}$ for all $\lambda \in \mathbb{R}$. Then

$$
\begin{aligned}
\mathbf{0} \notin t \mathbf{f}(\mathbf{x})+(1-t) \mathbf{x}(\mathbf{x}, t) & \in \partial \Omega \times[0,1] \\
\mathbf{0} \notin t \mathbf{f}(\mathbf{x})-(1-t) \mathbf{x},(\mathbf{x}, t) & \in \partial \Omega \times[0,1]
\end{aligned}
$$

Thus there exists a homotopy of $\mathbf{f}$ and $I$ and a homotopy of $\mathbf{f}$ and $-I$. Then by the homotopy invariance of degree,

$$
d(\mathbf{f}, \Omega, \mathbf{0})=d(I, \Omega, \mathbf{0}), d(\mathbf{f}, \Omega, \mathbf{0})=d(-I, \Omega, \mathbf{0})
$$

But this is impossible because $d(I, \Omega, \mathbf{0})=1$ but $d(-I, \Omega, \mathbf{0})=(-1)^{n}=-1$.

### 23.5 Product Formula, Jordan Separation Theorem

This section is on the product formula for the degree which is used to prove the Jordan separation theorem. To begin with is a significant observation which is used without comment below. Recall that the connected components of an open set are open. The formula is all about the composition of continuous functions.

$$
\Omega \xrightarrow{\mathbf{f}} \mathbf{f}(\Omega) \subseteq \mathbb{R}^{p} \xrightarrow{\mathbf{g}} \mathbb{R}^{p}
$$

Lemma 23.5.1 Let $\left\{K_{i}\right\}_{i=1}^{\infty}$ be the connected components of $\mathbb{R}^{p} \backslash C$ where $C$ is a closed set. Then $\partial K_{i} \subseteq C$.

Proof: Since $K_{i}$ is a connected component of an open set, it is itself open. See Theorem 7.13.10. Thus $\partial K_{i}$ consists of all limit points of $K_{i}$ which are not in $K_{i}$. Let $\mathbf{p}$ be such a point. If it is not in $C$ then it must be in some other $K_{j}$ which is impossible because these are disjoint open sets. Thus if $\mathbf{x}$ is a point in $U$ it cannot be a limit point of $V$ for $V$ disjoint from $U$.

Definition 23.5.2 Let the connected components of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$ be denoted by $K_{i}$. From the properties of the degree listed in Theorem 23.2.2, $d(\mathbf{f}, \Omega, \cdot)$ is constant on each of these components. Denote by $d\left(\mathbf{f}, \Omega, K_{i}\right)$ the constant value on the component $K_{i}$.

The following is the product formula. Note that if $K$ is an unbounded component of $\mathbf{f}(\partial \Omega)^{C}$, then $d(\mathbf{f}, \Omega, \mathbf{y})=0$ for all $\mathbf{y} \in K$ by homotopy invariance and the fact that for large enough $\|\mathbf{y}\|, \mathbf{f}^{-1}(\mathbf{y})=\emptyset$ since $\mathbf{f}(\bar{\Omega})$ is compact.

Theorem 23.5.3 (product formula)Let $\left\{K_{i}\right\}_{i=1}^{\infty}$ be the bounded components of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$ for $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$, let $\mathbf{g} \in C\left(\mathbb{R}^{p}, \mathbb{R}^{p}\right)$, and suppose that $\mathbf{y} \notin \mathbf{g}(\mathbf{f}(\partial \Omega))$ or in other words, $\mathbf{g}^{-1}(\mathbf{y}) \cap \mathbf{f}(\partial \Omega)=\emptyset$. Then

$$
\begin{equation*}
d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y})=\sum_{i=1}^{\infty} d\left(\mathbf{f}, \Omega, K_{i}\right) d\left(\mathbf{g}, K_{i}, \mathbf{y}\right) \tag{23.5.11}
\end{equation*}
$$

All but finitely many terms in the sum are zero. If there are no bounded components of $\mathbf{f}(\partial \Omega)^{C}$, then $d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y})=0$.

Proof: The compact set $\mathbf{f}(\bar{\Omega}) \cap \mathbf{g}^{-1}(\mathbf{y})$ is contained in $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$ and so, $\mathbf{f}(\bar{\Omega}) \cap$ $\mathbf{g}^{-1}(\mathbf{y})$ is covered by finitely many of the components $K_{j}$ one of which may be the unbounded component. Since these components are disjoint, the other components fail to intersect $\mathbf{f}(\bar{\Omega}) \cap \mathbf{g}^{-1}(\mathbf{y})$. Thus, if $K_{i}$ is one of these others, either it fails to intersect $\mathbf{g}^{-1}(\mathbf{y})$ or $K_{i}$ fails to intersect $\mathbf{f}(\bar{\Omega})$. Thus either $d\left(\mathbf{f}, \Omega, K_{i}\right)=0$ because $K_{i}$ fails to intersect $\mathbf{f}(\bar{\Omega})$ or $d\left(\mathbf{g}, K_{i}, \mathbf{y}\right)=0$ if $K_{i}$ fails to intersect $\mathbf{g}^{-1}(\mathbf{y})$. Thus the sum is always a finite sum. I am using Theorem 23.2.2, the part which says that if $\mathbf{y} \notin \mathbf{h}(\bar{\Omega})$, then $d(\mathbf{h}, \Omega, \mathbf{y})=0$. Note that $\partial K_{i} \subseteq \mathbf{f}(\partial \Omega)$ so $\mathbf{y} \notin \mathbf{g}\left(\partial K_{i}\right)$.

Let $\tilde{\mathbf{g}}$ be in $C^{\infty}\left(\mathbb{R}^{p}, \mathbb{R}^{p}\right)$ and let $\|\tilde{\mathbf{g}}-\mathbf{g}\|_{\infty}$ be so small that for each of the finitely many $K_{i}$ intersecting $\mathbf{f}(\bar{\Omega}) \cap \mathbf{g}^{-1}(\mathbf{y})$,

$$
\begin{align*}
d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y}) & =d(\tilde{\mathbf{g}} \circ \mathbf{f}, \Omega, \mathbf{y}) \\
d\left(\mathbf{g}, K_{i}, \mathbf{y}\right) & =d\left(\tilde{\mathbf{g}}, K_{i}, \mathbf{y}\right) \tag{23.5.12}
\end{align*}
$$

Since $\partial K_{i} \subseteq \mathbf{f}(\partial \Omega)$, both conditions are obtained by letting

$$
\|\mathbf{g}-\tilde{\mathbf{g}}\|_{\infty, \mathbf{f}(\bar{\Omega})}<\operatorname{dist}(\mathbf{y}, \mathbf{g}(\mathbf{f}(\partial \Omega)))
$$

By Lemma 23.1.5, there exists $\tilde{\mathbf{g}}$ such that $\mathbf{y}$ is a regular value of $\tilde{\mathbf{g}}$ in addition to 23.5 .12 and $\tilde{\mathbf{g}}^{-1}(\mathbf{y}) \cap \mathbf{f}(\partial \Omega)=\emptyset$. Then $\tilde{\mathbf{g}}^{-1}(\mathbf{y})$ is contained in the union of the $K_{i}$ along with the unbounded component(s) and by Lemma 23.1.5 $\tilde{\mathbf{g}}^{-1}(\mathbf{y})$ is countable. As discussed there, $\tilde{\mathbf{g}}^{-1}(\mathbf{y}) \cap K_{i}$ is finite if $K_{i}$ is bounded. Let $\tilde{\mathbf{g}}^{-1}(\mathbf{y}) \cap K_{i}=\left\{\mathbf{x}_{j}^{i}\right\}_{j=1}^{m_{i}}, m_{i} \leq \infty . m_{i}$ could only be $\infty$ on the unbounded component.

Now use Lemma 23.1.5 again to get $\tilde{\mathbf{f}}$ in $C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ such that each $\mathbf{x}_{j}^{i}$ is a regular value of $\tilde{\mathbf{f}}$ on $\Omega$ and also $\|\tilde{\mathbf{f}}-\mathbf{f}\|_{\infty}$ is very small, so small that

$$
d(\tilde{\mathbf{g}} \circ \tilde{\mathbf{f}}, \Omega, \mathbf{y})=d(\tilde{\mathbf{g}} \circ \mathbf{f}, \Omega, \mathbf{y})=d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y})
$$

and

$$
d\left(\tilde{\mathbf{f}}, \Omega, \mathbf{x}_{j}^{i}\right)=d\left(\mathbf{f}, \Omega, \mathbf{x}_{j}^{i}\right)
$$

for each $i, j$.
Thus, from the above,

$$
\begin{aligned}
d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y}) & =d(\tilde{\mathbf{g}} \circ \tilde{\mathbf{f}}, \Omega, \mathbf{y}) \\
d\left(\tilde{\mathbf{f}}, \Omega, \mathbf{x}_{j}^{i}\right) & =d\left(\mathbf{f}, \Omega, \mathbf{x}_{j}^{i}\right)=d\left(\mathbf{f}, \Omega, K_{i}\right) \\
d\left(\tilde{\mathbf{g}}, K_{i}, \mathbf{y}\right) & =d\left(\mathbf{g}, K_{i}, \mathbf{y}\right)
\end{aligned}
$$

Is $\mathbf{y}$ a regular value for $\tilde{\mathbf{g}} \circ \tilde{\mathbf{f}}$ on $\Omega$ ? Suppose $\mathbf{z} \in \Omega$ and $\mathbf{y}=\tilde{\mathbf{g}} \circ \tilde{\mathbf{f}}(\mathbf{z})$ so $\tilde{\mathbf{f}}(\mathbf{z}) \in \tilde{\mathbf{g}}^{-1}(\mathbf{y})$. Then $\tilde{\mathbf{f}}(\mathbf{z})=\mathbf{x}_{j}^{i}$ for some $i, j$ and $D \tilde{\mathbf{f}}(\mathbf{z})^{-1}$ exists. Hence $D(\tilde{\mathbf{g}} \circ \tilde{\mathbf{f}})(\mathbf{z})=D \tilde{\mathbf{g}}\left(\mathbf{x}_{j}^{i}\right) D \tilde{\mathbf{f}}(\mathbf{z})$, both linear transformations invertible. Thus $\mathbf{y}$ is a regular value of $\tilde{\mathbf{g}} \circ \tilde{\mathbf{f}}$ on $\Omega$.

What of $\mathbf{x}_{j}^{i}$ in $K_{i}$ where $K_{i}$ is unbounded? Then as observed above, the sum of the terms $\operatorname{sgn}(\operatorname{det} D \tilde{\mathbf{f}}(\mathbf{z}))$ for $\mathbf{z} \in \tilde{\mathbf{f}}^{-1}\left(\mathbf{x}_{j}^{i}\right)$ is $d\left(\tilde{\mathbf{f}}, \Omega, \mathbf{x}_{j}^{i}\right)$ and is 0 because the degree is constant on $K_{i}$ which is unbounded.

From the definition of the degree, the left side of $23.5 .11 d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y})$ equals

$$
\sum\left\{\operatorname{sgn}(\operatorname{det} D \tilde{\mathbf{g}}(\tilde{\mathbf{f}}(\mathbf{z}))) \operatorname{sgn}(\operatorname{det} D \tilde{\mathbf{f}}(\mathbf{z})): \mathbf{z} \in \tilde{\mathbf{f}}^{-1}\left(\tilde{\mathbf{g}}^{-1}(\mathbf{y})\right)\right\}
$$

The $\tilde{\mathbf{g}}^{-1}(\mathbf{y})$ are the $\mathbf{x}_{j}^{i}$. Thus the above is of the form

$$
=\sum_{i} \sum_{j} \sum_{\mathbf{z} \in \tilde{\mathbf{f}}^{-1}\left(\mathbf{x}_{j}^{i}\right)} \operatorname{sgn}\left(\operatorname{det}\left(D \tilde{\mathbf{g}}\left(\mathbf{x}_{j}^{i}\right)\right)\right) \operatorname{sgn}(\operatorname{det}(D \tilde{\mathbf{f}}(\mathbf{z})))
$$

As mentioned, if $\mathbf{x}_{j}^{i} \in K_{i}$ an unbounded component, then

$$
\sum_{\mathbf{z} \in \tilde{\mathbf{f}}^{-1}\left(\mathbf{x}_{j}^{i}\right)} \operatorname{sgn}\left(\operatorname{det}\left(D \tilde{\mathbf{g}}\left(\mathbf{x}_{j}^{i}\right)\right)\right) \operatorname{sgn}(\operatorname{det}(D \tilde{\mathbf{f}}(\mathbf{z})))=0
$$

and so, it suffices to only consider bounded components in what follows and the sum makes sense because there are finitely many $\mathbf{x}_{j}^{i}$ in bounded $K_{i}$. This also shows that if there are no bounded components of $\mathbf{f}(\partial \Omega)^{C}$, then $d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y})=0$. Thus $d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{y})$ equals

$$
\begin{aligned}
& =\sum_{i} \sum_{j} \operatorname{sgn}\left(\operatorname{det}\left(D \tilde{\mathbf{g}}\left(\mathbf{x}_{j}^{i}\right)\right)\right) \sum_{\mathbf{z} \in \tilde{\mathbf{f}}^{-1}\left(\mathbf{x}_{j}^{i}\right)} \operatorname{sgn}(\operatorname{det}(D \tilde{\mathbf{f}}(\mathbf{z}))) \\
& =\sum_{i} d\left(\tilde{\mathbf{g}}, K_{i}, \mathbf{y}\right) d\left(\tilde{\mathbf{f}}, \Omega, K_{i}\right)
\end{aligned}
$$

For the last step, $\sum_{\mathbf{z} \in \tilde{\mathbf{f}}^{-1}\left(\mathbf{x}_{j}^{i}\right)} \operatorname{sgn}(\operatorname{det}(D \tilde{\mathbf{f}}(\mathbf{z}))) \equiv d\left(\tilde{\mathbf{f}}, \Omega, \mathbf{x}_{j}^{i}\right)=d\left(\tilde{\mathbf{f}}, \Omega, K_{i}\right)$. This proves the product formula because $\tilde{\mathbf{g}}$ and $\tilde{\mathbf{f}}$ were chosen close enough to $\mathbf{f}, \mathbf{g}$ respectively that

$$
\sum_{i} d\left(\tilde{\mathbf{f}}, \Omega, K_{i}\right) d\left(\tilde{\mathbf{g}}, K_{i}, \mathbf{y}\right)=\sum_{i} d\left(\mathbf{f}, \Omega, K_{i}\right) d\left(\mathbf{g}, K_{i}, \mathbf{y}\right)
$$

Before the general Jordan separation theorem, I want to first consider the examples of most interest.

Recall that if a function $\mathbf{f}$ is continuous and one to one on a compact set $K$, then $\mathbf{f}$ is a homeomorphism of $K$ and $\mathbf{f}(K)$. Also recall that if $U$ is a nonempty open set, the boundary of $U$, denoted as $\partial U$ and meaning those points $\mathbf{x}$ with the property that for all $r>0 B(\mathbf{x}, r)$ intersects both $U$ and $U^{C}$, is $\bar{U} \backslash U$.

Proposition 23.5.4 Let $H$ be a compact set and let $\mathbf{f}: H \rightarrow \mathbb{R}^{p}, p \geq 2$ be one to one and continuous so that $H$ and $\mathbf{f}(H) \equiv C$ are homeomorphic. Suppose $H^{C}$ has only one connected component so $H^{C}$ is connected. Then $C^{C}$ also has only one component.

Proof: I want to show that $C^{C}$ has no bounded components so suppose it has a bounded component $K$. Extend $\mathbf{f}$ to all of $\mathbb{R}^{p}$ and let $\mathbf{g}$ be an extension of $\mathbf{f}^{-1}$ to all of $\mathbb{R}^{p}$. Then, by the above Lemma 23.5.1, $\partial K \subseteq C$. Since $\mathbf{f} \circ \mathbf{g}(\mathbf{x})=\mathbf{x}$ on $\partial K \subseteq C$, if $\mathbf{z} \in K$, it follows that $1=d(\mathbf{f} \circ \mathbf{g}, K, \mathbf{z})$. Now $\mathbf{g}(\partial K) \subseteq \mathbf{g}(C)=H$. Thus $\mathbf{g}(\partial K)^{C} \supseteq H^{C}$ and $H^{C}$ is unbounded and connected. If a component of $\mathbf{g}(\partial K)^{C}$ is bounded, then it cannot contain the unbounded $H^{C}$ which must be contained in the component of $\mathbf{g}(\partial K)^{C}$ which it intersects. Thus, the only bounded components of $\mathbf{g}(\partial K)^{C}$ must be contained in $H$. Let the set of such bounded components be denoted by $\mathscr{Q}$. By the product formula,

$$
d(\mathbf{f} \circ \mathbf{g}, K, \mathbf{z})=\sum_{Q \in \mathscr{Q}} d(\mathbf{g}, K, Q) d(\mathbf{f}, Q, \mathbf{z})
$$

However, $\mathbf{f}(\bar{Q}) \subseteq \mathbf{f}(H)=C$ and $\mathbf{z}$ is contained in a component of $C^{C}$ so for each $Q \in \mathscr{Q}$, $d(\mathbf{f}, Q, \mathbf{z})=0$. Hence, by the product formula, $d(\mathbf{f} \circ \mathbf{g}, K, \mathbf{z})=0$ which is a contradiction to $1=d(\mathbf{f} \circ \mathbf{g}, K, \mathbf{z})$. Thus there is no bounded component of $C^{C}$.

It is obvious that the unit sphere $S^{p-1}$ divides $\mathbb{R}^{p}$ into two disjoint open sets, the inside and the outside. The following shows that this also holds for any homeomorphic image of $S^{p-1}$.

Proposition 23.5.5 Let $B$ be the ball $B(\mathbf{0}, 1)$ with $S^{p-1}$ its boundary, $p \geq 2$. Suppose $\mathbf{f}: S^{p-1} \rightarrow C \equiv \mathbf{f}\left(S^{p-1}\right) \subseteq \mathbb{R}^{p}$ is a homeomorphism. Then $C^{C}$ also has exactly two components, a bounded and an unbounded.

Proof: I need to show there is only one bounded component of $C^{C}$. From Proposition 23.5.4, there is at least one. Otherwise, $S^{p-1}$ would have no bounded components which is obviously false.

Let $\mathbf{f}$ be a continuous extension of $\mathbf{f}$ off $S^{p-1}$ and let $\mathbf{g}$ be a continuous extension of $\mathbf{g}$ off $C$. Let $\left\{K_{i}\right\}$ be the bounded components of $C^{C}$. Now $\partial K_{i} \subseteq C$ and so $\mathbf{g}\left(\partial K_{i}\right) \subseteq \mathbf{g}(C)=$ $S^{p-1}$. Let $G$ be those points $\mathbf{x}$ with $|\mathbf{x}|>1$.

Let a bounded component of $\mathbf{g}\left(\partial K_{i}\right)^{C}$ be $H$. If $H$ intersects $B$ then $H$ must contain $B$ because $B$ is connected and contained in $\left(S^{p-1}\right)^{C} \subseteq \mathbf{g}\left(\partial K_{i}\right)^{C}$ which means that $B$ is contained in the union of components of $\mathbf{g}\left(\partial K_{i}\right)^{C}$. The same is true if $H$ intersects $G$. However, $H$ cannot contain the unbounded $G$ and so $H$ cannot intersect $G$. Since $H$ is open and cannot intersect $G$, it cannot intersect $S^{p-1}$ either. Thus $H=B$ and so there is only one bounded component of $\mathbf{g}\left(\partial K_{i}\right)^{C}$ and it is $B$. Now let $\mathbf{z} \in K_{i} . \mathbf{f} \circ \mathbf{g}=I$ on $\partial K_{i} \subseteq C$ and so if $\mathbf{z} \in K_{i}$, since the degree is determined by values on the boundary, the product formula implies

$$
1=d\left(\mathbf{f} \circ \mathbf{g}, K_{i}, \mathbf{z}\right)=d\left(\mathbf{g}, K_{i}, B\right) d(\mathbf{f}, B, \mathbf{z})=d\left(\mathbf{g}, K_{i}, B\right) d\left(\mathbf{f}, B, K_{i}\right)
$$

If there are $n$ of these $K_{i}$, it follows $\sum_{i} d\left(\mathbf{g}, K_{i}, B\right) d\left(\mathbf{f}, B, K_{i}\right)=n$. Now pick $\mathbf{y} \in B$. Then, since $\mathbf{g} \circ \mathbf{f}(\mathbf{x})=\mathbf{x}$ on $\partial B$, the product formula shows

$$
1=d(\mathbf{g} \circ \mathbf{f}, B, \mathbf{y})=\sum_{i} d\left(\mathbf{f}, B, K_{i}\right) d\left(\mathbf{g}, K_{i}, \mathbf{y}\right)=\sum_{i} d\left(\mathbf{f}, B, K_{i}\right) d\left(\mathbf{g}, K_{i}, B\right)=n
$$

Thus $n=1$ and there is only one bounded component of $C^{C}$.
It remains to show that, in the above $\mathbf{f}\left(S^{p-1}\right)$ is the boundary of both components, the bounded one and the unbounded one.

Theorem 23.5.6 Let $S^{p-1}$ be the unit sphere in $\mathbb{R}^{p}, p \geq 2$. Suppose $\gamma: S^{p-1} \rightarrow \Gamma \subseteq \mathbb{R}^{p}$ is one to one onto and continuous. Then $\mathbb{R}^{p} \backslash \Gamma$ consists of two components, a bounded component (called the inside) $U_{i}$ and an unbounded component (called the outside), $U_{o}$. Also the boundary of each of these two components of $\mathbb{R}^{p} \backslash \Gamma$ is $\Gamma$ and $\Gamma$ has empty interior.

Proof: $\gamma^{-1}$ is continuous since $S^{p-1}$ is compact and $\gamma$ is one to one. By the Jordan separation theorem, $\mathbb{R}^{p} \backslash \Gamma=U_{o} \cup U_{i} \quad$ where these on the right are the connected components of the set on the left, both open sets. Only one of them is bounded, $U_{i}$. Thus $\Gamma \cup U_{i} \cup U_{o}=\mathbb{R}^{p}$. Since both $U_{i}, U_{o}$ are open, $\partial U \equiv \bar{U} \backslash U$ for $U$ either $U_{o}$ or $U_{i}$. If $\mathbf{x} \in \Gamma$, and is not a limit point of $U_{i}$, then there is $B(\mathbf{x}, r)$ which contains no points of $U_{i}$. Let $S$ be those points $\mathbf{x}$ of $\Gamma$ for which $B(\mathbf{x}, r)$ contains no points of $U_{i}$ for some $r>0$. This $S$ is open in $\Gamma$. Let $\hat{\Gamma}$ be $\Gamma \backslash S$. Then if $\hat{C}=\gamma^{-1}(\hat{\Gamma})$, it follows that $\hat{C}$ is a closed set in $S^{p-1}$ and is a proper subset of $S^{p-1}$. It is obvious that taking a relatively open set from $S^{p-1}$ results in a compact set whose complement is an open connected set. By Proposition 23.5.4, $\mathbb{R}^{p} \backslash \hat{\Gamma}$ is also an open connected set. Start with $\mathbf{x} \in U_{i}$ and consider a continuous curve which goes from $\mathbf{x}$ to $\mathbf{y} \in U_{o}$ which is contained in $\mathbb{R}^{p} \backslash \hat{\Gamma}$. Thus the curve contains no points of $\hat{\Gamma}$.

However, it must contain points of $\Gamma$ which can only be in $S$. The first point of $\Gamma$ intersected by this curve is a point in $\overline{U_{i}}$ and so this point of intersection is not in $S$ after all because every ball containing it must contain points of $U_{i}$. Thus $S=\emptyset$ and every point of $\Gamma$ is in $\overline{U_{i}}$. Similarly, every point of $\Gamma$ is in $\overline{U_{o}}$. Thus $\Gamma \subseteq \overline{U_{i}} \backslash U_{i}$ and $\Gamma \subseteq \overline{U_{o}} \backslash U_{o}$. However, if $\mathbf{x} \in \overline{U_{i}} \backslash U_{i}$, then $\mathbf{x} \notin U_{o}$ because it is a limit point of $U_{i}$ and so $\mathbf{x} \in \Gamma$. It is similar with $U_{o}$. Thus $\Gamma=\overline{U_{i}} \backslash U_{i}$ and $\Gamma=\overline{U_{o}} \backslash U_{o}$. This could not happen if $\Gamma$ had an interior point. Such a point would be in $\Gamma$ but would fail to be in either $\partial U_{i}$ or $\partial U_{o}$.

When $p=2$, this theorem is called the Jordan curve theorem.
What if $\gamma$ maps $\bar{B}$ to $\mathbb{R}^{p}$ instead of just $S^{p-1}$ ? Obviously, one should be able to say a little more.

Corollary 23.5.7 Let $B$ be an open ball and let $\gamma: \bar{B} \rightarrow \mathbb{R}^{p}$ be one to one and continuous. Let $U_{i}, U_{o}$ be as in the above theorem, the bounded and unbounded components of $\gamma(\partial B)^{C}$. Then $U_{i}=\gamma(B)$.

Proof: By connectedness and the observation that $\gamma(B)$ contains no points of $C \equiv$ $\gamma(\partial B)$, it follows that $\gamma(B) \subseteq U_{i}$ or $U_{o}$. Suppose $\gamma(B) \subseteq U_{i}$. I want to show that $\gamma(B)$ is not a proper subset of $U_{i}$. If $\gamma(B)$ is a proper subset of $U_{i}$, then if $\mathbf{x} \in U_{i} \backslash \gamma(B)$, it follows also that $\mathbf{x} \in U_{i} \backslash \gamma(\bar{B})$ because $\mathbf{x} \notin C=\gamma(\partial B)$. Let $H$ be the component of $U_{i} \backslash \gamma(\bar{B})$ determined by $\mathbf{x}$. In particular $H$ and $U_{o}$ are separated since they are disjoint open sets. Now $\gamma(\bar{B})^{C}$ and $\bar{B}^{C}$ each have only one component. This is true for $\bar{B}^{C}$ and by the Jordan separation theorem, also true for $\gamma(\bar{B})^{C}$. However, $H$ is in $\gamma(\bar{B})^{C}$ as is $U_{o}$ and so $\gamma(\bar{B})^{C}$ has at least two components after all. If $\gamma(B) \subseteq U_{o}$ the argument works exactly the same. Thus either $\gamma(B)=U_{i}$ or $\gamma(B)=U_{o}$. The second alternative cannot take place because $\gamma(B)$ is bounded. Hence $\gamma(B)=U_{i}$.

Note that this essentially gives the invariance of domain theorem.

### 23.6 The Jordan Separation Theorem

What follows is the general Jordan separation theorem.
Lemma 23.6.1 Let $\Omega$ be a bounded open set in $\mathbb{R}^{p}, \mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$, and suppose $\left\{\Omega_{i}\right\}_{i=1}^{\infty}$ are disjoint open sets contained in $\Omega$ such that

$$
\mathbf{y} \notin \mathbf{f}\left(\bar{\Omega} \backslash \cup_{j=1}^{\infty} \Omega_{j}\right)
$$

Then

$$
d(\mathbf{f}, \Omega, \mathbf{y})=\sum_{j=1}^{\infty} d\left(\mathbf{f}, \Omega_{j}, \mathbf{y}\right)
$$

where the sum has all but finitely many terms equal to 0 .
Proof: By assumption, the compact set $\mathbf{f}^{-1}(\mathbf{y}) \equiv\{\mathbf{x} \in \bar{\Omega}: \mathbf{f}(\mathbf{x})=\mathbf{y}\}$ has empty intersection with

$$
\bar{\Omega} \backslash \cup_{j=1}^{\infty} \Omega_{j}
$$

and so this compact set is covered by finitely many of the $\Omega_{j}$, say $\left\{\Omega_{1}, \cdots, \Omega_{n-1}\right\}$ and

$$
\mathbf{y} \notin \mathbf{f}\left(\cup_{j=n}^{\infty} \Omega_{j}\right) .
$$

By Theorem 23.2.2 and letting $O=\cup_{j=n}^{\infty} \Omega_{j}$,

$$
d(\mathbf{f}, \Omega, \mathbf{y})=\sum_{j=1}^{n-1} d\left(\mathbf{f}, \Omega_{j}, \mathbf{y}\right)+d(\mathbf{f}, O, \mathbf{y})=\sum_{j=1}^{\infty} d\left(\mathbf{f}, \Omega_{j}, \mathbf{y}\right)
$$

because $d(\mathbf{f}, O, \mathbf{y})=0$ as is $d\left(\mathbf{f}, \Omega_{j}, \mathbf{y}\right)$ for every $j \geq n$.
To help remember some symbols, here is a short diagram. I have a little trouble remembering what is what when I read the proof.

| bounded components $\mathbb{R}^{p} \backslash C$ | bounded components $\mathbb{R}^{p} \backslash \mathbf{f}(C)$ |
| :---: | :---: |
| $\mathscr{K}$ | $\mathscr{L}$ |

For $K \in \mathscr{K}, K$ a bounded component of $\mathbb{R}^{p} \backslash C$,

| bounded components of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial K)$ |
| :---: |
| $\mathscr{H}$ |
| $\mathscr{L}_{H}$ sets of $\mathscr{L}$ contained in $H \in \mathscr{H}$ |
| $\mathscr{H}_{1}$ those sets of $\mathscr{H}$ which intersect a set of $\mathscr{L}$ |

Note that the sets of $\mathscr{H}$ will tend to be larger than the sets of $\mathscr{L}$. The following lemma relating to the above definitions is interesting.

Lemma 23.6.2 If a component $L$ of $\mathbb{R}^{p} \backslash \mathbf{f}(C)$ intersects a component $H$ of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial K), K$ a component of $\mathbb{R}^{p} \backslash C$, then $L \subseteq H$.

Proof: First note that by Lemma 23.5.1 for $K \in \mathscr{K}, \partial K \subseteq C$.
Next suppose $L \in \mathscr{L}$ and $L \cap H \neq \emptyset$ where $\mathscr{H}$ is as described above. Suppose $\mathbf{y} \in L \backslash H$ so $L$ is not contained in $H$. Since $\mathbf{y} \in L$, it follows that $\mathbf{y} \notin \mathbf{f}(C)$ and so $\mathbf{y} \notin \mathbf{f}(\partial K)$ either, by Lemma 23.5.1. It follows that $\mathbf{y} \in \tilde{H}$ for some other $\tilde{H}$ a component of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial K)$. Now $\mathbb{R}^{p} \backslash \mathbf{f}(\partial K) \supseteq \mathbb{R}^{p} \backslash \mathbf{f}(C)$ and so $\cup \mathscr{H} \supseteq L$ and so

$$
L=\cup\{L \cap H: H \in \mathscr{H}\}
$$

and these are disjoint open sets with two of them nonempty. Hence $L$ would not be connected which is a contradiction. Hence if $L \cap H \neq \emptyset$, then $L \subseteq H$.

The following is the Jordan separation theorem. It is based on a use of the product formula and splitting up the sets of $\mathscr{L}$ into $\mathscr{L}_{H}$ for various $H \in \mathscr{H}$, those in $\mathscr{L}_{H}$ being the ones which intersect $H$ thanks to the above lemma.

Theorem 23.6.3 (Jordan separation theorem) Let $\mathbf{f}$ be a homeomorphism of $C$ and $\mathbf{f}(C)$ where $C$ is a compact set in $\mathbb{R}^{p}$. Then $\mathbb{R}^{p} \backslash C$ and $\mathbb{R}^{p} \backslash \mathbf{f}(C)$ have the same number of connected components.

Proof: Denote by $\mathscr{K}$ the bounded components of $\mathbb{R}^{p} \backslash C$ and denote by $\mathscr{L}$, the bounded components of $\mathbb{R}^{p} \backslash \mathbf{f}(C)$. Also, using the Tietze extension theorem on components of a vector valued function, there exists $\overline{\mathbf{f}}$ an extension of $\mathbf{f}$ to all of $\mathbb{R}^{p}$ and let $\overline{\mathbf{f}^{-1}}$ be an extension of $\mathbf{f}^{-1}$ to all of $\mathbb{R}^{p}$. Pick $K \in \mathscr{K}$ and take $\mathbf{y} \in K$. Then $\partial K \subseteq C$ and so
$\mathbf{y} \notin \overline{\mathbf{f}^{-1}}(\overline{\mathbf{f}}(\partial K))$. Since $\overline{\mathbf{f}^{-1}} \circ \overline{\mathbf{f}}$ equals the identity $I$ on $\partial K$, it follows from the properties of the degree that

$$
1=d(I, K, \mathbf{y})=d\left(\overline{\mathbf{f}^{-1}} \circ \overline{\mathbf{f}}, K, \mathbf{y}\right)
$$

Recall that if two functions agree on the boundary, then they have the same degree. Let $\mathscr{H}$ denote the set of bounded components of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial K)$. Then

$$
\cup \mathscr{H}=\mathbb{R}^{p} \backslash \mathbf{f}(\partial K) \supseteq \mathbb{R}^{p} \backslash \mathbf{f}(C)
$$

Thus if $L \in \mathscr{L}$, then $L \subseteq \cup \mathscr{H}$ and so it must intersect some set $H$ of $\mathscr{H}$. By the above Lemma 23.6.2, $L$ is contained in this set of $\mathscr{H}$ so it is in $\mathscr{L}_{H}$.

By the product formula,

$$
\begin{equation*}
1=d\left(\overline{\mathbf{f}^{-1}} \circ \overline{\mathbf{f}}, K, \mathbf{y}\right)=\sum_{H \in \mathscr{H}} d(\overline{\mathbf{f}}, K, H) d\left(\overline{\mathbf{f}^{-1}}, H, \mathbf{y}\right) \tag{23.6.13}
\end{equation*}
$$

the sum being a finite sum. That is, there are finitely many $H$ involved in the sum, the other terms being zero, this by the general result in the product formula.

What about those sets of $\mathscr{H}$ which contain no set of $\mathscr{L}$ ? These sets also have empty intersection with all sets of $\mathscr{L}$ and empty intersection with the unbounded component(s) of $\mathbb{R}^{p} \backslash \mathbf{f}(C)$ by Lemma 23.6.2. Therefore, for $H$ one of these, $H \subseteq \mathbf{f}(C)$ because $H$ has no points of $\mathbb{R}^{p} \backslash \mathbf{f}(C)$ which equals

$$
\cup \mathscr{L} \cup\left\{\text { unbounded component(s) of } \mathbb{R}^{p} \backslash \mathbf{f}(C)\right\} .
$$

Therefore,

$$
d\left(\overline{\mathbf{f}^{-1}}, H, \mathbf{y}\right)=d\left(\mathbf{f}^{-1}, H, \mathbf{y}\right)=0
$$

because $\mathbf{y} \in K$ a bounded component of $\mathbb{R}^{p} \backslash C$, but for $\mathbf{u} \in H \subseteq \mathbf{f}(C), \mathbf{f}^{-1}(\mathbf{u}) \in C$ so $\mathbf{f}^{-1}(\mathbf{u}) \neq \mathbf{y}$ implying that $d\left(\mathbf{f}^{-1}, H, \mathbf{y}\right)=0$. Thus in 23.6.13, all such terms are zero. Then letting $\mathscr{H}_{1}$ be those sets of $\mathscr{H}$ which contain (intersect) some sets of $\mathscr{L}$, the above sum reduces to

$$
1=\sum_{H \in \mathscr{H}_{1}} d(\overline{\mathbf{f}}, K, H) d\left(\overline{\mathbf{f}^{-1}}, H, \mathbf{y}\right)
$$

Note also that for $H \in \mathscr{H}_{1}, \bar{H} \backslash \cup \mathscr{L}_{H}=\bar{H} \backslash \cup \mathscr{L}$ and it has no points of $\mathbb{R}^{p} \backslash \mathbf{f}(C)=\cup \mathscr{L}$ so $\bar{H} \backslash \cup \mathscr{L}_{H}$ is contained in $\mathbf{f}(C)$. Thus $\mathbf{y} \notin \overline{\mathbf{f}^{-1}}\left(\bar{H} \backslash \cup \mathscr{L}_{H}\right) \subseteq C$ because $\mathbf{y} \notin C$.

It follows from Lemma 23.6.1 which comes from Theorem 23.2.2, the part about having disjoint open sets in $\Omega$ and getting a sum of degrees over these being equal to $d(\mathbf{f}, \Omega, \mathbf{y})$ that

$$
\begin{aligned}
\sum_{H \in \mathscr{H}_{1}} d(\overline{\mathbf{f}}, K, H) d\left(\overline{\mathbf{f}^{-1}}, H, \mathbf{y}\right) & =\sum_{H \in \mathscr{H}_{1}} d(\overline{\mathbf{f}}, K, H) \sum_{L \in \mathscr{L}_{H}} d\left(\overline{\mathbf{f}^{-1}}, L, \mathbf{y}\right) \\
& =\sum_{H \in \mathscr{H}_{1}} \sum_{L \in \mathscr{\mathscr { L }}_{H}} d(\overline{\mathbf{f}}, K, H) d\left(\overline{\mathbf{f}^{-1}}, L, \mathbf{y}\right)
\end{aligned}
$$

where $\mathscr{L}_{H}$ are those sets of $\mathscr{L}$ contained in $H$.

Now $d(\overline{\mathbf{f}}, K, H)=d(\overline{\mathbf{f}}, K, L)$ where $L \in \mathscr{L}_{H}$. This is because $L$ is an open connected subset of $H$ and $\mathbf{z} \rightarrow d(\overline{\mathbf{f}}, K, \mathbf{z})$ is constant on $H$. Therefore,

$$
\sum_{H \in \mathscr{H}_{1}} \sum_{L \in \mathscr{L}_{H}} d(\overline{\mathbf{f}}, K, H) d\left(\overline{\mathbf{f}^{-1}}, L, \mathbf{y}\right)=\sum_{H \in \mathscr{H}_{1}} \sum_{L \in \mathscr{L}_{H}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, \mathbf{y}\right)
$$

As noted above, there are finitely many $H \in \mathscr{H}$ which are involved.

$$
\mathbb{R}^{p} \backslash \mathbf{f}(C) \subseteq \mathbb{R}^{p} \backslash \mathbf{f}(\partial K)
$$

and so every $L$ must be contained in some $H \in \mathscr{H}_{1}$. It follows that the above reduces to

$$
\sum_{L \in \mathscr{L}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, \mathbf{y}\right)
$$

Where this is a finite sum because all but finitely many terms are 0 .
Thus from 23.6.13,

$$
\begin{equation*}
1=\sum_{L \in \mathscr{L}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, \mathbf{y}\right)=\sum_{L \in \mathscr{L}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, K\right) \tag{23.6.14}
\end{equation*}
$$

Let $|\mathscr{K}|$ denote the number of components in $\mathscr{K}$ and similarly, $|\mathscr{L}|$ denotes the number of components in $\mathscr{L}$. Thus

$$
|\mathscr{K}|=\sum_{K \in \mathscr{K}} 1=\sum_{K \in \mathscr{K}} \sum_{L \in \mathscr{L}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, K\right)
$$

Similarly, the argument taken another direction yields

$$
|\mathscr{L}|=\sum_{L \in \mathscr{L}} 1=\sum_{L \in \mathscr{L}} \sum_{K \in \mathscr{K}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, K\right)
$$

If $|\mathscr{K}|<\infty$, then $\sum_{K \in \mathscr{K}} \overbrace{\sum_{L \in \mathscr{L}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, K\right)}^{1}<\infty$. The summation which equals 1 is a finite sum and so is the outside sum. Hence we can switch the order of summation and get

$$
|\mathscr{K}|=\sum_{L \in \mathscr{L}} \sum_{K \in \mathscr{K}} d(\overline{\mathbf{f}}, K, L) d\left(\overline{\mathbf{f}^{-1}}, L, K\right)=|\mathscr{L}|
$$

A similar argument applies if $|\mathscr{L}|<\infty$. Thus if one of these numbers $|\mathscr{K}|,|\mathscr{L}|$ is finite, so is the other and they are equal. This proves the theorem because if $p>1$ there is exactly one unbounded component to both $\mathbb{R}^{p} \backslash C$ and $\mathbb{R}^{p} \backslash \mathbf{f}(C)$ and if $p=1$ there are exactly two unbounded components.

As an application, here is a very interesting little result. It has to do with $d(\mathbf{f}, \Omega, \mathbf{f}(\mathbf{x}))$ in the case where $\mathbf{f}$ is one to one and $\Omega$ is connected. You might imagine this should equal 1 or -1 based on one dimensional analogies. Recall a one to one map defined on an interval is either increasing or decreasing. It either preserves or reverses orientation. It is similar in $n$ dimensions and it is a nice application of the Jordan separation theorem and the product formula.

Proposition 23.6.4 Let $\Omega$ be an open connected bounded set in $\mathbb{R}^{p}, p \geq 1$ such that $\mathbb{R}^{p} \backslash$ $\partial \Omega$ consists of two, three if $n=1$, connected components. Let $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$ be continuous and one to one. Then $\mathbf{f}(\Omega)$ is the bounded component of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$ and for $\mathbf{y} \in \mathbf{f}(\Omega)$, $d(\mathbf{f}, \Omega, \mathbf{y})$ either equals 1 or -1 .

Proof: First suppose $n \geq 2$. By the Jordan separation theorem, $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$ consists of two components, a bounded component $B$ and an unbounded component $U$. Using the Tietze extention theorem, there exists $\mathbf{g}$ defined on $\mathbb{R}^{p}$ such that $\mathbf{g}=\mathbf{f}^{-1}$ on $\mathbf{f}(\bar{\Omega})$. Thus on $\partial \Omega, \mathbf{g} \circ \mathbf{f}=\mathrm{id}$. It follows from this and the product formula that

$$
\begin{aligned}
1 & =d(\mathrm{id}, \Omega, \mathbf{g}(\mathbf{y}))=d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{g}(\mathbf{y})) \\
& =d(\mathbf{g}, B, \mathbf{g}(\mathbf{y})) d(\mathbf{f}, \Omega, B)+d(\mathbf{f}, \Omega, U) d(\mathbf{g}, U, \mathbf{g}(\mathbf{y})) \\
& =d(\mathbf{g}, B, \mathbf{g}(\mathbf{y})) d(\mathbf{f}, \Omega, B)
\end{aligned}
$$

The reduction happens because $d(\mathbf{f}, \Omega, U)=0$ as explained above. Since $U$ is unbounded, there are points in $U$ which cannot be in the compact set $\mathbf{f}(\bar{\Omega})$. For such, the degree is 0 but the degree is constant on $U$, one of the components of $\mathbf{f}(\partial \Omega)$. Therefore, $d(\mathbf{f}, \Omega, B) \neq 0$ and so for every $\mathbf{z} \in B$, it follows $\mathbf{z} \in \mathbf{f}(\Omega)$. Thus $B \subseteq \mathbf{f}(\Omega)$. On the other hand, $\mathbf{f}(\Omega)$ cannot have points in both $U$ and $B$ because it is a connected set. Therefore $\mathbf{f}(\Omega) \subseteq B$ and this shows $B=\mathbf{f}(\Omega)$. Thus $d(\mathbf{f}, \Omega, B)=d(\mathbf{f}, \Omega, \mathbf{y})$ for each $\mathbf{y} \in B$ and the above formula shows this equals either 1 or -1 because the degree is an integer. In the case where $n=1$, the argument is similar but here you have 3 components in $\mathbb{R}^{1} \backslash \mathbf{f}(\partial \Omega)$ so there are more terms in the above sum although two of them give 0 .

Here is another nice application of the Jordan separation theorem to the Jordan curve theorem and generalizations to higher dimensions.

### 23.7 Uniqueness of the Degree

The degree exists and has the above properties which allow one to prove amazing theorems. This is plenty to justify it. However, one might wonder whether, if we have a degree function with these properties, it will be the same? The answer is yes. It is likely possible to give a shorter list of desired properties however. Nevertheless, we want all these properties. First are some simple applications of the product formula which is one of the items which it is assumed satisfied by the degree.
Lemma 23.7.1 Let $\mathbf{h}: \mathbb{R}^{p} \rightarrow \mathbb{R}^{p}$ be a homeomorphism. Then

$$
1=d(\mathbf{h}, \Omega, \mathbf{h}(\mathbf{y})) d\left(\mathbf{h}^{-1}, \mathbf{h}(\Omega), \mathbf{y}\right)
$$

whenever $\mathbf{y} \notin \partial \Omega$ for $\Omega$ a bounded open set. Similarly,

$$
1=d\left(\mathbf{h}^{-1}, \Omega, \mathbf{h}^{-1}(\mathbf{y})\right) d\left(\mathbf{h}, \mathbf{h}^{-1}(\Omega), \mathbf{y}\right)
$$

Thus both terms in the factor equal either 1 or -1 .
Proof: It is known that $\mathbf{y} \notin \partial \Omega$. Let $\mathscr{L}$ be the components of $\mathbb{R}^{p} \backslash \mathbf{h}(\partial \Omega)$. Thus $\mathbf{h}(\mathbf{y}) \notin$ $\mathbf{h}(\partial \Omega)$. The product formula gives

$$
1=d\left(\mathbf{h}^{-1} \circ \mathbf{h}, \Omega, \mathbf{y}\right)=\sum_{L \in \mathscr{L}} d(\mathbf{h}, \Omega, L) d\left(\mathbf{h}^{-1}, L, \mathbf{y}\right)
$$

$d\left(\mathbf{h}^{-1}, L, \mathbf{y}\right)$ might be nonzero if $\mathbf{y} \in \mathbf{h}^{-1}(L)$. But, since $\mathbf{h}^{-1}$ is one to one, if $\mathbf{y} \in \mathbf{h}^{-1}(L)$, then $\mathbf{y} \notin \mathbf{h}^{-1}(\tilde{L})$ for any other $\tilde{L} \in \mathscr{L}$. Thus there is only one term in the above sum.

$$
\begin{gathered}
1=d(\mathbf{h}, \Omega, L) d\left(\mathbf{h}^{-1}, L, \mathbf{y}\right), \mathbf{y} \in \mathbf{h}^{-1}(L) \\
1=d(\mathbf{h}, \Omega, \mathbf{h}(\mathbf{y})) d\left(\mathbf{h}^{-1}, \mathbf{h}(\Omega), \mathbf{y}\right)
\end{gathered}
$$

Since the degree is an integer, both factors are either 1 or -1 .
The following assumption is convenient and seems like something which should be true. It says just a little more than $d(\mathrm{id}, \Omega, \mathbf{y})=1$ for $\mathbf{y} \in \Omega$. Actually, you could prove it by adding in a succession of $\frac{\mathbf{z}}{n}$ to id for $n$ large till you get to $\mathbf{h}$ in the first argument and $\mathbf{h}_{\mathbf{z}}(\mathbf{y})$ in the last and use the property that the degree is continuous in the first and last places. However, this is such a reasonable thing to assume, that it seems like we might as well have assumed it instead of $d(\mathrm{id}, \Omega, \mathbf{y})=1$ for $\mathbf{y} \in \Omega$.

Assumption 23.7.2 If $\mathbf{h}_{\mathbf{z}}(\mathbf{x})=\mathbf{x}+\mathbf{z}$, then for $\mathbf{y} \notin \partial \Omega, \mathbf{y} \in \Omega$,

$$
d\left(\mathbf{h}_{\mathbf{z}}, \Omega, \mathbf{h}_{\mathbf{z}}(\mathbf{y})\right)=d(\mathrm{id}, \Omega, \mathbf{y})=1
$$

That is, $d(\cdot+\mathbf{z}, \Omega, \mathbf{z}+\mathbf{y})=1$. From the above lemma, $d\left(\mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{y}\right)=1$ also.
Now let $\mathbf{h}_{\mathbf{z}}(\mathbf{x}) \equiv \mathbf{x}+\mathbf{z}$. Let $\mathbf{y} \notin \mathbf{g}(\partial \Omega)$ and consider

$$
d\left(\mathbf{h}_{-\mathbf{y}} \circ \mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{h}_{-\mathbf{y}}(\mathbf{y})\right)=d\left(\mathbf{h}_{-\mathbf{y}} \circ \mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{0}\right)
$$

Let $\mathscr{L}$ be the components of $\mathbb{R}^{p} \backslash \mathbf{g} \circ \mathbf{h}_{\mathbf{z}}\left(\partial\left(\mathbf{h}_{-\mathbf{z}}(\Omega)\right)\right)=\mathbb{R}^{p} \backslash \mathbf{g}(\partial \Omega)$. Then the product rule gives $d\left(\mathbf{h}_{-\mathbf{y}} \circ \mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{0}\right)=$

$$
\sum_{L \in \mathscr{L}} d\left(\mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), L\right) d\left(\mathbf{h}_{-y}, L, \mathbf{0}\right)
$$

Now $\mathbf{h}_{-\mathbf{y}}$ is one to one and so if $\mathbf{0} \in \mathbf{h}_{-\mathbf{y}}(L)$, then this is true for only that single $L$ and so there is only one term in the sum. For a single $L$ where $\mathbf{0} \in \mathbf{h}_{-\mathbf{y}}(L)$ so $\mathbf{y} \in L$,

$$
d\left(\mathbf{h}_{-\mathbf{y}} \circ \mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{h}_{-\mathbf{y}}(\mathbf{y})\right)=d\left(\mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), L\right) d\left(\mathbf{h}_{-y}, L, \mathbf{h}_{-\mathbf{y}}(\mathbf{y})\right)
$$

Now from the assumption, this equals $d\left(\mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), L\right)=d\left(\mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{y}\right)$. Now we use the product rule on this. Letting $\mathscr{K}$ be the bounded components of

$$
\begin{gathered}
\mathbb{R}^{p} \backslash \mathbf{h}_{\mathbf{z}}\left(\partial \mathbf{h}_{-\mathbf{z}}(\Omega)\right)=\mathbb{R}^{p} \backslash \partial \Omega \\
d\left(\mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{y}\right)=\sum_{K \in \mathscr{K}} d\left(\mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), K\right) d(\mathbf{g}, K, \mathbf{y})
\end{gathered}
$$

The points of $K$ are not in $\partial \Omega$ and so, from the assumption, $d\left(\mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), K\right)=1$. Thus this whole thing reduces to $\sum_{K \in \mathscr{K}} d(\mathbf{g}, K, \mathbf{y})=d(\mathbf{g}, \Omega, \mathbf{y})$. This shows the following lemma.

Lemma 23.7.3 The following formula holds

$$
d\left(\mathbf{h}_{-\mathbf{y}} \circ \mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), \mathbf{h}_{-\mathbf{y}}(\mathbf{y})\right)=d\left(\mathbf{g} \circ \mathbf{h}_{\mathbf{z}}, \mathbf{h}_{-\mathbf{z}}(\Omega), L\right)=d(\mathbf{g}, \Omega, \mathbf{y})
$$

In other words, $d(\mathbf{g}, \Omega, \mathbf{y})=d(\mathbf{g}(\cdot+\mathbf{z}), \Omega-\mathbf{z}, \mathbf{y})=d(\mathbf{g}(\cdot+\mathbf{z})-\mathbf{y}, \Omega-\mathbf{z}, \mathbf{0})$.

Theorem 23.7.4 You have a function $d$ which has integer values $d(\mathbf{g}, \Omega, \mathbf{y}) \in \mathbb{Z}$ whenever $\mathbf{y} \notin \mathbf{g}(\partial \Omega)$ for $\mathbf{g} \in C\left(\bar{\Omega} ; \mathbb{R}^{p}\right)$. Assume it satisfies the following properties which the one above satisfies.

1. (homotopy invariance) If

$$
\mathbf{h} \in C\left(\bar{\Omega} \times[0,1], \mathbb{R}^{p}\right)
$$

and $\mathbf{y}(t) \notin \mathbf{h}(\partial \Omega, t)$ for all $t \in[0,1]$ where $\mathbf{y}$ is continuous, then

$$
t \rightarrow d(\mathbf{h}(\cdot, t), \Omega, \mathbf{y}(t))
$$

is constant for $t \in[0,1]$.
2. If $\Omega \supseteq \Omega_{1} \cup \Omega_{2}$ where $\Omega_{1} \cap \Omega_{2}=\emptyset$, for $\Omega_{i}$ an open set, then if

$$
\mathbf{y} \notin \mathbf{f}\left(\bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)\right)
$$

then

$$
d\left(\mathbf{f}, \Omega_{1}, \mathbf{y}\right)+d\left(\mathbf{f}, \Omega_{2}, \mathbf{y}\right)=d(\mathbf{f}, \Omega, \mathbf{y})
$$

3. $d(\mathrm{id}, \Omega, \mathbf{y})=1$ if $\mathbf{y} \in \Omega$.
4. $d(\mathbf{f}, \Omega, \cdot)$ is continuous and constant on every connected component of $\mathbb{R}^{p} \backslash \mathbf{f}(\partial \Omega)$.
5. If $\mathbf{y} \notin \mathbf{f}(\partial \Omega)$, and if $d(\mathbf{f}, \Omega, \mathbf{y}) \neq 0$, then there exists $\mathbf{x} \in \Omega$ such that $\mathbf{f}(\mathbf{x})=\mathbf{y}$.
6. Product formula, Assumption 23.7.2.

Then $d$ is the degree which was defined above. Thus, in a sense, the degree is unique if we want it to do these things.

Proof: First note that $\mathbf{h} \rightarrow d(\mathbf{h}, \Omega, \mathbf{y})$ is continuous on $C\left(\bar{\Omega}, \mathbb{R}^{p}\right)$. Say $\|\mathbf{g}-\mathbf{h}\|_{\infty}<$ $\operatorname{dist}(\mathbf{h}(\partial \Omega), \mathbf{y})$. Then if $\mathbf{x} \in \partial \Omega, t \in[0,1]$,

$$
\begin{aligned}
\|\mathbf{g}(\mathbf{x})+t(\mathbf{h}-\mathbf{g})(\mathbf{x})-\mathbf{y}\| & =\|\mathbf{g}(\mathbf{x})-\mathbf{h}(\mathbf{x})+t(\mathbf{h}-\mathbf{g})(\mathbf{x})+\mathbf{h}(\mathbf{x})-\mathbf{y}\| \\
& \geq \operatorname{dist}(\mathbf{h}(\partial \Omega), \mathbf{y})-(1-t)\|\mathbf{g}-\mathbf{h}\|_{\infty}>0
\end{aligned}
$$

By homotopy invariance, $d(\mathbf{g}, \Omega, \mathbf{y})=d(\mathbf{h}, \Omega, \mathbf{y})$. By the approximation lemma, if we can identify the degree for $\mathbf{g} \in C^{\infty}\left(\bar{\Omega}, \mathbb{R}^{p}\right)$ with $\mathbf{y}$ a regular value, $\mathbf{y} \notin \mathbf{g}(\partial \Omega)$ then we know what the degree is. Say $\mathbf{g}^{-1}(\mathbf{y})=\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\}$. Using the inverse function theorem there are balls $B_{i r}$ containing $\mathbf{x}_{i}$ such that none of these balls of radius $r$ intersect and $\mathbf{g}$ is one to one on each. Then from the theorem on the fundamental properties assumed above,

$$
\begin{equation*}
d(\mathbf{g}, \Omega, \mathbf{y})=\sum_{i=1}^{n} d\left(\mathbf{g}, B_{i r}, \mathbf{y}\right) \tag{23.7.15}
\end{equation*}
$$

and by assumption, this is

$$
\sum_{i=1}^{n} d\left(\mathbf{g}\left(\cdot+\mathbf{x}_{i}\right), B(\mathbf{0}, r), \mathbf{y}\right)=\sum_{i=1}^{n} d\left(\mathbf{g}\left(\cdot+\mathbf{x}_{i}\right)-\mathbf{y}, B(\mathbf{0}, r), \mathbf{0}\right)=\sum_{i=1}^{n} d(\mathbf{h}, B(\mathbf{0}, r), \mathbf{0})
$$

where $\mathbf{h}(\mathbf{x}) \equiv \mathbf{g}\left(\mathbf{x}+\mathbf{x}_{i}\right)-\mathbf{y}$. There is no restriction on the size of $r$. Consider one of the terms in the sum. $d(\mathbf{h}, B(\mathbf{0}, r), \mathbf{y})$. Note $D \mathbf{h}(\mathbf{0})=D \mathbf{g}\left(\mathbf{x}_{i}\right)$.

$$
\begin{equation*}
\mathbf{h}(\mathbf{x})=D \mathbf{h}(\mathbf{0}) \mathbf{x}+\mathbf{o}(\mathbf{x}) \tag{23.7.16}
\end{equation*}
$$

Now let

$$
L\left(\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}\right) \equiv\left(\begin{array}{c}
\nabla h_{1}\left(\mathbf{z}_{1}\right) \\
\vdots \\
\nabla h_{p}\left(\mathbf{z}_{p}\right)
\end{array}\right)
$$

By the mean value theorem applied to the components of $\mathbf{h}$, if $\mathbf{x} \neq \mathbf{0},\|\mathbf{x}\| \leq r$, there exist $\mathbf{z}_{1}, \ldots, \mathbf{z}_{p} \in \overline{B(\mathbf{0}, r)} \times \cdots \times \overline{B(\mathbf{0}, r)}$

$$
\begin{equation*}
\frac{\|\mathbf{h}(\mathbf{x})-\mathbf{h}(\mathbf{0})\|}{\|\mathbf{x}\|}=\frac{\|\mathbf{h}(\mathbf{x})-\mathbf{0}\|}{\|\mathbf{x}\|}=\frac{\left\|L\left(\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}\right) \mathbf{x}\right\|}{\|\mathbf{x}\|}=\left\|L\left(\mathbf{z}_{1}, \ldots, \mathbf{z}_{n}\right)\left(\frac{\mathbf{x}}{\|\mathbf{x}\|}\right)\right\| \tag{23.7.17}
\end{equation*}
$$

Since $D \mathbf{h}(\mathbf{0})^{-1}$ exists, we can choose $r$ small enough that for all $\left(\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}\right) \in \overline{B(\mathbf{0}, r)} \times$ $\cdots \times \overline{B(\mathbf{0}, r)}$

$$
\operatorname{det}\left(L\left(\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}\right)\right) \neq 0
$$

Hence, for such sufficiently small $r$, there is $\delta>0$ such that for $S$ the unit sphere,

$$
\begin{gathered}
\{\mathbf{x}:\|\mathbf{x}\|=1\} \\
\inf \left\{\left\|L\left(\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}\right) \mathbf{x}\right\|:\left(\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}, \mathbf{x}\right) \in \overline{B(\mathbf{0}, r)} \times \cdots \times \overline{B(\mathbf{0}, r)} \times S\right\}=\delta>0
\end{gathered}
$$

Then it follows from 23.7 .17 that if $\|\mathbf{x}\| \leq r, \frac{\|\mathbf{h}(\mathbf{x})\|}{\|\mathbf{x}\|} \geq \delta$ so $\|\mathbf{h}(\mathbf{x})-\mathbf{0}\| \geq \delta\|\mathbf{x}\|$. Letting $\|\mathbf{x}\|=r$ so $\mathbf{x} \in \mathbf{h}(\partial B(\mathbf{0}, r))$,

$$
\operatorname{dist}(\mathbf{h}(\partial B(\mathbf{0}, r)), \mathbf{0}) \geq \delta r
$$

Now pick $\varepsilon<\delta$. Making $r$ still smaller if necessary, it follows from 23.7.16 that if $\|\mathbf{x}\| \leq r$,

$$
\|\mathbf{h}(\mathbf{x})-D \mathbf{h}(\mathbf{0}) \mathbf{x}\| \leq \varepsilon\|\mathbf{x}\|<\delta r \leq \operatorname{dist}(\mathbf{h}(\partial B(\mathbf{0}, r)), \mathbf{0})
$$

Thus,

$$
\|\mathbf{h}-D \mathbf{h}(\mathbf{0})(\cdot)\|_{\infty, \overline{B(\mathbf{0}, r)}}<\operatorname{dist}(\mathbf{h}(\partial B(\mathbf{0}, r)), \mathbf{0})
$$

and so $d(\mathbf{h}, B(\mathbf{0}, r), \mathbf{0})=d(D \mathbf{h}(\mathbf{0})(\cdot), B(\mathbf{0}, r), \mathbf{0})$.
Say $A=D \mathbf{h}(\mathbf{0})$ an invertible matrix. Then if $U$ is any open set containing $\mathbf{0}$, it follows from the properties of the degree that $d(A, U, \mathbf{0})=d(A, B(\mathbf{0}, r), \mathbf{0})$ whenever $r$ is small enough. By the product formula and 3. above,

$$
\left.\begin{array}{rl} 
& 1=d(I, B(\mathbf{0}, r), \mathbf{0})=d\left(A^{-1} A, B(\mathbf{0}, r), \mathbf{0}\right) \\
= & d(A, B(\mathbf{0}, r), A B(\mathbf{0}, r)) d\left(A^{-1}, A B(\mathbf{0}, r), \mathbf{0}\right) \\
& +d(A, B(\mathbf{0}, r), \overline{A B(\mathbf{0}, r)} \\
C
\end{array}\right) d\left(A^{-1}, \overline{A B(\mathbf{0}, r)}^{c}, \mathbf{0}\right)
$$

From 5. above, this reduces to

$$
1=d(A, B(\mathbf{0}, r), A B(\mathbf{0}, r)) d\left(A^{-1}, A B(\mathbf{0}, r), \mathbf{0}\right)
$$

Thus, since the degree is an integer, either both $d(A, B(\mathbf{0}, r), \mathbf{0}), d\left(A^{-1}, A B(\mathbf{0}, r), \mathbf{0}\right)$ are 1 or they are both -1 . This would hold if when $A$ is invertible,

$$
d(A, B(\mathbf{0}, r), \mathbf{0})=\operatorname{sgn}(\operatorname{det}(A))=\operatorname{sgn}\left(\operatorname{det}\left(A^{-1}\right)\right)
$$

It would also hold if $d(A, B(\mathbf{0}, r), \mathbf{0})=-\operatorname{sgn}(\operatorname{det}(A))$. However, the latter of the two alternatives is not the one wanted because, doing something like the above,

$$
\begin{aligned}
d\left(A^{2}, B(\mathbf{0}, r), \mathbf{0}\right) & =d(A, B(\mathbf{0}, r), A B(\mathbf{0}, r)) d(A, A B(\mathbf{0}, r), \mathbf{0}) \\
& =d(A, B(\mathbf{0}, r), \mathbf{0}) d(A, A B(\mathbf{0}, r), \mathbf{0})
\end{aligned}
$$

If you had for a definition $d(A, B(\mathbf{0}, r), \mathbf{0})=-\operatorname{sgn} \operatorname{det}(A)$, then you would have

$$
-\operatorname{sgn} \operatorname{det}\left(A^{2}\right)=-1=(-\operatorname{sgn} \operatorname{det}(A))^{2}=1
$$

Hence the only reasonable definition is to let $d(A, B(\mathbf{0}, r), \mathbf{0})=\operatorname{sgn}(\operatorname{det}(A))$. It follows from 23.7.15 that $d(\mathbf{g}, \Omega, \mathbf{y})=\sum_{i=1}^{n} d\left(\mathbf{g}, B_{i r}, \mathbf{y}\right)=\sum_{i=1}^{n} \operatorname{sgn}\left(\operatorname{det}\left(D \mathbf{g}\left(\mathbf{x}_{i}\right)\right)\right)$. Thus, if the above conditions hold, then in whatever manner you construct the degree, it amounts to the definition given above in this chapter in the sense that for $\mathbf{y}$ a regular point of a smooth function, you get the definition of the chapter.

### 23.8 A Function With Values In Smaller Dimensions

Recall that we have the degree defined $d(f, \Omega, y)$ for continuous functions on $\bar{\Omega}$ and $y \notin$ $f(\partial \Omega)$. It had properties as follows.

1. $d(\mathrm{id}, \Omega, \mathbf{y})=1$ if $\mathbf{y} \in \Omega$.
2. If $\Omega_{i} \subseteq \Omega, \Omega_{i}$ open, and $\Omega_{1} \cap \Omega_{2}=\emptyset$ and if $\mathbf{y} \notin \mathbf{f}\left(\bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)\right)$, then $d\left(\mathbf{f}, \Omega_{1}, \mathbf{y}\right)+$ $d\left(\mathbf{f}, \Omega_{2}, \mathbf{y}\right)=d(\mathbf{f}, \Omega, \mathbf{y})$.
3. If $\mathbf{y} \notin \mathbf{f}\left(\bar{\Omega} \backslash \Omega_{1}\right)$ and $\Omega_{1}$ is an open subset of $\Omega$, then

$$
d(\mathbf{f}, \Omega, \mathbf{y})=d\left(\mathbf{f}, \Omega_{1}, \mathbf{y}\right)
$$

4. For $\mathbf{y} \in \mathbb{R}^{n} \backslash \mathbf{f}(\partial \Omega)$, if $d(\mathbf{f}, \Omega, \mathbf{y}) \neq 0$ then $\mathbf{f}^{-1}(\mathbf{y}) \cap \Omega \neq \emptyset$.
5. If $t \rightarrow \mathbf{y}(t)$ is continuous $\mathbf{h}: \bar{\Omega} \times[0,1] \rightarrow \mathbb{R}^{n}$ is continuous and if $\mathbf{y}(t) \notin \mathbf{h}(\partial \Omega, t)$ for all $t$, then $t \rightarrow d(\mathbf{h}(\cdot, t), \Omega, \mathbf{y}(t))$ is constant.
6. $d(\cdot, \Omega, \mathbf{y})$ is defined and constant on

$$
\left\{\mathbf{g} \in C\left(\bar{\Omega} ; \mathbb{R}^{n}\right):\|\mathbf{g}-\mathbf{f}\|_{\infty}<r\right\}
$$

where $r=\operatorname{dist}(\mathbf{y}, \mathbf{f}(\partial \Omega))$.
7. $d(\mathbf{f}, \Omega, \cdot)$ is constant on every connected component of $\mathbb{R}^{n} \backslash \mathbf{f}(\partial \Omega)$.
8. $d(\mathbf{g}, \Omega, \mathbf{y})=d(\mathbf{f}, \Omega, \mathbf{y})$ if $\left.\mathbf{g}\right|_{\partial \Omega}=\left.\mathbf{f}\right|_{\partial \Omega}$.

Theorem 23.8.1 Let $\Omega$ be a bounded open set in $\mathbb{R}^{n}$ and let $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}_{m}^{n}\right)$ where $\mathbb{R}_{m}^{n}=$ $\left\{\mathbf{x} \in \mathbb{R}^{n}: x_{k}=0\right.$ for $\left.k>m\right\}$. Thus $\mathbf{x}$ concludes with a column of $n-m$ zeros. Let $\mathbf{y} \in \mathbb{R}_{m}^{n} \backslash$ $(\mathrm{id}-\mathbf{f})(\partial \Omega)$. Then $d(\mathrm{id}-\mathbf{f}, \Omega, \mathbf{y})=d\left(\left.(\mathrm{id}-\mathbf{f})\right|_{\Omega \cap \mathbb{R}_{m}^{n}}, \Omega \cap \mathbb{R}_{m}^{n}, \mathbf{y}\right)$.

Proof: To save space, let $\mathbf{g}=\mathrm{id}-\mathbf{f}$. Then there is no loss of generality in assuming at the outset that $\mathbf{y}$ is a regular value for $\mathbf{g}$. Indeed, everything above was reduced to this case. Then for $\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})$ and letting $\mathbf{x}_{m}$ be the first $m$ variables for $\mathbf{x}$,

$$
D \mathbf{g}(\mathbf{x})=\left(\begin{array}{cc}
D_{\mathbf{x}_{m}} \mathbf{g}(\mathbf{x}) & * \\
0 & I_{n-m}
\end{array}\right)
$$

Then it follows that

$$
\begin{aligned}
0 & \neq \operatorname{det}(D \mathbf{g}(\mathbf{x}))=\operatorname{det}\left(\begin{array}{cc}
D_{\mathbf{x}_{m}} \mathbf{g}(\mathbf{x}) & * \\
0 & I_{n-m}
\end{array}\right) \\
& =\operatorname{det}\left(\begin{array}{cc}
D_{\mathbf{x}_{m}} \mathbf{g}(\mathbf{x}) & 0 \\
0 & I_{n-m}
\end{array}\right)=\operatorname{det}\left(D_{\mathbf{x}_{m}} \mathbf{g}(\mathbf{x})\right)
\end{aligned}
$$

This last is just the determinant of the derivative of the function which results from restricting $\mathbf{g}$ to the first $m$ variables. Now $\mathbf{y} \in \mathbb{R}_{m}^{n}$ and $\mathbf{f}$ also is given to have values in $\mathbb{R}_{m}^{n}$ so if $\mathbf{g}(\mathbf{x})=\mathbf{y}$, then you have $\mathbf{x}-\mathbf{f}(\mathbf{x})=\mathbf{y}$ which requires $\mathbf{x} \in \mathbb{R}_{m}^{n}$ also. Therefore, $\mathbf{g}^{-1}(\mathbf{y})$ consists of points in $\mathbb{R}_{m}^{n}$ only. Thus, $\mathbf{y}$ is also a regular value of the function which results from restricting $\mathbf{g}$ to $\overline{\mathbb{R}_{m}^{n} \cap \Omega}$.

$$
\begin{gathered}
d(\mathrm{id}-\mathbf{f}, \Omega, \mathbf{y})=d(\mathbf{g}, \Omega, \mathbf{y}) \\
=\sum_{\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})} \operatorname{sign}(\operatorname{det}(D \mathbf{g}(\mathbf{x}))) \\
=\sum_{\mathbf{x} \in \mathbf{g}^{-1}(\mathbf{y})} \operatorname{sign}\left(\operatorname{det}\left(D_{\mathbf{x}_{m}} \mathbf{g}(\mathbf{x})\right)\right) \equiv d\left(\left.(\mathrm{id}-\mathbf{f})\right|_{\Omega \cap \mathbb{R}_{m}^{n}}, \Omega \cap \mathbb{R}_{m}^{n}, \mathbf{y}\right)
\end{gathered}
$$

Recall that for $\mathbf{g} \in C^{2}\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$,

$$
d(\mathbf{g}, \Omega, \mathbf{y}) \equiv \lim _{\varepsilon \rightarrow 0} \int_{\Omega} \phi_{\varepsilon}(\mathbf{g}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{g}(\mathbf{x}) d x
$$

In fact, it can be shown that the degree is unique based on its Properties, $1,2,5$ above. It involves reducing to linear maps and then some complicated arguments involving linear algebra. It is done in [38]. Here we will be a little less ambitious. The following lemma will be useful when extending the degree to finite dimensional normed linear spaces and from there to Banach spaces. It is motivated by the following diagram.

$$
\begin{array}{lll}
\theta^{-1}(y) & \stackrel{\theta^{-1}}{\leftarrow} & y \\
\uparrow \theta^{-1} \circ g \circ \theta & & \uparrow g \\
\theta^{-1}(\Omega) & \xrightarrow{\theta} & \Omega
\end{array}
$$

Lemma 23.8.2 Let $\mathbf{y} \notin \mathbf{g}(\partial \Omega)$ and let $\theta$ be an isomorphism of $\mathbb{R}^{n}$. That is, $\theta$ is one to one onto and linear. Then

$$
d\left(\theta^{-1} \circ \mathbf{g} \circ \theta, \theta^{-1}(\Omega), \theta^{-1} \mathbf{y}\right)=d(\mathbf{g}, \Omega, \mathbf{y})
$$

Proof: It suffices to consider $\mathbf{g} \in C^{2}\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$ for which $\mathbf{y}$ is a regular value because you can get such a $\hat{\mathbf{g}}$ with $\|\hat{\mathbf{g}}-\mathbf{g}\|_{\infty}<\delta$ where

$$
B(\mathbf{y}, 2 \delta) \cap \mathbf{g}(\partial \Omega)=\emptyset
$$

Thus $B(\mathbf{y}, \delta) \cap \hat{\mathbf{g}}(\partial \Omega)=\emptyset$ and so $d(\mathbf{g}, \Omega, \mathbf{y})=d(\hat{\mathbf{g}}, \Omega, \mathbf{y})$. One can assume similarly that $\|\hat{\mathbf{g}}-\mathbf{g}\|_{\infty}$ is sufficiently small that

$$
d\left(\theta^{-1} \mathbf{g} \circ \theta, \theta^{-1}(\Omega), \theta^{-1} \mathbf{y}\right)=d\left(\theta^{-1} \hat{\mathbf{g}} \circ \theta, \theta^{-1}(\Omega), \theta^{-1} \mathbf{y}\right)
$$

because both $\theta$ and $\theta^{-1}$ are continuous. Thus it suffices to consider at the outset $\mathbf{g} \in$ $C^{2}\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$. Then from the definition of degree for $C^{2}$ maps,

$$
\begin{aligned}
& d\left(\theta^{-1} \circ \mathbf{g} \circ \theta, \theta^{-1}(\Omega), \theta^{-1} \mathbf{y}\right) \\
= & \lim _{\varepsilon \rightarrow 0} \int_{\theta^{-1} \Omega} \phi_{\varepsilon}\left(\left(\theta^{-1} \circ \mathbf{g} \circ \theta\right)(\mathbf{z})-\theta^{-1} \mathbf{y}\right) \operatorname{det} D\left(\theta^{-1} \circ \mathbf{g} \circ \theta\right)(\mathbf{z}) d z
\end{aligned}
$$

Now $D\left(\theta^{-1} \circ \mathbf{g} \circ \theta\right)(\mathbf{z})=\theta^{-1} D(\mathbf{g} \circ \theta)(\mathbf{z})=\theta^{-1} D \mathbf{g}(\theta(\mathbf{z})) \theta \mathbf{z}$. Changing the variables $\mathbf{x}=\theta \mathbf{z}, \mathbf{z}=\theta^{-1} \mathbf{x}$, this last integral equals

$$
\begin{aligned}
& \int_{\Omega} \phi_{\varepsilon}\left(\left(\theta^{-1} \mathbf{g} \circ \theta\right)\left(\theta^{-1}(\mathbf{x})\right)-\theta^{-1} \mathbf{y}\right) \operatorname{det} D \mathbf{g}(\mathbf{x})|\operatorname{det} \theta|\left|\operatorname{det} \theta^{-1}\right|^{2} d x \\
= & \int_{\Omega} \phi_{\varepsilon}\left(\theta^{-1} \mathbf{g}(\mathbf{x})-\theta^{-1} \mathbf{y}\right)\left|\operatorname{det} \theta^{-1}\right| \operatorname{det} D \mathbf{g}(\mathbf{x}) d x
\end{aligned}
$$

Recall that $\phi_{\varepsilon}$ is a mollifier which is nonzero only in $B(\mathbf{0}, \varepsilon)$. Now

$$
\mathbf{g}^{-1}(\mathbf{y})=\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{m}\right\}=\left(\theta^{-1} \mathbf{g}\right)^{-1}\left(\theta^{-1} \mathbf{y}\right)
$$

and so $\mathbf{g}\left(\mathbf{x}_{i}\right)=\mathbf{y}$ and $\theta^{-1} \mathbf{g}\left(\mathbf{x}_{i}\right)=\theta^{-1} \mathbf{y}$. By the inverse function theorem, there exist disjoint open sets $U_{i}$ with $\mathbf{x}_{i} \in U_{i}$, such that $\theta^{-1} \mathbf{g}$ is one to one on $U_{i}$ with $\operatorname{det}\left(D\left(\theta^{-1} \mathbf{g}\right)(\mathbf{x})\right)=$ $\operatorname{det}\left(\theta^{-1}\right) \operatorname{det} D \mathbf{g}(\mathbf{x})$ having constant sign on $U_{i}$ and $\theta^{-1} \mathbf{g}\left(U_{i}\right)$ is an open set containing $\theta^{-1} \mathbf{y}$. Then let $\varepsilon$ be small enough that $B\left(\theta^{-1} \mathbf{y}, \varepsilon\right) \subseteq \cap_{i=1}^{m} \theta^{-1} \mathbf{g}\left(U_{i}\right)$ and let

$$
V_{i} \equiv\left(\theta^{-1} \mathbf{g}\right)^{-1}\left(B\left(\theta^{-1} \mathbf{y}, \varepsilon\right)\right) \cap U_{i}
$$

Thus for small $\varepsilon$, the $V_{i}$ are disjoint open sets in $\Omega$ and

$$
\begin{aligned}
& \int_{\Omega} \phi_{\varepsilon}\left(\theta^{-1} \mathbf{g}(\mathbf{x})-\theta^{-1} \mathbf{y}\right) \operatorname{det} D \mathbf{g}(\mathbf{x})\left|\operatorname{det} \theta^{-1}\right| d x \\
= & \sum_{i=1}^{m} \int_{V_{i}} \phi_{\varepsilon}\left(\theta^{-1}(\mathbf{g}(\mathbf{x})-\mathbf{y})\right) \operatorname{det} D \mathbf{g}(\mathbf{x})\left|\operatorname{det} \theta^{-1}\right| d x
\end{aligned}
$$

Now just let $\mathbf{z}=\mathbf{g}(\mathbf{x})-\mathbf{y}$ and change the variables.

$$
=\sum_{i=1}^{m}\left|\operatorname{det} \theta^{-1}\right| \int_{\mathbf{g}\left(V_{i}\right)-\mathbf{y}} \phi_{\varepsilon}\left(\theta^{-1} \mathbf{z}\right) \operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\left|\operatorname{det} D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right| d z
$$

By the chain rule, $I=D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right) D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})$ and so

$$
\begin{aligned}
& \operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\left|\operatorname{det} D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right| \\
= & \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\right) \\
& \left|\operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\right|\left|\operatorname{det} D \mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right| \\
= & \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{g}^{-1}(\mathbf{y}+\mathbf{z})\right)\right) \\
= & \operatorname{sgn}(\operatorname{det} D \mathbf{g}(\mathbf{x}))=\operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right) .
\end{aligned}
$$

and so it all reduces to

$$
\begin{aligned}
& \sum_{i=1}^{m} \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right) \int_{\mathbf{g}\left(V_{i}\right)-\mathbf{y}} \phi_{\varepsilon}\left(\theta^{-1} \mathbf{z}\right) d z \\
= & \sum_{i=1}^{m} \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right) \int_{\theta B(\mathbf{0}, \varepsilon)}\left|\operatorname{det} \theta^{-1}\right| \phi_{\varepsilon}\left(\theta^{-1} \mathbf{z}\right) d z \\
= & \sum_{i=1}^{m} \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right) \int_{B(\mathbf{0}, \boldsymbol{\varepsilon})} \phi_{\varepsilon}(\mathbf{w})\left|\operatorname{det} \theta^{-1}\right||\operatorname{det} \theta| d w \\
= & \sum_{i=1}^{m} \operatorname{sgn}\left(\operatorname{det} D \mathbf{g}\left(\mathbf{x}_{i}\right)\right)=d(\mathbf{g}, \Omega, \mathbf{y}) .
\end{aligned}
$$

What about functions which have values in finite dimensional vector spaces?
Theorem 23.8.3 Let $\Omega$ be an open bounded set in $V$ a real normed $n$ dimensional vector space. Then there exists a topological degree d $(f, \Omega, y)$ for $f \in C(\bar{\Omega}, V), y \notin f(\partial \Omega)$ which satisfies all the properties of the degree for functions having values in $\mathbb{R}^{n}$ described above,

1. $d(\mathrm{id}, \Omega, y)=1$ if $\mathbf{y} \in \Omega$.
2. If $\Omega_{i} \subseteq \Omega, \Omega_{i}$ open, and $\Omega_{1} \cap \Omega_{2}=\emptyset$ and if $y \notin f\left(\bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)\right)$, then $d\left(f, \Omega_{1}, y\right)+$ $d\left(f, \Omega_{2}, y\right)=d(f, \Omega, y)$.
3. If $y \notin f\left(\bar{\Omega} \backslash \Omega_{1}\right)$ and $\Omega_{1}$ is an open subset of $\Omega$, then

$$
d(f, \Omega, y)=d\left(f, \Omega_{1}, y\right)
$$

4. For $y \in \mathbb{R}^{n} \backslash f(\partial \Omega)$, if $d(f, \Omega, y) \neq 0$ then $f^{-1}(y) \cap \Omega \neq \emptyset$.
5. If $t \rightarrow \mathbf{y}(t)$ is continuous $\mathbf{h}: \bar{\Omega} \times[0,1] \rightarrow \mathbb{R}^{n}$ is continuous and if $\mathbf{y}(t) \notin \mathbf{h}(\partial \Omega, t)$ for all $t$, then $t \rightarrow d(\mathbf{h}(\cdot, t), \Omega, \mathbf{y}(t))$ is constant.
6. $d(\cdot, \Omega, y)$ is defined and constant on

$$
\left\{g \in C\left(\bar{\Omega} ; \mathbb{R}^{n}\right):\|g-f\|_{\infty}<r\right\}
$$

where $r=\operatorname{dist}(y, f(\partial \Omega))$.
7. $d(f, \Omega, \cdot)$ is constant on every connected component of $\mathbb{R}^{n} \backslash f(\partial \Omega)$.
8. $d(g, \Omega, y)=d(f, \Omega, y)$ if $\left.g\right|_{\partial \Omega}=\left.f\right|_{\partial \Omega}$.

Proof: There is an isomorphism $\theta: \mathbb{R}^{n} \rightarrow V$ which also preserves all topological properties. This follows from the properties of finite dimensional vector spaces. In fact, every algebraic isomorphism is automatically a homeomorphism preserving all topological properties. Then it is pretty easy to see what the degree should be.

$$
d(f, \Omega, y) \equiv d\left(\theta^{-1} \circ f \circ \theta, \theta^{-1}(\Omega), \theta^{-1} y\right)
$$

Then by standard material on finite dimensional vector spaces, the norm on $V$ is equivalent to the norm defined by $|v| \equiv\left|\theta^{-1} v\right|_{\mathbb{R}^{n}}$. Hence all of those properties hold. By Lemma 23.8.2 this definition does not depend on the particular isomorphism used. If $\hat{\theta}$ is another one, then one would need to verify that

$$
d\left(\theta^{-1} \circ f \circ \theta, \theta^{-1}(\Omega), \theta^{-1} y\right)=d\left(\hat{\theta}^{-1} \circ f \circ \hat{\theta}, \hat{\theta}^{-1}(\Omega), \hat{\theta}^{-1} y\right)
$$

However, you could use that lemma to conclude that

$$
\begin{aligned}
& d\left(\hat{\theta}^{-1} \circ f \circ \hat{\theta}, \hat{\theta}^{-1}(\Omega), \hat{\theta}^{-1} y\right) \\
= & d\left(\alpha^{-1} \circ \hat{\theta}^{-1} \circ f \circ \hat{\theta} \circ \alpha, \alpha^{-1} \hat{\theta}^{-1}(\Omega), \alpha^{-1} \hat{\theta}^{-1} y\right)
\end{aligned}
$$

where $\alpha$ is such that $\hat{\theta} \circ \alpha=\theta$. Then this verifies the appropriate equation.
Next one considers what happens when the function $I-f$ has values in a smaller dimensional subspace.

Theorem 23.8.4 Let $\Omega$ be a bounded open set in $V$ an $n$ dimensional normed linear space and let $f \in C\left(\bar{\Omega} ; V_{m}\right)$ where $V_{m}$ is an $m$ dimensional subspace. Let $y \in V_{m} \backslash(I-f)(\partial \Omega)$. Then $d(I-f, \Omega, y)=d\left(\left.(I-f)\right|_{\overline{\Omega \cap V_{m}}}, \Omega \cap V_{m}, y\right)$.

Proof: Letting $\left\{v_{1}, \cdots, v_{m}\right\}$ be a basis for $V_{m}$, let a basis for $V$ be

$$
\left\{v_{1}, \cdots, v_{m}, v_{m+1}, \cdots, v_{n}\right\}
$$

Let $\theta$ be the isomorphism which satisfies $\theta \mathbf{e}_{i}=v_{i}$ where the $\mathbf{e}_{i}$ denotes the standard basis vectors for $\mathbb{R}^{n}$. Then from the above,

$$
\begin{aligned}
d(I-f, \Omega, y) & \equiv d\left(\theta^{-1} \circ(I-f) \circ \theta, \theta^{-1} \Omega, \theta^{-1} y\right) \\
& =d\left(\left.\theta^{-1} \circ(I-f) \circ \theta\right|_{\overline{\theta^{-1}(\Omega) \cap \mathbb{R}_{m}^{n}}}, \theta^{-1}(\Omega) \cap \mathbb{R}_{m}^{n}, \theta^{-1} y\right) \\
& \equiv d\left(\left.(I-f)\right|_{\overline{\Omega \cap V_{m}}}, \Omega \cap V_{m}, y\right) .
\end{aligned}
$$

### 23.9 The Leray Schauder Degree

This is a very important generalization to Banach spaces. It turns out you can define the degree of $I-F$ where $F$ is a compact mapping. To recall what one of these is, here is the definition.

Definition 23.9.1 Let $\Omega$ be a bounded open set in $X$ a Banach space and let $F: \bar{\Omega} \rightarrow X$ be continuous. Then $F$ is called compact if $F(B)$ is precompact whenever $B$ is bounded. That is, if $\left\{x_{n}\right\}$ is a bounded sequence, then there is a subsequence $\left\{x_{n_{k}}\right\}$ such that $\left\{F\left(x_{n_{k}}\right)\right\}$ converges.

Theorem 23.9.2 Let $F: \bar{\Omega} \rightarrow X$ as above be compact. Then for each $\varepsilon>0$, there exists $F_{\varepsilon}: \bar{\Omega} \rightarrow X$ such that $F$ has values in a finite dimensional subspace of $X$ and

$$
\sup _{x \in \bar{\Omega}}\left\|F_{\varepsilon}(x)-F(x)\right\|<\varepsilon
$$

In addition to this, $(I-F)^{-1}$ (compact set) $=$ compact set. (This is called "proper".)
Proof: It is known that $\overline{F(\Omega)}$ is compact. Therefore, there is an $\varepsilon$ net for $F(\Omega)$, $\left\{F x_{k}\right\}_{k=1}^{n}$ satisfying

$$
\overline{F(\Omega)} \subseteq \cup_{k} B\left(F x_{k}, \varepsilon\right)
$$

Now let

$$
\phi_{k}(F x) \equiv\left(\varepsilon-\left\|F x-F x_{k}\right\|\right)^{+}
$$

Thus this is equal to 0 if $\left\|F x_{k}-F x\right\| \geq \varepsilon$ and is positive if $\left\|F x_{k}-F x\right\|<\varepsilon$. Then consider

$$
F_{\varepsilon}(x) \equiv \sum_{k=1}^{n} F\left(x_{k}\right) \frac{\phi_{k}(F x)}{\sum_{i} \phi_{i}(F x)}
$$

It clearly has values in $\operatorname{span}\left(\left\{F x_{k}\right\}_{k=1}^{n}\right)$. How close is it to $F(x)$ ? Say $F x \in B\left(F x_{k}, \boldsymbol{\varepsilon}\right)$. Then for such $x,\left\|F(x)-F\left(x_{k}\right)\right\|<\varepsilon$ by definition. Hence

$$
\begin{aligned}
\left\|F(x)-F_{\varepsilon}(x)\right\| & =\sum_{k:\left\|F(x)-F x_{k}\right\|<\varepsilon}\left\|F\left(x_{k}\right)-F(x)\right\| \frac{\phi_{k}(F x)}{\sum_{i} \phi_{i}(F x)} \\
& <\varepsilon \sum_{k} \frac{\phi_{k}(F x)}{\sum_{i} \phi_{i}(F x)}=\varepsilon
\end{aligned}
$$

Of course $x$ is arbitrary and so

$$
\sup _{x \in \bar{\Omega}}\left\|F_{\varepsilon}(x)-F(x)\right\|<\varepsilon
$$

Next consider the second claim. Let $K$ be compact. Consider

$$
\left\{x_{k}\right\} \subseteq(I-F)^{-1}(K)
$$

It is necessary to show that it has a convergent subsequence. Then $\left\{(I-F)\left(x_{k}\right)\right\}$ is a sequence in $K$ and so it has a convergent subsequence still denoted with subscript $k$ such that $(I-F)\left(x_{k}\right) \rightarrow y$. The $x_{k}$ are in a bounded set $\Omega$ and so, from compactness of $F$, there is a further subsequence, still denoted with subscript $k$ such that $F x_{k} \rightarrow z$. It follows that $x_{k} \rightarrow y-z$ and hence every sequence in $(I-F)^{-1}(K)$ has a convergent subsequence.

Corollary 23.9.3 Let $F: \bar{\Omega} \rightarrow X$ as above be compact. Then for each $\varepsilon>0$, there exists $F_{\varepsilon}: \bar{\Omega} \rightarrow X$ such that $F$ has values in a finite dimensional subspace of $X$ and

$$
\sup _{x \in \bar{\Omega}}\left\|F_{\varepsilon}(x)-F(x)\right\|<\varepsilon
$$

. . In addition to this, $(I-F)^{-1}($ compact set $)=$ compact set. (This is called "proper".) If $\Omega$ is symmetric and $F$ is odd $(F(-x)=-F(x))$ then one can also assume $F_{\varepsilon}$ is also odd.

Proof: Suppose $\Omega$ is symmetric in that $x \in \Omega$ iff $-x \in \Omega$. Suppose also that $F$ is odd. Thus $F(\Omega)$ is also symmetric. Thus $\overline{F(\Omega)}$ is compact and symmetric. If $y \in F(\Omega)$, then $y=F x$ and so $-y=-F(x)=F(-x) \in F(\Omega)$. Choose the $\varepsilon$ net to be symmetric. That is, you have $(F x)_{k}$ in the net if and only if $-(F x)_{k}$ is in the net. Just add them in if needed. Therefore, there is an $\varepsilon$ net for $F(\Omega),\left\{(F x)_{k}\right\}_{k=-m_{\varepsilon}}^{m_{\varepsilon}}$ satisfying

$$
\overline{F(\Omega)} \subseteq \cup_{k} B\left(F x_{k}, \varepsilon\right),\left\{F x_{k}\right\} \text { is symmetric. }
$$

Number these so that

$$
F x_{-k}=-F x_{k}=F\left(-x_{k}\right),|k| \leq m_{\varepsilon}
$$

Now let

$$
\begin{aligned}
\phi_{k}(F x) & \equiv\left(\varepsilon-\left\|F x-F x_{k}\right\|\right)^{+} \\
\phi_{-k}(F x) & \equiv\left(\varepsilon-\left\|F x-F x_{-k}\right\|\right)^{+} \\
& =\left(\varepsilon-\left\|F x+F x_{k}\right\|\right)^{+} \\
& =\left(\varepsilon-\left\|F x-\left(-F x_{k}\right)\right\|\right)^{+} \\
& =\phi_{k}(-F x)
\end{aligned}
$$

that is, $\phi_{-k}$ is centered at $-F x_{k}$ while $\phi_{k}$ is centered at $F x_{k}$, each function equal to 0 off $B\left(F x_{k}, \varepsilon\right)$ and is positive on $B\left(F x_{k}, \varepsilon\right)$. Then consider

$$
\begin{gathered}
F_{\varepsilon}(x) \equiv \sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F\left(x_{k}\right) \frac{\phi_{k}(F x)}{\sum_{i} \phi_{i}(F x)} \\
F_{\varepsilon}(-x)=\sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F\left(x_{k}\right) \frac{\phi_{k}(F(-x))}{\sum_{i} \phi_{i}(F(-x))}=\sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F\left(x_{k}\right) \frac{\phi_{-k}(F(x))}{\sum_{i} \phi_{-i}(F(x))} \\
=-\sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F\left(-x_{k}\right) \frac{\phi_{-k}(F(x))}{\sum_{i} \phi_{-i}(F(x))}=-\sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F\left(x_{-k}\right) \frac{\phi_{-k}(F(x))}{\sum_{i} \phi_{-i}(F(x))} \\
=-\sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F\left(x_{k}\right) \frac{\phi_{k}(F(x))}{\sum_{i} \phi_{i}(F(x))}=-F_{\varepsilon}(x)
\end{gathered}
$$

The rest of the argument is the same.
Now let $F: \bar{\Omega} \rightarrow X$ be compact and consider $I-F$. Is $(I-F)(\partial \Omega)$ closed? Suppose $(I-F) x_{k} \rightarrow y$. Then $K \equiv y \cup\left\{(I-F) x_{k}\right\}_{k=1}^{\infty}$ is a compact set because if you have any open
cover, one of the open sets contains $y$ and hence it contains all $(I-F) x_{k}$ except for finitely many which can then be covered by finitely many open sets in the open cover. Hence, since $(I-F)$ is proper, $(I-F)^{-1}(K)$ is compact. It follows that there is a subsequence, still called $x_{k}$ such that $x_{k} \rightarrow x \in(I-F)^{-1}(K)$. Then by continuity of $F$,

$$
\begin{aligned}
& (I-F)\left(x_{k}\right) \rightarrow(I-F)(x) \\
& (I-F)\left(x_{k}\right) \rightarrow y
\end{aligned}
$$

It follows $y=(I-F) x$ and so in fact $(I-F)(\partial \Omega)$ is closed.
Lemma 23.9.4 If $F: \bar{\Omega} \rightarrow X$ is compact and $\Omega$ is a bounded open set in $X$, then

$$
(I-F)(\partial \Omega)
$$

is closed.

## Justification for definition of Leray Schauder Degree

Now let $y \notin(I-F)(\partial \Omega)$, a closed set. Hence dist $(y,(I-F)(\partial \Omega))>4 \delta>0$. Now let $F_{k}$ be a sequence of approximations to $F$ which have values in an increasing sequence of finite dimensional subsets $V_{k}$ each of which contains $y$. Thus

$$
\lim _{k \rightarrow \infty}
$$

$\sup _{x \in \bar{\Omega}}\left\|F(x)-F_{k}(x)\right\|=0$. Consider

$$
d\left(I-\left.F_{k}\right|_{V_{k}}, \Omega \cap V_{k}, y\right)
$$

Each of these is a well defined integer according to Theorem 23.8.3. For all $k$ large enough,

$$
\sup _{x \in \bar{\Omega}}\left\|(I-F)(x)-\left(I-F_{k}\right)(x)\right\|<\delta
$$

Hence, for all such $k$,

$$
\begin{equation*}
B(y, 3 \delta) \cap\left(I-F_{k}\right)(\partial \Omega)=\emptyset, \text { that is } \operatorname{dist}\left(y,\left(I-F_{k}\right)(\partial \Omega)\right)>3 \delta \tag{23.9.18}
\end{equation*}
$$

Note that this implies

$$
\operatorname{dist}\left(y,\left(I-F_{k}\right)(\partial(\Omega \cap V))\right)>3 \delta
$$

for any subspace $V$. If $k<l$ are two such indices, then consider

$$
d\left(I-F_{k} \mid V_{k}, \Omega \cap V_{k}, y\right), d\left(I-\left.F_{l}\right|_{V_{l}}, \Omega \cap V_{l}, y\right)
$$

Are they equal? Let $V=V_{k}+V_{l}$. Then by Theorem 23.8.4,

$$
\begin{aligned}
& d\left(I-\left.F_{l}\right|_{V_{l}}, \Omega \cap V_{l}, y\right)=d\left(I-\left.F_{l}\right|_{V}, \Omega \cap V, y\right) \\
& d\left(I-\left.F_{k}\right|_{V_{k}}, \Omega \cap V_{k}, y\right)=d\left(I-\left.F_{k}\right|_{V}, \Omega \cap V, y\right)
\end{aligned}
$$

So what about $d\left(I-\left.F_{l}\right|_{V}, \Omega \cap V, y\right), d\left(I-\left.F_{k}\right|_{V}, \Omega \cap V, y\right)$ ? Are these equal?

$$
\sup _{x \in \overline{\Omega \cap V}}\left\|F_{l}(x)-F_{k}(x)\right\| \leq \sup _{x \in \overline{\Omega \cap V}}\left\|F_{l}(x)-F(x)\right\|+\sup _{x \in \overline{\Omega \cap V}}\left\|F(x)-F_{k}(x)\right\|<2 \delta
$$

This implies for

$$
h(x, t)=t\left(I-F_{l}\right)(x)+(1-t)\left(I-F_{k}\right)(x)
$$

and $x \in \overline{\Omega \cap V}, y \notin h(\partial(\Omega \cap V), t)$ for all $t \in[0,1]$. To see this, let $x \in \partial \Omega$

$$
\begin{aligned}
& \left\|t\left(I-F_{l}\right)(x)+(1-t)\left(I-F_{k}\right)(x)-y\right\| \\
= & \left\|t\left(I-F_{k}\right)(x)+t\left(F_{k} x-F_{l} x\right)+(1-t)\left(I-F_{k}\right)(x)-y\right\| \\
= & \left\|\left(I-F_{k}\right)(x)+t\left(F_{k} x-F_{l} x\right)\right\| \geq 3 \delta-t 2 \delta \geq \delta
\end{aligned}
$$

Hence

$$
d\left(I-\left.F_{l}\right|_{V}, \Omega \cap V, y\right)=d\left(I-\left.F_{k}\right|_{V}, \Omega \cap V, y\right)
$$

and so

$$
\lim _{k \rightarrow \infty} d\left(I-\left.F_{k}\right|_{V_{k}}, \Omega \cap V_{k}, y\right)
$$

exists. A similar argument shows that this limit is independent of the sequence $\left\{F_{k}\right\}$ of approximating functions having values in a finite dimensional space. Thus we have the following definition of the Leray Schauder degree.

Definition 23.9.5 Let $X$ be a Banach space and let $F: X \rightarrow X$ be compact. That is, $F(\Omega)$ is precompact whenever $\Omega$ is bounded. Let $\Omega$ be a bounded open set in $X$ and let $y \notin$ $(I-F)(\partial \Omega)$. Let $F_{k}$ be a sequence of operators which have values in finite dimensional spaces $V_{k}$ such that $V_{k} \subseteq V_{k+1} \cdots, y \in V_{k}$, and $\lim _{k \rightarrow \infty} \sup _{x \in \bar{\Omega}}\left\|F(x)-F_{k}(x)\right\|=0$. Then

$$
D(I-F, \Omega, y) \equiv \lim _{k \rightarrow \infty} d\left(I-\left.F_{k}\right|_{V_{k}}, \Omega \cap V_{k}, y\right)
$$

In fact, the sequence on the right is eventually constant. So

$$
D(I-F, \Omega, y) \equiv d\left(I-\left.F_{k}\right|_{V_{k}}, \Omega \cap V_{k}, y\right)
$$

for all $k$ sufficiently large.
The main properties of the Leray Schauder degree follow from the corresponding properties of Brouwer degree.

Theorem 23.9.6 Let $D$ be the Leray Schauder degree just defined and let $\Omega$ be a bounded open set $y \notin(I-F)(\partial \Omega)$ where $F$ is always a compact mapping. Then the following properties hold:

1. $D(I, \Omega, y)=1$
2. If $\Omega_{i} \subseteq \Omega$ where $\Omega_{i}$ is open, $\Omega_{1} \cap \Omega_{2}=\emptyset$, and $y \notin \bar{\Omega} \backslash\left(\Omega_{1} \cup \Omega_{2}\right)$ then

$$
D(I-F, \Omega, y)=D\left(I-F, \Omega_{1}, y\right)+D\left(I-F, \Omega_{2}, y\right)
$$

3. If $t \rightarrow y(t)$ is continuous $h: \bar{\Omega} \times[0,1] \rightarrow X$ is continuous, $(x, t) \rightarrow h(x, t)$ is compact, (It takes bounded subsets of $\bar{\Omega} \times[0,1]$ to precompact sets in $X$ ) and if $y(t) \notin$ $(I-h)(\partial \Omega, t)$ for all $t$, then $t \rightarrow D((I-h)(\cdot, t), \Omega, y(t))$ is constant.

Proof: The mapping $x \rightarrow 0$ is clearly compact. Then an approximating sequence is $F_{k}, F_{k} x=0$ for all $k$. Then

$$
D(I, \Omega, y)=\lim _{k \rightarrow \infty} d\left(\left.I\right|_{V_{k}}, \Omega \cap V_{k}, y\right)=1
$$

For the second part, let $k$ be large enough that for $U=\Omega, \Omega_{1}, \Omega_{2}$,

$$
D(I-F, U, y)=d\left(I-F_{k} \mid V_{k}, U \cap V_{k}, y\right)
$$

where $F_{k}$ is the sequence of approximating functions having finite dimensional range. Then the result follows from the Brouwer degree. In fact,

$$
\begin{aligned}
D(I-F, \Omega, y) & =d\left(I-F_{k} \mid V_{k}, \Omega \cap V_{k}, y\right) \\
& =d\left(I-F_{k} \mid V_{k}, \Omega_{1} \cap V_{k}, y\right)+d\left(I-F_{k} \mid V_{k}, \Omega_{2} \cap V_{k}, y\right) \\
& =D\left(I-F, \Omega_{1}, y\right)+D\left(I-F, \Omega_{2}, y\right)
\end{aligned}
$$

this does the second claim of the theorem. Now consider the third one about homotopy invariance.

Claim: If $\operatorname{dist}(y,(I-F) \partial \Omega) \geq 6 \delta$, and if $\|y-z\|<\delta$, then

$$
D(I-F, \Omega, y)=D(I-F, \Omega, z)
$$

Proof of claim: Let $F_{k}$ be the approximations and include both $y, z$ in all the finite dimensional subspaces $V_{k}$. Then for $k$ large enough, $\sup _{x \in \bar{\Omega}}\left\|F(x)-F_{k}(x)\right\|<\delta$ and also,

$$
\begin{aligned}
& D(I-F, \Omega, y)=d\left(\left.\left(I-F_{k}\right)\right|_{V_{k}}, \Omega \cap V_{k}, y\right) \\
& D(I-F, \Omega, z)=d\left(\left.\left(I-F_{k}\right)\right|_{V_{k}}, \Omega \cap V_{k}, z\right)
\end{aligned}
$$

Now for $x \in \partial\left(\Omega \cap V_{k}\right)$,

$$
\begin{aligned}
\left\|\left(I-F_{k}\right)(x)-y\right\| & \geq\left\|(I-F)(x)+\left(F(x)-F_{k}(x)\right)-y\right\| \\
& \geq\|(I-F)(x)-y\|-\left\|F(x)-F_{k}(x)\right\| \\
& >6 \delta-\delta=5 \delta
\end{aligned}
$$

Hence dist $\left(y,\left(I-F_{k}\right) \partial \Omega\right) \geq 5 \delta$ while $\|y-z\|<\delta$. Hence

$$
d\left(\left.\left(I-F_{k}\right)\right|_{V_{k}}, \Omega \cap V_{k}, y\right)=d\left(\left.\left(I-F_{k}\right)\right|_{V_{k}}, \Omega \cap V_{k}, z\right)
$$

by Theorem 23.2.2.
From compactness of $h$, there is an $\varepsilon$ net for $h(\bar{\Omega} \times[0,1]),\left\{h\left(x_{k}, t_{k}\right)\right\}$ such that

$$
h(\bar{\Omega} \times[0, T]) \subseteq \cup_{k=1}^{n} B\left(h\left(x_{k}, t_{k}\right), \varepsilon\right) .
$$

Say the $t_{k}$ are ordered. Then, as before,

$$
\begin{aligned}
& \phi_{k}(x) \equiv\left(\varepsilon-\left\|h(x, t)-h\left(x_{k}, t_{k}\right)\right\|\right)^{+} \\
& h_{\varepsilon}(x, t) \equiv \sum_{k=1}^{n} h\left(x_{k}, t_{k}\right) \frac{\phi_{k}(h(x, t))}{\sum_{i} \phi_{i}(h(x, t))}
\end{aligned}
$$

Then this is clearly continuous and has values in $\operatorname{span}\left(\left\{h\left(x_{k}, t_{k}\right)\right\}_{k=1}^{n}\right)$. How well does it approximate? Say $h(x, t) \in h(\bar{\Omega} \times[0, T])$. Then it is in some

$$
B\left(h\left(x_{k}, t_{k}\right), \varepsilon\right),
$$

maybe several. Thus letting $\mathscr{K}(x, t)$ be those indices $k$ such that

$$
\begin{aligned}
& h(x, t) \in B\left(h\left(x_{k}, t_{k}\right), \varepsilon\right) \\
\left\|h_{\varepsilon}(x, t)-h(x, t)\right\| & \leq \sum_{k \in \mathscr{K}(x, t)}\left\|h\left(x_{k}, t_{k}\right)-h(x, t)\right\| \frac{\phi_{k}(h(x, t))}{\sum_{i} \phi_{i}(h(x, t))} \\
& \leq \varepsilon \sum_{k=1}^{n} \frac{\phi_{k}(h(x, t))}{\sum_{i} \phi_{i}(h(x, t))}=\varepsilon
\end{aligned}
$$

Now here is a claim.
Claim: There exists $\delta>0$ such that for all $t \in[0,1]$,

$$
\operatorname{dist}(y(t),(I-h)(\partial \Omega, t))>6 \delta
$$

Proof of claim: If not, there is $\left(x_{n}, t_{n}\right) \in \partial \Omega \times[0,1]$ such that

$$
\left\|y\left(t_{n}\right)-(I-h)\left(x_{n}, t_{n}\right)\right\|<1 / n
$$

Then $h\left(x_{n}, t_{n}\right)$ is in a compact set because of compactness of $h$. Also, the $y\left(t_{n}\right)$ are in a compact set because $y$ is continuous and $y([0, T])$ must therefore be compact. It follows that $\left(x_{n}, t_{n}\right)$ must be in a compact subset of $\partial \Omega \times[0,1]$. It follows there is a subsequence, still denoted as $\left(x_{n}, t_{n}\right)$ which converges to $(x, t)$ in $\partial \Omega \times[0,1]$. then by continuity, $\|y(t)-(I-h)(x, t)\|=0$ contrary to assumption. This proves the claim.

As with $h$ there exists a sequence $\left\{y_{k}(t)\right\}$ such that $y_{k}(t) \rightarrow y(t)$ uniformly in $t \in[0,1]$ but $y_{k}$ has values in a finite dimensional subspace of $X, Y_{k}$. Choose $k_{0}$ large enough that for all $t \in[0,1],\left\|y(t)-y_{k_{0}}(t)\right\|<\delta$. Thus by the first claim,

$$
D(h(\cdot, t), \Omega, y(t))=D\left(h(\cdot, t), \Omega, y_{k_{0}}(t)\right)
$$

for all $t$. Also,

$$
\operatorname{dist}\left(y_{0}(t),(I-h)(\partial \Omega, t)\right)>5 \delta
$$

From the above, let $h_{k} \rightarrow h$ uniformly on $\bar{\Omega} \times[0,1]$ but $h_{k}$ has values in a finite dimensional subspace $V_{k}$. Let all the $V_{k}$ contain the values of $y_{k_{0}}$ and so, for all $k$ large enough,

$$
\sup _{\bar{\Omega} \times[0, T]}\left\|h(t, x)-h_{k}(t, x)\right\|<\delta
$$

so for such $k$,

$$
\begin{aligned}
& \operatorname{dist}\left(y_{0}(t),\left(I-h_{k}\right)\left(\partial\left(\Omega \cap V_{k}\right), t\right)\right) \\
\geq \quad & \operatorname{dist}\left(y_{0}(t),\left(I-h_{k}\right)(\partial \Omega, t)\right)>4 \delta
\end{aligned}
$$

Then

$$
\begin{aligned}
D(h(\cdot, t), \Omega, y(t)) & =D\left(h(\cdot, t), \Omega, y_{k_{0}}(t)\right) \\
& =\lim _{k \rightarrow \infty} d\left(\left.h_{k}(\cdot, t)\right|_{\overline{\Omega \cap V_{k}}}, \Omega \cap V_{k}, y_{k_{0}}(t)\right)
\end{aligned}
$$

and $d\left(\left.h_{k}(\cdot, t)\right|_{\overline{\Omega \cap V_{k}}}, \Omega \cap V_{k}, y_{k_{0}}(t)\right)$ is constant in $t$ for all large enough $k$. Thus

$$
D(h(\cdot, t), \Omega, y(t))=\lim _{k \rightarrow \infty} a_{k}, a_{k} \text { independent of } t .
$$

One of the nice results which follows right away from this is the Schauder fixed point theorem.

Theorem 23.9.7 Let $B=\overline{B(0, r)}$ and let $F: B \rightarrow B$ be compact. Then $F$ has a fixed point.
Proof: Suppose it does not. Then consider $D(I-t F, B(0, r), 0)$. If $t=1$, then $0 \notin$ $(I-t F)(\partial B)$ since otherwise, there would be a fixed point. If $t<1$ there is no point of $\partial B$ which $I-t F$ sends to 0 because if so,

$$
x-t F x=0,\|x\|=1,\|F x\| \leq 1
$$

Therefore, by homotopy invariance, $t \rightarrow D(I-t F, B(0, r), 0)$ is constant for $t \in[0,1]$. It must equal

$$
D(I-F, B(0, r), 0)=D(I, B(0, r), 0)=1 .
$$

Therefore, there exists $x \in B(0, r)$ such that $(I-F)(x)=0$ so $F$ which means $F$ has a fixed point after all.

One can get an improved version of this easily.
Theorem 23.9.8 Let $K$ be a closed bounded convex subset of a Banach space $X$ and suppose $F: K \rightarrow K$ is compact. Then $F$ has a fixed point.

Proof: By Theorem $16.2 .5, K$ is a retract. Thus there is a continuous function $R: X \rightarrow K$ which leaves points of $K$ unchanged. Then you consider $F \circ R$. It is still a compact mapping obviously. Let $B(0, r)$ be so large that it contains $K$. Then from the above theorem, it has a fixed point in $\overline{B(0, r)}$ denoted as $x$. Then $F(R(x))=x$. But $F(R(x)) \in K$ and so $x \in K$. Hence $R x=x$ and so $F x=x$.

There is an easy modification of the above which is often useful. If $F: X \rightarrow F(X)$ where $F(X)$ is bounded and in a compact set, and $F$ is a compact map, then you could consider $F$ : $\overline{\operatorname{conv}(F(X))} \rightarrow F(X) \subseteq \overline{\operatorname{conv}(F(X))}$ where here $\overline{\operatorname{conv}(F(X))}$ is a closed bounded convex subset of $X$. Then by the Schauder theorem, there is a fixed point for $F$.

Here is an easy application of this theorem to ordinary differential equations.

Theorem 23.9.9 Let $g:[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be continuous. Let

$$
F: C\left([0, T] ; \mathbb{R}^{n}\right) \rightarrow C\left([0, T] ; \mathbb{R}^{n}\right)
$$

be given by

$$
F(y)(t)=y_{0}+\int_{0}^{t} g(s, y(s)) d s
$$

Suppose that whenever

$$
y(s)=F(y)(s), \text { for } s \leq t
$$

it follows that $\max _{s \in[0, t]}|y(s)|<M,\left|y_{0}\right|<M$. Then there exists a solution to the integral equation

$$
y(t)=y_{0}+\int_{0}^{t} g(s, y(s)) d s
$$

for $t \in[0, T]$.
Proof: Let $r_{M}$ be the radial projection in $\mathbb{R}^{n}$ onto $\overline{B(0, M)}$. Then $F \circ r_{M}$ is compact because $\left|g\left(s, r_{M} y\right)\right|$ is bounded. It also maps into a compact subset of $C\left([0, T] ; \mathbb{R}^{n}\right)$ thanks to the Arzela Ascoli theorem. Then by the Schauder fixed point theorem, there exists a solution $y=F \circ r_{M}$ to

$$
y(t)=y_{0}+\int_{0}^{t} g\left(s, r_{M} y(s)\right) d s
$$

Then for $s \in[0, \hat{T}]$ where $\hat{T}$ is the largest such that $\|y(s)\| \leq M$ for $s \in[0, \hat{T}]$. Thus on $[0, \hat{T}], r_{M}$ has no effect. If $\hat{T}<T$, then by the estimate, $|y(\hat{T})|<M$. Hence $\hat{T}$ is not really the last. Thus $\hat{T}=T$.

The Schauder alternative or Schaefer fixed point theorem is as follows [38].
Theorem 23.9.10 Let $f: X \rightarrow X$ be a compact map. Then either

1. There is a fixed point for $t f$ for all $t \in[0,1]$ or
2. For every $r>0$, there exists a solution to $x=t f(x)$ for $t \in(0,1)$ such that $\|x\|>r$.

Proof: Suppose there is $t_{0} \in[0,1]$ such that $t_{0} f$ has no fixed point. Then $t_{0} \neq 0 . t_{0} f$ obviously has a fixed point if $t_{0}=0$. Thus $t_{0} \in(0,1]$. Then let $r_{M}$ be the radial retraction onto $\overline{B(0, M)}$. By Schauder's theorem there exists $x \in \overline{B(0, M)}$ such that $t_{0} r_{M} f(x)=x$. Then if $\|f(x)\| \leq M, r_{M}$ has no effect and so $t_{0} f(x)=x$ which is assumed not to take place. Hence $\|f(x)\|>M$ and so $\left\|r_{M} f(x)\right\|=M$ so $\|x\|=t_{0} M$. Also $t_{0} r_{M} f(x)=t_{0} M \frac{f(x)}{\|f(x)\|}=$ $x$ and so $x=\hat{t} f(x), \hat{t}=t_{0} \frac{M}{\|f(x)\|}<1$. Since $M$ is arbitrary, it follows that the solutions to $x=t f(x)$ for $t \in(0,1)$ are unbounded. It was just shown that there is a solution to $x=\hat{t} f(x), \hat{t}<1$ such that $\|x\|=t_{0} M$ where $M$ is arbitrary. Thus the second of the two alternatives holds.

There is a lot more on degree theory in [43]. Here is a very interesting theorem from this reference which pertains specifically to infinite dimensional spaces.

Theorem 23.9.11 Let $X$ be an infinite dimensional Banach space and let $0 \notin \partial \Omega$ where $\Omega$ is an open bounded subset of $X$. Let $F: \bar{\Omega} \rightarrow X$ be compact. Suppose that $F x \neq \lambda x$ for all $x \in \partial \Omega$ and that $0 \notin \overline{F(\partial \Omega)}$. Then $D(I-F, \Omega, 0)=0$.

Proof: Recall that $D(I-F, \Omega, 0) \equiv \lim _{k \rightarrow \infty} d\left(I-F_{k}, \Omega \cap V_{k}, 0\right)$ where $F_{k}$ has values in a finite dimensional subspace $V_{k}$,

$$
\sup _{x \in \bar{\Omega}}\left\|F_{k}(x)-F(x)\right\|<1 / k
$$

Since the dimension of $X$ is infinite, it can always be assumed that $\operatorname{span}\left(-F_{k}(\bar{\Omega})\right)$ is a proper subspace of $V_{k}$ and this will be assumed. This is where it is significant that the dimension of $X$ is infinite. Also recall that in the limit, eventually $d\left(I-F_{k}, \Omega \cap V_{k}, 0\right)$ is a constant. Then the fact that $F x \neq \lambda x$ for all $x \in \partial \Omega$ will persist for $F_{k}$ for all $k$ large enough.

If not, then there exists $x_{k} \in \partial \Omega, F_{k} x_{k}=\lambda_{k} x_{k}$ for some $x_{k} \in \partial \Omega$ and $\lambda_{k} \in[0,1]$. Then there are subsequence $\lambda_{k} \rightarrow \lambda_{0} \in[0,1]$. Then

$$
F x_{k}-\lambda_{k} x_{k} \rightarrow 0
$$

because it is uniformly close to $F_{k} x_{k}-\lambda_{k} x_{k}$. Now by assumption $0 \notin \overline{F(\partial \Omega)}$. If $\lambda_{0}=0$, then you would have $F x_{k} \rightarrow 0$ which does not happen because 0 is at a positive distance from $\overline{F(\partial \Omega)}$. Hence for all $k$ large enough,

$$
F_{k} x \neq \lambda x
$$

for all $\lambda \in[0,1]$. Pick $k$ sufficiently large that in the limit for the Leray Schauder degree $d\left(I-F_{k}, \Omega \cap V_{k}, 0\right)$ remains constant. Then for $\lambda \in[0,1]$,

$$
d\left(\lambda I-F_{k}, \Omega \cap V_{k}, 0\right)=d\left(-F_{k}, \Omega \cap V_{k}, 0\right)=d\left(-F_{k}, \Omega \cap V_{k}, p\right)
$$

for all $p \notin \operatorname{span}\left(-F_{k}(\bar{\Omega})\right)$ which is also close enough to 0 . Hence, since the degree of this last equals 0 for such $p$, it follows that

$$
d\left(I-F_{k}, \Omega \cap V_{k}, 0\right)=0
$$

Hence $D(I-F, \Omega, 0)=0$ as claimed.
This theorem implies a very strange fixed point theorem. It is strange because it only applies to infinite dimensions.

Corollary 23.9.12 Let $X$ be an infinite dimensional Banach space. Let $0 \in \Omega_{0} \subseteq \Omega$ be two open sets. Let $F: \bar{\Omega} \rightarrow X$ be a compact mapping which satisfies

1. $\|F x\| \leq\|x\|$ for $x \in \partial \Omega_{0}$
2. $\|F x\| \geq\|x\|$ for $x \in \partial \Omega$

Then $F$ has a fixed point in $\overline{\Omega \backslash \Omega_{0}}$.

Proof: First note that $\overline{\Omega \backslash \Omega_{0}}$ is like an annulus with both edges included. Suppose $F$ does not have a fixed point in $\overline{\Omega \backslash \Omega_{0}}$. What if $t=1$ and $x \in \partial \Omega$ ? Could $0=(I-F)(x)$ ? If so, the fixed point is obtained so assume this is not so. Then for $t<1$ and $x \in \partial \Omega$, if you have $x=t^{-1} F x$, this would mean that $\|F x\|=t\|x\|$ and $\|F x\|<\|x\|$ which is assumed not to happen. Hence for $t \in(0,1]$ we can assume that $0 \notin\left(I-t^{-1} F\right)(\partial \Omega)$. If $(I-F)(x)=0$ for $x \notin \partial \Omega_{0}$ then the fixed point has been found. For $t \in[0,1)$, you can't have $(I-t F)(x)=$ 0 for $x \in \partial \Omega_{0}$ because then you would have $\|x\|=t\|F x\|$ and so $\|F x\|>\|x\|$ which is assumed not to happen. Therefore, we can assume that for $x \in \partial \Omega_{0},(I-t F)(x) \neq 0$. Therefore, $D\left(I-F, \Omega_{0}, 0\right)=D\left(I, \Omega_{0}, 0\right)=1$ by homotopy invariance. Also from properties of the degree,

$$
D\left(I-F, \Omega_{0}, 0\right)+D\left(I-F, \Omega \backslash \overline{\Omega_{0}}, 0\right)=D(I-F, \Omega, 0)
$$

Recall that this is true if $0 \notin(I-F)\left(\bar{\Omega}-\Omega_{0}\right)$ which is assumed to take place when we assume there is no fixed point. It is desired to use the above theorem so we need to consider $\overline{F(\partial \Omega)}$ and whether 0 is in this set. Condition 2 implies 0 is not in this set. Then Theorem 23.9.11 implies that $D(I-F, \Omega, 0)=0$ and so $D\left(I-F, \Omega \backslash \overline{\Omega_{0}}, 0\right)=-1$. Hence there is a fixed point in $\overline{\Omega \backslash \Omega_{0}}$ after all contrary to the assumption that there was no such thing.

This only works in infinite dimensions. Consider an annulus in $\mathbb{R}^{2}$ and let $F$ be a rotation through an angle of 30 degrees. It clearly has no fixed point but the above conditions are satisfied. This seems very interesting, something which happens in infinite dimensions but not in finite dimensions.

### 23.10 Exercises

1. Show the Brouwer fixed point theorem is equivalent to the nonexistence of a continuous retraction onto the boundary of $B(\mathbf{0}, r)$.
2. Using the Jordan separation theorem, prove the invariance of domain theorem $n \geq 2$. Thus an open ball goes to some open. Hint: You might consider $B(\mathbf{x}, r)$ and show $\mathbf{f}$ maps the inside to one of two components of $\mathbb{R}^{n} \backslash \mathbf{f}(\partial B(\mathbf{x}, r))$. etc.
3. Give a version of Proposition 23.6.4 which is valid for the case where $n=1$.
4. It was shown that if $\mathbf{f}$ is locally one to one and continuous, $\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$, and

$$
\lim _{|\mathbf{x}| \rightarrow \infty}|\mathbf{f}(\mathbf{x})|=\infty
$$

then $\mathbf{f}$ maps $\mathbb{R}^{n}$ onto $\mathbb{R}^{n}$. Suppose you have $\mathbf{f}: \mathbb{R}^{m} \rightarrow \mathbb{R}^{n}$ where $\mathbf{f}$ is one to one and $\lim _{|\mathbf{x}| \rightarrow \infty}|\mathbf{f}(\mathbf{x})|=\infty$. Show that $\mathbf{f}$ cannot be onto.
5. Can there exists a one to one onto continuous map, $\mathbf{f}$ which takes the unit interval $[0,1]$ to the unit disk $\overline{B(\mathbf{0}, 1)}$ ? Hint: Think in terms of invariance of domain.
6. Let $m<n$ and let $B_{m}(\mathbf{0}, r)$ be the ball in $\mathbb{R}^{m}$ and $B_{n}(\mathbf{0}, r)$ be the ball in $\mathbb{R}^{n}$. Show that there is no one to one continuous map from $\overline{B_{m}(\mathbf{0}, r)}$ to $\overline{B_{n}(\mathbf{0}, r)}$. Hint: It is like the above problem.
7. Consider the unit disk,

$$
\left\{(x, y): x^{2}+y^{2} \leq 1\right\} \equiv D
$$

and the annulus

$$
\left\{(x, y): \frac{1}{2} \leq x^{2}+y^{2} \leq 1\right\} \equiv A
$$

Is it possible there exists a one to one onto continuous map $\mathbf{f}$ such that $\mathbf{f}(D)=A$ ? Thus $D$ has no holes and $A$ is really like $D$ but with one hole punched out. Can you generalize to different numbers of holes? Hint: Consider the invariance of domain theorem. The interior of $D$ would need to be mapped to the interior of $A$. Where do the points of the boundary of $A$ come from? Consider Theorem 7.13.3.
8. Suppose $C$ is a compact set in $\mathbb{R}^{n}$ which has empty interior and $\mathbf{f}: C \rightarrow \Gamma \subseteq \mathbb{R}^{n}$ is one to one onto and continuous with continuous inverse. Could $\Gamma$ have nonempty interior? Show also that if $\mathbf{f}$ is one to one and onto $\Gamma$ then if it is continuous, so is $\mathbf{f}^{-1}$.
9. Let $K$ be a nonempty closed and convex subset of $\mathbb{R}^{n}$. Recall $K$ is convex means that if $\mathbf{x}, \mathbf{y} \in K$, then for all $t \in[0,1], t \mathbf{x}+(1-t) \mathbf{y} \in K$. Show that if $\mathbf{x} \in \mathbb{R}^{n}$ there exists a unique $\mathbf{z} \in K$ such that

$$
|\mathbf{x}-\mathbf{z}|=\min \{|\mathbf{x}-\mathbf{y}|: \mathbf{y} \in K\} .
$$

This $\mathbf{z}$ will be denoted as $P \mathbf{x}$. Hint: First note you do not know $K$ is compact. Establish the parallelogram identity if you have not already done so,

$$
|\mathbf{u}-\mathbf{v}|^{2}+|\mathbf{u}+\mathbf{v}|^{2}=2|\mathbf{u}|^{2}+2|\mathbf{v}|^{2}
$$

Then let $\left\{\mathbf{z}_{k}\right\}$ be a minimizing sequence,

$$
\lim _{k \rightarrow \infty}\left|\mathbf{z}_{k}-\mathbf{x}\right|^{2}=\inf \{|\mathbf{x}-\mathbf{y}|: \mathbf{y} \in K\} \equiv \lambda
$$

Now using convexity, explain why

$$
\left|\frac{\mathbf{z}_{k}-\mathbf{z}_{m}}{2}\right|^{2}+\left|\mathbf{x}-\frac{\mathbf{z}_{k}+\mathbf{z}_{m}}{2}\right|^{2}=2\left|\frac{\mathbf{x}-\mathbf{z}_{k}}{2}\right|^{2}+2\left|\frac{\mathbf{x}-\mathbf{z}_{m}}{2}\right|^{2}
$$

and then use this to argue $\left\{\mathbf{z}_{k}\right\}$ is a Cauchy sequence. Then if $\mathbf{z}_{i}$ works for $i=1,2$, consider $\left(\mathbf{z}_{1}+\mathbf{z}_{2}\right) / 2$ to get a contradiction.
10. In Problem 9 show that $P \mathbf{x}$ satisfies the following variational inequality.

$$
(\mathbf{x}-P \mathbf{x}) \cdot(\mathbf{y}-P \mathbf{x}) \leq 0
$$

for all $\mathbf{y} \in K$. Then show that $\left|P \mathbf{x}_{1}-P \mathbf{x}_{2}\right| \leq\left|\mathbf{x}_{1}-\mathbf{x}_{2}\right|$. Hint: For the first part note that if $\mathbf{y} \in K$, the function $t \rightarrow|\mathbf{x}-(P \mathbf{x}+t(\mathbf{y}-P \mathbf{x}))|^{2}$ achieves its minimum on $[0,1]$ at $t=0$. For the second part,

$$
\left(\mathbf{x}_{1}-P \mathbf{x}_{1}\right) \cdot\left(P \mathbf{x}_{2}-P \mathbf{x}_{1}\right) \leq 0,\left(\mathbf{x}_{2}-P \mathbf{x}_{2}\right) \cdot\left(P \mathbf{x}_{1}-P \mathbf{x}_{2}\right) \leq 0
$$

Explain why

$$
\left(\mathbf{x}_{2}-P \mathbf{x}_{2}-\left(\mathbf{x}_{1}-P \mathbf{x}_{1}\right)\right) \cdot\left(P \mathbf{x}_{2}-P \mathbf{x}_{1}\right) \geq 0
$$

and then use a some manipulations and the Cauchy Schwarz inequality to get the desired inequality. Thus $P$ is called a retraction onto $K$.
11. Establish the Brouwer fixed point theorem for any convex compact set in $\mathbb{R}^{n}$. Hint: If $K$ is a compact and convex set, let $R$ be large enough that the closed ball, $D(\mathbf{0}, R) \supseteq K$. Let $P$ be the projection onto $K$ as in Problem 10 above. If $\mathbf{f}$ is a continuous map from $K$ to $K$, consider $\mathbf{f} \circ P$. You want to show $\mathbf{f}$ has a fixed point in $K$.
12. Suppose $D$ is a set which is homeomorphic to $\overline{B(\mathbf{0}, 1)}$. This means there exists a continuous one to one map, $\mathbf{h}$ such that $\mathbf{h}(\overline{B(\mathbf{0}, 1)})=D$ such that $\mathbf{h}^{-1}$ is also one to one. Show that if $\mathbf{f}$ is a continuous function which maps $D$ to $D$ then $\mathbf{f}$ has a fixed point. Now show that it suffices to say that $\mathbf{h}$ is one to one and continuous. In this case the continuity of $\mathbf{h}^{-1}$ is automatic. Sets which have the property that continuous functions taking the set to itself have at least one fixed point are said to have the fixed point property. Work Problem 7 using this notion of fixed point property. What about a solid ball and a donut? Could these be homeomorphic?
13. Suppose $\Omega$ is any open bounded subset of $\mathbb{R}^{n}$ which contains $\mathbf{0}$ and that $\mathbf{f}: \bar{\Omega} \rightarrow \mathbb{R}^{n}$ is continuous with the property that

$$
\mathbf{f}(\mathbf{x}) \cdot \mathbf{x} \geq 0
$$

for all $\mathbf{x} \in \partial \Omega$. Show that then there exists $\mathbf{x} \in \bar{\Omega}$ such that $\mathbf{f}(\mathbf{x})=\mathbf{0}$. Give a similar result in the case where the above inequality is replaced with $\leq$. Hint: You might consider the function

$$
\mathbf{h}(t, \mathbf{x}) \equiv t \mathbf{f}(\mathbf{x})+(1-t) \mathbf{x}
$$

14. Suppose $\Omega$ is an open set in $\mathbb{R}^{n}$ containing $\mathbf{0}$ and suppose that $\mathbf{f}: \bar{\Omega} \rightarrow \mathbb{R}^{n}$ is continuous and $|\mathbf{f}(\mathbf{x})| \leq|\mathbf{x}|$ for all $\mathbf{x} \in \partial \Omega$. Show $\mathbf{f}$ has a fixed point in $\bar{\Omega}$. Hint: Consider $\mathbf{h}(t, \mathbf{x}) \equiv t(\mathbf{x}-\mathbf{f}(\mathbf{x}))+(1-t) \mathbf{x}$ for $t \in[0,1]$. If $t=1$ and some $\mathbf{x} \in \partial \Omega$ is sent to $\mathbf{0}$, then you are done. Suppose therefore, that no fixed point exists on $\partial \Omega$. Consider $t<1$ and use the given inequality.
15. Let $\Omega$ be an open bounded subset of $\mathbb{R}^{n}$ and let $\mathbf{f}, \mathbf{g}: \bar{\Omega} \rightarrow \mathbb{R}^{n}$ both be continuous such that

$$
|\mathbf{f}(\mathbf{x})|-|\mathbf{g}(\mathbf{x})|>0
$$

for all $\mathbf{x} \in \partial \Omega$. Show that then

$$
d(\mathbf{f}-\mathbf{g}, \Omega, \mathbf{0})=d(\mathbf{f}, \Omega, \mathbf{0})
$$

Show that if there exists $\mathbf{x} \in \mathbf{f}^{-1}(\mathbf{0})$, then there exists $\mathbf{x} \in(\mathbf{f}-\mathbf{g})^{-1}(\mathbf{0})$. Hint: You might consider $\mathbf{h}(t, \mathbf{x}) \equiv(1-t) \mathbf{f}(\mathbf{x})+t(\mathbf{f}(\mathbf{x})-\mathbf{g}(\mathbf{x}))$ and argue $\mathbf{0} \notin \mathbf{h}(t, \partial \Omega)$ for $t \in[0,1]$.
16. Suppose $\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ is continuous and satisfies

$$
|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})| \geq \alpha|\mathbf{x}-\mathbf{y}|, \alpha>0
$$

Show that $\mathbf{f}$ must map $\mathbb{R}^{n}$ onto $\mathbb{R}^{n}$. Hint: First show $\mathbf{f}$ is one to one. Then use invariance of domain. Next show, using the inequality, that the points not in $\mathbf{f}\left(\mathbb{R}^{n}\right)$ must form an open set because if $\mathbf{y}$ is such a point, then there can be no sequence $\left\{\mathbf{f}\left(\mathbf{x}_{n}\right)\right\}$ converging to it. Finally recall that $\mathbb{R}^{n}$ is connected.
It is obvious that $\mathbf{f}$ is one to one. This follows from the inequality. If $U$ are the points not in the image of $\mathbf{f}$, then $U$ must be open because if not, then for $\mathbf{y}$ one of these points, there would be a sequence $\mathbf{f}\left(\mathbf{x}_{n}\right) \rightarrow \mathbf{y}$. Then by the inequality, $\left\{\mathbf{x}_{n}\right\}$ is a Cauchy sequence and so it converges to $\mathbf{x}$. Thus $\mathbf{f}(\mathbf{x})=\lim _{n \rightarrow \infty} \mathbf{f}\left(\mathbf{x}_{n}\right)=\mathbf{y}$. Now by invariance of domain, $\mathbf{f}\left(\mathbb{R}^{n}\right)$ is open. However, $\mathbb{R}^{n}$ is connected and so in fact, $U$ is empty.
17. Let $f: \mathbb{C} \rightarrow \mathbb{C}$ where $\mathbb{C}$ is the field of complex numbers. Thus $f$ has a real and imaginary part. Letting $z=x+i y$,

$$
f(z)=u(x, y)+i v(x, y)
$$

Recall that the norm in $\mathbb{C}$ is given by $|x+i y|=\sqrt{x^{2}+y^{2}}$ and this is the usual norm in $\mathbb{R}^{2}$ for the ordered pair $(x, y)$. Thus complex valued functions defined on $\mathbb{C}$ can be considered as $\mathbb{R}^{2}$ valued functions defined on some subset of $\mathbb{R}^{2}$. Such a complex function is said to be analytic if the usual definition holds. That is

$$
f^{\prime}(z)=\lim _{h \rightarrow 0} \frac{f(z+h)-f(z)}{h}
$$

In other words,

$$
\begin{equation*}
f(z+h)=f(z)+f^{\prime}(z) h+o(h) \tag{23.10.19}
\end{equation*}
$$

at a point $z$ where the derivative exists. Let $f(z)=z^{n}$ where $n$ is a positive integer. Thus $z^{n}=p(x, y)+i q(x, y)$ for $p, q$ suitable polynomials in $x$ and $y$. Show this function is analytic. Next show that for an analytic function and $u$ and $v$ the real and imaginary parts, the Cauchy Riemann equations hold.

$$
u_{x}=v_{y}, u_{y}=-v_{x} .
$$

In terms of mappings show 23.10.19 has the form

$$
\begin{aligned}
& \binom{u\left(x+h_{1}, y+h_{2}\right)}{v\left(x+h_{1}, y+h_{2}\right)} \\
= & \binom{u(x, y)}{v(x, y)}+\left(\begin{array}{ll}
u_{x}(x, y) & u_{y}(x, y) \\
v_{x}(x, y) & v_{y}(x, y)
\end{array}\right)\binom{h_{1}}{h_{2}}+\mathbf{o}(\mathbf{h}) \\
= & \binom{u(x, y)}{v(x, y)}+\left(\begin{array}{cc}
u_{x}(x, y) & -v_{x}(x, y) \\
v_{x}(x, y) & u_{x}(x, y)
\end{array}\right)\binom{h_{1}}{h_{2}}+\mathbf{o}(\mathbf{h})
\end{aligned}
$$

where $\mathbf{h}=\left(h_{1}, h_{2}\right)^{T}$ and $h$ is given by $h_{1}+i h_{2}$. Thus the determinant of the above matrix is always nonnegative. Letting $B_{r}$ denote the ball $B(0, r)=B((0,0), r)$ show

$$
d\left(f, B_{r}, \mathbf{0}\right)=n .
$$

where $f(z)=z^{n}$. In terms of mappings on $\mathbb{R}^{2}$,

$$
\mathbf{f}(x, y)=\binom{u(x, y)}{v(x, y)}
$$

Thus show

$$
d\left(\mathbf{f}, B_{r}, \mathbf{0}\right)=n
$$

Hint: You might consider

$$
g(z) \equiv \prod_{j=1}^{n}\left(z-a_{j}\right)
$$

where the $a_{j}$ are small real distinct numbers and argue that both this function and $f$ are analytic but that $\mathbf{0}$ is a regular value for $\mathbf{g}$ although it is not so for $\mathbf{f}$. However, for each $a_{j}$ small but distinct $d\left(\mathbf{f}, B_{r}, \mathbf{0}\right)=d\left(\mathbf{g}, B_{r}, \mathbf{0}\right)$.
18. Using Problem 17, prove the fundamental theorem of algebra as follows. Let $p(z)$ be a nonconstant polynomial of degree $n$,

$$
p(z)=a_{n} z^{n}+a_{n-1} z^{n-1}+\cdots
$$

Show that for large enough $r,|p(z)|>\left|p(z)-a_{n} z^{n}\right|$ for all $z \in \partial B(0, r)$. Now from Problem 15 you can conclude $d\left(p, B_{r}, 0\right)=d\left(f, B_{r}, 0\right)=n$ where $f(z)=a_{n} z^{n}$.
19. The proof of Sard's lemma made use of the hard Vitali covering theorem. Here is another way to do something similar. Let $U$ be a bounded open set and let $\mathbf{f}: U \rightarrow \mathbb{R}^{n}$ be in $C^{1}(U)$. Let $S$ denote the set of $x \in U$ such that $D \mathbf{f}(x)$ has rank less than $n$. Thus it is a closed set. Let $U_{m}=\{\mathbf{x} \in U:\|D \mathbf{f}(\mathbf{x})\| \leq m\}$, a closed set. It suffices to show that for $S_{m} \equiv U_{m} \cap S, \mathbf{f}\left(S_{m}\right)$ has measure zero because $\mathbf{f}(S)=\cup_{m} \mathbf{f}\left(S_{m}\right)$ these sets increasing in $m$. By definition of differentiability,

$$
\lim _{k \rightarrow \infty} \sup _{\|\mathbf{v}\| \leq 1 / k} \frac{\|\mathbf{f}(\mathbf{x}+\mathbf{v})-\mathbf{f}(\mathbf{x})-D \mathbf{f}(\mathbf{x}) \mathbf{v}\|}{\|\mathbf{v}\|}=0
$$

for each $\mathbf{x} \in U$. Explain why the above function of $\mathbf{x}$ is measurable. Now by Eggoroff's theorem, there is measurable set $A$ of measure less than $\frac{\varepsilon}{m^{n} 10^{n}}$ such that off $A$, the convergence is uniform. Let $\mathscr{C}_{k}$ be a countable union of non overlapping half open rectangles one of which is of the form $\prod_{i=1}^{n}\left(a_{i}, b_{i}\right]$ such that each has diameter less than $2^{-k}$. Consider the half open rectangles which have nonempty intersection with $S_{m} \backslash A, \mathscr{I}_{k}$. Then repeat the argument given in the first section of this chapter. Show that for $k$ large enough, the rank condition and uniform convergence above implies that $m_{n}\left(\cup\left\{\mathbf{f}(I): I \in \mathscr{I}_{k}\right\}\right)$ is less than $\varepsilon$. Now show that $\mathbf{f}(A)$ is contained in a set of measure no more than $m^{n} 10^{n} \frac{\varepsilon}{m^{n} 10^{n}}=2 \varepsilon$. Thus $\mathbf{f}\left(S_{m}\right)$ has measure no more than $3 \varepsilon$. Since $\varepsilon$ is arbitrary, this establishes the desired conclusion.
20. Let $X$ be a Banach space and let $\Omega$ be a symmetric and bounded open set. Let $F: \Omega \rightarrow X$ be odd and compact $0 \notin(I-F)(\partial \Omega)$. Show using Corollary 23.9.3 that $D(I-F, \Omega, 0)$ is an odd integer.
21. Let $F$ be compact. Suppose $I-F$ is one to one on $\overline{B(0, r)}$. Then using similar reasoning to the finite dimensional case, show that there is a $\delta>0$ such that

$$
(I-F)(0)+B(0, \delta) \subseteq(I-F)(B(0, r))
$$

22. Let $F$ be compact. Suppose $I-F$ is locally one to one on an open set $\Omega$. Show that $(I-F)$ maps open sets to open sets. This is a version of invariance of domain.
23. Suppose $(I-F)$ is locally one to one and $F$ is compact. Suppose also that

$$
\lim _{\|x\| \rightarrow \infty}\|(I-F) x\|=\infty
$$

Show that $(I-F)$ is onto.
24. As a variation of the above problem, suppose $F: X \rightarrow X$ is compact and

$$
\lim _{\|x\| \rightarrow \infty} \frac{\|F(x)\|}{\|x\|}=0
$$

Then $I-F$ is onto. Note that $I-F$ is not one to one.
25. Suppose $F$ is compact and $\|(I-F) x-(I-F) y\| \geq \alpha\|x-y\|$. Show that then $(I-F)$ is onto.
26. The Jordan curve theorem is: Let $C$ denote the unit circle,

$$
\left\{(x, y) \in \mathbb{R}^{2}: x^{2}+y^{2}=1\right\}
$$

Suppose $\gamma: C \rightarrow \Gamma \subseteq \mathbb{R}^{2}$ is one to one onto and continuous. Then $\mathbb{R}^{2} \backslash \Gamma$ consists of two components, a bounded component (called the inside) $U_{1}$ and an unbounded component (called the outside), $U_{2}$. Also the boundary of each of these two components of $\mathbb{R}^{2} \backslash \Gamma$ is $\Gamma$ and $\Gamma$ has empty interior. Using the Jordan separation theorem, prove this important result.
27. This problem is from [43] Recall Theorem 23.9.11. It allowed you to say that $D(I-F, \Omega, 0)=0$ provided $0 \notin \overline{F(\partial \Omega)}$ and $\lambda x \neq F x$ for all $x \in \partial \Omega, \lambda \in[0,1]$. This was for $F$ compact and defined on an infinite dimensional space $X$. Suppose now that $F$ is compact and $F: \bar{\Omega} \rightarrow X$ where $0 \in \Omega$ an open set in $X$. Suppose also that $F(0)=0$ and that

$$
\lim \inf _{x \rightarrow 0} \frac{\|F(x)\|}{\|x\|} \equiv \lim _{r \rightarrow 0+} \inf \left\{\frac{\|F(x)\|}{\|x\|}:\|x\| \leq r\right\}=\infty
$$

Show that there is a sequence $\alpha_{n} \rightarrow 0$ each $\alpha_{n} \neq 0$, and for some $x_{n} \neq 0, x_{n}-$ $\alpha_{n} F\left(x_{n}\right)=0$. Note that when $\alpha=0$, there is only one solution to $(I-\alpha F)(x)=0$,
but this says that there are many small $\alpha_{n} \neq 0$ for which there is a nonzero solution to $\left(I-\alpha_{n} F\right)(x)=0$. That is there exist arbitrarily small $\alpha_{n}$ such that $\left(I-\alpha_{n}\right) F\left(x_{n}\right)=$ 0 . This says that 0 is a bifurcation point for $I-\alpha F$. Hint: Let $\alpha_{n} \downarrow 0$ and pick $r_{n}$ such that for all $\|x\|=r_{n}$,

$$
\left\|\alpha_{n} F(x)\right\|>\|x\|
$$

Thus $0 \notin \overline{\alpha_{n} F\left(\partial B\left(0, r_{n}\right)\right)}$ and also $\alpha_{n} F(x) \neq \lambda x$ for all $x \in \partial B\left(0, r_{n}\right)$. Use the theorem to conclude that

$$
D\left(I-\alpha_{n} F, B\left(0, r_{n}\right), 0\right)=0
$$

and then consider the homotopy $I-\alpha_{n} t F$. If it sends no point of $\partial B\left(0, r_{n}\right)$ to 0 then you would have

$$
D\left(I-\alpha_{n} t F, B\left(0, r_{n}\right), 0\right)=D\left(I, B\left(0, r_{n}\right), 0\right)=1
$$

## Chapter 24

## Critical Points

### 24.1 Mountain Pass Theorem In Hilbert Space

This is from Evans [49]. It is an interesting theorem. See also [55] for more general versions. It has to do with differentiable functions defined on a Hilbert space $H$. Thus $I: H \rightarrow \mathbb{R}$ will be differentiable. Then the following is the Palais Smale condition.

Definition 24.1.1 A functional I satisfies the Palais Smale conditions means that if $\left\{I\left(u_{k}\right)\right\}$ is a bounded sequence and $I^{\prime}\left(u_{k}\right) \rightarrow 0$, then $\left\{u_{k}\right\}$ is precompact. That is, it has a subsequence which converges.

It will be assumed that $I$ is $C^{1}(H ; \mathbb{R})$ and also that $I^{\prime}$ is Lipschitz on bounded sets. By $I^{\prime}(u)$ is meant the element of $H$ such that

$$
I(u+v)=I(u)+\left(I^{\prime}(u), v\right)_{H}+o(v)
$$

Such exists because of the Riesz representation theorem. Note that, from the assumption that $I^{\prime}$ is Lipschitz continuous, it follows that $I^{\prime}$ is bounded on every bounded set.

First is a deformation theorem. The notation $[I(u) \in S]$ means $\{u: I(u) \in S\}$.
Theorem 24.1.2 Let I be $C^{1}$, I is non constant, satisfy the Palais Smale condition, and $I^{\prime}$ is Lipschitz continuous on bounded sets. Also suppose that $c \in \mathbb{R}$ is such that either $[I(u) \in[c-\delta, c+\delta]]=\emptyset$ for some $\delta>0$ or $[I(u) \in[c-\delta, c+\delta]] \neq \emptyset$ for all $\delta>0$ and IF $I(u)=c$, then $I^{\prime}(u) \neq 0$. Then for each sufficiently small $\varepsilon>0$, there is a constant $\delta \in(0, \varepsilon)$ and a function $\eta:[0,1] \times H \rightarrow H$ such that

1. $\eta(0, u)=u$
2. $\eta(1, u)=u$ on $[I(u) \notin(c-\varepsilon, c+\varepsilon)]$
3. $I(\eta(t, u)) \leq I(u)$
4. $\eta(1,[I(u) \leq c+\delta]) \subseteq[I(u) \leq c-\delta]$

The main part of this conclusion is the statement about $u \rightarrow \eta(1, u)$ contained in parts 2. and 4. The other two parts are there to facilitate these two although they are certainly interesting for their own sake.

Proof: Suppose $[I(u) \in[c-\delta, c+\delta]]=\emptyset$ for some $\delta>0$. Then $[I(u) \leq c+\delta / 2] \subseteq$ $[I(u) \leq c-\delta / 2]$ and you could take $\varepsilon=\delta$ and let $\eta(t, u)=u$. Therefore, assume

$$
[I(u) \in[c-\delta, c+\delta]] \neq \emptyset
$$

for all $\delta>0$. Since $I$ is nonconstant, $\varepsilon>0$ can be chosen small enough that

$$
[I(u) \notin(c-\varepsilon, c+\varepsilon)] \neq \emptyset
$$

Always let $\varepsilon$ be this small.

Claim 1: For all small enough $\varepsilon>0$, if $u \in[I(u) \in[c-\varepsilon, c+\varepsilon]], I^{\prime}(u) \neq 0$ and in fact, for such $\varepsilon$, there exists $\sigma(\varepsilon)>0$ such that $\sigma(\varepsilon)<\varepsilon,\left\|I^{\prime}(u)\right\|>\sigma(\varepsilon)$ for all $u \in$ $[I(u) \in[c-\varepsilon, c+\varepsilon]]$.

Proof of Claim 1: If claim is not so, then there is $\left\{u_{k}\right\}, \varepsilon_{k}, \sigma_{k} \rightarrow 0,\left\|I^{\prime}\left(u_{k}\right)\right\|<\sigma_{k}$, and $I\left(u_{k}\right) \in\left[c-\varepsilon_{k}, c+\varepsilon_{k}\right]$ but $\left\|I^{\prime}\left(u_{k}\right)\right\| \leq \sigma_{k}$. However, from the Palais Smale condition, there is a subsequence, still denoted as $u_{k}$ which converges to some $u$. Now $I\left(u_{k}\right) \in$ $\left[c-\varepsilon_{k}, c+\varepsilon_{k}\right]$ and so $I(u)=c$ while $I^{\prime}(u)=0$ contrary to the hypothesis. This proves Claim 1. From now on, $\varepsilon$ will be sufficiently small.

Now define for $\delta<\varepsilon$ (The description of small $\delta$ will be described later.)

$$
\begin{aligned}
A & \equiv[I(u) \notin(c-\varepsilon, c+\varepsilon)] \\
B & \equiv[I(u) \in[c-\delta, c+\delta]]
\end{aligned}
$$

Thus $A$ and $B$ are disjoint closed sets. Recall that it is assumed that $B \neq \emptyset$ since otherwise, there is nothing to prove. Also it is assumed throughout that $\varepsilon>0$ is such that $A \neq \emptyset$ thanks to $I$ not being constant. Thus these are nonempty sets and we do not have to fuss with worrying about meaning when one is empty.

Claim 2: For any $u, \operatorname{dist}(u, A)+\operatorname{dist}(u, B)>0$.
This is so because if not, then both would be zero and this requires that $u \in A \cap B$ since these sets are closed. But $A \cap B=\emptyset$.

Now define a function

$$
g(u) \equiv \frac{\operatorname{dist}(u, A)}{\operatorname{dist}(u, A)+\operatorname{dist}(u, B)}
$$

It is a continuous function of $u$ which has values in $[0,1]$. Consider the ordinary differential initial value problem

$$
\begin{gather*}
\eta^{\prime}(t, u)+g(u) h\left(\left\|I^{\prime}(\eta(t, u))\right\|\right) I^{\prime}(\eta(t, u))=0  \tag{24.1.1}\\
\eta(0, u)=u \tag{24.1.2}
\end{gather*}
$$

where $r \rightarrow h(r)$ is a decreasing function which has values in $(0,1]$ and equals 1 for $r \in[0,1]$ and equals $1 / r$ for $r>1$. Here $u$ is given and the $\eta^{\prime}$ is the time derivative is with respect to $t$. Thus, by assumption, the function

$$
\eta \rightarrow g(u) h\left(\left\|I^{\prime}(\eta)\right\|\right) I^{\prime}(\eta)
$$

is Lipschitz continuous on bounded sets and so there exists a solution to the above initial value problem valid for all $t \in[0,1]$. To see this, you can let $P$ be the projection map onto the closed ball of radius $M>\|u\|$ and the system

$$
\begin{gathered}
\eta^{\prime}(t, u)+g(u) h\left(\left\|I^{\prime}(P(\eta(t, u)))\right\|\right) I^{\prime}(P(\eta(t, u)))=0 \\
\eta(0, u)=u
\end{gathered}
$$

Then by Lipschitz continuity, there is a global solution for all $t \geq 0$. Hence there is a local solution to 24.1.1, 24.1.2. Note that

$$
\begin{aligned}
& \left\|g(u) h\left(\left\|I^{\prime}(P(\eta(t, u)))\right\|\right) I^{\prime}(P(\eta(t, u)))\right\| \\
= & g(u) h\left(\left\|I^{\prime}(P(\eta(t, u)))\right\|\right)\left\|I^{\prime}(P(\eta(t, u)))\right\| \leq 1
\end{aligned}
$$

Taking inner products with $\eta(t, u)$, and integrating $\int_{0}^{t}$ for this local solution,

$$
\begin{aligned}
& \frac{1}{2}\|\eta(t, u)\|^{2}-\frac{1}{2}\|u\|^{2}+\int_{0}^{t} g(u) h\left(\left\|I^{\prime}(P \eta(s, u))\right\|\right)\left(I^{\prime}(P \eta(s, u)), \eta(s, u)\right) d s=0 \\
& \frac{1}{2}\|\eta(t, u)\|^{2} \leq \frac{1}{2}\|u\|^{2}+\int_{0}^{t} g(u) h\left(\left\|I^{\prime}(P \eta(t, u))\right\|\right)\left\|I^{\prime}(P \eta(t, u))\right\|\|\eta(s, u)\| d s
\end{aligned}
$$

It follows that for $t \leq 1$,

$$
\begin{gathered}
\|\eta(t, u)\|^{2} \leq\|u\|^{2}+2 \int_{0}^{t}\|\eta(s, u)\| d s \\
\leq\|u\|^{2}+1+\int_{0}^{t}\|\eta(s, u)\|^{2} d s
\end{gathered}
$$

and so from Gronwall's inequality, for $t \leq 1$,

$$
\|\eta(t, u)\|^{2} \leq\left(\|u\|^{2}+1\right) e^{1}
$$

Thus we pick $M>e\left(\|u\|^{2}+1\right)$ and then we obtain that for $t \in[0,1]$, the projection map does not change anything. Hence there exists a solution to 24.1.1, 24.1.2 on $[0,1]$ as desired.

Then for this solution, $\eta(0, u)=u$ because of the above initial condition. If $u \in$ $[I(u) \notin[c-\varepsilon, c+\varepsilon]]$, then $u \in A$ and so $g(u)=0$ so $\eta(t, u)=u$ for all $t \in[0,1]$. This gives the first two conditions. Consider the third.

$$
\begin{aligned}
\frac{d}{d t}(I(\eta(t, u))) & =\left(I^{\prime}(\eta), \eta^{\prime}\right)=-\left(I^{\prime}(\eta), g(u) h\left(\left\|I^{\prime}(\eta)\right\|\right) I^{\prime}(\eta)\right) \\
& =-g(u) h\left(\left\|I^{\prime}(\eta)\right\|\right)\left\|I^{\prime}(\eta)\right\|^{2}
\end{aligned}
$$

and so this implies the third condition since it says that the function $t \rightarrow I(\eta(t, u))$ is decreasing.

It remains to consider the last condition. This involves choosing $\delta$ still smaller if necessary. It is desired to verify that

$$
\eta(1,[I(u) \leq c+\delta]) \subseteq[I(u) \leq c-\delta]
$$

Suppose it is not so. Then there exists $u \in[I(u) \leq c+\delta]$ but $I(\eta(1, u))>c-\delta$.

$$
\begin{aligned}
c-\delta & <I(\eta(1, u))=I(u)-\int_{0}^{1}\left(I^{\prime}(\eta), g(u) h\left(\left\|I^{\prime}(\eta)\right\|\right) I^{\prime}(\eta)\right) d t \\
& =I(u)-g(u) \int_{0}^{1} h\left(\left\|I^{\prime}(\eta)\right\|\right)\left\|I^{\prime}(\eta(t, u))\right\|^{2} d t \\
& <c+\delta-g(u) \int_{0}^{1} h\left(\left\|I^{\prime}(\eta)\right\|\right)\left\|I^{\prime}(\eta(t, u))\right\|^{2} d t
\end{aligned}
$$

Then

$$
c-2 \delta+g(u) \int_{0}^{1} h\left(\left\|I^{\prime}(\eta(t, u))\right\|\right)\left\|I^{\prime}(\eta(t, u))\right\|^{2} d t<c
$$

If $I(u) \leq c-\delta$, there is nothing to show because in this case $I(\eta(1, u)) \leq I(u) \leq c-\delta$. Hence we can assume that $I(u)>c-\delta$ and also that $I(u) \leq c+\delta$. Thus $u \in B$ and so $g(u)=1$. Thus

$$
c-2 \delta+\int_{0}^{1} h\left(\left\|I^{\prime}(\eta(t, u))\right\|\right)\left\|I^{\prime}(\eta(t, u))\right\|^{2} d t<c
$$

Also, it is being assumed that $I(\eta(1, u))>c-\delta$ and so by the third conclusion shown above, $\eta(t, u) \in B$ for $t \in[0,1]$. We also know that for such values of $\eta(t, u)$,

$$
\left\|I^{\prime}(\eta(t, u))\right\| \geq \sigma(\varepsilon)
$$

from Claim 1. If $\left\|I^{\prime}(\eta(t, u))\right\|>1$, the integrand equals

$$
\left\|I^{\prime}(\eta(t, u))\right\| \geq \sigma(\varepsilon)
$$

if $\left\|I^{\prime}(\eta(t, u))\right\| \leq 1$, the integrand is $\left\|I^{\prime}(\eta(t, u))\right\|^{2} \geq \sigma(\varepsilon)^{2}$. Thus

$$
c-2 \delta+\int_{0}^{1} \min \left(\sigma(\varepsilon), \sigma(\varepsilon)^{2}\right) d t<c
$$

and the only restriction on $\delta$ was that it should be smaller than $\varepsilon$. Although it was not mentioned above, $\delta$ was chosen so small that $-2 \delta+\min \left(\sigma(\varepsilon), \sigma(\varepsilon)^{2}\right)>0$. Hence this yields a contradiction. Thus the last conclusion is verified.

Imagine a valley surrounded by a ring of mountains. On the other side of this ring of moutains, there is another low place. Then there must be some path from the valley to the exterior low place which goes through a point where the gradient equals 0 , the gradient being the gradient of a function $f$ which gives the altitude of the land. This is the idea of the mountain pass theorem. The critical point where $\nabla f=0$ is the mountain pass.

Theorem 24.1.3 Let $H$ be a Hilbert space and let $I: H \rightarrow \mathbb{R}$ be a $C^{1}$ functional having $I^{\prime}$ Lipschitz continuous and such that I satisfies the Palais Smale condition. Suppose $I(0)=0$ and $I(u) \geq a>0$ for all $\|u\|=r$. Suppose also that there exists $v,\|v\|>r$ such that $I(v) \leq 0$. Then define

$$
\Gamma \equiv\{g \in C([0,1] ; H): g(0)=0, g(1)=v\}
$$

Let

$$
c \equiv \inf _{g \in \Gamma 0 \leq t \leq 1} \max _{0} I(g(t))
$$

Then $c$ is a critical value of I meaning that there exists $u$ such that $I(u)=c$ and $I^{\prime}(u)=0$. In particular, there is $u \neq 0$ such that $I^{\prime}(u)=0$.

Proof: First note that $c \geq a>0$. Suppose $c$ is not a critical value. Then by the deformation theorem, for $\varepsilon>0, \varepsilon$ sufficiently small, there is $\eta: H \rightarrow H$ and a $\delta<\varepsilon$ small enough that

$$
\eta([I(u) \leq c+\delta]) \subseteq[I(u) \leq c-\delta]
$$

and $\eta$ leaves unchanged $[I(u) \notin(c-\varepsilon, c+\varepsilon)]$. Then there is $g \in \Gamma$ such that

$$
\max _{t \in[0,1]} I(g(t))<c+\delta
$$

Then in particular, $I(g(t))<c+\delta$ for every $t$. Hence you look at $\eta \circ g$. We know that $g(0), g(1)$ are both in the set $[I(u) \notin(c-\varepsilon, c+\varepsilon)]$ because they are both 0 and so $\eta$ leaves these unchanged. Hence $\eta \circ g \in \Gamma$ and

$$
I(\eta \circ g(t)) \leq c-\delta
$$

for all $t \in[0,1]$. Thus
which is clearly a contradiction.
The Palais Smale conditions are pretty restrictive. For example, let $I(x)=\cos x$. Thus $I: \mathbb{R} \rightarrow \mathbb{R}$. Then let $u_{k}=k \pi$. Clearly $I\left(u_{k}\right)$ is bounded and $\lim _{k \rightarrow \infty} I\left(u_{k}\right)=0$ but $\left\{u_{k}\right\}$ is not precompact. However, here is a simple case which does satisfy the Palais Smale conditions.

Example 24.1.4 Let $I: \mathbb{R}^{d} \rightarrow \mathbb{R}$ satisfy $\lim _{|\mathbf{x}| \rightarrow \infty} I(\mathbf{x})=\infty$. Then I satisfies the Palais Smale conditions.

The growth condition implies that if $I\left(\mathbf{x}_{k}\right)$ is bounded, then so is $\left\{\mathbf{x}_{k}\right\}$ and so this sequence is precompact. Nothing needs to be said about $I^{\prime}\left(\mathbf{x}_{k}\right)$.

### 24.1.1 A Locally Lipschitz Selection, Pseudogradients

When you have a functional $\phi$ defined on a Banach space $X, \phi^{\prime}(u)$ is in $X^{\prime}$ and it isn't obvious how you can understand it in terms of an element in $X$ like what is done with Hilbert space using the Riesz representation theorem. However, there is something called a pseudogradient which is defined next.

Definition 24.1.5 Let $\phi: X \rightarrow \mathbb{R}$ be $C^{1}$. Then $v$ is a pseudogradient for $\phi$ at $x$ if the following hold.

1. $\|v\|_{X} \leq 2\left\|\phi^{\prime}(x)\right\|_{X^{\prime}}$
2. $\left\|\phi^{\prime}(x)\right\|_{X^{\prime}}^{2} \leq\left\langle\phi^{\prime}(x), v\right\rangle$

A pseudogradient field $V$ is a locally Lipschitz selection of $G(x)$ where $G(x)$ is defined to be the set of pseudogradients of $\phi$ at $x$. Thus $V(x) \in G(x)$ and $V(x)$ is a pseudogradient for $\phi$ at each $x$ a regular point of $\phi$.

Note how this generalizes the case of Hilbert space. In the Hilbert space case, you have $\phi^{\prime}(x)$ which technically is in $H^{\prime}$ and you have the gradient, written here as $\nabla \phi$ which is in $H$ such that

$$
(\nabla \phi(x), v)_{H} \equiv\left\langle\phi^{\prime}(x), v\right\rangle_{H^{\prime}, H}
$$

the existence of $\nabla \phi(x)$ coming from the Riesz representation theorem which also gives that $\nabla \phi(x)=R^{-1} \phi^{\prime}(x)$ and so $\|\nabla \phi(x)\|_{H}=\left\|\phi^{\prime}(x)\right\|_{H^{\prime}}$ so the above two conditions hold for the gradient field except for one thing. Why is $x \rightarrow \nabla \phi(x)$ locally Lipschitz. We don't know this, but with a pseudogradient field, we do. Also, the pseudogradient field is only required at regular points of $\phi$ where $\phi^{\prime}(x) \neq 0$. If you had strict inequalities holding in the above definition, then they would continue to hold for $\hat{x}$ near $x$. Thus if you had

$$
\|v\|_{X}<2\left\|\phi^{\prime}(x)\right\|_{X^{\prime}}, \quad\left\|\phi^{\prime}(x)\right\|_{X^{\prime}}^{2}<\left\langle\phi^{\prime}(x), v\right\rangle
$$

and $\Gamma(x)$ were the set of such $v$, then there would be an open set $U$ containing $x$ such that $\cap_{\hat{x} \in U} \Gamma(\hat{x}) \neq \emptyset$. In fact, the intersection would contain $v$.

This very nice lemma is from Gasinski L. and Papageorgiou N. [55]. It is a lovely application of Stone's theorem and partitions of unity for a metric space.

Lemma 24.1.6 Let $Y$ be a metric space and let $X$ be a normed linear space. (We will want to add in $X$.) Let $\Gamma: Y \rightarrow \mathscr{P}(X)$ such that $\Gamma(y)$ is a nonempty convex set. Suppose that for each $y \in Y$, there exists an open set $U$ containing $y$ such that

$$
\emptyset \neq \cap_{\hat{y} \in U} \Gamma(\hat{y})
$$

Then there exists a locally Lipschitz map $\gamma: Y \rightarrow X$ such that $\gamma(y) \in \Gamma(y)$ for all $y$.
Proof: Let $\mathscr{U}$ denote the collection of all open sets $U$ such that the nonempty intersection described above holds. Let $\mathscr{V}$ be a locally finite open refinement which also covers. Thus for any $V \in \mathscr{V}$

$$
\emptyset \neq \cap_{\hat{y} \in V} \Gamma(\hat{y})
$$

because it is a smaller intersection. Let $\left\{\phi_{V}\right\}_{V \in \mathscr{V}}$ be a partition of unity subordinate to the open covering $\mathscr{V}$. In fact, we can have $\phi_{V}$ locally Lipschitz. This follows from the above construction of the partition of unity in Theorem 16.1.1. Pick $x_{V} \in \cap_{\hat{y} \in V} \Gamma(\hat{y})$. Then consider

$$
\gamma(y)=\sum_{V \in \mathscr{V}} x_{V} \phi_{V}(y)
$$

It is clearly locally Lipschitz because near any point $y$, it is a finite sum of Lipschitz functions. Pick $y \in Y$. Then it is in some $V \in \mathscr{V}$. In fact, it is finitely many, $V_{1}, \cdots, V_{n}$ and for other $V \in \mathscr{V}, \phi_{V}(y)=0$. Therefore,

$$
\gamma(y)=\sum_{i=1}^{n} x_{V_{i}} \phi_{V_{i}}(y)
$$

which is a convex combination of the $x_{V_{i}}$. Now $x_{V_{i}} \in \cap_{\hat{y} \in V_{i}} \Gamma(\hat{y}) \subseteq \Gamma(y)$, this for each $i$. Hence this is a convex combination of points in a nonempty convex set $\Gamma(y)$. Thus $\gamma(y) \in$ $\Gamma(y)$.

The following lemma says that if $\phi$ is $C^{1}$ on $X$, then it has a pseudogradient field on $\left\{x: \phi^{\prime}(x) \neq 0\right\}$, the set of regular points.

Lemma 24.1.7 Let $\phi$ be a $C^{1}$ function defined on $X$ a Banach space. Then there exists a pseudogradient field for $\phi$ on the set of regular points. $(V(x) \in G(x)$ and $x \rightarrow V(x)$ is locally Lipschitz on the set of regular points.)

Proof: First consider whether $G(x)$, the set of pseudogradients of $\phi$ at $x$ is nonempty for $\phi^{\prime}(x) \neq 0$. From the definition of the operator norm, there exists $u$ such that $\|u\|_{X}=1$ and $\left\langle\phi^{\prime}(x), u\right\rangle \geq \delta\left\|\phi^{\prime}(x)\right\|_{X^{\prime}}$ where $\delta \in(0,1)$. Then let $v=r u\left\|\phi^{\prime}(x)\right\|_{X^{\prime}}$ where $r \in(1,2)$.

$$
\left\langle\phi^{\prime}(x), v\right\rangle=\left\langle\phi^{\prime}(x), r u\left\|\phi^{\prime}(x)\right\|\right\rangle=r\left\langle\phi^{\prime}(x), u\right\rangle\left\|\phi^{\prime}(x)\right\| \geq r \delta\left\|\phi^{\prime}(x)\right\|^{2}
$$

Then choose $r, \delta$ such that $r \delta>1$ and $r<2$. Then if these were chosen this way in the above reasoning, it follows that

$$
\|v\|<2\left\|\phi^{\prime}(x)\right\| \text { and }\left\langle\phi^{\prime}(x), v\right\rangle>\left\|\phi^{\prime}(x)\right\|^{2}
$$

That $\phi^{\prime}(x) \neq 0$ is needed to insure that the above strict inequalities hold.
Thus, letting $Y$ be the metric space consisting of the regular points of $\phi$, the continuity of $\phi^{\prime}$ implies that the above inequalities persist for all $y$ close enough to $x$. Thus there is an open set $U$ containing $x$ such that $v$ satisfies the above inequalities for $x$ replaced with arbitrary $y \in U$. Thus

$$
v \in \cap_{y \in U} G(y)
$$

Since it is clear that each $G(y)$ is convex, Lemma 24.1.6 implies the existence of a locally Lipschitz selection from $G$. That is $x \rightarrow V(x)$ is locally Lipschitz and $V(x) \in G(x)$ for all regular $x$.

It will be important to consider $y^{\prime}=f(y)$ where $f$ is locally Lipschitz and $y$ is just in a Banach space. This is more complicated than in Hilbert space because of the lack of a convenient projection map.

Theorem 24.1.8 Let $f: U \rightarrow X$ be locally Lipschitz, where $X$ is a Banach space and $U$ is an open set. Then there exists a unique local solution to the IVP

$$
y^{\prime}=f(y), \quad y(0)=y_{0} \in U
$$

Proof: Let $B$ be a closed ball of radius $R$ centered at $y_{0}$ such that $f$ has Lipschitz constant $K$ on $B$. Then

$$
y_{1}(t)=y_{0}+\int_{0}^{t} f\left(y_{0}\right) d s
$$

and if $y_{n}(t)$ has been obtained,

$$
\begin{equation*}
y_{n+1}(t)=y_{0}+\int_{0}^{t} f\left(y_{n}(s)\right) d s \tag{24.1.3}
\end{equation*}
$$

Now $t<T$ where $T$ is so small that $\left\|f\left(y_{0}\right)\right\| T e^{K T}<R$.
Claim: $\left\|y_{n}(t)-y_{n-1}(t)\right\| \leq\left\|f\left(y_{0}\right)\right\| t^{n} K^{n-1} \frac{1}{(n-1)!}$.
Proof of claim: First

$$
\left\|y_{1}(t)-y_{0}\right\| \leq \int_{0}^{t}\left\|f\left(y_{0}\right)\right\| d s \leq\left\|f\left(y_{0}\right)\right\| t
$$

Now suppose it is so for $n$. Then

$$
\left\|y_{n+1}(t)-y_{n}(t)\right\| \leq \int_{0}^{t}\left\|f\left(y_{n}(s)\right)-f\left(y_{n-1}(s)\right)\right\| d s
$$

By induction, $y_{n}(s), y_{n-1}(s)$ are still in $B$. This is because

$$
\begin{align*}
& \left\|y_{n}(t)-y_{0}\right\| \leq \sum_{k=1}^{n}\left\|y_{k}(t)-y_{k-1}(t)\right\| \\
& \quad \leq \sum_{k=1}^{n}\left\|f\left(y_{0}\right)\right\| \frac{1}{(k-1)!} t^{k} K^{k-1} \\
& \quad \leq\left\|f\left(y_{0}\right)\right\| t e^{K t}<R \tag{24.1.4}
\end{align*}
$$

showing that $y_{n}(t)$ stays in $B$. Then since all values of the iterates remain in $B$, induction gives

$$
\begin{aligned}
& \left\|y_{n+1}(t)-y_{n}(t)\right\| \leq \int_{0}^{t} K\left\|y_{n}(s)-y_{n-1}(s)\right\| d s \\
& \leq \quad K \int_{0}^{t}\left\|f\left(y_{0}\right)\right\| \frac{1}{(n-1)!} s^{n} K^{n-1} d s=K^{n} \frac{1}{(n-1)!}\left\|f\left(y_{0}\right)\right\| \int_{0}^{t} s^{n} d s \\
& =\quad K^{n} \frac{1}{n!}\left\|f\left(y_{0}\right)\right\| t^{n+1}
\end{aligned}
$$

which proves the claim. Since the inequality of the claim shows that $\left\|y_{n}-y_{n-1}\right\|$ is summable, it follows that $\left\{y_{n}\right\}$ is a Cauchy sequence in $C([0, T], X)$. It satsifies $\left\|y_{n}-y_{0}\right\|<R$ and so $y_{n}$ converges uniformly to some $y \in C([0, T], X)$. Hence one can pass to a limit in 24.1.3 and obtain

$$
y(t)=y_{0}+\int_{0}^{t} f(y(s)) d s
$$

for $t \in[0, T]$. Also $\left\|y(t)-y_{0}\right\| \leq R$ and on $B\left(y_{0}, R\right), f$ is Lipschitz continuous so Gronwall's inequality gives uniqueness of solutions which remain in $B$.

Here is an alternate proof which other than the ugly lemma, seems more elegant to me. However, it is a useful lemma.

## Lemma 24.1.9 Define

$$
\gamma(x) \equiv\left\{\begin{array}{c}
x \text { if }\left\|x-y_{0}\right\| \leq R \\
y_{0}+\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R \text { if }\left\|x-y_{0}\right\|>R
\end{array}\right.
$$

Then $\|\gamma(x)-\gamma(y)\| \leq 3\|x-y\|$ for all $x, y \in X$. Thus

$$
\left\|\gamma(x)-y_{0}\right\| \leq R
$$

Proof: In case both of $x, y$ are in $B=\overline{B\left(y_{0}, R\right)}$, there is nothing to show. Suppose then that $\left\|y-y_{0}\right\| \leq R$ but $\left\|x-y_{0}\right\|>R$. Then, assuming $y-y_{0} \neq 0$,

$$
\|\gamma(x)-\gamma(y)\|=\left\|y_{0}+\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R-y\right\|=\left\|\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R-\left(y-y_{0}\right)\right\|
$$

$$
\begin{gathered}
=\left\|\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R-\frac{\left\|y-y_{0}\right\|}{\left\|y-y_{0}\right\|}\left(y-y_{0}\right)\right\| \\
\leq\left\|\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R-\frac{\left(y-y_{0}\right)}{\left\|y-y_{0}\right\|} R\right\|+ \\
+\left\|\frac{R}{\left\|y-y_{0}\right\|}\left(y-y_{0}\right)-\frac{\left\|y-y_{0}\right\|}{\left\|y-y_{0}\right\|}\left(y-y_{0}\right)\right\|=A+B
\end{gathered}
$$

Now

$$
\begin{gathered}
B=\left(R-\left\|y-y_{0}\right\|\right)<\left\|x-y_{0}\right\|-\left\|y-y_{0}\right\| \leq\|y-x\| \\
A \leq\left\|\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R-\frac{\left(y-y_{0}\right)}{\left\|y-y_{0}\right\|} R\right\| \leq R \frac{\left\|\left(x-y_{0}\right)\right\| y-y_{0}\left\|-\left(y-y_{0}\right)\right\| x-y_{0}\| \|}{\left\|x-y_{0}\right\|\left\|y-y_{0}\right\|} \\
\leq \frac{R}{\left\|x-y_{0}\right\|\left\|y-y_{0}\right\|}\binom{\left\|\left(x-y_{0}\right)\right\| y-y_{0}\left\|-\left(y-y_{0}\right)\right\| y-y_{0}\| \|}{+\left\|\left(y-y_{0}\right)\right\| y-y_{0}\left\|-\left(y-y_{0}\right)\right\| x-y_{0}\| \|} \\
\leq \frac{R}{\left\|x-y_{0}\right\|\left\|y-y_{0}\right\|}\left(\left\|y-y_{0}\right\|\|x-y\|+\left\|y-y_{0}\right\|\|y-x\|\right) \\
\leq \frac{R}{\left\|x-y_{0}\right\|}(\|x-y\|+\|y-x\|)<2\|y-x\|
\end{gathered}
$$

In case $y=y_{0}$, you have

$$
\|\gamma(x)-\gamma(y)\|=\left\|\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R\right\|=\left\|\frac{x-y}{\left\|x-y_{0}\right\|} R\right\|<\|x-y\|
$$

The only other case is where both $x, y$ are in $X \backslash B$. In this case, you get

$$
\begin{aligned}
\|\gamma(x)-\gamma(y)\| & =\left\|y_{0}+\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R-\left(y_{0}+\frac{y-y_{0}}{\left\|y-y_{0}\right\|} R\right)\right\| \\
& =\left\|\frac{x-y_{0}}{\left\|x-y_{0}\right\|} R-\frac{y-y_{0}}{\left\|y-y_{0}\right\|} R\right\| \leq 2\|x-y\|
\end{aligned}
$$

by the same reasoning used above to estimate $A$.
Alternate Proof of Theorem 24.1.8: Let $B$ be a closed ball of radius $R$ centered at $y_{0}$ such that $f$ has Lipschitz constant $K$ on $B$. Let $\gamma$ be as in Lemma 24.1.9. Consider $g(x) \equiv f(\gamma(x))$. Then

$$
\|g(x)-g(y)\|=\|f(\gamma(x))-f(\gamma(y))\| \leq K\|\gamma(x)-\gamma(y)\| \leq 3 K\|x-y\|
$$

Now consider for $y \in C([0, T], X)$

$$
F y(t) \equiv y_{0}+\int_{0}^{t} g(y(s)) d s
$$

Then

$$
\|F y(t)-F z(t)\| \leq \int_{0}^{t} K\|y(s)-z(s)\| d s
$$

Thus, iterating this inequality, it follows that a large enough power of $F$ is a contraction map. Therefore, there is a unique fixed point. Now letting $y$ be this fixed point,

$$
\left\|y(t)-y_{0}\right\| \leq \int_{0}^{t} 3 K\left\|y(s)-y_{0}\right\| d s+\left\|f\left(y_{0}\right)\right\| T
$$

It follows that

$$
\left\|y(t)-y_{0}\right\| \leq\left\|f\left(y_{0}\right)\right\| T e^{3 K T}
$$

Choosing $T$ small enough, it follows that $\left\|y(t)-y_{0}\right\|<R$ on $[0, T]$ and so $\gamma$ has no effect. Thus this yields a local solution to the initial value problem.

In the case that $U=X$, the above argument shows that there exists a solution on some $[0, T)$ where $T$ is maximal.

$$
y(t)=y_{0}+\int_{0}^{t} f(y(s)) d s, t<T
$$

Suppose $T<\infty$. Suppose $\int_{0}^{T}\|f(y(s))\| d s<\infty$. Then you can consider $y_{0}+\int_{0}^{T} f(y(s)) d s$ as an initial condition for the equation and obtain a unique solution $z$ valid on $[T, T+\delta]$. Then one could consider $\hat{y}(t)=y(t)$ for $t<T$ and for $t \geq T, \hat{y}(t)=z(t)$. Then for $t \in$ $[T, T+\delta]$,

$$
\begin{aligned}
\hat{y}(t) & =z(t)=y_{0}+\int_{0}^{T} f(y(s)) d+\int_{T}^{t} f(\hat{y}(s)) d s \\
& =y_{0}+\int_{0}^{T} f(\hat{y}(s)) d+\int_{T}^{t} f(\hat{y}(s)) d s
\end{aligned}
$$

and so in fact, for all $t \in[0, T+\delta]$,

$$
\hat{y}(t)=y_{0}+\int_{0}^{t} f(\hat{y}(s)) d s
$$

contrary to the maximality of $T$. Hence it cannot be the case that $T<\infty$. Thus it must be the case that $\int_{0}^{T}\|f(y(s))\| d s=\infty$ if the solution is not global.

From the above observation, here is a corollary.
Corollary 24.1.10 Let $f: X \rightarrow X$ be locally Lipschitz where $X$ is a Banach space. Then there exists a unique local solution to the IVP

$$
y^{\prime}=f(y), \quad y(0)=y_{0}
$$

If $f$ is bounded, then in fact the solutions exists on $[0, T]$ for any $T>0$.
Proof: Say $\|f(x)\| \leq M$ for all $M$. Then letting $[0, \hat{T})$ be the maximal interval, it must be the case that $\int_{0}^{\hat{T}}\|f(y(t))\| d t=\infty$, but this does not happen if $f$ is bounded.

Note that this conclusion holds just as well if $f$ has linear growth, $\|f(u)\| \leq a+b\|u\|$ for $a, b \geq 0$. One just uses an application of Gronwall's inequality to verify a similar conclusion.

One can also give a simple modification of these theorems as follows.

Corollary 24.1.11 Suppose $f: X \rightarrow X$ is continuous and $f$ is locally Lipschitz on $U$, an open subset of $X$, a Banach space. Suppose also that $f(x)=0$ for all $x \notin U$ and that $\|f(x)\|<M$ for all $x \in X$. Then there exists a solution to the IVP

$$
y^{\prime}=f(y), \quad y(0)=y_{0}
$$

for $t \in[0, T]$ for any $T>0$.
Proof: Let $T$ be given. If $y_{0} \notin U$, there is nothing to show. The solution is $y(t) \equiv$ $y_{0}$. Suppose then that $y_{0} \in U$. Then by Theorem 24.1.8, there exists a unique solution to the initial value problem on an interval $[0, \hat{T})$ of maximal length. If $\hat{T}=T$, then as $t_{n} \rightarrow T,\left\{y\left(t_{n}\right)\right\}$ must converge. This is because for $t_{m}<t_{n}$,

$$
\left\|y\left(t_{n}\right)-y\left(t_{m}\right)\right\| \leq M\left|t_{n}-t_{m}\right|
$$

showing that this is a Cauchy sequence. Since all such sequences lead to a Cauchy sequence, it must be the case that $\lim _{t \rightarrow T} y(t)$ exists. Thus it equals

$$
y_{0}+\int_{0}^{T} f(y(t)) d t
$$

We let $y(T)$ equal the above and it follows from Gronwall's inequality that there is a unique solution to the IVP on $[0, T]$ so the claim is true in this case.

Otherwise, if $\hat{T}<T$, then one can define

$$
y(\hat{T}) \equiv y_{0}+\int_{0}^{\hat{T}} f(y(s)) d s
$$

If $y(\hat{T}) \in U$, then by the assumption that $f$ is bounded, one could consider a new initial condition and extend the solution further violating the maximality of the length of $[0, \hat{T})$. Therefore, it must be the case that $y(\hat{T}) \in U^{C}$. Then the solution is

$$
\hat{y}(t)=\left\{\begin{array}{c}
y(t), t<\hat{T} \\
y(\hat{T}), t>\hat{T}
\end{array}\right.
$$

because $f(y(\hat{T}))=0$ by assumption.
One could also change the above argument for Corollary 24.1.11 to include the case that $f$ has linear growth.

### 24.1.2 Mountain Pass Theorem In Banach Space

In this section, is a more general version of the mountain pass theorem. It is generalized in two ways. First, the space is not a Hilbert space and second, the derivative of the functional is not assumed to be Lipschitz. Instead of using $I^{\prime}$ one uses the pseudogradient in an appropriate differential equation. This is a significant generalization because there is no convenient projection map from $X^{\prime}$ to $X$ like there is in Hilbert space. This is why the use of the psedogradient is so interesting. For many more considerations of this sort of thing, see [55]. First is a deformation theorem. Here $I$ will be defined on a Banach space $X$ and $I^{\prime}(x) \in X^{\prime}$. First recall the Palais Smale conditions.

Definition 24.1.12 A functional I satisfies the Palais Smale conditions if $\left\{I\left(u_{k}\right)\right\}$ is a bounded sequence and $I^{\prime}\left(u_{k}\right) \rightarrow 0$, then $\left\{u_{k}\right\}$ is precompact. That is, it has a subsequence which converges.

Here is a picture which illustrates the main conclusion of the following theorem. The idea is that you modify the functional on some set making it smaller and leaving it unchanged off that set.

Theorem 24.1.13 Let I be $C^{1}$, I is non constant, satisfy the Palais Smale condition, and $I^{\prime}$ is bounded on bounded sets. Also suppose that $c \in \mathbb{R}$ is such that either $I^{-1}([c-\delta, c+\delta])=$ $\emptyset$ for some $\delta>0$ or $I^{-1}([c-\delta, c+\delta]) \neq \emptyset$ for all $\delta>0$ and $\boldsymbol{I F} I(u)=c$, then $I^{\prime}(u) \neq 0$. Then for each sufficiently small $\varepsilon>0$, there is a constant $\delta \in(0, \varepsilon)$ and a function $\eta$ : $[0,1] \times X \rightarrow X$ such that

1. $\eta(0, u)=u$
2. $\eta(1, u)=u$ on $I^{-1}(X \backslash(c-\varepsilon, c+\varepsilon))$
3. $I(\eta(t, u)) \leq I(u)$
4. $\eta\left(1, I^{-1}(-\infty, c+\delta]\right) \subseteq I^{-1}(-\infty, c-\delta]$, so $I(\eta(1, u)) \leq c-\delta$ if $I(u) \leq c+\delta$.

The main part of this conclusion is the statement about $u \rightarrow \eta(1, u)$ contained in parts 2. and 4. The other two parts are there to facilitate these two although they are certainly interesting for their own sake.

Proof: Suppose $I^{-1}([c-\hat{\delta}, c+\hat{\delta}])=\emptyset$ for some $\hat{\delta}>0$. Then

$$
I^{-1}\left(\left(-\infty, c+\frac{\hat{\delta}}{2}\right]\right) \subseteq I^{-1}\left(\left(-\infty, c-\frac{\hat{\delta}}{2}\right]\right)
$$

and you could take $\varepsilon=\delta$ and let $\eta(t, u)=u$. The conclusion holds with $\delta=\hat{\delta} / 2$.
Therefore, assume $I^{-1}([c-\delta, c+\delta]) \neq \emptyset$ for all $\delta>0$. Since $I$ is nonconstant, $\varepsilon>0$ can be chosen small enough that

$$
I^{-1}(X \backslash(c-\varepsilon, c+\varepsilon)) \neq \emptyset
$$

Always let $\varepsilon$ be this small. Note that $I$ nonconstant is part of the assumptions.
Claim 1: For all small enough $\varepsilon>0$, if $u \in I^{-1}([c-\varepsilon, c+\varepsilon])$, then $I^{\prime}(u) \neq 0$ and in fact, for such $\varepsilon$, there exists $\sigma(\varepsilon)>0$, such that $\sigma(\varepsilon)<\min (\varepsilon, 1),\left\|I^{\prime}(u)\right\|>\sigma(\varepsilon)$ for all $u \in I^{-1}([c-\varepsilon, c+\varepsilon])$.

Proof of Claim 1: If the claim is not so, then there is $\left\{u_{k}\right\}, \varepsilon_{k}, \sigma_{k} \rightarrow 0,\left\|I^{\prime}\left(u_{k}\right)\right\|_{X^{\prime}}<$ $\sigma_{k}$, and $I\left(u_{k}\right) \in\left[c-\varepsilon_{k}, c+\varepsilon_{k}\right]$ but $\left\|I^{\prime}\left(u_{k}\right)\right\|_{X^{\prime}} \leq \sigma_{k}$. However, from the Palais Smale condition, there is a subsequence, still denoted as $u_{k}$ which converges to some $u$. Now $I\left(u_{k}\right) \in\left[c-\varepsilon_{k}, c+\varepsilon_{k}\right]$ and so $I(u)=c$ while $I^{\prime}(u)=0$ contrary to the hypothesis. This proves Claim 1. From now on, $\varepsilon$ will be sufficiently small that this holds.

Now define for $\delta<\varepsilon$ (The precise description of small $\delta$ will be described later. However, it will be $\delta<\sigma(\varepsilon) / 2$, but this exact description is only used at the end.)

$$
\begin{aligned}
A & \equiv I^{-1}(X \backslash(c-\varepsilon, c+\varepsilon)) \\
B & \equiv I^{-1}([c-\delta, c+\delta])
\end{aligned}
$$

Thus $A$ and $B$ are disjoint closed sets. Recall that it is assumed that $B \neq \emptyset$ since otherwise, there is nothing to prove. Also it is assumed throughout that $\varepsilon>0$ is such that $A \neq \emptyset$ thanks to $I$ not being constant. Thus these are nonempty sets and we do not have to fuss with worrying about meaning when one is empty.

Claim 2: For any $u, \operatorname{dist}(u, A)+\operatorname{dist}(u, B)>0$.
This is so because if not, then both summands would be zero and this requires that $u \in A \cap B$ since these sets are closed. But $A \cap B=\emptyset$.

Now define a function

$$
g(u) \equiv \frac{\operatorname{dist}(u, A)}{\operatorname{dist}(u, A)+\operatorname{dist}(u, B)}
$$

It is a continuous function of $u$ which has values in $[0,1]$. It is 1 on $B$ and 0 on $A$. Also define $V(x)$ as a pseudogradient field for $I$ on the regular points of $I$. At points where $I^{\prime}(x)=0$, let $V(x)=0$. Recall what this means:

$$
\begin{equation*}
\left\|I^{\prime}(x)\right\|_{X^{\prime}}^{2} \leq\left\langle I^{\prime}(x), V(x)\right\rangle, \quad\|V(x)\|_{X} \leq 2\left\|I^{\prime}(x)\right\|_{X^{\prime}} \tag{24.1.5}
\end{equation*}
$$

and also $V$ is locally Lipschitz on the regular points of $I$. Thus $x \rightarrow V(x)$ is continuous on $X$, thanks to continuity of $I^{\prime}$, satisfies the above inequalities, and is locally Lipschitz on $U=\left\{x: I^{\prime}(x) \neq 0\right\}$. It exists because of Lemma 24.1.7. Consider the ordinary differential initial value problem

$$
\begin{gather*}
\eta^{\prime}(t, u)+g(u) h(\|V(\eta(t, u))\|) V(\eta(t, u))=0  \tag{24.1.6}\\
\eta(0, u)=u \tag{24.1.7}
\end{gather*}
$$

where $r \rightarrow h(r)$ is a decreasing function which has values in $(0,1]$ and equals 1 for $r \in[0,1]$ and equals $1 / r$ for $r>1$.

Here $u$ is given and the $\eta^{\prime}$ is the time derivative is with respect to $t$. By Corollary 24.1.11, there exists a solution to this for $t \in[0,1]$.

Then for this solution, $\eta(0, u)=u$ because of the above initial condition. If $u \in$ $I^{-1}(X \backslash[c-\varepsilon, c+\varepsilon])$, then $u \in A$ and so $g(u)=0$ so $\eta(t, u)=u$ for all $t \in[0,1]$. This gives the first two conditions. Consider the third.

$$
\begin{aligned}
\frac{d}{d t}(I(\eta(t, u))) & =\left\langle I^{\prime}(\eta), \eta^{\prime}\right\rangle=-\left\langle I^{\prime}(\eta), g(u) h(\|V(\eta(t, u))\|) V(\eta(t, u))\right\rangle \\
& =-g(u) h(\|V(\eta(t, u))\|)\left\langle I^{\prime}(\eta), V(\eta(t, u))\right\rangle \\
& \leq-g(u) h(\|V(\eta(t, u))\|)\left\|I^{\prime}(\eta)\right\|_{X^{\prime}}^{2} \leq 0
\end{aligned}
$$

this last inequality from the inequalities of 24.1 .5 , and so this implies the third condition since it says that the function $t \rightarrow I(\eta(t, u))$ is decreasing.

It remains to consider the last condition. This involves an appropriate choice of small $\delta$. It was chosen small and now it will be seen how small. It is desired to verify that

$$
\eta\left(1, I^{-1}((-\infty, c+\delta])\right) \subseteq I^{-1}((-\infty, c-\delta])
$$

Suppose it is not so. Then there exists $u$ such that $I(u) \in(c-\delta, c+\delta]$ but $I(\eta(1, u))>$ $c-\delta$. We can assume that $I(u) \in(c-\delta, c+\delta]$ because if $I(u) \leq c-\delta$, then so is $I(\eta(1, u))$ from what was just shown. Hence $g(u)=1$. Then using the fact that $g(u)=1$,

$$
\begin{aligned}
c & -\delta<I(\eta(1, u))=I(u)+\int_{0}^{1} \frac{d}{d t}(I(\eta)) d t \\
& =I(u)-\int_{0}^{1}\left\langle I^{\prime}(\eta), h(\|V(\eta)\|) V(\eta)\right\rangle d t \\
& =I(u)+\int_{0}^{1}-h(\|V(\eta)\|)\left\langle I^{\prime}(\eta), V(\eta)\right\rangle d t \\
& \leq c+\delta \\
& \leq(u)+\int_{0}^{1}\left(-h(\|V(\eta)\|)\left\|I^{\prime}(\eta)\right\|^{2}\right) d t
\end{aligned}
$$

Then

$$
c-\delta+\int_{0}^{1} h(\|V(\eta)\|)\left\|I^{\prime}(\eta)\right\|^{2} d t<I(u) \leq c+\delta
$$

Thus

$$
c-2 \delta+\int_{0}^{1} h(\|V(\eta)\|)\left\|I^{\prime}(\eta)\right\|^{2} d t<c
$$

Also, it is being assumed that $I(\eta(1, u))>c-\delta$ and so by the third conclusion shown above, $\eta(t, u) \in B$ for $t \in[0,1]$. We also know that for such values of $\eta(t, u)$,

$$
\left\|I^{\prime}(\eta(t, u))\right\| \geq \sigma(\varepsilon)
$$

from Claim 1. Now

$$
\left\|I^{\prime}(x)\right\|_{X^{\prime}}^{2} \leq\left\langle I^{\prime}(x), V(x)\right\rangle \leq\left\|I^{\prime}(x)\right\|\|V(x)\|
$$

and so

$$
\begin{equation*}
\|V(\eta(t, u))\|_{X} \geq\left\|I^{\prime}(\eta(t, u))\right\|_{X^{\prime}} \geq \sigma(\varepsilon) \tag{24.1.8}
\end{equation*}
$$

Thus the above inequality yields

$$
c-2 \delta+\int_{0}^{1} h(\|V(\eta)\|) \sigma(\varepsilon)^{2} d t<c
$$

Now what is the value of $h(\|V(\eta)\|)$ ? From 24.1.8

$$
h\left(\|V(\eta(t, u))\|_{X}\right) \leq h\left(\left\|I^{\prime}(\eta(t, u))\right\|_{X^{\prime}}\right) \leq h(\sigma(\varepsilon)) \leq \frac{1}{\sigma(\varepsilon)}
$$

In fact, $\sigma(\varepsilon)<1$ so $h(\sigma(\varepsilon))=1$ so the above estimate, while correct is sloppy. Hence

$$
c-2 \delta+\int_{0}^{1} \frac{1}{\sigma(\varepsilon)} \sigma(\varepsilon)^{2} d t<c
$$

So far it was only assumed $\delta<\varepsilon$. As indicated above, $\delta$ was chosen small enough that $-2 \delta+\sigma(\varepsilon)>0$. Hence this yields a contradiction. Thus the last conclusion is verified.

Imagine a valley surrounded by a ring of mountains. On the other side of this ring of moutains, there is another low place. Then there must be some path from the valley to the exterior low place which goes through a point where the gradient equals 0 , the gradient being the gradient of a function $f$ which gives the altitude of the land. This is the idea of the mountain pass theorem. The critical point where $\nabla f=0$ is the mountain pass.

Theorem 24.1.14 Let $X$ be a Banach space and let $I: X \rightarrow \mathbb{R}$ be a $C^{1}$ functional having $I^{\prime}$ bounded on bounded sets and such that I satisfies the Palais Smale condition. Suppose $I(0)=0$ and $I(u) \geq a>0$ for all $\|u\|=r$. Suppose also that there exists $v,\|v\|>r$ such that $I(v) \leq 0$. Then define

$$
\Gamma \equiv\{g \in C([0,1] ; X): g(0)=0, g(1)=v\}
$$

Let

$$
c \equiv \inf _{g \in \Gamma} \max _{0 \leq t \leq 1} I(g(t))
$$

Then $c$ is a critical value of I meaning that there exists $u$ such that $I(u)=c$ and $I^{\prime}(u)=0$. In particular, there is $u \neq 0$ such that $I^{\prime}(u)=0$.

Proof: First note that $c \geq a>0$. Suppose $c$ is not a critical value. Then either $I^{-1}((c-\delta, c+\delta))=\emptyset$ for some $\delta>0$ in which case the conclusion of the deformation theorem, (Theorem 24.1.13) holds, or for all $\delta>0, I^{-1}((c-\delta, c+\delta)) \neq \emptyset$ and if $I(u)=c$, then $I^{\prime}(u) \neq 0$ in which case the deformation theorem also holds. Then by this theorem, for $\varepsilon>0, \varepsilon$ sufficiently small, $\varepsilon<c$, there is $\eta: X \rightarrow X$ and a $\delta<\varepsilon$ small enough that

$$
\eta\left(I^{-1}((-\infty, c+\delta])\right) \subseteq I^{-1}((-\infty, c-\delta])
$$

and $\eta$ leaves unchanged $I^{-1}(X \backslash(c-\varepsilon, c+\varepsilon))$. Then there is $g \in \Gamma$ such that

$$
\max _{t \in[0,1]} I(g(t))<c+\delta
$$

Then in particular, $I(g(t))<c+\delta$ for every $t$. Hence you look at $\eta \circ g$. We know that $g(0), g(1)$ are both in the set $[I(u) \notin(c-\varepsilon, c+\varepsilon)]$ because they are both 0 or less than 0 and so $\eta$ leaves these unchanged. Hence $\eta \circ g \in \Gamma$ and

$$
I(\eta \circ g(t)) \leq c-\delta
$$

for all $t \in[0,1]$. Thus
which is clearly a contradiction.

## Chapter 25

## Nonlinear Operators

In this chapter, is a discussion of various kinds of nonlinear operators. Some standard references on these operators are [39], [40], [22], [24], [13], [91], [116], [25] and references listed there. The most important examples of these operators seem to be due to Brezis in the 1960's and these things have been generalized and used by many others since this time. I am following many of these, but the stuff about maximal monotone operators is mainly from Barbu [13]. I am trying to include all the necessary basic results such as fixed point theorems which are needed to prove the main theorems and also to re write in a manner understandable to me.

It seems like the main issue is the following. When does $\left\langle f_{n}, x_{n}\right\rangle$ converge to $\langle f, x\rangle$ given that $f_{n}$ and $x_{n}$ both converge weakly to $f$ and $x$ respectively? There is no problem in finite dimensions because in finite dimensions, there is only one meaning for convergence. However, in infinite dimensions, there certainly is a problem as can be instantly realized by consideration of the Riemann Lebesgue lemma, for example. You know that $\int_{-\pi}^{\pi} f(x) \sin (n x) d x \rightarrow 0$ so $\sin (n x)$ converges weakly to 0 but $\int_{-\pi}^{\pi} \sin ^{2}(n x) d x$ certainly does not converge to 0 .

The idea behind all of these considerations is that $f_{n}$ is to come from some nonlinear operator which has properties which will allow one to successfully pass to a limit. When the operator is linear, there usually is no problem because the graph is a subspace and so if it is closed, it will also be weakly closed. Thus, if $x_{n} \rightarrow x$ weakly and $L x_{n} \rightarrow f$ weakly, then $f=L x$. However, nothing like this happens with nonlinear operators. Consideration of when this happens is the purpose of this catalogue of nonlinear operators, and also to generalize to set valued operators. First is a section on single valued nonlinear operators and then the case of set valued nonlinear operators is discussed.

### 25.1 Some Nonlinear Single Valued Operators

Here is an assortment of nonlinear operators which are useful in applications to nonlinear partial differential equations. Generalizations of the notion of a pseudomonotone map will be presented later to include the case of set valued pseudomonotone maps. This is on the single valued version of some of these and these ideas originate with Brezis in the 1960's. A good description is given in Lions [91].

Definition 25.1.1 For $V$ a real Banach space, $A: V \rightarrow V^{\prime}$ is a pseudomonotone map if whenever

$$
\begin{equation*}
u_{n} \rightharpoonup u \tag{25.1.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq 0 \tag{25.1.2}
\end{equation*}
$$

it follows that for all $v \in V$,

$$
\begin{equation*}
\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle \tag{25.1.3}
\end{equation*}
$$

The half arrows denote weak convergence.

If $V$ is finite dimensional, then pseudomonotone maps are continuous. Also the property of being pseudomonotone is preserved when restriction is made to finite dimensional spaces. The notation is explained in the following diagram.

$$
\begin{array}{ccc}
W^{\prime} & \stackrel{i^{*}}{\leftarrow} & V^{\prime} \\
W & \stackrel{\rightarrow}{\rightarrow} & V
\end{array}
$$

The map $i$ is just the inclusion map. $i w \equiv w$ and $i^{*}$ is the usual adjoint map. $\left\langle i^{*} f, w\right\rangle_{W^{\prime}, W} \equiv$ $\langle f, i w\rangle_{V^{\prime}, V}=\langle f, w\rangle_{V^{\prime}, V}$. Thus $i^{*} A i(w) \in W^{\prime}$ and it is defined by

$$
\left\langle i^{*} A i(w), z\right\rangle_{W^{\prime}, W} \equiv\langle A w, z\rangle_{V^{\prime}, V}
$$

in other words, you restrict $A$ to $W$ and only consider what the resulting functional does to things in $W$.

Proposition 25.1.2 Let $V$ be finite dimensional and let $A: V \rightarrow V^{\prime}$ be pseudomonotone and bounded (meaning A maps bounded sets to bounded sets). Then A is continuous. Also, if $A: V \rightarrow V^{\prime}$ is pseudomonotone and bounded, and if $W \subseteq V$ is a finite dimensional subspace, then $i^{*} A i$ is pseudomonotone as a map from $W$ to $W^{\prime}$.

Proof: Say $u_{n} \rightarrow u$. Does it follow that $A u_{n} \rightarrow A u$ ? If not, then there is a subsequence such that $A u_{n} \rightarrow \xi \neq A u$ thanks to $\left\{A u_{n}\right\}$ being bounded. Then the limsup condition holds obviously. In fact the limit of $\left\langle A u_{n}, u_{n}-u\right\rangle$ exists and equals 0 . Hence for all $v$,

$$
\lim _{n \rightarrow \infty} \inf _{n}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle
$$

Therefore,

$$
\langle\xi, u-v\rangle \geq\langle A u, u-v\rangle
$$

for all $v$ and so in fact $\xi=A u$ after all. Thus $A$ must be continuous.
As to the second part of this proposition, if you have $w_{n} \rightharpoonup w$ in $W$, then in fact convergence takes place strongly because weak and strong convergence are the same in finite dimensions. Hence the same argument given above holds to show that $i^{*} A i$ is continuous.

Definition 25.1.3 $A: V \rightarrow V^{\prime}$ is monotone if for all $v, u \in V$,

$$
\langle A u-A v, u-v\rangle \geq 0
$$

and $A$ is Hemicontinuous if for all $v, u \in V$,

$$
\lim _{t \rightarrow 0+}\langle A(u+t(v-u)), u-v\rangle=\langle A u, u-v\rangle .
$$

Theorem 25.1.4 Let $V$ be a Banach space and let $A: V \rightarrow V^{\prime}$ be monotone and hemicontinuous. Then A is pseudomonotone.

Proof: Let $A$ be monotone and Hemicontinuous. First here is a claim.
Claim: If 25.1.1 and 25.1.2 hold, then $\lim _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=0$.

Proof of the claim: Since $A$ is monotone,

$$
\left\langle A u_{n}-A u, u_{n}-u\right\rangle \geq 0
$$

so

$$
\left\langle A u_{n}, u_{n}-u\right\rangle \geq\left\langle A u, u_{n}-u\right\rangle .
$$

Therefore,

$$
0=\lim \inf _{n \rightarrow \infty}\left\langle A u, u_{n}-u\right\rangle \leq \lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq \lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq 0
$$

Now using that $A$ is monotone again, then letting $t>0$,

$$
\left\langle A u_{n}-A(u+t(v-u)), u_{n}-u+t(u-v)\right\rangle \geq 0
$$

and so

$$
\left\langle A u_{n}, u_{n}-u+t(u-v)\right\rangle \geq\left\langle A(u+t(v-u)), u_{n}-u+t(u-v)\right\rangle .
$$

Taking the liminf on both sides and using the claim and $t>0$,

$$
t \lim _{n \rightarrow \infty} \inf _{n}\left\langle A u_{n}, u-v\right\rangle \geq t\langle A(u+t(v-u)),(u-v)\rangle
$$

Next divide by $t$ and use the Hemicontinuity of $A$ to conclude that

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle A u_{n}, u-v\right\rangle \geq\langle A u, u-v\rangle
$$

From the claim,

$$
\begin{aligned}
\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u-v\right\rangle & =\lim \inf _{n \rightarrow \infty}\left(\left\langle A u_{n}, u_{n}-v\right\rangle+\left\langle A u_{n}, u-u_{n}\right\rangle\right) \\
& =\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle \text { ■ }
\end{aligned}
$$

Monotonicity is very important in the above proof. The next example shows that even if the operator is linear and bounded, it is not necessarily pseudomonotone.

Example 25.1.5 Let $H$ be any Hilbert space (complete inner product space, more on these later) and let $A: H \rightarrow H^{\prime}$ be given by

$$
\langle A x, y\rangle \equiv(-x, y)_{H}
$$

Then A fails to be pseudomonotone.
Proof: Let $\left\{x_{n}\right\}_{n=1}^{\infty}$ be an orthonormal set of vectors in $H$. Then Parsevall's inequality implies

$$
\|x\|^{2} \geq \sum_{n=1}^{\infty}\left|\left(x_{n}, x\right)\right|^{2}
$$

and so for any $x \in H, \lim _{n \rightarrow \infty}\left(x_{n}, x\right)=0$. Thus $x_{n} \rightharpoonup 0 \equiv x$. Also

$$
\lim \sup _{n \rightarrow \infty}\left\langle A x_{n}, x_{n}-x\right\rangle=
$$

$$
\lim \sup _{n \rightarrow \infty}\left\langle A x_{n}, x_{n}-0\right\rangle=\lim \sup _{n \rightarrow \infty}\left(-\left\|x_{n}\right\|^{2}\right)=-1 \leq 0
$$

If $A$ were pseudomonotone, we would need to be able to conclude that for all $y \in H$,

$$
\lim \inf _{n \rightarrow \infty}\left\langle A x_{n}, x_{n}-y\right\rangle \geq\langle A x, x-y\rangle=0
$$

However,

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow 2}\left\langle A x_{n}, x_{n}-0\right\rangle=-1<0=\langle A 0,0-0\rangle
$$

The following proposition is useful.
Proposition 25.1.6 Suppose $A: V \rightarrow V^{\prime}$ is pseudomonotone and bounded where $V$ is separable. Then it must be demicontinuous. This means that if $u_{n} \rightarrow u$, then $A u_{n} \rightharpoonup A u$. In case that $V$ is reflexive, you don't need the assumption that $V$ is separable.

Proof: Since $u_{n} \rightarrow u$ is strong convergence and since $A u_{n}$ is bounded, it follows

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=0
$$

Suppose this is not so that $A u_{n}$ converges weakly to $A u$. Since $A$ is bounded, there exists a subsequence, still denoted by $n$ such that $A u_{n} \rightharpoonup \xi$ weak $*$. I need to verify $\xi=A u$. From the above, it follows that for all $v \in V$

$$
\begin{aligned}
\langle A u, u-v\rangle & \leq \lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \\
& =\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u-v\right\rangle=\langle\xi, u-v\rangle
\end{aligned}
$$

Hence $\xi=A u$.
There is another type of operator which is more general than pseudomonotone.
Definition 25.1.7 Let $A: V \rightarrow V^{\prime}$ be an operator. Then $A$ is called type $M$ if whenever $u_{n} \rightharpoonup u$ and $A u_{n} \rightharpoonup \xi$, and

$$
\lim _{\sup _{n \rightarrow \infty}}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

it follows that $A u=\xi$.
Proposition 25.1.8 If $A$ is pseudomonotone, then $A$ is type $M$.
Proof: Suppose $A$ is pseudomonotone and $u_{n} \rightharpoonup u$ and $A u_{n} \rightharpoonup \xi$, and

$$
\lim _{\sup _{n \rightarrow \infty}}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

Then

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle-\langle\xi, u\rangle \leq 0
$$

Hence

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle
$$

for all $v \in V$. Consequently, for all $v \in V$,

$$
\begin{aligned}
\langle A u, u-v\rangle & \leq \lim _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \\
& =\lim _{n \rightarrow \infty}\left(\left\langle A u_{n}, u-v\right\rangle+\left\langle A u_{n}, u_{n}-u\right\rangle\right) \\
& =\langle\xi, u-v\rangle+\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq\langle\xi, u-v\rangle
\end{aligned}
$$

and so $A u=\xi$.
An interesting result is the following which states that a monotone linear function added to a type $M$ is also type $M$.

Proposition 25.1.9 Suppose $A: V \rightarrow V^{\prime}$ is type $M$ and suppose $L: V \rightarrow V^{\prime}$ is monotone, bounded and linear. Then $L+A$ is type $M$. Let $V$ be separable or reflexive so that the weak convergences in the following argument are valid.

Proof: Suppose $u_{n} \rightharpoonup u$ and $A u_{n}+L u_{n} \rightharpoonup \xi$ and also that

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}+L u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

Does it follow that $\xi=A u+L u$ ? Suppose not. There exists a further subsequence, still called $n$ such that $L u_{n} \rightharpoonup L u$. This follows because $L$ is linear and bounded. Then from monotonicity,

$$
\left\langle L u_{n}, u_{n}\right\rangle \geq\left\langle L u_{n}, u\right\rangle+\left\langle L(u), u_{n}-u\right\rangle
$$

Hence with this further subsequence, the lim sup is no larger and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle+\lim _{n \rightarrow \infty}\left(\left\langle L u_{n}, u\right\rangle+\left\langle L(u), u_{n}-u\right\rangle\right) \leq\langle\xi, u\rangle
$$

and so

$$
\lim _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi-L u, u\rangle
$$

It follows since $A$ is type $M$ that $A u=\xi-L u$, which contradicts the assumption that $\xi \neq$ $A u+L u$.

There is also the following useful generalization of the above proposition.
Corollary 25.1.10 Suppose $A: V \rightarrow V^{\prime}$ is type $M$ and suppose $L: W \rightarrow W^{\prime}$ is monotone, bounded and linear where $V \subseteq W$ and $V$ is dense in $W$ so that $W^{\prime} \subseteq V^{\prime}$. Then for $u_{0} \in W$ define $M(u) \equiv L\left(u-u_{0}\right)$. Then $M+A$ is type $M$. Let $V$ be separable or reflexive so that the weak convergences in the following argument are valid.

Proof: Suppose $u_{n} \rightharpoonup u$ and $A u_{n}+M u_{n} \rightharpoonup \xi$ and also that

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}+M u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

Does it follow that $\xi=A u+M u$ ? Suppose not. By assumption, $u_{n} \rightharpoonup u$ and so,

$$
u_{n}-u_{0} \rightharpoonup u-u_{0} \text { weak convergence in } W
$$

since $L$ is bounded, there is a further subsequence, still called $n$ such that

$$
M u_{n}=L\left(u_{n}-u_{0}\right) \rightharpoonup L\left(u-u_{0}\right)=M u
$$

Since $M$ is monotone,

$$
\left\langle M u_{n}-M u, u_{n}-u\right\rangle \geq 0
$$

Thus

$$
\left\langle M u_{n}, u_{n}\right\rangle-\left\langle M u_{n}, u\right\rangle-\left\langle M u, u_{n}\right\rangle+\langle M u, u\rangle \geq 0
$$

and so

$$
\left\langle M u_{n}, u_{n}\right\rangle \geq\left\langle M u_{n}, u\right\rangle+\left\langle M u, u_{n}-u\right\rangle
$$

Hence with this further subsequence, the limsup is no larger and so

$$
\begin{gathered}
\langle\xi, u\rangle \geq \lim \sup _{n \rightarrow \infty}\left\langle A u_{n}+M u_{n}, u_{n}\right\rangle \\
\geq \lim \sup _{n \rightarrow \infty}\left(\left\langle A u_{n}, u_{n}\right\rangle+\left\langle M u_{n}, u\right\rangle+\left\langle M u, u_{n}-u\right\rangle\right) \\
=\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle+\lim _{n \rightarrow \infty}\left(\left\langle M u_{n}, u\right\rangle+\left\langle M(u), u_{n}-u\right\rangle\right) \leq\langle\xi, u\rangle
\end{gathered}
$$

and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}\right\rangle \leq\langle\xi-M u, u\rangle
$$

It follows since $A$ is type $M$ that $A u=\xi-M u$, which contradicts the assumption that $\xi \neq A u+M u$.

The following is Browder's lemma. It is a very interesting application of the Brouwer fixed point theorem.

Lemma 25.1.11 (Browder) Let $K$ be a convex closed and bounded set in $\mathbb{R}^{n}$ and let $A$ : $K \rightarrow \mathbb{R}^{n}$ be continuous and $\mathbf{f} \in \mathbb{R}^{n}$. Then there exists $\mathbf{x} \in K$ such that for all $\mathbf{y} \in K$,

$$
(\mathbf{f}-A \mathbf{x}, \mathbf{y}-\mathbf{x})_{\mathbb{R}^{n}} \leq 0
$$

If $K$ is convex, closed, bounded subset of $V$ a finite dimensional vector space, then the same conclusion holds. If $f \in V^{\prime}$, there exists $x \in K$ such that for all $y \in K$,

$$
\langle f-A x, y-x\rangle_{V^{\prime}, V} \leq 0
$$

Proof: Let $P_{K}$ denote the projection onto $K$. Thus $P_{K}$ is Lipschitz continuous.

$$
\mathbf{x} \rightarrow P_{K}(\mathbf{f}-A \mathbf{x}+\mathbf{x})
$$

is a continuous map from $K$ to $K$. By the Brouwer fixed point theorem, it has a fixed point $\mathbf{x} \in K$. Therefore, for all $\mathbf{y} \in K$,

$$
(\mathbf{f}-A \mathbf{x}+\mathbf{x}-\mathbf{x}, \mathbf{y}-\mathbf{x})=(\mathbf{f}-A \mathbf{x}, \mathbf{y}-\mathbf{x}) \leq 0
$$

As to the second claim. Consider the following diagram.

$$
\begin{array}{lll}
\mathbb{R}^{n} & \stackrel{\theta^{*}}{\leftarrow} & V^{\prime} \\
\mathbb{R}^{n} & \stackrel{\theta}{\rightarrow} & V
\end{array}
$$

where

$$
\theta(\mathbf{x})=\sum_{i=1}^{n} x_{i} v_{i}
$$

Thus $\theta$ and $\theta^{*}$ are both continuous linear and one to one and onto. Hence there is $\mathbf{x} \in \theta^{-1} K$ a closed convex and bounded subset of $\mathbb{R}^{n}$ such that $\mathbf{x}=\theta^{-1} u, u \in K$, and

$$
\left(\theta^{*} f-\theta^{*} A \theta\left(\theta^{-1} u\right), \theta^{-1} y-\theta^{-1} u\right)_{\mathbb{R}^{n}} \equiv\langle f-A u, y-u\rangle_{V^{\prime}, V} \leq 0
$$

for all $y \in K$.
From this lemma, there is an interesting theorem on surjectivity.
Proposition 25.1.12 Let $A: V \rightarrow V^{\prime}$ be continuous and coercive,

$$
\lim _{\|v\| \rightarrow \infty} \frac{\left\langle A\left(v+v_{0}\right), v\right\rangle}{\|v\|_{V}}=\infty
$$

for some $v_{0}$. Then for all $f \in V^{\prime}$, there exists $v \in V$ such that $A v=f$.
Proof: Define the closed convex sets $B_{n} \equiv \overline{B\left(v_{0}, n\right)}$. By Browder's lemma, there exists $\mathbf{x}_{n}$ such that

$$
\left(f-A v_{n}, y-v_{n}\right) \leq 0
$$

for all $y \in B_{n}$. Then taking $y=v_{0}$,

$$
\left\langle A v_{n}, v_{n}-v_{0}\right\rangle \leq\left\langle f, v_{n}-v_{0}\right\rangle
$$

letting $w_{n}=v_{n}-v_{0}$,

$$
\left\langle A\left(w_{n}+v_{0}\right), w_{n}\right\rangle \leq\left\langle f, w_{n}\right\rangle
$$

and so

$$
\frac{\left\langle A\left(w_{n}+v_{0}\right), w_{n}\right\rangle}{\left\|w_{n}\right\|} \leq\|f\|
$$

which implies that the $\left\|w_{n}\right\|$ and hence the $\left\|v_{n}\right\|$ are bounded. It follows that for large $n, v_{n}$ is an interior point of $B_{n}$. Therefore,

$$
\left\langle f-A v_{n}, z\right\rangle_{V^{\prime}, V} \leq 0
$$

for all $z$ in some open ball centered at $v_{0}$. Hence $f-A v_{n}=0$.
Lemma 25.1.13 Let $A: V \rightarrow V^{\prime}$ be type $M$ and bounded and suppose $V$ is reflexive or $V$ is separable. Then $A$ is demicontinuous.

Proof: Suppose $u_{n} \rightarrow u$ and $A u_{n}$ fails to converge weakly to $A u$. Then there is a further subsequence, still denoted as $u_{n}$ such that $A u_{n} \rightharpoonup \zeta \neq A u$. Then thanks to the strong convergence, you have

$$
\lim _{\sup _{n \rightarrow \infty}}\left\langle A u_{n}, u_{n}\right\rangle=\langle\zeta, u\rangle
$$

which implies $\zeta=A u$ after all.
With these lemmas and the above proposition, there is a very interesting surjectivity result.

Theorem 25.1.14 Let $A: V \rightarrow V^{\prime}$ be type $M$, bounded, and coercive

$$
\begin{equation*}
\lim _{\|u\| \rightarrow \infty} \frac{\left\langle A\left(u+u_{0}\right), u\right\rangle}{\|u\|}=\infty \tag{25.1.4}
\end{equation*}
$$

for some $u_{0}$, where $V$ is a separable reflexive Banach space. Then $A$ is surjective.
Proof: Since $V$ is separable, there exists an increasing sequence of finite dimensional subspaces $\left\{V_{n}\right\}$ such that $\overline{\cup_{n} V_{n}}=V$ and each $V_{n}$ contains $u_{0}$. Say $\operatorname{span}\left(v_{1}, \cdots, v_{n}\right)=V_{n}$. Then consider the following diagram.

$$
\begin{array}{lll}
V_{n}^{\prime} & \stackrel{i^{*}}{\leftarrow} & V^{\prime} \\
V_{n} & \xrightarrow{i} & V
\end{array}
$$

The map $i$ is the inclusion map. Consider the map $i^{*} A i$. By Lemma 25.1.13 this map is continuous.

$$
\frac{\left\langle i^{*} A i\left(v+u_{0}\right), v\right\rangle_{V_{n}^{\prime} V_{n}}}{\|v\|}=\frac{\left\langle A\left(v+u_{0}\right), v\right\rangle_{V^{\prime}, V}}{\|v\|}
$$

Hence $i^{*} A i$ is coercive. Let $f \in V^{\prime}$. Then from Proposition 25.1.12, there exists $\mathbf{x}_{n}$ such that

$$
i^{*} A i v_{n}=i^{*} f
$$

In other words,

$$
\begin{equation*}
\left\langle A v_{n}, y\right\rangle_{V^{\prime} V}=\langle f, y\rangle_{V^{\prime} V} \tag{25.1.5}
\end{equation*}
$$

for all $y \in V_{n}$. Letting $y \equiv v_{n}-u_{0} \equiv w_{n}$,

$$
\left\langle A\left(w_{n}+u_{0}\right), w_{n}\right\rangle=\left\langle f, w_{n}\right\rangle
$$

Then from the coercivity condition 25.1.4, the $w_{n}$ are bounded independent of $n$. Hence this is also true of the $v_{n}$. Since $V$ is reflexive, there is a subsequence, still called $\left\{v_{n}\right\}$ which converges weakly to $v \in V$. Since $A$ is bounded, it can also be assumed that $A v_{n} \rightharpoonup \zeta \in V^{\prime}$. Then

$$
\lim \sup _{n \rightarrow \infty}\left\langle A v_{n}, v_{n}\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle f, v_{n}\right\rangle=\langle f, v\rangle
$$

Also, passing to the limit in 25.1.5,

$$
\langle\zeta, y\rangle=\langle f, y\rangle
$$

for any $y \in V_{n}$, this for any $n$. Since the union of these $V_{n}$ is dense, it follows that the above equation holds for all $y \in V$. Therefore, $f=\zeta$ and so

$$
\lim \sup _{n \rightarrow \infty}\left\langle A v_{n}, v_{n}\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle f, v_{n}\right\rangle=\langle f, v\rangle=\langle\zeta, v\rangle
$$

Since $A$ is type $M, A v=\zeta=f$.
You can generalize pseudomonotone slightly without any trouble.
Definition 25.1.15 Let $V$ be a Banach space and let $K$ be a closed convex nonempty subset of $V$. Then $A: K \rightarrow V^{\prime}$ is pseudomonotone if similar conditions hold as above. That is, if

$$
\begin{equation*}
u_{n} \rightharpoonup u \tag{25.1.6}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq 0 \tag{25.1.7}
\end{equation*}
$$

it follows that for all $v \in K$,

$$
\begin{equation*}
\lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \geq\langle A u, u-v\rangle \tag{25.1.8}
\end{equation*}
$$

Then it is easy to give a nice result on variational inequalities.
Proposition 25.1.16 Let $K$ be a closed convex nonempty subset of $V$ a separable reflexive Banach space. Let $A: K \rightarrow V^{\prime}$ be pseudomonotone and bounded. Also assume that either $K$ is bounded or there is a coercivity condition

$$
\lim _{\|u\| \rightarrow \infty} \frac{\left\langle A u, u-u_{0}\right\rangle}{\|u\|}=\infty, u_{0} \in K
$$

then for $f \in V^{\prime}$, there exists $u \in K$ such that for all $v \in K$,

$$
\langle A u, u-v\rangle \leq\langle f, u-v\rangle
$$

Proof: Let $V_{n}$ be finite dimensional spaces whose union is dense in $V, \cdots V_{n} \subseteq V_{n+1} \cdots$, each containing $u_{0}, n>\left\|u_{0}\right\|$. By a repeat of the proof of Proposition 25.1.2, $i^{*} A i$ will be continuous on $K$. Therefore, by Browder's lemma, there exists $u_{n} \in K_{n} \equiv K \cap B(0, n) \cap V_{n}$ such that for all $v \in K_{n}$,

$$
\left\langle i^{*} f-i^{*} A i u_{n}, v-u_{n}\right\rangle_{V_{n}^{\prime}, V_{n}}=\left\langle f-A u_{n}, v-u_{n}\right\rangle_{V^{\prime}, V} \leq 0
$$

Now assume we don't know that $K$ is bounded. In case it is bounded, the argument simplifies. In the harder case, the coercivity condition implies that the $u_{n}$ are bounded in $V$. This follows from letting $v=u_{0}$ in the above inequality. Thus

$$
\left\langle f, u_{n}-u_{0}\right\rangle \geq\left\langle A u_{n}, u_{n}-u_{0}\right\rangle
$$

Hence

$$
\frac{\left\langle A u_{n}, u_{n}-u_{0}\right\rangle}{\left\|u_{n}\right\|} \leq \frac{\|f\|\left\|u_{n}-u_{0}\right\|}{\left\|u_{n}\right\|}
$$

The right side is bounded and so it follows that the left side is also bounded. Therefore, $\left\|u_{n}\right\|$ must be bounded. Taking a subsequence and using the assumption that $V$ is reflexive, we can obtain

$$
u_{n} \rightarrow u \text { weakly in } V
$$

By the fact that convex closed sets are weakly closed also, it follows that $u \in K$. Also, given $M$, eventually all $\left\|u_{n}\right\|$ and $\|u\|$ are less than $M$. Now from the inequality,

$$
\left\langle A u_{n}, u_{n}-v\right\rangle \leq\left\langle f, u_{n}-v\right\rangle
$$

Thus

$$
\left\langle A u_{n}, u_{n}-u\right\rangle+\left\langle A u_{n}, u-v\right\rangle \leq\left\langle f, u_{n}-u\right\rangle+\langle f, u-v\rangle
$$

Then taking limsup ${ }_{n \rightarrow \infty}$ one gets

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle+\langle\xi, u-v\rangle \leq\langle f, u-v\rangle
$$

This holds for $v \in K_{m}$ where $m$ is arbitrary. Hence one could let $v_{m} \rightarrow u$. Thus eventually $\left\|v_{m}\right\|<M$ and so for large $m, v_{m} \in K_{m}$. Then it follows that

$$
\lim \sup _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-u\right\rangle \leq 0
$$

Consequently, by the assumption that $A$ is pseudomonotone on $K$, for every $v \in K$,

$$
\begin{equation*}
\langle A u, u-v\rangle \leq \lim \inf _{n \rightarrow \infty}\left\langle A u_{n}, u_{n}-v\right\rangle \tag{*}
\end{equation*}
$$

for all $v \in K$. Then from the inequality obtained from Browder's lemma,

$$
\left\langle A u_{n}, u_{n}-v\right\rangle_{V^{\prime}, V} \leq\left\langle f, u_{n}-v\right\rangle_{V^{\prime}, V}
$$

and so *implies on taking liminf that for all $v \in K$,

$$
\langle A u, u-v\rangle_{V^{\prime}, V} \leq\langle f, u-v\rangle_{V^{\prime}, V}
$$

### 25.2 Duality Maps

The duality map is an attempt to duplicate some of the features of the Riesz map in Hilbert space which is discussed in the chapter on Hilbert space.

Definition 25.2.1 A Banach space is said to be strictly convex if whenever $\|x\|=\|y\|$ and $x \neq y$, then

$$
\left\|\frac{x+y}{2}\right\|<\|x\|
$$

$F: X \rightarrow X^{\prime}$ is said to be a duality map if it satisfies the following: a.) $\|F(x)\|=\|x\|^{p-1}$. b.) $F(x)(x)=\|x\|^{p}$, where $p>1$.

Duality maps exist. Here is why. Let

$$
F(x) \equiv\left\{x^{*}:\left\|x^{*}\right\| \leq\|x\|^{p-1} \text { and } x^{*}(x)=\|x\|^{p}\right\}
$$

Then $F(x)$ is not empty because you can let $f(\alpha x)=\alpha\|x\|^{p}$. Then $f$ is linear and defined on a subspace of $X$. Also

$$
\sup _{\|\alpha x\| \leq 1}|f(\alpha x)|=\sup _{\|\alpha x\| \leq 1}|\alpha|\|x\|^{p} \leq\|x\|^{p-1}
$$

Also from the definition,

$$
f(x)=\|x\|^{p}
$$

and so, letting $x^{*}$ be a Hahn Banach extension, it follows $x^{*} \in F(x)$. Also, $F(x)$ is closed and convex. It is clearly closed because if $x_{n}^{*} \rightarrow x^{*}$, the condition on the norm clearly holds and also the other one does too. It is convex because

$$
\left\|x^{*} \lambda+(1-\lambda) y^{*}\right\| \leq \lambda\left\|x^{*}\right\|+(1-\lambda)\left\|y^{*}\right\| \leq \lambda\|x\|^{p-1}+(1-\lambda)\|x\|^{p-1}
$$

If the conditions hold for $x^{*}$, then we can show that in fact $\left\|x^{*}\right\|=\|x\|^{p-1}$. This is because

$$
\left\|x^{*}\right\| \geq\left|x^{*}\left(\frac{x}{\|x\|}\right)\right|=\frac{1}{\|x\|}\left|x^{*}(x)\right|=\|x\|^{p-1}
$$

Now how many things are in $F(x)$ assuming the norm on $X^{\prime}$ is strictly convex? Suppose $x_{1}^{*}$, and $x_{2}^{*}$ are two things in $F(x)$. Then by convexity, so is $\left(x_{1}^{*}+x_{2}^{*}\right) / 2$. Hence by strict convexity, if the two are different, then

$$
\left\|\frac{x_{1}^{*}+x_{2}^{*}}{2}\right\|=\|x\|^{p-1}<\frac{1}{2}\left\|x_{1}^{*}\right\|+\frac{1}{2}\left\|x_{2}^{*}\right\|=\|x\|^{p-1}
$$

which is a contradiction. Therefore, $F$ is an actual mapping.
What are some of its properties? First is one which is similar to the Cauchy Schwarz inequality. Since $p-1=p / p^{\prime}$,

$$
\sup _{\|y\| \leq 1}|\langle F x, y\rangle|=\|x\|^{p / p^{\prime}}
$$

and so for arbitrary $y \neq 0$,

$$
\begin{aligned}
|\langle F x, y\rangle| & =\|y\|\left|\left\langle F x, \frac{y}{\|y\|}\right\rangle\right| \leq\|y\|\|x\|^{p / p^{\prime}} \\
& =|\langle F y, y\rangle|^{1 / p}|\langle F x, x\rangle|^{1 / p^{\prime}}
\end{aligned}
$$

Next we can show that $F$ is monotone.

$$
\begin{aligned}
\langle F x-F y, x-y\rangle & =\langle F x, x\rangle-\langle F x, y\rangle-\langle F y, x\rangle+\langle F y, y\rangle \\
& \geq\|x\|^{p}+\|y\|^{p}-\|y\|\|x\|^{p / p^{\prime}}-\|y\|^{p / p^{\prime}}\|x\|
\end{aligned}
$$

$$
\geq\|x\|^{p}+\|y\|^{p}-\left(\frac{\|y\|^{p}}{p}+\frac{\|x\|^{p}}{p^{\prime}}\right)-\left(\frac{\|y\|^{p}}{p^{\prime}}+\frac{\|x\|^{p}}{p}\right)=0
$$

Next it can be shown that $F$ is hemicontinuous. By the construction, $F(x+t y)$ is bounded as $t \rightarrow 0$. Let $t \rightarrow 0$ be a subsequence such that

$$
F(x+t y) \rightarrow \xi \text { weak } *
$$

Then we ask: Does $\xi$ do what it needs to do in order to be $F(x)$ ? The answer is yes. First of all $\|F(x+t y)\|=\|x+t y\|^{p-1} \rightarrow\|x\|^{p-1}$. The set

$$
\left\{x^{*}:\left\|x^{*}\right\| \leq\|x\|^{p-1}+\varepsilon\right\}
$$

is closed and convex and so it is weak $*$ closed as well. For all small enough $t$, it follows $F(x+t y)$ is in this set. Therefore, the weak limit is also in this set and it follows $\|\xi\| \leq$ $\|x\|^{p-1}+\varepsilon$. Since $\varepsilon$ is arbitrary, it follows $\|\xi\| \leq\|x\|^{p-1}$. Is $\xi(x)=\|x\|^{p}$ ? We have

$$
\begin{aligned}
\|x\|^{p} & =\lim _{t \rightarrow 0}\|x+t y\|^{p}=\lim _{t \rightarrow 0}\langle F(x+t y), x+t y\rangle \\
& =\lim _{t \rightarrow 0}\langle F(x+t y), x\rangle=\langle\xi, x\rangle
\end{aligned}
$$

and so, $\xi$ does what it needs to do to be $F(x)$. This would be clear if $\|\xi\|=\|x\|^{p-1}$. However, $|\langle\xi, x\rangle|=\|x\|^{p}$ and so $\|\xi\| \geq\left|\left\langle\xi, \frac{x}{\|x\|}\right\rangle\right|=\|x\|^{p-1}$. Thus $\|\xi\|=\|x\|^{p-1}$ which shows $\xi$ does everyting it needs to do to equal $F(x)$ and so it is $F(x)$. Since this conclusion follows for any convergent sequence, it follows that $F(x+t y)$ converges to $F(x)$ weakly as $t \rightarrow 0$. This is what it means to be hemicontinuous. This proves the following theorem. One can show also that $F$ is demicontinuous which means strongly convergent sequences go to weakly convergent sequences. Here is a proof for the case where $p=2$. You can clearly do the same thing for arbitrary $p$.

Lemma 25.2.2 Let $F$ be a duality map for $p=2$ where $X, X^{\prime}$ are reflexive and have strictly convex norms. (If $X$ is reflexive, there is always an equivalent strictly convex norm [8].) Then $F$ is demicontinuous.

Proof: Say $x_{n} \rightarrow x$. Then does it follow that $F x_{n} \rightharpoonup F x$ ? Suppose not. Then there is a subsequence, still denoted as $x_{n}$ such that $x_{n} \rightarrow x$ but $F x_{n} \rightharpoonup y \neq F x$ where here $\rightharpoonup$ denotes weak convergence. This follows from the Eberlein Smulian theorem. Then

$$
\langle y, x\rangle=\lim _{n \rightarrow \infty}\left\langle F x_{n}, x_{n}\right\rangle=\lim _{n \rightarrow \infty}\left\|x_{n}\right\|^{2}=\|x\|^{2}
$$

Also, there exists $z,\|z\|=1$ and $\langle y, z\rangle \geq\|y\|-\varepsilon$. Then

$$
\|y\|-\varepsilon \leq\langle y, z\rangle=\lim _{n \rightarrow \infty}\left\langle F x_{n}, z\right\rangle \leq \lim \inf _{n \rightarrow \infty}\left\|F x_{n}\right\|=\lim \inf _{n \rightarrow \infty}\left\|x_{n}\right\|=\|x\|
$$

and since $\varepsilon$ is arbitrary, $\|y\| \leq\|x\|$. It follows from the above construction of $F x$, that $y=F x$ after all, a contradiction.

Theorem 25.2.3 Let $X$ be a reflexive Banach space with $X^{\prime}$ having strictly convex norm ${ }^{1}$. Then for $p>1$, there exists a mapping $F: X \rightarrow X^{\prime}$ which is bounded, monotone, hemicontinuous, coercive in the sense that $\lim _{|x| \rightarrow \infty}\langle F x, x\rangle /|x|=\infty$, which also satisfies the inequalities

$$
|\langle F x, y\rangle| \leq|\langle F x, x\rangle|^{1 / p^{\prime}}|\langle F y, y\rangle|^{1 / p}
$$

Note that these conclusions about duality maps show that they map onto the dual space.
The duality map was onto and it was monotone. This was shown above. Consider the form of a duality map for the $L^{p}$ spaces. Let $F: L^{p} \rightarrow\left(L^{p}\right)^{\prime}$ be the one which satisfies

$$
\|F f\|=\|f\|^{p-1},\langle F f, f\rangle=\|f\|^{p}
$$

Then in this case,

$$
F f=|f|^{p-2} \bar{f}
$$

This is because it does what it needs to do.

$$
\begin{aligned}
\|F f\|_{L^{p^{\prime}}} & =\left(\int_{\Omega}\left(|f|^{p-1}\right)^{p^{\prime}} d \mu\right)^{1 / p^{\prime}}=\left(\int_{\Omega}\left(|f|^{p / p^{\prime}}\right)^{p^{\prime}} d \mu\right)^{1 / p^{\prime}} \\
& =\left(\int_{\Omega}|f|^{p} d \mu\right)^{1-(1 / p)}=\left(\left(\int_{\Omega}|f|^{p} d \mu\right)^{1 / p}\right)^{p-1}=\|f\|_{L^{p}}^{p-1}
\end{aligned}
$$

while it is obvious that

$$
\langle F f, f\rangle=\int_{\Omega}|f|^{p} d \mu=\|f\|_{L^{p}(\Omega)}^{p}
$$

Now here is an interesting inequality which I will only consider in the case where the quantities are real valued.

Lemma 25.2.4 Let $p \geq 2$. Then for $a, b$ real numbers,

$$
\left(|a|^{p-2} a-|b|^{p-2} b\right)(a-b) \geq C|a-b|^{p}
$$

for some constant $C$ independent of $a, b$.
Proof: There is nothing to show if $a=b$. Without loss of generality, assume $a>b$. Also assume $p>2$. There is nothing to show if $p=2$. I want to show that there exists a constant $C$ such that for $a>b$,

$$
\begin{equation*}
\frac{|a|^{p-2} a-|b|^{p-2} b}{|a-b|^{p-1}} \geq C \tag{25.2.9}
\end{equation*}
$$

First assume also that $b \geq 0$. Now it is clear that as $a \rightarrow \infty$, the quotient above converges to 1. Take the derivative of this quotient. This yields

$$
(p-1)|a-b|^{p-2} \frac{|a|^{p-2}|a-b|-\left(|a|^{p-2} a-|b|^{p-2} b\right)}{|a-b|^{2 p-2}}
$$

[^22]Now remember $a>b$. Then the above reduces to

$$
(p-1)|a-b|^{p-2} b \frac{|b|^{p-2}-|a|^{p-2}}{|a-b|^{2 p-2}}
$$

Since $b \geq 0$, this is negative and so 1 would be a lower bound. Now suppose $b<0$. Then the above derivative is negative for $b<a \leq-b$ and then it is positive for $a>-b$. It equals 0 when $a=-b$. Therefore the quotient in 25.2.9 achieves its minimum value when $a=-b$. This value is

$$
\frac{|-b|^{p-2}(-b)-|b|^{p-2} b}{|-b-b|^{p-1}}=|b|^{p-2} \frac{-2 b}{|2 b|^{p-1}}=|b|^{p-2} \frac{1}{|2 b|^{p-2}}=\frac{1}{2^{p-2}} .
$$

Therefore, the conclusion holds whenever $p \geq 2$. That is

$$
\left(|a|^{p-2} a-|b|^{p-2} b\right)(a-b) \geq \frac{1}{2^{p-2}}|a-b|^{p}
$$

This proves the lemma.
However, in the context of strictly convex norms on the reflexive Banach space $X$, the following important result holds. I will give it first for the case where $p=2$ since this is the case of most interest.

Theorem 25.2.5 Let $X$ be a reflexive Banach space and $X, X^{\prime}$ have strictly convex norms as discussed above. Let $F$ be the duality map with $p=2$. Then $F$ is strictly monotone. This means

$$
\langle F u-F v, u-v\rangle \geq 0
$$

and it equals 0 if and only if $u-v$.
Proof: First why is it monotone? By definition of $F,\langle F(u), u\rangle=\|u\|^{2}$ and $\|F(u)\|=$ $\|u\|$. Then

$$
|\langle F u, v\rangle|=\left|\left\langle F u, \frac{v}{\|v\|}\right\rangle\right|\|v\| \leq\|F u\|\|v\|=\|u\|\|v\|
$$

Hence

$$
\begin{aligned}
\langle F u-F v, u-v\rangle & =\|u\|^{2}+\|v\|^{2}-\langle F u, v\rangle-\langle F v, u\rangle \\
& \geq\|u\|^{2}+\|v\|^{2}-2\|u\|\|v\| \geq 0
\end{aligned}
$$

Now suppose $\|x\|=\|y\|=1$ but $x \neq y$. Then

$$
\left\langle F x, \frac{x+y}{2}\right\rangle \leq\left\|\frac{x+y}{2}\right\|<\frac{\|x\|+\|y\|}{2}=1
$$

It follows that

$$
\frac{1}{2}\langle F x, x\rangle+\frac{1}{2}\langle F x, y\rangle=\frac{1}{2}+\frac{1}{2}\langle F x, y\rangle<1
$$

and so

$$
\langle F x, y\rangle<1
$$

For arbitrary $x, y, x /\|x\| \neq y /\|y\|$

$$
\langle F x, y\rangle=\|x\|\|y\|\left\langle F\left(\frac{x}{\|x\|}\right),\left(\frac{y}{\|y\|}\right)\right\rangle
$$

It is easy to check that $F(\alpha x)=\alpha F(x)$. Therefore,

$$
|\langle F x, y\rangle|=\|x\|\|y\|\left\langle F\left(\frac{x}{\|x\|}\right),\left(\frac{y}{\|y\|}\right)\right\rangle<\|x\|\|y\|
$$

Now say that $x \neq y$ and consider

$$
\langle F x-F y, x-y\rangle
$$

First suppose $x=\alpha y$. Then the above is

$$
\begin{aligned}
\langle F(\alpha y)-F y,(\alpha-1) y\rangle & =(\alpha-1)\left(\langle F(\alpha y), y\rangle-\|y\|^{2}\right) \\
& =(\alpha-1)\left(\langle\alpha F(y), y\rangle-\|y\|^{2}\right) \\
& =(\alpha-1)^{2}\|y\|^{2}>0
\end{aligned}
$$

The other case is that $x /\|x\| \neq y /\|y\|$ and in this case,

$$
\begin{gathered}
\langle F x-F y, x-y\rangle=\|x\|^{2}+\|y\|^{2}-\langle F x, y\rangle-\langle F y, x\rangle \\
>\|x\|^{2}+\|y\|^{2}-2\|x\|\|y\| \geq 0
\end{gathered}
$$

Thus $F$ is strictly monotone as claimed.
As mentioned, this will hold for any $p>1$. Here is a proof in the case that the Banach space is real which is the usual case of interest. First here is a simple observation.

Observation 25.2.6 Let $p>1$. Then $x \rightarrow|x|^{p-2} x$ is strictly monotone. Here $x \in \mathbb{R}$.
To verify this observation,

$$
\frac{d}{d x}\left(\left(x^{2}\right)^{\frac{p-2}{2}} x\right)=\frac{1}{x^{2}}(p-1)\left(x^{2}\right)^{\frac{1}{2} p}>0
$$

Theorem 25.2.7 Let $X$ be a real reflexive Banach space and $X, X^{\prime}$ have strictly convex norms as discussed above. Let $F$ be the duality map for $p>1$. Then $F$ is strictly monotone. This means

$$
\langle F u-F v, u-v\rangle \geq 0
$$

and it equals 0 if and only if $u-v$.
Proof: First why is it monotone? By definition of $F,\langle F(u), u\rangle=\|u\|^{p}$ and $\|F(u)\|=$ $\|u\|^{p-1}$. Then

$$
|\langle F u, v\rangle|=\left|\left\langle F u, \frac{v}{\|v\|}\right\rangle\right|\|v\| \leq\|F u\|\|v\|=\|u\|^{p-1}\|v\|
$$

Hence

$$
\begin{aligned}
\langle F u-F v, u-v\rangle & =\|u\|^{p}+\|v\|^{p}-\langle F u, v\rangle-\langle F v, u\rangle \\
& \geq\|u\|^{p}+\|v\|^{p}-\|u\|^{p-1}\|v\|-\|u\|\|v\|^{p-1} \\
\geq\|u\|^{p}+\|v\|^{p} & -\left(\frac{\|u\|^{p}}{p^{\prime}}+\frac{\|v\|^{p}}{p}\right)-\left(\frac{\|u\|^{p}}{p}+\frac{\|v\|^{p}}{p^{\prime}}\right)=0
\end{aligned}
$$

Now suppose $\|x\|=\|y\|=1$ but $x \neq y$. Then

$$
\left\langle F x, \frac{x+y}{2}\right\rangle \leq\|x\|^{p-1}\left\|\frac{x+y}{2}\right\|<\frac{\|x\|+\|y\|}{2}=1
$$

It follows that

$$
\frac{1}{2}\langle F x, x\rangle+\frac{1}{2}\langle F x, y\rangle=\frac{1}{2}+\frac{1}{2}\langle F x, y\rangle<1
$$

and so

$$
\langle F x, y\rangle<1
$$

It is easy to check that for nonzero $\alpha, F(\alpha x)=|\alpha|^{p-2} \alpha F(x)$. This is because

$$
\begin{gathered}
\left\||\alpha|^{p-2} \alpha F(x)\right\|=|\alpha|^{p-1}\|x\|^{p-1}=\|\alpha x\|^{p-1} \\
\left.\left.\langle | \alpha\right|^{p-2} \alpha F(x), \alpha x\right\rangle=|\alpha|^{p}\|x\|^{p}=\|\alpha x\|^{p}
\end{gathered}
$$

and so, since $|\alpha|^{p-2} \alpha F(x)$ acts like $F(\alpha x)$, it is $F(\alpha x)$. It follows that for arbitrary $x, y$, such that $x /\|x\| \neq y /\|y\|$

$$
\langle F x, y\rangle=\|x\|^{p-1}\|y\|\left\langle F\left(\frac{x}{\|x\|}\right),\left(\frac{y}{\|y\|}\right)\right\rangle
$$

Therefore,

$$
\begin{equation*}
\langle F x, y\rangle=\|x\|^{p-1}\|y\|\left\langle F\left(\frac{x}{\|x\|}\right),\left(\frac{y}{\|y\|}\right)\right\rangle<\|x\|^{p-1}\|y\| \tag{25.2.10}
\end{equation*}
$$

Now say that $x \neq y$ and consider

$$
\langle F x-F y, x-y\rangle
$$

First suppose $x=\alpha y$. This is the case where $x$ is a multiple of $y$. Then the above is

$$
\begin{gathered}
\langle F(\alpha y)-F y,(\alpha-1) y\rangle=(\alpha-1)\left(\langle F(\alpha y), y\rangle-\|y\|^{p}\right) \\
=(\alpha-1)\left(|\alpha|^{p-2} \alpha\|y\|^{p}-\|y\|^{p}\right)=(\alpha-1)\left(|\alpha|^{p-2} \alpha-1\right)\|y\|^{p}>0
\end{gathered}
$$

by the above observation that $x \rightarrow|x|^{p-2} x$ is strictly monotone. Similarly,

$$
\langle F x-F y, x-y\rangle>0
$$

if $y=\alpha x$ for $\alpha \neq 1$.
Thus the desired result holds in the case that one vector is a multiple of the other. The other case is that neither vector is a multiple of the other. Thus, in particular, $x /\|x\| \neq$ $y /\|y\|$, and in this case, it follows from 25.2.10

$$
\begin{gathered}
\langle F x-F y, x-y\rangle=\|x\|^{p}+\|y\|^{p}-\langle F x, y\rangle-\langle F y, x\rangle \\
>\|x\|^{p}+\|y\|^{p}-\|x\|^{p-1}\|y\|-\|y\|^{p-1}\|x\| \\
\geq\|x\|^{p}+\|y\|^{p}-\left(\frac{\|x\|^{p}}{p^{\prime}}+\frac{\|y\|^{p}}{p}\right)-\left(\frac{\|y\|^{p}}{p^{\prime}}+\frac{\|x\|^{p}}{p}\right)=0
\end{gathered}
$$

Thus $F$ is strictly monotone as claimed.
Another useful observation about duality maps for $p=2$ is that $\left\|F^{-1} y^{*}\right\|_{V}=\left\|y^{*}\right\|_{V^{\prime}}$. This is because

$$
\left\|y^{*}\right\|_{V^{\prime}}=\left\|F F^{-1} y^{*}\right\|_{V^{\prime}}=\left\|F^{-1} y^{*}\right\|_{V}
$$

also from similar reasoning,

$$
\left\langle y^{*}, F^{-1} y^{*}\right\rangle=\left\langle F F^{-1} y^{*}, F^{-1} y^{*}\right\rangle=\left\|F^{-1} y^{*}\right\|_{V}^{2}=\left\|y^{*}\right\|_{V^{\prime}}^{2}
$$

You can give specific inequalities in certain cases. Here is a nice little inequality which will allow this.

Theorem 25.2.8 Let $p \geq 2$ then for $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{n}$,

$$
\begin{equation*}
\left(|\mathbf{x}|^{p-2} \mathbf{x}-|\mathbf{y}|^{p-2} \mathbf{y}, \mathbf{x}-\mathbf{y}\right) \geq \frac{1}{2^{p-1}}|\mathbf{x}-\mathbf{y}|^{p} \tag{*}
\end{equation*}
$$

Proof: We have $(\mathbf{x}, \mathbf{y})=\frac{1}{2}\left(|\mathbf{x}|^{2}+|\mathbf{y}|^{2}-|\mathbf{x}-\mathbf{y}|^{2}\right)$. Consider the following.

$$
\frac{1}{2}\left(\frac{|\mathbf{x}|^{p-2}+|\mathbf{y}|^{p-2}}{|\mathbf{x}-\mathbf{y}|^{p-2}}\right)|\mathbf{x}-\mathbf{y}|^{p}+\frac{1}{2}\left(|\mathbf{x}|^{p-2}-|\mathbf{y}|^{p-2}\right)\left(|\mathbf{x}|^{2}-|\mathbf{y}|^{2}\right)
$$

multiplying this out gives

$$
\frac{1}{2}\left(|\mathbf{x}|^{p-2}+|\mathbf{y}|^{p-2}\right)\left(|\mathbf{x}|^{2}+|\mathbf{y}|^{2}-2(\mathbf{x}, \mathbf{y})\right)+\frac{1}{2}\left(|\mathbf{x}|^{p}-|\mathbf{x}|^{2}|\mathbf{y}|^{p-2}+|\mathbf{y}|^{p}-|\mathbf{x}|^{p-2}|\mathbf{y}|^{2}\right)
$$

thus this yields

$$
\begin{aligned}
& \frac{1}{2}\left[|\mathbf{x}|^{p}+|\mathbf{y}|^{p-2}|\mathbf{x}|^{2}+|\mathbf{x}|^{p-2}|\mathbf{y}|^{2}+|\mathbf{y}|^{p}-\left(2(\mathbf{x}, \mathbf{y})|\mathbf{x}|^{p-2}+2(\mathbf{x}, \mathbf{y})|\mathbf{y}|^{p-2}\right)\right] \\
& +\frac{1}{2}\left(|\mathbf{x}|^{p}+|\mathbf{y}|^{p}-\left(|\mathbf{x}|^{2}|\mathbf{y}|^{p-2}+|\mathbf{x}|^{p-2}|\mathbf{y}|^{2}\right)\right)
\end{aligned}
$$

It simplifies to

$$
|\mathbf{x}|^{p}+|\mathbf{y}|^{p}-2(\mathbf{x}, \mathbf{y})\left(|\mathbf{x}|^{p-2}+|\mathbf{y}|^{p-2}\right)
$$

On the left side of $*$, when you multiply it out, you get

$$
|\mathbf{x}|^{p}-|\mathbf{x}|^{p-2}(\mathbf{x}, \mathbf{y})-|\mathbf{y}|^{p-2}(\mathbf{x}, \mathbf{y})+|\mathbf{y}|^{p}
$$

which is exactly the same thing. Therefore,

$$
\begin{align*}
\left(|\mathbf{x}|^{p-2} \mathbf{x}-|\mathbf{y}|^{p-2} \mathbf{y}, \mathbf{x}-\mathbf{y}\right)= & \frac{1}{2}\left(\frac{|\mathbf{x}|^{p-2}+|\mathbf{y}|^{p-2}}{|\mathbf{x}-\mathbf{y}|^{p-2}}\right)|\mathbf{x}-\mathbf{y}|^{p}  \tag{**}\\
& +\frac{1}{2}\left(|\mathbf{x}|^{p-2}-|\mathbf{y}|^{p-2}\right)\left(|\mathbf{x}|^{2}-|\mathbf{y}|^{2}\right)
\end{align*}
$$

Suppose first that $p \geq 3$. Now $p \geq 3$ and so $|\mathbf{x}|^{p-2}$ is convex. Hence

$$
\left|\frac{\mathbf{x}+(-\mathbf{y})}{2}\right|^{p-2} \leq \frac{1}{2}\left(|\mathbf{x}|^{p-2}+|-\mathbf{y}|^{p-2}\right)
$$

and so

$$
\left(|\mathbf{x}|^{p-2} \mathbf{x}-|\mathbf{y}|^{p-2} \mathbf{y}, \mathbf{x}-\mathbf{y}\right) \geq\left|\frac{\mathbf{x}-\mathbf{y}}{2}\right|^{p-2} \frac{1}{|\mathbf{x}-\mathbf{y}|^{p-2}}|\mathbf{x}-\mathbf{y}|^{p}=\frac{1}{2^{p-2}}|\mathbf{x}-\mathbf{y}|^{p}
$$

Next suppose $p>2$. There is nothing to show if $p=2$. Then for a positive integer $m$, you can get $m(p-2)>1$. Then

$$
\left(|\mathbf{x}|^{p-2}+|\mathbf{y}|^{p-2}\right)^{m} \geq|\mathbf{x}|^{m(p-2)}+|\mathbf{y}|^{m(p-2)} \geq 2^{1-m(p-2)}|\mathbf{x}-\mathbf{y}|^{m(p-2)}
$$

Thus we can raise both sides of the above to $1 / \mathrm{m}$ and conclude

$$
|\mathbf{x}|^{p-2}+|\mathbf{y}|^{p-2} \geq 2^{1 / m-(p-2)}|\mathbf{x}-\mathbf{y}|^{p-2}
$$

Then we use this in $* *$ to obtain

$$
\begin{gathered}
\left(|\mathbf{x}|^{p-2} \mathbf{x}-|\mathbf{y}|^{p-2} \mathbf{y}, \mathbf{x}-\mathbf{y}\right) \geq \frac{1}{2}\left(\frac{|\mathbf{x}|^{p-2}+|\mathbf{y}|^{p-2}}{|\mathbf{x}-\mathbf{y}|^{p-2}}\right)|\mathbf{x}-\mathbf{y}|^{p} \\
\quad \geq \frac{1}{2} \frac{1}{2^{(p-2)-(1 / m)}}|\mathbf{x}-\mathbf{y}|^{p} \geq \frac{1}{2^{p-1}}|\mathbf{x}-\mathbf{y}|^{p}
\end{gathered}
$$

Thus, if you have the duality map $F$ for $p \geq 2$ for real valued $L^{p}(\Omega)$ to $L^{p^{\prime}}(\Omega)$, it is clear that $F f=|f|^{p-2} f$ and so

$$
\begin{aligned}
& \langle F f-F g, f-g\rangle=\int_{\Omega}\left(|f|^{p-2} f-|g|^{p-2} g\right)(f-g) d \mu \geq \frac{1}{2^{p-1}} \int_{\Omega}|f-g|^{p} d \mu \\
& \langle F f-F g, f-g\rangle \geq \frac{1}{2^{p-1}}\|f-g\|_{L^{p}(\Omega)}^{p}
\end{aligned}
$$

A similar result would hold for the duality map from $\left(L^{p}(\Omega)\right)^{n}$ to $\left(L^{p^{\prime}}(\Omega)\right)^{n}$.

### 25.3 Penalizaton And Projection Operators

In this section, $X$ will be a reflexive Banach space such that $X, X^{\prime}$ has a strictly convex norm. Let $K$ be a closed convex set in $X$. Then the following lemma is obtained.

Lemma 25.3.1 Let $K$ be closed and convex nonempty subset of $X$ a reflexive Banach space which has strictly convex norm. Then there exists a projection map $P$ such that $P x \in K$ and for all $y \in K$,

$$
\|y-x\| \geq\|x-P x\|
$$

Proof: Let $\left\{y_{n}\right\}$ be a minimizing sequence for $y \rightarrow\|y-x\|$ for $y \in K$. Thus

$$
d \equiv \inf \{\|y-x\|: y \in K\}=\lim _{n \rightarrow \infty}\left\|y_{n}-x\right\|
$$

Then obviously $\left\{y_{n}\right\}$ is bounded. Hence there is a subsequence, still denoted by $n$ such that $y_{n} \rightarrow w \in K$. Then

$$
\|w-x\| \leq \lim \inf _{n \rightarrow \infty}\left\|y_{n}-x\right\|=d
$$

How many closest points to $x$ are there? Suppose $w_{1}$ is another one. Then

$$
\left\|\frac{w_{1}+w}{2}-x\right\|=\left\|\frac{w_{1}-x+w-x}{2}\right\|<\left\|\frac{w_{1}-x}{2}\right\|+\left\|\frac{w-x}{2}\right\|=d
$$

contradicting the assumption that both $w, w_{1}$ are closest points to $x$. Therefore, $P x$ consists of a single point.

Denote by $F$ the duality map such that $\langle F x, x\rangle=\|x\|^{2}$. This is described earlier but there is also a very nice treatment which is somewhat different in [13]. Everything can be generalized and is in [91] but here I will only consider this case. First here is a useful result.

Proposition 25.3.2 Let $F$ be the duality map just described. Let $\phi(x) \equiv \frac{\|x\|^{2}}{2}$. Then $F(x)=$ $\partial \phi(x)$.

Proof: This follows from

$$
\begin{aligned}
\langle F x, y-x\rangle & \leq\langle F x, y\rangle-\langle F x, x\rangle \leq\langle F x, x\rangle^{1 / 2}\langle F y, y\rangle^{1 / 2}-\langle F x, x\rangle \\
& \leq \frac{\langle F y, y\rangle}{2}-\frac{\langle F x, x\rangle}{2}=\frac{\|y\|^{2}}{2}-\frac{\|x\|^{2}}{2} .
\end{aligned}
$$

Next is a really nice result about the characterization of $P x$ in terms of $F$.
Proposition 25.3.3 Let $K$ be a nonempty closed convex set in $X$ a reflexive Banach space in which both $X, X^{\prime}$ have strictly convex norms. Then $w \in K$ is equal to $P x$ if and only if

$$
\langle F(x-w), y-w\rangle \leq 0
$$

for every $y \in K$.

Proof: First suppose the condition. Then for $y \in K$, it follows from the above proposition about the subgradient,

$$
\frac{1}{2}\|x-y\|^{2}-\frac{1}{2}\|x-w\|^{2} \geq\langle F(x-w), w-y\rangle \geq 0
$$

and so since this holds for all $y$ it follows that

$$
\|x-y\| \geq\|x-w\|
$$

for all $y$ which says that $w=P x$.
Next, using the subgradient idea again, for $\theta \in[0,1]$, suppose $w=P x$ then for $y \in K$ arbitrary,

$$
0 \geq \frac{1}{2}\|x-w\|^{2}-\frac{1}{2}\|x-(w+\theta(y-w))\|^{2} \geq\langle F(x-(w+\theta(y-w))), \theta(y-x)\rangle
$$

Now divide by $\theta$ and let $\theta \downarrow 0$ and use the hemicontinuity of $F$ given above. Then

$$
0 \geq\langle F(x-w), y-x\rangle
$$

Definition 25.3.4 An operator of penalization is an operator $f: X \rightarrow X^{\prime}$ such that $f=0$ on $K, f$ is monotone and nonzero off $K$ as well as demicontinuous. (Strong convergence goes to weak convergence.) Actually, in applications, it is usually easy to give an ad hoc description of an appropriate penalization operator.

Proposition 25.3.5 Let $K$ be a closed convex nonempty subset of $X$ a reflexive Banach space such that $X, X^{\prime}$ have strictly convex norms. Then

$$
f(x) \equiv F(x-P x)
$$

is an operator of penalization. Here $P$ is the projection onto $K$. This operator of penalization is demicontinuous.

Proof: First, observe that $f(x)$ is 0 on $K$ and nonzero off $K$. Why is it monotone?

$$
\begin{aligned}
& \left\langle F(x-P x)-F\left(x_{1}-P x_{1}\right), x-x_{1}\right\rangle \\
& =\left\langle F(x-P x)-F\left(x_{1}-P x_{1}\right), x-P x-\left(x_{1}-P x_{1}\right)\right\rangle \\
& +\left\langle F(x-P x)-F\left(x_{1}-P x_{1}\right), P x-P x_{1}\right\rangle
\end{aligned}
$$

The first term is $\geq 0$ because $F$ is monotone. As to the second, it equals

$$
\left\langle F(x-P x), P x-P x_{1}\right\rangle+\left\langle F\left(x_{1}-P x_{1}\right), P x_{1}-P x\right\rangle
$$

and both of these are $\geq 0$ because of Proposition 25.3 .3 which characterizes the projection map.

Now why is this hemicontinuous? Let $x_{n} \rightarrow x$. Then $P x_{n}$ is clearly bounded. Taking a subsequence, it can be assumed that $P x_{n} \rightarrow \xi$ weakly. Is $\xi=P x$ ?

$$
\begin{aligned}
\|x-P x\| & \leq\left\|x-P x_{n}\right\| \leq\left\|x-x_{n}\right\|+\left\|x_{n}-P x_{n}\right\| \\
\left\|x_{n}-P x_{n}\right\| & \leq\left\|x_{n}-P x\right\| \leq\left\|x_{n}-x\right\|+\|x-P x\|
\end{aligned}
$$

It follows that

$$
\begin{aligned}
& \|x-P x\|-\left\|x_{n}-P x_{n}\right\| \leq\left\|x-x_{n}\right\| \\
& \left\|x_{n}-P x_{n}\right\|-\|x-P x\| \leq\left\|x-x_{n}\right\|
\end{aligned}
$$

Hence $\left\|x_{n}-P x_{n}\right\| \rightarrow\|x-P x\|$. However, from convexity and strong lower semicontinuity implying weak lower semicontinuity,

$$
\|x-\xi\| \leq \lim \inf _{n \rightarrow \infty}\left\|x_{n}-P x_{n}\right\|=\|x-P x\|
$$

and so $\xi=P x$ because there is only one value in $P x$. This has shown that, thanks to uniqueness of $P x, x_{n} \rightarrow x$ implies $P x_{n} \rightarrow P x$ weakly.

Next we show that $f$ is demicontinuous. Suppose $x_{n} \rightarrow x$. Then from what was just shown, $P x_{n} \rightarrow P x$ weakly. Thus $x_{n}-P x_{n} \rightarrow x-P x$ weakly. Then

$$
\begin{aligned}
& \lim \sup _{n \rightarrow \infty}\left\langle F\left(x_{n}-P x_{n}\right), x_{n}-P x_{n}-(x-P x)\right\rangle \\
= & \lim \sup _{n \rightarrow \infty}\left\langle F\left(x_{n}-P x_{n}\right), P x-P x_{n}\right\rangle \leq 0
\end{aligned}
$$

from Proposition 25.3 .3 which characterizes the projection map. It follows that, since $F$ is monotone hemicontinuous and bounded, it is also pseudomonotone and so for all $v$

$$
\begin{gathered}
\lim _{n \rightarrow \infty} \inf _{n}\left\langle F\left(x_{n}-P x_{n}\right),\left(x_{n}-P x_{n}\right)-v\right\rangle \\
\geq\langle F(x-P x),(x-P x)-v\rangle
\end{gathered}
$$

Now $F\left(x_{n}-P x_{n}\right)$ is bounded. If it converges to $\xi$, then

$$
\begin{gathered}
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle F\left(x_{n}-P x_{n}\right),\left(x_{n}-P x_{n}\right)-v\right\rangle \\
\leq \lim \sup _{n \rightarrow \infty}\left[\begin{array}{c}
\left\langle F\left(x_{n}-P x_{n}\right),\left(x_{n}-P x_{n}\right)-(x-P x)\right\rangle \\
+\left\langle F\left(x_{n}-P x_{n}\right),(x-P x)-v\right\rangle
\end{array}\right] \\
\leq\langle\xi,(x-P x)-v\rangle
\end{gathered}
$$

It follows that

$$
\begin{aligned}
\langle\xi,(x-P x)-v\rangle & \geq \lim _{n \rightarrow \infty}\left\langle F\left(x_{n}-P x_{n}\right),\left(x_{n}-P x_{n}\right)-v\right\rangle \\
& \geq\langle F(x-P x),(x-P x)-v\rangle
\end{aligned}
$$

Since $v$ is arbitrary, it follows that $\xi=F(x-P x)$. Hence $F\left(x_{n}-P x_{n}\right) \rightarrow F(x-P x)$ weakly. Thus this is demicontinuous.

### 25.4 Set-Valued Maps, Pseudomonotone Operators

In the abstract theory of partial differential equations and variational inequalities, it is important to consider set-valued maps from a Banach space to the power set of its dual. In this section we give an introduction to this theory by proving a general result on surjectivity for a class of such operators.

To begin with, if $A: X \rightarrow \mathscr{P}(Y)$ is a set-valued map, define the graph of $A$ by

$$
G(A) \equiv\{(x, y): y \in A x\} .
$$

First consider a map $A$ which maps $\mathbb{C}^{n}$ to $\mathscr{P}\left(\mathbb{C}^{n}\right)$ which satisfies
$A \mathbf{x}$ is compact and convex.
and also the condition that if $O$ is open and $O \supseteq A \mathbf{x}$, then there exists $\delta>0$ such that if

$$
\begin{equation*}
\mathbf{y} \in B(\mathbf{x}, \boldsymbol{\delta}), \text { then } A \mathbf{y} \subseteq O \tag{25.4.12}
\end{equation*}
$$

This last condition is sometimes referred to as upper semicontinuity. In words, $A$ is upper semicontinuous and has values which are compact and convex. As to the last condition of upper semi continuity, here is the formal definition.
Definition 25.4.1 Let $F: X \rightarrow \mathscr{P}(Y)$ be a set valued function. Then $F$ is upper semicontinuous at $x$ if for every open $V \supseteq F(x)$ there exists an open set $U$ containing $x$ such that whenever $\hat{x} \in U$, it follows that $F(\hat{x}) \subseteq V$.

Lemma 25.4.2 Let A satisfy 25.4.12. Then $A K$ is a subset of a compact set whenever $K$ is compact. Also the graph of $A$ is closed if $A \mathbf{x}$ is closed.

Proof: Let $\mathbf{x} \in K$. Then $A \mathbf{x}$ is compact and contained in some open set whose closure is compact, $U_{\mathbf{x}}$. By assumption 25.4.12 there exists an open set $V_{\mathbf{X}}$ containing $\mathbf{x}$ such that if $\mathbf{y} \in V_{\mathbf{x}}$, then $A \mathbf{y} \subseteq U_{\mathbf{x}}$. Let $V_{\mathbf{x}_{1}}, \cdots, V_{\mathbf{x}_{m}}$ cover $K$. Then $A K \subseteq \cup_{k=1}^{m} \bar{U}_{\mathbf{x}_{k}}$, a compact set.

To see the graph of $A$ is closed when $A \mathbf{x}$ is closed, let $\mathbf{x}_{k} \rightarrow \mathbf{x}, \mathbf{y}_{k} \rightarrow \mathbf{y}$ where $\mathbf{y}_{k} \in A \mathbf{x}_{k}$. Then letting $O=A \mathbf{x}+B(\mathbf{0}, r)$ it follows from 25.4.12 that $\mathbf{y}_{k} \in A \mathbf{x}_{k} \subseteq O$ for all $k$ large enough. Therefore, $\mathbf{y} \in A \mathbf{x}+B(\mathbf{0}, 2 r)$ and since $r>0$ is arbitrary and $A \mathbf{x}$ is closed it follows $\mathbf{y} \in A \mathbf{x}$.

Also, there is a general consideration relative to upper semicontinuous functions.
Lemma 25.4.3 If $\mathbf{f}$ is upper semicontinuous on some set $K$ and $\mathbf{g}$ is continuous and defined on $\mathbf{f}(K)$, then $\mathbf{g} \circ \mathbf{f}$ is also upper semicontinuous.

Proof: Let $\mathbf{x}_{n} \rightarrow \mathbf{x}$ in $K$. Let $U \supseteq \mathbf{g} \circ \mathbf{f}(\mathbf{x})$. Is $\mathbf{g} \circ \mathbf{f}\left(\mathbf{x}_{n}\right) \in U$ for all $n$ large enough? We have $\mathbf{f}(\mathbf{x}) \in \mathbf{g}^{-1}(U)$, an open set. Therefore, if $n$ is large enough, $\mathbf{f}\left(\mathbf{x}_{n}\right) \in \mathbf{g}^{-1}(U)$. It follows that for large enough $n, \mathbf{g} \circ \mathbf{f}\left(\mathbf{x}_{n}\right) \in U$ and so $\mathbf{g} \circ \mathbf{f}$ is upper semicontinuous on $K$.

The next theorem is an application of the Brouwer fixed point theorem. First define an $n$ simplex, denoted by $\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]$, to be the convex hull of the $n+1$ points, $\left\{\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right\}$ where $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are independent. Thus

$$
\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right] \equiv\left\{\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}: \sum_{i=0}^{n} t_{i}=1, t_{i} \geq 0\right\}
$$

Since $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ is independent, the $t_{i}$ are uniquely determined. If two of them are

$$
\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}=\sum_{i=0}^{n} s_{i} \mathbf{x}_{i}
$$

Then

$$
\sum_{i=0}^{n} t_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)=\sum_{i=0}^{n} s_{i}\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right)
$$

so $t_{i}=s_{i}$ for $i \geq 1$. Since the $s_{i}$ and $t_{i}$ sum to 1 , it follows that also $s_{0}=t_{0}$. If $n \leq 2$, the simplex is a triangle, line segment, or point. If $n \leq 3$, it is a tetrahedron, triangle, line segment or point. To say that $\left\{\mathbf{x}_{i}-\mathbf{x}_{0}\right\}_{i=1}^{n}$ are independent is to say that $\left\{\mathbf{x}_{i}-\mathbf{x}_{r}\right\}_{i \neq r}$ are independent for each fixed $r$. Indeed, if $\mathbf{x}_{i}-\mathbf{x}_{r}=\sum_{j \neq i, r} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{r}\right)$, then you would have

$$
\mathbf{x}_{i}-\mathbf{x}_{0}+\mathbf{x}_{0}-\mathbf{x}_{r}=\sum_{j \neq i, r} c_{j}\left(\mathbf{x}_{j}-\mathbf{x}_{0}\right)+\left(\sum_{j \neq i, r} c_{j}\right) \mathbf{x}_{0}
$$

and it follows that $\mathbf{x}_{i}-\mathbf{x}_{0}$ is a linear combination of the $\mathbf{x}_{j}-\mathbf{x}_{0}$ for $j \neq i$, contrary to assumption. A collection of simplices is a tiling of $\mathbb{R}^{n}$ if $\mathbb{R}^{n}$ is contained in their union and if $S_{1}, S_{2}$ are two simplices in the tiling, with

$$
S_{j}=\left[\mathbf{x}_{0}^{j}, \cdots, \mathbf{x}_{n}^{j}\right]
$$

then

$$
S_{1} \cap S_{2}=\left[\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right]
$$

where

$$
\left\{\mathbf{x}_{k_{0}}, \cdots, \mathbf{x}_{k_{r}}\right\} \subseteq\left\{\mathbf{x}_{0}^{1}, \cdots, \mathbf{x}_{n}^{1}\right\} \cap\left\{\mathbf{x}_{0}^{2}, \cdots, \mathbf{x}_{n}^{2}\right\}
$$

or else the two simplices do not intersect. The collection of simplices is said to be locally finite if, for every point, there exists a ball containing that point which also intersects only finitely many of the simplices in the collection. It is left to the reader to verify that for each $\varepsilon>0$, there exists a locally finite tiling of $\mathbb{R}^{n}$ which is composed of simplices which have diameters less than $\varepsilon$. The local finiteness ensures that for each $\varepsilon$ the vertices have no limit point. To see how to do this, consider the case of $\mathbb{R}^{2}$. Tile the plane with identical small squares and then form the triangles indicated in the following picture. It is clear something similar can be done in any dimension. Making the squares identical ensures that the little triangles are locally finite.

In general, you could consider $[0,1]^{n}$. The point at the center is $(1 / 2, \cdots, 1 / 2)$. Then there are $2 n$ faces. Form the $2 n$ pyramids having this point along with the $2^{n-1}$ vertices of the face. Then use induction on each of these faces to form smaller dimensional simplices tiling that face. Corresponding to each of these $2 n$ pyramids, it is the union of the simplices whose vertices consist of the center point along with those of these new simplicies tiling the chosen face. In general, you can write any $n$ dimensional cube as the translate of a scaled $[0,1]^{n}$. Thus one can express each of identical cubes as a tiling of $m(n)$ simplices of the appropriate size and thereby obtain a tiling of $\mathbb{R}^{n}$ with simplices. A ball will intersect only finitely many of the cubes and hence finitely many of the simplices. To get their diameters small as desired, just use $[0, r]^{n}$ instead of $[0,1]^{n}$.

Thus one can give a function any value desired on these vertices and extend appropriately to the rest of the simplex and obtain a continuous function.

The Kakutani fixed point theorem is a generalization of the Brouwer fixed point theorem from continuous single valued maps to upper semicontinuous maps which have closed convex values.

Theorem 25.4.4 Let $K$ be a compact convex subset of $\mathbb{R}^{n}$ and let $A: K \rightarrow \mathscr{P}(K)$ such that $A \mathbf{x}$ is a closed convex subset of $K$ and $A$ is upper semicontinuous. Then there exists $\mathbf{x}$ such that $\mathbf{x} \in A \mathbf{x}$. This is the "fixed point".

Proof: Let there be a locally finite tiling of $\mathbb{R}^{n}$ consisting of simplices having diameter no more than $\varepsilon$. Let $P \mathbf{x}$ be the point in $K$ which is closest to $\mathbf{x}$. For each vertex $\mathbf{x}_{k}$, pick $A_{\varepsilon} \mathbf{x}_{k} \in A P \mathbf{x}_{k}$ and define $A_{\varepsilon}$ on all of $\mathbb{R}^{n}$ by the following rule. If

$$
\mathbf{x} \in\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{n}\right]
$$

so $\mathbf{x}=\sum_{i=0}^{n} t_{i} \mathbf{x}_{i}, t_{i} \in[0,1], \sum_{i} t_{i}=1$, then

$$
A_{\mathcal{E}} \mathbf{x} \equiv \sum_{k=0}^{n} t_{k} A_{\mathcal{E}} \mathbf{x}_{k}
$$

Now by construction $A_{\varepsilon} \mathbf{x}_{k} \in A P \mathbf{x}_{k} \in K$ and so $A_{\varepsilon}$ is a continuous map defined on $\mathbb{R}^{n}$ with values in $K$ thanks to the local finiteness of the collection of simplices. By the Brouwer fixed point theorem $A_{\mathcal{\varepsilon}}$ has a fixed point $\mathbf{x}_{\varepsilon}$ in $K, A_{\varepsilon} \mathbf{x}_{\varepsilon}=\mathbf{x}_{\varepsilon}$.

$$
\mathbf{x}_{\varepsilon}=\sum_{k=0}^{n} t_{k}^{\varepsilon} A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon}, A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon} \in A P \mathbf{x}_{k}^{\varepsilon} \in K
$$

where a simplex containing $\mathbf{x}_{\varepsilon}$ is

$$
\left[\mathbf{x}_{0}^{\varepsilon}, \cdots, \mathbf{x}_{n}^{\varepsilon}\right], \mathbf{x}_{\varepsilon}=\sum_{k=0}^{n} t_{k}^{\varepsilon} \mathbf{x}_{k}^{\varepsilon}
$$

Also, $\mathbf{x}_{\varepsilon} \in K$ and is closer than $\varepsilon$ to each $\mathbf{x}_{k}^{\varepsilon}$ so each $\mathbf{x}_{k}^{\varepsilon}$ is within $\varepsilon$ of $K$. It follows that for each $k,\left|P \mathbf{x}_{k}^{\varepsilon}-\mathbf{x}_{k}^{\varepsilon}\right|<\varepsilon$ and so

$$
\lim _{\varepsilon \rightarrow 0}\left|P \mathbf{x}_{k}^{\varepsilon}-\mathbf{x}_{k}^{\varepsilon}\right|=0
$$

By compactness of $K$, there exists a subsequence, still denoted with the subscript of $\varepsilon$ such that for each $k$, the following convergences hold as $\varepsilon \rightarrow 0$

$$
t_{k}^{\varepsilon} \rightarrow t_{k}, A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon} \rightarrow \mathbf{y}_{k}, P \mathbf{x}_{k}^{\varepsilon} \rightarrow \mathbf{z}_{k}, \mathbf{x}_{k}^{\varepsilon} \rightarrow \mathbf{z}_{k}
$$

Any pair of the $\mathbf{x}_{k}^{\varepsilon}$ are within $\varepsilon$ of each other. Hence, any pair of the $P \mathbf{x}_{k}^{\varepsilon}$ are within $\varepsilon$ of each other because $P$ reduces distances. Therefore, in fact, $\mathbf{z}_{k}$ does not depend on $k$.

$$
\lim _{\varepsilon \rightarrow 0} P \mathbf{x}_{k}^{\varepsilon}=\lim _{\varepsilon \rightarrow 0} \mathbf{x}_{k}^{\varepsilon}=\mathbf{z}, \quad \lim _{\varepsilon \rightarrow 0} \mathbf{x}_{\varepsilon}=\lim _{\varepsilon \rightarrow 0} \sum_{k=0}^{n} t_{k}^{\varepsilon} \mathbf{x}_{k}^{\varepsilon}=\sum_{k=0}^{n} t_{k} \mathbf{z}=\mathbf{z}
$$

By upper semicontinuity of $A$, for all $\varepsilon$ small enough,

$$
A P \mathbf{x}_{k}^{\varepsilon} \subseteq A \mathbf{z}+B(\mathbf{0}, r)
$$

In particular, since $A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon} \in A P \mathbf{x}_{k}^{\varepsilon}$,

$$
A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon} \in A \mathbf{z}+B(\mathbf{0}, r) \text { for } \varepsilon \text { small enough }
$$

Since $r$ is arbitrary and $A \mathbf{z}$ is closed, it follows

$$
\mathbf{y}_{k} \in A \mathbf{z}
$$

It follows that since $K$ is closed,

$$
\mathbf{x}_{\mathcal{E}} \rightarrow \mathbf{z}=\sum_{k=0}^{n} t_{k} \mathbf{y}_{k}, t_{k} \geq 0, \sum_{k=0}^{n} t_{k}=1
$$

Now by convexity of $A \mathbf{z}$ and the fact just shown that $\mathbf{y}_{k} \in A \mathbf{z}$,

$$
\mathbf{z}=\sum_{k=0}^{n} t_{k} \mathbf{y}_{k} \in A \mathbf{z}
$$

and so $\mathbf{z} \in A \mathbf{z}$. This is the fixed point.
One can replace $\mathbb{R}^{n}$ with $\mathbb{C}^{n}$ in the above theorem because it is essentially $\mathbb{R}^{2 n}$. Also the theorem holds with no change for any finite dimensional normed linear space since these are homeomorpic to $\mathbb{R}^{n}$ or $\mathbb{C}^{n}$.

Lemma 25.4.5 Suppose $A: \mathbb{C}^{n} \rightarrow \mathscr{P}\left(\mathbb{C}^{n}\right)$ satisfies $A \mathbf{x}$ is compact and convex, and $A$ is upper semicontinuous, 25.4.12 and $K$ is a nonempty compact convex set in $\mathbb{C}^{n}$. Then if $\mathbf{y} \in \mathbb{C}^{n}$ there exists $[\mathbf{x}, \mathbf{w}] \in G(A)$ such that $\mathbf{x} \in K$ and

$$
\operatorname{Re}(\mathbf{y}-\mathbf{w}, \mathbf{z}-\mathbf{x}) \leq 0
$$

for all $\mathbf{z} \in K$.
Proof: Tile $\mathbb{C}^{n}$ with $2 n$ simplices such that the collection is locally finite and each simplex has diameter less than $\varepsilon<1$. This collection of simplices is determined by a
countable collection of vertices. For each vertex $\mathbf{x}$, pick $A_{\mathcal{E}} \mathbf{x} \in A \mathbf{x}$ and define $A_{\mathcal{\varepsilon}}$ on all of $\mathbb{C}^{n}$ by the following rule. If

$$
\mathbf{x} \in\left[\mathbf{x}_{0}, \cdots, \mathbf{x}_{2 n}\right]
$$

so $\mathbf{x}=\sum_{i=0}^{2 n} t_{i} \mathbf{x}_{i}$, then

$$
A_{\mathcal{\varepsilon}} \mathbf{x} \equiv \sum_{k=0}^{2 n} t_{k} A_{\mathcal{\varepsilon}} \mathbf{x}_{k}
$$

Thus $A_{\varepsilon}$ is a continuous map defined on $\mathbb{C}^{n}$ thanks to the local finiteness of the collection of simplices. Let $P_{K}$ denote the projection on the convex set $K$. By the Brouwer fixed point theorem, there exists a fixed point, $\mathbf{x}_{\varepsilon} \in K$ such that

$$
P_{K}\left(\mathbf{y}-A_{\varepsilon} \mathbf{x}_{\varepsilon}+\mathbf{x}_{\varepsilon}\right)=\mathbf{x}_{\varepsilon}
$$

By Corollary 19.1.9 this requires

$$
\operatorname{Re}\left(\mathbf{y}-A_{\mathcal{E}} \mathbf{x}_{\mathcal{E}}, \mathbf{z}-\mathbf{x}_{\varepsilon}\right) \leq 0
$$

for all $\mathbf{z} \in K$.
Suppose $\mathbf{x}_{\varepsilon} \in\left[\mathbf{x}_{0}^{\varepsilon}, \cdots, \mathbf{x}_{2 n}^{\varepsilon}\right]$ so $\mathbf{x}_{\varepsilon}=\sum_{k=0}^{2 n} t_{k}^{\varepsilon} \mathbf{x}_{k}^{\varepsilon}$. Then since $\mathbf{x}_{\varepsilon}$ is contained in $K$, a compact set, and the diameter of each simplex is less than 1, it follows that $A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon}$ is contained in $\overline{A(K+B(\mathbf{0}, 1)})$, which is contained in a compact set thanks to Lemma 25.4.2. The reason is that $A$ is assumed to take bounded sets to bounded sets and $K+B(0,1)$ is a bounded set.

From the Heine Borel theorem, there exists a sequence $\varepsilon \rightarrow 0$ such that

$$
t_{k}^{\varepsilon} \rightarrow t_{k}, \mathbf{x}_{\varepsilon} \rightarrow \mathbf{x} \in K, A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon} \rightarrow \mathbf{y}_{k}
$$

for $k=0, \cdots, 2 n$. Since the diameter of the simplex containing $\mathbf{x}_{\varepsilon}$ converges to 0 , it follows

$$
\mathbf{x}_{k}^{\varepsilon} \rightarrow \mathbf{x}, A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon} \rightarrow \mathbf{y}_{k}
$$

By upper semicontinuity, it follows that for all $r>0, A \mathbf{x}_{k}^{\varepsilon} \subseteq A \mathbf{x}+B(0, r)$ for all $\varepsilon$ small enough. Since $A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon} \in A \mathbf{x}_{k}^{\varepsilon}$, and $A \mathbf{x}$ is closed, this implies $\mathbf{y}_{k} \in A \mathbf{x}$. Since $A \mathbf{x}$ is convex,

$$
\sum_{k=1}^{2 n} t_{k} \mathbf{y}_{k} \in A \mathbf{x}
$$

Hence for all $\mathbf{z} \in K$,

$$
\begin{gathered}
\operatorname{Re}\left(\mathbf{y}-\sum_{k=1}^{2 n} t_{k} \mathbf{y}_{k}, \mathbf{z}-\mathbf{x}\right)=\lim _{\varepsilon \rightarrow 0} \operatorname{Re}\left(\mathbf{y}-\sum_{k=1}^{2 n} t_{k}^{\varepsilon} A_{\varepsilon} \mathbf{x}_{k}^{\varepsilon}, \mathbf{z}-\mathbf{x}_{\varepsilon}\right) \\
=\lim _{\varepsilon \rightarrow 0} \operatorname{Re}\left(\mathbf{y}-A_{\varepsilon} \mathbf{x}_{\varepsilon}, \mathbf{z}-\mathbf{x}_{\varepsilon}\right) \leq 0
\end{gathered}
$$

Let $\mathbf{w}=\sum_{k=1}^{2 n} t_{k} \mathbf{y}_{k}$.
You could replace $A$ with $A \circ P_{K}$ in the above and assume only that $A$ is only defined on $K$. This is because $\mathbf{x} \in K$.

Lemma 25.4.6 Suppose in addition to 25.4.11 and 25.4.12, (compact convex valued and upper semicontinuous) $A$ is coercive,

$$
\lim _{|\mathbf{x}| \rightarrow \infty} \inf \left\{\frac{\operatorname{Re}(\mathbf{y}, \mathbf{x})}{|\mathbf{x}|}: \mathbf{y} \in A \mathbf{x}\right\}=\infty
$$

Then $A$ is onto.
Proof: Let $\mathbf{y} \in \mathbb{C}^{n}$ and let $K_{r} \equiv \overline{B(\mathbf{0}, r)}$. By Lemma 25.4.5 there exists $\mathbf{x}_{r} \in K_{r}$ and $\mathbf{w}_{r} \in A \mathbf{x}_{r}$ such that

$$
\begin{equation*}
\operatorname{Re}\left(\mathbf{y}-\mathbf{w}_{r}, \mathbf{z}-\mathbf{x}_{r}\right) \leq 0 \tag{25.4.13}
\end{equation*}
$$

for all $\mathbf{z} \in K_{r}$. Letting $\mathbf{z}=\mathbf{0}$,

$$
\operatorname{Re}\left(\mathbf{w}_{r}, \mathbf{x}_{r}\right) \leq \operatorname{Re}\left(\mathbf{y}, \mathbf{x}_{r}\right)
$$

Therefore,

$$
\inf \left\{\frac{\operatorname{Re}\left(\mathbf{w}, \mathbf{x}_{r}\right)}{\left|\mathbf{x}_{r}\right|}: \mathbf{w} \in A \mathbf{x}_{r}\right\} \leq|\mathbf{y}|
$$

It follows from the assumption of coercivity that $\left|\mathbf{x}_{r}\right|$ is bounded independent of $r$. Therefore, picking $r$ strictly larger than this bound, 25.4.13 implies

$$
\operatorname{Re}\left(\mathbf{y}-\mathbf{w}_{r}, \mathbf{v}\right) \leq 0
$$

for all $\mathbf{v}$ in some open ball containing $\mathbf{0}$. Therefore, for all $\mathbf{v}$ in this ball

$$
\operatorname{Re}\left(\mathbf{y}-\mathbf{w}_{r}, \mathbf{v}\right)=0
$$

and hence this holds for all $\mathbf{v} \in \mathbb{C}^{n}$ and so $\mathbf{y}=\mathbf{w}_{r} \in A \mathbf{x}_{r}$. This proves the lemma.
Lemma 25.4.7 Let $F$ be a finite dimensional Banach space of dimension $n$, and let $T$ be a mapping from $F$ to $\mathscr{P}\left(F^{\prime}\right)$ such that 25.4.11 and 25.4.12 both hold for $F^{\prime}$ in place of $\mathbb{C}^{n}$. Then if $T$ is also coercive,

$$
\begin{equation*}
\lim _{\|\mathbf{u}\| \rightarrow \infty} \inf \left\{\frac{\operatorname{Re} \mathbf{y}^{*}(\mathbf{u})}{\|\mathbf{u}\|}: \mathbf{y}^{*} \in T \mathbf{u}\right\}=\infty \tag{25.4.14}
\end{equation*}
$$

it follows $T$ is onto.
Proof: Let $|\cdot|$ be an equivalent norm for $F$ such that there is an isometry of $\mathbb{C}^{n}$ and $F, \theta$. Now define $A: \mathbb{C}^{n} \rightarrow \mathscr{P}\left(\mathbb{C}^{n}\right)$ by $A \mathbf{x} \equiv \theta^{*} T \theta \mathbf{x}$.

$$
\begin{array}{cll}
\mathscr{P}\left(F^{\prime}\right) & \stackrel{\theta^{*}}{\rightarrow} & \mathbb{C}^{n} \\
T \uparrow & \circ & \uparrow A \\
F & \stackrel{\theta}{\leftarrow} & \mathbb{C}^{n}
\end{array}
$$

Thus $\mathbf{y} \in A \mathbf{x}$ means that there exists $\mathbf{z}^{*} \in T \theta \mathbf{x}$ such that

$$
(\mathbf{w}, \mathbf{y})_{\mathbb{C}^{n}}=\mathbf{z}^{*}(\theta \mathbf{w})
$$

for all $\mathbf{w} \in \mathbb{C}^{n}$. Then $A$ satisfies the conditions of Lemma 25.4.6 and so $A$ is onto. Consequently $T$ is also onto.

With these lemmas, it is possible to prove a very useful result about a class of mappings which map a reflexive Banach space to the power set of its dual space. For more theorems about these mappings and their applications, see [99]. In the discussion below, we will use the symbol, $\rightharpoonup$, to denote weak convergence.

Definition 25.4.8 Let $V$ be a Reflexive Banach space. We say $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is pseudomonotone if the following conditions hold.

> Tu is closed, nonempty, convex.

If $F$ is a finite dimensional subspace of $V$, then if $u \in F$ and $W \supseteq T u$ for $W$ a weakly open set in $V^{\prime}$, then there exists $\delta>0$ such that

$$
\begin{equation*}
v \in B(u, \delta) \cap F \text { implies } T v \subseteq W \tag{25.4.16}
\end{equation*}
$$

If $u_{k} \rightharpoonup u$ and if $u_{k}^{*} \in T u_{k}$ is such that

$$
\limsup _{k \rightarrow \infty} \operatorname{Re} u_{k}^{*}\left(u_{k}-u\right) \leq 0
$$

then for all $v \in V$, there exists $u^{*}(v) \in T u$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \operatorname{Re} u_{k}^{*}\left(u_{k}-v\right) \geq \operatorname{Re} u^{*}(v)(u-v) \tag{25.4.17}
\end{equation*}
$$

We say $T$ is coercive if

$$
\begin{equation*}
\lim _{\|v\| \rightarrow \infty} \inf \left\{\frac{\operatorname{Re} z^{*}(v)}{\|v\|}: z^{*} \in T v\right\}=\infty . \tag{25.4.18}
\end{equation*}
$$

In the case that $T$ takes bounded sets to bounded sets so it is a bounded set valued operator, it turns out you don't have to consider the second of the above conditions about the upper semicontinuity. It follows from the other conditions. It is convenient to use the notation

$$
\left\langle u^{*}, v\right\rangle \equiv u^{*}(v), u^{*} \in V^{\prime}, v \in V
$$

and this will be used interchangeably with the earlier notation from now on.
The next lemma has to do with upper semicontinuity being obtained from simpler conditions.

Lemma 25.4.9 Let $T: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ satisfy conditions 25.4.15 and 25.4.17 above and suppose $T$ is bounded (Tx for $x$ in a bounded set is bounded). Then if $x_{n} \rightarrow x$ in $X$, and if $U$ is a weakly open set containing $T x$, then $T x_{n} \subseteq U$ for all $n$ large enough. If fact the limit condition 25.4.17 can be weakened to the following more general condition: If $u_{k} \rightharpoonup u$, and

$$
\begin{equation*}
\limsup _{k \rightarrow \infty} \operatorname{Re} u_{k}^{*}\left(u_{k}-u\right) \leq 0 \tag{**}
\end{equation*}
$$

then there exists a subsequence still denoted as $\left\{u_{k}\right\}$, such that if $u_{k}^{*} \in T u_{k}$, then for all $v \in V$, there exists $u^{*}(v) \in T u$ such that

$$
\begin{equation*}
\underset{k \rightarrow \infty}{\lim } \inf _{k} \operatorname{Re} u_{k}^{*}\left(u_{k}-v\right) \geq \operatorname{Re} u^{*}(v)(u-v) \tag{25.4.19}
\end{equation*}
$$

(This weaker condition says that if the lim sup condition holds for the original sequence, then there is a subsequence such that the lim inf condition holds for all v. In particular, for this subsequence, the lim sup condition continues to hold.)

Proof: If this is not true, there exists $x_{n} \rightarrow x$, also a weakly open set $U$, containing $T x$ and $z_{n} \in T x_{n}$, but $z_{n} \notin U$. Then, taking a further subsequence, we can assume $z_{n} \rightarrow z$ weakly and $z \notin U$. Then the strong convergence implies

$$
\lim _{n \rightarrow \infty} \operatorname{sep}\left\langle z_{n}, x_{n}-x\right\rangle \leq 0
$$

By assumption, there is a subsequence still denoted with $n$ such that for any $y$,

$$
\lim _{k \rightarrow \infty} \inf \left\langle z_{n}, x_{n}-y\right\rangle \geq \operatorname{Re}\langle z(y), x-y\rangle, \text { some } z(y) \in T(x)
$$

Then in particular, for this subsequence,

$$
0 \geq \lim \sup _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-x\right\rangle \geq \lim _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-x\right\rangle \geq \operatorname{Re}\langle z(x), x-x\rangle=0
$$

so for this subsequence,

$$
\lim _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-x\right\rangle=0
$$

Therefore, if $y \in X$ there exists $z(y) \in T x$ such that

$$
\operatorname{Re}\langle z, x-y\rangle=\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-y\right\rangle \geq \operatorname{Re}\langle z(y), x-y\rangle
$$

Letting $w=x-y$, this shows, since $y \in X$ is arbitrary, that the following inequality holds for every $w \in X$. (If you have $w \in X$, then you just choose $y=x-w$.)

$$
\operatorname{Re}\langle z, w\rangle \geq \operatorname{Re}\langle z(x-w), w\rangle, z(x-w) \in T x
$$

In particular, we may replace $w$ with $-w$ and obtain

$$
\operatorname{Re}\langle z,-w\rangle \geq \operatorname{Re}\langle z(x+w),-w\rangle
$$

which implies

$$
\operatorname{Re}\langle z(x-w), w\rangle \leq \operatorname{Re}\langle z, w\rangle \leq \operatorname{Re}\langle z(x+w), w\rangle
$$

Therefore, there exists, $\lambda \in[0,1]$,

$$
z_{\lambda}(y) \equiv \lambda z(x-w)+(1-\lambda) z(x+w) \in A x
$$

such that

$$
\operatorname{Re}\langle z, w\rangle=\operatorname{Re}\left\langle z_{\lambda}(y), w\right\rangle
$$

But this is a contradiction to $z \notin T x$ because if $z \notin T x$, it follows from separation theorems there exists $w \in X$ such that for all $z_{1} \in T x$,

$$
\operatorname{Re}\langle z, w\rangle>\operatorname{Re}\left\langle z_{1}, w\right\rangle
$$

You pick that $w$ in the above. Therefore, $z \in T x$ which contradicts the assumption that $z_{n}$ and consequently $z$ are not contained in $U$.

What if $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ for $V$ a finite dimensional vector space such that $T$ is upper semicontinuous and bounded? If $u_{n} \rightarrow u$ weakly, then this also happens strongly because the weak convergence and strong convergence are the same in finite dimensions. Therefore, by upper semicontinuity, there is a subsequence still denoted with $n$ and $z_{n} \in T u_{n}$ such that $z_{n} \rightarrow z$ for some $z$. Then since $T u$ is closed, we must have $z \in T u$ thanks to upper semicontinuity. Then for this subsequence and arbitrary $v$,

$$
\lim \inf _{n \rightarrow \infty} \operatorname{Re} z_{n}\left(u_{n}-v\right)=\operatorname{Re} z(u-v)
$$

Also, this limit condition holds whenever $u_{n} \rightarrow u$ and $z_{n} \rightarrow z$ even without an assumption that $T$ is bounded. This mostly proves the following.

Proposition 25.4.10 Let $V$ be finite dimensional and let $T: V \rightarrow \mathscr{P}(V)$ be upper semicontinuous with closed values. Then if $u_{n} \rightarrow u$ and $z_{n} \in T u_{n}$ with $z_{n} \rightarrow z$, then

$$
\lim _{n \rightarrow \infty} \inf _{n} \operatorname{Re} z_{n}\left(u_{n}-v\right)=\operatorname{Re} z(u-v), z \in T u
$$

If $T$ is bounded, and $u_{n} \rightarrow u$, then if $v$ is given,

$$
\lim _{n \rightarrow \infty} \operatorname{Re} z_{n}\left(u_{n}-v\right)=\operatorname{Re} z(u-v), \text { some } z \in T u
$$

Proof: Consider the last claim and suppose the limit condition does not hold for some v. Then take a subsequence such that

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \operatorname{Re} z_{n}\left(u_{n}-v\right)=\lim _{n \rightarrow \infty} \operatorname{Re} z_{n}\left(u_{n}-v\right)
$$

By boundedness, there is a further subsequence such that $z_{n} \rightarrow z$. Then from upper semicontinuity and $T u$ being closed, $z \in T u$ and so

$$
\lim _{n \rightarrow \infty} \operatorname{Re} z_{n}\left(u_{n}-v\right)=\lim \inf _{n \rightarrow \infty} \operatorname{Re} z_{n}\left(u_{n}-v\right)=\operatorname{Re} z(u-v)
$$

This more general limit condition is sometimes useful if not essential to use. The following is a definition of this more general condition used in the above lemma.

Definition 25.4.11 Say $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is modified bounded pseudomonotone if the following conditions hold.

> Tu is closed, nonempty, convex.
$T$ is bounded meaning it takes bounded sets to bounded sets.
If $u_{k} \rightharpoonup u$ and if

$$
\limsup _{k \rightarrow \infty} \operatorname{Re} u_{k}^{*}\left(u_{k}-u\right) \leq 0
$$

then there exists a subsequence, still denoted as $\left\{u_{k}\right\}$ such that if $u_{k}^{*} \in T u_{k}$ then for all $v \in V$, there exists $u^{*}(v) \in T u$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \inf u_{k}^{*}\left(u_{k}-v\right) \geq \operatorname{Re} u^{*}(v)(u-v) \tag{25.4.21}
\end{equation*}
$$

In this limit condition, there is a subsequence which works for all $v$. However, the preservation of lower semicontinuity happens under even less.

Definition 25.4.12 Say $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is generalized bounded pseudomonotone if the following conditions hold.
Tu is closed, nonempty, convex.
$T$ is bounded meaning it takes bounded sets to bounded sets.
If $u_{k} \rightharpoonup u$ and if

$$
\limsup _{k \rightarrow \infty} \operatorname{Re} u_{k}^{*}\left(u_{k}-u\right) \leq 0
$$

then if $v$ is given there exists a subsequence, still denoted as $\left\{u_{k}\right\}$ possibly depending on $v$ such that if $u_{k}^{*} \in T u_{k}$ then, there exists $u^{*}(v) \in T u$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \inf u_{k}^{*}\left(u_{k}-v\right) \geq \operatorname{Re} u^{*}(v)(u-v) \tag{25.4.23}
\end{equation*}
$$

This is more general because in this situation, the subsequence depends on the choice of $v$.
In case $T$ is single valued, this condition is equivalent to type $M$.
Proposition 25.4.13 A single valued bounded operator $T: V \rightarrow V^{\prime}, V$ reflexive is generalized bounded pseudomonotone then it is bounded and type $M$.

Proof: Suppose that $u_{n} \rightarrow u$ weakly and $T u_{n} \rightarrow \xi$ weakly and

$$
\lim \sup _{n \rightarrow \infty}\left\langle T u_{n}, u_{n}\right\rangle \leq\langle\xi, u\rangle
$$

Then

$$
\lim \sup _{n \rightarrow \infty}\left\langle T u_{n}, u_{n}-u\right\rangle \leq 0
$$

and so there is a subsequence depending on $v$ and a further one depending on $u$ such that

$$
\begin{aligned}
& \lim \inf _{n \rightarrow \infty}\left\langle T u_{n}, u_{n}-u\right\rangle \geq\langle T u, u-u\rangle=0 \\
& \lim \inf _{n \rightarrow \infty}\left\langle T u_{n}, u_{n}-v\right\rangle \geq\langle T u, u-v\rangle
\end{aligned}
$$

The first in the above shows with the limsup condition that $\lim _{n \rightarrow \infty}\left\langle T u_{n}, u_{n}-u\right\rangle=0$. Therefore, the second condition implies

$$
\langle\xi, u-v\rangle \geq\langle T u, u-v\rangle
$$

since $v$ is arbitrary, it follows that $\xi=T u$. Thus $T$ is type M .
If $T$ is generalized bounded pseudomonotone, then it is upper semicontinuous from the strong to the weak topology.

Lemma 25.4.14 Let $T: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ satisfy conditions 25.4 .15 and 25.4.17 above and suppose $T$ is bounded. Then if $x_{n} \rightarrow x$ in $X$, and if $U$ is a weakly open set containing $T x$, then $T x_{n} \subseteq U$ for all $n$ large enough. If fact the limit condition 25.4 .17 can be weakened to the following more general condition: If $u_{k} \rightharpoonup u$, and

$$
\begin{equation*}
\lim _{\sup _{k \rightarrow \infty}} \operatorname{Re} u_{k}^{*}\left(u_{k}-u\right) \leq 0 \tag{**}
\end{equation*}
$$

then for each $v$, there exists a subsequence still denoted as $\left\{u_{k}\right\}$, possibly depending on $v$ such that if $u_{k}^{*} \in T u_{k}$, then there exists $u^{*}(v) \in T u$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \operatorname{Re} u_{k}^{*}\left(u_{k}-v\right) \geq \operatorname{Re} u^{*}(v)(u-v) \tag{25.4.24}
\end{equation*}
$$

(This weaker condition says that if the lim sup condition holds for the original sequence, then for given $v$ there is a subsequence such that the lim inf condition holds for that $v$. In particular, for this subsequence, the lim sup condition continues to hold.)

Proof: If this is not true, there exists $x_{n} \rightarrow x$, and a weakly open set $U$, containing $T x$ and $z_{n} \in T x_{n}$, but $z_{n} \notin U$. Then, taking a further subsequence, we can assume $z_{n} \rightarrow z$ weakly and $z \notin U$. Then the strong convergence implies

$$
\lim _{n \rightarrow \infty} \sup \left\langle z_{n}, x_{n}-x\right\rangle \leq 0
$$

By separation theorems, there exists $w$ such that for all $\hat{w} \in T(x)$,

$$
\begin{equation*}
\operatorname{Re}\langle z, w\rangle<\operatorname{Re}\langle\hat{w}, w\rangle \tag{*}
\end{equation*}
$$

Thus, choose $y$ such that $w=x-y$. By assumption, there is a subsequence still denoted with $n$ such that

$$
\begin{gathered}
\lim _{k \rightarrow \infty} \inf \operatorname{Re}\left\langle z_{n}, x_{n}-y\right\rangle \geq \operatorname{Re}\langle z(y), x-y\rangle, \text { some } z(y) \in T(x) \\
\lim \inf _{k \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-x\right\rangle \geq \operatorname{Re}\langle z(x), x-x\rangle=0, \text { some } z(x) \in T(x)
\end{gathered}
$$

To get this subsequence, get one which goes with $y$ and then note that the limsup only gets smaller when you go to a subsequence. Hence you can apply the condition to get a further subsequence which goes with $x$. By doing so, the liminf condition for $y$ is strengthened. Then in particular, for this subsequence,

$$
0 \geq \lim \sup _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-x\right\rangle \geq \lim _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-x\right\rangle \geq \operatorname{Re}\langle z(x), x-x\rangle=0
$$

so for this subsequence,

$$
\lim _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-x\right\rangle=0
$$

Therefore, from the assumed condition, there is a further subsequence such that

$$
\operatorname{Re}\langle z, x-y\rangle=\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \operatorname{Re}\left\langle z_{n}, x_{n}-y\right\rangle \geq \operatorname{Re}\langle z(y), x-y\rangle, z(y) \in T(x)
$$

Since $w=x-y$,

$$
\operatorname{Re}\langle z, w\rangle \geq \operatorname{Re}\langle z(y), w\rangle
$$

where $z(y) \in T x$. which contradicts $*$. Thus $z \in U$ as claimed.

### 25.5 Sum Of Pseudomonotone Operators

One of the nice properties of pseudomonotone maps is that when you add two of them, you get another one. I will give a proof in the case that the two pseudomonotone maps are both bounded. It is probably true in general, but as just noted, it is less trouble to verify if you don't have to worry about as many conditions. I will also assume the spaces are all real so it will not be necessary to constantly write the real part. Actually, we do a slightly more general version which says that a bounded pseudomonotone added to a modified bounded pseudomonotone is a modified bounded pseudomonotone. First is the theorem about the sum of two bounded set valued pseudomonotone operators.

Theorem 25.5.1 Say $A, B$ are set valued bounded pseudomonotone operators. Then their sum is also a set valued bounded pseudomonotone operator. Also, if $u_{n} \rightarrow u$ weakly, $z_{n} \rightarrow z$ weakly, $z_{n} \in A\left(u_{n}\right)$, and $w_{n} \rightarrow w$ weakly with $w_{n} \in B\left(u_{n}\right)$, then if

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0
$$

it follows that

$$
\liminf _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-v\right\rangle \geq\langle z(v)+w(v), u-v\rangle, z(v) \in A(u), w(v) \in B(u)
$$

and $z \in A(u), w \in B(u)$.
Proof: Say $z_{n} \in A\left(u_{n}\right), w_{n} \in B\left(u_{n}\right), u_{n} \rightarrow u$ weakly and

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0
$$

Claim: Both of $\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle, \limsup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle$ are no larger than 0 .
Proof of the claim: Suppose $\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle=\delta>0$. Then take a subsequence such that the limsup equals lim. The limsup only gets smaller when you go to a subsequence. Thus, continuing to denote the subsequence with $n$ we still have

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0
$$

But from the fact that we just took a subsequence for which the lim sup $=\lim$,

$$
\begin{aligned}
\limsup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle & =\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle+\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \\
& =\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle+\delta \leq 0
\end{aligned}
$$

and so $\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=-\delta<0$. Therefore by the limit condition,

$$
\lim _{n \rightarrow \infty} \inf _{n}\left\langle z_{n}, u_{n}-u\right\rangle \geq\langle z(u), u-u\rangle=0
$$

and so

$$
0>-\delta \geq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \geq \lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \geq 0
$$

a contradiction. Thus the claim is established. We have

$$
\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \leq 0, \quad \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0
$$

Thus we can apply the limit condition to the two operators separately. This refers to the original sequence now. If $v$ is given, then

$$
\lim _{n \rightarrow \infty} \inf _{n}\left\langle w_{n}, u_{n}-v\right\rangle \geq\langle w(v), u-v\rangle, \lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle
$$

where $w(v) \in B(u)$ and $z(v) \in A(u)$. Thus

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-v\right\rangle & \geq \lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle+\lim \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-v\right\rangle \\
& \geq\langle w(v)+z(v), u-v\rangle
\end{aligned}
$$

and $w(v)+z(v) \in A(u)+B(u)$ which shows that the sum is pseudomonotone.
In addition, from the claim, we know that

$$
\liminf \left\langle z_{n}, u_{n}-u\right\rangle \geq\langle z(u), u-u\rangle=0
$$

similar for $w_{n}$. Thus $\liminf \left\langle z_{n}, u_{n}-u\right\rangle \geq 0 \geq \limsup \left\langle z_{n}, u_{n}-u\right\rangle$ so $\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=0$, similar for $\left\langle w_{n}, u_{n}-u\right\rangle$. Therefore, if $z_{n} \rightarrow z$ weakly and $w_{n} \rightarrow w$ weakly,

$$
\begin{aligned}
\langle z, u-v\rangle & =\lim \left\langle z_{n}, u-v\right\rangle=\lim _{n \rightarrow \infty}\left[\left\langle z_{n}, u-u_{n}\right\rangle+\left\langle z_{n}, u_{n}-v\right\rangle\right] \\
& \geq \lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle, z(v) \in A(u)
\end{aligned}
$$

It follows that $\langle z, u-v\rangle \geq\langle z(v), u-v\rangle$ for all $v$ which could be violated using separation theorems if $z$ is not in $A(u)$. Thus $z \in A(u)$. Similarly $w \in B(u)$.

The above is the main result but we can attempt to see what happens if one of the operators is only modified pseudomonotone.

Note that if $B$ is bounded pseudomonotone, then it is certainly modified bounded pseudomonotone.

Theorem 25.5.2 Suppose $A, B: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ are both pseudomonotone and bounded. Then so is their sum. If $A$ is bounded pseudomonotone and $B$ is modified bounded pseudomonotone, then $A+B$ is modified bounded pseudomonotone.

Proof: It is clear that $A x+B x$ is closed and convex because this is true of both of the sets in the sum. It is also bounded because both terms in the sum are bounded. It only remains to verify the limit condition. Suppose then that

$$
u_{n} \rightarrow u \text { weakly }
$$

Will the limit condition hold for $A+B$ when applied to this further subsequence? Suppose $z_{n} \in A x_{n}, w_{n} \in B x_{n}$ and

$$
\begin{equation*}
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0 \tag{25.5.25}
\end{equation*}
$$

Is there a subsequence such that the liminf condition holds? From the above,

$$
\begin{equation*}
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle+\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \tag{25.5.26}
\end{equation*}
$$

and so, if the second term $\leq 0$, since $B$ is modified bounded pseudomonotone, there is a subsequence, still denoted with $n$ for which

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-v\right\rangle \geq\langle w(v), u-v\rangle, w(v) \in B(u) \tag{*}
\end{equation*}
$$

for all $v$. In particular,

$$
\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq\langle w(u), u-u\rangle=0
$$

Hence you would have

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq 0 \geq \lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle
$$

and so $\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle=0$ for this subsequence still denoted with $n$. Hence for this subsequence,

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0
$$

Then using that $A$ is bounded pseudomonotone, $\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=0$ also. It follows for any $v$,

$$
\left.\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle
$$

Then from this it is routine to establish the modified pseudomonotone limit condition for the sum $A+B$. For the subsequence just described, still denoted with $n$,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0
$$

and $*$. In fact, you would have for any $v$,

$$
\begin{aligned}
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle & \geq\langle z(v), u-v\rangle, z(v) \in A(u) \\
\lim \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-v\right\rangle & \geq\langle w(v), u-v\rangle, w(v) \in A(u)
\end{aligned}
$$

Then you would get

$$
\begin{aligned}
\lim _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-v\right\rangle & =\lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle+\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq \lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle\right)+\lim \inf _{n \rightarrow \infty}\left(\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq\langle z(v), u-v\rangle+\langle w(v), u-v\rangle
\end{aligned}
$$

and $z(v)+w(v) \in(A+B)(u)$.
Returning to 25.5.26, the other case to consider is that

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0
$$

Then in this case, the assumption that $A$ is pseudomonotone implies that for any $v$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle, z(v) \in A(u) \tag{***}
\end{equation*}
$$

No subsequence here. However, if you use a subsequence, the inequality is only strengthened. In particular,

$$
0 \geq \lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=\langle z(u), u-u\rangle=0 \geq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle
$$

and so for the original sequence,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=0
$$

Then back to 25.5.26,

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \leq 0
$$

Now by assumption that $B$ is modified bounded pseudomonotone, there is a subsequence, still denoted with $n$ such that for any $v$

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-v\right\rangle \geq\langle w(v), u-v\rangle, w(v) \in B(u) \tag{****}
\end{equation*}
$$

In particular, for this subsequence,

$$
0 \geq \lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq \lim \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq\langle w(u), u-u\rangle=0
$$

and so for this subsequence, $\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle=0$. Then for this subsequence, it follows from $* * *$, and $* * * *$,

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \inf _{n}\left\langle z_{n}+w_{n}, u_{n}-v\right\rangle & =\lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle+\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq \lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle\right)+\lim \inf _{n \rightarrow \infty}\left(\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq\langle z(v), u-v\rangle+\langle w(v), u-v\rangle
\end{aligned}
$$

We continue to be in the situation of 25.5 .25 and we are asking for a subsequence such that the liminf condition will hold for the subsequence. Suppose this liminf condition is not obtained for any subsequence. The desired liminf condition will hold for a subsequence if either $\limsup \sin _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle$ or $\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle$ is $\leq 0$. This was shown above. Therefore, if there is no subsequence yielding the liminf condition, you must have both of these strictly positive. Say $\delta>0$ is smaller than both. Let $n$ denote a subsequence such that

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle>\delta>0
$$

If, for this new subsequence, $\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle<0$, then, since the limsup gets smaller for a subsequence,

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle+\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \leq 0
$$

then you could apply the above argument and obtain a further subsequence for which the liminf condition would hold for the sum. Thus, we must have for this new subsequence,

$$
\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq 0
$$

Then, using this subsequence,

$$
0 \geq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \geq \delta+\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq \delta
$$

which is a contradiction. Thus the liminf condition must hold for some subsequence. In case both are bounded and pseudomonotone, things are easier. You don't have to take a subsequence.

It is not entirely clear whether the sum of modified bounded pseudomonotone operators is modified bounded pseudomonotone. This is because when you go to a subsequence, the limsup gets smaller and so it is not entirely clear whether the subsequence for $A$ will continue to yield the limit condition if a further subsequence is taken.

In fact, you can add a bounded pseudomonotone to a generalized bounded pseudomonotone and get a generalized bounded pseudomonotone. The proof is just like the above and is given next.

Theorem 25.5.3 Suppose $A, B: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$. If $A$ is bounded pseudomonotone and $B$ is generalized bounded pseudomonotone, then $A+B$ is generalized bounded pseudomonotone.

Proof: It is clear that $A x+B x$ is closed and convex because this is true of both of the sets in the sum. It is also bounded because both terms in the sum are bounded. It only remains to verify the limit condition. Suppose then that

$$
u_{n} \rightarrow u \text { weakly }
$$

Will the limit condition hold for $A+B$ when applied to this further subsequence? Suppose $z_{n} \in A x_{n}, w_{n} \in B x_{n}$ and

$$
\begin{equation*}
\limsup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0 \tag{25.5.27}
\end{equation*}
$$

If $v$ is given, is there a subsequence such that the liminf condition holds? From the above,

$$
\begin{equation*}
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle+\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \tag{25.5.28}
\end{equation*}
$$

and so, if the second term $\leq 0$, since $B$ is modified bounded pseudomonotone, there is a subsequence, still denoted with $n$ for which

$$
\begin{gather*}
\lim \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-v\right\rangle \geq\langle w(v), u-v\rangle, w(v) \in B(u)  \tag{*}\\
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq\langle w(u), u-u\rangle=0
\end{gather*}
$$

You just get a subsequence which works for $v$ and note that the limsup condition is only strengthened for the subsequence and then obtain a further subsequence which goes with
$u$ to get the second condition along with the first. Note that liminf gets bigger when you go to a subsequence so if $*$ holds for the first subsequence, then it holds even better for the second.

Hence you would have, for this subsequence depending on $v$

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq 0 \geq \lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle
$$

and so $\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle=0$ for this subsequence still denoted with $n$. Hence for this subsequence,

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0
$$

Then using that $A$ is bounded pseudomonotone, $\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=0$ also. It follows for any $v$,

$$
\lim _{n \rightarrow \infty} \inf _{n}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle
$$

Then from this it is routine to establish the modified pseudomonotone limit condition for the sum $A+B$. For the subsequence just described, still denoted with $n$,

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \leq 0
$$

and $*$. In fact, you would have

$$
\begin{aligned}
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle & \geq\langle z(v), u-v\rangle, z(v) \in A(u) \\
\lim \inf _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-v\right\rangle & \geq\langle w(v), u-v\rangle, w(v) \in A(u)
\end{aligned}
$$

Then you would get

$$
\begin{aligned}
\liminf _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-v\right\rangle & =\lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle+\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq \lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle\right)+\lim \inf _{n \rightarrow \infty}\left(\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq\langle z(v), u-v\rangle+\langle w(v), u-v\rangle
\end{aligned}
$$

and $z(v)+w(v) \in(A+B)(u)$.
Returning to 25.5.28, the other case to consider is that

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq 0
$$

Then in this case, the assumption that $A$ is pseudomonotone implies that for any $v$,

$$
\begin{equation*}
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-v\right\rangle \geq\langle z(v), u-v\rangle, z(v) \in A(u) \tag{***}
\end{equation*}
$$

No subsequence here. In particular,

$$
0 \geq \lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=\langle z(u), u-u\rangle=0 \geq \lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle
$$

and so for the original sequence,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=0
$$

Then back to 25.5.28,

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \leq 0
$$

Now by assumption that $B$ is generalized bounded pseudomonotone, there is a subsequence, still denoted with $n$ such that for the given $v$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \inf _{n}\left\langle w_{n}, u_{n}-v\right\rangle \geq\langle w(v), u-v\rangle, w(v) \in B(u) \tag{****}
\end{equation*}
$$

Then taking a further subsequence to go with $u$ in the third inequality below, the first inequality is preserved and

$$
0 \geq \lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq \lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle w_{n}, u_{n}-u\right\rangle \geq\langle w(u), u-u\rangle=0
$$

and so for this further subsequence, $\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle=0$. Then for this subsequence, it follows from $* * *$, and $* * * *$,

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle z_{n}+w_{n}, u_{n}-v\right\rangle & =\lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle+\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq \lim _{n \rightarrow \infty}\left(\left\langle z_{n}, u_{n}-v\right\rangle\right)+\lim \inf _{n \rightarrow \infty}\left(\left\langle w_{n}, u_{n}-v\right\rangle\right) \\
& \geq\langle z(v), u-v\rangle+\langle w(v), u-v\rangle
\end{aligned}
$$

We continue to be in the situation of 25.5 .27 and we are asking for a subsequence such that the liminf condition will hold for some subsequence depending on $v$. Suppose this liminf condition is not obtained for any subsequence. The desired liminf condition will hold for a subsequence if either $\limsup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle \leq$ or $\limsup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle$ is $\leq 0$. This was shown above. Therefore, if there is no subsequence yielding the liminf condition, you must have both of these strictly positive. Say $\delta>0$ is smaller than both. Let $n$ denote a subsequence such that

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle>\delta>0
$$

If, for this new subsequence, $\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle<0$, then, since the limsup gets smaller for a subsequence,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle z_{n}, u_{n}-u\right\rangle+\lim _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \leq 0
$$

then you could apply the above argument and obtain a further subsequence for which the liminf condition would hold for the sum. Thus, we must have for this new subsequence,

$$
\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq 0
$$

Then, using this subsequence,

$$
0 \geq \lim \sup _{n \rightarrow \infty}\left\langle z_{n}+w_{n}, u_{n}-u\right\rangle \geq \delta+\lim \sup _{n \rightarrow \infty}\left\langle w_{n}, u_{n}-u\right\rangle \geq \delta
$$

which is a contradiction. Thus the liminf condition must hold for some subsequence.
The following is mostly in [99].
Theorem 25.5.4 Let $V$ be a reflexive Banach space and let $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ be pseudomonotone, bounded, and coercive. Then $T$ is onto. More generally, the same holds if $T$ is modified or generalized bounded pseudomonotone and coercive.

Proof: The proof is for modified bounded pseudomonotone since this is more general. Let $\mathscr{F}$ be the set of finite dimensional subspaces of $V$ and let $F \in \mathscr{F}$. Then define $T_{F}$ as

$$
T_{F} \equiv i_{F}^{*} T i_{F}
$$

where here $i_{F}$ is the identity map from $F$ to $V$. Then $T_{F}$ satisfies the conditions of Lemma 25.4.7 thanks to Lemma 25.4.9 or Lemma 25.4.14 and so $T_{F}$ is onto $\mathscr{P}\left(F^{\prime}\right)$. Let $w^{*} \in V^{\prime}$. Then since $T_{F}$ is onto, there exists $u_{F} \in F$ such that

$$
i_{F}^{*} w^{*} \in i_{F}^{*} T i_{F} u_{F}
$$

Thus for each finite dimensional subspace $F$, there exists $u_{F} \in F$ such that for all $v \in F$,

$$
\begin{equation*}
\left\langle w^{*}, v\right\rangle=\left\langle u_{F}^{*}, v\right\rangle, u_{F}^{*} \in T u_{F} . \tag{25.5.29}
\end{equation*}
$$

Replacing $v$ with $u_{F}$, in 25.5.29,

$$
\frac{\left\langle u_{F}^{*}, u_{F}\right\rangle}{\left\|u_{F}\right\|}=\frac{\left\langle w^{*}, u_{F}\right\rangle}{\left\|u_{F}\right\|} \leq\left\|w^{*}\right\| .
$$

Therefore, the assumption that $T$ is coercive implies $\left\{u_{F}: F \in \mathscr{F}\right\}$ is bounded in $V$. Now define

$$
W_{F} \equiv \cup\left\{u_{F^{\prime}}: F^{\prime} \supseteq F\right\}
$$

Then $W_{F}$ is bounded and if $\overline{W_{F}} \equiv$ weak closure of $W_{F}$, then

$$
\left\{\overline{W_{F}}: F \in \mathscr{F}\right\}
$$

is a collection of nonempty weakly compact (since $V$ is reflexive and the $u_{F}$ were just shown bounded) sets having the finite intersection property because $W_{F} \neq \emptyset$ for each $F$. (If $F_{i}, i=1, \cdots, n$ are finite dimensional subspaces, let $F$ be a finite dimensional subspace which contains all of these. Then $W_{F} \neq \emptyset$ and $W_{F} \subseteq \cap_{i=1}^{n} \overline{W_{F_{i}}}$.) Thus there exists

$$
u \in \cap\left\{\overline{W_{F}}: F \in \mathscr{F}\right\} .
$$

I will show $w^{*} \in T u$. If $w^{*} \notin T u$, a closed convex set, there exists $v \in V$ such that

$$
\begin{equation*}
\operatorname{Re}\left\langle w^{*}, u-v\right\rangle<\operatorname{Re}\left\langle u^{*}, u-v\right\rangle \tag{25.5.30}
\end{equation*}
$$

for all $u^{*} \in T u$. This follows from the separation theorems. (These theorems imply there exists $z \in V$ such that

$$
\operatorname{Re}\left\langle w^{*}, z\right\rangle<\operatorname{Re}\left\langle u^{*}, z\right\rangle
$$

for all $u^{*} \in T u$. Define $u-v \equiv z$.)
Now let $F \supseteq\{u, v\}$. Since $u \in \overline{W_{F}}$, a weakly sequentially compact set, there exists a sequence, $\left\{u_{k}\right\}$, such that

$$
u_{k} \rightharpoonup u, u_{k} \in W_{F}
$$

Then since $F \supseteq\{u, v\}$, there exists $u_{k}^{*} \in T u_{k}$ such that

$$
\left\langle u_{k}^{*}, u_{k}-u\right\rangle=\left\langle w^{*}, u_{k}-u\right\rangle
$$

Therefore,

It follows by the assumption that $T$ is modified bounded pseudomonotone or generalized bounded pseudomonotone and the pseudomonotone limit condition, a further subsequence corresponding to $v$ such that the following holds for the $v$ defined above in 25.5.30.

$$
\lim _{k \rightarrow \infty} \operatorname{Re}\left\langle u_{k}^{*}, u_{k}-v\right\rangle \geq \operatorname{Re}\left\langle u^{*}(v), u-v\right\rangle, u^{*}(v) \in T u
$$

But since $v \in F, \operatorname{Re}\left\langle u_{k}^{*}, u_{k}-v\right\rangle=\operatorname{Re}\left\langle w^{*}, u_{k}-v\right\rangle$ and so

$$
\lim \inf _{k \rightarrow \infty} \operatorname{Re}\left\langle u_{k}^{*}, u_{k}-v\right\rangle=\underset{k \rightarrow \infty}{\lim \inf _{k} \operatorname{Re}\left\langle w^{*}, u_{k}-v\right\rangle=\operatorname{Re}\left\langle w^{*}, u-v\right\rangle, ~ ;, ~}
$$

so from 25.5.30, $\operatorname{Re}\left\langle w^{*}, u-v\right\rangle<\operatorname{Re}\left\langle u^{*}, u-v\right\rangle$ for all $u^{*} \in T u$,

$$
\begin{aligned}
& \operatorname{Re}\left\langle w^{*}, u-v\right\rangle=\lim _{k \rightarrow \infty} \inf \left\langle u_{k}^{*}, u_{k}-v\right\rangle \\
& \geq \operatorname{Re}\left\langle u^{*}(v), u-v\right\rangle>\operatorname{Re}\left\langle w^{*}, u-v\right\rangle,
\end{aligned}
$$

a contradiction. Thus, $w^{*} \in T u$.
This is likely a good place to put an extremely interesting convergence theorem. It is a version of one in Aubin and Cellina [9]. It is a perfectly marvelous use of the fact that the weak and strong closures of a convex set are the same.

Proposition 25.5.5 Let $X, Y$ be Banach spaces, and let $F:(0, T) \times X \rightarrow \mathscr{P}(Y)$ be a multifunction such that

1. The values of $F$ are nonempty, closed and convex subsets of $Y$
2. For a.e. $t \in(0, T), F(t, \cdot)$ is upper semicontinuous from $X$ into $Y$ with the weak topology

Then let $x_{n}:(0, T) \rightarrow X, y_{n}:(0, T) \rightarrow Y$ be measurable functions such that the sequence $\left\{x_{n}\right\}$ converges a.e. on $(0, T)$ to a function $x:(0, T) \rightarrow X$ and $y_{n}$ converges weakly in $L^{1}(0, T ; Y)$ to $y \in L^{1}(0, T, Y)$. If $y_{n}(t) \in F\left(t, x_{n}(t)\right)$ for all $n \in \mathbb{N}$ and a.e.t, then $y(t) \in$ $F(t, x(t))$ for a.e. $t \in(0, T)$.

Proof: It is given that $y_{n} \rightarrow y$ weakly in $L^{1}(0, T ; Y)$. It is too bad that this does not confer pointwise convergence of some subsequence. However, what can be said is this:

$$
\text { weak closure of } \operatorname{co}\left(\cup_{k=n}^{\infty} y_{k}\right)=\text { strong closure of } \operatorname{co}\left(\cup_{k=n}^{\infty} y_{k}\right)
$$

Here co signifies the convex hull. Thus something is in co $\left(\cup_{k=n}^{\infty} y_{k}\right)$ means it is of the form

$$
\begin{equation*}
v_{n}=\sum_{k=n}^{\infty} c_{k}^{n} y_{k} \tag{*}
\end{equation*}
$$

where all but finitely many of the $c_{k}^{n}$ are zero and they sum to 1 , each being a number in $[0,1]$. Now it is given that $y$ is in the weak closure of $\operatorname{co}\left(\cup_{k=n}^{\infty} y_{k}\right)$. In fact $y_{n}$ converges weakly to $y$. Therefore, from the above observation, $y$ is in the strong closure of co $\left(\cup_{k=n}^{\infty} y_{k}\right)$. Let $v_{n}$ be of the form in $*$ and let it converge in $L^{1}(0, T ; Y)$ to $y$. Then there is a subsequence, still denoted as $v_{n}$ such that for a.e. $t$,

$$
v_{n}(t) \rightarrow y(t) \text { in } Y
$$

Pick such a $t$.
If $y(t) \notin F(t, x(t))$, there exist numbers $k>l$ and $y^{*} \in Y^{\prime}$ such that

$$
\left\langle y^{*}, y(t)\right\rangle>k>l>\left\langle y^{*}, z\right\rangle \text { for all } z \in F(t, x(t))
$$

This follows from separation theorems due to the assumption that $F(t, x(t))$ is a closed convex set. Thus for all $n$ large enough,

$$
\begin{equation*}
\left\langle y^{*}, v_{n}(t)\right\rangle>k>l>\left\langle y^{*}, z\right\rangle \text { for all } z \in F(t, x(t)) \tag{**}
\end{equation*}
$$

Let $k-l>2 \varepsilon>0$. Consider

$$
F(t, x(t))+B_{y_{*}}(0, \varepsilon)
$$

where the ball signifies all $z \in Y$ such that

$$
\left|\left\langle y^{*}, z\right\rangle\right|<\varepsilon
$$

By the weak upper semicontinuity assumption of $F(t, \cdot)$ and $x_{n}(t) \rightarrow x(t)$, it follows that for $k$ large enough,

$$
y_{k}(t) \in F\left(t, x_{k}(t)\right) \subseteq F(t, x(t))+B_{y_{*}}(0, \varepsilon)
$$

Now $v_{n}$ is a convex combination of $y_{k}$ for $k \geq n$ and so it follows that for $n$ large enough,

$$
v_{n}(t) \in F(t, x(t))+B_{y_{*}}(0, \varepsilon)
$$

which says that there exists $z_{n} \in F(t, x(t))$ such that

$$
\left|\left\langle y^{*}, v_{n}(t)\right\rangle-\left\langle y^{*}, z_{n}\right\rangle\right|<\varepsilon
$$

However, this is a contradiction to $* *$ because it says two things are closer than $\varepsilon$ and also farther than $k-l>2 \varepsilon$. Thus $y(t) \in F(t, x(t))$.

It does not use that the measure space is Lebesgue measure on $[0, T]$ that I can see. I think it appears to work for $[0, T]$ replaced with $\Omega$ and $t$ replaced with $\omega \in \Omega$ where $(\Omega, \mathscr{F}, \mu)$ is just some measure space.

### 25.6 Generalized Gradients

This is an interesting theorem, but one might wonder if there are easy to verify examples of such possibly set valued mappings. In what follows consider only real spaces because the essential ideas are included in this case which is also the case of most use in applications. Of course, you might with some justification, make the claim that the following is not really very easy to verify any more than the original definition.

Definition 25.6.1 Let $V$ be a real reflexive Banach space and let $f: V \rightarrow \mathbb{R}$ be a locally Lipschitz function, meaning that $f$ is Lipschitz near every point of $V$ although $f$ need not be Lipschitz on all of $V$. Under these conditions,

$$
\begin{equation*}
f^{0}(x, y) \equiv \lim \sup _{\mu \rightarrow 0+h \rightarrow 0} \frac{f(x+h+\mu y)-f(x+h)}{\mu} \tag{25.6.31}
\end{equation*}
$$

and $\partial f(x) \subseteq X^{\prime}$ is defined by

$$
\begin{equation*}
\partial f(x) \equiv\left\{x^{*} \in X^{\prime}: x^{*}(y) \leq f^{0}(x, y) \text { for all } y \in X\right\} \tag{25.6.32}
\end{equation*}
$$

The set just described is called the generalized gradient. In 25.6.31 we mean the following by the right hand side.

$$
\lim _{(r, \delta) \rightarrow(0,0)} \sup \left\{\frac{f(x+h+\mu y)-f(x+h)}{\mu}: \mu \in(0, r), h \in B(0, \delta)\right\}
$$

I will show, following [99], that these generalized gradients of locally Lipschitz functions are sometimes pseudomonotone. First here is a lemma.

Lemma 25.6.2 Let $f$ be as described in the above definition. Then $\partial f(x)$ is a closed, bounded, convex, and non empty subset of $V^{\prime}$. Furthermore, for $x^{*} \in \partial f(x)$,

$$
\begin{equation*}
\left\|x^{*}\right\| \leq \operatorname{Lip}_{x}(f) \tag{25.6.33}
\end{equation*}
$$

Proof: It is left as an exercise to verify the assertions that $\partial f(x)$ is closed, and convex. It follows directly from the definition. To verify this set is bounded, let $\operatorname{Lip}_{x}(f)$ denote a Lipschitz constant valid near $x \in V$ and let $x^{*} \in \partial f(x)$. Then choosing $y$ with $\|y\|=1$ and $x^{*}(y) \geq \frac{1}{2}\left\|x^{*}\right\|$,

$$
\begin{equation*}
\frac{1}{2}\left\|x^{*}\right\|=x^{*}(y) \leq f^{0}(x, y) \tag{25.6.34}
\end{equation*}
$$

Also, for small $\mu$ and $h$,

$$
\left|\frac{f(x+h+\mu y)-f(x+h)}{\mu}\right| \leq \operatorname{Lip}_{x}(f)\|y\|=\operatorname{Lip}_{x}(f)
$$

Therefore, $f^{0}(x, y) \leq \operatorname{Lip}_{x}(f)$ and so 25.6 .34 shows $\left\|x^{*}\right\| \leq 2 L i p_{x}(f)$.
The interesting part of this Lemma is that $\partial f(x) \neq \emptyset$. To verify this first note that the definition of $f^{0}$ implies that $y \rightarrow f^{0}(x, y)$ is a gauge function. Now fix $y \in V$ and define on $\mathbb{R} y$ a linear map $x_{0}^{*}$ by

$$
x_{0}^{*}(\alpha y) \equiv \alpha f^{0}(x, y)
$$

Then if $\alpha \geq 0$,

$$
x_{0}^{*}(\alpha y)=\alpha f^{0}(x, y)=f^{0}(x, \alpha y)
$$

If $\alpha<0$,

$$
\begin{gathered}
x_{0}^{*}(\alpha y) \equiv \alpha f^{0}(x, y)= \\
\lim _{\mu \rightarrow 0+h \rightarrow 0} \inf \frac{(-\alpha) f(x+h)-(-\alpha) f(x+h+\mu y)}{\mu}= \\
(-\alpha) \lim _{\mu \rightarrow 0+h \rightarrow 0} \inf ^{\mu} \frac{f(x+h-\mu y)-f(x+h)}{\mu} \leq \\
(-\alpha) f^{0}(x,-y)=f^{0}(x, \alpha y)
\end{gathered}
$$

Therefore, $x_{0}^{*}(\alpha y) \leq f^{0}(x, \alpha y)$ for all $\alpha$. By the Hahn Banach theorem there is an extension of $x_{0}^{*}$ to all of $V, x^{*}$ which satisfies,

$$
x^{*}(y) \leq f^{0}(x, y)
$$

for all $y$. It remains to verify $x^{*}$ is continuous. This follows easily from

$$
\begin{gathered}
\left|x^{*}(y)\right|=\max \left(x^{*}(-y), x^{*}(y)\right) \leq \\
\max \left(f^{0}(x, y), f^{0}(x,-y)\right) \leq \operatorname{Lip}_{x}(f)\|y\|,
\end{gathered}
$$

which verifies 25.6 .33 and proves the lemma.
This lemma has verified the first condition needed in the definition of pseudomonotone. The next lemma verifies that these generalized subgradients satisfy the second of the conditions needed in the definition. In fact somewhat more than is needed in the definition is shown.

Lemma 25.6.3 Let $U$ be weakly open in $V^{\prime}$ and suppose $\partial f(x) \subseteq U$. Then $\partial f(z) \subseteq U$ whenever $z$ is close enough to $x$.

Proof: Suppose to the contrary there exists $z_{n} \rightarrow x$ but $z_{n}^{*} \in \partial f\left(z_{n}\right) \backslash U$. From the first lemma, we may assert that $\left\|z_{n}^{*}\right\| \leq 2 \operatorname{Lip}(f)$ for all $n$ large enough. Therefore, there is a subsequence, still denoted by $n$ such that $z_{n}^{*}$ converges weakly to $z^{*} \notin U$.

Claim: $f^{0}(x, y) \geq \limsup _{n \rightarrow \infty} f^{0}\left(x_{n}, y\right)$.
Proof of the claim: There exists $\delta>0$ such that if $\mu,\|h\|<\delta$, then

$$
\varepsilon+f^{0}(x, y) \geq \frac{f(x+h+\mu y)-f(x+h)}{\mu}
$$

Thus, for $\|h\|<\delta$,

$$
\varepsilon+f^{0}(x, y) \geq \frac{f\left(x_{n}+\left(x-x_{n}\right)+h+\mu y\right)-f\left(x_{n}+\left(x-x_{n}\right)+h\right)}{\mu}
$$

Now let $\left\|h^{\prime}\right\|<\frac{\delta}{2}$ and let $n$ be so large that $\left\|x-x_{n}\right\|<\frac{\delta}{2}$. Suppose $\left\|h^{\prime}\right\|<\frac{\delta}{2}$. Then choosing $h \equiv h^{\prime}-\left(x-x_{n}\right)$, it follows the above inequality holds because $\|h\|<\delta$. Therefore, if $\left\|h^{\prime}\right\|<\frac{\delta}{2}$, and $n$ is sufficiently large,

$$
\varepsilon+f^{0}(x, y) \geq \frac{f\left(x_{n}+h^{\prime}+\mu y\right)-f\left(x_{n}+h^{\prime}\right)}{\mu}
$$

Consequently, for all $n$ large enough,

$$
\varepsilon+f^{0}(x, y) \geq f^{0}\left(x_{n}, y\right)
$$

which proves the claim.
Now with the claim,

$$
z^{*}(y)=\lim \sup _{n \rightarrow \infty} z_{n}^{*}(y) \leq \lim \sup _{n \rightarrow \infty} f^{0}\left(x_{n}, y\right) \leq f^{0}(x, y)
$$

so $z^{*} \in \partial f(x)$ contradicting the assumption that $z^{*} \notin U$. This proves the lemma.
It is necessary to assume more on $f^{0}$ in order to obtain the third axiom defining pseudomonotone. The following theorem describes the situation.

Theorem 25.6.4 Let $f: V \rightarrow V^{\prime}$ be locally Lipschitz and suppose it satisfies the condition that whenever

$$
x_{n} \text { converges weakly to } x
$$

and

$$
\lim _{n \rightarrow \infty} \sup _{n \rightarrow \infty} f^{0}\left(x_{n}, x-x_{n}\right) \geq 0
$$

it follows that

$$
\lim \sup _{n \rightarrow \infty} f^{0}\left(x_{n}, z-x_{n}\right) \leq f^{0}(x, z-x)
$$

for all $z \in V$. Then $\partial f$ is pseudomonotone.
Proof: 25.4.15 and 25.4.16 both are satisfied thanks to Lemmas 25.6.1 and 25.6.2. It remains to verify 25.4.17. To do so, I will adopt the convention that $x^{*} \in \partial f(x)$. Suppose

$$
\begin{equation*}
\limsup _{n \rightarrow \infty} x_{n}^{*}\left(x_{n}-x\right) \leq 0 \tag{25.6.35}
\end{equation*}
$$

This implies $\liminf _{n \rightarrow \infty} x_{n}^{*}\left(x-x_{n}\right) \geq 0$. Thus,

$$
\begin{gathered}
0 \leq \lim \inf _{n \rightarrow \infty} x_{n}^{*}\left(x-x_{n}\right) \leq \liminf f^{0}\left(x_{n}, x-x_{n}\right) \\
\leq \lim \sup _{n \rightarrow \infty} f^{0}\left(x_{n}, x-x_{n}\right)
\end{gathered}
$$

which implies, by the above assumption that for all $z$,

$$
\begin{equation*}
\limsup x_{n}^{*}\left(z-x_{n}\right) \leq \limsup f^{0}\left(x_{n}, z-x_{n}\right) \leq f^{0}(x, z-x) \tag{25.6.36}
\end{equation*}
$$

In particular, this holds for $z=x$ and this implies $\limsup x_{n}^{*}\left(x-x_{n}\right) \leq 0$ which along with 25.6.35 yields

$$
\begin{equation*}
\lim _{n \rightarrow \infty} x_{n}^{*}\left(x_{n}-x\right)=0 \tag{25.6.37}
\end{equation*}
$$

Now let $z$ be arbitrary. There exists a subsequence, $n_{k}$, depending on $z$ such that

$$
\lim _{k \rightarrow \infty} x_{n_{k}}^{*}\left(x_{n_{k}}-z\right)=\liminf x_{n_{k}}^{*}\left(x_{n_{k}}-z\right)
$$

Now from Lemma 25.6.2 and its proof, the $\left\|x_{n}^{*}\right\|$ are all bounded by $\operatorname{Lip}_{x}(f)$ whenever $n$ is large enough. Therefore, there is a further subsequence, still denoted by $n_{k}$ such that

$$
x_{n_{k}}^{*} \text { converges weakly to } x^{*}(z) .
$$

We need to verify that $x^{*}(z) \in \partial f(x)$. To do so, let $y$ be arbitrary. Then from the definition,

$$
\begin{equation*}
x_{n}^{*}\left(y-x_{n}\right) \leq f^{0}\left(x_{n}, y-x_{n}\right) . \tag{25.6.38}
\end{equation*}
$$

From 25.6.37, we can take the limsup of both sides and obtain, using 25.6.36

$$
x^{*}(z)(y-x) \leq \lim \sup f^{0}\left(x_{n}, y-x_{n}\right) \leq f^{0}(x, y-x) .
$$

Since $y$ is arbitrary, this shows $x^{*}(z) \in \partial f(x)$ and proves the theorem.

### 25.7 Maximal Monotone Operators

Here it is assumed that the spaces are all real spaces to simplify the presentation.
Definition 25.7.1 Let $A: D(A) \subseteq X \rightarrow \mathscr{P}(X)$ be a set valued map. It is said to be monotone if whenever $y_{i} \in A x_{i}$,

$$
\left\langle y_{1}-y_{2}, x_{1}-x_{2}\right\rangle \geq 0
$$

Denote by $\mathscr{G}(A)$ the graph of $A$ consisting of all pairs $(x, y)$ where $y \in A x$. Such a monotone operator is said to be maximal monotone if

$$
F+A
$$

is onto where $F$ is the duality map with $p=2$.
Actually, it is more usual to say that the graph is maximal monotone if the graph is monotone and there is no monotone graph which properly contains the given graph. However, the two conditions are equivalent and I am more used to using the version in the above definition.

There is a fundamental result about these which is given next.
Theorem 25.7.2 Let $X, X^{\prime}$ be reflexive and have strictly convex norms. Let A be a monotone set valued map as just described. Then if $\lambda F+A$ is onto for some $\lambda>0$, then whenever

$$
\langle y-z, x-u\rangle \geq 0 \text { for all }[x, y] \in \mathscr{G}(A)
$$

it follows that $z \in A u$ and $u \in D(A)$. That is, the graph is maximal.

Proof: Suppose that for all $[x, y] \in \mathscr{G}(A)$,

$$
\langle y-z, x-t\rangle \geq 0
$$

Does it follow that $z \in A t$ ? By assumption, $z+\lambda F(t)=\lambda F \hat{x}+\hat{\xi}, \hat{\xi} \in A \hat{x}$. Then replacing $y$ with $\hat{\xi}$ and $x$ with $\hat{x}$,

$$
\langle\hat{\xi}-(\lambda F \hat{x}+\hat{\xi}-\lambda F t), \hat{x}-t\rangle \geq 0
$$

and so

$$
\lambda\langle F t-F \hat{x}, t-\hat{x}\rangle \leq 0
$$

which implies from Theorem 25.2.5 that $t=\hat{x}$ and so the graph of $A$ is indeed maximal monotone.

$$
z+\lambda F(t)=\lambda F \hat{x}+\hat{\xi} \Rightarrow z=\hat{\xi} \in A \hat{x}=A t
$$

Note that this would have worked with no change if the duality map had been for arbitrary $p>1$.

### 25.7.1 The min max Theorem

In fact, these two conditions are equivalent. This is shown in [13]. We give a proof of this here. First it is necessary to prove a min max theorem. The proof given follows Brezis [24] which is where I found $i$. Here is the min max theorem. A function $f$ is convex if

$$
f(\lambda x+(1-\lambda) y) \leq \lambda f(x)+(1-\lambda) f(y)
$$

It is concave if the inequality is turned around. It can be shown that in finite dimensions, convex functions are automatically continuous, similar for concave functions. Recall the following definition of upper and lower semicontinuous functions defined on a metric space and having values in $[-\infty, \infty]$.

Definition 25.7.3 A function is upper semicontinuous if whenever $x_{n} \rightarrow x$, it follows that $f(x) \geq \limsup _{n \rightarrow \infty} f\left(x_{n}\right)$ and it is lower semicontinuous if $f(x) \leq \liminf _{n \rightarrow \infty} f\left(x_{n}\right)$.

Lemma 25.7.4 If $\mathscr{F}$ is a set of functions which are upper semicontinuous, then $g(x) \equiv$ $\inf \{f(x): f \in \mathscr{F}\}$ is also upper semicontinuous. Similarly, if $\mathscr{F}$ is a set offunctions which are lower semicontinuous, then if $g(x) \equiv \sup \{f(x): f \in \mathscr{F}\}$ it follows that $g$ is lower semicontinuous.

Proof: Let $f \in \mathscr{F}$ where these functions are upper semicontinuous. Then if $x_{n} \rightarrow x$, and $g(x) \equiv \inf \{f(x): f \in \mathscr{F}\}$,

$$
f(x) \geq \lim \sup _{n \rightarrow \infty} f\left(x_{n}\right) \geq \lim \sup _{n \rightarrow \infty} g\left(x_{n}\right)
$$

Since this is true for each $f \in \mathscr{F}$, then it follows that you can take the infimum and obtain $g(x) \geq \lim \sup _{n \rightarrow \infty} g\left(x_{n}\right)$. Similarly, lower semicontinuity is preserved on taking sup.

Note that in a metric space, the above definitions up upper and lower semicontinuity in terms of sequences are equivalent to the definitions that

$$
\begin{aligned}
& f(x) \geq \lim _{r \rightarrow 0} \sup \{f(y): y \in B(x, r)\} \\
& f(x) \leq \lim _{r \rightarrow 0} \inf \{f(y): y \in B(x, r)\}
\end{aligned}
$$

respectively.
Here is a technical lemma which will make the proof shorter. It seems fairly interesting also.

Lemma 25.7.5 Suppose $H: A \times B \rightarrow \mathbb{R}$ is strictly convex in the first argument and concave in the second argument where $A, B$ are compact convex nonempty subsets of Banach spaces $E, F$ respectively and $x \rightarrow H(x, y)$ is lower semicontinuous while $y \rightarrow H(x, y)$ is upper semicontinuous. Let

$$
H(g(y), y) \equiv \min _{x \in A} H(x, y)
$$

Then $g(y)$ is uniquely defined and also for $t \in[0,1]$,

$$
\lim _{t \rightarrow 0} g(y+t(z-y))=g(y)
$$

Proof: First suppose both $z, w$ yield the definition of $g(y)$. Then

$$
H\left(\frac{z+w}{2}, y\right)<\frac{1}{2} H(z, y)+\frac{1}{2} H(w, y)
$$

which contradicts the definition of $g(y)$. As to the existence of $g(y)$ this is nothing more than the theorem that a lower semicontinuous function defined on a compact set achieves its minimum.

Now consider the last claim about "hemicontinuity". For all $x \in A$, it follows from the definition of $g$ that

$$
H(g(y+t(z-y)), y+t(z-y)) \leq H(x, y+t(z-y))
$$

By concavity of $H$ in the second argument,

$$
\begin{align*}
& (1-t) H(g(y+t(z-y)), y)+t H(g(y+t(z-y)), z)  \tag{25.7.39}\\
\leq & H(x, y+t(z-y)) \tag{25.7.40}
\end{align*}
$$

Now let $t_{n} \rightarrow 0$. Does $g\left(y+t_{n}(z-y)\right) \rightarrow g(y)$ ? Suppose not. By compactness, the expression $g\left(y+t_{n}(z-y)\right)$ is in a compact set and so there is a further subsequence, still denoted by $t_{n}$ such that

$$
g\left(y+t_{n}(z-y)\right) \rightarrow \hat{x} \in A
$$

Then passing to a limit in 25.7.40, one obtains, using the upper semicontinuity in one and lower semicontinuity in the other the following inequality.

$$
H(\hat{x}, y) \leq \lim _{n \rightarrow \infty} \inf _{n}\left(1-t_{n}\right) H\left(g\left(y+t_{n}(z-y)\right), y\right)+
$$

$$
\begin{gathered}
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} H\left(g\left(y+t_{n}(z-y)\right), z\right) \\
\leq \lim \inf _{n \rightarrow \infty}\binom{\left(1-t_{n}\right) H\left(g\left(y+t_{n}(z-y)\right), y\right)}{+t_{n} H\left(g\left(y+t_{n}(z-y)\right), z\right)} \\
\leq \lim _{n \rightarrow \infty} H\left(x, y+t_{n}(z-y)\right) \leq H(x, y)
\end{gathered}
$$

This shows that $\hat{x}=g(y)$ because this holds for every $x$. Since $t_{n} \rightarrow 0$ was arbitrary, this shows that in fact

$$
\lim _{t \rightarrow 0+} g(y+t(z-y))=g(y)
$$

Now with this preparation, here is the min-max theorem. A norm is called strictly convex if whenever $x \neq y,\left\|\frac{x+y}{2}\right\|<\frac{\|x\|}{2}+\frac{\|y\|}{2}$.

Theorem 25.7.6 Let $E, F$ be Banach spaces with $E$ having a strictly convex norm. Also suppose that $A \subseteq E, B \subseteq F$ are compact and convex sets and that $H: A \times B \rightarrow \mathbb{R}$ is such that

$$
\begin{gathered}
x \rightarrow H(x, y) \text { is convex } \\
y \rightarrow H(x, y) \text { is concave }
\end{gathered}
$$

Thus $H$ is continuous in each variable in the case of finite dimensional spaces. Here assume that $x \rightarrow H(x, y)$ is lower semicontinuous and $y \rightarrow H(x, y)$ is upper semicontinuous. Then

$$
\min _{x \in A} \max _{y \in B} H(x, y)=\max _{y \in B} \min _{x \in A} H(x, y)
$$

This condition is equivalent to the existence of $\left(x_{0}, y_{0}\right) \in A \times B$ such that

$$
\begin{equation*}
H\left(x_{0}, y\right) \leq H\left(x_{0}, y_{0}\right) \leq H\left(x, y_{0}\right) \text { for all } x, y \tag{25.7.41}
\end{equation*}
$$

Proof: One part of the main equality is obvious.

$$
\max _{y \in B} H(x, y) \geq H(x, y) \geq \min _{x \in A} H(x, y)
$$

and so for each $x$,

$$
\max _{y \in B} H(x, y) \geq \max _{y \in B} \min _{x \in A} H(x, y)
$$

and so

$$
\begin{equation*}
\min _{x \in A} \max _{y \in B} H(x, y) \geq \max _{y \in B} \min _{x \in A} H(x, y) \tag{25.7.42}
\end{equation*}
$$

Next consider the other direction.
Define $H_{\mathcal{\varepsilon}}(x, y) \equiv H(x, y)+\varepsilon\|x\|^{2}$ where $\varepsilon>0$. Then $H_{\varepsilon}$ is strictly convex in the first variable. This results from the observation that

$$
\left\|\frac{x+y}{2}\right\|^{2}<\left(\frac{\|x\|+\|y\|}{2}\right)^{2} \leq \frac{1}{2}\left(\|x\|^{2}+\|y\|^{2}\right)
$$

Then by Lemma 25.7.5 there exists a unique $x \equiv g(y)$ such that

$$
H_{\varepsilon}(g(y), y) \equiv \min _{x \in A} H_{\varepsilon}(x, y)
$$

and also, whenever $y, z \in A$,

$$
\lim _{t \rightarrow 0+} g(y+t(z-y))=g(y) .
$$

Thus $H_{\mathcal{E}}(g(y), y)=\min _{x \in A} H_{\mathcal{E}}(x, y)$. But also this shows that $y \rightarrow H_{\mathcal{E}}(g(y), y)$ is the minimum of functions which are upper semicontinuous and so this function is also upper semicontinuous. Hence there exists $y^{*}$ such that

$$
\begin{equation*}
\max _{y \in B} H_{\varepsilon}(g(y), y)=H_{\varepsilon}\left(g\left(y^{*}\right), y^{*}\right)=\max _{y \in B} \min _{x \in A} H_{\varepsilon}(x, y) \tag{25.7.43}
\end{equation*}
$$

Thus from concavity in the second argument and what was just defined, for $t \in(0,1)$,

$$
\begin{gather*}
H_{\varepsilon}\left(g\left(y^{*}\right), y^{*}\right) \geq H_{\varepsilon}\left(g\left((1-t) y^{*}+t y\right),(1-t) y^{*}+t y\right) \\
\geq(1-t) H_{\varepsilon}\left(g\left((1-t) y^{*}+t y\right), y^{*}\right)+t H_{\varepsilon}\left(g\left((1-t) y^{*}+t y\right), y\right) \\
\geq(1-t) H_{\varepsilon}\left(g\left(y^{*}\right), y^{*}\right)+t H_{\varepsilon}\left(g\left((1-t) y^{*}+t y\right), y\right) \tag{25.7.44}
\end{gather*}
$$

This is because $\min _{x} H_{\varepsilon}\left(x, y^{*}\right) \equiv H_{\varepsilon}\left(g\left(y^{*}\right), y^{*}\right)$ so

$$
H_{\varepsilon}\left(g\left((1-t) y^{*}+t y\right), y^{*}\right) \geq H_{\varepsilon}\left(g\left(y^{*}\right), y^{*}\right)
$$

Then subtracting the first term on the right, one gets

$$
t H_{\mathcal{E}}\left(g\left(y^{*}\right), y^{*}\right) \geq t H_{\mathcal{E}}\left(g\left((1-t) y^{*}+t y\right), y\right)
$$

and cancelling the $t$,

$$
H_{\mathcal{E}}\left(g\left(y^{*}\right), y^{*}\right) \geq H_{\mathcal{E}}\left(g\left((1-t) y^{*}+t y\right), y\right)
$$

Now apply Lemma 25.7.5 and let $t \rightarrow 0+$. This along with lower semicontinuity yields

$$
\begin{equation*}
H_{\varepsilon}\left(g\left(y^{*}\right), y^{*}\right) \geq \lim \inf _{t \rightarrow 0+} H_{\varepsilon}\left(g\left((1-t) y^{*}+t y\right), y\right)=H_{\varepsilon}\left(g\left(y^{*}\right), y\right) \tag{25.7.45}
\end{equation*}
$$

Hence for every $x, y$

$$
H_{\mathcal{E}}\left(x, y^{*}\right) \geq H_{\mathcal{E}}\left(g\left(y^{*}\right), y^{*}\right) \geq H_{\mathcal{E}}\left(g\left(y^{*}\right), y\right)
$$

Thus

$$
\min _{x} H_{\mathcal{E}}\left(x, y^{*}\right) \geq H_{\mathcal{E}}\left(g\left(y^{*}\right), y^{*}\right) \geq \max _{y} H_{\mathcal{E}}\left(g\left(y^{*}\right), y\right)
$$

and so

$$
\begin{aligned}
\max _{y \in B} \min _{x \in A} H_{\varepsilon}(x, y) & \geq \min _{x} H_{\varepsilon}\left(x, y^{*}\right) \geq H_{\mathcal{\varepsilon}}\left(g\left(y^{*}\right), y^{*}\right) \\
& \geq \max _{y} H_{\varepsilon}\left(g\left(y^{*}\right), y\right) \geq \min _{x \in A} \max _{y \in B} H_{\varepsilon}(x, y)
\end{aligned}
$$

Thus, letting $C \equiv \max \{\|x\|: x \in A\}$

$$
\varepsilon C^{2}+\max _{y \in B} \min _{x \in A} H(x, y) \geq \min _{x \in A} \max _{y \in B} H(x, y)
$$

Since $\varepsilon$ is arbitrary, it follows that

$$
\max _{y \in B} \min _{x \in A} H(x, y) \geq \min _{x \in A} \max _{y \in B} H(x, y)
$$

This proves the first part because it was shown above in 25.7.42 that

$$
\min _{x \in A} \max _{y \in B} H(x, y) \geq \max _{y \in B} \min _{x \in A} H(x, y)
$$

Now consider 25.7.41 about the existence of a "saddle point" given the equality of min max and max min. Let

$$
\alpha=\max _{y \in B} \min _{x \in A} H(x, y)=\min _{x \in A} \max _{y \in B} H(x, y)
$$

Then from

$$
y \rightarrow \min _{x \in A} H(x, y) \text { and } x \rightarrow \max _{y \in B} H(x, y)
$$

being upper semicontinuous and lower semicontinuous respectively, there exist $y_{0}$ and $x_{0}$ such that

$$
\alpha=\min _{x \in A} H\left(x, y_{0}\right)=\max _{y \in B} \min _{x \in A}^{\operatorname{minimum} \text { of u.s.c }} H(x, y)=\min _{x \in A} \operatorname{maximum~of~l.s.c.~}_{\max _{y \in B} H(x, y)}=\max _{y \in B} H\left(x_{0}, y\right)
$$

Then

$$
\begin{aligned}
\alpha & =\max _{y \in B} H\left(x_{0}, y\right) \geq H\left(x_{0}, y_{0}\right) \\
\alpha & =\min _{x \in A} H\left(x, y_{0}\right) \leq H\left(x_{0}, y_{0}\right)
\end{aligned}
$$

so in fact $\alpha=H\left(x_{0}, y_{0}\right)$ and from the above equalities,

$$
\begin{aligned}
& H\left(x_{0}, y_{0}\right)=\alpha=\min _{x \in A} H\left(x, y_{0}\right) \leq H\left(x, y_{0}\right) \\
& H\left(x_{0}, y_{0}\right)=\alpha=\max _{y \in B} H\left(x_{0}, y\right) \geq H\left(x_{0}, y\right)
\end{aligned}
$$

and so

$$
H\left(x_{0}, y\right) \leq H\left(x_{0}, y_{0}\right) \leq H\left(x, y_{0}\right)
$$

Thus if the min max condition holds, then there exists a saddle point, namely $\left(x_{0}, y_{0}\right)$.
Finally suppose there is a saddle point $\left(x_{0}, y_{0}\right)$ where

$$
H\left(x_{0}, y\right) \leq H\left(x_{0}, y_{0}\right) \leq H\left(x, y_{0}\right)
$$

Then

$$
\min _{x \in A} \max _{y \in B} H(x, y) \leq \max _{y \in B} H\left(x_{0}, y\right) \leq H\left(x_{0}, y_{0}\right) \leq \min _{x \in A} H\left(x, y_{0}\right) \leq \max _{y \in B} \min _{x \in A} H(x, y)
$$

However, as noted above, it is always the case that

$$
\max _{y \in B} \min _{x \in A} H(x, y) \leq \min _{x \in A} \max _{y \in B} H(x, y)
$$

Of course all of this works with no change if you have $E, F$ reflexive Banach spaces and the sets $A, B$ are just closed and bounded and convex. Then you just use the fact that the functional is weakly lower semicontinuous in the first variable and weakly upper semicontinuous in the second. Recall that lower semicontinuous and convex implies weakly lower semicontinuity. Then just use weak convergence instead of strong convergence in the above argument. Recall that closed bounded and convex sets with the weak topology can be considered metric spaces. I think the above is most interesting in finite dimensions. Of course in this case, you can simply assume the norm is the standard Euclidean norm and there is then no need to assume one of the norms is strictly convex. It comes automatically. Just use an equivalent norm which is strictly convex.

### 25.7.2 Equivalent Conditions For Maximal Monotone

Next is the theorem about the graph being maximal being equivalent to the operator being maximal monotone. It is a very convenient result to have. The proof is a modified version of one in Barbu [13]. It is based on the following lemma also in Barbu. This is a little like the Browder lemma but is based on the min max theorem above. It is also a very interesting argument.

Lemma 25.7.7 Let $E$ be a finite dimensional Banach space and let $K$ be a convex and compact subset of $E . \operatorname{Let} \mathscr{G}(A)$ be a monotone subset of $E \times E^{\prime}$ such that $D(A) \subseteq K$ and $B$ is a single valued monotone and continuous operator from $E$ to $E^{\prime}$. Then there exists $x \in K$ such that

$$
\langle B x+v, u-x\rangle_{E^{\prime}, E} \geq 0 \text { for all }[u, v] \in \mathscr{G}(A) .
$$

If $B$ is coercive

$$
\lim _{\|x\| \rightarrow \infty} \frac{\langle B x, x\rangle}{\|x\|}=\infty
$$

and $0 \in D(A)$, then one can assume only that $K$ is convex and closed.
Proof: Let $T: E \rightarrow K$ be the multivalued operator defined by

$$
T y \equiv\left\{x \in K:\langle B y+v, u-x\rangle_{E^{\prime}, E} \geq 0 \text { for all }[u, v] \in \mathscr{G}(A)\right\}
$$

Here $y \in E$ and it is desired to show that $T y \neq \emptyset$ for all $y \in K$. For $[u, v] \in \mathscr{G}(A)$, let

$$
K_{u, v}=\left\{x \in K:\langle B y+v, u-x\rangle_{E^{\prime}, E} \geq 0\right\}
$$

Then $K_{u, v}$ is a closed, hence compact subset of $K$. The thing to do is to show that

$$
\cap_{[u, v] \in \mathscr{G}(A)} K_{u, v} \equiv T y \neq \emptyset
$$

whenever $y \in K$. Then one argues that $T$ is set valued, has convex compact values and is upper semicontinuous. Then one applies the Kakutani fixed point theorem to get $x \in T x$.

Since these sets $K_{u, v}$ are compact, it suffices to show that they satisfy the finite intersection property. Thus for $\left\{\left[u_{i}, v_{i}\right]\right\}_{i=1}^{n}$ a finite set of elements of $\mathscr{G}(A)$, it is necessary to show that there exists a solution $x$ to the inequalities

$$
\left\langle u_{i}-x, B y+v_{i}\right\rangle \geq 0, i=1,2, \cdots, n
$$

and then it follows from finite intersection property that there exists

$$
x \in \cap_{[u, v] \in \mathscr{G}(A)} K_{u, v}
$$

which is what was desired. Let $P_{n}$ be all $\vec{\lambda}=\left(\lambda_{1}, \cdots, \lambda_{n}\right)$ such that each $\lambda_{k} \geq 0$ and $\sum_{k=1}^{n} \lambda_{k}=1$. Let $H: P_{n} \times P_{n} \rightarrow \mathbb{R}$ be given by

$$
\begin{equation*}
H(\vec{\mu}, \vec{\lambda}) \equiv \sum_{i=1}^{n} \mu_{i}\left\langle B y+v_{i}, \sum_{j=1}^{n} \lambda_{j} u_{j}-u_{i}\right\rangle \tag{25.7.46}
\end{equation*}
$$

Then this is both convex and concave in both $\vec{\lambda}, \vec{\mu}$ and so by Theorem 25.7.6, there exists $\vec{\mu}_{0}, \vec{\lambda}_{0}$ both in $P_{n}$ such that for all $\vec{\mu}, \vec{\lambda}$,

$$
\begin{equation*}
H\left(\vec{\mu}, \vec{\lambda}_{0}\right) \leq H\left(\vec{\mu}_{0}, \vec{\lambda}_{0}\right) \leq H\left(\vec{\mu}_{0}, \vec{\lambda}\right) \tag{25.7.47}
\end{equation*}
$$

However, plugging in $\vec{\mu}=\vec{\lambda}$ in 25.7.46,

$$
\begin{gathered}
H(\vec{\lambda}, \vec{\lambda})=\sum_{i=1}^{n} \lambda_{i}\left\langle B y+v_{i}, \sum_{j=1}^{n} \lambda_{j} u_{j}-u_{i}\right\rangle \\
=\sum_{i=1}^{n}\left\langle B y+v_{i}, \sum_{j=1}^{n} \lambda_{i} \lambda_{j} u_{j}-\lambda_{i} u_{i}\right\rangle \\
=\sum_{i=1}^{n}\left\langle B y+v_{i}, \sum_{j=1}^{n}\left(\lambda_{i} \lambda_{j} u_{j}-\lambda_{i} \lambda_{j} u_{i}\right)\right\rangle \\
=\overbrace{\left\langle B y, \sum_{i=1}^{n} \sum_{j=1}^{n}\left(\lambda_{i} \lambda_{j} u_{j}-\lambda_{i} \lambda_{j} u_{i}\right)\right\rangle}^{=0}+\sum_{i=1}^{n}\left\langle v_{i}, \sum_{j=1}^{n}\left(\lambda_{i} \lambda_{j} u_{j}-\lambda_{i} \lambda_{j} u_{i}\right)\right\rangle
\end{gathered}
$$

The first term obviously equals 0 . Consider the second. This term equals

$$
\sum_{i} \sum_{j} \lambda_{i} \lambda_{j}\left\langle v_{i},\left(u_{j}-u_{i}\right)\right\rangle
$$

The terms equal 0 when $j=i$ or they come in pairs

$$
\begin{aligned}
& \lambda_{i} \lambda_{j}\left\langle v_{i},\left(u_{j}-u_{i}\right)\right\rangle+\lambda_{i} \lambda_{j}\left\langle v_{j},\left(u_{i}-u_{j}\right)\right\rangle \\
= & \lambda_{i} \lambda_{j}\left(\left\langle v_{i},\left(u_{j}-u_{i}\right)\right\rangle-\left\langle v_{j},\left(u_{j}-u_{i}\right)\right\rangle\right) \\
= & \lambda_{i} \lambda_{j}\left(\left\langle v_{i},\left(u_{j}-u_{i}\right)\right\rangle-\left\langle v_{j},\left(u_{j}-u_{i}\right)\right\rangle\right) \leq 0
\end{aligned}
$$

by monotonicity of $A$. Hence $H(\vec{\lambda}, \vec{\lambda}) \leq 0$. Then from 25.7.47, for all $\vec{\mu}$

$$
H\left(\vec{\mu}, \vec{\lambda}_{0}\right) \leq H\left(\vec{\mu}_{0}, \vec{\lambda}_{0}\right) \leq H\left(\vec{\mu}_{0}, \vec{\mu}_{0}\right) \leq 0
$$

It follows that

$$
\begin{aligned}
& \sum_{i=1}^{m} \mu_{i}\left\langle B y+v_{i}, \sum_{j=1}^{n} \lambda_{j}^{0} u_{j}-u_{i}\right\rangle \leq 0 \\
& \sum_{i=1}^{m} \mu_{i}\left\langle B y+v_{i}, u_{i}-\sum_{j=1}^{n} \lambda_{j}^{0} u_{j}\right\rangle \geq 0
\end{aligned}
$$

where $\vec{\lambda}_{0} \equiv\left(\lambda_{1}^{0}, \cdots, \lambda_{n}^{0}\right)$. This is true for any choice of $\vec{\mu}$. In particular, you could let $\vec{\mu}$ equal 1 in the $i^{t h}$ position and 0 elsewhere and conclude that for all $i=1, \cdots, n$,

$$
\left\langle B y+v_{i}, u_{i}-\sum_{j=1}^{n} \lambda_{j}^{0} u_{j}\right\rangle \geq 0
$$

so you let $x=\sum_{j=1}^{n} \lambda_{j}^{0} u_{j}$ and this shows that $T y \neq \emptyset$ because the sets $K_{u, v}$ have the finite intersection property.

Thus $T: K \rightarrow \mathscr{P}(K)$ and for each $y \in K, T y \neq \emptyset$. In fact this is true for any $y$ but we are only considering $y \in K$. Now $T y$ is clearly a closed subset of $K$. It is also clearly convex. Is it upper semicontinuous? Let $y_{k} \rightarrow y$ and consider $T y+B(0, r)$. Is $T y_{k} \in T y+B(0, r)$ for all $k$ large enough? If not, then there is a subsequence, denoted as $z_{k} \in T y_{k}$ which is outside this open set $T y+B(0, r)$. Then taking a further subsequence, still denoted as $z_{k}$, it follows that $z_{k} \rightarrow z \notin T y+B(0, r)$. Now

$$
\left\langle B y_{k}+v, u-z_{k}\right\rangle \geq 0 \text { all }[u, v] \in \mathscr{G}(A)
$$

Therefore, from continuity of $B$,

$$
\langle B y+v, u-z\rangle \geq 0 \text { all }[u, v] \in \mathscr{G}(A)
$$

which means $z \in T y$ contrary to the assumption that $T$ is not upper semicontinuous. Since $T$ is upper semicontinuous and maps to compact convex sets, it follows from Theorem 25.4.4 that $T$ has a fixed point $x \in T x$. Hence there exists a solution $x$ to

$$
\langle B x+v, u-x\rangle \geq 0 \text { all }[u, v] \in \mathscr{G}(A)
$$

Next suppose that $K$ is only closed and convex but $B$ is coercive and $0 \in D(A)$. Then let $K_{n} \equiv \overline{B(0, n)} \cap K$ and let $A_{n}$ be the restriction of $A$ to $\overline{B(0, n)}$. It follows that there exists $x_{n} \in K_{n}$ such that for all $[u, v] \in \mathscr{G}\left(A_{n}\right)$,

$$
\left\langle B x_{n}+v, u-x_{n}\right\rangle \geq 0
$$

Then since $0 \in D(A)$, one can pick $v_{0} \in A 0$ and obtain

$$
\left\langle B x_{n}+v_{0},-x_{n}\right\rangle \geq 0,\left\langle v_{0},-x_{n}\right\rangle \geq\left\langle B x_{n}, x_{n}\right\rangle
$$

from which it follows from coercivity of $B$ that the $x_{n}$ are bounded independent of $n$. Say $\left\|x_{n}\right\|<C$. Then there is a subsequence still denoted as $x_{n}$ such that $x_{n} \rightarrow x \in K$, thanks to the assumption that $K$ is closed and convex. Let $[u, v] \in \mathscr{G}(A)$. Then for all $n$ large enough $\|u\|<n$ and so

$$
\left\langle B x_{n}+v, u-x_{n}\right\rangle \geq 0
$$

Then letting $n \rightarrow \infty$ and using the continuity of $B$,

$$
\langle B x+v, u-x\rangle \geq 0
$$

Since $[u, v]$ was arbitrary, this proves the lemma.
Observation 25.7.8 If you have a monotone set valued function, then its graph can always be considered a subset of the graph of a maximal monotone graph. If $A$ is monotone, then let $\mathscr{F}$ be $\mathscr{G}(B)$ such that $\mathscr{G}(B) \supseteq \mathscr{G}(A)$ and $B$ is monotone. Partially order by set inclusion. Then let $\mathscr{C}$ be a maximal chain. Let $\mathscr{G}(\hat{A})=\cup \mathscr{C}$. If $\left[x_{i}, y_{i}\right] \in \mathscr{G}(\hat{A})$, then both are in some $B \in \mathscr{C}$. Hence $\left(y_{1}-y_{2}, x_{1}-x_{2}\right) \geq 0$ so monotone and must be maximal monotone because if $\langle z-v, x-u\rangle \geq 0$ for all $[u, v] \in \mathscr{G}(\hat{A})$ and $[x, z] \notin \hat{A}$, then you could include this ordered pair and contradict maximality of the chain $\mathscr{C}$.

Next is an interesting theorem which comes from this lemma. It is an infinite dimensional version of the above lemma.

Theorem 25.7.9 Let $X$ be a reflexive Banach space and let $K$ be a closed convex subset of $X$. Let $A, B$ be monotone such that

1. $D(A) \subseteq K, 0 \in D(A)$.
2. $B$ is single valued, hemicontinuous, bounded and coercive mapping $X$ to $X^{\prime}$.

Then there exists $x \in K$ such that

$$
\langle B x+v, u-x\rangle_{X^{\prime}, X} \geq 0 \text { for all }[u, v] \in \mathscr{G}(A)
$$

Before giving the proof, here is an easy lemma.
Lemma 25.7.10 Let $E$ be finite dimensional and let $B: E \rightarrow E^{\prime}$ be monotone and hemicontinuous. Then B is continuous.

Proof: The space can be considered a finite dimensional Hilbert space $\left(\mathbb{R}^{n}\right)$ and so weak and strong convergence are exactly the same. First it is desired to show that $B$ is bounded. Suppose it is not. Then there exists $\left\|x_{k}\right\|_{E}=1$ but $\left\|B x_{n}\right\|_{E^{\prime}} \rightarrow \infty$. Since finite dimensional, there is a subsequence still denoted as $x_{k}$ such that $x_{k} \rightarrow x,\|x\|_{E}=1$.

$$
\left\langle B x_{k}-B x, x_{k}-x\right\rangle \geq 0
$$

Hence

$$
\left\langle\frac{B x_{k}-B x}{\left\|B x_{k}\right\|_{E^{\prime}}}, x_{k}-x\right\rangle \geq 0
$$

Then taking another subsequence, written with index $k$, it can be assumed that

$$
B x_{k} /\left\|B x_{k}\right\| \rightarrow y^{*} \in E^{\prime},\left\|y^{*}\right\|_{E^{\prime}}=1
$$

Hence,

$$
\left\langle y^{*}, x_{k}-x\right\rangle \geq 0
$$

for all $x \in E$, but this requires that $y^{*}=0$, a contradiction. Thus $B$ is monotone, hemicontinuous, and bounded. It follows from Theorem 25.1 .4 which says that monotone and hemicontinuous operators are pseudomonotone and Proposition 25.1 .6 which says that bounded pseudomonotone operators are demicontinuous that $B$ is demicontinuous, hence continuous because, as just noted above, weak and strong convergence are the same for finite dimensional spaces. In case $B$ is bounded, then this follows from Proposition 25.1.6 above. It is pseudomonotone and bounded hence demicontinuous and weak and strong convergence is the same in finite dimensions.

Proof of Theorem 25.7.9: Let $\left\{X_{n}\right\}$ be an increasing sequence of finite dimensional subspaces. Let $\hat{A}$ be maximal monotone on $\cup_{n} X_{n}$ and extending $A$. By this is meant that the graph of $\hat{A}$ contains the graph of $A$ restricted to $\cup_{n} X_{n}, \hat{A}$ is monotone and there is no other larger graph with these properties. See the above observation. Let $j_{n}: X_{n} \rightarrow X$ be the inclusion map and $j_{n}^{*}: X^{\prime} \rightarrow X_{n}^{\prime}$ be the dual map. Then $j_{n}^{*} \hat{A} j_{n} \equiv A_{n}$ and $j_{n}^{*} B j_{n} \equiv B_{n}$ have monotone graphs from $X_{n}$ to $\mathscr{P}\left(X_{n}^{\prime}\right)$ with $B_{n}$ being continuous and single valued. This follows from the hemicontinuity and the above lemma which states that on finite dimensional spaces, hemicontinuity and monotonicity imply continuity. Then

$$
[u, v] \in \mathscr{G}\left(A_{n}\right)
$$

means

$$
u \in D(A) \cap X_{n} \text { and } v \in j_{n}^{*} \hat{A} j_{n}(u)=j_{n}^{*} \hat{A}(u) \text { since } u \in X_{n}
$$

Then from Lemma 25.7.7, there exists $x_{n} \in X_{n}$ such that

$$
\left\langle B_{n} x_{n}+v_{n}, u_{n}-x_{n}\right\rangle_{X^{\prime}, X} \geq 0 \text { all }\left[u_{n}, v_{n}\right] \in \mathscr{G}\left(A_{n}\right)
$$

That is, there exists $x_{n} \in K \cap X_{n}$ such that for all $u \in D(\hat{A}) \cap X_{n},[u, v] \in \mathscr{G}(\hat{A})$

$$
\begin{equation*}
\left\langle B x_{n}+v, u-x_{n}\right\rangle_{X^{\prime}, X} \geq 0 \tag{25.7.48}
\end{equation*}
$$

Then

$$
\begin{equation*}
\left\langle v, u-x_{n}\right\rangle \geq\left\langle B x_{n}, x_{n}-u\right\rangle \tag{25.7.49}
\end{equation*}
$$

From the assumption that $0 \in D(\hat{A})$, one can let $u=0$ and then pick $v_{0} \in \hat{A} 0$. Then the above reduces to

$$
\left\langle v_{0},-x_{n}\right\rangle \geq\left\langle B x_{n}, x_{n}\right\rangle
$$

By coercivity of $B$, these $x_{n}$ are all bounded and so by the Eberlien Smulian theorem, there is a subsequence $\left\{x_{n}\right\}$ which satisfies

$$
\begin{aligned}
x_{n} & \rightarrow x \text { weakly in } X \\
B x_{n} & \rightarrow y \text { weakly in } X^{\prime}
\end{aligned}
$$

Then from 25.7.48

$$
\left\langle v, u-x_{n}\right\rangle+\left\langle B x_{n}, u\right\rangle \geq\left\langle B x_{n}, x_{n}\right\rangle
$$

Then it follows that

$$
\left\langle v, u-x_{n}\right\rangle+\left\langle B x_{n}, u\right\rangle-\left\langle B x_{n}, x\right\rangle \geq\left\langle B x_{n}, x_{n}-x\right\rangle
$$

It follows that

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \sup _{n}\left\langle B x_{n}, x_{n}-x\right\rangle & \leq\langle v, u-x\rangle+\langle y, u\rangle-\langle y, x\rangle \\
& =\langle v+y, u-x\rangle
\end{aligned}
$$

Claim: limsup $\operatorname{sim}_{n \rightarrow \infty}\left\langle B x_{n}, x_{n}-x\right\rangle \leq 0$.
Proof of claim: This is so if $\langle v+y, u-x\rangle \leq 0$ for some $[u, v] \in \mathscr{G}(\hat{A})$.If $\langle v+y, u-x\rangle$ is greater than 0 for all $[u, v]$, then since $\hat{A}$ is maximal, it would follow that $-y \in \hat{A} x$. Now consider 25.7.49.

$$
\langle v, u-x\rangle \geq \lim \sup _{n \rightarrow \infty}\left\langle B x_{n}, x_{n}\right\rangle-\langle y, u\rangle
$$

Since $x \in D(\hat{A})$, you could put in $u=x$ in the above and obtain

$$
0 \geq \lim \sup _{n \rightarrow \infty}\left\langle B x_{n}, x_{n}\right\rangle-\langle y, x\rangle=\lim \sup _{n \rightarrow \infty}\left\langle B x_{n}, x_{n}-x\right\rangle
$$

which shows the claim is true.
Since $B$ is monotone and hemicontinuous, it satisfies the pseudomonotone condition, Theorem 25.1.4. Hence for any $z$,

$$
\begin{aligned}
\langle y, x-z\rangle & \geq \lim \sup _{n \rightarrow \infty}\left\langle B x_{n}, x_{n}-x\right\rangle+\lim \sup _{n \rightarrow \infty}\left\langle B x_{n}, x-z\right\rangle \\
& \geq \lim \sup _{n \rightarrow \infty}\left(\left\langle B x_{n}, x_{n}-x\right\rangle+\left\langle B x_{n}, x-z\right\rangle\right) \\
& \geq \lim _{n \rightarrow \infty}\left(\left\langle B x_{n}, x_{n}-z\right\rangle\right) \geq\langle B x, x-z\rangle
\end{aligned}
$$

Since $z$ is arbitrary, this shows that $y=B x$. It follows from 25.7.48 that for any $[u, v] \in$ $\mathscr{G}(\hat{A})$,

$$
\begin{gathered}
\left\langle B x_{n}+v, u-x_{n}\right\rangle=\left\langle B x_{n}+v, u-x\right\rangle+\left\langle B x_{n}+v, x-x_{n}\right\rangle \geq 0 \\
\left\langle B x_{n}+v, u-x\right\rangle \geq\left\langle B x_{n}, x_{n}-x\right\rangle \geq\left\langle B x, x_{n}-x\right\rangle
\end{gathered}
$$

Now take a limit of both sides and use the fact that $y=B x$ to obtain

$$
\langle B x+v, u-x\rangle \geq 0
$$

for all $[u, v] \in \mathscr{G}(\hat{A})$. Here $\hat{A}$ extends $A$ on $\cup_{n} X_{n}$. Why does it follow from this that there exists an $x$ such that the inequality holds for all $[u, v] \in \mathscr{G}(A)$ ?

Let $V$ be a finite dimensional subspace.

$$
K_{V} \equiv\left\{x \in K:\langle B x+v, u-x\rangle_{X^{\prime}, X} \geq 0 \text { for all }[u, v] \in \mathscr{G}(A), u \in V\right\}
$$

Then from the above argument, $K_{V} \neq \emptyset$. You just choose your subspaces $X_{n}$ to all include $V$. Also, from coercivity of $B$ and the above argument, these $K_{V}$ are all bounded and weakly closed. Hence they are weakly compact. Then if you have finitely many of them, you can let your subspaces include each $V$ and conclude that these $K_{V}$ have finite intersection property and so there exists $x \in \cap_{V} K_{V}$ which gives the desired $x$.

Note that there is only one place where $0 \in D(A)$ was used and it was to get the estimate. In the argument,

$$
\left\langle v, u-x_{n}\right\rangle \geq\left\langle B x_{n}, x_{n}-u\right\rangle
$$

and it was convenient to be able to take $u=0$. However, you could also assume other things on $B$ such as that it satisfies an estimate of the form

$$
\|B x\| \leq C\|x\|+C
$$

and if you did this, you could also obtain the necessary estimate as follows.

$$
\begin{aligned}
\left\langle v, u-x_{n}\right\rangle & \geq\left\langle B x_{n}, x_{n}-u\right\rangle \\
\left\langle v, u-x_{n}\right\rangle+\left\langle B x_{n}, u\right\rangle & \geq\left\langle B x_{n}, x_{n}\right\rangle \\
\|v\|\left(\|u\|+\left\|x_{n}\right\|\right)+\left(\left[C\left\|x_{n}\right\|+C\right]\|u\|\right) & \geq\left\langle B x_{n}, x_{n}\right\rangle
\end{aligned}
$$

and then pick some $[u, v]$. Thus the following corollary comes right away. This would have worked just as well if you had an estimate of the form

$$
\|B x\| \leq C\|x\|^{p-1}+C, p>1
$$

Corollary 25.7.11 Let $X$ be a reflexive Banach space and let $K$ be a closed convex subset of $X$. Let $A, B$ be monotone such that

1. $D(A) \subseteq K$
2. $B$ is single valued, hemicontinuous, bounded and coercive mapping $X$ to $X^{\prime}$ which satisfies the estimate

$$
\|B x\| \leq C\|x\|+C \text { or more generally }\|B x\| \leq C\|x\|^{p-1}+C, p>1
$$

Then there exists $x \in K$ such that

$$
\langle B x+v, u-x\rangle_{X^{\prime}, X} \geq 0 \text { for all }[u, v] \in \mathscr{G}(A)
$$

Now here is the equivalence between maximal monotone graph and having $F+A$ be onto. It was already shown that if $\lambda F+A$ is onto, then the graph of $A$ is maximal monotone in the sense that there is no monotone operator whose graph properly contains the graph of A. This was Theorem 25.7.2 above which is stated here as a reminder of what it said.

Theorem 25.7.12 Let $X, X^{\prime}$ be reflexive and have strictly convex norms. Let A be a monotone set valued map as just described. Then if

$$
\lambda F+A \text { onto }
$$

for some $\lambda>0$, then whenever

$$
\langle y-z, x-u\rangle \geq 0 \text { for all }[x, y] \in \mathscr{G}(A)
$$

it follows that $z \in A u$ and $u \in D(A)$. That is, the graph is maximal.
Theorem 25.7.13 Let $X$ be a strictly convex reflexive Banach space. Suppose the graph of $A: X \rightarrow \mathscr{P}(X)$ is maximal monotone in the sense that it is monotone and no monotone graph can properly contain the graph of $A$. Then for all $\lambda>0, \lambda F+A$ is onto. Conversely, if for some $\lambda>0, \lambda F+A$ is onto, then the graph of $A$ is maximal with respect to being monotone.

Proof: In Theorem 25.7.9, let $B x \equiv \lambda F(x)-y_{0}$. Then from the properties of the duality map, Theorem 25.2.3 above, it follows that $B$ satisfies the necessary conditions to use the result of Corollary 25.7.11 with $K=X$. This $B$ is monotone hemicontinuous, and coercive. Thus there exists $x$ such that for all $[u, v] \in \mathscr{G}(A)$,

$$
\begin{aligned}
\left\langle\lambda F(x)-y_{0}+v, u-x\right\rangle_{X^{\prime}, X} & \geq 0 \\
\left\langle v-\left(y_{0}-\lambda F(x)\right), u-x\right\rangle_{X^{\prime}, X} & \geq 0
\end{aligned}
$$

By maximality of the graph, it follows that $x \in D(A)$ and

$$
y_{0}-\lambda F(x) \in A(x), \quad y_{0}=\lambda F(x)+A(x)
$$

so $\lambda F+A$ is onto as claimed. The converse was proved in Theorem 25.7.2.
Note that this theorem holds if $F$ is a duality map for $p>1$. That is, $\langle F x, x\rangle=$ $\|x\|^{p},\|F x\|=\|x\|^{p-1}$.

Suppose $A: X \rightarrow \mathscr{P}(X)$ is maximal monotone. Then let $z \in X$ and define a new mapping $\hat{A}$ as follows.

$$
D(\hat{A}) \equiv\left\{x: x-x_{0} \in D(A)\right\}, \hat{A}(x) \equiv A\left(x-x_{0}\right)
$$

Proposition 25.7.14 Let $A, \hat{A}$ be as just defined. Then $\hat{A}$ is also maximal monotone.
Proof: From Theorem 25.7.13 it suffices to show that graph of $\hat{A}$ is monotone and is maximal. Suppose then that $x_{i}^{*} \in \hat{A} x_{i}$. Then

$$
\left\langle x_{1}^{*}-x_{2}^{*}, x_{1}-x_{2}\right\rangle=\left\langle x_{1}^{*}-x_{2}^{*}, x_{1}-x_{0}-\left(x_{2}-x_{0}\right)\right\rangle
$$

by definition, $x_{i}^{*} \in A\left(x_{i}-x_{0}\right)$ and so the above is $\geq 0$. Next suppose for all $\left[x, x^{*}\right] \in \mathscr{G}(\hat{A})$,

$$
\left\langle x^{*}-z^{*}, x-z\right\rangle \geq 0
$$

Does it follow that $\left[z, z^{*}\right] \in \mathscr{G}(\hat{A})$ ? The above says that

$$
\left\langle x^{*}-z^{*}, x-x_{0}-\left(z-x_{0}\right)\right\rangle \geq 0
$$

whenever $x-x_{0} \in D(A)$ and $x^{*} \in A\left(x-x_{0}\right)$. Hence, since $A$ is given to be maximal monotone, $z-x_{0} \in D(A)$ and $z^{*} \in A\left(z-x_{0}\right)$ which says that $z^{*} \in \hat{A}(z)$. Thus $\hat{A}$ is maximal monotone by the Theorem 25.7.13.

### 25.7.3 Surjectivity Theorems

As an interesting example of this theorem, here is another result in Barbu [13]. It is interesting because it is not assumed $B$ is bounded.

Theorem 25.7.15 Let $B: X \rightarrow X^{\prime}$ be monotone hemicontinuous. Then $B$ is maximal monotone. If $B$ is coercive, then $B$ is also onto. Here $X$ is a strictly convex reflexive Banach space.

Proof: Suppose $B$ is not maximal monotone. Then there exists $\left(x_{0}, x_{0}^{*}\right) \in X \times X^{\prime}$ such that for all $x$,

$$
\left\langle B x-x_{0}^{*}, x-x_{0}\right\rangle \geq 0
$$

and yet $x_{0}^{*} \neq B x_{0}$. This is going to be a contradiction. Let $u \in X$ and consider $x_{t} \equiv t x_{0}+$ $(1-t) u, t \in(0,1)$. Then consider

$$
\left\langle B x_{t}-x_{0}^{*}, x_{t}-x_{0}\right\rangle
$$

However, $x_{t}-x_{0}=t x_{0}+(1-t) u-x_{0}=(1-t)\left(u-x_{0}\right)$ and so, for each $t \in(0,1)$,

$$
0 \leq\left\langle B x_{t}-x_{0}^{*}, x_{t}-x_{0}\right\rangle=(1-t)\left\langle B x_{t}-x_{0}^{*}, u-x_{0}\right\rangle
$$

Divide by $(1-t)$ and then let $t \uparrow 1$. This yields the following by hemicontinuity.

$$
\left\langle B x_{0}-x_{0}^{*}, u-x_{0}\right\rangle \geq 0
$$

which holds for all $u$. Hence $B x_{0}=x_{0}^{*}$ after all. Thus $B$ is indeed maximal monotone.
Next suppose $B$ is coercive. Let $F$ be the duality map (or the duality map for arbitrary $p>1$ ). Then from Theorem 25.7.13 there exists a solution $x_{\lambda}$ to

$$
\begin{equation*}
\lambda F x_{\lambda}+B x_{\lambda}=x_{0}^{*} \in X^{\prime} \tag{25.7.50}
\end{equation*}
$$

Then the $x_{\lambda}$ are bounded because, doing both sides to $x_{\lambda}$,

$$
\lambda\left\|x_{\lambda}\right\|^{2}+\left\langle B x_{\lambda}, x_{\lambda}\right\rangle=\left\langle x_{0}^{*}, x_{\lambda}\right\rangle
$$

and so

$$
\frac{\left\langle B x_{\lambda}, x_{\lambda}\right\rangle}{\left\|x_{\lambda}\right\|} \leq\left\|x_{0}^{*}\right\|
$$

Thus the coercivity of $B$ implies that the $x_{\lambda}$ are bounded. There exists a subsequence such that

$$
x_{\lambda} \rightarrow x \text { weakly. }
$$

Then from the equation 25.7.50 $\left\|\lambda F x_{\lambda}\right\|=\lambda\left\|x_{\lambda}\right\|$ and so,

$$
B x_{\lambda} \rightarrow x_{0}^{*} \text { strongly. }
$$

Since $B$ is monotone and hemicontinuous, it satisfies the pseudomonotone condition, Theorem 25.1.4. The above strong convergence implies

$$
\lim _{\lambda \rightarrow 0}\left\langle B x_{\lambda}, x_{\lambda}-x\right\rangle=0
$$

Hence for all $y$,

$$
\lim \inf _{\lambda \rightarrow 0}\left\langle B x_{\lambda}, x_{\lambda}-y\right\rangle=\lim \inf _{\lambda \rightarrow 0}\left\langle B x_{\lambda}, x-y\right\rangle=\left\langle x_{0}^{*}, x-y\right\rangle \geq\langle B x, x-y\rangle
$$

Since $y$ is arbitrary, this shows that $x_{0}^{*}=B x$ and so $B$ is onto as claimed.
Again, note that it really didn't matter about the particular duality map used, although the usual one was featured in the argument.

There are some more things which can be said about maximal monotone operators. To include some of these, here is a very interesting lemma found in [13].

Lemma 25.7.16 Let $X$ be a Banach space and suppose that

$$
x_{n} \rightarrow 0, \quad\left\|x_{n}^{*}\right\| \rightarrow \infty
$$

Then denoting by $D_{r}$ the closed disk centered at 0 with radius $r$. It follows that for every $D_{r}$, there exists $y_{0} \in D_{r}$ and a subsequence with index $n_{k}$ such that

$$
\left\langle x_{n_{k}}^{*}, x_{n_{k}}-y_{0}\right\rangle \rightarrow-\infty
$$

Proof: Suppose this is not true. Then there exists $D_{r}$ which has the property that for all $u \in D_{r}$,

$$
\left\langle x_{n}^{*}, x_{n}-u\right\rangle \geq C_{u}
$$

for all $n$. Now let

$$
E_{k} \equiv\left\{y \in D_{r}:\left\langle x_{n}^{*}, x_{n}-y\right\rangle \geq-k \text { for all } n\right\}
$$

Then this is a closed set, being the intersection of closed sets. Also, by assumption, the union of these $E_{k}$ equals $D_{r}$ which is a complete metric space. Hence one of these $E_{k}$ must have nonempty interior by the Bair category theorem, say for $k_{0}$. Say $B(y, \varepsilon) \subseteq D_{r}$. Then for all $\|u-y\|<\varepsilon$,

$$
\left\langle x_{n}^{*}, x_{n}-u\right\rangle \geq-k_{0} \text { for all } n
$$

Of course $-y \in D_{r}$ also, and so there is $C$ such that

$$
\left\langle x_{n}^{*}, x_{n}+y\right\rangle \geq C \text { for all } n
$$

Then

$$
\left\langle x_{n}^{*}, 2 x_{n}+y-u\right\rangle \geq C-k_{0} \text { for all } n
$$

whenever $\|y-u\|<\varepsilon$. Now recall that $x_{n} \rightarrow 0$. Consider only $u$ such that $\|y-u\|<\varepsilon / 2$. Therefore, for all $n$ large enough, the expression $2 x_{n}+y-u$ for such $u$ contains a small ball centered at the origin, say $D_{\delta}$. (The set of all $y-u$ for $u$ closer to $y$ than $\varepsilon / 2$ is the ball $B(0, \varepsilon / 2)$ and then the $2 x_{n}$ does not move it by much provided $n$ is large enough.) Therefore,

$$
\left\langle x_{n}^{*}, v\right\rangle \geq C-k_{0}
$$

for all $\|v\| \leq \delta$. This contradicts the assumption that $\left\|x_{n}^{*}\right\| \rightarrow \infty$.

Corollary 25.7.17 Let $X$ be a Banach space and suppose that

$$
x_{n} \rightarrow x, \quad\left\|x_{n}^{*}\right\| \rightarrow \infty
$$

Then denoting by $D_{r}$ the closed disk centered at $x$ with radius $r$. It follows that for every $D_{r}$, there exists $y_{0} \in D_{r}$ and a subsequence with index $n_{k}$ such that

$$
\left\langle x_{n_{k}}^{*}, x_{n_{k}}-y_{0}\right\rangle \rightarrow-\infty
$$

Proof: It follows that $x_{n}-x \rightarrow 0$. Therefore, from Lemma 25.7.16, for every $r>0$, there exists $\hat{y}_{0} \in \overline{B(0, r)}$ and a subsequence $x_{n_{k}}$ such that

$$
\left\langle x_{n_{k}}^{*},\left(x_{n_{k}}-x\right)-\hat{y}_{0}\right\rangle \rightarrow-\infty
$$

Thus

$$
\left\langle x_{n_{k}}^{*}, x_{n_{k}}-\left(x+\hat{y}_{0}\right)\right\rangle \rightarrow-\infty
$$

Just let $y_{0}=x+\hat{y}_{0}$. Then $y_{0} \in D_{r}$ and satisfies the desired conditions.
Definition 25.7.18 $A$ set valued mapping $A: D(A) \rightarrow \mathscr{P}(X)$ is locally bounded at $x \in$ $\overline{D(A)}$ if whenever $x_{n} \rightarrow x, x_{n} \in D(A)$ it follows that

$$
\limsup _{n \rightarrow \infty}\left\{\left\|x_{n}^{*}\right\|: x_{n}^{*} \in A x_{n}\right\}<\infty
$$

Lemma 25.7.19 $A$ set valued operator $A$ is locally bounded at $x \in \overline{D(A)}$ if and only if there exists $r>0$ such that $A$ is bounded on $\overline{B(x, r)} \cap D(A)$.

Proof: Say the limit condition holds. Then if no such $r$ exists, it follows that $A$ is unbounded on every $B(x, r) \cap D(A)$. Hence, you can let $r_{n} \rightarrow 0$ and pick $x_{n} \in B\left(x, r_{n}\right) \cap$ $D(A)$ with $x_{n}^{*} \in A x_{n}$ such that $\left\|x_{n}^{*}\right\|>n$, violating the limit condition. Hence some $r$ exists such that $A$ is bounded on $\overline{B(x, r)} \cap D(A)$. Conversely, suppose $A$ is bounded on $\overline{B(x, r)} \cap$ $D(A)$ by $M$. Then if $x_{n} \rightarrow x$, it follows that for all $n$ large enough, $x_{n} \in B(x, r)$ and so if $x_{n}^{*} \in A x_{n},\left\|x_{n}^{*}\right\| \leq M$. Hence $\lim \sup _{n \rightarrow \infty}\left\{\left\|x_{n}^{*}\right\|: x_{n}^{*} \in A x_{n}\right\} \leq M<\infty$ which verifies the limit condition.

With this definition, here is a very interesting result.
Theorem 25.7.20 Let $A: D(A) \rightarrow X^{\prime}$ be monotone. Then if $x$ is an interior point of $D(A)$, it follows that $A$ is locally bounded at $x$.

Proof: You could use Corollary 25.7.17. If $x$ is an interior point of $D(A)$, and $A$ is not locally bounded, then there exists $x_{n} \rightarrow x$ and $x_{n}^{*} \in A x_{n}$ such that $\left\|x_{n}^{*}\right\| \rightarrow \infty$. Then by Corollary 25.7.17, there exists $y_{0}$ close to $x$, in $D(A)$ and a subsequence $x_{n_{k}}$ such that

$$
\left\langle x_{n_{k}}^{*}, x_{n_{k}}-y_{0}\right\rangle \rightarrow-\infty
$$

Letting $y_{0}^{*} \in A y_{0}$,

$$
\left\langle x_{n_{k}}^{*}-y_{0}^{*}, x_{n_{k}}-y_{0}\right\rangle \geq 0
$$

and so

$$
\left\langle x_{n_{k}}^{*}, x_{n_{k}}-y_{0}\right\rangle \geq\left\langle y_{0}^{*}, x_{n_{k}}-y_{0}\right\rangle
$$

and the right side is bounded below because it converges to $\left\langle y_{0}^{*}, x-y_{0}\right\rangle$ and this is a contradiction.

Does the same proof work if $x$ is a limit point of $D(A)$ ? No. Suppose $x$ is a limit point of $D(A)$. If $A$ is not locally bounded, then there exists $x_{n} \rightarrow x, x_{n} \in D(A)$ and $x_{n}^{*} \in A x_{n}$ and $\left\|x_{n}^{*}\right\| \rightarrow \infty$. Then there is $y_{0}$ close to $x$ such that $\left\langle x_{n_{k}}^{*}, x_{n_{k}}-y_{0}\right\rangle \rightarrow-\infty$ but now everything crashes in flames because it is not known that $y_{0} \in D(A)$.

It follows from the above theorem that if $A$ is defined on all of $X$ and is maximal monotone, then it is locally bounded everywhere. Now here is a very interesting result which is like the one which involves monotone and hemicontinuous conditions. It is in [55].

Theorem 25.7.21 Let $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ be monotone and satisfies the following conditions:

1. If $\lambda_{n} \rightarrow \lambda, \lambda_{n} \in[0,1]$ and $z_{n} \in A\left(u+\lambda_{n}(v-u)\right)$, then if $B$ is any weakly open set containing $0, z_{n} \in A(u)+B$ for all n large enough. (Upper semicontinuous into weak topology along a line segment)
2. $A(x)$ is closed and convex.

Then one can conclude that A is maximal monotone.
Proof: Let $\hat{A}$ be a monotone extension of $A$. Let $[\hat{u}, \hat{w}]$ be such that $\hat{w} \in \hat{A}(\hat{u})$. Now also by assumption, $A(x)$ is not just convex but also closed.

If $[\hat{u}, \hat{w}]$ is not in the graph of $A$, then by separation theorems, there is $u$ such that

$$
\left\langle x^{*}, u\right\rangle<\langle\hat{w}, u\rangle \text { for all } x^{*} \in A(\hat{u})
$$

Then for $\lambda>0$, let $x_{\lambda} \equiv \hat{u}+\lambda u, x_{\lambda}^{*} \in A\left(x_{\lambda}\right)$. Then from monotonicity of $\hat{A}$,

$$
0 \leq\left\langle x_{\lambda}^{*}-\hat{w}, x_{\lambda}-\hat{u}\right\rangle=\lambda\left\langle x_{\lambda}^{*}-\hat{w}, u\right\rangle
$$

Thus

$$
\left\langle x_{\lambda}^{*}-\hat{w}, u\right\rangle \geq 0
$$

By Theorem 25.7.20, the monotonicity of $A$ on $X$ implies $A$ is locally bounded also. Thus in particular, $A x_{\lambda}$ for small $\lambda$ is contained in a bounded set. Now by that hemicontinuity assumption, you can get a subsequence $\lambda_{n} \rightarrow 0$ for which $x_{\lambda_{n}}^{*}$ converges weakly to $x^{*} \in A \hat{u}$. Therefore, passing to the limit in the above, we get

$$
\begin{gathered}
\left\langle x^{*}-\hat{w}, u\right\rangle \geq 0 \\
\left\langle x^{*}, u\right\rangle \geq\langle\hat{w}, u\rangle>\left\langle x^{*}, u\right\rangle
\end{gathered}
$$

a contradiction. Thus there is no proper extension and this shows that $A$ is maximal monotone.

Recall the definition of a pseudomonotone operator.

Definition 25.7.22 $A$ set valued operator $B$ is quasi-bounded if whenever $x \in D(B)$ and $x^{*} \in B x$ are such that

$$
\left|\left\langle x^{*}, x\right\rangle\right|,\|x\| \leq M
$$

it follows that $\left\|x^{*}\right\| \leq K_{M}$. Bounded would mean that if $\|x\| \leq M$, then $\left\|x^{*}\right\| \leq K_{M}$. Here you only know this if there is another condition.

By Proposition 25.7.23 an example of a quasi-bounded operator is a maximal monotone operator $G$ for which $0 \in \operatorname{int}(D(G))$.

Then there is a useful result which gives examples of quasi-bounded operators [25].
Proposition 25.7.23 Let $A: D(A) \subseteq X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ be maximal monotone and suppose $0 \in$ $\operatorname{int}(D(A))$. Then $A$ is quasi-bounded.

Proof: From local boundedness, Theorem 25.7.20, there exists $\delta, C>0$ such that

$$
\sup \left\{\left\|x^{*}\right\|: x^{*} \in A(x) \text { for }\|x\| \leq \delta\right\}<C
$$

Now suppose that $\|x\|,\left|\left\langle x^{*}, x\right\rangle\right| \leq M$. Then letting $\|y\| \leq \delta, y^{*} \in A y$,

$$
0 \leq\left\langle x^{*}-y^{*}, x-y\right\rangle=\left\langle x^{*}, x\right\rangle-\left\langle x^{*}, y\right\rangle-\left\langle y^{*}, x\right\rangle+\left\langle y^{*}, y\right\rangle
$$

and so for $\|y\| \leq \delta$,

$$
\left\langle x^{*}, y\right\rangle \leq\left\langle x^{*}, x\right\rangle-\left\langle y^{*}, x\right\rangle+\left\langle y^{*}, y\right\rangle \leq M+M C+C \delta
$$

Hence, $\left\|x^{*}\right\| \leq M+M C+C \delta \equiv K_{M}$.
This is actually quite a restrictive requirement and leaves out a lot which would be interesting.

Definition 25.7.24 Let $V$ be a Reflexive Banach space. We say $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ is pseudomonotone if the following conditions hold.

> Tu is closed, nonempty, convex.

If $F$ is a finite dimensional subspace of $V$, then if $u \in F$ and $W \supseteq T u$ for $W$ a weakly open set in $V^{\prime}$, then there exists $\delta>0$ such that

$$
\begin{equation*}
v \in B(u, \delta) \cap F \text { implies } T v \subseteq W \tag{25.7.52}
\end{equation*}
$$

If $u_{k} \rightharpoonup u$ and if $u_{k}^{*} \in T u_{k}$ is such that

$$
\limsup _{k \rightarrow \infty} u_{k}^{*}\left(u_{k}-u\right) \leq 0
$$

then for all $v \in V$, there exists $u^{*}(v) \in T u$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \inf _{k} u_{k}^{*}\left(u_{k}-v\right) \geq u^{*}(v)(u-v) \tag{25.7.53}
\end{equation*}
$$

Then here is an interesting result [39].

Theorem 25.7.25 Suppose $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ is maximal monotone. That is, $D(A)=X$. Then A is pseudomonotone.

Proof: Consider the first condition. Say $x_{i}^{*} \in A x$. Let $u^{*} \in A u$. For $\lambda \in[0,1]$,

$$
\begin{aligned}
& \left\langle\lambda x_{1}^{*}+(1-\lambda) x_{2}^{*}-u^{*}, x-u\right\rangle \\
= & \lambda\left\langle x_{1}^{*}-u^{*}, x-u\right\rangle+(1-\lambda)\left\langle x_{2}^{*}-u^{*}, x-u\right\rangle \geq 0
\end{aligned}
$$

and so, since $\left[u, u^{*}\right]$ is arbitrary, it follows that $\lambda x_{1}^{*}+(1-\lambda) x_{2}^{*} \in A x$. Thus $A x$ is convex. Is it closed? Say $x_{n}^{*} \in A x$ and $x_{n}^{*} \rightarrow x^{*}$. Is it the case that $x^{*} \in D(A)$ ? Let $\left[u, u^{*}\right] \in \mathscr{G}(A)$ be arbitrary. Then

$$
\left\langle x^{*}-u^{*}, x-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle x_{n}^{*}-u^{*}, x_{n}-u\right\rangle \geq 0
$$

and so $A x$ is also closed.
Consider the second condition. It is to show that if $x_{n} \rightarrow x$ in $V$ a finite dimensional subspace and if $U$ is a weakly open set containing 0 , then eventually $A x_{n} \subseteq A x+U$. Suppose then that this is not the case. Then there exists $x_{n}^{*}$ outside of $A x+U$ but in $A x_{n}$. Since $A$ is locally bounded at $x$, it follows that the $\left\|x_{n}^{*}\right\|$ are bounded. Thus there is a subsequence, still denoted as $x_{n}$ and $x_{n}^{*}$ such that $x_{n}^{*} \rightarrow x^{*}$ weakly and $x^{*} \notin A x+U$. Now let $\left[u, u^{*}\right] \in \mathscr{G}(A)$.

$$
\left\langle x^{*}-u^{*}, x-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle x_{n}^{*}-u^{*}, x_{n}-u\right\rangle \geq 0
$$

and since $\left[u, u^{*}\right]$ is arbitrary, it follows that $x^{*} \in A x$ and so is inside $A x+U$. Thus the second condition holds also.

Consider the third. Say $x_{k} \rightarrow x$ weakly and letting $x_{k}^{*} \in A x_{k}$,suppose

$$
\limsup _{k \rightarrow \infty}\left\langle x_{k}^{*}, x_{k}-x\right\rangle \leq 0
$$

Is it the case that there exists $x^{*}(y) \in A x$ such that

$$
\lim _{k \rightarrow \infty}\left\langle x_{k}^{*}, x_{k}-y\right\rangle \geq\left\langle x^{*}(y), x-y\right\rangle ?
$$

The proof goes just like it did earlier in the case of single valued pseudomonotone operators. It is just a little more complicated. First, let $x^{*} \in A x$.

$$
\left\langle x_{k}^{*}-x^{*}, x_{k}-x\right\rangle \geq 0
$$

and so

$$
\lim _{k \rightarrow \infty}\left\langle x_{k}^{*}, x_{k}-x\right\rangle \geq \lim \inf _{k \rightarrow \infty}\left\langle x^{*}, x_{k}-x\right\rangle=0 \geq \limsup \left\langle x_{k}^{*}, x_{k}-x\right\rangle
$$

Thus

$$
\lim _{k \rightarrow \infty}\left\langle x_{k}^{*}, x_{k}-x\right\rangle=0
$$

Now let $x_{t}^{*} \in A(x+t(y-x)), t \in(0,1)$, where here $y$ is arbitrary. Then

$$
\left\langle x_{n}^{*}-x_{t}^{*}, x_{n}-x+t(x-y)\right\rangle \geq 0
$$

Hence

$$
\lim \inf _{n \rightarrow \infty}\left\langle x_{n}^{*}, x_{n}-x+t(x-y)\right\rangle \geq \lim \inf _{n \rightarrow \infty}\left\langle x_{t}^{*}, x_{n}-x+t(x-y)\right\rangle
$$

and so from the above limit,

$$
t \lim _{n \rightarrow \infty}\left\langle x_{n}^{*}, x-y\right\rangle \geq t\left\langle x_{t}^{*}, x-y\right\rangle
$$

Cancel the $t$.

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle x_{n}^{*}, x-y\right\rangle=\lim \inf _{n \rightarrow \infty}\left\langle x_{n}^{*}, x_{n}-y\right\rangle \geq\left\langle x_{t}^{*}, x-y\right\rangle
$$

Now you have a fixed $y$ and $x_{t}^{*} \in A(x+t(y-x))$. The subspace determined by $x, y$ is finite dimensional. Also it was shown above that $A$ is locally bounded at $x$ and so there is a subsequence, still denoted as $x_{t}^{*}$ such that $x_{t}^{*} \rightarrow x^{*}(y)$ weakly. Now from the upper semicontinuity on finite dimensional spaces shown above, for every $S$ a finite subset of $X$ and $\varepsilon>0$, it follows that for all $t$ small enough,

$$
x_{t}^{*} \in A x+B_{S}(0, \varepsilon)
$$

Thus $x^{*}(y) \in A x$. Hence, there exists $x^{*}(y) \in A x$ such that

$$
\lim _{n \rightarrow \infty}\left\langle x_{n}^{*}, x_{n}-y\right\rangle \geq\left\langle x^{*}(y), x-y\right\rangle
$$

I found this in a paper by Peng. It is a very nice result.
Proposition 25.7.26 Let $X$ and $Y$ be reflexive Banach spaces with $Y \subseteq X^{\prime}$. Let $1<p<\infty$ and let $q=\frac{p}{p-1}=p^{\prime}$ so $\frac{1}{p}+\frac{1}{q}=1$. Let $F:[0, T] \times X \rightarrow \mathscr{P}(Y)$ be multivalued and satisfies.

1. $F(\cdot, x)$ has a measurable selection for each $x \in X$
2. $F(t, \cdot)$ is maximal monotone for a.e. $t \in[0, T]$
3. $\|y\|_{Y} \leq \rho_{1}(t)+\rho_{2}\|x\|_{X}^{p-1}$ where $y \in F(t, x)$ for a.e. $t$, and where $\rho_{1} \in L^{q}(0, T)$ and $\rho_{2}>0$

Let $0 \leq a<b \leq T$ with $b-a=\tau$. Define

$$
F_{\tau} x \equiv\left\{\begin{array}{c}
\frac{1}{\tau} \int_{a}^{b} y(t) d t: t \rightarrow y(t) \text { is measurable } \\
\text { and } y(t) \in F(t, x) \text { a.e. } t \in(a, b)
\end{array}\right\}
$$

Then $F_{\tau}: X \rightarrow \mathscr{P}(Y)$ is maximal monotone.
Proof: First note that $F_{\tau} x$ is convex and nonempty. To see this, say $z, \hat{z}$ are in $F_{\tau} x$. and let $y, \hat{y}$ be the corresponding functions. Then for $\lambda \in[0,1]$

$$
\lambda z+(1-\lambda) \hat{z}=\frac{1}{\tau} \int_{a}^{b}(\lambda y(t)+(1-\lambda) \hat{y}(t)) d t
$$

and $\lambda y(t)+(1-\lambda) \hat{y}(t) \in F(t, x)$ because $F(t, \cdot)$ is maximal monotone which implies that the set values are convex.

Next is a claim that $F_{\tau} x$ is closed and also has the property that if $z_{n} \in F_{\tau} x_{n}$ and if $x_{n} \rightarrow x$ strongly in $X$ and $z_{n} \rightarrow z$ weakly in $Y$, then $z \in F_{\tau} x$. Let $y_{n}(t) \in F\left(t, x_{n}\right)$ a.e. such that $z_{n}=\frac{1}{\tau} \int_{a}^{b} y_{n}(t) d t$. These $x_{n}$ are bounded and so by the assumed estimate, it follows that the $y_{n}$ are bounded in $L^{q}(0, T ; Y)$. Therefore, there is a subsequence, still denoted with $n$ such that $y_{n} \rightarrow \hat{y}$ weakly in $L^{q}(0, T ; Y)$. Now this means that $\hat{y}$ is in the weak closure of the convex hull of $\left\{y_{k}: k \geq n\right\}$. However, this is the same as the strong closure because convex and closed is the same as convex and weakly closed. Therefore, there are functions

$$
\lim _{n \rightarrow \infty} \sum_{k=n}^{\infty} c_{k}^{n} y_{k}=\hat{y} \text { strongly in } L^{q}(0, T ; Y) \text { where } \sum_{k=n}^{\infty} c_{k}^{n}=1, c_{k}^{n} \geq 0
$$

and only finitely many are nonzero. Thus a subsequence still denoted with subscript $n$ also converges to $\hat{y}(t)$ for each $t$ off a set of measure zero. The function $F(t, \cdot)$ is maximal monotone and defined on $X$ and so it is pseudomonotone by Theorem 25.7.25. The estimate also shows that it is bounded. Therefore, as shown in the section on set valued pseudomonotone operators, $x \rightarrow F(t, x)$ is upper semicontinuous from strong to weak topology. Thus, for large $n$ depending on $t$, all of the $F\left(t, x_{n}\right)$ are contained in $F(t, x)+B_{S}(0, r / 2)$ where $S$ is a finite subset of points of $X$.

$$
B \equiv B_{S}(0, r / 2) \equiv\left\{w^{*}:\left|w^{*}(x)\right|<\frac{r}{2} \text { for all } x \in S\right\}
$$

Thus, for a fixed $t$ not in the exceptional set, off which the above pointwise convergence takes place, $\hat{y}(t) \in F(t, x)+D$ where

$$
D \equiv\left\{w^{*}:\left|w^{*}(x)\right| \leq r \text { for all } x \in S\right\}
$$

Since $S, r$ are arbitrary, separation theorems imply that $\hat{y}(t) \in F(t, x)$ for $t$ off a set of measure zero: If not, there would exist $u \in X$ such that $\hat{y}(t)(u)>l>l-\delta>p(u)$ for all $p \in F(t, x)$. But then you could take $r=\delta / 2$ and $B_{u}(0, \delta / 2)$ and find that $\hat{y}(t)=p+w^{*}$ where $p \in F(t, x)$ and $\left|w^{*}(u)\right| \leq \delta$. Hence $p(u)=\hat{y}(t)(u)-w^{*}(u)>l-\delta>p(u)$ an obvious contradiction. Is $z \in F_{\tau} x$ ? Certainly so if $z=\frac{1}{\tau} \int_{a}^{b} \hat{y}(t) d t$. Letting $\phi \in X$,

$$
\begin{aligned}
\langle z, \phi\rangle & =\lim _{n \rightarrow \infty}\left\langle z_{n}, \phi\right\rangle=\lim _{n \rightarrow \infty}\left\langle\frac{1}{\tau} \int_{a}^{b} y_{n}(t) d t, \phi\right\rangle=\lim _{n \rightarrow \infty}\left\langle\frac{1}{\tau} \int_{a}^{b} \sum_{k=n}^{\infty} c_{k}^{n} y_{k}(t) d t, \phi\right\rangle \\
& =\left\langle\frac{1}{\tau} \int_{a}^{b} \hat{y}(t) d t, \phi\right\rangle
\end{aligned}
$$

Since $\phi$ is arbitrary, it follows that $z=\frac{1}{\tau} \int_{a}^{b} \hat{y}(t) d t$ and so $z \in F_{\tau} x$.
Is $F_{\tau}$ monotone? Say $z, \hat{z}$ are in $F_{\tau}(x), F_{\tau}(\hat{x})$ respectively. Consider

$$
\langle z-\hat{z}, x-\hat{x}\rangle=\left\langle\frac{1}{\tau} \int_{a}^{b} y(t)-\hat{y}(t) d t, x-\hat{x}\right\rangle=\frac{1}{\tau} \int_{a}^{b}\langle y(t)-\hat{y}(t), x-\hat{x}\rangle d t
$$

but $y(t) \in F(t, x)$ similar for $\hat{y}$ and so the above is $\geq 0$. Thus $F_{\tau}$ is indeed monotone. This has also shown that $F_{\tau}$ satisfies the necessary modified hemicontinuity condition of

Theorem 25.7.21 to conclude that $F_{\tau}$ is indeed maximal monotone because it has convex closed values, the hemicontinuity condition, and is monotone.

Suppose $T$ is a bounded pseudomonotone operator and $S$ is a maximal monotone operator, both defined on a strictly convex reflexive Banach space. What of their sum? Is $(T+S)(x)$ convex and closed? Say $t_{i} \in T x$ and $s_{i} \in S x$ is it the case that $\theta\left(s_{1}+t_{1}\right)+$ $(1-\theta)\left(s_{2}+t_{2}\right) \in(T+S)(x)$ whenever $\theta \in[0,1]$ ? Of course this is so. Thus $T+S$ has convex values. Does it have closed values? Suppose $\left\{s_{n}+t_{n}\right\}$ converges to $z \in X^{\prime}, s_{n} \in$ $S x, t_{n} \in T x$. Is $z \in(T+S)(x)$ ? Taking a subsequence, and using the assumption that $T$ is bounded, it can be assumed that $t_{n} \rightarrow t \in T x$ weakly. Therefore, $s_{n}$ must also converge weakly and so it converges to some $s=z-t \in S x$. Convex and closed implies weakly closed. Thus $T+S$ has closed convex values. Is it upper semicontinuous on finite dimensional subspaces? Suppose $x_{n} \rightarrow x$ in a finite dimensional subspace $F$. Does it follow that

$$
(S+T) x_{n} \subseteq(S+T) x+B(0, r)
$$

for all $n$ sufficiently large? It is known that $S x_{n} \subseteq S x+B(0, r / 2)$ and $T x_{n} \subseteq T x+B(0, r / 2)$ whenever $n$ is sufficiently large and so it follows that

$$
(S+T) x_{n} \subseteq(S+T) x+B(0, r / 2)+B(0, r / 2) \subseteq(S+T) x+B(0, r)
$$

whenever $n$ is large enough.
What of the pseudomonotone condition? Suppose

$$
\limsup _{n \rightarrow \infty}\left\langle u_{n}^{*}+v_{n}^{*}, x_{n}-x\right\rangle \leq 0
$$

where $u_{n}^{*} \in S x_{n}$ and $v_{n}^{*} \in T x_{n}$ where $x_{n} \rightarrow x$ weakly. Is it the case that for every $y$, there exists $u^{*} \in S x$ and $v^{*} \in T x$ such that

$$
\lim _{n \rightarrow \infty}\left\langle u_{n}^{*}+v_{n}^{*}, x_{n}-y\right\rangle \geq\left\langle u^{*}+v^{*}, x-y\right\rangle ?
$$

By monotonicity,

$$
\begin{aligned}
0 & \geq \lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}+v_{n}^{*}, x_{n}-x\right\rangle \geq \lim \sup _{n \rightarrow \infty}\left\langle u^{*}+v_{n}^{*}, x_{n}-x\right\rangle \\
& =\lim \sup _{n \rightarrow \infty}\left\langle v_{n}^{*}, x_{n}-x\right\rangle
\end{aligned}
$$

Hence

$$
\lim \sup _{n \rightarrow \infty}\left\langle v_{n}^{*}, x_{n}-x\right\rangle \leq 0
$$

which implies

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow}\left\langle v_{n}^{*}, x_{n}-x\right\rangle \geq\left\langle\hat{v}^{*}, x-x\right\rangle=0 \geq \lim _{n \rightarrow \infty}\left\langle v_{n}^{*}, x_{n}-x\right\rangle
$$

showing that

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\langle v_{n}^{*}, x_{n}-x\right\rangle=0 \tag{25.7.54}
\end{equation*}
$$

It follows that if $y$ is given, there exists $v^{*} \in T(x)$ such that

$$
\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty}\left\langle v_{n}^{*}, x_{n}-y\right\rangle \geq\left\langle v^{*}, x-y\right\rangle
$$

Now let $u_{t}^{*} \in S(x+t(y-x))$ for $t>0$. Thus

$$
\begin{gathered}
\left\langle u_{n}^{*}-u_{t}^{*}, x_{n}-x+t(x-y)\right\rangle \geq 0 \\
\left\langle u_{n}^{*}, x_{n}-x+t(x-y)\right\rangle \geq\left\langle u_{t}^{*}, x_{n}-x+t(x-y)\right\rangle
\end{gathered}
$$

Then using the above and the convergence in 25.7.54,

$$
\begin{gathered}
\lim _{n \rightarrow \infty}\left\langle u_{n}^{*}+v_{n}^{*}, x_{n}-y\right\rangle \geq \lim _{n \rightarrow \infty}\left\langle u_{t}^{*}+v_{n}^{*}, x_{n}-y\right\rangle \\
=\left\langle u_{t}^{*}, x-y\right\rangle+\left\langle v^{*}, x-y\right\rangle
\end{gathered}
$$

Now as before where it was shown that maximal monotone and defined on $X$ implied pseudomonotone, and the theorem which says that maximal monotone operators are locally bounded on the interior of their domains, it follows that there exists a sequence, still denoted as $u_{t}^{*}$ which converges to something called $u^{*}$. Then as before, the subspace spanned by $x, y$ is finite dimensional and so from upper semicontinuity, for all $t$ small enough,

$$
u_{t}^{*} \in S(x)+B(0, r)
$$

Note that weak convergence is the same as strong on finite dimensional spaces. Since this is true for all $r$ and $S(x)$ is closed, it follows that $u^{*} \in S(x)$. Thus, passing to a limit as $t \rightarrow 0$ one gets $u^{*} \in S(x), v^{*} \in T(x)$, and

$$
\lim _{n \rightarrow \infty}\left\langle u_{n}^{*}+v_{n}^{*}, x_{n}-y\right\rangle \geq\left\langle u^{*}+v^{*}, x-y\right\rangle
$$

This proves the following generalization of Theorem 25.7.25.
Theorem 25.7.27 Let $T, S: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ where $X$ is a strictly convex reflexive Banach space and suppose $T$ is bounded and pseudomonotone while $S$ is maximal monotone. Then $T+S$ is pseudomonotone.

Also, there is an interesting result which is based on the obvious observation that if $A$ is maximal monotone, then so is $\hat{A}(x) \equiv A\left(x_{0}+x\right)$.

Lemma 25.7.28 Let A be maximal monotone. Then for each $\lambda>0$,

$$
x \rightarrow \lambda F\left(x-x_{0}\right)+A x
$$

is onto.
Proof: Let $\hat{A}(x) \equiv A\left(x_{0}+x\right)$ so as earlier, $\hat{A}$ is maximal monotone. Then let $y^{*} \in X^{\prime}$. Then there exists $y$ such that $\hat{A}(y)+\lambda F(y) \ni y^{*}$. Now define $x \equiv y+x_{0}$. Then

$$
\hat{A}(y)+\lambda F(y) \ni y^{*}, \hat{A}\left(x-x_{0}\right)+\lambda F\left(x-x_{0}\right) \ni y^{*}, A(x)+\lambda F\left(x-x_{0}\right) \ni y^{*}
$$

Definition 25.7.29 Let $A: D(A) \rightarrow \mathscr{P}\left(X^{\prime}\right)$ be maximal monotone. Let $A^{-1}: A(D(A)) \rightarrow$ $\mathscr{P}\left(X^{\prime}\right)$ be defined as follows.

$$
x \in A^{-1} x^{*} \text { if and only if } x^{*} \in A x
$$

Observation 25.7.30 $A^{-1}$ is also maximal monotone. This is easily seen as follows. $[x, y] \in$ $\mathscr{G}(A)$ if and only if $[y, x] \in \mathscr{G}\left(A^{-1}\right)$.

Earlier, it was shown that if $B$ is monotone and hemicontinuous and coercive, then it was onto. It was not necessary to assume that $B$ is bounded. The same thing holds for $A$ maximal monotone. This will follow from the next result. Recall that a maximal monotone operator is locally bounded at every interior point of its domain which was shown above. Also it appears to not be possible to show that a maximal monotone operator is locally bounded at a limit point of $D(A)$. The following result is in [13] although he claims a better result than what I am proving here in which it is only necessary to verify $A^{-1}$ is locally bounded at every point of $A(D(A))$. However, I was unable to follow the argument and so I am proving another theorem with the same argument he uses. It looks like a typo to me but I often have trouble following hard theorems so I am not sure. Anyway, the following is the best I can do. I think it is still a very interesting result.

Theorem 25.7.31 Suppose $A^{-1}$ is locally bounded at every point of $\overline{A(D(A))}$. Then in fact $A(D(A))=X^{\prime}$ and in fact $\overline{A(D(A))}=A(D(A))$.

Proof: This is done by showing that $A(D(A))$ is both open and closed. Since it is nonempty, it must be all of $X^{\prime}$ because $X^{\prime}$ is connected. First it is shown that $A(D(A))$ is closed. Suppose $y_{n} \in A x_{n}$ and $y_{n} \rightarrow y$. Does it follow that $y \in A(D(A))$ ? Since $y$ is a limit point of $A(D(A))$, it follows that $A^{-1}$ is locally bounded at $y$. Thus there is a subsequence still denoted by $y_{n}$ such that $y_{n} \rightarrow y$ and for $x_{n} \in A^{-1} y_{n}$ or in other words, $y_{n} \in A x_{n}$, it follows that $x_{n}$ is bounded. Hence there exists a subsequence, still denoted with the subscript $n$ such that $x_{n} \rightarrow x$ weakly and $y_{n} \rightarrow y$ strongly. Hence if $[u, v] \in \mathscr{G}(A)$,

$$
\langle y-v, x-u\rangle=\lim _{n \rightarrow \infty}\left\langle y_{n}-v, x_{n}-x\right\rangle \geq 0
$$

Since $[u, v]$ is arbitrary and $A$ is maximal monotone, it follows that $y \in A x$ or in other words, $x \in A^{-1} y$ and $y \in A(D(A))$. Thus $A(D(A))$ is closed.

Next consider why $A(D(A))$ is open. Let $y_{0} \in A(D(A))$. Then there exists $D_{r} \equiv$ $\overline{B\left(y_{0}, r\right)}$ centered at $y_{0}$ such that $A^{-1}$ is bounded on $D_{r}$. Since $A$ is maximal montone, for each $y \in X^{\prime}$ there is a solution $x_{\varepsilon}$ to the inclusion

$$
y \in \varepsilon F\left(x_{\varepsilon}-x_{0}\right)+A x_{\varepsilon}, y_{\varepsilon} \equiv y-\varepsilon F\left(x_{\varepsilon}-x_{0}\right) \in A x_{\varepsilon}
$$

Consider only $y \in B\left(y_{0}, \frac{r}{2}\right)$.

$$
\left\langle\left(y-\varepsilon F\left(x_{\varepsilon}-x_{0}\right)\right)-y_{0}, x_{\varepsilon}-x_{0}\right\rangle \geq 0
$$

Then using $\langle F z, z\rangle=\|z\|^{2}$,

$$
\left\|y-y_{0}\right\|\left\|x_{\varepsilon}-x_{0}\right\| \geq\left\langle y-y_{0}, x_{\varepsilon}-x_{0}\right\rangle \geq \varepsilon\left\|x_{\varepsilon}-x_{0}\right\|^{2}
$$

and so $\varepsilon\left\|x_{\varepsilon}-x_{0}\right\|=\varepsilon\left\|F\left(x_{\varepsilon}-x_{0}\right)\right\| \leq\left\|y-y_{0}\right\|<r / 2$. Thus $y_{\varepsilon}$ stays in $B\left(y_{0}, r\right)$. This is because $y$ is closer to $y_{0}$ than $r / 2$ while $y_{\varepsilon}$ is within $r / 2$ of $y$. It follows that the $x_{\varepsilon}$ are bounded and so $x_{\varepsilon}-x_{0}$ is bounded and so $\varepsilon F\left(x_{\varepsilon}-x_{0}\right) \rightarrow 0$. Thus $y_{\varepsilon} \rightarrow y$ strongly. Since the $x_{\varepsilon}$ are bounded, there exists a further subsequence, still denoted as $x_{\varepsilon}$ such that $x_{\varepsilon} \rightarrow x$, some point of $X$. Then if $[u, v] \in \mathscr{G}(A)$,

$$
\left\langle y_{\varepsilon}-v, x_{\varepsilon}-u\right\rangle \geq 0
$$

and letting $\varepsilon \rightarrow 0$ using the strong convergence of $y_{\varepsilon}$ one obtains

$$
\langle y-v, x-u\rangle \geq 0
$$

which shows that $y \in A x$. Thus $B\left(y_{0}, \frac{r}{2}\right) \subseteq A(D(A)) \equiv D\left(A^{-1}\right)$ and so $A(D(A))$ is open.
The proof featured the usual duality map.
Note that as part of the proof $A(D(A))$ was shown to be closed so although it was assumed at the outset that $A^{-1}$ was locally bounded on $\overline{A(D(A))}$, this is the same as saying that $A^{-1}$ is locally bounded on $A(D(A))$.

Corollary 25.7.32 Suppose $A: D(A) \rightarrow \mathscr{P}\left(X^{\prime}\right)$ is maximal monotone and coercive. Then $A$ is onto.

Proof: From Theorem 25.7 .31 it suffics to show that $A^{-1}$ is locally bounded at $y^{*} \in$ $\overline{A(D(A))}$. The case of an interior point follows from Theorem 25.7.20. Assume then that $y^{*}$ is a limit point of $A(D(A))$. Of course this includes the case of interior points. Then there exists $y_{n}^{*} \rightarrow y^{*}$ where $y_{n}^{*} \in A x_{n}$. Then

$$
\frac{\left\langle y_{n}^{*}, x_{n}\right\rangle}{\left\|x_{n}\right\|} \leq\left\|y_{n}^{*}\right\|
$$

and the right side is bounded. Hence by coercivity, so is $\left\|x_{n}\right\|$. Therefore, there is a further subsequence, still denoted as $x_{n}$ such that $x_{n} \rightarrow x$ weakly while $y_{n}^{*} \rightarrow y^{*}$ strongly. Then letting $\left[u, v^{*}\right] \in \mathscr{G}(A)$,

$$
\left\langle y^{*}-v^{*}, x-u\right\rangle=\lim _{n \rightarrow \infty}\left\langle y_{n}^{*}-v^{*}, x_{n}-u\right\rangle \geq 0
$$

Hence $y^{*} \in A x$ and $y^{*} \in A(D(A))$. Thus $A^{-1}$ is locally bounded on $\overline{A(D(A))}$ and so $A$ is onto from the above theorem.

### 25.7.4 Approximation Theorems

This section continues following Barbu [13]. Always it is assumed that the situation is of a real reflexive Banach space $X$ having strictly convex norm and its dual $X^{\prime}$. As observed earlier, there exists a solution $x_{\lambda}$ to the inclusion

$$
0 \in F\left(x_{\lambda}-x\right)+\lambda A\left(x_{\lambda}\right)
$$

To see this, you consider $\hat{A}(y) \equiv A(x+y)$. Then $\hat{A}$ is also maximal monotone and so there exists a solution to

$$
0 \in F(\hat{x})+\lambda \hat{A}(\hat{x})=F(\hat{x})+\lambda A(x+\hat{x})
$$

Now let $x_{\lambda}=x+\hat{x}$ so $\hat{x}=x_{\lambda}-x$. Hence

$$
0 \in F\left(x_{\lambda}-x\right)+\lambda A x_{\lambda}
$$

Here you could have $F$ the duality map for any given $p>1$.
The symbol $\lim \sup _{n, n \rightarrow \infty} a_{m n}$ means $\lim _{N \rightarrow \infty}\left(\sup _{m \geq N, n \geq N} a_{m n}\right)$. Then here is a simple observation.

Lemma 25.7.33 Suppose $\limsup _{n, n \rightarrow \infty} a_{m n} \leq 0$. Then

$$
\lim \sup _{m \rightarrow \infty}\left(\lim \sup _{n \rightarrow \infty} a_{m n}\right) \leq 0
$$

Proof: There exists $N$ such that if both $m, n \geq N, a_{m n} \leq \varepsilon$. Then

$$
\limsup _{n \rightarrow \infty} a_{m n}=\lim \sup _{n \rightarrow \infty, n>N} a_{m n} \leq \varepsilon
$$

Thus also

$$
\lim \sup _{m \rightarrow \infty}\left(\lim \sup _{n \rightarrow \infty} a_{m n}\right)=\lim \sup _{m \rightarrow \infty, m \geq N}\left(\lim \sup _{n \rightarrow \infty} a_{m n}\right) \leq \varepsilon
$$

The argument will be based on the following lemma.
Lemma 25.7.34 Let $A: D(A) \rightarrow \mathscr{P}\left(X^{\prime}\right)$ be maximal monotone and let $v_{n} \in A u_{n}$ and

$$
u_{n} \rightarrow u, v_{n} \rightarrow v \text { weakly. }
$$

Also suppose that

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle \leq 0
$$

or

$$
\lim \sup _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle \leq 0
$$

Then $[u, v] \in \mathscr{G}(A)$ and $\left\langle v_{n}, u_{n}\right\rangle \rightarrow\langle v, u\rangle$.
Proof: By monotonicity,

$$
\lim _{m, n \rightarrow \infty}\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle=0
$$

Suppose then that $\left\langle v_{n}, u_{n}\right\rangle$ fails to converge to $\langle v, u\rangle$. Then there is a subsequence, still denoted with subscript $n$ such that $\left\langle v_{n}, u_{n}\right\rangle \rightarrow \mu \neq\langle v, u\rangle$. Let $\varepsilon>0$. Then there exists $M$ such that if $n, m>M$, then

$$
\left|\left\langle v_{n}, u_{n}\right\rangle-\mu\right|<\varepsilon,\left|\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle\right|<\varepsilon
$$

Then if $m, n>M$,

$$
\left|\left\langle v_{n}-v_{m}, u_{n}-u_{m}\right\rangle\right|=\left|\left\langle v_{n}, u_{n}\right\rangle+\left\langle v_{m}, u_{m}\right\rangle-\left\langle v_{n}, u_{m}\right\rangle-\left\langle v_{m}, u_{n}\right\rangle\right|<\varepsilon
$$

Hence it is also true that

$$
\left|\left\langle v_{n}, u_{n}\right\rangle+\left\langle v_{m}, u_{m}\right\rangle-\left\langle v_{n}, u_{m}\right\rangle-\left\langle v_{m}, u_{n}\right\rangle\right| \leq\left|2 \mu-\left(\left\langle v_{n}, u_{m}\right\rangle+\left\langle v_{m}, u_{n}\right\rangle\right)\right|<3 \varepsilon
$$

Now take a limit first with respect to $n$ and then with respect to $m$ to obtain

$$
|2 \mu-(\langle v, u\rangle+\langle v, u\rangle)|<3 \varepsilon
$$

Since $\boldsymbol{\varepsilon}$ is arbitrary, $\mu=\langle v, u\rangle$ after all. Hence the claim that $\left\langle v_{n}, u_{m}\right\rangle \rightarrow\langle v, u\rangle$ is verified. Next suppose $[x, y] \in \mathscr{G}(A)$ and consider

$$
\begin{aligned}
& \langle v-y, u-x\rangle=\langle v, u\rangle-\langle v, x\rangle-\langle y, u\rangle+\langle y, x\rangle \\
& =\lim _{n \rightarrow \infty}\left(\left\langle v_{n}, u_{n}\right\rangle-\left\langle v_{n}, x\right\rangle-\left\langle y, u_{n}\right\rangle+\langle y, x\rangle\right) \\
& =\lim _{n \rightarrow \infty}\left\langle v_{n}-y, u_{n}-x\right\rangle \geq 0
\end{aligned}
$$

and since $[x, y]$ is arbitrary, it follows that $v \in A u$.
Next suppose $\lim \sup _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle \leq 0$. It is not known that $[u, v] \in \mathscr{G}(A)$.

$$
\begin{array}{r}
\limsup _{n \rightarrow \infty}\left[\left\langle v_{n}, u_{n}\right\rangle-\left\langle v, u_{n}\right\rangle-\left\langle v_{n}, u\right\rangle+\langle v, u\rangle\right] \leq 0 \\
\lim \sup _{n \rightarrow \infty}\left\langle v_{n}, u_{n}\right\rangle-\langle v, u\rangle \leq 0
\end{array}
$$

Thus $\lim \sup _{n \rightarrow \infty}\left\langle v_{n}, u_{n}\right\rangle \leq\langle v, u\rangle$. Now let $[x, y] \in \mathscr{G}(A)$

$$
\begin{aligned}
& \langle v-y, u-x\rangle=\langle v, u\rangle-\langle v, x\rangle-\langle y, u\rangle+\langle y, x\rangle \\
& \geq \lim \sup _{n \rightarrow \infty}\left[\left\langle v_{n}, u_{n}\right\rangle-\left\langle v_{n}, x\right\rangle-\left\langle y, u_{n}\right\rangle+\langle y, x\rangle\right] \\
& \geq \lim _{n \rightarrow \infty}\left[\left\langle v_{n}-y, u_{n}-x\right\rangle\right] \geq 0
\end{aligned}
$$

Hence $[u, v] \in \mathscr{G}(A)$. Now

$$
\lim \sup _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle \leq 0 \leq \lim _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle
$$

the second coming from monotonicity and the fact that $v \in A u$. Therefore,

$$
\lim _{n \rightarrow \infty}\left\langle v_{n}-v, u_{n}-u\right\rangle=0
$$

which shows that $\lim _{n \rightarrow \infty}\left\langle v_{n}, u_{n}\right\rangle=\langle v, u\rangle$.

Definition 25.7.35 Let $x_{\lambda}$ just defined

$$
0 \in F\left(x_{\lambda}-x\right)+\lambda A x_{\lambda}
$$

be denoted by $J_{\lambda} x$ and define also

$$
A_{\lambda}(x)=-\lambda^{-(p-1)} F\left(x_{\lambda}-x\right)=-\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right)
$$

This is for $F$ a duality map with $p>1$. Thus for the usual duality map, you would have

$$
A_{\lambda}(x)=-\lambda^{-1} F\left(J_{\lambda} x-x\right)
$$

Recall how this $x_{\lambda}$ is defined. In general,

$$
0 \in F\left(J_{\lambda} x-x\right)+\lambda^{p-1} A x_{\lambda}
$$

Thus, from the definition,

$$
A_{\lambda}(x) \in A\left(J_{\lambda} x\right)
$$

Formally, and to help remember what is going on, you are looking at a generalization of

$$
A_{\lambda} x=\frac{A}{1+\lambda A} x=\frac{1}{\lambda}\left(x-(I+\lambda A)^{-1} x\right)
$$

This is in the case where $F=I$ to keep things simpler. You have $0=x_{\lambda}-x+\lambda A x_{\lambda}$ and so formally $x_{\lambda}=(I+\lambda A)^{-1} x$. Thus you are looking at $\frac{1}{\lambda}\left(x-x_{\lambda}\right)=\frac{1}{\lambda}\left(x-(I+\lambda A)^{-1} x\right)=$ $A_{\lambda} x$. In fact, this is exactly what you do when you are in a single Hilbert space. This is just a generalization to mappings between Banach spaces and their duals.

Then there are some things which can be said about these operators. It is presented for the general duality map for $p>1$.

Theorem 25.7.36 The following hold. Here $X$ is a reflexive Banach space with strictly convex norm. $A: D(A) \rightarrow \mathscr{P}\left(X^{\prime}\right)$ is maximal monotone. Then

1. $J_{\lambda}$ and $A_{\lambda}$ are bounded single valued operators defined on $X$. Bounded means they take bounded sets to bounded sets. Also $A_{\lambda}$ is a monotone operator.
2. $A_{\lambda}, J_{\lambda}$ are demicontinuous. That is, strongly convergent sequences are mapped to weakly convergent sequences.
3. For every $x \in D(A)$,

$$
\left\|A_{\lambda}(x)\right\| \leq|A x| \equiv \inf \left\{\left\|y^{*}\right\|: y^{*} \in A x\right\}
$$

For every $x \in \overline{\operatorname{conv}(D(A))}$, it follows that $\lim _{\lambda \rightarrow 0} J_{\lambda}(x)=x$. The new symbol means the closure of the convex hull. It is the closure of the set of all convex combinations of points of $D(A)$.

Proof: 1.) It is clear that these are single valued operators. What about the assertion that they are bounded? Let $y^{*} \in A x_{\lambda}$ such that the inclusion defining $x_{\lambda}$ becomes an equality. Thus

$$
F\left(x_{\lambda}-x\right)+\lambda^{p-1} y^{*}=0
$$

Then let $x_{0} \in D(A)$ be given.

$$
\left\langle F\left(x_{\lambda}-x\right), x_{\lambda}-x\right\rangle+\lambda^{p-1}\left\langle y^{*}, x_{\lambda}-x_{0}\right\rangle+\lambda^{p-1}\left\langle y^{*}, x_{0}-x\right\rangle=0
$$

Then by monotonicity of $A$,

$$
\left\|x_{\lambda}-x\right\|^{p}+\lambda^{p-1}\left\langle y_{0}^{*}, x_{\lambda}-x_{0}\right\rangle+\lambda^{p-1}\left\langle y^{*}, x_{0}-x\right\rangle \leq 0
$$

It follows that

$$
\left\|x_{\lambda}-x\right\|^{p} \leq \lambda^{p-1}\left\|y_{0}^{*}\right\|\left\|x_{\lambda}-x_{0}\right\|+\lambda^{p-1}\left\|y^{*}\right\|\left\|x_{0}-x\right\|
$$

Hence if $x$ is in a bounded set, it follows the resulting $x_{\lambda}=J_{\lambda} x$ remain in a bounded set. Now from the definition of $A_{\lambda}$, it follows that this is also a bounded operator.

Why is $A_{\lambda}$ monotone?

$$
\begin{aligned}
0= & \left\langle A_{\lambda} x-A_{\lambda} y, x-y\right\rangle=\left\langle A_{\lambda} x-A_{\lambda} y, x-J_{\lambda} x-\left(y-J_{\lambda} y\right)\right\rangle \\
& +\left\langle A_{\lambda} x-A_{\lambda} y, J_{\lambda} x-J_{\lambda} y\right\rangle \\
= & \left\langle\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right)-\lambda^{-(p-1)} F\left(J_{\lambda} y-y\right), J_{\lambda} x-x-\left(J_{\lambda} y-y\right)\right\rangle \\
& +\left\langle A_{\lambda} x-A_{\lambda} y, J_{\lambda} x-J_{\lambda} y\right\rangle
\end{aligned}
$$

and both terms are nonnegative, the first because $F$ is monotone so indeed $A_{\lambda}$ is monotone.
2.) What of the demicontinuity of $A_{\lambda}$ ? This one is really tricky. Suppose $x_{n} \rightarrow x$. Does it follow that $A_{\lambda} x_{n} \rightarrow A_{\lambda} x$ weakly? The proof will be based on a pair of equations. These are

$$
\lim _{m, n \rightarrow \infty}\left\langle F\left(J_{\lambda} x_{n}-x_{n}\right)-F\left(J_{\lambda} x_{m}-x_{m}\right), J_{\lambda} x_{n}-x_{n}-\left(J_{\lambda} x_{m}-x_{m}\right)\right\rangle=0
$$

and

$$
\lim _{m, n \rightarrow \infty}\left\langle A_{\lambda}\left(x_{n}\right)-A_{\lambda}\left(x_{m}\right), J_{\lambda} x_{n}-J_{\lambda} x_{m}\right\rangle=0
$$

When these have been established, Lemma 25.7 .34 is used to get the desired result for a subsequence. It will be shown that every sequence has a subsequence which gives the right sort of weak convergence and from this the desired weak convergence of $A_{\lambda} x_{n}$ to $A_{\lambda} x$ follows.

$$
\begin{gathered}
0 \in F\left(J_{\lambda} x_{n}-x_{n}\right)+\lambda^{p-1} A\left(J_{\lambda} x_{n}\right) \\
0 \in F\left(J_{\lambda} x-x\right)+\lambda^{p-1} A\left(J_{\lambda} x\right) \\
-\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right) \equiv A_{\lambda}(x) \in A\left(J_{\lambda} x\right) \\
-\lambda^{-(p-1)} F\left(J_{\lambda} x_{n}-x_{n}\right) \equiv A_{\lambda}\left(x_{n}\right) \in A\left(J_{\lambda} x_{n}\right)
\end{gathered}
$$

Note also that for a given $x$ there is only one solution $J_{\lambda} x$ to $0 \in F\left(J_{\lambda} x-x\right)+\lambda^{p-1} A\left(J_{\lambda} x\right)$. By monotonicity of $F$,

$$
0 \leq\left\langle F\left(J_{\lambda} x_{n}-x_{n}\right)-F\left(J_{\lambda} x_{m}-x_{m}\right), x_{m}-x_{n}+J_{\lambda} x_{n}-J_{\lambda} x_{m}\right\rangle
$$

Then from the above,

$$
\begin{aligned}
& \left\langle F\left(J_{\lambda} x_{n}-x_{n}\right)-F\left(J_{\lambda} x_{m}-x_{m}\right), x_{n}-x_{m}\right\rangle \\
\leq & \left\langle F\left(J_{\lambda} x_{n}-x_{n}\right)-F\left(J_{\lambda} x_{m}-x_{m}\right), J_{\lambda} x_{n}-J_{\lambda} x_{m}\right\rangle
\end{aligned}
$$

Now from the boundedness of these operators, the left side of the above inequality converges to 0 as $n, m \rightarrow \infty$. Thus

$$
\begin{equation*}
\lim _{m, n \rightarrow \infty} \inf \left\langle F\left(J_{\lambda} x_{n}-x_{n}\right)-F\left(J_{\lambda} x_{m}-x_{m}\right), J_{\lambda} x_{n}-J_{\lambda} x_{m}\right\rangle \geq 0 \tag{25.7.55}
\end{equation*}
$$

$$
\begin{aligned}
& \lim \inf _{m, n \rightarrow \infty}\left\langle-\lambda^{p-1} A_{\lambda}\left(x_{n}\right)-\left(-\lambda^{p-1} A_{\lambda}\left(x_{m}\right)\right), J_{\lambda} x_{n}-J_{\lambda} x_{m}\right\rangle \geq 0 \\
& \lim _{\inf _{m, n}\langle }\langle\lambda^{p-1} \overbrace{A_{\lambda}\left(x_{m}\right)}^{\in A\left(J_{\lambda} x_{m}\right)}-\lambda^{p-1} \overbrace{A_{\lambda}\left(x_{n}\right)}^{A\left(J_{\lambda} x_{n}\right)}, J_{\lambda} x_{n}-J_{\lambda} x_{m}\rangle \geq 0
\end{aligned}
$$

The expression on the left in the above is non positive. Multiplying by -1 ,

$$
\begin{align*}
0 & \geq \lim \sup _{m, n \rightarrow \infty}\left\langle A_{\lambda}\left(x_{n}\right)-A_{\lambda}\left(x_{m}\right), J_{\lambda} x_{n}-J_{\lambda} x_{m}\right\rangle \\
& \geq \lim _{m, n \rightarrow \infty}\left\langle A_{\lambda}\left(x_{n}\right)-A_{\lambda}\left(x_{m}\right), J_{\lambda} x_{n}-J_{\lambda} x_{m}\right\rangle \geq 0 \tag{25.7.56}
\end{align*}
$$

Thus, in fact, the expression in 25.7 .55 converges to 0 . By boundedness considerations and the strong convergence given,

$$
\begin{equation*}
\lim _{m, n \rightarrow \infty}\left\langle F\left(J_{\lambda} x_{n}-x_{n}\right)-F\left(J_{\lambda} x_{m}-x_{m}\right), J_{\lambda} x_{n}-x_{n}-\left(J_{\lambda} x_{m}-x_{m}\right)\right\rangle=0 \tag{25.7.57}
\end{equation*}
$$

From boundedness again, there is a subsequence still denoted with the subscript $n$ such that

$$
J_{\lambda} x_{n}-x_{n} \rightarrow a-x, F\left(J_{\lambda} x_{n}-x_{n}\right) \rightarrow b \text { both weakly. }
$$

Since $F$ is maximal monotone, (Theorem 25.7.9) it follows from Lemma 25.7.34 that $[a-x, b] \in \mathscr{G}(F)$ and so in fact $F(a-x)=b$. Thus this has just shown that $F\left(J_{\lambda} x_{n}-x_{n}\right) \rightarrow$ $F(a-x)$. Next consider 25.7.56. We have $J_{\lambda} x_{n} \rightarrow a$ weakly and

$$
A_{\lambda}\left(x_{n}\right)=-\lambda^{-(p-1)} F\left(J_{\lambda} x_{n}-x_{n}\right) \rightarrow-\lambda^{-(p-1)} b
$$

weakly. Then from Lemma 25.7 .34 again, $\left[a,-\lambda^{-(p-1)} b\right] \in \mathscr{G}(A)$ so $-\lambda^{-(p-1)} b \in A(a)$ so $b \in-\lambda^{p-1} A(a)$. But it was just shown that $b=F(a-x)$ and so

$$
F(a-x) \in-\lambda^{p-1} A(a) \text { so } 0 \in F(a-x)+\lambda^{p-1} A(a), \text { so } a=J_{\lambda} x
$$

As noted at the beginning, there is only one solution to this inclusion for a given $x$ and it is $a=J_{\lambda} x$. This has shown that in terms of weak convergence,

$$
A_{\lambda}\left(x_{n}\right) \rightarrow-\lambda^{-(p-1)} b=-\lambda^{-(p-1)} F(a-x)=-\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right) \equiv A_{\lambda}(x)
$$

This has shown that $A_{\lambda}$ is demicontinuous. Also it has shown that $J_{\lambda}$ is also demicontinuous. (This result is a lot nicer in Hilbert space. )
3.) Why is $\left\|A_{\lambda}(x)\right\| \leq|A x|$ whenever $x \in D(A)$ ?

$$
A_{\lambda}(x)=-\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right)
$$

where $0 \in F\left(J_{\lambda} x-x\right)+\lambda^{p-1} A\left(J_{\lambda} x\right)$. Therefore, $A_{\lambda}(x) \in A\left(J_{\lambda} x\right)$. Then letting $[u, v] \in$ $\mathscr{G}(A)$,

$$
0 \leq\left\langle v-A_{\lambda}(x), u-J_{\lambda} x\right\rangle
$$

In particular, if $y \in A x$

$$
0 \leq\left\langle y-A_{\lambda}(x), x-J_{\lambda} x\right\rangle=\left\langle y+\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right), x-J_{\lambda} x\right\rangle
$$

Hence

$$
\lambda^{-(p-1)}\left\|J_{\lambda} x-x\right\|^{p} \leq\|y\|\left\|J_{\lambda} x-x\right\|
$$

and so

$$
\lambda^{-(p-1)}\left\|J_{\lambda} x-x\right\|^{p-1}=\lambda^{-(p-1)}\left\|F\left(J_{\lambda} x-x\right)\right\|=\left\|A_{\lambda}(x)\right\| \leq\|y\|
$$

and since $y \in A x$ is arbitrary, $\left\|A_{\lambda}(x)\right\| \leq|A x| \equiv \inf \{\|y\|: y \in A x\}$.
Next consider the claim that for all $x \in \overline{\operatorname{conv}(D(A))}$, it follows that

$$
\lim _{\lambda \rightarrow 0} J_{\lambda}(x)=x
$$

Let $[u, v] \in \mathscr{G}(A)$ and $x$ is arbitrary.

$$
\begin{gathered}
0 \leq\left\langle v-A_{\lambda}(x), u-J_{\lambda} x\right\rangle=\left\langle v+\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right), u-J_{\lambda} x\right\rangle \\
=\left\langle v+\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right), u-x\right\rangle+\left\langle v+\lambda^{-(p-1)} F\left(J_{\lambda} x-x\right), x-J_{\lambda} x\right\rangle
\end{gathered}
$$

Thus

$$
\begin{equation*}
\left\|J_{\lambda} x-x\right\|^{p} \leq \lambda^{p-1}\langle v, u-x\rangle+\left\langle F\left(J_{\lambda} x-x\right), u-x\right\rangle+\lambda^{p-1}\left\langle v, x-J_{\lambda} x\right\rangle \tag{25.7.58}
\end{equation*}
$$

for $x$ arbitrary and $u$ anything in $D(A)$. It follows that 25.7 .58 holds for any $u \in \operatorname{conv}(D(A))$. Say $u=x_{n} \in \operatorname{conv}(D(A))$ where $x_{n} \rightarrow x$. Then

$$
\begin{gathered}
\left\|J_{\lambda} x-x\right\|^{p} \leq \lambda^{p-1}\left\langle v, x_{n}-x\right\rangle+\left\langle F\left(J_{\lambda} x-x\right), x_{n}-x\right\rangle+\lambda^{p-1}\left\langle v, x-J_{\lambda} x\right\rangle \\
\leq \lambda^{p-1}\|v\|\left\|x_{n}-x\right\|+\left\|J_{\lambda} x-x\right\|^{p-1}\left\|x_{n}-x\right\|+\lambda^{p-1}\|v\|\left\|J_{\lambda} x-x\right\|
\end{gathered}
$$

You have something like this: $y_{\lambda}=\left\|J_{\lambda} x-x\right\|, a_{n}=\left\|x_{n}-x\right\|$,

$$
y_{\lambda}^{p} \leq \lambda^{p-1}\|v\| a_{n}+y_{\lambda}^{p-1} a_{n}+\lambda^{p-1}\|v\| y_{\lambda}, \quad y_{\lambda} \geq 0
$$

where $p>1$ and $a_{n} \rightarrow 0$. Then

$$
\lim \sup _{\lambda \rightarrow 0} y_{\lambda}^{p} \leq \lim \sup _{\lambda \rightarrow 0} y_{\lambda}^{p-1} a_{n}
$$

and so,

$$
\limsup _{\lambda \rightarrow 0} y_{\lambda} \leq a_{n}
$$

Hence

$$
\lim \sup _{\lambda \rightarrow 0}\left\|J_{\lambda} x-x\right\| \leq\left\|x_{n}-x\right\|
$$

Since $x_{n}$ is arbitrary, it follows that for every $\varepsilon>0$,

$$
\lim \sup _{\lambda \rightarrow 0}\left\|J_{\lambda} x-x\right\| \leq \varepsilon
$$

and so in fact, $\limsup _{\lambda \rightarrow \infty}\left\|J_{\lambda} x-x\right\|=0$.
Now here is an interesting corollary.

Corollary 25.7.37 Let A be maximal monotone. $A: X \rightarrow X^{\prime}$ where $X$ is a strictly convex reflexive Banach space. Then $\overline{D(A)}$ is convex.

Proof: It is known that $J_{\lambda}: X \rightarrow D(A)$ for any $\lambda$. Also, if $x \in \overline{\operatorname{conv}(D(A))}$, then it was shown that $J_{\lambda} x \rightarrow x$. Clearly

$$
\overline{\operatorname{conv}(D(A))} \supseteq \overline{D(A)}
$$

Now if $x$ is in the set on the left, $J_{\lambda} x \rightarrow x$ and so in fact, since $J_{\lambda} x \in D(A)$, it must be the case that $x \in \overline{D(A)}$. Thus the two sets are the same and so in fact, $\overline{D(A)}$ is closed and convex.

Note that this implies that $\overline{A(D(A))}$ is also convex. This is because $A^{-1}$ described above, is maximal monotone with domain $A(D(A))$.

Next is a useful generalization of some of the earlier material used to establish the above results on approximation. It will include the general case of $F$ a duality map for $p>1$.

Proposition 25.7.38 Suppose $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ where $X$ is a reflexive Banach space with strictly convex norm. Suppose also that $A$ is maximal monotone. Then if $\lambda_{n} \rightarrow 0$ and if $x_{n} \rightarrow x$ weakly, $A_{\lambda_{n}} x_{n} \rightarrow x^{*}$ weakly, and

$$
\lim \sup _{n, m \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-A_{\lambda_{m}} x_{m}, x_{n}-x_{m}\right\rangle \leq 0
$$

Then

$$
\lim _{n, m \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-A_{\lambda_{m}} x_{m}, x_{n}-x_{m}\right\rangle=0
$$

$\left[x, x^{*}\right] \in \mathscr{G}(A)$, and $\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle \rightarrow\left\langle x^{*}, x\right\rangle$.

Proof: Let $\alpha=\limsup \sin _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle$. It is finite because the expression is bounded independent of $n$. Then

$$
\lim \sup _{m \rightarrow \infty}\left({\lim \sup _{n \rightarrow \infty}}\binom{\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle+\left\langle A_{\lambda_{m}} x_{m}, x_{m}\right\rangle}{-\left[\left\langle A_{\lambda_{n}} x_{n}, x_{m}\right\rangle+\left\langle A_{\lambda_{m}} x_{m}, x_{n}\right\rangle\right]}\right) \leq 0
$$

Thus

$$
\lim _{m \rightarrow \infty} \sup _{m}\left(\alpha+\left\langle A_{\lambda_{m}} x_{m}, x_{m}\right\rangle-\left[\left\langle x^{*}, x_{m}\right\rangle+\left\langle A_{\lambda_{m}} x_{m}, x\right\rangle\right]\right) \leq 0
$$

and so

$$
2 \alpha-2\left\langle x^{*}, x\right\rangle \leq 0
$$

The next simple observation is that

$$
\left\|A_{\lambda_{n}} x_{n}\right\|=\left\|\lambda_{n}^{-(p-1)} F\left(J_{\lambda_{n}} x_{n}-x_{n}\right)\right\| \leq C
$$

due to the weak convergence. Hence $\lambda_{n}^{-(p-1)}\left\|J_{\lambda_{n}} x_{n}-x_{n}\right\|^{p-1} \leq C$ and so

$$
\begin{equation*}
\left\|J_{\lambda_{n}} x_{n}-x_{n}\right\| \leq \lambda_{n} C^{1 /(p-1)} \tag{25.7.59}
\end{equation*}
$$

Thus if $\left[u, u^{*}\right] \in \mathscr{G}(A)$,

$$
\lim \inf _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-u^{*}, x_{n}-u\right\rangle=\lim \inf _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-u^{*}, J_{\lambda_{n}} x_{n}-u\right\rangle \geq 0
$$

because $A_{\lambda} x \in A J_{\lambda} x$. However, the left side satisfies

$$
\begin{aligned}
0 & \leq \lim \inf _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-u^{*}, x_{n}-u\right\rangle \leq \lim \sup _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-u^{*}, x_{n}-u\right\rangle \\
& =\lim \sup _{n \rightarrow \infty}\left[\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle-\left\langle A_{\lambda_{n}} x_{n}, u\right\rangle-\left\langle u^{*}, x_{n}\right\rangle+\left\langle u^{*}, u\right\rangle\right] \\
& =\alpha-\left\langle x^{*}, u\right\rangle-\left\langle u^{*}, x\right\rangle+\left\langle u^{*}, u\right\rangle \leq\left\langle x^{*}, x\right\rangle-\left\langle x^{*}, u\right\rangle-\left\langle u^{*}, x\right\rangle+\left\langle u^{*}, u\right\rangle \\
& =\left\langle x^{*}-u^{*}, x-u\right\rangle
\end{aligned}
$$

and this shows that $\left[x, x^{*}\right] \in \mathscr{G}(A)$ since $\left[u, u^{*}\right]$ was arbitrary.
Next let $\left[u, u^{*}\right] \in \mathscr{G}(A)$. Then thanks to 25.7.59,

$$
\begin{aligned}
0 & \leq \lim \inf _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-u^{*}, J_{\lambda_{n}} x_{n}-u\right\rangle=\lim \inf _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-u^{*}, x_{n}-u\right\rangle \\
& \leq \lim \sup _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-u^{*}, x_{n}-u\right\rangle \\
& =\lim \sup _{n \rightarrow \infty}\left(\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle-\left\langle A_{\lambda_{n}} x_{n}, u\right\rangle-\left\langle u^{*}, x_{n}\right\rangle+\left\langle u^{*}, u\right\rangle\right) \\
& =\lim \sup _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle-\left\langle x^{*}, u\right\rangle-\left\langle u^{*}, x\right\rangle+\left\langle u^{*}, u\right\rangle \\
& \leq\left\langle x^{*}, x\right\rangle-\left\langle x^{*}, u\right\rangle-\left\langle u^{*}, x\right\rangle+\left\langle u^{*}, u\right\rangle=\left\langle x^{*}-u^{*}, x-u\right\rangle
\end{aligned}
$$

In particular, you could let $\left[u, u^{*}\right]=\left[x, x^{*}\right]$ and conclude that

$$
\begin{aligned}
\lim _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-x^{*}, x_{n}-x\right\rangle & =\lim _{n \rightarrow \infty}\left(\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle-\left\langle A_{\lambda_{n}} x_{n}, x\right\rangle+\left\langle x^{*}, x\right\rangle-\left\langle x^{*}, x_{n}\right\rangle\right) \\
& =\lim _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle-\left\langle x^{*}, x\right\rangle+\left\langle x^{*}, x\right\rangle-\left\langle x^{*}, x\right\rangle=0
\end{aligned}
$$

which shows that $\lim _{n \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}, x_{n}\right\rangle=\left\langle x^{*}, x\right\rangle$. Then it follows from this that

$$
\lim _{n, m \rightarrow \infty}\left\langle A_{\lambda_{n}} x_{n}-A_{\lambda_{m}} x_{m}, x_{n}-x_{m}\right\rangle=0
$$

For the rest of this, the usual duality map for $p=2$ will be used. It may be that one could change this, but I don't have a need to do it right now so from now on, $F$ will be the usual thing.

### 25.7.5 Sum Of Maximal Monotone Operators

To begin with, here is a nice lemma.
Lemma 25.7.39 Let $0 \in D(A)$ and let $A$ be maximal monotone and let $B: X \rightarrow X^{\prime}$ be monotone hemicontinuous, bounded, and coercive. Then $B+A$ is also maximal monotone. Also $B+A$ is onto.

Proof: By Theorem 25.7.9, there exists $x \in \overline{D(A)}$ such that for all $\left[u, u^{*}\right] \in \mathscr{G}(A)$,

$$
\left\langle B x+F x-y^{*}+u^{*}, u-x\right\rangle \geq 0
$$

Hence for all $\left[u, u^{*}\right]$,

$$
\left\langle u^{*}-\left(y^{*}-(B x+F x)\right), u-x\right\rangle \geq 0
$$

It follows that

$$
y^{*}-(B x+F x) \in A x
$$

and so $y^{*} \in B x+A x+F x$ showing that $B+A$ is maximal monotone because it added to $F$ is onto. As to the last claim, just don't add in $F$ in the argument. Thus for all $\left[u, u^{*}\right]$,

$$
\left\langle B x-y^{*}+u^{*}, u-x\right\rangle \geq 0
$$

Then the rest is as before. You find that $y^{*}-B x \in A x$.
Corollary 25.7.40 Suppose instead of $0 \in D(A)$, it is known that $x_{0} \in D(A)$ and

$$
\lim _{\|x\| \rightarrow \infty} \frac{\left\langle B\left(x_{0}+x\right), x\right\rangle}{\|x\|}=\infty
$$

Then if $B$ is monotone and hemicontinuous and $A$ is maximal monotone, then $B+A$ is onto.
Proof: Let $\hat{A}(x) \equiv A\left(x_{0}+x\right)$ so in fact $0 \in D(\hat{A})$. Then letting $\hat{B}$ be defined similarly, it follows from the above lemma that if $y^{*} \in X^{\prime}$, there exists $x$ such that

$$
y^{*} \in \hat{A} x+\hat{B} x \equiv A\left(x_{0}+x\right)+B\left(x_{0}+x\right)
$$

Lemma 25.7.41 Let 0 be on the interior of $D(A)$ and also in $D(B)$. Also let $0 \in B(0)$ and $0 \in A(0)$. Then if $A, B$ are maximal monotone, so is $A+B$.

Proof: Note that, since $0 \in A(0)$, if $x^{*} \in A x$, then $\left\langle x^{*}, x\right\rangle \geq 0$. Also note that $\left\|B_{\lambda}(0)\right\| \leq$ $|B(0)|=0$ and so also $\left\langle B_{\lambda} x, x\right\rangle \geq 0$. It is necessary to show that $F+A+B$ is onto. However, $B_{\lambda}$ is monotone hemicontinuous, bounded and coercive. Hence, by Lemma 25.7.39, $B_{\lambda}+A$ is maximal monotone. If $x^{*} \in X^{\prime}$ is given, there exists a solution to

$$
x^{*} \in F x_{\lambda}+B_{\lambda} x_{\lambda}+A x_{\lambda}
$$

Do both sides to $x_{\lambda}$ and let $x_{\lambda}^{*} \in A x_{\lambda}$ be such that equality holds in the above.

$$
\begin{equation*}
x^{*}=F x_{\lambda}+B_{\lambda} x_{\lambda}+x_{\lambda}^{*} \tag{25.7.60}
\end{equation*}
$$

Then

$$
\left\langle x^{*}, x_{\lambda}\right\rangle=\left\|x_{\lambda}\right\|^{2}+\left\langle x_{\lambda}^{*}, x_{\lambda}\right\rangle
$$

It follows that

$$
\begin{equation*}
\left\|x_{\lambda}\right\| \leq\left\|x^{*}\right\|, \quad\left\langle x_{\lambda}^{*}, x_{\lambda}\right\rangle \leq\left\langle x^{*}, x_{\lambda}\right\rangle \leq\left\|x^{*}\right\|\left\|x_{\lambda}\right\| \leq\left\|x^{*}\right\|^{2} \tag{25.7.61}
\end{equation*}
$$

Next, 0 is on the interior of $D(A)$ and so from Theorem 25.7.20, there exists $\rho>0$ such that if $y^{*} \in A x$ for $\|x\| \leq \rho$, then $\left\|y^{*}\right\|<M$ and in fact, all such $x$ are in $D(A)$. Now let

$$
y_{\lambda}=\frac{1}{2\left\|x_{\lambda}^{*}\right\|} F^{-1}\left(x_{\lambda}^{*}\right) \text { so }\left\|y_{\lambda}\right\|<\rho
$$

Thus $y_{\lambda} \in D(A)$ and if $y_{\lambda}^{*} \in A y_{\lambda}$, then $\left\|y_{\lambda}^{*}\right\|<M$. Then for such bounded $y_{\lambda}^{*}$,

$$
0 \leq\left\langle y_{\lambda}^{*}-x_{\lambda}^{*}, y_{\lambda}-x_{\lambda}\right\rangle=\left\langle y_{\lambda}^{*}, y_{\lambda}\right\rangle-\left\langle x_{\lambda}^{*}, y_{\lambda}\right\rangle-\left\langle y_{\lambda}^{*}, x_{\lambda}\right\rangle+\left\langle x_{\lambda}^{*}, x_{\lambda}\right\rangle
$$

Then

$$
\begin{gathered}
\frac{1}{2}\left\|x_{\lambda}^{*}\right\|=\left\langle x_{\lambda}^{*}, \frac{1}{2\left\|x_{\lambda}^{*}\right\|} F^{-1}\left(x_{\lambda}^{*}\right)\right\rangle=\left\langle x_{\lambda}^{*}, y_{\lambda}\right\rangle \leq\left\langle y_{\lambda}^{*}, y_{\lambda}\right\rangle-\left\langle y_{\lambda}^{*}, x_{\lambda}\right\rangle+\left\langle x_{\lambda}^{*}, x_{\lambda}\right\rangle \\
\leq M \rho+M\left\|x_{\lambda}\right\|+\left\langle x_{\lambda}^{*}, x_{\lambda}\right\rangle
\end{gathered}
$$

From 25.7.61,

$$
\left\|x_{\lambda}^{*}\right\| \leq 2\left(M \rho+M\left\|x^{*}\right\|+\left\|x^{*}\right\|^{2}\right)
$$

Thus from 25.7.61, $x_{\lambda}, x_{\lambda}^{*}, F x_{\lambda}$ are all bounded. Hence it follows from 25.7.60 that $B_{\lambda} x_{\lambda}$ is also bounded. Therefore, there is a sequence, $\lambda_{n} \rightarrow 0$ such that

$$
\begin{gathered}
x_{\lambda_{n}} \rightarrow z \text { weakly } \\
x_{\lambda}^{*} \rightarrow w^{*} \text { weakly } \\
F x_{\lambda} \rightarrow u^{*} \text { weakly } \\
B_{\lambda_{n}} x_{\lambda_{n}} \rightarrow b^{*} \text { weakly }
\end{gathered}
$$

Using 25.7.60, it follows that

$$
\left\langle F x_{\lambda_{n}}+x_{\lambda_{n}}^{*}+B_{\lambda_{n}} x_{\lambda_{n}}-\left(F x_{\lambda_{m}}+x_{\lambda_{m}}^{*}+B_{\lambda_{m}} x_{\lambda_{m}}\right), x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle=0
$$

Thus

$$
\begin{equation*}
\left\langle F x_{\lambda_{n}}+x_{\lambda_{n}}^{*}-\left(F x_{\lambda_{m}}+x_{\lambda_{m}}^{*}\right), x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle+\left\langle B_{\lambda_{n}} x_{\lambda_{n}}-B_{\lambda_{m}} x_{\lambda_{m}}, x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle=0 \tag{25.7.62}
\end{equation*}
$$

Now $F+A$ is surely monotone and so

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle B_{\lambda_{n}} x_{\lambda_{n}}-B_{\lambda_{m}} x_{\lambda_{m}}, x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle \leq 0
$$

By Proposition 25.7.38, $b^{*} \in B z$ and

$$
\lim _{m, n \rightarrow \infty}\left\langle B_{\lambda_{n}} x_{\lambda_{n}}-B_{\lambda_{m}} x_{\lambda_{m}}, x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle=0
$$

Then returning to 25.7.62,

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle F x_{\lambda_{n}}+x_{\lambda_{n}}^{*}-\left(F x_{\lambda_{m}}+x_{\lambda_{m}}^{*}\right), x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle \leq 0
$$

Now from Lemma 25.7.39, $F+A$ is maximal monotone. Hence Proposition 25.7.38 applies again and it follows that $u^{*}+w^{*} \in F z+A z$. Then passing to the limit as $n \rightarrow \infty$ in

$$
x^{*}=F x_{\lambda_{n}}+B_{\lambda_{n}} x_{\lambda_{n}}+x_{\lambda_{n}}^{*}
$$

it follows that

$$
x^{*}=u^{*}+b^{*}+w^{*}=F z+A z+B z
$$

and this shows that $A+B$ is maximal monotone because $x^{*}$ was arbitrary.
You don't need to assume all that stuff about $0 \in A(0), 0 \in B(0), 0$ on interior of $D(A)$ and so forth.

Theorem 25.7.42 Suppose $A, B$ are maximal monotone and the interior of $D(A)$ has nonempty intersection with $D(B)$. Then $A+B$ is maximal monotone.

Proof: Let $x_{0}$ be on the interior of $D(A)$ and also in $D(B)$. Let $\hat{A}(x)=A\left(x_{0}+x\right)-x_{0}^{*}$ where $x_{0}^{*} \in A\left(x_{0}\right)$. Thus $0 \in D(\hat{A})$ and $0 \in \hat{A}(0)$. Do the same thing for $B$ to get $\hat{B}$ defined similarly. Are these still maximal monotone? Suppose for all $\left[u, u^{*}\right] \in \mathscr{G}(\hat{A})$

$$
\left\langle y^{*}-u^{*}, y-u\right\rangle \geq 0
$$

Does it follow that $y^{*} \in \hat{A} y$ ? It is given that $u^{*} \in A\left(x_{0}+u\right)$. The above implies for all $\left[u, u^{*}\right] \in \mathscr{G}(\hat{A})$

$$
\left\langle y^{*}+x_{0}^{*}-\left(u^{*}+x_{0}^{*}\right),\left(y+x_{0}\right)-\left(u+x_{0}\right)\right\rangle \geq 0
$$

and since $u+x_{0}$ is a generic element of $D(A)$ for $u \in D(\hat{A})$, the above implies $y^{*}+x_{0}^{*} \in$ $A\left(y+x_{0}\right)$ and so $y \in A\left(y+x_{0}\right)-x_{0}^{*} \equiv \hat{A}(y)$. Hence the graph is maximal. Similar for $\hat{B}$. Thus the lemma can be applied to $\hat{A}, \hat{B}$ to conclude that the sum of these is maximal
monotone. Now a repeat of the above reasoning which shows that $\hat{A}$ is maximal monotone shows that the fact that $\hat{A}+\hat{B}$ is maximal monotone implies that $A+B$ is also. You just shift with $-x_{0}$ instead of $x_{0}$. It amounts to nothing more than the observation that maximal graphs don't lose their maximality by shifting their ranges and domains.

Suppose $B, A$ are maximal monotone. Does there always exist a solution $x$ to

$$
\begin{equation*}
x^{*} \in F x+B_{\lambda} x+A x ? \tag{25.7.63}
\end{equation*}
$$

Consider the monotone hemicontinuous and bounded operator $F+B_{\lambda}$.Is $\hat{F}+\hat{B}_{\lambda}$ defined by

$$
\left(\hat{F}+\hat{B}_{\lambda}\right)(x) \equiv\left(\hat{F}+\hat{B}_{\lambda}\right)\left(x+x_{0}\right)
$$

also coercive for some $x_{0} \in D(A)$ ? If so, the existence of the desired solution to the above inclusion follows from Corollary 25.7.40. Then for all $\|x\|$ large enough that $\left\|x+x_{0}\right\|>$ $\left\|x_{0}\right\|$,

$$
\begin{gathered}
\frac{\left\langle F\left(x+x_{0}\right)+B_{\lambda}\left(x+x_{0}\right), x\right\rangle}{\|x\|} \\
=\frac{\left\langle F\left(x+x_{0}\right), x\right\rangle}{\|x\|}+\frac{\left\langle B_{\lambda}\left(x+x_{0}\right)-B_{\lambda}\left(x_{0}\right), x\right\rangle}{\|x\|}+\frac{\left\langle B_{\lambda}\left(x_{0}\right), x\right\rangle}{\|x\|} \\
\geq \frac{1}{2} \frac{\left\langle F\left(x+x_{0}\right), x\right\rangle}{\left\|x+x_{0}\right\|}-\left\|B_{\lambda}\left(x_{0}\right)\right\| \\
\geq \frac{1}{2} \frac{\left\langle F\left(x+x_{0}\right), x+x_{0}\right\rangle}{\left\|x+x_{0}\right\|}-\frac{1}{2} \frac{\left\langle F\left(x+x_{0}\right), x_{0}\right\rangle}{\left\|x+x_{0}\right\|}-\left\|B_{\lambda}\left(x_{0}\right)\right\| \\
\geq \frac{1}{2} \frac{\left\langle F\left(x+x_{0}\right), x+x_{0}\right\rangle}{\left\|x+x_{0}\right\|}-\frac{1}{2} \frac{\left\langle F\left(x+x_{0}\right), x_{0}\right\rangle}{\left\|x_{0}\right\|}-\left\|B_{\lambda}\left(x_{0}\right)\right\| \\
\geq \frac{1}{2} \frac{\left\langle F\left(x+x_{0}\right), x+x_{0}\right\rangle}{\left\|x+x_{0}\right\|}-\frac{1}{2}\left\|x+x_{0}\right\|-\left\|B_{\lambda}\left(x_{0}\right)\right\| \\
=\frac{1}{2}\left\|x+x_{0}\right\|^{2}-\frac{1}{2}\left\|x+x_{0}\right\|-\left\|B_{\lambda}\left(x_{0}\right)\right\|
\end{gathered}
$$

which shows that

$$
\lim _{\|x\| \rightarrow \infty} \frac{\left\langle F\left(x+x_{0}\right)+B_{\lambda}\left(x+x_{0}\right), x\right\rangle}{\|x\|}=\infty
$$

and so by Corollary 25.7.40, there exists a solution to 25.7.63. This shows half of the following interesting theorem which is another version of the above major result.

Theorem 25.7.43 Suppose $A, B$ are maximal monotone operators. Then for each $x^{*} \in X^{\prime}$, there exists a solution $x_{\lambda}$ to

$$
\begin{equation*}
x^{*} \in F x_{\lambda}+B x_{\lambda} x_{\lambda}+A x_{\lambda}, \lambda>0 \tag{25.7.64}
\end{equation*}
$$

If for $\lambda \in(0, \delta),\left\{B_{\lambda} x_{\lambda}\right\}$ is bounded, then there exists a solution $x$ to

$$
x^{*} \in F x+B x+A x
$$

Proof: The existence of a solution to the inclusion 25.7 .64 comes from the above discussion. The last claim follows from almost a repeat of the last part of the proof of the above theorem. Since $\left\{B_{\lambda} x_{\lambda}\right\}$ is given to be bounded for $\lambda \in(0, \delta)$, there is a sequence, $\lambda_{n} \rightarrow 0$ such that

$$
\begin{gathered}
x_{\lambda_{n}} \rightarrow z \text { weakly } \\
x_{\lambda}^{*} \rightarrow w^{*} \text { weakly } \\
F x_{\lambda} \rightarrow u^{*} \text { weakly } \\
B_{\lambda_{n}} x_{\lambda_{n}} \rightarrow b^{*} \text { weakly }
\end{gathered}
$$

Using 25.7.64, it follows that

$$
\left\langle F x_{\lambda_{n}}+x_{\lambda_{n}}^{*}+B_{\lambda_{n}} x_{\lambda_{n}}-\left(F x_{\lambda_{m}}+x_{\lambda_{m}}^{*}+B_{\lambda_{m}} x_{\lambda_{m}}\right), x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle=0
$$

Thus

$$
\begin{gather*}
\left\langle F x_{\lambda_{n}}+x_{\lambda_{n}}^{*}-\left(F x_{\lambda_{m}}+x_{\lambda_{m}}^{*}\right), x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle \\
\quad+\left\langle B_{\lambda_{n}} x_{\lambda_{n}}-B_{\lambda_{m}} x_{\lambda_{m}}, x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle=0 \tag{25.7.65}
\end{gather*}
$$

Now $F+A$ is surely monotone and so

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle B_{\lambda_{n}} x_{\lambda_{n}}-B_{\lambda_{m}} x_{\lambda_{m}}, x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle \leq 0
$$

By Proposition 25.7.38, $b^{*} \in B z$ and

$$
\lim _{m, n \rightarrow \infty}\left\langle B_{\lambda_{n}} x_{\lambda_{n}}-B_{\lambda_{m}} x_{\lambda_{m}}, x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle=0
$$

Then returning to 25.7 .65 ,

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle F x_{\lambda_{n}}+x_{\lambda_{n}}^{*}-\left(F x_{\lambda_{m}}+x_{\lambda_{m}}^{*}\right), x_{\lambda_{n}}-x_{\lambda_{m}}\right\rangle \leq 0
$$

Now from Corollary 25.7.40, $F+A$ is maximal monotone (In fact, $F+A$ is onto). Hence Proposition 25.7.38 applies again and it follows that $u^{*}+w^{*} \in F z+A z$. Then passing to the limit as $n \rightarrow \infty$ in

$$
x^{*}=F x_{\lambda_{n}}+B_{\lambda_{n}} x_{\lambda_{n}}+x_{\lambda_{n}}^{*}
$$

it follows that

$$
x^{*}=u^{*}+b^{*}+w^{*}=F z+A z+B z
$$

### 25.7.6 Convex Functions, An Example

As before, $X$ will be a Banach space in what follows. Sometimes it will be a reflexive Banach space and in this case, it will be assumed that the norm is strictly convex.

Definition 25.7.44 Let $\phi: X \rightarrow(-\infty, \infty]$. Then $\phi$ is convex if whenever $t \in[0,1], x, y \in X$,

$$
\phi(t x+(1-t) y) \leq t \phi(x)+(1-t) \phi(y)
$$

The epigraph of $\phi$ is defined by

$$
\operatorname{epi}(\phi) \equiv\{(x, y): y \geq \phi(x)\}
$$

When epi $(\phi)$ is closed in $X \times(-\infty, \infty]$, we say that $\phi$ is lower semicontinuous, l.s.c. The function is called proper if $\phi(x)<\infty$ for some $x$. The collection of all such $x$ is called $D(\phi)$, the domain of $\phi$.

This definition of lower semicontinuity is equivalent to the usual definition.
Lemma 25.7.45 The above definition of lower semicontinuity is equivalent to the assertion that whenever $x_{n} \rightarrow x$, it follows that $\phi(x) \leq \liminf _{n \rightarrow \infty} \phi\left(x_{n}\right)$. In case that $\phi$ is convex, lower semicontinuity is equivalent to weak lower semicontinuity. That is epi $(\phi)$ is closed if and only if epi $(\phi)$ is weakly closed. In this case, the limit condition: If $x_{x} \rightarrow x$ weakly, then $\phi(x) \leq \liminf _{n \rightarrow \infty} \phi\left(x_{n}\right)$ is valid.

Proof: Suppose the limit condition holds. Why is epi $(\phi)$ closed? Why is $X \times(-\infty, \infty] \backslash$ epi $(\phi) \equiv$ epi $(\phi)^{C}$ open? Let $(x, \alpha) \in \operatorname{epi}(\phi)^{C}$. Then $\alpha<\phi(x), \alpha+\delta<\phi(x)$. Consider $B(x, r) \times\left(\alpha-\frac{\delta}{2}, \alpha+\frac{\delta}{2}\right)$. If every such open set contains a point of epi $(\phi)$, then there exists $x_{n} \rightarrow x, y_{n}<\alpha+\frac{\delta}{2}, y_{n} \geq \phi\left(x_{n}\right)$. Hence, from the limit condition,

$$
\phi(x) \leq \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \leq \lim \inf _{n \rightarrow \infty} y_{n} \leq \alpha+\frac{\delta}{2}<\alpha+\delta<\phi(x)
$$

a contradiction. It follows that there exists $r>0$ such that $B(x, r) \times\left(\alpha-\frac{\delta}{2}, \alpha+\frac{\delta}{2}\right) \cap$ epi $(\phi)=\emptyset$. Since epi $(\phi)^{C}$ is open, it follows that epi $(\phi)$ is closed.

Next suppose epi $(\phi)$ is closed. Why does the limit condition hold? Suppose $x_{n} \rightarrow x$. Then $\left(x_{n}, \phi\left(x_{n}\right)\right) \in \operatorname{epi}(\phi)$. There is a subsequence such that

$$
\alpha \equiv \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right)=\lim _{k \rightarrow \infty} \phi\left(x_{n_{k}}\right)
$$

and so $\left(x_{n_{k}}, \phi\left(x_{n_{k}}\right)\right) \rightarrow(x, \alpha)$. Since epi $(\phi)$ is closed, this means $(x, \alpha) \in \operatorname{epi}(\phi)$. Hence

$$
\alpha \equiv \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq \phi(x)
$$

Consider the last claim. In this case, epi $(\phi)$ is convex. If it is closed, then it is weakly closed thanks to separation theorems: If $(x, \alpha) \in \operatorname{epi}(\phi)^{C}$, then $\alpha<\infty$ and so there exists $\left(x^{*}, \beta\right) \in(X \times \mathbb{R})^{\prime}$ and $l$ such that for all $(t, \gamma) \in \operatorname{epi}(\phi)$,

$$
x^{*}(t)+\beta \gamma>l>x^{*}(x)+\alpha \beta
$$

Then $B_{\left(x^{*}, \beta\right)}((x, \alpha), \delta)$ is a weakly open set containing $(x, \alpha)$. For $\delta$ small enough, it does not intersect epi $(\phi)$ since if not so, there would exist $\left(t_{n}, \gamma_{n}\right) \in \operatorname{epi}(\phi) \cap B_{\left(x^{*}, \beta\right)}\left((x, \alpha), \frac{1}{n}\right)$ and so

$$
x^{*}\left(t_{n}\right)+\beta \gamma_{n} \rightarrow x^{*}(x)+\alpha \beta
$$

contrary to the above inequality. Thus epi $(\phi)$ is weakly closed. Also, if epi $(\phi)$ is weakly closed, then it is obviously strongly closed.

What of the limit condition using weak convergence instead of strong convergence? Say $x_{n} \rightarrow x$ weakly. Does it follow that if epi $(\phi)$ is weakly closed that $\phi(x) \leq \liminf _{n \rightarrow \infty} \phi\left(x_{n}\right)$ ? It is just as above. There is a subsequence such that

$$
\alpha \equiv \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right)=\lim _{k \rightarrow \infty} \phi\left(x_{n_{k}}\right)
$$

and so $\left(x_{n_{k}}, \phi\left(x_{n_{k}}\right)\right) \rightarrow(x, \alpha)$ weakly. Since epi $(\phi)$ is weakly closed, this means $(x, \alpha) \in$ epi $(\phi)$. Hence

$$
\alpha \equiv \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq \phi(x)
$$

There is also another convenient characterization of what it means for a function to be lower semicontinuous.

Lemma 25.7.46 Let $\phi: X \rightarrow(-\infty, \infty]$. Then $\phi$ is lower semicontinuous if and only if $\phi^{-1}((a, \infty])$ is open for any $a \in \mathbb{R}$.

Proof: Suppose first that epi $(\phi)$ is closed. Consider $x \in \phi^{-1}((a, \infty])$. Thus $\phi(x)>a$. Thus $(x, a) \in \operatorname{epi}(\phi)^{C}$ because $a<\phi(x)$. Since epi $(\phi)$ is closed, there exists $r, \varepsilon>0$ such that

$$
B(x, r) \times(a-\varepsilon, a+\varepsilon) \subseteq \operatorname{epi}(\phi)^{C}
$$

Hence if $y \in B(x, r)$, it follows that $\phi(y) \geq a+\varepsilon$ since otherwise there would be a point of epi $(\phi)^{C}$ in this open set $B(x, r) \times(a-\varepsilon, a+\varepsilon)$. Hence $B(x, r) \subseteq \phi^{-1}((a, \infty])$.

Conversely, suppose $\phi^{-1}((a, \infty])$ is open for any $a$ and let $(x, b) \in \operatorname{epi}(\phi)^{C}$. Then $\phi(x)>b$. Thus there exists $B(x, r)$ such that for $y \in B(x, r)$, it follows that $\phi(y)>b$. That is, $y \in \phi^{-1}((b, \infty])$. So consider $B(x, r) \times(-\infty, b)$. If $(y, \alpha) \in B(x, r) \times(-\infty, b)$, then since $\phi(y)>b, \alpha<\phi(y)$ and so there is no point of intersection between epi $(\phi)$ and this open set $B(x, r) \times(-\infty, b)$.

Of course one can define upper semicontinuous the same way that $\phi^{-1}(-\infty, a)$ is open. Thus a function is continuous if and only if it is both upper and lower semicontinuous.

In case $X$ is reflexive, the limit condition implies that epi $(\phi)$ is weakly closed. Suppose $(x, \alpha)$ is a weak limit point of epi $(\phi)$. Then by the Eberlein Smulian theorem, there is a subsequence of points of $X,\left(x_{n}, \alpha_{n}\right)$ which converges weakly to $(x, \alpha)$. Thus if the limit condition holds,

$$
\phi(x) \leq \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \leq \lim \inf _{n \rightarrow \infty} \alpha_{n}=\alpha
$$

and so $(x, \alpha) \in \mathrm{epi}(\phi)$. If $X$ is not reflexive, this isn't all that clear because it is not clear that a limit point is the limit of a sequence. However, one could consider a limit condition involving nets and get a similar result.

Definition 25.7.47 Let $\phi: X \rightarrow(-\infty, \infty]$ be convex lower semicontinuous, and proper. Then

$$
\partial \phi(x) \equiv\left\{x^{*}: \phi(y)-\phi(x) \geq\left\langle x^{*}, y-x\right\rangle \text { for all } y\right\}
$$

The domain of $\partial \phi$, denoted as $D(\partial \phi)$ is just the set of all $x$ for which $\partial \phi(x) \neq \emptyset$. Note that $D(\partial \phi) \subseteq D(\phi)$ since if $x \notin D(\phi)$, the defining inequality could not hold for all y because the left side would be $-\infty$ for some $y$.

Theorem 25.7.48 For $X$ a real Banach space, let $\phi(x) \equiv \frac{1}{2}\|x\|^{2}$. Then $F(x)=\partial \phi(x)$. Here $F$ was the set valued map satisfying $x^{*} \in F x$ means

$$
\left\|x^{*}\right\|=\|F x\|,\langle F x, x\rangle=\|x\|^{2}
$$

Proof: Let $x^{*} \in F(x)$. Then

$$
\begin{aligned}
\left\langle x^{*}, y-x\right\rangle & =\left\langle x^{*}, y\right\rangle-\left\langle x^{*}, x\right\rangle \\
& \leq\|x\|\|y\|-\|x\|^{2} \leq \frac{1}{2}\|y\|^{2}-\frac{1}{2}\|x\|^{2} .
\end{aligned}
$$

This shows $F(x) \subseteq \partial \phi(x)$.
Now let $x^{*} \in \partial \phi(x)$. Then for all $t \in \mathbb{R}$,

$$
\begin{equation*}
\left\langle x^{*}, t y\right\rangle=\left\langle x^{*},(t y+x)-x\right\rangle \leq \frac{1}{2}\left(\|x+t y\|^{2}-\|x\|^{2}\right) \tag{25.7.66}
\end{equation*}
$$

Now if $t>0$, divide both sides by $t$. This yields

$$
\begin{aligned}
\left\langle x^{*}, y\right\rangle & \leq \frac{1}{2 t}\left((\|x\|+t\|y\|)^{2}-\|x\|^{2}\right) \\
& =\frac{1}{2 t}\left(2 t\|x\|\|y\|+t^{2}\|y\|^{2}\right)
\end{aligned}
$$

Letting $t \rightarrow 0$,

$$
\begin{equation*}
\left\langle x^{*}, y\right\rangle \leq\|x\|\|y\| . \tag{25.7.67}
\end{equation*}
$$

Next suppose $t=-s$, where $s>0$ in 25.7.66. Then, since when you divide by a negative, you reverse the inequality, for $s>0$

$$
\begin{gather*}
\left\langle x^{*}, y\right\rangle \geq \frac{1}{2 s}\left[\|x\|^{2}-\|x-s y\|^{2}\right] \geq \\
\frac{1}{2 s}\left[\|x-s y\|^{2}-2\|x-s y\|\|s y\|+\|s y\|^{2}-\|x-s y\|\right]^{2}  \tag{25.7.68}\\
=\frac{1}{2 s}\left[-2\|x-s y\|\|s y\|+\|s y\|^{2}\right] \tag{25.7.69}
\end{gather*}
$$

Taking a limit as $s \rightarrow 0$ yields

$$
\begin{equation*}
\left\langle x^{*}, y\right\rangle \geq-\|x\|\|y\| . \tag{25.7.70}
\end{equation*}
$$

It follows from 25.7.70 and 25.7.67 that

$$
\left|\left\langle x^{*}, y\right\rangle\right| \leq\|x\|\|y\|
$$

and that, therefore, $\left\|x^{*}\right\| \leq\|x\|$ and $\left|\left\langle x^{*}, x\right\rangle\right| \leq\|x\|^{2}$. Now return to 25.7.69 and let $y=x$. Then

$$
\begin{aligned}
\left\langle x^{*}, x\right\rangle & \geq \frac{1}{2 s}\left[-2\|x-s x\|\|s x\|+\|s x\|^{2}\right] \\
& =-\|x\|^{2}(1-s)+s\|x\|^{2}
\end{aligned}
$$

Letting $s \rightarrow 1$,

$$
\left\langle x^{*}, x\right\rangle \geq\|x\|^{2}
$$

Since it was already shown that $\left|\left\langle x^{*}, x\right\rangle\right| \leq\|x\|^{2}$, this shows $\left\langle x^{*}, x\right\rangle=\|x\|^{2}$ and also $\left\|x^{*}\right\| \leq$ $\|x\|$. Thus

$$
\left\|x^{*}\right\| \geq\left\langle x^{*} \frac{x}{\|x\|}\right\rangle=\|x\|
$$

so in fact $x^{*} \in F(x)$.
The next result gives conditions under which the subgradient is onto. This means that if $y^{*} \in X^{\prime}$, then there exists $x \in X$ such that $y^{*} \in \partial \phi(x)$.

Theorem 25.7.49 Suppose $X$ is a reflexive Banach space and suppose $\phi: X \rightarrow(-\infty, \infty]$ is convex, proper, l.s.c., and for all $y^{*} \in X^{\prime}, x \rightarrow \phi(x)-\left\langle y^{*}, x\right\rangle$ is coercive,

$$
\lim _{\|x\| \rightarrow \infty} \phi(x)-\left\langle y^{*}, x\right\rangle=\infty
$$

Then $\partial \phi$ is onto.
Proof: The function $x \rightarrow \phi(x)-y^{*}(x) \equiv \psi(x)$ is convex, proper, l.s.c., and coercive. Let

$$
\lambda \equiv \inf \left\{\phi(x)-\left\langle y^{*}, x\right\rangle: x \in X\right\}
$$

and let $\left\{x_{n}\right\}$ be a minimizing sequence satisfying

$$
\lambda=\lim _{n \rightarrow \infty} \phi\left(x_{n}\right)-\left\langle y^{*}, x_{n}\right\rangle
$$

By coercivity,

$$
\lim _{\|x\| \rightarrow \infty} \phi(x)-\left\langle y^{*}, x\right\rangle=\infty
$$

and so this minimizing sequence is bounded. By the Eberlein Smulian theorem, Theorem 17.5.12, there is a weakly convergent subsequence $x_{n_{k}} \rightarrow x$. By Lemma 25.7.45,

$$
\lambda=\phi(x)-\left\langle y^{*}, x\right\rangle \leq \lim \inf _{k \rightarrow \infty} \phi\left(x_{n_{k}}\right)-\left\langle y^{*}, x_{n_{k}}\right\rangle=\lambda
$$

so there exists $x$ which minimizes $x \rightarrow \phi(x)-\left\langle y^{*}, x\right\rangle \equiv \psi(x)$. Therefore, $0 \in \partial \psi(x)$ because

$$
\psi(y)-\psi(x) \geq 0=\langle 0, y-x\rangle
$$

Thus, $0 \in \partial \psi(x)=\partial \phi(x)-y^{*}$.
Now let $\phi$ be a convex proper lower semicontinuous function defined on $X$ where $X$ is a reflexive Banach space with strictly convex norm. Consider $\partial \phi$. Is it maximal monotone?

Is it the case that $F+\partial \phi$ is onto? First of all, is $\partial \phi$ monotone? Let $x^{*} \in \partial \phi(x), y^{*} \in \partial \phi(y)$. Then

$$
\begin{aligned}
\phi(y)-\phi(x) & \geq\left\langle x^{*}, y-x\right\rangle \\
\phi(x)-\phi(y) & \geq\left\langle y^{*}, x-y\right\rangle
\end{aligned}
$$

Hence adding these yields

$$
\left\langle y^{*}-x^{*}, x-y\right\rangle \leq 0,\left\langle y^{*}-x^{*}, y-x\right\rangle \geq 0 .
$$

Yes, $\partial \phi$ is certainly monotone. Is it maximal monotone?
Theorem 25.7.50 Let $\phi$ be convex, proper, and lower semicontinuous on $X$ where $X$ is a reflexive Banach space having strictly convex norm. Then $\partial \phi$ is maximal monotone.

Proof: It is necessary to show that $F+\partial \phi$ is onto. To do this, let

$$
\psi(x) \equiv \frac{1}{2}\|x\|^{2}+\phi(x)-\left\langle y^{*}, x\right\rangle
$$

where $y^{*}$ is a given element of $X^{\prime}$ and the idea is to show that $y^{*} \in F(x)+\partial \phi(x)$ for some $x$. Then by separation theorems, $\phi(x) \geq b+\left\langle z^{*}, x\right\rangle$ for some $b, z^{*}$. Hence it is clear that $\psi$ is convex, lower semicontinuous and coercive in the sense that

$$
\lim _{\|x\| \rightarrow \infty} \psi(x)=\infty
$$

It follows that any minimizing sequence for $\psi$ is bounded. Hence by the weak lower semicontinuity, this function has a minimum at $x_{0}$ say. Thus

$$
\frac{1}{2}\left\|x_{0}\right\|^{2}+\phi\left(x_{0}\right)-\left\langle y^{*}, x_{0}\right\rangle \leq \frac{1}{2}\|x\|^{2}+\phi(x)-\left\langle y^{*}, x\right\rangle
$$

for all $x$. Then

$$
\frac{1}{2}\left\|x_{0}\right\|^{2}-\frac{1}{2}\|x\|^{2}+\left\langle y^{*}, x-x_{0}\right\rangle \leq \phi(x)-\phi\left(x_{0}\right)
$$

Now from Theorem 25.7.48,

$$
\left\langle F(x), x_{0}-x\right\rangle \leq \frac{1}{2}\left\|x_{0}\right\|^{2}-\frac{1}{2}\|x\|^{2}
$$

and so, the above reduces to

$$
\left\langle F(x), x_{0}-x\right\rangle+\left\langle y^{*}, x-x_{0}\right\rangle \leq \phi(x)-\phi\left(x_{0}\right)
$$

Next let $x=x_{0}+t\left(z-x_{0}\right), t \in(0,1)$, where $z$ is arbitary. Then

$$
-t\left\langle F\left(x_{0}+t\left(z-x_{0}\right)\right), z-x_{0}\right\rangle+t\left\langle y^{*}, z-x_{0}\right\rangle \leq \phi\left(x_{0}+t\left(z-x_{0}\right)\right)-\phi\left(x_{0}\right)
$$

and so, by convexity,

$$
-t\left\langle F\left(x_{0}+t\left(z-x_{0}\right)\right), z-x_{0}\right\rangle+t\left\langle y^{*}, z-x_{0}\right\rangle \leq(1-t) \phi\left(x_{0}\right)+t \phi(z)-\phi\left(x_{0}\right)
$$

$$
t\left\langle y^{*}, z-x_{0}\right\rangle \leq t\left(\phi(z)-\phi\left(x_{0}\right)\right)+t\left\langle F\left(x_{0}+t\left(z-x_{0}\right)\right), z-x_{0}\right\rangle
$$

Now cancel the $t$ on both sides to obtain

$$
\left\langle y^{*}, z-x_{0}\right\rangle \leq\left(\phi(z)-\phi\left(x_{0}\right)\right)+\left\langle F\left(x_{0}+t\left(z-x_{0}\right)\right), z-x_{0}\right\rangle
$$

By the fact that $F$ is hemicontinuous, actually demicontinuous, one can let $t \downarrow 0$ and obtain

$$
\left\langle y^{*}, z-x_{0}\right\rangle \leq\left(\phi(z)-\phi\left(x_{0}\right)\right)+\left\langle F\left(x_{0}\right), z-x_{0}\right\rangle
$$

This says that $y^{*}-F\left(x_{0}\right) \in \partial \phi\left(x_{0}\right)$ from the definition of what $\partial \phi\left(x_{0}\right)$ means.
There is a much harder approach to this theorem which is based on a theorem about when the subgradient of a sum equals the sum of the subgradients. This major theorem is given next. Much of the above is in [13] but I don't remember where I found the following proof.

Theorem 25.7.51 Let $\phi_{1}$ and $\phi_{2}$ be convex, l.s.c. and proper having values in $(-\infty, \infty]$. Then

$$
\begin{equation*}
\partial\left(\lambda \phi_{i}\right)(x)=\lambda \partial \phi_{i}(x), \partial\left(\phi_{1}+\phi_{2}\right)(x) \supseteq \partial \phi_{1}(x)+\partial \phi_{2}(x) \tag{25.7.71}
\end{equation*}
$$

if $\lambda>0$. If there exists $\bar{x} \in \operatorname{dom}\left(\phi_{1}\right) \cap \operatorname{dom}\left(\phi_{2}\right)$ and $\phi_{1}$ is continuous at $\bar{x}$ then for all $x \in X$,

$$
\begin{equation*}
\partial\left(\phi_{1}+\phi_{2}\right)(x)=\partial \phi_{1}(x)+\partial \phi_{2}(x) . \tag{25.7.72}
\end{equation*}
$$

Proof: 25.7 .71 is obvious so we only need to show 25.7.72. Suppose $\bar{x}$ is as described. It is clear 25.7.72 holds whenever $x \notin \operatorname{dom}\left(\phi_{1}\right) \cap \operatorname{dom}\left(\phi_{2}\right)$ since then $\partial\left(\phi_{1}+\phi_{2}\right)=\emptyset$. Therefore, assume

$$
x \in \operatorname{dom}\left(\phi_{1}\right) \cap \operatorname{dom}\left(\phi_{2}\right)
$$

in what follows. Let $x^{*} \in \partial\left(\phi_{1}+\phi_{2}\right)(x)$. Is $x^{*}$ is the sum of an element of $\partial \phi_{1}(x)$ and $\partial \phi_{2}(x)$ ? Does there exist $x_{1}^{*}$ and $x_{2}^{*}$ such that for every $y$,

$$
\begin{aligned}
x^{*}(y-x) & =x_{1}^{*}(y-x)+x_{2}^{*}(y-x) \\
& \leq \phi_{1}(y)-\phi_{1}(x)+\phi_{2}(y)-\phi_{2}(x) ?
\end{aligned}
$$

If so, then

$$
\phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x) \geq \phi_{2}(x)-\phi_{2}(y)
$$

Define

$$
\begin{aligned}
C_{1} \equiv & \left\{(y, a) \in X \times \mathbb{R}: \phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x) \leq a\right\}, \\
& C_{2} \equiv\left\{(y, a) \in X \times \mathbb{R}: a \leq \phi_{2}(x)-\phi_{2}(y)\right\} .
\end{aligned}
$$

I will show $\operatorname{int}\left(C_{1}\right) \cap C_{2}=\emptyset$ and then by Theorem 18.2.14 there exists an element of $X^{\prime}$ which does something interesting.

Both $C_{1}$ and $C_{2}$ are convex and nonempty. Say $y_{1}, y_{2} \in C_{1}$ and $t \in[0,1]$. Then

$$
\phi_{1}\left(\left(t y_{1}\right)+(1-t) y_{2}\right)-\phi_{1}(x)-x^{*}\left(\left(\left(t y_{1}\right)+(1-t) y_{2}\right)-x\right)
$$

$$
\begin{gathered}
\leq t \phi\left(y_{1}\right)+(1-t) \phi\left(y_{2}\right)-\left(t \phi_{1}(x)+(1-t) \phi(x)\right) \\
-\left(t x^{*}\left(y_{1}-x\right)+(1-t) x^{*}\left(y_{2}-x\right)\right) \\
\leq t a+(1-t) a=a
\end{gathered}
$$

so $C_{1}$ is indeed convex. The case of $C_{2}$ is similar.
$C_{1}$ is nonempty because it contains $\left(\bar{x}, \phi_{1}(\bar{x})-\phi_{1}(x)-x^{*}(\bar{x}-x)\right)$ since

$$
\phi_{1}(\bar{x})-\phi_{1}(x)-x^{*}(\bar{x}-x) \leq \phi_{1}(\bar{x})-\phi_{1}(x)-x^{*}(\bar{x}-x)
$$

$C_{2}$ is also nonempty because it contains $\left(\bar{x}, \phi_{2}(x)-\phi_{2}(\bar{x})\right)$ since

$$
\phi_{2}(x)-\phi_{2}(\bar{x}) \leq \phi_{2}(x)-\phi_{2}(\bar{x})
$$

In addition to this,

$$
\left(\bar{x}, \phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1\right) \in \operatorname{int}\left(C_{1}\right)
$$

due to the assumed continuity of $\phi_{1}$ at $\bar{x}$ and so $\operatorname{int}\left(C_{1}\right) \neq \emptyset$. If $(y, a) \in \operatorname{int}\left(C_{1}\right)$ then

$$
\phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x) \leq a-\varepsilon
$$

whenever $\varepsilon$ is small enough. Therefore, if $(y, a)$ is also in $C_{2}$, the assumption that $x^{*} \in$ $\partial\left(\phi_{1}+\phi_{2}\right)(x)$ implies

$$
a-\varepsilon \geq \phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x) \geq \phi_{2}(x)-\phi_{2}(y) \geq a
$$

a contradiction. Therefore $\operatorname{int}\left(C_{1}\right) \cap C_{2}=\emptyset$ and so by Theorem 18.2.14, there exists $\left(w^{*}, \boldsymbol{\beta}\right) \in X^{\prime} \times \mathbb{R}$ with

$$
\begin{equation*}
\left(w^{*}, \beta\right) \neq(0,0) \tag{25.7.73}
\end{equation*}
$$

and

$$
\begin{equation*}
w^{*}(y)+\beta a \geq w^{*}\left(y_{1}\right)+\beta a_{1}, \tag{25.7.74}
\end{equation*}
$$

whenever $(y, a) \in C_{1}$ and $\left(y_{1}, a_{1}\right) \in C_{2}$.
Claim: $\beta>0$.
Proof of claim: If $\beta<0$ let

$$
\begin{gathered}
a=\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1, \\
a_{1}=\phi_{2}(x)-\phi_{2}(\bar{x}), \text { and } y=y_{1}=\bar{x} .
\end{gathered}
$$

Then from 25.7.74

$$
\beta\left(\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1\right) \geq \beta\left(\phi_{2}(x)-\phi_{2}(\bar{x})\right) .
$$

Dividing by $\beta$ yields

$$
\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1 \leq \phi_{2}(x)-\phi_{2}(\bar{x})
$$

and so

$$
\begin{aligned}
\phi_{1}(\bar{x}) & +\phi_{2}(\bar{x})-\left(\phi_{1}(x)+\phi_{2}(x)\right)+1 \leq x^{*}(\bar{x}-x) \\
& \leq \phi_{1}(\bar{x})+\phi_{2}(\bar{x})-\left(\phi_{1}(x)+\phi_{2}(x)\right),
\end{aligned}
$$

a contradiction. Therefore, $\beta \geq 0$.
Now suppose $\beta=0$. Letting

$$
\begin{gathered}
a=\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1, \\
(\bar{x}, a) \in \operatorname{int}\left(C_{1}\right),
\end{gathered}
$$

and so there exists an open set $U$ containing 0 and $\eta>0$ such that

$$
\bar{x}+U \times(a-\eta, a+\eta) \subseteq C_{1} .
$$

Therefore, 25.7.74 applied to $(\bar{x}+z, a) \in C_{1}$ and $\left(\bar{x}, \phi_{2}(x)-\phi_{2}(\bar{x})\right) \in C_{2}$ for $z \in U$ yields

$$
w^{*}(\bar{x}+z) \geq w^{*}(\bar{x})
$$

for all $z \in U$. Hence $w^{*}(z)=0$ on $U$ which implies $w^{*}=0$, contradicting 25.7.73. This proves the claim.

Now with the claim, it follows $\beta>0$ and so, letting $z^{*}=w^{*} / \beta, 25.7 .74$ and Lemma 18.2.15 implies

$$
\begin{equation*}
z^{*}(y)+a \geq z^{*}\left(y_{1}\right)+a_{1} \tag{25.7.75}
\end{equation*}
$$

whenever $(y, a) \in C_{1}$ and $\left(y_{1}, a_{1}\right) \in C_{2}$. In particular,

$$
\begin{equation*}
\left(y, \phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x)\right) \in C_{1} \tag{25.7.76}
\end{equation*}
$$

because

$$
\phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x) \leq \phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x)
$$

and

$$
\begin{equation*}
\left(y_{1}, \phi_{2}(x)-\phi_{2}\left(y_{1}\right)\right) \in C_{2} . \tag{25.7.77}
\end{equation*}
$$

by similar reasoning so letting $y=x$,

$$
z^{*}(x)+(\overbrace{\phi_{1}(x)-x^{*}(x-x)-\phi_{1}(x)}^{=0}) \geq z^{*}\left(y_{1}\right)+\phi_{2}(x)-\phi_{2}\left(y_{1}\right) .
$$

Therefore,

$$
z^{*}\left(y_{1}-x\right) \leq \phi_{2}\left(y_{1}\right)-\phi_{2}(x)
$$

for all $y_{1}$ and so $z^{*} \in \partial \phi_{2}(x)$. Now let $y_{1}=x$ in 25.7.77 and using 25.7.75 and 25.7.76, it follows

$$
\begin{gathered}
z^{*}(y)+\phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x) \geq z^{*}(x) \\
\phi_{1}(y)-\phi_{1}(x) \geq x^{*}(y-x)-z^{*}(y-x)
\end{gathered}
$$

and so $x^{*}-z^{*} \in \partial \phi_{1}(x)$ so $x^{*}=z^{*}+\left(x^{*}-z^{*}\right) \in \partial \phi_{2}(x)+\partial \phi_{1}(x)$.

Corollary 25.7.52 Let $\phi: X \rightarrow(-\infty, \infty]$ be convex, proper, and lower semicontinuous. Here $X$ is a Banach space. Then $\partial \phi$ is maximal monotone.

Proof: Let $\psi(x)=\frac{1}{2}\|x\|^{2}$. There exists $x^{*}$ and some number $b$ such that $\phi(x) \geq$ $b+\left\langle x^{*}, x\right\rangle$. Therefore, $\psi+\phi$ is convex, lower semicontinuous, and bounded. It follows $\partial(\psi+\phi)$ is onto by Theorem 25.7.49. However, $\psi$ is continuous everywhere, in particular at every point of the domain of $\phi$. Therefore, $\partial \psi+\partial \phi=\partial(\phi+\psi)$ and by Theorem 25.7.48, this shows that $F+\partial \phi$ is onto.

It seems to me that the above are the most important results about convex proper lower semicontinuous functions. However, there are many other very interesting properties known.

Proposition 25.7.53 Let $\phi: X \rightarrow(-\infty, \infty]$ be convex proper and lower semicontinuous. Then $D(\partial \phi)$ is dense in $D(\phi)$ and so $\overline{D(\partial \phi)}=\overline{D(\phi)}$.

Proof: Let $x_{\lambda}$ be the solution to $0 \in F\left(x_{\lambda}-x\right)+\lambda \partial \phi\left(x_{\lambda}\right)$. Here $x \in D(\phi)$. Say $u_{\lambda}^{*} \in$ $\partial \phi\left(x_{\lambda}\right)$ such that the inclusion becomes an equality. Then

$$
\begin{aligned}
0 & =\left\langle F\left(x_{\lambda}-x\right)+\lambda u_{\lambda}^{*}, x_{\lambda}-x\right\rangle=\left\|x_{\lambda}-x\right\|^{2}-\lambda\left\langle u_{\lambda}^{*}, x-x_{\lambda}\right\rangle \\
& \geq\left\|x_{\lambda}-x\right\|^{2}-\lambda\left(\phi(x)-\phi\left(x_{\lambda}\right)\right)
\end{aligned}
$$

Hence, letting $z^{*}, b$ be such that $\phi(y) \geq b+\left\langle z^{*}, y-x\right\rangle$,

$$
\begin{gathered}
\lambda\left(\phi(x)-\left[b+\left\langle z^{*}, x_{\lambda}-x\right\rangle\right]\right) \geq \lambda\left(\phi(x)-\phi\left(x_{\lambda}\right)\right) \geq\left\|x_{\lambda}-x\right\|^{2} \\
\lambda \phi(x)-\lambda b \geq\left\|x_{\lambda}-x\right\|^{2}-\lambda\left\|z^{*}\right\|\left\|x_{\lambda}-x\right\| \\
\geq\left\|x_{\lambda}-x\right\|^{2}-\lambda\left(\frac{\left\|z^{*}\right\|^{2}}{2}+\frac{\left\|x_{\lambda}-x\right\|^{2}}{2}\right)
\end{gathered}
$$

Thus

$$
\lambda \phi(x)-\lambda b+\lambda \frac{\left\|z^{*}\right\|^{2}}{2} \geq\left(1-\frac{\lambda}{2}\right)\left\|x_{\lambda}-x\right\|^{2}
$$

It follows that $x_{\lambda} \rightarrow x$. This shows that $D(\phi) \subseteq \overline{D(\partial \phi)}$ and so $\overline{D(\phi)} \subseteq \overline{D(\partial \phi)} \subseteq \overline{D(\phi)}$.
There is a really amazing theorem, Moreau's theorem. It is in [24], [13] and [116]. It involves approximating a convex function with one which is differentiable, at least in the case where you have a Hilbert space. In the general case considered in this chapter, the function is continuous.

Theorem 25.7.54 Let $\phi$ be a convex lower semicontinuous proper function defined on $X$. Define $A \equiv \partial \phi, A_{\lambda}=(\partial \phi)_{\lambda}$

$$
\phi_{\lambda}(x) \equiv \min _{y \in X}\left(\frac{1}{2 \lambda}\|x-y\|^{2}+\phi(y)\right)
$$

Then the function is well defined, convex, Gateaux differentiable,

$$
D_{z} \phi_{\lambda}(x) \equiv \lim _{t \downarrow 0} \frac{\phi_{\lambda}(x+t z)-\phi_{\lambda}(x)}{t}=\left\langle A_{\lambda} x, z\right\rangle
$$

so the Gateaux derivative is just $A_{\lambda} x$ and for all $x \in X$,

$$
\lim _{\lambda \rightarrow 0} \phi_{\lambda}(x)=\phi(x)
$$

In addition,

$$
\begin{equation*}
\phi_{\lambda}(x)=\frac{1}{2 \lambda}\left\|x-J_{\lambda} x\right\|^{2}+\phi\left(J_{\lambda}(x)\right) \tag{25.7.78}
\end{equation*}
$$

where $J_{\lambda} x$ is as before, the solution to

$$
0 \in F\left(J_{\lambda} x-x\right)+\lambda \partial \phi\left(J_{\lambda} x\right)
$$

Proof: First of all, why does the minimum take place? By the convexity, closed epigraph, and assumption that $\phi$ is proper, separation theorems apply and one can say that there exists $z^{*}$ such that for all $y \in H$,

$$
\begin{equation*}
\frac{1}{2 \lambda}\|x-y\|^{2}+\phi(y) \geq \frac{1}{2 \lambda}\|x-y\|^{2}+\left(z^{*}, y\right)+c \tag{25.7.79}
\end{equation*}
$$

It follows easily that a minimizing sequence is bounded and so from lower semicontinuity which implies weak lower semicontinuity due to convexity, there exists $y_{x}$ such that

$$
\min _{y \in H}\left(\frac{1}{2 \lambda}\|x-y\|^{2}+\phi(y)\right)=\left(\frac{1}{2 \lambda}\left\|x-y_{x}\right\|^{2}+\phi\left(y_{x}\right)\right)
$$

Why is $\phi_{\lambda}$ convex? For $\theta \in[0,1]$,

$$
\begin{gathered}
\phi_{\lambda}(\theta x+(1-\theta) z) \equiv \frac{1}{2 \lambda}\left\|\theta x+(1-\theta) z-y_{(\theta x+(1-\theta) z)}\right\|^{2}+\phi\left(y_{\theta x+(1-\theta) z}\right) \\
\leq \frac{1}{2 \lambda}\left|\theta x+(1-\theta) z-\left(\theta y_{x}+(1-\theta) y_{z}\right)\right|^{2}+\phi\left(\theta y_{x}+(1-\theta) y_{z}\right) \\
\leq \frac{\theta}{2 \lambda}\left|x-y_{x}\right|^{2}+\frac{1-\theta}{2 \lambda}\left|z-y_{z}\right|^{2}+\theta \phi\left(y_{x}\right)+(1-\theta) \phi\left(y_{z}\right) \\
=\theta \phi_{\lambda}(x)+(1-\theta) \phi_{\lambda}(z)
\end{gathered}
$$

So is there a formula for $y_{x}$ ? Since it involves minimization of the functional, it follows that

$$
0 \in-\frac{1}{\lambda} F\left(x-y_{x}\right)+\partial \phi\left(y_{x}\right)=\frac{1}{\lambda} F\left(y_{x}-x\right)+\partial \phi\left(y_{x}\right)
$$

Recall that if $\psi(x)=\frac{1}{2}\|x\|^{2}$, then $\partial \psi(x)=F(x)$. Thus

$$
y_{x}=J_{\lambda} x
$$

because this was how $J_{\lambda} x$ was defined. Therefore,

$$
\phi_{\lambda}(x)=\frac{1}{2 \lambda}\left\|x-J_{\lambda} x\right\|^{2}+\phi\left(J_{\lambda}(x)\right)=\frac{\lambda}{2}\left\|A_{\lambda} x\right\|^{2}+\phi\left(J_{\lambda} x\right), A=\partial \phi
$$

It follows from this equation that

$$
\begin{equation*}
\phi\left(J_{\lambda} x\right) \leq \phi_{\lambda}(x) \leq \phi(x) \tag{25.7.80}
\end{equation*}
$$

the second inequality following from taking $y=x$ in the definition of $\phi_{\lambda}$.
Next consider the claim about $\phi_{\lambda}(x) \uparrow \phi(x)$. First suppose that $x \in D(\phi)$. Then from Proposition 25.7.53, $x \in \overline{D(\partial \phi)}$ and so from the material on approximations, Theorem 25.7.36, it follows that $J_{\lambda} x \rightarrow x$. Hence from 25.7.80 and lower semicontinuity of $\phi$,

$$
\phi(x) \leq \lim \inf _{\lambda \rightarrow 0} \phi\left(J_{\lambda} x\right) \leq \lim \inf _{\lambda \rightarrow 0} \phi_{\lambda}(x) \leq \lim \sup _{\lambda \rightarrow 0} \phi_{\lambda}(x) \leq \phi(x)
$$

showing that in this case, $\lim _{\lambda \rightarrow 0} \phi_{\lambda}(x)=\phi(x)$. Next suppose $x \notin D(\phi)$ so that $\phi(x)=\infty$. Why does $\phi_{\lambda}(x) \rightarrow \infty$ ? Suppose not. Then from the description of $\phi_{\lambda}$ given above and using the fact that the epigraph is closed and convex, there would exist a subsequence, still denoted as $\lambda$ such that

$$
C \geq \phi_{\lambda}(x)=\frac{1}{2 \lambda}\left\|x-J_{\lambda} x\right\|^{2}+\phi\left(J_{\lambda}(x)\right) \geq \frac{1}{2 \lambda}\left\|x-J_{\lambda} x\right\|^{2}+\left\langle z^{*}, x-J_{\lambda} x\right\rangle+b
$$

Then multiplying by $\lambda$, it follows that for a suitable constant $M$,

$$
\left\|x-J_{\lambda} x\right\|^{2} \leq M \lambda+\lambda M\left\|x-J_{\lambda} x\right\|
$$

and so a use of the quadratic formula implies

$$
\left\|x-J_{\lambda} x\right\| \leq \frac{M}{2}(1+\sqrt{5}) \lambda
$$

Hence $J_{\lambda} x \rightarrow x$ and so in 25.7.80 it follows from lower semicontinuity again that

$$
\infty=\phi(x) \leq \lim \inf _{\lambda \rightarrow 0} \phi\left(J_{\lambda} x\right) \leq \lim \inf _{\lambda \rightarrow 0} \phi_{\lambda}(x) \leq \lim \sup _{\lambda \rightarrow 0} \phi_{\lambda}(x) \leq \phi(x)
$$

and so again, $\lim _{\lambda \rightarrow 0} \phi_{\lambda}(x)=\infty$. Also note that if $\lambda>\mu$, then

$$
\min _{y \in X}\left(\frac{1}{2 \lambda}\|x-y\|^{2}+\phi(y)\right) \leq \min _{y \in X}\left(\frac{1}{2 \mu}\|x-y\|^{2}+\phi(y)\right)
$$

because for a given $y, \frac{1}{2 \lambda}\|x-y\|^{2}+\phi(y) \leq \frac{1}{2 \mu}\|x-y\|^{2}+\phi(y)$. Thus $\phi_{\lambda}(x) \uparrow \phi(x)$.
Next consider the claim about the Gateaux differentiability. Using the description 25.7.78

$$
\begin{gather*}
\phi_{\lambda}(y)-\phi_{\lambda}(x)= \\
\frac{1}{2 \lambda}\left\|y-J_{\lambda} y\right\|^{2}+\phi\left(J_{\lambda}(y)\right)-\left(\frac{1}{2 \lambda}\left\|x-J_{\lambda} x\right\|^{2}+\phi\left(J_{\lambda}(x)\right)\right) \tag{25.7.81}
\end{gather*}
$$

Using the fact that if $\psi(x)=\|x\|^{2}$, then $\partial \psi(x)=F x$, and that $A_{\lambda} x \in \partial \phi\left(J_{\lambda} x\right)$,

$$
\begin{aligned}
& \geq \lambda^{-1}\left\langle F\left(x-J_{\lambda}(x)\right),\left(y-J_{\lambda} y\right)-\left(x-J_{\lambda} x\right)\right\rangle+\left\langle A_{\lambda} x, J_{\lambda}(y)-J_{\lambda}(x)\right\rangle \\
& =\left\langle A_{\lambda}(x),\left(y-J_{\lambda} y\right)-\left(x-J_{\lambda} x\right)\right\rangle+\left\langle A_{\lambda} x, J_{\lambda}(y)-J_{\lambda}(x)\right\rangle=\left\langle A_{\lambda} x, y-x\right\rangle
\end{aligned}
$$

Hence

$$
\left(\phi_{\lambda}(y)-\phi_{\lambda}(x)\right)-\left\langle A_{\lambda} x, y-x\right\rangle \geq 0
$$

Also from 25.7.81

$$
\begin{aligned}
& \frac{1}{2 \lambda}\left\|y-J_{\lambda} y\right\|^{2}-\frac{1}{2 \lambda}\left\|x-J_{\lambda} x\right\|^{2}=-\left(\frac{1}{2 \lambda}\left\|x-J_{\lambda} x\right\|^{2}-\frac{1}{2 \lambda}\left\|y-J_{\lambda} y\right\|^{2}\right) \\
& \leq-\frac{1}{\lambda}\left\langle F\left(y-J_{\lambda} y\right),\left(x-J_{\lambda} x\right)-\left(y-J_{\lambda} y\right)\right\rangle=\left\langle A_{\lambda} y,\left(y-J_{\lambda} y\right)-\left(x-J_{\lambda} x\right)\right\rangle
\end{aligned}
$$

Similarly, from 25.7.81,

$$
\begin{gathered}
\phi\left(J_{\lambda}(y)\right)-\phi\left(J_{\lambda}(x)\right)=-\left(\phi\left(J_{\lambda}(x)\right)-\phi\left(J_{\lambda}(y)\right)\right) \\
\leq-\left\langle A_{\lambda}(y), J_{\lambda}(x)-J_{\lambda}(y)\right\rangle=\left\langle A_{\lambda}(y), J_{\lambda}(y)-J_{\lambda}(x)\right\rangle
\end{gathered}
$$

It follows that

$$
\begin{aligned}
& \left\langle A_{\lambda}(y), J_{\lambda}(y)-J_{\lambda}(x)\right\rangle+\left\langle A_{\lambda} y,\left(y-J_{\lambda} y\right)-\left(x-J_{\lambda} x\right)\right\rangle \\
\geq & \left(\phi_{\lambda}(y)-\phi_{\lambda}(x)\right) \geq\left\langle A_{\lambda} x, y-x\right\rangle
\end{aligned}
$$

and so

$$
\left\langle A_{\lambda}(y), y-x\right\rangle \geq\left(\phi_{\lambda}(y)-\phi_{\lambda}(x)\right) \geq\left\langle A_{\lambda} x, y-x\right\rangle
$$

Therefore,

$$
\left\langle A_{\lambda}(y)-A_{\lambda}(x), y-x\right\rangle \geq\left(\phi_{\lambda}(y)-\phi_{\lambda}(x)\right)-\left\langle A_{\lambda} x, y-x\right\rangle \geq 0
$$

Next let $y=x+t z$ for $t>0$. Then

$$
t\left\langle A_{\lambda}(x+t z)-A_{\lambda}(x), z\right\rangle \geq\left(\phi_{\lambda}(x+t z)-\phi_{\lambda}(x)\right)-t\left\langle A_{\lambda} x, z\right\rangle \geq 0
$$

Using the demicontinuity of $A_{\lambda}$, you can divide by $t$ and pass to a limit to obtain

$$
\lim _{t \downarrow 0} \frac{\phi_{\lambda}(x+t z)-\phi_{\lambda}(x)}{t}=\left\langle A_{\lambda} x, z\right\rangle
$$

A much better theorem is available in case $X=X^{\prime}=H$ a Hilbert space. In this case $\phi_{\lambda}$ is also Frechet differentiable. See Theorem 35.3 .24 which is presented later. Everything is much nicer in the Hilbert space setting because $F$ is just replaced with the identity and the approximations are defined more easily.

$$
\begin{aligned}
0 & \in J_{\lambda} x-x+\lambda A J_{\lambda} x, \\
x & \in J_{\lambda} x+\lambda A J_{\lambda} x=(I+\lambda A) J_{\lambda} x \\
J_{\lambda} x & =(I+\lambda A)^{-1} x
\end{aligned}
$$

Then one can show that $J_{\lambda}$ is Lipschitz continuous and many other nice things happen.
Next is an interesting result about when the sum of a maximal monotone operator and a subgradient is also maximal monotone. A version of this is well known in the case of a
single Hilbert space. In the case of a single Hilbert space, this result can be used to produce very regular solutions to evolution equations for functions which have values in the Hilbert space. You would get this by letting $X=X^{\prime}$ equal to a Hilbert space and your maximal monotone operator $A$ would be defined on $L^{2}(0, T ; H)=X$ a space of Hilbert space valued functions which are square integrable. Then you could take $L u=u^{\prime}$ with domain equal to those functions in $X$ which are equal to 0 at the left end of the interval for example. This is done more generally later. In this case the duality map is just the identity. The next theorem includes the case of two different spaces. I am not sure whether this is a useful result at this time, in terms of evolution equations. However, it is good to have conditions which show that the sum of two maximal monotone operators is maximal monotone.

Theorem 25.7.55 Let $X$ be a reflexive Banach space with strictly convex norm and let $\Phi$ be non negative, convex, proper, and lower semicontinuous. Suppose also that $A: D(A) \rightarrow$ $\mathscr{P}\left(X^{\prime}\right)$ is a maximal monotone operator and there exists

$$
\begin{equation*}
\xi \in D(A) \cap D(\Phi) . \tag{25.7.82}
\end{equation*}
$$

Suppose also that

$$
\begin{equation*}
\Phi\left(J_{\lambda} x\right) \leq \Phi(x)+C \lambda \tag{25.7.83}
\end{equation*}
$$

Then $A+\partial \Phi$ is maximal monotone.
Proof: Recall that

$$
A_{\lambda} x=-\lambda^{-1} F\left(J_{\lambda} x-x\right), \text { where } 0 \in F\left(J_{\lambda} x-x\right)+\lambda \partial A\left(J_{\lambda} x\right)
$$

Let $y^{*} \in X^{\prime}$. From Theorem 25.7.43 there exists $x_{\lambda} \in H$ such that

$$
y^{*} \in F x_{\lambda}+A_{\lambda} x_{\lambda}+\partial \Phi\left(x_{\lambda}\right)
$$

It is desired to show that $A_{\lambda} x_{\lambda}$ is bounded. From the above,

$$
\begin{equation*}
y^{*}-F x_{\lambda}-A_{\lambda} x_{\lambda} \in \partial \Phi\left(x_{\lambda}\right) \tag{25.7.84}
\end{equation*}
$$

and so

$$
\begin{equation*}
\left\langle y^{*}-F x_{\lambda}-A_{\lambda} x_{\lambda}, J_{\lambda} x_{\lambda}-x_{\lambda}\right\rangle \leq \Phi\left(J_{\lambda} x_{\lambda}\right)-\Phi\left(x_{\lambda}\right) \leq C \lambda \tag{25.7.85}
\end{equation*}
$$

which implies

$$
\left\langle y^{*}-F x_{\lambda}-A_{\lambda} x_{\lambda},(-\lambda) F^{-1}\left(A_{\lambda} x\right)\right\rangle \leq \Phi\left(J_{\lambda} x_{\lambda}\right)-\Phi\left(x_{\lambda}\right) \leq C \lambda
$$

and so

$$
\left\langle y^{*}-F x_{\lambda}-A_{\lambda} x_{\lambda},-F^{-1}\left(A_{\lambda} x\right)\right\rangle \leq C
$$

Hence

$$
\begin{equation*}
\left\langle y^{*}-F x_{\lambda},-F^{-1}\left(A_{\lambda} x_{\lambda}\right)\right\rangle+\left\|A_{\lambda} x_{\lambda}\right\|^{2} \leq C \tag{25.7.86}
\end{equation*}
$$

I claim $\left\{\left\|x_{\lambda}\right\|\right\}$ are bounded independent of $\lambda$.
By 25.7.84 and monotonicity of $A_{\lambda}$,

$$
\Phi(\xi)-\Phi\left(x_{\lambda}\right) \geq\left\langle y^{*}-F x_{\lambda}-A_{\lambda} x_{\lambda}, \xi-x_{\lambda}\right\rangle
$$

$$
\begin{gathered}
\geq\left\langle y^{*}-F x_{\lambda}, \xi-x_{\lambda}\right\rangle-\left\langle A_{\lambda} x_{\lambda}, \xi-x_{\lambda}\right\rangle \\
\geq\left\langle y^{*}-F x_{\lambda}, \xi-x_{\lambda}\right\rangle-\left\langle A_{\lambda} \xi, \xi-x_{\lambda}\right\rangle \\
=\left\langle y^{*}, \xi\right\rangle-\left\langle y^{*}, x_{\lambda}\right\rangle-\left\langle F x_{\lambda}, \xi\right\rangle+\left\|x_{\lambda}\right\|^{2}-\left\|\xi-x_{\lambda}\right\|\left\|A_{\lambda} \xi\right\| \\
\geq-\left\|y^{*}\right\|\|\xi\|-\left\|y^{*}\right\|\left\|x_{\lambda}\right\|-\left\|x_{\lambda}\right\|\|\xi\|-\|\xi\||A \xi|-\left\|x_{\lambda}\right\||A \xi|+\left\|x_{\lambda}\right\|^{2}
\end{gathered}
$$

Therefore, there exist constants, $C_{1}$ and $C_{2}$, depending on $\xi$ and $y^{*}$ but not on $\lambda$ such that

$$
\Phi(\xi) \geq \Phi\left(x_{\lambda}\right)+\left\|x_{\lambda}\right\|^{2}-C_{1}\left\|x_{\lambda}\right\|-C_{2} .
$$

Since $\Phi \geq 0$, the above shows that $\left\|x_{\lambda}\right\|$ is indeed bounded. Now from 25.7.86 it follows that $\left\{A_{\lambda} x_{\lambda}\right\}$ is bounded for small positive $\lambda$. By Theorem 25.7.43, there exists a solution $x$ to

$$
y^{*} \in F x+A x+\partial \Phi(x)
$$

and since $y^{*}$ is arbitrary, this shows that $A+\partial \Phi$ is maximal monotone.

### 25.8 Perturbation Theorems

In this section gives surjectivity of the sum of a pseudomonotone set valued map with a linear maximal monotone map and also with another maximal monotone operator added in. It generalizes the surjectivity results given earlier because one could have 0 for the maximal monotone linear operator. The theorems developed here lead to nice results on evolution equations because the linear maximal monotone operator can be something like a time derivative and $X$ can be some sort of an $L^{p}$ space for functions having values in a suitable Banach space. This is presented later in the material on Bochner integrals.

The notation $\left\langle z^{*}, u\right\rangle_{V^{\prime}, V}$ will mean $z^{*}(u)$ in this section. We will not worry about the order either. Thus

$$
\left\langle u, z^{*}\right\rangle \equiv z^{*}(u) \equiv\left\langle z^{*}, u\right\rangle
$$

This is just convenient in writing things down. Also, it is assumed that all Banach spaces are real to simplify the presentation. It is also usually assumed that the Banach spaces are reflexive. Thus we can regard

$$
\left(V \times V^{\prime}\right)^{\prime}=V^{\prime} \times V
$$

and $\left\langle\left(y^{*}, x\right),\left(u, v^{*}\right)\right\rangle \equiv\left\langle y^{*}, u\right\rangle+\left\langle x, v^{*}\right\rangle$. It is known [8] that for a reflexive Banach space, there is always an equivalent strictly convex norm. It is therefore, assumed that the norm for the reflexive Banach space is strictly convex.

Definition 25.8.1 Let $L: D(L) \subseteq V \rightarrow V^{\prime}$ be a linear map where we always assume $D(L)$ is dense in $V$. Then

$$
D\left(L^{*}\right) \equiv\{u \in V:|\langle L v, u\rangle| \leq C\|v\| \text { for all } v \in D(L)\}
$$

For such $u$, it follows that on a dense subset of $V$, namely $D(L), v \rightarrow\langle L z, u\rangle$ is a continuous linear map. Hence there exists a unique element of $V^{\prime}$, denoted as $L^{*} u$ such that for all $v \in D(L)$,

$$
\langle L v, u\rangle_{V^{\prime}, V}=\left\langle L^{*} u, v\right\rangle_{V^{\prime}, V}
$$

Thus

$$
\begin{aligned}
& L: D(L) \subseteq V \rightarrow V^{\prime} \\
& L^{*}: D\left(L^{*}\right) \subseteq V \rightarrow V^{\prime}
\end{aligned}
$$

There is an interesting description of $L^{*}$ in terms of $L$ which will be quite useful.
Proposition 25.8.2 Let $\tau: V \times V^{\prime} \rightarrow V^{\prime} \times V$ be given by $\tau(a, b) \equiv(-b, a)$. Also for $S \subseteq X$ a reflexive Banach space,

$$
S^{\perp} \equiv\left\{z^{*} \in X^{\prime}:\left\langle z^{*}, s\right\rangle=0 \text { for all } s \in S\right\}
$$

Also denote by $\mathscr{G}(L) \equiv\{(x, L x): x \in D(L)\}$. Then

$$
\mathscr{G}\left(L^{*}\right)=(\tau \mathscr{G}(L))^{\perp}
$$

Proof: Let $\left(x, L^{*} x\right) \in \mathscr{G}\left(L^{*}\right)$. This means that

$$
|\langle L y, x\rangle| \leq C\|y\| \text { for all } y \in D(L)
$$

and $\langle L y, x\rangle=\left\langle L^{*} x, y\right\rangle$ for all $y \in D(L)$. Let $(y, L y) \in \mathscr{G}(L)$. Then $\tau(y, L y)=(-L y, y)$. Then

$$
\left\langle\left(x, L^{*} x\right),(-L y, y)\right\rangle=\langle x,-L y\rangle+\left\langle L^{*} x, y\right\rangle=-\langle x, L y\rangle+\left\langle x, L^{*} y\right\rangle=0
$$

Thus $\mathscr{G}\left(L^{*}\right) \subseteq(\tau \mathscr{G}(L))^{\perp}$. Next suppose $\left(x, y^{*}\right) \in(\tau \mathscr{G}(L))^{\perp}$. This means that if $(u, L u) \in$ $\mathscr{G}(L)$, then

$$
\left\langle\left(x, y^{*}\right),(-L u, u)\right\rangle \equiv\langle x,-L u\rangle+\left\langle y^{*}, u\right\rangle=0
$$

and so for all $u \in D(L)$,

$$
\left\langle y^{*}, u\right\rangle=\langle x, L u\rangle
$$

and so $x \in D\left(L^{*}\right)$. Hence for all $u \in D(L)$,

$$
\left\langle y^{*}, u\right\rangle=\langle x, L u\rangle=\left\langle L^{*} x, u\right\rangle
$$

Then, since $D(L)$ is dense, it follows that $y^{*}=L^{*} x$ and so $(x, y) \in \mathscr{G}\left(L^{*}\right)$. Thus these are the same.

Theorem 25.5 .4 is a very nice surjectivity result for set valued pseudomonotone operators. We recall what it said here. Recall the meaning of coercive.

$$
\lim _{\|v\| \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, v\right\rangle}{\|v\|}: z^{*} \in T v\right\}=\infty
$$

In this section, we use the convenient notation $\left\langle z^{*}, x\right\rangle_{V^{\prime}, V} \equiv z^{*}(x)$.
Theorem 25.8.3 Let $V$ be a reflexive Banach space and let $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ be pseudomonotone, bounded and coercive. Then $T$ is onto. More generally, this continues to hold if $T$ is modified bounded pseudomonotone.

Recall the definition of pseudomonotone.

Definition 25.8.4 For $X$ a reflexive Banach space, we say $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ is pseudomonotone if the following hold.

1. The set $A u$ is nonempty, closed and convex for all $u \in X$.
2. If $F$ is a finite dimensional subspace of $X, u \in F$, and if $U$ is a weakly open set in $V^{\prime}$ such that $A u \subseteq U$, then there exists a $\delta>0$ such that if $v \in B_{\delta}(u) \cap F$ then $A v \subseteq U$. (Weakly upper semicontinuous on finite dimensional subspaces.)
3. If $u_{i} \rightarrow u$ weakly in $X$ and $u_{i}^{*} \in A u_{i}$ is such that

$$
\begin{equation*}
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle \leq 0 \tag{25.8.87}
\end{equation*}
$$

then, for each $v \in X$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\liminf _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle \tag{25.8.88}
\end{equation*}
$$

Also recall the definition of modified bounded pseudomonotone. It is just the above except that the limit condition is replaced with the following condition: If $u_{i} \rightarrow u$ weakly in $X$ and

$$
\begin{equation*}
\limsup _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-u\right\rangle \leq 0 \tag{25.8.89}
\end{equation*}
$$

then there exists a subsequence, still denoted as $\left\{u_{i}\right\}$ such that for each $v \in X$, there exists $u^{*}(v) \in A u$ such that

$$
\begin{equation*}
\lim \inf _{i \rightarrow \infty}\left\langle u_{i}^{*}, u_{i}-v\right\rangle \geq\left\langle u^{*}(v), u-v\right\rangle \tag{25.8.90}
\end{equation*}
$$

Also recall that this more general limit condition along with the assumption 1 and the assumption that $A$ is bounded is sufficient to obtain condition 2. This was Lemma 25.4.9 proved earlier and stated here for convenience.

Lemma 25.8.5 Let $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ satisfy conditions 1 and 3 above and suppose $A$ is bounded. Also suppose the condition that if $x_{n} \rightarrow x$ weakly and

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}, x_{n}-x\right\rangle \leq 0
$$

implies there exists a subsequence $\left\{x_{n_{k}}\right\}$ such that for any $y$,

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n_{k}}, x_{n_{k}}-y\right\rangle \geq\langle z(y), x-y\rangle
$$

for $z(y)$ some element of $A x$. Then if this weaker condition holds, you have that if $U$ is a weakly open set containing $A x$, then $A x_{n} \subseteq U$ for all $n$ large enough.

Definition 25.8.6 Now let $L: D(L) \subseteq V \rightarrow V^{\prime}$ such that $L$ is linear, monotone, $D(L)$ is dense in $V, L$ is closed, and $L^{*}$ is monotone. Let $A: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ be a bounded operator. Then $A$ is called $L$ pseudomonotone if $A v$ is closed and convex in $V^{\prime}$ and for any sequence $\left\{u_{n}\right\} \subseteq D(L)$ such that $u_{n} \rightarrow u$ weakly in $V$ and $L u_{n} \rightarrow L u$ weakly in $V^{\prime}$, and for $z_{n}^{*} \in A u_{n}$,

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}^{*}, u_{n}-u\right\rangle \leq 0
$$

then for every $v \in V$, there exists $z^{*}(v) \in A u$ such that

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}^{*}, u_{n}-v\right\rangle \geq\left\langle z^{*}(v), u-v\right\rangle
$$

It is called L modified bounded pseudomonotone if the above liminf condition holds for some subsequence whenever $u_{n} \rightarrow u$ weakly and $L u_{n} \rightarrow L u$ weakly and

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}^{*}, u_{n}-u\right\rangle \leq 0
$$

Lemma 25.8.7 Suppose $X$ is the Banach space

$$
X=D(L),\|u\|_{X} \equiv\|u\|_{V}+\|L u\|_{V^{\prime}}
$$

where $L$ is as described in the above definition. Also assume that $A$ is bounded. Then if $A$ is $L$ pseudomonotone, it follows that $A$ is pseudomonotone as a map from $X$ to $\mathscr{P}\left(X^{\prime}\right)$. If A is L modified bounded pseudomonotone, then $A$ is modified bounded pseudomonotone as a map from $X$ to $\mathscr{P}\left(X^{\prime}\right)$.

Proof: Is $A$ bounded? Of course, because the norm of $X$ is stronger than the norm on $V$. Is $A u$ convex and closed? This also follows because $X \subseteq V$. It is clear that $A u$ is convex. If $\left\{z_{n}\right\} \subseteq A u$ and $z_{n} \rightarrow z$ in $X^{\prime}$, then does it follow that $z \in A u$ ? Since $A$ is bounded, there is a further subsequence which converges weakly to $w$ in $V^{\prime}$. However, $A u$ is convex and closed so it is weakly closed. Hence $w \in A u$ and also $w=z$. It only remains to verify the pseudomonotone limit condition. Suppose then that $u_{n} \rightarrow u$ weakly in $X$ and for $z_{n}^{*} \in A u_{n}$,

$$
\lim \sup _{n \rightarrow \infty}\left\langle z_{n}^{*}, u_{n}-u\right\rangle \leq 0
$$

Then it follows that $L u_{n} \rightarrow L u$ weakly in $V^{\prime}$ and $u_{n} \rightarrow u$ weakly in $V$ so $u \in X$. Hence the assumption that $A$ is $L$ pseudomonotone implies that for every $v \in V$, and for every $v \in X$, there exists $z^{*}(v) \in A u \subseteq V^{\prime} \subseteq X^{\prime}$ such that

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}^{*}, u_{n}-v\right\rangle \geq\left\langle z^{*}(v), u-v\right\rangle
$$

The last claim goes the same way. You just have to take a subsequence.
Then we have the following major surjectivity result. In this theorem, we will assume for simplicity that all spaces are real spaces. Versions of this appear to be due to Brezis [23] and Lions [91]. Of course the theorem holds for complex spaces as well. You just need to use $\operatorname{Re}\rangle$ instead of $\rangle$.

Theorem 25.8.8 Let $L: D(L) \subseteq V \rightarrow V^{\prime}$ where $D(L)$ is dense, $L$ is monotone, $L$ is closed, and $L^{*}$ is monotone, L a linear map. Let $A: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ be L pseudomonotone, bounded, coercive. Then $L+A$ is onto. Here $V$ is a reflexive Banach space such that the norms for $V$ and $V^{\prime}$ are strictly convex. In case that $A$ is strictly monotone $(\langle A u-A v, u-v\rangle>0$ implies $u \neq v$ ) the solution $u$ to $f \in L u+A u$ is unique. If, in addition to this, $\langle A u-A v, u-v\rangle \geq$ $r\left(\|u-v\|_{U}\right)$ where $U$ is some Banach space containing $V$, and $r$ is a positive strictly increasing function for which $\lim _{t \rightarrow 0+} r(t)=0$, then the map $f \rightarrow u$ where $f \in L u+A u$ is continuous as a map from $V^{\prime}$ to $U$. The conclusion holds if $A$ is only $L$ modified bounded pseudomonotone.

Proof: Let $F$ be the duality map for $p=2$. Consider the Banach space $X$ given by

$$
X=D(L),\|u\|_{X} \equiv\|u\|_{V}+\|L u\|_{V^{\prime}}
$$

This is isometric with the graph of $L$ with the graph norm and so $X$ is reflexive. Now define a set valued map $G_{\varepsilon}$ on $X$ as follows. $z^{*} \in G_{\varepsilon}(u)$ means there exists $w^{*} \in A u$ such that.

$$
\left\langle z^{*}, v\right\rangle_{X^{\prime}, X}=\varepsilon\left\langle L v, F^{-1}(L u)\right\rangle_{V^{\prime}, V}+\langle L u, v\rangle_{V^{\prime}, V}+\left\langle w^{*}, v\right\rangle_{V^{\prime}, V}
$$

It follows from Lemma 25.8.7 that $G_{\varepsilon}$ is the sum of a set valued $L$ modified bounded pseudomonotone operator with an operator which is demicontinuous, bounded, and monotone, hence pseudomonotone. Thus by Lemma 25.5.2 it is $L$ modified bounded pseudomonotone. Is it coercive?

$$
\lim _{\|u\|_{X} \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, u\right\rangle+\varepsilon\left\langle L u, F^{-1}(L u)\right\rangle_{V^{\prime}, V}+\langle L u, u\rangle_{V^{\prime}, V}}{\|u\|_{X}}: z^{*} \in A u\right\}=\infty ?
$$

It equals

$$
\lim _{\|u\|_{X} \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, u\right\rangle+\varepsilon\left\langle F F^{-1}(L u), F^{-1}(L u)\right\rangle_{V^{\prime}, V}+\langle L u, u\rangle_{V^{\prime}, V}}{\|u\|_{X}}: z^{*} \in A u\right\}
$$

and this is

$$
\begin{aligned}
& \geq \lim _{\|u\|_{X} \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, u\right\rangle+\varepsilon\left\|F^{-1}(L u)\right\|_{V}^{2}}{\|u\|_{X}}: z^{*} \in A u\right\} \\
& =\lim _{\|u\|_{X} \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, u\right\rangle+\varepsilon\|L u\|_{V^{\prime}}^{2}}{\|u\|_{V}+\|L u\|_{V^{\prime}}}: z^{*} \in A u\right\}
\end{aligned}
$$

because $L$ is monotone. Now let $M$ be an arbitrary positive number. By assumption, there exists $R$ such that if $\|u\|_{V}>R$, then

$$
\inf \left\{\frac{\left\langle z^{*}, u\right\rangle}{\|u\|_{V}}: z^{*} \in A u\right\}>M
$$

and so for every $z^{*} \in A u$,

$$
\frac{\left\langle z^{*}, u\right\rangle}{\|u\|_{V}}>M,\left\langle z^{*}, u\right\rangle>M\|u\|_{V}
$$

Thus if $\|u\|_{V}>R$,

$$
\inf \left\{\frac{\left\langle z^{*}, u\right\rangle+\varepsilon\|L u\|_{V^{\prime}}^{2}}{\|u\|_{V}+\|L u\|_{V^{\prime}}}: z^{*} \in A u\right\} \geq \frac{M\|u\|_{V}+\varepsilon\|L u\|_{V^{\prime}}^{2}}{\|u\|_{V}+\|L u\|_{V^{\prime}}}
$$

I claim that if $\|u\|_{X}$ is large enough, the above is larger than $M / 2$. If not, then there exists $\left\{u_{n}\right\}$ such that $\left\|u_{n}\right\|_{X} \rightarrow \infty$ but the right side is less than $M / 2$. First say $\left\|L u_{n}\right\|$ is bounded.
then there is an obvious contradiction since the right hand side then converges to $M$. Thus it can be assumed that $\left\|L u_{n}\right\|_{V^{\prime}} \rightarrow \infty$. Hence, for all $n$ large enough, $\varepsilon\|L u\|_{V^{\prime}}^{2}>M\left\|L u_{n}\right\|_{V^{\prime}}$. However, this implies the right side is larger than

$$
\frac{M\left\|u_{n}\right\|_{V}+M\left\|L u_{n}\right\|_{V^{\prime}}}{\left\|u_{n}\right\|_{V}+\left\|L u_{n}\right\|_{V^{\prime}}}=M>M / 2
$$

This is a contradiction. Hence the right side is larger than $M / 2$ for all $n$ large enough. It follows since $M$ is arbitrary, that

$$
\lim _{\|u\|_{X} \rightarrow \infty} \inf \left\{\frac{\left\langle z^{*}, u\right\rangle+\varepsilon\|L u\|_{V^{\prime}}^{2}}{\|u\|_{V}+\|L u\|_{V^{\prime}}}: z^{*} \in A u\right\}=\infty
$$

It follows from Theorem 25.5.4 that if $f \in V^{\prime}$, there exists $u_{\varepsilon}$ such that for all $v \in$ $D(L)=X$,

$$
\begin{equation*}
\varepsilon\left\langle L v, F^{-1}\left(L u_{\varepsilon}\right)\right\rangle_{V^{\prime}, V}+\left\langle L u_{\varepsilon}, v\right\rangle_{V^{\prime}, V}+\left\langle w_{\varepsilon}^{*}, v\right\rangle_{V^{\prime}, V}=\langle f, v\rangle, w_{\varepsilon}^{*} \in A u_{\varepsilon} \tag{25.8.91}
\end{equation*}
$$

First we get an estimate.

$$
\begin{gathered}
\varepsilon\left\langle L u_{\varepsilon}, F^{-1}\left(L u_{\varepsilon}\right)\right\rangle_{V^{\prime}, V}+\left\langle L u_{\varepsilon}, u_{\varepsilon}\right\rangle_{V^{\prime}, V}+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle_{V^{\prime}, V}=\left\langle f, u_{\varepsilon}\right\rangle \\
\varepsilon\left\|L u_{\varepsilon}\right\|_{V^{\prime}}^{2}+\left\langle L u_{\varepsilon}, u_{\varepsilon}\right\rangle_{V^{\prime}, V}+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}\right\rangle_{V^{\prime}, V}=\left\langle f, u_{\varepsilon}\right\rangle
\end{gathered}
$$

Hence it follows from the coercivity of $A$ that $\left\|u_{\varepsilon}\right\|_{V}$ is bounded independent of $\varepsilon$. Thus the $w_{\varepsilon}^{*}$ are also bounded in $V^{\prime}$ because it is assumed that $A$ is bounded. Now from the equation solved 25.8.91, it follows that $F^{-1}\left(L u_{\varepsilon}\right) \in D\left(L^{*}\right)$. Thus the first term is just $\varepsilon\left\langle L^{*}\left(F^{-1}\left(L u_{\varepsilon}\right)\right), v\right\rangle_{V^{\prime}, V}$. It follows, since $D(L)=X$ is dense in $V$ that

$$
\begin{equation*}
\varepsilon L^{*}\left(F^{-1}\left(L u_{\varepsilon}\right)\right)+L u_{\varepsilon}+w_{\varepsilon}^{*}=f \tag{25.8.92}
\end{equation*}
$$

Then act on $F^{-1}\left(L u_{\varepsilon}\right)$ on both sides. From monotonicity of $L^{*}$, this yields $\left\|L u_{\varepsilon}\right\|_{V^{\prime}}$ is bounded independent of $\varepsilon>0$. Thus there is a subsequence still denoted with a subscript of $\varepsilon$ such that

$$
\begin{gathered}
u_{\varepsilon} \rightharpoonup u \text { in } V \\
L u_{\varepsilon} \rightharpoonup L u \text { in } V^{\prime}
\end{gathered}
$$

This because of the fact that the graph of $L$ is closed, hence weakly closed. Thus $u \in X$. Also

$$
w_{\varepsilon}^{*} \rightharpoonup w^{*} \text { in } V^{\prime} .
$$

It follows that we can pass to a limit in 25.8.92 and obtain

$$
\begin{equation*}
L u+w^{*}=f \tag{25.8.93}
\end{equation*}
$$

Now by assumption on $A$, it is $L$ modified bounded pseudomonotone and so there is a subsequence, still denoted as $u_{\mathcal{\varepsilon}}$ such that the liminf pseudomonotone limit condition holds. This will be what is referred to in what follows. Then

$$
\left\langle\varepsilon L^{*}\left(F^{-1}\left(L u_{\varepsilon}\right)\right), u_{\varepsilon}-u\right\rangle+\left\langle L u_{\varepsilon}, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle=\left\langle f, u_{\varepsilon}-u\right\rangle
$$

and so,

$$
\varepsilon\left\langle F^{-1}\left(L u_{\varepsilon}\right), L u_{\varepsilon}-L u\right\rangle+\left\langle L u_{\varepsilon}, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle=\left\langle f, u_{\varepsilon}-u\right\rangle
$$

using the monotonicity of $L$,

$$
\begin{gathered}
\varepsilon\left\langle L u_{\varepsilon}-L u, F^{-1}\left(L u_{\varepsilon}\right)-F^{-1}(L u)\right\rangle+\varepsilon\left\langle L u_{\varepsilon}-L u, F^{-1}(L u)\right\rangle \\
+\left\langle L u, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq\left\langle f, u_{\varepsilon}-u\right\rangle
\end{gathered}
$$

Now using monotonicity of $F^{-1}$,

$$
\varepsilon\left\langle L u_{\varepsilon}-L u, F^{-1}(L u)\right\rangle+\left\langle L u, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq\left\langle f, u_{\varepsilon}-u\right\rangle
$$

and so, passing to a limit as $\varepsilon \rightarrow 0$,

$$
\limsup _{\varepsilon \rightarrow 0}\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle \leq 0
$$

It follows that for all $v \in X=D(L)$ there exists $w^{*}(v) \in A u$

$$
\lim \inf _{\varepsilon \rightarrow 0}\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-v\right\rangle \geq\left\langle w^{*}(v), u-v\right\rangle
$$

But the left side equals

$$
\begin{aligned}
& \lim \inf _{\varepsilon \rightarrow 0}\left[\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle+\left\langle w_{\varepsilon}^{*}, u-v\right\rangle\right] \\
\leq \quad & \lim \sup _{\varepsilon \rightarrow 0}\left\langle w_{\varepsilon}^{*}, u_{\varepsilon}-u\right\rangle+\left\langle w^{*}, u-v\right\rangle \leq\left\langle w^{*}, u-v\right\rangle
\end{aligned}
$$

and so

$$
\left\langle w^{*}, u-v\right\rangle \geq\left\langle w^{*}(v), u-v\right\rangle
$$

for all $v$.
Is $w^{*} \in A u$ ? Suppose not. Then $A u$ is a closed convex set and $w^{*}$ is not in it. Hence, since $V$ is reflexive, there exists $z \in V$ such that whenever $y^{*} \in A u,\left\langle w^{*}, z\right\rangle<\left\langle y^{*}, z\right\rangle$. Now simply choose $v$ such that $u-v=z$ and it follows that

$$
\left\langle w^{*}(v), u-v\right\rangle>\left\langle w^{*}, u-v\right\rangle \geq\left\langle w^{*}(v), u-v\right\rangle
$$

which is clearly a contradiction. Hence $w^{*} \in A u$. Thus from 25.8.93, this has shown that $L+A$ is onto.

Consider the claim about uniqueness and continuous dependence. Say you have $f_{i} \in$ $L u_{i}+A u_{i}, i=1,2$. Let $z_{i}^{*} \in A u_{i}$ be such that equality holds in the two inclusions. Then

$$
f_{1}-f_{2}=z_{1}^{*}-z_{2}^{*}+L u_{1}-L u_{2}
$$

It follows that

$$
\left\langle f_{1}-f_{2}, u_{1}-u_{2}\right\rangle=\left\langle z_{1}^{*}-z_{2}^{*}+L u_{1}-L u_{2}, u_{1}-u_{2}\right\rangle \geq r\left(\left\|u_{1}-u_{2}\right\|\right)
$$

Thus if $f_{1}=f_{2}$, then $u_{1}=u_{2}$. If $f_{n} \rightarrow f$ in $V^{\prime}$, then $r\left(\left\|u-u_{n}\right\|\right) \rightarrow 0$ where $u_{n}$ goes with $f_{n}$ and $u$ with $f$ as just described, and so $u_{n} \rightarrow u$ because the coercivity estimate given above shows that the $u_{n}$ and $u$ are all bounded. Thus the map just described is continuous.

The following lemma is interesting in terms of the hypotheses of the above theorem. [23]

Lemma 25.8.9 Let $L: D(L) \rightarrow X^{\prime}$ where $D(L)$ is dense and $L$ is a closed operator. Then $L$ is maximal monotone if and only if both $L, L^{*}$ are monotone.

Proof: Suppose both $L, L^{*}$ are monotone. One must show that $\lambda F+L$ is onto. However, $F$ is monotone and hemicontinuous (actually demicontinuous) and coercive. Hence the fact that $\lambda F+L$ is onto follows from Theorem 25.8.8. Next suppose $L$ is maximal monotone. If $L$ is maximal monotone, then for every $\varepsilon>0$ there exists a solution $u_{\varepsilon}$ such that $\varepsilon L u_{\varepsilon}+$ $F\left(u_{\varepsilon}-u\right)=0$. Here $u \in D\left(L^{*}\right)$. This is from Lemma 25.7.28. It is originally due to Browder [26]. Then

$$
\varepsilon\left\langle L u_{\varepsilon}, u_{\varepsilon}\right\rangle+\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}\right\rangle=0
$$

and so $\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}\right\rangle \leq 0$. Then

$$
\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}-u\right\rangle \leq\left\langle F\left(u_{\varepsilon}-u\right), u\right\rangle
$$

so $\left\|u_{\varepsilon}-u\right\|^{2} \leq\left\|u_{\varepsilon}-u\right\|\|u\|$ and so

$$
\left\|u_{\varepsilon}-u\right\| \leq\|u\|
$$

Thus the $u_{\varepsilon}$ are bounded.
Next let $v \in D(L)$.

$$
\begin{gathered}
\left\|u_{\varepsilon}-u\right\|^{2}=\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}-u\right\rangle=\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}-v\right\rangle+\left\langle F\left(u_{\varepsilon}-u\right), v-u\right\rangle \\
\leq \varepsilon\left\langle L u_{\varepsilon}, v-u_{\varepsilon}\right\rangle+\left\langle F\left(u_{\varepsilon}-u\right), v-u\right\rangle \leq \varepsilon\left\langle L v, v-u_{\varepsilon}\right\rangle+\left\langle F\left(u_{\varepsilon}-u\right), v-u\right\rangle
\end{gathered}
$$

Hence

$$
\begin{aligned}
\lim \sup _{\varepsilon \rightarrow 0}\left\|u_{\varepsilon}-u\right\|^{2} & \leq \lim \sup _{\varepsilon \rightarrow 0}\left(\varepsilon\left\langle L v, v-u_{\varepsilon}\right\rangle+\left\langle F\left(u_{\varepsilon}-u\right), v-u\right\rangle\right) \\
& \leq \lim \sup _{\varepsilon \rightarrow 0}\left\langle F\left(u_{\varepsilon}-u\right), v-u\right\rangle \leq \lim \sup _{\varepsilon \rightarrow 0}\left\|u_{\varepsilon}-u\right\|\|v-u\|
\end{aligned}
$$

and so $u_{\varepsilon} \rightarrow u$ strongly. Also

$$
\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}\right\rangle=-\varepsilon\left\langle L u_{\varepsilon}, u_{\varepsilon}\right\rangle \leq 0
$$

Then

$$
\begin{gathered}
\left\langle L^{*} u, u\right\rangle=\lim _{\varepsilon \rightarrow 0}\left\langle L^{*} u, u_{\varepsilon}\right\rangle=\lim _{\varepsilon \rightarrow 0}\left\langle L u_{\varepsilon}, u\right\rangle=\lim _{\varepsilon \rightarrow 0} \frac{1}{\varepsilon}\left\langle-F\left(u_{\varepsilon}-u\right), u\right\rangle \\
=\lim _{\varepsilon \rightarrow 0} \frac{1}{\varepsilon}\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}-u\right\rangle-\lim _{\varepsilon \rightarrow 0} \frac{1}{\varepsilon}\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}\right\rangle
\end{gathered}
$$

Both of these last terms are nonnegative, the first obviously and the second from the above where it was shown that $\left\langle F\left(u_{\varepsilon}-u\right), u_{\varepsilon}\right\rangle \leq 0$.

In the hypotheses of Theorem 25.8 .8 , one could have simply said that $L$ is closed, linear, densely defined and maximal monotone. One can also show that if $L$ is maximal monotone, then it must be densely defined. This is done in [23].

One can go further in obtaining a perturbation theorem like the above. Let linear $L$ be densely defined with $L$ closed and $L, L^{*}$ monotone. In short, $L$ is densely defined and
maximal monotone, $L: X \rightarrow X^{\prime}$. Let $A$ be a set valued $L$ pseudomonotone operator which is coercive and bounded. Also let $B: D(B) \rightarrow \mathscr{P}(X)$ be maximal monotone. It is of interest to consider whether $L+A+B$ is onto $X^{\prime}$. In considering this, I will add further assumptions as needed. First note that $\langle L x, x\rangle=\langle L x-L 0, x-0\rangle \geq 0$.

Definition 25.8.10 Define $\limsup _{m, n \rightarrow \infty} a_{m, n} \equiv \lim _{k \rightarrow \infty} \sup \left\{a_{m, n}: \min (m, n) \geq k\right\}$
Then

$$
\lim \sup _{m, n \rightarrow \infty} a_{m, n} \geq \lim \sup _{m \rightarrow \infty}\left(\lim \sup _{n \rightarrow \infty} a_{m, n}\right)
$$

To see this, suppose $a>\limsup _{m, n \rightarrow \infty} a_{m, n}$. Then there exist $k$ such that whenever $m, n>k$,

$$
a_{m, n}<a
$$

It follows that for $m \geq k$,

$$
\lim \sup _{n \rightarrow \infty} a_{m, n} \leq a
$$

Hence

$$
\lim \sup _{m \rightarrow \infty}\left(\lim \sup _{n \rightarrow \infty} a_{m, n}\right) \leq a
$$

Since $a>\limsup _{m, n \rightarrow \infty} a_{m, n}$ is arbitrary, it follows that

$$
\lim \sup _{m \rightarrow \infty}\left(\lim \sup _{n \rightarrow \infty} a_{m, n}\right) \leq \lim \sup _{m, n \rightarrow \infty} a_{m, n}
$$

Then the following lemma is useful. I found this result in a paper by Gasinski, Migorski and Ochal [54]. They begin with the following interesting lemma or something like it which is similar to some of the ideas used in the section on approximation of maximal monotone operators.

Lemma 25.8.11 Suppose $A$ is a set valued operator, $A: X \rightarrow \mathscr{P}(X)$ and $u_{n}^{*} \in A u_{n}$. Suppose also that $u_{n} \rightarrow u$ weakly and $u_{n}^{*} \rightarrow u^{*}$ weakly. Suppose also that

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle u_{n}^{*}-u_{m}^{*}, u_{n}-u_{m}\right\rangle \leq 0
$$

Then one can conclude that

$$
\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}-u\right\rangle \leq 0
$$

Proof: Let $\alpha \equiv \lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}\right\rangle$. It is a finite number because these sequences are bounded. Then using the weak convergence,

$$
\begin{aligned}
0 & \geq \lim \sup _{m \rightarrow \infty}\left(\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}-u_{m}^{*}, u_{n}-u_{m}\right\rangle\right) \\
& =\lim \sup _{m \rightarrow \infty}\left(\lim \sup _{n \rightarrow \infty}\left(\left\langle u_{n}^{*}, u_{n}\right\rangle+\left\langle u_{m}^{*}, u_{m}\right\rangle-\left\langle u_{n}^{*}, u_{m}\right\rangle-\left\langle u_{m}^{*}, u_{n}\right\rangle\right)\right) \\
& =\lim \sup _{m \rightarrow \infty}\left(\alpha+\left\langle u_{m}^{*}, u_{m}\right\rangle-\left\langle u^{*}, u_{m}\right\rangle-\left\langle u_{m}^{*}, u\right\rangle\right) \\
& =\left(\alpha+\alpha-\left\langle u^{*}, u\right\rangle-\left\langle u^{*}, u\right\rangle\right)=2 \alpha-2\left\langle u^{*}, u\right\rangle
\end{aligned}
$$

Now

$$
\lim \sup _{n \rightarrow \infty}\left\langle u_{n}^{*}, u_{n}-u\right\rangle=\alpha-\left\langle u^{*}, u\right\rangle \leq 0
$$

To begin with, consider the approximate problem which is to determine whether $L+$ $A+B_{\lambda}$ is onto. Here $B_{\lambda} x=-\lambda^{-1} F\left(x_{\lambda}-x\right)$ where $0 \in F\left(x_{\lambda}-x\right)+\lambda B x$. In the notation given above, $B_{\lambda} x=-\lambda^{-1} F\left(J_{\lambda} x-x\right)$. Then by Theorem 25.7.36, $B_{\lambda}$ is monotone, demicontinuous, and bounded. In addition, we assume $0 \in D(B)$. Then

$$
\begin{equation*}
\left\langle B_{\lambda} x, x\right\rangle \geq\left\langle B_{\lambda} 0, x\right\rangle \geq-|B(0)|\|x\| \tag{25.8.94}
\end{equation*}
$$

Lemma 25.8.12 Let A be pseudomonotone, bounded and coercive and let $0 \in D(B)$. Then if $y^{*} \in X^{\prime}$, there exists a solution $x_{\lambda}$ to

$$
y^{*} \in L x_{\lambda}+A x_{\lambda}+B_{\lambda} x_{\lambda}
$$

Proof: From the inequality $25.8 .94, A+B_{\lambda}$ is coercive. It is also bounded and pseudomonotone. It is pseudomonotone from Theorem 25.7.27. Therefore, there exists a solution $x_{\lambda}$ by Theorem 25.8.8.

Acting on $x_{\lambda}$ and using the inequality 25.8 .94 , it follows that these solutions $x_{\lambda}$ lie in a bounded set. The details follow. Letting $z_{\lambda}^{*} \in A x_{\lambda}$ be such that equality holds in the above inclusion,

$$
\begin{align*}
& y^{*}=L x_{\lambda}+z_{\lambda}^{*}+B_{\lambda} x_{\lambda}  \tag{25.8.95}\\
&\left\|y^{*}\right\| \geq \frac{\left\langle y^{*}, x_{\lambda}\right\rangle}{\left\|x_{\lambda}\right\|}=\frac{\left\langle L x_{\lambda}, x_{\lambda}\right\rangle+\left\langle z_{\lambda}^{*}, x_{\lambda}\right\rangle+\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}\right\rangle}{\left\|x_{\lambda}\right\|} \\
& \geq \frac{\left\langle L x_{\lambda}, x_{\lambda}\right\rangle+\left\langle z_{\lambda}^{*}, x_{\lambda}\right\rangle-|B(0)|\left\|x_{\lambda}\right\|}{\left\|x_{\lambda}\right\|} \\
& \geq \frac{\left\langle z_{\lambda}^{*}, x_{\lambda}\right\rangle}{\left\|x_{\lambda}\right\|}-|B(0)|
\end{align*}
$$

Thus, from coercivity, $\left\|x_{\lambda}\right\|$ are bounded. Then since $A$ is bounded, the $z_{\lambda}^{*}$ are all bounded also independent of $\lambda$. The top line shows also that

$$
\begin{align*}
\left\langle y^{*}, x_{\lambda}\right\rangle & =\left\langle L x_{\lambda}, x_{\lambda}\right\rangle+\left\langle z_{\lambda}^{*}, x_{\lambda}\right\rangle+\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}\right\rangle \geq\left\langle z_{\lambda}^{*}, x_{\lambda}\right\rangle+\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}\right\rangle \\
& \geq\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}\right\rangle-\hat{M} \geq-|B(0)|\left\|x_{\lambda}\right\|-\hat{M} \tag{25.8.96}
\end{align*}
$$

where $\left|\left\langle z_{\lambda}^{*}, x_{\lambda}\right\rangle\right| \leq \hat{M}$ for all $\lambda$. Hence there is a constant $M$ such that

$$
\left|\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}\right\rangle\right| \leq M
$$

Definition 25.8.13 A set valued operator $B$ is quasi-bounded if whenever $x \in D(B)$ and $x^{*} \in B x$ are such that

$$
\left|\left\langle x^{*}, x\right\rangle\right|,\|x\| \leq M
$$

it follows that $\left\|x^{*}\right\| \leq K_{M}$. Bounded would mean that if $\|x\| \leq M$, then $\left\|x^{*}\right\| \leq K_{M}$. Here you only know this if there is another condition.

Lemma 25.8.14 In the above situation, suppose the maximal monotone operator $B$ is quasi-bounded and $\left|\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}\right\rangle\right| \leq M$. Then the $B_{\lambda} x_{\lambda}$ are bounded. Also

$$
\left\|J_{\lambda} x_{\lambda}-x_{\lambda}\right\|^{2} \leq M \lambda
$$

Proof: Now $B_{\lambda} x_{\lambda} \in B J_{\lambda} x_{\lambda}$

$$
\begin{gathered}
-|B(0)|\left\|x_{\lambda}\right\| \leq\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}\right\rangle=\left\langle B_{\lambda} x_{\lambda}, J_{\lambda} x_{\lambda}\right\rangle+\left\langle B_{\lambda} x_{\lambda}, x_{\lambda}-J_{\lambda} x_{\lambda}\right\rangle \\
=\left\langle B_{\lambda} x_{\lambda}, J_{\lambda} x_{\lambda}\right\rangle+\left\langle\lambda^{-1} F\left(J_{\lambda} x_{\lambda}-x_{\lambda}\right), J_{\lambda} x_{\lambda}-x_{\lambda}\right\rangle \\
=\left\langle B_{\lambda} x_{\lambda}, J_{\lambda} x_{\lambda}\right\rangle+\lambda^{-1}\left\|J_{\lambda} x_{\lambda}-x_{\lambda}\right\|^{2} \leq M
\end{gathered}
$$

This inequality shows that $J_{\lambda} x_{\lambda}-x_{\lambda} \rightarrow 0$ and so $J_{\lambda} x_{\lambda}$ is bounded as is $x_{\lambda}$ which was shown above. Also $B_{\lambda} x_{\lambda} \in B J_{\lambda} x_{\lambda}$ and since $B$ is quasi-bounded, it follows that $B_{\lambda} x_{\lambda}$ is bounded.

Assume from now on that $B$ is quasi-bounded. Then the estimate 25.8.96 and this lemma shows that $B_{\lambda} x_{\lambda}$ is also bounded independent of $\lambda$. Thus, adjusting the constants, there exists an estimate of the form

$$
\begin{equation*}
\left\|x_{\lambda}\right\|+\left\|J_{\lambda} x_{\lambda}\right\|+\left\|B_{\lambda} x_{\lambda}\right\|+\left\|z_{\lambda}^{*}\right\|+\left\|L x_{\lambda}\right\| \leq C, \quad\left\|x_{\lambda}-J_{\lambda} x_{\lambda}\right\| \leq \sqrt{\lambda} M \tag{25.8.97}
\end{equation*}
$$

Let $\lambda=1 / n$. Also denote by $J_{n}$ the the operator $J_{1 / n}$ to save notation. There exists a subsequence

$$
\begin{aligned}
& x_{n} \rightarrow x \text { weakly } \\
& J_{n} x_{n} \rightarrow x \text { weakly } \\
& B_{n} x_{n} \rightarrow g^{*} \text { weakly } \\
& z_{n}^{*} \rightarrow z^{*} \text { weakly } \\
& L x_{n} \rightarrow L x \text { weakly }
\end{aligned}
$$

Now from the inclusion satisfied,

$$
\begin{equation*}
0=\left\langle z_{n}^{*}-z_{m}^{*}, x_{n}-x_{m}\right\rangle+\left\langle B_{n} x_{n}-B_{m} x_{m}, x_{n}-x_{m}\right\rangle \tag{25.8.98}
\end{equation*}
$$

Consider that last term. $B_{n} x_{n} \in B J_{n} x_{n}$ similar for $B_{m} x_{m}$. Hence this term is of the form

$$
\begin{aligned}
& \left\langle B_{n} x_{n}-B_{m} x_{m}, x_{n}-x_{m}\right\rangle=\overbrace{\left\langle B_{n} x_{n}-B_{m} x_{m}, J_{n} x_{n}-J_{m} x_{m}\right\rangle}^{\geq 0} \\
& \quad+\left\langle B_{n} x_{n}-B_{m} x_{m},\left(x_{n}-J_{n} x_{n}\right)-\left(x_{m}-J_{m} x_{m}\right)\right\rangle
\end{aligned}
$$

From the estimate 25.8.97,

$$
\left\langle B_{n} x_{n}-B_{m} x_{m}, x_{n}-x_{m}\right\rangle \geq\left\langle B_{n} x_{n}-B_{m} x_{m},\left(x_{n}-J_{n} x_{n}\right)-\left(x_{m}-J_{m} x_{m}\right)\right\rangle
$$

and

$$
\left|\left\langle B_{n} x_{n}-B_{m} x_{m},\left(x_{n}-J_{n} x_{n}\right)-\left(x_{m}-J_{m} x_{m}\right)\right\rangle\right| \leq 2 C\left(\sqrt{\frac{1}{n}}+\sqrt{\frac{1}{m}}\right)
$$

Then from 25.8.98,

$$
0 \geq\left\langle z_{n}^{*}-z_{m}^{*}, x_{n}-x_{m}\right\rangle+e_{n, m}
$$

where $e_{n, m} \rightarrow 0$ as $n, m \rightarrow \infty$. Hence

$$
\lim \sup _{m, n \rightarrow \infty}\left\langle z_{n}^{*}-z_{m}^{*}, x_{n}-x_{m}\right\rangle \leq 0
$$

From Lemma 25.8.11,

$$
\limsup _{n \rightarrow \infty}\left\langle z_{n}^{*}, x_{n}-x\right\rangle \leq 0
$$

Hence, since $A$ is pseudomonotone, for every $y$, there exists $z^{*}(y) \in A x$ such that

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}^{*}, x_{n}-y\right\rangle \geq\left\langle z^{*}(y), x-y\right\rangle
$$

In particular, if $x=y$, this shows that

$$
\lim \inf _{n \rightarrow \infty}\left\langle z_{n}^{*}, x_{n}-x\right\rangle \geq 0 \geq \lim _{n \rightarrow \infty}\left\langle z_{n}^{*}, x_{n}-x\right\rangle
$$

showing that

$$
\lim _{n \rightarrow \infty}\left\langle z_{n}^{*}, x_{n}\right\rangle=\left\langle z^{*}, x\right\rangle
$$

Next, returning to the inclusion solved,

$$
0=L x_{n}+z_{n}^{*}+B_{n} x_{n}
$$

Act on $\left(x_{n}-x\right)$. Then from monotonicity of $L$,

$$
0 \geq\left\langle L x, x_{n}-x\right\rangle+\left\langle z_{n}^{*}, x_{n}-x\right\rangle+\left\langle B_{n} x_{n}, x_{n}-x\right\rangle
$$

Thus, taking limsup of both sides,

$$
\lim \sup _{n \rightarrow \infty}\left\langle B_{n} x_{n}, x_{n}-x\right\rangle=\lim \sup _{n \rightarrow \infty}\left\langle B_{n} x_{n}, J_{n} x_{n}-x\right\rangle \leq 0
$$

Hence

$$
\lim \sup _{n \rightarrow \infty}\left\langle B_{n} x_{n}, J_{n} x_{n}\right\rangle \leq\left\langle g^{*}, x\right\rangle
$$

Letting $\left[a, b^{*}\right] \in \mathscr{G}(B)$,

$$
\left\langle B_{n} x_{n}-b^{*}, J_{n} x_{n}-a\right\rangle=\left\langle B_{n} x_{n}, J_{n} x_{n}\right\rangle-\left\langle B_{n} x_{n}, a\right\rangle-\left\langle b^{*}, J_{n} x_{n}\right\rangle+\left\langle b^{*}, a\right\rangle
$$

Then taking limsup,

$$
\begin{aligned}
0 & \leq \lim \sup _{n \rightarrow \infty}\left\langle B_{n} x_{n}-b^{*}, J_{n} x_{n}-a\right\rangle \\
& \leq\left\langle g^{*}, x\right\rangle-\left\langle g^{*}, a\right\rangle-\left\langle b^{*}, x\right\rangle+\left\langle b^{*}, a\right\rangle=\left\langle g^{*}-b^{*}, x-a\right\rangle
\end{aligned}
$$

It follows that $g^{*} \in B(x)$ and $x \in D(B)$.
Thus, passing to the limit in the equation 25.8 .95 where, as explained $\lambda=1 / n$, one obtains

$$
y^{*}=L u+z^{*}+g^{*}
$$

where $z^{*} \in A x$ and $g^{*} \in B x$. This proves the following nice generalization of the above perturbation theorem.

Theorem 25.8.15 Let $B$ be maximal monotone from $X$ to $\mathscr{P}\left(X^{\prime}\right), 0 \in D(B)$, and $B$ is quasi-bounded as explained above. Let $A: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ be pseudomonotone, bounded, and coercive. Also let $L$ be a densely defined linear operator such that both $L$ and $L^{*}$ are monotone. (That is, $L$ is linear and maximal monotone.) Then $L+A+B$ is onto $X^{\prime}$.

## Integrals And Derivatives

### 26.1 The Fundamental Theorem Of Calculus

The version of the fundamental theorem of calculus found in Calculus has already been referred to frequently. It says that if $f$ is a Riemann integrable function, the function

$$
x \rightarrow \int_{a}^{x} f(t) d t
$$

has a derivative at every point where $f$ is continuous. It is natural to ask what occurs for $f$ in $L^{1}$. It is an amazing fact that the same result is obtained aside from a set of measure zero even though $f$, being only in $L^{1}$ may fail to be continuous anywhere. Proofs of this result are based on some form of the Vitali covering theorem presented above. In what follows, the measure space is $\left(\mathbb{R}^{n}, \mathscr{S}, m\right)$ where $m$ is $n$-dimensional Lebesgue measure although the same theorems can be proved for arbitrary Radon measures [84]. To save notation, $m$ is written in place of $m_{n}$.

By Lemma 12.1.9 on Page 278 and the completeness of $m$, the Lebesgue measurable sets are exactly those measurable in the sense of Caratheodory. Also, to save on notation $m$ is also the name of the outer measure defined on all of $\mathscr{P}\left(\mathbb{R}^{n}\right)$ which is determined by $m_{n}$. Recall

$$
\begin{equation*}
B(\mathbf{p}, r)=\{\mathbf{x}:|\mathbf{x}-\mathbf{p}|<r\} . \tag{26.1.1}
\end{equation*}
$$

Also define the following.

$$
\begin{equation*}
\text { If } B=B(\mathbf{p}, r), \text { then } \widehat{B}=B(\mathbf{p}, 5 r) \tag{26.1.2}
\end{equation*}
$$

The first version of the Vitali covering theorem presented above will now be used to establish the fundamental theorem of calculus. The space of locally integrable functions is the most general one for which the maximal function defined below makes sense.

Definition 26.1.1 $f \in L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$ means $f \mathscr{X}_{B(0, R)} \in L^{1}\left(\mathbb{R}^{n}\right)$ for all $R>0$. For $f \in L_{\text {loc }}^{1}\left(\mathbb{R}^{n}\right)$, the Hardy Littlewood Maximal Function, $M f$, is defined by

$$
M f(\mathbf{x}) \equiv \sup _{r>0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})| d y .
$$

Theorem 26.1.2 If $f \in L^{1}\left(\mathbb{R}^{n}\right)$, then for $\alpha>0$,

$$
\bar{m}([M f>\alpha]) \leq \frac{5^{n}}{\alpha}\|f\|_{1}
$$

(Here and elsewhere, $[M f>\alpha] \equiv\left\{\mathbf{x} \in \mathbb{R}^{n}: M f(\mathbf{x})>\alpha\right\}$ with other occurrences of [] being defined similarly.)

Proof: Let $S \equiv[M f>\alpha]$. For $\mathbf{x} \in S$, choose $r_{\mathbf{x}}>0$ with

$$
\frac{1}{m\left(B\left(\mathbf{x}, r_{\mathbf{x}}\right)\right)} \int_{B\left(\mathbf{x}, r_{\mathbf{x}}\right)}|f| d m>\alpha
$$

The $r_{\mathbf{x}}$ are all bounded because

$$
m\left(B\left(\mathbf{x}, r_{\mathbf{x}}\right)\right)<\frac{1}{\alpha} \int_{B\left(\mathbf{x}, r_{\mathbf{x}}\right)}|f| d m<\frac{1}{\alpha}\|f\|_{1}
$$

By the Vitali covering theorem, there are disjoint balls $B\left(\mathbf{x}_{i}, r_{i}\right)$ such that

$$
S \subseteq \cup_{i=1}^{\infty} B\left(\mathbf{x}_{i}, 5 r_{i}\right)
$$

and

$$
\frac{1}{m\left(B\left(\mathbf{x}_{i}, r_{i}\right)\right)} \int_{B\left(\mathbf{x}_{i}, r_{i}\right)}|f| d m>\alpha
$$

Therefore

$$
\begin{aligned}
\bar{m}(S) & \leq \sum_{i=1}^{\infty} m\left(B\left(\mathbf{x}_{i}, 5 r_{i}\right)\right)=5^{n} \sum_{i=1}^{\infty} m\left(B\left(\mathbf{x}_{i}, r_{i}\right)\right) \\
& \leq \frac{5^{n}}{\alpha} \sum_{i=1}^{\infty} \int_{B\left(\mathbf{x}_{i}, r_{i}\right)}|f| d m \\
& \leq \frac{5^{n}}{\alpha} \int_{\mathbb{R}^{n}}|f| d m
\end{aligned}
$$

the last inequality being valid because the balls $B\left(\mathbf{x}_{i}, r_{i}\right)$ are disjoint. This proves the theorem.

Note that at this point it is unknown whether $S$ is measurable. This is why $\bar{m}(S)$ and not $m(S)$ is written.

The following is the fundamental theorem of calculus from elementary calculus.
Lemma 26.1.3 Suppose $g$ is a continuous function. Then for all $\mathbf{x}$,

$$
\lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} g(\mathbf{y}) d y=g(\mathbf{x})
$$

Proof: Note that

$$
g(\mathbf{x})=\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} g(\mathbf{x}) d y
$$

and so

$$
\begin{aligned}
& \left|g(\mathbf{x})-\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} g(\mathbf{y}) d y\right| \\
= & \left|\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}(g(\mathbf{y})-g(\mathbf{x})) d y\right| \\
\leq & \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|g(\mathbf{y})-g(\mathbf{x})| d y .
\end{aligned}
$$

Now by continuity of $g$ at $\mathbf{x}$, there exists $r>0$ such that if $|\mathbf{x}-\mathbf{y}|<r,|g(\mathbf{y})-g(\mathbf{x})|<\varepsilon$. For such $r$, the last expression is less than

$$
\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} \varepsilon d y<\varepsilon
$$

This proves the lemma.

Definition 26.1.4 Let $f \in L^{1}\left(\mathbb{R}^{k}, m\right)$. A point, $\mathbf{x} \in \mathbb{R}^{k}$ is said to be a Lebesgue point if

$$
\limsup \sup _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m=0
$$

Note that if $\mathbf{x}$ is a Lebesgue point, then

$$
\lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} f(\mathbf{y}) d m=f(\mathbf{x})
$$

and so the symmetric derivative exists at all Lebesgue points.
Theorem 26.1.5 (Fundamental Theorem of Calculus) Let $f \in L^{1}\left(\mathbb{R}^{k}\right)$. Then there exists a set of measure $0, N$, such that if $\mathbf{x} \notin N$, then

$$
\lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d y=0
$$

Proof: Let $\lambda>0$ and let $\varepsilon>0$. By density of $C_{c}\left(\mathbb{R}^{k}\right)$ in $L^{1}\left(\mathbb{R}^{k}, m\right)$ there exists $g \in$ $C_{c}\left(\mathbb{R}^{k}\right)$ such that $\|g-f\|_{L^{1}\left(\mathbb{R}^{k}\right)}<\varepsilon$. Now since $g$ is continuous,

$$
\begin{aligned}
& \lim \sup _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m \\
= & \lim \sup _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m \\
& -\lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|g(\mathbf{y})-g(\mathbf{x})| d m
\end{aligned}
$$

$$
=\lim \sup _{r \rightarrow 0}\left(\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})|-|g(\mathbf{y})-g(\mathbf{x})| d m\right)
$$

$$
\leq \quad \lim \sup _{r \rightarrow 0}\left(\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}\|f(\mathbf{y})-f(\mathbf{x})|-| g(\mathbf{y})-g(\mathbf{x})\| d m\right)
$$

$$
\leq \quad \lim \sup _{r \rightarrow 0}\left(\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-g(\mathbf{y})-(f(\mathbf{x})-g(\mathbf{x}))| d m\right)
$$

$$
\leq \quad \lim \sup _{r \rightarrow 0}\left(\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-g(\mathbf{y})| d m\right)+|f(\mathbf{x})-g(\mathbf{x})|
$$

$$
\leq M([f-g])(\mathbf{x})+|f(\mathbf{x})-g(\mathbf{x})|
$$

Therefore,

$$
\begin{aligned}
& {\left[\mathbf{x}: \lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m>\lambda\right] } \\
\subseteq & {\left[M([f-g])>\frac{\lambda}{2}\right] \cup\left[|f-g|>\frac{\lambda}{2}\right] }
\end{aligned}
$$

Now

$$
\begin{aligned}
\varepsilon & >\int|f-g| d m \geq \int_{\left[|f-g|>\frac{\lambda}{2}\right]}|f-g| d m \\
& \geq \frac{\lambda}{2} m\left(\left[|f-g|>\frac{\lambda}{2}\right]\right)
\end{aligned}
$$

This along with the weak estimate of Theorem 26.1.2 implies

$$
\begin{aligned}
& m\left(\left[\mathbf{x}: \lim _{r \rightarrow 0} \sup _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m>\lambda\right]\right) \\
< & \left(\frac{2}{\lambda} 5^{k}+\frac{2}{\lambda}\right)\|f-g\|_{L^{1}\left(\mathbb{R}^{k}\right)} \\
< & \left(\frac{2}{\lambda} 5^{k}+\frac{2}{\lambda}\right) \varepsilon .
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, it follows

$$
m_{n}\left(\left[\mathbf{x}: \lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m>\lambda\right]\right)=0
$$

Now let

$$
N=\left[\mathbf{x}: \limsup _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m>0\right]
$$

and

$$
N_{n}=\left[\mathbf{x}: \limsup _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m>\frac{1}{n}\right]
$$

It was just shown that $m\left(N_{n}\right)=0$. Also, $N=\cup_{n=1}^{\infty} N_{n}$. Therefore, $m(N)=0$ also. It follows that for $\mathbf{x} \notin N$,

$$
\limsup \sup _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d m=0
$$

and this proves a.e. point is a Lebesgue point.
Of course it is sufficient to assume $f$ is only in $L_{l o c}^{1}\left(\mathbb{R}^{k}\right)$.
Corollary 26.1.6 (Fundamental Theorem of Calculus) Let $f \in L_{l o c}^{1}\left(\mathbb{R}^{k}\right)$. Then there exists a set of measure $0, N$, such that if $\mathbf{x} \notin N$, then

$$
\lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d y=0
$$

Proof: Consider $B(\mathbf{0}, n)$ where $n$ is a positive integer. Then $f_{n} \equiv f \mathscr{X}_{B(\mathbf{0}, n)} \in L^{1}\left(\mathbb{R}^{k}\right)$ and so there exists a set of measure $0, N_{n}$ such that if $\mathbf{x} \in B(\mathbf{0}, n) \backslash N_{n}$, then

$$
\begin{aligned}
& \lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}\left|f_{n}(\mathbf{y})-f_{n}(\mathbf{x})\right| d y \\
= & \lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d y=0 .
\end{aligned}
$$

Let $N=\cup_{n=1}^{\infty} N_{n}$. Then if $\mathbf{x} \notin N$, the above equation holds.

Corollary 26.1.7 If $f \in L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$, then

$$
\begin{equation*}
\lim _{r \rightarrow 0} \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} f(\mathbf{y}) d y=f(\mathbf{x}) \text { a.e. } \mathbf{x} \text {. } \tag{26.1.3}
\end{equation*}
$$

Proof:

$$
\begin{aligned}
& \left|\frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} f(\mathbf{y}) d y-f(\mathbf{x})\right| \\
\leq & \frac{1}{m(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d y
\end{aligned}
$$

and the last integral converges to 0 a.e. $\mathbf{x}$.
Definition 26.1.8 For $N$ the set of Theorem 26.1.5 or Corollary 26.1.6, $N^{C}$ is called the Lebesgue set or the set of Lebesgue points.

The next corollary is a one dimensional version of what was just presented.
Corollary 26.1.9 Let $f \in L^{1}(\mathbb{R})$ and let

$$
F(x)=\int_{-\infty}^{x} f(t) d t
$$

Then for a.e. $x, F^{\prime}(x)=f(x)$.
Proof: For $h>0$

$$
\frac{1}{h} \int_{x}^{x+h}|f(y)-f(x)| d y \leq 2\left(\frac{1}{2 h}\right) \int_{x-h}^{x+h}|f(y)-f(x)| d y
$$

By Theorem 26.1.5, this converges to 0 a.e. Similarly

$$
\frac{1}{h} \int_{x-h}^{x}|f(y)-f(x)| d y
$$

converges to 0 a.e. $x$.

$$
\begin{equation*}
\left|\frac{F(x+h)-F(x)}{h}-f(x)\right| \leq \frac{1}{h} \int_{x}^{x+h}|f(y)-f(x)| d y \tag{26.1.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\frac{F(x)-F(x-h)}{h}-f(x)\right| \leq \frac{1}{h} \int_{x-h}^{x}|f(y)-f(x)| d y . \tag{26.1.5}
\end{equation*}
$$

Now the expression on the right in 26.1.4 and 26.1.5 converges to zero for a.e. $x$. Therefore, by 26.1.4, for a.e. $x$ the derivative from the right exists and equals $f(x)$ while from 26.1.5 the derivative from the left exists and equals $f(x)$ a.e. It follows

$$
\lim _{h \rightarrow 0} \frac{F(x+h)-F(x)}{h}=f(x) \text { a.e. } x
$$

This proves the corollary.

### 26.2 Absolutely Continuous Functions

Definition 26.2.1 Let $[a, b]$ be a closed and bounded interval and let $F:[a, b] \rightarrow \mathbb{R}$. Then $F$ is said to be absolutely continuous if for every $\varepsilon>0$ there exists $\delta>0$ such that if $\sum_{i=1}^{m}\left|y_{i}-x_{i}\right|<\delta$ where the intervals $\left(x_{i}, y_{i}\right)$ are non-overlapping, then

$$
\sum_{i=1}^{m}\left|F\left(y_{i}\right)-F\left(x_{i}\right)\right|<\varepsilon
$$

Definition 26.2.2 A finite subset, $P$ of $[a, b]$ is called a partition of $[x, y] \subseteq[a, b]$ if $P=$ $\left\{x_{0}, x_{1}, \cdots, x_{n}\right\}$ where

$$
x=x_{0}<x_{1}<\cdots,<x_{n}=y .
$$

For $f:[a, b] \rightarrow \mathbb{R}$ and $P=\left\{x_{0}, x_{1}, \cdots, x_{n}\right\}$ define

$$
V_{P}[x, y] \equiv \sum_{i=1}^{n}\left|f\left(x_{i}\right)-f\left(x_{i-1}\right)\right| .
$$

Denoting by $\mathscr{P}[x, y]$ the set of all partitions of $[x, y]$ define

$$
V[x, y] \equiv \sup _{P \in \mathscr{P}[x, y]} V_{P}[x, y] .
$$

For simplicity, $V[a, x]$ will be denoted by $V(x)$. It is called the total variation of the function, $f$.

There are some simple facts about the total variation of an absolutely continuous function, $f$ which are contained in the next lemma.

Lemma 26.2.3 Let $f$ be an absolutely continuous function defined on $[a, b]$ and let $V$ be its total variation function as described above. Then $V$ is an increasing bounded function. Also if $P$ and $Q$ are two partitions of $[x, y]$ with $P \subseteq Q$, then $V_{P}[x, y] \leq V_{Q}[x, y]$ and if $[x, y] \subseteq[z, w]$,

$$
\begin{equation*}
V[x, y] \leq V[z, w] \tag{26.2.6}
\end{equation*}
$$

If $P=\left\{x_{0}, x_{1}, \cdots, x_{n}\right\}$ is a partition of $[x, y]$, then

$$
\begin{equation*}
V[x, y]=\sum_{i=1}^{n} V\left[x_{i}, x_{i-1}\right] \tag{26.2.7}
\end{equation*}
$$

Also if $y>x$,

$$
\begin{equation*}
V(y)-V(x) \geq|f(y)-f(x)| \tag{26.2.8}
\end{equation*}
$$

and the function, $x \rightarrow V(x)-f(x)$ is increasing. The total variation function, $V$ is absolutely continuous.

Proof: The claim that $V$ is increasing is obvious as is the next claim about $P \subseteq Q$ leading to $V_{P}[x, y] \leq V_{Q}[x, y]$. To verify this, simply add in one point at a time and verify that from the triangle inequality, the sum involved gets no smaller. The claim that $V$ is
increasing consistent with set inclusion of intervals is also clearly true and follows directly from the definition.

Now let $t<V[x, y]$ where $P_{0}=\left\{x_{0}, x_{1}, \cdots, x_{n}\right\}$ is a partition of $[x, y]$. There exists a partition, $P$ of $[x, y]$ such that $t<V_{P}[x, y]$. Without loss of generality it can be assumed that $\left\{x_{0}, x_{1}, \cdots, x_{n}\right\} \subseteq P$ since if not, you can simply add in the points of $P_{0}$ and the resulting sum for the total variation will get no smaller. Let $P_{i}$ be those points of $P$ which are contained in $\left[x_{i-1}, x_{i}\right]$. Then

$$
t<V_{p}[x, y]=\sum_{i=1}^{n} V_{P_{i}}\left[x_{i-1}, x_{i}\right] \leq \sum_{i=1}^{n} V\left[x_{i-1}, x_{i}\right] .
$$

Since $t<V[x, y]$ is arbitrary,

$$
\begin{equation*}
V[x, y] \leq \sum_{i=1}^{n} V\left[x_{i}, x_{i-1}\right] \tag{26.2.9}
\end{equation*}
$$

Note that 26.2.9 does not depend on $f$ being absolutely continuous. Suppose now that $f$ is absolutely continuous. Let $\delta$ correspond to $\varepsilon=1$. Then if $[x, y]$ is an interval of length no larger than $\delta$, the definition of absolute continuity implies

$$
V[x, y]<1
$$

Then from 26.2.9

$$
V[a, n \delta] \leq \sum_{i=1}^{n} V[a+(i-1) \delta, a+i \delta]<\sum_{i=1}^{n} 1=n
$$

Thus $V$ is bounded on $[a, b]$. Now let $P_{i}$ be a partition of $\left[x_{i-1}, x_{i}\right]$ such that

$$
V_{P_{i}}\left[x_{i-1}, x_{i}\right]>V\left[x_{i-1}, x_{i}\right]-\frac{\varepsilon}{n}
$$

Then letting $P=\cup P_{i}$,

$$
-\varepsilon+\sum_{i=1}^{n} V\left[x_{i-1}, x_{i}\right]<\sum_{i=1}^{n} V_{P_{i}}\left[x_{i-1}, x_{i}\right]=V_{P}[x, y] \leq V[x, y] .
$$

Since $\varepsilon$ is arbitrary, 26.2.7 follows from this and 26.2.9.
Now let $x<y$

$$
\begin{aligned}
V(y)-f(y)-(V(x)-f(x)) & =V(y)-V(x)-(f(y)-f(x)) \\
& \geq V(y)-V(x)-|f(y)-f(x)| \geq 0
\end{aligned}
$$

It only remains to verify that $V$ is absolutely continuous.
Let $\varepsilon>0$ be given and let $\delta$ correspond to $\varepsilon / 2$ in the definition of absolute continuity applied to $f$. Suppose $\sum_{i=1}^{n}\left|y_{i}-x_{i}\right|<\delta$ and consider $\sum_{i=1}^{n}\left|V\left(y_{i}\right)-V\left(x_{i}\right)\right|$. By 26.2.9 this last is no larger than $\sum_{i=1}^{n} V\left[x_{i}, y_{i}\right]$. Now let $P_{i}$ be a partition of $\left[x_{i}, y_{i}\right]$ such that $V_{P_{i}}\left[x_{i}, y_{i}\right]+$ $\frac{\varepsilon}{2 n}>V\left[x_{i}, y_{i}\right]$. Then by the definition of absolute continuity,

$$
\begin{aligned}
\sum_{i=1}^{n}\left|V\left(y_{i}\right)-V\left(x_{i}\right)\right| & =\sum_{i=1}^{n} V\left[x_{i}, y_{i}\right] \\
& \leq \sum_{i=1}^{n} V_{P_{i}}\left[x_{i}, y_{i}\right]+\eta<\varepsilon / 2+\varepsilon / 2=\varepsilon
\end{aligned}
$$

and shows $V$ is absolutely continuous as claimed.
Lemma 26.2.4 Suppose $f:[a, b] \rightarrow \mathbb{R}$ is absolutely continuous and increasing. Then $f^{\prime}$ exists a.e., is in $L^{1}([a, b])$, and

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t
$$

Proof: Define $L$, a positive linear functional on $C([a, b])$ by

$$
L g \equiv \int_{a}^{b} g d f
$$

where this integral is the Riemann Stieltjes integral with respect to the integrating function, $f$. By the Riesz representation theorem for positive linear functionals, there exists a unique Radon measure, $\mu$ such that $L g=\int g d \mu$. Now consider the following picture for $g_{n} \in$ $C([a, b])$ in which $g_{n}$ equals 1 for $x$ between $x+1 / n$ and $y$.

Then $g_{n}(t) \rightarrow \mathscr{X}_{(x, y]}(t)$ pointwise. Therefore, by the dominated convergence theorem,

$$
\mu((x, y])=\lim _{n \rightarrow \infty} \int g_{n} d \mu
$$

However,

$$
\begin{aligned}
& \left(f(y)-f\left(x+\frac{1}{n}\right)\right) \\
\leq & \int g_{n} d \mu=\int_{a}^{b} g_{n} d f \leq\left(f\left(y+\frac{1}{n}\right)-f(y)\right) \\
& +\left(f(y)-f\left(x+\frac{1}{n}\right)\right)+\left(f\left(x+\frac{1}{n}\right)-f(x)\right)
\end{aligned}
$$

and so as $n \rightarrow \infty$ the continuity of $f$ implies

$$
\mu((x, y])=f(y)-f(x) .
$$

Similarly, $\mu(x, y)=f(y)-f(y)$ and $\mu([x, y])=f(y)-f(x)$, the argument used to establish this being very similar to the above. It follows in particular that

$$
f(x)-f(a)=\int_{[a, x]} d \mu
$$

Note that up till now, no referrence has been made to the absolute continuity of $f$. Any increasing continuous function would be fine.

Now if $E$ is a Borel set such that $m(E)=0$, Then the outer regularity of $m$ implies there exists an open set, $V$ containing $E$ such that $m(V)<\delta$ where $\delta$ corresponds to $\varepsilon$ in the definition of absolute continuity of $f$. Then letting $\left\{I_{k}\right\}$ be the connected components of $V$ it follows $E \subseteq \cup_{k=1}^{\infty} I_{k}$ with $\sum_{k} m\left(I_{k}\right)=m(V)<\delta$. Therefore, from absolute continuity of $f$, it follows that for $I_{k}=\left(a_{k}, b_{k}\right)$ and each $n$

$$
\mu\left(\cup_{k=1}^{n} I_{k}\right)=\sum_{k=1}^{n} \mu\left(I_{k}\right)=\sum_{k=1}^{n}\left|f\left(b_{k}\right)-f\left(a_{k}\right)\right|<\varepsilon
$$

and so letting $n \rightarrow \infty$,

$$
\mu(E) \leq \mu(V)=\sum_{k=1}^{\infty}\left|f\left(b_{k}\right)-f\left(a_{k}\right)\right| \leq \varepsilon
$$

Since $\varepsilon$ is arbitrary, it follows $\mu(E)=0$. Therefore, $\mu \ll m$ and so by the Radon Nikodym theorem there exists a unique $h \in L^{1}([a, b])$ such that

$$
\mu(E)=\int_{E} h d m
$$

In particular,

$$
\mu([a, x])=f(x)-f(a)=\int_{[a, x]} h d m
$$

From the fundamental theorem of calculus $f^{\prime}(x)=h(x)$ at every Lebesgue point of $h$. Therefore, writing in usual notation,

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t
$$

as claimed. This proves the lemma.
With the above lemmas, the following is the main theorem about absolutely continuous functions.

Theorem 26.2.5 Let $f:[a, b] \rightarrow \mathbb{R}$ be absolutely continuous if and only if $f^{\prime}(x)$ exists a.e., $f^{\prime} \in L^{1}([a, b])$ and

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t
$$

Proof: Suppose first that $f$ is absolutely continuous. By Lemma 26.2.3 the total variation function, $V$ is absolutely continuous and $f(x)=V(x)-(V(x)-f(x))$ where both $V$ and $V-f$ are increasing and absolutely continuous. By Lemma 26.2.4

$$
\begin{aligned}
f(x)-f(a) & =V(x)-V(a)-[(V(x)-f(x))-(V(a)-f(a))] \\
& =\int_{a}^{x} V^{\prime}(t) d t-\int_{a}^{x}(V-f)^{\prime}(t) d t
\end{aligned}
$$

Now $f^{\prime}$ exists and is in $L^{1}$ becasue $f=V-(V-f)$ and $V$ and $V-f$ have derivatives in $L^{1}$. Therefore, $(V-f)^{\prime}=V^{\prime}-f^{\prime}$ and so the above reduces to

$$
f(x)-f(a)=\int_{a}^{x} f^{\prime}(t) d t
$$

This proves one half of the theorem.
Now suppose $f^{\prime} \in L^{1}$ and $f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t$. It is necessary to verify that $f$ is absolutely continuous. But this follows easily from Lemma 11.5.2 on Page 256 which implies that a single function, $f^{\prime}$ is uniformly integrable. This lemma implies that if $\sum_{i}\left|y_{i}-x_{i}\right|$ is sufficiently small then

$$
\sum_{i}\left|\int_{x_{i}}^{y_{i}} f^{\prime}(t) d t\right|=\sum_{i}\left|f\left(y_{i}\right)-f\left(x_{i}\right)\right|<\varepsilon .
$$

The following simple corollary is a case of Rademacher's theorem.
Corollary 26.2.6 Suppose $f:[a, b] \rightarrow \mathbb{R}$ is Lipschitz continuous,

$$
|f(x)-f(y)| \leq K|x-y|
$$

Then $f^{\prime}(x)$ exists a.e. and

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t
$$

Proof: It is easy to see that $f$ is absolutely continuous. Therefore, Theorem 26.2.5 applies.

### 26.3 Weak Derivatives

A related concept is that of weak derivatives. Let $\Omega \subseteq \mathbb{R}^{n}$. A distribution on $\Omega$ is defined to be a linear functional on $C_{c}^{\infty}(\Omega)$, called the space of test functions. The space of all such linear functionals will be denoted by $\mathscr{D}^{*}(\Omega)$. Actually, more is sometimes done here. One imposes a topology on $C_{c}^{\infty}(\Omega)$ making it into a topological vector space, and when this has been done, $\mathscr{D}^{\prime}(\Omega)$ is defined as the dual space of this topological vector space. To see this, consult the book by Yosida [127] or the book by Rudin [114].

Example: The space $L_{l o c}^{1}(\Omega)$ may be considered as a subset of $\mathscr{D}^{*}(\Omega)$ as follows.

$$
f(\phi) \equiv \int_{\Omega} f(\mathbf{x}) \phi(\mathbf{x}) d x
$$

for all $\phi \in C_{c}^{\infty}(\Omega)$. Recall that $f \in L_{l o c}^{1}(\Omega)$ if $f \mathscr{X}_{K} \in L^{1}(\Omega)$ whenever $K$ is compact.
The following lemma is the main result which makes this identification possible.
Lemma 26.3.1 Suppose $f \in L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$ and suppose

$$
\int f \phi d x=0
$$

for all $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. Then $f(\mathbf{x})=0$ a.e. $\mathbf{x}$.

Proof: Without loss of generality $f$ is real-valued. Let

$$
E \equiv\{\mathbf{x}: f(\mathbf{x})>\varepsilon\}
$$

and let

$$
E_{m} \equiv E \cap B(0, m)
$$

We show that $m\left(E_{m}\right)=0$. If not, there exists an open set, $V$, and a compact set $K$ satisfying

$$
\begin{gathered}
K \subseteq E_{m} \subseteq V \subseteq B(0, m), m(V \backslash K)<4^{-1} m\left(E_{m}\right), \\
\int_{V \backslash K}|f| d x<\varepsilon 4^{-1} m\left(E_{m}\right) .
\end{gathered}
$$

Let $H$ and $W$ be open sets satisfying

$$
K \subseteq H \subseteq \bar{H} \subseteq W \subseteq \bar{W} \subseteq V
$$

and let

$$
\bar{H} \prec g \prec W
$$

where the symbol, $\prec$, has the same meaning as it does in Chapter 12. Then let $\phi_{\delta}$ be a mollifier and let $h \equiv g * \phi_{\delta}$ for $\delta$ small enough that

$$
K \prec h \prec V .
$$

Thus

$$
\begin{aligned}
0 & =\int f h d x=\int_{K} f d x+\int_{V \backslash K} f h d x \\
& \geq \varepsilon m(K)-\varepsilon 4^{-1} m\left(E_{m}\right) \\
& \geq \varepsilon\left(m\left(E_{m}\right)-4^{-1} m\left(E_{m}\right)\right)-\varepsilon 4^{-1} m\left(E_{m}\right) \\
& \geq 2^{-1} \varepsilon m\left(E_{m}\right)
\end{aligned}
$$

Therefore, $m\left(E_{m}\right)=0$, a contradiction. Thus

$$
m(E) \leq \sum_{m=1}^{\infty} m\left(E_{m}\right)=0
$$

and so, since $\varepsilon>0$ is arbitrary,

$$
m(\{\mathbf{x}: f(\mathbf{x})>0\})=0 .
$$

Similarly $m(\{\mathbf{x}: f(\mathbf{x})<0\})=0$. This proves the lemma.
Example: $\delta_{x} \in \mathscr{D}^{*}(\Omega)$ where $\delta_{\mathbf{x}}(\phi) \equiv \phi(\mathbf{x})$.
It will be observed from the above two examples and a little thought that $\mathscr{D}^{*}(\Omega)$ is truly enormous. We shall define the derivative of a distribution in such a way that it agrees with the usual notion of a derivative on those distributions which are also continuously differentiable functions. With this in mind, let $f$ be the restriction to $\Omega$ of a smooth function defined on $\mathbb{R}^{n}$. Then $D_{x_{i}} f$ makes sense and for $\phi \in C_{c}^{\infty}(\Omega)$

$$
D_{x_{i}} f(\phi) \equiv \int_{\Omega} D_{x_{i}} f(\mathbf{x}) \phi(\mathbf{x}) d x=-\int_{\Omega} f D_{x_{i}} \phi d x=-f\left(D_{x_{i}} \phi\right)
$$

Motivated by this, here is the definition of a weak derivative.

Definition 26.3.2 For $T \in \mathscr{D}^{*}(\Omega)$

$$
D_{x_{i}} T(\phi) \equiv-T\left(D_{x_{i}} \phi\right)
$$

Of course one can continue taking derivatives indefinitely. Thus,

$$
D_{x_{i} x_{j}} T \equiv D_{x_{i}}\left(D_{x_{j}} T\right)
$$

and it is clear that all mixed partial derivatives are equal because this holds for the functions in $C_{c}^{\infty}(\Omega)$. Thus one can differentiate virtually anything, even functions that may be discontinuous everywhere. However the notion of "derivative" is very weak, hence the name, "weak derivatives".

Example: Let $\Omega=\mathbb{R}$ and let

$$
H(x) \equiv\left\{\begin{array}{l}
1 \text { if } x \geq 0 \\
0 \text { if } x<0
\end{array}\right.
$$

Then

$$
D H(\phi)=-\int H(x) \phi^{\prime}(x) d x=\phi(0)=\delta_{0}(\phi)
$$

Note that in this example, $D H$ is not a function.
What happens when $D f$ is a function?
Theorem 26.3.3 Let $\Omega=(a, b)$ and suppose that $f$ and $D f$ are both in $L^{1}(a, b)$. Then $f$ is equal to a continuous function a.e., still denoted by $f$ and

$$
f(x)=f(a)+\int_{a}^{x} D f(t) d t
$$

The proof of Theorem 26.3.3 depends on the following lemma.
Lemma 26.3.4 Let $T \in \mathscr{D}^{*}(a, b)$ and suppose $D T=0$. Then there exists a constant $C$ such that

$$
T(\phi)=\int_{a}^{b} C \phi d x
$$

Proof: $T(D \phi)=0$ for all $\phi \in C_{c}^{\infty}(a, b)$ from the definition of $D T=0$. Let

$$
\phi_{0} \in C_{c}^{\infty}(a, b), \int_{a}^{b} \phi_{0}(x) d x=1
$$

and let

$$
\psi_{\phi}(x)=\int_{a}^{x}\left[\phi(t)-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right] d t
$$

for $\phi \in C_{c}^{\infty}(a, b)$. Thus $\psi_{\phi} \in C_{c}^{\infty}(a, b)$ and

$$
D \psi_{\phi}=\phi-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}
$$

Therefore,

$$
\phi=D \psi_{\phi}+\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}
$$

and so

$$
T(\phi)=T\left(D \psi_{\phi}\right)+\left(\int_{a}^{b} \phi(y) d y\right) T\left(\phi_{0}\right)=\int_{a}^{b} T\left(\phi_{0}\right) \phi(y) d y
$$

Let $C=T \phi_{0}$. This proves the lemma.
Proof of Theorem 36.2.2 Since $f$ and $D f$ are both in $L^{1}(a, b)$,

$$
D f(\phi)-\int_{a}^{b} D f(x) \phi(x) d x=0
$$

Consider

$$
f(\cdot)-\int_{a}^{(\cdot)} D f(t) d t
$$

and let $\phi \in C_{c}^{\infty}(a, b)$.

$$
\begin{gathered}
D\left(f(\cdot)-\int_{a}^{(\cdot)} D f(t) d t\right)(\phi) \\
\equiv-\int_{a}^{b} f(x) \phi^{\prime}(x) d x+\int_{a}^{b}\left(\int_{a}^{x} D f(t) d t\right) \phi^{\prime}(x) d x \\
=D f(\phi)+\int_{a}^{b} \int_{t}^{b} D f(t) \phi^{\prime}(x) d x d t \\
=D f(\phi)-\int_{a}^{b} D f(t) \phi(t) d t=0
\end{gathered}
$$

By Lemma 36.2.3, there exists a constant, $C$, such that

$$
\left(f(\cdot)-\int_{a}^{(\cdot)} D f(t) d t\right)(\phi)=\int_{a}^{b} C \phi(x) d x
$$

for all $\phi \in C_{c}^{\infty}(a, b)$. Thus

$$
\int_{a}^{b}\left\{\left(f(x)-\int_{a}^{x} D f(t) d t\right)-C\right\} \phi(x) d x=0
$$

for all $\phi \in C_{c}^{\infty}(a, b)$. It follows from Lemma 26.3.1 in the next section that

$$
f(x)-\int_{a}^{x} D f(t) d t-C=0 \text { a.e. } x
$$

Thus we let $f(a)=C$ and write

$$
f(x)=f(a)+\int_{a}^{x} D f(t) d t
$$

This proves Theorem 36.2.2.

Theorem 36.2.2 says that

$$
f(x)=f(a)+\int_{a}^{x} D f(t) d t
$$

whenever it makes sense to write $\int_{a}^{x} D f(t) d t$, if $D f$ is interpreted as a weak derivative. Somehow, this is the way it ought to be. It follows from the fundamental theorem of calculus that $f^{\prime}(x)$ exists for a.e. $x$ in the classical sense where the derivative is taken in the sense of a limit of difference quotients and $f^{\prime}(x)=D f(x)$. This raises an interesting question. Suppose $f$ is continuous on $[a, b]$ and $f^{\prime}(x)$ exists in the classical sense for a.e. $x$. Does it follow that

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t ?
$$

The answer is no. You can build such an example from the Cantor function which is increasing and has a derivative a.e. which equals 0 a.e. and yet climbs from 0 to 1 . Thus this function is not recovered from integrating its classical derivative. Thus, in a sense weak derivatives are more agreeable than the classical ones.

### 26.4 Lipschitz Functions

Definition 26.4.1 A function $f:[a, b] \rightarrow \mathbb{R}$ is Lipschitz if there is a constant $K$ such that for all $x, y$,

$$
|f(x)-f(y)| \leq K|x-y|
$$

More generally, $f$ is Lipschitz on a subset of $\mathbb{R}^{n}$ iffor all $\mathbf{x}, \mathbf{y}$ in this set,

$$
|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

Lemma 26.4.2 Suppose $f:[a, b] \rightarrow \mathbb{R}$ is Lipschitz continuous and increasing. Then $f^{\prime}$ exists a.e., is in $L^{1}([a, b])$, and

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t
$$

If $f: \mathbb{R} \rightarrow \mathbb{R}$ is Lipschitz, then it is in $L_{\text {loc }}^{1}(\mathbb{R})$.
Proof: The Dini derivates are defined as follows.

$$
\begin{aligned}
D^{+} f(x) & \equiv \lim \sup _{h \rightarrow 0+} \frac{f(x+h)-f(x)}{h}, D_{+} f(x) \equiv \lim \inf _{h \rightarrow 0+} \frac{f(x+h)-f(x)}{h} \\
D^{-} f(x) & \equiv \lim \sup _{h \rightarrow 0+} \frac{f(x)-f(x-h)}{h}, D_{-} f(x) \equiv \lim \inf _{h \rightarrow 0+} \frac{f(x)-f(x-h)}{h}
\end{aligned}
$$

For convenience, just let $f$ equal $f(a)$ for $x<a$ and equal $f(b)$ for $x>b$. Let $(a, b)$ be an open interval and let

$$
N_{a b} \equiv\left\{x \in(a, b): D^{+} f(x)>q>p>D_{+} f(x)\right\}
$$

Let $V \subseteq(a, b)$ be an open set containing $N_{p q}$ such that $m(V)<m\left(N_{p q}\right)+\varepsilon$. By assumption, if $x \in N_{p q}$, there exist arbitrarily small $h$ such that

$$
\frac{f(x+h)-f(x)}{h}<p
$$

These intervals $[x, x+h]$ are then a Vitali covering of $N_{p q}$. It follows from Corollary 13.4.6 that there is a disjoint union of countably many, $\left\{\left[x_{i}, x_{i}+h_{i}\right]\right\}_{i=1}^{\infty}$ which cover all of $N_{p q}$ except for a set of measure zero. Thus also the open intervals $\left\{\left(x_{i}, x_{i}+h_{i}\right)\right\}_{i=1}^{\infty}$ also cover all of $N_{p q}$ except for a set of measure zero. Now for points $x^{\prime}$ of $N_{p q}$ so covered, there are arbitrarily small $h$ such that

$$
\frac{f\left(x^{\prime}+h^{\prime}\right)-f\left(x^{\prime}\right)}{h^{\prime}}>q
$$

and $\left[x^{\prime}, x^{\prime}+h^{\prime}\right]$ is contained in one of these original open intervals $\left(x_{i}, x_{i}+h_{i}\right)$. By the Vitali covering theorem again, Corollary 13.4.6, it follows that there exists a countable disjoint sequence $\left\{\left[x_{j}^{\prime}, x_{j}^{\prime}+h_{j}^{\prime}\right]\right\}_{j=1}^{\infty}$ which covers all of $N_{p q}$ except for a set of measure zero, each of these $\left[x_{j}^{\prime}, x_{j}^{\prime}+h_{j}^{\prime}\right]$ being contained in some $\left(x_{i}, x_{i}+h_{i}\right)$. Then it follows that

$$
\begin{aligned}
q m\left(N_{p q}\right) & \leq q \sum_{j} h_{j}^{\prime} \leq \sum_{j} f\left(x_{j}^{\prime}+h_{j}^{\prime}\right)-f\left(x_{j}^{\prime}\right) \leq \sum_{i} f\left(x_{i}+h_{i}\right)-f\left(x_{i}\right) \\
& \leq p \sum_{i} h_{i} \leq p m(V) \leq p\left(m\left(N_{p q}\right)+\varepsilon\right)
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this shows that $q m\left(N_{p q}\right) \leq p m\left(N_{p q}\right)$ and so $m\left(N_{p q}\right)=0$. Now taking the union of all $N_{p q}$ for $p, q \in \mathbb{Q}$, it follows that for a.e. $x, D^{+} f(x)=D_{+} f(x)$ and so the derivative from the right exists. Similar reasoning shows that off a set of measure zero the derivative from the left also exists. You just do the same argument using $D^{-} f(x)$ and $D_{-} f(x)$ to obtain the existence of a derivative from the left. Next you can use the same argument to verify that $D^{-} f(x)=D_{+} f(x)$ off a set of measure zero. This is outlined next. Define a new $N_{p q}$,

$$
N_{p q} \equiv\left\{x \in(a, b): D_{+} f(x)>q>p>D^{-} f(x)\right\}
$$

Let $V$ be an open set containing $N_{p q}$ such that $m(V)<m\left(N_{p q}\right)+\varepsilon$. For each $x \in N_{p q}$ there are arbitrarily small $h$ such that

$$
\frac{f(x)-f(x-h)}{h}<p
$$

Then as before, there is a countable disjoint sequence of closed intervals contained in $V,\left\{\left[x_{i}-h_{i}, x_{i}\right]\right\}_{i=1}^{\infty}$ such that their union includes all of $N_{p q}$ except a set of measure zero. Thus this is also true of the open intervals $\left\{\left(x_{i}-h_{i}, x_{i}\right)\right\}_{i=1}^{\infty}$. Then for the points of $N_{p q}$ covered by these open intervals $x^{\prime}$, there are arbitrarily small $h^{\prime}$ such that

$$
\frac{f\left(x^{\prime}+h^{\prime}\right)-f\left(x^{\prime}\right)}{h^{\prime}}>q
$$

and each $\left[x^{\prime}, x^{\prime}+h^{\prime}\right]$ is contained in an interval $\left(x_{i}-h_{i}, x_{i}\right)$. Then by the Vitali covering theorem again, Corollary 13.4.6 there are countably many disjoint closed intervals $\left\{\left[x_{j}^{\prime}, x_{j}^{\prime}+h_{j}^{\prime}\right]\right\}_{j=1}^{\infty}$ whose union includes all of $N_{p q}$ except for a set of measure zero such that each of these is contained in some $\left(x_{i}-h_{i}, x_{i}\right)$ described earlier. Then as before,

$$
\begin{aligned}
q m\left(N_{p q}\right) & \leq q \sum_{j} h_{j}^{\prime} \leq \sum_{j} f\left(x_{j}^{\prime}+h_{j}^{\prime}\right)-f\left(x_{j}^{\prime}\right) \leq \sum_{i} f\left(x_{i}\right)-f\left(x_{i}-h_{i}\right) \\
& \leq p \sum_{i} h_{i} \leq p m(V) \leq p\left(m\left(N_{p q}\right)+\varepsilon\right)
\end{aligned}
$$

Then as before, this shows that $q m\left(N_{p q}\right) \leq p m\left(N_{p q}\right)$ and so $m\left(N_{p q}\right)=0$. Then taking the union of all such for $p, q \in \mathbb{Q}$ yields $D_{+} f(x)=D^{-} f(x)$ for a.e. $x$. Taking the union of all these sets of measure zero and considering points not in this union, it follows that $f^{\prime}(x)$ exists for a.e. $x$. Thus $f^{\prime}(t) \geq 0$ and is a limit of measurable even continuous functions for a.e. $x$ so $f^{\prime}$ is clearly measurable. The issue is whether $f(y)-f(x)=\int \mathscr{X}_{[x, y]}(t) f^{\prime}(t) d m$. Up to now, the only thing used has been that $f$ is increasing.

Let $h>0$.

$$
\begin{aligned}
\int_{a}^{x} \frac{f(t)-f(t-h)}{h} d t & =\frac{1}{h} \int_{a}^{x} f(t) d t-\frac{1}{h} \int_{a}^{x} f(t-h) d t \\
& =\frac{1}{h} \int_{a}^{x} f(t) d t-\frac{1}{h} \int_{a-h}^{x-h} f(t) d t \\
& =\frac{1}{h} \int_{x-h}^{x} f(t) d t-\frac{1}{h} \int_{a-h}^{a} f(t) d t \\
& =\frac{1}{h} \int_{x-h}^{x} f(t) d t-f(a)
\end{aligned}
$$

Therefore, by continuity of $f$ it follows from Fatou's lemma that

$$
\int_{a}^{x} D_{-} f(t) d t=\int_{a}^{x} f^{\prime}(t) d t \leq \lim \inf _{h \rightarrow 0+} \int_{a}^{x} \frac{f(t)-f(t-h)}{h} d t=f(x)-f(a)
$$

and this shows that $f^{\prime}$ is in $L^{1}$. This part only used the fact that $f$ is increasing and continuous. That $f$ is Lipschitz has not been used.

If it were known that there is a dominating function for $t \rightarrow \frac{f(t)-f(t-h)}{h}$, then you could simply apply the dominated convergence theorem in the above inequality instead of Fatou's lemma and get the desired result. But from Lipschitz continuity, you have

$$
\left|\frac{f(t)-f(t-h)}{h}\right| \leq K
$$

and so one can indeed apply the dominated convergence theorem and conclude that

$$
\int_{a}^{x} f^{\prime}(t) d t=f(x)-f(a)
$$

The last claim follows right away from consideration of intervals since the restriction of a Lipschitz function is Lipschitz.

With the above lemmas, the following is the main theorem about absolutely continuous functions.

The following simple corollary is a case of Rademacher's theorem.
Corollary 26.4.3 Suppose $f:[a, b] \rightarrow \mathbb{R}$ is Lipschitz continuous,

$$
|f(x)-f(y)| \leq K|x-y|
$$

Then $f^{\prime}(x)$ exists a.e. and

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t
$$

Proof: If $f$ were increasing, this would follow from the above lemma. Let $g(x)=$ $2 K x-f(x)$. Then $g$ is Lipschitz with a different Lipschitz constant and also if $x<y$,

$$
\begin{aligned}
& g(y)-g(x)=2 K y-f(y)-(2 K x-f(x)) \\
& \quad \geq 2 K(y-x)-K|y-x|=k|y-x| \geq 0
\end{aligned}
$$

and so Lemma 26.4.2 applies to $g$ and this shows that $f^{\prime}(t)$ exists for a.e. $t$ and $g^{\prime}(x)=$ $2 K-f^{\prime}(x)$. Also

$$
\begin{aligned}
& 2 K(x-a)-(f(x)-f(a)) \\
= & g(x)-g(a)=2 K x-f(x)-(2 K a-f(a))=\int_{a}^{x}\left(2 K-f^{\prime}(t)\right) \\
= & 2 K(x-a)-\int_{a}^{x} f^{\prime}(t) d t
\end{aligned}
$$

showing that $f(x)-f(a)=\int_{a}^{x} f^{\prime}(t) d t$.

### 26.5 Rademacher's Theorem

To begin with is a useful proposition which says the the set where a sequence converges is a measurable set.

Proposition 26.5.1 Let $\left\{f_{n}\right\}$ be measurable with values in a complete normed vector space. Let $A \equiv\left\{\omega:\left\{f_{n}(\omega)\right\}\right.$ converges $\}$. Then $A$ is measurable.

Proof: The set $A$ is the same as the set on which $\left\{f_{n}(\omega)\right\}$ is a Cauchy sequence. This set is

$$
\cap_{n=1}^{\infty} \cup_{m=1}^{\infty} \cap_{p, q>m}\left[\left\|f_{p}(\omega)-f_{q}(\omega)\right\|<\frac{1}{n}\right]
$$

which is a measurable set thanks to the measurability of each $f_{n}$.
It turns out that Lipschitz functions on $\mathbb{R}^{p}$ can be differentiated a.e. This is called Rademacher's theorem. It also can be shown to follow from the Lebesgue theory of differentiation. We denote $D_{\mathbf{v}} f(\mathbf{x})$ the directional derivative of $f$ in the direction $\mathbf{v}$. Here $\mathbf{v}$ is a unit vector. In the following lemma, notation is abused slightly. The symbol $f(\mathbf{x}+t \mathbf{v})$ will mean $t \rightarrow f(\mathbf{x}+t \mathbf{v})$ and $\frac{d}{d t} f(\mathbf{x}+t \mathbf{v})$ will refer to the derivative of this function of $t$.

Lemma 26.5.2 Let $u: \mathbb{R}^{p} \rightarrow \mathbb{R}$ be Lipschitz with Lipschitz constant $K$. Let $u_{n} \equiv u * \phi_{n}$ where $\left\{\phi_{n}\right\}$ is a mollifier,

$$
\phi_{n}(\mathbf{y}) \equiv n^{p} \phi(n \mathbf{y}), \int \phi(\mathbf{y}) d m_{p}(\mathbf{y})=1, \phi(\mathbf{y}) \geq 0, \phi \in C_{c}^{\infty}(B(\mathbf{0}, 1))
$$

Then

$$
\begin{equation*}
\nabla u_{n}(\mathbf{x})=\nabla u * \phi_{n}(\mathbf{x}) \tag{26.5.10}
\end{equation*}
$$

where $\nabla u$ is defined almost everywhere according to Corollary 26.2.6. In fact,

$$
\begin{equation*}
\int_{a}^{b} \frac{\partial u}{\partial x_{i}}\left(\mathbf{x}+t \mathbf{e}_{i}\right) d t=u\left(\mathbf{x}+b \mathbf{e}_{i}\right)-u\left(\mathbf{x}+a \mathbf{e}_{i}\right) \tag{26.5.11}
\end{equation*}
$$

and $\left|\frac{\partial u}{\partial x_{i}}\right| \leq K$. Also, $u_{n}(\mathbf{x}) \rightarrow u(\mathbf{x})$ uniformly on $\mathbb{R}^{p}$ and for a suitable subsequence, still denoted with $n, \nabla u_{n}(\mathbf{x}) \rightarrow \nabla u(\mathbf{x})$ for a.e. $\mathbf{x}$.

Proof: To get the existence of the gradient satisfying the condition given in 26.5.11, apply the corollary to each variable. Now

$$
\begin{aligned}
\frac{u_{n}\left(\mathbf{x}+h \mathbf{e}_{i}\right)-u_{n}(\mathbf{x})}{h} & =\int_{\mathbb{R}^{p}}\left(\frac{u\left(\mathbf{x}+h \mathbf{e}_{i}-\mathbf{y}\right)-u(\mathbf{x}-\mathbf{y})}{h}\right) \phi_{n}(\mathbf{y}) d m_{p}(\mathbf{y}) \\
& =\int_{B\left(\mathbf{0}, \frac{1}{n}\right)}\left(\frac{u\left(\mathbf{x}+h \mathbf{e}_{i}-\mathbf{y}\right)-u(\mathbf{x}-\mathbf{y})}{h}\right) \phi_{n}(\mathbf{y}) d m_{p}(\mathbf{y})
\end{aligned}
$$

Now that difference quotient converges to $\frac{\partial u}{\partial x_{i}}(\mathbf{x}-\mathbf{y})$ for $y_{i}$ off a set of measure zero $N(\hat{\mathbf{y}})$ where $m_{1}(N)=0$ and $\hat{\mathbf{y}} \in \mathbb{R}^{p-1}$. You just use Corollary 26.2 .6 on the $i^{t h}$ variable. Also, the difference quotients are bounded thanks to the Lipshitz condition. Therefore, you can apply the dominated convergence theorem to get

$$
\begin{aligned}
& \lim _{h \rightarrow 0} \int_{\mathbb{R}^{p-1}} \int_{\mathbb{R}}\left(\frac{u\left(\mathbf{x}+h \mathbf{e}_{i}-\mathbf{y}\right)-u(\mathbf{x}-\mathbf{y})}{h}\right) \phi_{n}(\mathbf{y}) d m_{1}\left(y_{i}\right) d m_{p-1}(\hat{\mathbf{y}}) \\
= & \int_{\mathbb{R}^{p-1}} \int_{\mathbb{R}} \frac{\partial u(\mathbf{x}-\mathbf{y})}{\partial x_{i}} \phi_{n}(\mathbf{y}) d m_{1}\left(y_{i}\right) d m_{p-1}(\hat{\mathbf{y}})=\frac{\partial u}{\partial x_{i}} * \phi_{n}(\mathbf{x})
\end{aligned}
$$

The set of $\mathbf{y}$ in $\mathbb{R}^{p}$ where $\frac{u\left(\mathbf{x}+h \mathbf{e}_{i}-\mathbf{y}\right)-u(\mathbf{x}-\mathbf{y})}{h}$ converges as $h \rightarrow 0$ through a sequence of values is a measurable set thanks to Proposition 26.5.1 and for each $\hat{\mathbf{y}}$, the convergence takes place off a set of $m_{1}$ measure zero. Thus there are no measurability issues here and off a set of measure zero, the difference quotient converges to the partial derivative. This proves 26.5.10.

$$
\left\|u_{n}(\mathbf{x})-u(\mathbf{x})\right\| \leq \int_{\mathbb{R}^{p}}\|u(\mathbf{x}-\mathbf{y})-u(\mathbf{x})\| \phi_{n}(\mathbf{y}) d m_{p}(\mathbf{y})
$$

by uniform continuity of $u$ coming from the Lipschitz condition, when $n$ is large enough, this is no larger than

$$
\int_{\mathbb{R}^{p}} \varepsilon \psi_{n}(\mathbf{y}) d m_{p}(\mathbf{y})=\varepsilon
$$

and so uniform convergence holds.
Now consider the last claim. From the first part,

$$
\begin{aligned}
&\left\|u_{n x_{i}}(\mathbf{x})-u_{x_{i}}(\mathbf{x})\right\|=\left\|\int_{B\left(\mathbf{0}, \frac{1}{n}\right)} u_{x_{i}}(\mathbf{x}-\mathbf{y}) \phi_{n}(\mathbf{y}) d m_{p}(\mathbf{y})-u_{x_{i}}(\mathbf{x})\right\| \\
&=\left\|\int_{B\left(\mathbf{x}, \frac{1}{n}\right)} u_{x_{i}}(\mathbf{z}) \phi_{n}(\mathbf{x}-\mathbf{z}) d m_{p}(\mathbf{z})-u_{x_{i}}(\mathbf{x})\right\| \\
&\left\|u_{n x_{i}}(\mathbf{x})-u_{x_{i}}(\mathbf{x})\right\| \leq \leq \int_{\mathbb{R}^{p}}\left\|u_{x_{i}}(\mathbf{x}-\mathbf{y})-u_{x_{i}}(\mathbf{x})\right\| \phi_{n}(\mathbf{y}) d m_{p}(\mathbf{y}) \\
&=\int_{B\left(\mathbf{0}, \frac{1}{n}\right)}\left\|u_{x_{i}}(\mathbf{x}-\mathbf{y})-u_{x_{i}}(\mathbf{x})\right\| \phi_{n}(\mathbf{y}) d m_{p}(\mathbf{y})
\end{aligned}
$$

Now $\phi_{n}(\mathbf{y})=n^{p} \phi(n \mathbf{y})=\frac{m_{p}(B(\mathbf{0}, 1))}{m_{p}\left(B\left(\mathbf{0}, \frac{1}{n}\right)\right)} \phi(n \mathbf{y})$. Therefore, the above equals

$$
\begin{aligned}
& =\frac{m_{p}(B(\mathbf{0}, 1))}{m_{p}\left(B\left(\mathbf{0}, \frac{1}{n}\right)\right)} \int_{B\left(\mathbf{0}, \frac{1}{n}\right)}\left\|u_{x_{i}}(\mathbf{x}-\mathbf{y})-u_{x_{i}}(\mathbf{x})\right\| \phi(n \mathbf{y}) d m_{p}(\mathbf{y}) \\
& =\frac{m_{p}(B(\mathbf{0}, 1))}{m_{p}\left(B\left(\mathbf{0}, \frac{1}{n}\right)\right)} \int_{B\left(\mathbf{x}, \frac{1}{n}\right)}\left\|u_{x_{i}}(\mathbf{z})-u_{x_{i}}(\mathbf{x})\right\| \phi(n(\mathbf{x}-\mathbf{z})) d m_{p}(\mathbf{z}) \\
& \leq C \frac{m_{p}(B(\mathbf{0}, 1))}{m_{p}\left(B\left(\mathbf{x}, \frac{1}{n}\right)\right)} \int_{B\left(\mathbf{x}, \frac{1}{n}\right)}\left\|u_{x_{i}}(\mathbf{z})-u_{x_{i}}(\mathbf{x})\right\| d m_{p}(\mathbf{z})
\end{aligned}
$$

which converges to 0 for a.e. $\mathbf{x}$, in fact at any Lebesgue point. This is because $u_{x_{i}}$ is bounded by $K$ and so is in $L_{l o c}^{1}$.

The following lemma gives an interesting inequality due to Morrey. To simplify notation $d z$ will mean $d m_{p}(\mathbf{z})$.

Lemma 26.5.3 Let $u$ be a $C^{1}$ function on $\mathbb{R}^{p}$. Then there exists a constant $C$, depending only on $p$ such that for any $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{p}$,

$$
\begin{gather*}
|u(\mathbf{x})-u(\mathbf{y})| \\
\leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}\left(|\mathbf{x}-\mathbf{y}|^{(1-p / q)}\right) \tag{26.5.12}
\end{gather*}
$$

Here $q>p$.
Proof: In the argument $C$ will be a generic constant which depends on $p$. Consider the following picture.

This is a picture of two balls of radius $r$ in $\mathbb{R}^{p}, U$ and $V$ having centers at $\mathbf{x}$ and $\mathbf{y}$ respectively, which intersect in the set $W$. The center of $U$ is on the boundary of $V$ and the center of $V$ is on the boundary of $U$ as shown in the picture. There exists a constant, $C$, independent of $r$ depending only on $p$ such that

$$
\frac{m(W)}{m(U)}=\frac{m(W)}{m(V)}=\frac{1}{C}
$$

You could compute this constant if you desired but it is not important here.
Then

$$
\begin{aligned}
|u(\mathbf{x})-u(\mathbf{y})| & =\frac{1}{m(W)} \int_{W}|u(\mathbf{x})-u(\mathbf{y})| d z \\
& \leq \frac{1}{m(W)} \int_{W}|u(\mathbf{x})-u(\mathbf{z})| d z+\frac{1}{m(W)} \int_{W}|u(\mathbf{z})-u(\mathbf{y})| d z \\
& =\frac{C}{m(U)}\left[\int_{W}|u(\mathbf{x})-u(\mathbf{z})| d z+\int_{W}|u(\mathbf{z})-u(\mathbf{y})| d z\right] \\
& \leq \frac{C}{m(U)}\left[\int_{U}|u(\mathbf{x})-u(\mathbf{z})| d z+\int_{V}|u(\mathbf{y})-u(\mathbf{z})| d z\right]
\end{aligned}
$$

Now consider these two terms. Let $q>p$
Using spherical coordinates and letting $U_{0}$ denote the ball of the same radius as $U$ but with center at $\mathbf{0}$,

$$
\begin{aligned}
& \frac{1}{m(U)} \int_{U}|u(\mathbf{x})-u(\mathbf{z})| d z \\
= & \frac{1}{m\left(U_{0}\right)} \int_{U_{0}}|u(\mathbf{x})-u(\mathbf{z}+\mathbf{x})| d z
\end{aligned}
$$

Now using spherical coordinates, Section 13.9, and letting $C$ denote a generic constant which depends on $p$,

$$
\begin{aligned}
&=\frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{p-1} \int_{S^{p-1}}|u(\mathbf{x})-u(\rho \mathbf{w}+\mathbf{x})| d \sigma(w) d \rho \\
& \leq \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{p-1} \int_{S^{p-1}} \int_{0}^{\rho}\left|D_{\mathbf{w}} u(\mathbf{x}+t \mathbf{w})\right| d t d \sigma(w) d \rho \\
&=\frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{p-1} \int_{S^{p-1}} \int_{0}^{\rho}|\nabla u(\mathbf{x}+t \mathbf{w}) \cdot \mathbf{w}| d t d \sigma(w) d \rho \\
& \leq \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{p-1} \int_{S^{p-1}} \int_{0}^{r}|\nabla u(\mathbf{x}+t \mathbf{w}) \cdot \mathbf{w}| d t d \sigma(w) d \rho \\
&=\frac{1}{m\left(U_{0}\right)} \int_{S^{p-1}} \int_{0}^{r}|\nabla u(\mathbf{x}+t \mathbf{w}) \cdot \mathbf{w}| \int_{0}^{r} \rho^{p-1} d \rho d t d \sigma(w) \\
&=C \int_{0}^{r} \int_{S^{p-1}}|\nabla u(\mathbf{x}+t \mathbf{w})| d \sigma(w) d t=C \int_{0}^{r} \int_{S^{p-1}} \frac{|\nabla u(\mathbf{x}+t \mathbf{w})|}{t^{p-1}} t^{p-1} d \sigma(w) d t
\end{aligned}
$$

But this is just the polar coordinates description of what follows.

$$
\begin{gathered}
=C \int_{U_{0}} \frac{|\nabla u(\mathbf{x}+\mathbf{z})|}{|\mathbf{z}|^{p-1}} d z \\
\leq C\left(\int_{U_{0}}|\nabla u(\mathbf{x}+\mathbf{z})|^{q} d z\right)^{1 / q}\left(\int_{U_{0}}|\mathbf{z}|^{q^{\prime}-p q^{\prime}}\right)^{1 / q^{\prime}} \\
=C\left(\int_{U}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}\left(\int_{S^{p-1}} \int_{0}^{r} \rho^{q^{\prime}-p q^{\prime}} \rho^{p-1} d \rho d \sigma\right)^{(q-1) / q} \\
=C\left(\int_{U}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}\left(\int_{S^{p-1}} \int_{0}^{r} \frac{1}{\left.\rho^{\frac{p-1}{q-1}} d \rho d \sigma\right)^{(q-1) / q}}\right. \\
=C\left(\frac{q-1}{q-p}\right)^{(q-1) / q}\left(\int_{U}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q} r^{1-\frac{p}{q}} \\
=C\left(\frac{q-1}{q-p}\right)^{(q-1) / q}\left(\int_{U}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}|^{1-\frac{p}{q}}
\end{gathered}
$$

Similarly,

$$
\frac{1}{m(V)} \int_{U}|u(\mathbf{y})-u(\mathbf{z})| d z \leq C\left(\frac{q-1}{q-p}\right)^{(q-1) / q}\left(\int_{V}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}|^{1-\frac{p}{q}}
$$

Therefore,

$$
|u(\mathbf{x})-u(\mathbf{y})| \leq C\left(\frac{q-1}{q-p}\right)^{(q-1) / q}\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}|^{1-\frac{p}{q}}
$$

because $B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|) \supseteq V \cup U$.
Corollary 26.5.4 Let $u$ be Lipschitz on $\mathbb{R}^{p}$ with constant $K$. Then there is a constant $C$ depending only on $p$ such that

$$
\begin{equation*}
|u(\mathbf{x})-u(\mathbf{y})| \leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}\left(|\mathbf{x}-\mathbf{y}|^{(1-p / q)}\right) \tag{26.5.13}
\end{equation*}
$$

Here $q>p$.
Proof: Let $u_{n}=u * \phi_{n}$ where $\left\{\phi_{n}\right\}$ is a mollifier as in Lemma 26.5.2. Then from Lemma 26.5.3, there is a constant depending only on $p$ such that

$$
\left|u_{n}(\mathbf{x})-u_{n}(\mathbf{y})\right| \leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}\left|\nabla u_{n}(\mathbf{z})\right|^{q} d z\right)^{1 / q}\left(|\mathbf{x}-\mathbf{y}|^{(1-p / q)}\right)
$$

Now $\left|\nabla u_{n}\right|=\left|\nabla u * \phi_{n}\right|$ by Lemma 26.5.2 and this last is bounded. Also, by this lemma, $\nabla u_{n}(\mathbf{z}) \rightarrow \nabla u(\mathbf{z})$ a.e. and $u_{n}(\mathbf{x}) \rightarrow u(\mathbf{x})$ for all $\mathbf{x}$. Therefore, we can pass to a limit in the above and obtain 26.5.13.

Note you can write 26.5.13 in the form

$$
\begin{aligned}
|u(\mathbf{x})-u(\mathbf{y})| & \leq C\left(\frac{1}{|\mathbf{x}-\mathbf{y}|^{p}} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}| \\
& =\hat{C}\left(\frac{1}{m_{p}(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}|
\end{aligned}
$$

Before leaving this remarkable formula, note that if you are in any situation where the above formula holds and $\nabla u$ exists in some sense and is in $L^{q}, q>p$, then $u$ would need to be continuous. This is the basis for the Sobolev embedding theorem.

Here is Rademacher's theorem.
Theorem 26.5.5 Suppose $u$ is Lipschitz with constant $K$ then if $\mathbf{x}$ is a point where $\nabla u(\mathbf{x})$ exists,

$$
|u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})|
$$

$$
\begin{equation*}
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}| \tag{26.5.14}
\end{equation*}
$$

Also $u$ is differentiable at a.e. $\mathbf{x}$ and also

$$
\begin{equation*}
u(\mathbf{x}+t \mathbf{v})-u(\mathbf{x})=\int_{0}^{t} D_{\mathbf{v}} u(\mathbf{x}+s \mathbf{v}) d s \tag{26.5.15}
\end{equation*}
$$

Proof: This follows easily from letting $g(\mathbf{y}) \equiv u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})$. As explained above, $|\nabla u(\mathbf{x})| \leq \sqrt{p} K$ at every point where $\nabla u$ exists, the exceptional points being in a set of measure zero. Then $g(\mathbf{x})=0$, and $\nabla g(\mathbf{y})=\nabla u(\mathbf{y})-\nabla u(\mathbf{x})$ at the points $\mathbf{y}$ where the gradient of $g$ exists. From Corollary 26.5.4,

$$
\begin{aligned}
& |u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})| \\
= & |g(\mathbf{y})|=|g(\mathbf{y})-g(\mathbf{x})| \\
\leq & C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}|^{1-\frac{p}{q}} \\
= & C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{q} d z\right)^{1 / q} \frac{1}{|\mathbf{x}-\mathbf{y}|^{p}} \\
& \frac{1}{q} \\
= & C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{y}|}\right. \\
& \left.|\nabla u(\mathbf{y})-\nabla u(\mathbf{x})|^{q} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}| .
\end{aligned}
$$

Now this is no larger than

$$
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|(2 \sqrt{p} K)^{q-1} d z\right)^{1 / q}|\mathbf{x}-\mathbf{y}|
$$

It follows that at Lebesgue points of $\nabla u$, the above expression is $o(|\mathbf{x}-\mathbf{y}|)$ and so at all such points $u$ is differentiable. As to 26.5.15, this follows from an application of Corollary 26.2.6 to $f(t)=u(\mathbf{x}+t \mathbf{v})$.

Note that for a.e. $\mathbf{x}, D_{\mathbf{v}} u(\mathbf{x})=\nabla u(\mathbf{x}) \cdot \mathbf{v}$. If you have a line with direction vector $\mathbf{v}$, does it follow that $D u(\mathbf{x}+t \mathbf{v})$ exists for a.e. $t$ ? We know the directional derivative exists a.e. $t$ but it might not be clear that it is $\nabla u(\mathbf{x}) \cdot \mathbf{v}$.

For $|\mathbf{w}|=1$, denote the measure of Section 13.9 defined on the unit sphere $S^{p-1}$ as $\sigma$. Let $N_{\mathbf{w}}$ be defined as those $t \in[0, \infty)$ for which $D_{\mathbf{w}} u(\mathbf{x}+t \mathbf{w}) \neq \nabla u(\mathbf{x}+t \mathbf{w}) \cdot \mathbf{w}$.

$$
B \equiv\left\{\mathbf{w} \in S^{p-1}: N_{\mathbf{w}} \text { has positive measure }\right\}
$$

This is contained in the set of points of $\mathbb{R}^{p}$ where the derivative of $v(\cdot) \equiv u(\mathbf{x}+\cdot)$ fails to exist.Thus from Section 13.9 the measure of this set is

$$
\int_{B} \int_{N_{\mathrm{w}}} \rho^{n-1} d \rho d \sigma(w)
$$

This must equal zero from what was just shown about the derivative of the Lipschitz function $v$ existing a.e. and so $\sigma(B)=0$. The claimed formula follows from this. Thus we obtain the following corollary.

Corollary 26.5.6 Let $u$ be Lipschitz. Then for any $\mathbf{x}$ and $\mathbf{v} \in S^{p-1} \backslash B_{\mathbf{x}}$ where $\sigma\left(B_{\mathbf{x}}\right)=0$, it follows that for all $t$,

$$
u(\mathbf{x}+t \mathbf{v})-u(\mathbf{x})=\int_{0}^{t} D_{\mathbf{v}} u(\mathbf{x}+s \mathbf{v}) d s=\int_{0}^{t} \nabla u(\mathbf{x}+s \mathbf{v}) \cdot \mathbf{v} d s
$$

In the all of the above, the function $u$ is defined on all of $\mathbb{R}^{p}$. However, it is always the case that Lipschitz functions can be extended off a given set. Thus if a Lipschitz function is defined on some set $\Omega$, then it can always be considered the restriction to $\Omega$ of a Lipschitz map defined on all of $\mathbb{R}^{p}$.

Theorem 26.5.7 If $\mathbf{h}: \Omega \rightarrow \mathbb{R}^{m}$ is Lipschitz, then there exists $\overline{\mathbf{h}}: \mathbb{R}^{p} \rightarrow \mathbb{R}^{m}$ which extends h and is also Lipschitz.

Proof: It suffices to assume $m=1$ because if this is shown, it may be applied to the components of $\mathbf{h}$ to get the desired result. Suppose

$$
\begin{equation*}
|h(\mathbf{x})-h(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}| . \tag{26.5.16}
\end{equation*}
$$

Define

$$
\begin{equation*}
\bar{h}(\mathbf{x}) \equiv \inf \{h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|: \mathbf{w} \in \Omega\} . \tag{26.5.17}
\end{equation*}
$$

If $\mathbf{x} \in \Omega$, then for all $\mathbf{w} \in \Omega$,

$$
h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}| \geq h(\mathbf{x})
$$

by 26.5.16. This shows $h(\mathbf{x}) \leq \bar{h}(\mathbf{x})$. But also you could take $\mathbf{w}=\mathbf{x}$ in 26.5.17 which yields $\bar{h}(\mathbf{x}) \leq h(\mathbf{x})$. Therefore $\bar{h}(\mathbf{x})=h(\mathbf{x})$ if $\mathbf{x} \in \Omega$.

Now suppose $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{p}$ and consider $|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|$. Without loss of generality assume $\bar{h}(\mathbf{x}) \geq \bar{h}(\mathbf{y})$. (If not, repeat the following argument with $\mathbf{x}$ and $\mathbf{y}$ interchanged.) Pick $\mathbf{w} \in \Omega$ such that

$$
h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\varepsilon<\bar{h}(\mathbf{y})
$$

Then

$$
\begin{aligned}
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|=\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y}) & \leq h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|- \\
{[h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\boldsymbol{\varepsilon}] } & \leq K|\mathbf{x}-\mathbf{y}|+\boldsymbol{\varepsilon}
\end{aligned}
$$

Since $\varepsilon$ is arbitrary,

$$
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

### 26.6 Rademacher's Theorem

It turns out that Lipschitz functions on $\mathbb{R}^{n}$ can be differentiated a.e. This is called Rademacher's theorem. It also can be shown to follow from the Lebesgue theory of differentiation.

### 26.6.1 Morrey's Inequality

The following inequality will be called Morrey's inequality. It relates an expression which is given pointwise to an integral of the $p^{t h}$ power of the derivative.

Lemma 26.6.1 Let $u \in C^{1}\left(\mathbb{R}^{n}\right)$ and $p>n$. Then there exists a constant, $C$, depending only on $n$ such that for any $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{n}$,

$$
\begin{gather*}
|u(\mathbf{x})-u(\mathbf{y})| \\
\leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}\left(|\mathbf{x}-\mathbf{y}|^{(1-n / p)}\right) \tag{26.6.18}
\end{gather*}
$$

Proof: In the argument $C$ will be a generic constant which depends on $n$. Consider the following picture.

This is a picture of two balls of radius $r$ in $\mathbb{R}^{n}, U$ and $V$ having centers at $\mathbf{x}$ and $\mathbf{y}$ respectively, which intersect in the set, $W$. The center of $U$ is on the boundary of $V$ and the center of $V$ is on the boundary of $U$ as shown in the picture. There exists a constant, $C$, independent of $r$ depending only on $n$ such that

$$
\frac{m(W)}{m(U)}=\frac{m(W)}{m(V)}=C
$$

You could compute this constant if you desired but it is not important here.

Define the average of a function over a set, $E \subseteq \mathbb{R}^{n}$ as follows.

$$
f_{E} f d x \equiv \frac{1}{m(E)} \int_{E} f d x
$$

Then

$$
\begin{aligned}
|u(\mathbf{x})-u(\mathbf{y})| & =f_{W}|u(\mathbf{x})-u(\mathbf{y})| d z \\
& \leq f_{W}|u(\mathbf{x})-u(\mathbf{z})| d z+f_{W}|u(\mathbf{z})-u(\mathbf{y})| d z \\
& =\frac{C}{m(U)}\left[\int_{W}|u(\mathbf{x})-u(\mathbf{z})| d z+\int_{W}|u(\mathbf{z})-u(\mathbf{y})| d z\right] \\
& \leq C\left[f_{U}|u(\mathbf{x})-u(\mathbf{z})| d z+f_{V}|u(\mathbf{y})-u(\mathbf{z})| d z\right]
\end{aligned}
$$

Now consider these two terms. Using spherical coordinates and letting $U_{0}$ denote the ball of the same radius as $U$ but with center at $\mathbf{0}$,

$$
\begin{aligned}
& f_{U}|u(\mathbf{x})-u(\mathbf{z})| d z \\
= & \frac{1}{m\left(U_{0}\right)} \int_{U_{0}}|u(\mathbf{x})-u(\mathbf{z}+\mathbf{x})| d z \\
= & \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{n-1} \int_{S^{n-1}}|u(\mathbf{x})-u(\rho \mathbf{w}+\mathbf{x})| d \sigma(w) d \rho \\
\leq & \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{n-1} \int_{S^{n-1}} \int_{0}^{\rho}|\nabla u(\mathbf{x}+t \mathbf{w}) \cdot \mathbf{w}| d t d \sigma d \rho \\
\leq & \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{n-1} \int_{S^{n-1}} \int_{0}^{\rho}|\nabla u(\mathbf{x}+t \mathbf{w})| d t d \sigma d \rho \\
\leq & C \frac{1}{r} \int_{0}^{r} \int_{S^{n-1}} \int_{0}^{r}|\nabla u(\mathbf{x}+t \mathbf{w})| d t d \sigma d \rho \\
= & C \frac{1}{r} \int_{0}^{r} \int_{S^{n-1}} \int_{0}^{r} \frac{|\nabla u(\mathbf{x}+t \mathbf{w})|}{t^{n-1}} t^{n-1} d t d \sigma d \rho \\
= & C \int_{S^{n-1}} \int_{0}^{r} \frac{|\nabla u(\mathbf{x}+t \mathbf{w})|}{t^{n-1}} t^{n-1} d t d \sigma \\
= & C \int_{U_{0}} \frac{|\nabla u(\mathbf{x}+\mathbf{z})|}{|\mathbf{z}|^{n-1}} d z \\
\leq & C\left(\int_{U_{0}}|\nabla u(\mathbf{x}+\mathbf{z})|^{p} d z\right)^{1 / p}\left(\int_{U}|\mathbf{z}|^{p^{\prime}-n p^{\prime}}\right){ }^{1 / p^{\prime}}
\end{aligned}
$$

$$
\begin{gathered}
=C\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}\left(\int_{S^{n-1}} \int_{0}^{r} \rho^{p^{\prime}-n p^{\prime}} \rho^{n-1} d \rho d \sigma\right)^{(p-1) / p} \\
=C\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}\left(\int_{S^{n-1}} \int_{0}^{r} \frac{1}{\rho^{\frac{n-1}{p-1}}} d \rho d \sigma\right)^{(p-1) / p} \\
=C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p} r^{1-\frac{n}{p}} \\
=C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}}
\end{gathered}
$$

Similarly,

$$
f_{V}|u(\mathbf{y})-u(\mathbf{z})| d z \leq C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{V}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}}
$$

Therefore,

$$
|u(\mathbf{x})-u(\mathbf{y})| \leq C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}}
$$

because $B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|) \supseteq V \cup U$. This proves the lemma.
The following corollary is also interesting
Corollary 26.6.2 Suppose $u \in C^{1}\left(\mathbb{R}^{n}\right)$. Then

$$
\begin{gather*}
|u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})| \\
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}| \tag{26.6.19}
\end{gather*}
$$

Proof: This follows easily from letting $g(\mathbf{y}) \equiv u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})$. Then $g \in C^{1}\left(\mathbb{R}^{n}\right), g(\mathbf{x})=0$, and $\nabla g(\mathbf{z})=\nabla u(\mathbf{z})-\nabla u(\mathbf{x})$. From Lemma 26.6.1,

$$
\begin{aligned}
& |u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})| \\
= & |g(\mathbf{y})|=|g(\mathbf{y})-g(\mathbf{x})| \\
\leq & C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{x})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}} \\
= & C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}| .
\end{aligned}
$$

This proves the corollary.
It may be interesting at this point to recall the definition of differentiability on Page 117. If you knew the above inequality held for $\nabla u$ having components in $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$, then at Lebesgue points of $\nabla u$, the above would imply $D u(\mathbf{x})$ exists.

### 26.6.2 Rademacher's Theorem

Lemma 26.6.3 Let u be a Lipschitz continuous function which vanishes outside some compact set. Then there exists a unique $u_{, i} \in L^{\infty}\left(\mathbb{R}^{n}\right)$ such that

$$
\lim _{h \rightarrow 0} \frac{u(\cdot+h)-u(\cdot)}{h}=u_{, i} \text { weak } * \operatorname{in} L^{\infty}\left(\mathbb{R}^{n}\right)
$$

Proof: By the Lipschitz condition, the above difference quotient is bounded in $L^{\infty}$ by $K$ the Lipschitz constant of $u$. It follows from the Banach Aloglu theorem and Corollary 17.5.6 on Page 463 that there exists a subsequence $h_{k} \rightarrow 0$ and $g \in L^{\infty}\left(\mathbb{R}^{n}\right)$ such that

$$
\frac{u\left(\cdot+h_{k}\right)-u(\cdot)}{h_{k}} \rightarrow g \text { weak } * \text { in } L^{\infty}\left(\mathbb{R}^{n}\right)
$$

Letting $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$, it follows

$$
\int g \phi d x=\lim _{k \rightarrow \infty} \int \frac{u\left(\cdot+h_{k}\right)-u(\cdot)}{h_{k}} \phi d x=-\int u \phi_{, i} d x
$$

This also shows that $g$ must vanish outside some compact set because the integral on the right shows that if $\operatorname{spt} \phi$ does not intersect $\operatorname{spt} u$, then $\int g \phi d x=0$. Thus $g \in L^{2}\left(\mathbb{R}^{n}\right)$. If $g_{1}$ is a weak $*$ limit of another subsequence $h_{j} \rightarrow 0$, the same result follows. Thus for any $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$

$$
\int\left(g-g_{1}\right) \phi d x=0
$$

and since $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is dense in $L^{2}\left(\mathbb{R}^{n}\right)$, this requires $g=g_{1}$ in $L^{2}$ and so they are equal a.e. Since every sequence of $h \rightarrow 0$ has a subsequence which when applied to the difference quotient, always converges to the same thing, it follows the claimed limit exists. This is called $u_{, i}$. This proves the lemma.

Lemma 26.6.4 Let u be a Lipschitz continuous function which vanishes outside a compact set and let $u_{, i}$ be described above. For $\phi_{\varepsilon}$ a mollifier and $u_{\varepsilon} \equiv u * \phi_{\varepsilon}$,

$$
u_{\varepsilon, i}=u_{, i} * \phi_{\varepsilon}
$$

where the symbol $u_{\varepsilon, i}$ means the usual partial derivative with respect to the $i^{\text {th }}$ variable. Also for any $p>n$,

$$
u_{\varepsilon, i} \rightarrow u_{, i} \text { in } L^{p}\left(\mathbb{R}^{n}\right)
$$

Proof: This follows from a computation and Lemma 26.6.3.

$$
\begin{aligned}
u_{\varepsilon, i}(\mathbf{x}) & \equiv \lim _{h \rightarrow 0} \int \frac{u\left(\mathbf{x}-\mathbf{y}+h \mathbf{e}_{i}\right)-u(\mathbf{x}-\mathbf{y})}{h} \phi_{\varepsilon}(\mathbf{y}) d y \\
& =\lim _{h \rightarrow 0} \int \frac{u\left(\mathbf{z}+h \mathbf{e}_{i}\right)-u(\mathbf{z})}{h} \phi_{\varepsilon}(\mathbf{x}-\mathbf{z}) d z \\
& =\int u_{i i}(\mathbf{z}) \phi_{\varepsilon}(\mathbf{x}-\mathbf{z}) d z=u_{i,} * \phi_{\varepsilon}(\mathbf{x})
\end{aligned}
$$

It remains to verify the last assertion. Note that $u_{, i} \in L^{p}\left(\mathbb{R}^{n}\right)$ for any $p>1$ because it is bounded and vanishes outside some compact set. By the first part,

$$
\left(\int\left|u_{\varepsilon, i}-u_{, i}\right|^{p} d x\right)^{1 / p}=\left(\int\left|\int\left(u_{, i}(\mathbf{x}-\mathbf{y})-u_{, i}(\mathbf{x})\right) \phi_{\varepsilon}(\mathbf{y}) d y\right|^{p} d x\right)^{1 / p}
$$

and by Minkowski's inequality,

$$
\begin{aligned}
& \leq \int \phi_{\varepsilon}(\mathbf{y})\left(\int\left|\left(u_{, i}(\mathbf{x}-\mathbf{y})-u_{, i}(\mathbf{x})\right)\right|^{p} d x\right)^{1 / p} d y \\
& =\int_{B(\mathbf{0}, \boldsymbol{\varepsilon})} \phi_{\varepsilon}(\mathbf{y})\left\|\left(u_{, i}\right)_{\mathbf{y}}-u_{i, i}\right\|_{L^{p}\left(\mathbb{R}^{n}\right)} d y
\end{aligned}
$$

which converges to 0 from continuity of translation. This proves the lemma.
Now from Corollary 26.6.2 applied to $u_{\varepsilon}$ just described and letting $\mathbf{y}-\mathbf{x}=\mathbf{v}$

$$
\begin{gathered}
\left|u_{\varepsilon}(\mathbf{x}+\mathbf{v})-u_{\varepsilon}(\mathbf{x})-\nabla u_{\varepsilon}(\mathbf{x}) \cdot \mathbf{v}\right| \\
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{v}|))} \int_{B(\mathbf{x}, 2|\mathbf{v}|)}\left|\nabla u_{\mathcal{\varepsilon}}(\mathbf{z})-\nabla u_{\varepsilon}(\mathbf{x})\right|^{p} d z\right)^{1 / p}|\mathbf{v}| .
\end{gathered}
$$

From Lemma 26.6.4, there is a subsequence, still denoted as $\varepsilon$ such that for each $i, u_{\varepsilon, i} \rightarrow u_{, i}$ pointwise a.e. and in $L^{p}\left(\mathbb{R}^{n}\right)$ where $p>n$ is given. $\nabla u$ is the vector $\left(u_{, 1}, u_{, 2}, \cdots, u_{, n}\right)^{T}$. Then passing to the limit as $\varepsilon \rightarrow 0$, for a.e. $\mathbf{x}$,

$$
\begin{gathered}
|u(\mathbf{x}+\mathbf{v})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot \mathbf{v}| \\
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{v}|))} \int_{B(\mathbf{x}, 2|\mathbf{v}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{v}| .
\end{gathered}
$$

At every Lebesgue point $\mathbf{x}$ of $\nabla u$, the above shows $u(\mathbf{x}+\mathbf{v})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot \mathbf{v}=\mathbf{o}(\mathbf{v})$. Thus this has proved the following.

Lemma 26.6.5 Let u be Lipschitz continuous and vanish outside some bounded set. Then $D u(\mathbf{x})$ exists for a.e. $\mathbf{x}$.

This is a good result but it is easy to give an even easier to use result. First here is a theorem which says you can extend a Lipschitz map.

Theorem 26.6.6 If $\mathbf{h}: \Omega \rightarrow \mathbb{R}^{m}$ is Lipschitz, then there exists $\overline{\mathbf{h}}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ which extends h and is also Lipschitz.

Proof: It suffices to assume $m=1$ because if this is shown, it may be applied to the components of $\mathbf{h}$ to get the desired result. Suppose

$$
\begin{equation*}
|h(\mathbf{x})-h(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}| . \tag{26.6.20}
\end{equation*}
$$

Define

$$
\begin{equation*}
\bar{h}(\mathbf{x}) \equiv \inf \{h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|: \mathbf{w} \in \Omega\} \tag{26.6.21}
\end{equation*}
$$

If $\mathbf{x} \in \Omega$, then for all $\mathbf{w} \in \Omega$,

$$
h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}| \geq h(\mathbf{x})
$$

by 26.6.20. This shows $h(\mathbf{x}) \leq \bar{h}(\mathbf{x})$. But also you could take $\mathbf{w}=\mathbf{x}$ in 26.6.21 which yields $\bar{h}(\mathbf{x}) \leq h(\mathbf{x})$. Therefore $\bar{h}(\mathbf{x})=h(\mathbf{x})$ if $\mathbf{x} \in \Omega$.

Now suppose $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{n}$ and consider $|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|$. Without loss of generality assume $\bar{h}(\mathbf{x}) \geq \bar{h}(\mathbf{y})$. (If not, repeat the following argument with $\mathbf{x}$ and $\mathbf{y}$ interchanged.) Pick $\mathbf{w} \in \Omega$ such that

$$
h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\varepsilon<\bar{h}(\mathbf{y})
$$

Then

$$
\begin{aligned}
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|=\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y}) & \leq h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|- \\
{[h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\varepsilon] } & \leq K|\mathbf{x}-\mathbf{y}|+\varepsilon .
\end{aligned}
$$

Since $\varepsilon$ is arbitrary,

$$
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

and this proves the theorem.
With this theorem, here is the main result called Rademacher's theorem.
Theorem 26.6.7 Let $\mathbf{h}: \Omega \rightarrow \mathbb{R}^{m}$ be Lipschitz on $\Omega$ where $\Omega$ is some nonempty measurable set in $\mathbb{R}^{n}$. Then $D \mathbf{h}(\mathbf{x})$ exists for a.e. $\mathbf{x} \in \Omega$. If $\Omega=\mathbb{R}^{n}$, then for each $\mathbf{e}_{i}$,

$$
\lim _{h \rightarrow 0} \frac{\mathbf{h}\left(\cdot+h \mathbf{e}_{i}\right)-\mathbf{h}(\cdot)}{h}=\mathbf{h}_{, i} \text { weak } * \operatorname{in} L^{\infty}\left(\mathbb{R}^{n}\right)
$$

and whenever $\phi_{\varepsilon}$ is a mollifier,

$$
\left(\mathbf{h} * \phi_{\varepsilon}\right)_{, i} \rightarrow \mathbf{h}_{, i} \text { in } L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{m}\right)
$$

Proof: The last two claims follow from the above argument applied to the components of $\mathbf{h}$. By Theorem 26.6.6 the function can be extended to a Lipschitz function defined on all of $\mathbb{R}^{n}$, still denoted as $\mathbf{h}$. Let $\Omega_{r} \equiv \Omega \cap B(\mathbf{0}, r)$. Now let $\psi \in C_{c}^{\infty}(B(\mathbf{0}, 2 r))$ such that $\psi=1$ on $B\left(\mathbf{0}, \frac{3}{2} r\right)$. Then $\psi \mathbf{h}$ is Lipschitz on $\mathbb{R}^{n}$ and vanishes off a bounded set. It follows from Lemma 26.6.5 applied to the components of $\mathbf{h}$ that this function has a derivative off a set of measure zero $N_{r}$. If $\mathbf{x} \in \Omega_{r} \backslash N_{r}$ it follows since $\psi=1$ near $\mathbf{x}$ that $D \mathbf{h}(\mathbf{x})$ exists. Letting $N=\cup_{r=1}^{\infty} N_{r}$, it follows that if $\mathbf{x} \in \Omega \backslash N$, then $D \mathbf{h}(\mathbf{x})$ exists. This proves the theorem.

For $u$ Lipschitz as described above, the limit of the difference quotient $u_{, i}$ is called the weak partial derivative of $u$. For $p>n$ and an assertion that the difference quotients are bounded in $L^{p}$ everything done above would work out the same way and one can therefore generalize parts of the above theorem. The extension is problematic but one can give the following results with essentially the same proof as the above.
Lemma 26.6.8 Let $u \in L^{p}\left(\mathbb{R}^{n}\right)$. There exists $u_{, i} \in L^{p}\left(\mathbb{R}^{n}\right)$ such that

$$
\lim _{h \rightarrow 0} \frac{u\left(\cdot+h \mathbf{e}_{i}\right)-u(\cdot)}{h}=u_{, i} \text { weakly in } L^{p}\left(\mathbb{R}^{n}\right)
$$

if and only if the difference quotients $\frac{u\left(\cdot+h \mathbf{e}_{i}\right)-u(\cdot)}{h}$ are bounded in $L^{p}\left(\mathbb{R}^{n}\right)$ for all nonzero $h$.

Proof: If the weak limit exists, then the difference quotients must be bounded. This follows from the uniform boundedness theorem, Theorem 17.1.8. Here is why. Denote the difference quotient by $D_{h}$ to save space. Weak convergence requires $\int D_{h} f \rightarrow \int u_{i} f$ for all $f \in L^{p^{\prime}}$. Could there exist $h_{k}$ such that $\left\|D_{h_{k}}\right\|_{L^{p}} \rightarrow \infty$ ? Not unless a subsequence satisfies $h_{k} \rightarrow 0$ because if this sequence is bounded away from 0 , the formula for $D_{h}$ will yield the difference quotients are bounded. However, if $h_{k} \rightarrow 0$, then for each $f \in L^{p^{\prime}}$,

$$
\sup _{k} \int D_{h_{k}} f<\infty
$$

because in fact, $\lim _{k \rightarrow \infty} \int D_{h_{k}} f$ exists so it must be bounded. Now $D_{h_{k}}$ can be considered in $\left(L^{p^{\prime}}\right)^{\prime}$ and this shows it is pointwise bounded on $L^{p^{\prime}}$. Therefore, $D_{h_{k}}$ is bounded in $\left(L^{p^{\prime}}\right)^{\prime}$ but the norm on this is the same as the norm in $L^{p}$. Thus $D_{h_{k}}$ is bounded after all.

Conversely, if the difference quotients are bounded, the same argument used earlier, involving convergence of a subsequence, this time coming from the Eberlein Smulian theorem, Theorem 17.5.12 and showing that every subsequence converges to the same thing, shows the difference quotients converge weakly in $L^{p}\left(\mathbb{R}^{n}\right)$ to something we can call $u_{, i}$. This proves the lemma.

Definition 26.6.9 A function $f \in L^{p}\left(\mathbb{R}^{n}\right)$ is said to have weak partial derivatives in $L^{p}\left(\mathbb{R}^{n}\right)$ if the difference quotients $\frac{u\left(\cdot+h \mathbf{e}_{i}\right)-u(\cdot)}{h}$ for each $i=1,2, \cdots, n$ are bounded for $h \neq 0$. If $\mathbf{f} \in L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{m}\right)$, it has weak partial derivatives in $L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{m}\right)$ if each component function has weak partial derivatives in $L^{p}\left(\mathbb{R}^{n}\right)$.

This following theorem may also be referred to as Rademacher's theorem.
Theorem 26.6.10 Let $\mathbf{h}$ be in $L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{m}\right), p>n$, and suppose it has weak derivatives $\mathbf{h}_{, i} \in L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{m}\right)$ for $i=1, \cdots, n$. Then $D \mathbf{h}(\mathbf{x})$ exists a.e. and $\mathbf{h}$ is almost everywhere equal to a continuous function. Also if $\phi_{\varepsilon}$ is a mollifier,

$$
\left(\mathbf{h} * \phi_{\varepsilon}\right)_{, i}=\mathbf{h}_{, i} * \phi_{\varepsilon},\left(\mathbf{h} * \phi_{\varepsilon}\right)_{, i} \rightarrow \mathbf{h}_{, i}
$$

in $L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{m}\right)$.
Proof: As before,

$$
\begin{aligned}
& \left(\mathbf{h} * \phi_{\varepsilon}\right)_{, i}(\mathbf{x}) \equiv \lim _{h \rightarrow 0} \int \frac{\mathbf{h}\left(\mathbf{x}+h \mathbf{e}_{i}-\mathbf{y}\right)-\mathbf{h}(\mathbf{x}-\mathbf{y})}{h} \phi_{\varepsilon}(\mathbf{y}) d y \\
= & \lim _{h \rightarrow 0} \int \frac{\mathbf{h}\left(\mathbf{z}+h \mathbf{e}_{i}\right)-\mathbf{h}(\mathbf{z})}{h} \phi_{\varepsilon}(\mathbf{x}-\mathbf{z}) d y \equiv \int \mathbf{h}_{, i}(\mathbf{z}) \phi_{\varepsilon}(\mathbf{x}-\mathbf{y}) d y \\
= & \mathbf{h}_{, i} * \phi_{\varepsilon}(\mathbf{x})
\end{aligned}
$$

and now $\left(\mathbf{h} * \phi_{\varepsilon}\right)_{, i} \rightarrow \mathbf{h}_{, i}$ follows as before from a use of Minkowski's inequality. Letting $u$ be one of the component functions of $\mathbf{h}$, Morrey's inequality holds for $u_{\varepsilon} \equiv u * \phi_{\varepsilon}$. Thus

$$
\left|u_{\varepsilon}(\mathbf{x})-u_{\varepsilon}(\mathbf{y})\right| \leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}\left|\nabla u_{\varepsilon}(\mathbf{z})\right|^{p} d z\right)^{1 / p}\left(|\mathbf{x}-\mathbf{y}|^{1-n / p}\right)
$$

Now there exists a subsequence such that $u_{\varepsilon} \rightarrow u$ pointwise a.e. and also each $u_{\varepsilon, i} \rightarrow u_{, i}$ pointwise a.e. as well as in $L^{p}$. Therefore, for $\mathbf{x}, \mathbf{y}$ not in a set of measure zero,

$$
|u(\mathbf{x})-u(\mathbf{y})| \leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}\left(|\mathbf{x}-\mathbf{y}|^{1-n / p}\right)
$$

which shows the claim about $u$ being equal to a continuous function off a set of measure zero. Thus $\mathbf{h}$ is also continuous off a set of measure zero.

As before, letting $g(\mathbf{y}) \equiv u_{\varepsilon}(\mathbf{y})-u_{\varepsilon}(\mathbf{x})-\nabla u_{\varepsilon}(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})$ and writing Morrey's inequality,

$$
\begin{aligned}
& \left|u_{\varepsilon}(\mathbf{y})-u_{\varepsilon}(\mathbf{x})-\nabla u_{\varepsilon}(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})\right| \\
\leq & C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}\left|\nabla u_{\varepsilon}(\mathbf{z})-\nabla u_{\varepsilon}(\mathbf{x})\right|^{p} d z\right)^{1 / p}\left(|\mathbf{x}-\mathbf{y}|^{1-n / p}\right)
\end{aligned}
$$

Then taking a suitable subsequence and passing to the limit while also letting $\mathbf{v}=\mathbf{y}-\mathbf{x}$, it follows

$$
\begin{aligned}
& |u(\mathbf{x}+\mathbf{v})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot \mathbf{v}| \\
\leq & C\left(\int_{B(\mathbf{x}, 2|\mathbf{v}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}\left(|\mathbf{v}|^{1-n / p}\right) \\
= & C\left(\frac{1}{|\mathbf{v}|^{n}} \int_{B(\mathbf{x}, 2|\mathbf{v}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{v}| \\
= & C^{\prime}\left(\frac{1}{B(\mathbf{x}, 2|\mathbf{v}|)} \int_{B(\mathbf{x}, 2|\mathbf{v}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{v}|
\end{aligned}
$$

for all $\mathbf{x}, \mathbf{x}+\mathbf{v} \notin N$, a set of measure zero. Defining $u, \nabla u$ at the points of $N$ so that the inequality continues to hold, $D u(\mathbf{x})$ exists at every Lebesgue point of $\nabla u$. Also $D \mathbf{h}$ exists a.e. because this is true of the component functions. This proves the theorem.

### 26.7 Differentiation Of Measures

Recall the Vitali covering theorem in Corollary 13.4.5 on Page 350.
Corollary 26.7.1 Let $E \subseteq \mathbb{R}^{n}$ and let $\mathscr{F}$, be a collection of open balls of bounded radii such that $\mathscr{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\bar{m}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.

Definition 26.7.2 Let $\mu$ be a Radon measure defined on $\mathbb{R}^{n}$. Then

$$
\frac{d \mu}{d m}(\mathbf{x}) \equiv \lim _{r \rightarrow 0} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}
$$

whenever this limit exists.
It turns out this limit exists for $m$ a.e. $\mathbf{x}$. To verify this here is another definition.

Definition 26.7.3 Let $f(r)$ be a function having values in $[-\infty, \infty]$. Then

$$
\begin{aligned}
\lim _{\sup _{r \rightarrow 0+}} f(r) & \equiv \lim _{r \rightarrow 0}(\sup \{f(t): t \in[0, r]\}) \\
\lim _{r \rightarrow 0+} f(r) & \equiv \lim _{r \rightarrow 0}(\inf \{f(t): t \in[0, r]\})
\end{aligned}
$$

This is well defined because the function $r \rightarrow \inf \{f(t): t \in[0, r]\}$ is increasing and $r \rightarrow$ $\sup \{f(t): t \in[0, r]\}$ is decreasing. Also note that $\lim _{r \rightarrow 0+} f(r)$ exists if and only if

$$
\lim \sup _{r \rightarrow 0+} f(r)=\lim \inf _{r \rightarrow 0+} f(r)
$$

and if this happens

$$
\lim _{r \rightarrow 0+} f(r)=\lim \inf _{r \rightarrow 0+} f(r)=\lim \sup _{r \rightarrow 0+} f(r) .
$$

The claims made in the above definition follow immediately from the definition of what is meant by a limit in $[-\infty, \infty]$ and are left for the reader.

Theorem 26.7.4 Let $\mu$ be a Borel measure on $\mathbb{R}^{n}$ then $\frac{d \mu}{d m}(\mathbf{x})$ exists in $[-\infty, \infty] m$ a.e.
Proof:Let $p<q$ and let $p, q$ be rational numbers. Define

$$
\begin{aligned}
N_{p q}(M) \equiv & \left\{\mathbf{x} \in \mathbb{R}^{n} \text { such that } \lim _{r \rightarrow 0+} \sup _{r \rightarrow 0} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>q\right. \\
& \left.>p>\lim _{r \rightarrow 0+} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}\right\} \cap B(\mathbf{0}, M) \\
N_{p q} \equiv & \left\{\mathbf{x} \in \mathbb{R}^{n} \text { such that } \lim _{r \rightarrow 0+} \sup \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>q\right. \\
& \left.>p>\lim _{r \rightarrow 0+} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}\right\} \\
N \equiv & \left\{\mathbf{x} \in \mathbb{R}^{n} \text { such that } \lim _{r \rightarrow 0+} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>\right. \\
& \left.\lim \inf _{r \rightarrow 0+} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}\right\}
\end{aligned}
$$

I will show $\bar{m}\left(N_{p q}(M)\right)=0$. Use outer regularity to obtain an open set, $V$ containing $N_{p q}(M)$ such that

$$
\bar{m}\left(N_{p q}(M)\right)+\varepsilon>m(V) .
$$

From the definition of $N_{p q}(M)$, it follows that for each $\mathbf{x} \in N_{p q}(M)$ there exist arbitrarily small $r>0$ such that

$$
\frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}<p
$$

Only consider those $r$ which are small enough to be contained in $B(\mathbf{0}, M)$ so that the collection of such balls has bounded radii. This is a Vitali cover of $N_{p q}(M)$ and so by Corollary 26.7.1 there exists a sequence of disjoint balls of this sort, $\left\{B_{i}\right\}_{i=1}^{\infty}$ such that

$$
\begin{equation*}
\mu\left(B_{i}\right)<p m\left(B_{i}\right), \bar{m}\left(N_{p q}(M) \backslash \cup_{i=1}^{\infty} B_{i}\right)=0 \tag{26.7.22}
\end{equation*}
$$

Now for $\mathbf{x} \in N_{p q}(M) \cap\left(\cup_{i=1}^{\infty} B_{i}\right)$ (most of $N_{p q}(M)$ ), there exist arbitrarily small balls, $B(\mathbf{x}, r)$, such that $B(\mathbf{x}, r)$ is contained in some set of $\left\{B_{i}\right\}_{i=1}^{\infty}$ and

$$
\frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>q
$$

This is a Vitali cover of $N_{p q}(M) \cap\left(\cup_{i=1}^{\infty} B_{i}\right)$ and so there exists a sequence of disjoint balls of this sort, $\left\{B_{j}^{\prime}\right\}_{j=1}^{\infty}$ such that

$$
\begin{equation*}
\bar{m}\left(\left(N_{p q}(M) \cap\left(\cup_{i=1}^{\infty} B_{i}\right)\right) \backslash \cup_{j=1}^{\infty} B_{j}^{\prime}\right)=0, \mu\left(B_{j}^{\prime}\right)>q m\left(B_{j}^{\prime}\right) \tag{26.7.23}
\end{equation*}
$$

It follows from 26.7.22 and 26.7.23 that

$$
\begin{equation*}
\bar{m}\left(N_{p q}(M)\right) \leq \bar{m}\left(\left(N_{p q}(M) \cap\left(\cup_{i=1}^{\infty} B_{i}\right)\right)\right) \leq m\left(\cup_{j=1}^{\infty} B_{j}^{\prime}\right) \tag{26.7.24}
\end{equation*}
$$

Therefore,

$$
\begin{aligned}
\sum_{j} \mu\left(B_{j}^{\prime}\right) & >q \sum_{j} m\left(B_{j}^{\prime}\right) \geq q \bar{m}\left(N_{p q}(M) \cap\left(\cup_{i} B_{i}\right)\right)=q \bar{m}\left(N_{p q}(M)\right) \\
& \geq p \bar{m}\left(N_{p q}(M)\right) \geq p(m(V)-\varepsilon) \geq p \sum_{i} m\left(B_{i}\right)-p \varepsilon \\
& \geq \sum_{i} \mu\left(B_{i}\right)-p \varepsilon \geq \sum_{j} \mu\left(B_{j}^{\prime}\right)-p \varepsilon
\end{aligned}
$$

It follows

$$
p \varepsilon \geq(q-p) \bar{m}\left(N_{p q}(M)\right)
$$

Since $\varepsilon$ is arbitrary, $m\left(N_{p q}(M)\right)=0$. Now $N_{p q} \subseteq \cup_{M=1}^{\infty} N_{p q}(M)$ and so $m\left(N_{p q}\right)=0$. Now

$$
N=\cup_{p . q \in \mathbb{Q}} N_{p q}
$$

and since this is a countable union of sets of measure zero, $m(N)=0$ also. This proves the theorem.

From Theorem 20.2.5 on Page 605 it follows that if $\mu$ is a complex measure then $|\mu|$ is a finite measure. This makes possible the following definition.

Definition 26.7.5 Let $\mu$ be a real measure. Define the following measures. For $E$ a measurable set,

$$
\begin{aligned}
\mu^{+}(E) & \equiv \frac{1}{2}(|\mu|+\mu)(E) \\
\mu^{-}(E) & \equiv \frac{1}{2}(|\mu|-\mu)(E)
\end{aligned}
$$

These are measures thanks to Theorem 20.2.3 on Page 603 and $\mu^{+}-\mu^{-}=\mu$. These measures have values in $[0, \infty)$. They are called the positive and negative parts of $\mu$ respectively. For $\mu$ a complex measure, define $\operatorname{Re} \mu$ and $\operatorname{Im} \mu$ by

$$
\begin{aligned}
\operatorname{Re} \mu(E) & \equiv \frac{1}{2}(\mu(E)+\overline{\mu(E)}) \\
\operatorname{Im} \mu(E) & \equiv \frac{1}{2 i}(\mu(E)-\overline{\mu(E)})
\end{aligned}
$$

Then $\operatorname{Re} \mu$ and $\operatorname{Im} \mu$ are both real measures. Thus for $\mu$ a complex measure,

$$
\begin{aligned}
\mu & =\operatorname{Re} \mu^{+}-\operatorname{Re} \mu^{-}+i\left(\operatorname{Im} \mu^{+}-\operatorname{Im} \mu^{-}\right) \\
& =v_{1}-v_{1}+i\left(v_{3}-v_{4}\right)
\end{aligned}
$$

where each $v_{i}$ is a real measure having values in $[0, \infty)$.
Then there is an obvious corollary to Theorem 26.7.4.
Corollary 26.7.6 Let $\mu$ be a complex Borel measure on $\mathbb{R}^{n}$. Then $\frac{d \mu}{d m}(\mathbf{x})$ exists a.e.
Proof: Letting $v_{i}$ be defined in Definition 26.7.5. By Theorem 26.7.4, for $m$ a.e. $\mathbf{x}$, $\frac{d v_{i}}{d m}(\mathbf{x})$ exists. This proves the corollary because $\mu$ is just a finite sum of these $v_{i}$.

Theorem 20.1.2 on Page 597, the Radon Nikodym theorem, implies that if you have two finite measures, $\mu$ and $\lambda$, you can write $\lambda$ as the sum of a measure absolutely continuous with respect to $\mu$ and one which is singular to $\mu$ in a unique way. The next topic is related to this. It has to do with the differentiation of a measure which is singular with respect to Lebesgue measure.

Theorem 26.7.7 Let $\mu$ be a Radon measure on $\mathbb{R}^{n}$ and suppose there exists a $\mu$ measurable set, $N$ such that for all Borel sets, $E, \mu(E)=\mu(E \cap N)$ where $\bar{m}(N)=0$. Then

$$
\frac{d \mu}{d m}(\mathbf{x})=0 m \text { a.e. }
$$

Proof: For $k \in \mathbb{N}$, let

$$
\begin{aligned}
B_{k}(M) & \equiv\left\{\mathbf{x} \in N^{C}: \lim \sup _{r \rightarrow 0+} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>\frac{1}{k}\right\} \cap B(\mathbf{0}, M) \\
B_{k} & \equiv\left\{\mathbf{x} \in N^{C}: \lim \sup _{r \rightarrow 0+} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>\frac{1}{k}\right\} \\
B & \equiv\left\{\mathbf{x} \in N^{C}: \lim _{\sup _{r \rightarrow 0+}} \frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>0\right\}
\end{aligned}
$$

Let $\varepsilon>0$. Since $\mu$ is regular, there exists $H$, a compact set such that $H \subseteq N \cap B(\mathbf{0}, M)$ and

$$
\mu(N \cap B(\mathbf{0}, M) \backslash H)<\varepsilon
$$

For each $\mathbf{x} \in B_{k}(M)$, there exist arbitrarily small $r>0$ such that $B(\mathbf{x}, r) \subseteq B(\mathbf{0}, M) \backslash H$ and

$$
\begin{equation*}
\frac{\mu(B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}>\frac{1}{k} \tag{26.7.25}
\end{equation*}
$$

Two such balls are illustrated in the above picture. This is a Vitali cover of $B_{k}(M)$ and so there exists a sequence of disjoint balls of this sort, $\left\{B_{i}\right\}_{i=1}^{\infty}$ such that $\bar{m}\left(B_{k}(M) \backslash \cup_{i} B_{i}\right)=0$. Therefore,

$$
\begin{aligned}
\bar{m}\left(B_{k}(M)\right) & \leq \bar{m}\left(B_{k}(M) \cap\left(\cup_{i} B_{i}\right)\right) \leq \sum_{i} \bar{m}\left(B_{i}\right) \leq k \sum_{i} \mu\left(B_{i}\right) \\
& =k \sum_{i} \mu\left(B_{i} \cap N\right)=k \sum_{i} \mu\left(B_{i} \cap N \cap B(\mathbf{0}, M)\right) \\
& \leq k \mu(N \cap B(\mathbf{0}, M) \backslash H)<\varepsilon k
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows $\bar{m}\left(B_{k}(M)\right)=0$.
Therefore,

$$
\bar{m}\left(B_{k}\right) \leq \sum_{M=1}^{\infty} \bar{m}\left(B_{k}(M)\right)=0
$$

and $\bar{m}(B) \leq \sum_{k} \bar{m}\left(B_{k}\right)=0$. Since $\bar{m}(N)=0$, this proves the theorem.
It is easy to obtain a different version of the above theorem. This is done with the aid of the following lemma.

Lemma 26.7.8 Suppose $\mu$ is a Borel measure on $\mathbb{R}^{n}$ having values in $[0, \infty)$. Then there exists a Radon measure, $\mu_{1}$ such that $\mu_{1}=\mu$ on all Borel sets.

Proof: By assumption, $\mu\left(\mathbb{R}^{n}\right)<\infty$ and so it is possible to define a positive linear functional, $L$ on $C_{c}\left(\mathbb{R}^{n}\right)$ by

$$
L f \equiv \int f d \mu
$$

By the Riesz representation theorem for positive linear functionals of this sort, there exists a unique Radon measure, $\mu_{1}$ such that for all $f \in C_{c}\left(\mathbb{R}^{n}\right)$,

$$
\int f d \mu_{1}=L f=\int f d \mu
$$

Now let $V$ be an open set and let $K_{k} \equiv\left\{\mathbf{x} \in V\right.$ : $\left.\operatorname{dist}\left(\mathbf{x}, V^{C}\right) \leq 1 / k\right\} \cap \overline{B(\mathbf{0}, k)}$. Then $\left\{K_{k}\right\}$ is an incresing sequence of compact sets whose union is $V$. Let $K_{k} \prec f_{k} \prec V$. Then $f_{k}(\mathbf{x}) \rightarrow$ $\mathscr{X}_{V}(\mathbf{x})$ for every $\mathbf{x}$. Therefore,

$$
\mu_{1}(V)=\lim _{k \rightarrow \infty} \int f_{k} d \mu_{1}=\lim _{k \rightarrow \infty} \int f_{k} d \mu=\mu(V)
$$

and so $\mu=\mu_{1}$ on open sets. Now if $K$ is a compact set, let

$$
V_{k} \equiv\left\{\mathbf{x} \in \mathbb{R}^{n}: \operatorname{dist}(\mathbf{x}, K)<1 / k\right\}
$$

Then $V_{k}$ is an open set and $\cap_{k} V_{k}=K$. Letting $K \prec f_{k} \prec V_{k}$, it follows that $f_{k}(\mathbf{x}) \rightarrow \mathscr{X}_{K}(\mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^{n}$. Therefore, by the dominated convergence theorem with a dominating function, $\mathscr{X}_{\mathbb{R}^{n}}$

$$
\mu_{1}(K)=\lim _{k \rightarrow \infty} \int f_{k} d \mu_{1}=\lim _{k \rightarrow \infty} \int f_{k} d \mu=\mu(K)
$$

and so $\mu$ and $\mu_{1}$ are equal on all compact sets. It follows $\mu=\mu_{1}$ on all countable unions of compact sets and countable intersections of open sets.

Now let $E$ be a Borel set. By regularity of $\mu_{1}$, there exist sets, $H$ and $G$ such that $H$ is the countable union of an increasing sequence of compact sets, $G$ is the countable intersection of a decreasing sequence of open sets, $H \subseteq E \subseteq G$, and $\mu_{1}(H)=\mu_{1}(G)=$ $\mu_{1}(E)$. Therefore,

$$
\mu_{1}(H)=\mu(H) \leq \mu(E) \leq \mu(G)=\mu_{1}(G)=\mu_{1}(E)=\mu_{1}(H)
$$

therefore, $\mu(E)=\mu_{1}(E)$ and this proves the lemma.
Corollary 26.7.9 Suppose $\mu$ is a complex Borel measure defined on $\mathbb{R}^{n}$ for which there exists a $\mu$ measurable set, $N$ such that for all Borel sets, $E, \mu(E)=\mu(E \cap N)$ where $\bar{m}(N)=0$. Then

$$
\frac{d \mu}{d m}(\mathbf{x})=0 m \text { a.e. }
$$

Proof: Each of $\operatorname{Re} \mu^{+}, \operatorname{Re} \mu^{-}, \operatorname{Im} \mu^{+}$, and $\operatorname{Im} \mu^{-}$are real measures having values in $[0, \infty)$ and so by Lemma 26.7 .8 each is a Radon measure having the same property that $\mu$ has in terms of being supported on a set of $m$ measure zero. Therefore, for $v$ equal to any of these, $\frac{d v}{d m}(\mathbf{x})=0 m$ a.e. This proves the corollary.

### 26.8 Exercises

1. Suppose $A$ and $B$ are sets of positive Lebesgue measure in $\mathbb{R}^{n}$. Show that $A-B$ must contain $B(\mathbf{c}, \varepsilon)$ for some $\mathbf{c} \in \mathbb{R}^{n}$ and $\varepsilon>0$.

$$
A-B \equiv\{\mathbf{a}-\mathbf{b}: \mathbf{a} \in A \text { and } \mathbf{b} \in B\}
$$

Hint: First assume both sets are bounded. This creates no loss of generality. Next there exist $\mathbf{a}_{0} \in A, \mathbf{b}_{0} \in B$ and $\delta>0$ such that

$$
\int_{B\left(a_{0}, \delta\right)} \mathscr{X}_{A}(t) d t>\frac{3}{4} m\left(B\left(\mathbf{a}_{0}, \boldsymbol{\delta}\right)\right), \int_{B\left(b_{0}, \delta\right)} \mathscr{X}_{B}(t) d t>\frac{3}{4} m\left(B\left(\mathbf{b}_{0}, \boldsymbol{\delta}\right)\right) .
$$

Now explain why this implies

$$
m\left(A-\mathbf{a}_{0} \cap B(\mathbf{0}, \boldsymbol{\delta})\right)>\frac{3}{4} m(B(\mathbf{0}, \boldsymbol{\delta}))
$$

and

$$
m\left(B-\mathbf{b}_{0} \cap B(\mathbf{0}, \boldsymbol{\delta})\right)>\frac{3}{4} m(B(\mathbf{0}, \boldsymbol{\delta}))
$$

Explain why

$$
m\left(\left(A-\mathbf{a}_{0}\right) \cap\left(B-\mathbf{b}_{0}\right)\right)>\frac{1}{2} m(B(\mathbf{0}, \delta))>0
$$

Let

$$
f(\mathbf{x}) \equiv \int \mathscr{X}_{A-\mathbf{a}_{0}}(\mathbf{x}+\mathbf{t}) \mathscr{X}_{B-\mathbf{b}_{0}}(\mathbf{t}) d t
$$

Explain why $f(\mathbf{0})>0$. Next explain why $f$ is continuous and why $f(\mathbf{x})>0$ for all $\mathbf{x} \in B(\mathbf{0}, \varepsilon)$ for some $\varepsilon>0$. Thus if $|\mathbf{x}|<\varepsilon$, there exists $\mathbf{t}$ such that $\mathbf{x}+\mathbf{t} \in A-\mathbf{a}_{0}$ and $\mathbf{t} \in B-\mathbf{b}_{0}$. Subtract these.
2. Show $M f$ is Borel measurable by verifying that $[M f>\lambda] \equiv E_{\lambda}$ is actually an open set. Hint: If $\mathbf{x} \in E_{\lambda}$ then for some $r, \int_{B(\mathbf{x}, r)}|f| d m>\lambda m(B(\mathbf{x}, r))$. Then for $\delta$ a small enough positive number, $\int_{B(\mathbf{x}, r)}|f| d m>\lambda m(B(\mathbf{x}, r+2 \delta))$. Now pick $\mathbf{y} \in B(\mathbf{x}, \delta)$ and argue that $B(\mathbf{y}, \delta+r) \supseteq B(\mathbf{x}, r)$. Therefore show that,

$$
\int_{B(\mathbf{y}, \delta+r)}|f| d m>\int_{B(\mathbf{x}, \mathbf{r})}|f| d m>\lambda B(\mathbf{x}, r+2 \delta) \geq \lambda m(B(\mathbf{y}, r+\delta))
$$

Thus $B(\mathbf{x}, \delta) \subseteq E_{\lambda}$.
3. Consider the following nested sequence of compact sets, $\left\{P_{n}\right\}$. Let $P_{1}=[0,1], P_{2}=$ $\left[0, \frac{1}{3}\right] \cup\left[\frac{2}{3}, 1\right]$, etc. To go from $P_{n}$ to $P_{n+1}$, delete the open interval which is the middle third of each closed interval in $P_{n}$. Let $P=\cap_{n=1}^{\infty} P_{n}$. By the finite intersection property of compact sets, $P \neq \emptyset$. Show $m(P)=0$. If you feel ambitious also show there is a one to one onto mapping of $[0,1]$ to $P$. The set $P$ is called the Cantor set. Thus, although $P$ has measure zero, it has the same number of points in it as $[0,1]$ in the sense that there is a one to one and onto mapping from one to the other. Hint: There are various ways of doing this last part but the most enlightenment is obtained by exploiting the topological properties of the Cantor set rather than some silly representation in terms of sums of powers of two and three. All you need to do is use the Schroder Bernstein theorem and show there is an onto map from the Cantor set to $[0,1]$. If you do this right and remember the theorems about characterizations of compact metric spaces, Proposition 7.6 .5 on Page 144, you may get a pretty good idea why every compact metric space is the continuous image of the Cantor set.
4. Consider the sequence of functions defined in the following way. Let $f_{1}(x)=x$ on $[0,1]$. To get from $f_{n}$ to $f_{n+1}$, let $f_{n+1}=f_{n}$ on all intervals where $f_{n}$ is constant. If $f_{n}$ is nonconstant on $[a, b]$, let $f_{n+1}(a)=f_{n}(a), f_{n+1}(b)=f_{n}(b), f_{n+1}$ is piecewise linear and equal to $\frac{1}{2}\left(f_{n}(a)+f_{n}(b)\right)$ on the middle third of $[a, b]$. Sketch a few of these and you will see the pattern. The process of modifying a nonconstant section of the graph of this function is illustrated in the following picture.

Show $\left\{f_{n}\right\}$ converges uniformly on $[0,1]$. If $f(x)=\lim _{n \rightarrow \infty} f_{n}(x)$, show that $f(0)=$ $0, f(1)=1, f$ is continuous, and $f^{\prime}(x)=0$ for all $x \notin P$ where $P$ is the Cantor set of Problem 3. This function is called the Cantor function.It is a very important example to remember. Note it has derivative equal to zero a.e. and yet it succeeds in climbing from 0 to 1 . Explain why this interesting function is not absolutely continuous although it is continuous. Hint: This isn't too hard if you focus on getting a careful estimate on the difference between two successive functions in the list considering only a typical small interval in which the change takes place. The above picture should be helpful.
5. A function, $f:[a, b] \rightarrow \mathbb{R}$ is Lipschitz if $|f(x)-f(y)| \leq K|x-y|$. Show that every Lipschitz function is absolutely continuous. Thus every Lipschitz function is differentiable a.e., $f^{\prime} \in L^{1}$, and $f(y)-f(x)=\int_{x}^{y} f^{\prime}(t) d t$.
6. Suppose $f, g$ are both absolutely continuous on $[a, b]$. Show the product of these functions is also absolutely continuous. Explain why $(f g)^{\prime}=f^{\prime} g+g^{\prime} f$ and show the usual integration by parts formula

$$
f(b) g(b)-f(a) g(a)-\int_{a}^{b} f g^{\prime} d t=\int_{a}^{b} f^{\prime} g d t
$$

7. In Problem $4 f^{\prime}$ failed to give the expected result for $\int_{a}^{b} f^{\prime} d x^{1}$ but at least $f^{\prime} \in L^{1}$. Suppose $f^{\prime}$ exists for $f$ a continuous function defined on $[a, b]$. Does it follow that $f^{\prime}$ is measurable? Can you conclude $f^{\prime} \in L^{1}([a, b])$ ?
8. A sequence of sets, $\left\{E_{i}\right\}$ containing the point $\mathbf{x}$ is said to shrink to $\mathbf{x}$ nicely if there exists a sequence of positive numbers, $\left\{r_{i}\right\}$ and a positive constant, $\alpha$ such that $r_{i} \rightarrow 0$ and

$$
m\left(E_{i}\right) \geq \alpha m\left(B\left(\mathbf{x}, r_{i}\right)\right), E_{i} \subseteq B\left(\mathbf{x}, r_{i}\right)
$$

Show the above theorems about differentiation of measures with respect to Lebesgue measure all have a version valid for $E_{i}$ replacing $B(\mathbf{x}, r)$.
9. Suppose $F(x)=\int_{a}^{x} f(t) d t$. Using the concept of nicely shrinking sets in Problem 8 show $F^{\prime}(x)=f(x)$ a.e.

[^23]10. A random variable, $X$ is a measurable real valued function defined on a measure space, $(\Omega, \mathscr{S}, P)$ where $P$ is just a measure with $P(\Omega)=1$ called a probability measure. The distribution function for $X$ is the function, $F(x) \equiv P([X \leq x])$ in words, $F(x)$ is the probability that $X$ has values no larger than $x$. Show that $F$ is a right continuous increasing function with the property that $\lim _{x \rightarrow-\infty} F(x)=0$ and $\lim _{x \rightarrow \infty} F(x)=1$.
11. Suppose $F$ is an increasing right continuous function.
(a) Show that $L f \equiv \int_{a}^{b} f d F$ is a well defined positive linear functional on $C_{c}(\mathbb{R})$ where here $[a, b]$ is a closed interval containing the support of $f \in C_{c}(\mathbb{R})$.
(b) Using the Riesz representation theorem for positive linear functionals on $C_{c}(\mathbb{R})$, let $\mu$ denote the Radon measure determined by $L$. Show that $\mu((a, b])=F(b)-$ $F(a)$ and $\mu(\{b\})=F(b)-F(b-)$ where $F(b-) \equiv \lim _{x \rightarrow b-} F(x)$.
(c) Review Corollary 20.1.4 on Page 601 at this point. Show that the conditions of this corollary hold for $\mu$ and $m$. Consider $\mu_{\perp}+\mu_{\|}$, the Lebesgue decomposition of $\mu$ where $\mu_{\|} \ll m$ and there exists a set of $m$ measure zero, $N$ such that $\mu_{\perp}(E)=\mu_{\perp}(E \cap N)$. Show $\mu((0, x])=\mu_{\perp}((0, x])+\int_{0}^{x} h(t) d t$ for some $h \in L^{\perp}(m)$. Using Theorem 26.7.7 show $h(x)=F^{\prime}(x) m$ a.e. Explain why $F(x)=F(0)+S(x)+\int_{0}^{x} F^{\prime}(t) d t$ for some function, $S(x)$ which is increasing but has $S^{\prime}(x)=0$ a.e. Note this shows in particular that a right continuous increasing function has a derivative a.e.
12. Suppose now that $G$ is just an increasing function defined on $\mathbb{R}$. Show that $G^{\prime}(x)$ exists a.e. Hint: You can mimic the proof of Theorem 26.7.4. The Dini derivates are defined as
\[

$$
\begin{aligned}
D_{+} G(x) & \equiv \lim _{\inf _{h \rightarrow 0+}} \frac{G(x+h)-G(x)}{h} \\
D^{+} G(x) & \equiv \lim \sup _{h \rightarrow 0+} \frac{G(x+h)-G(x)}{h} \\
D_{-} G(x) & \equiv \lim \inf _{h \rightarrow 0+} \frac{G(x)-G(x-h)}{h} \\
D^{-} G(x) & \equiv \lim \sup _{h \rightarrow 0+} \frac{G(x)-G(x-h)}{h}
\end{aligned}
$$
\]

When $D_{+} G(x)=D^{+} G(x)$ the derivative from the right exists and when $D^{-} G(x)=$ $D_{-} G(x)$, then the derivative from the left exists. Let $(a, b)$ be an open interval and let

$$
N_{p q} \equiv\left\{x \in(a, b): D^{+} G(x)>q>p>D_{+} G(x)\right\} .
$$

Let $V \subseteq(a, b)$ be an open set containing $N_{p q}$ such that $m(V)<m\left(N_{p q}\right)+\varepsilon$. Show using a Vitali covering theorem there is a disjoint sequence of intervals contained in
$V,\left\{\left(x_{i}, x_{i}+h_{i}\right)\right\}_{i=1}^{\infty}$ such that

$$
\frac{G\left(x_{i}+h_{i}\right)-G\left(x_{i}\right)}{h_{i}}<p
$$

Next show there is a disjoint sequence of intervals $\left\{\left(x_{i}^{\prime}, x_{j}^{\prime}+h_{j}^{\prime}\right)\right\}_{j=1}^{\infty}$ such that each of these is contained in one of the former intervals and

$$
\frac{G\left(x_{j}^{\prime}+h_{j}^{\prime}\right)-G\left(x_{j}^{\prime}\right)}{h_{j}^{\prime}}>q, \sum_{j} h_{j}^{\prime} \geq m\left(N_{p q}\right) .
$$

Then

$$
\begin{aligned}
q m\left(N_{p q}\right) & \leq q \sum_{j} h_{j}^{\prime} \leq \sum_{j} G\left(x_{j}^{\prime}+h_{j}^{\prime}\right)-G\left(x_{j}^{\prime}\right) \leq \sum_{i} G\left(x_{i}+h_{i}\right)-G\left(x_{i}\right) \\
& \leq p \sum_{i} h_{i} \leq p m(V) \leq p\left(m\left(N_{p q}\right)+\varepsilon\right)
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows $m\left(N_{p q}\right)=0$. Taking a union of all $N_{p q}$ for $p, q$ rational, shows the derivative from the right exists a.e. Do a similar argument to show the derivative from the left exists a.e. and then show the derivative from the left equals the derivative from the right a.e. using a simlar argument. Thus $G^{\prime}(x)$ exists on $(a, b)$ a.e. and so it exists a.e. on $\mathbb{R}$ because $(a, b)$ was arbitrary.

## Chapter 27

## Orlitz Spaces

### 27.1 Basic Theory

All the theorems about the $L^{p}$ spaces have generalizations to something called an Orlitz space. [1], [94] Instead of the convex function, $A(t)=t^{p} / p$, one considers a more general convex increasing function called an $N$ function.

Definition 27.1.1 $A:[0, \infty) \rightarrow[0, \infty)$ is an $N$ function if the following two conditions hold.

$$
\begin{align*}
& A \text { is convex and strictly increasing }  \tag{27.1.1}\\
& \lim _{t \rightarrow 0+} \frac{A(t)}{t}=0, \lim _{t \rightarrow \infty} \frac{A(t)}{t}=\infty . \tag{27.1.2}
\end{align*}
$$

For $A$ an $N$ function,

$$
\begin{equation*}
\widetilde{A}(s) \equiv \max \{s t-A(t): t \geq 0\} \tag{27.1.3}
\end{equation*}
$$

As an example see the following picture of a typical $N$ function.

Note that from the assumption, 27.1.2 the maximum in the definition of $\widetilde{A}$ must exist. This is because for $t \neq 0$

$$
(s-A(t) / t) t
$$

is negative for all $t$ large enough. On the other hand, it equals 0 when $t=0$ and so it suffices to consider only $t$ in a compact set.

Lemma 27.1.2 Let $\phi: \mathbb{R} \rightarrow \mathbb{R}$ be a convex function. Then $\phi$ is Lipschitz continuous on $[a, b]$.

Proof: Since it is convex, the difference quotients,

$$
\frac{\phi(t)-\phi(a)}{t-a}
$$

are increasing because by convexity, if $a<t<x$

$$
\frac{t-a}{x-a} \phi(x)+\left(1-\frac{t-a}{x-a}\right) \phi(a) \geq \phi(t)
$$

and this reduces to

$$
\frac{\phi(t)-\phi(a)}{t-a} \leq \frac{\phi(x)-\phi(a)}{x-a}
$$

Also these difference quotients are bounded below by

$$
\frac{\phi(a)-\phi(a-1)}{1}=\phi(a)-\phi(a-1) .
$$

Let

$$
A \equiv \inf \left\{\frac{\phi(t)-\phi(a)}{t-a}: t \in(a, b)\right\}
$$

Then $A$ is some finite real number. Similarly there exists a real number $B$ such that for all $t \in(a, b)$,

$$
B \geq \frac{\phi(b)-\phi(t)}{b-t}
$$

Now let $a \leq s<t \leq b$. Then

$$
\frac{\phi(t)-\phi(s)}{t-s} \geq \frac{\phi(t)-\theta \phi(a)-(1-\theta) \phi(t)}{t-s}
$$

where $\theta$ is such that $\theta a+(1-\theta) t=s$. Thus

$$
\theta=\frac{t-s}{t-t_{1}}
$$

and so the above implies

$$
\frac{\phi(t)-\phi(s)}{t-s} \geq \frac{t-s}{t-t_{1}} \frac{\phi(t)-\phi(a)}{t-s}=\frac{\phi(t)-\phi(a)}{t-t_{1}} \geq A .
$$

Similarly,

$$
\begin{aligned}
\frac{\phi(t)-\phi(s)}{t-s} & \leq \frac{\theta \phi(b)+(1-\theta) \phi(s)-\phi(s)}{t-s} \\
& =\frac{t-s}{b-s} \frac{\phi(b)-\phi(s)}{t-s} \leq B
\end{aligned}
$$

It follows

$$
|\phi(t)-\phi(s)| \leq(|A|+|B|)|t-s|
$$

and this proves the lemma.
The following is like the inequality, $s t \leq t^{p} / p+s^{q} / q$, important in the study of $L^{p}$ spaces.

Proposition 27.1.3 If $A$ is an $N$ function, then so is $\widetilde{A}$ and

$$
\begin{equation*}
A(t)=\max \{t s-\widetilde{A}(s): s \geq 0\} \tag{27.1.4}
\end{equation*}
$$

so $\widetilde{\widetilde{A}}=A$. Also

$$
\begin{equation*}
s t \leq A(t)+\widetilde{A}(s) \text { for all } s, t \geq 0 \tag{27.1.5}
\end{equation*}
$$

and for all $s>0$,

$$
\begin{equation*}
A\left(\frac{\widetilde{A}(s)}{s}\right) \leq \widetilde{A}(s) \tag{27.1.6}
\end{equation*}
$$

Proof: First consider the claim $\widetilde{A}$ is convex. Let $\lambda \in[0,1]$.

$$
\begin{aligned}
& \widetilde{A}\left(\lambda s_{1}+(1-\lambda) s_{2}\right) \equiv \max \left\{\left[s_{1} \lambda+(1-\lambda) s_{2}\right] t-A(t): t \geq 0\right\} \\
& \leq \lambda \max \left\{s_{1} t-A(t): t \geq 0\right\}+(1-\lambda) \max \left\{s_{2} t-A(t): t \geq 0\right\} \\
& =\lambda \widetilde{A}\left(s_{1}\right)+(1-\lambda) \widetilde{A}\left(s_{2}\right)
\end{aligned}
$$

It is obvious $\widetilde{A}$ is stictly increasing because $s t$ is strictly increasing in $s$. Next consider 27.1.2.

For $s>0$ let $t_{s}$ denote the number where the maximum is achieved. That is,

$$
\widetilde{A}(s) \equiv s t_{s}-A\left(t_{s}\right)
$$

Thus

$$
\begin{equation*}
\frac{\widetilde{A}(s)}{s}=t_{s}-\frac{A\left(t_{s}\right)}{s} \geq 0 \tag{27.1.7}
\end{equation*}
$$

It follows from this that

$$
\lim _{s \rightarrow 0+} t_{s}=0
$$

since otherwise, a contradiction results to 27.1.7, the expression becoming negative for small enough $s$. Thus

$$
t_{s} \geq \frac{\widetilde{A}(s)}{s} \geq 0
$$

and this shows

$$
\lim _{s \rightarrow 0+} \frac{\widetilde{A}(s)}{s}=0
$$

which shows 27.1.2.
To verify the second part of 27.1.2, let $t_{s}$ be as just described. Then for any $t>0$

$$
\frac{\widetilde{A}(s)}{s}=t_{s}-\frac{A\left(t_{s}\right)}{s} \geq t-\frac{A(t)}{s}
$$

It follows

$$
\lim \inf _{s \rightarrow \infty} \frac{\widetilde{A}(s)}{s} \geq t
$$

Since $t$ is arbitrary, this proves the second part of 27.1.2.
The inequality 27.1.5 follows from the definition of $\widetilde{A}(s)$.

Next consider 27.1.4. It must be shown that

$$
A\left(t_{0}\right)=\max \left\{t_{0} s-\widetilde{A}(s): s \geq 0\right\}
$$

To do so, first note

$$
\widetilde{A}(s)=\max \{s t-A(t): t \geq 0\} \geq s t_{0}-A\left(t_{0}\right)
$$

Hence

$$
\max \left\{t_{0} s-\widetilde{A}(s): s \geq 0\right\} \leq \max \left\{t_{0} s-\left[s t_{0}-A\left(t_{0}\right)\right]\right\}=A\left(t_{0}\right)
$$

Now let

$$
s_{0} \equiv \inf \left\{\frac{A(t)-A\left(t_{0}\right)}{t-t_{0}}: t>t_{0}\right\}
$$

By convexity, the above difference quotients are nondecreasing in $t$ and so

$$
s_{0}\left(t-t_{0}\right) \leq A(t)-A\left(t_{0}\right)
$$

for all $t \neq t_{0}$. Hence for all $t$,

$$
s_{0} t-A(t) \leq s_{0} t_{0}-A\left(t_{0}\right)
$$

and so

$$
\widetilde{A}\left(s_{0}\right)=s_{0} t_{0}-A\left(t_{0}\right)
$$

implying

$$
A\left(t_{0}\right)=s_{0} t_{0}-\widetilde{A}\left(s_{0}\right) \leq \max \left\{s t_{0}-\widetilde{A}(s): s \geq 0\right\} \leq A\left(t_{0}\right)
$$

Therefore, 27.1.4 holds.
Consider 27.1.6 next. To do so, let $a=A^{\prime}$ so that

$$
A(t)=\int_{0}^{t} a(r) d r, a \text { increasing. }
$$

This is possible by Rademacher's theorem, Corollary 26.4.3 and the fact that since $A$ is convex, it is locally Lipshitz found in Lemma 27.1.2 above. That $a$ is increasing follows from convexity of $A$. Here is why. For a.e. $s, t \geq 0$, and letting $\lambda \in[0,1]$,

$$
\begin{aligned}
\frac{A(s+\lambda(t-s))-A(s)}{\lambda} & \leq \frac{(1-\lambda) A(s)+\lambda A(t)-A(s)}{\lambda} \\
& =A(t)-A(s)
\end{aligned}
$$

Then passing to a limit as $\lambda \rightarrow 0+$,

$$
a(s)(t-s) \leq A(t)-A(s)
$$

Similarly

$$
a(t)(s-t) \leq A(s)-A(t)
$$

and so

$$
(a(t)-a(s))(t-s) \geq 0
$$

(If you like, you can simply assume from the beginning that $A(t)$ is given this way as an integral of a positive increasing function, $a$, and verify directly that such an $A$ is convex and satisfies the properties of an $N$ function. There is no loss of generality in doing so.) Thus geometrically, $A(t)$ equals the area under the curve defined by $a$ and above the $x$ axis from $x=0$ to $x=t$. In the definition of $\widetilde{A}(s)$ let $t_{s}$ be the point where the maximum is achieved. Then

$$
\widetilde{A}(s)=s t_{s}-A\left(t_{s}\right)
$$

and so at this point, $\widetilde{A}(s)+A\left(t_{s}\right)=s t_{s}$. This means that $\tilde{A}(s)$ is the area to the left of the graph of $a$ which is to the right of the $y$ axis for $y$ between 0 and $a\left(t_{s}\right)$ and that in fact $a\left(t_{s}\right)=s$. The following picture illustrates the reasoning which follows.

Therefore,

$$
\begin{aligned}
\frac{\tilde{A}(s)}{s} & =t_{s}-\frac{A\left(t_{s}\right)}{s}=t_{s}-\frac{1}{s} \int_{0}^{t_{s}} a(r) d r \\
& =t_{s}-\frac{1}{a\left(t_{s}\right)} \int_{0}^{t_{s}} a(r) d r=\frac{1}{a\left(t_{s}\right)}\left(t_{s} s-\int_{0}^{t_{s}} a(r) d r\right)
\end{aligned}
$$

and so

$$
\begin{aligned}
A\left(\frac{\widetilde{A}(s)}{s}\right) & =\int_{0}^{\widetilde{A}(s) / s} a(r) d r=\int_{0}^{\frac{1}{a\left(t_{s}\right)} \int_{0}^{t_{s}}(s-a(r)) d r} a(\tau) d \tau \\
& \leq \int_{0}^{t_{s}} s-a(r) d r=s t_{s}-A\left(t_{s}\right)=\widetilde{A}(s)
\end{aligned}
$$

The inequality results from replacing $a(\tau)$ with $a\left(t_{s}\right)$ in the last integral on the top line.
An example of an $N$ function is $A(t)=\frac{t^{p}}{p}$ for $t \geq 0$ and $p>1$. For this example, $\widetilde{A}(s)=\frac{s^{p^{\prime}}}{p^{\prime}}$ where $\frac{1}{p}+\frac{1}{p^{\prime}}=1$.

Definition 27.1.4 Let $A$ be an $N$ function and let $(\Omega, \mathscr{S}, \mu)$ be a measure space. Define

$$
\begin{equation*}
K_{A}(\Omega) \equiv\left\{\text { u measurable such that } \int_{\Omega} A(|u|) d \mu<\infty\right\} \tag{27.1.8}
\end{equation*}
$$

This is called the Orlitz class. Also define

$$
\begin{equation*}
L_{A}(\Omega) \equiv\left\{\lambda u: u \in K_{A}(\Omega) \text { and } \lambda \in \mathbb{F}\right\} \tag{27.1.9}
\end{equation*}
$$

where $\mathbb{F}$ is the field of scalars, assumed to be either $\mathbb{R}$ or $\mathbb{C}$.
The pair $(A, \Omega)$ is called $\Delta$ regular if either of the following conditions hold.

$$
\begin{equation*}
A(r x) \leq K_{r} A(x) \text { for all } x \in[0, \infty) \tag{27.1.10}
\end{equation*}
$$

or $\mu(\Omega)<\infty$ and for all $r>0$, there exists $M_{r}$ and $K_{r}>0$ such that

$$
\begin{equation*}
A(r x) \leq K_{r} A(x) \text { for all } x \geq M_{r} \tag{27.1.11}
\end{equation*}
$$

Note there are $N$ functions which are not $\Delta$ regular. For example, consider

$$
A(x) \equiv e^{x^{2}}-1
$$

It can't be $\Delta$ regular because

$$
\lim _{r \rightarrow \infty} \frac{e^{r^{2} x^{2}}-1}{e^{x^{2}}-1}=\infty
$$

However, functions like $x^{p} / p$ for $p>1$ are $\Delta$ regular.
Then the following proposition is important.
Proposition 27.1.5 If $(A, \Omega)$ is $\Delta$ regular, then $K_{A}(\Omega)=L_{A}(\Omega)$. In any case, $L_{A}(\Omega)$ is a vector space and $K_{A}(\Omega) \subseteq L_{A}(\Omega)$.

Proof: Suppose $(A, \Omega)$ is $\Delta$ regular. Then I claim $K_{A}(\Omega)$ is a vector space. This will verify $K_{A}(\Omega)=L_{A}(\Omega)$. Let $f, g \in K_{A}(\Omega)$ and suppose 27.1.10. Then

$$
A(|f+g|)=A\left(2\left(\frac{|f+g|}{2}\right)\right) \leq K_{2} A\left(\frac{|f+g|}{2}\right) \leq K_{2} \frac{1}{2}[A(|f|)+A(|g|)]
$$

so $f+g \in K_{A}(\Omega)$ in this case. Now suppose 27.1.11

$$
\begin{gathered}
\int_{\Omega} A(|f+g|) d \mu=\int_{\left[|f+g| \leq M_{2}\right]} A(|f+g|) d \mu+\int_{\left[|f+g|>M_{2}\right]} A(|f+g|) d \mu \\
\leq A\left(M_{2}\right) \mu(\Omega)+\int_{\Omega} \frac{K_{2}}{2}(A(|f|)+A(|g|)) d \mu<\infty
\end{gathered}
$$

Thus $f+g \in K_{A}(\Omega)$ in this case also.
Next consider scalar multiplication. First consider the case of 27.1.10. If $f \in K_{A}(\Omega)$ and $\alpha \in \mathbb{F}$,

$$
\int_{\Omega} A(|\alpha||f|) d \mu \leq K_{|\alpha|} \int_{\Omega} A(f) d \mu
$$

so in the case of 27.1.10 $\alpha f \in K_{A}(\Omega)$ whenever $f \in K_{A}(\Omega)$. In the case of 27.1.11,

$$
\begin{aligned}
\int_{\Omega} A(|\alpha||f|) d \mu & =\int_{\left[|\alpha||f| \leq M_{|\alpha|}\right]} A(|\alpha||f|) d \mu+\int_{\left[|\alpha||f|>M_{|\alpha|}\right]} A(|\alpha||f|) d \mu \\
& \leq A\left(M_{|\alpha|}\right) \mu(\Omega)+\int_{\Omega} K_{|\alpha|} A(|f|) d \mu<\infty
\end{aligned}
$$

This establishes the first part of the proposition.
Next consider the claim that $L_{A}(\Omega)$ is always a vector space. First note $K_{A}(\Omega)$ is always convex due to convexity of $A$. Let $\lambda u, \alpha v \in L_{A}(\Omega)$ where $u, v \in K_{A}(\Omega)$ and let $a, b$ be scalars in $\mathbb{F}$. Then

$$
a \lambda u+b \alpha v=|a \lambda| \omega u+|b \alpha| \theta v
$$

where $|\omega|=|\theta|=1$. Then

$$
=(|a \lambda|+|b \alpha|)\left(\frac{|a \lambda| \omega u+|b \alpha| \theta v}{|a \lambda|+|b \alpha|}\right)
$$

which exhibits $a \lambda u+b \alpha v$ as a multiple of a convex combination of two elements of $K_{A}(\Omega), \omega u$ and $\theta v$. Thus $L_{A}(\Omega)$ is closed with respect to linear combinations. This shows it is a vector space. This proves the proposition.

The following norm for $L_{A}(\Omega)$ is due to Luxemburg [94]. You might compare this to the definition of a Minkowski functional. The definition of $L_{A}(\Omega)$ above was cooked up so that the following norm does make sense.

## Definition 27.1.6 Define

$$
\|u\|_{A}=\|u\|_{A, \Omega} \equiv \inf \left\{t>0: \int_{\Omega} A\left(\frac{|u(x)|}{t}\right) d \mu \leq 1\right\}
$$

If two functions of $L_{A}(\Omega)$ are equal a.e. they are considered to be the same in the usual way.

Proposition 27.1.7 The number defined in Definition 27.1.6 is a norm on $L_{A}(\Omega)$. Also, if $\Omega_{1} \subseteq \Omega$, then

$$
\|u\|_{A, \Omega_{1}} \leq\|u\|_{A, \Omega}
$$

Proof: Clearly $\|u\|_{A} \geq 0$. Is $\|u\|_{A}$ finite for $u \in L_{A}(\Omega)$ ? Let $u \in L_{A}(\Omega)$ so $u=\lambda v$ where $v \in K_{A}(\Omega)$. Then for $s>0$

$$
\int_{\Omega} A\left(\frac{|u|}{s|\lambda|}\right) d \mu=\int_{\Omega} A\left(\frac{|v|}{s}\right) d \mu<\infty
$$

whenever $s>1$. Therefore, from the dominated convergence theorem, if $s$ is large enough,

$$
\int_{\Omega} A\left(\frac{|u|}{s|\lambda|}\right) d \mu \leq 1
$$

and this shows there are values of $t>0$ such that

$$
\int_{\Omega} A\left(\frac{|u(x)|}{t}\right) d \mu \leq 1
$$

Thus $\|u\|_{A}$ is finite as hoped.

Now suppose $\|u\|_{A}=0$ and let

$$
E_{n} \equiv\left\{x:|u(x)| \geq \frac{1}{n}\right\}
$$

Then for arbitrarily small values of $t$,

$$
\int_{E_{n}} A\left(\frac{(1 / n)}{t}\right) d \mu \leq \int_{\Omega} A\left(\frac{|u(x)|}{t}\right) d \mu \leq 1
$$

and so for arbitrarily small values of $t$,

$$
A\left(\frac{(1 / n)}{t}\right) \mu\left(E_{n}\right) \leq 1
$$

Letting $t \rightarrow 0+$ yields a contradiction unless $\mu\left(E_{n}\right)=0$. Now

$$
\mu([|u(x)|>0]) \leq \sum_{n=1}^{\infty} \mu\left(E_{n}\right)=0
$$

Thus $u=0$ as claimed.
Consider the other axioms of a norm. Let $u, v \in L_{A}(\Omega)$ and let $\alpha, \beta$ be scalars. Then

$$
\|\alpha u+\beta v\|_{A} \equiv \inf \left\{t>0: \int_{\Omega} A\left(\frac{|u(x)+v(x)|}{t}\right) d \mu \leq 1\right\}
$$

Without loss of generality $\|u\|_{A},\|v\|_{A}<\infty$ since otherwise there is nothing to prove.

$$
\begin{aligned}
& \|u+v\|_{A} \equiv \inf \left\{t>0: \int_{\Omega} A\left(\frac{|\alpha u(x)+\beta v(x)|}{t}\right) d \mu \leq 1\right\} \\
& \leq \inf \left\{t>0: \int_{\Omega} A\left(\frac{|\alpha||u|+|\beta||v|}{t}\right) d \mu \leq 1\right\} \\
& =\inf \left\{t>0: \int_{\Omega} A\left(\frac{|\alpha| \frac{(|\alpha|+|\beta|)|u|}{t}+|\beta| \frac{(|\alpha|+|\beta|)|v|}{t}}{(|\alpha|+|\beta|)}\right) d \mu \leq 1\right\} \\
& \leq \quad \inf \left\{t>0: \frac{|\alpha|}{(|\alpha|+|\beta|)} \int_{\Omega} A\left(\frac{|u|}{t /(|\alpha|+|\beta|)}\right) d \mu \leq 1\right\} \\
& \quad+\inf \left\{t>0: \frac{|\beta|}{(|\alpha|+|\beta|)} \int_{\Omega} A\left(\frac{|v|}{t /(|\alpha|+|\beta|)}\right) d \mu \leq 1\right\} \\
& =\quad|\alpha| \inf \left\{t /(|\alpha|+|\beta|)>0: \int_{\Omega} A\left(\frac{|u|}{t /(|\alpha|+|\beta|)}\right) d \mu \leq 1\right\} \\
& \quad+|\beta| \inf \left\{t /(|\alpha|+|\beta|)>0: \int_{\Omega} A\left(\frac{|v|}{t /(|\alpha|+|\beta|)}\right) d \mu \leq 1\right\}
\end{aligned}
$$

$$
=|\alpha|\|u\|_{A}+|\beta|\|v\|_{A}
$$

Now let $\Omega_{1} \subseteq \Omega$.

$$
\begin{aligned}
\|u\|_{A, \Omega_{1}} & \equiv \inf \left\{t>0: \int_{\Omega_{1}} A\left(\frac{|u(x)|}{t}\right) d \mu \leq 1\right\} \\
& \leq \inf \left\{t>0: \int_{\Omega} A\left(\frac{|u(x)|}{t}\right) d \mu \leq 1\right\} \equiv\|u\|_{A, \Omega}
\end{aligned}
$$

This occurs because if $t$ is in the second set, then it is in the first so the infimum of the second is no smaller than that of the first. This proves the proposition.

Next it is shown that $L_{A}(\Omega)$ is a Banach space.
Theorem 27.1.8 $L_{A}(\Omega)$ is a Banach space and every Cauchy sequence has a subsequence which also converges pointwise a.e.

Proof: Let $\left\{f_{n}\right\}$ be a Cauchy sequence in $L_{A}(\Omega)$ and select a subsequence $\left\{f_{n_{k}}\right\}$ such that

$$
\left\|f_{n_{k+1}}-f_{n_{k}}\right\|_{A} \leq 2^{-k}
$$

Thus

$$
f_{n_{m}}(x)=f_{n_{1}}(x)+\sum_{k=1}^{m-1} f_{n_{k+1}}(x)-f_{n_{k}}(x) .
$$

Let

$$
g_{m}(x) \equiv\left|f_{n_{1}}(x)\right|+\sum_{k=1}^{m-1}\left|f_{n_{k+1}}(x)-f_{n_{k}}(x)\right|
$$

Then

$$
\left\|g_{m}\right\|_{A} \leq\left\|f_{n_{1}}\right\|_{A}+\sum_{k=1}^{\infty} 2^{-k} \equiv K<\infty
$$

Let

$$
g(x) \equiv \lim _{m \rightarrow \infty} g_{m}(x) \equiv\left|f_{n_{1}}(x)\right|+\sum_{k=1}^{\infty}\left|f_{n_{k+1}}(x)-f_{n_{k}}(x)\right|
$$

Now $K>\left\|g_{m}\right\|_{A}$ so

$$
1 \geq \int_{\Omega} A\left(\frac{\left|g_{m}(x)\right|}{K}\right) d \mu
$$

By the monotone convergence theorem,

$$
1 \geq \int_{\Omega} A\left(\frac{|g(x)|}{K}\right) d \mu
$$

showing $g(x)<\infty$ a.e., say for all $x \notin E$ where $E$ is a measurable set having measure zero. Let

$$
\begin{aligned}
f(x) & \equiv \mathscr{X}_{E^{C}}(x)\left(f_{n_{1}}(x)+\sum_{k=1}^{\infty}\left(f_{n_{k+1}}(x)-f_{n_{k}}(x)\right)\right) \\
& =\lim _{m \rightarrow \infty} \mathscr{X}_{E^{C}}(x) f_{n_{m}}(x)
\end{aligned}
$$

Thus $f$ is measurable and $f_{n_{m}}(x) \rightarrow f(x)$ a.e. as $m \rightarrow \infty$.
For $l>k$,

$$
\left\|f_{n_{k}}-f_{n_{l}}\right\|_{A}<\frac{1}{2^{k-2}}
$$

and so

$$
1 \geq \int_{\Omega} A\left(\frac{\left|f_{n_{l}}(x)-f_{n_{k}}(x)\right|}{\left(\frac{1}{2^{k-2}}\right)}\right) d \mu
$$

By Fatou's lemma, let $l \rightarrow \infty$ and obtain

$$
1 \geq \int_{\Omega} A\left(\frac{\left|f(x)-f_{n_{k}}(x)\right|}{\left(\frac{1}{2^{k-2}}\right)}\right) d \mu
$$

and so $\left(f-f_{n_{k}}\right) 2^{k-2} \in K_{A}(\Omega)$ and so $f-f_{n_{k}} \in L_{A}(\Omega), f_{n_{k}} \in L_{A}(\Omega)$. Since $L_{A}(\Omega)$ is a vector space, this shows $f \in L_{A}(\Omega)$. Also

$$
\left\|f-f_{n_{k}}\right\|_{A} \leq \frac{1}{2^{k-2}}
$$

showing that $f_{n_{k}} \rightarrow f$ in $L_{A}(\Omega)$. Since a subsequence converges in $L_{A}(\Omega)$, it follows the original Cauchy sequence also converges to $f$ in $L_{A}(\Omega)$. This proves the theorem.

Next consider the space, $E_{A}(\Omega)$ which will be a subspace of the Orlitz class, $K_{A}(\Omega)$ just as $L_{A}(\Omega)$ is a vector space containing the Orlitz class.

Definition 27.1.9 Let $\mathbb{S}$ denote the set of simple functions, $s$, such that

$$
\mu(\{x: s(x) \neq 0\})<\infty .
$$

Then define

$$
E_{A}(\Omega) \equiv \text { the closure in } L_{A}(\Omega) \text { of } \mathbb{S} .
$$

Proposition 27.1.10 $E_{A}(\Omega) \subseteq K_{A}(\Omega) \subseteq L_{A}(\Omega)$ and they are all equal if $(A, \Omega)$ is $\Delta$ regular.

Proof: First note that $\mathbb{S} \subseteq K_{A}(\Omega) \cap E_{A}(\Omega)$. Let $f \in E_{A}(\Omega)$. Then by the definition of $E_{A}(\Omega)$, there exists $s_{n} \in \mathbb{S}$ such that

$$
\left\|s_{n}-f\right\|_{A} \rightarrow 0
$$

Therefore, for $n$ large enough,

$$
\left\|s_{n}-f\right\|_{A}<\frac{1}{2}
$$

and so

$$
\int_{\Omega} A\left(\frac{\left|f-s_{n}\right|}{\left(\frac{1}{2}\right)}\right) d \mu=\int_{\Omega} A\left(\left|2 f-2 s_{n}\right|\right) d \mu<\infty
$$

Since $\mathbb{S} \subseteq K_{A}(\Omega)$,

$$
\int_{\Omega} A\left(2\left|s_{n}\right|\right) d \mu<\infty
$$

Therefore, $2 f-2 s_{n} \in K_{A}(\Omega)$ and $2 s_{n} \in K_{A}(\Omega)$ and so, since $K_{A}(\Omega)$ is convex,

$$
\frac{2 f-2 s_{n}}{2}+\frac{2 s_{n}}{2}=f \in K_{A}(\Omega)
$$

This shows $E_{A}(\Omega) \subseteq K_{A}(\Omega)$.
Next consider the claim these spaces are all equal in the case that $(A, \Omega)$ is $\Delta$ regular. It was already shown in Proposition 27.1.5 that in this case,

$$
K_{A}(\Omega)=L_{A}(\Omega)
$$

so it remains to show $E_{A}(\Omega)=K_{A}(\Omega)$. Is every $f \in K_{A}(\Omega)$ the limit in $L_{A}(\Omega)$ of functions from $\mathbb{S}$ ? First suppose $\mu(\Omega)=\infty$. Then $A(r|f|) \leq K_{r} A(|f|)$ and so $A(r|f|) \in L^{1}(\Omega)$ for any $r$. Let $\varepsilon>0$ be given and let

$$
\Omega_{\delta} \equiv\{x:|f(x)| \geq \delta\}
$$

Then by the dominated convergence theorem,

$$
\lim _{\delta \rightarrow 0+} \int_{\Omega \backslash \Omega_{\delta}} A\left(\frac{|f|}{\varepsilon}\right) d \mu=0
$$

Choose $\delta$ such that

$$
\int_{\Omega \backslash \Omega_{\delta}} A\left(\frac{|f|}{\varepsilon}\right) d \mu<\frac{1}{2}
$$

and let $s_{n} \rightarrow f \mathscr{X}_{\Omega_{\delta}}$ pointwise with $\left|s_{n}\right| \leq\left|f \mathscr{X}_{\Omega_{\delta}}\right|$. Then $s_{n}=0$ on $\Omega \backslash \Omega_{\delta}$ and so

$$
\begin{aligned}
& \int_{\Omega} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu=\int_{\Omega_{\delta}} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu \\
+ & \int_{\Omega \backslash \Omega_{\delta}} A\left(\frac{|f|}{\varepsilon}\right) d \mu \leq \int_{\Omega_{\delta}} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu+\frac{1}{2} .
\end{aligned}
$$

By the dominated convergence theorem,

$$
\int_{\Omega_{\delta}} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu<\frac{1}{2}
$$

for all $n$ large enough. Therefore, for such $n$,

$$
\int_{\Omega} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu<1
$$

and so $\left\|f-s_{n}\right\|_{A} \leq \varepsilon$ showing that in this case $E_{A}(\Omega) \supseteq K_{A}(\Omega)$ since $\varepsilon>0$ is arbitrary.

Now suppose $\mu(\Omega)<\infty$. In this case, only assume $A(r t) \leq K_{r} A(t)$ for $t$ large enough, say for $t \geq M_{r}$. However, this is enough to conclude $A(r|f|) \in L^{1}(\Omega)$ for any $r>0$ because $\mu(\Omega)<\infty$ and $f \in K_{A}(\Omega)$. Let $s_{n} \rightarrow f$ pointwise with $\left|s_{n}\right| \leq|f|$, and $s$ simple. Then

$$
A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) \leq A\left(\frac{2}{\varepsilon}|f|\right) \in L^{1}(\Omega)
$$

and so the dominated convergence theorem implies

$$
\lim _{n \rightarrow \infty} \int_{\Omega} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu=0
$$

Hence

$$
\int_{\Omega} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu<1
$$

for all $n$ large enough and so for such $n$,

$$
\left\|f-s_{n}\right\|_{A} \leq \varepsilon
$$

which proves the proposition.
It turns out $E_{A}(\Omega)$ is the largest linear subspace of $K_{A}(\Omega)$.
Proposition 27.1.11 $E_{A}(\Omega)$ is the maximal linear subspace of $K_{A}(\Omega)$.
Proof: Let $M$ be a subspace of $K_{A}(\Omega)$. Is $M \subseteq E_{A}(\Omega)$ ? For $f \in M, f / \varepsilon \in K_{A}(\Omega)$ for all $\varepsilon>0$ because of the fact that $M$ is a subspace and $f \in M$. Thus $A(|f| / \varepsilon)$ is in $L^{1}(\Omega)$. Let $\varepsilon>0$ be given, choose $\delta>0$ and let

$$
F_{\delta} \equiv\{x:|f(x)| \leq \delta\}
$$

By the dominated convergence theorem there exists $\delta$ small enough that

$$
\int_{F_{\delta}} A\left(\frac{2|f|}{\varepsilon}\right) d \mu<\frac{1}{2}
$$

Let $\left|s_{n}\right| \leq|f| \mathscr{X}_{F_{\delta}^{C}}$ and $s_{n} \rightarrow f \mathscr{X}_{F_{\delta}^{C}}$ pointwise for $s_{n}$ a simple function. Thus $s_{n}=0$ on $F_{\delta}$ and so $s_{n} \in \mathbb{S}$ because $\mu\left(F_{\delta}^{C}\right)<\infty$. Now

$$
\begin{aligned}
\int_{\Omega} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu & =\int_{F_{\delta}} A\left(\frac{|f|}{\varepsilon}\right) d \mu+\int_{F_{\delta}^{C}} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu \\
& <\frac{1}{2}+\int_{F_{\delta}^{C}} A\left(\frac{\left|f-s_{n}\right|}{\varepsilon}\right) d \mu
\end{aligned}
$$

The integrand in the last integral is no larger than $\frac{2|f|}{\varepsilon}$ and so by the dominated convergence theorem, this integral converges to 0 as $n \rightarrow \infty$. In particular, it is eventually less than $\frac{1}{2}$. Therefore, for such $n$,

$$
\left\|f-s_{n}\right\|_{A} \leq r
$$

Since $r$ is arbitrary, this shows that $f \in E_{A}(\Omega)$ which proves the proposition.
Next is a comparison of these function spaces for different choices of the $N$ function. The notation $X \hookrightarrow Y$ for two normed linear spaces means $X$ is a subset of $Y$ and the identity map is continuous.

Proposition 27.1.12 $L_{B}(\Omega) \hookrightarrow L_{A}(\Omega)$ if either

$$
\begin{equation*}
B(t) \geq A(t) \text { for all } t \geq 0 \tag{27.1.12}
\end{equation*}
$$

or if

$$
\begin{equation*}
B(t) \geq A(t) \text { for all } t>M \tag{27.1.13}
\end{equation*}
$$

and $\mu(\Omega)<\infty$.
Proof: Let $f \in L_{B}(\Omega)$ and let

$$
\int_{\Omega} B\left(\frac{|f|}{t}\right) d \mu \leq 1
$$

Then if 27.1.12 holds, it follows

$$
\int_{\Omega} A\left(\frac{|f|}{t}\right) d \mu \leq 1
$$

Thus if $t \geq\|f\|_{B}$ then $t \geq\|f\|_{A}$ which implies $\|f\|_{B} \geq\|f\|_{A}$.
Now suppose 27.1.13 holds and $\mu(\Omega)<\infty$. Then $\max (A, B)$ is an $N$ function dominating both $A$ and $B$ for all $t$. By what was just shown $L_{\max (A, B)}(\Omega) \hookrightarrow L_{B}(\Omega)$. Then let $f \in L_{B}(\Omega)$ and let

$$
\int_{\Omega} B\left(\frac{|f|}{t}\right) d \mu<1
$$

Then

$$
\begin{gathered}
\int_{\Omega} \max (A, B)\left(\frac{|f|}{t}\right) d \mu=\int_{\left[\frac{|f|}{t}>M\right]} B\left(\frac{|f|}{t}\right) d \mu \\
\quad+\int_{\left[\frac{|f|}{t} \leq M\right]} \max (A, B)\left(\frac{|f|}{t}\right) d \mu \\
\leq \int_{\Omega} B\left(\frac{|f|}{t}\right) d \mu+\mu(\Omega) \max (A, B)(M)<\infty .
\end{gathered}
$$

It follows $\frac{|f|}{t} \in K_{\max (A, B)}(\Omega)$ and so $f \in L_{\max (A, B)}(\Omega)$. Hence $L_{B}(\Omega)=L_{\max (A, B)}(\Omega)$ and the identity map from $L_{\max (A, B)}(\Omega)$ to $L_{B}(\Omega)$ is continuous. Therefore, by the open mapping theorem, the norms $\left\|\|_{B}\right.$ and $\| \|_{\max (A, B)}$ are equivalent. Hence for $f \in L_{B}(\Omega)$,

$$
\|f\|_{A} \leq\|f\|_{\max (A, B)} \leq C\|f\|_{B} .
$$

This proves the proposition.

Corollary 27.1.13 Suppose there exists $C>0$, a constant such that either

$$
C B(t) \geq A(t)
$$

for all $t \geq 0$ or

$$
C B(t) \geq A(t)
$$

for all $t>M$ and $\mu(\Omega)<\infty$. Then

$$
L_{B}(\Omega) \hookrightarrow L_{A}(\Omega)
$$

Proof: If $f \in L_{B}(\Omega)$ then $f=\lambda u$ where $u \in K_{B}(\Omega)=K_{C B}(\Omega)$. Hence $L_{C B}(\Omega)=$ $L_{B}(\Omega)$ and the two norms on $L_{B}(\Omega)$,

$$
\left\|\|_{C B}, \text { and }\right\| \|_{B}
$$

are equivalent norms by the open mapping theorem. Hence by the Proposition 27.1.12, if $f \in L_{B}(\Omega)$,

$$
\|f\|_{A} \leq C_{1}\|f\|_{C B} \leq C_{2}\|f\|_{B}
$$

which proves the corollary.
Definition 27.1.14 A increases essentially more slowly than $B$ if for all $a>0$,

$$
\lim _{t \rightarrow \infty} \frac{A(a t)}{B(t)}=0
$$

The next theorem gives added information on how these spaces are related in case that one $N$ function increases essentially more slowly than the other.

Theorem 27.1.15 Suppose $\mu(\Omega)<\infty$ and $A$ increases essentially more slowly than $B$. Then

$$
L_{B}(\Omega) \hookrightarrow E_{A}(\Omega)
$$

Proof: Let $f \in L_{B}(\Omega)$. Then there exists $\lambda>0$ such that

$$
\int_{\Omega} B\left(\frac{|f|}{\lambda}\right) d \mu \leq 1
$$

Let $r$ be such that for $t \geq r$,

$$
A(|\lambda| t) \leq B(t)
$$

Then

$$
\begin{aligned}
\int_{\Omega} A(|f|) d \mu & =\int_{[|f| \geq r]} A(|f|) d \mu+\int_{[|f|<r]} A(|f|) d \mu \\
& \leq \int_{\Omega} B\left(\frac{|f|}{|\lambda|}\right) d \mu+A(r) \mu(\Omega) \\
& <1+A(r) \mu(\Omega)
\end{aligned}
$$

Therefore, $L_{B}(\Omega)$ is a linear space contained in $K_{A}(\Omega)$. It follows from Proposition 27.1.11 that $L_{B}(\Omega) \subseteq E_{A}(\Omega)$. This proves the theorem.

The norm of $E_{A}(\Omega)$ is the same as the norm on $L_{A}(\Omega)$ so this shows $L_{B}(\Omega) \hookrightarrow L_{A}(\Omega)$.
Note that for $1<p<q$ and $A(t)=t^{p} / p, B(t)=t^{q} / q$,

$$
A(r t)=r^{p} t^{p}
$$

and

$$
\lim _{t \rightarrow \infty} \frac{A(r t)}{B(t)}=0
$$

showing this case is covered by the above theorem.
If $A$ is increasing essentially more slowly than $B$ and $\mu(\Omega)<\infty$, this has shown the following inclusions

$$
E_{B}(\Omega) \subseteq K_{B}(\Omega) \subseteq L_{B}(\Omega) \hookrightarrow E_{A}(\Omega) \subseteq K_{A}(\Omega) \subseteq L_{A}(\Omega)
$$

In the case of $A(t)=t^{p} / p, B(t)=t^{q} / q$ both $(A, \Omega)$ and $(B, \Omega)$ are $\Delta$ regular and so in this case or any other case where the $N$ functions are $\Delta$ regular, the above sequence of inclusions reduces to

$$
E_{B}(\Omega)=K_{B}(\Omega)=L_{B}(\Omega) \hookrightarrow E_{A}(\Omega)=K_{A}(\Omega)=L_{A}(\Omega)
$$

### 27.2 Dual Spaces In Orlitz Space

Recall that for $s, t \geq 0$,

$$
s t \leq A(t)+\widetilde{A}(s)
$$

Let $v \in L_{\widetilde{A}}(\Omega)$ and $u \in L_{A}(\Omega)$. Then there is a version of Holder's inequality as follows. For $\varepsilon>0$,

$$
\frac{|v|}{\|v\|_{\widetilde{A}}+\varepsilon} \in K_{\widetilde{A}}(\Omega), \frac{|u|}{\|u\|_{A}+\varepsilon} \in K_{A}(\Omega)
$$

Therefore,

$$
\begin{aligned}
\int_{\Omega}\left(\frac{|u|}{\|u\|_{A}+\varepsilon}\right. & )\left(\frac{|v|}{\|v\|_{\widetilde{A}}+\varepsilon}\right) d \mu \leq \int_{\Omega} A\left(\frac{|u|}{\|u\|_{A}+\varepsilon}\right) d \mu \\
& +\int_{\Omega} \widetilde{A}\left(\frac{|v|}{\|v\|_{\tilde{A}}+\varepsilon}\right) d \mu \leq 2
\end{aligned}
$$

and so $u v \in L^{1}(\Omega)$ and

$$
\left|\int_{\Omega} u v d \mu\right| \leq \int_{\Omega}|u||v| d \mu \leq 2\left(\|v\|_{\tilde{A}}+\varepsilon\right)\left(\|u\|_{A}+\varepsilon\right)
$$

Since $\varepsilon$ is arbitrary this shows

$$
\begin{equation*}
\left|\int_{\Omega} u v d \mu\right| \leq \int_{\Omega}|u||v| d \mu \leq 2\|v\|_{\tilde{A}}\|u\|_{A} \tag{27.2.14}
\end{equation*}
$$

Defining $L_{v}$ for $v \in \widetilde{A}$ by

$$
L_{v}(u) \equiv \int_{\Omega} u v d \mu
$$

it follows $L_{v} \in L_{A}(\Omega)^{\prime}$. From now on assume the measure space is $\sigma$ finite. That is, there exist measurable sets, $\Omega_{k}$ satisfying the following:

$$
\Omega=\cup_{k=1}^{\infty} \Omega_{k}, \mu\left(\Omega_{k}\right)<\infty, \Omega_{k} \subseteq \Omega_{k+1}
$$

Then
Proposition 27.2.1 For $v \in L_{\widetilde{A}}(\Omega)$, the following inequality holds.

$$
\|v\|_{\tilde{A}} \leq\left\|L_{v}\right\| \leq 2\|v\|_{\widetilde{A}}
$$

Here $L_{v}$ is considered as either an element of $E_{A}(\Omega)^{\prime}$ or $L_{A}(\Omega)^{\prime}$ and $\left\|L_{v}\right\|$ refers to the operator norm in either dual space.

Proof: The inequality 27.2 .14 implies $\left\|L_{v}\right\| \leq 2\|v\|_{\tilde{A}}$. It remains to show the other half of the inequality. If $L_{v}=0$ there is nothing to show because this would imply that $v=0$ so assume $\left\|L_{v}\right\|>0$. Define a measurable function, $u$, as follows. Letting $r \in(0,1)$,

$$
u(x) \equiv\left\{\begin{array}{l}
\widetilde{A}\left(\frac{r|v(x)|}{\left\|L_{v}\right\|}\right) / \frac{v(x)}{\left\|L_{v}\right\|} \text { if } v(x) \neq 0  \tag{27.2.15}\\
0 \text { if } v(x)=0 .
\end{array}\right.
$$

Now let

$$
\begin{equation*}
F_{n} \equiv\{x:|u(x)| \leq n\} \cap \Omega_{n} \cap\{x: v(x) \neq 0\} \tag{27.2.16}
\end{equation*}
$$

and define

$$
\begin{equation*}
u_{n}(x) \equiv u(x) \mathscr{X}_{F_{n}}(x) . \tag{27.2.17}
\end{equation*}
$$

Thus $u_{n}$ is bounded and equals zero off a set which has finite measure. It follows that

$$
A\left(\frac{\left|u_{n}\right|}{\alpha}\right) \in L^{1}(\Omega)
$$

for all $\alpha>0$. I claim that $\left\|u_{n}\right\|_{A} \leq 1$. If not, there exists $\varepsilon>0$ such that $\left\|u_{n}\right\|_{A}-\varepsilon>1$. Then since $A$ is convex,

$$
1<\int_{\Omega} A\left(\frac{\left|u_{n}\right|}{\left\|u_{n}\right\|_{A}-\varepsilon}\right) d \mu \leq \frac{1}{\left\|u_{n}\right\|_{A}-\varepsilon} \int_{\Omega} A\left(\left|u_{n}\right|\right) d \mu
$$

Taking $\varepsilon \rightarrow 0+$, using 27.1.6, and convexity of $A$ along with 27.2.15 and 27.2.17,

$$
\begin{aligned}
\left\|u_{n}\right\|_{A} & \leq \int_{\Omega} A\left(\left|u_{n}\right|\right) d \mu=\int_{F_{n}} A\left(r \widetilde{A}\left(\frac{r|v(x)|}{\left\|L_{v}\right\|}\right) / \frac{r v(x)}{\left\|L_{v}\right\|}\right) d \mu \\
& \leq r \int_{F_{n}} A\left(\widetilde{A}\left(\frac{r|v(x)|}{\left\|L_{v}\right\|}\right) / \frac{r v(x)}{\left\|L_{v}\right\|}\right) d \mu \leq r \int_{F_{n}} \widetilde{A}\left(\frac{r|v(x)|}{\left\|L_{v}\right\|}\right) d \mu \\
& =r \frac{1}{\left\|L_{v}\right\|} \int_{\Omega} u_{n}(x) v(x) d \mu \leq r \frac{1}{\left\|L_{v}\right\|}\left\|u_{n}\right\|_{A}\left\|L_{v}\right\|=r\left\|u_{n}\right\|_{A}
\end{aligned}
$$

a contradiction since $r<1$. Therefore, from 27.2.15,

$$
\left\|L_{v}\right\| \geq\left|L_{v}\left(u_{n}\right)\right| \equiv \int_{F_{n}} v(x) u(x) d \mu=\left\|L_{v}\right\| \int_{F_{n}} \widetilde{A}\left(\frac{r|v(x)|}{\left\|L_{v}\right\|}\right) d \mu
$$

and so

$$
1 \geq \int_{F_{n}} \tilde{A}\left(\frac{r|v(x)|}{\left\|L_{v}\right\|}\right) d \mu
$$

By the monotone convergence theorem, letting $n \rightarrow \infty$,

$$
1 \geq \int_{\Omega} \widetilde{A}\left(\frac{r|v(x)|}{\left\|L_{v}\right\|}\right) d \mu
$$

showing that

$$
\|v\|_{\tilde{A}} \leq \frac{\left\|L_{v}\right\|}{r}
$$

Since this holds for all $r \in(0,1)$, it follows $\left\|L_{v}\right\| \geq\|v\|_{\widetilde{A}}$ as claimed. This proves the proposition.

Now what follows is the Riesz representation theorem for the dual space of $E_{A}(\Omega)$.
Theorem 27.2.2 Suppose $\mu(\Omega)<\infty$ and suppose $L \in E_{A}(\Omega)^{\prime}$. Then the map $v \rightarrow L_{v}$ from $L_{\widetilde{A}}(\Omega)$ to $E_{A}(\Omega)^{\prime}$ is one to one continuous, linear, and onto. If $(\Omega, A)$ is $\Delta$ regular then $v \rightarrow L_{v}$ is one to one, linear, onto and continuous as a map from $L_{\widetilde{A}}(\Omega)$ to $L_{A}(\Omega)^{\prime}$.

Proof: It is obvious this map is linear. From Proposition 27.2.1 it is continuous and one to one. It remains only to verify that it is onto. Let $L \in E_{A}(\Omega)^{\prime}$ and define a complex valued function, $\lambda$, mapping the measurable sets to $\mathbb{C}$ as follows.

$$
\lambda(F) \equiv L\left(\mathscr{X}_{F}\right)
$$

In case $\mu(F) \neq 0$,

$$
\begin{aligned}
\int_{\Omega} A\left(\mathscr{X}_{F}(x) A^{-1}\left(\frac{1}{\mu(F)}\right)\right) d \mu & =\int_{F} A\left(A^{-1}\left(\frac{1}{\mu(F)}\right)\right) d \mu \\
& =\int_{F} \frac{1}{\mu(F)} d \mu=1
\end{aligned}
$$

and so

$$
\begin{equation*}
\left\|\mathscr{X}_{F}\right\|_{A} \leq \frac{1}{A^{-1}\left(\frac{1}{\mu(F)}\right)} \tag{27.2.18}
\end{equation*}
$$

In fact, $\lambda$ is actually a complex measure. To see this, suppose $F_{i} \uparrow F$. Then from the formula just derived,

$$
\left\|\mathscr{X}_{F_{i}}-\mathscr{X}_{F}\right\|_{A}=\left\|\mathscr{X}_{F \backslash F_{i}}\right\|_{A} \leq \frac{1}{A^{-1}\left(\frac{1}{\mu\left(F \backslash F_{i}\right)}\right)}
$$

which converges to zero as $i \rightarrow \infty$. Therefore, if the $F_{i}$ are disjoint and $F=\cup_{i=1}^{\infty} F_{i}$, let $S_{m} \equiv \cup_{i=1}^{m} F_{i}$ so that $S_{m} \uparrow F$. Then since $\mathscr{X}_{S_{m}} \rightarrow \mathscr{X}_{F}$ in $E_{A}(\Omega)$ and $L$ is continuous,

$$
\begin{aligned}
\lambda(F) & \equiv L\left(\mathscr{X}_{F}\right)=\lim _{m \rightarrow \infty} L\left(\mathscr{X}_{S_{m}}\right) \\
& =\lim _{m \rightarrow \infty} \sum_{i=1}^{m} L\left(\mathscr{X}_{F_{i}}\right)=\sum_{i=1}^{\infty} \lambda\left(F_{i}\right) .
\end{aligned}
$$

Next observe that $\lambda$ is absolutely continuous with respect to $\mu$. To see this, suppose $\mu(F)=0$. Then if $t>0$,

$$
\int_{\Omega} A\left(\frac{\mathscr{X}_{F}(x)}{t}\right) d \mu=0<1
$$

for all $t>0$ and so $\left\|\mathscr{X}_{F}\right\|_{A}=0$. Therefore, $\lambda(F) \equiv L\left(\mathscr{X}_{F}\right)=0$.
It follows by the Radon Nikodym theorem there exists $v \in L^{1}(\Omega)$ such that

$$
L\left(\mathscr{X}_{F}\right)=\lambda(F)=\int_{F} v d \mu
$$

Therefore, for all $s \in \mathbb{S}$,

$$
\begin{equation*}
L(s)=\int_{F} s v d \mu \tag{27.2.19}
\end{equation*}
$$

I need to show that $v$ is actually in $L_{\widetilde{A}}(\Omega)$. If $v=0$ a.e., there is nothing to prove so assume this is not so. Let $u$ be defined by.

$$
u(x) \equiv\left\{\begin{array}{l}
\widetilde{A}\left(\frac{r \mid v(x) \|}{\|L\|}\right) / \frac{v(x)}{\|L\|} \text { if } v(x) \neq 0  \tag{27.2.20}\\
0 \text { if } v(x)=0
\end{array}\right.
$$

for $r \in(0,1)$. Now let

$$
\begin{equation*}
F_{n} \equiv\{x:|u(x)| \leq n\} \cap\{x: v(x) \neq 0\} \tag{27.2.21}
\end{equation*}
$$

and define

$$
\begin{equation*}
u_{n}(x) \equiv u(x) \mathscr{X}_{F_{n}}(x) \tag{27.2.22}
\end{equation*}
$$

I claim $\left\|u_{n}\right\|_{A} \leq 1$. It is clear that since $\mu(\Omega)<\infty, u_{n} \in E_{A}(\Omega)$. If $\left\|u_{n}\right\|_{A}>1$, Then for $\varepsilon$ small enough,

$$
\left\|u_{n}\right\|_{A}-\varepsilon>1
$$

and so, by convexity of $A$ and the fact that $A(0)=0$,

$$
1<\int_{\Omega} A\left(\frac{\left|u_{n}(x)\right|}{\left\|u_{n}\right\|_{A}-\varepsilon}\right) d \mu \leq \frac{1}{\left\|u_{n}\right\|_{A}-\varepsilon} \int_{\Omega} A\left(\left|u_{n}(x)\right|\right) d \mu
$$

and so, letting $\varepsilon \rightarrow 0+$ and using 27.1.6 and convexity of $A$ as in the proof of the preceeding proposition,

$$
\begin{align*}
\left\|u_{n}\right\|_{A} & \leq \int_{\Omega} A\left(\left|u_{n}(x)\right|\right) d \mu \leq \int_{F_{n}} A\left(r \widetilde{A}\left(\frac{r|v(x)|}{\|L\|}\right) / \frac{r|v(x)|}{\|L\|}\right) d \mu \\
& \leq r \int_{F_{n}} A\left(\widetilde{A}\left(\frac{r|v(x)|}{\|L\|}\right) / \frac{r|v(x)|}{\|L\|}\right) d \mu \leq r \int_{F_{n}} \widetilde{A}\left(\frac{r|v(x)|}{\|L\|}\right) d \mu \\
& \leq r \frac{1}{\|L\|} \int_{F_{n}} u(x) v(x) d \mu=\frac{r}{\|L\|} \int_{\Omega} u_{n} v d \mu \tag{27.2.23}
\end{align*}
$$

Now by Theorem 11.3.9 applied to the positive and negative parts of real and imaginary parts, there exists a uniformly bounded sequence of simple functions, $\left\{s_{k}\right\}$ converging uniformly to $u_{n}$, implying convergence in $E_{A}(\Omega)$, and so

$$
\begin{equation*}
L u_{n}=\lim _{k \rightarrow \infty} L s_{k}=\lim _{k \rightarrow \infty} \int_{\Omega} s_{k} v d \mu=\int_{\Omega} u_{n} v d \mu \tag{27.2.24}
\end{equation*}
$$

therefore, from 27.2.23,

$$
\left\|u_{n}\right\|_{A} \leq \frac{r}{\|L\|} \int_{\Omega} u_{n} v d \mu=\frac{r}{\|L\|} L\left(u_{n}\right) \leq \frac{r}{\|L\|}\|L\|\left\|u_{n}\right\|_{A}
$$

which is a contradiction since $r<1$. Therefore, $\left\|u_{n}\right\|_{A} \leq 1$ and from 27.2.23,

$$
\begin{aligned}
\|L\| & \geq\|L\|\left\|u_{n}\right\|_{A} \geq\left|L u_{n}\right|=\int_{\Omega} u_{n} v d \mu \\
& \geq\|L\| \int_{F_{n}} \widetilde{A}\left(\frac{r|v(x)|}{\|L\|}\right) d \mu
\end{aligned}
$$

Letting $n \rightarrow \infty$ the monotone convergence theorem and the above imply

$$
\int_{\Omega} \widetilde{A}\left(\frac{r|v(x)|}{\|L\|}\right) d \mu \leq 1
$$

which shows that $v \in L_{\widetilde{A}}(\Omega)$ and $\|v\|_{\widetilde{A}} \leq \frac{\|L\|}{r}$ for all $r \in(0,1)$. Therefore, $\|v\|_{\widetilde{A}} \leq\|L\|$.
Since $v \in L_{\widetilde{A}}(\Omega)$ it follows $L_{v}=L$ on $\mathbb{S}$ and so $L_{v}=L$ because $\mathbb{S}$ is dense in the set $E_{A}(\Omega)$. The last assertion follows from Proposition 27.1.10. This completes the proof.

## Chapter 28

## Hausdorff Measure

### 28.1 The Definition

This chapter is on Hausdorff measures. First I will discuss some outer measures. In all that is done here, $\alpha(n)$ will be the volume of the ball in $\mathbb{R}^{n}$ which has radius 1 .

Definition 28.1.1 For a set $E$, denote by $r(E)$ the number which is half the diameter of $E$. Thus

$$
r(E) \equiv \frac{1}{2} \sup \{|\mathbf{x}-\mathbf{y}|: \mathbf{x}, \mathbf{y} \in E\} \equiv \frac{1}{2} \operatorname{diam}(E)
$$

Let $E \subseteq \mathbb{R}^{n}$.

$$
\begin{gathered}
\mathscr{H}_{\delta}^{s}(E) \equiv \inf \left\{\sum_{j=1}^{\infty} \beta(s)\left(r\left(C_{j}\right)\right)^{s}: E \subseteq \cup_{j=1}^{\infty} C_{j}, \operatorname{diam}\left(C_{j}\right) \leq \delta\right\} \\
\mathscr{H}^{s}(E) \equiv \lim _{\delta \rightarrow 0+} \mathscr{H}_{\delta}^{s}(E)
\end{gathered}
$$

Note that $\mathscr{H}_{\delta}^{s}(E)$ is increasing as $\delta \rightarrow 0+$ so the limit clearly exists.
In the above definition, $\beta(s)$ is an appropriate positive constant depending on $s$. It will turn out that for $n$ an integer, $\beta(n)=\alpha(n)$ where $\alpha(n)$ is the Lebesgue measure of the unit ball, $B(\mathbf{0}, 1)$ where the usual norm is used to determine this ball.

Lemma 28.1.2 $\mathscr{H}^{s}$ and $\mathscr{H}_{\delta}^{s}$ are outer measures.
Proof: It is clear that $\mathscr{H}^{s}(\emptyset)=0$ and if $A \subseteq B$, then $\mathscr{H}^{s}(A) \leq \mathscr{H}^{s}(B)$ with similar assertions valid for $\mathscr{H}_{\delta}^{s}$. Suppose $E=\cup_{i=1}^{\infty} E_{i}$ and $\mathscr{H}_{\delta}^{s}\left(E_{i}\right)<\infty$ for each $i$. Let $\left\{C_{j}^{i}\right\}_{j=1}^{\infty}$ be a covering of $E_{i}$ with

$$
\sum_{j=1}^{\infty} \beta(s)\left(r\left(C_{j}^{i}\right)\right)^{s}-\varepsilon / 2^{i}<\mathscr{H}_{\delta}^{s}\left(E_{i}\right)
$$

and $\operatorname{diam}\left(C_{j}^{i}\right) \leq \delta$. Then

$$
\begin{aligned}
\mathscr{H}_{\delta}^{s}(E) & \leq \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \beta(s)\left(r\left(C_{j}^{i}\right)\right)^{s} \\
& \leq \sum_{i=1}^{\infty} \mathscr{H}_{\delta}^{s}\left(E_{i}\right)+\varepsilon / 2^{i} \\
& \leq \varepsilon+\sum_{i=1}^{\infty} \mathscr{H}_{\delta}^{s}\left(E_{i}\right) .
\end{aligned}
$$

It follows that since $\varepsilon>0$ is arbitrary,

$$
\mathscr{H}_{\delta}^{s}(E) \leq \sum_{i=1}^{\infty} \mathscr{H}_{\delta}^{s}\left(E_{i}\right)
$$

which shows $\mathscr{H}_{\delta}^{s}$ is an outer measure. Now notice that $\mathscr{H}_{\delta}^{s}(E)$ is increasing as $\delta \rightarrow 0$. Picking a sequence $\delta_{k}$ decreasing to 0 , the monotone convergence theorem implies

$$
\mathscr{H}^{s}(E) \leq \sum_{i=1}^{\infty} \mathscr{H}^{s}\left(E_{i}\right)
$$

The outer measure $\mathscr{H}^{s}$ is called $s$ dimensional Hausdorff measure when restricted to the $\sigma$ algebra of $\mathscr{H}^{s}$ measurable sets.

Next I will show the $\sigma$ algebra of $\mathscr{H}^{s}$ measurable sets includes the Borel sets. This is done by the following very interesting condition known as Caratheodory's criterion.

### 28.1.1 Properties

Definition 28.1.3 For two sets, $A, B$ in a metric space, we define

$$
\operatorname{dist}(A, B) \equiv \inf \{d(x, y): x \in A, y \in B\}
$$

Theorem 28.1.4 Let $\mu$ be an outer measure on the subsets of $(X, d)$, a metric space. If

$$
\mu(A \cup B)=\mu(A)+\mu(B)
$$

whenever $\operatorname{dist}(A, B)>0$, then the $\sigma$ algebra of measurable sets contains the Borel sets.
Proof: It suffices to show that closed sets are in $\mathscr{S}$, the $\sigma$-algebra of measurable sets, because then the open sets are also in $\mathscr{S}$ and consequently $\mathscr{S}$ contains the Borel sets. Let $K$ be closed and let $S$ be a subset of $\Omega$. Is $\mu(S) \geq \mu(S \cap K)+\mu(S \backslash K)$ ? It suffices to assume $\mu(S)<\infty$. Let

$$
K_{n} \equiv\left\{x: \operatorname{dist}(x, K) \leq \frac{1}{n}\right\}
$$

By Lemma 7.1 .7 on Page $136, x \rightarrow \operatorname{dist}(x, K)$ is continuous and so $K_{n}$ is closed. By the assumption of the theorem,

$$
\begin{equation*}
\mu(S) \geq \mu\left((S \cap K) \cup\left(S \backslash K_{n}\right)\right)=\mu(S \cap K)+\mu\left(S \backslash K_{n}\right) \tag{28.1.1}
\end{equation*}
$$

since $S \cap K$ and $S \backslash K_{n}$ are a positive distance apart. Now

$$
\begin{equation*}
\mu\left(S \backslash K_{n}\right) \leq \mu(S \backslash K) \leq \mu\left(S \backslash K_{n}\right)+\mu\left(\left(K_{n} \backslash K\right) \cap S\right) \tag{28.1.2}
\end{equation*}
$$

If $\lim _{n \rightarrow \infty} \mu\left(\left(K_{n} \backslash K\right) \cap S\right)=0$ then the theorem will be proved because this limit along with 28.1.2 implies $\lim _{n \rightarrow \infty} \mu\left(S \backslash K_{n}\right)=\mu(S \backslash K)$ and then taking a limit in 28.1.1, $\mu(S) \geq$ $\mu(S \cap K)+\mu(S \backslash K)$ as desired. Therefore, it suffices to establish this limit.

Since $K$ is closed, a point, $x \notin K$ must be at a positive distance from $K$ and so

$$
K_{n} \backslash K=\cup_{k=n}^{\infty} K_{k} \backslash K_{k+1}
$$

Therefore

$$
\begin{equation*}
\mu\left(S \cap\left(K_{n} \backslash K\right)\right) \leq \sum_{k=n}^{\infty} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right) . \tag{28.1.3}
\end{equation*}
$$

If

$$
\begin{equation*}
\sum_{k=1}^{\infty} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right)<\infty \tag{28.1.4}
\end{equation*}
$$

then $\mu\left(S \cap\left(K_{n} \backslash K\right)\right) \rightarrow 0$ because it is dominated by the tail of a convergent series so it suffices to show 28.1.4.

$$
\begin{gather*}
\sum_{k=1}^{M} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right)= \\
\sum_{k \text { even }, k \leq M} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right)+\sum_{k o d d, k \leq M} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right) . \tag{28.1.5}
\end{gather*}
$$

By the construction, the distance between any pair of sets, $S \cap\left(K_{k} \backslash K_{k+1}\right)$ for different even values of $k$ is positive and the distance between any pair of sets, $S \cap\left(K_{k} \backslash K_{k+1}\right)$ for different odd values of $k$ is positive. Therefore,

$$
\begin{aligned}
& \sum_{k \text { even, } k \leq M} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right)+\sum_{\text {kodd, } k \leq M} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right) \leq \\
& \mu\left(\bigcup_{\text {keven }} S \cap\left(K_{k} \backslash K_{k+1}\right)\right)+\mu\left(\bigcup_{\text {kodd }} S \cap\left(K_{k} \backslash K_{k+1}\right)\right) \leq 2 \mu(S)<\infty
\end{aligned}
$$

and so for all $M, \sum_{k=1}^{M} \mu\left(S \cap\left(K_{k} \backslash K_{k+1}\right)\right) \leq 2 \mu(S)$ showing 28.1.4
With the above theorem, the following theorem is easy to obtain.
Theorem 28.1.5 The $\sigma$ algebra of $\mathscr{H}^{s}$ measurable sets contains the Borel sets and $\mathscr{H}^{s}$ has the property that for all $E \subseteq \mathbb{R}^{n}$, there exists a Borel set $F \supseteq E$ such that $\mathscr{H}^{s}(F)=$ $\mathscr{H}^{s}(E)$.

Proof: Let $\operatorname{dist}(A, B)=2 \delta_{0}>0$. Is it the case that

$$
\mathscr{H}^{s}(A)+\mathscr{H}^{s}(B)=\mathscr{H}^{s}(A \cup B) ?
$$

This is what is needed to use Caratheodory's criterion.
Let $\left\{C_{j}\right\}_{j=1}^{\infty}$ be a covering of $A \cup B$ such that $\operatorname{diam}\left(C_{j}\right) \leq \delta<\delta_{0}$ for each $j$ and

$$
\mathscr{H}_{\delta}^{s}(A \cup B)+\varepsilon>\sum_{j=1}^{\infty} \beta(s)\left(r\left(C_{j}\right)\right)^{s}
$$

Thus

$$
\mathscr{H}_{\delta}^{s}(A \cup B)+\varepsilon>\sum_{j \in J_{1}} \beta(s)\left(r\left(C_{j}\right)\right)^{s}+\sum_{j \in J_{2}} \beta(s)\left(r\left(C_{j}\right)\right)^{s}
$$

where

$$
J_{1}=\left\{j: C_{j} \cap A \neq \emptyset\right\}, J_{2}=\left\{j: C_{j} \cap B \neq \emptyset\right\} .
$$

Recall $\operatorname{dist}(A, B)=2 \delta_{0}, J_{1} \cap J_{2}=\emptyset$. It follows

$$
\mathscr{H}_{\delta}^{s}(A \cup B)+\varepsilon>\mathscr{H}_{\delta}^{s}(A)+\mathscr{H}_{\delta}^{s}(B)
$$

Letting $\delta \rightarrow 0$, and noting $\varepsilon>0$ was arbitrary, yields

$$
\mathscr{H}^{s}(A \cup B) \geq \mathscr{H}^{s}(A)+\mathscr{H}^{s}(B)
$$

Equality holds because $\mathscr{H}^{s}$ is an outer measure. By Caratheodory's criterion, $\mathscr{H}^{s}$ is a Borel measure.

To verify the second assertion, note first there is no loss of generality in letting $\mathscr{H}^{s}(E)<$ $\infty$. Let

$$
E \subseteq \cup_{j=1}^{\infty} C_{j}, r\left(C_{j}\right)<\delta
$$

and

$$
\mathscr{H}_{\delta}^{s}(E)+\delta>\sum_{j=1}^{\infty} \beta(s)\left(r\left(C_{j}\right)\right)^{s}
$$

Let

$$
F_{\delta}=\cup_{j=1}^{\infty} \overline{C_{j}}
$$

Thus $F_{\delta} \supseteq E$ and

$$
\begin{aligned}
\mathscr{H}_{\delta}^{s}(E) & \leq \mathscr{H}_{\delta}^{s}\left(F_{\delta}\right) \leq \sum_{j=1}^{\infty} \beta(s)\left(r\left(\overline{C_{j}}\right)\right)^{s} \\
& =\sum_{j=1}^{\infty} \beta(s)\left(r\left(C_{j}\right)\right)^{s}<\delta+\mathscr{H}_{\delta}^{s}(E) .
\end{aligned}
$$

Let $\delta_{k} \rightarrow 0$ and let $F=\cap_{k=1}^{\infty} F_{\delta_{k}}$. Then $F \supseteq E$ and

$$
\mathscr{H}_{\delta_{k}}^{s}(E) \leq \mathscr{H}_{\delta_{k}}^{s}(F) \leq \mathscr{H}_{\delta_{k}}^{s}\left(F_{\delta}\right) \leq \boldsymbol{\delta}_{k}+\mathscr{H}_{\delta_{k}}^{s}(E)
$$

Letting $k \rightarrow \infty$,

$$
\mathscr{H}^{s}(E) \leq \mathscr{H}^{s}(F) \leq \mathscr{H}^{s}(E)
$$

A measure satisfying the conclusion of Theorem 28.1.5 is called a Borel regular measure.

## $28.2 \quad \mathscr{H}^{p}$ and $m_{p}$

Next I will compare $\mathscr{H}^{p}$ and $m_{p}$. To do this, recall the following covering theorem which is a summary of Corollary 13.4.5 found on Page 350.

Theorem 28.2.1 Let $E \subseteq \mathbb{R}^{p}$ and let $\mathscr{F}$ be a collection of balls of bounded radii such that $\mathscr{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\overline{m_{p}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.

In the next lemma, the balls are the usual balls taken with respect to the usual distance in $\mathbb{R}^{p}$ coming from the Euclidean norm.

Lemma 28.2.2 If $S \subseteq \mathbb{R}^{p}$ and $m_{p}(S)=0$, then $\mathscr{H}^{p}(S)=\mathscr{H}_{\delta}^{p}(S)=0$. Also, there exists a constant $k$ such that $\mathscr{H}^{p}(E) \leq k m_{p}(E)$ for all $E$ Borel $k \equiv \frac{\beta(p)}{\alpha(p)}$. Also, if $Q_{0} \equiv[0,1)^{p}$, the unit cube, then $\mathscr{H}^{p}\left([0,1)^{p}\right)>0$.

Proof: Suppose first $m_{p}(S)=0$. Without loss of generality, $S$ is bounded. Then by outer regularity, there exists a bounded open $V$ containing $S$ and $m_{p}(V)<\varepsilon$. For each $\mathbf{x} \in S$, there exists a ball $B_{\mathbf{x}}$ such that $\widehat{B_{\mathbf{x}}} \subseteq V$ and $\delta>r\left(\widehat{B_{\mathbf{x}}}\right)$. By the Vitali covering theorem there is a sequence of disjoint balls $\left\{B_{k}\right\}$ such that $\left\{\widehat{B_{k}}\right\}$ covers $S$. Here $\widehat{B_{k}}$ has the same center as $B_{k}$ but 5 times the radius. Then letting $\alpha(p)$ be the Lebesgue measure of the unit ball in $\mathbb{R}^{p}$

$$
\begin{aligned}
\mathscr{H}_{\delta}^{p}(S) & \leq \sum_{k} \beta(p) r\left(\widehat{B_{k}}\right)^{p}=\frac{\beta(p)}{\alpha(p)} 5^{p} \sum_{k} \alpha(p) r\left(B_{k}\right)^{p} \\
& \leq \frac{\beta(p)}{\alpha(p)} 5^{p} m_{p}(V)<\frac{\beta(p)}{\alpha(p)} 5^{p} \varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this shows $\mathscr{H}_{\delta}^{p}(S)=0$ and now it follows that

$$
\mathscr{H}^{p}(S) \equiv \lim _{\delta \rightarrow 0} \mathscr{H}_{\delta}^{p}(S)=0
$$

Letting $U$ be an open set and $\delta>0$, consider all balls $B$ contained in $U$ which have diameters less than $\delta$. This is a Vitali covering of $U$ and therefore by Theorem 28.2.1, there exists $\left\{B_{i}\right\}$, a sequence of disjoint balls of radii less than $\delta$ contained in $U$ such that $\cup_{i=1}^{\infty} B_{i}$ differs from $U$ by a set of Lebesgue measure zero. Let $\alpha(p)$ be the Lebesgue measure of the unit ball in $\mathbb{R}^{p}$. Then from what was just shown,

$$
\begin{aligned}
\mathscr{H}_{\delta}^{p}(U) & =\mathscr{H}_{\delta}^{p}\left(\cup_{i} B_{i}\right) \leq \sum_{i=1}^{\infty} \beta(p) r\left(B_{i}\right)^{p}=\frac{\beta(p)}{\alpha(p)} \sum_{i=1}^{\infty} \alpha(p) r\left(B_{i}\right)^{p} \\
& =\frac{\beta(p)}{\alpha(p)} \sum_{i=1}^{\infty} m_{p}\left(B_{i}\right)=\frac{\beta(p)}{\alpha(p)} m_{p}(U) \equiv k m_{p}(U), k \equiv \frac{\beta(p)}{\alpha(p)}
\end{aligned}
$$

Now letting $E$ be Lebesgue measurable, it follows from the outer regularity of $m_{p}$ there exists a decreasing sequence of open sets, $\left\{V_{i}\right\}$ containing $E$ such such that $m_{p}\left(V_{i}\right) \rightarrow$ $m_{p}(E)$. Then from the above,

$$
\mathscr{H}_{\delta}^{p}(E) \leq \lim _{i \rightarrow \infty} \mathscr{H}_{\delta}^{p}\left(V_{i}\right) \leq \lim _{i \rightarrow \infty} k m_{p}\left(V_{i}\right)=k m_{p}(E)
$$

Since $\delta>0$ is arbitrary, it follows that also $\mathscr{H}^{p}(E) \leq k m_{p}(E)$. This proves the first part of the lemma.

To verify the second part, note that it is obvious $\mathscr{H}_{\delta}^{p}$ and $\mathscr{H}^{p}$ are translation invariant because diameters of sets do not change when translated. Therefore, if $\mathscr{H}^{p}\left([0,1)^{p}\right)=0$, it follows $\mathscr{H}^{p}\left(\mathbb{R}^{p}\right)=0$ because $\mathbb{R}^{p}$ is the countable union of translates of $Q_{0} \equiv[0,1)^{p}$. Since each $\mathscr{H}_{\delta}^{p}$ is no larger than $\mathscr{H}^{p}, \mathscr{H}_{\delta}^{p}\left([0,1)^{p}\right)=0$. Therefore, there exists a sequence of sets, $\left\{C_{i}\right\}$ each having diameter less than $\delta$ such that the union of these sets equals $\mathbb{R}^{p}$ but $1>\sum_{i=1}^{\infty} \beta(p) r\left(C_{i}\right)^{p}$. Now let $B_{i}$ be a ball having radius $r_{i}$ equal to diam $\left(C_{i}\right)=2 r\left(C_{i}\right)$ which contains $C_{i}$. These $B_{i}$ cover $\mathbb{R}^{p}, \frac{1}{2} r_{i}=r\left(C_{i}\right)$. It follows that

$$
1>\sum_{i=1}^{\infty} \beta(p) r\left(C_{i}\right)^{p}=\sum_{i=1}^{\infty} \frac{\beta(p)}{\alpha(p) 2^{p}} m_{p}\left(B_{i}\right)=\infty
$$

a contradiction.

Lemma 28.2.3 Every open set $U$ in $\mathbb{R}^{p}$ is a countable disjoint union of half open boxes of the form $Q \equiv \prod_{i=1}^{p}\left[a_{i}, a_{i}+2^{-k}\right)$ where $a_{i}=l 2^{-k}$ for $l$ some integer.

Proof: It is clear that there exists $\mathscr{Q}_{k}$ a countable disjoint collection of these half open boxes each of sides of length $2^{-k}$ whose union is all of $\mathbb{R}^{p}$. Let $\mathscr{B}_{1}$ be those sets of $\mathscr{Q}_{1}$ which are contained in $U$, if any. Having chosen $\mathscr{B}_{k-1}$, let $\mathscr{B}_{k}$ consist of those sets of $\mathscr{Q}_{k}$ which are contained in $U$ such that none of these are contained in $\mathscr{B}_{k-1}$. Then $\cup_{k=1}^{\infty} \mathscr{B}_{k}$ is a countable collection of disjoint boxes of the right sort whose union is $U$. This is because if $R$ is a box of $\mathscr{Q}_{k}$ and $\hat{R}$ is a box of $\mathscr{Q}_{k-1}$, then either $R \subseteq \hat{R}$ or $R \cap \hat{R}=\emptyset$.

Theorem 28.2.4 By choosing $\beta(p)$ properly, one can obtain $\mathscr{H}^{p}=m_{p}$ on all Lebesgue measurable sets.

Proof: I will show $\mathscr{H}^{p}$ is a positive multiple of $m_{p}$ for any choice of $\beta(p)$. Define $k=$ $\frac{m_{p}\left(Q_{0}\right)}{\mathscr{H}^{p}\left(Q_{0}\right)}$ where $Q_{0}=[0,1)^{p}$ is the half open unit cube in $\mathbb{R}^{p}$. I will show $k \mathscr{H}^{p}(E)=m_{p}(E)$ for any Lebesgue measurable set. When this is done, it will follow that by adjusting $\beta(p)$ the multiple can be taken to be 1 .

Let $Q=\prod_{i=1}^{p}\left[a_{i}, a_{i}+2^{-k}\right)$ be a half open box where $a_{i}=l 2^{-k}$. Thus $Q_{0}$ is the union of $\left(2^{k}\right)^{p}$ of these identical half open boxes. By translation invariance, of $\mathscr{H}^{p}$ and $m_{p}$,

$$
\left(2^{k}\right)^{p} \mathscr{H}^{p}(Q)=\mathscr{H}^{p}\left(Q_{0}\right)=\frac{1}{k} m_{p}\left(Q_{0}\right)=\frac{1}{k}\left(2^{k}\right)^{p} m_{p}(Q) .
$$

Therefore, $k \mathscr{H}^{p}(Q)=m_{p}(Q)$ for any such half open box and by translation invariance, for the translation of any such half open box. It follows that $k \mathscr{H}^{p}(U)=m_{p}(U)$ for all open sets because each open set is a countable disjoint union of such half open boxes. It follows immediately, since every compact set is the countable intersection of open sets that $k \mathscr{H}^{p}=m_{p}$ on compact sets. Therefore, $k \mathscr{H}^{p}=m_{p}$ on all closed sets because every closed set is the countable union of compact sets. Now let $F$ be an arbitrary Lebesgue measurable set. I will show that $F$ is $\mathscr{H}^{p}$ measurable and that $k \mathscr{H}^{p}(F)=m_{p}(F)$. Let $F_{l}=B(\mathbf{0}, l) \cap F$. By Proposition 11.7.3, there exists $H$ a countable union of compact sets and $G$ a countable intersection of open sets such that $H \subseteq F_{l} \subseteq G$ and $m_{p}(G \backslash H)=0$ which implies by Lemma 28.2.2 that $m_{p}(G \backslash H)=k \mathscr{H}^{p}(G \backslash H)=0$. Then by completeness of $\mathscr{H}^{p}$ it follows $F_{l}$ is $\mathscr{H}^{p}$ measurable and $k \mathscr{H}^{p}\left(F_{l}\right)=k \mathscr{H}^{p}(H)=m_{p}(H)=m_{p}\left(F_{l}\right)$. Now taking $l \rightarrow \infty$, it follows $F$ is $\mathscr{H}^{p}$ measurable and $k \mathscr{H}^{p}(F)=m_{p}(F)$. Therefore, adjusting $\beta(p)$ it can be assumed the constant $k$ is 1 .

The exact determination of $\beta(p)$ is more technical.

### 28.3 Technical Considerations

Let $\alpha(n)$ be the volume of the unit ball in $\mathbb{R}^{n}$. Thus the volume of $B(\mathbf{0}, r)$ in $\mathbb{R}^{n}$ is $\alpha(n) r^{n}$ from the change of variables formula. There is a very important and interesting inequality known as the isodiametric inequality which says that if $A$ is any set in $\mathbb{R}^{n}$, then

$$
\bar{m}(A) \leq \alpha(n)\left(2^{-1} \operatorname{diam}(A)\right)^{n}=\alpha(n) r(A)^{n}
$$

This inequality may seem obvious at first but it is not really. The reason it is not is that there are sets which are not subsets of any sphere having the same diameter as the set. For example, consider an equilateral triangle.

Lemma 28.3.1 Let $f: \mathbb{R}^{n-1} \rightarrow[0, \infty)$ be Borel measurable and let

$$
S=\{(\mathbf{x}, y):|y|<f(\mathbf{x})\} .
$$

Then $S$ is a Borel set in $\mathbb{R}^{n}$.
Proof: Set $s_{k}$ be an increasing sequence of Borel measurable functions converging pointwise to $f$.

$$
s_{k}(\mathbf{x})=\sum_{m=1}^{N_{k}} c_{m}^{k} \mathscr{X}_{E_{m}^{k}}(\mathbf{x})
$$

Let

$$
S_{k}=\cup_{m=1}^{N_{k}} E_{m}^{k} \times\left(-c_{m}^{k}, c_{m}^{k}\right)
$$

Then $(\mathbf{x}, y) \in S_{k}$ if and only if $f(\mathbf{x})>0$ and $|y|<s_{k}(\mathbf{x}) \leq f(\mathbf{x})$. It follows that $S_{k} \subseteq S_{k+1}$ and

$$
S=\cup_{k=1}^{\infty} S_{k} .
$$

But each $S_{k}$ is a Borel set and so $S$ is also a Borel set. This proves the lemma.
Let $P_{i}$ be the projection onto

$$
\operatorname{span}\left(\mathbf{e}_{1}, \cdots, \mathbf{e}_{i-1}, \mathbf{e}_{i+1}, \cdots, \mathbf{e}_{n}\right)
$$

where the $\mathbf{e}_{k}$ are the standard basis vectors in $\mathbb{R}^{n}, \mathbf{e}_{k}$ being the vector having a 1 in the $k^{t h}$ slot and a 0 elsewhere. Thus $P_{i} \mathbf{x} \equiv \sum_{j \neq i} x_{j} \mathbf{e}_{j}$. Also let

 function defined on $P_{i}\left(\mathbb{R}^{n}\right)$.

Proof: Let $\mathscr{K}$ be the $\pi$ system consisting of sets of the form $\prod_{j=1}^{n} A_{j}$ where $A_{i}$ is Borel. Also let $\mathscr{G}$ denote those Borel sets of $\mathbb{R}^{n}$ such that if $A \in \mathscr{G}$ then

$$
P_{i} \mathbf{x} \rightarrow m\left(\left(A \cap R_{k}\right)_{P_{i} \mathbf{x}}\right) \text { is Borel measurable. }
$$

where $R_{k}=(-k, k)^{n}$. Thus $\mathscr{K} \subseteq \mathscr{G}$. If $A \in \mathscr{G}$

$$
P_{i} \mathbf{x} \rightarrow m\left(\left(A^{C} \cap R_{k}\right)_{P_{i} \mathbf{x}}\right)
$$

is Borel measurable because it is of the form

$$
m\left(\left(R_{k}\right)_{P_{i} \mathbf{x}}\right)-m\left(\left(A \cap R_{k}\right)_{P_{i} \mathbf{x}}\right)
$$

and these are Borel measurable functions of $P_{i} \mathbf{x}$. Also, if $\left\{A_{i}\right\}$ is a disjoint sequence of sets in $\mathscr{G}$ then

$$
m\left(\left(\cup_{i} A_{i} \cap R_{k}\right)_{P_{i} \mathbf{x}}\right)=\sum_{i} m\left(\left(A_{i} \cap R_{k}\right)_{P_{i} \mathbf{x}}\right)
$$

and each function of $P_{i} \mathbf{x}$ is Borel measurable. Thus by the lemma on $\pi$ systems, Lemma 12.12.3, $\mathscr{G}=\mathscr{B}\left(\mathbb{R}^{n}\right)$ and this proves the lemma.

Now let $A \subseteq \mathbb{R}^{n}$ be Borel. Let $P_{i}$ be the projection onto

$$
\operatorname{span}\left(\mathbf{e}_{1}, \cdots, \mathbf{e}_{i-1}, \mathbf{e}_{i+1}, \cdots, \mathbf{e}_{n}\right)
$$

and as just described,

$$
A_{P_{i} \mathbf{x}}=\left\{y \in \mathbb{R}: P_{i} \mathbf{x}+y \mathbf{e}_{i} \in A\right\}
$$

Thus for $\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)$,

$$
A_{P_{i} \mathbf{x}}=\left\{y \in \mathbb{R}:\left(x_{1}, \cdots, x_{i-1}, y, x_{i+1}, \cdots, x_{n}\right) \in A\right\} .
$$

Since $A$ is Borel, it follows from Lemma 28.3.1 that

$$
P_{i} \mathbf{x} \rightarrow m\left(A_{P_{i} \mathbf{x}}\right)
$$

is a Borel measurable function on $P_{i} \mathbb{R}^{n}=\mathbb{R}^{n-1}$.

### 28.3.1 Steiner Symmetrization

Define

$$
S\left(A, \mathbf{e}_{i}\right) \equiv\left\{\mathbf{x}=P_{i} \mathbf{x}+y \mathbf{e}_{i}:|y|<2^{-1} m\left(A_{P_{i} \mathbf{x}}\right)\right\}
$$

Lemma 28.3.3 Let $A$ be a Borel subset of $\mathbb{R}^{n}$. Then $S\left(A, \mathbf{e}_{i}\right)$ satisfies

$$
\begin{gather*}
P_{i} \mathbf{x}+y \mathbf{e}_{i} \in S\left(A, \mathbf{e}_{i}\right) \text { if and only if } P_{i} \mathbf{x}-y \mathbf{e}_{i} \in S\left(A, \mathbf{e}_{i}\right), \\
S\left(A, \mathbf{e}_{i}\right) \text { is a Borel set in } \mathbb{R}^{n}, \\
m_{n}\left(S\left(A, \mathbf{e}_{i}\right)\right)=m_{n}(A)  \tag{28.3.6}\\
\operatorname{diam}\left(S\left(A, \mathbf{e}_{i}\right)\right) \leq \operatorname{diam}(A) \tag{28.3.7}
\end{gather*}
$$

Proof: The first assertion is obvious from the definition. The Borel measurability of $S\left(A, \mathbf{e}_{i}\right)$ follows from the definition and Lemmas 28.3.2 and 28.3.1. To show Formula 28.3.6,

$$
\begin{aligned}
m_{n}\left(S\left(A, \mathbf{e}_{i}\right)\right) & =\int_{P_{i} \mathbb{R}^{n}} \int_{-2^{-1} m\left(A A_{P_{i} x}\right)}^{2^{-1} m\left(A P_{i}\right)} d x_{i} d x_{1} \cdots d x_{i-1} d x_{i+1} \cdots d x_{n} \\
& =\int_{P_{i} \mathbb{R}^{n}} m\left(A_{P_{i} \mathbf{x}}\right) d x_{1} \cdots d x_{i-1} d x_{i+1} \cdots d x_{n} \\
& =m(A) .
\end{aligned}
$$

Now suppose $\mathbf{x}_{1}$ and $\mathbf{x}_{2} \in S\left(A, \mathbf{e}_{i}\right)$

$$
\mathbf{x}_{1}=P_{i} \mathbf{x}_{1}+y_{1} \mathbf{e}_{i}, \mathbf{x}_{2}=P_{i} \mathbf{x}_{2}+y_{2} \mathbf{e}_{i} .
$$

For $\mathbf{x} \in A$ define

$$
\begin{aligned}
& l(\mathbf{x})=\sup \left\{y: P_{i} \mathbf{x}+y \mathbf{e}_{i} \in A\right\} . \\
& g(\mathbf{x})=\inf \left\{y: P_{i} \mathbf{x}+y \mathbf{e}_{i} \in A\right\} .
\end{aligned}
$$

Then it is clear that

$$
\begin{align*}
& l\left(\mathbf{x}_{1}\right)-g\left(\mathbf{x}_{1}\right) \geq m\left(A_{P_{i} \mathbf{x}_{1}}\right) \geq 2\left|y_{1}\right|  \tag{28.3.8}\\
& l\left(\mathbf{x}_{2}\right)-g\left(\mathbf{x}_{2}\right) \geq m\left(A_{P_{i} \mathbf{x}_{2}}\right) \geq 2\left|y_{2}\right| \tag{28.3.9}
\end{align*}
$$

Claim: $\left|y_{1}-y_{2}\right| \leq\left|l\left(\mathbf{x}_{1}\right)-g\left(\mathbf{x}_{2}\right)\right|$ or $\left|y_{1}-y_{2}\right| \leq\left|l\left(\mathbf{x}_{2}\right)-g\left(\mathbf{x}_{1}\right)\right|$.
Proof of Claim: If not,

$$
\begin{gathered}
2\left|y_{1}-y_{2}\right|>\left|l\left(\mathbf{x}_{1}\right)-g\left(\mathbf{x}_{2}\right)\right|+\left|l\left(\mathbf{x}_{2}\right)-g\left(\mathbf{x}_{1}\right)\right| \\
\geq\left|l\left(\mathbf{x}_{1}\right)-g\left(\mathbf{x}_{1}\right)+l\left(\mathbf{x}_{2}\right)-g\left(\mathbf{x}_{2}\right)\right| \\
=l\left(\mathbf{x}_{1}\right)-g\left(\mathbf{x}_{1}\right)+l\left(\mathbf{x}_{2}\right)-g\left(\mathbf{x}_{2}\right) . \\
\geq 2\left|y_{1}\right|+2\left|y_{2}\right|
\end{gathered}
$$

by 28.3.8 and 28.3.9 contradicting the triangle inequality.
Now suppose $\left|y_{1}-y_{2}\right| \leq\left|l\left(\mathbf{x}_{1}\right)-g\left(\mathbf{x}_{2}\right)\right|$. From the claim,

$$
\begin{aligned}
\left|\mathbf{x}_{1}-\mathbf{x}_{2}\right| & =\left(\left|P_{i} \mathbf{x}_{1}-P_{i} \mathbf{x}_{2}\right|^{2}+\left|y_{1}-y_{2}\right|^{2}\right)^{1 / 2} \\
& \leq\left(\left|P_{i} \mathbf{x}_{1}-P_{i} \mathbf{x}_{2}\right|^{2}+\left|l\left(\mathbf{x}_{1}\right)-g\left(\mathbf{x}_{2}\right)\right|^{2}\right)^{1 / 2} \\
& \leq\left(\left|P_{i} \mathbf{x}_{1}-P_{i} \mathbf{x}_{2}\right|^{2}+\left(\left|z_{1}-z_{2}\right|+2 \varepsilon\right)^{2}\right)^{1 / 2} \\
& \leq \operatorname{diam}(A)+O(\sqrt{\varepsilon})
\end{aligned}
$$

where $z_{1}$ and $z_{2}$ are such that $P_{i} \mathbf{x}_{1}+z_{1} \mathbf{e}_{i} \in A, P_{i} \mathbf{x}_{2}+z_{2} \mathbf{e}_{i} \in A$, and

$$
\left|z_{1}-l\left(\mathbf{x}_{1}\right)\right|<\varepsilon \text { and }\left|z_{2}-g\left(\mathbf{x}_{2}\right)\right|<\varepsilon .
$$

If $\left|y_{1}-y_{2}\right| \leq\left|l\left(\mathbf{x}_{2}\right)-g\left(\mathbf{x}_{1}\right)\right|$, then we use the same argument but let

$$
\left|z_{1}-g\left(\mathbf{x}_{1}\right)\right|<\varepsilon \text { and }\left|z_{2}-l\left(\mathbf{x}_{2}\right)\right|<\varepsilon
$$

Since $\mathbf{x}_{1}, \mathbf{x}_{2}$ are arbitrary elements of $S\left(A, \mathbf{e}_{i}\right)$ and $\varepsilon$ is arbitrary, this proves 28.3.7.
The next lemma says that if $A$ is already symmetric with respect to the $j^{\text {th }}$ direction, then this symmetry is not destroyed by taking $S\left(A, \mathbf{e}_{i}\right)$.

Lemma 28.3.4 Suppose $A$ is a Borel set in $\mathbb{R}^{n}$ such that $P_{j} \mathbf{x}+\mathbf{e}_{j} x_{j} \in A$ if and only if $P_{j} \mathbf{x}+\left(-x_{j}\right) \mathbf{e}_{j} \in A$. Then if $i \neq j, P_{j} \mathbf{x}+\mathbf{e}_{j} x_{j} \in S\left(A, \mathbf{e}_{i}\right)$ if and only if $P_{j} \mathbf{x}+\left(-x_{j}\right) \mathbf{e}_{j} \in S\left(A, \mathbf{e}_{i}\right)$.

Proof: By definition,

$$
P_{j} \mathbf{x}+\mathbf{e}_{j} x_{j} \in S\left(A, \mathbf{e}_{i}\right)
$$

if and only if

$$
\left|x_{i}\right|<2^{-1} m\left(A_{P_{i}\left(P_{j} \mathbf{x}+\mathbf{e}_{j} x_{j}\right)}\right) .
$$

Now

$$
x_{i} \in A_{P_{i}\left(P_{j} \mathbf{x}+\mathbf{e}_{j} x_{j}\right)}
$$

if and only if

$$
x_{i} \in A_{P_{i}\left(P_{j} \mathbf{x}+\left(-x_{j}\right) \mathbf{e}_{j}\right)}
$$

by the assumption on $A$ which says that $A$ is symmetric in the $\mathbf{e}_{j}$ direction. Hence

$$
P_{j} \mathbf{x}+\mathbf{e}_{j} x_{j} \in S\left(A, \mathbf{e}_{i}\right)
$$

if and only if

$$
\left|x_{i}\right|<2^{-1} m\left(A_{P_{i}\left(P_{j} \mathbf{x}+\left(-x_{j}\right) \mathbf{e}_{j}\right)}\right)
$$

if and only if

$$
P_{j} \mathbf{x}+\left(-x_{j}\right) \mathbf{e}_{j} \in S\left(A, \mathbf{e}_{i}\right)
$$

This proves the lemma.

### 28.3.2 The Isodiametric Inequality

The next theorem is called the isodiametric inequality. It is the key result used to compare Lebesgue and Hausdorff measures.
Theorem 28.3.5 Let A be any Lebesgue measurable set in $\mathbb{R}^{n}$. Then

$$
m_{n}(A) \leq \alpha(n)(r(A))^{n}
$$

Proof: Suppose first that $A$ is Borel. Let $A_{1}=S\left(A, \mathbf{e}_{1}\right)$ and let $A_{k}=S\left(A_{k-1}, \mathbf{e}_{k}\right)$. Then by the preceding lemmas, $A_{n}$ is a Borel set, $\operatorname{diam}\left(A_{n}\right) \leq \operatorname{diam}(A), m_{n}\left(A_{n}\right)=m_{n}(A)$, and $A_{n}$ is symmetric. Thus $\mathbf{x} \in A_{n}$ if and only if $-\mathbf{x} \in A_{n}$. It follows that

$$
A_{n} \subseteq \overline{B\left(\mathbf{0}, r\left(A_{n}\right)\right)}
$$

(If $\mathbf{x} \in A_{n} \backslash \overline{B\left(\mathbf{0}, r\left(A_{n}\right)\right)}$, then $-\mathbf{x} \in A_{n} \backslash \overline{B\left(\mathbf{0}, r\left(A_{n}\right)\right)}$ and so $\operatorname{diam}\left(A_{n}\right) \geq 2|\mathbf{x}|>\operatorname{diam}\left(A_{n}\right)$.) Therefore,

$$
m_{n}\left(A_{n}\right) \leq \alpha(n)\left(r\left(A_{n}\right)\right)^{n} \leq \alpha(n)(r(A))^{n}
$$

It remains to establish this inequality for arbitrary measurable sets. Letting $A$ be such a set, let $\left\{K_{n}\right\}$ be an increasing sequence of compact subsets of $A$ such that

$$
m(A)=\lim _{k \rightarrow \infty} m\left(K_{k}\right)
$$

Then

$$
\begin{aligned}
m(A) & =\lim _{k \rightarrow \infty} m\left(K_{k}\right) \leq \lim \sup _{k \rightarrow \infty} \alpha(n)\left(r\left(K_{k}\right)\right)^{n} \\
& \leq \alpha(n)(r(A))^{n}
\end{aligned}
$$

This proves the theorem.

### 28.4 The Proper Value Of $\beta(n)$

I will show that the proper determination of $\beta(n)$ is $\alpha(n)$, the volume of the unit ball. Since $\beta(n)$ has been adjusted such that $k=1, m_{n}(B(\mathbf{0}, 1))=\mathscr{H}^{n}(B(\mathbf{0}, 1))$. There exists a covering of $B(\mathbf{0}, 1)$ of sets of radii less than $\delta,\left\{C_{i}\right\}_{i=1}^{\infty}$ such that

$$
\mathscr{H}_{\delta}^{n}(B(\mathbf{0}, 1))+\varepsilon>\sum_{i} \beta(n) r\left(C_{i}\right)^{n}
$$

Then by Theorem 28.3.5, the isodiametric inequality,

$$
\begin{aligned}
\mathscr{H}_{\delta}^{n}(B(\mathbf{0}, 1))+\varepsilon & >\sum_{i} \beta(n) r\left(C_{i}\right)^{n}=\frac{\beta(n)}{\alpha(n)} \sum_{i} \alpha(n) r\left(\bar{C}_{i}\right)^{n} \\
& \geq \frac{\beta(n)}{\alpha(n)} \sum_{i} m_{n}\left(\bar{C}_{i}\right) \geq \frac{\beta(n)}{\alpha(n)} m_{n}(B(\mathbf{0}, 1))=\frac{\beta(n)}{\alpha(n)} \mathscr{H}^{n}(B(\mathbf{0}, 1))
\end{aligned}
$$

Now taking the limit as $\delta \rightarrow 0$,

$$
\mathscr{H}^{n}(B(\mathbf{0}, 1))+\varepsilon \geq \frac{\beta(n)}{\alpha(n)} \mathscr{H}^{n}(B(\mathbf{0}, 1))
$$

and since $\varepsilon>0$ is arbitrary, this shows $\alpha(n) \geq \beta(n)$.
By the Vitali covering theorem, there exists a sequence of disjoint balls, $\left\{B_{i}\right\}$ such that

$$
B(\mathbf{0}, 1)=\left(\cup_{i=1}^{\infty} B_{i}\right) \cup N
$$

where $m_{n}(N)=0$. Then $\mathscr{H}_{\delta}^{n}(N)=0$ can be concluded because $\mathscr{H}_{\delta}^{n} \leq \mathscr{H}^{n}$ and Lemma 28.2.2. Using $m_{n}(B(\mathbf{0}, 1))=\mathscr{H}^{n}(B(\mathbf{0}, 1))$ again,

$$
\begin{aligned}
\mathscr{H}_{\delta}^{n}(B(\mathbf{0}, 1)) & =\mathscr{H}_{\delta}^{n}\left(\cup_{i} B_{i}\right) \leq \sum_{i=1}^{\infty} \beta(n) r\left(B_{i}\right)^{n} \\
& =\frac{\beta(n)}{\alpha(n)} \sum_{i=1}^{\infty} \alpha(n) r\left(B_{i}\right)^{n}=\frac{\beta(n)}{\alpha(n)} \sum_{i=1}^{\infty} m_{n}\left(B_{i}\right) \\
& =\frac{\beta(n)}{\alpha(n)} m_{n}\left(\cup_{i} B_{i}\right)=\frac{\beta(n)}{\alpha(n)} m_{n}(B(\mathbf{0}, 1))=\frac{\beta(n)}{\alpha(n)} \mathscr{H}^{n}(B(\mathbf{0}, 1))
\end{aligned}
$$

which implies $\alpha(n) \leq \beta(n)$ and so the two are equal. This proves that if $\alpha(n)=\beta(n)$, then the $\mathscr{H}^{n}=m_{n}$ on the measurable sets of $\mathbb{R}^{n}$.

This gives another way to think of Lebesgue measure which is a particularly nice way because it is coordinate free, depending only on the notion of distance.

For $s<n$, note that $\mathscr{H}^{s}$ is not a Radon measure because it will not generally be finite on compact sets. For example, let $n=2$ and consider $\mathscr{H}^{1}(L)$ where $L$ is a line segment joining $(0,0)$ to $(1,0)$. Then $\mathscr{H}^{1}(L)$ is no smaller than $\mathscr{H}^{1}(L)$ when $L$ is considered a subset of $\mathbb{R}^{1}, n=1$. Thus by what was just shown, $\mathscr{H}^{1}(L) \geq 1$. Hence $\mathscr{H}^{1}([0,1] \times[0,1])=\infty$. The situation is this: $L$ is a one-dimensional object inside $\mathbb{R}^{2}$ and $\mathscr{H}^{1}$ is giving a onedimensional measure of this object. In fact, Hausdorff measures can make such heuristic remarks as these precise. Define the Hausdorff dimension of a set, $A$, as

$$
\operatorname{dim}(A)=\inf \left\{s: \mathscr{H}^{s}(A)=0\right\}
$$

### 28.4.1 A Formula For $\alpha(n)$

What is $\alpha(n)$ ? Recall the gamma function which makes sense for all $p>0$.

$$
\Gamma(p) \equiv \int_{0}^{\infty} e^{-t} t^{p-1} d t
$$

Lemma 28.4.1 The following identities hold.

$$
\begin{gathered}
p \Gamma(p)=\Gamma(p+1) \\
\Gamma(p) \Gamma(q)=\left(\int_{0}^{1} x^{p-1}(1-x)^{q-1} d x\right) \Gamma(p+q) \\
\Gamma\left(\frac{1}{2}\right)=\sqrt{\pi}
\end{gathered}
$$

Proof: Using integration by parts,

$$
\begin{aligned}
\Gamma(p+1) & =\int_{0}^{\infty} e^{-t} t^{p} d t=-\left.e^{-t} t^{p}\right|_{0} ^{\infty}+p \int_{0}^{\infty} e^{-t} t^{p-1} d t \\
& =p \Gamma(p)
\end{aligned}
$$

Next

$$
\begin{aligned}
\Gamma(p) \Gamma(q) & =\int_{0}^{\infty} e^{-t} t^{p-1} d t \int_{0}^{\infty} e^{-s} s^{q-1} d s \\
& =\int_{0}^{\infty} \int_{0}^{\infty} e^{-(t+s)} t^{p-1} s^{q-1} d t d s \\
& =\int_{0}^{\infty} \int_{s}^{\infty} e^{-u}(u-s)^{p-1} s^{q-1} d u d s \\
& =\int_{0}^{\infty} \int_{0}^{u} e^{-u}(u-s)^{p-1} s^{q-1} d s d u \\
& =\int_{0}^{\infty} \int_{0}^{1} e^{-u}(u-u x)^{p-1}(u x)^{q-1} u d x d u \\
& =\int_{0}^{\infty} \int_{0}^{1} e^{-u} u^{p+q-1}(1-x)^{p-1} x^{q-1} d x d u \\
& =\Gamma(p+q)\left(\int_{0}^{1} x^{p-1}(1-x)^{q-1} d x\right)
\end{aligned}
$$

It remains to find $\Gamma\left(\frac{1}{2}\right)$.

$$
\Gamma\left(\frac{1}{2}\right)=\int_{0}^{\infty} e^{-t} t^{-1 / 2} d t=\int_{0}^{\infty} e^{-u^{2}} \frac{1}{u} 2 u d u=2 \int_{0}^{\infty} e^{-u^{2}} d u
$$

Now

$$
\begin{aligned}
\left(\int_{0}^{\infty} e^{-x^{2}} d x\right)^{2} & =\int_{0}^{\infty} e^{-x^{2}} d x \int_{0}^{\infty} e^{-y^{2}} d y=\int_{0}^{\infty} \int_{0}^{\infty} e^{-\left(x^{2}+y^{2}\right)} d x d y \\
& =\int_{0}^{\infty} \int_{0}^{\pi / 2} e^{-r^{2}} r d \theta d r=\frac{1}{4} \pi
\end{aligned}
$$

and so

$$
\Gamma\left(\frac{1}{2}\right)=2 \int_{0}^{\infty} e^{-u^{2}} d u=\sqrt{\pi}
$$

This proves the lemma.
Next let $n$ be a positive integer.
Theorem 28.4.2 $\alpha(n)=\pi^{n / 2}(\Gamma(n / 2+1))^{-1}$ where $\Gamma(s)$ is the gamma function

$$
\Gamma(s)=\int_{0}^{\infty} e^{-t} t^{s-1} d t
$$

Proof: First let $n=1$.

$$
\Gamma\left(\frac{3}{2}\right)=\frac{1}{2} \Gamma\left(\frac{1}{2}\right)=\frac{\sqrt{\pi}}{2}
$$

Thus

$$
\pi^{1 / 2}(\Gamma(1 / 2+1))^{-1}=\frac{2}{\sqrt{\pi}} \sqrt{\pi}=2=\alpha(1)
$$

and this shows the theorem is true if $n=1$.
Assume the theorem is true for $n$ and let $B_{n+1}$ be the unit ball in $\mathbb{R}^{n+1}$. Then by the result in $\mathbb{R}^{n}$,

$$
\begin{gathered}
m_{n+1}\left(B_{n+1}\right)=\int_{-1}^{1} \alpha(n)\left(1-x_{n+1}^{2}\right)^{n / 2} d x_{n+1} \\
=2 \alpha(n) \int_{0}^{1}\left(1-t^{2}\right)^{n / 2} d t
\end{gathered}
$$

Doing an integration by parts and using Lemma 28.4.1

$$
\begin{aligned}
& =2 \alpha(n) n \int_{0}^{1} t^{2}\left(1-t^{2}\right)^{(n-2) / 2} d t \\
& =2 \alpha(n) n \frac{1}{2} \int_{0}^{1} u^{1 / 2}(1-u)^{n / 2-1} d u \\
& =n \alpha(n) \int_{0}^{1} u^{3 / 2-1}(1-u)^{n / 2-1} d u \\
& =n \alpha(n) \Gamma(3 / 2) \Gamma(n / 2)(\Gamma((n+3) / 2))^{-1} \\
& =n \pi^{n / 2}(\Gamma(n / 2+1))^{-1}(\Gamma((n+3) / 2))^{-1} \Gamma(3 / 2) \Gamma(n / 2) \\
& =n \pi^{n / 2}(\Gamma(n / 2)(n / 2))^{-1}(\Gamma((n+1) / 2+1))^{-1} \Gamma(3 / 2) \Gamma(n / 2) \\
& =2 \pi^{n / 2} \Gamma(3 / 2)(\Gamma((n+1) / 2+1))^{-1} \\
& =\pi^{(n+1) / 2}(\Gamma((n+1) / 2+1))^{-1}
\end{aligned}
$$

This proves the theorem.
From now on, in the definition of Hausdorff measure, it will always be the case that $\beta(s)=\alpha(s)$. As shown above, this is the right thing to have $\beta(s)$ to equal if $s$ is a positive integer because this yields the important result that Hausdorff measure is the same as Lebesgue measure. Note the formula, $\pi^{s / 2}(\Gamma(s / 2+1))^{-1}$ makes sense for any $s \geq 0$.

### 28.4.2 Hausdorff Measure And Linear Transformations

Hausdorff measure makes possible a unified development of $n$ dimensional area. As in the case of Lebesgue measure, the first step in this is to understand basic considerations related to linear transformations. Recall that for $L \in \mathscr{L}\left(\mathbb{R}^{k}, \mathbb{R}^{l}\right), L^{*}$ is defined by

$$
(L \mathbf{u}, \mathbf{v})=\left(\mathbf{u}, L^{*} \mathbf{v}\right)
$$

Also recall Theorem 5.9.6 on Page 94 which is stated here for convenience. This theorem says you can write a linear transformation as the composition of two linear transformations, one which preserves length and the other which distorts, the right polar decomposition. The one which distorts is the one which will have a nontrivial interaction with Hausdorff measure while the one which preserves lengths does not change Hausdorff measure. These ideas are behind the following theorems and lemmas.

Theorem 28.4.3 Let $F$ be an $n \times m$ matrix where $m \geq n$. Then there exists an $m \times n$ matrix $R$ and $a n \times n$ matrix $U$ such that

$$
F=R U, U=U^{*}
$$

all eigenvalues of $U$ are non negative,

$$
U^{2}=F^{*} F, R^{*} R=I
$$

and $|R \mathbf{x}|=|\mathbf{x}|$.
Lemma 28.4.4 Let $R \in \mathscr{L}\left(\mathbb{R}^{n}, \mathbb{R}^{m}\right), n \leq m$, and $R^{*} R=I$. Then if $A \subseteq \mathbb{R}^{n}$,

$$
\mathscr{H}^{n}(R A)=\mathscr{H}^{n}(A)
$$

In fact, if $P: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ satisfies $|P \mathbf{x}-P \mathbf{y}|=|\mathbf{x}-\mathbf{y}|$, then

$$
\mathscr{H}^{n}(P A)=\mathscr{H}^{n}(A)
$$

Proof: Note that

$$
|R(\mathbf{x}-\mathbf{y})|^{2}=(R(\mathbf{x}-\mathbf{y}), R(\mathbf{x}-\mathbf{y}))=\left(R^{*} R(\mathbf{x}-\mathbf{y}), \mathbf{x}-\mathbf{y}\right)=|\mathbf{x}-\mathbf{y}|^{2}
$$

Thus $R$ preserves lengths.
Now let $P$ be an arbitrary mapping which preserves lengths and let $A$ be bounded, $P(A) \subseteq \cup_{j=1}^{\infty} C_{j}, r\left(C_{j}\right)<\delta$, and

$$
\mathscr{H}_{\delta}^{n}(P A)+\varepsilon>\sum_{j=1}^{\infty} \alpha(n)\left(r\left(C_{j}\right)\right)^{n}
$$

Since $P$ preserves lengths, it follows $P$ is one to one on $P\left(\mathbb{R}^{n}\right)$ and $P^{-1}$ also preserves lengths on $P\left(\mathbb{R}^{n}\right)$. Replacing each $C_{j}$ with $C_{j} \cap(P A)$,

$$
\begin{aligned}
\mathscr{H}_{\delta}^{n}(P A)+\varepsilon & >\sum_{j=1}^{\infty} \alpha(n) r\left(C_{j} \cap(P A)\right)^{n} \\
& =\sum_{j=1}^{\infty} \alpha(n) r\left(P^{-1}\left(C_{j} \cap(P A)\right)\right)^{n} \\
& \geq \mathscr{H}_{\delta}^{n}(A) .
\end{aligned}
$$

Thus $\mathscr{H}_{\delta}^{n}(P A) \geq \mathscr{H}_{\delta}^{n}(A)$.
Now let $A \subseteq \cup_{j=1}^{\infty} C_{j}, \operatorname{diam}\left(C_{j}\right) \leq \delta$, and

$$
\mathscr{H}_{\delta}^{n}(A)+\varepsilon \geq \sum_{j=1}^{\infty} \alpha(n)\left(r\left(C_{j}\right)\right)^{n}
$$

Then

$$
\begin{aligned}
\mathscr{H}_{\delta}^{n}(A)+\varepsilon & \geq \sum_{j=1}^{\infty} \alpha(n)\left(r\left(C_{j}\right)\right)^{n} \\
& =\sum_{j=1}^{\infty} \alpha(n)\left(r\left(P C_{j}\right)\right)^{n} \geq \mathscr{H}_{\delta}^{n}(P A)
\end{aligned}
$$

Hence $\mathscr{H}_{\delta}^{n}(P A)=\mathscr{H}_{\delta}^{n}(A)$. Letting $\delta \rightarrow 0$ yields the desired conclusion in the case where $A$ is bounded. For the general case, let $A_{r}=A \cap B(0, r)$. Then $\mathscr{H}^{n}\left(P A_{r}\right)=\mathscr{H}^{n}\left(A_{r}\right)$. Now let $r \rightarrow \infty$.

Lemma 28.4.5 Let $F \in \mathscr{L}\left(\mathbb{R}^{n}, \mathbb{R}^{m}\right), n \leq m$, and let $F=R U$ where $R$ and $U$ are described in Theorem 5.9.6 on Page 94. Then if $A \subseteq \mathbb{R}^{n}$ is Lebesgue measurable,

$$
\mathscr{H}^{n}(F A)=\operatorname{det}(U) m_{n}(A)
$$

Proof: Using Theorem 13.5.7 on Page 354 and Theorem 28.2.4,

$$
\begin{gathered}
\mathscr{H}^{n}(F A)=\mathscr{H}^{n}(R U A) \\
=\mathscr{H}^{n}(U A)=m_{n}(U A)=\operatorname{det}(U) m_{n}(A) .
\end{gathered}
$$

Definition 28.4.6 Define $J$ to equal $\operatorname{det}(U)$. Thus

$$
J=\operatorname{det}\left(\left(F^{*} F\right)^{1 / 2}\right)=\left(\operatorname{det}\left(F^{*} F\right)\right)^{1 / 2}
$$

## Chapter 29

## The Area Formula

I am grateful to those who have found errors in this material, some of which were egregious. I would not have found these mistakes because I never teach this material and I don't use it in my research. I do think it is wonderful mathematics however.

To begin with is a simple theorem about extending Lipschitz functions.
Theorem 29.0.1 If $\mathbf{h}: \Omega \rightarrow \mathbb{R}^{m}$ is Lipschitz, then there exists $\overline{\mathbf{h}}: \mathbb{R}^{p} \rightarrow \mathbb{R}^{m}$ which extends h and is also Lipschitz.

Proof: It suffices to assume $m=1$ because if this is shown, it may be applied to the components of $\mathbf{h}$ to get the desired result. Suppose

$$
\begin{equation*}
|h(\mathbf{x})-h(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}| \tag{29.0.1}
\end{equation*}
$$

Define

$$
\begin{equation*}
\bar{h}(\mathbf{x}) \equiv \inf \{h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|: \mathbf{w} \in \Omega\} \tag{29.0.2}
\end{equation*}
$$

If $\mathbf{x} \in \Omega$, then for all $\mathbf{w} \in \Omega$,

$$
h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}| \geq h(\mathbf{x})
$$

by 29.0.1. This shows $h(\mathbf{x}) \leq \bar{h}(\mathbf{x})$. But also you could take $\mathbf{w}=\mathbf{x}$ in 29.0.2 which yields $\bar{h}(\mathbf{x}) \leq h(\mathbf{x})$. Therefore $\bar{h}(\mathbf{x})=h(\mathbf{x})$ if $\mathbf{x} \in \Omega$.

Now suppose $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{p}$ and consider $|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|$. Without loss of generality assume $\bar{h}(\mathbf{x}) \geq \bar{h}(\mathbf{y})$. (If not, repeat the following argument with $\mathbf{x}$ and $\mathbf{y}$ interchanged.) Pick $\mathbf{w} \in \Omega$ such that

$$
h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\varepsilon<\bar{h}(\mathbf{y})
$$

Then

$$
\begin{aligned}
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|=\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y}) & \leq h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|- \\
{[h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\varepsilon] } & \leq K|\mathbf{x}-\mathbf{y}|+\varepsilon .
\end{aligned}
$$

Since $\varepsilon$ is arbitrary,

$$
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

### 29.1 Estimates for Hausdorff Measure

It was shown in Lemma 28.4.5 that

$$
\mathscr{H}^{n}(F A)=\operatorname{det}(U) m_{n}(A)
$$

where $F=R U$ with $R$ preserving distances and $U$ a symmetric matrix having all positive eigenvalues. The area formula gives a generalization of this simple relationship to the case where $F$ is replaced by a nonlinear mapping $\mathbf{h}$. It contains as a special case the earlier change of variables formula. There are two parts to this development. The first part is to generalize Lemma 28.4.5 to the case of nonlinear maps. When this is done, the area formula can be presented.

In the first version of the area formula $\mathbf{h}$ will be a Lipschitz function,

$$
|\mathbf{h}(\mathbf{x})-\mathbf{h}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

defined on $\mathbb{R}^{n}$. This is no loss of generality because of Theorem 29.0.1.
The following lemma states that Lipschitz maps take sets of measure zero to sets of measure zero. It also gives a convenient estimate. It involves the consideration of $\mathscr{H}^{n}$ as an outer measure. Thus it is not necessary to know the set $B$ is measurable.

Lemma 29.1.1 If $\mathbf{h}$ is Lipschitz with Lipschitz constant $K$ then

$$
\mathscr{H}^{n}(\mathbf{h}(B)) \leq K^{n} \mathscr{H}^{n}(B)
$$

Also, if $T$ is a set in $\mathbb{R}^{n}, m_{n}(T)=0$, then $\mathscr{H}^{n}(\mathbf{h}(T))=0$. It is not necessary that $\mathbf{h}$ be one to one.

Proof: Let $\left\{C_{i}\right\}_{i=1}^{\infty}$ cover $B$ with each having diameter less than $\delta$ and let this cover be such that

$$
\sum_{i} \beta(n) \frac{1}{2} \operatorname{diam}\left(C_{i}\right)^{n}<\mathscr{H}_{\delta}^{n}(B)+\varepsilon
$$

Then $\left\{\mathbf{h}\left(C_{i}\right)\right\}$ covers $\mathbf{h}(B)$ and each set has diameter no more than $K \boldsymbol{\delta}$. Then

$$
\begin{aligned}
\mathscr{H}_{K \delta}^{n}(\mathbf{h}(B)) & \leq \sum_{i} \beta(n)\left(\frac{1}{2} \operatorname{diam}\left(\mathbf{h}\left(C_{i}\right)\right)\right)^{n} \\
& \leq K^{n} \sum_{i} \beta(n)\left(\frac{1}{2} \operatorname{diam}\left(C_{i}\right)\right)^{n} \leq K^{n}\left(\mathscr{H}_{\delta}^{n}(B)+\varepsilon\right)
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this shows that

$$
\mathscr{H}_{K \delta}^{n}(\mathbf{h}(B)) \leq K^{n} \mathscr{H}_{\delta}^{n}(B)
$$

Now take a limit as $\delta \rightarrow 0$. The second claim follows from $m_{n}=\mathscr{H}^{n}$ on Lebesgue measurable sets of $\mathbb{R}^{n}$.

Lemma 29.1.2 If $S$ is a Lebesgue measurable set and $\mathbf{h}$ is Lipschitz then $\mathbf{h}(S)$ is $\mathscr{H}^{n}$ measurable. Also, if $\mathbf{h}$ is Lipschitz with constant $K$,

$$
\mathscr{H}^{n}(\mathbf{h}(S)) \leq K^{n} m_{n}(S)
$$

It is not necessary that $\mathbf{h}$ be one to one.
Proof: The estimate follows from Lemma 29.1.1 and the observation that, as shown before, Theorem 28.2.4, if $S$ is Lebesgue measurable in $\mathbb{R}^{n}$, then $\mathscr{H}^{n}(S)=m_{n}(S)$. The estimate also shows that $\mathbf{h}$ maps sets of Lebesgue measure zero to sets of $\mathscr{H}^{n}$ measure zero. Why is $\mathbf{h}(S) \mathscr{H}^{n}$ measurable if $S$ is Lebesgue measurable? This follows from completeness of $\mathscr{H}^{n}$. Indeed, let $F$ be $F_{\sigma}$ and contained in $S$ with $m_{n}(S \backslash F)=0$. Then

$$
\mathbf{h}(S)=\mathbf{h}(S \backslash F) \cup \mathbf{h}(F)
$$

The second set is Borel and the first has $\mathscr{H}^{n}$ measure zero. By completeness of $\mathscr{H}^{n}, \mathbf{h}(S)$ is $\mathscr{H}^{n}$ measurable.

By Theorem 5.9.6 on Page 94 , when $D \mathbf{h}(\mathbf{x})$ exists,

$$
D \mathbf{h}(\mathbf{x})=R(\mathbf{x}) U(\mathbf{x})
$$

where $(U(\mathbf{x}) \mathbf{u}, \mathbf{v})=(U(\mathbf{x}) \mathbf{v}, \mathbf{u}),(U(\mathbf{x}) \mathbf{u}, \mathbf{u}) \geq 0$ and $R^{*} R=I$ so $R$ preserves lengths. This convention will be used in what follows.

Lemma 29.1.3 In this situation where $R^{*} R=I,\left|R^{*} \mathbf{u}\right| \leq|\mathbf{u}|$.
Proof: First note that

$$
\begin{aligned}
\left(\mathbf{u}-R R^{*} \mathbf{u}, R R^{*} \mathbf{u}\right) & =\left(\mathbf{u}, R R^{*} \mathbf{u}\right)-\left|R R^{*} \mathbf{u}\right|^{2} \\
& =\left|R^{*} \mathbf{u}\right|^{2}-\left|R^{*} \mathbf{u}\right|^{2}=0
\end{aligned}
$$

and so

$$
\begin{aligned}
|\mathbf{u}|^{2} & =\left|\mathbf{u}-R R^{*} \mathbf{u}+R R^{*} \mathbf{u}\right|^{2} \\
& =\left|\mathbf{u}-R R^{*} \mathbf{u}\right|^{2}+\left|R R^{*} \mathbf{u}\right|^{2} \\
& =\left|\mathbf{u}-R R^{*} \mathbf{u}\right|^{2}+\left|R^{*} \mathbf{u}\right|^{2} .
\end{aligned}
$$

Then the following corollary follows from Lemma 29.1.3.
Corollary 29.1.4 Let $T \subseteq \mathbb{R}^{m}$. Then

$$
\mathscr{H}^{n}(T) \geq \mathscr{H}^{n}\left(R^{*} T\right)
$$

### 29.2 Comparison Theorems

First is a simple lemma which is fairly interesting which involves comparison of two linear transformations.

Lemma 29.2.1 Suppose $S, T$ are linear defined on a finite dimensional normed linear space, $S^{-1}$ exists and let $\delta \in(0,1)$. Then whenever $\|S-T\|$ is small enough, it follows that

$$
\begin{equation*}
\frac{|T \mathbf{v}|}{|S \mathbf{v}|} \in(1-\delta, 1+\delta) \tag{29.2.3}
\end{equation*}
$$

for all $\mathbf{v} \neq \mathbf{0}$. Similarly if $T^{-1}$ exists and $\|S-T\|$ is small enough,

$$
\frac{|T \mathbf{v}|}{|S \mathbf{v}|} \in(1-\delta, 1+\delta)
$$

Proof: Say $S^{-1}$ exists. Then $\mathbf{v} \rightarrow|S \mathbf{v}|$ is a norm. Then by equivalence of norms, Theorem 8.4.9, there exists $\eta>0$ such that for all $\mathbf{v},|S \mathbf{v}| \geq \eta|\mathbf{v}|$. Say $\|T-S\|<r<\delta \eta$

$$
\frac{|S \mathbf{v}|-\|T-S\||\mathbf{v}|}{|S \mathbf{v}|} \leq \frac{|T \mathbf{v}|}{|S \mathbf{v}|}=\frac{|[S+(T-S)] \mathbf{v}|}{|S \mathbf{v}|} \leq \frac{|S \mathbf{v}|+\|T-S\||\mathbf{v}|}{|S \mathbf{v}|}
$$

and so

$$
\begin{aligned}
1-\delta & \leq 1-\frac{r|\mathbf{v}|}{\eta|\mathbf{v}|} \leq \frac{|S \mathbf{v}|-\|T-S\||\mathbf{v}|}{|S \mathbf{v}|} \leq \frac{|T \mathbf{v}|}{|S \mathbf{v}|} \\
& \leq \frac{|S \mathbf{v}|+\|T-S\||\mathbf{v}|}{|S \mathbf{v}|} \leq 1+\frac{r|\mathbf{v}|}{\eta|\mathbf{v}|}=1+\delta
\end{aligned}
$$

The last assertion follows by noting that if $T^{-1}$ is given to exist and $S$ is close to $T$ then

$$
\frac{|S \mathbf{v}|}{|T \mathbf{v}|} \in(1-\delta, 1+\delta) \text { so } \frac{|T \mathbf{v}|}{|S \mathbf{v}|} \in\left(\frac{1}{1+\delta}, \frac{1}{1-\delta}\right) \subseteq(1-\hat{\delta}, 1+\hat{\delta})
$$

By choosing $\delta$ appropriately, one can achieve the last inclusion for given $\hat{\delta}$.
In short, the above lemma says that if one of $S, T$ is invertible and the other is close to it, then it is also invertible and the quotient of $|S \mathbf{v}|$ and $|T \mathbf{v}|$ is close to 1 . Then the following lemma is fairly obvious.

Lemma 29.2.2 Let $S, T$ be $n \times n$ matrices which are invertible. Then

$$
\mathbf{o}(T \mathbf{v})=\mathbf{o}(S \mathbf{v})=\mathbf{o}(\mathbf{v})
$$

and if $L$ is a continuous linear transformation such that for $a<b$,

$$
\sup _{\mathbf{v} \neq \mathbf{0}} \frac{|L \mathbf{v}|}{|S \mathbf{v}|}<b, \inf _{\mathbf{v} \neq \mathbf{0}} \frac{|L \mathbf{v}|}{|S \mathbf{v}|}>a
$$

If $\|S-T\|$ is small enough, it follows that the same inequalities hold with $S$ replaced with $T$. Here $\|\cdot\|$ denotes the operator norm.

Proof: Consider the first claim. For

$$
\frac{|o(T \mathbf{v})|}{|\mathbf{v}|}=\frac{|o(T \mathbf{v})|}{|T \mathbf{v}|} \frac{|T \mathbf{v}|}{|\mathbf{v}|} \leq \frac{|o(T \mathbf{v})|}{|T \mathbf{v}|}\|T\|
$$

Thus $o(T \mathbf{v})=o(\mathbf{v})$. It is similar for $T$ replaced with $S$.
Consider the second claim. Pick $\delta$ sufficiently small. Then by Lemma 29.2.1

$$
\sup _{\mathbf{v} \neq \mathbf{0}} \frac{|L \mathbf{v}|}{|T \mathbf{v}|}=\sup _{\mathbf{v} \neq \mathbf{0}} \frac{|L \mathbf{v}|}{|S \mathbf{v}|} \frac{|S \mathbf{v}|}{|T \mathbf{v}|} \leq(1+\delta) \sup _{\mathbf{v} \neq \mathbf{0}} \frac{|L \mathbf{v}|}{|S \mathbf{v}|}<b
$$

if $\delta$ is small enough. The other inequality is shown exactly similar.

### 29.3 A Decomposition

This follows [47] which is where I encountered this material. Assume the following:

$$
\begin{equation*}
D \mathbf{h}(\mathbf{x}) \text { exists at } a . e . \mathbf{x} \in G \text { say at all } \mathbf{x} \in A \subseteq G \tag{29.3.4}
\end{equation*}
$$

By regularity, we can and will assume $A$ is a Borel set. Of course this is automatic if $\mathbf{h}$ is Lipschitz. I have in mind the assumption that $\mathbf{h}$ is Lipschitz. This makes things very convenient because then $\mathbf{h}(E)$ is $\mathscr{H}^{n}$ Hausdorff measurable whenever $E$ is $n$ dimensional Lebesgue measurable. However, there are interesting things which don't depend on Lipschitz continuity. Initially, I will only assume that $\mathbf{h}$ is continuous on $G$ and differentiable on $A$.

For $\mathbf{x} \in A$, let $D \mathbf{h}(\mathbf{x}) \equiv R(\mathbf{x}) U(\mathbf{x})$ where $R(\mathbf{x})$ preserves lengths and

$$
U(\mathbf{x}) \equiv\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)^{1 / 2}
$$

Let $A^{+}$denote those points of $A$ for which $U(\mathbf{x})^{-1}$ exists. Thus this is a measurable subset of $A$.

Let $B$ be a Borel measurable subset of $A^{+}$and let $\mathbf{b} \in B$. Let $\mathscr{S}$ be a countable dense subset of the space of symmetric invertible matrices and let $\mathscr{C}$ be a countable dense subset of $B$. The idea is to decompose $B$ into countably many Borel sets $E$ on which $\mathbf{h}$ is one to one and Lipschitz with $\mathbf{h}^{-1}$ Lipschitz on $\mathbf{h}(E)$. This will be done by establishing 29.3.10 given below where $T$ is an invertible symmetric transformation.

Let $\varepsilon$ be a small number. Since $U(\mathbf{b})$ is invertible, Lemma 29.2.2 implies $\mathbf{o}(\mathbf{a}-\mathbf{b})=$ $\mathbf{o}(U(\mathbf{b})(\mathbf{a}-\mathbf{b}))$ and so

$$
\begin{equation*}
|\mathbf{h}(\mathbf{a})-\mathbf{h}(\mathbf{b})-D \mathbf{h}(\mathbf{b})(\mathbf{a}-\mathbf{b})|<\varepsilon|U(\mathbf{b})(\mathbf{a}-\mathbf{b})| \tag{29.3.5}
\end{equation*}
$$

provided that $\mathbf{a} \in B\left(\mathbf{b}, \frac{2}{i}\right)$ for $i$ sufficiently large. By Lemma 29.2.1,

$$
\begin{equation*}
|\mathbf{h}(\mathbf{a})-\mathbf{h}(\mathbf{b})-D \mathbf{h}(\mathbf{b})(\mathbf{a}-\mathbf{b})|<\varepsilon|T(\mathbf{a}-\mathbf{b})| \tag{29.3.6}
\end{equation*}
$$

where $U(\mathbf{b})$ is replaced by another linear one to one and onto symmetric mapping $T$ provided $T$ is sufficiently close to $U(\mathbf{b})$.

Now let $\mathbf{c} \in \mathscr{C}$ be close enough to $\mathbf{b}$ that $\mathbf{b} \in B\left(\mathbf{c}, \frac{1}{i}\right)$. Thus $\mathbf{b} \in E(T, \mathbf{c}, i)$ where for $i \in \mathbb{N}, \mathbf{c} \in \mathscr{C}, T \in \mathscr{S}, E(T, \mathbf{c}, i)$ consists of those $\mathbf{b} \in B\left(\mathbf{c}, \frac{1}{i}\right)$ such that for all $\mathbf{a} \in B\left(\mathbf{b}, \frac{2}{i}\right)$, 29.3.6 holds and also

$$
\begin{align*}
& \inf _{\mathbf{v} \neq \mathbf{0}} \frac{|D \mathbf{h}(\mathbf{b}) \mathbf{v}|}{|T \mathbf{v}|}=\inf _{\mathbf{v} \neq \mathbf{0}} \frac{|U(\mathbf{b}) \mathbf{v}|}{|T \mathbf{v}|}>1-\varepsilon,  \tag{29.3.7}\\
& \sup _{\mathbf{v} \neq \mathbf{0}} \frac{|D \mathbf{h}(\mathbf{b}) \mathbf{v}|}{|T \mathbf{v}|}=\sup _{\mathbf{v} \neq \mathbf{0}} \frac{|U(\mathbf{b}) \mathbf{v}|}{|T \mathbf{v}|}<1+\varepsilon \tag{29.3.8}
\end{align*}
$$

It follows then from the above inequalities and 29.3.6 that for all $\mathbf{a} \in B\left(\mathbf{b}, \frac{2}{i}\right)$,

$$
\begin{align*}
|\mathbf{h}(\mathbf{a})-\mathbf{h}(\mathbf{b})| & \leq(1+2 \varepsilon)|T(\mathbf{a}-\mathbf{b})| \\
|\mathbf{h}(\mathbf{a})-\mathbf{h}(\mathbf{b})| & \geq(1-2 \varepsilon)|T(\mathbf{a}-\mathbf{b})| \tag{29.3.9}
\end{align*}
$$

and so

$$
\begin{equation*}
(1-2 \varepsilon)|T(\mathbf{a}-\mathbf{b})| \leq|\mathbf{h}(\mathbf{a})-\mathbf{h}(\mathbf{b})| \leq(1+2 \varepsilon)|T(\mathbf{a}-\mathbf{b})| \tag{29.3.10}
\end{equation*}
$$

Then if $\mathbf{a}, \mathbf{b} \in E(T, \mathbf{c}, i), 29.3 .10$ holds for these two $\mathbf{a}, \mathbf{b}$ because $|\mathbf{a}-\mathbf{b}|<2 / i$.

Note that this proves that on $E(T, \mathbf{c}, i)$ the function $\mathbf{h}$ is one to one and $T$ is a close approximation to $U(\mathbf{b})$ for each $\mathbf{b} \in E(T, \mathbf{c}, i)$. It also shows the Lipschitz continuity of $\mathbf{h}$ and $\mathbf{h}^{-1}$ on $E$ by comparison with $T$. What has just been shown is a very interesting result for its own sake. It is summarized in the following lemma.

### 29.4 Estimates and a Limit

Lemma 29.4.1 Let $\mathbf{h}$ be differentiable on $A \subseteq G$ and let $A^{+}$consist of those points $\mathbf{x}$ where $\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)>0$. Then if B is any Borel subset of $A^{+}$, there is a disjoint sequence of Borel sets and invertible symmetric transformations $T_{k},\left\{\left(E_{k}, T_{k}\right)\right\}, \cup_{k} E_{k}=B$ such that $\mathbf{h}$ is Lipschitz on $E_{k}$ and $\mathbf{h}^{-1}$ is Lipschitz on $\mathbf{h}(E(T, \mathbf{c}, i))$. Also for any $\mathbf{b} \in E_{k}, 29.3 .7$ and 29.3.8 both hold. Also, for $\mathbf{b} \in E_{k}$

$$
\begin{equation*}
(1-\boldsymbol{\varepsilon})\left|T_{k} \mathbf{v}\right|<|D \mathbf{h}(\mathbf{b}) \mathbf{v}|=|U(\mathbf{b}) \mathbf{v}|<(1+\boldsymbol{\varepsilon})\left|T_{k} \mathbf{v}\right| \tag{29.4.11}
\end{equation*}
$$

One can also conclude that for $\mathbf{b} \in E_{k}$,

$$
\begin{equation*}
(1-\varepsilon)^{-n}\left|\operatorname{det}\left(T_{k}\right)\right| \leq \operatorname{det}(U(\mathbf{b})) \leq(1+\varepsilon)^{n}\left|\operatorname{det}\left(T_{k}\right)\right| \tag{29.4.12}
\end{equation*}
$$

Proof: It follows from 29.3.10 that for $\mathbf{x}, \mathbf{y} \in T(E(T, \mathbf{c}, i))$

$$
\begin{equation*}
\left|\mathbf{h}\left(T^{-1}(\mathbf{x})\right)-\mathbf{h}\left(T^{-1}(\mathbf{y})\right)\right| \leq(1+2 \varepsilon)|\mathbf{x}-\mathbf{y}| \tag{29.4.13}
\end{equation*}
$$

and for $\mathbf{x}, \mathbf{y}$ in $\mathbf{h}(E(T, \mathbf{c}, i))$,

$$
\begin{equation*}
\left|T\left(\mathbf{h}^{-1}(\mathbf{x})\right)-T\left(\mathbf{h}^{-1}(\mathbf{y})\right)\right| \leq \frac{1}{(1-2 \varepsilon)}|\mathbf{x}-\mathbf{y}| \tag{29.4.14}
\end{equation*}
$$

The symbol $\mathbf{h}^{-1}$ refers to the restriction to $\mathbf{h}(E(T, \mathbf{c}, i))$ of the inverse image of $\mathbf{h}$. Thus, on this set, $\mathbf{h}^{-1}$ is actually a function even though $\mathbf{h}$ might not be one to one. This also shows that $\mathbf{h}^{-1}$ is Lipschitz on $\mathbf{h}(E(T, \mathbf{c}, i))$ and $\mathbf{h}$ is Lipschitz on $E(T, \mathbf{c}, i)$. Indeed, from 29.4.13, letting $T^{-1}(\mathbf{x})=\mathbf{a}$ and $T^{-1}(\mathbf{y})=\mathbf{b}$,

$$
\begin{equation*}
|\mathbf{h}(\mathbf{a})-\mathbf{h}(\mathbf{b})| \leq(1+2 \varepsilon)|T(\mathbf{a})-T(\mathbf{b})| \leq(1+2 \varepsilon)\|T\||\mathbf{a}-\mathbf{b}| \tag{29.4.15}
\end{equation*}
$$

and using the fact that $T$ is one to one, there is $\delta>0$ such that $|T \mathbf{z}| \geq \delta|\mathbf{z}|$ so 29.4.14 implies that

$$
\begin{equation*}
\left|\mathbf{h}^{-1}(\mathbf{x})-\mathbf{h}^{-1}(\mathbf{y})\right| \leq \frac{1}{\delta(1-2 \varepsilon)}|\mathbf{x}-\mathbf{y}| \tag{29.4.16}
\end{equation*}
$$

Now let $\left(E_{k}, T_{k}\right)$ result from a disjoint union of measurable subsets of the countably many $E(T, \mathbf{c}, i)$ such that $B=\cup_{k} E_{k}$. Thus the above Lipschitz conditions 29.4.13 and
29.4.14 hold for $T_{k}$ in place of $T$. It is not necessary to assume $\mathbf{h}$ is one to one in this lemma. $\mathbf{h}^{-1}$ refers to the inverse image of $\mathbf{h}$ restricted to $\mathbf{h}\left(E_{k}\right)$ as discussed above.

Finally, consider 29.4.12. 29.4.11 implies that

$$
(1-\varepsilon)|\mathbf{v}|<\left|U(\mathbf{b}) T_{k}^{-1} \mathbf{v}\right|<(1+\boldsymbol{\varepsilon})|\mathbf{v}|
$$

A generic vector in $B(\mathbf{0}, 1-\varepsilon)$ is $(1-\varepsilon) \mathbf{v}$ where $|\mathbf{v}|<1$. Thus, the above inequality implies

$$
B(\mathbf{0}, 1-\varepsilon) \subseteq U(\mathbf{b}) T_{k}^{-1} B(\mathbf{0}, 1) \subseteq B(\mathbf{0}, 1+\varepsilon)
$$

This implies

$$
\alpha(n)(1-\varepsilon)^{n} \leq \operatorname{det}\left(U(\mathbf{b}) T_{k}^{-1}\right) \alpha(n) \leq \alpha(n)(1+\varepsilon)^{n}
$$

and so $(1-\varepsilon)^{n} \leq \operatorname{det}(U(\mathbf{b})) \operatorname{det}\left(T_{k}^{-1}\right) \leq(1+\varepsilon)^{n}$ and so for $\mathbf{b} \in E_{k}$,

$$
(1-\varepsilon)^{n}\left|\operatorname{det}\left(T_{k}\right)\right| \leq \operatorname{det}(U(\mathbf{b})) \leq(1+\varepsilon)^{n}\left|\operatorname{det}\left(T_{k}\right)\right|
$$

Recall that $B$ was a Borel measurable subset of $A^{+}$the set where $U(\mathbf{x})^{-1}$ exists. Now the above estimates can be used to estimate $\mathscr{H}^{n}\left(\mathbf{h}\left(E_{k}\right)\right)$. There is no problem about measurability of $\mathbf{h}\left(E_{k}\right)$ due to Lipschitz continuity of $\mathbf{h}$ on $E_{k}$. From Lemma 29.1.1 about the relationship between Hausdorff measure and Lipschitz mappings, it follows from 29.4.13 and 29.4.12,

$$
\begin{aligned}
\mathscr{H}^{n}\left(\mathbf{h}\left(E_{k}\right)\right) & =\mathscr{H}^{n}\left(\mathbf{h} \circ T_{k}^{-1}\left(T_{k}\left(E_{k}\right)\right)\right) \leq(1+2 \varepsilon)^{n} \mathscr{H}^{n}\left(T_{k}\left(E_{k}\right)\right) \\
& =(1+2 \varepsilon)^{n} m_{n}\left(T_{k}\left(E_{k}\right)\right) \leq(1+2 \varepsilon)^{n}\left|\operatorname{det}\left(T_{k}\right)\right| m_{n}\left(E_{k}\right)
\end{aligned}
$$

also,

$$
\begin{equation*}
m_{n}\left(T_{k}\left(E_{k}\right)\right)=\mathscr{H}^{n}\left(\left(T_{k} \circ \mathbf{h}^{-1}\left(\mathbf{h}\left(E_{k}\right)\right)\right)\right) \leq\left(\frac{1}{1-2 \varepsilon}\right)^{n} \mathscr{H}^{n}\left(\mathbf{h}\left(E_{k}\right)\right) \tag{29.4.17}
\end{equation*}
$$

Summarizing,

$$
\left(\frac{1}{1-2 \varepsilon}\right)^{n} \mathscr{H}^{n}\left(\mathbf{h}\left(E_{k}\right)\right) \geq m_{n}\left(T_{k}\left(E_{k}\right)\right) \geq \frac{1}{(1+2 \varepsilon)^{n}} \mathscr{H}^{n}\left(\mathbf{h}\left(E_{k}\right)\right)
$$

Then the above inequality and 29.4.12, 29.4.17 imply the following.

$$
\begin{gather*}
\frac{1}{(1+2 \varepsilon)^{n}} \mathscr{H}^{n}\left(\mathbf{h}\left(E_{k}\right)\right) \leq m_{n}\left(T_{k}\left(E_{k}\right)\right) \leq\left(\frac{1}{1-2 \varepsilon}\right)^{n}\left|\operatorname{det}\left(T_{k}\right)\right| m_{n}\left(E_{k}\right) \\
\leq\left(\frac{1}{1-2 \varepsilon}\right)^{n}(1-\varepsilon)^{n} \int_{E_{k}} \operatorname{det}(U(\mathbf{x})) d m_{n} \leq\left(\frac{1}{1-2 \varepsilon}\right)^{n}(1+\varepsilon)^{n}\left|\operatorname{det}\left(T_{k}\right)\right| m_{n}\left(E_{k}\right) \\
\leq \frac{(1+2 \varepsilon)^{n}}{(1-2 \varepsilon)^{n}} m_{n}\left(T_{k} E_{k}\right) \leq \frac{(1+2 \varepsilon)^{n}}{(1-2 \varepsilon)^{n}}\left(\frac{1}{1-2 \varepsilon}\right)^{n} \mathscr{H}^{n}\left(\mathbf{h}\left(E_{k}\right)\right) \tag{29.4.18}
\end{gather*}
$$

Assume now that $\mathbf{h}$ is one to one on $B$. Summing over all $E_{k}$ yields the following thanks to the assumption that $\mathbf{h}$ is one to one.

$$
\frac{1}{(1+2 \varepsilon)^{n}} \mathscr{H}^{n}(\mathbf{h}(B)) \leq(1-2 \varepsilon)^{-n}(1-\varepsilon)^{n} \int_{B} \operatorname{det}(U(\mathbf{x})) d x
$$

$$
\leq \frac{(1+2 \varepsilon)^{n}}{(1-2 \varepsilon)^{n}}\left(\frac{1}{1-2 \varepsilon}\right)^{n} \mathscr{H}^{n}(\mathbf{h}(B))
$$

$\varepsilon$ was arbitrary and so when $\mathbf{h}$ is one to one on $B$,

$$
\mathscr{H}^{n}(\mathbf{h}(B)) \leq \int_{B} \operatorname{det}(U(\mathbf{x})) d x \leq \mathscr{H}^{n}(\mathbf{h}(B))
$$

Now $B$ was completely arbitrary. Let it equal $B(\mathbf{x}, r) \cap A^{+}$where $\mathbf{x} \in A^{+}$. Then for $\mathbf{x} \in A^{+}$,

$$
\mathscr{H}^{n}\left(\mathbf{h}\left(B(\mathbf{x}, r) \cap A^{+}\right)\right)=\int_{B(\mathbf{x}, r)} \mathscr{X}_{A^{+}}(\mathbf{y}) \operatorname{det}(U(\mathbf{y})) d y
$$

Divide by $m_{n}(B(\mathbf{x}, r))$ and use the fundamental theorem of calculus. This yields that for $\mathbf{x}$ off a set of $m_{n}$ measure zero,

$$
\begin{equation*}
\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}\left(\mathbf{h}\left(B(\mathbf{x}, r) \cap A^{+}\right)\right)}{m_{n}(B(\mathbf{x}, r))}=\mathscr{X}_{A^{+}}(\mathbf{x}) \operatorname{det}(U(\mathbf{x})) \tag{29.4.19}
\end{equation*}
$$

This has proved the following lemma.
Lemma 29.4.2 Let $\mathbf{h}$ be continuous on $G$ and differentiable on $A \subseteq G$ and one to one on $A^{+}$which is as defined above. There is a set of measure zero $N$ such that for $\mathbf{x} \in A^{+} \backslash N$,

$$
\lim _{r \rightarrow 0+} \frac{\mathscr{H}^{n}\left(\mathbf{h}\left(B(\mathbf{x}, r) \cap A^{+}\right)\right)}{m_{n}(B(\mathbf{x}, r))}=\operatorname{det}(U(\mathbf{x}))
$$

The next theorem removes the assumption that $U(\mathbf{x})^{-1}$ exists and replaces $A^{+}$with A. From now on $J_{*}(\mathbf{x}) \equiv \operatorname{det}(U(\mathbf{x}))$. Also note that if $F$ is measurable and a subset of $A^{+}, \mathbf{h}\left(E_{k} \cap F\right)$ is Hausdorff measurable because of the Lipschitz continuity of $\mathbf{h}$ on $E_{k}$.

Theorem 29.4.3 Let $\mathbf{h}: G \subseteq \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ for $n \leq m, G$ an open set in $\mathbb{R}^{n}$, and suppose $\mathbf{h}$ is continuous on $G$ differentiable and one to one on $A$. Then for a.e. $\mathbf{x} \in A$, the set in $G$ where Dh(x) exists,

$$
\begin{equation*}
J_{*}(\mathbf{x})=\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))} \tag{29.4.20}
\end{equation*}
$$

where $J_{*}(\mathbf{x}) \equiv \operatorname{det}(U(\mathbf{x}))=\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)^{1 / 2}$.
Proof: The above argument shows that the conclusion of the theorem holds when $J_{*}(\mathbf{x}) \neq 0$ at least with $A$ replaced with $A^{+}$. I will apply this to a modified function in which the corresponding $U(\mathbf{x})$ always has an inverse. Let $\mathbf{k}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m} \times \mathbb{R}^{n}$ be defined as

$$
\mathbf{k}(\mathbf{x}) \equiv\binom{\mathbf{h}(\mathbf{x})}{\varepsilon \mathbf{x}}
$$

in which dependence of $\mathbf{k}$ on $\varepsilon$ is suppressed. Then $D \mathbf{k}(\mathbf{x})^{*} D \mathbf{k}(\mathbf{x})=D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})+\varepsilon^{2} I_{n}$ and so

$$
J_{*} \mathbf{k}(\mathbf{x})^{2} \equiv \operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})+\varepsilon^{2} I_{n}\right)=\operatorname{det}\left(Q^{*} D Q+\varepsilon^{2} I_{n}\right)>0
$$

where $D$ is a diagonal matrix having the nonnegative eigenvalues of $D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})$ down the main diagonal, $Q$ an orthogonal matrix. $A$ is where $\mathbf{h}$ is differentiable. However, it is $A^{+}$when referring to $\mathbf{k}$. Then Lemma 29.4.2 implies

$$
\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{k}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))}=J_{*} \mathbf{k}(\mathbf{x})
$$

This is true for each choice of $\varepsilon>0$. Pick such an $\varepsilon$ small enough that $J_{*} \mathbf{k}(\mathbf{x})<J_{*} \mathbf{h}(\mathbf{x})+\delta$.
Let

$$
\begin{gathered}
T \equiv\left\{(\mathbf{h}(\mathbf{w}), \mathbf{0})^{T}: \mathbf{w} \in B(\mathbf{x}, r) \cap A\right\} \\
T_{\varepsilon} \equiv\left\{(\mathbf{h}(\mathbf{w}), \varepsilon \mathbf{w})^{T}: \mathbf{w} \in B(\mathbf{x}, r) \cap A\right\} \equiv \mathbf{k}(B(\mathbf{x}, r) \cap A)
\end{gathered}
$$

then $T=\left(\begin{array}{ll}P T_{\varepsilon} & \mathbf{0}\end{array}\right)^{T}$ where $P$ is the projection map defined by $P\binom{\mathbf{x}}{\mathbf{y}} \equiv \mathbf{x}$. Since $P$ decreases distances, it follows from Lemma 29.1.1

$$
\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r) \cap A))=\mathscr{H}^{n}\left(P T_{\varepsilon}\right) \leq \mathscr{H}^{n}\left(T_{\varepsilon}\right)=\mathscr{H}^{n}(\mathbf{k}(B(\mathbf{x}, r)) \cap A)
$$

Thus for a.e. $\mathbf{x} \in A^{+}$,

$$
\begin{align*}
& J_{*} \mathbf{h}(\mathbf{x})+\delta \geq J_{*} \mathbf{k}(\mathbf{x})=\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{k}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))} \geq \lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))} \\
& \geq \lim \inf _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))} \geq \lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}\left(\mathbf{h}\left(B(\mathbf{x}, r) \cap A^{+}\right)\right)}{m_{n}(B(\mathbf{x}, r))}=J_{*} \mathbf{h}(\mathbf{x}) \tag{29.4.21}
\end{align*}
$$

Thus, since $\delta$ is arbitrary, $\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))}=\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)^{1 / 2}$ when $\mathbf{x} \in A^{+}$. If $\mathbf{x} \notin A^{+}$, the above 29.4.21 shows that

$$
J_{*} \mathbf{h}(\mathbf{x})=0 \geq \lim \sup _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))} \geq 0
$$

and so this has shown that for a.e. $\mathbf{x} \in A$,

$$
\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r) \cap A))}{m_{n}(B(\mathbf{x}, r))}=J_{*}(\mathbf{x})
$$

Another good idea is in the following lemma.
Lemma 29.4.4 Let $\mathbf{k}$ be as defined above. Let A be the set of points where Dhexists so $A=A^{+}$relative to $\mathbf{k}$. Then if $F$ is Lebesgue measurable, $\mathbf{h}(F \cap A)$ is $\mathscr{H}^{n}$ measurable. Also $\mathscr{H}^{n}(\mathbf{h}(N \cap A))=0$ if $m_{n}(N)=0$.

Proof: By Lemma 29.4.1, there are disjoint Borel sets $E_{k}$ such that $\mathbf{k}$ is Lipschitz on each $E_{k}$ and $\cup_{k} E_{k}=A=A^{+}$where $A^{+}$refers to $\mathbf{k}$. Thus

$$
P \mathbf{k}\left(E_{k} \cap F \cap A\right)=\mathbf{h}\left(E_{k} \cap F \cap A\right)
$$

is $H^{n}$ measurable by Lemma 29.1.2. Hence $\mathbf{h}(F \cap A)=\cup_{k} \mathbf{h}\left(E_{k} \cap F \cap A\right)$ is $\mathscr{H}^{n}$ measurable. The last claim follows from Lemma 29.1.2.

$$
\mathscr{H}^{n}\left(\mathbf{h}\left(E_{k} \cap N \cap A\right)\right) \leq \mathscr{H}^{n}\left(\mathbf{k}\left(E_{k} \cap N \cap A\right)\right)=0
$$

and so the result follows.

### 29.5 The Area Formula

At this point, I will begin assuming $\mathbf{h}$ is Lipschitz continuous to avoid the fuss with whether sets are appropriately measurable and to ensure that the measure considered below is absolutely continuous without any heroics. Let $\mathbf{h}$ be Lipschitz continuous on $G$, an open set containing $A$, the set where $\mathbf{h}$ is differentiable. Suppose also that $\mathbf{h}$ is one to one on $A$. Then $\mathscr{H}^{n}(\mathbf{h}(G \backslash A))=0$ because $m_{n}(G \backslash A)=0$ by Rademacher's theorem. Hence Lemma 29.1.2 applies.

Lemma 29.5.1 Let $\mathbf{h}$ be Lipschitz. Let $\mathbf{h}$ be one to one and differentiable on $A$ with $m_{n}(G \backslash A)=0$. If $N \subseteq G$ has measure zero, then $\mathbf{h}(N)$ has $\mathscr{H}^{n}$ measure zero and if $E$ is Lebesgue measurable subset of $G$, then $\mathbf{h}(E)$ is $\mathscr{H}^{n}$ measurable subset of $\mathbb{R}^{m}$. If $v(E) \equiv \mathscr{H}^{n}(\mathbf{h}(E))$, then $v \ll m_{n}$.

Proof: Lemma 29.1.2 implies $\mathbf{h}(N)=0$ if $m_{n}(N)=0$.Also from this lemma, $\mathbf{h}(E)$ is $\mathscr{H}^{n}$ measurable if $E$ is. Is $v$ a measure? Suppose $\left\{E_{i}\right\}$ are disjoint Lebesgue measurable subsets of $G$. Then for $A$ the set where $D \mathbf{h}$ exists as above,

$$
\begin{aligned}
v\left(\cup_{i} E_{i}\right) & \equiv \mathscr{H}^{n}\left(\mathbf{h}\left(\cup_{i} E_{i}\right)\right) \leq \mathscr{H}^{n}\left(\mathbf{h}\left(\cup_{i} E_{i} \cap A\right) \cup \mathbf{h}(G \backslash A)\right) \\
& \leq \sum_{i} \mathscr{H}^{n}\left(\mathbf{h}\left(E_{i} \cap A\right)\right)+\mathscr{H}^{n}(\mathbf{h}(G \backslash A))=\sum_{i} \mathscr{H}^{n}\left(\mathbf{h}\left(E_{i} \cap A\right)\right)=\sum_{i} v\left(E_{i}\right)
\end{aligned}
$$

Thus $v \ll m_{n}$.
It follows from the Radon Nikodym theorem for Radon measures, that

$$
v(E) \equiv \mathscr{H}^{n}(\mathbf{h}(E))=\int_{E} D_{m_{n}} v d m_{n}
$$

but $D_{m_{n}} v \equiv \lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r)))}{m_{n}(\mathbf{x}, r)}=\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(\mathbf{h}(B(\mathbf{x}, r)) \cap A)}{m_{n}(\mathbf{x}, r)}=J_{*}(\mathbf{x})$ for a.e. $\mathbf{x}$ from Theorem 29.4.3. Also, $v$ is finite on closed balls so it is regular thanks to Corollary 11.6.8. This shows from the Radon Nikodym theorem, Theorem 31.3.5 that

$$
\int \mathscr{X}_{\mathbf{h}(E)} d \mathscr{H}^{n}=\int_{E} D_{m_{n}} v d m_{n}=\int \mathscr{X}_{E}(\mathbf{x}) J_{*} d m_{n}
$$

Note also that, since $A^{C}$ has measure zero,

$$
\int_{\mathbf{h}(A)} \mathscr{X}_{\mathbf{h}(E)} d \mathscr{H}^{n}=\int_{A} \mathscr{X}_{E}(\mathbf{x}) J_{*} d m_{n}
$$

Now let $F$ be a Borel set in $\mathbb{R}^{m}$. Recall this implies $F$ is $\mathscr{H}^{n}$ measurable. Then

$$
\begin{align*}
\int_{\mathbf{h}(A)} \mathscr{X}_{F}(\mathbf{y}) d \mathscr{H}^{n} & =\int \mathscr{X}_{F \cap \mathbf{h}(A)}(\mathbf{y}) d \mathscr{H}^{n}=\mathscr{H}^{n}\left(\mathbf{h}\left(\mathbf{h}^{-1}(F) \cap A\right)\right) \\
& =v\left(\mathbf{h}^{-1}(F)\right)=\int \mathscr{X}_{A \cap \mathbf{h}^{-1}(F)}(\mathbf{x}) J_{*}(\mathbf{x}) d m_{n} \\
& =\int_{A} \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n} \tag{29.5.22}
\end{align*}
$$

Note there are no measurability questions in the above formula because $\mathbf{h}^{-1}(F)$ is a Borel set due to the continuity of $\mathbf{h}$. The Borel measurability of $J_{*}(\mathbf{x})$ also follows from the observation that $\mathbf{h}$ is continuous and therefore, the partial derivatives are Borel measurable, being the limit of continuous functions. Then $J_{*}(\mathbf{x})$ is just a continuous function of these partial derivatives. However, things are not so clear if $F$ is only assumed $\mathscr{H}^{n}$ measurable. Is there a similar formula for $F$ only $\mathscr{H}^{n}$ measurable?

Let $\lambda(E) \equiv \mathscr{H}^{n}(E \cap \mathbf{h}(A))$ for $E$ an arbitrary bounded $\mathscr{H}^{n}$ measurable set. This measure is finite on finite balls from what was shown above. Therefore, from Proposition 11.7.3, there exists an $F_{\sigma}$ set $F$ and a $G_{\delta}$ set $H$ such that $F \subseteq E \subseteq H$ and $\lambda(H \backslash F)=0$. Thus

$$
\mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) \leq \mathscr{X}_{E}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) \leq \mathscr{X}_{H}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x})
$$

where the functions on the ends are measurable. Then

$$
\begin{aligned}
& \int_{A}\left(\mathscr{X}_{H}(\mathbf{h}(\mathbf{x}))-\mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x})\right) J_{*}(\mathbf{x}) d m_{n} \\
= & \lambda(H)-\lambda(F)=0
\end{aligned}
$$

and so $\mathscr{X}_{E}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x})=\mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x})=\mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x})$ off a set of Lebesgue measure zero showing by completeness of Lebesgue measure that $\mathbf{x} \rightarrow \mathscr{X}_{E}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x})$ is Lebesgue measurable. Then

$$
\begin{aligned}
\int_{\mathbf{h}(A)} \mathscr{X}_{F}(\mathbf{y}) d \mathscr{H}^{n} & =\int_{A} \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n}=\int_{A} \mathscr{X}_{E}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n} \\
& =\int_{A} \mathscr{X}_{H}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n}=\int_{\mathbf{h}(A)} \mathscr{X}_{H}(\mathbf{y}) d \mathscr{H}^{n} \\
& =\int_{\mathbf{h}(A)} \mathscr{X}_{E}(\mathbf{y}) d \mathscr{H}^{n}=\int_{\mathbf{h}(A)} \mathscr{X}_{F}(\mathbf{y}) d \mathscr{H}^{n}
\end{aligned}
$$

If $E$ is not bounded, then replace with $E_{r} \equiv E \cap B(\mathbf{0}, r)$ and pass to a limit using the monotone convergence theorem. This proves the following lemma.

Lemma 29.5.2 Whenever $E$ is Lebesgue measurable,

$$
\begin{equation*}
\int_{\mathbf{h}(A)} \mathscr{X}_{E}(\mathbf{y}) d \mathscr{H}^{n}=\int_{A} \mathscr{X}_{E}(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n} \tag{29.5.23}
\end{equation*}
$$

From this, it follows that if $s$ is a nonnegative, $\mathscr{H}^{n}$ measurable simple function, 29.5.23 continues to be valid with $s$ in place of $\mathscr{X}_{E}$. Then approximating an arbitrary nonnegative $\mathscr{H}^{n}$ measurable function $g$ by an increasing sequence of simple functions, it follows that 29.5.23 holds with $g$ in place of $\mathscr{X}_{E}$ and there are no measurability problems because $\mathbf{x} \rightarrow g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x})$ is Lebesgue measurable. This proves the following theorem which is the area formula.

Theorem 29.5.3 Let $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ be Lipschitz continuous for $m \geq n$. Let $A \subseteq G$ for $G$ an open set be the set of $\mathbf{x} \in G$ on which $D \mathbf{h}(\mathbf{x})$ exists, and let $g: \mathbf{h}(A) \rightarrow[0, \infty]$ be $\mathscr{H}^{n}$ measurable. Then

$$
\mathbf{x} \rightarrow(g \circ \mathbf{h})(\mathbf{x}) J_{*}(\mathbf{x})
$$

is Lebesgue measurable and

$$
\int_{\mathbf{h}(A)} g(\mathbf{y}) d \mathscr{H}^{n}=\int_{A} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n}
$$

where $J_{*}(\mathbf{x})=\operatorname{det}(U(\mathbf{x}))=\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)^{1 / 2}$.
Since $\mathscr{H}^{n}=m_{n}$ on $\mathbb{R}^{n}$, this is just a generalization of the usual change of variables formula. This is much better because it is not limited to $\mathbf{h}$ having values in $\mathbb{R}^{n}$. Also note that you could replace $A$ with $G$ since they differ by a set of measure zero thanks to Rademacher's theorem. Note that if you assume that $\mathbf{h}$ is Lipschitz on $G$ then it has a Lipschitz extension to $\mathbb{R}^{n}$. The conclusion has to do with integrals over $G$. It is not really necessary to have $\mathbf{h}$ be Lipschitz continuous on $\mathbb{R}^{n}$, but you might as well assume this because of the existence of the Lipschitz extension. Here is another interesting change of variables theorem.

Theorem 29.5.4 Let $\mathbf{h}: G \subseteq \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ be continuous where $G$ is an open set and let $A \subseteq G$ where $A$ is the Borel measurable set consisting of $\mathbf{x}$ where Dh( $\mathbf{x})$ exists. Suppose $\mathbf{h}$ is differentiable and one to one on $A$. Also let $g: \mathbf{h}(G) \rightarrow[0, \infty]$ be $\mathscr{H}^{n}$ measurable. Then

$$
\mathbf{x} \rightarrow(g \circ \mathbf{h})(\mathbf{x}) J_{*}(\mathbf{x})
$$

is Lebesgue measurable and

$$
\begin{equation*}
\int_{\mathbf{h}(A)} g(\mathbf{y}) d \mathscr{H}^{n}=\int_{A} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n} \tag{29.5.24}
\end{equation*}
$$

where $J_{*}(\mathbf{x})=\operatorname{det}(U(\mathbf{x}))=\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)^{1 / 2}$.
Proof: By Lemma 29.4.4, $v(E) \equiv \mathscr{H}^{n}(\mathbf{h}(E \cap A))$ is a measure defined on the Lebesgue measurable sets contained in $G$ and $v \ll m_{n}$. The reason it is a measure is

$$
\begin{aligned}
v\left(\cup_{i} E_{i}\right) & \equiv \mathscr{H}^{n}\left(\mathbf{h}\left(\cup_{i} E_{i} \cap A\right)\right)=\mathscr{H}^{n}\left(\mathbf{h}\left(\cup_{i} E_{i} \cap A\right)\right) \\
& =\mathscr{H}^{n}\left(\cup_{i} \mathbf{h}\left(E_{i} \cap A\right)\right)=\sum_{i} \mathscr{H}^{n}\left(E_{i} \cap A\right)=\sum_{i} v\left(E_{i}\right)
\end{aligned}
$$

This measure is finite on compact sets. Therefore, by Corollary 11.6.8, it is a regular measure. By the Radon Nikodym theorem for Radon measures, Theorem 31.3.5,

$$
v(E)=\int_{E} D_{m_{n}} v d m_{n}
$$

where $D_{m_{n}} v$ is the symmetric derivative given by

$$
\lim _{r \rightarrow 0} \frac{\mathscr{H}^{n}(B(\mathbf{x}, r) \cap A)}{m_{n}(B(\mathbf{x}, r))}
$$

However, from Theorem 29.4.3 this limit equals $J_{*}(\mathbf{x})$ described above as

$$
\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)^{1 / 2}
$$

Now the rest of the argument is identical to that presented above leading to Theorem 29.5.3.

Note that from 29.5.24, $\mathscr{H}^{n}\left(\mathbf{h}\left(A \backslash A^{+}\right)\right)=0$ so this also gives a generalization of Sard's theorem used earlier in the case that $\mathbf{h}$ is one to one.

### 29.6 Mappings that are not One to One

Let $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ be Lipschitz. We drop the requirement that $\mathbf{h}$ be one to one. Again, let $A$ be the set on which $D \mathbf{h}(\mathbf{x})$ exists. Let $\mathbf{k}$ be as used earlier in Theorem 29.4.3. Thus $J \mathbf{k}(\mathbf{x}) \neq 0$ for all $\mathbf{x} \in A$ the set where $D \mathbf{h}(\mathbf{x})$ exists. Thus there is a sequence of disjoint Borel sets $\left\{E_{k}\right\}$ whose union is $A$ such that $\mathbf{k}$ is Lipschitz on $E_{k}$. Let $S$ be given by

$$
S \equiv\left\{\mathbf{x} \in A, \text { such that } U(\mathbf{x})^{-1} \text { does not exist }\right\}
$$

Then $S$ is a Borel set and so letting $S_{k j} \equiv S \cap E_{k} \cap B(\mathbf{0}, j)$, the change of variables formula above implies

$$
\mathscr{H}^{n}\left(\mathbf{h}\left(S_{k j}\right)\right) \leq \mathscr{H}^{n}\left(\mathbf{k}\left(S_{k j}\right)\right)=\int_{\mathbf{k}\left(S_{k j}\right)} d \mathscr{H}^{n}=\int_{A} \mathscr{X}_{S_{k j}}(\mathbf{x}) J_{*} \mathbf{k}(\mathbf{x}) d m_{n} \leq \delta m_{n}\left(S_{k j}\right)
$$

where $\mathbf{k}$ is chosen with $\varepsilon$ small enough that $J_{*} \mathbf{k}(\mathbf{x})<\delta . \delta$ is arbitrary, so $\mathscr{H}^{n}\left(\mathbf{h}\left(S_{k j}\right)\right)=0$ and so $\mathscr{H}^{n}\left(\mathbf{h}\left(S \cap E_{k}\right)\right)=0$. Consequently $\mathscr{H}^{n}(\mathbf{h}(S))=0$. This is stated as the following lemma. Note how this includes the earlier Sard's theorem.

Lemma 29.6.1 For $S$ defined above, $\mathscr{H}^{n}(\mathbf{h}(S))=0$.
Thus $m_{n}(N)=0$ where $N$ is the set where $D \mathbf{h}(\mathbf{x})$ does not exist. Then by Lemma 29.1.2

$$
\begin{equation*}
\mathscr{H}^{n}(\mathbf{h}(S \cup N)) \leq \mathscr{H}^{n}(\mathbf{h}(S))+\mathscr{H}^{n}(\mathbf{h}(N))=0 \tag{29.6.25}
\end{equation*}
$$

Let $B \equiv \mathbb{R}^{n} \backslash(S \cup N)$.
Recall Lemma 29.4.1 above which said that for each $\mathbf{x} \in A^{+}$the set where $U(\mathbf{x})$ is invertible there is a Borel set $F$ containing $\mathbf{x}$ on which $\mathbf{h}$ is one to one. In fact it was one of countably many sets of the form $E(T, \mathbf{c}, i)$. By enumerating these sets as done earlier, referring to them as $E_{k}$, one can let $F_{1} \equiv E_{1}$, and if $F_{1}, \cdots, F_{n}$ have been chosen, $F_{n+1} \equiv$ $E_{n+1} \backslash \cup_{i=1}^{n} F_{i}$ to obtain the result of the following lemma.

Lemma 29.6.2 There exists a sequence of disjoint measurable sets, $\left\{F_{i}\right\}$, such that

$$
\cup_{i=1}^{\infty} F_{i}=B \subseteq A^{+}
$$

and $\mathbf{h}$ is one to one on $F_{i}$.
The following corollary will not be needed right away but it is of interest. Recall that $A$ is the set where $\mathbf{h}$ is differentiable and $A^{+}$is the set where $\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)>0$. Part of Lemma 29.4.1 is reviewed in the following corollary.

Corollary 29.6.3 For each $F_{i}$ in Lemma 29.6.2, $\mathbf{h}^{-1}$ is Lipschitz on $\mathbf{h}\left(F_{i}\right)$.
Now let $g: \mathbf{h}\left(\mathbb{R}^{n}\right) \rightarrow[0, \infty]$ be $\mathscr{H}^{n}$ measurable. By Theorem 29.5.3,

$$
\begin{equation*}
\int_{\mathbf{h}(A)} \mathscr{X}_{\mathbf{h}\left(F_{i}\right)}(\mathbf{y}) g(\mathbf{y}) d \mathscr{H}^{n}=\int_{F_{i}} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m \tag{29.6.26}
\end{equation*}
$$

Now define

$$
\mathfrak{n}(\mathbf{y})=\sum_{i=1}^{\infty} \mathscr{X}_{\mathbf{h}\left(F_{i}\right)}(\mathbf{y})
$$

By Lemma 29.1.2, $\mathbf{h}\left(F_{i}\right)$ is $\mathscr{H}^{n}$ measurable and so $\mathfrak{n}$ is a $\mathscr{H}^{n}$ measurable function. For each $\mathbf{y} \in B, \mathfrak{n}(\mathbf{y})$ gives the number of elements in $\mathbf{h}^{-1}(\mathbf{y}) \cap B$. From 29.6.26,

$$
\begin{equation*}
\int_{\mathbf{h}\left(\mathbb{R}^{n}\right)} \mathfrak{n}(\mathbf{y}) g(\mathbf{y}) d \mathscr{H}^{n}=\int_{B} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m \tag{29.6.27}
\end{equation*}
$$

Now define

$$
\#(\mathbf{y}) \equiv \text { number of elements in } \mathbf{h}^{-1}(\mathbf{y})
$$

Theorem 29.6.4 Let $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ be Lipschitz. Then the function $\mathbf{y} \rightarrow \#(\mathbf{y})$ is $\mathscr{H}^{n}$ measurable and if

$$
g: \mathbf{h}\left(\mathbb{R}^{n}\right) \rightarrow[0, \infty]
$$

is $\mathscr{H}^{n}$ measurable, then

$$
\int_{\mathbf{h}\left(\mathbb{R}^{n}\right)} g(\mathbf{y}) \#(\mathbf{y}) d \mathscr{H}^{n}=\int_{\mathbb{R}^{n}} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m
$$

Proof: If $\mathbf{y} \notin \mathbf{h}(S \cup N)$, then $\mathfrak{n}(\mathbf{y})=\#(\mathbf{y})$. By 29.6.25

$$
\mathscr{H}^{n}(\mathbf{h}(S \cup N))=0
$$

and so $\mathfrak{n}(\mathbf{y})=\#(\mathbf{y})$ a.e. Since $\mathscr{H}^{n}$ is a complete measure, \#(.) is $\mathscr{H}^{n}$ measurable. Letting

$$
G \equiv \mathbf{h}\left(\mathbb{R}^{n}\right) \backslash \mathbf{h}(S \cup N)
$$

29.6.27 implies

$$
\begin{aligned}
\int_{\mathbf{h}\left(\mathbb{R}^{n}\right)} g(\mathbf{y}) \#(\mathbf{y}) d \mathscr{H}^{n} & =\int_{G} g(\mathbf{y}) \mathfrak{n}(\mathbf{y}) d \mathscr{H}^{n}=\int_{B} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m \\
& =\int_{\mathbb{R}^{n}} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n} .
\end{aligned}
$$

Note that the same argument would hold if $\mathbf{h}: G \rightarrow \mathbb{R}^{m}$ is continuous and if $A$ is the set where $\mathbf{h}$ is differentiable and $\mathscr{H}^{n}(\mathbf{h}(G \backslash A))=0$, then for $g$ as above,

$$
\int_{\mathbf{h}(A)} g(\mathbf{y}) \#(\mathbf{y}) d \mathscr{H}^{n}=\int_{A} g(\mathbf{h}(\mathbf{x})) J_{*}(\mathbf{x}) d m_{n}
$$

The details are left to the reader.

### 29.7 The Divergence Theorem

As an important application of the area formula I will give a general version of the divergence theorem for sets in $\mathbb{R}^{p}$. It will always be assumed $p \geq 2$. Actually it is not necessary to make this assumption but what results in the case where $p=1$ is nothing more than the fundamental theorem of calculus and the considerations necessary to draw this conclusion seem unneccessarily tedious. You have to consider $\mathscr{H}^{0}$, zero dimensional Hausdorff measure. It is left as an exercise but I will not present it.

It will be convenient to have some lemmas and theorems in hand before beginning the proof. First recall the Tietze extension theorem on Page 158. It is stated next for convenience.

Theorem 29.7.1 Let $M$ be a closed nonempty subset of a metric space $(X, d)$ and let $f$ : $M \rightarrow[a, b]$ be continuous at every point of $M$. Then there exists a function, $g$ continuous on all of $X$ which coincides with $f$ on $M$ such that $g(X) \subseteq[a, b]$.

The next topic needed is the concept of an infinitely differentiable partition of unity. This was discussed earlier in Lemma 37.1.6.

Definition 29.7.2 Let $\mathfrak{C}$ be a set whose elements are subsets of $\mathbb{R}^{p} .{ }^{1}$ Then $\mathfrak{C}$ is said to be locally finite if for every $\mathbf{x} \in \mathbb{R}^{p}$, there exists an open set, $U_{\mathbf{x}}$ containing $\mathbf{x}$ such that $U_{\mathbf{x}}$ has nonempty intersection with only finitely many sets of $\mathfrak{C}$.

The following was proved mostly in Theorem 7.5.5.
Lemma 29.7.3 Let $\mathfrak{C}$ be a set whose elements are open subsets of $\mathbb{R}^{p}$ and suppose $\cup \mathfrak{C} \supseteq H$, a closed set. Then there exists a countable list of open sets, $\left\{U_{i}\right\}_{i=1}^{\infty}$ such that each $U_{i}$ is bounded, each $U_{i}$ is a subset of some set of $\mathfrak{C}$, and $\cup_{i=1}^{\infty} U_{i} \supseteq H$. One can also assume that $\left\{U_{i}\right\}_{i=1}^{\infty}$ is locally finite.

Proof: The first part was proved earlier. Since $\mathbb{R}^{p}$ is separable, it is completely separable with a countable basis of balls called $\mathscr{B}$. For each $\mathbf{x} \in H$, let $U$ be a ball from $\mathscr{B}$ having diameter no more than 1 which is contained in some set of $\mathfrak{C}$. This collection of balls is countable because $\mathscr{B}$ is. Let $H_{m} \equiv \overline{B(\mathbf{0}, m) \cap H} \backslash(B(\mathbf{0}, m-1) \cap H)$ where $H_{0} \equiv \emptyset$. Thus each $H_{m}$ is compact closed and bounded. Let $\left\{U_{i}\right\}_{i=1}^{k_{m}} \equiv \mathscr{U}_{m}$ be a finite subset of $\left\{U_{i}\right\}_{i=1}^{\infty} \equiv \mathscr{U}$ which have nonempty intersection with $H_{m}$ and whose union includes $H_{m}$. Thus $\cup_{k=1}^{\infty} \mathscr{U}_{k}$ is a locally finite cover of $H$. To see this, if $\mathbf{x}$ is any point, consider $B\left(\mathbf{x}, \frac{1}{4}\right)$. Can it intersect a set of $\mathscr{U}_{m}$ for arbitrarily large $m$ ? If so, $\mathbf{x}$ would need to be within 2 of $H_{m}$ for arbitrarily large $m$. However, this is not possible because it would require that $\|\mathbf{x}\| \geq m-3$ for infinitely many $m$. Thus this ball can intersect only finitely many sets of $\cup_{k=1}^{\infty} \mathscr{U}_{k}$.

Recall Corollary 11.6.8 and Proposition 11.7.3. What is needed is listed here for convenience.

Lemma 29.7.4 Let $\Omega$ be a complete separable metric space and suppose $\mu$ is a complete measure defined on a $\sigma$ algebra which contains the Borel sets of $\Omega$ which is finite on balls, the closures of these balls being compact. Then $\mu$ must be both inner and outer regular.

[^24]One more lemma will be useful. It involves approximating a continuous function uniformly with one which is infinitely differentiable.

Lemma 29.7.5 Let $V$ be a bounded open set and let $X$ be the closed subspace of $C(\bar{V})$, the space of continuous functions defined on $\bar{V}$, which is given by the following.

$$
X=\{u \in C(\bar{V}): u(\mathbf{x})=0 \text { on } \partial V\} .
$$

Then $C_{c}^{\infty}(V)$ is dense in $X$ with respect to the norm given by

$$
\|u\|=\max \{|u(x)|: x \in \bar{V}\}
$$

Proof: Let $O \subseteq \bar{O} \subseteq W \subseteq \bar{W} \subseteq V$ be such that $\operatorname{dist}\left(\bar{O}, V^{C}\right)<\eta$ and let $\psi_{\delta}(\cdot)$ be a mollifier. Let $u \in X$ and consider $\mathscr{X}_{W} u * \psi_{\delta}$. Let $\varepsilon>0$ be given and let $\eta$ be small enough that $|u(\mathbf{x})|<\varepsilon / 2$ whenever $\mathbf{x} \in V \backslash \bar{O}$. Then if $\delta$ is small enough $\left|\mathscr{X}_{W} u * \psi_{\delta}(\mathbf{x})-u(\mathbf{x})\right|<\varepsilon$ for all $\mathbf{x} \in \bar{O}$ and $\mathscr{X}_{W} u * \psi_{\delta}$ is in $C_{c}^{\infty}(V)$. For $\mathbf{x} \in V \backslash \bar{O},\left|\mathscr{X}_{W} u * \psi_{\delta}(\mathbf{x})\right| \leq \varepsilon / 2$ and so for such $\mathbf{x}$,

$$
\left|\mathscr{X}_{W} u * \psi_{\delta}(\mathbf{x})-u(\mathbf{x})\right| \leq \varepsilon .
$$

This proves the lemma since $\varepsilon$ was arbitrary.
Lemma 29.7.6 Let $\alpha_{1}, \cdots, \alpha_{p}$ be real numbers and let $A\left(\alpha_{1}, \cdots, \alpha_{p}\right)$ be the matrix which has $1+\alpha_{i}^{2}$ in the $i i^{\text {th }}$ slot and $\alpha_{i} \alpha_{j}$ in the $i j^{\text {th }}$ slot when $i \neq j$. Then

$$
\operatorname{det} A=1+\sum_{i=1}^{p} \alpha_{i}^{2}
$$

Proof of the claim: The matrix, $A\left(\alpha_{1}, \cdots, \alpha_{p}\right)$ is of the form

$$
A\left(\alpha_{1}, \cdots, \alpha_{p}\right)=\left(\begin{array}{cccc}
1+\alpha_{1}^{2} & \alpha_{1} \alpha_{2} & \cdots & \alpha_{1} \alpha_{p} \\
\alpha_{1} \alpha_{2} & 1+\alpha_{2}^{2} & & \alpha_{2} \alpha_{p} \\
\vdots & & \ddots & \vdots \\
\alpha_{1} \alpha_{p} & \alpha_{2} \alpha_{p} & \cdots & 1+\alpha_{p}^{2}
\end{array}\right)
$$

Now consider the product of a matrix and its transpose, $B^{T} B$ below.

$$
\left(\begin{array}{ccccc}
1 & 0 & \cdots & 0 & \alpha_{1}  \tag{29.7.28}\\
0 & 1 & & 0 & \alpha_{2} \\
\vdots & & \ddots & & \vdots \\
0 & & & 1 & \alpha_{p} \\
-\alpha_{1} & -\alpha_{2} & \cdots & -\alpha_{p} & 1
\end{array}\right)\left(\begin{array}{ccccc}
1 & 0 & \cdots & 0 & -\alpha_{1} \\
0 & 1 & & 0 & -\alpha_{2} \\
\vdots & & \ddots & & \vdots \\
0 & & & 1 & -\alpha_{p} \\
\alpha_{1} & \alpha_{2} & \cdots & \alpha_{p} & 1
\end{array}\right)
$$

This product equals a matrix of the form

$$
\left(\begin{array}{cc}
A\left(\alpha_{1}, \cdots, \alpha_{p}\right) & \mathbf{0} \\
\mathbf{0} & 1+\sum_{i=1}^{p} \alpha_{i}^{2}
\end{array}\right)
$$

Therefore, $\left(1+\sum_{i=1}^{p} \alpha_{i}^{2}\right) \operatorname{det}\left(A\left(\alpha_{1}, \cdots, \alpha_{p}\right)\right)=\operatorname{det}(B)^{2}=\operatorname{det}\left(B^{T}\right)^{2}$. However, using row operations,

$$
\operatorname{det} B^{T}=\operatorname{det}\left(\begin{array}{ccccc}
1 & 0 & \cdots & 0 & \alpha_{1} \\
0 & 1 & & 0 & \alpha_{2} \\
\vdots & & \ddots & & \vdots \\
0 & & & 1 & \alpha_{p} \\
0 & 0 & \cdots & 0 & 1+\sum_{i=1}^{p} \alpha_{i}^{2}
\end{array}\right)=1+\sum_{i=1}^{p} \alpha_{i}^{2}
$$

and therefore,

$$
\left(1+\sum_{i=1}^{p} \alpha_{i}^{2}\right) \operatorname{det}\left(A\left(\alpha_{1}, \cdots, \alpha_{p}\right)\right)=\left(1+\sum_{i=1}^{p} \alpha_{i}^{2}\right)^{2}
$$

which shows $\operatorname{det}\left(A\left(\alpha_{1}, \cdots, \alpha_{p}\right)\right)=\left(1+\sum_{i=1}^{p} \alpha_{i}^{2}\right)$.
Definition 29.7.7 A bounded open set, $U \subseteq \mathbb{R}^{p}$ is said to have a Lipschitz boundary and to lie on one side of its boundary if the following conditions hold. There exist open boxes, $Q_{1}, \cdots, Q_{N}$,

$$
Q_{i}=\prod_{j=1}^{p}\left(a_{j}^{i}, b_{j}^{i}\right)
$$

such that $\partial U \equiv \bar{U} \backslash U$ is contained in their union. Also, for each $Q_{i}$, there exists $k$ and $a$ Lipschitz function, $g_{i}$ such that $U \cap Q_{i}$ is of the form

$$
\left\{\begin{array}{c}
\mathbf{x}:\left(x_{1}, \cdots, x_{k-1}, x_{k+1}, \cdots, x_{p}\right) \in \prod_{j=1}^{k-1}\left(a_{j}^{i}, b_{j}^{i}\right) \times  \tag{29.7.29}\\
\prod_{j=k+1}^{p}\left(a_{j}^{i}, b_{j}^{i}\right) \text { and } a_{k}^{i}<x_{k}<g_{i}\left(x_{1}, \cdots, x_{k-1}, x_{k+1}, \cdots, x_{p}\right)
\end{array}\right\}
$$

or else of the form

$$
\left\{\begin{array}{c}
\mathbf{x}:\left(x_{1}, \cdots, x_{k-1}, x_{k+1}, \cdots, x_{p}\right) \in \prod_{j=1}^{k-1}\left(a_{j}^{i}, b_{j}^{i}\right) \times  \tag{29.7.30}\\
\prod_{j=k+1}^{p}\left(a_{j}^{i}, b_{j}^{i}\right) \text { and } g_{i}\left(x_{1}, \cdots, x_{k-1}, x_{k+1}, \cdots, x_{p}\right)<x_{k}<b_{j}^{i}
\end{array}\right\}
$$

The function, $g_{i}$ has a derivative on $A_{i} \subseteq \prod_{j=1}^{k-1}\left(a_{j}^{i}, b_{j}^{i}\right) \times \prod_{j=k+1}^{p}\left(a_{j}^{i}, b_{j}^{i}\right)$ where

$$
m_{p-1}\left(\prod_{j=1}^{k-1}\left(a_{j}^{i}, b_{j}^{i}\right) \times \prod_{j=k+1}^{p}\left(a_{j}^{i}, b_{j}^{i}\right) \backslash A_{i}\right)=0
$$

Also, there exists an open set, $Q_{0}$ such that $Q_{0} \subseteq \overline{Q_{0}} \subseteq U$ and $\bar{U} \subseteq Q_{0} \cup Q_{1} \cup \cdots \cup Q_{N}$.
Note that since there are only finitely many $Q_{i}$ and each $g_{i}$ is Lipschitz, it follows from an application of Lemma 29.1.1 that $\mathscr{H}^{p-1}(\partial U)<\infty$. Also from Lemma 29.7.4 $\mathscr{H}^{p-1}$ is inner and outer regular on $\partial U$. In the following, $d x$ will be used in place of $d m_{p}$ to conform with more standard notation from calculus.

Lemma 29.7.8 Suppose $U$ is a bounded open set as described above. Then there exists a unique function in $L^{\infty}\left(\partial U, \mathscr{H}^{p-1}\right)^{p}, \mathbf{n}(\mathbf{y})$ for $\mathbf{y} \in \partial U$ such that $|\mathbf{n}(\mathbf{y})|=1, \mathbf{n}$ is $\mathscr{H}^{p-1}$ measurable, (meaning each component of $\mathbf{n}$ is $\mathscr{H}^{p-1}$ measurable) and for every $\mathbf{w} \in \mathbb{R}^{p}$ satisfying $|\mathbf{w}|=1$, and for every $f \in C_{c}^{1}\left(\mathbb{R}^{p}\right)$,

$$
\lim _{t \rightarrow 0} \int_{U} \frac{f(\mathbf{x}+t \mathbf{w})-f(\mathbf{x})}{t} d x=\int_{\partial U} f(\mathbf{n} \cdot \mathbf{w}) d \mathscr{H}^{p-1}
$$

Proof: Let $\bar{U} \subseteq V \subseteq \bar{V} \subseteq \cup_{i=0}^{N} Q_{i}$ and let $\left\{\psi_{i}\right\}_{i=0}^{N}$ be a $C^{\infty}$ partition of unity on $\bar{V}$ such that $\operatorname{spt}\left(\psi_{i}\right) \subseteq Q_{i}$. Then for all $t$ small enough and $\mathbf{x} \in U$,

$$
\frac{f(\mathbf{x}+t \mathbf{w})-f(\mathbf{x})}{t}=\frac{1}{t} \sum_{i=0}^{N} \psi_{i} f(\mathbf{x}+t \mathbf{w})-\psi_{i} f(\mathbf{x})
$$

Thus using the dominated convergence theorem and Rademacher's theorem,

$$
\begin{gather*}
\lim _{t \rightarrow 0} \int_{U} \frac{f(\mathbf{x}+t \mathbf{w})-f(\mathbf{x})}{t} d x \\
=\lim _{t \rightarrow 0} \int_{U}\left(\frac{1}{t} \sum_{i=0}^{N} \psi_{i} f(\mathbf{x}+t \mathbf{w})-\psi_{i} f(\mathbf{x})\right) d x \\
=\int_{U} \sum_{i=0}^{N} \sum_{j=1}^{p} D_{j}\left(\psi_{i} f\right)(\mathbf{x}) w_{j} d x \\
=\int_{U} \sum_{j=1}^{p} D_{j}\left(\psi_{0} f\right)(\mathbf{x}) w_{j} d x+\sum_{i=1}^{N} \int_{U} \sum_{j=1}^{p} D_{j}\left(\psi_{i} f\right)(\mathbf{x}) w_{j} d x \tag{29.7.31}
\end{gather*}
$$

Since $\operatorname{spt}\left(\psi_{0}\right) \subseteq Q_{0}$, it follows the first term in the above equals zero. In the second term, fix $i$. Without loss of generality, suppose the $k$ in the above definition equals $p$ and 29.7.29 holds. This just makes things a little easier to write. Thus $g_{i}$ is a function of

$$
\left(x_{1}, \cdots, x_{p-1}\right) \in \prod_{j=1}^{p-1}\left(a_{j}^{i}, b_{j}^{i}\right) \equiv B_{i}
$$

Then

$$
\begin{aligned}
& \int_{U} \sum_{j=1}^{p} D_{j}\left(\psi_{i} f\right)(\mathbf{x}) w_{j} d x \\
= & \int_{B_{i}} \int_{a_{p}^{i}}^{g_{i}\left(x_{1}, \cdots, x_{p-1}\right)} \sum_{j=1}^{p} D_{j}\left(\psi_{i} f\right)(\mathbf{x}) w_{j} d x_{p} d x_{1} \cdots d x_{p-1} \\
= & \int_{B_{i}} \int_{-\infty}^{g_{i}\left(x_{1}, \cdots, x_{p-1}\right)} \sum_{j=1}^{p} D_{j}\left(\psi_{i} f\right)(\mathbf{x}) w_{j} d x_{p} d x_{1} \cdots d x_{p-1}
\end{aligned}
$$

Letting $x_{p}=y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)$ and changing the variable, this equals

$$
\begin{aligned}
= & \int_{B_{i}} \int_{-\infty}^{0} \sum_{j=1}^{p} D_{j}\left(\psi_{i} f\right)\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) . \\
& w_{j} d y d x_{1} \cdots d x_{p-1} \\
= & \int_{A_{i}} \int_{-\infty}^{0} \sum_{j=1}^{p} D_{j}\left(\psi_{i} f\right)\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) . \\
& w_{j} d y d x_{1} \cdots d x_{p-1}
\end{aligned}
$$

Recall $A_{i}$ is all of $B_{i}$ except for the set of measure zero where the derivative does not exist. Also $D_{j}$ refers to the partial derivative taken with respect to the entry in the $j^{t h}$ slot. In the $p^{t h}$ slot is found not just $x_{p}$ but $y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)$ so a differentiation with respect to $x_{j}$ will not be the same as $D_{j}$. In fact, it will introduce another term involving $g_{i, j}$. Thus from the chain rule,

$$
\begin{gather*}
=\int_{A_{i}} \int_{-\infty}^{0} \sum_{j=1}^{p-1} \frac{\partial}{\partial x_{j}}\left(\psi_{i} f\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)\right) w_{j}- \\
D_{p}\left(\psi_{i} f\right)\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) \cdot g_{i, j}\left(x_{1}, \cdots, x_{p-1}\right) w_{j} d y d x_{1} \cdots d x_{p-1} \\
+\int_{A_{i}} \int_{-\infty}^{0} D_{p}\left(\psi_{i} f\right)\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) w_{p} d y d x_{1} \cdots d x_{p-1} \tag{29.7.32}
\end{gather*}
$$

Consider the term

$$
\int_{A_{i}} \int_{-\infty}^{0} \sum_{j=1}^{p-1} \frac{\partial}{\partial x_{j}}\left(\psi_{i} f\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)\right) w_{j} d y d x_{1} \cdots d x_{p-1}
$$

This equals

$$
\int_{B_{i}} \int_{-\infty}^{0} \sum_{j=1}^{p-1} \frac{\partial}{\partial x_{j}}\left(\psi_{i} f\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)\right) w_{j} d y d x_{1} \cdots d x_{p-1}
$$

and now interchanging the order of integration and using the fact that $\operatorname{spt}\left(\psi_{i}\right) \subseteq Q_{i}$, it follows this term equals zero. The reason this is valid is that

$$
x_{j} \rightarrow \psi_{i} f\left(x_{1}, \cdots, x_{p-1}, y+g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)
$$

is the composition of Lipschitz functions and is therefore Lipschitz. Therefore, this function can be recovered by integrating its derivative, Lemma 26.2.6.

Then, changing the variable back to $x_{p}$ it follows 29.7.32 reduces to

$$
-\int_{A_{i}} \int_{-\infty}^{g_{i}\left(x_{1}, \cdots, x_{p-1}\right)}\binom{\sum_{j=1}^{p-1} D_{p}\left(\psi_{i} f\right)\left(x_{1}, \cdots, x_{p-1}, x_{p}\right)}{\cdot g_{i, j}\left(x_{1}, \cdots, x_{p-1}\right) w_{j}} d x_{p} d x_{1} \cdots d x_{p-1}
$$

$$
+\int_{A_{i}} \int_{-\infty}^{g_{i}\left(x_{1}, \cdots, x_{p-1}\right)} D_{p}\left(\psi_{i} f\left(x_{1}, \cdots, x_{p-1}, x_{p}\right)\right) w_{p} d x_{p} d x_{1} \cdots d x_{p-1}
$$

Doing the integrals using the observation that $g_{i, j}\left(x_{1}, \cdots, x_{p-1}\right)$ does not depend on $x_{p}$, this reduces further to

$$
\begin{equation*}
\int_{A_{i}}\left(\psi_{i} f\right)\left(x_{1}, \cdots, x_{p-1}, x_{p}\right) \mathbf{N}_{i}\left(x_{1}, \cdots, x_{p-1}, g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) \cdot \mathbf{w} d m_{p-1} \tag{29.7.33}
\end{equation*}
$$

where $\mathbf{N}_{i}\left(x_{1}, \cdots, x_{p-1}, g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)$ is given by

$$
\begin{equation*}
\left(-g_{i, 1}\left(x_{1}, \cdots, x_{p-1}\right),-g_{i, 2}\left(x_{1}, \cdots, x_{p-1}\right), \cdots,-g_{i, p-1}\left(x_{1}, \cdots, x_{p-1}\right), 1\right) \tag{29.7.34}
\end{equation*}
$$

At this point I need a technical lemma which will allow the use of the area formula. The part of the boundary of $U$ which is contained in $Q_{i}$ is the image of the map, $\mathbf{h}_{i}\left(x_{1}, \cdots, x_{p-1}\right)$ given by $\left(x_{1}, \cdots, x_{p-1}, g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)$ for $\left(x_{1}, \cdots, x_{p-1}\right) \in A_{i}$. I need a formula for

$$
\operatorname{det}\left(D \mathbf{h}_{i}\left(x_{1}, \cdots, x_{p-1}\right)^{*} D \mathbf{h}_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)^{1 / 2}
$$

To avoid interupting the argument, I will state the lemma here and prove it later.

## Lemma 29.7.9

$$
\begin{gathered}
\operatorname{det}\left(D \mathbf{h}_{i}\left(x_{1}, \cdots, x_{p-1}\right)^{*} D \mathbf{h}_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)^{1 / 2} \\
=\sqrt{1+\sum_{j-1}^{p-1} g_{i, j}\left(x_{1}, \cdots, x_{p-1}\right)^{2}} \equiv J_{* i}\left(x_{1}, \cdots, x_{p-1}\right)
\end{gathered}
$$

For

$$
\mathbf{y}=\left(x_{1}, \cdots, x_{p-1}, g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) \in \partial U \cap Q_{i}
$$

and $\mathbf{n}$ defined by

$$
\mathbf{n}_{i}(\mathbf{y})=\frac{1}{J_{* i}\left(x_{1}, \cdots, x_{p-1}\right)} \mathbf{N}_{i}(\mathbf{y})
$$

it follows from the description of $J_{* i}\left(x_{1}, \cdots, x_{p-1}\right)$ given in the above lemma, that $\mathbf{n}_{i}$ is a unit vector. All components of $\mathbf{n}_{i}$ are continuous functions of limits of continuous functions. Therefore, $\mathbf{n}_{i}$ is Borel measurable and so it is $\mathscr{H}^{p-1}$ measurable. Now 29.7.33 reduces to

$$
\begin{aligned}
& \int_{A_{i}}\left(\psi_{i} f\right)\left(x_{1}, \cdots, x_{p-1}, g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) \times \\
& \mathbf{n}_{i}\left(x_{1}, \cdots, x_{p-1}, g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right) \cdot \mathbf{w} J_{* i}\left(x_{1}, \cdots, x_{p-1}\right) d m_{p-1}
\end{aligned}
$$

By the area formula this equals

$$
\int_{\mathbf{h}\left(A_{i}\right)} \psi_{i} f(\mathbf{y}) \mathbf{n}_{i}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}
$$

Now by Lemma 29.1.1 and the equality of $m_{p-1}$ and $\mathscr{H}^{p-1}$ on $\mathbb{R}^{p-1}$, the above integral equals

$$
\int_{\partial U \cap Q_{i}} \psi_{i} f(\mathbf{y}) \mathbf{n}_{i}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}=\int_{\partial U} \psi_{i} f(\mathbf{y}) \mathbf{n}_{i}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}
$$

Similar arguments apply to the other terms and therefore,

$$
\begin{aligned}
& \lim _{t \rightarrow 0} \int_{U} \frac{f(\mathbf{x}+t \mathbf{w})-f(\mathbf{x})}{t} d m_{p}=\sum_{i=1}^{N} \int_{\partial U} \psi_{i} f(\mathbf{y}) \mathbf{n}_{i}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1} \\
= & \int_{\partial U} f(\mathbf{y}) \sum_{i=1}^{N} \psi_{i}(\mathbf{y}) \mathbf{n}_{i}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}=\int_{\partial U} f(\mathbf{y}) \mathbf{n}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}(29.7 .35)
\end{aligned}
$$

Then let $\mathbf{n}(\mathbf{y}) \equiv \sum_{i=1}^{N} \psi_{i}(\mathbf{y}) \mathbf{n}_{i}(\mathbf{y})$.
I need to show first there is no other $\mathbf{n}$ which satisfies 29.7 .35 and then I need to show that $|\mathbf{n}(\mathbf{y})|=1$. Note that it is clear $|\mathbf{n}(\mathbf{y})| \leq 1$ because each $\mathbf{n}_{i}$ is a unit vector and this is just a convex combination of these. Suppose then that $\mathbf{n}_{1} \in L^{\infty}\left(\partial U, \mathscr{H}^{p-1}\right)$ also works in 29.7.35. Then for all $f \in C_{c}^{1}\left(\mathbb{R}^{p}\right)$,

$$
\int_{\partial U} f(\mathbf{y}) \mathbf{n}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}=\int_{\partial U} f(\mathbf{y}) \mathbf{n}_{1}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}
$$

Suppose $h \in C(\partial U)$. Then by the Tietze extension theorem, there exists $f \in C_{c}\left(\mathbb{R}^{p}\right)$ such that the restriction of $f$ to $\partial U$ equals $h$. Now by Lemma 29.7.5 applied to a bounded open set containing the support of $f$, there exists a sequence $\left\{f_{m}\right\}$ of functions in $C_{c}^{1}\left(\mathbb{R}^{p}\right)$ converging uniformly to $f$. Therefore,

$$
\begin{aligned}
& \int_{\partial U} h(\mathbf{y}) \mathbf{n}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}=\lim _{m \rightarrow \infty} \int_{\partial U} f_{m}(\mathbf{y}) \mathbf{n}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1} \\
= & \lim _{m \rightarrow \infty} \int_{\partial U} f_{m}(\mathbf{y}) \mathbf{n}_{1}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1}=\int_{\partial U} h(\mathbf{y}) \mathbf{n}_{1}(\mathbf{y}) \cdot \mathbf{w} d \mathscr{H}^{p-1} .
\end{aligned}
$$

Now $\mathscr{H}^{p-1}$ is a Radon measure on $\partial U$ and so the continuous functions on $\partial U$ are dense in $L^{1}\left(\partial U, \mathscr{H}^{p-1}\right)$. It follows $\mathbf{n} \cdot \mathbf{w}=\mathbf{n}_{1} \cdot \mathbf{w}$ a.e. Now let $\left\{\mathbf{w}_{m}\right\}_{m=1}^{\infty}$ be a countable dense subset of the unit sphere. From what was just shown, $\mathbf{n} \cdot \mathbf{w}_{m}=\mathbf{n}_{1} \cdot \mathbf{w}_{m}$ except for a set of measure zero, $N_{m}$. Letting $N=\cup_{m} N_{m}$, it follows that for $\mathbf{y} \notin N, \mathbf{n}(\mathbf{y}) \cdot \mathbf{w}_{m}=\mathbf{n}_{1}(\mathbf{y}) \cdot \mathbf{w}_{m}$ for all $m$. Since the set is dense, it follows $\mathbf{n}(\mathbf{y}) \cdot \mathbf{w}=\mathbf{n}_{1}(\mathbf{y}) \cdot \mathbf{w}$ for all $\mathbf{y} \notin N$ and for all $\mathbf{w}$ a unit vector. Therefore, $\mathbf{n}(\mathbf{y})=\mathbf{n}_{1}(\mathbf{y})$ for all $\mathbf{y} \notin N$ and this shows $\mathbf{n}$ is unique. In particular, although it appears to depend on the partition of unity $\left\{\psi_{i}\right\}$ from its definition, this is not the case.

It only remains to verify $|\mathbf{n}(\mathbf{y})|=1$ a.e. I will do this by showing how to compute $\mathbf{n}$. In particular, I will show that $\mathbf{n}=\mathbf{n}_{i}$ a.e. on $\partial U \cap Q_{i}$. Let $W \subseteq \bar{W} \subseteq Q_{i} \cap \partial U$ where $W$ is open in $\partial U$. Let $O$ be an open set such that $O \cap \partial U=W$ and $\overline{\bar{O}} \subseteq Q_{i}$. Using Corollary 16.1.2 there exists a $C^{\infty}$ partition of unity $\left\{\psi_{m}\right\}$ such that $\psi_{i}=1$ on $\bar{O}$. Therefore, if $m \neq i, \psi_{m}=0$ on $\bar{O}$. Then if $f \in C_{c}^{1}(O)$,

$$
\begin{aligned}
& \int_{W} f \mathbf{w} \cdot \mathbf{n} d \mathscr{H}^{p-1}=\int_{\partial U} f \mathbf{w} \cdot \mathbf{n} d \mathscr{H}^{p-1} \\
= & \int_{U} \nabla f \cdot \mathbf{w} d m_{p}=\int_{U} \nabla\left(\psi_{i} f\right) \cdot \mathbf{w} d m_{p}
\end{aligned}
$$

which by the first part of the argument given above equals

$$
\int_{W} \psi_{i} f \mathbf{n}_{i} \cdot \mathbf{w} d \mathscr{H}^{p-1}=\int_{W} f \mathbf{w} \cdot \mathbf{n}_{i} d \mathscr{H}^{p-1}
$$

Thus for all $f \in C_{c}^{1}(O)$,

$$
\begin{equation*}
\int_{W} f \mathbf{w} \cdot \mathbf{n} d \mathscr{H}^{p-1}=\int_{W} f \mathbf{w} \cdot \mathbf{n}_{i} d \mathscr{H}^{p-1} \tag{29.7.36}
\end{equation*}
$$

Since $C_{c}^{1}(O)$ is dense in $C_{c}(O)$, the above equation is also true for all $f \in C_{c}(O)$. Now letting $h \in C_{c}(W)$, the Tietze extension theorem implies there exists $f_{1} \in C(\bar{O})$ whose restriction to $\bar{W}$ equals $h$. Let $f$ be defined by

$$
f_{1}(\mathbf{x}) \frac{\operatorname{dist}\left(\mathbf{x}, O^{C}\right)}{\operatorname{dist}(\mathbf{x}, \operatorname{spt}(h))+\operatorname{dist}\left(\mathbf{x}, O^{C}\right)}=f(\mathbf{x}) .
$$

Then $f=h$ on $W$ and so this has shown that for all $h \in C_{c}(W), 29.7 .36$ holds for $h$ in place of $f$. But as observed earlier, $\mathscr{H}^{p-1}$ is outer and inner regular on $\partial U$ and so $C_{c}(W)$ is dense in $L^{1}\left(W, \mathscr{H}^{p-1}\right)$ which implies $\mathbf{w} \cdot \mathbf{n}(\mathbf{y})=\mathbf{w} \cdot \mathbf{n}_{i}(\mathbf{y})$ for a.e. $\mathbf{y}$. Considering a countable dense subset of the unit sphere as above, this implies $\mathbf{n}(\mathbf{y})=\mathbf{n}_{i}(\mathbf{y})$ a.e. $\mathbf{y}$. This proves $|\mathbf{n}(\mathbf{y})|=1$ a.e. and in fact $\mathbf{n}(\mathbf{y})$ can be computed by using the formula for $\mathbf{n}_{i}(\mathbf{y})$.

It remains to prove Lemma 29.7.9.
Proof of Lemma 29.7.9: Let $\mathbf{h}(\mathbf{x})=\left(x_{1}, \cdots, x_{p-1}, g\left(x_{1}, \cdots, x_{p-1}\right)\right)^{T}$

$$
D \mathbf{h}(\mathbf{x})=\left(\begin{array}{lll}
1 & & 0 \\
\vdots & \ddots & \vdots \\
0 & & 1 \\
g_{, x_{1}} & \cdots & g_{, x_{p-1}}
\end{array}\right)
$$

Then,

$$
J_{*}(\mathbf{x})=\left(\operatorname{det}\left(D \mathbf{h}(\mathbf{x})^{*} D \mathbf{h}(\mathbf{x})\right)\right)^{1 / 2}
$$

Therefore, $J_{*}(\mathbf{x})$ is the square root of the determinant of the following $(p-1) \times(p-1)$ matrix.

$$
\left(\begin{array}{llll}
1+\left(g_{, x_{1}}\right)^{2} & g_{, x_{1}} g_{, x_{2}} & \cdots & g_{, x_{1}} g_{, x_{p-1}}  \tag{29.7.37}\\
g_{, x_{2}} g_{, x_{1}} & 1+\left(g_{, x_{2}}\right)^{2} & \cdots & g_{, x_{2}} g_{, x_{p-1}} \\
\vdots & & \ddots & \vdots \\
g_{, x_{p-1}} g_{, x_{1}} & g_{, x_{p-1}} g_{, x_{2}} & \cdots & 1+\left(g_{, x_{p-1}}\right)^{2}
\end{array}\right)
$$

By Lemma 29.7.6, this determinant is $1+\sum_{i=1}^{p-1}\left(g_{, x_{i}}(\mathbf{x})\right)^{2}$
Now Lemma 29.7.8 implies the divergence theorem.
Theorem 29.7.10 Let $U$ be a bounded open set with a Lipschitz boundary which lies on one side of its boundary. Then if $f \in C_{c}^{1}\left(\mathbb{R}^{p}\right)$,

$$
\begin{equation*}
\int_{U} f_{, k}(\mathbf{x}) d m_{p}=\int_{\partial U} f n_{k} d \mathscr{H}^{p-1} \tag{29.7.38}
\end{equation*}
$$

where $\mathbf{n}=\left(n_{1}, \cdots, n_{n}\right)$ is the $\mathscr{H}^{p-1}$ measurable unit vector of Lemma 29.7.8. Also, if $\mathbf{F}$ is a vector field such that each component is in $C_{c}^{1}\left(\mathbb{R}^{p}\right)$, then

$$
\begin{equation*}
\int_{U} \nabla \cdot \mathbf{F}(\mathbf{x}) d m_{p}=\int_{\partial U} \mathbf{F} \cdot \mathbf{n} d \mathscr{H}^{p-1} \tag{29.7.39}
\end{equation*}
$$

Proof: To obtain 29.7.38 apply Lemma 29.7.8 to $\mathbf{w}=\mathbf{e}_{k}$. Then to obtain 29.7.39 from this,

$$
\begin{aligned}
& \int_{U} \nabla \cdot \mathbf{F}(\mathbf{x}) d m_{p} \\
= & \sum_{j=1}^{p} \int_{U} F_{j, j} d m_{p}=\sum_{j=1}^{p} \int_{\partial U} F_{j} n_{j} d \mathscr{H}^{p-1} \\
= & \int_{\partial U} \sum_{j=1}^{p} F_{j} n_{j} d \mathscr{H}^{p-1}=\int_{\partial U} \mathbf{F} \cdot \mathbf{n} d \mathscr{H}^{p-1} .
\end{aligned}
$$

What is the geometric significance of the vector, $\mathbf{n}$ ? Recall that in the part of the boundary contained in $Q_{i}$, this vector points in the same direction as the vector

$$
\mathbf{N}_{i}\left(x_{1}, \cdots, x_{p-1}, g_{i}\left(x_{1}, \cdots, x_{p-1}\right)\right)
$$

given by

$$
\begin{equation*}
\left(-g_{i, 1}\left(x_{1}, \cdots, x_{p-1}\right),-g_{i, 2}\left(x_{1}, \cdots, x_{p-1}\right), \cdots,-g_{i, p-1}\left(x_{1}, \cdots, x_{p-1}\right), 1\right) \tag{29.7.40}
\end{equation*}
$$

in the case where $k=p$. This vector is the gradient of the function,

$$
x_{p}-g_{i}\left(x_{1}, \cdots, x_{p-1}\right)
$$

and so is perpendicular to the level surface given by

$$
x_{p}-g_{i}\left(x_{1}, \cdots, x_{p-1}\right)=0
$$

in the case where $g_{i}$ is $C^{1}$. It also points away from $U$ so the vector $\mathbf{n}$ is the unit outer normal. The other cases work similarly.

### 29.8 The Reynolds Transport Formula

Next is an interesting version of the chain rule for Lipschitz maps. The proof of this theorem is based on the following lemma.

Lemma 29.8.1 If $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ is Lipschitz, then if $\mathbf{h}(\mathbf{x})=\mathbf{0}$ for all $\mathbf{x} \in A$, then

$$
\operatorname{det}(D \mathbf{h}(\mathbf{x}))=0 \text { a.e } . \mathbf{x} \in A
$$

Proof: By the area formula, $0=\int_{\{0\}} \#(\mathbf{y}) d y=\int_{A}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x$, and so it follows that $\operatorname{det}(D \mathbf{h}(\mathbf{x}))=0$ a.e.

Theorem 29.8.2 Let $\mathbf{f}, \mathbf{g}$ be Lipschitz mappings from $\mathbb{R}^{n}$ to $\mathbb{R}^{n}$ with $\mathbf{g}(\mathbf{f}(\mathbf{x}))=\mathbf{x}$ on $A$, a measurable set. Then for a.e. $\mathbf{x} \in A, D \mathbf{g}(\mathbf{f}(\mathbf{x})), D \mathbf{f}(\mathbf{x})$, and $D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})$ all exist and $I=D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})=D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x})$.

Proof: By Lemma 29.8.1 there is a set of measure zero $N_{1}$ off which $\operatorname{det}(D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})-I)=$ 0 and in particular $D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})$ exists. Let $N_{2}$ be the set of measure zero off which $\mathbf{f}$ is differentiable. Let $M$ be the set of points in $\mathbf{f}\left(\mathbb{R}^{n} \backslash N_{2}\right)$ where, $\mathbf{g}$ fails to be differentiable. What about $\mathbf{f}^{-1}(M)$ ? If $\mathbf{x} \in \mathbf{f}^{-1}(M)$ then $D \mathbf{g}(\mathbf{f}(\mathbf{x}))$ fails to exist and so $\mathbf{x}$ is in the first exceptional set $N_{1}$ or else in $N_{2}$ because $D(\mathbf{g} \circ \mathbf{f})(\mathbf{x})$ will fail to exist. Thus $\mathbf{f}^{-1}(M)$ is a set of measure zero. So let $\mathbf{x} \notin N_{1} \cup N_{2}$. Then for such $\mathbf{x}, D(\mathbf{g} \circ \mathbf{f})(\mathbf{x}), D \mathbf{g}(\mathbf{f}(\mathbf{x})), D \mathbf{f}(\mathbf{x})$ all exist and $I=D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x})$.

You could give a generalization to the above by essentially repeating the argument.
Corollary 29.8.3 Suppose $\mathbf{h}$ is differentiable on A, a measurable set and that $\mathbf{f}, \mathbf{g}$ are Lipschitz with $\mathbf{g}(\mathbf{f}(\mathbf{x}))=\mathbf{h}(\mathbf{x})$ for $\mathbf{x} \in A$. Then for a.e. $\mathbf{x} \in A$,

$$
D \mathbf{h}(\mathbf{x})=D \mathbf{g}(\mathbf{f}(\mathbf{x})) D \mathbf{f}(\mathbf{x})
$$

In other words, the chain rule holds off a set of measure zero.
The Reynolds transport formula is an interesting application of the divergence theorem which is a generalization of the formula for taking the derivative under an integral.

$$
\frac{d}{d t} \int_{a(t)}^{b(t)} f(x, t) d x=\int_{a(t)}^{b(t)} \frac{\partial f}{\partial t}(x, t) d x+f(b(t), t) b^{\prime}(t)-f(a(t), t) a^{\prime}(t)
$$

First is an interesting lemma about the determinant. A $p \times p$ matrix can be thought of as a vector in $\mathbb{C}^{p^{2}}$. Just imagine stringing it out into one long list of numbers. In fact, a way to give the norm of a matrix is just $\sum_{i} \sum_{j}\left|A_{i j}\right|^{2} \equiv\|A\|^{2}$. This is called the Frobenius norm for a matrix. It makes no difference since all norms are equivalent, but this one is convenient in what follows. Also recall that det maps $p \times p$ matrices to $\mathbb{C}$. It makes sense to ask for the derivative of det on the set of invertible matrices, an open subset of $\mathbb{C}^{p^{2}}$ with the norm measured as just described because $A \rightarrow \operatorname{det}(A)$ is continuous, so the set where $\operatorname{det}(A) \neq 0$ would be an open set. Recall from linear algebra that the sum of the entries on the main diagonal satisfies trace $(A B)=$ trace $(B A)$ whenever both products make sense. Indeed, $\operatorname{trace}(A B) \equiv \sum_{i} \sum_{j} A_{i j} B_{j i}=\operatorname{trace}(B A)$

This next lemma is a very interesting observation about the determinant of a matrix added to the identity.

Lemma 29.8.4 $\operatorname{det}(I+U)=1+\operatorname{trace}(U)+o(U)$ where $o(U)$ is defined in terms of the Frobenius norm for $p \times p$ matrices.

Proof: This is obvious if $p=1$ or 2 . Assume true for $n-1$. Then for $U$ an $n \times n$, expand the matrix along the last column and use induction on the cofactor of $1+U_{n n}$.

With this lemma, it is easy to find $D \operatorname{det}(F)$ whenever $F$ is invertible.

$$
\begin{aligned}
\operatorname{det}(F+U) & =\operatorname{det}\left(F\left(I+F^{-1} U\right)\right)=\operatorname{det}(F) \operatorname{det}\left(I+F^{-1} U\right) \\
& =\operatorname{det}(F)\left(1+\operatorname{trace}\left(F^{-1} U\right)+o(U)\right) \\
& =\operatorname{det}(F)+\operatorname{det}(F) \operatorname{trace}\left(F^{-1} U\right)+o(U)
\end{aligned}
$$

Therefore,

$$
\operatorname{det}(F+U)-\operatorname{det}(F)=\operatorname{det}(F) \operatorname{trace}\left(F^{-1} U\right)+o(U)
$$

This proves the following.
Proposition 29.8.5 Let $F^{-1}$ exist. Then $D \operatorname{det}(F)(U)=\operatorname{det}(F) \operatorname{trace}\left(F^{-1} U\right)$.
From this, suppose $F(t)$ is a $p \times p$ matrix and all entries are differentiable. Then the following describes $\frac{d}{d t} \operatorname{det}(F)(t)$.

Proposition 29.8.6 Let $F(t)$ be a $p \times p$ matrix and all entries are differentiable. Then for a.e. $t$

$$
\begin{align*}
\frac{d}{d t} \operatorname{det}(F)(t) & =\operatorname{det}(F(t)) \operatorname{trace}\left(F^{-1}(t) F^{\prime}(t)\right) \\
& =\operatorname{det}(F(t)) \operatorname{trace}\left(F^{\prime}(t) F^{-1}(t)\right) \tag{29.8.41}
\end{align*}
$$

Let $\mathbf{y}=\mathbf{h}(t, \mathbf{x})$ with $F=F(t, \mathbf{x})=D_{2} \mathbf{h}(t, \mathbf{x})$. I will write $\nabla_{\mathbf{y}}$ to indicate the gradient with respect to the $\mathbf{y}$ variables and $F^{\prime}$ to indicate $\frac{\partial}{\partial t} F(t, \mathbf{x})$. Note that $\mathbf{h}(t, \mathbf{x})=\mathbf{y}$ and so by the inverse function theorem, this defines $\mathbf{x}$ as a function of $\mathbf{y}$, also as smooth as $\mathbf{h}$ because it is always assumed $\operatorname{det} F>0$.

Now let $V_{t}$ be $\mathbf{h}\left(t, V_{0}\right)$ where $V_{0}$ is an open bounded set. Let $V_{0}$ have a Lipschitz boundary so one can use the divergence theorem on $V_{0}$. Let $(t, \mathbf{y}) \rightarrow \mathbf{f}(t, \mathbf{y})$ be Lipschitz. The idea is to simplify $\frac{d}{d t} \int_{V_{t}} \mathbf{f}(t, \mathbf{y}) d m_{p}(y)$. This will involve the change of variables in which the Jacobian will be $\operatorname{det}(F)$ which is assumed positive. In applications of this theory, $\operatorname{det}(F) \leq 0$ is not physically possible. Since $\mathbf{h}(t, \cdot)$ is Lipschitz and the boundary of $V_{0}$ is Lipschitz, $V_{t}$ will be such that one can use the divergence theorem because the composition of Lipschitz functions is Lipschitz. Then, using the dominated convergence theorem as needed along with the area formula,

$$
\begin{align*}
& \frac{d}{d t} \int_{V_{t}} \mathbf{f}(t, \mathbf{y}) d m_{p}(y)=\frac{d}{d t} \int_{V_{0}} \mathbf{f}(t, \mathbf{h}(t, \mathbf{x})) \operatorname{det}(F) d m_{p}(x)  \tag{29.8.42}\\
&=\int_{V_{0}} \frac{\partial}{\partial t} \mathbf{f}(\cdot, \mathbf{h}(\cdot, \mathbf{x})) \operatorname{det}(F) d m_{p}(x)+\int_{V_{0}} \mathbf{f}(t, \mathbf{h}(t, \mathbf{x})) \frac{\partial}{\partial t}(\operatorname{det}(F)) d m_{p}(x) \\
&= \int_{V_{0}} \frac{\partial}{\partial t}(\mathbf{f}(t, \mathbf{h}(t, \mathbf{x}))) \operatorname{det}(F) d m_{p}(x) \\
&+\int_{V_{0}} \mathbf{f}(t, \mathbf{h}(t, \mathbf{x})) \operatorname{trace}\left(F^{\prime} F^{-1}\right) \operatorname{det}(F) d m_{p}(x) \\
&= \int_{V_{0}}\left(\frac{\partial}{\partial t} \mathbf{f}(t, \mathbf{h}(t, \mathbf{x}))+\sum_{i} \frac{\partial \mathbf{f}}{\partial y_{i}} \frac{\partial y_{i}}{\partial t}\right) \operatorname{det}(F) d m_{p}(x) \\
&+\int_{V_{0}} \mathbf{f}(t, \mathbf{h}(t, \mathbf{x})) \operatorname{trace}\left(F^{\prime} F^{-1}\right) \operatorname{det}(F) d m_{p}(x)
\end{align*}
$$

$$
=\int_{V_{t}} \frac{\partial}{\partial t} \mathbf{f}(t, \mathbf{y}) d m_{p}(y)+\int_{V_{t}} \sum_{i} \frac{\partial \mathbf{f}}{\partial y_{i}} \frac{\partial y_{i}}{\partial t}+\mathbf{f}(t, \mathbf{y}) \operatorname{trace}\left(F^{\prime} F^{-1}\right) d m_{p}(y)
$$

Now $\mathbf{v} \equiv \frac{\partial}{\partial t} \mathbf{h}(t, \mathbf{x})$ and also, as noted above, $\mathbf{y} \equiv \mathbf{h}(t, \mathbf{x})$ defines $\mathbf{y}$ as a function of $\mathbf{x}$ and so $\operatorname{trace}\left(F^{\prime} F^{-1}\right)=\sum_{\alpha} \frac{\partial v_{i}}{\partial x_{\alpha}} \frac{\partial x_{\alpha}}{\partial y_{i}}$. Hence the double sum $\sum_{\alpha, i} \frac{\partial v_{i}}{\partial x_{\alpha}} \frac{\partial x_{\alpha}}{\partial y_{i}}$ is $\frac{\partial v_{i}}{\partial y_{i}}=\nabla_{\mathbf{y}} \cdot \mathbf{v}$. The above then gives

$$
\begin{align*}
& \int_{V_{t}} \frac{\partial}{\partial t} \mathbf{f}(t, \mathbf{y}) d m_{p}(y)+\int_{V_{t}}\left(\sum_{i} \frac{\partial \mathbf{f}}{\partial y_{i}} \frac{\partial y_{i}}{\partial t}+\mathbf{f}(t, \mathbf{y}) \nabla_{\mathbf{y}} \cdot \mathbf{v}\right) d m_{p}(y) \\
= & \int_{V_{t}} \frac{\partial}{\partial t} \mathbf{f}(t, \mathbf{y}) d m_{p}(y)+\int_{V_{t}}\left(D_{2} \mathbf{f}(t, \mathbf{y}) \mathbf{v}+\mathbf{f}(t, \mathbf{y}) \nabla_{\mathbf{y}} \cdot \mathbf{v}\right) d m_{p}(y) \tag{29.8.43}
\end{align*}
$$

Now consider the $i^{\text {th }}$ component of the second integral in the above. It is

$$
\begin{aligned}
& \int_{V_{t}} \nabla_{\mathbf{y}} f_{i}(t, \mathbf{y}) \cdot \mathbf{v}+f_{i}(t, \mathbf{y}) \nabla_{\mathbf{y}} \cdot \mathbf{v} d m_{p}(y) \\
= & \int_{V_{t}} \nabla_{\mathbf{y}} \cdot\left(f_{i}(t, \mathbf{y}) \mathbf{v}\right) d m_{p}(y)
\end{aligned}
$$

At this point, use the divergence theorem to get this equals $=\int_{\partial V_{t}} f_{i}(t, \mathbf{y}) \mathbf{v} \cdot \mathbf{n} d \mathscr{H}^{p-1}$. Therefore, from 29.8.43 and 29.8.42,

$$
\begin{equation*}
\frac{d}{d t} \int_{V_{t}} \mathbf{f}(t, \mathbf{y}) d m_{p}(y)=\int_{V_{t}} \frac{\partial}{\partial t} \mathbf{f}(t, \mathbf{y}) d m_{p}(y)+\int_{\partial V_{t}} \mathbf{f}(t, \mathbf{y}) \mathbf{v} \cdot \mathbf{n} d A \tag{29.8.44}
\end{equation*}
$$

this is the Reynolds transport formula.
Proposition 29.8.7 Let $\mathbf{y}=\mathbf{h}(t, \mathbf{x})$ where $\mathbf{h}$ is Lipschitz continuous and let $\mathbf{f}$ also be Lipschitz continuous and let $V_{t} \equiv \mathbf{h}\left(t, V_{0}\right)$ where $V_{0}$ is a bounded open set which is on one side of a Lipschitz boundary so that the divergence theorem holds for $V_{0}$. Then 29.8.44 is obtained.

### 29.9 The Coarea Formula

The area formula was discussed above. This formula implies that for $E$ a measurable set

$$
\mathscr{H}^{n}(\mathbf{f}(E))=\int \mathscr{X}_{E}(\mathbf{x}) J_{*}(\mathbf{x}) d m
$$

where $\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ for $\mathbf{f}$ a Lipschitz mapping and $m \geq n$. It is a version of the change of variables formula for multiple integrals. The coarea formula is a statement about the Hausdorff measure of a set which involves the inverse image of $\mathbf{f}$. It is somewhat reminiscent of Fubini's theorem. Recall that if $n>m$ and $\mathbb{R}^{n}=\mathbb{R}^{m} \times \mathbb{R}^{n-m}$, we may take a product measurable set, $E \subseteq \mathbb{R}^{n}$, and obtain its Lebesgue measure by the formula

$$
\begin{aligned}
m_{n}(E) & =\int_{\mathbb{R}^{m}} \int_{\mathbb{R}^{n-m}} \mathscr{X}_{E}(\mathbf{y}, \mathbf{x}) d m_{n-m} d m_{m} \\
& =\int_{\mathbb{R}^{m}} m_{n-m}\left(E^{\mathbf{y}}\right) d m_{m}=\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(E^{\mathbf{y}}\right) d m_{m}
\end{aligned}
$$

Let $\pi_{1}$ and $\pi_{2}$ be defined by $\pi_{2}(\mathbf{y}, \mathbf{x})=\mathbf{x}, \pi_{1}(\mathbf{y}, \mathbf{x})=\mathbf{y}$. Then $E^{\mathbf{y}}=\pi_{2}\left(\pi_{1}^{-1}(\mathbf{y}) \cap E\right)$ and so

$$
\begin{align*}
m_{n}(E) & =\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\pi_{2}\left(\pi_{1}^{-1}(\mathbf{y}) \cap E\right)\right) d m_{m} \\
& =\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\pi_{1}^{-1}(\mathbf{y}) \cap E\right) d m_{m} \tag{29.9.45}
\end{align*}
$$

Thus, the notion of product measure yields a formula for the measure of a set in terms of the inverse image of one of the projection maps onto a smaller dimensional subspace. The coarea formula gives a generalization of 29.9.45 in the case where $\pi_{1}$ is replaced by an arbitrary Lipschitz function mapping $\mathbb{R}^{n}$ to $\mathbb{R}^{m}$. In general, we will take $m<n$ in this presentation. Whereas in the area formula the Lipschitz function has $m \geq n$.

It is possible to obtain the coarea formula as a computation involving the area formula and some simple linear algebra and this is the approach taken here. I found this formula in [47]. This is a good place to obtain a slightly different proof. This argument follows [84] which came from [47]. I find this material very hard, so I hope what follows doesn't have grievous errors. I have never had occasion to use this coarea formula, but I think it is obviously of enormous significance and gives a very interesting geometric assertion. I will use the form of the chain rule in Theorem 29.8.2 as needed.

To begin with we give the linear algebra identity which will be used. Recall that for a real matrix $A^{*}$ is just the transpose of $A$. Thus $A A^{*}$ and $A^{*} A$ are symmetric.
Theorem 29.9.1 Let $A$ be an $m \times n$ matrix and let $B$ be an $n \times m$ matrix for $m \leq n$. Then for I an appropriate size identity matrix,

$$
\operatorname{det}(I+A B)=\operatorname{det}(I+B A)
$$

Proof: Use block multiplication to write

$$
\begin{aligned}
& \left(\begin{array}{cc}
I+A B & 0 \\
B & I
\end{array}\right)\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)=\left(\begin{array}{cc}
I+A B & A+A B A \\
B & B A+I
\end{array}\right) \\
& \left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)\left(\begin{array}{cc}
I & 0 \\
B & I+B A
\end{array}\right)=\left(\begin{array}{cc}
I+A B & A+A B A \\
B & I+B A
\end{array}\right)
\end{aligned}
$$

Hence

$$
\left(\begin{array}{cc}
I+A B & 0 \\
B & I
\end{array}\right)\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)=\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)\left(\begin{array}{cc}
I & 0 \\
B & I+B A
\end{array}\right)
$$

so

$$
\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)^{-1}\left(\begin{array}{cc}
I+A B & 0 \\
B & I
\end{array}\right)\left(\begin{array}{cc}
I & A \\
0 & I
\end{array}\right)=\left(\begin{array}{cc}
I & 0 \\
B & I+B A
\end{array}\right)
$$

which shows that the two matrices

$$
\left(\begin{array}{cc}
I+A B & 0 \\
B & I
\end{array}\right),\left(\begin{array}{cc}
I & 0 \\
B & I+B A
\end{array}\right)
$$

are similar and so they have the same determinant. Thus

$$
\operatorname{det}(I+A B)=\operatorname{det}(I+B A)
$$

Note that the two matrices are different sizes.

Corollary 29.9.2 Let $A$ be an $m \times n$ real matrix. Then

$$
\operatorname{det}\left(I+A A^{*}\right)=\operatorname{det}\left(I+A^{*} A\right)
$$

It is convenient to define the following [47] for a measure space $(\Omega, \mathscr{S}, \mu)$ and $f: \Omega \rightarrow$ $[0, \infty]$, an arbitrary function, maybe not measurable.

$$
\int^{*} f d \mu \equiv \int_{\Omega}^{*} f d \mu \equiv \inf \left\{\int_{\Omega} g d \mu: g \geq f, \text { and } g \text { measurable }\right\}
$$

This is just like an outer measure. It resembles an old idea found in Hobson [66] called a generalized Stieltjes integral.

Lemma 29.9.3 Suppose $f_{n} \geq 0$ and $\limsup _{n \rightarrow \infty} \int^{*} f_{n} d \mu=0$. Then there is a subsequence $f_{n_{k}}$ such that $f_{n_{k}}(\omega) \rightarrow 0$ a.e. $\omega$.

Proof: For $n$ large enough, $\int^{*} f_{n} d \mu<\infty$. Let $n$ be this large and pick $g_{n} \geq f_{n}, g_{n}$ measurable, such that

$$
\int^{*} f_{n} d \mu+n^{-1}>\int g_{n} d \mu
$$

Thus

$$
\limsup \int g_{n} d \mu=\liminf \int g_{n} d \mu=\lim \int g_{n} d \mu=0
$$

If $n=1,2, \cdots$, let $k_{n}>\max \left(k_{n-1}, n\right)$ be such that $\int g_{k_{n}} d \mu<2^{-n}$. Thus

$$
\mu\left(\left[g_{k_{n}} \geq n^{-1}\right]\right) \leq 2^{-n} n \text { and } \sum_{n=1}^{\infty} \mu\left(\left[g_{k_{n}} \geq n^{-1}\right]\right)<\infty
$$

so for all $N$,

$$
\mu\left(\cap_{n=1}^{\infty} \cup_{m \geq n}\left[g_{k_{m}} \geq m^{-1}\right]\right) \leq \sum_{n=N}^{\infty} \mu\left(\left[g_{k_{m}} \geq m^{-1}\right]\right) \leq \sum_{n=N}^{\infty} n 2^{-n}
$$

Thus $\mu\left(\cap_{n=1}^{\infty} \cup_{m \geq n}\left[g_{k_{m}} \geq m^{-1}\right]\right)=0$. Therefore, for $\omega \notin \cap_{n=1}^{\infty} \cup_{m \geq n}\left[g_{k_{m}} \geq m^{-1}\right]$, a set of measure zero, for all $m$ large enough, $\left[g_{k_{m}}<m^{-1}\right]$ and so $g_{k_{m}}(\omega) \rightarrow 0$ a.e. $\omega$. Since $f_{k_{m}}(\omega) \leq g_{k_{m}}(\omega)$, this proves the lemma.

It might help a little before proceeding further to recall the concept of a level surface of a function of $n$ variables. If $f: U \subseteq \mathbb{R}^{n} \rightarrow \mathbb{R}$, such a level surface is of the form $f^{-1}(y)$ and we would expect it to be an $n-1$ dimensional thing in some sense. In the next lemma, consider a more general construction in which the function has values in $\mathbb{R}^{m}, m \leq n$. In this more general case, one would expect $\mathbf{f}^{-1}(\mathbf{y})$ to be something which is in some sense $n-m$ dimensional. As earlier, sets will not be assumed measurable and $\mathscr{H}^{k}$ will refer to an outer measure.

Lemma 29.9.4 Let $A \subseteq \mathbb{R}^{p}$ and let $\mathbf{f}: \mathbb{R}^{p} \rightarrow \mathbb{R}^{m}$ be Lipschitz. Then

$$
\int_{\mathbb{R}^{m}}^{*} \mathscr{H}^{s}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d \mathscr{H}^{m} \leq \frac{\beta(s) \beta(m)}{\beta(s+m)}(\operatorname{Lip}(\mathbf{f}))^{m} \mathscr{H}^{s+m}(A) .
$$

Proof: The formula is obvious if $\mathscr{H}^{s+m}(A)=\infty$ so assume $\mathscr{H}^{s+m}(A)<\infty$. The diameter of the closure of a set is the same as the diameter of the set and so one can assume

$$
A \subseteq \cup_{i=1}^{\infty} B_{i}^{j}, r\left(B_{i}^{j}\right) \leq j^{-1}, B_{i}^{j} \text { is closed }
$$

and

$$
\begin{equation*}
\mathscr{H}_{j^{-1}}^{s+m}(A)+j^{-1} \geq \sum_{i=1}^{\infty} \beta(s+m)\left(r\left(B_{i}^{j}\right)\right)^{s+m} \tag{29.9.46}
\end{equation*}
$$

Now define $g_{i}^{j}(\mathbf{y}) \equiv \beta(s)\left(r\left(B_{i}^{j}\right)\right)^{s} \mathscr{X}_{\mathbf{f}\left(B_{i}^{j}\right)}(\mathbf{y})$. If $\mathbf{f}^{-1}(\mathbf{y}) \notin B_{i}^{j}$, this indicator function $\mathscr{X}_{\mathbf{f}\left(B_{i}^{j}\right)}$ just gives 0 . If $\mathbf{f}^{-1}(\mathbf{y}) \in B_{i}^{j}$ then $\mathbf{y} \in B_{i}^{j}$. Thus

$$
\mathscr{H}_{j^{-1}}^{s}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) \leq \sum_{i=1}^{\infty} \beta(s)\left(r\left(B_{i}^{j}\right)\right)^{s} \mathscr{X}_{\mathbf{f}\left(B_{i}^{j}\right)}(\mathbf{y})=\sum_{i=1}^{\infty} g_{i}^{j}(\mathbf{y}),
$$

a Borel measurable function. It follows,

$$
\begin{aligned}
\int_{\mathbb{R}^{m}}^{*} \mathscr{H}^{s}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d \mathscr{H}^{m} & =\int_{\mathbb{R}^{m}}^{*} \lim _{j \rightarrow \infty} \mathscr{H}_{j^{-1}}^{s}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d \mathscr{H}^{m} \\
& \leq \int_{\mathbb{R}^{m}}^{*} \lim _{j \rightarrow \infty} \inf _{j=1}^{\infty} g_{i}^{j}(\mathbf{y}) d \mathscr{H}^{m}
\end{aligned}
$$

By Borel measurability of the integrand, the last term is no more than

$$
\int_{\mathbb{R}^{m}} \lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty} g_{i}^{j}(\mathbf{y}) d \mathscr{H}^{m}
$$

By Fatou's lemma,

$$
\begin{gathered}
\leq \lim \inf _{j \rightarrow \infty} \int_{\mathbb{R}^{m}} \sum_{i=1}^{\infty} g_{i}^{j}(\mathbf{y}) d \mathscr{H}^{m}=\lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty} \beta(s)\left(r\left(B_{i}^{j}\right)\right)^{s} \int_{\mathbb{R}^{m}} \mathscr{X}_{\mathbf{f}\left(B_{i}^{j}\right)}(\mathbf{y}) d \mathscr{H}^{m} \\
=\lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty} \beta(s)\left(r\left(B_{i}^{j}\right)\right)^{s} \mathscr{H}^{m}\left(\mathbf{f}\left(B_{i}^{j}\right)\right)
\end{gathered}
$$

Recall the equality of $\mathscr{H}^{m}$ and Lebesgue measure on $\mathbb{R}^{m}$, (Recall this was how $\beta(m)$ was chosen. Theorem 28.2.4) Then the above is

$$
\begin{gathered}
\leq \lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty} \beta(s)\left(r\left(B_{i}^{j}\right)\right)^{s} m_{m}\left(\mathbf{f}\left(B_{i}^{j}\right)\right) \\
\leq \lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty} \beta(s) \alpha(m) \operatorname{Lip}(\mathbf{f})^{m} r\left(B_{i}^{j}\right)^{m}\left(r\left(B_{i}^{j}\right)\right)^{s} \\
=\operatorname{Lip}(\mathbf{f})^{m} \beta(s) \alpha(m) \lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty} r\left(B_{i}^{j}\right)^{m}\left(r\left(B_{i}^{j}\right)\right)^{s}
\end{gathered}
$$

$$
\begin{gathered}
=\operatorname{Lip}(\mathbf{f})^{m} \frac{\beta(s) \alpha(m)}{\beta(m+s)} \lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty} \beta(m+s) r\left(B_{i}^{j}\right)^{m+s} \\
\leq \operatorname{Lip}(\mathbf{f})^{m} \frac{\beta(s) \alpha(m)}{\beta(m+s)} \mathscr{H}^{s+m}(A)
\end{gathered}
$$

from 29.9.46. However, it was shown earlier that $\alpha(m)=\beta(m)$.
This last identification that $\alpha(m)=\beta(m)$ depended on the technical material involving isodiametric inequality. It isn't all that important to know the exact value of this constant $\frac{\beta(s) \alpha(m)}{\beta(m+s)}$ so one could simply write $C(s, m)$ in its place and suffer no lack of utility.

Can one change $\int^{*}$ to $\int$ ? The next lemma will enable the change in notation.
Lemma 29.9.5 Let $A \subseteq \mathbb{R}^{n}$ be Lebesgue measurable and

$$
\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}
$$

be Lipschitz, $m<n$. Then

$$
\mathbf{y} \rightarrow \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right)
$$

is Lebesgue measurable. If A is compact, this function is Borel measurable.
Proof: Suppose first that $A$ is compact. Then $A \cap \mathbf{f}^{-1}(\mathbf{y})$ is also and so it is $\mathscr{H}^{n-m}$ measurable. Suppose $\mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right)<t$. Then for all $\delta>0$,

$$
\mathscr{H}_{\delta}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right)<t
$$

and so there exist sets $S_{i}$, satisfying

$$
r\left(S_{i}\right)<\delta, A \cap \mathbf{f}^{-1}(\mathbf{y}) \subseteq \cup_{i=1}^{\infty} S_{i}, \sum_{i=1}^{\infty} \beta(n-m)\left(r\left(S_{i}\right)\right)^{n-m}<t
$$

Replacing $S_{i}$ with the open set $\hat{S}_{i} \equiv S_{i}+B\left(\mathbf{0}, \eta_{i}\right)$ where the $\hat{S}_{i}$ satisfy the above inequality, it can be assumed each $S_{i}$ is open.

Claim: If $\mathbf{z}$ is close enough to $\mathbf{y}$, then $A \cap \mathbf{f}^{-1}(\mathbf{z}) \subseteq \cup_{i=1}^{\infty} S_{i}$.
Proof: If not, then there exists a sequence $\left\{\mathbf{z}_{k}\right\}$ such that $\mathbf{z}_{k} \rightarrow \mathbf{y}$, and $\mathbf{x}_{k} \in(A \cap$ $\left.\mathbf{f}^{-1}\left(\mathbf{z}_{k}\right)\right) \backslash \cup_{i=1}^{\infty} S_{i}$. Thus $\mathbf{f}\left(\mathbf{x}_{k}\right)=\mathbf{z}_{k}$. Taking a subsequence still denoted by $k$ we can have

$$
\mathbf{z}_{k} \rightarrow \mathbf{y}, \mathbf{x}_{k} \rightarrow \mathbf{x} \in A \backslash \cup_{i=1}^{\infty} S_{i}
$$

Hence $\mathbf{f}(\mathbf{x})=\lim _{k \rightarrow \infty} \mathbf{f}\left(\mathbf{x}_{k}\right)=\lim _{k \rightarrow \infty} \mathbf{z}_{k}=\mathbf{y}$, so $\mathbf{x} \in \mathbf{f}^{-1}(\mathbf{y}) \cap A \backslash \cup_{i=1}^{\infty} S_{i}$ contrary to the assumption that $A \cap \mathbf{f}^{-1}(\mathbf{y}) \subseteq \cup_{i=1}^{\infty} S_{i}$.

It follows from this claim that whenever $\mathbf{z}$ is close enough to $\mathbf{y}$,

$$
\mathscr{H}_{\delta}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{z})\right)<t .
$$

Thus if

$$
U_{\delta} \equiv\left\{\mathbf{z}: \mathscr{H}_{\delta}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{z})\right)<t+\delta\right\}
$$

then $U_{\delta}$ is open. Hence, letting $\delta_{i} \rightarrow 0+$,

$$
\left\{\mathbf{z}: \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{z})\right) \leq t\right\}=\cap_{i=1}^{\infty} U_{\delta_{i}}=\text { Borel set. }
$$

Thus, if $A$ is compact, then for each $\mathbf{y} \in \mathbb{R}^{m}, A \cap \mathbf{f}^{-1}(\mathbf{y})$ is $\mathscr{H}^{n-m}$ measurable and also the function

$$
\mathbf{y} \rightarrow \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right)
$$

is a Borel measurable function, hence Lebesgue measurable.
Let $A$ be Lebesgue measurable not just compact. Then by regularity, there exists $F \subseteq A$ where $F$ is the countable union of compact sets and $m_{m}(A \backslash F)=0$. Say $F=\cup_{k} F_{k}, F_{k+1} \supseteq$ $F_{k}$ and each $F_{k}$ is compact. Then $\mathscr{H}^{n-m}\left(F \cap \mathbf{f}^{-1}(\mathbf{y})\right)=\lim _{n \rightarrow \infty} \mathscr{H}^{n-m}\left(F_{n} \cap \mathbf{f}^{-1}(\mathbf{y})\right)$ so $\mathbf{y} \rightarrow \mathscr{H}^{n-m}\left(F \cap \mathbf{f}^{-1}(\mathbf{y})\right)$ is Lebesgue measurable.

$$
\int_{\mathbb{R}^{m}}^{*} \mathscr{H}^{n-m}\left((A \backslash F) \cap \mathbf{f}^{-1}(\mathbf{y})\right) d \mathscr{H}^{n-m} \leq C_{m, n} \mathscr{H}^{n}(A \backslash F)=C_{m, n} m_{n}(A \backslash F)=0
$$

From Lemma 29.9.3 $\mathscr{H}^{n-m}\left((A \backslash F) \cap \mathbf{f}^{-1}(\mathbf{y})\right)=0$ for $\mathscr{H}^{n-m}$ a.e. y. Hence, regarding $\mathscr{H}^{n-m}$ as an outer measure,

$$
\begin{aligned}
\mathscr{H}^{n-m}\left(F \cap \mathbf{f}^{-1}(\mathbf{y})\right) & \leq \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) \\
& \leq \mathscr{H}^{n-m}\left((A \backslash F) \cap \mathbf{f}^{-1}(\mathbf{y})\right)+\mathscr{H}^{n-m}\left(F \cap \mathbf{f}^{-1}(\mathbf{y})\right) \\
& =\mathscr{H}^{n-m}\left(F \cap \mathbf{f}^{-1}(\mathbf{y})\right)
\end{aligned}
$$

and so $\mathbf{y} \rightarrow \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right)=\mathscr{H}^{n-m}\left(F \cap \mathbf{f}^{-1}(\mathbf{y})\right)$ is Lebesgue measurable.
With this lemma proved, it is possible to obtain the following useful inequality which will be used repeatedly.

Lemma 29.9.6 If $A \subseteq \mathbb{R}^{n}$ is Lebesgue measurable, then

$$
\begin{gathered}
\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y \\
\leq C(n, m)(\operatorname{Lip}(\mathbf{f}))^{m} m_{n}(A), C(n, m)=\frac{\beta(n-m) \beta(m)}{\beta(n)}
\end{gathered}
$$

Proof: This follows from Lemma 29.9.4 and Lemma 29.9.5. Since

$$
\mathbf{y} \rightarrow \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right)
$$

is measurable,

$$
\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y=\int_{\mathbb{R}^{m}}^{*} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y
$$

Now let $p=n$, and $s=n-m$ in Lemma 29.9.4.
With these lemmas it is now possible to establish the coarea formula. First we define $\Lambda(n, m)$ as all possible ordered lists of $m$ numbers taken from $\{1,2, \ldots, n\}$. Recall $\mathbf{x} \in$
$\mathbb{R}^{n}$ and $\mathbf{f}(\mathbf{x}) \in \mathbb{R}^{m}$ where $m \leq n$. Recall that this was part of the Binet Cauchy theorem, Theorem 30.2.1,

$$
\operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)=\sum_{\mathbf{i} \in \Lambda(n, m)}\left(\operatorname{det} D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{x})\right)^{2}
$$

Now let $\mathbf{i}_{c} \in \Lambda(n, n-m)$ consist of the remaining indices taken in order where $\mathbf{i} \in \Lambda(n, m)$. For $\mathbf{i}=\left(i_{1}, \cdots, i_{m}\right)$, define $\mathbf{x}_{\mathbf{i}} \equiv\left(x_{i_{1}}, \ldots, x_{i_{m}}\right)$ and $\mathbf{x}_{\mathbf{i}_{c}}$ to be the other components of $\mathbf{x}$ taken in order. Then let

$$
\mathbf{f}^{\mathbf{i}}(\mathbf{x}) \equiv\binom{\mathbf{f}(\mathbf{x})}{\mathbf{x}_{\mathbf{i}_{c}}}
$$

Thus there are $C(n, n-m)=D(n, m)$ different $\mathbf{f}^{\mathbf{i}}$.
Example 29.9.7 Say $\mathbf{f}: \mathbb{R}^{4} \rightarrow \mathbb{R}^{2}$. Here are some examples for $\mathbf{f}^{\mathbf{i}}$ :

$$
\left(\begin{array}{c}
f_{1}\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \\
f_{2}\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \\
x_{2} \\
x_{4}
\end{array}\right),\left(\begin{array}{c}
f_{1}\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \\
f_{2}\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \\
x_{1} \\
x_{2}
\end{array}\right),\left(\begin{array}{c}
f_{1}\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \\
f_{2}\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \\
x_{3} \\
x_{4}
\end{array}\right)
$$

Thus $\mathbf{f}^{\mathbf{i}}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$. For example, if $\mathbf{i}$ consists of the first $m$ of these indices, you have

$$
D \mathbf{f}^{\mathbf{i}}(\mathbf{x})=\left(\begin{array}{cc}
D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{x}) & * \\
0 & I
\end{array}\right)
$$

and so

$$
\begin{equation*}
\operatorname{det} D \mathbf{f}^{\mathbf{i}}(\mathbf{x})=\operatorname{det} D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{x}) \tag{29.9.47}
\end{equation*}
$$

It is the same with other $\mathbf{i} \in \Lambda(n, m)$, except you may have a minus sign. This will not matter here.

Earlier with the area formula, we integrated $J_{*}(\mathbf{x}) \equiv \operatorname{det}\left(D \mathbf{f}(\mathbf{x})^{*} D \mathbf{f}(\mathbf{x})\right)^{1 / 2}$. With the coarea formula, we integrate $J^{*}(\mathbf{x}) \equiv \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2}$. This proof involves doing this integration and seeing what happens.

Theorem 29.9.8 Let A be a measurable set in $\mathbb{R}^{n}$ and let $\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ be a Lipschitz map. Then the following formula holds along with all measurability assertions needed for it to make sense.

$$
\begin{equation*}
\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y=\int_{A} J^{*}(\mathbf{x}) d x \tag{29.9.48}
\end{equation*}
$$

where

$$
J^{*}(\mathbf{x}) \equiv \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2}
$$

Proof: First note that $\operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)=\sum_{\mathbf{i} \in \Lambda(n, m)} \operatorname{det}\left(D \mathbf{f}^{\mathbf{i}}(\mathbf{x})\right)^{2}$ by the Binet Cauchy theorem. Let $S \equiv\left\{\mathbf{x}: J^{*}(\mathbf{x})=0\right\}$. For each $\mathbf{i}, \mathbf{f}^{\mathbf{i}}\left(\left\{\mathbf{x}: \operatorname{det}\left(D \mathbf{f}^{\mathbf{i}}(\mathbf{x})\right)=0\right\}\right)$ has measure zero due to Sard's theorem and so it will follow from the argument presented below that $S^{\mathbf{i}} \equiv \mathbf{f}^{\mathbf{i}}\left(\left\{\mathbf{x}: \operatorname{det}\left(D \mathbf{f}^{\mathbf{i}}(\mathbf{x})\right)=0\right\}\right)$ has measure zero. Thus $S^{\mathbf{i}} \backslash S$ can be neglected. For $N \equiv$ $\{\mathbf{x}: D \mathbf{f}(\mathbf{x})$ does not exist $\}, m_{n}(N)=0$ by Rademacher's theorem. Thus in what follows, we can always assume that either $D \mathbf{f}^{\mathbf{i}}(\mathbf{x})$ does not exist or $\operatorname{det}\left(D \mathbf{f}^{\mathbf{i}}(\mathbf{x})\right)$ exists and is not 0 . This
will be clear from the argument. Let $A$ be a closed subset of $\mathbb{R}^{n} \backslash\{S \cup N\}$. By Lemma 29.4.1, there exist disjoint Borel measurable sets $\left\{F_{j}^{\mathbf{i}}\right\}_{j=1}^{\infty}$ such that $\mathbf{f}^{\mathbf{i}}$ is one to one on $F_{j}^{\mathbf{i}}$, $\left(\mathbf{f}^{\mathbf{i}}\right)^{-1}$ is Lipschitz on $\mathbf{f}^{\mathbf{i}}\left(F_{j}^{\mathbf{i}}\right)$, and

$$
\cup_{j=1}^{\infty} F_{j}^{\mathbf{i}}=\left\{\mathbf{x}: D \mathbf{f}^{\mathbf{i}}(\mathbf{x}) \text { exists and } \operatorname{det} D \mathbf{f}^{\mathbf{i}}(\mathbf{x}) \neq 0\right\} .
$$

If $\mathbf{x} \in \mathbb{R}^{n} \backslash\{S \cup N\}$, it follows $\mathbf{x} \in F_{j}^{\mathbf{i}}$ for some $\mathbf{i}$ and $j$. Hence $\cup_{\mathbf{i}, j} F_{j}^{\mathbf{i}} \supseteq A$.
Now let $\left\{E_{j}^{\mathbf{i}}\right\}$ be measurable sets such that $E_{j}^{\mathbf{i}} \subseteq F_{k}^{\mathbf{i}}$ for some $k$, the sets $E_{j}^{\mathbf{i}}$ are disjoint, and their union coincides with $\cup_{\mathbf{i}, j} F_{j}^{\mathbf{i}}$. Let $\mathbf{g}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be a Lipschitz function which equals $\left(\mathbf{f}^{\mathbf{i}}\right)^{-1}$ on $\mathbf{f}^{\mathbf{i}}\left(E_{j}^{\mathbf{i}}\right)$. I am supressing the dependence on $\mathbf{i}$. Then for any $\mathbf{x} \in E_{j}^{\mathbf{i}}, \mathbf{g}\left(\mathbf{f}^{\mathbf{i}}(\mathbf{x})\right)=\mathbf{x}$. In particular, $\mathbf{g}_{\mathbf{i}_{c}}\left(\mathbf{f}^{\mathbf{1}}(\mathbf{x})\right)=\mathbf{x}_{\mathbf{i}_{c}}$ where

$$
\mathbf{g}_{\mathbf{i}}(\mathbf{y}) \equiv\left(\begin{array}{lll}
g_{i_{1}}(\mathbf{y}) & \cdots & g_{i_{m}}(\mathbf{y})
\end{array}\right)^{T}
$$

for $\mathbf{i} \equiv\left(i_{1}, \cdots, i_{m}\right)$ with $\mathbf{g}_{\mathbf{i}_{c}}(\mathbf{y})$ defined similarly and $\mathbf{x} \in E_{j}^{\mathbf{i}}$, with

$$
\begin{gather*}
\mathbf{y} \equiv\binom{\mathbf{y}_{1}}{\mathbf{y}_{2}} \equiv\binom{\mathbf{f}(\mathbf{x})}{\mathbf{x}_{\mathbf{i}_{c}}} \equiv \mathbf{f}^{\mathbf{i}}(\mathbf{x}) \in \mathbf{f}^{\mathbf{i}}\left(E_{j}^{\mathbf{i}}\right), \\
\mathbf{x}_{\mathbf{i}}=\mathbf{g}_{\mathbf{i}}\left(\mathbf{f}^{\mathbf{i}}(\mathbf{x})\right), \mathbf{y}_{2} \equiv \mathbf{x}_{\mathbf{i}_{c}}=\mathbf{g}_{\mathbf{i}_{c}}\left(\mathbf{f}^{\mathbf{i}}(\mathbf{x})\right) \tag{29.9.49}
\end{gather*}
$$

Then, by definition,

$$
\begin{equation*}
\int_{A} J^{*}(\mathbf{x}) d x \equiv \int_{A} \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2} d x \tag{29.9.50}
\end{equation*}
$$

First, using Theorem 29.8.2, and the fact that Lipschitz mappings take sets of measure zero to sets of measure zero, replace $E_{j}^{\mathbf{i}}$ with $\widetilde{E}_{j}^{\mathbf{i}} \subseteq E_{j}^{\mathbf{i}}$ such that $E_{j}^{\mathbf{i}} \backslash \widetilde{E}_{j}^{\mathbf{i}}$ has measure zero and

$$
\begin{equation*}
D \mathbf{f}^{\mathbf{i}}(\mathbf{g}(\mathbf{y})) D \mathbf{g}(\mathbf{y})=I,|\operatorname{det}(D \mathbf{g}(\mathbf{y}))|=\left|\operatorname{det} D \mathbf{f}^{\mathbf{i}}(\mathbf{g}(\mathbf{y}))\right|^{-1} \tag{29.9.51}
\end{equation*}
$$

on $\mathbf{f}^{\mathbf{i}}\left(\widetilde{E}_{j}^{\mathbf{i}}\right)$. Changing the variables using the area formula and 29.9.51, the expression in 29.9.50 equals

$$
\begin{align*}
& \int_{A} J^{*}(\mathbf{x}) d x=\sum_{j=1}^{\infty} \sum_{\mathbf{i} \in \Lambda(n, m)} \int_{\widetilde{E}_{j}^{\mathbf{i}} \cap A}\left(\operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)\right)^{1 / 2} d x \\
&=\sum_{j=1}^{\infty} \sum_{\mathbf{i} \in \Lambda(n, m)} \int_{E_{j}^{\mathbf{i}} \cap A}\left(\operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)\right)^{1 / 2} d x \\
&=\sum_{j=1}^{\infty} \sum_{\mathbf{i} \in \Lambda(n, m)} \int_{\mathbf{f}^{\mathbf{i}}\left(E_{j}^{\mathbf{i}} \cap A\right)}\left(\operatorname{det}\left(D \mathbf{f}(\mathbf{g}(\mathbf{y})) D \mathbf{f}(\mathbf{g}(\mathbf{y}))^{*}\right)\right)^{1 / 2}\left|\operatorname{det} D \mathbf{f}^{\mathbf{i}}(\mathbf{g}(\mathbf{y}))\right|^{-1} d y \tag{29.9.52}
\end{align*}
$$

Recall everything is Borel measurable. I will consider one of the integrals in the sum. For convenience, replace $E_{j}^{\mathbf{i}}$ with a compact set, $K_{j}^{\mathbf{i}}$ contained in it to obtain Borel measurability in what follows.

$$
\begin{gather*}
\int_{K_{j}^{\mathrm{i}} \cap A} \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2} d x  \tag{29.9.53}\\
=\int_{\mathbf{f}^{\mathrm{i}}\left(K_{j}^{\mathbf{i}} \cap A\right)} \operatorname{det}\left(D \mathbf{f}(\mathbf{g}(\mathbf{y})) D \mathbf{f}(\mathbf{g}(\mathbf{y}))^{*}\right)^{1 / 2}|D \mathbf{g}(\mathbf{y})| d y \\
=\int_{\mathbf{f}^{\mathbf{i}}\left(K_{j}^{\mathrm{i}} \cap A\right)} \operatorname{det}\left(D \mathbf{f}(\mathbf{g}(\mathbf{y})) D \mathbf{f}(\mathbf{g}(\mathbf{y}))^{*}\right)^{1 / 2}\left|\operatorname{det} D \mathbf{f}^{\mathbf{i}}(\mathbf{g}(\mathbf{y}))\right|^{-1} d y
\end{gather*}
$$

Now $\binom{\mathbf{y}_{1}}{\mathbf{y}_{2}}=\mathbf{f}^{\mathbf{i}}(\mathbf{x})=\binom{\mathbf{f}(\mathbf{x})}{\mathbf{x}_{\mathbf{i}_{c}}}$ for $\mathbf{x} \in K_{j}^{\mathbf{i}} \cap A$ if and only if $\mathbf{x}$ is also in $\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right)$ which recall is a vector in $\mathbb{R}^{n}$. Therefore, by 29.9.47, the above equals the following iterated integral.

$$
\begin{equation*}
=\int_{\mathbb{R}^{m}} \int_{\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A} \operatorname{det}\left(D \mathbf{f}(\mathbf{g}(\mathbf{y})) D \mathbf{f}(\mathbf{g}(\mathbf{y}))^{*}\right)^{1 / 2}\left|\operatorname{det} D \mathbf{f}_{\mathbf{x}_{\mathbf{i}}}(\mathbf{g}(\mathbf{y}))\right|^{-1} d y_{2} d y_{1} \tag{29.9.54}
\end{equation*}
$$

where $\mathbf{y}_{1}=\mathbf{f}(\mathbf{x})$ and $\mathbf{y}_{2}=\mathbf{x}_{\mathbf{i}_{c}}$. Since $\mathbf{y}_{1}$ is fixed in the inner integral of 29.9.54, and $\mathbf{y}_{1}=$ $\mathbf{f}(\mathbf{g}(\mathbf{y}))$, and by definition $\mathbf{g}_{\mathbf{i}_{c}}\left(\mathbf{f}^{\mathbf{i}}(\mathbf{x})\right)=\mathbf{y}_{2}$, one can take the partial derivative of $\mathbf{y}_{1}=$ $\mathbf{f}(\mathbf{g}(\mathbf{y}))$ with respect to $\mathbf{y}_{2}$ to obtain

$$
\begin{align*}
\mathbf{0} & =D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{g}(\mathbf{y})) D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}}(\mathbf{y})+D_{\mathbf{x}_{\mathbf{i}_{c}}} \mathbf{f}(\mathbf{g}(\mathbf{y})) D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}_{c}}(\mathbf{y}) \\
& =D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{g}(\mathbf{y})) D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}}(\mathbf{y})+D_{\mathbf{x}_{\mathbf{i}_{c}}} \mathbf{f}(\mathbf{g}(\mathbf{y})) \tag{29.9.55}
\end{align*}
$$

Now consider the inner integral in 29.9.54 in which $\mathbf{y}_{1}$ is fixed. The integrand equals

$$
\begin{equation*}
\operatorname{det}\left[\left(D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{g}(\mathbf{y})) D_{\mathbf{x}_{\mathbf{i}_{c}}} \mathbf{f}(\mathbf{g}(\mathbf{y}))\right)\binom{D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{g}(\mathbf{y}))^{*}}{D_{\mathbf{x}_{\mathbf{i}_{c}}} \mathbf{f}(\mathbf{g}(\mathbf{y}))^{*}}\right]^{1 / 2}\left|\operatorname{det} D \mathbf{f}_{\mathbf{x}_{\mathbf{i}}}(\mathbf{g}(\mathbf{y}))\right|^{-1} . \tag{29.9.56}
\end{equation*}
$$

Let $A \equiv D_{\mathbf{x}_{\mathbf{i}}} \mathbf{f}(\mathbf{g}(\mathbf{y}))$ so $A$ is $m \times m$ and $B \equiv D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}}(\mathbf{y})$ an $m \times(n-m)$, and using 29.9.55, 29.9.56 is of the form

$$
\begin{aligned}
& \operatorname{det}\left[\left(\begin{array}{ll}
A & -A B
\end{array}\right)\binom{A^{*}}{-B^{*} A^{*}}\right]^{1 / 2}|\operatorname{det} A|^{-1} \\
= & \operatorname{det}\left[A A^{*}+A B B^{*} A^{*}\right]^{1 / 2}|\operatorname{det} A|^{-1} \\
= & \operatorname{det}\left[A\left(I+B B^{*}\right) A^{*}\right]^{1 / 2}|\operatorname{det} A|^{-1}=\operatorname{det}\left(I+B B^{*}\right)^{1 / 2}
\end{aligned}
$$

which, by Corollary 29.9.2, equals $\operatorname{det}\left(I+B^{*} B\right)^{1 / 2}$. (Note the size of the identity changes in these two expressions.) Since $B=D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}}(\mathbf{y})$ and $D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{g}_{c}}(\mathbf{y})=I$, the above reduces to

$$
\begin{gathered}
\operatorname{det}\left(I+B^{*} B\right)^{1 / 2}=\operatorname{det}\left[\left(\begin{array}{cc}
B^{*} & I
\end{array}\right)\binom{B}{I}\right]^{1 / 2}= \\
\operatorname{det}\left[\left(\begin{array}{ll}
D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}}(\mathbf{y})^{*} & D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}_{c}}(\mathbf{y})^{*}
\end{array}\right)\binom{D_{\mathbf{y}_{2}} \mathbf{g}_{\mathbf{i}}(\mathbf{y})}{D_{\mathbf{y}_{2}} \mathbf{g}_{c}(\mathbf{y})}\right]^{1 / 2}=\operatorname{det}\left(D_{\mathbf{y}_{2}} \mathbf{g}(\mathbf{y})^{*} D_{\mathbf{y}_{2}} \mathbf{g}(\mathbf{y})\right)^{1 / 2}
\end{gathered}
$$

Therefore, 29.9.53 reduces to $\int_{K_{j}^{\mathbf{i}} \cap A} \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2} d x=$

$$
\begin{equation*}
\int_{\mathbb{R}^{m}} \int_{\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A} \operatorname{det}\left(D_{\mathbf{y}_{2}} \mathbf{g}(\mathbf{y})^{*} D_{\mathbf{y}_{2}} \mathbf{g}(\mathbf{y})\right)^{1 / 2} d y_{2} d y_{1} \tag{29.9.57}
\end{equation*}
$$

Then $\mathbf{z} \in \mathbf{g}\left(\mathbf{y}_{1}, \mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A\right)$ if and only if

$$
\mathbf{f}^{\mathbf{i}}(\mathbf{z})=\binom{\mathbf{f}(\mathbf{z})}{\mathbf{z}_{\mathbf{i}_{c}}} \in\binom{\mathbf{y}_{1}}{\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A}
$$

if and only if $\mathbf{z} \in \mathbf{f}^{-1}\left(\mathbf{y}_{1}\right)$ and $\mathbf{z}_{\mathbf{i}_{c}} \in \mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A$. Letting $\hat{\mathbf{g}}$ be the function $\mathbf{y}_{2} \rightarrow$ $\mathbf{g}\left(\mathbf{y}_{1}, \mathbf{y}_{2}\right)$, this shows that $\mathbf{z} \in \hat{\mathbf{g}}\left(\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A\right)$ if and only if $\mathbf{y}_{2}=\mathbf{z}_{\mathbf{i}_{c}} \in \mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A$ and so $\hat{\mathbf{g}}\left(\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A\right)=\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A$. Of course $\hat{\mathbf{g}}$ actually depends on $\mathbf{y}_{1}$ but this is suppressed here. Therefore,

$$
\mathbf{g}\left(\mathbf{y}_{1}, \mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A\right)=\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A
$$

By this observation and the area formula, the equations 29.9.53, 29.9.57 imply

$$
\int_{K_{j}^{\mathrm{i}} \cap A} \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2} d x=\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{f}^{-1}\left(\mathbf{y}_{1}\right) \cap K_{j}^{\mathbf{i}} \cap A\right) d y_{1} .
$$

Using Lemmas 29.9 .6 and 29.9.5, along with the inner regularity of Lebesgue measure, $K_{j}^{\mathbf{i}}$ can be replaced with $E_{j}^{\mathbf{i}}$. Therefore, summing the terms over all $\mathbf{i}$ and $j$,

$$
\int_{A} \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2} d x=\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{f}^{-1}(\mathbf{y}) \cap A\right) d y
$$

which verifies the coarea formula whenever $A$ is a closed subset of $\mathbb{R}^{n} \backslash\{S \cup N\}$.
By Lemma 29.9.6 again, this formula is true for all $A$ a closed subset of $\mathbb{R}^{n} \backslash S$. Using the same two lemmas again, we see this coarea formula holds for all $A$ a measurable subset of $\mathbb{R}^{n} \backslash S$.

It remains to verify the formula for all measurable sets $A$, regardless of whether they intersect $S$. Recall

$$
S \equiv\left\{\mathbf{x}: \sum_{\mathbf{i}} \operatorname{det}\left(D \mathbf{f}^{\mathbf{i}}(\mathbf{x})\right)^{2}=0\right\}=\left\{\mathbf{x}: \operatorname{det} U(\mathbf{x}) \equiv J^{*}(\mathbf{x})=0\right\}
$$

Consider the case where $A \subseteq S$. Let $A$ be compact so that by Lemma 29.9.5, $\mathbf{y} \rightarrow$ $\mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right)$ is Borel measurable. For $\varepsilon>0$, define $\mathbf{k}_{\varepsilon}, \mathbf{p}: \mathbb{R}^{n} \times \mathbb{R}^{m} \rightarrow \mathbb{R}^{m}$ by

$$
\mathbf{k}_{\varepsilon}(\mathbf{x}, \mathbf{z}) \equiv \mathbf{f}(\mathbf{x})+\varepsilon \mathbf{z}, \mathbf{p}(\mathbf{x}, \mathbf{z}) \equiv \mathbf{z}
$$

Then $D \mathbf{k}_{\varepsilon}(\mathbf{x}, \mathbf{z})=\left(\begin{array}{ll}D \mathbf{f}(\mathbf{x}) & \varepsilon I\end{array}\right)=\left(\begin{array}{ll}U R & \varepsilon I\end{array}\right)$ where the dependence of $U$ and $R$ on $\mathbf{x}$ has been suppressed. Here $R R^{*}=I$ and $U$ is a non-negative symmetric transformation. Thus

$$
\left(\begin{array}{ll}
\left.J^{*} \mathbf{k}_{\varepsilon}\right)^{2}=\operatorname{det}\left(\begin{array}{ll}
U R & \varepsilon I
\end{array}\right)\binom{R^{*} U}{\varepsilon I}=\operatorname{det}\left(U^{2}+\varepsilon^{2} I\right), ~\left(\begin{array}{ll}
\end{array}\right) .
\end{array}\right.
$$

$$
\begin{gather*}
=\operatorname{det}\left(Q^{*} D Q Q^{*} D Q+\varepsilon^{2} I\right)=\operatorname{det}\left(D^{2}+\varepsilon^{2} I\right) \\
=\prod_{i=1}^{m}\left(\lambda_{i}^{2}+\varepsilon^{2}\right) \in\left[\varepsilon^{2 m}, C^{2} \varepsilon^{2}\right] \tag{29.9.58}
\end{gather*}
$$

since one of the $\lambda_{i}$ equals 0 due to $\operatorname{det}(U)=0$. All the eigenvalues of $U$ must be bounded independent of $\mathbf{x}$, since $\|D \mathbf{f}(\mathbf{x})\|$ is bounded independent of $\mathbf{x}$ due to the assumption that $\mathbf{f}$ is Lipschitz. Since the corresponding $S=\emptyset$, the first part of the argument implies

$$
\begin{gather*}
\varepsilon C m_{n+m}(A \times \overline{B(\mathbf{0}, 1)}) \geq \int_{A \times B \overline{(\mathbf{0}, 1)}}\left|J^{*} \mathbf{k}_{\varepsilon}\right| d m_{n+m} \\
=\int_{\mathbb{R}^{m}} \mathscr{H}^{n}\left(\mathbf{k}_{\varepsilon}^{-1}(\mathbf{y}) \cap A \times \overline{B(\mathbf{0}, 1)}\right) d y \tag{29.9.59}
\end{gather*}
$$

Now it is clear that $\mathbf{k}_{\varepsilon}^{-1}(\underline{y}) \supseteq \mathbf{f}^{-1}(\mathbf{y})$. Indeed, if $\mathbf{f}(\mathbf{x})=\mathbf{y}$, then $\mathbf{f}(\mathbf{x})+\varepsilon \mathbf{0}=\mathbf{y}$.
Note that $A \subseteq \mathbb{R}^{n}$ and $\overline{B(\mathbf{0}, 1)} \in \mathbb{R}^{m}$. By Lemma 29.9.4, and what was just noted,

$$
\begin{gathered}
\mathscr{H}^{n}\left(\mathbf{k}_{\varepsilon}^{-1}(\mathbf{y}) \cap A \times \overline{B(\mathbf{0}, 1)}\right) \geq \\
C_{n m} \frac{1}{(\operatorname{Lip}(\mathbf{p}))^{m}} \int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{k}_{\varepsilon}^{-1}(\mathbf{y}) \cap \mathbf{p}^{-1}(\mathbf{w}) \cap A \times \overline{B(\mathbf{0}, 1)}\right) d w
\end{gathered}
$$

Therefore, from 29.9.59,

$$
\begin{gather*}
\varepsilon C m_{n+m}(A \times \overline{B(\mathbf{0}, 1)}) \geq \\
C_{n m} \int_{\mathbb{R}^{m}} \int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{k}_{\varepsilon}^{-1}(\mathbf{y}) \cap \mathbf{p}^{-1}(\mathbf{w}) \cap A \times \overline{B(\mathbf{0}, 1)}\right) d w d y  \tag{29.9.60}\\
\geq C_{n m} \int_{\mathbb{R}^{m}} \int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{f}^{-1}(\mathbf{y}) \cap \mathbf{p}^{-1}(\mathbf{w}) \cap A \times \overline{B(\mathbf{0}, 1)}\right) d w d y
\end{gather*}
$$

The inside set is $\mathbf{f}^{-1}(\mathbf{y}) \cap \mathbf{p}^{-1}(\mathbf{w}) \cap A \times \overline{B(\mathbf{0}, 1)}$. That is,

$$
\{(\mathbf{x}, \mathbf{w}) \in A \times \overline{B(\mathbf{0}, 1)}: \mathbf{f}(\mathbf{x})=\mathbf{y}\}
$$

thus the set inside $\mathscr{H}^{n-m}$ is $\left(\mathbf{f}^{-1}(\mathbf{y}) \cap A\right) \times \overline{B(\mathbf{0}, 1)}$, then continuing the chain of inequalities,

$$
\begin{aligned}
& \geq C_{n m} \int_{\mathbb{R}^{m}} \int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\left(\mathbf{f}^{-1}(\mathbf{y}) \cap A\right) \times \overline{B(\mathbf{0}, 1)}\right) d w d y \\
& \geq C_{n m} \int_{\mathbb{R}^{m}} \int_{\overline{B(\mathbf{0}, 1)}} \mathscr{H}^{n-m}\left(\mathbf{f}^{-1}(\mathbf{y}) \cap A\right) d w d y \\
& \quad=\quad C_{n m} \int_{\overline{B(\mathbf{0}, 1)}} \int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{f}^{-1}(\mathbf{y}) \cap A\right) d y d w \\
& \quad=C_{n m} \alpha_{n} \int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{f}^{-1}(\mathbf{y}) \cap A\right) d y
\end{aligned}
$$

Since $\varepsilon$ is arbitrary in 29.9.60, this shows that $\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(\mathbf{f}^{-1}(\mathbf{y}) \cap A\right) d y=0=\int_{A} J^{*}(\mathbf{x}) d x$. Since this holds for arbitrary compact sets in $S$, it follows from Lemma 29.9.6 and inner regularity of Lebesgue measure that the equation holds for all measurable subsets of $S$. This completes the proof of the coarea formula.

There is a simple corollary to this theorem in the case of locally Lipschitz maps.
Corollary 29.9.9 Let $\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ where $m \leq n$ and $\mathbf{f}$ is locally Lipschitz. This means that for each $r>0, \mathbf{f}$ is Lipschitz on $B(\mathbf{0}, r)$. Then the coarea formula, 29.9.48, holds for $\mathbf{f}$.

Proof: Let $A \subseteq B(\mathbf{0}, r)$ and let $\mathbf{f}_{r}$ be Lipschitz with $\mathbf{f}(\mathbf{x})=\mathbf{f}_{r}(\mathbf{x})$ for $\mathbf{x} \in B(\mathbf{0}, r+1)$. Then

$$
\begin{gathered}
\int_{A} J^{*} \mathbf{f}(\mathbf{x}) d x=\int_{A} J\left(D \mathbf{f}_{r}(\mathbf{x})\right) d x=\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}_{r}^{-1}(\mathbf{y})\right) d y \\
=\int_{\mathbf{f}_{r}(A)} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}_{r}^{-1}(\mathbf{y})\right) d y=\int_{\mathbf{f}(A)} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y \\
=\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y
\end{gathered}
$$

Now for arbitrary measurable $A$ the above shows for $k=1,2, \cdots$

$$
\int_{A \cap B(\mathbf{0}, k)} J^{*} \mathbf{f}(\mathbf{x}) d x=\int_{\mathbb{R}^{m}} \mathscr{H}^{n-m}\left(A \cap B(\mathbf{0}, k) \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y
$$

Use the monotone convergence theorem to obtain 29.9.48.
From the definition of Hausdorff measure, it is easy to verify that $\mathscr{H}^{0}(E)$ equals the number of elements in $E$. Thus, if $n=m$, the Coarea formula implies

$$
\int_{A} J^{*} \mathbf{f}(\mathbf{x}) d x=\int_{\mathbf{f}(A)} \mathscr{H}^{0}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y=\int_{\mathbf{f}(A)} \#(y) d y
$$

Note also that this gives a version of Sard's theorem by letting $S=A$.

### 29.10 Change of Variables

We say that the coarea formula holds for $\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}, n \geq m$ if whenever $A$ is a Lebesgue measurable subset of $\mathbb{R}^{n}, 29.9 .48$ holds. Note this is the same as

$$
\int_{A} J^{*}(\mathbf{x}) d x=\int_{\mathbf{f}(A)} \mathscr{H}^{n-m}\left(A \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y, J^{*}(\mathbf{x}) \equiv \operatorname{det}\left(D \mathbf{f}(\mathbf{x}) D \mathbf{f}(\mathbf{x})^{*}\right)^{1 / 2}
$$

Now let $s(\mathbf{x})=\sum_{i=1}^{p} c_{i} \mathscr{X}_{E_{i}}(\mathbf{x})$ where $E_{i}$ is measurable and $c_{i} \geq 0$. Then

$$
\begin{gather*}
\int_{\mathbb{R}^{n}} s(\mathbf{x}) J^{*} \mathbf{f}(\mathbf{x}) d x=\sum_{i=1}^{p} c_{i} \int_{E_{i}} J^{*} \mathbf{f}(\mathbf{x}) d x=\sum_{i=1}^{p} c_{i} \int_{\mathbf{f}\left(E_{i}\right)} \mathscr{H}^{n-m}\left(E_{i} \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y \\
=\int_{\mathbf{f}\left(\mathbb{R}^{n}\right)} \sum_{i=1}^{p} c_{i} \mathscr{H}^{n-m}\left(E_{i} \cap \mathbf{f}^{-1}(\mathbf{y})\right) d y=\int_{\mathbf{f}\left(\mathbb{R}^{n}\right)}\left[\int_{\mathbf{f}^{-1}(\mathbf{y})} s d \mathscr{H}^{n-m}\right] d y \\
=\int_{\mathbf{f}\left(\mathbb{R}^{n}\right)}\left[\int_{\mathbf{f}^{-1}(\mathbf{y})} s d \mathscr{H}^{n-m}\right] d y \tag{29.10.61}
\end{gather*}
$$

Theorem 29.10.1 Let $g \geq 0$ be Lebesgue measurable and let

$$
\mathbf{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}, n \geq m
$$

satisfy the Coarea formula. Then

$$
\int_{\mathbb{R}^{n}} g(\mathbf{x}) J^{*} \mathbf{f}(\mathbf{x}) d x=\int_{\mathbf{f}\left(\mathbb{R}^{n}\right)}\left[\int_{\mathbf{f}^{-1}(\mathbf{y})} g d \mathscr{H}^{n-m}\right] d y .
$$

Proof: Let $s_{i} \uparrow g$ where $s_{i}$ is a simple function satisfying 29.10.61. Then let $i \rightarrow \infty$ and use the monotone convergence theorem to replace $s_{i}$ with $g$. This proves the change of variables formula.

Note that this formula is a nonlinear version of Fubini's theorem. The " $n-m$ dimensional surface", $\mathbf{f}^{-1}(\mathbf{y})$, plays the role of $\mathbb{R}^{n-m}$ and $\mathscr{H}^{n-m}$ is like $n-m$ dimensional Lebesgue measure. The term, $J^{*} \mathbf{f}(\mathbf{x})$, corrects for the error occurring because of the lack of flatness of $\mathbf{f}^{-1}(\mathbf{y})$.

The following is an easy example of the use of the coarea formula to give a familiar relation.

Example 29.10.2 Let $f: \mathbb{R}^{n} \rightarrow \mathbb{R}$ be given by $f(\mathbf{x}) \equiv|\mathbf{x}|$. Then $J^{*}(\mathbf{x})$ ends up being 1 . Then by the coarea formula,

$$
\int_{B(\mathbf{0}, r)} d m_{n}=\int_{0}^{r} \mathscr{H}^{n-1}\left(B(\mathbf{0}, r) \cap f^{-1}(y)\right) d y=\int_{0}^{r} \mathscr{H}^{n-1}(\partial B(\mathbf{0}, y)) d y
$$

Then $m_{n}(B(\mathbf{0}, r)) \equiv \alpha_{n} r^{n}=\int_{0}^{r} \mathscr{H}^{n-1}(\partial B(\mathbf{0}, y)) d y$. Then differentiate both sides to obtain $n \alpha_{n} r^{n-1}=\mathscr{H}^{n-1}(\partial B(\mathbf{0}, r))$. In particular $\mathscr{H}^{2}(\partial B(\mathbf{0}, r))=3 \frac{4}{3} \pi r^{2}=4 \pi r^{2}$. Of course $\alpha_{n}$ was computed earlier. Recall from Theorem 28.4.2 on Page 1005

$$
\alpha_{n}=\pi^{n / 2}(\Gamma(n / 2+1))^{-1}
$$

Therefore, the $n-1$ dimensional Hausdorf measure of the boundary of the ball of radius $r$ in $\mathbb{R}^{n}$ is $n \pi^{p / 2}(\Gamma(n / 2+1))^{-1} r^{n-1}$.

I think it is clear that you could generalize this to other more complicated situations. The above is nice because $J^{*}(\mathbf{x})=1$. This won't be so in general when considering other level surfaces.

### 29.11 Integration and the Degree

There is a very interesting application of the degree to integration [52]. Recall Lemma 23.1.11. I want to generalize this to the case where $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ is only Lipschitz continuous, vanishing outside a bounded set. In the following proposition, let $\phi_{\varepsilon}$ be a symmetric nonnegative mollifier,

$$
\phi_{\varepsilon}(\mathbf{x}) \equiv \frac{1}{\varepsilon^{n}} \phi\left(\frac{\mathbf{x}}{\varepsilon}\right), \operatorname{spt} \phi \subseteq B(\mathbf{0}, 1) .
$$

$\Omega$ will be a bounded open set. By Theorem 26.6.7, h satisfies

$$
\begin{equation*}
D \mathbf{h}(\mathbf{x}) \text { exists a.e., } \tag{29.11.62}
\end{equation*}
$$

For any $p>n$,

$$
\begin{equation*}
\lim _{m \rightarrow \infty} D\left(\mathbf{h} * \psi_{m}\right)=D \mathbf{h} \text { in } L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n \times n}\right) \tag{29.11.63}
\end{equation*}
$$

where $\psi_{m}$ is a mollifier.
Proposition 29.11.1 Let $S \subseteq \mathbf{h}(\partial \Omega)^{C}$ such that

$$
\operatorname{dist}(S, \mathbf{h}(\partial \Omega))>0
$$

where $\Omega$ is a bounded open set and also let $\mathbf{h}$ be Lipschitz continuous, vanishing outside some bounded set. Then whenever $\varepsilon>0$ is small enough,

$$
d(\mathbf{h}, \Omega, \mathbf{y})=\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x
$$

for all $\mathbf{y} \in S$.
Proof: Let $\varepsilon_{0}>0$ be small enough that for all $\mathbf{y} \in S$,

$$
B\left(\mathbf{y}, 5 \varepsilon_{0}\right) \cap \mathbf{h}(\partial \Omega)=\emptyset
$$

Now let $\psi_{m}$ be a mollifier as $m \rightarrow \infty$ with support in $B\left(\mathbf{0}, m^{-1}\right)$ and let

$$
\mathbf{h}_{m} \equiv \mathbf{h} * \psi_{m}
$$

Thus $\mathbf{h}_{m} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$ and for any $p>n$,

$$
\begin{equation*}
\left\|\mathbf{h}_{m}-\mathbf{h}\right\|_{L^{\infty}(\Omega)},\left\|D \mathbf{h}_{m}-D \mathbf{h}\right\|_{L^{p}(\Omega)} \rightarrow 0 \tag{29.11.64}
\end{equation*}
$$

as $m \rightarrow \infty$. The first claim above is obvious and the second follows by 29.11.63. Choose $M$ such that for $m \geq M$,

$$
\begin{equation*}
\left\|\mathbf{h}_{m}-\mathbf{h}\right\|_{\infty}<\varepsilon_{0} \tag{29.11.65}
\end{equation*}
$$

Thus $\mathbf{h}_{m} \in \mathscr{U}_{\mathbf{y}} \cap C^{2}\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$ for all $\mathbf{y} \in S$.
For $\mathbf{y} \in S$, let $\mathbf{z} \in B(\mathbf{y}, \varepsilon)$ where $\varepsilon<\varepsilon_{0}$ and suppose $\mathbf{x} \in \partial \Omega$, and $k, m \geq M$. Then for $t \in[0,1]$,

$$
\begin{aligned}
\left|(1-t) \mathbf{h}_{m}(\mathbf{x})+\mathbf{h}_{k}(\mathbf{x}) t-\mathbf{z}\right| & \geq\left|\mathbf{h}_{m}(\mathbf{x})-\mathbf{z}\right|-t\left|\mathbf{h}_{k}(\mathbf{x})-\mathbf{h}_{m}(\mathbf{x})\right| \\
& >2 \varepsilon_{0}-t 2 \varepsilon_{0} \geq 0
\end{aligned}
$$

showing that for each $\mathbf{y} \in S, B(\mathbf{y}, \varepsilon) \cap\left((1-t) \mathbf{h}_{m}+t \mathbf{h}_{k}\right)(\partial \Omega)=\emptyset$. By Lemma 23.1.11, for all $\mathbf{y} \in S$,

$$
\begin{gather*}
\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x= \\
\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{k}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{k}(\mathbf{x})\right) d x \tag{29.11.66}
\end{gather*}
$$

for all $k, m \geq M$. By this lemma again, which says that for small enough $\varepsilon$ the integral is constant and the definition of the degree in Definition 23.1.10,

$$
\begin{equation*}
d\left(\mathbf{y}, \Omega, \mathbf{h}_{m}\right)=\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x \tag{29.11.67}
\end{equation*}
$$

for all $\varepsilon$ small enough. For $\mathbf{x} \in \partial \Omega, \mathbf{y} \in S$, and $t \in[0,1]$,

$$
\begin{aligned}
\left|(1-t) \mathbf{h}(\mathbf{x})+\mathbf{h}_{m}(\mathbf{x}) t-\mathbf{y}\right| & \geq|\mathbf{h}(\mathbf{x})-\mathbf{y}|-t\left|\mathbf{h}(\mathbf{x})-\mathbf{h}_{m}(\mathbf{x})\right| \\
& >3 \varepsilon_{0}-t 2 \varepsilon_{0}>0
\end{aligned}
$$

and so by Theorem 23.2.2, the part about homotopy, for each $\mathbf{y} \in S$,

$$
\begin{gathered}
d(\mathbf{y}, \Omega, \mathbf{h})=d\left(\mathbf{y}, \Omega, \mathbf{h}_{m}\right)= \\
\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x
\end{gathered}
$$

whenever $\varepsilon$ is small enough. Fix such an $\varepsilon<\varepsilon_{0}$ and use 29.11.66 to conclude the right side of the above equation is independent of $m>M$.

By 29.11.64, there exists a subsequence still denoted by $m$ such that $D \mathbf{h}_{m}(\mathbf{x}) \rightarrow D \mathbf{h}(\mathbf{x})$ a.e. Since $p>n$, $\operatorname{det}\left(D \mathbf{h}_{m}\right)$ is bounded in $L^{r}(\Omega)$ for some $r>1$ and so the integrands in the following are uniformly integrable. By the Vitali convergence theorem, one can pass to the limit as follows.

$$
\begin{aligned}
d(\mathbf{y}, \Omega, \mathbf{h}) & =\lim _{m \rightarrow \infty} \int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x \\
& =\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det}(D \mathbf{h}(\mathbf{x})) d x
\end{aligned}
$$

This proves the proposition.
Next is an interesting change of variables theorem. Let $\Omega$ be a bounded open set with the property that $\partial \Omega$ has measure zero and let $\mathbf{h}$ be Lipschitz continuous on $\mathbb{R}^{n}$. Then from Lemma 29.1.1, $\mathbf{h}(\partial \Omega)$ also has measure zero.

Now suppose $f \in C_{c}\left(\mathbf{h}(\partial \Omega)^{C}\right)$. There are finitely many components of $\mathbf{h}(\partial \Omega)^{C}$ which have nonempty intersection with $\operatorname{spt}(f)$. From the Proposition above,

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int f(\mathbf{y}) \lim _{\varepsilon \rightarrow 0} \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x d y
$$

Actually, there exists an $\varepsilon$ small enough that for all $\mathbf{y} \in \operatorname{spt}(f)$,

$$
\begin{aligned}
\lim _{\varepsilon \rightarrow 0} \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x & =\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x \\
& =d(\mathbf{y}, \Omega, \mathbf{h})
\end{aligned}
$$

This is because $\operatorname{spt}(f)$ is at a positive distance from the compact set $\mathbf{h}(\partial \Omega)^{C}$. Therefore, for all $\varepsilon$ small enough,

$$
\begin{aligned}
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y & =\iint_{\Omega} f(\mathbf{y}) \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x d y \\
& =\int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int f(\mathbf{y}) \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) d y d x
\end{aligned}
$$

Using the uniform continuity of $f$, you can now pass to a limit and obtain using the fact that $\operatorname{det} D \mathbf{h}(\mathbf{x})$ is in $L^{r}\left(\mathbb{R}^{n}\right)$ for some $r>1$,

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} f(\mathbf{h}(\mathbf{x})) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x
$$

This has proved the following interesting lemma.
Lemma 29.11.2 Let $f \in C_{c}\left(\mathbf{h}(\partial \Omega)^{C}\right)$ for $\Omega$ a bounded open set and let $\mathbf{h}$ be Lipschitz on $\mathbb{R}^{n}$. Say $\partial \Omega$ has measure zero so that $\mathbf{h}(\partial \Omega)$ has measure zero. Then everything is measurable which needs to be and

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} \operatorname{det}(D \mathbf{h}(\mathbf{x})) f(\mathbf{h}(\mathbf{x})) d x
$$

Note that $\mathbf{h}$ is not necessarily one to one. Next is a simple corollary which replaces $C_{c}\left(\mathbb{R}^{n}\right)$ with $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$ in the case that $\mathbf{h}$ is one to one. Also another assumption is made on there being finitely many components.

Corollary 29.11.3 Let $f \in L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$ and let $\mathbf{h}$ be one to one and satisfy 29.11.62-29.11.63, $\partial \Omega$ has measure zero for $\Omega$ a bounded open set and $\mathbf{h}(\partial \Omega)^{C}$ has finitely many components. Then everything is measurable which needs to be and

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) f(\mathbf{h}(\mathbf{x})) d x
$$

Proof: Since $d(\mathbf{y}, \Omega, \mathbf{h})=0$ for all $|\mathbf{y}|$ large enough due to $\mathbf{y} \notin \mathbf{h}(\Omega)$ for large $\mathbf{y}$, there is no loss of generality in assuming $f$ is in $L^{1}\left(\mathbb{R}^{n}\right)$. For all $\mathbf{y} \notin \mathbf{h}(\partial \Omega)$, a set of measure zero, $d(\mathbf{y}, \Omega, \mathbf{h})$ is bounded by some constant, depending on the maximum of the degree on the various components of $\mathbf{h}(\partial \Omega)^{C}$. Then from Proposition 29.11.1

$$
\begin{equation*}
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int f(\mathbf{y}) \lim _{\varepsilon \rightarrow 0} \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x d y \tag{29.11.68}
\end{equation*}
$$

This time, use the area formula to write

$$
\begin{gathered}
\left|\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x\right| \leq \int_{\mathbb{R}^{n}} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y})|\operatorname{det} D \mathbf{h}(\mathbf{x})| d x \\
\leq K \int_{\mathbb{R}^{n}} \phi_{\varepsilon}(\mathbf{z}-\mathbf{y}) d z<\infty
\end{gathered}
$$

and so using the dominated convergence theorem in 29.11.68, it equals

$$
\begin{aligned}
& \lim _{\varepsilon \rightarrow 0} \int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int f(\mathbf{y}) \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) d y d x \\
= & \lim _{\varepsilon \rightarrow 0} \int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int f(\mathbf{h}(\mathbf{x})-\mathbf{y}) \phi_{\varepsilon}(\mathbf{y}) d y d x \\
= & \lim _{\varepsilon \rightarrow 0} \int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int_{B(0,1)} f(\mathbf{h}(\mathbf{x})-\varepsilon \mathbf{u}) \phi(\mathbf{u}) d u d x
\end{aligned}
$$

Now

$$
\begin{gathered}
\mid \int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int_{B(\mathbf{0}, 1)} f(\mathbf{h}(\mathbf{x})-\varepsilon \mathbf{u}) \phi(\mathbf{u}) d u d x \\
-\int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) f(\mathbf{h}(\mathbf{x})) d x \mid \leq \\
\left|\int_{B(\mathbf{0}, 1)} \int_{\Omega}\right| \operatorname{det} D \mathbf{h}(\mathbf{x})||f(\mathbf{h}(\mathbf{x})-\varepsilon \mathbf{u})-f(\mathbf{h}(\mathbf{x}))| d x \phi(\mathbf{u}) d u|
\end{gathered}
$$

which needs to converge to 0 as $\varepsilon \rightarrow 0$. However, from the area formula, Theorem 29.5.3 applied to the inside integral, the above equals

$$
\int_{B(\mathbf{0}, 1)} \int_{\mathbf{h}(\Omega)}|f(\mathbf{y}-\varepsilon \mathbf{u})-f(\mathbf{y})| d y \phi(\mathbf{u}) d u \leq \int_{B(\mathbf{0}, 1)}\left\|f_{\varepsilon \mathbf{u}}-f\right\|_{L^{1}\left(\mathbb{R}^{n}\right)} \phi(\mathbf{u}) d u
$$

which converges to 0 by continuity of translation in $L^{1}\left(\mathbb{R}^{n}\right)$. Thus as in the lemma,

$$
\begin{aligned}
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y & =\lim _{\varepsilon \rightarrow 0} \int f(\mathbf{y}) \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x d y \\
& =\lim _{\varepsilon \rightarrow 0} \int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int_{B(\mathbf{0}, 1)} f(\mathbf{h}(\mathbf{x})-\varepsilon \mathbf{u}) \phi(\mathbf{u}) d u d x \\
& =\int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) f(\mathbf{h}(\mathbf{x})) d x
\end{aligned}
$$

and this proves the corollary.
Note that in this corollary $\mathbf{h}$ is one to one.

### 29.12 The Case Of $W^{1, p}$

There is a very interesting application of the degree to integration [52]. Recall Lemma 23.1.11. I want to generalize this to the case where $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ has the property that its weak partial derivatives and $\mathbf{h}$ are in $L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right), p>n$. This is denoted by saying

$$
\mathbf{h} \in W^{1, p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right)
$$

In the following proposition, let $\phi_{\varepsilon}$ be a symmetric nonnegative mollifier,

$$
\phi_{\varepsilon}(\mathbf{x}) \equiv \frac{1}{\varepsilon^{n}} \phi\left(\frac{\mathbf{x}}{\varepsilon}\right), \operatorname{spt} \phi \subseteq B(\mathbf{0}, 1)
$$

$\Omega$ will be a bounded open set. By Theorem 26.6.10, h may be considered continuous and it satisfies

$$
\begin{equation*}
D \mathbf{h}(\mathbf{x}) \text { exists a.e., } \tag{29.12.69}
\end{equation*}
$$

For any $p>n$,

$$
\begin{equation*}
\lim _{m \rightarrow \infty} D\left(\mathbf{h} * \psi_{m}\right)=D \mathbf{h} \text { in } L^{p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n \times n}\right) \tag{29.12.70}
\end{equation*}
$$

where $\psi_{m}$ is a mollifier. Here $\mathbb{R}^{n \times n}$ denotes the $n \times n$ matrices with any norm you like.

Proposition 29.12.1 Let $S \subseteq \mathbf{h}(\partial \Omega)^{C}$ such that

$$
\operatorname{dist}(S, \mathbf{h}(\partial \Omega))>0
$$

where $\Omega$ is a bounded open set and also let $\mathbf{h}$ be in $W^{1, p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right)$. Then whenever $\varepsilon>0$ is small enough,

$$
d(\mathbf{h}, \Omega, \mathbf{y})=\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x
$$

for all $\mathbf{y} \in S$.
Proof: Let $\varepsilon_{0}>0$ be small enough that for all $\mathbf{y} \in S$,

$$
B\left(\mathbf{y}, 3 \varepsilon_{0}\right) \cap \mathbf{h}(\partial \Omega)=\emptyset
$$

Now let $\psi_{m}$ be a mollifier as $m \rightarrow \infty$ with support in $B\left(\mathbf{0}, m^{-1}\right)$ and let

$$
\mathbf{h}_{m} \equiv \mathbf{h} * \psi_{m}
$$

Thus $\mathbf{h}_{m} \in C^{\infty}\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$ and,

$$
\begin{equation*}
\left\|\mathbf{h}_{m}-\mathbf{h}\right\|_{L^{\infty}(\Omega)},\left\|D \mathbf{h}_{m}-D \mathbf{h}\right\|_{L^{p}(\Omega)} \rightarrow 0 \tag{29.12.71}
\end{equation*}
$$

as $m \rightarrow \infty$. The first claim above follows from the definition of convolution and the uniform continuity of $\mathbf{h}$ on the compact set $\bar{\Omega}$ and the second follows by 29.12.70. Choose $M$ such that for $m \geq M$,

$$
\begin{equation*}
\left\|\mathbf{h}_{m}-\mathbf{h}\right\|_{L^{\infty}(\Omega)}<\varepsilon_{0} \tag{29.12.72}
\end{equation*}
$$

Thus $\mathbf{h}_{m} \in \mathscr{U}_{\mathbf{y}} \cap C^{2}\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$ for all $\mathbf{y} \in S$.
For $\mathbf{y} \in S$, let $\mathbf{z} \in B(\mathbf{y}, \boldsymbol{\varepsilon})$ where $\varepsilon<\varepsilon_{0}$ and suppose $\mathbf{x} \in \partial \Omega$, and $k, m \geq M$. Then for $t \in[0,1]$,

$$
\begin{aligned}
\left|(1-t) \mathbf{h}_{m}(\mathbf{x})+\mathbf{h}_{k}(\mathbf{x}) t-\mathbf{z}\right| & \geq\left|\mathbf{h}_{m}(\mathbf{x})-\mathbf{z}\right|-t\left|\mathbf{h}_{k}(\mathbf{x})-\mathbf{h}_{m}(\mathbf{x})\right| \\
& >2 \varepsilon_{0}-t 2 \varepsilon_{0} \geq 0
\end{aligned}
$$

showing that for each $\mathbf{y} \in S, B(\mathbf{y}, \varepsilon) \cap\left((1-t) \mathbf{h}_{m}+t \mathbf{h}_{k}\right)(\partial \Omega)=\emptyset$. By Lemma 23.1.11, for all $\mathbf{y} \in S$,

$$
\begin{gather*}
\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x= \\
\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{k}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{k}(\mathbf{x})\right) d x \tag{29.12.73}
\end{gather*}
$$

for all $k, m \geq M$. By this lemma again, which says that for small enough $\varepsilon$ the integral is constant and the definition of the degree in Definition 23.1.10,

$$
\begin{equation*}
d\left(\mathbf{y}, \Omega, \mathbf{h}_{m}\right)=\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x \tag{29.12.74}
\end{equation*}
$$

for all $\varepsilon$ small enough. For $\mathbf{x} \in \partial \Omega, \mathbf{y} \in S$, and $t \in[0,1]$,

$$
\begin{aligned}
\left|(1-t) \mathbf{h}(\mathbf{x})+\mathbf{h}_{m}(\mathbf{x}) t-\mathbf{y}\right| & \geq|\mathbf{h}(\mathbf{x})-\mathbf{y}|-t\left|\mathbf{h}(\mathbf{x})-\mathbf{h}_{m}(\mathbf{x})\right| \\
& >3 \varepsilon_{0}-t 2 \varepsilon_{0}>0
\end{aligned}
$$

and so by Theorem 23.2.2, the part about homotopy, for each $\mathbf{y} \in S$,

$$
\begin{gathered}
d(\mathbf{y}, \Omega, \mathbf{h})=d\left(\mathbf{y}, \Omega, \mathbf{h}_{m}\right)= \\
\int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x
\end{gathered}
$$

whenever $\varepsilon$ is small enough. Fix such an $\varepsilon<\varepsilon_{0}$ and use 29.12.73 to conclude the right side of the above equation is independent of $m>M$.

By 29.12.71, there exists a subsequence still denoted by $m$ such that $D \mathbf{h}_{m}(\mathbf{x}) \rightarrow D \mathbf{h}(\mathbf{x})$ a.e. Since $p>n, \operatorname{det}\left(D \mathbf{h}_{m}\right)$ is bounded in $L^{r}(\Omega)$ for some $r>1$ and so the integrands in the following are uniformly integrable. By the Vitali convergence theorem, one can pass to the limit as follows.

$$
\begin{aligned}
d(\mathbf{y}, \Omega, \mathbf{h}) & =\lim _{m \rightarrow \infty} \int_{\Omega} \phi_{\varepsilon}\left(\mathbf{h}_{m}(\mathbf{x})-\mathbf{y}\right) \operatorname{det}\left(D \mathbf{h}_{m}(\mathbf{x})\right) d x \\
& =\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det}(D \mathbf{h}(\mathbf{x})) d x
\end{aligned}
$$

This proves the proposition.
Next is an interesting change of variables theorem. Let $\Omega$ be a bounded open set and let $\mathbf{h} \in W^{1, p}\left(\mathbb{R}^{n}\right)$. Also assume

$$
m(\mathbf{h}(\partial \Omega))=0
$$

From Proposition 29.12.1, for $\mathbf{y} \notin \mathbf{h}(\partial \Omega)$,

$$
d(\mathbf{y}, \Omega, \mathbf{h})=\lim _{\varepsilon \rightarrow 0} \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x
$$

showing that $\mathbf{y} \rightarrow d(\mathbf{y}, \Omega, \mathbf{h})$ is a measurable function since it is the limit of continuous functions off the set of measure zero $\mathbf{h}(\partial \Omega)$.

Now suppose $f \in C_{c}\left(\mathbf{h}(\partial \Omega)^{C}\right)$. There are finitely many components of $\mathbf{h}(\partial \Omega)^{C}$ which have nonempty intersection with $\operatorname{spt}(f)$. From the Proposition above,

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int f(\mathbf{y}) \lim _{\varepsilon \rightarrow 0} \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x d y
$$

Actually, from Proposition 29.12.1 there exists an $\varepsilon$ small enough that for all $\mathbf{y} \in \operatorname{spt}(f)$,

$$
\begin{aligned}
\lim _{\varepsilon \rightarrow 0} \int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x & =\int_{\Omega} \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x \\
& =d(\mathbf{y}, \Omega, \mathbf{h})
\end{aligned}
$$

This is because $\operatorname{spt}(f)$ is at a positive distance from $\mathbf{h}(\partial \Omega)^{C}$. Therefore, for all $\varepsilon$ small enough,

$$
\begin{aligned}
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y & =\iint_{\Omega} f(\mathbf{y}) \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x d y \\
& =\int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int f(\mathbf{y}) \phi_{\varepsilon}(\mathbf{h}(\mathbf{x})-\mathbf{y}) d y d x \\
& =\int_{\Omega} \operatorname{det} D \mathbf{h}(\mathbf{x}) \int f(\mathbf{h}(\mathbf{x})-\varepsilon \mathbf{u}) \phi(\mathbf{u}) d u d x
\end{aligned}
$$

Using the uniform continuity of $f$, you can now pass to a limit as $\varepsilon \rightarrow 0$ and obtain, using the fact that $\operatorname{det} D \mathbf{h}(\mathbf{x})$ is in $L^{r}\left(\mathbb{R}^{n}\right)$ for some $r>1$,

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} f(\mathbf{h}(\mathbf{x})) \operatorname{det} D \mathbf{h}(\mathbf{x}) d x
$$

This has proved the following interesting lemma.
Lemma 29.12.2 Let $f \in C_{c}\left(\mathbf{h}(\partial \Omega)^{C}\right)$ and let $\mathbf{h} \in W^{1, p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right), p>n, \mathbf{h}(\partial \Omega)$ has measure zero for $\Omega$ a bounded open set. Then everything is measurable which needs to be and

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} \operatorname{det}(D \mathbf{h}(\mathbf{x})) f(\mathbf{h}(\mathbf{x})) d x
$$

Note that $\mathbf{h}$ is not necessarily one to one. The difficult issue is handling $d(\mathbf{y}, \Omega, \mathbf{h})$ which has integer values constant on each component of $\mathbf{h}(\partial \Omega)^{C}$ and the difficulty arrises in not knowing how many components there are. What if there are infinitely many, for example, and what if the degree changes sign. If this happens, it is hard to exploit convergence theorems to get generalizations of $f \in C_{c}\left(\mathbf{h}(\partial \Omega)^{C}\right)$. One way around this is to insist $\mathbf{h}$ be one to one and that $\Omega$ be connected having a boundary which separates $\mathbb{R}^{n}$ into two components, three if $n=1$. That way, you can use the Jordan separation theorem and assert $\mathbf{h}(\partial \Omega)$ also separates $\mathbb{R}^{n}$ into the same number of components with $\mathbf{h}(\Omega)$ being the only one on which the degree is nonzero.

First recall the following proposition.
Proposition 29.12.3 Let $\Omega$ be an open connected bounded set in $\mathbb{R}^{n}, n \geq 1$ such that $\mathbb{R}^{n} \backslash$ $\partial \Omega$ consists of two, three if $n=1$, connected components. Let $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$ be continuous and one to one. Then $\mathbf{f}(\Omega)$ is the bounded component of $\mathbb{R}^{n} \backslash \mathbf{f}(\partial \Omega)$ and for $\mathbf{y} \in \mathbf{f}(\Omega)$, $d(\mathbf{f}, \Omega, \mathbf{y})$ either equals 1 or -1 .

Proof: First suppose $n \geq 2$. By the Jordan separation theorem, $\mathbb{R}^{n} \backslash \mathbf{f}(\partial \Omega)$ consists of two components, a bounded component $B$ and an unbounded component $U$. Using the Tietze extention theorem, there exists $\mathbf{g}$ defined on $\mathbb{R}^{n}$ such that $\mathbf{g}=\mathbf{f}^{-1}$ on $\mathbf{f}(\bar{\Omega})$. Thus on $\partial \Omega, \mathbf{g} \circ \mathbf{f}=\mathrm{id}$. It follows from this and the product formula that

$$
\begin{aligned}
1 & =d(\mathrm{id}, \Omega, \mathbf{g}(\mathbf{y}))=d(\mathbf{g} \circ \mathbf{f}, \Omega, \mathbf{g}(\mathbf{y})) \\
& =d(\mathbf{g}, B, \mathbf{g}(\mathbf{y})) d(\mathbf{f}, \Omega, B)+d(\mathbf{f}, \Omega, U) d(\mathbf{g}, U, \mathbf{g}(\mathbf{y})) \\
& =d(\mathbf{g}, B, \mathbf{g}(\mathbf{y})) d(\mathbf{f}, \Omega, B)
\end{aligned}
$$

Therefore, $d(\mathbf{f}, \Omega, B) \neq 0$ and so for every $\mathbf{z} \in B$, it follows $\mathbf{z} \in \mathbf{f}(\Omega)$. Thus $B \subseteq \mathbf{f}(\Omega)$. On the other hand, $\mathbf{f}(\Omega)$ cannot have points in both $U$ and $B$ because it is a connected set. Therefore $\mathbf{f}(\Omega) \subseteq B$ and this shows $B=\mathbf{f}(\Omega)$. Thus $d(\mathbf{f}, \Omega, B)=d(\mathbf{f}, \Omega, \mathbf{y})$ for each $\mathbf{y} \in B$ and the above formula shows this equals either 1 or -1 because the degree is an integer. In the case where $n=1$, the argument is similar but here you have 3 components in $\mathbb{R}^{1} \backslash \mathbf{f}(\partial \Omega)$ so there are more terms in the above sum although two of them give 0 . This proves the proposition.

The following is a version of the area formula.

Lemma 29.12.4 Let $\mathbf{h} \in W^{1, p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right), p>n$ where $\mathbf{h}$ is one to one, $\mathbf{h}(\partial \Omega), \partial \Omega$ have measure zero for $\Omega$ a bounded open connected set in $\mathbb{R}^{n}$. Then $\mathbf{h}(\partial \Omega)^{C}$ has two components, three if $n=1$, and for $\mathbf{y} \in \mathbf{h}(\Omega)$, and $f \in C_{c}\left(\mathbb{R}^{n}\right)$.

$$
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x
$$

If $O$ is an open set, it is also true that

$$
\int_{\mathbf{h}(\Omega)} \mathscr{X}_{O}(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{O}(\mathbf{h}(\mathbf{x})) d x
$$

Also if $f$ is any nonnegative Borel measurable function

$$
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x
$$

Proof: Consider the first claim. Let $\delta$ be such that $\overline{B\left(\mathbf{x}_{1}, \delta\right)} \subseteq \Omega$ and let $\left\{f_{j}(\mathbf{y})\right\}_{j=1}^{\infty}$ be nonnegative, increasing in $j$ and converging pointwise to $\mathscr{X}_{\mathbf{h}\left(B\left(\mathbf{x}_{1}, \delta\right)\right)}(\mathbf{y})$. This can be done because $\mathbf{h}\left(B\left(\mathbf{x}_{1}, \boldsymbol{\delta}\right)\right)$ is an open bounded set thanks to invariance of domain, Theorem 23.4.3. By Proposition 29.12.3, $d(\mathbf{y}, \Omega, \mathbf{h})$ either equals 1 or -1 . Suppose it equals -1 . Then from Lemma 29.11.2

$$
\int_{\mathbf{h}(\Omega)} f_{j}(\mathbf{y}) d y=-\int_{\Omega} \operatorname{det}(D \mathbf{h}(\mathbf{x})) f_{j}(\mathbf{h}(\mathbf{x})) d x
$$

The integrand on the right is uniformly integrable thanks to the fact the $f_{j}$ are bounded and $\operatorname{det}(D \mathbf{h}(\mathbf{x}))$ is in $L^{r}(\Omega)$ for some $r>1$. Therefore, by the Vitali convergence theorem and the monotone convergence theorem,

$$
\int_{\mathbf{h}(\Omega)} \mathscr{X}_{\mathbf{h}\left(B\left(\mathbf{x}_{1}, \delta\right)\right)}(\mathbf{y}) d y=-\int_{\Omega} \operatorname{det}(D \mathbf{h}(\mathbf{x})) \mathscr{X}_{B\left(\mathbf{x}_{1}, \delta\right)}(\mathbf{x}) d x
$$

so

$$
m\left(\mathbf{h}\left(B\left(\mathbf{x}_{1}, \boldsymbol{\delta}\right)\right)\right) \frac{1}{m\left(B\left(\mathbf{x}_{1}, \boldsymbol{\delta}\right)\right)}=-\frac{1}{m\left(B\left(\mathbf{x}_{1}, \boldsymbol{\delta}\right)\right)} \int_{B\left(\mathbf{x}_{1}, \boldsymbol{\delta}\right)} \operatorname{det}(D \mathbf{h}(\mathbf{x})) d x
$$

If $\mathbf{x}_{1}$ is a Lebesgue point of $\operatorname{det}(D \mathbf{h}(\mathbf{x}))$, then you can pass to the limit as $\delta \rightarrow 0$ and conclude

$$
-\operatorname{det}\left(D \mathbf{h}\left(\mathbf{x}_{1}\right)\right) \geq 0
$$

Since a.e. point is a Lebesgue point, it follows that in the case where $d(\mathbf{y}, \Omega, \mathbf{h})=-1$,

$$
-\operatorname{det}(D \mathbf{h}(\mathbf{x}))=|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \text { a.e. } \mathbf{x} \in \Omega
$$

The case where the degree equals 1 is similar. Thus $\operatorname{det}(D \mathbf{h}(\mathbf{x}))$ has the same sign on $\mathbf{h}(\Omega)$.

Now let $O$ be an open set. Then by invariance of domain, $\mathbf{h}(O)$ is also an open set. Let $V_{k}$ denote a decreasing sequence of open sets, $V_{k} \supseteq \overline{V_{k+1}}$ whose intersection is the compact
set $\mathbf{h}(\partial \Omega)$ such that $m\left(\overline{V_{k}}\right)<1 / k$. Then if $f \prec \mathbf{h}(O) \backslash \overline{V_{k}}$, it follows since $\mathbf{h}(O) \backslash \overline{V_{k}}$ is an open set which is at a positive distance from $\mathbf{h}(\partial \Omega)$, Lemma 29.11.2 implies

$$
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x
$$

Taking a sequence of such $f$ increasing to $\mathscr{X}_{\mathbf{h}(O) \backslash \overline{V_{k}}}$, it follows from monotone convergence theorem in the above that

$$
\begin{aligned}
\int_{\mathbf{h}(\Omega)} \mathscr{X}_{\mathbf{h}(O) \backslash \overline{V_{k}}}(\mathbf{y}) d y & =\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{\mathbf{h}(O) \backslash \overline{V_{k}}}(\mathbf{h}(\mathbf{x})) d x \\
& =\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{O \backslash \mathbf{h}^{-1}\left(\overline{V_{k}}\right)}(\mathbf{x}) d x
\end{aligned}
$$

Now letting $k \rightarrow \infty$, it follows from the monotone convergence theorem that

$$
\int_{\mathbf{h}(\Omega)} \mathscr{X}_{\mathbf{h}(O) \backslash \mathbf{h}(\partial \Omega)}(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{O \backslash \partial \Omega}(\mathbf{x}) d x
$$

Since both $\partial \Omega$ and $\mathbf{h}(\partial \Omega)$ have measure zero, this implies

$$
\int_{\mathbf{h}(\Omega)} \mathscr{X}_{\mathbf{h}(O)}(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{O}(\mathbf{x}) d x
$$

Now let $\mathscr{G}$ denote the Borel sets $E$ with the property that

$$
\int_{\mathbf{h}(\Omega)} \mathscr{X}_{\mathbf{h}(E)}(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{E}(\mathbf{x}) d x
$$

It follows easily that if $E \in \mathscr{G}$ then so does $E^{C}$. This is because $\mathbf{h}(\Omega)$ has finite measure and $|\operatorname{det}(D \mathbf{h}(\mathbf{x}))|$ is in $L^{1}(\Omega)$. If $E_{i}$ is a sequence of disjoint sets of $\mathscr{G}$ then the monotone convergence theorem implies $\cup E_{i}$ is also in $\mathscr{G}$. It was shown above that the $\pi$ system of open sets is contained in $\mathscr{G}$. Therefore, it follows from the lemma on $\pi$ systems, Lemma 12.12 .3 on Page $329, \mathscr{G}$ equals the Borel sets. Now the desired result follows from approximating $f \geq 0$ and Borel measurable with a sequence of Borel simple functions which converge pointwise to $f$. This proves the theorem.

The following corollary follows right away by splitting $f$ into positive and negative parts of real and imaginary parts.

Corollary 29.12.5 Let $\mathbf{h}$ be one to one and in $W^{1, p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right), p>n$. Let $\Omega$ be a bounded, open, connected set in $\mathbb{R}^{n}$ and suppose $\partial \Omega, \mathbf{h}(\partial \Omega)$ have measure zero. Let $f \in L^{1}(\mathbf{h}(\Omega))$ where $f$ is also Borel measurable. Then

$$
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x
$$

It can also be written in the form

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} \operatorname{det}(D \mathbf{h}(\mathbf{x})) f(\mathbf{h}(\mathbf{x})) d x
$$

Note this is a general area formula under somewhat more restrictive hypotheses than the usual area formula because it involves an assumption that $\Omega$ is connected and a troublesome condition on the measure of $\mathbf{h}(\partial \Omega), \partial \Omega$ being zero, but it does not require $\mathbf{h}$ to be Lipschitz. It looks like a strange result because $|\operatorname{det} D \mathbf{h}(\mathbf{x})|$ is not in $L^{\infty}$ and so it is not clear why the integral on the right should even be finite just because $f$ is in $L^{1}$. If the result is correct, it is surprising.

The condition on the measure of $\partial \Omega$ and $\mathbf{h}(\partial \Omega)$ is not necessary. Neither is it necessary to assume $\Omega$ is connected. This is shown next.

Theorem 29.12.6 Let $\mathbf{h}$ be one to one on $\bar{\Omega}$ and in $W^{1, p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right), p>n$. Let $\Omega$ be a bounded, open set in $\mathbb{R}^{n}$. Let $f \in L^{1}(\mathbf{h}(\Omega))$ where $f$ is also Borel measurable. Then

$$
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x
$$

It can also be written in the form

$$
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} \operatorname{det}(D \mathbf{h}(\mathbf{x})) f(\mathbf{h}(\mathbf{x})) d x
$$

Proof: Let $\bar{\Omega} \subseteq[-R, R]^{n} \equiv Q$. Let $p_{i}(\mathbf{x}) \equiv x_{i}$ where $\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)^{T}$. Then here is a claim.

Claim: Let $b$ be given. There exists $a,|a-b| \leq 4^{-k}$ such that

$$
m\left(\mathbf{h}\left(\left[p_{i} \mathbf{x}=a\right] \cap Q\right)\right)=0
$$

Here $\left[p_{i} \mathbf{x}=a\right]$ is short for $\left\{\mathbf{x}: p_{i} \mathbf{x}=a\right\}$.
Proof of claim: If this is not so, then for every $a$ in an interval centered at $b$,

$$
m\left(\mathbf{h}\left(\left[p_{i} \mathbf{x}=a\right] \cap Q\right)\right)>0
$$

However,

$$
m\left(\cup_{a \in\left[b-4^{-k}, b+4^{-k}\right]} \mathbf{h}\left(\left[p_{i} \mathbf{x}=a\right] \cap Q\right)\right)=m\left(\mathbf{h}\left(\prod_{j} A_{j}\right)\right)
$$

where $A_{j}=[-R, R]$ if $j \neq i$ and $A_{i}=\left[b-4^{-k}, b+4^{-k}\right]$. This is finite because $\mathbf{h}\left(\Pi_{j} A_{j}\right)$ is a compact set, being the continuous image of such a set. Since $\mathbf{h}$ is one to one, this compact set would then be the union of uncountably many disjoint sets, each having positive measure. Thus for some $1 / l>0$ there must be infinitely many of these disjoint sets having measure larger than $1 / l, l \in \mathbb{N}$ a contradiction to the set having finite measure. This proves the claim.

Now from the claim, consider $b_{k}, k \in \mathbb{Z}$ given by $b_{k}=k 2^{-(m+1)}$ and for each $i=1, \cdots, n$, let $a_{i k}$ denote a value of the claim, $\left|a_{i k}-b_{k}\right| \leq 4^{-m}$. Thus

$$
m\left(\mathbf{h}\left(\left[p_{i} \mathbf{x}=a_{i k}\right] \cap Q\right)\right)=0, i=1, \cdots, n
$$

Thus also

$$
\left|a_{i k}-a_{i(k+1)}\right| \leq\left|a_{i k}-b_{k}\right|+\left|b_{k+1}-a_{i(k+1)}\right|+\left|b_{k+1}-b_{k}\right|
$$

$$
\leq 4^{-m}+4^{-m}+2^{-(m+1)}<2^{-m}
$$

Consider boxes of the form $\prod_{i=1}^{n}\left[a_{i k}, a_{i(k+1)}\right]$. Denote these boxes as $\mathscr{B}_{m}$. Thus they are non overlapping boxes the sides of which are of length less than $2^{-m}$. Let $\Omega_{1}$ denote the union of the finitely many boxes of $\mathscr{B}_{1}$ which are contained in $\Omega$. Next let $\Omega_{2}$ denote the union of the boxes of $\mathscr{B}_{2} \cup \mathscr{B}_{1}$ which are contained in $\Omega$ and so forth. Then $\cup_{k=1}^{\infty} \Omega_{k} \subseteq \Omega$. Suppose now that $\mathbf{p} \in \Omega$. Then it is at positive distance from $\partial \Omega$. Let $k$ be the first such that $\mathbf{p}$ is contained in a box of $\mathscr{B}_{k}$ which is contained in $\Omega$. Then $\mathbf{p} \in \Omega_{k}$. Therefore, this has shown that $\Omega$ is a countable union of non overlapping closed boxes $B$ which have the property that $\partial B, \mathbf{h}(\partial B)$ have measure zero. Denote these boxes as $\left\{B_{k}\right\}$.

First assume $f$ is nonnegative and Borel measurable. Then from Corollary 29.12.5,

$$
\int_{\mathbf{h}\left(B_{k}\right)} f(\mathbf{y}) d y=\int_{B_{k}}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x
$$

Since $\mathbf{h}\left(\partial B_{k}\right)$ has measure zero,

$$
\begin{aligned}
\int_{\mathbf{h}\left(\cup_{k=1}^{m} B_{k}\right)} f(\mathbf{y}) d y & =\sum_{k=1}^{m} \int_{\mathbf{h}\left(B_{k}\right)} f(\mathbf{y}) d y \\
& =\sum_{k=1}^{m} \int_{B_{k}}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x \\
& =\int_{\cup_{k=1}^{m} B_{k}}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x
\end{aligned}
$$

and now letting $m \rightarrow \infty$ and using the monotone convergence theorem,

$$
\begin{equation*}
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x \tag{29.12.75}
\end{equation*}
$$

Next assume in addition that $f$ is also in $L^{1}(\mathbf{h}(\Omega))$. Recall that from properties of the degree, $d(\mathbf{y}, U, \mathbf{h})$ is constant on $\mathbf{h}(U)$ for $U$ a component of $\Omega$. Since $\mathbf{h}$ is one to one, Proposition 23.6.4 implies this constant is either -1 or 1 . Let the components of $\Omega$ be $\left\{U_{i}\right\}_{i=1}^{\infty}$. Also from Theorem 23.2.2 and the assumption that $\mathbf{h}$ is one to one, if $\mathbf{y} \in \mathbf{h}\left(U_{i}\right)$, then $\mathbf{y} \notin \mathbf{h}\left(\cup_{j \neq i} U_{j}\right)$ and

$$
d\left(\mathbf{y}, U_{i}, \mathbf{h}\right)+d\left(\mathbf{y}, \cup_{j \neq i} U_{j}, \mathbf{h}\right)=d(\mathbf{y}, \Omega, \mathbf{h})
$$

Since $\mathbf{y} \notin \mathbf{h}\left(\cup_{j \neq i} U_{j}\right)$ the second term on the left is 0 and so $d\left(\mathbf{y}, U_{i}, \mathbf{h}\right)=d(\mathbf{y}, \Omega, \mathbf{h})$. Therefore, by Corollary 29.12.5,

$$
\begin{gather*}
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\sum_{i=1}^{\infty} \int_{\mathbf{h}\left(U_{i}\right)} f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y \\
=\sum_{i=1}^{\infty} \int_{\mathbf{h}\left(U_{i}\right)} f(\mathbf{y}) d\left(\mathbf{y}, U_{i}, \mathbf{h}\right) d y=\sum_{i=1}^{\infty} \int \mathscr{X}_{U_{i}}(\mathbf{x}) f(\mathbf{h}(\mathbf{x})) \operatorname{det}(D \mathbf{h}(\mathbf{x})) d x \tag{29.12.76}
\end{gather*}
$$

From 29.12.75

$$
\begin{aligned}
& \sum_{i=1}^{\infty} \int \mathscr{X}_{U_{i}}(\mathbf{x}) f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x \\
= & \int \sum_{i=1}^{\infty} \mathscr{X}_{U_{i}}(\mathbf{x}) f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x \\
= & \int \mathscr{X}_{\Omega} f(\mathbf{h}(\mathbf{x}))|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| d x<\infty
\end{aligned}
$$

and so by Fubini's theorem, the sum and the integral may be interchanged in 29.12.76 to obtain from the dominated convergence theorem,

$$
\begin{aligned}
& \int \sum_{i=1}^{\infty} \mathscr{X}_{U_{i}}(\mathbf{x}) f(\mathbf{h}(\mathbf{x})) \operatorname{det}(D \mathbf{h}(\mathbf{x})) d x \\
= & \int_{\Omega} f(\mathbf{h}(\mathbf{x})) \operatorname{det}(D \mathbf{h}(\mathbf{x})) d x
\end{aligned}
$$

which shows

$$
\begin{equation*}
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} f(\mathbf{h}(\mathbf{x})) \operatorname{det}(D \mathbf{h}(\mathbf{x})) d x \tag{29.12.77}
\end{equation*}
$$

Now if $f$ is Borel measurable and in $L^{1}(\Omega)$, the above may be applied to the positive parts of the real and imaginary parts of $f$ to obtain 29.12.77 for such $f$. This proves the theorem.

Not surprisingly, it is not necessary to assume $f$ is Borel measurable.
Corollary 29.12.7 Let $\mathbf{h}$ be one to one on $\bar{\Omega}$ and in $W^{1, p}\left(\mathbb{R}^{n} ; \mathbb{R}^{n}\right), p>n$. Let $\Omega$ be a bounded, open set in $\mathbb{R}^{n}$. Let $f \in L^{1}(\mathbf{h}(\Omega))$ where $f$ is Lebesgue measurable. Then $\mathbf{x} \rightarrow|\operatorname{det}(\operatorname{Dh}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x}))$ is Lebesgue measurable and

$$
\begin{equation*}
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d y=\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| f(\mathbf{h}(\mathbf{x})) d x \tag{29.12.78}
\end{equation*}
$$

It can also be written in the form

$$
\begin{equation*}
\int f(\mathbf{y}) d(\mathbf{y}, \Omega, \mathbf{h}) d y=\int_{\Omega} \operatorname{det}(D \mathbf{h}(\mathbf{x})) f(\mathbf{h}(\mathbf{x})) d x \tag{29.12.79}
\end{equation*}
$$

Proof: Let $E$ be a Lebesgue measurable subset of $\mathbf{h}(\Omega)$. By regularity of the measure, there exist Borel sets $F \subseteq E \subseteq G$ such that $F$ and $G$ are both Borel measurable sets contained in $\mathbf{h}(\Omega)$ with $m(G \backslash F)=0$. Then by Theorem 29.12.6

$$
\begin{align*}
\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) d x & =\int_{\mathbf{h}(\Omega)} \mathscr{X}_{F}(\mathbf{y}) d y \\
& =\int_{\mathbf{h}(\Omega)} \mathscr{X}_{E}(\mathbf{y}) d y=\int_{\mathbf{h}(\Omega)} \mathscr{X}_{G}(\mathbf{y}) d y \\
& =\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{G}(\mathbf{h}(\mathbf{x})) d x \tag{29.12.80}
\end{align*}
$$

which shows that

$$
\begin{aligned}
|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) & =|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{G}(\mathbf{h}(\mathbf{x})) \\
& =|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))
\end{aligned}
$$

a.e. and so, by completeness, it follows $\mathbf{x} \rightarrow|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{E}(\mathbf{h}(\mathbf{x}))$ must be Lebesgue measurable. This is because the function $\mathbf{x} \rightarrow|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{G}(\mathbf{h}(\mathbf{x}))$ is Borel measurable due to the continuity of $\mathbf{h}$ which forces $\mathbf{x} \rightarrow \operatorname{det}(D \mathbf{h}(\mathbf{x}))$ to be Borel measurable, and the other function in the product is of the form $\mathscr{X}_{\mathbf{h}^{-1}(G)}(\mathbf{x})$ and since $G$ is Borel, so is $\mathbf{h}^{-1}(G)$. Now the desired result follows because

$$
\int_{\Omega}|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| \mathscr{X}_{E}(\mathbf{h}(\mathbf{x})) d x
$$

is between the ends of 29.12 .80 . The rest of the argument involves the usual technique of approximating a nonnegative function with an increasing sequence of simple functions followed by consideration of the positive and negative parts of the real and imaginary parts of an arbitrary function in $L^{1}(\Omega)$. The other version of the formula follows as in the proof of Theorem 29.12.6. This proves the corollary.

## Chapter 30

## Integration Of Differential Forms

### 30.1 Manifolds

Manifolds are sets which resemble $\mathbb{R}^{n}$ locally. To make the concept of a manifold more precise, here is a definition.

Definition 30.1.1 Let $\Omega \subseteq \mathbb{R}^{m}$. A set, $U$, is open in $\Omega$ if it is the intersection of an open set from $\mathbb{R}^{m}$ with $\Omega$. Equivalently, a set, $U$ is open in $\Omega$ if for every point, $\mathbf{x} \in U$, there exists $\delta>0$ such that if $|\mathbf{x}-\mathbf{y}|<\delta$ and $\mathbf{y} \in \Omega$, then $\mathbf{y} \in U$. A set, $H$, is closed in $\Omega$ if it is the intersection of a closed set from $\mathbb{R}^{m}$ with $\Omega$. Equivalently, a set, $H$, is closed in $\Omega$ if whenever, $\mathbf{y}$ is a limit point of $H$ and $\mathbf{y} \in \Omega$, it follows $\mathbf{y} \in H$.

Recall the following definition.
Definition 30.1.2 Let $V \subseteq \mathbb{R}^{n} . C^{k}\left(\bar{V} ; \mathbb{R}^{m}\right)$ is the set of functions which are restrictions to $V$ of some function defined on $\mathbb{R}^{n}$ which has $k$ continuous derivatives and compact support. When $k=0$, it means the restriction to $V$ of continuous functions with compact support.

Definition 30.1.3 A closed and bounded subset of $\mathbb{R}^{m}, \Omega$, will be called an $n$ dimensional manifold with boundary, $n \geq 1$, if there are finitely many sets, $U_{i}$, open in $\Omega$ and continuous one to one functions, $\mathbf{R}_{i} \in C^{0}\left(\overline{U_{i}}, \mathbb{R}^{n}\right)$ such that $\mathbf{R}_{i} U_{i}$ is relatively open in $\mathbb{R}_{\leq}^{n} \equiv\left\{\mathbf{u} \in \mathbb{R}^{n}: u_{1} \leq 0\right\}, \mathbf{R}_{i}^{-1}$ is continuous. These mappings, $\mathbf{R}_{i}$, together with their domains, $U_{i}$, are called charts and the totality of all the charts, $\left(U_{i}, \mathbf{R}_{i}\right)$ just described is called an atlas for the manifold. Define

$$
\operatorname{int}(\Omega) \equiv\left\{\mathbf{x} \in \Omega: \text { for some } i, \mathbf{R}_{i} \mathbf{x} \in \mathbb{R}_{<}^{n}\right\}
$$

where $\mathbb{R}_{<}^{n} \equiv\left\{\mathbf{u} \in \mathbb{R}^{n}: u_{1}<0\right\}$. Also define

$$
\partial \Omega \equiv\left\{\mathbf{x} \in \Omega: \text { for some } i, \mathbf{R}_{i} \mathbf{x} \in \mathbb{R}_{0}^{n}\right\}
$$

where

$$
\mathbb{R}_{0}^{n} \equiv\left\{\mathbf{u} \in \mathbb{R}^{n}: u_{1}=0\right\}
$$

and $\partial \Omega$ is called the boundary of $\Omega$. Note that if $n=1, \mathbb{R}_{0}^{n}$ is just the single point 0 . By convention, we will consider the boundary of such a 0 dimensional manifold to be empty.

This definition is a little too restrictive. In general the collection of sets, $U_{i}$ is not finite. However, in the case where $\Omega$ is closed and bounded, compactness of $\Omega$ can be used to get a finite covering and since this is the case of most interest here, the assumption that the collection of sets, $U_{i}$, is finite is made. However, most of what is presented here can be generalized to the case of a locally finite atlas.

Theorem 30.1.4 Let $\partial \Omega$ and $\operatorname{int}(\Omega)$ be as defined above. Then $\operatorname{int}(\Omega)$ is open in $\Omega$ and $\partial \Omega$ is closed in $\Omega$. Furthermore, $\partial \Omega \cap \operatorname{int}(\Omega)=\emptyset, \Omega=\partial \Omega \cup \operatorname{int}(\Omega)$, and for $n \geq 2, \partial \Omega$ is an $n-1$ dimensional manifold for which $\partial(\partial \Omega)=\emptyset$. The property of being in int $(\Omega)$ or $\partial \Omega$ does not depend on the choice of atlas.

Proof: It is clear that $\Omega=\partial \Omega \cup \operatorname{int}(\Omega)$. First consider the claim that $\partial \Omega \cap \operatorname{int}(\Omega)=\emptyset$. Suppose this does not happen. Then there would exist $\mathbf{x} \in \partial \Omega \cap \operatorname{int}(\Omega)$. Therefore, there would exist two mappings $\mathbf{R}_{i}$ and $\mathbf{R}_{j}$ such that $\mathbf{R}_{j} \mathbf{x} \in \mathbb{R}_{0}^{n}$ and $\mathbf{R}_{i} \mathbf{x} \in \mathbb{R}_{<}^{n}$ with $\mathbf{x} \in U_{i} \cap U_{j}$. Now consider the map, $\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}$, a continuous one to one map from $\mathbb{R}_{\leq}^{n}$ to $\mathbb{R}_{\leq}^{n}$ having a continuous inverse. By continuity, there exists $r>0$ small enough that,

$$
\mathbf{R}_{i}^{-1} B\left(\mathbf{R}_{i} \mathbf{x}, r\right) \subseteq U_{i} \cap U_{j}
$$

Therefore, $\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\left(B\left(\mathbf{R}_{i} \mathbf{x}, r\right)\right) \subseteq \mathbb{R}_{\leq}^{n}$ and contains a point on $\mathbb{R}_{0}^{n}, \mathbf{R}_{j} \mathbf{x}$. However, this cannot occur because it contradicts the theorem on invariance of domain, Theorem 23.4.3, which requires that $\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\left(B\left(\mathbf{R}_{i} \mathbf{x}, r\right)\right)$ must be an open subset of $\mathbb{R}^{n}$ and this one isn't because of the point on $\mathbb{R}_{0}^{n}$. Therefore, $\partial \Omega \cap \operatorname{int}(\Omega)=\emptyset$ as claimed. This same argument shows that the property of being in $\operatorname{int}(\Omega)$ or $\partial \Omega$ does not depend on the choice of the atlas.

To verify that $\partial(\partial \Omega)=\emptyset$, let $\mathbf{S}_{i}$ be the restriction of $\mathbf{R}_{i}$ to $\partial \Omega \cap U_{i}$. Thus

$$
\mathbf{S}_{i}(\mathbf{x})=\left(0,\left(\mathbf{R}_{i} \mathbf{x}\right)_{2}, \cdots,\left(\mathbf{R}_{i} \mathbf{x}\right)_{n}\right)
$$

and the collection of such points for $\mathbf{x} \in \partial \Omega \cap U_{i}$ is an open bounded subset of

$$
\left\{\mathbf{u} \in \mathbb{R}^{n}: u_{1}=0\right\}
$$

identified with $\mathbb{R}^{n-1}$. $\mathbf{S}_{i}\left(\partial \Omega \cap U_{i}\right)$ is bounded because $\mathbf{S}_{i}$ is the restriction of a continuous function defined on $\mathbb{R}^{m}$ and $\partial \Omega \cap U_{i} \equiv V_{i}$ is contained in the compact set $\Omega$. Thus if $\mathbf{S}_{i}$ is modified slightly, to be of the form

$$
\mathbf{S}_{i}^{\prime}(\mathbf{x})=\left(\left(\mathbf{R}_{i} \mathbf{x}\right)_{2}-k_{i}, \cdots,\left(\mathbf{R}_{i} \mathbf{x}\right)_{n}\right)
$$

where $k_{i}$ is chosen sufficiently large enough that $\left(\mathbf{R}_{i}\left(V_{i}\right)\right)_{2}-k_{i}<0$, it follows that $\left\{\left(V_{i}, \mathbf{S}_{i}^{\prime}\right)\right\}$ is an atlas for $\partial \Omega$ as an $n-1$ dimensional manifold such that every point of $\partial \Omega$ is sent to to $\mathbb{R}_{<}^{n-1}$ and none gets sent to $\mathbb{R}_{0}^{n-1}$. It follows $\partial \Omega$ is an $n-1$ dimensional manifold with empty boundary. In case $n=1$, the result follows by definition of the boundary of a 0 dimensional manifold.

Next consider the claim that $\operatorname{int}(\Omega)$ is open in $\Omega$. If $\mathbf{x} \in \operatorname{int}(\Omega)$, are all points of $\Omega$ which are sufficiently close to $\mathbf{x}$ also in $\operatorname{int}(\Omega)$ ? If this were not true, there would exist $\left\{\mathbf{x}_{n}\right\}$ such that $\mathbf{x}_{n} \in \partial \Omega$ and $\mathbf{x}_{n} \rightarrow \mathbf{x}$. Since there are only finitely many charts of interest, this would imply the existence of a subsequence, still denoted by $\mathbf{x}_{n}$ and a single map, $\mathbf{R}_{i}$ such that $\mathbf{R}_{i}\left(\mathbf{x}_{n}\right) \in \mathbb{R}_{0}^{n}$. But then $\mathbf{R}_{i}\left(\mathbf{x}_{n}\right) \rightarrow \mathbf{R}_{i}(\mathbf{x})$ and so $\mathbf{R}_{i}(\mathbf{x}) \in \mathbb{R}_{0}^{n}$ showing $\mathbf{x} \in \partial \Omega$, a contradiction to $\operatorname{int}(\Omega) \cap \partial \Omega=\emptyset$. Now it follows that $\partial \Omega$ is closed in $\Omega$ because $\partial \Omega=\Omega \backslash \operatorname{int}(\Omega)$. This proves the Theorem.

Definition 30.1.5 An $n$ dimensional manifold with boundary, $\Omega$ is a $C^{k}$ manifold with boundary for some $k \geq 1$ if

$$
\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1} \in C^{k}\left(\overline{\mathbf{R}_{i}\left(U_{i} \cap U_{j}\right)} ; \mathbb{R}^{n}\right)
$$

and $\mathbf{R}_{i}^{-1} \in C^{k}\left(\overline{\mathbf{R}_{i} U_{i}} ; \mathbb{R}^{m}\right)$. It is called a continuous or Lipschitz manifold with boundary if the mappings, $\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}, \mathbf{R}_{i}^{-1}, \mathbf{R}_{i}$ are respectively continuous or Lipschitz continuous. In
the case where $\Omega$ is a $C^{k}, k \geq 1$ manifold, it is called orientable if in addition to this there exists an atlas, $\left(U_{r}, \mathbf{R}_{r}\right)$, such that whenever $U_{i} \cap U_{j} \neq \emptyset$,

$$
\begin{equation*}
\operatorname{det}\left(D\left(\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\right)\right)(\mathbf{u})>0 \text { for all } \mathbf{u} \in \mathbf{R}_{i}\left(U_{i} \cap U_{j}\right) \tag{30.1.1}
\end{equation*}
$$

The mappings, $\mathbf{R}_{i} \circ \mathbf{R}_{j}^{-1}$ are called the overlap maps. In the case where $k=0$, the $\mathbf{R}_{i}$ are only assumed continuous so there is no differentiability available and in this case, the manifold is oriented if whenever $A$ is an open connected subset of $\operatorname{int}\left(\mathbf{R}_{i}\left(U_{i} \cap U_{j}\right)\right)$ whose boundary has measure zero and separates $\mathbb{R}^{n}$ into two components,

$$
\begin{equation*}
d\left(\mathbf{y}, A, \mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\right) \in\{1,0\} \tag{30.1.2}
\end{equation*}
$$

depending on whether $\mathbf{y} \in \mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}(A)$. An atlas satisfying 30.1.1 or more generally 30.1.2 is called an oriented atlas.

It follows from Proposition 23.6.4 the degree in 30.1.2 is either undefined if $\mathbf{y} \in \mathbf{R}_{j} \circ$ $\mathbf{R}_{i}^{-1} \partial A$ or it is $1,-1$, or 0 .

The study of manifolds is really a generalization of something with which everyone who has taken a normal calculus course is familiar. We think of a point in three dimensional space in two ways. There is a geometric point and there are coordinates associated with this point. There are many different coordinate systems which describe a point. There are spherical coordinates, cylindrical coordinates and rectangular coordinates to name the three most popular coordinate systems. These coordinates are like the vector $\mathbf{u}$. The point, $\mathbf{x}$ is like the geometric point although it is always assumed $\mathbf{x}$ has rectangular coordinates in $\mathbb{R}^{m}$ for some $m$. Under fairly general conditions, it can be shown there is no loss of generality in making such an assumption. Next is some algebra.

### 30.2 The Binet Cauchy Formula

The Binet Cauchy formula is a generalization of the theorem which says the determinant of a product is the product of the determinants. The situation is illustrated in the following picture.

Theorem 30.2.1 Let $A$ be an $n \times m$ matrix with $n \geq m$ and let $B$ be a $m \times n$ matrix. Also let $A_{i}$

$$
i=1, \cdots, C(n, m)
$$

be the $m \times m$ submatrices of $A$ which are obtained by deleting $n-m$ rows and let $B_{i}$ be the $m \times m$ submatrices of $B$ which are obtained by deleting corresponding $n-m$ columns. Then

$$
\operatorname{det}(B A)=\sum_{k=1}^{C(n, m)} \operatorname{det}\left(B_{k}\right) \operatorname{det}\left(A_{k}\right)
$$

Proof: This follows from a computation. By Corollary 5.4.5 on Page 71, $\operatorname{det}(B A)=$

$$
\begin{gathered}
\frac{1}{m!} \sum_{\left(i_{1} \cdots i_{m}\right)} \sum_{\left(j_{1} \cdots j_{m}\right)} \operatorname{sgn}\left(i_{1} \cdots i_{m}\right) \operatorname{sgn}\left(j_{1} \cdots j_{m}\right)(B A)_{i_{1} j_{1}}(B A)_{i_{2} j_{2}} \cdots(B A)_{i_{m} j_{m}} \\
\frac{1}{m!} \sum_{\left(i_{1} \cdots i_{m}\right)} \sum_{\left(j_{1} \cdots j_{m}\right)} \operatorname{sgn}\left(i_{1} \cdots i_{m}\right) \operatorname{sgn}\left(j_{1} \cdots j_{m}\right) \\
\sum_{r_{1}=1}^{n} B_{i_{1} r_{1}} A_{r_{1} j_{1}} \sum_{r_{2}=1}^{n} B_{i_{2} r_{2}} A_{r_{2} j_{2}} \cdots \sum_{r_{m}=1}^{n} B_{i_{m} r_{m}} A_{r_{m} j_{m}}
\end{gathered}
$$

Now denote by $I_{k}$ one subsets of $\{1, \cdots, n\}$ having $m$ elements. Thus there are $C(n, m)$ of these. Then the above equals

$$
\begin{aligned}
= & \sum_{k=1}^{C(n, m)} \sum_{\left\{r_{1}, \cdots, r_{m}\right\}=I_{k}} \frac{1}{m!} \sum_{\left(i_{1} \cdots i_{m}\right)} \sum_{\left(j_{1} \cdots j_{m}\right)} \operatorname{sgn}\left(i_{1} \cdots i_{m}\right) \operatorname{sgn}\left(j_{1} \cdots j_{m}\right) . \\
& B_{i_{1} r_{1}} A_{r_{1} j_{1} B_{1}} B_{i_{2} r_{2}} A_{r_{2} j_{2}} \cdots B_{i_{m} r_{m}} A_{r_{m} j_{m}} \\
& \sum_{k=1}^{C(n, m)} \sum_{\left\{r_{1}, \cdots, r_{m}\right\}=I_{k}} \frac{1}{m!} \sum_{\left(i_{1} \cdots i_{m}\right)} \operatorname{sgn}\left(i_{1} \cdots i_{m}\right) B_{i_{1} r_{1}} B_{i_{2} r_{2}} \cdots B_{i_{m} r_{m}} \\
& \sum_{\left(j_{1} \cdots j_{m}\right)} \operatorname{sgn}\left(j_{1} \cdots j_{m}\right) A_{r_{1} j_{1}} A_{r_{2} j_{2}} \cdots A_{r_{m} j_{m}} \\
= & \sum_{k=1}^{C(n, m)} \sum_{\left\{r_{1}, \cdots, r_{m}\right\}=I_{k}} \frac{1}{m!} \operatorname{sgn}\left(r_{1} \cdots r_{m}\right)^{2} \operatorname{det}\left(B_{k}\right) \operatorname{det}\left(A_{k}\right) \\
= & \sum_{k=1}^{C(n, m)} \operatorname{det}\left(B_{k}\right) \operatorname{det}\left(A_{k}\right)
\end{aligned}
$$

since there are $m$ ! ways of arranging the indices $\left\{r_{1}, \cdots, r_{m}\right\}$.

### 30.3 Integration Of Differential Forms On Manifolds

This section presents the integration of differential forms on manifolds. This topic is a higher dimensional version of what is done in calculus in finding the work done by a force field on an object which moves over some path. There you evaluated line integrals. Differential forms are just a higher dimensional version of this idea and it turns out they are what it makes sense to integrate on manifolds. The following lemma, on Page 429 used in establishing the definition of the degree and in giving a proof of the Brouwer fixed point theorem is also a fundamental result in discussing the integration of differential forms.

Lemma 30.3.1 Let $\mathbf{g}: U \rightarrow V$ be $C^{2}$ where $U$ and $V$ are open subsets of $\mathbb{R}^{n}$. Then

$$
\sum_{j=1}^{n}(\operatorname{cof}(D \mathbf{g}))_{i j, j}=0
$$

where here $(D \mathbf{g})_{i j} \equiv g_{i, j} \equiv \frac{\partial g_{i}}{\partial x_{j}}$.
Also recall the interesting relation of the degree to integration in Corollary 29.11.3
Corollary 30.3.2 Let $f \in L_{\text {loc }}^{p}\left(\mathbb{R}^{n}\right)$ for $p \geq 1$ and let $\mathbf{h}$ be Lipschitz where $\partial U$ has measure zero for $U$ a bounded open set and $\mathbf{h}(\partial U)^{C}$ has finitely many components. Then everything is measurable which needs to be and

$$
\int f(\mathbf{y}) d(\mathbf{y}, U, \mathbf{h}) d y=\int_{U} \operatorname{det} D \mathbf{h}(\mathbf{x}) f(\mathbf{h}(\mathbf{x})) d x
$$

(Recall that if $\mathbf{y} \notin \mathbf{h}(U)$, then $d(\mathbf{y}, U, \mathbf{h})=0$.)
Recall Proposition 23.6.4.
Proposition 30.3.3 Let $\Omega$ be an open connected bounded set in $\mathbb{R}^{n}$ such that $\mathbb{R}^{n} \backslash \partial \Omega$ consists of two, three if $n=1$, connected components. Let $\mathbf{f} \in C\left(\bar{\Omega} ; \mathbb{R}^{n}\right)$ be continuous and one to one. Then $\mathbf{f}(\Omega)$ is the bounded component of $\mathbb{R}^{n} \backslash \mathbf{f}(\partial \Omega)$ and for $\mathbf{y} \in \mathbf{f}(\Omega)$, $d(\mathbf{f}, \Omega, \mathbf{y})$ either equals 1 or -1 .

Also recall the following fundamental lemma on partitions of unity in Corollary 15.5.9.
Lemma 30.3.4 Let $K$ be a compact set in $\mathbb{R}^{n}$ and let $\left\{U_{i}\right\}_{i=1}^{\infty}$ be an open cover of $K$. Then there exist functions, $\psi_{k} \in C_{c}^{\infty}\left(U_{i}\right)$ such that $\psi_{i} \prec U_{i}$ and for all $\mathbf{x} \in K$,

$$
\sum_{i=1}^{\infty} \psi_{i}(\mathbf{x})=1
$$

If $K$ is a compact subset of $U_{1}\left(U_{i}\right)$ there exist such functions such that also $\psi_{1}(\mathbf{x})=1$ ( $\psi_{i}(\mathbf{x})=1$ ) for all $\mathbf{x} \in K$.

With the above, what follows is the definition of what a differential form is and how to integrate one.

Definition 30.3.5 Let I denote an ordered list of $n$ indices taken from the set, $\{1, \cdots, m\}$. Thus $I=\left(i_{1}, \cdots, i_{n}\right)$. It is an ordered list because the order matters. A differential form of order $n$ in $\mathbb{R}^{m}$ is a formal expression,

$$
\omega=\sum_{I} a_{I}(\mathbf{x}) d \mathbf{x}^{I}
$$

where $a_{I}$ is at least Borel measurable $d \mathbf{x}^{I}$ is short for the expression

$$
d x^{i_{1}} \wedge \cdots \wedge d x^{i_{n}}
$$

and the sum is taken over all ordered lists of indices taken from the set, $\{1, \cdots, m\}$. For $\Omega$ an orientable $n$ dimensional manifold with boundary, define

$$
\begin{equation*}
\int_{\Omega} \omega \tag{30.3.3}
\end{equation*}
$$

according to the following procedure in which it is assumed the integrals which occur make sense. Let $\left\{\left(U_{i}, \mathbf{R}_{i}\right)\right\}$ be an oriented atlas for $\Omega$. Each $U_{i}$ is the intersection of an open set in $\mathbb{R}^{m}, O_{i}$, with $\Omega$ and so there exists a $C^{\infty}$ partition of unity subordinate to the open cover, $\left\{O_{i}\right\}$ which sums to 1 on $\Omega$. Thus $\psi_{i} \in C_{c}^{\infty}\left(O_{i}\right)$, has values in $[0,1]$ and satisfies $\sum_{i} \psi_{i}(\mathbf{x})=1$ for all $\mathbf{x} \in \Omega$. Then define 30.3.3 by

$$
\begin{equation*}
\int_{\Omega} \omega \equiv \sum_{i=1}^{p} \sum_{I} \int_{\mathbf{R}_{i} U_{i}} \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u \tag{30.3.4}
\end{equation*}
$$

where that symbol at the end denotes

$$
\operatorname{det}\left(\begin{array}{cccc}
x_{i_{1}, u_{1}} & x_{i_{1}, u_{2}} & \cdots & x_{i_{1}, u_{n}} \\
x_{i_{2}, u_{1}} & x_{i_{2}, u_{2}} & \cdots & x_{i_{2}, u_{2}} \\
\vdots & \vdots & \ddots & \vdots \\
x_{i_{n}, u_{1}} & x_{i_{n}, u_{2}} & \cdots & x_{i_{n}, u_{n}}
\end{array}\right)(\mathbf{u})
$$

for $\left(x_{1}, x_{2}, \cdots, x_{n}\right)=\mathbf{R}_{i}^{-1}(\mathbf{u})$.
Of course there are all sorts of questions related to whether this definition is well defined. The formula 30.3.3 makes no mention of partitions of unity or a particular atlas. What if you had a different atlas and a different partition of unity? Would $\int_{\Omega} \omega$ change? In general, the answer is yes. However, there is a sense in which 30.3 .3 is well defined. This involves the concept of orientation. This looks a lot like the concept of an oriented manifold.

Definition 30.3.6 Suppose $\Omega$ is an $n$ dimensional orientable manifold with boundary and let $\left(U_{i}, \mathbf{R}_{i}\right)$ and $\left(V_{i}, \mathbf{S}_{i}\right)$ be two oriented atlass of $\Omega$. They have the same orientation if for all open connected sets $A \subseteq \mathbf{S}_{j}\left(V_{j} \cap U_{i}\right)$ with $\partial A$ having measure zero and separating $\mathbb{R}^{n}$ into two components,

$$
d\left(\mathbf{u}, \mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}, A\right) \in\{0,1\}
$$

depending on whether $\mathbf{u} \in \mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}(A)$.
The above definition of $\int_{\Omega} \omega$ is well defined in the sense that any two atlass which have the same orientation deliver the same value for this symbol.

Theorem 30.3.7 Suppose $\Omega$ is an $n$ dimensional Lipschitz orientable manifold with boundary and let $\left(U_{i}, \mathbf{R}_{i}\right)$ and $\left(V_{i}, \mathbf{S}_{i}\right)$ be two oriented atlass of $\Omega$. Suppose the two atlass have the same orientation. Then if $\int_{\Omega} \omega$ is computed with respect to the two atlass the same number is obtained.

Proof: Let $\left\{\psi_{i}\right\}$ be a partition of unity as described in Lemma 30.3.4 which is associated with the atlas $\left(U_{i}, \mathbf{R}_{i}\right)$ and let $\left\{\eta_{i}\right\}$ be a partition of unity associated in the same manner with the atlas $\left(V_{i}, \mathbf{S}_{i}\right)$. First note the following.

$$
\begin{gather*}
\sum_{I} \int_{\mathbf{R}_{i} U_{i}} \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u  \tag{30.3.5}\\
=\sum_{j=1}^{q} \sum_{I} \int_{\mathbf{R}_{i}\left(U_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u \\
=\sum_{j=1}^{q} \sum_{I} \int_{\operatorname{int} \mathbf{R}_{i}\left(U_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u
\end{gather*}
$$

The reason this can be done is that points not on the interior of $\mathbf{R}_{i}\left(U_{i} \cap V_{j}\right)$ are on the plane $u_{1}=0$ which is a set of measure zero.

Now let $A$ be an open connected set contained in $\mathbf{S}_{j}\left(U_{i} \cap V_{j}\right)$ whose boundary $\partial A$ separates $\mathbb{R}^{n}$ into two components. Then by assumption,

$$
\begin{align*}
& \int_{\mathbf{R}_{i} \mathbf{S}_{j}^{-1}(A)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u  \tag{30.3.6}\\
&= \int_{\mathbf{R}_{i} \mathbf{S}_{j}^{-1}(A)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \\
& \cdot \frac{\partial\left(x_{\left.i_{1} \cdots x_{i_{n}}\right)}^{\partial\left(u_{1} \cdots u_{n}\right)} d\left(\mathbf{u}, A, \mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}\right) d u\right.}{}
\end{align*}
$$

because that degree is given to be 1 . (Unless $\mathbf{u} \in \mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}(A)$, the above degree equals 0 .) By Corollary 30.3.2, this equals

$$
\begin{aligned}
& \int_{A} \eta_{j}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \psi_{i}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) a_{I}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \\
& \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)}\left(\mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}(\mathbf{v})\right) \operatorname{det}\left(D\left(\mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}\right)(\mathbf{v})\right) d v
\end{aligned}
$$

and by the chain rule and Rademacher's theorem, Theorem 26.6.7, this equals

$$
\begin{equation*}
\int_{A} \eta_{j}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \psi_{i}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) a_{I}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(v_{1} \cdots v_{n}\right)} d v \tag{30.3.7}
\end{equation*}
$$

Thus for every open $A$ of the sort described $30.3 .7=30.3 .6$. By the Vitali covering theorem, there exists a sequence of disjoint open balls $\left\{B_{k}\right\}$ whose union fills up int $\left(\mathbf{S}_{j}\left(U_{i} \cap V_{j}\right)\right)$ except for a set of measure zero $N$. Since $\mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}$ is Lipschitz, it follows $\mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}(N)$ also has measure zero. Therefore,

$$
\begin{equation*}
\int_{\mathbf{R}_{i}\left(U_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u \tag{30.3.8}
\end{equation*}
$$

$$
\begin{align*}
& =\int_{\operatorname{int}^{2}\left(\mathbf{R}_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u \\
& =\sum_{k=1}^{\infty} \int_{\mathbf{R}_{i} \circ \mathbf{S}_{j}^{-1}\left(B_{k}\right)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u \\
& =\sum_{k=1}^{\infty} \int_{B_{k}} \eta_{j}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \psi_{i}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) a_{I}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(v_{1} \cdots v_{n}\right)} d v \\
& =\int_{\mathrm{int}^{\mathbf{S}}\left(U_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \psi_{i}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) a_{I}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(v_{1} \cdots v_{n}\right)} d v \\
& =\int_{\mathbf{S}_{j}\left(U_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \psi_{i}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) a_{I}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(v_{1} \cdots v_{n}\right)} d v \tag{30.3.9}
\end{align*}
$$

The equality of 30.3 .8 and 30.3.9 was the goal. With this, the definition of $\int \omega$ using the atlas $\left(U_{i}, \mathbf{R}_{i}\right)$ and partition of unity $\left\{\psi_{i}\right\}_{i=1}^{p}$ given in 30.3 .5 is

$$
\begin{gathered}
\sum_{i=1}^{p} \sum_{I} \int_{\mathbf{R}_{i} U_{i}} \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1} \cdots x_{i_{n}}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u \\
=\sum_{j=1}^{q} \sum_{i=1}^{p} \sum_{I} \int_{\mathbf{R}_{i}\left(U_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \psi_{i}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) a_{I}\left(\mathbf{R}_{i}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(u_{1} \cdots u_{n}\right)} d u
\end{gathered}
$$

and from 30.3.8-30.3.9, this equals

$$
\begin{gathered}
=\sum_{j=1}^{q} \sum_{i=1}^{p} \sum_{I} \int_{\mathbf{S}_{j}\left(U_{i} \cap V_{j}\right)} \eta_{j}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \psi_{i}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) a_{I}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(v_{1} \cdots v_{n}\right)} d v \\
=\sum_{j=1}^{q} \sum_{I} \int_{\mathbf{S}_{j}\left(V_{j}\right)} \eta_{j}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) a_{I}\left(\mathbf{S}_{j}^{-1}(\mathbf{v})\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n}}\right)}{\partial\left(v_{1} \cdots v_{n}\right)} d v
\end{gathered}
$$

which is the definition of $\int \omega$ using the other atlas and partition of unity. This proves the theorem.

### 30.3.1 The Derivative Of A Differential Form

The derivative of a differential form is defined next.
Definition 30.3.8 Let $\omega=\sum_{I} a_{I}(\mathbf{x}) d x_{i_{1}} \wedge \cdots \wedge d x_{i_{n-1}}$ be a differential form of order $n-1$ where $a_{I}$ has weak partial derivatives. Then define $d \omega$, a differential form of order $n$ by replacing $a_{I}(\mathbf{x})$ with

$$
\begin{equation*}
d a_{I}(\mathbf{x}) \equiv \sum_{k=1}^{m} \frac{\partial a_{I}(\mathbf{x})}{\partial x_{k}} d x_{k} \tag{30.3.10}
\end{equation*}
$$

and putting $a$ wedge after the $d x_{k}$. Therefore,

$$
\begin{equation*}
d \omega \equiv \sum_{I} \sum_{k=1}^{m} \frac{\partial a_{I}(\mathbf{x})}{\partial x_{k}} d x_{k} \wedge d x_{i_{1}} \wedge \cdots \wedge d x_{i_{n-1}} \tag{30.3.11}
\end{equation*}
$$

### 30.4 Stoke's Theorem And The Orientation Of $\partial \Omega$

Here $\Omega$ will be an $n$ dimensional orientable Lipschitz manifold with boundary in $\mathbb{R}^{m}$. Let an oriented manifold for it be $\left\{U_{i}, \mathbf{R}_{i}\right\}_{i=1}^{p}$ and let a $C^{\infty}$ partition of unity be $\left\{\psi_{i}\right\}_{i=1}^{p}$. Also let

$$
\omega=\sum_{I} a_{I}(\mathbf{x}) d x_{i_{1}} \wedge \cdots \wedge d x_{i_{n-1}}
$$

be a differential form such that $a_{I}$ is $C^{1}(\bar{\Omega})$. Since $\sum \psi_{i}(\mathbf{x})=1$ on $\Omega$,

$$
d \omega=\sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}(\mathbf{x}) d x_{k} \wedge d x_{i_{1}} \wedge \cdots \wedge d x_{i_{n-1}}
$$

It follows

$$
\begin{gather*}
\int d \omega=\sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \int_{\mathbf{R}_{j}\left(U_{j}\right)} \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{k}, x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)} d \mathbf{u} \\
=\sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \int_{\mathbf{R}_{j}\left(U_{j}\right)} \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j \varepsilon}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{k \varepsilon}, x_{i_{1} \varepsilon} \cdots x_{i_{n-1} \varepsilon}\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)} d \mathbf{u}+ \\
\quad \sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \int_{\mathbf{R}_{j}\left(U_{j}\right)} \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{k}, x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)} d \mathbf{u} \\
-\sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \int_{\mathbf{R}_{j}\left(U_{j}\right)} \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j \varepsilon}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{k \varepsilon}, x_{i_{1} \varepsilon} \cdots x_{i_{n-1} \varepsilon}\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)} d \mathbf{u} \tag{30.4.12}
\end{gather*}
$$

where those last two expressions sum to $e(\varepsilon)$ which converges to 0 as $\varepsilon \rightarrow 0$ for a suitable subsequence. Here is why.

$$
\frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j \varepsilon}^{-1}(\mathbf{u})\right) \rightarrow \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j}^{-1}(\mathbf{u})\right)
$$

because of the uniform convergence of $\mathbf{R}_{j \varepsilon}^{-1}$ to $\mathbf{R}_{j}^{-1}$. In addition to this,

$$
\frac{\partial\left(x_{k \varepsilon}, x_{i_{1} \varepsilon} \varepsilon x_{i_{n-1}} \varepsilon\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)} \rightarrow \frac{\partial\left(x_{k}, x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)}
$$

in $L^{r}\left(\mathbf{R}_{j}\left(U_{j}\right)\right)$ for any $r>0$ and so a suitable subsequence converges pointwise. The integrands are also uniformly integrable. Thus the Vitali convergence theorem can be applied to each of the integrals in the above sum and obtain that for a suitable subsequence, $e(\varepsilon) \rightarrow 0$.

Then 30.4.12 equals

$$
=\sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \int_{\mathbf{R}_{j}\left(U_{j}\right)} \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j \varepsilon}^{-1}(\mathbf{u})\right) \sum_{l=1}^{m} \frac{\partial x_{k \varepsilon}}{\partial u_{l}} A_{1 l} d \mathbf{u}+e(\varepsilon)
$$

where $A_{1 l}$ is the $1 l^{\text {th }}$ cofactor for the determinant

$$
\frac{\partial\left(x_{k \varepsilon}, x_{i_{1} \varepsilon} \cdots x_{i_{n-1}} \varepsilon\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)}
$$

which is determined by a particular $I$. I am suppressing the $\varepsilon$ for the sake of notation. Then the above reduces to

$$
\begin{align*}
& =\sum_{I} \sum_{j=1}^{p} \int_{\mathbf{R}_{j}\left(U_{j}\right)} \sum_{l=1}^{n} A_{1 l} \sum_{k=1}^{m} \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}\left(\mathbf{R}_{j \varepsilon}^{-1}(\mathbf{u})\right) \frac{\partial x_{k \varepsilon}}{\partial u_{l}} d \mathbf{u}+e(\varepsilon) \\
& =\sum_{I} \sum_{j=1}^{p} \sum_{l=1}^{n} \int_{\mathbf{R}_{j}\left(U_{j}\right)} A_{1 l} \frac{\partial}{\partial u_{l}}\left(\psi_{j} a_{I} \circ \mathbf{R}_{j \varepsilon}^{-1}\right)(\mathbf{u}) d \mathbf{u}+e(\varepsilon) \tag{30.4.13}
\end{align*}
$$

(Note $l$ goes up to $n$ not $m$.) Recall $\mathbf{R}_{j}\left(U_{j}\right)$ is relatively open in $\mathbb{R}_{\leq}^{n}$. Consider the integral where $l>1$. Integrate first with respect to $u_{l}$. In this case the boundary term vanishes because of $\psi_{j}$ and you get

$$
\begin{equation*}
-\int_{\mathbf{R}_{j}\left(U_{j}\right)} A_{1 l, l}\left(\psi_{j} a_{I} \circ \mathbf{R}_{j \varepsilon}^{-1}\right)(\mathbf{u}) d \mathbf{u} \tag{30.4.14}
\end{equation*}
$$

Next consider the case where $l=1$. Integrating first with respect to $u_{1}$, the term reduces to

$$
\begin{equation*}
\int_{\mathbf{R}_{j} V_{j}} \psi_{j} a_{I} \circ \mathbf{R}_{j \varepsilon}^{-1}\left(0, u_{2}, \cdots, u_{n}\right) A_{11} d \mathbf{u}_{1}-\int_{\mathbf{R}_{j}\left(U_{j}\right)} A_{11,1}\left(\psi_{j} a_{I} \circ \mathbf{R}_{j \varepsilon}^{-1}\right)(\mathbf{u}) d \mathbf{u} \tag{30.4.15}
\end{equation*}
$$

where $\mathbf{R}_{j} V_{j}$ is an open set in $\mathbb{R}^{n-1}$ consisting of

$$
\left\{\left(u_{2}, \cdots, u_{n}\right) \in \mathbb{R}^{n-1}:\left(0, u_{2}, \cdots, u_{n}\right) \in \mathbf{R}_{j}\left(U_{j}\right)\right\}
$$

and $d \mathbf{u}_{1}$ represents $d u_{2} d u_{3} \cdots d u_{n}$ on $\mathbf{R}_{j} V_{j}$ for short. Thus $V_{j}$ is just the part of $\partial \Omega$ which is in $U_{j}$ and the mappings $\mathbf{S}_{j}^{-1}$ given on $\mathbf{R}_{j} V_{j}=\mathbf{R}_{j}\left(U_{j} \cap \partial \Omega\right)$ by

$$
\mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \equiv \mathbf{R}_{j}^{-1}\left(0, u_{2}, \cdots, u_{n}\right)
$$

are such that $\left\{\left(\mathbf{S}_{j}, V_{j}\right)\right\}$ is an atlas for $\partial \Omega$. Then if 30.4.14 and 30.4.15 are placed in 30.4.13, then it follows from Lemma 30.3.1 that this reduces to

$$
\sum_{I} \sum_{j=1}^{p} \int_{\mathbf{R}_{j} V_{j}} \psi_{j} a_{I} \circ \mathbf{R}_{j \varepsilon}^{-1}\left(0, u_{2}, \cdots, u_{n}\right) A_{11} d \mathbf{u}_{1}+e(\varepsilon)
$$

Now as before, there exists a subsequence, still denoted as $\varepsilon$ such that each $\partial x_{s \varepsilon} / \partial u_{r}$ converges pointwise to $\partial x_{s} / \partial u_{r}$ and then using that these are bounded in every $L^{p}$, one can use the Vitali convergence theorem to pass to a limit obtaining finally

$$
\begin{aligned}
& \sum_{I} \sum_{j=1}^{p} \int_{\mathbf{R}_{j} V_{j}} \psi_{j} a_{I} \circ \mathbf{R}_{j}^{-1}\left(0, u_{2}, \cdots, u_{n}\right) A_{11} d \mathbf{u}_{1} \\
= & \sum_{I} \sum_{j=1}^{p} \int_{\mathbf{S}_{j} V_{j}} \psi_{j} a_{I} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) A_{11} d \mathbf{u}_{1}
\end{aligned}
$$

$$
\begin{equation*}
=\sum_{I} \sum_{j=1}^{p} \int_{\mathbf{S}_{j} V_{j}} \psi_{j} a_{I} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\left(0, u_{2}, \cdots, u_{n}\right) d \mathbf{u}_{1} \tag{30.4.16}
\end{equation*}
$$

This of course is the definition of $\int_{\partial \Omega} \omega$ provided $\partial \Omega$ is orientable. This is shown next.
What if spt $a_{I} \subseteq K \subseteq U_{i} \cap U_{j}$ for each $I$ ? Then using Lemma 30.3.4 it can be shown that $\int d \omega=$

$$
\sum_{I} \int_{\mathbf{S}_{j}\left(V_{j} \cap V_{j}\right)} a_{I} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\left(0, u_{2}, \cdots, u_{n}\right) d \mathbf{u}_{1}
$$

This is done by using a partition of unity which has the property that $\psi_{j}$ equals 1 on $K$ which forces all the other $\psi_{k}$ to equal zero there. Using the same trick involving a judicious choice of the partition of unity, $\int d \omega$ is also equal to

$$
\sum_{I} \int_{\mathbf{S}_{i}\left(V_{j} \cap V_{j}\right)} a_{I} \circ \mathbf{S}_{i}^{-1}\left(v_{2}, \cdots, v_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(v_{2}, \cdots, v_{n}\right)}\left(0, v_{2}, \cdots, v_{n}\right) d \mathbf{v}_{1}
$$

Similarly if $A$ is an open connected subset of $\mathbf{S}_{i}\left(V_{j} \cap V_{j}\right)$ whose measure zero boundary separates $\mathbb{R}^{n}$ into two components, and $K$ is a compact subset of $\mathbf{S}_{i}^{-1}(A)$, containing spt $a_{I}$ for all $I, \int d \omega$ equals each of 30.4.18 and 30.4.17 below.

$$
\begin{array}{r}
\sum_{I} \int_{A} a_{I} \circ \mathbf{S}_{i}^{-1}\left(v_{2}, \cdots, v_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(v_{2}, \cdots, v_{n}\right)}\left(0, v_{2}, \cdots, v_{n}\right) d \mathbf{v}_{1} \\
\sum_{I} \int_{\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(A)} a_{I} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)} d \mathbf{u}_{1} \tag{30.4.18}
\end{array}
$$

By Corollary 30.3.2 applied to $\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}\left(\mathbf{v}_{1}\right)=\mathbf{u}_{1}$, the expression in 30.4.17 equals

$$
\sum_{I} \int_{\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(A)} a_{I} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)} d\left(\mathbf{u}_{1}, A, \mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}\right) d \mathbf{u}_{1}
$$

and so, subtracting 30.4.18 and the above,

$$
\begin{gathered}
\sum_{I} \int_{\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(A)} a_{I} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)} \\
\left(1-d\left(\mathbf{u}_{1}, A, \mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}\right)\right) d \mathbf{u}_{1}=0
\end{gathered}
$$

Now by invariance of domain, it follows $\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(A)$ is an open connected set contained in a single component of $\left(\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(\partial A)\right)^{C}$ and so the above degree is constant on $\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(A)$. If this degree is not 1 then it follows that for any choice of the $a_{I}$ having compact support in $\mathbf{S}_{i}^{-1}(A)$,

$$
\begin{equation*}
\sum_{I} \int_{\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(A)} a_{I} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)} d \mathbf{u}_{1}=0 \tag{30.4.19}
\end{equation*}
$$

Next let $I$ always denote an increasing list of indices. Note that $\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}$ maps the open set $A$ to an open set which therefore has positive Lebesgue measure. It follows from the area formula that

$$
\begin{equation*}
\operatorname{det}\left(D\left(\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}\right)\right)=\operatorname{det}(\overbrace{D\left(\mathbf{S}_{j}\left(\mathbf{S}_{i}^{-1}(\mathbf{u})\right)\right) D \mathbf{S}_{i}^{-1}(\mathbf{u})}^{n \times m}) \tag{30.4.20}
\end{equation*}
$$

must be nonzero on a set of positive measure. It follows that at least some

$$
\frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}
$$

must be nonzero since by the Binet Cauchy theorem, the above determinant in 30.4.20 is the sum of products of these multiplied by other determinants which come from deleting corresponding columns in the matrix for $D\left(\mathbf{S}_{j}\left(\mathbf{S}_{i}^{-1}(\mathbf{u})\right)\right)$. It follows that

$$
\sum_{I}\left(\frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\right)^{2}
$$

is positive on a set of positive measure. Let

$$
\lim _{p \rightarrow \infty} a_{I p} \circ \mathbf{S}_{j}^{-1}=\frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}
$$

in $L^{2}\left(\mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}(A)\right)$ for each $I=\left(i_{1}, \cdots, i_{n-1}\right)$. Replacing $a_{I} \circ \mathbf{S}_{j}^{-1}$ with $a_{I p} \circ \mathbf{S}_{j}^{-1}$ in 30.4.19 and passing to the limit, it follows

$$
\begin{aligned}
0 & =\lim _{p \rightarrow \infty} \int_{\mathbf{S}_{j} \mathbf{S}_{i}^{-1}(A)} \sum_{I} a_{I p} \circ \mathbf{S}_{j}^{-1}\left(\mathbf{u}_{1}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)} d \mathbf{u}_{1} \\
& =\int_{\mathbf{S}_{j} \mathbf{S}_{i}^{-1}(A)} \sum_{I}\left(\frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\right)^{2} d \mathbf{u}_{1}>0
\end{aligned}
$$

a contradiction. Therefore, $d\left(\mathbf{u}_{1}, A, \mathbf{S}_{j} \circ \mathbf{S}_{i}^{-1}\right)=1$ and this shows the atlas is an oriented atlas for $\partial \Omega$. This has proved a general Stokes theorem.

Theorem 30.4.1 Let $\Omega$ be an oriented Lipschitz manifold and let

$$
\omega=\sum_{I} a_{I}(\mathbf{x}) d x_{i_{1}} \wedge \cdots \wedge d x_{i_{n-1}}
$$

where each $a_{I}$ is $C^{1}(\bar{\Omega})$. For $\left\{U_{j}, \mathbf{R}_{j}\right\}_{j=0}^{p}$ an oriented atlas for $\Omega$ where $\mathbf{R}_{j}\left(U_{j}\right)$ is a relatively open set in

$$
\left\{\mathbf{u} \in \mathbb{R}^{n}: u_{1} \leq 0\right\}
$$

define an atlas for $\partial \Omega,\left\{V_{j}, \mathbf{S}_{j}\right\}$ where $V_{j} \equiv \partial \Omega \cap U_{j}$ and $\mathbf{S}_{j}$ is just the restriction of $\mathbf{R}_{j}$ to $V_{j}$. Then this is an oriented atlas for $\partial \Omega$ and

$$
\int_{\partial \Omega} \omega=\int_{\Omega} d \omega
$$

where the two integrals are taken with respect to the given oriented atlass.
What if $a_{I}$ is only the restriction to $\Omega$ of a function in $W^{1, p}\left(\mathbb{R}^{m}\right), p>1$ ? Would the same formula still hold? Let $\phi_{\varepsilon}$ be a mollifier and let $a_{I \varepsilon} \equiv a_{I} * \phi_{\varepsilon}$. Then Stoke's theorem applies to the mollified situation and it follows

$$
\begin{aligned}
& \int_{\Omega} d \omega_{\varepsilon} \\
= & \sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \int_{\mathbf{R}_{j}\left(U_{j}\right)} \frac{\partial\left(\psi_{j} a_{I \varepsilon}\right)}{\partial x_{k}}\left(\mathbf{R}_{j}^{-1}(\mathbf{u})\right) \frac{\partial\left(x_{k}, x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)} d \mathbf{u} \\
= & \sum_{I} \sum_{j=1}^{p} \int_{\mathbf{s}_{j} V_{j}} \psi_{j} a_{I \varepsilon} \circ \mathbf{S}_{j}^{-1}\left(u_{2}, \cdots, u_{n}\right) \frac{\partial\left(x_{i_{1}} \cdots x_{i_{n-1}}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\left(0, u_{2}, \cdots, u_{n}\right) d \mathbf{u}_{1} \\
\equiv & \int_{\partial \Omega} \omega_{\varepsilon}
\end{aligned}
$$

Now if you let $\varepsilon \rightarrow 0$, it follows from the definition of convolution that

$$
\frac{\partial\left(\psi_{j} a_{I \varepsilon}\right)}{\partial x_{k}} \rightarrow \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}} \text { in } L^{p}\left(\mathbb{R}^{m}\right)
$$

and so there is a subsequence such that for each $k$,

$$
\frac{\partial\left(\psi_{j} a_{I \varepsilon}\right)}{\partial x_{k}}(\mathbf{x}) \rightarrow \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}}(\mathbf{x})
$$

pointwise a.e. Since $\mathbf{R}_{j}^{-1}, \mathbf{R}_{j}$ are Lipschitz, they take sets of measure zero to sets of measure zero. Hence

$$
\frac{\partial\left(\psi_{j} a_{I \varepsilon}\right)}{\partial x_{k}} \circ \mathbf{R}_{j}^{-1} \rightarrow \frac{\partial\left(\psi_{j} a_{I}\right)}{\partial x_{k}} \circ \mathbf{R}_{j}^{-1}
$$

pointwise a.e. on $\mathbf{R}_{j}\left(U_{j}\right)$. Similar considerations apply to $a_{I \varepsilon}$. Using the Vitali convergence theorem in $\int_{\Omega} d \omega_{\varepsilon}, \int_{\Omega} \omega_{\varepsilon}$, it is possible to pass to the limit. This is because the integrands are bounded in $L^{p}$ and so they are uniformly integrable. This proves the following corollary.

Corollary 30.4.2 Let $\Omega$ be an oriented Lipschitz manifold and let

$$
\omega=\sum_{I} a_{I}(\mathbf{x}) d x_{i_{1}} \wedge \cdots \wedge d x_{i_{n-1}}
$$

where each $a_{I}$ is in $W^{1, p}\left(\mathbb{R}^{m}\right)$ where $p>1$. For $\left\{U_{j}, \mathbf{R}_{j}\right\}_{j=0}^{p}$ an oriented atlas for $\Omega$ where $\mathbf{R}_{j}\left(U_{j}\right)$ is a relatively open set in

$$
\left\{\mathbf{u} \in \mathbb{R}^{n}: u_{1} \leq 0\right\}
$$

define an atlas for $\partial \Omega,\left\{V_{j}, \mathbf{S}_{j}\right\}$ where $V_{j} \equiv \partial \Omega \cap U_{j}$ and $\mathbf{S}_{j}$ is just the restriction of $\mathbf{R}_{j}$ to $V_{j}$. Then this is an oriented atlas for $\partial \Omega$ and

$$
\int_{\partial \Omega} \omega=\int_{\Omega} d \omega
$$

where the two integrals are taken with respect to the given oriented atlass.

### 30.5 Green's Theorem

Green's theorem is a well known result in calculus and it pertains to a region in the plane. I am going to generalize to an open set in $\mathbb{R}^{n}$ with sufficiently smooth boundary using the methods of differential forms described above.

### 30.5.1 An Oriented Manifold

A bounded open subset, $\Omega$, of $\mathbb{R}^{n}, n \geq 2$ has Lipschitz boundary and lies locally on one side of its boundary if it satisfies the following conditions.

For each $p \in \partial \Omega \equiv \bar{\Omega} \backslash \Omega$, there exists an open set, $Q$, containing $p$, an open interval $(a, b)$, a bounded open set $B \subseteq \mathbb{R}^{n-1}$, and an orthogonal transformation $R$ such that $\operatorname{det} R=$ 1,

$$
B \times(a, b)=R Q
$$

and letting $W=Q \cap \Omega$,

$$
R W=\left\{\mathbf{u} \in \mathbb{R}^{n}: a<u_{1}<g\left(u_{2}, \cdots, u_{n}\right),\left(u_{2}, \cdots, u_{n}\right) \in B\right\}
$$

where $g$ is Lipschitz continuous on $\mathbb{R}^{n-1}, g\left(u_{2}, \cdots, u_{n}\right)<b$ for $\left(u_{2}, \cdots, u_{n}\right) \in B$, and $g$ vanishing outside some compact set in $\mathbb{R}^{n-1}$.

$$
R(\partial \Omega \cap Q)=\left\{\mathbf{u} \in \mathbb{R}^{n}: u_{1}=g\left(u_{2}, \cdots, u_{n}\right),\left(u_{2}, \cdots, u_{n}\right) \in B\right\}
$$

Note that finitely many of these sets $Q$ cover $\partial \Omega$ because $\partial \Omega$ is compact. The following picture describes the situation.

Define $\mathbf{P}_{1}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n-1}$ by

$$
\mathbf{P}_{1} \mathbf{u} \equiv\left(u_{2}, \cdots, u_{n}\right)
$$

and $\Sigma: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ given by

$$
\begin{gathered}
\Sigma \mathbf{u} \equiv \mathbf{u}-g\left(\mathbf{P}_{1} \mathbf{u}\right) \mathbf{e}_{1} \\
\equiv \mathbf{u}-g\left(u_{2}, \cdots, u_{n}\right) \mathbf{e}_{1} \\
\equiv\left(u_{1}-g\left(u_{2}, \cdots, u_{n}\right), u_{2}, \cdots, u_{n}\right)
\end{gathered}
$$

Thus $\Sigma$ is invertible and

$$
\begin{gathered}
\Sigma^{-1} \mathbf{u}=\mathbf{u}+g\left(\mathbf{P}_{1} \mathbf{u}\right) \mathbf{e}_{1} \\
\equiv\left(u_{1}+g\left(u_{2}, \cdots, u_{n}\right), u_{2}, \cdots, u_{n}\right)
\end{gathered}
$$

For $\mathbf{x} \in \partial \Omega \cap Q$, it follows the first component of $R \mathbf{x}$ is $g\left(\mathbf{P}_{1}(R \mathbf{x})\right)$. Now define $\mathbf{R}: W \rightarrow \mathbb{R}_{\leq}^{n}$ as

$$
\mathbf{u} \equiv \mathbf{R} \mathbf{x} \equiv R \mathbf{x}-g\left(\mathbf{P}_{1}(R \mathbf{x})\right) \mathbf{e}_{1} \equiv \Sigma R \mathbf{x}
$$

and so it follows

$$
\mathbf{R}^{-1}=R^{*} \Sigma^{-1}
$$

These mappings $\mathbf{R}$ involve first a rotation followed by a variable sheer in the direction of the $u_{1}$ axis.

Since $\partial \Omega$ is compact, there are finitely many of these open sets, $Q_{1}, \cdots, Q_{p}$ which cover $\partial \Omega$. Let the orthogonal transformations and other quantities described above also be indexed by $k$ for $k=1, \cdots, p$. Also let $Q_{0}$ be an open set with $\overline{Q_{0}} \subseteq \Omega$ and $\bar{\Omega}$ is covered by $Q_{0}, Q_{1}, \cdots, Q_{p}$. Let $\mathbf{u} \equiv \mathbf{R}_{0} \mathbf{x} \equiv \mathbf{x}-k \mathbf{e}_{1}$ where $k$ is large enough that $\mathbf{R}_{0} Q_{0} \subseteq \mathbb{R}_{<}^{n}$. Thus in this case, the orthogonal transformation $R_{0}$ equals $I$ and $\Sigma_{0} \mathbf{x} \equiv \mathbf{x}-k \mathbf{e}_{1}$. I claim $\Omega$ is an oriented manifold with boundary and the charts are $\left(W_{i}, \mathbf{R}_{i}\right)$.

Letting $A$ be an open set contained in $\mathbf{R}_{i}\left(W_{i} \cap W_{j}\right)$ such that $\partial A$ has measure 0 and $\partial A$ separates $\mathbb{R}^{n}$ into two components, consider

$$
d\left(\mathbf{u}, A, \mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\right), \mathbf{u} \notin \mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}(\partial A)
$$

By convolving $g$ with a mollifier, there exists a sequence of infinitely differentiable functions $g_{\varepsilon}$ which converge uniformly to $g$ on all of $\mathbb{R}^{n-1}$ as $\varepsilon \rightarrow 0$. Therefore, letting $\Sigma_{\varepsilon}$ be the corresponding functions defined above with $g$ replaced with $g_{\varepsilon}$, it follows the $\Sigma_{\varepsilon}$ will converge uniformly to $\Sigma$ and $\Sigma_{\varepsilon}^{-1}$ will converge uniformly to $\Sigma^{-1}$. Thus from the above descriptions of $\mathbf{R}_{j}^{-1}$, it follows $\mathbf{R}_{j \varepsilon}^{-1}$ converges uniformly to $\mathbf{R}_{j}^{-1}$ for each $j$. Therefore, if $\varepsilon$ is small enough, $\mathbf{u} \notin\left(t \mathbf{R}_{j \varepsilon} \circ \mathbf{R}_{i \varepsilon}^{-1}+(1-t) \mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\right)(\partial A)$ and so from properties of the degree, the mappings $\mathbf{R}_{j}$ and $\mathbf{R}_{i}^{-1}$ can be replaced with smooth ones in computing the degree. To save on notation, I will drop the $\varepsilon$. The mapping involved is

$$
\Sigma_{j} R_{j} R_{i}^{*} \Sigma_{i}^{-1}
$$

and it is a one to one mapping. What is the determinant of its derivative? By the chain rule,

$$
D\left(\Sigma_{j} R_{j} R_{i}^{*} \Sigma_{i}^{-1}\right)=D \Sigma_{j}\left(R_{j} R_{i}^{*} \Sigma_{i}^{-1}\right) D R_{j}\left(R_{i}^{*} \Sigma_{i}^{-1}\right) D R_{i}^{*}\left(\Sigma_{i}^{-1}\right) D \Sigma_{i}^{-1}
$$

However,

$$
\operatorname{det}\left(D \Sigma_{j}\right)=1=\operatorname{det}\left(D \Sigma_{j}^{-1}\right)
$$

and $\operatorname{det}\left(R_{i}\right)=\operatorname{det}\left(R_{i}^{*}\right)=1$ by assumption. Therefore, if $\mathbf{u} \in\left(\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\right)(A)$, the above degree is 1 and if $\mathbf{u}$ is not in this set, the above degree is 0 or undefined if $\mathbf{u}$ is on $\left(\mathbf{R}_{j} \circ \mathbf{R}_{i}^{-1}\right)(\partial A)$. By Definition 30.1.5 $\Omega$ is indeed an oriented manifold.

### 30.5.2 Green's Theorem

The general Green's theorem is the following. It follows from Corollary 30.4.2.
Theorem 30.5.1 Let $\Omega$ be a bounded open set having Lipschitz boundary as described above. Also let

$$
\omega=\sum_{I} a_{I}(\mathbf{x}) d x_{i_{1}} \wedge \cdots \wedge d x_{i_{n-1}}
$$

be a differential form where $a_{I}$ is assumed to be the restriction to $\Omega$ of a function in $W^{1, p}\left(\mathbb{R}^{n}\right), p>1$. Then

$$
\int_{\partial \Omega} \omega=\int_{\Omega} d \omega
$$

It can be shown that, since the boundary is Lipschitz, it would have sufficed to assume $u \in W^{1, p}(\Omega)$ and then it is automatically the restriction of one in $W^{1, p}\left(\mathbb{R}^{n}\right)$. However, these terms have not all been defined and the necessary results are not proved till the topic of Sobolev spaces is discussed.

Another thing to notice is that, while the above result is pretty general, including the usual calculus result in the plane as a special case, it does not have the generality of the best results in the plane which involve only a rectifiable simple closed curve. The issue whether $\partial \Omega$ is an oriented manifold was dealt with in the general Stokes theorem described above.

Next is a general version of the divergence theorem which comes from choosing the differential form in an auspicious manner.

### 30.6 The Divergence Theorem

From Green's theorem, one can quickly obtain a general Divergence theorem for $\Omega$ as described above in Section 30.5.1. First note that from the above description of the $\mathbf{R}_{j}$,

$$
\frac{\partial\left(x_{k}, x_{i_{1}}, \cdots x_{i_{n-1}}\right)}{\partial\left(u_{1}, \cdots, u_{n}\right)}=\operatorname{sgn}\left(k, i_{1} \cdots, i_{n-1}\right)
$$

So let $\mathbf{F}(\mathbf{x})$ be a Lipschitz vector field. Say $\mathbf{F}=\left(F_{1}, \cdots, F_{n}\right)$. Consider the differential form

$$
\omega(\mathbf{x}) \equiv \sum_{k=1}^{n} F_{k}(\mathbf{x})(-1)^{k-1} d x_{1} \wedge \cdots \wedge \widehat{d x_{k}} \wedge \cdots \wedge d x_{n}
$$

where the hat means $d x_{k}$ is being left out. Here it is assumed $F_{k}$ is the restriction to $\Omega$ of a function in $W^{1, p}\left(\mathbb{R}^{n}\right)$ where $p>1$. Then

$$
\begin{aligned}
d \omega(\mathbf{x}) & =\sum_{k=1}^{n} \sum_{j=1}^{n} \frac{\partial F_{k}}{\partial x_{j}}(-1)^{k-1} d x_{j} \wedge d x_{1} \wedge \cdots \wedge \widehat{d x_{k}} \wedge \cdots \wedge d x_{n} \\
& =\sum_{k=1}^{n} \frac{\partial F_{k}}{\partial x_{k}} d x_{1} \wedge \cdots \wedge d x_{k} \wedge \cdots \wedge d x_{n} \\
& \equiv \operatorname{div}(\mathbf{F}) d x_{1} \wedge \cdots \wedge d x_{k} \wedge \cdots \wedge d x_{n}
\end{aligned}
$$

The assertion between the first and second lines follows right away from properties of determinants and the definition of the integral of the above wedge products in terms of determinants. From Green's theorem and the change of variables formula applied to the individual terms in the description of $\int_{\Omega} d \omega$

$$
\begin{gathered}
\int_{\Omega} \operatorname{div}(\mathbf{F}) d x= \\
\sum_{j=1}^{p} \int_{B_{j}} \sum_{k=1}^{n}(-1)^{k-1} \frac{\partial\left(x_{1}, \cdots \widehat{x_{k}} \cdots, x_{n}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\left(\psi_{j} F_{k}\right) \circ \mathbf{R}_{j}^{-1}\left(0, u_{2}, \cdots, u_{n}\right) d \mathbf{u}_{1}
\end{gathered}
$$

$d \mathbf{u}_{1}$ short for $d u_{2} d u_{3} \cdots d u_{n}$. Also, this shows the result on the right of the equal sign does not depend on the choice of partition of unity or on the atlas.

I want to write this in a more attractive manner which will give more insight in terms of the Hausdorff measure on $\partial \Omega$. The above involves a particular partition of unity, the functions being the $\psi_{i}$. Replace $\mathbf{F}$ in the above with $\psi_{s} \mathbf{F}$. Next let $\left\{\eta_{j}\right\}$ be a partition of unity $\eta_{j} \prec O_{j}$ such that $\eta_{s}=1$ on spt $\psi_{s}$. This partition of unity exists by Lemma 30.3.4. Then

$$
\begin{gather*}
\int_{\Omega} \operatorname{div}\left(\psi_{s} \mathbf{F}\right) d x= \\
\sum_{j=1}^{p} \int_{B_{j}} \sum_{k=1}^{n}(-1)^{k-1} \frac{\partial\left(x_{1}, \cdots \widehat{x_{k}} \cdots, x_{n}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\left(\eta_{j} \psi_{s} F_{k}\right) \circ \mathbf{R}_{j}^{-1}\left(0, u_{2}, \cdots, u_{n}\right) d \mathbf{u}_{1} \\
=\int_{B_{s}} \sum_{k=1}^{n}(-1)^{k-1} \frac{\partial\left(x_{1}, \cdots \widehat{x}_{k} \cdots, x_{n}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\left(\psi_{s} F_{k}\right) \circ \mathbf{R}_{s}^{-1}\left(0, u_{2}, \cdots, u_{n}\right) d \mathbf{u}_{1} \tag{30.6.21}
\end{gather*}
$$

because since $\eta_{s}=1$ on $\operatorname{spt} \psi_{s}$, it follows all the other $\eta_{j}$ equal zero there. Consider the vector defined for $\mathbf{u}_{1} \in \mathbf{R}_{s}\left(W_{s}\right) \cap \mathbb{R}_{0}^{n}$ whose $k^{t h}$ component is

$$
\begin{equation*}
(-1)^{k-1} \frac{\partial\left(x_{1}, \cdots \widehat{x_{k}} \cdots, x_{n}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}=(-1)^{k+1} \frac{\partial\left(x_{1}, \cdots \widehat{x_{k}} \cdots, x_{n}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)} \tag{30.6.22}
\end{equation*}
$$

Suppose you dot this vector with a "tangent" vector $\partial \mathbf{R}_{s}^{-1} / \partial u_{i}$. For each $j$ this yields

$$
\sum_{j}(-1)^{k+1} \frac{\partial\left(x_{1}, \cdots \widehat{x_{k}} \cdots, x_{n}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)} \frac{\partial x_{k}}{\partial u_{i}}=0
$$

because it is the expansion of

$$
\left|\begin{array}{cccc}
x_{1, i} & x_{1,2} & \cdots & x_{1, n} \\
x_{2, i} & x_{2,2} & \cdots & x_{2, n} \\
\vdots & \vdots & \ddots & \vdots \\
x_{n, i} & x_{n, 2} & \cdots & x_{n, n}
\end{array}\right|
$$

a determinant with two equal columns. Thus this vector is at least in some sense normal to $\Omega$. Since it works in the divergence theorem, it is called the exterior normal.

One could normalize the vector of 30.6 .22 by dividing by its magnitude. Then it would be the unit exterior normal $\mathbf{n}$. Letting $J\left(\mathbf{u}_{1}\right)$ be its usual Euclidean norm, this equals

$$
J\left(\mathbf{u}_{1}\right)^{2}=\sum_{k=1}^{n}\left(\frac{\partial\left(x_{1}, \cdots \widehat{x_{k}} \cdots, x_{n}\right)}{\partial\left(u_{2}, \cdots, u_{n}\right)}\right)^{2}
$$

and by the Binet Cauchy theorem this equals

$$
\operatorname{det}\left(D \mathbf{R}_{s}^{-1}(\mathbf{u})^{*} D \mathbf{R}_{s}^{-1}(\mathbf{u})\right)^{1 / 2}
$$

Thus the expression in 30.6.21 reduces to

$$
\int_{B_{s}}\left(\psi_{s} \mathbf{F} \circ \mathbf{R}_{s}^{-1}\left(\mathbf{u}_{1}\right)\right) \cdot \mathbf{n}\left(\mathbf{R}_{s}^{-1}\left(\mathbf{u}_{1}\right)\right) J\left(\mathbf{u}_{1}\right) d \mathbf{u}_{1} .
$$

By the area formula, Theorem 29.5.3, this reduces to

$$
\int_{\partial \Omega \cap W_{s}} \psi_{s} \mathbf{F} \cdot \mathbf{n} d \mathscr{H}^{n-1}=\int_{\partial \Omega} \psi_{s} \mathbf{F} \cdot \mathbf{n} d \mathscr{H}^{n-1}
$$

It follows upon summing over $s$ and using that the $\psi_{s}$ add to 1 ,

$$
\begin{aligned}
& \int_{\partial \Omega} \mathbf{F} \cdot \mathbf{n} d \mathscr{H}^{n-1}=\int_{\Omega} \sum_{s=1}^{p} \operatorname{div}\left(\psi_{s} \mathbf{F}\right) d x \\
& =\int_{\Omega} \sum_{s=1}^{p} \psi_{s, k} F_{k}+\psi_{s} \operatorname{div}(\mathbf{F}) d x=\int_{\Omega} F_{k}\left(\sum_{s=1}^{p} \psi_{s}\right)_{, k}+\psi_{s} \operatorname{div}(\mathbf{F}) d x \\
& =\int_{\Omega} \operatorname{div}(\mathbf{F}) d x
\end{aligned}
$$

This proves the following general divergence theorem.
Theorem 30.6.1 Let $\Omega$ be a bounded open set having Lipschitz boundary as described above. Also let $\mathbf{F}$ be a vector field with the property that for each component function of $\mathbf{F}, F_{k}$ is the restriction to $\Omega$ of a function in $W^{1, p}\left(\mathbb{R}^{n}\right), p>1$. Then there exists a normal vector $\mathbf{n}$ which is defined a.e. on $\partial \Omega$ such that

$$
\int_{\partial \Omega} \mathbf{F} \cdot \mathbf{n} d \mathscr{H}^{n-1}=\int_{\Omega} \operatorname{div}(\mathbf{F}) d x
$$

It is clear $\mathbf{n}$ is unique $\mathscr{H}^{n-1}$ a.e. since if there were two, then a simple manipulation shows for all such $\mathbf{F}$,

$$
\int_{\partial \Omega} \mathbf{F} \cdot\left(\mathbf{n}-\mathbf{n}_{1}\right) d \mathscr{H}^{n-1}=0
$$

Thus $\mathbf{n}-\mathbf{n}_{1}=\mathbf{0}$ a.e.

## Chapter 31

## Differentiation, Radon Measures

This is a brief chapter on certain important topics on the differentiation theory for general Radon measures. For different proofs and some results which are not discussed here, a good source is [47] which is where I first read some of these things.

### 31.1 Fundamental Theorem Of Calculus

In this section the Besicovitch covering theorem will be used to give a generalization of the Lebesgue differentiation theorem to general Radon measures. In what follows, $\mu$ will be a Radon measure,

$$
Z \equiv\left\{\mathbf{x} \in \mathbb{R}^{n}: \mu(B(\mathbf{x}, r))=0 \text { for some } r>0\right\}
$$

Lemma 31.1.1 $Z$ is measurable and $\mu(Z)=0$.
Proof: For each $\mathbf{x} \in Z$, there exists a ball $B(\mathbf{x}, r)$ with $\mu(B(\mathbf{x}, r))=0$. Let $\mathscr{C}$ be the collection of these balls. Since $\mathbb{R}^{n}$ has a countable basis, a countable subset, $\widetilde{\mathscr{C}}$, of $\mathscr{C}$ also covers $Z$. Let

$$
\widetilde{\mathscr{C}}=\left\{B_{i}\right\}_{i=1}^{\infty}
$$

Then letting $\bar{\mu}$ denote the outer measure determined by $\mu$,

$$
\bar{\mu}(Z) \leq \sum_{i=1}^{\infty} \bar{\mu}\left(B_{i}\right)=\sum_{i=1}^{\infty} \mu\left(B_{i}\right)=0
$$

Therefore, $Z$ is measurable and has measure zero as claimed.
Let $M f: \mathbb{R}^{n} \rightarrow[0, \infty]$ by

$$
M f(\mathbf{x}) \equiv\left\{\begin{array}{l}
\sup _{r \leq 1} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f| d \mu \text { if } \mathbf{x} \notin Z \\
0 \text { if } \mathbf{x} \in Z
\end{array}\right.
$$

Theorem 31.1.2 Let $\mu$ be a Radon measure and let $f \in L^{1}\left(\mathbb{R}^{n}, \mu\right)$. Then for a.e. $\mathbf{x}$,

$$
\lim _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d \mu(y)=0
$$

Proof: First consider the following claim which is a weak type estimate of the same sort used when differentiating with respect to Lebesgue measure.

Claim 1: The following inequality holds for $N_{n}$ the constant of the Besicovitch covering theorem.

$$
\bar{\mu}([M f>\varepsilon]) \leq N_{n} \varepsilon^{-1}\|f\|_{1}
$$

Proof: First note $[M f>\varepsilon] \cap Z=\emptyset$ and without loss of generality, you can assume $\bar{\mu}([M f>\varepsilon])>0$. Next, for each $\mathbf{x} \in[M f>\varepsilon]$ there exists a ball $B_{\mathbf{x}}=B\left(\mathbf{x}, r_{\mathbf{x}}\right)$ with $r_{\mathbf{x}} \leq 1$ and

$$
\mu\left(B_{\mathbf{x}}\right)^{-1} \int_{B\left(\mathbf{x}, r_{\mathbf{x}}\right)}|f| d \mu>\varepsilon
$$

Let $\mathscr{F}$ be this collection of balls so that $[M f>\varepsilon]$ is the set of centers of balls of $\mathscr{F}$. By the Besicovitch covering theorem,

$$
[M f>\varepsilon] \subseteq \cup_{i=1}^{N_{n}}\left\{B: B \in \mathscr{G}_{i}\right\}
$$

where $\mathscr{G}_{i}$ is a collection of disjoint balls of $\mathscr{F}$. Now for some $i$,

$$
\bar{\mu}([M f>\varepsilon]) / N_{n} \leq \mu\left(\cup\left\{B: B \in \mathscr{G}_{i}\right\}\right)
$$

because if this is not so, then

$$
\begin{aligned}
\bar{\mu}([M f>\varepsilon]) & \leq \sum_{i=1}^{N_{n}} \mu\left(\cup\left\{B: B \in \mathscr{G}_{i}\right\}\right) \\
& <\sum_{i=1}^{N_{n}} \frac{\bar{\mu}([M f>\varepsilon])}{N_{n}}=\bar{\mu}([M f>\varepsilon])
\end{aligned}
$$

a contradiction. Therefore for this $i$,

$$
\begin{aligned}
\frac{\bar{\mu}([M f>\varepsilon])}{N_{n}} & \leq \mu\left(\cup\left\{B: B \in \mathscr{G}_{i}\right\}\right)=\sum_{B \in \mathscr{G}_{i}} \mu(B) \leq \sum_{B \in \mathscr{G}_{i}} \varepsilon^{-1} \int_{B}|f| d \mu \\
& \leq \varepsilon^{-1} \int_{\mathbb{R}^{n}}|f| d \mu=\varepsilon^{-1}| | f \|_{1}
\end{aligned}
$$

This shows Claim 1.
Claim 2: If $g$ is any continuous function defined on $\mathbb{R}^{n}$, then for $\mathbf{x} \notin Z$,

$$
\lim _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|g(\mathbf{y})-g(\mathbf{x})| d \mu(y)=0
$$

and

$$
\begin{equation*}
\lim _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} g(\mathbf{y}) d \mu(y)=g(\mathbf{x}) \tag{31.1.1}
\end{equation*}
$$

Proof: Since $g$ is continuous at $\mathbf{x}$, whenever $r$ is small enough,

$$
\frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|g(\mathbf{y})-g(\mathbf{x})| d \mu(y) \leq \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} \varepsilon d \mu(y)=\varepsilon .
$$

31.1.1 follows from the above and the triangle inequality. This proves the claim.

Now let $g \in C_{c}\left(\mathbb{R}^{n}\right)$ and $\mathbf{x} \notin Z$. Then from the above observations about continuous functions,

$$
\begin{align*}
& \bar{\mu}\left(\left[\mathbf{x} \notin Z: \lim _{r \rightarrow 0} \sup _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d \mu(y)>\varepsilon\right]\right)  \tag{31.1.2}\\
& \quad \leq \\
& \quad \bar{\mu}\left(\left[\mathbf{x} \notin Z: \lim \sup _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-g(\mathbf{y})| d \mu(y)>\frac{\varepsilon}{2}\right]\right) \\
& \quad+\bar{\mu}\left(\left[\mathbf{x} \notin Z:|g(\mathbf{x})-f(\mathbf{x})|>\frac{\varepsilon}{2}\right]\right) .
\end{align*}
$$

$$
\begin{equation*}
\leq \bar{\mu}\left(\left[M(f-g)>\frac{\varepsilon}{2}\right]\right)+\bar{\mu}\left(\left[|f-g|>\frac{\varepsilon}{2}\right]\right) \tag{31.1.3}
\end{equation*}
$$

Now

$$
\int_{\left[|f-g|>\frac{\varepsilon}{2}\right]}|f-g| d \mu \geq \frac{\varepsilon}{2} \bar{\mu}\left(\left[|f-g|>\frac{\varepsilon}{2}\right]\right)
$$

and so from Claim 1 31.1.3 and hence 31.1.2 is dominated by

$$
\left(\frac{2}{\varepsilon}+\frac{N_{n}}{\varepsilon}\right)\|f-g\|_{L^{1}\left(\mathbb{R}^{n}, \mu\right)}
$$

But by regularity of Radon measures, $C_{c}\left(\mathbb{R}^{n}\right)$ is dense in $L^{1}\left(\mathbb{R}^{n}, \mu\right)$, and so since $g$ in the above is arbitrary, this shows 31.1.2 equals 0 . Now

$$
\begin{aligned}
& \bar{\mu}\left(\left[\mathbf{x} \notin Z:{\lim \sup _{r \rightarrow 0}}^{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d \mu(y)>0\right]\right) \\
\leq & \sum_{k=1}^{\infty} \bar{\mu}\left(\left[\mathbf{x} \notin Z: \lim _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d \mu(y)>\frac{1}{k}\right]\right)=0
\end{aligned}
$$

By completeness of $\mu$ this implies

$$
\left[\mathbf{x} \notin Z: \lim \sup _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d \mu(y)>0\right]
$$

is a set of $\mu$ measure zero
The following corollary is the main result referred to as the Lebesgue Besicovitch Differentiation theorem.

Corollary 31.1.3 If $f \in L_{\text {loc }}^{1}\left(\mathbb{R}^{n}, \mu\right)$, then for a.e. $\mathbf{x} \notin Z$,

$$
\begin{equation*}
\lim _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d \mu(y)=0 \tag{31.1.4}
\end{equation*}
$$

Proof: If $f$ is replaced by $f \mathscr{X}_{B(\mathbf{0}, k)}$ then the conclusion 31.1.4 holds for all $\mathbf{x} \notin F_{k}$ where $F_{k}$ is a set of $\mu$ measure 0 . Letting $k=1,2, \cdots$, and $F \equiv \cup_{k=1}^{\infty} F_{k}$, it follows that $F$ is a set of measure zero and for any $\mathbf{x} \notin F$, and $k \in\{1,2, \cdots\}, 31.1 .4$ holds if $f$ is replaced by $f \mathscr{X}_{B(\mathbf{0}, k)}$. Picking any such $\mathbf{x}$, and letting $k>|\mathbf{x}|+1$, this shows

$$
\begin{gathered}
\lim _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}|f(\mathbf{y})-f(\mathbf{x})| d \mu(y) \\
=\lim _{r \rightarrow 0} \frac{1}{\mu(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)}\left|f \mathscr{X}_{B(\mathbf{0}, k)}(\mathbf{y})-f \mathscr{X}_{B(\mathbf{0}, k)}(\mathbf{x})\right| d \mu(y)=0 .
\end{gathered}
$$

### 31.2 Slicing Measures

Let $\mu$ be a finite Radon measure. I will show here that a formula of the following form holds.

$$
\mu(F)=\int_{F} d \mu=\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} \mathscr{X}_{F}(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x)
$$

where $\alpha(E)=\mu\left(E \times \mathbb{R}^{m}\right)$. When this is done, the measures, $v_{\mathbf{x}}$, are called slicing measures and this shows that an integral with respect to $\mu$ can be written as an iterated integral in terms of the measure $\alpha$ and the slicing measures, $v_{\mathbf{x}}$. This is like going backwards in the construction of product measure. One starts with a measure $\mu$, defined on the Cartesian product and produces $\alpha$ and an infinite family of slicing measures from it whereas in the construction of product measure, one starts with two measures and obtains a new measure on a $\sigma$ algebra of subsets of the Cartesian product of two spaces. These slicing measures are dependent on $\mathbf{x}$. Later, this will be tied to the concept of independence or not of random variables. First here are two technical lemmas.

Lemma 31.2.1 The space $C_{c}\left(\mathbb{R}^{m}\right)$ with the norm

$$
\|f\| \equiv \sup \left\{|f(\mathbf{y})|: \mathbf{y} \in \mathbb{R}^{m}\right\}
$$

is separable.
Proof: Let $\mathscr{D}_{l}$ consist of all functions which are of the form

$$
\sum_{|\alpha| \leq N} a_{\alpha} \mathbf{y}^{\alpha}\left(\operatorname{dist}\left(\mathbf{y}, B(\mathbf{0}, l+1)^{C}\right)\right)^{n_{\alpha}}
$$

where $a_{\alpha} \in \mathbb{Q}, \alpha$ is a multi-index, and $n_{\alpha}$ is a positive integer. Consider $\mathscr{D} \equiv \cup_{l} \mathscr{D}_{l}$. Then $\mathscr{D}$ is countable. If $f \in C_{c}\left(\mathbb{R}^{n}\right)$, then choose $l$ large enough that $\operatorname{spt}(f) \subseteq B(\mathbf{0}, l+1)$, a locally compact space, $f \in C_{0}(B(\mathbf{0}, l+1))$. Then since $\mathscr{D}_{l}$ separates the points of $B(\mathbf{0}, l+1)$ is closed with respect to conjugates, and annihilates no point, it is dense in $C_{0}(B(\mathbf{0}, l+1))$ by the Stone Weierstrass theorem. Alternatively, $\mathscr{D}$ is dense in $C_{0}\left(\mathbb{R}^{n}\right)$ by Stone Weierstrass and $C_{c}\left(\mathbb{R}^{n}\right)$ is a subspace so it is also separable. So is $C_{c}\left(\mathbb{R}^{n}\right)^{+}$, the nonnegative functions in $C_{c}\left(\mathbb{R}^{n}\right)$.

From the regularity of Radon measures, the following lemma follows.
Lemma 31.2.2 If $\mu$ and $v$ are two Radon measures defined on $\sigma$ algebras, $\mathscr{S}_{\mu}$ and $\mathscr{S}_{v}$, of subsets of $\mathbb{R}^{n}$ and if $\mu(V)=v(V)$ for all $V$ open, then $\mu=v$ and $\mathscr{S}_{\mu}=\mathscr{S}_{v}$.

Proof: Every compact set is a countable intersection of open sets so the two measures agree on every compact set. Hence it is routine that the two measures agree on every $G_{\delta}$ and $F_{\sigma}$ set. (Recall $G_{\delta}$ sets are countable intersections of open sets and $F_{\sigma}$ sets are countable unions of closed sets.) Now suppose $E \in \mathscr{S}_{v}$ is a bounded set. Then by regularity of $v$ there exists $G$ a $G_{\delta}$ set and $F$, an $F_{\sigma}$ set such that $F \subseteq E \subseteq G$ and $v(G \backslash F)=0$. Then it is also true that $\mu(G \backslash F)=0$. Hence $E=F \cup(E \backslash F)$ and $E \backslash F$ is a subset of $G \backslash F$, a set of $\mu$ measure zero. By completeness of $\mu$, it follows $E \in \mathscr{S}_{\mu}$ and

$$
\mu(E)=\mu(F)=v(F)=v(E)
$$

If $E \in \mathscr{S}_{v}$ not necessarily bounded, let $E_{m}=E \cap B(0, m)$ and then $E_{m} \in \mathscr{S}_{\mu}$ and $\mu\left(E_{m}\right)=$ $v\left(E_{m}\right)$. Letting $m \rightarrow \infty, E \in \mathscr{S}_{\mu}$ and $\mu(E)=v(E)$. Similarly, $\mathscr{S}_{\mu} \subseteq \mathscr{S}_{v}$ and the two measures are equal on $\mathscr{S}_{\mu}$.

The main result in the section is the following theorem.
Theorem 31.2.3 Let $\mu$ be a finite Radon measure on $\mathbb{R}^{n+m}$ defined on a $\sigma$ algebra, $\mathscr{F}$. Then there exists a unique finite Radon measure $\alpha$, defined on a $\sigma$ algebra $\mathscr{S}$, of sets of $\mathbb{R}^{n}$ which satisfies

$$
\begin{equation*}
\alpha(E)=\mu\left(E \times \mathbb{R}^{m}\right) \tag{31.2.5}
\end{equation*}
$$

for all E Borel. There also exists a Borel set of $\alpha$ measure zero $N$, such that for each $\mathbf{x} \notin N$, there exists a Radon probability measure $v_{\mathbf{x}}$ such that if $f$ is a nonnegative $\mu$ measurable function or a $\mu$ measurable function in $L^{1}(\mu)$,

$$
\begin{gather*}
\mathbf{y} \rightarrow f(\mathbf{x}, \mathbf{y}) \text { is } v_{\mathbf{x}} \text { measurable } \alpha \text { a.e. } \\
\mathbf{x} \rightarrow \int_{\mathbb{R}^{m}} f(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) \text { is } \alpha \text { measurable } \tag{31.2.6}
\end{gather*}
$$

and

$$
\begin{equation*}
\int_{\mathbb{R}^{n+m}} f(\mathbf{x}, \mathbf{y}) d \mu=\int_{\mathbb{R}^{n}}\left(\int_{\mathbb{R}^{m}} f(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y)\right) d \alpha(x) \tag{31.2.7}
\end{equation*}
$$

If $\widehat{v}_{\mathbf{x}}$ is any other collection of Radon measures satisfying 31.2.6 and 31.2.7, then $\widehat{v}_{\mathbf{x}}=v_{\mathbf{x}}$ for $\alpha$ a.e. $\mathbf{x}$.

## Proof:

## Existence and uniqueness of $\alpha$

First consider the uniqueness of $\alpha$. Suppose $\alpha_{1}$ is another Radon measure satisfying 31.2.5. Then in particular, $\alpha_{1}$ and $\alpha$ agree on open sets and so the two measures are the same by Lemma 31.2.2.

To establish the existence of $\alpha$, define $\alpha_{0}$ on Borel sets by

$$
\alpha_{0}(E)=\mu\left(E \times \mathbb{R}^{m}\right)
$$

Thus $\alpha_{0}$ is a finite Borel measure and so it is finite on compact sets. Lemma 14.2.3 on Page 388 implies the existence of the Radon measure $\alpha$ extending $\alpha_{0}$.

## Uniqueness of $v_{\mathbf{x}}$

Next consider the uniqueness of $v_{\mathbf{x}}$. Suppose $v_{\mathbf{x}}$ and $\widehat{v}_{\mathbf{x}}$ satisfy all conclusions of the theorem with exceptional sets denoted by $N$ and $\widehat{N}$ respectively. Then, enlarging $N$ and $\widehat{N}$, one may also assume, using Lemma 31.1.1, that for $\mathbf{x} \notin N \cup \widehat{N}, \alpha(B(\mathbf{x}, r))>0$ whenever $r>0$. Now let

$$
A=\prod_{i=1}^{m}\left(a_{i}, b_{i}\right]
$$

where $a_{i}$ and $b_{i}$ are rational. Thus there are countably many such sets. Then from the conclusion of the theorem, if $\mathbf{x}_{0} \notin N \cup \widehat{N}$,

$$
\begin{aligned}
& \frac{1}{\alpha\left(B\left(\mathbf{x}_{0}, r\right)\right)} \int_{B\left(\mathbf{x}_{0}, r\right)} \int_{\mathbb{R}^{m}} \mathscr{X}_{A}(\mathbf{y}) d v_{\mathbf{x}}(y) d \alpha \\
= & \frac{1}{\alpha\left(B\left(\mathbf{x}_{0}, r\right)\right)} \int_{B\left(\mathbf{x}_{0}, r\right)} \int_{\mathbb{R}^{m}} \mathscr{X}_{A}(\mathbf{y}) d \widehat{v}_{\mathbf{x}}(y) d \alpha
\end{aligned}
$$

and by the Lebesgue Besicovitch Differentiation theorem, there exists a set of $\alpha$ measure zero, $E_{A}$, such that if $\mathbf{x}_{0} \notin E_{A} \cup N \cup \widehat{N}$, then the limit in the above exists as $r \rightarrow 0$ and yields

$$
v_{\mathbf{x}_{0}}(A)=\widehat{v}_{\mathbf{x}_{0}}(A)
$$

Letting $E$ denote the union of all the sets $E_{A}$ for $A$ as described above, it follows that $E$ is a set of measure zero and if $\mathbf{x}_{0} \notin E \cup N \cup \widehat{N}$ then $V_{\mathbf{x}_{0}}(A)=\widehat{v}_{\mathbf{x}_{0}}(A)$ for all such sets $A$. But every open set can be written as a disjoint union of sets of this form and so for all such $\mathbf{x}_{0}, v_{\mathbf{x}_{0}}(V)=\widehat{v}_{\mathbf{x}_{0}}(V)$ for all $V$ open. By Lemma 31.2.2 this shows the two measures are equal and proves the uniqueness assertion for $v_{\mathbf{x}}$. It remains to show the existence of the measures $v_{\mathbf{x}}$.

## Existence of $v_{\mathbf{x}}$

For $f \geq 0, f, g \in C_{c}\left(\mathbb{R}^{m}\right)$ and $C_{c}\left(\mathbb{R}^{n}\right)$ respectively, define

$$
g \rightarrow \int_{\mathbb{R}^{n+m}} g(\mathbf{x}) f(\mathbf{y}) d \mu
$$

Since $f \geq 0$, this is a positive linear functional on $C_{c}\left(\mathbb{R}^{n}\right)$. Therefore, there exists a unique Radon measure $v_{f}$ such that for all $g \in C_{c}\left(\mathbb{R}^{n}\right)$,

$$
\int_{\mathbb{R}^{n+m}} g(\mathbf{x}) f(\mathbf{y}) d \mu=\int_{\mathbb{R}^{n}} g(\mathbf{x}) d v_{f}
$$

I claim that $v_{f} \ll \alpha$, the two being considered as measures on $\mathscr{B}\left(\mathbb{R}^{n}\right)$. Suppose then that $K$ is a compact set and $\alpha(K)=0$. Then let $K \prec g \prec V$ where $V$ is open.

$$
\begin{gathered}
v_{f}(K)=\int_{\mathbb{R}^{n}} \mathscr{X}_{K}(\mathbf{x}) d v_{f}(\mathbf{x}) \leq \int_{\mathbb{R}^{n}} g(\mathbf{x}) d v_{f}(\mathbf{x})=\int_{\mathbb{R}^{n+m}} g(\mathbf{x}) f(\mathbf{y}) d \mu \\
\quad \leq \int_{\mathbb{R}^{m+m}} \mathscr{X}_{V \times \mathbb{R}^{m}}(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) d \mu \leq\|f\|_{\infty} \mu\left(V \times \mathbb{R}^{m}\right)=\|f\|_{\infty} \alpha(V)
\end{gathered}
$$

Then for any $\varepsilon>0$, one can choose $V$ such that the right side is less than $\varepsilon$. Therefore, $v_{f}(K)=0$ also. By regularity considerations, $v_{f} \ll \alpha$ as claimed.

It follows from the Radon Nikodym theorem the existence of a function $h_{f} \in L^{1}(\alpha)$ such that for all $g \in C_{c}\left(\mathbb{R}^{n}\right)$,

$$
\begin{equation*}
\int_{\mathbb{R}^{n+m}} g(\mathbf{x}) f(\mathbf{y}) d \mu=\int_{\mathbb{R}^{n}} g(\mathbf{x}) d v_{f}=\int_{\mathbb{R}^{n}} g(\mathbf{x}) h_{f}(\mathbf{x}) d \alpha \tag{31.2.8}
\end{equation*}
$$

It is obvious from the formula that the map from $f \in C_{c}\left(\mathbb{R}^{m}\right)$ to $L^{1}(\alpha)$ given by $f \rightarrow h_{f}$ is linear. However, this is not sufficiently specific because functions in $L^{1}(\alpha)$ are only determined a.e. However, for $h_{f} \in L^{1}(\alpha)$, you can specify a particular representative $\alpha$ a.e. By the fundamental theorem of calculus,

$$
\begin{equation*}
\widehat{h_{f}}(\mathbf{x}) \equiv \lim _{r \rightarrow 0} \frac{1}{\alpha(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} h_{f}(\mathbf{z}) d \alpha(z) \tag{31.2.9}
\end{equation*}
$$

exists off some set of measure zero $Z_{f}$. Note that since this involves the integral over a ball, it does not matter which representative of $h_{f}$ is placed in the formula. Therefore, $\widehat{h_{f}}(\mathbf{x})$ is well defined pointwise for all $\mathbf{x}$ not in some set of measure zero $Z_{f}$. Since $\widehat{h_{f}}=h_{f}$ a.e. it follows that $\widehat{h_{f}}$ is well defined and will work in the formula 31.2.8. Let

$$
Z=\cup\left\{Z_{f}: f \in \mathscr{D}\right\}
$$

where $\mathscr{D}$ is a countable dense subset of $C_{c}\left(\mathbb{R}^{m}\right)^{+}$. Of course it is desired to have the limit 31.2.9 hold for all $f$, not just $f \in \mathscr{D}$. We will show that this limit holds for all $\mathbf{x} \notin Z$. Thus, we will have $\mathbf{x} \rightarrow \widehat{h_{f}}(\mathbf{x})$ defined by the above limit off $Z$ and so, since $\widehat{h_{f}}(\mathbf{x})=h_{f}(\mathbf{x})$ a.e., it follows that

$$
\int_{\mathbb{R}^{n+m}} g(\mathbf{x}) f(\mathbf{y}) d \mu=\int_{\mathbb{R}^{n}} g(\mathbf{x}) d v_{f}=\int_{\mathbb{R}^{n}} g(\mathbf{x}) \widehat{h_{f}}(\mathbf{x}) d \alpha
$$

One could then take $\widehat{h_{f}}(\mathbf{x})$ to be defined as 0 for $\mathbf{x} \notin Z$.
For $f$ an arbitrary function in $C_{c}\left(\mathbb{R}^{m}\right)^{+}$and $f^{\prime} \in \mathscr{D}$, a dense countable subset of $C_{c}\left(\mathbb{R}^{n}\right)^{+}$, it follows from 31.2.8,

$$
\left|\int_{\mathbb{R}^{n}} g(\mathbf{x})\left(h_{f}(\mathbf{x})-h_{f^{\prime}}(\mathbf{x})\right) d \alpha\right| \leq\left|\left|f-f^{\prime} \|_{\infty} \int_{\mathbb{R}^{n+m}}\right| g(\mathbf{x})\right| d \mu
$$

Let $g_{k}(\mathbf{x}) \uparrow \mathscr{X}_{B(\mathbf{z}, r)}(\mathbf{x})$ where $\mathbf{z} \notin Z$. Then by the dominated convergence theorem, the above implies

$$
\left|\int_{B(\mathbf{z}, r)}\left(h_{f}(\mathbf{x})-h_{f^{\prime}}(\mathbf{x})\right) d \alpha\right| \leq\left\|f-f^{\prime}\right\|_{\infty} \int_{B(\mathbf{z}, r) \times \mathbb{R}^{m}} d \mu=\left\|f-f^{\prime}\right\|_{\infty} \alpha(B(\mathbf{z}, r)) .
$$

Dividing by $\alpha(B(\mathbf{z}, r))$, it follows that if $\alpha(B(\mathbf{z}, r))>0$ for all $r>0$, then for all $r>0$,

$$
\left|\frac{1}{\alpha(B(\mathbf{z}, r))} \int_{B(\mathbf{z}, r)}\left(h_{f}(\mathbf{x})-h_{f^{\prime}}(\mathbf{x})\right) d \alpha\right| \leq\left\|f-f^{\prime}\right\|_{\infty}
$$

It follows that for $f \in C_{c}\left(\mathbb{R}^{m}\right)^{+}$arbitrary and $\mathbf{z} \notin Z$,

$$
\begin{aligned}
& \lim \sup _{r \rightarrow 0} \frac{1}{\alpha(B(\mathbf{z}, r))} \int_{B(\mathbf{z}, r)} h_{f}(\mathbf{x}) d \alpha-\lim _{r \rightarrow 0} \inf _{r(B(\mathbf{z}, r))} \frac{1}{B(\mathbf{z}, r)} h_{f}(\mathbf{x}) d \alpha \\
= & \lim \sup _{r \rightarrow 0} \frac{1}{\alpha(B(\mathbf{z}, r))} \int_{B(\mathbf{z}, r)}\left(h_{f}(\mathbf{x})-h_{f^{\prime}}(\mathbf{x})\right) d \alpha(x) \\
& -\liminf _{r \rightarrow 0} \frac{1}{\alpha(B(\mathbf{z}, r))} \int_{B(\mathbf{z}, r)}\left(h_{f}(\mathbf{x})-h_{f^{\prime}}(\mathbf{x})\right) d \alpha(x) \\
\leq & \left|\limsup _{r \rightarrow 0} \frac{1}{\alpha(B(\mathbf{z}, r))} \int_{B(\mathbf{z}, r)}\left(h_{f}(\mathbf{x})-h_{f^{\prime}}(\mathbf{x})\right) d \alpha(x)\right| \\
& +\left|\lim _{r \rightarrow 0} \frac{1}{\alpha(B(\mathbf{z}, r))} \int_{B(\mathbf{z}, r)}\left(h_{f}(\mathbf{x})-h_{f^{\prime}}(\mathbf{x})\right) d \alpha(x)\right| \\
\leq & 2\left|\left|f-f^{\prime}\right|\right|_{\infty}
\end{aligned}
$$

and since $f^{\prime}$ is arbitrary, it follows that the limit of 31.2 .9 holds for all $f \in C_{c}\left(\mathbb{R}^{m}\right)^{+}$whenever $\mathbf{z} \notin Z$, the above set of measure zero.

Now for $f$ an arbitrary real valued function of $C_{c}\left(\mathbb{R}^{n}\right)$, simply apply the above result to positive and negative parts to obtain $h_{f} \equiv h_{f^{+}}-h_{f^{-}}$and $\widehat{h_{f}} \equiv \widehat{h_{f^{+}}}-\widehat{h_{f^{-}}}$. Then it follows that for all $f \in C_{c}\left(\mathbb{R}^{m}\right)$ and $g \in C_{c}\left(\mathbb{R}^{m}\right)$

$$
\int_{\mathbb{R}^{n+m}} g(\mathbf{x}) f(\mathbf{y}) d \mu=\int_{\mathbb{R}^{n}} g(\mathbf{x}) \widehat{h_{f}}(\mathbf{x}) d \alpha
$$

It is obvious from the description given above that for each $\mathbf{x} \notin Z$, the set of measure zero given above, that $f \rightarrow \widehat{h_{f}}(\mathbf{x})$ is a positive linear functional. It is clear that it acts like a linear map for nonnegative $f$ and so the usual trick just described above is well defined and delivers a positive linear functional. Hence by the Riesz representation theorem, there exists a unique $v_{\mathbf{x}}$ such that for all $\mathbf{x}$

$$
\widehat{h_{f}}(\mathbf{x})=\int_{\mathbb{R}^{m}} f(\mathbf{y}) d v_{\mathbf{x}}(y)
$$

It follows that

$$
\begin{equation*}
\int_{\mathbb{R}^{n+m}} g(\mathbf{x}) f(\mathbf{y}) d \mu=\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} g(\mathbf{x}) f(\mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x) \tag{31.2.10}
\end{equation*}
$$

and $\mathbf{x} \rightarrow \int_{\mathbb{R}^{m}} f(\mathbf{y}) d v_{\mathbf{x}}$ is $\alpha$ measurable and $v_{\mathbf{x}}$ is a Radon measure.
Now let $f_{k} \uparrow \mathscr{X}_{\mathbb{R}^{m}}$ and $g \geq 0$. Then by monotone convergence theorem,

$$
\int_{\mathbb{R}^{n+m}} g(\mathbf{x}) d \mu=\int_{\mathbb{R}^{n}} g(\mathbf{x}) \int_{\mathbb{R}^{m}} d v_{\mathbf{x}} d \alpha
$$

If $g_{k} \uparrow \mathscr{X}_{\mathbb{R}^{n}}$, the monotone convergence theorem shows that $\mathbf{x} \rightarrow \int_{\mathbb{R}^{m}} d v_{\mathbf{x}}$ is $L^{1}(\alpha)$.
Next let $g_{k} \uparrow \mathscr{X}_{B(\mathbf{x}, r)}$ and use monotone convergence theorem to write

$$
\alpha(B(\mathbf{x}, r)) \equiv \int_{B(\mathbf{x}, r) \times \mathbb{R}^{m}} d \mu=\int_{B(\mathbf{x}, r)} \int_{\mathbb{R}^{m}} d v_{\mathbf{x}} d \alpha
$$

Then dividing by $\alpha(B(\mathbf{x}, r))$ and taking a limit as $r \rightarrow 0$, it follows that for $\alpha$ a.e. $\mathbf{x}$, $1=v_{\mathbf{x}}\left(\mathbb{R}^{m}\right)$, so these $v_{\mathbf{x}}$ are probability measures off a set of $\alpha$ measure zero. Letting $g_{k}(\mathbf{x}) \uparrow \mathscr{X}_{A}(\mathbf{x}), f_{k}(\mathbf{y}) \uparrow \mathscr{X}_{B}(\mathbf{y})$ for $A, B$ open, it follows that 31.2.10 is valid for $g(\mathbf{x})$ replaced with $\mathscr{X}_{A}(\mathbf{x})$ and $f(\mathbf{y})$ replaced with $\mathscr{X}_{B}(\mathbf{y})$.

Now let $\mathscr{G}$ denote the Borel sets $F$ of $\mathbb{R}^{n+m}$ such that

$$
\int_{\mathbb{R}^{n+m}} \mathscr{X}_{F}(\mathbf{x}, \mathbf{y}) d \mu(x, y)=\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} \mathscr{X}_{F}(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x)
$$

and that all the integrals make sense. As just explained, this includes all Borel sets of the form $F=A \times B$ where $A, B$ are open. It is clear that $\mathscr{G}$ is closed with respect to countable disjoint unions and complements, while sets of the form $A \times B$ for $A, B$ open form a $\pi$ system. Therefore, by Lemma $12.12 .3, \mathscr{G}$ contains the Borel sets which is the smallest $\sigma$ algebra which contains such products of open sets. It follows from the usual approximation with simple functions that if $f \geq 0$ and is Borel measurable, then

$$
\int_{\mathbb{R}^{n+m}} f(\mathbf{x}, \mathbf{y}) d \mu(x, y)=\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} f(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x)
$$

with all the integrals making sense.
This proves the theorem in the case where $f$ is Borel measurable and nonnegative. It just remains to extend this to the case where $f$ is only $\mu$ measurable. However, from regularity of $\mu$ there exist Borel measurable functions $g, h, g \leq f \leq h$ such that

$$
\begin{aligned}
\int_{\mathbb{R}^{n+m}} f(\mathbf{x}, \mathbf{y}) d \mu(x, y) & =\int_{\mathbb{R}^{n+m}} g(\mathbf{x}, \mathbf{y}) d \mu(x, y) \\
& =\int_{\mathbb{R}^{n+m}} h(\mathbf{x}, \mathbf{y}) d \mu(x, y)
\end{aligned}
$$

It follows

$$
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} g(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x)=\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} h(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x)
$$

and so, since for $\alpha$ a.e. $\mathbf{x}, \mathbf{y} \rightarrow \mathbf{g}(\mathbf{x}, \mathbf{y})$ and $\mathbf{y} \rightarrow \mathbf{h}(\mathbf{x}, \mathbf{y})$ are $v_{\mathbf{x}}$ measurable with

$$
0=\int_{\mathbb{R}^{m}}(h(\mathbf{x}, \mathbf{y})-g(\mathbf{x}, \mathbf{y})) d v_{\mathbf{x}}(y)
$$

and $v_{\mathbf{x}}$ is a Radon measure, hence complete, it follows for $\alpha$ a.e. $\mathbf{x}, \mathbf{y} \rightarrow f(\mathbf{x}, \mathbf{y})$ must be $v_{\mathbf{x}}$ measurable because it is equal to $\mathbf{y} \rightarrow g(\mathbf{x}, \mathbf{y}), v_{\mathbf{x}}$ a.e. Therefore, for $\alpha$ a.e. $\mathbf{x}$, it makes sense to write

$$
\int_{\mathbb{R}^{m}} f(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y)
$$

Similar reasoning applies to the above function of $\mathbf{x}$ being $\alpha$ measurable due to $\alpha$ being complete. It follows

$$
\begin{aligned}
\int_{\mathbb{R}^{n+m}} f(\mathbf{x}, \mathbf{y}) d \mu(x, y) & =\int_{\mathbb{R}^{n+m}} g(\mathbf{x}, \mathbf{y}) d \mu(x, y) \\
& =\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} g(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x) \\
& =\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{m}} f(\mathbf{x}, \mathbf{y}) d v_{\mathbf{x}}(y) d \alpha(x)
\end{aligned}
$$

with everything making sense.

### 31.3 Differentiation of Radon Measures

This section is a generalization of earlier ideas in which differentiation was with respect to Lebesgue measure. Here an arbitrary Radon measure, not necessarily an integral with respect to Lebesuge measure, will be differentiated with respect to another arbitrary Radon measure. This requires a more sophisticated covering theorem. In this section, $B(\mathbf{x}, r)$ will denote a closed ball with center $\mathbf{x}$ and radius $r$. Also, let $\lambda$ and $\mu$ be Radon measures and as above, $Z$ will denote a $\mu$ measure zero set off of which $\mu(B(\mathbf{x}, r))>0$ for all $r>0$.

Definition 31.3.1 For $\mathbf{x} \notin Z$, define the upper and lower symmetric derivatives as

$$
\bar{D}_{\mu} \lambda(\mathbf{x}) \equiv \lim \sup _{r \rightarrow 0} \frac{\lambda(B(\mathbf{x}, r))}{\mu(B(\mathbf{x}, r))}, \underline{D}_{\mu} \lambda(\mathbf{x}) \equiv \lim _{r \rightarrow 0} \inf \frac{\lambda(B(\mathbf{x}, r))}{\mu(B(\mathbf{x}, r))}
$$

respectively. Also define

$$
D_{\mu} \lambda(\mathbf{x}) \equiv \bar{D}_{\mu} \lambda(\mathbf{x})=\underline{D}_{\mu} \lambda(\mathbf{x})
$$

in the case when both the upper and lower derivatives are equal.
Lemma 31.3.2 Let $\lambda$ and $\mu$ be Radon measures. If $A$ is a bounded subset of

$$
\left\{\mathbf{x} \notin Z: \bar{D}_{\mu} \lambda(\mathbf{x}) \geq a\right\}
$$

then

$$
\bar{\lambda}(A) \geq a \bar{\mu}(A)
$$

and if $A$ is a bounded subset of $\left\{\mathbf{x} \notin Z: \underline{D}_{\mu} \lambda(\mathbf{x}) \leq a\right\}$, then

$$
\bar{\lambda}(A) \leq a \bar{\mu}(A)
$$

The same conclusion holds even if A is not necessarily bounded.
Proof: Suppose first that $A$ is a bounded subset of $\left\{\mathbf{x} \notin Z: \bar{D}_{\mu} \lambda(\mathbf{x}) \geq a\right\}$, let $\varepsilon>0$, and let $V$ be a bounded open set with $V \supseteq A$ and $\lambda(V)-\varepsilon<\bar{\lambda}(A), \mu(V)-\varepsilon<\bar{\mu}(A)$. Then if $\mathbf{x} \in A$,

$$
\frac{\lambda(B(\mathbf{x}, r))}{\mu(B(\mathbf{x}, r))}>a-\varepsilon, B(\mathbf{x}, r) \subseteq V
$$

for infinitely many values of $r$ which are arbitrarily small. Thus the collection of such balls constitutes a Vitali cover for $A$. By Corollary 13.14.3 there is a disjoint sequence of these closed balls $\left\{B_{i}\right\}$ such that

$$
\begin{equation*}
\bar{\mu}\left(A \backslash \cup_{i=1}^{\infty} B_{i}\right)=0 \tag{31.3.11}
\end{equation*}
$$

Therefore,

$$
(a-\varepsilon) \sum_{i=1}^{\infty} \mu\left(B_{i}\right)<\sum_{i=1}^{\infty} \lambda\left(B_{i}\right) \leq \lambda(V)<\varepsilon+\bar{\lambda}(A)
$$

and so

$$
\begin{align*}
a \sum_{i=1}^{\infty} \mu\left(B_{i}\right) & \leq \varepsilon+\varepsilon \mu(V)+\bar{\lambda}(A) \\
& \leq \varepsilon+\varepsilon(\bar{\mu}(A)+\varepsilon)+\bar{\lambda}(A) \tag{31.3.12}
\end{align*}
$$

Now

$$
\bar{\mu}\left(A \backslash \cup_{i=1}^{\infty} B_{i}\right)+\bar{\mu}\left(\cup_{i=1}^{\infty} B_{i}\right) \geq \bar{\mu}(A)
$$

and so by 31.3.11 and the fact the $B_{i}$ are disjoint, it follows from 31.3.12,

$$
\begin{align*}
a \bar{\mu}(A) & \leq a \bar{\mu}\left(\cup_{i=1}^{\infty} B_{i}\right)=a \sum_{i=1}^{\infty} \mu\left(B_{i}\right) \\
& \leq \varepsilon+\varepsilon(\bar{\mu}(A)+\varepsilon)+\bar{\lambda}(A) \tag{31.3.13}
\end{align*}
$$

Hence $a \bar{\mu}(A) \leq \bar{\lambda}(A)$ since $\varepsilon>0$ was arbitrary.
Now suppose $A$ is a bounded subset of $\left\{\mathbf{x} \notin Z: \underline{D}_{\mu} \lambda(\mathbf{x}) \leq a\right\}$ and let $V$ be a bounded open set containing $A$ with $\mu(V)-\varepsilon<\bar{\mu}(A)$. Then if $\mathbf{x} \in A$,

$$
\frac{\lambda(B(\mathbf{x}, r))}{\mu(B(\mathbf{x}, r))}<a+\varepsilon, B(\mathbf{x}, r) \subseteq V
$$

for values of $r$ which are arbitrarily small. Therefore, by Corollary 13.14.3 again, there exists a disjoint sequence of these balls, $\left\{B_{i}\right\}$ satisfying this time,

$$
\bar{\lambda}\left(A \backslash \cup_{i=1}^{\infty} B_{i}\right)=0
$$

Then by arguments similar to the above,

$$
\bar{\lambda}(A) \leq \sum_{i=1}^{\infty} \lambda\left(B_{i}\right)<(a+\varepsilon) \mu(V)<(a+\varepsilon)(\bar{\mu}(A)+\varepsilon) .
$$

Since $\varepsilon$ was arbitrary, this proves the lemma in case $A$ is bounded. In general, for

$$
A \in\left\{\mathbf{x} \notin Z: \bar{D}_{\mu} \lambda(\mathbf{x}) \geq a\right\}
$$

One obtains from the first part

$$
\lambda(A \cap B(\mathbf{0}, n)) \geq a \mu(A \cap B(\mathbf{0}, n))
$$

Then, passing to a limit as $n \rightarrow \infty$ gives the desired result. The case where

$$
A \subseteq\left\{\mathbf{x} \notin Z: \underline{D}_{\mu} \lambda(\mathbf{x}) \leq a\right\}
$$

is similar.
Theorem 31.3.3 There exists a set of measure zero $N$ containing $Z$ such that for $\mathbf{x} \notin$ $N, D_{\mu} \lambda(\mathbf{x})$ exists and also $\mathscr{X}_{N^{C}}(\cdot) D_{\mu} \lambda(\cdot)$ is a $\mu$ measurable function. Furthermore, $D_{\mu} \lambda(\mathbf{x})<\infty \mu$ a.e.

Proof: First I show $D_{\mu} \lambda(\mathbf{x})$ exists a.e. Let $0 \leq a<b<\infty$ and let $A$ be any bounded subset of

$$
N(a, b) \equiv\left\{\mathbf{x} \notin Z: \bar{D}_{\mu} \lambda(\mathbf{x})>b>a>\underline{D}_{\mu} \lambda(\mathbf{x})\right\} .
$$

By Lemma 31.3.2,

$$
a \bar{\mu}(A) \geq \bar{\lambda}(A) \geq b \bar{\mu}(A)
$$

and so $\mu(A)=0$ and $A$ is $\mu$ measurable. It follows $\mu(N(a, b))=0$ because

$$
\mu(N(a, b)) \leq \sum_{m=1}^{\infty} \mu(N(a, b) \cap B(\mathbf{0}, m))=0 .
$$

Define

$$
N_{0} \equiv\left\{\mathbf{x} \notin Z: \bar{D}_{\mu} \lambda(\mathbf{x})>\underline{D}_{\mu} \lambda(\mathbf{x})\right\}
$$

Thus $\mu\left(N_{0}\right)=0$ because

$$
N_{0} \subseteq \cup\{N(a, b): 0 \leq a<b, \text { and } a, b \in \mathbb{Q}\}
$$

Therefore, $N_{0}$ is also $\mu$ measurable and has $\mu$ measure zero. Letting $N \equiv N_{0} \cup Z$, it follows $D_{\mu} \lambda(\mathbf{x})$ exists on $N^{C}$. We can assume also that $N$ is a $G_{\delta}$ set. It remains to verify $\mathscr{X}_{N^{C}}(\cdot) D_{\mu} \lambda(\cdot)$ is finite a.e. and is $\mu$ measurable.

Let

$$
I=\left\{\mathbf{x}: D_{\mu} \lambda(\mathbf{x})=\infty\right\}
$$

Then by Lemma 31.3.2

$$
\bar{\lambda}(I \cap B(\mathbf{0}, m)) \geq a \bar{\mu}(I \cap B(\mathbf{0}, m))
$$

for all $a$ and since $\lambda$ is finite on bounded sets, the above implies $\bar{\mu}(I \cap B(\mathbf{0}, m))=0$ for each $m$ which implies that $I$ is $\mu$ measurable and has $\mu$ measure zero since

$$
I=\cup_{m=1}^{\infty} I \cap B(\mathbf{0}, m)
$$

Now the issue is measurability. Let $\lambda$ be an arbitrary Radon measure. I need show that $\mathbf{x} \rightarrow \lambda(B(\mathbf{x}, r))$ is measurable. Here is where it is convenient to have the balls be closed balls. If $V$ is an open set containing $B(\mathbf{x}, r)$, then for $\mathbf{y}$ close enough to $\mathbf{x}, B(\mathbf{y}, r) \subseteq V$ also and so,

$$
\limsup _{\mathbf{y} \rightarrow \mathbf{x}} \lambda(B(\mathbf{y}, r)) \leq \lambda(V)
$$

However, since $V$ is arbitrary and $\lambda$ is outer regular or observing that $B(\mathbf{x}, r)$ the closed ball is the intersection of nested open sets, it follows that

$$
\lim \sup _{\mathbf{y} \rightarrow \mathbf{x}} \lambda(B(\mathbf{y}, r)) \leq \lambda(B(\mathbf{x}, r))
$$

Thus $\mathbf{x} \rightarrow \lambda(B(\mathbf{x}, r))$ is upper semicontinuous and so,

$$
\mathbf{x} \rightarrow \frac{\lambda(B(\mathbf{x}, r))}{\mu(B(\mathbf{x}, r))}
$$

is measurable. Hence $\mathscr{X}_{N^{C}}(\mathbf{x}) D_{\mu}(\lambda)(\mathbf{x})=\lim _{r_{i} \rightarrow 0} \mathscr{X}_{N^{C}}(\mathbf{x}) \frac{\lambda(B(\mathbf{x}, r))}{\mu(B(\mathbf{x}, r))}$ is also measurable.
Typically I will write $D_{\mu} \lambda(\mathbf{x})$ rather than the more precise $\mathscr{X}_{N^{C}}(\mathbf{x}) D_{\mu} \lambda(\mathbf{x})$ since the values on the set of measure zero $N$ are not important due to the completeness of the measure $\mu$.

### 31.3.1 Radon Nikodym Theorem for Radon Measures

The Radon Nikodym theorem is an abstract result but this will be a special version for Radon measures which is based on these covering theorems and related theory.

Definition 31.3.4 Let $\lambda, \mu$ be two Radon measures defined on $\mathscr{F}$, a $\sigma$ algebra of subsets of an open set $U$. Then $\lambda \ll \mu$ means that whenever $\mu(E)=0$, it follows that $\lambda(E)=0$.

Next is a representation theorem for $\lambda$ in terms of an integral involving $D_{\mu} \lambda$.
Theorem 31.3.5 Let $\lambda$ and $\mu$ be Radon measures defined on $\mathscr{F}$ a $\sigma$ algebra of the open set $U$ then there exists a set of $\mu$ measure zero $N$ such that $D_{\mu} \lambda(\mathbf{x})$ exists off $N$ and if $E \subseteq N^{C}, E \in \mathscr{F}$, then

$$
\lambda(E)=\int_{U}\left(D_{\mu} \lambda\right) \mathscr{X}_{E} d \mu
$$

If $\lambda \ll \mu, \lambda(E)=\int_{E} D_{\mu} \lambda d \mu$. In any case, $\lambda(E) \geq \int_{E} D_{\mu} \lambda d \mu$.
Proof: The proof is based on Lemma 31.3.2. Let $E \subseteq N^{C}$ where $N$ has measure 0 and includes the set $Z$ along with the set where the symmetric derivative does not exist. It can be assumed that $N$ is a $G_{\delta}$ set. Assume $E$ is bounded to begin with. Then $E \cap$ $\left\{\mathbf{x} \in N^{C}: D_{\mu} \lambda(\mathbf{x})=0\right\}$ has measure zero. This is because by Lemma 31.3.2,

$$
\begin{aligned}
\lambda\left(E \cap\left\{\mathbf{x} \in N^{C}: D_{\mu} \lambda(\mathbf{x})=0\right\}\right) & \leq a \mu\left(E \cap\left\{\mathbf{x} \in N^{C}: D_{\mu} \lambda(\mathbf{x})=0\right\}\right) \\
& \leq a \mu(E), \mu(E)<\infty
\end{aligned}
$$

for all positive $a$ and so

$$
\lambda\left(E \cap\left\{\mathbf{x} \in N^{C}: D_{\mu} \lambda(\mathbf{x})=0\right\}\right)=0
$$

Thus, the set where $D_{\mu} \lambda(\mathbf{x})=0$ can be ignored.
Let $\left\{a_{k}^{n}\right\}_{k=1}^{\infty}$ be positive numbers such that $\left|a_{k}^{n}-a_{k+1}^{n}\right|=2^{-n}$. Specifically, let $\left\{a_{k}^{n}\right\}_{k=0}^{\infty}$ be given by

$$
0,2^{-n}, 2\left(2^{-n}\right), 3\left(2^{-n}\right), 4\left(2^{-n}\right), \ldots
$$

Define disjoint half open intervals whose union is all of $(0, \infty), I_{k}^{n}$ having end points $a_{k-1}^{n}$ and $a_{k}^{n}$. Say $I_{k}^{n}=\left(a_{k-1}^{n}, a_{k}^{n}\right]$.

$$
E_{k}^{n} \equiv E \cap\left\{\mathbf{x} \in \mathbb{R}^{p}: D_{\mu} \lambda(\mathbf{x}) \in I_{k}^{n}\right\} \equiv E \cap\left(D_{\mu} \lambda\right)^{-1}\left(I_{k}^{n}\right)
$$

Since the intervals are Borel sets, $\left(D_{\mu} \lambda\right)^{-1}\left(I_{k}^{n}\right)$ is measurable. Thus $\cup_{k=1}^{\infty} E_{k}^{n}=E$ and the $k \rightarrow E_{k}^{n}$ are disjoint measurable sets. From Lemma 31.3.2,

$$
\mu\left(E_{k}^{n}\right) a_{k}^{n} \geq \lambda\left(E_{k}^{n}\right) \geq a_{k-1}^{n} \mu\left(E_{k}^{n}\right)
$$

Then

$$
\sum_{k=1}^{\infty} a_{k}^{n} \mu\left(E_{k}^{n}\right) \geq \lambda(E)=\sum_{k=1}^{\infty} \lambda\left(E_{k}^{n}\right) \geq \sum_{k=1}^{\infty} a_{k-1}^{n} \mu\left(E_{k}^{n}\right)
$$

Let $l_{n}(\mathbf{x}) \equiv \sum_{k=1}^{\infty} a_{k-1}^{n} \mathscr{X}_{\left(D_{\mu} \lambda\right)^{-1}\left(l_{k}^{n}\right)}(\mathbf{x})$ and $u_{n}(\mathbf{x}) \equiv \sum_{k=1}^{\infty} a_{k}^{n} \mathscr{X}_{\left(D_{\mu} \lambda\right)^{-1}\left(l_{k}^{n}\right)}(\mathbf{x})$. Then the above implies

$$
\lambda(E) \in\left[\int_{E} l_{n} d \mu, \int_{E} u_{n} d \mu\right]
$$

Now both $l_{n}$ and $u_{n}$ converge to $D_{\mu} \lambda(\mathbf{x})$ which is nonnegative and measurable as shown earlier. The construction shows that $l_{n}$ increases to $D_{\mu} \lambda(\mathbf{x})$. Also, $u_{n}(\mathbf{x})-l_{n}(\mathbf{x})=2^{-n}$. Thus

$$
\lambda(E) \in\left[\int_{E} l_{n} d \mu, \int_{E} l_{n} d \mu+2^{-n} \mu(E)\right]
$$

By the monotone convergence theorem, this shows $\lambda(E)=\int_{E} D_{\mu} \lambda d \mu$.
Now if $E$ is an arbitrary set in $N^{C}$, maybe not bounded, the above shows

$$
\lambda(E \cap B(\mathbf{0}, n))=\int_{E \cap B(\mathbf{0}, n)} D_{\mu} \lambda d \mu
$$

Let $n \rightarrow \infty$ and use the monotone convergence theorem. Thus for all $E \subseteq N^{C}, \lambda(E)=$ $\int_{E} D_{\mu} \lambda d \mu$. For the last claim, $\int_{E} D_{\mu} \lambda d \mu=\int_{E \cap N^{C}} D_{\mu} \lambda d \mu=\lambda\left(E \cap N^{C}\right) \leq \lambda(E)$.

In case, $\lambda \ll \mu$, it does not matter that $E \subseteq N^{C}$ because, since $\mu(N)=0$, so is $\lambda(N)$ and so

$$
\lambda(E)=\lambda\left(E \cap N^{C}\right)=\int_{E \cap N^{C}} D_{\mu} \lambda d \mu=\int_{E} D_{\mu} \lambda d \mu
$$

for any $E \in \mathscr{F}$.
What if $\lambda$ and $\mu$ are just two arbitrary Radon measures defined on $\mathscr{F}$ ? What then? It was shown above that $D_{\mu} \lambda(\mathbf{x})$ exists for $\mu$ a.e. $\mathbf{x}$, off a $G_{\delta}$ set $N$ of $\mu$ measure 0 which includes $Z$, the set of $\mathbf{x}$ where $\mu(B(\mathbf{x}, r))=0$ for some $r>0$. Also, it was shown above that if $E \subseteq N^{C}$, then $\lambda(E)=\int_{E} D_{\mu} \lambda(\mathbf{x}) d \mu$. Define for arbitrary $E \in \mathscr{F}$,

$$
\lambda_{\mu}(E) \equiv \lambda\left(E \cap N^{C}\right), \lambda_{\perp}(E) \equiv \lambda(E \cap N)
$$

Then

$$
\begin{aligned}
\lambda(E) & =\lambda(E \cap N)+\lambda\left(E \cap N^{C}\right)=\lambda_{\perp}(E)+\lambda_{\mu}(E) \\
& =\lambda(E \cap N)+\int_{E \cap N^{C}} D_{\mu} \lambda(\mathbf{x}) d \mu \\
& =\lambda(E \cap N)+\int_{E} D_{\mu} \lambda(\mathbf{x}) d \mu \equiv \lambda(E \cap N)+\lambda_{\mu}(E) \\
& \equiv \lambda_{\perp}(E)+\lambda_{\mu}(E)
\end{aligned}
$$

This shows most of the following corollary.
Corollary 31.3.6 Let $\mu, \lambda$ be two Radon measures. Then there exist two measures, $\lambda_{\mu}, \lambda_{\perp}$ such that

$$
\lambda_{\mu} \ll \mu, \lambda=\lambda_{\mu}+\lambda_{\perp}
$$

and a set of $\mu$ measure zero $N$ such that

$$
\lambda_{\perp}(E)=\lambda(E \cap N)
$$

Also $\lambda_{\mu}$ is given by the formula

$$
\lambda_{\mu}(E) \equiv \int_{E} D_{\mu} \lambda(\mathbf{x}) d \mu
$$

Proof: If $\mathbf{x} \in N$, this could happen two ways, either $\mathbf{x} \in Z$ or $D_{\mu} \lambda(\mathbf{x})$ fails to exist. It only remains to verify that $\lambda_{\mu}$ given above satisfies $\lambda_{\mu} \ll \mu$. However, this is obvious because if $\mu(E)=0$, then clearly $\int_{E} D_{\mu} \lambda(\mathbf{x}) d \mu=0$.

Since $D_{\mu} \lambda(\mathbf{x})=D_{\mu} \lambda(\mathbf{x}) \mathscr{X}_{N^{C}}(\mathbf{x})$, it doesn't matter which we use but maybe $D_{\mu} \lambda(\mathbf{x})$ doesn't exist at some points of $N$.

This is sometimes called the Lebesgue decomposition.

## Chapter 32

## Fourier Transforms

### 32.1 An Algebra Of Special Functions

First recall the following definition of a polynomial.
Definition 32.1.1 $\alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right)$ for $\alpha_{1} \cdots \alpha_{n}$ positive integers is called a multi-index. For $\alpha$ a multi-index, $|\alpha| \equiv \alpha_{1}+\cdots+\alpha_{n}$ and if $\mathbf{x} \in \mathbb{R}^{n}$,

$$
\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)
$$

and $f$ a function, define

$$
\mathbf{x}^{\alpha} \equiv x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \cdots x_{n}^{\alpha_{n}}
$$

A polynomial in $n$ variables of degree $m$ is a function of the form

$$
p(\mathbf{x})=\sum_{|\alpha| \leq m} a_{\alpha} \mathbf{x}^{\alpha}
$$

Here $\alpha$ is a multi-index as just described and $a_{\alpha} \in \mathbb{C}$. Also define for $\alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right)$ a multi-index

$$
D^{\alpha} f(\mathbf{x}) \equiv \frac{\partial^{|\alpha|} f}{\partial x_{1}^{\alpha_{1}} \partial x_{2}^{\alpha_{2}} \cdots \partial x_{n}^{\alpha_{n}}}
$$

Definition 32.1.2 Define $\mathscr{G}_{1}$ to be the functions of the form $p(\mathbf{x}) e^{-a|\mathbf{x}|^{2}}$ where $a>0$ and $p(\mathbf{x})$ is a polynomial. Let $\mathscr{G}$ be all finite sums of functions in $\mathscr{G}_{1}$. Thus $\mathscr{G}$ is an algebra of functions which has the property that if $f \in \mathscr{G}$ then $\bar{f} \in \mathscr{G}$.

It is always assumed, unless stated otherwise that the measure will be Lebesgue measure.

Lemma 32.1.3 $\mathscr{G}$ is dense in $C_{0}\left(\mathbb{R}^{n}\right)$ with respect to the norm,

$$
\|f\|_{\infty} \equiv \sup \left\{|f(\mathbf{x})|: \mathbf{x} \in \mathbb{R}^{n}\right\}
$$

Proof: By the Weierstrass approximation theorem, it suffices to show $\mathscr{G}$ separates the points and annihilates no point. It was already observed in the above definition that $\bar{f} \in \mathscr{G}$ whenever $f \in \mathscr{G}$. If $\mathbf{y}_{1} \neq \mathbf{y}_{2}$ suppose first that $\left|\mathbf{y}_{1}\right| \neq\left|\mathbf{y}_{2}\right|$. Then in this case, you can let $f(\mathbf{x}) \equiv e^{-|\mathbf{x}|^{2}}$ and $f \in \mathscr{G}$ and $f\left(\mathbf{y}_{1}\right) \neq f\left(\mathbf{y}_{2}\right)$. If $\left|\mathbf{y}_{1}\right|=\left|\mathbf{y}_{2}\right|$, then suppose $y_{1 k} \neq y_{2 k}$. This must happen for some $k$ because $\mathbf{y}_{1} \neq \mathbf{y}_{2}$. Then let $f(\mathbf{x}) \equiv x_{k} e^{-|\mathbf{x}|^{2}}$. Thus $\mathscr{G}$ separates points. Now $e^{-|\mathbf{x}|^{2}}$ is never equal to zero and so $\mathscr{G}$ annihilates no point of $\mathbb{R}^{n}$. This proves the lemma.

These functions are clearly quite specialized. Therefore, the following theorem is somewhat surprising.

Theorem 32.1.4 For each $p \geq 1, p<\infty, \mathscr{G}$ is dense in $L^{p}\left(\mathbb{R}^{n}\right)$.

Proof: Let $f \in L^{p}\left(\mathbb{R}^{n}\right)$. Then there exists $g \in C_{c}\left(\mathbb{R}^{n}\right)$ such that $\|f-g\|_{p}<\varepsilon$. Now let $b>0$ be large enough that

$$
\int_{\mathbb{R}^{n}}\left(e^{-b|\mathbf{x}|^{2}}\right)^{p} d x<\varepsilon^{p}
$$

Then $\mathbf{x} \rightarrow g(\mathbf{x}) e^{b|\mathbf{x}|^{2}}$ is in $C_{c}\left(\mathbb{R}^{n}\right) \subseteq C_{0}\left(\mathbb{R}^{n}\right)$. Therefore, from Lemma 32.1.3 there exists $\psi \in \mathscr{G}$ such that

$$
\left\|g e^{b|\cdot|^{2}}-\psi\right\|_{\infty}<1
$$

Therefore, letting $\phi(\mathbf{x}) \equiv e^{-b|\mathbf{x}|^{2}} \psi(\mathbf{x})$ it follows that $\phi \in \mathscr{G}$ and for all $\mathbf{x} \in \mathbb{R}^{n}$,

$$
|g(\mathbf{x})-\phi(\mathbf{x})|<e^{-b|\mathbf{x}|^{2}}
$$

Therefore,

$$
\left(\int_{\mathbb{R}^{n}}|g(\mathbf{x})-\phi(\mathbf{x})|^{p} d x\right)^{1 / p} \leq\left(\int_{\mathbb{R}^{n}}\left(e^{-b|\mathbf{x}|^{2}}\right)^{p} d x\right)^{1 / p}<\varepsilon
$$

It follows

$$
\|f-\phi\|_{p} \leq\|f-g\|_{p}+\|g-\phi\|_{p}<2 \varepsilon
$$

Since $\varepsilon>0$ is arbitrary, this proves the theorem.
The following lemma is also interesting even if it is obvious.
Lemma 32.1.5 For $\psi \in \mathscr{G}$, p a polynomial, and $\alpha, \beta$ multiindices, $D^{\alpha} \psi \in \mathscr{G}$ and $p \psi \in \mathscr{G}$. Also

$$
\sup \left\{\left|\mathbf{x}^{\beta} D^{\alpha} \psi(\mathbf{x})\right|: \mathbf{x} \in \mathbb{R}^{n}\right\}<\infty
$$

### 32.2 Fourier Transforms Of Functions In $\mathscr{G}$

Definition 32.2.1 For $\psi \in \mathscr{G}$ Define the Fourier transform, $F$ and the inverse Fourier transform, $F^{-1}$ by

$$
\begin{aligned}
& F \psi(\mathbf{t}) \equiv(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} \psi(\mathbf{x}) d x \\
& F^{-1} \psi(\mathbf{t}) \equiv(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} \psi(\mathbf{x}) d x
\end{aligned}
$$

where $\mathbf{t} \cdot \mathbf{x} \equiv \sum_{i=1}^{n} t_{i} x_{i}$.Note there is no problem with this definition because $\psi$ is in $L^{1}\left(\mathbb{R}^{n}\right)$ and therefore,

$$
\left|e^{i \mathbf{t} \cdot \mathbf{x}} \psi(\mathbf{x})\right| \leq|\psi(\mathbf{x})|,
$$

an integrable function.
One reason for using the functions, $\mathscr{G}$ is that it is very easy to compute the Fourier transform of these functions. The first thing to do is to verify $F$ and $F^{-1} \operatorname{map} \mathscr{G}$ to $\mathscr{G}$ and that $F^{-1} \circ F(\psi)=\psi$.

Lemma 32.2.2 The following formulas are true. $(c>0)$

$$
\begin{gather*}
\int_{\mathbb{R}} e^{-c t^{2}} e^{-i s t} d t=\int_{\mathbb{R}} e^{-c t^{2}} e^{i s t} d t=e^{-\frac{s^{2}}{4 c}} \frac{\sqrt{\pi}}{\sqrt{c}}  \tag{32.2.1}\\
\int_{\mathbb{R}^{n}} e^{-c|t|^{2}} e^{-i s \cdot \mathbf{t}} d t=\int_{\mathbb{R}^{n}} e^{-c|\mathbf{t}|^{2}} e^{i s \cdot \mathbf{t}} d t=e^{-\frac{|s|^{2}}{4 c}}\left(\frac{\sqrt{\pi}}{\sqrt{c}}\right)^{n} . \tag{32.2.2}
\end{gather*}
$$

Proof: Consider the first one. Let $h(s)$ be given by the left side. Then

$$
H(s) \equiv \int_{\mathbb{R}} e^{-c t^{2}} e^{-i s t} d t=\int_{\mathbb{R}} e^{-c t^{2}} \cos (s t) d t
$$

Then using the dominated convergence theorem to differentiate,

$$
H^{\prime}(s)=\int_{\mathbb{R}}-e^{-c t^{2}} t \sin (s t) d t=\left.\frac{e^{-c t^{2}}}{2 c} \sin (s t)\right|_{-\infty} ^{\infty}-\frac{s}{2 c} \int_{\mathbb{R}} e^{-c t^{2}} \cos (s t) d t=-\frac{s}{2 c} H(s)
$$

Also $H(0)=\int_{\mathbb{R}} e^{-c t^{2}} d t$. Thus $H(0)=\int_{\mathbb{R}} e^{-c x^{2}} d x \equiv I$ and so

$$
I^{2}=\int_{\mathbb{R}^{2}} e^{-c\left(x^{2}+y^{2}\right)} d x d y=\int_{0}^{\infty} \int_{0}^{2 \pi} e^{-c r^{2}} r d \theta d r=\frac{\pi}{c}
$$

Hence

$$
H^{\prime}(s)+\frac{s}{2 c} H(s)=0, H(0)=\sqrt{\frac{\pi}{c}}
$$

It follows that $H(s)=e^{-\frac{s^{2}}{4 c}} \frac{\sqrt{\pi}}{\sqrt{c}}$. The second formula follows right away from Fubini's theorem.

With these formulas, it is easy to verify $F, F^{-1} \operatorname{map} \mathscr{G}$ to $\mathscr{G}$ and $F \circ F^{-1}=F^{-1} \circ F=i d$.
Theorem 32.2.3 Each of $F$ and $F^{-1} \operatorname{map} \mathscr{G}$ to $\mathscr{G}$. Also $F^{-1} \circ F(\psi)=\psi$ and $F \circ F^{-1}(\psi)=$ $\psi$.

Proof: The first claim will be shown if it is shown that $F \psi \in \mathscr{G}$ for $\psi(\mathbf{x})=\mathbf{x}^{\alpha} e^{-b|\mathbf{x}|^{2}}$ because an arbitrary function of $\mathscr{G}$ is a finite sum of scalar multiples of functions such as $\psi$. Using Lemma 32.2.2,

$$
\begin{aligned}
F \psi(\mathbf{t}) & \equiv\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} \mathbf{x}^{\alpha} e^{-b|\mathbf{x}|^{2}} d x \\
& =\left(\frac{1}{2 \pi}\right)^{n / 2}(i)^{-|\alpha|} D_{t}^{\alpha}\left(\int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} e^{-b|\mathbf{x}|^{2}} d x\right) \\
& =\left(\frac{1}{2 \pi}\right)^{n / 2}(i)^{-|\alpha|} D_{t}^{\alpha}\left(e^{-\frac{|\mathbf{t}|^{2}}{4 b}}\left(\frac{\sqrt{\pi}}{\sqrt{b}}\right)^{n}\right)
\end{aligned}
$$

and this is clearly in $\mathscr{G}$ because it equals a polynomial times $e^{-\frac{|t|^{2}}{4 b}}$.

It remains to verify the other assertion. As in the first case, it suffices to consider $\psi(\mathbf{x})=\mathbf{x}^{\alpha} e^{-b|\mathbf{x}|^{2}}$.

$$
\begin{aligned}
& F^{-1} \circ F(\psi)(\mathbf{s}) \equiv\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{i s \cdot \mathbf{t}} F(\psi)(\mathbf{t}) d t \\
= & \left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{s} \cdot \mathbf{t}}\left(\frac{1}{2 \pi}\right)^{n / 2}(i)^{-|\alpha|} D_{t}^{\alpha}\left(e^{-\frac{|t|^{2}}{4 b}}\left(\frac{\sqrt{\pi}}{\sqrt{b}}\right)^{n}\right) d t \\
= & \left(\frac{1}{2 \pi}\right)^{n}(i)^{-|\alpha|} \int_{\mathbb{R}^{n}} e^{i \mathbf{s} \cdot \mathbf{t}} D_{t}^{\alpha}\left(e^{-\frac{|\mathbf{t}|^{2}}{4 b}}\left(\frac{\sqrt{\pi}}{\sqrt{b}}\right)^{n}\right) d t \\
= & \left(\frac{1}{2 \pi}\right)^{n}(i)^{-|\alpha|} \int_{\mathbb{R}^{n}}(i)^{|\alpha|} \mathbf{s}^{\alpha} e^{i \mathbf{s} \cdot \mathbf{t}}\left(e^{-\frac{|\mathbf{t}|^{2}}{4 b}}\left(\frac{\sqrt{\pi}}{\sqrt{b}}\right)^{n}\right) d t
\end{aligned}
$$

and by Lemma 32.2.2,

$$
\begin{aligned}
& =\left(\frac{1}{2 \pi}\right)^{n}\left(\frac{\sqrt{\pi}}{\sqrt{b}}\right)^{n} \int_{\mathbb{R}^{n}} \mathbf{s}^{\alpha} e^{i \mathbf{s} \cdot \mathbf{t}}\left(e^{-\frac{|\mathrm{t}|^{2}}{4 b}}\right) d t \\
& =\overbrace{\left(\frac{1}{2 \pi}\right)^{n}\left(\frac{\sqrt{\pi}}{\sqrt{b}}\right)^{n}\left(\frac{\sqrt{\pi}}{\sqrt{1 / 4 b}}\right)^{n}}^{=1} \mathbf{s}^{\alpha} e^{-b|\mathbf{s}|^{2}}=\psi(\mathbf{s}) .
\end{aligned}
$$

### 32.3 Fourier Transforms Of Just About Anything

### 32.3.1 Fourier Transforms Of $\mathscr{G}^{*}$

Definition 32.3.1 Let $\mathscr{G}^{*}$ denote the vector space of linear functions defined on $\mathscr{G}$ which have values in $\mathbb{C}$. Thus $T \in \mathscr{G}^{*}$ means $T: \mathscr{G} \rightarrow \mathbb{C}$ and $T$ is linear,

$$
T(a \psi+b \phi)=a T(\psi)+b T(\phi) \text { for all } a, b \in \mathbb{C}, \quad \psi, \phi \in \mathscr{G}
$$

Let $\psi \in \mathscr{G}$. Then we can regard $\psi$ as an element of $\mathscr{G}^{*}$ by defining

$$
\psi(\phi) \equiv \int_{\mathbb{R}^{n}} \psi(\mathbf{x}) \phi(\mathbf{x}) d x
$$

Then we have the following important lemma.

Lemma 32.3.2 The following is obtained for all $\phi, \psi \in \mathscr{G}$.

$$
F \psi(\phi)=\psi(F \phi), F^{-1} \psi(\phi)=\psi\left(F^{-1} \phi\right)
$$

Also if $\psi \in \mathscr{G}$ and $\psi=0$ in $\mathscr{G}^{*}$ so that $\psi(\phi)=0$ for all $\phi \in \mathscr{G}$, then $\psi=0$ as a function.

Proof:

$$
\begin{aligned}
F \psi(\phi) & \equiv \int_{\mathbb{R}^{n}} F \psi(\mathbf{t}) \phi(\mathbf{t}) d t \\
& =\int_{\mathbb{R}^{n}}\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} \psi(\mathbf{x}) d x \phi(\mathbf{t}) d t \\
& =\int_{\mathbb{R}^{n}} \psi(\mathbf{x})\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} \phi(\mathbf{t}) d t d x \\
& =\int_{\mathbb{R}^{n}} \psi(\mathbf{x}) F \phi(\mathbf{x}) d x \equiv \psi(F \phi)
\end{aligned}
$$

The other claim is similar.
Suppose now $\psi(\phi)=0$ for all $\phi \in \mathscr{G}$. Then

$$
\int_{\mathbb{R}^{n}} \psi \phi d x=0
$$

for all $\phi \in \mathscr{G}$. Therefore, this is true for $\phi=\psi$ and so $\psi=0$.
This lemma suggests a way to define the Fourier transform of something in $\mathscr{G}^{*}$.
Definition 32.3.3 For $T \in \mathscr{G}^{*}$, define $F T, F^{-1} T \in \mathscr{G}^{*}$ by

$$
F T(\phi) \equiv T(F \phi), F^{-1} T(\phi) \equiv T\left(F^{-1} \phi\right)
$$

Lemma 32.3.4 $F$ and $F^{-1}$ are both one to one, onto, and are inverses of each other.
Proof: First note $F$ and $F^{-1}$ are both linear. This follows directly from the definition. Suppose now $F T=0$. Then $F T(\phi)=T(F \phi)=0$ for all $\phi \in \mathscr{G}$. But $F$ and $F^{-1}$ map $\mathscr{G}$ onto $\mathscr{G}$ because if $\psi \in \mathscr{G}$, then as shown above, $\psi=F\left(F^{-1}(\psi)\right)$. Therefore, $T=0$ and so $F$ is one to one. Similarly $F^{-1}$ is one to one. Now

$$
F^{-1}(F T)(\phi) \equiv(F T)\left(F^{-1} \phi\right) \equiv T\left(F\left(F^{-1}(\phi)\right)\right)=T \phi
$$

Therefore, $F^{-1} \circ F(T)=T$. Similarly, $F \circ F^{-1}(T)=T$. Thus both $F$ and $F^{-1}$ are one to one and onto and are inverses of each other as suggested by the notation.

Probably the most interesting things in $\mathscr{G}^{*}$ are functions of various kinds. The following lemma will be useful in considering this situation.

Lemma 32.3.5 If $f \in L_{\text {loc }}^{1}\left(\mathbb{R}^{n}\right)$ and $\int_{\mathbb{R}^{n}} f \phi d x=0$ for all $\phi \in C_{c}\left(\mathbb{R}^{n}\right)$, then $f=0$ a.e.
Proof: For $r>0$, let

$$
E \equiv\{\mathbf{x}: f(\mathbf{x}) \geq r\}, E_{R} \equiv E \cap B(\mathbf{0}, R)
$$

Let $K_{m}$ be an increasing sequence of compact sets, and let $V_{m}$ be a decreasing sequence of open sets satisfying

$$
K_{m} \subseteq E_{R} \subseteq V_{m}, m_{n}\left(V_{m}\right) \leq m_{n}\left(K_{m}\right)+2^{-m}, V_{1} \subseteq B(\mathbf{0}, R)
$$

Therefore,

$$
m_{n}\left(V_{m} \backslash K_{m}\right) \leq 2^{-m}
$$

Let

$$
\phi_{m} \in C_{c}\left(V_{m}\right), K_{m} \prec \phi_{m} \prec V_{m} .
$$

The statement $K_{m} \prec \phi_{m} \prec V_{m}$ means that $\phi_{m}$ equals 1 on $K_{m}$, has compact support in $V_{m}$, maps into $[0,1]$, and is continuous. Then $\phi_{m}(\mathbf{x}) \rightarrow \mathscr{X}_{E_{R}}(\mathbf{x})$ a.e. because the set where $\phi_{m}(\mathbf{x})$ fails to converge to this set is contained in the set of all $\mathbf{x}$ which are in infinitely many of the sets $V_{m} \backslash K_{m}$. This set has measure zero because

$$
\sum_{m=1}^{\infty} m_{n}\left(V_{m} \backslash K_{m}\right)<\infty
$$

Thus $\phi_{m}$ converges pointwise $a . e$ to $\mathscr{X}_{E_{R}}$ and so, by the dominated convergence theorem,

$$
0=\lim _{m \rightarrow \infty} \int_{\mathbb{R}^{n}} f \phi_{m} d x=\lim _{m \rightarrow \infty} \int_{V_{1}} f \phi_{m} d x=\int_{E_{R}} f d x \geq r m\left(E_{R}\right)
$$

Thus, $m_{n}\left(E_{R}\right)=0$ and therefore $m_{n}(E)=\lim _{R \rightarrow \infty} m_{n}\left(E_{R}\right)=0$. Since $r>0$ is arbitrary, it follows

$$
\begin{aligned}
m_{n}([f>0]) & =\cup_{k=1}^{\infty} m_{n}\left(\left[f>k^{-1}\right]\right) \\
& =\cup_{k=1}^{\infty} m_{n}\left(\left[f^{+}>k^{-1}\right]\right)=m_{n}\left(\left[f^{+}>0\right]\right)=0
\end{aligned}
$$

Hence $f^{+}=0$ a.e. It follows that $\int f^{-} \phi d x=0$ for all $\phi \in C_{c}\left(\mathbb{R}^{n}\right)$ because

$$
\int f^{-} \phi d x=\int f^{+} \phi-\int f \phi=0
$$

Thus from what was just shown, with $f^{-}$taking the place of $f$, it follows $\frac{\left|f^{-}\right|+f^{-}}{2}=0$ and so $f^{-}=0$ a.e. also.

Corollary 32.3.6 Let $f \in L^{1}\left(\mathbb{R}^{n}\right)$ and suppose

$$
\int_{\mathbb{R}^{n}} f(\mathbf{x}) \phi(\mathbf{x}) d x=0
$$

for all $\phi \in \mathscr{G}$. Then $f=0$ a.e.
Proof: Let $\psi \in C_{c}\left(\mathbb{R}^{n}\right)$. Then by the Stone Weierstrass approximation theorem, there exists a sequence of functions, $\left\{\phi_{k}\right\} \subseteq \mathscr{G}$ such that $\phi_{k} \rightarrow \psi$ uniformly. Then by the dominated convergence theorem,

$$
\int f \psi d x=\lim _{k \rightarrow \infty} \int f \phi_{k} d x=0
$$

By Lemma 32.3.5 $f=0$.
The next theorem is the main result of this sort.

Theorem 32.3.7 Let $f \in L^{p}\left(\mathbb{R}^{n}\right), p \geq 1$, or suppose $f$ is measurable and has polynomial growth,

$$
|f(\mathbf{x})| \leq K\left(1+|\mathbf{x}|^{2}\right)^{m}
$$

for some $m \in \mathbb{N}$. Then if

$$
\int f \psi d x=0
$$

for all $\psi \in \mathscr{G}$, then it follows $f=0$.
Proof: First note that if $f \in L^{p}\left(\mathbb{R}^{n}\right)$ or has polynomial growth, then it makes sense to write the integral $\int f \psi d x$ described above. This is obvious in the case of polynomial growth. In the case where $f \in L^{p}\left(\mathbb{R}^{n}\right)$ it also makes sense because

$$
\int|f||\psi| d x \leq\left(\int|f|^{p} d x\right)^{1 / p}\left(\int|\psi|^{p^{\prime}} d x\right)^{1 / p^{\prime}}<\infty
$$

due to the fact mentioned above that all these functions in $\mathscr{G}$ are in $L^{p}\left(\mathbb{R}^{n}\right)$ for every $p \geq 1$. Suppose now that $f \in L^{p}, p \geq 1$. The case where $f \in L^{1}\left(\mathbb{R}^{n}\right)$ was dealt with in Corollary 32.3.6. Suppose $f \in L^{p}\left(\mathbb{R}^{n}\right)$ for $p>1$. Then

$$
|f|^{p-2} \bar{f} \in L^{p^{\prime}}\left(\mathbb{R}^{n}\right),\left(p^{\prime}=q, \frac{1}{p}+\frac{1}{q}=1\right)
$$

and by density of $\mathscr{G}$ in $L^{p^{\prime}}\left(\mathbb{R}^{n}\right)$ (Theorem 32.1.4), there exists a sequence $\left\{g_{k}\right\} \subseteq \mathscr{G}$ such that

$$
\left\|g_{k}-|f|^{p-2} \bar{f}\right\|_{p^{\prime}} \rightarrow 0
$$

Then

$$
\begin{aligned}
\int_{\mathbb{R}^{n}}|f|^{p} d x & =\int_{\mathbb{R}^{n}} f\left(|f|^{p-2} \bar{f}-g_{k}\right) d x+\int_{\mathbb{R}^{n}} f g_{k} d x \\
& =\int_{\mathbb{R}^{n}} f\left(|f|^{p-2} \bar{f}-g_{k}\right) d x \\
& \leq\|f\|_{L^{p}}\left|\left\|g_{k}-|f|^{p-2} \bar{f}\right\|_{p^{\prime}}\right.
\end{aligned}
$$

which converges to 0 . Hence $f=0$.
It remains to consider the case where $f$ has polynomial growth. Thus $\mathbf{x} \rightarrow f(\mathbf{x}) e^{-|\mathbf{x}|^{2}} \in$ $L^{1}\left(\mathbb{R}^{n}\right)$. Therefore, for all $\psi \in \mathscr{G}$,

$$
0=\int f(\mathbf{x}) e^{-|\mathbf{x}|^{2}} \psi(\mathbf{x}) d x
$$

because $e^{-|\mathbf{x}|^{2}} \psi(\mathbf{x}) \in \mathscr{G}$. Therefore, by the first part, $f(\mathbf{x}) e^{-|\mathbf{x}|^{2}}=0$ a.e.
The following theorem shows that you can consider most functions you are likely to encounter as elements of $\mathscr{G}^{*}$.

Theorem 32.3.8 Let $f$ be a measurable function with polynomial growth,

$$
|f(\mathbf{x})| \leq C\left(1+|\mathbf{x}|^{2}\right)^{N} \quad \text { for some } N
$$

or let $f \in L^{p}\left(\mathbb{R}^{n}\right)$ for some $p \in[1, \infty]$. Then $f \in \mathscr{G}^{*}$ if

$$
f(\phi) \equiv \int f \phi d x
$$

Proof: Let $f$ have polynomial growth first. Then the above integral is clearly well defined and so in this case, $f \in \mathscr{G}^{*}$.

Next suppose $f \in L^{p}\left(\mathbb{R}^{n}\right)$ with $\infty>p \geq 1$. Then it is clear again that the above integral is well defined because of the fact that $\phi$ is a sum of polynomials times exponentials of the form $e^{-c|\mathbf{x}|^{2}}$ and these are in $L^{p^{\prime}}\left(\mathbb{R}^{n}\right)$. Also $\phi \rightarrow f(\phi)$ is clearly linear in both cases.

This has shown that for nearly any reasonable function, you can define its Fourier transform as described above. You could also define the Fourier transform of a finite Borel measure $\mu$ because for such a measure

$$
\psi \rightarrow \int_{\mathbb{R}^{n}} \psi d \mu
$$

is a linear functional on $\mathscr{G}$. This includes the very important case of probability distribution measures. The theoretical basis for this assertion will be given a little later.

### 32.3.2 Fourier Transforms Of Functions In $L^{1}\left(\mathbb{R}^{n}\right)$

First suppose $f \in L^{1}\left(\mathbb{R}^{n}\right)$.
Theorem 32.3.9 Let $f \in L^{1}\left(\mathbb{R}^{n}\right)$. Then $F f(\phi)=\int_{\mathbb{R}^{n}} g \phi d t$ where

$$
g(\mathbf{t})=\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} f(\mathbf{x}) d x
$$

and $F^{-1} f(\phi)=\int_{\mathbb{R}^{n}} g \phi d t$ where $g(\mathbf{t})=\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{i \cdot \mathbf{x}} f(\mathbf{x}) d x$. In short,

$$
\begin{aligned}
& F f(\mathbf{t}) \equiv(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} f(\mathbf{x}) d x \\
& F^{-1} f(\mathbf{t}) \equiv(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} f(\mathbf{x}) d x
\end{aligned}
$$

Proof: From the definition and Fubini's theorem,

$$
\begin{aligned}
F f(\phi) & \equiv \int_{\mathbb{R}^{n}} f(\mathbf{t}) F \phi(\mathbf{t}) d t=\int_{\mathbb{R}^{n}} f(\mathbf{t})\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} \phi(\mathbf{x}) d x d t \\
& =\int_{\mathbb{R}^{n}}\left(\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} f(\mathbf{t}) e^{-i \mathbf{t} \cdot \mathbf{x}} d t\right) \phi(\mathbf{x}) d x
\end{aligned}
$$

Since $\phi \in \mathscr{G}$ is arbitrary, it follows from Theorem 32.3.7 that $F f(\mathbf{x})$ is given by the claimed formula. The case of $F^{-1}$ is identical.

Here are interesting properties of these Fourier transforms of functions in $L^{1}$.

Theorem 32.3.10 If $f \in L^{1}\left(\mathbb{R}^{n}\right)$ and $\left\|f_{k}-f\right\|_{1} \rightarrow 0$, then $F f_{k}$ and $F^{-1} f_{k}$ converge uniformly to $F f$ and $F^{-1} f$ respectively. If $f \in L^{1}\left(\mathbb{R}^{n}\right)$, then $F^{-1} f$ and $F f$ are both continuous and bounded. Also,

$$
\begin{equation*}
\lim _{|\mathbf{x}| \rightarrow \infty} F^{-1} f(\mathbf{x})=\lim _{|\mathbf{x}| \rightarrow \infty} F f(\mathbf{x})=0 \tag{32.3.3}
\end{equation*}
$$

Furthermore, for $f \in L^{1}\left(\mathbb{R}^{n}\right)$ both $F f$ and $F^{-1} f$ are uniformly continuous.
Proof: The first claim follows from the following inequality.

$$
\begin{aligned}
\left|F f_{k}(\mathbf{t})-F f(\mathbf{t})\right| & \leq(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}}\left|e^{-i \boldsymbol{t} \cdot \mathbf{x}} f_{k}(\mathbf{x})-e^{-i \mathbf{t} \cdot \mathbf{x}} f(\mathbf{x})\right| d x \\
& =(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}}\left|f_{k}(\mathbf{x})-f(\mathbf{x})\right| d x \\
& =(2 \pi)^{-n / 2}\left\|f-f_{k}\right\|_{1}
\end{aligned}
$$

which a similar argument holding for $F^{-1}$.
Now consider the second claim of the theorem.

$$
\left|F f(\mathbf{t})-F f\left(\mathbf{t}^{\prime}\right)\right| \leq(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}}\left|e^{-i \mathbf{t} \cdot \mathbf{x}}-e^{-i \mathbf{t}^{\prime} \cdot \mathbf{x}}\right||f(\mathbf{x})| d x
$$

The integrand is bounded by $2|f(\mathbf{x})|$, a function in $L^{1}\left(\mathbb{R}^{n}\right)$ and converges to 0 as $\mathbf{t}^{\prime} \rightarrow \mathbf{t}$ and so the dominated convergence theorem implies $F f$ is continuous. To see $F f(\mathbf{t})$ is uniformly bounded,

$$
|F f(\mathbf{t})| \leq(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}}|f(\mathbf{x})| d x<\infty
$$

A similar argument gives the same conclusions for $F^{-1}$.
It remains to verify 32.3 .3 and the claim that $F f$ and $F^{-1} f$ are uniformly continuous.

$$
|F f(\mathbf{t})| \leq\left|(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} f(\mathbf{x}) d x\right|
$$

Now let $\varepsilon>0$ be given and let $g \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ such that $(2 \pi)^{-n / 2}\|g-f\|_{1}<\varepsilon / 2$. Then

$$
\begin{aligned}
|F f(\mathbf{t})| \leq & (2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}}|f(\mathbf{x})-g(\mathbf{x})| d x \\
& +\left|(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} g(\mathbf{x}) d x\right| \\
\leq & \varepsilon / 2+\left|(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} g(\mathbf{x}) d x\right|
\end{aligned}
$$

Now integrating by parts, it follows that for $\|\mathbf{t}\|_{\infty} \equiv \max \left\{\left|t_{j}\right|: j=1, \cdots, n\right\}>0$

$$
\begin{equation*}
|F f(\mathbf{t})| \leq \varepsilon / 2+(2 \pi)^{-n / 2}\left|\frac{1}{\|\mathbf{t}\|_{\infty}} \int_{\mathbb{R}^{n}} \sum_{j=1}^{n}\right| \frac{\partial g(\mathbf{x})}{\partial x_{j}}|d x| \tag{32.3.4}
\end{equation*}
$$

and this last expression converges to zero as $\|\mathbf{t}\|_{\infty} \rightarrow \infty$. The reason for this is that if $t_{j} \neq 0$, integration by parts with respect to $x_{j}$ gives

$$
(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} g(\mathbf{x}) d x=(2 \pi)^{-n / 2} \frac{1}{-i t_{j}} \int_{\mathbb{R}^{n}} e^{-i \boldsymbol{t} \cdot \mathbf{x}} \frac{\partial g(\mathbf{x})}{\partial x_{j}} d x
$$

Therefore, choose the $j$ for which $\|\mathbf{t}\|_{\infty}=\left|t_{j}\right|$ and the result of 32.3.4 holds. Therefore, from 32.3.4, if $\|\mathbf{t}\|_{\infty}$ is large enough, $|F f(\mathbf{t})|<\varepsilon$. Similarly, $\lim _{\|\mathbf{t}\| \rightarrow \infty} F^{-1}(\mathbf{t})=0$. Consider the claim about uniform continuity. Let $\varepsilon>0$ be given. Then there exists $R$ such that if $\|\mathbf{t}\|_{\infty}>R$, then $|F f(\mathbf{t})|<\frac{\varepsilon}{2}$. Since $F f$ is continuous, it is uniformly continuous on the compact set $[-R-1, R+1]^{n}$. Therefore, there exists $\delta_{1}$ such that if $\left\|\mathbf{t}-\mathbf{t}^{\prime}\right\|_{\infty}<\delta_{1}$ for $\mathbf{t}^{\prime}, \mathbf{t} \in[-R-1, R+1]^{n}$, then

$$
\begin{equation*}
\left|F f(\mathbf{t})-F f\left(\mathbf{t}^{\prime}\right)\right|<\varepsilon / 2 . \tag{32.3.5}
\end{equation*}
$$

Now let $0<\delta<\min \left(\delta_{1}, 1\right)$ and suppose $\left\|\mathbf{t}-\mathbf{t}^{\prime}\right\|_{\infty}<\delta$. If both $\mathbf{t}, \mathbf{t}^{\prime}$ are contained in $[-R, R]^{n}$, then 32.3.5 holds. If $\mathbf{t} \in[-R, R]^{n}$ and $\mathbf{t}^{\prime} \notin[-R, R]^{n}$, then both are contained in $[-R-1, R+1]^{n}$ and so this verifies 32.3.5 in this case. The other case is that neither point is in $[-R, R]^{n}$ and in this case,

$$
\begin{aligned}
\left|F f(\mathbf{t})-F f\left(\mathbf{t}^{\prime}\right)\right| & \leq|F f(\mathbf{t})|+\left|F f\left(\mathbf{t}^{\prime}\right)\right| \\
& <\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon .
\end{aligned}
$$

There is a very interesting relation between the Fourier transform and convolutions.
Theorem 32.3.11 Let $f, g \in L^{1}\left(\mathbb{R}^{n}\right)$. Then $f * g \in L^{1}$ and $F(f * g)=(2 \pi)^{n / 2} F f F g$.
Proof: Consider

$$
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}}|f(\mathbf{x}-\mathbf{y}) g(\mathbf{y})| d y d x
$$

The function, $(\mathbf{x}, \mathbf{y}) \rightarrow|f(\mathbf{x}-\mathbf{y}) g(\mathbf{y})|$ is Lebesgue measurable and so by Fubini's theorem,

$$
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}}|f(\mathbf{x}-\mathbf{y}) g(\mathbf{y})| d y d x=\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}}|f(\mathbf{x}-\mathbf{y}) g(\mathbf{y})| d x d y=\|f\|_{1}\|g\|_{1}<\infty .
$$

It follows that for a.e. $\mathbf{x}, \int_{\mathbb{R}^{n}}|f(\mathbf{x}-\mathbf{y}) g(\mathbf{y})| d y<\infty$ and for each of these values of $\mathbf{x}$, it follows that $\int_{\mathbb{R}^{n}} f(\mathbf{x}-\mathbf{y}) g(\mathbf{y}) d y$ exists and equals a function of $\mathbf{x}$ which is in $L^{1}\left(\mathbb{R}^{n}\right), f *$ $g(\mathbf{x})$. Now

$$
\begin{aligned}
& F(f * g)(\mathbf{t}) \equiv(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} f * g(\mathbf{x}) d x \\
= & (2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \boldsymbol{t} \cdot \mathbf{x}} \int_{\mathbb{R}^{n}} f(\mathbf{x}-\mathbf{y}) g(\mathbf{y}) d y d x \\
= & (2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{y}} g(\mathbf{y}) \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot(\mathbf{x}-\mathbf{y})} f(\mathbf{x}-\mathbf{y}) d x d y \\
= & (2 \pi)^{n / 2} F f(\mathbf{t}) F g(\mathbf{t}) .
\end{aligned}
$$

There are other considerations involving Fourier transforms of functions in $L^{1}\left(\mathbb{R}^{n}\right)$.

### 32.3.3 Fourier Transforms Of Functions In $L^{2}\left(\mathbb{R}^{n}\right)$

Consider $F f$ and $F^{-1} f$ for $f \in L^{2}\left(\mathbb{R}^{n}\right)$. First note that the formula given for $F f$ and $F^{-1} f$ when $f \in L^{1}\left(\mathbb{R}^{n}\right)$ will not work for $f \in L^{2}\left(\mathbb{R}^{n}\right)$ unless $f$ is also in $L^{1}\left(\mathbb{R}^{n}\right)$. Recall that $\overline{a+i b}=a-i b$.

Theorem 32.3.12 For $\phi \in \mathscr{G},\|F \phi\|_{2}=\left\|F^{-1} \phi\right\|_{2}=\|\phi\|_{2}$.
Proof: First note that for $\psi \in \mathscr{G}$,

$$
\begin{equation*}
F(\bar{\psi})=\overline{F^{-1}(\psi)}, F^{-1}(\bar{\psi})=\overline{F(\psi)} \tag{32.3.6}
\end{equation*}
$$

This follows from the definition. For example,

$$
\begin{aligned}
F \bar{\psi}(\mathbf{t}) & =\frac{(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} \bar{\psi}(\mathbf{x}) d x}{} \\
= & (2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} \psi(\mathbf{x}) d x
\end{aligned}
$$

Let $\phi, \psi \in \mathscr{G}$. It was shown above that

$$
\int_{\mathbb{R}^{n}}(F \phi) \psi(\mathbf{t}) d t=\int_{\mathbb{R}^{n}} \phi(F \psi) d x
$$

Similarly,

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} \phi\left(F^{-1} \psi\right) d x=\int_{\mathbb{R}^{n}}\left(F^{-1} \phi\right) \psi d t \tag{32.3.7}
\end{equation*}
$$

Now, 32.3.6-32.3.7 imply

$$
\begin{aligned}
\int_{\mathbb{R}^{n}}|\phi|^{2} d x & =\int_{\mathbb{R}^{n}} \phi \overline{F^{-1}(F \phi)} d x=\int_{\mathbb{R}^{n}} \phi F(\overline{F \phi}) d x \\
& =\int_{\mathbb{R}^{n}} F \phi(\overline{F \phi}) d x=\int_{\mathbb{R}^{n}}|F \phi|^{2} d x
\end{aligned}
$$

Similarly

$$
\|\phi\|_{2}=\left\|F^{-1} \phi\right\|_{2} .
$$

Lemma 32.3.13 Let $f \in L^{2}\left(\mathbb{R}^{n}\right)$ and let $\phi_{k} \rightarrow f$ in $L^{2}\left(\mathbb{R}^{n}\right)$ where $\phi_{k} \in \mathscr{G}$. (Such a sequence exists because of density of $\mathscr{G}$ in $L^{2}\left(\mathbb{R}^{n}\right)$.) Then $F f$ and $F^{-1} f$ are both in $L^{2}\left(\mathbb{R}^{n}\right)$ and the following limits take place in $L^{2}$.

$$
\lim _{k \rightarrow \infty} F\left(\phi_{k}\right)=F(f), \lim _{k \rightarrow \infty} F^{-1}\left(\phi_{k}\right)=F^{-1}(f)
$$

Proof: Let $\psi \in \mathscr{G}$ be given. Then

$$
\begin{aligned}
F f(\psi) & \equiv f(F \psi) \equiv \int_{\mathbb{R}^{n}} f(\mathbf{x}) F \psi(\mathbf{x}) d x \\
& =\lim _{k \rightarrow \infty} \int_{\mathbb{R}^{n}} \phi_{k}(\mathbf{x}) F \psi(\mathbf{x}) d x=\lim _{k \rightarrow \infty} \int_{\mathbb{R}^{n}} F \phi_{k}(\mathbf{x}) \psi(\mathbf{x}) d x
\end{aligned}
$$

Also by Theorem 32.3.12 $\left\{F \phi_{k}\right\}_{k=1}^{\infty}$ is Cauchy in $L^{2}\left(\mathbb{R}^{n}\right)$ and so it converges to some $h \in L^{2}\left(\mathbb{R}^{n}\right)$. Therefore, from the above,

$$
F f(\psi)=\int_{\mathbb{R}^{n}} h(\mathbf{x}) \psi(\mathbf{x})
$$

which shows that $F(f) \in L^{2}\left(\mathbb{R}^{n}\right)$ and $h=F(f)$. The case of $F^{-1}$ is entirely similar.
Since $F f$ and $F^{-1} f$ are in $L^{2}\left(\mathbb{R}^{n}\right)$, this also proves the following theorem.
Theorem 32.3.14 If $f \in L^{2}\left(\mathbb{R}^{n}\right), F f$ and $F^{-1} f$ are the unique elements of $L^{2}\left(\mathbb{R}^{n}\right)$ such that for all $\phi \in \mathscr{G}$,

$$
\begin{align*}
\int_{\mathbb{R}^{n}} F f(\mathbf{x}) \phi(\mathbf{x}) d x & =\int_{\mathbb{R}^{n}} f(\mathbf{x}) F \phi(\mathbf{x}) d x  \tag{32.3.8}\\
\int_{\mathbb{R}^{n}} F^{-1} f(\mathbf{x}) \phi(\mathbf{x}) d x & =\int_{\mathbb{R}^{n}} f(\mathbf{x}) F^{-1} \phi(\mathbf{x}) d x \tag{32.3.9}
\end{align*}
$$

Theorem 32.3.15 (Plancherel)

$$
\begin{equation*}
\|f\|_{2}=\|F f\|_{2}=\left\|F^{-1} f\right\|_{2} \tag{32.3.10}
\end{equation*}
$$

Proof: Use the density of $\mathscr{G}$ in $L^{2}\left(\mathbb{R}^{n}\right)$ to obtain a sequence, $\left\{\phi_{k}\right\}$ converging to $f$ in $L^{2}\left(\mathbb{R}^{n}\right)$. Then by Lemma 32.3.13

$$
\|F f\|_{2}=\lim _{k \rightarrow \infty}\left\|F \phi_{k}\right\|_{2}=\lim _{k \rightarrow \infty}\left\|\phi_{k}\right\|_{2}=\|f\|_{2}
$$

Similarly,

$$
\|f\|_{2}=\left\|F^{-1} f\right\|_{2} .
$$

The following corollary is a simple generalization of this. To prove this corollary, use the following simple lemma which comes as a consequence of the Cauchy Schwarz inequality.

Lemma 32.3.16 Suppose $f_{k} \rightarrow f$ in $L^{2}\left(\mathbb{R}^{n}\right)$ and $g_{k} \rightarrow g$ in $L^{2}\left(\mathbb{R}^{n}\right)$. Then

$$
\lim _{k \rightarrow \infty} \int_{\mathbb{R}^{n}} f_{k} g_{k} d x=\int_{\mathbb{R}^{n}} f g d x
$$

Proof:

$$
\begin{gathered}
\left|\int_{\mathbb{R}^{n}} f_{k} g_{k} d x-\int_{\mathbb{R}^{n}} f g d x\right| \leq\left|\int_{\mathbb{R}^{n}} f_{k} g_{k} d x-\int_{\mathbb{R}^{n}} f_{k} g d x\right|+ \\
\left|\int_{\mathbb{R}^{n}} f_{k} g d x-\int_{\mathbb{R}^{n}} f g d x\right| \\
\leq\left\|f_{k}\right\|_{2}| | g-g_{k}\left\|_{2}+\right\| g\left\|_{2}\right\| f_{k}-f \|_{2} .
\end{gathered}
$$

Now $\left\|f_{k}\right\|_{2}$ is a Cauchy sequence and so it is bounded independent of $k$. Therefore, the above expression is smaller than $\varepsilon$ whenever $k$ is large enough.

Corollary 32.3.17 For $f, g \in L^{2}\left(\mathbb{R}^{n}\right)$,

$$
\int_{\mathbb{R}^{n}} f \bar{g} d x=\int_{\mathbb{R}^{n}} F f \overline{F g} d x=\int_{\mathbb{R}^{n}} F^{-1} f \overline{F^{-1} g} d x
$$

Proof: First note the above formula is obvious if $f, g \in \mathscr{G}$. To see this, note

$$
\begin{aligned}
& \int_{\mathbb{R}^{n}} F f \overline{F g} d x=\int_{\mathbb{R}^{n}} F f(\mathbf{x}) \overline{\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} e^{-i \mathbf{x} \cdot \mathbf{t}} g(\mathbf{t}) d t d x} \\
= & \int_{\mathbb{R}^{n}} \frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} e^{i \mathbf{X} \cdot \mathbf{t}} F f(\mathbf{x}) d x \overline{g(\mathbf{t})} d t=\int_{\mathbb{R}^{n}}\left(F^{-1} \circ F\right) f(\mathbf{t}) \overline{g(\mathbf{t})} d t \\
= & \int_{\mathbb{R}^{n}} f(\mathbf{t}) \overline{g(\mathbf{t})} d t .
\end{aligned}
$$

The formula with $F^{-1}$ is exactly similar.
Now to verify the corollary, let $\phi_{k} \rightarrow f$ in $L^{2}\left(\mathbb{R}^{n}\right)$ and let $\psi_{k} \rightarrow g$ in $L^{2}\left(\mathbb{R}^{n}\right)$. Then by Lemma 32.3.13

$$
\int_{\mathbb{R}^{n}} F f \overline{F g} d x=\lim _{k \rightarrow \infty} \int_{\mathbb{R}^{n}} F \phi_{k} \overline{F \psi_{k}} d x=\lim _{k \rightarrow \infty} \int_{\mathbb{R}^{n}} \phi_{k} \overline{\psi_{k}} d x=\int_{\mathbb{R}^{n}} f \bar{g} d x
$$

A similar argument holds for $F^{-1}$.
How does one compute $F f$ and $F^{-1} f$ ?
Theorem 32.3.18 For $f \in L^{2}\left(\mathbb{R}^{n}\right)$, let $f_{r}=f \mathscr{X}_{E_{r}}$ where $E_{r}$ is a bounded measurable set with $E_{r} \uparrow \mathbb{R}^{n}$. Then the following limits hold in $L^{2}\left(\mathbb{R}^{n}\right)$.

$$
F f=\lim _{r \rightarrow \infty} F f_{r}, F^{-1} f=\lim _{r \rightarrow \infty} F^{-1} f_{r}
$$

Proof: $\left\|f-f_{r}\right\|_{2} \rightarrow 0$ and so $\left\|F f-F f_{r}\right\|_{2} \rightarrow 0$ and $\left\|F^{-1} f-F^{-1} f_{r}\right\|_{2} \rightarrow 0$ by Plancherel's Theorem.

What are $F f_{r}$ and $F^{-1} f_{r}$ ? Let $\phi \in \mathscr{G}$

$$
\begin{aligned}
\int_{\mathbb{R}^{n}} F f_{r} \phi d x & =\int_{\mathbb{R}^{n}} f_{r} F \phi d x \\
& =(2 \pi)^{-\frac{n}{2}} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f_{r}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} \phi(\mathbf{y}) d y d x \\
& =\int_{\mathbb{R}^{n}}\left[(2 \pi)^{-\frac{n}{2}} \int_{\mathbb{R}^{n}} f_{r}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x\right] \phi(\mathbf{y}) d y .
\end{aligned}
$$

Since this holds for all $\phi \in \mathscr{G}$, a dense subset of $L^{2}\left(\mathbb{R}^{n}\right)$, it follows that

$$
F f_{r}(\mathbf{y})=(2 \pi)^{-\frac{n}{2}} \int_{\mathbb{R}^{n}} f_{r}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x
$$

Similarly

$$
F^{-1} f_{r}(\mathbf{y})=(2 \pi)^{-\frac{n}{2}} \int_{\mathbb{R}^{n}} f_{r}(\mathbf{x}) e^{i \mathbf{x} \cdot \mathbf{y}} d x
$$

This shows that to take the Fourier transform of a function in $L^{2}\left(\mathbb{R}^{n}\right)$, it suffices to take the limit as $r \rightarrow \infty$ in $L^{2}\left(\mathbb{R}^{n}\right)$ of $(2 \pi)^{-\frac{n}{2}} \int_{\mathbb{R}^{n}} f_{r}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x$. A similar procedure works for the inverse Fourier transform.

Note this reduces to the earlier definition in case $f \in L^{1}\left(\mathbb{R}^{n}\right)$. Now consider the convolution of a function in $L^{2}$ with one in $L^{1}$.

Theorem 32.3.19 Let $h \in L^{2}\left(\mathbb{R}^{n}\right)$ and let $f \in L^{1}\left(\mathbb{R}^{n}\right)$. Then $h * f \in L^{2}\left(\mathbb{R}^{n}\right)$,

$$
\begin{gathered}
F^{-1}(h * f)=(2 \pi)^{n / 2} F^{-1} h F^{-1} f, \\
F(h * f)=(2 \pi)^{n / 2} F h F f,
\end{gathered}
$$

and

$$
\begin{equation*}
\|h * f\|_{2} \leq\|h\|_{2}\|f\|_{1} . \tag{32.3.11}
\end{equation*}
$$

Proof: An application of Minkowski’s inequality yields

$$
\begin{equation*}
\left(\int_{\mathbb{R}^{n}}\left(\int_{\mathbb{R}^{n}}|h(\mathbf{x}-\mathbf{y})||f(\mathbf{y})| d y\right)^{2} d x\right)^{1 / 2} \leq\|f\|_{1}\|h\|_{2} \tag{32.3.12}
\end{equation*}
$$

Hence $\int|h(\mathbf{x}-\mathbf{y})||f(\mathbf{y})| d y<\infty$ a.e. $\mathbf{x}$ and

$$
\mathbf{x} \rightarrow \int h(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y
$$

is in $L^{2}\left(\mathbb{R}^{n}\right)$. Let $E_{r} \uparrow \mathbb{R}^{n}, m\left(E_{r}\right)<\infty$. Thus,

$$
h_{r} \equiv \mathscr{X}_{E_{r}} h \in L^{2}\left(\mathbb{R}^{n}\right) \cap L^{1}\left(\mathbb{R}^{n}\right)
$$

and letting $\phi \in \mathscr{G}$,

$$
\begin{aligned}
& \int F\left(h_{r} * f\right)(\phi) d x \\
\equiv & \int\left(h_{r} * f\right)(F \phi) d x \\
= & (2 \pi)^{-n / 2} \iiint h_{r}(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) e^{-i \mathbf{x} \cdot \mathbf{t}} \phi(\mathbf{t}) d t d y d x \\
= & (2 \pi)^{-n / 2} \iint\left(\int h_{r}(\mathbf{x}-\mathbf{y}) e^{-i(\mathbf{x}-\mathbf{y}) \cdot \mathbf{t}} d x\right) f(\mathbf{y}) e^{-i \mathbf{y} \cdot \mathbf{t}} d y \phi(\mathbf{t}) d t \\
= & \int(2 \pi)^{n / 2} F h_{r}(\mathbf{t}) F f(\mathbf{t}) \phi(\mathbf{t}) d t .
\end{aligned}
$$

Since $\phi$ is arbitrary and $\mathscr{G}$ is dense in $L^{2}\left(\mathbb{R}^{n}\right)$,

$$
F\left(h_{r} * f\right)=(2 \pi)^{n / 2} F h_{r} F f .
$$

Now by Minkowski's Inequality, $h_{r} * f \rightarrow h * f$ in $L^{2}\left(\mathbb{R}^{n}\right)$ and also it is clear that $h_{r} \rightarrow h$ in $L^{2}\left(\mathbb{R}^{n}\right)$; so, by Plancherel's theorem, you may take the limit in the above and conclude

$$
F(h * f)=(2 \pi)^{n / 2} F h F f .
$$

The assertion for $F^{-1}$ is similar and 32.3.11 follows from 32.3.12.

### 32.3.4 The Schwartz Class

The problem with $\mathscr{G}$ is that it does not contain $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. I have used it in presenting the Fourier transform because the functions in $\mathscr{G}$ have a very specific form which made some technical details work out easier than in any other approach I have seen. The Schwartz class is a larger class of functions which does contain $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ and also has the same nice properties as $\mathscr{G}$. The functions in the Schwartz class are infinitely differentiable and they vanish very rapidly as $|\mathbf{x}| \rightarrow \infty$ along with all their partial derivatives. This is the description of these functions, not a specific form involving polynomials times $e^{-\alpha|\mathbf{x}|^{2}}$. To describe this precisely requires some notation.

Definition 32.3.20 $f \in \mathfrak{S}$, the Schwartz class, if $f \in C^{\infty}\left(\mathbb{R}^{n}\right)$ and for all positive integers $N$,

$$
\rho_{N}(f)<\infty
$$

where

$$
\rho_{N}(f)=\sup \left\{\left(1+|\mathbf{x}|^{2}\right)^{N}\left|D^{\alpha} f(\mathbf{x})\right|: \mathbf{x} \in \mathbb{R}^{n},|\alpha| \leq N\right\}
$$

Thus $f \in \mathfrak{S}$ if and only if $f \in C^{\infty}\left(\mathbb{R}^{n}\right)$ and

$$
\begin{equation*}
\sup \left\{\left|\mathbf{x}^{\beta} D^{\alpha} f(\mathbf{x})\right|: \mathbf{x} \in \mathbb{R}^{n}\right\}<\infty \tag{32.3.13}
\end{equation*}
$$

for all multi indices $\alpha$ and $\beta$.
Also note that if $f \in \mathfrak{S}$, then $p(f) \in \mathfrak{S}$ for any polynomial, $p$ with $p(0)=0$ and that

$$
\mathfrak{S} \subseteq L^{p}\left(\mathbb{R}^{n}\right) \cap L^{\infty}\left(\mathbb{R}^{n}\right)
$$

for any $p \geq 1$. To see this assertion about the $p(f)$, it suffices to consider the case of the product of two elements of the Schwartz class. If $f, g \in \mathfrak{S}$, then $D^{\alpha}(f g)$ is a finite sum of derivatives of $f$ times derivatives of $g$. Therefore, $\rho_{N}(f g)<\infty$ for all $N$. You may wonder about examples of things in $\mathfrak{S}$. Clearly any function in $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is in $\mathfrak{S}$. However there are other functions in $\mathfrak{S}$. For example $e^{-|\mathbf{x}|^{2}}$ is in $\mathfrak{S}$ as you can verify for yourself and so is any function from $\mathscr{G}$. Note also that the density of $C_{c}\left(\mathbb{R}^{n}\right)$ in $L^{p}\left(\mathbb{R}^{n}\right)$ shows that $\mathfrak{S}$ is dense in $L^{p}\left(\mathbb{R}^{n}\right)$ for every $p$.

Recall the Fourier transform of a function in $L^{1}\left(\mathbb{R}^{n}\right)$ is given by

$$
F f(\mathbf{t}) \equiv(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{-i \mathbf{t} \cdot \mathbf{x}} f(\mathbf{x}) d x
$$

Therefore, this gives the Fourier transform for $f \in \mathfrak{S}$. The nice property which $\mathfrak{S}$ has in common with $\mathscr{G}$ is that the Fourier transform and its inverse map $\mathfrak{S}$ one to one onto $\mathfrak{S}$. This means I could have presented the whole of the above theory in terms of $\mathfrak{S}$ rather than in terms of $\mathscr{G}$. However, it is more technical.

Theorem 32.3.21 If $f \in \mathfrak{S}$, then $F f$ and $F^{-1} f$ are also in $\mathfrak{S}$.

Proof: To begin with, let $\alpha=\mathbf{e}_{j}=(0,0, \cdots, 1,0, \cdots, 0)$, the 1 in the $j^{\text {th }}$ slot.

$$
\begin{equation*}
\frac{F^{-1} f\left(\mathbf{t}+h \mathbf{e}_{j}\right)-F^{-1} f(\mathbf{t})}{h}=(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} f(\mathbf{x})\left(\frac{e^{i h x_{j}}-1}{h}\right) d x \tag{32.3.14}
\end{equation*}
$$

Consider the integrand in 32.3.14.

$$
\begin{aligned}
\left|e^{i \cdot \mathbf{x}} f(\mathbf{x})\left(\frac{e^{i h x_{j}}-1}{h}\right)\right| & =|f(\mathbf{x})|\left|\left(\frac{e^{i(h / 2) x_{j}}-e^{-i(h / 2) x_{j}}}{h}\right)\right| \\
& =|f(\mathbf{x})|\left|\frac{i \sin \left((h / 2) x_{j}\right)}{(h / 2)}\right| \leq|f(\mathbf{x})|\left|x_{j}\right|
\end{aligned}
$$

and this is a function in $L^{1}\left(\mathbb{R}^{n}\right)$ because $f \in \mathfrak{S}$. Therefore by the Dominated Convergence Theorem,

$$
\begin{aligned}
\frac{\partial F^{-1} f(\mathbf{t})}{\partial t_{j}} & =(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} i x_{j} f(\mathbf{x}) d x \\
& =i(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} \mathbf{x}^{\mathbf{e}_{j}} f(\mathbf{x}) d x
\end{aligned}
$$

Now $\mathbf{x}^{\mathbf{e}_{j}} f(\mathbf{x}) \in \mathfrak{S}$ and so one can continue in this way and take derivatives indefinitely. Thus $F^{-1} f \in C^{\infty}\left(\mathbb{R}^{n}\right)$ and from the above argument,

$$
D^{\alpha} F^{-1} f(\mathbf{t})=(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}}(i \mathbf{x})^{\alpha} f(\mathbf{x}) d x
$$

To complete showing $F^{-1} f \in \mathfrak{S}$,

$$
\mathbf{t}^{\beta} D^{\alpha} F^{-1} f(\mathbf{t})=(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} e^{i \mathbf{t} \cdot \mathbf{x}} \mathbf{t}^{\beta}(i \mathbf{x})^{a} f(\mathbf{x}) d x
$$

Integrate this integral by parts to get

$$
\begin{equation*}
\mathbf{t}^{\beta} D^{\alpha} F^{-1} f(\mathbf{t})=(2 \pi)^{-n / 2} \int_{\mathbb{R}^{n}} i^{|\beta|} e^{i \mathbf{t} \cdot \mathbf{x}} D^{\beta}\left((i \mathbf{x})^{a} f(\mathbf{x})\right) d x \tag{32.3.15}
\end{equation*}
$$

Here is how this is done.

$$
\begin{aligned}
\int_{\mathbb{R}} e^{i t_{j} x_{j}} t_{j}^{\beta_{j}}(i \mathbf{x})^{\alpha} f(\mathbf{x}) d x_{j}= & \left.\frac{e^{i t_{j} x_{j}}}{i t_{j}} t_{j}^{\beta_{j}}(i \mathbf{x})^{\alpha} f(\mathbf{x})\right|_{-\infty} ^{\infty}+ \\
& i \int_{\mathbb{R}} e^{i t_{j} x_{j}} t_{j}^{\beta_{j}-1} D^{\mathbf{e}_{j}}\left((i \mathbf{x})^{\alpha} f(\mathbf{x})\right) d x_{j}
\end{aligned}
$$

where the boundary term vanishes because $f \in \mathfrak{S}$. Returning to 32.3 .15 , use the fact that $\left|e^{i a}\right|=1$ to conclude

$$
\left|\mathbf{t}^{\beta} D^{\alpha} F^{-1} f(\mathbf{t})\right| \leq C \int_{\mathbb{R}^{n}}\left|D^{\beta}\left((i \mathbf{x})^{a} f(\mathbf{x})\right)\right| d x<\infty
$$

It follows $F^{-1} f \in \mathfrak{S}$. Similarly $F f \in \mathfrak{S}$ whenever $f \in \mathfrak{S}$.
Of course $\mathfrak{S}$ can be considered a subset of $\mathscr{G}^{*}$ as follows. For $\psi \in \mathfrak{S}$,

$$
\psi(\phi) \equiv \int_{\mathbb{R}^{n}} \psi \phi d x
$$

Theorem 32.3.22 Let $\psi \in \mathfrak{S}$. Then $\left(F \circ F^{-1}\right)(\psi)=\psi$ and $\left(F^{-1} \circ F\right)(\psi)=\psi$ whenever $\psi \in \mathfrak{S}$. Also $F$ and $F^{-1}$ map $\mathfrak{S}$ one to one and onto $\mathfrak{S}$.

Proof: The first claim follows from the fact that $F$ and $F^{-1}$ are inverses of each other on $\mathscr{G}^{*}$ which was established above. For the second, let $\psi \in \mathfrak{S}$. Then $\psi=F\left(F^{-1} \psi\right)$. Thus $F$ maps $\mathfrak{S}$ onto $\mathfrak{S}$. If $F \psi=0$, then do $F^{-1}$ to both sides to conclude $\psi=0$. Thus $F$ is one to one and onto. Similarly, $F^{-1}$ is one to one and onto.

### 32.3.5 Convolution

To begin with it is necessary to discuss the meaning of $\phi f$ where $f \in \mathscr{G}^{*}$ and $\phi \in \mathscr{G}$. What should it mean? First suppose $f \in L^{p}\left(\mathbb{R}^{n}\right)$ or measurable with polynomial growth. Then $\phi f$ also has these properties. Hence, it should be the case that $\phi f(\psi)=\int_{\mathbb{R}^{n}} \phi f \psi d x=$ $\int_{\mathbb{R}^{n}} f(\phi \psi) d x$. This motivates the following definition.

Definition 32.3.23 Let $T \in \mathscr{G}^{*}$ and let $\phi \in \mathscr{G}$. Then $\phi T \equiv T \phi \in \mathscr{G}^{*}$ will be defined by

$$
\phi T(\psi) \equiv T(\phi \psi) .
$$

The next topic is that of convolution. It was just shown that

$$
F(f * \phi)=(2 \pi)^{n / 2} F \phi F f, F^{-1}(f * \phi)=(2 \pi)^{n / 2} F^{-1} \phi F^{-1} f
$$

whenever $f \in L^{2}\left(\mathbb{R}^{n}\right)$ and $\phi \in \mathscr{G}$ so the same definition is retained in the general case because it makes perfect sense and agrees with the earlier definition.

Definition 32.3.24 Let $f \in \mathscr{G}^{*}$ and let $\phi \in \mathscr{G}$. Then define the convolution of $f$ with an element of $\mathscr{G}$ as follows.

$$
f * \phi \equiv(2 \pi)^{n / 2} F^{-1}(F \phi F f) \in \mathscr{G}^{*}
$$

There is an obvious question. With this definition, is it true that

$$
F^{-1}(f * \phi)=(2 \pi)^{n / 2} F^{-1} \phi F^{-1} f
$$

as it was earlier?
Theorem 32.3.25 Let $f \in \mathscr{G}^{*}$ and let $\phi \in \mathscr{G}$.

$$
\begin{gather*}
F(f * \phi)=(2 \pi)^{n / 2} F \phi F f,  \tag{32.3.16}\\
F^{-1}(f * \phi)=(2 \pi)^{n / 2} F^{-1} \phi F^{-1} f . \tag{32.3.17}
\end{gather*}
$$

Proof: Note that 32.3.16 follows from Definition 32.3.24 and both assertions hold for $f \in \mathscr{G}$. Consider 32.3.17. Here is a simple formula involving a pair of functions in $\mathscr{G}$.

$$
\left(\psi * F^{-1} F^{-1} \phi\right)(\mathbf{x})
$$

$$
\begin{aligned}
& =\left(\iiint \psi(\mathbf{x}-\mathbf{y}) e^{i \mathbf{y} \cdot \mathbf{y}_{1}} e^{i \mathbf{y}_{1} \cdot \mathbf{z}} \phi(\mathbf{z}) d z d y_{1} d y\right)(2 \pi)^{n} \\
& =\left(\iiint \psi(\mathbf{x}-\mathbf{y}) e^{-i \mathbf{y} \cdot \tilde{\mathbf{y}}_{1}} e^{-i \tilde{\mathbf{y}}_{1} \cdot \mathbf{z}} \phi(\mathbf{z}) d z d \tilde{y}_{1} d y\right)(2 \pi)^{n} \\
& =(\psi * F F \phi)(\mathbf{x}) .
\end{aligned}
$$

Now for $\psi \in \mathscr{G}$,

$$
\begin{gather*}
(2 \pi)^{n / 2} F\left(F^{-1} \phi F^{-1} f\right)(\psi) \equiv(2 \pi)^{n / 2}\left(F^{-1} \phi F^{-1} f\right)(F \psi) \equiv \\
(2 \pi)^{n / 2} F^{-1} f\left(F^{-1} \phi F \psi\right) \equiv(2 \pi)^{n / 2} f\left(F^{-1}\left(F^{-1} \phi F \psi\right)\right)= \\
f\left((2 \pi)^{n / 2} F^{-1}\left(\left(F F^{-1} F^{-1} \phi\right)(F \psi)\right)\right) \equiv \\
f\left(\psi * F^{-1} F^{-1} \phi\right)=f(\psi * F F \phi) \tag{32.3.18}
\end{gather*}
$$

Also

$$
\begin{gather*}
(2 \pi)^{n / 2} F^{-1}(F \phi F f)(\psi) \equiv(2 \pi)^{n / 2}(F \phi F f)\left(F^{-1} \psi\right) \equiv \\
(2 \pi)^{n / 2} F f\left(F \phi F^{-1} \psi\right) \equiv(2 \pi)^{n / 2} f\left(F\left(F \phi F^{-1} \psi\right)\right)= \\
=f\left(F\left((2 \pi)^{n / 2}\left(F \phi F^{-1} \psi\right)\right)\right) \\
=f\left(F\left((2 \pi)^{n / 2}\left(F^{-1} F F \phi F^{-1} \psi\right)\right)\right)=f\left(F\left(F^{-1}(F F \phi * \psi)\right)\right) \\
f(F F \phi * \psi)=f(\psi * F F \phi) . \tag{32.3.19}
\end{gather*}
$$

The last line follows from the following.

$$
\begin{aligned}
\int F F \phi(\mathbf{x}-\mathbf{y}) \psi(\mathbf{y}) d y & =\int F \phi(\mathbf{x}-\mathbf{y}) F \psi(\mathbf{y}) d y \\
& =\int F \psi(\mathbf{x}-\mathbf{y}) F \phi(\mathbf{y}) d y \\
& =\int \psi(\mathbf{x}-\mathbf{y}) F F \phi(y) d y
\end{aligned}
$$

From 32.3.19 and 32.3.18, since $\psi$ was arbitrary,

$$
(2 \pi)^{n / 2} F\left(F^{-1} \phi F^{-1} f\right)=(2 \pi)^{n / 2} F^{-1}(F \phi F f) \equiv f * \phi
$$

which shows 32.3.17.

### 32.4 Exercises

1. For $f \in L^{1}\left(\mathbb{R}^{n}\right)$, show that if $F^{-1} f \in L^{1}$ or $F f \in L^{1}$, then $f$ equals a continuous bounded function a.e.
2. Suppose $f, g \in L^{1}(\mathbb{R})$ and $F f=F g$. Show $f=g$ a.e.
3. Show that if $f \in L^{1}\left(\mathbb{R}^{n}\right)$, then $\lim _{|\mathbf{x}| \rightarrow \infty} F f(\mathbf{x})=0$.
4. $\uparrow$ Suppose $f * f=f$ or $f * f=0$ and $f \in L^{1}(\mathbb{R})$. Show $f=0$.
5. For this problem define $\int_{a}^{\infty} f(t) d t \equiv \lim _{r \rightarrow \infty} \int_{a}^{r} f(t) d t$. Note this coincides with the Lebesgue integral when $f \in L^{1}(a, \infty)$. Show
(a) $\int_{0}^{\infty} \frac{\sin (u)}{u} d u=\frac{\pi}{2}$
(b) $\lim _{r \rightarrow \infty} \int_{\delta}^{\infty} \frac{\sin (r u)}{u} d u=0$ whenever $\delta>0$.
(c) If $f \in L^{1}(\mathbb{R})$, then $\lim _{r \rightarrow \infty} \int_{\mathbb{R}} \sin (r u) f(u) d u=0$.

Hint: For the first two, use $\frac{1}{u}=\int_{0}^{\infty} e^{-u t} d t$ and apply Fubini's theorem to

$$
\int_{0}^{R} \sin u \int_{\mathbb{R}} e^{-u t} d t d u
$$

For the last part, first establish it for $f \in C_{c}^{\infty}(\mathbb{R})$ and then use the density of this set in $L^{1}(\mathbb{R})$ to obtain the result. This is sometimes called the Riemann Lebesgue lemma.
6. $\uparrow$ Suppose that $g \in L^{1}(\mathbb{R})$ and that at some $x>0, g$ is locally Holder continuous from the right and from the left. This means

$$
\lim _{r \rightarrow 0+} g(x+r) \equiv g(x+)
$$

exists,

$$
\lim _{r \rightarrow 0+} g(x-r) \equiv g(x-)
$$

exists and there exist constants $K, \delta>0$ and $r \in(0,1]$ such that for $|x-y|<\delta$,

$$
|g(x+)-g(y)|<K|x-y|^{r}
$$

for $y>x$ and

$$
|g(x-)-g(y)|<K|x-y|^{r}
$$

for $y<x$. Show that under these conditions,

$$
\begin{gathered}
\lim _{r \rightarrow \infty} \frac{2}{\pi} \int_{0}^{\infty} \frac{\sin (u r)}{u}\left(\frac{g(x-u)+g(x+u)}{2}\right) d u \\
=\frac{g(x+)+g(x-)}{2}
\end{gathered}
$$

7. $\uparrow$ Let $g \in L^{1}(\mathbb{R})$ and suppose $g$ is locally Holder continuous from the right and from the left at $x$. Show that then

$$
\lim _{R \rightarrow \infty} \frac{1}{2 \pi} \int_{-R}^{R} e^{i x t} \int_{-\infty}^{\infty} e^{-i t y} g(y) d y d t=\frac{g(x+)+g(x-)}{2}
$$

This is very interesting. If $g \in L^{2}(\mathbb{R})$, this shows $F^{-1}(F g)(x)=\frac{g(x+)+g(x-)}{2}$, the midpoint of the jump in $g$ at the point, $x$. In particular, if $g \in \mathscr{G}, F^{-1}(F g)=g$. Hint: Show the left side of the above equation reduces to

$$
\frac{2}{\pi} \int_{0}^{\infty} \frac{\sin (u r)}{u}\left(\frac{g(x-u)+g(x+u)}{2}\right) d u
$$

and then use Problem 6 to obtain the result.
8. $\uparrow$ A measurable function $g$ defined on $(0, \infty)$ has exponential growth if $|g(t)| \leq C e^{\eta t}$ for some $\eta$. For $\operatorname{Re}(s)>\eta$, define the Laplace Transform by

$$
L g(s) \equiv \int_{0}^{\infty} e^{-s u} g(u) d u
$$

Assume that $g$ has exponential growth as above and is Holder continuous from the right and from the left at $t$. Pick $\gamma>\eta$. Show that

$$
\lim _{R \rightarrow \infty} \frac{1}{2 \pi} \int_{-R}^{R} e^{\gamma t} e^{i y t} L g(\gamma+i y) d y=\frac{g(t+)+g(t-)}{2}
$$

This formula is sometimes written in the form

$$
\frac{1}{2 \pi i} \int_{\gamma-i \infty}^{\gamma+i \infty} e^{s t} \operatorname{Lg}(s) d s
$$

and is called the complex inversion integral for Laplace transforms. It can be used to find inverse Laplace transforms. Hint:

$$
\begin{gathered}
\frac{1}{2 \pi} \int_{-R}^{R} e^{\gamma t} e^{i y t} L g(\gamma+i y) d y= \\
\frac{1}{2 \pi} \int_{-R}^{R} e^{\gamma t} e^{i y t} \int_{0}^{\infty} e^{-(\gamma+i y) u} g(u) d u d y
\end{gathered}
$$

Now use Fubini's theorem and do the integral from $-R$ to $R$ to get this equal to

$$
\frac{e^{\gamma t}}{\pi} \int_{-\infty}^{\infty} e^{-\gamma u} \bar{g}(u) \frac{\sin (R(t-u))}{t-u} d u
$$

where $\bar{g}$ is the zero extension of $g$ off $[0, \infty)$. Then this equals

$$
\frac{e^{\gamma t}}{\pi} \int_{-\infty}^{\infty} e^{-\gamma(t-u)} \bar{g}(t-u) \frac{\sin (R u)}{u} d u
$$

which equals

$$
\frac{2 e^{\gamma t}}{\pi} \int_{0}^{\infty} \frac{\bar{g}(t-u) e^{-\gamma(t-u)}+\bar{g}(t+u) e^{-\gamma(t+u)}}{2} \frac{\sin (R u)}{u} d u
$$

and then apply the result of Problem 6.
9. Suppose $f \in \mathfrak{S}$. Show $F\left(f_{x_{j}}\right)(\mathbf{t})=i t_{j} F f(\mathbf{t})$.
10. Let $f \in \mathfrak{S}$ and let $k$ be a positive integer.

$$
\|f\|_{k, 2} \equiv\left(\|f\|_{2}^{2}+\sum_{|\alpha| \leq k}\left\|D^{\alpha} f\right\|_{2}^{2}\right)^{1 / 2}
$$

One could also define

$$
\||f|\|_{k, 2} \equiv\left(\int_{R^{n}}|F f(\mathbf{x})|^{2}\left(1+|\mathbf{x}|^{2}\right)^{k} d x\right)^{1 / 2}
$$

Show both $\left\|\left\|\|_{k, 2}\right.\right.$ and $\left.\|\right\|\left\|\|_{k, 2}\right.$ are norms on $\mathfrak{S}$ and that they are equivalent. These are Sobolev space norms. For which values of $k$ does the second norm make sense? How about the first norm?
11. $\uparrow$ Define $H^{k}\left(\mathbb{R}^{n}\right), k \geq 0$ by $f \in L^{2}\left(\mathbb{R}^{n}\right)$ such that

$$
\begin{gathered}
\left(\int|F f(\mathbf{x})|^{2}\left(1+|\mathbf{x}|^{2}\right)^{k} d x\right)^{\frac{1}{2}}<\infty \\
\left\|\left||f| \|_{k, 2} \equiv\left(\int|F f(\mathbf{x})|^{2}\left(1+|\mathbf{x}|^{2}\right)^{k} d x\right)^{\frac{1}{2}}\right.\right.
\end{gathered}
$$

Show $H^{k}\left(\mathbb{R}^{n}\right)$ is a Banach space, and that if $k$ is a positive integer, $H^{k}\left(\mathbb{R}^{n}\right)=\{f \in$ $L^{2}\left(\mathbb{R}^{n}\right)$ : there exists $\left\{u_{j}\right\} \subseteq \mathscr{G}$ with $\left\|u_{j}-f\right\|_{2} \rightarrow 0$ and $\left\{u_{j}\right\}$ is a Cauchy sequence in $\left\|\|_{k, 2}\right.$ of Problem 10$\}$. This is one way to define Sobolev Spaces. Hint: One way to do the second part of this is to define a new measure, $\mu$ by

$$
\mu(E) \equiv \int_{E}\left(1+|\mathbf{x}|^{2}\right)^{k} d x
$$

Then show $\mu$ is a Radon measure and show there exists $\left\{g_{m}\right\}$ such that $g_{m} \in \mathscr{G}$ and $g_{m} \rightarrow F f$ in $L^{2}(\mu)$. Thus $g_{m}=F f_{m}, f_{m} \in \mathscr{G}$ because $F$ maps $\mathscr{G}$ onto $\mathscr{G}$. Then by Problem 10, $\left\{f_{m}\right\}$ is Cauchy in the norm $\left\|\|_{k, 2}\right.$.
12. $\uparrow$ If $2 k>n$, show that if $f \in H^{k}\left(\mathbb{R}^{n}\right)$, then $f$ equals a bounded continuous function a.e. Hint: Show that for $k$ this large, $F f \in L^{1}\left(\mathbb{R}^{n}\right)$, and then use Problem 1. To do this, write

$$
|F f(\mathbf{x})|=|F f(\mathbf{x})|\left(1+|\mathbf{x}|^{2}\right)^{\frac{k}{2}}\left(1+|\mathbf{x}|^{2}\right)^{\frac{-k}{2}}
$$

So

$$
\int|F f(\mathbf{x})| d x=\int|F f(\mathbf{x})|\left(1+|\mathbf{x}|^{2}\right)^{\frac{k}{2}}\left(1+|\mathbf{x}|^{2}\right)^{\frac{-k}{2}} d x
$$

Use the Cauchy Schwarz inequality. This is an example of a Sobolev imbedding Theorem.
13. Let $u \in \mathscr{G}$. Then $F u \in \mathscr{G}$ and so, in particular, it makes sense to form the integral,

$$
\int_{\mathbb{R}} F u\left(\mathbf{x}^{\prime}, x_{n}\right) d x_{n}
$$

where $\left(\mathbf{x}^{\prime}, x_{n}\right)=\mathbf{x} \in \mathbb{R}^{n}$. For $u \in \mathscr{G}$, define $\gamma u\left(\mathbf{x}^{\prime}\right) \equiv u\left(\mathbf{x}^{\prime}, 0\right)$. Find a constant such that $F(\gamma u)\left(\mathbf{x}^{\prime}\right)$ equals this constant times the above integral. Hint: By the dominated convergence theorem

$$
\int_{\mathbb{R}} F u\left(\mathbf{x}^{\prime}, x_{n}\right) d x_{n}=\lim _{\varepsilon \rightarrow 0} \int_{\mathbb{R}} e^{-\left(\varepsilon x_{n}\right)^{2}} F u\left(\mathbf{x}^{\prime}, x_{n}\right) d x_{n} .
$$

Now use the definition of the Fourier transform and Fubini's theorem as required in order to obtain the desired relationship.
14. Recall the Fourier series of a function in $L^{2}(-\pi, \pi)$ converges to the function in $L^{2}(-\pi, \pi)$. Prove a similar theorem with $L^{2}(-\pi, \pi)$ replaced by $L^{2}(-m \pi, m \pi)$ and the functions

$$
\left\{(2 \pi)^{-(1 / 2)} e^{i n x}\right\}_{n \in \mathbb{Z}}
$$

used in the Fourier series replaced with

$$
\left\{(2 m \pi)^{-(1 / 2)} e^{i \frac{n}{m} x}\right\}_{n \in \mathbb{Z}}
$$

Now suppose $f$ is a function in $L^{2}(\mathbb{R})$ satisfying $F f(t)=0$ if $|t|>m \pi$. Show that if this is so, then

$$
f(x)=\frac{1}{\pi} \sum_{n \in \mathbb{Z}} f\left(\frac{-n}{m}\right) \frac{\sin (\pi(m x+n))}{m x+n} .
$$

Here $m$ is a positive integer. This is sometimes called the Shannon sampling theorem.Hint: First note that since $F f \in L^{2}$ and is zero off a finite interval, it follows $F f \in L^{1}$. Also

$$
f(t)=\frac{1}{\sqrt{2 \pi}} \int_{-m \pi}^{m \pi} e^{i t x} F f(x) d x
$$

and you can conclude from this that $f$ has all derivatives and they are all bounded. Thus $f$ is a very nice function. You can replace $F f$ with its Fourier series. Then consider carefully the Fourier coefficient of $F f$. Argue it equals $f\left(\frac{-n}{m}\right)$ or at least an appropriate constant times this. When you get this the rest will fall quickly into place if you use $F f$ is zero off $[-m \pi, m \pi]$.

## Chapter 33

## Fourier Analysis In $\mathbb{R}^{n}$

The purpose of this chapter is to present some of the most important theorems on Fourier analysis in $\mathbb{R}^{n}$. These theorems are the Marcinkiewicz interpolation theorem, the Calderon Zygmund decomposition, and Mihlin's theorem. They are all fundamental results whose proofs depend on the methods of real analysis.

### 33.1 The Marcinkiewicz Interpolation Theorem

Let $(\Omega, \mu, \mathscr{S})$ be a measure space.
Definition 33.1.1 $L^{p}(\Omega)+L^{1}(\Omega)$ will denote the space of measurable functions, $f$, such that $f$ is the sum of a function in $L^{p}(\Omega)$ and $L^{1}(\Omega)$. Also, if $T: L^{p}(\Omega)+L^{1}(\Omega) \rightarrow$ space of measurable functions, $T$ is subadditive if

$$
|T(f+g)(x)| \leq|T f(x)|+|T g(x)|
$$

$T$ is of type $(p, p)$ if there exists a constant independent of $f \in L^{p}(\Omega)$ such that

$$
\|T f\|_{p} \leq A\|f\|_{p}, f \in L^{p}(\Omega)
$$

$T$ is weak type $(p, p)$ if there exists a constant $A$ independent of $f$ such that

$$
\mu([x:|T f(x)|>\alpha]) \leq\left(\frac{A}{\alpha}\|f\|_{p}\right)^{p}, f \in L^{p}(\Omega)
$$

The following lemma involves writing a function as a sum of a functions whose values are small and one whose values are large.
Lemma 33.1.2 If $p \in[1, r]$, then $L^{p}(\Omega) \subseteq L^{1}(\Omega)+L^{r}(\Omega)$.
Proof: Let $\lambda>0$ and let $f \in L^{p}(\Omega)$

$$
f_{1}(x) \equiv\left\{\begin{array}{l}
f(x) \text { if }|f(x)| \leq \lambda \\
0 \text { if }|f(x)|>\lambda
\end{array} \quad, \quad f_{2}(x) \equiv\left\{\begin{array}{l}
f(x) \text { if }|f(x)|>\lambda \\
0 \text { if }|f(x)| \leq \lambda
\end{array}\right.\right.
$$

Thus $f(x)=f_{1}(x)+f_{2}(x)$.

$$
\int\left|f_{1}(x)\right|^{r} d \mu=\int_{[|f| \leq \lambda]}|f(x)|^{r} d \mu \leq \lambda^{r-p} \int_{[|f| \leq \lambda]}|f(x)|^{p} d \mu<\infty
$$

Therefore, $f_{1} \in L^{r}(\Omega)$.

$$
\int\left|f_{2}(x)\right| d \mu=\int_{[|f|>\lambda]}|f(x)| d \mu \leq \mu[|f|>\lambda]^{1 / p^{\prime}}\left(\int|f|^{p} d \mu\right)^{1 / p}<\infty
$$

This proves the lemma since $f=f_{1}+f_{2}, f_{1} \in L^{r}$ and $f_{2} \in L^{1}$.
For $f$ a function having nonnegative real values, $\alpha \rightarrow \mu([f>\alpha])$ is called the distribution function.

Lemma 33.1.3 Let $\phi(0)=0, \phi$ is strictly increasing, and $C^{1}$. Let $f: \Omega \rightarrow[0, \infty)$ be measurable. Then

$$
\begin{equation*}
\int_{\Omega}(\phi \circ f) d \mu=\int_{0}^{\infty} \phi^{\prime}(\alpha) \mu[f>\alpha] d \alpha \tag{33.1.1}
\end{equation*}
$$

Proof: First suppose

$$
f=\sum_{i=1}^{m} a_{i} \mathscr{X}_{E_{i}}
$$

where $a_{i}>0$ and the $a_{i}$ are all distinct nonzero values of $f$, the sets, $E_{i}$ being disjoint. Thus,

$$
\int_{\Omega}(\phi \circ f) d \mu=\sum_{i=1}^{m} \phi\left(a_{i}\right) \mu\left(E_{i}\right)
$$

Suppose without loss of generality $a_{1}<a_{2}<\cdots<a_{m}$. Observe

$$
\alpha \rightarrow \mu([f>\alpha])
$$

is constant on the intervals $\left[0, a_{1}\right),\left[a_{1}, a_{2}\right), \cdots$. For example, on $\left[a_{i}, a_{i+1}\right)$, this function has the value

$$
\sum_{j=i+1}^{m} \mu\left(E_{j}\right)
$$

The function equals zero on $\left[a_{m}, \infty\right)$. Therefore,

$$
\alpha \rightarrow \phi^{\prime}(\alpha) \mu([|f|>\alpha])
$$

is Lebesgue measurable and letting $a_{0}=0$, the second integral in 33.1.1 equals

$$
\begin{aligned}
\int_{0}^{\infty} \phi^{\prime}(\alpha) \mu([f>\alpha]) d \alpha & =\sum_{i=1}^{m} \int_{a_{i-1}}^{a_{i}} \phi^{\prime}(\alpha) \mu([f>\alpha]) d \alpha \\
& =\sum_{i=1}^{m} \sum_{j=i}^{m} \mu\left(E_{j}\right) \int_{a_{i-1}}^{a_{i}} \phi^{\prime}(\alpha) d \alpha \\
& =\sum_{j=1}^{m} \sum_{i=1}^{j} \mu\left(E_{j}\right)\left(\phi\left(a_{i}\right)-\phi\left(a_{i-1}\right)\right) \\
& =\sum_{j=1}^{m} \mu\left(E_{j}\right) \phi\left(a_{j}\right)=\int_{\Omega}(\phi \circ f) d \mu
\end{aligned}
$$

and so this establishes 33.1 .1 in the case when $f$ is a nonnegative simple function. Since every measurable nonnegative function may be written as the pointwise limit of such simple functions, the desired result will follow by the Monotone convergence theorem and the next claim.

Claim: If $f_{n} \uparrow f$, then for each $\alpha>0$,

$$
\mu([f>\alpha])=\lim _{n \rightarrow \infty} \mu\left(\left[f_{n}>\alpha\right]\right)
$$

Proof of the claim: $\left[f_{n}>\alpha\right] \uparrow[f>\alpha]$ because if $f(x)>\alpha$ then for large enough $n$, $f_{n}(x)>\alpha$ and so

$$
\mu\left(\left[f_{n}>\alpha\right]\right) \uparrow \mu([f>\alpha])
$$

This proves the lemma. (Note the importance of the strict inequality in $[f>\alpha]$ in proving the claim.)

The next theorem is the main result in this section. It is called the Marcinkiewicz interpolation theorem.

Theorem 33.1.4 Let $(\Omega, \mu, \mathscr{S})$ be a $\sigma$ finite measure space, $1<r<\infty$, and let

$$
T: L^{1}(\Omega)+L^{r}(\Omega) \rightarrow \text { space of measurable functions }
$$

be subadditive, weak $(r, r)$, and weak $(1,1)$. Then $T$ is of type $(p, p)$ for every $p \in(1, r)$ and

$$
\|T f\|_{p} \leq A_{p}\|f\|_{p}
$$

where the constant $A_{p}$ depends only on $p$ and the constants in the definition of weak $(1,1)$ and weak $(r, r)$.

Proof: Let $\alpha>0$ and let $f_{1}$ and $f_{2}$ be defined as in Lemma 33.1.2,

$$
f_{1}(x) \equiv\left\{\begin{array}{l}
f(x) \text { if }|f(x)| \leq \alpha \\
0 \text { if }|f(x)|>\alpha
\end{array} \quad, f_{2}(x) \equiv\left\{\begin{array}{l}
f(x) \text { if }|f(x)|>\alpha \\
0 \text { if }|f(x)| \leq \alpha
\end{array} .\right.\right.
$$

Thus $f=f_{1}+f_{2}$ where $f_{1} \in L^{r}$ and $f_{2} \in L^{1}$. Since $T$ is subadditive,

$$
[|T f|>\alpha] \subseteq\left[\left|T f_{1}\right|>\alpha / 2\right] \cup\left[\left|T f_{2}\right|>\alpha / 2\right]
$$

Let $p \in(1, r)$. By Lemma 33.1.3,

$$
\begin{aligned}
& \int|T f|^{p} d \mu \leq p \int_{0}^{\infty} \alpha^{p-1} \mu\left(\left[\left|T f_{1}\right|>\alpha / 2\right]\right) d \alpha+ \\
& \quad+p \int_{0}^{\infty} \alpha^{p-1} \mu\left(\left[\left|T f_{2}\right|>\alpha / 2\right]\right) d \alpha
\end{aligned}
$$

Therefore, since $T$ is weak $(1,1)$ and weak $(r, r)$,

$$
\begin{equation*}
\int|T f|^{p} d \mu \leq p \int_{0}^{\infty} \alpha^{p-1}\left(\frac{2 A_{r}}{\alpha}\left\|f_{1}\right\|_{r}\right)^{r} d \alpha+p \int_{0}^{\infty} \alpha^{p-1} \frac{2 A_{1}}{\alpha}\left\|f_{2}\right\|_{1} d \alpha \tag{33.1.2}
\end{equation*}
$$

Therefore, the right side of 33.1.2 equals

$$
\begin{gathered}
p\left(2 A_{r}\right)^{r} \int_{0}^{\infty} \alpha^{p-1-r} \int_{\Omega}\left|f_{1}\right|^{r} d \mu d \alpha+2 A_{1} p \int_{0}^{\infty} \alpha^{p-2} \int_{\Omega}\left|f_{2}\right| d \mu d \alpha= \\
p\left(2 A_{r}\right)^{r} \int_{\Omega} \int_{0}^{\infty} \alpha^{p-1-r}\left|f_{1}\right|^{r} d \alpha d \mu+2 A_{1} p \int_{\Omega} \int_{0}^{\infty} \alpha^{p-2}\left|f_{2}\right| d \alpha d \mu
\end{gathered}
$$

Now $f_{1}(x)=0$ unless $\left|f_{1}(x)\right| \leq \alpha$ and $f_{2}(x)=0$ unless $\left|f_{2}(x)\right|>\alpha$ so this equals

$$
p\left(2 A_{r}\right)^{r} \int_{\Omega}|f(x)|^{r} \int_{|f(x)|}^{\infty} \alpha^{p-1-r} d \alpha d \mu+2 A_{1} p \int_{\Omega}|f(x)| \int_{0}^{|f(x)|} \alpha^{p-2} d \alpha d \mu
$$

which equals

$$
\begin{aligned}
& \frac{2^{r} A_{r}^{r} p}{r-p} \int_{\Omega}|f(x)|^{p} d \mu+\frac{2 p A_{1}}{p-1} \int_{\Omega}|f(x)|^{p} d \mu \\
& \quad \leq \max \left(\frac{2^{r} A_{r}^{r} p}{r-p}, \frac{2 p A_{1}}{p-1}\right)\|f\|_{L^{p}(\Omega)}^{p}
\end{aligned}
$$

and this proves the theorem.

### 33.2 The Calderon Zygmund Decomposition

For a given nonnegative integrable function, $\mathbb{R}^{n}$ can be decomposed into a set where the function is small and a set which is the union of disjoint cubes on which the average of the function is under some control. The measure in this section will always be Lebesgue measure on $\mathbb{R}^{n}$. This theorem depends on the Lebesgue theory of differentiation.

Theorem 33.2.1 Let $f \geq 0, \int f d x<\infty$, and let $\alpha$ be a positive constant. Then there exist sets $F$ and $\Omega$ such that

$$
\begin{gather*}
\mathbb{R}^{n}=F \cup \Omega, F \cap \Omega=\emptyset  \tag{33.2.3}\\
f(x) \leq \alpha \text { a.e. on } F \tag{33.2.4}
\end{gather*}
$$

$\Omega=\cup_{k=1}^{\infty} Q_{k}$ where the interiors of the cubes are disjoint and for each cube, $Q_{k}$,

$$
\begin{equation*}
\alpha<\frac{1}{m\left(Q_{k}\right)} \int_{Q_{k}} f(x) d x \leq 2^{n} \alpha . \tag{33.2.5}
\end{equation*}
$$

Proof: Let $S_{0}$ be a tiling of $\mathbb{R}^{n}$ into cubes having sides of length $M$ where $M$ is chosen large enough that if $Q$ is one of these cubes, then

$$
\begin{equation*}
\frac{1}{m(Q)} \int_{Q} f d m \leq \alpha \tag{33.2.6}
\end{equation*}
$$

Suppose $S_{0}, \cdots, S_{m}$ have been chosen. To get $S_{m+1}$, replace each cube of $S_{m}$ by the $2^{n}$ cubes obtained by bisecting the sides. Then $S_{m+1}$ consists of exactly those cubes of $S_{m}$ for which 33.2.6 holds and let $T_{m+1}$ consist of the bisected cubes from $S_{m}$ for which 33.2.6 does not hold. Now define

$$
\begin{gathered}
F \equiv\left\{\mathbf{x}: \mathbf{x} \text { is contained in some cube from } S_{m} \text { for all } m\right\}, \\
\Omega \equiv \mathbb{R}^{n} \backslash F=\cup_{m=1}^{\infty} \cup\left\{Q: Q \in T_{m}\right\}
\end{gathered}
$$

Note that the cubes from $T_{m}$ have pair wise disjoint interiors and also the interiors of cubes from $T_{m}$ have empty intersections with the interiors of cubes of $T_{k}$ if $k \neq m$.

Let $\mathbf{x}$ be a point of $\Omega$ and let $\mathbf{x}$ be in a cube of $T_{m}$ such that $m$ is the first index for which this happens. Let $Q$ be the cube in $S_{m-1}$ containing $\mathbf{x}$ and let $Q^{*}$ be the cube in the bisection of $Q$ which contains $\mathbf{x}$. Therefore 33.2.6 does not hold for $Q^{*}$. Thus

$$
\alpha<\frac{1}{m\left(Q^{*}\right)} \int_{Q^{*}} f d x \leq \frac{m(Q)}{m\left(Q^{*}\right)} \overbrace{\frac{1}{m(Q)} \int_{Q} f d x}^{\leq \alpha} \leq 2^{n} \alpha
$$

which shows $\Omega$ is the union of cubes having disjoint interiors for which 33.2 .5 holds.
Now a.e. point of $F$ is a Lebesgue point of $f$. Let $\mathbf{x}$ be such a point of $F$ and suppose $\mathbf{x}$ $\in Q_{k}$ for $Q_{k} \in S_{k}$. Let $d_{k} \equiv$ diameter of $Q_{k}$. Thus $d_{k} \rightarrow 0$.

$$
\begin{gathered}
\frac{1}{m\left(Q_{k}\right)} \int_{Q_{k}}|f(\mathbf{y})-f(\mathbf{x})| d y \leq \frac{1}{m\left(Q_{k}\right)} \int_{B\left(\mathbf{x}, d_{k}\right)}|f(\mathbf{y})-f(\mathbf{x})| d y \\
\quad=\frac{m\left(B\left(\mathbf{x}, d_{k}\right)\right)}{m\left(Q_{k}\right)} \frac{1}{m\left(B\left(\mathbf{x}, d_{k}\right)\right)} \int_{B\left(\mathbf{x}, d_{k}\right)}|f(\mathbf{x})-f(\mathbf{y})| d y \\
\quad \leq K_{n} \frac{1}{m\left(B\left(\mathbf{x}, d_{k}\right)\right)} \int_{B\left(\mathbf{x}, d_{k}\right)}|f(\mathbf{x})-f(\mathbf{y})| d y
\end{gathered}
$$

where $K_{n}$ is a constant which depends on $n$ and measures the ratio of the volume of a ball with diamiter $2 d$ and a cube with diameter $d$. The last expression converges to 0 because $\mathbf{x}$ is a Lebesgue point. Hence

$$
f(\mathbf{x})=\lim _{k \rightarrow \infty} \frac{1}{m\left(Q_{k}\right)} \int_{Q_{k}} f(\mathbf{y}) d y \leq \alpha
$$

and this shows $f(\mathbf{x}) \leq \alpha$ a.e. on $F$. This proves the theorem.

### 33.3 Mihlin's Theorem

In this section, the Marcinkiewicz interpolation theorem and Calderon Zygmund decomposition will be used to establish a remarkable theorem of Mihlin, a generalization of Plancherel's theorem to the $L^{p}$ spaces. It is of fundamental importance in the study of elliptic partial differential equations and can also be used to give proofs for the theory of singular integrals. Mihlin's theorem involves a conclusion which is of the form

$$
\begin{equation*}
\left\|F^{-1} \rho * \phi\right\|_{p} \leq A_{p}\|\phi\|_{p} \tag{33.3.7}
\end{equation*}
$$

for $p>1$ and $\phi \in \mathscr{G}$. Thus $F^{-1} \rho *$ extends to a continuous linear map defined on $L^{p}$ because of the density of $\mathscr{G}$. It is proved by showing various weak type estimates and then applying the Marcinkiewicz Interpolation Theorem to get an estimate like the above.

Recall that by Corollary 32.3.19, if $f \in L^{2}\left(\mathbb{R}^{n}\right)$ and if $\phi \in \mathscr{G}$, then $f * \phi \in L^{2}\left(\mathbb{R}^{n}\right)$ and

$$
F(f * \phi)(\mathbf{x})=(2 \pi)^{n / 2} F \phi(\mathbf{x}) F f(\mathbf{x})
$$

The next lemma is essentially a weak $(1,1)$ estimate. The inequality 33.3 .7 is established under the condition, 33.3.8 and then it is shown there exist conditions which are easier to
verify which imply condition 33.3.8. I think the approach used here is due to Hormander [69] and is found in Berg and Lofstrom [16]. For many more references and generalizations, you might look in Triebel [124]. A different proof based on singular integrals is in Stein [122]. Functions, $\rho$ which yield an inequality of the sort in 33.3.7 are called $L^{p}$ multipliers.

Lemma 33.3.1 Suppose $\rho \in L^{\infty}\left(\mathbb{R}^{n}\right) \cap L^{2}\left(\mathbb{R}^{n}\right)$ and suppose also there exists a constant $C_{1}$ such that

$$
\begin{equation*}
\int_{|\mathbf{x}| \geq 2|\mathbf{y}|}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho(\mathbf{x})\right| d x \leq C_{1} . \tag{33.3.8}
\end{equation*}
$$

Then there exists a constant A depending only on $C_{1},\|\rho\|_{\infty}$, and $n$ such that

$$
m\left(\left[\mathbf{x}:\left|F^{-1} \rho * \phi(\mathbf{x})\right|>\alpha\right]\right) \leq \frac{A}{\alpha}\|\phi\|_{1}
$$

for all $\phi \in \mathscr{G}$.
Proof: Let $\phi \in \mathscr{G}$ and use the Calderon decomposition to write $\mathbb{R}^{n}=E \cup \Omega$ where $\Omega$ is a union of cubes, $\left\{Q_{i}\right\}$ with disjoint interiors such that

$$
\begin{equation*}
\alpha m\left(Q_{i}\right) \leq \int_{Q_{i}}|\phi(\mathbf{x})| d x \leq 2^{n} \alpha m\left(Q_{i}\right),|\phi(\mathbf{x})| \leq \alpha \text { a.e. on } E . \tag{33.3.9}
\end{equation*}
$$

The proof is accomplished by writing $\phi$ as the sum of a good function and a bad function and establishing a similar weak inequality for these two functions separately. Then this information is used to obtain the desired conclusion.

$$
g(\mathbf{x})=\left\{\begin{array}{l}
\phi(\mathbf{x}) \text { if } \mathbf{x} \in E  \tag{33.3.10}\\
\frac{1}{m\left(Q_{i}\right)} \int_{Q_{i}} \phi(\mathbf{x}) d x \text { if } \mathbf{x} \in Q_{i} \subseteq \Omega
\end{array}, g(\mathbf{x})+b(\mathbf{x})=\phi(\mathbf{x}) .\right.
$$

Thus

$$
\begin{align*}
\int_{Q_{i}} b(\mathbf{x}) d x & =\int_{Q_{i}}(\phi(\mathbf{x})-g(\mathbf{x})) d x=\int_{Q_{i}} \phi(\mathbf{x}) d x-\int_{Q_{i}} \phi(\mathbf{x}) d x=0  \tag{33.3.11}\\
b(\mathbf{x}) & =0 \text { if } \mathbf{x} \notin \Omega \tag{33.3.12}
\end{align*}
$$

## Claim:

$$
\begin{equation*}
\|g\|_{2}^{2} \leq \alpha\left(1+4^{n}\right)\|\phi\|_{1},\|g\|_{1} \leq\|\phi\|_{1} . \tag{33.3.13}
\end{equation*}
$$

## Proof of claim:

$$
\|g\|_{2}^{2}=\|g\|_{L^{2}(E)}^{2}+\|g\|_{L^{2}(\Omega)}^{2} .
$$

Thus

$$
\begin{aligned}
\|g\|_{L^{2}(\Omega)}^{2} & =\sum_{i} \int_{Q_{i}}|g(x)|^{2} d x \\
& \leq \sum_{i} \int_{Q_{i}}\left(\frac{1}{m\left(Q_{i}\right)} \int_{Q_{i}}|\phi(y)| d y\right)^{2} d x \\
& \leq \sum_{i} \int_{Q_{i}}\left(2^{n} \alpha\right)^{2} d x \leq 4^{n} \alpha^{2} \sum_{i} m\left(Q_{i}\right) \\
& \leq 4^{n} \alpha^{2} \frac{1}{\alpha} \sum_{i} \int_{Q_{i}}|\phi(x)| d x \leq 4^{n} \alpha\|\phi\|_{1} .
\end{aligned}
$$

$$
\|g\|_{L^{2}(E)}^{2}=\int_{E}|\phi(x)|^{2} d x \leq \alpha \int_{E}|\phi(x)| d x=\alpha\|\phi\|_{1} .
$$

Now consider the second of the inequalities in 33.3.13.

$$
\begin{aligned}
\|g\|_{1} & =\int_{E}|g(\mathbf{x})| d x+\int_{\Omega}|g(\mathbf{x})| d x \\
& =\int_{E}|\phi(\mathbf{x})| d x+\sum_{i} \int_{Q_{i}}|g| d x \\
& \leq \int_{E}|\phi(\mathbf{x})| d x+\sum_{i} \int_{Q_{i}} \frac{1}{m\left(Q_{i}\right)} \int_{Q_{i}}|\phi(\mathbf{x})| d m(x) d m \\
& =\int_{E}|\phi(\mathbf{x})| d x+\sum_{i} \int_{Q_{i}}|\phi(\mathbf{x})| d m(x)=\|\phi\|_{1}
\end{aligned}
$$

This proves the claim. From the claim, it follows that $b \in L^{2}\left(\mathbb{R}^{n}\right) \cap L^{1}\left(\mathbb{R}^{n}\right)$.
Because of 33.3.13, $g \in L^{1}\left(\mathbb{R}^{n}\right)$ and so $F^{-1} \rho * g \in L^{2}\left(\mathbb{R}^{n}\right)$. (Since $\rho \in L^{2}$, it follows $F^{-1} \rho \in L^{2}$ and so this convolution is indeed in $L^{2}$.) By Plancherel's theorem,

$$
\left\|F^{-1} \rho * g\right\|_{2}=\left\|F\left(F^{-1} \rho * g\right)\right\|_{2}
$$

By Corollary 32.3.19 on Page 1110, the expression on the right equals

$$
(2 \pi)^{n / 2}\|\rho F g\|_{2}
$$

and so

$$
\left\|F^{-1} \rho * g\right\|_{2}=(2 \pi)^{n / 2}\|\rho F g\|_{2} \leq C_{n}\|\rho\|_{\infty}\|g\|_{2}
$$

From this and 33.3.13

$$
\begin{gather*}
m\left(\left[\left|F^{-1} \rho * g\right| \geq \alpha / 2\right]\right) \\
\leq \frac{C_{n}\|\rho\|_{\infty}^{2}}{\alpha^{2}} \alpha\left(1+4^{n}\right)\|\phi\|_{1}=C_{n} \alpha^{-1}\|\phi\|_{1} . \tag{33.3.14}
\end{gather*}
$$

This is what is wanted so far as $g$ is concerned. Next it is required to estimate

$$
m\left(\left[\left|F^{-1} \rho * b\right| \geq \alpha / 2\right]\right)
$$

If $Q$ is one of the cubes whose union is $\Omega$, let $Q^{*}$ be the cube with the same center as $Q$ but whose sides are $2 \sqrt{n}$ times as long.

Let

$$
\Omega^{*} \equiv \cup_{i=1}^{\infty} Q_{i}^{*}
$$

and let

$$
E^{*} \equiv \mathbb{R}^{n} \backslash \Omega^{*}
$$

Thus $E^{*} \subseteq E$. Let $\mathbf{x} \in E^{*}$. Then because of 33.3.11,

$$
\begin{gather*}
\int_{Q_{i}} F^{-1} \rho(\mathbf{x}-\mathbf{y}) b(\mathbf{y}) d y \\
=\int_{Q_{i}}\left[F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho\left(\mathbf{x}-\mathbf{y}_{i}\right)\right] b(\mathbf{y}) d y \tag{33.3.15}
\end{gather*}
$$

where $\mathbf{y}_{i}$ is the center of $Q_{i}$. Consequently if the sides of $Q_{i}$ have length $2 t / \sqrt{n}$, 33.3.15 implies

$$
\begin{gather*}
\int_{E^{*}}\left|\int_{Q_{i}} F^{-1} \rho(\mathbf{x}-\mathbf{y}) b(\mathbf{y}) d y\right| d x \leq  \tag{33.3.16}\\
\\
\int_{E^{*}} \int_{Q_{i}}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho\left(\mathbf{x}-\mathbf{y}_{i}\right)\right||b(\mathbf{y})| d y d x  \tag{33.3.17}\\
=  \tag{33.3.18}\\
\int_{Q_{i}} \int_{E^{*}}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho\left(\mathbf{x}-\mathbf{y}_{i}\right)\right| d x|b(\mathbf{y})| d y \\
\leq \\
\int_{Q_{i}} \int_{\left|\mathbf{x}-\mathbf{y}_{i}\right| \geq 2 t}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho\left(\mathbf{x}-\mathbf{y}_{i}\right)\right| d x|b(\mathbf{y})| d y
\end{gather*}
$$

since if $\mathbf{x} \in E^{*}$, then $\left|\mathbf{x}-\mathbf{y}_{i}\right| \geq 2 t$. Now for $\mathbf{y} \in Q_{i}$,

$$
\left|\mathbf{y}-\mathbf{y}_{i}\right| \leq\left(\sum_{j=1}^{n}\left(\frac{t}{\sqrt{n}}\right)^{2}\right)^{1 / 2}=t
$$

From 33.3.8 and the change of variables $\mathbf{u}=\mathbf{x}-\mathbf{y}_{i}$ 33.3.16-33.3.18 imply

$$
\begin{equation*}
\int_{E^{*}}\left|\int_{Q_{i}} F^{-1} \rho(\mathbf{x}-\mathbf{y}) b(\mathbf{y}) d y\right| d x \leq C_{1} \int_{Q_{i}}|b(\mathbf{y})| d y \tag{33.3.19}
\end{equation*}
$$

Now from 33.3.19, and the fact that $b=0$ off $\Omega$,

$$
\begin{aligned}
\int_{E^{*}}\left|F^{-1} \rho * b(\mathbf{x})\right| d x & =\int_{E^{*}}\left|\int_{\mathbb{R}^{n}} F^{-1} \rho(\mathbf{x}-\mathbf{y}) b(\mathbf{y}) d y\right| d x \\
& =\int_{E^{*}}\left|\sum_{i=1}^{\infty} \int_{Q_{i}} F^{-1} \rho(\mathbf{x}-\mathbf{y}) b(\mathbf{y}) d y\right| d x \\
& \leq \int_{E^{*}} \sum_{i=1}^{\infty}\left|\int_{Q_{i}} F^{-1} \rho(\mathbf{x}-\mathbf{y}) b(\mathbf{y}) d y\right| d x \\
& =\sum_{i=1}^{\infty} \int_{E^{*}}\left|\int_{Q_{i}} F^{-1} \rho(\mathbf{x}-\mathbf{y}) b(\mathbf{y}) d y\right| d x \\
& \leq \sum_{i=1}^{\infty} C_{1} \int_{Q_{i}}|b(\mathbf{y})| d y=C_{1}| | b \|_{1}
\end{aligned}
$$

Thus, by 33.3.13,

$$
\begin{aligned}
\int_{E^{*}}\left|F^{-1} \rho * b(\mathbf{x})\right| d x & \leq C_{1}\|b\|_{1} \\
& \leq C_{1}\left[\|\phi\|_{1}+\|g\|_{1}\right] \\
& \leq C_{1}\left[\|\phi\|_{1}+\|\phi\|_{1}\right] \\
& \leq 2 C_{1}\|\phi\|_{1}
\end{aligned}
$$

Consequently,

$$
m\left(\left[\left|F^{-1} \rho * b\right| \geq \frac{\alpha}{2}\right] \cap E^{*}\right) \leq \frac{4 C_{1}}{\alpha}\|\phi\|_{1}
$$

From 33.3.10, 33.3.14, and 33.3.9,

$$
\begin{gathered}
m\left[\left|F^{-1} \rho * \phi\right|>\alpha\right] \leq m\left[\left|F^{-1} \rho * g\right| \geq \frac{\alpha}{2}\right]+m\left[\left|F^{-1} \rho * b\right| \geq \frac{\alpha}{2}\right] \\
\leq \frac{C_{n}}{\alpha}\|\phi\|_{1}+m\left(\left[\left|F^{-1} \rho * b\right| \geq \frac{\alpha}{2}\right] \cap E^{*}\right)+m\left(\Omega^{*}\right) \\
\leq \frac{C_{n}}{\alpha}\|\phi\|_{1}+\frac{4 C_{1}}{\alpha}\|\phi\|_{1}+C_{n} m(\Omega) \leq \frac{A}{\alpha}\|\phi\|_{1}
\end{gathered}
$$

because

$$
m(\Omega) \leq \alpha^{-1}\|\phi\|_{1}
$$

by 33.3.9. This proves the lemma.
The next lemma extends this lemma by giving a weak $(2,2)$ estimate and a $(2,2)$ estimate.

Lemma 33.3.2 Suppose $\rho \in L^{\infty}\left(\mathbb{R}^{n}\right) \cap L^{2}\left(\mathbb{R}^{n}\right)$ and suppose also that there exists a constant $C_{1}$ such that

$$
\begin{equation*}
\int_{|\mathbf{x}|>2|\mathbf{y}|}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho(\mathbf{x})\right| d x \leq C_{1} \tag{33.3.20}
\end{equation*}
$$

Then $F^{-1} \rho *$ maps $L^{1}\left(\mathbb{R}^{n}\right)+L^{2}\left(\mathbb{R}^{n}\right)$ to measurable functions and there exists a constant $A$ depending only on $C_{1}, n,\|\rho\|_{\infty}$ such that

$$
\begin{gather*}
m\left(\left[\left|F^{-1} \rho * f\right|>\alpha\right]\right) \leq A \frac{\|f\|_{1}}{\alpha} \text { if } f \in L^{1}\left(\mathbb{R}^{n}\right)  \tag{33.3.21}\\
m\left(\left[\left|F^{-1} \rho * f\right|>\alpha\right]\right) \leq\left(A \frac{\|f\|_{2}}{\alpha}\right)^{2} \text { if } f \in L^{2}\left(\mathbb{R}^{n}\right) \tag{33.3.22}
\end{gather*}
$$

Thus, $F^{-1} \rho *$ is weak type $(1,1)$ and weak type $(2,2)$. Also

$$
\begin{equation*}
\left\|F^{-1} \rho * f\right\|_{2} \leq A\|f\|_{2} \text { if } f \in L^{2}\left(\mathbb{R}^{n}\right) \tag{33.3.23}
\end{equation*}
$$

Proof: By Plancherel's theorem $F^{-1} \rho$ is in $L^{2}\left(\mathbb{R}^{n}\right)$. If $f \in L^{1}\left(\mathbb{R}^{n}\right)$, then by Minkowski's inequality,

$$
F^{-1} \rho * f \in L^{2}\left(\mathbb{R}^{n}\right)
$$

Now let $g \in L^{2}\left(\mathbb{R}^{n}\right)$. By Holder's inequality,

$$
\int\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})\right||g(\mathbf{y})| d y \leq\left(\int\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})\right|^{2} d y\right)^{1 / 2}\left(\int|g(\mathbf{y})|^{2} d y\right)^{1 / 2}<\infty
$$

and so the following is well defined a.e.

$$
F^{-1} \rho * g(\mathbf{x}) \equiv \int F^{-1} \rho(\mathbf{x}-\mathbf{y}) g(\mathbf{y}) d y
$$

also,

$$
\begin{aligned}
\left|F^{-1} \rho * g(\mathbf{x})-F^{-1} \rho * g\left(\mathbf{x}^{\prime}\right)\right| & \leq \int\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho\left(\mathbf{x}^{\prime}-\mathbf{y}\right)\right||g(\mathbf{y})| d y \\
& \leq\left\|F^{-1} \rho-F^{-1} \rho_{\mathbf{x}^{\prime}-\mathbf{x}}\right\|\|g\|_{l^{2}}
\end{aligned}
$$

and by continuity of translation in $L^{2}\left(\mathbb{R}^{n}\right)$, this shows $\mathbf{x} \rightarrow F^{-1} \rho * g(\mathbf{x})$ is continuous. Therefore, $F^{-1} \rho * \operatorname{maps} L^{1}\left(\mathbb{R}^{n}\right)+L^{2}\left(\mathbb{R}^{n}\right)$ to the space of measurable functions. (Continuous functions are measurable.) It is clear that $F^{-1} \rho *$ is subadditive.

If $\phi \in \mathscr{G}$, Plancherel's theorem implies as before,

$$
\begin{gather*}
\left\|F^{-1} \rho * \phi\right\|_{2}=\left\|F\left(F^{-1} \rho * \phi\right)\right\|_{2}= \\
(2 \pi)^{n / 2}\|\rho F \phi\|_{2} \leq(2 \pi)^{n / 2}\|\rho\|_{\infty}\|\phi\|_{2} \tag{33.3.24}
\end{gather*}
$$

Now let $f \in L^{2}\left(\mathbb{R}^{n}\right)$ and let $\phi_{k} \in \mathscr{G}$, with

$$
\left\|\phi_{k}-f\right\|_{2} \rightarrow 0
$$

Then by Holder's inequality,

$$
\int F^{-1} \rho(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y=\lim _{k \rightarrow \infty} \int F^{-1} \rho(\mathbf{x}-\mathbf{y}) \phi_{k}(\mathbf{y}) d y
$$

and so by Fatou's lemma, Plancherel's theorem, and 33.3.24,

$$
\begin{gathered}
\left\|F^{-1} \rho * f\right\|_{2}=\left(\int\left|\int F^{-1} \rho(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y\right|^{2} d x\right)^{1 / 2} \leq \\
\leq \lim _{k \rightarrow \infty}\left(\int\left|\int F^{-1} \rho(\mathbf{x}-\mathbf{y}) \phi_{k}(\mathbf{y}) d y\right|^{2} d x\right)^{1 / 2}=\lim _{k \rightarrow \infty} \inf \left\|F^{-1} \rho * \phi_{k}\right\|_{2} \\
\leq\|\rho\|_{\infty}(2 \pi)^{n / 2} \lim _{k \rightarrow \infty} \inf _{k \rightarrow \infty} \phi_{k}\left\|_{2}=\right\| \rho\left\|_{\infty}(2 \pi)^{n / 2}\right\| f \|_{2} .
\end{gathered}
$$

Thus, 33.3.23 holds with $A=\|\rho\|_{\infty}(2 \pi)^{n / 2}$. Consequently,

$$
\begin{aligned}
A\|f\|_{2} \geq & \left(\int_{\left[\left|F^{-1} \rho * f\right|>\alpha\right]}\left|F^{-1} \rho * f(\mathbf{x})\right|^{2} d x\right)^{1 / 2} \\
& \geq \alpha m\left(\left[\left|F^{-1} \rho * f\right|>\alpha\right]\right)^{1 / 2}
\end{aligned}
$$

and so 33.3.22 follows.
It remains to prove 33.3.21 which holds for all $f \in \mathscr{G}$ by Lemma 33.3.1. Let $f \in L^{1}\left(\mathbb{R}^{n}\right)$ and let $\phi_{k} \rightarrow f$ in $L^{1}\left(\mathbb{R}^{n}\right), \phi_{k} \in \mathscr{G}$. Without loss of generality, assume that both $f$ and $F^{-1} \rho$ are Borel measurable. Therefore, by Minkowski's inequality, and Plancherel's theorem,

$$
\begin{aligned}
& \left\|F^{-1} \rho * \phi_{k}-F^{-1} \rho * f\right\|_{2} \\
& \leq\left(\int\left|\int F^{-1} \rho(\mathbf{x}-\mathbf{y})\left(\phi_{k}(\mathbf{y})-f(\mathbf{y})\right) d y\right|^{2} d x\right)^{1 / 2} \\
& \leq\left\|\phi_{k}-f\right\|_{1}\|\rho\|_{2}
\end{aligned}
$$

which shows that $F^{-1} \rho * \phi_{k}$ converges to $F^{-1} \rho * f$ in $L^{2}\left(\mathbb{R}^{n}\right)$. Therefore, there exists a subsequence such that the convergence is pointwise a.e. Then, denoting the subsequence by $k$,

$$
\mathscr{X}_{\left[\left|F^{-1} \rho * f\right|>\alpha\right]}(\mathbf{x}) \leq \lim _{k \rightarrow \infty} \operatorname{Xin}_{\left[\left|F^{-1} \rho * \phi_{k}\right|>\alpha\right]}(\mathbf{x}) \text { a.e. } \mathbf{x} .
$$

Thus by Lemma 33.3.1 and Fatou's lemma, there exists a constant, $A$, depending on $C_{1}, n$, and $\|\rho\|_{\infty}$ such that

$$
\begin{aligned}
m\left(\left[\left|F^{-1} \rho * f\right|>\alpha\right]\right) & \leq \lim _{k \rightarrow \infty} m\left(\left[\left|F^{-1} \rho * \phi_{k}\right|>\alpha\right]\right) \\
& \leq \lim _{k \rightarrow \infty} A \frac{\left\|\phi_{k}\right\|_{1}}{\alpha}=A \frac{\|f\|_{1}}{\alpha}
\end{aligned}
$$

This shows 33.3.21 and proves the lemma.
Theorem 33.3.3 Let $\rho \in L^{2}\left(\mathbb{R}^{n}\right) \cap L^{\infty}\left(\mathbb{R}^{n}\right)$ and suppose

$$
\int_{|\mathbf{x}| \geq 2|\mathbf{y}|}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho(\mathbf{x})\right| d x \leq C_{1}
$$

Then for each $p \in(1, \infty)$, there exists a constant, $A_{p}$, depending only on

$$
p, n,\|\rho\|_{\infty}
$$

and $C_{1}$ such that for all $\phi \in \mathscr{G}$,

$$
\left\|F^{-1} \rho * \phi\right\|_{p} \leq A_{p}\|\phi\|_{p}
$$

Proof: From Lemma 33.3.2, $F^{-1} \rho *$ is weak $(1,1)$, weak $(2,2)$, and maps

$$
L^{1}\left(\mathbb{R}^{n}\right)+L^{2}\left(\mathbb{R}^{n}\right)
$$

to measurable functions. Therefore, by the Marcinkiewicz interpolation theorem, there exists a constant $A_{p}$ depending only on $p, C_{1}, n$, and $\|\rho\|_{\infty}$ for $p \in(1,2]$, such that for $f \in L^{p}\left(\mathbb{R}^{n}\right)$, and $p \in(1,2]$,

$$
\left\|F^{-1} \rho * f\right\|_{p} \leq A_{p}\|f\|_{p}
$$

Thus the theorem is proved for these values of $p$. Now suppose $p>2$. Then $p^{\prime}<2$ where

$$
\frac{1}{p}+\frac{1}{p^{\prime}}=1
$$

By Plancherel's theorem and Theorem 32.3.25,

$$
\begin{aligned}
\int F^{-1} \rho * \phi(\mathbf{x}) \psi(\mathbf{x}) d x & =(2 \pi)^{n / 2} \int \rho(\mathbf{x}) F \phi(\mathbf{x}) F \psi(\mathbf{x}) d x \\
& =\int F\left(F^{-1} \rho * \psi\right) F \phi d x \\
& =\int\left(F^{-1} \rho * \psi\right)(\phi) d x
\end{aligned}
$$

Thus by the case for $p \in(1,2)$ and Holder's inequality,

$$
\begin{aligned}
\left|\int F^{-1} \rho * \phi(\mathbf{x}) \psi(\mathbf{x}) d x\right| & =\left|\int\left(F^{-1} \rho * \psi\right)(\phi) d x\right| \\
& \leq\left\|F^{-1} \rho * \psi\right\|_{p^{\prime}}\|\phi\|_{p} \\
& \leq A_{p^{\prime}}\|\psi\|_{p^{\prime}}\|\phi\|_{p} .
\end{aligned}
$$

Letting $L \psi \equiv \int F^{-1} \rho * \phi(\mathbf{x}) \psi(\mathbf{x}) d x$, this shows that $L \in L^{p^{\prime}}\left(\mathbb{R}^{n}\right)^{\prime}$ and also that $\|L\|_{\left(L^{p^{\prime}}\right)^{\prime}} \leq$ $A_{p^{\prime}}\|\phi\|_{p}$ which implies by the Riesz representation theorem that $F^{-1} \rho * \phi$ represents $L$ and

$$
\|L\|_{\left(L^{p^{\prime}}\right)^{\prime}}=\left\|F^{-1} \rho * \phi\right\|_{L^{p}} \leq A_{p^{\prime}}\|\phi\|_{p}
$$

Since $p^{\prime}=p /(p-1)$, this proves the theorem.
It is possible to give verifiable conditions on $\rho$ which imply 33.3.20. The condition on $\rho$ which is presented here is the existence of a constant, $C_{0}$ such that

$$
\begin{gathered}
C_{0} \geq \sup \left\{|\mathbf{x}|^{|\alpha|}\left|D^{\alpha} \rho(\mathbf{x})\right|:|\alpha| \leq L, \mathbf{x} \in \mathbb{R}^{n} \backslash\{\boldsymbol{0}\}\right\}, L>n / 2 \\
\rho \in C^{L}\left(\mathbb{R}^{n} \backslash\{\mathbf{0}\}\right) \text { where } L \text { is an integer. }
\end{gathered}
$$

Here $\alpha$ is a multi-index and $|\alpha|=\sum_{i=1}^{n} \alpha_{i}$. The condition says roughly that $\rho$ is pretty smooth away from $\mathbf{0}$ and all the partial derivatives vanish pretty fast as $|\mathbf{x}| \rightarrow \infty$. Also recall the notation

$$
\mathbf{x}^{\alpha} \equiv x_{1}^{\alpha_{1}} \cdots x_{n}^{\alpha_{n}}
$$

where $\alpha=\left(\alpha_{1} \cdots \alpha_{n}\right)$. For more general conditions, see [69].

Lemma 33.3.4 Let 33.3.25 hold and suppose $\psi \in C_{c}^{\infty}\left(\mathbb{R}^{n} \backslash\{\mathbf{0}\}\right)$. Then for each $\alpha,|\alpha| \leq$ $L$, there exists a constant $C \equiv C(\alpha, n, \psi)$ independent of $k$ such that

$$
\sup _{\mathbf{x} \in \mathbb{R}^{n}}|\mathbf{x}|^{|\alpha|}\left|D^{\alpha}\left(\rho(\mathbf{x}) \psi\left(2^{k} \mathbf{x}\right)\right)\right| \leq C C_{0}
$$

Proof:

$$
\begin{aligned}
& |\mathbf{x}|^{|\alpha|}\left|D^{\alpha}\left(\rho(\mathbf{x}) \psi\left(2^{k} \mathbf{x}\right)\right)\right| \leq|\mathbf{x}|^{|\alpha|} \sum_{\beta+\gamma=\alpha}\left|D^{\beta} \rho(\mathbf{x})\right| 2^{k|\gamma|}\left|D^{\gamma} \psi\left(2^{k} \mathbf{x}\right)\right| \\
& =\sum_{\beta+\gamma=\alpha}|\mathbf{x}|^{|\beta|}\left|D^{\beta} \rho(\mathbf{x})\right|\left|2^{k} \mathbf{x}\right| \\
& \leq C_{0} C(\alpha, n)\left|D^{\gamma} \psi\left(2^{k} \mathbf{x}\right)\right| \\
& \sum_{|\gamma| \leq|\alpha|} \sup \left\{|\mathbf{z}|^{|\gamma|}\left|D^{\gamma} \psi(\mathbf{z})\right|: \mathbf{z} \in \mathbb{R}^{n}\right\}=C_{0} C(\alpha, n, \psi)
\end{aligned}
$$

and this proves the lemma.
Lemma 33.3.5 There exists

$$
\phi \in C_{c}^{\infty}\left(\left[\mathbf{x}: 4^{-1}<|\mathbf{x}|<4\right]\right), \phi(\mathbf{x}) \geq 0
$$

and

$$
\sum_{k=-\infty}^{\infty} \phi\left(2^{k} \mathbf{x}\right)=1
$$

for each $\mathbf{x} \neq \mathbf{0}$.
Proof: Let

$$
\begin{gathered}
\psi \geq 0, \psi=1 \text { on }\left[2^{-1} \leq|\mathbf{x}| \leq 2\right] \\
\operatorname{spt}(\psi) \subseteq\left[4^{-1}<|\mathbf{x}|<4\right]
\end{gathered}
$$

Consider

$$
g(\mathbf{x})=\sum_{k=-\infty}^{\infty} \psi\left(2^{k} \mathbf{x}\right)
$$

Then for each $\mathbf{x}$, only finitely many terms are not equal to 0 . Also, $g(\mathbf{x})>0$ for all $\mathbf{x} \neq \mathbf{0}$. To verify this last claim, note that for some $k$ an integer, $|\mathbf{x}| \in\left[2^{l}, 2^{l+2}\right]$. Therefore, choose $k$ an integer such that $2^{k}|\mathbf{x}| \in\left[2^{-1}, 2\right]$. For example, let $k=-l-1$. This works because $2^{k}|\mathbf{x}| \in$ $\left[2^{l} 2^{k}, 2^{l+2} 2^{k}\right]=\left[2^{l-l-1}, 2^{l+2-l-1}\right]=\left[2^{-1}, 2\right]$. Therefore, for this value of $k, \psi\left(2^{k} \mathbf{x}\right)=1$ so $g(\mathbf{x})>0$.

Now notice that

$$
g\left(2^{r} \mathbf{x}\right)=\sum_{k=-\infty}^{\infty} \psi\left(2^{k} 2^{r} \mathbf{x}\right)=\sum_{k=-\infty}^{\infty} \psi\left(2^{k} \mathbf{x}\right)=g(\mathbf{x})
$$

Let $\phi(\mathbf{x}) \equiv \psi(\mathbf{x}) g(\mathbf{x})^{-1}$. Then

$$
\sum_{k=-\infty}^{\infty} \phi\left(2^{k} \mathbf{x}\right)=\sum_{k=-\infty}^{\infty} \frac{\psi\left(2^{k} \mathbf{x}\right)}{g\left(2^{k} \mathbf{x}\right)}=g(\mathbf{x})^{-1} \sum_{k=-\infty}^{\infty} \psi\left(2^{k} \mathbf{x}\right)=1
$$

for each $\mathbf{x} \neq \mathbf{0}$. This proves the lemma.
Now define

$$
\rho_{m}(\mathbf{x}) \equiv \sum_{k=-m}^{m} \rho(\mathbf{x}) \phi\left(2^{k} \mathbf{x}\right), \gamma_{k}(\mathbf{x}) \equiv \rho(\mathbf{x}) \phi\left(2^{k} \mathbf{x}\right)
$$

Let $t>0$ and let $|\mathbf{y}| \leq t$. Consider the problem of estimating

$$
\begin{equation*}
\int_{|\mathbf{x}| \geq 2 t}\left|F^{-1} \gamma_{k}(\mathbf{x}-\mathbf{y})-F^{-1} \gamma_{k}(\mathbf{x})\right| d x \tag{33.3.26}
\end{equation*}
$$

In the following estimates, $C(a, b, \cdots, d)$ will denote a generic constant depending only on the indicated objects, $a, b, \cdots, d$. For the first estimate, note that since $|\mathbf{y}| \leq t, 33.3 .26$ is no larger than

$$
\begin{aligned}
& 2 \int_{|\mathbf{x}| \geq t}\left|F^{-1} \gamma_{k}(\mathbf{x})\right| d x=2 \int_{|\mathbf{x}| \geq t}\left|F^{-1} \gamma_{k}(\mathbf{x})\right||\mathbf{x}|^{-L}|\mathbf{x}|^{L} d x \\
\leq & 2\left(\int_{|\mathbf{x}| \geq t}|\mathbf{x}|^{-2 L} d x\right)^{1 / 2}\left(\int_{|\mathbf{x}| \geq t}|\mathbf{x}|^{2 L}\left|F^{-1} \gamma_{k}(\mathbf{x})\right|^{2} d x\right)^{1 / 2}
\end{aligned}
$$

Using spherical coordinates and Plancherel's theorem,

$$
\begin{align*}
& \leq C(n, L) t^{n / 2-L}\left(\int|\mathbf{x}|^{2 L}\left|F^{-1} \gamma_{k}(\mathbf{x})\right|^{2} d x\right)^{1 / 2} \\
\leq & C(n, L) t^{n / 2-L}\left(\int \sum_{j=1}^{n}\left|x_{j}\right|^{2 L}\left|F^{-1} \gamma_{k}(\mathbf{x})\right|^{2} d x\right)^{1 / 2} \\
\leq & C(n, L) t^{n / 2-L}\left(\sum_{j=1}^{n} \int\left|F^{-1} D_{j}^{L} \gamma_{k}(\mathbf{x})\right|^{2} d x\right)^{1 / 2}  \tag{33.3.27}\\
= & C(n, L) t^{n / 2-L}\left(\sum_{j=1}^{n} \int_{S_{k}}\left|D_{j}^{L} \gamma_{k}(\mathbf{x})\right|^{2} d x\right)^{1 / 2}
\end{align*}
$$

where

$$
\begin{equation*}
S_{k} \equiv\left[\mathbf{x}: 2^{-2-k}<|\mathbf{x}|<2^{2-k}\right] \tag{33.3.28}
\end{equation*}
$$

a set containing the support of $\gamma_{k}$. Now from the definition of $\gamma_{k}$,

$$
\left|D_{j}^{L} \gamma_{k}(\mathbf{z})\right|=\left|D_{j}^{L}\left(\rho(\mathbf{z}) \phi\left(2^{k} \mathbf{z}\right)\right)\right|
$$

By Lemma 33.3.4, this is no larger than

$$
\begin{equation*}
C(L, n, \phi) C_{0}|\mathbf{z}|^{-L} . \tag{33.3.29}
\end{equation*}
$$

It follows, using polar coordinates, that the last expression in 33.3.27 is no larger than

$$
\begin{equation*}
C\left(n, L, \phi, C_{0}\right) t^{n / 2-L}\left(\int_{S_{k}}|\mathbf{z}|^{-2 L} d z\right)^{1 / 2} \leq C\left(n, L, \phi, C_{0}\right) t^{n / 2-L} \tag{33.3.30}
\end{equation*}
$$

$$
\left(\int_{2^{-2-k}}^{2^{2-k}} \rho^{n-1-2 L} d \rho\right)^{1 / 2} \leq C\left(n, L, \phi, C_{0}\right) t^{n / 2-L} 2^{k(L-n / 2)} .
$$

Now estimate 33.3.26 in another way. The support of $\gamma_{k}$ is in $S_{k}$, a bounded set, and so $F^{-1} \gamma_{k}$ is differentiable. Therefore,

$$
\begin{gather*}
\int_{|\mathbf{x}| \geq 2 t}\left|F^{-1} \gamma_{k}(\mathbf{x}-\mathbf{y})-F^{-1} \gamma_{k}(\mathbf{x})\right| d x= \\
\int_{|\mathbf{x}| \geq 2 t}\left|\int_{0}^{1} \sum_{j=1}^{n} D_{j} F^{-1} \gamma_{k}(\mathbf{x}-s \mathbf{y}) y_{j} d s\right| d x \\
\leq t \int_{|\mathbf{x}| \geq 2 t} \int_{0}^{1} \sum_{j=1}^{n}\left|D_{j} F^{-1} \gamma_{k}(\mathbf{x}-s \mathbf{y})\right| d s d x \\
\leq t \int \sum_{j=1}^{n}\left|D_{j} F^{-1} \gamma_{k}(\mathbf{x})\right| d x \\
\leq \quad t \sum_{j=1}^{n}\left(\int\left(1+\left|2^{-k} \mathbf{x}\right|^{2}\right)^{-L} d x\right)^{1 / 2} \\
\\
\quad\left(\int\left(1+\left|2^{-k} \mathbf{x}\right|^{2}\right)^{L}\left|D_{j} F^{-1} \gamma_{k}(\mathbf{x})\right|^{2} d x\right)^{1 / 2}  \tag{33.3.31}\\
\leq C(n, L) t 2^{k n / 2} \sum_{j=1}^{n}\left(\int\left(1+\left|2^{-k} \mathbf{x}\right|^{2}\right)^{L}\left|D_{j} F^{-1} \gamma_{k}(\mathbf{x})\right|^{2} d x\right)^{1 / 2} .
\end{gather*}
$$

Now consider the $j^{t h}$ term in the last sum in 33.3.31.

$$
\begin{gather*}
\int\left(1+\left|2^{-k} \mathbf{x}\right|^{2}\right)^{L}\left|D_{j} F^{-1} \gamma_{k}(\mathbf{x})\right|^{2} d x \leq \\
C(n, L) \int \sum_{|\alpha| \leq L} 2^{-2 k|\alpha|} \mathbf{x}^{2 \alpha}\left|D_{j} F^{-1} \gamma_{k}(\mathbf{x})\right|^{2} d x  \tag{33.3.32}\\
=C(n, L) \sum_{|\alpha| \leq L} 2^{-2 k|\alpha|} \int \mathbf{x}^{2 \alpha}\left|F^{-1}\left(\pi_{j} \gamma_{k}\right)(\mathbf{x})\right|^{2} d x
\end{gather*}
$$

where $\pi_{j}(\mathbf{z}) \equiv z_{j}$. This last assertion follows from

$$
D_{j} \int e^{-i \mathbf{x} \cdot \mathbf{y}} \gamma_{k}(\mathbf{y}) d y=\int(-i) e^{-i \mathbf{x} \cdot \mathbf{y}} y_{j} \gamma_{k}(\mathbf{y}) d y
$$

Therefore, a similar computation and Plancherel's theorem implies 33.3.32 equals

$$
=C(n, L) \sum_{|\alpha| \leq L} 2^{-2 k|\alpha|} \int\left|F^{-1} D^{\alpha}\left(\pi_{j} \gamma_{k}\right)(\mathbf{x})\right|^{2} d x
$$

$$
\begin{equation*}
=C(n, L) \sum_{|\alpha| \leq L} 2^{-2 k|\alpha|} \int_{S_{k}}\left|D^{\alpha}\left(z_{j} \gamma_{k}(\mathbf{z})\right)\right|^{2} d z \tag{33.3.33}
\end{equation*}
$$

where $S_{k}$ is given in 33.3.28. Now

$$
\begin{aligned}
\left|D^{\alpha}\left(z_{j} \gamma_{k}(\mathbf{z})\right)\right| & =2^{-k}\left|D^{\alpha}\left(\rho(\mathbf{z}) z_{j} 2^{k} \phi\left(2^{k} \mathbf{z}\right)\right)\right| \\
& =2^{-k}\left|D^{\alpha}\left(\rho(\mathbf{z}) \psi_{j}\left(2^{k} \mathbf{z}\right)\right)\right|
\end{aligned}
$$

where $\psi_{j}(\mathbf{z}) \equiv z_{j} \phi(\mathbf{z})$. By Lemma 33.3.4, this is dominated by

$$
2^{-k} C\left(\alpha, n, \phi, j, C_{0}\right)|\mathbf{z}|^{-|\alpha|}
$$

Therefore, 33.3.33 is dominated by

$$
\begin{aligned}
& C\left(L, n, \phi, j, C_{0}\right) \sum_{|\alpha| \leq L} 2^{-2 k|\alpha|} \int_{S_{k}} 2^{-2 k}|\mathbf{z}|^{-2|\alpha|} d z \\
& \leq C\left(L, n, \phi, j, C_{0}\right) \sum_{|\alpha| \leq L} 2^{-2 k|\alpha|} 2^{-2 k}\left(2^{-2-k}\right)^{(-2|\alpha|)}\left(2^{2-k}\right)^{n} \\
& \leq C\left(L, n, \phi, j, C_{0}\right) \sum_{|\alpha| \leq L} 2^{-k n-2 k} \\
& \leq C\left(L, n, \phi, j, C_{0}\right) 2^{-k n} 2^{-2 k}
\end{aligned}
$$

It follows that 33.3 .31 is no larger than

$$
\begin{equation*}
C\left(L, n, \phi, C_{0}\right) t 2^{k n / 2} 2^{-k n / 2} 2^{-k}=C\left(L, n, \phi, C_{0}\right) t 2^{-k} \tag{33.3.34}
\end{equation*}
$$

It follows from 33.3.34 and 33.3.30 that if $|\mathbf{y}| \leq t$,

$$
\begin{aligned}
& \int_{|\mathbf{x}| \geq 2 t}\left|F^{-1} \gamma_{k}(\mathbf{x}-\mathbf{y})-F^{-1} \gamma_{k}(\mathbf{x})\right| d x \leq \\
& C\left(L, n, \phi, C_{0}\right) \min \left(t 2^{-k},\left(2^{-k} t\right)^{n / 2-L}\right)
\end{aligned}
$$

With this inequality, the next lemma which is the desired result can be obtained.
Lemma 33.3.6 There exists a constant depending only on the indicated objects, $C_{1}=$ $C\left(L, n, \phi, C_{0}\right)$ such that when $|\mathbf{y}| \leq t$,

$$
\begin{gather*}
\int_{|\mathbf{x}| \geq 2 t}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho(\mathbf{x})\right| d x \leq C_{1} \\
\int_{|\mathbf{x}| \geq 2 t}\left|F^{-1} \rho_{m}(\mathbf{x}-\mathbf{y})-F^{-1} \rho_{m}(\mathbf{x})\right| d x \leq C_{1} \tag{33.3.35}
\end{gather*}
$$

Proof: $F^{-1} \rho=\lim _{m \rightarrow \infty} F^{-1} \rho_{m}$ in $L^{2}\left(\mathbb{R}^{n}\right)$. Let $m_{k} \rightarrow \infty$ be such that convergence is pointwise a.e. Then if $|\mathbf{y}| \leq t$, Fatou's lemma implies

$$
\begin{gather*}
\int_{|\mathbf{x}| \geq 2 t}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho(\mathbf{x})\right| d x \leq \\
\quad \lim \inf _{l \rightarrow \infty} \int_{|\mathbf{x}| \geq 2 t}\left|F^{-1} \rho_{m_{l}}(\mathbf{x}-\mathbf{y})-F^{-1} \rho_{m_{l}}(\mathbf{x})\right| d x \\
\leq \lim _{l \rightarrow \infty} \inf _{l=-m_{l}} \sum_{l|x| \geq 2 t}^{m_{l}} \int_{\mid=1}\left|F^{-1} \gamma_{k}(\mathbf{x}-\mathbf{y})-F^{-1} \gamma_{k}(\mathbf{x})\right| d x \\
\leq C\left(L, n, \phi, C_{0}\right) \sum_{k=-\infty}^{\infty} \min \left(t 2^{-k},\left(2^{-k} t\right)^{n / 2-L}\right) . \tag{33.3.36}
\end{gather*}
$$

Now consider the sum in 33.3.36,

$$
\begin{equation*}
\sum_{k=-\infty}^{\infty} \min \left(t 2^{-k},\left(2^{-k} t\right)^{n / 2-L}\right) \tag{33.3.37}
\end{equation*}
$$

$t 2^{j}=\min \left(t 2^{j},\left(2^{j} t\right)^{n / 2-L}\right)$ exactly when $t 2^{j} \leq 1$. This occurs if and only if

$$
j \leq-\ln (t) / \ln (2)
$$

Therefore 33.3 .37 is no larger than

$$
\sum_{j \leq-\ln (t) / \ln (2)} 2^{j} t+\sum_{j \geq-\ln (t) / \ln (2)}\left(2^{j} t\right)^{n / 2-L} .
$$

Letting $a=L-n / 2$, this equals

$$
\begin{aligned}
& t \sum_{k \geq \ln (t) / \ln (2)} 2^{-k}+t^{-\alpha} \sum_{j \geq-\ln (t) / \ln (2)}\left(2^{-a}\right)^{j} \\
\leq & 2 t\left(\frac{1}{2}\right)^{\ln (t) / \ln (2)}+t^{-a}\left(\frac{1}{2^{a}}\right)^{-\ln (t) / \ln (2)} \\
= & 2 t\left(\frac{1}{2}\right)^{\log _{2}(t)}+t^{-a}\left(\frac{1}{2^{a}}\right)^{-\log _{2}(t)} \\
= & 2+1=3 .
\end{aligned}
$$

Similarly, 33.3.35 holds. This proves the lemma.
Now it is possible to prove Mihlin's theorem.
Theorem 33.3.7 (Mihlin's theorem) Suppose $\rho$ satisfies

$$
C_{0} \geq \sup \left\{|\mathbf{x}|^{|\alpha|}\left|D^{\alpha} \rho(\mathbf{x})\right|:|\alpha| \leq L, \mathbf{x} \in \mathbb{R}^{n} \backslash\{\mathbf{0}\}\right\}
$$

where $L$ is an integer greater than $n / 2$ and $\rho \in C^{L}\left(\mathbb{R}^{n} \backslash\{\mathbf{0}\}\right)$. Then for every $p>1$, there exists a constant $A_{p}$ depending only on $p, C_{0}, \phi, n$, and $L$, such that for all $\psi \in \mathscr{G}$,

$$
\left\|F^{-1} \rho * \psi\right\|_{p} \leq A_{p}\|\psi\|_{p}
$$

Proof: Since $\rho_{m}$ satisfies 33.3.35, and is obviously in $L^{2}\left(\mathbb{R}^{n}\right) \cap L^{\infty}\left(\mathbb{R}^{n}\right)$, Theorem 33.3.3 implies there exists a constant $A_{p}$ depending only on $p, n,\left\|\rho_{m}\right\|_{\infty}$, and $C_{1}$ such that for all $\psi \in \mathscr{G}$ and $p \in(1, \infty)$,

$$
\left\|F^{-1} \rho_{m} * \psi\right\|_{p} \leq A_{p}\|\psi\|_{p}
$$

Now $\left\|\rho_{m}\right\|_{\infty} \leq\|\rho\|_{\infty}$ because

$$
\begin{equation*}
\left|\rho_{m}(\mathbf{x})\right| \leq|\rho(\mathbf{x})| \sum_{k=-m}^{m} \phi\left(2^{k} \mathbf{x}\right) \leq|\rho(\mathbf{x})| . \tag{33.3.38}
\end{equation*}
$$

Therefore, since $C_{1}=C_{1}\left(L, n, \phi, C_{0}\right)$ and $C_{0} \geq\|\rho\|_{\infty}$,

$$
\left\|F^{-1} \rho_{m} * \psi\right\|_{p} \leq A_{p}\left(L, n, \phi, C_{0}, p\right)\|\psi\|_{p}
$$

In particular, $A_{p}$ does not depend on $m$. Now, by 33.3.38, the observation that $\rho \in L^{\infty}\left(\mathbb{R}^{n}\right)$, $\lim _{m \rightarrow \infty} \rho_{m}(\mathbf{y})=\rho(\mathbf{y})$ and the dominated convergence theorem, it follows that for $\theta \in \mathscr{G}$.

$$
\begin{gathered}
\left|\left(F^{-1} \rho * \psi\right)(\theta)\right| \equiv\left|(2 \pi)^{n / 2} \int \rho(\mathbf{x}) F \psi(\mathbf{x}) F^{-1} \theta(\mathbf{x}) d x\right| \\
=\lim _{m \rightarrow \infty}\left|\left(F^{-1} \rho_{m} * \psi\right)(\theta)\right| \leq \lim _{m \rightarrow \infty} \sup \left\|F^{-1} \rho_{m} * \psi\right\|\left\|_{p}\right\| \theta \|_{p^{\prime}} \\
\leq A_{p}\left(L, n, \phi, C_{0}, p\right)\|\psi\|_{p}\|\theta\|_{p^{\prime}}
\end{gathered}
$$

Hence $F^{-1} \rho * \psi \in L^{p}\left(\mathbb{R}^{n}\right)$ and $\left\|F^{-1} \rho * \psi\right\|_{p} \leq A_{p}\|\psi\|_{p}$. This proves the theorem.

### 33.4 Singular Integrals

If $K \in L^{1}\left(\mathbb{R}^{n}\right)$ then when $p>1$,

$$
\|K * f\|_{p} \leq\|f\|_{p}
$$

It turns out that some meaning can be assigned to $K * f$ for some functions $K$ which are not in $L^{1}$. This involves assuming a certain form for $K$ and exploiting cancellation. The resulting theory of singular integrals is very useful. To illustrate, an application will be given to the Helmholtz decomposition of vector fields in the next section. Like Mihlin's theorem, the theory presented here rests on Theorem 33.3.3, restated here for convenience.
Theorem 33.4.1 Let $\rho \in L^{2}\left(\mathbb{R}^{n}\right) \cap L^{\infty}\left(\mathbb{R}^{n}\right)$ and suppose

$$
\int_{|\mathbf{x}| \geq 2|\mathbf{y}|}\left|F^{-1} \rho(\mathbf{x}-\mathbf{y})-F^{-1} \rho(\mathbf{x})\right| d x \leq C_{1}
$$

Then for each $p \in(1, \infty)$, there exists a constant, $A_{p}$, depending only on

$$
p, n,\|\rho\|_{\infty}
$$

and $C_{1}$ such that for all $\phi \in \mathscr{G}$,

$$
\left\|F^{-1} \rho * \phi\right\|_{p} \leq A_{p}\|\phi\|_{p}
$$

Lemma 33.4.2 Suppose

$$
\begin{equation*}
K \in L^{2}\left(\mathbb{R}^{n}\right),\|F K\|_{\infty} \leq B<\infty, \tag{33.4.39}
\end{equation*}
$$

and

$$
\int_{|\mathbf{x}|>2|\mathbf{y}|}|K(\mathbf{x}-\mathbf{y})-K(\mathbf{x})| d x \leq B
$$

Then for all $p>1$, there exists a constant, $A(p, n, B)$, depending only on the indicated quantities such that

$$
\|K * f\|_{p} \leq A(p, n, B)\|f\|_{p}
$$

for all $f \in \mathscr{G}$.
Proof: Let $F K=\rho$ so $F^{-1} \rho=K$. Then from 33.4.39 $\rho \in L^{2}\left(\mathbb{R}^{n}\right) \cap L^{\infty}\left(\mathbb{R}^{n}\right)$ and $K=$ $F^{-1} \rho$. By Theorem 33.3.3 listed above,

$$
\|K * f\|_{p}=\left\|F^{-1} \rho * f\right\|_{p} \leq A(p, n, B)\|f\|_{p}
$$

for all $f \in \mathscr{G}$. This proves the lemma.
The next lemma provides a situation in which the above conditions hold.
Lemma 33.4.3 Suppose

$$
\begin{gather*}
|K(\mathbf{x})| \leq B|\mathbf{x}|^{-n},  \tag{33.4.40}\\
\int_{a<|\mathbf{x}|<b} K(\mathbf{x}) d x=0,  \tag{33.4.41}\\
\int_{|\mathbf{x}|>2|\mathbf{y}|}|K(\mathbf{x}-\mathbf{y})-K(\mathbf{x})| d x \leq B . \tag{33.4.42}
\end{gather*}
$$

Define

$$
K_{\varepsilon}(\mathbf{x})=\left\{\begin{array}{l}
K(\mathbf{x}) \text { if }|\mathbf{x}| \geq \varepsilon  \tag{33.4.43}\\
0 \text { if }|\mathbf{x}|<\varepsilon
\end{array}\right.
$$

Then there exists a constant $C(n)$ such that

$$
\begin{equation*}
\int_{|\mathbf{x}|>2|\mathbf{y}|}\left|K_{\mathcal{\varepsilon}}(\mathbf{x}-\mathbf{y})-K_{\mathcal{\varepsilon}}(\mathbf{x})\right| d x \leq C(n) B \tag{33.4.44}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\|F K_{\mathcal{\varepsilon}}\right\|_{\infty} \leq C(n) B \tag{33.4.45}
\end{equation*}
$$

Proof: In the argument, $C(n)$ will denote a generic constant depending only on $n$. Consider 33.4.44 first. The integral is broken up according to whether $|\mathbf{x}|,|\mathbf{x}-\mathbf{y}|>\varepsilon$.

| $\|\mathbf{x}\|$ | $>\varepsilon$ | $>\varepsilon$ | $<\varepsilon$ | $<\varepsilon$ |
| :--- | :---: | :---: | :---: | :---: |
| $\|\mathbf{x}-\mathbf{y}\|$ | $>\varepsilon$ | $<\varepsilon$ | $<\varepsilon$ | $>\varepsilon$ |

$$
\begin{align*}
& \int_{|\mathbf{x}| \geq 2|\mathbf{y}|}\left|K_{\mathcal{E}}(\mathbf{x}-\mathbf{y})-K_{\mathcal{E}}(\mathbf{x})\right| d x= \\
& \int_{|\mathbf{x}| \geq 2|\mathbf{y}|,|\mathbf{x}-\mathbf{y}|>\varepsilon,|\mathbf{x}|<\varepsilon}\left|K_{\mathcal{E}}(\mathbf{x}-\mathbf{y})-K_{\mathcal{E}}(\mathbf{x})\right| d x+ \\
& +\int_{|\mathbf{x}| \geq 2|\mathbf{y}|,|\mathbf{x}-\mathbf{y}|<\varepsilon,|\mathbf{x}| \geq \varepsilon}\left|K_{\mathcal{\varepsilon}}(\mathbf{x}-\mathbf{y})-K_{\mathcal{\varepsilon}}(\mathbf{x})\right| d x+  \tag{33.4.46}\\
& \left|\int_{|\mathbf{x}| \geq 2|\mathbf{y}|,|\mathbf{x}-\mathbf{y}|>\varepsilon,|\mathbf{x}|>\varepsilon}\right| K_{\mathcal{E}}(\mathbf{x}-\mathbf{y})-K_{\mathcal{E}}(\mathbf{x}) \mid d x+ \\
& +\int_{|\mathbf{x}| \geq 2|\mathbf{y}|,|\mathbf{x}-\mathbf{y}|<\varepsilon,|\mathbf{x}|<\varepsilon}\left|K_{\mathcal{E}}(\mathbf{x}-\mathbf{y})-K_{\mathcal{E}}(\mathbf{x})\right| d x .
\end{align*}
$$

Now consider the terms in the above expression. The last integral in 33.4.46 equals 0 from the definition of $K_{\varepsilon}$. The third integral on the right is no larger than $B$ by the definition of $K_{\varepsilon}$ and 33.4.42. Consider the second integral on the right. This integral is no larger than

$$
\int_{|\mathbf{x}| \geq 2|\mathbf{y}|,|\mathbf{x}| \geq \varepsilon,|\mathbf{x}-\mathbf{y}|<\varepsilon} B|\mathbf{x}|^{-n} d x .
$$

Now $|\mathbf{x}| \leq|\mathbf{y}|+\varepsilon \leq|\mathbf{x}| / 2+\varepsilon$ and so $|\mathbf{x}|<2 \varepsilon$. Thus this is no larger than

$$
\int_{\varepsilon \leq|\mathbf{x}| \leq 2 \varepsilon} B|\mathbf{x}|^{-n} d x=B \int_{S^{n-1}} \int_{\varepsilon}^{2 \varepsilon} \rho^{n-1} \frac{1}{\rho^{n}} d \rho d \sigma \leq B C(n) \ln 2=C(n) B .
$$

It remains to estimate the first integral on the right in 33.4.46. This integral is bounded by

$$
\int_{|\mathbf{x}| \geq 2|\mathbf{y}|,|\mathbf{x}-\mathbf{y}|>\varepsilon,|\mathbf{x}|<\varepsilon} B|\mathbf{x}-\mathbf{y}|^{-n} d x
$$

In the integral above, $|\mathbf{x}|<\varepsilon$ and so $|\mathbf{x}-\mathbf{y}|-|\mathbf{y}|<\varepsilon$. Therefore, $|\mathbf{x}-\mathbf{y}|<\varepsilon+|\mathbf{y}|<\varepsilon+$ $|\mathbf{x}| / 2<\varepsilon+\varepsilon / 2=(3 / 2) \varepsilon$. Hence $\varepsilon \leq|\mathbf{x}-\mathbf{y}| \leq(3 / 2)|\mathbf{x}-\mathbf{y}|$. Therefore, the above integral is no larger than

$$
\int_{\varepsilon}^{(3 / 2) \varepsilon} B|\mathbf{z}|^{-n} d z=B \int_{S^{n-1}} \int_{\varepsilon}^{(3 / 2) \varepsilon} \rho^{-1} d \rho d \sigma=B C(n) \ln (3 / 2) .
$$

This establishes 33.4.44.
Now it remains to show 33.4.45, a statement about the Fourier transforms of $K_{\varepsilon}$. Fix $\varepsilon$ and let $\mathbf{y} \neq \mathbf{0}$ also be given.

$$
K_{\varepsilon R}(\mathbf{y}) \equiv\left\{\begin{array}{l}
K_{\varepsilon}(\mathbf{y}) \text { if }|\mathbf{y}|<R \\
0 \text { if }|\mathbf{y}| \geq R
\end{array}\right.
$$

where $R>\frac{3 \pi}{|\mathbf{y}|}$. (The 3 here isn't important. It just needs to be larger than 1.) Then

$$
\left|F K_{\varepsilon R}(\mathbf{y})\right| \leq\left|\int_{0<|\mathbf{x}|<3 \pi|\mathbf{y}|^{-1}} K_{\varepsilon}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x\right|+\left|\int_{\beta \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\varepsilon}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x\right|
$$

$$
\begin{equation*}
=\mathbf{A}+\mathbf{B} . \tag{33.4.47}
\end{equation*}
$$

Consider A. By 33.4.41

$$
\int_{\varepsilon<|\mathbf{x}|<3 \pi|\mathbf{y}|^{-1}} K_{\varepsilon}(\mathbf{x}) d x=0
$$

and so

$$
\mathbf{A}=\left|\int_{\varepsilon<|\mathbf{x}|<3 \pi|\mathbf{y}|^{-1}} K_{\mathcal{\varepsilon}}(\mathbf{x})\left(e^{-i \mathbf{x} \cdot \mathbf{y}}-1\right) d x\right|
$$

Now

$$
\left|e^{-i \mathbf{x} \cdot \mathbf{y}}-1\right|=|2-2 \cos (\mathbf{x} \cdot \mathbf{y})|^{1 / 2} \leq 2|\mathbf{x} \cdot \mathbf{y}| \leq 2|\mathbf{x}||\mathbf{y}|
$$

so, using polar coordinates, this expression is no larger than

$$
2 B \int_{\varepsilon<|\mathbf{x}|<3 \pi|\mathbf{y}|^{-1}}|\mathbf{x}|^{-n}|\mathbf{x}||\mathbf{y}| d x \leq C(n) B|\mathbf{y}| \int_{\varepsilon}^{3 \pi /|\mathbf{y}|} d \rho \leq B C(n)
$$

Next, consider B. This estimate is based on the trick which follows. Let

$$
\mathbf{z} \equiv \mathbf{y} \pi /|\mathbf{y}|^{2}
$$

so that

$$
|\mathbf{z}|=\pi /|\mathbf{y}|, \mathbf{z} \cdot \mathbf{y}=\pi
$$

Then

$$
\begin{gather*}
\int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x=\frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x  \tag{33.4.48}\\
-\frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\varepsilon}(\mathbf{x}) e^{-i(\mathbf{x}+\mathbf{z}) \cdot \mathbf{y}} d x .
\end{gather*}
$$

Here is why. Note in the second of these integrals,

$$
\begin{aligned}
& -\frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i(\mathbf{x}+\mathbf{z}) \cdot \mathbf{y}} d x \\
= & -\frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} e^{-i \mathbf{z} \cdot \mathbf{y}} d x \\
= & -\frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} e^{-i \pi} d x \\
= & \frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\varepsilon}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x .
\end{aligned}
$$

Then changing the variables in 33.4.48,

$$
\begin{gathered}
\int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \\
=\frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \\
-\frac{1}{2} \int_{3 \pi|\mathbf{y}|^{-1}<|\mathbf{x}-\mathbf{z}| \leq R} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x .
\end{gathered}
$$

Thus

$$
\begin{gather*}
\int K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x= \\
+\frac{1}{2} \int_{|\mathbf{x}-\mathbf{z}| \leq 3 \pi|\mathbf{y}|^{-1}} \int_{|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x-\frac{1}{2} K_{|\mathbf{x}-\mathbf{y}| \leq 3 \pi|\mathbf{y}|^{-1}} \int_{\mathcal{L}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y} \mid \leq R} d x-\frac{1}{2} \int_{\mathcal{\varepsilon}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x . \tag{33.4.49}
\end{gather*}
$$

Since $|\mathbf{z}|=\pi /|\mathbf{y}|$, it follows $|\mathbf{z}|=\frac{\pi}{|\mathbf{y}|}<\frac{3 \pi}{|\mathbf{y}|}<R$ and so the following picture describes the situation. In this picture, the radius of each ball equals either $R$ or $3 \pi|\mathbf{y}|^{-1}$ and each integral above is taken over one of the two balls in the picture, either the one centered at $\mathbf{0}$ or the one centered at $\mathbf{z}$.

To begin with, consider the integrals which involve $K_{\mathcal{E}}(\mathbf{x}-\mathbf{z})$.

$$
\begin{gather*}
\int_{|\mathbf{x}-\mathbf{z}| \leq R} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \\
=\int_{|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \\
-\int_{|\mathbf{x}-\mathbf{z}|>R,|\mathbf{x}|<R} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x  \tag{33.4.50}\\
+\int_{|\mathbf{x}-\mathbf{z}|<R,|\mathbf{x}|>R} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x .
\end{gather*}
$$

Look at the picture. Similarly,

$$
\begin{gather*}
\iint_{\mid \mathbf{x}} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \\
=\int_{|\mathbf{z}| \leq 3 \pi|\mathbf{y}|^{-1}} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \\
-\int_{|\mathbf{x}-\mathbf{z}|>3 \pi|\mathbf{y}|^{-1}}^{|\mathbf{y}|^{-1},|\mathbf{x}|<3 \pi|\mathbf{y}|^{-1}} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x+  \tag{33.4.51}\\
\int_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x
\end{gather*}
$$

The last integral in 33.4.50 is taken over a set that is contained in

$$
B(\mathbf{0}, R+|\mathbf{z}|) \backslash B(\mathbf{0}, R)
$$

illustrated in the following picture as the region between the small ball centered at $\mathbf{0}$ and the big ball which surrounds the two small balls

and so this integral is dominated by

$$
B\left(\frac{1}{(R-|\mathbf{z}|)^{n}}\right) \alpha(n)\left((R+|\mathbf{z}|)^{n}-R^{n}\right)
$$

an expression which converges to 0 as $R \rightarrow \infty$. Similarly, the second integral on the right in 33.4.50 converges to zero as $R \rightarrow \infty$. Now consider the last two integrals in 33.4.51. Letting $3 \pi|\mathbf{y}|^{-1}$ play the role of $R$ and using $|\mathbf{z}|=\pi /|\mathbf{y}|$, these are each dominated by an expression of the form

$$
\begin{gathered}
B\left(\frac{1}{\left(3 \pi|\mathbf{y}|^{-1}-|\mathbf{z}|\right)^{n}}\right) \alpha(n)\left(\left(3 \pi|\mathbf{y}|^{-1}+|\mathbf{z}|\right)^{n}-\left(3 \pi|\mathbf{y}|^{-1}\right)^{n}\right) \\
=B\left(\frac{1}{\left(3 \pi|\mathbf{y}|^{-1}-\pi|\mathbf{y}|^{-1}\right)^{n}}\right) \alpha(n) \\
\left(\left(3 \pi|\mathbf{y}|^{-1}+\pi|\mathbf{y}|^{-1}\right)^{n}-\left(3 \pi|\mathbf{y}|^{-1}\right)^{n}\right)
\end{gathered}
$$

$$
=\alpha(n) B \frac{|\mathbf{y}|^{n}}{(2 \pi)^{n}} \frac{1}{|\mathbf{y}|^{n}}\left((4 \pi)^{n}-(3 \pi)^{n}\right)=C(n) B .
$$

Returning to 33.4.49, the terms involving $\mathbf{x}-\mathbf{y}$ have now been estimated. Thus, collecting the terms which have not yet been estimated along with those that have,

$$
\begin{gathered}
\mathbf{B}=\left|\int_{\beta \pi|\mathbf{y}|^{-1}<|\mathbf{x}| \leq R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x\right| \\
\leq \frac{1}{2} \int_{|\mathbf{x}|<R} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x-\int_{|\mathbf{x}|<R} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \\
+\int_{|\mathbf{x}|<3 \pi|\mathbf{y}|^{-1}} K_{\mathcal{E}}(\mathbf{x}-\mathbf{z}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x-\int_{|\mathbf{x}|<3 \pi|\mathbf{y}|^{-1}} K_{\mathcal{E}}(\mathbf{x}) e^{-i \mathbf{x} \cdot \mathbf{y}} d x \mid \\
+C(n) B+g(R)
\end{gathered}
$$

where $g(R) \rightarrow 0$ as $R \rightarrow \infty$. Using $|\mathbf{z}|=\pi /|\mathbf{y}|$ again,

$$
\mathbf{B} \leq \frac{1}{2} \int_{3|\mathbf{z}|<|\mathbf{x}|<R}\left|K_{\mathcal{E}}(\mathbf{x})-K_{\mathcal{E}}(\mathbf{x}-\mathbf{z})\right| d x+C(n) B+g(R) .
$$

But the integral in the above is dominated by $C(n) B$ by 33.4 .44 which was established earlier. Therefore, from 33.4.47,

$$
\left|F K_{\varepsilon R}\right| \leq C(n) B+g(R)
$$

where $g(R) \rightarrow 0$.
Now $K_{\varepsilon R} \rightarrow K_{\varepsilon}$ in $L^{2}\left(\mathbb{R}^{n}\right)$ because

$$
\begin{aligned}
\left\|K_{\varepsilon R}-K_{\mathcal{E}}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)} & \leq B \int_{|\mathbf{x}|>R} \frac{1}{|\mathbf{x}|^{2 n}} d x \\
& =B \int_{S^{n-1}} \int_{R}^{\infty} \frac{1}{\rho^{n+1}} d \rho d \sigma
\end{aligned}
$$

which converges to 0 as $R \rightarrow \infty$ and so $F K_{\varepsilon R} \rightarrow F K_{\varepsilon}$ in $L^{2}\left(\mathbb{R}^{n}\right)$ by Plancherel's theorem. Therefore, by taking a subsequence, still denoted by $R, F K_{\varepsilon R}(\mathbf{y}) \rightarrow F K_{\mathcal{\varepsilon}}(\mathbf{y})$ a.e. which shows

$$
\left|F K_{\varepsilon}(\mathbf{y})\right| \leq C(n) B \text { a.e. }
$$

This proves the lemma.
Corollary 33.4.4 Suppose 33.4.40-33.4.42 hold. Then if $g \in C_{c}^{1}\left(\mathbb{R}^{n}\right), K_{\mathcal{\varepsilon}} * g$ converges uniformly and in $L^{p}\left(\mathbb{R}^{n}\right)$ as $\varepsilon \rightarrow 0$.

Proof:

$$
K_{\mathcal{\varepsilon}} * g(\mathbf{x}) \equiv \int K_{\mathcal{\varepsilon}}(\mathbf{y}) g(\mathbf{x}-\mathbf{y}) d y
$$

Let $0<\eta<\varepsilon$. Then since $g \in C_{c}^{1}\left(\mathbb{R}^{n}\right)$, there exists a constant, $K$ such that $K|\mathbf{u}-\mathbf{v}| \geq$ $|g(\mathbf{u})-g(\mathbf{v})|$ for all $\mathbf{u}, \mathbf{v} \in \mathbb{R}^{n}$.

$$
\begin{aligned}
\left|K_{\varepsilon} * g(\mathbf{x})-K_{\eta} * g(\mathbf{x})\right| & \leq B K \int_{\eta<|\mathbf{y}|<\varepsilon} \frac{1}{|\mathbf{y}|^{n}}|\mathbf{y}| d y \\
& =B K \int_{S^{n-1}} \int_{\eta}^{\varepsilon} d \rho d \sigma=C_{n}|\varepsilon-\eta|
\end{aligned}
$$

This proves the corollary.
Theorem 33.4.5 Suppose 33.4.40-33.4.42. Then for $K_{\varepsilon}$ given by 33.4.43 and $p>1$, there exists a constant $A(p, n, B)$ such that for all $f \in L^{p}\left(\mathbb{R}^{n}\right)$,

$$
\begin{equation*}
\left\|K_{\varepsilon} * f\right\|_{p} \leq A(p, n, B)\|f\|_{p} \tag{33.4.52}
\end{equation*}
$$

Also, for each $f \in L^{p}\left(\mathbb{R}^{n}\right)$,

$$
\begin{equation*}
T f \equiv \lim _{\varepsilon \rightarrow 0} K_{\mathcal{E}} * f \tag{33.4.53}
\end{equation*}
$$

exists in $L^{p}\left(\mathbb{R}^{n}\right)$ and for all $f \in L^{p}\left(\mathbb{R}^{n}\right)$,

$$
\begin{equation*}
\|T f\|_{p} \leq A(p, n, B)\|f\|_{p} \tag{33.4.54}
\end{equation*}
$$

Thus $T$ is a linear and continuous map defined on $L^{p}\left(\mathbb{R}^{n}\right)$ for each $p>1$.
Proof: From 33.4.40 it follows $K_{\mathcal{E}} \in L^{p^{\prime}}\left(\mathbb{R}^{n}\right) \cap L^{2}\left(\mathbb{R}^{n}\right)$ where, as usual, $1 / p+1 / p^{\prime}=1$. By continuity of translation in $L^{p^{\prime}}\left(\mathbb{R}^{n}\right), x \rightarrow K_{\mathcal{\varepsilon}} * f(x)$ is a continuous function.By Lemma 33.4.3, $\left\|F K_{\mathcal{E}}\right\|_{\infty} \leq C(n) B$ for all $\varepsilon$. Therefore, by Lemma 33.4.2,

$$
\left\|K_{\varepsilon} * g\right\|_{p} \leq A(p, n, B)\|g\|_{p}
$$

for all $g \in \mathscr{G}$. Now let $f \in L^{p}\left(\mathbb{R}^{n}\right)$ and $g_{k} \rightarrow f$ in $L^{p}\left(\mathbb{R}^{n}\right)$ where $g_{k} \in \mathscr{G}$. Then

$$
\begin{aligned}
\left|K_{\mathcal{\varepsilon}} * f(\mathbf{x})-K_{\mathcal{\varepsilon}} * g_{k}(\mathbf{x})\right| & \leq \int\left|K_{\mathcal{\varepsilon}}(\mathbf{x}-\mathbf{y})\right|\left|g_{k}(\mathbf{y})-f(\mathbf{y})\right| d y \\
& \leq\left\|K_{\mathcal{E}}\right\|_{p^{\prime}}\left\|g_{k}-f\right\|_{p}
\end{aligned}
$$

which shows that $K_{\mathcal{\varepsilon}} * g_{k}(\mathbf{x}) \rightarrow K_{\mathcal{\varepsilon}} * f(\mathbf{x})$ pointwise and so by Fatou's lemma,

$$
\begin{aligned}
\left\|K_{\varepsilon} * f\right\|_{p} & \leq \lim _{k \rightarrow \infty} \inf _{k \rightarrow}\left\|K_{\mathcal{\varepsilon}} * g_{k}\right\|_{p} \leq \lim _{k \rightarrow \infty} \inf _{k \rightarrow \infty}(p, n, B)\left\|g_{k}\right\|_{p} \\
& =A(p, n, B)\|f\|_{p}
\end{aligned}
$$

This verifies 33.4.52.
To verify 33.4 .53 , let $\delta>0$ be given and let

$$
f \in L^{p}\left(\mathbb{R}^{n}\right), g \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)
$$

$$
\begin{aligned}
& \| K_{\mathcal{\varepsilon}} * f- K_{\eta} * f \|_{p} \leq \\
&\left\|K_{\varepsilon} *(f-g)\right\|_{p}+\left\|K_{\varepsilon} * g-K_{\eta} * g\right\|_{p} \\
&+\left\|K_{\eta} *(f-g)\right\|_{p} \\
& \leq 2 A(p, n, B)\|f-g\|_{p}+\left\|K_{\varepsilon} * g-K_{\eta} * g\right\|_{p}
\end{aligned}
$$

Choose $g$ such that $2 A(p, n, B)\|f-g\|_{p} \leq \delta / 2$. Then if $\varepsilon, \eta$ are small enough, Corollary 33.4.4 implies the last term is also less than $\delta / 2$. Thus, $\lim _{\varepsilon \rightarrow 0} K_{\varepsilon} * f$ exists in $L^{p}\left(\mathbb{R}^{n}\right)$. Let $T f$ be the element of $L^{p}\left(\mathbb{R}^{n}\right)$ to which it converges. Then 33.4.54 follows and $T$ is obviously linear because

$$
\begin{aligned}
T(a f+b g) & =\lim _{\varepsilon \rightarrow 0} K_{\varepsilon} *(a f+b g)=\lim _{\varepsilon \rightarrow 0}\left(a K_{\mathcal{\varepsilon}} * f+b K_{\mathcal{\varepsilon}} * g\right) \\
& =a T f+b T g .
\end{aligned}
$$

This proves the theorem.
When do conditions 33.4.40-33.4.42 hold? It turns out this happens for $K$ given by the following.

$$
\begin{equation*}
K(\mathbf{x}) \equiv \frac{\Omega(\mathbf{x})}{|\mathbf{x}|^{n}} \tag{33.4.55}
\end{equation*}
$$

where

$$
\begin{gather*}
\Omega(\lambda \mathbf{x})=\Omega(\mathbf{x}) \text { for all } \lambda>0  \tag{33.4.56}\\
\Omega \text { is Lipschitz on } S^{n-1} \\
\int_{S^{n-1}} \Omega(\mathbf{x}) d \sigma=0 \tag{33.4.57}
\end{gather*}
$$

Theorem 33.4.6 For $K$ given by 33.4.55-33.4.57, it follows there exists a constant B such that

$$
\begin{gather*}
|K(\mathbf{x})| \leq B|\mathbf{x}|^{-n}  \tag{33.4.58}\\
\int_{a<|\mathbf{x}|<b} K(\mathbf{x}) d x=0  \tag{33.4.59}\\
\int_{|\mathbf{x}|>2|\mathbf{y}|}|K(\mathbf{x}-\mathbf{y})-K(\mathbf{x})| d x \leq B \tag{33.4.60}
\end{gather*}
$$

Consequently, the conclusions of Theorem 33.4.5 hold also.
Proof: 33.4.58 is obvious. To verify 33.4.59,

$$
\begin{aligned}
\int_{a<|\mathbf{x}|<b} K(\mathbf{x}) d x & =\int_{a}^{b} \int_{S^{n-1}} \frac{\Omega(\rho \mathbf{w})}{\rho^{n}} \rho^{n-1} d \sigma d \rho \\
& =\int_{a}^{b} \frac{1}{\rho} \int_{S^{n-1}} \Omega(\mathbf{w}) d \sigma d \rho=0
\end{aligned}
$$

It remains to show 33.4.60.

$$
\begin{align*}
K(\mathbf{x}-\mathbf{y})-K(\mathbf{x})= & |\mathbf{x}-\mathbf{y}|^{-n}\left(\Omega\left(\frac{\mathbf{x}-\mathbf{y}}{|\mathbf{x}-\mathbf{y}|}\right)-\Omega\left(\frac{\mathbf{x}}{|\mathbf{x}|}\right)\right) \\
& +\Omega(\mathbf{x})\left(\frac{1}{|\mathbf{x}-\mathbf{y}|^{n}}-\frac{1}{|\mathbf{x}|^{n}}\right) \tag{33.4.61}
\end{align*}
$$

where 33.4 .56 was used to write $\Omega\left(\frac{\mathbf{z}}{|\mathbf{z}|}\right)=\Omega(\mathbf{z})$. The first group of terms in 33.4.61 is dominated by

$$
|\mathbf{x}-\mathbf{y}|^{-n} \operatorname{Lip}(\Omega)\left|\frac{\mathbf{x}-\mathbf{y}}{|\mathbf{x}-\mathbf{y}|}-\frac{\mathbf{x}}{|\mathbf{x}|}\right|
$$

and an estimate is required for $|\mathbf{x}|>2|\mathbf{y}|$. Since $|\mathbf{x}|>2|\mathbf{y}|$,

$$
|\mathbf{x}-\mathbf{y}|^{-n} \leq(|\mathbf{x}|-|\mathbf{y}|)^{-n} \leq \frac{2^{n}}{|\mathbf{x}|^{n}}
$$

Also

$$
\begin{gathered}
\left|\frac{\mathbf{x}-\mathbf{y}}{|\mathbf{x}-\mathbf{y}|}-\frac{\mathbf{x}}{|\mathbf{x}|}\right|=\left|\frac{(\mathbf{x}-\mathbf{y})|\mathbf{x}|-\mathbf{x}|\mathbf{x}-\mathbf{y}|}{|\mathbf{x}||\mathbf{x}-\mathbf{y}|}\right| \\
\leq\left|\frac{(\mathbf{x}-\mathbf{y})|\mathbf{x}|-\mathbf{x}|\mathbf{x}-\mathbf{y}|}{|\mathbf{x}|(|\mathbf{x}|-|\mathbf{y}|)}\right| \leq\left|\frac{(\mathbf{x}-\mathbf{y})|\mathbf{x}|-\mathbf{x}|\mathbf{x}-\mathbf{y}|}{|\mathbf{x}|(|\mathbf{x}| / 2)}\right| \\
=\frac{2}{|\mathbf{x}|^{2}}|\mathbf{x}| \mathbf{x}|-\mathbf{y}| \mathbf{x}|-\mathbf{x}| \mathbf{x}-\mathbf{y}| |=\frac{2}{|\mathbf{x}|^{2}}|\mathbf{x}(|\mathbf{x}|-|\mathbf{x}-\mathbf{y}|)-\mathbf{y}| \mathbf{x}| | \\
\leq \frac{2}{|\mathbf{x}|^{2}}|\mathbf{x}|| | \mathbf{x}|-|\mathbf{x}-\mathbf{y}||+|\mathbf{y}||\mathbf{x}| \leq \frac{2}{|\mathbf{x}|^{2}}(|\mathbf{x}||\mathbf{x}-(\mathbf{x}-\mathbf{y})|+|\mathbf{y}||\mathbf{x}|) \\
\leq \frac{4}{|\mathbf{x}|^{2}}|\mathbf{x}||\mathbf{y}|=4 \frac{|\mathbf{y}|}{|\mathbf{x}|}
\end{gathered}
$$

Therefore,

$$
\begin{align*}
\int_{|\mathbf{x}|>2|\mathbf{y}|} & |\mathbf{x}-\mathbf{y}|^{-n}\left|\Omega\left(\frac{\mathbf{x}-\mathbf{y}}{|\mathbf{x}-\mathbf{y}|}\right)-\Omega\left(\frac{\mathbf{x}}{|\mathbf{x}|}\right)\right| d x \\
& \leq 4\left(2^{n}\right) \int_{|\mathbf{x}|>2|\mathbf{y}|} \frac{1}{|\mathbf{x}|^{n}} \frac{|\mathbf{y}|}{|\mathbf{x}|} d x \operatorname{Lip}(\Omega) \\
& =C(n, \operatorname{Lip} \Omega) \int_{|\mathbf{x}|>2|\mathbf{y}|} \frac{|\mathbf{y}|}{|\mathbf{x}|^{n+1}} d x \\
& =C(n, \operatorname{Lip} \Omega) \int_{|\mathbf{u}|>2} \frac{1}{|\mathbf{u}|^{n+1}} d u \tag{33.4.62}
\end{align*}
$$

It remains to consider the second group of terms in 33.4.61 when $|\mathbf{x}|>2|\mathbf{y}|$.

$$
\begin{aligned}
& \left|\frac{1}{|\mathbf{x}-\mathbf{y}|^{n}}-\frac{1}{|\mathbf{x}|^{n}}\right|=\left|\frac{|\mathbf{x}|^{n}-|\mathbf{x}-\mathbf{y}|^{n}}{|\mathbf{x}-\mathbf{y}|^{n}|\mathbf{x}|^{n}}\right| \\
& \left.\quad \leq\left.\frac{2^{n}}{|\mathbf{x}|^{2 n}}| | \mathbf{x}\right|^{n}-|\mathbf{x}-\mathbf{y}|^{n} \right\rvert\, \\
& \leq \frac{2^{n}}{|\mathbf{x}|^{2 n}}|\mathbf{y}|\left[|\mathbf{x}|^{n-1}+|\mathbf{x}|^{n-2}|\mathbf{x}-\mathbf{y}|+\right. \\
& \left.\cdots+|\mathbf{x}||\mathbf{x}-\mathbf{y}|^{n-2}+|\mathbf{x}-\mathbf{y}|^{n-1}\right]
\end{aligned}
$$

$$
\leq \frac{2^{n}|\mathbf{y}| C(n)|\mathbf{x}|^{n-1}}{|\mathbf{x}|^{2 n}}=\frac{C(n) 2^{n}|\mathbf{y}|}{|\mathbf{x}|^{n+1}}
$$

Thus

$$
\begin{gather*}
\int_{|\mathbf{x}|>2|\mathbf{y}|}\left|\Omega(\mathbf{x})\left(\frac{1}{|\mathbf{x}-\mathbf{y}|^{n}}-\frac{1}{|\mathbf{x}|^{n}}\right)\right| d x \\
\leq \quad C(n) \int_{|\mathbf{x}|>2|\mathbf{y}|} \frac{|\mathbf{y}|}{|\mathbf{x}|^{n+1}} d x \\
\leq C(n) \int_{|\mathbf{u}|>2} \frac{1}{|\mathbf{u}|^{n+1}} d u . \tag{33.4.63}
\end{gather*}
$$

From 33.4.62 and 33.4.63,

$$
\int_{|\mathbf{x}|>2|\mathbf{y}|}|K(\mathbf{x}-\mathbf{y})-K(\mathbf{x})| d x \leq C(n, \operatorname{Lip} \Omega) .
$$

This proves the theorem.

### 33.5 Helmholtz Decompositions

It turns out that every vector field which has its components in $L^{p}$ can be written as a sum of a gradient and a vector field which has zero divergence. This is a very remarkable result, especially when applied to vector fields which are only in $L^{p}$. Recall that for $u$ a function of $n$ variables, $\Delta u=\sum_{i=1}^{n} \frac{\partial^{2} u}{\partial x_{i}^{2}}$.
Definition 33.5.1 Define

$$
\Phi(\mathbf{y}) \equiv\left\{\begin{array}{l}
-\frac{1}{a_{1}} \ln |\mathbf{y}|, \text { if } n=2 \\
\frac{1}{(n-2) a_{n-1}}|\mathbf{y}|^{2-n}, \text { if } n>2
\end{array}\right.
$$

where $a_{k}$ denotes the area of the unit sphere, $S^{k}$.
Then it is routine to verify $\Delta \Phi=0$ away from 0 . In fact, if $n>2$,

$$
\begin{equation*}
\Phi_{, i i}(\mathbf{y})=C_{n}\left[\frac{1}{|\mathbf{y}|^{n}}-n \frac{y_{i}^{2}}{|\mathbf{y}|^{n+2}}\right], \Phi_{, i j}(\mathbf{y})=C_{n} \frac{y_{i} y_{j}}{|\mathbf{y}|^{n+2}} \tag{33.5.64}
\end{equation*}
$$

while if $n=2$,

$$
\begin{gathered}
\Phi_{, 22}(\mathbf{y})=C_{2} \frac{y_{1}^{2}-y_{2}^{2}}{\left(y_{1}^{2}+y_{2}^{2}\right)^{2}}, \Phi_{, 11}(\mathbf{y})=C_{2} \frac{y_{2}^{2}-y_{1}^{2}}{\left(y_{1}^{2}+y_{2}^{2}\right)^{2}} \\
\Phi_{, i j}(\mathbf{y})=C_{2} \frac{y_{1} y_{2}}{\left(y_{1}^{2}+y_{2}^{2}\right)^{2}}
\end{gathered}
$$

Also,

$$
\begin{equation*}
\nabla \Phi(\mathbf{y})=\frac{-\mathbf{y}}{a_{n-1}|\mathbf{y}|^{n}} \tag{33.5.65}
\end{equation*}
$$

In the above the subscripts following a comma denote partial derivatives.

Lemma 33.5.2 For $n \geq 2$

$$
\Phi_{, i j}(\mathbf{y})=\frac{\Omega_{i j}(\mathbf{y})}{|\mathbf{y}|^{n}}
$$

where

$$
\begin{gather*}
\Omega_{i j} \text { is Lipschitz continuous on } S^{n-1},  \tag{33.5.66}\\
\Omega_{i j}(\lambda \mathbf{y})=\Omega_{i j}(\mathbf{y}) \tag{33.5.67}
\end{gather*}
$$

for all $\lambda>0$, and

$$
\begin{equation*}
\int_{S^{n-1}} \Omega_{i j}(\mathbf{y}) d \sigma=0 \tag{33.5.68}
\end{equation*}
$$

Proof:
Proof: The case $n=2$ is left to the reader. 33.5.66 and 33.5.67 are obvious from the above descriptions. It remains to verify 33.5 .68. If $n \geq 3$ and $i \neq j$, then this formula is also clear from 33.5.64. Thus consider the case when $n \geq 3$ and $i=j$. By symmetry,

$$
I \equiv \int_{S^{n-1}} 1-n y_{i}^{2} d \sigma=\int_{S^{n-1}} 1-n y_{j}^{2} d \sigma
$$

Hence

$$
\begin{aligned}
n I & =\sum_{i=1}^{n} \int_{S^{n-1}} 1-n y_{i}^{2} d \sigma=\int_{S^{n-1}}\left(n-n \sum_{i} y_{i}^{2}\right) d \sigma \\
& =\int_{S^{n-1}}(n-n) d \sigma=0 .
\end{aligned}
$$

This proves the lemma.
Let $U$ be a bounded open set locally on one side of its boundary having Lipschitz boundary so the divergence theorem holds and let $B=B(\mathbf{0}, R)$ where

$$
B \supseteq U-U \equiv\{\mathbf{x}-\mathbf{y}: \mathbf{x} \in U, \mathbf{y} \in U\}
$$

Let $f \in C_{c}^{\infty}(U)$ and define for $\mathbf{x} \in U$,

$$
u(\mathbf{x}) \equiv \int_{B} \Phi(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) d y=\int_{U} \Phi(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y
$$

Let $h(\mathbf{y})=f(\mathbf{x}-\mathbf{y})$. Then since $\Phi$ is in $L^{1}(B)$,

$$
\begin{aligned}
& \Delta u(\mathbf{x})=\int_{B} \Phi(\mathbf{y}) \Delta f(\mathbf{x}-\mathbf{y}) d y=\int_{B} \Phi(\mathbf{y}) \Delta h(\mathbf{y}) d y \\
&=\int_{B \backslash B(\mathbf{0}, \varepsilon)} \nabla \cdot(\nabla h(\mathbf{y}) \Phi(\mathbf{y}))-\nabla \Phi(\mathbf{y}) \cdot \nabla h(\mathbf{y}) d y \\
&+\int_{B(\mathbf{0}, \varepsilon)} \Phi(\mathbf{y}) \Delta h(\mathbf{y}) d y
\end{aligned}
$$

The last term converges to 0 as $\varepsilon \rightarrow 0$ because $\Phi$ is in $L^{1}$ and $\Delta h$ is bounded. Since $\operatorname{spt}(h) \subseteq B$, the divergence theorem implies

$$
\begin{equation*}
\Delta u(\mathbf{x})=-\int_{\partial B(\mathbf{0}, \varepsilon)} \Phi(\mathbf{y}) \nabla h(\mathbf{y}) \cdot \mathbf{n} d \sigma-\int_{B \backslash B(\mathbf{0}, \varepsilon)} \nabla \Phi(\mathbf{y}) \cdot \nabla h(\mathbf{y}) d y+e(\varepsilon) \tag{33.5.69}
\end{equation*}
$$

where here and below, $e(\varepsilon) \rightarrow 0$ as $\varepsilon \rightarrow 0$. The first term in 33.5 .69 converges to 0 as $\varepsilon \rightarrow 0$ because

$$
\left|\int_{\partial B(\mathbf{0}, \varepsilon)} \Phi(\mathbf{y}) \nabla h(\mathbf{y}) \cdot \mathbf{n} d \sigma\right| \leq\left\{\begin{array}{l}
C_{n h} \frac{1}{\varepsilon^{n-2}} \varepsilon^{n-1}=C_{n h} \varepsilon \text { if } n>2 \\
C_{h}(\ln \varepsilon) \varepsilon \text { if } n=2
\end{array}\right.
$$

and since $\Delta \Phi(\mathbf{y})=0$,

$$
\nabla \Phi(\mathbf{y}) \cdot \nabla h(\mathbf{y})=\nabla \cdot(\nabla \Phi(\mathbf{y}) h(\mathbf{y}))
$$

Consequently

$$
\Delta u(\mathbf{x})=-\int_{B \backslash B(\mathbf{0}, \varepsilon)} \nabla \cdot(\nabla \Phi(\mathbf{y}) h(\mathbf{y})) d y+e(\varepsilon)
$$

Thus, by the divergence theorem, 33.5.65, and the definition of $h$ above,

$$
\begin{aligned}
\Delta u(\mathbf{x}) & =\int_{\partial B(\mathbf{0}, \varepsilon)} f(\mathbf{x}-\mathbf{y}) \nabla \Phi(\mathbf{y}) \cdot \mathbf{n} d \sigma+e(\varepsilon) \\
& =\int_{\partial B(\mathbf{0}, \varepsilon)} f(\mathbf{x}-\mathbf{y})\left(-\frac{\mathbf{y}}{a_{n-1}|\mathbf{y}|^{n}}\right) \cdot\left(-\frac{\mathbf{y}}{|\mathbf{y}|}\right) d \sigma+e(\varepsilon) \\
& =-\left(\int_{\partial B(\mathbf{0}, \varepsilon)} f(\mathbf{x}-\mathbf{y}) d \sigma(y)\right) \frac{1}{a_{n-1} \varepsilon^{n-1}}+e(\varepsilon)
\end{aligned}
$$

Letting $\varepsilon \rightarrow 0$,

$$
-\Delta u(\mathbf{x})=f(\mathbf{x})
$$

This proves the following lemma.
Lemma 33.5.3 Let $U$ be a bounded open set in $\mathbb{R}^{n}$ with Lipschitz boundary and let $B \supseteq$ $U-U$ where $B=B(\mathbf{0}, R)$. Let $f \in C_{c}^{\infty}(U)$. Then for $\mathbf{x} \in U$,

$$
\int_{B} \Phi(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) d y=\int_{U} \Phi(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y
$$

and it follows that if $u$ is given by one of the above formulas, then for all $x \in U$,

$$
-\Delta u(\mathbf{x})=f(\mathbf{x})
$$

Theorem 33.5.4 Let $f \in L^{p}(U)$. Then there exists $u \in L^{p}(U)$ whose weak derivatives are also in $L^{p}(U)$ such that in the sense of weak derivatives,

$$
-\Delta u=f
$$

It is given by

$$
\begin{equation*}
u(\mathbf{x})=\int_{B} \Phi(\mathbf{y}) \tilde{f}(\mathbf{x}-\mathbf{y}) d y=\int_{U} \Phi(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y \tag{33.5.70}
\end{equation*}
$$

where $\tilde{f}$ denotes the zero extension of $f$ off of $U$.

Proof: Let $f \in L^{p}(U)$ and let $f_{k} \in C_{c}^{\infty}(U),\left\|f_{k}-f\right\|_{L^{p}(U)} \rightarrow 0$, and let $u_{k}$ be given by 33.5.70 with $f_{k}$ in place of $f$. Then by Minkowski's inequality,

$$
\begin{aligned}
\left\|u-u_{k}\right\|_{L^{p}(U)} & =\left(\int_{U}\left(\int_{B} \Phi(\mathbf{y})\left|\widetilde{f}(\mathbf{x}-\mathbf{y})-f_{k}(\mathbf{x}-\mathbf{y})\right| d y\right)^{p} d x\right)^{1 / p} \\
& \leq\left(\int_{B}|\Phi(\mathbf{y})|\left(\int_{U}\left|\widetilde{f}(\mathbf{x}-\mathbf{y})-f_{k}(\mathbf{x}-\mathbf{y})\right|^{p} d x\right)^{1 / p} d y\right) \\
& \leq \int_{B}|\Phi(\mathbf{y})| d y| | f-f_{k}\left\|_{L^{p}(U)}=C(B)\right\| f-f_{k} \|_{L^{p}(U)}
\end{aligned}
$$

and so $u_{k} \rightarrow u$ in $L^{p}(U)$. Also

$$
u_{k, i}(\mathbf{x})=\int_{U} \Phi_{, i}(\mathbf{x}-\mathbf{y}) f_{k}(\mathbf{y}) d y=\int_{B} f_{k}(\mathbf{x}-\mathbf{y}) \Phi_{, i}(\mathbf{y}) d y
$$

Now let

$$
\begin{equation*}
w_{i} \equiv \int_{B} \widetilde{f}(\mathbf{x}-\mathbf{y}) \Phi_{, i}(\mathbf{y}) d y \tag{33.5.71}
\end{equation*}
$$

and since $\Phi_{, i} \in L^{1}(B)$, it follows from Minkowski's inequality that

$$
\begin{aligned}
& \left\|u_{k, i}-w_{i}\right\|_{L^{p}(U)} \\
\leq & \left(\int_{U}\left(\int_{B}\left|f_{k}(\mathbf{x}-\mathbf{y})-\widetilde{f}(\mathbf{x}-\mathbf{y})\right|\left|\Phi_{, i}(\mathbf{y})\right| d y\right)^{p} d x\right)^{1 / p} \\
\leq & \int_{B}\left|\Phi_{, i}(\mathbf{y})\right|\left(\int_{U}\left|f_{k}(\mathbf{x}-\mathbf{y})-\widetilde{f}(\mathbf{x}-\mathbf{y})\right|^{p} d x\right)^{1 / p} d y \\
\leq & C(B)\left\|f_{k}-f\right\|_{L^{p}(U)}
\end{aligned}
$$

and so $u_{k, i} \rightarrow w_{i}$ in $L^{p}(U)$.
Now let $\phi \in C_{c}^{\infty}(U)$. Then

$$
\int_{U} w_{i} \phi d x=-\lim _{k \rightarrow \infty} \int_{U} u_{k} \phi_{, i} d x=-\int_{U} u \phi_{, i} d x
$$

Thus $u_{, i}=w_{i} \in L^{p}\left(\mathbb{R}^{n}\right)$ and so if $\phi \in C_{c}^{\infty}(U)$,

$$
\int_{U} f \phi d x=\lim _{k \rightarrow \infty} \int_{U} f_{k} \phi d x=\lim _{k \rightarrow \infty} \int_{U} \nabla u_{k} \cdot \nabla \phi d x=\int_{U} \nabla u \cdot \nabla \phi d x
$$

and so $-\Delta u=f$ as claimed. This proves the theorem.
One could also ask whether the second weak partial derivatives of $u$ are in $L^{p}(U)$. This is where the theory singular integrals is used. Recall from 33.5 .70 and 33.5 .71 along with the argument of the above lemma, that if $u$ is given by 33.5.70, then $u_{, i}$ is given by 33.5.71 which equals

$$
\int_{U} \Phi_{, i}(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y
$$

Lemma 33.5.5 Let $f \in L^{p}(U)$ and let

$$
w_{i}(\mathbf{x}) \equiv \int_{U} \Phi_{, i}(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y
$$

Then $w_{i, j} \in L^{p}(U)$ for each $j=1 \cdots n$ and the map $f \rightarrow w_{i, j}$ is continuous and linear on $L^{p}(U)$.

Proof: First let $f \in C_{c}^{\infty}(U)$. For such $f$,

$$
\begin{aligned}
w_{i}(\mathbf{x}) & =\int_{U} \Phi_{, i}(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y=\int_{\mathbb{R}^{n}} \Phi_{, i}(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y \\
& =\int_{\mathbb{R}^{n}} \Phi_{, i}(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) d y=\int_{B} \Phi_{, i}(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) d y
\end{aligned}
$$

and

$$
\begin{aligned}
w_{i, j}(\mathbf{x}) & =\int_{B} \Phi_{, i}(\mathbf{y}) f_{, j}(\mathbf{x}-\mathbf{y}) d y \\
& =\int_{B \backslash B(\mathbf{0}, \boldsymbol{\varepsilon})} \Phi_{, i}(\mathbf{y}) f_{, j}(\mathbf{x}-\mathbf{y}) d y+\int_{B(\mathbf{0}, \boldsymbol{\varepsilon})} \Phi_{, i}(\mathbf{y}) f_{, j}(\mathbf{x}-\mathbf{y}) d y
\end{aligned}
$$

The second term converges to 0 because $f_{, j}$ is bounded and by 33.5.65, $\Phi_{, i} \in L_{l o c}^{1}$. Thus

$$
\begin{aligned}
w_{i, j}(\mathbf{x}) & =\int_{B \backslash B(\mathbf{0}, \varepsilon)} \Phi_{, i}(\mathbf{y}) f_{, j}(\mathbf{x}-\mathbf{y}) d y+e(\varepsilon) \\
& =\int_{B \backslash B(\mathbf{0}, \varepsilon)}-\left(\Phi_{, i}(\mathbf{y}) f(\mathbf{x}-\mathbf{y})\right)_{, j}+\Phi_{, i j}(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) d y+e(\varepsilon)
\end{aligned}
$$

where $e(\varepsilon) \rightarrow 0$ as $\varepsilon \rightarrow 0$. Using the divergence theorem, this yields

$$
w_{i, j}(\mathbf{x})=\int_{\partial B(\mathbf{0}, \varepsilon)} \Phi_{, i}(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) n_{j} d \sigma+\int_{B \backslash B(\mathbf{0}, \varepsilon)} \Phi_{, i j}(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) d y+e(\varepsilon) .
$$

Consider the first term on the right. This term equals, after letting $\mathbf{y}=\varepsilon \mathbf{z}$,

$$
\begin{aligned}
\varepsilon^{n-1} \int_{\partial B(\mathbf{0}, 1)} \Phi_{, i}(\varepsilon \mathbf{z}) f(\mathbf{x}-\varepsilon \mathbf{z}) n_{j} d \sigma & =C_{n} \varepsilon^{n-1} \int_{\partial B(\mathbf{0}, 1)} \varepsilon^{1-n} z_{i} z_{j} f(\mathbf{x}-\varepsilon \mathbf{z}) d \sigma(z) \\
& =C_{n} \int_{\partial B(\mathbf{0}, 1)} z_{i} z_{j} f(\mathbf{x}-\varepsilon \mathbf{z}) d \sigma(z)
\end{aligned}
$$

and this converges to 0 if $i \neq j$ and it converges to

$$
C_{n} f(\mathbf{x}) \int_{\partial B(\mathbf{0}, 1)} z_{i}^{2} d \sigma(z)
$$

if $i=j$. Thus

$$
w_{i, j}(\mathbf{x})=C_{n} \delta_{i j} f(\mathbf{x})+\int_{B \backslash B(\mathbf{0}, \varepsilon)} \Phi_{, i j}(\mathbf{y}) f(\mathbf{x}-\mathbf{y}) d y+e(\varepsilon)
$$

Letting

$$
\Phi_{i j}^{\varepsilon} \equiv\left\{\begin{array}{l}
0 \text { if }|\mathbf{y}|<\varepsilon \\
\Phi_{, i j}(\mathbf{y}) \text { if }|\mathbf{y}| \geq \varepsilon
\end{array}\right.
$$

it follows

$$
w_{i, j}(\mathbf{x})=C_{n} \delta_{i j} f(\mathbf{x})+\Phi_{i j}^{\varepsilon} * \widetilde{f}(\mathbf{x})+e(\varepsilon)
$$

By the theory of singular integrals, there exists a continuous linear map,

$$
K_{i j} \in \mathscr{L}\left(L^{p}\left(\mathbb{R}^{n}\right), L^{p}\left(\mathbb{R}^{n}\right)\right)
$$

such that

$$
K_{i j} f \equiv \lim _{\varepsilon \rightarrow 0} \Phi_{i j}^{\varepsilon} * f
$$

Therefore, letting $\varepsilon \rightarrow 0$,

$$
w_{i, j}=C_{n} \delta_{i j} f+K_{i j} \widetilde{f}
$$

whenever $f \in C_{c}^{\infty}(U)$.
Now let $f \in L^{p}(U)$, let

$$
\left\|f_{k}-f\right\|_{L^{p}(U)} \rightarrow 0
$$

where $f_{k} \in C_{c}^{\infty}(U)$, and let

$$
w_{i}^{k}(\mathbf{x})=\int_{U} \Phi_{, i}(\mathbf{x}-\mathbf{y}) f_{k}(\mathbf{y}) d y
$$

Then it follows as before that $w_{i}^{k} \rightarrow w_{i}$ in $L^{p}(U)$ and

$$
w_{i, j}^{k}=C_{n} \delta_{i j} f_{k}+K_{i j} \widetilde{f}_{k} .
$$

Now let $\phi \in C_{c}^{\infty}(U)$.

$$
\begin{aligned}
w_{i, j}(\phi) & \equiv-\int_{U} w_{i} \phi_{, j} d x=-\lim _{k \rightarrow \infty} \int_{U} w_{i}^{k} \phi_{, j} d x \\
& =\lim _{k \rightarrow \infty} \int_{U} w_{i, j}^{k} \phi d x=\lim _{k \rightarrow \infty} \int_{U}\left(C_{n} \delta_{i j} \widetilde{f}_{k}+K_{i j} \widetilde{f}_{k}\right) \phi d x \\
& =\int_{U}\left(C_{n} \delta_{i j} \widetilde{f}+K_{i j} \widetilde{f}\right) \phi d x
\end{aligned}
$$

It follows

$$
w_{i, j}=C_{n} \delta_{i j} \tilde{f}+K_{i j} \tilde{f}
$$

and this proves the lemma.
Corollary 33.5.6 In the situation of Theorem 33.5.4, all weak derivatives of $u$ of order 2 are in $L^{p}(U)$ and also $f \rightarrow u_{, i j}$ is a continuous map.

Proof:

$$
u_{, i}(\mathbf{x})=\int_{U} \Phi_{, i}(\mathbf{x}-\mathbf{y}) f(\mathbf{y}) d y
$$

and so $u_{, i j} \in L^{p}(U)$ and $f \rightarrow u_{, i j}$ is continuous by Lemma 33.5.5.
With this preparation, it is possible to consider the Helmholtz decomposition. Let $\mathbf{F} \in$ $L^{p}\left(U ; \mathbb{R}^{n}\right)$ and define

$$
\begin{equation*}
\phi(\mathbf{x}) \equiv \int_{U} \nabla \Phi(\mathbf{x}-\mathbf{y}) \cdot \mathbf{F}(\mathbf{y}) d y \tag{33.5.72}
\end{equation*}
$$

Then by Lemma 33.5.5,

$$
\phi_{, j}=C_{n} \widetilde{F}_{j}+\sum_{i} K_{i j} \widetilde{F}_{i} \in L^{p}\left(\mathbb{R}^{n}\right)
$$

and the mapping $\mathbf{F} \rightarrow \nabla \phi$ is continuous from $L^{p}\left(U ; \mathbb{R}^{n}\right)$ to $L^{p}\left(U ; \mathbb{R}^{n}\right)$.
Now suppose $\mathbf{F} \in C_{c}^{\infty}\left(U ; \mathbb{R}^{n}\right)$. Then

$$
\begin{aligned}
\phi(\mathbf{x}) & =\int_{U} \sum_{i=1}^{n}-\frac{\partial}{\partial y^{i}}\left(\Phi(\mathbf{x}-\mathbf{y}) F_{i}(\mathbf{y})\right)+\Phi(\mathbf{x}-\mathbf{y}) \nabla \cdot \mathbf{F}(\mathbf{y}) d y \\
& =\int_{U} \Phi(\mathbf{x}-\mathbf{y}) \nabla \cdot \mathbf{F}(\mathbf{y}) d y
\end{aligned}
$$

and so by Lemma 33.5.3,

$$
\nabla \cdot \nabla \phi=\Delta \phi=-\nabla \cdot \mathbf{F}
$$

This continues to hold in the sense of weak derivatives if $\mathbf{F}$ is only in $L^{p}\left(U ; \mathbb{R}^{n}\right)$ because by Minkowski's inequality and 33.5 .72 the $\operatorname{map} \mathbf{F} \rightarrow \phi$ is continuous. Also note that for $\mathbf{F}$ $\in C_{c}^{\infty}\left(U ; \mathbb{R}^{n}\right)$,

$$
\phi(\mathbf{x})=\int_{B} \Phi(\mathbf{y}) \nabla \cdot \mathbf{F}(\mathbf{x}-\mathbf{y}) d y
$$

Next define $\pi: L^{p}\left(U ; \mathbb{R}^{n}\right) \rightarrow L^{p}\left(U ; \mathbb{R}^{n}\right)$ by

$$
\pi \mathbf{F}=-\nabla \phi, \phi(\mathbf{x})=\int_{U} \nabla \Phi(\mathbf{x}-\mathbf{y}) \cdot \mathbf{F}(\mathbf{y}) d y
$$

It was already shown that $\pi$ is continuous, linear, and $\nabla \cdot \pi \mathbf{F}=\nabla \cdot \mathbf{F}$. It is also true that $\pi$ is a projection. To see this, let $\mathbf{F} \in C_{c}^{\infty}\left(U ; \mathbb{R}^{n}\right)$. Then for $B$ large enough,

$$
\begin{aligned}
\pi^{2} \mathbf{F}(\mathbf{x}) & =-\nabla \int_{B} \Phi(\mathbf{z}) \nabla \cdot \pi \mathbf{F}(\mathbf{x}-\mathbf{z}) d z \\
& =-\nabla \int_{B} \Phi(\mathbf{z}) \nabla \cdot \nabla \int_{B} \Phi(\mathbf{w}) \nabla \cdot \mathbf{F}(\mathbf{x}-\mathbf{z}-\mathbf{w}) d w d z \\
& =-\nabla \int_{B} \Phi(\mathbf{z}) \nabla \cdot \mathbf{F}(\mathbf{x}-\mathbf{z}) d z=\pi \mathbf{F}(\mathbf{x})
\end{aligned}
$$

Since $\pi$ is continuous and $C_{c}^{\infty}\left(U ; \mathbb{R}^{n}\right)$ is dense in $L^{p}\left(U ; \mathbb{R}^{n}\right)$, it follows that $\pi^{2} \mathbf{F}=\pi \mathbf{F}$ for all $\mathbf{F} \in L^{p}\left(U ; \mathbb{R}^{n}\right)$. This proves the following theorem which is the Helmholtz decomposition.

Theorem 33.5.7 There exists a continuous projection

$$
\pi: L^{p}\left(U ; \mathbb{R}^{n}\right) \rightarrow L^{p}\left(U ; \mathbb{R}^{n}\right)
$$

such that $\pi \mathbf{F}$ is a gradient and

$$
\nabla \cdot(\mathbf{F}-\pi \mathbf{F})=0
$$

in the sense of weak derivatives.
Note this theorem shows that any $L^{p}$ vector field is the sum of a gradient and a part which is divergence free. $\mathbf{F}=\mathbf{F}-\pi \mathbf{F}+\pi \mathbf{F}$.

## Chapter 34

## Gelfand Triples And Related Stuff

Let $H$ be a separable real Hilbert space and let $V \subseteq H$ be a separable Banach space which is embedded continuously into $H$ and which is also dense in $H$. Then identifying $H$ and $H^{\prime}$ you can write

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

This is called a Gelfand triple. If $V$ is reflexive, you could conclude separability of $V$ from the separability of $H$. However, if $V$ is not reflexive, this might not happen. For example, you could take $V=L^{\infty}(0,1)$ and $H=L^{2}(0,1)$.

Proposition 34.0.1 Suppose $V$ is reflexive and a subset of $H$ a separable Hilbert space with the inclusion map continuous. Suppose also that $V$ is dense in $H$. Then identifying $H$ and $H^{\prime}$, it follows that $H$ is dense in $V^{\prime}$ and $V$ is separable.

Proof: If $H$ is not dense in $V^{\prime}$, then by the Hahn Banach theorem, there exists $\phi^{* *} \in V^{\prime \prime}$ such that $\phi^{* *}(H)=0$ but $\phi^{* *}\left(\phi^{*}\right) \neq 0$ for some $\phi^{*} \in V^{\prime} \backslash \bar{H}$. Since $V$ is reflexive there exists $v \in V$ such that $\phi^{* *}=J v$ for $J$ the standard mapping from $V$ to $V^{\prime \prime}$. Thus

$$
\phi^{* *}(h) \equiv\langle h, v\rangle \equiv(v, h)_{H}=0
$$

for all $h \in H$. Therefore, $v=0$ and so $J v=0=\phi^{* *}$ which contradicts $\phi^{* *}\left(\phi^{*}\right) \neq 0$. Therefore, $H$ is dense in $V^{\prime}$. Now by Theorem 21.1.16 which says separability of the dual space implies separability of the space, it follows $V$ is separable as claimed. This proves the proposition.

From now on, it is assumed $V$ and $V^{\prime}$ are both separable and that $H$ is dense in $V^{\prime}$. This is summarized in the following definition.

Definition 34.0.2 $V, H, V^{\prime}$ will be called a Gelfand triple if $V, V^{\prime}$ are separable, $V \subseteq H$ with the inclusion map continuous, $H=H^{\prime}$, and $H=H^{\prime}$ is dense in $V^{\prime}$.

What about the Borel sets on $V$ and $H$ ?
Proposition 34.0.3 Denote by $\mathscr{B}(X)$ the Borel sets of $X$ where $X$ is any separable Banach space. Then

$$
\mathscr{B}(X)=\sigma\left(X^{\prime}\right)
$$

Here $\sigma\left(X^{\prime}\right)$ is the smallest $\sigma$ algebra such that each $\phi \in X^{\prime}$ is measurable. Also in the context of the above definition, $\mathscr{B}(V)=\sigma\left(i^{*} H^{\prime}\right)$ because $H^{\prime}$ is dense in $V^{\prime}$. Here $i^{*}$ is the restriction to $V$ so that $i^{*} h(v) \equiv h(v) \equiv(h, v)_{H}$ for all $v \in V$ and $\sigma\left(i^{*} H^{\prime}\right)$ denotes the smallest $\sigma$ algebra such that $i^{*} h$ is measurable for each $h \in H^{\prime}$.

Proof: By Lemma 21.1.6 there exists a countable subset of the unit ball in $X^{\prime}$

$$
\left\{\phi_{n}\right\}_{n=1}^{\infty}=D^{\prime}
$$

such that

$$
\|v\|_{X}=\sup \left\{|\phi(v)|: \phi \in D^{\prime}\right\}
$$

Consider a closed ball $\overline{B\left(v_{0}, r\right)}$ in $X$. This equals

$$
\left\{v \in X: \sup _{n}\left|\phi_{n}(v)-\phi_{n}\left(v_{0}\right)\right| \leq r\right\}=\cap_{n=1}^{\infty} \phi_{n}^{-1}\left(\overline{B\left(\phi_{n}\left(v_{0}\right), r\right)}\right)
$$

and this last set is in $\sigma\left(D^{\prime}\right)$. Therefore, every closed ball is in $\sigma\left(D^{\prime}\right)$ which implies every open ball is also in $\sigma\left(D^{\prime}\right)$ since open balls are the countable union of closed balls. Since $X$ is separable, it follows every open set is the countable union of balls and so every open set is in $\sigma\left(D^{\prime}\right)$. It follows $\mathscr{B}(X) \subseteq \sigma\left(D^{\prime}\right) \subseteq \sigma\left(X^{\prime}\right)$. On the other hand, every $\phi \in X^{\prime}$ is continuous and so it is Borel measurable. Hence $\sigma\left(X^{\prime}\right) \subseteq \mathscr{B}(X)$.

Now consider the last claim. From Lemma 21.1.6 and density of $H^{\prime}=H$ in $V^{\prime}$, it can be assumed $D^{\prime} \subseteq H=H^{\prime}$. Therefore, from the first part of the argument

$$
\mathscr{B}(V) \subseteq \sigma\left(D^{\prime}\right) \subseteq \sigma\left(i^{*} H^{\prime}\right)
$$

Also each $i^{*} h$ is continuous on $V$ so in fact, equality holds in the above because $\sigma\left(i^{*} H^{\prime}\right) \subseteq$ $\mathscr{B}(V)$. This proves the proposition.

Next I want to verify that $V$ is in $\mathscr{B}(H)$. This will be true if $V$ is reflexive. More generally, here is an interesting result.

Proposition 34.0.4 Let $X \subseteq Y, X$ dense in $Y$ and suppose $X, Y$ are Banach spaces and that $X$ is reflexive. Then $X \in \mathscr{B}(Y)$.

Proof: Define the functional

$$
\phi(x) \equiv\left\{\begin{array}{l}
\|x\|_{X} \text { if } x \in X \\
\infty \text { if } x \in Y \backslash X
\end{array}\right.
$$

Then $\phi$ is lower semicontinuous on $Y$. Here is why. Suppose $(x, a) \notin \mathrm{epi}(\phi)$ so that $a<$ $\phi(x)$. I need to verify this situation persists for $(x, b)$ near $(x, a)$. If this is not so, there exists $x_{n} \rightarrow x$ and $a_{n} \rightarrow a$ such that $a_{n} \geq \phi\left(x_{n}\right)$. If $\liminf _{n \rightarrow \infty} \phi\left(x_{n}\right)<\infty$, then there exists a subsequence still denoted by $n$ such that $\left\|x_{n}\right\|_{X}$ is bounded. Then by the Eberlein Smulian theorem, there exists a further subsequence such that $x_{n}$ converges weakly in $X$ to some $z$. Now since $X$ is dense in $Y$ it follows $Y^{\prime}$ can be considered a subspace of $X^{\prime}$ and so for $f \in Y^{\prime}$

$$
f\left(x_{n}\right) \rightarrow f(z), f\left(x_{n}\right) \rightarrow f(x)
$$

and so $f(z-x)=0$ for all $f \in Y^{\prime}$ which requires $z=x$. Now $x \rightarrow\|x\|_{X}$ is convex and lower semicontinuous on $X$ so it follows from Corollary 18.2.12

$$
a=\lim \inf _{n \rightarrow \infty} a_{n} \geq \lim \inf _{n \rightarrow \infty} \phi\left(x_{n}\right) \geq \phi(x)>a
$$

which is a contradiction. If $\liminf _{n \rightarrow \infty} \phi\left(x_{n}\right)=\infty$, then

$$
\infty>a=\lim \inf _{n \rightarrow \infty} a_{n}=\infty
$$

another contradiction. Therefore, epi $(\phi)$ is closed and so $\phi$ is lower semicontinuous as claimed. Therefore,

$$
X=Y \backslash\left(\cap_{n=1}^{\infty} \phi^{-1}((n, \infty))\right)
$$

and since $\phi$ is lower semicontinuous, each $\phi^{-1}((n, \infty))$ is open. Hence $X$ is a Borel subset of $Y$. This proves the proposition.

### 34.1 An Unnatural Example

Recall Gelfand triples are of the form

$$
V \subseteq H \subseteq V^{\prime}
$$

where $H$ is a Hilbert space and $V$ is a Banach space contained in $H$ and each of the above inclusions is continuous and each space is dense in the next one. The standard example of a Gelfand triple is $H_{0}^{1}(D) \subseteq L^{2}(D) \subseteq\left(H_{0}^{1}(D)\right)^{\prime}$ with the convention that $L^{2}(D)$ is identified with its dual space. Thus for $f \in L^{2}(D), f$ is considered as something in $\left(H_{0}^{1}(D)\right)^{\prime}$ according to the rule

$$
\langle f, \phi\rangle \equiv(f, \phi)_{L^{2}(D)}
$$

This is a very pleasant thing to contemplate and it is natural and transparent. However, there are other ways to come up with a Gelfand triple which are much more perverse. The following is an example of such a thing along with an application. See [108] and references given there. I think this idea is due to Lions.

First consider the following situation.

$$
X \xrightarrow{\theta} Y
$$

where $\theta$ is continuous, linear and one to one and $X$ is a Banach space. Then $\theta(X) \subseteq Y$ and you could define

$$
\|\theta x\|_{\theta(X)} \equiv\|x\|_{X} .
$$

Then $\theta(X)$ can be considered the same thing as $X$ because $\theta$ preserves distances and all algebraic properties. Thus people write $X \subseteq Y$ to save space. In the above simple example, it is obvious what $\theta$ is. This is because the things in $H_{0}^{1}$ and things in $L^{2}$ are both functions defined on $D$ and we can simply take $\theta$ to be the identity map. However, you might have $H$ be the dual space of something. Thus it consists of bounded linear transformations defined on some Banach space. Then it becomes necessary to specify the manner in which vectors in $V$ can be considered as vectors of $H$.

Let $\infty>p \geq 2$. Then letting $D$ be a bounded open set, $H_{0}^{1}(D)$ embedds continuously into $L^{p^{\prime}}(D)$. That is

$$
\begin{equation*}
\|\phi\|_{L^{p^{\prime}}} \leq C\|\phi\|_{H_{0}^{1}} \tag{34.1.1}
\end{equation*}
$$

Here $\frac{1}{p^{\prime}}+\frac{1}{p}=1$. Also note that an equivalent inner product on $H_{0}^{1}(D)$ is

$$
(f, g)_{H_{0}^{1}} \equiv \int_{D} \nabla f \cdot \nabla g d x
$$

Then with respect to this inner product, the Riesz map is given by $-\Delta$.

$$
-\Delta: H_{0}^{1}(D) \rightarrow\left(H_{0}^{1}(D)\right)^{\prime}
$$

Thus a typical vector of $\left(H_{0}^{1}(D)\right)^{\prime}$ is of the form $-\Delta \phi$ where $\phi \in H_{0}^{1}(D)$ and the following hold.

$$
(\phi, \psi)_{H_{0}^{1}} \equiv\langle-\Delta \phi, \psi\rangle,(-\Delta \phi,-\Delta \psi)_{\left(H_{0}^{1}\right)^{\prime}} \equiv(\phi, \psi)_{H_{0}^{1}}=\langle-\Delta \psi, \phi\rangle
$$

The following is about the Gelfand triple

$$
V=L^{p}(D) \subseteq\left(H_{0}^{1}\right)^{\prime} \subseteq\left(L^{p}(D)\right)^{\prime}
$$

Lemma 34.1.1 It is possible to consider $L^{p}(D) \equiv V$ as a dense subspace of $\left(H_{0}^{1}\right)^{\prime} \equiv H$ as follows. For $f \in L^{p}(D)$ and $\phi \in H_{0}^{1}(D)$,

$$
\langle f, \phi\rangle \equiv \int_{D} f(x) \phi(x) d x
$$

One can also consider $H \equiv\left(H_{0}^{1}\right)^{\prime}$ as a dense subspace of $\left(L^{p}(D)\right)^{\prime} \equiv V^{\prime}$ as follows. For $-\Delta \phi \in H$ and $f \in L^{p}(D)$,

$$
\langle-\Delta \phi, f\rangle \equiv(-\Delta \phi, f)_{H} \equiv\langle f, \phi\rangle
$$

$-\Delta$ maps $H_{0}^{1}(D)$ to $H \equiv\left(H_{0}^{1}\right)^{\prime} \subseteq V^{\prime} .-\Delta$ can be extended to yield a map $-\Delta_{1}$ from $L^{p^{\prime}}(D)$ to $V^{\prime}$.

$$
\begin{aligned}
& H_{0}^{1}(D) \xrightarrow{-\Delta}\left(H_{0}^{1}\right)^{\prime} \\
& L^{p^{\prime}}(D)=V \xrightarrow{-\Delta_{1}} V^{\prime}
\end{aligned}
$$

Proof: First of all, note that by 34.1.1

$$
|\langle f, \phi\rangle| \leq\|f\|_{L^{p}}\|\phi\|_{L^{p^{\prime}}} \leq C\|f\|_{L^{p}}\|\phi\|_{H_{0}^{1}}
$$

and so it is certainly possible to consider $L^{p} \subseteq H \equiv\left(H_{0}^{1}\right)^{\prime}$ as just claimed. Now why can $L^{p}(D)$ be considered dense in $H \equiv\left(H_{0}^{1}\right)^{\prime}$ ? If it isn't dense, then there exists $\psi \in$ $H_{0}^{1}(D), \psi \neq 0$ such that

$$
(-\Delta \psi, f)_{H}=0
$$

for all $f \in L^{p}(D)$. However, the above would say that for all $f \in L^{p}$,

$$
(-\Delta \psi, f)_{H} \equiv\langle f, \psi\rangle \equiv \int_{D} f \psi=0
$$

But $\psi \in L^{p^{\prime}}(D)$ because $H_{0}^{1}(D)$ embedds continuously into $L^{p^{\prime}}(D)$ and so the above holding for all $f \in L^{p}(D)$ implies by the usual Riesz representation theorem that $\psi=0$ contrary to the way $\psi$ was chosen.

Now consider the next claim. For $-\Delta \phi \in H \equiv\left(H_{0}^{1}\right)^{\prime}$ and $f \in L^{p}(D)$ and from the first part

$$
|\langle-\Delta \phi, f\rangle| \equiv\left|(-\Delta \phi, f)_{H}\right| \equiv|\langle f, \phi\rangle| \leq C\|f\|_{L^{p}}\|\phi\|_{H_{0}^{1}(D)}
$$

Thus $-\Delta \phi \in H$ can be considered in $\left(L^{p}(D)\right)^{\prime}$. Why should $H$ be dense in $\left(L^{p}(D)\right)^{\prime}$ ? If it is not dense, then there exists $g^{*} \in\left(L^{p}(D)\right)^{\prime}$ which is not the limit of vectors of $H$. Then
since $L^{p}(D)$ is reflexive, an application of the Hahn Banach theorem shows there exists $f \in L^{p}(D)$ such that

$$
\begin{equation*}
\left\langle g^{*}, f\right\rangle_{\left(L^{p}(D)\right)^{\prime}, L^{p}(D)} \neq 0,\langle-\Delta \phi, f\rangle_{\left(L^{p}(D)\right)^{\prime}, L^{p}(D)}=0 \tag{34.1.2}
\end{equation*}
$$

for all $-\Delta \phi \in H$. However, it was just shown $H$ could be considered a subset of $\left(L^{p}(D)\right)^{\prime}$ in the manner described above. Therefore, the last equation in the above is of the form

$$
0=(-\Delta \phi, f)_{H}=\langle f, \phi\rangle=\int_{D} f \phi d x
$$

and since this holds for all $\phi \in H_{0}^{1}(D)$, it follows by density of $H_{0}^{1}(D)$ in $L^{p^{\prime}}(D)$, that $f=0$ and now this contradicts the inequality in 34.1.2.

Now $\Delta$ is defined on $H_{0}^{1}(D)$ and it delivers something in $\left(H_{0}^{1}\right)^{\prime} \equiv H$. Of course $H_{0}^{1}(D)$ is dense in $L^{p^{\prime}}(D)$. Can $\Delta$ be extended to all of $L^{p^{\prime}}(D)$ ? The answer is yes and it is more of the same given above. For $\phi \in H_{0}^{1}(D),-\Delta \phi \in H \subseteq\left(L^{p}(D)\right)^{\prime}$. Then by the above, for $\phi \in H_{0}^{1}(D)$ and $f \in L^{p}(D)$,

$$
\begin{gathered}
\langle-\Delta \phi, f\rangle \equiv\langle f, \phi\rangle \equiv \int_{D} f \phi d x \\
|\langle-\Delta \phi, f\rangle| \equiv|\langle f, \phi\rangle| \equiv\left|\int_{D} f \phi d s\right| \leq\|\phi\|_{L^{p^{\prime}(D)}}\|f\|_{L^{p}(D)}
\end{gathered}
$$

and so $-\Delta$ is a continuous linear mapping defined on a dense subspace $H_{0}^{1}(D)$ of $L^{p^{\prime}}(D)$ and so this does indeed extend to a continuous linear map defined on all of $L^{p^{\prime}}(D)$ given by the formula

$$
\langle-\Delta g, f\rangle \equiv \int_{D} f g d x
$$

This proves the lemma.
Thus letting $V \equiv L^{p}(D)$, and $H \equiv\left(H_{0}^{1}(D)\right)^{\prime}$, it follows $V \subseteq H \subseteq V^{\prime}$ is a Gelfand triple with the understanding of what it means for one space to be included in another described above. To emphasize the above, for $-\Delta \phi \in H, f \in L^{p}$,

$$
\langle-\Delta \phi, f\rangle \equiv(-\Delta \phi, f)_{H} \equiv\langle f, \phi\rangle \equiv \int_{D} f \phi d x
$$

More generally, for $g \in L^{p^{\prime}}(D),-\Delta g \in\left(L^{p}(D)\right)^{\prime}$ according to the rule

$$
\langle-\Delta g, f\rangle \equiv \int_{D} f g d x
$$

With this example of a Gelfand triple, one can define a "porous medium operator" $A: V \rightarrow V^{\prime}$. Let $\Psi$ be a real valued function defined on $\mathbb{R}$ which satisfies

$$
\begin{equation*}
\Psi \text { is continuous } \tag{34.1.3}
\end{equation*}
$$

$$
\begin{equation*}
(t-s)(\Psi(t)-\Psi(s)) \geq 0 \tag{34.1.4}
\end{equation*}
$$

There exists $p \geq 2, p<\infty$ and $\alpha \in(0, \infty)$ such that for all $s \in \mathbb{R}$

$$
\begin{equation*}
s \Psi(s) \geq \alpha|s|^{p}-c \tag{34.1.5}
\end{equation*}
$$

There exist $c_{3}, c_{4} \in(0, \infty)$ such that for all $s \in \mathbb{R}$

$$
\begin{equation*}
|\Psi(s)| \leq c_{4}+c_{3}|s|^{p-1} \tag{34.1.6}
\end{equation*}
$$

Note that 34.1.6 implies that if $v \in L^{p}(D)$, Then

$$
\int_{D}|\Psi(v)|^{p^{\prime}} d x \leq C \int_{D}\left(1+|v|^{p^{\prime}(p-1)}\right) d x=C \int_{D}\left(1+|v|^{p}\right) d x<\infty
$$

Thus for $v \in L^{p}(D), \Psi(v)$ is something you can do $\Delta$ to and obtain something in $V^{\prime}$. The porous medium operator $A: V \rightarrow V^{\prime}$ is given as follows.

$$
\langle A v, w\rangle_{V^{\prime}, V} \equiv\langle\Delta \Psi(v), w\rangle_{V^{\prime}, V} \equiv-\int_{D} \Psi(v) w d x
$$

What are the properties of $A$ ?

$$
\langle A(u+\lambda v), w\rangle \equiv-\int_{D} \Psi(u+\lambda v) w d x
$$

and this is easily seen to be a continuous function of $\lambda$ Thus $A$ is Hemicontinuous.

$$
\langle A(u)-A(v), u-v\rangle \equiv-\int_{D} \Psi(u)(u-v) d x+\int_{D} \Psi(v)(u-v) d x \leq 0
$$

Thus $-A$ is monotone. Also there is a coercivity estimate which is routine.

$$
\langle A(v), v\rangle \equiv-\int_{D} \Psi(v) v \leq \int_{D} c-\alpha|v|^{p} d x=C-\alpha\|v\|_{V}^{p}
$$

This operator also has a boundedness estimate.

$$
\begin{aligned}
& \|A(v)\|_{V^{\prime}} \equiv \sup _{\|w\|_{V} \leq 1}|\langle A(v), w\rangle| \equiv \sup _{\|w\|_{V} \leq 1}\left|\int_{D} \Psi(v) w\right| \\
& \leq \sup _{\|w\|_{V} \leq 1}\left(\int_{D}\left(c_{4}+c_{3}|v|^{p-1}\right) w d x\right) \\
& \leq\left(\int_{D} C\left(1+|v|^{p}\right) d x\right)^{1 / p^{\prime}} \leq C+C\left(\int_{D}|v|^{p} d x\right)^{1 / p^{\prime}} \\
& =C+C\|v\|_{V}^{p / p^{\prime}}=C+C\|v\|_{V}^{p-1} .
\end{aligned}
$$

Since $\Psi$ is continuous, it will also follow that $A$ is $\mathscr{B}(V)$ measurable. Consider

$$
u \rightarrow\langle A u, w\rangle \equiv-\int_{D} \Psi(u) w d x
$$

for fixed $w \in V$. Suppose $u_{n} \rightarrow u$ in $V$ and fix $w \in L^{\infty}(D) \subseteq V$. Then it follows from an easy argument using the Vitali convergence theorem and the fact that from the estimates above

$$
\Psi\left(u_{n}\right) w
$$

is uniformly integrable that

$$
u \rightarrow-\int_{D} \Psi(u) w d x
$$

is continuous. For general $w \in L^{p}(D)$, let $w_{n} \rightarrow w$ in $L^{p}(D)$ where each $w_{n}$ is in $L^{\infty}(D)$. Then the function

$$
\begin{equation*}
u \rightarrow-\int_{D} \Psi(u) w d x \equiv\langle A u, w\rangle \tag{34.1.7}
\end{equation*}
$$

is the limit of the continuous functions

$$
u \rightarrow-\int_{D} \Psi(u) w_{n} d x
$$

and so the function 34.1.7 is Borel measurable. Now by the Pettis theorem this shows $A: V \rightarrow V^{\prime}$ is $\mathscr{B}(V)$ measurable. This shows $A$ is an example of an operator which satisfies some conditions which will be considered later.

### 34.2 Standard Techniques In Evolution Equations

In this section, several significant theorems are presented. Unless indicated otherwise, the measure will be Lebesgue measure. First here is a lemma.

Lemma 34.2.1 Suppose $g \in L^{1}([a, b] ; X)$ where $X$ is a Banach space. Then if

$$
\int_{a}^{b} g(t) \phi(t) d t=0
$$

for all $\phi \in C_{c}^{\infty}(a, b)$, then $g(t)=0$ a.e.
Proof: Let $S$ be a measurable subset of $(a, b)$ and let $K \subseteq S \subseteq V \subseteq(a, b)$ where $K$ is compact, $V$ is open and $m(V \backslash K)<\varepsilon$. Let $K \prec h \prec V$ as in the proof of the Riesz representation theorem for positive linear functionals. Enlarging $K$ slightly and convolving with a mollifier, it can be assumed $h \in C_{c}^{\infty}(a, b)$. Then

$$
\begin{aligned}
\left|\int_{a}^{b} \mathscr{X}_{S}(t) g(t) d t\right| & =\left|\int_{a}^{b}\left(\mathscr{X}_{S}(t)-h(t)\right) g(t) d t\right| \\
& \leq \int_{a}^{b}\left|\mathscr{X}_{S}(t)-h(t)\right|\|g(t)\| d t \\
& \leq \int_{V \backslash K}\|g(t)\| d t
\end{aligned}
$$

Now let $K_{n} \subseteq S \subseteq V_{n}$ with $m\left(V_{n} \backslash K_{n}\right)<2^{-n}$. Then from the above,

$$
\left|\int_{a}^{b} \mathscr{X}_{S}(t) g(t) d t\right| \leq \int_{a}^{b} \mathscr{X}_{V_{n} \backslash K_{n}}(t)\|g(t)\| d t
$$

and the integrand of the last integral converges to 0 a.e. as $n \rightarrow \infty$ because $\sum_{n} m\left(V_{n} \backslash K_{n}\right)<$ $\infty$. By the dominated convergence theorem, this last integral converges to 0 . Therefore, whenever $S \subseteq(a, b)$,

$$
\int_{a}^{b} \mathscr{X}_{S}(t) g(t) d t=0
$$

Since the endpoints have measure zero, it also follows that for any measurable $S$, the above equation holds.

Now $g \in L^{1}([a, b] ; X)$ and so it is measurable. Therefore, $g([a, b])$ is separable. Let $D$ be a countable dense subset and let $E$ denote the set of linear combinations of the form $\sum_{i} a_{i} d_{i}$ where $a_{i}$ is a rational point of $\mathbb{F}$ and $d_{i} \in D$. Thus $E$ is countable. Denote by $Y$ the closure of $E$ in $X$. Thus $Y$ is a separable closed subspace of $X$ which contains all the values of $g$.

Now let $S_{n} \equiv g^{-1}\left(B\left(y_{n},\left\|y_{n}\right\| / 2\right)\right)$ where $E=\left\{y_{n}\right\}_{n=1}^{\infty}$. Then $\cup_{n} S_{n}=g^{-1}(X \backslash\{0\})$. This follows because if $x \in Y$ and $x \neq 0$, then in $B\left(x, \frac{\|x\|}{4}\right)$ there is a point of $E, y_{n}$. Therefore, $\left\|y_{n}\right\|>\frac{3}{4}\|x\|$ and so $\frac{\left\|y_{n}\right\|}{2}>\frac{3\|x\|}{8}>\frac{\|x\|}{4}$ so $x \in B\left(y_{n},\left\|y_{n}\right\| / 2\right)$. It follows that if each $S_{n}$ has measure zero, then $g(t)=0$ for a.e. $t$. Suppose then that for some $n$, the set, $S_{n}$ has positive measure. Then from what was shown above,

$$
\begin{aligned}
\left\|y_{n}\right\| & =\left\|\frac{1}{m\left(S_{n}\right)} \int_{S_{n}} g(t) d t-y_{n}\right\|=\left\|\frac{1}{m\left(S_{n}\right)} \int_{S_{n}} g(t)-y_{n} d t\right\| \\
& \leq \frac{1}{m\left(S_{n}\right)} \int_{S_{n}}\left\|g(t)-y_{n}\right\| d t \leq \frac{1}{m\left(S_{n}\right)} \int_{S_{n}}\left\|y_{n}\right\| / 2 d t=\left\|y_{n}\right\| / 2
\end{aligned}
$$

and so $y_{n}=0$ which implies $S_{n}=\emptyset$, a contradiction to $m\left(S_{n}\right)>0$. This contradiction shows each $S_{n}$ has measure zero and so as just explained, $g(t)=0$ a.e.

Definition 34.2.2 For $f \in L^{1}(a, b ; X)$, define an extension, $\bar{f}$ defined on

$$
[2 a-b, 2 b-a]=[a-(b-a), b+(b-a)]
$$

as follows.

$$
\bar{f}(t) \equiv\left\{\begin{array}{l}
f(t) \text { if } t \in[a, b] \\
f(2 a-t) \text { if } t \in[2 a-b, a] \\
f(2 b-t) \text { if } t \in[b, 2 b-a]
\end{array}\right.
$$

Definition 34.2.3 Also if $f \in L^{p}(a, b ; X)$ and $h>0$, define for $t \in[a, b], f_{h}(t) \equiv \bar{f}(t-h)$ for all $h<b-a$. Thus the map $f \rightarrow f_{h}$ is continuous and linear on $L^{p}(a, b ; X)$. It is continuous because

$$
\begin{aligned}
\int_{a}^{b}\left\|f_{h}(t)\right\|^{p} d t & =\int_{a}^{a+h}\|f(2 a-t+h)\|^{p} d t+\int_{a}^{b-h}\|f(t)\|^{p} d t \\
& =\int_{a}^{a+h}\|f(t)\|^{p} d t+\int_{a}^{b-h}\|f(t)\|^{p} d t \leq 2\|f\|_{p}^{p}
\end{aligned}
$$

The following lemma is on continuity of translation in $L^{p}(a, b ; X)$.

Lemma 34.2.4 Let $\bar{f}$ be as defined in Definition 34.2.2. Then for $f \in L^{p}(a, b ; X)$ for $p \in$ $[1, \infty)$,

$$
\lim _{\delta \rightarrow 0} \int_{a}^{b}\|\bar{f}(t-\delta)-f(t)\|_{X}^{p} d t=0
$$

Proof: Regarding the measure space as $(a, b)$ with Lebesgue measure, by regularity of the measure, there exists $g \in C_{c}(a, b ; X)$ such that $\|f-g\|_{p}<\varepsilon$. Here the norm is the norm in $L^{p}(a, b ; X)$. Therefore,

$$
\begin{aligned}
\left\|f_{h}-f\right\|_{p} & \leq\left\|f_{h}-g_{h}\right\|_{p}+\left\|g_{h}-g\right\|_{p}+\|g-f\|_{p} \\
& \leq\left(2^{1 / p}+1\right)\|f-g\|_{p}+\left\|g_{h}-g\right\|_{p} \\
& <\left(2^{1 / p}+1\right) \varepsilon+\varepsilon
\end{aligned}
$$

whenever $h$ is sufficiently small. This is because of the uniform continuity of $g$. Therefore, since $\varepsilon>0$ is arbitrary, this proves the lemma.

Definition 34.2.5 Let $f \in L^{1}(a, b ; X)$. Then the distributional derivative in the sense of $X$ valued distributions is given by

$$
f^{\prime}(\phi) \equiv-\int_{a}^{b} f(t) \phi^{\prime}(t) d t
$$

Then $f^{\prime} \in L^{1}(a, b ; X)$ if there exists $h \in L^{1}(a, b ; X)$ such that for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
f^{\prime}(\phi)=\int_{a}^{b} h(t) \phi(t) d t
$$

Then $f^{\prime}$ is defined to equal $h$. Here $f$ and $f^{\prime}$ are considered as vector valued distributions in the same way as was done for scalar valued functions.

Lemma 34.2.6 The above definition is well defined.
Proof: Suppose both $h$ and $g$ work in the definition for $f^{\prime}$. Then for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b}(h(t)-g(t)) \phi(t) d t=0 .
$$

Therefore, by Lemma 34.2.1, $h(t)-g(t)=0$ a.e.
The other thing to notice about this is the following lemma. It follows immediately from the definition.

Lemma 34.2.7 Suppose $f, f^{\prime} \in L^{1}(a, b ; X)$. Then if $[c, d] \subseteq[a, b]$, it follows that $\left(\left.f\right|_{[c, d]}\right)^{\prime}=$ $\left.f^{\prime}\right|_{[c, d]}$. This notation means the restriction to $[c, d]$.

Recall that in the case of scalar valued functions, if you had both $f$ and its weak derivative, $f^{\prime}$ in $L^{1}(a, b)$, then you were able to conclude that $f$ is almost everywhere equal to a continuous function, still denoted by $f$ and

$$
f(t)=f(a)+\int_{a}^{t} f^{\prime}(s) d s
$$

In particular, you can define $f(a)$ to be the initial value of this continuous function. It turns out that an identical theorem holds in this case. To begin with here is the same sort of lemma which was used earlier for the case of scalar valued functions. It says that if $f^{\prime}=0$ where the derivative is taken in the sense of $X$ valued distributions, then $f$ equals a constant.

Lemma 34.2.8 Suppose $f \in L^{1}(a, b ; X)$ and for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b} f(t) \phi^{\prime}(t) d t=0
$$

Then there exists a constant, $a \in X$ such that $f(t)=a$ a.e.
Proof: Let $\phi_{0} \in C_{c}^{\infty}(a, b), \int_{a}^{b} \phi_{0}(x) d x=1$ and define for $\phi \in C_{c}^{\infty}(a, b)$

$$
\psi_{\phi}(x) \equiv \int_{a}^{x}\left[\phi(t)-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right] d t
$$

Then $\psi_{\phi} \in C_{c}^{\infty}(a, b)$ and $\psi_{\phi}^{\prime}=\phi-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}$. Then

$$
\begin{aligned}
\int_{a}^{b} f(t)(\phi(t)) d t & =\int_{a}^{b} f(t)\left(\psi_{\phi}^{\prime}(t)+\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right) d t \\
& =\overbrace{\int_{a}^{b} f(t) \psi_{\phi}^{\prime}(t) d t}^{=0 \text { by assumption }}+\left(\int_{a}^{b} \phi(y) d y\right) \int_{a}^{b} f(t) \phi_{0}(t) d t \\
& =\left(\int_{a}^{b}\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right) \phi(y) d y\right) .
\end{aligned}
$$

It follows that for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b}\left(f(y)-\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right)\right) \phi(y) d y=0
$$

and so by Lemma 34.2.1,

$$
f(y)-\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right)=0 \text { a.e. } y
$$

Theorem 34.2.9 Suppose $f, f^{\prime}$ both are in $L^{1}(a, b ; X)$ where the derivative is taken in the sense of $X$ valued distributions. Then there exists a unique point of $X$, denoted by $f(a)$ such that the following formula holds a.e. $t$.

$$
f(t)=f(a)+\int_{a}^{t} f^{\prime}(s) d s
$$

## Proof:

$$
\int_{a}^{b}\left(f(t)-\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t=\int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t
$$

Now consider $\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t$. Let $\Lambda \in X^{\prime}$. Then it is routine from approximating $f^{\prime}$ with simple functions to verify

$$
\Lambda\left(\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t\right)=\int_{a}^{b} \int_{a}^{t} \Lambda\left(f^{\prime}(s)\right) \phi^{\prime}(t) d s d t
$$

Now the ordinary Fubini theorem can be applied to obtain

$$
=\int_{a}^{b} \int_{s}^{b} \Lambda\left(f^{\prime}(s)\right) \phi^{\prime}(t) d t d s=\Lambda\left(\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s\right)
$$

Since $X^{\prime}$ separates the points of $X$, it follows

$$
\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t=\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s
$$

Therefore,

$$
\begin{aligned}
& \int_{a}^{b}\left(f(t)-\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} f^{\prime}(s) \int_{s}^{b} \phi^{\prime}(t) d t d s \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{a}^{b} f^{\prime}(s) \phi(s) d s=0 .
\end{aligned}
$$

Therefore, by Lemma 34.2.8, there exists a constant, denoted as $f(a)$ such that

$$
f(t)-\int_{a}^{t} f^{\prime}(s) d s=f(a)
$$

There is also a useful theorem about continuity of pointwise evaluation.
Corollary 34.2.10 Let $f, f^{\prime} \in L^{1}(a, b ; X)$ so that

$$
\begin{equation*}
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \tag{34.2.8}
\end{equation*}
$$

where in this formula, $t \rightarrow f(t)$ is the continuous representative of $f$. Then there exists $a$ constant $C$ such that for each $t \in[a, b]$,

$$
\|f(t)\|_{X} \leq C\left(\|f\|_{L^{1}(a, b ; X)}+\left\|f^{\prime}\right\|_{L^{1}(a, b ; X)}\right)
$$

Proof: From the integral equation 34.2.8,

$$
\begin{gathered}
f(t)=f(s)+\int_{s}^{t} f^{\prime}(r) d r \\
\|f(t)\|_{X} \leq\|f(s)\|_{X}+\left|\int_{s}^{t}\left\|f^{\prime}(r)\right\|_{X} d r\right| \\
\leq\|f(s)\|_{X}+\int_{a}^{b}\left\|f^{\prime}(r)\right\|_{X} d r
\end{gathered}
$$

and so, integrating both sides with respect to $s$

$$
(b-a)\|f(t)\|_{X} \leq\|f\|_{L^{1}(a, b ; X)}+(b-a)\left\|f^{\prime}\right\|_{L^{1}(a, b ; X)}
$$

and so

$$
\|f(t)\|_{X} \leq\left(\frac{1}{b-a}+1\right)\left(\|f\|_{L^{1}(a, b ; X)}+\left\|f^{\prime}\right\|_{L^{1}(a, b ; X)}\right)
$$

Let $\mathfrak{X}$ be the space of functions $f \in L^{1}(a, b ; X)$ such that their weak derivatives $f^{\prime}$ are also in $L^{1}(a, b ; X)$. Then $\mathfrak{X}$ is a Banach space with norm given by

$$
\|f\|_{\mathfrak{X}} \equiv\|f\|_{L^{1}(a, b ; X)}+\left\|f^{\prime}\right\|_{L^{1}(a, b ; X)}
$$

This is because the map $f \rightarrow f^{\prime}$ is a closed map. If $f_{n} \rightarrow f$ in $L^{1}(a, b ; X)$ and $f_{n}^{\prime} \rightarrow \xi$ in $L^{1}(a, b ; X)$, then for $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b} \xi \phi d t=\lim _{n \rightarrow \infty} \int_{a}^{b} f_{n}^{\prime} \phi d t=\lim _{n \rightarrow \infty}-\int_{a}^{b} f_{n} \phi^{\prime} d t=-\int_{a}^{b} f \phi^{\prime} d t
$$

showing that $\xi=f^{\prime}$. Thus if you have a Cauchy sequence in $\mathfrak{X},\left\{f_{n}\right\}$, then $f_{n} \rightarrow f$ in $L^{1}(a, b ; X)$ and $f_{n}^{\prime} \rightarrow \xi$ in $L^{1}(a, b ; X)$ for some $\xi$. Hence $f^{\prime}=\xi$.

Then the above corollary says that pointwise evaluation is continuous as a map from $\mathfrak{X}$ to $X$. This is clearly a linear map. Also the formula obtained shows that in fact, this is continuous into $C([a, b] ; X)$.

$$
\|f\|_{C([a, b] ; X)}=\sup _{t \in[a, b]}\|f(t)\|_{X} \leq C\left(\|f\|_{L^{1}(a, b ; X)}+\left\|f^{\prime}\right\|_{L^{1}(a, b ; X)}\right)=C\|f\|_{\mathfrak{X}}
$$

Now let $\theta: \mathfrak{X} \rightarrow C([a, b] ; X)$ be given by $\theta f(t) \equiv f(t)$ where $f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s$, $f$ being the continuous representative of $f$. Then $\theta$ is continuous and linear. If $\theta_{t} f \equiv f(t)$ so that it is pointwise evaluation at $t$, then this $\theta_{t}$ is also continuous and linear. Suppose $X$ is also reflexive. It follows that if you have a sequence in $X\left\{f_{n}\right\}$ which is converging weakly to $f \in \mathfrak{X}$, then you would also have $\theta_{t} f_{n}=f_{n}(t) \rightarrow \theta_{t} f \equiv f(t)$ weakly in $X$. If this is not so, then since $X$ is reflexive, there is a subsequence, still denoted as $f_{n}$ such that $f_{n}(t) \rightarrow \xi \neq f(t)$. However, this says that $(f, \boldsymbol{\xi})$ is in the weak closure of the graph of $\theta_{t}$. Since this graph is strongly closed and convex, it is also weakly closed and hence $\xi=\theta_{t} f \equiv f(t)$, a contradiction. This proves the following nice corollary.

Corollary 34.2.11 Suppose $f_{n} \rightarrow f$ weakly in $\mathfrak{X}$ where we assume also that $X$ is reflexive. Then $f_{n}(t) \rightarrow f(t)$ weakly in $X$.

The integration by parts formula is also important.

Corollary 34.2.12 Suppose $f, f^{\prime} \in L^{1}(a, b ; X)$ and suppose $\phi \in C^{1}([a, b])$. Then the following integration by parts formula holds.

$$
\int_{a}^{b} f(t) \phi^{\prime}(t) d t=f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(t) \phi(t) d t
$$

Proof: From Theorem 34.2.9

$$
\begin{aligned}
& \int_{a}^{b} f(t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b}\left(f(a)+\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) d s \phi^{\prime}(t) d t \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} f^{\prime}(s) \int_{s}^{b} \phi^{\prime}(t) d t d s \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} f^{\prime}(s)(\phi(b)-\phi(s)) d s \\
= & f(a)(\phi(b)-\phi(a))-\int_{a}^{b} f^{\prime}(s) \phi(s) d s+(f(b)-f(a)) \phi(b) \\
= & f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(s) \phi(s) d s .
\end{aligned}
$$

The interchange in order of integration is justified as in the proof of Theorem 34.2.9.
With this integration by parts formula, the following interesting lemma is obtained. This lemma shows why it was appropriate to define $\bar{f}$ as in Definition 34.2.2.

Lemma 34.2.13 Let $\bar{f}$ be given in Definition 34.2.2 and suppose $f, f^{\prime} \in L^{1}(a, b ; X)$. Then $\bar{f}, \bar{f}^{\prime} \in L^{1}(2 a-b, 2 b-a ; X)$ also and

$$
\bar{f}^{\prime}(t) \equiv\left\{\begin{array}{l}
f^{\prime}(t) \text { if } t \in[a, b]  \tag{34.2.9}\\
-f^{\prime}(2 a-t) \text { if } t \in[2 a-b, a] \\
-f^{\prime}(2 b-t) \text { if } t \in[b, 2 b-a]
\end{array}\right.
$$

Proof: It is clear from the definition of $\bar{f}$ that $\bar{f} \in L^{1}(2 a-b, 2 b-a ; X)$ and that in fact

$$
\begin{equation*}
\|\bar{f}\|_{L^{1}(2 a-b, 2 b-a ; X)} \leq 3\|f\|_{L^{1}(a, b ; X)} \tag{34.2.10}
\end{equation*}
$$

Let $\phi \in C_{c}^{\infty}(2 a-b, 2 b-a)$. Then from the integration by parts formula,

$$
\begin{aligned}
& \int_{2 a-b}^{2 b-a} \bar{f}(t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{b}^{2 b-a} f(2 b-t) \phi^{\prime}(t) d t+\int_{2 a-b}^{a} f(2 a-t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{a}^{b} f(u) \phi^{\prime}(2 b-u) d u+\int_{a}^{b} f(u) \phi^{\prime}(2 a-u) d u \\
= & f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(t) \phi(t) d t-f(b) \phi(b)+f(a) \phi(2 b-a) \\
& +\int_{a}^{b} f^{\prime}(u) \phi(2 b-u) d u-f(b) \phi(2 a-b) \\
& +f(a) \phi(a)+\int_{a}^{b} f^{\prime}(u) \phi(2 a-u) d u \\
= & -\int_{a}^{b} f^{\prime}(t) \phi(t) d t+\int_{a}^{b} f^{\prime}(u) \phi(2 b-u) d u+\int_{a}^{b} f^{\prime}(u) \phi(2 a-u) d u \\
= & -\int_{a}^{b} f^{\prime}(t) \phi(t) d t-\int_{b}^{2 b-a}-f^{\prime}(2 b-t) \phi(t) d t-\int_{2 a-b}^{a}-f^{\prime}(2 a-t) \phi(t) d t \\
= & -\int_{2 a-b}^{2 b-a} \bar{f}^{\prime}(t) \phi(t) d t
\end{aligned}
$$

where $\bar{f}^{\prime}(t)$ is given in 34.2.9.
Definition 34.2.14 Let $V$ be a Banach space and let $H$ be a Hilbert space. (Typically $H=L^{2}(\Omega)$ ) Suppose $V \subseteq H$ is dense in $H$ meaning that the closure in $H$ of $V$ gives $H$. Then it is often the case that $H$ is identified with its dual space, and then because of the density of $V$ in $H$, it is possible to write

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

When this is done, $H$ is called a pivot space. Another notation which is often used is $\langle f, g\rangle$ to denote $f(g)$ for $f \in V^{\prime}$ and $g \in V$. This may also be written as $\langle f, g\rangle_{V^{\prime}, V}$. Another term is that $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ is called a Gelfand triple.

The next theorem is an example of a trace theorem. In this theorem, $f \in L^{p}(0, T ; V)$ while $f^{\prime} \in L^{p}\left(0, T ; V^{\prime}\right)$. It makes no sense to consider the initial values of $f$ in $V$ because it is not even continuous with values in $V$. However, because of the derivative of $f$ it will turn out that $f$ is continuous with values in a larger space and so it makes sense to consider initial values of $f$ in this other space. This other space is called a trace space.

Theorem 34.2.15 Let $V$ and $H$ be a Banach space and Hilbert space as described in Definition 34.2.14. Suppose $f \in L^{p}(0, T ; V)$ and $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$. Then $f$ is a.e. equal to a continuous function mapping $[0, T]$ to $H$. Furthermore, there exists $f(0) \in H$ such that

$$
\begin{equation*}
\frac{1}{2}|f(t)|_{H}^{2}-\frac{1}{2}|f(0)|_{H}^{2}=\int_{0}^{t}\left\langle f^{\prime}(s), f(s)\right\rangle d s \tag{34.2.11}
\end{equation*}
$$

and for all $t \in[0, T]$,

$$
\begin{equation*}
\int_{0}^{t} f^{\prime}(s) d s \in H \tag{34.2.12}
\end{equation*}
$$

and for a.e. $t \in[0, T]$,

$$
\begin{equation*}
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } H \tag{34.2.13}
\end{equation*}
$$

Here $f^{\prime}$ is being taken in the sense of $V^{\prime}$ valued distributions and $\frac{1}{p}+\frac{1}{p^{\prime}}=1$ and $p \geq 2$.
Proof: Let $\Psi \in C_{c}^{\infty}(-T, 2 T)$ satisfy $\Psi(t)=1$ if $t \in[-T / 2,3 T / 2]$ and $\Psi(t) \geq 0$. For $t \in \mathbb{R}$, define

$$
\widehat{f}(t) \equiv\left\{\begin{array}{l}
\bar{f}(t) \Psi(t) \text { if } t \in[-T, 2 T] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

and

$$
\begin{equation*}
f_{n}(t) \equiv \int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s \tag{34.2.14}
\end{equation*}
$$

where $\phi_{n}$ is a mollifier having support in $(-1 / n, 1 / n)$. Then by Minkowski's inequality

$$
\begin{aligned}
\| f_{n}- & \widehat{f} \|_{L^{p}(\mathbb{R} ; V)}=\left(\int_{\mathbb{R}}\left\|\widehat{f}(t)-\int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s\right\|_{V}^{p} d t\right)^{1 / p} \\
& =\left(\int_{\mathbb{R}}\left\|\int_{-1 / n}^{1 / n}(\widehat{f}(t)-\widehat{f}(t-s)) \phi_{n}(s) d s\right\|_{V}^{p} d t\right)^{1 / p} \\
& \leq\left(\int_{\mathbb{R}}\left(\int_{-1 / n}^{1 / n}\|\widehat{f}(t)-\widehat{f}(t-s)\|_{V} \phi_{n}(s) d s\right)^{p} d t\right)^{1 / p} \\
& \leq \int_{-1 / n}^{1 / n} \phi_{n}(s)\left(\int_{\mathbb{R}}\|\widehat{f}(t)-\widehat{f}(t-s)\|_{V}^{p} d t\right)^{1 / p} d s \\
& \leq \int_{-1 / n}^{1 / n} \phi_{n}(s) \varepsilon d s=\varepsilon
\end{aligned}
$$

provided $n$ is large enough. This follows from continuity of translation in $L^{p}$ with Lebesgue measure. Since $\varepsilon>0$ is arbitrary, it follows $f_{n} \rightarrow \widehat{f}$ in $L^{p}(\mathbb{R} ; V)$. Similarly, $f_{n} \rightarrow f$ in $L^{2}(\mathbb{R} ; H)$. This follows because $p \geq 2$ and the norm in $V$ and norm in $H$ are related by $|x|_{H} \leq C\|x\|_{V}$ for some constant, $C$. Now

$$
\widehat{f}(t)=\left\{\begin{array}{l}
\Psi(t) f(t) \text { if } t \in[0, T] \\
\Psi(t) f(2 T-t) \text { if } t \in[T, 2 T] \\
\Psi(t) f(-t) \text { if } t \in[0, T] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

An easy modification of the argument of Lemma 34.2.13 yields

$$
\widehat{f}^{\prime}(t)=\left\{\begin{array}{l}
\Psi^{\prime}(t) f(t)+\Psi(y) f^{\prime}(t) \text { if } t \in[0, T] \\
\Psi^{\prime}(t) f(2 T-t)-\Psi(t) f^{\prime}(2 T-t) \text { if } t \in[T, 2 T] \\
\Psi^{\prime}(t) f(-t)-\Psi(t) f^{\prime}(-t) \text { if } t \in[-T, 0] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

Recall

$$
\begin{aligned}
f_{n}(t) & =\int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s=\int_{\mathbb{R}} \widehat{f}(t-s) \phi_{n}(s) d s \\
& =\int_{\mathbb{R}} \widehat{f}(s) \phi_{n}(t-s) d s
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
f_{n}^{\prime}(t) & =\int_{\mathbb{R}} \widehat{f}(s) \phi_{n}^{\prime}(t-s) d s=\int_{-T-\frac{1}{n}}^{2 T+\frac{1}{n}} \widehat{f}(s) \phi_{n}^{\prime}(t-s) d s \\
& =\int_{-T-\frac{1}{n}}^{2 T+\frac{1}{n}} \widehat{f}^{\prime}(s) \phi_{n}(t-s) d s=\int_{\mathbb{R}} \widehat{f}^{\prime}(s) \phi_{n}(t-s) d s \\
& =\int_{\mathbb{R}} \widehat{f}^{\prime}(t-s) \phi_{n}(s) d s=\int_{-1 / n}^{1 / n} \widehat{f}^{\prime}(t-s) \phi_{n}(s) d s
\end{aligned}
$$

and it follows from the first line above that $f_{n}^{\prime}$ is continuous with values in $V$ for all $t \in \mathbb{R}$. Also note that both $f_{n}^{\prime}$ and $f_{n}$ equal zero if $t \notin[-T, 2 T]$ whenever $n$ is large enough. Exactly similar reasoning to the above shows that $f_{n}^{\prime} \rightarrow \widehat{f}^{\prime}$ in $L^{p^{\prime}}\left(\mathbb{R} ; V^{\prime}\right)$.

Now let $\phi \in C_{c}^{\infty}(0, T)$.

$$
\begin{align*}
\int_{\mathbb{R}}\left|f_{n}(t)\right|_{H}^{2} \phi^{\prime}(t) d t & =\int_{\mathbb{R}}\left(f_{n}(t), f_{n}(t)\right)_{H} \phi^{\prime}(t) d t  \tag{34.2.15}\\
=-\int_{\mathbb{R}} 2\left(f_{n}^{\prime}(t), f_{n}(t)\right) \phi(t) d t & =-\int_{\mathbb{R}} 2\left\langle f_{n}^{\prime}(t), f_{n}(t)\right\rangle \phi(t) d t
\end{align*}
$$

Now

$$
\begin{aligned}
& \left|\int_{\mathbb{R}}\left\langle f_{n}^{\prime}(t), f_{n}(t)\right\rangle \phi(t) d t-\int_{\mathbb{R}}\left\langle f^{\prime}(t), f(t)\right\rangle \phi(t) d t\right| \\
\leq & \int_{\mathbb{R}}\left(\left|\left\langle f_{n}^{\prime}(t)-f^{\prime}(t), f_{n}(t)\right\rangle\right|+\left|\left\langle f^{\prime}(t), f_{n}(t)-f(t)\right\rangle\right|\right) \phi(t) d t
\end{aligned}
$$

From the first part of this proof which showed that $f_{n} \rightarrow \widehat{f}$ in $L^{p}(\mathbb{R} ; V)$ and $f_{n}^{\prime} \rightarrow \widehat{f}^{\prime}$ in $L^{p^{\prime}}\left(\mathbb{R} ; V^{\prime}\right)$, an application of Holder's inequality shows the above converges to 0 as $n \rightarrow \infty$. Therefore, passing to the limit as $n \rightarrow \infty$ in the 34.2.16,

$$
\int_{\mathbb{R}}|\widehat{f}(t)|_{H}^{2} \phi^{\prime}(t) d t=-\int_{\mathbb{R}} 2\left\langle\widehat{f}^{\prime}(t), \widehat{f}(t)\right\rangle \phi(t) d t
$$

which shows $t \rightarrow|\widehat{f}(t)|_{H}^{2}$ equals a continuous function a.e. and it also has a weak derivative equal to $2\left\langle\widehat{f}^{\prime}, \widehat{f}\right\rangle$.

It remains to verify that $\widehat{f}$ is continuous on $[0, T]$. Of course $\widehat{f}=f$ on this interval. Let
$N$ be large enough that $f_{n}(-T)=0$ for all $n>N$. Then for $m, n>N$ and $t \in[-T, 2 T]$

$$
\begin{aligned}
\left|f_{n}(t)-f_{m}(t)\right|_{H}^{2} & =2 \int_{-T}^{t}\left(f_{n}^{\prime}(s)-f_{m}^{\prime}(s), f_{n}(s)-f_{m}(s)\right) d s \\
& =2 \int_{-T}^{t}\left\langle f_{n}^{\prime}(s)-f_{m}^{\prime}(s), f_{n}(s)-f_{m}(s)\right\rangle_{V^{\prime}, V} d s \\
& \leq 2 \int_{\mathbb{R}}\left\|f_{n}^{\prime}(s)-f_{m}^{\prime}(s)\right\|_{V^{\prime}}\left\|f_{n}(s)-f_{m}(s)\right\|_{V} d s \\
& \leq 2\left\|f_{n}-f_{m}\right\|_{L^{p^{\prime}\left(\mathbb{R} ; V^{\prime}\right)}}\left\|f_{n}-f_{m}\right\|_{L^{p}(\mathbb{R} ; V)}
\end{aligned}
$$

which shows from the above that $\left\{f_{n}\right\}$ is uniformly Cauchy on $[-T, 2 T]$ with values in $H$. Therefore, there exists $g$ a continuous function defined on $[-T, 2 T]$ having values in $H$ such that

$$
\lim _{n \rightarrow \infty} \max \left\{\left|f_{n}(t)-g(t)\right|_{H} ; t \in[-T, 2 T]\right\}=0
$$

However, $g=\widehat{f}$ a.e. because $f_{n}$ converges to $f$ in $L^{p}(0, T ; V)$. Therefore, taking a subsequence, the convergence is a.e. It follows from the fact that $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ and Theorem 34.2.9, there exists $f(0) \in V^{\prime}$ such that for a.e. $t$,

$$
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } V^{\prime}
$$

Now $g=f$ a.e. and $g$ is continuous with values in $H$ hence continuous with values in $V^{\prime}$ and so

$$
g(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } V^{\prime}
$$

for all $t$. Since $g$ is continuous with values in $H$ it is continuous with values in $V^{\prime}$. Taking the limit as $t \downarrow 0$ in the above, $g(a)=\lim _{t \rightarrow 0+} g(t)=f(0)$, showing that $f(0) \in H$. Therefore, for a.e. $t$,

$$
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } H, \int_{0}^{t} f^{\prime}(s) d s \in H
$$

Note that if $f \in L^{p}(0, T ; V)$ and $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$, then you can consider the initial value of $f$ and it will be in $H$. What if you start with something in $H$ ? Is it an initial condition for a function $f \in L^{p}(0, T ; V)$ such that $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ ? This is worth thinking about. If it is not so, what is the space of initial values? How can you give this space a norm? What are its properties? It turns out that if $V$ is a closed subspace of the Sobolev space, $W^{1, p}(\Omega)$ which contains $W_{0}^{1, p}(\Omega)$ for $p \geq 2$ and $H=L^{2}(\Omega)$ the answer to the above question is yes. Not surprisingly, there are many generalizations of the above ideas.

### 34.3 An Important Formula

It is not necessary to have $p>2$ in order to do the sort of thing just described. First is an approximation theorem which says that a given functionin $L^{p}([0, T] ; E)$ can be approximated by step functions.

Lemma 34.3.1 Let $\Phi:[0, T] \rightarrow E$, be Lebesgue measurable and suppose

$$
\Phi \in K \equiv L^{p}([0, T] ; E), p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
\Phi_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t) \\
\Phi_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t)
\end{aligned}
$$

both converge to $\Phi$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

In the formulas, define $\Phi(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero.

Note that it would make no difference in terms of the conclusion of this lemma if you defined

$$
\Phi_{k}^{l}(t) \equiv \sum_{j=1}^{m_{k}} \Phi\left(t_{j-1}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t)
$$

because the modified function equals the one given above off a countable subset of $[0, T]$, the union of the mesh points.

Proof: For $t \in \mathbb{R}$ let $\gamma_{n}(t) \equiv k / 2^{n}, \delta_{n}(t) \equiv(k+1) / 2^{n}$, where

$$
t \in\left(k / 2^{n},(k+1) / 2^{n}\right]
$$

and $2^{-n}<T / 4$. Also suppose $\Phi$ is defined to equal 0 on $[0, T]^{C} \times \Omega$. There exists a set of measure zero $N$ such that for $\omega \notin N, t \rightarrow\|\Phi(t, \omega)\|$ is in $L^{p}(\mathbb{R})$. Therefore by continuity of translation, as $n \rightarrow \infty$ it follows that for $\omega \notin N$, and $t \in[0, T]$,

$$
\int_{\mathbb{R}}\left\|\Phi\left(\gamma_{n}(t)+s\right)-\Phi(t+s)\right\|_{E}^{p} d s \rightarrow 0
$$

The above is dominated by

$$
\begin{aligned}
& \int_{\mathbb{R}} 2^{p-1}\left(\|\Phi(s)\|^{p}+\|\Phi(s)\|^{p}\right) \mathscr{X}_{[-2 T, 2 T]}(s) d s \\
= & \int_{-2 T}^{2 T} 2^{p-1}\left(\|\Phi(s)\|^{p}+\|\Phi(s)\|^{p}\right) d s<\infty
\end{aligned}
$$

Consider

$$
\int_{-2 T}^{2 T}\left(\int_{\mathbb{R}}\left\|\Phi\left(\gamma_{n}(t)+s\right)-\Phi(t+s)\right\|_{E}^{p} d s\right) d t
$$

By the dominated convergence theorem, this converges to 0 as $n \rightarrow \infty$. Now Fubini. This yields

$$
\int_{\mathbb{R}} \int_{-2 T}^{2 T}\left\|\Phi\left(\gamma_{n}(t)+s\right)-\Phi(t+s)\right\|_{E}^{p} d t d s
$$

Change the variables on the inside.

$$
\int_{\mathbb{R}} \int_{-2 T+s}^{2 T+s}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s
$$

Now by definition, $\Phi(t)$ vanishes if $t \notin[0, T]$, thus the above reduces to

$$
\begin{gathered}
\int_{\mathbb{R}} \int_{0}^{T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s \\
+\int_{\mathbb{R}} \int_{-2 T+s}^{2 T+s} \mathscr{X}_{[0, T]}^{C}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)\right\|_{E}^{p} d t d s \\
=\quad \int_{\mathbb{R}} \int_{0}^{T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s \\
+\int_{\mathbb{R}} \int_{-2 T+s}^{2 T+s} \mathscr{X}_{[0, T]^{c}}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s
\end{gathered}
$$

Also by definition, $\gamma_{n}(t-s)+s$ is within $2^{-n}$ of $t$ and so the integrand in the integral on the right equals 0 unless $t \in\left[-2^{-n}-T, T+2^{-n}\right] \subseteq[-2 T, 2 T]$. Thus the above reduces to

$$
\int_{\mathbb{R}} \int_{-2 T}^{2 T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s
$$

This converges to 0 as $n \rightarrow \infty$ as was shown above. Therefore,

$$
\int_{0}^{T} \int_{0}^{T}\left\|\Phi\left(\gamma_{n}(t-s)+s\right)-\Phi(t)\right\|_{E}^{p} d t d s
$$

also converges to 0 as $n \rightarrow \infty$. The only problem is that $\gamma_{n}(t-s)+s \geq t-2^{-n}$ and so $\gamma_{n}(t-s)+s$ could be less than 0 for $t \in\left[0,2^{-n}\right]$. Since this is an interval whose measure converges to 0 it follows

$$
\int_{0}^{T} \int_{0}^{T}\left\|\Phi\left(\left(\gamma_{n}(t-s)+s\right)^{+}\right)-\Phi(t)\right\|_{E}^{p} d t d s
$$

converges to 0 as $n \rightarrow \infty$. Let

$$
m_{n}(s)=\int_{0}^{T}\left\|\Phi\left(\left(\gamma_{n}(t-s)+s\right)^{+}\right)-\Phi(t)\right\|_{E}^{p} d t
$$

Then letting $\mu$ denote Lebesgue measure,

$$
\mu\left(\left[m_{n}(s)>\lambda\right]\right) \leq \frac{1}{\lambda} \int_{0}^{T} m_{n}(s) d s
$$

It follows there exists a subsequence $n_{k}$ such that

$$
\mu\left(\left[m_{n_{k}}(s)>\frac{1}{k}\right]\right)<2^{-k}
$$

Hence by the Borel Cantelli lemma, there exists a set of measure zero $N$ such that for $s \notin N$,

$$
m_{n_{k}}(s) \leq 1 / k
$$

for all $k$ sufficiently large. Pick such an $s$. Then consider $t \rightarrow \Phi\left(\left(\gamma_{n_{k}}(t-s)+s\right)^{+}\right)$. For $n_{k}, t \rightarrow\left(\gamma_{n_{k}}(t-s)+s\right)^{+}$has jumps at points of the form $0, s+l 2^{-n_{k}}$ where $l$ is an integer. Thus $\mathscr{P}_{n_{k}}$ consists of points of $[0, T]$ which are of this form and these partitions are nested. Define $\Phi_{k}^{l}(0) \equiv 0, \Phi_{k}^{l}(t) \equiv \Phi\left(\left(\gamma_{n_{k}}(t-s)+s\right)^{+}\right)$. Now suppose $N_{1}$ is a set of measure zero. Can $s$ be chosen such that all jumps for all partitions occur off $N_{1}$ ? Let $(a, b)$ be an interval contained in $[0, T]$. Let $S_{j}$ be the points of $(a, b)$ which are translations of the measure zero set $N_{1}$ by $t_{j}^{l}$ for some $j$. Thus $S_{j}$ has measure 0 . Now pick $s \in(a, b) \backslash \cup_{j} S_{j}$. To get the other sequence of step functions, the right step functions, just use a similar argument with $\delta_{n}$ in place of $\gamma_{n}$. Just apply the argument to a subsequence of $n_{k}$ so that the same $s$ can hold for both.

Theorem 34.3.2 Let $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ be a Gelfand triple and suppose $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right) \equiv$ $K^{\prime}$ and

$$
\begin{equation*}
X(t)=X_{0}+\int_{0}^{t} Y(s) d s \text { in } V^{\prime} \tag{34.3.16}
\end{equation*}
$$

where $X_{0} \in H$, and it is known that $X \in L^{p}(0, T, V) \equiv K$ for $p>1$. Then $t \rightarrow X(t)$ is in $C([0, T], H)$ and also

$$
\frac{1}{2}|X(t)|_{H}^{2}=\frac{1}{2}\left|X_{0}\right|_{H}^{2}+\int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Proof: By Lemma 34.3.1, there exists a sequence of uniform partitions $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}=$ $\mathscr{P}_{n}, \mathscr{P}_{n} \subseteq \mathscr{P}_{n+1}$, of $[0, T]$ such that the step functions

$$
\begin{aligned}
\sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{l}(t) \\
\sum_{k=0}^{m_{n}-1} X\left(t_{k+1}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{r}(t)
\end{aligned}
$$

converge to $X$ in $K$ and in $L^{2}([0, T], H)$.

Lemma 34.3.3 Let $s<t$. Then for $X, Y$ satisfying 34.3.16

$$
\begin{equation*}
|X(t)|^{2}=|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-|X(t)-X(s)|^{2} \tag{34.3.17}
\end{equation*}
$$

Proof: It follows from the following computations

$$
\begin{gathered}
X(t)-X(s)=\int_{s}^{t} Y(u) d u \\
-|X(t)-X(s)|^{2}=-|X(t)|^{2}+2(X(t), X(s))-|X(s)|^{2} \\
=-|X(t)|^{2}+2\left(X(t), X(t)-\int_{s}^{t} Y(u) d u\right)-|X(s)|^{2} \\
=-|X(t)|^{2}+2|X(t)|^{2}-2\left\langle\int_{s}^{t} Y(u) d u, X(t)\right\rangle-|X(s)|^{2}
\end{gathered}
$$

Hence

$$
|X(t)|^{2}=|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-|X(t)-X(s)|^{2}
$$

Lemma 34.3.4 In the above situation,

$$
\sup _{t \in[0, T]}|X(t)|_{H} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Also, $t \rightarrow X(t)$ is weakly continuous with values in $H$.
Proof: From the above formula applied to the $k^{t h}$ partition of $[0, T]$ described above,

$$
\begin{aligned}
& \left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=\sum_{j=0}^{m-1}\left|X\left(t_{j+1}\right)\right|^{2}-\left|X\left(t_{j}\right)\right|^{2} \\
= & \sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle d u-\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2} \\
= & \sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u-\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2}
\end{aligned}
$$

Thus, discarding the negative terms and denoting by $\mathscr{P}_{k}$ the $k^{t h}$ of these partitions,

$$
\begin{gathered}
\sup _{t_{j} \in \mathscr{P}_{k}}\left|X\left(t_{j}\right)\right|_{H}^{2} \leq\left|X_{0}\right|^{2}+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u \\
\quad \leq\left|X_{0}\right|^{2}+2 \int_{0}^{T}\|Y(u)\|_{V^{\prime}}\left\|X_{k}^{r}(u)\right\|_{V} d u
\end{gathered}
$$

$$
\leq\left|X_{0}\right|^{2}+2\left(\int_{0}^{T}\|Y(u)\|_{V^{\prime}}^{p^{\prime}} d u\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p} d u\right)^{1 / p} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

because these partitions are chosen such that

$$
\lim _{k \rightarrow \infty}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p}\right)^{1 / p}=\left(\int_{0}^{T}\|X(u)\|_{V}^{p}\right)^{1 / p}
$$

and so these are bounded. This has shown that for the dense subset of $[0, T], D \equiv \cup_{k} \mathscr{P}_{k}$,

$$
\sup _{t \in D}|X(t)|<C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Now let $\left\{g_{k}\right\}_{k=1}^{\infty}$ be linearly independent vectors of $V$ whose span is dense in $V$. This is possible because $V$ is separable. Then let $\left\{e_{j}\right\}_{j=1}^{\infty}$ be an orthonormal basis for $H$ such that $e_{k} \in \operatorname{span}\left(g_{1}, \ldots, g_{k}\right)$ and each $g_{k} \in \operatorname{span}\left(e_{1}, \ldots, e_{k}\right)$. This is done with the Gram Schmidt process. Then it follows that $\operatorname{span}\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ is dense in $V$. I claim

$$
|y|_{H}^{2}=\sum_{j=1}^{\infty}\left|\left\langle y, e_{j}\right\rangle\right|^{2}
$$

This is certainly true if $y \in H$ because

$$
\left\langle y, e_{j}\right\rangle=\left(y, e_{j}\right)_{H}
$$

If $y \notin H$, then the series must diverge since otherwise, you could consider the infinite sum

$$
\sum_{j=1}^{\infty}\left\langle y, e_{j}\right\rangle e_{j} \in H
$$

because

$$
\left|\sum_{j=p}^{q}\left\langle y, e_{j}\right\rangle e_{j}\right|^{2}=\sum_{j=p}^{q}\left|\left\langle y, e_{j}\right\rangle\right|^{2} \rightarrow 0 \text { as } p, q \rightarrow \infty
$$

Letting $z=\sum_{j=1}^{\infty}\left\langle y, e_{j}\right\rangle e_{j}$, it follows that $\left\langle y, e_{j}\right\rangle$ is the $j^{\text {th }}$ Fourier coefficient of $z$ and that

$$
\langle z-y, v\rangle=0
$$

for all $v \in \operatorname{span}\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ which is dense in $V$. Therefore, $z=y$ in $V^{\prime}$ and so $y \in H$.
It follows

$$
|X(t)|^{2}=\sup _{n} \sum_{j=1}^{n}\left|\left\langle X(t), e_{j}\right\rangle\right|^{2}
$$

which is just the sup of continuous functions of $t$. Therefore, $t \rightarrow|X(t)|^{2}$ is lower semicontinuous. It follows that for any $t$, letting $t_{j} \rightarrow t$ for $t_{j} \in D$,

$$
|X(t)|^{2} \leq \lim \inf _{j \rightarrow \infty}\left|X\left(t_{j}\right)\right|^{2} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

This proves the first claim of the lemma.
Consider now the claim that $t \rightarrow X(t)$ is weakly continuous. Letting $v \in V$,

$$
\lim _{t \rightarrow s}(X(t), v)=\lim _{t \rightarrow s}\langle X(t), v\rangle=\langle X(s), v\rangle=(X(s), v)
$$

Since it was shown that $|X(t)|$ is bounded independent of $t$, and since $V$ is dense in $H$, the claim follows.

Now

$$
\begin{aligned}
-\sum_{j=0}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2} & =\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}-\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u \\
& =\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}-2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u
\end{aligned}
$$

Thus, since the partitions are nested, eventually $\left|X\left(t_{m}\right)\right|^{2}$ is constant for all $k$ large enough and the integral term converges to

$$
\int_{0}^{t_{m}}\langle Y(u), X(u)\rangle d u
$$

It follows that the term on the left does converge to something. It just remains to consider what it does converge to. However, from the equation solved by $X$,

$$
X\left(t_{j+1}\right)-X\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Y(u) d u
$$

Therefore, this term is dominated by an expression of the form

$$
\begin{gathered}
\sum_{j=0}^{m_{k}-1}\left(\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right) \\
=\sum_{j=0}^{m_{k}-1}\left\langle\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle d u \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle-\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j}\right)\right\rangle \\
=\int_{0}^{T}\left\langle Y(u), X^{r}(u)\right\rangle d u-\int_{0}^{T}\left\langle Y(u), X^{l}(u)\right\rangle d u
\end{gathered}
$$

However, both $X^{r}$ and $X^{l}$ converge to $X$ in $K=L^{p}(0, T, V)$. Therefore, this term must converge to 0 . Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t$,

$$
|X(t)|^{2}=\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

It remains to verify that this holds for all $t$. Let $t \notin D$ and let $t(k) \in \mathscr{P}_{k}$ be the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$
X(t(m))=X_{0}+\int_{0}^{t(m)} Y(s) d s
$$

a similar formula for $X(t(k))$. Thus for $t>t(m)$,

$$
X(t)-X(t(m))=\int_{t(m)}^{t} Y(s) d s
$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $X_{0}=0$. Therefore,

$$
|X(t(k))-X(t(m))|^{2}=2 \int_{t(m)}^{t(k)}\langle Y(s), X(s)-X(t(m))\rangle d s
$$

Thus, for $m \leq k$

$$
\lim _{m, k \rightarrow \infty}|X(t(k))-X(t(m))|^{2}=0
$$

Hence $\{X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $H$. Does it converge to $X(t)$ ? Let $\xi(t) \in H$ be what it does converge to. Let $v \in V$. Then

$$
(\xi(t), v)=\lim _{k \rightarrow \infty}(X(t(k)), v)=\lim _{k \rightarrow \infty}\langle X(t(k)), v\rangle=\langle X(t), v\rangle=(X(t), v)
$$

because it is known that $t \rightarrow X(t)$ is continuous into $V^{\prime}$ and it is also known that $X(t) \in H$ and that the $X(t)$ for $t \in[0, T]$ are uniformly bounded. Therefore, since $V$ is dense in $H$, it follows that $\xi(t)=X(t)$.

Now for every $t \in D$, it was shown above that

$$
|X(t)|^{2}=\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Thus, using what was just shown, if $t \notin D$ and $t_{k} \rightarrow t$,

$$
\begin{aligned}
|X(t)|^{2} & =\lim _{k \rightarrow \infty}\left|X\left(t_{k}\right)\right|^{2}=\lim _{k \rightarrow \infty}\left(\left|X_{0}\right|^{2}+2 \int_{0}^{t_{k}}\langle Y(s), X(s)\rangle d s\right) \\
& =\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(s), X(s)\rangle d s
\end{aligned}
$$

which proves the desired formula. From this it follows right away that $t \rightarrow X(t)$ is continuous into $H$ because it was just shown that $t \rightarrow|X(t)|$ is continuous and $t \rightarrow X(t)$ is weakly continuous. Since Hilbert space is uniformly convex, this implies the $t \rightarrow X(t)$ is continuous. To see this in the special case of Hilbert space,

$$
|X(t)-X(s)|^{2}=|X(t)|^{2}-2(X(s), X(t))+|X(s)|^{2}
$$

Then $\lim _{t \rightarrow s}\left(|X(t)|^{2}-2(X(s), X(t))+|X(s)|^{2}\right)=0$ by weak convergence of $X(t)$ to $X(s)$ and the convergence of $|X(t)|^{2}$ to $|X(s)|^{2}$.

### 34.4 The Implicit Case

The above theorem can be generalized to the case where the formula is of the form

$$
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s
$$

This involves an operator $B \in \mathscr{L}\left(W, W^{\prime}\right)$ and $B$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle
$$

for

$$
V \subseteq W, W^{\prime} \subseteq V^{\prime}
$$

Where $V$ is dense in the Banach space $W$. Before giving the theorem, here is a technical lemma. First is one which is not so technical.

Lemma 34.4.1 Let $V$ be a separable Banach space. Then there exists $\left\{g_{k}\right\}_{k=1}^{\infty}$ which are linearly independent and whose span is dense in $V$.

Proof: Let $\left\{f_{k}\right\}$ be a countable dense subset. Thus their span is dense. Delete $f_{k_{1}}$ such that $k_{1}$ is the first index such that $f_{k}$ is in the span of the other vectors. That is, it is the first which is a finite linear combination of the others. If no such vector exists, then you have what is wanted. Next delete $f_{k_{2}}$ where $k_{2}$ is the next for which $f_{k}$ is a linear combination of the others. Continue. The remaining vectors must be linearly independent. If not, there would be a first which is a linear combination of the others. Say $f_{m}$. But the process would have eliminated it at the $m^{t h}$ step.

Lemma 34.4.2 Suppose $V, W$ are separable Banach spaces such that $V$ is dense in $W$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle, B \neq 0 .
$$

Then there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2},
$$

and also

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i},
$$

the series converging in $W^{\prime}$. If $B=B(\omega)$ and $B$ is $\mathscr{F}$ measurable into $\mathscr{L}\left(W, W^{\prime}\right)$ and if the $e_{i}=e_{i}(\omega)$ are as described above, then these $e_{i}$ are measurable into $V$. If $t \rightarrow B(t, \omega)$ is $C^{1}\left([0, T], \mathscr{L}\left(W, W^{\prime}\right)\right)$ and iffor each $w \in W$,

$$
\left\langle B^{\prime}(t, \omega) w, w\right\rangle \leq k_{w, \omega}(t)\langle B(t, \omega) w, w\rangle
$$

Where $k_{w, \omega} \in L^{1}([0, T])$, then the vectors $e_{i}(t)$ can be chosen to also be right continuous functions of $t$.

In the case of dependence on $t$, the extra condition is trivial if $\langle B(t, \omega) x, x\rangle \geq \delta\|w\|_{W}^{2}$ for example. This includes the usual case of evolution equations where $W=H=H^{\prime}=W^{\prime}$. It also includes the case where $B$ does not depend on $t$.

Proof: Let $\left\{g_{k}\right\}_{k=1}^{\infty}$ be linearly independent vectors of $V$ whose span is dense in $V$. This is possible because $V$ is separable. Thus, their span is also dense in $W$. Let $n_{1}$ be the first index such that $\left\langle B g_{n_{1}}, g_{n_{1}}\right\rangle \neq 0$.

Claim: If there is no such index, then $B=0$.
Proof of claim: First note that if there is no such first index, then if $x=\sum_{i=1}^{k} a_{i} g_{i}$

$$
\begin{aligned}
|\langle B x, x\rangle| & =\left|\sum_{i \neq j} a_{i} a_{j}\left\langle B g_{i}, g_{j}\right\rangle\right| \leq \sum_{i \neq j}\left|a_{i}\right|\left|a_{j}\right|\left|\left\langle B g_{i}, g_{j}\right\rangle\right| \\
& \leq \sum_{i \neq j}\left|a_{i}\right|\left|a_{j}\right|\left\langle B g_{i}, g_{i}\right\rangle^{1 / 2}\left\langle B g_{j}, g_{j}\right\rangle^{1 / 2}=0
\end{aligned}
$$

Therefore, if $x$ is given, you could take $x_{k}$ in the span of $\left\{g_{1}, \cdots, g_{k}\right\}$ such that $\left\|x_{k}-x\right\|_{W} \rightarrow$ 0 . Then

$$
|\langle B x, y\rangle|=\lim _{k \rightarrow \infty}\left|\left\langle B x_{k}, y\right\rangle\right| \leq \lim _{k \rightarrow \infty}\left\langle B x_{k}, x_{k}\right\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2}=0
$$

because $\left\langle B x_{k}, x_{k}\right\rangle$ is zero by what was just shown. Hence the conclusion of the lemma is trivially true. Just pick $e_{1}=g_{1}$ and let $\left\{e_{1}\right\}$ be your set of vectors.

Thus assume there is such a first index. Let

$$
e_{1} \equiv \frac{g_{n_{1}}}{\left\langle B g_{n_{1}}, g_{n_{1}}\right\rangle^{1 / 2}}
$$

Then $\left\langle B e_{1}, e_{1}\right\rangle=1$. Now if you have constructed $e_{j}$ for $j \leq k$,

$$
e_{j} \in \operatorname{span}\left(g_{n_{1}}, \cdots, g_{n_{k}}\right),\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

$g_{n_{j+1}}$ being the first in the list $\left\{g_{j}\right\}$ for which

$$
\left\langle B g_{n_{j+1}}-\sum_{i=1}^{j}\left\langle B g_{n_{j+1}}, e_{i}\right\rangle B e_{i}, g_{n_{j+1}}-\sum_{i=1}^{j}\left\langle B g_{n j}, e_{i}\right\rangle e_{i}\right\rangle \neq 0
$$

and

$$
\operatorname{span}\left(g_{n_{1}}, \cdots, g_{n_{k}}\right)=\operatorname{span}\left(e_{1}, \cdots, e_{k}\right)
$$

let $g_{n_{k+1}}$ be such that $g_{n_{k+1}}$ is the first in the list $\left\{g_{n}\right\} n_{k+1}>n_{k}$ such that

$$
\left\langle B g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle B e_{i}, g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right\rangle \neq 0
$$

Note the difference between this and the Gram Schmidt process. Here you don't necessarily use all of the $g_{k}$ due to the possible degeneracy of $B$.

Claim: If there is no such first $g_{n_{k+1}}$, then $B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)=B W$ so in this case, $\left\{B e_{i}\right\}_{i=1}^{k}$ is actually a basis for $B W$.

Proof: To see this, note that if $p \in\left(n_{j}, n_{j+1}\right)$, then by assumption,

$$
\left\langle B\left(g_{p}-\sum_{i=1}^{j}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right), g_{p}-\sum_{i=1}^{j}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right\rangle=0
$$

Therefore,

$$
B g_{p}=\sum_{i=1}^{j}\left\langle B g_{p}, e_{i}\right\rangle B e_{i}
$$

Also, by assumption, if $p>n_{k}$

$$
\left\langle B\left(g_{p}-\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right), g_{p}-\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right\rangle=0
$$

so

$$
B g_{p}=\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle B e_{i}
$$

which shows that span $\left(\left\{B g_{j}\right\}_{j=1}^{\infty}\right) \subseteq \operatorname{span}\left(\left\{B e_{i}\right\}_{i=1}^{k}\right)$. If $\sum_{i=1}^{k} c_{i} B e_{i}=0$, then for $j \leq k$,

$$
0=\sum_{i=1}^{k} c_{i}\left\langle B e_{i}, e_{j}\right\rangle=c_{j}
$$

so $\left\{B e_{i}\right\}_{i=1}^{k}$ is a basis for $\operatorname{span}\left(\left\{B g_{j}\right\}_{j=1}^{\infty}\right)=B\left(\operatorname{span}\left(\left\{g_{j}\right\}_{j=1}^{\infty}\right)\right)$. Hence if $x \in W$, then letting $x_{r} \in \operatorname{span}\left(\left\{g_{j}\right\}_{j=1}^{\infty}\right)$ with $x_{r} \rightarrow x$ in $W$, it follows

$$
B x_{r}=\sum_{i=1}^{k} a_{i} B e_{i}=\sum_{i=1}^{k}\left\langle B x_{r}, e_{i}\right\rangle B e_{i}
$$

Then passing to a limit, you get

$$
B x=\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

Thus $\left\{B e_{i}\right\}_{i=1}^{k}$ is a basis for $B W$. This proves the claim.
If this happens, the process being described stops. You have found what is desired which has only finitely many vectors involved.

If the process does not stop, let

$$
e_{k+1} \equiv \frac{g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}}{\left\langle B\left(g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right), g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right\rangle^{1 / 2}}
$$

Thus, as in the usual argument for the Gram Schmidt process, $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$ for $i, j \leq k+1$. This is already known for $i, j \leq k$. Letting $l \leq k$, and using the orthogonality already shown,

$$
\begin{aligned}
\left\langle B e_{k+1}, e_{l}\right\rangle & =C\left\langle B\left(g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right), e_{l}\right\rangle \\
& =C\left(\left\langle B g_{k+1}, e_{l}\right\rangle-\left\langle B g_{n_{k+1}}, e_{l}\right\rangle\right)=0
\end{aligned}
$$

Consider

$$
\left\langle B g_{p}-B\left(\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right), g_{p}-\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right\rangle
$$

If $p \in\left(n_{k}, n_{k+1}\right)$, then the above equals zero which implies

$$
B g_{p}=\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle B e_{i}
$$

On the other hand, suppose $g_{p}=g_{n_{k+1}}$ for some $n_{k+1}$ and so, from the construction, $g_{n_{k+1}}=$ $g_{p} \in \operatorname{span}\left(e_{1}, \cdots, e_{k+1}\right)$ and therefore,

$$
g_{p}=\sum_{j=1}^{k+1} a_{j} e_{j}
$$

which requires easily that

$$
B g_{p}=\sum_{i=1}^{k+1}\left\langle B g_{p}, e_{i}\right\rangle B e_{i},
$$

the above holding for all $k$ large enough. To see this last claim, note that the coefficients of $B g=\sum_{j=1}^{m} a_{j} B e_{j}$ are required to be $a_{j}=\left\langle B g, e_{j}\right\rangle$ and from the construction, $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$. Thus if the upper limit is increased beyond what is needed, the new terms are all zero. It follows that for any $x \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$, (finite linear combination of vectors in $\left\{g_{k}\right\}_{k=1}^{\infty}$ )

$$
\begin{equation*}
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i} \tag{34.4.18}
\end{equation*}
$$

because for all $k$ large enough,

$$
B x=\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

Also note that for such $x \in \operatorname{span}\left(\left\{g_{j}\right\}_{j=1}^{\infty}\right)$,

$$
\begin{aligned}
\langle B x, x\rangle & =\left\langle\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}, x\right\rangle=\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle\left\langle B x, e_{i}\right\rangle \\
& =\sum_{i=1}^{k}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
\end{aligned}
$$

Now for $x$ arbitrary, let $x_{k} \rightarrow x$ in $W$ where $x_{k} \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$. Then by Fatou's lemma,

$$
\begin{align*}
\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2} & \leq \lim \inf _{k \rightarrow \infty} \sum_{i=1}^{\infty}\left|\left\langle B x_{k}, e_{i}\right\rangle\right|^{2} \\
& =\lim \inf _{k \rightarrow \infty}\left\langle B x_{k}, x_{k}\right\rangle=\langle B x, x\rangle  \tag{34.4.19}\\
& \leq\|B x\|_{W^{\prime}}\|x\|_{W} \leq\|B\|\|x\|_{W}^{2}
\end{align*}
$$

Thus the series on the left converges. Then also, from the above inequality,

$$
\begin{aligned}
& \left|\left\langle\sum_{i=p}^{q}\left\langle B x, e_{i}\right\rangle B e_{i}, y\right\rangle\right| \leq \sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|\left|\left\langle B e_{i}, y\right\rangle\right| \\
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=p}^{q}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}
\end{aligned}
$$

By 34.4.19,

$$
\leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\|B\|\|y\|_{W}^{2}\right)^{1 / 2} \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}\|y\|_{W}
$$

It follows that

$$
\begin{equation*}
\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i} \tag{34.4.20}
\end{equation*}
$$

converges in $W^{\prime}$ because it was just shown that

$$
\left\|\sum_{i=p}^{q}\left\langle B x, e_{i}\right\rangle B e_{i}\right\|_{W^{\prime}} \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}
$$

and it was shown above that $\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}<\infty$, so the partial sums of the series 34.4.20 are a Cauchy sequence in $W^{\prime}$. Also, the above estimate shows that for $\|y\|=1$,

$$
\begin{aligned}
\left|\left\langle\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}, y\right\rangle\right| & \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}
\end{aligned}
$$

and so

$$
\begin{equation*}
\left\|\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\|_{W^{\prime}} \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2} \tag{34.4.21}
\end{equation*}
$$

Now for $x$ arbitrary, let $x_{k} \in \operatorname{span}\left(\left\{g_{j}\right\}_{j=1}^{\infty}\right)$ and $x_{k} \rightarrow x$ in $W$. Then for a fixed $k$ large enough,

$$
\left\|B x-\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\| \leq\left\|B x-B x_{k}\right\|
$$

$$
\begin{gathered}
+\left\|B x_{k}-\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}\right\|+\left\|\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}-\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\| \\
\leq \varepsilon+\left\|\sum_{i=1}^{\infty}\left\langle B\left(x_{k}-x\right), e_{i}\right\rangle B e_{i}\right\|
\end{gathered}
$$

the term

$$
\left\|B x_{k}-\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}\right\|
$$

equaling 0 by 34.4.18. From 34.4.21 and 34.4.19,

$$
\begin{aligned}
& \leq \varepsilon+\|B\|^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B\left(x_{k}-x\right), e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq \varepsilon+\|B\|^{1 / 2}\left\langle B\left(x_{k}-x\right), x_{k}-x\right\rangle^{1 / 2}<2 \varepsilon
\end{aligned}
$$

whenever $k$ is large enough, the second inequality being implied by 34.4.19. Therefore,

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

in $W^{\prime}$. It follows that

$$
\langle B x, x\rangle=\lim _{k \rightarrow \infty}\left\langle\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}, x\right\rangle=\lim _{k \rightarrow \infty} \sum_{i=1}^{k}\left|\left\langle B x, e_{i}\right\rangle\right|^{2} \equiv \sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
$$

Now consider the measurability assertion on the $e_{i}$. Consider first $e_{1}$. Begin by considering $n_{1}(\omega)$

$$
E_{k}^{1} \equiv\left\{\omega:\left\langle B(\omega) g_{k}, g_{k}\right\rangle \neq 0\right\} \cap \cap_{j<k}\left\{\omega:\left\langle B(\omega) g_{j}, g_{j}\right\rangle=0\right\}
$$

As explained above, $B(\omega)=0$, if and only if $E_{k}^{1}=\emptyset$ for all $k$. Also note that these $E_{k}^{1}$ are disjoint and $\mathscr{F}$ measurable. Then

$$
n_{1}(\omega) \equiv\left\{\begin{array}{l}
1 \text { if } \omega \notin \cup_{k} E_{k}^{1}=\emptyset \\
k \text { if } \omega \in E_{k}^{1}
\end{array}\right.
$$

Then $n_{1}(\omega)$ is clearly measurable because it is constant on measurable sets. Then from the algorithm,

$$
e_{1}(\omega) \equiv \mathscr{X}_{\cup_{k} E_{k}^{1}}(\omega) \frac{g_{n_{1}(\omega)}}{\left\langle B g_{n_{1}(\omega)}, g_{n_{1}(\omega)}\right\rangle^{1 / 2}}
$$

Thus $e_{1}(\omega)=0$ if $\omega \notin \cup_{k} E_{k}^{1}$. Also $e_{1}(\omega)$ is measurable because $\omega \rightarrow n_{1}(\omega)$ is measurable. Thus $e_{1}$ has constant values on measurable sets. So suppose $n_{i}(\omega)$ is measurable for $i \leq m$. Then define $E_{p}^{m+1} \equiv$

$$
\left\{\omega:\left\langle B g_{p}-\sum_{i=1}^{m}\left\langle B g_{p}, e_{i}\right\rangle B e_{i}, g_{p}-\sum_{i=1}^{m}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right\rangle \neq 0\right\} \cap\left\{\omega: n_{m}(\omega)<p\right\}
$$

$$
\cap_{n_{m}(\omega)<r<p}\left\{\omega:\left\langle B g_{r}-\sum_{i=1}^{m}\left\langle B g_{r}, e_{i}\right\rangle B e_{i}, g_{r}-\sum_{i=1}^{m}\left\langle B g_{r}, e_{i}\right\rangle e_{i}\right\rangle=0\right\}
$$

As earlier, these sets $\left\{E_{p}^{m+1}\right\}_{p=1}^{\infty}$ are disjoint and measurable. As before, let $n_{m+1}(\omega)=p$ where $\omega \in E_{p}^{m+1}$. Then from the algorithm, $e_{m+1}(\omega) \equiv$

$$
\mathscr{X}_{\cup_{p} E_{p}^{m+1}}(\omega) \frac{g_{n_{m+1}(\omega)}-\sum_{i=1}^{m}\left\langle B g_{n_{m+1}(\omega)}, e_{i}\right\rangle e_{i}}{D_{m}}
$$

where $D_{m}=$

$$
\left\langle\begin{array}{c}
B\left(g_{n_{m+1}(\omega)}-\sum_{i=1}^{m}\left\langle B g_{n_{m+1}(\omega)}, e_{i}\right\rangle e_{i}\right), \\
g_{n_{m+1}(\omega)}-\sum_{i=1}^{m}\left\langle B g_{n_{m+1}(\omega)}, e_{i}\right\rangle e_{i}
\end{array}\right\rangle^{1 / 2}
$$

Thus the $e_{k}(\omega)$ are all measurable into $W$ thanks to the algorithm. However, they all have values in $V$. Thus if $\phi \in V^{\prime}$, let $\phi_{n} \rightarrow \phi$ in $V^{\prime}$ where $\phi_{n} \in W^{\prime}$.

$$
\left\langle\phi, e_{k}(\omega)\right\rangle_{V^{\prime}, V}=\lim _{n \rightarrow \infty}\left\langle\phi_{n}, e_{k}(\omega)\right\rangle_{V^{\prime}, V}=\lim _{n \rightarrow \infty}\left\langle\phi_{n}, e_{k}(\omega)\right\rangle_{W^{\prime}, W}
$$

which is the limit of measurable functions. By the Pettis theorem, this shows $e_{k}$ is measurable into $V$ also.

To verify the assertion on right continuity, the same kind of argument holds. We suppress the dependence on $\omega$. Consider first $e_{1}$. Begin by considering $n_{1}(t)$

$$
E_{k}^{1} \equiv\left\{t:\left\langle B(t) g_{k}, g_{k}\right\rangle \neq 0\right\} \cap \cap_{j<k}\left\{t:\left\langle B(t) g_{j}, g_{j}\right\rangle=0\right\}
$$

As explained above, $B(t)=0$, if and only if $E_{k}^{1}=\emptyset$ for all $k$. Also note that these $E_{k}^{1}$ are disjoint. Then

$$
n_{1}(t) \equiv\left\{\begin{array}{l}
1 \text { if } t \notin \cup_{k} E_{k}^{1}=\emptyset \\
k \text { if } t \in E_{k}^{1}
\end{array}\right.
$$

If $t \in E_{k}^{1}$, then from the definition, $\left\langle B(t) g_{k}, g_{k}\right\rangle \neq 0$ and $k$ is the first index for which this is nonzero. Let $t_{l} \downarrow t$. Then by continuity, for all $l$ large enough, $\left\langle B\left(t_{l}\right) g_{k}, g_{k}\right\rangle \neq 0$. What of $\left\langle B\left(t_{l}\right) g_{j}, g_{j}\right\rangle$ for $j<k$ ? By assumption,

$$
\left\langle B^{\prime}(t) g_{j}, g_{j}\right\rangle \leq k_{g_{j}}(t)\left\langle B(t) g_{j}, g_{j}\right\rangle
$$

and so, letting $K_{g_{j}}(t)=\int_{0}^{t} k_{g_{j}}(s) d s$,

$$
\begin{gathered}
\frac{d}{d t}\left(e^{-K_{g_{j}}(t)}\left\langle B(t) g_{j}, g_{j}\right\rangle\right) \leq 0 \\
e^{-K_{g_{j}}\left(t_{l}\right)}\left\langle B\left(t_{l}\right) g_{j}, g_{j}\right\rangle \leq e^{-K_{g_{j}}(t)}\left\langle B(t) g_{j}, g_{j}\right\rangle=0
\end{gathered}
$$

Thus one obtains right continuity of $t \rightarrow n_{1}(t)$ and for $E_{k}^{1}$, there is an interval $[t, t+\boldsymbol{\delta}) \subseteq E_{k}^{1}$. From the algorithm,

$$
e_{1}(t) \equiv \mathscr{X}_{\cup_{k} E_{k}^{1}}(t) \frac{g_{n_{1}(t)}}{\left\langle B g_{n_{1}(t)}, g_{n_{1}(t)}\right\rangle^{1 / 2}}
$$

Thus $e_{1}(t)=0$ if $t \notin \cup_{k} E_{k}^{1}$. Also $e_{1}(t)$ is right continuous because $t \rightarrow n_{1}(t)$ is. Thus $e_{1}$ has constant values on a small interval starting at $t$. But what about $t \notin \cup_{k} E_{k}^{1}$ ? Why should it be right continuous there? If you have such a $t$, then as explained above, $B(t)=0$. Then letting $s$ be arbitrary, $s>t$ and $x \in W$,

$$
\left\langle B^{\prime}(s) x, x\right\rangle \leq k_{x}\langle B(s) x, x\rangle
$$

and so as above,

$$
e^{-K_{x}(s)}\langle B(s) x, x\rangle \leq 0
$$

Thus this case reduces to having $B(s) \equiv 0$ for all $s \geq t$ and there is nothing to prove. You have $n_{1}(s)=1$ and $e_{1}(s)=0$ for all $s \geq t$.

Suppose $t \rightarrow n_{i}(t)$ is right continuous for $i \leq m$ and that $e_{i}$ is also. Then define $E_{p}^{m+1} \equiv$

$$
\begin{gathered}
\left\{t:\left\langle B g_{p}-\sum_{i=1}^{m}\left\langle B g_{p}, e_{i}\right\rangle B e_{i}, g_{p}-\sum_{i=1}^{m}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right\rangle \neq 0\right\} \cap\left\{t: n_{m}(t)<p\right\} \\
\cap_{n_{m}(t)<r<p}\left\{t:\left\langle B g_{r}-\sum_{i=1}^{m}\left\langle B g_{r}, e_{i}\right\rangle B e_{i}, g_{r}-\sum_{i=1}^{m}\left\langle B g_{r}, e_{i}\right\rangle e_{i}\right\rangle=0\right\}
\end{gathered}
$$

As earlier, these sets $\left\{E_{p}^{m+1}\right\}_{p=1}^{\infty}$ are disjoint. As before, let $n_{m+1}(t)=p$ where $t \in E_{p}^{m+1}$. Then by similar reasoning to the above, for small $\boldsymbol{\delta},[t, t+\boldsymbol{\delta}) \in E_{p}^{m+1}$ and $n_{m+1}(s)=p$ for $s \in[t, t+\delta)$. Then from the algorithm, $e_{m+1}(t) \equiv$

$$
\mathscr{X}_{\cup_{p} E_{p}^{m+1}}(t) \frac{g_{n_{m+1}(t)}-\sum_{i=1}^{m}\left\langle B g_{n_{m+1}(t)}, e_{i}(t)\right\rangle e_{i}(t)}{D_{m}}
$$

where $D_{m}=$

$$
\left\langle\begin{array}{c}
B\left(g_{n_{m+1}(t)}-\sum_{i=1}^{m}\left\langle B g_{n_{m+1}(t)}, e_{i}(t)\right\rangle e_{i}(t)\right), \\
g_{n_{m+1}(t)}-\sum_{i=1}^{m}\left\langle B g_{n_{m+1}(t)}, e_{i}(t)\right\rangle e_{i}(t)
\end{array}\right\rangle^{1 / 2}
$$

and so is right continuous. What of $t \notin \cup_{p} E_{p}^{m+1}$ ? In this case, the process has terminated and what is desired has been found.

Then the main result in this section is the following integration by parts theorem.
Theorem 34.4.3 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, and let $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ and

$$
\begin{equation*}
B u(t)=B u_{0}+\int_{0}^{t} Y(s) d s \text { in } V^{\prime}, u_{0} \in W, B u(t)=B(u(t)) \text { for a.e. } t \tag{34.4.22}
\end{equation*}
$$

As indicated, $B u$ is the name of a function satisfying the above equation which satisfies $B u(t)=B(u(t))$ for a.e. $t$. Thus $Y=(B u)^{\prime}$ as a weak derivative in the sense of $V^{\prime}$ valued distributions. It is known that $u \in L^{p}(0, T, V)$ for $p>1$. Then $t \rightarrow B u(t)$ is continuous into $W^{\prime}$ for $t$ off a set of measure zero $N$ and also there exists a continuous function $t \rightarrow$ $\langle B u, u\rangle(t)$ such that for all $t \notin N,\langle B u, u\rangle(t)=\langle B(u(t)), u(t)\rangle, B u(t)=B(u(t))$, and for all t,

$$
\frac{1}{2}\langle B u, u\rangle(t)=\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\langle Y(s), u(s)\rangle d s
$$

Note that $\langle B u, u\rangle(0)=\left\langle B u_{0}, u_{0}\right\rangle$.

Proof: By Lemma 34.3.1, there exists a sequence of partitions $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}=\mathscr{P}_{n}, \mathscr{P}_{n} \subseteq$ $\mathscr{P}_{n+1}$, of $[0, T]$ such that the lengths of the sub intervals converge uniformly to 0 as $n \rightarrow \infty$ and the step functions

$$
\begin{aligned}
\sum_{k=0}^{m_{n}-1} u\left(t_{k}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv u^{l}(t) \\
\sum_{k=0}^{m_{n}-1} u\left(t_{k+1}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv u^{r}(t)
\end{aligned}
$$

converge to $u$ in $L^{p}(0, T ; V) \equiv K$. We assume that all of these partition points have empty intersection with the set of measure zero where $B u(t) \neq B(u(t))$. Thus, at every partition point, $B u\left(t_{k}\right)=B\left(u\left(t_{k}\right)\right)$. As just mentioned, $L^{p}(0, T ; V) \equiv K, L^{p^{\prime}}\left(0, T ; V^{\prime}\right)=K^{\prime}$.

Lemma 34.4.4 Let $s<t$. Then for $u, Y$ satisfying 34.4.22

$$
\begin{gather*}
\langle B u(t), u(t)\rangle=\langle B u(s), u(s)\rangle \\
+2 \int_{s}^{t}\langle Y(r), u(t)\rangle d r-\langle B u(t)-B u(s), u(t)-u(s)\rangle \tag{34.4.23}
\end{gather*}
$$

Proof: It follows from the following computations

$$
B u(t)-B u(s)=\int_{s}^{t} Y(r) d r
$$

and so

$$
\begin{gathered}
2 \int_{s}^{t}\langle Y(r), u(t)\rangle d r-\langle B u(t)-B u(s), u(t)-u(s)\rangle \\
=2\left\langle\int_{s}^{t} Y(r) d r, u(t)\right\rangle-\langle B u(t)-B u(s), u(t)-u(s)\rangle \\
=2\langle B u(t)-B u(s), u(t)\rangle-\langle B u(t)-B u(s), u(t)-u(s)\rangle \\
=\quad 2\langle B u(t), u(t)\rangle-2\langle B u(s), u(t)\rangle-\langle B u(t), u(t)\rangle \\
\quad+2\langle B u(s), u(t)\rangle-\langle B u(s), u(s)\rangle \\
=\langle B u(t), u(t)\rangle-\langle B u(s), u(s)\rangle
\end{gathered}
$$

Thus

$$
\begin{gathered}
\langle B u(t), u(t)\rangle-\langle B u(s), u(s)\rangle \\
=2 \int_{s}^{t}\langle Y(r), u(t)\rangle d r-\langle B u(t)-B u(s), u(t)-u(s)\rangle
\end{gathered}
$$

Note that in case $s=0$, you can simply write $B u(0)=B u_{0}$ and the same argument appears to work.

Lemma 34.4.5 In the above situation,

$$
\sup _{t \in N^{C}}\langle B u(t), u(t)\rangle \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

Also, $t \rightarrow B u(t)$ is weakly continuous with values in $W^{\prime}$ on $N^{C}$ where $N$ is the set of measure zero where $B u(t) \neq B(u(t))$.

Proof: From the above formula of Lemma 34.4.4 applied to the $k^{t h}$ partition of $[0, T]$ described above,

$$
\begin{aligned}
& \left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle-\left\langle B u_{0}, u_{0}\right\rangle=\sum_{j=0}^{m-1}\left\langle B u\left(t_{j+1}\right), u\left(t_{j+1}\right)\right\rangle-\left\langle B u\left(t_{j}\right), u\left(t_{j}\right)\right\rangle \\
& =\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j+1}\right)\right\rangle d r-\left\langle B\left(u\left(t_{j+1}\right)-u\left(t_{j}\right)\right), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle \\
& =\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u_{k}^{r}(r)\right\rangle d r-\left\langle B\left(u\left(t_{j+1}\right)-u\left(t_{j}\right)\right), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle
\end{aligned}
$$

Thus, discarding the negative terms and denoting by $\mathscr{P}_{k}$ the $k^{t h}$ of these partitions,

$$
\begin{aligned}
& \sup _{t_{j} \in \mathscr{P}_{k}}\left\langle B u\left(t_{j}\right), u\left(t_{j}\right)\right\rangle \leq\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{T}\left|\left\langle Y(r), u_{k}^{r}(r)\right\rangle\right| d r \\
& \leq\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{T}\|Y(r)\|_{V^{\prime}}\left\|u_{k}^{r}(r)\right\|_{V} d r \\
& \leq\left\langle B u_{0}, u_{0}\right\rangle+2\left(\int_{0}^{T}\|Y(r)\|_{V^{\prime}}^{p^{\prime}} d r\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|u_{k}^{r}(r)\right\|_{V}^{p} d r\right)^{1 / p} \\
& \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
\end{aligned}
$$

because these partitions are chosen such that

$$
\lim _{k \rightarrow \infty}\left(\int_{0}^{T}\left\|u_{k}^{r}(r)\right\|_{V}^{p}\right)^{1 / p}=\left(\int_{0}^{T}\|u(r)\|_{V}^{p}\right)^{1 / p}
$$

and so these are bounded. This has shown that for the dense subset of $[0, T], D \equiv \cup_{k} \mathscr{P}_{k}$,

$$
\sup _{t \in D}\langle B u(t), u(t)\rangle<C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

From Lemma 34.4.2 above, there exists $\left\{e_{i}\right\} \subseteq V$ such that $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$ and for $t \notin N$,

$$
\langle B u(t), u(t)\rangle=\sum_{k=1}^{\infty}\left|\left\langle B u(t), e_{i}\right\rangle\right|^{2}=\sup _{m} \sum_{k=1}^{m}\left|\left\langle B u(t), e_{i}\right\rangle\right|^{2}
$$

Thus, if $s_{n} \rightarrow t, s_{n} \in D$, Fatou's lemma implies

$$
\begin{aligned}
\langle B u, u\rangle(t) & =\langle B(u(t)), u(t)\rangle=\sum_{k=1}^{\infty}\left|\left\langle B u(t), e_{i}\right\rangle\right|^{2} \\
& \leq \lim \inf _{n \rightarrow \infty} \sum_{k=1}^{\infty}\left|\left\langle B u\left(s_{n}\right), e_{i}\right\rangle\right|^{2} \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
\end{aligned}
$$

and so

$$
\sup _{t \in N^{C}}\langle B u, u\rangle(t)=\sup _{t \in N^{C}}\langle B(u(t)), u(t)\rangle \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

It only remains to verify the claim about weak continuity.
Consider now the claim that $t \rightarrow B u(t)$ is weakly continuous on $N^{C}$. Letting $v \in V, s \in$ $N^{C}$,

$$
\begin{equation*}
\lim _{t \rightarrow s}\langle B u(t), v\rangle=\langle B u(s), v\rangle=\langle B u(s), v\rangle \tag{34.4.24}
\end{equation*}
$$

The limit follows from the formula 34.4.22 which implies $t \rightarrow B u(t)$ is continuous into $V^{\prime}$. Now for $t \in N^{C}$,

$$
\|B u(t)\|=\sup _{\|v\| \leq 1}|\langle B u(t), v\rangle| \leq\langle B v, v\rangle^{1 / 2}\langle B u(t), u(t)\rangle^{1 / 2}
$$

which was shown to be bounded for $t, s \in N^{C}$. Now let $w \in W$. Then

$$
|\langle B u(t), w\rangle-\langle B u(s), w\rangle| \leq|\langle B u(t)-B u(s), w-v\rangle|+|\langle B u(t)-B u(s), v\rangle|
$$

Then the first term is less than $\varepsilon$ if $v$ is close enough to $w$ and the second converges to 0 so 34.4.24 holds for all $v \in W$ and so this shows the weak continuity on $N^{C}$.

Now pick $t \in D$, the union of all the mesh points. Then for all $k$ large enough, $t \in \mathscr{P}_{k}$. Say $t=t_{m}$. From Lemma 34.4.4,

$$
\begin{gathered}
-\sum_{j=0}^{m-1}\left\langle B\left(u\left(t_{j+1}\right)-u\left(t_{j}\right)\right),\left(u\left(t_{j+1}\right)-u\left(t_{j}\right)\right)\right\rangle= \\
\left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle-\left\langle B u_{0}, u_{0}\right\rangle-2 \sum_{j=0}^{m-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u_{k}^{r}(r)\right\rangle d r
\end{gathered}
$$

Thus, $\left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle$ is constant for all $k$ large enough and the integral term converges to

$$
\int_{0}^{t_{m}}\langle Y(r), u(r)\rangle d r
$$

It follows that the term on the left does converge to something as $k \rightarrow \infty$. It just remains to consider what it does converge to. However, from the equation solved by $u$,

$$
B u\left(t_{j+1}\right)-B u\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Y(r) d r
$$

Therefore, this term is dominated by an expression of the form

$$
\begin{aligned}
& \quad\left|\sum_{j=0}^{m_{k}-1}\left\langle\int_{t_{j}}^{t_{j+1}} Y(r) d r, u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle\right| \\
& =\left|\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle d r\right| \\
& =\left|\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j+1}\right)\right\rangle-\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j}\right)\right\rangle\right| \\
& =\left|\int_{0}^{t_{m}}\left\langle Y(r), u^{r}(r)\right\rangle d r-\int_{0}^{t_{m}}\left\langle Y(r), u^{l}(r)\right\rangle d r\right| \\
& \leq \int_{0}^{T}\left|\left\langle Y(r), u^{r}(r)-u^{l}(r)\right\rangle\right| d r
\end{aligned}
$$

However, both $u^{r}$ and $u^{l}$ converge to $u$ in $K=L^{p}(0, T, V)$. Therefore, this term must converge to 0 . Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t \in D$,

$$
\langle B u(t), u(t)\rangle=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r
$$

It remains to verify that this holds for all $t \notin N$. Let $t \in N^{C} \backslash D$ and let $t(k) \in \mathscr{P}_{k}$ be the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$
B u(t(m))=B u_{0}+\int_{0}^{t(m)} Y(s) d s
$$

a similar formula for $u(t(k))$. Thus for $t>t(m)$,

$$
B u(t)-B u(t(m))=\int_{t(m)}^{t} Y(s) d s
$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $u_{0}=0$. Therefore,

$$
\begin{aligned}
& \langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle \\
= & 2 \int_{t(m)}^{t(k)}\langle Y(s), u(s)-u(t(m))\rangle d s
\end{aligned}
$$

Thus, for $m \leq k$

$$
\begin{equation*}
\lim _{m, k \rightarrow \infty}\langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle=0 \tag{34.4.25}
\end{equation*}
$$

Hence $\{B u(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $W^{\prime}$ because

$$
\begin{aligned}
& |\langle B(u(t(k))-u(t(m))), y\rangle| \\
\leq & \langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2} \\
\leq & \langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle^{1 / 2}\|B\|^{1 / 2}\|y\|_{W}
\end{aligned}
$$

Does it converge to $B u(t)$ ? Let $\xi(t) \in W^{\prime}$ be what it does converge to. Let $v \in V$. Then

$$
\langle\xi(t), v\rangle=\lim _{k \rightarrow \infty}\langle B u(t(k)), v\rangle=\lim _{k \rightarrow \infty}\langle B u(t(k)), v\rangle=\langle B u(t), v\rangle
$$

because it is known that $t \rightarrow B u(t)$ is continuous into $V^{\prime}$. It is also known that for $t \in N^{C}$, $B u(t) \in W^{\prime} \subseteq V^{\prime}$ and that the $B u(t)$ for $t \in N^{C}$ are uniformly bounded in $W^{\prime}$. Therefore, since $V$ is dense in $W$, it follows that $\xi(t)=B u(t)$.

Now for every $t \in D$, it was shown above that

$$
\langle B u(t), u(t)\rangle=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r
$$

Also it was just shown that $B u(t(k)) \rightarrow B u(t)$ for $t \notin N$. Then for $t \notin N$

$$
\begin{gathered}
|\langle B u(t(k)), u(t(k))\rangle-\langle B u(t), u(t)\rangle| \\
\leq|\langle B u(t(k)), u(t(k))-u(t)\rangle|+|\langle B u(t(k))-B u(t), u(t)\rangle|
\end{gathered}
$$

Then the second term converges to 0 . The first equals

$$
\begin{aligned}
& |\langle B u(t(k))-B u(t), u(t(k))\rangle| \\
\leq & \langle B(u(t(k))-u(t)), u(t(k))-u(t)\rangle^{1 / 2}\langle B u(t(k)), u(t(k))\rangle^{1 / 2}
\end{aligned}
$$

From the above, this is dominated by an expression of the form

$$
\langle B(u(t(k))-u(t)), u(t(k))-u(t)\rangle^{1 / 2} C
$$

Then using the lower semicontinuity of $t \rightarrow\langle B(u(t(k))-u(t)), u(t(k))-u(t)\rangle$ on $N^{C}$ which follows from the above, this is no larger than

$$
\lim \inf _{m \rightarrow \infty}\langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle^{1 / 2} C<\varepsilon
$$

provided $k$ is large enough. This follows from 34.4.25. Since $\varepsilon$ is arbitrary, it follows that

$$
\lim _{k \rightarrow \infty}|\langle B u(t(k)), u(t(k))\rangle-\langle B u(t), u(t)\rangle|=0
$$

Then from the formula,

$$
\langle B u(t), u(t)\rangle=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r
$$

valid for $t \in D$, it follows that the same formula holds for all $t \notin N$. Then define $\langle B u, u\rangle(t)$ to equal $\langle B u(t), u(t)\rangle$ off $N$ and the right side for $t \in N$. Thus $t \rightarrow\langle B u, u\rangle(t)$ is continuous and for all $t \in[0, T]$,

$$
\langle B u, u\rangle(t)=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r
$$

Also recall that $t \rightarrow B u(t)$ was shown to be weakly continuous into $W^{\prime}$ on $N^{C}$. Then for $t, s \in N^{C}$,

$$
\begin{aligned}
& \langle B(u(t)-u(s)), u(t)-u(s)\rangle \\
= & \langle B u(t), u(t)\rangle-2\langle B u(t), u(s)\rangle+\langle B u(s), u(s)\rangle
\end{aligned}
$$

From this, it follows that $t \rightarrow B u(t)$ is continuous into $W^{\prime}$ on $N^{C}$ because $\lim _{t \rightarrow s}$ of the right side gives 0 and so the same is true of the left. Hence,

$$
\begin{aligned}
|\langle B(u(t)-u(s)), y\rangle| & \leq\langle B y, y\rangle^{1 / 2}\langle B(u(t)-u(s)), u(t)-u(s)\rangle^{1 / 2} \\
& \leq\|B\|^{1 / 2}\langle B(u(t)-u(s)), u(t)-u(s)\rangle^{1 / 2}\|y\|
\end{aligned}
$$

so

$$
\|B(u(t)-u(s))\|_{W^{\prime}} \leq\|B\|^{1 / 2}\langle B(u(t)-u(s)), u(t)-u(s)\rangle^{1 / 2}
$$

which converges to 0 as $t \rightarrow s$.
Consider the case that $t \rightarrow B(u(t))$ has a weak derivative, denoted as $(B u)^{\prime}(t)$ which is in $L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$. Then as shown above, there is a continuous function, denoted as $B u(t)$ which equals $B(u(t))$ for a.e. $t$ and

$$
B u(t)=B u(0)+\int_{0}^{t}(B u)^{\prime}(s) d s
$$

Then the above theorem applies. Then one obtains the following corollary.
Corollary 34.4.6 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ is nonnegative and self adjoint. Also suppose $t \rightarrow B(u(t))$ has a weak derivative $(B u)^{\prime} \in$ $L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ for $u \in L^{p}(0, T ; V)$. Then there is a continuous function denoted as $B u(t)$ which equals $B(u(t))$ a.e. $t$. Say for $t \notin N$. Suppose $B u(0)=B u_{0}, u_{0} \in W$. Then

$$
\begin{equation*}
B u(t)=B u_{0}+\int_{0}^{t}(B u)^{\prime}(s) d s \text { in } V^{\prime} \tag{34.4.26}
\end{equation*}
$$

Then $t \rightarrow B u(t)$ is in $C\left(N^{C}, W^{\prime}\right)$ and also for such $t$,

$$
\frac{1}{2}\langle B u(t), u(t)\rangle=\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s
$$

There exists a continuous function $t \rightarrow\langle B u, u\rangle(t)$ which equals the right side of the above for all $t$ and equals $\langle B u(t), u(t)\rangle$ off $N$. This also satisfies

$$
\sup _{t \in[0, T]}\langle B u, u\rangle(t) \leq C\left(\left\|(B u)^{\prime}\right\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)},\|u\|_{L^{p}(0, T, V)}\right)
$$

where we can take the right side to equal

$$
\left\langle B u_{0}, u_{0}\right\rangle+2\left\|(B u)^{\prime}\right\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)}\|u\|_{L^{p}(0, T, V)}
$$

This follows from the above theorem, in particular Lemma 34.4.5.
This also makes it easy to verify continuity of pointwise evaluation of $B u$. Let $L u=$ $(B u)^{\prime}$.

$$
\begin{gather*}
u=D(L) \equiv\left\{u \in L^{p}(0, T ; V): L u \equiv(B u)^{\prime} \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)\right\} \\
\|u\|_{X} \equiv\|u\|_{L^{p}(0, T, V)}+\|L u\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)} \tag{34.4.27}
\end{gather*}
$$

Since $L$ is closed, this $X$ is a Banach space.
Then the following theorem is obtained.
Theorem 34.4.7 $\operatorname{Say}(B u)^{\prime} \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)$ so

$$
B u(t)=B u(0)+\int_{0}^{t}(B u)^{\prime}(s) d s \text { in } V^{\prime}
$$

the map $u \rightarrow B u(t)$ is continuous as a map from $X$ to $V^{\prime}$. Also, if $Y$ denotes those $f \in$ $L^{p}([0, T] ; V)$ for which $f^{\prime} \in L^{p}([0, T] ; V)$, so that $f$ has a representative such that $f(t)=$ $f(0)+\int_{0}^{t} f^{\prime}(s) d s$, then if $\|f\|_{Y} \equiv\|f\|_{L^{p}([0, T] ; V)}+\left\|f^{\prime}\right\|_{L^{p}([0, T] ; V)}$, the map $f \rightarrow f(t)$ is continuous.

Proof: First, why is $u \rightarrow B u(0)$ continuous? Say $u, v \in X$ and say $p \geq 2$ first.

$$
B u(t)-B v(t)=B u(0)-B v(0)+\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s
$$

and so,

$$
\|B u(0)-B v(0)\|_{V^{\prime}} \leq\|B u(t)-B v(t)\|_{V^{\prime}}+\int_{0}^{t}\left\|(B u)^{\prime}(s)-(B v)^{\prime}(s)\right\|_{V^{\prime}} d s
$$

then using the triangle inequality,

$$
\begin{aligned}
& \left(\int_{0}^{T}\|B u(0)-B v(0)\|_{V^{\prime}}^{p^{\prime}} d t\right)^{1 / p^{\prime}} \leq\left(\int_{0}^{T}\|B u(t)-B v(t)\|_{V^{\prime}}^{p^{\prime}} d t\right)^{1 / p^{\prime}} \\
& +\left(\int_{0}^{T}\left\|\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s\right\|^{p^{\prime}} d t\right)^{1 / p^{\prime}}
\end{aligned}
$$

and so

$$
\begin{gathered}
\|B u(0)-B v(0)\|_{V^{\prime}} T^{1 / p^{\prime}} \leq \\
\left(\|B\|\|u-v\|_{L^{p^{\prime}}([0, T] ; V)}+T^{1 / p^{\prime}}\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)}\right) \\
\leq\left(\|B\|\|u-v\|_{L^{p}([0, T] ; V)}+T^{1 / p^{\prime}}\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)}\right)
\end{gathered}
$$

$$
\leq C(\|B\|, T)\|u-v\|_{X}
$$

Thus $u \rightarrow B u(0)$ is continuous into $V^{\prime}$. If $p<2$, then you do something similar.

$$
\begin{gathered}
\left(\int_{0}^{T}\|B u(0)-B v(0)\|_{V^{\prime}}^{p} d t\right)^{1 / p} \leq\left(\int_{0}^{T}\|B u(t)-B v(t)\|_{V^{\prime}}^{p} d t\right)^{1 / p} \\
+\left(\int_{0}^{T}\left\|\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s\right\|^{p} d t\right)^{1 / p} \\
\leq\|B\|\|u-v\|_{L^{p}([0, T] ; V)}+\int_{0}^{T}\left(\int_{0}^{T}\left\|(B u)^{\prime}(s)-(B v)^{\prime}(s)\right\|^{p} d t\right)^{1 / p} d s \\
\leq\|B\|\|u-v\|_{L^{p}([0, T] ; V)}+T^{1 / p} \int_{0}^{T}\left\|(B u)^{\prime}(s)-(B v)^{\prime}(s)\right\| d s \\
\leq\|B\|\|u-v\|_{L^{p}([0, T] ; V)}+C T^{1 / p}\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)}
\end{gathered}
$$

Thus

$$
\begin{aligned}
\|B u(0)-B v(0)\|_{V^{\prime}} T^{1 / p} & \leq\|B\|\|u-v\|_{L^{p}([0, T] ; V)}+C(T)\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)} \\
& \leq C(\|B\|, T)\|u-v\|_{X}
\end{aligned}
$$

However, one could just as easily have done this for an arbitrary $s<T$ by repeating the argument for

$$
B u(t)=B u(s)+\int_{s}^{t}(B u)^{\prime}(r) d r
$$

Thus this mapping is certainly continuous into $V^{\prime}$. The last assertion is similar. You just use $f$ instead of $B u$ and make easy modifications in the argument. It is all happening in one space in the second case.

For $u \in X$ defined above,

$$
B u(t)=B u(0)+\int_{0}^{t}(B u)^{\prime}(s) d s
$$

and also

$$
\frac{1}{2}\langle B u(t), u(t)\rangle=\frac{1}{2}\langle B u, u\rangle(0)+\int_{0}^{t}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s
$$

This follows from a similar argument given above, (Note we write $\langle B u, u\rangle(0)$ instead of $\left\langle B u_{0}, u_{0}\right\rangle$ since no $u_{0}$ is mentioned. One could also use the above by considering the problem on $[s, t]$ where $s$ is not in the exceptional set where it makes a difference between writing $B u(s)$ and $B(u(s))$. Then you would get the above with 0 replaced with $s$ and then let $s \rightarrow 0$ to finally obtain the above displayed formula. ) and

$$
\sup _{t \in[0, T]}\langle B u, u\rangle(t) \leq C\left(\left\|(B u)^{\prime}\right\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)},\|u\|_{L^{p}(0, T, V)}\right)=C\left(\|u\|_{X}\right)
$$

where $X$ was defined in 34.4.27, then

$$
\sup _{t \in[0, T]}\left\langle B \frac{u}{\|u\|_{X}}, \frac{u}{\|u\|_{X}}\right\rangle(t) \leq C(1)=C
$$

and so

$$
\sup _{t \in[0, T]}\langle B u, u\rangle(t) \leq C\|u\|_{X}^{2}
$$

Now define for $u, v \in X$

$$
\langle B u, v\rangle(t) \equiv \frac{1}{2}[\langle B(u+v), u+v\rangle(t)-(\langle B u, u\rangle(t)+\langle B v, v\rangle(t))]
$$

and so for a.e. $t,\langle B u, v\rangle(t)=\langle B(u(t)), v(t)\rangle$ and $t \rightarrow\langle B u, v\rangle(t)$ is continous. Also, there must exist $C$ such that for all $u, v$ and $t \in[0, T]$,

$$
|\langle B u, v\rangle(t)| \leq C\|u\|_{X}\|v\|_{X}
$$

If this is not so, then you could get $u_{n}, v_{n}$ having norm equal to 1 in $X$ such that

$$
\sup _{t \in[0, T]}\left|\left\langle B u_{n}, v_{n}\right\rangle(t)\right|>n
$$

But then, letting $t_{n}$ be a point where $\left|\left\langle B u_{n}, v_{n}\right\rangle\left(t_{n}\right)\right|>n$,

$$
n<\left|\left\langle B u_{n}, v_{n}\right\rangle\left(t_{n}\right)\right| \leq \frac{1}{2}\left[C\left(\left\|u_{n}+v_{n}\right\|_{X}^{2}+\|u\|_{X}^{2}+\|v\|_{X}^{2}\right)\right]=\frac{C}{2}(4+1+1)=3 C
$$

which is clearly a contradiction. It follows that one can define $K: X \rightarrow X^{\prime}$ as follows.

$$
\langle K u, v\rangle \equiv \int_{0}^{T}\langle L u, v\rangle d s+\langle B u, v\rangle(0)
$$

Thus $K$ is linear and continuous. In addition,

$$
\langle K u, u\rangle=\frac{1}{2}[\langle B u, u\rangle(T)+\langle B u, u\rangle(0)]
$$

To see this, Corollary 34.4.6 implies

$$
\frac{1}{2}\langle B u, u\rangle(T)=\frac{1}{2}\langle B u, u\rangle(0)+\int_{0}^{T}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s
$$

and so

$$
\begin{aligned}
& \frac{1}{2}\langle B u, u\rangle(T)+\langle B u, u\rangle(0) \\
= & \frac{1}{2}\langle B u, u\rangle(0)+\int_{0}^{T}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s+\langle B u, u\rangle(0)
\end{aligned}
$$

and so, this yields

$$
\int_{0}^{T}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s+\langle B u, u\rangle(0)=\langle K u, u\rangle=\frac{1}{2}[\langle B u, u\rangle(T)+\langle B u, u\rangle(0)]
$$

as claimed. This proves most of the following.

Proposition 34.4.8 Let

$$
X=\left\{u \in L^{p}(0, T ; V) \equiv \mathscr{V}: L u \equiv(B u)^{\prime} \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)\right\}
$$

where $V$ is a reflexive Banach space. Let a norm on $X$ be given by

$$
\|u\|_{X} \equiv\|u\|_{\mathscr{V}}+\|L u\|_{\mathscr{V}^{\prime}}
$$

Then there is a continuous function $t \rightarrow\langle B u, v\rangle(t)$ such that $\langle B u, v\rangle(t)=\langle B(u(t)), v(t)\rangle$ a.e. $t$ such that

$$
\sup _{t \in[0, T]}|\langle B u, v\rangle(t)| \leq C\|u\|_{X}\|v\|_{X}
$$

and if $K: X \rightarrow X^{\prime}$

$$
\langle K u, v\rangle \equiv \int_{0}^{T}\langle L u, v\rangle d s+\langle B u, v\rangle(0)
$$

Then $K$ is continuous and linear and

$$
\langle K u, u\rangle=\frac{1}{2}[\langle B u, u\rangle(T)+\langle B u, u\rangle(0)]
$$

If $u \in X$ and $B u(0)=0$ then there exists a sequence $\left\{u_{n}\right\}$ such that $\left\|u_{n}-u\right\|_{X} \rightarrow 0$ but $u_{n}(t)=0$ for all t close to 0 .

Proof: It only remains to verify the last assertion. Let $\psi_{n}$ be increasing and piecewise linear such that $\psi_{n}(t)=1$ for $t \geq 2 / n$ and equals 0 on $[0,1 / n]$. Then clearly $\psi_{n} u \rightarrow u$ in $\mathscr{V}$.

$$
\left(B\left(\psi_{n} u\right)\right)^{\prime}=\psi_{n}^{\prime} B u+\psi_{n}(B u)^{\prime}
$$

The second term converges to $(B u)^{\prime}$ in $\mathscr{V}^{\prime}$. It remains to consider the first term.

$$
\begin{gathered}
\int_{0}^{T}\left\|\psi_{n}^{\prime} B u\right\|_{V^{\prime}}^{p^{\prime}} d t \leq \int_{0}^{2 / n} n\left\|\int_{0}^{t}(B u)^{\prime} d s\right\|^{p^{\prime}} d t \\
\leq n \int_{0}^{2 / n} t^{p^{\prime}-1} \int_{0}^{t}\left\|(B u)^{\prime}\right\|_{V^{\prime}}^{p^{\prime}} d s d t \leq \int_{0}^{2 / n}\left\|(B u)^{\prime}\right\|_{V^{\prime}}^{p^{\prime}} d s \frac{1}{p^{\prime}}(2 / n)^{p^{\prime}} n
\end{gathered}
$$

Since $p^{\prime}>1$, this converges to 0 .
Note that, by convolving with a mollifier, we could assume each $u_{n}$ is also smooth. In addition to this, we can draw a similar conclusion at the right endpoint. That is, if $B u(T)=0$ there is a sequence $\left\{u_{n}\right\} \subseteq X$ where $u_{n}(t)=0$ for $t$ near $T$ which converges to $u$ in $X$.

### 34.5 The Implicit Case, $B=B(t)$

The above theorem can be generalized to the case where the formula is of the form

$$
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s
$$

This involves an operator $B(t) \in \mathscr{L}\left(W, W^{\prime}\right)$ and $B(t)$ satisfies

$$
\langle B(t) x, x\rangle \geq 0,\langle B(t) x, y\rangle=\langle B(t) y, x\rangle
$$

for

$$
V \subseteq W, W^{\prime} \subseteq V^{\prime}
$$

Where we assume $t \rightarrow B(t)$ is in $C^{1}\left([0, T] ; \mathscr{L}\left(W, W^{\prime}\right)\right)$ and $V$ is dense in the Banach space $W$.

Then the main result in this section is the following integration by parts theorem.
Theorem 34.5.1 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, and let $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ and

$$
\begin{equation*}
B u(t)=B u_{0}+\int_{0}^{t} Y(s) d s \text { in } V^{\prime}, u_{0} \in W, B u(t)=B(t)(u(t)) \text { for a.e. } t \tag{34.5.28}
\end{equation*}
$$

As indicated, $B u$ is the name of a function satisfying the above equation which satisfies $B u(t)=B(t)(u(t))$ for a.e. $t$. Thus $Y=(B u)^{\prime}$ as a weak derivative in the sense of $V^{\prime}$ valued distributions. Suppose that $u \in L^{p}([0, T], V)$ and $(s, t) \rightarrow B^{\prime}(s) u(t)$ is bounded in $V^{\prime}$ in case $p<2$. (If $B(t)$ is constant in this is obvious.) In the case where $p \geq 2$, it is enough to assume $B^{\prime} \in C^{1}\left([0, T] ; \mathscr{L}\left(W, W^{\prime}\right)\right)$. Then $t \rightarrow B u(t)$ is continuous into $W^{\prime}$ for $t$ off a set of measure zero $N$ and also there exists a continuous function $t \rightarrow\langle B u, u\rangle(t)$ such that for all $t \notin N,\langle B u, u\rangle(t)=\langle B(u(t)), u(t)\rangle, B u(t)=B(t)(u(t))$, and for all $t$,

$$
\frac{1}{2}\langle B u, u\rangle(t)+\frac{1}{2} \int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d s=\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\langle Y(s), u(s)\rangle d s
$$

Proof: By Lemma 34.3.1, there exists a sequence of partitions $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}=\mathscr{P}_{n}, \mathscr{P}_{n} \subseteq$ $\mathscr{P}_{n+1}$, of $[0, T]$ such that the lengths of the sub intervals converge uniformly to 0 as $n \rightarrow \infty$ and the step functions

$$
\begin{aligned}
\sum_{k=0}^{m_{n}-1} u\left(t_{k}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv u_{n}^{l}(t) \\
\sum_{k=0}^{m_{n}-1} u\left(t_{k+1}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv u_{n}^{r}(t)
\end{aligned}
$$

converge to $u$ in $L^{p}(0, T ; V) \equiv K$. We assume that all of these partition points have empty intersection with the set of measure zero where $B u(t) \neq B(t)(u(t))$. Thus, at every partition point, $B u\left(t_{k}\right)=B\left(t_{k}\right)\left(u\left(t_{k}\right)\right)$. As just mentioned, $L^{p}(0, T ; V) \equiv K, L^{p^{\prime}}\left(0, T ; V^{\prime}\right)=K^{\prime}$.

Taking a subsequence, we can have

$$
\begin{align*}
& \quad\left\|u_{n}^{l}-u\right\|_{K}+\left\|u_{n}^{r}-u\right\|_{K}+\left\|B u_{n}^{l}-B u\right\|_{K^{\prime}}+\left\|B u_{n}^{r}-B u\right\|_{K^{\prime}} \\
& +\left\|B^{\prime} u_{n}^{r}-B^{\prime} u\right\|_{L^{2}\left([0, T], W^{\prime}\right)}+\left\|B^{\prime} u_{n}^{l}-B^{\prime} u\right\|_{L^{2}\left([0, T], W^{\prime}\right)}<2^{-n} \tag{34.5.29}
\end{align*}
$$

and so, we can assume that $a . e$. convergence also takes place for $B u_{n}^{l}, B u_{n}^{r}, B^{\prime} u_{n}^{l}, B^{\prime} u_{n}^{r}, u_{n}^{r}, u_{n}^{l}$.
Is $B u(0)=B(0) u_{0}$ ? The integral equation gives this it seems. To save notation, $B(0) u_{0}$ will be written as $B u_{0}$. This is not inconsistent because $t \rightarrow B(t) u_{0}$ is continuous and its value at 0 is $B(0) u_{0}$.

Lemma 34.5.2 Let $s<t$. Then for $u, Y$ satisfying 34.5.28

$$
\begin{gather*}
\langle B u(t), u(t)\rangle-\langle B u(s), u(s)\rangle+\langle(B(t)-B(s)) u(s), u(t)\rangle \\
+\langle(B(t)-B(s)) u(s), u(t)-u(s)\rangle=2 \int_{s}^{t}\langle Y(r), u(t)\rangle d r \\
-\langle B(t) u(t)-B(t) u(s), u(t)-u(s)\rangle \tag{34.5.30}
\end{gather*}
$$

Proof: It follows from the following computations

$$
B(t) u(t)-B(s) u(s)=\int_{s}^{t} Y(r) d r
$$

and so

$$
\begin{gathered}
2 \int_{s}^{t}\langle Y(r), u(t)\rangle d r-\langle B(t) u(t)-B(s) u(s), u(t)-u(s)\rangle \\
=2\left\langle\int_{s}^{t} Y(r) d r, u(t)\right\rangle-\langle B(t) u(t)-B(s) u(s), u(t)-u(s)\rangle \\
=2\langle B(t) u(t)-B(s) u(s), u(t)\rangle-\langle B(t) u(t)-B(s) u(s), u(t)-u(s)\rangle \\
=\quad 2\langle B(t) u(t), u(t)\rangle-2\langle B(s) u(s), u(t)\rangle-\langle B(t) u(t), u(t)\rangle \\
+\langle B(t) u(t), u(s)\rangle+\langle B(s) u(s), u(t)\rangle-\langle B(s) u(s), u(s)\rangle \\
=\quad\langle B(t) u(t), u(t)\rangle-\langle B(s) u(s), u(s)\rangle \\
+[\langle B(t) u(t), u(s)\rangle-\langle B(s) u(s), u(t)\rangle] \\
=\quad\langle B(t) u(t), u(t)\rangle-\langle B(s) u(s), u(s)\rangle \\
\\
+\langle(B(t)-B(s)) u(s), u(t)\rangle
\end{gathered}
$$

Thus

$$
\begin{aligned}
& \langle B u(t), u(t)\rangle-\langle B u(s), u(s)\rangle+\langle(B(t)-B(s)) u(s), u(t)\rangle \\
= & 2 \int_{s}^{t}\langle Y(r), u(t)\rangle d r-\langle B(t) u(t)-B(s) u(s), u(t)-u(s)\rangle
\end{aligned}
$$

Now consider the last term. It equals

$$
\begin{gathered}
\langle B(t) u(t)-(B(s)-B(t)+B(t)) u(s), u(t)-u(s)\rangle \\
=\langle B(t) u(t)-((B(s)-B(t)) u(s)+B(t) u(s)), u(t)-u(s)\rangle \\
=\langle B(t) u(t)-B(t) u(s), u(t)-u(s)\rangle+\langle(B(t)-B(s)) u(s), u(t)-u(s)\rangle
\end{gathered}
$$

It follows that

$$
\langle B u(t), u(t)\rangle-\langle B u(s), u(s)\rangle+\langle(B(t)-B(s)) u(s), u(t)\rangle
$$

$$
\begin{gathered}
+\langle(B(t)-B(s)) u(s), u(t)-u(s)\rangle \\
=2 \int_{s}^{t}\langle Y(r), u(t)\rangle d r-\langle B(t) u(t)-B(t) u(s), u(t)-u(s)\rangle
\end{gathered}
$$

Of course this computation is under the assumption that neither $s, t$ are in the exceptional set off which $B(t) u(t)=B u(t)$. In case $s=0$ the same formula holds except you need to replace $u(s)$ with $u_{0}$ and $B u(s)$ with $B(0) u_{0}=B u(0)$.

It is good to emphasize part of the above.

$$
\begin{gathered}
\langle B(t) u(t)-B(t) u(s), u(t)-u(s)\rangle-\langle B(t) u(t)-B(s) u(s), u(t)-u(s)\rangle \\
=\langle(B(s)-B(t)) u(s), u(t)-u(s)\rangle
\end{gathered}
$$

Lemma 34.5.3 Let the partitions $\mathscr{P}_{k}$ be as above such that 34.5.29, $\mathscr{P}_{k}=\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$. Then for any $m \leq m_{k}$,

$$
\begin{aligned}
& \sum_{j=0}^{m-1}\left\langle B\left(t_{j+1}^{k}\right) u\left(t_{j+1}^{k}\right)-B\left(t_{j+1}^{k}\right) u\left(t_{j}^{k}\right), u\left(t_{j+1}^{k}\right)-u\left(t_{j}^{k}\right)\right\rangle- \\
& \sum_{j=0}^{m-1}\left\langle B\left(t_{j+1}^{k}\right) u\left(t_{j+1}^{k}\right)-B\left(t_{j}^{k}\right) u\left(t_{j}^{k}\right), u\left(t_{j+1}^{k}\right)-u\left(t_{j}^{k}\right)\right\rangle=\varepsilon^{m}(k)
\end{aligned}
$$

where $\lim _{k \rightarrow \infty} \varepsilon^{m}(k)=0$. Here

$$
\varepsilon^{m}(k)=\sum_{j=0}^{m-1}\left\langle\left(B\left(t_{j}^{k}\right)-B\left(t_{j+1}^{k}\right)\right) u\left(t_{j}^{k}\right), u\left(t_{j+1}^{k}\right)-u\left(t_{j}^{k}\right)\right\rangle
$$

Proof: From the above lemma, the absolute value of the left side is no larger than

$$
\begin{align*}
& \sum_{j=0}^{m-1}\left|\left\langle\left(B\left(t_{j}^{k}\right)-B\left(t_{j+1}^{k}\right)\right) u\left(t_{j}^{k}\right), u\left(t_{j+1}^{k}\right)-u\left(t_{j}^{k}\right)\right\rangle\right| \\
\leq & \sum_{j=0}^{m-1} \int_{t_{j}^{k}}^{t_{j+1}^{k}}\left\|B^{\prime}(\tau) u\left(t_{j}^{k}\right)\right\|_{W^{\prime}} d \tau\left\|u\left(t_{j+1}^{k}\right)-u\left(t_{j}^{k}\right)\right\|_{W} \tag{34.5.31}
\end{align*}
$$

In case $p \geq 2$ then for $C \geq \max _{s}\left\|B^{\prime}(s)\right\|_{\mathscr{L}\left(W, W^{\prime}\right)}$,

$$
\begin{aligned}
& \leq C \sum_{j=0}^{m-1} \int_{t_{j}^{k}}^{t_{j+1}^{k}}\left\|u^{l}(\tau)\right\|_{W}\left\|u_{k}^{r}(\tau)-u_{k}^{l}(\tau)\right\|_{W} d \tau \\
& =C \sum_{j=0}^{m-1} \int_{0}^{t_{m}^{k}} \mathscr{X}_{\left[t_{j}^{k}, t_{j+1}^{k}\right]}(\tau)\left\|u_{k}^{l}(\tau)\right\|_{W}\left\|u_{k}^{r}(\tau)-u_{k}^{l}(\tau)\right\|_{W} d \tau \\
& =C \int_{0}^{t_{m}^{k}} \sum_{j=0}^{m-1} \mathscr{X}_{\left[t_{j}^{k}, t_{j+1}^{k}\right]}(\tau)\left\|u_{k}^{l}(\tau)\right\|_{W}\left\|u_{k}^{r}(\tau)-u_{k}^{l}(\tau)\right\|_{W} d \tau \\
& =C \int_{0}^{t_{m}^{k}}\left\|u^{l}(\tau)\right\|_{W}\left\|u_{k}^{r}(\tau)-u_{k}^{l}(\tau)\right\|_{W} d \tau \\
& \leq C\left\|u_{k}^{l}\right\|_{L^{p}([0, T], V)}\left\|u_{k}^{r}(\tau)-u_{k}^{l}(\tau)\right\|_{L^{p}([0, T], V)} \\
& \leq \hat{C}(2) 2^{-k}
\end{aligned}
$$

by 34.5.29. In case $p<2$, then from assumption and 34.5.31, the absolute value of the left side is no larger than

$$
\begin{aligned}
& \sum_{j=0}^{m-1} C\left(t_{j+1}^{k}-t_{j}^{k}\right)\left\|u\left(t_{j+1}^{k}\right)-u\left(t_{j}^{k}\right)\right\|_{W} \\
= & C \sum_{j=0}^{m-1} \int_{t_{j}^{k}}^{t_{j+1}^{k}} \mathscr{X}_{\left[\left[_{j}^{k}, t_{j+1}^{k}\right]\right.}(s)\left\|u_{k}^{r}(s)-u_{k}^{l}(s)\right\|_{W} \\
= & C \int_{0}^{t_{m}^{k}}\left\|u_{k}^{r}(s)-u_{k}^{l}(s)\right\|_{W}
\end{aligned}
$$

which converges to 0 as $k \rightarrow \infty$ thanks to 34.5.29.
Lemma 34.5.4 In the above situation,

$$
\sup _{t \in N^{C}}\langle B u(t), u(t)\rangle+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

Also, $t \rightarrow B u(t)$ is weakly continuous with values in $W^{\prime}$ on $N^{C}$ where $N$ is a set of measure zero including the set where $B u(t) \neq B(t)(u(t))$.

Proof: From the above formula of Lemma 34.5.2 applied to the $k^{t h}$ partition of $[0, T]$ described above,

$$
\begin{gathered}
\left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle-\left\langle B u_{0}, u_{0}\right\rangle+\sum_{j=0}^{m-1}\left\langle\left(B\left(t_{j+1}\right)-B\left(t_{j}\right)\right) u\left(t_{j}\right), u\left(t_{j+1}\right)\right\rangle \\
+\sum_{j=0}^{m-1}\left\langle\left(B\left(t_{j+1}\right)-B\left(t_{j}\right)\right) u\left(t_{j}\right), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle
\end{gathered}
$$

$$
\begin{equation*}
=\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j+1}\right)\right\rangle d r-\left\langle B\left(t_{j+1}\right) u\left(t_{j+1}\right)-B\left(t_{j+1}\right) u\left(t_{j}\right), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle \tag{34.5.32}
\end{equation*}
$$

Consider the third term on the left,

$$
\begin{aligned}
& \sum_{j=0}^{m_{n}-1}\left\langle\left(B\left(t_{j+1}^{n}\right)-B\left(t_{j}^{n}\right)\right) u\left(t_{j}^{n}\right), u\left(t_{j+1}^{n}\right)\right\rangle \\
= & \int_{0}^{t_{m_{n}}}\left\langle\sum_{j=0}^{m_{n}-1} \mathscr{X}_{\left(t_{j}^{n}, t_{j+1}^{n}\right]}(t) \frac{B\left(t_{j+1}^{n}\right)-B\left(t_{j}^{n}\right)}{t_{j+1}^{n}-t_{j}^{n}} u_{n}^{l}(t), u_{n}^{r}(t)\right\rangle d t
\end{aligned}
$$

Using a simple approximate identity argument and the assumption that $t \rightarrow B(t)$ is in $C^{1}\left([0, T], \mathscr{L}\left(W, W^{\prime}\right)\right)$,

$$
\sum_{j=0}^{m_{n}-1} \mathscr{X}_{\left(t_{j}^{n}, t_{j+1}^{n}\right]}(t) \frac{B\left(t_{j+1}^{n}\right)-B\left(t_{j}^{n}\right)}{t_{j+1}^{n}-t_{j}^{n}} \rightarrow B^{\prime}(t)
$$

uniformly on $(0, T]$. Then

$$
\sum_{j=0}^{m_{n}-1} \mathscr{X}_{\left(t_{j}^{n}, t_{j+1}^{n}\right]}(t) \frac{B\left(t_{j+1}^{n}\right)-B\left(t_{j}^{n}\right)}{t_{j+1}^{n}-t_{j}^{n}} u_{n}^{l} \rightarrow B^{\prime} u
$$

strongly in $L^{2}\left([0, T], W^{\prime}\right)$ while $u_{n}^{r} \rightarrow u$ strongly in $L^{2}([0, T] ; W)$. It follows that the third term on the left in 34.5 .32 is

$$
\varepsilon(k)+2 \int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s, \varepsilon(k) \rightarrow 0 .
$$

whenever $n$ is sufficiently large. Also, $T$ could be replaced with $t_{j}$ for any of the mesh points.

Next consider the term labelled $*$. From Lemma 34.5.3, it is of the form $\varepsilon^{m}(k)$ where $\lim _{k \rightarrow \infty} \varepsilon^{m}(k)=0$. Thus 34.5 .32 reduces to

$$
\begin{align*}
& \left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle-\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t_{m}}\left\langle B^{\prime} u, u\right\rangle d s=\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u_{k}^{r}(r)\right\rangle d r \\
& -\sum_{j=0}^{m-1}\left\langle B\left(t_{j+1}\right) u\left(t_{j+1}\right)-B\left(t_{j+1}\right) u\left(t_{j}\right), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle+\varepsilon(k) \tag{34.5.33}
\end{align*}
$$

where $t_{m} \in \mathscr{P}_{k}$.
Thus, discarding the negative terms which occur at the end and denoting by $\mathscr{P}_{k}$ the $k^{\text {th }}$ of these partitions,

$$
\sup _{t_{j} \in \mathscr{P}_{k}}\left\langle B u\left(t_{j}\right), u\left(t_{j}\right)\right\rangle+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s \leq\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{T}\left|\left\langle Y(r), u_{k}^{r}(r)\right\rangle\right| d r+\varepsilon
$$

$$
\begin{aligned}
& \leq\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{T}\|Y(r)\|_{V^{\prime}}\left\|u_{k}^{r}(r)\right\|_{V} d r+\varepsilon \\
\leq & \left\langle B u_{0}, u_{0}\right\rangle+2\left(\int_{0}^{T}\|Y(r)\|_{V^{\prime}}^{p^{\prime}} d r\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|u_{k}^{r}(r)\right\|_{V}^{p} d r\right)^{1 / p}+\varepsilon \\
\leq & C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)+\varepsilon
\end{aligned}
$$

whenever $k$ is large enough because these partitions are chosen such that

$$
\lim _{k \rightarrow \infty}\left(\int_{0}^{T}\left\|u_{k}^{r}(r)\right\|_{V}^{p}\right)^{1 / p}=\left(\int_{0}^{T}\|u(r)\|_{V}^{p}\right)^{1 / p}
$$

and so these are bounded. This has shown that for the dense subset of $[0, T], D \equiv \cup_{k} \mathscr{P}_{k}$,

$$
\sup _{t \in D}\langle B(t) u(t), u(t)\rangle+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s<C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)+\varepsilon
$$

However, $\varepsilon$ was arbitrary and the partitions are nested. Hence the above holds for all $\varepsilon$ and so

$$
\sup _{t \in D}\langle B(t) u(t), u(t)\rangle+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s<C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

By 34.5.29 and the integral equation, there is a set of measure zero including all the earlier sets of measure zero $N$ such that for $t \notin N, u_{n}^{l}(t), u_{n}^{r}(t) \rightarrow u(t)$ pointwise in $V$. Also, $B(t) u_{n}^{r}(t) \rightarrow B u(t)$ in $V^{\prime}$. This last can be obtained from the integral equation solved. $t \rightarrow$ $B u(t)$ is continuous into $V^{\prime}$. Then let $t \notin N$. We have $u_{n}^{r}(t) \rightarrow u(t)$ in $V$. Now $B(t) u_{n}^{r}(t)=$ $B(t) u\left(s_{n}\right)$ where $s_{n} \in D$ and $s_{n} \rightarrow t$. Then $B u(t)=B(t) u(t)$ and

$$
\begin{gathered}
\left\|B\left(s_{n}\right) u\left(s_{n}\right)-B(t) u(t)\right\|_{V^{\prime}} \leq\left\|\left(B\left(s_{n}\right)-B(t)\right) u\left(s_{n}\right)\right\|_{V^{\prime}}+\left\|B(t)\left(u\left(s_{n}\right)-u(t)\right)\right\|_{V^{\prime}} \\
\leq C_{t}\left\|B\left(s_{n}\right)-B(t)\right\|+C\left\|u\left(s_{n}\right)-u(t)\right\|_{V}
\end{gathered}
$$

where $C_{t}$ is a constant which comes because $u\left(s_{n}\right) \rightarrow u(t)$ in $V$ and so is bounded. The constant $C$ is just $\max _{t \in[0, T]}\|B(t)\|$. Then, since the two terms on the right converge to 0 as $n \rightarrow \infty$, it follows that as $s_{n} \rightarrow t, B\left(s_{n}\right) u\left(s_{n}\right) \rightarrow B(t) u(t)=B u(t)$ in $V^{\prime}$ while $u\left(s_{n}\right) \rightarrow u(t)$ in $V$. It follows that for $t \notin N$,

$$
\langle B u(t), u(t)\rangle+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s=\lim _{n \rightarrow \infty}\left\langle B u\left(s_{n}\right), u\left(s_{n}\right)\right\rangle+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

Hence,

$$
\sup _{t \notin N}\langle B u(t), u(t)\rangle+\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

It only remains to verify the claim about weak continuity.
Consider now the claim that $t \rightarrow B u(t)$ is weakly continuous on $N^{C}$. Letting $v \in V, s \in$ $N^{C}$,

$$
\begin{equation*}
\lim _{t \rightarrow s}\langle B u(t), v\rangle=\langle B u(s), v\rangle=\langle B u(s), v\rangle \tag{34.5.34}
\end{equation*}
$$

The limit follows from the formula 34.5.28 which implies $t \rightarrow B u(t)$ is continuous into $V^{\prime}$. Now for $t \in N^{C}$,

$$
\begin{aligned}
\|B u(t)\|_{W^{\prime}} & =\sup _{\|v\|_{W} \leq 1}|\langle B u(t), v\rangle| \leq\langle B v, v\rangle^{1 / 2}\langle B u(t), u(t)\rangle^{1 / 2} \\
& \leq\left(C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)-\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s\right) \\
\sup _{t \notin N}\|B u(t)\|_{W^{\prime}} & \leq\left(C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)-\int_{0}^{T}\left\langle B^{\prime} u, u\right\rangle d s\right)
\end{aligned}
$$

Now let $w \in W$. Then

$$
|\langle B u(t), w\rangle-\langle B u(s), w\rangle| \leq|\langle B u(t)-B u(s), w-v\rangle|+\left|\langle B u(t)-B u(s), v\rangle_{V^{\prime}, V}\right|
$$

Then the first term is less than $\varepsilon$ if $v$ is close enough to $w$ and the second converges to 0 by continuity of $t \rightarrow B u(t)$ which comes from the integral equation, so 34.5 .34 holds for all $v \in W$ and so this shows the weak continuity of $t \rightarrow B u(t)$ on $N^{C}$.

Now pick $t \in D$, the union of all the mesh points. Then for all $k$ large enough, $t \in \mathscr{P}_{k}$. Say $t=t_{m}$. From

$$
\begin{gather*}
\left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle-\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t_{m}}\left\langle B^{\prime} u, u\right\rangle d s=\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u^{r}(r)\right\rangle d r+\varepsilon(k) \\
\quad-\sum_{j=0}^{m-1}\left\langle B\left(t_{j+1}\right) u\left(t_{j+1}\right)-B\left(t_{j+1}\right) u\left(t_{j}\right), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle \tag{34.5.35}
\end{gather*}
$$

where $\varepsilon(k) \rightarrow 0$. By Lemma 34.5.3, you can modify $\varepsilon(k)$ and write this in the form

$$
\begin{gather*}
\left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle-\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t_{m}}\left\langle B^{\prime} u, u\right\rangle d s=\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u^{r}(r)\right\rangle d r+\varepsilon(k) \\
\quad-\sum_{j=0}^{m-1}\left\langle B\left(t_{j+1}\right) u\left(t_{j+1}\right)-B\left(t_{j}\right) u\left(t_{j}\right), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle \tag{34.5.36}
\end{gather*}
$$

Thus, $\left\langle B u\left(t_{m}\right), u\left(t_{m}\right)\right\rangle$ is constant for all $k$ large enough and the integral term on the right converges as $k \rightarrow \infty$ to

$$
\int_{0}^{t_{m}}\langle Y(r), u(r)\rangle d r
$$

It follows that the last term on the right does converge to something as $k \rightarrow \infty$. It just remains to consider what it does converge to. However, from the equation solved by $u$,

$$
B u\left(t_{j+1}\right)-B u\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Y(r) d r
$$

Therefore, this term is dominated by an expression of the form

$$
\begin{aligned}
&\left|\sum_{j=0}^{m_{k}-1}\left\langle\int_{t_{j}}^{t_{j+1}} Y(r) d r, u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle\right| \\
&=\left|\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j+1}\right)-u\left(t_{j}\right)\right\rangle d r\right| \\
&=\left|\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j+1}\right)\right\rangle-\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(r), u\left(t_{j}\right)\right\rangle\right| \\
&=\left|\int_{0}^{t_{m}}\left\langle Y(r), u^{r}(r)\right\rangle d r-\int_{0}^{t_{m}}\left\langle Y(r), u^{l}(r)\right\rangle d r\right| \\
& \leq \int_{0}^{T}\left|\left\langle Y(r), u^{r}(r)-u^{l}(r)\right\rangle\right| d r
\end{aligned}
$$

However, both $u^{r}$ and $u^{l}$ converge to $u$ in $K=L^{p}(0, T, V)$. Therefore, this term must converge to 0 . Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t \in D$,

$$
\langle B u(t), u(t)\rangle+\int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d r=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r
$$

It remains to verify that this holds for all $t \notin N$. Let $t \in N^{C} \backslash D$ and let $t(k) \in \mathscr{P}_{k}$ be the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$
B u(t(m))=B u_{0}+\int_{0}^{t(m)} Y(s) d s
$$

a similar formula for $u(t(k))$. Thus for $t>t(m)$,

$$
B u(t)-B u(t(m))=\int_{t(m)}^{t} Y(s) d s
$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $u_{0}=0$. Therefore,

$$
\begin{aligned}
& \langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle \\
& +\int_{t(m)}^{t(k)}\left\langle B^{\prime}(s)(u(s)-u(t(m))), u(s)-u(t(m))\right\rangle \\
& \quad=2 \int_{t(m)}^{t(k)}\langle Y(s), u(s)-u(t(m))\rangle d s
\end{aligned}
$$

Thus, for $m \leq k$

$$
\begin{equation*}
\lim _{m, k \rightarrow \infty}\langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle=0 \tag{34.5.37}
\end{equation*}
$$

Hence $\{B u(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $W^{\prime}$ because

$$
\begin{aligned}
& |\langle B(u(t(k))-u(t(m))), y\rangle| \\
\leq & \langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2} \\
\leq & \langle B(u(t(k))-u(t(m))), u(t(k))-u(t(m))\rangle^{1 / 2}\|B\|^{1 / 2}\|y\|_{W}
\end{aligned}
$$

Does it converge to $B u(t)$ ? Let $\xi(t) \in W^{\prime}$ be what it does converge to. Let $v \in V$. Then

$$
\langle\xi(t), v\rangle=\lim _{k \rightarrow \infty}\langle B u(t(k)), v\rangle=\lim _{k \rightarrow \infty}\langle B u(t(k)), v\rangle=\langle B u(t), v\rangle
$$

because it is known that $t \rightarrow B u(t)$ is continuous into $V^{\prime}$. It is also known that for $t \in N^{C}$, $B u(t) \in W^{\prime} \subseteq V^{\prime}$ and that the $B u(t)$ for $t \in N^{C}$ are uniformly bounded in $W^{\prime}$. Therefore, since $V$ is dense in $W$, it follows that $\xi(t)=B u(t)$.

Now for every $t \in D$, it was shown above that

$$
\langle B u(t), u(t)\rangle+\int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d r=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r
$$

Also it was just shown that $B u(t(k)) \rightarrow B u(t)$ for $t \notin N$. Then for $t \notin N$

$$
\begin{gathered}
|\langle B u(t(k)), u(t(k))\rangle-\langle B u(t), u(t)\rangle| \\
\leq|\langle B(t(k)) u(t(k)), u(t(k))-u(t)\rangle|+|\langle B u(t(k))-B u(t), u(t)\rangle|
\end{gathered}
$$

Then the second term converges to 0 . The first equals

$$
\begin{aligned}
& |\langle B(t(k)) u(t(k))-B(t(k)) u(t), u(t(k))\rangle| \\
\leq & \langle B(t(k))(u(t(k))-u(t)), u(t(k))-u(t)\rangle^{1 / 2}\langle B u(t(k)), u(t(k))\rangle^{1 / 2}
\end{aligned}
$$

From the above, this is dominated by an expression of the form

$$
\langle B(t(k))(u(t(k))-u(t)), u(t(k))-u(t)\rangle^{1 / 2} C
$$

Then from the choice of $N$ and the pointwise convergence of $u_{n}^{r}$ to $u$ off $N$ the above converges to 0 for each $t \notin N$. It follows that

$$
\lim _{k \rightarrow \infty}|\langle B u(t(k)), u(t(k))\rangle-\langle B u(t), u(t)\rangle|=0
$$

Then from the formula,

$$
\langle B u(t), u(t)\rangle=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r-\int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d r
$$

valid for $t \in D$, it follows that the same formula holds for all $t \notin N$. Then define $\langle B u, u\rangle(t)$ to equal $\langle B u(t), u(t)\rangle$ off $N$ and the right side for $t \in N$. Thus $t \rightarrow\langle B u, u\rangle(t)$ is continuous and for all $t \in[0, T]$,

$$
\langle B u, u\rangle(t)=\left\langle B u_{0}, u_{0}\right\rangle+2 \int_{0}^{t}\langle Y(r), u(r)\rangle d r-\int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d r
$$

Also recall that $t \rightarrow B(t) u(t)$ was shown to be weakly continuous into $W^{\prime}$ on $N^{C}$. Is it continuous on $N^{C}$ ? Suppose $t \in N^{C}$ and let $s_{n} \rightarrow t$ where $s_{n} \in D$. Then $u\left(s_{n}\right)=u_{m_{n}}^{r}(t)$ because $s_{n}$ is one of the mesh points. Since $s_{n} \rightarrow t$ one can assume that $m_{n} \rightarrow \infty$. Hence $u\left(s_{n}\right)=u_{m_{n}}^{r}(t) \rightarrow u(t)$ by the pointwise convergence implied by 34.5.29. Then obviously

$$
B\left(s_{n}\right) u\left(s_{n}\right)=B\left(s_{n}\right) u_{m_{n}}^{l}(t) \rightarrow B(t) u(t)
$$

Now suppose you just have $t_{n} \rightarrow t$ where each of $t_{n}, t$ are in $N^{C}$. Does it always follow that $B\left(t_{n}\right) u\left(t_{n}\right) \rightarrow B(t) u(t)$ ? Suppose not. Then there exists such a sequence $t_{n} \rightarrow t$ of points in $N^{C}$ and $\varepsilon>0$ such that

$$
\left\|B\left(t_{n}\right) u\left(t_{n}\right)-B(t) u(t)\right\| \geq \varepsilon
$$

However, from the density of $D$ and what was just shown, there exists $s_{n} \in D$ such that $\left|s_{n}-t_{n}\right|<\frac{1}{2^{n}}$ and

$$
\left\|B\left(s_{n}\right) u\left(s_{n}\right)-B\left(t_{n}\right) u\left(t_{n}\right)\right\|<\frac{1}{2^{n}}
$$

Then

$$
\begin{aligned}
\varepsilon & \leq\left\|B\left(t_{n}\right) u\left(t_{n}\right)-B\left(s_{n}\right) u\left(s_{n}\right)\right\|+\left\|B\left(s_{n}\right) u\left(s_{n}\right)-B(t) u(t)\right\| \\
& <\frac{1}{2^{n}}+\left\|B\left(s_{n}\right) u\left(s_{n}\right)-B(t) u(t)\right\|
\end{aligned}
$$

Since $s_{n} \rightarrow t$, what was just shown implies both terms on the right converge to 0 . This is a contradiction. Thus $t \rightarrow B(t) u(t)$ must be continuous on $N^{C}$ into $W^{\prime}$.

Consider the case that $t \rightarrow B(u(t))$ has a weak derivative, denoted as $(B u)^{\prime}(t)$ which is in $L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$. Then as shown above, there is a continuous function, denoted as $B u(t)$ which equals $B(t)(u(t))$ for a.e. $t$ and

$$
B u(t)=B u(0)+\int_{0}^{t}(B u)^{\prime}(s) d s
$$

Then the above theorem applies. Then one obtains the following corollary.
Corollary 34.5.5 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, and $B(t) \in \mathscr{L}\left(W, W^{\prime}\right)$ is nonnegative and self adjoint, $B \in C^{1}\left([0, T] ; W^{\prime}\right)$. Also suppose $t \rightarrow B(u(t))$ has a weak derivative $(B u)^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ for $u \in L^{p}([0, T] ; V) \cap L^{2}([0, T] ; W)$. Then there is a continuous function denoted as $B u(t)$ which equals $B(t)(u(t))$ a.e. $t$. Say for $t \notin N$. Suppose $B u(0)=B u_{0}, u_{0} \in W$. Then

$$
\begin{equation*}
B u(t)=B u_{0}+\int_{0}^{t}(B u)^{\prime}(s) d s \text { in } V^{\prime} \tag{34.5.38}
\end{equation*}
$$

Then $t \rightarrow B u(t)$ is in $C\left(N^{C}, W^{\prime}\right)$ and also for such $t$,

$$
\frac{1}{2}\langle B u(t), u(t)\rangle+\frac{1}{2} \int_{0}^{t}\left\langle B^{\prime}(s) u(s), u(s)\right\rangle d s=\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s
$$

There exists a continuous function $t \rightarrow\langle B u, u\rangle(t)$ which equals the right side of the above for all $t$ and equals $\langle B(t) u(t), u(t)\rangle$ off $N$. This satisfies

$$
\sup _{t \in[0, T]}\langle B u, u\rangle(t) \leq C\left(\|Y\|_{K^{\prime}},\|u\|_{K}\right)
$$

In particular, this last inequality follows from Lemma 34.5.4 and the assumption that $B^{\prime}$ is bounded.

Note how if everything is nice and smooth, this integration by parts formula is what you would be expected to get. To see this, assume $u$ is smooth and formally work on the right side.

$$
\begin{aligned}
\frac{d}{d t}\langle B u, u\rangle & =\left\langle(B u)^{\prime}, u\right\rangle+\left\langle B u, u^{\prime}\right\rangle \\
& =\left\langle(B u)^{\prime}, u\right\rangle+\left\langle B u^{\prime}, u\right\rangle \\
& =2\left\langle(B u)^{\prime}, u\right\rangle-\left\langle B^{\prime} u, u\right\rangle
\end{aligned}
$$

Thus

$$
\begin{aligned}
& \frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\int_{0}^{t}\left\langle(B u)^{\prime}(s), u(s)\right\rangle d s \\
& =\frac{1}{2}\left\langle B u_{0}, u_{0}\right\rangle+\frac{1}{2}\left[\int_{0}^{t} \frac{d}{d s}\langle B u, u\rangle d s+\int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d s\right] \\
& =\frac{1}{2}\langle B u(t), u(t)\rangle+\frac{1}{2} \int_{0}^{t}\left\langle B^{\prime} u, u\right\rangle d s
\end{aligned}
$$

which equals the left side.
A related topic is the continuity of pointwise evaluation of $B u$. Let $L u=(B u)^{\prime}$.

$$
\begin{aligned}
u & =D(L) \equiv\left\{u \in L^{p}(0, T ; V): L u \in L^{p^{\prime}}\left(0, T, V^{\prime}\right)\right\} \\
\|u\|_{X} & \equiv\|u\|_{L^{p}(0, T, V)}+\|L u\|_{L^{p^{\prime}}\left(0, T, V^{\prime}\right)}
\end{aligned}
$$

Since $L$ is closed, this $X$ is a Banach space. Then the following theorem is obtained.
Theorem 34.5.6 In the above corollary, the map $u \rightarrow B u(t)$ is continuous as a map from $X$ to $V^{\prime}$. Also if $Y$ denotes those $f \in L^{p}([0, T] ; V)$ for which $f^{\prime} \in L^{p}([0, T] ; V)$, so that $f$ has a representative such that $f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s$, then if $\|f\|_{Y} \equiv\|f\|_{L^{p}([0, T] ; V)}+$ $\left\|f^{\prime}\right\|_{L^{p}([0, T] ; V)}$ the map $f \rightarrow f(t)$ is continuous.

Proof: First, why is $u \rightarrow B u(0)$ continuous? Say $u, v \in X$ and say $p \geq 2$ first.

$$
B u(t)-B v(t)=B u(0)-B v(0)+\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s
$$

and so,

$$
\left(\int_{0}^{T}\|B u(0)-B v(0)\|_{V^{\prime}}^{p^{\prime}} d t\right)^{1 / p^{\prime}} \leq\left(\int_{0}^{T}\|B u(t)-B v(t)\|_{V^{\prime}}^{p^{\prime}} d t\right)^{1 / p^{\prime}}
$$

$$
+\left(\int_{0}^{T}\left\|\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s\right\|^{p^{\prime}} d t\right)^{1 / p^{\prime}}
$$

and so

$$
\begin{gathered}
\|B u(0)-B v(0)\|_{V^{\prime}} T^{1 / p^{\prime}} \leq \\
\left(\|B\|\|u-v\|_{L^{p^{\prime}}([0, T] ; V)}+T^{1 / p^{\prime}}\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}\left([0, T] ; V^{\prime}\right)}}\right) \\
\leq C(\|B\|, T)\|u-v\|_{X}
\end{gathered}
$$

Thus $u \rightarrow B u(0)$ is continuous into $V^{\prime}$. If $p<2$, then you do something similar.

$$
\begin{gathered}
\left(\int_{0}^{T}\|B u(0)-B v(0)\|_{V^{\prime}}^{p} d t\right)^{1 / p} \leq\left(\int_{0}^{T}\|B u(t)-B v(t)\|_{V^{\prime}}^{p} d t\right)^{1 / p} \\
+\left(\int_{0}^{T}\left\|\int_{0}^{t}(B u)^{\prime}(s)-(B v)^{\prime}(s) d s\right\|^{p} d t\right)^{1 / p} \\
\|B u(0)-B v(0)\|_{V^{\prime}} T^{1 / p} \leq\|B\|\|u-v\|_{L^{p}}+C(T)\left\|(B u)^{\prime}-(B v)^{\prime}\right\|_{L^{p^{\prime}}\left([0, T] ; V^{\prime}\right)} \\
\leq C(\|B\|, T)\|u-v\|_{X}
\end{gathered}
$$

However, one could just as easily have done this for an arbitrary $s<T$ by repeating the argument for

$$
B u(t)=B u(s)+\int_{s}^{t}(B u)^{\prime}(r) d r
$$

Thus this mapping is certainly continuous into $V^{\prime}$. The last assertion is similar.

### 34.6 Another Approach

The above approach is pretty interesting, but there is a quicker way to do it discussed in this section. I am also including the case where the operator $B$ is actually a function of $t$. I have never had a reason to use this level of generality, but it is here if it is of any interest. Also, this is presented in the context of complex Banach spaces. In addition, it is shown that by including $i^{*}$ in various formulas, you don't need to have $V$ dense in $W$. Of course, this is typically not of any interest, but for the sake of generality, it is included. The approach is due to Lions. It is assumed for convenience that $p \geq 2$. This was apparently not needed in the last section. It may be that this approach can also be generalized to not require this.

Let $B(t) \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfy

$$
\begin{gather*}
\langle B(t) u, v\rangle=\overline{\langle B(t) v, u\rangle}, u, v \in W  \tag{34.6.39}\\
\langle B(t) u, u\rangle \geq 0  \tag{34.6.40}\\
B(t)=B(0)+\int_{0}^{t} B^{\prime}(s) d s \tag{34.6.41}
\end{gather*}
$$

where $B^{\prime} \in L^{\infty}\left(0, T ; \mathscr{L}\left(W, W^{\prime}\right)\right)$. Here $W$ is a Banach space such that $V \subseteq W$. Also $\mathscr{V}_{I} \equiv$ $L^{p}(I ; V)$ and $\mathscr{W}_{I} \equiv L^{2}(I ; W)$.

Now let $I=[a, b]$ and $c<a<b<d$. Here and in what follows $\phi_{n}(t)=n \phi(n t)$ where $\phi \geq 0, \phi \in C_{0}^{\infty}(-1,1)$, and $\int \phi d t=1$. The following proposition is known and the essential features of its proof may be found in [92]. We give a proof for the convenience of the reader.

Proposition 34.6.1 Suppose $D(t) \in \mathscr{L}\left(W, W^{\prime}\right)$ and $D(t)=0$ if $t \notin(c, d)$. Suppose also that

$$
D(t)=\int_{c}^{t} D^{\prime}(s) d s, D^{\prime} \in L^{\infty}\left(c, d ; \mathscr{L}\left(W, W^{\prime}\right)\right)
$$

For $u \in \mathscr{W}_{I}$ and $a-n^{-1}>c, b+n^{-1}<d$, define

$$
\begin{equation*}
T_{n} u=\left(D\left(u * \phi_{n}\right)\right)^{\prime}-\left((D u) * \phi_{n}\right)^{\prime} \tag{34.6.42}
\end{equation*}
$$

where we let $u=0$ off I. Then

$$
\begin{equation*}
\left\|T_{n} u\right\|_{\mathscr{W}_{I}^{\prime}} \rightarrow 0 \tag{34.6.43}
\end{equation*}
$$

Proof: First, we show that $\left\|T_{n}\right\|$ is uniformly bounded. Letting $w=0$ off $I$,

$$
\begin{gathered}
\left|\left\langle T_{n} u, w\right\rangle\right|=\left|\int_{\mathbb{R}}\left\langle D^{\prime}(t) \int_{\mathbb{R}} u(s) \phi_{n}(t-s) d s, w(t)\right\rangle d t\right| \\
+\left|\int_{\mathbb{R}}\left\langle\int_{\mathbb{R}}(D(t)-D(s)) u(s) \phi_{n}^{\prime}(t-s) d s, w(t)\right\rangle d t\right| \\
\leq C\|u\|_{W_{I}}\|w\|_{\mathscr{W}_{I}}+\int_{\mathbb{R}} \int_{\mathbb{R}}\|D(t)-D(s)\|\|u(s)\| n^{2}\left|\phi^{\prime}(n(t-s))\right|\|w(t)\| d s d t \\
\leq C\|u\|_{\mathscr{W}_{I}}\|w\|_{\mathscr{W}_{I}}+ \\
\int_{\mathbb{R}} \int_{-1}^{1}\left\|D(t)-D\left(t-\frac{r}{n}\right)\right\|\left\|u\left(t-\frac{r}{n}\right)\right\| n^{2}\left|\phi^{\prime}(r)\right|\|w(t)\| \frac{1}{n} d r d t \\
\leq C\|u\|_{\mathscr{W}_{I}}\|w\|_{\mathscr{W}_{I}}+C \int_{-1}^{1} \int_{\mathbb{R}}\left\|u\left(t-\frac{r}{n}\right)\right\|_{W}\|w(t)\|_{W} d t d r \\
\leq C\|u\|_{\mathscr{W}_{I}}\|w\|_{\mathscr{W}_{I}} .
\end{gathered}
$$

Where $C$ is a positive constant independent of $n$ and $u$. Thus $\left\|T_{n}\right\|$ is bounded independent of $n$.

Next let $u \in C_{0}^{\infty}(I ; V)$, a dense subset of $\mathscr{W}_{I}$. Then a little computation shows

$$
\begin{gathered}
\left|\left\langle T_{n} u, w\right\rangle_{\mathscr{W}}\right| \leq \\
C(\phi) \int_{a}^{b} \int_{-1}^{1}\left\|\left\lvert\, D^{\prime}(t)-D^{\prime}\left(t-\frac{r}{n}\right)\right.\right\|\left\|u\left(t-\frac{r}{n}\right)\right\|\left\|_{W}\right\| w(t) \|_{W} d r d t \\
+\left.C(\phi) \int_{a}^{b} \int_{-1}^{1}\left\|D(t)-D\left(t-\frac{r}{n}\right)\right\|\left\|u^{\prime}\left(t-\frac{r}{n}\right)\right\|\right|_{W}\|w(t)\|_{W} d r d t \\
\equiv \mathbf{A}+\mathbf{B} .
\end{gathered}
$$

Now

$$
\mathbf{B} \leq C\left(\phi, D^{\prime}\right) n^{-1 / 2}\left\|u^{\prime}\right\|_{\mathscr{W}_{I}}\|w\|_{\mathscr{W}_{I}} .
$$

Since $u$ is bounded,

$$
\begin{aligned}
\mathbf{A} & \leq C(\phi, u) \int_{a}^{b} \int_{-1}^{1}\left\|D^{\prime}(t)-D^{\prime}\left(t-\frac{r}{n}\right)\right\|\|w(t)\|_{W} d r d t \\
& \leq C(\phi, u) \int_{a}^{b}\|w(t)\|_{W} n \int_{t-n^{-1}}^{t+n^{-1}}\left\|D^{\prime}(t)-D^{\prime}(s)\right\| d s d t
\end{aligned}
$$

By Holder's inequality, this is no larger than

$$
C(\phi, u)\left(\int_{a}^{b}\left(n \int_{t-n^{-1}}^{t+n^{-1}}\left\|D^{\prime}(t)-D^{\prime}(s)\right\| d s\right)^{2} d t\right)^{1 / 2}\|w\|_{\mathscr{W}_{I}}
$$

If $t$ is a Lebesgue point,

$$
n \int_{t-n^{-1}}^{t+n^{-1}}\left\|D^{\prime}(t)-D^{\prime}(s)\right\| d s \rightarrow 0
$$

and also

$$
n \int_{t-n^{-1}}^{t+n^{-1}}\left\|D^{\prime}(t)-D^{\prime}(s)\right\| d s \leq 4\left\|D^{\prime}\right\|_{\infty}
$$

so the dominated convergence theorem implies

$$
\int_{a}^{b}\left(n \int_{t-n^{-1}}^{t+n^{-1}}\left\|D^{\prime}(t)-D^{\prime}(s)\right\| d s\right)^{2} d t \rightarrow 0
$$

Hence

$$
\begin{gathered}
\left\|T_{n} u\right\|_{\mathscr{W}_{I}^{\prime}} \leq \\
C\left(\phi, u, D^{\prime}\right)\left(n^{-1 / 2}+\left(\int_{a}^{b}\left(n \int_{t-n^{-1}}^{t+n^{-1}}\left\|D^{\prime}(t)-D^{\prime}(s)\right\| d s\right)^{2} d t\right)^{1 / 2}\right)
\end{gathered}
$$

and so $T_{n} u \rightarrow 0$ for all $u$ in the dense subset, $C_{0}^{\infty}(I ; V)$.
We have also the following simple corollary.
Corollary 34.6.2 In the situation of Proposition 34.6.1,

$$
\left\|\left(i^{*} D\left(u * \phi_{n}\right)\right)^{\prime}-\left(\left(i^{*} D u\right) * \phi_{n}\right)^{\prime}\right\|_{\mathscr{Y}_{I}^{\prime}} \rightarrow 0
$$

where $i$ is the inclusion map of $V$ into $W$.
For $f \in L^{1}\left(a, b ; V^{\prime}\right)$ we define $f^{\prime}$ in the sense of $V^{\prime}$ valued distributions as follows. For $\phi \in C_{0}^{\infty}(a, b)$,

$$
f^{\prime}(\phi) \equiv-\int_{a}^{b} f(t) \phi^{\prime}(t) d t
$$

We say $f^{\prime} \in L^{1}\left(a, b ; V^{\prime}\right)$ if there exists $g \in L^{1}\left(a, b ; V^{\prime}\right)$, necessarily unique, such that for all $\phi \in C_{0}^{\infty}(a, b)$,

$$
\int_{a}^{b} g(t) \phi(t) d t=f^{\prime}(\phi)
$$

To save on notation, we let $\mathscr{V} \equiv \mathscr{V}_{[0, T]}$ and $\mathscr{W} \equiv \mathscr{W}_{[0, T]}$. Define

$$
\begin{align*}
D(L) & \equiv\left\{u \in \mathscr{V}:\left(i^{*} B u\right)^{\prime} \in \mathscr{V}^{\prime}\right\}  \tag{34.6.44}\\
L u & \equiv\left(i^{*} B u\right)^{\prime} \text { for } u \in D(L) \tag{34.6.45}
\end{align*}
$$

Note that for $u \in D(L)$, it is automatically the case that $i^{*} B u \in \mathscr{V}^{\prime}$.

Lemma 34.6.3 L is a closed operator.

We define

$$
X \equiv D(L),\|u\|_{X} \equiv\|L u\|_{\mathscr{V}^{\prime}}+\|u\|_{\mathscr{V}} .
$$

Then $X$ is isometric to a closed subspace of a product of reflexive Banach spaces and so $X$ is reflexive by Lemma 17.5.11.

Theorem 34.6.4 Let $p \geq 2$ in what follows. For $u, v \in X$, the following hold.

1. $t \rightarrow\langle B(t) u(t), v(t)\rangle_{W^{\prime}, W}$ equals an absolutely continuous function a.e., denoted by $\langle B u, v\rangle(\cdot)$.
2. $\operatorname{Re}\langle L u(t), u(t)\rangle=\frac{1}{2}\left[\langle B u, u\rangle^{\prime}(t)+\left\langle B^{\prime}(t) u(t), u(t)\right\rangle\right]$ a.e. $t$
3. $|\langle B u, v\rangle(t)| \leq C\|u\|_{X}\|v\|_{X}$ for some $C>0$ and for all $t \in[0, T]$.
4. $t \rightarrow B(t) u(t)$ equals a function in $C\left(0, T ; W^{\prime}\right)$ a.e., denoted by $B u(\cdot)$.
5. $\sup \left\{\|B u(t)\|_{W^{\prime}}, t \in[0, T]\right\} \leq C\|u\|_{X}$ for some $C>0$.

If $K: X \rightarrow X^{\prime}$ is given by

$$
\langle K u, v\rangle_{X^{\prime}, X} \equiv \int_{0}^{T}\langle L u(t), v(t)\rangle d t+\langle B u, v\rangle(0),
$$

then
6. K is linear, continuous and weakly continuous.
7. $\operatorname{Re}\langle K u, u\rangle=\frac{1}{2}[\langle B u, u\rangle(T)+\langle B u, u\rangle(0)]+\frac{1}{2} \int_{0}^{T}\left\langle B^{\prime}(t) u(t), u(t)\right\rangle d t$.
8. If $B u(0)=0$, for $u \in X$, there exists $u_{n} \rightarrow u$ in $X$ such that $u_{n}(t)$ is 0 near 0 . A similar conclusion could be deduced at $T$ if $B u(T)=0$.

Proof: For $h$ a function defined on $[0, T]$, let $h_{1}$ be even, $2 T$ periodic, and $h_{1}(t)=h(t)$ for all $t \in[0, T]$. Let $C(\cdot) \in C_{0}^{\infty}(-T, 2 T), C(t) \in[0,1], C(t)=1$ on $[0, T]$.

Let $\tilde{B}(t)=C(t) B_{1}(t)$ for all $t \in \mathbb{R}$ and define

$$
\tilde{u}(t)=\left\{\begin{array}{l}
u_{1}(t), t \in[-T, 2 T] \\
0, t \notin[-T, 2 T]
\end{array}\right.
$$

Now let $u \in X$. Then

$$
\left(i^{*} \tilde{B} \tilde{u}\right)^{\prime}(t)=\left\{\begin{array}{l}
0, t<-T  \tag{34.6.46}\\
C^{\prime}(t)\left(i^{*} B u\right)(-t)-C(t)\left(i^{*} B u\right)^{\prime}(-t), t \in[-T, 0] \\
\left(i^{*} B u\right)^{\prime}(t), t \in[0, T] \\
C^{\prime}(t)\left(i^{*} B u\right)(2 T-t)-C(t)\left(i^{*} B u\right)^{\prime}(2 T-t), t \in[T, 2 T] \\
0, t>2 T
\end{array}\right.
$$

Thus, if $I \supseteq[-T, 2 T]$, then $\left(i^{*} \tilde{B} \tilde{u}\right)^{\prime} \in \mathscr{V}_{I}^{\prime}$. Defining $u_{n} \equiv \tilde{u} * \phi_{n}$, then for a.e. $t$,

$$
\begin{equation*}
\operatorname{Re}\left\langle\left(i^{*} \tilde{B} u_{n}\right)^{\prime}(t), u_{n}(t)\right\rangle=\frac{1}{2}\left[\left\langle\tilde{B} u_{n}, u_{n}\right\rangle^{\prime}(t)+\left\langle\tilde{B}^{\prime}(t) u_{n}(t), u_{n}(t)\right\rangle\right] . \tag{34.6.47}
\end{equation*}
$$

From 34.6.46 and Proposition 34.6.1, the following holds in $\mathscr{V}_{[-T, 2 T]}^{\prime}$.

$$
\begin{align*}
\lim _{n \rightarrow \infty}\left(i^{*} \tilde{B} u_{n}\right)^{\prime} & =\lim _{n \rightarrow \infty}\left(i^{*} \tilde{B}\left(\tilde{u} * \phi_{n}\right)\right)^{\prime}  \tag{34.6.48}\\
& =\lim _{n \rightarrow \infty}\left(\left(i^{*} \tilde{B} \tilde{u}\right) * \phi_{n}\right)^{\prime} \\
& =\lim _{n \rightarrow \infty}\left(i^{*} \tilde{B} \tilde{u}\right)^{\prime} * \phi_{n} \\
& =\left(i^{*} \tilde{B} \tilde{u}\right)^{\prime}
\end{align*}
$$

Where the second equality follows from Corollary 34.6.2, the third follows from the pointwise a.e. equality of $\left(\left(i^{*} \tilde{B} \tilde{u}\right) * \phi_{n}\right)^{\prime}$ and $\left(i^{*} \tilde{B} \tilde{u}\right)^{\prime} * \phi_{n}$, while the fourth follows from 34.6.46 and standard properties of convolutions.

By choosing a subsequence we can use 34.6 .48 to obtain

$$
\begin{gather*}
u_{n} \rightarrow u \text { a.e. and in } \mathscr{V}  \tag{34.6.49}\\
\left(i^{*} \tilde{B} u_{n}\right)^{\prime} \rightarrow\left(i^{*} B u\right)^{\prime} \text { a.e. and in } \mathscr{V}^{\prime} .
\end{gather*}
$$

From 34.6.49,

$$
\begin{align*}
\operatorname{Re}\left\langle\left(i^{*} \tilde{B} u_{n}\right)^{\prime}(t), u_{n}(t)\right\rangle & \rightarrow \operatorname{Re}\left\langle\left(i^{*} B u\right)^{\prime}(t), u(t)\right\rangle \text { a.e. } t \in[0, T]  \tag{34.6.50}\\
\left\langle B^{\prime}(t) u_{n}(t), u_{n}(t)\right\rangle & \rightarrow\left\langle B^{\prime}(t) u(t), u(t)\right\rangle \text { a.e. } t \in[0, T] \tag{34.6.51}
\end{align*}
$$

If $g \in L^{\infty}(0, T)$,

$$
\begin{gathered}
\lim _{n \rightarrow \infty} \int_{0}^{T} g(t)\left\langle\left(i^{*} \tilde{B} u_{n}\right)^{\prime}(t), u_{n}(t)\right\rangle d t=\lim _{n \rightarrow \infty}\left\langle\left(i^{*} \tilde{B} u_{n}\right)^{\prime}, g u_{n}(t)\right\rangle \\
=\left\langle\left(i^{*} B u\right)^{\prime}, g u\right\rangle=\int_{0}^{T} g(t)\left\langle\left(i^{*} B u\right)^{\prime}(t), u(t)\right\rangle d t
\end{gathered}
$$

Thus we have the following weak convergence:

$$
\operatorname{Re}\left\langle\left(i^{*} \tilde{B} u_{n}\right)^{\prime}, u_{n}\right\rangle \rightharpoonup \operatorname{Re}\left\langle\left(i^{*} B u\right)^{\prime}, u\right\rangle \text { in } L^{1}(0, T)
$$

Similarly,

$$
\left\langle B^{\prime} u_{n}, u_{n}\right\rangle \rightharpoonup\left\langle B^{\prime} u, u\right\rangle \text { in } L^{1}(0, T)
$$

It follows from 34.6.47 that
$\left\langle\tilde{B} u_{n}, u_{n}\right\rangle^{\prime}(\cdot)$ converges a.e. and weakly in $L^{1}(0, T)$.

$$
\left\langle\tilde{B} u_{n}, u_{n}\right\rangle(\cdot) \text { converges a.e. and strongly in } L^{1}(0, T) \text { to }\langle B u, u\rangle(\cdot) .
$$

Therefore, $\left\langle\tilde{B} u_{n}, u_{n}\right\rangle^{\prime}(\cdot)$ converges a.e. and weakly in $L^{1}(0, T)$ to $\langle B u, u\rangle^{\prime}(\cdot)$. Since $\langle\tilde{B} u, u\rangle$ and $\langle\tilde{B} u, u\rangle^{\prime}$ are both in $L^{1}(0, T)$, this proves part 1 in the case where $v=u$. This also establishes formula 2. To get 1 for $u \neq v$, apply what was just shown to

$$
\langle B(t)(u(t)+v(t)), u(t)+v(t)\rangle .
$$

Next let $t \in[0, T]$ and use 34.6 .47 to write

$$
\begin{gather*}
\left\langle\tilde{B} u_{n}, u_{n}\right\rangle(t)= \\
2 \operatorname{Re} \int_{-T}^{t}\left\langle\left(i^{*} \tilde{B} u_{n}\right)^{\prime}(s), u_{n}(s)\right\rangle d s-2 \operatorname{Re} \int_{-T}^{t}\left\langle\tilde{B}^{\prime}(s) u_{n}(s), u_{n}(s)\right\rangle d s \tag{34.6.52}
\end{gather*}
$$

Using 34.6.49, we let $n \rightarrow \infty$ in 34.6.52 and obtain

$$
\begin{equation*}
\langle\tilde{B} u, u\rangle(t)=2 \operatorname{Re} \int_{-T}^{t}\left\langle\left(i^{*} \tilde{B} \tilde{u}\right)^{\prime}(s), \tilde{u}(s)\right\rangle d s-2 \operatorname{Re} \int_{-T}^{t}\left\langle\tilde{B}^{\prime}(s) \tilde{u}(s), \tilde{u}(s)\right\rangle d s . \tag{34.6.53}
\end{equation*}
$$

Hence from 34.6.46,

$$
|\langle\tilde{B} u, u\rangle(t)| \leq C\left[\left\|\left(i^{*} \tilde{B} \tilde{u}\right)^{\prime}\right\|_{\mathscr{Y}_{[-T, 2 T]}^{\prime}}\|\tilde{u}\|_{Y_{[-T, 2 T]}}+\|\tilde{u}\|_{\left.V_{[-T, 2 T]}\right]}^{2}\right]
$$

$$
\begin{equation*}
\leq C\left[\|L u\|_{\mathscr{V}_{[0, T]}^{\prime}}^{2}+\|u\|_{\left.\mathscr{V}_{[0, T]}\right]}^{2}\right] \leq C\|u\|_{X}^{2} . \tag{34.6.54}
\end{equation*}
$$

This verifies 3 in the case $u=v$. To obtain the general case,

$$
|\langle B u, v\rangle(t)| \leq\langle B u, u\rangle^{1 / 2}(t)\langle B v, v\rangle^{1 / 2}(t) \leq C\|u\|_{X}\|v\|_{X}
$$

To verify 4 , use 34.6 .47 to write for $t \in[0, T]$ and $I=[-T, 2 T]$,

$$
\begin{gather*}
\left|\left\langle\tilde{B} u_{n}(t)-\tilde{B} u_{m}(t), u_{n}(t)-u_{m}(t)\right\rangle\right| \\
\leq 2\left|\int_{-T}^{2 T}\left\langle\left(i^{*} \tilde{B}\left(u_{n}-u_{m}\right)\right)^{\prime}(s), u_{n}(s)-u_{m}(s)\right\rangle d s\right| \\
C\left[\left\|\left(i^{*} \tilde{B} u_{n}\right)^{\prime}-\left(i^{*} \tilde{B} u_{m}\right)^{\prime}\right\|_{\mathscr{V}_{I}^{\prime}}^{2 T}\left|\left\langle\tilde{B}^{\prime}(s)\left(u_{n}(s)-u_{m}(s)\right), u_{n}(s)-u_{m}(s)\right\rangle\right| d s \leq\right.  \tag{34.6.55}\\
\left.\mathscr{V}_{I}+\left\|u_{n}-u_{m}\right\|_{\mathscr{W}_{I}}^{2}\right] \equiv E_{n m} .
\end{gather*}
$$

Then from 34.6.48, $\lim _{n, m \rightarrow \infty} E_{n m}=0$ and so, for $t \in[0, T]$,

$$
\left|\left\langle\tilde{B} u_{n}(t)-\tilde{B} u_{m}(t), w\right\rangle\right| \leq E_{n m}^{1 / 2}\langle B(t) w, w\rangle^{1 / 2} \leq C E_{n m}^{1 / 2}\|w\|_{W}
$$

It follows that $\tilde{B} u_{n}(\cdot)$ is uniformly Cauchy in the space of continuous functions $C\left(0, T ; W^{\prime}\right)$ and so it converges to $z \in C\left(0, T ; W^{\prime}\right)$. But $\tilde{B} u_{n}$ converges in $L^{2}\left(0, T ; W^{\prime}\right)$ to $B u(\cdot)$. Therefore $B(t) u(t)=z(t)$ a.e. Letting $B u(\cdot)=z(\cdot)$, this shows 4 . Formula 5 follows from 3 and the following argument.

$$
|\langle B u(t), w\rangle| \leq\langle B u, u\rangle^{1 / 2}(t)\langle B w, w\rangle^{1 / 2} \leq C\|u\|_{X}\|w\|_{W} .
$$

Assertion 6 follows easily from the first five parts. It remains to get 7 .

$$
\begin{aligned}
\operatorname{Re}\langle K u, u\rangle & =\int_{0}^{T} \operatorname{Re}\langle L u, u\rangle d t+\langle B u, u\rangle(0) \\
& =\int_{0}^{T} \frac{1}{2}\left[\langle B u, u\rangle^{\prime}(t)+\left\langle B^{\prime}(t) u(t), u(t)\right\rangle\right] d t+\langle B u, u\rangle(0) \\
& =\frac{1}{2}\langle B u, u\rangle(T)+\frac{1}{2}\langle B u, u\rangle(0)+\frac{1}{2} \int_{0}^{T}\left\langle B^{\prime}(t) u(t), u(t)\right\rangle d t
\end{aligned}
$$

It only remains to verify the last assertion. Let $\psi_{n}$ be increasing and piecewise linear such that $\psi_{n}(t)=1$ for $t \geq 2 / n$ and equals 0 on $[0,1 / n]$. Then clearly $\psi_{n} u \rightarrow u$ in $\mathscr{V}$. Also

$$
\left(B\left(\psi_{n} u\right)\right)^{\prime}=\psi_{n}^{\prime} B u+\psi_{n}(B u)^{\prime}
$$

The latter term converges to $(B u)^{\prime}$ in $\mathscr{V}^{\prime}$. Now consider the first term.

$$
\begin{gathered}
\int_{0}^{T}\left\|\psi_{n}^{\prime} B u\right\|_{V^{\prime}}^{p^{\prime}} d t \leq \int_{0}^{2 / n} n\left\|\int_{0}^{t}(B u)^{\prime} d s\right\|^{p^{\prime}} d t \\
\leq n \int_{0}^{2 / n}{ }_{t} t^{p^{\prime}-1} \int_{0}^{t}\left\|(B u)^{\prime}\right\|_{V^{\prime}}^{p^{\prime}} d s d t \leq \int_{0}^{2 / n}\left\|(B u)^{\prime}\right\|_{V^{\prime}}^{p^{\prime}} d s \frac{1}{p^{\prime}}(2 / n)^{p^{\prime}} n
\end{gathered}
$$

Since $p^{\prime}>1$, this converges to 0 .

Corollary 34.6.5 If $B u(0)=0$ for $u \in X$, then $\langle B u, u\rangle(0)=0$. The converse is also true. An analogous result will hold with 0 replaced with $T$.

Proof: Let $u_{n} \rightarrow u$ in $X$ with $u_{n}(t)=0$ for all $t$ close enough to 0 . For $t$ off a set of measure zero consisting of the union of sets of measure zero corresponding to $u_{n}$ and $u$,

$$
\begin{gathered}
\left\langle B u_{n}, u_{n}\right\rangle(t)=\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle,\langle B u, u\rangle(t)=\langle B(t) u(t), u(t)\rangle, \\
\left\langle B\left(u-u_{n}\right), u\right\rangle(t)=\left\langle B(t)\left(u(t)-u_{n}(t)\right), u(t)\right\rangle \\
\left\langle B u_{n}, u-u_{n}\right\rangle(t)=\left\langle B(t) u_{n}(t), u(t)-u_{n}(t)\right\rangle
\end{gathered}
$$

Then, considering such $t$,

$$
\begin{aligned}
\langle B(t) u(t), u(t)\rangle-\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle= & \left\langle B(t)\left(u(t)-u_{n}(t)\right), u(t)\right\rangle \\
& +\left\langle B(t) u_{n}(t), u(t)-u_{n}(t)\right\rangle
\end{aligned}
$$

Hence from Theorem 34.6.4,

$$
\left|\langle B(t) u(t), u(t)\rangle-\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle\right| \leq C\left\|u-u_{n}\right\|_{X}\left(\|u\|_{X}+\left\|u_{n}\right\|_{X}\right)
$$

Thus if $n$ is sufficiently large,

$$
\left|\langle B(t) u(t), u(t)\rangle-\left\langle B(t) u_{n}(t), u_{n}(t)\right\rangle\right|<\varepsilon
$$

So let $n$ be fixed and this large and now let $t_{k} \rightarrow 0$ to obtain $\left\langle B\left(t_{k}\right) u_{n}\left(t_{k}\right), u_{n}\left(t_{k}\right)\right\rangle=0$ for $k$ large enough. Hence

$$
\langle B u, u\rangle(0)=\lim _{k \rightarrow \infty}\left\langle B\left(t_{k}\right) u\left(t_{k}\right), u\left(t_{k}\right)\right\rangle<\varepsilon
$$

Since $\varepsilon$ is arbitrary, $\langle B u, u\rangle(0)=0$.
Next suppose $\langle B u, u\rangle(0)=0$. Then letting $v \in X$, with $v$ smooth,

$$
\langle B u(0), v(0)\rangle=\langle B u, v\rangle(0)=\langle B u, u\rangle^{1 / 2}(0)\langle B v, v\rangle^{1 / 2}(0)=0
$$

and it follows that $B u(0)=0$.

### 34.7 Some Imbedding Theorems

The next theorem is very useful in getting estimates in partial differential equations. It is called Erling's lemma.

Definition 34.7.1 Let $E, W$ be Banach spaces such that $E \subseteq W$ and the injection map from $E$ into $W$ is continuous. The injection map is said to be compact if every bounded set in $E$ has compact closure in $W$. In other words, if a sequence is bounded in $E$ it has a convergent subsequence converging in $W$. This is also referred to by saying that bounded sets in $E$ are precompact in $W$.

Theorem 34.7.2 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then for every $\varepsilon>0$ there exists a constant, $C_{\varepsilon}$ such that for all $u \in E$,

$$
\|u\|_{W} \leq \varepsilon\|u\|_{E}+C_{\varepsilon}\|u\|_{X}
$$

Proof: Suppose not. Then there exists $\varepsilon>0$ and for each $n \in \mathbb{N}, u_{n}$ such that

$$
\left\|u_{n}\right\|_{W}>\varepsilon\left\|u_{n}\right\|_{E}+n\left\|u_{n}\right\|_{X}
$$

Now let $v_{n}=u_{n} /\left\|u_{n}\right\|_{E}$. Therefore, $\left\|v_{n}\right\|_{E}=1$ and

$$
\left\|v_{n}\right\|_{W}>\varepsilon+n\left\|v_{n}\right\|_{X}
$$

It follows there exists a subsequence, still denoted by $v_{n}$ such that $v_{n}$ converges to $v$ in $W$. However, the above inequality shows that $\left\|v_{n}\right\|_{X} \rightarrow 0$. Therefore, $v=0$. But then the above inequality would imply that $\left\|v_{n}\right\|_{W}>\varepsilon$ and passing to the limit yields $0>\varepsilon$, a contradiction.

Definition 34.7.3 Define $C([a, b] ; X)$ the space of functions continuous at every point of $[a, b]$ having values in $X$.

You should verify that this is a Banach space with norm

$$
\|u\|_{\infty, X}=\max \left\{\left\|u_{n_{k}}(t)-u(t)\right\|_{X}: t \in[a, b]\right\} .
$$

The following theorem is an infinite dimensional version of the Ascoli Arzela theorem. It is like a well known result due to Simon [117]. It is an appropriate generalization when you do not have weak derivatives.

Theorem 34.7.4 Let $q>1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$
\left\{u \text { such that }\|u(t)\|_{E} \leq R \text { for all } t \in[a, b], \text { and }\|u(s)-u(t)\|_{X} \leq R|t-s|^{1 / q}\right\}
$$

Thus $S$ is bounded in $L^{\infty}(a, b, E)$ and in addition, the functions are uniformly Holder continuous into $X$. Then $S \subseteq C([a, b] ; W)$ and if $\left\{u_{n}\right\} \subseteq S$, there exists a subsequence, $\left\{u_{n_{k}}\right\}$ which converges to a function $u \in C([a, b] ; W)$ in the following way.

$$
\lim _{k \rightarrow \infty}\left\|u_{n_{k}}-u\right\|_{\infty, W}=0
$$

Proof: First consider the issue of $S$ being a subset of $C([a, b] ; W)$. Let $\varepsilon>0$ be given. Then by Theorem 34.7.2 there exists a constant, $C_{\varepsilon}$ such that for all $u \in W$

$$
\|u\|_{W} \leq \frac{\varepsilon}{6 R}\|u\|_{E}+C_{\varepsilon}\|u\|_{X}
$$

Therefore, for all $u \in S$,

$$
\begin{align*}
\|u(t)-u(s)\|_{W} & \leq \frac{\varepsilon}{6 R}\|u(t)-u(s)\|_{E}+C_{\varepsilon}\|u(t)-u(s)\|_{X} \\
& \leq \frac{\varepsilon}{6 R}\left(\|u(t)\|_{E}+\|u(s)\|_{E}\right)+C_{\varepsilon}\|u(t)-u(s)\|_{X} \\
& \leq \frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q} \tag{34.7.56}
\end{align*}
$$

Since $\varepsilon$ is arbitrary, it follows $u \in C([a, b] ; W)$.
Let $D=\mathbb{Q} \cap[a, b]$ so $D$ is a countable dense subset of $[a, b]$. Let $D=\left\{t_{n}\right\}_{n=1}^{\infty}$. By compactness of the embedding of $E$ into $W$, there exists a subsequence $u_{(n, 1)}$ such that as $n \rightarrow \infty, u_{(n, 1)}\left(t_{1}\right)$ converges to a point in $W$. Now take a subsequence of this, called $(n, 2)$ such that as $n \rightarrow \infty, u_{(n, 2)}\left(t_{2}\right)$ converges to a point in $W$. It follows that $u_{(n, 2)}\left(t_{1}\right)$ also converges to a point of $W$. Continue this way. Now consider the diagonal sequence, $u_{k} \equiv$ $u_{(k, k)}$ This sequence is a subsequence of $u_{(n, l)}$ whenever $k>l$. Therefore, $u_{k}\left(t_{j}\right)$ converges for all $t_{j} \in D$.

Claim: Let $\left\{u_{k}\right\}$ be as just defined, converging at every point of $D \equiv[a, b] \cap \mathbb{Q}$. Then $\left\{u_{k}\right\}$ converges at every point of $[a, b]$.

Proof of claim: Let $\varepsilon>0$ be given. Let $t \in[a, b]$. Pick $t_{m} \in D \cap[a, b]$ such that in 34.7.56 $C_{\varepsilon} R\left|t-t_{m}\right|<\varepsilon / 3$. Theefore it follows that there exists $N$ such that if $l, n>N$, then $\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\|_{X}<\varepsilon / 3$. It follows that for $l, n>N$,

$$
\begin{aligned}
\left\|u_{l}(t)-u_{n}(t)\right\|_{W} \leq & \left\|u_{l}(t)-u_{l}\left(t_{m}\right)\right\|_{W}+\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\|_{W} \\
& +\left\|u_{n}\left(t_{m}\right)-u_{n}(t)\right\|_{W} \\
\leq & \frac{2 \varepsilon}{3}+\frac{\varepsilon}{3}+\frac{2 \varepsilon}{3}<2 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows $\left\{u_{k}(t)\right\}_{k=1}^{\infty}$ is a Cauchy sequence. Since $W$ is complete, this shows this sequence converges.

Now for $t \in[a, b]$, it was just shown that if $\varepsilon>0$ there exists $N_{t}$ such that if $n, m>N_{t}$, then

$$
\left\|u_{n}(t)-u_{m}(t)\right\|_{W}<\frac{\varepsilon}{3}
$$

Now let $s \neq t$. Then

$$
\left\|u_{n}(s)-u_{m}(s)\right\|_{W} \leq\left\|u_{n}(s)-u_{n}(t)\right\|_{W}+\left\|u_{n}(t)-u_{m}(t)\right\|_{W}+\left\|u_{m}(t)-u_{m}(s)\right\|_{W}
$$

From 34.7.56

$$
\left\|u_{n}(s)-u_{m}(s)\right\|_{W} \leq 2\left(\frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q}\right)+\left\|u_{n}(t)-u_{m}(t)\right\|_{W}
$$

and so it follows that if $\delta$ is sufficiently small and $s \in B(t, \delta)$, then when $n, m>N_{t}$

$$
\left\|u_{n}(s)-u_{m}(s)\right\|<\varepsilon .
$$

Since $[a, b]$ is compact, there are finitely many of these balls, $\left\{B\left(t_{i}, \delta\right)\right\}_{i=1}^{p}$, such that for $s \in B\left(t_{i}, \delta\right)$ and $n, m>N_{t_{i}}$, the above inequality holds. Let $N>\max \left\{N_{t_{1}}, \cdots, N_{t_{p}}\right\}$. Then
if $m, n>N$ and $s \in[a, b]$ is arbitrary, it follows the above inequality must hold. Therefore, this has shown the following claim.

Claim: Let $\varepsilon>0$ be given. Then there exists $N$ such that if $m, n>N$, then

$$
\left\|u_{n}-u_{m}\right\|_{\infty, W}<\varepsilon
$$

Now let $u(t)=\lim _{k \rightarrow \infty} u_{k}(t)$.

$$
\begin{equation*}
\|u(t)-u(s)\|_{W} \leq\left\|u(t)-u_{n}(t)\right\|_{W}+\left\|u_{n}(t)-u_{n}(s)\right\|_{W}+\left\|u_{n}(s)-u(s)\right\|_{W} \tag{34.7.57}
\end{equation*}
$$

Let $N$ be in the above claim and fix $n>N$. Then

$$
\left\|u(t)-u_{n}(t)\right\|_{W}=\lim _{m \rightarrow \infty}\left\|u_{m}(t)-u_{n}(t)\right\|_{W} \leq \varepsilon
$$

and similarly, $\left\|u_{n}(s)-u(s)\right\|_{W} \leq \varepsilon$. Then if $|t-s|$ is small enough, 34.7 .56 shows the middle term in 34.7 .57 is also smaller than $\varepsilon$. Therefore, if $|t-s|$ is small enough,

$$
\|u(t)-u(s)\|_{W}<3 \varepsilon
$$

Thus $u$ is continuous. Finally, let $N$ be as in the above claim. Then letting $m, n>N$, it follows that for all $t \in[a, b]$,

$$
\left\|u_{m}(t)-u_{n}(t)\right\|_{W}<\varepsilon
$$

Therefore, letting $m \rightarrow \infty$, it follows that for all $t \in[a, b]$,

$$
\left\|u(t)-u_{n}(t)\right\|_{W} \leq \varepsilon
$$

and so $\left\|u-u_{n}\right\|_{\infty, W} \leq \varepsilon$.
Here is an interesting corollary. Recall that for $E$ a Banach space $C^{0, \alpha}([0, T], E)$ is the space of continuous functions $u$ from $[0, T]$ to $E$ such that

$$
\|u\|_{\alpha, E} \equiv\|u\|_{\infty, E}+\rho_{\alpha, E}(u)<\infty
$$

where here

$$
\rho_{\alpha, E}(u) \equiv \sup _{t \neq s} \frac{\|u(t)-u(s)\|_{E}}{|t-s|^{\alpha}}
$$

Corollary 34.7.5 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then if $\gamma>\alpha$, the embedding of $C^{0, \gamma}([0, T], E)$ into $C^{0, \alpha}([0, T], X)$ is compact.

Proof: Let $\phi \in C^{0, \gamma}([0, T], E)$

$$
\begin{gathered}
\frac{\|\phi(t)-\phi(s)\|_{X}}{|t-s|^{\alpha}} \leq\left(\frac{\|\phi(t)-\phi(s)\|_{W}}{|t-s|^{\gamma}}\right)^{\alpha / \gamma}\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)} \\
\leq\left(\frac{\|\phi(t)-\phi(s)\|_{E}}{|t-s|^{\gamma}}\right)^{\alpha / \gamma}\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)} \leq \rho_{\gamma, E}(\phi)\|\phi(t)-\phi(s)\|_{W}^{1-(\alpha / \gamma)}
\end{gathered}
$$

Now suppose $\left\{u_{n}\right\}$ is a bounded sequence in $C^{0, \gamma}([0, T], E)$. By Theorem 34.7.4 above, there is a subsequence still called $\left\{u_{n}\right\}$ which converges in $C^{0}([0, T], W)$. Thus from the above inequality

$$
\begin{aligned}
& \frac{\left\|u_{n}(t)-u_{m}(t)-\left(u_{n}(s)-u_{m}(s)\right)\right\|_{X}}{|t-s|^{\alpha}} \\
\leq & \rho_{\gamma, E}\left(u_{n}-u_{m}\right)\left\|u_{n}(t)-u_{m}(t)-\left(u_{n}(s)-u_{m}(s)\right)\right\|_{W}^{1-(\alpha / \gamma)} \\
\leq & C\left(\left\{u_{n}\right\}\right)\left(2\left\|u_{n}-u_{m}\right\|_{\infty, W}\right)^{1-(\alpha / \gamma)}
\end{aligned}
$$

which converges to 0 as $n, m \rightarrow \infty$. Thus

$$
\rho_{\alpha, X}\left(u_{n}-u_{m}\right) \rightarrow 0 \text { as } n, m \rightarrow \infty
$$

Also $\left\|u_{n}-u_{m}\right\|_{\infty, X} \rightarrow 0$ as $n, m \rightarrow \infty$ so this is a Cauchy sequence in $C^{0, \alpha}([0, T], X)$.
The next theorem is a well known result probably due to Lions, Temam, or Aubin.
Theorem 34.7.6 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $p \geq 1$, let $q>1$, and define

$$
\begin{gathered}
S \equiv\left\{u \in L^{p}([a, b] ; E): \text { for some } C,\|u(t)-u(s)\|_{X} \leq C|t-s|^{1 / q}\right. \\
\text { and } \left.\|u\|_{L^{p}([a, b] ; E)} \leq R\right\} .
\end{gathered}
$$

Thus $S$ is bounded in $L^{p}([a, b] ; E)$ and Holder continuous into $X$. Then $S$ is precompact in $L^{p}([a, b] ; W)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b] ; W)$.

Proof: By Proposition 7.6 .5 on Page 144 it suffices to show that for each $\eta>0, S$ has an $\eta$ net in $L^{p}([a, b] ; W)$.

If not, there exists $\eta>0$ and a sequence $\left\{u_{n}\right\} \subseteq S$, such that

$$
\begin{equation*}
\left\|u_{n}-u_{m}\right\| \geq \eta \tag{34.7.58}
\end{equation*}
$$

for all $n \neq m$ and the norm refers to $L^{p}([a, b] ; W)$. Let

$$
a=t_{0}<t_{1}<\cdots<t_{k}=b, t_{i}-t_{i-1}=(b-a) / k
$$

Now define

$$
\bar{u}_{n}(t) \equiv \sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t), \bar{u}_{n_{i}} \equiv \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s .
$$

The idea is to show that $\bar{u}_{n}$ approximates $u_{n}$ well and then to argue that a subsequence of the $\left\{\bar{u}_{n}\right\}$ is a Cauchy sequence yielding a contradiction to 34.7.58.

Therefore,

$$
u_{n}(t)-\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{n}(t) \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
$$

$$
\begin{gathered}
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(t) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{gathered}
$$

It follows from Jensen's inequality that

$$
\begin{aligned}
& \left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} \\
= & \sum_{i=1}^{k}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
\leq & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{aligned}
$$

and so

$$
\begin{align*}
& \int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \\
\leq & \int_{a}^{b} \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) d t \\
= & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s d t \tag{34.7.59}
\end{align*}
$$

From Theorem 34.7.2 if $\varepsilon>0$, there exists $C_{\varepsilon}$ such that

$$
\begin{gathered}
\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} \leq \varepsilon\left\|u_{n}(t)-u_{n}(s)\right\|_{E}^{p}+C_{\varepsilon}\left\|u_{n}(t)-u_{n}(s)\right\|_{X}^{p} \\
\leq 2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}|t-s|^{p / q}
\end{gathered}
$$

This is substituted in to 34.7 .59 to obtain

$$
\begin{aligned}
& \int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \leq \\
& \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left(2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}|t-s|^{p / q}\right) d s d t \\
= & \sum_{i=1}^{k} 2^{p} \varepsilon \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)\right\|_{W}^{p}+\frac{C_{\varepsilon}}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}|t-s|^{p / q} d s d t \\
\leq & 2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}} d s d t \\
= & 2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q}\left(t_{i}-t_{i-1}\right)^{2} \\
\leq & 2^{p} \varepsilon R^{p}+C_{\varepsilon} \sum_{i=1}^{k}\left(t_{i}-t_{i-1}\right)^{1+p / q}=2^{p} \varepsilon R^{p}+C_{\varepsilon} k\left(\frac{b-a}{k}\right)^{1+p / q} .
\end{aligned}
$$

Taking $\varepsilon$ so small that $2^{p} \varepsilon R^{p}<\eta^{p} / 8^{p}$ and then choosing $k$ sufficiently large, it follows

$$
\left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}([a, b] ; W)}<\frac{\eta}{4} .
$$

Thus $k$ is fixed and $\bar{u}_{n}$ at a step function with $k$ steps having values in $E$. Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that $\left\{\bar{u}_{n}\right\}$ is Cauchy in $L^{p}(a, b ; W)$ and use this to contradict 34.7.58. The details follow.

Suppose $\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{i}^{n} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)$. Thus

$$
\left\|\bar{u}_{n}(t)\right\|_{E}=\sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
$$

and so

$$
R \geq \int_{a}^{b}\left\|\bar{u}_{n}(t)\right\|_{E}^{p} d t=\frac{T}{k} \sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E}^{p}
$$

Therefore, the $\left\{u_{i}^{n}\right\}$ are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence $\left\{u_{n_{k}}\right\}$ such that $u_{n_{k}}$ is a Cauchy sequence in $L^{p}(a, b ; W)$. You simply get a subsequence such that $u_{i}^{n_{k}}$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,

$$
\begin{aligned}
\left\|u_{n}-u_{m}\right\|_{L^{p}(a, b ; W)} \leq & \left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}(a, b ; W)} \\
& +\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\left\|\bar{u}_{m}-u_{m}\right\|_{L^{p}(a, b ; W)} \\
\leq & \frac{\eta}{4}+\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\frac{\eta}{4}<\eta
\end{aligned}
$$

provided $m, n$ are large enough, contradicting 34.7.58.
You can give a different version of the above to include the case where there is, instead of a Holder condition, a bound on $u^{\prime}$ for $u \in S$. It is stated next. See [117].

Corollary 34.7.7 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $p \geq 1$, let $q>1$, and define

$$
\begin{gathered}
S \equiv\left\{u \in L^{p}([a, b] ; E): \text { for some } C,\|u(t)-u(s)\|_{X} \leq C|t-s|^{1 / q}\right. \\
\text { and } \left.\|u\|_{L^{p}([a, b] ; E)} \leq R\right\} .
\end{gathered}
$$

Thus $S$ is bounded in $L^{p}([a, b] ; E)$ and Holder continuous into $X$. Then $S$ is precompact in $L^{p}([a, b] ; W)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b] ; W)$. The same conclusion can be drawn if it is known instead of the Holder condition that $\left\|u^{\prime}\right\|_{L^{1}([a, b] ; X)}$ is bounded.

Proof: The first part is Theorem 34.7.6. Therefore, we just prove the new stuff which involves a bound on the $L^{1}$ norm of the derivative. By Proposition 7.6.5 on Page 144 it suffices to show $S$ has an $\eta$ net in $L^{p}([a, b] ; W)$ for each $\eta>0$.

If not, there exists $\eta>0$ and a sequence $\left\{u_{n}\right\} \subseteq S$, such that

$$
\begin{equation*}
\left\|u_{n}-u_{m}\right\| \geq \eta \tag{34.7.60}
\end{equation*}
$$

for all $n \neq m$ and the norm refers to $L^{p}([a, b] ; W)$. Let

$$
a=t_{0}<t_{1}<\cdots<t_{k}=b, t_{i}-t_{i-1}=(b-a) / k
$$

Now define

$$
\bar{u}_{n}(t) \equiv \sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t), \bar{u}_{n_{i}} \equiv \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s
$$

The idea is to show that $\bar{u}_{n}$ approximates $u_{n}$ well and then to argue that a subsequence of the $\left\{\bar{u}_{n}\right\}$ is a Cauchy sequence yielding a contradiction to 34.7.60.

Therefore,

$$
\begin{gathered}
u_{n}(t)-\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{n}(t) \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(t) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)-\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{gathered}
$$

It follows from Jensen's inequality that

$$
\begin{aligned}
& \left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} \\
= & \sum_{i=1}^{k}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{aligned}
$$

And so

$$
\begin{gather*}
\int_{0}^{T}\left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} d t=\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} d t \\
\leq \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}} \varepsilon\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{E}^{p} d t \\
\quad+C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{X}^{p} d t \tag{34.7.61}
\end{gather*}
$$

Consider the second of these. It equals

$$
C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{s}^{t} u_{n}^{\prime}(\tau) d \tau d s\right\|_{X}^{p} d t
$$

This is no larger than

$$
\leq C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left(\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau d s\right)^{p} d t
$$

$$
\begin{aligned}
& =C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left(\int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p} d t \\
= & C_{\varepsilon} \sum_{i=1}^{k}\left(\left(t_{i}-t_{i-1}\right)^{1 / p} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p}
\end{aligned}
$$

Since $p \geq 1$,

$$
\begin{aligned}
& \leq C_{\varepsilon}\left(\sum_{i=1}^{k}\left(t_{i}-t_{i-1}\right)^{1 / p} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p} \\
& \leq \frac{C_{\varepsilon}(b-a)}{k}\left(\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}^{\prime}(\tau)\right\|_{X} d \tau\right)^{p} \\
& =\frac{C_{\varepsilon}(b-a)}{k}\left(\left\|u_{n}^{\prime}\right\|_{L^{1}([a, b], X)}\right)^{p}<\frac{\eta^{p}}{10^{p}}
\end{aligned}
$$

if $k$ is chosen large enough. Now consider the first in 34.7.61. By Jensen's inequality

$$
\begin{gathered}
\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}} \varepsilon\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{E}^{p} d t \leq \\
\sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}} \varepsilon \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{E}^{p} d s d t \\
\leq \quad \varepsilon 2^{p-1} \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right) d s d t \\
=\quad 2 \varepsilon 2^{p-1} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_{i}}\left(\left\|u_{n}(t)\right\|^{p}\right) d t=\varepsilon(2)\left(2^{p-1}\right)\left\|u_{n}\right\|_{L^{p}([a, b], E)} \leq M \varepsilon
\end{gathered}
$$

Now pick $\varepsilon$ sufficiently small that $M \varepsilon<\frac{\eta^{p}}{10^{p}}$ and then $k$ large enough that the second term in 34.7 .61 is also less than $\eta^{p} / 10^{p}$. Then it will follow that

$$
\left\|\bar{u}_{n}-u_{n}\right\|_{L^{p}([a, b], W)}<\left(\frac{2 \eta^{p}}{10^{p}}\right)^{1 / p}=2^{1 / p} \frac{\eta}{10} \leq \frac{\eta}{5}
$$

Thus $k$ is fixed and $\bar{u}_{n}$ at a step function with $k$ steps having values in $E$. Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that $\left\{\bar{u}_{n}\right\}$ is Cauchy in $L^{p}([a, b] ; W)$ and use this to contradict 34.7.60. The details follow.

Suppose $\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{i}^{n} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)$. Thus

$$
\left\|\bar{u}_{n}(t)\right\|_{E}=\sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
$$

and so

$$
R \geq \int_{a}^{b}\left\|\bar{u}_{n}(t)\right\|_{E}^{p} d t=\frac{T}{k} \sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E}^{p}
$$

Therefore, the $\left\{u_{i}^{n}\right\}$ are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence $\left\{u_{n_{k}}\right\}$ such that $u_{n_{k}}$ is a Cauchy sequence in $L^{p}([a, b] ; W)$. You simply get a subsequence such that $u_{i}^{n_{k}}$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,

$$
\begin{aligned}
\left\|u_{n}-u_{m}\right\|_{L^{p}(a, b ; W)} \leq & \left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}(a, b ; W)} \\
& +\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\left\|\bar{u}_{m}-u_{m}\right\|_{L^{p}(a, b ; W)} \\
\leq & \frac{\eta}{4}+\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\frac{\eta}{4}<\eta
\end{aligned}
$$

provided $m, n$ are large enough, contradicting 34.7.60.

### 34.8 Some Evolution Inclusions

Let $H$ be a Hilbert space and let $\mathscr{H}$ denote $L^{2}(0, T ; H)$. Here will be an application to an evolution equation having values in $\mathscr{H}$. It will always be the case that $H=H^{\prime}$ so this is the simplest sort of a Gelfand triple, $V=H=H^{\prime}=V^{\prime}$. First is given a maximal monotone operator.

Definition 34.8.1 Let $D(L) \equiv\left\{u \in \mathscr{H}\right.$ such that $u^{\prime} \in \mathscr{H}$ and $\left.u(0)=u_{0}\right\}$. Then for $u \in$ $D(L), L u \equiv u^{\prime}$.

Note that $L$ is not linear.
Lemma 34.8.2 For $L$ as just defined, $L$ is maximal monotone $L: \mathscr{H} \rightarrow \mathscr{H}$.
Proof: To show it is maximal monotone, it suffices to verify that $L+I$ is onto. This is by Theorem 25.7.13 on Page 881. Thus consider the equation

$$
u^{\prime}+u=f, u(0)=u_{0}
$$

Is there a solution? Of course there is and it equals

$$
u(t)=e^{-t} u_{0}+\int_{0}^{t} e^{-(t-s)} f(s) d s
$$

by the usual application of integrating factors and so forth.
Then with this, the following is from Theorem 25.7.55 on Page 919. This is a well known result found in Brezis [24].

Theorem 34.8.3 Let $u_{0} \in D(\phi)$ where $\phi: H \rightarrow[0, \infty]$ is proper, lower semicontinuous, and convex. Also let $f \in \mathscr{H}$ be given and $u_{0} \in D(\phi)$. Then there exists a solution $u$ to the evolution initial value problem,

$$
u^{\prime}(t)+\partial \phi(u(t)) \ni f(t) \text { a.e.in } H, u(0)=u_{0}
$$

This solution satisfies $u(t) \in D(\partial \phi)$ for a.e. $t$, there exists $z \in \mathscr{H}$ such that $z(t) \in \partial \phi(u(t))$ for a.e. $t$ such that the inclusion is an equation with $\partial \phi(u(t))$ replaced with $z(t)$.

Proof: Define a function $\Phi: \mathscr{H} \rightarrow \mathbb{R}$

$$
\Phi(u) \equiv \int_{0}^{T} \phi(u) d t
$$

There are no measurability issues because $\phi$ is lower semicontinuous and so the composition $\phi(u)$ will be appropriately measurable. Then this is clearly convex. It is proper because $\Phi\left(u_{0}\right)=\phi\left(u_{0}\right) T$ so $u_{0} \in D(\Phi)$. If $u_{n} \rightarrow u$ in $\mathscr{H}$, does it follow that

$$
\lim _{n \rightarrow \infty} \Phi\left(u_{n}\right) \geq \Phi(u)
$$

Suppose not so $\Phi(u)>\liminf _{n \rightarrow \infty} \Phi\left(u_{n}\right)$. Then choosing a subsequence such that

$$
u_{n} \rightarrow u \text { pointwise a.e., }
$$

$$
\begin{aligned}
\Phi(u) & >\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \Phi\left(u_{n}\right) \equiv \lim \inf _{n \rightarrow \infty} \int_{0}^{T} \phi\left(u_{n}\right) d t \\
& \geq \int_{0}^{T} \lim _{n \rightarrow \infty} \phi\left(u_{n}\right) d t=\int_{0}^{T} \phi(u) d t=\Phi(u)
\end{aligned}
$$

which is a contradiction. Thus $\Phi$ is also lower semicontinuous.
The constant function $u \equiv u_{0}$ is in $D(L) \cap D(\Phi)$. To use Theorem 25.7.55 on Page 919, it is required to show that

$$
\Phi\left(J_{\lambda} u\right) \leq \Phi(u)+C \lambda
$$

In this case, the duality map is just the identity map. Hence $J_{\lambda} u$ is the solution to

$$
0=\left(J_{\lambda} u-u\right)+\lambda L\left(J_{\lambda} u\right)
$$

Hence letting $J_{\lambda} u$ be denoted by $u_{\lambda}$, it follows that $u_{\lambda}$ would be the solution to

$$
\lambda u_{\lambda}^{\prime}+u_{\lambda}=u, u_{\lambda}(0)=u_{0}
$$

Using the usual integrating factor procedure, it follows that

$$
u_{\lambda}(t)=e^{-(1 / \lambda) t} u_{0}+\int_{0}^{t} e^{-(1 / \lambda)(t-s)} \frac{1}{\lambda} u(s) d s
$$

Note that

$$
e^{-(1 / \lambda) t}+\int_{0}^{t} \frac{1}{\lambda} e^{-(1 / \lambda)(t-s)} d s=1
$$

Thus by Jensen's inequality,

$$
\phi\left(u_{\lambda}(t)\right) \leq e^{-(1 / \lambda) t} \phi\left(u_{0}\right)+\int_{0}^{t} e^{-(1 / \lambda)(t-s)} \frac{1}{\lambda} \phi(u(s)) d s
$$

Then

$$
\Phi\left(u_{\lambda}\right) \leq \int_{0}^{T} e^{-(1 / \lambda) t} \phi\left(u_{0}\right) d t+\int_{0}^{T} \int_{0}^{t} e^{-(1 / \lambda)(t-s)} \frac{1}{\lambda} \phi(u(s)) d s d t
$$

$$
=\int_{0}^{T} e^{-(1 / \lambda) t} \phi\left(u_{0}\right) d t+\int_{0}^{T} \phi(u(s)) \int_{s}^{T} e^{-(1 / \lambda)(t-s)} \frac{1}{\lambda} d t d s
$$

Now $\int_{s}^{T} e^{-(1 / \lambda)(t-s)} \frac{1}{\lambda} d t=1-e^{\frac{1}{\lambda} s-\frac{1}{\lambda} T}<1$ and since $\phi \geq 0$, this shows that

$$
\Phi\left(u_{\lambda}\right) \leq \phi\left(u_{0}\right) \int_{0}^{\infty} e^{-(1 / \lambda) t} d t+\int_{0}^{T} \phi(u(s)) d t
$$

so

$$
\Phi\left(u_{\lambda}\right) \leq \phi\left(u_{0}\right) \lambda+\Phi(u)
$$

It follows that the conditions of Theorem 25.7.55 on Page 919 are satisfied and so $L+\partial \Phi$ is maximal monotone. Thus if $f \in \mathscr{H}$, there exists $u \in D(L) \cap D(\partial \Phi)$ such that for each $v \in \mathscr{H}$ there exists a solution $u_{v}$ to

$$
u_{v}^{\prime}+z_{v}+u_{v}=f+v, u_{v}(0)=u_{0} \in D(\phi)
$$

where $z_{v} \in \partial \Phi\left(u_{v}\right)$. I will show that $v \rightarrow u_{v}$ has a fixed point. Note that if $z_{i} \in \partial \Phi\left(u_{i}\right)$, then

$$
\int_{t-h}^{t}\left(z_{1}-z_{2}, u_{1}-u_{2}\right) d s \geq 0, \text { any } h \leq t
$$

To see this, you could simply let $u_{2}=u_{1}$ off $[t-h, t]$ and pick $z_{1}=z_{2}$ also on this set. Also, you can conclude that $u \in \partial \Phi$ implies $u(t) \in \partial \phi$ for a.e. $t$. I show this now. Let $[a, b] \in \mathscr{G}(\partial \phi)$. Then as just noted, for $[u, z] \in \mathscr{G}(\partial \Phi)$,

$$
\int_{t-h}^{t}(z-b, u-a) d s \geq 0
$$

Then by the fundamental theorem of calculus, for a.e. $t,(z(t)-b, u(t)-a) \geq 0$ a.e. Letting $\left\{\left[a_{i}, b_{i}\right]\right\}_{i=1}^{\infty}$ be a dense subset of $\mathscr{G}(\partial \phi)$, one can take the union of countably many sets of measure zero, one for each $\left[a_{i}, b_{i}\right]$ and conclude that off this set of measure zero, $\left(z(t)-b_{i}, u(t)-a_{i}\right) \geq 0$ for all $i$. Hence this is also true for all $[a, b] \in \mathscr{G}(\partial \phi)$ and so $z(t) \in \partial \phi(u(t))$ for a.e. $t$.

Then if you have $v_{i}, i=1,2$

$$
L u_{v_{1}}-L u_{v_{2}}+z_{v_{1}}-z_{v_{2}}+u_{v_{1}}-u_{v_{2}}=v_{1}-v_{2}
$$

Then taking inner products with $u_{v_{1}}-u_{v_{2}}$ and integrating up to $t$,

$$
\begin{aligned}
& \frac{1}{2}\left|\left(u_{v_{1}}-u_{v_{2}}\right)(t)\right|_{H}^{2}+\int_{0}^{t}\left(z_{v_{1}}-z_{v_{2}}, u_{v_{1}}-u_{v_{2}}\right) d t+\int_{0}^{t}\left|u_{v_{1}}-u_{v_{2}}\right|^{2} d s \\
\leq & \frac{1}{2} \int_{0}^{t}\left|v_{1}-v_{2}\right|^{2} d s+\frac{1}{2} \int_{0}^{t}\left|u_{v_{1}}-u_{v_{2}}\right|^{2} d s
\end{aligned}
$$

Now by monotonicity of $\phi$ and the above,

$$
\left|\left(u_{v_{1}}-u_{v_{2}}\right)(t)\right|_{H}^{2} \leq \int_{0}^{t}\left|v_{1}-v_{2}\right|^{2} d s
$$

which shows that a high enough power of the mapping $v \rightarrow u_{v}$ is a contraction map on $\mathscr{H}$ and so there exists a unique fixed point $u$. Thus $u_{u}=u$ and so

$$
u^{\prime}+z+u=f+u, u_{v}(0)=u_{0} \in D(\phi), z(t) \in \partial \phi(t) \text { a.e. }
$$

and so

$$
u^{\prime}+z=f \text { in } \mathscr{H}, u(t) \in D(\partial \phi) \text { a.e., } z(t) \in \partial \phi(u(t)) \text { a.e., } u^{\prime} \in \mathscr{H}, \text { and } u(0)=u_{0}
$$

Note that in the above, the initial condition only needs to be in $D(\phi)$, not in the smaller $D(\partial \phi)$, although the solution is in $D(\partial \phi)$ for a.e. $t$. Also note that $f$ has no smoothness. It only is in $\mathscr{H}$. This is really a nice result.

## Chapter 35

## Maximal Monotone Operators, Hilbert Space

### 35.1 Basic Theory

Here is provided a short introduction to some of the most important properties of maximal monotone operators in Hilbert space. The following definition describes them. It is more specialized than the earlier material on maximal monotone operators from a Banach space to its dual and therefore, better results can be obtained. More on this can be read in [24] and [116].

Definition 35.1.1 Let $H$ be a real Hilbert space and let $A: D(A) \rightarrow \mathscr{P}(H)$ have the following properties.

1. For each $y \in H$ there exists $x \in D(A)$ such that $y \in x+A x$.
2. $A$ is monotone. That is, if $z \in A x$ and $w \in$ Ay then

$$
(z-w, x-y) \geq 0
$$

Such an operator is called a maximal monotone operator.
It turns out that whenever $A$ is maximal monotone, so is $\lambda A$ for all $\lambda>0$.
Lemma 35.1.2 Suppose $A$ is maximal monotone. Then so is $\lambda A$. Also $J_{\lambda} \equiv(I+\lambda A)^{-1}$ makes sense for each $\lambda>0$ and is Lipschitz continuous.

Proof: To begin with consider $(I+A)^{-1}$. Suppose

$$
x_{1}, x_{2} \in(I+A)^{-1}(y)
$$

Then $y \in(I+A) x_{i}$ and so $y-x_{i} \in A x_{i}$. By monotonicity

$$
\left(y-x_{1}-\left(y-x_{2}\right), x_{1}-x_{2}\right) \geq 0
$$

and so

$$
0 \geq\left|x_{1}-x_{2}\right|^{2}
$$

which shows $J_{1} \equiv(I+A)^{-1}$ makes sense. In fact this is Lipschitz with Lipschitz constant 1. Here is why. $x \in(I+A) J_{1} x$ and $y \in(I+A) J_{1} y$. Then

$$
x-J_{1} x \in A J_{1} x, y-J_{1} y \in A J_{1} y
$$

and so by monotonicity

$$
0 \leq\left(x-J_{1} x-\left(y-J_{1} y\right), J_{1} x-J_{1} y\right)
$$

which yields

$$
\begin{aligned}
\left|J_{1} x-J_{1} y\right|^{2} & \leq\left(x-y, J_{1} x-J_{1} y\right) \\
& \leq|x-y|\left|J_{1} x-J_{1} y\right|
\end{aligned}
$$

which yields the result.
Next consider the claim that $\lambda A$ is maximal monotone. The monotone part is immediate. The only thing in question is whether $I+\lambda A$ is onto. Let $r \in(-1,1)$ and pick $f \in H$. Consider solving the equation for $u$

$$
\begin{equation*}
(1+r) u+A u \ni(1+r) f \tag{35.1.1}
\end{equation*}
$$

This is equivalent to finding $u$ such that

$$
(I+A) u \ni(1+r) f-r u
$$

or in other words finding $u$ such that

$$
u=J_{1}((1+r) f-r u)
$$

However, if

$$
T u \equiv J_{1}((1+r) f-r u)
$$

then since $|r|<1, T$ is a contraction mapping and so there exists a unique solution to 35.1.1. Thus

$$
u+\frac{1}{1+r} A u \ni f
$$

It follows for any $|r|<1,(1+r)^{-1} A$ is maximal monotone. This takes care of all $\lambda \in$ $\left(\frac{1}{2}, \infty\right)$. Now do the same thing for $(2 / 3) A$ to get the result for all $\lambda \in\left(\left(\frac{2}{3}\right)\left(\frac{1}{2}\right), \infty\right)$. Now apply the same argument to $(2 / 3)^{2} A$ to get the result for all $\lambda \in\left(\left(\frac{2}{3}\right)^{2}\left(\frac{1}{2}\right), \infty\right)$. Next consider the same argument to $(2 / 3)^{3} A$ to get the desired result for all $\lambda \in\left(\left(\frac{2}{3}\right)^{3}\left(\frac{1}{2}\right), \infty\right)$. Continuing this way shows $\lambda A$ is maximal monotone for all $\lambda>0$. Also from the first part of the proof $(I+\lambda A)^{-1}$ is Lipschitz continuous with Lipschitz constant 1 . This proves the lemma.

A maximal monotone operator can be approximated with a Lipschitz continuous operator which is also monotone and has certain salubrious properties. This operator is called the Yosida approximation and as in the case of linear operators it is obtained by formally considering

$$
\frac{A}{1+\lambda A}
$$

If you do the division formally you get the definition for $A_{\lambda}$,

$$
\begin{equation*}
A_{\lambda} x \equiv \frac{1}{\lambda} x-\frac{1}{\lambda} J_{\lambda} x \tag{35.1.2}
\end{equation*}
$$

where $J_{\lambda}=(I+\lambda A)^{-1}$ as above. It is obvious that $A_{\lambda}$ is Lipschitz continuous with Lipschitz constant no more than $2 / \lambda$. Actually you can show $1 / \lambda$ also works but this is not important here.

Lemma 35.1.3 $A_{\lambda} x \in A J_{\lambda} x$ and $\left|A_{\lambda} x\right| \leq|y|$ for all $y \in A x$ whenever $x \in D(A)$. Also $A_{\lambda}$ is monotone.

Proof: Consider the first claim. From the definition,

$$
A_{\lambda} x \equiv \frac{1}{\lambda} x-\frac{1}{\lambda} J_{\lambda} x
$$

Is

$$
\frac{1}{\lambda} x-\frac{1}{\lambda} J_{\lambda} x \in A J_{\lambda} x ?
$$

Is

$$
x-J_{\lambda} x \in \lambda A J_{\lambda} x ?
$$

Is

$$
x \in J_{\lambda} x+\lambda A J_{\lambda} x ?
$$

Is

$$
x \in(I+\lambda A) J_{\lambda} x ?
$$

Certainly so. This is how $J_{\lambda}$ is defined.
Now consider the second claim. Let $y \in A x$ for some $x \in D(A)$. Then by monotonicity and what was just shown

$$
0 \leq\left(A_{\lambda} x-y, J_{\lambda} x-x\right)=-\lambda\left(A_{\lambda} x-y, A_{\lambda} x\right)
$$

and so

$$
\left|A_{\lambda} x\right|^{2} \leq\left(y, A_{\lambda} x\right) \leq|y|\left|A_{\lambda} x\right|
$$

Finally, to show $A_{\lambda}$ is monotone,

$$
\begin{gathered}
\left(A_{\lambda} x-A_{\lambda} y, x-y\right)= \\
\left(\frac{1}{\lambda} x-\frac{1}{\lambda} J_{\lambda} x-\left(\frac{1}{\lambda} y-\frac{1}{\lambda} J_{\lambda} y\right), x-y\right) \\
=\frac{1}{\lambda}|x-y|^{2}-\frac{1}{\lambda}\left(J_{\lambda} x-J_{\lambda} y, x-y\right) \\
\geq \frac{1}{\lambda}|x-y|^{2}-\frac{1}{\lambda}|x-y|\left|J_{\lambda} x-J_{\lambda} y\right| \\
\geq \frac{1}{\lambda}|x-y|^{2}-\frac{1}{\lambda}|x-y|^{2}=0
\end{gathered}
$$

and this proves the lemma.
Proposition 35.1.4 Suppose $D(A)$ is dense in $H$. Then for all $x \in H$,

$$
\left|J_{\lambda} x-x\right| \rightarrow 0
$$

Proof: From the above, if $u \in D(A)$ and $y \in A u$, then

$$
\left|\frac{1}{\lambda} u-\frac{1}{\lambda} J_{\lambda} u\right| \leq|y|
$$

Hence $J_{\lambda} u \rightarrow u$. Now for $x$ arbitrary,

$$
\begin{aligned}
\left|J_{\lambda} x-x\right| & \leq\left|J_{\lambda} x-J_{\lambda} u\right|+\left|J_{\lambda} u-u\right|+|u-x| \\
& <2 \varepsilon+\left|J_{\lambda} u-u\right|
\end{aligned}
$$

where the last term converges to 0 as $\lambda \rightarrow 0$. Since $\varepsilon$ is arbitrary, this shows the proposition.
Thus in the case where $D(A)$ is dense, if you have

$$
x \in \varepsilon A x_{\varepsilon}+x_{\varepsilon}
$$

so that $x_{\varepsilon}=J_{\varepsilon} x$, then $\left|x-x_{\varepsilon}\right| \rightarrow 0$.
The next lemma gives a way to determine whether a pair $[x, y]$ is in the graph of $A$ defined as

$$
\{[x, y]: y \in A x\} \equiv \mathscr{G}(A)
$$

Here I am writing $[\cdot, \cdot]$ rather than $(\cdot, \cdot)$ to avoid confusion with the inner product. It is the conclusion of this lemma which accounts for the use of the term "maximal". It essentially says there is no larger monotone graph which includes the one for $A$.

Lemma 35.1.5 Suppose $\left(y_{1}-y, x_{1}-x\right) \geq 0$ for all $[x, y] \in \mathscr{G}(A)$ where $A$ is maximal monotone. Then $x_{1} \in D(A)$ and $y_{1} \in A x_{1}$. Also if $\left[x_{k}, y_{k}\right] \in \mathscr{G}(A)$ and $x_{k} \rightarrow x, y_{k} \rightharpoonup y$ where the half arrow denotes weak convergence, then $[x, y] \in \mathscr{G}(A)$.

Proof: I want to show $y_{1} \in A x_{1}$ or in other words I want to show

$$
x_{1}+\lambda y_{1} \in x_{1}+\lambda A x_{1}
$$

or in other words

$$
J_{\lambda}\left(x_{1}+\lambda y_{1}\right)=x_{1} .
$$

This is the motivation for the following argument.
From Lemma 35.1.3 $A_{\lambda}\left(x_{1}+\lambda y_{1}\right) \in A J_{\lambda}\left(x_{1}+\lambda y_{1}\right)$ and so by the above assumption

$$
\begin{aligned}
& \quad 0 \leq\left(y_{1}-A_{\lambda}\left(x_{1}+\lambda y_{1}\right), x_{1}-J_{\lambda}\left(x_{1}+\lambda y_{1}\right)\right) \\
& =\left(y_{1}-\left(\frac{1}{\lambda}\left(x_{1}+\lambda y_{1}\right)-\frac{1}{\lambda} J_{\lambda}\left(x_{1}+\lambda y_{1}\right)\right), x_{1}-J_{\lambda}\left(x_{1}+\lambda y_{1}\right)\right) \\
& =\left(\left(-\frac{1}{\lambda} x_{1}+\frac{1}{\lambda} J_{\lambda}\left(x_{1}+\lambda y_{1}\right)\right), x_{1}-J_{\lambda}\left(x_{1}+\lambda y_{1}\right)\right) \\
& =-\frac{1}{\lambda}\left(x_{1}-J_{\lambda}\left(x_{1}+\lambda y_{1}\right), x_{1}-J_{\lambda}\left(x_{1}+\lambda y_{1}\right)\right)
\end{aligned}
$$

which requires

$$
x_{1}=J_{\lambda}\left(x_{1}+\lambda y_{1}\right)
$$

and this says $x_{1} \in D(A)$ because $J_{\lambda}$ maps into $D(A)$. Also it says

$$
x_{1}+A x_{1} \ni x_{1}+\lambda y_{1}
$$

and so $y_{1} \in A x_{1}$.
This makes the last claim pretty easy. Suppose $x_{k} \rightarrow x$ where $x_{k} \in D(A)$ and that $y_{k} \in$ $A x_{k}$ and $y_{k} \rightharpoonup y$. I need to verify $y=A x$ and $x \in D(A)$. Let $[u, v] \in \mathscr{G}(A)$. Then

$$
(y-v, x-u)=\lim _{k \rightarrow \infty}\left(y_{k}-v, x_{k}-u\right) \geq 0
$$

and so, by the first part, $x \in D(A)$ and $y \in A x$. Why does that limit hold? It is because

$$
\begin{gathered}
\left|(y-v, x-u)-\left(y_{k}-v, x_{k}-u\right)\right| \\
\leq\left|(y-v, x-u)-\left(y_{k}-v, x-u\right)\right|+\left|\left(y_{k}-v, x_{k}-x\right)\right|
\end{gathered}
$$

The second term is no larger than

$$
\left|y_{k}-v\right|\left|x_{k}-x\right|
$$

which converges to 0 since $y_{k}$ is weakly convergent, hence bounded. The first term converges to 0 because of the assumption that $y_{k}$ converges weakly to $y$. This proves the lemma.

What about the sum of maximal monotone operators? This might not be maximal monotone but what you can say is the following.

Proposition 35.1.6 Let A be maximal monotone and let B be Lipschitz and monotone. Then $A+B$ is maximal monotone.

Proof: First suppose $B$ has a Lipschitz constant less than 1. The monotonicity is obvious. I need to show that for any $y$ there exists $x \in D(A)$ such that

$$
y \in x+B x+A x
$$

This hapens if and only if

$$
y-B x \in(I+A) x
$$

if and only if $x=(I+A)^{-1}(y-B x)$. Let

$$
T x \equiv(I+A)^{-1}(y-B x)
$$

Then $T$ is clearly a contraction mapping because $(I+A)^{-1}$ is Lipschits with Lipschitz constant 1. Therefore, there exists a unique fixed point and this shows $A+B$ is maximal monotone. Now the same argument applied to $A+B$ shows that $A+2 B$ is maximal monotone. Continuing this way $A+n B$ is maximal monotone. Now for arbitrary $B$ let $n$ be large enough that $n^{-1} B$ has Lipschitz constant less than 1. Then as just explained, $A+n\left(n^{-1} B\right)=A+B$ is maximal monotone. This proves the proposition.

The following is a useful result for determining conditions under which $A+B$ is maximal monotone or more particularly whether a given $y$ is in $(I+A+B)(H)$ where $A, B$ are both maximal monotone.

Theorem 35.1.7 Let $A$ and $B$ be maximal monotone, let

$$
y \in x_{\lambda}+B_{\lambda} x_{\lambda}+A x_{\lambda}
$$

and suppose $B_{\lambda} x_{\lambda}$ is bounded independent of $\lambda$. Then there exists $x \in D(A) \cap D(B)$ such that $y=x+A x+B x$.

Proof: First of all, it follows from Proposition 35.1.6 that there exists a unique $x_{\lambda}$. Note

$$
\begin{aligned}
y-x_{\lambda}-B_{\lambda} x_{\lambda} & \in A x_{\lambda} \\
y-x_{\mu}-B_{\mu} x_{\mu} & \in A x_{\mu}
\end{aligned}
$$

and so by monotonicity of $A$,

$$
\left(x_{\mu}-x_{\lambda}+B_{\mu} x_{\mu}-B_{\lambda} x_{\lambda}, x_{\lambda}-x_{\mu}\right) \geq 0
$$

and so

$$
\begin{align*}
\left|x_{\lambda}-x_{\mu}\right|^{2} & \leq\left(B_{\mu} x_{\mu}-B_{\lambda} x_{\lambda}, x_{\lambda}-x_{\mu}\right) \\
& =-\left(B_{\lambda} x_{\lambda}-B_{\mu} x_{\mu}, x_{\lambda}-x_{\mu}\right) \tag{35.1.3}
\end{align*}
$$

I want to write as many things as possible in terms of the $B_{\lambda}$ and $B_{\mu}$. Denote as $J_{\lambda}(B)$ the operator $(I+\lambda B)^{-1}$. Then

$$
B_{\lambda} x_{\lambda}=\frac{1}{\lambda}\left(x_{\lambda}-J_{\lambda}(B) x_{\lambda}\right)
$$

and so

$$
x_{\lambda}=\lambda B_{\lambda} x_{\lambda}+J_{\lambda}(B) x_{\lambda}
$$

Thus 35.1.3 becomes

$$
\begin{gathered}
\left|x_{\lambda}-x_{\mu}\right|^{2}= \\
-\left(B_{\lambda} x_{\lambda}-B_{\mu} x_{\mu}, \lambda B_{\lambda} x_{\lambda}+J_{\lambda}(B) x_{\lambda}-\left(\mu B_{\mu} x_{\mu}+J_{\mu}(B) x_{\mu}\right)\right) \\
=-\left(B_{\lambda} x_{\lambda}-B_{\mu} x_{\mu}, \lambda B_{\lambda} x_{\lambda}-\mu B_{\mu} x_{\mu}\right) \\
+\left(B_{\mu} x_{\mu}-B_{\lambda} x_{\lambda}, J_{\lambda}(B) x_{\lambda}-J_{\mu}(B) x_{\mu}\right) \\
=-\left(B_{\lambda} x_{\lambda}-B_{\mu} x_{\mu}, \lambda B_{\lambda} x_{\lambda}-\lambda B_{\mu} x_{\mu}\right)-\left(B_{\lambda} x_{\lambda}-B_{\mu} x_{\mu},(\lambda-\mu) B_{\mu} x_{\mu}\right) \\
-\left(B_{\lambda} x_{\lambda}-B_{\mu} x_{\mu}, J_{\lambda}(B) x_{\lambda}-J_{\mu}(B) x_{\mu}\right)
\end{gathered}
$$

Now recall $B_{\mu} x \in B J_{\mu}(B) x$. Then by monotonicity the first and last terms to the right of the equal sign in the above are negative. Therefore,

$$
\left|x_{\lambda}-x_{\mu}\right|^{2} \leq\left|\left(B_{\lambda} x_{\lambda}-B_{\mu} x_{\mu},(\lambda-\mu) B_{\mu} x_{\mu}\right)\right| \leq C|\lambda-\mu|
$$

where $C$ is some constant which comes from the assumption the $B_{\lambda} x_{\lambda}$ are bounded.

Therefore, letting $\lambda$ denote a sequence converging to 0 it follows

$$
\lim _{\lambda \rightarrow 0} x_{\lambda}=x_{1} \in H
$$

for some $x$, the convergence being strong convergence. Also taking a further subsequence and using weak compactness it can be assumed

$$
B_{\lambda} x_{\lambda} \rightharpoonup z_{1}
$$

where this time the convergence is weak. Taking another subsequence, it can also be assumed

$$
\begin{equation*}
y-x_{\lambda}-B_{\lambda} x_{\lambda} \rightharpoonup z_{2} \tag{35.1.4}
\end{equation*}
$$

the convergence being weak convergence. Recall $B_{\lambda} x_{\lambda} \in B J_{\lambda}(B) x_{\lambda}$ and also note that by assumption there is a constant $C$ independent of $\lambda$ such that

$$
C \geq\left|B_{\lambda} x_{\lambda}\right| \geq \frac{1}{\lambda}\left(x_{\lambda}-J_{\lambda}(B) x\right)
$$

which shows

$$
J_{\lambda}(B) x_{\lambda} \rightarrow x_{1}
$$

also. Now it follows from Lemma 35.1.5 that $x_{1} \in D(B)$ and $z_{1} \in B x_{1}$. Recall

$$
y-x_{\lambda}-B_{\lambda} x_{\lambda} \in A x_{\lambda}
$$

and so by the same lemma again,

$$
x_{1} \in D(A), z_{2} \in A x_{1}
$$

By 35.1.4 it follows

$$
y-x_{1}-z_{1}=z_{2} \in A x_{1}
$$

Thus

$$
y=x_{1}+z_{1}+z_{2} \in x_{1}+B x_{1}+A x_{1}
$$

and this proves the theorem.

### 35.2 Evolution Inclusions

One of the interesting things about maximal monotone operators is the concept of evolution inclusions. To facilitate this, here is a little lemma.

Lemma 35.2.1 Let $f:[0, T] \rightarrow \mathbb{R}$ be continuous and suppose

$$
D^{+} f(t) \equiv \lim \sup _{h \rightarrow 0+} \frac{f(t+h)-f(t)}{h}<g(t)
$$

where $g$ is a continuous function. Then

$$
f(t)-f(0) \leq \int_{0}^{t} g(s) d s
$$

Proof: Suppose this is not so. Then let

$$
S \equiv\left\{t \in[0, T]: f(t)-f(0)>\int_{0}^{t} g(s) d s\right\}
$$

and it would follow that $S \neq \emptyset$. Let $a=\inf S$. Then there exists a decreasing sequence $h_{n} \rightarrow 0$ such that

$$
\begin{equation*}
f\left(a+h_{n}\right)-f(0)>\int_{0}^{a+h_{n}} g(s) d s \tag{35.2.5}
\end{equation*}
$$

First suppose $a=0$. Then dividing by $h_{n}$ and taking the limit,

$$
g(0)>D^{+} f(0) \geq g(0)
$$

a contradiction. Therefore, assume $a>0$. Then by continuity

$$
f(a)-f(0) \geq \int_{0}^{a} g(s) d s
$$

If strict inequality holds, then $a \neq \inf S$. It follows

$$
f(a)-f(0)=\int_{0}^{a} g(s) d s
$$

and so from 35.2.5

$$
\frac{f\left(a+h_{n}\right)-f(a)}{h_{n}}>\frac{1}{h_{n}} \int_{a}^{a+h_{n}} g(s) d s
$$

Then doing limsup ${ }_{n \rightarrow \infty}$ to both sides,

$$
g(a)>D^{+} f(a) \geq g(a)
$$

the same sort of contradiction obtained earlier. Thus $S=\emptyset$ and this proves the lemma.
The following is the main result.
Theorem 35.2.2 Let $H$ be a Hilbert space and let $A$ be a maximal monotone operator as described above. Let $f:[0, T] \rightarrow H$ be continuous such that $f^{\prime} \in L^{2}(0, T ; H)$. Then there exists a unique solution to the evolution inclusion

$$
y^{\prime}+A y \ni f, y(0)=y_{0} \in D(A)
$$

Here $y^{\prime}$ exists a.e., $y(t) \in D(A)$ a.e., $y$ is continuous.
Proof: Let $y_{\lambda}$ be the solution to

$$
y_{\lambda}^{\prime}+A_{\lambda} y_{\lambda}=f, y_{\lambda}(0)=y_{0}
$$

I will base the entire proof on estimating the solutions to the corresponding integral equation

$$
\begin{equation*}
y_{\lambda}(t)-y_{0}+\int_{0}^{t} A_{\lambda} y_{\lambda}(s) d s=\int_{0}^{t} f(s) d s \tag{35.2.6}
\end{equation*}
$$

Let $h, k$ be small positive numbers. Then

$$
\begin{equation*}
y_{\lambda}(t+h)-y_{\lambda}(t)+\int_{t}^{t+h} A_{\lambda} y_{\lambda}(s) d s=\int_{t}^{t+h} f(s) d s \tag{35.2.7}
\end{equation*}
$$

Next consider the difference operator

$$
D_{k} g(t) \equiv \frac{g(t+k)-g(t)}{k}
$$

Do this $D_{k}$ to both sides of 35.2 .7 where $k<h$. This gives

$$
\begin{align*}
D_{k}\left(y_{\lambda}(t+h)-\right. & \left.y_{\lambda}(t)\right)+\frac{1}{k}\left(\int_{t+h}^{t+h+k} A_{\lambda} y_{\lambda}(s) d s-\int_{t}^{t+k} A_{\lambda} y_{\lambda}(s) d s\right) \\
& =\frac{1}{k}\left(\int_{t+h}^{t+h+k} f(s) d s-\int_{t}^{t+k} f(s) d s\right) \tag{35.2.8}
\end{align*}
$$

Now multiply both sides by $y_{\lambda}(t+h+k)-y_{\lambda}(t+k)$. Consider the first term. To simplify the ideas consider instead

$$
\begin{align*}
\left(D_{k} g(t), g(t+k)\right) & =\frac{1}{k}\left(|g(t+k)|^{2}-(g(t), g(t+k))\right) \\
& \geq \frac{1}{k}\left(|g(t+k)|^{2}-|g(t)||g(t+h)|\right) \\
& \geq \frac{1}{k}\left(\frac{1}{2}|g(t+k)|^{2}-\frac{1}{2}|g(t)|^{2}\right) \tag{35.2.9}
\end{align*}
$$

Then applying this simple observation to 35.2.8,

$$
\begin{gathered}
\frac{1}{2} \frac{1}{k}\left(\left|y_{\lambda}(t+h+k)-y_{\lambda}(t+k)\right|^{2}-\left|y_{\lambda}(t+h)-y_{\lambda}(t)\right|^{2}\right)+ \\
\left(\frac{1}{k}\left(\int_{t+h}^{t+h+k} A_{\lambda} y_{\lambda}(s) d s-\int_{t}^{t+k} A_{\lambda} y_{\lambda}(s) d s\right), y_{\lambda}(t+h+k)-y_{\lambda}(t+k)\right)+ \\
\leq\left(\frac{1}{k}\left(\int_{t+h}^{t+h+k} f(s) d s-\int_{t}^{t+k} f(s) d s\right), y_{\lambda}(t+h+k)-y_{\lambda}(t+k)\right)
\end{gathered}
$$

Taking limsup ${ }_{k \rightarrow 0}$ of both sides yields

$$
\begin{gathered}
\frac{1}{2} D^{+}\left(\left|y_{\lambda}(t+h)-y_{\lambda}(t)\right|^{2}\right)+\left(A_{\lambda} y_{\lambda}(t+h)-A_{\lambda} y_{\lambda}(t), y_{\lambda}(t+h)-y_{\lambda}(t)\right) \\
\leq\left(f(t+h)-f(t), y_{\lambda}(t+h)-y_{\lambda}(t)\right)
\end{gathered}
$$

Now recall that $A_{\lambda}$ is monotone. Therefore,

$$
D^{+}\left(\left|y_{\lambda}(t+h)-y_{\lambda}(t)\right|^{2}\right) \leq|f(t+h)-f(t)|^{2}+\left|y_{\lambda}(t+h)-y_{\lambda}(t)\right|^{2}
$$

From Lemma 35.2.1 it follows that for all $\varepsilon>0$,

$$
\begin{aligned}
& \left|y_{\lambda}(t+h)-y_{\lambda}(t)\right|^{2}-\left|y_{\lambda}(h)-y_{0}\right|^{2} \\
\leq & \int_{0}^{t}|f(s+h)-f(s)|^{2} d s+\int_{0}^{t}\left|y_{\lambda}(s+h)-y_{\lambda}(s)\right|^{2} d s+\varepsilon t
\end{aligned}
$$

and so since $\varepsilon$ is arbitrary, the term $\varepsilon t$ can be eliminated. By Gronwall's inequality,

$$
\begin{equation*}
\left|y_{\lambda}(t+h)-y_{\lambda}(t)\right|^{2} \leq e^{t}\left(\left|y_{\lambda}(h)-y_{0}\right|^{2}+\int_{0}^{t}|f(s+h)-f(s)|^{2} d s\right) \tag{35.2.10}
\end{equation*}
$$

The last integral equals

$$
\begin{gathered}
\int_{0}^{t}\left|\int_{s}^{s+h} f^{\prime}(r) d r\right|^{2} d s \leq \int_{0}^{t} h \int_{s}^{s+h}\left|f^{\prime}(r)\right|^{2} d r d s \\
=h\left[\int_{0}^{h} \int_{0}^{r}\left|f^{\prime}(r)\right|^{2} d s d r+\int_{h}^{t} \int_{r-h}^{r}\left|f^{\prime}(r)\right|^{2} d s d r+\int_{t}^{t+h} \int_{r-h}^{t}\left|f^{\prime}(r)\right|\right]^{2} d s d r \\
\leq h^{2} \int_{0}^{t+h}\left|f^{\prime}(r)\right|^{2} d r
\end{gathered}
$$

and now it follows that for all $t+h<T$,

$$
\begin{equation*}
\left|\frac{y_{\lambda}(t+h)-y_{\lambda}(t)}{h}\right|^{2} \leq e^{T}\left(\left|\frac{y_{\lambda}(h)-y_{0}}{h}\right|^{2}+\left\|f^{\prime}\right\|_{L^{2}(0, T ; H)}^{2}\right) \tag{35.2.11}
\end{equation*}
$$

Now return to 35.2.7.

$$
\left|\frac{y_{\lambda}(h)-y_{0}}{h}\right| \leq\left|\frac{1}{h} \int_{0}^{h} A_{\lambda} y_{\lambda}(s) d s\right|+\left|\frac{1}{h} \int_{0}^{h} f(s) d s\right|
$$

Then taking limsup ${ }_{h \rightarrow 0}$ of both sides

$$
\limsup \sup _{h \rightarrow 0}\left|\frac{y_{\lambda}(h)-y_{0}}{h}\right| \leq\left|A_{\lambda} y_{0}\right|+|f(0)|
$$

From Lemma 35.1.3, $\left|A_{\lambda} y_{0}\right| \leq|a|$ for all $a \in A y_{0}$. This is where $y_{0} \in D(A)$ is used. Thus from 35.2.11, there exists a constant $C$ independent of $t$ and $h$ and $\lambda$ such that

$$
\left|\frac{y_{\lambda}(t+h)-y_{\lambda}(t)}{h}\right|^{2} \leq C
$$

From the estimate just obtained and 35.2.7, this implies

$$
\begin{equation*}
\frac{y_{\lambda}(t+h)-y_{\lambda}(t)}{h}+\frac{1}{h} \int_{t}^{t+h} A_{\lambda} y_{\lambda}(s) d s=\frac{1}{h} \int_{t}^{t+h} f(s) d s \tag{35.2.12}
\end{equation*}
$$

Now letting $h \rightarrow 0$, it follows that for all $t \in[0, T)$, there exists a constant $C$ independent of $t, \lambda$ such that

$$
\begin{equation*}
\left|A_{\lambda} y_{\lambda}(t)\right| \leq C \tag{35.2.13}
\end{equation*}
$$

This is a very nice estimate. The next task is to show uniform convergence of the $y_{\lambda}$ as $\lambda \rightarrow 0$. From 35.2.7

$$
\begin{gathered}
\left(D_{h}\left(y_{\lambda}(t)-y_{\mu}(t)\right), y_{\lambda}(t+h)-y_{\mu}(t+h)\right)+ \\
\left(\frac{1}{h} \int_{t}^{t+h}\left(A_{\lambda} y_{\lambda}(s)-A_{\mu} y_{\mu}(s)\right) d s, y_{\lambda}(t+h)-y_{\mu}(t+h)\right)=0
\end{gathered}
$$

Then from the argument in 35.2.9,

$$
\begin{gathered}
\frac{1}{h} \frac{1}{2}\left(\left|y_{\lambda}(t+h)-y_{\mu}(t+h)\right|^{2}-\left|y_{\lambda}(t)-y_{\mu}(t)\right|^{2}\right) \\
+\left(\frac{1}{h} \int_{t}^{t+h}\left(A_{\lambda} y_{\lambda}(s)-A_{\mu} y_{\mu}(s)\right) d s, y_{\lambda}(t+h)-y_{\mu}(t+h)\right) \leq 0
\end{gathered}
$$

Now take limsup $\sin _{h \rightarrow 0}$ to obtain

$$
\frac{1}{2} D^{+}\left|y_{\lambda}(t)-y_{\mu}(t)\right|^{2}+\left(A_{\lambda} y_{\lambda}(t)-A_{\mu} y_{\mu}(t), y_{\lambda}(t)-y_{\mu}(t)\right) \leq 0
$$

Using the definition of $A_{\lambda}$ this equals

$$
\begin{gathered}
\frac{1}{2} D^{+}\left|y_{\lambda}(t)-y_{\mu}(t)\right|^{2}+ \\
\left(A_{\lambda} y_{\lambda}(t)-A_{\mu} y_{\mu}(t), \lambda A_{\lambda} y_{\lambda}(t)+J_{\lambda} y_{\lambda}(t)-\left(\mu A_{\mu} y_{\mu}(t)+J_{\mu} y_{\mu}(t)\right)\right) \leq 0
\end{gathered}
$$

Now this last term splits into the following sum

$$
\begin{aligned}
& \left(A_{\lambda} y_{\lambda}(t)-A_{\mu} y_{\mu}(t), \lambda A_{\lambda} y_{\lambda}(t)-\mu A_{\mu} y_{\mu}(t)\right) \\
& +\left(A_{\lambda} y_{\lambda}(t)-A_{\mu} y_{\mu}(t), J_{\lambda} y_{\lambda}(t)-J_{\mu} y_{\mu}(t)\right)
\end{aligned}
$$

By Lemma 35.1.3 the second of these terms is nonnegative. Also from the estimate 35.2.13, the first term converges to 0 uniformly in $t$ as $\lambda, \mu \rightarrow 0$. Then by Lemma 35.2.1 it follows that if $\lambda$ is any sequence converging to $0, y_{\lambda}(t)$ is uniformly Cauchy. Let

$$
y(t) \equiv \lim _{\lambda \rightarrow 0} y_{\lambda}(t) .
$$

Thus $y$ is continuous because it is the uniform limit of continuous functions. Since $A_{\lambda} y_{\lambda}(t)$ is uniformly bounded, it also follows

$$
\begin{equation*}
y(t)=\lim _{\lambda \rightarrow 0} J_{\lambda} y_{\lambda}(t) \text { uniformly in } t \tag{35.2.14}
\end{equation*}
$$

Taking a further subsequence, you can assume

$$
\begin{equation*}
A_{\lambda} y_{\lambda} \rightharpoonup z \text { weak } * \text { in } L^{\infty}(0, T ; H) \tag{35.2.15}
\end{equation*}
$$

Thus $z \in L^{\infty}(0, T ; H)$. Recall $A_{\lambda} y_{\lambda} \in A J_{\lambda} y_{\lambda}$.

Now $A$ can be considered a maximal monotone operator on $L^{2}(0, T ; H)$ according to the rule

$$
A y(t) \equiv A(y(t))
$$

where

$$
D(A) \equiv\left\{f \in L^{2}(0, T ; H): f(t) \in D(A) \text { a.e. } t\right\}
$$

By Lemma 35.1.5 applied to $A$ considered as a maximal monotone operator on $L^{2}(0, T ; H)$ and using 35.2.14 and 35.2.15, it follows $y(t) \in D(A)$ a.e. $t$ and $z(t) \in A y(t)$ a.e. $t$. Then passing to the limit in 35.2.6 yields

$$
\begin{equation*}
y(t)-y_{0}+\int_{0}^{t} z(s) d s=\int_{0}^{t} f(s) d s \tag{35.2.16}
\end{equation*}
$$

Then by fundamental theorem of calculus, $y^{\prime}(t)$ exists a.e. $t$ and

$$
y^{\prime}+z=f, y(0)=y_{0}
$$

where $z(t) \in A y(t)$ a.e.
It remains to verify uniqueness. Suppose $\left[y_{1}, z_{1}\right]$ is another pair which works. Then from 35.2.16,

$$
\begin{aligned}
& y(t)-y_{1}(t)+\int_{0}^{t}\left(z(r)-z_{1}(r)\right) d r=0 \\
& y(s)-y_{1}(s)+\int_{0}^{s}\left(z(r)-z_{1}(r)\right) d r=0
\end{aligned}
$$

Therefore for $s<t$,

$$
y(t)-y_{1}(t)-\left(y(s)-y_{1}(s)\right)=\int_{s}^{t}\left(z(r)-z_{1}(r)\right) d r
$$

and so

$$
\left|\left|y(t)-y_{1}(t)\right|-\left|y(s)-y_{1}(s) \| \leq K\right| s-t\right|
$$

for some $K$ depending on $\|z\|_{L^{\infty}},\left\|z_{1}\right\|_{L^{\infty}}$. Since $y, y_{1}$ are bounded, it follows that $t \rightarrow$ $\left|y(t)-y_{1}(t)\right|^{2}$ is also Lipschitz. Therefore by Corollary 26.4.3, it is the integral of its derivative which exists a.e. So what is this derivative? As before,

$$
\begin{gathered}
\left(D_{h}\left(y(t)-y_{1}(t)\right), y(t+h)-y_{1}(t+h)\right) \\
+\left(\frac{1}{h} \int_{t}^{t+h}\left(z(s)-z_{1}(s)\right) d s, y(t+h)-y_{1}(t+h)\right)=0
\end{gathered}
$$

and so

$$
\begin{aligned}
& \frac{1}{h}\left(\frac{\left|y(t+h)-y_{1}(t+h)\right|^{2}}{2}-\frac{\left|y(t)-y_{1}(t)\right|^{2}}{2}\right) \\
&+\left(\frac{1}{h} \int_{t}^{t+h}\left(z(s)-z_{1}(s)\right) d s, y(t+h)-y_{1}(t+h)\right) \leq 0
\end{aligned}
$$

Then taking $\lim _{h \rightarrow 0}$ it follows that for a.e. $t$ (Lebesgue points of $z-z_{1}$ intersected with the points where $\left|y-y_{1}\right|^{2}$ has a derivative)

$$
\frac{1}{2} \frac{d}{d t}\left|y(t)-y_{1}(t)\right|^{2}+\left(z(t)-z_{1}(t), y(t)-y_{1}(t)\right) \leq 0
$$

Thus for a.e. $t$,

$$
\frac{d}{d t}\left|y(t)-y_{1}(t)\right|^{2} \leq 0
$$

and so

$$
\left|y(t)-y_{1}(t)\right|^{2}-\left|y_{0}-y_{0}\right|^{2}=\int_{0}^{t} \frac{d}{d t}\left|y(s)-y_{1}(s)\right|^{2} d s \leq 0
$$

This proves the theorem.

### 35.3 Subgradients

### 35.3.1 General Results

Definition 35.3.1 Let $X$ be a real locally convex topological vector space. For $x \in X$, $\delta \phi(x) \subseteq X^{\prime}$, possibly $\emptyset$. This subset of $X^{\prime}$ is defined by $y^{*} \in \delta \phi(x)$ means for all $z \in X$,

$$
y^{*}(z-x) \leq \phi(z)-\phi(x)
$$

Also $x \in \delta \phi^{*}\left(y^{*}\right)$ means that for all $z^{*} \in X^{\prime}$,

$$
\left(z^{*}-y^{*}\right)(x) \leq \phi^{*}\left(z^{*}\right)-\phi^{*}\left(y^{*}\right)
$$

We define $\operatorname{dom}(\delta \phi) \equiv\{x: \delta \phi(x) \neq \emptyset\}$.
The subgradient is an attempt to generalize the derivative. For example, a function may have a subgradient but fail to be differentiable at some point. A good example is $f(x)=|x|$. At $x=0$, this function fails to have a derivative but it does have a subgradient. In fact, $\delta f(0)=[-1,1]$.

To begin with consider the question of existence of the subgradient of a convex function. There is a very simple criterion for existence. It is essentially that the subgradient is nonempty at every point of the interior of the domain of $\phi$. First recall Lemma 18.2.15 which says the interior of a convex set is convex and if nonempty, then every point of the convex set can be obtained as the limit of a sequence of points of the interior.

Theorem 35.3.2 Let $\phi: X \rightarrow(-\infty, \infty]$ be convex and suppose for some $u \in \operatorname{dom}(\phi), \phi$ is continuous. Then $\delta \phi(x) \neq \emptyset$ for all $x \in \operatorname{int}(\operatorname{dom}(\phi))$. Thus

$$
\operatorname{dom}(\delta \phi) \supseteq \operatorname{int}(\operatorname{dom}(\phi))
$$

Proof: Let $x_{0} \in \operatorname{int}(\operatorname{dom}(\phi))$ and let

$$
A \equiv\left\{\left(x_{0}, \phi\left(x_{0}\right)\right)\right\}, B \equiv \operatorname{epi}(\phi) \cap X \times \mathbb{R}
$$

Then $A$ and $B$ are both nonempty and convex. Recall epi $(\phi)$ can contain a point like $(x, \infty)$. Since $\phi$ is continuous at $u \in \operatorname{dom}(\phi)$,

$$
(u, \phi(u)+1) \in \operatorname{int}(\operatorname{epi} \phi \cap X \times \mathbb{R}) .
$$

Thus $\operatorname{int}(B) \neq \emptyset$ and also $\operatorname{int}(B) \cap A=\emptyset$. By Lemma $18.2 .15 \operatorname{int}(B)$ is convex and so by Theorem 18.2.14 there exists $x^{*} \in X^{\prime}$ and $\beta \in \mathbb{R}$ such that

$$
\begin{equation*}
\left(x^{*}, \beta\right) \neq(0,0) \tag{35.3.17}
\end{equation*}
$$

and for all $(x, a) \in \operatorname{int} B$,

$$
\begin{equation*}
x^{*}(x)+\beta a>x^{*}\left(x_{0}\right)+\beta \phi\left(x_{0}\right) . \tag{35.3.18}
\end{equation*}
$$

From Lemma 18.2.15, whenever $x \in \operatorname{dom}(\phi)$,

$$
x^{*}(x)+\beta \phi(x) \geq x^{*}\left(x_{0}\right)+\beta \phi\left(x_{0}\right) .
$$

If $\beta=0$, this would mean $x^{*}\left(x-x_{0}\right) \geq 0$ for all $x \in \operatorname{dom}(\phi)$. Since $x_{0} \in \operatorname{int}(\operatorname{dom}(\phi))$, this implies $x^{*}=0$, contradicting 35.3.17. If $\beta<0$, apply 35.3 .18 to the case when $a=$ $\phi\left(x_{0}\right)+1$ and $x=x_{0}$ to obtain a contradiction. It follows $\beta>0$ and so

$$
\phi(x)-\phi\left(x_{0}\right) \geq-\frac{x^{*}}{\beta}\left(x-x_{0}\right)
$$

which says $-x^{*} / \beta \in \delta \phi\left(x_{0}\right)$. This proves the theorem.
Definition 35.3.3 Let $\phi: X \rightarrow(-\infty, \infty]$ be some function, not necessarily convex but satisfying $\phi(y)<\infty$ for some $y \in X$. Define $\phi^{*}: X^{\prime} \rightarrow(-\infty, \infty]$ by

$$
\phi^{*}\left(x^{*}\right) \equiv \sup \left\{x^{*}(y)-\phi(y): y \in X\right\} .
$$

This function, $\phi^{*}$, defined above, is called the conjugate function of $\phi$ or the polar of $\phi$. Note $\phi^{*}\left(x^{*}\right) \neq-\infty$ because $\phi(y)<\infty$ for some $y$.

Theorem 35.3.4 Let $X$ be a real Banach space. Then $\phi^{*}$ is convex and l.s.c.
Proof: Let $\lambda \in[0,1]$. Then

$$
\begin{gathered}
\phi^{*}\left(\lambda x^{*}+(1-\lambda) y^{*}\right)=\sup \left\{\left(\lambda x^{*}+(1-\lambda) y^{*}\right)(y)-\phi(y): y \in X\right\} \\
\sup \left\{\lambda\left(x^{*}(y)-\phi(y)\right)+(1-\lambda)\left(y^{*}(y)-\phi(y)\right): y \in X\right\} \\
\leq \lambda \phi^{*}\left(x^{*}\right)+(1-\lambda) \phi^{*}\left(y^{*}\right)
\end{gathered}
$$

It remains to show the function is l.s.c. Consider $f_{y}\left(x^{*}\right) \equiv x^{*}(y)-\phi(y)$. Then $f_{y}$ is obviously convex. Also to say that $(x, \alpha) \in \operatorname{epi}\left(\phi^{*}\right)$ is to say that $\alpha \geq x^{*}(y)-\phi(y)$ for all $y$. Thus

$$
\operatorname{epi}\left(\phi^{*}\right)=\cap_{y \in X} \operatorname{epi}\left(f_{y}\right)
$$

Therefore, if epi $\left(f_{y}\right)$ is closed, this will prove the theorem. If $\left(x^{*}, a\right) \notin \mathrm{epi}\left(f_{y}\right)$, then $a<$ $x^{*}(y)-\phi(y)$ and, by continuity, for $b$ close enough to $a$ and $y^{*}$ close enough to $x^{*}$ then

$$
b<y^{*}(y)-\phi(y),\left(y^{*}, b\right) \notin \operatorname{epi}\left(f_{y}\right)
$$

Thus epi $\left(f_{y}\right)$ is closed.
Note this theorem holds with no change in the proof if $X$ is only a locally convex topological vector space and $X^{\prime}$ is given the weak $*$ topology.

Definition 35.3.5 We define $\phi^{* *}$ on $X$ by

$$
\phi^{* *}(x) \equiv \sup \left\{x^{*}(x)-\phi^{*}\left(x^{*}\right), x^{*} \in X^{\prime}\right\} .
$$

The following lemma comes from separation theorems. First is a simple observation.
Observation 35.3.6 $f \in(X \times \mathbb{R})^{\prime}$ if and only if there exists $x^{*} \in X^{\prime}$ and $\alpha \in \mathbb{R}$ such that $f(x, \lambda)=x^{*}(x)+\lambda \alpha$. To get $x^{*}$, you can simply define $x^{*}(x) \equiv f(x, 0)$ and to get $\alpha$ you just let $\alpha \lambda \equiv f(0, \lambda)$. Why does such an $\alpha$ exist? You know that $f(0, a \lambda+b \delta)=$ $a f(0, \alpha)+b f(0, \delta)$ and so in fact $\lambda \rightarrow f(0, \lambda)$ satisfies the Cauchy functional equation $g(x+y)=g(x)+g(y)$ and is continuous so there is only one thing it can be and that is $f(0, \lambda)=\alpha \lambda$ for some $\alpha$.

This picture illustrates the conclusion of the following lemma.

Lemma 35.3.7 Let $\phi: X \rightarrow(-\infty, \infty]$ be convex and lower semicontinuous and $\phi(x)<\infty$ for some $x$. (proper). Then if $\beta<\phi\left(x_{0}\right)$ so that $\left(x_{0}, \beta\right)$ is not in epi $(\phi)$, it follows that there exists $\delta>0$ and $z^{*} \in X^{\prime}$ such that for all $y$,

$$
z^{*}\left(y-x_{0}\right)+\beta+\delta<\phi(y), \text { all } y \in X
$$

Proof: Let $C=\operatorname{epi}(\phi) \cap(X \times \mathbb{R})$. Then $C$ is a closed convex nonempty set and it does not contain the point $\left(x_{0}, \beta\right)$. Let $\hat{\beta}>\beta$ be slightly larger so that also $\left(x_{0}, \hat{\beta}\right) \notin C$. Thus there exists $y^{*} \in X^{\prime}$ and $\alpha \in \mathbb{R}$ such that for some $\hat{c}$, and all $y \in X$,

$$
y^{*}\left(x_{0}\right)+\alpha \hat{\beta}>\hat{c}>y^{*}(y)+\alpha \phi(y)
$$

for all $y \in X$. Now you can't have $\alpha \geq 0$ because

$$
\alpha(\hat{\beta}-\phi(y))>y^{*}\left(y-x_{0}\right)
$$

and you can let $y=x_{0}$ to have

$$
\alpha(\overbrace{\hat{\beta}-\phi\left(x_{0}\right)}^{<0})>0
$$

Hence $\alpha<0$ and so, dividing by it yields that for all $y \in X$,

$$
x^{*}\left(x_{0}\right)+\hat{\beta}<c<x^{*}(y)+\phi(y)
$$

where $x^{*}=y^{*} / \alpha, \hat{c} / \alpha \equiv c$. Then

$$
\begin{aligned}
\left(-x^{*}\right)\left(y-x_{0}\right)+\beta+(\hat{\beta}-\beta) & <c-x^{*}(y)<\phi(y) \\
\left(-x^{*}\right)\left(y-x_{0}\right)+\beta+\delta & <\phi(y), \delta \equiv \hat{\beta}-\beta
\end{aligned}
$$

Let $z^{*}=-x^{*}$.
Theorem 35.3.8 $\phi^{* *}(x) \leq \phi(x)$ for all $x$ and if $\phi$ is convex and l.s.c., $\phi^{* *}(x)=\phi(x)$ for all $x \in X$.

Proof:

$$
\begin{aligned}
\phi^{* *}(x) \equiv & \sup \{x^{*}(x)-\overbrace{\sup \left\{x^{*}(y)-\phi(y): y \in X\right\}}^{\phi^{*}\left(x^{*}\right)}: x^{*} \in X^{\prime}\} \\
& \leq \sup \left\{x^{*}(x)-\left(x^{*}(x)-\phi(x)\right)\right\}=\phi(x) .
\end{aligned}
$$

Next suppose $\phi$ is convex and l.s.c. If $\phi^{* *}\left(x_{0}\right)<\phi\left(x_{0}\right)$, then using Lemma 35.3.7, there exists $x_{0}^{*}, \delta>0$ such that for all $y \in X$,

$$
\begin{gathered}
\left(x_{0}^{*}\right)\left(y-x_{0}\right)+\phi^{* *}\left(x_{0}\right)+\delta<\phi(y) \\
x_{0}^{*}(y)-\phi(y)+\delta<x_{0}^{*}\left(x_{0}\right)-\phi^{* *}\left(x_{0}\right)
\end{gathered}
$$

Thus, since this holds for all $y$,

$$
\begin{aligned}
\phi^{*}\left(x_{0}^{*}\right)+\delta & \leq x_{0}^{*}\left(x_{0}\right)-\phi^{* *}\left(x_{0}\right) \\
\phi^{* *}\left(x_{0}\right)+\delta & \leq x_{0}^{*}\left(x_{0}\right)-\phi^{*}\left(x_{0}^{*}\right)
\end{aligned}
$$

Then

$$
\begin{aligned}
\phi^{* *}\left(x_{0}\right) & \equiv \sup \left\{x^{*}\left(x_{0}\right)-\phi^{*}\left(x^{*}\right), x^{*} \in X^{\prime}\right\} \\
& \geq x_{0}^{*}\left(x_{0}\right)-\phi^{*}\left(x_{0}^{*}\right) \geq \phi^{* *}\left(x_{0}\right)+\delta
\end{aligned}
$$

a contradiction.
The following corollary is descriptive of the situation just discussed. It says that to find epi $\left(\phi^{* *}\right)$ it suffices to take the intersection of all closed convex sets which contain epi $(\phi)$.

Corollary 35.3.9 epi $\left(\phi^{* *}\right)$ is the smallest closed convex set containing epi $(\phi)$.
Proof: epi $\left(\phi^{* *}\right) \supseteq$ epi $(\phi)$ from Theorem 35.3.8. Also epi $\left(\phi^{* *}\right)$ is closed by the proof of Theorem 35.3.4. Suppose epi $(\phi) \subseteq K \subseteq \operatorname{epi}\left(\phi^{* *}\right)$ and $K$ is convex and closed. Let

$$
\psi(x) \equiv \min \{a:(x, a) \in K\}
$$

( $\{a:(x, a) \in K\}$ is a closed subset of $(-\infty, \infty]$ so the minimum exists.) $\psi$ is also a convex function with epi $(\psi)=K$. To see $\psi$ is convex, let $\lambda \in[0,1]$. Then, by the convexity of $K$,

$$
\begin{gathered}
\lambda(x, \psi(x))+(1-\lambda)(y, \psi(y)) \\
=(\lambda x+(1-\lambda) y, \lambda \psi(x)+(1-\lambda) \psi(y)) \in K
\end{gathered}
$$

It follows from the definition of $\psi$ that

$$
\psi(\lambda x+(1-\lambda) y) \leq \lambda \psi(x)+(1-\lambda) \psi(y)
$$

Then

$$
\phi^{* *} \leq \psi \leq \phi
$$

and so from the definitions,

$$
\phi^{* * *} \geq \psi^{*} \geq \phi^{*}
$$

which implies from the definitions and Theorem 35.3.8 that

$$
\phi^{* *}=\phi^{* * * *} \leq \psi^{* *}=\psi \leq \phi^{* *}
$$

Therefore, $\psi=\phi^{* *}$ and epi $\left(\phi^{* *}\right)$ is the smallest closed convex set containing epi $(\phi)$ as claimed.

There is an interesting symmetry which relates $\delta \phi, \delta \phi^{*}, \phi$, and $\phi^{*}$.
Theorem 35.3.10 Suppose $\phi$ is convex, l.s.c. (lower semicontinuous or in other words having a closed epigraph), and proper. Then

$$
y^{*} \in \delta \phi(x) \text { if and only if } x \in \delta \phi^{*}\left(y^{*}\right)
$$

where this last expression means

$$
\left(z^{*}-y^{*}\right)(x) \leq \phi^{*}\left(z^{*}\right)-\phi^{*}\left(y^{*}\right)
$$

for all $z^{*}$ and in this case,

$$
y^{*}(x)=\phi^{*}\left(y^{*}\right)+\phi(x)
$$

Proof: If $y^{*} \in \delta \phi(x)$ then $y^{*}(z-x) \leq \phi(z)-\phi(x)$ and so

$$
y^{*}(z)-\phi(z) \leq y^{*}(x)-\phi(x)
$$

for all $z \in X$. Therefore,

$$
\phi^{*}\left(y^{*}\right) \leq y^{*}(x)-\phi(x) \leq \phi^{*}\left(y^{*}\right)
$$

Hence

$$
\begin{equation*}
y^{*}(x)=\phi^{*}\left(y^{*}\right)+\phi(x) . \tag{35.3.19}
\end{equation*}
$$

Now if $z^{*} \in X^{\prime}$ is arbitrary, 35.3 .19 shows

$$
\left(z^{*}-y^{*}\right)(x)=z^{*}(x)-y^{*}(x)=z^{*}(x)-\phi(x)-\phi^{*}\left(y^{*}\right) \leq \phi^{*}\left(z^{*}\right)-\phi^{*}\left(y^{*}\right)
$$

and this shows $x \in \delta \phi^{*}\left(y^{*}\right)$.
Now suppose $x \in \delta \phi^{*}\left(y^{*}\right)$. Then for $z^{*} \in X^{\prime}$,

$$
\left(z^{*}-y^{*}\right)(x) \leq \phi^{*}\left(z^{*}\right)-\phi^{*}\left(y^{*}\right)
$$

so

$$
z^{*}(x)-\phi^{*}\left(z^{*}\right) \leq y^{*}(x)-\phi^{*}\left(y^{*}\right)
$$

and so, taking sup over all $z^{*}$, and using Theorem 35.3.8,

$$
\phi^{* *}(x)=\phi(x) \leq y^{*}(x)-\phi^{*}\left(y^{*}\right) \leq \phi^{* *}(x)
$$

Thus

$$
y^{*}(x)=\phi^{*}\left(y^{*}\right)+\phi^{* *}(x)=\phi^{*}\left(y^{*}\right)+\phi(x) \geq \overbrace{y^{*}(z)-\phi(z)}^{\leq \phi^{*}\left(y^{*}\right)}+\phi(x)
$$

for all $z \in X$ and this implies for all $z \in X$,

$$
\phi(z)-\phi(x) \geq y^{*}(z-x)
$$

so $y^{*} \in \delta \phi(x)$ and this proves the theorem.
Definition 35.3.11 If $X$ is a Banach space define $u \in W^{1, p}([0, T] ; X)$ if there exists $g \in$ $L^{p}([0, T] ; X)$ such that

$$
u(t)=u(0)+\int_{0}^{t} g(s) d s
$$

When this occurs define $u^{\prime}(\cdot) \equiv g(\cdot)$. As usual, $p>1$.
The next Lemma is quite interesting for its own sake but it is also used in the next theorem.

Lemma 35.3.12 Suppose $g \in L^{p}(0, T ; X)$. Then as $h \rightarrow 0$,

$$
\frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} g(s) d s \mathscr{X}_{[0, T-h]}(\cdot) \rightarrow g
$$

in $L^{p}([0, T] ; X)$.
Proof: Let

$$
\widetilde{g}(u) \equiv\left\{\begin{array}{l}
g(u) \text { if } u \in[0, T] \\
0 \text { if } u \notin[0, T]
\end{array}, \phi_{h}(r) \equiv \frac{1}{h} \mathscr{X}_{[-h, 0]}(r)\right.
$$

Thus $\widetilde{g} \in L^{p}(\mathbb{R} ; X)$ and

$$
\widetilde{g} * \phi_{h}(t) \equiv \int_{\mathbb{R}} \widetilde{g}(t-s) \phi_{h}(s) d s
$$

Then

$$
\left\|\widetilde{g} * \phi_{h}-\widetilde{g}\right\|_{L^{p}(\mathbb{R} ; X)} \leq\left(\int_{\mathbb{R}}\left(\int_{\mathbb{R}}\|\widetilde{g}(t)-\widetilde{g}(t-s)\|_{X} \phi_{h}(s) d s\right)^{p} d t\right)^{1 / p}
$$

which by Minkowski's inequality for integrals is no larger than

$$
\begin{gathered}
\leq \int_{\mathbb{R}} \phi_{h}(s)\left(\int_{\mathbb{R}}\|\widetilde{g}(t)-\widetilde{g}(t-s)\|_{X}^{p} d t\right)^{1 / p} d s \\
=\frac{1}{h} \int_{-h}^{0}\left(\int_{\mathbb{R}}\|\widetilde{g}(t)-\widetilde{g}(t-s)\|_{X}^{p} d t\right)^{1 / p} d s<\frac{1}{h} \int_{-h}^{0} \varepsilon d s=\varepsilon
\end{gathered}
$$

whenever $h$ is small enough. This follows from continuity of translation in $L^{p}(\mathbb{R} ; X)$, a consequence of the regularity of the measure. Thus, $\tilde{g} * \phi_{h} \rightarrow \tilde{g}$ in $L^{p}(\mathbb{R} ; X)$. Now

$$
\begin{aligned}
& \widetilde{g} * \phi_{h}(t)-\frac{1}{h} \int_{t}^{t+h} g(s) d s \mathscr{X}_{[0, T-h]}(t) \\
& =\left\{\begin{array}{l}
0 \text { if } t \in[0, T-h] \\
\frac{1}{h} \int_{t}^{t+h} \widetilde{g}(u) d u \text { if } t \notin[0, T-h]
\end{array}\right.
\end{aligned}
$$

and therefore,

$$
\begin{gathered}
\left\|\widetilde{g} * \phi_{h}(\cdot)-\frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} g(s) d s \mathscr{X}_{[0, T-h]}(\cdot)\right\|_{L^{p}(\mathbb{R} ; X)}= \\
\left(\int_{-h}^{0}\left\|\frac{1}{h} \int_{t}^{t+h} \widetilde{g}(u) d u\right\|_{X}^{p} d t\right)^{1 / p}+\left(\int_{T-h}^{T}\left\|\frac{1}{h} \int_{t}^{t+h} \widetilde{g}(u) d u\right\|_{X}^{p} d t\right)^{1 / p} \\
\leq \frac{1}{h}\left(\int_{-h}^{0}\left(\int_{-h}^{h}\|\widetilde{g}(u)\|_{X} d u\right)^{p} d t\right)^{1 / p} \\
+\frac{1}{h}\left(\int_{T-h}^{T}\left(\int_{T-h}^{T+h}\|\widetilde{g}(u)\|_{X} d u\right)^{p} d t\right)^{1 / p}
\end{gathered}
$$

which by Minkowski's inequality for integrals is no larger than

$$
\begin{gathered}
\leq \frac{1}{h} \int_{-h}^{h}\left(\int_{-h}^{0}\|\widetilde{g}(u)\|_{X}^{p} d t\right)^{1 / p} d u+\frac{1}{h} \int_{T-h}^{T+h}\left(\int_{T-h}^{T}\|\widetilde{g}(u)\|_{X}^{p} d t\right)^{1 / p} d u \\
\leq \frac{1}{h} \int_{-h}^{h} \varepsilon d u+\frac{1}{h} \int_{T-h}^{T+h} \varepsilon d u=4 \varepsilon
\end{gathered}
$$

whenever $h$ is small enough because of the fact that $\|\widetilde{g}\|_{X}^{p} \in L^{1}(\mathbb{R} ; X)$. Since $\varepsilon$ is arbitrary, this shows

$$
\left\|\widetilde{g} * \phi_{h}(\cdot)-\frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} g(s) d s \mathscr{X}_{[0, T-h]}(\cdot)\right\|_{L^{p}(\mathbb{R} ; X)} \rightarrow 0
$$

and also, it was shown above that

$$
\left\|\widetilde{g} * \phi_{h}(\cdot)-\tilde{g}\right\|_{L^{p}(\mathbb{R} ; X)} \rightarrow 0
$$

It follows that

$$
\frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} g(s) d s \mathscr{X}_{[0, T-h]}(\cdot) \rightarrow \widetilde{g}
$$

in $L^{p}(\mathbb{R} ; X)$ and consequently in $L^{p}([0, T] ; X)$ as well. But $\widetilde{g}=g$ on $[0, T]$.
The following theorem is a form of the chain rule in which the derivative is replaced by the subgradient.

Theorem 35.3.13 Suppose $u \in W^{1, p}([0, T] ; X), z \in L^{p^{\prime}}\left([0, T] ; X^{\prime}\right)$, and $z(t) \in \delta \phi(u(t))$ a.e $t \in[0, T]$. Then the function, $t \rightarrow \phi(u(t))$ is in $L^{1}(0, T)$ and its weak derivative equals $\left\langle z, u^{\prime}\right\rangle$. In particular,

$$
\phi(u(t))-\phi(u(0))=\int_{0}^{t}\left\langle z(s), u^{\prime}(s)\right\rangle d s
$$

Proof: Modify $u$ on a set of measure zero such that $\delta \phi(u(t)) \neq \emptyset$ for all $t$. Next modify $z$ on a set of measure zero such that for $\widetilde{u}$ and $\widetilde{z}$ the modified functions, $\widetilde{z}(t) \in \delta \phi(\widetilde{u}(t))$ for all $t$. First I claim $t \rightarrow \phi(\widetilde{u}(t))$ is in $L^{1}(0, T)$. Pick $t_{0} \in[0, T]$ and let

$$
\widetilde{z}\left(t_{0}\right) \in \delta \phi\left(\widetilde{u}\left(t_{0}\right)\right)
$$

Then for $t \in[0, T]$,

$$
\begin{gather*}
\left\langle\widetilde{z}\left(t_{0}\right), \widetilde{u}(t)-\widetilde{u}\left(t_{0}\right)\right\rangle+\phi\left(\widetilde{u}\left(t_{0}\right)\right) \leq \\
\phi(\widetilde{u}(t)) \leq\left\langle\widetilde{z}(t), \widetilde{u}(t)-\widetilde{u}\left(t_{0}\right)\right\rangle+\phi\left(\widetilde{u}\left(t_{0}\right)\right) \tag{35.3.20}
\end{gather*}
$$

Then 35.3 .20 shows $t \rightarrow \phi(\widetilde{u}(t))$ is in $L^{1}(0, T)$ since $\widetilde{z} \in L^{p^{\prime}}\left([0, T] ; X^{\prime}\right), \widetilde{u} \in L^{p}([0, T] ; X)$. Also, for $t \in[0, T-h]$,

$$
\begin{gathered}
\left\langle\mathscr{X}_{[0, T-h]}(t) \widetilde{z}(t), \frac{\widetilde{u}(t+h)-\widetilde{u}(t)}{h}\right\rangle \leq \mathscr{X}_{[0, T-h]}(t) \frac{\phi(\widetilde{u}(t+h))-\phi(\widetilde{u}(t))}{h} \\
\leq\left\langle\mathscr{X}_{[0, T-h]}(t) \widetilde{z}(t+h), \frac{\widetilde{u}(t+h)-\widetilde{u}(t)}{h}\right\rangle
\end{gathered}
$$

Now $\mathscr{X}_{[0, T-h]}(\cdot) \widetilde{z}(\cdot+h) \rightarrow z(\cdot)$ in $L^{p^{\prime}}\left(0, T ; X^{\prime}\right)$ by continuity of translation. Also,

$$
\begin{gathered}
\mathscr{X}_{[0, T-h]}(\cdot) \frac{\widetilde{u}(\cdot+h)-\widetilde{u}(\cdot)}{h}=\mathscr{X}_{[0, T-h]}(\cdot) \frac{u(\cdot+h)-u(\cdot)}{h} \\
=\mathscr{X}_{[0, T-h]}(\cdot) \frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} u^{\prime}(s) d s
\end{gathered}
$$

in $L^{p}(0, T ; X)$ and so by Lemma 35.3.12,

$$
\mathscr{X}_{[0, T-h]}(\cdot) \frac{\phi(\widetilde{u}(\cdot+h))-\phi(\widetilde{u}(\cdot))}{h} \rightarrow\left\langle z, u^{\prime}\right\rangle
$$

in $L^{1}(0, T)$.
It follows from the definition of weak derivatives that in the sense of weak derivatives,

$$
\frac{d}{d t}(\phi(u(\cdot)))=\left\langle z, u^{\prime}\right\rangle \in L^{1}(0, T)
$$

Note that by Theorem 26.3.3 this implies that for a.e. $t \in[0, T], \phi(u(t))$ is equal to a continuous function, $\phi \circ u$, and that

$$
(\phi \circ u)(t)-(\phi \circ u)(0)=\int_{0}^{t}\left\langle z(s), u^{\prime}(s)\right\rangle d s
$$

There are other rules of calculus which have a generalization to subgradients. The following theorem is on such a generalization. It generalizes the theorem which states that the derivative of a sum equals the sum of the derivatives.

Theorem 35.3.14 Let $\phi_{1}$ and $\phi_{2}$ be convex, l.s.c. and proper having values in $(-\infty, \infty]$. Then

$$
\begin{equation*}
\delta\left(\lambda \phi_{i}\right)(x)=\lambda \delta \phi_{i}(x), \delta\left(\phi_{1}+\phi_{2}\right)(x) \supseteq \delta \phi_{1}(x)+\delta \phi_{2}(x) \tag{35.3.21}
\end{equation*}
$$

if $\lambda>0$. If there exists $\bar{x} \in \operatorname{dom}\left(\phi_{1}\right) \cap \operatorname{dom}\left(\phi_{2}\right)$ and $\phi_{1}$ is continuous at $\bar{x}$ then for all $x \in X$,

$$
\begin{equation*}
\delta\left(\phi_{1}+\phi_{2}\right)(x)=\delta \phi_{1}(x)+\delta \phi_{2}(x) . \tag{35.3.22}
\end{equation*}
$$

Proof: 35.3 .21 is obvious so we only need to show 35.3.22. Suppose $\bar{x}$ is as described. It is clear 35.3.22 holds whenever $x \notin \operatorname{dom}\left(\phi_{1}\right) \cap \operatorname{dom}\left(\phi_{2}\right)$ since then both sides equal $\emptyset$. Therefore, assume

$$
x \in \operatorname{dom}\left(\phi_{1}\right) \cap \operatorname{dom}\left(\phi_{2}\right)
$$

in what follows. Let $x^{*} \in \delta\left(\phi_{1}+\phi_{2}\right)(x)$. Is $x^{*}$ is the sum of an element of $\delta \phi_{1}(x)$ and $\delta \phi_{2}(x)$ ? Does there exist $x_{1}^{*}$ and $x_{2}^{*}$ such that for every $y$,

$$
\begin{aligned}
x^{*}(y-x) & =x_{1}^{*}(y-x)+x_{2}^{*}(y-x) \\
& \leq \phi_{1}(y)-\phi_{1}(x)+\phi_{2}(y)-\phi_{2}(x) ?
\end{aligned}
$$

If so, then

$$
\phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x) \geq \phi_{2}(x)-\phi_{2}(y)
$$

Define

$$
\begin{aligned}
C_{1} \equiv & \left\{(y, a) \in X \times \mathbb{R}: \phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x) \leq a\right\}, \\
& C_{2} \equiv\left\{(y, a) \in X \times \mathbb{R}: a \leq \phi_{2}(x)-\phi_{2}(y)\right\} .
\end{aligned}
$$

I will show $\operatorname{int}\left(C_{1}\right) \cap C_{2}=\emptyset$ and then by Theorem 18.2.14 there exists an element of $X^{\prime}$ which does something interesting.

Both $C_{1}$ and $C_{2}$ are convex and nonempty. $C_{1}$ is nonempty because it contains

$$
\left(\bar{x}, \phi_{1}(\bar{x})-\phi_{1}(x)-x^{*}(\bar{x}-x)\right)
$$

since

$$
\phi_{1}(\bar{x})-\phi_{1}(x)-x^{*}(\bar{x}-x) \leq \phi_{1}(\bar{x})-\phi_{1}(x)-x^{*}(\bar{x}-x)
$$

$C_{2}$ is also nonempty because it contains $\left(\bar{x}, \phi_{2}(x)-\phi_{2}(\bar{x})\right)$ since

$$
\phi_{2}(x)-\phi_{2}(\bar{x}) \leq \phi_{2}(x)-\phi_{2}(\bar{x})
$$

In addition to this,

$$
\left(\bar{x}, \phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1\right) \in \operatorname{int}\left(C_{1}\right)
$$

due to the assumed continuity of $\phi_{1}$ at $\bar{x}$ and so $\operatorname{int}\left(C_{1}\right) \neq \emptyset$. If $(y, a) \in \operatorname{int}\left(C_{1}\right)$ then

$$
\phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x) \leq a-\varepsilon
$$

whenever $\varepsilon$ is small enough. Therefore, if $(y, a)$ is also in $C_{2}$, the assumption that $x^{*} \in$ $\boldsymbol{\delta}\left(\phi_{1}+\phi_{2}\right)(x)$ implies

$$
a-\varepsilon \geq \phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x) \geq \phi_{2}(x)-\phi_{2}(y) \geq a
$$

a contradiction. Therefore $\operatorname{int}\left(C_{1}\right) \cap C_{2}=\emptyset$ and so by Theorem 18.2.14, there exists $\left(w^{*}, \boldsymbol{\beta}\right) \in X^{\prime} \times \mathbb{R}$ with

$$
\begin{equation*}
\left(w^{*}, \beta\right) \neq(0,0) \tag{35.3.23}
\end{equation*}
$$

and

$$
\begin{equation*}
w^{*}(y)+\beta a \geq w^{*}\left(y_{1}\right)+\beta a_{1} \tag{35.3.24}
\end{equation*}
$$

whenever $(y, a) \in C_{1}$ and $\left(y_{1}, a_{1}\right) \in C_{2}$.
Claim: $\beta>0$.
Proof of claim: If $\beta<0$ let

$$
\begin{aligned}
a & =\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1 \\
a_{1} & =\phi_{2}(x)-\phi_{2}(\bar{x}), \text { and } y=y_{1}=\bar{x}
\end{aligned}
$$

Then from 35.3.24

$$
\beta\left(\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1\right) \geq \beta\left(\phi_{2}(x)-\phi_{2}(\bar{x})\right) .
$$

Dividing by $\beta$ yields

$$
\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1 \leq \phi_{2}(x)-\phi_{2}(\bar{x})
$$

and so

$$
\begin{aligned}
\phi_{1}(\bar{x}) & +\phi_{2}(\bar{x})-\left(\phi_{1}(x)+\phi_{2}(x)\right)+1 \leq x^{*}(\bar{x}-x) \\
& \leq \phi_{1}(\bar{x})+\phi_{2}(\bar{x})-\left(\phi_{1}(x)+\phi_{2}(x)\right),
\end{aligned}
$$

a contradiction. Therefore, $\beta \geq 0$.
Now suppose $\beta=0$. Letting

$$
\begin{gathered}
a=\phi_{1}(\bar{x})-x^{*}(\bar{x}-x)-\phi_{1}(x)+1, \\
(\bar{x}, a) \in \operatorname{int}\left(C_{1}\right)
\end{gathered}
$$

and so there exists an open set $U$ containing 0 and $\eta>0$ such that

$$
\bar{x}+U \times(a-\eta, a+\eta) \subseteq C_{1} .
$$

Therefore, 35.3.24 applied to $(\bar{x}+z, a) \in C_{1}$ and $\left(\bar{x}, \phi_{2}(x)-\phi_{2}(\bar{x})\right) \in C_{2}$ for $z \in U$ yields

$$
w^{*}(\bar{x}+z) \geq w^{*}(\bar{x})
$$

for all $z \in U$. Hence $w^{*}(z)=0$ on $U$ which implies $w^{*}=0$, contradicting 35.3.23. This proves the claim.

Now with the claim, it follows $\beta>0$ and so, letting $z^{*}=w^{*} / \beta, 35.3 .24$ and Lemma 18.2.15 implies

$$
\begin{equation*}
z^{*}(y)+a \geq z^{*}\left(y_{1}\right)+a_{1} \tag{35.3.25}
\end{equation*}
$$

whenever $(y, a) \in C_{1}$ and $\left(y_{1}, a_{1}\right) \in C_{2}$. In particular,

$$
\begin{equation*}
\left(y, \phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x)\right) \in C_{1} \tag{35.3.26}
\end{equation*}
$$

because

$$
\phi_{1}(y)-\phi_{1}(x)-x^{*}(y-x) \leq \phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x)
$$

and

$$
\begin{equation*}
\left(y_{1}, \phi_{2}(x)-\phi_{2}\left(y_{1}\right)\right) \in C_{2} \tag{35.3.27}
\end{equation*}
$$

by similar reasoning so letting $y=x$,

$$
z^{*}(x)+(\overbrace{\phi_{1}(x)-x^{*}(x-x)-\phi_{1}(x)}^{=0}) \geq z^{*}\left(y_{1}\right)+\phi_{2}(x)-\phi_{2}\left(y_{1}\right) .
$$

Therefore,

$$
z^{*}\left(y_{1}-x\right) \leq \phi_{2}\left(y_{1}\right)-\phi_{2}(x)
$$

for all $y_{1}$ and so $z^{*} \in \delta \phi_{2}(x)$. Now let $y_{1}=x$ in 35.3.27 and using 35.3.25 and 35.3.26, it follows

$$
\begin{gathered}
z^{*}(y)+\phi_{1}(y)-x^{*}(y-x)-\phi_{1}(x) \geq z^{*}(x) \\
\phi_{1}(y)-\phi_{1}(x) \geq x^{*}(y-x)-z^{*}(y-x)
\end{gathered}
$$

and so $x^{*}-z^{*} \in \delta \phi_{1}(x)$ so $x^{*}=z^{*}+\left(x^{*}-z^{*}\right) \in \delta \phi_{2}(x)+\delta \phi_{1}(x)$ and this proves the theorem.

Next is a very important example known as the duality map from a Banach space to its dual space. Before doing this, consider a Hilbert space $H$. Define a map $R$ from $H$ to $H^{\prime}$, called the Riesz map, by the rule

$$
R(x)(y) \equiv(y, x)
$$

By the Riesz representation theorem, this map is onto and one to one with the properties

$$
R(x)(x)=\|x\|^{2}, \text { and }\|R x\|^{2}=\|x\|^{2} .
$$

The duality map from a Banach space to its dual is an attempt to generalize this notion of Riesz map to an arbitrary Banach space.

Definition 35.3.15 For $X$ a Banach space define $F: X \rightarrow \mathscr{P}\left(X^{\prime}\right)$ by

$$
F(x) \equiv\left\{x^{*} \in X^{\prime}: x^{*}(x)=\|x\|^{2},\left\|x^{*}\right\| \leq\|x\|\right\}
$$

Lemma 35.3.16 With $F(x)$ defined as above, it follows that

$$
F(x)=\left\{x^{*} \in X^{\prime}: x^{*}(x)=\|x\|^{2},\left\|x^{*}\right\|=\|x\|\right\}
$$

and $F(x)$ is a closed, nonempty, convex subset of $X^{\prime}$.
Proof: If $x^{*}$ is in the set described in 35.3.28,

$$
x^{*}\left(\frac{x}{\|x\|}\right)=\|x\|
$$

and so $\left\|x^{*}\right\| \geq\|x\|$. Therefore

$$
x^{*} \in\left\{x^{*} \in X^{\prime}: x^{*}(x)=\|x\|^{2},\left\|x^{*}\right\|=\|x\|\right\} .
$$

This shows this set and the set of 35.3.28 are equal. It is also clear the set of 35.3.28 is closed and convex. It only remains to show this set is nonempty.

Define $f: \mathbb{R} x \rightarrow \mathbb{R}$ by $f(\alpha x)=\alpha\|x\|^{2}$. Then the norm of $f$ on $\mathbb{R} x$ is $\|x\|$ and $f(x)=$ $\|x\|^{2}$. By the Hahn Banach theorem, $f$ has an extension to all of $X x^{*}$, and this extension is in the set of 35.3 .28 , showing this set is nonempty as required.

The next theorem shows this duality map is the subgradient of $\frac{1}{2}\|x\|^{2}$.
Theorem 35.3.17 For $X$ a real Banach space, let $\phi(x) \equiv \frac{1}{2}\|x\|^{2}$. Then $F(x)=\delta \phi(x)$.
Proof: Let $x^{*} \in F(x)$. Then

$$
\begin{aligned}
\left\langle x^{*}, y-x\right\rangle & =\left\langle x^{*}, y\right\rangle-\left\langle x^{*}, x\right\rangle \\
& \leq\|x\|\|y\|-\|x\|^{2} \leq \frac{1}{2}\|y\|^{2}-\frac{1}{2}\|x\|^{2} .
\end{aligned}
$$

This shows $F(x) \subseteq \delta \phi(x)$.
Now let $x^{*} \in \delta \phi(x)$. Then for all $t \in \mathbb{R}$,

$$
\begin{equation*}
\left\langle x^{*}, t y\right\rangle=\left\langle x^{*},(t y+x)-x\right\rangle \leq \frac{1}{2}\left(\|x+t y\|^{2}-\|x\|^{2}\right) . \tag{35.3.29}
\end{equation*}
$$

Now if $t>0$, divide both sides by $t$. This yields

$$
\begin{aligned}
\left\langle x^{*}, y\right\rangle & \leq \frac{1}{2 t}\left((\|x\|+t\|y\|)^{2}-\|x\|^{2}\right) \\
& =\frac{1}{2 t}\left(2 t\|x\|\|y\|+t^{2}\|y\|^{2}\right)
\end{aligned}
$$

Letting $t \rightarrow 0$,

$$
\begin{equation*}
\left\langle x^{*}, y\right\rangle \leq\|x\|\|y\| . \tag{35.3.30}
\end{equation*}
$$

Next suppose $t=-s$, where $s>0$ in 25.7.66. Then, since when you divide by a negative, you reverse the inequality, for $s>0$

$$
\begin{gather*}
\left\langle x^{*}, y\right\rangle \geq \frac{1}{2 s}\left[\|x\|^{2}-\|x-s y\|^{2}\right] \geq \\
\frac{1}{2 s}\left[\|x-s y\|^{2}-2\|x-s y\|\|s y\|+\|s y\|^{2}-\|x-s y\|\right]^{2}  \tag{35.3.31}\\
=\frac{1}{2 s}\left[-2\|x-s y\|\|s y\|+\|s y\|^{2}\right] \tag{35.3.32}
\end{gather*}
$$

Taking a limit as $s \rightarrow 0$ yields

$$
\begin{equation*}
\left\langle x^{*}, y\right\rangle \geq-\|x\|\|y\| . \tag{35.3.33}
\end{equation*}
$$

It follows from 35.3.33 and 35.3.30 that

$$
\left|\left\langle x^{*}, y\right\rangle\right| \leq\|x\|\|y\|
$$

and that, therefore, $\left\|x^{*}\right\| \leq\|x\|$ and $\left|\left\langle x^{*}, x\right\rangle\right| \leq\|x\|^{2}$. Now return to 35.3.32 and let $y=x$. Then

$$
\begin{aligned}
\left\langle x^{*}, x\right\rangle & \geq \frac{1}{2 s}\left[-2\|x-s x\|\|s x\|+\|s x\|^{2}\right] \\
& =-\|x\|^{2}(1-s)+s\|x\|^{2}
\end{aligned}
$$

Letting $s \rightarrow 1$,

$$
\left\langle x^{*}, x\right\rangle \geq\|x\|^{2}
$$

Since it was already shown that $\left|\left\langle x^{*}, x\right\rangle\right| \leq\|x\|^{2}$, this shows $\left\langle x^{*}, x\right\rangle=\|x\|^{2}$ and also $\left\|x^{*}\right\| \leq$ $\|x\|$. Thus

$$
\left\|x^{*}\right\| \geq\left\langle x^{*} \frac{x}{\|x\|}\right\rangle=\|x\|
$$

so in fact $x^{*} \in F(x)$.
The next result gives conditions under which the subgradient is onto. This means that if $y^{*} \in X^{\prime}$, then there exists $x \in X$ such that $y^{*} \in \delta \phi(x)$.

Theorem 35.3.18 Suppose $X$ is a reflexive Banach space and suppose $\phi: X \rightarrow(-\infty, \infty]$ is convex, proper, l.s.c., and for all $y^{*} \in X^{\prime}, x \rightarrow \phi(x)-y^{*}(x)$ is coercive. Then $\delta \phi$ is onto.

Proof: The function $x \rightarrow \phi(x)-y^{*}(x) \equiv \psi(x)$ is convex, proper, l.s.c., and coercive. Let

$$
\lambda \equiv \inf \left\{\phi(x)-y^{*}(x): x \in X\right\}
$$

and let $\left\{x_{n}\right\}$ be a minimizing sequence satisfying

$$
\lambda=\lim _{n \rightarrow \infty} \phi\left(x_{n}\right)-y^{*}\left(x_{n}\right)
$$

By coercivity,

$$
\lim _{\|x\| \rightarrow \infty} \phi(x)-y^{*}(x)=\infty
$$

and so this minimizing sequence is bounded. By the Eberlein Smulian theorem, Theorem 17.5.12, there is a weakly convergent subsequence $x_{n_{k}} \rightarrow x$. By Theorem $18.2 .11 \phi$ is also weakly lower semicontinuous. Therefore,

$$
\lambda=\phi(x)-y^{*}(x) \leq \lim \inf _{k \rightarrow \infty} \phi\left(x_{n_{k}}\right)-y^{*}\left(x_{n_{k}}\right)=\lambda
$$

so there exists $x$ which minimizes $x \rightarrow \phi(x)-y^{*}(x) \equiv \psi(x)$. Therefore, $0 \in \delta \psi(x)$ because

$$
\psi(y)-\psi(x) \geq 0=0(y-x)
$$

by Theorem 35.3.14, $0 \in \delta \psi(x)=\delta \phi(x)-y^{*}$ and this proves the theorem.
Corollary 35.3.19 Suppose $X$ is a reflexive Banach space and $\phi: X \rightarrow(-\infty, \infty]$ is convex, proper, and l.s.c. Then for each $y^{*} \in X^{\prime}$ there exist $x \in X, x_{1}^{*} \in F(x)$, and $x_{2}^{*} \in \delta \phi(x)$ such that

$$
y^{*}=x_{1}^{*}+x_{2}^{*} .
$$

Proof: Apply Theorem 35.3 .18 to the convex function $\frac{1}{2}\|x\|^{2}+\phi(x)$ and use Theorems 35.3.14 and 35.3.17.

### 35.3.2 Hilbert Space

In this section the subgradients are of a slightly different form and defined on a subset of $H$, a real Hilbert space. In Hilbert space the duality map is just the Riesz map defined earlier by

$$
R x(y) \equiv(y, x)
$$

Definition 35.3.20 $\operatorname{dom}(\partial \phi) \equiv \operatorname{dom}(\delta \phi)$ and for $x \in \operatorname{dom}(\partial \phi)$,

$$
\partial \phi(x) \equiv R^{-1} \delta \phi(x)
$$

Thus $y \in \partial \phi(x)$ if and only if for all $z \in H$,

$$
R y(z-x)=(y, z-x) \leq \phi(z)-\phi(x)
$$

Recall the definition of a maximal monotone operator.
Definition 35.3.21 A mapping $A: D(A) \subseteq H \rightarrow \mathscr{P}(H)$ is called monotone if whenever $y_{i} \in A x_{i}$,

$$
\left(y_{1}-y_{2}, x_{1}-x_{2}\right) \geq 0 .
$$

A monotone map is called maximal monotone if whenever $z \in H$, there exists $x \in D(A)$ and $y \in A(x)$ such that $z=y+x$. Put more simply, $I+A$ maps $D(A)$ onto $H$.

The following lemma states, among other things, that when $\phi$ is a convex, proper, l.s.c. function defined on a Hilbert space, $\partial \phi$ is maximal monotone.

Lemma 35.3.22 If $\phi$ is a convex, proper, l.s.c. function defined on a Hilbert space, then $\partial \phi$ is maximal monotone and $(I+\partial \phi)^{-1}$ is a Lipschitz continuous map from $H$ to dom $(\partial \phi)$ having Lipschitz constant 1.

Proof: Let $y \in H$. Then $R y \in H^{\prime}$ and by Corollary 35.3.19, there exists $x \in \operatorname{dom}(\delta \phi)$ such that $R x+\delta \phi(x) \ni R y$. Multiplying by $R^{-1}$ we see $y \in x+\partial \phi(x)$. This shows $I+\partial \phi$ is onto. If $y_{i} \in \partial \phi\left(x_{i}\right)$, then $R y_{i} \in \delta \phi\left(x_{i}\right)$ and so by the definition of subgradients,

$$
\begin{aligned}
\left(y_{1}-y_{2}, x_{1}-x_{2}\right) & =R\left(y_{1}-y_{2}\right)\left(x_{1}-x_{2}\right) \\
& =R y_{1}\left(x_{1}-x_{2}\right)-R y_{2}\left(x_{1}-x_{2}\right) \\
& \geq \phi\left(x_{1}\right)-\phi\left(x_{2}\right)-\left(\phi\left(x_{1}\right)-\phi\left(x_{2}\right)\right)=0
\end{aligned}
$$

showing $\partial \phi$ is monotone. Now suppose $x_{i} \in(I+\partial \phi)^{-1}(y)$. Then $y-x_{i} \in \partial \phi\left(x_{i}\right)$ and by monotonicity of $\partial \phi$,

$$
-\left|x_{1}-x_{2}\right|^{2}=\left(y-x_{1}-\left(y-x_{2}\right), x_{1}-x_{2}\right) \geq 0
$$

and so $x_{1}=x_{2}$. Thus $(I+\partial \phi)^{-1}$ is well defined. If $x_{i}=(I+\partial \phi)^{-1}\left(y_{i}\right)$, then by the monotonicity of $\partial \phi$,

$$
\left(y_{1}-x_{1}-\left(y_{1}-x_{2}\right), x_{1}-x_{2}\right) \geq 0
$$

and so

$$
\left|y_{1}-y_{2}\right|\left|x_{1}-x_{2}\right| \geq\left|x_{1}-x_{2}\right|^{2}
$$

which shows

$$
\left|(I+\partial \phi)^{-1}\left(y_{1}\right)-(I+\partial \phi)^{-1}\left(y_{2}\right)\right| \leq\left|y_{1}-y_{2}\right| .
$$

This proves the lemma.
Here is another proof.
Lemma 35.3.23 Let $\phi$ be convex, proper and lower semicontinuous on $X$ a reflexive Banach space having strictly convex norm, then for each $\alpha>0$,

$$
I+\alpha \partial \phi
$$

is onto.
Proof: By separation theorems applied to the eipgraph of $\phi$, and since $\phi$ is proper, there exists $w^{*}$ such that

$$
\left(w^{*}, x\right)+b \leq \alpha \phi(x)
$$

for all $x$. Pick $y \in H$. Then consider

$$
\frac{1}{2}|y-x|^{2}+\alpha \phi(x)
$$

This functional of $x$ is bounded below by

$$
\frac{1}{2}|y-x|^{2}+\left(w^{*}, x\right)+b
$$

Thus it is clearly coercive. Hence any minimizing sequence has a weakly convergent subsequence. It follows from lower semicontinuity that there exists $x_{0}$ which minimizes this functional. Hence, if $z \neq x_{0}$,

$$
0 \leq \frac{1}{2}|y-z|^{2}+\alpha \phi(z)-\left(\frac{1}{2}\left|y-x_{0}\right|^{2}+\alpha \phi\left(x_{0}\right)\right)
$$

Then writing $|y-z|^{2}=\left|y-x_{0}\right|^{2}+\left|z-x_{0}\right|^{2}-2\left(y-x_{0}, z-x_{0}\right)$,

$$
\begin{aligned}
=\frac{1}{2}\left|y-x_{0}\right|^{2} & +\frac{1}{2}\left|z-x_{0}\right|^{2}-\left(y-x_{0}, z-x_{0}\right)+\alpha \phi(z)-\frac{1}{2}\left|y-x_{0}\right|^{2}-\alpha \phi\left(x_{0}\right) \\
& =\frac{1}{2}\left|z-x_{0}\right|^{2}-\left(y-x_{0}, z-x_{0}\right)+\alpha \phi(z)-\alpha \phi\left(x_{0}\right)
\end{aligned}
$$

Thus, letting $z$ be replaced with $x_{0}+t\left(z-x_{0}\right)$ for small positive $t$,

$$
\begin{gathered}
t\left(y-x_{0}, z-x_{0}\right) \leq \frac{t^{2}}{2}\left|z-x_{0}\right|^{2}+\alpha \phi\left(x_{0}+t\left(z-x_{0}\right)\right)-\alpha \phi\left(x_{0}\right) \\
\leq \frac{t^{2}}{2}\left|z-x_{0}\right|^{2}+\alpha \phi\left(x_{0}+t\left(z-x_{0}\right)\right)-\alpha \phi\left(x_{0}\right)
\end{gathered}
$$

Using convexity of $\phi$,

$$
\leq \frac{t^{2}}{2}\left|z-x_{0}\right|^{2}+t \alpha \phi(z)-t \alpha \phi\left(x_{0}\right)
$$

Divide by $t$ and let $t \rightarrow 0$ to obtain that

$$
\left(y-x_{0}, z-x_{0}\right) \leq \alpha \phi(z)-\alpha \phi\left(x_{0}\right)
$$

and so

$$
y-x_{0} \in \partial\left(\alpha \phi\left(x_{0}\right)\right)
$$

Thus $y=x_{0}+\alpha \partial \phi\left(x_{0}\right)$ because $\partial(\alpha \phi)=\alpha \partial \phi$.
Thus $\partial \phi$ is maximal monotone.
There is a really amazing theorem, Moreau's theorem. It is in [24], [13] and [116]. It involves approximating a convex function with one which is differentiable.

Theorem 35.3.24 Let $\phi$ be a convex lower semicontinuous proper function defined on $H$. Define

$$
\phi_{\lambda}(x) \equiv \min _{y \in H}\left(\frac{1}{2 \lambda}|x-y|^{2}+\phi(y)\right)
$$

Then the function is well defined, convex, Frechet differentiable, and for all $x \in H$,

$$
\lim _{\lambda \rightarrow 0} \phi_{\lambda}(x)=\phi(x)
$$

$\phi_{\lambda}(x)$ increasing as $\lambda$ decreases. In addition,

$$
\phi_{\lambda}(x)=\frac{1}{2 \lambda}\left|x-J_{\lambda} x\right|^{2}+\phi\left(J_{\lambda}(x)\right)
$$

where $J_{\lambda} x \equiv(I+\lambda \partial \phi)^{-1}(x)$. The Frechet derivative at $x$ equals $A_{\lambda} x$ where

$$
A_{\lambda}=\frac{1}{\lambda}-\frac{1}{\lambda}(I+\lambda \partial \phi)^{-1}=\frac{1}{\lambda}-\frac{1}{\lambda} J_{\lambda}
$$

Also, there is an interesting relation between the domain of $\phi$ and the domain of $\partial \phi$

$$
D(\partial \phi) \subseteq D(\phi) \subseteq \overline{D(\partial \phi)}
$$

Proof: First of all, why does the minimum take place? By the convexity, closed epigraph, and assumption that $\phi$ is proper, separation theorems apply and one can say that there exists $z^{*}$ such that for all $y \in H$,

$$
\begin{equation*}
\frac{1}{2 \lambda}|x-y|^{2}+\phi(y) \geq \frac{1}{2 \lambda}|x-y|^{2}+\left(z^{*}, y\right)+c \tag{35.3.34}
\end{equation*}
$$

It follows easily that a minimizing sequence is bounded and so from lower semicontinuity which implies weak lower semicontinuity, there exists $y_{x}$ such that

$$
\min _{y \in H}\left(\frac{1}{2 \lambda}|x-y|^{2}+\phi(y)\right)=\left(\frac{1}{2 \lambda}\left|x-y_{x}\right|^{2}+\phi\left(y_{x}\right)\right)
$$

Why is $\phi_{\lambda}$ convex? For $\theta \in[0,1]$,

$$
\begin{gathered}
\phi_{\lambda}(\theta x+(1-\theta) z)=\frac{1}{2 \lambda}\left|\theta x+(1-\theta) z-y_{(\theta x+(1-\theta) z)}\right|^{2}+\phi\left(y_{\theta x+(1-\theta) z}\right) \\
\leq \frac{1}{2 \lambda}\left|\theta x+(1-\theta) z-\left(\theta y_{x}+(1-\theta) y_{z}\right)\right|^{2}+\phi\left(\theta y_{x}+(1-\theta) y_{z}\right) \\
\leq \frac{\theta}{2 \lambda}\left|x-y_{x}\right|^{2}+\frac{1-\theta}{2 \lambda}\left|z-y_{z}\right|^{2}+\theta \phi\left(y_{x}\right)+(1-\theta) \phi\left(y_{z}\right) \\
=\theta \phi_{\lambda}(x)+(1-\theta) \phi_{\lambda}(z)
\end{gathered}
$$

So is there a formula for $y_{x}$ ? Since it involves minimization of the functional, it follows as in Lemma 35.3.23 that

$$
\frac{1}{\lambda}\left(x-y_{x}\right) \in \partial \phi\left(y_{x}\right)
$$

Thus

$$
x \in y_{x}+\lambda \partial \phi\left(y_{x}\right)
$$

and so

$$
y_{x}=J_{\lambda} x
$$

Thus

$$
\phi_{\lambda}(x)=\frac{1}{2 \lambda}\left|x-J_{\lambda} x\right|^{2}+\phi\left(J_{\lambda}(x)\right)=\frac{\lambda}{2}\left|A_{\lambda} x\right|^{2}+\phi\left(J_{\lambda} x\right)
$$

Note that $J_{\lambda} x \in D(\partial \phi)$ and so it must also be in $D(\phi)$. Now also

$$
A_{\lambda} x \equiv \frac{x}{\lambda}-\frac{1}{\lambda} J_{\lambda} x \in \partial \phi\left(J_{\lambda} x\right)
$$

This is so if and only if

$$
x \in J_{\lambda} x+\lambda \partial \phi\left(J_{\lambda} x\right)=(I+\lambda \partial \phi)\left(J_{\lambda} x\right)=(I+\lambda \partial \phi)(I+\lambda \partial \phi)^{-1} x
$$

which is clearly true by definition.
Next consider the claim about differentiability.

$$
\phi_{\lambda}(y)-\phi_{\lambda}(x)=\frac{\lambda}{2}\left|A_{\lambda} y\right|^{2}+\phi\left(J_{\lambda} y\right)-\left(\frac{\lambda}{2}\left|A_{\lambda} x\right|^{2}+\phi\left(J_{\lambda} x\right)\right)
$$

$$
\begin{gather*}
=\frac{\lambda}{2}\left(\left|A_{\lambda} y\right|^{2}-\left|A_{\lambda} x\right|^{2}\right)+\phi\left(J_{\lambda} y\right)-\phi\left(J_{\lambda} x\right) \\
\geq \frac{\lambda}{2}\left(\left|A_{\lambda} y\right|^{2}-\left|A_{\lambda} x\right|^{2}\right)+\left(A_{\lambda} x, J_{\lambda} y-J_{\lambda} x\right) \\
=\frac{\lambda}{2}\left(\left|A_{\lambda} y\right|^{2}-\left|A_{\lambda} x\right|^{2}\right)+\left(A_{\lambda} x, y-\lambda A_{\lambda} y-\left(x-\lambda A_{\lambda} x\right)\right) \\
=\frac{\lambda}{2}\left(\left|A_{\lambda} y\right|^{2}-\left|A_{\lambda} x\right|^{2}\right)+\left(A_{\lambda} x, y-x\right)+\lambda\left(A_{\lambda} x, A_{\lambda} x-A_{\lambda} y\right) \\
\geq \frac{\lambda}{2}\left(\left|A_{\lambda} y\right|^{2}-\left|A_{\lambda} x\right|^{2}\right)+\lambda\left|A_{\lambda} x\right|^{2}-\frac{\lambda}{2}\left|A_{\lambda} x\right|^{2}-\frac{\lambda}{2}\left|A_{\lambda} y\right|^{2}+\left(A_{\lambda} x, y-x\right) \\
=\left(A_{\lambda} x, y-x\right)=\left(A_{\lambda} x-A_{\lambda} y, y-x\right)+\left(A_{\lambda} y, y-x\right) \tag{35.3.35}
\end{gather*}
$$

Then it follows that

$$
-\left(A_{\lambda} x-A_{\lambda} y, y-x\right) \geq \phi_{\lambda}(x)-\phi_{\lambda}(y)-\left(A_{\lambda} y, x-y\right)
$$

However, $A_{\lambda}$ is Lipschitz continuous with constant $1 / \lambda$ and so

$$
\begin{equation*}
\frac{1}{\lambda}|x-y|^{2} \geq \phi_{\lambda}(x)-\phi_{\lambda}(y)-\left(A_{\lambda} y, x-y\right) \tag{35.3.36}
\end{equation*}
$$

Then switching $x, y$ in the equation 35.3.36,

$$
\begin{equation*}
\frac{1}{\lambda}|x-y|^{2} \geq \phi_{\lambda}(y)-\phi_{\lambda}(x)-\left(A_{\lambda} x, y-x\right) \tag{35.3.37}
\end{equation*}
$$

But also that term on the end in 35.3.36 equals $\left(A_{\lambda} y, y-x\right) \geq\left(A_{\lambda} x, y-x\right)$ and so it is also the case that

$$
\begin{align*}
\frac{1}{\lambda}|x-y|^{2} & \geq \phi_{\lambda}(x)-\phi_{\lambda}(y)+\left(A_{\lambda} x, y-x\right) \\
& =-\left(\phi_{\lambda}(y)-\phi_{\lambda}(x)-\left(A_{\lambda} x, y-x\right)\right) \tag{35.3.38}
\end{align*}
$$

From 35.3.37 and 35.3.38 it follows that

$$
\frac{1}{\lambda}|x-y|^{2} \geq\left|\phi_{\lambda}(y)-\phi_{\lambda}(x)-\left(A_{\lambda} x, y-x\right)\right|
$$

which shows that $D \phi_{\lambda}(x)=A_{\lambda} x$. This proves the differentiability part.
Next recall that for any maximal monotone operatior $A$, if you have $x \in \overline{D(A)}$, then

$$
\lim _{\lambda \rightarrow 0} J_{\lambda} x=x
$$

Recall why this was so. If $x \in D(A)$, then

$$
x-J_{\lambda} x \in \lambda A x
$$

and so, $\left|x-J_{\lambda} x\right| \rightarrow 0$ as $\lambda \rightarrow 0$. If $x$ is only in $\overline{D(A)}$, it also works because for $y \in D(A)$

$$
\begin{aligned}
\left|x-J_{\lambda} x\right| & \leq|x-y|+\left|y-J_{\lambda} y\right|+\left|J_{\lambda} y-J_{\lambda} x\right| \\
& \leq 2|x-y|+\left|y-J_{\lambda} y\right|
\end{aligned}
$$

If $\varepsilon$ is given, simply pick $|y-x|<\varepsilon / 2$ and then

$$
\left|x-J_{\lambda} x\right| \leq \varepsilon+\left|y-J_{\lambda} y\right|
$$

and the last converges to 0 . Therefore, $J_{\lambda} x \rightarrow x$ on $\overline{D(A)}$.
Returning to the proof of the theorem, if $x \in \overline{D(\partial \phi)}$ then recall that

$$
\phi_{\lambda}(x)=\frac{1}{2 \lambda}\left|x-J_{\lambda} x\right|^{2}+\phi\left(J_{\lambda} x\right)
$$

and so,

$$
\lim \inf _{\lambda \rightarrow 0} \phi_{\lambda}(x) \geq \lim _{\lambda \rightarrow 0} \inf _{\lambda \rightarrow 0} \phi\left(J_{\lambda} x\right) \geq \phi(x) \geq \lim _{\lambda \rightarrow 0} \sup _{\lambda \rightarrow 0}(x)
$$

which shows the desired result in case $x \in \overline{D(\partial \phi)}$. Now consider the case where $x \notin$ $\overline{D(\partial \phi)}$. In this case, there is a positive lower bound $\delta$ to $\left|x-J_{\lambda} x\right|$ because each $J_{\lambda} x \in$ $D(\partial \phi)$. Then from the definition and what was shown above,

$$
\begin{aligned}
\phi_{\lambda}(x)= & \frac{\lambda}{2}\left|A_{\lambda} x\right|^{2}+\phi\left(J_{\lambda} x\right) \geq \frac{\lambda}{2}\left|A_{\lambda} x\right|^{2}+\left(z^{*}, J_{\lambda} x\right)+c \\
& \geq \frac{\lambda}{2}\left|A_{\lambda} x\right|^{2}+\left(z^{*}, J_{\lambda} x-x\right)+\left(z^{*}, x\right)+c \\
\geq & \frac{1}{2}\left|A_{\lambda} x\right|\left|x-J_{\lambda} x\right|-\left|z^{*}\right|\left|J_{\lambda} x-x\right|-\left|z^{*}\right||x|+c \\
\geq & \frac{1}{2}\left(\left|A_{\lambda} x\right|-\left|z^{*}\right|\right) \delta-\left|z^{*}\right||x|+c \\
\geq & \frac{1}{2}\left(\frac{\delta}{\lambda}-\left|z^{*}\right|\right) \delta-\left|z^{*}\right||x|+c
\end{aligned}
$$

Hence $\phi_{\lambda}(x) \rightarrow \infty$ and since $\phi(x) \geq \phi_{\lambda}(x)$ by construction, it follows that $\phi(x)=\infty$. The construction of $\phi_{\lambda}$ also shows that as $\lambda$ decreases, $\phi_{\lambda}(x)$ increases.

Note that the last part of the argument shows that if $x \notin \overline{D(\partial \phi)}$, then $x \notin D(\phi)$. Hence this shows that

$$
D(\partial \phi) \subseteq D(\phi) \subseteq \overline{D(\partial \phi)}
$$

### 35.4 A Perturbation Theorem

In this section is a simple perturbation theorem found in [24] and [116].
Recall that for $B$ a maximal monotone operator, $B_{\lambda}$, the Yosida approximation, is defined by

$$
B_{\lambda} x \equiv \frac{1}{\lambda}\left(x-J_{\lambda} x\right), J_{\lambda} x \equiv(I+\lambda B)^{-1} x .
$$

This follows from Theorem 35.1.7 on Page 1234

Theorem 35.4.1 Let $A$ and $B$ be maximal monotone operators and let $x_{\lambda}$ be the solution to

$$
y \in x_{\lambda}+B_{\lambda} x_{\lambda}+A x_{\lambda} .
$$

Then $y \in x+B x+A x$ for some $x \in D(A) \cap D(B)$ if $B_{\lambda} x_{\lambda}$ is bounded independent of $\lambda$.
The following is the perturbation theorem of this section. See [24] and [116].
Theorem 35.4.2 Let $H$ be a real Hilbert space and let $\Phi$ be non negative, convex, proper, and lower semicontinuous. Suppose also that A is a maximal monotone operator and there exists

$$
\begin{equation*}
\xi \in D(A) \cap D(\Phi) . \tag{35.4.39}
\end{equation*}
$$

Suppose also that for $J_{\lambda} x \equiv(I+\lambda A)^{-1} x$,

$$
\begin{equation*}
\Phi\left(J_{\lambda} x\right) \leq \Phi(x)+C \lambda \tag{35.4.40}
\end{equation*}
$$

Then $A+\partial \Phi$ is maximal monotone.
Proof: Letting $A_{\lambda}$ be the Yosida approximation of $A$,

$$
A_{\lambda} x=\frac{1}{\lambda}\left(x-J_{\lambda} x\right)
$$

and letting $y \in H$, it follows from the Hilbert space version of Proposition 35.1.6 there exists $x_{\lambda} \in H$ such that

$$
y \in x_{\lambda}+A_{\lambda} x_{\lambda}+\partial \Phi\left(x_{\lambda}\right) .
$$

Consequently,

$$
\begin{equation*}
y-x_{\lambda}-A_{\lambda} x_{\lambda} \in \partial \Phi\left(x_{\lambda}\right) \tag{35.4.41}
\end{equation*}
$$

and so

$$
\begin{equation*}
\left(y-x_{\lambda}-A_{\lambda} x_{\lambda}, J_{\lambda} x_{\lambda}-x_{\lambda}\right) \leq \Phi\left(J_{\lambda} x_{\lambda}\right)-\Phi\left(x_{\lambda}\right) \leq C \lambda \tag{35.4.42}
\end{equation*}
$$

which implies

$$
\begin{equation*}
-\left(y-x_{\lambda}-A_{\lambda} x_{\lambda}, A_{\lambda} x_{\lambda}\right)=\left|A_{\lambda} x_{\lambda}\right|^{2}-\left|y-x_{\lambda}\right|\left|A_{\lambda} x_{\lambda}\right| \leq C . \tag{35.4.43}
\end{equation*}
$$

By 35.4.41 and monotonicity of $A_{\lambda}$,

$$
\begin{gathered}
\Phi(\xi)-\Phi\left(x_{\lambda}\right) \geq(\overbrace{y-x_{\lambda}-A_{\lambda} x_{\lambda}}^{\in \partial \Phi\left(x_{\lambda}\right)}, \xi-x_{\lambda}) \\
=\left(y-x_{\lambda}, \xi-x_{\lambda}\right)-\left(A_{\lambda} x_{\lambda}, \xi-x_{\lambda}\right) \\
\geq\left(y-x_{\lambda}, \xi-x_{\lambda}\right)-\left(A_{\lambda} \xi, \xi-x_{\lambda}\right) \\
\geq\left(y-\xi, \xi-x_{\lambda}\right)+\left|\xi-x_{\lambda}\right|^{2}-\left(A_{\lambda} \xi, \xi-x_{\lambda}\right) \\
=\left|\xi-x_{\lambda}\right|^{2}+\left(y-\xi-A_{\lambda} \xi, \xi-x_{\lambda}\right)
\end{gathered}
$$

$$
\geq\left|\xi-x_{\lambda}\right|^{2}-C_{\xi y}\left|\xi-x_{\lambda}\right|
$$

where $C_{\xi y}$ depends on $\xi$ and $y$ but is independent of $\lambda$ because of the assumption that $\xi \in D(A) \cap D(\Phi)$ and Lemma 35.1.3 which gives a bound on $\left|A_{\lambda} \xi\right|$ in terms $|y|$ for $y \in A x$. Therefore, there exist constants, $C_{1}$ and $C_{2}$, depending on $\xi$ and $y$ but not on $\lambda$ such that

$$
\Phi(\xi) \geq \Phi\left(x_{\lambda}\right)+\left|x_{\lambda}\right|^{2}-C_{1}\left|x_{\lambda}\right|-C_{2}
$$

Since $\Phi \geq 0$, this shows that $\left|x_{\lambda}\right|$ is bounded independent of $\lambda$.

$$
2\left(\Phi(\xi)+C_{2}+\frac{C_{1}^{2}}{2}\right) \geq \Phi\left(x_{\lambda}\right)+\left|x_{\lambda}\right|^{2}
$$

This shows $\left|x_{\lambda}\right|$ is bounded independent of $\lambda$. Therefore, by 35.4.43, $\left|A_{\lambda} x_{\lambda}\right|$ is bounded independent of $\lambda$. By Theorem 35.4.1 this shows there exists $x \in D(\partial \Phi) \cap D(A)$ such that

$$
y \in A x+\partial \Phi(x)+x
$$

and so $A+\partial \Phi$ is maximal monotone since $y \in H$ was arbitrary.

### 35.5 An Evolution Inclusion

In this section is a theorem on existence and uniqueness for the initial value problem

$$
x^{\prime}+\partial \phi(x) \ni f, x(0)=x_{0}
$$

Suppose $\phi$ is a mapping from $H$ to $[0, \infty]$ which satisfy the following axioms.

$$
\begin{equation*}
\phi \text { is convex and lower semicontinuous, and proper, } \tag{35.5.44}
\end{equation*}
$$

Lemma 35.5.1 For $x \in L^{2}(0, T ; H), t \rightarrow \phi(x)$ is measurable.
Proof: This follows because $\phi$ is Borel measurable and so $\phi \circ x$ is also measurable. Now define the following function $\Phi$, on the Hilbert space, $L^{2}(0, T ; H)$.

$$
\Phi(x) \equiv\left\{\begin{array}{l}
\int_{0}^{T} \phi(x(t)) d t \text { if } x(t) \in D \text { for a.e. } t  \tag{35.5.45}\\
+\infty \text { otherwise }
\end{array}\right.
$$

Lemma 35.5.2 $\Phi$ is convex, nonnegative, and lower semicontinuous on $L^{2}(0, T ; H)$.
Proof: Since $\phi$ is nonnegative and convex, it follows that $\Phi$ is also nonnegative and convex. It remains to verify lower semicontinuity. Suppose, $x_{n} \rightarrow x$ in $L^{2}(0, T ; H)$ and let

$$
\lambda=\lim _{n \rightarrow \infty} \inf _{n} \Phi\left(x_{n}\right)
$$

Is $\lambda \geq \Phi(x)$ ? Then is suffices to assume $\lambda<\infty$. Suppose not. Then $\lambda<\Phi(x)$. Taking a subsequence, we can have $\lambda=\lim _{n \rightarrow \infty} \Phi\left(x_{n}\right)$ and we can take a further subsequence for which convergence of $x_{n}$ to $x$ is pointwise a.e. Then

$$
\begin{aligned}
\lambda & <\Phi(x) \equiv \int_{0}^{T} \phi(x(t)) d t \leq \int_{0}^{T} \lim _{n \rightarrow \infty} \inf _{n} \phi\left(x_{n}(t)\right) d t \\
& \leq \lim \inf _{n \rightarrow \infty} \int_{0}^{T} \phi\left(x_{n}(t)\right) d t=\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \Phi\left(x_{n}\right)=\lambda
\end{aligned}
$$

which is a contradiction.
Define

$$
\begin{gather*}
D(L) \equiv\left\{x \in L^{2}(0, T ; H):\right. \text { such that } \\
\left.x(t)=x_{0}+\int_{0}^{t} x^{\prime}(s) d s \text { where } x^{\prime} \in L^{2}(0, T ; H)\right\} \tag{35.5.46}
\end{gather*}
$$

and for $x \in D(L)$,

$$
L x \equiv x^{\prime}
$$

Then $L$ is maximal monotone. To see this, consider the equation

$$
\lambda x^{\prime}+x=z, x(0)=x_{0}
$$

It clearly has a solution so $\lambda L+I$ is onto. In fact, the solution is

$$
x=e^{\frac{-t}{\lambda}} x_{0}+\frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{1}{\lambda} s} z(s) d s
$$

Also,

$$
\begin{aligned}
(L x & -L y, x-y)_{L^{2}(0, T ; H)}=\int_{0}^{T}\left(\left(x^{\prime}-y^{\prime}\right), x-y\right)_{H} d t \\
& =\int_{0}^{T}\left(x^{\prime}(t)-y^{\prime}(t), \int_{0}^{t} x^{\prime}(s)-y^{\prime}(s) d s\right) d t \\
& =\frac{1}{2} \int_{0}^{T} \frac{d}{d t}\left(\left|\int_{0}^{t} x^{\prime}(s)-y^{\prime}(s) d s\right|^{2}\right) d t \\
& =\left|\int_{0}^{T} x^{\prime}(s)-y^{\prime}(s) d s\right|_{H}^{2} \geq 0
\end{aligned}
$$

Thus we have the following lemma.
Lemma 35.5.3 L is maximal monotone and if $z \in L^{2}(0, T ; H)$, then $J_{\lambda} z$ is given by

$$
\begin{equation*}
J_{\lambda}[z](t) \equiv(I+\lambda L)^{-1}([z])(t)=e^{\frac{-t}{\lambda}} x_{0}+\frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{1}{\lambda} s} z(s) d s \tag{35.5.47}
\end{equation*}
$$

The main theorem is the following.
Theorem 35.5.4 Let $x_{0} \in D \equiv D(\phi)$. Then $L+\partial \Phi$ is maximal monotone so there exists $a$ unique solution to

$$
\begin{equation*}
L x+x+\partial \Phi(x) \ni f \tag{35.5.48}
\end{equation*}
$$

for every $f \in L^{2}(0, T ; H)$. Thus there exists $x \in L^{2}(0, T ; H)$ such that

$$
x^{\prime} \in L^{2}(0, T ; H), x(0)=x_{0} \in D(\phi)
$$

and

$$
x^{\prime}+x+\partial \Phi(x) \ni f, x(0)=x_{0}
$$

Proof: This is from Theorem 35.4.2. Since $x_{0} \in D$, it follows that $\phi\left(x_{0}\right)<\infty$.
Let $z \in D(\Phi)$, the effective domain of $\Phi$. Then $\int_{0}^{T} \phi(z(t)) d t<\infty$, so by convexity of $\phi$ and 35.5.47,

$$
\begin{equation*}
\phi\left(J_{\lambda} z(t)\right) \leq e^{\frac{-t}{\lambda}} \phi\left(x_{0}\right)+\frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{s}{\lambda}} \phi(z(s)) d s . \tag{35.5.49}
\end{equation*}
$$

Then

$$
\begin{gathered}
\Phi\left(J_{\lambda} z\right)= \\
\int_{0}^{T} \phi\left(J_{\lambda} z(t)\right) d t \leq \phi\left(x_{0}\right) \lambda+\int_{0}^{T} \frac{1}{\lambda} \int_{0}^{t} e^{-(t-s) / \lambda} \phi(z(s)) d s d t \\
\leq \lambda \phi\left(x_{0}\right)+\frac{1}{\lambda} \int_{0}^{T} \phi(z(s)) \int_{s}^{T} e^{-(t-s) / \lambda} d t d s \\
\leq \lambda \phi\left(x_{0}\right)+\left(\int_{0}^{T} \phi(z(s)) d s\right) \frac{1}{\lambda} \int_{0}^{\infty} e^{-t / \lambda} d t \\
=\phi\left(x_{0}\right) \lambda+\int_{0}^{T} \phi(z(s)) d s \\
=\phi\left(x_{0}\right) \lambda+\Phi(z)
\end{gathered}
$$

The conditions of Theorem 35.4.2 are satisfied. This proves $L+\partial \Phi$ is maximal monotone on $L^{2}(0, T ; H)$ and consequently there exists a unique solution to the differential inclusion of the theorem.

Then the main result is the following.
Theorem 35.5.5 Let $f \in L^{2}(0, T ; H)$ and $x_{0} \in D$. Let $\phi$ be as described above, a lower semicontinuous convex proper function defined on $H$. Then there exists a unique solution $x \in L^{2}(0, T ; H), x^{\prime} \in L^{2}(0, T ; H)$, to

$$
x^{\prime}+\partial \Phi(x) \ni f \text { in } L^{2}(0, T ; H), x(0)=x_{0}
$$

This satisfies the pointwise condition

$$
x^{\prime}(t)+\partial \phi(x(t)) \ni f(t) \text { for a.e. } t, x(0)=x_{0}
$$

Proof: From Theorem 35.5.4, there exists a unique solution to

$$
x_{v}^{\prime}+\partial \Phi\left(x_{v}\right)+x_{v} \ni f+v \text { in } L^{2}(0, T ; H), x_{v}(0)=x_{0}
$$

whenever $v \in L^{2}(0, T ; H)$. Then a simple argument based on fundamental theorem of calculus implies that for a.e. $t$,

$$
x_{v}^{\prime}(t)+\partial \phi\left(x_{v}(t)\right)+x_{v}(t) \ni f(t)+v(t)
$$

Then for given $v, u$ one can act on $x_{v}(t)-x_{u}(t)$ and integrate. This yields

$$
\frac{1}{2}\left|x_{v}(t)-x_{u}(t)\right|_{H}^{2}+\int_{0}^{t}\left|x_{v}-x_{u}\right|^{2} d s \leq \int_{0}^{t}|v(s)-u(s)|_{H}^{2} d s
$$

It follows that a sufficiently high power of the mapping $u \rightarrow x_{u}$ is a contraction map on $L^{2}(0, T ; H)$ and so there exists a unique fixed point $v$ in $L^{2}(0, T ; H)$. Thus $x_{v}=v$ and so

$$
v^{\prime}+\partial \Phi(v) \ni f \text { in } L^{2}(0, T ; H), v(0)=x_{0}
$$

### 35.6 A More Complicated Perturbation Theorem

In this section is a simple perturbation theorem which is a small generalization of one found in [24] and [116].

Recall that for $B$ a maximal monotone operator, $B_{\lambda}$, the Yosida approximation, is defined by

$$
B_{\lambda} x \equiv \frac{1}{\lambda}\left(x-J_{\lambda} x\right), J_{\lambda} x \equiv(I+\lambda B)^{-1} x .
$$

This follows from Theorem 35.1.7 on Page 1234
Theorem 35.6.1 Let $A$ and $B$ be maximal monotone operators and let $x_{\lambda}$ be the solution to

$$
y \in x_{\lambda}+B_{\lambda} x_{\lambda}+A x_{\lambda} .
$$

Then $y \in x+B x+A x$ for some $x \in D(A) \cap D(B)$ if $B_{\lambda} x_{\lambda}$ is bounded independent of $\lambda$.
The following is the perturbation theorem of this section. It generalizes a well known result in [24] and [116].

Theorem 35.6.2 Let $H$ be a real Hilbert space and let $\Phi$ be non negative, convex, proper, and lower semicontinuous. Suppose also that A is a maximal monotone operator and there exists

$$
\begin{equation*}
\xi \in D(A) \cap D(\Phi) \tag{35.6.50}
\end{equation*}
$$

Suppose also that for $J_{\lambda} x \equiv(I+\lambda A)^{-1} x$,

$$
\begin{equation*}
\Phi\left(J_{\lambda} x\right) \leq \Phi(x)+C(x) \lambda \tag{35.6.51}
\end{equation*}
$$

where for some constants, $K_{1}, K_{2}$,

$$
\begin{equation*}
K_{2}+K_{1}\left(\Phi(x)+|x|^{2}\right) \geq C(x) \tag{35.6.52}
\end{equation*}
$$

Then $A+\partial \Phi$ is maximal monotone.
Proof: Letting $A_{\lambda}$ be the Yosida approximation of $A$,

$$
A_{\lambda} x=\frac{1}{\lambda}\left(x-J_{\lambda} x\right)
$$

and letting $y \in H$, it follows from the Hilbert space version of Proposition 35.1.6 there exists $x_{\lambda} \in H$ such that

$$
y \in x_{\lambda}+A_{\lambda} x_{\lambda}+\partial \Phi\left(x_{\lambda}\right)
$$

Consequently,

$$
\begin{equation*}
y-x_{\lambda}-A_{\lambda} x_{\lambda} \in \partial \Phi\left(x_{\lambda}\right) \tag{35.6.53}
\end{equation*}
$$

and so

$$
\begin{equation*}
\left(y-x_{\lambda}-A_{\lambda} x_{\lambda}, J_{\lambda} x_{\lambda}-x_{\lambda}\right) \leq \Phi\left(J_{\lambda} x_{\lambda}\right)-\Phi\left(x_{\lambda}\right) \leq C\left(x_{\lambda}\right) \lambda \tag{35.6.54}
\end{equation*}
$$

which implies

$$
\begin{equation*}
-\left(y-x_{\lambda}-A_{\lambda} x_{\lambda}, A_{\lambda} x_{\lambda}\right) \leq C\left(x_{\lambda}\right) . \tag{35.6.55}
\end{equation*}
$$

I claim $\left\{C\left(x_{\lambda}\right)\right\}$ and $\left\{\left|x_{\lambda}\right|\right\}$ are bounded independent of $\lambda$.
By 35.6.53 and monotonicity of $A_{\lambda}$,

$$
\begin{gathered}
\Phi(\xi)-\Phi\left(x_{\lambda}\right) \geq\left(y-x_{\lambda}-A_{\lambda} x_{\lambda}, \xi-x_{\lambda}\right) \\
\geq\left(y-x_{\lambda}, \xi-x_{\lambda}\right)-\left(A_{\lambda} x_{\lambda}, \xi-x_{\lambda}\right) \\
\geq\left(y-x_{\lambda}, \xi-x_{\lambda}\right)-\left(A_{\lambda} \xi, \xi-x_{\lambda}\right) \\
\geq\left(y-\xi, \xi-x_{\lambda}\right)+\left|\xi-x_{\lambda}\right|^{2}-\left(A_{\lambda} \xi, \xi-x_{\lambda}\right) \\
\geq\left|\xi-x_{\lambda}\right|^{2}-C_{\xi y}\left|\xi-x_{\lambda}\right|
\end{gathered}
$$

where $C_{\xi y}$ depends on $\xi$ and $y$ but is independent of $\lambda$ because of the assumption that $\xi \in D(A) \cap D(\Phi)$ and Lemma 35.1.3 which gives a bound on $\left|A_{\lambda} \xi\right|$ in terms $|y|$ for $y \in A x$. Therefore, there exist constants, $C_{1}$ and $C_{2}$, depending on $\xi$ and $y$ but not on $\lambda$ such that

$$
\Phi(\xi) \geq \Phi\left(x_{\lambda}\right)+\left|x_{\lambda}\right|^{2}-C_{1}\left|x_{\lambda}\right|-C_{2}
$$

Since $\Phi \geq 0$,

$$
2\left(\Phi(\xi)+C_{2}+\frac{C_{1}^{2}}{2}\right) \geq \Phi\left(x_{\lambda}\right)+\left|x_{\lambda}\right|^{2}
$$

This shows $\left|x_{\lambda}\right|$ is bounded independent of $\lambda$. Therefore, by 35.6 .52

$$
K_{2}+2 K_{1}\left(\Phi(\xi)+C_{2}+\frac{C_{1}^{2}}{2}\right) \geq K_{2}+K_{1}\left(\Phi\left(x_{\lambda}\right)+\left|x_{\lambda}\right|^{2}\right) \geq C\left(x_{\lambda}\right)
$$

showing that both $\left|x_{\lambda}\right|$ and $C\left(x_{\lambda}\right)$ are bounded independent of $\lambda$. Therefore, from 35.6.55, it follows $A_{\lambda} x_{\lambda}$ is bounded independent of $\lambda$. By Theorem 35.6.1 this shows there exists $x \in D(\partial \Phi) \cap D(A)$ such that

$$
y \in A x+\partial \Phi(x)+x
$$

and so $A+\partial \Phi$ is maximal monotone since $y \in H$ was arbitrary. This proves the theorem.

### 35.7 An Evolution Inclusion

In this section is a theorem on existence and uniqueness for the initial value problem

$$
x^{\prime}+\partial_{2} \phi(t, x) \ni f, x(0)=x_{0}
$$

Suppose $\{\phi(t, \cdot)\}_{t \in[0, T]}$ is a family of functions mapping $H$ to $[0, \infty]$ which satisfy the following axioms.

$$
\begin{align*}
& \phi(t, \cdot) \text { is convex and lower semicontinuous, }  \tag{35.7.56}\\
& D(\phi(t, \cdot))=D, \text { independent of } t \in[0, T] \tag{35.7.57}
\end{align*}
$$

There exists a constant, $K$, such that for all $x \in D$,

$$
\begin{equation*}
|\phi(t, x)-\phi(s, x)| \leq K\left(\phi(r, x)+|x|^{2}+1\right)|t-s| \tag{35.7.58}
\end{equation*}
$$

for all $r \in[0, T]$.

Lemma 35.7.1 Under the conditions, 35.7.56-35.7.58, $\phi: H \times[0, T] \rightarrow[0, \infty]$ is lower semicontinuous.

Proof: Let $\left(x_{n}, t_{n}\right) \rightarrow(x, t)$ and let $\lambda \equiv \liminf _{n \rightarrow \infty} \phi\left(t_{n}, x_{n}\right)$. Is

$$
\phi(t, x) \leq \lambda ?
$$

It suffices to assume $\lambda<\infty$ and by taking a subsequence, $x_{n} \in D$ for all $n$ and

$$
\phi\left(t_{n}, x_{n}\right) \rightarrow \lambda .
$$

Then

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \inf _{n} \phi\left(t_{n}, x_{n}\right)=\lim \inf _{n \rightarrow \infty}\left[\phi\left(t_{n}, x_{n}\right)-\phi\left(t, x_{n}\right)+\phi\left(t, x_{n}\right)\right] . \tag{35.7.59}
\end{equation*}
$$

Now

$$
\begin{gathered}
\lim \sup _{n \rightarrow \infty}\left|\phi\left(t_{n}, x_{n}\right)-\phi\left(t, x_{n}\right)\right| \leq \\
\lim \sup _{n \rightarrow \infty} K\left(\phi\left(t_{n}, x_{n}\right)+\left|x_{n}\right|^{2}+1\right)\left|t_{n}-t\right|=0 .
\end{gathered}
$$

Therefore, from 35.7.59

$$
\lambda=\lim \inf _{n \rightarrow \infty} \phi\left(t_{n}, x_{n}\right)=\lim \inf _{n \rightarrow \infty} \phi\left(t, x_{n}\right) \geq \phi(t, x)
$$

because of the assumption that $\phi(t, \cdot)$ is lower semicontinuous. This proves the lemma.
In all that follows $[x]$ is an element of $L^{2}(0, T ; H)$. Thus $[x]$ is the equivalence class of measurable square integrable functions which equal $x$ a.e. This seems a little fussy but since the existence results are based on surjectivity theorems and the Hilbert space they apply to is $L^{2}(0, T ; H)$, it seems best to emphasize the equivalence classes of functions by using this notation, at least while proving theorems on existence and uniqueness.

Corollary 35.7.2 For $[x] \in L^{2}(0, T ; H), t \rightarrow \phi(t, x(t))$ is measurable.
Proof: This follows because, due to Lemma 35.7.1, $\phi$ is Borel measurable and so $\phi \circ x$ is also measurable.

Now define the following function, $\Phi$, on the Hilbert space, $L^{2}(0, T ; H)$.

$$
\Phi([x]) \equiv\left\{\begin{array}{l}
\int_{0}^{T} \phi(t, x(t)) d t \text { if } x(t) \in D \text { for all } t \text { for some } x(\cdot) \in[x]  \tag{35.7.60}\\
+\infty \text { otherwise }
\end{array}\right.
$$

Note that since the functions $\phi(t, \cdot)$ are proper, the top condition is equivalent to the condition

$$
\int_{0}^{T} \phi(t, x(t)) d t \text { if } x(t) \in D \text { a.e. for all } x(\cdot) \in[x] .
$$

Lemma 35.7.3 $\Phi$ is convex, nonnegative, and lower semicontinuous on $L^{2}(0, T ; H)$.

Proof: Since each $\phi(t, \cdot)$ is nonnegative and convex, it follows that $\Phi$ is also nonnegative and convex. It remains to verify lower semicontinuity. Suppose, $\left[x_{n}\right] \rightarrow[x]$ in $L^{2}(0, T ; H)$ and let

$$
\lambda=\lim \inf _{n \rightarrow \infty} \Phi\left(\left[x_{n}\right]\right) .
$$

Is $\lambda \geq \Phi([x])$ ? It suffices to assume $\lambda<\infty, x_{n}(t) \in D$ for all $t$, and $x_{n}(t) \rightarrow x(t)$ a.e. say for $t \notin N$ where $N$ has measure zero. Let

$$
\widetilde{x}(t)=\left\{\begin{array}{c}
x(t) \text { if } t \notin N \\
x_{1}(t) \text { if } t \in N
\end{array}\right.
$$

Then $[\widetilde{x}]=[x]$ and $\widetilde{x}(t) \in D$ for all $t$. Then by pointwise convergence and Fatou's lemma,

$$
\begin{aligned}
\Phi([x]) & =\Phi([\widetilde{x}])=\int_{0}^{T} \phi(t, \widetilde{x}(t)) d t \leq \int_{0}^{T} \lim _{n \rightarrow \infty} \inf _{n} \phi\left(t, x_{n}(t)\right) d t \\
\leq & \lim \inf _{n \rightarrow \infty} \int_{0}^{T} \phi\left(t, x_{n}(t)\right) d t=\lim _{n \rightarrow \infty} \inf _{n \rightarrow \infty} \Phi\left(\left[x_{n}\right]\right) \equiv \lambda
\end{aligned}
$$

This proves the lemma.
Define

$$
\begin{align*}
D(L) & \equiv\left\{[x] \in L^{2}(0, T ; H): \text { for some } x \in[x]\right. \text { such that } \\
x(t) & \left.=x_{0}+\int_{0}^{t} x^{\prime}(s) d s \text { where }\left[x^{\prime}\right] \in L^{2}(0, T ; H)\right\} \tag{35.7.61}
\end{align*}
$$

and for $[x] \in D(L)$,

$$
L[x] \equiv\left[x^{\prime}\right] .
$$

The following lemma is easily obtained.
Lemma 35.7.4 $L$ is maximal monotone and if $[z] \in L^{2}(0, T ; H)$, then the equivalence class, $\left[J_{\lambda}[z]\right]$ is determined by the function,

$$
\begin{equation*}
J_{\lambda}[z](t) \equiv(I+\lambda L)^{-1}([z])(t)=e^{\frac{-t}{\lambda}} x_{0}+\frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{1}{\lambda} s} z(s) d s \tag{35.7.62}
\end{equation*}
$$

The main theorem is the following.
Theorem 35.7.5 Let $x_{0} \in D$. Then $L+\partial \Phi$ is maximal monotone so there exists a unique solution to

$$
\begin{equation*}
L[x]+[x]+\partial \Phi([x]) \ni[f] \tag{35.7.63}
\end{equation*}
$$

for every $[f] \in L^{2}(0, T ; H)$.
Proof: This is from Theorem 35.6.2. Since $x_{0} \in D$, it follows from 35.7.58 that $\phi\left(t, x_{0}\right)$ is bounded.

Let $[z] \in D(\Phi)$, the effective domain of $\Phi$. Then there exists $z \in[z]$ such that $z(t) \in D$ for all $t$, and $\int_{0}^{T} \phi(t, z(t)) d t<\infty$, so by convexity of $\phi(t, \cdot)$ and 35.7.62,

$$
\begin{equation*}
\phi\left(t, J_{\lambda}[z](t)\right) \leq e^{\frac{-t}{\lambda}} \phi\left(t, x_{0}\right)+\frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{s}{\lambda}} \phi(t, z(s)) d s . \tag{35.7.64}
\end{equation*}
$$

Now the first term in 35.7.64 is bounded so consider the second. The integral in this term is of the form

$$
\begin{equation*}
\int_{0}^{t} e^{\frac{s}{\lambda}} \phi(s, z(s)) d s+\int_{0}^{t} e^{\frac{s}{\lambda}}(\phi(t, z(s))-\phi(s, z(s))) d s \tag{35.7.65}
\end{equation*}
$$

Since $[z] \in D(\Phi), \phi(s, z(s))<\infty$ for all $s$ and also the first integral in 35.7.65 is finite. By 35.7.58, the second term in 35.7.65 is dominated by

$$
C_{\lambda} \int_{0}^{t} K\left(1+\phi(s, z(s))+|z(s)|^{2}\right)|t-s| d s<\infty
$$

This shows $\phi\left(t, J_{\lambda}[z](t)\right)<\infty$ for all $t$ and so $\Phi\left(\left[J_{\lambda}[z]\right]\right)$ is given by the top line of 35.7.60. Therefore, by convexity of $\phi(t, \cdot)$ and Jensen's inequality,

$$
\begin{align*}
& \Phi\left(\left[J_{\lambda}[z]\right]\right)=\int_{0}^{T} \phi\left(t, e^{\frac{-t}{\lambda}} x_{0}+\frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{s}{\lambda}} z(s) d s\right) d t \\
& \leq \int_{0}^{T}\left(e^{\frac{-t}{\lambda}} \phi\left(t, x_{0}\right)+\frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{s}{\lambda}} \phi(t, z(s)) d s\right) d t \\
& =\int_{0}^{T} e^{\frac{-t}{\lambda}} \phi\left(t, x_{0}\right) d t+\int_{0}^{T} \frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{s}{\lambda}} \phi(s, z(s)) d s d t \\
& \quad+\int_{0}^{T} \frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{s}{\lambda}}(\phi(t, z(s))-\phi(s, z(s))) d s d t \tag{35.7.66}
\end{align*}
$$

By 35.7.58, the last term is dominated by

$$
\begin{gather*}
\int_{0}^{T} \int_{0}^{t} \frac{1}{\lambda} e^{\frac{-(t-s)}{\lambda}} K\left(1+\phi(s, z(s))+|z(s)|^{2}\right)|t-s| d s d t= \\
\int_{0}^{T} \int_{s}^{T} e^{\frac{-(t-s)}{\lambda}} \frac{t-s}{\lambda} d t K\left(1+\phi(s, z(s))+|z(s)|^{2}\right) d s \\
\leq C \lambda+C \lambda\left(\Phi([z])+|[z]|^{2}\right) \tag{35.7.67}
\end{gather*}
$$

for some constant, $C$. From 35.7.58, $\phi\left(t, x_{0}\right)$ is bounded and so the first term in 35.7.66 is dominated by an expression of the form $C \lambda$. Now consider the middle term of 35.7.66. Since $\phi$ is nonnegative,

$$
\begin{gather*}
\int_{0}^{T} \frac{1}{\lambda} e^{\frac{-t}{\lambda}} \int_{0}^{t} e^{\frac{s}{\lambda}} \phi(s, z(s)) d s d t=\int_{0}^{T} \int_{s}^{T} \frac{1}{\lambda} e^{\frac{-(t-s)}{\lambda}} d t \phi(s, z(s)) d s \\
\leq \int_{0}^{T} \int_{0}^{\infty} e^{-u} d u \phi(s, z(s)) d s=\Phi([z]) \tag{35.7.68}
\end{gather*}
$$

It follows

$$
\Phi\left(\left[J_{\lambda}[z]\right]\right) \leq \Phi([z])+C \lambda+C \lambda\left(\Phi([z])+|[z]|^{2}\right)
$$

The conditions of Theorem 35.6 .2 are satisfied with $K_{1}=K_{2}=C$. This proves $L+\partial \Phi$ is maximal monotone on $L^{2}(0, T ; H)$ and consequently there exists a unique solution to the differential inclusion of the theorem.

Of course it is desirable to be able to say that $[y] \in \partial \Phi([x])$ if and only if $y(t) \in$ $\partial_{2} \phi(t, x(t))$ for some $x \in[x]$. To obtain this, here are two more assumptions. For all $x \in H$,

$$
\begin{equation*}
t \rightarrow J_{1}(t) x \text { is measurable } \tag{35.7.69}
\end{equation*}
$$

where $J_{1}(t) x$ is the solution, $y$, to $y(t)+\partial_{2} \phi(t, y(t)) \ni x$, and there exists $[\xi] \in L^{2}(0, T ; H)$ such that

$$
\begin{equation*}
\left[J_{1}(\cdot)[\xi]\right] \in L^{2}(0, T ; H) . \tag{35.7.70}
\end{equation*}
$$

Lemma 35.7.6 If 35.7.69 and 35.7.70 hold, and if $[y] \in L^{2}(0, T ; H)$, then $[y] \in \partial \Phi([x])$ if and only if there exists $x \in[x]$ such that $\partial_{2} \phi(t, x(t)) \neq \emptyset$ for all $t$ and $y(t) \in \partial_{2} \phi(t, x(t))$ a.e.

Proof: First suppose $y(t) \in \partial_{2} \phi(t, x(t))$ a.e. and $\partial_{2} \phi(t, x(t)) \neq \emptyset$ for all $t$ where $x \in[x]$. Then for all $[w] \in L^{2}(0, T ; H)$,

$$
\begin{gathered}
([y],[w])_{L^{2}(0, T ; H)} \equiv \int_{0}^{T}(y(t), w(t))_{H} d t \\
\leq \int_{0}^{T} \phi(t, x(t)+w(t)) d t-\int_{0}^{T} \phi(t, x(t)) d t \leq \Phi([x]+[w])-\Phi([x])
\end{gathered}
$$

To prove the converse, define $A: D(\partial \Phi) \rightarrow \mathscr{P}\left(L^{2}(0, T ; H)\right)$ as follows.

$$
\begin{gathered}
{[y] \in A[x] \text { if and only if for some } x \in[x]} \\
\partial_{2} \phi(t, x(t)) \neq \emptyset \text { for all } t \text { and } y(t) \in \partial_{2} \phi(t, x(t)) \text { a.e. } t .
\end{gathered}
$$

It follows $A$ is monotone. I will show $A$ is maximal monotone. From the first part of the proof, the graph of $A$ is contained in the graph of $\partial \Phi$. Since $A$ is maximal, this will imply $A=\partial \Phi$ and prove the lemma.

It remains to show $A$ is maximal monotone. By 35.7.69, for each $x \in H, J_{1}(t) x$ is measurable. Now from 35.7.70, and using the fact that $J_{1}(t)$ is a contraction,

$$
\left|J_{1}(t) x-J_{1}(t) \xi(t)\right| \leq|x-\xi(t)|
$$

and so $\left[J_{1}(\cdot) x\right]$ is in $L^{2}(0, T ; H)$. Now if

$$
s(t)=\sum_{i=1}^{n} \mathscr{X}_{E_{i}}(t) x_{i}
$$

is a simple function,

$$
J_{1}(t) s(t)=\sum_{i=1}^{n} \mathscr{X}_{E_{i}}(t) J_{1}(t) x
$$

and $\left[J_{1}(\cdot) s\right]$ is in $L^{2}(0, T ; H)$. If $[f] \in L^{2}(0, T ; H)$ is arbitrary, take a sequence of simple functions, $s_{n}$ converging to $f$ pointwise and $\left[s_{n}\right] \rightarrow[f]$ in $L^{2}(0, T ; H)$. Then

$$
\left|J_{1}(t) s_{n}(t)-J_{1}(t) f(t)\right| \leq\left|s_{n}(t)-f(t)\right|
$$

and it follows $J_{1}(t) s_{n}(t)$ converges pointwise to $J_{1}(t) f(t)$ showing that $t \rightarrow J_{1}(t) f(t)$ is measurable. Now the equivalence class of functions equal to this one a.e. is in $L^{2}(0, T ; H)$ by Fatou's lemma and the assumption that the simple functions, $s_{n}$ converge in $L^{2}(0, T ; H)$. This shows $A$ is maximal and proves the lemma.

Conditions 35.7.69 and 35.7.70 are just what is needed to obtain the conclusion of Lemma 35.7 .6 but it may not be clear how to verify these conditions easily. The following lemma gives sufficient conditions which are easy to verify which imply 35.7.69 and 35.7.70.

Lemma 35.7.7 Suppose there exists $[\xi] \in L^{2}(0, T ; H)$ such that

$$
J_{1}(t) \xi(t), \phi\left(t, J_{1}(t) \xi(t)\right)
$$

are bounded independent of $t \in[0, T]$ and $t \rightarrow J_{1}(t) \xi(t)$ is measurable. Then the conclusion of Lemma 35.7.6 holds.

Proof: Let $y(t)=J_{1}(t) \xi(t)$. Thus

$$
y(t)+\partial_{2} \phi(t, y(t)) \ni \xi(t) .
$$

Now suppose $x \in H$ and let

$$
\begin{equation*}
x(s)+z(s)=x \tag{35.7.71}
\end{equation*}
$$

where $z(s) \in \partial_{2} \phi(s, x(s))$, so $x(s)=J_{1}(s) x$. Take the inner product of both sides with $x(s)-y(s)$ to obtain

$$
(x(s), x(s)-y(s))_{H}+(z(s), x(s)-y(s))_{H}=(x, x(s)-y(s))_{H}
$$

and therefore,

$$
\begin{gathered}
\frac{1}{2}|x(s)|_{H}^{2}-\frac{1}{2}|y(s)|_{H}^{2} \leq \phi(s, y(s))-\phi(s, x(s)) \\
+|x|_{H}|x(s)|_{H}+|x|_{H}|y(s)|_{H} \leq \frac{1}{4}|x(s)|_{H}^{2}+c|x|_{H}^{2}+\frac{1}{2}|y(s)|_{H}^{2} \\
+\phi(s, y(s))-\phi(s, x(s))
\end{gathered}
$$

Consequently,

$$
\begin{equation*}
\phi(s, x(s))+\frac{1}{4}|x(s)|_{H}^{2} \leq|y(s)|_{H}^{2}+c|x|_{H}^{2}+\phi(s, y(s))<C \tag{35.7.72}
\end{equation*}
$$

a constant depending on $x$. Replacing $s$ with $t$ in 35.7.71 and subtracting yields

$$
x(t)-x(s)+z(t)-z(s)=0
$$

Now taking the inner product of this with $x(t)-x(s)$ it follows from 35.7.58,

$$
\begin{gathered}
|x(s)-x(t)|_{H}^{2}=(z(s)-z(t), x(t)-x(s))_{H} \\
\leq \phi(s, x(t))-\phi(s, x(s))+\phi(t, x(s))-\phi(t, x(t)) \\
\leq\left(K\left(\phi(t, x(t))+|x(t)|_{H}^{2}+1\right)+K\left(\phi(s, x(s))+|x(s)|_{H}^{2}+1\right)\right)|t-s|
\end{gathered}
$$

which shows by 35.7.72 that $x(\cdot)$ is Lipschitz continuous and is therefore measurable which verifies 35.7.69. The assumptions of the lemma include 35.7.70. It follows the conclusion of Lemma 35.7.6 holds.

Remark 35.7.8 Note that if $\phi(t, \cdot)$ has a minimum at $\xi(t)$ and if $t \rightarrow \xi(t)$ and $t \rightarrow$ $\phi(t, \xi(t))$ are bounded and measurable, then

$$
\xi(t)+0=\xi(t)
$$

and $0 \in \partial_{2} \phi(t, \xi(t))$. Therefore, in this case $J_{1}(t) \xi(t)=\xi(t)$ and so the hypotheses of Lemma 35.7.7 hold.

Corollary 35.7.9 Assume 35.7.56-35.7.58 and 35.7.69, 35.7.70. Let $x_{0} \in D$ and let $[f] \in$ $L^{2}(0, T ; H)$. Then there exists a unique function, $x$, satisfying

$$
[x] \text { and }\left[x^{\prime}\right] \text { are in } L^{2}(0, T ; H)
$$

which is a solution to

$$
\begin{equation*}
x^{\prime}+\partial_{2} \phi(t, x) \ni f \text { a.e., } x(0)=x_{0}, x(t)=x_{0}+\int_{0}^{t} x^{\prime}(s) d s \tag{35.7.73}
\end{equation*}
$$

Proof: Let $[v] \in L^{2}(0, T ; H)$ and let $[x]$ be the unique solution to

$$
\begin{equation*}
L[x]+[x]+\partial \Phi([x]) \ni[f]+[v] . \tag{35.7.74}
\end{equation*}
$$

Letting $\left[x_{i}\right]$ be the solution corresponding to 35.7 .74 in which $v$ is replaced with $v_{i}$, and $x_{i} \in\left[x_{i}\right]$ is such that

$$
x_{i}(t)=x_{0}+\int_{0}^{t} x_{i}^{\prime}(s) d s, i=1,2
$$

from Lemma 35.7.6 and 35.7.74 that for each $t \in[0, T]$,

$$
\frac{1}{2}\left|x_{1}(t)-x_{2}(t)\right|_{H}^{2}+\frac{1}{2} \int_{0}^{t}\left|x_{1}-x_{2}\right|_{H}^{2} d s \leq \frac{1}{2} \int_{0}^{t}\left|v_{1}(s)-v_{2}(s)\right|_{H}^{2} d s
$$

and so

$$
\left|x_{1}(t)-x_{2}(t)\right|_{H}^{2} \leq \int_{0}^{t}\left|v_{1}(s)-v_{2}(s)\right|_{H}^{2} d s
$$

Now define a mapping, $\Lambda: L^{2}(0, T ; H) \rightarrow L^{2}(0, T ; H)$ by $\Lambda[v]=[x]$ where $[x]$ is the solution to 35.7.74. Then, if $\left[v_{i}\right]$ is in $L^{2}(0, T ; H)$ and $\left[x_{i}\right]$ is the corresponding solution to 35.7.74,

$$
\left\|\Lambda\left[v_{1}\right]-\Lambda\left[v_{2}\right]\right\|_{L^{2}(0, t ; H)}^{2} \equiv
$$

$$
\int_{0}^{t}\left|x_{1}(s)-x_{2}(s)\right|_{H}^{2} d s \leq \int_{0}^{t} \int_{0}^{s}\left|v_{1}(r)-v_{2}(r)\right|_{H}^{2} d r d s
$$

Iterating this inequality, by replacing $\Lambda$ with $\Lambda^{k}$, it follows that for all $k$ large enough, $\Lambda^{k}$ is a contraction map on $L^{2}(0, T ; H)$. Thus there exists a unique fixed point for $\Lambda,[x]$. Thus

$$
L[x]+[x]+\partial \Phi([x]) \ni[f]+[x] .
$$

Let $x \in[x]$ be such that

$$
x(t)=x_{0}+\int_{0}^{t} x^{\prime}(s) d s
$$

By Lemma 35.7.6,

$$
x^{\prime}+x+\partial_{2} \phi(t, x) \ni f+x
$$

This function, $x(\cdot)$ is the unique solution to 35.7 .73 because if $x_{1}$ is another solution, then $\left[x_{1}\right]=[x]$ and since both functions are continuous, they must coincide. This proves the corollary.

## Part III

## Sobolev Spaces

## Chapter 36

## Weak Derivatives

### 36.1 Weak $*$ Convergence

A very important sort of convergence in applications of functional analysis is the concept of weak or weak $*$ convergence. It is important because it allows you to assert the existence of a convergent subsequence of a given bounded sequence. The only problem is the convergence is very weak so it does not tell you as much as you would like. Nevertheless, it is a very useful concept. The big theorems in the subject are the Eberlein Smulian theorem and the Banach Alaoglu theorem about the weak or weak $*$ compactness of the closed unit balls in either a Banach space or its dual space. These theorems are proved in Yosida [127]. Here I will present a special case which turns out to be by far the most important in applications and it is not hard to get from the Riesz representation theorem for $L^{p}$. First I define weak and weak $*$ convergence.

Definition 36.1.1 Let $X^{\prime}$ be the dual of a Banach space $X$ and let $\left\{x_{n}^{*}\right\}$ be a sequence of elements of $X^{\prime}$. Then $x_{n}^{*}$ converges weak $*$ to $x^{*}$ if and only if for all $x \in X$,

$$
\lim _{n \rightarrow \infty} x_{n}^{*}(x)=x^{*}(x)
$$

A sequence in $X,\left\{x_{n}\right\}$ converges weakly to $x \in X$ if and only if for all $x^{*} \in X^{\prime}$

$$
\lim _{n \rightarrow \infty} x^{*}\left(x_{n}\right)=x^{*}(x)
$$

The main result is contained in the following lemma.
Lemma 36.1.2 Let $X^{\prime}$ be the dual of a Banach space, $X$ and suppose $X$ is separable. Then if $\left\{x_{n}^{*}\right\}$ is a bounded sequence in $X^{\prime}$, there exists a weak $*$ convergent subsequence.

Proof: Let $D$ be a dense countable set in $X$. Then the sequence, $\left\{x_{n}^{*}(x)\right\}$ is bounded for all $x$ and in particular for all $x \in D$. Use the Cantor diagonal process to obtain a subsequence, still denoted by $n$ such that $x_{n}^{*}(d)$ converges for each $d \in D$. Now let $x \in X$ be completely arbitrary. In fact $\left\{x_{n}^{*}(x)\right\}$ is a Cauchy sequence. Let $\varepsilon>0$ be given and pick $d \in D$ such that for all $n$

$$
\left|x_{n}^{*}(x)-x_{n}^{*}(d)\right|<\frac{\varepsilon}{3}
$$

This is possible because $D$ is dense. By the first part of the proof, there exists $N_{\varepsilon}$ such that for all $m, n>N_{\varepsilon}$,

$$
\left|x_{n}^{*}(d)-x_{m}^{*}(d)\right|<\frac{\varepsilon}{3}
$$

Then for such $m, n$,

$$
\begin{aligned}
\left|x_{n}^{*}(x)-x_{m}^{*}(x)\right| & \leq\left|x_{n}^{*}(x)-x_{n}^{*}(d)\right|+\left|x_{n}^{*}(d)-x_{m}^{*}(d)\right| \\
+\left|x_{m}^{*}(d)-x_{m}^{*}(x)\right| & <\frac{\varepsilon}{3}+\frac{\varepsilon}{3}+\frac{\varepsilon}{3}=\varepsilon .
\end{aligned}
$$

Since $\mathcal{\varepsilon}$ is arbitrary, this shows $\left\{x_{n}^{*}(x)\right\}$ is a Cauchy sequence for all $x \in X$.

Now define $f(x) \equiv \lim _{n \rightarrow \infty} x_{n}^{*}(x)$. Since each $x_{n}^{*}$ is linear, it follows $f$ is also linear. In addition to this,

$$
|f(x)|=\lim _{n \rightarrow \infty}\left|x_{n}^{*}(x)\right| \leq K\|x\|
$$

where $K$ is some constant which is larger than all the norms of the $x_{n}^{*}$. Such a constant exists because the sequence, $\left\{x_{n}^{*}\right\}$ was bounded. This proves the lemma.

The lemma implies the following important theorem.
Theorem 36.1.3 Let $\Omega$ be a measurable subset of $\mathbb{R}^{n}$ and let $\left\{f_{k}\right\}$ be a bounded sequence in $L^{p}(\Omega)$ where $1<p \leq \infty$. Then there exists a weak $*$ convergent subsequence.

Proof: Since $L^{p^{\prime}}(\Omega)$ is separable, this follows from the Riesz representation theorem.
Note that from the Riesz representation theorem, it follows that if $p<\infty$, then the sequence converges weakly.

### 36.2 Test Functions And Weak Derivatives

In elementary courses in mathematics, functions are often thought of as things which have a formula associated with them and it is the formula which receives the most attention. For example, in beginning calculus courses the derivative of a function is defined as the limit of a difference quotient. You start with one function which tends to be identified with a formula and, by taking a limit, you get another formula for the derivative. A jump in abstraction occurs as soon as you encounter the derivative of a function of $n$ variables where the derivative is defined as a certain linear transformation which is determined not by a formula but by what it does to vectors. When this is understood, it reduces to the usual idea in one dimension. The idea of weak partial derivatives goes further in the direction of defining something in terms of what it does rather than by a formula, and extra generality is obtained when it is used. In particular, it is possible to differentiate almost anything if the notion of what is meant by the derivative is sufficiently weak. This has the advantage of allowing the consideration of the weak partial derivative of a function without having to agonize over the important question of existence but it has the disadvantage of not being able to say much about the derivative. Nevertheless, it is the idea of weak partial derivatives which makes it possible to use functional analytic techniques in the study of partial differential equations and it is shown in this chapter that the concept of weak derivative is useful for unifying the discussion of some very important theorems. Certain things which shold be true are.

Let $\Omega \subseteq \mathbb{R}^{n}$. A distribution on $\Omega$ is defined to be a linear functional on $C_{c}^{\infty}(\Omega)$, called the space of test functions. The space of all such linear functionals will be denoted by $\mathscr{D}^{*}(\Omega)$. Actually, more is sometimes done here. One imposes a topology on $C_{c}^{\infty}(\Omega)$ making it into a topological vector space, and when this has been done, $\mathscr{D}^{\prime}(\Omega)$ is defined as the dual space of this topological vector space. To see this, consult the book by Yosida [127] or the book by Rudin [114].

Example: The space $L_{l o c}^{1}(\Omega)$ may be considered as a subset of $\mathscr{D}^{*}(\Omega)$ as follows.

$$
f(\phi) \equiv \int_{\Omega} f(\mathbf{x}) \phi(\mathbf{x}) d x
$$

for all $\phi \in C_{c}^{\infty}(\Omega)$. Recall that $f \in L_{l o c}^{1}(\Omega)$ if $f \mathscr{X}_{K} \in L^{1}(\Omega)$ whenever $K$ is compact.
Example: $\delta_{x} \in \mathscr{D}^{*}(\Omega)$ where $\delta_{\mathbf{x}}(\phi) \equiv \phi(\mathbf{x})$.
It will be observed from the above two examples and a little thought that $\mathscr{D}^{*}(\Omega)$ is truly enormous. The derivative of a distribution will be defined in such a way that it agrees with the usual notion of a derivative on those distributions which are also continuously differentiable functions. With this in mind, let $f$ be the restriction to $\Omega$ of a smooth function defined on $\mathbb{R}^{n}$. Then $D_{x_{i}} f$ makes sense and for $\phi \in C_{c}^{\infty}(\Omega)$

$$
D_{x_{i}} f(\phi) \equiv \int_{\Omega} D_{x_{i}} f(\mathbf{x}) \phi(\mathbf{x}) d x=-\int_{\Omega} f D_{x_{i}} \phi d x=-f\left(D_{x_{i}} \phi\right)
$$

This motivates the following definition.
Definition 36.2.1 For $T \in \mathscr{D}^{*}(\Omega)$

$$
D_{x_{i}} T(\phi) \equiv-T\left(D_{x_{i}} \phi\right)
$$

Of course one can continue taking derivatives indefinitely. Thus,

$$
D_{x_{i} x_{j}} T \equiv D_{x_{i}}\left(D_{x_{j}} T\right)
$$

and it is clear that all mixed partial derivatives are equal because this holds for the functions in $C_{c}^{\infty}(\Omega)$. In this weak sense, the derivative of almost anything exists, even functions that may be discontinuous everywhere. However the notion of "derivative" is very weak, hence the name, "weak derivatives".

Example: Let $\Omega=\mathbb{R}$ and let

$$
H(x) \equiv\left\{\begin{array}{l}
1 \text { if } x \geq 0 \\
0 \text { if } x<0
\end{array}\right.
$$

Then

$$
D H(\phi)=-\int H(x) \phi^{\prime}(x) d x=\phi(0)=\delta_{0}(\phi)
$$

Note that in this example, $D H$ is not a function.
What happens when $D f$ is a function?
Theorem 36.2.2 Let $\Omega=(a, b)$ and suppose that $f$ and $D f$ are both in $L^{1}(a, b)$. Then $f$ is equal to a continuous function a.e., still denoted by $f$ and

$$
f(x)=f(a)+\int_{a}^{x} D f(t) d t
$$

In proving Theorem 36.2.2 the following lemma is useful.
Lemma 36.2.3 Let $T \in \mathscr{D}^{*}(a, b)$ and suppose $D T=0$. Then there exists a constant $C$ such that

$$
T(\phi)=\int_{a}^{b} C \phi d x
$$

Proof: $T(D \phi)=0$ for all $\phi \in C_{c}^{\infty}(a, b)$ from the definition of $D T=0$. Let

$$
\phi_{0} \in C_{c}^{\infty}(a, b), \int_{a}^{b} \phi_{0}(x) d x=1
$$

and let

$$
\psi_{\phi}(x)=\int_{a}^{x}\left[\phi(t)-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right] d t
$$

for $\phi \in C_{c}^{\infty}(a, b)$. Thus $\psi_{\phi} \in C_{c}^{\infty}(a, b)$ and

$$
D \psi_{\phi}=\phi-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}
$$

Therefore,

$$
\phi=D \psi_{\phi}+\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}
$$

and so

$$
T(\phi)=T\left(D \psi_{\phi}\right)+\left(\int_{a}^{b} \phi(y) d y\right) T\left(\phi_{0}\right)=\int_{a}^{b} T\left(\phi_{0}\right) \phi(y) d y
$$

Let $C=T \phi_{0}$. This proves the lemma.
Proof of Theorem 36.2.2 Since $f$ and $D f$ are both in $L^{1}(a, b)$,

$$
D f(\phi)-\int_{a}^{b} D f(x) \phi(x) d x=0
$$

Consider

$$
f(\cdot)-\int_{a}^{(\cdot)} D f(t) d t
$$

and let $\phi \in C_{c}^{\infty}(a, b)$.

$$
\begin{gathered}
D\left(f(\cdot)-\int_{a}^{(\cdot)} D f(t) d t\right)(\phi) \\
\equiv-\int_{a}^{b} f(x) \phi^{\prime}(x) d x+\int_{a}^{b}\left(\int_{a}^{x} D f(t) d t\right) \phi^{\prime}(x) d x \\
=D f(\phi)+\int_{a}^{b} \int_{t}^{b} D f(t) \phi^{\prime}(x) d x d t \\
=D f(\phi)-\int_{a}^{b} D f(t) \phi(t) d t=0
\end{gathered}
$$

By Lemma 36.2.3, there exists a constant, $C$, such that

$$
\left(f(\cdot)-\int_{a}^{(\cdot)} D f(t) d t\right)(\phi)=\int_{a}^{b} C \phi(x) d x
$$

for all $\phi \in C_{c}^{\infty}(a, b)$. Thus

$$
\int_{a}^{b}\left\{\left(f(x)-\int_{a}^{x} D f(t) d t\right)-C\right\} \boldsymbol{\phi}(x) d x=0
$$

for all $\phi \in C_{c}^{\infty}(a, b)$. It follows from Lemma 36.3.3 in the next section that

$$
f(x)-\int_{a}^{x} D f(t) d t-C=0 \text { a.e. } x
$$

Thus let $f(a)=C$ and write

$$
f(x)=f(a)+\int_{a}^{x} D f(t) d t
$$

This proves Theorem 36.2.2.
Theorem 36.2.2 says that

$$
f(x)=f(a)+\int_{a}^{x} D f(t) d t
$$

whenever it makes sense to write $\int_{a}^{x} D f(t) d t$, if $D f$ is interpreted as a weak derivative. Somehow, this is the way it ought to be. It follows from the fundamental theorem of calculus that $f^{\prime}(x)$ exists for a.e. $x$ where the derivative is taken in the sense of a limit of difference quotients and $f^{\prime}(x)=D f(x)$. This raises an interesting question. Suppose $f$ is continuous on $[a, b]$ and $f^{\prime}(x)$ exists in the classical sense for a.e. $x$. Does it follow that

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t ?
$$

The answer is no. To see an example, consider Problem 4 on Page 970 which gives an example of a function which is continuous on $[0,1]$, has a zero derivative for a.e. $x$ but climbs from 0 to 1 on $[0,1]$. Thus this function is not recovered from integrating its classical derivative.

In summary, if the notion of weak derivative is used, one can at least give meaning to the derivative of almost anything, the mixed partial derivatives are always equal, and, in one dimension, one can recover the function from integrating its derivative. None of these claims are true for the classical derivative. Thus weak derivatives are convenient and rule out pathologies.

### 36.3 Weak Derivatives In $L_{l o c}^{p}$

Definition 36.3.1 Let $U$ be an open set in $\mathbb{R}^{n} . f \in L_{l o c}^{p}(U)$ if $f \mathscr{X}_{K} \in L^{p}$ whenever $K$ is a compact subset of $U$.

Definition 36.3.2 For $\alpha=\left(k_{1}, \cdots, k_{n}\right)$ where the $k_{i}$ are nonnegative integers, define

$$
|\alpha| \equiv \sum_{i=1}^{n}\left|k_{x_{i}}\right|, D^{\alpha} f(\mathbf{x}) \equiv \frac{\partial^{|\alpha|} f(\mathbf{x})}{\partial x_{1}^{k_{1}} \partial x_{2}^{k_{2}} \cdots \partial x_{n}^{k_{n}}}
$$

Also define $\phi_{k}$ to be a mollifier if

$$
\operatorname{spt}\left(\phi_{k}\right) \subseteq B\left(\mathbf{0}, \frac{1}{k}\right), \phi_{k} \geq 0
$$

, $\int \phi_{k} d x=1$, and $\phi_{k} \in C_{c}^{\infty}\left(B\left(\mathbf{0}, \frac{1}{k}\right)\right)$. In the case a Greek letter like $\delta$ or $\varepsilon$ is used as a subscript, it will mean $\operatorname{spt}\left(\phi_{\delta}\right) \subseteq B(\mathbf{0}, \boldsymbol{\delta}), \phi_{\delta} \geq 0, \int \phi_{\delta} d x=1$, and $\phi_{\delta} \in C_{c}^{\infty}(B(\mathbf{0}, \boldsymbol{\delta}))$. You can always get a mollifier by letting $\phi \geq 0, \phi \in C_{c}^{\infty}(B(\mathbf{0}, 1)), \int \phi d x=1$, and then defining $\phi_{k}(\mathbf{x}) \equiv k^{n} \phi(k \mathbf{x})$ or in the case of a Greek subscript, $\phi_{\delta}(\mathbf{x})=\frac{1}{\delta^{n}} \phi\left(\frac{\mathbf{x}}{\delta}\right)$.

Consider the case where $u$ and $D^{\alpha} u$ for $|\alpha|=1$ are each in $L_{l o c}^{p}\left(\mathbb{R}^{n}\right)$. The next lemma is the one alluded to in the proof of Theorem 36.2.2.

Lemma 36.3.3 Suppose $f \in L_{l o c}^{1}(U)$ and suppose

$$
\int f \phi d x=0
$$

for all $\phi \in C_{c}^{\infty}(U)$. Then $f(\mathbf{x})=0$ a.e. $\mathbf{x}$.
Proof: Without loss of generality $f$ is real valued. Let

$$
E \equiv\{\mathbf{x}: f(\mathbf{x})>\varepsilon\}
$$

and let

$$
E_{m} \equiv E \cap B(0, m)
$$

Is $m\left(E_{m}\right)=0$ ? If not, there exists an open set, $V$, and a compact set $K$ satisfying

$$
\begin{gathered}
K \subseteq E_{m} \subseteq V \subseteq B(0, m), m(V \backslash K)<4^{-1} m\left(E_{m}\right), \\
\int_{V \backslash K}|f| d x<\varepsilon 4^{-1} m\left(E_{m}\right)
\end{gathered}
$$

Let $H$ and $W$ be open sets satisfying

$$
K \subseteq H \subseteq \bar{H} \subseteq W \subseteq \bar{W} \subseteq V
$$

and let

$$
\bar{H} \prec g \prec W
$$

where the symbol, $\prec$, in the above implies $\operatorname{spt}(g) \subseteq W, g$ has all values in $[0,1]$, and $g(\mathbf{x})=1$ on $\bar{H}$. Then let $\phi_{\delta}$ be a mollifier and let $h \equiv g * \phi_{\delta}$ for $\delta$ small enough that

$$
K \prec h \prec V .
$$

Thus

$$
\begin{aligned}
0 & =\int f h d x=\int_{K} f d x+\int_{V \backslash K} f h d x \\
& \geq \varepsilon m(K)-\varepsilon 4^{-1} m\left(E_{m}\right) \\
& \geq \varepsilon\left(m\left(E_{m}\right)-4^{-1} m\left(E_{m}\right)\right)-\varepsilon 4^{-1} m\left(E_{m}\right) \\
& \geq 2^{-1} \varepsilon m\left(E_{m}\right)
\end{aligned}
$$

Therefore, $m\left(E_{m}\right)=0$, a contradiction. Thus

$$
m(E) \leq \sum_{m=1}^{\infty} m\left(E_{m}\right)=0
$$

and so, since $\varepsilon>0$ is arbitrary,

$$
m(\{\mathbf{x}: f(\mathbf{x})>0\})=0
$$

Similarly $m(\{\mathbf{x}: f(\mathbf{x})<0\})=0$. This proves the lemma.
This lemma allows the following definition.
Definition 36.3.4 Let $U$ be an open subset of $\mathbb{R}^{n}$ and let $u \in L_{l o c}^{1}(U)$. Then $D^{\alpha} u \in L_{l o c}^{1}(U)$ if there exists a function $g \in L_{l o c}^{1}(U)$, necessarily unique by Lemma 36.3.3, such that for all $\phi \in C_{c}^{\infty}(U)$,

$$
\int_{U} g \phi d x=D^{\alpha} u(\phi) \equiv \int_{U}(-1)^{|\alpha|} u\left(D^{\alpha} \phi\right) d x
$$

Then $D^{\alpha} u$ is defined to equal $g$ when this occurs.
Lemma 36.3.5 Let $u \in L_{\text {loc }}^{1}\left(\mathbb{R}^{n}\right)$ and suppose $u_{, i} \in L_{\text {loc }}^{1}\left(\mathbb{R}^{n}\right)$, where the subscript on the $u$ following the comma denotes the $i^{\text {th }}$ weak partial derivative. Then if $\phi_{\varepsilon}$ is a mollifier and $u_{\varepsilon} \equiv u * \phi_{\varepsilon}$, it follows $u_{\varepsilon, i} \equiv u_{, i} * \phi_{\varepsilon}$.

Proof: If $\psi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$, then

$$
\begin{aligned}
\int u(\mathbf{x}-\mathbf{y}) \psi_{, i}(\mathbf{x}) d x & =\int u(\mathbf{z}) \psi_{, i}(\mathbf{z}+\mathbf{y}) d z \\
& =-\int u_{, i}(\mathbf{z}) \psi(\mathbf{z}+\mathbf{y}) d z \\
& =-\int u_{, i}(\mathbf{x}-\mathbf{y}) \psi(\mathbf{x}) d x
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
u_{\varepsilon, i}(\psi) & =-\int u_{\varepsilon} \psi_{, i}=-\iint u(\mathbf{x}-\mathbf{y}) \phi_{\varepsilon}(\mathbf{y}) \psi_{, i}(\mathbf{x}) d y d x \\
& =-\iint u(\mathbf{x}-\mathbf{y}) \psi_{, i}(\mathbf{x}) \phi_{\varepsilon}(\mathbf{y}) d x d y \\
& =\iint u_{, i}(\mathbf{x}-\mathbf{y}) \psi(\mathbf{x}) \phi_{\varepsilon}(\mathbf{y}) d x d y \\
& =\int u_{, i} * \phi_{\varepsilon}(\mathbf{x}) \psi(\mathbf{x}) d x
\end{aligned}
$$

The technical questions about product measurability in the use of Fubini's theorem may be resolved by picking a Borel measurable representative for $u$. This proves the lemma.

What about the product rule? Does it have some form in the context of weak derivatives?

Lemma 36.3.6 Let $U$ be an open set, $\psi \in C^{\infty}(U)$ and suppose $u, u_{, i} \in L_{\text {loc }}^{p}(U)$. Then $(u \psi)_{, i}$ and $u \psi$ are in $L_{l o c}^{p}(U)$ and

$$
(u \psi)_{, i}=u_{, i} \psi+u \psi_{, i} .
$$

Proof: Let $\phi \in C_{c}^{\infty}(U)$ then

$$
\begin{aligned}
(u \psi)_{, i}(\phi) & \equiv-\int_{U} u \psi \phi_{, i} d x \\
& =-\int_{U} u\left[(\psi \phi)_{, i}-\phi \psi_{, i}\right] d x \\
& =\int_{U}\left(u_{, i} \psi \phi+u \psi_{, i} \phi\right) d x \\
& =\int_{U}\left(u_{, i} \psi+u \psi_{, i}\right) \phi d x
\end{aligned}
$$

This proves the lemma.
Recall the notation for the gradient of a function.

$$
\nabla u(\mathbf{x}) \equiv\left(u_{, 1}(\mathbf{x}) \cdots u_{, n}(\mathbf{x})\right)^{T}
$$

thus

$$
D u(\mathbf{x}) \mathbf{v}=\nabla u(\mathbf{x}) \cdot \mathbf{v}
$$

### 36.4 Morrey's Inequality

The following inequality will be called Morrey's inequality. It relates an expression which is given pointwise to an integral of the $p^{t h}$ power of the derivative.

Lemma 36.4.1 Let $u \in C^{1}\left(\mathbb{R}^{n}\right)$ and $p>n$. Then there exists a constant, $C$, depending only on $n$ such that for any $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{n}$,

$$
\begin{gather*}
|u(\mathbf{x})-u(\mathbf{y})| \\
\leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}\left(|\mathbf{x}-\mathbf{y}|^{(1-n / p)}\right) . \tag{36.4.1}
\end{gather*}
$$

Proof: In the argument $C$ will be a generic constant which depends on $n$. Consider the following picture.

This is a picture of two balls of radius $r$ in $\mathbb{R}^{n}, U$ and $V$ having centers at $\mathbf{x}$ and $\mathbf{y}$ respectively, which intersect in the set, $W$. The center of $U$ is on the boundary of $V$ and the
center of $V$ is on the boundary of $U$ as shown in the picture. There exists a constant, $C$, independent of $r$ depending only on $n$ such that

$$
\frac{m(W)}{m(U)}=\frac{m(W)}{m(V)}=C
$$

You could compute this constant if you desired but it is not important here.
Define the average of a function over a set, $E \subseteq \mathbb{R}^{n}$ as follows.

$$
f_{E} f d x \equiv \frac{1}{m(E)} \int_{E} f d x
$$

Then

$$
\begin{aligned}
|u(\mathbf{x})-u(\mathbf{y})| & =f_{W}|u(\mathbf{x})-u(\mathbf{y})| d z \\
& \leq f_{W}|u(\mathbf{x})-u(\mathbf{z})| d z+f_{W}|u(\mathbf{z})-u(\mathbf{y})| d z \\
& =\frac{C}{m(U)}\left[\int_{W}|u(\mathbf{x})-u(\mathbf{z})| d z+\int_{W}|u(\mathbf{z})-u(\mathbf{y})| d z\right] \\
& \leq C\left[f_{U}|u(\mathbf{x})-u(\mathbf{z})| d z+f_{V}|u(\mathbf{y})-u(\mathbf{z})| d z\right]
\end{aligned}
$$

Now consider these two terms. Using spherical coordinates and letting $U_{0}$ denote the ball of the same radius as $U$ but with center at $\mathbf{0}$,

$$
\begin{aligned}
& f_{U}|u(\mathbf{x})-u(\mathbf{z})| d z \\
= & \frac{1}{m\left(U_{0}\right)} \int_{U_{0}}|u(\mathbf{x})-u(\mathbf{z}+\mathbf{x})| d z \\
= & \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{n-1} \int_{S^{n-1}}|u(\mathbf{x})-u(\rho \mathbf{w}+\mathbf{x})| d \sigma(w) d \rho \\
\leq & \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{n-1} \int_{S^{n-1}} \int_{0}^{\rho}|\nabla u(\mathbf{x}+t \mathbf{w}) \cdot \mathbf{w}| d t d \sigma d \rho \\
\leq & \frac{1}{m\left(U_{0}\right)} \int_{0}^{r} \rho^{n-1} \int_{S^{n-1}} \int_{0}^{\rho}|\nabla u(\mathbf{x}+t \mathbf{w})| d t d \sigma d \rho \\
\leq & C \frac{1}{r} \int_{0}^{r} \int_{S^{n-1}} \int_{0}^{r}|\nabla u(\mathbf{x}+t \mathbf{w})| d t d \sigma d \rho \\
= & C \frac{1}{r} \int_{0}^{r} \int_{S^{n-1}} \int_{0}^{r} \frac{|\nabla u(\mathbf{x}+t \mathbf{w})|}{t^{n-1}} t^{n-1} d t d \sigma d \rho
\end{aligned}
$$

$$
\begin{aligned}
& =C \int_{S^{n-1}} \int_{0}^{r} \frac{|\nabla u(\mathbf{x}+t \mathbf{w})|}{t^{n-1}} t^{n-1} d t d \sigma \\
& =C \int_{U_{0}} \frac{|\nabla u(\mathbf{x}+\mathbf{z})|}{|\mathbf{z}|^{n-1}} d z \\
& \leq C\left(\int_{U_{0}}|\nabla u(\mathbf{x}+\mathbf{z})|^{p} d z\right)^{1 / p}\left(\int_{U}|\mathbf{z}|^{p^{\prime}-n p^{\prime}}\right)^{1 / p^{\prime}} \\
& =C\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}\left(\int_{S^{n-1}} \int_{0}^{r} \rho^{p^{\prime}-n p^{\prime}} \rho^{n-1} d \rho d \sigma\right)^{(p-1) / p} \\
& =C\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}\left(\int_{S^{n-1}} \int_{0}^{r} \frac{1}{\left.\rho^{\frac{n-1}{p-1}} d \rho d \sigma\right)^{(p-1) / p}}\right. \\
& =C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p} r^{1-\frac{n}{p}} \\
& =C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{U}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}}
\end{aligned}
$$

Similarly,

$$
f_{V}|u(\mathbf{y})-u(\mathbf{z})| d z \leq C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{V}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}}
$$

Therefore,

$$
|u(\mathbf{x})-u(\mathbf{y})| \leq C\left(\frac{p-1}{p-n}\right)^{(p-1) / p}\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}}
$$

because $B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|) \supseteq V \cup U$. This proves the lemma.
The following corollary is also interesting
Corollary 36.4.2 Suppose $u \in C^{1}\left(\mathbb{R}^{n}\right)$. Then

$$
\begin{gather*}
|u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})| \\
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}| . \tag{36.4.2}
\end{gather*}
$$

Proof: This follows easily from letting $g(\mathbf{y}) \equiv u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})$. Then $g \in C^{1}\left(\mathbb{R}^{n}\right), g(\mathbf{x})=0$, and $\nabla g(\mathbf{z})=\nabla u(\mathbf{z})-\nabla u(\mathbf{x})$. From Lemma 36.4.1,

$$
\begin{aligned}
& |u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})| \\
= & |g(\mathbf{y})|=|g(\mathbf{y})-g(\mathbf{x})| \\
\leq & C\left(\int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}} \\
= & C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}| .
\end{aligned}
$$

This proves the corollary.
It may be interesting at this point to recall the definition of differentiability on Page 117. If you knew the above inequality held for $\nabla u$ having components in $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$, then at Lebesgue points of $\nabla u$, the above would imply $D u(\mathbf{x})$ exists. This is exactly the approach taken below.

### 36.5 Rademacher's Theorem

The inequality of Corollary 36.4 .2 can be extended to the case where $u$ and $u_{, i}$ are in $L_{l o c}^{p}\left(\mathbb{R}^{n}\right)$ for $p>n$. This leads to an elegant proof of the differentiability a.e. of a Lipschitz continuous function as well as a more general theorem.

Theorem 36.5.1 Suppose $u$ and all its weak partial derivatives, $u_{, i}$ are in $L_{\text {loc }}^{p}\left(\mathbb{R}^{n}\right)$. Then there exists a set of measure zero, $E$ such that if $\mathbf{x}, \mathbf{y} \notin E$ then inequalities 36.4.2 and 36.4.1 are both valid. Furthermore, u equals a continuous function a.e.

Proof: Let $u \in L_{l o c}^{p}\left(\mathbb{R}^{n}\right)$ and $\psi_{k} \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right), \psi_{k} \geq 0$, and $\psi_{k}(\mathbf{z})=1$ for all $\mathbf{z} \in B(\mathbf{0}, k)$. Then it is routine to verify that

$$
u \psi_{k},\left(u \psi_{k}\right)_{, i} \in L^{p}\left(\mathbb{R}^{n}\right)
$$

Here is why:

$$
\begin{aligned}
\left(u \psi_{k}\right)_{, i}(\phi) & \equiv-\int_{\mathbb{R}^{n}} u \psi_{k} \phi_{, i} d x \\
& =-\int_{\mathbb{R}^{n}} u \psi_{k} \phi_{, i} d x-\int_{\mathbb{R}^{n}} u \psi_{k, i} \phi d x+\int_{\mathbb{R}^{n}} u \psi_{k, i} \phi d x \\
& =-\int_{\mathbb{R}^{n}} u\left(\psi_{k} \phi\right)_{, i} d x+\int_{\mathbb{R}^{n}} u \psi_{k, i} \phi d x \\
& =\int_{\mathbb{R}^{n}}\left(u_{, i} \psi_{k}+u \psi_{k, i}\right) \phi d x
\end{aligned}
$$

which shows

$$
\left(u \psi_{k}\right)_{, i}=u_{, i} \psi_{k}+u \psi_{k, i}
$$

as expected.
Let $\phi_{\varepsilon}$ be a mollifier and consider

$$
\left(u \psi_{k}\right)_{\varepsilon} \equiv u \psi_{k} * \phi_{\varepsilon}
$$

By Lemma 36.3.5 on Page 1281,

$$
\left(u \psi_{k}\right)_{\varepsilon, i}=\left(u \psi_{k}\right)_{, i} * \phi_{\varepsilon}
$$

Therefore

$$
\begin{equation*}
\left(u \psi_{k}\right)_{\mathcal{\varepsilon}, i} \rightarrow\left(u \psi_{k}\right)_{, i} \text { in } L^{p}\left(\mathbb{R}^{n}\right) \tag{36.5.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(u \psi_{k}\right)_{\varepsilon} \rightarrow u \psi_{k} \operatorname{in} L^{p}\left(\mathbb{R}^{n}\right) \tag{36.5.4}
\end{equation*}
$$

as $\varepsilon \rightarrow 0$. By 36.5.4, there exists a subsequence $\varepsilon \rightarrow 0$ such that for $|\mathbf{z}|<k$ and for each $i=1,2, \cdots, n$

$$
\begin{gather*}
\left(u \psi_{k}\right)_{\varepsilon, i}(\mathbf{z}) \rightarrow\left(u \psi_{k}\right)_{, i}(\mathbf{z})=u_{, i}(\mathbf{z}) \text { a.e. } \\
\quad\left(u \psi_{k}\right)_{\varepsilon}(\mathbf{z}) \rightarrow u \psi_{k}(\mathbf{z})=u(\mathbf{z}) \text { a.e. } \tag{36.5.5}
\end{gather*}
$$

Denoting the exceptional set by $E_{k}$, let

$$
\mathbf{x}, \mathbf{y} \notin \cup_{k=1}^{\infty} E_{k} \equiv E
$$

and let $k$ be so large that

$$
B(\mathbf{0}, k) \supseteq B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|) .
$$

Then by 36.4.1 and for $\mathbf{x}, \mathbf{y} \notin E$,

$$
\begin{gathered}
\left|\left(u \psi_{k}\right)_{\varepsilon}(\mathbf{x})-\left(u \psi_{k}\right)_{\varepsilon}(\mathbf{y})\right| \\
\leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{y}-\mathbf{x}|)}\left|\nabla\left(u \psi_{k}\right)_{\varepsilon}\right|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{(1-n / p)}
\end{gathered}
$$

where $C$ depends only on $n$. Similarly, by 36.4.2,

$$
\begin{gathered}
\left|\left(u \psi_{k}\right)_{\varepsilon}(\mathbf{x})-\left(u \psi_{k}\right)_{\varepsilon}(\mathbf{y})-\nabla\left(u \psi_{k}\right)_{\mathcal{\varepsilon}}(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})\right| \leq \\
C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}\left|\nabla\left(u \psi_{k}\right)_{\mathcal{\varepsilon}}(\mathbf{z})-\nabla\left(u \psi_{k}\right)_{\mathcal{\varepsilon}}(\mathbf{x})\right|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}| .
\end{gathered}
$$

Now by 36.5 .5 and 36.5 .3 passing to the limit as $\varepsilon \rightarrow 0$ yields

$$
\begin{equation*}
|u(\mathbf{x})-u(\mathbf{y})| \leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{y}-\mathbf{x}|)}|\nabla u|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{(1-n / p)} \tag{36.5.6}
\end{equation*}
$$

and

$$
\begin{gather*}
|u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})| \\
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}| . \tag{36.5.7}
\end{gather*}
$$

Redefining $u$ on the set of mesure zero, $E$ yields 36.5 .6 for all $\mathbf{x}, \mathbf{y}$. This proves the theorem.
Corollary 36.5.2 Let $u, u_{, i} \in L_{l o c}^{p}\left(\mathbb{R}^{n}\right)$ for $i=1, \cdots, n$ and $p>n$. Then the representative of $u$ described in Theorem 36.5.1 is differentiable a.e.

Proof: From Theorem 36.5.1

$$
\begin{gather*}
|u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})| \\
\leq C\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}| \tag{36.5.8}
\end{gather*}
$$

and at every Lebesgue point, $\mathbf{x}$ of $\nabla u$

$$
\lim _{\mathbf{y} \rightarrow \mathbf{x}}\left(\frac{1}{m(B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|))} \int_{B(\mathbf{x}, 2|\mathbf{x}-\mathbf{y}|)}|\nabla u(\mathbf{z})-\nabla u(\mathbf{x})|^{p} d z\right)^{1 / p}=0
$$

and so at each of these points,

$$
\lim _{\mathbf{y} \rightarrow \mathbf{x}} \frac{|u(\mathbf{y})-u(\mathbf{x})-\nabla u(\mathbf{x}) \cdot(\mathbf{y}-\mathbf{x})|}{|\mathbf{x}-\mathbf{y}|}=0
$$

which says that $u$ is differentiable at $\mathbf{x}$ and $D u(\mathbf{x})(\mathbf{v})=\nabla u(\mathbf{x}) \cdot(\mathbf{v})$. See Page 117. This proves the corollary.

Definition 36.5.3 Now suppose $u$ is Lipschitz on $\mathbb{R}^{n}$,

$$
|u(\mathbf{x})-u(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

for some constant $K$. Define $\operatorname{Lip}(u)$ as the smallest value of $K$ that works in this inequality.
The following corollary is known as Rademacher's theorem. It states that every Lipschitz function is differentiable a.e.

Corollary 36.5.4 If $u$ is Lipschitz continuous then $u$ is differentiable a.e. and $\left\|u_{, i}\right\|_{\infty} \leq$ $\operatorname{Lip}(u)$.

Proof: This is done by showing that Lipschitz continuous functions have weak derivatives in $L^{\infty}\left(\mathbb{R}^{n}\right)$ and then using the previous results. Let

$$
D_{\mathbf{e}_{i}}^{h} u(\mathbf{x}) \equiv h^{-1}\left[u\left(\mathbf{x}+h \mathbf{e}_{i}\right)-u(\mathbf{x})\right] .
$$

Then $D_{\mathbf{e}_{i}}^{h} u$ is bounded in $L^{\infty}\left(\mathbb{R}^{n}\right)$ and

$$
\left\|D_{\mathbf{e}_{i}}^{h} u\right\|_{\infty} \leq \operatorname{Lip}(u)
$$

It follows that $D_{\mathbf{e}_{i}}^{h} u$ is contained in a ball in $L^{\infty}\left(\mathbb{R}^{n}\right)$, the dual space of $L^{1}\left(\mathbb{R}^{n}\right)$. By Theorem 36.1.3 on Page 1276, there is a subsequence $h \rightarrow 0$ such that

$$
D_{\mathbf{e}_{i}}^{h} u \rightharpoonup w,\|w\|_{\infty} \leq \operatorname{Lip}(u)
$$

where the convergence takes place in the weak $*$ topology of $L^{\infty}\left(\mathbb{R}^{n}\right)$. Let $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. Then

$$
\begin{gathered}
\int w \phi d x=\lim _{h \rightarrow 0} \int D_{\mathbf{e}_{i}}^{h} u \phi d x \\
=\lim _{h \rightarrow 0} \int u(\mathbf{x}) \frac{\left(\phi\left(\mathbf{x}-h \mathbf{e}_{i}\right)-\phi(\mathbf{x})\right)}{h} d x \\
=-\int u(\mathbf{x}) \phi_{, i}(\mathbf{x}) d x
\end{gathered}
$$

Thus $w=u_{, i}$ and $u_{, i} \in L^{\infty}\left(\mathbb{R}^{n}\right)$ for each $i$. Hence $u, u_{, i} \in L_{l o c}^{p}\left(\mathbb{R}^{n}\right)$ for all $p>n$ and so $u$ is differentiable a.e. by Corollary 36.5.2. This proves the corollary.

### 36.6 Change Of Variables Formula Lipschitz Maps

With Rademacher's theorem, one can give a general change of variables formula involving Lipschitz maps. First here is an elementary estimate.

Lemma 36.6.1 Suppose $V$ is an $n-1$ dimensional subspace of $\mathbb{R}^{n}$ and $K$ is a compact subset of $V$. Then letting

$$
K_{\varepsilon} \equiv \cup_{\mathbf{x} \in K} B(\mathbf{x}, \boldsymbol{\varepsilon})=K+B(\mathbf{0}, \varepsilon),
$$

it follows that

$$
m_{n}\left(K_{\varepsilon}\right) \leq 2^{n} \varepsilon(\operatorname{diam}(K)+\varepsilon)^{n-1}
$$

Proof: Let an orthonormal basis for $V$ be $\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{n-1}\right\}$ and let

$$
\left\{\mathbf{v}_{1}, \cdots, \mathbf{v}_{n-1}, \mathbf{v}_{n}\right\}
$$

be an orthonormal basis for $\mathbb{R}^{n}$. Now define a linear transformation, $Q$ by $Q \mathbf{v}_{i}=\mathbf{e}_{i}$. Thus $Q Q^{*}=Q^{*} Q=I$ and $Q$ preserves all distances because

$$
\left|Q \sum_{i} a_{i} \mathbf{e}_{i}\right|^{2}=\left|\sum_{i} a_{i} \mathbf{v}_{i}\right|^{2}=\sum_{i}\left|a_{i}\right|^{2}=\left|\sum_{i} a_{i} \mathbf{e}_{i}\right|^{2}
$$

Letting $\mathbf{k}_{0} \in K$, it follows $K \subseteq B\left(\mathbf{k}_{0}, \operatorname{diam}(K)\right)$ and so,

$$
Q K \subseteq B^{n-1}\left(Q \mathbf{k}_{0}, \operatorname{diam}(Q K)\right)=B^{n-1}\left(Q \mathbf{k}_{0}, \operatorname{diam}(K)\right)
$$

where $B^{n-1}$ refers to the ball taken with respect to the usual norm in $\mathbb{R}^{n-1}$. Every point of $K_{\varepsilon}$ is within $\varepsilon$ of some point of $K$ and so it follows that every point of $Q K_{\varepsilon}$ is within $\varepsilon$ of some point of $Q K$. Therefore,

$$
Q K_{\varepsilon} \subseteq B^{n-1}\left(Q \mathbf{k}_{0}, \operatorname{diam}(Q K)+\varepsilon\right) \times(-\varepsilon, \varepsilon)
$$

To see this, let $\mathbf{x} \in Q K_{\varepsilon}$. Then there exists $\mathbf{k} \in Q K$ such that $|\mathbf{k}-\mathbf{x}|<\varepsilon$. Therefore, $\left|\left(x_{1}, \cdots, x_{n-1}\right)-\left(k_{1}, \cdots, k_{n-1}\right)\right|<\varepsilon$ and $\left|x_{n}-k_{n}\right|<\varepsilon$ and so $\mathbf{x}$ is contained in the set on the right in the above inclusion because $k_{n}=0$. However, the measure of the set on the right is smaller than

$$
[2(\operatorname{diam}(Q K)+\varepsilon)]^{n-1}(2 \varepsilon)=2^{n}[(\operatorname{diam}(K)+\varepsilon)]^{n-1} \varepsilon
$$

This proves the lemma.
Next is the definition of a point of density. This is sort of like an interior point but not as good.

Definition 36.6.2 Let $E$ be a Lebesgue measurable set. $\mathbf{x} \in E$ is a point of density if

$$
\lim _{r \rightarrow 0} \frac{m(E \cap B(\mathbf{x}, r))}{m(B(\mathbf{x}, r))}=1
$$

You see that if $\mathbf{x}$ were an interior point of $E$, then this limit will equal 1. However, it is sometimes the case that the limit equals 1 even when $\mathbf{x}$ is not an interior point. In fact, these points of density make sense even for sets that have empty interior.

Lemma 36.6.3 Let $E$ be a Lebesgue measurable set. Then there exists a set of measure zero, $N$, such that if $\mathbf{x} \in E \backslash N$, then $\mathbf{x}$ is a point of density of $E$.

Proof: Consider the function, $f(\mathbf{x})=\mathscr{X}_{E}(\mathbf{x})$. This function is in $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$. Let $N^{C}$ denote the Lebesgue points of $f$. Then for $\mathbf{x} \in E \backslash N$,

$$
\begin{aligned}
1 & =\mathscr{X}_{E}(\mathbf{x})=\lim _{r \rightarrow 0} \frac{1}{m_{n}(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} \mathscr{X}_{E}(\mathbf{y}) d m_{n} \\
& =\lim _{r \rightarrow 0} \frac{m_{n}(B(\mathbf{x}, r) \cap E)}{m_{n}(B(\mathbf{x}, r))}
\end{aligned}
$$

In this section, $\Omega$ will be a Lebesgue measurable set in $\mathbb{R}^{n}$ and $\mathbf{h}: \Omega \rightarrow \mathbb{R}^{n}$ will be Lipschitz. Recall the following definition and theorems. See Page 13.4.2 for the proofs and more discussion.

Definition 36.6.4 Let $\mathscr{F}$ be a collection of balls that cover a set, $E$, which have the property that if $\mathbf{x} \in E$ and $\varepsilon>0$, then there exists $B \in \mathscr{F}$, diameter of $B<\varepsilon$ and $\mathbf{x} \in B$. Such a collection covers $E$ in the sense of Vitali.

Theorem 36.6.5 Let $E \subseteq \mathbb{R}^{n}$ and suppose $\overline{m_{n}}(E)<\infty$ where $\overline{m_{n}}$ is the outer measure determined by $m_{n}, n$ dimensional Lebesgue measure, and let $\mathscr{F}$, be a collection of closed balls of bounded radii such that $\mathscr{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathscr{F},\left\{B_{j}\right\}_{j=1}^{\infty}$, such that $\overline{m_{n}}\left(E \backslash \cup_{j=1}^{\infty} B_{j}\right)=0$.

Now this theorem implies a simple lemma which is what will be used.
Lemma 36.6.6 Let $V$ be an open set in $\mathbb{R}^{r}, m_{r}(V)<\infty$. Then there exists a sequence of disjoint open balls $\left\{B_{i}\right\}$ having radii less than $\delta$ and a set of measure $0, T$, such that

$$
V=\left(\cup_{i=1}^{\infty} B_{i}\right) \cup T
$$

As in the proof of the change of variables theorem given earlier, the first step is to show that $\mathbf{h}$ maps Lebesgue measurable sets to Lebesgue measurable sets. In showing this the key result is the next lemma which states that $\mathbf{h}$ maps sets of measure zero to sets of measure zero.

Lemma 36.6.7 If $m_{n}(T)=0$ then $m_{n}(\mathbf{h}(T))=0$.
Proof: Let $V$ be an open set containing $T$ whose measure is less than $\varepsilon$. Now using the Vitali covering theorem, there exists a sequence of disjoint balls $\left\{B_{i}\right\}, B_{i}=B\left(\mathbf{x}_{i}, r_{i}\right)$ which are contained in $V$ such that the sequence of enlarged balls, $\left\{\widehat{B}_{i}\right\}$, having the same center but 5 times the radius, covers $T$. Then

$$
m_{n}(\mathbf{h}(T)) \leq m_{n}\left(\mathbf{h}\left(\cup_{i=1}^{\infty} \widehat{B}_{i}\right)\right)
$$

$$
\begin{aligned}
& \leq \sum_{i=1}^{\infty} m_{n}\left(\mathbf{h}\left(\widehat{B}_{i}\right)\right) \\
& \leq \sum_{i=1}^{\infty} \alpha(n)(\operatorname{Lip}(\mathbf{h}))^{n} 5^{n} r_{i}^{n}=5^{n}(\operatorname{Lip}(\mathbf{h}))^{n} \sum_{i=1}^{\infty} m_{n}\left(B_{i}\right) \\
& \leq \quad(\operatorname{Lip}(\mathbf{h}))^{n} 5^{n} m_{n}(V) \leq \varepsilon(\operatorname{Lip}(\mathbf{h}))^{n} 5^{n} .
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this proves the lemma.
With the conclusion of this lemma, the next lemma is fairly easy to obtain.
Lemma 36.6.8 If A is Lebesgue measurable, then $\mathbf{h}(A)$ is $m_{n}$ measurable. Furthermore,

$$
\begin{equation*}
m_{n}(\mathbf{h}(A)) \leq(\operatorname{Lip}(\mathbf{h}))^{n} m_{n}(A) . \tag{36.6.9}
\end{equation*}
$$

Proof: Let $A_{k}=A \cap B(\mathbf{0}, k), k \in \mathbb{N}$. Let $V \supseteq A_{k}$ and let $m_{n}(V)<\infty$. By Lemma 36.6.6, there is a sequence of disjoint balls $\left\{B_{i}\right\}$ and a set of measure $0, T$, such that

$$
V=\cup_{i=1}^{\infty} B_{i} \cup T, B_{i}=B\left(x_{i}, r_{i}\right) .
$$

By Lemma 36.6.7,

$$
\begin{gathered}
\overline{m_{n}}\left(\mathbf{h}\left(A_{k}\right)\right) \leq \overline{m_{n}}(\mathbf{h}(V)) \\
\leq \overline{m_{n}}\left(\mathbf{h}\left(\cup_{i=1}^{\infty} B_{i}\right)\right)+\overline{m_{n}}(\mathbf{h}(T))=\overline{m_{n}}\left(\mathbf{h}\left(\cup_{i=1}^{\infty} B_{i}\right)\right) \\
\leq \sum_{i=1}^{\infty} \overline{m_{n}}\left(\mathbf{h}\left(B_{i}\right)\right) \leq \sum_{i=1}^{\infty} \overline{m_{n}}\left(B\left(\mathbf{h}\left(x_{i}\right), \operatorname{Lip}(\mathbf{h}) r_{i}\right)\right) \\
\leq \sum_{i=1}^{\infty} \alpha(n)\left(\operatorname{Lip}(\mathbf{h}) r_{i}\right)^{n}=\operatorname{Lip}(\mathbf{h})^{n} \sum_{i=1}^{\infty} m_{n}\left(B_{i}\right)=\operatorname{Lip}(\mathbf{h})^{n} m_{n}(V)
\end{gathered}
$$

Therefore,

$$
\overline{m_{n}}\left(\mathbf{h}\left(A_{k}\right)\right) \leq \operatorname{Lip}(\mathbf{h})^{n} m_{n}(V) .
$$

Since $V$ is an arbitrary open set containing $A_{k}$, it follows from regularity of Lebesgue measure that

$$
\begin{equation*}
\overline{m_{n}}\left(\mathbf{h}\left(A_{k}\right)\right) \leq \operatorname{Lip}(\mathbf{h})^{n} m_{n}\left(A_{k}\right) . \tag{36.6.10}
\end{equation*}
$$

Now let $k \rightarrow \infty$ to obtain 36.6.9. This proves the formula. It remains to show $\mathbf{h}(A)$ is measurable.

By inner regularity of Lebesgue measure, there exists a set, $F$, which is the countable union of compact sets and a set $T$ with $m_{n}(T)=0$ such that

$$
F \cup T=A_{k} .
$$

Then $\mathbf{h}(F) \subseteq \mathbf{h}\left(A_{k}\right) \subseteq \mathbf{h}(F) \cup \mathbf{h}(T)$. By continuity of $\mathbf{h}, \mathbf{h}(F)$ is a countable union of compact sets and so it is Borel. By 36.6.10 with $T$ in place of $A_{k}$,

$$
\overline{m_{n}}(\mathbf{h}(T))=0
$$

and so $\mathbf{h}(T)$ is $m_{n}$ measurable. Therefore, $\mathbf{h}\left(A_{k}\right)$ is $m_{n}$ measurable because $m_{n}$ is a complete measure and this exhibits $\mathbf{h}\left(A_{k}\right)$ between two $m_{n}$ measurable sets whose difference has measure 0 . Now

$$
\mathbf{h}(A)=\cup_{k=1}^{\infty} \mathbf{h}\left(A_{k}\right)
$$

so $\mathbf{h}(A)$ is also $m_{n}$ measurable and this proves the lemma.
The following lemma, depending on the Brouwer fixed point theorem and found in Rudin [113], will be important for the following arguments. The idea is that if a continuous function mapping a ball in $\mathbb{R}^{k}$ to $\mathbb{R}^{k}$ doesn't move any point very much, then the image of the ball must contain a slightly smaller ball.

Lemma 36.6.9 Let $B=B(\mathbf{0}, r)$, a ball in $\mathbb{R}^{k}$ and let $\mathbf{F}: \bar{B} \rightarrow \mathbb{R}^{k}$ be continuous and suppose for some $\varepsilon<1$,

$$
|\mathbf{F}(\mathbf{v})-\mathbf{v}|<\varepsilon r
$$

for all $\mathbf{v} \in \bar{B}$. Then

$$
\mathbf{F}(\bar{B}) \supseteq \overline{B(\mathbf{0}, r(1-\varepsilon))}
$$

Proof: Suppose $\mathbf{a} \in \overline{B(\mathbf{0}, r(1-\boldsymbol{\varepsilon}))} \backslash \mathbf{F}(\bar{B})$ and let

$$
\mathbf{G}(\mathbf{v}) \equiv \frac{r(\mathbf{a}-\mathbf{F}(\mathbf{v}))}{|\mathbf{a}-\mathbf{F}(\mathbf{v})|}
$$

Then by the Brouwer fixed point theorem, $\mathbf{G}(\mathbf{v})=\mathbf{v}$ for some $\mathbf{v} \in \bar{B}$. Using the formula for $\mathbf{G}$, it follows $|\mathbf{v}|=r$. Taking the inner product with $\mathbf{v}$,

$$
\begin{aligned}
(\mathbf{G}(\mathbf{v}), \mathbf{v}) & =|\mathbf{v}|^{2}=r^{2}=\frac{r}{|\mathbf{a}-\mathbf{F}(\mathbf{v})|}(\mathbf{a}-\mathbf{F}(\mathbf{v}), \mathbf{v}) \\
& =\frac{r}{|\mathbf{a}-\mathbf{F}(\mathbf{v})|}(\mathbf{a}-\mathbf{v}+\mathbf{v}-\mathbf{F}(\mathbf{v}), \mathbf{v}) \\
& =\frac{r}{|\mathbf{a}-\mathbf{F}(\mathbf{v})|}[(\mathbf{a}-\mathbf{v}, \mathbf{v})+(\mathbf{v}-\mathbf{F}(\mathbf{v}), \mathbf{v})] \\
& =\frac{r}{|\mathbf{a}-\mathbf{F}(\mathbf{v})|}\left[(\mathbf{a}, \mathbf{v})-|\mathbf{v}|^{2}+(\mathbf{v}-\mathbf{F}(\mathbf{v}), \mathbf{v})\right] \\
& \leq \frac{r}{|\mathbf{a}-\mathbf{F}(\mathbf{v})|}\left[r^{2}(1-\varepsilon)-r^{2}+r^{2} \varepsilon\right]=0
\end{aligned}
$$

a contradiction. Therefore, $\overline{B(\mathbf{0}, r(1-\varepsilon))} \backslash \mathbf{F}(\bar{B})=\emptyset$ and this proves the lemma.
Now let $\Omega$ be a Lebesgue measurable set and suppose $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ is Lipschitz continuous and one to one on $\Omega$. Let

$$
\begin{gather*}
N \equiv\{\mathbf{x} \in \Omega: D \mathbf{h}(\mathbf{x}) \text { does not exist }\}  \tag{36.6.11}\\
S \equiv\left\{\mathbf{x} \in \Omega \backslash N: D \mathbf{h}(\mathbf{x})^{-1} \text { does not exist }\right\} \tag{36.6.12}
\end{gather*}
$$

Lemma 36.6.10 Let $\mathbf{x} \in \Omega \backslash(S \cup N)$. Then if $\varepsilon \in(0,1)$ the following hold for all $r$ small enough.

$$
\begin{equation*}
m_{n}(\mathbf{h}(\overline{B(\mathbf{x}, r)})) \geq m_{n}(D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r(1-\varepsilon))) \tag{36.6.13}
\end{equation*}
$$

$$
\begin{gather*}
\mathbf{h}(B(\mathbf{x}, r)) \subseteq \mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r(1+\varepsilon))  \tag{36.6.14}\\
m_{n}(\mathbf{h}(\overline{B(\mathbf{x}, r)})) \leq m_{n}(D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r(1+\varepsilon))) \tag{36.6.15}
\end{gather*}
$$

If $\mathbf{x} \in \Omega \backslash(S \cup N)$ is also a point of density of $\Omega$, then

$$
\begin{equation*}
\lim _{r \rightarrow 0} \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r) \cap \Omega))}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))}=1 \tag{36.6.16}
\end{equation*}
$$

If $\mathbf{x} \in \Omega \backslash N$, then

$$
\begin{equation*}
|\operatorname{det} D \mathbf{h}(\mathbf{x})|=\lim _{r \rightarrow 0} \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))}{m_{n}(B(\mathbf{x}, r))} \text { a.e. } \tag{36.6.17}
\end{equation*}
$$

Proof: Since $D \mathbf{h}(\mathbf{x})^{-1}$ exists,

$$
\begin{align*}
\mathbf{h}(\mathbf{x}+\mathbf{v}) & =\mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x}) \mathbf{v}+o(|\mathbf{v}|)  \tag{36.6.18}\\
& =\mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x})(\mathbf{v}+\overbrace{D \mathbf{h}(\mathbf{x})^{-1} o(|\mathbf{v}|)}^{=o(|\mathbf{v}|)}) \tag{36.6.19}
\end{align*}
$$

Consequently, when $r$ is small enough, 36.6 .14 holds. Therefore, 36.6 .15 holds. From 36.6.19, and the assumption that $D \mathbf{h}(\mathbf{x})^{-1}$ exists,

$$
\begin{equation*}
D \mathbf{h}(\mathbf{x})^{-1} \mathbf{h}(\mathbf{x}+\mathbf{v})-D \mathbf{h}(\mathbf{x})^{-1} \mathbf{h}(\mathbf{x})-\mathbf{v}=o(|\mathbf{v}|) \tag{36.6.20}
\end{equation*}
$$

Letting

$$
\mathbf{F}(\mathbf{v})=D \mathbf{h}(\mathbf{x})^{-1} \mathbf{h}(\mathbf{x}+\mathbf{v})-D \mathbf{h}(\mathbf{x})^{-1} \mathbf{h}(\mathbf{x})
$$

apply Lemma 36.6.9 in 36.6.20 to conclude that for $r$ small enough, whenever $|\mathbf{v}|<r$,

$$
D \mathbf{h}(\mathbf{x})^{-1} \mathbf{h}(\mathbf{x}+\mathbf{v})-D \mathbf{h}(\mathbf{x})^{-1} \mathbf{h}(\mathbf{x}) \supseteq B(\mathbf{0},(1-\varepsilon) r) .
$$

Therefore,

$$
\mathbf{h}(\overline{B(\mathbf{x}, r)}) \supseteq \mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x}) B(\mathbf{0},(1-\varepsilon) r)
$$

which implies

$$
m_{n}(\mathbf{h}(\overline{B(\mathbf{x}, r)})) \geq m_{n}(D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r(1-\boldsymbol{\varepsilon})))
$$

which shows 36.6.13.
Now suppose that $\mathbf{x}$ is a point of density of $\Omega$ as well as being a point where $D \mathbf{h}(\mathbf{x})^{-1}$ and $D \mathbf{h}(\mathbf{x})$ exist. Then whenever $r$ is small enough,

$$
1-\varepsilon<\frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r) \cap \Omega))}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))} \leq 1
$$

and so

$$
\begin{aligned}
1-\varepsilon & <\frac{m_{n}\left(\mathbf{h}\left(B(\mathbf{x}, r) \cap \Omega^{C}\right)\right)}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))}+\frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r) \cap \Omega))}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))} \\
& \leq \frac{m_{n}\left(\mathbf{h}\left(B(\mathbf{x}, r) \cap \Omega^{C}\right)\right)}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))}+1
\end{aligned}
$$

which implies

$$
\begin{equation*}
m_{n}(B(\mathbf{x}, r) \backslash \Omega)<\varepsilon \alpha(n) r^{n} . \tag{36.6.21}
\end{equation*}
$$

Then for such $r$,

$$
\begin{gathered}
1 \geq \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r) \cap \Omega))}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))} \\
\geq \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))-m_{n}(\mathbf{h}(B(\mathbf{x}, r) \backslash \Omega))}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))} .
\end{gathered}
$$

From Lemma 36.6.8, 36.6.21, and 36.6.13, this is no larger than

$$
1-\frac{\operatorname{Lip}(\mathbf{h})^{n} \varepsilon \alpha(n) r^{n}}{m_{n}(D \mathbf{h}(\mathbf{x}) B(\mathbf{0}, r(1-\varepsilon)))}
$$

By the theorem on the change of variables for a linear map, this expression equals

$$
1-\frac{\operatorname{Lip}(\mathbf{h})^{n} \varepsilon \alpha(n) r^{n}}{|\operatorname{det}(D \mathbf{h}(\mathbf{x}))| r^{n} \alpha(n)(1-\varepsilon)^{n}} \equiv 1-g(\varepsilon)
$$

where $\lim _{\varepsilon \rightarrow 0} g(\varepsilon)=0$. Then for all $r$ small enough,

$$
1 \geq \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r) \cap \Omega))}{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))} \geq 1-g(\varepsilon)
$$

which shows 36.6 .16 since $\varepsilon$ is arbitrary. It remains to verify 36.6.17.
In case $\mathbf{x} \in S$, for small $|\mathbf{v}|$,

$$
\mathbf{h}(\mathbf{x}+\mathbf{v})=\mathbf{h}(\mathbf{x})+D \mathbf{h}(\mathbf{x}) \mathbf{v}+o(|\mathbf{v}|)
$$

where $|o(|\mathbf{v}|)|<\varepsilon|\mathbf{v}|$. Therefore, for small enough $r$,

$$
\mathbf{h}(B(\mathbf{x}, r))-\mathbf{h}(\mathbf{x}) \subseteq K+B(\mathbf{0}, r \varepsilon)
$$

where $K$ is a compact subset of an $n-1$ dimensional subspace contained in $D \mathbf{h}(\mathbf{x})\left(\mathbb{R}^{n}\right)$ which has diameter no more than $2\|D \mathbf{h}(\mathbf{x})\| r$. By Lemma 36.6.1 on Page 1288,

$$
\begin{aligned}
m_{n}(\mathbf{h}(B(\mathbf{x}, r))) & =m_{n}(\mathbf{h}(B(\mathbf{x}, r))-\mathbf{h}(\mathbf{x})) \\
& \leq 2^{n} \varepsilon r(2\|D \mathbf{h}(\mathbf{x})\| r+r \varepsilon)^{n-1}
\end{aligned}
$$

and so, in this case, letting $r$ be small enough,

$$
\frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))}{m_{n}(B(\mathbf{x}, r))} \leq \frac{2^{n} \varepsilon r(2\|D \mathbf{h}(\mathbf{x})\| r+r \varepsilon)^{n-1}}{\alpha(n) r^{n}} \leq C \varepsilon
$$

Since $\varepsilon$ is arbitrary, the limit as $r \rightarrow 0$ of this quotient equals 0 .
If $\mathbf{x} \notin S$, use 36.6.13-36.6.15 along with the change of variables formula for linear maps. This proves the Lemma.

Since $\mathbf{h}$ is one to one, there exists a measure, $\mu$, defined by

$$
\mu(E) \equiv m_{n}(\mathbf{h}(E))
$$

on the Lebesgue measurable subsets of $\Omega$. By Lemma $36.6 .8 \mu \ll m_{n}$ and so by the Radon Nikodym theorem, there exists a nonnegative function, $J(\mathbf{x})$ in $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$ such that whenever $E$ is Lebesgue measurable,

$$
\begin{equation*}
\mu(E)=m_{n}(\mathbf{h}(E \cap \Omega))=\int_{E \cap \Omega} J(\mathbf{x}) d m_{n} \tag{36.6.22}
\end{equation*}
$$

Extend $J$ to equal zero off $\Omega$.
Lemma 36.6.11 The function, $J(\mathbf{x})$ equals $|\operatorname{det} D \mathbf{h}(\mathbf{x})|$ a.e.
Proof: Define

$$
\begin{aligned}
Q \equiv & \{\mathbf{x} \in \Omega: \mathbf{x} \text { is not a point of density of } \Omega\} \cup N \cup \\
& \{\mathbf{x} \in \Omega: \mathbf{x} \text { is not a Lebesgue point of } J\}
\end{aligned}
$$

Then $Q$ is a set of measure zero and if $\mathbf{x} \notin Q$, then by 36.6.17, and 36.6.16,

$$
\begin{aligned}
& |\operatorname{det} D \mathbf{h}(\mathbf{x})| \\
= & \lim _{r \rightarrow 0} \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))}{m_{n}(B(\mathbf{x}, r))} \\
= & \lim _{r \rightarrow 0} \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r)))}{m_{n}(\mathbf{h}(B(\mathbf{x}, r) \cap \Omega))} \frac{m_{n}(\mathbf{h}(B(\mathbf{x}, r) \cap \Omega))}{m_{n}(B(\mathbf{x}, r))} \\
= & \lim _{r \rightarrow 0} \frac{1}{m_{n}(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r) \cap \Omega} J(\mathbf{y}) d m_{n} \\
= & \lim _{r \rightarrow 0} \frac{1}{m_{n}(B(\mathbf{x}, r))} \int_{B(\mathbf{x}, r)} J(\mathbf{y}) d m_{n}=J(\mathbf{x}) .
\end{aligned}
$$

the last equality because $J$ was extended to be zero off $\Omega$. This proves the lemma.
Here is the change of variables formula for Lipschitz mappings. It is a special case of the area formula.

Theorem 36.6.12 Let $\Omega$ be a Lebesgue measurable set, let $f \geq 0$ be Lebesgue measurable. Then for $\mathbf{h}$ a Lipschitz mapping defined on $\mathbb{R}^{n}$ which is one to one on $\Omega$,

$$
\begin{equation*}
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d m_{n}=\int_{\Omega} f(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \mathbf{h}(\mathbf{x})| d m_{n} \tag{36.6.23}
\end{equation*}
$$

Proof: Let $F$ be a Borel set. It follows that $\mathbf{h}^{-1}(F)$ is a Lebesgue measurable set. Therefore, by 36.6.22,

$$
\begin{align*}
& m_{n}\left(\mathbf{h}\left(\mathbf{h}^{-1}(F) \cap \Omega\right)\right)  \tag{36.6.24}\\
= & \int_{\mathbf{h}(\Omega)} \mathscr{X}_{F}(\mathbf{y}) d m_{n}=\int_{\Omega} \mathscr{X}_{\mathbf{h}^{-1}(F)}(\mathbf{x}) J(\mathbf{x}) d m_{n} \\
= & \int_{\Omega} \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) d m_{n} .
\end{align*}
$$

What if $F$ is only Lebesgue measurable? Note there are no measurability problems with the above expression because $\mathbf{x} \rightarrow \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))$ is Borel measurable due to the assumption that $\mathbf{h}$ is continuous while $J$ is given to be Lebesgue measurable. However, if $F$ is Lebesgue measurable, not necessarily Borel measurable, then it is no longer clear that $\mathbf{x} \rightarrow \mathscr{X}_{F}(\mathbf{h}(\mathbf{x}))$ is measurable. In fact this is not always even true. However, $\mathbf{x} \rightarrow \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J(\mathbf{x})$ is measurable and 36.6.24 holds.

Let $F$ be Lebesgue measurable. Then by inner regularity, $F=H \cup N$ where $N$ has measure zero, $H$ is the countable union of compact sets so it is a Borel set, and $H \cap N=\emptyset$. Therefore, letting $N^{\prime}$ denote a Borel set of measure zero which contains $N$,

$$
\begin{aligned}
& b(\mathbf{x}) \equiv \mathscr{X}_{H}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) \leq \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) \\
= & \mathscr{X}_{H}(\mathbf{h}(\mathbf{x})) J(\mathbf{x})+\mathscr{X}_{N}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) \\
\leq & \mathscr{X}_{H}(\mathbf{h}(\mathbf{x})) J(\mathbf{x})+\mathscr{X}_{N^{\prime}}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) \equiv u(\mathbf{x})
\end{aligned}
$$

Now since $N^{\prime}$ is Borel,

$$
\begin{aligned}
& \int_{\Omega}(u(\mathbf{x})-b(\mathbf{x})) d m_{n}=\int_{\Omega} \mathscr{X}_{N^{\prime}}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) d m_{n} \\
& =m_{n}\left(\mathbf{h}\left(\mathbf{h}^{-1}\left(N^{\prime}\right) \cap \Omega\right)\right)=m_{n}\left(N^{\prime} \cap \mathbf{h}(\Omega)\right)=0
\end{aligned}
$$

and this shows $\mathscr{X}_{H}(\mathbf{h}(\mathbf{x})) J(\mathbf{x})=\mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J(\mathbf{x})$ except on a set of measure zero. By completeness of Lebesgue measure, it follows $\mathbf{x} \rightarrow \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J(\mathbf{x})$ is Lebesgue measurable and also since $\mathbf{h}$ maps sets of measure zero to sets of measure zero,

$$
\begin{aligned}
\int_{\Omega} \mathscr{X}_{F}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) d m_{n} & =\int_{\Omega} \mathscr{X}_{H}(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) d m_{n} \\
& =\int_{\mathbf{h}(\Omega)} \mathscr{X}_{H}(\mathbf{y}) d m_{n} \\
& =\int_{\mathbf{h}(\Omega)} \mathscr{X}_{F}(\mathbf{y}) d m_{n}
\end{aligned}
$$

It follows that if $s$ is any nonnegative Lebesgue measurable simple function,

$$
\begin{equation*}
\int_{\Omega} s(\mathbf{h}(\mathbf{x})) J(\mathbf{x}) d m_{n}=\int_{\mathbf{h}(\Omega)} s(\mathbf{y}) d m_{n} \tag{36.6.25}
\end{equation*}
$$

and now, if $f \geq 0$ is Lebesgue measurable, let $s_{k}$ be an increasing sequence of Lebesgue measurable simple functions converging pointwise to $f$. Then since 36.6 .25 holds for $s_{k}$, the monotone convergence theorem applies and yields 36.6.23. This proves the theorem.

It turns out that a Lipschitz function defined on some subset of $\mathbb{R}^{n}$ always has a Lipschitz extension to all of $\mathbb{R}^{n}$. The next theorem gives a proof of this. For more on this sort of theorem see Federer [50]. He gives a better but harder theorem than what follows.

Theorem 36.6.13 If $\mathbf{h}: \Omega \rightarrow \mathbb{R}^{m}$ is Lipschitz, then there exists $\overline{\mathbf{h}}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ which extends h and is also Lipschitz.

Proof: It suffices to assume $m=1$ because if this is shown, it may be applied to the components of $\mathbf{h}$ to get the desired result. Suppose

$$
\begin{equation*}
|h(\mathbf{x})-h(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}| \tag{36.6.26}
\end{equation*}
$$

Define

$$
\begin{equation*}
\bar{h}(\mathbf{x}) \equiv \inf \{h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|: \mathbf{w} \in \Omega\} \tag{36.6.27}
\end{equation*}
$$

If $\mathbf{x} \in \Omega$, then for all $\mathbf{w} \in \Omega$,

$$
h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}| \geq h(\mathbf{x})
$$

by 36.6.26. This shows $h(\mathbf{x}) \leqq \bar{h}(\mathbf{x})$. But also you could take $\mathbf{w}=\mathbf{x}$ in 36.6.27 which yields $\bar{h}(\mathbf{x}) \leq h(\mathbf{x})$. Therefore $\bar{h}(\mathbf{x})=h(\mathbf{x})$ if $\mathbf{x} \in \Omega$.

Now suppose $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{n}$ and consider $|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|$. Without loss of generality assume $\bar{h}(\mathbf{x}) \geq \bar{h}(\mathbf{y})$. (If not, repeat the following argument with $\mathbf{x}$ and $\mathbf{y}$ interchanged.) Pick $\mathbf{w} \in \Omega$ such that

$$
h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\varepsilon<\bar{h}(\mathbf{y})
$$

Then

$$
\begin{aligned}
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})|=\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y}) & \leq h(\mathbf{w})+K|\mathbf{x}-\mathbf{w}|- \\
{[h(\mathbf{w})+K|\mathbf{y}-\mathbf{w}|-\varepsilon] } & \leq K|\mathbf{x}-\mathbf{y}|+\varepsilon .
\end{aligned}
$$

Since $\varepsilon$ is arbitrary,

$$
|\bar{h}(\mathbf{x})-\bar{h}(\mathbf{y})| \leq K|\mathbf{x}-\mathbf{y}|
$$

and this proves the theorem.
This yields a simple corollary to Theorem 36.6.12.
Corollary 36.6.14 Let $\mathbf{h}: \Omega \rightarrow \mathbb{R}^{n}$ be Lipschitz continuous and one to one where $\Omega$ is a Lebesgue measurable set. Then if $f \geq 0$ is Lebesgue measurable,

$$
\begin{equation*}
\int_{\mathbf{h}(\Omega)} f(\mathbf{y}) d m_{n}=\int_{\Omega} f(\mathbf{h}(\mathbf{x}))|\operatorname{det} D \overline{\mathbf{h}}(\mathbf{x})| d m_{n} \tag{36.6.28}
\end{equation*}
$$

where $\overline{\mathbf{h}}$ denotes a Lipschitz extension of $\mathbf{h}$.

## Chapter 37

## Integration On Manifolds

You can do integration on various manifolds by using the Hausdorff measure of an appropriate dimension. However, it is possible to discuss this through the use of the Riesz representation theorem and some of the machinery for accomplishing this is interesting for its own sake so I will present this alternate point of view.

### 37.1 Partitions Of Unity

This material has already been mostly discussed starting on Page 1023. However, that was a long time ago and it seems like it might be good to go over it again and so, for the sake of convenience, here it is again.

Definition 37.1.1 Let $\mathfrak{C}$ be a set whose elements are subsets of $\mathbb{R}^{n} .{ }^{1}$ Then $\mathfrak{C}$ is said to be locally finite if for every $\mathbf{x} \in \mathbb{R}^{n}$, there exists an open set, $U_{\mathbf{x}}$ containing $\mathbf{x}$ such that $U_{\mathbf{x}}$ has nonempty intersection with only finitely many sets of $\mathfrak{C}$.

Lemma 37.1.2 Let $\mathfrak{C}$ be a set whose elements are open subsets of $\mathbb{R}^{n}$ and suppose $\cup \mathfrak{C} \supseteq H$, a closed set. Then there exists a countable list of open sets, $\left\{U_{i}\right\}_{i=1}^{\infty}$ such that each $U_{i}$ is bounded, each $U_{i}$ is a subset of some set of $\mathfrak{C}$, and $\cup_{i=1}^{\infty} U_{i} \supseteq H$.

Proof: Let $W_{k} \equiv B(\mathbf{0}, k), W_{0}=W_{-1}=\emptyset$. For each $\mathbf{x} \in H \cap \overline{W_{k}}$ there exists an open set, $U_{\mathbf{x}}$ such that $U_{\mathbf{x}}$ is a subset of some set of $\mathfrak{C}$ and $U_{\mathbf{x}} \subseteq W_{k+1} \backslash \overline{W_{k-1}}$. Then since $H \cap \overline{W_{k}}$ is compact, there exist finitely many of these sets, $\left\{U_{i}^{k}\right\}_{i=1}^{m(k)}$ whose union contains $H \cap \overline{W_{k}}$. If $H \cap \overline{W_{k}}=\emptyset$, let $m(k)=0$ and there are no such sets obtained.The desired countable list of open sets is $\cup_{k=1}^{\infty}\left\{U_{i}^{k}\right\}_{i=1}^{m(k)}$. Each open set in this list is bounded. Furthermore, if $\mathbf{x} \in \mathbb{R}^{n}$, then $\mathbf{x} \in W_{k}$ where $k$ is the first positive integer with $\mathbf{x} \in W_{k}$. Then $W_{k} \backslash \overline{W_{k-1}}$ is an open set containing $\mathbf{x}$ and this open set can have nonempty intersection only with with a set of $\left\{U_{i}^{k}\right\}_{i=1}^{m(k)} \cup\left\{U_{i}^{k-1}\right\}_{i=1}^{m(k-1)}$, a finite list of sets. Therefore, $\cup_{k=1}^{\infty}\left\{U_{i}^{k}\right\}_{i=1}^{m(k)}$ is locally finite.

The set, $\left\{U_{i}\right\}_{i=1}^{\infty}$ is said to be a locally finite cover of $H$. The following lemma gives some important reasons why a locally finite list of sets is so significant. First of all consider the rational numbers, $\left\{r_{i}\right\}_{i=1}^{\infty}$ each rational number is a closed set.

$$
\mathbb{Q}=\left\{r_{i}\right\}_{i=1}^{\infty}=\cup_{i=1}^{\infty} \overline{\left\{r_{i}\right\}} \neq \overline{\cup_{i=1}^{\infty}\left\{r_{i}\right\}}=\mathbb{R}
$$

The set of rational numbers is definitely not locally finite.
Lemma 37.1.3 Let $\mathfrak{C}$ be locally finite. Then

$$
\overline{\cup \mathfrak{C}}=\cup\{\bar{H}: H \in \mathfrak{C}\}
$$

Next suppose the elements of $\mathfrak{C}$ are open sets and that for each $U \in \mathfrak{C}$, there exists a differentiable function, $\psi_{U}$ having $\operatorname{spt}\left(\psi_{U}\right) \subseteq U$. Then you can define the following finite sum for each $\mathbf{x} \in \mathbb{R}^{n}$

$$
f(\mathbf{x}) \equiv \sum\left\{\psi_{U}(\mathbf{x}): \mathbf{x} \in U \in \mathfrak{C}\right\}
$$

[^25]Furthermore, $f$ is also a differentiable function ${ }^{2}$ and

$$
D f(\mathbf{x})=\sum\left\{D \psi_{U}(\mathbf{x}): \mathbf{x} \in U \in \mathfrak{C}\right\} .
$$

Proof: Let $\mathbf{p}$ be a limit point of $\cup \mathfrak{C}$ and let $W$ be an open set which intersects only finitely many sets of $\mathfrak{C}$. Then $\mathbf{p}$ must be a limit point of one of these sets. It follows $\mathbf{p} \in \cup\{\bar{H}: H \in \mathfrak{C}\}$ and so $\overline{\cup C} \subseteq \cup\{\bar{H}: H \in \mathfrak{C}\}$. The inclusion in the other direction is obvious.

Now consider the second assertion. Letting $\mathbf{x} \in \mathbb{R}^{n}$, there exists an open set, $W$ intersecting only finitely many open sets of $\mathfrak{C}, U_{1}, U_{2}, \cdots, U_{m}$. Then for all $\mathbf{y} \in W$,

$$
f(\mathbf{y})=\sum_{i=1}^{m} \psi_{U_{i}}(\mathbf{y})
$$

and so the desired result is obvious. It merely says that a finite sum of differentiable functions is differentiable. Recall the following definition.

Definition 37.1.4 Let $K$ be a closed subset of an open set, $U . K \prec f \prec U$ if $f$ is continuous, has values in $[0,1]$, equals 1 on $K$, and has compact support contained in $U$.

Lemma 37.1.5 Let $U$ be a bounded open set and let $K$ be a closed subset of $U$. Then there exist an open set, $W$, such that $W \subseteq \bar{W} \subseteq U$ and a function, $f \in C_{c}^{\infty}(U)$ such that $K \prec f \prec U$.

Proof: The set, $K$ is compact so is at a positive distance from $U^{C}$. Let

$$
W \equiv\left\{\mathbf{x}: \operatorname{dist}(\mathbf{x}, K)<3^{-1} \operatorname{dist}\left(K, U^{C}\right)\right\}
$$

Also let

$$
W_{1} \equiv\left\{\mathbf{x}: \operatorname{dist}(\mathbf{x}, K)<2^{-1} \operatorname{dist}\left(K, U^{C}\right)\right\}
$$

Then it is clear

$$
K \subseteq W \subseteq \bar{W} \subseteq W_{1} \subseteq \overline{W_{1}} \subseteq U
$$

Now consider the function,

$$
h(\mathbf{x}) \equiv \frac{\operatorname{dist}\left(\mathbf{x}, W_{1}^{C}\right)}{\operatorname{dist}\left(\mathbf{x}, W_{1}^{C}\right)+\operatorname{dist}(\mathbf{x}, \bar{W})}
$$

Since $\bar{W}$ is compact it is at a positive distance from $W_{1}^{C}$ and so $h$ is a well defined continuous function which has compact support contained in $\bar{W}_{1}$, equals 1 on $W$, and has values in $[0,1]$. Now let $\phi_{k}$ be a mollifier. Letting

$$
k^{-1}<\min \left(\operatorname{dist}\left(K, W^{C}\right), 2^{-1} \operatorname{dist}\left(\bar{W}_{1}, U^{C}\right)\right)
$$

it follows that for such $k$, the function, $h * \phi_{k} \in C_{c}^{\infty}(U)$, has values in $[0,1]$, and equals 1 on $K$. Let $f=h * \phi_{k}$.

The above lemma is used repeatedly in the following.

[^26]Lemma 37.1.6 Let $K$ be a closed set and let $\left\{V_{i}\right\}_{i=1}^{\infty}$ be a locally finite list of bounded open sets whose union contains $K$. Then there exist functions, $\psi_{i} \in C_{c}^{\infty}\left(V_{i}\right)$ such that for all $\mathbf{x} \in K$,

$$
1=\sum_{i=1}^{\infty} \psi_{i}(\mathbf{x})
$$

and the function $f(\mathbf{x})$ given by

$$
f(\mathbf{x})=\sum_{i=1}^{\infty} \psi_{i}(\mathbf{x})
$$

is in $C^{\infty}\left(\mathbb{R}^{n}\right)$.
Proof: Let $K_{1}=K \backslash \cup_{i=2}^{\infty} V_{i}$. Thus $K_{1}$ is compact because $K_{1} \subseteq V_{1}$. Let

$$
K_{1} \subseteq W_{1} \subseteq \bar{W}_{1} \subseteq V_{1}
$$

Thus $W_{1}, V_{2}, \cdots, V_{n}$ covers $K$ and $\bar{W}_{1} \subseteq V_{1}$. Suppose $W_{1}, \cdots, W_{r}$ have been defined such that $\overline{W_{i}} \subseteq V_{i}$ for each $i$, and $W_{1}, \cdots, W_{r}, V_{r+1}, \cdots, V_{n}$ covers $K$. Then let

$$
K_{r+1} \equiv K \backslash\left(\left(\cup_{i=r+2}^{\infty} V_{i}\right) \cup\left(\cup_{j=1}^{r} W_{j}\right)\right)
$$

It follows $K_{r+1}$ is compact because $K_{r+1} \subseteq V_{r+1}$. Let $W_{r+1}$ satisfy

$$
K_{r+1} \subseteq W_{r+1} \subseteq \bar{W}_{r+1} \subseteq V_{r+1}
$$

Continuing this way defines a sequence of open sets, $\left\{W_{i}\right\}_{i=1}^{\infty}$ with the property

$$
\overline{W_{i}} \subseteq V_{i}, K \subseteq \cup_{i=1}^{\infty} W_{i}
$$

Note $\left\{W_{i}\right\}_{i=1}^{\infty}$ is locally finite because the original list, $\left\{V_{i}\right\}_{i=1}^{\infty}$ was locally finite. Now let $U_{i}$ be open sets which satisfy

$$
\bar{W}_{i} \subseteq U_{i} \subseteq \bar{U}_{i} \subseteq V_{i}
$$

Similarly, $\left\{U_{i}\right\}_{i=1}^{\infty}$ is locally finite.

Since the set, $\left\{W_{i}\right\}_{i=1}^{\infty}$ is locally finite, it follows $\overline{\cup_{i=1}^{\infty} W_{i}}=\cup_{i=1}^{\infty} \overline{W_{i}}$ and so it is possible to define $\phi_{i}$ and $\gamma$, infinitely differentiable functions having compact support such that

$$
\bar{U}_{i} \prec \phi_{i} \prec V_{i}, \cup_{i=1}^{\infty} \bar{W}_{i} \prec \gamma \prec \cup_{i=1}^{\infty} U_{i} .
$$

Now define

$$
\psi_{i}(\mathbf{x})=\left\{\begin{array}{l}
\gamma(\mathbf{x}) \phi_{i}(\mathbf{x}) / \sum_{j=1}^{\infty} \phi_{j}(\mathbf{x}) \text { if } \sum_{j=1}^{\infty} \phi_{j}(\mathbf{x}) \neq 0 \\
0 \text { if } \sum_{j=1}^{\infty} \phi_{j}(\mathbf{x})=0
\end{array}\right.
$$

If $\mathbf{x}$ is such that $\sum_{j=1}^{\infty} \phi_{j}(\mathbf{x})=0$, then $\mathbf{x} \notin \cup_{i=1}^{\infty} \overline{U_{i}}$ because $\phi_{i}$ equals one on $\overline{U_{i}}$. Consequently $\gamma(\mathbf{y})=0$ for all $\mathbf{y}$ near $\mathbf{x}$ thanks to the fact that $\cup_{i=1}^{\infty} \overline{U_{i}}$ is closed and so $\psi_{i}(\mathbf{y})=0$ for all $\mathbf{y}$ near $\mathbf{x}$. Hence $\psi_{i}$ is infinitely differentiable at such $\mathbf{x}$. If $\sum_{j=1}^{\infty} \phi_{j}(\mathbf{x}) \neq 0$, this situation persists near $\mathbf{x}$ because each $\phi_{j}$ is continuous and so $\psi_{i}$ is infinitely differentiable at such points also thanks to Lemma 37.1.3. Therefore $\psi_{i}$ is infinitely differentiable. If $\mathbf{x} \in K$, then $\gamma(\mathbf{x})=1$ and so $\sum_{j=1}^{\infty} \psi_{j}(\mathbf{x})=1$. Clearly $0 \leq \psi_{i}(\mathbf{x}) \leq 1$ and $\operatorname{spt}\left(\psi_{j}\right) \subseteq V_{j}$. This proves the theorem.

The method of proof of this lemma easily implies the following useful corollary.
Corollary 37.1.7 If $H$ is a compact subset of $V_{i}$ for some $V_{i}$ there exists a partition of unity such that $\psi_{i}(x)=1$ for all $x \in H$ in addition to the conclusion of Lemma 37.1.6.

Proof: Keep $V_{i}$ the same but replace $V_{j}$ with $\widetilde{V}_{j} \equiv V_{j} \backslash H$. Now in the proof above, applied to this modified collection of open sets, if $j \neq i, \phi_{j}(x)=0$ whenever $x \in H$. Therefore, $\psi_{i}(x)=1$ on $H$.

Theorem 37.1.8 Let $H$ be any closed set and let $\mathfrak{C}$ be any open cover of $H$. Then there exist functions $\left\{\psi_{i}\right\}_{i=1}^{\infty}$ such that $\operatorname{spt}\left(\psi_{i}\right)$ is contained in some set of $\mathfrak{C}$ and $\psi_{i}$ is infinitely differentiable having values in $[0,1]$ such that on $H, \sum_{i=1}^{\infty} \psi_{i}(\mathbf{x})=1$. Furthermore, the function, $f(\mathbf{x}) \equiv \sum_{i=1}^{\infty} \psi_{i}(\mathbf{x})$ is infinitely differentiable on $\mathbb{R}^{n}$. Also, $\operatorname{spt}\left(\psi_{i}\right) \subseteq U_{i}$ where $U_{i}$ is a bounded open set with the property that $\left\{U_{i}\right\}_{i=1}^{\infty}$ is locally finite and each $U_{i}$ is contained in some set of $\mathfrak{C}$.

Proof: By Lemma 37.1.2 there exists an open cover of $H$ composed of bounded open sets, $U_{i}$ such that each $U_{i}$ is a subset of some set of $\mathfrak{C}$ and the collection, $\left\{U_{i}\right\}_{i=1}^{\infty}$ is locally finite. Then the result follows from Lemma 37.1.6 and Lemma 37.1.3.

Corollary 37.1.9 Let $H$ be any closed set and let $\left\{V_{i}\right\}_{i=1}^{m}$ be a finite open cover of H. Then there exist functions $\left\{\phi_{i}\right\}_{i=1}^{m}$ such that $\operatorname{spt}\left(\phi_{i}\right) \subseteq V_{i}$ and $\phi_{i}$ is infinitely differentiable having values in $[0,1]$ such that on $H, \sum_{i=1}^{m} \phi_{i}(\mathbf{x})=1$.

Proof: By Theorem 37.1.8 there exists a set of functions, $\left\{\psi_{i}\right\}_{i=1}^{\infty}$ having the properties listed in this theorem relative to the open covering, $\left\{V_{i}\right\}_{i=1}^{m}$. Let $\phi_{1}(\mathbf{x})$ equal the sum of all $\psi_{j}(\mathbf{x})$ such that $\operatorname{spt}\left(\psi_{j}\right) \subseteq V_{1}$. Next let $\phi_{2}(\mathbf{x})$ equal the sum of all $\psi_{j}(\mathbf{x})$ which have not already been included and for which $\operatorname{spt}\left(\psi_{j}\right) \subseteq V_{2}$. Continue in this manner. Since the open sets, $\left\{U_{i}\right\}_{i=1}^{\infty}$ mentioned in Theorem 37.1.8 are locally finite, it follows from Lemma 37.1.3 that each $\phi_{i}$ is infinitely differentiable having support in $V_{i}$. This proves the corollary.

### 37.2 Integration On Manifolds

Manifolds are things which locally appear to be $\mathbb{R}^{n}$ for some $n$. The extent to which they have such a local appearance varies according to various analytical characteristics which the manifold possesses.

Definition 37.2.1 Let $U \subseteq \mathbb{R}^{n}$ be an open set and let $\mathbf{h}: U \rightarrow \mathbb{R}^{m}$. Then for $r \in[0,1)$, $\mathbf{h} \in C^{k, r}(U)$ for $k$ a nonnegative integer means that $D^{\alpha} \mathbf{h}$ exists for all $|\alpha| \leq k$ and each $D^{\alpha} \mathbf{h}$ is Holder continuous with exponent $r$. That is

$$
\left|D^{\alpha} \mathbf{h}(\mathbf{x})-D^{\alpha} \mathbf{h}(\mathbf{y})\right| \leq K|\mathbf{x}-\mathbf{y}|^{r} .
$$

Also $\mathbf{h} \in C^{k, r}(\bar{U})$ if it is the restriction of a function of $C^{k, r}\left(\mathbb{R}^{n}\right)$ to $U$.
Definition 37.2.2 Let $\Gamma$ be a closed subset of $\mathbb{R}^{p}$ where $p \geq n$. Suppose $\Gamma=\cup_{i=1}^{\infty} \Gamma_{i}$ where $\Gamma_{i}=\Gamma \cap W_{i}$ for $W_{i}$ a bounded open set. Suppose also $\left\{W_{i}\right\}_{i=1}^{\infty}$ is locally finite. This means every bounded open set intersects only finitely many. Also suppose there are open bounded sets, $U_{i}$ having Lipschitz boundaries and functions $\mathbf{h}_{i}: U_{i} \rightarrow \Gamma_{i}$ which are one to one, onto, and in $C^{m, 1}\left(U_{i}\right)$. Suppose also there exist functions, $\mathbf{g}_{i}: W_{i} \rightarrow U_{i}$ such that $\mathbf{g}_{i}$ is $C^{m, 1}\left(W_{i}\right)$, and $\mathbf{g}_{i} \circ \mathbf{h}_{i}=\mathrm{id}$ on $U_{i}$ while $\mathbf{h}_{i} \circ \mathbf{g}_{i}=\mathrm{id}$ on $\Gamma_{i}$. The collection of sets, $\Gamma_{j}$ and mappings, $\mathbf{g}_{j},\left\{\left(\Gamma_{j}, \mathbf{g}_{j}\right)\right\}$ is called an atlas and an individual entry in the atlas is called a chart. Thus $\left(\Gamma_{j}, \mathbf{g}_{j}\right)$ is a chart. Then $\Gamma$ as just described is called a $C^{m, 1}$ manifold. The number, $m$ is just a nonnegative integer. When $m=0$ this would be called a Lipschitz manifold, the least smooth of the manifolds discussed here.

For example, take $p=n+1$ and let

$$
\mathbf{h}_{i}(\mathbf{u})=\left(u_{1}, \cdots, u_{i}, \phi_{i}(\mathbf{u}), u_{i+1}, \cdots, u_{n}\right)^{T}
$$

for $\mathbf{u}=\left(u_{1}, \cdots, u_{i}, u_{i+1}, \cdots, u_{n}\right)^{T} \in U_{i}$ for $\phi_{i} \in C^{m, 1}\left(U_{i}\right)$ and $\mathbf{g}_{i}: U_{i} \times \mathbb{R} \rightarrow U_{i}$ given by

$$
\mathbf{g}_{i}\left(u_{1}, \cdots, u_{i}, y, u_{i+1}, \cdots, u_{n}\right) \equiv \mathbf{u}
$$

for $i=1,2, \cdots, p$. Then for $\mathbf{u} \in U_{i}$, the definition gives

$$
\mathbf{g}_{i} \circ \mathbf{h}_{i}(\mathbf{u})=\mathbf{g}_{i}\left(u_{1}, \cdots, u_{i}, \phi_{i}(\mathbf{u}), u_{i+1}, \cdots, u_{n}\right)=\mathbf{u}
$$

and for $\Gamma_{i} \equiv \mathbf{h}_{i}\left(U_{i}\right)$ and $\left(u_{1}, \cdots, u_{i}, \phi_{i}(\mathbf{u}), u_{i+1}, \cdots, u_{n}\right)^{T} \in \Gamma_{i}$,

$$
\begin{aligned}
& \mathbf{h}_{i} \circ \mathbf{g}_{i}\left(u_{1}, \cdots, u_{i}, \phi_{i}(\mathbf{u}), u_{i+1}, \cdots, u_{n}\right) \\
= & \mathbf{h}_{i}(\mathbf{u})=\left(u_{1}, \cdots, u_{i}, \phi_{i}(\mathbf{u}), u_{i+1}, \cdots, u_{n}\right)^{T}
\end{aligned}
$$

This example can be used to describe the boundary of a bounded open set and since $\phi_{i} \in$ $C^{m, 1}\left(U_{i}\right)$, such an open set is said to have a $C^{m, 1}$ boundary. Note also that in this example, $U_{i}$ could be taken to be $\mathbb{R}^{n}$ or if $U_{i}$ is given, both $\mathbf{h}_{i}$ and and $\mathbf{g}_{i}$ can be taken as restrictions of functions defined on all of $\mathbb{R}^{n}$ and $\mathbb{R}^{p}$ respectively.

The symbol, $I$ will refer to an increasing list of $n$ indices taken from $\{1, \cdots, p\}$. Denote by $\Lambda(p, n)$ the set of all such increasing lists of $n$ indices.

Let

$$
J_{i}(\mathbf{u}) \equiv\left[\sum_{I \in \Lambda(p, n)}\left(\frac{\partial\left(x^{i_{1}} \cdots x^{i_{n}}\right)}{\partial\left(u^{1} \cdots u^{n}\right)}\right)^{2}\right]^{1 / 2}
$$

where here the sum is taken over all possible increasing lists of $n$ indices, $I$, from $\{1, \cdots, p\}$ and $\mathbf{x}=\mathbf{h}_{i} \mathbf{u}$. Thus there are $\binom{p}{n}$ terms in the sum. In this formula, $\frac{\partial\left(x^{i} \ldots x^{i n}\right)}{\partial\left(u^{1} \ldots u^{n}\right)}$ is defined to be the determinant of the following matrix.

$$
\left(\begin{array}{ccc}
\frac{\partial x^{i_{1}}}{\partial u_{1}} & \cdots & \frac{\partial x^{i_{1}}}{\partial u_{n}} \\
\vdots & & \vdots \\
\frac{\partial x^{i_{n}}}{\partial u_{1}} & \cdots & \frac{\partial i^{i_{n}}}{\partial u_{n}}
\end{array}\right) .
$$

Note that if $p=n$ there is only one term in the sum, the absolute value of the determinant of $D \mathbf{x}(\mathbf{u})$. Define a positive linear functional, $\Lambda$ on $C_{c}(\Gamma)$ as follows: First let $\left\{\psi_{i}\right\}$ be a $C^{\infty}$ partition of unity subordinate to the open sets, $\left\{W_{i}\right\}$. Thus $\psi_{i} \in C_{c}^{\infty}\left(W_{i}\right)$ and $\sum_{i} \psi_{i}(\mathbf{x})=1$ for all $\mathbf{x} \in \Gamma$. Then

$$
\begin{equation*}
\Lambda f \equiv \sum_{i=1}^{\infty} \int_{\mathbf{g}_{i} \Gamma_{i}} f \psi_{i}\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u \tag{37.2.1}
\end{equation*}
$$

Is this well defined?
Lemma 37.2.3 The functional defined in 37.2. 1 does not depend on the choice of atlas or the partition of unity.

Proof: In 37.2.1, let $\left\{\psi_{i}\right\}$ be a $C^{\infty}$ partition of unity which is associated with the atlas $\left(\Gamma_{i}, \mathbf{g}_{i}\right)$ and let $\left\{\eta_{i}\right\}$ be a $C^{\infty}$ partition of unity associated in the same manner with the atlas $\left(\Gamma_{i}^{\prime}, \mathbf{g}_{i}^{\prime}\right)$. In the following argument, the local finiteness of the $\Gamma_{i}$ implies that all sums are finite. Using the change of variables formula with $\mathbf{u}=\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}^{\prime}\right) \mathbf{v}$

$$
\begin{gather*}
\sum_{i=1}^{\infty} \int_{\mathbf{g}_{i} \Gamma_{i}} \psi_{i} f\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u=  \tag{37.2.2}\\
\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_{\mathbf{g}_{i} \Gamma_{i}} \eta_{j} \psi_{i} f\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u=\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_{\mathbf{g}_{j}^{\prime}\left(\Gamma_{i} \cap \Gamma_{j}^{\prime}\right)} . \\
\eta_{j}\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) \psi_{i}\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) f\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) J_{i}(\mathbf{u})\left|\frac{\partial\left(u^{1} \cdots u^{n}\right)}{\partial\left(v^{1} \cdots v^{n}\right)}\right| d v \\
=\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_{\mathbf{g}_{j}^{\prime}\left(\Gamma_{i} \cap \Gamma_{j}^{\prime}\right)} \eta_{j}\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) \psi_{i}\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) f\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) J_{j}(\mathbf{v}) d v . \tag{37.2.3}
\end{gather*}
$$

Thus

$$
\begin{gathered}
\text { the definition of } \Lambda f \text { using }\left(\Gamma_{i}, \mathbf{g}_{i}\right) \equiv \\
\sum_{i=1}^{\infty} \int_{\mathbf{g}_{i} \Gamma_{i}} \psi_{i} f\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u= \\
\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_{\mathbf{g}_{j}^{\prime}\left(\Gamma_{i} \cap \Gamma_{j}^{\prime}\right)} \eta_{j}\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) \psi_{i}\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) f\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) J_{j}(\mathbf{v}) d v
\end{gathered}
$$

$$
=\sum_{j=1}^{\infty} \int_{\mathbf{g}_{j}^{\prime}\left(\Gamma_{j}^{\prime}\right)} \eta_{j}\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) f\left(\mathbf{h}_{j}^{\prime}(\mathbf{v})\right) J_{j}(\mathbf{v}) d v
$$

the definition of $\Lambda f$ using $\left(V_{i}, \mathbf{g}_{i}^{\prime}\right)$.
This proves the lemma.
This lemma and the Riesz representation theorem for positive linear functionals implies the part of the following theorem which says the functional is well defined.

Theorem 37.2.4 Let $\Gamma$ be a $C^{m, 1}$ manifold. Then there exists a unique Radon measure, $\mu$, defined on $\Gamma$ such that whenever $f$ is a continuous function having compact support which is defined on $\Gamma$ and $\left(\Gamma_{i}, \mathbf{g}_{i}\right)$ denotes an atlas and $\left\{\psi_{i}\right\}$ a partition of unity subordinate to this atlas,

$$
\begin{equation*}
\Lambda f=\int_{\Gamma} f d \mu=\sum_{i=1}^{\infty} \int_{\mathbf{g}_{i} \Gamma_{i}} \psi_{i} f\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u \tag{37.2.4}
\end{equation*}
$$

Also, a subset, $A$, of $\Gamma$ is $\mu$ measurable if and only if for all $r, \mathbf{g}_{r}\left(\Gamma_{r} \cap A\right)$ is $v_{r}$ measurable where $v_{r}$ is the measure defined by

$$
v_{r}\left(\mathbf{g}_{r}\left(\Gamma_{r} \cap A\right)\right) \equiv \int_{\mathbf{g}_{r}\left(\Gamma_{r} \cap A\right)} J_{r}(\mathbf{u}) d u
$$

Proof: To begin, here is a claim.
Claim : A set, $S \subseteq \Gamma_{i}$, has $\mu$ measure zero if and only if $\mathbf{g}_{i} S$ has measure zero in $\mathbf{g}_{i} \Gamma_{i}$ with respect to the measure, $v_{i}$.

Proof of the claim: Let $\varepsilon>0$ be given. By outer regularity, there exists a set, $V \subseteq \Gamma_{i}$, open $^{3}$ in $\Gamma$ such that $\mu(V)<\varepsilon$ and $S \subseteq V \subseteq \Gamma_{i}$. Then $\mathbf{g}_{i} V$ is open in $\mathbb{R}^{n}$ and contains $\mathbf{g}_{i} S$. Letting $h \prec \mathbf{g}_{i} V$ and $h_{1}(\mathbf{x}) \equiv h\left(\mathbf{g}_{i}(\mathbf{x})\right)$ for $\mathbf{x} \in \Gamma_{i}$ it follows $h_{1} \prec V$. By Corollary 37.1.7 on Page 1300 there exists a partition of unity such that $\operatorname{spt}\left(h_{1}\right) \subseteq\left\{\mathbf{x} \in \mathbb{R}^{p}: \psi_{i}(\mathbf{x})=1\right\}$. Thus $\psi_{j} h_{1}\left(\mathbf{h}_{j}(u)\right)=0$ unless $j=i$ when this reduces to $h_{1}\left(\mathbf{h}_{i}(u)\right)$. It follows

$$
\begin{aligned}
\varepsilon & \geq \mu(V) \geq \int_{V} h_{1} d \mu=\int_{\Gamma} h_{1} d \mu \\
& =\sum_{j=1}^{\infty} \int_{\mathbf{g}_{j} \Gamma_{j}} \psi_{j} h_{1}\left(\mathbf{h}_{j}(\mathbf{u})\right) J_{j}(\mathbf{u}) d u \\
& =\int_{\mathbf{g}_{i} \Gamma_{i}} h_{1}\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u=\int_{\mathbf{g}_{i} \Gamma_{i}} h(\mathbf{u}) J_{i}(\mathbf{u}) d u \\
& =\int_{\mathbf{g}_{i} V} h(\mathbf{u}) J_{i}(\mathbf{u}) d u
\end{aligned}
$$

Now this holds for all $h \prec \mathbf{g}_{i} V$ and so

$$
\int_{\mathbf{g}_{i} V} J_{i}(\mathbf{u}) d u \leq \varepsilon
$$

[^27]Since $\varepsilon$ is arbitrary, this shows $\mathbf{g}_{i} V$ has measure no more than $\varepsilon$ with respect to the measure, $v_{i}$. Since $\varepsilon$ is arbitrary, $\mathbf{g}_{i} S$ has measure zero.

Consider the converse. Suppose $\mathbf{g}_{i} S$ has $v_{i}$ measure zero. Then there exists an open set, $O \subseteq \mathbf{g}_{i} \Gamma_{i}$ such that $O \supseteq \mathbf{g}_{i} S$ and

$$
\int_{O} J_{i}(\mathbf{u}) d u<\varepsilon
$$

Thus $\mathbf{h}_{i}(O)$ is open in $\Gamma$ and contains $S$. Let $h \prec \mathbf{h}_{i}(O)$ be such that

$$
\begin{equation*}
\int_{\Gamma} h d \mu+\varepsilon>\mu\left(\mathbf{h}_{i}(O)\right) \geq \mu(S) \tag{37.2.5}
\end{equation*}
$$

As in the first part, Corollary 37.1 .7 on Page 1300 implies there exists a partition of unity such that $h(\mathbf{x})=0$ off the set,

$$
\left\{\mathbf{x} \in \mathbb{R}^{p}: \psi_{i}(\mathbf{x})=1\right\}
$$

and so as in this part of the argument,

$$
\begin{align*}
\int_{\Gamma} h d \mu & \equiv \sum_{j=1}^{\infty} \int_{\mathbf{g}_{j} U_{j}} \psi_{j} h\left(\mathbf{h}_{j}(\mathbf{u})\right) J_{j}(\mathbf{u}) d u \\
& =\int_{\mathbf{g}_{i} \Gamma_{i}} h\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u \\
& =\int_{O \mathbf{g}_{i} \Gamma_{i}} h\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u \\
& \leq \int_{O} J_{i}(\mathbf{u}) d u<\varepsilon \tag{37.2.6}
\end{align*}
$$

and so from 37.2 .5 and $37.2 .6 \mu(S) \leq 2 \varepsilon$. Since $\varepsilon$ is arbitrary, this proves the claim.
For the last part of the theorem, it suffices to let $A \subseteq \Gamma_{r}$ because otherwise, the above argument would apply to $A \cap \Gamma_{r}$. Thus let $A \subseteq \Gamma_{r}$ be $\mu$ measurable. By the regularity of the measure, there exists an $F_{\sigma}$ set, $F$ and a $G_{\delta}$ set, $G$ such that $\Gamma_{r} \supseteq G \supseteq A \supseteq F$ and $\mu(G \backslash F)=0$. (Recall a $G_{\delta}$ set is a countable intersection of open sets and an $F_{\sigma}$ set is a countable union of closed sets.) Then since $\overline{\Gamma_{r}}$ is compact, it follows each of the closed sets whose union equals $F$ is a compact set. Thus if $F=\cup_{k=1}^{\infty} F_{k}, \mathbf{g}_{r}\left(F_{k}\right)$ is also a compact set and so $\mathbf{g}_{r}(F)=\cup_{k=1}^{\infty} \mathbf{g}_{r}\left(F_{k}\right)$ is a Borel set. Similarly, $\mathbf{g}_{r}(G)$ is also a Borel set. Now by the claim,

$$
\int_{\mathbf{g}_{r}(G \backslash F)} J_{r}(\mathbf{u}) d u=0
$$

Since $\mathbf{g}_{r}$ is one to one,

$$
\mathbf{g}_{r} G \backslash \mathbf{g}_{r} F=\mathbf{g}_{r}(G \backslash F)
$$

and so

$$
\mathbf{g}_{r}(F) \subseteq \mathbf{g}_{r}(A) \subseteq \mathbf{g}_{r}(G)
$$

where $\mathbf{g}_{r}(G) \backslash \mathbf{g}_{r}(F)$ has measure zero. By completeness of the measure, $v_{r}, \mathbf{g}_{r}(A)$ is measurable. It follows that if $A \subseteq \Gamma$ is $\mu$ measurable, then $\mathbf{g}_{r}\left(\Gamma_{r} \cap A\right)$ is $v_{r}$ measurable for all $r$. The converse is entirely similar. This proves the theorem.

Corollary 37.2.5 Let $f \in L^{1}(\Gamma ; \mu)$ and suppose $f(\mathbf{x})=0$ for all $\mathbf{x} \notin \Gamma_{r}$ where $\left(\Gamma_{r}, \mathbf{g}_{r}\right)$ is a chart. Then

$$
\begin{equation*}
\int_{\Gamma} f d \mu=\int_{\Gamma_{r}} f d \mu=\int_{\mathbf{g}_{r} \Gamma_{r}} f\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u \tag{37.2.7}
\end{equation*}
$$

Furthermore, if $\left\{\left(\Gamma_{i}, \mathbf{g}_{i}\right)\right\}$ is an atlas and $\left\{\psi_{i}\right\}$ is a partition of unity as described earlier, then for any $f \in L^{1}(\Gamma, \mu)$,

$$
\begin{equation*}
\int_{\Gamma} f d \mu=\sum_{r=1}^{\infty} \int_{\mathbf{g}_{r} \Gamma_{r}} \psi_{r} f\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u \tag{37.2.8}
\end{equation*}
$$

Proof: Let $f \in L^{1}(\Gamma, \mu)$ with $f=0$ off $\Gamma_{r}$. Without loss of generality assume $f \geq 0$ because if the formulas can be established for this case, the same formulas are obtained for an arbitrary complex valued function by splitting it up into positive and negative parts of the real and imaginary parts in the usual way. Also, let $K \subseteq \Gamma_{r}$ a compact set. Since $\mu$ is a Radon measure there exists a sequence of continuous functions, $\left\{f_{k}\right\}, f_{k} \in C_{c}\left(\Gamma_{r}\right)$, which converges to $f$ in $L^{1}(\Gamma, \mu)$ and for $\mu$ a.e. $\mathbf{x}$. Take the partition of unity, $\left\{\psi_{i}\right\}$ to be such that

$$
K \subseteq\left\{\mathbf{x}: \psi_{r}(\mathbf{x})=1\right\}
$$

Therefore, the sequence $\left\{f_{k}\left(\mathbf{h}_{r}(\cdot)\right)\right\}$ is a Cauchy sequence in the sense that

$$
\lim _{k, l \rightarrow \infty} \int_{\mathbf{g}_{r}(K)}\left|f_{k}\left(\mathbf{h}_{r}(\mathbf{u})\right)-f_{l}\left(\mathbf{h}_{r}(\mathbf{u})\right)\right| J_{r}(\mathbf{u}) d u=0
$$

It follows there exists $g$ such that

$$
\int_{\mathbf{g}_{r}(K)}\left|f_{k}\left(\mathbf{h}_{r}(\mathbf{u})\right)-g(\mathbf{u})\right| J_{r}(\mathbf{u}) d u \rightarrow 0
$$

and

$$
g \in L^{1}\left(\mathbf{g}_{r} K ; v_{r}\right)
$$

By the pointwise convergence and the claim used in the proof of Theorem 37.2.4,

$$
g(\mathbf{u})=f\left(\mathbf{h}_{r}(\mathbf{u})\right)
$$

for $\mu$ a.e. $\mathbf{h}_{r}(\mathbf{u}) \in K$. Therefore,

$$
\begin{align*}
\int_{K} f d \mu & =\lim _{k \rightarrow \infty} \int_{K} f_{k} d \mu=\lim _{k \rightarrow \infty} \int_{\mathbf{g}_{r}(K)} f_{k}\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u \\
& =\int_{\mathbf{g}_{r}(K)} g(\mathbf{u}) J_{r}(\mathbf{u}) d u=\int_{\mathbf{g}_{r}(K)} f\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u \tag{37.2.9}
\end{align*}
$$

Now let $\cdots K_{j} \subseteq K_{j+1} \cdots$ and $\cup_{j=1}^{\infty} K_{j}=\Gamma_{r}$ where $K_{j}$ is compact for all $j$. Replace $K$ in 37.2.9 with $K_{j}$ and take a limit as $j \rightarrow \infty$. By the monotone convergence theorem,

$$
\int_{\Gamma_{r}} f d \mu=\int_{\mathbf{g}_{r}\left(\Gamma_{r}\right)} f\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u
$$

This establishes 37.2.7.
To establish 37.2.8, let $f \in L^{1}(\Gamma, \mu)$ and let $\left\{\left(\Gamma_{i}, \mathbf{g}_{i}\right)\right\}$ be an atlas and $\left\{\psi_{i}\right\}$ be a partition of unity. Then $f \psi_{i} \in L^{1}(\Gamma, \mu)$ and is zero off $\Gamma_{i}$. Therefore, from what was just shown,

$$
\begin{aligned}
\int_{\Gamma} f d \mu & =\sum_{i=1}^{\infty} \int_{\Gamma_{i}} f \psi_{i} d \mu \\
& =\sum_{r=1}^{\infty} \int_{\mathbf{g}_{r}\left(\Gamma_{r}\right)} \psi_{r} f\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u
\end{aligned}
$$

### 37.3 Comparison With $\mathscr{H}^{n}$

The above gives a measure on a manifold, $\Gamma$. I will now show that the measure obtained is nothing more than $\mathscr{H}^{n}$, the $n$ dimensional Hausdorff measure. Recall $\Lambda(p, n)$ was the set of all increasing lists of $n$ indices taken from $\{1,2, \cdots, p\}$

Recall

$$
J_{i}(\mathbf{u}) \equiv\left[\sum_{I \in \Lambda(p, n)}\left(\frac{\partial\left(x^{i_{1}} \cdots x^{i_{n}}\right)}{\partial\left(u^{1} \cdots u^{n}\right)}\right)^{2}\right]^{1 / 2}
$$

where here the sum is taken over all possible increasing lists of $n$ indices, $I$, from $\{1, \cdots, p\}$ and $\mathbf{x}=\mathbf{h}_{i} \mathbf{u}$ and the functional was given as

$$
\begin{equation*}
\Lambda f \equiv \sum_{i=1}^{\infty} \int_{\mathbf{g}_{i} \Gamma_{i}} f \psi_{i}\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u \tag{37.3.10}
\end{equation*}
$$

where the $\left\{\psi_{i}\right\}_{i=1}^{\infty}$ was a partition of unity subordinate to the open sets, $\left\{W_{i}\right\}_{i=1}^{\infty}$ as described above. I will show

$$
J_{i}(\mathbf{u})=\operatorname{det}\left(D \mathbf{h}(\mathbf{u})^{*} D \mathbf{h}(\mathbf{u})\right)^{1 / 2}
$$

and then use the area formula. The key result is really a special case of the Binet Cauchy theorem and this special case is presented in the next lemma.

Lemma 37.3.1 Let $A=\left(a_{i j}\right)$ be a real $p \times n$ matrix in which $p \geq n$. For $I \in \Lambda(p, n)$ denote by $A_{I}$ the $n \times n$ matrix obtained by deleting from $A$ all rows except for those corresponding to an element of I. Then

$$
\sum_{I \in \Lambda(p, n)} \operatorname{det}\left(A_{I}\right)^{2}=\operatorname{det}\left(A^{*} A\right)
$$

Proof: For $\left(j_{1}, \cdots, j_{n}\right) \in \Lambda(p, n)$, define $\theta\left(j_{k}\right) \equiv k$. Then for

$$
\left\{k_{1}, \cdots, k_{n}\right\}=\left\{j_{1}, \cdots, j_{n}\right\}
$$

define

$$
\operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) \equiv \operatorname{sgn}\left(\theta\left(k_{1}\right), \cdots, \theta\left(k_{n}\right)\right)
$$

Then from the definition of the determinant and matrix multiplication,

$$
\begin{gathered}
\operatorname{det}\left(A^{*} A\right)=\sum_{i_{1}, \cdots, i_{n}} \operatorname{sgn}\left(i_{1}, \cdots, i_{n}\right) \sum_{k_{1}=1}^{p} a_{k_{1} i_{1}} a_{k_{1} 1} \sum_{k_{2}=1}^{p} a_{k_{2} i_{2}} a_{k_{2} 2} \\
\cdots \sum_{k_{n}=1}^{p} a_{k_{n} i_{n}} a_{k_{n} n} \\
=\sum_{J \in \Lambda(p, n)} \sum_{\left\{k_{1}, \cdots, k_{n}\right\}=J i_{1}, \cdots, i_{n}} \operatorname{sgn}\left(i_{1}, \cdots, i_{n}\right) a_{k_{1} i_{1}} a_{k_{1} 1} a_{k_{2} i_{2}} a_{k_{2} 2} \cdots a_{k_{n} i_{n}} a_{k_{n} n} \\
=\sum_{J \in \Lambda(p, n)} \sum_{\left\{k_{1}, \cdots, k_{n}\right\}=J i_{1}, \cdots, i_{n}} \operatorname{sgn}\left(i_{1}, \cdots, i_{n}\right) a_{k_{1} i_{1}} a_{k_{2} i_{2}} \cdots a_{k_{n} i_{n}} \cdot a_{k_{1} 1} a_{k_{2} 2} \cdots a_{k_{n} n} \\
=\sum_{J \in \Lambda(p, n)\left\{k_{1}, \cdots, k_{n}\right\}=J} \operatorname{sgn}\left(k_{1}, \cdots, k_{n}\right) \operatorname{det}\left(A_{J}\right) a_{k_{1} 1} a_{k_{2} 2} \cdots a_{k_{n} n} \\
=\sum_{J \in \Lambda(p, n)} \operatorname{det}\left(A_{J}\right) \operatorname{det}\left(A_{J}\right)
\end{gathered}
$$

and this proves the lemma.
It follows from this lemma that

$$
J_{i}(\mathbf{u})=\operatorname{det}\left(D \mathbf{h}(\mathbf{u})^{*} D \mathbf{h}(\mathbf{u})\right)^{1 / 2}
$$

From 37.3.10 and the area formula, the functional equals

$$
\begin{aligned}
\Lambda f & \equiv \sum_{i=1}^{\infty} \int_{\mathbf{g}_{i} \Gamma_{i}} f \psi_{i}\left(\mathbf{h}_{i}(\mathbf{u})\right) J_{i}(\mathbf{u}) d u \\
& =\sum_{i=1}^{\infty} \int_{\Gamma_{i}} f \psi_{i}(\mathbf{y}) d \mathscr{H}^{n}=\int_{\Gamma} f(\mathbf{y}) d \mathscr{H}^{n}
\end{aligned}
$$

Now $\mathscr{H}^{n}$ is a Borel measure defined on $\Gamma$ which is finite on all compact subsets of $\Gamma$. This finiteness follows from the above formula. If $K$ is a compact subset of $\Gamma$, then there exists an open set, $W$ whose closure is compact and a continuous function with compact support, $f$ such that $K \prec f \prec W$. Then $\mathscr{H}^{n}(K) \leq \int_{\Gamma} f(\mathbf{y}) d \mathscr{H}^{n}<\infty$ because of the above formula.

Lemma 37.3.2 $\mu=\mathscr{H}^{n}$ on every $\mu$ measurable set.
Proof: The Riesz representation theorem shows that

$$
\int_{\Gamma} f d \mu=\int_{\Gamma} f d \mathscr{H}^{n}
$$

for every continuous function having compact support. Therefore, since every open set is the countable union of compact sets, it follows $\mu=\mathscr{H}^{n}$ on all open sets. Since compact sets can be obtained as the countable intersection of open sets, these two measures are also equal on all compact sets. It follows they are also equal on all countable unions of compact sets. Suppose now that $E$ is a $\mu$ measurable set of finite measure. Then there exist sets,
$F, G$ such that $G$ is the countable intersection of open sets each of which has finite measure and $F$ is the countable union of compact sets such that $\mu(G \backslash F)=0$ and $F \subseteq E \subseteq G$. Thus $\mathscr{H}^{n}(G \backslash F)=0$,

$$
\mathscr{H}^{n}(G)=\mu(G)=\mu(F)=\mathscr{H}^{n}(F)
$$

By completeness of $\mathscr{H}^{n}$ it follows $E$ is $\mathscr{H}^{n}$ measurable and $\mathscr{H}^{n}(E)=\mu(E)$. If $E$ is not of finite measure, consider $E_{r} \equiv E \cap B(\mathbf{0}, r)$. This is contained in the compact set $\Gamma \cap \overline{B(\mathbf{0}, r)}$ and so $\mu\left(E_{r}\right)$ if finite. Thus from what was just shown, $\mathscr{H}^{n}\left(E_{r}\right)=\mu\left(E_{r}\right)$ and so, taking $r \rightarrow \infty \mathscr{H}^{n}(E)=\mu(E)$.

This shows you can simply use $\mathscr{H}^{n}$ for the measure on $\Gamma$.

## Chapter 38

## Basic Theory Of Sobolev Spaces

Definition 38.0.1 Let $U$ be an open set of $\mathbb{R}^{n}$. Define $X^{m, p}(U)$ as the set of all functions in $L^{p}(U)$ whose weak partial derivatives up to order $m$ are also in $L^{p}(U)$ where $1 \leq p$. The norm ${ }^{1}$ in this space is given by

$$
\|u\|_{m, p} \equiv\left(\int_{U} \sum_{|\alpha| \leq m}\left|D^{\alpha} u\right|^{p} d x\right)^{1 / p}
$$

where $\alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right) \in \mathbb{N}^{n}$ and $|\alpha| \equiv \sum \alpha_{i}$.Here $D^{\mathbf{0}} u \equiv u . C^{\infty}(\bar{U})$ is defined to be the set of functions which are restrictions to $U$ of a function in $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. Thus $C^{\infty}(\bar{U}) \subseteq W^{m, p}(U)$. The Sobolev space, $W^{m, p}(U)$ is defined to be the closure of $C^{\infty}(\bar{U})$ in $X^{m, p}(U)$ with respect to the above norm. Denote this norm by $\|u\|_{W^{m, p}(U)},\|u\|_{X^{m, p}(U)}$, or $\|u\|_{m, p, U}$ when it is important to identify the open set, $U$.

Also the following notation will be used pretty consistently.
Definition 38.0.2 Let u be a function defined on $U$. Define

$$
\widetilde{u}(\mathbf{x}) \equiv\left\{\begin{array}{c}
u(\mathbf{x}) \text { if } \mathbf{x} \in U \\
0 \text { if } \mathbf{x} \notin U
\end{array}\right.
$$

Theorem 38.0.3 Both $X^{m, p}(U)$ and $W^{m, p}(U)$ are separable reflexive Banach spaces provided $p>1$.

Proof: Define $\Lambda: X^{m, p}(U) \rightarrow L^{p}(U)^{w}$ where $w$ equals the number of multi indices, $\alpha$, such that $|\alpha| \leq m$ as follows. Letting $\left\{\alpha_{i}\right\}_{i=1}^{w}$ be the set of all multi indices with $\alpha_{1}=\mathbf{0}$,

$$
\Lambda(u) \equiv\left(D^{\alpha_{1}} u, D^{\alpha_{2}} u, \cdots, D^{\alpha_{w}} u\right)=\left(u, D^{\alpha_{2}} u, \cdots, D^{\alpha_{w}} u\right)
$$

Then $\Lambda$ is one to one because one of the multi indices is $\mathbf{0}$. Also

$$
\Lambda\left(X^{m, p}(U)\right)
$$

is a closed subspace of $L^{p}(U)^{w}$. To see this, suppose

$$
\left(u_{k}, D^{\alpha_{2}} u_{k}, \cdots, D^{\alpha_{w}} u_{k}\right) \rightarrow\left(f_{1}, f_{2}, \cdots, f_{w}\right)
$$

in $L^{p}(U)^{w}$. Then $u_{k} \rightarrow f_{1}$ in $L^{p}(U)$ and $D^{\alpha_{j}} u_{k} \rightarrow f_{j}$ in $L^{p}(U)$. Therefore, letting $\phi \in$ $C_{c}^{\infty}(U)$ and letting $k \rightarrow \infty$,

$$
\begin{array}{cc}
\int_{U}\left(D^{\alpha_{j}} u_{k}\right) \phi d x & =(-1)^{|\alpha|} \int_{U} u_{k} D^{\alpha_{j}} \phi d x \\
\downarrow & \downarrow \\
\int_{U} f_{j} \phi d x & (-1)^{|\alpha|} \int_{U} f_{1} D^{\alpha_{j}} \phi d x \quad \equiv D^{\alpha_{j}}\left(f_{1}\right)(\phi)
\end{array}
$$

[^28]It follows $D^{\alpha_{j}}\left(f_{1}\right)=f_{j}$ and so $\Lambda\left(X^{m, p}(U)\right)$ is closed as claimed. This is clearly also a subspace of $L^{p}(U)^{w}$ and so it follows that $\Lambda\left(X^{m, p}(U)\right)$ is a reflexive Banach space. This is because $L^{p}(U)^{w}$, being the product of reflexive Banach spaces, is reflexive and any closed subspace of a reflexive Banach space is reflexive. Now $\Lambda$ is an isometry of $X^{m, p}(U)$ and $\Lambda\left(X^{m, p}(U)\right)$ which shows that $X^{m, p}(U)$ is a reflexive Banach space. Finally, $W^{m, p}(U)$ is a closed subspace of the reflexive Banach space, $X^{m, p}(U)$ and so it is also reflexive. To see $X^{m, p}(U)$ is separable, note that $L^{p}(U)^{w}$ is separable because it is the finite product of the separable hence completely separable metric space, $L^{p}(U)$ and $\Lambda\left(X^{m, p}(U)\right)$ is a subset of $L^{p}(U)^{w}$. Therefore, $\Lambda\left(X^{m, p}(U)\right)$ is separable and since $\Lambda$ is an isometry, it follows $X^{m, p}(U)$ is separable also. Now $W^{m, p}(U)$ must also be separable because it is a subset of $X^{m, p}(U)$.

The following theorem is obvious but is worth noting because it says that if a function has a weak derivative in $L^{p}(U)$ on a large open set, $U$ then the restriction of this weak derivative is also the weak derivative for any smaller open set.

Theorem 38.0.4 Suppose $U$ is an open set and $U_{0} \subseteq U$ is another open set. Suppose also $D^{\alpha} u \in L^{p}(U)$. Then for all $\psi \in C_{c}^{\infty}\left(U_{0}\right)$,

$$
\int_{U_{0}}\left(D^{\alpha} u\right) \psi d x=(-1)^{|\alpha|} \int_{U_{0}} u\left(D^{\alpha} \psi\right)
$$

The following theorem is a fundamental approximation result for functions in $X^{m, p}(U)$.

Theorem 38.0.5 Let $U$ be an open set and let $U_{0}$ be an open subset of $U$ with the property that $\operatorname{dist}\left(\overline{U_{0}}, U^{C}\right)>0$. Then if $u \in X^{m, p}(U)$ and $\widetilde{u}$ denotes the zero extention of $u$ off $U$,

$$
\lim _{l \rightarrow \infty}\left\|\widetilde{u} * \phi_{l}-u\right\|_{X^{m, p}\left(U_{0}\right)}=0
$$

Proof: Always assume $l$ is large enough that $1 / l<\operatorname{dist}\left(\overline{U_{0}}, U^{C}\right)$. Thus for $\mathbf{x} \in U_{0}$,

$$
\begin{equation*}
\widetilde{u} * \phi_{l}(\mathbf{x})=\int_{B\left(\mathbf{0}, \frac{1}{l}\right)} u(\mathbf{x}-\mathbf{y}) \phi_{l}(\mathbf{y}) d y \tag{38.0.1}
\end{equation*}
$$

The theorem is proved if it can be shown that $D^{\alpha}\left(\widetilde{u} * \phi_{l}\right) \rightarrow D^{\alpha} u$ in $L^{p}\left(U_{0}\right)$. Let $\psi \in$ $C_{c}^{\infty}\left(U_{0}\right)$

$$
\begin{aligned}
D^{\alpha}\left(\widetilde{u} * \phi_{l}\right)(\psi) & \equiv(-1)^{|\alpha|} \int_{U_{0}}\left(\widetilde{u} * \phi_{l}\right)\left(D^{\alpha} \psi\right) d x \\
& =(-1)^{|\alpha|} \int_{U_{0}} \int \widetilde{u}(\mathbf{y}) \phi_{l}(\mathbf{x}-\mathbf{y})\left(D^{\alpha} \psi\right)(\mathbf{x}) d y d x \\
& =(-1)^{|\alpha|} \int_{U} u(\mathbf{y}) \int_{U_{0}} \phi_{l}(\mathbf{x}-\mathbf{y})\left(D^{\alpha} \psi\right)(\mathbf{x}) d x d y
\end{aligned}
$$

Also,

$$
\begin{aligned}
\left(\widetilde{D^{\alpha} u} * \phi_{l}\right)(\psi) & \equiv \int_{U_{0}}\left(\int \widetilde{D^{\alpha} u}(\mathbf{y}) \phi_{l}(\mathbf{x}-\mathbf{y}) d y\right) \psi(\mathbf{x}) d x \\
& =\int_{U_{0}}\left(\int_{U} D^{\alpha} u(\mathbf{y}) \phi_{l}(\mathbf{x}-\mathbf{y}) d y\right) \psi(\mathbf{x}) d x \\
& =\int_{U_{0}}\left(\int_{U} u(\mathbf{y})\left(D^{\alpha} \phi_{l}\right)(\mathbf{x}-\mathbf{y}) d y\right) \psi(\mathbf{x}) d x \\
& =\int_{U} u(\mathbf{y}) \int_{U_{0}}\left(D^{\alpha} \phi_{l}\right)(\mathbf{x}-\mathbf{y}) \psi(\mathbf{x}) d x d y \\
& =(-1)^{|\alpha|} \int_{U} u(\mathbf{y}) \int_{U_{0}} \phi_{l}(\mathbf{x}-\mathbf{y})\left(D^{\alpha} \psi\right)(\mathbf{x}) d x d y
\end{aligned}
$$

It follows that $D^{\alpha}\left(\widetilde{u} * \phi_{l}\right)=\left(\widetilde{D^{\alpha} u} * \phi_{l}\right)$ as weak derivatives defined on $C_{c}^{\infty}\left(U_{0}\right)$. Therefore,

$$
\begin{aligned}
\left\|D^{\alpha}\left(\widetilde{u} * \phi_{l}\right)-D^{\alpha} u\right\|_{L^{p}\left(U_{0}\right)} & =\left\|\widetilde{D^{\alpha} u} * \phi_{l}-D^{\alpha} u\right\|_{L^{p}\left(U_{0}\right)} \\
& \leq \| \widetilde{D^{\alpha} u * \phi_{l}-\widetilde{D^{\alpha} u} \|_{L^{p}\left(\mathbb{R}^{n}\right)} \rightarrow 0} .
\end{aligned}
$$

This proves the theorem.
As part of the proof of the theorem, the following corollary was established.
Corollary 38.0.6 Let $U_{0}$ and $U$ be as in the above theorem. Then for all l large enough and $\phi_{l}$ a mollifier,

$$
\begin{equation*}
D^{\alpha}\left(\widetilde{u} * \phi_{l}\right)=\left(\widetilde{D^{\alpha} u} * \phi_{l}\right) \tag{38.0.2}
\end{equation*}
$$

as distributions on $C_{c}^{\infty}\left(U_{0}\right)$.
Definition 38.0.7 Let $U$ be an open set. $C^{\infty}(U)$ denotes the set of functions which are defined and infinitely differentiable on $U$.

Note that $f(x)=\frac{1}{x}$ is a function in $C^{\infty}(0,1)$. However, it is not equal to the restriction to $(0,1)$ of some function which is in $C_{c}^{\infty}(\mathbb{R})$. This illustrates the distinction between $C^{\infty}(U)$ and $C^{\infty}(\bar{U})$. The set, $C^{\infty}(\bar{U})$ is a subset of $C^{\infty}(U)$. The following theorem is known as the Meyer Serrin theorem.

Theorem 38.0.8 (Meyer Serrin) Let $U$ be an open subset of $\mathbb{R}^{n}$. Then if $\delta>0$ and $u \in$ $X^{m, p}(U)$, there exists $J \in C^{\infty}(U)$ such that $\|J-u\|_{m, p, U}<\delta$.

Proof: Let $\cdots U_{k} \subseteq \overline{U_{k}} \subseteq U_{k+1} \cdots$ be a sequence of open subsets of $U$ whose union equals $U$ such that $\overline{U_{k}}$ is compact for all $k$. Also let $U_{-3}=U_{-2}=U_{-1}=U_{0}=\emptyset$. Now define $V_{k} \equiv U_{k+1} \backslash \overline{U_{k-1}}$. Thus $\left\{V_{k}\right\}_{k=1}^{\infty}$ is an open cover of $U$. Note the open cover is locally finite and therefore, there exists a partition of unity subordinate to this open cover,
$\left\{\eta_{k}\right\}_{k=1}^{\infty}$ such that each $\operatorname{spt}\left(\eta_{k}\right) \in C_{c}\left(V_{k}\right)$. Let $\psi_{m}$ denote the sum of all the $\eta_{k}$ which are non zero at some point of $V_{m}$. Thus

$$
\begin{equation*}
\operatorname{spt}\left(\psi_{m}\right) \subseteq U_{m+2} \backslash \overline{U_{m-2}}, \psi_{m} \in C_{c}^{\infty}(U), \sum_{m=1}^{\infty} \psi_{m}(\mathbf{x})=1 \tag{38.0.3}
\end{equation*}
$$

for all $\mathbf{x} \in U$, and $\psi_{m} u \in W^{m, p}\left(U_{m+2}\right)$.
Now let $\phi_{l}$ be a mollifier and consider

$$
\begin{equation*}
J \equiv \sum_{m=0}^{\infty} u \psi_{m} * \phi_{l_{m}} \tag{38.0.4}
\end{equation*}
$$

where $l_{m}$ is chosen large enough that the following two conditions hold:

$$
\begin{gather*}
\operatorname{spt}\left(u \psi_{m} * \phi_{l_{m}}\right) \subseteq U_{m+3} \backslash \overline{U_{m-3}},  \tag{38.0.5}\\
\left\|\left(u \psi_{m}\right) * \phi_{l_{m}}-u \psi_{m}\right\|_{m, p, U_{m+3}}=\left\|\left(u \psi_{m}\right) * \phi_{l_{m}}-u \psi_{m}\right\|_{m, p, U}<\frac{\delta}{2^{m+5}}, \tag{38.0.6}
\end{gather*}
$$

where 38.0.6 is obtained from Theorem 38.0.5. Because of 38.0 .3 only finitely many terms of the series in 38.0.4 are nonzero and therefore, $J \in C^{\infty}(U)$. Now let $N>10$, some large value.

$$
\begin{aligned}
\|J-u\|_{m, p, U_{N-3}} & =\left\|\sum_{k=0}^{N}\left(u \psi_{k} * \phi_{l_{k}}-u \psi_{k}\right)\right\|_{m, p, U_{N-3}} \\
& \leq \sum_{k=0}^{N}\left\|u \psi_{k} * \phi_{l_{k}}-u \psi_{k}\right\|_{m, p, U_{N-3}} \\
& \leq \sum_{k=0}^{N} \frac{\delta}{2^{m+5}}<\delta .
\end{aligned}
$$

Now apply the monotone convergence theorem to conclude that $\|J-u\|_{m, p, U} \leq \delta$. This proves the theorem.

Note that $J=0$ on $\partial U$. Later on, you will see that this is pathological.
In the study of partial differential equations it is the space $W^{m, p}(U)$ which is of the most use, not the space $X^{m, p}(U)$. This is because of the density of $C^{\infty}(\bar{U})$. Nevertheless, for reasonable open sets, $U$, the two spaces coincide.

Definition 38.0.9 An open set, $U \subseteq \mathbb{R}^{n}$ is said to satisfy the segment condition if for all $\mathbf{z} \in \bar{U}$, there exists an open set $U_{\mathbf{z}}$ containing $\mathbf{z}$ and a vector $\mathbf{a}$ such that

$$
\bar{U} \cap \bar{U}_{\mathbf{z}}+t \mathbf{a} \subseteq U
$$

for all $t \in(0,1)$.

You can imagine open sets which do not satisfy the segment condition. For example, a pair of circles which are tangent at their boundaries. The condition in the above definition breaks down at their point of tangency.

Here is a simple lemma which will be used in the proof of the following theorem.
Lemma 38.0.10 If $u \in W^{m, p}(U)$ and $\psi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$, then $u \psi \in W^{m, p}(U)$.
Proof: Let $|\alpha| \leq m$ and let $\phi \in C_{c}^{\infty}(U)$. Then

$$
\begin{aligned}
\left(D_{x_{i}}(u \psi)\right)(\phi) & \equiv-\int_{U} u \psi \phi_{, x_{i}} d x \\
& =-\int_{U} u\left((\psi \phi)_{x_{i}}-\phi \psi_{, x_{i}}\right) d x \\
& =\left(D_{x_{i}} u\right)(\psi \phi)+\int_{U} u \psi_{, x_{i}} \phi d x \\
& =\int_{U}\left(\psi D_{x_{i}} u+u \psi_{, x_{i}}\right) \phi d x
\end{aligned}
$$

Therefore, $D_{x_{i}}(u \psi)=\psi D_{x_{i}} u+u \psi_{x_{i}} \in L^{p}(U)$. In other words, the product rule holds. Now considering the terms in the last expression, you can do the same argument with each of these as long as they all have derivatives in $L^{p}(U)$. Therefore, continuing this process the lemma is proved.

Theorem 38.0.11 Let $U$ be an open set and suppose there exists a locally finite covering ${ }^{2}$ of $\bar{U}$ which is of the form $\left\{U_{i}\right\}_{i=1}^{\infty}$ such that each $U_{i}$ is a bounded open set which satisfies the conditions of Definition 38.0.9. Thus there exist vectors, $\mathbf{a}_{i}$ such that for all $t \in(0,1)$,

$$
\overline{U_{i}} \cap U+t \mathbf{a}_{i} \subseteq U
$$

Then $C^{\infty}(\bar{U})$ is dense in $X^{m, p}(U)$ and so $W^{m, p}(U)=X^{m, p}(U)$.

[^29]Proof: Let $\left\{\psi_{i}\right\}_{i=1}^{\infty}$ be a partition of unity subordinate to the given open cover with $\psi_{i} \in C_{c}^{\infty}\left(U_{i}\right)$ and let $u \in X^{m, p}(U)$. Thus

$$
u=\sum_{k=1}^{\infty} \psi_{k} u .
$$

Consider $U_{k}$ for some $k$. Let $\mathbf{a}_{k}$ be the special vector associated with $U_{k}$ such that

$$
\begin{equation*}
t \mathbf{a}_{k}+\bar{U} \cap \overline{U_{k}} \subseteq U \tag{38.0.7}
\end{equation*}
$$

for all $t \in(0,1)$ and consider only $t$ small enough that

$$
\begin{equation*}
\operatorname{spt}\left(\psi_{k}\right)-t \mathbf{a}_{k} \subseteq U_{k} \tag{38.0.8}
\end{equation*}
$$

Pick $l(t)>1 / t$ which is also large enough that

$$
\begin{equation*}
t \mathbf{a}_{k}+\bar{U} \cap \overline{U_{k}}+B\left(\mathbf{0}, \frac{1}{l(t)}\right) \subseteq U, \overline{\operatorname{spt}\left(\psi_{k}\right)+B\left(\mathbf{0}, \frac{1}{l\left(t_{k}\right)}\right)-t \mathbf{a}_{k}} \subseteq U_{k} \tag{38.0.9}
\end{equation*}
$$

This can be done because $t \mathbf{a}_{k}+\bar{U} \cap \overline{U_{k}}$ is a compact subset of $U$ and so has positive distance to $U^{C}$ and $\operatorname{spt}\left(\psi_{k}\right)-t \mathbf{a}_{k}$ is a compact subset of $U_{k}$ having positive distance to $U_{k}^{C}$. Let $t_{k}$ be such a value for $t$ and for $\phi_{l}$ a mollifier, define

$$
\begin{equation*}
v_{t_{k}}(\mathbf{x}) \equiv \int_{\mathbb{R}^{n}} \widetilde{u}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) \psi_{k}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) \phi_{l\left(t_{k}\right)}(\mathbf{y}) d y \tag{38.0.10}
\end{equation*}
$$

where as usual, $\widetilde{u}$ is the zero extention of $u$ off $U$. For $v_{t_{k}}(\mathbf{x}) \neq 0$, it is necessary that $\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y} \in \operatorname{spt}\left(\psi_{k}\right)$ for some $\mathbf{y} \in B\left(\mathbf{0}, \frac{1}{l\left(t_{k}\right)}\right)$. Therefore, using 38.0.9, for $v_{t_{k}}(\mathbf{x}) \neq 0$, it is necessary that

$$
\begin{gathered}
\mathbf{x} \in \mathbf{y}-t_{k} \mathbf{a}_{k}+U \cap \operatorname{spt}\left(\psi_{k}\right) \subseteq B\left(\mathbf{0}, \frac{1}{l\left(t_{k}\right)}\right)+\operatorname{spt}\left(\psi_{k}\right)-t_{k} \mathbf{a}_{k} \\
\subseteq \overline{B\left(\mathbf{0}, \frac{1}{l\left(t_{k}\right)}\right)+\operatorname{spt}\left(\psi_{k}\right)-t_{k} \mathbf{a}_{k}} \subseteq U_{k}
\end{gathered}
$$

showing that $v_{t_{k}}$ has compact support in $U_{k}$. Now change variables in 38.0.10 to obtain

$$
\begin{equation*}
v_{t_{k}}(\mathbf{x}) \equiv \int_{\mathbb{R}^{n}} \widetilde{u}(\mathbf{y}) \psi_{k}(\mathbf{y}) \phi_{l\left(t_{k}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) d y \tag{38.0.11}
\end{equation*}
$$

For $\mathbf{x} \in U \cap U_{k}$, the above equals zero unless

$$
\mathbf{y}-t_{k} \mathbf{a}_{k}-\mathbf{x} \in B\left(\mathbf{0}, \frac{1}{l\left(t_{k}\right)}\right)
$$

which implies by 38.0.9 that

$$
\mathbf{y} \in t_{k} \mathbf{a}_{k}+U \cap U_{k}+B\left(\mathbf{0}, \frac{1}{l\left(t_{k}\right)}\right) \subseteq U
$$

Therefore, for such $\mathbf{x} \in U \cap U_{k}, 38.0 .11$ reduces to

$$
\begin{aligned}
v_{t_{k}}(\mathbf{x}) & =\int_{\mathbb{R}^{n}} u(\mathbf{y}) \psi_{k}(\mathbf{y}) \phi_{l\left(t_{k}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) d y \\
& =\int_{U} u(\mathbf{y}) \psi_{k}(\mathbf{y}) \phi_{l\left(t_{k}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) d y
\end{aligned}
$$

It follows that for $|\alpha| \leq m$, and $\mathbf{x} \in U \cap U_{k}$

$$
\begin{align*}
D^{\alpha} v_{t_{k}}(\mathbf{x}) & =\int_{U} u(\mathbf{y}) \psi_{k}(\mathbf{y}) D^{\alpha} \phi_{l\left(t_{k}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) d y \\
& =\int_{U} D^{\alpha}\left(u \psi_{k}\right)(\mathbf{y}) \phi_{l\left(t_{k}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) d y \\
& =\int_{\mathbb{R}^{n}} \widetilde{\left.D^{\alpha\left(u \psi_{k}\right.}\right)}(\mathbf{y}) \phi_{l\left(t_{k}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) d y \\
& =\int_{\mathbb{R}^{n}} \widetilde{\left.D^{\alpha\left(u \psi_{k}\right.}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right) \phi_{l\left(t_{k}\right)}(\mathbf{y}) d y \tag{38.0.12}
\end{align*}
$$

Actually, this formula holds for all $\mathbf{x} \in U$. If $\mathbf{x} \in U$ but $\mathbf{x} \notin U_{k}$, then the left side of the above formula equals zero because, as noted above, $\operatorname{spt}\left(v_{t_{k}}\right) \subseteq U_{k}$. The integrand of the right side equals zero unless

$$
\mathbf{x} \in B\left(\mathbf{0}, \frac{1}{l\left(t_{k}\right)}\right)+\operatorname{spt}\left(\psi_{k}\right)-t_{k} \mathbf{a}_{k} \subseteq U_{k}
$$

by 38.0.9 and here $\mathbf{x} \notin U_{k}$.
Next an estimate is obtained for $\left\|D^{\alpha} v_{t_{k}}-D^{\alpha}\left(u \psi_{k}\right)\right\|_{L^{p}(U)}$. By 38.0.12,

$$
\begin{gathered}
\| D^{\alpha} v_{t_{k}}-\left.D^{\alpha}\left(u \psi_{k}\right)\right|_{L^{p}(U)} \leq \\
\left(\int _ { U } \left(\int_{\mathbb{R}^{n}}\left|\widetilde{\left.D^{\alpha\left(u \psi_{k}\right.}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right)-\widetilde{\left.D^{\alpha\left(u \psi_{k}\right.}\right)}(\mathbf{x})\right| \widetilde{\left.\left.\phi_{l\left(t_{k}\right)}(\mathbf{y}) d y\right)^{p} d x\right)^{1 / p}}\right.\right. \\
\leq \int_{\mathbb{R}^{n}} \phi_{l\left(t_{k}\right)}(\mathbf{y})\left(\int_{U}\left|\widetilde{\left.D^{\alpha\left(u \psi_{k}\right.}\right)}\left(\mathbf{x}+t_{k} \mathbf{a}_{k}-\mathbf{y}\right)-\widetilde{\left.D^{\alpha\left(u \psi_{k}\right.}\right)}(\mathbf{x})\right|^{p} d x\right)^{1 / p} d y \\
\leq \frac{\varepsilon}{2^{k}}
\end{gathered}
$$

whenever $t_{k}$ is taken small enough. Pick $t_{k}$ this small and let $w_{k} \equiv v_{t_{k}}$. Thus

$$
\left\|D^{\alpha} w_{k}-D^{\alpha}\left(u \psi_{k}\right)\right\|_{L^{p}(U)} \leq \frac{\varepsilon}{2^{k}}
$$

and $w_{k} \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. Now let

$$
J(\mathbf{x}) \equiv \sum_{k=1}^{\infty} w_{k}
$$

Since the $U_{k}$ are locally finite and $\operatorname{spt}\left(w_{k}\right) \subseteq U_{k}$ for each $k$, it follows

$$
D^{\alpha} J=\sum_{k=0}^{\infty} D^{\alpha} w_{k}
$$

and the sum is always finite. Similarly,

$$
D^{\alpha} \sum_{k=1}^{\infty}\left(\psi_{k} u\right)=\sum_{k=1}^{\infty} D^{\alpha}\left(\psi_{k} u\right)
$$

and the sum is always finite. Therefore,

$$
\begin{aligned}
\left\|D^{\alpha} J-D^{\alpha} u\right\|_{L^{p}(U)} & =\left\|\sum_{k=1}^{\infty} D^{\alpha} w_{k}-D^{\alpha}\left(\psi_{k} u\right)\right\|_{L^{p}(U)} \\
& \leq \sum_{k=1}^{\infty}\left\|D^{\alpha} w_{k}-D^{\alpha}\left(\psi_{k} u\right)\right\|_{L^{p}(U)} \leq \sum_{k=1}^{\infty} \frac{\varepsilon}{2^{k}}=\varepsilon
\end{aligned}
$$

By choosing $t_{k}$ small enough, such an inequality can be obtained for

$$
\left\|D^{\beta} J-D^{\beta} u\right\|_{L^{p}(U)}
$$

for each multi index, $\beta$ such that $|\beta| \leq m$. Therefore, there exists

$$
J \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)
$$

such that

$$
\|J-u\|_{W^{m, p}(U)} \leq \varepsilon K
$$

where $K$ equals the number of multi indices no larger than $m$. Since $\varepsilon$ is arbitrary, this proves the theorem.

Corollary 38.0.12 Let $U$ be an open set which has the segment property. Then $W^{m, p}(U)=$ $X^{m, p}(U)$.

Proof: Start with an open covering of $\bar{U}$ whose sets satisfy the segment condition and obtain a locally finite refinement consisting of bounded sets which are of the sort in the above theorem.

Now consider a situation where $\mathbf{h}: U \rightarrow V$ where $U$ and $V$ are two open sets in $\mathbb{R}^{n}$ and $D^{\alpha} \mathbf{h}$ exists and is continuous and bounded if $|\alpha|<m-1$ and $D^{\alpha} \mathbf{h}$ is Lipschitz if $|\alpha|=m-1$.

Definition 38.0.13 Whenever $\mathbf{h}: U \rightarrow V$, define $\mathbf{h}^{*}$ mapping the functions which are defined on $V$ to the functions which are defined on $U$ as follows.

$$
\mathbf{h}^{*} f(\mathbf{x}) \equiv f(\mathbf{h}(\mathbf{x}))
$$

$\mathbf{h}: U \rightarrow V$ is bilipschitz if $\mathbf{h}$ is one to one, onto and Lipschitz and $\mathbf{h}^{-1}$ is also one to one, onto and Lipschitz.

Theorem 38.0.14 Let $\mathbf{h}: U \rightarrow V$ be one to one and onto where $U$ and $V$ are two open sets. Also suppose that $D^{\alpha} \mathbf{h}$ and $D^{\alpha}\left(\mathbf{h}^{-1}\right)$ exist and are Lipschitz continuous if $|\alpha| \leq m-1$ for $m$ a positive integer. Then

$$
\mathbf{h}^{*}: W^{m, p}(V) \rightarrow W^{m, p}(U)
$$

is continuous, linear, one to one, and has an inverse with the same properties, the inverse being $\left(\mathbf{h}^{-1}\right)^{*}$.

Proof: It is clear that $\mathbf{h}^{*}$ is linear. It is required to show it is one to one and continuous. First suppose $\mathbf{h}^{*} f=0$. Then

$$
0=\int_{V}|f(\mathbf{h}(\mathbf{x}))|^{p} d x
$$

and so $f(\mathbf{h}(\mathbf{x}))=0$ for a.e. $\mathbf{x} \in U$. Since $\mathbf{h}$ is Lipschitz, it takes sets of measure zero to sets of measure zero. Therefore, $f(\mathbf{y})=0$ a.e. This shows $\mathbf{h}^{*}$ is one to one.

By the Meyer Serrin theorem, Theorem 38.0.8, it suffices to verify that $\mathbf{h}^{*}$ is continuous on functions in $C^{\infty}(V)$. Let $f$ be such a function. Then using the chain rule and product $\operatorname{rule},\left(\mathbf{h}^{*} f\right)_{, i}(\mathbf{x})=f_{, k}(\mathbf{h}(\mathbf{x})) h_{k, i}(\mathbf{x})$,

$$
\begin{aligned}
\left(\mathbf{h}^{*} f\right)_{, i j}(\mathbf{x}) & =\left(f_{, k}(\mathbf{h}(\mathbf{x})) h_{k, i}(\mathbf{x})\right)_{, j} \\
& =f_{, k l}(\mathbf{h}(\mathbf{x})) h_{l, j}(\mathbf{x}) h_{k, i}(\mathbf{x})+f_{, k}(\mathbf{h}(\mathbf{x})) h_{k, i j}(\mathbf{x})
\end{aligned}
$$

etc. In general, for $|\alpha| \leq m-1$, succsessive applications of the product rule and chain rule yield that $D^{\alpha}\left(\mathbf{h}^{*} f\right)(\mathbf{x})$ has the form

$$
D^{\alpha}\left(\mathbf{h}^{*} f\right)(\mathbf{x})=\sum_{|\beta| \leq|\alpha|} \mathbf{h}^{*}\left(D^{\beta} f\right)(\mathbf{x}) g_{\beta}(\mathbf{x})
$$

where $g_{\beta}$ is a bounded Lipschitz function with Lipschitz constant dependent on $\mathbf{h}$ and its derivatives. It only remains to take one more derivative of the functions, $D^{\alpha} f$ for $|\alpha|=$ $m-1$. This can be done again but this time you have to use Rademacher's theorem which assures you that the derivative of a Lipschitz function exists a.e. in order to take the partial derivative of the $g_{\beta}(\mathbf{x})$. When this is done, the above formula remains valid for all $|\alpha| \leq m$. Therefore, using the change of variables formula for multiple integrals, Corollary 36.6.14 on Page 1296,

$$
\begin{aligned}
\int_{U}\left|D^{\alpha}\left(\mathbf{h}^{*} f\right)(\mathbf{x})\right|^{p} d x & \leq C_{m, p, \mathbf{h}} \sum_{|\beta| \leq m} \int_{U}\left|\mathbf{h}^{*}\left(D^{\beta} f\right)(\mathbf{x})\right|^{p} d x \\
& =C_{m, p, \mathbf{h}} \sum_{|\beta| \leq m} \int_{U}\left|\left(D^{\beta} f\right)(\mathbf{h}(\mathbf{x}))\right|^{p} d x \\
& =C_{m, p, \mathbf{h}} \sum_{|\beta| \leq m} \int_{V}\left|\left(D^{\beta} f\right)(\mathbf{y})\right|^{p}\left|\operatorname{det} D \mathbf{h}^{-1}(\mathbf{y})\right| d y \\
& \leq C_{m, p, \mathbf{h}, \mathbf{h}^{-1}} \|\left. f\right|_{m, p, V}
\end{aligned}
$$

This shows $\mathbf{h}^{*}$ is continuous on $C^{\infty}(V) \cap W^{m, p}(U)$ and since this set is dense, this proves $\mathbf{h}^{*}$ is continuous. The same argument applies to $\left(\mathbf{h}^{-1}\right)^{*}$ and now the definitions of $\mathbf{h}^{*}$ and $\left(\mathbf{h}^{-1}\right)^{*}$ show these are inverses.

### 38.1 Embedding Theorems For $W^{m, p}\left(\mathbb{R}^{n}\right)$

Recall Theorem 36.5.1 which is listed here for convenience.

Theorem 38.1.1 Suppose $u, u_{, i} \in L_{\text {loc }}^{p}\left(\mathbb{R}^{n}\right)$ for $i=1, \cdots, n$ and $p>n$. Then $u$ has a representative, still denoted by $u$, such that for all $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{n}$,

$$
\begin{equation*}
|u(\mathbf{x})-u(\mathbf{y})| \leq C\left(\int_{B(\mathbf{x}, 2|\mathbf{y}-\mathbf{x}|)}|\nabla u|^{p} d z\right)^{1 / p}|\mathbf{x}-\mathbf{y}|^{(1-n / p)} \tag{38.1.13}
\end{equation*}
$$

This amazing result shows that every $u \in W^{m, p}\left(\mathbb{R}^{n}\right)$ has a representative which is continuous provided $p>n$.

Using the above inequality, one can give an important embedding theorem.
Definition 38.1.2 Let $X, Y$ be two Banach spaces and let $f: X \rightarrow Y$ be a function. Then $f$ is a compact map if whenever $S$ is a bounded set in $X$, it follows that $f(S)$ is precompact in $Y$.

Theorem 38.1.3 Let $U$ be a bounded open set and for $u$ a function defined on $\mathbb{R}^{n}$, let $r_{U} u(\mathbf{x}) \equiv u(\mathbf{x})$ for $\mathbf{x} \in \bar{U}$. Then if $p>n, r_{U}: W^{1, p}\left(\mathbb{R}^{n}\right) \rightarrow C(\bar{U})$ is continuous and compact.

Proof: First suppose $u_{k} \rightarrow 0$ in $W^{1, p}\left(\mathbb{R}^{n}\right)$. Then if $r_{U} u_{k}$ does not converge to 0 , it follows there exists a sequence, still denoted by $k$ and $\varepsilon>0$ such that $u_{k} \rightarrow 0$ in $W^{1, p}\left(\mathbb{R}^{n}\right)$ but $\left\|r_{U} u_{k}\right\|_{\infty} \geq \varepsilon$. Selecting a further subsequence which is still denoted by $k$, you can also assume $u_{k}(\mathbf{x}) \rightarrow 0$ a.e. Pick such an $\mathbf{x}_{0} \in U$ where this convergence takes place. Then from 38.1.13, for all $\mathbf{x} \in \bar{U}$,

$$
\left|u_{k}(\mathbf{x})\right| \leq\left|u_{k}\left(\mathbf{x}_{0}\right)\right|+C\left\|u_{k}\right\|_{1, p, \mathbb{R}^{n}} \operatorname{diam}(U)
$$

showing that $u_{k}$ converges uniformly to 0 on $\bar{U}$ contrary to $\left\|r_{U} u_{k}\right\|_{\infty} \geq \varepsilon$. Therefore, $r_{U}$ is continuous as claimed.

Next let $S$ be a bounded subset of $W^{1, p}\left(\mathbb{R}^{n}\right)$ with $\|u\|_{1, p}<M$ for all $u \in S$. Then for $u \in S$

$$
r^{p} m_{n}([|u|>r] \cap U) \leq \int_{[|u|>r] \cap U}|u|^{p} d m_{n} \leq M^{p}
$$

and so

$$
m_{n}([|u|>r] \cap U) \leq \frac{M^{p}}{r^{p}}
$$

Now choosing $r$ large enough, $M^{p} / r^{p}<m_{n}(U)$ and so, for such $r$, there exists $\mathbf{x}_{u} \in U$ such that $\left|u\left(\mathbf{x}_{u}\right)\right| \leq r$. Therefore from 38.1.13, whenever $\mathbf{x} \in U$,

$$
\begin{aligned}
|u(\mathbf{x})| & \leq\left|u\left(\mathbf{x}_{u}\right)\right|+C M \operatorname{diam}(U)^{1-n / p} \\
& \leq r+C M \operatorname{diam}(U)^{1-n / p}
\end{aligned}
$$

showing that $\left\{r_{U} u: u \in S\right\}$ is uniformly bounded. But also, for $\mathbf{x}, \mathbf{y} \in \bar{U}, 38.1 .13$ implies

$$
|u(\mathbf{x})-u(\mathbf{y})| \leq C M|\mathbf{x}-\mathbf{y}|^{1-\frac{n}{p}}
$$

showing that $\left\{r_{U} u: u \in S\right\}$ is equicontinuous. By the Ascoli Arzela theorem, it follows $r_{U}(S)$ is precompact and so $r_{U}$ is compact.

Definition 38.1.4 Let $\alpha \in(0,1]$ and $K$ a compact subset of $\mathbb{R}^{n}$

$$
C^{\alpha}(K) \equiv\left\{f \in C(K): \rho_{\alpha}(f)+\|f\| \equiv\|f\|_{\alpha}<\infty\right\}
$$

where

$$
\|f\| \equiv\|f\|_{\infty} \equiv \sup \{|f(\mathbf{x})|: \mathbf{x} \in K\}
$$

and

$$
\rho_{\alpha}(f) \equiv \sup \left\{\frac{|f(\mathbf{x})-f(\mathbf{y})|}{|\mathbf{x}-\mathbf{y}|^{\alpha}}: \mathbf{x}, \mathbf{y} \in K, \mathbf{x} \neq \mathbf{y}\right\}
$$

Then $\left(C^{\alpha}(K),\|\cdot\|_{\alpha}\right)$ is a complete normed linear space called a Holder space.
The verification that this is a complete normed linear space is routine and is left for you. More generally, one considers the following class of Holder spaces.

Definition 38.1.5 Let $K$ be a compact subset of $\mathbb{R}^{n}$ and let $\lambda \in(0,1]$. $C^{m, \lambda}(K)$ denotes the set of functions, $u$ which are restrictions of functions defined on $\mathbb{R}^{n}$ to Ksuch that for $|\alpha| \leq m$,

$$
D^{\alpha} u \in C(K)
$$

and if $|\alpha|=m$,

$$
D^{\alpha} u \in C^{\lambda}(K) .
$$

Thus $C^{0, \lambda}(K)=C^{\lambda}(K)$. The norm of a function in $C^{m, \lambda}(K)$ is given by

$$
\|u\|_{m, \lambda} \equiv \sup _{|\alpha|=m} \rho_{\lambda}\left(D^{\alpha} u\right)+\sum_{|\alpha| \leq m}\left\|D^{\alpha} u\right\|_{\infty}
$$

Lemma 38.1.6 Let $m$ be a positive integer, $K$ a compact subset of $\mathbb{R}^{n}$, and let $0<\beta<\lambda \leq$ 1. Then the identity map from $C^{m, \lambda}(K)$ into $C^{m, \beta}(K)$ is compact.

Proof: First note that the containment is obvious because for any function, $f$, if

$$
\rho_{\lambda}(f) \equiv \sup \left\{\frac{|f(\mathbf{x})-f(\mathbf{y})|}{|\mathbf{x}-\mathbf{y}|^{\lambda}}: \mathbf{x}, \mathbf{y} \in K, \mathbf{x} \neq \mathbf{y}\right\}<\infty
$$

Then

$$
\begin{aligned}
\rho_{\beta}(f) & \equiv \sup \left\{\frac{|f(\mathbf{x})-f(\mathbf{y})|}{|\mathbf{x}-\mathbf{y}|^{\beta}}: \mathbf{x}, \mathbf{y} \in K, \mathbf{x} \neq \mathbf{y}\right\} \\
& =\sup \left\{\frac{|f(\mathbf{x})-f(\mathbf{y})|}{|\mathbf{x}-\mathbf{y}|^{\lambda}}|\mathbf{x}-\mathbf{y}|^{\lambda-\beta}: \mathbf{x}, \mathbf{y} \in K, \mathbf{x} \neq \mathbf{y}\right\} \\
& \leq \sup \left\{\frac{|f(\mathbf{x})-f(\mathbf{y})|}{|\mathbf{x}-\mathbf{y}|^{\lambda}} \operatorname{diam}(K)^{\lambda-\beta}: \mathbf{x}, \mathbf{y} \in K, \mathbf{x} \neq \mathbf{y}\right\}<\infty .
\end{aligned}
$$

Suppose the identity map, id, is not compact. Then there exists $\varepsilon>0$ and a sequence, $\left\{f_{k}\right\}_{k=1}^{\infty} \subseteq C^{m, \lambda}(K)$ such that $\left\|f_{k}\right\|_{m, \lambda}<M$ for all $k$ but $\left\|f_{k}-f_{l}\right\|_{\beta} \geq \varepsilon$ whenever $k \neq l$. By
the Ascoli Arzela theorem, there exists a subsequence of this, still denoted by $f_{k}$ such that $\sum_{|\alpha| \leq m}\left\|D^{\alpha}\left(f_{l}-f_{k}\right)\right\|_{\infty}<\delta$ where $\delta$ satisfies

$$
\begin{equation*}
0<\delta<\min \left(\frac{\varepsilon}{2},\left(\frac{\varepsilon}{8}\right)\left(\frac{\varepsilon}{8 M}\right)^{\beta /(\lambda-\beta)}\right) \tag{38.1.14}
\end{equation*}
$$

Therefore, $\sup _{|\alpha|=m} \rho_{\beta}\left(D^{\alpha}\left(f_{k}-f_{l}\right)\right) \geq \varepsilon-\delta$ for all $k \neq l$. It follows that there exist pairs of points and a multi index, $\alpha$ with $|\alpha|=m,\left\{\mathbf{x}_{k l}, \mathbf{y}_{k l}, \alpha\right\}$ such that

$$
\begin{equation*}
\frac{\varepsilon-\delta}{2}<\frac{\left|\left(D^{\alpha} f_{k}-D^{\alpha} f_{l}\right)\left(\mathbf{x}_{k l}\right)-\left(\left(D^{\alpha} f_{k}-D^{\alpha} f_{l}\right)\left(\mathbf{y}_{k l}\right)\right)\right|}{\left|\mathbf{x}_{k l}-\mathbf{y}_{k l}\right|^{\beta}} \leq 2 M\left|\mathbf{x}_{k l}-\mathbf{y}_{k l}\right|^{\lambda-\beta} \tag{38.1.15}
\end{equation*}
$$

and so considering the ends of the above inequality,

$$
\left(\frac{\varepsilon-\delta}{4 M}\right)^{1 /(\lambda-\beta)}<\left|\mathbf{x}_{k l}-\mathbf{y}_{k l}\right|
$$

Now also, since $\sum_{|\alpha| \leq m}\left\|D^{\alpha}\left(f_{l}-f_{k}\right)\right\|_{\infty}<\boldsymbol{\delta}$, it follows from the first inequality in 38.1.15 that

$$
\frac{\varepsilon-\delta}{2}<\frac{2 \delta}{\left(\frac{\varepsilon-\delta}{4 M}\right)^{\beta /(\lambda-\beta)}}
$$

Since $\delta<\varepsilon / 2$, this implies

$$
\frac{\varepsilon}{4}<\frac{2 \delta}{\left(\frac{\varepsilon}{8 M}\right)^{\beta /(\lambda-\beta)}}
$$

and so

$$
\left(\frac{\varepsilon}{8}\right)\left(\frac{\varepsilon}{8 M}\right)^{\beta /(\lambda-\beta)}<\delta
$$

contrary to 38.1 .14 . This proves the lemma.
Corollary 38.1.7 Let $p>n, U$ and $r_{U}$ be as in Theorem 38.1.3 and let $m$ be a nonnegative integer. Then $r_{U}: W^{m+1, p}\left(\mathbb{R}^{n}\right) \rightarrow C^{m, \lambda}(\bar{U})$ is continuous as a map into $C^{m, \lambda}(\bar{U})$ for all $\lambda \in\left[0,1-\frac{n}{p}\right]$ and $r_{U}$ is compact if $\lambda<1-\frac{n}{p}$.

Proof: Suppose $u_{k} \rightarrow 0$ in $W^{m+1, p}\left(\mathbb{R}^{n}\right)$. Then from 38.1.13, if $\lambda \leq 1-\frac{n}{p}$ and $|\alpha|=m$

$$
\rho_{\lambda}\left(D^{\alpha} u_{k}\right) \leq C\left\|D^{\alpha} u_{k}\right\|_{1, p} \operatorname{diam}(U)^{1-\frac{n}{p}-\lambda} .
$$

Therefore, $\rho_{\lambda}\left(D^{\alpha} u_{k}\right) \rightarrow 0$. From Theorem 38.1.3 it follows that for $|\alpha| \leq m$,

$$
\left\|D^{\alpha} u_{k}\right\|_{\infty} \rightarrow 0
$$

and so $\left\|u_{k}\right\|_{m, \lambda} \rightarrow 0$. This proves the claim about continuity. The claim about compactness for $\lambda<1-\frac{n}{p}$ follows from Lemma 38.1.6 and this.
(Bounded in $W^{m, p}\left(\mathbb{R}^{n}\right) \xrightarrow{r_{U}}$ Bounded in $C^{m, 1-\frac{n}{p}}(\bar{U}) \xrightarrow{\text { id }}$ Compact in $C^{m, \lambda}(\bar{U})$.)
It is just as important to consider the case where $p<n$. To do this case the following lemma due to Gagliardo [53] will be of interest. See also [1].

Lemma 38.1.8 Suppose $n \geq 2$ and $w_{j}$ does not depend on the $j^{\text {th }}$ component of $\mathbf{x}, x_{j}$. Then

$$
\int_{\mathbb{R}^{n}} \prod_{j=1}^{n}\left|w_{j}(\mathbf{x})\right| d m_{n} \leq \prod_{i=1}^{n}\left(\int_{\mathbb{R}^{n-1}}\left|w_{j}(\mathbf{x})\right|^{n-1} d m_{n-1}\right)^{1 /(n-1)}
$$

In this inequality, assume all the functions are continuous so there can be no measurability questions.

Proof: First note that for $n=2$ the inequality reduces to the statement

$$
\iint\left|w_{1}\left(x_{2}\right)\right|\left|w_{2}\left(x_{1}\right)\right| d x_{1} d x_{2} \leq \int\left|w_{1}\left(x_{2}\right)\right| d x_{2} \int\left|w_{2}\left(x_{1}\right)\right| d x_{1}
$$

which is obviously true. Suppose then that the inequality is valid for some $n$. Using Fubini's theorem, Holder's inequality, and the induction hypothesis,

$$
\begin{aligned}
& \int_{\mathbb{R}^{n+1}} \prod_{j=1}^{n+1}\left|w_{j}(\mathbf{x})\right| d m_{n+1} \\
= & \int_{\mathbb{R}} \int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right| \prod_{j=1}^{n}\left|w_{j}(\mathbf{x})\right| d m_{n} d x_{n+1} \\
= & \int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right| \int_{\mathbb{R}} \prod_{j=1}^{n}\left|w_{j}(\mathbf{x})\right| d x_{n+1} d m_{n} \\
= & \int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right|\left(\prod_{j=1}^{n} \int_{\mathbb{R}}\left|w_{j}(\mathbf{x})\right|^{n} d x_{n+1}\right)^{1 / n} d m_{n} \\
& =\int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right| \prod_{j=1}^{n}\left(\int_{\mathbb{R}}\left|w_{j}(\mathbf{x})\right|^{n} d x_{n+1}\right)^{1 / n} d m_{n} \\
\leq & \left(\int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right|^{n} d m_{n}\right)^{1 / n} \cdot \\
& \left(\int_{\mathbb{R}^{n}}\left(\prod_{j=1}^{n}\left(\int_{\mathbb{R}}\left|w_{j}(\mathbf{x})\right|^{n} d x_{n+1}\right)^{1 / n}\right)^{n /(n-1)} d m_{n}\right)^{(n-1) / n} \\
= & \left(\int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right|^{n} d m_{n}\right)^{1 / n} \cdot \\
& \left(\int_{\mathbb{R}^{n}} \prod_{j=1}^{n}\left(\int_{\mathbb{R}}\left|w_{j}(\mathbf{x})\right|^{n} d x_{n+1}\right)^{1 /(n-1)} d m_{n}\right)^{(n-1) / n}
\end{aligned}
$$

$$
\begin{aligned}
\leq & \left(\int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right|^{n} d m_{n}\right)^{1 / n} \\
& \left(\prod_{j=1}^{n}\left(\int_{\mathbb{R}^{n-1}}\left(\int_{\mathbb{R}}\left|w_{j}(\mathbf{x})\right|^{n} d x_{n+1}\right) d m_{n-1}\right)^{1 /(n-1)}\right)^{(n-1) / n} \\
= & \left(\int_{\mathbb{R}^{n}}\left|w_{n+1}(\mathbf{x})\right|^{n} d m_{n}\right)^{1 / n} \prod_{j=1}^{n}\left(\int_{\mathbb{R}^{n}}\left|w_{j}(\mathbf{x})\right|^{n} d m_{n}\right)^{1 / n} \\
= & \prod_{j=1}^{n+1}\left(\int_{\mathbb{R}^{n}}\left|w_{j}(\mathbf{x})\right|^{n} d m_{n}\right)^{1 / n}
\end{aligned}
$$

This proves the lemma.
Lemma 38.1.9 If $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ and $n \geq 1$, then

$$
\|\phi\|_{n /(n-1)} \leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n}\left\|\frac{\partial \phi}{\partial x_{j}}\right\|_{1}
$$

Proof: The case where $n=1$ is obvious if $n /(n-1)$ is interpreted as $\infty$. Assume then that $n>1$ and note that for $a_{i} \geq 0$,

$$
n \prod_{i=1}^{n} a_{i} \leq\left(\sum_{j=1}^{n} a_{i}\right)^{n}
$$

In fact, the term on the left is one of many terms of the expression on the right. Therefore, taking $n^{\text {th }}$ roots

$$
\prod_{i=1}^{n} a_{i}^{1 / n} \leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} a_{i}
$$

Then observe that for each $j=1,2, \cdots, n$,

$$
|\phi(\mathbf{x})| \leq \int_{-\infty}^{\infty}\left|\phi_{, j}(\mathbf{x})\right| d x_{j}
$$

so

$$
\begin{aligned}
& \|\phi\|_{n /(n-1)}^{n /(n-1)} \equiv \int_{\mathbb{R}^{n}}|\phi(\mathbf{x})|^{n /(n-1)} d m_{n} \\
\leq & \int_{\mathbb{R}^{n}} \prod_{j=1}^{n}\left(\int_{-\infty}^{\infty}\left|\phi_{, j}(\mathbf{x})\right| d x_{j}\right)^{1 /(n-1)} d m_{n}
\end{aligned}
$$

and from Lemma 38.1.8 this is dominated by

$$
\leq \prod_{j=1}^{n}\left(\int_{\mathbb{R}^{n}}\left|\phi_{, j}(\mathbf{x})\right| d m_{n}\right)^{1 /(n-1)}
$$

Hence $\prod_{i=1}^{n} a_{i}^{1 / n} \leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} a_{i}$

$$
\begin{aligned}
\|\phi\|_{n /(n-1)} & \leq \prod_{j=1}^{n}\left(\int_{\mathbb{R}^{n}}\left|\phi_{, j}(\mathbf{x})\right| d m_{n}\right)^{1 / n} \\
& \leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} \int_{\mathbb{R}^{n}}\left|\phi_{, j}(\mathbf{x})\right| d m_{n} \\
& =\frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n}\left\|\phi_{, i}\right\|_{1}
\end{aligned}
$$

and this proves the lemma.
The above lemma is due to Gagliardo and Nirenberg.
With this lemma, it is possible to prove a major embedding theorem which follows.
Theorem 38.1.10 Let $1 \leq p<n$ and $\frac{1}{q}=\frac{1}{p}-\frac{1}{n}$. Then if $f \in W^{1, p}\left(\mathbb{R}^{n}\right)$,

$$
\|f\|_{q} \leq \frac{1}{\sqrt[n]{n}} \frac{(n-1) p}{n-p}\|f\|_{1, p, \mathbb{R}^{n}}
$$

Proof: From the definition of $W^{1, p}\left(\mathbb{R}^{n}\right), C_{c}^{1}\left(\mathbb{R}^{n}\right)$ is dense in $W^{1, p}$. Here $C_{c}^{1}\left(\mathbb{R}^{n}\right)$ is the space of continuous functions having continuous derivatives which have compact support. The desired inequality will be established for such $\phi$ and then the density of this set in $W^{1, p}\left(\mathbb{R}^{n}\right)$ will be exploited to obtain the inequality for all $f \in W^{1, p}\left(\mathbb{R}^{n}\right)$. First note that the case where $p=1$ follows immediately from the above lemma and so it is only necessary to consider the case where $p>1$.

Let $\phi \in C_{c}^{1}\left(\mathbb{R}^{n}\right)$ and consider $|\phi|^{r}$ where $r>1$. Then a short computation shows $|\phi|^{r} \in$ $C_{c}^{1}\left(\mathbb{R}^{n}\right)$ and

$$
\left||\phi|_{, i}^{r}\right|=r|\phi|^{r-1}\left|\phi_{, i}\right| .
$$

Therefore, from Lemma 38.1.9,

$$
\begin{aligned}
& \left(\int|\phi|^{\frac{r n}{n-1}} d m_{n}\right)^{(n-1) / n} \\
\leq & \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n} \int|\phi|^{r-1}\left|\phi_{, i}\right| d m_{n} \\
\leq & \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n}\left(\int\left|\phi_{, i}\right|^{p}\right)^{1 / p}\left(\int\left(|\phi|^{r-1}\right)^{p /(p-1)} d m_{n}\right)^{(p-1) / p} .
\end{aligned}
$$

Now choose $r$ such that

$$
\frac{(r-1) p}{p-1}=\frac{r n}{n-1}
$$

That is, let $r=\frac{p(n-1)}{n-p}>1$ and so $\frac{r n}{n-1}=\frac{n p}{n-p}$. Then this reduces to

$$
\left(\int|\phi|^{\frac{n p}{n-p}} d m_{n}\right)^{(n-1) / n} \leq \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n}\left(\int\left|\phi_{, i}\right|^{p}\right)^{1 / p}\left(\int|\phi|^{\frac{n p}{n-p}} d m_{n}\right)^{(p-1) / p}
$$

Also, $\frac{n-1}{n}-\frac{p-1}{p}=\frac{n-p}{n p}$ and so, dividing both sides by the last term yields

$$
\left(\int|\phi|^{\frac{n p}{n-p}} d m_{n}\right)^{\frac{n-p}{n p}} \leq \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n}\left(\int\left|\phi_{, i}\right|^{p}\right)^{1 / p} \leq \frac{r}{\sqrt[n]{n}}\|\phi\|_{1, p, \mathbb{R}^{n}}
$$

Letting $q=\frac{n p}{n-p}$, it follows $\frac{1}{q}=\frac{n-p}{n p}=\frac{1}{p}-\frac{1}{n}$ and

$$
\|\phi\|_{q} \leq \frac{r}{\sqrt[n]{n}}\|\phi\|_{1, p, \mathbb{R}^{n}}
$$

Now let $f \in W^{m, p}\left(\mathbb{R}^{n}\right)$ and let $\left\|\phi_{k}-f\right\|_{1, p, \mathbb{R}^{n}} \rightarrow 0$ as $k \rightarrow \infty$. Taking another subsequence, if necessary, you can also assume $\phi_{k}(\mathbf{x}) \rightarrow f(\mathbf{x})$ a.e. Therefore, by Fatou's lemma,

$$
\begin{aligned}
\|f\|_{q} & \leq \lim \inf _{k \rightarrow \infty}\left(\int_{\mathbb{R}^{n}}\left|\phi_{k}(\mathbf{x})\right|^{q} d m_{n}\right)^{1 / q} \\
& \leq \lim _{k \rightarrow \infty} \frac{r}{\sqrt[n]{n}}\left\|\phi_{k}\right\|_{1, p, \mathbb{R}^{n}}=\|f\|_{1, p, \mathbb{R}^{n}}
\end{aligned}
$$

This proves the theorem.
Corollary 38.1.11 Suppose $m p<n$. Then $W^{m, p}\left(\mathbb{R}^{n}\right) \subseteq L^{q}\left(\mathbb{R}^{n}\right)$ where $q=\frac{n p}{n-m p}$ and the identity map, id : $W^{m, p}\left(\mathbb{R}^{n}\right) \rightarrow L^{q}\left(\mathbb{R}^{n}\right)$ is continuous.

Proof: This is true if $m=1$ according to Theorem 38.1.10. Suppose it is true for $m-1$ where $m>1$. If $u \in W^{m, p}\left(\mathbb{R}^{n}\right)$ and $|\alpha| \leq 1$, then $D^{\alpha} u \in W^{m-1, p}\left(\mathbb{R}^{n}\right)$ so by induction, for all such $\alpha$,

$$
D^{\alpha} u \in L^{\frac{n p}{n-(m-1) p}}\left(\mathbb{R}^{n}\right)
$$

Thus $u \in W^{1, q_{1}}\left(\mathbb{R}^{n}\right)$ where

$$
q_{1}=\frac{n p}{n-(m-1) p}
$$

By Theorem 38.1.10, it follows that $u \in L^{q}\left(\mathbb{R}^{n}\right)$ where

$$
\frac{1}{q}=\frac{n-(m-1) p}{n p}-\frac{1}{n}=\frac{n-m p}{n p}
$$

This proves the corollary.
There is another similar corollary of the same sort which is interesting and useful.
Corollary 38.1.12 Suppose $m \geq 1$ and $j$ is a nonnegative integer satisfying $j p<n$. Then

$$
W^{m+j, p}\left(\mathbb{R}^{n}\right) \subseteq W^{m, q}\left(\mathbb{R}^{n}\right)
$$

for

$$
\begin{equation*}
q \equiv \frac{n p}{n-j p} \tag{38.1.16}
\end{equation*}
$$

and the identity map is continuous.

Proof: If $|\alpha| \leq m$, then $D^{\alpha} u \in W^{j, p}\left(\mathbb{R}^{n}\right)$ and so by Corollary 38.1.11, $D^{\alpha} u \in L^{q}\left(\mathbb{R}^{n}\right)$ where $q$ is given above. This means $u \in W^{m, q}\left(\mathbb{R}^{n}\right)$.

The above corollaries imply yet another interesting corollary which involves embeddings in the Holder spaces.

Corollary 38.1.13 Suppose $j p<n<(j+1) p$ and let $m$ be a positive integer. Let $U$ be any bounded open set in $\mathbb{R}^{n}$. Then letting $r_{U}$ denote the restriction to $\bar{U}, r_{U}: W^{m+j, p}\left(\mathbb{R}^{n}\right) \rightarrow$ $C^{m-1, \lambda}(\bar{U})$ is continuous for every $\lambda \leq \lambda_{0} \equiv(j+1)-\frac{n}{p}$ and if $\lambda<(j+1)-\frac{n}{p}$, then $r_{U}$ is compact.

Proof: From Corollary 38.1.12 $W^{m+j, p}\left(\mathbb{R}^{n}\right) \subseteq W^{m, q}\left(\mathbb{R}^{n}\right)$ where $q$ is given by 38.1.16. Therefore,

$$
\frac{n p}{n-j p}>n
$$

and so by Corollary 38.1.7, $W^{m, q}\left(\mathbb{R}^{n}\right) \subseteq C^{m-1, \lambda}(\bar{U})$ for all $\lambda$ satisfying

$$
0<\lambda<1-\frac{(n-j p) n}{n p}=\frac{p(j+1)-n}{p}=(j+1)-\frac{n}{p} .
$$

The assertion about compactness follows from the compactness of the embedding of

$$
C^{m-1, \lambda_{0}}(\bar{U})
$$

into $C^{m-1, \lambda}(\bar{U})$ for $\lambda<\lambda_{0}$. See Lemma 38.1.6.
There are other embeddings of this sort available. You should see Adams [1] for a more complete listing of these. Next are some theorems about compact embeddings. This requires some consideration of which subsets of $L^{p}(U)$ are compact. The main theorem is the following. See [1].

Theorem 38.1.14 Let $K$ be a bounded subset of $L^{p}(U)$ and suppose that for all $\varepsilon>0$, there exist a $\delta>0$ such that if $|\mathbf{h}|<\delta$, then

$$
\begin{equation*}
\int_{\mathbb{R}^{n}}|\widetilde{u}(\mathbf{x}+\mathbf{h})-\widetilde{u}(\mathbf{x})|^{p} d x<\varepsilon^{p} \tag{38.1.17}
\end{equation*}
$$

Suppose also that for each $\varepsilon>0$ there exists an open set, $G \subseteq U$ such that $\bar{G}$ is compact and for all $u \in K$,

$$
\begin{equation*}
\int_{U \backslash \bar{G}}|u(\mathbf{x})|^{p} d x<\varepsilon^{p} \tag{38.1.18}
\end{equation*}
$$

Then $K$ is precompact in $L^{p}\left(\mathbb{R}^{n}\right)$.
Proof: To save fussing first consider the case where $U=\mathbb{R}^{n}$ so that $\widetilde{u}=u$. Suppose the two conditions hold and let $\phi_{k}$ be a mollifier of the form $\phi_{k}(\mathbf{x})=k^{n} \phi(k \mathbf{x})$ where $\operatorname{spt}(\phi) \subseteq B(\mathbf{0}, 1)$. Consider

$$
K_{k} \equiv\left\{u * \phi_{k}: u \in K\right\}
$$

and verify the conditions for the Ascoli Arzela theorem for these functions defined on $\bar{G}$. Say $\|u\|_{p} \leq M$ for all $u \in K$.

First of all, for $u \in K$ and $\mathbf{x} \in \mathbb{R}^{n}$,

$$
\begin{aligned}
\left|u * \phi_{k}(\mathbf{x})\right|^{p} & \leq\left(\int\left|u(\mathbf{x}-\mathbf{y}) \phi_{k}(\mathbf{y})\right| d y\right)^{p} \\
& =\left(\int\left|u(\mathbf{y}) \phi_{k}(\mathbf{x}-\mathbf{y})\right| d y\right)^{p} \\
& \leq \int|u(\mathbf{y})|^{p} \phi_{k}(\mathbf{x}-\mathbf{y}) d y \\
& \leq\left(\sup _{\mathbf{z} \in \mathbb{R}^{n}} \phi_{k}(\mathbf{z})\right) \int|u(\mathbf{y})| d y \leq M\left(\sup _{\mathbf{z} \in \mathbb{R}^{n}} \phi_{k}(\mathbf{z})\right)
\end{aligned}
$$

showing the functions in $K_{k}$ are uniformly bounded.
Next suppose $\mathbf{x}, \mathbf{x}_{1} \in K_{k}$ and consider

$$
\begin{aligned}
& \left|u * \phi_{k}(\mathbf{x})-u * \phi_{k}\left(\mathbf{x}_{1}\right)\right| \\
\leq & \int\left|u(\mathbf{x}-\mathbf{y})-u\left(\mathbf{x}_{1}-\mathbf{y}\right)\right| \phi_{k}(\mathbf{y}) d y \\
\leq & \left(\int\left|u(\mathbf{x}-\mathbf{y})-u\left(\mathbf{x}_{1}-\mathbf{y}\right)\right|^{p} d y\right)^{1 / p}\left(\int \phi_{k}(\mathbf{y})^{q} d y\right)^{q}
\end{aligned}
$$

which by assumption 38.1 .17 is small independent of the choice of $u$ whenever $\left|\mathbf{x}-\mathbf{x}_{1}\right|$ is small enough. Note that $k$ is fixed in the above. Therefore, the set, $K_{k}$ is precompact in $C(\bar{G})$ thanks to the Ascoli Arzela theorem. Next consider how well $u \in K$ is approximated by $u * \phi_{k}$ in $L^{p}\left(\mathbb{R}^{n}\right)$. By Minkowski’s inequality,

$$
\begin{aligned}
& \left(\int\left|u(\mathbf{x})-u * \phi_{k}(\mathbf{x})\right|^{p} d x\right)^{1 / p} \\
\leq & \left(\int\left(\int|u(\mathbf{x})-u(\mathbf{x}-\mathbf{y})| \phi_{k}(\mathbf{y}) d y\right)^{p} d x\right)^{1 / p} \\
\leq & \int_{B\left(\mathbf{0}, \frac{1}{k}\right)} \phi_{k}(\mathbf{y})\left(\int|u(\mathbf{x})-u(\mathbf{x}-\mathbf{y})|^{p} d x\right)^{1 / p} d y
\end{aligned}
$$

Now let $\eta>0$ be given. From 38.1.17 there exists $k$ large enough that for all $u \in K$,

$$
\int_{B\left(\mathbf{0}, \frac{1}{k}\right)} \phi_{k}(\mathbf{y})\left(\int|u(\mathbf{x})-u(\mathbf{x}-\mathbf{y})|^{p} d x\right)^{1 / p} d y \leq \int_{B\left(\mathbf{0}, \frac{1}{k}\right)} \phi_{k}(\mathbf{y}) \eta d y=\eta
$$

Now let $\varepsilon>0$ be given and let $\delta$ and $G$ correspond to $\varepsilon$ as given in the hypotheses and let $1 / k<\delta$ and also $k$ is large enough that for all $u \in K$,

$$
\left\|u-u * \phi_{k}\right\|_{p}<\varepsilon
$$

as in the above inequality. By the Ascoli Arzela theorem there exists an

$$
\left(\frac{\varepsilon}{m(\bar{G}+B(\mathbf{0}, 1))}\right)^{1 / p}
$$

net for $K_{k}$ in $C(\bar{G})$. That is, there exist $\left\{u_{i}\right\}_{i=1}^{m} \subseteq K$ such that for any $u \in K$,

$$
\left\|u * \phi_{k}-u_{j} * \phi_{k}\right\|_{\infty}<\left(\frac{\varepsilon}{m(\bar{G}+B(\mathbf{0}, 1))}\right)^{1 / p}
$$

for some $j$. Letting $u \in K$ be given, let $u_{j} \in\left\{u_{i}\right\}_{i=1}^{m} \subseteq K$ be such that the above inequality holds. Then

$$
\begin{aligned}
&\left\|u-u_{j}\right\|_{p} \leq\left\|u-u * \phi_{k}\right\|_{p}+\left\|u * \phi_{k}-u_{j} * \phi_{k}\right\|_{p}+\left\|u_{j} * \phi_{k}-u_{j}\right\|_{p} \\
&<2 \varepsilon+\left\|u * \phi_{k}-u_{j} * \phi_{k}\right\|_{p} \\
& \leq 2 \varepsilon+\left(\int_{\bar{G}+B(\mathbf{0}, 1)}\left|u * \phi_{k}-u_{j} * \phi_{k}\right|^{p} d x\right)^{1 / p} \\
&+\left(\int_{\mathbb{R}^{n} \backslash(\bar{G}+B(\mathbf{0}, 1))}\left|u * \phi_{k}-u_{j} * \phi_{k}\right|^{p} d x\right)^{1 / p} \\
& \leq 2 \varepsilon+\varepsilon^{1 / p} \\
&+\left(\int_{\mathbb{R}^{n} \backslash(\bar{G}+B(\mathbf{0}, 1))}\left(\int\left|u(\mathbf{x}-\mathbf{y})-u_{j}(\mathbf{x}-\mathbf{y})\right| \phi_{k}(\mathbf{y}) d y\right)^{p} d x\right)^{1 / p} \\
& \leq 2 \varepsilon+\varepsilon^{1 / p} \\
&+\int \phi_{k}(\mathbf{y})\left(\int_{\mathbb{R}^{n} \backslash(\bar{G}+B(\mathbf{0}, 1))}\left(|u(\mathbf{x}-\mathbf{y})|+\left|u_{j}(\mathbf{x}-\mathbf{y})\right|\right)^{p} d x\right)^{1 / p} d y \\
& \leq 2 \varepsilon+\varepsilon^{1 / p}+\int \phi_{k}(\mathbf{y})\left(\int_{\mathbb{R}^{n} \backslash \bar{G}}\left(|u(\mathbf{x})|+\left|u_{j}(\mathbf{x})\right|\right)^{p} d x\right)^{1 / p} d y \\
& \leq 2 \varepsilon+\varepsilon^{1 / p}+2^{p-1} \int \phi_{k}(\mathbf{y})\left(\int_{\mathbb{R}^{n} \backslash \bar{G}}\left(|u(\mathbf{x})|^{p}+\left|u_{j}(\mathbf{x})\right|^{p}\right) d x\right)^{1 / p} d y \\
& \leq 2 \varepsilon+\varepsilon^{1 / p}+2^{p-1} 2^{1 / p} \varepsilon
\end{aligned}
$$

and since $\varepsilon>0$ is arbitrary, this shows that $K$ is totally bounded and is therefore precompact.

Now for an arbitrary open set, $\underset{\sim}{U}$ and $K$ given in the hypotheses of the theorem, let $\widetilde{K} \equiv\{\widetilde{u}: u \in K\}$ and observe that $\widetilde{K}$ is precompact in $L^{p}\left(\mathbb{R}^{n}\right)$. But this is the same as saying that $K$ is precompact in $L^{p}(U)$. This proves the theorem.

Actually the converse of the above theorem is also true [1] but this will not be needed so I have left it as an exercise for anyone interested.

Lemma 38.1.15 Let $u \in W^{1,1}(U)$ for $U$ an open set and let $\phi \in C_{c}^{\infty}(U)$. Then there exists a constant,

$$
C\left(\phi,\|u\|_{1,1, U}\right)
$$

depending only on the indicated quantities such that whenever $\mathbf{v} \in \mathbb{R}^{n}$ with

$$
|\mathbf{v}|<\operatorname{dist}\left(\operatorname{spt}(\phi), U^{C}\right)
$$

it follows that

$$
\int_{\mathbb{R}^{n}}|\widetilde{\phi u}(\mathbf{x}+\mathbf{v})-\widetilde{\phi u}(\mathbf{x})| d x \leq C\left(\phi,\|u\|_{1,1, U}\right)|\mathbf{v}| .
$$

Proof: First suppose $u \in C^{\infty}(\bar{U})$. Then for any $\mathbf{x} \in \operatorname{spt}(\phi) \cup(\operatorname{spt}(\phi)-\mathbf{v}) \equiv G_{\mathbf{v}}$, the chain rule implies

$$
\begin{aligned}
|\phi u(\mathbf{x}+\mathbf{v})-\phi u(\mathbf{x})| & \leq \int_{0}^{1} \sum_{i=1}^{n}\left|(\phi u)_{, i}(\mathbf{x}+t \mathbf{v}) v_{i}\right| d t \\
& \leq \int_{0}^{1} \sum_{i=1}^{n}\left|\left(\phi_{, i} u+u_{, i} \phi\right)(\mathbf{x}+t \mathbf{v})\right| d t|\mathbf{v}|
\end{aligned}
$$

Therefore, for such $u$,

$$
\begin{aligned}
& \int_{\mathbb{R}^{n}}|\widetilde{\phi u}(\mathbf{x}+\mathbf{v})-\widetilde{\phi u}(\mathbf{x})| d x \\
= & \int_{G_{\mathbf{v}}}|\phi u(\mathbf{x}+\mathbf{v})-\phi u(\mathbf{x})| d x \\
\leq & \int_{G_{\mathbf{v}}} \int_{0}^{1} \sum_{i=1}^{n}\left|\left(\phi_{, i} u+u_{, i} \phi\right)(\mathbf{x}+t \mathbf{v})\right| d t d x|\mathbf{v}| \\
\leq & \int_{0}^{1} \int_{G_{\mathbf{v}}} \sum_{i=1}^{n}\left|\left(\phi_{, i} u+u_{, i} \phi\right)(\mathbf{x}+t \mathbf{v})\right| d x d t|\mathbf{v}| \\
\leq & C\left(\phi,\|u\|_{1,1, U}\right)|\mathbf{v}|
\end{aligned}
$$

where $C$ is a continuous function of $\|u\|_{1,1, U}$. Now for general $u \in W^{1,1}(U)$, let $u_{k} \rightarrow u$ in $W^{1,1}(U)$ where $u_{k} \in C^{\infty}(\bar{U})$. Then for $|\mathbf{v}|<\operatorname{dist}\left(\operatorname{spt}(\phi), U^{C}\right)$,

$$
\begin{aligned}
& \int_{\mathbb{R}^{n}}|\widetilde{\phi u}(\mathbf{x}+\mathbf{v})-\widetilde{\phi u}(\mathbf{x})| d x \\
= & \int_{G_{\mathbf{v}}}|\phi u(\mathbf{x}+\mathbf{v})-\phi u(\mathbf{x})| d x \\
= & \lim _{k \rightarrow \infty} \int_{G_{\mathbf{v}}}\left|\phi u_{k}(\mathbf{x}+\mathbf{v})-\phi u_{k}(\mathbf{x})\right| d x \\
\leq & \lim _{k \rightarrow \infty} C\left(\phi,\left\|u_{k}\right\|_{1,1, U}\right)|\mathbf{v}| \\
= & C\left(\phi,\|u\|_{1,1, U}\right)|\mathbf{v}| .
\end{aligned}
$$

This proves the lemma.

Lemma 38.1.16 Let $U$ be a bounded open set and define for $p>1$

$$
\begin{equation*}
S \equiv\left\{u \in W^{1,1}(U) \cap L^{p}(U):\|u\|_{1,1, U}+\|u\|_{L^{p}(U)} \leq M\right\} \tag{38.1.19}
\end{equation*}
$$

and let $\phi \in C_{c}^{\infty}(U)$ and

$$
\begin{equation*}
S_{1} \equiv\{u \phi: u \in S\} \tag{38.1.20}
\end{equation*}
$$

Then $S_{1}$ is precompact in $L^{q}(U)$ where $1 \leq q<p$.
Proof: This depends on Theorem 38.1.14. The second condition is satisfied by taking $G \equiv \operatorname{spt}(\phi)$. Thus, for $w \in S_{1}$,

$$
\int_{U \backslash \bar{G}}|w(\mathbf{x})|^{q} d x=0<\varepsilon^{p} .
$$

It remains to satisfy the first condition. It is necessary to verify there exists $\delta>0$ such that if $|\mathbf{v}|<\delta$, then

$$
\begin{equation*}
\int_{\mathbb{R}^{n}}|\widetilde{\phi} u(\mathbf{x}+\mathbf{v})-\widetilde{\phi u}(\mathbf{x})|^{q} d x<\varepsilon^{p} \tag{38.1.21}
\end{equation*}
$$

Let $\operatorname{spt}(\phi) \cup(\operatorname{spt}(\phi)-\mathbf{v}) \equiv G_{\mathbf{v}}$. Now if $h$ is any measurable function, and if $\theta \in(0,1)$ is chosen small enough that $\theta q<1$,

$$
\begin{align*}
\int_{G_{\mathbf{v}}}|h|^{q} d x & =\int_{G_{\mathbf{V}}}|h|^{\theta q}|h|^{(1-\theta) q} d x \\
& \leq\left(\int_{G_{\mathbf{v}}}|h| d x\right)^{\theta q}\left(\int_{G_{\mathbf{v}}}\left(|h|^{(1-\theta) q}\right)^{\frac{1}{1-\theta q}}\right)^{1-\theta q} \\
& =\left(\int_{G_{\mathbf{v}}}|h| d x\right)^{\theta q}\left(\int_{G_{\mathbf{v}}}|h|^{\frac{(1-\theta) q}{1-\theta q}}\right)^{1-\theta q} \tag{38.1.22}
\end{align*}
$$

Now let $\theta$ also be small enough that there exists $r>1$ such that

$$
r \frac{(1-\theta) q}{1-\theta q}=p
$$

and use Holder's inequality in the last factor of the right side of 38.1.22. Then 38.1.22 is dominated by

$$
\begin{aligned}
& \left(\int_{G_{\mathbf{v}}}|h| d x\right)^{\theta q}\left(\int_{G_{\mathbf{v}}}|h|^{p}\right)^{\frac{1-\theta q}{r}}\left(\int_{G_{\mathbf{v}}} 1 d x\right)^{1 / r^{\prime}} \\
= & C\left(\|h\|_{L^{p}\left(G_{\mathbf{v}}\right)}, m_{n}\left(G_{\mathbf{v}}\right)\right)\left(\int_{G_{\mathbf{v}}}|h| d x\right)^{\theta q}
\end{aligned}
$$

Therefore, for $u \in S$,

$$
\int_{\mathbb{R}^{n}}|\widetilde{\phi u}(\mathbf{x}+\mathbf{v})-\widetilde{\phi} u(\mathbf{x})|^{q} d x=\int_{G_{\mathbf{v}}}|\phi u(\mathbf{x}+\mathbf{v})-\phi u(\mathbf{x})|^{q} d x \leq
$$

$$
\begin{gather*}
C\left(\|\phi u(\cdot+\mathbf{v})-\phi u(\cdot)\|_{L^{p}\left(G_{\mathbf{v}}\right)}, m_{n}\left(G_{\mathbf{v}}\right)\right)\left(\int_{G_{\mathbf{v}}}|\phi u(\mathbf{x}+\mathbf{v})-\phi u(\mathbf{x})| d x\right)^{\theta q} \\
\leq C\left(2\|\phi u(\cdot)\|_{L^{p}(U)}, m_{n}(U)\right)\left(\int_{G_{\mathbf{v}}}|\phi u(\mathbf{x}+\mathbf{v})-\phi u(\mathbf{x})| d x\right)^{\theta q} \\
\leq C\left(\phi, M, m_{n}(U)\right)\left(\int_{G_{\mathbf{v}}}|\phi u(\mathbf{x}+\mathbf{v})-\phi u(\mathbf{x})| d x\right)^{\theta q} \\
\quad=C\left(\phi, M, m_{n}(U)\right)\left(\int_{\mathbb{R}^{n}}|\widetilde{\phi} u(\mathbf{x}+\mathbf{v})-\widetilde{\phi u}(\mathbf{x})| d x\right)^{\theta q} \tag{38.1.23}
\end{gather*}
$$

Now by Lemma 38.1.15,

$$
\begin{equation*}
\int_{\mathbb{R}^{n}}|\widetilde{\phi u}(\mathbf{x}+\mathbf{v})-\widetilde{\phi u}(\mathbf{x})| d x \leq C\left(\phi,\|u\|_{1,1, U}\right)|\mathbf{v}| \tag{38.1.24}
\end{equation*}
$$

and so from 38.1.23 and 38.1.24, and adjusting the constants

$$
\begin{aligned}
\int_{\mathbb{R}^{n}}|\widetilde{\phi u}(\mathbf{x}+\mathbf{v})-\widetilde{\phi u}(\mathbf{x})|^{q} d x & \leq C\left(\phi, M, m_{n}(U)\right)\left(C\left(\phi,\|u\|_{1,1, U}\right)|\mathbf{v}|\right)^{\theta q} \\
& =C\left(\phi, M, m_{n}(U)\right)|\mathbf{v}|^{\theta q}
\end{aligned}
$$

which verifies 38.1 .21 whenever $|\mathbf{v}|$ is sufficiently small. This proves the lemma because the conditions of Theorem 38.1.14 are satisfied.

Theorem 38.1.17 Let $U$ be a bounded open set and define for $p>1$

$$
\begin{equation*}
S \equiv\left\{u \in W^{1,1}(U) \cap L^{p}(U):\|u\|_{1,1, U}+\|u\|_{L^{p}(U)} \leq M\right\} \tag{38.1.25}
\end{equation*}
$$

Then $S$ is precompact in $L^{q}(U)$ where $1 \leq q<p$.
Proof: If suffices to show that every sequence, $\left\{u_{k}\right\}_{k=1}^{\infty} \subseteq S$ has a subsequence which converges in $L^{q}(U)$. Let $\left\{K_{m}\right\}_{m=1}^{\infty}$ denote a sequence of compact subsets of $U$ with the property that $K_{m} \subseteq K_{m+1}$ for all $m$ and $\cup_{m=1}^{\infty} K_{m}=U$. Now let $\phi_{m} \in C_{c}^{\infty}(U)$ such that $\phi_{m}(\mathbf{x}) \in[0,1]$ and $\phi_{m}(\mathbf{x})=1$ for all $\mathbf{x} \in K_{m}$. Let $S_{m} \equiv\left\{\phi_{m} u: u \in S\right\}$. By Lemma 38.1.16 there exists a subsequence of $\left\{u_{k}\right\}_{k=1}^{\infty}$, denoted here by $\left\{u_{1, k}\right\}_{k=1}^{\infty}$ such that $\left\{\phi_{1} u_{1, k}\right\}_{k=1}^{\infty}$ converges in $L^{q}(U)$. Now $S_{2}$ is also precompact in $L^{q}(U)$ and so there exists a subsequence of $\left\{u_{1, k}\right\}_{k=1}^{\infty}$, denoted by $\left\{u_{2, k}\right\}_{k=1}^{\infty}$ such that $\left\{\phi_{2} u_{2, k}\right\}_{k=1}^{\infty}$ converges in $L^{2}(U)$. Thus it is also the case that $\left\{\phi_{1} u_{2, k}\right\}_{k=1}^{\infty}$ converges in $L^{q}(U)$. Continue taking subsequences in this manner such that for all $l \leq m,\left\{\phi_{l} u_{m, k}\right\}_{k=1}^{\infty}$ converges in $L^{q}(U)$. Let $\left\{w_{m}\right\}_{m=1}^{\infty}=\left\{u_{m, m}\right\}_{m=1}^{\infty}$ so that $\left\{w_{k}\right\}_{k=m}^{\infty}$ is a subsequence of $\left\{u_{m, k}\right\}_{k=1}^{\infty}$. Then it follows for all $k,\left\{\phi_{k} w_{m}\right\}_{m=1}^{\infty}$ must converge in $L^{q}(U)$. For $u \in S$,

$$
\begin{aligned}
\left\|u-\phi_{k} u\right\|_{L^{q}(U)}^{q} & =\int_{U}|u|^{q}\left(1-\phi_{k}\right)^{q} d x \\
& \leq\left(\int_{U}|u|^{p} d x\right)^{q / p}\left(\int_{U}\left(1-\phi_{k}\right)^{q r} d x\right)^{1 / r} \\
& \leq M\left(\int_{U}\left(1-\phi_{k}\right)^{q r} d x\right)^{1 / r}
\end{aligned}
$$

where $q / p+1 / r=1$. Now $\phi_{l}(\mathbf{x}) \rightarrow \mathscr{X}_{U}(\mathbf{x})$ and so the integrand in the last integral converges to 0 by the dominated convergence theorem. Therefore, $k$ may be chosen large enough that for all $u \in S$,

$$
\left\|u-\phi_{k} u\right\|_{L^{q}(U)}^{q} \leq\left(\frac{\varepsilon}{3}\right)^{q} .
$$

Fix such a value of $k$. Then

$$
\begin{gathered}
\left\|w_{q}-w_{p}\right\|_{L^{q}(U)} \leq \\
\left\|w_{q}-\phi_{k} w_{q}\right\|_{L^{q}(U)}+\left\|\phi_{k} w_{q}-\phi_{k} w_{p}\right\|_{L^{q}(U)}+\left\|w_{p}-\phi_{k} w_{p}\right\|_{L^{q}(U)} \\
\leq \frac{2 \varepsilon}{3}+\left\|\phi_{k} w_{q}-\phi_{k} w_{p}\right\|_{L^{q}(U)}
\end{gathered}
$$

But $\left\{\phi_{k} w_{m}\right\}_{m=1}^{\infty}$ converges in $L^{q}(U)$ and so the last term in the above is less than $\varepsilon / 3$ whenever $p, q$ are large enough. Thus $\left\{w_{m}\right\}_{m=1}^{\infty}$ is a Cauchy sequence and must therefore converge in $L^{q}(U)$. This proves the theorem.

### 38.2 An Extension Theorem

Definition 38.2.1 An open subset, $U$, of $\mathbb{R}^{n}$ has a Lipschitz boundary if it satisfies the following conditions. For each $p \in \partial U \equiv \bar{U} \backslash U$, there exists an open set, $Q$, containing $p$, an open interval $(a, b)$, a bounded open box $B \subseteq \mathbb{R}^{n-1}$, and an orthogonal transformation $R$ such that

$$
\begin{gather*}
R Q=B \times(a, b),  \tag{38.2.26}\\
R(Q \cap U)=\left\{\mathbf{y} \in \mathbb{R}^{n}: \widehat{\mathbf{y}} \in B, a<y_{n}<g(\widehat{\mathbf{y}})\right\} \tag{38.2.27}
\end{gather*}
$$

where $g$ is Lipschitz continuous on $\bar{B}, a<\min \{g(\mathbf{x}): \mathbf{x} \in \bar{B}\}$, and

$$
\widehat{\mathbf{y}} \equiv\left(y_{1}, \cdots, y_{n-1}\right) .
$$

Letting $W=Q \cap U$ the following picture describes the situation.

The following lemma is important.
Lemma 38.2.2 If $U$ is an open subset of $\mathbb{R}^{n}$ which has a Lipschitz boundary, then it satisfies the segment condition and so $X^{m, p}(U)=W^{m, p}(U)$.

Proof: For $\mathbf{x} \in \partial U$, simply look at a single open set, $Q_{\mathbf{x}}$ described in the above which contains $\mathbf{x}$. Then consider an open set whose intersection with $U$ is of the form

$$
R^{T}\left(\left\{\mathbf{y}: \widehat{\mathbf{y}} \in B, g(\widehat{\mathbf{y}})-\varepsilon<y_{n}<g(\widehat{\mathbf{y}})\right\}\right)
$$

and a vector of the form $\varepsilon R^{T}\left(-\mathbf{e}_{n}\right)$ where $\varepsilon$ is chosen smaller than $\min \{g(\mathbf{x}): \mathbf{x} \in \bar{B}\}-a$. There is nothing to prove for points of $U$.

One way to extend many of the above theorems to more general open sets than $\mathbb{R}^{n}$ is through the use of an appropriate extension theorem. In this section, a fairly general one will be presented.

Lemma 38.2.3 Let $B \times(a, b)$ be as described in Definition 38.2.1 and let

$$
V^{-} \equiv\left\{\left(\widehat{\mathbf{y}}, y_{n}\right): y_{n}<g(\widehat{\mathbf{y}})\right\}, V^{+} \equiv\left\{\left(\widehat{\mathbf{y}}, y_{n}\right): y_{n}>g(\widehat{\mathbf{y}})\right\}
$$

for $g$ a Lipschitz function of the sort described in this definition. Suppose $u^{+}$and $u^{-}$are Lipschitz functions defined on $\overline{V^{+}}$and $\overline{V^{-}}$respectively and suppose that $u^{+}(\widehat{\mathbf{y}}, g(\widehat{\mathbf{y}}))=$ $u^{-}(\widehat{\mathbf{y}}, g(\widehat{\mathbf{y}}))$ for all $\widehat{\mathbf{y}} \in B$. Let

$$
u\left(\widehat{\mathbf{y}}, y_{n}\right) \equiv \begin{cases}u^{+}\left(\widehat{\mathbf{y}}, y_{n}\right) & \text { if }\left(\widehat{\mathbf{y}}, y_{n}\right) \in V^{+} \\ u^{-}\left(\widehat{\mathbf{y}}, y_{n}\right) & \text { if }\left(\widehat{\mathbf{y}}, y_{n}\right) \in V^{-}\end{cases}
$$

and suppose $\operatorname{spt}(u) \subseteq B \times(a, b)$. Then extending $u$ to be 0 off of $B \times(a, b)$, $u$ is continuous and the weak partial derivatives, $u_{, i}$, are all in $L^{\infty}\left(\mathbb{R}^{n}\right) \cap L^{p}\left(\mathbb{R}^{n}\right)$ for all $p>1$ and $u_{, i}=$ $\left(u^{+}\right)_{, i}$ on $V^{+}$and $u_{, i}=\left(u^{-}\right)_{, i}$ on $V^{-}$.

Proof: Consider the following picture which is descriptive of the situation.

Note first that $u$ is Lipschitz continuous. To see this, consider $\left|u\left(\mathbf{y}_{1}\right)-u\left(\mathbf{y}_{2}\right)\right|$ where $\left(\widehat{\mathbf{y}}_{i}, y_{n}^{i}\right)=\mathbf{y}_{i}$. There are various cases to consider depending on whether $y_{n}^{i}$ is above $g\left(\widehat{\mathbf{y}}_{i}\right)$. Suppose $y_{n}^{1}<g\left(\widehat{\mathbf{y}}_{1}\right)$ and $y_{n}^{2}>g\left(\widehat{\mathbf{y}}_{2}\right)$. Then letting $K \geq \max \left(\operatorname{Lip}\left(u^{+}\right), \operatorname{Lip}\left(u^{-}\right), \operatorname{Lip}(g)\right)$,

$$
\left|u\left(\widehat{\mathbf{y}}_{1}, y_{n}^{1}\right)-u\left(\widehat{\mathbf{y}}_{2}, y_{n}^{2}\right)\right| \leq
$$

$$
\begin{aligned}
& \left|u\left(\widehat{\mathbf{y}}_{1}, y_{n}^{1}\right)-u\left(\widehat{\mathbf{y}}_{2}, y_{n}^{1}\right)\right|+\left|u\left(\widehat{\mathbf{y}}_{2}, y_{n}^{1}\right)-u\left(\widehat{\mathbf{y}}_{2}, g\left(\widehat{\mathbf{y}}_{2}\right)\right)\right| \\
& +\left|u\left(\widehat{\mathbf{y}}_{2}, g\left(\widehat{\mathbf{y}}_{2}\right)\right)-u\left(\widehat{\mathbf{y}}_{2}, y_{n}^{2}\right)\right| \\
\leq & K\left|\widehat{\mathbf{y}}_{1}-\widehat{\mathbf{y}}_{2}\right|+K\left[\left|g\left(\widehat{\mathbf{y}}_{2}\right)-g\left(\widehat{\mathbf{y}}_{1}\right)\right|+g\left(\widehat{\mathbf{y}}_{1}\right)-y_{n}^{1}+y_{n}^{2}-g\left(\widehat{\mathbf{y}}_{2}\right)\right] \\
\leq & \left(2 K+K^{2}\right)\left|\widehat{\mathbf{y}}_{1}-\widehat{\mathbf{y}}_{2}\right|+K\left|y_{n}^{1}-y_{n}^{2}\right| \\
= & \left(2 K+K^{2}\right)\left(\left|\widehat{\mathbf{y}}_{1}-\widehat{\mathbf{y}}_{2}\right|+\left|y_{n}^{1}-y_{n}^{2}\right|\right) \leq\left(2 K+K^{2}\right) \sqrt{2}\left|\mathbf{y}_{1}-\mathbf{y}_{2}\right|
\end{aligned}
$$

The other cases are similar. Thus $u$ is a Lipschitz continuous function which has compact support. By Corollary 36.5 . 4 on Page 1287 it follows that $u_{, i} \in L^{\infty}\left(\mathbb{R}^{n}\right) \cap L^{p}\left(\mathbb{R}^{n}\right)$ for all $p>1$. It remains to verify $u_{, i}=\left(u^{+}\right)_{, i}$ on $V^{+}$and $u_{, i}=\left(u^{-}\right)_{, i}$ on $V^{-}$. The last claim is obvious from the definition of weak derivatives.

Lemma 38.2.4 In the situation of Lemma 38.2.3 let $u \in C^{1}\left(\overline{V^{-}}\right) \cap C_{c}^{1}(B \times(a, b))^{3}$ and define

$$
w\left(\widehat{\mathbf{y}}, y_{n}\right) \equiv\left\{\begin{array}{l}
u\left(\widehat{\mathbf{y}}, y_{n}\right) \text { if } \widehat{\mathbf{y}} \in B \text { and } y_{n} \leq g(\widehat{\mathbf{y}}) \\
u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right), \text { if } \widehat{\mathbf{y}} \in B \text { and } y_{n}>g(\widehat{\mathbf{y}}) \\
0 \text { if } \widehat{\mathbf{y}} \notin B .
\end{array}\right.
$$

Then $w \in W^{1, p}\left(\mathbb{R}^{n}\right)$ and there exists a constant, $C$ depending only on $\operatorname{Lip}(g)$ and dimension such that

$$
\|w\|_{W^{1, p}\left(\mathbb{R}^{n}\right)} \leq C\|u\|_{W^{1, p}\left(V^{-}\right)}
$$

Denote $w$ by $E_{0} u$. Thus $E_{0}(u)(\mathbf{y})=u(\mathbf{y})$ for all $\mathbf{y} \in V^{-}$but $E_{0} u=w$ is defined on all of $\mathbb{R}^{n}$. Also, $E_{0}$ is a linear mapping.

Proof: As in the previous lemma, $w$ is Lipschitz continuous and has compact support so it is clear $w \in W^{1, p}\left(\mathbb{R}^{n}\right)$. The main task is to find $w_{i}$ for $\widehat{\mathbf{y}} \in B$ and $y_{n}>g(\widehat{\mathbf{y}})$ and then to extract an estimate of the right sort. Denote by $U$ the set of points of $\mathbb{R}^{n}$ with the property that $\left(\widehat{\mathbf{y}}, y_{n}\right) \in U$ if and only if $\widehat{\mathbf{y}} \notin B$ or $\widehat{\mathbf{y}} \in B$ and $y_{n}>g(\widehat{\mathbf{y}})$. Then letting $\phi \in C_{c}^{\infty}(U)$, suppose first that $i<n$. Then

$$
\begin{gather*}
\int_{U} w\left(\widehat{\mathbf{y}}, y_{n}\right) \phi_{, i}(\mathbf{y}) d y \\
\equiv \lim _{h \rightarrow 0} \int_{U} \phi(\mathbf{y}) \frac{u\left(\widehat{\mathbf{y}}-h \mathbf{e}_{i}^{n-1}, 2 g\left(\widehat{\mathbf{y}}-h \mathbf{e}_{i}^{n-1}\right)-y_{n}\right)-u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)}{h} d y  \tag{38.2.28}\\
=\lim _{h \rightarrow 0}\left\{\frac { - 1 } { h } \int _ { U } \phi ( \mathbf { y } ) \left[D_{1} u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\left(h \mathbf{e}_{i}^{n-1}\right)\right.\right. \\
\left.+2 D_{2} u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\left(g\left(\widehat{\mathbf{y}}-h \mathbf{e}_{i}^{n-1}\right)-g(\widehat{\mathbf{y}})\right)\right] d y \\
\left.+\frac{-1}{h} \int_{U} \phi(\mathbf{y})\left[o\left(g\left(\widehat{\mathbf{y}}-h \mathbf{e}_{i}^{n-1}\right)-g(\widehat{\mathbf{y}})\right)+o(h)\right] d y\right\}
\end{gather*}
$$

[^30]where $\mathbf{e}_{i}^{n-1}$ is the unit vector in $\mathbb{R}^{n-1}$ having all zeros except for a 1 in the $i^{t h}$ position. Now by Rademacher's theorem, $D g(\widehat{\mathbf{y}})$ exists for a.e. $\widehat{\mathbf{y}}$ and so except for a set of measure zero, the expression, $o\left(g\left(\widehat{\mathbf{y}}-h \mathbf{e}_{i}^{n-1}\right)-g(\widehat{\mathbf{y}})\right)$ is $o(h)$ and also for $\widehat{\mathbf{y}}$ not in the exceptional set,
$$
g\left(\widehat{\mathbf{y}}-h \mathbf{e}_{i}^{n-1}\right)-g(\widehat{\mathbf{y}})=-h D g(\widehat{\mathbf{y}}) \mathbf{e}_{i}^{n-1}+o(h)
$$

Therefore, since the integrand in 38.2.28 has compact support and because of the Lipschitz continuity of all the functions, the dominated convergence theorem may be applied to obtain

$$
\begin{gathered}
\int_{U} w\left(\widehat{\mathbf{y}}, y_{n}\right) \phi_{, i}(\mathbf{y}) d y= \\
\int_{U} \phi(\mathbf{y})\left[-D_{1} u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\left(\mathbf{e}_{i}^{n-1}\right)+2 D_{2} u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\left(D g(\widehat{\mathbf{y}}) \mathbf{e}_{i}^{n-1}\right)\right] d y \\
=\int_{U} \phi(\mathbf{y})\left[-\frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)+2 \frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right) \frac{\partial g(\widehat{\mathbf{y}})}{\partial y_{i}}\right] d y
\end{gathered}
$$

and so

$$
\begin{equation*}
w_{, i}(\mathbf{y})=\frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)-2 \frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right) \frac{\partial g(\widehat{\mathbf{y}})}{\partial y_{i}} \tag{38.2.29}
\end{equation*}
$$

whenever $i<n$ which is what you would expect from a formal application of the chain rule. Next suppose $i=n$.

$$
\begin{gathered}
\int_{U} w\left(\widehat{\mathbf{y}}, y_{n}\right) \phi_{, n}(\mathbf{y}) d y \\
=\lim _{h \rightarrow 0}-\int_{U} \frac{u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-\left(y_{n}+h\right)\right)-u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)}{h} \phi(\mathbf{y}) d y \\
=\lim _{h \rightarrow 0} \int_{U} \frac{D_{2} u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right) h+o(h)}{h} \phi(\mathbf{y}) d y \\
=\int_{U} \frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right) \phi(\mathbf{y}) d y
\end{gathered}
$$

showing that

$$
\begin{equation*}
w_{, n}(\mathbf{y})=\frac{-\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right) \tag{38.2.30}
\end{equation*}
$$

which is also expected.
From the definnition, for $\mathbf{y} \in \mathbb{R}^{n} \backslash U \equiv\left\{\left(\widehat{\mathbf{y}}, y_{n}\right): y_{n} \leq g(\widehat{\mathbf{y}})\right\}$ it follows $w_{, i}=u_{, i}$ and on $U, w_{, i}$ is given by 38.2.29 and 38.2.30. Consider $\left\|w_{, i}\right\|_{L^{p}(U)}^{p}$ for $i<n$. From 38.2.29

$$
\begin{aligned}
&\left\|w_{, i}\right\|_{L^{p}(U)}^{p}=\int_{U} \mid \frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)-\left.2 \frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right) \frac{\partial g(\widehat{\mathbf{y}})}{\partial y_{i}}\right|^{p} d y \\
& \quad \leq 2^{p-1} \int_{U}\left|\frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} \\
&+2^{p}\left|\frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} \operatorname{Lip}(g)^{p} d y
\end{aligned}
$$

$$
\begin{gathered}
\leq 4^{p}\left(1+\operatorname{Lip}(g)^{p}\right) \int_{U}\left|\frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} \\
+\left|\frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} d y \\
=4^{p}\left(1+\operatorname{Lip}(g)^{p}\right) \int_{B} \int_{g(\widehat{\mathbf{y}})}^{\infty}\left|\frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} \\
+\left|\frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} d y_{n} d \widehat{y} \\
=4^{p}\left(1+\operatorname{Lip}(g)^{p}\right) \int_{B} \int_{-\infty}^{g(\widehat{\mathbf{y}})}\left|\frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, z_{n}\right)\right|^{p}+\left|\frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, z_{n}\right)\right|^{p} d z_{n} d \widehat{y} \\
=4^{p}\left(1+\operatorname{Lip}(g)^{p}\right) \int_{B} \int_{a}^{g(\hat{\mathbf{y}})}\left|\frac{\partial u}{\partial y_{i}}\left(\widehat{\mathbf{y}}, z_{n}\right)\right|^{p} \\
+\left|\frac{\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, z_{n}\right)\right|^{p} d z_{n} d \widehat{y} \leq 4^{p}\left(1+\operatorname{Lip}(g)^{p}\right)\|u\|_{1, p, V^{-}}^{p}
\end{gathered}
$$

Now by similar reasoning,

$$
\begin{aligned}
\left\|w_{, n}\right\|_{L^{p}(U)}^{p} & =\int_{U}\left|\frac{-\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} d y \\
& =\int_{B} \int_{g(\widehat{\mathbf{y}})}^{\infty}\left|\frac{-\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p} d y_{n} d \widehat{y} \\
& =\int_{B} \int_{a}^{g(\widehat{\mathbf{y}})}\left|\frac{-\partial u}{\partial y_{n}}\left(\widehat{\mathbf{y}}, z_{n}\right)\right|^{p} d z_{n} d \widehat{y}=\left\|u_{, n}\right\|_{1, p, V^{-}}^{p} .
\end{aligned}
$$

It follows

$$
\begin{aligned}
\|w\|_{1, p, \mathbb{R}^{n}}^{p} & =\|w\|_{1, p, U}^{p}+\|u\|_{1, p, V^{-}}^{p} \\
& \leq 4^{p} n\left(1+\operatorname{Lip}(g)^{p}\right)\|u\|_{1, p, V^{-}}^{p}+\|u\|_{1, p, V^{-}}^{p}
\end{aligned}
$$

and so

$$
\|w\|_{1, p, \mathbb{R}^{n}}^{p} \leq 4^{p} n\left(2+\operatorname{Lip}(g)^{p}\right)\|u\|_{1, p, V^{-}}^{p}
$$

which implies

$$
\|w\|_{1, p, \mathbb{R}^{n}} \leq 4 n^{1 / p}\left(2+\operatorname{Lip}(g)^{p}\right)^{1 / p}\|u\|_{1, p, V^{-}}
$$

It is obvious that $E_{0}$ is a continuous linear mapping. This proves the lemma.
Now recall Definition 38.2.1, listed here for convenience.
Definition 38.2.5 An open subset, $U$, of $\mathbb{R}^{n}$ has a Lipschitz boundary if it satisfies the following conditions. For each $p \in \partial U \equiv \bar{U} \backslash U$, there exists an open set, $Q$, containing $p$, an open interval $(a, b)$, a bounded open box $B \subseteq \mathbb{R}^{n-1}$, and an orthogonal transformation $R$ such that

$$
\begin{equation*}
R Q=B \times(a, b), \tag{38.2.31}
\end{equation*}
$$

$$
\begin{equation*}
R(Q \cap U)=\left\{\mathbf{y} \in \mathbb{R}^{n}: \widehat{\mathbf{y}} \in B, a<y_{n}<g(\widehat{\mathbf{y}})\right\} \tag{38.2.32}
\end{equation*}
$$

where $g$ is Lipschitz continuous on $\bar{B}, a<\min \{g(\mathbf{x}): \mathbf{x} \in \bar{B}\}$, and

$$
\widehat{\mathbf{y}} \equiv\left(y_{1}, \cdots, y_{n-1}\right) .
$$

Letting $W=Q \cap U$ the following picture describes the situation.

Lemma 38.2.6 In the situation of Definition 38.2.1 let $u \in C^{1}(\bar{U}) \cap C_{c}^{1}(Q)$ and define

$$
E u \equiv R^{*} E_{0}\left(R^{T}\right)^{*} u
$$

where $\left(R^{T}\right)^{*}$ maps $W^{1, p}(U \cap Q)$ to $W^{1, p}(R(W))$. Then $E$ is linear and satisfies

$$
\|E u\|_{W^{1, p}\left(\mathbb{R}^{n}\right)} \leq C\|u\|_{W^{1, p}(Q \cap U)}, E u(\mathbf{x})=u(\mathbf{x}) \text { for } \mathbf{x} \in Q \cap U .
$$

where $C$ depends only on the dimension and $\operatorname{Lip}(g)$.
Proof: This follows from Theorem 38.0.14 and Lemma 38.2.4.
The following theorem is a general extension theorem for Sobolev spaces.
Theorem 38.2.7 Let $U$ be a bounded open set which has Lipschitz boundary. Then for each $p \geq 1$, there exists $E \in \mathscr{L}\left(W^{1, p}(U), W^{1, p}\left(\mathbb{R}^{n}\right)\right)$ such that $E u(\mathbf{x})=u(\mathbf{x})$ a.e. $\mathbf{x} \in U$.

Proof: Let $\partial U \subseteq \cup_{i=1}^{p} Q_{i}$ Where the $Q_{i}$ are as described in Definition 38.2.5. Also let $R_{i}$ be the orthogonal trasformation and $g_{i}$ the Lipschitz functions associated with $Q_{i}$ as in this definition. Now let $Q_{0} \subseteq \overline{Q_{0}} \subseteq U$ be such that $\bar{U} \subseteq \cup_{i=0}^{p} Q_{i}$, and let $\psi_{i} \in C_{c}^{\infty}\left(Q_{i}\right)$ with $\psi_{i}(\mathbf{x}) \in[0,1]$ and $\sum_{i=0}^{p} \psi_{i}(\mathbf{x})=1$ on $\bar{U}$. For $u \in C^{\infty}(\bar{U})$, let $E^{0}\left(\psi_{0} u\right) \equiv \psi_{0} u$ on $Q_{0}$ and 0 off $Q_{0}$. Thus

$$
\left\|E^{0}\left(\psi_{0} u\right)\right\|_{1, p, \mathbb{R}^{n}}=\left\|\psi_{0} u\right\|_{1, p, U}
$$

For $i \geq 1$, let

$$
E^{i}\left(\psi_{i} u\right) \equiv R_{i}^{*} E_{0}\left(R^{T}\right)^{*}\left(\psi_{i} u\right)
$$

Thus, by Lemma 38.2.6

$$
\left\|E^{1}\left(\psi_{i} u\right)\right\|_{1, p, \mathbb{R}^{n}} \leq C\left\|\psi_{i} u\right\|_{1, p, Q_{i} \cap U}
$$

where the constant depends on $\operatorname{Lip}\left(g_{i}\right)$ but is independent of $u \in C^{\infty}(\bar{U})$. Now define $E$ as follows.

$$
E u \equiv \sum_{i=0}^{p} E^{i}\left(\psi_{i} u\right)
$$

Thus for $u \in C^{\infty}(\bar{U})$, it follows $E u(\mathbf{x})=u(\mathbf{x})$ for all $\mathbf{x} \in U$. Also,

$$
\begin{align*}
\|E u\|_{1, p, \mathbb{R}^{n}} & \leq \sum_{i=0}^{p}\left\|E^{i}\left(\psi_{i} u\right)\right\| \leq \sum_{i=0}^{p} C_{i}\left\|\psi_{i} u\right\|_{1, p, Q_{i} \cap U} \\
& =\sum_{i=0}^{p} C_{i}\left\|\psi_{i} u\right\|_{1, p, U} \leq \sum_{i=0}^{p} C_{i}\|u\|_{1, p, U} \\
& \leq(p+1) \sum_{i=0}^{p} C_{i}\|u\|_{1, p, U} \equiv C\|u\|_{1, p, U} \tag{38.2.33}
\end{align*}
$$

where $C$ depends on the $\psi_{i}$ and the $g_{i}$ but is independent of $u \in C^{\infty}(\bar{U})$. Therefore, by density of $C^{\infty}(\bar{U})$ in $W^{1, p}(U), E$ has a unique continuous extension to $W^{1, p}(U)$ still denoted by $E$ satisfying the inequality determined by the ends of 38.2.33. It remains to verify that $E u(\mathbf{x})=u(\mathbf{x})$ a.e. for $\mathbf{x} \in U$.

Let $u_{k} \rightarrow u$ in $W^{1, p}(U)$ where $u_{k} \in C^{\infty}(\bar{U})$. Therefore, by 38.2.33, $E u_{k} \rightarrow E u$ in $W^{1, p}\left(\mathbb{R}^{n}\right)$. Since $E u_{k}(\mathbf{x})=u_{k}(\mathbf{x})$ for each $k$,

$$
\begin{aligned}
\|u-E u\|_{L^{p}(U)} & =\lim _{k \rightarrow \infty}\left\|u_{k}-E u_{k}\right\|_{L^{p}(U)} \\
& =\lim _{k \rightarrow \infty}\left\|E u_{k}-E u_{k}\right\|_{L^{p}(U)}=0
\end{aligned}
$$

which shows $u(\mathbf{x})=E u(\mathbf{x})$ for a.e. $\mathbf{x} \in U$ as claimed. This proves the theorem.
Definition 38.2.8 Let $U$ be an open set. Then $W_{0}^{m, p}(U)$ is the closure of the set, $C_{c}^{\infty}(U)$ in $W^{m, p}(U)$.

Corollary 38.2.9 Let $U$ be a bounded open set which has Lipschitz boundary and let $W$ be an open set containing $\bar{U}$. Then for each $p \geq 1$, there exists $E_{W} \in \mathscr{L}\left(W^{1, p}(U), W_{0}^{1, p}(W)\right)$ such that $E_{W} u(\mathbf{x})=u(\mathbf{x})$ a.e. $\mathbf{x} \in U$.

Proof: Let $\psi \in C_{c}^{\infty}(W)$ and $\psi=1$ on $U$. Then let $E_{W} u \equiv \psi E u$ where $E$ is the extension operator of Theorem 38.2.7.

Extension operators of the above sort exist for many open sets, $U$, not just for bounded ones. In particular, the above discussion would apply to an open set, $U$, not necessarily bounded, if you relax the condition that the $Q_{i}$ must be bounded but require the existence of a finite partition of unity $\left\{\psi_{i}\right\}_{i=1}^{p}$ having the property that $\psi_{i}$ and $\psi_{i, j}$ are uniformly bounded for all $i, j$. The proof would be identical to the above. My main interest is in bounded open sets so the above theorem will suffice. Such an extension operator will be referred to as a $(1, p)$ extension operator.

### 38.3 General Embedding Theorems

With the extension theorem it is possible to give a useful theory of embeddings.
Theorem 38.3.1 Let $1 \leq p<n$ and $\frac{1}{q}=\frac{1}{p}-\frac{1}{n}$ and let $U$ be any open set for which there exists a $(1, p)$ extension operator. Then if $u \in W^{1, p}(U)$, there exists a constant independent of $u$ such that

$$
\|u\|_{L^{q}(U)} \leq C\|u\|_{1, p, U}
$$

If $U$ is bounded and $r<q$, then id : $W^{1, p}(U) \rightarrow L^{r}(U)$ is also compact.
Proof: Let $E$ be the $(1, p)$ extension operator. Then by Theorem 38.1.10 on Page 1323

$$
\begin{aligned}
\|u\|_{L^{q}(U)} & \leq\|E u\|_{L^{q}\left(\mathbb{R}^{n}\right)} \leq \frac{1}{\sqrt[n]{n}} \frac{(n-1) p}{(n-p)}\|E u\|_{1, p, \mathbb{R}^{n}} \\
& \leq C\|u\|_{1, p, U}
\end{aligned}
$$

It remains to prove the assertion about compactness. If $S \subseteq W^{1, p}(U)$ is bounded then

$$
\sup _{u \in S}\left\{\|u\|_{1,1, U}+\|u\|_{L^{q}(U)}\right\}<\infty
$$

and so by Theorem 38.1.17 on Page 1330, it follows $S$ is precompact in $L^{r}(U)$.This proves the theorem.

Corollary 38.3.2 Suppose $m p<n$ and $U$ is an open set satisfying the segment condition which has a $(1, p)$ extension operator for all $p$. Then $\mathrm{id} \in \mathscr{L}\left(W^{m, p}(U), L^{q}(U)\right)$ where $q=\frac{n p}{n-m p}$.

Proof: This is true if $m=1$ according to Theorem 38.3.1. Suppose it is true for $m-1$ where $m>1$. If $u \in W^{m, p}(U)$ and $|\alpha| \leq 1$, then $D^{\alpha} u \in W^{m-1, p}(U)$ so by induction, for all such $\alpha$,

$$
D^{\alpha} u \in L^{\frac{n p}{n-(m-1) p}}(U)
$$

Thus, since $U$ has the segment condition, $u \in W^{1, q_{1}}(U)$ where

$$
q_{1}=\frac{n p}{n-(m-1) p}
$$

By Theorem 38.3.1, it follows $u \in L^{q}\left(\mathbb{R}^{n}\right)$ where

$$
\frac{1}{q}=\frac{n-(m-1) p}{n p}-\frac{1}{n}=\frac{n-m p}{n p}
$$

This proves the corollary.
There is another similar corollary of the same sort which is interesting and useful.

Corollary 38.3.3 Suppose $m \geq 1$ and $j$ is a nonnegative integer satisfying $j p<n$. Also suppose $U$ has $a(1, p)$ extension operator for all $p \geq 1$ and satisfies the segment condition. Then

$$
\mathrm{id} \in \mathscr{L}\left(W^{m+j, p}(U), W^{m, q}(U)\right)
$$

where

$$
\begin{equation*}
q \equiv \frac{n p}{n-j p} \tag{38.3.34}
\end{equation*}
$$

If, in addition to the above, $U$ is bounded and $1 \leq r<q$, then

$$
\mathrm{id} \in \mathscr{L}\left(W^{m+j, p}(U), W^{m, r}(U)\right)
$$

and is compact.
Proof: If $|\alpha| \leq m$, then $D^{\alpha} u \in W^{j, p}(U)$ and so by Corollary 38.3.2, $D^{\alpha} u \in L^{q}(U)$ where $q$ is given above. Since $U$ has the segment property, this means $u \in W^{m, q}(U)$. It remains to verify the assertion about compactness of id.

Let $S$ be bounded in $W^{m+j, p}(U)$. Then $S$ is bounded in $W^{m, q}(U)$ by the first part. Now let $\left\{u_{k}\right\}_{k=1}^{\infty}$ be any sequence in $S$. The corollary will be proved if it is shown that any such sequence has a convergent subsequence in $W^{m, r}(U)$. Let $\left\{\alpha_{1}, \alpha_{2}, \cdots, \alpha_{h}\right\}$ denote the indices satisfying $|\alpha| \leq m$. Then for each of these indices, $\alpha$,

$$
\sup _{u \in S}\left\{\left\|D^{\alpha} u\right\|_{1,1, U}+\left\|D^{\alpha} u\right\|_{L^{q}(U)}\right\}<\infty
$$

and so for each such $\alpha$, satisfying $|\alpha| \leq m$, it follows from Lemma 38.1.16 on Page 1328 that $\left\{D^{\alpha} u: u \in S\right\}$ is precompact in $L^{r}(U)$. Therefore, there exists a subsequence, still denoted by $u_{k}$ such that $D^{\alpha_{1}} u_{k}$ converges in $L^{r}(U)$. Applying the same lemma, there exists a subsequence of this subsequence such that both $D^{\alpha_{1}} u_{k}$ and $D^{\alpha_{2}} u_{k}$ converge in $L^{r}(U)$. Continue taking subsequences until you obtain a subsequence, $\left\{u_{k}\right\}_{k=1}^{\infty}$ for which $\left\{D^{\alpha} u_{k}\right\}_{k=1}^{\infty}$ converges in $L^{r}(U)$ for all $|\alpha| \leq m$. But this must be a convergent subsequence in $W^{m, r}(U)$ and this proves the corollary.

Theorem 38.3.4 Let $U$ be a bounded open set having $a(1, p)$ extension operator and let $p>n$. Then id : $W^{1, p}(U) \rightarrow C(\bar{U})$ is continuous and compact.

Proof: Theorem 38.1.3 on Page 38.1.3 implies $r_{U}: W^{1, p}\left(\mathbb{R}^{n}\right) \rightarrow C(\bar{U})$ is continuous and compact. Thus

$$
\|u\|_{\infty, U}=\|E u\|_{\infty, U} \leq C\|E u\|_{1, p, \mathbb{R}^{n}} \leq C\|u\|_{1, p, U} .
$$

This proves continuity. If $S$ is a bounded set in $W^{1, p}(U)$, then define $S_{1} \equiv\{E u: u \in S\}$. Then $S_{1}$ is a bounded set in $W^{1, p}\left(\mathbb{R}^{n}\right)$ and so by Theorem 38.1.3 the set of restrictions to $U$, is precompact. However, the restrictions to $U$ are just the functions of $S$. Therefore, id is compact as well as continuous.

Corollary 38.3.5 Let $p>n$, let $U$ be a bounded open set having $a(1, p)$ extension operator which also satisfies the segment condition, and let $m$ be a nonnegative integer. Then id : $W^{m+1, p}(U) \rightarrow C^{m, \lambda}(\bar{U})$ is continuous for all $\lambda \in\left[0,1-\frac{n}{p}\right]$ and id is compact if $\lambda<1-\frac{n}{p}$.

Proof: Let $u_{k} \rightarrow 0$ in $W^{m+1, p}(U)$. Then it follows that for each $|\alpha| \leq m, D^{\alpha} u_{k} \rightarrow 0$ in $W^{1, p}(U)$. Therefore,

$$
E\left(D^{\alpha} u_{k}\right) \rightarrow 0 \text { in } W^{1, p}\left(\mathbb{R}^{n}\right)
$$

Then from Morrey's inequality, 38.1.13 on Page 1318, if $\lambda \leq 1-\frac{n}{p}$ and $|\alpha|=m$

$$
\rho_{\lambda}\left(E\left(D^{\alpha} u_{k}\right)\right) \leq C\left\|E\left(D^{\alpha} u_{k}\right)\right\|_{1, p, \mathbb{R}^{n}} \operatorname{diam}(U)^{1-\frac{n}{p}-\lambda} .
$$

Therefore, $\rho_{\lambda}\left(E\left(D^{\alpha} u_{k}\right)\right)=\rho_{\lambda}\left(D^{\alpha} u_{k}\right) \rightarrow 0$. From Theorem 38.3.4 it follows that for $|\alpha| \leq$ $m,\left\|D^{\alpha} u_{k}\right\|_{\infty} \rightarrow 0$ and so $\left\|u_{k}\right\|_{m, \lambda} \rightarrow 0$. This proves the claim about continuity. The claim about compactness for $\lambda<1-\frac{n}{p}$ follows from Lemma 38.1.6 on Page 1319 and this. (Bounded in $W^{m, p}(U) \xrightarrow{\text { id }}$ Bounded in $C^{m, 1-\frac{n}{p}}(\bar{U}) \xrightarrow{\text { id }}$ Compact in $\left.C^{m, \lambda}(\bar{U}).\right)$

Theorem 38.3.6 Suppose $j p<n<(j+1) p$ and let $m$ be a positive integer. Let $U$ be any bounded open set in $\mathbb{R}^{n}$ which has a $(1, p)$ extension operator for each $p \geq 1$ and the segment property. Then $\mathrm{id} \in \mathscr{L}\left(W^{m+j, p}(U), C^{m-1, \lambda}(\bar{U})\right)$ for every $\lambda \leq \lambda_{0} \equiv(j+1)-\frac{n}{p}$ and if $\lambda<(j+1)-\frac{n}{p}$, id is compact.

Proof: From Corollary 38.3.3 $W^{m+j, p}(U) \subseteq W^{m, q}(U)$ where $q$ is given by 38.3.34. Therefore,

$$
\frac{n p}{n-j p}>n
$$

and so by Corollary 38.3.5, $W^{m, q}(U) \subseteq C^{m-1, \lambda}(\bar{U})$ for all $\lambda$ satisfying

$$
0<\lambda<1-\frac{(n-j p) n}{n p}=\frac{p(j+1)-n}{p}=(j+1)-\frac{n}{p} .
$$

The assertion about compactness follows from the compactness of the embedding of

$$
C^{m-1, \lambda_{0}}(\bar{U})
$$

into $C^{m-1, \lambda}(\bar{U})$ for $\lambda<\lambda_{0}$, Lemma 38.1.6 on Page 1319.

### 38.4 More Extension Theorems

The theorem about the existence of a $(1, p)$ extension is all that is needed to obtain general embedding theorems for Sobolev spaces. However, a more general theory is needed in order to tie the theory of Sobolev spaces presented thus far to a very appealing description using Fourier transforms. First the problem of extending $W^{k, p}(H)$ to $W^{k, p}\left(\mathbb{R}^{n}\right)$ is considered for $\mathrm{H}^{-}$a half space

$$
\begin{equation*}
H^{-} \equiv\left\{\mathbf{y} \in \mathbb{R}^{n}: y_{n}<0\right\} \tag{38.4.35}
\end{equation*}
$$

I am following Adams [1].

Lemma 38.4.1 Let $H^{-}$be a half space as in 38.4.35. Let $H^{+}$be the half space in which $y_{n}<0$ is replaced with $y_{n}>0$. Also let $\left(\mathbf{y}^{\prime}, y_{n}\right)=\mathbf{y}$

$$
u\left(\mathbf{y}^{\prime}, y_{n}\right) \equiv\left\{\begin{array}{ll}
u^{+}\left(\mathbf{y}^{\prime}, y_{n}\right) & \text { if } \mathbf{y} \in H^{+} \\
u^{-}\left(\mathbf{y}^{\prime}, y_{n}\right) & \text { if } \mathbf{y} \in H^{-}
\end{array},\right.
$$

suppose $u^{+} \in C^{\infty}\left(\overline{H^{+}}\right)$and $u^{-} \in C^{\infty}\left(\overline{H^{-}}\right)$, and that for $l \leq k-1$,

$$
D^{l \mathbf{e}_{n}} \mathbf{u}^{+}\left(\mathbf{y}^{\prime}, 0\right)=D^{l \mathbf{e}_{n}} \mathbf{u}^{-}\left(\mathbf{y}^{\prime}, 0\right)
$$

Then $u \in W^{k, p}\left(\mathbb{R}^{n}\right)$. Furthermore,

$$
D^{\alpha} u\left(\mathbf{y}^{\prime}, y_{n}\right) \equiv\left\{\begin{array}{l}
D^{\alpha} u^{+}\left(\mathbf{y}^{\prime}, y_{n}\right) \text { if } \mathbf{y} \in H^{+} \\
D^{\alpha} u^{-}\left(\mathbf{y}^{\prime}, y_{n}\right) \text { if } \mathbf{y} \in H^{-}
\end{array}\right.
$$

Proof: Consider the following for $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ and $|\alpha| \leq k$.

$$
(-1)^{|\alpha|}\left(\int_{\mathbb{R}^{n-1}} \int_{0}^{\infty} u^{+} D^{\alpha} \phi d y_{n} d y^{\prime}+\int_{\mathbb{R}^{n-1}} \int_{-\infty}^{0} u^{-} D^{\alpha} \phi d y_{n} d y^{\prime}\right)
$$

Integrating by parts, this yields

$$
\begin{aligned}
& (-1)^{|\alpha|}(-1)^{|\beta|}\left(\int_{\mathbb{R}^{n-1}} \int_{0}^{\infty} D^{\beta} u^{+} D^{\alpha_{n} \mathbf{e}_{n}} \phi d y_{n} d y^{\prime}\right. \\
& \left.+\int_{\mathbb{R}^{n-1}} \int_{-\infty}^{0} D^{\beta} u^{-} D^{\alpha_{n} \mathbf{e}_{n}} \phi d y_{n} d y^{\prime}\right)
\end{aligned}
$$

where $\beta \equiv\left(\alpha_{1}, \alpha_{2}, \cdots \alpha_{n-1}, 0\right)$. Do integration by parts on the inside integral and by assumption, the boundary terms will cancel and the whole thing reduces to

$$
\begin{aligned}
& (-1)^{|\alpha|}(-1)^{|\beta|}(-1)^{\alpha_{n}}\left(\int_{\mathbb{R}^{n-1}} \int_{0}^{\infty} D^{\alpha} u^{+} \phi d y_{n} d y^{\prime}\right. \\
& \left.+\int_{\mathbb{R}^{n-1}} \int_{-\infty}^{0} D^{\alpha} u^{-} \phi d y_{n} d y^{\prime}\right) \\
= & \left(\int_{\mathbb{R}^{n-1}} \int_{0}^{\infty} D^{\alpha} u^{+} \phi d y_{n} d y^{\prime}+\int_{\mathbb{R}^{n-1}} \int_{-\infty}^{0} D^{\alpha} u^{-} \phi d y_{n} d y^{\prime}\right)
\end{aligned}
$$

which proves the lemma.
Lemma 38.4.2 Let $H^{-}$be the half space in 38.4.35 and let $u \in C^{\infty}\left(\overline{H^{-}}\right)$. Then there exists a mapping,

$$
E: C^{\infty}\left(\overline{H^{-}}\right) \rightarrow W^{k, p}\left(\mathbb{R}^{n}\right)
$$

and a constant, $C$ which is independent of $u \in C^{\infty}\left(\overline{H^{-}}\right)$such that $E$ is linear and for all $l \leq k$,

$$
\begin{equation*}
\|E u\|_{l, p, \mathbb{R}^{n}} \leq C\|u\|_{l, p, H^{-}} \tag{38.4.36}
\end{equation*}
$$

Proof: Define

$$
E u\left(\mathbf{x}^{\prime}, x_{n}\right) \equiv\left\{\begin{array}{l}
u\left(\mathbf{x}^{\prime}, x_{n}\right) \text { if } x_{n}<0 \\
\sum_{j=1}^{k} \lambda_{j} u\left(\mathbf{x}^{\prime},-j x_{n}\right) \text { if } x_{n} \geq 0
\end{array}\right.
$$

where the $\lambda_{j}$ are chosen in such a way that for $l \leq k-1$,

$$
D^{l \mathbf{e}_{n}} u\left(\mathbf{x}^{\prime}, 0\right)-D^{l \mathbf{e}_{n}}\left(\sum_{j=1}^{k} \lambda_{j} u\right)\left(\mathbf{x}^{\prime}, 0\right)=0
$$

so that Lemma 38.4.1 may be applied. Do there exist such $\lambda_{j}$ ? It is necessary to have the following hold for each $r=0,1, \cdots, k-1$.

$$
\sum_{j=1}^{k}(-j)^{r} \lambda_{j} D^{r \mathbf{e}_{n}} u\left(\mathbf{x}^{\prime}, 0\right)=D^{r \mathbf{e}_{n}} u\left(\mathbf{x}^{\prime}, 0\right)
$$

This is satisfied if

$$
\sum_{j=1}^{k}(-j)^{r} \lambda_{j}=1
$$

for $r=0,1, \cdots, k-1$. This is a system of $k$ equations for the $k$ variables, the $\lambda_{j}$. The matrix of coefficients is of the form

$$
\left(\begin{array}{ccccc}
1 & 1 & 1 & \cdots & 1 \\
-1 & -2 & -3 & \cdots & -k \\
1 & 4 & 9 & \cdots & k^{2} \\
\vdots & \vdots & \vdots & & \vdots \\
(-1)^{k} & (-2)^{k} & (-3)^{k} & \cdots & (-k)^{k}
\end{array}\right)
$$

This matrix has an inverse because its determinant is nonzero.
Now from Lemma 38.4.1, it follows from the above description of $E$ that for $|\alpha| \leq k$,

$$
D^{\alpha}(E u)\left(\mathbf{x}^{\prime}, x_{n}\right) \equiv\left\{\begin{array}{l}
D^{\alpha} u\left(\mathbf{x}^{\prime}, x_{n}\right) \text { if } x_{n}<0 \\
\sum_{j=1}^{k} \lambda_{j}(-j)^{\alpha_{n}}\left(D^{\alpha} u\right)\left(\mathbf{x}^{\prime},-j x_{n}\right) \text { if } x_{n} \geq 0
\end{array}\right.
$$

It follows that $E$ is linear and there exists a constant, $C$ independent of $u$ such that 38.4.36 holds. This proves the lemma.

Corollary 38.4.3 Let $H^{-}$be the half space of 38.4.35. There exists $E$ with the property that $E: W^{l, p}\left(H^{-}\right) \rightarrow W^{l, p}\left(\mathbb{R}^{n}\right)$ and is linear and continuous for each $l \leq k$.

Proof: This immediate from the density of $C_{c}^{\infty}\left(\overline{H^{-}}\right)$in $W^{k, p}\left(\overline{H^{-}}\right)$and Lemma 38.4.2.
There is nothing sacred about a half space or this particular half space. It is clear that everything works as well for a half space of the form

$$
H_{k}^{-} \equiv\left\{\mathbf{x}: x_{k}<0\right\}
$$

Thus the half space featured in the above discussion is $H_{n}^{-}$.

Corollary 38.4.4 Let $\left\{k_{1}, \cdots, k_{r}\right\} \subseteq\{1, \cdots, n\}$ where the $k_{i}$ are distinct and let

$$
\begin{equation*}
H_{k_{1} \cdots k_{r}}^{-} \equiv H_{k_{1}}^{-} \cap H_{k_{2}}^{-} \cap \cdots \cap H_{k_{r}}^{-} . \tag{38.4.37}
\end{equation*}
$$

Then there exists $E: W^{k, p}\left(H_{k_{1} \cdots k_{r}}^{-}\right) \rightarrow W^{k, p}\left(\mathbb{R}^{n}\right)$ such that $E$ is linear and continuous.
Proof: Follow the above argument with minor modifications to first extend from $H_{k_{1} \cdots k_{r}}^{-}$ to $H_{k_{1} \cdots k_{r-1}}^{-}$and then from from $H_{k_{1} \cdots k_{r-1}}^{-}$to $H_{k_{1} \cdots k_{r-2}}^{-}$etc.

This easily implies the ability to extend off bounded open sets which near their boundaries look locally like an intersection of half spaces.

Theorem 38.4.5 Let $U$ be a bounded open set and suppose $U_{0}, U_{1}, \cdots, U_{m}$ are open sets with the property that $\bar{U} \subseteq \cup_{k=0}^{m} U_{k}, \overline{U_{0}} \subseteq U$, and $\partial U \subseteq \cup_{k=1}^{m} U_{k}$. Suppose also there exist one to one and onto functions, $\mathbf{h}_{k}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}, \mathbf{h}_{k}\left(U_{k} \cap U\right)=W_{k}$ where $W_{k}$ equals the intersection of a bounded open set with a finite intersection of half spaces, $H_{k_{1} \cdots k_{r}}^{-}$, as in 38.4 .37 such that $\mathbf{h}_{k}\left(\partial U \cap U_{k}\right) \subseteq \partial H_{k_{1} \cdots k_{r}}^{-}$. Suppose also that for all $|\alpha| \leq k-1$,

$$
D^{\alpha} \mathbf{h}_{k} \text { and } D^{\alpha} \mathbf{h}_{k}^{-1}
$$

exist and are Lipschitz continuous. Then letting $W$ be an open set which contains $\bar{U}$, there exists $E: W^{k, p}(U) \rightarrow W^{k, p}(W)$ such that $E$ is a linear continuous map from $W^{l, p}(U)$ to $W^{l, p}(W)$ for each $l \leq k$.

Proof: Let $\psi_{j} \in C_{c}^{\infty}\left(U_{j}\right), \psi_{j}(\mathbf{x}) \in[0,1]$ for all $\mathbf{x} \in \mathbb{R}^{n}$, and $\sum_{j=0}^{m} \psi_{j}(\mathbf{x})=1$ on $\bar{U}$. This is a $C^{\infty}$ partition of unity on $\bar{U}$. By Theorem 38.0.14 $\left(\mathbf{h}_{j}^{-1}\right)^{*} u \psi_{j} \in W^{k, p}\left(W_{j}\right)$. By the assumption that $\mathbf{h}_{j}\left(\partial U \cap U_{j}\right) \subseteq \partial H_{k_{1} \cdots k_{r}}^{-}$, the zero extension of $\left(\mathbf{h}_{j}^{-1}\right)^{*} u \psi_{j}$ to the rest of $H_{k_{1} \cdots k_{r}}^{-}$results in an element of $W^{k, p}\left(H_{k_{1} \cdots k_{r}}^{-}\right)$. Apply Corollary 38.4.4 to conclude there exists $E_{j}: W^{k, p}\left(H_{k_{1} \cdots k_{r}}^{-}\right) \rightarrow W^{k, p}\left(\mathbb{R}^{n}\right)$ which is continuous and linear. Abusing notation slightly, by using $\left(\mathbf{h}_{j}^{-1}\right)^{*} u \psi_{j}$ as the above zero extension, it follows $E_{j}\left(\left(\mathbf{h}_{j}^{-1}\right)^{*} u \psi_{j}\right) \in$ $W^{k, p}\left(\mathbb{R}^{n}\right)$. Now let $\eta$ be a function in $C_{c}^{\infty}(\mathbf{h}(W))$ such that $\eta(\mathbf{y})=1$ on $\mathbf{h}(\bar{U})$. Then Define

$$
E u \equiv \sum_{j=0}^{m} \mathbf{h}_{j}^{*} \eta E_{j}\left(\left(\mathbf{h}_{j}^{-1}\right)^{*}\left(u \psi_{j}\right)\right)
$$

Clearly $E u(\mathbf{x})=u(\mathbf{x})$ if $\mathbf{x} \in U$. It is also clear that $E$ is linear. It only remains to verify $E$ is continuous. In what follows, $C_{j}$ will denote a constant which is independent of $u$ which may change from line to line. By Theorem 38.0.14,

$$
\begin{aligned}
\|E u\|_{k, p, W} & \leq \sum_{j=0}^{m}\left\|\mathbf{h}_{j}^{*} \eta E_{j}\left(\left(\mathbf{h}_{j}^{-1}\right)^{*}\left(u \psi_{j}\right)\right)\right\|_{k, p, W} \\
& \leq \sum_{j=0}^{m} C_{j}\left\|\eta E_{j}\left(\left(\mathbf{h}_{j}^{-1}\right)^{*}\left(u \psi_{j}\right)\right)\right\|_{k, p, \mathbf{h}(W)}
\end{aligned}
$$

$$
\begin{gathered}
=\sum_{j=0}^{m} C_{j}\left\|\eta E_{j}\left(\left(\mathbf{h}_{j}^{-1}\right)^{*}\left(u \psi_{j}\right)\right)\right\|_{k, p, \mathbb{R}^{n}} \leq \sum_{j=0}^{m} C_{j}\left\|E_{j}\left(\left(\mathbf{h}_{j}^{-1}\right)^{*}\left(u \psi_{j}\right)\right)\right\|_{k, p, \mathbb{R}^{n}} \\
\leq \sum_{j=0}^{m} C_{j}\left\|\left(\mathbf{h}_{j}^{-1}\right)^{*}\left(u \psi_{j}\right)\right\|_{k, p, \mathbf{h}_{j}\left(U \cap U_{j}\right)} \leq \sum_{j=0}^{m} C_{j}\left\|u \psi_{j}\right\|_{k, p, U \cap U_{k}} \\
\leq \sum_{j=0}^{m} C_{j}\|u\|_{k, p, U \cap U_{k}} \leq\left(\sum_{j=0}^{m} C_{j}\right)\|u\|_{k, p, U} .
\end{gathered}
$$

Similarly $E: W^{l, p}(U) \rightarrow W^{l, p}(U)$ for $l \leq k$. This proves the theorem.
Definition 38.4.6 When $E$ is a linear continuous map from $W^{l, p}(U)$ to $W^{l, p}\left(\mathbb{R}^{n}\right)$ for each $l \leq k$. it is called a strong ( $k, p$ ) extension map.

There is also a very easy sort of extension theorem for the space, $W_{0}^{m, p}(U)$ which does not require any assumptions on the boundary of $U$ other than $m_{n}(\partial U)=0$. First here is the definition of $W_{0}^{m, p}(U)$.

Definition 38.4.7 Denote by $W_{0}^{m, p}(U)$ the closure of $C_{c}^{\infty}(U)$ in $W^{m, p}(U)$.
Theorem 38.4.8 For $u \in W_{0}^{m, p}(U)$, define

$$
E u(\mathbf{x}) \equiv\left\{\begin{array}{l}
u(\mathbf{x}) \text { if } \mathbf{x} \in U \\
0 \text { if } \mathbf{x} \notin U
\end{array}\right.
$$

Then $E$ is a strong ( $k, p$ ) extension map.
Proof: Letting $l \leq m$, it is clear that for $|\alpha| \leq l$,

$$
D^{\alpha} E u=\left\{\begin{array}{l}
D^{\alpha} u \text { for } \mathbf{x} \in U \\
0 \text { for } \mathbf{x} \notin U
\end{array}\right.
$$

This follows because, since $m_{n}(\partial U)=0$ it suffices to consider $\phi \in C_{c}^{\infty}(U)$ and

$$
\phi \in C_{c}^{\infty}\left(\bar{U}^{C}\right) .
$$

Therefore, $\|E u\|_{l, p, \mathbb{R}^{n}}=\|u\|_{l, p, U}$.
There are many other extension theorems and if you are interested in pursuing this further, consult Adams [1]. One of the most famous which is discussed in this reference is due to Calderon and depends on the theory of singular integrals.

## Chapter 39

## Sobolev Spaces Based On $L^{2}$

### 39.1 Fourier Transform Techniques

Much insight can be obtained easily through the use of Fourier transform methods. This technique will be developed in this chapter. When this is done, it is necessary to use Sobolev spaces of the form $W^{k, 2}(U)$, those Sobolev spaces which are based on $L^{2}(U)$. It is true there are generalizations which use Fourier transform methods in the context of $L^{p}$ but the spaces so considered are called Bessel potential spaces. They are not really Sobolev spaces. Furthermore, it is Mihlin's theorem rather than the Plancherel theorem which is the main tool of the analysis. This is a hard theorem.

It is convenient to consider the Schwartz class of functions, $\mathfrak{S}$. These are functions which have infinitely many derivatives and vanish quickly together with their derivatives as $|\mathbf{x}| \rightarrow \infty$. In particular, $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is contained in $\mathfrak{S}$ which is not true of the functions, $\mathscr{G}$ used earlier in defining the Fourier transforms which are a suspace of $\mathfrak{S}$. Recall the following definition.

Definition 39.1.1 $f \in \mathfrak{S}$, the Schwartz class, if $f \in C^{\infty}\left(\mathbb{R}^{n}\right)$ and for all positive integers $N$,

$$
\rho_{N}(f)<\infty
$$

where

$$
\rho_{N}(f)=\sup \left\{\left(1+|\mathbf{x}|^{2}\right)^{N}\left|D^{\alpha} f(\mathbf{x})\right|: \mathbf{x} \in \mathbb{R}^{n},|\alpha| \leq N\right\}
$$

Thus $f \in \mathfrak{S}$ if and only if $f \in C^{\infty}\left(\mathbb{R}^{n}\right)$ and

$$
\begin{equation*}
\sup \left\{\left|\mathbf{x}^{\beta} D^{\alpha} f(\mathbf{x})\right|: \mathbf{x} \in \mathbb{R}^{n}\right\}<\infty \tag{39.1.1}
\end{equation*}
$$

for all multi indices $\alpha$ and $\beta$.
Thus all partial derivatives of a function in $\mathfrak{S}$ are in $L^{p}\left(\mathbb{R}^{n}\right)$ for all $p \geq 1$. Therefore, for $f \in \mathfrak{S}$, the Fourier and inverse Fourier transforms are given in the usual way,

$$
F f(\mathbf{t})=\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} f(\mathbf{x}) e^{-i \mathbf{t} \cdot \mathbf{x}} d x, F^{-1} f(\mathbf{t})=\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} f(\mathbf{x}) e^{i \mathbf{t} \cdot \mathbf{x}} d x
$$

Also recall that the Fourier transform and its inverse are one to one and onto maps from $\mathfrak{S}$ to $\mathfrak{S}$.

To tie the Fourier transform technique in with what has been done so far, it is necessary to make the following assumption on the set, $U$. This assumption is made so that it is possible to consider elements of $W^{k, 2}(U)$ as restrictions of elements of $W^{k, 2}\left(\mathbb{R}^{n}\right)$.

Assumption 39.1.2 Assume $U$ satisfies the segment condition and that for any $m$ of interest, there exists $E \in \mathscr{L}\left(W^{m, p}(U), W^{m, p}\left(\mathbb{R}^{n}\right)\right)$ such that for each

$$
k \leq m, E \in \mathscr{L}\left(W^{k, p}(U), W^{k, p}\left(\mathbb{R}^{n}\right)\right)
$$

That is, there exists a stong ( $m, p$ ) extension operator.

Lemma 39.1.3 The Schwartz class, $\mathfrak{S}$, is dense in $W^{m, p}\left(\mathbb{R}^{n}\right)$.
Proof: The set, $\mathbb{R}^{n}$ satisfies the segment condition and so $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is dense in $W^{m, p}\left(\mathbb{R}^{n}\right)$. However, $C_{c}^{\infty}\left(\mathbb{R}^{n}\right) \subseteq \mathfrak{S}$. This proves the lemma.

Recall now Plancherel's theorem which states that $\|f\|_{0,2, \mathbb{R}^{n}}=\|F f\|_{0,2, \mathbb{R}^{n}}$ whenever $f \in L^{2}\left(\mathbb{R}^{n}\right)$. Also it is routine to verify from the definition of the Fourier transform that for $u \in \mathfrak{S}$,

$$
F \partial_{k} u=i x_{k} F u .
$$

From this it follows that

$$
\left\|D^{\alpha} u\right\|_{0,2, \mathbb{R}^{n}}=\left\|\mathbf{x}^{\alpha} F u\right\|_{0,2, \mathbb{R}^{n}}
$$

Here $\mathbf{x}^{\alpha}$ denotes the function $\mathbf{x} \rightarrow \mathbf{x}^{\alpha}$. Therefore,

$$
\|u\|_{m, 2, \mathbb{R}^{n}}=\left(\int_{\mathbb{R}^{n}} \sum_{|\alpha| \leq m} x_{1}^{2 \alpha_{1}} \cdots x_{n}^{2 \alpha_{n}}|F u(\mathbf{x})|^{2} d x\right)^{1 / 2}
$$

Also, it is not hard to verify that

$$
\sum_{|\alpha| \leq m} x_{1}^{2 \alpha_{1}} \cdots x_{n}^{2 \alpha_{n}} \leq\left(1+\sum_{j=1}^{n} x_{j}^{2}\right)^{m} \leq C(n, m) \sum_{|\alpha| \leq m} x_{1}^{2 \alpha_{1}} \cdots x_{n}^{2 \alpha_{n}}
$$

where $C(n, m)$ is the largest of the multinomial coefficients obtained in the expansion,

$$
\left(1+\sum_{j=1}^{n} x_{j}^{2}\right)^{m}
$$

Therefore, for all $u \in \mathfrak{S}$,

$$
\begin{equation*}
\|u\|_{m, 2, \mathbb{R}^{n}} \leq\left(\int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{m}|F u(\mathbf{x})|^{2} d x\right)^{1 / 2} \leq C(n, m)\|u\|_{m, 2, \mathbb{R}^{n}} \tag{39.1.2}
\end{equation*}
$$

This motivates the following definition.
Definition 39.1.4 Let $H^{m}\left(\mathbb{R}^{n}\right) \equiv$

$$
\begin{equation*}
\left\{u \in L^{2}\left(\mathbb{R}^{n}\right):\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)} \equiv\left(\int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{m}|F u(\mathbf{x})|^{2} d x\right)^{1 / 2}<\infty\right\} \tag{39.1.3}
\end{equation*}
$$

Lemma 39.1.5 $\mathfrak{S}$ is dense in $H^{m}\left(\mathbb{R}^{n}\right)$ and $H^{m}\left(\mathbb{R}^{n}\right)=W^{2, m}\left(\mathbb{R}^{n}\right)$. Furthermore, the norms are equivalent.

Proof: First it is shown that $\mathfrak{S}$ is dense in $H^{m}\left(\mathbb{R}^{n}\right)$. Let $u \in H^{m}\left(\mathbb{R}^{n}\right)$. Let $\mu(E) \equiv$ $\int_{E}\left(1+|\mathbf{x}|^{2}\right)^{m} d x$. Thus $\mu$ is a regular measure and $u \in H^{m}\left(\mathbb{R}^{n}\right)$ just means that $F u \in$ $L^{2}(\mu)$, the space of functions which are in $L^{2}\left(\mathbb{R}^{n}\right)$ with respect to this measure, $\mu$. Therefore, from the regularity of the measure, $\mu$, there exists $u_{k} \in C_{c}\left(\mathbb{R}^{n}\right)$ such that

$$
\left\|u_{k}-F u\right\|_{L^{2}(\mu)} \rightarrow 0
$$

Now let $\psi_{\varepsilon}$ be a mollifier and pick $\varepsilon_{k}$ small enough that

$$
\left\|u_{k} * \psi_{\varepsilon_{k}}-u_{k}\right\|_{L^{2}(\mu)}<\frac{1}{2^{k}} .
$$

Then $u_{k} * \psi_{\varepsilon_{k}} \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right) \subseteq \mathfrak{S}$. Therefore, there exists $w_{k} \in \mathscr{G}$ such that $F w_{k}=u_{k} * \psi_{\varepsilon_{k}}$. It follows

$$
\left\|F w_{k}-F u\right\|_{L^{2}(\mu)} \leq\left\|F w_{k}-u_{k}\right\|_{L^{2}(\mu)}+\left\|u_{k}-F u\right\|_{L^{2}(\mu)}
$$

and these last two terms converge to 0 as $k \rightarrow \infty$. Therefore, $w_{k} \rightarrow u$ in $H^{m}\left(\mathbb{R}^{n}\right)$ and this proves the first part of this lemma.

Now let $u \in H^{m}\left(\mathbb{R}^{n}\right)$. By what was just shown, there exists a sequence, $u_{k} \rightarrow u$ in $H^{m}\left(\mathbb{R}^{n}\right)$ where $u_{k} \in \mathfrak{S}$. It follows from 39.1.2 that

$$
\left\|u_{k}-u_{l}\right\|_{H^{m}} \geq\left\|u_{k}-u_{l}\right\|_{m, 2, \mathbb{R}^{n}}
$$

and so $\left\{u_{k}\right\}$ is a Cauchy sequence in $W^{m, 2}\left(\mathbb{R}^{n}\right)$. Therefore, there exists $w \in W^{m, 2}\left(\mathbb{R}^{n}\right)$ such that

$$
\left\|u_{k}-w\right\|_{m, 2, \mathbb{R}^{n}} \rightarrow 0
$$

But this implies

$$
0=\lim _{k \rightarrow \infty}\left\|u_{k}-w\right\|_{0,2, \mathbb{R}^{n}}=\lim _{k \rightarrow \infty}\left\|u_{k}-u\right\|_{0,2, \mathbb{R}^{n}}
$$

showing $u=w$ which verifies $H^{m}\left(\mathbb{R}^{n}\right) \subseteq W^{2, m}\left(\mathbb{R}^{n}\right)$. The opposite inclusion is proved the same way, using density of $\mathfrak{S}$ and the fact that the norms in both spaces are larger than the norms in $L^{2}\left(\mathbb{R}^{n}\right)$. The equivalence of the norms follows from the density of $\mathfrak{S}$ and the equivalence of the norms on $\mathfrak{S}$. This proves the lemma.

The conclusion of this lemma with the density of $\mathfrak{S}$ and 39.1.2 implies you can use either norm, $\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}$ or $\|u\|_{m, 2, \mathbb{R}^{n}}$ when working with these Sobolev spaces.

What of open sets satisfying Assumption 39.1.2? How does $W^{m, 2}(U)$ relate to the Fourier transform?

Definition 39.1.6 Let $U$ be an open set in $\mathbb{R}^{n}$. Then

$$
\begin{equation*}
H^{m}(U) \equiv\left\{u: u=\left.v\right|_{U} \text { for some } v \in H^{m}\left(\mathbb{R}^{n}\right)\right\} \tag{39.1.4}
\end{equation*}
$$

Here the notation, $\left.v\right|_{U}$ means $v$ restricted to $U$. Define the norm in this space by

$$
\begin{equation*}
\|u\|_{H^{m}(U)} \equiv \inf \left\{\|v\|_{H^{m}\left(\mathbb{R}^{n}\right)}:\left.v\right|_{U}=u\right\} \tag{39.1.5}
\end{equation*}
$$

Lemma 39.1.7 $H^{m}(U)$ is a Banach space.
Proof: First it is necessary to verify that the given norm really is a norm. Suppose then that $u=0$. Is $\|u\|_{H^{m}(U)}=0$ ? Of course it is. Just take $v \equiv 0$. Then $\left.v\right|_{U}=u$ and $\|v\|_{H^{m}}=0$. Next suppose $\|u\|_{H^{m}(U)}=0$. Does it follow that $u=0$ ? Letting $\varepsilon>0$ be given, there exists $v \in H^{m}\left(\mathbb{R}^{n}\right)$ such that $\left.v\right|_{U}=u$ and $\|v\|_{H^{m}\left(\mathbb{R}^{n}\right)}<\varepsilon$. Therefore,

$$
\|u\|_{0, U} \leq\|v\|_{0, \mathbb{R}^{n}} \leq\|v\|_{H^{m}(U)}<\varepsilon
$$

Since $\varepsilon>0$ is arbitrary, it follows $u=0$ a.e. Next suppose $u_{i} \in H^{m}(U)$ for $i=1,2$. There exists $v_{i} \in H^{m}\left(\mathbb{R}^{n}\right)$ such that

$$
\left\|v_{i}\right\|_{H^{m}\left(\mathbb{R}^{n}\right)}<\left\|u_{i}\right\|_{H^{m}(U)}+\varepsilon
$$

Therefore,

$$
\begin{aligned}
\left\|u_{1}+u_{2}\right\|_{H^{m}(U)} & \leq\left\|v_{1}+v_{2}\right\|_{H^{m}\left(\mathbb{R}^{n}\right)} \leq\left\|v_{1}\right\|_{H^{m}\left(\mathbb{R}^{n}\right)}+\left\|v_{2}\right\|_{H^{m}\left(\mathbb{R}^{n}\right)} \\
& \leq\left\|u_{1}\right\|_{H^{m}(U)}+\left\|u_{2}\right\|_{H^{m}(U)}+2 \varepsilon
\end{aligned}
$$

and since $\varepsilon>0$ is arbitrary, this shows the triangle inequality.
The interesting question is the one about completeness. Suppose then $\left\{u_{k}\right\}$ is a Cauchy sequence in $H^{m}(U)$. There exists $N_{k}$ such that if $k, l \geq N_{k}$, it follows $\left\|u_{k}-u_{l}\right\|_{H^{m}(U)}<\frac{1}{2^{k}}$ and the numbers, $N_{k}$ can be taken to be strictly increasing in $k$. Thus for

$$
l \geq N_{k},| | u_{l}-u_{N_{k}} \|_{H^{m}(U)}<1 / 2^{l}
$$

Therefore, there exists $w_{l} \in H^{m}\left(\mathbb{R}^{n}\right)$ such that

$$
\left.w_{l}\right|_{U}=u_{l}-u_{N_{k}},\left\|w_{l}\right\|_{H^{m}\left(\mathbb{R}^{n}\right)}<\frac{1}{2^{l}}
$$

Also let $\left.v_{N_{k}}\right|_{U}=u_{N_{k}}$ with $v_{N_{k}} \in H^{m}\left(\mathbb{R}^{n}\right)$ and

$$
\left|\left|v_{N_{k}}\right|\right|_{H^{m}\left(\mathbb{R}^{n}\right)}<\| u_{N_{k}}| |_{H^{m}(U)}+\frac{1}{2^{k}}
$$

Now for $l>N_{k}$, define $v_{l}$ by $v_{l}-v_{N_{k}}=w_{N_{k}}$ so that $\left|\mid v_{l}-v_{N_{k}} \|_{H^{m}\left(\mathbb{R}^{n}\right)}<1 / 2^{k}\right.$. In particular,

$$
\left\|v_{N_{k+1}}-v_{N_{k}}\right\|_{H^{m}\left(\mathbb{R}^{n}\right)}<1 / 2^{k}
$$

which shows that $\left\{v_{N_{k}}\right\}_{k=1}^{\infty}$ is a Cauchy sequence. Consequently it must converge to $v \in$ $H^{m}\left(\mathbb{R}^{n}\right)$. Let $u=\left.v\right|_{U}$. Then

$$
\left\|u-\left.u_{N_{k}}\right|_{H^{m}(U)} \leq\right\| v-\left.v_{N_{k}}\right|_{H^{m}\left(\mathbb{R}^{n}\right)}
$$

which shows the subsequence, $\left\{u_{N_{k}}\right\}_{k}$ converges to $u$. Since $\left\{u_{k}\right\}$ is a Cauchy sequence, it follows it too must converge to $u$. This proves the lemma.

The main result is next.
Theorem 39.1.8 Suppose $U$ satisfies Assumption 39.1.2. Then for $m$ a nonnegative integer, $H^{m}(U)=W^{m, 2}(U)$ and the two norms are equivalent.

Proof: Let $u \in H^{m}(U)$. Then there exists $v \in H^{m}\left(\mathbb{R}^{n}\right)$ such that $\left.v\right|_{U}=u$. Hence $v \in W^{k, 2}\left(\mathbb{R}^{n}\right)$ and so all its weak derivatives up to order $m$ are in $L^{2}\left(\mathbb{R}^{n}\right)$. Therefore, the restrictions of these weak derivitves are in $L^{2}(U)$. Since $U$ satisfies the segment condition, it follows $u \in W^{m, 2}(U)$ which shows $H^{m}(U) \subseteq W^{m, 2}(U)$.

Next take $u \in W^{m, 2}(U)$. Then $E u \in W^{m, 2}\left(\mathbb{R}^{n}\right)=H^{m}\left(\mathbb{R}^{n}\right)$ and this shows $u \in H^{m}(U)$. This has shown the two spaces are the same. It remains to verify their norms are equivalent. Let $u \in H^{m}(U)$ and let $\left.v\right|_{U}=u$ where $v \in H^{m}\left(\mathbb{R}^{n}\right)$ and

$$
\|u\|_{H^{m}(U)}+\varepsilon>\|v\|_{H^{m}\left(\mathbb{R}^{n}\right)} .
$$

Then recalling that $\|\cdot\|_{H^{m}\left(\mathbb{R}^{n}\right)}$ and $\|\cdot\|_{m, 2, \mathbb{R}^{n}}$ are equivalent norms for $H^{m}\left(\mathbb{R}^{n}\right)$, there exists a constant, $C$ such that

$$
\|u\|_{H^{m}(U)}+\varepsilon>\|v\|_{H^{m}\left(\mathbb{R}^{n}\right)} \geq C\|v\|_{m, 2, \mathbb{R}^{n}} \geq C\|u\|_{m, 2, U}
$$

Now consider the two Banach spaces,

$$
\left(H^{m}(U),\|\cdot\|_{H^{m}(U)}\right),\left(W^{m, 2}(U),\|\cdot\|_{m, 2, U}\right)
$$

The above inequality shows since $\varepsilon>0$ is arbitrary that

$$
\text { id }:\left(H^{m}(U),\|\cdot\|_{H^{m}(U)}\right) \rightarrow\left(W^{m, 2}(U),\|\cdot\|_{m, 2, U}\right)
$$

is continuous. By the open mapping theorem, it follows id is continuous in the other direction. Thus there exists a constant, $K$ such that $\|u\|_{H^{m}(U)} \leq K\|u\|_{k, 2, U}$. Hence the two norms are equivalent as claimed.

Specializing Corollary 38.3.3 and Theorem 38.3.6 starting on Page 1339 to the case of $p=2$ while also assuming more on $U$ yields the following embedding theorems.

Theorem 39.1.9 Suppose $m \geq 0$ and $j$ is a nonnegative integer satisfying $2 j<n$. Also let $U$ bean open set which satisfies Assumption 39.1.2. Then id $\in \mathscr{L}\left(H^{m+j}(U), W^{m, q}(U)\right)$ where

$$
\begin{equation*}
q \equiv \frac{2 n}{n-2 j} \tag{39.1.6}
\end{equation*}
$$

If, in addition to the above, $U$ is bounded and $1 \leq r<q$, then

$$
\mathrm{id} \in \mathscr{L}\left(H^{m+j}(U), W^{m, r}(U)\right)
$$

and is compact.
Theorem 39.1.10 Suppose for $j$ a nonnegative integer, $2 j<n<2(j+1)$ and let $m$ be a positive integer. Let $U$ be any bounded open set in $\mathbb{R}^{n}$ which satisfies Assumption 39.1.2. Then $\operatorname{id} \in \mathscr{L}\left(H^{m+j}(U), C^{m-1, \lambda}(\bar{U})\right)$ for every $\lambda \leq \lambda_{0} \equiv(j+1)-\frac{n}{2}$ and if $\lambda<(j+1)-$ $\frac{n}{2}$, id is compact.

### 39.2 Fractional Order Spaces

What has been gained by all this? The main thing is that $H^{m+s}(U)$ makes sense for any $s \in(0,1)$ and $m$ an integer. You simply replace $m$ with $m+s$ in the above for $s \in(0,1)$. This gives what is meant by $H^{m+s}\left(\mathbb{R}^{n}\right)$

Definition 39.2.1 For $m$ an integer and $s \in(0,1)$, let $H^{m+s}\left(\mathbb{R}^{n}\right) \equiv$

$$
\begin{equation*}
\left\{u \in L^{2}\left(\mathbb{R}^{n}\right):\|u\|_{H^{m+s}\left(\mathbb{R}^{n}\right)} \equiv\left(\int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{m+s}|F u(\mathbf{x})|^{2} d x\right)^{1 / 2}<\infty\right\} \tag{39.2.7}
\end{equation*}
$$

You could also simply refer to $H^{t}\left(\mathbb{R}^{n}\right)$ where $t$ is a real number replacing the $m+s$ in the above formula with $t$ but I want to emphasize the notion that $t=m+s$ where $m$ is a nonnegative integer. Therefore, I will often write $m+s$. Let $U$ be an open set in $\mathbb{R}^{n}$. Then

$$
\begin{equation*}
H^{m+s}(U) \equiv\left\{u: u=\left.v\right|_{U} \text { for some } v \in H^{m+s}\left(\mathbb{R}^{n}\right)\right\} \tag{39.2.8}
\end{equation*}
$$

Define the norm in this space by

$$
\begin{equation*}
\|u\|_{H^{m+s}(U)} \equiv \inf \left\{\|v\|_{H^{m+s}\left(\mathbb{R}^{n}\right)}:\left.v\right|_{U}=u\right\} \tag{39.2.9}
\end{equation*}
$$

Lemma 39.2.2 $H^{m+s}(U)$ is a Banach space.
Proof: Just repeat the proof of Lemma 39.1.7.
The theorem about density of $\mathfrak{S}$ also remains true in $H^{m+s}\left(\mathbb{R}^{n}\right)$. Just repeat the proof of that part of Lemma 39.1.5 replacing the integer, $m$, with the symbol, $m+s$.

Lemma 39.2.3 $\mathfrak{S}$ is dense in $H^{m+s}\left(\mathbb{R}^{n}\right)$.
In fact, more can be said.
Corollary 39.2.4 Let $U$ be an open set and let $\left.\mathfrak{S}\right|_{U}$ denote the restrictions of functions of $\mathfrak{S}$ to $U$. Then $\left.\mathfrak{S}\right|_{U}$ is dense in $H^{t}(U)$.

Proof: Let $u \in H^{t}(U)$ and let $v \in H^{t}\left(\mathbb{R}^{n}\right)$ such that $\left.v\right|_{U}=u$ a.e. Then since $\mathfrak{S}$ is dense in $H^{t}\left(\mathbb{R}^{n}\right)$, there exists $w \in \mathfrak{S}$ such that

$$
\|w-v\|_{H^{t}\left(\mathbb{R}^{n}\right)}<\varepsilon .
$$

It follows that

$$
\begin{aligned}
\|u-w\|_{H^{t}(U)} & \leq\|u-v\|_{H^{t}(U)}+\|v-w\|_{H^{t}(U)} \\
& \leq 0+\|v-w\|_{H^{t}\left(\mathbb{R}^{n}\right)}<\varepsilon
\end{aligned}
$$

These fractional order spaces are important when trying to understand the trace on the boundary. The Fourier transform description also makes it very easy to establish interesting inequalities such as interpolation inequalities.

Lemma 39.2.5 Let $0 \leq r<s<t$. Then if $u \in H^{t}\left(\mathbb{R}^{n}\right)$,

$$
\|u\|_{H^{s}\left(\mathbb{R}^{n}\right)} \leq\|u\|_{H^{r}\left(\mathbb{R}^{n}\right)}^{\theta}\|u\|_{H^{t}\left(\mathbb{R}^{n}\right)}^{1-\theta}
$$

where $\theta$ is a positve number such that $\theta r+(1-\theta) t=s$.

Proof: This follows from Holder's inequality applied to the measure $\mu$ given by

$$
\mu(E)=\int_{E}|F u|^{2} d x
$$

Thus

$$
\begin{aligned}
& \int\left(1+|\mathbf{x}|^{2}\right)^{s}|F u|^{2} d x \\
= & \int\left(1+|\mathbf{x}|^{2}\right)^{r \theta}\left(1+|\mathbf{x}|^{2}\right)^{(1-\theta) t}|F u|^{2} d x \\
\leq & \left(\int\left(1+|\mathbf{x}|^{2}\right)^{r}|F u|^{2} d x\right)^{\theta}\left(\int\left(1+|\mathbf{x}|^{2}\right)^{(1-\theta) t}|F u|^{2} d x\right)^{1-\theta} \\
= & \|u\|_{H^{r}\left(\mathbb{R}^{n}\right)}^{2 \theta}| | u \|_{H^{t}\left(\mathbb{R}^{n}\right)}^{2(1-\theta)} .
\end{aligned}
$$

Taking square roots yields the desired inequality.
Corollary 39.2.6 Let $U$ be an open set satisfying Assumption 39.1.2 and let $p<q$ where $p, q$ are two nonnegative integers. Also let $t \in(p, q)$. Then exists a constant, $C$ independent of $u \in H^{q}(U)$ such that for all $u \in H^{q}(U)$,

$$
\|u\|_{H^{t}(U)} \leq C\|u\|_{H^{p}(U)}^{\theta}\|u\|_{H^{q}(U)}^{1-\theta}
$$

where $\theta$ is such that $t=\theta p+(1-\theta) q$.
Proof: Let $E \in \mathscr{L}\left(H^{q}(U), H^{q}\left(\mathbb{R}^{n}\right)\right)$ such that for all positive integers, $l$ less than or equal to $q, E \in \mathscr{L}\left(H^{l}(U), H^{l}\left(\mathbb{R}^{n}\right)\right)$. Then $\left.E u\right|_{U}=u$ and $E u \in H^{t}\left(\mathbb{R}^{n}\right)$. Therefore, by Lemma 39.2.5,

$$
\begin{aligned}
\|u\|_{H^{t}(U)} & \leq\|E u\|_{H^{t}\left(\mathbb{R}^{n}\right)} \leq\|E u\|_{H^{p}\left(\mathbb{R}^{n}\right)}^{\theta}\|E u\|_{H^{q}\left(\mathbb{R}^{n}\right)}^{1-\theta} \\
& \leq C\|u\|_{H^{p}(U)}^{\theta}\|u\|_{H^{q}(U)}^{1-\theta} .
\end{aligned}
$$

Now recall the very important Theorem 38.0.14 on Page 1316 which is listed here for convenience.

Theorem 39.2.7 Let $\mathbf{h}: U \rightarrow V$ be one to one and onto where $U$ and $V$ are two open sets. Also suppose that $D^{\alpha} \mathbf{h}$ and $D^{\alpha}\left(\mathbf{h}^{-1}\right)$ exist and are Lipschitz continuous if $|\alpha| \leq m-1$ for $m$ a positive integer. Then

$$
\mathbf{h}^{*}: W^{m, p}(V) \rightarrow W^{m, p}(U)
$$

is continuous, linear, one to one, and has an inverse with the same properties, the inverse being $\left(\mathbf{h}^{-1}\right)^{*}$.

### 39.3 An Intrinsic Norm

Is there something like this for the fractional order spaces? Yes there is. However, in order to prove it, it is convenient to use an equivalent norm for $H^{m+s}\left(\mathbb{R}^{n}\right)$ which does not depend explicitly on the Fourier transform. The following theorem is similar to one in [68]. It describes the norm in $H^{m+s}\left(\mathbb{R}^{n}\right)$ in terms which are free of the Fourier transform. This is also called an intrinsic norm [1].

Theorem 39.3.1 Let $s \in(0,1)$ and let $m$ be a nonnegative integer. Then an equivalent norm for $H^{m+s}\left(\mathbb{R}^{n}\right)$ is

$$
\left\|\|u\|_{m+s}^{2} \equiv\right\| u \|_{m, 2, \mathbb{R}^{n}}^{2}+\sum_{|\alpha|=m} \iint\left|D^{\alpha} u(\mathbf{x})-D^{\alpha} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y
$$

Also if $|\beta| \leq m$, there are constants, $m(s)$ and $M(s)$ such that

$$
\begin{gather*}
m(s) \int|F u(\mathbf{z})|^{2}\left|\mathbf{z}^{\beta}\right|^{2}|\mathbf{z}|^{2 s} d z \leq \iint\left|D^{\beta} u(\mathbf{x})-D^{\beta} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
\leq M(s) \int|F u(\mathbf{z})|^{2}\left|\mathbf{z}^{\beta}\right|^{2}|\mathbf{z}|^{2 s} d z \tag{39.3.10}
\end{gather*}
$$

Proof: Let $u \in \mathfrak{S}$ which is dense in $H^{m+s}\left(\mathbb{R}^{n}\right)$. The Fourier transform of the function, $\mathbf{y} \rightarrow D^{\alpha} u(\mathbf{x}+\mathbf{y})-D^{\alpha} u(\mathbf{y})$ equals

$$
\left(e^{i \mathbf{x} \cdot \mathbf{z}}-1\right) F D^{\alpha} u(\mathbf{z})
$$

Now by Fubini's theorem and Plancherel's theorem along with the above, taking $|\alpha|=m$,

$$
\begin{align*}
& \iint\left|D^{\alpha} u(\mathbf{x})-D^{\alpha} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
= & \iint\left|D^{\alpha} u(\mathbf{y}+\mathbf{t})-D^{\alpha} u(\mathbf{y})\right|^{2}|\mathbf{t}|^{-n-2 s} d t d y \\
= & \int|\mathbf{t}|^{-n-2 s} \int\left|D^{\alpha} u(\mathbf{y}+\mathbf{t})-D^{\alpha} u(\mathbf{y})\right|^{2} d y d t \\
= & \int|\mathbf{t}|^{-n-2 s} \int\left|\left(e^{i \mathbf{t} \cdot \mathbf{z}}-1\right) F D^{\alpha} u(\mathbf{z})\right|^{2} d z d t \\
= & \int\left|F D^{\alpha} u(\mathbf{z})\right|^{2}\left(\int|\mathbf{t}|^{-n-2 s}\left|\left(e^{i \mathbf{t} \cdot \mathbf{z}}-1\right)\right|^{2} d t\right) d z \tag{39.3.11}
\end{align*}
$$

Consider the inside integral, the one taken with respect to $\mathbf{t}$.

$$
G(\mathbf{z}) \equiv\left(\int|\mathbf{t}|^{-n-2 s}\left|\left(e^{i \mathbf{t} \cdot \mathbf{z}}-1\right)\right|^{2} d t\right)
$$

The essential thing to notice about this function of $\mathbf{z}$ is that it is a positive real number whenever $\mathbf{z} \neq \mathbf{0}$. This is because for small $|\mathbf{t}|$, the integrand is dominated by $C|\mathbf{t}|^{-n+2(1-s)}$. Changing to polar coordinates, you see that

$$
\int_{[|\mathbf{t}| \leq 1]}|\mathbf{t}|^{-n-2 s}\left|\left(e^{i \mathbf{t} \cdot \mathbf{z}}-1\right)\right|^{2} d t<\infty
$$

Next, for $|\mathbf{t}|>1$, the integrand is bounded by $4|\mathbf{t}|^{-n-2 s}$, and changing to polar coordinates shows

$$
\int_{[|\mathbf{t}|>1]}|\mathbf{t}|^{-n-2 s}\left|\left(e^{i \mathbf{t} \cdot \mathbf{z}}-1\right)\right|^{2} d t \leq 4 \int_{[|\mathbf{t}|>1]}|\mathbf{t}|^{-n-2 s} d t<\infty .
$$

Now for $\alpha>0$,

$$
\begin{aligned}
G(\alpha \mathbf{z}) & =\int|\mathbf{t}|^{-n-2 s}\left|\left(e^{i \mathbf{t} \cdot \alpha \mathbf{z}}-1\right)\right|^{2} d t \\
& =\int|\mathbf{t}|^{-n-2 s}\left|\left(e^{i \alpha \mathbf{x} \cdot \mathbf{z}}-1\right)\right|^{2} d t \\
& =\int\left|\frac{\mathbf{r}}{\alpha}\right|^{-n-2 s}\left|\left(e^{i \mathbf{r} \cdot \mathbf{z}}-1\right)\right|^{2} \frac{1}{\alpha^{n}} d r \\
& =\alpha^{2 s} \int|\mathbf{r}|^{-n-2 s}\left|\left(e^{i \mathbf{r} \cdot \mathbf{z}}-1\right)\right|^{2} d r=\alpha^{2 s} G(\mathbf{z})
\end{aligned}
$$

Also $G$ is continuous and strictly positive. Letting

$$
0<m(s)=\min \{G(\mathbf{w}):|\mathbf{w}|=1\}
$$

and

$$
M(s)=\max \{G(\mathbf{w}):|\mathbf{w}|=1\}
$$

it follows from this, and letting $\alpha=|\mathbf{z}|, \mathbf{w} \equiv \mathbf{z} /|\mathbf{z}|$, that

$$
G(\mathbf{z}) \in\left(m(s)|\mathbf{z}|^{2 s}, M(s)|\mathbf{z}|^{2 s}\right)
$$

More can be said but this will suffice. Also observe that for $s \in(0,1)$ and $b>0$,

$$
(1+b)^{s} \leq 1+b^{s}, 2^{1-s}(1+b)^{s} \geq 1+b^{s}
$$

In what follows, $C(s)$ will denote a constant which depends on the indicated quantities which may be different on different lines of the argument. Then from 39.3.11,

$$
\begin{aligned}
& \iint\left|D^{\alpha} u(\mathbf{x})-D^{\alpha} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
& \quad \leq M(s) \int\left|F D^{\alpha} u(\mathbf{z})\right|^{2}|\mathbf{z}|^{2 s} d z \\
& \quad=M(s) \int|F u(\mathbf{z})|^{2}\left|\mathbf{z}^{\alpha}\right|^{2}|\mathbf{z}|^{2 s} d z
\end{aligned}
$$

No reference was made to $|\alpha|=m$ and so this establishes the top half of 39.3.10. Therefore,

$$
\begin{aligned}
\|u\| \|_{m+s}^{2} & \equiv\|u\|_{m, 2, \mathbb{R}^{n}}^{2}+\sum_{|\alpha|=m} \iint\left|D^{\alpha} u(\mathbf{x})-D^{\alpha} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
& \leq C \int\left(1+|\mathbf{z}|^{2}\right)^{m}|F u(\mathbf{z})|^{2} d z+M(s) \int|F u(\mathbf{z})|^{2} \sum_{|\alpha|=m}\left|\mathbf{z}^{\alpha}\right|^{2}|\mathbf{z}|^{2 s} d z
\end{aligned}
$$

Recall that

$$
\begin{equation*}
\sum_{|\alpha| \leq m} z_{1}^{2 \alpha_{1}} \cdots z_{n}^{2 \alpha_{n}} \leq\left(1+\sum_{j=1}^{n} z_{j}^{2}\right)^{m} \leq C(n, m) \sum_{|\alpha| \leq m} z_{1}^{2 \alpha_{1}} \cdots z_{n}^{2 \alpha_{n}} \tag{39.3.12}
\end{equation*}
$$

Therefore, where $C(n, m)$ is the largest of the multinomial coefficients obtained in the expansion,

$$
\left(1+\sum_{j=1}^{n} z_{j}^{2}\right)^{m}
$$

Therefore,

$$
\begin{aligned}
& \left\|\left||u \||_{m+s}^{2}\right.\right. \\
\leq & C \int\left(1+|\mathbf{z}|^{2}\right)^{m}|F u(\mathbf{z})|^{2} d z+M(s) \int|F u(\mathbf{z})|^{2} \sum_{|\alpha|=m}\left|\mathbf{z}^{\alpha}\right|^{2}|\mathbf{z}|^{2 s} d z \\
\leq & C \int\left(1+|\mathbf{z}|^{2}\right)^{m+s}|F u(\mathbf{z})|^{2} d z+M(s) \int|F u(\mathbf{z})|^{2}\left(1+|\mathbf{z}|^{2}\right)^{m}|\mathbf{z}|^{2 s} d z \\
\leq & C \int\left(1+|\mathbf{z}|^{2}\right)^{m+s}|F u(\mathbf{z})|^{2} d z=C\|u\|_{H^{m+s}\left(\mathbb{R}^{n}\right)}
\end{aligned}
$$

It remains to show the other inequality. From 39.3.11,

$$
\begin{aligned}
& \iint\left|D^{\alpha} u(\mathbf{x})-D^{\alpha} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
& \quad \geq m(s) \int\left|F D^{\alpha} u(\mathbf{z})\right|^{2}|\mathbf{z}|^{2 s} d z \\
& \quad=m(s) \int|F u(\mathbf{z})|^{2}\left|\mathbf{z}^{\alpha}\right|^{2}|\mathbf{z}|^{2 s} d z
\end{aligned}
$$

No reference was made to $|\alpha|=m$ and so this establishes the bottom half of 39.3.10. Therefore, from 39.3.12,

$$
\begin{aligned}
& \|\|u\|\|_{m+s}^{2} \\
\geq & C \int\left(1+|\mathbf{z}|^{2}\right)^{m}|F u(\mathbf{z})|^{2} d z+m(s) \int|F u(\mathbf{z})|^{2} \sum_{|\alpha|=m}\left|\mathbf{z}^{\alpha}\right|^{2}|\mathbf{z}|^{2 s} d z \\
\geq & C \int\left(1+|\mathbf{z}|^{2}\right)^{m}|F u(\mathbf{z})|^{2} d z+C \int|F u(\mathbf{z})|^{2}\left(1+|\mathbf{z}|^{2}\right)^{m}|\mathbf{z}|^{2 s} d z \\
= & C \int\left(1+|\mathbf{z}|^{2}\right)^{m}\left(1+|\mathbf{z}|^{2 s}\right)|F u(\mathbf{z})|^{2} d z \\
\geq & C \int\left(1+|\mathbf{z}|^{2}\right)^{m}\left(1+|\mathbf{z}|^{2}\right)^{s}|F u(\mathbf{z})|^{2} d z \\
= & C \int\left(1+|\mathbf{z}|^{2}\right)^{m+s}|F u(\mathbf{z})|^{2} d z=\|u\|_{H^{m+s}\left(\mathbb{R}^{n}\right)} .
\end{aligned}
$$

This proves the theorem.
With the above intrinsic norm, it becomes possible to prove the following version of Theorem 39.2.7.

Lemma 39.3.2 Let $\mathbf{h}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be one to one and onto. Also suppose that $D^{\alpha} \mathbf{h}$ and $D^{\alpha}\left(\mathbf{h}^{-1}\right)$ exist and are Lipschitz continuous if $|\alpha| \leq m$ for $m$ a positive integer. Then

$$
\mathbf{h}^{*}: H^{m+s}\left(\mathbb{R}^{n}\right) \rightarrow H^{m+s}\left(\mathbb{R}^{n}\right)
$$

is continuous, linear, one to one, and has an inverse with the same properties, the inverse being $\left(\mathbf{h}^{-1}\right)^{*}$.

Proof: Let $u \in \mathfrak{S}$. From Theorem 39.2.7 and the equivalence of the norms in $W^{m, 2}\left(\mathbb{R}^{n}\right)$ and $H^{m}\left(\mathbb{R}^{n}\right)$,

$$
\begin{gather*}
\left\|\mathbf{h}^{*} u\right\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2}+\iint \sum_{|\alpha|=m}\left|D^{\alpha} \mathbf{h}^{*} u(\mathbf{x})-D^{\alpha} \mathbf{h}^{*} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
\leq C\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2}+\iint \sum_{|\alpha|=m}\left|D^{\alpha} \mathbf{h}^{*} u(\mathbf{x})-D^{\alpha} \mathbf{h}^{*} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
=C\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2}+\iint \sum_{|\alpha|=m} \mid \sum_{|\beta(\alpha)| \leq m} \mathbf{h}^{*}\left(D^{\beta(\alpha)} u\right) g_{\beta(\alpha)}(\mathbf{x}) \\
\quad-\left.\mathbf{h}^{*}\left(D^{\beta(\alpha)} u\right) g_{\beta(\alpha)}(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y  \tag{39.3.13}\\
\leq C\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2}+C \iint \sum_{|\alpha|=m} \sum_{|\beta(\alpha)| \leq m} \mid \mathbf{h}^{*}\left(D^{\beta(\alpha)} u\right) g_{\beta(\alpha)}(\mathbf{x}) \\
\quad-\left.\mathbf{h}^{*}\left(D^{\beta(\alpha)} u\right) g_{\beta(\alpha)}(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y
\end{gather*}
$$

A single term in the last sum corresponding to a given $\alpha$ is then of the form,

$$
\begin{align*}
& \iint\left|\mathbf{h}^{*}\left(D^{\beta} u\right) g_{\beta}(\mathbf{x})-\mathbf{h}^{*}\left(D^{\beta} u\right) g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y  \tag{39.3.14}\\
\leq & {\left[\iint\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{x}) g_{\beta}(\mathbf{x})-\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y}) g_{\beta}(\mathbf{x})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y+\right.} \\
& \left.\iint\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y}) g_{\beta}(\mathbf{x})-\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y}) g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y\right] \\
\leq & {\left[C(\mathbf{h}) \iint\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{x})-\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y+\right.} \\
& \left.\iint\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y})\right|^{2}\left|g_{\beta}(\mathbf{x})-g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y\right]
\end{align*}
$$

Changing variables, and then using the names of the old variables to simplify the notation,

$$
\begin{aligned}
\leq & {\left[C\left(\mathbf{h}, \mathbf{h}^{-1}\right) \iint\left|\left(D^{\beta} u\right)(\mathbf{x})-\left(D^{\beta} u\right)(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y+\right.} \\
& \left.\iint\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y})\right|^{2}\left|g_{\beta}(\mathbf{x})-g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y\right]
\end{aligned}
$$

By 39.3.10,

$$
\begin{aligned}
\leq & C(\mathbf{h}) \int|F(u)(\mathbf{z})|^{2}\left|\mathbf{z}^{\beta}\right|^{2}|\mathbf{z}|^{2 s} d z \\
& +\iint\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y})\right|^{2}\left|g_{\beta}(\mathbf{x})-g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y
\end{aligned}
$$

In the second term, let $\mathbf{t}=\mathbf{x}-\mathbf{y}$. Then this term is of the form

$$
\begin{align*}
& \int\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y})\right|^{2} \int\left|g_{\beta}(\mathbf{y}+\mathbf{t})-g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{t}|^{-n-2 s} d t d y  \tag{39.3.15}\\
\leq & C \int\left|\mathbf{h}^{*}\left(D^{\beta} u\right)(\mathbf{y})\right|^{2} d y \leq C| | u \|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2} \tag{39.3.16}
\end{align*}
$$

because the inside integral equals a constant which depends on the Lipschitz constants and bounds of the function, $g_{\beta}$ and these things depend only on $\mathbf{h}$. The reason this integral is finite is that for $|\mathbf{t}| \leq 1$,

$$
\left|g_{\beta}(\mathbf{y}+\mathbf{t})-g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{t}|^{-n-2 s} \leq K|\mathbf{t}|^{2}|\mathbf{t}|^{-n-2 s}
$$

and using polar coordinates, you see

$$
\int_{[|\mathbf{t}| \leq 1]}\left|g_{\beta}(\mathbf{y}+\mathbf{t})-g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{t}|^{-n-2 s} d t<\infty
$$

Now for $|\mathbf{t}|>1$, the integrand in 39.3 .15 is dominated by $4|\mathbf{t}|^{-n-2 s}$ and using polar coordinates, this yields

$$
\int_{[|\mathbf{t}|>1]}\left|g_{\beta}(\mathbf{y}+\mathbf{t})-g_{\beta}(\mathbf{y})\right|^{2}|\mathbf{t}|^{-n-2 s} d t \leq 4 \int_{[|\mathbf{t}|>1]}|\mathbf{t}|^{-n-2 s} d t<\infty
$$

It follows 39.3.14 is dominated by an expression of the form

$$
C(\mathbf{h}) \int|F(u)(\mathbf{z})|^{2}\left|\mathbf{z}^{\beta}\right|^{2}|\mathbf{z}|^{2 s} d z+C\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2}
$$

and so the sum in 39.3.13 is dominated by

$$
\begin{aligned}
& C(m, \mathbf{h}) \int|F(u)(\mathbf{z})|^{2}|\mathbf{z}|^{2 s} \sum_{|\beta| \leq m}\left|\mathbf{z}^{\beta}\right|^{2} d z+C\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2} \\
\leq & C(m, \mathbf{h}) \int|F(u)(\mathbf{z})|^{2}\left(1+|\mathbf{z}|^{2}\right)^{s}\left(1+|\mathbf{z}|^{2}\right)^{m} d z+C\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{2} \\
\leq & C\|u\|_{H^{m+s}\left(\mathbb{R}^{n}\right)}^{2} .
\end{aligned}
$$

This proves the theorem because the assertion about $\mathbf{h}^{-1}$ is obvious. Just replace $\mathbf{h}$ with $\mathbf{h}^{-1}$ in the above argument.

Next consider the case where $U$ is an open set.
Lemma 39.3.3 Let $\mathbf{h}(U) \subseteq V$ where $U$ and $V$ are open subsets of $\mathbb{R}^{n}$ and suppose that $\mathbf{h}, \mathbf{h}^{-1}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ are both functions in $C^{m, 1}\left(\mathbb{R}^{n}\right)$. Recall this means $D^{\alpha} \mathbf{h}$ and $D^{\alpha} \mathbf{h}^{-1}$ exist and are Lipschitz continuous for all $|\alpha| \leq m$. Then $\mathbf{h}^{*} \in \mathscr{L}\left(H^{m+s}(V), H^{m+s}(U)\right)$.

Proof: Let $u \in H^{m+s}(V)$ and let $v \in H^{m+s}\left(\mathbb{R}^{n}\right)$ such that $\left.v\right|_{V}=u$. Then from the above, $\mathbf{h}^{*} v \in H^{m+s}\left(\mathbb{R}^{n}\right)$ and so $\mathbf{h}^{*} u \in H^{m+s}(U)$ because $\mathbf{h}^{*} u=\left.\mathbf{h}^{*} v\right|_{U}$. Then by Lemma 39.3.2,

$$
\left\|\mathbf{h}^{*} u\right\|_{H^{m+s}(U)} \leq\left\|\mathbf{h}^{*} v\right\|_{H^{m+s}\left(\mathbb{R}^{n}\right)} \leq C\|v\|_{H^{m+s}\left(\mathbb{R}^{n}\right)}
$$

Since this is true for all $v \in H^{m+s}\left(\mathbb{R}^{n}\right)$, it follows that

$$
\left\|\mathbf{h}^{*} u\right\|_{H^{m+s}(U)} \leq C\|u\|_{H^{m+s}(V)} .
$$

With harder work, you don't need to have $\mathbf{h}, \mathbf{h}^{-1}$ defined on all of $\mathbb{R}^{n}$ but I don't feel like including the details so this lemma will suffice.

Another interesting application of the intrinsic norm is the following.
Lemma 39.3.4 Let $\phi \in C^{m, 1}\left(\mathbb{R}^{n}\right)$ and suppose $\operatorname{spt}(\phi)$ is compact. Then there exists a constant, $C_{\phi}$ such that whenever $u \in H^{m+s}\left(\mathbb{R}^{n}\right)$,

$$
\|\phi u\|_{H^{m+s}\left(\mathbb{R}^{n}\right)} \leq C_{\phi}\|u\|_{H^{m+s}\left(\mathbb{R}^{n}\right)}
$$

Proof: It is a routine exercise in the product rule to verify that

$$
\|\phi u\|_{H^{m}\left(\mathbb{R}^{n}\right)} \leq C_{\phi}\|u\|_{H^{m}\left(\mathbb{R}^{n}\right)}
$$

It only remains to consider the term involving the integral. A typical term is

$$
\iint\left|D^{\alpha} \phi u(\mathbf{x})-D^{\alpha} \phi u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y
$$

This is a finite sum of terms of the form

$$
\iint\left|D^{\gamma} \phi(\mathbf{x}) D^{\beta} u(\mathbf{x})-D^{\gamma} \phi(\mathbf{y}) D^{\beta} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y
$$

where $|\gamma|$ and $|\beta| \leq m$.

$$
\begin{aligned}
\leq & 2 \iint\left|D^{\gamma} \phi(\mathbf{x})\right|^{2}\left|D^{\beta} u(\mathbf{x})-D^{\beta} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
& +2 \iint\left|D^{\beta} u(\mathbf{y})\right|^{2}\left|D^{\gamma} \phi(\mathbf{x})-D^{\gamma} \phi(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y
\end{aligned}
$$

By 39.3.10 and the Lipschitz continuity of all the derivatives of $\phi$, this is dominated by

$$
\begin{aligned}
& C M(s) \int|F u(\mathbf{z})|^{2}\left|\mathbf{z}^{\beta}\right|^{2}|\mathbf{z}|^{2 s} d z \\
& +K \iint\left|D^{\beta} u(\mathbf{y})\right|^{2}|\mathbf{x}-\mathbf{y}|^{2}|\mathbf{x}-\mathbf{y}|^{-n-2 s} d x d y \\
= & C M(s) \int|F u(\mathbf{z})|^{2}\left|\mathbf{z}^{\beta}\right|^{2}|\mathbf{z}|^{2 s} d z \\
& +K \int\left|D^{\beta} u(\mathbf{y})\right|^{2} \int|\mathbf{t}|^{-n+2(1-s)} d t d y \\
\leq & C(s)\left(\int|F u(\mathbf{z})|^{2}\left|\mathbf{z}^{\beta}\right|^{2}|\mathbf{z}|^{2 s} d z+K \int\left|D^{\beta} u(\mathbf{y})\right|^{2} d y\right) \\
\leq & C(s) \int\left(1+|\mathbf{y}|^{2}\right)^{m+s}|F u(\mathbf{y})|^{2} d y .
\end{aligned}
$$

Since there are only finitely many such terms, this proves the lemma.

Corollary 39.3.5 Let $t=m+s$ for $s \in[0,1)$ and let $U, V$ be open sets. Let $\phi \in C_{c}^{m, 1}(V)$. This means $\operatorname{spt}(\phi) \subseteq V$ and $\phi \in C^{m, 1}\left(\mathbb{R}^{n}\right)$. Then if $u \in H^{t}(U)$ then $u \phi \in H^{t}(U \cap V)$ and $\|u \phi\|_{H^{t}(U \cap V)} \leq C_{\phi}\|u\|_{H^{t}(U)}$.

Proof: Let $\left.v\right|_{U}=u$ a.e. where $v \in H^{t}\left(\mathbb{R}^{n}\right)$. Then by Lemma 39.3.4, $\phi v \in H^{t}\left(\mathbb{R}^{n}\right)$ and $\left.\phi v\right|_{U \cap V}=\phi u$ a.e. Therefore, $\phi u \in H^{t}(U \cap V)$ and

$$
\|\phi u\|_{H^{t}(U \cap V)} \leq\|\phi v\|_{H^{t}\left(\mathbb{R}^{n}\right)} \leq C_{\phi}\|v\|_{H^{t}\left(\mathbb{R}^{n}\right)}
$$

Taking the infimum for all such $v$ whose restrictions equal $u$, this yields

$$
\|\phi u\|_{H^{t}(U \cap V)} \leq C_{\phi}\|u\|_{H^{t}(U)}
$$

This proves the corollary.

### 39.4 Embedding Theorems

The Fourier transform description of Sobolev spaces makes possible fairly easy proofs of various embedding theorems.

Definition 39.4.1 Let $C_{b}^{m}\left(\mathbb{R}^{n}\right)$ denote the functions which are m times continuously differentiable and for which

$$
\sup _{|\alpha| \leq m x \in \mathbb{R}^{n}} \sup \left|D^{\alpha} u(\mathbf{x})\right| \equiv\|u\|_{C_{b}^{m}\left(\mathbb{R}^{n}\right)}<\infty
$$

For $U$ an open set, $C^{m}(\bar{U})$ denotes the functions which are restrictions of $C_{b}^{m}\left(\mathbb{R}^{n}\right)$ to $U$.
It is clear this is a Banach space, the proof being a simple exercise in the use of the fundamental theorem of calculus along with standard results about uniform convergence.

Lemma 39.4.2 Let $u \in \mathfrak{S}$ and let $\frac{n}{2}+m<t$. Then there exists $C$ independent of $u$ such that

$$
\|u\|_{C_{b}^{m}\left(\mathbb{R}^{n}\right)} \leq C\|u\|_{H^{t}\left(\mathbb{R}^{n}\right)}
$$

Proof: Using the fact that the Fourier transform maps $\mathfrak{S}$ to $\mathfrak{S}$ and the definition of the Fourier transform,

$$
\begin{aligned}
\left|D^{\alpha} u(\mathbf{x})\right| & \leq C\left\|F D^{\alpha} u\right\|_{L^{1}\left(\mathbb{R}^{n}\right)} \\
& =C \int\left|\mathbf{x}^{\alpha}\right||F u(\mathbf{x})| d x \\
& \leq C \int\left(1+|\mathbf{x}|^{2}\right)^{|\alpha| / 2}|F u(\mathbf{x})| d x \\
& \leq C \int\left(1+|\mathbf{x}|^{2}\right)^{m / 2}\left(1+|\mathbf{x}|^{2}\right)^{-t / 2}\left(1+|\mathbf{x}|^{2}\right)^{t / 2}|F u(\mathbf{x})| d x \\
& \leq C\left(\int\left(1+|\mathbf{x}|^{2}\right)^{m-t} d x\right)^{1 / 2}\left(\int\left(1+|\mathbf{x}|^{2}\right)^{t}|F u(\mathbf{x})|^{t}\right)^{1 / 2} \\
& \leq C\|u\|_{H^{t}\left(\mathbb{R}^{n}\right)}
\end{aligned}
$$

because for the given values of $t$ and $m$ the first integral is finite. This follows from a use of polar coordinates. Taking sup over all $\mathbf{x} \in \mathbb{R}^{n}$ and $|\alpha| \leq m$, this proves the lemma.

Corollary 39.4.3 Let $u \in H^{t}\left(\mathbb{R}^{n}\right)$ where $t>m+\frac{n}{2}$. Then $u$ is a.e. equal to a function of $C_{b}^{m}\left(\mathbb{R}^{n}\right)$ still denoted by $u$. Furthermore, there exists a constant, $C$ independent of $u$ such that

$$
\|u\|_{C_{b}^{m}\left(\mathbb{R}^{n}\right)} \leq C\|u\|_{H^{t}\left(\mathbb{R}^{n}\right)}
$$

Proof: This follows from the above lemma. Let $\left\{u_{k}\right\}$ be a sequence of functions of $\mathfrak{S}$ which converges to $u$ in $H^{t}$ and a.e. Then by the inequality of the above lemma, this sequence is also Cauchy in $C_{b}^{m}\left(\mathbb{R}^{n}\right)$ and taking the limit,

$$
\|u\|_{C_{b}^{m}\left(\mathbb{R}^{n}\right)}=\lim _{k \rightarrow \infty}\left\|u_{k}\right\|_{C_{b}^{m}\left(\mathbb{R}^{n}\right)} \leq C \lim _{k \rightarrow \infty}\left\|u_{k}\right\|_{H^{t}\left(\mathbb{R}^{n}\right)}=C\|u\|_{H^{t}\left(\mathbb{R}^{n}\right)}
$$

What about open sets, $U$ ?
Corollary 39.4.4 Let $t>m+\frac{n}{2}$ and let $U$ be an open set with $u \in H^{t}(U)$. Then $u$ is a.e. equal to a function of $C^{m}(\bar{U})$ still denoted by $u$. Furthermore, there exists a constant, $C$ independent of $u$ such that

$$
\|u\|_{C^{m}(\bar{U})} \leq C\|u\|_{H^{t}(U)}
$$

Proof: Let $u \in H^{t}(U)$ and let $v \in H^{t}\left(\mathbb{R}^{n}\right)$ such that $\left.v\right|_{U}=u$. Then

$$
\|u\|_{C^{m}(\bar{U})} \leq\|v\|_{C_{b}^{m}\left(\mathbb{R}^{n}\right)} \leq C\|v\|_{H^{t}\left(\mathbb{R}^{n}\right)}
$$

Now taking the inf for all such $v$ yields

$$
\|u\|_{C^{m}(\bar{U})} \leq C\|u\|_{H^{t}(U)}
$$

### 39.5 The Trace On The Boundary Of A Half Space

It is important to consider the restriction of functions in a Sobolev space onto a smaller dimensional set such as the boundary of an open set.

Definition 39.5.1 For $u \in \mathfrak{S}$, define $\gamma и$ a function defined on $\mathbb{R}^{n-1}$ by $\gamma u\left(\mathbf{x}^{\prime}\right) \equiv u\left(\mathbf{x}^{\prime}, 0\right)$ where $\mathbf{x}^{\prime} \in \mathbb{R}^{n-1}$ is defined by $\mathbf{x}=\left(\mathbf{x}^{\prime}, x_{n}\right)$.

The following elementary lemma featuring trig. substitutions is the basis for the proof of some of the arguments which follow.

Lemma 39.5.2 Consider the integral,

$$
\int_{\mathbb{R}}\left(a^{2}+x^{2}\right)^{-t} d x
$$

for $a>0$ and $t>1 / 2$. Then this integral is no more than $C_{t} a^{-2 t+1}$ where $C_{t}$ is some constant which depends on $t$.

Proof: If $t>1 / 2$ the integrand is in $L^{1}(\mathbb{R})$. This is easily seen because it is of the form $\frac{1}{\left(a^{2}+x^{2}\right)^{t}}$. Now change the variable letting $x=a u$ and the result is obtained.

Lemma 39.5.3 Let $u \in \mathfrak{S}$. Then there exists a constant, $C_{n}$, depending on $n$ but independent of $u \in \mathfrak{S}$ such that

$$
F \gamma u\left(\mathbf{x}^{\prime}\right)=C_{n} \int_{\mathbb{R}} F u\left(\mathbf{x}^{\prime}, x_{n}\right) d x_{n}
$$

Proof: Using the dominated convergence theorem,

$$
\begin{aligned}
& \int_{\mathbb{R}} F u\left(\mathbf{x}^{\prime}, x_{n}\right) d x_{n} \equiv \lim _{\varepsilon \rightarrow 0} \int_{\mathbb{R}} e^{-\left(\varepsilon x_{n}\right)^{2}} F u\left(\mathbf{x}^{\prime}, x_{n}\right) d x_{n} \\
\equiv & \lim _{\varepsilon \rightarrow 0} \int_{\mathbb{R}} e^{-\left(\varepsilon x_{n}\right)^{2}}\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} e^{-i\left(\mathbf{x}^{\prime} \cdot \mathbf{y}^{\prime}+x_{n} y_{n}\right)} u\left(\mathbf{y}^{\prime}, y_{n}\right) d y^{\prime} d y_{n} d x_{n} \\
= & \lim _{\varepsilon \rightarrow 0}\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} u\left(\mathbf{y}^{\prime}, y_{n}\right) e^{-i \mathbf{x}^{\prime} \cdot \mathbf{y}^{\prime}} \int_{\mathbb{R}} e^{-\left(\varepsilon x_{n}\right)^{2}} e^{-i x_{n} y_{n}} d x_{n} d y^{\prime} d y_{n} .
\end{aligned}
$$

Now $-\left(\varepsilon x_{n}\right)^{2}-i x_{n} y_{n}=-\varepsilon^{2}\left(x_{n}+\frac{i y_{n}}{2}\right)^{2}-\varepsilon^{2} \frac{y_{n}^{2}}{4}$ and so the above reduces to

$$
\begin{aligned}
& \lim _{\varepsilon \rightarrow 0}\left(\frac{1}{2 \pi}\right)^{n / 2} \int_{\mathbb{R}^{n}} u\left(\mathbf{y}^{\prime}, y_{n}\right) e^{-i \mathbf{x}^{\prime} \cdot \mathbf{y}^{\prime}} \int_{\mathbb{R}} e^{-\varepsilon^{2}\left(x_{n}+\frac{i y_{n}}{2}\right)^{2}-\varepsilon^{2} \frac{y_{n}^{2}}{4}} d x_{n} d y^{\prime} d y_{n} \\
= & \lim _{\varepsilon \rightarrow 0} K_{n} \int_{\mathbb{R}^{n}} u\left(\mathbf{y}^{\prime}, y_{n}\right) e^{-i \mathbf{x}^{\prime} \cdot \mathbf{y}^{\prime}} e^{-\varepsilon^{2} \frac{y_{n}^{2}}{4}} \int_{\mathbb{R}} e^{-\varepsilon^{2}\left(x_{n}+\frac{i y_{n}}{2}\right)^{2}} d x_{n} d y^{\prime} d y_{n} \\
= & \lim _{\varepsilon \rightarrow 0} K_{n} \int_{\mathbb{R}^{n}} u\left(\mathbf{y}^{\prime}, y_{n}\right) e^{-i \mathbf{x}^{\prime} \cdot y^{\prime}} e^{-\varepsilon^{2} \frac{y_{n}^{2}}{4}} \frac{1}{\varepsilon} d y^{\prime} d y_{n}
\end{aligned}
$$

which is an expression of the form

$$
\begin{aligned}
\lim _{\varepsilon \rightarrow 0} K_{n} \int_{\mathbb{R}} \frac{1}{\varepsilon} e^{-\varepsilon^{2} \frac{y_{n}^{2}}{4}} \int_{\mathbb{R}^{n-1}} u\left(\mathbf{y}^{\prime}, y_{n}\right) e^{-i \mathbf{x}^{\prime} \cdot \mathbf{y}^{\prime}} d y^{\prime} d y_{n} & =K_{n} \int_{\mathbb{R}^{n}} u\left(\mathbf{y}^{\prime}, 0\right) e^{-i \mathbf{x}^{\prime} \cdot \mathbf{y}^{\prime}} d y^{\prime} \\
& =K_{n} F \gamma u\left(\mathbf{x}^{\prime}\right)
\end{aligned}
$$

and this proves the lemma with $C_{n} \equiv K_{n}^{-1}$.
Earlier $H^{t}\left(\mathbb{R}^{n}\right)$ was defined and then for $U$ an open subset of $\mathbb{R}^{n}, H^{t}(U)$ was defined to be the space of restrictions of functions of $H^{t}\left(\mathbb{R}^{n}\right)$ to $U$ and a norm was given which made $H^{t}(U)$ into a Banach space. The next task is to consider $\mathbb{R}^{n-1} \times\{0\}$, a smaller dimensional subspace of $\mathbb{R}^{n}$ and examine the functions defined on this set, denoted by $\mathbb{R}^{n-1}$ for short which are restrictions of functions in $H^{t}\left(\mathbb{R}^{n}\right)$. You note this is somewhat different because heuristically, the dimension of the domain of the function is changing. An open set in $\mathbb{R}^{n}$ is considered an $n$ dimensional thing but $\mathbb{R}^{n-1}$ is only $n-1$ dimensional. I realize this is vague because the standard definition of dimension requires a vector space and an open set is not a vector space. However, think in terms of fatness. An open set is fat in $n$ directions whereas $\mathbb{R}^{n-1}$ is only fat in $n-1$ directions. Therefore, something interesting is likely to happen.

Let $\mathfrak{S}$ denote the Schwartz class of functions on $\mathbb{R}^{n}$ and $\mathfrak{S}^{\prime}$ the Schwartz class of functions on $\mathbb{R}^{n-1}$. Also, $\mathbf{y}^{\prime} \in \mathbb{R}^{n-1}$ while $\mathbf{y} \in \mathbb{R}^{n}$. Let $u \in \mathfrak{S}$. Then from Lemma 39.5.3
and $s>0$,

$$
\begin{gathered}
\int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{s}\left|F \gamma u\left(\mathbf{y}^{\prime}\right)\right|^{2} d y^{\prime} \\
=C_{n} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{s}\left|\int_{\mathbb{R}} F u\left(\mathbf{y}^{\prime}, y_{n}\right) d y_{n}\right|^{2} d y^{\prime} \\
=C_{n} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{s}\left|\int_{\mathbb{R}} F u\left(\mathbf{y}^{\prime}, y_{n}\right)\left(1+|\mathbf{y}|^{2}\right)^{t / 2}\left(1+|\mathbf{y}|^{2}\right)^{-t / 2} d y_{n}\right|^{2} d y^{\prime}
\end{gathered}
$$

Then by the Cauchy Schwarz inequality,

$$
\begin{equation*}
\leq C_{n} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{s} \int_{\mathbb{R}}\left|F u\left(\mathbf{y}^{\prime}, y_{n}\right)\right|^{2}\left(1+|\mathbf{y}|^{2}\right)^{t} d y_{n} \int_{\mathbb{R}}\left(1+|\mathbf{y}|^{2}\right)^{-t} d y_{n} d y^{\prime} \tag{39.5.17}
\end{equation*}
$$

Consider

$$
\int_{\mathbb{R}}\left(1+|\mathbf{y}|^{2}\right)^{-t} d y_{n}=\int_{\mathbb{R}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}+y_{n}^{2}\right)^{-t} d y_{n}
$$

by Lemma 39.5.2 and taking $a=\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{1 / 2}$, this equals

$$
C_{t}\left(\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{1 / 2}\right)^{-2 t+1}=C_{t}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{(-2 t+1) / 2}
$$

Now using this in 39.5.17,

$$
\begin{aligned}
& \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{s}\left|F \gamma u\left(\mathbf{y}^{\prime}\right)\right|^{2} d y^{\prime} \\
\leq & C_{n, t} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{s} \int_{\mathbb{R}}\left|F u\left(\mathbf{y}^{\prime}, y_{n}\right)\right|^{2}\left(1+|\mathbf{y}|^{2}\right)^{t} d y_{n} \\
& \left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{(-2 t+1) / 2} d y^{\prime} \\
= & C_{n, t} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{s+(-2 t+1) / 2} \int_{\mathbb{R}}\left|F u\left(\mathbf{y}^{\prime}, y_{n}\right)\right|^{2}\left(1+|\mathbf{y}|^{2}\right)^{t} d y_{n} d y^{\prime} .
\end{aligned}
$$

What is the correct choice of $t$ so that the above reduces to $\|u\|_{H^{t}\left(\mathbb{R}^{n}\right)}^{2}$ ? It is clearly the one for which

$$
s+(-2 t+1) / 2=0
$$

which occurs when $t=s+\frac{1}{2}$. Then for this choice of $t$, the following inequality is obtained for any $u \in \mathfrak{S}$.

$$
\begin{equation*}
\|\gamma u\|_{H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right)} \leq C_{n, t}\|u\|_{H^{t}\left(\mathbb{R}^{n}\right)} \tag{39.5.18}
\end{equation*}
$$

This has proved part of the following theorem.
Theorem 39.5.4 For each $t>1 / 2$ there exists a unique mapping

$$
\gamma \in \mathscr{L}\left(H^{t}\left(\mathbb{R}^{n}\right), H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right)\right)
$$

which has the property that for $u \in \mathfrak{S}, \gamma u\left(\mathbf{x}^{\prime}\right)=u\left(\mathbf{x}^{\prime}, 0\right)$. In addition to this, $\gamma$ is onto. In fact, there exists a continuous map, $\zeta \in \mathscr{L}\left(H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right), H^{t}\left(\mathbb{R}^{n}\right)\right)$ such that $\gamma \circ \zeta=\mathrm{id}$.

Proof: It only remains to verify that $\gamma$ is onto and that the continuous map, $\zeta$ exists. Now define

$$
\phi(\mathbf{y}) \equiv \phi\left(\mathbf{y}^{\prime}, y_{n}\right) \equiv \frac{\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{t-1 / 2}}{\left(1+|\mathbf{y}|^{2}\right)^{t}}
$$

Then for $u \in \mathfrak{S}^{\prime}$, let

$$
\begin{gather*}
\zeta u(\mathbf{x}) \equiv C F^{-1}(\phi F u)(\mathbf{x})= \\
C \int_{\mathbb{R}^{n}} e^{i \mathbf{y} \cdot \mathbf{x}} \frac{\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{t-1 / 2}}{\left(1+|\mathbf{y}|^{2}\right)^{t}} F u\left(\mathbf{y}^{\prime}\right) d y \tag{39.5.19}
\end{gather*}
$$

Here the inside Fourier transform is taken with respect to $\mathbb{R}^{n-1}$ because $u$ is only defined on $\mathbb{R}^{n-1}$ and $C$ will be chosen in such a way that $\gamma \circ \zeta=\mathrm{id}$. First the existence of $C$ such that $\gamma \circ \zeta=$ id will be shown. Since $u \in \mathfrak{S}^{\prime}$ it follows

$$
\mathbf{y} \rightarrow \frac{\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{t-1 / 2}}{\left(1+|\mathbf{y}|^{2}\right)^{t}} F u\left(\mathbf{y}^{\prime}\right)
$$

is in $\mathfrak{S}$. Hence the inverse Fourier transform of this function is also in $\mathfrak{S}$ and so for $u \in \mathfrak{S}^{\prime}$, it follows $\zeta u \in \mathfrak{S}$. Therefore, to check $\gamma \circ \zeta=$ id it suffices to plug in $x_{n}=0$. From Lemma 39.5.2 this yields

$$
\begin{gathered}
\gamma(\zeta u)\left(\mathbf{x}^{\prime}, 0\right) \\
=C \int_{\mathbb{R}^{n}} e^{i \mathbf{y}^{\prime} \cdot \mathbf{x}^{\prime}} \frac{\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{t-1 / 2}}{\left(1+|\mathbf{y}|^{2}\right)^{t}} F u\left(\mathbf{y}^{\prime}\right) d y \\
=C \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{t-1 / 2} e^{i \mathbf{y}^{\prime} \cdot \mathbf{x}^{\prime}} F u\left(\mathbf{y}^{\prime}\right) \int_{\mathbb{R}} \frac{1}{\left(1+|\mathbf{y}|^{2}\right)^{t}} d y_{n} d y^{\prime} \\
=C C_{t} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{t-1 / 2} e^{i \mathbf{y}^{\prime} \cdot \mathbf{x}^{\prime}} F u\left(\mathbf{y}^{\prime}\right)\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{\frac{-2 t+1}{2}} d y^{\prime} \\
=C C_{t} \int_{\mathbb{R}^{n-1}} e^{i \mathbf{y}^{\prime} \cdot \mathbf{x}^{\prime}} F u\left(\mathbf{y}^{\prime}\right) d y^{\prime}=C C_{t}(2 \pi)^{n / 2} F^{-1}(F u)\left(\mathbf{x}^{\prime}\right)
\end{gathered}
$$

and so the correct value of $C$ is $\left(C_{t}(2 \pi)^{n / 2}\right)^{-1}$ to obtain $\gamma \circ \zeta=\mathrm{id}$. It only remains to verify that $\zeta$ is continuous. From 39.5.19, and Lemma 39.5.2,

$$
\begin{aligned}
& \|\zeta u\|_{H^{t}\left(\mathbb{R}^{n}\right)}^{2} \\
= & \int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{t}|F \zeta u(\mathbf{x})|^{2} d x \\
= & C^{2} \int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{t}\left|F\left(F^{-1}(\phi F u)(\mathbf{x})\right)\right|^{2} d x
\end{aligned}
$$

$$
\begin{gathered}
=C^{2} \int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{t}\left|\phi(\mathbf{x}) F u\left(\mathbf{x}^{\prime}\right)\right|^{2} d x \\
=C^{2} \int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{t}\left|\frac{\left(1+\left|\mathbf{x}^{\prime}\right|^{2}\right)^{t-1 / 2}}{\left(1+\mid \mathbf{x}^{2}\right)^{t}} F u\left(\mathbf{x}^{\prime}\right)\right|^{2} d x \\
=C^{2} \int_{\mathbb{R}^{n}}\left(1+|\mathbf{x}|^{2}\right)^{-t}\left|\left(1+\left|\mathbf{x}^{\prime}\right|^{2}\right)^{t-1 / 2} F u\left(\mathbf{x}^{\prime}\right)\right|^{2} d x \\
=C^{2} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{x}^{\prime}\right|^{2}\right)^{2 t-1}\left|F u\left(\mathbf{x}^{\prime}\right)\right|^{2} \int_{\mathbb{R}}\left(1+|\mathbf{x}|^{2}\right)^{-t} d x_{n} d x^{\prime} \\
=C^{2} C_{t} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{x}^{\prime}\right|^{2}\right)^{2 t-1}\left|F u\left(\mathbf{x}^{\prime}\right)\right|^{2}\left(1+\left|\mathbf{y}^{\prime}\right|^{2}\right)^{\frac{-2 t+1}{2}} d x^{\prime} \\
=C^{2} C_{t} \int_{\mathbb{R}^{n-1}}\left(1+\left|\mathbf{x}^{\prime}\right|^{2}\right)^{t-1 / 2}\left|F u\left(\mathbf{x}^{\prime}\right)\right|^{2} d x^{\prime}=\left.C^{2} C_{t}| | u\right|_{H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right)} ^{2} .
\end{gathered}
$$

This proves the theorem because $\mathfrak{S}$ is dense in $\mathbb{R}^{n}$.
Actually, the assertion that $\gamma u\left(\mathbf{x}^{\prime}\right)=u\left(\mathbf{x}^{\prime}, 0\right)$ holds for more functions, $u$ than just $u \in$ $\mathfrak{S}$. I will make no effort to obtain the most general description of such functions but the following is a useful lemma which will be needed when the trace on the boundary of an open set is considered.

Lemma 39.5.5 Suppose $u$ is continuous and $u \in H^{1}\left(\mathbb{R}^{n}\right)$. Then there exists a set of $m_{1}$ measure zero, $N$ such that if $x_{n} \notin N$, then for every $\phi \in L^{2}\left(\mathbb{R}^{n-1}\right)$

$$
(\gamma u, \phi)_{H}+\int_{0}^{x_{n}}\left(u_{, n}(\cdot, t), \phi\right)_{H} d t=\left(u\left(\cdot, x_{n}\right), \phi\right)_{H}
$$

where here

$$
(f, g)_{H} \equiv \int_{\mathbb{R}^{n-1}} f \bar{g} d x^{\prime}
$$

just the inner product in $L^{2}\left(\mathbb{R}^{n-1}\right)$. Furthermore,

$$
u(\cdot, 0)=\gamma u \text { a.e. } \mathbf{x}^{\prime}
$$

Proof: Let $\left\{u_{k}\right\}$ be a sequence of functions from $\mathfrak{S}$ which converges to $u$ in $H^{1}\left(\mathbb{R}^{n}\right)$ and let $\left\{\phi_{k}\right\}$ denote a countable dense subset of $L^{2}\left(\mathbb{R}^{n-1}\right)$. Then

$$
\begin{equation*}
\left(\gamma u_{k}, \phi_{j}\right)_{H}+\int_{0}^{x_{n}}\left(u_{k, n}(\cdot, t), \phi_{j}\right)_{H} d t=\left(u_{k}\left(\cdot, x_{n}\right), \phi_{j}\right)_{H} \tag{39.5.20}
\end{equation*}
$$

Now

$$
\begin{aligned}
& \left(\int_{0}^{\infty}\left|\left(u_{k}\left(\cdot, x_{n}\right), \phi_{j}\right)_{H}-\left(u\left(\cdot, x_{n}\right), \phi_{j}\right)_{H}\right|^{2} d x_{n}\right)^{1 / 2} \\
= & \left(\int_{0}^{\infty}\left|\left(u_{k}\left(\cdot, x_{n}\right)-u\left(\cdot, x_{n}\right), \phi_{j}\right)_{H}\right|^{2} d x_{n}\right)^{1 / 2} \\
\leq & \left(\int_{0}^{\infty}\left|u_{k}\left(\cdot, x_{n}\right)-u\left(\cdot, x_{n}\right)\right|_{H}^{2}\left|\phi_{j}\right|_{H}^{2} d x_{n}\right)^{1 / 2} \\
= & \left|\phi_{j}\right|_{H}^{2}\left(\int_{0}^{\infty}\left|u_{k}\left(\cdot, x_{n}\right)-u\left(\cdot, x_{n}\right)\right|_{H}^{2} d x_{n}\right)^{1 / 2} \\
= & \left|\phi_{j}\right|_{H}^{2}\left(\int_{0}^{\infty} \int_{\mathbb{R}^{n-1}}\left|u_{k}\left(\mathbf{x}^{\prime}, x_{n}\right)-u\left(\mathbf{x}^{\prime}, x_{n}\right)\right|^{2} d x^{\prime} d x_{n}\right)^{1 / 2}
\end{aligned}
$$

which converges to zero. Therefore, there exists a set of measure zero, $N_{j}$ and a subsequence, still denoted by $k$ such that if $x_{n} \notin N_{j}$, then

$$
\left(u_{k}\left(\cdot, x_{n}\right), \phi_{j}\right)_{H} \rightarrow\left(u\left(\cdot, x_{n}\right), \phi_{j}\right)_{H} .
$$

Now by Theorem 39.5.4, $\gamma u_{k} \rightarrow \gamma u$ in $H=L^{2}\left(\mathbb{R}^{n-1}\right)$. It only remains to consider the term of 39.5.20 which involves an integral.

$$
\begin{aligned}
& \left|\int_{0}^{x_{n}}\left(u_{k, n}(\cdot, t), \phi_{j}\right)_{H} d t-\int_{0}^{x_{n}}\left(u_{, n}(\cdot, t), \phi_{j}\right)_{H} d t\right| \\
\leq & \int_{0}^{x_{n}}\left|\left(u_{k, n}(\cdot, t)-u_{, n}(\cdot, t), \phi_{j}\right)_{H}\right| d t \\
\leq & \int_{0}^{x_{n}}\left|u_{k, n}(\cdot, t)-u_{, n}(\cdot, t)\right|_{H}\left|\phi_{j}\right|_{H} d t \\
\leq & \left(\int_{0}^{x_{n}}\left|u_{k, n}(\cdot, t)-u_{, n}(\cdot, t)\right|_{H}^{2} d t\right)^{1 / 2}\left(\int_{0}^{x_{n}}\left|\phi_{j}\right|_{H}^{2} d t\right)^{1 / 2} \\
= & x_{n}^{1 / 2}\left|\phi_{j}\right|_{H}\left(\int_{0}^{x_{n}} \int_{\mathbb{R}^{n-1}}\left|u_{k, n}\left(\mathbf{x}^{\prime}, t\right)-u_{, n}\left(\mathbf{x}^{\prime}, t\right)\right|^{2} d x^{\prime}\right)^{1 / 2} d t
\end{aligned}
$$

and this converges to zero as $k \rightarrow \infty$. Therefore, using a diagonal sequence argument, there exists a subsequence, still denoted by $k$ and a set of measure zero, $N \equiv \cup_{j=1}^{\infty} N_{j}$ such that for $\mathbf{x}^{\prime} \notin N$, you can pass to the limit in 39.5.20 and obtain that for all $\phi_{j}$,

$$
\left(\gamma u, \phi_{j}\right)_{H}+\int_{0}^{x_{n}}\left(u_{, n}(\cdot, t), \phi_{j}\right)_{H} d t=\left(u\left(\cdot, x_{n}\right), \phi_{j}\right)_{H}
$$

By density of $\left\{\phi_{j}\right\}$, this equality holds for all $\phi \in L^{2}\left(\mathbb{R}^{n-1}\right)$. In particular, the equality holds for every $\phi \in C_{c}\left(\mathbb{R}^{n-1}\right)$. Since $u$ is uniformly continuous on the compact set, $\operatorname{spt}(\phi) \times[0,1]$, there exists a sequence, $\left(x_{n}\right)_{k} \rightarrow 0$ such that the above equality holds for
$x_{n}$ replaced with $\left(x_{n}\right)_{k}$ and $\phi$ in place of $\phi_{j}$. Now taking $k \rightarrow \infty$, this uniform continuity implies

$$
(\gamma u, \phi)_{H}=(u(\cdot, 0), \phi)_{H}
$$

This implies since $C_{c}\left(\mathbb{R}^{n-1}\right)$ is dense in $L^{2}\left(\mathbb{R}^{n-1}\right)$ that $\gamma u=u(\cdot, 0)$ a.e. and this proves the lemma.

Lemma 39.5.6 Suppose $U$ is an open subset of $\mathbb{R}^{n}$ of the form

$$
U \equiv\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U^{\prime} \text { and } 0<u_{n}<\phi\left(\mathbf{u}^{\prime}\right)\right\}
$$

where $U^{\prime}$ is an open subset of $\mathbb{R}^{n-1}$ and $\phi\left(\mathbf{u}^{\prime}\right)$ is a positive function such that $\phi\left(\mathbf{u}^{\prime}\right) \leq \infty$ and

$$
\inf \left\{\phi\left(\mathbf{u}^{\prime}\right): \mathbf{u}^{\prime} \in U^{\prime}\right\}=\delta>0
$$

Suppose $v \in H^{t}\left(\mathbb{R}^{n}\right)$ such that $v=0$ a.e. on $U$. Then $\gamma v=0 m_{n-1}$ a.e. point of $U^{\prime}$. Also, if $v \in H^{t}\left(\mathbb{R}^{n}\right)$ and $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$, then $\gamma v \gamma \phi=\gamma(\phi v)$.

Proof: First consider the second claim. Let $v \in H^{t}\left(\mathbb{R}^{n}\right)$ and let $v_{k} \rightarrow v$ in $H^{t}\left(\mathbb{R}^{n}\right)$ where $v_{k} \in \mathfrak{S}$. Then from Lemma 39.3.4 and Theorem 39.5.4

$$
\|\gamma(\phi v)-\gamma \phi \gamma v\|_{H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right)}=\lim _{k \rightarrow \infty}\left\|\gamma\left(\phi v_{k}\right)-\gamma \phi \gamma v_{k}\right\|_{H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right)}=0
$$

because each term in the sequence equals zero due to the observation that for $v_{k} \in \mathfrak{S}$ and $\phi \in C_{c}^{\infty}(U), \gamma\left(\phi v_{k}\right)=\gamma v_{k} \gamma \phi$.

Now suppose $v=0$ a.e. on $U$. Define for $0<r<\delta, v_{r}(\mathbf{x}) \equiv v\left(\mathbf{x}^{\prime}, x_{n}+r\right)$.
Claim: If $u \in H^{t}\left(\mathbb{R}^{n}\right)$, then

$$
\lim _{r \rightarrow 0}\left\|v_{r}-v\right\|_{H^{t}\left(\mathbb{R}^{n}\right)}=0
$$

Proof of claim: First of all, let $v \in \mathfrak{S}$. Then $v \in H^{m}\left(\mathbb{R}^{n}\right)$ for all $m$ and so by Lemma 39.2.5,

$$
\left\|v_{r}-v\right\|_{H^{t}\left(\mathbb{R}^{n}\right)} \leq\left\|v_{r}-v\right\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{\theta}\left\|v_{r}-v\right\|_{H^{m+1}\left(\mathbb{R}^{n}\right)}^{1-\theta}
$$

where $t \in[m, m+1]$. It follows from continuity of translation in $L^{p}\left(\mathbb{R}^{n}\right)$ that

$$
\lim _{r \rightarrow 0}\left\|v_{r}-v\right\|_{H^{m}\left(\mathbb{R}^{n}\right)}^{\theta}\left\|v_{r}-v\right\|_{H^{m+1}\left(\mathbb{R}^{n}\right)}^{1-\theta}=0
$$

and so the claim is proved if $v \in \mathfrak{S}$. Now suppose $u \in H^{t}\left(\mathbb{R}^{n}\right)$ is arbitrary. By density of $\mathfrak{S}$ in $H^{t}\left(\mathbb{R}^{n}\right)$, there exists $v \in \mathfrak{S}$ such that

$$
\|u-v\|_{H^{t}\left(\mathbb{R}^{n}\right)}<\varepsilon / 3 .
$$

Therefore,

$$
\begin{aligned}
\left\|u_{r}-u\right\|_{H^{t}\left(\mathbb{R}^{n}\right)} & \leq\left\|u_{r}-v_{r}\right\|_{H^{t}\left(\mathbb{R}^{n}\right)}+\left\|v_{r}-v\right\|_{H^{t}\left(\mathbb{R}^{n}\right)}+\|v-u\|_{H^{t}\left(\mathbb{R}^{n}\right)} \\
& =2 \varepsilon / 3+\left\|v_{r}-v\right\|_{H^{t}\left(\mathbb{R}^{n}\right)}
\end{aligned}
$$

Now using what was just shown, it follows that for $r$ small enough, $\left\|u_{r}-u\right\|_{H^{t}\left(\mathbb{R}^{n}\right)}<\varepsilon$ and this proves the claim.

Now suppose $v \in H^{t}\left(\mathbb{R}^{n}\right)$. By the claim,

$$
\left\|v_{r}-v\right\|_{H^{t}\left(\mathbb{R}^{n}\right)} \rightarrow 0
$$

and so by continuity of $\gamma$,

$$
\begin{equation*}
\gamma v_{r} \rightarrow \gamma v \text { in } H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right) \tag{39.5.21}
\end{equation*}
$$

Note $v_{r}=0$ a.e. on

$$
U_{r} \equiv\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U^{\prime} \text { and }-r<u_{n}<\phi\left(\mathbf{u}^{\prime}\right)-r\right\}
$$

Let $\phi \in C_{c}^{\infty}\left(U_{r}\right)$ and consider $\phi v_{r}$. Then it follows $\phi v_{r}=0$ a.e. on $\mathbb{R}^{n}$. Let $w \equiv 0$. Then $w \in \mathfrak{S}$ and so $\gamma w=0=\gamma\left(\phi v_{r}\right)=\gamma \phi \gamma v_{r}$ in $H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right)$. It follows that for $m_{n-1}$ a.e. $\mathbf{x}^{\prime} \in[\phi \neq 0] \cap \mathbb{R}^{n-1}, \gamma v_{r}\left(\mathbf{x}^{\prime}\right)=0$. Now let $U^{\prime}=\cup_{k=1}^{\infty} K_{k}$ where the $K_{k}$ are compact sets such that $K_{k} \subseteq K_{k+1}$ and let $\phi_{k} \in C_{c}^{\infty}(U)$ such that $\phi_{k}$ has values in $[0,1]$ and $\phi_{k}\left(\mathbf{x}^{\prime}\right)=1$ if $\mathbf{x}^{\prime} \in K_{k}$. Then from what was just shown, $\gamma v_{r}=0$ for a.e. point of $K_{k}$. Therefore, $\gamma v_{r}=0$ for $m_{n-1}$ a.e. point in $U^{\prime}$. Therefore, since each $\gamma v_{r}=0$, it follows from 39.5.21 that $\gamma \nu=0$ also. This proves the lemma.

Theorem 39.5.7 Let $t>1 / 2$ and let $U$ be of the form

$$
\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U^{\prime} \text { and } 0<u_{n}<\phi\left(\mathbf{u}^{\prime}\right)\right\}
$$

where $U^{\prime}$ is an open subset of $\mathbb{R}^{n-1}$ and $\phi\left(\mathbf{u}^{\prime}\right)$ is a positive function such that $\phi\left(\mathbf{u}^{\prime}\right) \leq \infty$ and

$$
\inf \left\{\phi\left(\mathbf{u}^{\prime}\right): \mathbf{u}^{\prime} \in U^{\prime}\right\}=\delta>0
$$

Then there exists a unique

$$
\gamma \in \mathscr{L}\left(H^{t}(U), H^{t-1 / 2}\left(U^{\prime}\right)\right)
$$

which has the property that if $u=\left.v\right|_{U}$ where $v$ is continuous and also a function of $H^{1}\left(\mathbb{R}^{n}\right)$, then $\gamma u\left(\mathbf{x}^{\prime}\right)=u\left(\mathbf{x}^{\prime}, 0\right)$ for a.e. $\mathbf{x}^{\prime} \in U^{\prime}$.

Proof: Let $u \in H^{t}(U)$. Then $u=\left.v\right|_{U}$ for some $v \in H^{t}\left(\mathbb{R}^{n}\right)$. Define

$$
\left.\gamma u \equiv \gamma v\right|_{U^{\prime}}
$$

Is this well defined? The answer is yes because if $\left.v_{i}\right|_{U}=u$ a.e., then $\gamma\left(v_{1}-v_{2}\right)=0$ a.e. on $U^{\prime}$ which implies $\gamma \nu_{1}=\gamma \nu_{2}$ a.e. and so the two different versions of $\gamma u$ differ only on a set of measure zero.

If $u=\left.v\right|_{U}$ where $v$ is continuous and also a function of $H^{1}\left(\mathbb{R}^{n}\right)$, then for a.e. $\mathbf{x}^{\prime} \in \mathbb{R}^{n-1}$, it follows from Lemma 39.5.5 on Page 1363 that $\gamma v\left(\mathbf{x}^{\prime}\right)=v\left(\mathbf{x}^{\prime}, 0\right)$. Hence, it follows that for a.e. $\mathbf{x}^{\prime} \in U^{\prime}, \gamma u\left(\mathbf{x}^{\prime}\right) \equiv u\left(\mathbf{x}^{\prime}, 0\right)$.

In particular, $\gamma$ is determined by $\gamma u\left(\mathbf{x}^{\prime}\right)=u\left(\mathbf{x}^{\prime}, 0\right)$ on $\left.\mathfrak{S}\right|_{U}$ and the density of $\left.\mathfrak{S}\right|_{U}$ and continuity of $\gamma$ shows $\gamma$ is unique.

It only remains to show $\gamma$ is continuous. Let $u \in H^{t}(U)$. Thus there exists $v \in H^{t}\left(\mathbb{R}^{n}\right)$ such that $u=\left.v\right|_{U}$. Then

$$
\|\gamma u\|_{H^{t-1 / 2}\left(U^{\prime}\right)} \leq\|\gamma v\|_{H^{t-1 / 2}\left(\mathbb{R}^{n-1}\right)} \leq C\|v\|_{H^{t}\left(\mathbb{R}^{n}\right)}
$$

for $C$ independent of $v$. Then taking the inf for all such $v \in H^{t}\left(\mathbb{R}^{n}\right)$ which are equal to $u$ a.e. on $U$, it follows

$$
\|\gamma u\|_{H^{t-1 / 2}\left(U^{\prime}\right)} \leq C\|v\|_{H^{t}\left(\mathbb{R}^{n}\right)}
$$

and this proves $\gamma$ is continuous.

### 39.6 Sobolev Spaces On Manifolds

### 39.6.1 General Theory

The type of manifold, $\Gamma$ for which Sobolev spaces will be defined on is:
Definition 39.6.1 1. $\Gamma$ is a closed subset of $\mathbb{R}^{p}$ where $p \geq n$.
2. $\Gamma=\cup_{i=1}^{\infty} \Gamma_{i}$ where $\Gamma_{i}=\Gamma \cap W_{i}$ for $W_{i}$ a bounded open set.
3. $\left\{W_{i}\right\}_{i=1}^{\infty}$ is locally finite.
4. There are open bounded sets, $U_{i}$ and functions $\mathbf{h}_{i}: U_{i} \rightarrow \Gamma_{i}$ which are one to one, onto, and in $C^{m, 1}\left(U_{i}\right)$. There exists a constant, $C$, such that $C \geq \operatorname{Lip} \mathbf{h}_{r}$ for all $r$.
5. There exist functions, $\mathbf{g}_{i}: W_{i} \rightarrow U_{i}$ such that $\mathbf{g}_{i}$ is $C^{m, 1}\left(W_{i}\right)$, and $\mathbf{g}_{i} \circ \mathbf{h}_{i}=\mathrm{id}$ on $U_{i}$ while $\mathbf{h}_{i} \circ \mathbf{g}_{i}=\mathrm{id}$ on $\Gamma_{i}$.
This will be referred to as a $C^{m, 1}$ manifold.
Lemma 39.6.2 Let $\mathbf{g}_{i}, \mathbf{h}_{i}, U_{i}, W_{i}$, and $\Gamma_{i}$ be as defined above. Then

$$
\mathbf{g}_{i} \circ \mathbf{h}_{k}: U_{k} \cap \mathbf{h}_{k}^{-1}\left(\Gamma_{i}\right) \rightarrow U_{i} \cap \mathbf{h}_{i}^{-1}\left(\Gamma_{k}\right)
$$

is $C^{m, 1}$. Furthermore, the inverse of this map is $\mathbf{g}_{k} \circ \mathbf{h}_{i}$.
Proof: First it is well to show it does indeed map the given open sets. Let $\mathbf{x} \in U_{k} \cap$ $\mathbf{h}_{k}^{-1}\left(\Gamma_{i}\right)$. Then $\mathbf{h}_{k}(\mathbf{x}) \in \Gamma_{k} \cap \Gamma_{i}$ and so $\mathbf{g}_{i}\left(\mathbf{h}_{k}(\mathbf{x})\right) \in U_{i}$ because $\mathbf{h}_{k}(\mathbf{x}) \in \Gamma_{i}$. Now since $\mathbf{h}_{k}(\mathbf{x}) \in \Gamma_{k}, \mathbf{g}_{i}\left(\mathbf{h}_{k}(\mathbf{x})\right) \in \mathbf{h}_{i}^{-1}\left(\Gamma_{k}\right)$ also and this proves the mappings do what they should in terms of mapping the two open sets. That $\mathbf{g}_{i} \circ \mathbf{h}_{k}$ is $C^{m, 1}$ follows immediately from the chain rule and the assumptions that the functions $\mathbf{g}_{i}$ and $\mathbf{h}_{k}$ are $C^{m, 1}$. The claim about the inverse follows immediately from the definitions of the functions.

Let $\left\{\psi_{i}\right\}_{i=1}^{\infty}$ be a partition of unity subordinate to the open cover $\left\{W_{i}\right\}$ satisfying $\psi_{i} \in$ $C_{c}^{\infty}\left(W_{i}\right)$. Then the following definition provides a norm for $H^{m+s}(\Gamma)$.

Definition 39.6.3 Let $s \in(0,1)$ and $m$ is a nonnegative integer. Also let $\mu$ denote the surface measure for $\Gamma$ defined in the last section. A $\mu$ measurable function, $u$ is in $H^{m+s}(\Gamma)$ if whenever $\left\{W_{i}, \psi_{i}, \Gamma_{i}, U_{i}, \mathbf{h}_{i}, \mathbf{g}_{i}\right\}_{i=1}^{\infty}$ is described above, $\mathbf{h}_{i}^{*}\left(u \psi_{i}\right) \in H^{m+s}\left(U_{i}\right)$ and

$$
\|u\|_{H^{m+s}(\Gamma)} \equiv\left(\sum_{i=1}^{\infty}\left\|\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)\right\|_{H^{m+s}\left(U_{i}\right)}^{2}\right)^{1 / 2}<\infty
$$

Are there functions which are in $H^{m+s}(\Gamma)$ ? The answer is yes. Just take the restriction to $\Gamma$ of any function, $u \in C_{c}^{\infty}\left(\mathbb{R}^{m}\right)$. Then each $\mathbf{h}_{i}^{*}\left(u \psi_{i}\right) \in H^{m+s}\left(U_{i}\right)$ and the sum is finite because $\operatorname{spt} u$ has nonempty intersection with only finitely many $W_{i}$.

It is not at all obvious this norm is well defined. What if $\left\{W_{i}^{\prime}, \psi_{i}^{\prime}, \Gamma_{i}^{\prime}, U_{i}, \mathbf{h}_{i}^{\prime}, \mathbf{g}_{i}^{\prime}\right\}_{i=1}^{\infty}$ is as described above? Would the two norms be equivalent? If they aren't, then this is not a good way to define $H^{m+s}(\Gamma)$ because it would depend on the choice of partition of unity and functions, $\mathbf{h}_{i}$ and choice of the open sets, $U_{i}$. To begin with pick a particular choice for $\left\{W_{i}, \psi_{i}, \Gamma_{i}, U_{i}, \mathbf{h}_{i}, \mathbf{g}_{i}\right\}_{i=1}^{\infty}$.

Lemma 39.6.4 $H^{m+s}(\Gamma)$ as just described, is a Banach space.
Proof: Let $\left\{u_{j}\right\}_{j=1}^{\infty}$ be a Cauchy sequence in $H^{m+s}(\Gamma)$. Then $\left\{\mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)\right\}_{j=1}^{\infty}$ is a Cauchy sequence in $H^{m+s}\left(U_{i}\right)$ for each $i$. Therefore, for each $i$, there exists $w_{i} \in H^{m+s}\left(U_{i}\right)$ such that

$$
\begin{equation*}
\lim _{j \rightarrow \infty} \mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)=w_{i} \text { in } H^{m+s}\left(U_{i}\right) \tag{39.6.22}
\end{equation*}
$$

It is required to show there exists $u \in H^{m+s}(\Gamma)$ such that $w_{i}=\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)$ for each $i$.
Now from Corollary 37.2 .5 it follows easily by approximating with simple functions that for ever nonnegative $\mu$ measurable function, $f$,

$$
\int_{\Gamma} f d \mu=\sum_{r=1}^{\infty} \int_{\mathbf{g}_{r} \Gamma_{r}} \psi_{r} f\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u
$$

Therefore,

$$
\begin{aligned}
\int_{\Gamma}\left|u_{j}-u_{k}\right|^{2} d \mu & =\sum_{r=1}^{\infty} \int_{\mathbf{g}_{r} \Gamma_{r}} \psi_{r}\left|u_{j}-u_{k}\right|^{2}\left(\mathbf{h}_{r}(\mathbf{u})\right) J_{r}(\mathbf{u}) d u \\
& \leq C \sum_{r=1}^{\infty} \int_{\mathbf{g}_{r} \Gamma_{r}} \psi_{r}\left|u_{j}-u_{k}\right|^{2}\left(\mathbf{h}_{r}(\mathbf{u})\right) d u \\
& =C \sum_{r=1}^{\infty}\left\|\mathbf{h}_{r}^{*}\left(\psi_{r}\left|u_{j}-u_{k}\right|\right)\right\|_{0,2, U_{r}}^{2} \\
& \leq C \| u_{j}-u_{k}| |_{H^{m+s}(\Gamma)}
\end{aligned}
$$

and it follows there exists $u \in L^{2}(\Gamma)$ such that

$$
\left\|u_{j}-u\right\|_{0,2, \Gamma} \rightarrow 0
$$

and a subsequence, still denoted by $u_{j}$ such that $u_{j}(\mathbf{x}) \rightarrow u(\mathbf{x})$ for $\mu$ a.e. $\mathbf{x} \in \Gamma$. It is required to show that $u \in H^{m+s}(\Gamma)$ such that $w_{i}=\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)$ for each $i$. First of all, $u$ is measurable because it is the limit of measurable functions. The pointwise convergence just established and the fact that sets of measure zero on $\Gamma_{i}$ correspond to sets of measure zero on $U_{i}$ which was discussed in the claim found in the proof of Theorem 37.2.4 on Page 1303 shows that

$$
\mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)(\mathbf{x}) \rightarrow \mathbf{h}_{i}^{*}\left(u \psi_{i}\right)(\mathbf{x})
$$

a.e. x. Therefore,

$$
\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)=w_{i}
$$

and this shows that $\mathbf{h}_{i}^{*}\left(u \psi_{i}\right) \in H^{m+s}\left(U_{i}\right)$. It remains to verify that $u \in H^{m+s}(\Gamma)$. This follows from Fatou's lemma. From 39.6.22,

$$
\left\|\mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)\right\|_{H^{m+s}\left(U_{i}\right)}^{2} \rightarrow\left\|\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)\right\|_{H^{m+s}\left(U_{i}\right)}^{2}
$$

and so

$$
\begin{aligned}
\sum_{i=1}^{\infty}\left\|\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)\right\|_{H^{m+s}\left(U_{i}\right)}^{2} & \leq \lim \inf _{j \rightarrow \infty} \sum_{i=1}^{\infty}\left\|\mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)\right\|_{H^{m+s}\left(U_{i}\right)}^{2} \\
& =\lim \inf _{j \rightarrow \infty}\left\|u_{j}\right\|_{H^{m+s}(\Gamma)}^{2}<\infty
\end{aligned}
$$

This proves the lemma.
In fact any two such norms are equivalent. This follows from the open mapping theorem. Suppose $\|\cdot\|_{1}$ and $\|\cdot\|_{2}$ are two such norms and consider the norm $\|\cdot\|_{3} \equiv$ $\max \left(\|\cdot\|_{1},\|\cdot\|_{2}\right)$. Then $\left(H^{m+s}(\Gamma),\|\cdot\|_{3}\right)$ is also a Banach space and the identity map from this Banach space to $\left(H^{m+s}(\Gamma),\|\cdot\|_{i}\right)$ for $i=1,2$ is continuous. Therefore, by the open mapping theorem, there exist constants, $C, C^{\prime}$ such that for all $u \in H^{m+s}(\Gamma)$,

$$
\|u\|_{1} \leq\|u\|_{3} \leq C\|u\|_{2} \leq C\|u\|_{3} \leq C C^{\prime}\|u\|_{1}
$$

Therefore,

$$
\|u\|_{1} \leq C\|u\|_{2},\|u\|_{2} \leq C^{\prime}\|u\|_{1} .
$$

This proves the following theorem.
Theorem 39.6.5 Let $\Gamma$ be described above. Defining $H^{t}(\Gamma)$ as in Definition 39.6.3, any two norms like those given in this definition are equivalent.

Suppose $\left(\Gamma, W_{i}, U_{i}, \Gamma_{i}, \mathbf{h}_{i}, \mathbf{g}_{i}\right)$ are as defined above where $\mathbf{h}_{i}, \mathbf{g}_{i}$ are $C^{m, 1}$ functions. Take $W$, an open set in $\mathbb{R}^{p}$ and define $\Gamma^{\prime} \equiv W \cap \Gamma$. Then letting

$$
W_{i}^{\prime} \equiv W \cap W_{i}, \Gamma_{i}^{\prime} \equiv W_{i}^{\prime} \cap \Gamma
$$

and

$$
U_{i}^{\prime} \equiv \mathbf{g}_{i}\left(\Gamma_{i}^{\prime}\right)=\mathbf{h}_{i}^{-1}\left(W_{i}^{\prime} \cap \Gamma\right)
$$

it follows that $U_{i}^{\prime}$ is an open set because $\mathbf{h}_{i}$ is continuous and $\left(\Gamma^{\prime}, W_{i}^{\prime}, U_{i}^{\prime}, \Gamma_{i}^{\prime}, \mathbf{h}_{i}^{\prime}, \mathbf{g}_{i}^{\prime}\right)$ is also a $C^{m, 1}$ manifold if you define $\mathbf{h}_{i}^{\prime}$ to be the restriction of $\mathbf{h}_{i}$ to $U_{i}^{\prime}$ and $\mathbf{g}_{i}^{\prime}$ to be the restriction of $\mathbf{g}_{i}$ to $W_{i}^{\prime}$.

As a case of this, consider a $C^{m, 1}$ manifold, $\Gamma$ where $\left(\Gamma, W_{i}, U_{i}, \Gamma_{i}, \mathbf{h}_{i}, \mathbf{g}_{i}\right)$ are as described in Definition 39.6.1 and the submanifold consisting of $\Gamma_{i}$. The next lemma shows there is a simple way to define a norm on $H^{t}\left(\Gamma_{i}\right)$ which does not depend on dragging in a partition of unity.

Lemma 39.6.6 Suppose $\Gamma$ is a $C^{m, 1}$ manifold and $\left(\Gamma, W_{i}, U_{i}, \Gamma_{i}, \mathbf{h}_{i}, \mathbf{g}_{i}\right)$ are as described in Definition 39.6.1. Then for $t \in[m, m+s)$, it follows that if $u \in H^{t}(\Gamma)$, then $u \in H^{t}\left(\Gamma_{k}\right)$ and the restriction map is continuous. Also an equivalent norm for $H^{t}\left(\Gamma_{k}\right)$ is given by

$$
\left\|\|u\|_{t} \equiv\right\| \mathbf{h}_{k}^{*} u \|_{H^{t}\left(U_{k}\right)} .
$$

Proof: Let $u \in H^{t}(\Gamma)$ and let $\left(\Gamma_{k}, W_{i}^{\prime}, U_{i}^{\prime}, \Gamma_{i}^{\prime}, \mathbf{h}_{i}^{\prime}, \mathbf{g}_{i}^{\prime}\right)$ be the sets and functions which define what is meant by $\Gamma_{k}$ being a $C^{m, 1}$ manifold as described in Definition 39.6.1. Also let $\left(\Gamma, W_{i}, U_{i}, \Gamma_{i}, \mathbf{h}_{i}, \mathbf{g}_{i}\right)$ be pertain to $\Gamma$ in the same way and let $\left\{\phi_{j}\right\}$ be a $C^{\infty}$ partition of unity for the $\left\{W_{j}\right\}$. Since the $\left\{W_{i}^{\prime}\right\}$ are locally finite, only finitely many can intersect $\Gamma_{k}$, say $\left\{W_{1}^{\prime}, \cdots, W_{s}^{\prime}\right\}$. Also only finitely many of the $W_{i}$ can intersect $\Gamma_{k}$, say $\left\{W_{1}, \cdots, W_{q}\right\}$. Then letting $\left\{\psi_{i}^{\prime}\right\}$ be a $C^{\infty}$ partition of unity subordinate to the $\left\{W_{i}^{\prime}\right\}$.

$$
\begin{gathered}
\sum_{i=1}^{\infty}\left\|\mathbf{h}_{i}^{\prime *}\left(u \psi_{i}^{\prime}\right)\right\|_{H^{t}\left(U_{i}^{\prime}\right)}=\sum_{i=1}^{s}\left\|\mathbf{h}_{i}^{\prime *}\left(\sum_{j=1}^{q} \phi_{j} u \psi_{i}^{\prime}\right)\right\|_{H^{t}\left(U_{i}^{\prime}\right)} \\
\leq \sum_{i=1}^{s} \sum_{j=1}^{q}\left\|\mathbf{h}_{i}^{\prime *} \phi_{j} u \psi_{i}^{\prime}\right\|_{H^{t}\left(U_{i}^{\prime}\right)}=\sum_{j=1}^{q} \sum_{i=1}^{s}\left\|\mathbf{h}_{i}^{* *} \phi_{j} u \psi_{i}^{\prime}\right\| \|_{H^{t}\left(U_{i}^{\prime}\right)} \\
=\sum_{j=1}^{q} \sum_{i=1}^{s}\left\|\left(\mathbf{g}_{j} \circ \mathbf{h}_{i}^{\prime}\right)^{*} \mathbf{h}_{j}^{*} \phi_{j} u \psi_{i}^{\prime}\right\|_{H^{t}\left(U_{i}^{\prime}\right)}
\end{gathered}
$$

By Lemma 39.3.3 on page 1356, there exists a single constant, $C$ such that the above is dominated by $C \sum_{j=1}^{q} \sum_{i=1}^{s}\left\|\mathbf{h}_{j}^{*} \phi_{j} u \psi_{i}^{\prime}\right\|_{H^{t}\left(U_{j}\right)}$. Now by Corollary 39.3.5 on Page 1358, this is no larger than

$$
C \sum_{j=1}^{q} \sum_{i=1}^{s} C_{\psi_{i}^{\prime}}\left\|\mathbf{h}_{j}^{*} \phi_{j} u\right\|_{H^{t}\left(U_{j}\right)} \leq C \sum_{j=1}^{q} \sum_{i=1}^{s}\left\|\mathbf{h}_{j}^{*} \phi_{j} u\right\|_{H^{t}\left(U_{j}\right)} \leq C \sum_{j=1}^{q}\left\|\mathbf{h}_{j}^{*} \phi_{j} u\right\|_{H^{t}\left(U_{j}\right)}<\infty
$$

This shows that $u$ restricted to $\Gamma_{k}$ is in $H^{t}\left(\Gamma_{k}\right)$. It also shows that the restriction map of $H^{t}(\Gamma)$ to $H^{t}\left(\Gamma_{k}\right)$ is continuous.

Now consider the norm $\||\cdot|\|_{t}$. For $u \in H^{t}\left(\Gamma_{k}\right)$, let $\left(\Gamma_{k}, W_{i}^{\prime}, U_{i}^{\prime}, \Gamma_{i}^{\prime}, \mathbf{h}_{i}^{\prime}, \mathbf{g}_{i}^{\prime}\right)$ be sets and functions which define an atlas for $\Gamma_{k}$. Since the $\left\{W_{i}^{\prime}\right\}$ are locally finite, only finitely many can have nonempty intersection with $\Gamma_{k}$, say $\left\{W_{1}, \cdots, W_{s}\right\}$. Thus $i \leq s$ for some finite $s$. The problem is to compare $\mid\|\cdot\| \|_{t}$ with $\|\cdot\|_{H^{t}\left(\Gamma_{k}\right)}$. As above, let $\left\{\psi_{i}^{\prime}\right\}$ denote a $C^{\infty}$ partition of unity subordinate to the $\left\{W_{j}^{\prime}\right\}$. Then

$$
\begin{gathered}
\|\mid u\|\left\|_{t} \equiv\right\| \mathbf{h}_{k}^{*} u\left\|_{H^{t}\left(U_{k}\right)}=\right\| \mathbf{h}_{k}^{*} \sum_{j=1}^{s} \psi_{j}^{\prime} u\left\|_{H^{t}\left(U_{k}\right)} \leq \sum_{j=1}^{s}\right\| \mathbf{h}_{k}^{*}\left(\psi_{j}^{\prime} u\right) \|_{H^{t}\left(U_{k}\right)} \\
=\sum_{j=1}^{s}\left\|\left(\mathbf{g}_{j}^{\prime} \circ \mathbf{h}_{k}\right)^{*} \mathbf{h}_{j}^{\prime *}\left(\psi_{j}^{\prime} u\right)\right\|_{H^{t}\left(U_{k}\right)} \leq C \sum_{j=1}^{s}\left\|\mathbf{h}_{j}^{\prime *}\left(\psi_{j}^{\prime} u\right)\right\|_{H^{t}\left(U_{j}^{\prime}\right)}
\end{gathered}
$$

$$
\leq C\left(\sum_{j=1}^{s}\left\|\mathbf{h}_{j}^{* *}\left(\psi_{j}^{\prime} u\right)\right\|_{H^{t}\left(U_{j}^{\prime}\right)}^{2}\right)^{1 / 2}=\|u\|_{H^{t}\left(\Gamma_{k}\right)}
$$

where Lemma 39.3.3 on page 1356 was used in the last step. Now also, from Lemma 39.3.3 on page 1356

$$
\begin{aligned}
& \|u\|_{H^{t}\left(\Gamma_{k}\right)}=\left(\sum_{j=1}^{s}\left\|\mathbf{h}_{j}^{\prime *}\left(\psi_{j}^{\prime} u\right)\right\|_{H^{t}\left(U_{j}^{\prime}\right)}^{2}\right)^{1 / 2}=\left(\sum_{j=1}^{s}\left\|\left(\mathbf{g}_{k} \circ \mathbf{h}_{j}^{\prime}\right)^{*} \mathbf{h}_{k}^{*}\left(\psi_{j}^{\prime} u\right)\right\|_{H^{t}\left(U_{j}^{\prime}\right)}^{2}\right)^{1 / 2} \\
& \leq C\left(\sum_{j=1}^{s}\left\|\mathbf{h}_{k}^{*}\left(\psi_{j}^{\prime} u\right)\right\|_{H^{t}\left(U_{k}\right)}^{2}\right)^{1 / 2} \leq C\left(\sum_{j=1}^{s}\left\|\mathbf{h}_{k}^{*} u\right\|_{H^{t}\left(U_{k}\right)}^{2}\right)^{1 / 2}=C_{S}\left\|\mathbf{h}_{k}^{*} u\right\|_{H^{t}\left(U_{k}\right)}=\|u\| \|_{t} .
\end{aligned}
$$

This proves the lemma.

### 39.6.2 The Trace On The Boundary

Definition 39.6.7 A bounded open subset, $\Omega$, of $\mathbb{R}^{n}$ has a $C^{m, 1}$ boundary if it satisfies the following conditions. For each $p \in \Gamma \equiv \bar{\Omega} \backslash \Omega$, there exists an open set, $W$, containing $p$, an open interval $(0, b)$, a bounded open box $U^{\prime} \subseteq \mathbb{R}^{n-1}$, and an affine orthogonal transformation, $R_{W}$ consisting of a distance preserving linear transformation followed by a translation such that

$$
\begin{gather*}
R_{W} W=U^{\prime} \times(0, b)  \tag{39.6.23}\\
R_{W}(W \cap \Omega)=\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U^{\prime}, 0<u_{n}<\phi_{W}\left(\mathbf{u}^{\prime}\right)\right\} \equiv U_{W} \tag{39.6.24}
\end{gather*}
$$

where $\phi_{W} \in C^{m, 1}\left(\overline{U^{\prime}}\right)$ meaning $\phi_{W}$ is the restriction to $U^{\prime}$ of a function, still denoted by $\phi_{W}$ which is in $C^{m, 1}\left(\mathbb{R}^{n-1}\right)$ and

$$
\inf \left\{\phi_{W}\left(\mathbf{u}^{\prime}\right): \mathbf{u}^{\prime} \in U^{\prime}\right\}>0
$$

The following picture depicts the situation.

For the situation described in the above definition, let $\mathbf{h}_{W}: U^{\prime} \rightarrow \Gamma \cap W$ be defined by

$$
\mathbf{h}_{W}\left(\mathbf{u}^{\prime}\right) \equiv R_{W}^{-1}\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)\right), \mathbf{g}_{W}(\mathbf{x}) \equiv\left(R_{W} \mathbf{x}\right)^{\prime}, \mathbf{H}_{W}(\mathbf{u}) \equiv R_{W}^{-1}\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)-u_{n}\right)
$$

where $\mathbf{x}^{\prime} \equiv\left(x_{1}, \cdots, x_{n-1}\right)$ for $\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)$. Thus $\mathbf{g}_{W} \circ \mathbf{h}_{W}=\mathrm{id}$ on $U^{\prime}$ and $\mathbf{h}_{W} \circ \mathbf{g}_{W}=\mathrm{id}$ on $\Gamma \cap W$. Also note that $\mathbf{H}_{W}$ is defined on all of $\mathbb{R}^{n}$ is $C^{m, 1}$, and has an inverse with the
same properties. To see this, let $\mathbf{G}_{W}(\mathbf{u})=\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)-u_{n}\right)$. Then $\mathbf{H}_{W}=R_{W}^{-1} \circ \mathbf{G}_{W}$ and $\mathbf{G}_{W}^{-1}=\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)-u_{n}\right)$ and so $\mathbf{H}_{W}^{-1}=\mathbf{G}_{W}^{-1} \circ R_{W}$. Note also that as indicated in the picture,

$$
R_{W}(W \cap \Omega)=\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U^{\prime} \text { and } 0<u_{n}<\phi_{W}\left(\mathbf{u}^{\prime}\right)\right\}
$$

Since $\Gamma=\partial \Omega$ is compact, there exist finitely many of these open sets, $W$, denoted by $\left\{W_{i}\right\}_{i=1}^{q}$ such that $\Gamma \subseteq \cup_{i=1}^{q} W_{i}$. Let the corresponding sets, $U^{\prime}$ be denoted by $U_{i}^{\prime}$ and let the functions, $\phi$ be denoted by $\phi_{i}$. Also let $\mathbf{h}_{i}=\mathbf{h}_{W_{i}}$ etc. Now let $\left\{\psi_{i}\right\}_{i=1}^{q}$ be a $C^{\infty}$ partition of unity subordinate to the $\left\{W_{i}\right\}_{i=1}^{q}$. If $u \in H^{t}(\Omega)$, then by Corollary 39.3.5 on Page 1358 it follows that $u \psi_{i} \in H^{t}\left(W_{i} \cap \Omega\right)$. Now

$$
\mathbf{H}_{i}: U_{i} \equiv\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U_{i}^{\prime}, 0<u_{n}<\phi_{i}\left(\mathbf{u}^{\prime}\right)\right\} \rightarrow W_{i} \cap \Omega
$$

and $\mathbf{H}_{i}$ and its inverse are defined on $\mathbb{R}^{n}$ and are in $C^{m, 1}\left(\mathbb{R}^{n}\right)$. Therefore, by Lemma 39.3.3 on Page 1356,

$$
\mathbf{H}_{i}^{*} \in \mathscr{L}\left(H^{t}\left(W_{i} \cap \Omega\right), H^{t}\left(U_{i}\right)\right)
$$

Provide $t=m+s$ where $s>0$.
Now it is possible to define the trace on $\Gamma \equiv \partial \Omega$. For $u \in H^{t}(\Omega)$,

$$
\begin{equation*}
\gamma u \equiv \sum_{i=1}^{q} \mathbf{g}_{i}^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right) . \tag{39.6.25}
\end{equation*}
$$

I must show it satisfies what it should. Recall the definition of what it means for a function to be in $H^{t-1 / 2}(\Gamma)$ where $t=m+s$.

Definition 39.6.8 Let $s \in(0,1)$ and $m$ is a nonnegative integer. Also let $\mu$ denote the surface measure for $\Gamma$. A $\mu$ measurable function, $u$ is in $H^{m+s}(\Gamma)$ if whenever

$$
\left\{W_{i}, \psi_{i}, \Gamma_{i}, U_{i}, \mathbf{h}_{i}, \mathbf{g}_{i}\right\}_{i=1}^{\infty}
$$

is described above, $\mathbf{h}_{i}^{*}\left(u \psi_{i}\right) \in H^{m+s}\left(U_{i}\right)$ and

$$
\|u\|_{H^{m+s}(\Gamma)} \equiv\left(\sum_{i=1}^{\infty}\left\|\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)\right\|_{H^{m+s}\left(U_{i}\right)}^{2}\right)^{1 / 2}<\infty
$$

Recall that all these norms which are obtained from various partitions of unity and functions, $\mathbf{h}_{i}$ and $\mathbf{g}_{i}$, are equivalent. Here there are only finitely many $W_{i}$ so the sum is a finite sum. The theorem is the following.

Theorem 39.6.9 Let $\Omega$ be a bounded open set having $C^{m, 1}$ boundary as discussed above in Definition 39.6.7. Then for $t \leq m+1$, there exists a unique

$$
\gamma \in \mathscr{L}\left(H^{t}(\Omega), H^{t-1 / 2}(\Gamma)\right)
$$

which has the property that for $\mu$ the measure on the boundary,

$$
\begin{equation*}
\gamma u(\mathbf{x})=u(\mathbf{x}) \text { for } \mu \text { a.e. } \mathbf{x} \in \Gamma \text { whenever }\left.u \in \mathfrak{S}\right|_{\Omega} \tag{39.6.26}
\end{equation*}
$$

Proof: First consider the claim that $\gamma \in \mathscr{L}\left(H^{t}(\Omega), H^{t-1 / 2}(\Gamma)\right)$. This involves first showing that for $u \in H^{t}(\Omega), \gamma u \in H^{t-1 / 2}(\Gamma)$. To do this, use the above definition.

$$
\begin{align*}
\mathbf{h}_{j}^{*}\left(\psi_{j}(\gamma u)\right) & =\sum_{i=1}^{q} \mathbf{h}_{j}^{*}\left(\psi_{j} \mathbf{g}_{i}^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right)=\sum_{i=1}^{q}\left(\mathbf{h}_{j}^{*} \psi_{j}\right)\left(\mathbf{h}_{j}^{*}\left(\mathbf{g}_{i}^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right)\right) \\
& =\sum_{i=1}^{q}\left(\mathbf{h}_{j}^{*} \psi_{j}\right)\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right) \tag{39.6.27}
\end{align*}
$$

First note that $\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right) \in H^{t-1 / 2}\left(U_{i}^{\prime}\right)$. Now $\mathbf{g}_{i} \circ \mathbf{h}_{j}$ and its inverse, $\mathbf{g}_{j} \circ \mathbf{h}_{i}$ are both functions in $C^{m, 1}\left(\mathbb{R}^{n-1}\right)$ and

$$
\mathbf{g}_{i} \circ \mathbf{h}_{j}: U_{j}^{\prime} \rightarrow U_{i}^{\prime}
$$

Therefore, by Lemma 39.3.3 on Page 1356,

$$
\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right) \in H^{t-1 / 2}\left(U_{j}^{\prime}\right)
$$

and $\left\|\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right\|_{H^{t-1 / 2}\left(U_{j}^{\prime}\right)} \leq C_{i j}\left\|\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right\|_{H^{t-1 / 2}\left(U_{i}^{\prime}\right)}$. Also it follows that $\mathbf{h}_{j}^{*} \psi_{j} \in C^{m, 1}\left(U_{j}^{\prime}\right)$ and has compact support in $U_{j}^{\prime}$ and so by Corollary 39.3.5 on Page 1358

$$
\left(\mathbf{h}_{j}^{*} \psi_{j}\right)\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right) \in H^{t-1 / 2}\left(U_{j}^{\prime}\right)
$$

and

$$
\begin{align*}
& \left\|\left(\mathbf{h}_{j}^{*} \psi_{j}\right)\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right\|_{H^{t-1 / 2}\left(U_{j}^{\prime}\right)} \\
& \quad \leq C_{i j}\left\|\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right\|_{H^{t-1 / 2}\left(U_{j}^{\prime}\right)}  \tag{39.6.28}\\
& \quad \leq C_{i j}\left\|\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right\|_{H^{t-1 / 2}\left(U_{i}^{\prime}\right)} \tag{39.6.29}
\end{align*}
$$

This shows $\gamma u \in H^{t-1 / 2}(\Gamma)$ because each $\mathbf{h}_{j}^{*}\left(\psi_{j}(\gamma u)\right) \in H^{t-1 / 2}\left(U_{j}^{\prime}\right)$. Also from 39.6.29 and 39.6.27

$$
\begin{gathered}
\|\gamma u\|_{H^{t-1 / 2}(\Gamma)}^{2} \leq \sum_{j=1}^{q}\left\|\mathbf{h}_{j}^{*}\left(\psi_{j}(\gamma u)\right)\right\|_{H^{t-1 / 2}\left(U_{j}^{\prime}\right)}^{2} \\
=\sum_{j=1}^{q}\left\|\mathbf{h}_{j}^{*}\left(\psi_{j}(\gamma u)\right)\right\|_{H^{t-1 / 2}\left(U_{j}^{\prime}\right)}^{2}=\sum_{j=1}^{q}\left\|\sum_{i=1}^{q}\left(\mathbf{h}_{j}^{*} \psi_{j}\right)\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right\|_{H^{t-1 / 2}\left(U_{j}^{\prime}\right)}^{2} \\
\leq C_{q} \sum_{j=1}^{q} \sum_{i=1}^{q}\left\|\left(\mathbf{h}_{j}^{*} \psi_{j}\right)\left(\mathbf{g}_{i} \circ \mathbf{h}_{j}\right)^{*}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right\|_{H^{t-1 / 2}\left(U_{j}^{\prime}\right)}^{2} \\
\leq C_{q} \sum_{j=1}^{q} \sum_{i=1}^{q} C_{i j}\left\|\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right\|_{H^{t-1 / 2}\left(U_{i}^{\prime}\right)}^{2} \leq C_{q} \sum_{i=1}^{q}\left\|\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\right\|_{H^{t-1 / 2}\left(U_{i}^{\prime}\right)}^{2}
\end{gathered}
$$

$$
\leq C_{q} \sum_{i=1}^{q}\left\|\mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right\|_{H^{t}\left(R_{i}\left(W_{i} \cap \Omega\right)\right)}^{2} \leq C_{q} \sum_{i=1}^{q}\left\|u \psi_{i}\right\|_{H^{t}\left(W_{i} \cap \Omega\right)}^{2} \leq C_{q}\|u\|_{H^{t}(\Omega)}^{2}
$$

Does $\gamma$ satisfy 39.6.26? Let $\mathbf{x} \in \Gamma$ and $\left.u \in \mathfrak{S}\right|_{\Omega}$. Let

$$
I_{\mathbf{x}} \equiv\left\{i \in\{1,2, \cdots, q\}: \mathbf{x}=\mathbf{h}_{i}\left(\mathbf{u}_{i}^{\prime}\right) \text { for some } \mathbf{u}_{i}^{\prime} \in U_{i}^{\prime}\right\}
$$

Then

$$
\gamma u(\mathbf{x})=\sum_{i \in I_{\mathbf{x}}}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\left(\mathbf{g}_{i}(\mathbf{x})\right)=\sum_{i \in I_{\mathbf{x}}}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\left(\mathbf{g}_{i}\left(\mathbf{h}_{i}\left(\mathbf{u}_{i}^{\prime}\right)\right)\right)=\sum_{i \in I_{\mathbf{x}}}\left(\gamma \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\right)\left(\mathbf{u}_{i}^{\prime}\right) .
$$

Now because $\mathbf{H}_{i}$ is Lipschitz continuous and $u \psi \in \mathfrak{S}$, it follows that $\mathbf{H}_{i}^{*}\left(u \psi_{i}\right) \in H^{1}\left(\mathbb{R}^{n}\right)$ and is continuous and so by Theorem 39.5.7 on Page 1366 for a.e. $\mathbf{u}_{i}^{\prime}$,

$$
=\sum_{i \in I_{\mathbf{x}}} \mathbf{H}_{i}^{*}\left(u \psi_{i}\right)\left(\mathbf{u}_{i}^{\prime}, 0\right)=\sum_{i \in I_{\mathbf{x}}} \mathbf{h}_{i}^{*}\left(u \psi_{i}\right)\left(\mathbf{u}_{i}^{\prime}\right)=\sum_{i \in I_{\mathbf{x}}}\left(u \psi_{i}\right)\left(\mathbf{h}_{i}\left(\mathbf{u}_{i}^{\prime}\right)\right)=u(\mathbf{x}) \text { for } \mu \text { a.e.x. }
$$

This verifies 39.6.26 and completes the proof of the theorem.

## Chapter 40

## Weak Solutions

### 40.1 The Lax Milgram Theorem

The Lax Milgram theorem is a fundamental result which is useful for obtaining weak solutions to many types of partial differential equations. It is really a general theorem in functional analysis.

Definition 40.1.1 Let $A \in \mathscr{L}\left(V, V^{\prime}\right)$ where $V$ is a Hilbert space. Then $A$ is said to be coercive if

$$
A(v)(v) \geq \boldsymbol{\delta}\|v\|^{2}
$$

for some $\delta>0$.
Theorem 40.1.2 (Lax Milgram) Let $A \in \mathscr{L}\left(V, V^{\prime}\right)$ be coercive. Then A maps one to one and onto.

Proof: The proof that $A$ is onto involves showing $A(V)$ is both dense and closed.
Consider first the claim that $A(V)$ is closed. Let $A x_{n} \rightarrow y^{*} \in V^{\prime}$. Then

$$
\delta\left\|x_{n}-x_{m}\right\|_{V}^{2} \leq\left\|A x_{n}-A x_{m}\right\|_{V^{\prime}}\left\|x_{n}-x_{m}\right\|_{V} .
$$

Therefore, $\left\{x_{n}\right\}$ is a Cauchy sequence in $V$. It follows $x_{n} \rightarrow x \in V$ and since $A$ is continuous, $A x_{n} \rightarrow A x$. This shows $A(V)$ is closed.

Now let $R: V \rightarrow V^{\prime}$ denote the Riesz map defined by $R x(y)=(y, x)$. Recall that the Riesz map is one to one, onto, and preserves norms. Therefore, $R^{-1}(A(V))$ is a closed subspace of $V$. If there $R^{-1}(A(V)) \neq V$, then $\left(R^{-1}(A(V))\right)^{\perp} \neq\{0\}$. Let $x \in\left(R^{-1}(A(V))\right)^{\perp}$ and $x \neq 0$. Then in particular,

$$
0=\left(x, R^{-1} A x\right)=R\left(R^{-1}(A(x))\right)(x)=A(x)(x) \geq \delta\|x\|_{V}^{2}
$$

a contradiction to $x \neq 0$. Therefore, $R^{-1}(A(V))=V$ and so $A(V)=R(V)=V^{\prime}$.
Since $A(V)$ is both closed and dense, $A(V)=V^{\prime}$. This shows $A$ is onto.
If $A x=A y$, then $0=A(x-y)(x-y) \geq \delta\|x-y\|_{V}^{2}$, and this shows $A$ is one to one. This proves the theorem.

Here is a simple example which illustrates the use of the above theorem. In the example the repeated index summation convention is being used. That is, you sum over the repeated indices.

Example 40.1.3 Let $U$ be an open subset of $\mathbb{R}^{n}$ and let $V$ be a closed subspace of $H^{1}(U)$. Let $\alpha^{i j} \in L^{\infty}(U)$ for $i, j=1,2, \cdots, n$. Now define $A: V \rightarrow V^{\prime}$ by

$$
A(u)(v) \equiv \int_{U}\left(\alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x})+u(\mathbf{x}) v(\mathbf{x})\right) d x
$$

Suppose also that

$$
\alpha^{i j} v_{i} v_{j} \geq \delta|\mathbf{v}|^{2}
$$

whenever $\mathbf{v} \in \mathbb{R}^{n}$. Then A maps $V$ to $V^{\prime}$ one to one and onto.

Here is why. It is obvious that $A$ is in $\mathscr{L}\left(V, V^{\prime}\right)$. It only remains to verify that it is coercive.

$$
\begin{aligned}
A(u)(u) & \equiv \int_{U}\left(\alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) u_{, j}(\mathbf{x})+u(\mathbf{x}) u(\mathbf{x})\right) d x \\
& \geq \int_{U} \delta|\nabla u(\mathbf{x})|^{2}+|u(\mathbf{x})|^{2} d x \\
& \geq \delta\|u\|_{H^{1}(U)}^{2}
\end{aligned}
$$

This proves coercivity and verifies the claim.
What has been obtained in the above example? This depends on how you choose $V$. In Example 40.1.3 suppose $U$ is a bounded open set with $C^{0,1}$ boundary and $V=H_{0}^{1}(U)$ where

$$
H_{0}^{1}(U) \equiv\left\{u \in H^{1}(U): \gamma u=0\right\}
$$

Also suppose $f \in L^{2}(U)$. Then you can consider $F \in V^{\prime}$ by defining

$$
F(v) \equiv \int_{U} f(\mathbf{x}) v(\mathbf{x}) d x
$$

According to the Lax Milgram theorem and the verification of its conditions in Example 40.1.3, there exists a unique solution to the problem of finding $u \in H_{0}^{1}(U)$ such that for all $v \in H_{0}^{1}(U)$,

$$
\begin{equation*}
\int_{U}\left(\alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x})+u(\mathbf{x}) v(\mathbf{x})\right) d x=\int_{U} f(\mathbf{x}) v(\mathbf{x}) d x \tag{40.1.1}
\end{equation*}
$$

In particular, this holds for all $v \in C_{c}^{\infty}(U)$. Thus for all such $v$,

$$
\int_{U}\left(-\left(\alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x})\right)_{, j}+u(\mathbf{x})-f(\mathbf{x})\right) v(\mathbf{x}) d x=0
$$

Therefore, in terms of weak derivatives,

$$
-\left(\alpha^{i j} u_{, i}\right)_{, j}+u=f
$$

and since $u \in H_{0}^{1}(U)$, it must be the case that $\gamma u=0$ on $\partial U$. This is why the solution to 40.1.1 is referred to as a weak solution to the boundary value problem

$$
-\left(\alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x})\right)_{, j}+u(\mathbf{x})=f(\mathbf{x}), u=0 \text { on } \partial U
$$

Of course you then begin to ask the important question whether $u$ really has two derivatives. It is not immediately clear that just because $-\left(\alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x})\right)_{, j} \in L^{2}(U)$ it follows that the second derivatives of $u$ exist. Actually this will often be true and is discussed somewhat in the next section.

Next suppose you choose $V=H^{1}(U)$ and let $g \in H^{1 / 2}(\partial U)$. Define $F \in V^{\prime}$ by

$$
F(v) \equiv \int_{U} f(\mathbf{x}) v(\mathbf{x}) d x+\int_{\partial U} g(\mathbf{x}) \gamma v(\mathbf{x}) d \mu
$$

Everything works the same way and you get the existence of a unique $u \in H^{1}(U)$ such that for all $v \in H^{1}(U)$,

$$
\begin{equation*}
\int_{U}\left(\alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x})+u(\mathbf{x}) v(\mathbf{x})\right) d x=\int_{U} f(\mathbf{x}) v(\mathbf{x}) d x+\int_{\partial U} g(\mathbf{x}) \gamma v(\mathbf{x}) d \mu \tag{40.1.2}
\end{equation*}
$$

is satisfied. If you pretend $u$ has all second order derivatives in $L^{2}(U)$ and apply the divergence theorem, you find that you have obtained a weak solution to

$$
-\left(\alpha^{i j} u_{, i}\right)_{, j}+u=f, \alpha^{i j} u_{, i} n_{j}=g \text { on } \partial U
$$

where $n_{j}$ is the $j^{\text {th }}$ component of $\mathbf{n}$, the unit outer normal. Therefore, $u$ is a weak solution to the above boundary value problem.

The conclusion is that the Lax Milgram theorem gives a way to obtain existence and uniqueness of weak solutions to various boundary value problems. The following theorem is often very useful in establishing coercivity. To prove this theorem, here is a definition.

Definition 40.1.4 Let $U$ be an open set and $\delta>0$. Then

$$
U_{\delta} \equiv\left\{\mathbf{x} \in U: \operatorname{dist}\left(\mathbf{x}, U^{C}\right)>\delta\right\}
$$

Theorem 40.1.5 Let $U$ be a connected bounded open set having $C^{0,1}$ boundary such that for some sequence, $\eta_{k} \downarrow 0$,

$$
\begin{equation*}
U=\cup_{k=1}^{\infty} U_{\eta_{k}} \tag{40.1.3}
\end{equation*}
$$

and $U_{\eta_{k}}$ is a connected open set. Suppose $\Gamma \subseteq \partial U$ has positive surface measure and that

$$
V \equiv\left\{u \in H^{1}(U): \gamma u=0 \text { a.e. on } \Gamma\right\} .
$$

Then the norm |||•||| given by

$$
\||u|\| \equiv\left(\int_{U}|\nabla u|^{2} d x\right)^{1 / 2}
$$

is equivalent to the usual norm on $V$.
Proof: First it is necessary to verify this is actually a norm. It clearly satisfies all the usual axioms of a norm except for the condition that $\|\|u\|\|=0$ if and only if $u=0$. Suppose then that $\|\|u\|\|=0$. Let $\delta_{0}=\eta_{k}$ for one of those $\eta_{k}$ mentioned above and define

$$
u_{\delta}(\mathbf{x}) \equiv \int_{B(\mathbf{0}, \delta)} u(\mathbf{x}-\mathbf{y}) \phi_{\delta}(\mathbf{y}) d y
$$

where $\phi_{\delta}$ is a mollifier having support in $B(\mathbf{0}, \boldsymbol{\delta})$. Then changing the variables, it follows that for $\mathbf{x} \in U_{\delta_{0}}$

$$
u_{\delta}(\mathbf{x})=\int_{B(\mathbf{x}, \delta)} u(\mathbf{t}) \phi_{\delta}(\mathbf{x}-\mathbf{t}) d t=\int_{U} u(\mathbf{t}) \phi_{\delta}(\mathbf{x}-\mathbf{t}) d t
$$

and so $u_{\delta} \in C^{\infty}\left(U_{\delta_{0}}\right)$ and

$$
\nabla u_{\delta}(\mathbf{x})=\int_{U} u(\mathbf{t}) \nabla \phi_{\delta}(\mathbf{x}-\mathbf{t}) d t=\int_{B(\mathbf{0}, \delta)} \nabla u(\mathbf{x}-\mathbf{y}) \phi_{\delta}(\mathbf{y}) d y=0
$$

Therefore, $u_{\delta}$ equals a constant on $U_{\delta_{0}}$ because $U_{\delta_{0}}$ is a connected open set and $u_{\delta}$ is a smooth function defined on this set which has its gradient equal to $\mathbf{0}$. By Minkowski's inequality,

$$
\begin{aligned}
& \left(\int_{U_{\delta_{0}}}\left|u(\mathbf{x})-u_{\delta}(\mathbf{x})\right|^{2} d x\right)^{1 / 2} \\
\leq & \int_{B(\mathbf{0}, \delta)} \phi_{\delta}(\mathbf{y})\left(\int_{U_{\delta_{0}}}|u(\mathbf{x})-u(\mathbf{x}-\mathbf{y})|^{2} d x\right)^{1 / 2} d y
\end{aligned}
$$

and this converges to 0 as $\delta \rightarrow 0$ by continuity of translation in $L^{2}$. It follows there exists a sequence of constants, $c_{\delta} \equiv u_{\delta}(\mathbf{x})$ such that $\left\{c_{\delta}\right\}$ converges to $u$ in $L^{2}\left(U_{\delta_{0}}\right)$. Consequently, a subsequence, still denoted by $u_{\delta}$, converges to $u$ a.e. By Eggoroff's theorem there exists a set, $N_{k}$ having measure no more than $3^{-k} m_{n}\left(U_{\delta_{0}}\right)$ such that $u_{\delta}$ converges to $u$ uniformly on $N_{k}^{C}$. Thus $u$ is constant on $N_{k}^{C}$. Now $\sum_{k} m_{n}\left(N_{k}\right) \leq \frac{1}{2} m_{n}\left(U_{\delta_{0}}\right)$ and so there exists $\mathbf{x}_{0} \in$ $U_{\delta_{0}} \backslash \cup_{k=1}^{\infty} N_{k}$. Therefore, if $\mathbf{x} \notin N_{k}$ it follows $u(\mathbf{x})=u\left(\mathbf{x}_{0}\right)$ and so, if $u(\mathbf{x}) \neq u\left(\mathbf{x}_{0}\right)$ it must be the case that $\mathbf{x} \in \cap_{k=1}^{\infty} N_{k}$, a set of measure zero. This shows that $u$ equals a constant a.e. on $U_{\delta_{0}}=U_{\eta_{k}}$. Since $k$ is arbitrary, 40.1.3 shows $u$ is a.e. equal to a constant on $U$. Therefore, $u$ equals the restriction of a function of $\mathfrak{S}$ to $U$ and so $\gamma u$ equals this constant in $L^{2}(\partial \Omega)$. Since the surface measure of $\Gamma$ is positive, the constant must equal zero. Therefore, $\|\|\cdot|\||$ is a norm.

It remains to verify that it is equivalent to the usual norm. It is clear that $\|\|u\|\| \leq\|u\|_{1,2}$. What about the other direction? Suppose it is not true that for some constant, $K,\|u\|_{1,2} \leq$ $K\|\|u\|\|$. Then for every $k \in \mathbb{N}$, there exists $u_{k} \in V$ such that

$$
\left\|u_{k}\right\|_{1,2}>k \mid\left\|u_{k}\right\| \|
$$

Replacing $u_{k}$ with $u_{k} /\left\|u_{k}\right\|_{1,2}$, it can be assumed that $\left\|u_{k}\right\|_{1,2}=1$ for all $k$. Therefore, using the compactness of the embedding of $H^{1}(U)$ into $L^{2}(U)$, there exists a subsequence, still denoted by $u_{k}$ such that

$$
\begin{align*}
u_{k} & \rightarrow u \text { weakly in } V,  \tag{40.1.4}\\
u_{k} & \rightarrow u \text { strongly in } L^{2}(U),  \tag{40.1.5}\\
\left\|\left\|u_{k} \mid\right\|\right. & \rightarrow 0,  \tag{40.1.6}\\
u_{k} & \rightarrow u \text { weakly in }(V,|\|\cdot|\||) . \tag{40.1.7}
\end{align*}
$$

From 40.1.6 and 40.1.7, it follows $u=0$. Therefore, $\left|u_{k}\right|_{L^{2}(U)} \rightarrow 0$. This with 40.1.6 contradicts the fact that $\left\|u_{k}\right\|_{1,2}=1$ and this proves the equivalence of the two norms.

The proof of the above theorem yields the following interesting corollary.

Corollary 40.1.6 Let $U$ be a connected open set with the property that for some sequence, $\eta_{k} \downarrow 0$,

$$
U=\cup_{k=1}^{\infty} U_{\eta_{k}}
$$

for $U_{\eta_{k}}$ a connected open set and suppose $u \in W^{1, p}(U)$ and $\nabla u=0$ a.e. Then $u$ equals $a$ constant a.e.

Example 40.1.7 Let $U$ be a bounded open connected subset of $\mathbb{R}^{n}$ and let $V$ be a closed subspace of $H^{1}(U)$ defined by

$$
V \equiv\left\{u \in H^{1}(U): \gamma u=0 \text { on } \Gamma\right\}
$$

where the surface measure of $\Gamma$ is positive.
Let $\alpha^{i j} \in L^{\infty}(U)$ for $i, j=1,2, \cdots, n$ and define $A: V \rightarrow V^{\prime}$ by

$$
A(u)(v) \equiv \int_{U} \alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x}) d x
$$

for

$$
\alpha^{i j} v_{i} v_{j} \geq \delta|\mathbf{v}|^{2}
$$

whenever $\mathbf{v} \in \mathbb{R}^{n}$. Then A maps $V$ to $V^{\prime}$ one to one and onto.
This follows from Theorem 40.1.5 using the equivalent norm defined there. Define $F \in V^{\prime}$ by

$$
\int_{U} f(\mathbf{x}) v(\mathbf{x}) d x+\int_{\partial U \backslash \Gamma} g(\mathbf{x}) \gamma v(\mathbf{x}) d x
$$

for $f \in L^{2}(U)$ and $g \in H^{1 / 2}(\partial U)$. Then the equation,

$$
A u=F \text { in } V^{\prime}
$$

which is equivalent to $u \in V$ and for all $v \in V$,

$$
\int_{U} \alpha^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x}) d x=\int_{U} f(\mathbf{x}) v(\mathbf{x}) d x+\int_{\partial U \backslash \Gamma} g(\mathbf{x}) \gamma v(\mathbf{x}) d \mu
$$

is a weak solution for the boundary value problem,

$$
-\left(\alpha^{i j} u_{, i}\right)_{, j}=f \text { in } U, \alpha^{i j} u_{, i} n_{j}=g \text { on } \partial U \backslash \Gamma, u=0 \text { on } \Gamma
$$

as you can verify by using the divergence theorem formally.

### 40.2 An Application Of The Mountain Pass Theorem

Recall the mountain pass theorem 24.1.3.
Theorem 40.2.1 Let $H$ be a Hilbert space and let $I: H \rightarrow \mathbb{R}$ be a $C^{1}$ functional having $I^{\prime}$ Lipschitz continuous and such that I satisfies the Palais Smale condition. Suppose I $(0)=0$
and $I(u) \geq a>0$ for all $\|u\|=r$. Suppose also that there exists $v,\|v\|>r$ such that $I(v) \leq 0$. Then define

$$
\Gamma \equiv\{g \in C([0,1] ; H): g(0)=0, g(1)=v\}
$$

Let

$$
c \equiv \inf _{g \in \Gamma 0 \leq t \leq 1} \max _{0} I(g(t))
$$

Then $c$ is a critical value of I meaning that there exists $u$ such that $I(u)=c$ and $I^{\prime}(u)=0$. In particular, there is $u \neq 0$ such that $I^{\prime}(u)=0$.

This nice example is in Evans [49]. Let the Hilbert space be $H_{0}^{1}(U)$ where $U$ is a bounded open set. To avoid cases, assume $U$ is in $\mathbb{R}^{3}$ or higher. The main results will work in general but it would involve cases. Consider the functional

$$
\frac{1}{2}\|u\|_{H_{0}^{1}}^{2}-\int_{U} F(u) d x \equiv I_{1}(u)-I_{2}(u)
$$

where $F^{\prime}(u)=f(u), f(0)=0$. Here it is assumed that

$$
\begin{equation*}
|f(u)| \leq C\left(1+|u|^{p}\right),\left|f^{\prime}(u)\right| \leq C\left(1+|u|^{p-1}\right), 1<p<\frac{n+2}{n-2} \tag{40.2.8}
\end{equation*}
$$

Also suppose that

$$
\begin{equation*}
0 \leq F(u) \leq \gamma f(u) u \text { where } 0<\gamma<1 / 2 \tag{40.2.9}
\end{equation*}
$$

and finally that

$$
\begin{equation*}
\alpha|u|^{p+1} \leq F(u) \leq A|u|^{p+1}, \alpha, A>0 \tag{40.2.10}
\end{equation*}
$$

Let $R: H_{0}^{1}(U) \rightarrow H^{-1}(U)$ be the Riesz map.

## Showing Functional is $C^{1,1}$

Then it is not hard to verify that $\left(I_{1}(u), v\right)=(u, v)$ and so it is clearly the case that $I^{\prime}(u)$ exists and is a continuous function of $u$. In addition to this, it is Lipschitz.

Next consider $I_{2}$.

$$
\begin{aligned}
& I_{2}(u+v)-I_{2}(u)=\int_{U} F(u+v)-F(u) d x \\
& \quad=\int_{U} f(u) v+\frac{1}{2} f^{\prime}(\hat{u}) v^{2} d x, \hat{u} \in[u, u+v]
\end{aligned}
$$

Now $H_{0}^{1}(U)$ embeds continuously into $L^{2 n /(n-2)}(U)$. Because of the estimate for $f(u)$, we can regard $f(u)$ as being in $H^{-1}(U)$ as follows.

$$
\begin{aligned}
\left|\int_{U} f(u) v d x\right| & \leq\left(\int_{U}|f(u)|^{2 n /(n+2)} d x\right)^{(n+2) / 2 n}\left(\int_{U}|v|^{2 n /(n-2)}\right)^{(n-2) / 2 n} \\
& \leq\left(\int_{U} C\left(1+|u|^{2 n /(n-2)}\right) d x\right)^{(n+2) / 2 n}\|v\|_{H_{0}^{1}}
\end{aligned}
$$

where $C$ will be adusted as needed here and elsewhere. Thus, writing in terms of the inner product on $H_{0}^{1}$,

$$
\left(I_{2}^{\prime}(u), v\right)_{H_{0}^{1}}=\left(R^{-1} f(u), v\right)_{H_{0}^{1}}
$$

This is so if the $\frac{1}{2} f^{\prime}(\hat{u}) v^{2}$ term is as it should be. We need to verify that

$$
\frac{\int_{U}\left|\frac{1}{2} f^{\prime}(\hat{u}) v^{2}\right| d x}{\|v\|_{H_{0}^{1}}} \rightarrow 0
$$

However, we can use the estimate and write that this is no larger than

$$
\begin{equation*}
\frac{\int_{U} C\left(1+|v|^{p-1}+|u|^{p-1}\right)\left|v^{2}\right| d x}{\left(\int_{U}|v|^{2 n /(n-2)} d x\right)^{(n-2) / 2 n}} \tag{40.2.11}
\end{equation*}
$$

Then consider the term involving $|u|$.

$$
\int_{U}|u|^{p-1}|v|^{2} d x \leq\left(\int_{U}|u|^{p+1}\right)^{\frac{p-1}{p+1}}\left(\int_{U}|v|^{p+1}\right)^{2 /(p+1)}
$$

Now $p+1 \leq 2 \frac{n}{n-2}$ and so the first factor is finite. As to the second, it equals

$$
\left(\left(\int_{U}|v|^{2 n /(n-2)}\right)^{\frac{1}{2 n}(n-2)}\right)^{2}
$$

and so this term from 40.2 .11 is $o(v)$ on $H_{0}^{1}(U)$. The term involving $|v|^{p-1}$ is obviously $o(v)$. Consider the constant term.

$$
\int_{U}|v|^{2} d x \leq\left(\left(\int_{U}|v|^{2 n /(n-2)} d x\right)^{(n-2) / 2 n}\right)^{2}
$$

so it is also all right. Thus the derivative is as claimed. Is this derivative Lipschitz on bounded sets?

$$
f(\hat{u})-f(u)=\int_{0}^{1} f^{\prime}(u+t(\hat{u}-u))(\hat{u}-u) d t
$$

Thus in $H^{-1}$ and using the estimates,

$$
\begin{aligned}
& \left|\int_{U}(f(\hat{u})-f(u)) v d x\right| \leq \int_{U} \int_{0}^{1} C\left(1+|u+t(\hat{u}-u)|^{p-1}\right)|\hat{u}-u| d t d x \\
& =\int_{0}^{1} \int_{U} C\left(1+|u+t(\hat{u}-u)|^{p-1}\right)|\hat{u}-u| d x d t \\
& \leq C\left(\int_{U}\left(1+|\hat{u}|^{p-1}+|u|^{p-1}\right)^{2 n /(n+2)}\right)^{\frac{n+2}{2 n}}\left(\int_{U}|\hat{u}-u|^{2 n /(n-2)}\right)^{(n-2) / 2 n} \\
& \leq C\left(\int_{U}\left(1+|\hat{u}|^{p-1}+|u|^{p-1}\right)^{2 n /(n+2)}\right)^{\frac{n+2}{2 n}}\|\hat{u}-u\|_{H_{0}^{1}(U)}
\end{aligned}
$$

Now $(p-1) \frac{2 n}{n+2} \leq\left(\frac{n+2}{n-2}-1\right) \frac{2 n}{n+2}=8 \frac{n}{n^{2}-4} \leq \frac{2 n}{n-2}$ and so the derivative is Lipschitz on bounded sets of $H_{0}^{1}(U)$.

## Palais Smale Conditions

Here we verify the Palais Smale conditions. Suppose then that $I\left(u_{k}\right)$ is bounded and $I^{\prime}\left(u_{k}\right) \rightarrow 0$ in $H_{0}^{1}(U)$. Then

$$
\begin{equation*}
\left|\frac{1}{2}\left\|u_{k}\right\|_{H_{0}^{1}}^{2}-\int_{U} F\left(u_{k}\right) d x\right| \leq C \tag{40.2.12}
\end{equation*}
$$

Since $I^{\prime}\left(u_{k}\right) \rightarrow 0$,

$$
\begin{equation*}
u_{k}-R^{-1} f\left(u_{k}\right) \rightarrow 0 \text { in } H_{0}^{1}(U) \tag{40.2.13}
\end{equation*}
$$

Take inner product of the second term with $u_{k}$.

$$
\left(R^{-1} f\left(u_{k}\right), u_{k}\right) \equiv\left\langle f\left(u_{k}\right), u_{k}\right\rangle_{H^{-1}, H_{0}^{1}}=\int_{U} f\left(u_{k}\right) u_{k} d x
$$

Then by assumption, for $\varepsilon>0$, and all $k$ large enough,

$$
\left|\left(I^{\prime}\left(u_{k}\right), u_{k}\right)\right| \leq\left|\left\|u_{k}\right\|_{H_{0}^{1}(U)}^{2}-\int_{U} f\left(u_{k}\right) u_{k} d x\right| \leq \varepsilon\left\|u_{k}\right\|_{H_{0}^{1}(U)}
$$

Then also for large $k$, letting $\varepsilon=1$,

$$
\left|\int_{U} f\left(u_{k}\right) u_{k} d x\right| \leq\left\|u_{k}\right\|_{H_{0}^{1}(U)}^{2}+\left\|u_{k}\right\|_{H_{0}^{1}(U)}
$$

Now from the estimates assumed and 40.2.12,

$$
\begin{aligned}
\frac{1}{2}\left\|u_{k}\right\|_{H_{0}^{1}}^{2} & \leq C+\int_{U} F\left(u_{k}\right) d x \leq C+\gamma \int_{U} f\left(u_{k}\right) u_{k} d x \\
& \leq C+\gamma\left(\left\|u_{k}\right\|_{H_{0}^{1}(U)}^{2}+\left\|u_{k}\right\|_{H_{0}^{1}(U)}\right)
\end{aligned}
$$

and since $\gamma<1 / 2$,

$$
\left(\frac{1}{2}-\gamma\right)\left\|u_{k}\right\|_{H_{0}^{1}}^{2} \leq C+\left\|u_{k}\right\|_{H_{0}^{1}(U)}
$$

and so $\left\|u_{k}\right\|_{H_{0}^{1}(U)}$ is bounded. Hence it has a subsequence still denoted as $u_{k}$ which converges weakly in $H_{0}^{1}(U)$ to $u \in H_{0}^{1}(U)$. Since $p<\frac{n+2}{n-2}$, it follows that

$$
p+1<\frac{n+2}{n-2}+1=\frac{2 n}{n-2}
$$

and so by compactness of the embedding, it follows that $u_{k} \rightarrow u$ strongly in $L^{p+1}(U)$. We can assume convergence also takes place pointwise by taking a suitable subsequence.

Now $|f(u) v| \leq C\left(1+|u|^{p}\right)|v|$. Therefore, adjusting the constants,

$$
\begin{aligned}
|f(u) v| & \leq C\left(1+|u|^{p}\right)|v| \leq C\left(1+|u|^{p+1}\right)^{p /(p+1)}|v| \\
\left|\int_{U} f(u) v d x\right| & \leq C\left(\int_{U}\left(1+|u|^{p+1}\right)\right)^{p /(p+1)}\left(\int_{U}|v|^{p+1}\right)^{1 /(p+1)} \\
& \leq C\left(\int_{U}\left(1+|u|^{p+1}\right)\right)^{p /(p+1)}\|v\|_{H_{0}^{1}(U)}
\end{aligned}
$$

and so

$$
\|f(u)\|_{H^{-1}(U)} \leq\|f(u)\|_{L^{p+1}(U)} \leq C\left(\int_{U}\left(1+|u|^{p+1}\right)\right)^{p /(p+1)}
$$

It follows that

$$
f\left(u_{k}\right) \rightarrow f(u) \text { pointwise }
$$

and also

$$
\left|f\left(u_{k}\right)-f(u)\right|^{p+1} \leq C_{p}\left(\left|f\left(u_{k}\right)\right|^{p+1}+|f(u)|^{p+1}\right)
$$

where

$$
\lim _{k \rightarrow \infty} \int_{U}\left(\left|f\left(u_{k}\right)\right|^{p+1}+|f(u)|^{p+1}\right) d x=\int_{U} 2|f(u)|^{p+1} d x
$$

then by the dominated convergence theorem or more precisely Corollary 11.4.10,

$$
\lim _{k \rightarrow \infty}\left(\int_{U}\left|f\left(u_{k}\right)-f(u)\right|^{p+1}\right)^{1 /(p+1)}=0
$$

It follows that $f\left(u_{k}\right) \rightarrow f(u)$ in $H^{-1}(U)$. Hence $R^{-1} f\left(u_{k}\right) \rightarrow R^{-1} f(u)$ in $H_{0}^{1}(U)$ and so from 40.2.13, $u_{k} \rightarrow u$ strongly in $H_{0}^{1}(U)$ also. Thus $\left\{u_{k}\right\}$ is precompact. This verifies the Palais Smale conditions.

## mountain pass conditions

It is clear that $I(0)=0$. It remains to verify that for some $r>0, I(u) \geq a>0$ whenever $\|u\|_{H_{0}^{1}(U)}=r$ and for some $v$ with $\|v\|>r, I(v)=0$. Now consider $r u$ where $\|u\|=1$.

$$
I(r u)=\frac{1}{2} r^{2}-\int_{U} F(r u) d x
$$

From the assumed estimates and Sobolev embedding,

$$
\begin{aligned}
I(r u) & \geq \frac{1}{2} r^{2}-\int_{U} A|u|^{p+1} r^{p+1} d x \geq \frac{1}{2} r^{2}-C A r^{p+1}\|u\|_{H_{0}^{1}(U)}^{p+1} \\
& =\frac{1}{2} r^{2}-C A r^{p+1}
\end{aligned}
$$

Now this is independent of $u$ such that $\|u\|=1$. Then the derivative of the right side is

$$
r-(p+1) C A r^{p}
$$

where $p>1$. Thus this is positive for a while and then when $r$ is larger, it becomes negative. Thus there is $r_{0}>0$ where $\frac{1}{2} r_{0}^{2}-C A r_{0}^{p+1} \equiv a>0$. Hence when $\|u\|=r_{0}$, you have $I(u) \geq$ $a>0$. This is part of the mountain pass conditions. Now consider the other part. Letting $\|u\|=1$ be fixed, the estimates imply

$$
I(r u) \leq \frac{1}{2} r^{2}-\int_{U} \alpha|u|^{p+1} r^{p+1} d x \leq \frac{1}{2} r^{2}-r^{p+1} C
$$

Hence, for $r$ large enough, the right side becomes negative because $p+1>2$. Therefore, $r \rightarrow I(r u)$ is positive for small $r$ and is eventually negative as $r$ gets larger. hence there is some value of $r$ where this equals 0 . Then $v=r u$. This verifies the conditions for the mountain pass theorem.

## conclusions

It follows from the mountain pass theorem that there is some $u \neq 0$ such that $I^{\prime}(u)=0$. From the above computations,

$$
u-R^{-1} f(u)=0
$$

Now $R=-\Delta$ the Laplacian. In terms of weak derivatives,

$$
\langle-\Delta u, v\rangle_{H^{-1}, H_{0}^{1}}=\int_{U} \nabla u \cdot \nabla v d x=(u, v)_{H_{0}^{1}(U)}
$$

and so in terms of weak derivatives,

$$
-\Delta u=f(u) \text { in } H^{-1}(U), u \in H_{0}^{1}(U) \text { so } u=0 \text { on } \partial U
$$

This proves the following theorem.
Theorem 40.2.2 Suppose the conditions 40.2.8-40.2.10 hold. Then there exists a nonzero $u \in H_{0}^{1}(U)$ such that

$$
-\Delta u=f(u)
$$

One can verify that an example of such a function $f(u)$ is

$$
f(u)=|u|^{p-2} u
$$

This is very exciting to a large number of people because it gives an interesting example of non uniqueness of a boundary value problem. It is clear that $u=0$ works.

## Chapter 41

## Korn's Inequality

A fundamental inequality used in elasticity to obtain coercivity and then apply the Lax Milgram theorem or some other theorem is Korn's inequality. The proof given here of this fundamental result follows [101] and [46].

### 41.1 A Fundamental Inequality

The proof of Korn's inequality depends on a fundamental inequality involving negative Sobolev space norms. The theorem to be proved is the following.

Theorem 41.1.1 Let $f \in L^{2}(\Omega)$ where $\Omega$ is a bounded Lipschitz domain. Then there exist constants, $C_{1}$ and $C_{2}$ such that

$$
C_{1}\|f\|_{0,2, \Omega} \leq\left(\|f\|_{-1,2, \Omega}+\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \Omega}\right) \leq C_{2}\|f\|_{0,2, \Omega}
$$

where here $\|\cdot\|_{0,2, \Omega}$ represents the $L^{2}$ norm and $\|\cdot\|_{-1,2, \Omega}$ represents the norm in the dual space of $H_{0}^{1}(\Omega)$, denoted by $H^{-1}(\Omega)$.

Similar conventions will apply for any domain in place of $\Omega$. The proof of this theorem will proceed through the use of several lemmas.

Lemma 41.1.2 Let $U^{-}$denote the set,

$$
\left\{\left(\mathbf{x}, x_{n}\right) \in \mathbb{R}^{n}: x_{n}<g(\mathbf{x})\right\}
$$

where $g: \mathbb{R}^{n-1} \rightarrow \mathbb{R}$ is Lipschitz and denote by $U^{+}$the set

$$
\left\{\left(\mathbf{x}, x_{n}\right) \in \mathbb{R}^{n}: x_{n}>g(\mathbf{x})\right\}
$$

Let $f \in L^{2}\left(U^{-}\right)$and extend $f$ to all of $\mathbb{R}^{n}$ in the following way.

$$
f\left(\mathbf{x}, x_{n}\right) \equiv-3 f\left(\mathbf{x}, 2 g(\mathbf{x})-x_{n}\right)+4 f\left(\mathbf{x}, 3 g(\mathbf{x})-2 x_{n}\right)
$$

Then there is a constant, $C_{g}$, depending on $g$ such that

$$
\|f\|_{-1,2, \mathbb{R}^{n}}+\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \mathbb{R}^{n}} \leq C_{g}\left(\|f\|_{-1,2, U^{-}}+\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\| \|_{-1,2, U^{-}}\right)
$$

Proof: Let $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. Then,

$$
\begin{align*}
\int_{\mathbb{R}^{n}} f \frac{\partial \phi}{\partial x_{n}} d x=\int_{U^{+}} \frac{\partial \phi}{\partial x_{n}}[ & \left.-3 f\left(\mathbf{x}, 2 g(\mathbf{x})-x_{n}\right)+4 f\left(\mathbf{x}, 3 g(\mathbf{x})-2 x_{n}\right)\right] d x \\
& +\int_{U^{-}} f \frac{\partial \phi}{\partial x_{n}} d x \tag{41.1.1}
\end{align*}
$$

Consider the first integral on the right in 41.1.1. Changing the variables, letting

$$
y_{n}=2 g(\mathbf{x})-x_{n}
$$

in the first term of the integrand and $3 g(\mathbf{x})-2 x_{n}$ in the next, it equals

$$
\begin{aligned}
& -3 \int_{U^{-}} \frac{\partial \phi}{\partial x_{n}}\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right) f\left(\mathbf{x}, y_{n}\right) d y_{n} d x \\
+ & 2 \int_{U^{-}} \frac{\partial \phi}{\partial x_{n}}\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right) f\left(\mathbf{x}, y_{n}\right) d y_{n} d x
\end{aligned}
$$

For $\left(\mathbf{x}, y_{n}\right) \in U^{-}$, and defining

$$
\psi\left(\mathbf{x}, y_{n}\right) \equiv \phi\left(\mathbf{x}, y_{n}\right)+3 \phi\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right)-4 \phi\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right)
$$

it follows $\psi=0$ when $y_{n}=g(\mathbf{x})$ and so

$$
\int_{\mathbb{R}^{n}} f \frac{\partial \phi}{\partial x_{n}} d x=\int_{U^{-}} \frac{\partial \psi}{\partial y_{n}} f\left(\mathbf{x}, y_{n}\right) d x d y_{n}
$$

Now from the definition of $\psi$ given above,

$$
\|\psi\|_{1,2, U^{-}} \leq C_{g}\|\phi\|_{1,2, U^{-}} \leq C_{g}\|\phi\|_{1,2, \mathbb{R}^{n}}
$$

and so

$$
\begin{gather*}
\|\left.\frac{\partial f}{\partial x_{n}}\right|_{-1,2, \mathbb{R}^{n}} \equiv \\
\sup \left\{\int_{\mathbb{R}^{n}} f \frac{\partial \phi}{\partial x_{n}} d x: \phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right),\|\phi\|_{1,2, \mathbb{R}^{n}} \leq 1\right\} \leq \\
\sup \left\{\left|\int_{U^{-}} f \frac{\partial \psi}{\partial x_{n}} d x d y_{n}\right|: \psi \in H_{0}^{1}\left(U^{-}\right),\|\psi\|_{1,2, U^{-}} \leq C_{g}\right\} \\
=C_{g}| | \frac{\partial f}{\partial x_{n}} \|\left.\right|_{-1,2, U^{-}} \tag{41.1.2}
\end{gather*}
$$

It remains to establish a similar inequality for the case where the derivatives are taken with respect to $x_{i}$ for $i<n$. Let $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$. Then

$$
\begin{gathered}
\int_{\mathbb{R}^{n}} f \frac{\partial \phi}{\partial x_{i}} d x=\int_{U^{-}} f \frac{\partial \phi}{\partial x_{i}} d x \\
\int_{U^{+}} \frac{\partial \phi}{\partial x_{i}}\left[-3 f\left(\mathbf{x}, g(\mathbf{x})-x_{n}\right)+4 f\left(\mathbf{x}, 3 g(\mathbf{x})-2 x_{n}\right)\right] d x .
\end{gathered}
$$

Changing the variables as before, this last integral equals

$$
-3 \int_{U^{-}} D_{i} \phi\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right) f\left(\mathbf{x}, y_{n}\right) d y_{n} d x
$$

$$
\begin{equation*}
+2 \int_{U^{-}} D_{i} \phi\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right) f\left(\mathbf{x}, y_{n}\right) d y_{n} d x \tag{41.1.3}
\end{equation*}
$$

Now let

$$
\psi_{1}\left(\mathbf{x}, y_{n}\right) \equiv \phi\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right), \psi_{2}\left(\mathbf{x}, y_{n}\right) \equiv \phi\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right)
$$

Then

$$
\begin{gathered}
\frac{\partial \psi_{1}}{\partial x_{i}}=D_{i} \phi\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right)+D_{n} \phi\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right) 2 D_{i} g(\mathbf{x}), \\
\frac{\partial \psi_{2}}{\partial x_{i}}=D_{i} \phi\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right)+D_{n} \phi\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right) \frac{3}{2} D_{i} g(\mathbf{x}) .
\end{gathered}
$$

Also

$$
\begin{gathered}
\frac{\partial \psi_{1}}{\partial y_{n}}\left(\mathbf{x}, y_{n}\right)=-D_{n} \phi\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right) \\
\frac{\partial \psi_{2}}{\partial y_{n}}\left(\mathbf{x}, y_{n}\right)=\left(\frac{-1}{2}\right) D_{n} \phi\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right)
\end{gathered}
$$

Therefore,

$$
\begin{gathered}
\frac{\partial \psi_{1}}{\partial x_{i}}\left(\mathbf{x}, y_{n}\right)=D_{i} \phi\left(\mathbf{x}, 2 g(\mathbf{x})-y_{n}\right)-2 \frac{\partial \psi_{1}}{\partial y_{n}}\left(\mathbf{x}, y_{n}\right) D_{i} g(\mathbf{x}), \\
\frac{\partial \psi_{2}}{\partial x_{i}}\left(\mathbf{x}, y_{n}\right)=D_{i} \phi\left(\mathbf{x}, \frac{3}{2} g(\mathbf{x})-\frac{y_{n}}{2}\right)-3 \frac{\partial \psi_{2}}{\partial y_{n}}\left(\mathbf{x}, y_{n}\right) D_{i} g(\mathbf{x}) .
\end{gathered}
$$

Using this in 41.1.3, the integrals in this expression equal

$$
\begin{gathered}
-3 \int_{U^{-}}\left[\frac{\partial \psi_{1}}{\partial x_{i}}\left(\mathbf{x}, y_{n}\right)+2 \frac{\partial \psi_{1}}{\partial y_{n}}\left(\mathbf{x}, y_{n}\right) D_{i} g(\mathbf{x})\right] f\left(\mathbf{x}, y_{n}\right) d y_{n} d x+ \\
2 \int_{U^{-}}\left[\frac{\partial \psi_{2}}{\partial x_{i}}\left(\mathbf{x}, y_{n}\right)+3 \frac{\partial \psi_{2}}{\partial y_{n}}\left(\mathbf{x}, y_{n}\right) D_{i} g(\mathbf{x})\right] f\left(\mathbf{x}, y_{n}\right) d y_{n} d x \\
=\int_{U^{-}}\left[-3 \frac{\partial \psi_{1}(\mathbf{x}, y)}{\partial x_{i}}+2 \frac{\partial \psi_{2}\left(\mathbf{x}, y_{n}\right)}{\partial x_{i}}\right] f\left(\mathbf{x}, y_{n}\right) d y_{n} d x
\end{gathered}
$$

Therefore,

$$
\int_{\mathbb{R}^{n}} \frac{\partial \phi}{\partial x_{i}} f d x=\int_{U^{-}}\left[\frac{\partial \phi}{\partial x_{i}}-3 \frac{\partial \psi_{1}}{\partial x_{i}}+2 \frac{\partial \psi_{2}}{\partial x_{i}}\right] f d x d y_{n}
$$

and also

$$
\begin{aligned}
& \phi(\mathbf{x}, g(\mathbf{x}))-3 \psi_{1}(\mathbf{x}, g(\mathbf{x}))+2 \psi_{2}(\mathbf{x}, g(\mathbf{x}))= \\
& \phi(\mathbf{x}, g(\mathbf{x}))-3 \phi(\mathbf{x}, g(\mathbf{x}))+2 \phi(\mathbf{x}, g(\mathbf{x}))=0
\end{aligned}
$$

and so $\phi-3 \psi_{1}+2 \psi_{2} \in H_{0}^{1}\left(U^{-}\right)$. It also follows from the definition of the functions, $\psi_{i}$ and the assumption that $g$ is Lipschitz, that

$$
\begin{equation*}
\left\|\psi_{i}\right\|_{1,2, U^{-}} \leq C_{g}\|\phi\|_{1,2, U^{-}} \leq C_{g}\|\phi\|_{1,2, \mathbb{R}^{n}} \tag{41.1.4}
\end{equation*}
$$

Therefore,

$$
\begin{gathered}
\| \frac{\partial f}{\partial x_{i}}| |_{-1,2, \mathbb{R}^{n}} \equiv \sup \left\{\left|\int_{\mathbb{R}^{n}} f \frac{\partial \phi}{\partial x_{i}} d x\right|:\|\phi\|_{1,2, \mathbb{R}^{n}} \leq 1\right\} \\
=\sup \left\{\left|\int_{U^{-}} f\left[\frac{\partial \phi}{\partial x_{i}}-3 \frac{\partial \psi_{1}}{\partial x_{i}}+2 \frac{\partial \psi_{2}}{\partial x_{i}}\right] d x\right|:\|\phi\|_{1,2, \mathbb{R}^{n}} \leq 1\right\} \\
\leq C_{g}| | \frac{\partial f}{\partial x_{i}}| |_{-1,2, U^{-}}
\end{gathered}
$$

where $C_{g}$ is a constant which depends on $g$. This inequality along with 41.1 .2 yields

$$
\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \mathbb{R}^{n}} \leq C_{g}\left(\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, U^{-}}\right)
$$

The inequality,

$$
\|f\|_{-1,2, \mathbb{R}^{n}} \leq C_{g}\|f\|_{-1,2, U^{-}}
$$

follows from 41.1.4 and the equation,

$$
\begin{aligned}
\int_{\mathbb{R}^{n}} f \phi d x= & \int_{U^{-}} f \phi d x-3 \int_{U^{-}} f\left(\mathbf{x}, y_{n}\right) \psi_{1}\left(\mathbf{x}, y_{n}\right) d x d y_{n} \\
& +2 \int_{U^{-}} f\left(\mathbf{x}, y_{n}\right) \psi_{2}\left(\mathbf{x}, y_{n}\right) d x d y_{n}
\end{aligned}
$$

which results in the same way as before by changing variables using the definition of $f$ off $U^{-}$. This proves the lemma.

The next lemma is a simple application of Fourier transforms.
Lemma 41.1.3 If $f \in L^{2}\left(\mathbb{R}^{n}\right)$, then the following formula holds.

$$
C_{n}\|f\|_{0,2, \mathbb{R}^{n}}=\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \mathbb{R}^{n}}+\|f\|_{-1,2, \mathbb{R}^{n}}
$$

Proof: For $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$

$$
\|\phi\|_{1,2, \mathbb{R}^{n}} \equiv\left(\int_{\mathbb{R}^{n}}\left(1+|\mathbf{t}|^{2}\right)|F \phi|^{2} d t\right)^{1 / 2}
$$

is an equivalent norm to the usual Sobolev space norm for $H_{0}^{1}\left(\mathbb{R}^{n}\right)$ and is used in the following argument which depends on Plancherel's theorem and the fact that $F\left(\frac{\partial \phi}{\partial x_{i}}\right)=$ $t_{i} F(\phi)$.

$$
\begin{aligned}
& \| \frac{\partial f}{\partial x_{i}}| |_{-1,2, \mathbb{R}^{n}} \equiv \sup \left\{\left|\int_{\mathbb{R}^{n}} \frac{\partial \phi}{\partial x_{i}} \bar{f} d x\right|:\|\phi\|_{1,2} \leq 1\right\} \\
& \quad=C_{n} \sup \left\{\left|\int_{\mathbb{R}^{n}} t_{i}(F \phi) \overline{(F f)} d t\right|:\|\phi\|_{1,2} \leq 1\right\}
\end{aligned}
$$

$$
\begin{gather*}
=C_{n} \sup \left\{\left|\int_{\mathbb{R}^{n}} \frac{t_{i}(F \phi)\left(1+|\mathbf{t}|^{2}\right)^{1 / 2}}{\left(1+|\mathbf{t}|^{2}\right)^{1 / 2}} \overline{(F f)} d t\right|:\|\phi\|_{1,2} \leq 1\right\} \\
=C_{n}\left(\int \frac{|F f|^{2} t_{i}^{2}}{\left(1+|\mathbf{t}|^{2}\right)} d t\right)^{1 / 2} \tag{41.1.5}
\end{gather*}
$$

Also,

$$
\begin{gathered}
\|f\|_{-1,2} \equiv \sup \left\{\left|\int_{\mathbb{R}^{n}} \phi \bar{f} d x\right|:\|\phi\|_{1,2} \leq 1\right\} \\
=C_{n} \sup \left\{\left|\int_{\mathbb{R}^{n}}(F \phi)(\overline{F f}) d x\right|:\|\phi\|_{1,2} \leq 1\right\} \\
=C_{n} \sup \left\{\left|\int_{\mathbb{R}^{n}} \frac{F \phi\left(1+|\mathbf{t}|^{2}\right)^{1 / 2}}{\left(1+|\mathbf{t}|^{2}\right)^{1 / 2}} \overline{(F f)} d t\right|:\|\phi\|_{1,2} \leq 1\right\} \\
=C_{n}\left(\int_{\mathbb{R}^{n}} \frac{|F f|^{2}}{\left(1+|\mathbf{t}|^{2}\right)} d t\right)^{1 / 2}
\end{gathered}
$$

This along with 41.1.5 yields the conclusion of the lemma because

$$
\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2}^{2}+\|f\|_{-1,2}^{2}=C_{n} \int_{\mathbb{R}^{n}}|F f|^{2} d x=C_{n}\|f\|_{0,2}^{2}
$$

Now consider Theorem 41.1.1. First note that by Lemma 41.1.2 and $U^{-}$defined there, Lemma 41.1.3 implies that for $f$ extended as in Lemma 41.1.2,

$$
\begin{align*}
\|f\|_{0,2, U^{-}} & \leq\|f\|_{0,2, \mathbb{R}^{n}}=C_{n}\left(\|f\|_{-1,2, \mathbb{R}^{n}}+\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \mathbb{R}^{n}}\right) \\
& \leq C_{g n}\left(\|f\|_{-1,2, U^{-}}+\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, U^{-}}\right) . \tag{41.1.6}
\end{align*}
$$

Let $\Omega$ be a bounded open set having Lipschitz boundary which lies locally on one side of its boundary. Let $\left\{Q_{i}\right\}_{i=0}^{p}$ be cubes of the sort used in the proof of the divergence theorem such that $\overline{Q_{0}} \subseteq \Omega$ and the other cubes cover the boundary of $\Omega$. Let $\left\{\psi_{i}\right\}$ be a $C^{\infty}$ partition of unity with $\operatorname{spt}\left(\psi_{i}\right) \subseteq Q_{i}$ and let $f \in L^{2}(\Omega)$. Then for $\phi \in C_{c}^{\infty}(\Omega)$ and $\psi$ one of these functions in the partition of unity,

$$
\left|\left|\frac{\partial(f \psi)}{\partial x_{i}} \|_{-1,2, \Omega} \leq \sup _{\|\phi\|_{1,2} \leq 1}\right| \int_{\Omega} f \frac{\partial}{\partial x_{i}}(\psi \phi) d x\right|+\sup _{\|\phi\|_{1,2} \leq 1}\left|\int_{\Omega} f \phi \frac{\partial \psi}{\partial x_{i}} d x\right|
$$

Now if $\|\phi\|_{1,2} \leq 1$, then for a suitable constant, $C_{\psi}$,

$$
\|\psi \phi\|_{1,2} \leq C_{\psi}\|\phi\|_{1,2} \leq C_{\psi},\left\|\phi \frac{\partial \psi}{\partial x_{i}}\right\|_{1,2} \leq C_{\psi}
$$

Therefore,

$$
\begin{gather*}
\left\|\frac{\partial(f \psi)}{\partial x_{i}}\right\| \|_{-1,2, \Omega} \leq \sup _{\|\eta\|_{1,2} \leq C_{\psi}}\left|\int_{\Omega} f \frac{\partial \eta}{\partial x_{i}} d x\right|+\sup _{\|\eta\|_{1,2} \leq C_{\psi}}\left|\int_{\Omega} f \eta d x\right| \\
\leq C_{\psi}\left(\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \Omega}+\|f\|_{-1,2, \Omega}\right) \tag{41.1.7}
\end{gather*}
$$

Now using 41.1.7 and 41.1.6

$$
\begin{gathered}
\left\|f \psi_{j}\right\|_{0,2, \Omega} \leq C_{g}\left(\left\|f \psi_{j}\right\|_{-1,2, \Omega}+\sum_{i=1}^{n}\left\|\frac{\partial\left(f \psi_{j}\right)}{\partial x_{i}}\right\|_{-1,2, \Omega}\right) \\
\leq C_{\psi_{j}} C_{g}\left(\|f\|_{-1,2, \Omega}+\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \Omega}\right)
\end{gathered}
$$

Therefore, letting $C=\sum_{j=1}^{p} C_{\psi_{j}} C_{g}$,

$$
\begin{equation*}
\|f\|_{0,2, \Omega} \leq \sum_{j=1}^{p}\left\|f \psi_{j}\right\|_{0,2, \Omega} \leq C\left(\|f\|_{-1,2, \Omega}+\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|_{-1,2, \Omega}\right) \tag{41.1.8}
\end{equation*}
$$

This proves the hard half of the inequality of Theorem 41.1.1.
To complete the proof, let $\bar{f}$ denote the zero extension of $f$ off $\Omega$. Then

$$
\begin{gathered}
\|f\|_{-1,2, \Omega}+\left.\sum_{i=1}^{n}\left\|\frac{\partial f}{\partial x_{i}}\right\|\right|_{-1,2, \Omega} \leq\|\bar{f}\|_{-1,2, \mathbb{R}^{n}}+\sum_{i=1}^{n}\left\|\frac{\partial \bar{f}}{\partial x_{i}}\right\| \|_{-1,2, \mathbb{R}^{n}} \\
\leq C_{n}\|\bar{f}\|_{0,2, \mathbb{R}^{n}}=C_{n}\|f\|_{0,2, \Omega}
\end{gathered}
$$

This along with 41.1.8 proves Theorem 41.1.1.

### 41.2 Korn's Inequality

The inequality in this section is known as Korn's second inequality. It is also known as coercivity of strains. For $\mathbf{u}$ a vector valued function in $\mathbb{R}^{n}$, define

$$
\varepsilon_{i j}(\mathbf{u}) \equiv \frac{1}{2}\left(u_{i, j}+u_{j, i}\right)
$$

This is known as the strain or small strain. Korn's inequality says that the norm given by,

$$
\begin{equation*}
\|\mid \mathbf{u}\| \equiv\left(\sum_{i=1}^{n}\left\|u_{i}\right\|_{0,2, \Omega}^{2}+\sum_{i=1}^{n} \sum_{j=1}^{n}\left\|\varepsilon_{i j}(\mathbf{u})\right\|_{0,2, \Omega}^{2}\right)^{1 / 2} \tag{41.2.9}
\end{equation*}
$$

is equivalent to the norm,

$$
\begin{equation*}
\|\mathbf{u}\| \equiv\left(\sum_{i=1}^{n}\left\|u_{i}\right\|_{0,2, \Omega}^{2}+\sum_{i=1}^{n} \sum_{j=1}^{n}\left\|\frac{\partial u_{i}}{\partial x_{j}}\right\|_{0,2, \Omega}^{2}\right)^{1 / 2} \tag{41.2.10}
\end{equation*}
$$

It is very significant because it is the strain as just defined which occurs in many of the physical models proposed in continuum mechanics. The inequality is far from obvious because the strains only involve certain combinations of partial derivatives.

Theorem 41.2.1 (Korn's second inequality) Let $\Omega$ be any domain for which the conclusion of Theorem 41.1.1 holds. Then the two norms in 41.2 .9 and 41.2.10 are equivalent.

Proof: Let $\mathbf{u}$ be such that $u_{i} \in H^{1}(\Omega)$ for each $i=1, \cdots, n$. Note that

$$
\frac{\partial^{2} u_{i}}{\partial x_{j}, \partial x_{k}}=\frac{\partial}{\partial x_{j}}\left(\varepsilon_{i k}(\mathbf{u})\right)+\frac{\partial}{\partial x_{k}}\left(\varepsilon_{i j}(\mathbf{u})\right)-\frac{\partial}{\partial x_{i}}\left(\varepsilon_{j k}(\mathbf{u})\right) .
$$

Therefore, by Theorem 41.1.1,

$$
\begin{aligned}
& \left\|\frac{\partial u_{i}}{\partial x_{j}}\right\|_{0,2, \Omega} \leq C\left[\left\|\frac{\partial u_{i}}{\partial x_{j}}\right\|_{-1,2, \Omega}+\sum_{k=1}^{n}\left\|\frac{\partial^{2} u_{i}}{\partial x_{j}, \partial x_{k}}\right\|_{-1,2, \Omega}\right] \\
& \quad \leq C\left[\left\|\frac{\partial u_{i}}{\partial x_{j}}\right\|_{-1,2, \Omega}+\sum_{r, s, p}\left\|\frac{\partial \varepsilon_{r s}(\mathbf{u})}{\partial x_{p}}\right\|_{-1,2, \Omega}\right] \\
& \quad \leq C\left[\left\|\frac{\partial u_{i}}{\partial x_{j}}\right\|_{-1,2, \Omega}+\sum_{r, s}\left\|\varepsilon_{r s}(\mathbf{u})\right\|_{0,2, \Omega}\right]
\end{aligned}
$$

But also by this theorem,

$$
\left\|u_{i}\right\|_{-1,2, \Omega}+\sum_{p}\left\|\frac{\partial u_{i}}{\partial x_{p}}\right\|_{-1,2, \Omega} \leq C\left\|u_{i}\right\|_{0,2, \Omega}
$$

and so

$$
\left\|\frac{\partial u_{i}}{\partial x_{j}}\right\|_{0,2, \Omega} \leq C\left[\left\|u_{i}\right\|_{0,2, \Omega}+\sum_{r, s}\left\|\varepsilon_{r s}(\mathbf{u})\right\|_{0,2, \Omega}\right]
$$

This proves the theorem.
Note that $\Omega$ did not need to be bounded. It suffices to be able to conclude the result of Theorem 41.1.1 which would hold whenever the boundary of $\Omega$ can be covered with finitely many boxes of the sort to which Lemma 41.1.2 can be applied.

## Chapter 42

## Elliptic Regularity

### 42.1 The Case Of A Half Space

Regularity theorems are concerned with obtaining more regularity given a weak solution. This extra regularity is essential in order to obtain error estimates for various problems. In this section a regularity is given for weak solutions to various elliptic boundary value problems. To save on notation, I will use the repeated index summation convention. Thus you sum over repeated indices. Consider the following picture.

Here $V$ is an open set,

$$
U \equiv\left\{\mathbf{y} \in V: y_{n}<0\right\}, \Gamma \equiv\left\{\mathbf{y} \in V: y_{n}=0\right\}
$$

and $U_{1}$ is an open set as shown for which $U_{1} \subseteq V \cap U$. Assume also that $V$ is bounded. Suppose

$$
\begin{gather*}
f \in L^{2}(U), \\
\alpha^{r s} \in C^{0,1}(\bar{U}),  \tag{42.1.1}\\
\alpha^{r s}(\mathbf{y}) v_{r} v_{s} \geq \delta|\mathbf{v}|^{2}, \delta>0 . \tag{42.1.2}
\end{gather*}
$$

The following technical lemma gives the essential ideas.
Lemma 42.1.1 Suppose

$$
\begin{align*}
w & \in H^{1}(U),  \tag{42.1.3}\\
\alpha^{r s} & \in C^{0,1}(\bar{U}),  \tag{42.1.4}\\
h_{s} & \in H^{1}(U),  \tag{42.1.5}\\
f & \in L^{2}(U) . \tag{42.1.6}
\end{align*}
$$

and

$$
\begin{equation*}
\int_{U} \alpha^{r s}(\mathbf{y}) \frac{\partial w}{\partial y^{r}} \frac{\partial z}{\partial y^{s}} d y+\int_{U} h_{s}(\mathbf{y}) \frac{\partial z}{\partial y^{s}} d y=\int_{U} f z d y \tag{42.1.7}
\end{equation*}
$$

for all $z \in H^{1}(U)$ having the property that $\operatorname{spt}(z) \subseteq V$. Then $w \in H^{2}\left(U_{1}\right)$ and for some constant $C$, independent of $f, w$, and $g$, the following estimate holds.

$$
\begin{equation*}
\|w\|_{H^{2}\left(U_{1}\right)}^{2} \leq C\left(\|w\|_{H^{1}(U)}^{2}+\|f\|_{L^{2}(U)}^{2}+\sum_{s}\left\|h_{s}\right\|_{H^{1}(U)}^{2}\right) \tag{42.1.8}
\end{equation*}
$$

Proof: Define for small real $h$,

$$
D_{k}^{h} l(\mathbf{y}) \equiv \frac{1}{h}\left(l\left(\mathbf{y}+h \mathbf{e}_{k}\right)-l(\mathbf{y})\right) .
$$

Let $U_{1} \subseteq \overline{U_{1}} \subseteq W \subseteq \bar{W} \subseteq V$ and let $\eta \in C_{c}^{\infty}(W)$ with $\eta(\mathbf{y}) \in[0,1]$, and $\eta=1$ on $\overline{U_{1}}$ as shown in the following picture.

For $h$ small $\left(3 h<\operatorname{dist}\left(\bar{W}, V^{C}\right)\right)$, let

$$
\begin{align*}
z(\mathbf{y}) \equiv & \frac{1}{h}\left\{\eta^{2}\left(\mathbf{y}-h \mathbf{e}_{k}\right)\left[\frac{w(\mathbf{y})-w\left(\mathbf{y}-h \mathbf{e}_{k}\right)}{h}\right]\right. \\
& \left.-\eta^{2}(\mathbf{y})\left[\frac{w\left(\mathbf{y}+h \mathbf{e}_{k}\right)-w(\mathbf{y})}{h}\right]\right\}  \tag{42.1.9}\\
\equiv & -D_{k}^{-h}\left(\eta^{2} D_{k}^{h} w\right) \tag{42.1.10}
\end{align*}
$$

where here $k<n$. Thus $z$ can be used in equation 42.1.7. Begin by estimating the left side of 42.1.7.

$$
\begin{aligned}
& \int_{U} \alpha^{r s}(\mathbf{y}) \frac{\partial w}{\partial y^{r}} \frac{\partial z}{\partial y^{s}} d y \\
= & \frac{1}{h} \int_{U} \alpha^{r s}\left(\mathbf{y}+h \mathbf{e}_{k}\right) \frac{\partial w}{\partial y^{r}}\left(\mathbf{y}+h \mathbf{e}_{k}\right) \frac{\partial\left(\eta^{2} D_{k}^{h} w\right)}{\partial y^{s}} d y \\
& -\frac{1}{h} \int_{U} \alpha^{r s}(\mathbf{y}) \frac{\partial w}{\partial y^{r}} \frac{\partial\left(\eta^{2} D_{k}^{h} w\right)}{\partial y^{s}} d y
\end{aligned}
$$

$$
\begin{gather*}
=\int_{U} \alpha^{r s}\left(\mathbf{y}+h \mathbf{e}_{k}\right) \frac{\partial\left(D_{k}^{h} w\right)}{\partial y^{r}} \frac{\partial\left(\eta^{2} D_{k}^{h} w\right)}{\partial y^{s}} d y+ \\
\frac{1}{h} \int_{U}\left(\alpha^{r s}\left(\mathbf{y}+h \mathbf{e}_{k}\right)-\alpha^{r s}(\mathbf{y})\right) \frac{\partial w}{\partial y^{r}} \frac{\partial\left(\eta^{2} D_{k}^{h} w\right)}{\partial y^{s}} d y \tag{42.1.11}
\end{gather*}
$$

Now

$$
\begin{equation*}
\frac{\partial\left(\eta^{2} D_{k}^{h} w\right)}{\partial y^{s}}=2 \eta \frac{\partial \eta}{\partial y^{s}} D_{k}^{h} w+\eta^{2} \frac{\partial\left(D_{k}^{h} w\right)}{\partial y^{s}} \tag{42.1.12}
\end{equation*}
$$

therefore,

$$
\begin{align*}
&= \int_{U} \eta^{2} \alpha^{r s}\left(\mathbf{y}+h \mathbf{e}_{k}\right) \frac{\partial\left(D_{k}^{h} w\right)}{\partial y^{r}} \frac{\partial\left(D_{k}^{h} w\right)}{\partial y^{s}} d y \\
&+\left\{\int_{W \cap U} \alpha^{r s}\left(\mathbf{y}+h \mathbf{e}_{k}\right) \frac{\partial\left(D_{k}^{h} w\right)}{\partial y^{r}} 2 \eta \frac{\partial \eta}{\partial y^{s}} D_{k}^{h} w d y\right. \\
&\left.+\frac{1}{h} \int_{W \cap U}\left(\alpha^{r s}\left(\mathbf{y}+h \mathbf{e}_{k}\right)-\alpha^{r s}(\mathbf{y})\right) \frac{\partial w}{\partial y^{r}} \frac{\partial\left(\eta^{2} D_{k}^{h} w\right)}{\partial y^{s}} d y\right\} \equiv A .+\{B .\} . \tag{42.1.13}
\end{align*}
$$

Now consider these two terms. From 42.1.2,

$$
\begin{equation*}
A . \geq \delta \int_{U} \eta^{2}\left|\nabla D_{k}^{h} w\right|^{2} d y \tag{42.1.14}
\end{equation*}
$$

Using the Lipschitz continuity of $\alpha^{r s}$ and 42.1.12,

$$
\begin{gather*}
B . \leq C(\eta, \operatorname{Lip}(\alpha), \alpha)\left\{\left\|D_{k}^{h} w\right\|_{L^{2}(W \cap U)}\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)}+\right. \\
\|\eta \nabla w\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)}\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)} \\
\left.+\|\eta \nabla w\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)}\left\|D_{k}^{h} w\right\|_{L^{2}(W \cap U)}\right\} .  \tag{42.1.15}\\
\leq C(\eta, \operatorname{Lip}(\alpha), \alpha) C_{\varepsilon}\left(\left\|D_{k}^{h} w\right\|_{L^{2}(W \cap U)}^{2}+\|\eta \nabla w\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)}^{2}\right)+ \\
\varepsilon C(\eta, \operatorname{Lip}(\alpha), \alpha)\left(\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)}^{2}+\left\|D_{k}^{h} w\right\|_{L^{2}(W \cap U)}^{2}\right) . \tag{42.1.16}
\end{gather*}
$$

Now

$$
\begin{equation*}
\left\|D_{k}^{h} w\right\|_{L^{2}(W)} \leq\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2} . \tag{42.1.17}
\end{equation*}
$$

To see this, observe that if $w$ is smooth, then

$$
\begin{aligned}
& \left(\int_{W}\left|\frac{w\left(\mathbf{y}+h \mathbf{e}_{k}\right)-w(\mathbf{y})}{h}\right|^{2} d y\right)^{1 / 2} \\
\leq & \left(\int_{W}\left|\frac{1}{h} \int_{0}^{h} \nabla w\left(\mathbf{y}+t \mathbf{e}_{k}\right) \cdot \mathbf{e}_{k} d t\right|^{2} d y\right)^{1 / 2}
\end{aligned}
$$

$$
\leq\left(\int_{0}^{h}\left(\int_{W}\left|\nabla w\left(\mathbf{y}+t \mathbf{e}_{k}\right) \cdot \mathbf{e}_{k}\right|^{2} d y\right)^{1 / 2} \frac{d t}{h}\right) \leq\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}
$$

so by density of such functions in $H^{1}(U), 42.1 .17$ holds. Therefore, changing $\varepsilon$, yields

$$
\begin{equation*}
B . \leq C_{\varepsilon}(\eta, \operatorname{Lip}(\alpha), \alpha)\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)}^{2} \tag{42.1.18}
\end{equation*}
$$

With 42.1.14 and 42.1.18 established, consider the other terms of 42.1.7.

$$
\begin{align*}
& \left|\int_{U} f z d y\right| \\
& \leq\left|\int_{U} f\left(-D_{k}^{-h} \eta^{2} D_{k}^{h} w\right) d y\right| \\
& \leq\left(\int_{U}|f|^{2} d y\right)^{1 / 2}\left(\int_{U}\left|D_{k}^{-h}\left(\eta^{2} D_{k}^{h} w\right)\right|^{2} d y\right)^{1 / 2} \\
& \leq\|f\|_{L^{2}(U)}\left\|\nabla\left(\eta^{2} D_{k}^{h} w\right)\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)} \\
& \leq\|f\|_{L^{2}(U)}\left(\left\|2 \eta \nabla \eta D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}+\left\|\eta^{2} \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}\right) \\
& \leq C\|f\|_{L^{2}(U)}| | \nabla w\left\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}+\right\| f\left\|_{L^{2}(U)} \mid\right\| \eta \nabla D_{k}^{h} w \|_{L^{2}\left(U ; \mathbb{R}^{n}\right)} \\
& \leq C_{\varepsilon}\left(\|f\|_{L^{2}(U)}^{2}+\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}\right)+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}  \tag{42.1.19}\\
& \left|\int_{U} h_{s}(\mathbf{y}) \frac{\partial z}{\partial y^{s}} d y\right| \\
& \leq\left|\int_{U} h_{s}(\mathbf{y}) \frac{\partial\left(-D_{k}^{-h}\left(\eta^{2} D_{k}^{h} w\right)\right)}{\partial y^{s}} d y\right| \\
& \leq\left|\int_{U} D_{k}^{h} h_{s}(\mathbf{y}) \frac{\partial\left(\left(\eta^{2} D_{k}^{h} w\right)\right)}{\partial y^{s}}\right| \\
& \leq \int_{U}\left|D_{k}^{h} h_{s} 2 \eta \frac{\partial \eta}{\partial y^{s}} D_{k}^{h} w\right| d y+\int_{U}\left|\left(\eta D_{k}^{h} h_{s}\right)\left(\eta \frac{\partial\left(D_{k}^{h} w\right)}{\partial y^{s}}\right)\right| d y \\
& \leq C \sum_{s}\left\|h_{S}\right\|_{H^{1}(U)}\left(\|w\|_{H^{1}(U)}+\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}\right) \\
& \leq C_{\varepsilon} \sum_{s}\left\|h_{s}\right\|_{H^{1}(U)}^{2}+\|w\|_{H^{1}(U)}^{2}+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2} . \tag{42.1.20}
\end{align*}
$$

The following inequalities in 42.1.14,42.1.18, 42.1.19and 42.1.20 are summarized here.

$$
A . \geq \delta \int_{U} \eta^{2}\left|\nabla D_{k}^{h} w\right|^{2} d y
$$

$$
\begin{gathered}
B . \leq C_{\varepsilon}(\eta, \operatorname{Lip}(\alpha), \alpha)\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(W \cap U ; \mathbb{R}^{n}\right)}^{2} \\
\left|\int_{U} f z d y\right| \leq C_{\varepsilon}\left(\|f\|_{L^{2}(U)}^{2}+\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}\right)+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2} \\
\left|\int_{U} h_{s}(\mathbf{y}) \frac{\partial z}{\partial y^{s}} d y\right| \leq
\end{gathered} \begin{gathered}
\leq \sum_{s}\left\|h_{s}\right\|_{H^{1}(U)}^{2} \\
+\|w\|_{H^{1}(U)}^{2}+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}
\end{gathered}
$$

Therefore,

$$
\begin{aligned}
& \delta\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2} \\
\leq & C_{\varepsilon}(\eta, \operatorname{Lip}(\alpha), \alpha)\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2} \\
& +C_{\varepsilon} \sum_{s}\left\|h_{S}\right\|_{H^{1}(U)}^{2}+\|w\|_{H^{1}(U)}^{2}+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2} \\
+ & C_{\varepsilon}\left(\|f\|_{L^{2}(U)}^{2}+\|\nabla w\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}\right)+\varepsilon\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2}
\end{aligned}
$$

Letting $\varepsilon$ be small enough and adjusting constants yields

$$
\begin{gathered}
\left\|\nabla D_{k}^{h} w\right\|_{L^{2}\left(U_{1} ; \mathbb{R}^{n}\right)}^{2} \leq\left\|\eta \nabla D_{k}^{h} w\right\|_{L^{2}\left(U ; \mathbb{R}^{n}\right)}^{2} \leq \\
C\left(\|w\|_{H^{1}(U)}^{2}+\|f\|_{L^{2}(U)}^{2}+C_{\varepsilon} \sum_{s}\left\|h_{s}\right\|_{H^{1}(U)}^{2}\right)
\end{gathered}
$$

where the constant, $C$, depends on $\eta, \operatorname{Lip}(\alpha), \alpha, \delta$. Since this holds for all $h$ small enough, it follows $\frac{\partial w}{\partial y^{k}} \in H^{1}\left(U_{1}\right)$ and

$$
\begin{gather*}
\left\|\nabla \frac{\partial w}{\partial y^{k}}\right\|_{L^{2}\left(U_{1} ; \mathbb{R}^{n}\right)}^{2} \leq \\
C\left(\|w\|_{H^{1}(U)}^{2}+\|f\|_{L^{2}(U)}^{2}+C_{\varepsilon} \sum_{s}\left\|h_{s}\right\|_{H^{1}(U)}^{2}\right) \tag{42.1.21}
\end{gather*}
$$

for each $k<n$. It remains to estimate $\left\|\frac{\partial^{2} w}{\partial y_{n}^{2}}\right\|_{L^{2}\left(U_{1}\right)}^{2}$. To do this return to 42.1 .7 which must hold for all $z \in C_{c}^{\infty}\left(U_{1}\right)$. Therefore, using 42.1.7 it follows that for all $z \in C_{c}^{\infty}\left(U_{1}\right)$,

$$
\int_{U} \alpha^{r s}(\mathbf{y}) \frac{\partial w}{\partial y^{r}} \frac{\partial z}{\partial y^{s}} d y=-\int_{U} \frac{\partial h_{s}}{\partial y^{s}} z d y+\int_{U} f z d y
$$

Now from the Lipschitz assumption on $\alpha^{r s}$, it follows

$$
\begin{aligned}
F \equiv & \sum_{r, s \leq n-1} \frac{\partial}{\partial y^{s}}\left(\alpha^{r s} \frac{\partial w}{\partial y^{r}}\right) \\
& +\sum_{\substack{s \leq n-1}} \frac{\partial}{\partial y^{s}}\left(\alpha^{n s} \frac{\partial w}{\partial y^{n}}\right)-\sum_{s} \frac{\partial h_{s}}{\partial y^{s}}+f \\
\in & L^{2}\left(U_{1}\right)
\end{aligned}
$$

and

$$
\begin{equation*}
\|F\|_{L^{2}\left(U_{1}\right)} \leq C\left(\|w\|_{H^{1}(U)}^{2}+\|f\|_{L^{2}(U)}^{2}+C_{\varepsilon} \sum_{s}\left\|h_{s}\right\|_{H^{1}(U)}^{2}\right) . \tag{42.1.22}
\end{equation*}
$$

Therefore, from density of $C_{c}^{\infty}\left(U_{1}\right)$ in $L^{2}\left(U_{1}\right)$,

$$
-\frac{\partial}{\partial y^{n}}\left(\alpha^{n n}(\mathbf{y}) \frac{\partial w}{\partial y^{n}}\right)=F, \text { no sum on } n
$$

and so

$$
-\frac{\partial \alpha^{n n}}{\partial y^{n}} \frac{\partial w}{\partial y^{n}}-\alpha^{n n} \frac{\partial^{2} w}{\partial\left(y^{n}\right)^{2}}=F
$$

By 42.1.2 $\alpha^{n n}(\mathbf{y}) \geq \delta$ and so it follows from 42.1.22 that there exists a constant, $C$ depending on $\delta$ such that

$$
\left|\frac{\partial^{2} w}{\partial\left(y^{n}\right)^{2}}\right|_{L^{2}\left(U_{1}\right)} \leq C\left(|F|_{L^{2}\left(U_{1}\right)}+\|w\|_{H^{1}(U)}\right)
$$

which with 42.1 .21 and 42.1 .22 implies the existence of a constant, $C$ depending on $\delta$ such that

$$
\|w\|_{H^{2}\left(U_{1}\right)}^{2} \leq C\left(\|w\|_{H^{1}(U)}^{2}+\|f\|_{L^{2}(U)}^{2}+C_{\varepsilon} \sum_{s}\left\|h_{S}\right\|_{H^{1}(U)}^{2}\right),
$$

proving the lemma.
What if more regularity is known for $f, h_{s}, \alpha^{r s}$ and $w$ ? Could more be said about the regularity of the solution? The answer is yes and is the content of the next corollary.

First here is some notation. For $\alpha$ a multi-index with $|\alpha|=k-1, \alpha=\left(\alpha_{1}, \cdots, \alpha_{n}\right)$ define

$$
D_{\alpha}^{h} l(\mathbf{y}) \equiv \prod_{k=1}^{n}\left(D_{k}^{h}\right)^{\alpha_{k}} l(\mathbf{y})
$$

Also, for $\alpha$ and $\tau$ multi indices, $\tau<\alpha$ means $\tau_{i}<\alpha_{i}$ for each $i$.
Corollary 42.1.2 Suppose in the context of Lemma 42.1.1 the following for $k \geq 1$.

$$
\begin{aligned}
w & \in H^{k}(U), \\
\alpha^{r s} & \in C^{k-1,1}(\bar{U}), \\
h_{s} & \in H^{k}(U), \\
f & \in H^{k-1}(U),
\end{aligned}
$$

and

$$
\begin{equation*}
\int_{U} \alpha^{r s}(\mathbf{y}) \frac{\partial w}{\partial y^{r}} \frac{\partial z}{\partial y^{s}} d y+\int_{U} h_{s}(\mathbf{y}) \frac{\partial z}{\partial y^{s}} d y=\int_{U} f z d y \tag{42.1.23}
\end{equation*}
$$

for all $z \in H^{1}(U)$ or $H_{0}^{1}(U)$ such that $\operatorname{spt}(z) \subseteq V$. Then there exists $C$ independent of $w$ such that

$$
\begin{equation*}
\|w\|_{H^{k+1}\left(U_{1}\right)} \leq C\left(\|f\|_{H^{k-1}(U)}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(U)}+\|w\|_{H^{k}(U)}\right) . \tag{42.1.24}
\end{equation*}
$$

Proof: The proof involves the following claim which is proved using the conclusion of Lemma 42.1.1 on Page 1393.

Claim : If $\alpha=\left(\alpha^{\prime}, 0\right)$ where $\left|\alpha^{\prime}\right| \leq k-1$, then there exists a constant independent of $w$ such that

$$
\begin{equation*}
\left\|D^{\alpha} w\right\|_{H^{2}\left(U_{1}\right)} \leq C\left(\|f\|_{H^{k-1}(U)}+\sum_{s}\left\|h_{s}\right\|_{H^{k}(U)}+\|w\|_{H^{k}(U)}\right) . \tag{42.1.25}
\end{equation*}
$$

Proof of claim: First note that if $|\alpha|=0$, then 42.1.25 follows from Lemma 42.1.1 on Page 1393. Now suppose the conclusion of the claim holds for all $|\alpha| \leq j-1$ where $j<k$. Let $|\alpha|=j$ and $\alpha=\left(\alpha^{\prime}, 0\right)$. Then for $z \in H^{1}(U)$ having compact support in $V$, it follows that for $h$ small enough,

$$
D_{\alpha}^{-h} z \in H^{1}(U), \operatorname{spt}\left(D_{\alpha}^{h} z\right) \subseteq V
$$

Therefore, you can replace $z$ in 42.1.23 with $D_{\alpha}^{-h} z$. Now note that you can apply the following manipulation.

$$
\int_{U} p(\mathbf{y}) D_{\alpha}^{-h} z(\mathbf{y}) d y=\int_{U} D_{\alpha}^{h} p(\mathbf{y}) z(\mathbf{y}) d y
$$

and obtain

$$
\begin{equation*}
\int_{U}\left(D_{\alpha}^{h}\left(\alpha^{r s} \frac{\partial w}{\partial y^{r}}\right) \frac{\partial z}{\partial y^{s}}+D_{\alpha}^{h}\left(h_{s}\right) \frac{\partial z}{\partial y^{s}}\right) d y=\int_{U}\left(\left(D_{\alpha}^{h} f\right) z\right) d y \tag{42.1.26}
\end{equation*}
$$

Letting $h \rightarrow 0$, this gives

$$
\int_{U}\left(D^{\alpha}\left(\alpha^{r s} \frac{\partial w}{\partial y^{r}}\right) \frac{\partial z}{\partial y^{s}}+D^{\alpha}\left(h_{s}\right) \frac{\partial z}{\partial y^{s}}\right) d y=\int_{U}\left(\left(D^{\alpha} f\right) z\right) d y
$$

Now

$$
D^{\alpha}\left(\alpha^{r s} \frac{\partial w}{\partial y^{r}}\right)=\alpha^{r s} \frac{\partial\left(D^{\alpha} w\right)}{\partial y^{r}}+\sum_{\tau<\alpha} C(\tau) D^{\alpha-\tau}\left(\alpha^{r s}\right) \frac{\partial\left(D^{\tau} w\right)}{\partial y^{r}}
$$

where $C(\tau)$ is some coefficient. Therefore, from 42.1.26,

$$
\int_{U} \alpha^{r s} \frac{\partial\left(D^{\alpha} w\right)}{\partial y^{r}} \frac{\partial z}{\partial y^{s}} d y+\int_{U}\left(\sum_{\tau<\alpha} C(\tau) D^{\alpha-\tau}\left(\alpha^{r s}\right) \frac{\partial\left(D^{\tau} w\right)}{\partial y^{r}}+D^{\alpha}\left(h_{s}\right)\right) \frac{\partial z}{\partial y^{s}} d y
$$

$$
\begin{equation*}
=\int_{U}\left(D^{\alpha} f\right) z d y \tag{42.1.27}
\end{equation*}
$$

Let $\widehat{U}_{1}$ be as indicated in the following picture

Now apply the induction hypothesis to $\widehat{U}_{1}$ in order to write

$$
\begin{gathered}
\left\|\frac{\partial\left(D^{\tau} w\right)}{\partial y^{r}}\right\|_{H^{1}\left(\widehat{U}_{1}\right)} \leq\left\|D^{\tau} w\right\|_{H^{2}\left(\widehat{U}_{1}\right)} \\
\leq C\left(\|f\|_{H^{k-1}(U)}+\sum_{s}\left\|h_{s}\right\|_{H^{k}(U)}+\|w\|_{H^{k}(U)}\right)
\end{gathered}
$$

Since $\alpha^{r s} \in C^{k-1,1}(\bar{U})$, it follows that each term from the sum in 42.1.27 satisfies an inequality of the form

$$
\begin{gathered}
\left\|C(\tau) D^{\alpha-\tau}\left(\alpha^{r s}\right) \frac{\partial\left(D^{\tau} w\right)}{\partial y^{r}}\right\|_{H^{1}\left(\widehat{U}_{1}\right)} \leq \\
C\left(\|f\|_{H^{k-1}(U)}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(U)}+\|w\|_{H^{k}(U)}\right)
\end{gathered}
$$

and consequently,

$$
\begin{gather*}
\left\|\sum_{\tau<\alpha} C(\tau) D^{\alpha-\tau}\left(\alpha^{r s}\right) \frac{\partial\left(D^{\tau} w\right)}{\partial y^{r}}+D^{\alpha}\left(h_{s}\right)\right\|_{H^{1}\left(\widehat{U}_{1}\right)} \leq \\
C\left(\|f\|_{H^{k-1}(U)}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(U)}+\|w\|_{H^{k}(U)}\right) . \tag{42.1.28}
\end{gather*}
$$

Now consider 42.1.27. The equation remains true if you replace $U$ with $\widehat{U}_{1}$ and require that $\operatorname{spt}(z) \subseteq \widehat{U}_{1}$. Therefore, by Lemma 42.1.1 on Page 1393 there exists a constant, $C$ independent of $w$ such that

$$
\left\|D^{\alpha} w\right\|_{H^{2}\left(U_{1}\right)} \leq C\left(\left\|D^{\alpha} f\right\|_{L^{2}\left(\widehat{U}_{1}\right)}+\left\|D^{\alpha} w\right\|_{H^{1}\left(\widehat{U}_{1}\right)}+\right.
$$

$$
\left.+\sum_{s}\left\|\sum_{\tau<\alpha} C(\tau) D^{\alpha-\tau}\left(\alpha^{r s}\right) \frac{\partial\left(D^{\tau} w\right)}{\partial y^{r}}+D^{\alpha}\left(h_{s}\right)\right\|_{H^{1}\left(\widehat{U}_{1}\right)}\right)
$$

and by 42.1.28, this implies

$$
\left\|D^{\alpha} w\right\|_{H^{2}\left(U_{1}\right)} \leq C\left(\|f\|_{H^{k-1}(U)}+\|w\|_{H^{k}(U)}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(U)}\right)
$$

which proves the Claim.
To establish 42.1 .24 it only remains to verify that if $|\alpha| \leq k+1$, then

$$
\begin{equation*}
\left\|D^{\alpha} w\right\|_{L^{2}\left(U_{1}\right)} \leq C\left(\|f\|_{H^{k-1}(U)}+\|w\|_{H^{k}(U)}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(U)}\right) . \tag{42.1.29}
\end{equation*}
$$

If $|\alpha|<k+1$, there is nothing to show because it is given that $w \in H^{k}(U)$. Therefore, assume $|\alpha|=k+1$. If $\alpha_{n}$ equals 0 the conclusion follows from the claim because in this case, you can subtract 1 from a pair of positive $\alpha_{i}$ and obtain a new multi index, $\beta$ such that $|\beta|=k-1$ and $\beta_{n}=0$ and then from the claim,

$$
\left\|D^{\alpha} w\right\|_{L^{2}\left(U_{1}\right)} \leq\left\|D^{\beta}\right\|_{H^{2}\left(U_{1}\right)} \leq C\left(\|f\|_{H^{k-1}(U)}+\|w\|_{H^{k}(U)}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(U)}\right)
$$

If $\alpha_{n}=1$, then subtract 1 from some positive $\alpha_{i}$ and consider

$$
\beta=\left(\alpha_{1}, \cdots, \alpha_{i}-1, \alpha_{i+1}, \cdots, \alpha_{n-1}, 0\right)
$$

Then from the claim,

$$
\left\|D^{\alpha} w\right\|_{L^{2}\left(U_{1}\right)} \leq\left\|D^{\beta} w\right\|_{H^{2}\left(U_{1}\right)} \leq C\left(\|f\|_{H^{k-1}(U)}+\|w\|_{H^{k}(U)}+\sum_{s}\left\|h_{s}\right\|_{H^{k}(U)}\right)
$$

Suppose 42.1.29 holds for $\alpha_{n} \leq j-1$ where $j-1 \geq 1$ and consider $\alpha$ for which $|\alpha|=k+1$ and $\alpha_{n}=j$. Let

$$
\beta \equiv\left(\alpha_{1}, \cdots, \alpha_{n-1}, \alpha_{n}-2\right)
$$

Thus $D^{\alpha}=D^{\beta} D_{n}^{2}$. Restricting 42.1.23 to $z \in C_{c}^{\infty}\left(U_{1}\right)$ and using the density of this set of functions in $L^{2}\left(U_{1}\right)$, it follows that

$$
-\frac{\partial}{\partial y^{s}}\left(\alpha^{r s}(\mathbf{y}) \frac{\partial w}{\partial y^{r}}\right)-\frac{\partial h_{s}}{\partial y^{s}}=f
$$

Therefore, from the product rule,

$$
\frac{\partial \alpha^{r s}}{\partial y^{s}} \frac{\partial w}{\partial y^{r}}+\alpha^{r s} \frac{\partial^{2} w}{\partial y^{s} \partial y^{r}}+\frac{\partial h_{s}}{\partial y^{s}}=-f
$$

and so

$$
\begin{aligned}
\alpha^{n n} D_{n}^{2} w= & -\left(\frac{\partial \alpha^{r s}}{\partial y^{s}} \frac{\partial w}{\partial y^{r}}+\sum_{r \leq n-1} \sum_{s \leq n-1} \alpha^{r s} \frac{\partial^{2} w}{\partial y^{s} \partial y^{r}}+\right. \\
& \left.\sum_{s} \alpha^{n s} \frac{\partial^{2} w}{\partial y^{s} \partial y^{n}}+\sum_{r} \alpha^{r n} \frac{\partial^{2} w}{\partial y^{n} \partial y^{r}}+\frac{\partial h_{s}}{\partial y^{s}}+f\right) .
\end{aligned}
$$

As noted earlier, the condition, 42.1.2 implies $\alpha^{n n}(\mathbf{y}) \geq \delta>0$ and so

$$
\begin{aligned}
D_{n}^{2} w= & -\frac{1}{\alpha^{n n}}\left(\frac{\partial \alpha^{r s}}{\partial y^{s}} \frac{\partial w}{\partial y^{r}}+\sum_{r \leq n-1} \sum_{s \leq n-1} \alpha^{r s} \frac{\partial^{2} w}{\partial y^{s} \partial y^{r}}+\right. \\
& \left.\sum_{s} \alpha^{n s} \frac{\partial^{2} w}{\partial y^{s} \partial y^{n}}+\sum_{r} \alpha^{r n} \frac{\partial^{2} w}{\partial y^{n} \partial y^{r}}+\frac{\partial h_{s}}{\partial y^{s}}+f\right) .
\end{aligned}
$$

It follows from $D^{\alpha}=D^{\beta} D_{n}^{2}$ that

$$
\begin{aligned}
D^{\alpha} w= & D^{\beta}\left[-\frac{1}{\alpha^{n n}}\left(\frac{\partial \alpha^{r s}}{\partial y^{s}} \frac{\partial w}{\partial y^{r}}+\sum_{r \leq n-1} \sum_{s \leq n-1} \alpha^{r s} \frac{\partial^{2} w}{\partial y^{s} \partial y^{r}}+\right.\right. \\
& \left.\left.\sum_{s} \alpha^{n s} \frac{\partial^{2} w}{\partial y^{s} \partial y^{n}}+\sum_{r} \alpha^{r n} \frac{\partial^{2} w}{\partial y^{n} \partial y^{r}}+\frac{\partial h_{s}}{\partial y^{s}}+f\right)\right]
\end{aligned}
$$

Now you note that terms like $D^{\beta}\left(\frac{\partial^{2} w}{\partial y^{5} \partial y^{n}}\right)$ have $\alpha_{n}=j-1$ and so, from the induction hypothesis along with the assumptions on the given functions,

$$
\left\|D^{\alpha} w\right\|_{L^{2}\left(U_{1}\right)} \leq C\left(\|f\|_{H^{k-1}(U)}+\|w\|_{H^{k}(U)}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(U)}\right)
$$

This proves the corollary.

### 42.2 The Case Of Bounded Open Sets

The main interest in all this is in the application to bounded open sets. Recall the following definition.

Definition 42.2.1 A bounded open subset, $\Omega$, of $\mathbb{R}^{n}$ has a $C^{m, 1}$ boundary if it satisfies the following conditions. For each $p \in \Gamma \equiv \bar{\Omega} \backslash \Omega$, there exists an open set, $W$, containing $p$, an open interval $(0, b)$, a bounded open box $U^{\prime} \subseteq \mathbb{R}^{n-1}$, and an affine orthogonal transformation, $R_{W}$ consisting of a distance preserving linear transformation followed by a translation such that

$$
\begin{gather*}
R_{W} W=U^{\prime} \times(0, b),  \tag{42.2.30}\\
R_{W}(W \cap \Omega)=\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U^{\prime}, 0<u_{n}<\phi_{W}\left(\mathbf{u}^{\prime}\right)\right\} \tag{42.2.31}
\end{gather*}
$$

where $\phi_{W} \in C^{m, 1}\left(\overline{U^{\prime}}\right)$ meaning $\phi_{W}$ is the restriction to $U^{\prime}$ of a function, still denoted by $\phi_{W}$ which is in $C^{m, 1}\left(\mathbb{R}^{n-1}\right)$ and

$$
\inf \left\{\phi_{W}\left(\mathbf{u}^{\prime}\right): \mathbf{u}^{\prime} \in U^{\prime}\right\}>0
$$

The following picture depicts the situation.

For the situation described in the above definition, let $\mathbf{h}_{W}: U^{\prime} \rightarrow \Gamma \cap W$ be defined by

$$
\mathbf{h}_{W}\left(\mathbf{u}^{\prime}\right) \equiv R_{W}^{-1}\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)\right), \mathbf{g}_{W}(\mathbf{x}) \equiv\left(R_{W} \mathbf{x}\right)^{\prime}, \mathbf{H}_{W}(\mathbf{u}) \equiv R_{W}^{-1}\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)-u_{n}\right) .
$$

where $\mathbf{x}^{\prime} \equiv\left(x_{1}, \cdots, x_{n-1}\right)$ for $\mathbf{x}=\left(x_{1}, \cdots, x_{n}\right)$. Thus $\mathbf{g}_{W} \circ \mathbf{h}_{W}=\mathrm{id}$ on $U^{\prime}$ and $\mathbf{h}_{W} \circ \mathbf{g}_{W}=\mathrm{id}$ on $\Gamma \cap W$. Also note that $\mathbf{H}_{W}$ is defined on all of $\mathbb{R}^{n}$ is $C^{m, 1}$, and has an inverse with the same properties. To see this, let $\mathbf{G}_{W}(\mathbf{u})=\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)-u_{n}\right)$. Then $\mathbf{H}_{W}=R_{W}^{-1} \circ \mathbf{G}_{W}$ and $\mathbf{G}_{W}^{-1}=\left(\mathbf{u}^{\prime}, \phi_{W}\left(\mathbf{u}^{\prime}\right)-u_{n}\right)$ and so $\mathbf{H}_{W}^{-1}=\mathbf{G}_{W}^{-1} \circ R_{W}$. Note also that as indicated in the picture,

$$
R_{W}(W \cap \Omega)=\left\{\mathbf{u} \in \mathbb{R}^{n}: \mathbf{u}^{\prime} \in U^{\prime} \text { and } 0<u_{n}<\phi_{W}\left(\mathbf{u}^{\prime}\right)\right\}
$$

Since $\Gamma=\partial \Omega$ is compact, there exist finitely many of these open sets, $W$, denoted by $\left\{W_{i}\right\}_{i=1}^{q}$ such that $\Gamma \subseteq \cup_{i=1}^{q} W_{i}$. Let the corresponding sets, $U^{\prime}$ be denoted by $U_{i}^{\prime}$ and let the functions, $\phi$ be denoted by $\phi_{i}$. Also let $\mathbf{h}_{i}=\mathbf{h}_{W_{i}}, G_{W_{i}}=G_{i}$ etc. Now let

$$
\mathbf{\square}_{i}: \mathbf{G}_{i} R_{i}(\Omega \cap W) \equiv V_{i} \rightarrow \Omega \cap W_{i}
$$

be defined by

$$
\mathbf{m}_{i}(\mathbf{y}) \equiv R_{i}^{-1} \circ \mathbf{G}_{i}^{-1}(\mathbf{y})
$$

Thus $\varpi_{i}, \varpi_{i}^{-1} \in C^{m, 1}\left(\mathbb{R}^{n}\right)$. The following picture might be helpful.

Therefore, by Lemma 39.3.3 on Page 1356, it follows that for $t \in[m, m+1)$,

$$
\mathbf{m}_{i}^{*} \in \mathscr{L}\left(H^{t}\left(W_{i} \cap \Omega\right), H^{t}\left(V_{i}\right)\right)
$$

Assume

$$
\begin{equation*}
a^{i j}(\mathbf{x}) v_{i} v_{j} \geq \delta|\mathbf{v}|^{2} \tag{42.2.32}
\end{equation*}
$$

Lemma 42.2.2 Let $W$ be one of the sets described in the above definition and let $m \geq 1$. Let $W_{1} \subseteq \overline{W_{1}} \subseteq W$ where $W_{1}$ is an open set. Suppose also that

$$
\begin{aligned}
u & \in H^{1}(\Omega), \\
\alpha^{r s} & \in C^{0,1}(\bar{\Omega}), \\
f & \in L^{2}(\Omega), \\
h_{k} & \in H^{1}(\Omega),
\end{aligned}
$$

and that for all $v \in H^{1}(\Omega \cap W)$ such that $\operatorname{spt}(v) \subseteq \Omega \cap W$,

$$
\begin{equation*}
\int_{\Omega} a^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x}) d x+\int_{\Omega} h_{k}(\mathbf{x}) v_{, k}(\mathbf{x}) d x=\int_{\Omega} f(\mathbf{x}) v(\mathbf{x}) d x \tag{42.2.33}
\end{equation*}
$$

Then there exists a constant, $C$, independent of $f, u$, and $g$ such that

$$
\begin{equation*}
\|u\|_{H^{2}\left(\Omega \cap W_{1}\right)}^{2} \leq C\left(\|f\|_{L^{2}(\Omega)}^{2}+\|u\|_{H^{1}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{1}(\Omega)}^{2}\right) . \tag{42.2.34}
\end{equation*}
$$

Proof: Let

$$
E \equiv\left\{v \in H^{1}(\Omega \cap W): \operatorname{spt}(v) \subseteq W\right\}
$$

$u$ restricted to $W \cap \Omega$ is in $H^{1}(\Omega \cap W)$ and

$$
\begin{equation*}
\int_{\Omega \cap W} a^{i j}(\mathbf{x}) u_{, i} v_{, j} d x+\int_{\Omega} h_{k}(\mathbf{x}) v_{, k}(\mathbf{x}) d x=\int_{\Omega} f(\mathbf{x}) v(\mathbf{x}) d x \text { for all } v \in E . \tag{42.2.35}
\end{equation*}
$$

Now let $\square_{i}(\mathbf{y})=\mathbf{x}$. For this particular $W$, denote $\Phi_{i}$ more simply by $\Phi, U_{i} \equiv \Phi_{i}\left(\Omega \cap W_{i}\right)$ by $U$, and $V_{i}$ by $V$. Denoting the coordinates of $V$ by $\mathbf{y}$, and letting $u(\mathbf{x}) \equiv w(\mathbf{y})$ and $v(\mathbf{x}) \equiv$ $z(\mathbf{y})$, it follows that in terms of the new coordinates, 42.2.35 takes the form

$$
\begin{aligned}
& \int_{U} a^{i j}(\Phi(\mathbf{y})) \frac{\partial w}{\partial y^{r}} \frac{\partial y^{r}}{\partial x^{i}} \frac{\partial z}{\partial y^{s}} \frac{\partial y^{s}}{\partial x^{j}}|\operatorname{det} D \Phi(\mathbf{y})| d y \\
& +\int_{U} h_{k}(\Phi(\mathbf{y})) \frac{\partial z}{\partial y^{l}} \frac{\partial y^{l}}{\partial x^{k}}|\operatorname{det} D \Phi(\mathbf{y})| d x \\
= & \int_{U} f(\Phi(\mathbf{y})) z(\mathbf{y})|\operatorname{det} D \Phi(\mathbf{y})| d y
\end{aligned}
$$

Let

$$
\begin{align*}
\alpha^{r s}(\mathbf{y}) & \equiv a^{i j}(\Phi(\mathbf{y})) \frac{\partial y^{r}}{\partial x^{i}} \frac{\partial y^{s}}{\partial x^{j}}|\operatorname{det} D \Phi(\mathbf{y})|  \tag{42.2.36}\\
\widetilde{h}_{l}(\mathbf{y}) & \equiv h_{k}(\Phi(\mathbf{y})) \frac{\partial y^{l}}{\partial x^{k}}|\operatorname{det} D \Phi(\mathbf{y})| \tag{42.2.37}
\end{align*}
$$

and

$$
\begin{equation*}
\widetilde{f}(\mathbf{y}) \equiv \Phi^{*} f|\operatorname{det} D \Phi|(\mathbf{y}) \equiv f(\Phi(\mathbf{y}))|\operatorname{det} D \Phi(\mathbf{y})| \tag{42.2.38}
\end{equation*}
$$

Now the function on the right in 42.2 .36 is in $C^{0,1}(\bar{U})$. This is because of the assumption that $m \geq 1$ in the statement of the lemma. This function is therefore a finite product of bounded functions in $C^{0,1}(\bar{U})$.

The function $\widetilde{h_{l}}$ defined in 42.2 .37 is in $H^{1}(U)$ and

$$
\left\|\widetilde{h}_{l}\right\|_{H^{1}(U)} \leq C \sum_{k}\left\|h_{k}\right\|_{H^{1}(\Omega \cap W)}
$$

again because $m \geq 1$.
Finally, the right side of 42.2 .38 is a function in $L^{2}(U)$ by Lemma 39.3.3 on Page 1356 and the observation that $|\operatorname{det} D \Phi(\cdot)| \in C^{0,1}(\bar{U})$ which follows from the assumption of the lemma that $m \geq 1$ so $\Phi \in C^{1,1}\left(\mathbb{R}^{n}\right)$. Also

$$
\|\widetilde{f}\|_{L^{2}(U)} \leq C\|f\|_{L^{2}(\Omega \cap W)}
$$

Therefore, 42.2 .35 is of the form

$$
\begin{equation*}
\int_{U} \alpha^{r s}(\mathbf{y}) w_{, r} z, s d y+\int_{U} \tilde{h}_{l} z_{, l} d y=\int_{U} \tilde{f} z d y \tag{42.2.39}
\end{equation*}
$$

for all $z$ in $H^{1}(U)$ having support in $V$.
Claim: There exists $r>0$ independent of $\mathbf{y} \in \bar{U}$ such that for all $\mathbf{y} \in \bar{U}$,

$$
\alpha^{r s}(\mathbf{y}) v_{r} v_{s} \geq r|\mathbf{v}|^{2}
$$

Proof of the claim: If this is not so, there exist vectors, $\mathbf{v}^{n},\left|\mathbf{v}^{n}\right|=1$, and $\mathbf{y}_{n} \in \bar{U}$ such that $\alpha^{r s}\left(\mathbf{y}_{n}\right) v_{r}^{n} v_{s}^{n} \leq \frac{1}{n}$. Taking a subsequence, there exists $\mathbf{y} \in \bar{U}$ and $|\mathbf{v}|=1$ such that $\alpha^{r s}(\mathbf{y}) v_{r} v_{s}=0$ contradicting 42.2.32.

Therefore, by Lemma 42.1.1, there exists a constant, $C$, independent of $f, g$, and $w$ such that

$$
\|w\|_{H^{2}\left(\Phi^{-1}\left(W_{1} \cap \Omega\right)\right)}^{2} \leq C\left(\|\widetilde{f}\|_{L^{2}(U)}^{2}+\|w\|_{H^{1}(U)}^{2}+\sum_{l}\left\|\widetilde{h}_{l}\right\|_{H^{1}(U)}^{2}\right)
$$

Therefore,

$$
\begin{aligned}
\|u\|_{H^{2}\left(W_{1} \cap \Omega\right)}^{2} & \leq C\left(\|f\|_{L^{2}(W \cap \Omega)}^{2}+\|w\|_{H^{1}(W \cap \Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{1}(W \cap \Omega)}^{2}\right) \\
& \leq C\left(\|f\|_{L^{2}(\Omega)}^{2}+\|w\|_{H^{1}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{1}(\Omega)}^{2}\right)
\end{aligned}
$$

which proves the lemma.
With this lemma here is the main result.
Theorem 42.2.3 Let $\Omega$ be a bounded open set with $C^{1,1}$ boundary as in Definition 42.2.1, let $f \in L^{2}(\Omega), h_{k} \in H^{1}(\Omega)$, and suppose that for all $\mathbf{x} \in \bar{\Omega}$,

$$
a^{i j}(\mathbf{x}) v_{i} v_{j} \geq \delta|\mathbf{v}|^{2}
$$

Suppose also that $u \in H^{1}(\Omega)$ and

$$
\int_{\Omega} a^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x}) d x+\int_{\Omega} h_{k}(\mathbf{x}) v_{, k}(\mathbf{x}) d x=\int_{\Omega} f(\mathbf{x}) v(\mathbf{x}) d x
$$

for all $v \in H^{1}(\Omega)$. Then $u \in H^{2}(\Omega)$ and for some $C$ independent of $f, g$, and $u$,

$$
\|u\|_{H^{2}(\Omega)}^{2} \leq C\left(\|f\|_{L^{2}(\Omega)}^{2}+\|u\|_{H^{1}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{1}(\Omega)}^{2}\right)
$$

Proof: Let the $W_{i}$ for $i=1, \cdots, l$ be as described in Definition 42.2.1. Thus $\partial \Omega \subseteq$ $\cup_{j=1}^{l} W_{j}$. Then let $C_{1} \equiv \partial \Omega \backslash \cup_{i=2}^{l} W_{i}$, a closed subset of $W_{1}$. Let $D_{1}$ be an open set satisfying

$$
C_{1} \subseteq D_{1} \subseteq \overline{D_{1}} \subseteq W_{1}
$$

Then $D_{1}, W_{2}, \cdots, W_{l} \operatorname{cover} \partial \Omega$. Let $C_{2}=\partial \Omega \backslash\left(D_{1} \cup\left(\cup_{i=3}^{l} W_{i}\right)\right)$. Then $C_{2}$ is a closed subset of $W_{2}$. Choose an open set, $D_{2}$ such that

$$
C_{2} \subseteq D_{2} \subseteq \overline{D_{2}} \subseteq W_{2}
$$

Thus $D_{1}, D_{2}, W_{3} \cdots, W_{l}$ covers $\partial \Omega$. Continue in this way to get $\overline{D_{i}} \subseteq W_{i}$, and $\partial \Omega \subseteq \cup_{i=1}^{l} D_{i}$, and $D_{i}$ is an open set. Now let

$$
D_{0} \equiv \Omega \backslash \cup_{i=1}^{l} \overline{D_{i}}
$$

Also, let $\overline{D_{i}} \subseteq V_{i} \subseteq \overline{V_{i}} \subseteq W_{i}$. Therefore, $D_{0}, V_{1}, \cdots, V_{l}$ covers $\Omega$. Then the same estimation process used above yields

$$
\|u\|_{H^{2}\left(D_{0}\right)} \leq C\left(\|f\|_{L^{2}(\Omega)}^{2}+\|u\|_{H^{1}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{1}(\Omega)}^{2}\right)
$$

From Lemma 42.2.2

$$
\|u\|_{H^{2}\left(V_{i} \cap \Omega\right)} \leq C\left(\|f\|_{L^{2}(\Omega)}^{2}+\|u\|_{H^{1}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{1}(\Omega)}^{2}\right)
$$

also. This proves the theorem since

$$
\|u\|_{H^{2}(\Omega)} \leq \sum_{i=1}^{l}\|u\|_{H^{2}\left(V_{i} \cap \Omega\right)}+\|u\|_{H^{2}\left(D_{0}\right)} .
$$

What about the Dirichlet problem? The same differencing procedure as above yields the following.

Theorem 42.2.4 Let $\Omega$ be a bounded open set with $C^{1,1}$ boundarybrownianmotiontheorem as in Definition 42.2.1, let $f \in L^{2}(\Omega), h_{k} \in H^{1}(\Omega)$, and suppose that for all $\mathbf{x} \in \bar{\Omega}$,

$$
a^{i j}(\mathbf{x}) v_{i} v_{j} \geq \delta|\mathbf{v}|^{2}
$$

Suppose also that $u \in H_{0}^{1}(\Omega)$ and

$$
\int_{\Omega} a^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x}) d x+\int_{\Omega} h_{k}(\mathbf{x}) v_{, k}(\mathbf{x}) d x=\int_{\Omega} f(\mathbf{x}) v(\mathbf{x}) d x
$$

for all $v \in H_{0}^{1}(\Omega)$. Then $u \in H^{2}(\Omega)$ and for some $C$ independent of $f, g$, and $u$,

$$
\|u\|_{H^{2}(\Omega)}^{2} \leq C\left(\|f\|_{L^{2}(\Omega)}^{2}+\|u\|_{H^{1}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{1}(\Omega)}^{2}\right)
$$

What about higher regularity?

Lemma 42.2.5 Let $W$ be one of the sets described in Definition 42.2.1 and let $m \geq k$. Let $W_{1} \subseteq \overline{W_{1}} \subseteq W$ where $W_{1}$ is an open set. Suppose also that

$$
\begin{aligned}
u & \in H^{k}(\Omega), \\
\alpha^{r s} & \in C^{k-1,1}(\bar{\Omega}), \\
f & \in H^{k-1}(\Omega), \\
h_{s} & \in H^{k}(\Omega),
\end{aligned}
$$

and that for all $v \in H^{1}(\Omega \cap W)$ such that $\operatorname{spt}(v) \subseteq \Omega \cap W$,

$$
\begin{equation*}
\int_{\Omega} a^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x}) d x+\int_{\Omega} h_{s}(\mathbf{x}) v_{, s}(\mathbf{x}) d x=\int_{\Omega} f(\mathbf{x}) v(\mathbf{x}) d x \tag{42.2.40}
\end{equation*}
$$

Then there exists a constant, $C$, independent of $f, u$, and $g$ such that

$$
\begin{equation*}
\|u\|_{H^{k+1}\left(\Omega \cap W_{1}\right)}^{2} \leq C\left(\|f\|_{H^{k-1}(\Omega)}^{2}+\|u\|_{H^{k}(\Omega)}^{2}+\sum_{s}\left\|h_{s}\right\|_{H^{k}(\Omega)}^{2}\right) . \tag{42.2.41}
\end{equation*}
$$

Proof: Let

$$
E \equiv\left\{v \in H^{k}(\Omega \cap W): \operatorname{spt}(v) \subseteq W\right\}
$$

$u$ restricted to $W \cap \Omega$ is in $H^{k}(\Omega \cap W)$ and

$$
\begin{gather*}
\int_{\Omega \cap W} a^{i j}(\mathbf{x}) u_{, i} v, j d x+\int_{\Omega} h_{s}(\mathbf{x}) v_{, s}(\mathbf{x}) d x \\
=\int_{\Omega} f(\mathbf{x}) v(\mathbf{x}) d x \text { for all } v \in E . \tag{42.2.42}
\end{gather*}
$$

Now let $\mathbf{\Xi}_{i}(\mathbf{y})=\mathbf{x}$. For this particular $W$, denote $\Phi_{i}$ more simply by $\Phi, U_{i} \equiv \Phi_{i}\left(\Omega \cap W_{i}\right)$ by $U$, and $V_{i}$ by $V$. Denoting the coordinates of $V$ by $\mathbf{y}$, and letting $u(\mathbf{x}) \equiv w(\mathbf{y})$ and $v(\mathbf{x}) \equiv$ $z(\mathbf{y})$, it follows that in terms of the new coordinates, 42.2.35 takes the form

$$
\begin{aligned}
& \int_{U} a^{i j}(\Phi(\mathbf{y})) \frac{\partial w}{\partial y^{r}} \frac{\partial y^{r}}{\partial x^{i}} \frac{\partial z}{\partial y^{s}} \frac{\partial y^{s}}{\partial x^{j}}|\operatorname{det} D \Phi(\mathbf{y})| d y \\
& +\int_{U} h_{k}(\Phi(\mathbf{y})) \frac{\partial z}{\partial y^{l}} \frac{\partial y^{l}}{\partial x^{k}}|\operatorname{det} D \Phi(\mathbf{y})| d x \\
= & \int_{U} f(\Phi(\mathbf{y})) z(\mathbf{y})|\operatorname{det} D \Phi(\mathbf{y})| d y
\end{aligned}
$$

Let

$$
\begin{gather*}
\alpha^{r s}(\mathbf{y}) \equiv a^{i j}(\Phi(\mathbf{y})) \frac{\partial y^{r}}{\partial x^{i}} \frac{\partial y^{s}}{\partial x^{j}}|\operatorname{det} D \Phi(\mathbf{y})|  \tag{42.2.43}\\
\widetilde{h}_{l}(\mathbf{y}) \equiv h_{k}(\Phi(\mathbf{y})) \frac{\partial y^{l}}{\partial x^{k}}|\operatorname{det} D \Phi(\mathbf{y})| \tag{42.2.44}
\end{gather*}
$$

and

$$
\begin{equation*}
\widetilde{f}(\mathbf{y}) \equiv \Phi^{*} f|\operatorname{det} D \Phi|(\mathbf{y}) \equiv f(\Phi(\mathbf{y}))|\operatorname{det} D \Phi(\mathbf{y})| \tag{42.2.45}
\end{equation*}
$$

Now the function on the right in 42.2 .43 is in $C^{k, 1}(\bar{U})$. This is because of the assumption that $m \geq k$ in the statement of the lemma. This function is therefore a finite product of bounded functions in $C^{k, 1}(\bar{U})$.

The function $\widetilde{h}_{l}$ defined in 42.2 .44 is in $H^{k}(U)$ and

$$
\left\|\widetilde{h}_{l}\right\|_{H^{k}(U)} \leq C \sum_{S}\left\|h_{s}\right\|_{H^{k}(\Omega \cap W)}
$$

again because $m \geq k$.
Finally, the right side of 42.2 .45 is a function in $H^{k-1}(U)$ by Lemma 39.3.3 on Page 1356 and the observation that $|\operatorname{det} D \Phi(\cdot)| \in C^{k-1,1}(\bar{U})$ which follows from the assumption of the lemma that $m \geq k$ so $\Phi \in C^{k-1,1}\left(\mathbb{R}^{n}\right)$. Also

$$
\|\widetilde{f}\|_{H^{k-1}(U)} \leq C\|f\|_{H^{k-1}(\Omega \cap W)}
$$

Therefore, 42.2.42 is of the form

$$
\begin{equation*}
\int_{U} \alpha^{r s}(\mathbf{y}) w_{, r} z, s d y+\int_{U} \widetilde{h}_{l} z_{, l} d y=\int_{U} \tilde{f} z d y \tag{42.2.46}
\end{equation*}
$$

for all $z$ in $H^{1}(U)$ having support in $V$.
Claim: There exists $r>0$ independent of $\mathbf{y} \in \bar{U}$ such that for all $\mathbf{y} \in \bar{U}$,

$$
\alpha^{r s}(\mathbf{y}) v_{r} v_{s} \geq r|\mathbf{v}|^{2}
$$

Proof of the claim: If this is not so, there exist vectors, $\mathbf{v}^{n},\left|\mathbf{v}^{n}\right|=1$, and $\mathbf{y}_{n} \in \bar{U}$ such that $\alpha^{r s}\left(\mathbf{y}_{n}\right) v_{r}^{n} v_{s}^{n} \leq \frac{1}{n}$. Taking a subsequence, there exists $\mathbf{y} \in \bar{U}$ and $|\mathbf{v}|=1$ such that $\alpha^{r s}(\mathbf{y}) v_{r} v_{s}=0$ contradicting 42.2.32.

Therefore, by Corollary 42.1.2, there exists a constant, $C$, independent of $f, g$, and $w$ such that

$$
\|w\|_{H^{k+1}\left(\Phi^{-1}\left(W_{1} \cap \Omega\right)\right)}^{2} \leq C\left(\|\widetilde{f}\|_{H^{k-1}(U)}^{2}+\|w\|_{H^{k}(U)}^{2}+\sum_{l}\left\|\widetilde{h}_{l}\right\|_{H^{k}(U)}^{2}\right)
$$

Therefore,

$$
\begin{aligned}
\|u\|_{H^{k+1}\left(W_{1} \cap \Omega\right)}^{2} & \leq C\left(\|f\|_{H^{k-1}(W \cap \Omega)}^{2}+\|w\|_{H^{k}(W \cap \Omega)}^{2}+\sum_{s}\left\|h_{S}\right\|_{H^{k}(W \cap \Omega)}^{2}\right) \\
& \leq C\left(\|f\|_{H^{k-1}(\Omega)}^{2}+\|w\|_{H^{k}(\Omega)}^{2}+\sum_{s}\left\|h_{s}\right\|_{H^{k}(\Omega)}^{2}\right)
\end{aligned}
$$

which proves the lemma.
Now here is a theorem which generalizes the one above in the case where more regularity is known.

Theorem 42.2.6 Let $\Omega$ be a bounded open set with $C^{k, 1}$ boundary as in Definition 42.2.1, let $f \in H^{k-1}(\Omega), h_{s} \in H^{k}(\Omega)$, and suppose that for all $\mathbf{x} \in \bar{\Omega}$,

$$
a^{i j}(\mathbf{x}) v_{i} v_{j} \geq \delta|\mathbf{v}|^{2}
$$

Suppose also that $u \in H^{k}(\Omega)$ and

$$
\int_{\Omega} a^{i j}(\mathbf{x}) u_{, i}(\mathbf{x}) v_{, j}(\mathbf{x}) d x+\int_{\Omega} h_{k}(\mathbf{x}) v_{, k}(\mathbf{x}) d x=\int_{\Omega} f(\mathbf{x}) v(\mathbf{x}) d x
$$

for all $v \in H^{k}(\Omega)$. Then $u \in H^{k+1}(\Omega)$ and for some $C$ independent of $f, g$, and $u$,

$$
\|u\|_{H^{k+1}(\Omega)}^{2} \leq C\left(\|f\|_{H^{k-1}(\Omega)}^{2}+\|u\|_{H^{k}(\Omega)}^{2}+\sum_{s}\left\|h_{s}\right\|_{H^{k}(\Omega)}^{2}\right)
$$

Proof: Let the $W_{i}$ for $i=1, \cdots, l$ be as described in Definition 42.2.1. Thus $\partial \Omega \subseteq$ $\cup_{j=1}^{l} W_{j}$. Then let $C_{1} \equiv \partial \Omega \backslash \cup_{i=2}^{l} W_{i}$, a closed subset of $W_{1}$. Let $D_{1}$ be an open set satisfying

$$
C_{1} \subseteq D_{1} \subseteq \overline{D_{1}} \subseteq W_{1}
$$

Then $D_{1}, W_{2}, \cdots, W_{l} \operatorname{cover} \partial \Omega$. Let $C_{2}=\partial \Omega \backslash\left(D_{1} \cup\left(\cup_{i=3}^{l} W_{i}\right)\right)$. Then $C_{2}$ is a closed subset of $W_{2}$. Choose an open set, $D_{2}$ such that

$$
C_{2} \subseteq D_{2} \subseteq \overline{D_{2}} \subseteq W_{2}
$$

Thus $D_{1}, D_{2}, W_{3} \cdots, W_{l}$ covers $\partial \Omega$. Continue in this way to get $\overline{D_{i}} \subseteq W_{i}$, and $\partial \Omega \subseteq \cup_{i=1}^{l} D_{i}$, and $D_{i}$ is an open set. Now let

$$
D_{0} \equiv \Omega \backslash \cup_{i=1}^{l} \overline{D_{i}}
$$

Also, let $\overline{D_{i}} \subseteq V_{i} \subseteq \overline{V_{i}} \subseteq W_{i}$. Therefore, $D_{0}, V_{1}, \cdots, V_{l}$ covers $\Omega$. Then the same estimation process used above yields

$$
\|u\|_{H^{k+1}\left(D_{0}\right)} \leq C\left(\|f\|_{H^{k-1}(\Omega)}^{2}+\|u\|_{H^{k}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{k}(\Omega)}^{2}\right)
$$

From Lemma 42.2.5

$$
\|u\|_{H^{k+1}\left(V_{i} \cap \Omega\right)} \leq C\left(\|f\|_{H^{k-1}(\Omega)}^{2}+\|u\|_{H^{k}(\Omega)}^{2}+\sum_{k}\left\|h_{k}\right\|_{H^{k}(\Omega)}^{2}\right)
$$

also. This proves the theorem since

$$
\|u\|_{H^{k+1}(\Omega)} \leq \sum_{i=1}^{l}\|u\|_{H^{k+1}\left(V_{i} \cap \Omega\right)}+\|u\|_{H^{k+1}\left(D_{0}\right)}
$$

## Chapter 43

## Interpolation In Banach Space

### 43.1 Some Standard Techniques In Evolution Equations

### 43.1.1 Weak Vector Valued Derivatives

In this section, several significant theorems are presented. Unless indicated otherwise, the measure will be Lebesgue measure. First here is a lemma.

Lemma 43.1.1 Suppose $g \in L^{1}([a, b] ; X)$ where $X$ is a Banach space. Then if

$$
\int_{a}^{b} g(t) \phi(t) d t=0
$$

for all $\phi \in C_{c}^{\infty}(a, b)$, then $g(t)=0$ a.e.
Proof: Let $E$ be a measurable subset of $(a, b)$ and let $K \subseteq E \subseteq V \subseteq(a, b)$ where $K$ is compact, $V$ is open and $m(V \backslash K)<\varepsilon$. Let $K \prec h \prec V$ as in the proof of the Riesz representation theorem for positive linear functionals. Enlarging $K$ slightly and convolving with a mollifier, it can be assumed $h \in C_{c}^{\infty}(a, b)$. Then

$$
\begin{aligned}
\left|\int_{a}^{b} \mathscr{X}_{E}(t) g(t) d t\right| & =\left|\int_{a}^{b}\left(\mathscr{X}_{E}(t)-h(t)\right) g(t) d t\right| \\
& \leq \int_{a}^{b}\left|\mathscr{X}_{E}(t)-h(t)\right|\|g(t)\| d t \\
& \leq \int_{V \backslash K}\|g(t)\| d t
\end{aligned}
$$

Now let $K_{n} \subseteq E \subseteq V_{n}$ with $m\left(V_{n} \backslash K_{n}\right)<2^{-n}$. Then from the above,

$$
\left|\int_{a}^{b} \mathscr{X}_{E}(t) g(t) d t\right| \leq \int_{a}^{b} \mathscr{X}_{V_{n} \backslash K_{n}}(t)\|g(t)\| d t
$$

and the integrand of the last integral converges to 0 a.e. as $n \rightarrow \infty$ because $\sum_{n} m\left(V_{n} \backslash K_{n}\right)<$ $\infty$. By the dominated convergence theorem, this last integral converges to 0 . Therefore, whenever $E \subseteq(a, b)$,

$$
\int_{a}^{b} \mathscr{X}_{E}(t) g(t) d t=0
$$

Since the endpoints have measure zero, it also follows that for any measurable $E$, the above equation holds.

Now $g \in L^{1}([a, b] ; X)$ and so it is measurable. Therefore, $g([a, b])$ is separable. Let $D$ be a countable dense subset and let $E$ denote the set of linear combinations of the form $\sum_{i} a_{i} d_{i}$ where $a_{i}$ is a rational point of $\mathbb{F}$ and $d_{i} \in D$. Thus $E$ is countable. Denote by $Y$ the closure of $E$ in $X$. Thus $Y$ is a separable closed subspace of $X$ which contains all the values of $g$.

Now let $S_{n} \equiv g^{-1}\left(B\left(y_{n},\left\|y_{n}\right\| / 2\right)\right)$ where $E=\left\{y_{n}\right\}_{n=1}^{\infty}$. Then, $\cup_{n} S_{n}=g^{-1}(X \backslash\{0\})$. This follows because if $x \in Y$ and $x \neq 0$, then in $B\left(x, \frac{\|x\|}{4}\right)$ there is a point of $E, y_{n}$. Therefore, $\left\|y_{n}\right\|>\frac{3}{4}\|x\|$ and so $\frac{\left\|y_{n}\right\|}{2}>\frac{3\|x\|}{8}>\frac{\|x\|}{4}$ so $x \in B\left(y_{n},\left\|y_{n}\right\| / 2\right)$. It follows that if each $S_{n}$ has measure zero, then $g(t)=0$ for a.e. $t$. Suppose then that for some $n$, the set, $S_{n}$ has positive mesure. Then from what was shown above,

$$
\begin{aligned}
\left\|y_{n}\right\| & =\left\|\frac{1}{m\left(S_{n}\right)} \int_{S_{n}} g(t) d t-y_{n}\right\|=\left\|\frac{1}{m\left(S_{n}\right)} \int_{S_{n}} g(t)-y_{n} d t\right\| \\
& \leq \frac{1}{m\left(S_{n}\right)} \int_{S_{n}}\left\|g(t)-y_{n}\right\| d t \leq \frac{1}{m\left(S_{n}\right)} \int_{S_{n}}\left\|y_{n}\right\| / 2 d t=\left\|y_{n}\right\| / 2
\end{aligned}
$$

and so $y_{n}=0$ which implies $S_{n}=\emptyset$, a contradiction to $m\left(S_{n}\right)>0$. This contradiction shows each $S_{n}$ has measure zero and so as just explained, $g(t)=0$ a.e.

Definition 43.1.2 For $f \in L^{1}(a, b ; X)$, define an extension, $\bar{f}$ defined on

$$
[2 a-b, 2 b-a]=[a-(b-a), b+(b-a)]
$$

as follows.

$$
\bar{f}(t) \equiv\left\{\begin{array}{l}
f(t) \text { if } t \in[a, b] \\
f(2 a-t) \text { if } t \in[2 a-b, a] \\
f(2 b-t) \text { if } t \in[b, 2 b-a]
\end{array}\right.
$$

Definition 43.1.3 Also if $f \in L^{p}(a, b ; X)$ and $h>0$, define for $t \in[a, b], f_{h}(t) \equiv \bar{f}(t-h)$ for all $h<b-a$. Thus the map $f \rightarrow f_{h}$ is continuous and linear on $L^{p}(a, b ; X)$. It is continuous because

$$
\begin{aligned}
\int_{a}^{b}\left\|f_{h}(t)\right\|^{p} d t & =\int_{a}^{a+h}\|f(2 a-t+h)\|^{p} d t+\int_{a}^{b-h}\|f(t)\|^{p} d t \\
& =\int_{a}^{a+h}\|f(t)\|^{p} d t+\int_{a}^{b-h}\|f(t)\|^{p} d t \leq 2\|f\|_{p}^{p}
\end{aligned}
$$

The following lemma is on continuity of translation in $L^{p}(a, b ; X)$.
Lemma 43.1.4 Let $\bar{f}$ be as defined in Definition 69.2.2. Then for $f \in L^{p}(a, b ; X)$ for $p \in$ $[1, \infty)$,

$$
\lim _{\delta \rightarrow 0} \int_{a}^{b}\|\bar{f}(t-\delta)-f(t)\|_{X}^{p} d t=0
$$

Proof: Regarding the measure space as $(a, b)$ with Lebesgue measure, by Lemma 21.5.9 there exists $g \in C_{c}(a, b ; X)$ such that $\|f-g\|_{p}<\varepsilon$. Here the norm is the norm in $L^{p}(a, b ; X)$. Therefore,

$$
\begin{aligned}
\left\|f_{h}-f\right\|_{p} & \leq\left\|f_{h}-g_{h}\right\|_{p}+\left\|g_{h}-g\right\|_{p}+\|g-f\|_{p} \\
& \leq\left(2^{1 / p}+1\right)\|f-g\|_{p}+\left\|g_{h}-g\right\|_{p} \\
& <\left(2^{1 / p}+1\right) \varepsilon+\varepsilon
\end{aligned}
$$

whenever $h$ is sufficiently small. This is because of the uniform continuity of $g$. Therefore, since $\varepsilon>0$ is arbitrary, this proves the lemma.

Definition 43.1.5 Let $f \in L^{1}(a, b ; X)$. Then the distributional derivative in the sense of $X$ valued distributions is given by

$$
f^{\prime}(\phi) \equiv-\int_{a}^{b} f(t) \phi^{\prime}(t) d t
$$

Then $f^{\prime} \in L^{1}(a, b ; X)$ if there exists $h \in L^{1}(a, b ; X)$ such that for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
f^{\prime}(\phi)=\int_{a}^{b} h(t) \phi(t) d t
$$

Then $f^{\prime}$ is defined to equal $h$. Here $f$ and $f^{\prime}$ are considered as vector valued distributions in the same way as was done for scalar valued functions.

Lemma 43.1.6 The above definition is well defined.
Proof: Suppose both $h$ and $g$ work in the definition. Then for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b}(h(t)-g(t)) \phi(t) d t=0
$$

Therefore, by Lemma 43.1.1, $h(t)-g(t)=0$ a.e.
The other thing to notice about this is the following lemma. It follows immediately from the definition.

Lemma 43.1.7 Suppose $f, f^{\prime} \in L^{1}(a, b ; X)$. Then if $[c, d] \subseteq[a, b]$, it follows that $\left(\left.f\right|_{[c, d]}\right)^{\prime}=$ $\left.f^{\prime}\right|_{[c, d]}$. This notation means the restriction to $[c, d]$.

Recall that in the case of scalar valued functions, if you had both $f$ and its weak derivative, $f^{\prime}$ in $L^{1}(a, b)$, then you were able to conclude that $f$ is almost everywhere equal to a continuous function, still denoted by $f$ and

$$
f(t)=f(a)+\int_{a}^{t} f^{\prime}(s) d s
$$

In particular, you can define $f(a)$ to be the initial value of this continuous function. It turns out that an identical theorem holds in this case. To begin with here is the same sort of lemma which was used earlier for the case of scalar valued functions. It says that if $f^{\prime}=0$ where the derivative is taken in the sense of $X$ valued distributions, then $f$ equals a constant.

Lemma 43.1.8 Suppose $f \in L^{1}(a, b ; X)$ and for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b} f(t) \phi^{\prime}(t) d t=0
$$

Then there exists a constant, $a \in X$ such that $f(t)=a$ a.e.

Proof: Let $\phi_{0} \in C_{c}^{\infty}(a, b), \int_{a}^{b} \phi_{0}(x) d x=1$ and define for $\phi \in C_{c}^{\infty}(a, b)$

$$
\psi_{\phi}(x) \equiv \int_{a}^{x}\left[\phi(t)-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right] d t
$$

Then $\psi_{\phi} \in C_{c}^{\infty}(a, b)$ and $\psi_{\phi}^{\prime}=\phi-\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}$. Then

$$
\begin{aligned}
\int_{a}^{b} f(t)(\phi(t)) d t & =\int_{a}^{b} f(t)\left(\psi_{\phi}^{\prime}(t)+\left(\int_{a}^{b} \phi(y) d y\right) \phi_{0}(t)\right) d t \\
& =\overbrace{\int_{a}^{b} f(t) \psi_{\phi}^{\prime}(t) d t+\left(\int_{a}^{b} \phi(y) d y\right) \int_{a}^{b} f(t) \phi_{0}(t) d t}^{=0 \text { by assumption }} \\
& =\left(\int_{a}^{b}\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right) \phi(y) d y\right) .
\end{aligned}
$$

It follows that for all $\phi \in C_{c}^{\infty}(a, b)$,

$$
\int_{a}^{b}\left(f(y)-\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right)\right) \phi(y) d y=0
$$

and so by Lemma 43.1.1,

$$
f(y)-\left(\int_{a}^{b} f(t) \phi_{0}(t) d t\right)=0 \text { a.e. } y
$$

Theorem 43.1.9 Suppose $f, f^{\prime}$ both are in $L^{1}(a, b ; X)$ where the derivative is taken in the sense of $X$ valued distributions. Then there exists a unique point of $X$, denoted by $f(a)$ such that the following formula holds a.e. $t$.

$$
f(t)=f(a)+\int_{a}^{t} f^{\prime}(s) d s
$$

Proof:

$$
\int_{a}^{b}\left(f(t)-\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t=\int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t
$$

Now consider $\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t$. Let $\Lambda \in X^{\prime}$. Then it is routine from approximating $f^{\prime}$ with simple functions to verify

$$
\Lambda\left(\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t\right)=\int_{a}^{b} \int_{a}^{t} \Lambda\left(f^{\prime}(s)\right) \phi^{\prime}(t) d s d t
$$

Now the ordinary Fubini theorem can be applied to obtain

$$
\begin{aligned}
& =\int_{a}^{b} \int_{s}^{b} \Lambda\left(f^{\prime}(s)\right) \phi^{\prime}(t) d t d s \\
& =\Lambda\left(\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s\right)
\end{aligned}
$$

Since $X^{\prime}$ separates the points of $X$, it follows

$$
\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) \phi^{\prime}(t) d s d t=\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s
$$

Therefore,

$$
\begin{aligned}
& \int_{a}^{b}\left(f(t)-\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} \int_{s}^{b} f^{\prime}(s) \phi^{\prime}(t) d t d s \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t-\int_{a}^{b} f^{\prime}(s) \int_{s}^{b} \phi^{\prime}(t) d t d s \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{a}^{b} f^{\prime}(s) \phi(s) d s=0
\end{aligned}
$$

Therefore, by Lemma 43.1.8, there exists a constant, denoted as $f(a)$ such that

$$
f(t)-\int_{a}^{t} f^{\prime}(s) d s=f(a)
$$

The integration by parts formula is also important.
Corollary 43.1.10 Suppose $f, f^{\prime} \in L^{1}(a, b ; X)$ and suppose $\phi \in C^{1}([a, b])$. Then the following integration by parts formula holds.

$$
\int_{a}^{b} f(t) \phi^{\prime}(t) d t=f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(t) \phi(t) d t
$$

Proof: From Theorem 43.1.9

$$
\begin{aligned}
& \int_{a}^{b} f(t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b}\left(f(a)+\int_{a}^{t} f^{\prime}(s) d s\right) \phi^{\prime}(t) d t \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} \int_{a}^{t} f^{\prime}(s) d s \phi^{\prime}(t) d t \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} f^{\prime}(s) \int_{s}^{b} \phi^{\prime}(t) d t d s \\
= & f(a)(\phi(b)-\phi(a))+\int_{a}^{b} f^{\prime}(s)(\phi(b)-\phi(s)) d s \\
= & f(a)(\phi(b)-\phi(a))-\int_{a}^{b} f^{\prime}(s) \phi(s) d s+(f(b)-f(a)) \phi(b) \\
= & f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(s) \phi(s) d s .
\end{aligned}
$$

The interchange in order of integration is justified as in the proof of Theorem 43.1.9.
There is an interesting theorem which is easy to present at this point.

Definition 43.1.11 Let

$$
H^{1}(0, T, X)
$$

denote the functions $f \in L^{2}(0, T, X)$ whose weak derivative $f^{\prime}$ is also in $L^{2}(0, T, X)$.
Proposition 43.1.12 Let $f \in H^{1}(0, T, X)$. Then $f \in C^{0,(1 / 2)}([0, T], X)$ and the inclusion map is continuous.

Proof: First note that

$$
f(t)-f(s)=\int_{s}^{t} f^{\prime}(r) d r
$$

and so

$$
\|f(t)-f(s)\|_{X} \leq \int_{s}^{t}\left\|f^{\prime}(r)\right\|_{X} d r \leq\|f\|_{H^{1}}|t-s|^{1 / 2}
$$

It follows that

$$
\sup _{0 \leq s<t \leq T} \frac{\|f(t)-f(s)\|}{|t-s|^{1 / 2}} \leq\|f\|_{H^{1}}
$$

Also

$$
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s
$$

so

$$
\|f(t)\| \leq\|f(0)\|+\int_{0}^{t}\left|f^{\prime}(s)\right| d s \leq\|f(0)\|+T^{1 / 2}\|f\|_{H^{1}}
$$

Now consider $\|f(0)\|$. Then integrating by parts yields

$$
\int_{0}^{T}(T-t) f^{\prime}(t) d t=\left.(T-t) f(t)\right|_{0} ^{T}+\int_{0}^{t} f(t) d t
$$

and so

$$
T\|f(0)\| \leq \int_{0}^{T}\|f(t)\| d t+T \int_{0}^{T}\left\|f^{\prime}(t)\right\| d t \leq C(T)\|f\|_{H^{1}}
$$

Hence

$$
\sup _{t \in[0, T]}\|f(t)\| \leq C(T)\|f\|_{H^{1}}
$$

Therefore, this has shown that

$$
\|f\|_{C^{0,(1 / 2)}([0, T], X)} \equiv \sup _{t \in[0, T]}\|f(t)\|+\sup _{0 \leq s<t \leq T} \frac{\|f(t)-f(s)\|}{|t-s|^{1 / 2}} \leq C(T)\|f\|_{H^{1}}
$$

You could imagine that other interesting versions of this are available with similar proof for the case where the function and its weak derivative are in $L^{p}(0, T, X)$ for $p>1$.

With this integration by parts formula, the following interesting lemma is obtained. This lemma shows why it was appropriate to define $\bar{f}$ as in Definition 43.1.2.

Lemma 43.1.13 Let $\bar{f}$ be given in Definition 43.1.2 and suppose $f, f^{\prime} \in L^{1}(a, b ; X)$. Then $\bar{f}, \bar{f}^{\prime} \in L^{1}(2 a-b, 2 b-a ; X)$ also and

$$
\bar{f}^{\prime}(t) \equiv\left\{\begin{array}{l}
f^{\prime}(t) \text { if } t \in[a, b]  \tag{43.1.1}\\
-f^{\prime}(2 a-t) \text { if } t \in[2 a-b, a] \\
-f^{\prime}(2 b-t) \text { if } t \in[b, 2 b-a]
\end{array}\right.
$$

Proof: It is clear from the definition of $\bar{f}$ that $\bar{f} \in L^{1}(2 a-b, 2 b-a ; X)$ and that in fact

$$
\begin{equation*}
\|\bar{f}\|_{L^{1}(2 a-b, 2 b-a ; X)} \leq 3\|f\|_{L^{1}(a, b ; X)} \tag{43.1.2}
\end{equation*}
$$

Let $\phi \in C_{c}^{\infty}(2 a-b, 2 b-a)$. Then from the integration by parts formula,

$$
\begin{aligned}
& \int_{2 a-b}^{2 b-a} \bar{f}(t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{b}^{2 b-a} f(2 b-t) \phi^{\prime}(t) d t+\int_{2 a-b}^{a} f(2 a-t) \phi^{\prime}(t) d t \\
= & \int_{a}^{b} f(t) \phi^{\prime}(t) d t+\int_{a}^{b} f(u) \phi^{\prime}(2 b-u) d u+\int_{a}^{b} f(u) \phi^{\prime}(2 a-u) d u \\
= & f(b) \phi(b)-f(a) \phi(a)-\int_{a}^{b} f^{\prime}(t) \phi(t) d t-f(b) \phi(b)+f(a) \phi(2 b-a) \\
& +\int_{a}^{b} f^{\prime}(u) \phi(2 b-u) d u-f(b) \phi(2 a-b) \\
& +f(a) \phi(a)+\int_{a}^{b} f^{\prime}(u) \phi(2 a-u) d u \\
= & -\int_{a}^{b} f^{\prime}(t) \phi(t) d t+\int_{a}^{b} f^{\prime}(u) \phi(2 b-u) d u+\int_{a}^{b} f^{\prime}(u) \phi(2 a-u) d u \\
= & -\int_{a}^{b} f^{\prime}(t) \phi(t) d t-\int_{b}^{2 b-a}-f^{\prime}(2 b-t) \phi(t) d t-\int_{2 a-b}^{a}-f^{\prime}(2 a-t) \phi(t) d t \\
= & -\int_{2 a-b}^{2 b-a} \bar{f}^{\prime}(t) \phi(t) d t
\end{aligned}
$$

where $\bar{f}^{\prime}(t)$ is given in 43.1.1.
Definition 43.1.14 Let $V$ be a Banach space and let $H$ be a Hilbert space. (Typically $H=L^{2}(\Omega)$ ) Suppose $V \subseteq H$ is dense in $H$ meaning that the closure in $H$ of $V$ gives $H$. Then it is often the case that $H$ is identified with its dual space, and then because of the density of $V$ in $H$, it is possible to write

$$
V \subseteq H=H^{\prime} \subseteq V^{\prime}
$$

When this is done, $H$ is called a pivot space. Another notation which is often used is $\langle f, g\rangle$ to denote $f(g)$ for $f \in V^{\prime}$ and $g \in V$. This may also be written as $\langle f, g\rangle_{V^{\prime}, V}$. Another term is that $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ is called a Gelfand triple.

The next theorem is an example of a trace theorem. In this theorem, $f \in L^{p}(0, T ; V)$ while $f^{\prime} \in L^{p}\left(0, T ; V^{\prime}\right)$. It makes no sense to consider the initial values of $f$ in $V$ because it is not even continuous with values in $V$. However, because of the derivative of $f$ it will turn out that $f$ is continuous with values in a larger space and so it makes sense to consider initial values of $f$ in this other space. This other space is called a trace space.

Theorem 43.1.15 Let $V$ and $H$ be a Banach space and Hilbert space as described in Definition 43.1.14. Suppose $f \in L^{p}(0, T ; V)$ and $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$. Then $f$ is a.e. equal to $a$ continuous function mapping $[0, T]$ to $H$. Furthermore, there exists $f(0) \in H$ such that

$$
\begin{equation*}
\frac{1}{2}|f(t)|_{H}^{2}-\frac{1}{2}|f(0)|_{H}^{2}=\int_{0}^{t}\left\langle f^{\prime}(s), f(s)\right\rangle d s \tag{43.1.3}
\end{equation*}
$$

and for all $t \in[0, T]$,

$$
\begin{equation*}
\int_{0}^{t} f^{\prime}(s) d s \in H \tag{43.1.4}
\end{equation*}
$$

and for a.e. $t \in[0, T]$,

$$
\begin{equation*}
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } H \tag{43.1.5}
\end{equation*}
$$

Here $f^{\prime}$ is being taken in the sense of $V^{\prime}$ valued distributions and $\frac{1}{p}+\frac{1}{p^{\prime}}=1$ and $p \geq 2$.
Proof: Let $\Psi \in C_{c}^{\infty}(-T, 2 T)$ satisfy $\Psi(t)=1$ if $t \in[-T / 2,3 T / 2]$ and $\Psi(t) \geq 0$. For $t \in \mathbb{R}$, define

$$
\widehat{f}(t) \equiv\left\{\begin{array}{l}
\bar{f}(t) \Psi(t) \text { if } t \in[-T, 2 T] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

and

$$
\begin{equation*}
f_{n}(t) \equiv \int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s \tag{43.1.6}
\end{equation*}
$$

where $\phi_{n}$ is a mollifier having support in $(-1 / n, 1 / n)$. Then by Minkowski's inequality

$$
\begin{aligned}
\| f_{n} & -\widehat{f} \|_{L^{p}(\mathbb{R} ; V)}=\left(\int_{\mathbb{R}}\left\|\widehat{f}(t)-\int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s\right\|_{V}^{p} d t\right)^{1 / p} \\
& =\left(\int_{\mathbb{R}}\left\|\int_{-1 / n}^{1 / n}(\widehat{f}(t)-\widehat{f}(t-s)) \phi_{n}(s) d s\right\|_{V}^{p} d t\right)^{1 / p} \\
& \leq\left(\int_{\mathbb{R}}\left(\int_{-1 / n}^{1 / n}\|\widehat{f}(t)-\widehat{f}(t-s)\|_{V} \phi_{n}(s) d s\right)^{p} d t\right)^{1 / p} \\
& \leq \int_{-1 / n}^{1 / n} \phi_{n}(s)\left(\int_{\mathbb{R}}\|\widehat{f}(t)-\widehat{f}(t-s)\|_{V}^{p} d t\right)^{1 / p} d s \\
& \leq \int_{-1 / n}^{1 / n} \phi_{n}(s) \varepsilon d s=\varepsilon
\end{aligned}
$$

provided $n$ is large enough. This follows from continuity of translation in $L^{p}$ with Lebesgue measure. Since $\varepsilon>0$ is arbitrary, it follows $f_{n} \rightarrow \widehat{f}$ in $L^{p}(\mathbb{R} ; V)$. Similarly, $f_{n} \rightarrow f$ in $L^{2}(\mathbb{R} ; H)$. This follows because $p \geq 2$ and the norm in $V$ and norm in $H$ are related by $|x|_{H} \leq C\|x\|_{V}$ for some constant, $C$. Now

$$
\widehat{f}(t)=\left\{\begin{array}{l}
\Psi(t) f(t) \text { if } t \in[0, T] \\
\Psi(t) f(2 T-t) \text { if } t \in[T, 2 T] \\
\Psi(t) f(-t) \text { if } t \in[0, T] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

An easy modification of the argument of Lemma 43.1.13 yields

$$
\widehat{f}^{\prime}(t)=\left\{\begin{array}{l}
\Psi^{\prime}(t) f(t)+\Psi(y) f^{\prime}(t) \text { if } t \in[0, T] \\
\Psi^{\prime}(t) f(2 T-t)-\Psi(t) f^{\prime}(2 T-t) \text { if } t \in[T, 2 T] \\
\Psi^{\prime}(t) f(-t)-\Psi(t) f^{\prime}(-t) \text { if } t \in[-T, 0] \\
0 \text { if } t \notin[-T, 2 T]
\end{array}\right.
$$

Recall

$$
\begin{aligned}
f_{n}(t) & =\int_{-1 / n}^{1 / n} \widehat{f}(t-s) \phi_{n}(s) d s=\int_{\mathbb{R}} \widehat{f}(t-s) \phi_{n}(s) d s \\
& =\int_{\mathbb{R}} \widehat{f}(s) \phi_{n}(t-s) d s
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
f_{n}^{\prime}(t) & =\int_{\mathbb{R}} \widehat{f}(s) \phi_{n}^{\prime}(t-s) d s=\int_{-T-\frac{1}{n}}^{2 T+\frac{1}{n}} \widehat{f}(s) \phi_{n}^{\prime}(t-s) d s \\
& =\int_{-T-\frac{1}{n}}^{2 T+\frac{1}{n}} \widehat{f}^{\prime}(s) \phi_{n}(t-s) d s=\int_{\mathbb{R}} \widehat{f}^{\prime}(s) \phi_{n}(t-s) d s \\
& =\int_{\mathbb{R}} \widehat{f}^{\prime}(t-s) \phi_{n}(s) d s=\int_{-1 / n}^{1 / n} \widehat{f}^{\prime}(t-s) \phi_{n}(s) d s
\end{aligned}
$$

and it follows from the first line above that $f_{n}^{\prime}$ is continuous with values in $V$ for all $t \in \mathbb{R}$. Also note that both $f_{n}^{\prime}$ and $f_{n}$ equal zero if $t \notin[-T, 2 T]$ whenever $n$ is large enough. Exactly similar reasoning to the above shows that $f_{n}^{\prime} \rightarrow \widehat{f}^{\prime}$ in $L^{p^{\prime}}\left(\mathbb{R} ; V^{\prime}\right)$.

Now let $\phi \in C_{c}^{\infty}(0, T)$.

$$
\begin{align*}
\int_{\mathbb{R}}\left|f_{n}(t)\right|_{H}^{2} \phi^{\prime}(t) d t & =\int_{\mathbb{R}}\left(f_{n}(t), f_{n}(t)\right)_{H} \phi^{\prime}(t) d t  \tag{43.1.7}\\
=-\int_{\mathbb{R}} 2\left(f_{n}^{\prime}(t), f_{n}(t)\right) \phi(t) d t & =-\int_{\mathbb{R}} 2\left\langle f_{n}^{\prime}(t), f_{n}(t)\right\rangle \phi(t) d t
\end{align*}
$$

Now

$$
\begin{aligned}
& \left|\int_{\mathbb{R}}\left\langle f_{n}^{\prime}(t), f_{n}(t)\right\rangle \phi(t) d t-\int_{\mathbb{R}}\left\langle f^{\prime}(t), f(t)\right\rangle \phi(t) d t\right| \\
\leq & \int_{\mathbb{R}}\left(\left|\left\langle f_{n}^{\prime}(t)-f^{\prime}(t), f_{n}(t)\right\rangle\right|+\left|\left\langle f^{\prime}(t), f_{n}(t)-f(t)\right\rangle\right|\right) \phi(t) d t
\end{aligned}
$$

From the first part of this proof which showed that $f_{n} \rightarrow \widehat{f}$ in $L^{p}(\mathbb{R} ; V)$ and $f_{n}^{\prime} \rightarrow \widehat{f^{\prime}}$ in $L^{p^{\prime}}\left(\mathbb{R} ; V^{\prime}\right)$, an application of Holder's inequality shows the above converges to 0 as $n \rightarrow \infty$. Therefore, passing to the limit as $n \rightarrow \infty$ in the 43.1.8,

$$
\int_{\mathbb{R}}|\widehat{f}(t)|_{H}^{2} \phi^{\prime}(t) d t=-\int_{\mathbb{R}} 2\left\langle\widehat{f}^{\prime}(t), \widehat{f}(t)\right\rangle \phi(t) d t
$$

which shows $t \rightarrow|\widehat{f}(t)|_{H}^{2}$ equals a continuous function a.e. and it also has a weak derivative equal to $2\left\langle\widehat{f}^{\prime}, \widehat{f}\right\rangle$.

It remains to verify that $\widehat{f}$ is continuous on $[0, T]$. Of course $\widehat{f}=f$ on this interval. Let $N$ be large enough that $f_{n}(-T)=0$ for all $n>N$. Then for $m, n>N$ and $t \in[-T, 2 T]$

$$
\begin{aligned}
\left|f_{n}(t)-f_{m}(t)\right|_{H}^{2} & =2 \int_{-T}^{t}\left(f_{n}^{\prime}(s)-f_{m}^{\prime}(s), f_{n}(s)-f_{m}(s)\right) d s \\
& =2 \int_{-T}^{t}\left\langle f_{n}^{\prime}(s)-f_{m}^{\prime}(s), f_{n}(s)-f_{m}(s)\right\rangle_{V^{\prime}, V} d s \\
& \leq 2 \int_{\mathbb{R}}\left\|f_{n}^{\prime}(s)-f_{m}^{\prime}(s)\right\|_{V^{\prime}}\left\|f_{n}(s)-f_{m}(s)\right\|_{V} d s \\
& \leq 2\left\|f_{n}-f_{m}\right\|_{L^{p^{\prime}\left(\mathbb{R} ; V^{\prime}\right)}}\left\|f_{n}-f_{m}\right\|_{L^{p}(\mathbb{R} ; V)}
\end{aligned}
$$

which shows from the above that $\left\{f_{n}\right\}$ is uniformly Cauchy on $[-T, 2 T]$ with values in $H$. Therefore, there exists $g$ a continuous function defined on $[-T, 2 T]$ having values in $H$ such that

$$
\lim _{n \rightarrow \infty} \max \left\{\left|f_{n}(t)-g(t)\right|_{H} ; t \in[-T, 2 T]\right\}=0
$$

However, $g=\widehat{f}$ a.e. because $f_{n}$ converges to $f$ in $L^{p}(0, T ; V)$. Therefore, taking a subsequence, the convergence is a.e. It follows from the fact that $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ and Theorem 43.1.9, there exists $f(0) \in V^{\prime}$ such that for a.e. $t$,

$$
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } V^{\prime}
$$

Now $g=f$ a.e. and $g$ is continuous with values in $H$ hence continuous with values in $V^{\prime}$ and so

$$
g(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } V^{\prime}
$$

for all $t$. Since $g$ is continuous with values in $H$ it is continuous with values in $V^{\prime}$. Taking the limit as $t \downarrow 0$ in the above, $g(a)=\lim _{t \rightarrow 0+} g(t)=f(0)$, showing that $f(0) \in H$. Therefore, for a.e. $t$,

$$
f(t)=f(0)+\int_{0}^{t} f^{\prime}(s) d s \text { in } H, \int_{0}^{t} f^{\prime}(s) d s \in H .
$$

Note that if $f \in L^{p}(0, T ; V)$ and $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$, then you can consider the initial value of $f$ and it will be in $H$. What if you start with something in $H$ ? Is it an initial condition for a function $f \in L^{p}(0, T ; V)$ such that $f^{\prime} \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right)$ ? This is worth thinking
about. If it is not so, what is the space of initial values? How can you give this space a norm? What are its properties? It turns out that if $V$ is a closed subspace of the Sobolev space, $W^{1, p}(\Omega)$ which contains $W_{0}^{1, p}(\Omega)$ for $p \geq 2$ and $H=L^{2}(\Omega)$ the answer to the above question is yes. Not surprisingly, there are many generalizations of the above ideas.

### 43.2 An Important Formula

It is not necessary to have $p>2$ in order to do the sort of thing just described. Here is a major result which will have a much more difficult stochastic version presented later. First is a simple version of an approximation theorem of Doob.

Lemma 43.2.1 Let $Y:[0, T] \rightarrow E$, be $\mathscr{B}([0, T])$ measurable and suppose

$$
Y \in L^{p}(0, T ; E) \equiv K, p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathscr{P}_{k} \subseteq \mathscr{P}_{k+1}$,

$$
\mathscr{P}_{k} \equiv\left\{t_{0}^{k}, \cdots, t_{m_{k}}^{k}\right\}
$$

such that the step functions given by

$$
\begin{aligned}
Y_{k}^{r}(t) & \equiv \sum_{j=1}^{m_{k}} Y\left(t_{j}^{k}\right) \mathscr{X}_{\left[t_{j-1}^{k}, t_{j}^{k}\right)}(t) \\
Y_{k}^{l}(t) & \equiv \sum_{j=1}^{m_{k}} Y\left(t_{j-1}^{k}\right) \mathscr{X}_{\left(t_{j-1}^{k}, t_{j}^{k}\right]}(t)
\end{aligned}
$$

both converge to $Y$ in $K$ as $k \rightarrow \infty$ and

$$
\lim _{k \rightarrow \infty} \max \left\{\left|t_{j}^{k}-t_{j+1}^{k}\right|: j \in\left\{0, \cdots, m_{k}\right\}\right\}=0
$$

Also, each $Y\left(t_{j}^{k}\right), Y\left(t_{j-1}^{k}\right)$ is in $E$. One can also assume that $Y(0)=0$. The mesh points $\left\{t_{j}^{k}\right\}_{j=0}^{m_{k}}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$
\left|t_{j}^{k}-t_{j-1}^{k}\right|=2^{-n_{k}}
$$

except for the case where $j=1$ or $j=m_{n_{k}}$ when this might not be so. In the case of the last subinterval defined by the partition, we can assume

$$
\left|t_{m}^{k}-t_{m-1}^{k}\right|=\left|T-t_{m-1}^{k}\right| \geq 2^{-\left(n_{k}+1\right)}
$$

Proof: For $t \in \mathbb{R}$ let $\gamma_{n}(t) \equiv k / 2^{n}, \delta_{n}(t) \equiv(k+1) / 2^{n}$, where $t \in\left(k / 2^{n},(k+1) / 2^{n}\right]$, and $2^{-n}<T / 4$. Also suppose $Y$ is defined to equal 0 on $[0, T]^{C}$. Then $t \rightarrow\|Y(t)\|$ is in $L^{p}(\mathbb{R})$. Therefore by continuity of translation, as $n \rightarrow \infty$ it follows that for $t \in[0, T]$,

$$
\int_{\mathbb{R}}\left\|Y\left(\gamma_{n}(t)+s\right)-Y(t+s)\right\|_{E}^{p} d s \rightarrow 0
$$

The above is dominated by

$$
\begin{aligned}
& \int_{\mathbb{R}} 2^{p-1}\left(\|Y(s)\|^{p}+\|Y(s)\|^{p}\right) \mathscr{X}_{[-2 T, 2 T]}(s) d s \\
= & \int_{-2 T}^{2 T} 2^{p-1}\left(\|Y(s)\|^{p}+\|Y(s)\|^{p}\right) d s<\infty
\end{aligned}
$$

Therefore,

$$
\lim _{n \rightarrow \infty} \int_{-2 T}^{2 T}\left(\int_{\mathbb{R}}\left\|Y\left(\gamma_{n}(t)+s\right)-Y(t+s)\right\|_{E}^{p} d s\right) d t=0
$$

by the dominated convergence theorem. Now Fubini. The above equals

$$
\int_{\mathbb{R}} \int_{-2 T}^{2 T}\left\|Y\left(\gamma_{n}(t)+s\right)-Y(t+s)\right\|_{E}^{p} d t d s
$$

Change the variables on the inside.

$$
\int_{\mathbb{R}} \int_{-2 T+s}^{2 T+s}\left\|Y\left(\gamma_{n}(t-s)+s\right)-Y(t)\right\|_{E}^{p} d t d s
$$

Since $\gamma_{n}(t-s)+s$ is within $2^{-n}$ of $t$ and $Y(t)$ vanishes if $t \notin[0, T]$, this reduces to

$$
\int_{\mathbb{R}} \int_{-2 T}^{2 T}\left\|Y\left(\gamma_{n}(t-s)+s\right)-Y(t)\right\|_{E}^{p} d t d s
$$

This converges to 0 as $n \rightarrow \infty$ as was shown above. Therefore,

$$
\int_{0}^{T} \int_{0}^{T}\left\|Y\left(\gamma_{n}(t-s)+s\right)-Y(t)\right\|_{E}^{p} d t d s
$$

also converges to 0 as $n \rightarrow \infty$. The only problem is that $\gamma_{n}(t-s)+s \geq t-2^{-n}$ and so $\gamma_{n}(t-s)+s$ could be less than 0 for $t \in\left[0,2^{-n}\right]$. Since this is an interval whose measure converges to 0 it follows

$$
\int_{0}^{T} \int_{0}^{T}\left\|Y\left(\left(\gamma_{n}(t-s)+s\right)^{+}\right)-Y(t)\right\|_{E}^{p} d t d s
$$

converges to 0 as $n \rightarrow \infty$. Let

$$
m_{n}(s)=\int_{0}^{T}\left\|Y\left(\left(\gamma_{n}(t-s)+s\right)^{+}\right)-Y(t)\right\|_{E}^{p} d t
$$

Then

$$
P\left(\left[m_{n}(s)>\lambda\right]\right) \leq \frac{1}{\lambda} \int_{0}^{T} m_{n}(s) d s
$$

It follows there exists a subsequence $n_{k}$ such that

$$
P\left(\left[m_{n_{k}}(s)>\frac{1}{k}\right]\right)<2^{-k}
$$

Hence by the Borel Cantelli lemma, there exists a set of measure zero $N$ such that for $s \notin N$,

$$
m_{n_{k}}(s) \leq 1 / k
$$

for all $k$ sufficiently large. Picking $s_{k} \notin N$,

$$
Y_{k}^{l}(t) \equiv Y\left(\left(\gamma_{n_{k}}\left(t-s_{k}\right)+s_{k}\right)^{+}\right)
$$

Then $t \rightarrow Y\left(\left(\gamma_{n_{k}}\left(t-s_{k}\right)+s_{k}\right)^{+}\right)$is a step function of the sort described above. Of course you can always simply define $Y_{k}^{l}(0) \equiv 0$. This is because the interval affected has length which converges to 0 as $k \rightarrow \infty$. The jumps in $t \rightarrow \gamma_{n_{k}}\left(t-s_{k}\right)$ determine the mesh points of the partition. By picking $s_{k}$ appropriately, you can have each of these mesh points miss a given set of measure zero except for the first and last point. This is because when you slide $s_{k}$ it just moves the mesh points of $\mathscr{P}_{k}$ except for the first point and last point. Let $N_{1}$ be a set of measure zero and let $(a, b) \subseteq[0, T]$. Now let $s$ move through $(a, b)$ and denote by $A_{j}$ the corresponding set of points obtained by the $j^{t h}$ mesh point. Thus $A_{j}$ has positive measure and so it is not contained in $N_{1}$. Let $S_{j}$ be the points of $(a, b)$ which correspond to $A_{j} \cap N_{1}$. Thus $S_{j}$ has measure 0 . Just pick $s_{k} \in(a, b) \backslash \cup_{j} S_{j}$. You can also choose $s_{k}$ such that

$$
T-s_{k}-\gamma_{n_{k}}\left(T-s_{k}\right)>2^{-\left(n_{k}+1\right)}
$$

which will cause the last condition mentioned above to hold.
To get the other sequence of step functions, just use a similar argument with $\boldsymbol{\delta}_{n}$ in place of $\gamma_{n}$.

Theorem 43.2.2 Let $V \subseteq H=H^{\prime} \subseteq V^{\prime}$ be a Gelfand triple and suppose $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right) \equiv$ $K^{\prime}$ and

$$
\begin{equation*}
X(t)=X_{0}+\int_{0}^{t} Y(s) d s \text { in } V^{\prime} \tag{43.2.8}
\end{equation*}
$$

where $X_{0} \in H$, and it is known that $X \in L^{p}(0, T, V) \equiv K$ for $p>1$. Then $t \rightarrow X(t)$ is in $C([0, T], H)$ and also

$$
\frac{1}{2}|X(t)|_{H}^{2}=\frac{1}{2}\left|X_{0}\right|_{H}^{2}+\int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Proof: By Lemma 43.2.1, there exists a sequence of uniform partitions $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}=$ $\mathscr{P}_{n}, \mathscr{P}_{n} \subseteq \mathscr{P}_{n+1}$, of $[0, T]$ such that the step functions

$$
\begin{aligned}
\sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{l}(t) \\
\sum_{k=0}^{m_{n}-1} X\left(t_{k+1}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{r}(t)
\end{aligned}
$$

converge to $X$ in $K$ and in $L^{2}([0, T], H)$.

Lemma 43.2.3 Let $s<t$. Then for $X, Y$ satisfying 43.2.8

$$
\begin{equation*}
|X(t)|^{2}=|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-|X(t)-X(s)|^{2} \tag{43.2.9}
\end{equation*}
$$

Proof: It follows from the following computations

$$
\begin{gathered}
X(t)-X(s)=\int_{s}^{t} Y(u) d u \\
-|X(t)-X(s)|^{2}=-|X(t)|^{2}+2(X(t), X(s))-|X(s)|^{2} \\
=-|X(t)|^{2}+2\left(X(t), X(t)-\int_{s}^{t} Y(u) d u\right)-|X(s)|^{2} \\
=-|X(t)|^{2}+2|X(t)|^{2}-2\left\langle\int_{s}^{t} Y(u) d u, X(t)\right\rangle-|X(s)|^{2}
\end{gathered}
$$

Hence

$$
|X(t)|^{2}=|X(s)|^{2}+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-|X(t)-X(s)|^{2}
$$

Lemma 43.2.4 In the above situation,

$$
\sup _{t \in[0, T]}|X(t)|_{H} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Also, $t \rightarrow X(t)$ is weakly continuous with values in $H$.
Proof: From the above formula applied to the $k^{t h}$ partition of $[0, T]$ described above,

$$
\begin{aligned}
& \left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}=\sum_{j=0}^{m-1}\left|X\left(t_{j+1}\right)\right|^{2}-\left|X\left(t_{j}\right)\right|^{2} \\
= & \sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle d u-\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2} \\
= & \sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u-\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2}
\end{aligned}
$$

Thus, discarding the negative terms and denoting by $\mathscr{P}_{k}$ the $k^{t h}$ of these partitions,

$$
\begin{gathered}
\sup _{t_{j} \in \mathscr{P}_{k}}\left|X\left(t_{j}\right)\right|_{H}^{2} \leq\left|X_{0}\right|^{2}+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u \\
\quad \leq\left|X_{0}\right|^{2}+2 \int_{0}^{T}\|Y(u)\|_{V^{\prime}}\left\|X_{k}^{r}(u)\right\|_{V} d u
\end{gathered}
$$

$$
\leq\left|X_{0}\right|^{2}+2\left(\int_{0}^{T}\|Y(u)\|_{V^{\prime}}^{p^{\prime}} d u\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p} d u\right)^{1 / p} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

because these partitions are chosen such that

$$
\lim _{k \rightarrow \infty}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p}\right)^{1 / p}=\left(\int_{0}^{T}\|X(u)\|_{V}^{p}\right)^{1 / p}
$$

and so these are bounded. This has shown that for the dense subset of $[0, T], D \equiv \cup_{k} \mathscr{P}_{k}$,

$$
\sup _{t \in D}|X(t)|<C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Now let $\left\{g_{k}\right\}_{k=1}^{\infty}$ be linearly independent vectors of $V$ whose span is dense in $V$. This is possible because $V$ is separable. Then let $\left\{e_{j}\right\}_{j=1}^{\infty}$ be an orthonormal basis for $H$ such that $e_{k} \in \operatorname{span}\left(g_{1}, \ldots, g_{k}\right)$ and each $g_{k} \in \operatorname{span}\left(e_{1}, \ldots, e_{k}\right)$. This is done with the Gram Schmidt process. Then it follows that $\operatorname{span}\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ is dense in $V$. I claim

$$
|y|_{H}^{2}=\sum_{j=1}^{\infty}\left|\left\langle y, e_{j}\right\rangle\right|^{2}
$$

This is certainly true if $y \in H$ because

$$
\left\langle y, e_{j}\right\rangle=\left(y, e_{j}\right)_{H}
$$

If $y \notin H$, then the series must diverge since otherwise, you could consider the infinite sum

$$
\sum_{j=1}^{\infty}\left\langle y, e_{j}\right\rangle e_{j} \in H
$$

because

$$
\left|\sum_{j=p}^{q}\left\langle y, e_{j}\right\rangle e_{j}\right|^{2}=\sum_{j=p}^{q}\left|\left\langle y, e_{j}\right\rangle\right|^{2} \rightarrow 0 \text { as } p, q \rightarrow \infty
$$

Letting $z=\sum_{j=1}^{\infty}\left\langle y, e_{j}\right\rangle e_{j}$, it follows that $\left\langle y, e_{j}\right\rangle$ is the $j^{\text {th }}$ Fourier coefficient of $z$ and that

$$
\langle z-y, v\rangle=0
$$

for all $v \in \operatorname{span}\left(\left\{e_{k}\right\}_{k=1}^{\infty}\right)$ which is dense in $V$. Therefore, $z=y$ in $V^{\prime}$ and so $y \in H$.
It follows

$$
|X(t)|^{2}=\sup _{n} \sum_{j=1}^{n}\left|\left\langle X(t), e_{j}\right\rangle\right|^{2}
$$

which is just the sup of continuous functions of $t$. Therefore, $t \rightarrow|X(t)|^{2}$ is lower semicontinuous. It follows that for any $t$, letting $t_{j} \rightarrow t$ for $t_{j} \in D$,

$$
|X(t)|^{2} \leq \lim \inf _{j \rightarrow \infty}\left|X\left(t_{j}\right)\right|^{2} \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

This proves the first claim of the lemma.
Consider now the claim that $t \rightarrow X(t)$ is weakly continuous. Letting $v \in V$,

$$
\lim _{t \rightarrow s}(X(t), v)=\lim _{t \rightarrow s}\langle X(t), v\rangle=\langle X(s), v\rangle=(X(s), v)
$$

Since it was shown that $|X(t)|$ is bounded independent of $t$, and since $V$ is dense in $H$, the claim follows.

Now

$$
\begin{aligned}
-\sum_{j=0}^{m-1}\left|X\left(t_{j+1}\right)-X\left(t_{j}\right)\right|_{H}^{2} & =\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}-\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u \\
& =\left|X\left(t_{m}\right)\right|^{2}-\left|X_{0}\right|^{2}-2 \int_{0}^{t_{m}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u
\end{aligned}
$$

Thus, since the partitions are nested, eventually $\left|X\left(t_{m}\right)\right|^{2}$ is constant for all $k$ large enough and the integral term converges to

$$
\int_{0}^{t_{m}}\langle Y(u), X(u)\rangle d u
$$

It follows that the term on the left does converge to something. It just remains to consider what it does converge to. However, from the equation solved by $X$,

$$
X\left(t_{j+1}\right)-X\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Y(u) d u
$$

Therefore, this term is dominated by an expression of the form

$$
\begin{gathered}
\sum_{j=0}^{m_{k}-1}\left(\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right) \\
=\sum_{j=0}^{m_{k}-1}\left\langle\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle d u \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle-\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j}\right)\right\rangle \\
=\int_{0}^{T}\left\langle Y(u), X^{r}(u)\right\rangle d u-\int_{0}^{T}\left\langle Y(u), X^{l}(u)\right\rangle d u
\end{gathered}
$$

However, both $X^{r}$ and $X^{l}$ converge to $X$ in $K=L^{p}(0, T, V)$. Therefore, this term must converge to 0 . Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t$,

$$
|X(t)|^{2}=\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

It remains to verify that this holds for all $t$. Let $t \notin D$ and let $t(k) \in \mathscr{P}_{k}$ be the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$
X(t(m))=X_{0}+\int_{0}^{t(m)} Y(s) d s
$$

a similar formula for $X(t(k))$. Thus for $t>t(m)$,

$$
X(t)-X(t(m))=\int_{t(m)}^{t} Y(s) d s
$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $X_{0}=0$. Therefore,

$$
|X(t(k))-X(t(m))|^{2}=2 \int_{t(m)}^{t(k)}\langle Y(s), X(s)-X(t(m))\rangle d s
$$

Thus, for $m \leq k$

$$
\lim _{m, k \rightarrow \infty}|X(t(k))-X(t(m))|^{2}=0
$$

Hence $\{X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $H$. Does it converge to $X(t)$ ? Let $\xi(t) \in H$ be what it does converge to. Let $v \in V$. Then

$$
(\xi(t), v)=\lim _{k \rightarrow \infty}(X(t(k)), v)=\lim _{k \rightarrow \infty}\langle X(t(k)), v\rangle=\langle X(t), v\rangle=(X(t), v)
$$

because it is known that $t \rightarrow X(t)$ is continuous into $V^{\prime}$ and it is also known that $X(t) \in H$ and that the $X(t)$ for $t \in[0, T]$ are uniformly bounded. Therefore, since $V$ is dense in $H$, it follows that $\xi(t)=X(t)$.

Now for every $t \in D$, it was shown above that

$$
|X(t)|^{2}=\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Thus, using what was just shown, if $t \notin D$ and $t_{k} \rightarrow t$,

$$
\begin{aligned}
|X(t)|^{2} & =\lim _{k \rightarrow \infty}\left|X\left(t_{k}\right)\right|^{2}=\lim _{k \rightarrow \infty}\left(\left|X_{0}\right|^{2}+2 \int_{0}^{t_{k}}\langle Y(s), X(s)\rangle d s\right) \\
& =\left|X_{0}\right|^{2}+2 \int_{0}^{t}\langle Y(s), X(s)\rangle d s
\end{aligned}
$$

which proves the desired formula. From this it follows right away that $t \rightarrow X(t)$ is continuous into $H$ because it was just shown that $t \rightarrow|X(t)|$ is continuous and $t \rightarrow X(t)$ is weakly continuous. Since Hilbert space is uniformly convex, this implies the $t \rightarrow X(t)$ is continuous. To see this in the special cas of Hilbert space,

$$
|X(t)-X(s)|^{2}=|X(t)|^{2}-2(X(s), X(t))+|X(s)|^{2}
$$

Then $\lim _{t \rightarrow s}\left(|X(t)|^{2}-2(X(s), X(t))+|X(s)|^{2}\right)=0$ by weak convergence of $X(t)$ to $X(s)$ and the convergence of $|X(t)|^{2}$ to $|X(s)|^{2}$.

### 43.3 The Implicit Case

The above theorem can be generalized to the case where the formula is of the form

$$
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s
$$

This involves an operator $B \in \mathscr{L}\left(W, W^{\prime}\right)$ and $B$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle
$$

for

$$
V \subseteq W, W^{\prime} \subseteq V^{\prime}
$$

Where $V$ is dense in the Hilbert space $W$. Before giving the theorem, here is a technical lemma.

Lemma 43.3.1 Suppose $V, W$ are separable Banach spaces, $W$ also a Hilbert space such that $V$ is dense in $W$ and $B \in \mathscr{L}\left(W, W^{\prime}\right)$ satisfies

$$
\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle, B \neq 0 .
$$

Then there exists a countable set $\left\{e_{i}\right\}$ of vectors in $V$ such that

$$
\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}
$$

and for each $x \in W$,

$$
\langle B x, x\rangle=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2},
$$

and also

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

the series converging in $W^{\prime}$.
Proof: Let $\left\{g_{k}\right\}_{k=1}^{\infty}$ be linearly independent vectors of $V$ whose span is dense in $V$. This is possible because $V$ is separable. Thus, their span is also dense in $W$. Let $n_{1}$ be the first index such that $\left\langle B g_{n_{1}}, g_{n_{1}}\right\rangle \neq 0$.

Claim: If there is no such index, then $B=0$.
Proof of claim: First note that if there is no such first index, then if $x=\sum_{i=1}^{k} a_{i} g_{i}$

$$
\begin{aligned}
|\langle B x, x\rangle| & =\left|\sum_{i \neq j} a_{i} a_{j}\left\langle B g_{i}, g_{j}\right\rangle\right| \leq \sum_{i \neq j}\left|a_{i}\right|\left|a_{j}\right|\left|\left\langle B g_{i}, g_{j}\right\rangle\right| \\
& \leq \sum_{i \neq j}\left|a_{i}\right|\left|a_{j}\right|\left\langle B g_{i}, g_{i}\right\rangle^{1 / 2}\left\langle B g_{j}, g_{j}\right\rangle^{1 / 2}=0
\end{aligned}
$$

Therefore, if $x$ is given, you could take $x_{k}$ in the span of $\left\{g_{1}, \cdots, g_{k}\right\}$ such that $\left\|x_{k}-x\right\|_{W} \rightarrow$ 0 . Then

$$
|\langle B x, y\rangle|=\lim _{k \rightarrow \infty}\left|\left\langle B x_{k}, y\right\rangle\right| \leq \lim _{k \rightarrow \infty}\left\langle B x_{k}, x_{k}\right\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2}=0
$$

because $\left\langle B x_{k}, x_{k}\right\rangle$ is zero by what was just shown.
Thus assume there is such a first index. Let

$$
e_{1} \equiv \frac{g_{n_{1}}}{\left\langle B g_{n_{1}}, g_{n_{1}}\right\rangle^{1 / 2}}
$$

Then $\left\langle B e_{1}, e_{1}\right\rangle=1$. Now if you have constructed $e_{j}$ for $j \leq k$,

$$
e_{j} \in \operatorname{span}\left(g_{n_{1}}, \cdots, g_{n_{k}}\right),\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j},
$$

$g_{n_{j+1}}$ being the first for which

$$
\left\langle B g_{n_{j+1}}-\sum_{i=1}^{j}\left\langle B g_{n_{j+1}}, e_{i}\right\rangle B e_{i}, g_{n_{j+1}}-\sum_{i=1}^{j}\left\langle B g_{n j}, e_{i}\right\rangle e_{i}\right\rangle \neq 0,
$$

and

$$
\operatorname{span}\left(g_{n_{1}}, \cdots, g_{n_{k}}\right)=\operatorname{span}\left(e_{1}, \cdots, e_{k}\right)
$$

let $g_{n_{k+1}}$ be such that $g_{n_{k+1}}$ is the first in the list $\left\{g_{n_{k}}\right\}$ such that

$$
\left\langle B g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle B e_{i}, g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right\rangle \neq 0
$$

Note the difference between this and the Gram Schmidt process. Here you don't necessarily use all of the $g_{k}$ due to the possible degeneracy of $B$.

Claim: If there is no such first $g_{n_{k+1}}$, then $B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)=B W$ so in this case, $\left\{B e_{i}\right\}_{i=1}^{k}$ is actually a basis for $B W$.

Proof: Let $x \in W$. Let $x_{r} \in \operatorname{span}\left(g_{1}, \cdots, g_{r}\right), r>n_{k}$ such that $\lim _{r \rightarrow \infty} x_{r}=x$ in $W$. Then

$$
\begin{equation*}
x_{r}=\sum_{i=1}^{k} c_{i}^{r} e_{i}+\sum_{i \notin\left\{n_{1}, \cdots, n_{k}\right\}}^{r} d_{i}^{r} g_{i} \equiv y_{r}+z_{r} \tag{43.3.10}
\end{equation*}
$$

If $l \notin\left\{n_{1}, \cdots, n_{k}\right\}$, then by the construction and the above assumption, for some $j \leq k$

$$
\begin{equation*}
\left\langle B g_{l}-\sum_{i=1}^{j}\left\langle B g_{l}, e_{i}\right\rangle B e_{i}, g_{l}-\sum_{i=1}^{j}\left\langle B g_{l}, e_{i}\right\rangle e_{i}\right\rangle=0 \tag{43.3.11}
\end{equation*}
$$

If $l<n_{k}$, this follows from the construction. If the above is nonzero all $j \leq k$, then $l$ would have been chosen but it wasn't. Thus

$$
B g_{l}=\sum_{i=1}^{j}\left\langle B g_{l}, e_{i}\right\rangle B e_{i}
$$

If $l>n_{k}$, then by assumption, 43.3.11 holds for $j=k$. Thus, in any case, it follows that for each $l \notin\left\{n_{1}, \cdots, n_{k}\right\}$,

$$
B g_{l} \in B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)
$$

Now it follows from 43.3.10 that

$$
\begin{aligned}
B x_{r} & =\sum_{i=1}^{k} c_{i}^{r} B e_{i}+\sum_{i \notin\left\{n_{1}, \cdots, n_{k}\right\}}^{r} d_{i}^{r} B g_{i} \\
& =\sum_{i=1}^{k} c_{i}^{r} B e_{i}+\sum_{i \notin\left\{n_{1}, \cdots, n_{k}\right\}}^{r} d_{i}^{r} \sum_{j=1}^{k} c_{j}^{i} B e_{j}
\end{aligned}
$$

and so $B x_{r} \in B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)$. Then

$$
B x=\lim _{r \rightarrow \infty} B x_{r}=\lim _{r \rightarrow \infty} B y_{r}
$$

where $y_{r} \in \operatorname{span}\left(e_{i}, \cdots, e_{k}\right)$. Say

$$
B x_{r}=\sum_{i=1}^{k} a_{i}^{r} B e_{i}
$$

It follows easily that $\left\langle B x_{r}, e_{j}\right\rangle=a_{j}^{r}$. (Act on $e_{j}$ by both sides and use $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$.) Now since $x_{r}$ is bounded, it follows that these $a_{j}^{r}$ are also bounded. Hence, defining $y_{r} \equiv \sum_{i=1}^{k} a_{i}^{r} e_{i}$, it follows that $y_{r}$ is bounded in $\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)$ and so, there exists a subsequence, still denoted by $r$ such that $y_{r} \rightarrow y \in \operatorname{span}\left(e_{i}, \cdots, e_{k}\right)$. Therefore, $B x=$ $\lim _{r \rightarrow \infty} B y_{r}=B y$. In other words, $B W=B\left(\operatorname{span}\left(e_{i}, \cdots, e_{k}\right)\right)$ as claimed. This proves the claim.

If this happens, the process being described stops. You have found what is desired which has only finitely many vectors involved.

As long as the process does not stop, let

$$
e_{k+1} \equiv \frac{g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}}{\left\langle B\left(g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right), g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right\rangle^{1 / 2}}
$$

Thus, as in the usual argument for the Gram Schmidt process, $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$ for $i, j \leq k+1$. This is already known for $i, j \leq k$. Letting $l \leq k$, and using the orthogonality already shown,

$$
\begin{aligned}
\left\langle B e_{k+1}, e_{l}\right\rangle & =C\left\langle B\left(g_{n_{k+1}}-\sum_{i=1}^{k}\left\langle B g_{n_{k+1}}, e_{i}\right\rangle e_{i}\right), e_{l}\right\rangle \\
& =C\left(\left\langle B g_{k+1}, e_{l}\right\rangle-\left\langle B g_{n_{k+1}}, e_{l}\right\rangle\right)=0
\end{aligned}
$$

Consider

$$
\left\langle B g_{p}-B\left(\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right), g_{p}-\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle e_{i}\right\rangle
$$

Either this equals 0 because $p$ is never one of the $n_{k}$ or eventually it equals 0 for some $k$ because $g_{p}=g_{n_{k}}$ for some $n_{k}$ and so, from the construction, $g_{n_{k}}=g_{p} \in \operatorname{span}\left(e_{1}, \cdots, e_{k}\right)$ and therefore,

$$
g_{p}=\sum_{j=1}^{k} a_{j} e_{j}
$$

which requires easily that

$$
B g_{p}=\sum_{i=1}^{k}\left\langle B g_{p}, e_{i}\right\rangle B e_{i}
$$

the above holding for all $k$ large enough. It follows that for any $x \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$, (finite linear combination of vectors in $\left\{g_{k}\right\}_{k=1}^{\infty}$ )

$$
\begin{equation*}
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i} \tag{43.3.12}
\end{equation*}
$$

because for all $k$ large enough,

$$
B x=\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

Also note that for such $x \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$,

$$
\begin{aligned}
\langle B x, x\rangle & =\left\langle\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}, x\right\rangle=\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle\left\langle B x, e_{i}\right\rangle \\
& =\sum_{i=1}^{k}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}=\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
\end{aligned}
$$

Now for $x$ arbitrary, let $x_{k} \rightarrow x$ in $W$ where $x_{k} \in \operatorname{span}\left(\left\{g_{k}\right\}_{k=1}^{\infty}\right)$. Then by Fatou's lemma,

$$
\begin{align*}
\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2} & \leq \lim _{k \rightarrow \infty} \sum_{i=1}^{\infty}\left|\left\langle B x_{k}, e_{i}\right\rangle\right|^{2} \\
& =\liminf _{k \rightarrow \infty}\left\langle B x_{k}, x_{k}\right\rangle=\langle B x, x\rangle  \tag{43.3.13}\\
& \leq\|B x\|_{W^{\prime}}\|x\|_{W} \leq\|B\|\|x\|_{W}^{2}
\end{align*}
$$

Thus the series on the left converges. Then also, from the above inequality,

$$
\begin{aligned}
& \left|\left\langle\sum_{i=p}^{q}\left\langle B x, e_{i}\right\rangle B e_{i}, y\right\rangle\right| \leq \sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|\left|\left\langle B e_{i}, y\right\rangle\right| \\
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=p}^{q}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}
\end{aligned}
$$

By 43.3.13,

$$
\begin{aligned}
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\|B\|\|y\|_{W}^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}\|y\|_{W}
\end{aligned}
$$

It follows that

$$
\begin{equation*}
\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i} \tag{43.3.14}
\end{equation*}
$$

converges in $W^{\prime}$ because it was just shown that

$$
\left\|\sum_{i=p}^{q}\left\langle B x, e_{i}\right\rangle B e_{i}\right\|_{W^{\prime}} \leq\left(\sum_{i=p}^{q}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}
$$

and it was shown above that $\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}<\infty$, so the partial sums of the series 43.3.14 are a Cauchy sequence in $W^{\prime}$. Also, the above estimate shows that for $\|y\|=1$,

$$
\begin{aligned}
\left|\left\langle\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}, y\right\rangle\right| & \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B y, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2}
\end{aligned}
$$

and so

$$
\begin{equation*}
\left\|\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\|_{W^{\prime}} \leq\left(\sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}\right)^{1 / 2}\|B\|^{1 / 2} \tag{43.3.15}
\end{equation*}
$$

Now for $x$ arbitrary, let $x_{k} \in \operatorname{span}\left(\left\{g_{j}\right\}_{j=1}^{\infty}\right)$ and $x_{k} \rightarrow x$ in $W$. Then for a fixed $k$ large enough,

$$
\begin{gathered}
\left\|B x-\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\| \leq\left\|B x-B x_{k}\right\| \\
+\left\|B x_{k}-\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}\right\|+\left\|\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}-\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}\right\| \\
\leq \varepsilon+\left\|\sum_{i=1}^{\infty}\left\langle B\left(x_{k}-x\right), e_{i}\right\rangle B e_{i}\right\|
\end{gathered}
$$

the term

$$
\left\|B x_{k}-\sum_{i=1}^{\infty}\left\langle B x_{k}, e_{i}\right\rangle B e_{i}\right\|
$$

equaling 0 by 43.3.12. From 43.3.15 and 43.3.13,

$$
\begin{aligned}
& \leq \varepsilon+\|B\|^{1 / 2}\left(\sum_{i=1}^{\infty}\left|\left\langle B\left(x_{k}-x\right), e_{i}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq \varepsilon+\|B\|^{1 / 2}\left\langle B\left(x_{k}-x\right), x_{k}-x\right\rangle^{1 / 2}<2 \varepsilon
\end{aligned}
$$

whenever $k$ is large enough. Therefore,

$$
B x=\sum_{i=1}^{\infty}\left\langle B x, e_{i}\right\rangle B e_{i}
$$

in $W^{\prime}$. It follows that

$$
\langle B x, x\rangle=\lim _{k \rightarrow \infty}\left\langle\sum_{i=1}^{k}\left\langle B x, e_{i}\right\rangle B e_{i}, x\right\rangle=\lim _{k \rightarrow \infty} \sum_{i=1}^{k}\left|\left\langle B x, e_{i}\right\rangle\right|^{2} \equiv \sum_{i=1}^{\infty}\left|\left\langle B x, e_{i}\right\rangle\right|^{2}
$$

Theorem 43.3.2 Let $V \subseteq W, W^{\prime} \subseteq V^{\prime}$ be separable Banach spaces, $W$ a separable Hilbert space, and let $Y \in L^{p^{\prime}}\left(0, T ; V^{\prime}\right) \equiv K^{\prime}$ and

$$
\begin{equation*}
B X(t)=B X_{0}+\int_{0}^{t} Y(s) d s \operatorname{in} V^{\prime} \tag{43.3.16}
\end{equation*}
$$

where $X_{0} \in W$, and it is known that $X \in L^{p}(0, T, V) \equiv K$ for $p>1$. Also assume $X \in$ $L^{2}(0, T, W)$. Then $t \rightarrow B X(t)$ is in $C\left([0, T], W^{\prime}\right)$ and also

$$
\frac{1}{2}\langle B X(t), X(t)\rangle=\frac{1}{2}\left\langle B X_{0}, X_{0}\right\rangle+\int_{0}^{t}\langle Y(s), X(s)\rangle d s
$$

Proof: By Lemma 43.2.1, there exists a sequence of uniform partitions $\left\{t_{k}^{n}\right\}_{k=0}^{m_{n}}=$ $\mathscr{P}_{n}, \mathscr{P}_{n} \subseteq \mathscr{P}_{n+1}$, of $[0, T]$ such that the step functions

$$
\begin{aligned}
\sum_{k=0}^{m_{n}-1} X\left(t_{k}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{l}(t) \\
\sum_{k=0}^{m_{n}-1} X\left(t_{k+1}^{n}\right) \mathscr{X}_{\left(t_{k}^{n}, t_{k+1}^{n}\right]}(t) & \equiv X^{r}(t)
\end{aligned}
$$

converge to $X$ in $K$ and also $B X^{l}, B X^{r} \rightarrow B X$ in $L^{2}\left([0, T], W^{\prime}\right)$.
Lemma 43.3.3 Let $s<t$. Then for $X, Y$ satisfying 43.3.16

$$
\begin{gather*}
\langle B X(t), X(t)\rangle=\langle B X(s), X(s)\rangle \\
+2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle \tag{43.3.17}
\end{gather*}
$$

Proof: It follows from the following computations

$$
B(X(t)-X(s))=\int_{s}^{t} Y(u) d u
$$

and so

$$
\begin{gathered}
2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle \\
=2\langle B(X(t)-X(s)), X(t)\rangle-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle \\
=2\langle B X(t), X(t)\rangle-2\langle B X(s), X(t)\rangle-\langle B X(t), X(t)\rangle \\
+2\langle B X(s), X(t)\rangle-\langle B X(s), X(s)\rangle \\
=\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle
\end{gathered}
$$

Thus

$$
\begin{gathered}
\langle B X(t), X(t)\rangle-\langle B X(s), X(s)\rangle \\
=2 \int_{s}^{t}\langle Y(u), X(t)\rangle d u-\langle B(X(t)-X(s)),(X(t)-X(s))\rangle
\end{gathered}
$$

Lemma 43.3.4 In the above situation,

$$
\sup _{t \in[0, T]}\langle B X(t), X(t)\rangle \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

Also, $t \rightarrow B X(t)$ is weakly continuous with values in $W^{\prime}$.
Proof: From the above formula applied to the $k^{t h}$ partition of $[0, T]$ described above,

$$
\begin{aligned}
& \left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle=\sum_{j=0}^{m-1}\left\langle B X\left(t_{j+1}\right), X\left(t_{j+1}\right)\right\rangle-\left\langle B X\left(t_{j}\right), X\left(t_{j}\right)\right\rangle \\
& =\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle d u-\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle \\
& =\sum_{j=0}^{m-1} 2 \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u-\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle
\end{aligned}
$$

Thus, discarding the negative terms and denoting by $\mathscr{P}_{k}$ the $k^{t h}$ of these partitions,

$$
\begin{gathered}
\sup _{t_{j} \in \mathscr{P}_{k}}\left\langle B X\left(t_{j}\right), X\left(t_{j}\right)\right\rangle \leq\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{T}\left|\left\langle Y(u), X_{k}^{r}(u)\right\rangle\right| d u \\
\leq\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{T}\|Y(u)\|_{V^{\prime}}\left\|X_{k}^{r}(u)\right\|_{V} d u
\end{gathered}
$$

$$
\begin{aligned}
& \leq\left\langle B X_{0}, X_{0}\right\rangle+2\left(\int_{0}^{T}\|Y(u)\|_{V^{\prime}}^{p^{\prime}} d u\right)^{1 / p^{\prime}}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p} d u\right)^{1 / p} \\
& \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
\end{aligned}
$$

because these partitions are chosen such that

$$
\lim _{k \rightarrow \infty}\left(\int_{0}^{T}\left\|X_{k}^{r}(u)\right\|_{V}^{p}\right)^{1 / p}=\left(\int_{0}^{T}\|X(u)\|_{V}^{p}\right)^{1 / p}
$$

and so these are bounded. This has shown that for the dense subset of $[0, T], D \equiv \cup_{k} \mathscr{P}_{k}$,

$$
\sup _{t \in D}\langle B X(t), X(t)\rangle<C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

From Lemma 43.3.1 above, there exists $\left\{e_{i}\right\} \subseteq V$ such that $\left\langle B e_{i}, e_{j}\right\rangle=\delta_{i j}$ and

$$
\langle B X(t), X(t)\rangle=\sum_{k=1}^{\infty}\left|\left\langle B X(t), e_{i}\right\rangle\right|^{2}=\sup _{m} \sum_{k=1}^{m}\left|\left\langle B X(t), e_{i}\right\rangle\right|^{2}
$$

Since each $e_{i} \in V$, and since $t \rightarrow B X(t)$ is continuous into $V^{\prime}$ thanks to the formula 43.3.16, it follows that $t \rightarrow \sum_{k=1}^{m}\left|\left\langle B X(t), e_{i}\right\rangle\right|$ is continuous and so $t \rightarrow\langle B X(t), X(t)\rangle$ is the sup of continuous functions. Therefore, this function of $t$ is lower semicontinuous. Since $D$ is dense in $[0, T]$, it follows that for all $t$,

$$
\langle B X(t), X(t)\rangle \leq C\left(\|Y\|_{K^{\prime}},\|X\|_{K}\right)
$$

It only remains to verify the claim about weak continuity.
Consider now the claim that $t \rightarrow B X(t)$ is weakly continuous. Letting $v \in V$,

$$
\begin{equation*}
\lim _{t \rightarrow s}\langle B X(t), v\rangle=\langle B X(s), v\rangle=\langle B X(s), v\rangle \tag{43.3.18}
\end{equation*}
$$

The limit follows from the formula 43.3.16 which implies $t \rightarrow B X(t)$ is continuous into $V^{\prime}$. Now

$$
\|B X(t)\|=\sup _{\|v\| \leq 1}|\langle B X(t), v\rangle| \leq\langle B v, v\rangle^{1 / 2}\langle B X(t), X(t)\rangle^{1 / 2}
$$

which was shown to be bounded for $t \in[0, T]$. Now let $w \in W$. Then

$$
|\langle B X(t), w\rangle-\langle B X(s), w\rangle| \leq|\langle B X(t)-B X(s), w-v\rangle|+|\langle B X(t)-B X(s), v\rangle|
$$

Then the first term is less than $\varepsilon$ if $v$ is close enough to $w$ and the second converges to 0 so 43.3.18 holds for all $v \in W$ and so this shows the weak continuity.

Now pick $t \in D$, the union of all the mesh points. Then for all $k$ large enough, $t \in \mathscr{P}_{k}$. Say $t=t_{m}$. From Lemma 43.3.3,

$$
-\sum_{j=0}^{m-1}\left\langle B\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right),\left(X\left(t_{j+1}\right)-X\left(t_{j}\right)\right)\right\rangle=
$$

$$
\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle-\left\langle B X_{0}, X_{0}\right\rangle-2 \sum_{j=0}^{m-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X_{k}^{r}(u)\right\rangle d u
$$

Thus, $\left\langle B X\left(t_{m}\right), X\left(t_{m}\right)\right\rangle$ is constant for all $k$ large enough and the integral term converges to

$$
\int_{0}^{t_{m}}\langle Y(u), X(u)\rangle d u
$$

It follows that the term on the left does converge to something as $k \rightarrow \infty$. It just remains to consider what it does converge to. However, from the equation solved by $X$,

$$
B X\left(t_{j+1}\right)-B X\left(t_{j}\right)=\int_{t_{j}}^{t_{j+1}} Y(u) d u
$$

Therefore, this term is dominated by an expression of the form

$$
\begin{gathered}
\sum_{j=0}^{m_{k}-1}\left(\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right) \\
=\sum_{j=0}^{m_{k}-1}\left\langle\int_{t_{j}}^{t_{j+1}} Y(u) d u, X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)-X\left(t_{j}\right)\right\rangle d u \\
=\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j+1}\right)\right\rangle-\sum_{j=0}^{m_{k}-1} \int_{t_{j}}^{t_{j+1}}\left\langle Y(u), X\left(t_{j}\right)\right\rangle \\
=\int_{0}^{T}\left\langle Y(u), X^{r}(u)\right\rangle d u-\int_{0}^{T}\left\langle Y(u), X^{l}(u)\right\rangle d u
\end{gathered}
$$

However, both $X^{r}$ and $X^{l}$ converge to $X$ in $K=L^{p}(0, T, V)$. Therefore, this term must converge to 0 . Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t \in D$,

$$
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

It remains to verify that this holds for all $t$. Let $t \notin D$ and let $t(k) \in \mathscr{P}_{k}$ be the largest point of $\mathscr{P}_{k}$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$
B X(t(m))=B X_{0}+\int_{0}^{t(m)} Y(s) d s
$$

a similar formula for $X(t(k))$. Thus for $t>t(m)$,

$$
B X(t)-B X(t(m))=\int_{t(m)}^{t} Y(s) d s
$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $X_{0}=0$. Therefore,

$$
\begin{aligned}
& \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle \\
= & 2 \int_{t(m)}^{t(k)}\langle Y(s), X(s)-X(t(m))\rangle d s
\end{aligned}
$$

Thus, for $m \leq k$

$$
\begin{equation*}
\lim _{m, k \rightarrow \infty}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle=0 \tag{43.3.19}
\end{equation*}
$$

Hence $\{B X(t(k))\}_{k=1}^{\infty}$ is a convergent sequence in $W^{\prime}$ because

$$
\begin{aligned}
& |\langle B(X(t(k))-X(t(m))), y\rangle| \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\langle B y, y\rangle^{1 / 2} \\
\leq & \langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2}\|B\|^{1 / 2}\|y\|_{W}
\end{aligned}
$$

Does it converge to $B X(t)$ ? Let $\xi(t) \in W^{\prime}$ be what it does converge to. Let $v \in V$. Then

$$
\langle\xi(t), v\rangle=\lim _{k \rightarrow \infty}\langle B X(t(k)), v\rangle=\lim _{k \rightarrow \infty}\langle B X(t(k)), v\rangle=\langle B X(t), v\rangle
$$

because it is known that $t \rightarrow B X(t)$ is continuous into $V^{\prime}$. It is also known that $B X(t) \in$ $W^{\prime} \subseteq V^{\prime}$ and that the $B X(t)$ for $t \in[0, T]$ are uniformly bounded in $W^{\prime}$. Therefore, since $V$ is dense in $W$, it follows that $\xi(t)=B X(t)$.

Now for every $t \in D$, it was shown above that

$$
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

Also it was just shown that $B X(t(k)) \rightarrow B X(t)$. Then

$$
\begin{gathered}
|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle| \\
\leq|\langle B X(t(k)), X(t(k))-X(t)\rangle|+|\langle B X(t(k))-B X(t), X(t)\rangle|
\end{gathered}
$$

Then the second term converges to 0 . The first equals

$$
\begin{aligned}
& |\langle B X(t(k))-B X(t), X(t(k))\rangle| \\
\leq & \langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2}\langle B X(t(k)), X(t(k))\rangle^{1 / 2}
\end{aligned}
$$

From the above, this is dominated by an expression of the form

$$
\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle^{1 / 2} C
$$

Then using the lower semicontinuity of $t \rightarrow\langle B(X(t(k))-X(t)), X(t(k))-X(t)\rangle$ which follows from the above, this is no larger than

$$
\lim \inf _{m \rightarrow \infty}\langle B(X(t(k))-X(t(m))), X(t(k))-X(t(m))\rangle^{1 / 2} C<\varepsilon
$$

provided $k$ is large enough. This follows from 43.3.19. Since $\varepsilon$ is arbitrary, it follows that

$$
\lim _{k \rightarrow \infty}|\langle B X(t(k)), X(t(k))\rangle-\langle B X(t), X(t)\rangle|=0
$$

Then from the formula,

$$
\langle B X(t), X(t)\rangle=\left\langle B X_{0}, X_{0}\right\rangle+2 \int_{0}^{t}\langle Y(u), X(u)\rangle d u
$$

valid for $t \in D$, it follows that the same formula holds for all $t$. This formula implies $t \rightarrow\langle B X(t), X(t)\rangle$ is continuous. Also recall that $t \rightarrow B X(t)$ was shown to be weakly continuous into $W^{\prime}$. Then

$$
\langle B(X(t)-X(s)), X(t)-X(s)\rangle=\langle B X(t), X(t)\rangle-2\langle B X(t), X(s)\rangle+\langle B X(s), X(s)\rangle
$$

From this, it follows that $t \rightarrow B X(t)$ is continuous into $W^{\prime}$ because $\lim _{t \rightarrow s}$ of the right side gives 0 and so the same is true of the left. Hence,

$$
\begin{aligned}
& |\langle B(X(t)-X(s)), y\rangle| \\
\leq & \langle B y, y\rangle^{1 / 2}\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2} \\
\leq & \|B\|^{1 / 2}\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2}\|y\|
\end{aligned}
$$

so

$$
\|B(X(t)-X(s))\|_{W^{\prime}} \leq\|B\|^{1 / 2}\langle B(X(t)-X(s)), X(t)-X(s)\rangle^{1 / 2}
$$

which converges to 0 as $t \rightarrow s$.

### 43.4 Some Implicit Inclusions

Let $B \in \mathscr{L}\left(W, W^{\prime}\right)$ and $B$ satisfies $\langle B x, x\rangle \geq 0,\langle B x, y\rangle=\langle B y, x\rangle$ for $V \subseteq W, W^{\prime} \subseteq V^{\prime}$. Where $V$ is dense in the Hilbert space $W$. Now let

$$
\begin{equation*}
D(L) \equiv\left\{u \in \mathscr{V}:(B u)^{\prime} \in \mathscr{V}^{\prime}, B u(0)=0\right\}, L u \equiv(B u)^{\prime} \tag{43.4.20}
\end{equation*}
$$

Then clearly $D(L)$ is dense in $\mathscr{V}$. Here $\mathscr{V} \equiv L^{p}([0, T], V)$ where $p \geq 2$ for simplicity. Now let

$$
\begin{equation*}
D(T) \equiv\left\{u \in \mathscr{V}: u^{\prime} \in \mathscr{V} \text { and } u(T)=0\right\}, T u \equiv-B\left(u^{\prime}\right) \tag{43.4.21}
\end{equation*}
$$

The idea is to show that $L=T^{*}$ and that $T$ is monotone. Then this will imply using Proposition 25.8.2 that $L^{*}$ is monotone. This is done by showing that $\mathscr{G}\left(L^{*}\right)=\overline{\mathscr{G}(T)}$.

Lemma 43.4. $T$ is monotone, $T^{*}=L$ and $L^{*}, L$ are both monotone.
Proof: First, why is $T$ monotone?

$$
\begin{aligned}
\int_{0}^{T}\left\langle-B u^{\prime}, u\right\rangle d t & =\int_{0}^{T}-\left\langle B u, u^{\prime}\right\rangle d t=-\left.\langle B u, u\rangle\right|_{0} ^{T}+\int_{0}^{T}\left\langle(B u)^{\prime}, u\right\rangle d t \\
& =\langle B u(0), u(0)\rangle+\int_{0}^{T}\left\langle B u^{\prime}, u\right\rangle d t
\end{aligned}
$$

and so

$$
2\langle T u, u\rangle=2 \int_{0}^{T}\left\langle-B u^{\prime}, u\right\rangle d t=\langle B u(0), u(0)\rangle \geq 0
$$

Next, why is $T^{*}=L$ ? Let $u \in D(L)$. Then for $v \in D(T)$,

$$
\begin{aligned}
\langle T v, u\rangle & =\int_{0}^{T}\left\langle-B v^{\prime}, u\right\rangle d t=\int_{0}^{T}\left\langle-B u, v^{\prime}\right\rangle d t=\left.\langle-B u, v\rangle\right|_{0} ^{T}+\int_{0}^{T}\left\langle(B u)^{\prime}, v\right\rangle d s \\
& =\langle L u, v\rangle
\end{aligned}
$$

Hence $u \in D\left(T^{*}\right)$ and $T^{*} u=L u$ since $D(T)$ is dense. Thus $D(L) \subseteq D\left(T^{*}\right)$ and on $D(L)$, these two are equal. Next suppose $u \in D\left(T^{*}\right)$. Then for all $v \in D(T),\langle T v, u\rangle \leq C\|v\|_{\mathscr{V}}$. Thus, by density and the Riesz representation theorem, there exists a unique $g^{*} \in \mathscr{V}^{\prime}$ such that

$$
\langle T v, u\rangle=\int_{0}^{T}\left\langle g^{*}, v\right\rangle d t=\int_{0}^{T}\left\langle-B v^{\prime}, u\right\rangle d t=-\int_{0}^{T}\left\langle B u, v^{\prime}\right\rangle d t
$$

In particular, it follows from the definition of weak $V^{\prime}$ valued distributions that $g^{*}=(B u)^{\prime}$. Simply specialize to letting $v(t)=v \phi(t)$ where $\phi \in C_{c}^{\infty}(0, T)$. Thus in particular $(B u)^{\prime} \in \mathscr{V}^{\prime}$ and the above reduces to

$$
\begin{gathered}
\langle T v, u\rangle=\int_{0}^{T}\left\langle(B u)^{\prime}, v\right\rangle d t \\
\langle T v, u\rangle= \\
=\int_{0}^{T}\left\langle-B v^{\prime}, u\right\rangle d t=\int_{0}^{T}\left\langle-B u, v^{\prime}\right\rangle d t=\left.\langle-B u, v\rangle\right|_{0} ^{T}+\int_{0}^{T}\left\langle(B u)^{\prime}, v\right\rangle d t \\
=
\end{gathered}
$$

Thus also $(B u)(0)=0$. Hence $D\left(T^{*}\right) \subseteq D(L)$ and this shows that $L=T^{*}$ as claimed.
Why is $L$ monotone? From the material on weak derivatives,

$$
B u(t)=\int_{0}^{t}(B u)^{\prime}(s) d s
$$

and now use Theorem 43.3.2 to obtain

$$
0 \leq\langle B u(t), u(t)\rangle=2 \int_{0}^{t}\left\langle(B u)^{\prime}, u\right\rangle d s
$$

In particular, this holds for $t=T$ and so $\langle L u, u\rangle \geq 0$.
Why is $L^{*}$ monotone? This follows from Proposition 25.8.2 and the fact that $L=T^{*}$ shown above.

$$
\mathscr{G}\left(L^{*}\right)=(\tau \mathscr{G}(L))^{\perp}
$$

Consider $(\tau S)^{\perp}$. To say that $\left(x, y^{*}\right) \in(\tau S)^{\perp}$ is to say that if $\left(a, b^{*}\right) \in S$, then

$$
\left\langle\left(x, y^{*}\right),\left(-b^{*}, a\right)\right\rangle=0
$$

or in other words, $\left\langle x, b^{*}\right\rangle=\left\langle y^{*}, a\right\rangle$. To say that $\left(x, y^{*}\right) \in \tau\left(S^{\perp}\right)$ is to say that $\left(x, y^{*}\right)=$ $\left(-c, d^{*}\right)$ where

$$
\left\langle\left(d^{*}, c\right),\left(a, b^{*}\right)\right\rangle=0
$$

for all $\left(a, b^{*}\right) \in S$. That is, $\left\langle\left(y^{*},-x\right),\left(a, b^{*}\right)\right\rangle=0$ for all $\left(a, b^{*}\right) \in S$. In other words $\left\langle y^{*}, a\right\rangle=$ $\left\langle x, b^{*}\right\rangle$ for all $\left(a, b^{*}\right) \in S$. Thus $(\tau S)^{\perp}=\tau\left(S^{\perp}\right)$. Now $\tau \tau(M)=M$ if $M$ is a subspace. and $\left(M^{\perp}\right)^{\perp}=\bar{M}$ if $M$ is a subspace. Hence

$$
\begin{aligned}
\mathscr{G}\left(L^{*}\right) & =(\tau \mathscr{G}(L))^{\perp}=\tau\left(\mathscr{G}(L)^{\perp}\right) \\
& =\tau\left(\left(\tau(\mathscr{G}(T))^{\perp}\right)^{\perp}\right)=\tau \tau\left(\mathscr{G}(T)^{\perp}\right)^{\perp}=\overline{\mathscr{G}(T)}
\end{aligned}
$$

Now it follows that, since $T$ is monotone, it follows that $L^{*}$ is also monotone.
Note that as part of this argument, we have proved that for $T$ a densely defined linear operator, $\mathscr{G}\left(T^{* *}\right)=\overline{\mathscr{G}(T)}$.

Now recall Theorem 25.8.8 on Page 923 which is listed next.

Theorem 43.4.2 Let $L: D(L) \subseteq V \rightarrow V^{\prime}$ where $D(L)$ is dense, $L$ is monotone, $L$ is closed, and $L^{*}$ is monotone, L a linear map. Let $T: V \rightarrow \mathscr{P}\left(V^{\prime}\right)$ be L pseudomonotone, bounded, coercive. Then $L+T$ is onto. Here $V$ is a reflexive Banach space such that the norms for $V$ and $V^{\prime}$ are strictly convex.

To apply this theorem, let $B$ be as above and $V \rightarrow \mathscr{V} \equiv L^{p}([0, T], V)$. Letting $u_{0} \in V$, let

$$
T(u) \equiv A\left(u+u_{0}\right)
$$

where $A: \mathscr{V} \rightarrow \mathscr{P}\left(\mathscr{V}^{\prime}\right)$. Suppose that $T$ just defined is set valued pseudomonotone and coercive. Let $L u=(B u)^{\prime}$ as described above in 43.4.20. Then from Theorem 43.4.2 and if $f \in \mathscr{V}^{\prime}$, there exists a solution $u$ to

$$
L u+A\left(u+u_{0}\right) \ni f
$$

Thus there exists $\xi \in A\left(u+u_{0}\right)$ such that $L u+\xi=f$ in $\mathscr{V}^{\prime}$. Then letting $w=u+u_{0}$, it follows that $\xi \in A(w)$ and $L\left(w-w_{0}\right)+\xi=f$. Thus,

$$
(B w)^{\prime}+\xi=f,(B w)(0)=B w_{0}
$$

Written in terms of $A,(B w)^{\prime}+A(w) \ni f$ in $\mathscr{V}^{\prime},(B w)(0)=B u_{0}$. This proves the following theorem about the existence of solutions to implicit evolution inclusions.

Theorem 43.4.3 Suppose $u \rightarrow A\left(u+u_{0}\right)$ is set valued pseudomonotone and coercive for $u_{0} \in V$. Also let

$$
V \subseteq W, W^{\prime} \subseteq V^{\prime}
$$

where $W$ is a Hilbert space, $V$ is a reflexive Banach space dense in $W$. Suppose $B: W \rightarrow W^{\prime}$ is self adjoint and nonnegative. Then there exists a solution $w \in \mathscr{V}$ to the implicit evolution equation

$$
(B w)^{\prime}+A(w) \ni f \text { in } \mathscr{V}^{\prime},(B w)(0)=B u_{0}
$$

### 43.5 Some Imbedding Theorems

The next theorem is very useful in getting estimates in partial differential equations. It is called Erling's lemma.

Definition 43.5.1 Let $E, W$ be Banach spaces such that $E \subseteq W$ and the injection map from $E$ into $W$ is continuous. The injection map is said to be compact if every bounded set in $E$ has compact closure in $W$. In other words, if a sequence is bounded in $E$ it has a convergent subsequence converging in $W$. This is also referred to by saying that bounded sets in $E$ are precompact in $W$.

Theorem 43.5.2 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then for every $\varepsilon>0$ there exists a constant, $C_{\varepsilon}$ such that for all $u \in E$,

$$
\|u\|_{W} \leq \varepsilon\|u\|_{E}+C_{\varepsilon}\|u\|_{X}
$$

Proof: Suppose not. Then there exists $\varepsilon>0$ and for each $n \in \mathbb{N}, u_{n}$ such that

$$
\left\|u_{n}\right\|_{W}>\varepsilon\left\|u_{n}\right\|_{E}+n\left\|u_{n}\right\|_{X}
$$

Now let $v_{n}=u_{n} /\left\|u_{n}\right\|_{E}$. Therefore, $\left\|v_{n}\right\|_{E}=1$ and

$$
\left\|v_{n}\right\|_{W}>\varepsilon+n\left\|v_{n}\right\|_{X}
$$

It follows there exists a subsequence, still denoted by $v_{n}$ such that $v_{n}$ converges to $v$ in $W$. However, the above inequality shows that $\left\|v_{n}\right\|_{X} \rightarrow 0$. Therefore, $v=0$. But then the above inequality would imply that $\left\|v_{n}\right\|>\varepsilon$ and passing to the limit yields $0>\varepsilon$, a contradiction.

Definition 43.5.3 Define $C([a, b] ; X)$ the space of functions continuous at every point of $[a, b]$ having values in $X$.

You should verify that this is a Banach space with norm

$$
\|u\|_{\infty, X}=\max \left\{\left\|u_{n_{k}}(t)-u(t)\right\|_{X}: t \in[a, b]\right\} .
$$

The following theorem is an infinite dimensional version of the Ascoli Arzela theorem. [117].

Theorem 43.5.4 Let $q>1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$
\left\{u \text { such that }\|u(t)\|_{E}+\left\|u^{\prime}\right\|_{L^{q}([a, b] ; X)} \leq R \text { for all } t \in[a, b]\right\}
$$

Then $S \subseteq C([a, b] ; W)$ and if $\left\{u_{n}\right\} \subseteq S$, there exists a subsequence, $\left\{u_{n_{k}}\right\}$ which converges to a function $u \in C([a, b] ; W)$ in the following way.

$$
\lim _{k \rightarrow \infty}\left\|u_{n_{k}}-u\right\|_{\infty, W}=0
$$

Proof: First consider the issue of $S$ being a subset of $C([a, b] ; W)$. By Theorem 43.1.9 on Page 1414 the following holds in $X$ for $u \in S$.

$$
u(t)-u(s)=\int_{s}^{t} u^{\prime}(r) d r
$$

Thus $S \subseteq C([a, b] ; X)$. Let $\varepsilon>0$ be given. Then by Theorem 43.5.2 there exists a constant, $C_{\varepsilon}$ such that for all $u \in W$

$$
\|u\|_{W} \leq \frac{\varepsilon}{4 R}\|u\|_{E}+C_{\varepsilon}\|u\|_{X}
$$

Therefore, for all $u \in S$,

$$
\begin{align*}
\|u(t)-u(s)\|_{W} & \leq \frac{\varepsilon}{6 R}\|u(t)-u(s)\|_{E}+C_{\varepsilon}\|u(t)-u(s)\|_{X} \\
& \leq \frac{\varepsilon}{3}+C_{\varepsilon}\left\|\int_{s}^{t} u^{\prime}(r) d r\right\|_{X} \\
& \leq \frac{\varepsilon}{3}+C_{\varepsilon} \int_{s}^{t}\left\|u^{\prime}(r)\right\|_{X} d r \leq \frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q} \tag{43.5.22}
\end{align*}
$$

Since $\varepsilon$ is arbitrary, it follows $u \in C([a, b] ; W)$.
Let $D=\mathbb{Q} \cap[a, b]$ so $D$ is a countable dense subset of $[a, b]$. Let $D=\left\{t_{n}\right\}_{n=1}^{\infty}$. By compactness of the embedding of $E$ into $W$, there exists a subsequence $u_{(n, 1)}$ such that as $n \rightarrow \infty, u_{(n, 1)}\left(t_{1}\right)$ converges to a point in $W$. Now take a subsequence of this, called $(n, 2)$ such that as $n \rightarrow \infty, u_{(n, 2)}\left(t_{2}\right)$ converges to a point in $W$. It follows that $u_{(n, 2)}\left(t_{1}\right)$ also converges to a point of $W$. Continue this way. Now consider the diagonal sequence, $u_{k} \equiv$ $u_{(k, k)}$ This sequence is a subsequence of $u_{(n, l)}$ whenever $k>l$. Therefore, $u_{k}\left(t_{j}\right)$ converges for all $t_{j} \in D$.

Claim: Let $\left\{u_{k}\right\}$ be as just defined, converging at every point of $D \equiv \mathbb{Q} \cap[a, b]$. Then $\left\{u_{k}\right\}$ converges at every point of $[a, b]$.

Proof of claim: Let $\varepsilon>0$ be given. Let $t \in[a, b]$. Pick $t_{m} \in D \cap[a, b]$ such that in 43.5.22 $C_{\varepsilon} R\left|t-t_{m}\right|<\varepsilon / 3$. Then there exists $N$ such that if $l, n>N$, then

$$
\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\|_{X}<\varepsilon / 3
$$

It follows that for $l, n>N$,

$$
\begin{aligned}
\left\|u_{l}(t)-u_{n}(t)\right\|_{X} \leq & \left\|u_{l}(t)-u_{l}\left(t_{m}\right)\right\|+\left\|u_{l}\left(t_{m}\right)-u_{n}\left(t_{m}\right)\right\| \\
& +\left\|u_{n}\left(t_{m}\right)-u_{n}(t)\right\| \\
\leq & \frac{2 \varepsilon}{3}+\frac{\varepsilon}{3}+\frac{2 \varepsilon}{3}<2 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ was arbitrary, this shows $\left\{u_{k}(t)\right\}_{k=1}^{\infty}$ is a Cauchy sequence. Since $W$ is complete, this shows this sequence converges.

Now for $t \in[a, b]$, it was just shown that if $\varepsilon>0$ there exists $N_{t}$ such that if $n, m>N_{t}$, then

$$
\left\|u_{n}(t)-u_{m}(t)\right\|<\frac{\varepsilon}{3}
$$

Now let $s \neq t$. Then

$$
\left\|u_{n}(s)-u_{m}(s)\right\| \leq\left\|u_{n}(s)-u_{n}(t)\right\|+\left\|u_{n}(t)-u_{m}(t)\right\|+\left\|u_{m}(t)-u_{m}(s)\right\|
$$

From 43.5.22

$$
\left\|u_{n}(s)-u_{m}(s)\right\| \leq 2\left(\frac{\varepsilon}{3}+C_{\varepsilon} R|t-s|^{1 / q}\right)+\left\|u_{n}(t)-u_{m}(t)\right\|
$$

and so it follows that if $\delta$ is sufficiently small and $s \in B(t, \boldsymbol{\delta})$, then when $n, m>N_{t}$

$$
\left\|u_{n}(s)-u_{m}(s)\right\|<\varepsilon .
$$

Since $[a, b]$ is compact, there are finitely many of these balls, $\left\{B\left(t_{i}, \delta\right)\right\}_{i=1}^{p}$, such that for $s \in B\left(t_{i}, \boldsymbol{\delta}\right)$ and $n, m>N_{t_{i}}$, the above inequality holds. Let $N>\max \left\{N_{t_{1}}, \cdots, N_{t_{p}}\right\}$. Then if $m, n>N$ and $s \in[a, b]$ is arbitrary, it follows the above inequality must hold. Therefore, this has shown the following claim.

Claim: Let $\varepsilon>0$ be given. There exists $N$ such that if $m, n>N$, then $\left\|u_{n}-u_{m}\right\|_{\infty, W}<\varepsilon$.
Now let $u(t)=\lim _{k \rightarrow \infty} u_{k}(t)$.

$$
\begin{equation*}
\|u(t)-u(s)\|_{W} \leq\left\|u(t)-u_{n}(t)\right\|_{W}+\left\|u_{n}(t)-u_{n}(s)\right\|_{W}+\left\|u_{n}(s)-u(s)\right\|_{W} \tag{43.5.23}
\end{equation*}
$$

Let $N$ be in the above claim and fix $n>N$. Then

$$
\left\|u(t)-u_{n}(t)\right\|_{W}=\lim _{m \rightarrow \infty}\left\|u_{m}(t)-u_{n}(t)\right\|_{W} \leq \varepsilon
$$

and similarly, $\left\|u_{n}(s)-u(s)\right\|_{W} \leq \varepsilon$. Then if $|t-s|$ is small enough, 43.5.22 shows the middle term in 43.5.23 is also smaller than $\varepsilon$. Therefore, if $|t-s|$ is small enough,

$$
\|u(t)-u(s)\|_{W}<3 \varepsilon
$$

Thus $u$ is continuous. Finally, let $N$ be as in the above claim. Then letting $m, n>N$, it follows that for all $t \in[a, b],\left\|u_{m}(t)-u_{n}(t)\right\|<\varepsilon$. Therefore, letting $m \rightarrow \infty$, it follows that for all $t \in[a, b],\left\|u(t)-u_{n}(t)\right\| \leq \varepsilon$. and so $\left\|u-u_{n}\right\|_{\infty, W} \leq \varepsilon$. Since $\varepsilon$ is arbitrary, this proves the theorem.

The next theorem is another such imbedding theorem found in [91]. It is often used in partial differential equations.

Theorem 43.5.5 Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $p \geq 1$, let $q>1$, and define

$$
\begin{aligned}
& S \equiv\left\{u \in L^{p}([a, b] ; E): u^{\prime} \in L^{q}([a, b] ; X)\right. \\
& \text { and } \left.\|u\|_{L^{p}([a, b] ; E)}+\left\|u^{\prime}\right\|_{L^{q}([a, b] ; X)} \leq R\right\} .
\end{aligned}
$$

Then $S$ is precompact in $L^{p}([a, b] ; W)$. This means that if $\left\{u_{n}\right\}_{n=1}^{\infty} \subseteq S$, it has a subsequence $\left\{u_{n_{k}}\right\}$ which converges in $L^{p}([a, b] ; W)$.

Proof: By Proposition 7.6 .5 on Page 144 it suffices to show $S$ has an $\eta$ net in the complete metric space $L^{p}([a, b] ; W)$ for each $\eta>0$.

If not, there exists $\eta>0$ and a sequence $\left\{u_{n}\right\} \subseteq S$, such that

$$
\begin{equation*}
\left\|u_{n}-u_{m}\right\| \geq \eta \tag{43.5.24}
\end{equation*}
$$

for all $n \neq m$ and the norm refers to $L^{p}([a, b] ; W)$. Let

$$
a=t_{0}<t_{1}<\cdots<t_{k}=b, t_{i}-t_{i-1}=(b-a) / k
$$

Now define

$$
\bar{u}_{n}(t) \equiv \sum_{i=1}^{k} \bar{u}_{n_{i}} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t), \bar{u}_{n_{i}} \equiv \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} u_{n}(s) d s
$$

The idea is to show that $\bar{u}_{n}$ approximates $u_{n}$ well and then to argue that a subsequence of the $\left\{\bar{u}_{n}\right\}$ is a Cauchy sequence yielding a contradiction to 43.5.24.

Therefore,

$$
u_{n}(t)-\bar{u}_{n}(t)=\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-\bar{u}_{n}(s)\right) d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) .
$$

It follows from Jensen's inequality that

$$
\begin{aligned}
& \left\|u_{n}(t)-\bar{u}_{n}(t)\right\|_{W}^{p} \\
= & \sum_{i=1}^{k}\left\|\frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left(u_{n}(t)-u_{n}(s)\right) d s\right\|_{W}^{p} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) \\
\leq & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
\end{aligned}
$$

and so

$$
\begin{align*}
& \int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \\
\leq & \int_{a}^{b} \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t) d t \\
= & \sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} d s d t \tag{43.5.25}
\end{align*}
$$

From Theorems 43.5 .2 and 43.1 .9 , if $\varepsilon>0$, there exists $C_{\varepsilon}$ such that

$$
\left\|u_{n}(t)-u_{n}(s)\right\|_{W}^{p} \leq \varepsilon\left\|u_{n}(t)-u_{n}(s)\right\|_{E}^{p}+C_{\varepsilon}\left\|u_{n}(t)-u_{n}(s)\right\|_{X}^{p}
$$

$$
\begin{aligned}
\leq & 2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}\left\|\int_{s}^{t} u_{n}^{\prime}(r) d r\right\|_{X}^{p} \\
\leq & 2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon}\left(\int_{s}^{t}\left\|u_{n}^{\prime}(r)\right\|_{X} d r\right)^{p} \\
\leq & 2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right) \\
& +C_{\varepsilon}\left(\left(\int_{s}^{t}\left\|u_{n}^{\prime}(r)\right\|_{X}^{q} d r\right)^{1 / q}|t-s|^{1 / q^{\prime}}\right)^{p} \\
= & 2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)+C_{\varepsilon} R^{p / q}|t-s|^{p / q^{\prime}}
\end{aligned}
$$

This is substituted in to 43.5 .25 to obtain

$$
\begin{gathered}
\int_{a}^{b}\left\|\left(u_{n}(t)-\bar{u}_{n}(s)\right)\right\|_{W}^{p} d s \leq \\
\\
\sum_{i=1}^{k} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}\left(2^{p-1} \varepsilon\left(\left\|u_{n}(t)\right\|^{p}+\left\|u_{n}(s)\right\|^{p}\right)\right. \\
\left.\quad+C_{\varepsilon} R^{p / q}|t-s|^{p / q^{\prime}}\right) d s d t \\
=\quad \sum_{i=1}^{k} 2^{p} \varepsilon \int_{t_{i-1}}^{t_{i}}\left\|u_{n}(t)\right\|_{W}^{p}+C_{\varepsilon} R^{p / q} \frac{1}{t_{i}-t_{i-1}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}}|t-s|^{p / q^{\prime}} d s d t \\
=\quad 2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} R^{p / q} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q^{\prime}} \int_{t_{i-1}}^{t_{i}} \int_{t_{i-1}}^{t_{i}} d s d t \\
=\quad 2^{p} \varepsilon \int_{a}^{b}\left\|u_{n}(t)\right\|^{p} d t+C_{\varepsilon} R^{p / q} \sum_{i=1}^{k} \frac{1}{\left(t_{i}-t_{i-1}\right)}\left(t_{i}-t_{i-1}\right)^{p / q^{\prime}}\left(t_{i}-t_{i-1}\right)^{2} \\
\leq \quad 2^{p} \varepsilon R^{p}+C_{\varepsilon} R^{p / q} \sum_{i=1}^{k}\left(t_{i}-t_{i-1}\right)^{1+p / q^{\prime}}=2^{p} \varepsilon R^{p}+C_{\varepsilon} R^{p / q} k\left(\frac{b-a}{k}\right)^{1+p / q^{\prime}} .
\end{gathered}
$$

Taking $\varepsilon$ so small that $2^{p} \varepsilon R^{p}<\eta^{p} / 8^{p}$ and then choosing $k$ sufficiently large, it follows

$$
\left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}([a, b] ; W)}<\frac{\eta}{4} .
$$

Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that $\left\{\bar{u}_{n}\right\}$ is Cauchy in $L^{p}(a, b ; W)$ and use this to contradict 43.5.24. The details follow.

Suppose $\bar{u}_{n}(t)=\sum_{i=1}^{k} u_{i}^{n} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)$. Thus

$$
\left\|\bar{u}_{n}(t)\right\|_{E}=\sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E} \mathscr{X}_{\left[t_{i-1}, t_{i}\right)}(t)
$$

and so

$$
R \geq \int_{a}^{b}\left\|\bar{u}_{n}(t)\right\|_{E}^{p} d t=\frac{T}{k} \sum_{i=1}^{k}\left\|u_{i}^{n}\right\|_{E}^{p}
$$

Therefore, the $\left\{u_{i}^{n}\right\}$ are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence $\left\{u_{n_{k}}\right\}$ such that $u_{n_{k}}$ is a Cauchy sequence in $L^{p}(a, b ; W)$. You simply get a subsequence such that $u_{i}^{n_{k}}$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,

$$
\begin{aligned}
\left\|u_{n}-u_{m}\right\|_{L^{p}(a, b ; W)} \leq & \left\|u_{n}-\bar{u}_{n}\right\|_{L^{p}(a, b ; W)} \\
& +\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\left\|\bar{u}_{m}-u_{m}\right\|_{L^{p}(a, b ; W)} \\
\leq & \frac{\eta}{4}+\left\|\bar{u}_{n}-\bar{u}_{m}\right\|_{L^{p}(a, b ; W)}+\frac{\eta}{4}<\eta
\end{aligned}
$$

provided $m, n$ are large enough, contradicting 43.5.24. This proves the theorem.

### 43.6 The $K$ Method

This considers the problem of interpolating Banach spaces. The idea is to build a Banach space between two others in a systematic way, thus constructing a new Banach space from old ones. The first method of defining intermediate Banach spaces is called the $K$ method. For more on this topic as well as the other topics on interpolation see [16] which is what I am following. See also [124]. There is far more on these subjects in these books than what I am presenting here! My goal is to present only enough to give an introduction to the topic and to use it in presenting more theory of Sobolev spaces.

In what follows a topological vector space is a vector space in which vector addition and scalar multiplication are continuous. That is $: ~: \mathbb{F} \times X \rightarrow X$ is continuous and $+: X \times X \rightarrow X$ is also continuous.

A common example of a topological vector space is the dual space, $X^{\prime}$ of a Banach space, $X$ with the weak $*$ topology. For $S \subseteq X$ a finite set, define

$$
B_{S}\left(x^{*}, r\right) \equiv\left\{y^{*} \in X^{\prime}:\left|y^{*}(x)-x^{*}(x)\right|<r \text { for all } x \in S\right\}
$$

Then the $B_{S}\left(x^{*}, r\right)$ for $S$ a finite subset of $X$ and $r>0$ form a basis for the topology on $X^{\prime}$ called the weak $*$ topology. You can check that the vector space operations are continuous.

Definition 43.6.1 Let $A_{0}$ and $A_{1}$ be two Banach spaces with norms $\|\cdot\|_{0}$ and $\|\cdot\|_{1}$ respectively, also written as $\|\cdot\|_{A_{0}}$ and $\|\cdot\|_{A_{1}}$ and let $X$ be a topological vector space such that $A_{i} \subseteq X$ for $i=1,2$, and the identity map from $A_{i}$ to $X$ is continuous. For each $t>0$, define a norm on $A_{0}+A_{1}$ by

$$
K(t, a) \equiv\|a\|_{t} \equiv \inf \left\{\left\|a_{0}\right\|_{0}+t\left\|a_{1}\right\|_{1}: a_{0}+a_{1}=a\right\}
$$

This is short for $K\left(t, a, A_{0}, A_{1}\right)$. Thus $K\left(t, a, A_{1}, A_{0}\right)$ will mean

$$
K\left(t, a, A_{1}, A_{0}\right) \equiv \inf \left\{\left\|a_{1}\right\|_{A_{1}}+t\left\|a_{0}\right\|_{A_{0}}: a_{0}+a_{1}=a\right\}
$$

but the default is $K\left(t, a, A_{0}, A_{1}\right)$ if $K(t, a)$ is written.
The following lemma is an interesting exercise.

Lemma 43.6.2 $\left(A_{0}+A_{1}, K(t, \cdot)\right)$ is a Banach space and all the norms, $K(t, \cdot)$ are equivalent.

Proof: First, why is $K(t, \cdot)$ a norm? It is clear that $K(t, a) \geq 0$ and that if $a=0$ then $K(t, a)=0$. Is this the only way this can happen? Suppose $K(t, a)=0$. Then there exist $a_{0 n} \in A_{0}$ and $a_{1 n} \in A_{1}$ such that $\left\|a_{0 n}\right\|_{0} \rightarrow 0,\left\|a_{1 n}\right\|_{1} \rightarrow 0$, and $a=a_{0 n}+a_{1 n}$. Since the embedding of $A_{i}$ into $X$ is continuous and since $X$ is a topological vector space ${ }^{1}$, it follows

$$
a=a_{0 n}+a_{1 n} \rightarrow 0
$$

and so $a=0$.
Let $\alpha$ be a nonzero scalar. Then

$$
\begin{aligned}
K(t, \alpha a) & =\inf \left\{\left\|a_{0}\right\|_{0}+t \mid a_{1} \|_{1}: a_{0}+a_{1}=\alpha a\right\} \\
& =\inf \left\{|\alpha|\left\|\frac{a_{0}}{\alpha}\right\|\left\|_{0}+t|\alpha|\right\| \frac{a_{1}}{\alpha} \|_{1}: \frac{a_{0}}{\alpha}+\frac{a_{1}}{\alpha}=a\right\} \\
& =|\alpha| \inf \left\{\left\|\frac{a_{0}}{\alpha}\right\|\left\|_{0}+t\right\| \frac{a_{1}}{\alpha}\| \|_{1}: \frac{a_{0}}{\alpha}+\frac{a_{1}}{\alpha}=a\right\} \\
& =|\alpha| \inf \left\{\left\|a_{0}\right\|_{0}+t\left\|a_{1}\right\|_{1}: a_{0}+a_{1}=a\right\}=|\alpha| K(t, a) .
\end{aligned}
$$

It remains to verify the triangle inequality. Let $\varepsilon>0$ be given. Then there exist $a_{0}, a_{1}, b_{0}$, and $b_{1}$ in $A_{0}, A_{1}, A_{0}$, and $A_{1}$ respectively such that $a_{0}+a_{1}=a, b_{0}+b_{1}=b$ and

$$
\begin{aligned}
\varepsilon+K(t, a)+K(t, b) & >\left\|a_{0}\right\|_{0}+t\left\|a_{1}\right\|_{1}+\left\|b_{0}\right\|_{0}+t\left\|b_{1}\right\|_{1} \\
& \geq\left\|a_{0}+b_{0}\right\|_{0}+t\left\|b_{1}+a_{1}\right\|_{1} \geq K(t, a+b)
\end{aligned}
$$

This has shown that $K(t, \cdot)$ is at least a norm. Are all these norms equivalent? If $0<s<t$ then it is clear that $K(t, a) \geq K(s, a)$. To show there exists a constant, $C$ such that $C K(s, a) \geq K(t, a)$ for all $a$,

$$
\begin{aligned}
\stackrel{t}{s} K(s, a) & \equiv \frac{t}{s} \inf \left\{\left\|a_{0}\right\|_{0}+s\left\|a_{1}\right\|_{1}: a_{0}+a_{1}=a\right\} \\
& =\inf \left\{\frac{t}{s}\left\|a_{0}\right\|_{0}+s-\frac{t}{s}\left\|a_{1}\right\|_{1}: a_{0}+a_{1}=a\right\} \\
& =\inf \left\{\frac{t}{s}\left\|a_{0}\right\|_{0}+t\left\|a_{1}\right\|_{1}: a_{0}+a_{1}=a\right\} \\
& \geq \inf \left\{\left\|a_{0}\right\|_{0}+t\left\|a_{1}\right\|_{1}: a_{0}+a_{1}=a\right\}=K(t, a)
\end{aligned}
$$

Therefore, the two norms are equivalent as hoped.
Finally, it is required to verify that $\left(A_{0}+A_{1}, K(t, \cdot)\right)$ is a Banach space. Since all these norms are equivalent, it suffices to only consider the norm, $K(1, \cdot)$. Let $\left\{a_{0 n}+a_{1 n}\right\}_{n=1}^{\infty}$ be a Cauchy sequence in $A_{0}+A_{1}$. Then for $m, n$ large enough,

$$
K\left(1, a_{0 n}+a_{1 n}-\left(a_{0 m}+a_{1 m}\right)\right)<\varepsilon .
$$

[^31]It follows there exist $x_{n} \in A_{0}$ and $y_{n} \in A_{1}$ such that $x_{n}+y_{n}=0$ for every $n$ and whenever $m, n$ are large enough,

$$
\left\|a_{0 n}+x_{n}-\left(a_{0 m}+x_{m}\right)\right\|_{0}+\left\|a_{1 n}+y_{n}-\left(a_{1 m}+y_{m}\right)\right\|_{1}<\varepsilon
$$

Hence $\left\{a_{1 n}+y_{n}\right\}$ is a Cauchy sequence in $A_{1}$ and $\left\{a_{0 n}+x_{n}\right\}$ is a Cauchy sequence in $A_{0}$. Let

$$
\begin{aligned}
a_{0 n}+x_{n} & \rightarrow a_{0} \in A_{0} \\
a_{1 n}+y_{n} & \rightarrow a_{1} \in A_{1} .
\end{aligned}
$$

Then

$$
\begin{aligned}
K\left(1, a_{0 n}+a_{1 n}-\left(a_{0}+a_{1}\right)\right) & =K\left(1, a_{0 n}+x_{n}+a_{1 n}+y_{n}-\left(a_{0}+a_{1}\right)\right) \\
& \leq\left\|a_{0 n}+x_{n}-a_{0}\right\|_{0}+\left\|a_{1 n}+y_{n}-a_{1}\right\|_{1}
\end{aligned}
$$

which converges to 0 . Thus $A_{0}+A_{1}$ is a Banach space as claimed.
With this, there exists a method for constructing a Banach space which lies between $A_{0} \cap A_{1}$ and $A_{0}+A_{1}$.

Definition 43.6.3 Let $1 \leq q<\infty, 0<\theta<1$. Define $\left(A_{0}, A_{1}\right)_{\theta, q}$ to be those elements of $A_{0}+A_{1}, a$, such that

$$
\|a\|_{\theta, q} \equiv\left[\int_{0}^{\infty}\left(t^{-\theta} K\left(t, a, A_{0}, A_{1}\right)\right)^{q} \frac{d t}{t}\right]^{1 / q}<\infty
$$

Theorem 43.6.4 $\left(A_{0}, A_{1}\right)_{\theta, q}$ is a normed linear space satisfying

$$
\begin{equation*}
A_{0} \cap A_{1} \subseteq\left(A_{0}, A_{1}\right)_{\theta, q} \subseteq A_{0}+A_{1} \tag{43.6.26}
\end{equation*}
$$

with the inclusion maps continuous, and

$$
\begin{equation*}
\left(\left(A_{0}, A_{1}\right)_{\theta, q},\|\cdot\|_{\theta, q}\right) \text { is a Banach space. } \tag{43.6.27}
\end{equation*}
$$

If $a \in A_{0} \cap A_{1}$, then

$$
\begin{equation*}
\|a\|_{\theta, q} \leq\left(\frac{1}{q \theta(1-\theta)}\right)^{1 / q}\|a\|_{1}^{\theta}\|a\|_{0}^{1-\theta} \tag{43.6.28}
\end{equation*}
$$

If $A_{0} \subseteq A_{1}$ with $\|\cdot\|_{0} \geq\|\cdot\|_{1}$, then

$$
A_{0} \cap A_{1}=A_{0} \subseteq\left(A_{0}, A_{1}\right)_{\theta, q} \subseteq A_{1}=A_{0}+A_{1} .
$$

Also, if bounded sets in $A_{0}$ have compact closures in $A_{1}$ then the same is true if $A_{1}$ is replaced with $\left(A_{0}, A_{1}\right)_{\theta, q}$. Finally, if

$$
\begin{equation*}
T \in \mathscr{L}\left(A_{0}, B_{0}\right), T \in \mathscr{L}\left(A_{1}, B_{1}\right) \tag{43.6.29}
\end{equation*}
$$

and $T$ is a linear map from $A_{0}+A_{1}$ to $B_{0}+B_{1}$ where the $A_{i}$ and $B_{i}$ are Banach spaces with the properties described above, then it follows

$$
\begin{equation*}
T \in \mathscr{L}\left(\left(A_{0}, A_{1}\right)_{\theta, q},\left(B_{0}, B_{1}\right)_{\theta, q}\right) \tag{43.6.30}
\end{equation*}
$$

and if $M$ is its norm, and $M_{0}$ and $M_{1}$ are the norms of $T$ as a map in $\mathscr{L}\left(A_{0}, B_{0}\right)$ and $\mathscr{L}\left(A_{1}, B_{1}\right)$ respectively, then

$$
\begin{equation*}
M \leq M_{0}^{1-\theta} M_{1}^{\theta} \tag{43.6.31}
\end{equation*}
$$

Proof: Suppose first $a \in A_{0} \cap A_{1}$. Then

$$
\begin{align*}
\|a\|_{\theta, q}^{q} & \equiv \int_{0}^{r}\left(t^{-\theta} K(t, a)\right)^{q} \frac{d t}{t}+\int_{r}^{\infty}\left(t^{-\theta} K(t, a)\right)^{q} \frac{d t}{t}  \tag{43.6.32}\\
& \leq \int_{0}^{r}\left(t^{-\theta}\|a\|_{1} t\right)^{q} \frac{d t}{t}+\int_{r}^{\infty}\left(t^{-\theta}\|a\|_{0}\right)^{q} \frac{d t}{t} \\
& =\|a\|_{1}^{q} \int_{0}^{r} t^{q(1-\theta)-1} d t+\|a\|_{0}^{q} \int_{r}^{\infty} t^{-1-\theta q} d t \\
& =\|a\|_{1}^{q} \frac{r^{q-q \theta}}{q-q \theta}+\|a\|_{0}^{q} \frac{r^{-\theta q}}{\theta q}<\infty \tag{43.6.33}
\end{align*}
$$

Which shows the first inclusion of 43.6.26. The above holds for all $r>0$ and in particular for the value of $r$ which minimizes the expression on the right in 43.6.33, $r=\|a\|_{0} /\|a\|_{1}$. Therefore, doing some calculus,

$$
\|a\|_{\theta, q}^{q} \leq \frac{1}{\theta q(1+\theta)}\|a\|_{0}^{q(1-\theta)}\|a\|_{1}^{q \theta}
$$

which shows 43.6.28. This also verifies that the first inclusion map is continuous in 43.6.26 because if $a_{n} \rightarrow 0$ in $A_{0} \cap A_{1}$, then $a_{n} \rightarrow 0$ in $A_{0}$ and in $A_{1}$ and so the above shows $a_{n} \rightarrow 0$ in $\left(A_{0}, A_{1}\right)_{\theta, q}$.

Now consider the second inclusion in 43.6.26. The inclusion is obvious since $\left(A_{0}, A_{1}\right)_{\theta, q}$ is given to be a subset of $A_{0}+A_{1}$ defined by

$$
\left(\int_{0}^{\infty}\left(t^{-\theta} K(t, a)\right)^{q} \frac{d t}{t}\right)^{1 / q}<\infty
$$

It remains to verify the inclusion map is continuous. Suppose $a_{n} \rightarrow 0$ in $\left(A_{0}, A_{1}\right)_{\theta, q}$. Since $a_{n} \rightarrow 0$ in $\left(A_{0}, A_{1}\right)_{\theta, q}$, it follows the function, $t \rightarrow t^{-\theta} K\left(t, a_{n}\right)$ converges to zero in $L^{q}(0, \infty)$ with respect to the measure, $d t / t$. Therefore, taking another subsequence, still denoted as $a_{n}$, you can assume this function converges to 0 a.e. Pick such a $t$ where this convergence takes place. Then $K\left(t, a_{n}\right) \rightarrow 0$ as $n \rightarrow \infty$ and so $a_{n} \rightarrow 0$ in $A_{0}+A_{1}$. (Recall all these norms $K(t, \cdot)$ are equivalent.) This shows that if $a_{n} \rightarrow 0$ in $\left(A_{0}, A_{1}\right)_{\theta, q}$, then there exists a subsequence $\left\{a_{n_{k}}\right\}$ such that $a_{n_{k}} \rightarrow 0$ in $A_{0}+A_{1}$. It follows that if $a_{n} \rightarrow 0$ in $\left(A_{0}, A_{1}\right)_{\theta, q}$, then $a_{n} \rightarrow 0$ in $A_{0}+A_{1}$. This proves the continuity of the embedding.

What about 43.6.27? Suppose $\left\{a_{n}\right\}$ is a Cauchy sequence in $\left(A_{0}, A_{1}\right)_{\theta, q}$. Then from what was just shown this is a Cauchy sequence in $A_{0}+A_{1}$ and so there exists $a \in A_{0}+A_{1}$
such that $a_{n} \rightarrow a$ in $A_{0}+A_{1}$ because $A_{0}+A_{1}$ is a Banach space. Thus, $K\left(t, a_{n}\right) \rightarrow K(t, a)$ for all $t>0$. (Recall all these norms $K(t, \cdot)$ are equivalent.) Therefore, by Fatou's lemma,

$$
\begin{aligned}
\left(\int_{0}^{\infty}\left(t^{-\theta} K(t, a)\right)^{q} \frac{d t}{t}\right)^{1 / q} & \leq \lim _{n \rightarrow \infty}\left(\int_{0}^{\infty}\left(t^{-\theta} K\left(t, a_{n}\right)\right)^{q} \frac{d t}{t}\right)^{1 / q} \\
& \leq \max \left\{\left\|a_{n}\right\|_{\theta, q}: n \in \mathbb{N}\right\}<\infty
\end{aligned}
$$

and so $a \in\left(A_{0}, A_{1}\right)_{\theta, q}$. Now

$$
\begin{aligned}
\left\|a-a_{n}\right\|_{\theta, q} & \leq \lim _{m \rightarrow \infty}\left(\int_{0}^{\infty}\left(t^{-\theta} K\left(t, a_{n}-a_{m}\right)\right)^{q} \frac{d t}{t}\right)^{1 / q} \\
& =\lim \inf _{m \rightarrow \infty}\left\|a_{n}-a_{m}\right\|_{\theta, q}<\varepsilon
\end{aligned}
$$

whenever $n$ is large enough. Thus $\left(A_{0}, A_{1}\right)_{\theta, q}$ is complete as claimed.
Next suppose $A_{0} \subseteq A_{1}$ and the inclusion map is compact. In this case, $A_{0} \cap A_{1}=A_{0}$ and so it has been shown above that $A_{0} \subseteq\left(A_{0}, A_{1}\right)_{\theta, q}$. It remains to show that every bounded subset, $S$, contained in $A_{0}$ has an $\eta$ net in $\left(A_{0}, A_{1}\right)_{\theta, q}$. Recall the inequality, 43.6.28

$$
\begin{aligned}
\|a\|_{\theta, q} & \leq\left(\frac{1}{q \theta(1-\theta)}\right)^{1 / q}\|a\|_{1}^{\theta}\|a\|_{0}^{1-\theta} \\
& =\frac{C}{\varepsilon}\|a\|_{1}^{\theta} \varepsilon\|a\|_{0}^{1-\theta}
\end{aligned}
$$

Now this implies

$$
\|a\|_{\theta, q} \leq\left(\frac{C}{\varepsilon}\right)^{1 / \theta} \theta\|a\|_{1}+\varepsilon^{1 /(1-\theta)}(1-\theta)\|a\|_{0}
$$

By compactness of the embedding of $A_{0}$ into $A_{1}$, it follows there exists an $\varepsilon^{(1+\theta) / \theta}$ net for $S$ in $A_{1},\left\{a_{1}, \cdots, a_{p}\right\}$. Then for $a \in S$, there exists $k$ such that $\left\|a-a_{k}\right\|_{1}<\varepsilon^{(1+\theta) / \theta}$. It follows

$$
\begin{aligned}
\left\|a-a_{k}\right\|_{\theta, q} & \leq\left(\frac{C}{\varepsilon}\right)^{1 / \theta} \theta\left\|a-a_{k}\right\|_{1}+\varepsilon^{1 /(1-\theta)}(1-\theta)\left\|a-a_{k}\right\|_{0} \\
& \leq\left(\frac{C}{\varepsilon}\right)^{1 / \theta} \theta \varepsilon^{(1+\theta) / \theta}+\varepsilon^{1 /(1-\theta)}(1-\theta) 2 M \\
& =C^{1 / \theta} \theta \varepsilon+\varepsilon^{1 /(1-\theta)}(1-\theta) 2 M
\end{aligned}
$$

where $M$ is large enough that $\|a\|_{0} \leq M$ for all $a \in S$. Since $\varepsilon$ is arbitrary, this shows the existence of a $\eta$ net and proves the compactness of the embedding into $\left(A_{0}, A_{1}\right)_{\theta, q}$.

It remains to verify the assertions 43.6.29-43.6.31. Let $T \in \mathscr{L}\left(A_{0}, B_{0}\right), T \in \mathscr{L}\left(A_{1}, B_{1}\right)$ with $T$ a linear map from $A_{0}+A_{1}$ to $B_{0}+B_{1}$. Let $a \in\left(A_{0}, A_{1}\right)_{\theta, q} \subseteq A_{0}+A_{1}$ and consider
$T a \in B_{0}+B_{1}$. Denote by $K(t, \cdot)$ the norm described above for both $A_{0}+A_{1}$ and $B_{0}+B_{1}$ since this will cause no confusion. Then

$$
\begin{equation*}
\|T a\|_{\theta, q} \equiv\left(\int_{0}^{\infty}\left(t^{-\theta} K(t, T a)\right)^{q} \frac{d t}{t}\right)^{1 / q} \tag{43.6.34}
\end{equation*}
$$

Now let $a_{0}+a_{1}=a$ and so $T a_{0}+T a_{1}=T a$

$$
\begin{aligned}
K(t, T a) & \leq\left\|T a_{0}\right\|_{0}+t\left\|T a_{1}\right\|_{1} \leq M_{0}\left\|a_{0}\right\|_{0}+M_{1} t\left\|a_{1}\right\|_{1} \\
& \leq M_{0}\left(\left\|a_{0}\right\|_{0}+t\left(\frac{M_{1}}{M_{0}}\right)\left\|a_{1}\right\|_{1}\right)
\end{aligned}
$$

and so, taking inf for all $a_{0}+a_{1}=a$, yields

$$
K(t, T a) \leq M_{0} K\left(t\left(\frac{M_{1}}{M_{0}}\right), a\right)
$$

It follows from 43.6.34 that

$$
\begin{aligned}
\|T a\|_{\theta, q} & \equiv\left(\int_{0}^{\infty}\left(t^{-\theta} K(t, T a)\right)^{q} \frac{d t}{t}\right)^{1 / q} \\
& \leq\left(\int_{0}^{\infty}\left(t^{-\theta} M_{0} K\left(t\left(\frac{M_{1}}{M_{0}}\right), a\right)\right)^{q} \frac{d t}{t}\right)^{1 / q} \\
& =M_{0}\left(\int_{0}^{\infty}\left(t^{-\theta} K\left(t\left(\frac{M_{1}}{M_{0}}\right), a\right)\right)^{q} \frac{d t}{t}\right)^{1 / q} \\
& =M_{0}\left(\int_{0}^{\infty}\left(\left(\frac{M_{0}}{M_{1}} s\right)^{-\theta} K(s, a)\right)^{q} \frac{d s}{s}\right)^{1 / q} \\
& =M_{1}^{\theta} M_{0}^{(1-\theta)}\left(\int_{0}^{\infty}\left(s^{-\theta} K(s, a)\right)^{q} \frac{d s}{s}\right)^{1 / q}=M_{1}^{\theta} M_{0}^{(1-\theta)}\|a\|_{\theta, q}
\end{aligned}
$$

This shows $T \in \mathscr{L}\left(\left(A_{0}, A_{1}\right)_{\theta, q},\left(B_{0}, B_{1}\right)_{\theta, q}\right)$ and if $M$ is the norm of $T, M \leq M_{0}^{1-\theta} M_{1}^{\theta}$ as claimed. This proves the theorem.

### 43.7 The $J$ Method

There is another method known as the $J$ method. Instead of

$$
K(t, a) \equiv \inf \left\{\left\|a_{0}\right\|_{A_{0}}+t\left\|a_{1}\right\|_{A_{1}}: a_{0}+a_{1}=a\right\}
$$

for $a \in A_{0}+A_{1}$, this method considers $a \in A_{0} \cap A_{1}$ and $J(t, a)$ defined below gives a norm on $A_{0} \cap A_{1}$.

Definition 43.7.1 For $A_{0}$ and $A_{1}$ Banach spaces as described above, and $a \in A_{0} \cap A_{1}$,

$$
\begin{equation*}
J(t, a) \equiv \max \left(\|a\|_{A_{0}}, t\|a\|_{A_{1}}\right) \tag{43.7.35}
\end{equation*}
$$

this is short for $J\left(t, a, A_{0}, A_{1}\right)$. Thus

$$
J\left(t, a, A_{1}, A_{0}\right) \equiv \max \left(\|a\|_{A_{1}}, t\|a\|_{A_{0}}\right)
$$

but unless indicated otherwise, $A_{0}$ will come first. Now for $\theta \in(0,1)$ and $q \geq 1$, define a space, $\left(A_{0}, A_{1}\right)_{\theta, q, J}$ as follows. The space, $\left(A_{0}, A_{1}\right)_{\theta, q, J}$ will consist of those elements, $a$, of $A_{0}+A_{1}$ which can be written in the form

$$
\begin{equation*}
a=\int_{0}^{\infty} u(t) \frac{d t}{t} \equiv \lim _{\varepsilon \rightarrow 0+} \int_{\varepsilon}^{1} u(t) \frac{d t}{t}+\lim _{r \rightarrow \infty} \int_{1}^{r} u(t) \frac{d t}{t} \tag{43.7.36}
\end{equation*}
$$

the limits taking place in $A_{0}+A_{1}$ with the norm

$$
K(1, a) \equiv \inf _{a=a_{0}+a_{1}}\left(\left\|a_{0}\right\|_{A_{0}}+\left\|a_{1}\right\|_{A_{1}}\right)
$$

where $u(t)$ is strongly measurable with values in $A_{0} \cap A_{1}$ and bounded on every compact subset of $(0, \infty)$ such that

$$
\begin{equation*}
\left(\int_{0}^{\infty}\left(t^{-\theta} J\left(t, u(t), A_{0}, A_{1}\right)\right)^{q} \frac{d t}{t}\right)^{1 / q}<\infty . \tag{43.7.37}
\end{equation*}
$$

For such $a \in A_{0}+A_{1}$, define

$$
\begin{equation*}
\|a\|_{\theta, q, J} \equiv \inf _{u}\left\{\left(\int_{0}^{\infty}\left(t^{-\theta} J\left(t, u(t), A_{0}, A_{1}\right)\right)^{q} \frac{d t}{t}\right)^{1 / q}\right\} \tag{43.7.38}
\end{equation*}
$$

where the infimum is taken over all u satisfying 43.7.36 and 43.7.37.
Note that a norm on $A_{0} \times A_{1}$ would be

$$
\left\|\left(a_{0}, a_{1}\right)\right\| \equiv \max \left(\left\|a_{0}\right\|_{A_{0}}, t\left\|a_{1}\right\|_{A_{1}}\right)
$$

and so $J(t, \cdot)$ is the restriction of this norm to the subspace of $A_{0} \times A_{1}$ defined by

$$
\left\{(a, a): a \in A_{0} \cap A_{1}\right\}
$$

Also for each $t>0 J(t, \cdot)$ is a norm on $A_{0} \cap A_{1}$ and furthermore, any two of these norms are equivalent. In fact, for $0<t<s$,

$$
\begin{aligned}
J(t, a) & =\max \left(\|a\|_{A_{0}}, t\|a\|_{A_{1}}\right) \\
& \geq \max \left(\|a\|_{A_{0}}, s\|a\|_{A_{1}}\right) \\
& =J(s, a) \\
& \geq \max \left(\frac{s}{t}\|a\|_{A_{0}}, s\|a\|_{A_{1}}\right) \\
& =\frac{s}{t} \max \left(\|a\|_{A_{0}}, t\|a\|_{A_{1}}\right) \\
& \geq{ }_{-}^{s} J(t, a)
\end{aligned}
$$

The following lemma is significant and follows immediately from the above definition.

Lemma 43.7.2 Suppose $a \in\left(A_{0}, A_{1}\right)_{\theta, q, J}$ and $a=\int_{0}^{\infty} u(t) \frac{d t}{t}$ where $u$ is described above. Then letting $r>1$,

$$
u_{r}(t) \equiv\left\{\begin{array}{l}
u(t) \text { if } t \in\left(\frac{1}{r}, r\right) \\
0 \text { otherwise }
\end{array}\right.
$$

it follows that

$$
\int_{0}^{\infty} u_{r}(t) \frac{d t}{t} \in A_{0} \cap A_{1}
$$

Proof: The integral equals $\int_{1 / r}^{r} u(t) \frac{d t}{t} \cdot \int_{1 / r}^{r} \frac{1}{t} d t=2 \ln r<\infty$. Now $u_{r}$ is measurable in $A_{0} \cap A_{1}$ and bounded. Therefore, there exists a sequence of measurable simple functions, $\left\{s_{n}\right\}$ having values in $A_{0} \cap A_{1}$ which converges pointwise and uniformly to $u_{r}$. It can also be assumed $J\left(r, s_{n}(t)\right) \leq J\left(r, u_{r}(t)\right)$ for all $t \in[1 / r, r]$. Therefore,

$$
\lim _{n, m \rightarrow \infty} \int_{1 / r}^{r} J\left(r, s_{m}-s_{n}\right) \frac{d t}{t}=0 .
$$

It follows from the definition of the Bochner integral that

$$
\lim _{n \rightarrow \infty} \int_{1 / r}^{r} s_{n} \frac{d t}{t}=\int_{1 / r}^{r} u_{r} \frac{d t}{t} \in A_{0} \cap A_{1} .
$$

This proves the lemma.
The remarkable thing is that the two spaces, $\left(A_{0}, A_{1}\right)_{\theta, q}$ and $\left(A_{0}, A_{1}\right)_{\theta, q, J}$ coincide and have equivalent norms. The following important lemma, called the fundamental lemma of interpolation theory in [16] is used to prove this. This lemma is really incredible.

Lemma 43.7.3 Suppose for $a \in A_{0}+A_{1}, \lim _{t \rightarrow 0+} K(t, a)=0$ and $\lim _{t \rightarrow \infty} \frac{K(t, a)}{t}=0$. Then for any $\varepsilon>0$, there is a representation,

$$
\begin{equation*}
a=\sum_{i=-\infty}^{\infty} u_{i}=\lim _{n, m \rightarrow \infty} \sum_{i=-m}^{n} u_{i}, u_{i} \in A_{0} \cap A_{1} \tag{43.7.39}
\end{equation*}
$$

the convergences taking place in $A_{0}+A_{1}$, such that

$$
\begin{equation*}
J\left(2^{i}, u_{i}\right) \leq 3(1+\varepsilon) K\left(2^{i}, a\right) \tag{43.7.40}
\end{equation*}
$$

Proof: For each $i$, there exist $a_{0, i} \in A_{0}$ and $a_{1, i} \in A_{1}$ such that

$$
a=a_{0, i}+a_{1, i}
$$

and

$$
\begin{equation*}
(1+\varepsilon) K\left(2^{i}, a\right) \geq\left\|a_{0, i}\right\|_{A_{0}}+2^{i}\left\|a_{1, i}\right\|_{A_{1}} . \tag{43.7.41}
\end{equation*}
$$

This follows directly from the definition of $K(t, a)$. From the assumed limit conditions on $K(t, a)$,

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\|a_{1, i}\right\|_{A_{1}}=0, \lim _{i \rightarrow-\infty}\left\|a_{0, i}\right\|_{A_{0}}=0 \tag{43.7.42}
\end{equation*}
$$

Then let $u_{i} \equiv a_{0, i}-a_{0, i-1}=a_{1, i-1}-a_{1, i}$. The reason these are equal is $a=a_{0, i}+a_{1, i}=$ $a_{0, i-1}+a_{1, i-1}$. Then

$$
\sum_{i=-m}^{n} u_{i}=a_{0, n}-a_{0,-(m+1)}=a_{1,-(m+1)}-a_{1, n}
$$

It follows $a-\sum_{i=-m}^{n} u_{i}=a-\left(a_{0, n}-a_{0,-(m+1)}\right)=a_{0,-(m+1)}+a_{1, n}$, and both terms converge to zero as $m$ and $n$ converge to $\infty$ by 43.7.42. Therefore,

$$
K\left(1, a-\sum_{i=-m}^{n} u_{i}\right) \leq\left\|a_{0,-(m+1)}\right\|+\left\|a_{1, n}\right\|
$$

and so this shows $a=\sum_{i=-\infty}^{\infty} u_{i}$ which is one of the claims of the lemma. Also

$$
\begin{gathered}
J\left(2^{i}, u_{i}\right) \equiv \max \left(\left\|u_{i}\right\|_{A_{0}}, 2^{i}\left\|u_{i}\right\|_{A_{1}}\right) \leq\left\|u_{i}\right\|_{A_{0}}+2^{i}\left\|u_{i}\right\|_{A_{1}} \\
\leq\left\|a_{0, i}\right\|_{A_{0}}+2^{i}\left\|a_{1, i}\right\|_{A_{1}}+\overbrace{\left\|a_{0, i-1}\right\|_{A_{0}}+2^{i}\left\|a_{1, i-1}\right\|_{A_{1}}}^{\leq 2\left(\left\|a_{0, i-1}\right\|_{A_{0}}+2^{i-1}\left\|a_{1, i-1}\right\|_{A_{1}}\right)} \\
\leq(1+\varepsilon) K\left(2^{i}, a\right)+2(1+\varepsilon) K\left(2^{i-1}, a\right) \leq 3(1+\varepsilon) K\left(2^{i}, a\right)
\end{gathered}
$$

because $t \rightarrow K(t, a)$ is nondecreasing. This proves the lemma.
Lemma 43.7.4 If $a \in A_{0} \cap A_{1}$, then $K(t, a) \leq \min \left(1, \frac{t}{s}\right) J(s, a)$.
Proof: If $s \geq t$, then $\min \left(1, \frac{t}{s}\right)=\frac{t}{s}$ and so

$$
\begin{aligned}
\min \left(1, \frac{t}{s}\right) J(s, a) & =\frac{t}{s} \max \left(\|a\|_{A_{0}}, s\|a\|_{A_{1}}\right) \geq\left(\frac{t}{s}\right) s\|a\|_{A_{1}} \\
& =t\|a\|_{A_{1}} \geq K(t, a)
\end{aligned}
$$

Now in case $s<t$, then $\min \left(1, \frac{t}{s}\right)=1$ and so

$$
\begin{aligned}
\min \left(1, \frac{t}{s}\right) J(s, a) & =\max \left(\|a\|_{A_{0}}, s\|a\|_{A_{1}}\right) \geq\|a\|_{A_{0}} \\
& \geq K(t, a)
\end{aligned}
$$

This proves the lemma.
Theorem 43.7.5 Let $A_{0}, A_{1}, K$ and $J$ be as described above. Then for all $q \geq 1$ and $\theta \in$ $(0,1)$,

$$
\left(A_{0}, A_{1}\right)_{\theta, q}=\left(A_{0}, A_{1}\right)_{\theta, q, J}
$$

and furthermore, the norms are equivalent.

Proof: Begin with $a \in\left(A_{0}, A_{1}\right)_{\theta, q}$. Thus

$$
\begin{equation*}
\|a\|_{\theta, q}^{q}=\int_{0}^{\infty}\left(t^{-\theta} K(t, a)\right)^{q} \frac{d t}{t}<\infty \tag{43.7.43}
\end{equation*}
$$

and it is necessary to produce $u(t)$ as described above,

$$
a=\int_{0}^{\infty} u(t) \frac{d t}{t} \text { where } \int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{q} \frac{d t}{t}<\infty .
$$

From 43.7.43, $\lim _{t \rightarrow 0+} K(t, a)=0$ since $t \rightarrow K(t, a)$ is nondecreasing and so if its limit is positive, the integrand would have a non integrable singularity like $t^{-\theta q-1}$. Next consider what happens to $\frac{K(t, a)}{t}$ as $t \rightarrow \infty$.

Claim: $t \rightarrow \frac{K(t, a)}{t}$ is decreasing.
Proof of the claim: Choose $a_{0} \in A_{0}$ and $a_{1} \in A_{1}$ such that $a_{0}+a_{1}=a$ and

$$
K(t, a)+\varepsilon t>\left\|a_{0}\right\|_{A_{0}}+t\left\|a_{1}\right\|_{A_{1}}
$$

let $s>t$. Then

$$
\frac{K(t, a)+t \varepsilon}{t} \geq \frac{\left\|a_{0}\right\|_{A_{0}}+t\left\|a_{1}\right\|_{A_{1}}}{t} \geq \frac{\left\|a_{0}\right\|_{A_{0}}+s\left\|a_{1}\right\|_{A_{1}}}{s} \geq \frac{K(s, a)}{s}
$$

Since $\varepsilon$ is arbitrary, this proves the claim.
Let $r \equiv \lim _{t \rightarrow \infty} \frac{K(t, a)}{t}$. Is $r=0$ ? Suppose to the contrary that $r>0$. Then the integrand of 43.7.43, is at least as large as

$$
\begin{gathered}
t^{-\theta q} K(t, a)^{q-1} \frac{K(t, a)}{t} \geq t^{-\theta q} K(t, a)^{q-1} r \\
\geq t^{-\theta q}(t r)^{q-1} r \geq r^{q} t^{q(1-\theta)-1}
\end{gathered}
$$

whose integral is infinite. Therefore, $r=0$.
Lemma 43.7.3, implies there exist $u_{i} \in A_{0} \cap A_{1}$ such that $a=\sum_{i=-\infty}^{\infty} u_{i}$, the convergence taking place in $A_{0}+A_{1}$ with the inequality of that Lemma holding,

$$
J\left(2^{i}, u_{i}\right) \leq 3(1+\varepsilon) K\left(2^{i}, a\right)
$$

For $i$ an integer and $t \in\left[2^{i-1}, 2^{i}\right)$, let

$$
u(t) \equiv u_{i} / \ln 2
$$

Then

$$
\begin{equation*}
a=\sum_{i=-\infty}^{\infty} u_{i}=\int_{0}^{\infty} u(t) \frac{d t}{t} \tag{43.7.44}
\end{equation*}
$$

Now

$$
\begin{aligned}
\|a\|_{\theta, q, J}^{q} & \leq \int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{q} \frac{d t}{t} \\
& =\sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^{i}}\left(t^{-\theta} J\left(t, \frac{u_{i}}{\ln 2}\right)\right)^{q} \frac{d t}{t} \\
& \leq\left(\frac{1}{\ln 2}\right)^{q} \sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^{i}}\left(t^{-\theta} J\left(2^{i}, u_{i}\right)\right)^{q} \frac{d t}{t} \\
& \leq\left(\frac{1}{\ln 2}\right)^{q} \sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^{i}}\left(t^{-\theta} 3(1+\varepsilon) K\left(2^{i}, a\right)\right)^{q} \frac{d t}{t}
\end{aligned}
$$

Using the above claim, $\frac{K\left(2^{i}, a\right)}{2^{i}} \leq \frac{K\left(2^{i-1}, a\right)}{2^{i-1}}$ and so $K\left(2^{i}, a\right) \leq 2 K\left(2^{i-1}, a\right)$. Therefore, the above is no larger than

$$
\begin{align*}
& \leq 2\left(\frac{1}{\ln 2}\right)^{q} \sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^{i}}\left(t^{-\theta} 3(1+\varepsilon) K\left(2^{i-1}, a\right)\right)^{q} \frac{d t}{t} \\
& \leq 2\left(\frac{1}{\ln 2}\right)^{q} \sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^{i}}\left(t^{-\theta} 3(1+\varepsilon) K(t, a)\right)^{q} \frac{d t}{t} \\
& =2\left(\frac{3(1+\varepsilon)}{\ln 2}\right)^{q} \int_{0}^{\infty}\left(t^{-\theta} K(t, a)\right)^{q} \frac{d t}{t} \equiv 2\left(\frac{3(1+\varepsilon)}{\ln 2}\right)^{q}\|a\|_{\theta, q}^{q} \tag{43.7.45}
\end{align*}
$$

This has shown that if $a \in\left(A_{0}, A_{1}\right)_{\theta, q}$, then by 43.7.44 and 43.7.45, $a \in\left(A_{0}, A_{1}\right)_{\theta, q, J}$ and

$$
\begin{equation*}
\|a\|_{\theta, q, J}^{q} \leq 2\left(\frac{3(1+\varepsilon)}{\ln 2}\right)^{q}\|a\|_{\theta, q}^{q} \tag{43.7.46}
\end{equation*}
$$

It remains to prove the other inclusion and norm inequality, both of which are much easier to obtain. Thus, let $a \in\left(A_{0}, A_{1}\right)_{\theta, q, J}$ with

$$
\begin{equation*}
a=\int_{0}^{\infty} u(t) \frac{d t}{t} \tag{43.7.47}
\end{equation*}
$$

where $u$ is a strongly measurable function having values in $A_{0} \cap A_{1}$ and for which

$$
\begin{gather*}
\int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{q} d t<\infty  \tag{43.7.48}\\
K(t, a)=K\left(t, \int_{0}^{\infty} u(s) \frac{d s}{s}\right) \leq \int_{0}^{\infty} K(t, u(s)) \frac{d s}{s} \tag{43.7.49}
\end{gather*}
$$

Now by Lemma 43.7.4, this is dominated by an expression of the form

$$
\begin{equation*}
\leq \int_{0}^{\infty} \min \left(1, \frac{t}{s}\right) J(s, u(s)) \frac{d s}{s}=\int_{0}^{\infty} \min \left(1, \frac{1}{s}\right) J(t s, u(t s)) \frac{d s}{s} \tag{43.7.50}
\end{equation*}
$$

where the equation follows from a change of variable. From Minkowski's inequality and 43.7.50,

$$
\begin{aligned}
\|a\|_{\theta, q} & \equiv\left(\int_{0}^{\infty}\left(t^{-\theta} K(t, a)\right)^{q} \frac{d t}{t}\right)^{1 / q} \\
& \leq\left(\int_{0}^{\infty}\left(t^{-\theta} \int_{0}^{\infty} \min \left(1, \frac{1}{s}\right) J(t s, u(t s)) \frac{d s}{s}\right)^{q} \frac{d t}{t}\right)^{1 / q} \\
\leq & \int_{0}^{\infty}\left(\int_{0}^{\infty}\left(t^{-\theta} \min \left(1, \frac{1}{s}\right) J(t s, u(t s))\right)^{q} \frac{d t}{t}\right)^{1 / q} \frac{d s}{s}
\end{aligned}
$$

Now change the variable in the inside integral to obtain, letting $t=\tau s$,

$$
\begin{aligned}
& \leq \int_{0}^{\infty} \min \left(1, \frac{1}{s}\right)\left(\int_{0}^{\infty}\left(t^{-\theta} J(t s, u(t s))\right)^{q} \frac{d t}{t}\right)^{1 / q} \frac{d s}{s} \\
& =\int_{0}^{\infty} \min \left(1, \frac{1}{s}\right) s^{\theta} \frac{d s}{s}\left(\int_{0}^{\infty}\left(\tau^{-\theta} J(\tau, u(\tau))\right)^{q} \frac{d \tau}{\tau}\right)^{1 / q} \\
& =\left(\frac{1}{(1-\theta) \theta}\right)\left(\int_{0}^{\infty}\left(\tau^{-\theta} J(\tau, u(\tau))\right)^{q} \frac{d \tau}{\tau}\right)^{1 / q} .
\end{aligned}
$$

This has shown that

$$
\|a\|_{\theta, q} \leq\left(\frac{1}{(1-\theta) \theta}\right)\left(\int_{0}^{\infty}\left(\tau^{-\theta} J(\tau, u(\tau))\right)^{q} \frac{d \tau}{\tau}\right)^{1 / q}<\infty
$$

for all $u$ satisfying 43.7.47 and 43.7.48. Therefore, taking the infimum it follows $a \in$ $\left(A_{0}, A_{1}\right)_{\theta, q}$ and

$$
\|a\|_{\theta, q} \leq\left(\frac{1}{(1-\theta) \theta}\right)\|a\|_{\theta, q, J}
$$

This proves the theorem.

### 43.8 Duality And Interpolation

In this section it will be assumed that $A_{0} \cap A_{1}$ is dense in $A_{i}$ for $i=0,1$. This is done so that $A_{i}^{\prime} \subseteq\left(A_{0} \cap A_{1}\right)^{\prime}$ and the inclusion map is continuous. Thus it makes sense to add something in $A_{0}^{\prime}$ to something in $A_{1}^{\prime}$.

What is the dual space of $\left(A_{0}, A_{1}\right)_{\theta, q}$ ? The answer is based on the following lemma,
[16]. Remember that

$$
J(t, a)=\max \left(\|a\|_{A_{0}}, t\|a\|_{A_{1}}\right)
$$

and this is a norm on $A_{0} \cap A_{1}$ and

$$
K(t, a)=\inf \left\{\left\|a_{0}\right\|_{A_{0}}+t\left\|a_{1}\right\|_{A_{1}}: a=a_{0}+a_{1}\right\}
$$

As mentioned above, $A_{0}^{\prime}+A_{1}^{\prime} \subseteq\left(A_{0} \cap A_{1}\right)^{\prime}$. In fact these two are equal. This is the first part of the following lemma.

Lemma 43.8.1 Suppose $A_{0} \cap A_{1}$ is dense in $A_{i}, i=0,1$. Then

$$
\begin{equation*}
A_{0}^{\prime}+A_{1}^{\prime}=\left(A_{0} \cap A_{1}\right)^{\prime} \tag{43.8.51}
\end{equation*}
$$

and for $a^{\prime} \in A_{0}^{\prime}+A_{1}^{\prime}=\left(A_{0} \cap A_{1}\right)^{\prime}$,

$$
\begin{equation*}
K\left(t, a^{\prime}\right)=\sup _{a \in A_{0} \cap A_{1}} \frac{\left|a^{\prime}(a)\right|}{J\left(t^{-1}, a\right)} \tag{43.8.52}
\end{equation*}
$$

Thus $K(t, \cdot)$ is an equivalent norm to the usual operator norm on $\left(A_{0} \cap A_{1}\right)^{\prime}$ taken with respect to $J\left(t^{-1}, \cdot\right)$. If, in addition to this, $A_{i}$ is reflexive, then for $a^{\prime} \in A_{0}^{\prime} \cap A_{1}^{\prime}$, and a $\in$ $A_{0} \cap A_{1}$,

$$
\begin{equation*}
J\left(t, a^{\prime}\right) K\left(t^{-1}, a\right) \geq\left|a^{\prime}(a)\right| \tag{43.8.53}
\end{equation*}
$$

Proof: First consider the claim that $A_{0}^{\prime}+A_{1}^{\prime}=\left(A_{0} \cap A_{1}\right)^{\prime}$. As noted above, $\subseteq$ is clear. Define a norm on $A_{0} \times A_{1}$ as follows.

$$
\begin{equation*}
\left\|\left(a_{0}, a_{1}\right)\right\|_{A_{0} \times A_{1}} \equiv \max \left(\left\|a_{0}\right\|_{A_{0}}, t^{-1}\left\|a_{1}\right\|_{A_{1}}\right) \tag{43.8.54}
\end{equation*}
$$

Let $a^{\prime} \in\left(A_{0} \cap A_{1}\right)^{\prime}$. Let

$$
E \equiv\left\{(a, a): a \in A_{0} \cap A_{1}\right\}
$$

with the norm $J\left(t^{-1}, a\right) \equiv \max \left(\|a\|_{A_{0}}, t^{-1}\|a\|_{A_{1}}\right)$. Now define $\lambda$ on $E$, the subspace of $A_{0} \times A_{1}$ by

$$
\lambda((a, a)) \equiv a^{\prime}(a)
$$

Thus $\lambda$ is a continuous linear map on $E$ and in fact,

$$
|\lambda((a, a))|=\left|a^{\prime}(a)\right| \leq \| a^{\prime}| | J\left(t^{-1}, a\right)
$$

By the Hahn Banach theorem there exists an extension of $\lambda$ to all of $A_{0} \times A_{1}$. This extension is of the form $\left(a_{0}^{\prime}, a_{1}^{\prime}\right) \in A_{0}^{\prime} \times A_{1}^{\prime}$. Thus

$$
\left(a_{0}^{\prime}, a_{1}^{\prime}\right)((a, a))=a_{0}^{\prime}(a)+a_{1}^{\prime}(a)=a^{\prime}(a)
$$

and therefore, $a_{0}^{\prime}+a_{1}^{\prime}=a^{\prime}$ provided $a_{0}^{\prime}+a_{1}^{\prime}$ is continuous. But

$$
\begin{aligned}
\left|\left(a_{0}^{\prime}+a_{1}^{\prime}\right)(a)\right| & =\left|a_{0}^{\prime}(a)+a_{1}^{\prime}(a)\right| \leq\left|a_{0}^{\prime}(a)\right|+\left|a_{1}^{\prime}(a)\right| \\
& \leq\left\|a_{0}^{\prime}\right\|\|a\|_{A_{0}}+\left\|a_{1}^{\prime}\right\|\|a\|_{A_{1}} \\
& \leq\left\|a_{0}^{\prime}\right\|\|a\|_{A_{0}}+t\left\|a_{1}^{\prime}\right\| t^{-1}\|a\|_{A_{1}} \\
& \leq\left(\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|\right) J\left(t^{-1}, a\right)
\end{aligned}
$$

which shows that $a_{0}^{\prime}+a_{1}^{\prime}$ is continuous and in fact

$$
\left\|a_{0}^{\prime}+a_{1}^{\prime}\right\|_{\left(A_{0} \cap A_{1}\right)^{\prime}} \leq\left(\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|\right) .
$$

This proves the first part of the lemma.
Claim: With this definition of the norm in 43.8.54, the operator norm of $\left(a_{0}^{\prime}, a_{1}^{\prime}\right) \in$ $\left(A_{0} \times A_{1}\right)^{\prime}=A_{0}^{\prime} \times A_{1}^{\prime}$ is

$$
\begin{equation*}
\left\|\left(a_{0}^{\prime}, a_{1}^{\prime}\right)\right\|_{\left(A_{0} \times A_{1}\right)^{\prime}}=\left\|a_{0}^{\prime}\right\|_{A_{0}^{\prime}}+t\left\|a_{1}^{\prime}\right\|_{A_{1}^{\prime}} \tag{43.8.55}
\end{equation*}
$$

Proof of the claim: $\left|\left(a_{0}^{\prime}, a_{1}^{\prime}\right)\left(a_{0}, a_{1}\right)\right| \leq\left\|a_{0}^{\prime}\right\|\left\|a_{0}\right\|+\left\|a_{1}^{\prime}\right\|\left\|a_{1}\right\|$. Now suppose that $\left\|a_{0}\right\|=\max \left(\left\|a_{0}\right\|, t^{-1}\left\|a_{1}\right\|\right)$. Then this is no larger than

$$
\left(\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|\right)\left\|a_{0}\right\|=\left(\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|\right) \max \left(\left\|a_{0}\right\|, t^{-1}\left\|a_{1}\right\|\right) .
$$

The other case is that $t^{-1}\left\|a_{1}\right\|=\max \left(\left\|a_{0}\right\|, t^{-1}\left\|a_{1}\right\|\right)$. In this case,

$$
\begin{aligned}
\left|\left(a_{0}^{\prime}, a_{1}^{\prime}\right)\left(a_{0}, a_{1}\right)\right| & \leq\left\|a_{0}^{\prime}\right\|\left\|a_{0}\right\|+\left\|a_{1}^{\prime}\right\|\left\|a_{1}\right\| \\
& \leq\left\|a_{0}^{\prime}\right\| t^{-1}\left\|a_{1}\right\|+\left\|a_{1}^{\prime}\right\|\left\|a_{1}\right\| \\
& =\left(\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|\right) t^{-1}\left\|a_{1}\right\| \\
& =\left(\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|\right) \max \left(\left\|a_{0}\right\|, t^{-1}\left\|a_{1}\right\|\right) .
\end{aligned}
$$

This shows $\left\|\left(a_{0}^{\prime}, a_{1}^{\prime}\right)\right\|_{\left(A_{0} \times A_{1}\right)^{\prime}} \leq\left(\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|\right)$. Is equality achieved? Let $a_{0 n}$ and $a_{1 n}$ be points of $A_{0}$ and $A_{1}$ respectively such that $\left\|a_{0 n}\right\|,\left\|a_{1 n}\right\| \leq 1$ and $\lim _{n \rightarrow \infty} a_{i}^{\prime}\left(a_{i n}\right)=\left\|a_{i}^{\prime}\right\|$. Then

$$
\left(a_{0}^{\prime}, a_{1}^{\prime}\right)\left(a_{0 n}, t a_{1 n}\right) \rightarrow\left\|a_{0}^{\prime}\right\|+t\left\|a_{1}^{\prime}\right\|
$$

and also, $\left\|\left(a_{0 n}, t a_{1 n}\right)\right\|_{A_{0} \times A_{1}}=\max \left(\left\|a_{0 n}\right\|, t^{-1} t\left\|a_{1 n}\right\|_{A_{1}}\right) \leq 1$. Therefore, equality is indeed achieved and this proves the claim.

Consider 43.8.52. Take $a^{\prime} \in A_{0}^{\prime}+A_{1}^{\prime}=\left(A_{0} \cap A_{1}\right)^{\prime}$ and let

$$
E \equiv\left\{(a, a) \in A_{0} \times A_{1}: a \in A_{0} \cap A_{1}\right\} .
$$

Now define a linear map, $\lambda$ on $E$ as before.

$$
\lambda((a, a)) \equiv a^{\prime}(a) .
$$

If $a^{\prime}=\widetilde{a}_{0}+\widetilde{a}_{1}^{\prime}$,

$$
\begin{aligned}
|\lambda((a, a))| & \leq\left\|\widetilde{a}_{0}\right\|_{A_{0}^{\prime}}\|a\|_{A_{0}}+\left\|\widetilde{a}_{1}\right\|\left\|_{A_{1}^{\prime}}\right\| a \|_{A_{1}} \\
& =\left\|\widetilde{a}_{0}\right\|_{A_{0}^{\prime}}\|a\|_{A_{0}}+t\left\|\widetilde{a}_{1}\right\|_{A_{1}^{\prime}} t^{-1}\|a\|_{A_{1}} \\
& \leq\left(\left\|\widetilde{a}_{0}\right\|+t\left\|\widetilde{a}_{1}\right\|\right)\|(a, a)\|_{A_{0} \times A_{1}}
\end{aligned}
$$

so $\lambda$ is continuous on the subspace, $E$ of $A_{0} \times A_{1}$ and

$$
\begin{equation*}
\|\lambda\|_{E^{\prime}} \leq\left\|\widetilde{a}_{0}\right\|+t\left\|\widetilde{a}_{1}\right\| . \tag{43.8.56}
\end{equation*}
$$

By the Hahn Banach theorem, there exists an extension of $\lambda$ defined on all of $A_{0} \times A_{1}$ with the same norm. Thus, from 43.8.55, there exists $\left(a_{0}^{\prime}, a_{1}^{\prime}\right) \in\left(A_{0} \times A_{1}\right)^{\prime}$ which is an extension of $\lambda$ such that

$$
\left\|\left(a_{0}^{\prime}, a_{1}^{\prime}\right)\right\|_{\left(A_{0} \times A_{1}\right)^{\prime}}=\left\|a_{0}^{\prime}\right\|_{A_{0}^{\prime}}+t\left\|a_{1}^{\prime}\right\|_{A_{1}^{\prime}}=\|\lambda\|_{E^{\prime}}
$$

and for all $a \in A_{0} \cap A_{1}$,

$$
a_{0}^{\prime}(a)+a_{1}^{\prime}(a)=\lambda((a, a))=a^{\prime}(a)
$$

It follows that $a_{0}^{\prime}+a_{1}^{\prime}=a^{\prime}$ in $\left(A_{0} \cap A_{1}\right)^{\prime}$. Therefore, from 43.8.56,

$$
\begin{align*}
\|\lambda\|_{E^{\prime}} & \leq \inf \left\{\left\|\widetilde{a}_{0}\right\|_{A_{0}}+t\left\|\widetilde{a}_{1}^{\prime}\right\|_{A_{1}}: a^{\prime}=\widetilde{a}_{0}+\widetilde{a}_{1}\right\} \equiv K\left(t, a^{\prime}\right)  \tag{43.8.57}\\
& \leq\left\|a_{0}^{\prime}\right\|_{A_{0}^{\prime}}+t\left\|a_{1}^{\prime}\right\|_{A_{1}^{\prime}}=\|\lambda\|_{E^{\prime}} \equiv \sup _{a \in A_{0} \cap A_{1}} \frac{\left|a^{\prime}(a)\right|}{J\left(t^{-1}, a\right)} \tag{43.8.58}
\end{align*}
$$

because on $E, J\left(t^{-1}, a\right)=\|(a, a)\|_{A_{0} \times A_{1}}$ which proves 43.8.52.
To obtain 43.8 .53 in the case that $A_{i}$ is reflexive, apply 43.8 .52 to the case where $A_{i}^{\prime \prime}$ plays the role of $A_{i}$ in 43.8 .52 . Thus, for $a^{\prime \prime} \in A_{0}^{\prime \prime}+A_{1}^{\prime \prime}$,

$$
K\left(t, a^{\prime \prime}\right)=\sup _{a^{\prime} \in A_{0}^{\prime} \cap A_{1}^{\prime}} \frac{\left|a^{\prime \prime}\left(a^{\prime}\right)\right|}{J\left(t^{-1}, a^{\prime}\right)}
$$

Now $a^{\prime \prime}=a_{1}^{\prime \prime}+a_{0}^{\prime \prime}=\eta_{1} a_{1}+\eta_{0} a_{0}$ where $\eta_{i}$ is the map from $A_{i}$ to $A_{i}^{\prime \prime}$ which is onto and preserves norms, given by $\eta a\left(a^{\prime}\right) \equiv a^{\prime}(a)$. Therefore, letting $a_{1}+a_{0}=a$

$$
\begin{aligned}
K(t, a) & =K\left(t, a^{\prime \prime}\right)=\sup _{a^{\prime} \in A_{0}^{\prime} \cap A_{1}^{\prime}} \frac{\left|a^{\prime \prime}\left(a^{\prime}\right)\right|}{J\left(t^{-1}, a^{\prime}\right)} \\
& =\sup _{a^{\prime} \in A_{0}^{\prime} \cap A_{1}^{\prime}} \frac{\left|\left(\eta_{1} a_{1}+\eta_{0} a_{0}\right)\left(a^{\prime}\right)\right|}{J\left(t^{-1}, a^{\prime}\right)}=\sup _{a^{\prime} \in A_{0}^{\prime} \cap A_{1}^{\prime}} \frac{\left|\left(a^{\prime}\left(a_{1}+a_{0}\right)\right)\right|}{J\left(t^{-1}, a^{\prime}\right)}
\end{aligned}
$$

and so

$$
K(t, a)=\sup _{a^{\prime} \in A_{0}^{\prime} \cap A_{1}^{\prime}} \frac{\left|a^{\prime}(a)\right|}{J\left(t^{-1}, a^{\prime}\right)}
$$

Changing $t \rightarrow t^{-1}$,

$$
K\left(t^{-1}, a\right) J\left(t, a^{\prime}\right) \geq\left|a^{\prime}(a)\right|
$$

which proves the lemma.
Consider $\left(A_{0}, A_{1}\right)_{\theta, q}^{\prime}$.
Definition 43.8.2 Let $q \geq 1$. Then $\lambda^{\theta, q}$ will denote the sequences, $\left\{\alpha_{i}\right\}_{i=-\infty}^{\infty}$ such that

$$
\sum_{i=-\infty}^{\infty}\left(\left|\alpha_{i}\right| 2^{-i \theta}\right)^{q}<\infty
$$

For $\alpha \in \lambda^{\theta, q}$,

$$
\|\alpha\|_{\lambda^{\theta, q}} \equiv\left(\sum_{i=-\infty}^{\infty}\left(\left|\alpha_{i}\right| 2^{-i \theta}\right)^{q}\right)^{1 / q}
$$

Thus $\alpha \in \lambda^{\theta, q}$ means $\left\{\alpha_{i} 2^{-i \theta}\right\} \in l_{q}$.

Lemma 43.8.3 Let $f(t) \geq 0$, and let $f(t)=\alpha_{i}$ for $t \in\left[2^{i}, 2^{i+1}\right)$ where $\alpha \in \lambda^{\theta, q}$. Then there exists a constant, $C$, such that

$$
\begin{equation*}
\left\|t^{-\theta} f\right\|_{L^{q}\left(0, \infty ; \frac{d t}{t}\right)} \leq C\|\alpha\|_{\lambda^{\theta, q}} \tag{43.8.59}
\end{equation*}
$$

Also, if whenever $\alpha \in \lambda^{\theta, q}$, and $\alpha_{i} \geq 0$ for all $i$,

$$
\begin{equation*}
\sum_{i} f\left(2^{i}\right) 2^{-i} \alpha_{i} \leq C\|\alpha\|_{\lambda^{\theta, q}} \tag{43.8.60}
\end{equation*}
$$

then

$$
\begin{equation*}
\left\|\left\{f\left(2^{i}\right)\right\}_{i=-\infty}^{\infty} \mid\right\|_{\lambda^{1-\theta, q^{\prime}}} \leq C \tag{43.8.61}
\end{equation*}
$$

Proof: Consider 43.8.59.

$$
\begin{gathered}
\int_{0}^{\infty}\left(t^{-\theta} f(t)\right)^{q} \frac{d t}{t}=\sum_{i} \int_{2^{i}}^{2^{i+1}} t^{-\theta q} \alpha_{i}^{q} \frac{d t}{t} \\
\leq \sum_{i} \int_{2^{i}}^{2^{i+1}}\left(2^{-i \theta} \alpha_{i}\right)^{q} \frac{d t}{t}=\ln 2 \sum_{i}\left(2^{-i \theta} \alpha_{i}\right)^{q}=\ln 2\|\alpha\|_{\lambda^{\theta, q}}^{q} .
\end{gathered}
$$

43.8.61 is next. By 43.8.60, whenever $\alpha \in \lambda^{\theta, q}$,

$$
\left|\sum_{i}\left(f\left(2^{i}\right) 2^{-(1-\theta) i}\right) 2^{-\theta i} \alpha_{i}\right| \leq C| |\left\{2^{-\theta i}\left|\alpha_{i}\right|\right\} \|\left.\right|_{l_{q}}
$$

It follows from the Riesz representation theorem that $\left\{f\left(2^{i}\right) 2^{-(1-\theta) i}\right\}$ is in $l_{q^{\prime}}$ and

$$
\left\|\left\{f\left(2^{i}\right) 2^{-(1-\theta) i}\right\}\right\|_{l_{q^{\prime}}}=\left\|\left\{f\left(2^{i}\right)\right\}\right\|_{\lambda^{1-\theta, q^{\prime}}} \leq C .
$$

This proves the lemma.
The dual space of $\left(A_{0}, A_{1}\right)_{\theta, q, J}$ is discussed next.
Lemma 43.8.4 Let $\theta \in(0,1)$ and let $q \geq 1$. Then,

$$
\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime} \subseteq\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}}
$$

and the inclusion map is continuous.
Proof: Let $a^{\prime} \in\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime}$. Now

$$
A_{0} \cap A_{1} \subseteq\left(A_{0}, A_{1}\right)_{\theta, q, J}
$$

and if

$$
a \in\left(A_{0}, A_{1}\right)_{\theta, q, J}
$$

then $a$ has a representation of the form

$$
a=\int_{0}^{\infty} u(t) \frac{d t}{t}
$$

where

$$
\int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{q} \frac{d t}{t}<\infty
$$

where

$$
J(t, u(t))=\max \left(\|u(t)\|_{A_{0}}, t\|u(t)\|_{A_{1}}\right)
$$

for $u(t) \in A_{0} \cap A_{1}$. Now let

$$
u_{r}(t) \equiv\left\{\begin{array}{l}
u(t) \text { if } t \in\left(\frac{1}{r}, r\right) \\
0 \text { otherwise }
\end{array}\right.
$$

Then $\int_{0}^{\infty}\left(t^{-\theta} J\left(t, u_{r}(t)\right)\right)^{q} \frac{d t}{t}<\infty$ and

$$
a_{r} \equiv \int_{0}^{\infty} u_{r}(t) \frac{d t}{t} \in A_{0} \cap A_{1}
$$

by Lemma 43.7.2. Also

$$
\begin{gathered}
\left\|a-a_{r}\right\|_{\theta, q, J}^{q} \leq \int_{0}^{\frac{1}{r}}\left(t^{-\theta} J(t, u(t))\right)^{q} \frac{d t}{t}+ \\
\int_{r}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{q} \frac{d t}{t}
\end{gathered}
$$

which is small whenever $r$ is large enough thanks to the dominated convergence theorem. Therefore, $A_{0} \cap A_{1}$ is dense in $\left(A_{0}, A_{1}\right)_{\theta, q, J}$ and so

$$
\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime} \subseteq\left(A_{0} \cap A_{1}\right)^{\prime}=A_{0}^{\prime}+A_{1}^{\prime},
$$

the equality following from Lemma 43.8.1.
It follows $a^{\prime} \in A_{0}^{\prime}+A_{1}^{\prime}$ and so, by Lemma 43.8.1, there exists $b_{i} \in A_{0} \cap A_{1}$ such that

$$
K\left(2^{-i}, a^{\prime}, A_{0}^{\prime}, A_{1}^{\prime}\right)-\varepsilon \min \left(1,2^{-i}\right) \leq \frac{a^{\prime}\left(b_{i}\right)}{J\left(2^{i}, b_{i}, A_{0}, A_{1}\right)}
$$

Now let $\alpha \in \lambda^{\theta, q}$ with $\alpha_{i} \geq 0$ for all $i$ and let

$$
\begin{equation*}
a_{\infty} \equiv \sum_{i} J\left(2^{i}, b_{i}, A_{0}, A_{1}\right)^{-1} b_{i} \alpha_{i} \tag{43.8.62}
\end{equation*}
$$

Consider first whether $a_{\infty}$ makes sense before proceeding further.

$$
a_{\infty} \equiv \sum_{i} \frac{b_{i} 2^{i \theta}}{\max \left(\left\|b_{i}\right\|_{A_{0}}, 2^{i}\left\|b_{i}\right\|_{A_{1}}\right)} 2^{-i \theta} \alpha_{i}
$$

Now

$$
\left\|\frac{b_{i} 2^{i \theta}}{\max \left(\left\|b_{i}\right\|_{A_{0}}, 2^{i}\left\|b_{i}\right\|_{A_{1}}\right)}\right\|_{A_{0}+A_{1}} \leq\left\{\begin{array}{l}
2^{i \theta} \text { if } i<0  \tag{43.8.63}\\
2^{-i(1-\theta)} \text { if } i \geq 0
\end{array} .\right.
$$

This is fairly routine to verify. Consider the case where $i \geq 0$. Then

$$
\left\|\frac{b_{i} 2^{i \theta}}{\max \left(\left\|b_{i}\right\|_{A_{0}}, 2^{i}\left\|b_{i}\right\|_{A_{1}}\right)}\right\|\left\|_{A_{0}+A_{1}} \leq\right\| \frac{b_{i} 2^{i \theta}}{2^{i}\left\|b_{i}\right\|_{A_{1}}} \|_{A_{0}+A_{1}} \leq 2^{-i(1-\theta)}
$$

because $\left\|b_{i}\right\|_{A_{1}} \geq\left\|b_{i}\right\|_{A_{0}+A_{1}}$. Therefore,

$$
\begin{gathered}
\sum_{i=0}^{M}\left\|\frac{b_{i} 2^{i \theta}}{\max \left(\left\|b_{i}\right\|_{A_{0}}, 2^{i}\left\|b_{i}\right\|_{A_{1}}\right)} 2^{-i \theta} \alpha_{i}\right\|_{A_{0}+A_{1}} \leq \\
\sum_{i=0}^{M} 2^{-i(1-\theta)} 2^{-i \theta} \alpha_{i} \leq\left(\sum_{i=0}^{\infty} 2^{-i(1-\theta) q^{\prime}}\right)^{1 / q^{\prime}}\left(\sum_{i=0}^{\infty} 2^{-i q \theta} \alpha_{i}^{q}\right)^{1 / q}<\infty
\end{gathered}
$$

and similarly,

$$
\sum_{i=-\infty}^{0}\left\|\frac{b_{i} 2^{i \theta}}{\max \left(\left\|b_{i}\right\|_{A_{0}}, 2^{i}\left\|b_{i}\right\|_{A_{1}}\right)} 2^{-i \theta} \alpha_{i}\right\|_{A_{0}+A_{1}}
$$

converges. Therefore, $a_{\infty}$ makes sense in $A_{0}+A_{1}$ and also from 43.8.63, we see that

$$
\left\{\frac{\left\|b_{i}\right\|_{A_{0}+A_{1}} 2^{i \theta}}{J\left(2^{i}, b_{i}\right)}\right\} \in \lambda^{(1-\theta) q^{\prime}}
$$

Now let

$$
u(t) \equiv \frac{\alpha_{i} b_{i}}{J\left(2^{i}, b_{i}\right) \ln 2} \text { on }\left[2^{i-1}, 2^{i}\right)
$$

Then

$$
\begin{aligned}
\int_{0}^{\infty} u(t) \frac{d t}{t} & =\sum_{i} \int_{2^{i-1}}^{2^{i}} \frac{\alpha_{i} b_{i}}{J\left(2^{i}, b_{i}\right) \ln 2} \frac{d t}{t} \\
& =\sum_{i} \frac{\alpha_{i} b_{i}}{J\left(2^{i}, b_{i}\right)}=a_{\infty}
\end{aligned}
$$

Also

$$
\begin{gathered}
\int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{q} \frac{d t}{t} \leq \sum_{i} \int_{2^{i-1}}^{2^{i}}\left(2^{(1-i) \theta} J\left(2^{i}, u\left(2^{i-1}\right)\right)\right) \frac{d t}{t} \\
\leq \sum_{i}\left[2^{-(i-1) \theta} J\left(2^{i}, u\left(2^{i-1}\right)\right)\right]^{q} \ln 2
\end{gathered}
$$

$$
\begin{gather*}
=\sum_{i}\left[2^{-(i-1) \theta} \frac{J\left(2^{i}, b_{i}\right) \alpha_{i}}{J\left(2^{i}, b_{i}\right) \ln 2}\right]^{q} \ln 2 \\
=C \sum_{i}\left(2^{-i \theta}\left|\alpha_{i}\right|\right)^{q}<\infty \tag{43.8.64}
\end{gather*}
$$

and so $\left\|a_{\infty}\right\|_{\theta, q, J}<\infty$. Now for $a^{\prime}$ as above, $a^{\prime} \in\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime} \subseteq\left(A_{0}+A_{1}\right)^{\prime}$, and so since the sum for $a_{\infty}$ converges in $A_{0}+A_{1}$, we have

$$
a^{\prime}\left(a_{\infty}\right)=\sum_{i} J\left(2^{i}, b_{i}\right)^{-1} \alpha_{i} a^{\prime}\left(b_{i}\right)
$$

Therefore,

$$
\begin{align*}
a^{\prime}\left(a_{\infty}\right) & \geq \sum_{i}\left[K\left(2^{-i}, a^{\prime}\right)-\varepsilon \min \left(1,2^{-i}\right)\right] \alpha_{i} \\
& =\sum_{i} K\left(2^{-i}, a^{\prime}\right) \alpha_{i}-\sum_{i} \varepsilon \min \left(1,2^{-i}\right) \alpha_{i} \\
& =\sum_{i} K\left(2^{-i}, a^{\prime}\right) \alpha_{i}-O(\varepsilon) \tag{43.8.65}
\end{align*}
$$

The reason for this is that $\alpha \in \lambda^{\theta, q}$ so $\left\{\alpha_{i} 2^{-i \theta}\right\} \in l_{q}$. Therefore,

$$
\begin{aligned}
& \sum_{i} \varepsilon \min \left(1,2^{-i}\right) \alpha_{i}=\varepsilon\left\{\sum_{i=0}^{\infty} 2^{-i} \alpha_{i}+\sum_{i=-\infty}^{-1} \alpha_{i}\right\} \\
& =\varepsilon\left\{\sum_{i=0}^{\infty} 2^{-i \theta} 2^{(\theta-1) i} \alpha_{i}+\sum_{i=-\infty}^{-1} \alpha_{i} 2^{-i \theta} 2^{i \theta}\right\} \\
& \leq \varepsilon\left\{\left(\sum_{i}\left|\alpha_{i} 2^{-i \theta}\right|^{q}\right)^{1 / q}\left(\sum_{i=0}^{\infty}\left(2^{(\theta-1) i}\right)^{q^{\prime}}\right)^{1 / q^{\prime}}\right. \\
& \left.+\left(\sum_{i}\left|\alpha_{i} 2^{-i \theta}\right|^{q}\right)^{1 / q}\left(\sum_{i=0}^{\infty}\left(2^{\theta i}\right)^{q^{\prime}}\right)^{1 / q^{\prime}}\right\}<C \varepsilon
\end{aligned}
$$

Also $\left|a^{\prime}\left(a_{\infty}\right)\right| \leq\left\|a^{\prime}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime}}\left\|a_{\infty}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q, J}}$. Now from the definition of $K$,

$$
K\left(2^{-i}, a^{\prime}, A_{0}^{\prime}, A_{1}^{\prime}\right)=2^{-i} K\left(2^{i}, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right)
$$

and so from 43.8.65

$$
\begin{aligned}
\sum_{i} 2^{-i} K\left(2^{i}, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right) \alpha_{i}-O(\varepsilon) & \leq a^{\prime}\left(a_{\infty}\right) \\
& \leq\left\|a^{\prime}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime}} C_{\theta}\|\alpha\|_{\lambda^{\theta, q}}
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, it follows that whenever, $\alpha \in \lambda^{\theta, q}, \alpha_{i} \geq 0$,

$$
\sum_{i} 2^{-i} K\left(2^{i}, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right) \alpha_{i} \leq\left\|a^{\prime}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime}} C_{\theta}\|\alpha\|_{\lambda^{\theta, q}}
$$

By Lemma 43.8.3, $\left\{K\left(2^{i}, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right)\right\} \in \lambda^{1-\theta, q^{\prime}}$ and

$$
\left\|\left\{K\left(2^{i}, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right)\right\}\right\|_{\lambda^{1-\theta, q^{\prime}}} \leq\left\|a^{\prime}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime}} C_{\theta}
$$

Therefore,

$$
\begin{aligned}
& \left(\frac{1}{\ln 2} \int_{0}^{\infty}\left(K\left(t, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right) t^{-(1-\theta)}\right)^{q^{\prime}} \frac{d t}{t}\right)^{1 / q^{\prime}} \\
= & \left(\sum_{i} \frac{1}{\ln 2} \int_{2^{i}}^{2^{i+1}}\left(K\left(t, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right) t^{-(1-\theta)}\right)^{q^{\prime}} \frac{d t}{t}\right)^{1 / q^{\prime}} \\
\leq & \left(\sum_{i}\left(2^{-i(1-\theta)} K\left(2^{i}, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right)\right)^{q^{\prime}}\right)^{1 / q^{\prime}} \\
\leq & \left\|a^{\prime}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime}} C_{\theta}
\end{aligned}
$$

Thus

$$
\left\|a^{\prime}\right\|_{\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}}} \equiv\left\|t^{-(1-\theta)} K\left(t, a^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right)\right\|_{L^{q^{\prime}}\left(0, \infty, \frac{d t}{t}\right)} \leq C\left\|a^{\prime}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime}}
$$

which shows that $\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime} \subseteq\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}}$ with the inclusion map continuous. This proves the lemma.

Lemma 43.8.5 If $A_{i}$ is reflexive for $i=0,1$ and if $A_{0} \cap A_{1}$ is dense in $A_{i}$, then

$$
\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}, J} \subseteq\left(A_{0}, A_{1}\right)_{\theta, q}^{\prime}
$$

and the inclusion map is continuous.
Proof: Let $a^{\prime} \in\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}, J}$. Thus, there exists $u^{*}$ bounded on compact subsets of $(0, \infty)$ and measurable with values in $A_{0} \cap A_{1}$ and

$$
\begin{gather*}
a^{\prime}=\int_{0}^{\infty} u^{*}(t) \frac{d t}{t}  \tag{43.8.66}\\
\int_{0}^{\infty}\left(t^{-(1-\theta)} J\left(t, u^{*}(t)\right)\right)^{q^{\prime}} \frac{d t}{t}<\infty .
\end{gather*}
$$

Then

$$
a^{\prime}=\sum_{i=-\infty}^{\infty} \int_{2^{i}}^{2^{i+1}} u^{*}(t) \frac{d t}{t} \equiv \sum_{i=-\infty}^{\infty} a_{i}^{\prime}
$$

where $a_{i}^{\prime} \in A_{1}^{\prime} \cap A_{0}^{\prime}$, the convergence taking place in $A_{1}^{\prime}+A_{0}^{\prime}$. Now let $a \in A_{0} \cap A_{1}$. From Lemma 43.8.1

$$
\begin{aligned}
&\left|a^{\prime}(a)\right| \leq \sum_{i=-\infty}^{\infty}\left|a_{i}^{\prime}(a)\right| \\
& \leq \sum_{i=-\infty}^{\infty} J\left(2^{-i}, a_{i}^{\prime}, A_{0}^{\prime}, A_{1}^{\prime}\right) K\left(2^{i}, a, A_{0}, A_{1}\right) \\
&= \sum_{i=-\infty}^{\infty} 2^{-i} J\left(2^{i}, a_{i}^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right) K\left(2^{i}, a, A_{0}, A_{1}\right) \\
& \leq\left(\sum_{i}\left(2^{-(1-\theta) i} J\left(2^{i}, a_{i}^{\prime}, A_{1}^{\prime}, A_{0}^{\prime}\right)\right)^{q^{\prime}}\right)^{1 / q^{\prime}} . \\
& \leq\left(\sum_{i}\left(2^{-\theta i} K\left(2^{i}, a, A_{0}, A_{1}\right)\right)^{q}\right)^{1 / q} \\
& \leq\left[\int_{0}^{\infty}\left(t^{-(1-\theta)} J\left(t, u^{*}(t), A_{1}^{\prime}, A_{0}^{\prime}\right)\right)^{q^{\prime}} \frac{d t}{t}\right]^{1 / q^{\prime}} . \\
& {\left[\int_{0}^{\infty}\left(t^{-\theta} K\left(t, a, A_{0}, A_{1}\right)\right)^{q} \frac{d t}{t}\right]^{1 / q} . }
\end{aligned}
$$

In going from the sums to the integrals, express the first sum as a sum of integrals on $\left[2^{i}, 2^{i+1}\right)$ and the second sum as a sum of integrals on $\left(2^{i-1}, 2^{i}\right]$.

Taking the infimum over all $u^{*}$ representing $a^{\prime}$,

$$
\left|a^{\prime}(a)\right| \leq C\left\|a^{\prime}\right\|_{\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}, J}}\|a\|_{\theta, q} .
$$

It follows $a^{\prime} \in\left(A_{0}, A_{1}\right)_{\theta, q}^{\prime}$ and $\left\|a^{\prime}\right\|_{\left(A_{0}, A_{1}\right)_{\theta, q}^{\prime}} \leq C\left\|a^{\prime}\right\|_{\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}, J}}$ which proves the lemma.
With these two lemmas the main result follows.
Theorem 43.8.6 Suppose $A_{0} \cap A_{1}$ is dense in $A_{i}$ and $A_{i}$ is reflexive. Then

$$
\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}}=\left(A_{0}, A_{1}\right)_{\theta, q}^{\prime}
$$

and the norms are equivalent.
Proof: By Theorem 43.7.5, and the last two lemmas,

$$
\begin{aligned}
\left(A_{0}, A_{1}\right)_{\theta, q}^{\prime} & =\left(A_{0}, A_{1}\right)_{\theta, q, J}^{\prime} \subseteq\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}} \\
& =\left(A_{1}^{\prime}, A_{0}^{\prime}\right)_{1-\theta, q^{\prime}, J} \subseteq\left(A_{0}, A_{1}\right)_{\theta, q}^{\prime}
\end{aligned}
$$

This proves the theorem.

## Chapter 44

## Trace Spaces

### 44.1 Definition And Basic Theory Of Trace Spaces

Another approach to these sorts of problems is to use trace spaces. This allows the consideration of fractional order Sobolev spaces. In so far as the subject of Sobolev spaces is concerned, I will present this material in a manner which is essentially independent of the previous material on interpolation spaces.

As in the case of interpolation spaces, suppose $A_{0}$ and $A_{1}$ are two Banach spaces which are continuously embedded in some topological vector space, $X$.

Definition 44.1.1 Define a norm on $A_{0}+A_{1}$ as follows.

$$
\begin{equation*}
\|a\|_{A_{0}+A_{1}} \equiv \inf \left\{\left\|a_{0}\right\|_{A_{0}}+\left\|a_{1}\right\|_{A_{1}}: a_{0}+a_{1}=a\right\} \tag{44.1.1}
\end{equation*}
$$

Lemma 44.1.2 $A_{0}+A_{1}$ with the norm just described is a Banach space.
Proof: This was already explained in the treatment of the $K$ method of interpolation. It is just $K(1, a)$.

Definition 44.1.3 Take $f^{\prime}$ in the sense of distributions for any

$$
f \in L_{l o c}^{1}\left(0, \infty ; A_{0}+A_{1}\right)
$$

as follows.

$$
f^{\prime}(\phi) \equiv \int_{0}^{\infty}-f(t) \phi^{\prime}(t) d t
$$

whenever $\phi \in C_{c}^{\infty}(0, \infty)$. Define a Banach space, $W\left(A_{0}, A_{1}, p, \theta\right)=W$ where $p \geq 1, \theta \in$ $(0,1)$. Let

$$
\begin{equation*}
\|f\|_{W} \equiv \max \left(\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)},\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}\right) \tag{44.1.2}
\end{equation*}
$$

and let $W$ consist of $f \in L_{l o c}^{1}\left(0, \infty ; A_{0}+A_{1}\right)$ such that $\|f\|_{W}<\infty$.
Note that to be in $W, f(t) \in A_{0}$ and $f^{\prime}(t) \in A_{1}$.
Lemma 44.1.4 If $f \in W$, then

$$
\operatorname{Trace}(f) \equiv f(0) \equiv \lim _{t \rightarrow 0} f(t)
$$

exists in $A_{0}+A_{1}$. Also $Z \equiv\{f \in W: f(0)=0\}$ is a closed subspace of $W$. In addition to this, for every $f \in W$ and $\varepsilon>0$ there exists a $g \in W$ such that $\|f-g\|_{W}<\varepsilon$ and $g \in C^{\infty}\left(0, \infty ; A_{0}\right)$ while $g^{\prime} \in C^{\infty}\left(0, \infty ; A_{1}\right)$.

Proof: Let $0<s<t$. Let $v+\frac{1}{p}=\theta$. Then for a generic $g$,

$$
\int_{0}^{\infty}\left\|\tau^{v} g(\tau)\right\|^{p} d \tau=\int_{0}^{\infty}\left\|\tau^{\theta} g(\tau)\right\|^{p} \frac{d \tau}{\tau}
$$

so that $t^{v} f^{\prime} \in L^{p}\left(0, \infty ; A_{1}\right)$, the measure in this case being usual Lebesgue measure. Then

$$
f(t)-f(s)=\int_{s}^{t} f^{\prime}(\tau) d \tau=\int_{s}^{t} \tau^{v} f^{\prime}(\tau) \tau^{-v} d \tau
$$

For $\frac{1}{p}+\frac{1}{p^{\prime}}=1, v p^{\prime}=\left(\theta-\frac{1}{p}\right) p^{\prime}<1$ because $\theta<1=\frac{1}{p^{\prime}}+\frac{1}{p}$. Therefore,

$$
\begin{align*}
& \|f(t)-f(s)\|_{A_{0}+A_{1}} \\
\leq & \int_{s}^{t}\left\|f^{\prime}(\tau)\right\|_{A_{0}+A_{1}} d \tau \\
\leq & \int_{s}^{t}\left\|f^{\prime}(\tau)\right\|_{A_{1}} d \tau=\int_{s}^{t}\left\|\tau^{v} f^{\prime}(\tau)\right\|_{A_{1}} \tau^{-v} d \tau \\
\leq & \left(\int_{s}^{t}\left\|\tau^{v} f^{\prime}(\tau)\right\|_{A_{1}}^{p} d \tau\right)^{1 / p}\left(\int_{s}^{t} \tau^{-v p^{\prime}} d \tau\right)^{1 / p^{\prime}} \\
\leq & \|f\|_{W}\left(\frac{t^{1-v p^{\prime}}}{1-v p^{\prime}}-\frac{s^{1-v p^{\prime}}}{1-v p^{\prime}}\right)  \tag{44.1.3}\\
\leq & \|f\|_{W} \frac{t^{1-v p^{\prime}}}{1-v p^{\prime}} .
\end{align*}
$$

which converges to 0 as $t \rightarrow 0$. This shows that $\lim _{t \rightarrow 0+} f(t)$ exists in $A_{0}+A_{1}$.
Clearly $Z$ is a subspace. Let $f_{n} \rightarrow f$ in $W$ and suppose $f_{n} \in Z$. Then since $f \in W, 44.1 .3$ implies $f$ is continuous. Using 44.1.3 and replacing $f$ with $f_{n}-f_{m}$ and then taking a limit as $s \rightarrow 0$,

$$
\left\|f_{n}(t)-f_{m}(t)\right\|_{A_{0}+A_{1}} \leq\left\|f_{n}-f_{m}\right\|_{W} C_{v} t^{1-v p^{\prime}}
$$

Taking a subsequence, it can be assumed $f_{n}(t)$ converges to $f(t)$ a.e. But the above inequality shows that $f_{n}(t)$ is a Cauchy sequence in $C\left([0, \beta] ; A_{0}+A_{1}\right)$ for all $\beta<\infty$. Therefore, $f_{n}(t) \rightarrow f(t)$ for all $t$. Also,

$$
\left\|f_{n}(t)\right\|_{A_{0}+A_{1}} \leq C_{v}\left\|f_{n}\right\|_{W} t^{1-v p^{\prime}} \leq K t^{1-v p^{\prime}}
$$

for some $K$ depending on $\max \left\{\left|\mid f_{n} \|: n \geq 1\right\}\right.$ and so

$$
\|f(t)\|_{A_{0}+A_{1}} \leq K t^{1-v p^{\prime}}
$$

which implies $f(0)=0$. Thus $Z$ is closed.
Consider the last claim. For a generic $t^{\theta} g \in L^{p}\left(0, \infty, \frac{d t}{t} ; A\right)$, changing variables $t=e^{\tau}$,

$$
\int_{0}^{\infty} t^{\theta p}|g(t)|^{p} \frac{d t}{t}=\int_{-\infty}^{\infty} e^{\tau \theta p}\left|g\left(e^{\tau}\right)\right|^{p} d \tau
$$

Let $\widetilde{g}(\tau) \equiv g\left(e^{\tau}\right)$. Thus $\tau \rightarrow e^{\tau \theta} \widetilde{g}(\tau)$ is $L^{p}(\mathbb{R} ; A)$ and $\widetilde{g} \in L_{l o c}^{1}(\mathbb{R})$. Now let $\psi_{\delta}$ be a mollifier and consider

$$
\begin{aligned}
e^{\theta \tau} \widetilde{g}_{\delta}(\tau) & \equiv \int_{-\infty}^{\infty} e^{\theta \sigma} \widetilde{g}(\sigma) \psi_{\delta}(\tau-\sigma) d \sigma \\
& =\int_{-\infty}^{\infty} e^{\theta(\tau-\sigma)} \widetilde{g}(\tau-\sigma) \psi_{\delta}(\sigma) d \sigma
\end{aligned}
$$

so that

$$
\begin{aligned}
\widetilde{g}_{\delta}(\tau) & =\int_{-\infty}^{\infty} e^{-\theta \sigma} \widetilde{g}(\tau-\sigma) \psi_{\delta}(\sigma) d \sigma \\
& =\int_{-\infty}^{\infty} e^{-\theta(\tau-\sigma)} \widetilde{g}(\sigma) \psi_{\delta}(\tau-\sigma) d \sigma
\end{aligned}
$$

Thus $\widetilde{g}_{\delta} \in C^{\infty}(\mathbb{R} ; A)$ and using Minkowski's inequality,

$$
\begin{gather*}
\left(\int_{-\infty}^{\infty}\left\|e^{\theta \tau} \widetilde{g}_{\delta}(\tau)-e^{\theta \tau} \widetilde{g}(\tau)\right\|^{p} d \tau\right)^{1 / p}=  \tag{44.1.4}\\
\left(\int_{-\infty}^{\infty}\left\|\int_{-\infty}^{\infty}\left(e^{\theta(\tau-\sigma)} \widetilde{g}(\tau-\sigma)-e^{\theta \tau} \widetilde{g}(\tau)\right) \psi_{\delta}(\sigma) d \sigma\right\|^{p} d \tau\right)^{1 / p} \\
\leq \int_{-\delta}^{\delta} \psi_{\delta}(\sigma)\left(\int_{-\infty}^{\infty}\left\|e^{\theta(\tau-\sigma)} \widetilde{g}(\tau-\sigma)-e^{\theta \tau} \widetilde{g}(\tau)\right\|^{p} d \tau\right)^{1 / p} d \sigma \\
\leq \varepsilon \int_{-\infty}^{\infty} \psi_{\delta}(\sigma) d s=\varepsilon
\end{gather*}
$$

provided $\delta$ is small enough due to continuity of translation in $L^{p}$. Thus changing variables in 44.1.4, letting $\tau=\ln (t)$ and $g_{\delta}(t) \equiv \widetilde{g}_{\delta}(\ln (t))$, it follows $g_{\delta} \in C^{\infty}(0, \infty ; A)$ and this integral equals

$$
\left(\int_{0}^{\infty} t^{\theta p}\left\|g_{\delta}(t)-g(t)\right\|^{p} \frac{d t}{t}\right)^{1 / p}
$$

This result applied to $f$ and $f^{\prime}$ with $A=A_{0}$ and then $A=A_{1}$ shows the last claim. This proves the lemma.

Definition 44.1.5 Let $W$ be a Banach space and let $Z$ be a closed subspace. Then the quotient space, denoted by $W / Z$ consists of the set of equivalence classes $[x]$ where the equivalence relation is defined by $x \backsim y$ means $x-y \in Z$. Then $W / Z$ is a vector space if the operations are defined by $\alpha[x] \equiv[\alpha x]$ and $[x]+[y] \equiv[x+y]$ and these vector space operations are well defined. The norm on the quotient space is defined as $\|[x]\| \equiv \inf \{\|x+z\|: z \in Z\}$.

The verification of the algebraic claims made in the above definition is left to the reader. It is routine. What is not as routine is the following lemma. However, it is similar to some topics in the presentation of the $K$ method of interpolation.

Lemma 44.1.6 Let $W$ be a Banach space and let $Z$ be a closed subspace of $W$. Then $W / Z$ with the norm described above is a Banach space.

Proof: That $W / Z$ is a vector space is left to the reader. Why is $\|\cdot\|$ a norm? Suppose $\alpha \neq 0$. Then

$$
\begin{aligned}
\|\alpha[x]\| & =\|[\alpha x]\| \equiv \inf \{\|\alpha x+z\|: z \in Z\} \\
& =\inf \{\|\alpha x+\alpha z\|: z \in Z\} \\
& =|\alpha| \inf \{\|x+z\|: z \in Z\}=|\alpha|\|[x]\| .
\end{aligned}
$$

Now let $\|[x]\| \geq\left\|x+z_{1}\right\|-\varepsilon$ and let $\|[y]\| \geq\left\|y+z_{2}\right\|-\varepsilon$ where $z_{i} \in Z$. Then

$$
\begin{aligned}
\|[x]+[y]\| & \equiv\|[x+y]\| \leq\left\|x+y+z_{1}+z_{2}\right\| \\
& \leq\left\|x+z_{1}\right\|+\left\|y+z_{2}\right\| \leq\|[x]\|+\|[y]\|+2 \varepsilon
\end{aligned}
$$

Since $\varepsilon$ is arbitrary, this shows the triangle inequality. Clearly, $\|[x]\| \geq 0$. It remains to show that the only way $\|[x]\|=0$ is for $x \in Z$. Suppose then that $\|[x]\|=0$. This means there exist $z_{n} \in Z$ such that $\left\|x+z_{n}\right\| \rightarrow 0$. Therefore, $-x$ is a limit of a sequence of points of $Z$ and since $Z$ is closed, this requires $-x \in Z$. Hence $x \in Z$ also because $Z$ is a subspace. This shows $\|\cdot\|$ is a norm on $W / Z$. It remains to verify that $W / Z$ is a Banach space.

Suppose $\left\{\left[x_{n}\right]\right\}$ is a Cauchy sequence in $W / Z$ and suppose $\left\|\left[x_{n}\right]-\left[x_{n+1}\right]\right\|<\frac{1}{2^{n+1}}$. Let $x_{1}^{\prime}=x_{1}$. If $x_{n}^{\prime}$ has been chosen let $x_{n+1}^{\prime}=x_{n+1}+z_{n+1}$ where $z_{n+1} \in Z$ be such that

$$
\begin{aligned}
\left\|x_{n+1}^{\prime}-x_{n}^{\prime}\right\| & \leq\left\|\left[x_{n+1}-x_{n}\right]\right\|+\frac{1}{2^{(n+1)}} \\
& =\left\|\left[x_{n+1}\right]-\left[x_{n}\right]\right\|+\frac{1}{2^{(n+1)}}<\frac{1}{2^{n}}
\end{aligned}
$$

It follows $\left\{x_{n}^{\prime}\right\}$ is a Cauchy sequence in $W$ and so it must converge to some $x \in W$. Now

$$
\left\|[x]-\left[x_{n}\right]\right\|=\left\|\left[x-x_{n}\right]\right\|=\left\|\left[x-x_{n}^{\prime}\right]\right\| \leq\left\|x-x_{n}^{\prime}\right\|
$$

which converges to 0 . Now if $\left\{\left[x_{n}\right]\right\}$ is just a Cauchy sequence, there exists a subsequence satisfying $\left\|\left[x_{n_{k}}\right]-\left[x_{n_{k+1}}\right]\right\|<\frac{1}{2^{k+1}}$ and so from the first part, the subsequence converges to some $[x] \in W / Z$ and so the original Cauchy sequence also converges. therefore, $W / Z$ is a Banach space as claimed.

Definition 44.1.7 Define $T\left(A_{0}, A_{1}, p, \theta\right)=T$, to consist of

$$
\left\{a \in A_{0}+A_{1}: a=\lim _{t \rightarrow 0+} f(t) \text { for some } f \in W\left(A_{0}, A_{1}, p, \theta\right)\right\}
$$

the limit taking place in $A_{0}+A_{1}$. Let $\gamma f$ be defined for $f \in W$ by $\gamma f \equiv \lim _{t \rightarrow 0+} f(t)$. Thus $T=\gamma(W)$. As above $Z \equiv\{f \in W: \gamma f=0\}=\operatorname{ker}(\gamma)$.

Lemma 44.1.8 $T$ is a Banach space with norm given by

$$
\begin{equation*}
\|a\|_{T} \equiv \inf \left\{\|f\|_{W}: f(0)=a\right\} \tag{44.1.5}
\end{equation*}
$$

Proof: Define a mapping, $\psi: W / Z \rightarrow T$ by

$$
\psi([f]) \equiv \gamma f
$$

Then $\psi$ is one to one and onto. Also

$$
\|[f]\| \equiv \inf \{\|f+g\|: g \in Z\}=\inf \left\{\|h\|_{W}: \gamma h=\gamma f\right\}=\|\gamma(f)\|_{T}
$$

Therefore, the Banach space, $W / Z$ and $T$ are isometric and so $T$ must be a Banach space since $W / Z$ is.

The following is an important interpolation inequality.
Theorem 44.1.9 If $a \in T$, then

$$
\begin{equation*}
\|a\|_{T}=\inf \left\{\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}^{1-\theta}\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}^{\theta}\right\} \tag{44.1.6}
\end{equation*}
$$

where the infimum is taken over all $f \in W$ such that $a=f(0)$. Also, if $a \in A_{0} \cap A_{1}$, then $a \in T$ and

$$
\begin{equation*}
\|a\|_{T} \leq K\|a\|_{A_{1}}^{1-\theta}\|a\|_{A_{0}}^{\theta} \tag{44.1.7}
\end{equation*}
$$

for some constant K. Also

$$
\begin{equation*}
A_{0} \cap A_{1} \subseteq T\left(A_{0}, A_{1}, p, \theta\right) \subseteq A_{0}+A_{1} \tag{44.1.8}
\end{equation*}
$$

and the inclusion maps are continuous.
Proof: First suppose $f(0)=a$ where $f \in W$. Then letting $f_{\lambda}(t) \equiv f(\lambda t)$, it follows that $f_{\lambda}(0)=a$ also and so

$$
\begin{aligned}
\|a\|_{T} & \leq \max \left(\left\|t^{\theta} f_{\lambda}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)},\left\|t^{\theta}\left(f_{\lambda}\right)^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}\right) \\
& =\max \left(\lambda^{-\theta}\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}, \lambda^{1-\theta}\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}\right) \\
& \equiv \max \left(\lambda^{-\theta} R, \lambda^{1-\theta} S\right)
\end{aligned}
$$

Now choose $\lambda=R / S$ to obtain

$$
\|a\|_{T} \leq R^{1-\theta} S^{\theta}=\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}^{1-\theta}\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}^{\theta}
$$

Thus

$$
\|a\|_{T} \leq \inf \left\{\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}^{1-\theta}\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}^{\theta}\right\}
$$

Next choose $f \in W$ such that $f(0)=a$ and $\|f\|_{W} \approx\|a\|_{T}$. More precisely, pick $f \in W$ such that $f(0)=a$ and $\|a\|_{T}>-\varepsilon+\|f\|_{W}$. Also let

$$
R \equiv\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}, S \equiv\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}
$$

Then as before,

$$
\begin{equation*}
\left\|t^{\theta} f_{\lambda}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}=\lambda^{-\theta} R,\left\|t^{\theta}\left(f_{\lambda}\right)^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}=\lambda^{1-\theta} S \tag{44.1.9}
\end{equation*}
$$

so that $\|f\|_{W}=\max (R, S)$. Then, changing the variables, letting $\lambda=R / S$,

$$
\begin{equation*}
\left\|t^{\theta} f_{\lambda}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}=\left\|t^{\theta}\left(f_{\lambda}\right)^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}=R^{1-\theta} S^{\theta} \tag{44.1.10}
\end{equation*}
$$

Since $f_{\lambda}(0)=a, f_{\lambda} \in W$, and it is always the case that for positive $R, S$,

$$
R^{1-\theta} S^{\theta} \leq \max (R, S)
$$

this shows that

$$
\begin{aligned}
\|a\|_{T} & \leq \max \left(\left\|t^{\theta} f_{\lambda}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)},\left\|t^{\theta}\left(f_{\lambda}\right)^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}\right) \\
& =R^{1-\theta} S^{\theta} \leq \max (R, S)=\|f\|_{W}<\|a\|_{T}+\varepsilon
\end{aligned}
$$

the first inequality holding because $\|a\|_{T}$ is the infimum of such things on the right. This shows 44.1.6.

It remains to verify 44.1.7. To do this, let $\psi \in C^{\infty}([0, \infty))$, with $\psi(0)=1$ and $\psi(t)=0$ for all $t>1$. Then consider the special $f \in W$ which is given by $f(t) \equiv a \psi(t)$ where $a \in A_{0} \cap A_{1}$. Thus $f \in W$ and $f(0)=a$ so $a \in T\left(A_{0}, A_{1}, p, \theta\right)$. From the first part, there exists a constant, $K$ such that

$$
\begin{aligned}
\|a\|_{T} & \leq\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)}^{1-\theta}\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}^{\theta} \\
& \leq K\|a\|_{A_{0}}^{1-\theta}\|a\|_{A_{1}}^{\theta}
\end{aligned}
$$

This shows 44.1.7 and the first inclusion in 44.1.8. From the inequality just obtained,

$$
\begin{aligned}
\|a\|_{T} & \leq K\left((1-\theta)\|a\|_{A_{0}}+\theta\|a\|_{A_{1}}\right) \\
& \leq K\|a\|_{A_{0} \cap A_{1}}
\end{aligned}
$$

This shows the first inclusion map of 44.1.8 is continuous.
Now take $a \in T$. Let $f \in W$ be such that $a=f(0)$ and

$$
\|a\|_{T}+\varepsilon>\|f\|_{W} \geq\|a\|_{T}
$$

By 44.1.3,

$$
\|a-f(t)\|_{A_{0}+A_{1}} \leq C_{v} t^{1-v p^{\prime}}\|f\|_{W}
$$

where $\frac{1}{p}+v=\theta$, and so

$$
\|a\|_{A_{0}+A_{1}} \leq\|f(t)\|_{A_{0}+A_{1}}+C_{v} t^{1-v p^{\prime}}\|f\|_{W}
$$

Now $\|f(t)\|_{A_{0}+A_{1}} \leq\|f(t)\|_{A_{0}}$.

$$
\begin{aligned}
\|a\|_{A_{0}+A_{1}} & \leq t^{v}\|f(t)\|_{A_{0}+A_{1}} t^{-v}+C_{v} t^{1-v p^{\prime}}\|f\|_{W} \\
& \leq t^{v}\|f(t)\|_{A_{0}} t^{-v}+C_{v} t^{1-v p^{\prime}}\|f\|_{W}
\end{aligned}
$$

Therefore, recalling that $v p^{\prime}<1$, and integrating both sides from 0 to 1 ,

$$
\|a\|_{A_{0}+A_{1}} \leq C_{V}\|f\|_{W} \leq C_{V}\left(\|a\|_{T}+\varepsilon\right)
$$

To see this,

$$
\begin{aligned}
\int_{0}^{1} t^{v}\|f(t)\|_{A_{0}} t^{-v} d t & \leq\left(\int_{0}^{1}\left(t^{v}\|f(t)\|_{A_{0}}\right)^{p} d t\right)^{1 / p}\left(\int_{0}^{1} t^{-v p^{\prime}} d t\right)^{1 / p^{\prime}} \\
& \leq C\|f\|_{W}
\end{aligned}
$$

Since $\varepsilon>0$ is arbitrary, this verifies the second inclusion and continuity of the inclusion map completing the proof of the theorem.

The interpolation inequality, 44.1 .7 is very significant. The next result concerns bounded linear transformations.

Theorem 44.1.10 Now suppose $A_{0}, A_{1}$ and $B_{0}, B_{1}$ are pairs of Banach spaces such that $A_{i}$ embeds continuously into a topological vector space, $X$ and $B_{i}$ embeds continuously into a topological vector space, $Y$. Suppose also that $L \in \mathscr{L}\left(A_{0}, B_{0}\right)$ and $L \in \mathscr{L}\left(A_{1}, B_{1}\right)$ where the operator norm of $L$ in these spaces is $K_{i}, i=0,1$. Then

$$
\begin{equation*}
L \in \mathscr{L}\left(A_{0}+A_{1}, B_{0}+B_{1}\right) \tag{44.1.11}
\end{equation*}
$$

with

$$
\begin{equation*}
\|L a\|_{B_{0}+B_{1}} \leq \max \left(K_{0}, K_{1}\right)\|a\|_{A_{0}+A_{1}} \tag{44.1.12}
\end{equation*}
$$

and

$$
\begin{equation*}
L \in \mathscr{L}\left(T\left(A_{0}, A_{1}, p, \theta\right), T\left(B_{0}, B_{1}, p, \theta\right)\right) \tag{44.1.13}
\end{equation*}
$$

and for $K$ the operator norm,

$$
\begin{equation*}
K \leq K_{0}^{1-\theta} K_{1}^{\theta} \tag{44.1.14}
\end{equation*}
$$

Proof: To verify 44.1.11, let $a \in A_{0}+A_{1}$ and pick $a_{0} \in A_{0}$ and $a_{1} \in A_{1}$ such that

$$
\|a\|_{A_{0}+A_{1}}+\varepsilon>\left\|a_{0}\right\|_{A_{0}}+\left\|a_{1}\right\|_{A_{1}}
$$

Then

$$
\begin{aligned}
& \|L(a)\|_{B_{0}+B_{1}}=\left\|L a_{0}+L a_{1}\right\|_{B_{0}+B_{1}} \leq\left\|L a_{0}\right\|_{B_{0}}+\left\|L a_{1}\right\|_{B_{1}} \\
& \leq K_{0}\left\|a_{0}\right\|_{A_{0}}+K_{1}\left\|a_{1}\right\|_{A_{1}} \leq \max \left(K_{0}, K_{1}\right)\left(\|a\|_{A_{0}+A_{1}}+\varepsilon\right) .
\end{aligned}
$$

This establishes 44.1.12. Now consider the other assertions.

Let $a \in T\left(A_{0}, A_{1}, p, \theta\right)$ and pick $f \in W\left(A_{0}, A_{1}, p, \theta\right)$ such that $\gamma f=a$ and

$$
\|a\|_{T\left(A_{0}, A_{1}, p, \theta\right)}+\varepsilon>\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t}, A_{0}\right)}^{1-\theta}\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t}, A_{1}\right)}^{\theta}
$$

Then consider $L f$. Since $L$ is continuous on $A_{0}+A_{1}$,

$$
L f(0)=L a
$$

and $L f \in W\left(B_{0}, B_{1}, p, \theta\right)$. Therefore, by Theorem 44.1.9,

$$
\begin{aligned}
\|L a\|_{T\left(B_{0}, B_{1}, p, \theta\right)} & \leq\left\|t^{\theta} L f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t}, B_{0}\right)}^{1-\theta}\left\|t^{\theta} L f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t}, B_{1}\right)}^{\theta} \\
& \leq K_{0}^{1-\theta} K_{1}^{\theta}\left\|t^{\theta} f\right\|_{L^{p}\left(0, \infty, \frac{d t}{t}, A_{0}\right)}^{1-\theta}\left\|t^{\theta} f^{\prime}\right\|_{L^{p}\left(0, \infty, \frac{d t}{t}, A_{1}\right)}^{\theta} \\
& \leq K_{0}^{1-\theta} K_{1}^{\theta}\left(\|a\|_{T\left(A_{0}, A_{1}, p, \theta\right)}+\varepsilon\right)
\end{aligned}
$$

and since $\varepsilon>0$ is arbitrary, this proves the theorem.

### 44.2 Trace And Interpolation Spaces

Trace spaces are equivalent to interpolation spaces. In showing this, a more general sort of trace space than that presented earlier will be used.

Definition 44.2.1 Define for $m$ a positive integer, $V^{m}=V^{m}\left(A_{0}, A_{1}, p, \theta\right)$ to be the set of functions, u such that

$$
\begin{equation*}
t \rightarrow t^{\theta} u(t) \in L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right) \tag{44.2.15}
\end{equation*}
$$

and

$$
\begin{equation*}
t \rightarrow t^{\theta+m-1} u^{(m)}(t) \in L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right) \tag{44.2.16}
\end{equation*}
$$

$V^{m}$ is a Banach space with the norm

$$
\|u\|_{V^{m}} \equiv \max \left(\left\|t^{\theta} u(t)\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)},\left\|t^{\theta+m-1} u^{(m)}(t)\right\|_{L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)}\right)
$$

Thus $V^{m}$ equals $W$ in the case when $m=1$. More generally, as in [16] different exponents are used for the two $L^{p}$ spaces, $p_{0}$ in place of $p$ for the space corresponding to $A_{0}$ and $p_{1}$ in place of $p$ for the space corresponding to $A_{1}$.

Definition 44.2.2 Denote by $T^{m}\left(A_{0}, A_{1}, p, \theta\right)$ the set of all $a \in A_{0}+A_{1}$ such that for some $u \in V^{m}$,

$$
\begin{equation*}
a=\lim _{t \rightarrow 0+} u(t) \equiv \operatorname{trace}(u) \tag{44.2.17}
\end{equation*}
$$

the limit holding in $A_{0}+A_{1}$. For the norm

$$
\begin{equation*}
\|a\|_{T^{m}} \equiv \inf \left\{\|u\|_{V^{m}}: \operatorname{trace}(u)=a\right\} \tag{44.2.18}
\end{equation*}
$$

The case when $m=1$ was discussed in Section 44.1. Note it is not known at this point whether $\lim _{t \rightarrow 0+} u(t)$ even exists for every $u \in V^{m}$. Of course, if $m=1$ this was shown earlier but it has not been shown for $m>1$. The following theorem is absolutely amazing. Note the lack of dependence on $m$ of the right side!

Theorem 44.2.3 The following hold.

$$
\begin{equation*}
T^{m}\left(A_{0}, A_{1}, p, \theta\right)=\left(A_{0}, A_{1}\right)_{\theta, p, J}=\left(A_{0}, A_{1}\right)_{\theta, p} \tag{44.2.19}
\end{equation*}
$$

Proof: It is enough to show the first equality because of Theorem 43.7 .5 which identifies $\left(A_{0}, A_{1}\right)_{\theta, p, J}$ and $\left(A_{0}, A_{1}\right)_{\theta, p}$. Let $a \in T^{m}$. Then there exists $u \in V^{m}$ such that

$$
a=\lim _{t \rightarrow 0+} u(t) \text { in } A_{0}+A_{1} .
$$

The first task is to modify this $u(t)$ to get a better one which is more usable in order to show $a \in\left(A_{0}, A_{1}\right)_{\theta, p, J}$. Remember, it is required to find $w(t) \in A_{0} \cap A_{1}$ for all $t \in(0, \infty)$ and $a=\int_{0}^{\infty} w(t) \frac{d t}{t}$, a representation which is not known at this time. To get such a thing, let

$$
\begin{equation*}
\phi \in C_{c}^{\infty}(0, \infty), \operatorname{spt}(\phi) \subseteq[\alpha, \beta] \tag{44.2.20}
\end{equation*}
$$

with $\phi \geq 0$ and

$$
\begin{equation*}
\int_{0}^{\infty} \phi(t) \frac{d t}{t}=1 \tag{44.2.21}
\end{equation*}
$$

Then define

$$
\begin{equation*}
\widetilde{u}(t) \equiv \int_{0}^{\infty} \phi\left(\frac{t}{\tau}\right) u(\tau) \frac{d \tau}{\tau}=\int_{0}^{\infty} \phi(s) u\left(\frac{t}{s}\right) \frac{d s}{s} \tag{44.2.22}
\end{equation*}
$$

Claim: $\lim _{t \rightarrow 0+} \widetilde{u}(t)=a$ and $\lim _{t \rightarrow \infty} \widetilde{u}^{(k)}(t)=0$ in $A_{0}+A_{1}$ for all $k \leq m$.
Proof of the claim: From 44.2 .22 and 44.2 .21 it follows that for $\|\cdot\|$ referring to $\|\cdot\|_{A_{0}+A_{1}}$,

$$
\begin{aligned}
\|\widetilde{u}(t)-a\| & \leq \int_{0}^{\infty}\left\|u\left(\frac{t}{s}\right)-a\right\| \phi(s) \frac{d s}{s} \\
& =\int_{0}^{\infty}\|u(\tau)-a\| \phi\left(\frac{t}{\tau}\right) \frac{d \tau}{\tau} \\
& =\int_{t / \beta}^{t / \alpha}\|u(\tau)-a\| \phi\left(\frac{t}{\tau}\right) \frac{d \tau}{\tau} \\
& \leq \int_{t / \beta}^{t / \alpha} \varepsilon \phi\left(\frac{t}{\tau}\right) \frac{d \tau}{\tau}=\varepsilon \int_{\alpha}^{\beta} \phi(s) \frac{d s}{s}=\varepsilon
\end{aligned}
$$

whenever $t$ is small enough due to the convergence of $u(t)$ to $a$ in $A_{0}+A_{1}$.
Now consider what occurs when $t \rightarrow \infty$. For $\|\cdot\|$ referring to the norm in $A_{0}$,

$$
\widetilde{u}^{(k)}(t)=\int_{0}^{\infty} \phi^{(k)}\left(\frac{t}{\tau}\right) \frac{1}{\tau^{k}} u(\tau) \frac{d \tau}{\tau}
$$

and so

$$
\begin{gathered}
\left\|\widetilde{u}^{(k)}(t)\right\|_{A_{0}} \leq C_{k} \int_{t / \beta}^{t / \alpha}\|u(\tau)\|_{A_{0}} \frac{d \tau}{\tau} \\
\leq C\left(\int_{t / \beta}^{t / \alpha} \frac{d \tau}{\tau}\right)^{1 / p^{\prime}}\left(\int_{t / \beta}^{t / \alpha}\|u(\tau)\|_{A_{0}}^{p} \frac{d \tau}{\tau}\right)^{1 / p}
\end{gathered}
$$

Now $\left(\frac{\beta}{t}\right)^{\theta} \tau^{\theta} \geq 1$ for $\tau \geq t / \beta$ and so the above expression

$$
\leq C\left(\ln \frac{\beta}{\alpha}\right)^{1 / p^{\prime}}\left(\frac{\beta}{t}\right)^{\theta}\left(\int_{t / \beta}^{\infty}\left(\tau^{\theta}\|u(\tau)\|_{A_{0}}\right)^{p} \frac{d \tau}{\tau}\right)^{1 / p}
$$

and so $\lim _{t \rightarrow \infty}\left\|\widetilde{u}^{(k)}(t)\right\|_{A_{0}}=0$ and therefore, this also holds in $A_{0}+A_{1}$. This proves the claim.

Thus $\widetilde{u}$ has the same properties as $u$ in terms of having $a$ as its trace. $\widetilde{u}$ is used to build the desired $w$, representing $a$ as an integral. Define

$$
\begin{gather*}
v(t) \equiv \frac{(-1)^{m} t^{m}}{(m-1)!} \widetilde{u}^{(m)}(t)=\frac{(-1)^{m}}{(m-1)!} \int_{0}^{\infty} \frac{t^{m}}{\tau^{m}} \phi^{(m)}\left(\frac{t}{\tau}\right) u(\tau) \frac{d \tau}{\tau} \\
=\frac{(-1)^{m}}{(m-1)!} \int_{0}^{\infty} s^{m} \phi^{(m)}(s) u\left(\frac{t}{s}\right) \frac{d s}{s} \tag{44.2.23}
\end{gather*}
$$

Then from the claim, and integration by parts in the last step,

$$
\begin{equation*}
\int_{0}^{\infty} v\left(\frac{1}{t}\right) \frac{d t}{t}=\int_{0}^{\infty} v(t) \frac{d t}{t}=\frac{(-1)^{m}}{(m-1)!} \int_{0}^{\infty} t^{m-1} \widetilde{u}^{(m)}(t) d t=a \tag{44.2.24}
\end{equation*}
$$

Thus $v\left(\frac{1}{t}\right)$ represents $a$ in the way desired for $\left(A_{0}, A_{1}\right)_{\theta, p, J}$ if it is also true that $v\left(\frac{1}{t}\right) \in$ $A_{0} \cap A_{1}$ and $t \rightarrow t^{-\theta} v\left(\frac{1}{t}\right)$ is in $L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)$ and $t \rightarrow t^{1-\theta_{v}}\left(\frac{1}{t}\right)$ is in $L^{p}\left(0, \infty, \frac{d t}{t} ; A_{1}\right)$. First consider whether $v(t) \in A_{0} \cap A_{1} . v(t) \in A_{0}$ for each $t$ from 44.2.23 and the assumption that $u \in L^{p}\left(0, \infty, \frac{d t}{t} ; A_{0}\right)$. To verify $v(t) \in A_{1}$, integrate by parts in 44.2.23 to obtain

$$
\begin{gather*}
v(t)=\frac{(-1)^{m}}{(m-1)!} \int_{0}^{\infty} \phi^{(m)}(s)\left(s^{m-1} u\left(\frac{t}{s}\right)\right) d s  \tag{44.2.25}\\
=\frac{1}{(m-1)!} \int_{0}^{\infty} \phi(s) \frac{d^{m}}{d s^{m}}\left(s^{m-1} u\left(\frac{t}{s}\right)\right) d s \\
=\frac{(-1)^{m}}{(m-1)!} \int_{0}^{\infty} \phi(s) \frac{t^{m}}{s^{m+1}} u^{(m)}\left(\frac{t}{s}\right) d s \in A_{1}
\end{gather*}
$$

The last step may look very mysterious. If so, consider the case where $m=2$.

$$
\begin{aligned}
& \phi(s)\left(s u\left(\frac{t}{s}\right)\right)^{\prime \prime} \\
= & \phi(s)\left(-\frac{t}{s} u^{\prime}\left(\frac{t}{s}\right)+u\left(\frac{t}{s}\right)\right)^{\prime} \\
= & \phi(s)\left(\left(-\frac{t}{s}\right) u^{\prime \prime}\left(\frac{t}{s}\right)\left(-\frac{t}{s^{2}}\right)+\frac{t}{s^{2}} u^{\prime}\left(\frac{t}{s}\right)-\frac{t}{s^{2}} u^{\prime}\left(\frac{t}{s}\right)\right) \\
= & \phi(s) \frac{t^{2}}{s^{3}} u^{\prime \prime}\left(\frac{t}{s}\right) .
\end{aligned}
$$

You can see the same pattern will take place for other values of $m$.
Now

$$
\begin{gather*}
\|a\|_{\theta, p, J} \leq\left(\int_{0}^{\infty}\left(t^{-\theta} J\left(t, v\left(\frac{1}{t}\right)\right)\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
\leq C_{p}\left\{\int_{0}^{\infty}\left[\left(t^{-\theta}\left\|v\left(\frac{1}{t}\right)\right\|_{A_{0}}\right)+\left(t^{1-\theta}\left\|v\left(\frac{1}{t}\right)\right\|_{A_{1}}\right)\right]^{p} \frac{d t}{t}\right\}^{1 / p} \\
\leq C_{p}\left\{\left(\int_{0}^{\infty}\left(t^{-\theta}\left\|v\left(\frac{1}{t}\right)\right\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p}\right. \\
\left.+\left(\int_{0}^{\infty}\left(t^{1-\theta}\left\|v\left(\frac{1}{t}\right)\right\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}\right\} \tag{44.2.26}
\end{gather*}
$$

The first term equals

$$
\begin{gather*}
\left(\int_{0}^{\infty}\left(t^{-\theta}\left\|v\left(\frac{1}{t}\right)\right\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
=\left(\int_{0}^{\infty}\left(t^{\theta}\|v(t)\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
=\left(\int_{0}^{\infty}\left(t^{\theta}\left\|\int_{0}^{\infty} s^{m} \phi^{(m)}(s) u\left(\frac{t}{s}\right) \frac{d s}{s}\right\| \|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
\leq \int_{0}^{\infty}\left(\int_{0}^{\infty}\left(t^{\theta} s^{m}\left|\phi^{(m)}(s)\right|\left\|u\left(\frac{t}{s}\right)\right\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \frac{d s}{s} \\
\leq \int_{0}^{\infty} s^{m}\left|\phi^{(m)}(s)\right|\left(\int_{0}^{\infty}\left(t^{\theta}\left\|u\left(\frac{t}{s}\right)\right\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \frac{d s}{s} \\
=\int_{0}^{\infty} s^{\theta+m}\left|\phi^{(m)}(s)\right| \frac{d s}{s}\left(\int_{0}^{\infty}\left(\tau^{\theta}\|u(\tau)\|_{A_{0}}\right)^{p} \frac{d \tau}{\tau}\right)^{1 / p} \\
=C\left(\int_{0}^{\infty}\left(\tau^{\theta}\|u(\tau)\|_{A_{0}}\right)^{p} \frac{d \tau}{\tau}\right)^{1 / p} \cdot \tag{44.2.27}
\end{gather*}
$$

The second term equals

$$
\begin{aligned}
& \left(\int_{0}^{\infty}\left(t^{1-\theta}\left\|v\left(\frac{1}{t}\right)\right\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}=\left(\int_{0}^{\infty}\left(t^{\theta-1}\|v(t)\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
& \quad=\left(\int_{0}^{\infty}\left(t^{\theta-1}\left\|\frac{1}{(m-1)!} \int_{0}^{\infty} \phi(s) \frac{t^{m}}{s^{m}} u^{(m)}\left(\frac{t}{s}\right) \frac{d s}{s}\right\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}
\end{aligned}
$$

$$
\begin{gather*}
\leq \int_{0}^{\infty}\left(\int_{0}^{\infty}\left(\left(\frac{t^{\theta+m-1}}{s^{m}}\right)|\phi(s)|\left\|u^{(m)}\left(\frac{t}{s}\right)\right\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \frac{d s}{s} \\
\leq \int_{0}^{\infty} \frac{|\phi(s)|}{s^{m}}\left(\int_{0}^{\infty}\left(t^{\theta+m-1}\left\|u^{(m)}\left(\frac{t}{s}\right)\right\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \frac{d s}{s} \\
=\int_{0}^{\infty} \frac{|\phi(s)|}{s^{m}} s^{\theta+m-1}\left(\int_{0}^{\infty}\left(\tau^{\theta+m-1}\left\|u^{(m)}(\tau)\right\|_{A_{1}}\right)^{p} \frac{d \tau}{\tau}\right)^{1 / p} \frac{d s}{s} \\
=C\left(\int_{0}^{\infty}\left(\tau^{\theta+m-1}\left\|u^{(m)}(\tau)\right\|_{A_{1}}\right)^{p} \frac{d \tau}{\tau}\right)^{1 / p} \tag{44.2.28}
\end{gather*}
$$

Now from the estimates on the two terms in 44.2.26 found in 44.2.27 and 44.2.28, and the simple estimate,

$$
2 \max (\alpha, \beta) \geq \alpha+\beta
$$

it follows

$$
\begin{align*}
& \|a\|_{\theta, p, J}  \tag{44.2.29}\\
\leq & C \max \left(\left(\int_{0}^{\infty}\left(\tau^{\theta}\|u(\tau)\|_{A_{0}}\right)^{p} \frac{d \tau}{\tau}\right)^{1 / p}\right.  \tag{44.2.30}\\
& \left.,\left(\int_{0}^{\infty}\left(\tau^{\theta+m-1}\left\|u^{(m)}(\tau)\right\|_{A_{1}}\right)^{p} \frac{d \tau}{\tau}\right)^{1 / p}\right) \tag{44.2.31}
\end{align*}
$$

which shows that after taking the infimum over all $u$ whose trace is $a$, it follows $a \in$ $\left(A_{0}, A_{1}\right)_{\theta, p, J}$.

$$
\begin{equation*}
\|a\|_{\theta, p, J} \leq C\|a\|_{T^{m}} \tag{44.2.32}
\end{equation*}
$$

Thus $T^{m}\left(A_{0}, A_{1}, \theta, p\right) \subseteq\left(A_{0}, A_{1}\right)_{\theta, p, J}$.
Is $\left(A_{0}, A_{1}\right)_{\theta, p, J} \subseteq T^{m}\left(A_{0}, A_{1}, \theta, p\right)$ ? Let $a \in\left(A_{0}, A_{1}\right)_{\theta, p, J}$. There exists $u$ having values in $A_{0} \cap A_{1}$ and such that

$$
a=\int_{0}^{\infty} u(t) \frac{d t}{t}=\int_{0}^{\infty} u\left(\frac{1}{t}\right) \frac{d t}{t}
$$

in $A_{0}+A_{1}$ such that

$$
\int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{p} d t<\infty, \text { where } J(t, a)=\max \left(\|a\|_{A_{0}}, t\|a\|_{A_{1}}\right)
$$

Then let

$$
\begin{gather*}
w(t) \equiv \int_{t}^{\infty}\left(1-\frac{t}{\tau}\right)^{m-1} u\left(\frac{1}{\tau}\right) \frac{d \tau}{\tau}=  \tag{44.2.33}\\
\int_{0}^{1 / t}(1-s t)^{m-1} u(s) \frac{d s}{s}=\int_{0}^{1}(1-\tau)^{m-1} u\left(\frac{\tau}{t}\right) \frac{d \tau}{\tau} \tag{44.2.34}
\end{gather*}
$$

It is routine to verify from 44.2.33 that

$$
\begin{equation*}
w^{(m)}(t)=(m-1)!(-1)^{m} \frac{u\left(\frac{1}{t}\right)}{t^{m}} \tag{44.2.35}
\end{equation*}
$$

For example, consider the case where $m=2$.

$$
\begin{aligned}
\left(\int_{t}^{\infty}\left(1-\frac{t}{\tau}\right) u\left(\frac{1}{\tau}\right) \frac{d \tau}{\tau}\right)^{\prime \prime} & =\left(0+\int_{t}^{\infty}\left(-\frac{1}{\tau}\right) u\left(\frac{1}{\tau}\right) \frac{d \tau}{\tau}\right)^{\prime} \\
& =\frac{1}{t^{2}} u\left(\frac{1}{t}\right)
\end{aligned}
$$

Also from 44.2.33, it follows that trace $(w)=a$. It remains to verify $w \in V^{m}$. From 44.2.35,

$$
\begin{gather*}
\left(\int_{0}^{\infty}\left(t^{\theta+m-1}\left\|w^{(m)}(t)\right\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}= \\
C_{m}\left(\int_{0}^{\infty}\left(t^{\theta-1}\left\|u\left(\frac{1}{t}\right)\right\| \|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}=C_{m}\left(\int_{0}^{\infty}\left(t^{1-\theta}\|u(t)\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
\leq C_{m}\left(\int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{p} \frac{d t}{t}\right)^{1 / p}<\infty \tag{44.2.36}
\end{gather*}
$$

It remains to consider $\left(\int_{0}^{\infty}\left(t^{\theta}\|w(t)\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p}$. From 44.2.34,

$$
\begin{aligned}
&\left(\int_{0}^{\infty}\left(t^{\theta}\|w(t)\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
&=\left(\int_{0}^{\infty}\left(t^{\theta}\left\|\int_{0}^{1}(1-\tau)^{m-1} u\left(\frac{\tau}{t}\right) \frac{d \tau}{\tau}\right\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
&=\left(\int_{0}^{\infty}\left(t^{-\theta}\left\|\int_{0}^{1}(1-\tau)^{m-1} u(\tau t) \frac{d \tau}{\tau}\right\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \\
& \leq \int_{0}^{1}\left(\int_{0}^{\infty}\left(t^{-\theta}(1-\tau)^{m-1}\|u(\tau t)\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p} \frac{d \tau}{\tau} \\
&= \int_{0}^{1} \tau^{\theta}(1-\tau)^{m-1}\left(\int_{0}^{\infty}\left(s^{-\theta}\|u(s)\|_{A_{0}}\right)^{p} \frac{d s}{s}\right)^{1 / p} \frac{d \tau}{\tau} \\
&=\left(\int_{0}^{1} \tau^{\theta-1}(1-\tau)^{m-1} d \tau\right)\left(\int_{0}^{\infty}\left(s^{-\theta}\|u(s)\|_{A_{0}}\right)^{p} \frac{d s}{s}\right)^{1 / p} \\
& \quad \leq C\left(\int_{0}^{\infty}\left(s^{-\theta}\|u(s)\|_{A_{0}}\right)^{p} \frac{d s}{s}\right)^{1 / p}
\end{aligned}
$$

$$
\begin{equation*}
\leq C\left(\int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{p} d t\right)^{1 / p}<\infty \tag{44.2.37}
\end{equation*}
$$

It follows that

$$
\begin{gathered}
\|w\|_{V^{m}} \equiv \\
\max \left(\left(\int_{0}^{\infty}\left(t^{\theta}\|w(t)\|_{A_{0}}\right)^{p} \frac{d t}{t}\right)^{1 / p},\left(\int_{0}^{\infty}\left(t^{\theta+m-1}\left\|w^{(m)}(t)\right\|_{A_{1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}\right) \\
\leq C\left(\int_{0}^{\infty}\left(t^{-\theta} J(t, u(t))\right)^{p} d t\right)^{1 / p}<\infty
\end{gathered}
$$

which shows that $a \in T^{m}\left(A_{0}, A_{1}, \theta, p\right)$. Taking the infimum,

$$
\|a\|_{T^{m}} \leq C\|a\|_{\theta, p, J}
$$

This together with 44.2 .32 proves the theorem.
By Theorem 44.2.3 and Theorem 43.8.6, we obtain the following important corollary describing the dual space of a trace space.

Corollary 44.2.4 Let $A_{0} \cap A_{1}$ be dense in $A_{i}$ for $i=0,1$ and suppose that $A_{i}$ is reflexive for $i=0,1$. Then for $\infty>p \geq 1$,

$$
T^{m}\left(A_{0}, A_{1}, \theta, p\right)^{\prime}=T^{m}\left(A_{1}^{\prime}, A_{0}^{\prime}, 1-\theta, p^{\prime}\right)
$$

## Chapter 45

## Traces Of Sobolev Spaces

### 45.1 Traces Of Sobolev Spaces, Half Space

In this section consider the trace of $W^{m, p}\left(\mathbb{R}_{+}^{n}\right)$ onto a Sobolev space of functions defined on $\mathbb{R}^{n-1}$. This latter Sobolev space will be defined in terms of the following theory in such a way that the trace map is continuous. The trace map is continuous as a map from $W^{m, p}\left(\mathbb{R}_{+}^{n}\right)$ to $W^{m-1, p}\left(\mathbb{R}^{n-1}\right)$ but here I will give a better conclusion using the above theory.

Definition 45.1.1 Let $\theta \in(0,1)$ and let $\Omega$ be an open subset of $\mathbb{R}^{m}$. We define

$$
W^{\theta, p}(\Omega) \equiv T\left(W^{1, p}(\Omega), L^{p}(\Omega), p, 1-\theta\right)
$$

Thus, from the above general theory, $W^{1, p}(\Omega) \hookrightarrow W^{\theta, p}(\Omega) \hookrightarrow L^{p}(\Omega)=L^{p}(\Omega)+$ $W^{1, p}(\Omega)$. Now we consider the trace map for Sobolev space.

Lemma 45.1.2 Let $\phi \in C^{\infty}\left(\overline{\mathbb{R}_{+}^{n}}\right)$. Then $\gamma \phi\left(\mathbf{x}^{\prime}\right) \equiv \phi\left(\mathbf{x}^{\prime}, 0\right)$. Then $\gamma: C^{\infty}\left(\overline{\mathbb{R}_{+}^{n}}\right) \rightarrow L^{p}\left(\mathbb{R}^{n-1}\right)$ is continuous as a map from $W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$ to $L^{p}\left(\mathbb{R}^{n-1}\right)$.

Proof: We know

$$
\phi\left(\mathbf{x}^{\prime}, x_{n}\right)=\gamma \phi\left(\mathbf{x}^{\prime}\right)+\int_{0}^{x_{n}} \frac{\partial \phi\left(\mathbf{x}^{\prime}, t\right)}{\partial t} d t
$$

Then by Jensen's inequality,

$$
\begin{aligned}
& \int_{\mathbb{R}^{n-1}}\left|\gamma \phi\left(\mathbf{x}^{\prime}\right)\right|^{p} d x^{\prime} \\
= & \int_{0}^{1} \int_{\mathbb{R}^{n-1}}\left|\gamma \phi\left(\mathbf{x}^{\prime}\right)\right|^{p} d x^{\prime} d x_{n} \\
\leq & C \int_{0}^{1} \int_{\mathbb{R}^{n-1}}\left|\phi\left(\mathbf{x}^{\prime}, x_{n}\right)\right|^{p} d x^{\prime} d x_{n} \\
& +C \int_{0}^{1} \int_{\mathbb{R}^{n-1}}\left|\int_{0}^{x_{n}} \frac{\partial \phi\left(\mathbf{x}^{\prime}, t\right)}{\partial t} d t\right|^{p} d x^{\prime} d x_{n} \\
\leq & C\|\phi\|_{0, p, \mathbb{R}_{+}^{n}}^{p}+C \int_{0}^{1} x_{n}^{p-1} \int_{\mathbb{R}^{n-1}} \int_{0}^{x_{n}}\left|\frac{\partial \phi\left(\mathbf{x}^{\prime}, t\right)}{\partial t}\right|^{p} d t d x^{\prime} d x_{n} \\
\leq & C\|\phi\|_{0, p, \mathbb{R}_{+}^{n}}^{p}+C \int_{0}^{1} x_{n}^{p-1} \int_{\mathbb{R}^{n-1}} \int_{0}^{\infty}\left|\frac{\partial \phi\left(\mathbf{x}^{\prime}, t\right)}{\partial t}\right|^{p} d t d x^{\prime} d x_{n} \\
\leq & C\|\phi\|_{0, p, \mathbb{R}_{+}^{n}}^{p}+\frac{C}{p} \int_{\mathbb{R}^{n-1}} \int_{0}^{\infty}\left|\frac{\partial \phi\left(\mathbf{x}^{\prime}, t\right)}{\partial t}\right|^{p} d t d x^{\prime} \\
\leq & C\|\phi\|_{1, p, \mathbb{R}_{+}^{n}}^{p}
\end{aligned}
$$

This proves the lemma.

Definition 45.1.3 We define the trace,

$$
\gamma: W^{1, p}\left(\mathbb{R}_{+}^{n}\right) \rightarrow L^{p}\left(\mathbb{R}^{n-1}\right)
$$

as follows. $\gamma \phi\left(\mathbf{x}^{\prime}\right) \equiv \phi\left(\mathbf{x}^{\prime}, 0\right)$ whenever $\phi \in C^{\infty}\left(\overline{\mathbb{R}_{+}^{n}}\right)$. For $u \in W^{1, p}\left(\overline{\mathbb{R}_{+}^{n}}\right)$, we define $\gamma u \equiv$ $\lim _{k \rightarrow \infty} \gamma \phi_{k}$ in $L^{p}\left(\mathbb{R}^{n-1}\right)$ where $\phi_{k} \rightarrow u$ in $W^{1, p}\left(\overline{\mathbb{R}_{+}^{n}}\right)$. Then the above lemma shows this is well defined.

Also from this lemma we obtain a constant, $C$ such that

$$
\|\phi\|_{0, p, \mathbb{R}^{n-1}} \leq C\|\phi\|_{1, p, \mathbb{R}_{+}^{n}}
$$

and the same constant holds for all $u \in W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$.
From the definition of the norm in the trace space, if $f \in C^{\infty}\left(\overline{\mathbb{R}_{+}^{n}}\right)$, and letting $\theta=$ $1-\frac{1}{p}$, it follows from the definition

$$
\begin{aligned}
& \|\gamma f\|_{1-\frac{1}{p}, p, \mathbb{R}^{n-1}} \\
\leq & \max \left(\left(\int_{0}^{\infty}\left(t^{1 / p}\|f(t)\|_{1, p, \mathbb{R}^{n-1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}\right. \\
& \left.,\left(\int_{0}^{\infty}\left(t^{1 / p}\left\|f^{\prime}(t)\right\|_{0, p, \mathbb{R}^{n-1}}\right)^{p} \frac{d t}{t}\right)^{1 / p}\right) \\
\leq & C\|f\|_{1, p, \mathbb{R}_{+}^{n}}
\end{aligned}
$$

Thus, if $f \in W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$, define $\gamma f \in W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right)$ according to the rule,

$$
\gamma f=\lim _{k \rightarrow \infty} \gamma \phi_{k}
$$

where $\phi_{k} \rightarrow f$ in $W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$ and $\phi_{k} \in C^{\infty}\left(\overline{\mathbb{R}_{+}^{n}}\right)$. This shows the continuity part of the following lemma.

Lemma 45.1.4 The trace map, $\gamma$, is a continuous map from $W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$ onto

$$
W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right)
$$

Furthermore, for $f \in W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$,

$$
\gamma f=f(0)=\lim _{t \rightarrow 0+} f(t)
$$

the limit taking place in $L^{p}\left(\mathbb{R}^{n-1}\right)$.
Proof: It remains to verify $\gamma$ is onto along with the displayed equation. But by definition, things in $W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right)$ are $\lim _{t \rightarrow 0+} f(t)$ where $f \in L^{p}\left(0, \infty ; W^{1, p}\left(\mathbb{R}^{n-1}\right)\right)$, and $f^{\prime} \in L^{p}\left(0, \infty ; L^{p}\left(\mathbb{R}^{n-1}\right)\right)$, the limit taking place in

$$
W^{1, p}\left(\mathbb{R}^{n-1}\right)+L^{p}\left(\mathbb{R}^{n-1}\right)=L^{p}\left(\mathbb{R}^{n-1}\right)
$$

and

$$
\left(\int_{0}^{\infty}\|f(t)\|_{1, p, \mathbb{R}^{n-1}}^{p} d t\right)^{1 / p}+\left(\int_{0}^{\infty}\left\|f^{\prime}(t)\right\|_{0, p}^{p} d t\right)^{1 / p}<\infty
$$

Then taking a measurable representative, we see $f \in W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$ and $f_{, x_{n}}=f^{\prime}$. Also, as an equation in $L^{p}\left(\mathbb{R}^{n-1}\right)$, the following holds for all $t>0$.

$$
f(\cdot, t)=f(0)+\int_{0}^{t} f_{, x_{n}}(\cdot, s) d s
$$

But also, for a.e. $\mathbf{x}^{\prime}$, the following equation holds for a.e. $t>0$.

$$
\begin{equation*}
f\left(\mathbf{x}^{\prime}, t\right)=\gamma f\left(\mathbf{x}^{\prime}\right)+\int_{0}^{t} f_{, x_{n}}\left(\mathbf{x}^{\prime}, s\right) d s \tag{45.1.1}
\end{equation*}
$$

showing that

$$
\gamma f=f(0) \in W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right) \equiv T\left(W^{1, p}(\Omega), L^{p}(\Omega), p, \frac{1}{p}\right)
$$

To see that 45.1 .1 holds, approximate $f$ with a sequence from $C^{\infty}\left(\overline{\mathbb{R}_{+}^{n}}\right)$ and finally obtain an equation of the form

$$
\int_{\mathbb{R}^{n-1}} \int_{0}^{\infty}\left[f\left(\mathbf{x}^{\prime}, t\right)-\gamma f\left(\mathbf{x}^{\prime}\right)-\int_{0}^{t} f_{, x_{n}}\left(\mathbf{x}^{\prime}, s\right) d s\right] \psi\left(\mathbf{x}^{\prime}, t\right) d t d x^{\prime}=0
$$

which holds for all $\psi \in C_{c}^{\infty}\left(\mathbb{R}_{+}^{n}\right)$. This proves the lemma.
Thus taking the trace on the boundary loses exactly $\frac{1}{p}$ derivatives.

### 45.2 A Right Inverse For The Trace For A Half Space

It is also important to show there is a continuous linear function,

$$
R: W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right) \rightarrow W^{1, p}\left(\mathbb{R}_{+}^{n}\right)
$$

which has the property that $\gamma(R g)=g$. Define this function as follows.

$$
\begin{equation*}
\operatorname{Rg}\left(\mathbf{x}^{\prime}, x_{n}\right) \equiv \int_{\mathbb{R}^{n-1}} g\left(\mathbf{y}^{\prime}\right) \phi\left(\frac{\mathbf{x}^{\prime}-\mathbf{y}^{\prime}}{x_{n}}\right) \frac{1}{x_{n}^{n-1}} d \mathbf{y}^{\prime} \tag{45.2.2}
\end{equation*}
$$

where $\phi$ is a mollifier having support in $B(\mathbf{0}, 1)$.
Lemma 45.2.1 Let $R$ be defined in 45.2.2. Then $R g \in W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$ and is a continuous linear map from $W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right)$ to $W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$ with the property that $\gamma R g=g$.

Proof: Let $f \in W^{1, p}\left(\mathbb{R}_{+}^{n}\right)$ be such that $\gamma f=g$. Let $\psi\left(x_{n}\right) \equiv\left(1-x_{n}\right)_{+}$and assume $f$ is Borel measurable by taking a Borel measurable representative. Then for a.e. $\mathbf{x}^{\prime}$ we have the following formula holding for a.e. $x_{n}$.

$$
\begin{aligned}
& \operatorname{Rg}\left(\mathbf{x}^{\prime}, x_{n}\right) \\
= & \int_{\mathbb{R}^{n-1}}\left[\psi\left(x_{n}\right) f\left(\mathbf{y}^{\prime}, \psi\left(x_{n}\right)\right)-\int_{0}^{\psi\left(x_{n}\right)}(\psi f)_{, n}\left(\mathbf{y}^{\prime}, t\right) d t\right] \phi\left(\frac{\mathbf{x}^{\prime}-\mathbf{y}^{\prime}}{x_{n}}\right) x_{n}^{1-n} d y^{\prime} .
\end{aligned}
$$

Using the repeated index summation convention to save space, we obtain that in terms of weak derivatives,

$$
\begin{gathered}
R g_{, n}\left(\mathbf{x}^{\prime}, x_{n}\right) \\
=\int_{\mathbb{R}^{n-1}}\left[\psi\left(x_{n}\right) f\left(\mathbf{y}^{\prime}, \psi\left(x_{n}\right)\right)-\int_{0}^{\psi\left(x_{n}\right)}(\psi f)_{, n}\left(\mathbf{y}^{\prime}, t\right) d t\right] \\
{\left[\phi_{, k}\left(\frac{\mathbf{x}^{\prime}-\mathbf{y}^{\prime}}{x_{n}}\right)\left(\frac{y_{k}-x_{k}}{x_{n}^{n}}\right)+\phi\left(\frac{\mathbf{x}^{\prime}-\mathbf{y}^{\prime}}{x_{n}}\right) \frac{(1-n)}{x_{n}^{n}}\right] d y^{\prime}} \\
=\int_{\mathbb{R}^{n-1}}\left[\psi\left(x_{n}\right) f\left(\mathbf{x}^{\prime}-x_{n} \mathbf{z}^{\prime}, \psi\left(x_{n}\right)\right)-\int_{0}^{\psi\left(x_{n}\right)}(\psi f)_{, n}\left(\mathbf{x}^{\prime}-x_{n} \mathbf{z}^{\prime}, t\right) d t\right] . \\
{\left[\phi_{, k}\left(\mathbf{z}^{\prime}\right)\left(\frac{y_{k}-x_{k}}{x_{n}^{n}}\right) z_{k}+\phi\left(\mathbf{z}^{\prime}\right) \frac{(1-n)}{x_{n}^{n}}\right] x_{n}^{n} d z^{\prime}}
\end{gathered}
$$

and so

$$
\begin{aligned}
\left|R g_{, n}\left(\mathbf{x}^{\prime}, x_{n}\right)\right| \leq & C(\phi) \mid \int_{B(\mathbf{0}, 1)}\left[\psi\left(x_{n}\right) f\left(\mathbf{x}^{\prime}-x_{n} \mathbf{z}^{\prime}, \psi\left(x_{n}\right)\right)\right. \\
& \left.-\int_{0}^{\psi\left(x_{n}\right)}(\psi f)_{, n}\left(\mathbf{x}^{\prime}-x_{n} \mathbf{z}^{\prime}, t\right) d t\right] \mid \\
\leq & \frac{C(\phi)}{x_{n}^{n-1}}\left\{\int_{B\left(\mathbf{0}, x_{n}\right)}\left|\psi\left(x_{n}\right) f\left(\mathbf{x}^{\prime}+\mathbf{y}^{\prime}, \psi\left(x_{n}\right)\right)\right| d y^{\prime}\right. \\
& \left.+\int_{B\left(\mathbf{0}, x_{n}\right)} \int_{0}^{\psi\left(x_{n}\right)}\left|(\psi f)_{, n}\left(\mathbf{x}^{\prime}+\mathbf{y}^{\prime}, t\right)\right| d t d y^{\prime}\right\}
\end{aligned}
$$

Therefore,

$$
\begin{gather*}
\left(\int_{0}^{\infty} \int_{\mathbb{R}^{n-1}}\left|R g_{, n}\left(\mathbf{x}^{\prime}, x_{n}\right)\right|^{p} d x^{\prime} d x_{n}\right)^{1 / p} \leq \\
C(\phi)\left(\int_{0}^{\infty} \int_{\mathbb{R}^{n-1}}\left(\frac{1}{x_{n}^{n-1}} \int_{B\left(\mathbf{0}, x_{n}\right)}\left|\psi\left(x_{n}\right) f\left(\mathbf{x}^{\prime}+\mathbf{y}^{\prime}, \psi\left(x_{n}\right)\right)\right| d y^{\prime}\right)^{p} d x^{\prime} d x_{n}\right)^{1 / p} \\
+C(\phi)\left(\int_{0}^{\infty} \int_{\mathbb{R}^{n-1}}\left(\frac{1}{x_{n}^{n-1}} \int_{B\left(\mathbf{0}, x_{n}\right)} \int_{0}^{\psi\left(x_{n}\right)}\left|(\psi f)_{, n}\left(\mathbf{x}^{\prime}+\mathbf{y}^{\prime}, t\right)\right| d t d y^{\prime}\right)^{p} d x^{\prime} d x_{n}\right)^{1 / p} \tag{45.2.3}
\end{gather*}
$$

Consider the first term on the right. We change variables, letting $\mathbf{y}^{\prime}=\mathbf{z}^{\prime} x_{n}$. Then this term becomes

$$
\begin{aligned}
& C(\phi)\left(\int_{0}^{1} \int_{\mathbb{R}^{n-1}}\left(\int_{B(\mathbf{0}, 1)}\left|\psi\left(x_{n}\right) f\left(\mathbf{x}^{\prime}+x_{n} \mathbf{z}^{\prime}, \psi\left(x_{n}\right)\right)\right| d z^{\prime}\right)^{p} d x^{\prime} d x_{n}\right)^{1 / p} \\
& \leq C(\phi) \int_{B(\mathbf{0}, 1)}\left(\int_{0}^{1} \int_{\mathbb{R}^{n-1}}\left|\psi\left(x_{n}\right) f\left(\mathbf{x}^{\prime}+x_{n} \mathbf{z}^{\prime}, \psi\left(x_{n}\right)\right)\right|^{p} d x^{\prime} d x_{n}\right)^{1 / p} d z^{\prime}
\end{aligned}
$$

Now we change variables, letting $t=\psi\left(x_{n}\right)$. This yields

$$
\begin{equation*}
=C(\phi) \int_{B(\mathbf{0}, 1)}\left(\int_{0}^{1} \int_{\mathbb{R}^{n-1}}\left|t f\left(\mathbf{x}^{\prime}+x_{n} \mathbf{z}^{\prime}, t\right)\right|^{p} d x^{\prime} d t\right)^{1 / p} d z^{\prime} \leq C(\phi)\|f\|_{0, p, \mathbb{R}_{+}^{n}} \tag{45.2.4}
\end{equation*}
$$

Now we consider the second term on the right in 45.2.3. Using the same arguments which were used on the first term involving Minkowski's inequality and changing the variables, we obtain the second term

$$
\begin{align*}
& \leq C(\phi) \int_{B(\mathbf{0}, 1)} \int_{0}^{1}\left(\int_{0}^{1} \int_{\mathbb{R}^{n-1}}\left|(\psi f)_{, n}\left(\mathbf{x}^{\prime}+x_{n} \mathbf{z}^{\prime}, t\right)\right|^{p} d \mathbf{x}^{\prime} d x_{n}\right)^{1 / p} d t d y^{\prime} \\
& \leq C(\phi)\|f\|_{1, p, \mathbb{R}_{+}^{n}} \tag{45.2.5}
\end{align*}
$$

It is somewhat easier to verify that

$$
\left\|R g_{, j}\right\|_{0, p, \mathbb{R}_{+}^{n}} \leq C(\phi)\|f\|_{1, p, \mathbb{R}_{+}^{n}}
$$

Therefore, we have shown that whenever $\gamma f=f(0)=g$,

$$
\|R g\|_{1, p, \mathbb{R}_{+}^{n}} \leq C(\phi)\|f\|_{1, p, \mathbb{R}_{+}^{n}}
$$

Taking the infimum over all such $f$ and using the definition of the norm in

$$
W^{1-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right)
$$

it follows

$$
\|R g\|_{1, p, \mathbb{R}_{+}^{n}} \leq C(\phi)\|g\|_{1-\frac{1}{p}, p, \mathbb{R}^{n-1}}
$$

showing that this map, $R$, is continuous as claimed. It is obvious that

$$
\lim _{x_{n} \rightarrow 0} \operatorname{Rg}\left(x_{n}\right)=g
$$

the convergence taking place in $L^{p}\left(\mathbb{R}^{n-1}\right)$ because of general results about convolution with mollifiers. This proves the lemma.

### 45.3 Intrinsic Norms

The above presentation is very abstract, involving the trace of a function in

$$
W\left(A_{0}, A_{1}, p, \theta\right)
$$

and a norm which was the infimum of norms of functions in $W$ which have trace equal to the given function. It is very useful to have a description of the norm in these fractional order spaces which is defined in terms of the function itself rather than functions which have the given function as trace. This leads to something called an intrinsic norm. I am following Adams [1].

The following interesting lemma is called Young's inequality. It holds more generally than stated.

Lemma 45.3.1 Let $g=f * h$ where $f \in L^{1}(\mathbb{R}), h \in L^{p}(\mathbb{R})$, and $f, h$ are all Borel measurable, $p \geq 1$. Then $g \in L^{p}(\mathbb{R})$ and

$$
\|g\|_{L^{p}(\mathbb{R})} \leq\|f\|_{L^{1}(\mathbb{R})}\|h\|_{L^{p}(\mathbb{R})}
$$

Proof: First of all it is good to show $g$ is well defined. Using Minkowski’s inequality

$$
\begin{aligned}
& \left(\int\left(\int|h(t-s) f(s)| d s\right)^{p} d t\right)^{1 / p} \\
& \leq \int\left(\int|h(t-s)|^{p}|f(s)|^{p} d t\right)^{1 / p} d s \\
& =\int|f(s)|\left(\int|h(t-s)|^{p} d t\right)^{1 / p} d s \\
& =\|f\|_{L^{1}}\|h\|_{L^{p}}
\end{aligned}
$$

Therefore, for a.e. $t$,

$$
\int|h(t-s) f(s)| d s=\int|h(s) f(t-s)| d s<\infty
$$

and so for all such $t$ the convolution $f * h(t)$ makes sense. The above also shows

$$
\|g\|_{L^{p}} \equiv\left(\int\left|\int f(t-s) h(s) d s\right|^{p} d t\right)^{1 / p} \leq\|f\|_{L^{1}}\|h\|_{L^{p}}
$$

and this proves the lemma.
The following is a very interesting inequality of Hardy Littlewood and Pólya.
Lemma 45.3.2 Let $f$ be a real valued function defined a.e. on $[0, \infty)$ and let $\alpha \in(-\infty, 1)$ and

$$
\begin{equation*}
g(t)=\frac{1}{t} \int_{0}^{t} f(\xi) d \xi \tag{45.3.6}
\end{equation*}
$$

For $1 \leq p<\infty$

$$
\begin{equation*}
\int_{0}^{\infty} t^{\alpha p}|g(t)|^{p} \frac{d t}{t} \leq \frac{1}{(1-\alpha)^{p}} \int_{0}^{\infty} t^{\alpha p}|f(t)|^{p} \frac{d t}{t} \tag{45.3.7}
\end{equation*}
$$

Proof: First it can be assumed the right side of 45.3 .7 is finite since otherwise there is nothing to show. Changing the variables letting $t=e^{\tau}$, the above inequality takes the form

$$
\int_{-\infty}^{\infty} e^{\tau p \alpha}\left|g\left(e^{\tau}\right)\right|^{p} d \tau \leq \frac{1}{(1-\alpha)^{p}} \int_{-\infty}^{\infty} e^{\tau p \alpha}\left|f\left(e^{\tau}\right)\right|^{p} d \tau
$$

Now from the definition of $g$ it follows

$$
\begin{aligned}
g\left(e^{\tau}\right) & =e^{-\tau} \int_{-\infty}^{e^{\tau}} f(\xi) d \xi \\
& =e^{-\tau} \int_{-\infty}^{\tau} f\left(e^{\sigma}\right) e^{\sigma} d \sigma
\end{aligned}
$$

and so the left side equals

$$
\begin{gathered}
\int_{-\infty}^{\infty} e^{\tau p(\alpha-1)}\left|\int_{-\infty}^{\tau} f\left(e^{\sigma}\right) e^{\sigma} d \sigma\right|^{p} d \tau \\
=\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\tau} e^{\tau \alpha} f\left(e^{\sigma}\right) e^{-(\tau-\sigma)} d \sigma\right|^{p} d \tau \\
=\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\tau} e^{(\tau-\sigma) \alpha} e^{-(\tau-\sigma)} e^{\sigma \alpha} f\left(e^{\sigma}\right) d \sigma\right|^{p} d \tau \\
=\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\infty} \mathscr{X}_{(-\infty, 0)}(\tau-\sigma) e^{(\tau-\sigma)(\alpha-1)} e^{\sigma \alpha} f\left(e^{\sigma}\right) d \sigma\right|^{p} d \tau
\end{gathered}
$$

and by Lemma 45.3.1,

$$
\begin{aligned}
& \leq\left(\int_{-\infty}^{0} e^{(\alpha-1) u} d u\right)^{p} \int_{-\infty}^{\infty} e^{p \sigma \alpha}\left|f\left(e^{\sigma}\right)\right|^{p} d \sigma \\
& =\left(\frac{1}{1-\alpha}\right)^{p} \int_{-\infty}^{\infty} e^{p \sigma \alpha}\left|f\left(e^{\sigma}\right)\right|^{p} d \sigma
\end{aligned}
$$

which was to be shown. This proves the lemma.
Next consider the case where $G(t), t>0$ is a continuous semigroup on $A_{1}$ and $A_{0} \equiv$ $D(\Lambda)$ where $\Lambda$ is the generator of this semigroup. Recall that from Proposition 19.14.5 on Page $577 \Lambda$ is a closed densely defined operator and so $A_{0}$ is a Banach space if the norm is given by

$$
\|u\|_{A_{0}} \equiv\|u\|_{A_{1}}+\|\Lambda u\|_{A_{1}}
$$

Also assume $\|G(t)\|$ is uniformly bounded for $t \in[0, \infty)$. I have in mind the case where $A_{1}=L^{p}\left(\mathbb{R}^{n}\right)$ and $G(t) u(\mathbf{x})=u\left(\mathbf{x}+t \mathbf{e}_{i}\right)$ but it is notationally easier to discuss this in the general case. First here is a simple lemma.

Lemma 45.3.3 Let $A_{0}=D(\Lambda)$ as just described. Then for $u \in A_{1}$

$$
\|u\|_{A_{1}+A_{0}}=\|u\|_{A_{1}}
$$

Proof: $D(\Lambda) \subseteq A_{1}$. Now let $u \in A_{1}$.

$$
\|u\|_{A_{0}+A_{1}} \equiv \inf \left\{\left\|u_{0}\right\|_{A_{1}}+\left\|\Lambda u_{0}\right\|_{A_{1}}+\left\|u_{1}\right\|_{A_{1}}: u=u_{0}+u_{1}\right\}
$$

To make this as small as possible you should clearly take $u_{1}=u$ because

$$
\begin{aligned}
\left\|u_{0}\right\|_{A_{1}}+\left\|\Lambda u_{0}\right\|_{A_{1}}+\left\|u_{1}\right\|_{A_{1}} & \geq\left\|u_{0}+u_{1}\right\|_{A_{1}}+\left\|\Lambda u_{0}\right\| \\
& =\|u\|_{A_{1}}+\left\|\Lambda u_{0}\right\|
\end{aligned}
$$

Therefore, the result of the lemma follows.

Lemma 45.3.4 Let $\Lambda$ be the generator of $G(t)$ and let $t \rightarrow g(t)$ be in $C^{1}\left(0, \infty ; A_{1}\right)$. Then there exists a unique solution to the initial value problem

$$
y^{\prime}-\Lambda y=g, y(0)=y_{0} \in D(\Lambda)
$$

and it is given by

$$
\begin{equation*}
y(t)=G(t) y_{0}+\int_{0}^{t} G(t-s) g(s) d s . \tag{45.3.8}
\end{equation*}
$$

This solution is continuous having continuous derivative and has values in $D(\Lambda)$.
Proof: First I show the following claim.
Claim: $\int_{0}^{t} G(t-s) g(s) d s \in D(\Lambda)$ and

$$
\Lambda\left(\int_{0}^{t} G(t-s) g(s) d s\right)=G(t) g(0)-g(t)+\int_{0}^{t} G(t-s) g^{\prime}(s) d s
$$

Proof of the claim:

$$
\begin{aligned}
& \frac{1}{h}\left(G(h) \int_{0}^{t} G(t-s) g(s) d s-\int_{0}^{t} G(t-s) g(s) d s\right) \\
= & \frac{1}{h}\left(\int_{0}^{t} G(t-s+h) g(s) d s-\int_{0}^{t} G(t-s) g(s) d s\right) \\
= & \frac{1}{h}\left(\int_{-h}^{t-h} G(t-s) g(s+h) d s-\int_{0}^{t} G(t-s) g(s) d s\right) \\
= & \frac{1}{h} \int_{-h}^{0} G(t-s) g(s+h) d s+\int_{0}^{t-h} G(t-s) \frac{g(s+h)-g(s)}{h} \\
& -\frac{1}{h} \int_{t-h}^{t} G(t-s) g(s) d s
\end{aligned}
$$

Using the estimate in Theorem 19.14.3 on Page 577 and the dominated convergence theorem the limit as $h \rightarrow 0$ of the above equals

$$
G(t) g(0)-g(t)+\int_{0}^{t} G(t-s) g^{\prime}(s) d s
$$

which proves the claim.
Since $y_{0} \in D(\Lambda)$,

$$
\begin{align*}
G(t) \Lambda y_{0} & =G(t) \lim _{h \rightarrow 0} \frac{G(h) y_{0}-y_{0}}{h} \\
& =\lim _{h \rightarrow 0} \frac{G(t+h)-G(t)}{h} y_{0} \\
& =\lim _{h \rightarrow 0} \frac{G(h) G(t) y_{0}-G(t) y_{0}}{h} \tag{45.3.9}
\end{align*}
$$

Since this limit exists, the last limit in the above exists and equals

$$
\begin{equation*}
\Lambda G(t) y_{0} \tag{45.3.10}
\end{equation*}
$$

and $G(t) y_{0} \in D(\Lambda)$. Now consider 45.3.8.

$$
\begin{gathered}
\frac{y(t+h)-y(t)}{h}=\frac{G(t+h)-G(t)}{h} y_{0}+ \\
\frac{1}{h}\left(\int_{0}^{t+h} G(t-s+h) g(s) d s-\int_{0}^{t} G(t-s) g(s) d s\right) \\
=\frac{G(t+h)-G(t)}{h} y_{0}+\frac{1}{h} \int_{t}^{t+h} G(t-s+h) g(s) d s \\
+\frac{1}{h}\left(G(h) \int_{0}^{t} G(t-s) g(s) d s-\int_{0}^{t} G(t-s) g(s) d s\right)
\end{gathered}
$$

From the claim and 45.3.9, 45.3.10 the limit of the right side is

$$
\begin{aligned}
& \Lambda G(t) y_{0}+g(t)+\Lambda\left(\int_{0}^{t} G(t-s) g(s) d s\right) \\
= & \Lambda\left(G(t) y_{0}+\int_{0}^{t} G(t-s) g(s) d s\right)+g(t)
\end{aligned}
$$

Hence

$$
y^{\prime}(t)=\Lambda y(t)+g(t)
$$

and from the formula, $y^{\prime}$ is continuous since by the claim and 45.3.10 it also equals

$$
G(t) \Lambda y_{0}+g(t)+G(t) g(0)-g(t)+\int_{0}^{t} G(t-s) g^{\prime}(s) d s
$$

which is continuous. The claim and 45.3 .10 also shows $y(t) \in D(\Lambda)$. This proves the existence part of the lemma.

It remains to prove the uniqueness part. It suffices to show that if

$$
y^{\prime}-\Lambda y=0, y(0)=0
$$

and $y$ is $C^{1}$ having values in $D(\Lambda)$, then $y=0$. Suppose then that $y$ is this way. Letting $0<s<t$,

$$
\begin{gathered}
\frac{d}{d s}(G(t-s) y(s)) \\
\equiv \lim _{h \rightarrow 0} G(t-s-h) \frac{y(s+h)-y(s)}{h} \\
-\frac{G(t-s) y(s)-G(t-s-h) y(s)}{h}
\end{gathered}
$$

provided the limit exists. Since $y^{\prime}$ exists and $y(s) \in D(\Lambda)$, this equals

$$
G(t-s) y^{\prime}(s)-G(t-s) \Lambda y(s)=0
$$

Let $y^{*} \in A_{1}^{\prime}$. This has shown that on the open interval $(0, t), s \rightarrow y^{*}(G(t-s) y(s))$ has a derivative equal to 0 . Also from continuity of $G$ and $y$, this function is continuous on $[0, t]$. Therefore, it is constant on $[0, t]$ by the mean value theorem. At $s=0$, this function equals 0 . Therefore, it equals 0 on $[0, t]$. Thus for fixed $s>0$ and letting $t>s, y^{*}(G(t-s) y(s))=0$. Now let $t$ decrease toward $s$. Then $y^{*}(y(s))=0$ and since $y^{*}$ was arbitrary, it follows $y(s)=0$. This proves uniqueness.

Definition 45.3.5 Let $G(t)$ be a uniformly bounded continuous semigroup defined on $A_{1}$ and let $\Lambda$ be its generator. Let the norm on $D(\Lambda)$ be given by

$$
\|u\|_{D(\Lambda)} \equiv\|u\|_{A_{1}}+\|\Lambda u\|_{A_{1}}
$$

so that by Lemma 45.3 .3 the norm on $A_{1}+D(\Lambda)$ is just $\|\cdot\|_{A_{1}}$. Let

$$
T_{0} \equiv\left\{u \in A_{1}:\|u\|_{A_{1}}^{p}+\int_{0}^{\infty} t^{\theta p}\left\|\frac{G(t) u-u}{t}\right\|_{A_{1}}^{p} \frac{d t}{t} \equiv\|u\|_{T_{0}}^{p}<\infty\right\}
$$

Theorem 45.3.6 $T_{0}=T\left(D(\Lambda), A_{1}, p, \theta\right) \equiv T$ and the two norms are equivalent.
Proof: Take $u \in T\left(D(\Lambda), A_{1}, p, \theta\right)$. I will show $\|u\|_{T_{0}} \leq C(\theta, p)\|u\|_{T}$. By the definition of the norm in $T$, there exists $f \in W\left(D(\Lambda), A_{1}, p, \theta\right)$ such that

$$
\|u\|_{T}^{p}+\delta>\|f\|_{W}^{p}, f(0)=u
$$

Now by Lemma 44.1.4 there exists $g_{r} \in W$ such that $\left\|g_{r}-f\right\|_{W}<r, g_{r} \in C^{\infty}(0, \infty ; D(\Lambda))$ and $g_{r}^{\prime} \in C^{\infty}\left(0, \infty ; A_{1}\right)$. Thus for each $\varepsilon>0, g_{r}(\varepsilon) \in D(\Lambda)$ although possibly $g_{r}(0) \notin D(\Lambda)$. Then letting $h_{r}(t)$ be defined by

$$
g_{r}^{\prime}(t)-\Lambda g_{r}(t)=h_{r}(t)
$$

it follows $h_{r} \in C^{1}\left(0, \infty ; A_{1}\right)$ and applying Lemma 45.3.4 on $[\varepsilon, \infty)$ it follows

$$
\begin{equation*}
g_{r}(t)=G(t-\varepsilon) g_{r}(\varepsilon)+\int_{\varepsilon}^{t} G(t-s) h_{r}(s) d s \tag{45.3.11}
\end{equation*}
$$

By Lemma 44.1.4 again, $g_{r}(\varepsilon)$ converges to $g_{r}(0)$ in $A_{1}$. Thus

$$
\int_{\mathcal{\varepsilon}}^{t}\left\|G(t-s) h_{r}(s)\right\|_{A_{1}} d s \leq C
$$

for some constant independent of $\varepsilon$. Thus $s \rightarrow G(t-s) h_{r}(s)$ is in $L^{1}\left(0, t ; A_{1}\right)$ and it is possible to pass to the limit in 45.3.11 as $\varepsilon \rightarrow 0$ to conclude

$$
g_{r}(t)=G(t) g_{r}(0)+\int_{0}^{t} G(t-s) h_{r}(s) d s
$$

Now

$$
\frac{G(t) g_{r}(0)-g_{r}(0)}{t}=\frac{1}{t} \int_{0}^{t} g_{r}^{\prime}(s) d s-\frac{1}{t} \int_{0}^{t} G(t-s) h_{r}(s) d s
$$

and so using the assumption that $G(t)$ is uniformly bounded,

$$
\begin{gathered}
\left\|\frac{G(t) g_{r}(0)-g_{r}(0)}{t}\right\| \leq \frac{1}{t} \int_{0}^{t}\left\|g_{r}^{\prime}\right\|_{A_{1}}+M\left\|h_{r}\right\|_{A_{1}} \\
\leq \frac{1}{t} \int_{0}^{t}\left\|g_{r}^{\prime}\right\|(M+1)+M\left\|\Lambda g_{r}\right\| d s \\
\leq \frac{M+1}{t} \int_{0}^{t}\left\|g_{r}^{\prime}\right\|_{A_{1}}+\left\|g_{r}\right\|_{D(\Lambda)} d s
\end{gathered}
$$

Therefore, from Lemma 45.3.2

$$
\begin{gathered}
\int_{0}^{\infty} t^{p \theta-p}\left\|G(t) g_{r}(0)-g_{r}(0)\right\|_{A_{1}}^{p} \frac{d t}{t} \\
=\int_{0}^{\infty} t^{p \theta}\left\|\frac{G(t) g_{r}(0)-g_{r}(0)}{t}\right\|_{A_{1}}^{p} \frac{d t}{t} \\
\leq \int_{0}^{\infty} t^{p \theta}\left|\frac{M+1}{t} \int_{0}^{t}\left\|g_{r}^{\prime}\right\|_{A_{1}}+\left\|g_{r}\right\|_{D(\Lambda)} d s\right|^{p} d t / t \\
\leq(M+1)^{p} 2^{p-1}\left(\frac{1}{1-\theta}\right)^{p} \int_{0}^{\infty} t^{p \theta}\left(\left\|g_{r}^{\prime}\right\|_{A_{1}}^{p}+\left\|g_{r}\right\|_{D(\Lambda)}^{p}\right)
\end{gathered}
$$

Now since $g_{r} \rightarrow f$ in $W$, it follows from Lemma 44.1.8 that $g_{r}(0) \rightarrow u$ in $T$ and hence by Theorem 44.1.9 this also in $A_{1}$. Therefore, using Fatou's lemma in the above along with the convergence of $g_{r}$ to $f$,

$$
\begin{aligned}
& \int_{0}^{\infty} t^{p \theta-p}\|G(t) u-u\|_{A_{1}}^{p} \frac{d t}{t} \\
\leq & (M+1)^{p} 2^{p-1}\left(\frac{1}{1-\theta}\right)^{p} \int_{0}^{\infty} t^{p \theta}\left(\left\|f^{\prime}\right\|_{A_{1}}^{p}+\|f\|_{D(\Lambda)}^{p}\right) \\
\leq & (M+1)^{p} 2^{p-1}\left(\frac{1}{1-\theta}\right)^{p}\left(\|u\|_{T}^{p}+\delta\right)
\end{aligned}
$$

Since $u \in T$, Theorem 44.1.9 implies $u \in A_{1}$ and $\|u\|_{A_{1}} \leq C\|u\|_{T}$. Therefore, since $\delta$ was arbitrary, this has shown that $u \in T_{0}$ and

$$
\|u\|_{T_{0}} \leq C(\theta, p)\|u\|_{T}
$$

This shows $T \subseteq T_{0}$ with continuous inclusion.
Now it is necessary to take $u \in T_{0}$ and show it is in $T$. Since $u \in T_{0}$

$$
\infty>\|u\|_{A_{1}}^{p}+\int_{0}^{\infty} t^{\theta p}\left\|\frac{G(t) u-u}{t}\right\|^{p} \frac{d t}{t} \equiv\|u\|_{T_{0}}^{p}
$$

Let $\phi$ be a nonnegative decreasing infinitely differentiable function such that $\phi(0)=1$ and $\phi(t)=0$ for all $t>1$. Then define

$$
f(t) \equiv \phi(t) \frac{1}{t} \int_{0}^{t} G(\tau) u d \tau
$$

It is easy to see that $f(t) \in D(\Lambda)$. In fact, changing variables as needed,

$$
\begin{aligned}
& \frac{1}{h}\left(G(h) \int_{0}^{t} G(\tau) u d \tau-\int_{0}^{t} G(\tau) u d \tau\right) \\
& =\frac{1}{h} \int_{h}^{t+h} G(\tau) u d \tau-\frac{1}{h} \int_{0}^{t} G(\tau) u d \tau \\
& =\frac{1}{h} \int_{t}^{t+h} G(\tau) u d \tau-\frac{1}{h} \int_{0}^{h} G(\tau) u d \tau
\end{aligned}
$$

which converges to $G(t) u-u$ and so

$$
\begin{equation*}
\Lambda \int_{0}^{t} G(\tau) u d \tau=G(t) u-u \tag{45.3.12}
\end{equation*}
$$

Thus

$$
\begin{aligned}
\int_{0}^{\infty} t^{p \theta}\|\Lambda f\|_{A_{1}}^{p} \frac{d t}{t} & \leq \int_{0}^{\infty} t^{p \theta}\left\|\frac{G(t) u-u}{t}\right\|_{A_{1}}^{p} \frac{d t}{t} \\
& \leq\|u\|_{T_{0}}^{p}
\end{aligned}
$$

Next it is necessary to consider

$$
\begin{gathered}
\int_{0}^{\infty} t^{p \theta}\left\|f^{\prime}\right\|_{A_{1}}^{p} \frac{d t}{t} \\
f^{\prime}(t)=\phi^{\prime}(t) \frac{1}{t} \int_{0}^{t} G(\tau) u d \tau+ \\
\phi(t)\left(-\frac{1}{t^{2}} \int_{0}^{t} G(\tau) u d \tau+\frac{1}{t} G(t) u\right) \\
=\phi^{\prime}(t) \frac{1}{t} \int_{0}^{t} G(\tau) u d \tau+\phi(t)\left(\frac{1}{t^{2}} \int_{0}^{t}(G(t) u-G(\tau) u) d \tau\right)
\end{gathered}
$$

and so there is a constant $C$ depending on $\phi$ and the uniform bound on $\|G(t)\|$ such that

$$
\begin{aligned}
\left\|f^{\prime}(t)\right\|_{A_{1}} & \leq C \mathscr{X}_{[0,1]}(t)\left(\|u\|_{A_{1}}+\frac{1}{t^{2}} \int_{0}^{t}\|G(t-\tau) u-u\| d \tau\right) \\
& =C \mathscr{X}_{[0,1]}(t)\left(\|u\|_{A_{1}}+\frac{1}{t^{2}} \int_{0}^{t}\|G(\tau) u-u\| d \tau\right)
\end{aligned}
$$

Now

$$
\int_{0}^{\infty} \mathscr{X}_{[0,1]}(t) t^{p \theta}\|u\|_{A_{1}}^{p} d t / t \leq C(p, \theta)\|u\|_{T_{0}}^{p}
$$

and using Lemma 45.3.2,

$$
\begin{gathered}
\int_{0}^{\infty} \mathscr{X}_{[0,1]}(t)\left|\frac{1}{t^{2}} \int_{0}^{t}\|G(\tau) u-u\| d \tau\right|^{p} t^{p \theta} \frac{d t}{t} \\
\leq \int_{0}^{\infty}\left|\frac{1}{t} \int_{0}^{t}\|G(\tau) u-u\| d \tau\right|^{p} t^{p(\theta-1)} \frac{d t}{t} \\
\leq \frac{1}{(1-(\theta-1))^{p}} \int_{0}^{\infty}\|G(\tau) u-u\|^{p} t^{p(\theta-1)} \frac{d t}{t} \\
=\frac{1}{(2-\theta)^{p}} \int_{0}^{\infty}\left\|\frac{G(\tau) u-u}{t}\right\|^{p} t^{p \theta} \frac{d t}{t} \leq C(\theta, p)\|u\|_{T_{0}}^{p}
\end{gathered}
$$

This proves the theorem.
Of course the case of most interest here is where $A_{1}=L^{p}\left(\mathbb{R}^{n}\right)$ and

$$
G(t) u(\mathbf{x}) \equiv u\left(\mathbf{x}+t \mathbf{e}_{i}\right)
$$

Thus $\Lambda u=\partial u / \partial x_{i}$, the weak derivative. The trace space $T\left(D(\Lambda), L^{p}\left(\mathbb{R}^{n}\right), p, 1-\theta\right)$ then is a space of functions in $L^{p}\left(\mathbb{R}^{n}\right)$ which have a fractional order partial derivative with respect to $x_{i}$.

Recall from Definition 45.1.1 that for $\theta \in(0,1)$,

$$
W^{\theta, p}\left(\mathbb{R}^{n}\right) \equiv T\left(W^{1, p}\left(\mathbb{R}^{n}\right), L^{p}\left(\mathbb{R}^{n}\right), p, 1-\theta\right)
$$

Let $f \in W\left(W^{1, p}\left(\mathbb{R}^{n}\right), L^{p}\left(\mathbb{R}^{n}\right), p, 1-\theta\right)$. Then

$$
\|f\|_{W} \equiv \max \left(\int_{0}^{\infty} t^{(1-\theta) p}\|f(t)\|_{W^{1, p}}^{p} \frac{d t}{t}, \int_{0}^{\infty} t^{(1-\theta) p}\left\|f^{\prime}(t)\right\|_{L^{p}}^{p} \frac{d t}{t}\right)
$$

Letting $G_{i}(t) u(\mathbf{x}) \equiv u\left(\mathbf{x}+t \mathbf{e}_{i}\right)$ and $\Lambda_{i}$ its generator,

$$
W^{1, p}(\Omega)=\cap_{i=1}^{n} D \Lambda_{i} \cap L^{p}\left(\mathbb{R}^{n}\right)
$$

with the norm given by

$$
\|u\|^{p}=\|u\|_{L^{p}}^{p}+\sum_{i=1}^{n}\left\|\Lambda_{i} u\right\|_{L^{p}}^{p}
$$

which is equivalent to the norm

$$
\|u\|^{p}=\sum_{i=1}^{n}\|u\|_{D\left(\Lambda_{i}\right)}^{p} .
$$

Then by considering each of the $G_{i}$ and repeating the above argument in Theorem 45.3.6, it follows an equivalent intrinsic norm is

$$
\|u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)}^{p}=\|u\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p}+\sum_{i=1}^{n} \int_{0}^{\infty} t^{(1-\theta) p}\left\|\frac{G_{i}(t) u-u}{t}\right\|_{L^{p}}^{p} \frac{d t}{t}
$$

$$
\begin{equation*}
=\|u\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p}+\sum_{i=1}^{n} \int_{0}^{\infty} t^{(1-\theta) p}\left\|\frac{u\left(\cdot+t \mathbf{e}_{i}\right)-u(\cdot)}{t}\right\|_{L^{p}}^{p} \frac{d t}{t} \tag{45.3.13}
\end{equation*}
$$

and $u \in W^{\theta, p}\left(\mathbb{R}^{n}\right)$ when this norm is finite. The only new detail is that in showing that for $u \in T_{0}$ it follows it is in $T$, you use the function

$$
f(t) \equiv \phi(t) \frac{1}{t^{n}} \int_{0}^{t} \cdots \int_{0}^{t} G_{1}\left(\tau_{1}\right) G_{2}\left(\tau_{2}\right) \cdots G_{n}\left(\tau_{n}\right) u d \tau_{1} \cdots d \tau_{n}
$$

and the fact that these semigroups commute. To get this started, note that

$$
g(t) \equiv \int_{0}^{t} \cdots \int_{0}^{t} G_{1}\left(\tau_{1}\right) G_{2}\left(\tau_{2}\right) \cdots G_{n}\left(\tau_{n}\right) u d \tau_{1} \cdots d \tau_{n} \in D\left(\Lambda_{i}\right)
$$

for each $i$. This follows from writing it as

$$
\int_{0}^{t} G_{i}\left(\tau_{i}\right)\left(w_{i}\right) d \tau_{i}
$$

for $w_{i} \in L^{p}$ coming from the other integrals and then repeating the earlier argument to get

$$
\Lambda_{i} g(t)=G_{i}(t) w_{i}-w_{i}
$$

and then

$$
\begin{gathered}
\int_{0}^{\infty} t^{p(1-\theta)}\left\|\Lambda_{i} f\right\|_{L^{p}}^{p} \frac{d t}{t} \\
\leq \int_{0}^{\infty} t^{p(1-\theta)}\left\|\frac{G_{i}(t) w_{i}-w_{i}}{t}\right\|_{L^{p}}^{p} \frac{d t}{t} \\
\leq C \int_{0}^{\infty} t^{p(1-\theta)}\left\|\frac{G_{i}(t) u-u}{t}\right\|_{L^{p}}^{p} \frac{d t}{t} \leq C\|u\|_{T_{0}}^{p}
\end{gathered}
$$

Thus all is well as far as $f$ is concerned and the proof will work as it did earlier in Theorem 45.3.6. What about $f^{\prime}$ ? As before, the only term which is problematic is

$$
\phi(t)\left(\frac{1}{t^{n}} \int_{0}^{t} \cdots \int_{0}^{t} G_{1}\left(\tau_{1}\right) G_{2}\left(\tau_{2}\right) \cdots G_{n}\left(\tau_{n}\right) u d \tau_{1} \cdots d \tau_{n}\right)^{\prime}
$$

After enough massaging, it becomes

$$
\sum_{i=1}^{n} \prod_{j \neq i} \frac{1}{t} \int_{0}^{t} G_{j}\left(\tau_{j}\right) d \tau_{j} \frac{1}{t^{2}} \int_{0}^{t}\left(G_{i}(t) u-G_{i}\left(\tau_{i}\right) u\right) d \tau_{i}
$$

where the operator $\sum_{i=1}^{n} \prod_{j \neq i} \frac{1}{t} \int_{0}^{t} G_{j}\left(\tau_{j}\right) d \tau_{j}$ is bounded. Thus similar arguments to those of Theorem 45.3 .6 will work, the only difference being a sum.

Theorem 45.3.7 An equivalent norm for $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ for $\theta \in(0,1)$ is

$$
\begin{gather*}
\|u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)}^{p}= \\
\|u\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p}+\sum_{i=1}^{n} \int_{0}^{\infty} t^{(1-\theta) p}\left\|\frac{G_{i}(t) u-u}{t}\right\|_{L^{p}}^{p} \frac{d t}{t} \\
=\|u\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p}+\sum_{i=1}^{n} \int_{0}^{\infty} t^{(1-\theta) p}\left\|\frac{u\left(\cdot+t \mathbf{e}_{i}\right)-u(\cdot)}{t}\right\|_{L^{p}}^{p} \frac{d t}{t} \tag{45.3.14}
\end{gather*}
$$

Note it is obvious from 45.3 .13 that a Lipschitz map takes $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ to $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ and is continuous.

The above description in Theorem 45.3.7 also makes possible the following corollary.
Corollary 45.3.8 $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ is reflexive.
Proof: Let $u \in W^{\theta, p}\left(\mathbb{R}^{n}\right)$. For each $i=1,2, \cdots, n$, define for $t>0$,

$$
\Delta_{i} u(t)(\mathbf{x}) \equiv \frac{u\left(\mathbf{x}+t \mathbf{e}_{i}\right)-u(\mathbf{x})}{t}
$$

Then by Theorem 45.3.7,

$$
\Delta_{i} u \in L^{p}\left((0, \infty) ; L^{p}\left(\mathbb{R}^{n}\right), \mu\right) \equiv Y
$$

where

$$
\mu(E) \equiv \int_{E} t^{(1-\theta) p} t^{-1} d t
$$

Clearly the measure space is $\sigma$ finite and so $Y$ is reflexive by Corollary 21.8.9 on Page 687. Also $\Delta_{i}$ is a closed operator whose domain is $W^{\theta, p}\left(\mathbb{R}^{n}\right)$. To see this, suppose $u_{n} \in W^{\theta, p}\left(\mathbb{R}^{n}\right)$ and $u_{n} \rightarrow u$ in $L^{p}\left(\mathbb{R}^{n}\right)$ while $\Delta_{i} u_{n} \rightarrow g$ in $Y$. Then in particular $\left\|\Delta_{i} u_{n}\right\|_{Y}$ is bounded. Now by Fatou's lemma,

$$
\begin{gathered}
\int_{0}^{\infty} t^{(1-\theta) p}\left\|\frac{u\left(\cdot+t \mathbf{e}_{i}\right)-u(\cdot)}{t}\right\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p} \frac{d t}{t} \leq \\
\lim \inf _{n \rightarrow \infty} \int_{0}^{\infty} t^{(1-\theta) p}\left\|\frac{u_{n}\left(\cdot+t \mathbf{e}_{i}\right)-u_{n}(\cdot)}{t}\right\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p} \frac{d t}{t}<\infty .
\end{gathered}
$$

Letting $\vec{\Delta} \equiv\left(\Delta_{1}, \Delta_{2}, \cdots, \Delta_{n}\right)$, it follows from similar reasoning that $\vec{\Delta}$ is a closed operator mapping $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ to $Y^{n}$. Therefore

$$
(\mathrm{id}, \vec{\Delta})\left(W^{\theta, p}\left(\mathbb{R}^{n}\right)\right) \subseteq L^{p}\left(\mathbb{R}^{n}\right) \times Y^{n}
$$

and is a closed subspace of the reflexive space $L^{p}\left(\mathbb{R}^{n}\right) \times Y^{n}$. With the norm in $L^{p}\left(\mathbb{R}^{n}\right) \times Y^{n}$ given as the sum of the norms of the components, it follows the mapping $(\mathrm{id}, \vec{\Delta})$ is a
norm preserving isomorphism between $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ and this closed subspace of $L^{p}\left(\mathbb{R}^{n}\right) \times Y^{n}$. Since $L^{p}\left(\mathbb{R}^{n}\right)$ and $Y$ is reflexive, their product is reflexive. By Lemma 21.2.7 on Page 655 it follows $(\mathrm{id}, \vec{\Delta})\left(W^{\theta, p}\left(\mathbb{R}^{n}\right)\right)$ and hence $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ is reflexive. This proves the theorem.

One can generalize this to find an intrinsic norm for $W^{\theta, p}(\Omega)$. The version given above will not do because it requires the function to be defined on all of $\mathbb{R}^{n}$ in order to make sense of the shift operators $G_{i}$. However, you can give a different version of this intrinsic norm which will make sense for $\Omega \neq \mathbb{R}^{n}$.

Lemma 45.3.9 Let $t \neq 0$ be a number. Then there is a constant $C(n, \theta, p)$ depending on the indicated quantities such that

$$
\int_{\mathbb{R}^{n-1}} \frac{1}{\left(t^{2}+|\mathbf{s}|^{2}\right)^{\frac{1}{2}(n+p \theta)}} d s=\frac{C(n, \theta, p)}{|t|^{1+p \theta}}
$$

Proof: Change the integral to polar coordinates. Thus the integral equals

$$
\int_{S^{n-1}} \int_{0}^{\infty} \frac{\rho^{n-2}}{\left(t^{2}+\rho^{2}\right)^{\frac{1}{2}(n+p \theta)}} d \rho d \sigma
$$

Now change the variables, $\rho=|t| u$. Then the above integral becomes

$$
\begin{gathered}
C_{n} \int_{0}^{\infty} \frac{|t|^{n-2} u^{n-2}|t|}{|t|^{n+p \theta}\left(1+u^{2}\right)^{\frac{1}{2}(n+p \theta)}} d u \\
=C_{n} \frac{1}{|t|^{1+p \theta}} \int_{0}^{\infty} \frac{u^{n-2}}{\left(1+u^{2}\right)^{\frac{1}{2}(n+p \theta)}} d u \equiv \frac{C(n, \theta, p)}{|t|^{1+p \theta}} .
\end{gathered}
$$

This proves the lemma.
Now let $u \in W^{\theta, p}\left(\mathbb{R}^{n}\right)$. This means the norm of $\|u\|_{W^{\theta, p}}^{p}$ can be taken as

$$
\begin{aligned}
& \|u\|_{L^{p}}^{p}+\sum_{i=1}^{n} \int_{0}^{\infty}|t|^{(1-\theta) p} \int_{\mathbb{R}^{n}}\left|\frac{u\left(\mathbf{x}+t \mathbf{e}_{i}\right)-u(\mathbf{x})}{t}\right|^{p} d x \frac{d t}{|t|} \\
= & \|u\|_{L^{p}}^{p}+\frac{1}{2} \sum_{i=1}^{n} \int_{-\infty}^{\infty}|t|^{(1-\theta) p} \int_{\mathbb{R}^{n}}\left|\frac{u\left(\mathbf{x}+t \mathbf{e}_{i}\right)-u(\mathbf{x})}{t}\right|^{p} d x \frac{d t}{|t|}
\end{aligned}
$$

That integral over $\mathbb{R}^{n}$ can be massaged and one obtains the above equal to

$$
\begin{gathered}
\|u\|_{L^{p}}^{p}+ \\
\left.\frac{1}{2} \sum_{i=1}^{n} \int_{-\infty}^{\infty} \int_{\mathbb{R}^{n-i}} \int_{\mathbb{R}^{i}} \frac{1}{t^{1+p \theta}} \right\rvert\, u\left(x_{1}, \cdots, x_{i}+t, y_{i+1}, \cdots, y_{n}\right) \\
-\left.u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p} d x_{i} d y_{n-i} d t
\end{gathered}
$$

where $d x_{i}$ refers to the first $i$ entries and $d y_{n-i}$ refers to the remaining entries. From Lemma 45.3.9, the complicated expression above equals

$$
\begin{aligned}
& \frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{-\infty}^{\infty} \int_{\mathbb{R}^{n-i}} \int_{\mathbb{R}^{i}} \int_{\mathbb{R}^{n-1}} \frac{1}{\left(t^{2}+|\mathbf{s}|^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, x_{i}+t, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p} \\
& d s d x_{i} d y_{n-i} d t
\end{aligned}
$$

Now Fubini this to get

$$
\begin{aligned}
& \frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{\mathbb{R}^{n-i}} \int_{\mathbb{R}^{i}} \int_{\mathbb{R}^{n-1}} \int_{-\infty}^{\infty} \frac{1}{\left(t^{2}+|\mathbf{s}|^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, x_{i}+t, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p} \\
& d t d s d x_{i} d y_{n-i}
\end{aligned}
$$

Changing the variable in the inside integral to $t=y_{i}-x_{i}$, this equals

$$
\begin{aligned}
& \frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{\mathbb{R}^{n-i}} \int_{\mathbb{R}^{i}} \int_{\mathbb{R}^{n-1}} \int_{-\infty}^{\infty} \frac{1}{\left(\left(y_{i}-x_{i}\right)^{2}+|\mathbf{s}|^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, y_{i}, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p} \\
& d y_{i} d s d x_{i} d y_{n-i}
\end{aligned}
$$

Next let

$$
\begin{aligned}
& \left(s_{1}, \cdots, s_{n-1}\right) \\
\equiv & \left(y_{1}-x_{1}, \cdots, y_{i-1}-x_{i-1}, x_{i+1}-y_{i+1}, \cdots, x_{n}-y_{n}\right)
\end{aligned}
$$

where the new variables of integration in the integral corresponding to $d s$ are $y_{1}, \cdots, y_{i-1}$ and $x_{i+1}, \cdots, x_{n}$. Then changing the variables, the above reduces to

$$
\begin{aligned}
& \frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{\mathbb{R}^{n-i}} \int_{\mathbb{R}^{i}} \int_{\mathbb{R}^{n-1}} \int_{-\infty}^{\infty} \frac{1}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, y_{i}, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p} \\
& d y_{i} d y_{1} \cdots d y_{i-1} d x_{i+1} \cdots d x_{n} d x_{1} \cdots d x_{i} d y_{i+1} \cdots d y_{n}
\end{aligned}
$$

Then if you Fubini again, it reduces to the expression

$$
\begin{gathered}
\frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \\
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{\left|u\left(x_{1}, \cdots, x_{i-1}, y_{i}, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y
\end{gathered}
$$

Now taking the sum inside and adjusting the constants yields

$$
\geq C(n, \theta, p) \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y
$$

Thus there exists a constant $C(n, \theta, p)$ such that

$$
\|u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)} \geq C(n, \theta, p)\left(\|u\|_{L^{p}}^{p}+\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y\right)^{1 / p}
$$

Next start with the right side of the above. It suffices to consider only the complicated term. First note that for a vector,

$$
\left(\sum_{i=1}^{n} a_{i}^{2}\right)^{p / 2} \geq\left|a_{i}\right|^{p}
$$

and so

$$
\sum_{i=1}^{n}\left|a_{i}\right|^{p} \leq n\left(\sum_{i=1}^{n} a_{i}^{2}\right)^{p / 2}=n|\mathbf{a}|^{p}
$$

from which it follows

$$
\frac{1}{n} \sum_{i=1}^{n}\left|a_{i}\right|^{p} \leq|\mathbf{a}|^{p}
$$

Then it follows

$$
\begin{gather*}
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y \geq \frac{1}{n} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \\
\frac{\sum_{i=1}^{n}\left|u\left(x_{1}, \cdots, x_{i-1}, y_{i}, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y \tag{45.3.15}
\end{gather*}
$$

Consider the $i^{t h}$ term. By Fubini's theorem it equals

$$
\begin{aligned}
& \frac{1}{n} \int \cdots \int \frac{1}{\left(\left(y_{i}-x_{i}\right)^{2}+\sum_{j \neq i}\left(y_{j}-x_{j}\right)^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, y_{i}, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p} \\
& d y_{i} d x_{1} \cdots d x_{i-1} d y_{i+1} \cdots d y_{n} d y_{1} \cdots d y_{i-1} d x_{i} \cdots d x_{n}
\end{aligned}
$$

Let $t=y_{i}-x_{i}$. Then it reduces to

$$
\begin{aligned}
& \frac{1}{n} \int \cdots \int \frac{1}{\left(t^{2}+\sum_{j \neq i}\left(y_{j}-x_{j}\right)^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, x_{i}+t, y_{i+1}, \cdots, y_{n}\right)-u\left(x_{1}, \cdots, x_{i}, y_{i+1}, \cdots, y_{n}\right)\right|^{p} \\
& d t d x_{1} \cdots d x_{i-1} d y_{i+1} \cdots d y_{n} d y_{1} \cdots d y_{i-1} d x_{i} \cdots d x_{n}
\end{aligned}
$$

Now let

$$
\begin{gathered}
\left(s_{1}, \cdots, s_{n-1}\right)= \\
\left(x_{1}-y_{1}, \cdots, x_{i-1}-y_{i-1}, y_{i+1}-x_{i+1}, \cdots, y_{n}-x_{n}\right)
\end{gathered}
$$

on the next $n-1$ iterated integrals. Then using Fubini's theorem again and changing the variables, it equals

$$
\begin{aligned}
& \frac{1}{n} \int \cdots \int \frac{1}{\left(t^{2}+|\mathbf{s}|^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \mid u\left(s_{1}+y_{1}, \cdots, y_{i-1}+s_{i-1}, x_{i}+t, x_{i+1}+s_{i}, \cdots, x_{n}+s_{n-1}\right) \\
& -\left.u\left(s_{1}+y_{1}, \cdots, y_{i-1}+s_{i-1}, x_{i}, x_{i+1}+s_{i}, \cdots, x_{n}+s_{n-1}\right)\right|^{p} \\
& d y_{1} \cdots d y_{i-1} d x_{i} \cdots d x_{n} d s_{1} \cdots d s_{i-1} d s_{i} \cdots d s_{n-1} d t
\end{aligned}
$$

By translation invariance of the measure, the inside integrals corresponding to

$$
d y_{1} \cdots d y_{i-1} d x_{i} \cdots d x_{n}
$$

simplify and the expression can be written as

$$
\begin{aligned}
& \frac{1}{n} \int \cdots \int \frac{1}{\left(t^{2}+|\mathbf{s}|^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, x_{i}+t, x_{i+1}, \cdots, x_{n}\right)-u\left(x_{1}, \cdots, x_{i-1}, x_{i}, x_{i+1}, \cdots, x_{n}\right)\right|^{p} \\
& d x_{1} \cdots d x_{i-1} d x_{i} \cdots d x_{n} d s_{1} \cdots d s_{i-1} d s_{i} \cdots d s_{n-1} d t
\end{aligned}
$$

where I just renamed the variables. Use Fubini's theorem again to get

$$
\begin{aligned}
& \frac{1}{n} \int \cdots \int \frac{1}{\left(t^{2}+|\mathbf{s}|^{2}\right)^{\frac{1}{2}(n+p \theta)}} \\
& \left|u\left(x_{1}, \cdots, x_{i-1}, x_{i}+t, x_{i+1}, \cdots, x_{n}\right)-u\left(x_{1}, \cdots, x_{i-1}, x_{i}, x_{i+1}, \cdots, x_{n}\right)\right|^{p} \\
& d s_{1} \cdots d s_{i-1} d s_{i} \cdots d s_{n-1} d x_{1} \cdots d x_{i-1} d x_{i} \cdots d x_{n} d t
\end{aligned}
$$

Now from Lemma 45.3.9, the inside $n-1$ integrals corresponding to

$$
d s_{1} \cdots d s_{i-1} d s_{i} \cdots d s_{n-1}
$$

can be replaced with

$$
\frac{C(n, \theta, p)}{|t|^{1+p \theta}}
$$

and this yields

$$
\begin{aligned}
& C(n, \theta, p) \int_{\mathbb{R}} \frac{1}{|t|^{p \theta}} \int_{\mathbb{R}^{n}}\left|u\left(\mathbf{x}+t \mathbf{e}_{i}\right)-u(\mathbf{x})\right|^{p} d x \frac{d t}{t} \\
= & \frac{1}{2} C(n, \theta, p) \int_{0}^{\infty} t^{p(1-\theta)} \frac{\| u\left(\cdot+t \mathbf{e}_{i}\right)-\left.u(\cdot)\right|_{L^{p}\left(\mathbb{R}^{n}\right)} ^{p}}{t^{p}} \frac{d t}{t}
\end{aligned}
$$

Applying this to each term of the sum in 45.3.15 and adjusting the constant, it follows

$$
\begin{gathered}
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y \geq \\
C(n, \theta, p) \sum_{i=1}^{n} \int_{0}^{\infty} t^{p(1-\theta)} \frac{\| u\left(\cdot+t \mathbf{e}_{i}\right)-\left.u(\cdot)\right|_{L^{p}\left(\mathbb{R}^{n}\right)} ^{p}}{t^{p}} \frac{d t}{t}
\end{gathered}
$$

Therefore,

$$
\begin{aligned}
& \|u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)} \\
\geq & C(n, \theta, p)\left(\|u\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p}+\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y\right)^{1 / p}
\end{aligned}
$$

This has proved most of the following theorem about the intrinsic norm.
Theorem 45.3.10 An equivalent norm for $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ is

$$
\begin{gathered}
\|u\|= \\
\left(\|u\|_{L^{p}\left(\mathbb{R}^{n}\right)}^{p}+\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y\right)^{1 / p}
\end{gathered}
$$

Also for any open subset of $\mathbb{R}^{n}$

$$
\|u\|=
$$

$$
\begin{equation*}
\left(\|u\|_{L^{p}(\Omega)}^{p}+\int_{\Omega} \int_{\Omega} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y\right)^{1 / p} \tag{45.3.16}
\end{equation*}
$$

is a norm.
Proof: It only remains to verify this is a norm. Recall the $l_{p}$ norm on $\mathbb{R}^{2}$ given by

$$
|(x, y)|_{l_{p}} \equiv\left(|x|^{p}+|y|^{p}\right)^{1 / p}
$$

For $u, v \in W^{\theta, p}$ denote by $\rho(u)$ the expression

$$
\left(\int_{\Omega} \int_{\Omega} \frac{|u(\mathbf{y})-u(\mathbf{x})|^{p}}{|\mathbf{x}-\mathbf{y}|^{(n+p \theta)}} d x d y\right)^{1 / p}
$$

a similar definition holding for $v$. Then it follows from the usual Minkowski inequality that $\rho(u+v) \leq \rho(u)+\rho(v)$. Then from 45.3.16

$$
\begin{gathered}
\|u+v\|=\left(\|u+v\|_{L^{p}}^{p}+\rho(u+v)^{p}\right)^{1 / p} \\
\leq\left(\left(\|u\|_{L^{p}}+\|v\|_{L^{p}}\right)^{p}+(\rho(u)+\rho(v))^{p}\right)^{1 / p}
\end{gathered}
$$

$$
\begin{gathered}
=\left|\left(\|u\|_{L^{p}}, \rho(u)\right)+\left(\|v\|_{L^{p}}, \rho(v)\right)\right|_{l_{p}} \\
\leq\left|\left(\|u\|_{L^{p}}, \rho(u)\right)\right|_{l_{p}}+\left|\left(\|v\|_{L^{p}}, \rho(v)\right)\right|_{l_{p}} \\
=\left(\|u\|_{L^{p}}^{p}+\rho(u)^{p}\right)^{1 / p}+\left(\|v\|_{L^{p}}^{p}+\rho(v)^{p}\right)^{1 / p} \\
=\|u\|+\|v\|
\end{gathered}
$$

The other properties of a norm are obvious. This proves the theorem.
As pointed out in the above theorem, this is a norm in 45.3.16. One could define a set of functions for which this norm is finite. In the case where $\Omega=\mathbb{R}^{n}$ the conclusion of Theorem 45.3.10 is that this space of functions is the same as $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ and the norms are equivalent. Does this happen for other open subsets of $\mathbb{R}^{n}$ ?
Definition 45.3.11 Denote by $\widetilde{W^{\theta, p}(U)}$ the functions in $L^{p}(U)$ for which the norm of Theorem 45.3.10 is finite. Here $\theta \in(0,1)$.

Proposition 45.3.12 Let $U$ be a bounded open set which has Lipschitz boundary and $\theta \in$ $(0,1)$. Then for each $p \geq 1$, there exists $E \in \mathscr{L}\left(\widehat{W^{\theta, p}(U)}, W^{\theta, p}\left(\mathbb{R}^{n}\right)\right)$ such that $E u(\mathbf{x})=$ $u(\mathbf{x})$ a.e. $\mathbf{x} \in U$.

Proof: In proving this, I will use the equivalent norm of Theorem 45.3.10 as the norm of $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ Consider the following picture.

The wavy line signifies a part of the boundary of $U$ and $\operatorname{spt}(u)$ is contained in the circle as shown. It is drawn as a circle but this is not important. Denote by $U^{+}$the region above the part of the boundary which is shown. Also let the boundary be given by $x_{n}=g(\widehat{\mathbf{x}})$ for $\widehat{\mathbf{x}} \in B \equiv B\left(\widehat{\mathbf{y}}_{0}, r\right) \subseteq \mathbb{R}^{n-1}$. Of course $u$ is only defined on $U$ so actually the support of $u$ is contained in the intersection of the circle with $\bar{U}$. Let the Lipschitz constant for $g$ be very small and denote it by $K$. In fact, assume $8 K^{2}<1$. I will first show how to extend when this condition holds and then I will remove it with a simple trick. Define

$$
E u\left(\widehat{\mathbf{x}}, x_{n}\right) \equiv\left\{\begin{array}{l}
u\left(\widehat{\mathbf{x}}, x_{n}\right) \text { if } x_{n} \leq g(\widehat{\mathbf{x}}) \\
u\left(\widehat{\mathbf{x}}, 2 g(\widehat{\mathbf{x}})-x_{n}\right) \text { if } x_{n}>g(\widehat{\mathbf{x}}) \\
0 \text { if } \widehat{\mathbf{x}} \notin B
\end{array}\right.
$$

I will write $U$ instead of $U \cap B \times(a, b)$ to save space but this does not matter because $u$ is assumed to be zero outside the indicated region. Then

$$
\begin{align*}
& \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{\left|E u\left(\widehat{\mathbf{x}}, x_{n}\right)-E u\left(\widehat{\mathbf{y}}, y_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d x d y \\
& =\int_{U} \int_{U} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}\right)-u\left(\widehat{\mathbf{y}}, y_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d x d y+ \\
& \int_{U^{+}} \int_{U} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}\right)-E u\left(\widehat{\mathbf{y}}, y_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d x d y+  \tag{45.3.17}\\
& \int_{U} \int_{U^{+}} \frac{\left|E u\left(\widehat{\mathbf{x}}, x_{n}\right)-u\left(\widehat{\mathbf{y}}, y_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d x d y+  \tag{45.3.18}\\
& \int_{U^{+}} \int_{U^{+}} \frac{\left|E u\left(\widehat{\mathbf{x}}, x_{n}\right)-E u\left(\widehat{\mathbf{y}}, y_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d x d y \tag{45.3.19}
\end{align*}
$$

Consider the second of the integrals on the right of the equal sign. Using Fubini's theorem, it equals

$$
\begin{aligned}
& \int_{U} \int_{U^{+}} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}\right)-u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p}}{|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d y d x \\
= & \int_{U} \int_{B} \int_{g(\widehat{\mathbf{y}})}^{\infty} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}\right)-u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d y_{n} d \widehat{y} d x \\
= & \int_{U} \int_{B} \int_{-\infty}^{g(\widehat{\mathbf{y}})} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}\right)-u\left(\widehat{\mathbf{y}}, z_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-\left(2 g(\widehat{\mathbf{y}})-z_{n}\right)\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d z_{n} d \widehat{y} d x
\end{aligned}
$$

I need to estimate $\left|x_{n}-z_{n}\right|$.

$$
\begin{aligned}
\left|x_{n}-z_{n}\right| & \leq\left|x_{n}-g(\widehat{\mathbf{x}})\right|+|g(\widehat{\mathbf{x}})-g(\widehat{\mathbf{y}})|+\left|g(\widehat{\mathbf{y}})-z_{n}\right| \\
& \leq g(\widehat{\mathbf{x}})-x_{n}+K|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|+y_{n}-g(\widehat{\mathbf{y}}) \\
& \leq\left|y_{n}-x_{n}\right|+2 K|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|
\end{aligned}
$$

and so

$$
\begin{aligned}
\left|x_{n}-z_{n}\right|^{2} & \leq 8 K^{2}|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|^{2}+2\left|y_{n}-x_{n}\right|^{2} \\
& \leq|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|^{2}+2\left|y_{n}-x_{n}\right|^{2}
\end{aligned}
$$

Thus,

$$
\left(y_{n}-x_{n}\right)^{2} \geq \frac{1}{2}\left|x_{n}-z_{n}\right|^{2}-\frac{1}{2}|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|^{2}
$$

and so, the above change of variables results in an expression which is dominated by

$$
\int_{U} \int_{U} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}\right)-u\left(\widehat{\mathbf{y}}, z_{n}\right)\right|^{p}}{\left|\frac{1}{2}\right| \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\frac{1}{2}\left(x_{n}-z_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d y d x
$$

where $y$ refers to $\left(\widehat{\mathbf{y}}, z_{n}\right)$ in the above formula. Hence there is a constant $C(n . \theta)$ such that 45.3.17 is dominated by $C(n . \theta)\|u\|_{W^{p, p}(U)}^{p}$. A similar inequality holds for the third term. Finally consider 45.3 .19 .This equals

$$
\int_{U^{+}} \int_{U^{+}} \frac{\left|u\left(\widehat{\mathbf{x}}, 2 g(\widehat{\mathbf{x}})-x_{n}\right)-u\left(\widehat{\mathbf{y}}, 2 g(\widehat{\mathbf{y}})-y_{n}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d x d y
$$

Changing variables, $x_{n}^{\prime}=2 g(\widehat{\mathbf{x}})-x_{n}, y_{n}^{\prime}=2 g(\widehat{\mathbf{y}})-y_{n}$, it equals

$$
\begin{equation*}
\int_{U^{+}} \int_{U^{+}} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}^{\prime}\right)-u\left(\widehat{\mathbf{y}}, y_{n}^{\prime}\right)\right|^{p}}{| | \widehat{\mathbf{x}}-\left.\widehat{\mathbf{y}}\right|^{2}+\left.\left(x_{n}-y_{n}\right)^{2}\right|^{(1 / 2)(n+p \theta)}} d x^{\prime} d y^{\prime} \tag{45.3.20}
\end{equation*}
$$

each of $x_{n}, y_{n}$ being a function of $x_{n}^{\prime}, y_{n}^{\prime}$ where an estimate needs to be obtained on $\left|x_{n}^{\prime}-y_{n}^{\prime}\right|$ in terms of $\left|x_{n}-y_{n}\right|$.

$$
\begin{aligned}
&\left(x_{n}^{\prime}-y_{n}^{\prime}\right)^{2}=\left(2(g(\widehat{\mathbf{x}})-g(\widehat{\mathbf{y}}))+y_{n}-x_{n}\right)^{2} \\
&=\left(y_{n}-x_{n}\right)^{2}+4(g(\widehat{\mathbf{x}})-g(\widehat{\mathbf{y}}))\left(y_{n}-x_{n}\right) \\
&+4(g(\widehat{\mathbf{x}})-g(\widehat{\mathbf{y}}))^{2} \\
& \leq\left(y_{n}-x_{n}\right)^{2}+2(g(\widehat{\mathbf{x}})-g(\widehat{\mathbf{y}}))^{2} \\
&+2\left(y_{n}-x_{n}\right)^{2}+4(g(\widehat{\mathbf{x}})-g(\widehat{\mathbf{y}}))^{2}
\end{aligned}
$$

and so

$$
\left(x_{n}^{\prime}-y_{n}^{\prime}\right)^{2} \leq 3\left(y_{n}-x_{n}\right)^{2}+6 K^{2}|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|^{2}
$$

which implies

$$
\left(y_{n}-x_{n}\right)^{2} \geq \frac{1}{3}\left(x_{n}^{\prime}-y_{n}^{\prime}\right)^{2}-2 K^{2}|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|^{2}
$$

Then substituting this in to 45.3.20, a short computation shows 45.3 .19 is dominated by an expression of the form $C(n, \theta)\|u\|_{W^{\theta, p(U)}}^{p}$ and this proves the existence of an extension operator provided the Lipschitz constant is small enough. It is clear $E$ is linear where $E$ is defined above.

Now this assumption on the smallness of $K$ needs to be removed. For $\left(\widehat{\mathbf{x}}, x_{n}\right) \in U$ define

$$
U^{\prime} \equiv\left\{\widehat{\mathbf{x}^{\prime}}=\lambda\left(\widehat{\mathbf{x}}-\widehat{\mathbf{b}}_{0}\right): \widehat{\mathbf{x}} \in U\right\}
$$

here this is centering at $\mathbf{0}$ and stretching $B$ since $\lambda$ will be large. Let $\mathbf{h}$ be the name of this mapping. Thus

$$
\begin{aligned}
\mathbf{h}(\widehat{\mathbf{x}}) & \equiv \lambda\left(\widehat{\mathbf{x}}-\widehat{\mathbf{b}}_{0}\right) \\
\mathbf{k}(\widehat{\mathbf{x}}) & \equiv \mathbf{h}^{-1}(\widehat{\mathbf{x}})=\frac{1}{\lambda} \widehat{\mathbf{x}}+\widehat{\mathbf{b}}_{0}
\end{aligned}
$$

These mappings are defined on all of $\mathbb{R}^{n}$. Now let $u^{\prime}$ be defined on $U^{\prime}$ as follows.

$$
u^{\prime}\left(\widehat{\mathbf{x}}, x_{n}\right) \equiv \mathbf{k}^{*} u\left(\widehat{\mathbf{x}}, x_{n}\right)
$$

Also let

$$
g^{\prime}(\widehat{\mathbf{x}}) \equiv \mathbf{k}^{*} g(\widehat{\mathbf{x}})
$$

Thus $g^{\prime}(\widehat{\mathbf{x}}) \equiv g\left(\frac{1}{\lambda} \widehat{\mathbf{x}}+\widehat{\mathbf{b}}_{0}\right)=g(\mathbf{k}(\widehat{\mathbf{x}}))$. Then choosing $\lambda$ large enough the Lipschitz condition for $g^{\prime}$ is as small as desired. Always assume $\lambda$ has been chosen this large and also $\lambda \geq 1$. Furthermore, $g^{\prime}\left(\widehat{\mathbf{x}^{\prime}}\right)=x_{n}^{\prime}$ describes the boundary in the same way as $x_{n}=g(\widehat{\mathbf{x}})$. Now I need to consider whether $u^{\prime} \in \widetilde{W^{\theta, p}\left(U^{\prime}\right)}$. Consider

$$
\begin{aligned}
& \int_{U^{\prime}} \int_{U^{\prime}} \frac{\left|u^{\prime}\left(\widehat{\mathbf{x}^{\prime}}, x_{n}\right)-u^{\prime}\left(\widehat{\mathbf{y}^{\prime}}, y_{n}\right)\right|^{p}}{\left(\left|\widehat{\mathbf{x}^{\prime}}-\widehat{\mathbf{y}^{\prime}}\right|^{2}+\left(x_{n}-y_{n}\right)^{2}\right)^{p+n \theta}} d x^{\prime} d y^{\prime} \\
= & \int_{U^{\prime}} \int_{U^{\prime}} \frac{\left|\mathbf{k}^{*} u\left(\widehat{\mathbf{x}^{\prime}}, x_{n}\right)-\mathbf{k}^{*} u\left(\widehat{\mathbf{y}^{\prime}}, y_{n}\right)\right|^{p}}{\left(\left|\widehat{\mathbf{x}^{\prime}}-\widehat{\mathbf{y}^{\prime}}\right|^{2}+\left(x_{n}-y_{n}\right)^{2}\right)^{p+n \theta}} d x^{\prime} d y^{\prime}
\end{aligned}
$$

Then change the variables $\widehat{\mathbf{x}^{\prime}}=\lambda\left(\widehat{\mathbf{x}}-\widehat{\mathbf{b}}_{0}\right)=\mathbf{h}(\widehat{\mathbf{x}})$ with a similar change for $\widehat{\mathbf{y}^{\prime}}$, the above expression equals

$$
\left(\lambda^{n-1}\right)^{2} \int_{U} \int_{U} \frac{\left|u\left(\widehat{\mathbf{x}}, x_{n}\right)-u\left(\widehat{\mathbf{y}}, y_{n}\right)\right|^{p}}{\left(\lambda^{2}|\widehat{\mathbf{x}}-\widehat{\mathbf{y}}|^{2}+\left(x_{n}-y_{n}\right)^{2}\right)^{p+n \theta}} d x d y
$$

Thus

$$
\begin{equation*}
\left\|u^{\prime}\right\|\left\|_{W^{\theta, p}\left(U^{\prime}\right)} \leq \lambda^{n-1}\right\| u \|_{W^{\theta, p}(U)}<\infty \tag{45.3.21}
\end{equation*}
$$

and $\mathbf{k}^{*}: \widetilde{W^{\theta, p}(U)}$ to $\widetilde{W^{\theta, p}\left(U^{\prime}\right)}$ is continuous and linear. Similar reasoning shows that $\mathbf{h}^{*}$ is continuous and linear mapping $\widetilde{W^{\theta, p}\left(\mathbb{R}^{n}\right)}$ to $\widetilde{W^{\theta, p}\left(\mathbb{R}^{n}\right)}$. By the first part of the argument there exists a continuous linear map

$$
E^{\prime}: \widetilde{W^{\theta, p}\left(U^{\prime}\right)} \rightarrow \widetilde{W^{\theta, p}\left(\mathbb{R}^{n}\right)}
$$

Now define

$$
E u \equiv \mathbf{h}^{*} E^{\prime}\left(\mathbf{k}^{*} u\right)
$$

Say $x_{n} \leq g(\widehat{\mathbf{x}})$. Then $\left(\widehat{\mathbf{x}}, x_{n}\right) \in U$ and so $\left(\mathbf{h}(\widehat{\mathbf{x}}), x_{n}\right) \in U^{\prime}$. Thus

$$
\begin{align*}
E u\left(\widehat{\mathbf{x}}, x_{n}\right) & \equiv \mathbf{h}^{*} E^{\prime}\left(\mathbf{k}^{*} u\right)\left(\widehat{\mathbf{x}}, x_{n}\right) \\
& \equiv E^{\prime}\left(\mathbf{k}^{*} u\right)\left(\mathbf{h}(\widehat{\mathbf{x}}), x_{n}\right) \tag{45.3.22}
\end{align*}
$$

Now $g(\widehat{\mathbf{x}}) \geq x_{n}$ and so $g^{\prime}(\mathbf{h}(\widehat{\mathbf{x}})) \geq x_{n}$ because

$$
g^{\prime}(\mathbf{h}(\widehat{\mathbf{x}})) \equiv \mathbf{k}^{*} g(\mathbf{h}(\widehat{\mathbf{x}}))=g(\widehat{\mathbf{x}})
$$

and so 45.3.22 equals

$$
=\left(\mathbf{k}^{*} u\right)\left(\mathbf{h}(\widehat{\mathbf{x}}), x_{n}\right)=u\left(\widehat{\mathbf{x}}, x_{n}\right)
$$

Thus $E$ leaves $u$ unchanged at points $\left(\widehat{\mathbf{x}}, x_{n}\right)$ where $x_{n} \leq g(\widehat{\mathbf{x}})$. Also

$$
\begin{aligned}
& \|E u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)}=\left\|\mathbf{h}^{*} E^{\prime} \mathbf{k}^{*} u\right\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)} \leq\left\|\mathbf{h}^{*}\right\|\left\|E^{\prime} \mathbf{k}^{*} u\right\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)} \\
& \quad \leq\left\|\mathbf{h}^{*}\right\|\left\|E^{\prime}\right\|\left\|\mathbf{k}^{*}\right\|\|u\|_{W^{\theta, p}(U)}=C\|u\|_{\widetilde{W^{\theta, p}(U)}}
\end{aligned}
$$

To complete the proof, cover $U$ with finitely many sets of this sort oriented with respect to one of the coordinate axes as this one was along with an open set whose closure is contained in $U$ and then use a smooth partition of unity to localize the function to the situation of the sort just discussed and one whose support is contained in $U$. Extend that one to equal zero off its support and treat the others as above. This proves the proposition.

Recall Theorem 38.2.7 which gives an extension operator which maps from the space $W^{1, p}(U)$ to $W^{1, p}\left(\mathbb{R}^{n}\right)$ also denoted by $E$. Now it is not hard to see that $\widetilde{W^{\theta, p}(U)}=$ $W^{\theta, p}(U)$ and the two norms are equivalent.

Theorem 45.3.13 Let $U$ be a bounded open set which has Lipschitz boundary and $\theta \in$ $(0,1)$. Then $\widetilde{W^{\theta, p}(U)}=W^{\theta, p}(U)$ and the two norms are equivalent.

Proof: Let $u \in \widetilde{W^{\theta, p}(U)}$. Letting $E$ be the extension operator of Lemma 45.3.12, there is a constant $C$ such that

$$
C\|u\|_{W^{\theta, p}(U)} \geq\|E u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)}=\|E u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)} \geq\|u\|_{W^{\theta, p}(U)}
$$

Thus if $u \in \widetilde{W^{\theta, p}(U)}$, then $u \in W^{\theta, p}(U)$ and the inclusion map is continuous.
Next suppose $u \in W^{\theta, p}(U)$ and let $\gamma f=u$ for

$$
f \in W\left(W^{1, p}(U), L^{p}(U), p, 1-\theta\right) \equiv W_{U}
$$

Then from Theorem 38.2.7 and the definition of the norm in $W_{U}$

$$
E f \in W\left(W^{1, p}\left(\mathbb{R}^{n}\right), L^{p}\left(\mathbb{R}^{n}\right), p, 1-\theta\right) \equiv W
$$

where this $E$ pertains to extending $W^{1, p}(U)$.

$$
C_{1}\|f\|_{W_{U}} \geq\|E f\|_{W} \geq\|E u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)} \geq\|u\|_{W^{\theta, p}(U)}
$$

Since this is true for every $f \in W_{U}$, it follows $u \in \widehat{W^{\theta, p}(U)}$ and

$$
\|u\|_{W^{\theta, p}(U)} \leq C_{1}\|u\|_{W^{\theta, p}(U)}
$$

This proves the theorem.
Corollary 45.3.14 Let $U$ be a bounded open set with Lipschitz boundary. Then $W^{\theta, p}(U)$ is reflexive.

Proof: From Proposition 45.3.12 and Theorem 45.3.13, there exists an extension operator $E: W^{\theta, p}(U) \rightarrow W^{\theta, p}\left(\mathbb{R}^{n}\right)$ which is continuous. This operator is one to one and continuous. Furthermore, $\|E u\|_{W^{\theta, p}\left(\mathbb{R}^{n}\right)} \geq\|u\|_{W^{\theta, p}(U)}$ and so $E\left(W^{\theta, p}(U)\right)$ is closed. Therefore, by Corollary 21.2.8 on Page 656 and the fact $W^{\theta, p}\left(\mathbb{R}^{n}\right)$ is reflexive which was shown in Corollary 45.3.8, it follows $W^{\theta, p}(U)$ is reflexive. This proves the corollary.

There may be other sets $U$ for which the intrinsic norm is an equivalent norm for $W^{\theta, p}(U)$ but this much will suffice. It should be routine to verify that this works for $U$ a half space for example and the extension argument should be much easier than that presented above. More generally, the assumption that $U$ was bounded in the above extension argument of Proposition 45.3 .12 was never needed except for giving finitely many of those special sets covering the boundary. If you just assumed this at the outset instead of an assumption the set is bounded, the same sort of extension would work.

### 45.4 Fractional Order Sobolev Spaces

Now it is time to define fractional order Sobolev spaces between $W^{m, p}$ and $W^{m+1, p}$.
Definition 45.4.1 Let $m$ be a nonnegative integer and let $s=m+\sigma$ where $\sigma \in(0,1)$. Then $W^{s, p}(\Omega)$ will consist of those elements of $W^{m, p}(\Omega)$ for which $D^{\alpha} u \in W^{\sigma, p}(\Omega)$ for all $|\alpha|=m$. The norm is given by the following.

$$
\|u\|_{s, p, \Omega} \equiv\left(\|u\|_{m, p, \Omega}^{p}+\sum_{|\alpha|=m}\left\|D^{\alpha} u\right\|_{\sigma, p, \Omega}^{p}\right)^{1 / p}
$$

Corollary 45.4.2 The space, $W^{s, p}(\Omega)$ is a reflexive Banach space whenever $p>1$.
Proof: From the theory of interpolation spaces, $W^{\sigma, p}(\Omega)$ is reflexive. This is because it is an iterpolation space for the two reflexive spaces, $L^{p}(\Omega)$ and $W^{1, p}(\Omega)$. (Alternatively, you could use Corollary 45.3 .14 in the case where $\Omega$ is a bounded open set with Lipschitz boundary or you could use Corollary 45.3 .8 in case $\Omega=\mathbb{R}^{n}$. In addition, the same ideas would work if $\Omega$ were any space for which there was a continuous extension map from $W^{\sigma, p}(\Omega)$ to $W^{\sigma, p}\left(\mathbb{R}^{n}\right)$.) Now the formula for the norm of an element in $W^{s, p}(\Omega)$ shows this space is isometric to a closed subspace of $W^{m, p}(\Omega) \times W^{\sigma, p}(\Omega)^{k}$ for suitable $k$. Therefore, from Corollary 21.2.8 on Page 656, $W^{s, p}(\Omega)$ is also reflexive.

Theorem 45.4.3 The trace map, $\gamma: W^{m, p}\left(\mathbb{R}_{+}^{n}\right) \rightarrow W^{m-\frac{1}{p}, p}\left(\mathbb{R}^{n-1}\right)$ is continuous.
Proof: Let $f \in \mathfrak{S}$, the Schwartz class. Let $\sigma=1-\frac{1}{p}$ so that $m-\left(\frac{1}{p}\right)=m-1+\sigma$. Then from the definition and using $f \in \mathfrak{S}$,

$$
\begin{aligned}
\|\gamma f\|_{m-\frac{1}{p}, p, \mathbb{R}^{n-1}} & =\left(\|\gamma f\|_{m-1, p, \mathbb{R}^{n-1}}^{p}+\sum_{|\alpha|=m-1}\left\|D^{\alpha} \gamma f\right\|_{1-\frac{1}{p}, p, \mathbb{R}^{n-1}}^{p}\right)^{1 / p} \\
& =\left(\|\gamma f\|_{m-1, p, \mathbb{R}^{n-1}}^{p}+\sum_{|\alpha|=m-1}\left\|\gamma D^{\alpha} f\right\|_{1-\frac{1}{p}, p, \mathbb{R}^{n-1}}^{p}\right)^{1 / p}
\end{aligned}
$$

and from Lemma 45.1.4, and the fact that the trace is continuous as a map from $W^{m, p}\left(\mathbb{R}_{+}^{n}\right)$ to $W^{m-1, p}\left(\mathbb{R}^{n-1}\right)$,

$$
\begin{aligned}
\|\gamma f\|_{m-\frac{1}{p}, p, \mathbb{R}^{n-1}} & \leq\left(C_{1}\|f\|_{m, p, \mathbb{R}_{+}^{n}}^{p}+C_{2} \sum_{|\alpha|=m-1}\left\|D^{\alpha} f\right\|_{1, p, \mathbb{R}^{n}}\right)^{1 / p} \\
& \leq C\|f\|_{m, p, \mathbb{R}^{n}+p} .
\end{aligned}
$$

Then using density of $\mathfrak{S}$ this implies the desired result.
With the definition of $W^{s, p}(\Omega)$ for $s$ not an integer, here is a generalization of an earlier theorem.

Theorem 45.4.4 Let $\mathbf{h}: U \rightarrow V$ where $U$ and $V$ are two open sets and suppose $\mathbf{h}$ is bilipschitz and that $D^{\alpha} \mathbf{h}$ and $D^{\alpha} \mathbf{h}^{-1}$ exist and are Lipschitz continuous if $|\alpha| \leq m$ where $m=0,1, \cdots$ and $s=m+\sigma$ where $\sigma \in(0,1)$. Then

$$
\mathbf{h}^{*}: W^{s, p}(V) \rightarrow W^{s, p}(U)
$$

is continuous, linear, one to one, and has an inverse with the same properties, the inverse being $\left(\mathbf{h}^{-1}\right)^{*}$.

Proof: In case $m=0$, the conclusion of the theorem is immediate from the general theory of trace spaces. Therefore, assume $m \geq 1$. It follows from the definition that

$$
\left\|\mathbf{h}^{*} u\right\|_{m+\sigma, p, U} \equiv\left[\left\|\mathbf{h}^{*} u\right\|_{m, p, U}^{p}+\sum_{|\alpha|=m}\left\|D^{\alpha}\left(\mathbf{h}^{*} u\right)\right\|_{\sigma, p, U}^{p}\right]^{1 / p}
$$

Consider the case when $m=1$. Then it is routine to verify that

$$
D_{j} \mathbf{h}^{*} u(\mathbf{x})=u_{, k}(\mathbf{h}(\mathbf{x})) h_{k, j}(\mathbf{x}) .
$$

Let $L_{k}: W^{1, p}(V) \rightarrow W^{1, p}(U)$ be defined by

$$
L_{k} v=\mathbf{h}^{*}(v) h_{k, j}
$$

Then $L_{k}$ is continuous as a map from $W^{1, p}(V)$ to $W^{1, p}(U)$ and as a map from $L^{p}(V)$ to $L^{p}(U)$ and therefore, it follows that $L_{k}$ is continuous as a map from $W^{\sigma, p}(V)$ to $W^{\sigma, p}(U)$. Therefore,

$$
\left\|L_{k}(v)\right\|_{\sigma, p, U} \leq C_{k}\|v\|_{\sigma, p, U}
$$

and so

$$
\begin{aligned}
\left\|D_{j}\left(\mathbf{h}^{*} u\right)\right\|_{\sigma, p, U} & \leq \sum_{k}\left\|L_{k}\left(u_{, k}\right)\right\|_{\sigma, p, U} \\
& \leq \sum_{k} C_{k}\left\|D_{k} u\right\|_{\sigma, p, V} \\
& \leq C\left(\sum_{k}\left\|D_{k} u\right\|_{\sigma, p, V}^{p}\right)^{1 / p}
\end{aligned}
$$

Therefore, it follows that

$$
\begin{aligned}
\left\|\mathbf{h}^{*} u\right\|_{1+\sigma, p, U} & \leq\left[\left\|\mathbf{h}^{*} u\right\|_{1, p, U}^{p}+\sum_{j} C^{p} \sum_{k}\left\|D_{k} u\right\|_{\sigma, p, V}^{p}\right]^{1 / p} \\
& \leq C\left[\|u\|_{1, p, V}^{p}+\sum_{k}\left\|D_{k} u\right\|_{\sigma, p, V}^{p}\right]^{1 / p}=C\|u\|_{1+\sigma, p, V}
\end{aligned}
$$

The general case is similar except for the use of a more complicated linear operator in place of $L_{k}$. This proves the theorem.

It is interesting to prove this theorem using Theorem 45.3.13 and the intrinsic norm.
Now we prove an important interpolation inequality for Sobolev spaces.
Theorem 45.4.5 Let $\Omega$ be an open set in $\mathbb{R}^{n}$ which has the segment property and let $f \in$ $W^{m+1, p}(\Omega)$ and $\sigma \in(0,1)$. Then for some constant, $C$, independent of $f$,

$$
\|f\|_{m+\sigma, p, \Omega} \leq C\|f\|_{m+1, p, \Omega}^{1-\sigma}\|f\|_{m, p, \Omega}^{\sigma}
$$

Also, if $L \in \mathscr{L}\left(W^{m, p}(\Omega), W^{m, p}(\Omega)\right)$ for all $m=0,1, \cdots$, and $L \circ D^{\alpha}=D^{\alpha} \circ L$ on $C^{\infty}(\bar{\Omega})$, then $L \in \mathscr{L}\left(W^{m+\sigma, p}(\Omega), W^{m+\sigma, p}(\Omega)\right)$ for any $m=0,1, \cdots$.

Proof: Recall from above, $W^{1-\theta, p}(\Omega) \equiv T\left(W^{1, p}(\Omega), L^{p}(\Omega), p, \theta\right)$. Therefore, from Theorem 44.1.9, if $f \in W^{1, p}(\Omega)$,

$$
\|f\|_{1-\theta, p, \Omega} \leq K\|f\|_{1, p, \Omega}^{\theta}\|f\|_{0, p, \Omega}^{1-\theta}
$$

Therefore,

$$
\begin{aligned}
\|f\|_{m+\sigma, p, \Omega} & \leq\left(\|f\|_{m, p, \Omega}^{p}+\sum_{|\alpha|=m} K\left(\left\|D^{\alpha} f\right\|_{1, p, \Omega}^{1-\sigma}\left\|D^{\alpha} f\right\|_{0, p, \Omega}^{\sigma}\right)^{p}\right)^{1 / p} \\
& \leq C\left[\|f\|_{m, p, \Omega}^{p}+\left(\|f\|_{m+1, p, \Omega}^{1-\sigma}\|f\|_{m, p, \Omega}^{\sigma}\right)^{p}\right]^{1 / p} \\
& \leq C\left[\left(\|f\|_{m+1, p, \Omega}^{1-\sigma}\|f\|_{m, p, \Omega}^{\sigma}\right)^{p}+\left(\|f\|_{m+1, p, \Omega}^{1-\sigma}\|f\|_{m, p, \Omega}^{\sigma}\right)^{p}\right]^{1 / p} \\
& \leq C\|f\|_{m+1, p, \Omega}^{1-\sigma}\|f\|_{m, p, \Omega}^{\sigma}
\end{aligned}
$$

This proves the first part. Now consider the second. Let $\phi \in C^{\infty}(\bar{\Omega})$

$$
\begin{gather*}
\|L \phi\|_{m+\sigma, p, \Omega}=\left(\|L \phi\|_{m, p, \Omega}^{p}+\sum_{|\alpha|=m}\left\|D^{\alpha} L \phi\right\|_{\sigma, p, \Omega}^{p}\right)^{1 / p} \\
=\left(\|L \phi\|_{m, p, \Omega}^{p}+\sum_{|\alpha|=m}\left\|L D^{\alpha} \phi\right\|_{T\left(W^{\left.1, p, L^{p}, p, 1-\sigma\right)}\right.}^{p}\right)^{1 / p} \\
=\left(\|L \phi\|_{m, p, \Omega}^{p}+\sum_{|\alpha|=m}\left[\inf \left(\left\|t^{1-\sigma} L f_{\alpha}\right\|_{1}^{\sigma}\left\|t^{1-\sigma} L f_{\alpha}^{\prime}\right\|_{2}^{1-\sigma}\right)\right]^{p}\right)^{1 / p} \tag{45.4.23}
\end{gather*}
$$

where

$$
\begin{gathered}
\inf \left(\left\|t^{1-\sigma} L f_{\alpha}\right\|_{1}^{\sigma}\left\|t^{1-\sigma} L f_{\alpha}^{\prime}\right\|_{2}^{1-\sigma}\right)= \\
\inf \left(\left\|t^{1-\sigma} L f_{\alpha}\right\|_{L^{p}\left(0, \infty ; \frac{d t}{t} ; W^{1, p}(\Omega)\right)}^{\sigma}\left\|t^{1-\sigma} L f_{\alpha}^{\prime}\right\|_{L^{p}\left(0, \infty ; \frac{d t}{t} ; L^{p}(\Omega)\right)}^{1-\sigma}\right)
\end{gathered}
$$

$f_{\alpha}(0) \equiv \lim _{t \rightarrow 0} f_{\alpha}(t)=D^{\alpha} \phi$ in $W^{1, p}(\Omega)+L^{p}(\Omega)$, and the infimum is taken over all such functions. Therefore, from 45.4.23, and letting $\|L\|_{1}$ denote the operator norm of $L$ in $W^{1, p}(\Omega)$ and $\|L\|_{2}$ denote the operator norm of $L$ in $L^{p}(\Omega)$,

$$
\begin{aligned}
& \|L \phi\|_{m+\sigma, p, \Omega} \\
\leq & \left(\|L \phi\|_{m, p, \Omega}^{p}+\sum_{|\alpha|=m}\left[\inf \left(\|L\|_{1}^{\sigma}\|L\|_{2}^{1-\sigma}\left\|t^{1-\sigma} f_{\alpha}\right\|_{1}^{\sigma}\left\|t^{1-\sigma} f_{\alpha}^{\prime}\right\|_{2}^{1-\sigma}\right)\right]^{p}\right)^{1 / p} \\
\leq & \left(\|L \phi\|_{m, p, \Omega}^{p}+\left(\|L\|_{1}^{\sigma}\|L\|_{2}^{1-\sigma}\right)^{p} \sum_{|\alpha|=m}\left[\inf \left(\left\|t^{1-\sigma} f_{\alpha}\right\|_{1}^{\sigma}\left\|t^{1-\sigma} f_{\alpha}^{\prime}\right\|_{2}^{1-\sigma}\right)\right]^{p}\right)^{1 / p} \\
\leq & C\left(\|\phi\|_{m, p, \Omega}^{p}+\sum_{|\alpha|=m}\left[\left\|D^{\alpha} \phi\right\|_{\sigma, p, \Omega}\right]^{p}\right)^{1 / p}=C\|\phi\|_{m+\sigma, p, \Omega}
\end{aligned}
$$

Since $C^{\infty}(\bar{\Omega})$ is dense in all the Sobolev spaces, this inequality establishes the desired result.

Definition 45.4.6 Define for $s \geq 0, W^{-s, p^{\prime}}\left(\mathbb{R}^{n}\right)$ to be the dual space of

$$
W^{s, p}\left(\mathbb{R}^{n}\right)
$$

Here $\frac{1}{p}+\frac{1}{p^{\prime}}=1$.
Note that in the case of $m=0$ this is consistent with the Riesz representation theorem for the $L^{p}$ spaces.

## Chapter 46

## Sobolev Spaces On Manifolds

### 46.1 Basic Definitions

Consider the following situation. There exists a set, $\Gamma \subseteq \mathbb{R}^{m}$ where $m>n$, mappings, $\mathbf{h}_{i}: U_{i} \rightarrow \Gamma_{i}=\Gamma \cap W_{i}$ for $W_{i}$ an open set in $\mathbb{R}^{m}$ with $\Gamma \subseteq \cup_{i=1}^{l} W_{i}$ and $U_{i}$ is an open subset of $\mathbb{R}^{n}$ which $\mathbf{h}_{i}$ one to one and onto. Assume $\mathbf{h}_{i}$ is of the form

$$
\begin{equation*}
\mathbf{h}_{i}(\mathbf{x})=\mathbf{H}_{i}(\mathbf{x}, \mathbf{0}) \tag{46.1.1}
\end{equation*}
$$

where for some open set, $O_{i}, \mathbf{H}_{i}: U_{i} \times O_{i} \rightarrow W_{i}$ is bilipschitz having bilipschitz inverse such that for $\mathbf{G}=\mathbf{H}_{i}$ or $\mathbf{H}_{i}^{-1}, D^{\alpha} \mathbf{G}$ is Lipschitz for $|\alpha| \leq k$.

For example, let $m=n+1$ and let

$$
\mathbf{H}_{i}(\mathbf{x}, y)=\binom{\mathbf{x}}{\phi(\mathbf{x})+y}
$$

where $\phi$ is a Lipschitz function having $D^{\alpha} \phi$ Lipschitz for all $|\alpha| \leq k$. This is an example of the sort of thing just described if $\mathbf{x} \in U_{i} \subseteq \mathbb{R}^{n}$ and $O_{i}=\mathbb{R}$, because it is obvious the inverse of $\mathbf{H}_{i}$ is given by

$$
\mathbf{H}_{i}^{-1}(\mathbf{x}, y)=\binom{\mathbf{x}}{y-\phi(\mathbf{x})}
$$

Also let $\left\{\psi_{i}\right\}_{i=1}^{l}$ be a partition of unity subordinate to the open cover $\left\{W_{i}\right\}$ satisfying $\psi_{i} \in$ $C_{c}^{\infty}\left(W_{i}\right)$. Then the definition of $W^{s, p}(\Gamma)$ follows.

Definition 46.1.1 $u \in W^{s, p}(\Gamma)$ if whenever $\left\{W_{i}, \psi_{i}, \Gamma_{i}, U_{i}, \mathbf{h}_{i}, \mathbf{H}_{i}\right\}_{i=1}^{l}$ is described above with $\mathbf{h}_{i} \in C^{k, 1}, \mathbf{h}_{i}^{*}\left(u \psi_{i}\right) \in W^{s, p}\left(U_{i}\right)$. The norm is given by

$$
\|u\|_{s, p, \Gamma} \equiv \sum_{i=1}^{l}\left\|\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)\right\|_{s, p, U_{i}}
$$

It is not at all obvious this norm is well defined. What if

$$
\left\{W_{i}^{\prime}, \phi_{i}, \Gamma_{i}, V_{i}, \mathbf{g}_{i}, \mathbf{G}_{i}\right\}_{i=1}^{r}
$$

is as described above. Would the two norms be equivalent? To begin with consider the following lemma which involves a particular choice for $\left\{W_{i}, \psi_{i}, \Gamma_{i}, U_{i}, \mathbf{h}_{i}, \mathbf{H}_{i}\right\}_{i=1}^{l}$.

Lemma 46.1.2 $W^{s, p}(\Gamma)$ as just described, is a Banach space. If $p>1$ then it is reflexive.
Proof: Let $L: W^{s, p}(\Gamma) \rightarrow \prod_{i=1}^{l} W^{s, p}\left(U_{i}\right)$ be defined by $(L u)_{i} \equiv \mathbf{h}_{i}^{*}\left(u \psi_{i}\right)$. Let $\left\{u_{j}\right\}_{j=1}^{\infty}$ be a Cauchy sequence in $W^{s, p}(\Gamma)$. Then $\left\{\mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)\right\}_{j=1}^{\infty}$ is a Cauchy sequence in $W^{s, p}\left(U_{i}\right)$ for each $i$. Therefore, for each $i$, there exists $w_{i} \in W^{s, p}\left(U_{i}\right)$ such that

$$
\lim _{j \rightarrow \infty} \mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)=w_{i} \text { in } W^{s, p}\left(U_{i}\right)
$$

But also, there exists a subsequence, still denoted by $j$ such that for each $i$

$$
\left\{\mathbf{h}_{i}^{*}\left(u_{j} \psi_{i}\right)(\mathbf{x})\right\}_{j=1}^{\infty}
$$

is a Cauchy sequence for a.e. $\mathbf{x}$. Since $\mathbf{h}_{i}$ is given to be Lipschitz, it maps sets of measure 0 to sets of $n$ dimensional Hausdorff measure zero. Therefore,

$$
\left\{u_{j} \psi_{i}(\mathbf{y})\right\}_{j=1}^{\infty}
$$

is a Cauchy sequence for $\mu$ a.e. $\mathbf{y} \in W_{i} \cap \Gamma$ where $\mu$ denotes the $n$ dimensional Hausdorff measure. It follows that for $\mu$ a.e. $\mathbf{y},\left\{u_{j}(\mathbf{y})\right\}_{j=1}^{\infty}$ is a Cauchy sequence and so it converges to a function denoted as $u(\mathbf{y})$.

$$
u_{j}(\mathbf{y}) \rightarrow u(\mathbf{y}) \mu \text { a.e. }
$$

Therefore, $w_{i}(\mathbf{x})=\mathbf{h}_{i}^{*}\left(u \psi_{i}\right)(\mathbf{x})$ a.e. and this shows $\mathbf{h}_{i}^{*}\left(u \psi_{i}\right) \in W^{s, p}\left(U_{i}\right)$. Thus $u \in W^{s, p}(\Gamma)$ showing completeness. It is clear $\|\cdot\|_{s, p, \Gamma}$ is a norm. Thus $L$ is an isometry of $W^{s, p}(\Gamma)$ and a closed subspace of $\prod_{i=1}^{l} W^{s, p}\left(U_{i}\right)$. By Corollary 45.4.2, $W^{s, p}\left(U_{i}\right)$ is reflexive which implies the product is reflexive. Closed subspaces of reflexive spaces are reflexive by Lemma 21.2.7 on Page 655 and so $W^{s, p}(\Gamma)$ is also reflexive. This proves the lemma.

I now show that any two such norms are equivalent.
Suppose $\left\{W_{j}^{\prime}, \phi_{j}, \Gamma_{j}, V_{j}, \mathbf{g}_{j}, \mathbf{G}_{j}\right\}_{j=1}^{r}$ and $\left\{W_{i}, \Psi_{i}, \Gamma_{i}, U_{i}, \mathbf{h}_{i}, \mathbf{H}_{i}\right\}_{i=1}^{l}$ both satisfy the conditions described above. Let $\|\cdot\|_{s, p, \Gamma}^{1}$ denote the norm defined by

$$
\begin{gather*}
\|u\|_{s, p, \Gamma}^{1} \equiv \sum_{j=1}^{r}\left\|\mathbf{g}_{j}^{*}\left(u \phi_{j}\right)\right\|_{s, p, V_{j}} \\
\leq \sum_{j=1}^{r}\left\|\mathbf{g}_{j}^{*}\left(\sum_{i=1}^{l} u \phi_{j} \psi_{i}\right)\right\|\left\|_{s, p, V_{j}} \leq \sum_{j, i}\right\| \mathbf{g}_{j}^{*}\left(u \phi_{j} \psi_{i}\right) \|_{s, p, V_{j}} \\
=\sum_{j, i}\left\|\mathbf{g}_{j}^{*}\left(u \phi_{j} \psi_{i}\right)\right\|_{s, p, \mathbf{g}_{j}^{-1}\left(W_{i} \cap W_{j}^{\prime}\right)} \tag{46.1.2}
\end{gather*}
$$

Now define a new norm $\|u\|_{s, p, \Gamma}^{1, \mathbf{g}}$ by the formula 46.1.2. This norm is determined by

$$
